Editorial

The Special Issue on *Advancement in Engineering Technology (2017–2018)* in the *Advances in Science, Technology and Engineering Systems Journal (ASTES Journal)* presents a comprehensive collection of scholarly contributions that reflect the accelerating pace of technological innovation across engineering disciplines. The period of 2017–2018 marked a significant phase in which emerging technologies began to mature and integrate more deeply into practical engineering applications. This special issue captures that transition, showcasing research that bridges the gap between theoretical development and real-world implementation, and highlighting the transformative impact of advanced technologies on engineering practice.

A prominent theme throughout this issue is the growing role of digitalization and intelligent systems in engineering technology. Contributions emphasize the integration of advanced computational tools, automation, and data-driven methodologies to enhance system design, monitoring, and control. The incorporation of artificial intelligence, machine learning, and Internet of Things (IoT) frameworks has enabled engineers to develop smarter and more responsive systems. These advancements are evident in applications ranging from intelligent manufacturing and process optimization to smart infrastructure and real-time system diagnostics, demonstrating how digital technologies are reshaping the engineering landscape.

Another key focus of this special issue is the advancement of materials and manufacturing technologies. The research presented explores innovative materials with enhanced properties, as well as modern fabrication techniques such as additive manufacturing and advanced machining processes. These developments have significantly expanded the possibilities for design and production, allowing for greater efficiency, customization, and performance. The integration of such technologies into engineering systems not only improves product quality but also contributes to reduced waste and more sustainable production practices.

Sustainability and energy efficiency also emerge as critical considerations within the collected works. As global demand for resources continues to rise, engineering technology must evolve to support environmentally responsible solutions. The studies included in this issue address challenges related to renewable energy systems, energy management, and sustainable design practices. By focusing on efficiency, resource optimization, and environmental impact, these contributions underscore the importance of aligning technological advancement with sustainable development goals.

Interdisciplinary collaboration remains a defining feature of the advancements highlighted in this issue. The complexity of modern engineering challenges requires the convergence of expertise from multiple domains, including mechanical, electrical, civil, and computer engineering. The research demonstrates how such collaboration fosters innovation, enabling the development of integrated systems that are more efficient, reliable, and adaptable. This interdisciplinary approach is particularly evident in areas such as robotics, mechatronics, and cyber-physical systems, where the synergy between hardware and software plays a crucial role.

The editorial team extends its sincere appreciation to all authors, reviewers, and contributors whose dedication and expertise have made this special issue possible. Their collective efforts have resulted in a high-quality compilation of research that not only advances academic understanding but also provides practical insights for industry and society. It is anticipated that

the findings presented herein will inspire further research and development, encouraging continued progress in engineering technology.

The Special Issue on *Advancement in Engineering Technology (2017–2018)* highlights the ongoing evolution of engineering practices in response to rapid technological change. The contributions reflect a shift toward more intelligent, efficient, and sustainable systems, driven by innovation and interdisciplinary collaboration. As engineering technology continues to advance, it will play an increasingly vital role in addressing the complex challenges of the modern world, paving the way for a more connected and resilient future.

ABSTRACT

Cloud providers seek to maximize their market share. Traditionally, they deploy datacenters with sufficient capacity to accommodate their entire computing demand while maintaining geographical affinity to its customers. Achieving these goals by a single cloud provider is increasingly unrealistic from a cost of ownership perspective. Moreover, the carbon emissions from underutilized datacenters place an increasing demand on electricity and is a growing factor in the cost of cloud provider datacenters. Cloud-based systems may be classified into two categories: serving systems and analytical systems. We studied two primary workload types, on-demand video streaming as a serving system and MapReduce jobs as an analytical systems and suggested two unique energy mix usage for processing that workloads. The recognition that on-demand video streaming now constitutes the bulk portion of traffic to Internet consumers provides a path to mitigate rising energy demand. On-demand video is usually served through Content Delivery Networks (CDN), often scheduled in backend and edge datacenters. This publication describes a CDN deployment solution that utilizes green energy to supply on-demand streaming workload. A cross-cloud provider collaboration will allow cloud providers to both operate near their customers and reduce operational costs, primarily by lowering the datacenter deployments per provider ratio. Our approach optimizes cross-datacenters deployment. Specifically, we model an optimized CDN-edge instance allocation system that maximizes, under a set of realistic constraints, green energy utilization. The architecture of this cross-cloud coordinator service is based on Ubernetes, an open source container cluster manager that is a federation of Kubernetes clusters. It is shown how, under reasonable constraints, it can reduce the projected datacenter's carbon emissions growth by 22% from the currently reported consumption. We also suggest operating datacenters using energy mix sources as a VoltDB-based fast data system to process offline workloads such as MapReduce jobs. We show how cross-cloud coordinator service can reduce the projected datacenters carbon emissions growth by 21% from the currently expected trajectory when processing offline MapReduce jobs.

1 Introduction

Over the past decade, cloud-based systems have been required to serve an increasing demand from users work flows and data. Cloud-based systems may be classified into two categories: *serving* systems and *analytical* systems. The former provides low-latency read or write access to data. For example, a user requests a web page to load online or requests video or audio streaming. The latter provides batch-like compute tasks that process the data offline that are later sourced to the serving systems. The service level objectives (SLO) for serving jobs are on the order of fractions of a second, while the SLO for analytical jobs are on the order of hours, sometimes days.

[*]Corresponding Author, ybiran@colostate.edu

https://dx.doi.org/10.25046/aj020601

Today, public cloud service providers (CSP) attempt to process both of these workloads with a rich platform that guarantees cost and SLO to their clients. Cloud computing is an emerging infrastructure with limited regulation and compliance requirements [1]. Recently the Office of Management and Budget issued a Federal Data Center Optimization Initiative that promotes increasing use of Green Energy and increased utilization efficiency for all US Federal datacenters [2]. Specific target numbers are set for the end of fiscal year 2018. This publication addresses how those federal requirements may be attained and how federated cloud computing is a key enabler for attaining those performance targets.

Beginning in 2013, the US government initiated a carbon-tax on IT organizations to encourage major CSPs to pursue green energy opportunities for their datacenters operations [3]. US datacenters are projected to consume approximately 73 billion kWh by 2020 [3] with a corresponding increase greenhouse gases. Green energy generation growth is expected to triple by 2040 [4]. However, there is no cohesive system existing to coordinate the rising datacenter energy demand with rising green energy supply. This chapter utilizes Cloud-Federation as a multi-cloud resource coordination system that matches computational resource demands with available energy supply to maximize the utilization of green energy for processing cloud-workloads.

Most CSPs seek more market share in competition with other CSPs. One outcome of such competition is an ever-growing infrastructure in the form of new datacenters across the globe with no countervailing forces to meet user demand more efficiently and satisfy societal environmental and energy requirements. This sub optimum use of infrastructure increases the carbon footprint attributable to cloud computing services and also drives up costs to CSP's. The following sections investigate two types of workloads, serving and analytical systems. This chapter will focus on two workload types, On-demand streaming as a representation of *serving* systems. It will also investigate *analytical* systems and present a unique model that allows optimal clean energy usage.

1.1 Enabling Green Content Distribution Network by Cloud Orchestration

On-demand streaming constitutes up to 85% of Internet traffic consumption [5]. On-demand streaming content is managed and distributed by content service providers. It then cached and distributed by Content Delivery Networks(CDN) located at the edges of the Internet network close to the consumers. Because streaming constitutes such a large fraction of Internet resource consumption, this paper will, of necessity, focus on methods to employ green energy to better operate CDN instances of on-demand streaming jobs, which include both video and audio content.

Meeting the Federally mandated approach of maximizing the utilization of green energy to operate CDN instances (for government with recommendations for private sector use as well) requires an energy source-demand coupling scheme that insures SLO levels of power availability but is structurally biased towards green energy sources over hydrocarbon fueled energy sources. A system to accomplish this will have to provide seamless failover in the case of sudden interruption of green energy to grid-energy sources or vice versa i.e., fallback from grid-energy to green energy when surplus green energy is available.

User expectations in on-demand streaming requires different service level requirements than other serving systems workloads. Serving systems workloads are comprised of interactive sessions that pivots on minimum latency. However, low latency is less critical in analytical on-demand streaming since application clients use buffering techniques to mitigate long latency effects. Therefore, on-demand streaming workloads fits, more closely than interactive workloads, with the observed intermittent and varying green energy availability characteristics.

Green energy supply is unpredictable and requires a complex, adaptable, resource allocation system to provide CDN services with steady energy supplies while concurrently seeking minimal carbon footprint. This dynamic availability of green energy resources in a smart grid requires real time communication of both short term and predictive energy needs from cloud service providers to green energy providers. The green energy providers need to disclose availability dynamically to CSPs, who, in turn, disclose their changing energy demands for near term computing. SPs can then better maximize the use of green energy for on-demand streaming processing.

This is a classical resource management and coordination problem [6, 7]. The following approach builds upon prior work that was done in this area [8, 9], specifically that done on alleviating the sudden lack of green energy to meet low-latency workloads. The approach herein employs an application-buffering scheme that better allows for opportunistic, green, on-demand streaming processing. It requires an extended, cohesive, federated system that aggregates supply and demand across multiple geographic locations employing the smart grid command and control infrastructure to achieve an optimal dynamic matching of green energy sources and computing loads.

This chapter proposes an implementation that utilizes a control component in a federated cloud that coordinates and optimizes the resource allocation among the participant CDN providers. It treats the volatile nature of green energy resources as a resource allocation problem, the solution of which is a resource orchestration system that is optimized with the goal to operate increasingly near to the limit of supply by green energy sources constrained by SLO reliability requirements. This system will be demonstrated by modeling a prototype that simulates resource allocation in a micro federated cloud eco-system to achieve an energy supply-computation demand match optimized within seconds.

Since the focus of this work is on green energy utilization in a federated cloud, the scheduling algorithms and resource management issues, while important, are discussed only to the extent necessary to help the reader understand the required architecture for heterogeneous energy compute clustering. This work is meant both as a case study in energy utilization, and a presentation of a novel method of coordinating high-velocity data streams, and extended to a unified orchestration system, to optimize the performance of federated cloud systems.

The chapter starts, with the on-demand streaming economics, increased green energy utilization and anticipated smart grid progressions as applied to on-demand streaming. Then it discusses the green energy utilization problem is analyzed. Finally, we present a cloud coordinator prototype that is built on Kubernetes [10, 11], an open source cluster manger, and extend that prototype to discusses the need for and requirements of a unified system that orchestrates cluster compute resources in a federated cloud.

1.1.1 On-Demand Streaming and CDN

Over the last decade, video and audio traffic became the dominant segment of consumer internet traffic. Cloud service-providers such as Netflix, Amazon Instant and YouTube disrupted the prior linear TV data distribution model. Also, video streams delivered by mobile terminals grew as mobile connectivity improved [12]. Video streaming is expected to constitute up to 85% of Internet consumers traffic [5] within a few years. The US portion of video streaming is 14%[1] and the number of US Unique IPv4 connected addresses is 17% [12]. The streaming workload is comprised of live streaming and on-demand streaming, with the relative fractions of 6% and 94% respectively [5]. Other predictions support similar ratios, 12% live-streaming and 88% for on-demand.

A key driver for the rapid expansion of streaming video was the shift from specialized streaming protocols and infrastructures such as RTSP, and RTMP [13] to a simple HTTP progressive download protocol. This led to a shift from proprietary streaming appliances to commodity servers. In turn, this change removed a barrier for CDN's to process on-demand workloads. Most present day, CDN service providers support a seamless integration with cloud-based object storage that pipelines the digital content from the organization site to the CDN instance that runs at the Internet provider edge[2]. Furthermore, the HTTP chunk-based streaming protocol support in a CDN allows the client application sufficient time to detect the optimal CDN instance to handle user workload. The optimal CDN instance assignment is done by the cloud control plane resource manager. The prototype described below will demonstrate such optimal resource allocation.

We used server utilization and power metrics from [3, 12] to design the prototype. Most of these sources we considered have limited utilization rates and server utilization distribution. Also, utilization and power consumption do not scale linearly [14]. However, for clarity, in the interest of maintaining focus on the larger goal of the paper, CDN resource management systems for green energy utilization, we assumed linear relationships and accepted the risk of loss of accuracy in our estimates. High fidelity simulation accuracy is not critical for the goal of this chapter.

1.1.2 Energy Saving Potential in Operating a Distributed CDN Resource Management System

The approach is to aggregate the required traffic for on-demand workload processing, and use standard compute device specification to assess the electrical energy and carbon footprint that will be required by that workload[3].

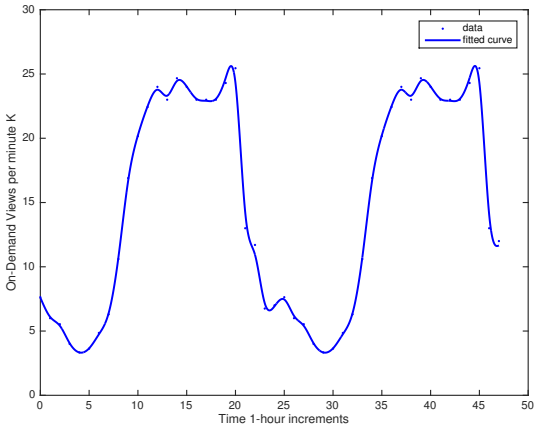

Figure 1: On-Demand Video views observed throughout 48 hours with 1-hour increments. Data was fitted with smoothingspline for curve and surface fitting [5]

The estimated data rate for streaming is given as $S_{total} = 63000PB/mo$ (where PB is Petabytes). Figure 1 shows users workload pattern of 9 busy hours in which the workload spans throughout 13 hours a day which yield $126PB/sec/mo/$ The on-demand streaming portion is estimated as 78% across four main US regions denoted by $k = 4$, the number of region used, for the purposes of this paper although k can be varied depending upon the degree of granularity desired in the simulations. $S_{on-demand}$ denote the on-demand portion.

$$S_{on-demand} = S_{total} \cdot 78\% = 49140PB/mo$$

$n_{hours/day}$ denotes the number of effective hours in a day for streaming.

$$n_{hours/day} = n_{busy} + k = 13$$

$$D_{rate} = \frac{S_{on-demand}}{n_{hours/day}} = 126PB/sec/mo$$

N_{max} denotes the estimated number of required servers in maximum CPU capacity. N_{max} is bounded by the maximum network throughput a single server can ingest. Standard commodity servers can handle up to 8.5Gbps i.e. 1.026GB/sec.

$$N_{max} = \frac{D_{rate}}{T_{max}} = \frac{126 \cdot 10^6 GB/sec}{1.026GB/sec} = 118588235.3$$

u_{opt} denotes the CPU utilization factor so servers has sufficient capacity to handle management tasks. We estimate 60% utilization factor $u_{opt} = 100/60$.

$$N_{opt} = N_{max} \cdot u_{opt} = 118588235.3 \cdot \frac{100}{60} = 197647058.8$$

E_s denotes the midrange server energy consumption for various server types s. We consider three types of servers:(1) compute server(5kWh/server), (2)

[1]Internet Statistics retrieved from https://www.statista.com/chart/2647/global-internet-usage-by-the-numbers/
[2]Cloud Front reference retrieved from https://aws.amazon.com/cloudfront/
[3]OpenCompute Project, Servers Specification guide retrieved from http://www.opencompute.org/wiki/Server

digital storage server(1.7kWh/server) and (3) network server(1kWh/server). Storage server acts the digital storage controller. The network server acts as the router and switch. The compute server is the server that processes the on-demand streaming.

$$E_y = N_{opt} \cdot \sum_{s \in S} E_s \quad (1)$$

$$= N_{opt} \cdot (5kWh + 1.7kWh + 1kWh)$$

$$= 1.521 \cdot 10^6 kWh/mo = 18.26GWh/y$$

The saving potential from running on-demand video streaming using green energy resources is 18.26GWh a year based on current on-demand consumption and expected to grow 89% by 2019 [4]. i.e. 34.5GWh per year for on-demand streaming. The next sections will explain the challenges in utilizing green energy followed by a method that addresses some of these challenges and thereby maximizes the utilization of green energy.

1.2 Coordinating Green Clouds as Data-Intensive Computing

The following paragraph focuses on *analytical* systems workloads that typically comprise 48% of the cloud workload [15]. Also, some of the workloads patterns can be predicted as recurring jobs [16] and the deadlines for *analytical* jobs are more liberal by an order of magnitude than the *serving* jobs. Finally, one of the ways to handle offline workloads is to process the data streams offline through a highly scalable data-parallel frameworks like MapReduce by submitting jobs to a control plane [17].

This chapter proposes a component in a federated cloud that will optimize the resource allocation and coordination among the participant CSPs. It will also focus on addressing the time and power volatile nature of renewable energy resources as a fast date problem. It will present a resource management system with a goal to increase the utilization of data-centers, and to operate increasingly to the limit of supply by renewable energy sources. Finally, a prototype is built to simulate resources allocation in a micro federated cloud eco-system to achieve a supply demand optimized match within seconds.

Clean energy sources are time and power volatile and require complex resource allocation and coordination systems to maintain highly available data-center service with steady energy at a minimal carbon footprint. Further, availability of clean energy resources in a smart grid can be pushed from a variety of energy sources deployed across the nation as can the pull needs of data-service centers. Thus, CSPs will publish their compute resources availability, and service providers (SP), will publish their changing energy demands for near term computing. These streams of data include both high-volume and high-velocity characteristics termed a fast-data problem [18]. Our proposal uses as a base previous work that was done in this area [8, 19, 20]. However, previous work treated clean energy within a single data-center operated by a CSP. The proposal below suggests an extended cohesive system that aggregates supply and demand across multiple geographic locations employing the smart grid sense command and control to achieve an optimal match.

1.2.1 Optimum Clean Energy Utilization is a Fast-Data Problem!

This study suggests that efficient, clean energy utilization requires three consecutive steps: (1) Clean energy resource availability signals. (2) Exploration and analysis of prior years seasonal solar data and current weather reports and evolving green energy capacity availability planning. (3) Acting fast enough based on the predictive analysis. The last step is the key component in solving the optimum allocation problem.

We judge that clean energy utilization is different from the classic big-data problem such as the Hadoop MapReduce Method. Big-data solutions solve the case where the data is at rest, not fully consistent (aka eventual consistency) and require liberal SLO that is later provided as computing trends, and other business intelligence applications. However, our case handles data in motion that requires consistent, real-time aggregation, and transaction processing. That is per-event decision making using both real-time contextual and historical data as dual guides for proper algorithms. Finally, we argue that based on the clean energies' volatile nature, processing streams of compute demand and clean energy supply requires that a need for a compute resources can be addressed with a currently available demand.

1.3 Why is Green Energy Utilization Hard?

The following section describes why utilizing green energy for compute purposes, while a justifiable goal, is limited by SLO reliability. It will present a scenario where balancing time-varying energy generation patterns with changing dynamic energy demands of cloud computing sometimes conflict. The green energy time varying generation patterns considered by us focuses on wind and solar generation. Figure 4 show historical data on dynamic nature of green energy sources and Figure 5 shows the dynamic cloud energy demand.

1.3.1 Frequency Stability in Wind-Power Generation

The daily wind power variation characteristics will be employed as a metric that illustrates the duration and level for a given amount if wind energy availability. The electricity generation process from wind is comprised of a wind turbine extracting a kinetic energy from the air flow. The wind is rarely steady; it is influenced by the weather system and the ground surface conditions, which are often turbulent [21]. Also, the generation process must happen at the same instant it is consumed [22] unless it is stored in grid level battery banks. Unfortunately, grid level energy storage technology is not keeping up with grid level energy generation technology.

Sample wind and power generation data were obtained from NREL [22]. We used datasets from 2006-2012 across different regions in the US and aggregated more than 600

[4] https://www2.deloitte.com/content/dam/Deloitte/in/Documents/technology-media-telecommunications/in-tmt-rise-of-on-demand-content.pdf

observations. Finally, the data were fit using smoothing splines[5]. The usable power generated from a wind turbine is generally described by a Rayleigh distribution [21]. It defines three main points in the wind power generation process: (1) the cut-in is the minimum viable wind speed for electricity generation from a wind turbine. (2) the rated level, describes the point where the power reached its local maximal capacity without adverse effects on the turbine life by too strong a wind. (3) Cut-Off, is the term for the local minimum for the generation cycle. Beneath that speed, there is not enough power for viable electricity generation. Thus, if the wind velocity is too low, the data-server gets no wind energy. Figure 2 shows wind generation variations that crudely fit a Rayleigh distribution with $b = 300$ assuming the form of the Rayleigh Probability Distribution Function is:

$$f(x|b) = \frac{x}{b^2} e^{\frac{-x^2}{2b^2}}$$

The measured generation cycles range between 140 and 180 minutes per cycle. Equation 2 expresses the generated power by a wind turbine, given a wind velocity. The function g describes a viable electricity generation given a wind power. The wind power availability indications will be generated by a wind turbine and fed into the coordinator database as a potential power source to datacenters in a region. Our prototype will assume wind power availability indications as the wind tuple {*region,cut-in,rated,cut-off*} indications.

$$P_{output}(wind_v) = \begin{cases} 0 & : \text{ if } wind_v \leq rated \\ g(wind_v) & : \text{ if } rated < wind_v \leq c_{out} \\ 0 & : \text{ if } wind_v \leq c_{out} \end{cases} \quad (2)$$

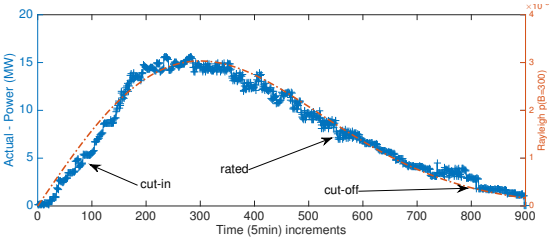

Figure 2: Aggregated wind power measurements between 2007-2012 that fits Rayleigh Distribution with b=300

1.3.2 Efficiency and Daily/Hourly Availability in Solar-Power Generation

Photovoltaic solar (PV) energy availability is defined by the solar power intensity denoted by s(*Watts/m2*), which varies with local daylight hours and the clear or cloudy sky conditions [22]. Moreover, the PV cells are most effective at lower temperatures [23]. The PV cells electrical power generation, defined by Equation 3, is a function of the solar intensity denoted by η_{solar}. Solar power generation also depends on the PV power efficiency denoted by s. It encapsulates both the predicated temperature,the sky conditions, the solar cell efficiency, and the DC to AC inverter efficiency. The solar cell area denoted by $a(m^2)$.

$$P_{output}(s) = \eta_{solar} \cdot s \cdot a \quad (3)$$

Our prototype will assume solar power availability indications as the solar-tuple {*region,power-efficiency*}. Based on the solar generation pattern presented in figure 3, the generation prediction utilizes the the local time in a region and the given power-efficiency

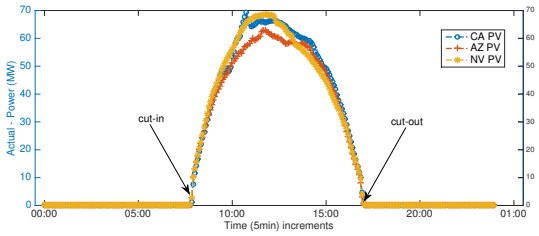

Figure 3: Aggregated solar power generation between 2008-2011 taken in Palm Springs CA, Prescott Airport CPV, AZ and Nevada Solar One, NV, indicating on a stable and fixed solar-based power [22]

1.3.3 Optimum Green Energy Utilization for On-Demand Streaming is a Resource Management Problem!

This study suggests that efficient; green energy utilization for on-demand video streaming workloads has three main requirements: (1) efficient compute resource discovery, (2) efficient load balancing among the provisioned compute resources and (3) smart failover mechanism that mask failover events from *green* CDN-edge instance to *grid* CDN-edge instance while end-users stream on-demand video [24]. These are discussed below.

Compute Resources Discovery. This assessment comprises both internal and external discovery. Internal discovery refers to CDN-edge instances that run in compute pods that must be able to be easily discovered and connected to control-plane endpoints consistently regardless of which cloud-service-provider is hosting the CDN-edge. External discovery refers to the ability of end-users discovering CDN-edge instances through DNS services for HTTP(S) on-demand video streaming.

Optimal Load Balancing is the seeking of the "best" CDN-edge, based on optimization criteria, for any given the workload processing. After initial discover and connection, clients should be served by the optimal instances based on proximity from the end-users, current load factor, and the availability of green energy resources. e.g., session requests originated from New Jersey should be served by US East as oppose to US West to avoid latency and signal loss.

Efficient Failover is a main component for on-demand video streaming based on green energy. If the endpoint becomes unavailable, in this case due to a sudden lack of green energy, the system must failover the client to another available endpoint that manages the streamed content. Also, failover must be completely automatic i.e. the clients end of the connection remains intact, and the end-user oblivious to the failover event, which means that the end-user's client software requires no support handling failover events. Finally, multiple CDN-edge instances co-located in a region should be accessible by end-users through Domain Naming

[5]Matlab Smoothing Splines retrieved from https://www.mathworks.com/help/curvefit/smoothing-splines.html?requestedDomain=www.mathworks.com

Service (DNS), as most clients-streaming (browsers) software supports DNS resolutions for finding available CDN-edges.

The green energy utilization model for processing on-demand video streaming is different than the classic scheduling problem where classical optimal resource allocation techniques are applied [25, 26]. We argue that based on the green energies' volatile nature and the on-demand video streaming workload characteristics, the optimal resource allocation approach should be opportunistic. It requires an effective resource management system for processing on-demand video streaming workloads. Our prototype will employ a Kubernetes flavor "Ubernetes" that implements the three main requirements above.

2 Clean Energy Mix Evaluation for Online On-Demand System

In the following section we evaluate a compute load coordination system component that harmonizes *on-demand streaming* job demands with available compute resources, with priority given to those powered by green energy sources. Such resources will be published to the coordination system through a resource availability tuple {*region,cut-in,rated,cut-off,power-efficiency*}, where *region* indicates the geographic availability region. *power-efficiency* indicates solar or wind based energy power efficiency. *cut-in, rated* and *cut-off* the values appropriate to those energies.

On-demand streaming job demand includes the specific *region, total-job workload, load-factor*, as well as *contract deadline* SLA. The *load-factor* indicates the required number of CPU cores per the *total-job-workload*. The geographic *region* indication will be used to optimize the match between the supply and demand. Also, the *total-job-workload* and the *deadline* will be compared against the *cut-in,rated, cutoff* time for wind or *power-efficiency* for solar, based on the published *load-factor*.

We suggest a hybrid datacenter that does not deviate from the common datacenter architecture. The core difference lies on an automatic transfer switch (ATS) that switches between different available power sources: generator, grid or green energy when available. In both cases the datacenter design does not change and requires incremental changes only by adding green energy power sources to the datacenter's ATS's (Figure 6).

We suggest two types of compute clusters, green-clusters powered by green energy and grid-clusters powered by the electrical grid. Figure 6 shows a simplified datacenter power distribution that supports green energy sources. In such datacenter, both *serving* and *analytical* systems deployed in grid clusters. Further, for incoming *analytical* workloads, few clusters use green resources when there are a viable green energy and mostly standby. As a mitigation strategy, a compute live migration procedure will be available in case of unpredicted lack of renewable resources during a workload processing which presents a risk for SLO violation.

2.1 Experiment Planning

Below is simulation of a cross-regional platform that is comprised of control-plane, workload-plane and coordinating components. This will be embodied in a resource allocation system (Kubernetes). This system will: (1) provision resources to be neared users; (2) optimize utilization by prioritizing the use of underutilized resources; and (3) seamlessly remove malfunctioning hardware from the system. The control-plane will enable an effective compute resource provisioning system that spans across different public cloud providers and regions. The coordinating components will accept user-workload demands as well as green energy availability from various regions and opportunistically seek to process streaming workloads using compute resources provisioned by green energy resources. The workload-plane will be comprised of edge streaming servers that process the end-user on-demand video streaming. It will built of standard Apache HTTP[6] servers that runs on the edge location.

The control-plane software infrastructure is based on Kubernetes [10], it facilitates internal discovery between CDN instances so instances can connect across different cloud boundaries and regions. Further, end-users can discover the optimal CDN-edges that are (1) nearby, (2) less loaded and (3) healthy. Finally, the Kubernetes automation framework allows the failover mechanism with no dependency upon the end-user client. In particular, we will exploit the *livenessProbe* option that automatically removes green-compute pods, a set of CDN-edge instances, in case of a sudden lack of green energy.

The coordinator component accepts incoming supply and demand traffic, calculates a potential match, within minutes, and notifies back the CSP and the SP for transaction completion. We use Redis[7] as the in-memory data store as the database that stores the system supply and demand calls originated by the end-user workload. The workload is generated by Jmeter instances[8]. The workload generated based on the on-demand video views observed by [12] depicted in Figure 1. Green energy availability simulated based on the known regional patterns depicted by Figure 2 and Figure 3.

We count the number of matches i.e. on-demand video streaming processed by CDN-edge instances operating on green energy. Also, we measure the false-positive cases where a match was suggested but did not met the SLO's deadline due to a violation that caused by a sudden lack of green energy resources. We use the data to extrapolate the possible energy (kWh) that could be generated by the using green CDN-edge instances depicts in Equation 1.

2.2 Execution - The Preparation

The prototype experiment included the setup of three virtual datacenters deployed in different regions: (1) Central US, (2) West US and (3) East US. The clusters were sized

[6] Apache Web Server reference retrieved from https://httpd.apache.org
[7] http://redis.io
[8] http://jmeter.apache.org

based on US population distribution[9] by regions i.e. 20% for West US, 40% for East US and 40% Central US. The cluster sizes for West US, Central US, and East US are 3, 7 and 7 machines respectively. Each machine is standard 2-CPU cores with 7.5GB of memory. Also, the user demand simulation will rely on the US population distribution. Finally, the green energy supply simulation will be based on wind or solar availability observed in the various regions.

The control-plane is comprised of docker API server and controller-manager. The controller coordinator component will need to allocate resources across several geographic regions different cloud providers. The API server will run a new federation namespace dedicated for the experiment in a manner such that resources are provisioned under a single system. Since the single system may expose external IPs it needs to be protected by an appropriate level of asynchronous encryption[10]. For simplicity, we use a single cloud provider, Google Container Engine, as it provides a multi-zone production-grade compute orchestration system. The compute instances that process the user workloads are deployed as Docker containers that run Ubuntu 15 loaded with Apache HTTP server. For simplicity, we avoid content distribution by embedding the video content to be streamed in the Docker image. We run 52 Docker containers that span across the three regions and act as CDN-edges. Green CDN-edge instances differ from grid CDN-edge instances by Kubernetes labeling. The simulation of the hybrid datacenter is depicted in Figure 6.

A coordination database system that aggregates green energy, solar or wind, availability, was built in software. When energy sources manifest the cut-in patterns depicted by Equation 2 and Equation 3, the coordination system starts green CDN edges in the availability regions. Also, when green energy availability reaches cut-off rates, the coordination system turns off green CDN edge instances.

2.3 Baseline and Variability of Workloads

The baseline execution included data populations of both green energy availability and user demand for video streaming. The data population was achieved by the Kubernetes-based Jmeter batch jobs. The loader jobs goal is to populate the coordinator database with green energy supply based on using a Weibull distribution, which is a generalization of the Rayleigh distribution described above for wind and a normal distribution for solar. Also, the user demand was populated according to the observed empirical patterns depicted by Figure 1.

We simulated the availability and unavailability of green energy using Jmeter-based workload plan against the coordination system. Our implementation starts green CDN-edge instances opportunistically upon green energy availability. Once a CDN-edge instance declares its availability it processes live workloads.

We use the Kubernetes *livenessProbe* for communication between CDN-edge instance pool and its load-balancer that divert traffic to its pool members. Finally, another workload Jmeter-based simulator generates on-demand streaming calls. This workload simulates end-user demand. It includes HTTP progressive download calls to pre-deployed video media in the CDN-edges.

2.4 Main Execution

In each of the three regional CDN-edge clusters the Kubernetes Jmeter batch jobs that generated green availability traffic to the coordination component were executed. The simulation is comprised of availability indication that are based on Figure 2 and Figure 3. We randomized solar production by using a factor of $\alpha = 0.2$ based on collected data between 2008-2011 in Palm Springs CA, Prescott Airport CPV, AZ and Nevada Solar One, NV [3]. Also, we randomized the wind production by a factor of $\beta = 0.4$ based on collected data between the years 2007-2012 [22]. The demand simulations included a set of calls to the coordinator component spread across 48 hours. The calls originated from three different timezones. The supply simulations consist of wind and solar-based energy time and power windows.

The experiment executions generated two main data traces that we used for the resulting generation computation. The first trace is the simulators logs. The simulator logs includes the demand and supply records. Demand records stored in the Redis key-value store under the key "DemandEvents" followed by timestamp, region and the required compute capacity. The supply calls were stored in the Redis key-value store under the key "SupplyEvents" follows by timestamp, region and supply phase i.e. cut_{in}, cut_{out} or *rated*. For query simplicity the loader ingested three types of records for each supply and demand the by the keys: (1) supply or demand (2) timestamp, and (3) by region. This approach optimized the coordinator queries by timestamp and regions for green CDN-edge instances allocation.

The second trace is the actual allocation logs. It is generated by the coordination system that invokes the Kuberenetes command for green CDN-edge instances initialization and disposal. This was used to determine the green energy utility translated into energy (kWh) that did not use grid energy sources.

2.4.1 Limitations

Every supply and demand was recorded three times to ease the query process. This approach was used since Redis provided limited query abilities by different keys. This approach might suffer data inconsistency issues where a supply metric was successfully committed to one key recode but missing on other key. Production systems should add extra safety gates when ingesting data. We used Redis because of its popularity in the Kubentese community. However, our approach is not limited to Redis or other database systems for that matter.

When measuring the green energy overall utility, we used the container initialization and disposal as indication that green energy utility was used. Specifically, we used the *'kubectl logs POD'* command based on the assumption that the coordination system invocation commands are tightly

[9] US Population Distribution retrieved from https://www.census.gov/popclock/data

[10] Simulation code and data retrieved from https://github.com/yahavb/green-content-delivery-network

coupled with green energy availability. It is likely that collecting the actual video streaming traces through the various Apache access logs of the CDN-edges will be more accurate.

In the case of a sudden lack of green energy while streaming video a failover occurs. Such failover event relies on domain naming services (DNS), the impact of DNS caching was not included since that might cause streaming delay on the user side. Also, when the coordinator algorithm determines there is enough green energy available it will take grid pods down and activate green pods up in a controlled fashion e.g., one at a time so that no requests are lost during the transition phase. For simplicity, the algorithm avoid that.

2.5 Analysis

The green energy supply simulation plotted in Figure 4 shows the energy generation in MW for both wind and solar sources. The simulated amounts were adjusted to the amount observed in the traces between 2007-2012 [22].

The user workload simulation plotted in Figure 4 follows the observed user patterns depicts in Figure 1. Also, it shows the aggregated green energy availability for each region. The cloud-coordinator uses these data sets to determine if there is enough green energy available before provisioning green-pods and possibly taking grid-pods down.

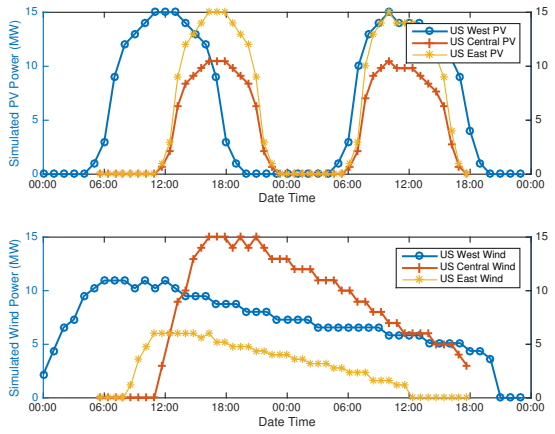

Figure 4: Green energy availability simulated in MW across three regions. Amounts are adjusted to NERL measurements i.e., wind generation in West US moderate, Central US outstanding, East US fair. For solar generation in West US strong, Central US moderate-high, and East US low.

The utility of the green energy was calculated based on the cases where sufficient green energy was available to run the green-CDN pods within the same region. Otherwise cross-regional latencies might degrade the on-demand video experience. The measurements in Figure 5 were adjusted to the estimates of required energy (kWh) for operating the green compute pods. The case where there was negative green energy available it was considered as a miss in the overall utility reckoning.

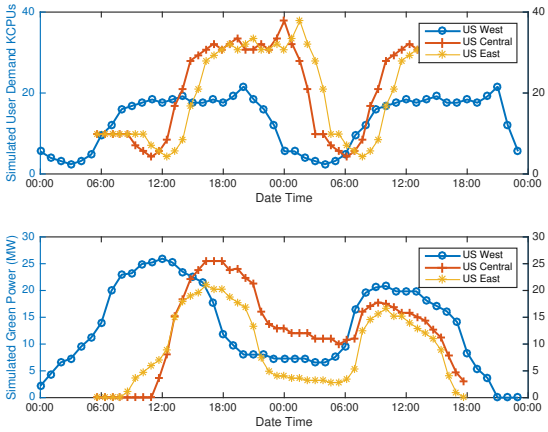

Figure 5: Video on-demand user workload per region adjusted with user population opposed to aggregated green energy availability, solar and wind energy.

2.6 Discussion on Energy Mix when Processing CDN Workloads

The scenario described above simulated the usage of green 801.3 *kWh* out of total 3642 *kWh* to process the video on-demand streaming workload. i.e. 22% by opportunistic matching. When counting the utility per region West US used 42% of the green energy. Central US used 28% of the simulated green energy. East US utilized only 18% as the initial ratio between user demand and green energy availability was relatively low. Although West US reached 40% utilization it contributed nationally only to the 20% portion it contains from the entire experiment test set. By way of comparison, Jeff Barr of AWS noted that their data centers utilize a 28% cleaner power mix[11]. Extrapolating the simulation results to the initial assessment in Equation 1 yields to a saving of:

$$(18.26(GWh) \cdot 1.89) \cdot 0.1(\$/kWh) \cdot 22\% = \$759,250.8/year$$

3 Clean Energy Mix Evaluation for Offline System

In the following section we evaluate a coordination component that harmonizes *analytics* jobs demands with available compute resources powered by green energy resources. Such resources will be published to the coordination system through a resource availability tuple {*region,cut-in,rated,cut-off,power-efficiency*}, where *region* and *power-efficiency* indicates solar or wind based energy and *region, cut-in, rated* and *cut-off* of those energies.

Analytics job demand includes the specific region, total-job workload, load-factor, as well as contract deadline stermed tuple. The *load-factor* indicates the required number of CPU cores per the *total-job-workload*. The region indication will optimize the match between the supply and demand. Also, the *total-job-workload* and the *deadline* will be checked against the *cut-in-rated, cutoff* time for wind or *power-efficiency* for solar, based on the published *load-factor*.

[11] Amazon Web Services Sustainability reference retrieved from https://aws.amazon.com/about-aws/sustainability/

We will suggest a hybrid data center structure that does not deviate from the common data-center architecture. The core difference lies on an automatic transfer switch (ATS) that switches between different available power sources: generator, grid or clean-energy when available. In both cases the data-center design does not change and requires incremental changes only by adding clean-energy power sources to the datacenter's ATS's (Figure 6).

Figure 6 shows a simplified data-center power distribution that supports clean energy sources. In a data-center with available clean-energy resources for both *serving* and *analytical* systems deployed in brown clusters. Further, few clusters use green resources when there are a viable clean energy and standby for incoming *analytical* workloads. As a mitigation strategy, a compute live migration procedure will be available in case of unpredicted lack of renewable resources during a workload processing with a risk for SLO violation.

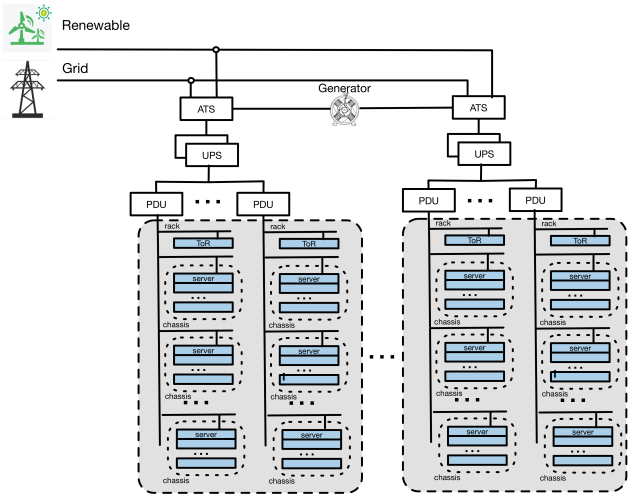

Figure 6: Datacenter Architecture - Compute server clusters aggregated by racks and chassis. Racks are fed by separate Power Distribution Unit (PDU) that connects to Uninterruptible Power Supply (UPS) that connects to the primary power source through Automatic Transfer Switch (ATS).

3.1 Experiment Planning

We wish to simulate an isolated group of computing resources so it can operate by various energy resources, especially available green ones. We use a group of leased resources from existing cloud providers to form a virtual-data-centers set that operates in a federated scheme. Each virtual-data-center includes with internal arbitrator component that collects and aggregates internal signals about its utilization and availability. The arbitrator then reports to the central coordination system. We use Apache Mesos[12] for the virtual-data-center abstraction.

Also, we build a highly available coordination component that accepts incoming supply and demand traffic, calculates a potential match, within minutes, and notifies back the cloud-service-provider and the service-provider for transaction completion. We use VoltDB[13] as the database and application server for the coordinator component.

[12]http://mesos.apache.org
[13]http://voltdb.com

Finally, we simulate customer's demand for compute resources through client simulator with a Java-based application that generates pseudo demand traffic to the coordinator service. The coordinator service will run on separate resources pool than the virtual-data-centers and the client simulator.(Figure 7)

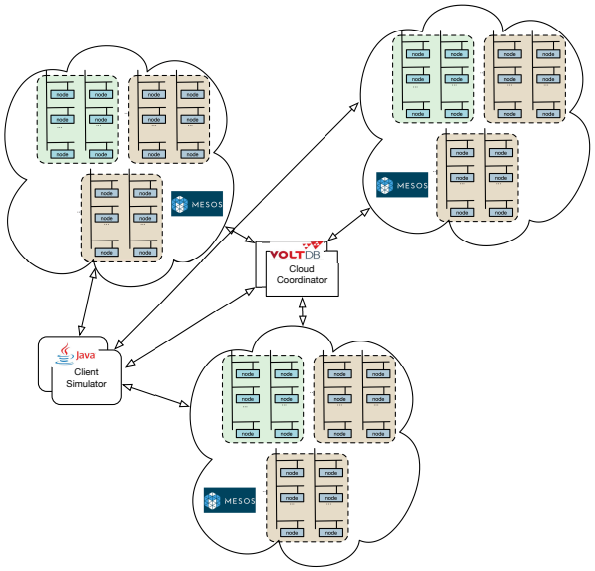

Figure 7: Experiment Architecture - Three virtual clusters deployed on a public cloud services located in a different regions grouped by Apache Mesos. A single VoltDB instance as the coordinator service. Finally, Client simulator that generates pseudo demand that sends data to process

The data collected includes customer workload for jobs processing and jobs deadline. Also, the number of matches found by the coordination component and processed by green clusters without SLO. Finally, we measure the false-positive cases where a match was suggested but not met the SLO's deadline due to a violation that caused by a sudden lack of clean energy resources. We use the data to extrapolate the possible carbon-footprint that could be generated by the used virtual clusters.

The research goal is to show a significant improvement in the carbon emission generation by data-centers. Let $MtCO_2e$ denote the carbon emission. Electrical usage can be consumed by the $Consumers$ set: {cooling, storage, servers, CPU, power} systems and denoted by EU measured in kWh. The average regional carbon dioxide emissions measured in lbs/kWh and denoted by RE_{co_2}. Therefore, the total electrical usage is:

$$EU_{Total}(kWh) = \sum_{c_i \in Consumers} EU(c_i) \tag{4}$$

and the carbon footprint generated by the workload is:

$$MtCO_2e = \frac{EU_{Total}(kWh) \cdot RE_{co_2}(lbs/kWh)}{2,204.6(lbs)} \tag{5}$$

As the experiment uses virtual data-centers, we do not have access to the power consumption by the cooling, power and storage system. The results capture compute jobs durations

measure in server $\frac{CPUcore}{time}$ and use the average Thermal Design Power (TDP) of 200W per core (0.2kW). c_i and t_i denotes the number of cores and time used per job respectively. The electric usage by server ($EU_{servers}$) will be the sum of the electric utilization of the executed jobs that was matched by the coordinator component (Equation 6)

$$EU_{servers}(kWh) = \sum_{i=1}^{jobs} c_i \cdot 0.2 \cdot t_i \quad (6)$$

We assume a linear relation between the power utilization of the cooling, power and storage systems with the servers power utilization. (Equation 4)

3.2 Execution - The Preparation

The Preparation for the execution included the setup of the three virtual data-centers each with 6 machines D4 series with 8 Intel(R) Xeon(R) CPU E5-2660 0 @ 2.20GHz cores, 10Gbps NICs, 28 GB memory and run Ubuntu 15.0. Each virtual data-center is located in a different geo-location. The virtual data-centers were simulated by Mesosphere cluster with three jobtracker(Mesos masters) and three tasktracker(Mesos slaves). We installed Hadoop Cloudera CDH 4.2.1-MR1 on the takstrackers. The Coordinator Database run on a separate resource pool with 1 machine D series similar to the virtual data-centers specification. Finally, the loaders run on a 3 D2 series machines with 2 cores Intel(R) Xeon(R) CPU E5-2660 0 @ 2.20GHz cores, 10Gbps NICs, 7 GB memory and run Ubuntu 15.0. Apache Hadoop ships with a pre-built sample app, the ubiquitous WordCount example. The input data file was created using */dev/urandom* on the takstrackers hosts[14]. The input data file was copied to the HDFS directory that was created as part of the Hadoop preparation (/user/foo/data).

Anticipated Required Deviations from the original job plan. The original plan was to simulate the scenario where the customer keeps his data at a different location than it might be processed. We plan on using a job migration scheme that was originally designed for workload migration across different geo-location[20]. The suggested method optimizes the bandwidth costs of transferring application state and data over the wide-area network. Our experiment generated the data file at the loader host and did not include the job migration. We believe that including the job migration aspect could impact the presented results. However, the job migrations proven efficiency and later studies minimize that deviation.

3.3 Baseline and Variability of Workloads

Baseline. The execution baseline included a load that runs without the coordinator component i.e. loaders generated load to the virtual data-centers resources for 48 hours. The load scenario included a single file generation that was submitted to one of the tasktrackers. The output of each executed jobs included the CPU time spent for each execution. The data collection included the execution log of the command: Hadoop jar loader.jar wordcount /user/foo/data /user/foo/out.

Variability of Workloads. The workload comprises of data files with words that need to be counted using the Hadoop WordCount. The load complexity depends on two factors, the file randomness level, and its size. We rely on the native operating system randomness, and our virtual data-centers and loaders are homogeneous. Therefore, the size is the remaining factor for differentiating workload types. We evaluated the federated-cloud coordinator by generating three load types simultaneously. The three types intend to cover the following cases (1) A match was found between workload and sufficient green energy resources. (2) A match was found, but there was not enough power to complete the job with no SLO deadline violation. (3) Like the former but with SLO deadline violation. The three types will be uniquely distributed across wind and solar based virtual data-centers.

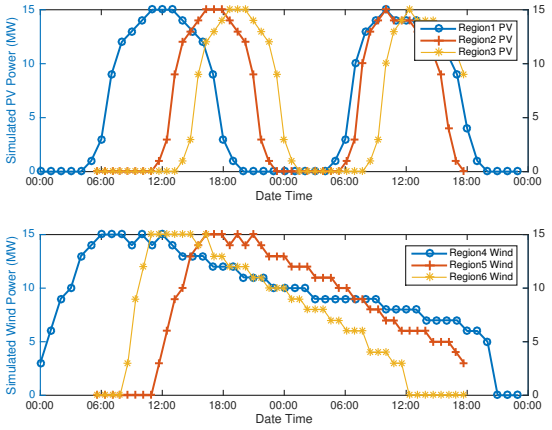

Figure 8: Green Energy availability simulated across six different timezones, three for PV power and the bottom three for wind. These indications are fed, in near-time, to the coordinator database that runs a temporal stored procedure that seeks for match with pending registered jobs.

3.4 Main Execution Issues

In each jobtracker host in a virtual data-center, we executed a simulator that generated green availability traffic to the coordination component. The simulation comprises of availability indication that are based on figure 2 and figure 3. We randomized solar production by using a missing factor of $\alpha = 0.2$ based on collected data between 2008-2011 in Palm Springs CA, Prescott Airport CPV, AZ and Nevada Solar One, NV [22]. Also, we randomized the wind production by a missing factor of $\beta = 0.4$ based on collected data between the years 2007-2012 [22]. The demand simulations included a set of calls to the coordinator component spread across 48 hours triggered by a Monte Carlo simulation inspired by [27]. We built a Rayleigh-based distribution model in the Monte Carlo simulation using Matlab Statistics and Machine Learning Toolbox[15]. The calls originated from three different timezones. Each call comprises of the tuple {region,total-job-workload, load-factor, contract deadlines}. The supply simulators are comprised of

[14]https://github.com/yahavb/GreenCloudCoordination/
[15]https://www.mathworks.com/products/statistics.html

the wind and solar-based energy time and power windows. Supply call to the coordinator includes the tuple {region,cut-in,rated,cut-off,power-efficiency}. The coordinator runs a temporal stored procedure that find a match between the supply and demand data. When a match found, the coordinator generates an assignment call to the jobtracker in the corresponded virtual data-center to execute the jobs. The execution will fetch the data to be processed and report temporal statuses to the coordinator. Every status call generates a check against the current demand levels in the particular region. If the demand changed, and the request cannot be fulfilled, the job considered as false-positive. If the jobs are completed successfully, the request counted as success along with the Core/hour saved.

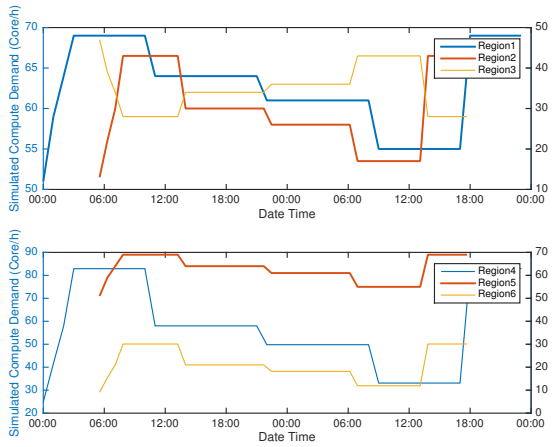

Figure 9: A Monte-Carlo-based simulated compute demand across six different timezones, three for PV power and the bottom three for wind. These indications are fed, in near-time, to the coordinator database that runs a temporal stored procedure that seeks for match with available green energy.

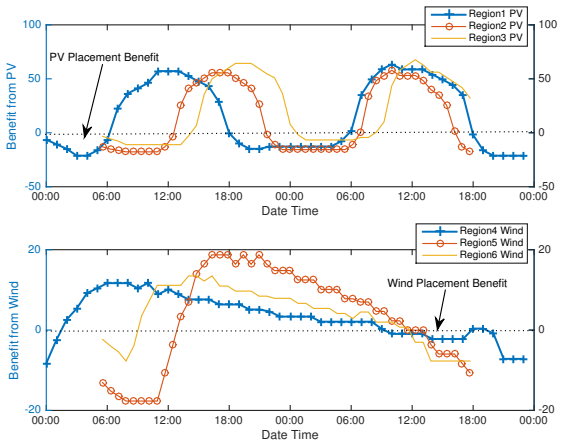

Figure 10: Job placement ranges denoted by the doted line in both the PV and the Wind plots. Any values above the zero levels indicate on potential benefits. However, assigned jobs might not be able to fully processed when unpredicted drop in the availability.

3.5 Analysis

The experiment executions generated three core data logs that we used for the result generation. The first data set is the simulators logs. The simulator logs comprise of the demand records. Demand records stored in the Demand VoltDB table. The supply calls were stored in the Supply VoltDB table. The match transactions stored in the Jobs VoltDB table with status and the number of cores/hour used for the job. Status values can be Success or False-Positive. Figure 9 shows the two supply indications. Both signals were generated based on Equation 2 and Equation 3. The demand data was generated based on known usage patterns that are spread across three timezones.

3.6 Discussion on Energy Mix when Processing Offline Workloads

The experiment simulated the usage of green 708 *kWh* out of total required 3,252 *kWh* for *analytical* systems workload processing i.e. 22% less carbon emission (Equation 5). 1822 *kWh*, 50% of the total workload consumption, was processed by brown energy because of false-positive events i.e. the coordinator assigned a job with no sufficient green recourses to process the job. We believe that optimizing the coordinator algorithm can improve the footprint reduction up to 50%.

Figure 10 shows the job placement ranges denoted by the dotted line in both the PV and the Wind plots. Any values above the zero levels indicate on potential benefits. However, such cases are subject to false positive events that can occur when an unpredicted drop in the availability. Further, such cases utilize the hybrid datacenter power scheme describes in figure 6.

4 Conclusions

The future growth of cloud computing will increase its energy consumption as a fraction of grid power and will cause a significant addition to the ever growing carbon emission since 70% of US power is generated by hydrocarbon fired power plants. Using rapidly emerging green energy for processing cloud computing workloads can limit the anticipated carbon emission growth. However, balancing time varying green energy utilization with time varying energy demands of cloud computing is a complex task that requires sophisticated command and control prediction algorithms beyond the scope of this paper but are emerging in the form of a smart grid system of systems [28]. Our study shows that green energy utilization for on-demand streaming workload is best described as a resource management problem. The solution presented demonstrates real time balance of green resource supply and cloud computing workload demand and utilizes Ubernetes, an open source container cluster manager. The results approximate within 21% those observed in a single cloud instance in the field. Our study also shows that green energy utilization for offline workload processing is a fast data problem. Its solution best utilizes VoltDB, an in-memory database, to allow near-time response for green resources supply and workload demand. Our future work will focus on optimizing the false-positive ratio, to further reducing the cloud computing carbon footprint by up to 50%.

Conflict of Interest The authors declare no conflict of interest.

ABSTRACT

The IoT is innovative and important phenomenon prone to several services and applications such as the blockchain which an emerging phenomenon. We can describe the blockchain as blockchain as a ser- vice because of the opportunity to use several applications based on this technology. We, indeed, should take into account the legal issues related to the data protection and privacy law to avoid breaches of the law. In this context, it is important to consider the new European General Data Protection Regulation (GDPR) that will be in force on 25 May 2018. The contribution describes the main legal issues related to data protection and privacy focusing on the Data Protection by Design approach, according to the GDPR. Furthermore, I resolutely believe that is possible to develop a global privacy standard framework that organisations can use for their data protection activities.

1 Introduction

To define the Internet of Things (IoT) could be a challenge [1] due to its technical and conceptual complexity [2]. The IoT is a phenomenon founded on a network of objects linked by a tag or microchip that send data to a system that receives it. The IoT includes every connection among objects, so we have machine-to-machine (M2M) systems, where each machine talks with other machine(s), communicating real-time data and information. Nowadays we are faced with several devices but mainly such as smartphones and apps, sensors, chip, and any other electronic system. We read [3]

> *The concept was simple but powerful. If all objects in daily life were equipped with identifiers and wireless connectivity, these objects could communicate with each other and be managed by computers.*

In 2012 the Global Standards Initiative on Internet of Things (IoT-GSI) the Internet of Things (IoT) defined the IoT as "the infrastructure of the information society[1]." Not that the IoT phenomenon is realised only when two or more objects are linked to each other in a network such as the Internet. Apart from this kind of connection, an object could also be indirectly linked to a person, thereby setting up a ring network among objects and people. Its very simple, for example, to imagine a ring network that could link a person with one or more objects (a clock, a chair, a lamp, etc.) equipped with a technological system (RFID, near field communication NFC, etc.). However, the IoT is a virtual reality that reproduces exactly what happens in the real world. Lets imagine that our clock, chair, and lamp all contain chips and are used by a person with special needs. From a medical point of view, it may be crucial, for instance, to know how many times he uses the chair. At the same time, it is necessary to help him by automatically turning on the lamp when he sits in the chair. Using chips, it is possible for the objects to communicate among themselves (e.g., the lamp turning on when the chair sends data that the man is sitting down) and at the same time send data over the Internet for, say, medical analysis. The information provided by each object can be aggregated, thereby creating a profile for him. The profile may contain sensitive information about the man, which raises the possibility of

[1] The Internet of Things (IoT) has been defined in Recommendation ITU-T Y.2060 (06/2012) as a global infrastructure for the information society, enabling advanced services by interconnecting (physical and virtual) things based on existing and evolving interoperable information and communication technologies [4].

https://dx.doi.org/10.25046/aj030201

his being monitored. This is a very important point for privacy. This scenario could present a lot of legal issues related to privacy and data protection law. The main goal is to evaluate the impact of the IoT phenomenon on the fundamental rights such as the right to respect for private and family life according to the European Convention on human rights [5]. There are others legal aspects to take into account developing a project on IoT. It is quite important to highlight that there are differences between data protection and privacy especially in Europe where the Charter of Fundamental Rights of the European Union identifies as fundamental rights privacy (article 7) and data protection (article 8).

2 The correct approach: privacy is not security

The main focal point to address a correct approach to any evaluation of data protection and/or privacy risks, in general, is to understand the differences between security and privacy. The correct equation is the following one:

$$security \neq privacy \tag{1}$$

where security is different from privacy. In fact, according to this principle, it is possible to adopt very high-security measures, but this can not mean to respect privacy law either protect users privacy. Often this concept is every indication that it is necessary to intervene on the security systems to be compliance with privacy law. Obviously, this is a big misunderstanding and could create confusion on the privacy approach and its consequences. Adopting security measures is certainly a value, but it is not the correct way to deal with privacy issues. To address privacy and data protection correctly, it is necessary to start from the privacy by design (or da- ta protection by design and by default) approach as further and better clarified below. Privacy is embedded into design2. More clearly Privacy, having been embedded into the system before the first element of information being collected, extends throughout the entire life-cycle of the data involved, from start to finish.

2.1 Protecting privacy through the privacy by design approach

The Internet of Things represents a global revolution: the objects that people use in the real world can talk to other objects and at the same time to the data subjects themselves. This scenario goes from the Internet of People (IoP) - because of the connection among people - to the Internet of Everything. This consciousness is the real engine that has pressed politicians and regulators to intervene in the IoT realm. In fact, there is a growing desire to create a general, comprehensive, and structured legal framework for the Internet of Things to protect users and consumers. In October 2010, the 32nd International Conference of Data Protection and Privacy Commissioners adopted a resolution on Privacy by Design (PbD) [6] that is a landmark and represents a turning point for the future of privacy. Instead of relying on compliance with laws and regulations as the solution to privacy threats, PbD takes the approach of embedding privacy into the design of systems from the very beginning.

The primary goal is to draw up two concepts: a) data protection and b) user. Regarding privacy, we have always thought in term of compliance with laws, failing to evaluate the real role of the user (and his or her personal data). To develop an adequate data protection and privacy approach, we must start any process with the user the person who has to be protected putting him or her at the centre. That means that during the design process, the organisation always has to be thinking of how it will protect the users privacy. By making the user the starting point in developing any project (or process), we realise a PbD approach.

This methodological approach is based on the following seven foundational principles [7]:

1. **Proactive not reactive; preventative not remedial;**
2. **Privacy as the default setting;**
3. **Privacy embedded into design;**
4. **Full functionality positive-sum, not zero-sum;**
5. **End-to-end security full lifecycle protection;**
6. **Visibility and transparency keep it open;**
7. **Respect for user privacy keep it user-centric.**

We can see why the Privacy by Design approach is so important in the IoT environment. In fact, the Internet of Things should adopt the PbD principles and statements, always placing the user at the centre. The European Data Protection Supervisor (EDPS) has promoted PbD, touting the concept in its March 2010 Opinion of the European Data Protection Supervisor on Promoting Trust in the Information Society by Fostering Data Protection and Privacy [8] as *a key tool for generating individual trust in ICT*. It was not long after this endorsement that the 32nd International Conference of Data Protection and Privacy Commissioners adopted the PbD concept as well. In Europe, this approach became *"Data Protection by Design and by Default"* (DPbDabD) in the EU Regulation 679/2016 [9] and indeed establishing this concept in the law is a welcome development. Nevertheless, it is kind of interesting to notice that the EU legislator used a different expression (i.e., data protection by design and by default) from the one adopted in the international context (i.e., Privacy by Design). These two expressions represent two different methodological approaches. Privacy by Design is structured in a trilogy of applications (information technology, accountable business practices, physical design) and the seven principles quoted above. The EU formulation is more descriptive and not based on a method; also, the by default

concept is autonomous, whereas the PbD approach embeds the same concept into by design. According to the text of Article 25 of the Regulation 679/2016, it is clear that the EU legislator considers by design and by default as different concepts, even though the words by design comprehend the concept by default, making the latter phrase redundant. The EU formulation is more descriptive and not based on a method; also, the by default concept is autonomous, whereas the PbD approach embeds the same concept into by design. Furthermore, the EU Regulation 679/2016 seems to pay a lot of attention to the technical and security aspects instead of the legal concerns, as seen in highlighting of the term "security". Hence, the Internet of Things should adopt the Privacy by Design principles and statements, always placing the user at the centre.

3 IoT evolution and its applications: a challenge

The IoT phenomenon makes to spring several applications in different sectors (Personal, Home, Vehicles, Enterprise, Industrial Internet) [10]. This is a continuously evolving system, and we see to the development of many application in each sector. In the last few years, it arose the interest (the needing) to guarantee highest security levels both for the Industries and the users.

The fields of Big Data and Blockchain are the leading emerging phenomena in the IoT ecosystem, but people paid attention more to the technical and security issues than the privacy ones.

Certainly, the security aspects are relevant to avoid or reduce the risks for data privacy. However, from a privacy point of view, we cannot dismiss the right approach, according to the PbD principles. In the first phase of analysis, any project has to be evaluated also thinking how to protect privacy data and personal information applying the PbD principles. In concrete, after the evaluation process, the project has to comply with the law and not after starting it. Once the project starts, it does not need any process of compliance with the law because, according to the PbD principles, the same project has to be already in compliance with the privacy law before starting it. In this case, (during the life cycle of the project) it is not required any evaluation of compliance with the law. In fact, any assessment it is necessary during the design phase of the project, just for the nature of the approach "by design", applying the PbD principles correctly.

Several IoT applications have been developed in the field named "smart", such as smart grid, smart city, smart home, smart car, etc. This indeed represents what is the IoT evolution that it will continue to grow and develop creating a lot of fields of action. In the "smart context," we cannot dismiss from the privacy and security risks related to the communication among objects especially in the case of processing personal data.

The main questions are:

- "Where are the users' personal data stored?"
- "Who manage the users' personal data?"
- "What kind of security measures has been adopted?"
- "Can it be considered a smart system compliance with the privacy law?"

The answers depend on the design model used during the developing preliminary phase. In fact, the "design" is a fundamental topic as we illustrate in the following considerations.

However, in the IoT echo-system are emerging two relevant and complex aspects in part closely related between them: **Big Data** and **Blockchain**. In the last few years, these have been items of interest in the IoT phenomenon, intensifying the interest by whom deals with it, especially because of the implications both from the side of the developers and from the users. Hence, Big Data and Blockchain represent the new challenge and the new applications of the IoT phenomenon.

This scenario entails the need to deepen these aspects, especially regarding the privacy and data protection issues.

3.1 Big Data: privacy issues and risks in the Internet of Things

Despite its many potential benefits, the Internet of Things poses important privacy and security risks because of the technologies involved.

According to the Gartner Newsroom [11], 6.4 Billion Connected Things will be in use in 2016, up 30 percent from 2015 and the device online are estimated to reach 20.8 billion by 2020. This represents a scenario to be monitored not only for the big data phenomenon but also for threats and risks to privacy and security.

A recent study on the threats to our privacy, security and safety, under the "Cyberhygiene" project [12], carried out the report (not yet published) named *"Understanding end-user cyber hygiene in the context of the Internet of Things: A Delphi-study with experts"*. This report, in the beginning, says that *"This study aimed to establish expert consensus concerning the 1) key malicious IoT threats, 2) key protective behaviours for users to safeguard themselves in IoT environments, and 3) key risky user behaviours that may undermine cyberhygiene in IoT environments"*[2]. In conclusion, this report says *"There was consensus on the need to consider behaviours across IoT lifecycles. By considering behaviour across each lifecycle, we have been able to identify key behaviours that users need to adopt when using IoT devices. Furthermore, we have been able to identify key threats that can, for example, put users sensitive information at risk and risky behaviours that may lead users to be at risk of a successful attack"*.

[2] See also "Review of Cyber Hygiene practices" - ENISA - https://www.enisa.europa.eu/publications/cyber-hygiene

No doubt, therefore, that even in the IoT ecosystem there are important risks and threats to privacy and it should take appropriate precautions.

On the one hand, we can control devices such as vending machines and stereo speakers with our smartphones, manage devices in our homes (domotics for energy saving, security, comfort, communication) by remote control, and use smartphone apps to book reservations or purchase services. Larger-scale IoT applications might include public security systems or warehouse inventory control systems. It is evident the acceleration of the technological evolution in the last few years and the IoT phenomenon it is not exempt[3]. IoT considers the pervasive presence in the environment of a variety of things, which through wireless and wired connections and unique addressing schemes can interact with each other and cooperate with other things to create new applications/services and reach common goals. In the last few years IoT has evolved from being simply a concept built around communication protocols and devices to a multidisciplinary domain. Devices, Internet technology, and people (via data and semantics) converge to create a complete ecosystem for business innovation, reusability, interoperability, that includes solving the security, privacy and trust implications.

On the other hand, we have seen the fast and exponential data growth, data traffic and, hence, another paradigm well-known as Big Data[4]. Big data implies data analysis and data mining procedures but working on big data values[5]. Nowadays it is very simple to develop apps that, by accessing to data, can execute data mining activities with every possible consequence. In this context, the primary goal is to protect data because of their highest value. Among the main risks we can indeed present the following:

- ***Identification of Personal Information***

The IoT system allows you to transfer data on the Internet, including personal data. Personal information may be transmitted only when the object in which the microchip installed is linked to a person. This connection may be direct or indirect.

We could have a direct link when the user is aware of the possible transmission of his or her personal data and gives consent. Alternatively, let us suppose that a person buys something. Alternatively, the connection may be indirect when the object is not linked directly to a person but only indirectly through the use of information that belongs to that person. For example, if we have x objects linked together by the Internet, I might know information about object nr. 1, but I cannot know to whom this information belongs. I can know, however, that objects nr. 2, 3, and so on are connected among themselves and to a person named Jane. In this way, it is possible to link every piece of information provided by the objects (2, 3, etc.) to Jane. Furthermore, if I know that it is possible to link object nr. 1 to the others (2, 3, etc.), I can also indirectly know that the information provided by object nr. 1 likewise belongs to Jane.

- ***Profiling***

There are several risks and threats in the Internet of Things, but the main one is probably profiling [13], [14]. If objects are linked to a person, it will be possible to obtain personal information about that person through the information transmitted over the Internet by each of those objects. Furthermore, these transmitted data may be stored in one or more servers. When a person can be identified through the use of credit or loyalty cards, its very simple to know the types of products purchased and so on to profile the person, learning about his or her habits and lifestyle. The person may have previously provided consent for the dissemination of data related to his or her purchases for advertising purposes. Regarding privacy, is it possible to protect a person? Who manages the personal data? Where will this data be stored? Profiling can also be an issue with the movement toward smart grids and cities, a phenomenon that is close in nature to the Internet of Things. For some years now, there has been an interest in modernising the existing electrical grid by introducing smart meters, which can communicate a consumers energy consumption data to the relevant utilities for monitoring and billing purposes. From a legal perspective, there is the need to consider the privacy issues arising from these initiatives, such as consumer profiling, data loss, data breach, and lack of consent (consent is mandatory by law).

- ***Geolocation***

Geolocation is another risk because nowadays, by our device (first of all the smartphones) it is very simple to find precise details on the location, for instance, digital photos. Inside each picture file there are some fields among them EXIF and GPS that contain the technical information about the photo and also the location where the picture was taken. If the user has not previously deactivated the geolocation service in the camera or smartphone, and the pictures have been published on a website or social network, anyone who views the photo can know exactly where the picture was taken and see who was there.

In this way, privacy could be compromised. When smartphones and other mobile devices are connected

[3]IoT is a concept and a paradigm with different visions, and multidisciplinary activities

[4]Big data is a term for datasets that are so large or complex that traditional data processing applications are inadequate to deal with them. Challenges include analysis, capture, data curation, search, sharing, storage, transfer, visualisation, querying, updating and information privacy. The term "big data" often refers only to the use of predictive analytics, user behaviour analytics, or certain other advanced data analytics methods that extract value from data, and seldom to a particular size of data set. *"There is little doubt that the quantities of data now available are indeed large, but thats not the most relevant characteristic of this new data ecosystem."* (Wikipedia)

[5]Is well-known the Four Vs of Big Data: Volume, Velocity, Variety and Veracity (IBM). Considering data as value it is possible extend the approach to 5 V (last V as value).

to the Internet, as they typically are, they contribute every day to the Internet of things, sending data ready to be used by other people.

- ***Liability for Data Breaches***

In Europe, there are numerous national and European Community (EC) laws relating to personal data breaches. Hence, the Internet of Things also has effects on liability in cases where the data being collected and transmitted lacks the appropriate security measures. For example, Directive 2002/58/EC [15] states that: *In case of a particular risk of a breach of the security of the network, the provider of a publicly available electronic communications service must inform the subscribers concerning such risk and, where the risk lies outside the scope of the measures to be taken by the service provider, of any possible remedies, including an indication of the likely costs involved.*

Another risk is the loss of data during processing. The consequences entail, of course, liability for the data controller and data processor related to each particular situation. In fact, because the processing of personal data involves risks to the data in question (such as the loss of it), the EU Regulation n. 679/2016 on data protection contains an article requiring data controllers to conduct a data protection impact assessment (DPIA)[6] an evaluation of data processing operations that pose particular risks to data subjects.

According to the Article 35, paragraph 1, of the EU Regulation n. 976/2016 (GDPR) *"Where a type of processing in particular using new technologies, and taking into account the nature, scope, context and purposes of the processing, is likely to result in a high risk to the rights and freedoms of natural persons, the controller shall, prior to the processing, carry out an assessment of the impact of the envisaged processing operations on the protection of personal data. A single assessment may address a set of similar processing operations that present similar high risks"*.
This is the law prescription on the need to conduct a data protection impact assessment (DPIA) in some cases. This preventive action could avoid or reduce risks for the fundamental rights such as data protection and privacy. This demonstrates as is crucial to pay attention to security and privacy in any project development.

3.2 Blockchain: what about privacy?

The blockchain *"is a shared, immutable ledger for recording the history of transactions"* [16]; it is a ledger of records. The blockchain was imagined by Satoshi Nakamoto [17]. Blockchain works as a distributed database, and its structure guarantees any modification or alteration due to the strong link and timestamp among each block.

The blockchain was theorised thinking to the web of trust principles and, hence, based on the consensus according to the proof of work concept related to the computational power made available by each one. Subsequently, the participation in the blockchain processes has been revised in terms of proof of stake according to the amount of cryptocurrency hold of each one. Given that, nowadays we can have different kind of participation in the blockchain consensus (proof of work - proof od stake), and according to the solution adopted, it will determined the blockchain governance. Furthermore, it is possible to distinguish three different kinds of blockchain:

1. Public blockchain;
2. Consortium blockchain;
3. Private blockchain [18]

The main differences are essentially related to the permission to write the blocks and participate in the consensus processes. The blockchain can be used to provide services, such as the guarantee about the personal identity. It is possible to implement an application for the electronic identification (eID) through which to store, securely in each block of the block- chain, the personal information that could be used to know with certainty the identity of a person. The blockchain can be also used for public services by the Public Bodies or to storage securely and without risks of modification electronic documents or any other resource.

The blockchain poses problems related to data protection and privacy, considering them as two different concepts (but they are rights). It is a field well-known by the engineers and developers, but often ad- dressed only increasing the security measures instead of considering the data protection and privacy law. Regarding privacy, Satoshi Nakamoto [17] argues that *"privacy can still be maintained by breaking the flow of information in another place: by keeping public keys anonymous"*. However, the author says also that *"The risk is that if the owner of a key is revealed, linking could reveal other transactions that belonged to the same owner"*. That represents a significant chink in the privacy perspective. Ensuring privacy and data protection is one of the main aims of any project which has to address "by design", not leaving any possibility to compromise personal data and/or personal information. Axon [19] argues that privacy issues can be dealt with "privacy-awareness" enabling *"two levels of anonymity: total anonymity, and anonymity to the neighbour group level"*. However, "privacy-awareness" do not seem a valid solution because this way it is not enough to be compliance with the EU GDPR, according to the Article 25 (Data protection by design and by default).

In another technical contribution [20] you read *"Maintaining privacy on the blockchain is a complicated issue"*. The authors propose *"A couple of ways to mitigate but not completely eliminate this issue, if privacy is important for the considered application"*. Privacy is certainly important on the blockchain, and for this reason, it would be better to address the issue finding a "legal" solution to be compliance with the law.

[6] In the rest of the world this is well-known as Privacy Impact Assessment (PIA).

Other authors [21] say *"Despite the benets provided by these services, critical privacy issues may arise. That is because the connected devices (the things) spread sensitive personal data and reveal behaviours and preferences of their owners. Peoples privacy is particularly at risk when such sensitive data are managed by centralised companies, which can make an illegitimate use of them . . . "*. It is very appreciable these authors' approach [21] because they propose a technical solution presenting it in terms of "private-by-design IoT" [7]. Despite the fact that this proposed solution highlights the concept "by design", from a legal point of view it does not seem to take on the issue related to the obligation required by the EU GDPR.

This short scenario shows how on the blockchain there are certainly privacy issues addressed only providing technical solutions, without any legal reference. Apart from the high technical solution, hence, we cannot dismiss the law obligations, where they are applicable, like in Europe, according to the GDPR mentioned above. This panorama confirms the equation according to security is different from privacy; a system could be very secure but not compliance with the privacy law. On the contrary, a system could be compliance with the privacy law and, hence, very secure (obviously if it has been adopted the security measures).

This is an obligation for the controller. Giving the structure of the blockchain, it seems that any subject or person or owner (as defined by Nakamoto) should be a controller and consequently bound to respect the EU GDPR. From this scenario arise many consequences for the "owner" regarding law obligations.

In fact, according to the GDPR, it is mandatory to "implement appropriate technical and organisational measures" [8]

In certain cases, if there are high risks to the rights and freedom of natural person, it is mandatory to provide a Data Protection Impact Assessment (DPIA) to carry out, prior to the processing, *an assessment of the impact of the envisaged processing operations on the protection of personal data* (Article 35). Another aspect is related to the consent according to the GDPR. In fact, according to the Article 6, paragraph 1.a, *the data subject has given consent to the processing of his or her personal data for one or more specific purposes*. Moreover, according to the Article 7, paragraph 3, *the data subject shall have the right to withdraw his or her consent at any time*. Against this background, it is clear that the technical infrastructure of the blockchain prevents the concrete withdrawal of the consent by the data subject because this solution implies the node deletion. The consent issue represents undoubtedly another legal point related to the blockchain and the data protection law.

According to the technical structure of the blockchain, all the system has not any controller because of the lack of a central controller (a general "supervisor") who is responsible for all the nodes. Each owner, hence, is a controller for the data processing of his node. In this perspective each owner, apart from the general securities profiles of the blockchain, has to respect the law and he is himself is a data processing controller. Due to the blockchain technical configuration, in the event of a node was compromised, it is possible to amount to a controller's liability and, in this case, there are certainly other consequences for the owner's node.

4 Conclusion

The Internet of Things involves all stakeholders from companies to consumers. Focusing on the user (consumer) is particularly important to guarantee a level of confidentiality that will earn the users trust. This solution is made possible by adopting the maximum level of security through the Privacy by Design (PbD or DPbDabD) approach and performing PIAs to evaluate the privacy risks of data collection and processing.

The industries may be wary of efforts to regulate the Internet of Things, as it regards the IoT phenomenon as a source of enormous business opportunities. For example, changes in lifestyle such as the use of more technological services like domotics applications can certainly increase the consumers quality of life (and industrys profits). It will be up to consumers, regulators, and privacy professionals to convince the business sector that understanding the risks related to the IoT will produce the same business opportunities to protect privacy and increase the quality of life.

As I hope I have shown, it is crucial to set up a privacy standard to facilitate a methodological approach to privacy and data protection. With the Internet of Things reaching ever more deeply into peoples lives, it would be beneficial to have an international privacy standard for processing personal data in the same way throughout the world using the forward-looking PbD (or DPbDabD) approach.

From a legal point of view, the main difficulty in setting up and using a privacy standard relates to existing laws, which are different in each nation (and even in different states and provinces within those nations). It is possible to develop a standard privacy framework that organisations can use for their data protection activities, adapting it to national legislation while keeping the central framework for all nation-

[7] You read "With the purpose of preventing this situation, the goal of our research is to encourage a decentralized and private-by-design IoT, where privacy is guaranteed by the technical design of the systems. We believe that this can be achieved by adopting Peer-to-Peer (P2P) systems."

[8] Article 25, par. 1, says *"Taking into account the state of the art, the cost of implementation and the nature, scope, context and purposes of processing as well as the risks of varying likelihood and severity for rights and freedoms of natural persons posed by the processing, the controller shall, both at the time of the determination of the means for processing and at the time of the processing itself, implement appropriate technical and organisational measures, such as pseudonymisation, which are designed to implement data-protection principles, such as data minimisation, in an effective manner and to integrate the necessary safeguards into the processing in order to meet the requirements of this Regulation and protect the rights of data subjects"*.

states.

Since the Privacy by Design (or DPbDabD) approach is the foundational methodological approach to privacy protection, the privacy standard should be adopted according to PbD principles and statements. At the moment we have no record of international privacy standard model.

A Privacy Management System (PMS) could be a reference model or a software system working on the PbD principles. To develop a PMS confers a benefit to all the stakeholders because in this way it is possible to automate every process guaranteeing a good data protection level, by reducing the privacy and security risks. Furthermore, it is feasible to use the Artificial Intelligence and Machine Learning principles to develop a software based on a PMS to facilitate professionals, public body, Industries and Organizations in their activities.

ABSTRACT

In the present article, we develop multilayer perceptron model for identification of some possible genes mediating different leukemia. The procedure involves grouping of gene based correlation coefficient and finally select of some possible genes. The procedure has been successfully applied three human leukemia gene expression data sets. The superiority of the procedure has been demonstrated seven existing gene selection methods like Support Vector Machine (SVM), Signal-to-Noise Ratio (SNR), Significance Analysis of Microarray (SAM), Bayesian Regularization (BR), Neighborhood Analysis (NA), Gaussian Mixture Model (GMM), Hidden Markov Model (HMM) is demonstrated, in terms of the affluence of each Go attribute of the important genes based on p-value statistics. The result are properly validated by before analysis, t-test, gene expression profile plots. The proposed procedure has been capable to select genes that are more biologically significant for mediating of leukemia then those obtained by existing methods.

1 Introduction

In the body, cancer is the uncontrolled enhancement of unusual cell. When the bodys normal control procedure stop the working, then cancer are build-up [1]. Old cells do not expire and in its place develop out of control, establishing fresh, abnormal cells. These additional cells may create a mass of tissue, called a tumor [2]. Leukemia is a cancer which starts in blood forming tissue, usually the bone marrow [3]. It leads to the over production of abnormal white blood cells [4]. However, the abnormal cells in leukemia do not function in the same way as normal white blood cells [5]. There are several types of leukemia, based upon how speedily the disease is growing up and the type of abnormal cells are generate. Peoples are may be affected at all stage by cancer [6]. In 2015, 54,270 people are prospective to be diagnosed with leukemia. The overall five-year correlative anointing rate for leukemia has more than four fold since 1960. From 1960 to 1965, the five-year correlative anointing rate among whites (only data available) with leukemia was 14%. From 1975 to 1980, the five-year correlative anointing rate for the total population with leukemia was 34.20% [7], and from 2004 to 2010, the overall correlative anointing rate was 60.30% [8]. From 2005-2010, the five-year relative correlative anointing overall were Chronic Myeloid Leukemia (CML) is 59.90% [9], Chronic Lymphocytic Leukemia (CLL) is 83.50%, Acute Myeloid Leukemia (AML) is 25.40% overall and 66.30% for children and adolescents younger than 15 years and Acute Lymphocytic Leukemia (ALL) is 70% overall [10], 91.80% for children and adolescents younger than 15 years, and 93% for children younger than 5 years. In 2015, 24,450 people are expected to die from leukemia with 14,040 males and 10,050 females [11]. In Us 2007-2011, leukemia was the fifth most common cause of cancer deaths in men and the sixth most common in women.

In the field of microarray data analysis, one of the most challenging remittance is gene selection [12]. In gene expression data normally contains a large number of variables genes compared to the numbers of samples [13]. The conventional data mining methodology cannot be directly used to the data due to this identity problem [14]. In this reason analysis of gene expression data used dimension reduction procedure [15]. The gene selection which deducts the genes

[*]Corresponding Author: Sougata Sheet & sougata.sheet@gmail.com

https://dx.doi.org/10.25046/aj030202

extremely related to the pattern of every types disease in order to escape such problems [16]. Parametric and non-parametric tests are the statistical approach [17]. For example *t*-test and Wilcoxon rank sum test have been thoroughly used for searching differentially revealed genes since they are instinctive to understand and implement [18]. But they have a restriction to propagate, if more than two classes and require time swallowing coordination to solve the problem of multiple testing [19]. For three or more groups, the Kruskal-Wallis test can be used. But it may be created biased result because of reliance on the number of samples, when it is used to microarray data whose sample size are normally unbalanced [20]. Many diseases, they are reason by the problems such as chromosomal disequilibrium and gene mutations, which give away abnormal gene expression patterns. These pattern get the information about underlying genetic process and states of several types disease. If these patterns can be analyzed appropriately, they can be effective for recognize the disease sample and identifying the extent to which a patient is affliction from the disease and which can be help in the supervision of disease.

The microarray gene expression data have been collected to underlying biological process of a number of diseases [21]. It is very essential to narrow down from thousands of genes to a few disease genes and gene ranking [18]. In microarry data analysis genes selection is most important phase. For classification of data analysis, several forms of technique have been proposed for gene ranking [22]. These are classified into three several types: filter, wrapper and embedded process [23]. Each of these categories has its personal advantages and disadvantages. For example, filter process are computationally useful and simple but minor performance than the other process. On the other hand, wrapper and embedded procedure are comparatively much complicated and computationally costly but it usually gives excellent classification performance as they mainly apply classifier characteristics in gene ranking. Filter procedure include T-score, which is *t*-statistic standardized interrelation between input and output class labels [15]. On the other hand, wrapper and embedded procedure include Support Vector Machine (SVM) and its variants, random forest-RFE, elastic net, guided regularized random forest [24], balanced iterative random forest [25] etc . Main distinction of filter process and wrapper or embedded procedure is how they behave samples when ranking genes. For example, in filter procedure, all the samples are usually used for gene ranking but the quality and relevance data samples are ignore [26]. On the other hand wrapper or embedded procedure, classifier such as boosting algorithm, logistic regression, Support Vector Machine (SVM) etc., are used to gene ranking [27].

For complicated data analysis, we can used an Artificial Neural Network (ANN) model [28]. An ANN was externally used for solve the problem such as diagnosis of different types of cancer such as speech recognition, breast cancer [28] [29]and cervical cancer. Several types of effective researches on blood cells using neural network model has been committed [30]. Ongun *et al* enhancement a completely automated classification of bone marrow and blood using several types of way such as neural network and support vector machine (SVM). The best performance of SVM with accuracy of 91.05% as parallelism to Multilayer Perceptron (MLP) network using Conjugate Gradient Descent, Linear Vector Quantization (LVQ), and k-Nearest Neighbors (KNN) classifier which generate accuracy of 89.74%, 83.33% and 80.76% respectively.

In this paper, we proposed a method based on neural network models for identify a set of possible genes mediating the development of cancerous growth in cell. We said this model is Multilayer Perceptron Model-1 (MLP-1) and Multilayer Perceptron Model-2 (MLP-2) [31]. At first we form group of genes using correlation coefficient, then we select the most important group. Finally, we present a set of possible genes get by this method, which may be responsible for cancerous growth in human cell. In this article, we consider three human leukemia gene expression data sets. The usefulness of the procedure, along with its excellent result over several others procedure, has been demonstrated three cancer related human leukemia gene expression data sets. The results have been compared seven existing gene selection methods like Support Vector Machine (SVM), Signal-to-Noise Ratio (SNR), Significance Analysis of Microarray (SAM), Bayesian Regularization (BR), Neighborhood Analysis (NA), Gaussian Mixture Model (GMM), and Hidden Markov Model (HMM). The results are appropriately validated by some previous investigations and gene expression profiles, and compared using *t*-test, *p*-value, and number of enriched attributes. Moreover, the proposed procedure has get more number of true positive genes than the existing ones in identifying responsible genes.

2 Related Work

In this article, we have proposed procedure based neural network models for identification of cancer mediating genes. On existing gene selection methods, we have made a survey for comparative analysis [32]. Among them, we have select some existing gene selection methods like SVM, SNR, SAM, BR, NA, GMM, HMM.

SVM is a one type of machine learning procedure which is differ two classes by maximizing the margin between them [33]. For cancer classification, support vector machines (SVMs) is used to identify important genes [34]. The Lasso (L1) SVM and standard SVM are often considered using quadratic and linear programming procedure. A recurrent algorithm is used to solve the Smoothly Clipped Absolute Deviation (SCAD) SVM efficiently. Almost all the cases, it is noticed that with smaller standard errors the SCAD-SVM selects a smaller and a more stable number of

genes than the L1-SVM. Another algorithm of gene selection using the weight magnitude as ranking criterion is Recursive Feature Elimination (RFE) SVM [35]. The SVM-RFE procedure ranks all the genes according to some scoring operation, and remove one or more genes with the lowest score values [36]. When the maximal classification accuracy is achieved, then the procedure will be stop [37].

Signal-to-noise ratio (SNR) is applied to rank the correlative genes according to their discriminative power. The procedure starts with the evaluation of a single gene, and frequently finding for other genes based on some statistical criteria [38]. The high SNR genes scores are select as the significant ones. Measurement of SNR score are affected by the size of variables [39]. When there are more than variables, the average and disunity of the other variables of another classes are dependent on the number of variables and data dispersion, which effect SNR ranking of the important variables due to the enhancement in noise in the data. The procedure is more efficient of finding and ranking a smaller number of important variables, when the number of variables can be decrease significantly.

Significance analysis of microarray (SAM) is a one type of gene selection procedure which use a set of gene specific t-test and identify genes with statistical significant changing in expression values [40]. The basis of change in the gene expression values, every gene is assigned a score value. If the gene score value the greater than a threshold value which indicate potentially significant [41]. False Discovery Rate (FDR) is the percentage of such genes identified by chance [42]. In order to calculate FDR, insignificance genes are identified by analyzing layout of the measurements. Identify the smaller or larger sets of genes can be adjusted by using threshold value, and FDRs are computed for every set. The main problem is that, in permutation step where entire gene group are put in one group for evaluation. This needs an expensive computation and it likely confuses the analysis because of the noise in gene expression data.

A simple Bayesian procedure has been used to remove the regularization parameter [43]. The value of a regularization parameter is determined by degree of sparsely, which is get an optimal result. Normally this include a model selection step, and calculate the minimization of cross validation error based on intensive search.

Neighborhood analysis (NA) is a procedure for clustering multivariate data analysis based on a given distance metric over the data. Functionally, purpose of NA and K-nearest neighbor algorithm are same [44]. Any significant correlation cannot detect and this is the main disadvantage. This problem may be due to the few number of genes and also likely that the phenotype is too complicated to be connected with a cluster of genes, and a more extend relationship may present in gene expression.

A Gaussian mixture model (GMM) is represented as a weighted sum of gaussian component densities which is based on a parametric probability density function [45]. For parameter selection GMM has been used. We have designed GMM on microarray gene expression data for gene selection. On the other hand, for genes identification, we have designed Hidden Markov Model (HMM) on microarray gene expression data sets. Normally HMMs provide an intuitional framework for representing genes with their several functional properties, and proficient algorithms can be creating to use these models to identify genes.

3 Methodology

Let us assume a set $G = (g_1, g_2, ..., g_i)$ of i genes are known which is hold the normal samples for first m expression values and diseased samples for subsequent n expression values. Now correlation coefficient of gene based normal samples are calculated. Therefore, correlation coefficient R_{qr} within q^{th} and r^{th} is given by [46] [47]

$$R_{qr} = \frac{\sum_{l=1}^{m}(g_{ql} - y_q) * (g_{rl} - y_r)}{\sqrt{(\sum_{l=1}^{m}(g_{ql} - y_q)^2) * \sqrt{(\sum_{l=1}^{m}(g_{rl} - y_r)^2)}}} \quad (1)$$

Here y_q and y_r are the mean of expression values of q^{th} and r^{th}, gene respectively in normal samples.

Similarly, for diseased samples the iteration coefficient R_{qr} between q^{th} and r^{th} genes is given by

$$R^{'}_{qr} = \frac{\sum_{l'=1}^{n}(g^{'}_{ql'} - y^{'}_{q}) * (g^{'}_{rl'} - y^{'}_{r})}{\sqrt{(\sum_{l'=1}^{n}(g^{'}_{ql'} - y^{'}_{q})^2) * \sqrt{(\sum_{l'=1}^{n}(g^{'}_{rl'} - y^{'}_{r})^2)}}} \quad (2)$$

Using equation 1 and 2 each pair of genes is computed. The genes are located in the similar group if $R_{qr} \geq 0.5$. Now we have used interrelation coefficient to narrow down hearted the invention space by searching genes of a comparable behavior in terms of related expression patterns. The set of responsible genes mediating certain cancers are recognized in this procedure. The choice of 0.50 as a threshold value has been done through extensive experimentation for which the distances among the cluster center have become maximize [48]. The main set of genes is obtained in this pathway [49].

An extremely simplified model of biological structures is an Artificial Neural Networks that imitative the conduct of the human brain. A huge number of interrelated processing components of the layered structure is composed and intended to imitative biological neurons. MLP model is the one of the most popular ANN types with back-propagation algorithm. Figure 1, show the architecture of MLP model containing of interconnected neurons of three layers [50]. This three layers are input layer, hidden layer, and output layer [51]. This model is represented as $n \times p \times q$. Where input layer consist of n number of neurons, hidden layer consist of p number of neurons and output layer consist of q number of neurons. In the higher layer every neuron in every layer is completely attached to all neurons and every link has a weight connected with it. In interconnected neurons, these

weights are define the nature and strength of the influence. The output signals from one layer are conducted to the consequent layer by using links that amplify the signals based on the interconnected weights [52]. Exception of the input layer neurons, the total input of every neuron is the sum of weighted outputs of the previous layer neurons. In hidden and output layers neurons, we can calculate the output by using sigmoid logistic function such as an activation function.

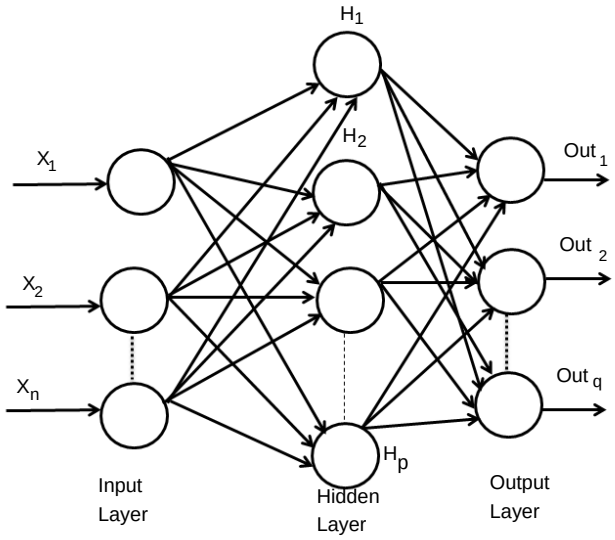

Figure 1: Architecture of an MLP network

Hidden layer neurons execute a non-linear alteration that qualifies the MLP model to simulate a more difficult and non-linear structure within the constraints of a three layer MLP model and more than one hidden layer are used. By employing an incremental adaptation approach, the MLP model has generalized curve fitting capability. Input patterns and output patterns was carried out by MLP model and specified proportion is randomly selected. A learning procedure to correct the linking weights recurrently and to reduce the system error mechanism by every forward processing of the input signal by using back-propagation algorithm. In the initial stage of the learning procedure, to create a input pattern from the input layer to the output layer. The error of every output neuron was calculated from the difference between the calculated and desired outputs. $\varepsilon(p)$ is the system error of p^{th} training pattern, which is defined as

$$\varepsilon(p) = \frac{1}{2}\sum_{k=1}^{q}(D_k(p) - x_k(p))^2 \tag{3}$$

Where $D_k(p)$ and $x_k(p)$ are the k^{th} element of the desired output and calculated output respectively. On the other hand number of neurons in output layer is q. Readjustment of the weights in the hidden layers and output layers is the next step by using a generalized delta rule which is minimizing the distinction between the desired outputs and calculated outputs. Every interconnection weight of the incremental correction can be calculated by

$$\Delta\omega_{kj} = -\gamma\frac{\partial\epsilon(p)}{\partial\omega_{kj}} + \rho\Delta\omega_{kj}(p-1) \tag{4}$$

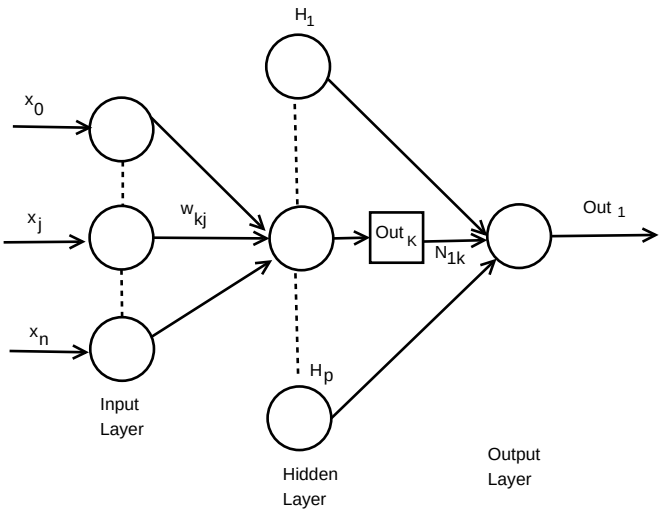

Figure 2: $n \times p \times 1$ MLP model architecture.

The incremental correction of the interconnection weight between j^{th} neurons and k^{th} neuron is $\Delta\omega_{kj}(p)$, in the last iteration, the incremental correction is $\Delta\omega_{kj}(p-1)$ learning rate is γ and the range of $0 < \gamma < 1$, momentum factor is the ρ and range is $0 \leq \rho < 1$. By using learning rate the updated weight is control and improve of the effectiveness of learning procedure by using momentum. Training set carried when the squared errors of average sum are over and all training patterns was globally reduced. On training period completion, the testing period was conduct those input pattern which was not present in the training set. Now we consider a MLP model with $n \times p \times 1$ network. Input layer, hidden layer and output layer are n, p, 1 respectively. Show in Figure 2. For both hidden and output neurons was select sigmoid function as the activation function. The mapping function of input-output are realize by the network Out_1 can be computed as

$$Out_1 = \phi(U_1) = \frac{1}{1 + exp^{(}-U_1)} \tag{5}$$

$$Out_k = \phi(u_k) = \frac{1}{1 + exp^{(}-u_k)} \tag{6}$$

Where

$$U_1 = \sum_{k=0}^{p} N_{1k} Out_k \tag{7}$$

$$u_k = \sum_{j=0}^{p} \omega_{kl} x_j \tag{8}$$

Algorithm 1 Training procedure - MLP-1

Step 1: Initialize all weight and bias.
Step 2: While terminating condition is not satisfied;
Step 2.1 For each training tuple; propagate the input forward,
Step 3: For each output layer of unit q,
Step 3.1: Output of an input unit, which is actual input values,
Step 4: For every hidden layers or output layers,
Step 4.1: Compute the net input of unit q with respect to the previous layer p;
Step 4.2: Compute the output of q, layer.
Step 5: Compute the error of output layer of unit q;
Step 6: Compute the error with respect to the next higher layers.
Step 7: Increment the weight of every layers.
Step 8: Update the weight of every layers.
Step 9: Increment the bias of every layers.
Step 10: Update the bias of each layers.
Step 11: After some iteration, when all $\Delta\omega_{pq}$ in the previous epoch were so small as to bellow specified threshold 0.05, then the procedure will be stop.

Algorithm 2 Training procedure - MLP-2

Step 1: Initialize the weight and bias.
Step 2: Perform a vector of row which is the weight interconnection between the hidden layers (p nodes) and output layer.
Step 2: Perform $n \times p\times$ matrix and interconnection weights between the input nodes (n) and hidden nodes (p) is ω.
Step 3: Row vector are computed.
Step 4: Relative weight of input node are computed.
Step 4: After some iteration, when all weight values in the previous epoch were so small as to bellow specified threshold 0.05, then the procedure will be stop.

Interconnection weight between the k^{th} hidden neuron and output neuron is N_{1k} interconnection weight between the k^{th} hidden neuron and j^{th} input neuron is ω_{kj}. In the j^{th} hidden neuron the output value is Out_k. x_j is the input of the j^{th} input neuron, where $Out_0 = -1$. The case belongs to class 1, where $Out \geq 0.05$ and case belongs to class 0 where $Out_1 < 0.05$. A node can recognized an output of that node given an input or set of inputs by using activation function. A linear access can be produce 1 or 0 output, but non-linear process the activation function can be generate the output in the specific limit. The activation function can be accepted large forms construct on the data sets. A set of training samples, comparing the networks prediction for each sample with the actual known class level are frequently generating by using back-propagation learning method. The weights are changes as to minimize the mean squared error between the actual class and the prediction network for each sample. The weight and every bias are initialized to small random number of the network. Now we can calculate the total input and output of each unit in the output layer and hidden layer. At first the sample are fed to the input layer of the network. Note that for unit q in the input layer, its output is equal to its input, that is $Out_q = \eta_q$ for input q. Given an unit q in a hidden layer or output layer, the net input η_q, to unit q is

$$\eta_q = \sum \omega_{pq} Out_p + \beta_q \tag{9}$$

Where ω_{pq} is the weight of the connection from unit p in the previous layer to unit q; Out_p is the output of unit p from the previous layer and β_q is the bias of the unit. Given the net input η_q to unit q and output of unit q is computed as

$$Out_q = \frac{1}{1 + \lambda^{-\eta_q}} \tag{10}$$

The error is created backwards by updating the weight and bias in the network. For a unit q in the output layer, the error κ_q is computed by

$$\kappa_q = Out_q(1 - Out_q)(\chi_q - Out_q) \tag{11}$$

Where Out_q is the actual output of unit q and χ_q is the true output. The error of hidden layer of unit of unit q is

$$\kappa_q = Out_q(1 - Out_q) \sum \kappa_r \alpha_{qr} \tag{12}$$

Where α_{qr} is the weight of the connection from unit q to unit r and κ_r is the error of unit r. Now the weight of every layer are incremented and update the weight value of each layer.

$$\Delta\omega_{pq} = (\mu)\kappa_q Out_q \tag{13}$$

$$\omega_{pq} = \omega_{pq} + \Delta\omega_{pq} \tag{14}$$

Now the bias of every layer are incremented and update the all bias value of each layer.

$$\Delta\beta_q = (\mu)\kappa_q \tag{15}$$

$$\beta_q = \beta_q + \Delta\beta_q \tag{16}$$

After some iteration, when all $\Delta\omega_{pq}$ in the previous epoch were so small as to bellow specified threshold 0.05, then the procedure will be stop. The procedure will be describe in algorithm 1 and algorithm 2.

4 Description of the Data sets

In this work, we can select three types of leukemia gene expression data sets. The data sets ID is GDS-2643, GDS-2501, GDS-3057 and title of the data set is Waldenstrom's macroglobulinemia (B lymphocytes and plasma cells), B-cell chronic lymphocytic leukemia, and Acute Myeloid Leukemia respectively. The data base web link is http://ncbi.nlm.nih.gov/projects/geo/.

The data set (GDS-2643) consists of 22,283 numbers of genes with 56 samples. Among them, there are 13 normal samples which consist of 8 normal for B lymphocytes and 5 normal plasma cells and 43 diseased samples which consist of 20 Waldenstrom's macroglobulinemia, 11chronic lymphocytic leukemia, 12 multiple myeloma samples.

The dataset (GDS-2501) data set consists of 22,283 numbers of genes with 16 samples. In this sample analysis of B-cell chronic lymphocytic leukemia (B-CLL) cells that express or do not express zeta-associated protein (ZAP-70) and CD38. The prognosis of patients with ZAP-70-CD38- B-CLL cells is good, those with ZAP-70+CD38+B-CLL cells is poor.

The dataset (GDS-3057) content 26 Acute Myeloid Leukemia (AML) patients with normal hematopoietic cells at a variety of different stages of maturation from 38 healthy donors The total data set consist of 22,283 number of genes with 64 samples. Among them, there are 38 normal samples which contents 10 normal for bone marrow, 10 normal samples for peripheral blood, 8 normal samples for bone marrow CD34 plus and 10 normal samples for Primed peripheral blood hematopoietic stem cells (PBSC) CD34 plus. On the other hand there are 26 leukemia samples which contents 7 bone marrow and 19 peripheral bloods.

5 Comparative Performance Evaluation of the Models

In this section, the usefulness of the procedure has been demonstrated three types of human leukemia gene expression data sets. Now we can apply comparative analysis with seven existing methods like SVM, SNR, SAM, BR, NA, GMM and HMM. We have applied this procedure on the gene expression data sets for selecting important genes. We have found two classifier groups. One is normal class and another is disease class. After some iteration, we have found normalized value of every gene. Here we have considered a threshold value which is 0.05. After normalization if the gene value is grater then 0.05, then which types of gene is normal gene. After normalization if the gene value is less than 0.05, then which types of gene is disease gene. We consider several genes that are most significant of our experiment. The gene expression values are significantly changes from normal samples to diseased samples. Applying this process on the first data set (GDS-2643), we have found that genes like CYBB, TPT1 and PRDM2 among the most important genes which are over the expressed the diseased samples. On the other hand CRYAB minimize the expression value and fully significant in diseased samples. The gene are recognize as an under expressed gene. In order to limited size of manuscript, we have showed only the profile plots of genes of GDS-2643 data set (depicted in Figure 3). In the case of GDS-2501 data set, the genes like ACTB, CENPN, ALCAM, PXN have changed their expression values for normal samples to diseased samples. Similarly, the dataset GDS-3057, like TDG, CTIF, LLS, NAB2 have changed their expression values for normal samples to diseased samples. The usefulness of the methodology has been shown three types of leukemia gene expression data. We have applied the methodology on the aforesaid gene expression data sets for selecting some important gene intercede diseases. Now we have applied the procedure on the previous gene expression data sets for selecting some important diseases mediating genes. In this procedure, at first based on correlation values the genes are placed into group. For GDS-2643, we have found six groups which holding 1869, 1131, 1033, 601, 537 and 1208 number of genes (Table 5). The most important group by both MLP-1 and MLP-2 has been selected 1869 number of group genes. Now we have considered two classes for both MLP-1 and MLP-2. One is normal samples class and other is diseased samples class. ω is a weight coefficient value which is initialized by random numbers. Both MLP-1 and MLP-2, we have found 28 and 30 number of genes respectively, when grouping of genes and most important groups selection are completed. Now we have found 20 numbers genes that are present in both procedure. Among them, based on their ω values we have selected 18 number of genes.

Similarly in GDS-2501, we have found eight groups which containing 652, 1031, 1217, 1301, 816, 539, 741 and 912 number of genes. Similarly in GDS-3057, eight group of genes which contain 2521, 2624, 2241, 2341, 2471, 803, 2191, and 2238. Now we have found 1869 genes for GDS-2643, 1217 genes for GDS-2501 and 2624 genes for GDS-3057 respectively by applying both MLP-1 and MLP-2. Finally we have found 24, 21 and 20 number of most important genes corresponding to the three data set by using MLP-1. On the other hand we have found 25, 21 and 19 number of most important genes corresponding to the three data set by using MLP-2. The number of genes which is found by both MLP-1 and MLP-2 are 18, 21 and 17 to these data sets. Table (5) show that for different sets of genes the number of functionally enriched attributes corresponding to these methods. It has been found that both procedure MLP-1 and MLP-2 performed the best results for all data sets. These results show that

Data set ID	Selected group	No of selected groups from selected group	Group	No genes in each group
GDS-2643	1	18	1	1869
			2	1131
			3	1033
			4	601
			5	537
			6	1208
GDS-2501	2	21	1	652
			2	1031
			3	1217
			4	1301
			5	816
			6	539
			7	741
			8	912
GDS-3057	4	17	1	2521
			2	2624
			3	2241
			4	2341
			5	2471
			6	803
			7	2191
			8	2238

Table 1: Selection of groups and genes for different data set

the both MLP-1 and MLP-2 procedure has been able to select the more number of important genes responsible for mediating a disease than the other seven existing procedure.

5.1 Validation of the Result

In this part, we have analysis the results which is founded by different types of procedure including MLP-1 and MLP-2. In this comparison we have using p-value, t-test, biochemical pathways, F-test and sensitivity.

5.1.1 Statistical Validation

Prosperity of every GO attributes of every genes has been computed by its p-value. When the p-value is low, it means that the genes are biologically significant. Now we have create a comparative analysis, by using some other procedure like SVM, SNR, SAM, BR, NA, GMM and HMM. For different sets of genes Table 2 show that number of functionally enriched attributes corresponding to these procedure. For all data set we have been show that MLP-1 and MLP-2 performed the best result. The more important genes are select by these procedure are show in these results. Both NFM-1 and NFM-2 are accomplished of getting more number of true positive genes in terms of identifying the GO attributes and cancer attributes with respect to other existing procedure are depicted in Figure(4). Now we have 478 GO attributes of 375 gene set are identified among them 102 GO attributes of cancer related are identified.

Now we validate the results statistically, we have performed t-test on the genes identified by DLM on each data sets. t-test is the statistical significance which indicate whether or not the difference between two groups average most likely reflects an original difference in the population from which the group wear sampled. The t-value show the most significant genes (99.9%) which p-value <0.001. For this three types of data set we can apply t-test and we get corresponding t-value. We have identify some important genes like IARS (4.78), MMP25 (5.68), TYMS (4.96), HPS6 (5.24), MLX (4.12), CALCA (4.32), HIC2 (4.12), ANP32B (5.16), TFPI (4.51), CRYAB (3.08), NCF1C (3.71), HNRNPH1 (3.12), etc. The number in the bracket shows t-value of the corresponding gene. The t-value of this genes exceeds the value for $p = 0.001$. This means that this gene is highly significant (99.9% level of significance). Similarly genes like ERCC5 (3.52), PRDM2 (3.45), PRIM2 (2.54), TPT1 (3.35), RPS26 (2.41), EFCAB11 (3.71), PRPSAP2 (3.43), PRKACA (2.44), etc exceed the t-value for $P = 0.01$. It indicated that this gene is significant at the level of 99%. Similarly genes like MED17 (2.55), MAPK1 (2.35), PIK3CB (2.45), NMD3 (2.15), ARG2 (2.16), EXOC3 (2.56), WHSC1 (2.71), RFC4 (2.35), GLB1L (2.71), HNF1A (2.41) etc exceeds the value for $P = 0.05$. It indicate that this genes significant at the level of 95%. Similarly genes like FLG (1.77), TXNL1 (1.24), RIN3 (1.34), CYBB (2.31), ZNF814 (1.45), KLF4 (1.18) etc exceeds the value for $P = 0.1$. It indicate that this type of genes significant at the level of 90%.

In GDS-2643, we have found cancer pathway for non-small cell and small cell leukemia. In these two

Data set	Gene Set	MLP-1	MLP-2	SVM	SNR	SAM	BR	NA	GMM	HMM
GDS-2643	First 5	60	58	59	10	12	15	10	27	20
	First 10	72	73	65	17	18	20	13	32	25
	First 15	77	79	71	21	22	26	12	41	29
	First 20	79	92	76	30	26	30	16	45	34
GDS-2501	First 5	83	78	85	15	55	48	33	39	48
	First 10	88	85	88	24	62	55	41	44	60
	First 15	101	98	95	31	68	72	52	51	55
	First 20	107	106	103	39	84	65	66	68	77
GDS-3057	First 5	45	52	37	21	24	26	24	19	20
	First 10	63	62	46	35	30	29	33	25	28
	First 15	67	65	57	37	29	31	39	27	35
	First 20	69	70	55	41	31	35	42	36	39

Table 2: Result of several sets of genes on number of attributes

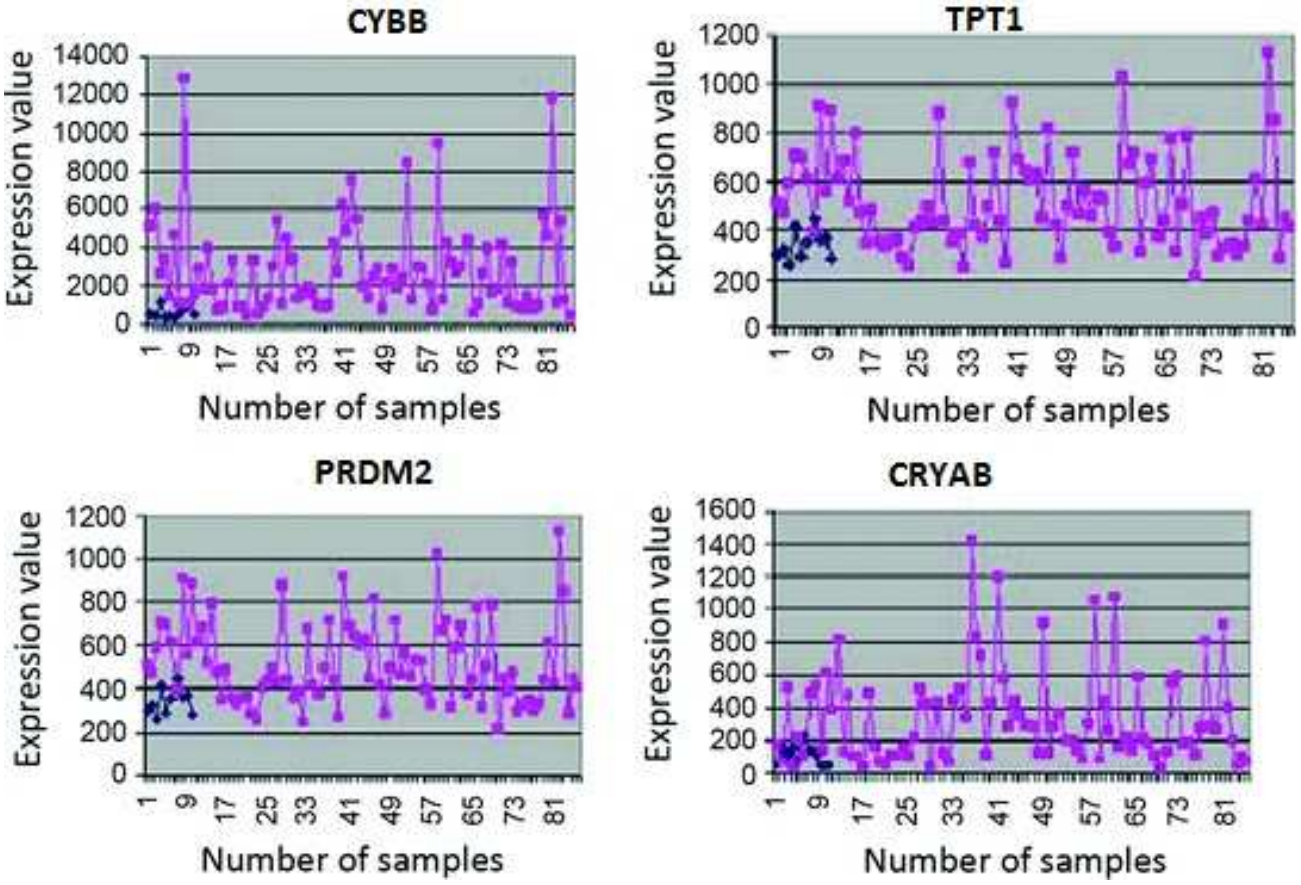

Figure 3: Expression profiles of some over-expressed genes (CYBB, TPT1, PRDM2) and under-express (CRYAB) in normal (shown by blue points) and disease (shown by red points) sample of human leukemia expression data.

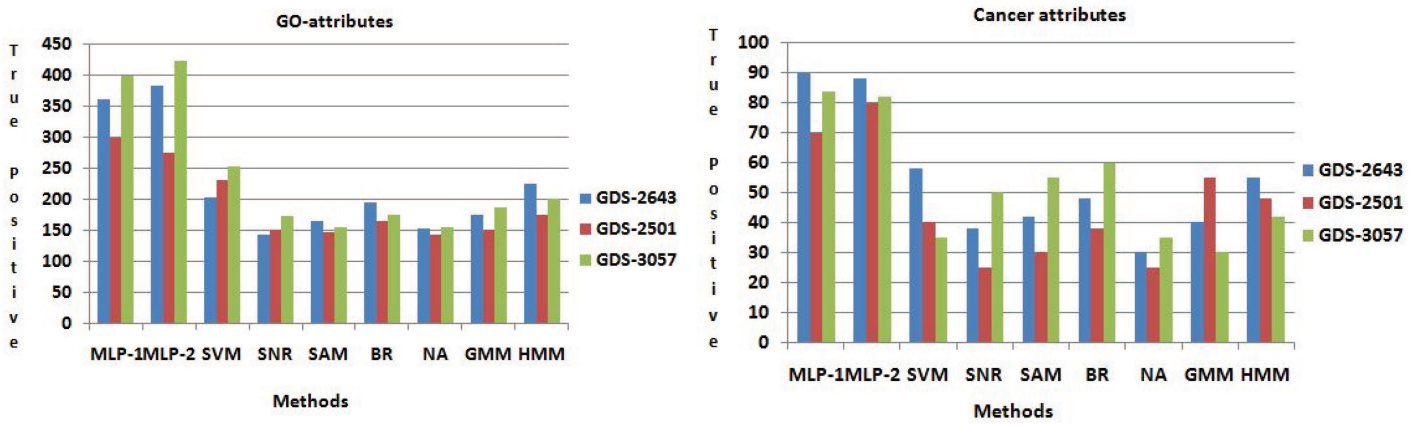

Figure 4: Identification of GO attributes and Cancer attributes the Performance comparisons of MLP-1 and MLP-2 with other seven existing methods.

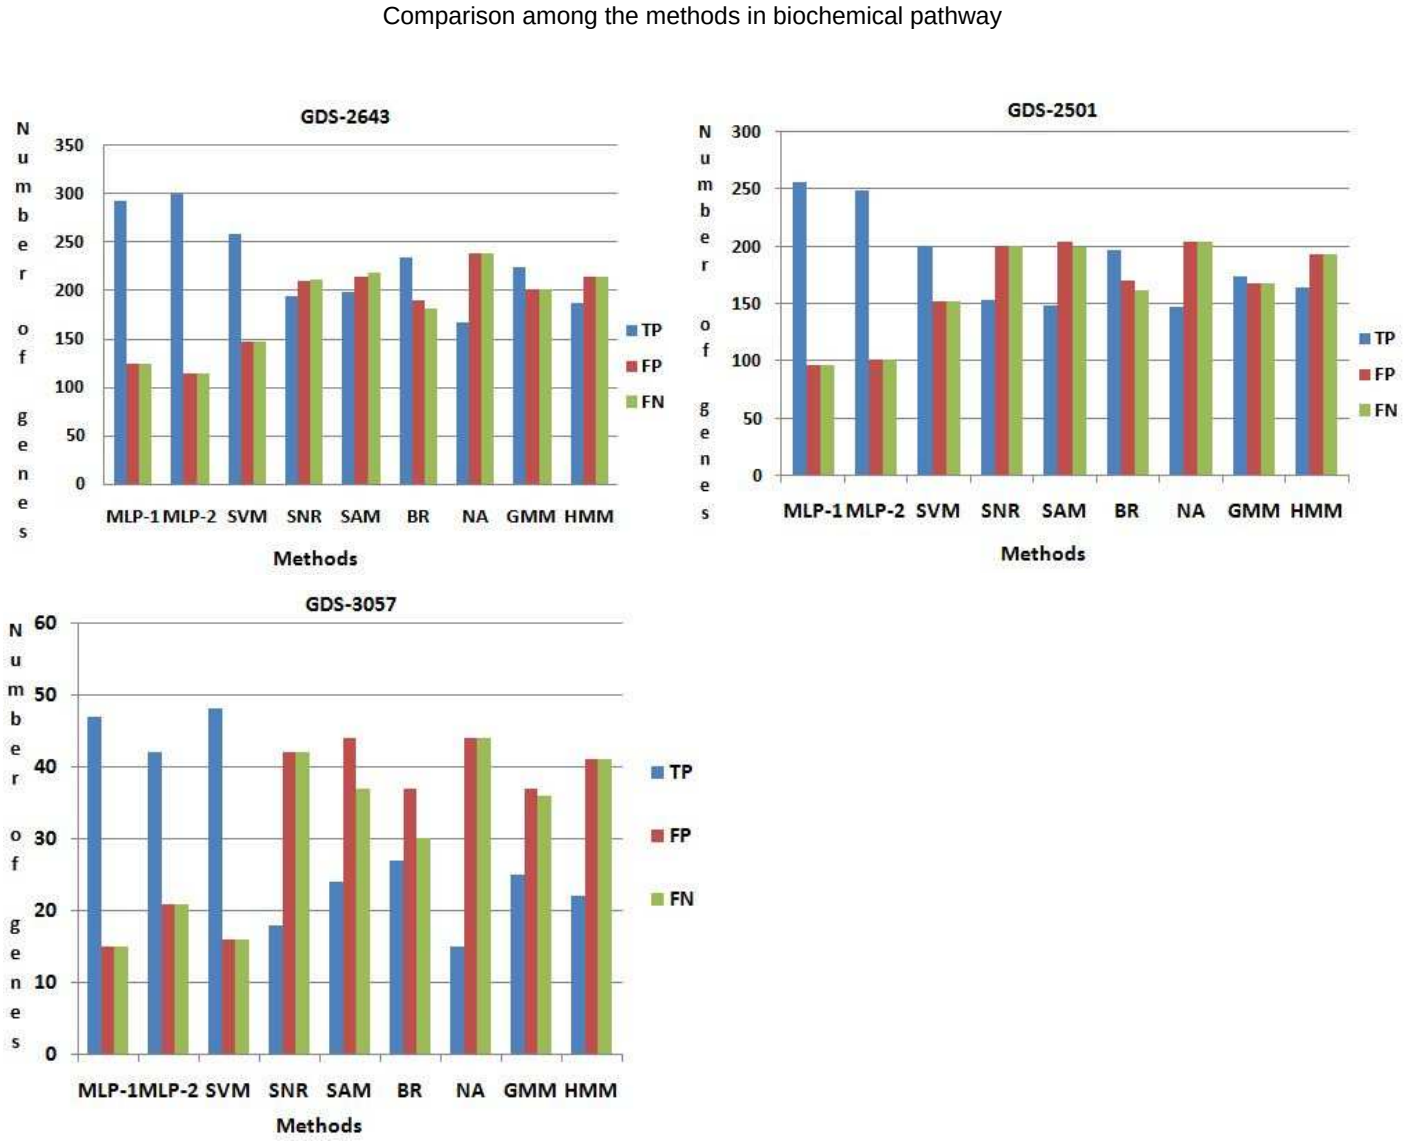

Figure 5: Comparison among the methods. Here TP, FP, FN indicate the number of *truepositive*, *falsepositive*, *falsenegative* respectively.

pathway we have found 407 number of genes. Now this set of genes, are compared with those obtained by seven existing procedures. Here 293 and 300 number of genes are identified which is common in database information and the results of both MLP-1 and MLP-2, respectively. These genes are called $truepositive(TP)$ genes. In top rank 407 genes, we have found 116 and 110 number of genes are present respectively in both procedure MLP-1 and MLP-2 but not present these pathway. These genes are called $falsepositive(FP)$ genes. Similarly we have found 116 and 110 number of genes are $falsenegative(FN)$ for both MLP-1 and MLP-2 procedure respectively. Now we have calculate the number of $truepositive(TP)$, $falsepositive(FP)$ and $falsenegative(FN)$ genes for other seven existing methods. From Figure (5) show that both NFM-1 and NFM-2 procedure have been able to identify more number of $truepositive$ genes, but less number of $falsepositive$ and $falsenegative$ genes compared to all the other procedures. Similarly in GDS-2501 and GDS-3057, we have been able to identify more number of $truepositive$ genes, but less number of $falsepositive$ and $falsenegative$ genes compared to all the other procedures and result are show in Figure (5).

5.1.2 Biological Validation

The disease mediating gene list corresponding to a specific disease can be founded by a gene database namely NCBI (http://www.ncbi.nlm.nih.gov/Database). We have found several set of genes for GDS-2643, GDS-2501 and GDS-3057 respectively. For GDS-2643, by using both MLP-1 and MLP-2, we have identified 351 numbers of genes. Now we have compared this set of genes with 351 genes from NCBI and both MLP-1 and MLP-2 can be identified 247 and 241 number of genes respectively, which is common both sets. These genes said $truepositive(TP)$. On the other hand, (351-247) = 104 and (351-241) = 110 number of genes are not present the list of genes which is found from NCBI for both procedure MLP-1 and MLP-2 respectively. These numbers of gene are called $falsepositive(FP)$ genes. Similarly (351-247) = 104 and (351-241) = 110 number of genes are present NCBI database but not present in the set of genes which is found by both procedure MLP-1 and MLP-2 respectively. These numbers of gene are called $falsenegative(FN)$ genes. Likewise other procedure, viz., SVM, SNR, SAM, BR, NA, GMM, HMM are compared our result on GDS-2643, GDS-2501 and GDS-3057 respectively. Figure (6) show that both MLP-1 and MLP-2 found the more number of true positive (TP) genes then the other existing procedure for GDS-2643, GDS-2501 and GDS-3057 respectively.

Now we can order to validate our result and calculate the Sensitivity of gene expression data sets. The Sensitivity is computed by using following formula:

$$Sensitivity = \frac{TP}{TP + FN} \tag{17}$$

At first we have computed the total number of true positive genes for every data set for every procedure. As our result, Sensitivity of both MLP-1 and MLP-2 procedure is more than the other existing procedure. Figure (7) show that Sensitivity of both MLP-1 and MLP-2 has performed the best for GDS-2501 data set.

6 Conclusion

In this article, we have proposed a model based on multilayer perceptron, which will select the genes that have been changed quite significantly from normal stage to disease stage. Base on vale of correlation, the different types of genes can be obtained and we have found most important groups. The gene of these groups are evaluated by using both procedure MLP-1 and MLP-2. The most important genes are gained by the procedure have also been corroborated by p-values of genes. The best result of the procedure compression too few standing once has been demonstrated. The output have been corroborated using biochemical pathway, p-value, t-test, sensitivity and some existing result expression profile plots. It has been obtained that the procedure has been capable to the genes are most significant.

Appendix

F-score: F-score are a statistical method for determining accuracy accounting for both precision and recall. The formula for traditional F-score is, F-score= $2 * (precision * recall/precision + recall)$. Where precision = $TP/TP + FP$, Recall = $TP/TP + FN$.
True Positive: A true positive test result is one that detect the condition when the condition is present. True positive rate = $TP/(TP + FN)$.
False Positive: A false positive is an error in some rating method in which a condition tested for is badly found to have been detected. A false positive test result is one that detect the condition when the condition is absent. False positive value = $FP/(FP + TN)$.
False Negative: A result that appears negative when it should not. A false negative test result is one that does not detect the condition when the condition is present. False negative value = $FN/(TP + FN)$.
True Negative: A true negative test result is one that does not detect the condition when the condition is absent. True negative value = $TN/(TN + FP)$.

Conflict of Interest The authors declare no conflict of interest.

Variability
voltage drop (IR drop)

ABSTRACT

In this paper, the performance and reliability of oxide-based Resistive RAM (ReRAM) memory is investigated in a 28nm FDSOI technology versus interconnects resistivity combined with device variability. Indeed, common problems with ReRAM are related to high variability in operating conditions and low yield. At a cell level ReRAMs suffer from variability. At an array level, ReRAMs suffer from different voltage drops seen across the cells due to line resistances. Although research has taken steps to resolve these issues, variability combined with resistive paths remain an important characteristic for ReRAMs. In this context, a deeper understanding of the impact of these characteristics on ReRAM performances is needed to propose variability tolerant designs to ensure the robustness of the technology. The presented study addresses the memory cell, the memory word up to the memory matrix.

1. Introduction

Because data storage and processing solutions are so central to modern technology, many research works are dedicated to pursue new types of computer memory. One of the major goal is to develop a universal memory (i.e. a storage medium that would combine the high speed of RAM with the non volatility of a Flash drive). Additionally, embedded memory is a fundamental component of any electronic system including high-performance System-on-Chip (SoC) and Internet of Things (IoT) devices. In this context, the presented work proposes a reliability analysis of the Resistive RAM memory which considered as a potential universal memory candidate. This study is an extension of work originally presented in [1], with an extension to a whole memory matrix. Moreover, a multilevel storage capability of ReRAM cells is demonstrated at a matrix level.

According to ITRS [2], embedded Non Volatile Memories (NVMs) are occupying a major part of the area of a typical (SoC). Although Flash memory is widely used today, it needs high voltage for Write and Erase operations and has reliability issues that are hard to handle, increasing the cost of circuit design and process integration. Thus, the industry is trying to find a good alternative NVM that can replace Flash memories. Possible candidates include Magnetic RAM (MRAM), ReRAM, Phase Change Memory (PCM), Ferroelectric RAM (FeRAM), etc. Compared to MRAM and PCM technologies, ReRAM technology is still in an emerging phase [3][4]. However, a considerable technological effort is currently driven worldwide to push this technology to prototype level. ReRAM advantages comprise non volatile data storage at low power and latency and high memory density while maintaining device performance and reliability [5]. Moreover, the 3D-staking technology developed for Flash memories can be transferred to ReRAM and the multilevel cell operation scheme of Flash memories can also be achieved in ReRAMs [6].

However, the continuous push for scalability to obtain high-density chips makes the ReRAM technology extremely sensitive to variability, physical defects and environmental influences that may severely compromise its correct behavior [7]. At sub 32nm node, size reduction increases the resistivity of interconnects, inducing a voltage drop along the memory matrix lines, which can cause reliability issues. Indeed, as ReRAM data is stored as two resistance states of the resistive switching device, these memories are sensitive to resistive paths [8]. On top of that, common problems with ReRAMs are related to high variability in operating conditions [9].

In memory devices relying on resistance change such as ReRAMs, complex physical mechanisms are responsible for reversible switching of the electrical conductivity between high and low resistance states. This resistivity change is generally attributed to the formation/dissolution of conductive paths between metallic electrodes [10]. A typical ReRAM device consists of two metallic electrodes that sandwich a thin dielectric layer serving as permanent storage medium making its leakage current close to

zero. Oxide-based Resistive Random Access Memory (so-called OxRAM) use transition metal oxides as a dielectric layer. In this study, an HfO_2 Oxide-based ReRAM stack is considered [11].

OxRAM cell operation is depicted in Figure 1. After an initial electroforming process, the memory element may be reversibly switched between two distinct resistance states. Electroforming stage corresponds to a voltage-induced resistance switching from an initial very high resistance state (virgin state) to a conductive state. After FORMING, resistive switching corresponds to an abrupt change between a High Resistance State (HRS or OFF state) and a Low Resistance State (LRS or ON state). This resistance change is achieved by applying specific voltage (i.e. V_{SET} and V_{RES}) to SET and RESET the memory cell.

It is important to note that the FORMING stage is the first and most critical step as it determines the switching characteristics during the future operation of the memory cell. Thus, the Forming Resistance State (R_{FRS}) which characterizes the filament creation is a key parameter in terms of reliability. Besides, the forming step requires high voltage levels (more important than V_{SET} and V_{RES}).

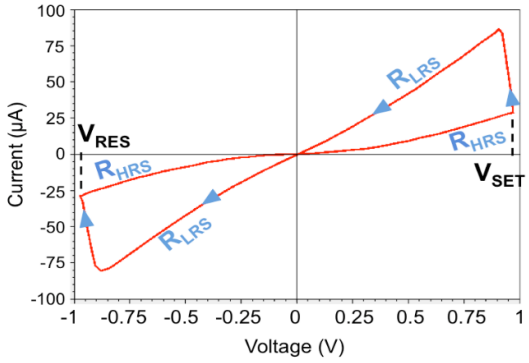

Figure 1. Typical I-V characteristic of a bipolar OxRAM cell

In this paper, the reliability of a ReRAM memory array is investigated versus interconnects and device variability. Section II presents the OxRAM model used for simulations. Section III address a 32-bit memory word. In section III, the study is extended to the memory matrix and the multilevel storage capability of ReRAM cells is demonstrated. Section IV concludes the paper. For each section simulation results based on a 28nm Fully-Depleted Silicon-On-Insulator (FDSOI) are proposed.

2. ReRAM elementary cell model

The proposed OxRAM modeling approach relies on electric field-induced creation/destruction of oxygen vacancies within the switching layer. The model enables continuously accounting for both SET and RESET operations into a single master equation in which the resistance is controlled by the radius of the conduction pathways (r_{CF}) [12]:

$$\frac{dr_{CF}}{dt} = \left(r_{CF\max} - r_{CF}\right)\cdot 10^{\beta_{RedOx}}\cdot e^{\frac{Ea - q\cdot\alpha_{red}\cdot V_{cell}}{k_b\cdot T}} - r_{CF}\cdot 10^{\beta_{RedOx}}\cdot e^{\frac{Ea + q\cdot\alpha_{ox}\cdot V_{cell}}{k_b\cdot T}} \quad (1)$$

Where β_{RedOx} is the nominal oxide reduction rate, E_a is the activation energy, α_{red} and α_{ox} are the transfer coefficients (ranging between 0 and 1 and representing the pathways creation/destruction dynamic), k_b is the Boltzmann constant, r_{CFmax} is the maximal size of the conductive filament radius, T is the temperature and V_{cell} the voltage across the cell.

Moreover, the model makes assumptions of a uniform radius of the conduction pathways, a uniform electric field in the cell and temperature triggered acceleration of the oxide reduction reactions ("redox"). Finally, the total current in the OxRAM includes two components, i.e. one is related to the conductive species (I_{CF}) and the other to the conduction through the oxide (I_{OX}).

$$I_{CF} = \frac{V_{Cell}}{L_x}\cdot\left(\pi\cdot r_{CF}^2\cdot\left(\sigma_{CF} - \sigma_{OX}\right) + \pi\cdot r_{CF\max}^2\cdot\sigma_{OX}\right) \quad (2)$$

$$I_{OX} = A_{HRS}\cdot S_{Cell}\left(\frac{V_{Cell}}{L_x}\right)^{\beta_{HRS}} \quad (3)$$

where L_x is the oxide thickness, S_{Cell} is the total area of the device, σ_{Ox} the oxidation rate and σ_{CF} the reduction rate. To take into account I_{OX} trap assisted current (Poole-Frenkel, Schottky emission, Space Charge Limited Current (SCLC)), a power law between the cell current and the applied bias is considered with two parameters A_{HRS} and β_{HRS}. Finally, the total current flowing through the cell is:

$$I_{Cell} = I_{CF} + I_{OX} \quad (4)$$

I_{CF} is the main contributor to LRS current (I_{LRS}) and I_{OX} is the main contributor to HRS current (I_{HRS}).

The memory cell compact model is calibrated on silicon. The model was confronted to quasi-static and dynamic experimental data before its implementation in electrical circuit simulators. As presented in Figure 2a (current voltage characteristic in logarithmic scale), after calibration, the model satisfactorily matches quasi-static and dynamic experimental data measured on actual HfO_2-based memory elements (TiN/Ti/HfO_x/TiN stack). In Figure 2b, the evolution of SET voltages (V_{app}) as a function of the programming ramp speed is presented. The model implementation focused on this dependence which is crucial for the model to be confidently implemented in circuit simulators.

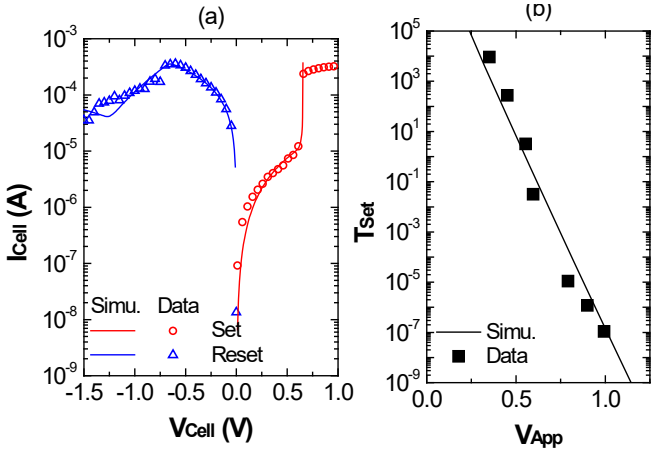

Figure 2. (a) I-V characteristic measured on HfO2-based devices and corresponding simulation using a bipolar OxRAM physical model. (b) SET voltage as a function of the programming ramp

Due to the stochastic nature of the switching process in OxRAMs, leading to large variability, the OxRAM model features a variability dependency. The variation is chosen to fit experimental data as presented in Figure 3. The model behaviour (lines) is consistent with experimental data (symbols). The cell variability modelling is based on OxRAM card model parameters variation. Variability is introduced through specific model parameters (*i.e.* β_{RedOx} and β_{HRS} parameters presented respectively in Equation 1 and Equation 3). Moreover, at sub 32nm node, MOSFET mismatch in the transistor subsystem (digital and analog blocks) increases inherent variability of OxRAM circuits, increasing the overall variability.

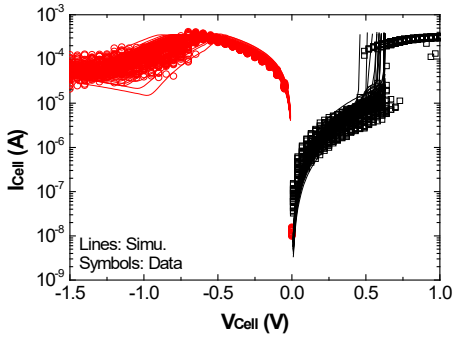

Figure 3. Measured and corresponding simulated I-V characteristic obtained from TiN/Ti/HfO2/TiN devices showing strong variation on R_{LHS} and R_{HRS}

3. ReRAM memory word

3.1. Memory word architecture

A 1T1R ReRAM cell (one MOS Transistor in series with one Resistor) placed in a 32-bit word is considered and presented in Figure 4. The word selection is achieved through the Word Line (WL) before any operation. Word programming is performed in 2 steps, considering that the FORMING operation occurs only once in the product lifetime. Once the word is selected, all cells are RESET in parallel (logical "0") through the Reset Word Line (WL_R), then memory cells are all SET (logical "1") through the Bit Line (BL). The WL_R line drives the whole word RESET current, making it sensitive to line resistivity.

Indeed, during a memory word program operation, a voltage drop occurs along the WL_R line, which can be critical in terms of programming efficiency. To monitor the programming efficiency, High Resistance State (R_{HRS}) and Low Resistance State (R_{LRS}) resistances are extracted after RESET and SET operations respectively.

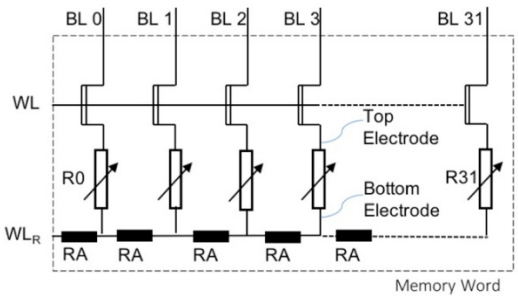

Figure 4. 32-bit ReRAM memory word

The memory word is simulated using the OxRAM model presented in section 2. The model is calibrated on silicon for a 28nm FDSOI technology. With respect to the programming conditions, typical values for LRS and HRS are R_{LRS}=10kΩ and R_{HRS}=130kΩ for the considered technology. The WL_R line resistance per cell (including vias) is called R_A (see Figure 4) and is evaluated to 1.6Ω [8].

3.2. Simulation results

Impact of line resistances on R_{HRS} and R_{LRS} is presented in Figure 5. The voltage drop induced by line resistances results in a weak FORMING (i.e. high resistive path between ReRAM electrodes). SET and RESET programming levels are thus impacted resulting in a higher R_{HRS} (+5%) and R_{LRS} (+30%) values for cells located at the end of the memory word.

Impact of line resistances combined with variability is presented in Figure 6. After 300 Monte Carlo runs, R_{HRS} and R_{LRS} distributions are extracted for 1 cell over 4 and displayed in box-plot forms. Figure 6a shows that LRS distribution spread increases along the word line. Besides, anomalous LRS residual cell populations (far from their typical LRS values, represented by dashed lines) are visible from cell 7. This effect is related to cells not properly formed due to line resistances. In Figure6b, HRS distributions are presented. One can notice the HRS mean distribution shift to higher values with the word length.

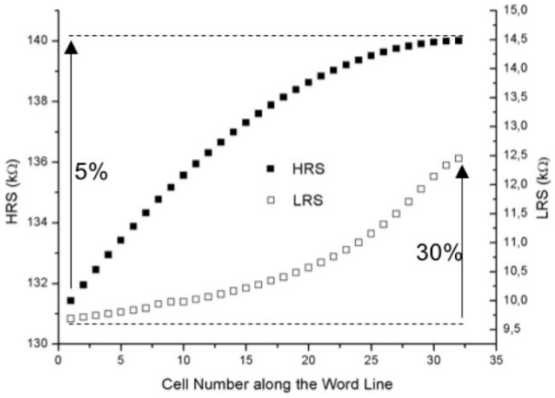

Figure 5. Resistances (HRS & LRS) along the WL

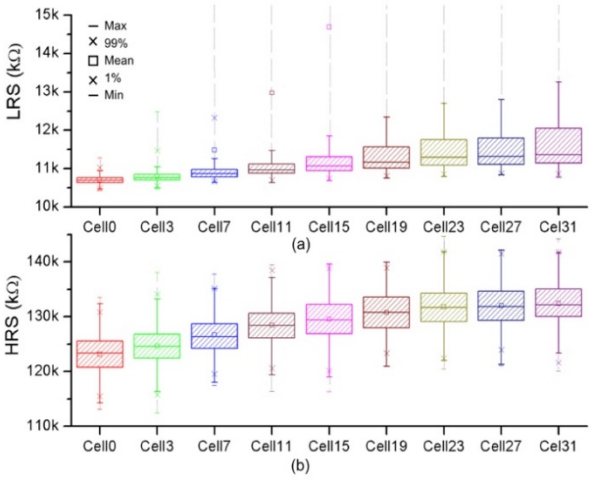

Figure 6. (a) LRS and (b) HRS distributions along the WL

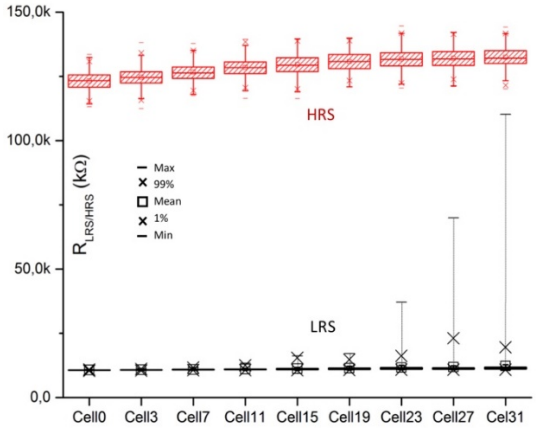

Figure 7. LRS and HRS distributions overlaps along the WL

For comparison purposes, Figure 7 presents the full range variation (from min to max) of each box-plot (HRS and LRS states). Along the WL, HRS/LRS distributions are getting closer and closer due to marginal LRS cells, affecting the memory reliability (i.e. HRS distribution generally larger than LRS distribution is much more degraded by resistive paths).

4. ReRAM memory array

4.1. Memory array architecture

Figure 8 presents the elementary array used for simulation which is constituted by a 3×3 1T1R cell matrix, a row decoder, a column decoder and a sense amplifier for the read operation. The memory cell is modeled by the OxRAM cell model presented in section 2.

The variability analysis is conducted through Monte Carlo simulations. Each Monte Carlo simulation targets specific elements of the circuit: the resistive element, the select transistor, the decoding blocs and the sense amplifier. As a result, R_{ON} and R_{OFF} distribution spreads are extracted. Thus, the contribution of each element in terms of memory performance degradation is demonstrated. A 28-nm Fully Depleted Silicon-On-Insulator (FDSOI) technology is considered for simulations [13].

Memory array cells are first placed in a virgin state. Then, the memory array programming is done in 2 cycles. First, all memory cells are set (logical "1"), then the memory array is reset (logical "0"). R_{ON} value is extracted after the SET operation and R_{OFF} after the RESET operation for each Monte Carlo run.

Variability introduced in the resistive element is chosen to feet experimental date whereas variability of the transistor subsystem is given by the considered technology.

4.2. Simulation results

In this study, 4 different configurations are considered: the "ALL" configuration considers variability in the memory cell (resistive element and select transistor) and the peripheral circuits. In the "CELL" configuration, variability affects only the resistive element. In the "SELECT" configuration, variability affects only the OxRAM select transistor. In the "NO CELL" configuration, variability affects only the peripheral circuits (transistor subsystem, including the select transistor). In this study, the impact of the select transistor variability is subject to special attention. Indeed, the select transistor compliance allows the control of the maximum available current during the set transition, impacting directly the ON/OFF resistance. Table 1 summarizes the 4 configurations to simulate.

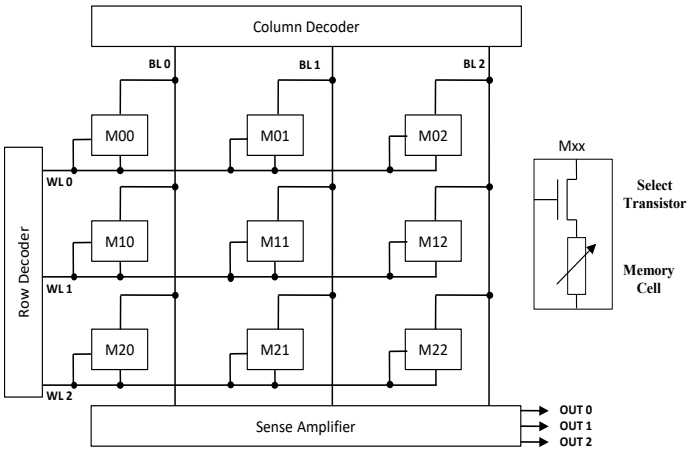

Figure 8. 3×3 OxRAM elementary memory array

Table 1: Simulated Configurations

Configuration	RUNS	Elements under variability
« ALL »	400	All circuit elements
« CELL »	400	Resistive element
« SELECT »	400	Select transistor
« NO CELL »	400	All elements excluding the resistive element

Figure 9 presents the impact of variability of the whole circuit elements (resistive element and transistor subsystem: "ALL" configuration) on R_{ON} and R_{OFF} distributions. Note that R_{OFF} distribution is much larger than R_{ON} distribution. In order to discriminate the contribution of each element of the circuit on ON/OFF resistances, a set of Monte Carlo simulations are also performed with "CELL", "SELECT" and "NO CELL" configurations.

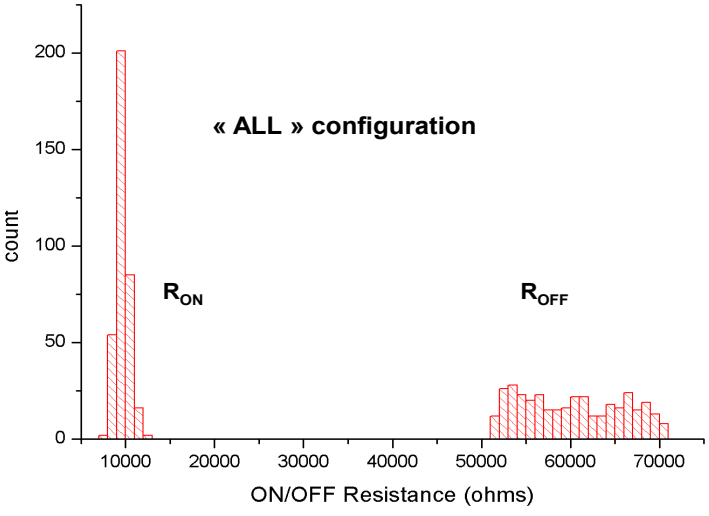

Figure 9. ON/OFF resistance distributions for the "ALL" configuration after 400 Monte Carlo simulations.

Figure 10 presents the impact of variability on R_{OFF} distributions (after RESET) for the 4 configurations. By comparing configuration "ALL" with configuration "CELL", it appears clearly that the impact of cell variability is more important than the impact of the transistor subsystem variability. The third and fourth configurations ("NO CELL" and "SELECT") shows that impact of transistors variability on R_{OFF} is negligible. Besides, the contribution of the select transistor variability is dominant in the peripheral circuit elements. Table 2 proposes a synthesis of results obtained in Figure 10 (mean values, standard deviation and standard deviation reported to the maximum standard deviation value).

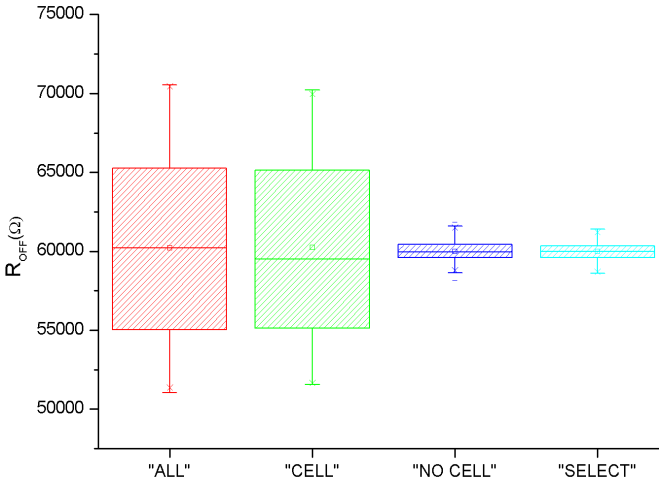

Figure 10. R_{OFF} distributions after 400 Monte Carlo simulations.

Table 2: R_{off} Distribution parameters

Configuration	Mean (Ω)	σ (Ω)	σ (%)
« ALL »	60200	5598	100
« CELL »	60240	5617	99
« NO CELL »	60004	598	9.6
« SELECT »	59990	536	10.6

Figure 11 presents the impact of variability on R_{ON} distributions (after SET) for the 4 configurations.

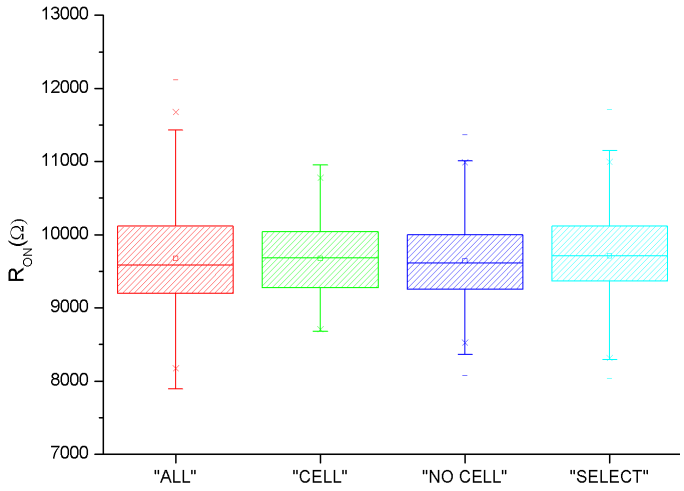

Figure 11. R_{ON} distributions after 400 Monte Carlo simulations.

Table 3: R_{on} Distribution Parameters

Configuration	Mean (Ω)	σ (Ω)	σ (%)
« ALL »	9674	724	100
« CELL »	9679	513	70.8
« NO CELL »	9642	550	78.7
« SELECT »	9713	570	75.9

Compared to Figure 10, it appears clearly that the cell variability impact is less pronounced for low resistive states (LRS), which is a common feature of all OxRAM technologies [14-15]. Moreover, the contribution of transistors variability is comparable to the contribution of the memory cell variability (see "CELL" and "NO CELL" configurations in Figure 11). Here again, simulation results show that the impact of the select transistor is not negligible. Table 3 proposes a synthesis of results obtained in Figure 11.

Figure12 shows a comparison between R_{ON} and R_{OFF} distributions. Based on the considered technology, it is shown that resistance variability in RESET state is much more important than variability in the SET state. This variability is mainly due to the memory cell. In addition, the impact of the select transistor is non-negligible. This effect is visible in the SET state where the impact of the memory cell variability is much less important, making the select transistor variability critical.

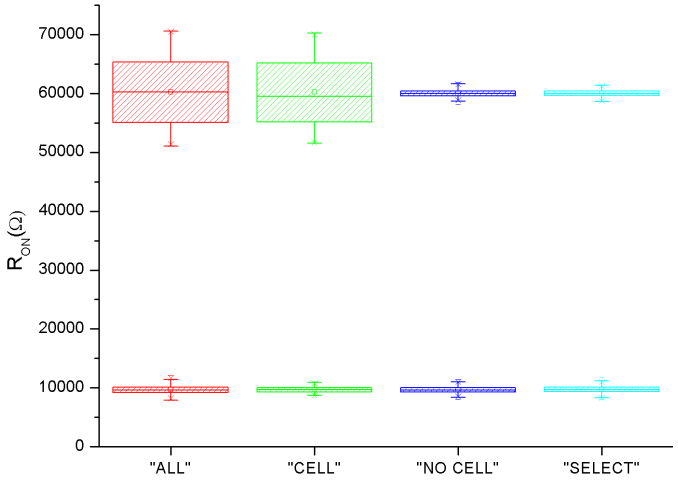

Figure 12. R_{ON}/R_{OFF} distributions after 400 Monte Carlo simulations.

4.3. Multi level approach

When a voltage is applied across a ReRAM cell, depending upon the voltage polarity, one or more Conductive Filaments (CFs) made out of oxygen vacancies are either formed or ruptured. Once the CFs are formed inside the metal oxide to bridge the top and bottom electrodes, current can flow through the CFs, and the cell is in a low resistance state. The larger the size of the CFs, the lower the resistance. Conversely, the rupture of the CFs disconnects the top electrode from the bottom electrode, resulting in a high resistance state (HRS) of the cell [16].

According to Equation 1, CF size is directly linked to the voltage across the cell, thus, multilevel LRS can be achieved in the 1T1R RRAM by modulating the SET voltage. In this study, the amplitude of the RESET voltage remains unchanged during the

cell programming operation. As HRS variation is generally larger than LRS variation, multilevel HRS is not considered. The HRS state is associated with an initial value, restored before each SET operation. Finally, to obtain intermediate SET states, programming is done in 2 steps: a RESET operation is first performed to switch the memory cell in its HRS initial state, then a SET operation sets the desired LRS level.

At a circuit level, different implementations of Multi-Level Cell (MLC) operation can be adopted. Multilevel operation can be achieved:

- By applying an increasing number of identical voltage pulses through the SET decoder. In this case, LRS level is function of the number of pulses [17].
- By modulating the gate voltage (WL) of the memory cell Select Transistor to control the SET current [18].
- By modulating directly the SET voltage generated from the SET decoder. In this case, LRS levels are achieved with different SET voltage values.

The first approach requires a pulse generator circuitry while the two others require different voltage levels generated from a specific circuitry. In this study, the third approach is considered as it is the most effective MLC approach for the considered technology. Four different LRS levels are generated by changing the amplitude of the SET voltage. Table 4 presents the different SET and RESET voltages values with the corresponding resistance nominal values.

Table 4: Programming Voltages and corresponding Resistance Values

	SET				RESET
Logical value	**00**	**01**	**10**	**11**	-
$V_{SET/RESET}$ (V)	1.4	1.8	2.2	2.8	-2.8
$R_{ON/OFF}$ (kΩ)	104	77	46	30	196

To assess the robustness of the analog resistance values, a Monte Carlo (MC) analysis is conducted using a 28-nm Fully Depleted Silicon-On-Insulator (FDSOI) technology. As a result, R_{ON} and R_{OFF} distribution spreads are extracted. The programming protocol is comparable to the one used in section 4.2. The memory array programming is done in 2 cycles. First, all memory cells are RESET (with an more important RESET voltage level), then the memory array is SET with specific SET voltage levels.

Figure 13 presents the impact of the memory cell variability on R_{ON} and R_{OFF} distributions after 300 MC simulations. Note that R_{OFF} distribution is much larger than R_{ON} distribution, preventing a HRS MLC implementation. R_{ON} distributions are narrower with a tendency to spread for small SET voltage values. In order to discriminate the different memory states during the read operation, no distribution overlap is permitted.

Figure 14 focuses on R_{ON} distributions and shows distinct R_{ON} resistance levels. Distributions are displayed in box-plot forms. The full range variation (from min to max) of each box-plot confirms the clear separation between each resistance level.

Figure 13 and Figure 14 results are presented for cell variability parameters included in the range ±15% of the standard deviation of a normal distribution (i.e. $\sigma_{Variability}$ = 15%). This variability is consistent with silicon data (see Figure 3) which means that a MLC approach can be considered for this technology.

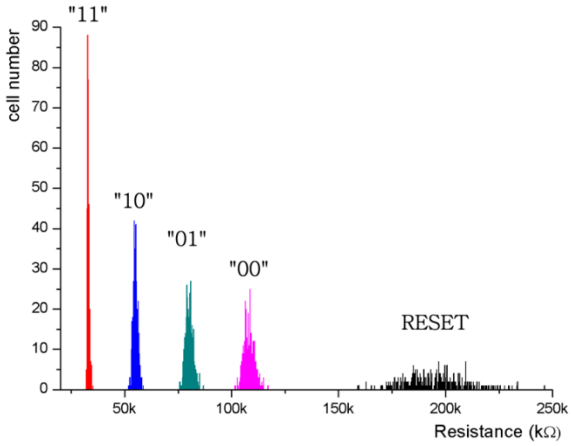

Figure 13. R_{ON} and R_{OFF} distributions versus cell variability ($\sigma_{Variability}$ = 15%) after 300 runs (SET and RESET states)

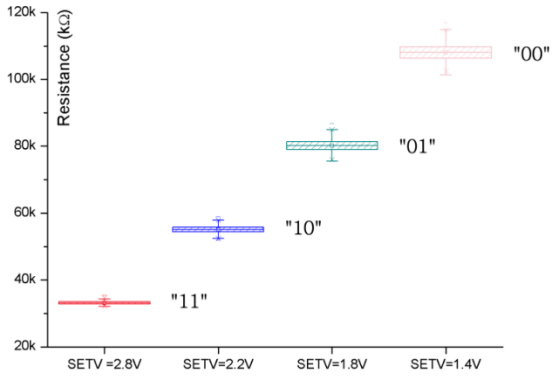

Figure 14. R_{ON} distribution box-plots versus cell variability ($\sigma_{Variability}$ = 15%) after 300 runs (SET states)

To evaluate the robustness of the technology, Figure 15 and Figure 16 results are provided for $\sigma_{Variability}$ = 20% and $\sigma_{Variability}$ = 25%, which is the worst case. An important spreading of R_{ON} is observed. The initial R_{ON} distribution spread increases as variability increase. Even for the worst case ($\sigma_{Variability}$ = 25%), no overlap between LRS distributions is observed which confirms the robustness of MLC approach. In Table 5, R_{ON} (SET) and R_{OFF} (RESET) distribution parameters (mean value and standard deviation) are reported for the different variability parameter values.

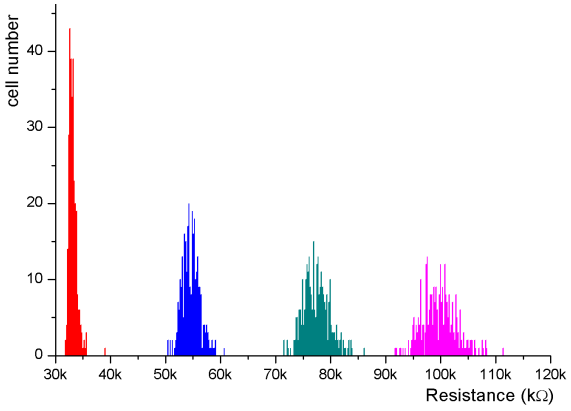

Figure 15. R_{ON} distributions versus cell variability ($\sigma_{Variability}$ = 20%) after 300 runs (SET states)

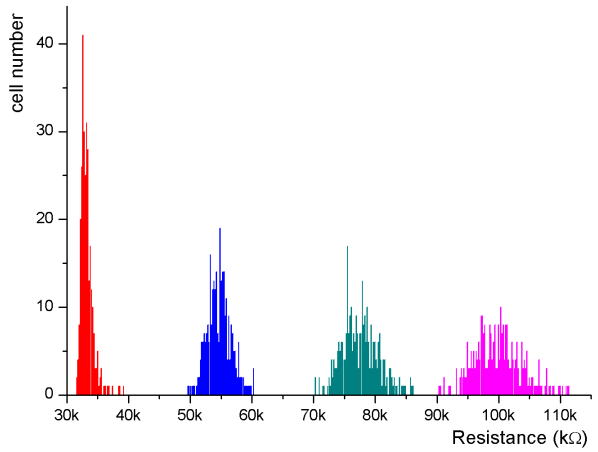

Figure 16. R_{ON} distributions versus cell variability ($\sigma_{Variability}$ = 25%) after 300 runs (SET states)

Table 5: Simulated Configurations

		SET				RESET
$\sigma_{Variability}$	Distributions	**11**	**10**	**01**	**00**	
15%	Mean (kΩ)	33.159	55.111	80.227	108.119	195.350
	σ (kΩ)	0.501	1.153	1.8550	2.5520	14.447
20%	Mean (kΩ)	33.239	54.681	77.402	99.672	196.639
	σ (kΩ)	0.768	1.614	2.408	3.174	19.520
25%	Mean (kΩ)	33.342	54.761	77.529	99.844	198.031
	σ (kΩ)	1.049	1.973	2.978	3.928	24.882

5. Conclusion

Variability combined with voltage drops due to resistive paths present a major challenge for ReRAM memory fabrication process and design engineers. In the proposed study, impact of variability combined with resistive paths is evaluated based on a 1T1R ReRAM elementary memory array. A specific attention is provided to the ReRAM memory word. To assess the technology reliability, the HRS/LRS resistance ratio is extracted at a memory word and at a memory array level to provide a valuable feedback for designers during ReRAM memory array design. At a word level, impact of line resistances combined with variability can affect the memory word operation from a word size greater than 8 bits. At a memory array level, resistance variability in RESET state is much more important than variability in the SET state. Additionally, a stable MLC operation of 2-bits/cell is demonstrated.

Cognitive Radio

ABSTRACT

Abstract — Cognitive Radio (CR) encompasses a number of technologies which enable adaptive self-programing of systems at different levels to provide more effective use of the increasingly congested radio spectrum. CRs have potential to use spectrum allocated to TV services, which is not used by the primary user (TV), without causing disruptive interference to licensed users by using appropriate propagation modelling in TV White Spaces (TVWS). In this paper we address two related aspects of channel occupancy prediction for cognitive radio. Firstly, we continue to investigate the best propagation model among three propagation models (Extended-Hata, Davidson-Hata and Egli) for use in the TV band, whilst also finding the optimum terrain data resolution to use (1000, 100 or 30 m). We compare modelled results with measurements taken in randomly-selected locations around Hull UK, using the two comparison criteria of implementation time and accuracy, when used for predicting TVWS system performance. Secondly, we describe how such models can be integrated into a database-driven tool for CR channel selection within the TVWS environment by creating a flexible simulation system for creating a TVWS database.

1. Introduction

As radios in future wireless systems become more flexible and reconfigurable and available radio spectrum becomes scarce, there is the possibility of using TV white space devices (WSDs) as secondary users in the Broadcast Bands without causing harmful interference to licensed incumbents. Currently, one candidate method could be to utilise a geolocation database approach. The white space device should be able to determine available channel opportunities for a given location by accessing a database of TV White Space (TVWS) channels including data on each transmitter and each site, variable channels, transmitter power, and time of validation [1]. Therefore, the TV channel can be protected from harmful interference by accurate prediction of TVWS using an appropriate propagation model. Design of any wireless network depends on accurate prediction of radio propagation, which impacts deployment and management strategies. In this paper we extended the previous work by investigating the best propagation model among three propagation models (Extended-Hata, Davidson-Hata and Egli), using various terrain data resolutions (1000, 100 and 30 m) and comparing with the real measurements taken around Hull UK using two the performance comparison criteria of implementation time and accuracy. Agreement between the measured and predicted values of path loss has investigated, using MATLAB to analyse and compare the variation of path loss between the measured and predicted values. The terrain profile was extracted from terrain database Global1 and then taken into account in selected propagation models. The flexible cognitive TVWS database system was built using different propagation models to calculate available channels in each pixel of the selected area.

2. Digital Terrain Elevation Data (DTED)

DTED was developed by the US Defense Mapping Agency (DMA) and can be used to improve signal detection accuracy. Currently, the paper has selected only three DTED levels of spatial resolution, which are available to the public [2].

Table 1: Resolution levels of DTED.

DTED Level	Post Spacing	Ground Dist	Row x Column
0	30 arcsecond	~ 1 km	121 x 121
1	3.0 arcsecond	~ 100m	1200 x 1200
2	1.0 arcsecond	~ 30 m	3600 x 3600

*Corresponding Author: Anwar Mohamed Fanan, School of Engineering, University of Hull, Cottingham Road, Hull, HU6 7RX, UK,

The elevation data of the resolution from 30 arcsecond (arcsec) to 1 arcsec (level 0,1 and 2) are avaliable for public use and can be downloaded as different DTED extension files in each resolution. The USGS web application has been used to define the desired research region by specifying latitude and longitude as shown in Figure 1, which identifies the required terrain tiles. Figure 2 classifies all tiles, identified by the web application earthexplorer.usgs.gov .

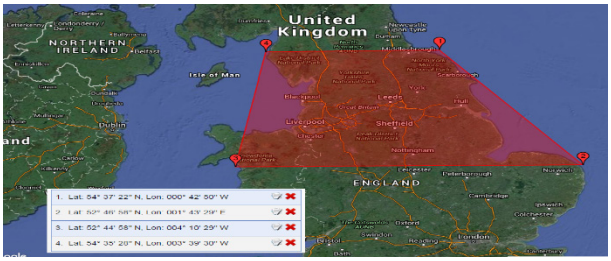

Figure 1. Region selected for terrain data acquisition

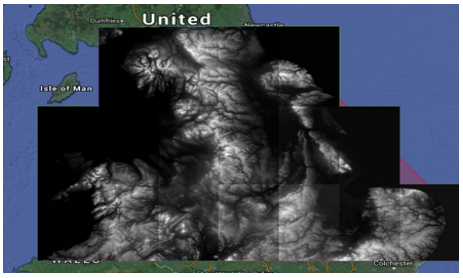

Figure 2. Research region of terrain elevation data by NASA's shuttle radar topography mission (SRTM) with resolution 1 arc sec (30 m)

3. TVWS Geolocation Database

The use of a TV white space geolocation database enables the most effective detection method for prediction of available channels and calculation of TV coverage maps for each pixel in the selected region by using an appropriate propagation model, selected for accuracy and efficiency. The technique can avoid signal detection problems caused by fading effects and shadowing. Construction of the geolocation database requires primary user information including frequency of operation, transmitted power, location, transmission time and height and type of transmit antenna. This information will protect spectrum incumbents from interference from secondary users who will access the database by sending a query to obtain available channels in a given area at a certain time. Furthermore, the geolocation database might have proxy to make queries and identify available channels for WSD [3].

4. Propagation Models

When planning wireless communication systems and designing wireless networks, the accuracy of the prediction of propagation characteristics of each environment should be taken into account. One of the most significant parameters, which can be provided by propagation prediction, is large-scale path loss, which affects directly the coverage of a base station placement and its performance. However, using field measurements to obtain these parameters without depending on propagation models is time-consuming and costly. The following subsections provide a brief explanation of several appropriate empirical propagation models [4] including the Extended Hata, Davidson-Hata and Egli models.

4.1. Extended Hata Model

The Extended Hata model was derived from Hata-Okumura which is widely used for signal prediction in urban areas, wholly based on measured data that have been collected in Tokyo Japan. Also, it does not have any analytical explanation, but includes empirical factors that depend on the type of environment. This model can be used in different environment by adding some correction factors to meet the requirements of ITU-R and also extending range up to 100 km as shown in the following equation:

$$PL_{Ex_Hata} = A + B\log(d)^b + C \quad (1)$$

$$A = 69.55 + 26.16\log_{10} f_c - 13.82\log_{10} h_{tx} - a(h_{rx})$$

$$B = 44.9 - 6.55\log_{10} h_{tx}$$

Where f_c represents the carrier frequency (150 to 1500 MHz), h_{tx} is the height of the base station antenna (m) and h_{rx} is the height of receive antenna (m). The distance from transmitter to receiver is d km. The value of the correction factors a(h_{rx}) and C depend on the type of environment. In small and medium sized cities and metropolitan areas the value of C will be 0, while in other environments such as suburban and rural areas, different equations are used [5]. The factor b denotes an extended range up to 100 km as shown in the following equation.

$$b = \begin{cases} 1, & ,d_{Km} \le 20 \\ 1 + (0.14 + 0.000187 f_c + 0.00107 h_t')(\log_{10} d_{Km}/20))^{0.8} & ,d_{Km} > 20 \end{cases} \quad (2)$$

$$h_t' = \frac{h_t}{1 + 7\times 10^{-6} h_t^{\,2}}$$

4.2. Davidson-Hata Model

$$PL_{David} = PL_{Hata} + A(h_t, d_{km}) - S_1(d_{km}) - S_2(h_t, d_{km}) - S_3(f_{MHz}) - S_4(f_{MHz}, d_{km}). \quad (2)$$

$$PL_{Hata} = 69.55 + 26.16\log_{10} f_{MHz} - 13.82\log_{10} h_t$$

$$- a(h_r) + (44.9 - 6.55\log_{10} h_t)\log_{10} d_{Km} \quad (3)$$

where A is a factor extending distance up to 300 Km, S1 and S2 are correction factors for extending transmitter height up to 2500m, while the factors S3 and S4 extend the frequency range over 30 to1500 MHz [6]. *a(h$_r$)* is a correction factor for receiver antenna height.

4.3. Egli Model

The Egli model was introduced by John Egli in 1957. The model includes a terrain model and was derived from real measurements of UHF and VHF television transmissions conducted in several large cities. It then used a point-to-point model for predicting the total path loss [7]. Thus, this model is commonly used for point to point communications to predict path loss in an urban or rural area, where transmission has to go over an irregular terrain between a fixed transmitter and receiver in the frequency range 40 to 900 MHz. The following equation illustrates the path loss calculation of the Egli model:

$$PL_{Egli} = \begin{cases} 20\log_{10} f_{MHz} + p_0 + 76.3, & h_2 < 10 \\ 20\log_{10} f_{MHz} + p_0 + 83.9, & h_2 < 10 \end{cases} \quad (4)$$

$$p_0 = 40\log_{10} d_{Km} - 20\log_{10} h_t - 10\log_{10} h_r \quad (5)$$

where h_t denotes the height of the transmitter antenna (m), h_r is the height of the receiver antenna (m), the distance between transmitter and receiver is denoted by d km and the transmission frequency is f (MHz) [8].

5. Field Measurement and Data Collection

The main goal of selection of various positions at which to conduct measurements is to examine the signal strength behavior in different environments at various distances from the transmitter and to observe how the terrain affects the received signal. The measurements have been taken at 23 locations distributed randomly around Kingston-upon Hull, UK as shown in Figure 3.

Figure 3. Measurement equipment and geographical location in Hull and surrounding areas.

The measurement equipment used includes an omnidirectional antenna (covering the frequency range 174 to 230 MHz (VHF) and 470 to 790 MHz (UHF) with gain of 3.5 dBi) and spectrum analyser (Agilent E4407B, frequency range 9 kHz to 26.5 GHz) which was connected with a laptop computer by using a general purpose interface bus. A Matlab program on the laptop received raw data and stored them in (bin) files. In addition, the measurement locations were determined by using a mobile GPS application.

6. ANALYSIS of Models' Performance

6.1. Propagation Path Loss Analysis

The main criterion for model assessment is path loss. A simulation program was implemented in Matlab, using channel 33 to conduct the comparison between the three propagation models and the measured results. In order to compare the real measurements with different propagation models, the path loss should be extracted from the real measurements by using the following equation in each location [9].

$$PL = TX + TX_{Gain} + RR_{Gain} - RP \quad (7)$$

Where TX denotes the transmitted power, transmitting antenna gain is represented as TX_{gain}, PL is the path loss, receiving antenna gain is denoted as PR_{gain} and RP is the received power, dBm.

To evaluate the propagation models against real measurements, several parameters might be used to identify the most accurate propagation model. The error between predicted and measured path loss values was calculated by Equation 8 and the average error calculated by Equation 9.

$$e_i = E_{pi} - M_{pi} \quad (8)$$

$$\bar{e} = \frac{1}{N}\sum_{i=1}^{N} e_i \quad (9)$$

In which e_i is denoted as the difference between the calculated path loss E_{Pi} and measured path loss M_{pi} derived from measured received power in each location.

Equations 8 and 9 are then used to calculate the standard deviation, Equation 10, whilst Root Mean Square Error (RMSE) is calculated by Equation 11, which also depends on the average error calculated in Equation 9.

$$\sigma = \sqrt{\frac{1}{N-1}\left(\sum_{i=1}^{N} e_i^{\,2} - N.(\bar{e})^2\right)} \quad (10)$$

$$RMSE = \sqrt{\frac{1}{N}\sum_{i=1}^{n} |e_i|^2} \quad (11)$$

To remove the influence of dispersion from the overall error, a significant metric can be derived from RMSE by subtracting the standard deviation of the absolute value of the error to obtain the Spread Corrected Root Mean Square Error (SCRMSE), as illustrated in Equations 12 and 13:

$$E_i = |e_i| - \sigma \quad (12)$$

$$SCRMSE = \sqrt{\frac{1}{N}\sum_{i=1}^{n} |E_i|^2} \quad (13)$$

6.2. Diffraction Factor Based on Terrain Profile Database

A common phenomenon that exemplifies the wave property of EM waves and light is diffraction, which is the bending of EM waves around obstacles. Diffraction is considered as a non-line of sight (NLOS) propagation mechanism which may occur when the propagation path is obscured by a barrier such as a mountain or hill or man-made obstacles including buildings. Diffraction can

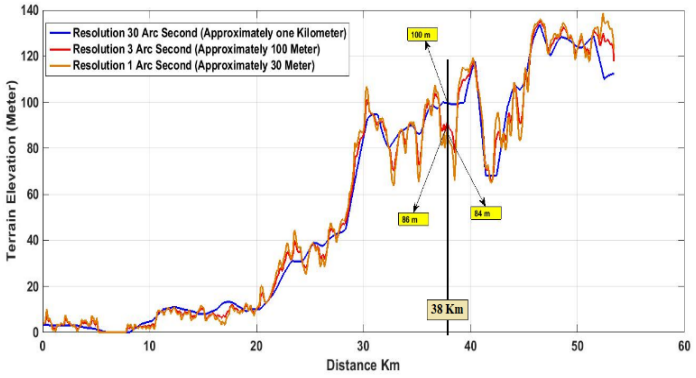
be the cause of significant signal weakness at the reception site, due to the presence of some of the aforementioned barriers between the transmitter and receiver. There are two types of diffraction. "Shadow diffraction", occurs when the received signal is blocked by obstacles and the received field strength will be decreased when the reception site is within the shadowed area. The second case, which occurs if the impediment is underneath the LOS, is called "lit diffraction," and commonly leads to multi-path interference. Shadow diffraction is the one of the main reasons for increased the path-loss. One of the common diffraction models is the single knife edge model, explained by Huygens's Principle, which states that when an electromagnetic wave is obstructed by a natural or man-made obstruction, the obstruction acts as a secondary source for creating a new wavefront which then propagates into the geometric shadow region of the obstruction [10].

6.3. Terrain Profile-based Diffraction Model

One of the main effects of the terrain profile is to cause diffraction or bending of EM waves around obstacles such as mountains, hills or man-made structures which obscure the direct path.

In previous work [11], we considered terrain resolutions of 1 and 30 arcsec and determined that each of them had advantages and disadvantages in terms of accuracy and calculation time.

In this work, we attempt to improve these results by investigating a third resolution value between 1 and 30 arcsec to improve the compromise between accuracy and implementation time. For example, whilst calculating diffraction using the three different resolutions and investigating its effect on the received signal, we noticed that in the location approximately 38 km along the path shown in Figure 4, in the 30 arcsec resolution the elevation value is 100 m, whilst when using 3 arcsec and 1 arcsec resolution, the elevation values are approximately 86 and 83 m respectively.



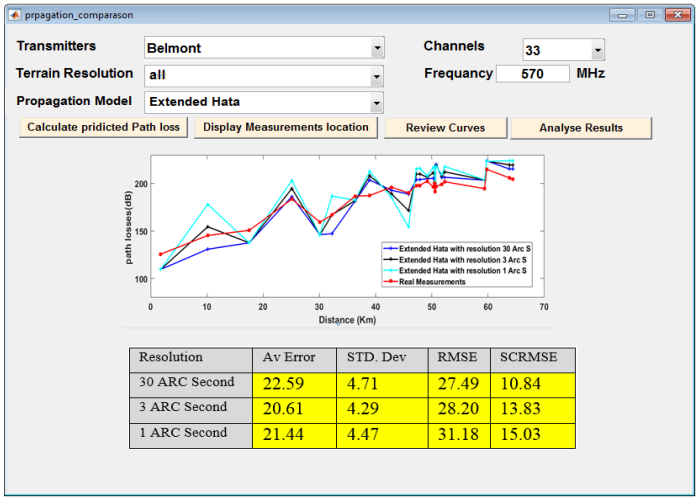


Figure 4. Terrain elevation data for the path from University of Hull to Belmont TV Transmitter in different resolutions

Using 30 arcsec resolution takes a short time for the implementation process but has less accuracy. When using 1 arcsec, we have good accuracy but a long time for the implementation process. However, using 3 arcsec resolution produces the best results in terms of the compromise between accuracy and implementation time.

7. Comparison and Results

The measurement study covered the area around the city of Hull, which was represented to measure the UHF TV band from 470 to 790 MHz with consideration of all radio and TV stations that feed the whole Hull area. Most of the channels transmitted into the area originate from the Belmont and Emley Moor transmitters (see Figure 3). The results of comparison of predicted path loss with measurements for two cases (excluding and including terrain modelling) are presented by using the previously defined criteria average error, standard deviation, RMSE and SCRMSE. Figure 5 shows our Graphical User Interface (GUI) of expected results including path loss curves for each propagation model and a table of calculated parameters.

Resolution	Av Error	STD. Dev	RMSE	SCRMSE
30 ARC Second	22.59	4.71	27.49	10.84
3 ARC Second	20.61	4.29	28.20	13.83
1 ARC Second	21.44	4.47	31.18	15.03

Figure 5. GUI showing propagation model comparison in the selected measurement locations

This analysis may be undertaken for all selected measurement points, by flexible selection of the transmitter name, terrain resolution, propagation model and transmitted channel. Results corresponding to all measurement locations and comparison of the three propagation models with real measurements along with parameter analysis, are discussed and classified in the following sections.

7.1. Influence of Terrain Resolution on Results from the Extended Hata Model.

In this and in the following sections, terrain profile databases with various spatial resolutions and equivalent single knife edge diffraction have been used to calculate the diffraction factors and then evaluate their impact on the performance of the propagation models. The results in Table 2 indicate that 30 arcsec resolution used with the Extended Hata model can be considered the best fit to the measured data with low error when applying the diffraction factor at different terrain resolutions. It can be clearly seen in Figure 6 that the behavior of path loss was influenced by diffraction, when compared with the path loss derived from measured data.

Thus, the propagation behaviour has been affected in most measurement locations when applying the terrain variation with 30 arcsec resolution. The impact of the propagation model is obvious after the third measurement point, where the first three points might be situated within the line of sight and the 1 km resolution results might have missed terrain features situated

along the path which might cause destructive or constructive diffraction. Thus, using 1 km resolution might not give accurate results. Also when using 1 arcsec resolution, the terrain variation becomes worse in this model, which additionally requires a significantly longer processing time. However, the 3 arcsec resolution gives only slightly different results and does not need a long time for calculation of terrain profile.

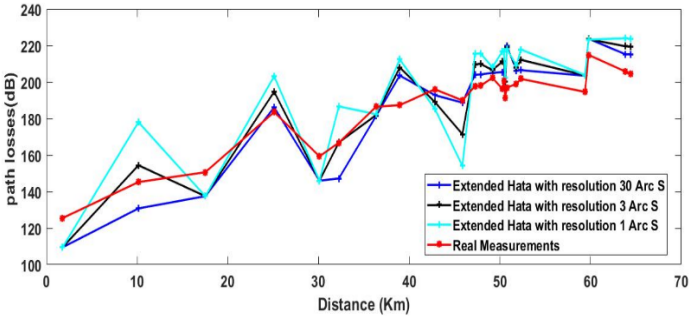

Figure 6. Impact of terrain resolution on results from the Extended Hata model

In Table 2 we can observe how the error statistics have been impacted by the diffraction factor and how the SCRMSE value are decreased in the selected terrain resolution. The results indicate that the 30 arcsec and extended Hata model has the best results of the SCRMSE, at 10.84 dB. On the other hand, the 3 arcsec result is seen to have less error compared with 1 arcsec by about 1.2 dB.

Table 2: Fitted Extended Hata model in different terrain resolution

Resolution, arcsec	Av Error, dB	STD. Dev, dB	RMSE, dB	SCRMSE, dB
30	23.34	4.87	23.52	11.07
3	21.43	4.47	22.82	9.95
1	22.23	4.64	25.02	9.81

7.2. Influence of Terrain Resolution on Egli Model Results.

Due to the nature of the terrain profile near the transmitter sites, which includes rough terrain and hills, the use of 1 arcsec and 3 arcsec resolutions will clearly affect the Egli propagation predictions, as illustrated in Figure 7. Here it may be seen clearly that there are large changes in the path loss at the distance of 48 km and that at other locations such around 52 km there is less variation where the receiver might be in line of sight of the transmitter.

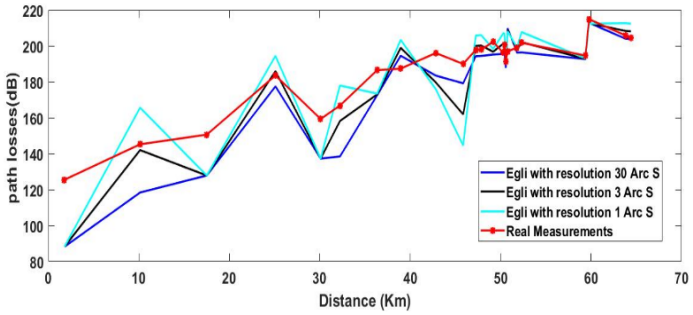

Figure 7. Impact of terrain resolution on the Egli model results

The error of the SCRMSE for the both 1 arcsec and 3 arcsec are slightly different by about 0.14 dB as can be seen in Table 3, whereas the SCRMSE values for 30 arcsec resolution have increased by 1.12 dB.

Table 3: Fitted Egli model in different terrain Resolutions

Resolution, arcsec	Av. Error, dB	STD. Dev, dB	RMSE, dB	SCRMSE, dB
30	22.59	4.71	27.49	10.84
3	20.61	4.29	28.20	13.83
1	21.44	4.47	31.18	15.03

7.3. Influence of Terrain Resolution on Davidson Model Results.

The Davidson model is clearly affected by terrain resolution in a similar manner to the Extended-Hata model at all selected resolution values, as shown in Figure 8.

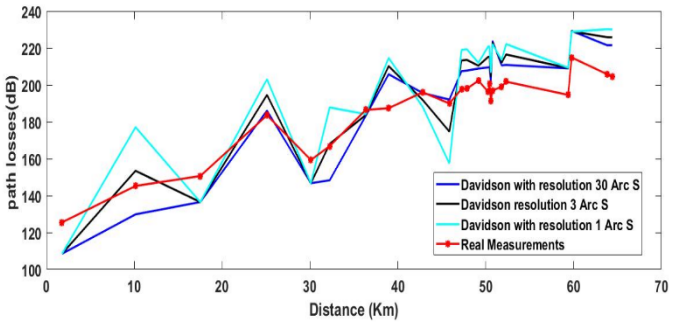

Figure 8. Impact of different terrain resolution on the Davidson model

It can be observed in the statistics of Table 4 that the SCRMSE is increased while the resolution value is decreased as Table 2 of the Extended-Hata behavior.

Table 4: Fitted Davidson model in different terrain Resolutions

Resolution, arcsec	Av Error, dB	STD. Dev, dB	RMSE, dB	SCRMSE, dB
30	24.46	5.10	30.70	12.48
3	22.44	4.68	31.50	15.60
1	22.99	4.79	34.38	16.94

According to the advantage and disadvantage of both previous results in terms of accuracy and processing time, we observed that 30 arcsec has short time and less accuracy, while 1 arcsec has high accuracy and long processing time. Therefore, the 3 arcsec resolution in the Egli model gives the best result when taking these chosen criteria into account when comparing SCRMSE results between different terrain resolutions.

8. Design of Flexible System for Creating TVWS Database by Using Different Propagation Models

Based on the previous results, which indicate that the Egli model is the best among the models that have been chosen for

comparison with the real measurements, a flexible system has been built that performs many functions related to propagation modelling and calculation of signal strength in each pixel. Among these tasks, it is possible to determine any geographic area based on latitude and longitude between two concentric points. In addition, it can be determined that the size of each pixel will affect the implementation time and propagation accuracy. Also, the system can perform three major operations at the same time to create a database for a selected geographic region that can be easily used when connected to the white space devices (WSD). In this work, for illustration, we considered only six transmitters, but more can be added using the "Add Transmitter Detail" button, as shown in Figure 9.

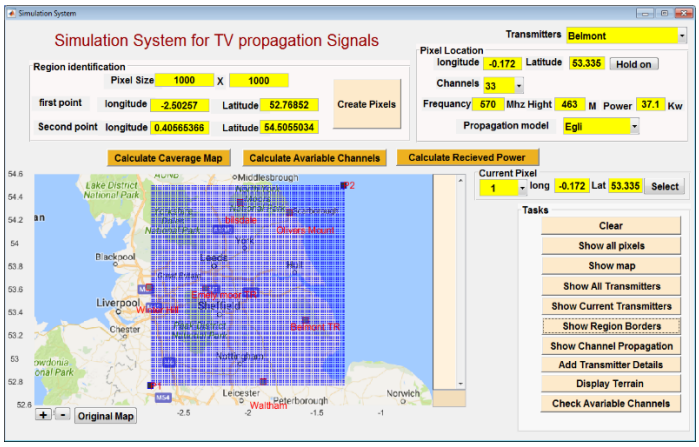

Figure 9. Display of all pixels in the selected region in the flexible simulation system for creating TVWS database.

8.1. Methodology for Calculation of Received Power

The second methodology to be implemented after creating the pixel file is to calculate the receiver power in each pixel in the frequency range 470 to 790 MHz, by considering the selected transmitters. The processing time depends on the number of pixels, propagation model and also the terrain resolution level. The process will be conducted only once to create a complete database of all the predicted TV signals in each pixel, as shown in Figure 10, which can be used for the next stages.

8.2. Methodology for Calculation of Available Channels

The main goal of the system is to calculate available channels with high accuracy and then store all available channels of each pixel in the database, in a way which makes it easy to retrieve the data from WSDs. All of the transmitter information, such as height, channels and transmitted power, is stored previously in the database. The process takes into account all channels of the selected transmitters that might be received in a specific pixel, considering the weak signals as well.

8.3. Methodology for Calculation of Coverage Map

This methodology must be used to translate the database that has been stored to show as a visual map of different levels of signal strength in the selected region for each transmitter, which are then stored in different files in the database as shown in Figure 11.

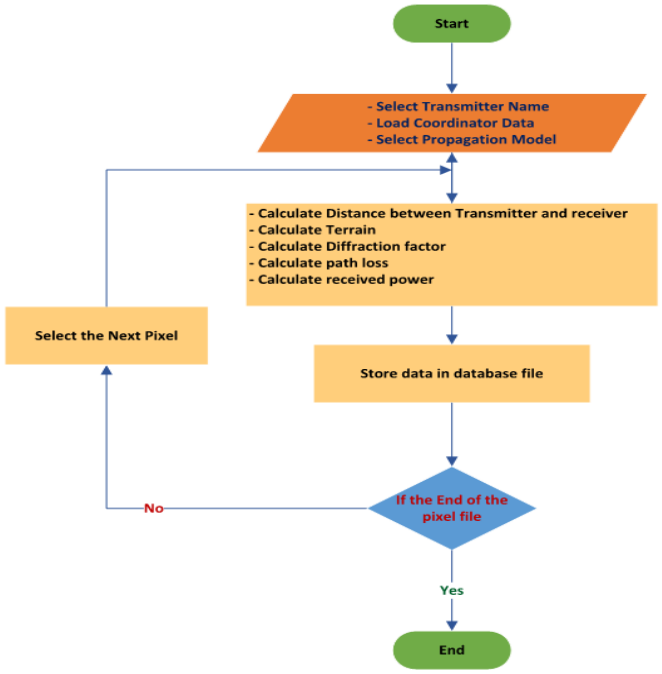

Figure 10. Algorithm of the received power calculation

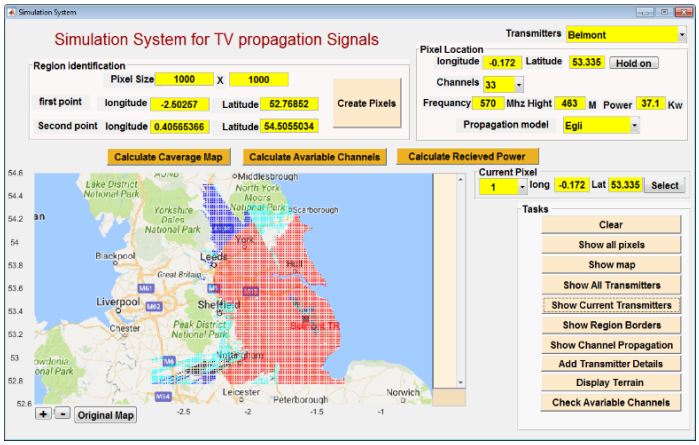

Figure.11 Display of the propagation signals for channel 33 using Egli model.

9. Conclusion

In this paper, TV signal strengths are calculated using various propagation models and then compared with real measurements that have been conducted in various locations. Using a single knife edge model to calculate the diffraction factor with consideration of terrain profile data at different resolutions, we investigate and prove how the terrain data resolution impacts the accuracy and implementation time of the propagation models. We have improved and extended results that have been published in our conference paper in 2016 [11]. RMSE and SCRMSE are the main criteria taken into account to assess the propagation models in different terrain resolutions. The results show that the Egli model still gives the best results when account is taken of the terrain profile data at a resolution of 3 arcsec (100m), providing SCRMSE of 0.14 dB, with shorter computation time and similar accuracy as compared with 1 arcsec. On the other hand, RMSE

and SCRMSE values of the extended Hata and Davidson models are still increasing and have poor performance when terrain data resolution is decreased. Therefore, 3 arcsec is considered the best resolution that can be used to calculate diffraction factor. The results also show that the Egli model is the best model giving a consistently good fit to measured data among other selected models and, with appropriate terrain data, will provide useful input to a system for facilitation of the cognitive radio decision process. In addition, the main benefits for designing the flexible system is to create a TVWS database for a specific area, by selecting the optimum pixel size, adding appropriate transmitter information and choosing a suitable propagation model. In future work, the system will be developed to use additional propagation models at various terrain data resolutions, providing a clear understanding of the differing results between propagation models taking into account the terrain resolution.

Acknowledgment

The lead author is grateful to his supervisor for his unlimited supporting to develop this study, by providing the suitable solutions and suggestions.

Conflict of Interest

The authors declare no conflict of interest.

ABSTRACT

This paper is an extension of work originally presented in WITS-2017 CONF. We extend our previous works by improving the Risk calculation formula, and risk assessment of an alert cluster instead of every single alert. Also, we presented the initial results of the implementation of our model based on risk assessment and alerts prioritization. The idea focuses on a new approach to estimate the risk of each alert and a cluster of alerts. This approach uses indicators such as priority, reliability and asset value as decision factors to calculate alert's risk. The objective is to determine the impact of alerts generated by Intrusion detection system (IDS) on the security status of an information system, and also improve the detection of intrusions using snort IDS by classifying the most critical alerts by their levels of risk. Thus, only alerts that present a real threat will be displayed to the security administrator. The implementation of this approach will reduce the number of false alerts and improve the performance of the IDS.

1. Introduction

This paper is an extension of work originally presented in International Conference on Wireless Technologies, Embedded and Intelligent Systems, EEE WITS-2017 [1]. Based on our work in [2], the goal is to improve the intrusion detection system (IDS) with a Risk Assessment method that can help to prioritize the generated alerts by their importance.

IDS systems generate enormous number of alerts. Often, there are duplicative events from various systems, and other alerts that could be characterized as noise (False Positive). A False Positive is normal events being classified as attacks. This is a major problem for many organizations [3,4]. An attack may in fact be happening, and the network administrator needs to be able to properly identify it, thus, he need to analyze each IDS alert manually, whether it is a false or true positive. So, it is a quite time consuming. Since the number of false positives is high, so alerts of real attacks are hidden among them. The optimal way to deal with this problem is to use an IDS solution that has the ability to prioritize alerts, calculate the risk of each one and correlate them, thereby to help the network administrator focus the efforts on detecting actual threats [5-7]. Therefore, an automated operation is needed to handle alerts and give a good perdition to the security administrator.

In this work, we propose the new Risk Assessment model as a method of prioritizing alerts according to the risk level of each one, and also evaluate the risk of a cluster of alerts. The risk is evaluated as a combination of certain parameters extracted from each alert.

This paper is organized as follows: Section 2 discusses the related work in risk assessment and alert prioritization; Section 3 presents the proposed model and the indicators that are used to support it; Section 4 discusses the implementation of the model and the experimental results to validate the proposed approach; and finally, in Section 5, we summarize the conclusions derived from this work and indicate possible future works.

2. Related Works

Intrusion detection system has an important role in the security and perseverance of active defense system against intruder attacks. They evolved from packet sniffers, used as a network troubleshooting tool to locate malfunctioning equipment and

[*]Corresponding Author: El Mostapha Chakir, IR2M Laboratory, FST, Univ Hassan 1, Settat, Morocco | Email: e.chakir@uhp.ac.ma

software by creating logs showing the activity of network packets [8,9]. Prior to the advent of network switches, IDS products could be connected to any port on a network hub and had a good chance of monitoring network packets on a local area network segment. Many researchers have proposed and implemented various models for IDS, but they often generate too many false positives due to their simplistic analysis [10].

Attacks are presented to a security administrator as alerts generated by IDSs. An IDS generates a large number of alerts and with this large number, security administrators are overwhelmed and it becomes difficult to manually distinguish between the real attacks and the false ones. To deal with this problem, two solutions have been proposed. The first one focuses on the monitoring device by enhancing its detection mechanism, optimizing its signatures, and choosing the right location [11]. Although this solution promises to reduce the number of alerts, it requires prior security administrator knowledge of detection mechanism. The second solution focuses on the sensor's outputs. Several IDS alert management techniques fall into this category and include aggregation, clustering, correlation and fusion [12].

Generally, reducing the number of false positives and prioritizing the most critical attacks are the main objectives of IDS alert management approaches. Furthermore, these techniques help the security administrators in understanding the situation revealed by the IDS.

In our previous work [2] we presented a new model to handle Intrusion detection system alerts based on a stateful pattern matching algorithm. In this paper we improve that model by proposing a new method based on risk assessment and alert prioritization using parameters extracted from alerts generated by IDS.

Risk assessment is the process of identifying security risks related to a system and determining their probability of occurrence, their impact, and the safeguards that would mitigate that impact [13]. Risks can be defined as the potential that a given threat will exploit vulnerabilities of an asset or group of assets to cause loss or damage to the assets. The main objective of risk assessment is to define appropriate controls for reducing or eliminating those risks.

Researchers have been proposed many approaches to prioritize alerts. In [13], the authors proposed a model that estimates the risk index for every single alert based upon indicators and input obtained from asset environments and attributes within the alerts themselves. The model uses a combination of two decision factors: impact on asset and likelihood of threat and vulnerability.

In [14], the authors proposed a method that evaluates IDS alerts based on a number of criteria. They used a Fuzzy Logic Inference mechanism in order to score alerts and developed a rescoring technique that enabled them to rescore alerts to show the early steps of the attackers, and applied their approach to the alerts generated by scanning DARPA 2000 LLDOS 1.0 dataset and they successfully prioritized the most critical alerts along with their preparation steps.

In [15], the authors applied a fuzzy system approach in accessing relative potential risks by associating potential vulnerabilities like the National Vulnerability Database (NVD) and Common Vulnerabilities and Exposures (CVE) with computer network assets.

In [16], the authors estimated risks by associating three criteria: computer network assets, attacks and vulnerabilities.

In [17], the authors proposed a model called "M-Correlator", an alert ranking system based on the likelihood of attacks to succeed, the value of targeted assets and the amount of interest in the type of attack.

All discussed approaches have the ability to priorities alerts, but they also have limitations, especially in the technical aspects of the methods adopted. They used multiple factors to estimate the risk, but do not consider different weightings based upon the importance of different decision factors.

3. The proposed Model

3.1. Overview

In [1] and [2] we have proposed the New System Alert Management for IDSs based on a stateful pattern matching algorithm, which can classify alerts by their importance and reduce number of false positives considerably. In order to improve our system, we propose in this paper more efficient method to prioritize alerts generated by IDSs by evaluating each risk. We assess the risk as a composition of indicators extracted from alerts itself and target assets, and then apply these results of the risk assessment to filter alerts produced by the IDS as **High Risk, Medium Risk** or **Low Risk.**

In our proposed system (Figure 1), we've used binary traffics files of KDD'99 which is used in our previous work. Snort [18] is used to produce alerts of KDD'99 dataset network traffics. Snort is an open source signature based IDS which gets KDD'99 online traffic and then generates alert log files; these files are entered into our proposed system as the inputs. A pattern matching algorithm is used to filter alerts and classify them to different form.

3.2. System architecture

Our approach encompasses three phases for processing events: **Pre-processing phase, Collection phase** and **Post- processing phase**. Each phase provides a level of abstraction to the following one. Figure 1 shows the three abovementioned units.

Pre-processing Phase: In this phase Snort analyzes KDD'99 binary traffic and generates alert files. These alert files are entered in our proposed model as Inputs.

Collection phase: We call this phase also "aggregation and normalization phase", For all data are received from Snort at one location. Aggregation aims at unify alerts in a single format on just one location. Normalization requires a parser familiar with the types and formats of generated alert from Snort after processing them. Snort list files contain information about all packets in KDD'99 dataset [19]. Using this method, we will be able to observe all alerts in the same format.

Post-processing phase: In this phase, once we have all the data in one place, we can implement mechanisms that will improve detection sensitivity and reliability.

In our model, we use three post-processing methods:

- **Classification and Filtering:** In this unit we extract the needed information, such as: Date, IP source, IP Destination, Attack name, etc., and we store them into a database. This information is extracted by parsing the alert file using Perl and regular expression as we will see in section 4.
- **Risk assessment:** Each alert is evaluated in relation to its attack type, and the target host. Several parameters make it possible to qualify the level of danger (Risk) of an alert. It is important to understand their significance in order to be able to manage correctly the alarms according to their level of importance (Table 1).
- **Prioritization:** We prioritize alerts received automatically after calculating the Risk. The priority of an alert depends on the architecture and inventory of the organization's devices. Prioritization is one of the most important steps in filtering alerts received from the Snort output. It means the evaluation of an alert's importance in relation to the organization's environment.

To calculate the Risk, we use the parameters described in Table 1. Each parameter has a value. For the Alert Priority and Alert Reliability, these values are stored in a MariaDB database. For device values, the security administrator must add all the organization's devices, including Servers, Firewalls, Switches, Access Points, Network Printers, etc., and must assign to each equipment a value between 1 and 5 according to the value and the criticality of the device. On the other hand, the other parameters are related to each type or classification of attack by Snort, these values are stored… in a MariaDB database for later use.

We calculate the risk using the three previous indicators by the following formula (3.7).

Alert Priority (P) = {1-5} **(3.1)**

Device Value (D) = {1-5} **(3.2)**

Alert Reliability (R) = {1-10} **(3.3)**

$$\textbf{Risk Assessment(RA)} = \frac{(\mathbf{P}) * (\mathbf{D}) * (\mathbf{R})}{\mathbf{X}} \quad \textbf{(3.4)}$$

The risk should be between 1 and 10 as we will see in Table 2, so the X value and obtained by calculating the Risk using the Maximum Value of each parameter, for example:

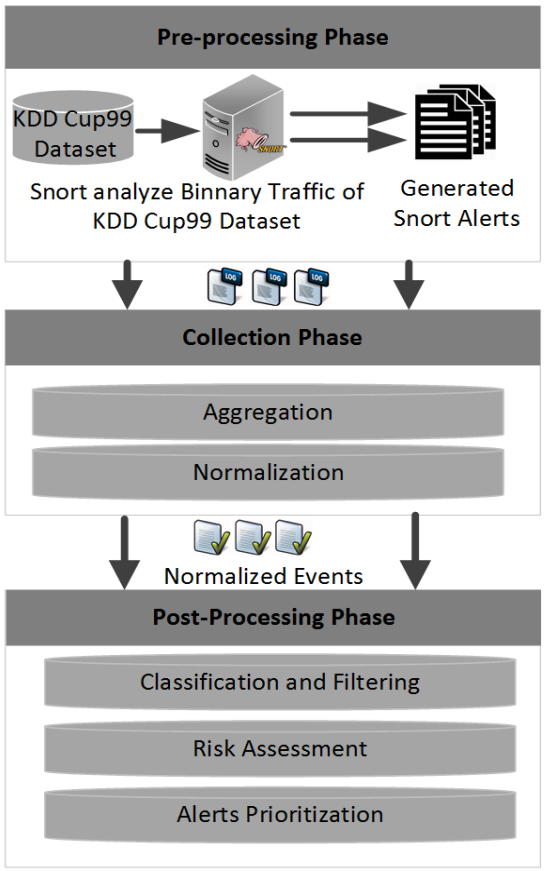

Figure 1: Proposed alert management system using real-time risk assessment and alert prioritization

Table 1. Description of parameters to assess the Risk of Alerts

Parameter	Description
Priority	Priority defines the order in which the action should be taken. A classification type rule assigns default priority that may be overridden with a priority rule [18]. In our model, we categorized priority into three types: **This should be Low = 1-2; Medium = 2-3; High = 4-5** These values are associated with each classification type of Snort IDS, and is stored into a MariaDB Database.
The value of the Destination Device associated with the event	This is a value to define the importance of a machine on the network. A DNS or Web server are more valuable resources for an organization than a network printer. As we will see later, these specifications will be taken into account when calculating the risk of each alert. This value must be between 1 and 5 (**1 = machine less important, 5 = very important machine**). This value is stored into a MariaDB Database for each device of the organization.
The likelihood that the event will occur **Reliability**	In terms of the risk, this parameter could be called "Reliability". This is defined for each independent event; an event may be a set of many alerts. The term reliability can be translated by the reliability that an event is not a *false positive*. The value of this parameter is between 1 and 10 **(equivalent to 1% =** this is a false **positive** and **100% =** it is not a false **positive).** This value is stored into a MariaDB Database and it is associated with an independent type of event (Alert Classification [18]).

Max(P)=5, Max(D)=5 and Max(R)=10

$$\mathbf{RiskAssessment(RA)} = \frac{\mathbf{5 * 5 * 10}}{\mathbf{X}} = \mathbf{10} \quad \textbf{(3.5)}$$

$$\mathbf{X} = \frac{\mathbf{250}}{\mathbf{10}} = \mathbf{25} \quad \textbf{(3.6)}$$

$$\mathbf{Risk\ Assessment(RA)} = \frac{\mathbf{(P) * (D) * (R)}}{\mathbf{25}} \quad \textbf{(3.7)}$$

The proposed model estimates the Risk for each alert. As we see in Table 1, the model uses a combination of three decision parameters.

Using the Risk Assessment, the Total Risk of an attack can be calculated according to the alert rate. Latter is calculated using formula (3.8) presented in [2], the Total Risk of an Attack (TRA) is used to evaluate the Risk of an attack type in a Meta-Alerts. Meta-Alerts can be generated for the clusters that contain all relevant information whereas the amount of data (i.e. alerts), for example all alerts to a specific host with the same attack type, or all alerts from the same source to the same destination and with the same attack type, etc., thus, the TRA is calculated using formula (3.9).

$$\mathbf{AR} = \frac{\mathbf{Number\ of\ Alerts\ byAttack}}{\mathbf{Tolal\ Alerts}} * \mathbf{100} \quad \textbf{(3.8)}$$

$$\mathbf{TRA} = \frac{\mathbf{(RA) * (AR)}}{\mathbf{100}} * \mathbf{10} \quad \textbf{(3.9)}$$

The resulting value can be mapped to the following Risk Categories, Table 2:

Table 2. Risk Assessment Categories

Risk Value	Signification
1-4	Low
5-7	Medium
8-10	High

3.3. Proposed Algorithm

The Algorithm can be explained as follows:

Algorithm: Filtering, classifying and prioritizing alerts according to the Risk Level

Input: Snort Log File (Generated by analyzing KDD'99 Dataset)
Output : Alerts with high Risk

1. Initializes the program
2. Processes the configuration and log files
3. While the number of alerts in log file is not reached
4. Extracts and records details of each alert into database
5. Correlate and classify alerts into many classes (attacks types)
6. Calculate the Alert Rate
7. For each alert in log file
8. Calculate the Risk of alert using (3.7)
9. End For
10. For each Meta-alert in log file
11. Calculate the Total Risk on an Attack TRA of Meta-Alerts using (3.9)
12. End For
13. Prioritize Alerts according to the Risk Assessment
14. Generate alarms if the Risk ≥ 70 %
15. End While

A basic flowchart diagram for the proposed algorithm is shown below (Figure 2):

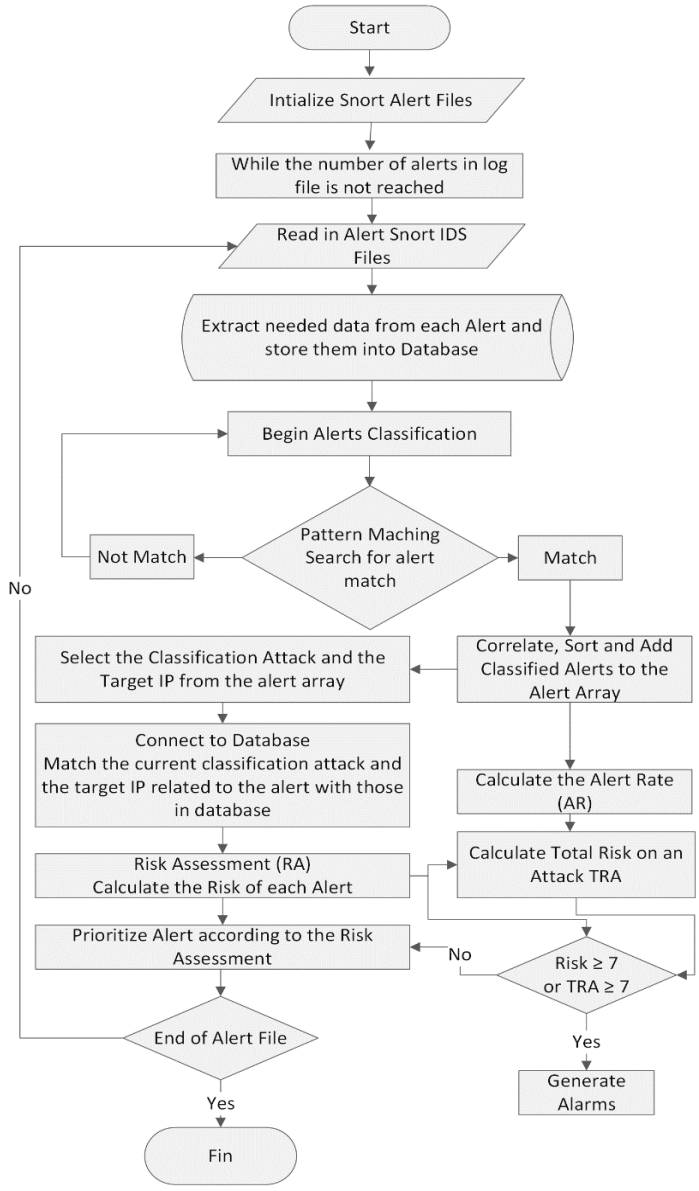

Figure 2: Flowchart of the proposed approach

4. Implementation and results

In order to test the effectiveness of our proposed model, we had it implemented and tested against the KDD'99 dataset. We also used Snort to scan the binary traffic of the dataset. Alerts generated by Snort were analyzed by our model using a pattern matching algorithm. To examine each alert, we wrote a Perl program using regular expression that parse the alerts and extract specific

parameters such as source IP, destination IP, attack name, priority etc... Finally, we use the formula (3.7) to assess the Risk of each alert and (3.9) to evaluate the Total Risk of attacks.

The example of alert below is just one sample of many alerts that we can find in one alert file. In this alert we can find many useful data, such as the Attack Name, Attack Classification, Target IP, Destination IP etc., to extract this useful information we use the Pattern matching rule below using Regular Expression (RE).

An example of alert to deal:

```
[**] [3:19187:7] PROTOCOL-DNS TMG Firewall Client long host entry exploit attempt [**] [Classification: Attempted User Privilege Gain] [Priority: 5] 03/19-16:01:43.762260 10.0.0.254:53 -> 172.16.2.11:1575 UDP TTL:64 TOS:0x0 ID:0 IpLen:20 DgmLen:201 DF Len: 173
```

These variables are stored into a MariaDB Database, thereby we can calculate the Risk for each generated Alert using these parameters and the formula (3.7), after that, using (3.9) we estimate the TRA.

Tables 3 and 4 below presents our experiment results using the output of Snort IDS and KDD'99 Dataset (with 99503 Alerts) that contains different 34 attempted attacks, 1056 Source IP, 485 Destination IP.

The Associated Pattern Matching rule:

```
^(?P<delimeter1>\[\*\*\])\s(?P<SigID_Rev>\[[0-
9:]+\])\s(?P<Attack_Name>[^\"]+)\s+(?P<delimeter2>\[\*\*\])\s\[Classification\:(?P<Attack_Class>[^\]]*)\]\s\[Priority\:(?P<Attack_Priority>[^\]]*)\]\s+(?P<Date>\d+\/\d+\-\d+\:\d+\:\d+)\.\d+\s(?P<SrcIP>\d{1,3}\.\d{1,3}\.\d{1,3}\.\d{1,3})\:(?P<SrcPORT>\d+)\s\->\s(?P<DstIP>\d{1,3}\.\d{1,3}\.\d{1,3}\.\d{1,3})\:(?P<DstPORT>\d+)\s(?P<Protocol>\w+)\s+[^\]]*.*$
```

Extracting Data to variables:

```
Attack_Name = PROTOCOL-DNS TMG Firewall Client long host entry exploit attempt
Attack_Class = Attempted User Privilege Gain
Attack_Priority =
SrcIP = 10.0.0.254
DstIP = 172.16.2.11
DstPORT=53
Protocol= UDP
```

Our platform for the experiment are described as follows:

- Processor: Intel (R) Core (TM) i7-6500U CPU @ 2.50GHZ 2.59 GHZ.
- Memory: 4 GB
- System (OS): Linux Ubuntu Server 16.04 64-bit

Table 3 present the classification of alerts according to the alert Rate; Alert Rate is measured by calculating the number of alert for each attack [2].

Table 4 shows the process of evaluating the risk of alerts. After classifying them into three categories, the security administrator will see just alerts with medium and high risk. The rest with low risk can be considered as false positives, this is related to the values of the target hosts and the reliability and priority of the attack. As we can see in Table 4, the risk is evaluated for each alert. For example, in the first row in the table, we notice that the attack "**(http_inspect) NO CONTENT-LENGTH OR+E3:E19 TRANSFER-ENCODING IN HTTP RESPONSE**", has been generated **45600** times to the target "**192.168.11.52**". The **RA** is **10** which is **High**. It is evaluated using the three parameters related to the alert: the priority, the reliability and the device target value. In other ways, the Total Risk of an Attack is evaluated according to the number of events of each attack in relation to the Alert Rate of this Attack.

The specific and complex characteristics of the network system environment make the implementation of Intrusion Detection System more difficult with the multitude of alerts and the huge number of false positives. Therefore, the new approach for detection and analysis of malicious activities is needed in order to check the effectiveness of the current security controls that protect information data.

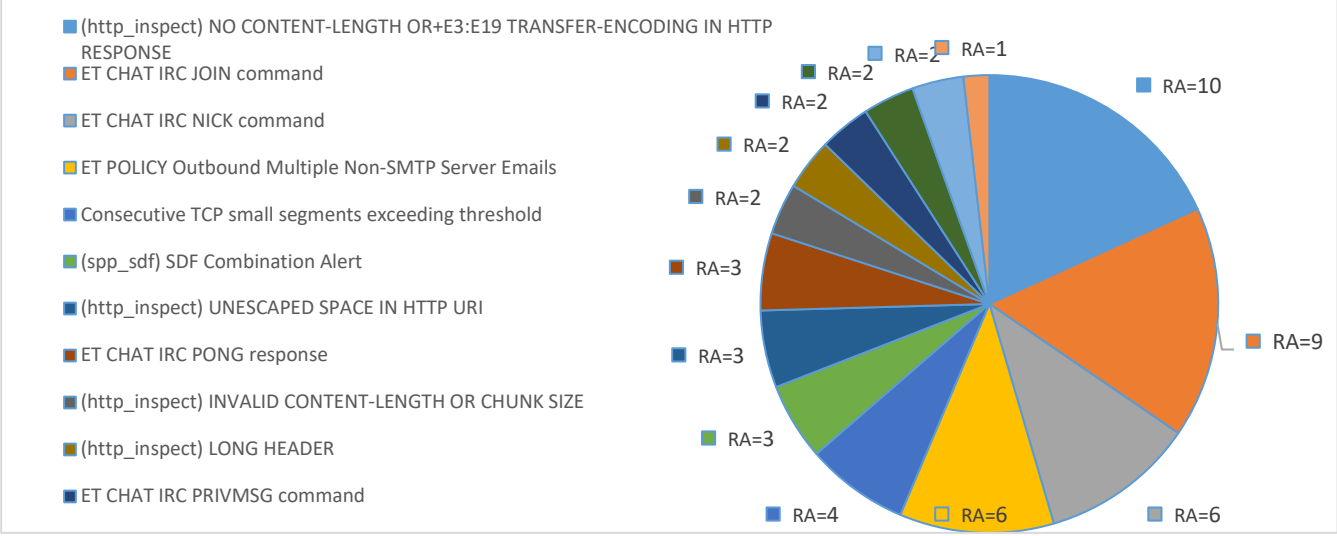

Figure 3: Alerts prioritization after risk assessment

Table 4. Risk Assessment according to the alert and target host parameters

No. of events	To Target	Attack Name	P	R	D	RA	RA Ranking	AR %	TRA %
45600	192.168.11.52	(http_inspect) NO CONTENT-LENGTH OR+E3:E19 TRANSFER-ENCODING IN HTTP RESPONSE	5	10	5	10	**High**	45.82 %	**4.6%**

In this work we demonstrated how the implementation of risk assessment reduces the number of false positive. With such an approach, the security network administrator will see just the alerts with a medium and high-risk level that presents a real threat to the organization. The rest of alerts will be considered as a false positive and will not be sent as alarms. Thus, the network security administrator can check the effectiveness of the current security controls that protect the organization's assets (Figure 3). In the next step of this work, we will set up a knowledge base for all the false positives to be compared further and to see if they are indeed.

5. Conclusion and future works

A novel approach that evaluates intrusion detection system alerts using a new risk assessment and alert prioritization is presented. We proposed a model that recognizes and analyzes malicious actions by calculating the risk related to attack pattern and qualify the level of dangerousness of each attack, thus prioritizing alerts generated by IDS. The implementation has demonstrated the efficiency of our approach in both decreasing the huge number of false positives that can reach over 95 % of alerts in the usual cases with a normal IDS, using our model we can control the rate of false positives; thus, we increase the effectiveness of the IDS system.

In the next step of this work, we will focus on the implementation of our approach with other IDSs. Moreover, we will improve our model by using advanced functions as well as more sophisticated algorithms such as machine learning algorithms to classify the attacks according to their dangerousness.

ABSTRACT

This research work is novel technique to control and optimize SSSC (Subsynchronous Series Controller) functions with degree of precision in between Qatar and Kingdom of Saudi Arabia. The SSSC model developed and simulated in order to identify and determine its control and functioning parameters by introducing new tuning parameters based on that the SSSC can be adjusted stringently to witness desired results lead to address outstanding reactive power management issue. The proposed new parameters are contributing significantly to control SSSC functions in multiple directions in a power system network in between QATAR and Kingdom of Saudi Arabia at different time-based transmission contingencies on the GCC Electrical-power grid. Strategically, the SSSC capacity and capability can be utilized fully in between Qatar and Kingdom of Saudi Arabia by introducing and optimizing its control and tuning parameters more tangibly under both steady and dynamic states

1. Introduction

The SSSC has operational controllability results are clearly indicating that introduction of SSSC in between Qatar and Kingdom of Saudi Arabia power network will equitably improve the power system loadability, curtailing the losses and value-added sustainability of the power system enactment by addressing control and operational issue throughout the GCC Electrical-power grid.

Hereafter, new SSSC optimization technique can thus be magnificently expended for this type of power system process optimization. This work published in 13th the IET International AC/DC Conference held in Manchester, February 14-16, 2017. Whereas a SSSC determines and validates the three control and effective limits which have been made-to-order at (minimum (+/-) medium (+/-), and maximum (+/-) compensation. These rheostats functioning limits are regulated by constituting their consequent PI control-values by exercising D.J. Cooper PID regulator Performance to achieve the following [1].

(1) Augmented Power flow
(2) Developed consistency & controllability
(3) Augmented angle and voltage constancy.

Therefore, FACTS Controllers are convincing candidate technology options centered on that following benefits can be perceived.

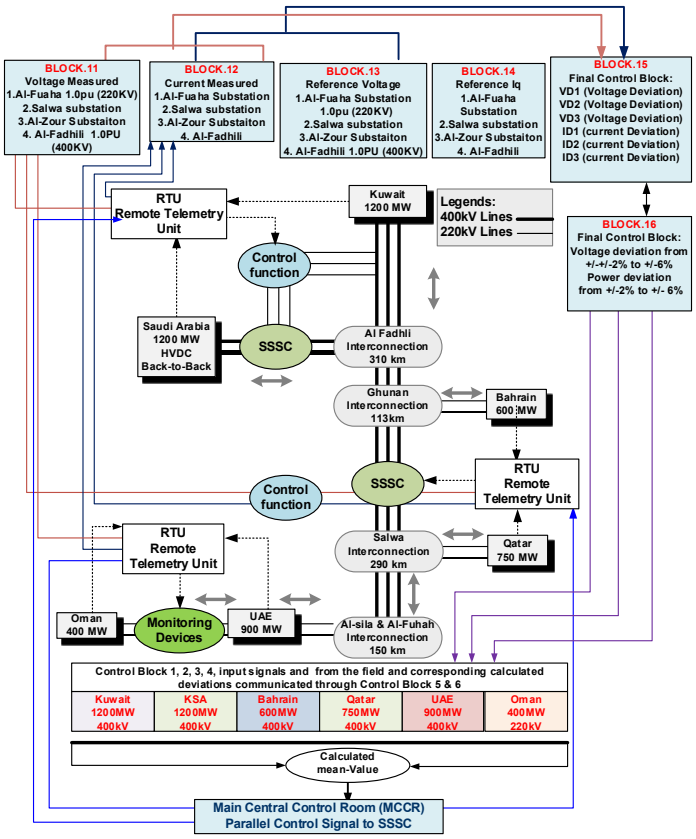

Figure 1. SSSC structure in between Qatar and Kingdom of Saudi Arabia

Figure 1 shows the GCC power network by retaining SSSC at augmented whereabouts by exercising Wideband-Delphi-Technique.

- Model reveals how much notional concentrated power can be dispensed in between QATAR and Kingdom of Saudi Arabia.
- At maximum conjectural power, what is borderline voltage
- Model reveals how much reactance must be retained by the orthodox series capacitance to double the power conveyance in between Qatar and Kingdom of Saudi Arabia if vital and prerequisite.
- Compute the introduced voltage by the series capacitor in between QATAR and Kingdom of Saudi Arabia
- By SSSC how much introduced and instilled/injected reactive voltage Vr is upheld at diverse compensation of SSSC in between Qatar and Kingdom of Saudi Arabia and Compute the determined power supplied at persistent introduced voltage Vr
- If the load angle decreases from 71 to 0 how much power will be produced by SSSC in between Qatar and Kingdom of Saudi Arabia.

2. GCC Electrical-power grid background

The GCC power-grid is constituted and employed into eight premeditated power system operational directions in order to meet national and industrial customers necessities in a consistent and viable demeanors at the GCC Electrical-power grid-network as shown in Figure 1 as considered and described with facts and figures, this is also published in [1] .

3. SSSC Operational Analyses

Principally, the SSSC-series counterbalance device location is not very much perilous it can be employed anyplace on the GCC Electrical-power grid. In this case the SSSC has been retained at the borderline to decrease the power-line transmission impedance unnaturally by SSSC which is controlling to upsurge the power flow in the power transmission system in (5) and (6) determine how much line impedance (X_C) has been Controlled and Managed after employing series but stable capacitor's K_{series} factor.

SSSC encompasses of capacitors and reactors to diverge the power-line impedance on domineering need basis vigorously. Predominantly, the SSSC injects the voltage in a series into the power transmission network at the midpoint of Kingdom of Saudi Arabia and Qatar whereas instilled/injected the voltage at midpoint Vr has been computed in (7). The SSSC stipulates or expends reactive-power in capacitive/inductive control-mode of functions on the GCC power-grid, wherein the SSSC instilled/injected voltage in phase quadrature with the line current of the power network.

Figure 2 denotes maroon trend in the graphical presentation of the SSSC processes in capacitive and inductive mode of functions. Practically, blue trends denote how much real power transferred can transferred when electrical-power transmission network compensation carried-out capacitive, inductive mode of operations or neutral without any compensation factor. Figure 3 signifies that a SSSC has a main and great influence on power steadiness and load flow, but ithas limited impact on voltage profile enhancement as exhibited in (28) that V_m, V_s, V_r has negligible or no effect with SSSC [2].

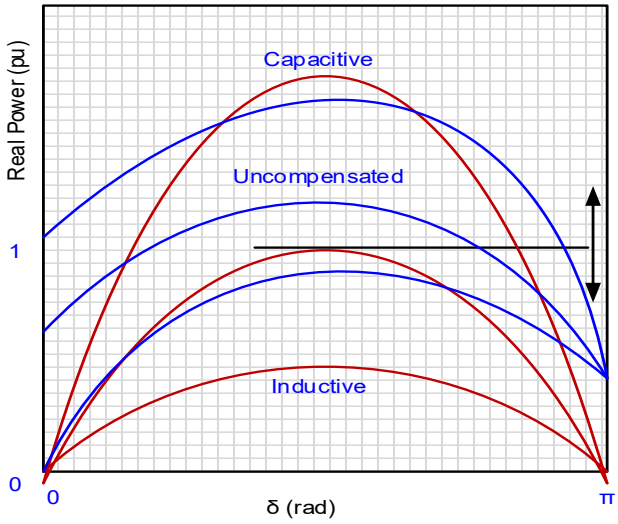

Figure 2. Signify the compensation factor by SSSC [2]

Principle of Operating parameters	SSSC Controller	Impact in between Qatar and KSA

	TPSC: Thryrister protected Series Compensation	o	ooo	o
	TCSC: Thryrister controlled Series Compensation	oo	ooo	o
Benchmark	o: Low or no Impact	o o: Medium		o o o: Strong

Figure 3. Denotes the SSSC impact.

3.1. By employing Series Fixed Capacitor to upsurge the Power on the GCC Electrical-power grid

Herein determined conjectural power can be dispensed and distributed without conservative or non-conventional series compensation, the voltage structured transitorily but not vigorously and unvaryingly which is outfitted at 800 km long electrical-power transmission network from Kingdom of Saudi Arabia to Qatar or vice versa along with its attendant substations. Now if series capacitor is connected at midpoint voltage as stated in Figure 3 to resource and expend sufficient reactive power to counterbalance as prerequisite. Equation (5) expended to compute series compensation factor to convalesce the power system steadiness and double the power at power transmission lines reactance X_C= 136.626 Ohms as intended in (6) and (7) [3].

$$K_{series} = \frac{X_c}{2 \times Z_a} cos\frac{\theta}{2} \tag{5}$$

$$X_c = 2 \times K_{series} \times Z_a tan\frac{\theta}{2} = 136.626\ Ohms \tag{6}$$

$$P_{max} = \frac{V^2}{Z_a - X_C \times Sin(43.26^{\circ})} = 1223\ MW \tag{7}$$

Equation (7) reveals the concentrated power by adapting power transmission line reactance by series capacitor Units.

3.2. By implementing Series-Capacitor to upsurge the Power on the GCC Electrical-power grid

The SSSC has a tremendous competence to upturn the electrical Power flow and improve dynamic steadiness to supplant usual and uneconomical fixed series capacitors are expended to govern the prerequisite reactive current at midpoint in between Qatar and Kingdom of Saudi Arabia for recompense [4].

Instill/Injected current with series capacitor is computed by exercising in (8), (9).

$$I_m = \frac{Vsin\frac{\delta}{2}}{(1 - K_{series})Z_a sin\frac{\theta}{2}} = 2.1159pu \tag{8}$$

Instilled/injected voltage as given below

$$\hat{V_r} = 1.5237 \times tan\frac{\theta}{2} = 0.8881pu \tag{9}$$

Equation (9) reveals the in a Phase injected/instill voltage

$$V_r = \hat{V_r} \times \frac{V}{\sqrt{3}} = 205.03\ kV \tag{10}$$

Equation (10) reveals the instilled/injected voltage in between QATAR and Kingdom of Saudi Arabia. Herein determined power flow can be sustained with unremitting voltage inserted by the SSSC at midpoint. Firstly, the SIL computed and determined by using Equation (11)

$$\hat{P} = \frac{P}{P_n} = Acos\delta + Bsin\frac{\delta}{2} \tag{11}$$

amount of real power can be dispensed in line with P_n, this is identified as a SIL in contradiction of the real electrical-power delivery.

Where

$$A = \frac{1}{sin\theta} = 1.40115\ \ ;\ \ B = \frac{\hat{V_r}}{2sin\frac{\theta}{2}} = 1.14735 \tag{12}$$

Equation (13) reveals electrical Power flow with unremitting reactive voltage instilled/injected whereas the $\hat{P}$ is determined

when $\frac{d\hat{P}}{d\delta} = 0$

$$\frac{d\hat{P}}{d\delta} = Acos\delta - Bsin\frac{\delta}{2} \tag{13}$$

Equation (14) resultant after substituting $\frac{d\hat{P}}{d\delta} = 0$ value

$$0 = Acos\delta - Bsin\frac{\delta}{2} \tag{14}$$

Unassumingly $cos\delta$ and $sin\delta$ are factorized as resultant in (15)

$$cos\delta = cos\left(\frac{\delta}{2} + \frac{\delta}{2}\right)\ \ ;\ \ sin\delta = sin\left(\frac{\delta}{2} + \frac{\delta}{2}\right) \tag{15}$$

Where

$$\cos(A + B) = CosA.CosB - SinA.SinB \tag{16}$$

Equation (17) resultant after replacing $cos\delta$ and $sin\delta$ values in (16)

$$cos\left(\frac{\delta}{2} + \frac{\delta}{2}\right) = cos\frac{\delta}{2}.cos\frac{\delta}{2} - sin\frac{\delta}{2}.sin\frac{\delta}{2} \tag{17}$$

Equation (17) is the streamlined and resultant in (18)

$$cos\delta = cos^2\frac{\delta}{2} - sin^2\frac{\delta}{2} \tag{18}$$

Equation (18) $cos\delta$ value subtract in (14) and resultant from (19)

$$0 = A\left(cos^2\frac{\delta}{2} - sin^2\frac{\delta}{2}\right) - Bsin\frac{\delta}{2} \tag{19}$$

Whereas

$$cos^2\frac{\delta}{2} = \left(1 - sin^2\frac{\delta}{2}\right) \tag{20}$$

Equation (20) $cos^2\frac{\delta}{2}$ subtracted in (19) and developed new (21)

$$0 = A\left(\left(1 - sin^2\frac{\delta}{2}\right) - sin^2\frac{\delta}{2}\right) - Bsin\frac{\delta}{2} \tag{21}$$

By adding the $x = sin\frac{\delta}{2}$

$$A(1 - x^2 - x^2) - Bx = 0 \quad (22)$$

$$-2Ax^2 + A - Bx = 0 \quad (23)$$

$$-(2Ax^2 - A + Bx) = 0 \quad (24)$$

$$2Ax^2 + Bx - A = 0 \quad (25)$$

Equation resultant from (25) to convert into Quadratic form.

$$\int(x) = \left(x + \frac{b}{2a}\right)^2 + \frac{4ac - b^2}{4a} \quad (26)$$

Equation (26) expressed the Quadratic function as detailed below with factors.

$$\left(x + \frac{B}{4A}\right)^2 + \frac{(4 \times 2A \times -A) - B^2}{4A} = 0 \quad (27)$$

$$\left(x + \frac{B}{4A}\right)^2 - \frac{8A^2 + B^2}{4A} = 0 \quad (28)$$

Equation (27) and (28) Quadratic roles are defined and extracted and resultant in (29)

$$x = -\frac{B}{4A} \pm \frac{\sqrt{8A^2 + B^2}}{4A} \quad (29)$$

Equation (29) subtracted A and B factors values as defined and calculated in (12) and resultant in new (30)

$$x = -\frac{1.401}{4 \times 1.4735} \pm \frac{\sqrt{8 \times 1.4735^2 + 1.401^2}}{4 \times 1.4735} \quad (30)$$

Finally, the "x" values are signified as given below:

$$x = 0.5314 = sin\frac{\delta}{2} =\rightarrow \delta = 64.2° \quad (31)$$

Equation (31) reveals the $x = 0.5314$ and electrical power angle resultant

Where

$$\hat{P}_{max} = Asin\delta + Bcos\theta \quad (32)$$

$$\hat{P}_{max} = Asin(64.2°) + Bcos(45.5°)\hat{P}_{max} = 2.06519 \quad (33)$$

Equation (32) subtract the A, B, $\emptyset$ and δ values and resultant the $\hat{P}_{max}$ value.

$$P_{max} = \hat{P}_{max} \times \frac{400^2}{316.228} = 1044.9\,MW \quad (34)$$

Equation (34) signifies the concentrated electrical power dispensed and distributed in the GCC Electrical-power grid by retaining SSSC to uphold persistent Vr vigorously in the Midpoint of QATAR and Kingdom of Saudi Arabia as illustrated in Figure 4 [5].

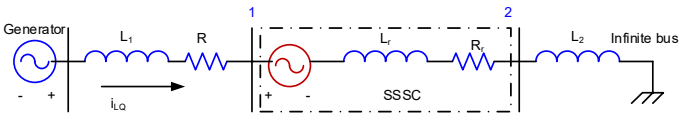

Figure 4: SSSC connected in between Qatar and Kingdom of Saudi Arabia

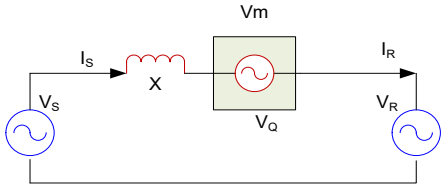

Figure 5: SSSC connected in between Qatar and Kingdom of Saudi Arabia

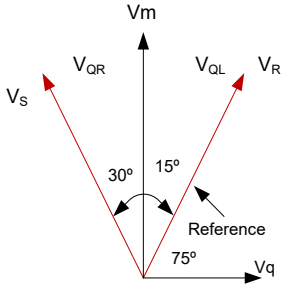

Figure 6. Phasor diagram of voltage profile

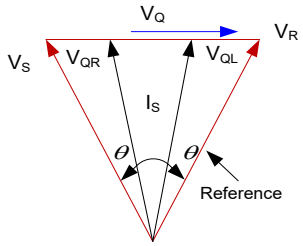

Figure 7. SSSC connected at the midpoint and instilled/injected V_Q toward V_R

Figure 5: signifies that counterbalance device employed in the middle of the of the power transmission line, this is voltage source only dispense reactive electrical power not a real power. Figure 6 displays the influence of location if counterbalance device employment on voltage profile, the voltage on left side of the counterbalance device would be V_{QL} and right side V_{QR}. Figure 7 illustrates that the series counterbalance device employed in the middle the worst voltage-profile occurred at each side of the counterbalance device, whereas the voltage-profile vector aligns with the current vector [5]. Therefore, the midpoint voltage-profile is the same with/without SSSC functions as exhibited in (37) and (38) SSSC power flow with $\delta = 0$[6].

$$P_{max} = 1.147 \times \frac{400^2}{316.2} = 580MW$$

$$\hat{V}_m = \frac{cos\frac{\delta}{2}}{cos\frac{\theta}{2}} \qquad \delta = 0 \quad (35)$$

Equation (35) reveals the midpoint voltage-profile if $\delta = 0$ and resultant midpoint voltage denotes from (36)

$$\hat{V}_m = \frac{1}{cos \times 22.76°} = 1.1\ pu \quad (36)$$

Equation (35) reveals the midpoint voltage if $\delta = 0$ therefore, $V_s and\ V_R$ voltage-profile are computed in (37) and (38). Sending end from the Kingdom of Saudi Arabia and receiving end at QATAR

$$V_s = V_m \angle 0 - j\frac{V_r}{2} = 1.171\angle 0 - j\frac{0.8881}{2} \quad (37)$$

$$V_R = V_m \angle 0 + j\frac{V_r}{2} = 1.171\angle 0 - j\frac{0.8881}{2} \quad (38)$$

3.3. SSSC input Data

Table 1: operating parameters and associated countries

Countries	Power Exchange
To/from Qatar to main transmission line	400kV, 50Hz, 750MW
To/from Kingdom of Saudi Arabia to main power-transmission line	400kV, 50Hz, 600 MW

Table 2: Conventional Reactive Power

Existing Power System	Reactive Power	Distance
VAR Demand at Al Jasra substation Kuwait	850MVAR	Ghunan Substation to Slawa Substation total distance 288Km
Reactive Power demand at Al-Al-Zour Substation	500MVAR	Slawa Substation total distance = 97Km

Table 3: Multivariable Controller's Configuration

Al-Zour Substation	Iq regular: Kp 14dB; Ki: 0.014 dB	Counterbalanced and regulated voltage at 0-2%
Rated SSC: +/- 500 MVAR	Ref V: 1.0 pu (400kV)	(VC voltage change from 2% to 4%)
P (proportional): 0.33, 0.38, 0.40, I (integral) 0.7, 0.9, 1.2	Droop: 0.033pu/100MVA; Kp:14dB; Ki: 3500dB	(VC voltage change from 4-6%)

4. Results and Discussion

4.1. Maximum level Vr voltage-injection

It has been simulated and authenticated that further real power can be up-surged in the power transmission line to touch its design specification by up-surging the SSSC compensation factor from 50% to 65% reactive voltage instilled/injected voltage would be 0.8864pu which is equivalent to 204kV and current Im = 2.1pu and $\boldsymbol{\delta = 63.87°}$ will activate consequently at different functioning condition total 1200MW power will be produced and distributed on the GCC electrical-Electrical-power grid. This is known as a determined compensation by implementing a SSSC and its compensation factor from 50% to 65% to obtained projected power produced and delivered in the electrical power transmission network on the GCC electrical-Electrical-power grid.

4.2. Medium level Vr voltage-injection

As simulated by Matlab/SIMULINK and scientific/ mathematical model V_r instilled/injected voltage 0.5936pu which is uniform and match to 137kV at 50% SSSC reactive voltage compensation whereas the midpoint current I_m = 1.4459pu, and $\boldsymbol{\delta = 71.32°}$ will activate consequently in this functioning circumstance to a total 1079 MW power which can be produced and distributed on the GCC Electrical-power grid as validated by the results. Infact, QATAR and Kingdom of Saudi Arabia system has been devised to produce and distribute concentrated 1200MW electrical-power in the GCC Electrical-power grid during a peak load, therefore Margin is obtainable to upsurge the power up to its projected specification. This is also identified as a medium compensation by a SSSC compensation factor from 20% to 50%. Therefore, the Control function block expended to readjust PI controller response as exhibited in Figure 10 to diverge the firing angle of the Thyrister control [7].

4.3. Minimum level Vr voltage-Injection

In the third challenge of operations, further this model was simulated and authenticated by exercising SSSC Controller. At minimum compensation of the SSSC compensation real power reduce considerably in the power transmission line to touch its projected specification by decreasing the SSSC compensation factor from 5% to 20% reactive voltage instilled/injected voltage would be 0.3710pu which is equal to 86.67kV and current Im = 0.974pu and $\boldsymbol{\delta = 77.57°}$ will activate consequently in this functioning condition total 986MW power will be produced and distributed on the GCC Electrical-power grid. This is identified as a minutest compensation by using a SSSC Controller and its compensation factor from 5 to 20% to achieve projected electrical power delivery of transmission network on the GCC Electrical-power grid. As instilled/injected voltage up-surged based on compensation from 5% to 20% there is considerable power flow and steadiness enhancement but very insignificant influence on voltage-profile as verified simulated consequences in Figure 8 (a) reactive power injection-waveform 8(b) indicates the total power delivered in between Qatar and Kingdom of Saudi Arabia, this is also computed in equation (34). The PI controller configured and demonstrated its operational response in Figure 9. Detailed configuration discussed as given in the appendices [8].

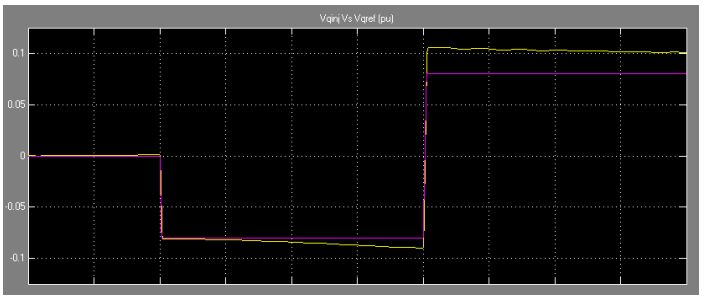

Figure 8 (a). Reactive power injection on the GCC Power Grid

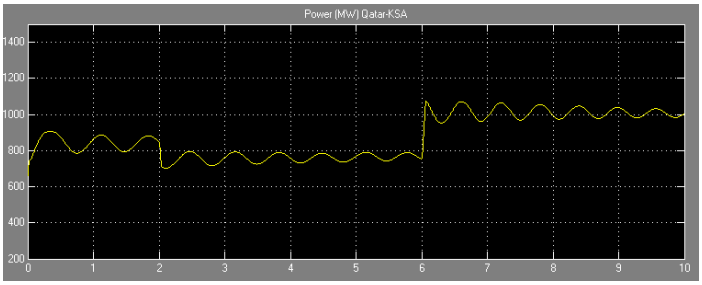

Figure 9 (b). Total active power delivered on the GCC Electrical-power grid

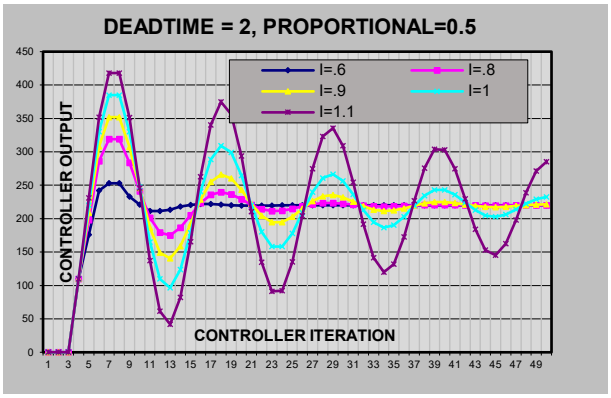

Figure 10. demonstrates the PI controller parameters

5. Conclusion

Fundamental creativity of the SSSC application in the GCC Electrical-power grid transmission line compensation is the subject of extensive significance. In this study, it has been computed and simulated how much maximum power can be produced and distributed in between QATAR and Kingdom of Saudi Arabia without any process vagueness. It has been reasonable how much reactance must be provided by the series capacitance to double the power supply in between Qatar and Kingdom of Saudi Arabia. It also has been also identified and unwavering amount of reactive voltage to be instilled/injected in between Qatar and Kingdom of Saudi Arabia in order to provide concentrated power delivery on the GCC Electrical-Power grid.

If the load angle as decreased below from 65 to 0 amount of electrical-power will be produced by SSSC in between Qatar and Kingdom of Saudi Arabia. Herein, the GCC electrical-power network will exclusively upsurge the power system loadability, decrease the losses and improve sustainability of the electrical-power system functioning. The results also illustrates that SSSC is multipurpose equipment with stupendous active capability to improve power system stability margin on the GCC Electrical-power grid. Based on these results, SSSC is a very strong-candidate to be instigated at GCC Electrical-power grid. It also demonstrates optimistic influence on neighboring countries' power system functions at the GCC Electrical-power grid.

ABSTRACT

Exploring communities and outliers in Social Network is based on considering of some nodes have overlapped neighbor node within the same group as well as some nodes have no any link to the other node or have no any overlapped value. The existing approaches are based on the overlapping community detection method were only defined the overlap nodes or group of overlap nodes without thinking of which nodes might have individual communities or which nodes are outliers. Detecting communities can be used the similarity measure based on neighborhood overlapping of nodes and identified nodes so called outliers which cannot be grouped into any of the communities. This paper proposed method to detect communities and outliers from Edge Structure with neighborhood overlap by using nodes similarity. The result implies the best quality with modularity measurement which leads to more accurate communities as well as improved their density after removing outliers in the network structure.

1. Introduction

This paper is an extension of work originally presented in 18thIEEE/ACIS International Conference on Software Engineering, Artificial Intelligence, Networking and parallel/Distributed Computing (SNPD 2017) [1] is used undirected and unweighted graph data based on overlapping neighborhood. It is explicitly focused on edge structure to detect outliers and significant communities with nodes similarity. Unfortunately, the number of outliers that implemented is higher than that we expected. Therefore, we continue improve our proposed approach to get the significant result by detecting outliers and community.

Social networks can be considered in graph theory point of view. Thinking of detection community in Social networks plays the important role in recent year. It is defined the presence of groups of nodes that are high tightly links connected with each other than with less links connected to nodes of different groups. The challenges in considering of community detection method are become popular in Social Network. The previous authors had finished thinking about them in various points of corners. In overlapping community detection method were only defined the overlap nodes or group of overlap nodes without thinking of which nodes might be included in its own individual communities . Then, the consideration of community detection does not force each node into a certain group, some independent nodes, which cannot be grouped into any communities, are allowed far outside the detected groups can be measured by the predefined threshold of minimal valid size (mvs) of communities as outliers. However, there are still challenges in considering of some nodes have no any common node within the same group as well as some nodes have no any link to the other node.

It can be used similarity measure based on neighborhood overlapping of nodes to organize communities and to identify outliers which cannot be grouped into any of the communities.

In this paper, we detect communities and outliers from Edge Structure with neighborhood overlap by using nodes similarity. This paper explores the use of neighborhood overlapping by using vertex similarity method for detecting outlier and significant

community. The heart of this approach is to represent the underlying dataset as an undirected graph, where a user refers to each node and friendship between two users represents each edge. Before we measure the similarity among neighborhood overlap, finding seed node by using the degree centrality is necessary which is designed to find nodes that are most "central" to the graph. We operate similarity from the most centrality node and its neighborhood nodes. The values of zero similarity are then used to identify as outliers. To illustrate, consider tiny graph which contain8 nodes and 11 edges as shown in Figure 1. Upon applying communities, rounded with two circles are group, and node h so called outlier is saturated with outside them. It can be seen clearly the significant communities and outliers in this toy example.

This paper proposed the method to detect communities, nodes which are high tightly linked each other as community and outliers which do not have links overlap values with another.

The rest of paper is organized as follows. We briefly surveyed related work in section 2. In section 3, we describe the background methodology of our work. And then, we briefly describe about our propose system in section 4. In section 5, we discuss about the experiment and evaluation of our work. Then, we conclude our work in section 6 and talk about our future idea.

2. Related Work

As described in section 1, this paper is an extension of work originally presented in 18thIEEE/ACIS International Conference on Software Engineering, Artificial Intelligence, Networking and parallel/Distributed Computing (SNPD 2017) [1] is used undirected and unweighted graph data based on overlapping neighborhood. It was explicitly focused on edge structure to detect outliers and significant communities with nodes similarity. Unfortunately, the number of outliers that implemented is higher than that we expected. Therefore, we continue improve our proposed approach to get the significant result by detecting outliers and community.

Many approaches of community and outlier detection algorithm have been proved over years. Each trend has efficient and effective in their ways. The proposal of a community discovery algorithm for large networks that iteratively finds communities based on only on local information only without considering the global information which was described in [2], this work is cited it in section. The paper based on considering of defining and evaluation networks community based on ground-truth [3] was discussed how to evaluate and measure the proposed system by comparing the previous and extracted community. In [4], the authors used proximity and random walks, to assess the normality of nodes in bipartite graphs. On the other hand, in [5], the authors proposed the one could use to compute various measures associated with the nodes in the given graph structure, dyads, triads, egonets, communities, as well as the global graph structure. The paper which was proposed an algorithm to detect anomalous nodes in weighted graphs is called OddBall was discussed in [6] that easily reveal nodes with strange behavior. However, it was only considered the side of outlier without community. This work is used some methods in the synthesis Lectures on Data Mining and Knowledge Discovery which is describe in [7] was the series publications on topics pertaining to data mining, web mining, text mining, and knowledge discovery, including tutorials and case studies.

In [8] , the authors proposed the efficient algorithm combined the hierarchical and spectral clustering in non-overlapping community. Then, [9] was represented the new community detection method on network model. In [10], the authors described modularity and community structure in networks based on the problem of detecting and characterizing this community structure was one of the outstanding issues in the study of networked systems. The proposed method for detecting such communities, built around the idea of using centrality indices to find community boundaries was described in [11] . [12] was presented several key features of Gephi in the context of interactive exploration and interpretation of networks. In [13], the authors proposed the method of detecting outliers with community by using minimum valid size (mvs). If the minimum size was 2, it would be chosen the single node and marked it as outlier. In [14], the authors surveyed on Social Community Detection which was also specially focus on to community evaluation since this step becomes important in social data mining. The results of proposed method of applying the metric, modularity, and several popular community quality metrics to two real dynamic networks was described in [15]. Continually, in [16], the authors discussed the attempting of a thorough exposition of the topic, from the definition of the main elements of the problem, to the presentation of most methods developed, with a special focus on techniques designed by statistical physicists, from the discussion of crucial issues like the significance of clustering and how methods should be tested and compared against each other, to the description of applications to real networks. Then, the paper in [17] was presented the graph-based approaches to uncovering anomalies in domains where the anomalies consist of unexpected entity/relationship deviations that resemble non-anomalous behavior. Using synthetic and real-world data, it was evaluated the effectiveness of these algorithms at discovering anomalies in a graph-based representation of data. The original citation of dataset, Zachary Karate Club was described in [18]. The paper was presented by the algorithms OCNS for detecting community overlapping base on node similarity was discussed in [19]. The following sections were described the method of the above references in detail which will be the background methodology for this paper.

3. Basic Definitions and Notations

3.1. Outliers

Nodes which have no overlapped values to its adjacent nodes as well as each node in a graph cannot be grouped into any of the communities is defined outliers. This system is based on edge structure approach in the graph to remove outliers before detecting community.

3.2. Node Degree and Its Neighborhood

In network G, the degree of any node i is the number of nodes adjacent to i. Generally, the more degree that the node has, the more important it will be. Two vertices v and u are called

neighbors, if they are connected by an edge. Let N_i be the neighborhood of vertex i in a graph, i.e., the set of vertices that are directly connected to i via an edge.

3.3. Community

Communities in Social network can be defined as group of nodes which have more links connecting nodes of the same group and comparatively less links connecting nodes of different groups. Communities may be groups of related individuals in social networks. Identifying communities in a network can be provided valuable information about the structural properties of network, the interactions among nodes in the communities, and the role of the nodes in each community. In an undirected graph (V, E), where the total number of node, $|V|=n$ and total number of edges,$|E|=m$ are defined. We can identify set of communities such that $Coms=\{V_1',V_2',\ldots\ldots..,V_{cn}'\}$ where $\bigcup_{i=1}^{cn} V_i' \subseteq V_i$and cn is the total number of communities Coms should satisfy, $V_i' \cap V_j' = \phi$.

Thus, the goal of community detection is to identify sets of nodes with a common (often external/latent) function based only the connectivity structure of the network. Then it can be considered an axiomatic approach and define four intuitive properties that communities would ideally have. Intuitively, a "good" community is cohesive, compact, and internally well connected while being also well separated from the rest of the network. This allows us to characterize which connectivity patterns a given structural definition detects and which ones it misses.

3.4. Degree Centrality

The importance of a node is determined by the number of nodes adjacent to it. The larger the degree of node, the more important the node is. Those high-degree nodes naturally have more impact are considered to be more important. The degree centrality is defined as

$$(v_i) = d_i = \Sigma A_{ij} \tag{1}$$

When one needs to compare two nodes in different networks, a normalized degree centrality should be used,

$$CD'(v_i) = d_i/(n-1) \tag{2}$$

Here, n is the number of nodes in a network. It is the proportion of nodes that are adjacent to node v_i.

Let N_i denote the neighbors of node v_i. Given a link $e(v_i, v_j)$the neighborhood overlap is defined as;

$$Overlap(v_i, v_j) = \frac{number\ of\ shared\ friends\ of\ both\ v_i\ and\ v_j}{number\ of\ friends\ who\ are\ adjacent\ to\ at\ least\ v_i\ and\ v_j} = \frac{|N_i \cap N_j|}{|N_i \cup N_j|} - 2; \tag{3}$$

We have -2 in the denominator just to exclude $v_i\ and\ v_j$ from the set $N_i \cup N_j$. If there are no overlap vertices in any two $N_i\ and\ N_j$ means $|N_i \cap N_j| = \emptyset$, we can identified N_j as outliers of N_i. Assuming like that, our work identify outliers are appeared with among separated communities.

3.5. Vertex Similarity

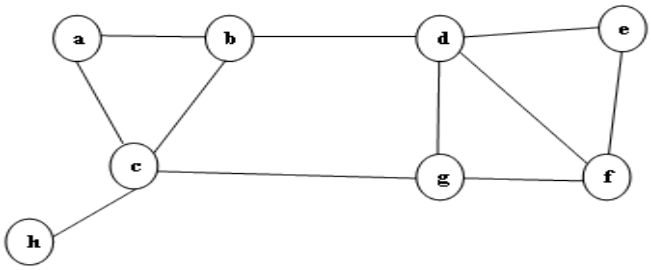
It can be assumed that communities are groups of vertices similar to each other. We can compute the similarity between each pair of vertices after searching seed nodes. Most existing similarity method are based on the measurement of distance called Euclidean, Manhattan and etc., Although, to considered the similarity between selected node and is neighborhood, Jaccard Similarity is more convenient in this work which we will measure the similarity based on the neighborhood overlap of seed nodes.

3.6. Graph

The definition of Social network can be imaged as graphs, users or things might be nodes and their relationship might be edges. This system will be represented their social network as an undirected and unweighted graph which mean no distinction between the two vertices associated with each edge. The notation of a graph $G = (V,E)$ consists of two sets V and E. The elements of $V = \{v_1, v_2, \ldots, v_N\}$ are the nodes or vertices of the graph G where each vertex vi is associated with the instance x_i from the input data X and the cardinality of $|V|$ is N. The elements of $E = \{e_1, e_2, \ldots, e_M\}$ are links or edges between nodes and the cardinality of $|E|$ is M. An edge connecting the vertices $v_i$and v_j is denoted by e_{ij}.

4. Community Detection Approach

There are two main components will be used to detect communities. They are (i) Finding seed nodes before detecting community and (ii) Detecting community using similarity measure.



4.1. Finding Seed nodes

This part presents in detail finding for detecting communities and making clear the processes of selecting the initial seed node, associating nodes which incident upon a seed node, and electing new seed nodes. The basic idea is inspired by the well-known degree centrality method. It can be used the centrality of nodes to measure which node is seed within that network. It is the most suitable centrality measure for the default measure which yields the most accurate results and also is easy to compute from which we experimented with our results. It is a simple centrality measure that counts how many neighbors a node has. The importance of a node is determined by the number of nodes adjacent to it. The larger the degree of node, the more important the node is. Those high-degree nodes naturally have more impact are considered to be more important. Degree centrality is defined in section 3.5. For example: by viewing Figure 1, the degree centralities become node c and node d by using equation (2).

4.2. Detecting community using similarity measure

In this component, we used the existing methods which is convenient in our work namely Jaccard Similarity which we will measure the similarity based on the neighborhood overlap of seed

nodes. This system will be assumed that communities are groups of vertices which of their neighbor nodes are overlapped to each other. We can compute the similarity between each pair of vertices after searching seed nodes to detect community. This method is shown in section 3.6. The example of vertex similarity is shown in the following.

Node ={a,b,c,d,e,f,g,h};

Edge ={(a,b),(a,c),(b,c),(b,d),(c,h),(c,g),(d,e),(d,f),(d,g),(e,f),(f,g)};

Figure 1: Tiny Graph

Table1: Finding Node Centrality

Node	Degree	Normalize Degree
a	2	2/7=0.28
b	3	3/7=0.42
c	4	4/7=0.57
d	4	4/7=0.57
e	2	2/7=0.28
f	3	3/7=0.28
g	3	3/7=0.28
h	1	1/7=0.14

The most centralities are node d and node , firstly we choose node c.

$c = \{a, b, h\};$

$$c \text{ and } a = \frac{(c \cap a)}{(c \cup a) - 2} = \frac{1}{4 - 2} = 0.5;$$

$$c \text{ and } b = \frac{(c \cap b)}{(c \cup b) - 2} = \frac{1}{4 - 2} = 0.5;$$

$$c \text{ and } h = \frac{(c \cap h)}{(c \cup h) - 2} = \frac{0}{0 - 2} = 0;$$

We got, there is no overlapped value between c and h. Therefore, we identified node h as outlier, then $node\ a$ and $node\ b$ are the members of community corresponding by their node centrality ($node\ c$). The community is shown in Figure 2.

Then, choose the most centrality value from the rest of the graph. Now, $node\ d$ is the most centrality.

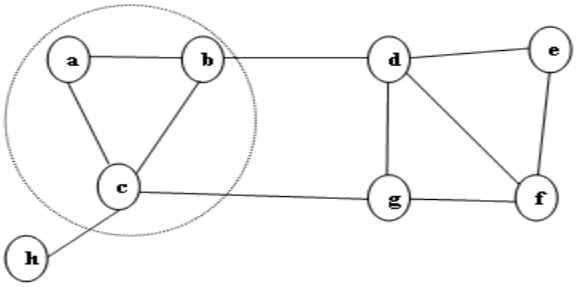


Figure 2: Community of node c Centrality

$d = b, g, e, f;\ b = a, c, d;\ e = d, f;\ f = d, e, g;\ g = c, d, f;$

$$d \text{ and } e = \frac{(d \cap e)}{(d \cup e) - 2} = \frac{1}{5 - 2} = 0.33;$$

$$d \text{ and } f = \frac{(d \cap f)}{(d \cup f) - 2} = \frac{2}{5 - 2} = 0.667;$$

$$d \text{ and } g = \frac{(d \cap g)}{(d \cup g) - 2} = \frac{1}{6 - 2} = 0.25;$$

We got, $node\ e$, $node\ f$ and $node\ g$ are the members of community corresponding by their node centrality ($node\ d$). Figure 3 and Figure 4 are the extracted communities after identifying outlier.

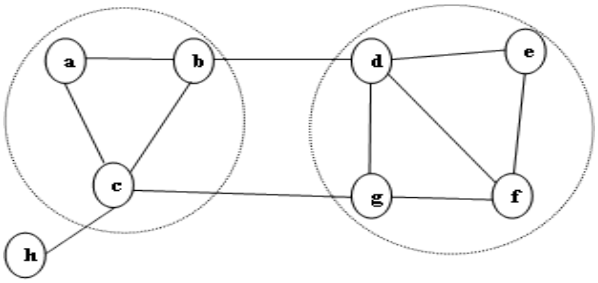

Figure 3: Community of node d Centrality

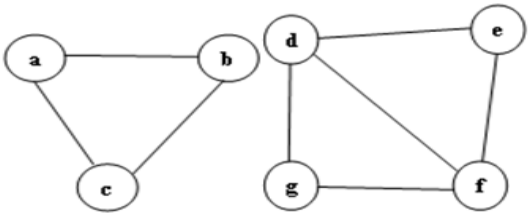

Figure 4: Two Communities after detecting and removing outliers

4.3. Descriptions of Algorithm

For undirected and un-weighted networks dataset, outliers is determined by a node which have no common values then identifying the communities based on the similarity measure in this approach. The following procedures are the steps of detecting outliers and communities:

Step1: Determine seed node by using vertex centrality method.
Step2: Compute the neighborhood overlap of seed nodes by using Jaccard Similarity measure.
Step3: If a node is adjacent to seed node and have overlapped value, determine it as a member of that seed node.
Step4: One node, the member of that seed node within the same community, has another node which is adjacent to its member node and there is overlapped value between them, then identify the linked node as the member of that related community.
Step5: One node which is adjacent to seed node but there is no overlapped values to that seed node is defined as outlier.
Step6: If there is no more adjacent node for that seed node; find another seed node which has the highest centrality value in the left stack of the degree centrality measurement and then repeat the process until there is no more node to be considered.

5. Experiments

5.1. Description of Dataset

In this paper, real undirected networks, Zachary Karate Club Dataset is used. In this Dataset statistics, "nodes" represents the number of friends; "edges" represents the number of friendship in the network. Zachary's karate club network is one of the popular studies in social network analysis and has been used as one of the typical test examples by many researchers to detect community structures in complex network. There are 34 member nodes, 78 edges and splits into two clubs, one is indicated as circles and the other is indicated as squares which are shown in Figure 5.

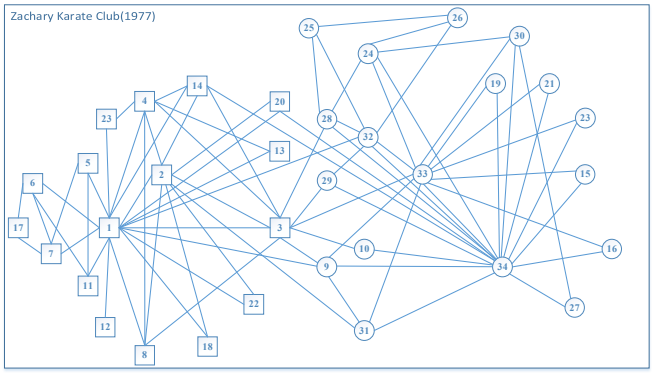

Figure 5: Zarchary Karate Club, Squares and circles indicate two communities observed by Zarchary (1977)

5.2. Evaluation Method

In this section, we show the results of communities and outliers. Before showing our experimental result, we first introduce the evaluation methods that are used in our proposed approach.

When there's no ground-truth for the communities to assess the quality of detected communities, it could be used quality measurement so called quality scoring functions which characterize how community like is the connectivity structure of a given set of nodes. The idea is that given a community scoring function, one can then find sets of nodes with high score and consider these sets as communities. All scoring functions build on the intuition that communities are sets of nodes with many connections between the members and few connections from the members to the rest of the network. And it can be formalized the intuition that "good" communities are both compact and well-connected internally while being relatively well-separated from the rest of the network. In quality measurement, it can be showed the quality of detecting communities in different point of view. There are many possible ways to mathematically formalize this intuition.

Among them it will be used the most useful five kinds of quality functions are as follows:

- Scoring functions based on internal connectivity
- Scoring functions based on external connectivity
- Scoring functions based on community goodness metrics
- Scoring functions based on a network model

5.2.1. Scoring functions based on internal connectivity

Internal density is defined as ratio between the intra-community edges and all the edges in the graph and is one of the simplest measures for community quality which is biased towards coarse-grained communities.
Internal density: $f(S) = \frac{m_S}{n_S(n_S-1)/2}$ is the internal edge density of the node set S where S be the set of nodes, m_S is the number of edges between the members of S and n_s is the number of nodes in S. The greater the value is the better for internal density.

5.2.2. Scoring functions based on external connectivity

The fraction of existing edges (out of all possible edges) leaving the cluster $f(S) = \frac{c_S}{n_S(n-n_S)}$ where n be the number of nodes in the network and c_S be the number of edges on the boundary of S. The smaller value is the better for this external connectivity compare with the internal density.

5.2.3. Scoring functions based on community goodness metrics

A clustering coefficient is a measure of the relationship to which people in a network tend to group together. Evidence suggests that in most real-world networks, and in particular social networks, nodes tend to create tightly knit groups characterized by a relatively high density of ties; this likelihood tends to be greater than the average probability of a tie randomly established between two nodes. It is a real number between zero and one that is zero when there is no community, and one for maximal community, which happens when the network consists of disjoint cliques.

Clustering coefficient (CC) $CC = \frac{2N_V}{K_V(K_V-1)}$ is based on the premise that network communities are manifestations of locally inhomogeneous distributions of edges, because pairs of nodes with common neighbors are more likely to be connected with each other.

5.2.4. Scoring function based on a network model

Modularity is defined as having more internal edges and less external edges as is defined as modularity measures the strength

of each partition by considering the degree distribution. One main problem with modularity approach is that it cannot detect well defined small communities when the graphs are extremely large. let us talk about the brief definition of modularity. The Q value is between 0 and 1 and the real network modularity function value is generally between 0.3 and 0.7. Community structure is more obvious with the greater value of modularity.

$$Q = \frac{1}{2m} \sum_{ij} \left[A_{ij} - \frac{k_i k_j}{2m} \right] \delta(c_i, c_j),$$

5.3. Results

To prove the proposed approach we first test it on the well-known karate friendship studied by Zachary, which has been become a classical studies workbench by many researchers for community detection algorithm testing. There are 34 member nodes, 78 edges and splits into two communities.

As shown in figure, node 34 and node 1 are seed nodes, the most important node among their neighboring is the main part of our proposed approach. We had to start those nodes to detect communities and identify outliers by using similarity measurement based on edge structure. We found that nodes which have no any overlapped value among their neighbors are determined as outliers which are node 10 and node 12. Table 2 is shown about the detected node community memberships better correspond to ground-truth node community memberships.

Table 2: Communities of Ground-Truth and Proposed Approach, their members and number of members in corresponding communities

Karate Dataset	Communities	Member (Node) in Community	No. of Members
Ground-Truth	Community1	34, 9,10, 15, 16, 19, 21, 23, 24, 25, 26,27, 28, 29, 30, 31, 32, 33	18
	Community2	1, 2, 3, 4, 5, 6, 7, 8, 11, 12, 13, 14, 17, 18, 20, 22	16
Proposed Approach	Community1	34, 9, 15, 16, 19, 21, 23, 24, 25, 26 27, 28, 29, 30, 31, 32, 33	17
	Community2	1, 2, 3, 4, 5, 6, 7, 8, 11, 13, 14, 17, 18, 20, 22	15

Table 3: Community C, Number of Intra-Nodes (Intra-N), Number of Intra-Edges(Intra-E), Internal Connectivity(IC), External Connectivity(EC) and Average Clustering Coefficient (ACC)

C	Intra-N	Intra-E	IC	EC	ACC
1	17	34	0.25	0.12	0.7033
2	15	32	0.3	0.11	

Some methods based on the idea that nodes can be the member of two or more communities. But some condition, in thinking of which user should be situated on individual community. Our proposed approach intends to split the multiple communities clearly and remove the nodes which are not necessary to group into any communities. In OCNS method had been proved that they can detect the overlapping node definitely. However, they could not be considered which overlapped node is the member of which community exactly. In considering of detection community without studying the overlapping node combines spectral methods with clustering techniques, and uses the concept of modularity in order to develop a working algorithm and the quantitative of individual communities are different from the ground truth community. Moreover, even removing the outliers, the modularity value (Q) of the proposed approach is better than the other system as shown in Table4.

Table 4: Comparison with other methods in Modularity Value(Q).

Algorithms	Q	No. of Communities	Outlier (node)
GN	0.4013	5	-
Detecting network communities: a new systematic and efficient algorithm	0.4	5	-
OCNS	0.4304	2	-
Gephi	0.416	4	-
Proposed Approach	0.534	2	10,12

6. Conclusion

This proposed approach was used neighborhood overlapping with vertex similarity to detect community and outlier based on edge structure. It showed the steps of detecting outliers and communities in detail. Then, it was discussed about the evaluation measurement in different point of view because of different community criteria. The experiments on real Zachary Karate club network show that our algorithm outperforms other community based algorithms in terms of modularity value, number of communities and members in communities. On the other hand, our approach gets the high quality measurement in the assumption of no ground-truth community. In similarity measurement, nodes

which have the overlapped values are detected as communities correspond with its vertex centrality. Nodes which have no any overlapped values in the communities or which need not be necessary to group into the community is defined by outliers. However, in case of node which has no any overlapped value and is connected with multiple communities are still leaving as our future work.

Virtual machine introspection

ABSTRACT

In today's information based world, it is increasingly important to safeguard the data owned by any organization, be it intellectual property or personal information. With ever increasing sophistication of malware, it is imperative to come up with an automated and advanced methods of attack vector recognition and isolation. Existing methods are not dynamic enough to adapt to the behavioral complexity of new malware. Widely used operating systems, especially Linux, have a popular perception of being more secure than other operating systems (e.g. Windows), but this is not necessarily true. The open source nature of the Linux operating system is a double edge sword; malicious actors having full access to the kernel code does not reassure the IT world of Linux's vulnerabilities. Recent widely reported hacking attacks on reputable organizations have mostly been on Linux servers. Most new malwares are able to neutralize existing defenses on the Linux operating system. A radical solution for malware detection is needed – one which cannot be detected and damaged by malicious code. In this paper, we propose a novel framework design that uses virtualization to isolate and monitor Linux environments. The framework uses the well-known Xen hypervisor to host server environments and uses a Virtual Memory Introspection framework to capture process behavior. The behavioral data is analyzed using sophisticated machine learning algorithms to flag potential cyber threats. The framework can be enhanced to have self-healing properties: any compromised hosts are immediately replaced by their uncompromised versions, limiting the exposure to the wider enterprise network.

1. Introduction

Dependency on computer systems has been growing exponentially in recent years. Government offices and business organizations are major targets of malicious actors for stealing highly valuable data. These entities are major Linux adopters nowadays because of its reputed safety and security. They are attempting to protect themselves from cyberattacks with digital defense techniques like encryption, firewalls and heuristic or signature scanning packages. Meanwhile, the number of attacks that involve infiltrating military data centers, targeting power grids, and stealing trade secrets from both private and public organizations continues to increase. The detection, response and reporting of these kinds of intrusions as well as other incidents involving computer systems, are crucial for cybersecurity professionals. This paper proposes a Virtual Memory Introspection based framework for detection, analysis and monitoring of malware behavior using memory forensics, during cyberspace attacks in a virtualized environment. The framework provides advanced instrumentation tools for control and monitoring of malware, fine-grained introspection of operating system Kernel and user process behavior using the well-known LibVMI technology, and analysis of behavioral data using state-of-art machine learning techniques. In study of research literature, one of the major methods of malware detection that has emerged over the years is Linux memory forensics [1] [2]. A number of authors have described novel detection systems using Memory Forensics, or using kernel data structure invariants as a reference frame to identify rootkit intrusions [3] [4]. The goal of this test technology is to facilitate threat assessment of malware, to understand its goals, and degrade impact on the compromised systems [5].

Further, as cyber-attacks continues to expand and the sophistication of the adversaries grows, defenders must adapt quickly in order to survive. There are numerous kinds of malware prevalent today, including Backdoors, Bots, Downloaders and Droppers, Ransomware, Rootkits, Scareware, Spyware, Exploits, Logic Bombs, Trojans, Viruses, Worms, etc. The detection,

*Dr. Himanshu Upadhyay, Email: upadhyay@fiu.edu

response and reporting of these kinds of intrusions as well as other incidents involving computer systems, are crucial for cybersecurity professionals. Present static methods used by anti-viruses are insufficient to stop advanced malware threats, which are capable of disabling the anti-viral software via root-kit mechanisms.

2. Virtualization & Data Analytics Framework

The proposed framework has the following major components as shown in Figure1:

2.1. Virtualization

The virtual machines, which are monitored for malware attacks, are collectively called the system under test (SUT). This system is hosted on a Xen hypervisor based virtualization platform. The behavioral data on the guest VMs is captured through Virtual Memory Introspection (VMI) using the LibVMI framework

2.2. Data Analytics

This platform consists of various traditional machine learning algorithms used to train the models and perform prediction using various test vectors consisting of malware and rootkits on the virtual machines (SUT). In this proposed framework, the authors are building an advanced data analytics platform on the database server, R runtime with in-memory analytics providing the scale and performance. Various traditional machines learning algorithms like Random Forest, Support Vector Machines, Logistics regression etc. will be utilized to perform Data Analytics. This platform analyzes the memory data structure captured on the VMI framework using cutting-edge machine learning algorithms. These algorithms are used to build the model to predict the malware behavior and display the results.

2.3. Test Control Center

The Test Control Center is an application that provides control and administration of the entire framework with an intuitive web based interface. The operator can create virtual machines (SUT), install benign applications and malware, capture behavioral information and use the Data Analytics platform to build the model and test virtual machines for malware using various traditional machine learning algorithms. Test Control Center is a centralized application to manage the test bed and execute various test cases. In the proposed framework, the authors are developing various modules like virtual machine management, network map, test case management, model management, configuration, testbed administration and help.

The three platforms working together will enable an organization to detect malware almost in real time and monitor its behavior in a virtual environment. The user provides a set of well-defined inputs to the virtualization platform based on predetermined test cases, and captures the kernel data structures information and transfers it to the Data Analytics platform. The Data Analytics platform uses traditional machine learning algorithms to build the model and predicts results based on the information extracted from guest virtual machine memory and displays the results on the Test Control Center. The following diagram in Figure 1 provides the overall system design of the framework:

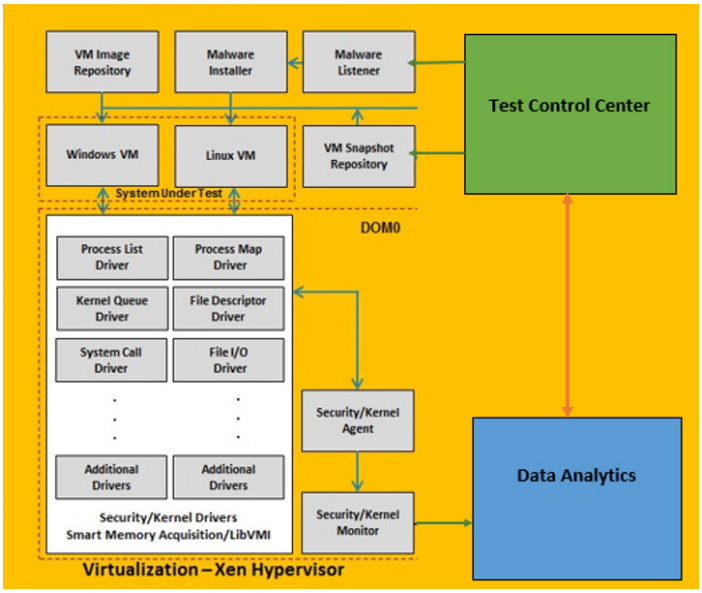

Figure 1: Virtualization & Data Analytics Framework System Diagram

The various components of the virtualization platform are discussed below.

I. VM Image Repository

Images of the different virtual machines will be stored in this location. It provides the user the ability to select the virtual machine images that will create the virtual machines for SUT with different configurations.

II. Malware Listener and Installer

This module listens to the command from the malware management module and communicates with the malware installer on the virtual machine to install the selected malware.

III. VM Snapshot Repository

This module will store the snapshots of normal operation which will later be used to roll back to the clean state after the test execution.

IV. Multiple Linux VMs

These are the guest virtual machines created by the operator based on predefined configurations.

V. Kernel Agent

Security/kernel agent manages all the drivers to extract the kernel data structures from the SUT. They are deployed on DOM 0 which is the secured location on the hypervisor with required privileges.

VI. Kernel Drivers

These the individual drivers which are used for smart memory acquisition of the kernel data structures from the SUT. These drivers use the LibVMI libraries for virtual memory introspection from the Dom0 level to extract kernel data structures. They are managed by Security/Kernel Agent.

VII. Kernel Monitor

This module communicates with data analytics platform and sends the data extracted by the Security/kernel agent to the listener on the data analytics platform to store the data in to the database.

VIII. Kernel Agent Listener

The Agent Listener plays a crucial role in the virtualization framework. This module communicates with the security/kernel monitor in the virtualization framework, and receives the extracted data from the security/kernel agent and stores it into the central database.

3. Virtual Memory Introspection (VMI) Framework

The VMI platform of this framework is built on the "Xen Hypervisor" which enables the operator to create multiple virtual machines with different configuration and perform system testing with the environment. The Linux machines are used as SUT, to be monitored for malware intrusion are hosted on this hypervisor. Xen hypervisor [6] provides two security domains for the hosted virtual machines. The virtual machine running under Dom0 (Domain 0) on the Hypervisor controls the resource allocation for the virtual machines that runs the Linux Guest operating system [7].

The major key objectives of virtualization framework are listed below:

I. Develop innovative ways to detect and monitor malware in a virtualized testbed with smart memory acquisition.

II. Deployment of virtualized environments along with advanced tools developed through this research for control and monitoring of the cyberspace test environment.

III. Cyber-attack emulation through infection and propagation of simulated endpoints.

IV. Virtual machine introspection, data collection, and monitoring of various aspects of the infrastructure through a centralized system.

V. Display results on the Test Control Center to monitor the impact of malware on SUT.

The SUT can be Linux or Windows guest virtual machines. Using the Test Control Center, the operator is able to create guest VMs on the Xen hypervisor from a virtual machine repository, introduce pre-determined malware into them, and capture kernel data structure information and stores them into the central database. We have developed an application called "Kernel Agent" that runs on the Dom0 virtual machine, and uses kernel drivers to perform smart memory acquisition on the guest operating system. This kernel information, which includes process details, memory data structures, and file system information, is written to a central database for data analytics.

Xen hypervisor is used to host, configure, and control the guest Linux virtual machine that will be tested for malware. The introspection is carried out through the "LibVMI" framework in conjunction with Google's "Rekall" profiles. The Rekall profile is a JSON file that contains the address mappings of all Linux Kernel data structures. By integrating LibVMI with Google Rekall, the process of extracting Kernel configuration parameters and data structures at run-time can be automated. This facilitates the smart memory acquisition of process behavioral data from the kernel. We are using Google's "Go" programming language for writing the introspector application, and to push the acquired data to the central database. The Go programming language can integrate with suitable C/C++ libraries, and significantly reduces the time needed for development and testing new build of each module. It provides better control over distribution and parallelization mechanisms of the Security Agent. We are using "Libvirt" library for management of the guest virtual machines through a custom built Introspector. Introspection requests are serviced by the LibVMI library, while the Libvirt library is used to facilitate the creation, starting, stopping, pausing and resuming of the guest Linux virtual machines [8].

The Introspector is comprised of several core subsystems that are necessary for lifecycle management and introspection of virtual machines on a host. The Introspector also maintains two socket connections that listen to requests for introspection or virtual machine administration coming from the Test Control Center.

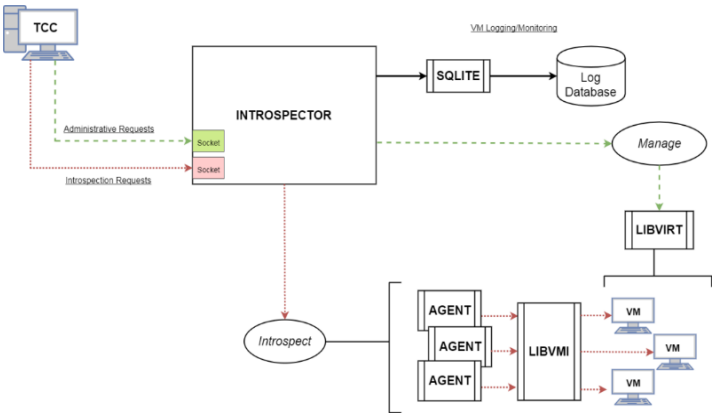

Figure 2: Proposed Virtual Machine Introspection Framework

Introspector: startup

Introspector (introspector.go) builds a Settings object (settings.go) by reading the values in the introspector.conf settings file. The configuration file is used to determine which IP/Port combination to use for handling virtual machine administration requests and introspection requests. The Introspector will also start the StateManager that manages a SQLite database containing the current state of the virtual machines in the system.

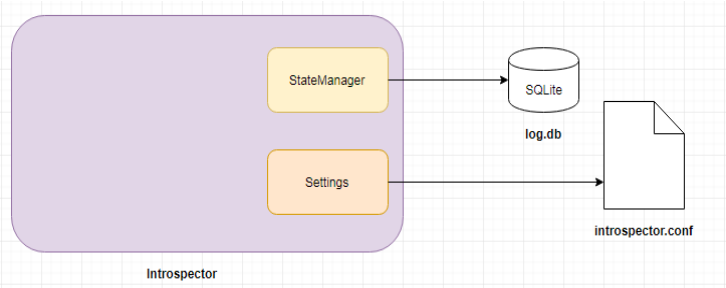

Figure 3: Introspector setup with Database

Next, a thread is spawned that opens a socket connection to listen for incoming requests for virtual machine administration from the Test Control Center while the main Introspector thread waits on another socket for incoming introspection requests. Administration requests are XML requests that have the root node <LibvirtServerMessage>

4. Research on Kernel Data Structures

The analysis conducted on the footprint of a process in kernel space is in near real-time, to distinguish between benign and malicious processes. The Linux Kernel maintains data structures that contain information about every action and resources used by a process. The study thus far has identified 15 features from 118 features which can effectively distinguish between benign and malicious processes [9] [10]. The next steps in the pipeline is to perform virtualization to extract threads, system call , invariant data structures like system call table and interrupt descriptor table, IP addresses, network sockets, URLs, open files, passwords, catches, clipboards and other user generated content, encrypted keys, and configurations of hardware and software [11].

5. Benign and Malware Applications

We have also performed research to extract the kernel data structures from the Linux kernel task structure using LibVMI library. The following Benign processes and Malwares samples have been identified to be installed on the Linux virtual machines. The Linux kernel version under consideration as of the writing of this paper is 3.16.0-23- generic.ko in Ubuntu 14.04 [11] [12].

GUI Applications	CLI Applications
1) Firefox - Web Browser 2) Thunderbird - Email client application 3) gpaint - Paint Application 4) Libre - Office writer 5) Rythmbox - Music player 6) Connectagram - Word unscrambling game 7) Arora - Cross platform web browser 8) Empathy- Internet messaging application 9) Alarm clock 10) Shotwell- Photo manager	1) Alpine-Pico- Is a text editor, uses the pine email client for writing email messages. Run from the terminal as pico, pico.alpine 2) Aaphoto- An image manipulation tool for automatic color correction of photos 3) ACL2- Programming language in which user can model computer systems and a tool to help prove properties of those models. 4) Python- Programming language 5) Gedit Text editing tool 6) Calcoo - scientific calculator 7) Calcurse- text based calendar and todo manager 8) Clamav-daemon- antivirus utility for unix-scanner daemon run from the terminal 9) Gzip- Zipping application

6. Linux Kernel Data Structure Extraction

At the outset we are going to extract the following task structure list from Linux data structures. Based on our research, the following list of features has been identified for extraction to test the virtualization framework in the pilot stage. These are the primary features of the processes that will run in the kernel of the Linux virtual machine at runtime [13] [14].

Sr. No.	Features' Name	Description
1	map_count	Number of memory regions of a process
2	page table lock	Used to manage the page table entries
3	hiwater rss	Number of page frames that a process owns
4	shared_vm	Number of pages in shared file memory mapping of a process
5	exec_vm	Number of pages in exec. memory mapping of process
6	nr_ptes	Number of page tables owned by a process
7	utime	Execution time of a process in user mode (tick count)
8	stime	Execution time of a process in kernel mode (tick count)
9	nvcsw	Volunteer context switches of a process
10	nivcsw	Involuntary context switches
11	total_vm	Size of process's address space in terms of Number of pages
12	min_flt	Minor page faults of a process
13	alloc lock.raw lock.slock	Used to lock memory manager, files and file system etc.
14	hiwater_vm	Max Number of pages appeared in memory region of process
15	fs.count	fs_struct's usage count to indicate the restrictions

7. Data Analytics and Results

The research on data analytics is currently on-going [15] [16]. The Data Analytics platform consists of centralized database servers for analytics and processing. The research will be focused on identifying the classification and anomaly detection machine learning algorithms that includes open source and commercial platforms, libraries with these platforms [17] [18] to detect malware [19] [20] that primarily focus on the Linux data structure extracted by the VMI Framework.

Once the framework is narrowed down and tuned as a viable solution for malware detection, the results will be summarized to demonstrate which machine learning models are powerful for malware detection and monitoring. The research outcome will consist of three components: memory data structures, algorithms with pros/cons and machine learning model performance data.

8. Conclusion and Future Work

The goal of the VMI framework research is to provide solid foundation for security of the Linux operating system as well as the capabilities to identify and monitor cyber threats in virtual environment. The key challenges of this research is to identify various data structures affected by modern malware, and in-depth

examination of various machine learning algorithms with memory forensics to solve key cybersecurity issues.

The focus of this research is to develop a system that can work with the latest Linux operating systems providing memory forensics capability in a virtual environment. In the future, we plan to explore all possible ways of data analytics with big data technologies and deep learning. With sufficient time and effort, the development of this framework can result in an extremely powerful system for early threat detection and defense.

Acknowledgment

This research is supported by Department of Defense (DOD) – Test Resource Management Center (TRMC), USA. We thank our colleagues who provided insight and expertise, directly or indirectly, that greatly assisted the research.

Wireless Local Area Network

ABSTRACT

IEEE 802.11 WLAN indoor networks face major inherent and environmental issues such as interference, noise, and obstacles. At the same time, they must provide a maximal service performance in highly changing radio environments and conformance to various applications' requirements. For this purpose, they require a solid design approach that considers both inputs from the radio interface and the upper-layer services at every design step. The modelization of radio area coverage is a key component in this process and must build on feasible work hypotheses. It should be able also to interpret highly varying characteristics of dense indoor environments, technology advances, service design best practices, end-to-end integration with other network parts: Local Area Network (LAN), Wide Area Network (WAN) or Data Center Network (DCN). This work focuses on Radio Resource Management (RRM) as a key tool to achieve a solid design in WLAN indoor environments by planning frequency channel assignment, transmit directions and corresponding power levels. Its scope is limited to tackle co-channel interference but can be easily extended to address cross-channel ones. In this paper, we consider beamforming and costing techniques to augment conventional RRM's Transmit Power Control (TPC) procedures that market-leading vendors has implemented and related research has worked on. We present a novel approach of radio coverage modelization and prove its additions to the cited related-work's models. Our solution model runs three algorithms to evaluate transmission opportunities of Wireless Devices (WD) under the coverage area. It builds on realistic hypotheses and a thorough system operation's understanding to evaluate such an opportunity to transmit, overcomes limitations from compared related-work's models, and integrates a hierarchical costing system to match Service Level Agreement (SLA) expectations. The term "opportunity" in this context relates also to the new transmission's possibilities that related-work misses often or overestimates.

1 Introduction

Designers face problems of two natures when building WLAN networks: issues that are inherent to radio resources' planning and those concerning their integration with other network parts and upper-layer services in response to developing customers' application needs such as mobility, real-time, interactive applications, business intelligence, and on-presence analytics. An accurate design should consider thoroughly both aspects and base its decision on a solid theoretical approach, on-field feedbacks, and best practices.

Design best practices dictate running two site surveys: one at the beginning of the project, before network's deployment, and a second, after network's deployment, to confirm resources' planning results and to calibrate the system's parameters in accordance to the real network's condition. An optional survey may be required if radio environment or its utilization has

*Mehdi Guessous, 7 avenue du General de Gaulle 91120 Palaiseau France, +33(0)614945485 & mehdiguessous@research.emi.ac.ma

https://dx.doi.org/10.25046/aj020604

changed and might affect the overall network capacity. The first survey qualifies mainly the exposure to on-reach foreign autonomous radio systems, and radio characteristics of the surface to cover (walls, floors, and other obstacles). The second site survey confirms the conformance of the actual deployment to design constraints in two ways:

1. by running a passive in-data-path survey that is based on passively reported statistics such as RSSI, SNR, PHY, MAC errors, packet count, etc. at radio interface level,

2. and an active one where in-data-path patterns simulate wireless client's traffic classes to gather actively statistics on Jitter, RTT, or any other measure concerning the rendered service, application or experience.

This approach is not very accurate as it lies on a set of preconfigured unchangeable parameters that result from special case deployments and testing contexts, which may be completely different from the on-field reality. In the market-leading implementations such as Cisco TPC or Aruba ARM, we observe that at a certain point, a reference is made to an "ideal" preconfigured parameter. The third neighbor's RSSI and a predefined hysteresis threshold [1] paremeters are used in the first case, and the "coverage index" [2] parameter in the second case, to decide on transmit power level planning network wide.

Inaccuracies come also from studies when they model the system as a pre-shaped radio coverage area in the form of a hierarchy of disks that delimit transmission ranges from interference or no-talk ones. Some limitations arise also from no-site-survey techniques that base their radio resource management solely on WLAN reported measures. Other limitations come from simplifications such as to consider that a client association and the corresponding CSMA/CA mechanisms rely entirely on the strongest access point's RSSI, because most of the interferences do not occur at MAC level, and radio measurements may differ from a vendor to another. Then it is necessary to ensure that model analysis inputs and outputs do not result in a contradiction.

Motivated by advances in beamforming techniques, especially from an array signal processing perspective, which make it possible to radiate energy in any direction and to easily estimate signal's direction of arrival, this work solution model aims at fixing many of previous limitations by considering the opportunity for an access point to transmit in one specific direction. This opportunity processing accepts data from upper-layer services such as to achieve a complete end-to-end integration with other network parts.

As it will be demonstrated in this work, the number of transmit directions at access point level, could be optimized in conjunction with planning transmit power levels and channel assignment to maximize the overall network capacity. A cost-based approach prices in a timely manner each direction for an eventual transmission. Access points in this scheme discover each other over-the-air and report useful information on transmit directions, power levels and channels, to a central intelligence that coordinates the overall network operation. The ultimate result is:

1. Cancellation of co-channel interferences in a majority of deployment cases.

2. Processing of new transmission opportunities that are missing in conventional work.

3. Enhancement of end-to-end network performance.

In the upcoming section, we present a foundation on unified WIFI architectures and beamforming as they relate to this work. In Sect. 4, we discuss more formally the problem and in Sect. 5, we present our solution model. Sect. 6 discusses our solution results. In the end, we conclude and further our work. This paper is an extension of work originally presented in 2017 International Conference on Information Networking (ICOIN) [3].

2 Related Work

Co-channel interference in WLAN networks is a major problem that has been widely studied. To tackle this issue RRM and related techniques such as Transmit Power Control (TPC), Dynamic Channel Assignment (DCA), constitute a very accurate solution. If we consider TPC that is the focus of this work, the related-work's approaches differ from each other in terms of the adopted interference's model, inputs TPC may work on, and their processing (predictive, heuristic, etc.). We further focus on related-work's adopted interference models.

To our knowledge, all models and derived TPC processing have considered only the transmission power level as a degree of freedom to limit co-channel interference. This work claims that the transmission direction could be an additional degree of freedom to overcome other models' limitations when it comes to modeling irregular coverage areas in indoor WLAN environments.

Authors in this work [4] concentrate, from a lower layer perspective, on the co-channel interferences as a function of the estimated distance between the Access Points (AP) and the Wireless Devices (WD). In this scheme, the WDs estimate the distance based on the RSSI information sent by the APs in RTS control packets. The transmission power level adjusts accordingly to achieve a better network performance and interference cancellation. The issue with this model is that the power level adjustment affects other on reach WDs and APs communications. In addition, this model does not include cases where the WD does not simply receive the RTS packets.

In [5], a WD measures the amount of interference as a function of the local AP's load, its signal's

strength and loads from the distant APs. Here interference is a linear function of the AP's load. This is interesting but as opposed to our work, this model misses the interpretation of interference from an energy radiation perspective. In our work, we still include AP's load consideration in the SLA applied to the processing of transmit opportunities.

Depending on the coverage area pattern: disks or Voronoi zones, the amount of interference in [6], is a function of different AP's areas overlap in the first case and to their borders in the second one. This work model is very accurate to describe how an AP's energy radiation could affect other neighboring APs. However, it is still insufficient to interpret many cases specific to indoor WLAN deployments that relate to on-reach and unreachable AP's. Subsection C of Sect. 4 discusses these cases in detail.

The authors in [7] consider both MAC and PHY layer inputs: data payload length, path loss condition, and frame retry counts, to find out the suitable PHY mode and power level combination. This procedure requires a control packet exchange that is similar to conventional RTC/CTS for this adaptation. This model is easy to implement but it is insufficient to interpret many cases specific to indoor WLAN similarly to the previous work. In addition and similarly to the first cited work, any PHY mode and corresponding power level change apply to all neighboring APs and WDs indistinguishably.

In [8], the authors concentrate on upper layer application performance such as FTP and HTTP, to find out an optimal power scheme or more exactly, an optimal combination between transmit power and supported load for a given distance between nodes. This model considers SLA as in the second and fourth cited works and augments its processing to include "behavioral" protocol aspects. However, the corresponding model misses the lower-level interpretation of AP's radiated energy.

The authors in [9], approach the problem from an inter-protocol coordination point of view: WIFI, BT, etc. which may be very helpful to base an integrated-system wide transmit decision or "etiquette" on the utilization of shared radio resources. In this scheme, all wireless devices broadcast the information on spectrum usage. This information includes transmit power level and frequency channel of use. In addition and based on costing policies, the system allocates resources: frequency, power and time, to wireless devices. This work is a generalization of the first and fourth previously cited works and may incur the same limitations.

In this work, we review the conventional co-channel wireless coverage models and show that the system could process more transmission opportunities and still conform to the SLA. In these works [4] [5], some of the transmission opportunities were missed in areas that were considered falsely as interference ranges or worst as no-talk ones. Our solution model considers inputs from upper-layer services to conform to the SLA on the end-to-end wireless client's experience as in works [7] [8] [9]. In addition, it takes advantage of the technological advances in beamforming and related techniques, to introduce, at a conceptual level in indoor WLAN networks, the direction of transmission as a new radio resource added to frequency channel and power level, to enhance work's like [9] results.

3 Theoretical Background

The next two subsections describe WIFI's unified architecture in addition to the beamforming techniques as they relate to our study. The main objective of this foundation is to justify the feasibility of the hypotheses we base our study on. These hypotheses relate to the possibility to correlate reported radio interface's information from different APs, to coordinate their operation network-wide, to concentrate the radiated energy in any direction, in a timely manner, and to estimate accurately the direction of known and unknown sources' signals.

3.1 WIFI's Unified Architecture

In dense indoor networks, the transmission is difficult to model and depends on radio environment's characteristics such as obstacles, interference, background noise, density of wireless clients, mobility applications, etc.

In this context, standalone APs' architectures do not scale with high number of APs and WDs that require high class QoS treatment. Such architectures are replaced gradually by controller-based or "unified" ones. They are marked as unified for two reasons:

1. a central decision-making and intelligence, that is a Wireless LAN Controller (WLC), manages the overall network's operation.
2. the WLAN integrates with the overall network parts: LAN, WAN, DCN, etc. from especially a QoS perspective.

The market-leading vendors implement such a central decision-making processor mainly in three ways:

1. appliance WLC-based,
2. virtual system WLC-based,
3. distributed AP-based.

In the latter implementation, the APs take over the WLC's role. The first two implementations require a WLC, a virtual or physical appliance, which is reachable by all network APs over the wire. Examples of such WLCs are Cisco 8540 Wireless Controller and Aruba 7280 Mobility Controller.

Cisco unified architecture [10] defines two protocols:

1. CAPWAP, used by APs to build protocol associations to the active WLC.

2. NDP, to send messages over the air (OTA) for APs to exchange proprietary and standard management or control information.

In addition to these protocols, Cisco APs integrate a set of on-chip RRM techniques: CLIENTLINK and CLEANAIR that monitor and measure radio environment characteristics among other features. The WLC gathers this information via the already established CAPWAP tunnels to APs. Further, platforms such as Cisco Prime Infrastructure (CPI) and Mobility Services Engine (MSE) extend the capability of CLEANAIR to perform analytics, locate clients, interferers, and build heat maps. Based on the APs' reported information, the WLC computes the channel assignment and power levels map network wide. Its decision still conforms to the pre-configured policy sets. Each of these sets defines a number of configurable variables and unchangeable settings such as acceptable signal levels, tolerable noise levels, usable power levels, frequencies and channels, etc.

In this work context, the WIFI unified architecture guarantees a coordinated operation between all network elements at a very low level, an accessible distributed intelligence, and a centralized decision-making. It focuses on how to enhance the centralized decision-making at WLC level and especially RRM processing. RRM is the set of tools, algorithms and services that processes inputs from AP's radio and LAN interfaces and outputs a wireless area coverage plan or map that conforms to a predefined utility function.

3.2 Beamforming

The majority of WLAN communicating systems are equipped with omnidirectional antennas or a set of limited number of unidirectional antennas to obtain an equivalent energy radiation's pattern. Ease and cost of such hardware configurations are some of the benefits of such designs but they lack many aspects regarding interference and noise cancellation, signal sources' localization, and power consumption.

Beamforming techniques by definition relate to both the direction of energy radiation and the estimation of signal's arrival direction [11] and from an array signal processing perspective, they offer the possibility to tackle previous issues and design limitations to the next level in three ways:

1. the radiation of energy toward actual receivers allows better performance and less impact on the other system's elements.

2. the estimation of direction of known and unknown sources allows better costing of a given directed transmission.

3. the on-chip beamforming techniques allows for a hardware real-time adaptation to extremely changing radio environments like in our context.

With reference to [11], beamforming concerns both sides of a communicating system: the emitter and the receiver. It allows the radiated energy to be concentrated in one direction and to estimate its corresponding source's location for both legitimate and rogue interferers at receiver level. Basically, beamforming could be achieved mechanically by manually or electronically gearing a directional antenna. From a signal processing perspective, beamforming is achieved by changing certain transmitter's characteristics such as array elements' phase shifting, source signals' amplitude increasing or addition weighting. Additionally, the desired array gain and beam's direction depend on the number and geometry of array elements.

To ease our study we consider that array beamformers achieve equivalent performance to mechanical ones concerning both the resultant beam radiation's angle and signal's gain.

Let us consider an antenna with a beamwidth of $2 * \theta_n$ such as the radiated energy in the zone delimited by this angle is equal to the maximum energy radiated by the antenna minus $n\ dB$. n is calculated in such manner to allow an AP to transmit in all corresponding directions at the same time without interfering with each other. A rough estimation of this number is:

$$N \approx (2 * \pi)/(2 * \theta_n) \tag{1}$$

In the contexts of [12] [13] studies on antenna arrays, the beamwidth is expressed as a function of the distance between array elements d, the number of elements M, and the wave length λ:

$$\Delta\theta_{main} \approx (2 * \lambda)/(d * M) \tag{2}$$

In general, the evolving antenna array's beamformers could be classified as data independent, statistically optimum, adaptative or partially adaptative [11]. In this work, data dependent data beamformers (statistically optimum and adaptative) are of interest. Some of these beamformers are Multiple Sidelobe Canceller (MSC), Reference Signal (RS), Max SNR, Linearly Constrained Minimum Variance (LCMV), Lean Mean Square (LMS), Recursive Least Squares (RLS).

The other part of beamforming relates to the estimation of the Direction of Arrival (DOA). DOA estimation methods may include Bartlett, Capon, MUSIC, Min-Norm, DML, SML, WSF, Root-Music, ESPRIT, IQML, and Root-WSF. SML, WSF and Root-WSF are statistically the most efficient depending on the array geometry [14]. They could be yield into two main categories: spectral-based techniques, which are computationally optimal, and parametric methods, which are more accurate than the previous ones.

Recent algorithms are more accurate in the estimation of signal's arrival of both known and unknown sources. They depend on the array size, antenna's radiation pattern, source signals' correlation,

data statistics, corresponding data generation framework, among others. However, for the rest of this study we could consider that beamforming techniques allow:

1. sufficient number of directions to mimic an omnidirectional operation,
2. geographically any direction is achievable,
3. patterns from different directions at the same AP level do not interfere and are uncorrelated,
4. on-chip real-time transmits and synchronization.

4 Problem Statement

In this section, we formalize mathematically the problem of determining the opportunity to transmit at any point under the wireless coverage area. We first focus on related-work's models. Then in the next sections, we present our solution model and compare its results to preceding studies.

In this problem statement, we focus mainly on how related-work estimates the interference at a given point under the wireless coverage area, applies radio and upper-layer constraints, and processes the corresponding transmit opportunity.

To ease this work we consider the wireless coverage area as a two-dimensional Euclidean plane. The APs and WDs are points of this plane. They transmit in the same channel and cause the majority of co-channel interference in this area. This study focuses on co-channel operation but is easily extendible to tackle cross-channel interference or noise issues in the context described before.

Let us define:

$\{AP_1, AP_2, \ldots, AP_n\}$— set of n access points.

P_j — a point under wireless coverage area.

(x_i, y_i)— coordinates of AP_i or P_i points in an Euclidean two-dimensional plane.

$w_i, w_{min}, w_{max}, w_{opt}$— AP_i's corresponding current, minimum, maximum and optimum transmit power levels.

$d_{i,j}$ — distance between AP_i and P_j points.

$I(), O()$— interference and transmit opportunity functions.

We categorize related-work's models into two categories: Range-based and Zone-based. In the upcoming subsections, we describe each of them and discuss their limitations.

4.1 Range-based Model

In works similar to [4], an AP's wireless coverage corresponds to one of these ranges: a transmission, interference or no-talk range. These ranges correspond to the estimation of the distance between the AP and a receiving point P (AP or WD). Further, they consider that an AP's wireless coverage pattern is omnidirectional in the form of a circle or a disk. In this configuration, the three circles that correspond to each range type and centered at the AP define the whole AP's wireless coverage area as in Figure 1.

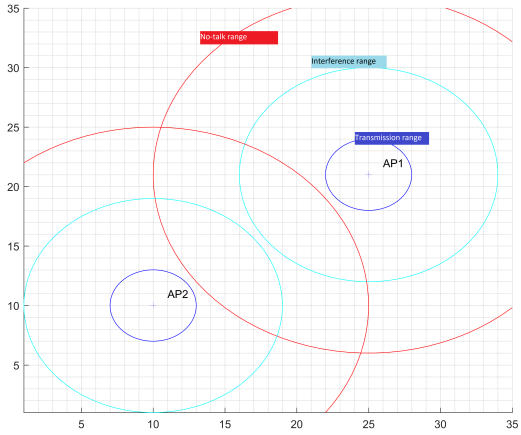

Figure 1: Range-based model's representation of an AP's wireless coverage

Let us further define:

$C_{i,tx}, C_{i,if}, C_{i,nt}$— AP_i attached circles that delimit corresponding transmission, interference and no-talk ranges.

$R_{i,tx}, R_{i,if}, R_{i,nt}$— AP_i corresponding ranges.

If we suppose that:

$$R_{i,tx} \leq R_{i,if} \leq R_{i,nt} \tag{3}$$

Then the interference and transmit opportunity are given as follows:

$$I(P_i) \approx \sum_{k=1}^{3} \alpha_k \sum_{j \neq i} \beta_j * intersection(C_{j,k}, C_{i,1}) \tag{4}$$

$$O(P_i) \approx \frac{1}{\sum_{k=1}^{3} \alpha_k \sum_{j \neq i} \beta_j * intersection(C_j, P_i)} \tag{5}$$

A weighted version of these functions is given further to account for inaccuracies and other constraints. The α and β weights are meant to reflect the non-linearity of interference addition, the power level's effect on interference strength, and the type of transmission's range. Here we consider that the interference at a given point P_i is a function of other AP_j's

signals except from the AP_i to which the point is associated. The opportunity processing is slightly different as it considers all AP's interference to P_i that is not associated to any AP_i yet.

4.2 Zone-based Model

Works such as [5] [6] that are based on this model are different from the previous ones as ranges here are not function only of the corresponding AP transmission's characteristics: channel, power level, etc., but depend also on the neighboring APs. The result of this is that the transmission range shape is no more a solid circle but a convex polygon with straight sides. Each straight side defines a borderline that separate two neighboring APs' transmission ranges. Consequently, it is important to note that a point in a transmission range of one AP could not be in another AP's transmission range. A Zone-based AP's wireless coverage is represented in Figure 2.

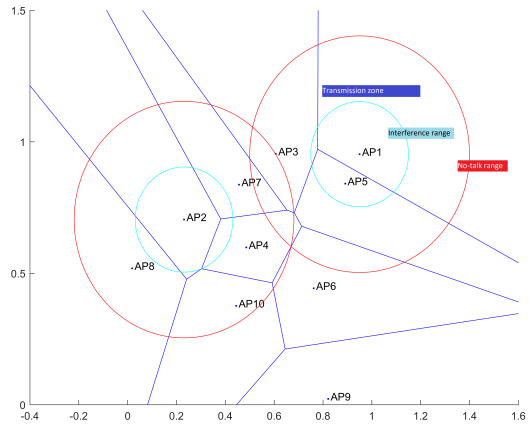

Figure 2: Zone-based model's representation of an AP's wireless coverage

Let us further define:

G_i — AP_i corresponding transmission range polygon or zone.

Then the interference and transmit opportunity are given as follows:

$$I(P_i) \approx \alpha_1 \sum_{j \neq i} \beta_j * intersection(C_{j,1}, C_{i,1})^{-\lambda} + \sum_{k=2}^{3} \alpha_k \sum_{j \neq i} \beta_j * intersection(C_{j,k}, C_{i,1}) \quad (6)$$

$$O(P_i) \approx \frac{1}{\sum_{k=2}^{3} \alpha_k \sum_{j \neq i} \beta_j * intersection(C_{j,k}, G_i)} \quad (7)$$

Similarly to formulas 4 and 5, α and β weights are meant to represent the impact of AP's transmission characteristics. λ is representative of the neighboring APs impact on AP_i borderlines. In this configuration, only transmission range is affected. The processing of other ranges are the same as in the previous model. It is also to note that opportunity in this model correspond to P_i in AP_i transmission's range or zone G_i rather than intersection of the neighboring APs like in the previous model.

4.3 First Observations

The presented models' functions of interference and opportunity do not reflect the accuracy of interference and opportunity measurements but rather the concept behind them and their possibilities to account for different WLAN design cases and aspects. At this stage, we see clearly that both models are limited in these ways:

1. both models are limited to consider that the strength of interference is only inversely proportional to the distance of an AP from interfering neighbors.
2. both models would interpret an increase in a transmission power level as an expanded reach in all directions: uniformly in case of Range-based models but depending on neighboring APs in case of Zone-based ones.
3. a point could not be in two transmission ranges of two different APs at the same time in Zone-based models.
4. transmission range does not depend on the strength of interference in Range-based models.
5. both models would interpret falsely obstacles to the signal propagation, as a weaker signal from an AP in the context of indoor WLAN networks does not mean necessarily that this AP is out of reach.
6. similarly to the previous point a stronger signal does not mean necessarily that an AP is in reach: it signal may be guided under some conditions.

The consequence of these limitations in indoor WLAN networks, is to reduce or overestimate the transmit opportunities that the network may offer. The upcoming section presents our solution to fix these modelization limitations.

5 Solution model

Our solution model is suitable for WLC-controlled indoor networks in the already explained conditions. For the purpose of this study, we suppose that APs are equivalent, support MIMO technologies such as beamforming and DOA, and operate over the same channel. The wireless devices (WD) are equipped with omnidirectional antennas and transmit at a lowered power level in comparison with APs.

The model runs three algorithms:

1. Transmit Direction Discovery (TDD) algorithm that builds a per direction neighbor discovery map, computes the optimal number of transmit directions and the corresponding per direction power levels.
2. Transmit Direction Mapping (TDM) algorithm estimates the impact that may have an AP on the network when it transmits in a specific direction and builds consequently, a per-direction transmit cost-based map that represents this information.
3. Transmit Direction Opportunity (TDO) algorithm processes data from both TDM and the upper-layer network services to optimize the transmission opportunities and build a per-direction transmit opportunity-based map to represent this information.

The next workflow in Figure **??** is an overview of our solution processing.

At initialization, the number of transmission directions is set to the minimum and the power level to the maximum. TDD processing stops after all APs are discovered and exactly one or no neighbor AP is discovered at any AP direction.

Based on results from TDD, TDM categorizes the coverage area points and costs a potential transmission at each of them. The coverage area points belong to one of these three categories: Not-On-Any-Transmit-Direction (NOATD), On-Discovered-Neighbor-Direction (ODND), and Not-ODND-On-Transmit-Direction (NOOTD). After the coverage area point's categorization, the system processes the transmission costs.

TDO algorithm evaluates the opportunity to transmit at a specific coverage area point. It returns the AP that may handle the transmission and the corresponding direction. This processing accepts inputs from TDM and the upper-layer SLA. The SLA processing is tight to the AP's wired network interface as opposed to the radio interface.

5.1 TDD algorithm

TDD algorithm processes the optimal number of transmission directions that APs may support and the corresponding per-direction transmit power levels. To ease this study, we consider these hypotheses and simplifications:

1. only a 2D plane operation is considered.
2. a uniform beamwidth in all directions.
3. APs are able to achieve an emulated omnidirectional operation.
4. two signals from the same AP in two different directions could not interfere.
5. all APs have the same optimal and maximal numbers of transmission directions and corresponding power levels.
6. neighbor discovery is bidirectional, occurs at the opposite direction, and at the same transmit power level.
7. an AP could not discover the same neighbor AP in two separate directions.
8. an AP could not discover itself.
9. at least one neighbor AP is reachable in any AP direction.

Points 2, 3, 4 and 5 are idealistic physical characteristics of AP's beamforming implementation. The 9^{th} point indicates that a co-channel interference condition is detected from a neighboring AP. The 6^{th}, 7^{th} and 8^{th} assumptions are further developed in separate work to cover and interpret cases where:

1. the optimal numbers of transmission directions and power levels are not the same among APs.
2. neighbor discovery is unidirectional or asymmetric.

Let us define:

(d_i, w_i)— the direction and power level associated with AP_i.

$d_{-j}(-x,-y)$— the opposite direction of $d_j(x,y)$ in an euclidean 2D plane.

$L(AP_i, d_j, w_k)$— the segment that represents the transmission range of AP_i in d_j direction at w_k transmit power level.

$a(i,j)$, $b(i,j)$, $c(i,j)$— respectively the segment $L()$ slope, intercept and end point.

$X(AP_i, d_j, w_k)$— the set of discovered AP neighbors by AP_i in d_j direction at w_k power level.

$O(AP_i, AP_j)$— a segment that represents an obstacle between AP_i and AP_j.

We formalize the problem as:

$$\forall i \in \mathbb{N}, \quad \exists j,k \in \mathbb{N} \quad \text{s. t.} \quad X(AP_i, d_j, w_k) \neq \emptyset \tag{8}$$

$$\forall i,j,k \in \mathbb{N}, \quad AP_i \notin X(AP_i, d_j, w_k) \tag{9}$$

$$\forall i,j,j',k,k' \in \mathbb{N}, \quad \text{and} \quad j \neq j', \quad X(AP_i, d_j, w_k) \cap X(AP_i, d'_j, w'_k) = \emptyset \tag{10}$$

$$\forall i,i',j,j',k,k' \in \mathbb{N}, \quad \text{and} \quad i \neq i', \quad AP_{i'} \in X(AP_i, d_j, w_k) \equiv AP_i \in X(AP_{i'}, d_{j'}, w_{k'}) \quad \text{and} \quad d_{j'} = d_{-j}, \quad w_k = w_{k'} \tag{11}$$

$$\forall i,j \in \mathbb{N}, \quad L(AP_i, d_j) = \left\{ a_{i,j} * x + b_{i,j} \quad | \quad x \in \left[x_i, x_i + c_{i,j} \right] \right\} \tag{12}$$

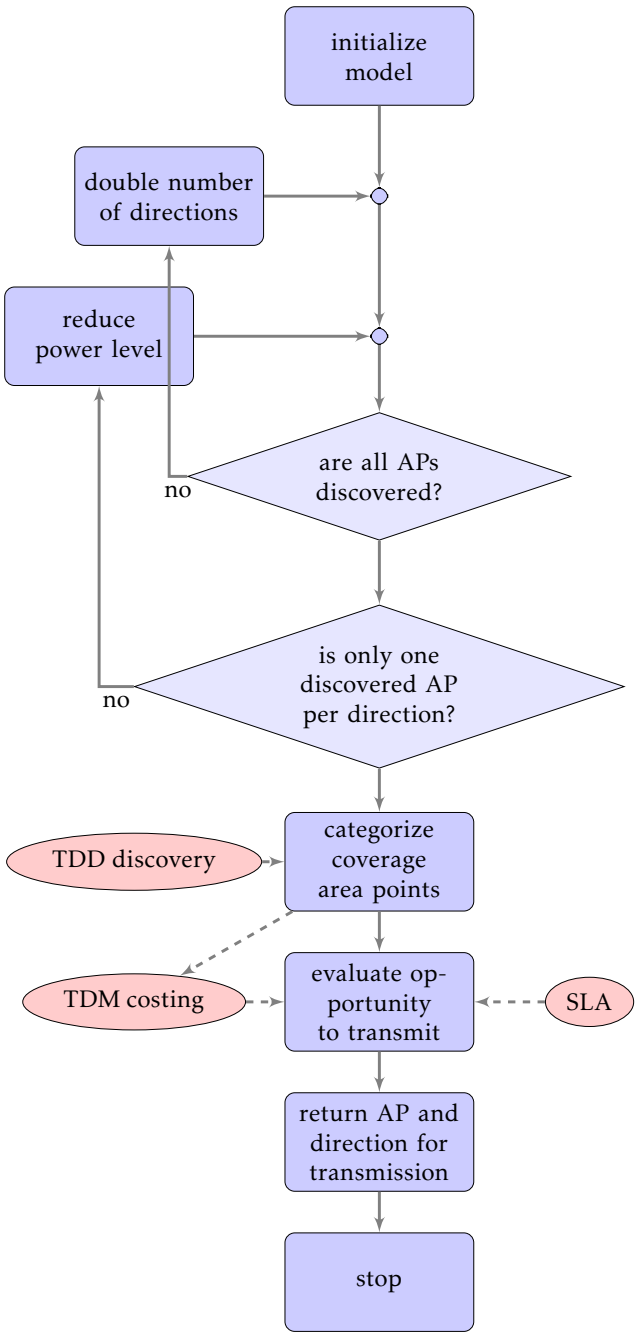

Figure 3: Flowchart of our solution model processing

The APs' distribution on the plan could be any random function or resulting from on-site surveys. However, we consider that the minimum and maximum distances between any of these APs are linear functions respectively of the corresponding minimum and maximum supported power levels. Figure 4 represents a simple network of seven APs with eight transmission directions each. Eight beams in red color are formed roughly around AP_i corresponding transmission directions.

The AP neighbor's per-direction discovery is based on the distance between APs that are on each other theoretical transmission range, on-site surveys, and radio interface sensing. Additionally the solution model allows the discovery of these two design special-case neighbors:

1. "isolated" neighbor AP that is at reach but separated by an obstacle.
2. "guided" neighbor AP that is not at reach but received with an acceptable signal level.

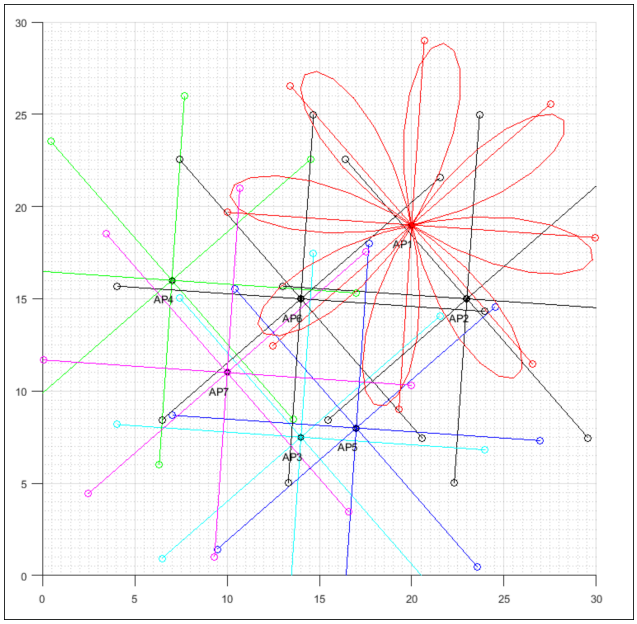

Figure 4: TDD Discovery Map example of 7 APs and 8 transmit directions

With reference to Figure 4 network's representation, the results of neighbor AP's discovery are given in Table. 1.

Table 1: Neighbor AP's discovery results

AP	d_1	d_2	d_3,	d_4	d_5	d_6	d_7	d_8
AP_1	AP_6	$\emptyset$	$\emptyset$	$\emptyset$	$\emptyset$	$\emptyset$	AP_2	$\emptyset$
AP_2	AP_5	AP_6	AP_1	$\emptyset$	$\emptyset$	$\emptyset$	AP_6	$\emptyset$
AP_3	$\emptyset$	$\emptyset$	AP_7	AP_6	$\emptyset$	AP_5	$\emptyset$	$\emptyset$
AP_4	$\emptyset$	$\emptyset$	$\emptyset$	$\emptyset$	AP_6	$\emptyset$	AP_7	$\emptyset$
AP_5	$\emptyset$	AP_3	$\emptyset$	$\emptyset$	AP_2	$\emptyset$	$\emptyset$	$\emptyset$
AP_6	AP_7	AP_4	$\emptyset$	$\emptyset$	AP_1	AP_2	$\emptyset$	AP_3
AP_7	$\emptyset$	$\emptyset$	AP_4	$\emptyset$	AP_6	$\emptyset$	AP_7	$\emptyset$

The optimization of APs transmission directions' number is a three-step process. For directions with more than one discovered neighbor, we calculate a new number such as to have the least possible number of neighbors per any AP's direction. Otherwise, we adjust the power levels to get some of these APs out of reach from the local AP. If no success, we revert to Range-based-like interference scheme to cost this transmission zone.

A simpler form of the proposed algorithm is given next:

1: $(d^{opt}, w^{opt}) \leftarrow (d^{min}, w^{max})$
2: $X \leftarrow \bigcup_{j=1}^{opt} X(AP_i, d_j^{max}, w_{opt})$
3: **for** $j = 1$ to opt **do**
4: **if** $opt \leq max$ **then**
5: **if card**$(X(AP_i, d_j^{opt}, w_{opt})) > 1$ **then**

$d_{opt} \leftarrow d_{2*opt}$
end if
else if card$(X(AP_i, d_j^{opt}, w_{opt})) > 1$ **then**
repeat
if $\bigcup_{j=1}^{opt} X(AP_i, d_j^{opt}, w_{opt-1}) = X$ **then**
$w_{opt} \leftarrow w_{opt-1}$
end if
until $\forall j$, **card**$(X(AP_i, d_j^{opt}, w_{opt})) \leq 1$
end if
end for

The optimum numbers of directions and power levels are respectively initialized to the minimum and the maximum numbers supported by AP_i. For every AP's direction, we check the number of discovered neighbors. If many neighbors are detected, we multiply the initial number of directions by two until we obtain only one neighbor per direction. If the maximum number of direction is reached then we reduce by one level the power and try to get the same result without altering X. X is the set of all neighboring APs that were detected previously in the maximum supported directions and at the maximum supported power level.

5.2 TDM algorithm

In the previous section, TDD returned the optimal number of transmission directions, the corresponding optimal number of power levels and the sets of AP's per-direction discovered neighbors. In addition to these elements, TDD interprets the presence of two kinds of obstacles: those that are preventing isolated neighbors from seeing each other, and those that are creating new transmission opportunities among guided neighbors. One way for TDD to interpret such kind of obstacles is by comparing the on-the-air discovery's results with on-site surveys' information. Based on the previous elements, TDM algorithm builds a transmission-costing map for APs to reach any point under the overall wireless coverage area.

A simpler form of the proposed algorithm is given next:

for $j = 1$ to opt **do**
if $P_i \in L(AP_i, d_j)$ and $X(AP_i, d_j) \neq \emptyset$ **then**
$Case_1$
else if $P_i \in L(AP_i, d_j)$ and $X(AP_i, d_j) = \emptyset$ **then**
$Case_2$
else
$Case_3$
end if
end for

TDM costing system categorizes WDs as NOATD, ODND, or NOOTD. These WDs could be represented roughly by circles with sufficiently small radii in comparison with APs transmit ranges, to not false processing results. We process carefully NOOTD points, which are not on discovered-neighbor APs' directions, as they are hard to detect.

Let us define:

$C_i^W D$— WD attached circle.

ρ_i — weights associated with each category.

$Cost(P_i)$— function of transmissions cost at P_i

Then for this preliminary work, the cost of a transmission could be expressed as follows:

$$Cost(P_i) \approx \begin{cases} \rho_1 I(P_i), & \text{if } NOATD \\ \rho_2 I(P_i), & \text{if } ODND \\ \rho_3 I(P_i), & \text{if } NOOTD \end{cases} \quad (13)$$

Where,

$$I(P_i) \approx \alpha_1 \sum_j \sum_k \beta_{j,k} * intersection(L_{j,k}, C_i^{WD}) + \sum_{k=2}^{3} \alpha_k \sum_{j \neq i} \beta_j * intersection(C_{j,k}, C_{i,1}) \quad (14)$$

Cost calculation results were plotted on Figure 5, for the same Figure 4 network example set of seven APs and eight transmission directions. On this map, transmission costs range from white color, lowest cost points, to red color that correspond to the highest costly points.

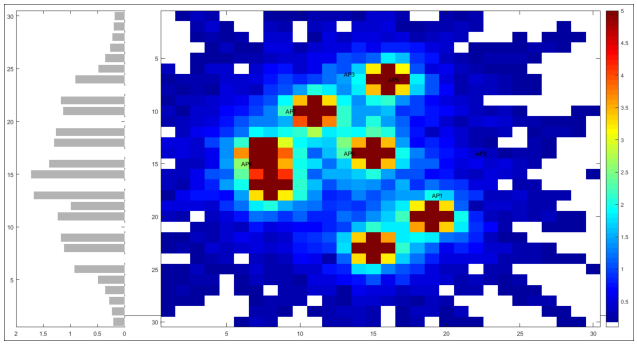

Figure 5: TDM Cost Map example of 7 APs and 8 transmit directions

5.3 TDO algorithm

TDO takes into consideration the worst-case analysis done by TDM when all the APs transmit at the same time in all supported directions at the maximum power level. Then for a given transmission, it prioritizes the directions with the least cost in duality with TDM but in addition, it integrates data from the upper service layers and returned SLA tests both on the passive and active communication's paths.

A more complex form of this opportunity processing relies on a system-wide APs transmit operation's synchronization to cancel costly directions and on-the-air tests to optimize NOOTD costs.

Let us define:

$s_{1,i}, s_{2,i}$— AP_i weights associated with defined SLA passive and active test results.

$O(P_i)$— opportunity of transmission function at P_i.

Then for this preliminary work, the transmission opportunity calculation at any point P_i is given by:

$$O(P_i) = s_{1,i} s_{2,i} \overline{I(P_i)} \tag{15}$$

The transmission opportunity processing results were plotted on Figure 6 for a set of seven APs and eight transmit directions.

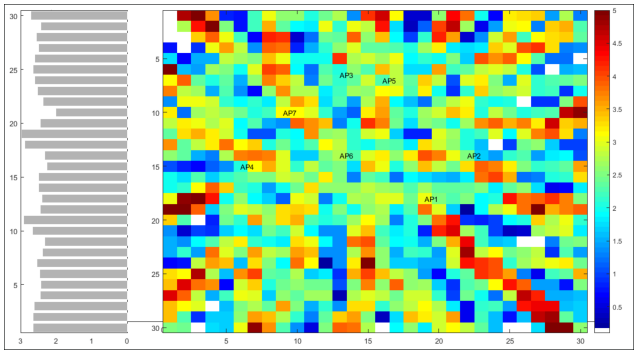

Figure 6: TDO Opportunity Map example of 7 APs and 8 transmit directions

$s_{1,i}$ and $s_{2,i}$ weights are calculated based on the simulated SLA active test results that may include: Packet Loss Rate, Round-Trip Time (RTT), Jitter, and on SLA passive measurements at PHY and MAC levels like: error rates, transmitted packets, etc. that are directly taken from the radio and LAN interfaces. In addition, these weights take into consideration the nature of the end-user application: real-time applications do not require the same service from the network as bulk ones.

5.4 Layered Transmit Opportunity Processing

With regard to this work opportunity processing, a transmission is a four-step procedure: discover, cost, evaluate, and transmit. Discovery is primarily done by APs and could be extended to any WD. The interpretation of discovery results, costing, and opportunity processing, are done at WLC level. Costing in this work has been solely based on interference estimation but could integrate any other radio interface's measurements: Signal to Noise Ratio (SNR), Received Channel Power Indicator (RCPI), and so on. Opportunity evaluation is based both on previous radio interface costing and on measures from upper layer services. These two measures have to be fully uncorrelated to not false results.

5.5 Transmit Synchronization

In this configuration, a transmission is not tight to the access point WD is associated with, but rather to the AP that offers the best transmit opportunity among a set of APs. In fact, the WD is associated with a virtual or pseudo AP that is representative of a set of physical APs with common characteristics with regard to this association. Any physical AP attached to the pseudo-AP could source an effective transmission to the associated WD. In the context of this work, we match the WD's corresponding pseudo-AP to a single physical AP.

6 Evaluation and Conclusion

At this stage, the evaluation is based on Matlab simulations of both our model and models from related-work [4] [5] [8] Range-based, and [6] Zone-based solutions. In the next step, we consider implementing this solution on a Linux-based APs and WDs and compare its performance with simulated related-work and vendor's implementations.

We compare our model performance to both Range-based and Zone-based models in these three transmission conditions:

1. a free space transmission condition,
2. the presence of obstacles, "isolated" neighbor's condition,
3. "guided" neighbor's condition.

We first evaluate the compared transmission opportunity for any set of 30 APs and ten times a randomly selected 100 WDs on a 2D grid. To ease this work we limit the maximum number of APs to 30 and the number of WDs test points to 100.

Figure 7 shows that for 30 APs and 10 random sets of 100 WDs on the grid, the average performance calculations is almost: 77% for our solution, 68% for Zone-based and only 57% for Range-based models. Figure 8 shows the average transmit opportunity for each model per WDs sets.

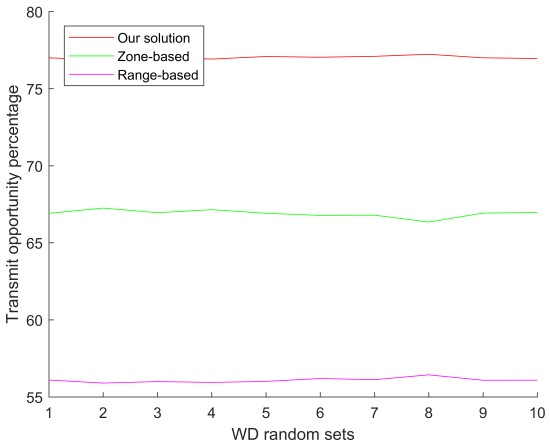

Figure 7: Performance comparison for 30 AP and 10 random sets of 100 WDs

Second, as in Figure 9, we evaluate the APs number impact on the compared performance for any set of 100 WDs. APs number ranges from 1 to 30. In Figure 10, we compare Zone-based to Range-based models.

We notice a general tendency of all models to perform similarly when APs are of limited number. However, for greater APs' numbers, the Zone-based models perform better than Range-based ones as in Figure 10. In Figure 9, our model returns a better transmit opportunity estimation when APs' number increases in comparison to other models.

Third, in Figure 11, we vary the number of the supported directions that is applicable only to our model and observe the compared average performance. For this test purpose, this number is tight to a variable α that takes these values: 12.5%, 25%, 50% and 75%. We only compare our model to Zone-based one.

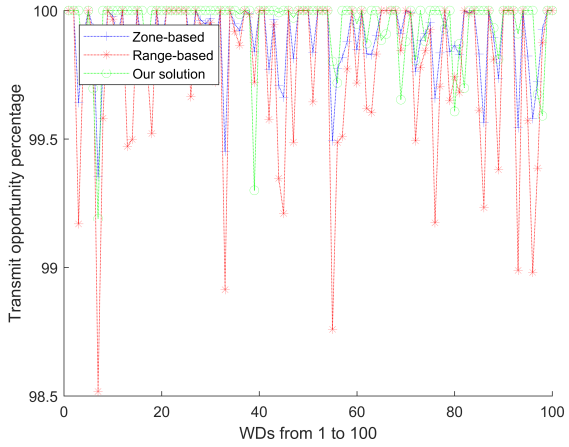

Figure 8: Average performance comparison per WDs in a network of 30 APs and 100 WDs

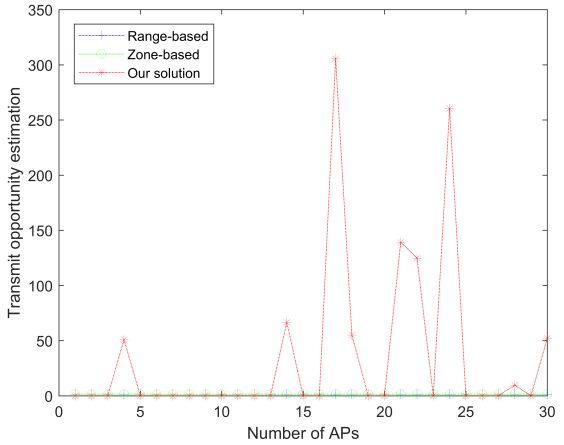

Figure 9: Comparison of our solution, Zone and Range-based models for any set of 100 WDs by APs number

We see clearly that our solution is comparable to Zone-based one when α is almost 75%. Our solution is near optimal when α is 12,5% but this is idealistic. However, achieving a 50% α is realistic with regards to these-days vendors APs system characteristics. A 50% α coefficient may correspond roughly to four transmission directions or beams.

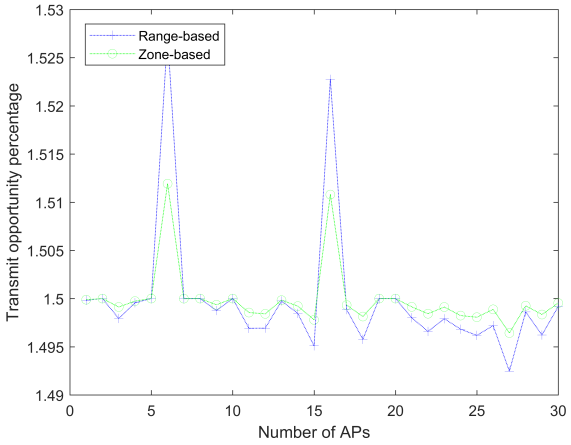

Figure 10: Comparison of Zone and Range-based models for any set of 100 WDs by APs number

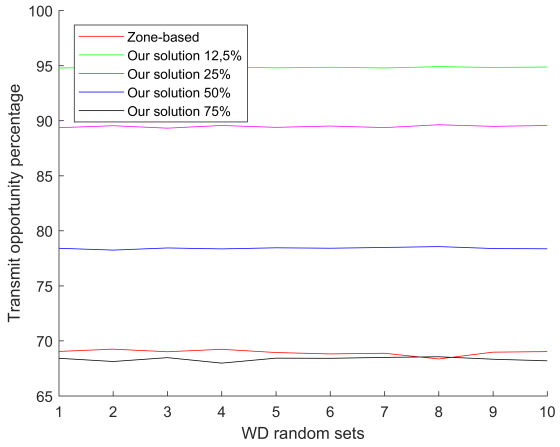

Figure 11: AP directions number impact on performance

As a conclusion, this work transmission processing is built on a new costing and opportunity evaluation model that leverages advances in antenna array processing such as beamforming techniques and WLAN integrated design best practices. In addition to the transmission channels and corresponding transmission power levels, it considers the direction of transmission or beam as an additional degree of freedom of dynamic RRM purposes. A comparison to other models indicates that our model is stable and performs better in very dense WLAN indoor and WLC-based network deployments.

Further work may focus on:

1. more complex neighbor AP discovery scenarios,
2. angle of incidence in TDM costing,
3. APs transmit operation coordination,
4. more complex costing layered approach for end-to-end to communications.

Conflict of Interest The authors declare no conflict of interest.

Acknowledgment We would thank colleagues : researchers, engineers, and anonymous reviewers for sharing their precious comments and on-field experience that improved the quality of this paper.

ABSTRACT

Convolutional Neural Networks (CNNs) have gained attention in recent years for their ability to perform complex machine learning tasks with high accuracy and resilient to noise of inputs. The time-consuming convolution operations of CNNs pose great challenges to both software as well as hardware designers. To achieve superior performance, a design involves careful concerns between exposing the massive computation parallelism and exploiting data reuse in complex data accesses. Existing designs lack comprehensive analysis on design techniques and decisions. The analytical discussion and quantitative proof behind the design criterion, such as choosing proper dimensions to parallelize, are not well studied. This paper performs a series of qualitative and quantitative studies on both the programming techniques and their implications on the GPU architecture. The observations reveal comprehensive understanding on the correlation between the design techniques and the resulting performance. Based on the analyses, we pinpoint the two major performance bottlenecks of CNN on GPGPU: performing computation and loading data from global memory. Software and hardware enhancements are proposed in this paper to alleviate these issues. Experimental results on a cycle-accurate GPGPU simulator have demonstrated up to 4.4x performance enhancement when compared with the reference design.

1. Introduction

Convolutional Neural Networks (CNNs) have gained attention in recent years for their ability to perform complex machine learning tasks. Followed by winning the 2012 ImageNet competition, CNNs have demonstrated superior results in a wide range of fields including image classification, natural language processing and automotive. In addition to high accuracy in object recognition, systems using CNNs are more robust and resilient to noise in the inputs when compared to conventional algorithmic solutions. However, the enormous amount of computing power required by CNNs poses a great challenge to software as well as architecture engineers. The most time-consuming operation in a CNN is the convolution operation, which takes up over 90% of the total runtime. Therefore, the convolution operation becomes one of the most important concerns when implementing CNNs.

GPGPUs have demonstrated superior performance on CNN by exploiting the inherent computation parallelism. Due to the scaling architectures as well as ease-of-programming environment, GPGPUs are among the most widely adopted platforms for CNN. However, it is not a trivial task to have an efficient CNN design on a GPGPU. To achieve superior performance, a design involves careful concerns between exposing the massive computation parallelism and exploiting data reuse in complex data accesses.

This paper is an extension of work originally presented in ICASI 2017 [1]. In this paper, we perform a series of qualitative and quantitative studies on both the programming techniques and their implications on the GPU architecture. The observations reveal comprehensive understanding on the correlation between the design techniques and the resulting performance. There exist several frameworks and libraries that provide solutions to performing convolution on GPGPUs, such as cuDNN [2], Caffe [3], fbfft [4], and cuda-convnet2 [5]. Among the existing solutions, cuda-convnet2 is one of the widely used open-source implementations that enable superior performance on a variety of CNN schemes [6]. It employs design techniques and optimization strategies mainly for NVidia GPGPU architectures. However, while providing a solid implementation, cuda-convnet2 lacks

*Corresponding Author: An-Ting Cheng, National Chiao Tung University, Email: ericcorter78.ee01@g2.nctu.edu.tw

comprehensive analysis on its design techniques and decisions. The analytical discussion and quantitative proof behind the design criterion, such as choosing proper dimensions to parallelize, are not well studied. In addition, current GPGPUs are not designed specifically for convolution. There exist potential architecture enhancements that could significantly enhance the computation efficiency with minor hardware and software cost.

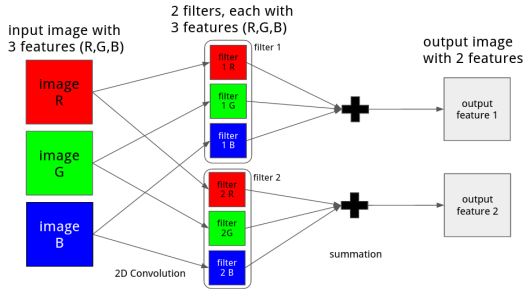

Figure 1: Convolution in CNN

This paper performs a series of qualitative and quantitative studies on both the programming techniques and their implications on the GPU architecture. The studies focus on the widely adopted NVidia GPGPU architecture and CUDA programming environment. The observations reveal comprehensive understanding on the correlation between the design techniques and the resulting performance. Based on the analyses, we pinpoint the two major performance bottlenecks of CNN on GPGPU: performing computation and loading data from global memory. Software and hardware enhancements are proposed in this paper to alleviate these issues. In the computation part, we demonstrate how to avoid excessive local memory accesses, the operations that severely degrade performance, by applying loop unrolling. We then propose two simple yet effective hardware accelerators to speed up the computation of the partial sums. In the data-loading part, we identify that a significant fraction of the time is spent on calculating addresses in the inner loops of CNN. We propose two software techniques to considerably reduce the computation. A low-cost address generator is then introduced to speed up the address calculation. Experimental results on a cycle-accurate GPGPU simulator, GPGPU-sim [7], have demonstrated up to 4.4x performance enhancement when compared with the original cuda-convnet2 design.

The rest of the paper is organized as follows. Section 2 discusses the implementation of the convolution kernel. The techniques of exposing parallelism and data reuse will also be discussed in Section 2. Section 3 and 4 describe the proposed software and hardware improvements to the convolution kernel. Section 5 discusses previous related works and Section 6 presents the conclusions.

2. Implementing Convolution on GPGPU

2.1 Convolution in CNN

Convolution is the basic building block as well as the most time-consuming operation in CNNs. The convolution operation in CNN does more than just convolving two 2D matrices. It takes a set of trainable filters and apply them to the input images, creating one output image for each input image. Each input image consists of one or more multiple feature maps, which means that every pixel in an image contains several features. For example, each pixel in an RGB picture contains three features: red, green and blue. Each filter also has the same number of features that correspond to the input images. When applying the filters to an input image, the filters are convolved across the width and height of the image, and the product of each feature is summed up to produce an output feature map. The number of features in each output image is therefore equal to the number of filters. Figure 1 illustrates an example of the convolution between one image and 2 filters with 3 features, producing one output with 2 features.

The high-level algorithm of the convolution operation in CNN is listed in Figure 2, where conv2 represents computing the 2D convolution between two 2D matrices. The inputs and outputs of the algorithm are all arranged in 4-dimensional arrays. Inputs to the algorithm are the image array images (image_count, height, width, image_features) and the filter array filters (image_features, filter_size, filter_size, filter_count). The output is the array outputs (image_count, height, width, filter_count). Each of the parameters used in the algorithm is described as below.

```
01: for (i = 0; i < image_count; i++) {
02:   for (j = 0; j < filter_count; j++) {
03:     result = zeros(height, width);
04:     for (k = 0; k < image_features; k++)
05:       result += conv2(images(k, :, :, i),
06:                       filters(k, :, :, j));
07:     outputs(j, :, :, i) = result;
08:   }
09: }
```

Figure 2: Pseudocode of convolution operations

image count. This parameter is the size of input mini-batch. A mini-batch contains multiple independent input images to be processed. Each image in the mini-batch will be processed by the same set of filters to produce one output image.

width, height. These two parameters are the width and height of the input images. All input images in the mini-batch have the same size. In this paper, the size of output images is the same as the size of the input images.

image_features. This parameter indicates the number of features maps in an input image. This is also the number of feature maps in a filter.

filter_size. In the context of CNNs, filters are always square-shaped. Therefore, we use only one parameter, which is filter_size, to represent both the width and height of a filter. As a result, the number of pixels in a filter is (filter_size * filter_size).

filter_count. This parameter is the total number of filters. Because each filter produces an output feature map, filter_count is also the number of output feature maps.

2.2 Exploiting Parallelism and Data Reuse in Convolution

This paper uses cuda-convnet2 [5] as the reference implementation of CNN on GPGPUs. Cuda-convnet2 is one of the widely used open-source implementations that enable superior

performance on a variety of CNN schemes [6]. It employs design techniques and optimization strategies mainly for NVidia GPGPU architectures. This section will discuss how to implement the convolution algorithm efficiently with CUDA [8].

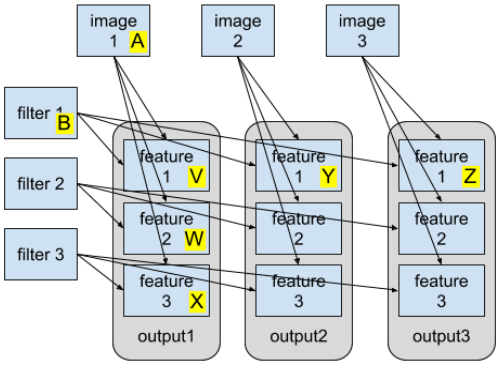

Figure 3: The relation between the input data (images and filters) and the output images.

CUDA is a design environment for massively parallel applications. CUDA applications exploit parallelism provided by the GPGPU by breaking down the task into blocks containing the same number of threads. Functionally speaking, blocks are independent to each other. Although some of them may be assigned to the same computing tile (a.k.a. SM (Streaming Multiprocessor in NVIDIA GPU), the computing model dictates that one block cannot communicate with another. Threads in a block are assigned to the same computing tile so that they can communicate and share data. This computing model leads to two important design decisions: 1) which dimensions to parallelize; and 2) what data to share and reuse between threads within a block.

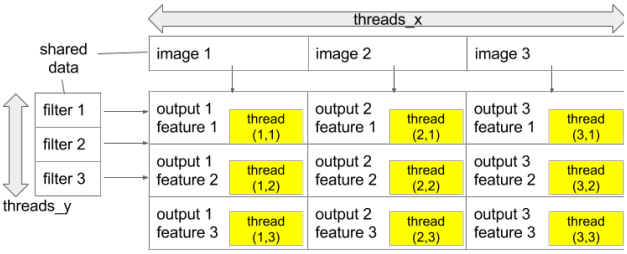

Figure 4: Configuration of threads in a block

Parallelizing one dimension means that the task is divided into smaller pieces by splitting at that dimension. For example, if we choose to parallelize the image_count dimension, computation for different images are divided into smaller tasks. In this case, each task is responsible for a small number of images. There are six dimensions in the inputs: image_count, image_features, width, height, filter_size and filter_count. A designer needs to decide which of these dimensions should be parallelized.

One limitation of the CUDA programming model is that different blocks cannot communicate with each other. Therefore, we can only parallelize dimensions that divide the problem into smaller independent tasks. In other words, outputs of each task should be stored separately without being combined into larger results. Based on this criterion, we will separately examine each of the dimensions to determine if it can be parallelized.

The dimension image_count represents the number of images. Because each image produces its own output independent of other images, we can parallelize the image_count dimension. The width and height dimensions can also be parallelized because computation of each output pixel is independent. Next, each filter produces its own output feature map, so the filter_count dimension can be parallelized. Now we are left with two dimensions to examine. The features dimension represents the number of feature maps in input images as well as filters. Because the results from different feature maps are summed to form a single output feature map (see Figure 1), we do not parallelize the feature dimension. Finally, we also do not parallelize filter_size because the products of filter pixels and image pixels are summed to form a single output pixel. To summarize, the dimensions that we are going to parallelize are image_count, width, height and filter_count.

The next step is to decide what data is reused and shared by different threads within a block. Figure 3 depicts the relation between the input data (images and filters) and the output images. Some input/output data set are labeled with capital letters for ease of explanation. The arrows in the figure indicates the input-output relation of the data. For example, the arrow pointing from A (image 1) to V (feature 1 of output 1) means that computation of V depends on A. From the figure we can see that different features in the same output image share the same input image (e.g. V, W, X all depend on A). Also, the same feature in different output images share the same filter (e.g. V, Y, Z all depend on B). These observations reveal some data-reuse opportunities.

To benefit from reusing both images and filters, a block should load pixels of multiple images and filters from the global memory. The threads also need to efficiently reuse the loaded data. This can be done by arranging the threads into a 2D configuration as show in Figure 4. The total number of threads in a block is threads_x * threads_y, and each thread is responsible of computing a single output pixel. All threads have an x and y index, where the x index determines which image the thread uses and the y index determines the filter. By doing this, the kernel only needs to load threads_x image pixels and threads_y filter pixels to compute threads_x * threads_y outputs. Each loaded image pixel is reused by threads_y threads, and each loaded filter pixel is reused by threads_x threads. As a result, this design reduces the memory access required to load the images to 1 / threads_y and that of the filters to 1 / threads_x.

```
01: __shared__ float
    images_pixel[features][filter_size*filter_size][threads_x];
02: __shared__ float
    filter_pixel [features][filter_size*filter_size][threads_y];
03: <collaboratively load images and filters>
04: float result = 0;
05: for (int i = 0; i < filter_size*filter_size; i++)
06:     for (int f = 0; f < features; f++)
07:         result +=
            image_pixel[f][i][threadIdx.x]*
filter_pixel[f][i][threadIdx.y];
08: <write result back to global memory>
```

Figure 5: High-level structure of the CUDA kernel

The high-level structure of the CUDA kernel is listed in Figure 5. Shared memory arrays are allocated to store the image and filter pixels to be reused. At the beginning, all threads work together to load the image and filter pixels required by the block. Then, each thread computes the output pixel it is responsible for. Finally, the computed results are written back to global memory.

```
01: __shared__ float
    images_pixel [features][cached_pixels][threads_x];
03: __shared__ float
    filter_pixel [features][cached_pixels][threads_y];
05:
06: <collaboratively load images and filters>
07:
08: float result = 0;
09: for (int p = 0; p < filter_size*filter_size; p += cached_pixels){
10:     for (int i = 0; i < cached_pixels; i++)
11:         for (int f = 0; f < features; f++)
12:             result += image_pixel[f][i][threadIdx.x] *
                filter_pixel[f][i][threadIdx.y];
13: }
14:
15: <write result back to global memory>
```

Figure 6: Modified kernel that loads data in chunks

This kernel is functional, but there are some details that can be improved. The first one is that this kernel loads the entire filter into shared memory, resulting in higher shared memory usage. This can be improved by loading the filter pixels in fixed-size chunks instead of loading as a whole. Due to the commutativity and associativity of summation, the final result is equal to the sum of the partial result of each chunk. Now we can modify the program by adding a parameter cached_pixels to set the size of the chunk. The modifications are listed in Figure 6. Note that both images and filters are loaded in chunks, or tiles. This technique is normally referred as tiling. As listed in (1), the shared memory usage after tiling ($SharedMem_{tile}$) can be greatly reduced from the original cost ($SharedMem_{original}$).

$$SharedMem_{tile} = x = \frac{\text{cached_pixels}}{\text{filter_size}^2} \times SharedMem_{original} \quad (1)$$

Currently, each thread in the kernel computes only one output pixel. We can generalize the kernel to compute multiple output pixels per thread. An output pixel is computed from one image and one filter, so we will add two extra kernel parameters images_per_thread and filters_per_thread to make the kernel compute multiple output pixels. These two parameters decide how many images and filters should each thread use. Because each pair of image and filter generate one output pixel, the number of outputs of each thread is images_per_thread * filters_per_thread. The modification to the program is listed in Figure 7. By adjusting images_per_thread and filters_per_thread, we can make each thread compute multiple outputs and therefore reduce the total number of blocks for the same problem size. For example, if the original kernel (equivalent to the modified kernel with images_per_thread = filters_per_thread = 1) has N blocks in total, the new kernel with images_per_thread = filters_per_thread = 2 only has N/4 blocks.

This kernel is used as the baseline program on which we propose enhancements. In the next section, we will describe how we choose the input sizes to use in our experiments.

2.3 Choosing the Input Size for Experiments

GPGPU-sim can obtain detailed execution behavior of CUDA programs on a GPU architecture similar to GTX-480. However, performance simulation in GPGPU-sim is very slow compared to a physical GPU. For example, a program that takes 100ms on an NVidia GTX480 can take up to 3 hours when running on GPGPU-sim. With such long simulation periods, changes to the program or the simulator itself cannot be quickly tested. Therefore, we think it is beneficial to reduce the size of the input dataset for shorter simulation time. But reducing the input data size, if done improperly, might produce inaccurate simulation results that deviates from the behavior of the original data. In this section, we will discuss a way to choose the size of the reduced data.

```
01: __shared__ float
    images_pixel [images_per_thread][features]
[cached_pixels][threads_x];
02: __shared__ float
    filter_pixel [filters_per_thread][features] [cached_pixels][threads_y];
03: <collaboratively load images and filters>
04: float result[images_per_thread][filters_per_thread] = {};
05: for (int p = 0; p < filter_size*filter_size; p += cached_pixels) {
06:     for (int i = 0; i < cached_pixels; i++)
07:         for (int f = 0; f < features; f++)
08:             for (int ii=0; ii<images_per_thread; ii++)
09:                 for (int if=0; if<filters_per_thread; if++)
10:                     result += image_pixel[ii][f][i][threadIdx.x] *
                        filter_pixel[if][f][i][threadIdx.y];
11: }
12: <write result back to global memory>
```

Figure 7: Modified kernel with multiple output in each thread

Computation in CUDA is broken down into independent blocks. Each block is assigned to a streaming multiprocessor (SM) so that every thread in the block can be run concurrently via fine-grain context switching of warps (groups of 32 threads). Also, each SM is capable of executing multiple blocks at the same time. On GTX480, the maximum number of blocks that a SM can run concurrently is limited by the following limiting factors:

1. An SM has 32768 registers.
2. An SM has 48kB of shared memory.
3. There should be no more than 8 blocks assigned to the same SM at the same time.

Each thread in a block has its own set of registers, so the number of registers used by each block is block *size*×*register per thread*. The limitation of blocks per SM due to the limiting factor 1 mentioned above is

$$\left\lfloor \frac{32768}{registers\ per\ block} \right\rfloor \quad (2)$$

Another limitation is the size of shared memory. Because an SM only has 48kB of shared memory, the limiting number of blocks per SM due to limiting factor 2 is

$$\left\lfloor \frac{48\text{kB}}{shared\ memory\ per\ block} \right\rfloor \quad (3)$$

At last, due to scheduler hardware limitations (limiting factor 3), a SM can only run at most 8 blocks concurrently. Concluding

(2), (3) and the hardware limitation, the actual maximum number of blocks per SM can be obtained by (4).

$$\min\left(\left\lfloor\frac{32768}{registers\ per\ block}\right\rfloor, \left\lfloor\frac{48\text{kB}}{shared\ memory\ per\ block}\right\rfloor\right) \tag{4}$$

In GTX480, there are 15 SMs. If each SM can run eight blocks in parallel, then the GPU can run 120 blocks concurrently. While using very large datasets, the total number of blocks will be much larger than 120 so that most of the time, all SMs on the GPU is doing some work. However, if the reduced dataset has less than 120 blocks, then some of the SMs on the GPU will be idle all the time, making occupancy lower than it should have been in larger datasets. Also, if the number of blocks is slightly more than 120 blocks, the GPU will execute the first 120 blocks in its full capability, and then execute the remaining blocks using only some of the SMs while leaving other SMs idle. This also makes measurements inaccurate in the same way.

Therefore, it is preferable to adjust the reduced data size so that blocks fill in all SMs during the entire simulation period. In other words, the total number of blocks divided by the maximum number of concurrent blocks should be a whole number or slightly less than a whole number (ex. 1.99). By reducing the data size like this, measurements will be closer to that of larger data sets.

Input parameters		Kernel parameters	
image_count	128	images_per_thread	4
image_width	5	filters_per_thread	4
image_height	6	threads_x	16
image_features	3	threads_y	4
filter_count	32	cached_pixels	4
filter_width, filter_height	32		

Table 1: Parameters used in the experiments

The actual input data size and kernel parameters we use in the experiment are listed in Table 1. According to these parameters, we can compute the total number of blocks using (5).

$$number\ of\ blocks = \left\lceil\frac{image_count}{thread_x \times images_per_thread}\right\rceil \times \left\lceil\frac{image_width \times image_height \times filter_count}{thread_y \times filters_per_thread}\right\rceil \tag{5}$$

After compiling this program, the compiler outputs the following information:

1. Each thread uses 28 registers.
2. Each block uses 3900 bytes of shared memory.

Now we compute the number of blocks per SM. The limitation caused by registers is

$$\left\lfloor\frac{registers\ per\ SM}{registers\ per\ thread \times block\ size}\right\rfloor = \left\lfloor\frac{32768}{28 \times (16 \times 4)}\right\rfloor = 18\ blocks\ per\ SM \tag{6}$$

The limitation caused by shared memory is

$$\left\lfloor\frac{\text{shared memory per SM}}{shared\ memory\ per\ block}\right\rfloor = \left\lfloor\frac{48\text{kB}}{3900}\right\rfloor = 12\ blocks\ per\ SM \tag{7}$$

Because both (6) and (7) exceed the hardware limitation of eight blocks per SM, maximum numbers of blocks per SM in this case is 8. Multiplying with the total numbers of SMs on GTX480, we get 8×15=120 blocks that can be executed on the GPGPU in parallel. Since there are exactly 120 blocks to be executed, all the blocks can be run in parallel without any SM stalling.

2.4 Summary of Design Concerns

In this section, we discussed an implementation of convolution in CUDA step-by-step. This convolution kernel employs a 2D block configuration to enable sharing of onboard data between threads through the shared memory, reducing accesses to the global memory. The kernels are also parameterized to enable adjusting the amount of work done by each thread. We also explained how we choose a relatively small input size that utilize all SMs. This method of choosing input sizes reduces the error of the experiment results caused by idle SMs. In all the following experiments, we will use the input sizes listed in Table 1.

According to simulation using GPGPU-sim, we identified that the two bottlenecks of the convolution kernel are computation of partial sums and loading of image and filter data. The following two sections, Section 3 and Section 4, will elaborate the proposed software and hardware improvements to speed up these two bottlenecks.

3. Accelerating Computation Part

The result of profiling the baseline implementation is shown in Figure 8. According to the profiling result, the most time-consuming part in the entire kernel is the computation part, which takes up over 97% of the overall runtime. In this section, we will focus on reducing the computation cost by various techniques including software and hardware modifications.

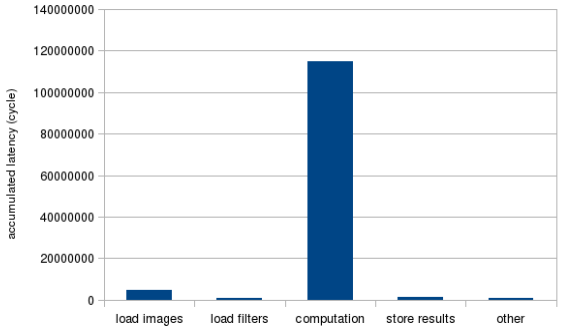

Figure 8: Initial Performance Breakdown

3.1 Avoid Local Memory Access

In order to improve the performance of the computation part, we need to understand what is responsible for its relatively long latency. Instruction-level breakdown of the profiling result listed in Figure 9 reveals that the latencies of instructions accessing local

memory are orders of magnitude greater than other instructions. In this section, we will discuss why there is local memory accessing in the code and how can we avoid it.

latency	instruction
…	…

Figure 9: Local memory access latency

3.1.1 Local Variables in CUDA

Before going into discussion, we will first briefly introduce how local variables (also known as automatic variables) are handled in NVidia GPGPUs. In the CUDA programming language, local variables are normally placed in the stack frame of the current function call. But compilers are also allowed to put them in registers if the architecture permits. Execution stack of CUDA threads are placed in a special memory space called local memory. Local memory resides in the global memory but is partitioned and allocated to each thread. Each thread can only see its own copy of local memory. Because global memory is much slower than registers, it is often preferable to put local variables in registers instead of local memory.

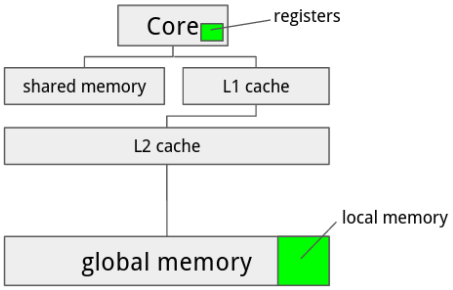

Figure 10: Registers and Local Memory

However, there are two limitations in CUDA regarding the use of registers. One limitation is that Fermi GPGPUs only have 32768 register in each core, so the total number of registers used by all threads in a block cannot exceed 32768. This limitation is less of a problem in convolution because the number of threads per block is relatively small (less than 100), and the number of register required for each thread is around 60. The other limitation is that registers have no addresses. This implies that an array can be put in registers only if no indexing is performed on them.

3.1.2 Loop Unrolling

In the convolution kernel, the partial sums computed by each thread are stored in a local array and accumulated over all pixels as shown in Figure 11. The loop counter f and g are used with the subscript operator to access the array element for each image and filter. In this case, the compiler needs to put the array in local memory because registers cannot be indexed. This will cause the GPU to access global memory in every iteration of the inner loop.

```
01: float result[filters_per_thread][images_per_thread];
02: for (int pixel = 0; pixel < filter_pixels; pixel += cached_pixels)
03: {
04:  <load filter pixels>
05:  <load image pixels>
06:     for (int i =0; i < cached_pixels*image_features; i++)
07:     {
08:        for (int f=0; f<filters_per_thread; f++)
09:        {
10:           for (int g=0; g<images_per_thread; g++)
11:           {
12:              result[f][g] += image_pixel[i][g] * filter_pixel[i][f];
13:           }
14:        }
15:     }
16: }
```

Figure 11: Local Array in the Convolution Kernel

It can be seen in the figure that the overall latency is dominated by local memory access (highlighted in boldface). The bottleneck can be totally avoided if the array elements are put in registers instead of local memory. However, the compiler cannot put the array in register because the array needs to be dynamically indexed.

One way to get around this limitation is to apply loop unrolling, which effectively eliminates all dynamic indexing on the array by expanding the loop and replacing the indices with constants. As long as the array is not dynamically indexed, the compiler can allocate registers for the array elements.

```
01: for (int i = 0; i < cached_pixels * image_features; i++) {
02:  #pragma unroll
03:    for (int f = 0; f < filters_per_thread; f++)
04:    {
05: #pragma unroll
06:       for (int g = 0; g < images_per_thread; g++)
07:       {
08:          result[f][g] += image_pixel[i][g] * filter_pixel[i][f];
09:       }
10:    }
11: }
```

Figure 12: Applying Loop Unrolling

Loop unrolling in CUDA can be enabled by setting up the preprocessing hint during compilation. A directive #pragma unroll is provided to let the programmer issue unrolling hints so that the compiler knows which loops should be unrolled. Using the unroll directive, we can apply loop unrolling to the original program (shown in Figure 12). By using loop unrolling on the two inner-most loops, the `result` array is expanded into multiple independent registers. As a result, the inner loop no longer requires local memory access. As shown in the profiling result in

Figure 13, latency of local memory accesses is completely eliminated after unrolling the loop.

latency	instruction
189822	ld.shared.f32 %f59, [%rd13+0];
1681	ld.shared.f32 %f60, [%rd16+0];
17345	mov.f32 %f61, %f2;
25172	mad.f32 %f62, %f59, %f60, %f61;

192675	mov.f32 %f75, %f74;
1707	ld.shared.f32 %f76, [%rd16+4];
16959	mov.f32 %f77, %f10;
...	…

Figure 13: Profiling result after applying loop unrolling

Before applying loop unrolling, it takes 524k cycles for the program to finish. The letter k is a postfix indicating 1,000. After applying loop unrolling, the number of cycles is reduced to 148k, resulting in a 71% improvement on the overall performance. The latency breakdown in Figure 14 shows that the computation part is dramatically improved by loop unrolling.

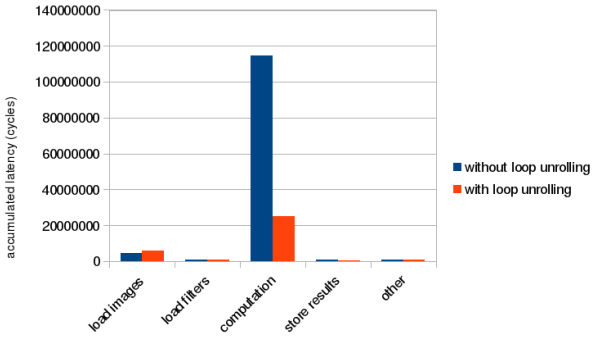

Figure 14: Loop unrolling performance improvement

3.2 Adding Inner Product Engine

The computation part (shown in Figure 15) is still the bottleneck even after applying loop unrolling, taking up about 69% of the overall execution time. Looking at the loop as a whole, what it does is computing the product between each image and filter pixel and sum them together. The partial sums are then accumulated in the array `result`.

```
01: for (int i = 0; i < cached_pixels * image_features; i++) {
02:   #pragma unroll
03:     for (int f = 0; f < filters_per_thread; f++)
04:     {
05:     #pragma unroll
06:       for (int g = 0; g < images_per_thread; g++)
07:       {
08:         result[f][g] += image_pixel[i][g]* filter_pixel[i][f];
09:       }
10:   }
11: }
```

Figure 15: Computation loop

If we exchange the order of the outmost loop with the two inner loops in Figure 16, the inner loops (Line 05 to Line 11) becomes an inner product operation between the two arrays. This modification does not change the behavior of the original function because there is no dependency between each loop iteration. Since the two outer loops are unrolled, the inner product becomes the only bottleneck.

```
01:  #pragma unroll
02:  for (int f=0; f < filters_per_thread; f++) {
03:    #pragma unroll
04:    for (int g=0; g < images_per_thread; g++) {
05:      for (int i=0;  i<cached_pixels* image_features; i++)
06:      {
07:        result[f][g] += image_pixel[i][g] * filter_pixel[i][f];
08:      }
09:    }
10: }
```

Figure 16: Inner product in the computation loop

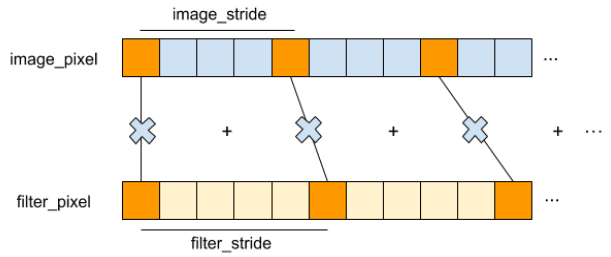

Figure 17: Inner Product

To reduce the bottleneck, we propose adding a hardware inner product accelerator to the cores, one unit for each thread. The accelerator loads pairs of image and filter pixels from shared memory, compute the product of each pair, and then sum all the products together. The program passes the starting addresses and strides of both arrays and the number of elements to the accelerator. These arguments are then stored in the internal registers of the accelerator and are reused until their values are changed again. The final result is also stored in the unit and can be retrieved in the program.

The hardware architecture of the inner product accelerator unit is shown in Figure 18. For each iteration, it loads two elements from shared memory and accumulate the product of them to a register. It requires one multiplier, one adder and a register to store the partial results. In the actual implementation, the multiplier and adder can be fused into a fused multiply-add (FMA) circuit. We assume that it requires 2 cycles to load the two elements from shared memory, and the latency of the FMA is also assumed to be 2 cycles. A 2-stage pipeline can then be used to repeatedly load elements and compute FMA. In our work, we model the latency of the inner product unit as 2 * N, where N is the number of elements to compute.

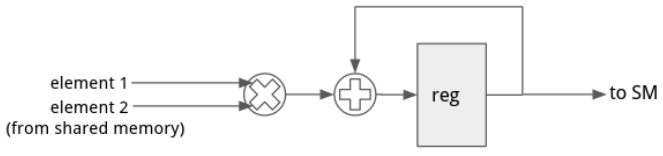

Figure 18: Inner Product Unit

Modeling the accelerator requires modifying both GPGPU-sim and the application. We modeled the inner product accelerator in GPGPU-sim by intercepting memory access to specific addresses. We modified the load (ld) and store (st) handlers to check if the source or target address matches any of the designated addresses. List of the addresses we use and their functions are listed in Table 2. If the address matches, the original memory access is skipped and the corresponding function of the accelerator is performed. For example, as soon as the thread writes 16 to address 0xffffffc8, GPGPU-sim sets the stride register of the accelerator to 16.

Table 2: Addresses used by the inner product engine

address	direction	function
0xffffffc0	write	address of image array
0xffffffc8	write	stride of image array
0xffffffd0	write	address of filter array
0xffffffd8	write	stride of filter array
0xfffffff0	write	number of elements
0xfffffff8	read	start computing and retrieve the result; stall the thread for N cycles

To use this inner product accelerator, the application needs to use the addresses to manipulate the registers inside the accelerator. First, the application should pass the starting address of the image and filter array to 0xffffffc0 and 0xffffffd0 respectively. The image stride is threads_x * images_per_thread, and the filter stride is threads_y * filters_per_thread. These two values are constant as the dimensions of the arrays are known in compile time, so it is only necessary to write them once at the beginning of the kernel. The fifth parameter, number of elements, is also known in compile time and only needs to be write once. Finally, after all parameters are set, the program needs to read from address 0xfffffff8 to retrieve the result of the inner product. The modified program is listed in Figure 19.

```
01: // beginning of the kernel
02: *(unsigned long long*)(0xffffffc8)  =  sizeof(shm_images[0]);
03: *(unsigned long long*)(0xffffffd8)  =  sizeof(shm_filters[0]);
04: *(unsigned long long*)(0xfffffff0)  =  cached_pixels * image_features;
05: // inside the computation part
06: #pragma unroll
07: for (int f = 0; f < filters_per_thread; f++) {
08:    *(float**)(0xffffffd0) = &shm_filters[0][threadIdx.y * filters_per_thread
       + f];
09: #pragma unroll
10:    for (int g = 0; g < images_per_thread; g++) {
11:       float partial_sum;
12:          *(float**)(0xffffffc0) = &shm_images[0][threadIdx.x *
             images_per_thread + g];
13:       partial_sum = *(float*)0xfffffff8;
14:       result[f][g] += partial_sum;
15:    }
16: }
```

Figure 19: Program modified to use the inner product engine

The profiling result of the modified program is listed as follows in Figure 20. As shown in the figure, the computation part is improved by 88% and results in 66% improvement on the overall performance. The bottleneck of the program is no longer the computation part.

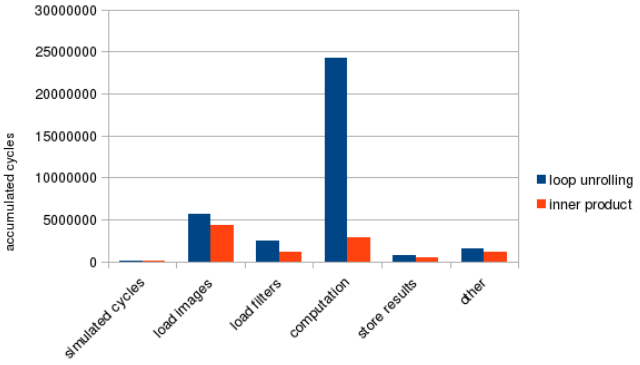

Figure 20: Loop unrolling performance improvement

3.3 Outer Product Engine

In this section, we will discuss an alternative way to accelerate at the computing part. The two inner loops (shown in line 03~09 in Figure 21) can also be viewed as computing the products of each pair of elements in image_pixel[i] and filter_pixel[i]. This operation is called the outer product, which can be represented as multiplying a column matrix with a row matrix as shown in the figure. Inputs to the outer product are two arrays image_pixels[i] and filter_pixel[i], each with length images_per_thread and filters_per_thread. Each element in the first array is multiplied with each element in the second array, producing a total of images_per_thread * filters_per_thread numbers. The outer product is performed cached_pixels * image_features times, and the output of each time is accumulated to produce the partial sums.

```
01: for (int i = 0;  i < cached_pixels * image_features;  i++) {
02:    for (int f = 0; f < filters_per_thread; f++) {
03:       for (int g = 0; g < images_per_thread; g++)
04:       {
05:          result[f][g] += image_pixel[i][g] * filter_pixel[i][f];
06:       }
07:    }
08: }
```

Figure 21: Outer product in the computation loop

We propose an accelerator to speed up the computation of the outer product. The accelerator has at least images_per_thread * filters_per_thread internal registers to store the computed partial sums. It loads two arrays, compute the product of each pair of elements, and accumulate the results to the internal registers. Values of the registers can be read or reset to zero by the program.

$$\begin{bmatrix} a \\ b \\ c \\ d \end{bmatrix} \begin{bmatrix} w & x & y & z \end{bmatrix} = \begin{bmatrix} aw & ax & ay & az \\ bw & bx & by & bz \\ cw & cx & cy & cz \\ dw & dx & dy & dz \end{bmatrix}$$

Figure 22: Outer product

The hardware architecture of the outer product accelerator unit is shown in Figure 23. For each iteration, it loads four elements from image array and one element from filter array

multiply them to a register, and the adder adds previous partial sum to the original register. It consumes four multiplier, one adder and number of image array * filter array registers to save the partial results. Suppose the multiplier requires 1 cycle to produce the result, storing result to register and loading pixel from shared memory also consumes 1 cycle. Then, a 3-stage pipeline can be applied to repeatedly load elements, compute outer product and store results. In our implementation, we model the latency of the outer product unit which assume that the accelerator can load one pixel from the shared memory each cycle. It will need to preload some pixels from the image array before using a 3-stage pipeline, and the number of preloaded pixels depends on image array length. Therefore, we can assume that the total latency of the accelerator is image array length + (2*N)-2 ,where N is the number of elements to compute.

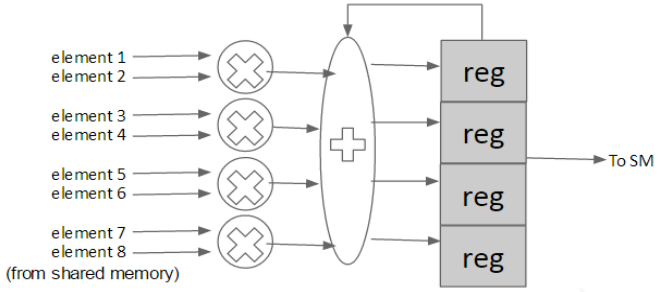

Figure 23: Outer Product Unit

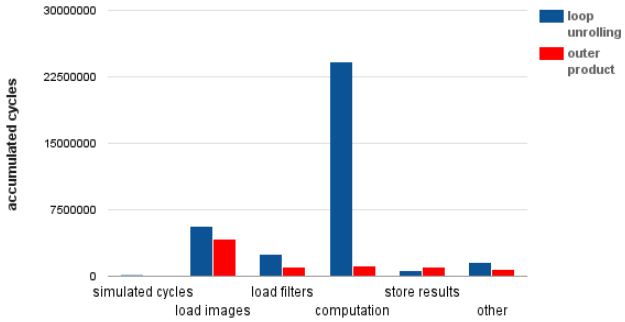

Figure 24: Outer product performance improvement

4. Accelerating Data-Loading

After applying the improvements described in Section IV, the computation part is improved a lot. As illustrated in *Figure 25*, the data-loading part, including loading of images and filters, becomes the bottleneck of the program.

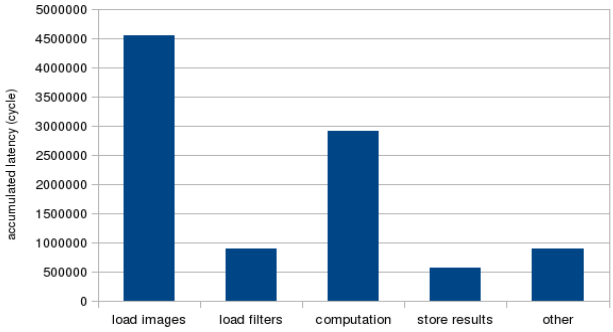

Figure 25: Performance breakdown after improvements

The data-loading part is responsible for loading image and filter pixels from global memory to shared memory. It is composed of deeply nested control structures of loops and conditionals. The control structures themselves also take time to execute, especially for the inner loops. Any subtle overhead inside inner loops can build up and become major bottlenecks. In this section, we propose two software approaches to reduce the overhead inside inner loops. We also propose a hardware accelerator to speed up address calculation in the image-loading part.

4.1 Strength Reduction

One of the major bottlenecks in inner loops is the computation of array indices for each iteration. In the data-loading loops, array indices in inner loops can contain complex arithmetic expressions that translates into larger number of instructions. Because the arithmetic instructions are executed in the inner loops, latencies of them can quickly build up and become a major bottleneck.

Take the program in Figure 26 as an example. To compute the array index for images, it needs to compute two multiplications and two additions for each iteration (line 4). If we work out the total number of operations, we will find that the program needs to carry out image_features * images_per_thread multiplications and additions in total.

```
01: for (f = 0; f < image_features; f++) {
02:    for (i = 0; i < images_per_thread; i++) {
03:       image_pixel[f][i] = images[ base + f * stride + i * threadIdx.x];
04:    }
05: }
```

Figure 26: Arithmetic operation in the inner loop

We propose a method based on strength reduction to improve the performance of this program. This method takes advantage of the fact that some arithmetic operations can be reduced to successive simpler operations. For example, multiplication can be done with repeated addition of the multiplier. Instead of computing the multiplication in each iteration, we can use a separate counter variable idx to accumulate the index throughout the entire loop and update it according to the following rule.

The arithmetic expression for computing the array index can be broken down into 3 parts:

a. loop invariants (terms that does not change throughout the nested loops)
b. multiples of the outer loop counter f
c. multiples of the outer inner loop counter i

Terms belonging to Part a is constant with respect to both the inner and outer loops. Therefore, the term `base` is used to initialize idx before entering the loops. Part b contains the term f * stride, whose value increases by stride whenever f is incremented. Therefore, stride is added to idx at the end of the outer loop. Part c contains the term i * threadIdx.x. The value of this term goes from 0 to (images_per_thread-1) * threadIdx.x in the inner loop and returns to zero again. Therefore, we will first save the value of idx before entering the inner loop, increment idx in each iteration, and restore idx after leaving the inner loop. The resulting program is listed in Figure 27.

```
01: for (int f = 0; f < image_features; f++) {
02:    for (int i = 0; i < images_per_thread; i++) {
03:       if (image_index + i < image_count) {
04:          /* load image `image_index + i` */
05:       }
06:    }
07: }
```

Figure 27: Applying strength reduction

In this transformed program, it only needs to compute one addition for each iteration in the inner loop and one addition for each iteration in the outer loop. In total, we get image_features * (images_per_thread+1) additions. The total number of operations is cut in half compared to the original program, so the modified program should run faster in the data-loading part. Profiling results in Figure 28 supports this prediction by showing that the performance of the image-loading and filter-loading parts are improved significantly. The impact of strength reduction is 25.9% on the overall performance.

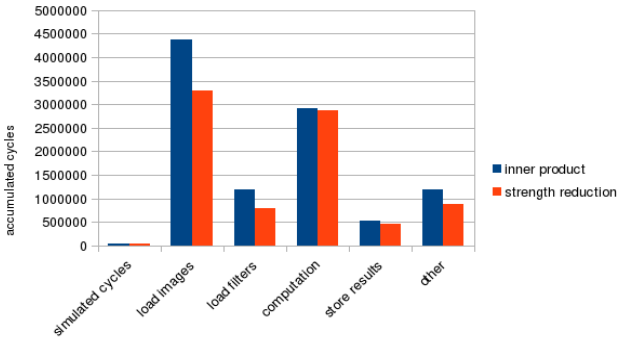

Figure 28: Strength reduction performance improvement

4.2 Extract Conditionals

In addition to strength reduction, we also identified another useful optimization strategy in the data-loading loop. The idea is to prevent unnecessary condition checks in inner loops by checking whether the conditional is necessary in the loop before entering the loop. To illustrate the case, consider the following code snippet taken from the convolution kernel:

```
01: int idx = base;
02: for (f = 0; f < image_features; f++) {
03:    int idx_save = idx;
04:    for (i = 0; i < images_per_thread; i++) {
05:       image_pixel[f][i] = images[idx];
06:       idx += threadIdx.x;
07:    }
08:    idx = idx_save;
09:    idx += stride;
10: }
```

Figure 29: Boundary checking in the data-loading loop

In the inner-most loop, it checks whether the index of image to load (image_index + i) is within bounds and only load the image if so. Because the total number of image is not always a multiple of images_per_thread, the boundary condition check is necessary here to ensure that the index to load is within bounds. However, checking for the boundary condition every time in an inner loop degrades performance. To eliminate redundant checks in inner loops, the loop is duplicated and modified into two variants: one with boundary checking, and the other without them. Without the checking overhead, the one without boundary checking will run faster. The problem we are left with is how to choose between these two variants.

Because the loop variable i is always less than or equal to images_per_thread - 1, image_index + i will always be less than or equal to image_index + images_per_thread - 1. If given image_index + images_per_thread - 1 < image_count, we will automatically get image_index + i < image_count. In other words, if image_index + images_per_thread <= image_count, there is no need to check for the boundary condition. As a result, we will choose the faster loop without boundary checking if image_index + images_per_thread <= image_count, or the slower loop otherwise. The resulting code is listed in Figure 30.

```
01: if (image_index + images_per_thread <= image_count) {
02:   for (int f = 0; f < image_features; f++) {
03:     for (int i = 0; i < images_per_thread; i++)
04:     { // no boundary check
05:       // load image `image_index + i`
06:     }
07:   }
08: } else {
09:   for (int f = 0; f < image_features; f++) {
10:     for (int i = 0; i < images_per_thread; i++)
11:     {
12:       if (image_index + i < image_count)
13:       { // boundary check
14:         // load image `image_index + i`
15:       }
16:     }
17: }
18: }
```

Figure 30: Reduced boundary check code

Profiling result before and after applying this technique is shown in Figure 31. This technique improves the overall performance by 2.6% compared to the previous version using only strength reduction.

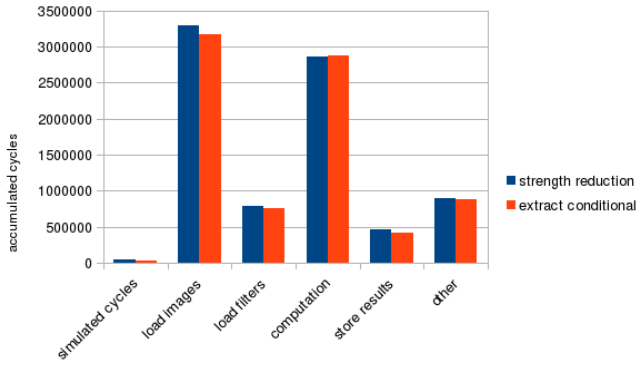

Figure 31: Extract conditionals performance improvement

4.3 Index Conversion Accelerator

In the data-loading part of the convolution kernel, filter and image pixels are loaded to shared memory one after another. Before loading each pixel from global memory, the program must compute the index of the pixel in the input arrays. In each iteration of the loop, the program first loads several filter pixels. While loading the filter, there is no need to compute the index because the loop counter itself represents the index of the filter pixel to load. However, for each filter pixel, it is still necessary to load the corresponding image pixel. Computing the index of image pixels is more involved. Sometimes the filter pixel is placed outside the

image and doesn't overlap with any pixel in the input. When this happens, the loaded image pixel should be set to zero because zero-padding is used outside the edges of the image. If the filter pixel is placed within the image, the filter pixel index should be converted into the image pixel index, which is then used to load the image pixel from global memory.

```
01:for (int p = 0; p < cached_pixels; p += threads_y) {
02:   int pixel_index = pixel + p + threadIdx.y;
03:   int x = image_pixel_x – filter_size / 2 + pixel_index % filter_size;
04:   int y = image_pixel_y - filter_size / 2 + pixel_index / filter_size;
05:   if (y >= 0 && y < image_height && x >= 0 && x < image_width)
06:   {
07:      int image_pixel_index = (y * image_width + x) * image_count;
08:      <load image pixel from image_pixel_index>
09:   } else {
10:     <set image pixel to 0>
11:   }
12: }
```

Figure 32: Index conversion in the data-loading loop

Computing the image pixel index and checking for the boundary condition takes up about 1/3 of the image-loading time. Therefore, we propose adding an accelerator to speed up this two tasks at the same time. Before describing what this accelerator should do, we will first look at the code to convert filter pixel index to image pixel index.

From the code listed above, we can see that there are three steps involved in converting filter pixel index to image filter index. The first step is break down filter pixel index to its x and y component and offset the coordinates by the location of the kernel. Then, boundary check is performed on the (x, y) point to ensure that there is a corresponding pixel in the input. Finally, the (x, y) is converted to the image pixel index. These steps are translated to tens of instructions and slows down the program.

```
01: for (int p = 0; p < cached_pixels; p += threads_y) {
02: <invoke index converter using inline assembly>
03:  // the result is stored in image_pixel_index
04:     if (image_pixel_index >= 0) {
05:     <load image pixel from image_pixel_index>
06:     } else {
07:     <set image pixel to 0>
08:     }
09: }
```

Figure 33: Modified program using the index conversion accelerator

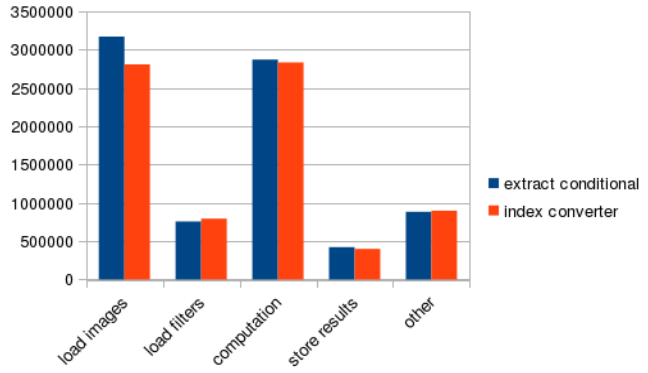

Figure 34: Index converter performance improvement

We propose adding a hardware accelerator to do the index conversion. The accelerator we propose will do the three steps altogether in one instruction. If the (x, y) point is within bounds, it returns the index of the image pixel. Otherwise, it returns -1. We implement the accelerator in GPGPU-sim as an instruction and use inline assembly in the convolution kernel to invoke the instruction. The modified program is listed in Figure 33. The performance improvement of using the index converter is listed in Figure 34. The overall performance is improved by 5%.

5. Related Work

Accelerating convolutional neural networks is a very popular research topic. Accelerators have been developed in different hardware technologies. Eyeriss [9][15] developed by Yu-Hsin Chen et al. is an ASIC CNN accelerator that can run AlexNet at 35fps with only 278mW of power consumption. There are other ASIC accelerators proposed to exploit the redundancy of CNN networks [16][17][18]. Cheng Zhang [10] implemented a CNN accelerator on FPGA and achieved 61.62 GFLOPS under 100MHz clock frequency. He also proposed an analytical design scheme using the roofline model.

The GPGPU is also a widely-used platform for CNN. NVidia developed a software library named cuDNN [2] that uses GPGPU to speed up convolution. When integrated with the Caffe framework, it can improve the performance by up to 36%. However, the cuDNN library is proprietary and cannot be studied by the community. The fbfft library [4] also uses GPGPU to speed up CNN, but it employs a different algorithm (FFT) to compute convolution. Cuda-convnet2 is an efficient implementation of CNN for NVidia GPGPU. It is by far the fastest open-source CNN implementation. However, it lacks analysis on the techniques it uses to improve the performance.

6. Conclusion

This paper describes an implementation of the convolution operation on NVidia GPGPU and analyze the techniques in the implementation. We propose software and hardware enhancements to the program to speed up the computation of partial sums and loading the input data, which are the two major bottlenecks. The experiments have shown that the proposed modifications have achieved 4.4x speedup compared with the baseline implementation.

ABSTRACT

To advance Java programming educations, we have developed the Java Programming Learning Assistant System (JPLAS) that provides the code writing problem. This problem asks a student to write a source code to satisfy the specification of a given assignment, where the correctness is verified by running test code on JUnit. For a novice student, a code of implementing the standard input/output with the exception handling should be mastered at the early stage as the first step programming for human interfaces. However, for a teacher, it is not easy to write the test code for it. In this paper, we propose a test code generation method to generate the test code using the reference source code for the assignment. In the evaluation of this proposal, all the students completed the codes using the generated test codes for exception handling, although the use of exception handling functions was sometimes insufficient or incorrect.

1 Introduction

Recently, the objected oriented programming language *Java* has been widely used in various practical application systems in societies and industries due to the high reliability, portability, and scalability. Java was selected as the most popular programming language in 2015 [2]. Therefore, there have been strong demands from industries for Java programming educations. Correspondingly, a plenty of universities and professional schools are currently offering Java programming courses to meet this challenge. A typical Java programming course consists of grammar instructions in the class and programming exercises in computer operations.

To advance Java programming educations, we have developed the Web-based *Java Programming Learning Assistant System (JPLAS)* [3]-[7]. JPLAS inspires students by offering sophisticated learning environments via quick responses to their answers for self-studies. At the same time, it supports teachers by reducing loads of evaluating codes. JPLAS has several types of problems to cover a variety of students at different learning levels. Among them, the *code writing problem* [4] asks a student to write a source code to satisfy the specification of a given assignment.

The *code writing problem* is implemented based on the *test-driven development (TDD) method* [8], using an open source framework *JUnit* [9]. *JUnit* automatically tests the codes on the server to verify their correctness using the *test code* when they are submitted by students. Thus, students can repeat the cycle of writing, testing, modifying, and resubmitting codes by themselves, until they can complete the correct codes for the assignments.

To register a new assignment for the code writing problem in JPLAS, a teacher has to prepare a *problem statement* describing the code specification, a *reference source code*, and a *test code* using a Web browser. It is noted that the reference source code is essential to verify the correctness of the problem statement and the test code. Then, a student should write a source code for the assignment while referring the statement and the test code, so that the source code can be tested by using the given test code on *JUnit*.

However, teachers at schools are not accustomed to writing a test code that can run on *JUnit*. A teacher may spend much time in struggling to write a test code, and may

[*]Nobuo Funabiki, Department of Electrical and Communication Engineering, Okayama University, Okayama, Japan, funabiki@okayama-u.ac.jp
This paper is an extension of work originally presented in 31st IEEE International Conference on Advanced Information Networking and Applications (AINA-2017) [1]

https://dx.doi.org/10.25046/aj030105

register an incomplete test code that does not verify some requirements described in the problem statement correctly. This incomplete test code must be avoided because it may produce inappropriate feedback to a student and undermine confidence to JPLAS. On the other hand, a commercial tool for generating a test code is usually expensive, and may not cover a test code that verifies the standard input/output with exception handling in a source code. The code of implementing the standard input/output with exception handling should be mastered by novice students at the early stage of Java programming educations as the first step programming for human interfaces.

In this paper, we propose a *test code generation method* for the code writing problem in JPLAS that generates a test code using a reference source code to test the standard input/output with exception handling. This method can generate a test code through the following steps: 1) a *test code template* is provided by our proposal, 2) a set of standard inputs to be tested are made by a teacher, 3) by running the reference code with each input, the corresponding expected standard output is extracted correctly, and 4) this pair of the standard input and the standard output are embedded into the test code template. By repeating steps 3) and 4) for every test standard input, the test code can be completed. To run the source code using the test code on *JUnit*, it introduces the classes to handle the standard input/output functions as the memory access functions in [10].

To evaluate the proposed method, first, we applied it to 97 source codes in Java programming textbooks or Web sites that contain the standard input/output. It has been proved that the generated test codes could correctly verify the source codes except for one code using a random generator. Then, we generated the test codes for three problems and asked five students who are currently studying Java programming to write the source codes using them. It was found that they completed the codes that can pass the test codes, whereas the use of exception handling functions was sometimes insufficient or incorrect.

The rest of this paper is organized as follows: Sections 2 and 3 introduce the TDD method and JPLAS respectively. Section 4 presents the test code generation method. Section 5 shows the evaluation result. Sections 6 shows related works. Finally, Section 7 concludes this paper with some future works.

2 Test-driven Development Method

In this section, we introduce the test-driven development method along with its features.

2.1 Outline of TDD Method

In the TDD method, the test code should be written before or while the source code is implemented, so that it can verify whether the current source code satisfies the required specifications during its development process. The basic cycle in the TDD method is as follows:

1) to write the test code to test each required specification,
2) to write the source code, and
3) to repeat modifications of the source code until it passes each test using the test code.

2.2 JUnit

In JPLAS, we adopt *JUnit* as an open-source Java framework to support the TDD method. *JUnit* can assist the unit test of a Java code unit or a *class*. Because *JUnit* has been designed with the Java-user friendly style, its use including the test code programming is less challenging for Java programmers. In *JUnit*, a test is performed by using a given method whose name starts from *assert*. This paper adopts the *assertThat* method to compare the execution result of the source code with its expected value.

2.3 Test Code

A test code should be written using libraries in *JUnit*. Here, by using the following **source code 1** for *MyMath* class, we explain how to write a test code. *MyMath* class returns the summation of two integer arguments.

source code 1

```
1  public class Math {
2    public int plus(int a, int b) {
3      return( a + b );
4    }
5  }
```

Then, the following **test code 1** can test the *plus* method in the *MyMath* class.

test code 1

```
1  import static org.junit.Assert.*;
2  import org.junit.Test;
3  public class MathTest {
4    @Test
5    public void testPlus() {
6      Math ma = new Math();
7      int result = ma.plus(1, 4);
8      assertThat(5, is(result));
9    }
10 }
```

The names in the test code should be related to those in the source code so that their correspondence becomes clear:

- The class name is given by the *test class name + Test*.
- The method name is given by the *test + test method name*.

The test code imports *JUnit* packages containing test methods at lines 1 and 2, and declares *MathTest* at line 3. *@Test* at line 4 indicates that the succeeding method represents the test method. Then, it describes the test method.

The test code performs the following functions:

1) to generate an instance for the *MyMath* class,
2) to call the method in the instance in 1) using the given arguments,
3) to compare the result with its expected value for the arguments in 2) using the *assertThat* method, where the first argument represents the expected value and the second one does the output data from the method in the source code under test.

2.4 Features in TDD Method

In the TDD method, the following features can be observed:

1. The test code can represent the specifications of the source code, because it must describe the function tested in the source code.
2. The test process for a source code becomes efficient, because each function can be tested individually.
3. The refactoring process of a source code becomes effective, because the modified code can be tested instantly.

Therefore, to study the TDD method and writing a test code is useful even for students, where the test code is equivalent to the source code specification. Besides, students should experience the software test that has become important in software companies.

3 Java Programming Learning Assistant System

In this section, we review the outline of our Java programming learning system *JPLAS*.

3.1 Server Platform

JPLAS is implemented as a Web application using *JSP/-Java*. For the server platform, it adopts the operating system *Linux*, the Web server *Apache*, the application server *Tomcat*, and the database system *MySQL*, as shown in Figure 1. For the browser, it assumes the use of *Firefox* with *HTML*, *CSS*, and *JavaScript*.

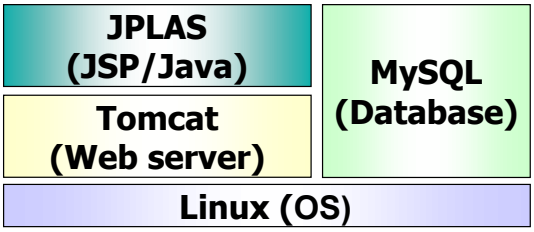

Figure 1: JPLAS server platform.

3.2 Teacher Service Functions

JPLAS has user functions both for teachers and students. *Teacher service functions* include the registration of courses, the registration and management of assignments, and the verification of source codes that are submitted by students. To register a new assignment, a teacher needs to input an assignment title, a problem statement, a reference (model) source code, and a test code. After the registration, they are disclosed to the students except for the source code. Note that the test code must be able to test the model code correctly. Using the correspondence between a source code and a test code in Section 2.3, it is possible to automatically generate a template for the test code from the source code. Then, a teacher merely needs to specify concrete values for the arguments in each test method to complete the test code.

To evaluate the difficulty of assignments and the comprehension of students, a teacher can refer to the number of submissions for code testing from each student. If a teacher finds an assignment with plenty of submissions, it can be considered as quite difficult for the students, and should be changed to an easier one. If a teacher finds a student who submitted codes in many times whereas other students did in a few times, this student may require additional assistance from the teacher.

3.3 Student Service Functions

Student service functions include the view of the assignments and the submission of source codes for the assignments. A student should write a source code for an assignment by referring the problem statement and the test code. It is requested to use the class/method names, the types, and the argument setting specified in the test code. JPLAS implements a Web-based source code editor called *CodePress* [11] so that a student can write codes on a Web browser. All submitted source codes will be stored in the database on the server as a reference for students.

4 Proposal of Test Code Generation Method

In this section, we propose the test code generation method for coding the standard input/output with exception handling.

4.1 Scope of Source Code under Test

At the early stage of the Java programming education, the responsibility of a student is to master how to write a source code that contains the standard input/output with exception handling. Thus, a teacher in a Java programming course should prepare a considerable number of assignments for writing source codes containing them, where many Java programming textbooks offer such assignments for novice students.

The source code in this paper must contain the functions for the standard input/output and the exception handling. Then, if the proper data is given to the code from the standard input, it must handle it correctly and outputs the message specified in the assignment to the standard output. On the other hand, if the improper data is given, it must handle it using the exception handling command without abortion and outputs the corresponding message.

4.2 Requirements in Test Code

Subsequently, the test code must satisfy the following requirements:

1. The input data from the standard input (keyboard) must be described in the test code to test the standard input in the source code.
2. The output data to the standard output (console) must be received by the test code to test the standard output in the source code.

3. The input data must be elaborated in the test code for the standard input.

4. The input data in the test code should cover any possible one for the standard input, including the proper and improper ones.

5. The expected output data for each input data must be narrated in the test code correctly.

4.3 Solutions for Requirements

Test code generation method adopts following functions and commands to solve the above mentioned requirements by referring the test code implementation in [10]:

- To describe the standard input data to the source code, the *Inputln* method in *StandardInputSnatcher* class is adopted in the test code. It is noted that *StandardInputSnatcher* class is extended from *InputStream* class.

- To receive the standard output data from the source code, the *readLine* method in *StandardOutputSnatcher* class is adopted in the test code. It is noted that *StandardOutputSnatcher* class is extended from *PrintStream* class.

- Any possible standard input data is prepared by a teacher beforehand. It is used in the argument of *Inputln*.

- To obtain the expected standard output data from the code for each input data, the reference source code is executed with this input data.

- Each pair of the standard input and output data is embedded into the test code.

4.4 Conditions of Source Code

Currently, to avoid the complexity, the proposed method confines the applicable source code that satisfies the following conditions:

1. it has the *main* method only.

2. it contains the standard input function.

3. it contains the standard output function for handling the proper input.

4. it contains the standard output function for handling the exception.

It is noted that a source code containing multiple standard input/output functions can be handled by increasing the number of *Inputln* or *assertThat* in the test code accordingly. Besides, if a code does not have the *main* method, it can be handled by describing the proper statements to execute the method for the standard input/output in the test code.

An example source code in this scope is as follows:

source code 2

```
1  import java.util.Scanner;
2  public class Sample {
3    public static void main(String args[]){
4      int number;
5      Scanner scan = new Scanner(System.in);
6      try{
7        System.out.print("Enter an integer");
8        String actual = scan.nextLine();
9        number = Integer.parseInt(actual);
10       System.out.println(number +": is input
         number");
11     } catch(NumberFormatException e) {
12       System.out.print("
         NumberFormatException occurs!");
13     }
14   }
15 }
```

source 2 accepts an integer data from a console and outputs a message with this data on a display. In this source code, 1) it has only the *main* method at line 3, 2) *scan* object of *Scanner* class is defined at line 5 as the standard input function, 3) *System.out.println* is called at line 10 as the standard output function for handling the proper input, and 4) *System.out.println* is called at line 12 as the standard output function for handling the exception.

4.5 Test Code Template

Then, the proposed method provides the *test code template* containing the required functions for the above mentioned source code. The following code describes the core part of the test code template starting from *@Test*. In advance, several *import* statements to use related libraries, and the instance generations for the *StandardInputSnatcher* and *StandardOutputSnatcher* classes are necessary. Besides, the definitions of these classes are also required to complete the test code template.

In this template, *in.Inputln* at line 29 gives the standard input data to the source code, where *in* is an instance of *StandardInputSnatcher* class. The statements at lines 30-37 run the source code and read the standard output data for this input data, where *out* is an instance of *StandardOutputSnatcher* class. *expected* at line 38 represents the expected output data of the source code. The blanks ″ ″ at lines 29 and 38 should be filled by the standard input and output data. *assertThat* at line 39 compares the expected data with the output data of the code. The whole statements at lines 25-40 should be prepared for each input data.

test code template

```
1  import static org.hamcrest.CoreMatchers.is;
2  import static org.junit.Assert.assertThat;
3  import static org.junit.Assert.*;
4  import java.io.InputStream;
5  import org.junit.Before;
6  import org.junit.Test;
7  import Snatcher.StandardOutputSnatcher;
8  import java.io.BufferedReader;
9  import java.io.ByteArrayOutputStream;
10 import java.io.IOException;
11 import java.io.InputStream;
12 import java.io.PrintStream;
13 import java.io.StringReader;
14
15 public class TemplateTest {
16   private StandardInputSnatcher in = new
       StandardInputSnatcher();
```

```
17      private StandardOutputSnatcher out = new
            StandardOutputSnatcher();
18
19      @Before
20      public void setUp() {
21        System.setIn(in);
22        System.setOut(out);
23      }
24
25      @Test
26      public void test1() throws Exception {
27        StringBuffer bf = new StringBuffer();
28        String actual,line,expected;
29        in.Inputln(""); // standard input
30        Sample.main(new String[0]);
31        System.out.flush();
32        while((line = out.readLine()) != null) {
33          if (bf.length() > 0)
34          bf.append("\n");
35          bf.append(line);
36        }
37        actual = bf.toString();
38        expected = ""; // expected standard output
39        assertThat(actual,is(expected));
40      }
41    }
```

4.6 Test Code Generation Procedure

The test code generation procedure using the *test code template* in the proposed method is as follows:

1) A teacher prepares the reference source code for the assignment.

2) He/she prepares a set of possible standard input data to the source code.

3) He/she runs the source code by using each standard input data and observes the corresponding standard output data.

4) He/she embeds the standard input data into ″ ″ at line 29 and the observed standard output data into ″ ″ at line 38 in the test code template.

As the possible standard input data in step 2), the following five data types should be considered. Then, the teacher needs to select one value for each data type, which is used in step 3).

- positive integer: 5
- negative integer: -14
- zero integer: 0
- floating-point number: 0.5
- one-byte character: abc
- two-byte character: A B C

4.7 Generated Test Code Example

This subsection introduces an example of the test code generated by applying the proposed method to **source code 2**. The file name for the generated test code is given as *SampleTest.java*. The following **test code 2** shows a part of the test code.

test code2

```
1   .....
2
3     @Test
4     public void test1() throws Exception {
5       StringBuffer bf = new StringBuffer();
6       String actual,line,expected;
7       in.Inputln("5"); // proper standard input data
8       Sample.main(new String[0]);
9       System.out.flush();
10      while((line = out.readLine()) != null) {
11        if (bf.length() > 0)
12        bf.append("\n");
13        bf.append(line);
14      }
15      actual = bf.toString();
16      expected = "Enter an integer" +
17       "5: is input number";
18      assertThat(actual,is(expected));
19    }
20
21    @Test
22    public void test2() throws Exception {
23      StringBuffer bf = new StringBuffer();
24      String actual,line,expected;
25      in.Inputln("abc"); // improper standard input
          data
26      Sample.main(new String[0]);
27      System.out.flush();
28      while((line = out.readLine()) != null) {
29        if (bf.length() > 0)
30        bf.append("\n");
31        bf.append(line);
32      }
33      actual = bf.toString();
34      expected = "Enter an integer" + "
          NumberFormatException occurs!";
35      assertThat(actual,is(expected));
36    }
37  .....
```

5 Evaluation

In this section, we evaluate the effectiveness of the proposed *test code generation method* in terms of generating test codes from existing source codes and writing source codes using the test codes by students.

5.1 Test Code Generation Results

First, we evaluate the method in generating test codes from source codes. For this purpose, 97 source codes were collected from Java programming textbooks or Web sites [12]-[16], and the test codes were generated by applying the proposed method. It is noted that some codes in [15] were modified to using the standard input/output through the console instead of using the dialog box. Then, the correctness of each test code was examined by testing the original source code. It was found that our method generated the test codes that can pass original codes correctly except for one source code, which outputs a random number generated in the code. Thus, the effectiveness of the proposed method was confirmed.

The following **source code 3** shows an example source code in [12] where the method successfully generates the test code shown in **test code 3**. It is noted that *try - catch* is used here instead of *throws* in the original source code.

source code 3

```
1  import java.io.*;
2  class Sample3 {
3    public static void main(String[] args) throws
       IOException {
4      try {
5        System.out.println("Enter two integers
         ");
6        BufferedReader br =
7          new BufferedReader(new
         InputStreamReader(System.in));
8        String str1 = br.readLine();
9        String str2 = br.readLine();
10       int num1 = Integer.parseInt(str1);
11       int num2 = Integer.parseInt(str2);
12       System.out.println("The sum is " + (
         num1+num2) + ".");
13     } catch(NumberFormatException e) {
14       System.out.print("
         NumberFormatException occurs!");
15     }
16   }
17 }
```

test code3

```
1  .....
2
3    @Test
4    public void test1() throws Exception {
5      StringBuffer bf = new StringBuffer();
6      String actual,line,expected;
7      in.Inputln("2"); in.Inputln("7");// proper
         standard input data
8      Sample.main(new String[0]);
9      System.out.flush();
10     while((line = out.readLine()) != null) {
11       if (bf.length() > 0)
12       bf.append("\n");
13       bf.append(line);
14     }
15     actual = bf.toString();
16     expected = "Enter two integers" +"The
         sum is 9.";
17     assertThat(actual,is(expected));
18   }
19
20   @Test
21   public void test2() throws Exception {
22     StringBuffer bf = new StringBuffer();
23     String actual,line,expected;
24     in.Inputln("0.5"); in.Inputln("-3");//
         improper standard input data
25     Sample.main(new String[0]);
26     System.out.flush();
27     while((line = out.readLine()) != null) {
28       if (bf.length() > 0)
29       bf.append("\n");
30       bf.append(line);
31     }
32     actual = bf.toString();
33     expected = "Enter two integers" + "
         NumberFormatException occurs!";
34     assertThat(actual,is(expected));
35   }
36 .....
```

5.2 Source Code Writing Results

Next, we evaluate the proposed method in writing source codes with generated test codes by five students who are currently studying Java programming and have same technical levels. For this purpose, we prepared the following three problems, where all the students completed the source codes that pass the test codes for any problem.

5.2.1 Problem #1

In problem #1, the code accepts an integer data from a console, and outputs a message with this data to a console, where **source 2** is the reference source code and **test 2** is the test code. The source code from a student is expected to use *NumberFormatException* to check the input data format. Then, three students use this class for the exception handling, and one uses *Exception*. However, one student does not use it where he implements the data format checking function.

5.2.2 Problem #2

In problem #2, the code accepts an integer index from a console, and outputs the indexed data from the data array. The student code is expected to use *ArrayIndexOutofBoundException* to check the range of the index. Then, only one student uses this class. The other students implement the index checking function in the codes. Two students use *IOException*, and two students do not use any class for the exception handling. No student use *NumberFormatException* to check the input data format, although the class was requested in problem #1. Unfortunately, many students cannot integrate the knowledge that has been studied sequentially.

5.2.3 Problem #3

In problem #3, the code accepts a file path from a console, and outputs the string at the first line in the file. The student code is expected to use *FileNotFoundException* or *IOException* to check the file path. Then, three students use *FileNotFoundException*, one uses *Exception*, and one uses *IOException*.

5.2.4 Summary of Student Applications

This simple experiment of our proposal shows that the students can generally complete source codes using standard input/output with exception handling that can pass the generated test codes. However, their use of the class for the exception handling is sometimes insufficient or incorrect. It has been observed that these students are not experts, which causes the difference in their source codes, although they have enough programming skills. To let them understand the correct use, it is necessary to improve the proposed method.

6 Related Works

In this section, we introduce some related works to this paper.

In [17], Fu presented a static exception-flow analysis that computes chains of semantically-related exception-flow links and reports entire exception propagation paths. These chains can be used, 1) to show the error handling architecture of a system, 2) to assess the vulnerability of a single component and the whole system, 3) to support the better testing of an error recovery code, and 4) to facilitate the tracing of the root cause of a logged problem.

In [18], Rashkovits showed that most of college students understand the concept of Java exception handling at the basic level, and the majority of them have difficulty in understanding advanced properties such as use of multiple exceptions, flow of control in the context of exceptions, handling exceptions further up the calling chain, catching and handling hierarchically related exceptions, and overriding methods that throw exceptions. They also provided a tutorial of exception handling, and quoted that exception handling is perceived as a relatively difficult task by novice programmers. In future works, we will consider to adopt their contributions.

In [19], Júnior presented a practical approach to preserve the *exception policy* in a system by automatically checking *exception handling design rules*. They are checked through executions of *JUnit* test cases with *dynamic mock objects* that are generated by the supporting tool. Four versions of *Mobile Media in SPL* were used to evaluate whether the policy was preserved or not. The results show that the approach can effectively detect violations on the policy of software product lines.

In [20], Nakshatri presented an empirical study of exception handling patterns in Java projects. It forces developers to think in sophisticated ways to handle the exceptions. In this study, empirical data was extracted from projects by analyzing data in *GitHub* and *SourceForge* repositories. The results were compared with recommendations for best practices in exception handling presented by Bloch [21]. It has been observed that most programmers ignore checking exceptions, and higher classes in the exception class hierarchy are more frequently used.

In [22], Brunet presented the concept of *design test* that automatically checks whether the code conforms to the specific *design rule* by using a test-like program. To support it, *DesignWizard (DW)* had been developed with a fully-fledged API that allows writing design tests for Java codes using *JUnit*. The proposal was applied to three software products in their group and student projects in the undergraduate course. The results showed that this approach was suitable to check conformance between the design rules and the code implementation. Moreover, it has been observed that both designers and programmers appreciated the design tests as executable documents that can be easily kept up to date.

In [23], Akahane presented a Web-based *automatic scoring system* for Java programming assignments to reduce loads of teachers in verifying a huge number of codes and in giving feedbacks to students. The system receives Java application programs submitted by students, and immediately returns the results of *JUnit* tests where the *Java Reflect API* is adopted for testing private classes and methods that have been commonly found in introductory courses. The regular expression is used to compare the output texts of each student program and those of the reference program. Through use in an actual course in their university, it was confirmed that this system was very helpful for students to improve programming skills by correcting mistakes in their programs and repeating their submissions.

In [24], Kitaya presented a Web-based scoring system of programming assignments to students, which is similar to JPLAS. Their test consists of compiler check, *JUnit* test, and result test. The result test verifies the correctness of a student code composed of only the *main* method that reads/writes data from/to the standard input/output devices, by comparing the results of this code and of the reference code. However, the method has several disadvantages from our proposal: 1) it is only applicable to a code composed of the *main* method with the standard input/output, 2) it uses other programs to use the redirection for handling the standard input/output, and 3) it needs several input files to check the correctness for different input data. On the other hand, our method is applicable to a code containing other than the *main* method, it needs only *JUnit* with a test code, and all the input data can be described in a single test code.

7 Conclusion

In this paper, we proposed the *test code generation method* for the code writing problem in JPLAS that requires implementing a Java source code containing the *standard input/output* with *exception handling*. To access the standard input/output from the test code on *JUnit*, the *test code template* is first prepared with the *input/output snatcher classes*. Then, the test code is completed by embedding the input and output extracted by running the *reference source code* into the template. This proposal is helpful in reducing the teacher load in writing the test code for the programming assignment that requires the standard input/output with exception handling, which is common for novice students. The effectiveness is evaluated through applying the method to 97 source codes in Java programming text books or Web sites, and asking five students to write source codes using the generated test codes for three problems. In future works, we will extend the proposed method to handle other input/output functions, other methods than the *main* method, and improve the readability of the generated test code to make it easier for novice students.

ABSTRACT

Ensuring the compliance of developed software with general and application-specific security requirements is a challenging task due to the lack of automatic and formal means to lead this verification. In this paper, we present our approach that aims at integrating the formal specification and verification of security guidelines in early stages of the development lifecycle by combining both the model checking analysis together with information flow analysis. We present our framework that is based on an extension of LTS (labelled transition Systems) by data dependence information to cover the end-to-end specification and verification of security guidelines.

1 Introduction

This paper is an extension of work originally presented in Pacific Rim International Symposium on Dependable Computing (PRDC 2017) [1]. About 64% of the 2500+ vulnerabilities in the National Vulnerability Database NVD were due to programming mistakes [2], and the majority of software vulnerabilities are caused by coding errors. Flaws and errors can be introduced during the different phases of the software development lifecycle, from design to development. The missed programming errors can turn into security vulnerabilities at run-time, and can be exploited by intruders who may cause serious damage to the software critical assets and resources. The undetected flaws can cause a cost increase, comprising maintenance and flaw correction fees. Using code analysis tools would avoid such issues and help produce safe and secure software. The last decades have witnessed the development of many analysis techniques that aim at detecting security vulnerabilities in the early stages of development lifecycle; however, most attention was devoted to control-flow, somehow ignoring the data dependencies source of vulnerabilities that can remain undetected.

On the one hand, it is important for developers to be aware of domain-specific requirements as failure to pass the verification and validation phase, and subsequent application corrections and maintenance may be costly, time-consuming, and affect the company's reputation. On the other hand, security guidelines should be expressed in a way that allows their understanding and easy implementation for developers who may not be security experts to develop and deliver secure software.

Security guidelines or security best practices serve as recommendations to developers to reduce the application exposure to security issues, and to ensure that the developed system will behave as expected in hostile environments.

The problems described above entail the need to add on top of the development process different types of verification such as the compliance with the general and application-specific security requirements. Applying formal methods in the different phases of the software engineering process can help further understanding of the system, and detect design flaws rather early in the development.

In our papers [3,4] we conducted a survey on the static code analysis methods with the objective of identifying the approach that best fits our needs in terms of information flow properties detection and

[*]Corresponding Author: Zeineb Zhioua, zeineb.zhioua@eurecom.fr

https://dx.doi.org/10.25046/aj030106

validation, as well as on the system abstraction models that constitute a strong basis in order to carry out the analysis.

The main problem we are tackling in this paper is how to automatically verify the systematic application and compliance of (being) developed software with security requirements expressed in natural language. This problem requires the transformation of the guidelines written informally into a precise formalism by security expert(s), and this is a very tedious task. Nowadays, formal methods, in particular formal verification, are increasingly being used to enforce security and safety of programs.

We propose a framework that first provides security experts with the means to express security guidelines in a more formal way than plain text. Then, our framework verifies the adherence to the guidelines over an abstraction of the program, and provides understandable and clear feedback to the developer to indicate the exact program location where the error occurred. The innovation of our framework relies on the combination between model checking and data dependencies together with the analysis of the system behavior without actually executing it. We focus on the current version of our framework on the Java programming language.

Below we provide a sample code (Figure 1) that presents an implicit violation of the guideline from the *OWASP Cryptographic Storage Cheat Sheet* [4]:"Store unencrypted keys away from the encrypted data" [1] explaining the encountered risks when the encryption key is stored in the same location as the encrypted data. If we want to verify if the code below meets this guideline or not, then we have first to annotate the sources and the sinks, and run the analysis. We need first to highlight several elements in the codes below; the data key *k* and *encrypted_cc* are stored respectively in file **keys.txt** and **encrypted_cards.txt**. One may conclude that the guideline is met, as key *k* and *encrypted_cc* are stored in separate files. However, the two files are located in the same file system, which constitutes a violation of the guideline. Let us look at the details of the code. The developer encrypts the secret data credit card number, and stores the cipher text into a file. At line 115, the developer creates a byte array *y* used as parameter for the instantiation of a SecretKeySpec named *k* (line 116). At line 119, the key *k* is stored in a file, through the invocation of method *save_to_file* (Figure 1). Once created, key *k* is provided as parameter to the method *save_to_file(String data, String file)* (Figure 1) The developer then encrypts the secret variable creditCardNumber using method *private static byte[] encrypt(Key k, String text)* which uses key *k* as parameter. The encrypted data is then stored using method *save_to_file(String data, String file)* (Figure 1). One can conclude that the guideline is met, as key *k* and *encypted_cc* are stored in separate files. But if we take a closer look, we would notice that the two files are located in the same file system. Hence, the code violated the guideline.

In this paper, we go through the approach that we propose in order to help solving the difficulty of capturing implicit and subtle dependencies that can be source of security guidelines violations.

```
106  public static void main(String[] args)
107      throws NoSuchAlgorithmException,
108      NoSuchProviderException,
109      FileNotFoundException {
110  int c = 123456;
111  Payment p = new Payment();
112  p.setCreditCardNumber(c);
113
114  String x = "0xe04fd020ea3a6910a2d808002b30309d";
115  byte[] y = hexStringToByteArray(x);
116  SecretKeySpec k = new SecretKeySpec(y, "AES");
117
118  // save
119  save_to_file(k,"C:/[redacted]"
120      + "//[redacted]//src//secGuidelines//keys.txt");
121
122  // encrypted data
123  byte[] encrypted_cc = encrypt(k, Integer.toString
124      (p.getCreditCardNumber()));
125
126  // save
127  save_to_file(encrypted_cc,"C:/[redacted]"
128   + "//[redacted]//src//secGuidelines//encrypted_cards.txt");
129  }
```

The flow of this paper is as follows: Section 2 introduces the security guidelines and discusses the motivation behind this work. In Section 3, we explain in detail the approach we carried out. We highlight several issues related with the guidelines presentation to developers in Section 4. In Section 5, we introduce the notion of information flow analysis that we make use of in our framework for the detection of implicit dependencies. In Section 6, we present our model construction methodology. We provide in Section 7 a comprehensive application of our formalism to specify and to verify the selected guideline. In section 8, we outline the related work, followed by a discussion in Section 9. And finally, Section 10 concludes the paper and discusses future work.

2 Security Guidelines

Organizations and companies define non-functional security requirements to be applied by software developers, and those requirements are generally abstract and high-level. Security requirements such as confidentiality and integrity are abstract, and their application requires defining explicit guidelines to be followed in order to meet the requirements. Security guidelines describe bad as well as good programming practices that can provide guidance and support to the developer in ensuring the quality of his developed software with respect to the security aspect, and hence, to reduce the program exposure to vulnerabilities when delivered and running on the customer platform (on premise or in the cloud). Bad programming practices define the negative code patterns to be avoided, and that can lead to exploitable vulnerabilities, while good programming practices represent the recommended code patterns to be applied on the code.

Official sources, such as OWASP [5], Oracle [6], CERT [7], NSA [8], NIST [9] propose rules and examples of good/bad programming practices. The presentation of the security guidelines differ from one source to another. For instance, CERT Oracle Coding Standard for Java [7] provides for each guideline a textual description, followed by a compliant sample code, and another sample code violating the guideline. OWASP [5] provides for most guidelines a detailed description, and examples of compliant and non-compliant solutions.

Motivation The OWASP Foundation[5] for instance introduces a set of guidelines and rules to be followed in order to protect data at rest. However, the guidelines are presented in an informal style, and their interpretation and implementation require security expertise, as stressed in [3]. In the *OWASP Storage Cheat Sheet* [5], OWASP introduces the guideline "Store unencrypted keys away from the encrypted data" [5] explaining the encountered risks when the encryption key is stored in the same location as encrypted data. This guideline recommends not to store encrypted together with the encryption key, as this operation can result in a compromise for both the sensitive data and the encryption keys. However, encryption keys can be declared as byte arrays with insignificant names, which makes their identification as secret and sensitive data very difficult.

Correctly applying this guideline would provide a strong protection mechanism against this attack scenario: an attacker can get access to the encryption server or client, and can retrieve the encrypted data with the encryption key. Fetching those two elements allows the deciphering of the encrypted sensitive information. This reminds the well known HeartBleed[2] [10] attack that occurred couple of years ago (April 2014), and that allowed an attacker to read the memory, steal users credentials directly from the systems protected by the vulnerable version of OpenSSL. This example emphasizes the critical attacks that can be performed if the guideline is not respected. OWASP provides a set of security guidelines that should be met by developers, but does not provide the means to ensure their correct implementation. We aim at covering this gap through the formal specification of security guidelines and their formal verification using formal proofs.

In the sample code that we provided in Section 1, we showed how we could implicitly violate the guideline. Detecting this violation is not trivial, as it includes subtle dependencies that should be analyzed with due consideration. This is the main objective of this paper, and we could achieve this through the approach that we depict in details in the next Section.

3 Approach

In this section, we go through the details of our approach that aims at filling the gap between the informal description of security guidelines presented in natural language, and their automatic verification on the code level to provide precise and comprehensive feedback to the developer.

We started first by doing attempts to extract security properties from the code level, but we found out that we needed to have a reference against which we can compare the extracted program parts. This brought the idea of performing a deep survey on the guidelines that we gathered from different sources, as explained in Section 4.

The positive (resp. negative) security guidelines serve to express the desired (resp. undesired) program behavior. However, we operate on the code level, meaning that we do not monitor the program execution. We need then to approximate the program behavior but still from a static point of view. This requires that we transform the program into a formal model that allows us to exploit its properties, and approximate its behavior. In addition, the program model that we construct should be able to represent the whole flow of information in order to be able to reason about how data propagates, and capture possible information leakage. This induces the need to choose a formalism to represent the information flows that can be checked over this program model. Having covered the aforementioned aspects, we proceed to verify whether the program meets the specified guidelines or not. As we aim to decrease considerably the heavy load on the developer, we propose an automatic formal verification of the guidelines. The purpose is to verify that security guidelines are met, and not to prove that the program is correct. To the best of our knowledge, no prior work has filled in this gap between the informal description of security guidelines and their automatic formal verification on the code level.

[2] http://heartbleed.com/

The big picture of the proposed approach is shown in Figure 3, highlighting the relevant steps towards fulfilling the transformation of security guidelines written in natural language into exploitable formulas that can be automatically verified over the program to analyze.

The crucial part of the work is the explicit mapping between abstract security guidelines formal specification, and concrete statements on the code.

In order to make the process more concrete, a *separation of duties* needs to be made. We make the distinction between the *security expert* and the *developer*. The former carries out the formal specification of the security guidelines and their translation from natural language to formulas and patterns. He establishes also the mapping between the abstract labels and possible Java language instructions. The latter invokes the framework that makes use of this specification to make the mapping between abstract labels and the program logic, and then to verify the compliance of his developed software with the security requirement.

The idea we propose, as depicted in Figure 3, is the following:

3.1 Formal Specification of Security Guidelines

Starting from the guidelines presented in an informal manner, we make the strong assumption that the **security expert** formally specifies the security guidelines by extracting the key elements, and builds the formulas or patterns based on formalism. The established formulas or patterns can be supported by standard model checking tools. We present in Section 7 how the guideline that we consider in this paper can be modeled in a formalism, and can be formally verified using a model checking tool.

3.2 Program Model Construction

Choosing a program representation depends on the intended application. In our case, the program should be abstracted in a way that preserves its properties, such as the explicit and the implicit dependencies, hence allowing the performance of deep information flow analysis. In our framework, we have chosen the Program Dependence Graph (PDG) (see section 6) as the representation model, for its ability to represent both control and data dependencies. The generated PDG is then augmented with details and information extracted from the formulas and patterns of the security guidelines. We performed Information Flow Analysis over the constructed PDG in order to augment it with further security-related details. This analysis aims at capturing the different dependencies that may occur between the different PDG nodes, hence, augmenting the generated PDG with relevant details, such as annotations mapping the PDG nodes to abstract labels of the security guidelines. Then, we generate form the augmented PDG, a Labelled Transition System tha is accepted by model checking tools.

3.3 Verification

As previously mentioned, security guidelines will be modeled in the form of sequence of atomic propositions or statements representing the behavior of the system. The security guidelines will then be verified over the Labelled Transition System that we generate from the PDG augmented with implicit and subtle dependencies. The verification phase can have the following outcomes:

- The security guideline is valid over all the feasible paths
- The security guideline is violated

The first case can be advanced further, meaning that the verification can provide more details to the developer (or the tester) about circumstances under which the security guideline is valid. In the second case, recommendations to make the necessary corrections on the program can then be proposed . The concrete mapping between the abstract propositions in the formal security guidelines and the program model is managed in the Security Knowledge Base (Section 9).

4 Security Guidelines Analysis

Security guidelines are usually presented in an informal and unstructured way. Their presentation differs from one source to another, which can be misleading to developers. We did the effort of analyzing the guidelines from different sources, and we raised different problems that we have discussed in [4]. Upon this survey, we noticed a lack of precision and a total absence of automation. From developers perspective, the understanding and interpretation of guidelines is not a trivial task, as there is no formalization that exposes the necessary program instructions for each guideline, or that explains how to apply them correctly in their software. In order to overcome this weakness, we come up with a centralized database that gathers the possible mappings between guidelines and Java instructions in the Security Knowledge Base. In the OWASP Secure Coding Practices guide [5], a set of security guidelines are presented in a checklist format arranged into classes, like Database Security, Communication Security, etc. The listed programming practices are general, in a sense that they are not tied to a specific programming language. Another programming practices guide we can consider for instance is the CERT Oracle Coding Standard for Java[7] ; for each guideline, the authors provide a detailed textual explanation. For most, there are also provided examples of compliant and non-compliant sample codes in addition to the description. We want to pinpoint another key element that gathered our attention; there is a huge effort invested in order to build and maintain the catalogs, but no attempt was undertaken to instrument their automatic verification on the code level.

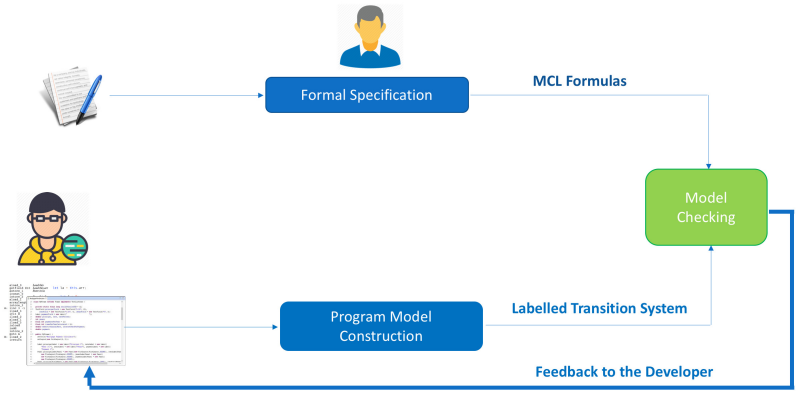

Figure 3: Framework for the formal specification and verification of Security Guidelines

5 Information Flow Analysis

In our framework, we make use of the Information Flow Analysis for many purposes, mainly the detection of implicit and subtle dependencies that can be source of covert channels and sensitive information leakage. From a security perspective, this might have serious damages on the security of the infrastructure as well as on users sensitive data. One might argue about using known security mechanisms such as access control to control the information propagation in a program. This aspect is of a paramount importance when dealing with information security. However, from a historic point of view, access control mechanisms, are used to verify the access rights at the point of access, and then, to allow or deny the access to the asset over which the mechanism is set. Access control mechanisms, just like encryption, can't provide assurance about where and how the data will propagate, where it will be stored, or where it will be sent or processed. This entails the need for controlling information flow using static code analysis. This same idea is emphasized by Andrei Sabelfeld and Andrew C. Myers [11], who deem necessary to analyze how the information flows through the program. According to the authors, a system is deemed to be secure regarding the property confidentiality, if the system as a whole ensures this property.

The main objectives of the information flow control [12] are to preserve the confidentiality and integrity of data; the former objective consists in guaranteeing that confidential data don't leak to public variables. As for the second objective, it consists in verifying that critical data is independent from public variables/output. Information flow control analyzes the software with the objective of verifying its compliance and conformance to some security policies. Different approaches have been proposed for Information Flow Control, where we can distinguish between *language-based* and *type-based* information flow control. The former has the advantage of exploiting the program source code and the programming language specificity, but falls short in covering different aspects such as physical side channels that is covered by other approaches[13] and execution environment properties. Language-based security mechanisms have been treated in the literature, including the bytecode verifiers and sandbox model. Those mechanisms enforce security through the Java language, but only the bytecode verifiers make use of the static code analysis. Type-based information flow control, on the other hand, basically makes use of the typing rules that capture illegal flows of information throughout a program, however, they are neither flow-insensitive, context-sensitive nor object-sensitive, which leads to imprecision, which in turn leads to false alarms.

6 Program Model Construction

The starting key element for this step is the standard PDG that we generate from the Java program bytecode using the JOANA tool [14]. In this PDG, control and (explicit/implicit) data dependencies are captured, which constitutes a strong basis to perform a precise analysis. Since our main objective is to automatically verify the adherence of programs to formalized security guidelines, we need to model check the guidelines MCL formulas over the program model. However, the PDG is not formal, and doesn't consist a basis for the formal verification through model checking. Thus, we need to construct from the augmented PDG a model that is accepted by a model checking tool, and that can be verified automatically through model checking techniques. We depict in Figure 4 the program model construction flow that we have adopted to generate the Labelled Transition System (LTS) from the PDG, that we generate from the program sources.

- Augmented Program Dependence Graph: this component first builds the program dependence graph (PDG) from the Java bytecode (.class) using the JOANA IFC tool [14]. We have chosen the Program Dependence Graph (PDG) as the abstraction model for its ability to represent both control and (explicit/implicit) data dependencies. The generated PDG is then annotated

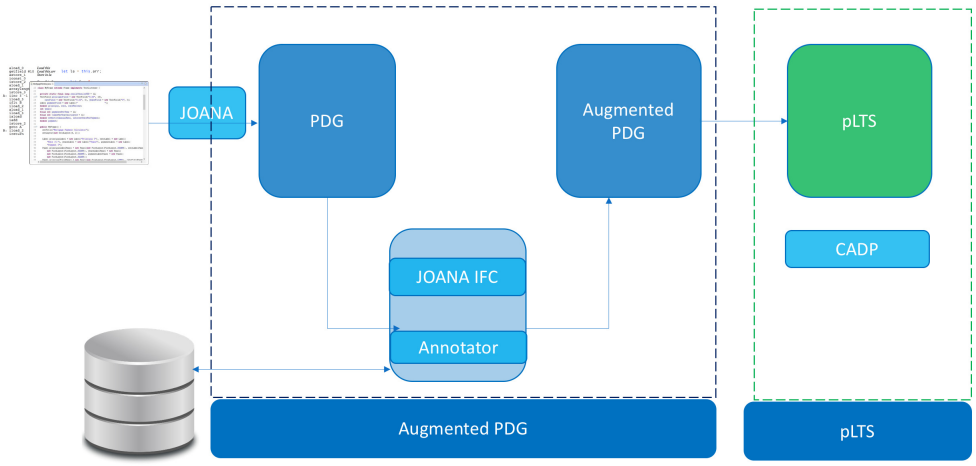

Figure 4: Methodology for the model construction: From program sources to the Augmented Program Dependence Graph, to the Labelled Transition System

by the **PDG Annotator** with specific annotations (labels in the MCL formulas). The **PDG Annotator** retrieves the nodes details (method signature) from the PDG, and fetches from the Security Knowledge Base the matching label if it exists. We run the information flow analysis using the JOANA IFC, that is formally proven [14] in order to capture the explicit and the implicit dependencies that may occur between the program variables. The operation results in a new PDG that we name the **Augmented PDG**. We show in Figure 5 the Augmented PDG of the sample code (Figure 1) that we consider in this paper.

- LTS Construction: this component translates automatically the **Augmented PDG** into a parameterized Labelled Transition System (pLTS) that is accepted by model checking tools. The annotations on the PDG nodes are transformed into labels on the transitions in the pLTS.

- Java Classes Parser: This component that we have developed [3] takes as input the URL of the Java class official documentation, and parses the HTML code (Javadoc) in order to extract all the relevant details: the class name, the inheritance, the description, the attributes, the constructor(s), the methods signatures, their return type and their parameters. This component populates the Security Knowledge Base with the extracted information.

6.1 Program Dependence Graphs

PDG (Program Dependence Graph) is a language-independent representation of program. This model was first proposed by Ferrante et al. [15] as a program representation taking into consideration both control and data relationships in a program. Formally, the PDG is a directed graph whose nodes correspond to program statements and whose edges model dependencies in the program. Those dependencies can be classified as either control or data dependencies. The nodes are predicates (variable declarations, assignments, control predicates) and edges are data and control dependencie representation; both types are computed using respectively control-flow and data-flow analysis.

PDGs have the ability to represent the information flow in a program, and have different properties, such as being *flow-sensitive*, *context-sensitive* and *object-sensitive* [13]. Being flow-sensitive is the ability of considering the order of statements in the program. The context-sensitivity is perceived from the fact that if the same method is invoked multiple times, then each call site will be represented a separate node in the graph, and will be analyzed separately. In other words, the methods calling context is considered, and this increases precision. The object sensitivity, on the other hand, is the ability to extend the analysis to the attributes level for Object Oriented Programs; object, which is an instance of a class, is not considered as an atomic entity, hence the analysis will be extended to the attributes level.
PDG abstracts away irrelevant details, such as independent and non-interacting program statements, that represent the unfeasible paths.

In our framework, we make use of the JOANA tool, that stands for Java Object sensitive Analysis [16] for the construction of the PDG. JOANA [14] is a framework that statically analyzes the byte code of Java programs; the tool first generates from the program byte code a PDG, which constitutes an over-approximation of the information flow in the program to analyze. The PDG contains apart from the nodes representing the statements and the variable declarations in the

[3] https://github.com/zeineb/Java-classes-parser

program, contains also edges referring to control and data dependencies between nodes. The dependencies represent explicit dependencies as well as transitive and implicit dependencies.

JOANA's strength relies on the ability to track how information propagates through a program, and captures both the explicit and implicit information flows.

6.2 Augmented Program Dependence Graph

We extend the definition of program dependence graphs to accommodate propositions over the set of program variables. Once the PDG is built, we compute all the propositions that are defined over the program. These propositions are parametrized by the variables defined within the program. Each node is annotated with a set of propositions.

There are two categories of information which can all be used as annotations. The first category is obtained by identifying the set of standard instructions: variables assignments, method calls, etc. at a given node. Example of methods are *encypt*, *hash*, *log*, *normalize*, *sanitize*. Second category is dedicated to relationship between variables, the dependencies in terms of explicit and implicit data dependencies between variables in a program.

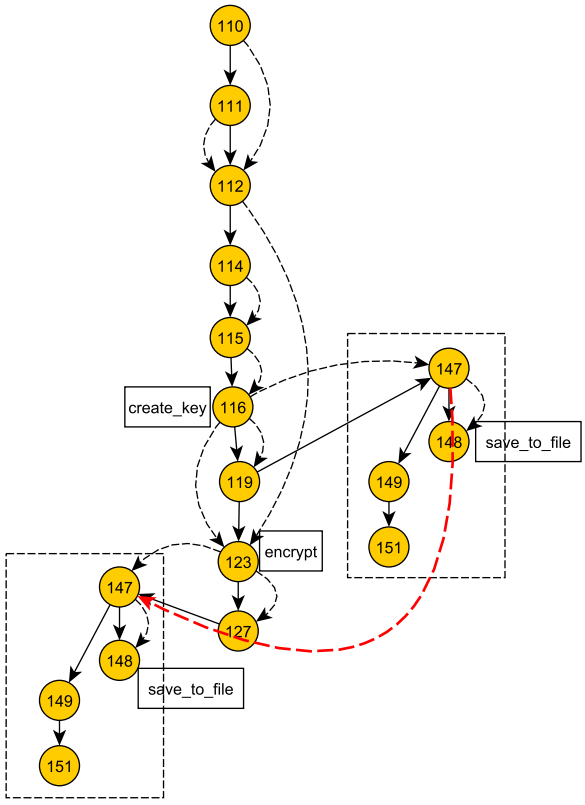

Figure 5: Augmented Program Dependence Graph for the sample code. Strong edges represent the control flows, the dashed edges refer to explicit and implicit data flows. Nodes are labeled with their corresponding instructions line numbers

Note that referring to our security knowledge base, different annotations on the PDG were pre-computed, like for instance the *save*, *userInput* and the *encyption_key*.

Automatic annotations. First, we have created our own annotations based on the atomic propositions of the security guidelines formulas. We made modifications on the source code of JOANA, and added the annotations *hash*, *userInput*, *Password*, *encrypt*, etc. in addition to the predefined annotations *SOURCE* and *SINK*. As shown in Figure 5, different program nodes are annotated with abstract labels, such as node 65 annotated as *Password*, node 73 annotated as *hash* and node 80 annotated as *log* or *store*. The log annotation was pre-computed after the PDG is built, meaning that the security knowledge base was accessed to fetch the concrete possible mappings between known APIs, methods, methods parameters mapped to the abstract labels the formulas are built upon. The mapping between the method invocation *logger.log* and the label *log* is already established. Same for the *hash* label. However, for the *Password*, the automatic annotation requires a semantic analysis to be performed over the code in order to determine the variable names matching password. The semantic analysis is not in the scope of this paper.

Annotations validation by the developer. Once the automatic detection of the atomic propositions on the PDG is performed, the intervention of developer is required to validate the added annotations. There might also be the case where the developer creates a method implementing the hash functionality, then the detection of the label *hash* on the program model will fail. In the sample code, the logging, which is one simple possible storing operation, was invoked. The developer, in our example, annotated the node 65 as *Password*, and the node 80 as *store* (in addition to the *log* automatic annotation).

6.3 Labelled Transition System

A parameterized Labelled Transition System (pLTS) is a labelled transition system with variables; a pLTS can have guards and assignment of variables on transitions. Variables can be manipulated, defined, or accessed in states, actions, guards, and assignments. JML [17], Z [18], B [19] allow to describe the states of the system through mathematics-based objects (machines, sets, etc.), and they describe pre- and post-conditions on the transitions between the states. Those languages deal with sequential programs and do not handle value passing for most.

Definition 1 (pLTS) *A parametrized LTS is a tuple* $pLTS \triangleq (S, s_0, L, \rightarrow)$ *where:*

- S *is a set of states.*
- $s_0 \in S$ *is the initial state.*

- *L is the set of labels of the form* $\langle \alpha, e_b, (x_j := e_j)^{j \in J} \rangle$, *where* α *is a parametrized action,* e_b *is a guard, and the variables* x_j *are assigned the expressions* e_j. *Variables in are assigned by the action, other variables can be assigned by the additional assignments.*
- $\rightarrow \subseteq S \times L \times S$ *is the transition relation.*

Informally, we interpret the behavior of a program as a set of reachable states and actions (instructions) that trigger a change of state. The states express the possible values of the program counter, they indicate whether a state is an entry point of a method (initial state), a sequence state (representing standard sequential instruction, including branching), a call to another method, a reply point to a method call, or a state which is of the method terminates. Each transition describes the execution of a given instruction, so the labels represent the instruction names.

The LTS labels can mainly be of three types: actions, data and dependencies.

- Actions: they refer mainly to all program instructions, representing standard sequential instructions, including branching and method invocations.
- Value passing: as performed analysis involves data, generated LTSs are parametrized, i.e, transitions are labelled by actions containing data values.
- Dependencies: in addition to program instructions, we added transitions that bring (implicit and explicit) data dependencies between two statements with the objective of tracking data flows. Indeed, transitions on LTS show the dependencies between the variables in the code. We label this kind of transition by *depend var1 var2* where *var1* and *var2* are two dependent variables.

7 Verification

With the objective of achieving our main goal consisting in helping a programmer verify that his program satisfies given security guidelines, we translate the augmented PDG into a formal description, which is precise in meaning and amenable to formal analysis. As usual, in the setting of distributed and concurrent applications, we provide behavioral semantics of analyzed programs in terms of a set of interacting finite state machines, called LTS [20]. An LTS is a structure consisting of states with transitions, labeled with actions between them. The states model the system states; the labeled transitions model the actions that a system can perform. Considered LTS are specific; their actions have a rich structure, for they take care of value passing actions and of assignment of state variables. They encode in a natural way the standard instructions of PDGs (as shown in Figure 5). Besides the classical behavior of a PDG, we encode in our LTS the result of tracking of explicit and implicit dependencies between program instructions. These dependencies are encoded by transitions labeled with the action *depend input_data output_data* (see Figure 6), allowing one to prove information flow properties.

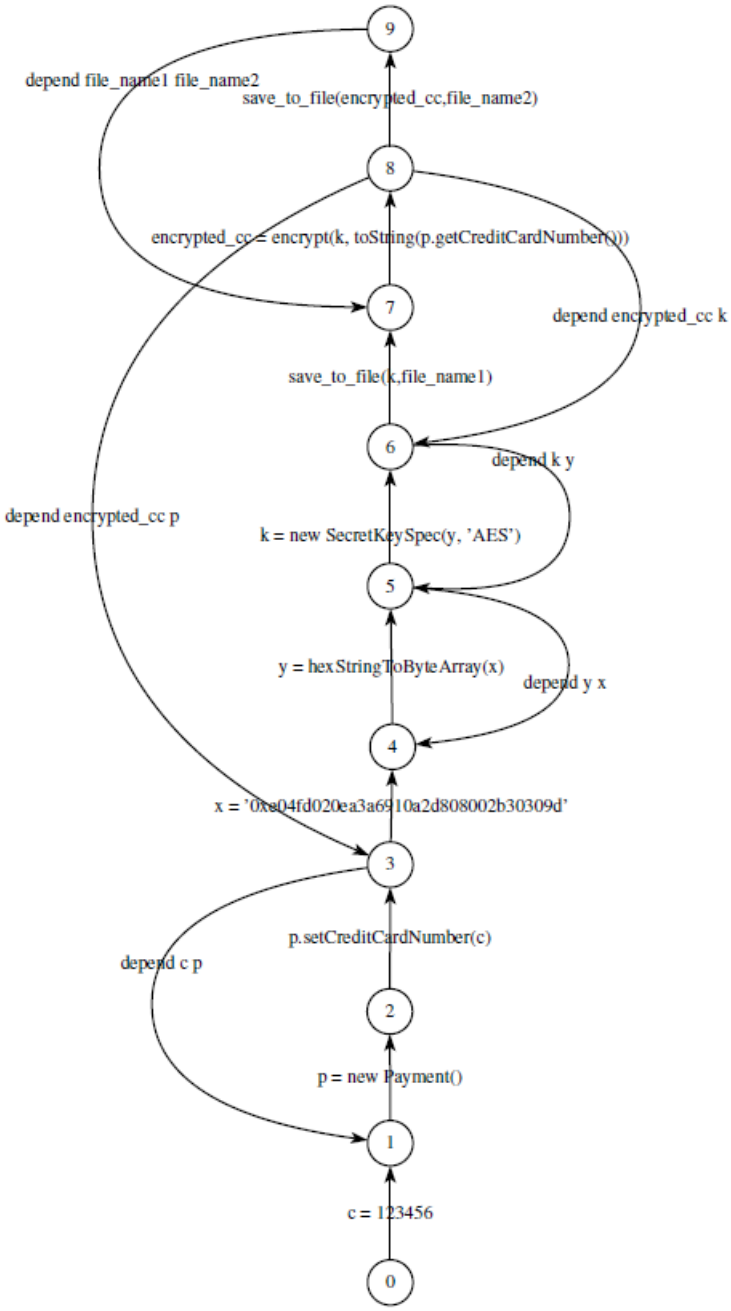

Figure 6: Labelled Transition System for the sample code given in Figure 1

Once the behavioral models are generated, we use model checking technique to automatically verify correctness of guidelines against the model.

For expressing the properties, we adopt MCL logic [21]. MCL (Model Checking Language) is an extension of of the alternation-free regular μ-calculus with facilities for manipulating data in a manner consistent with their usage in the system definition. The

MCL formula are logical formula built over regular expressions using boolean operators, modalities operators (necessity operator denoted by [ ] and the possibility operator denoted by ⟨ ⟩) and maximal fixed point operator (denoted by μ). For instance, the guideline *"Store unencrypted keys away from the encrypted data"* will be encoded directly by the following formula MCL:

```
[true*.{create_key ?key:String}.true*.
({save !key ?loc1:String}.true*.
{encrypt ?data:String !key}.true*.
{save !data ?loc2:String}.true*.
{depend !loc1 !loc2}
|
{encrypt ?data:String !key}.true*.
{save !key ?loc1:String}.true*.
{save !data ?loc2:String}.true*
.{depend !loc1 !loc2})] false
```

This formula presents five actions: the action {*create_key ?key:String*} denoting encryption key *key* (of type *String*) is created, the actions {*save !key ?loc1:String*}, {*save !data ?loc2:String*}, {*encrypt ?data:String !key*} denoting respectively the storage of the corresponding *key* in location *loc1*, the storage of the corresponding *data* in location *loc2*, the encryption of *data* using *key*, and the particular action *true* denoting any arbitrary action. Note that actions involving data variables are enclosed in braces ({ }). Another particular action that we make use of in this formula is {*depend !loc1 !loc2*}, denoting the implicit dependency between the file locations *loc1* and *loc2*; we captured this implicit dependency through advanced information flow analysis on the code.

This formula means that for all execution traces, undesirable behavior never occurs (false). The unexpected behavior is expressed by this sequence of actions: if encryption key *k* is saved in *loc1*, and *k* is used to encrypt *data* that is afterwords stored in *loc2*, then if *loc1* and *loc2* are dependent, the guideline is violated. The second undesirable behavior, expressed in the second sequence of the formula, means that if encryption of data using *k* occurs before the storage of *k* in *loc1*, and if *loc1* and *loc2* are dependent, then the guideline is violated.

We made use of the checker EVALUATOR of the CADP toolbox [22] to verify the property. From a behavioral point of view, the verification result is true, indicating that the guideline is verified. However, from a security point of view the answer should be false, as the variable *xx* containing the password in plain text, was leaked to the logging operation through and the implicit flow between this variable and the logging operation. To guarantee the reliability of the analysis, one needs to check secret/sensitive variables and depending variables as in the presented formula.

No surprise the answer is false. In addition to a *false*, the model checker produces a trace illustrating the violation from the initial state, as in Figure 7.

8 Related Work

Prior work in the area of information-flow security [23] has been developed during the last decades. A line of work [24] [25] adopts the Extended Static Checking, a specific technique for finding source code errors at compile-time. Eau Claire [21] framework operates as follows; it translates C program into Guard Commands (Guarded Command Language), that are afterwards translated into verification conditions for each function of the program. The generated verification conditions serve as input to automatic theorem prover. Adopting the prototype Eau Claire is very much-time consuming, requiring annotations entered by the developer, hence it is hard to integrate in the development phase.

De Francesco et al. [26] combine abstract interpretation and model checking to check secure information flow in concurrent systems. The authors make use of the abstract interpretation to build a finite representation of the program behavior: a labelled transition system . The security properties are specified in temporal logics, and are model checked over the built LTS. Their approach consists in verifying the non-interference property, meaning that the initial values of high level (secret) variables do not influence the final values of low level (public) variables. This approach checks for the non-interference only on two program states, which might miss possible information leakage within the process itself. In addition, the adopted formalism does not support value passing, and does not reason about data propagation.

The Verification Support Environment [27] is a tool for the formal specification and verification of complex systems. The approach adopted by the authors is similar to model-driven engineering, in the sense that the formal specification results in code generation from the model.

SecureDIS [28] makes use of model checking together with theorem-proving to verify and generate the proofs. The authors adopt the Event-B method, an extension of the B-Method, to specify the system and the security policies. The authors do not make it clear how the policies parameters are mapped to the system assets, and they do not extend the policy verification and enforcement on the program level. The work targets one specific system type (Data Integration System), and is more focused on access control enforcement policies, specifying the subject, the permissions and the object of the policy. However, access control mechanisms are not sufficient for the confidentiality property, as they can't provide assurance about where and how the data will propagate, where it will be stored, or where it will be sent or processed. The authors target system designers rather than developers or testers, and consider a specific category of policies focused on data leakage only.

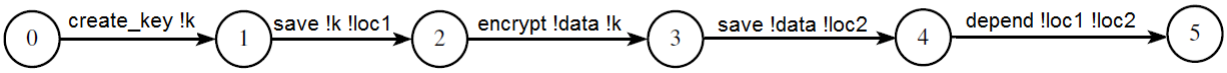

Figure 7: Path violating the guideline

GraphMatch [29] is a code analysis tool/prototype for security policy violation detection. GraphMatch considers examples of security properties covering both positive and negative ones, that meet good and bad programming practices. GraphMatch is more focused on control-flow security properties and mainly on the order and sequence of instructions, based on the mapping with security patterns. However, it doesn't seem to consider implicit information flows that can be the source of back-doors and secret variables leakage.

PIDGIN [30] introduces an approach similar to our work. The authors propose the use of PDGs to help developers verify security guidelines throughout the exploration of information flows in their developed software and also the specification and verification of adherence to those policies. Privacy policies are encoded in LEGALEASE language that allows to specify constraints on how user data can be handled, through the clauses ACCEPT and DENY [**?**]. The specification and verification of security properties rely on a custom PDG query language that serves to express the policies and to explore the PDG and verify satisfiability of the policies. The parameters of the queries are labels of PDG, which supposes that the developer is fully aware of the complex structure of PDGs, identify the sensitive information and the possible sinks they might leak to. For example, the authors propose a policy specifying that the guessing game program should not choose a random value that is deliberately different from the user's guess provided as input.

9 Discussion

We tackled in this paper the problem of verifying the adherence of the developed software to security guidelines that are presented in formal language. We raised the main issue regarding the interpretation, implementation and verification of the guidelines that are written in natural language, which might be subject to misinterpretation by developers. We worked towards stripping away ambiguities in [19] capturing implicit information flows that can be source of information leakage. We provided a centralized repository (Security Knowledge Base) gathering the security guidelines and patterns that we have discussed in detail in [19]. Apart from the patterns, we have centralized the labels that are used to build the formulas, mapped to the traditional information annotations (*SOURCE*, *SINK* and *DECLASS*) together with their security level (*HIGH* / *LOW*).

Security Knowledge Base *Security Knowledge Base* is a centralized repository gathering the labels of the formulas mapped to APIs, instructions, libraries or programs. This helps the automatic detection of labels on the system model. We built **Security Knowledge Base** using a Java classes parser [4] that operates as follows: for the different Java classes used in the program to analyze, we launch the parsing of this given class (html code, javadoc), and we extract all the relevant details, such as the description, the attributes, the constructors, the methods signatures and their parameters. Then, we made the effort of performing a semi-automatic semantic analysis to detect key elements, such as the keyword *secure*, *key*, *print*, *input*, etc. This operation is of a paramount importance, as it allows us to map the key words used to build the formulas, to the possible Java language instructions (methods invocations, constructors invocations, specific data types declarations, etc). For example, the Java API *KeyGenerator.generateKey()* is mapped to the label *isKey*. This label is also mapped to the traditional information flow annotation **high** level **source**.

As part of the Security Knowledge Base, we have also considered the vulnerabilities the program could eventually be exposed to if the guideline is violated. The Security Knowledge Base is rich yet extensible repository, that can be extended if new security concepts are introduced. For instance, the same guideline might be expressed through different MCL formulas and using different terms that are semantically equivalent. Let us take the example of the guideline *"Store unencrypted keys away from the encrypted data"* that we have previously formulated using those keywords: *create_key*, *save* and *encrypt*. Among the keywords contained in the dictionary that we provide to the security expert, the *create_key* is semantically equivalent to *isKey*, the word *save* is equivalent to *store*, and so on and so forth. Hence, the used keywords can be replaced with their equivalent as long as they do not alter the semantics of the guideline.

10 Conclusion

In this paper, we presented on a high level the approach that we propose with the objective of filling the gap for the verification of the security guidelines. We pinpoint different issues with the security guidelines that are present in different sources, but no verification means is provided to the developers to make sure that their being developed software adheres to those guidelines. Security guidelines are meant mainly for developers, but the way they are

[4] https://github.com/zeineb/Java-classes-parser

presented presents ambiguities, and this might lead to misinterpretation. Formalizing the guidelines would help strip away ambiguities, and prepare the ground for the formal verification. We stressed on the need for performing model checking as verification approach. This allows to have an automatic verification, hence to reduce the intervention of a human operator, whether the developer or the security expert leads this verification.

ABSTRACT

New multimedia applications such as mobile video, high-quality Internet video or digital television requires high-performance encoding of video signals to meet technical constraints such as runtime, bandwidth or latency. Video coding standard h.265 HEVC (High Efficiency Video Coding) was developed by JCT-VC to replace the MPEG-2, MPEG-4 and h.264 codecs and to respond to these new functional constraints. Currently, there are several implementations of this standard. Some implementations are based on software acceleration techniques; Others, on techniques of purely hardware acceleration and some others combine the two techniques. In software implementations, several techniques are used in order to decrease the video coding and decoding time. We quote data parallelism, tasks parallelism and combined solutions. In the other hand, In order to fulfill the computational demands of the new standard, HEVC includes several coding tools that allow dividing each picture into several partitions that can be processed in parallel, without degrading neither the quality nor the bitrate.

In this paper, we adapt one of these approaches, the Tile coding tool to propose a pipeline execution approach of the HEVC / h265 decoder application in its version HM Test model. This approach is based on a fine profiling by using code injection techniques supported by standard profiling tools such as Gprof and Valgrind. Profiling allowed us to divide functions into four groups according to three criteria: the first criterion is based on the minimization of communication between the different functions groups in order to have minimal intergroup communication and maximum intragroup communication. The second criterion is the load balancing between processors. The third criterion is the parallelism between functions. Experiments carried out in this paper are based on the Zedboard platform, which integrates a chip Zynq xilinx with a dual core ARM A9. We start with a purely sequential version to reach a version that use the pipeline techniques applied to the functional blocks that can run in parallel on the two processors of the experimental Platform. Results show that a gain of 30% is achieved compared to the sequential implementation.

1. Introduction

This paper is an extension of the work originally presented in [1].

In recent years, the number of applications processing digital video is steadily growing. Streaming videos, videoconferencing, web cameras, mobile video conversations are examples of digital video that require good video quality.

In addition, statistics show that by 2020 [2], Internet video streaming and downloads will increase to over 80% of all consumer Internet traffic. This growing demand for digital video processing encourages digital video coding market operators to design and develop new solutions that can meet this growing need.

Indeed, we are witnessing an increase in companies and research groups working to develop standards of video codec with better quality.

The JCT-VC (Joint Collaborative Team on Video Coding) group, formed by VCEG and MPEG, was created at the end of 2009 to create a new standard that meets the new requirements of video processing [3]. Following the work of this group, a new standard called H.265 / HEVC (High Efficiency Video Coding) was created with the aim of compressing a half-rate video from the previous H.264 / AVC standard to one Quality. This improvement in terms of efficiency is necessary to manage beyond high definition resolutions like HD, Quad-HD and Ultra-HD.

Many research groups and companies participate in standardization meetings and contribute to the growth of the standard with new algorithms. As a result, many implementations of this standard have been developed. One of these implementations is the test model software [4], which is a complete encoder and a decoder for the new algorithms.

To design video processing devices that implement standard video encoders, designers investigate several solutions. All solutions are based on improvement techniques based on software or hardware optimization approaches or a combination of both approaches.

The work undertaken in this paper is part of the LIP2 co-design flow.

In a co-design process, designers typically begin to run embedded application code on a host machine. Then, a thin profiling step is done to describe each function. This description can affect the execution time, memory size, number of calls, relationship between functions and other parameters that may be useful for the designer to make the best design decisions.

In this paper, we present a new approach to implement a pipeline solution of the HEVC H.265 application decoder based on the Zedboard platform [5]. The results show that a gain of 30% is achieved compared to the sequential implementation.

The rest of this article is organized as follows: Section 2 presents an overview of the HEVC Standard and HEVC h.265 decoders. In section 3, we present some works in relation with HEVC parallelization.

Section 4 gives a detailed description and profiling of the version of the test model of the decoder and analyses the results obtained. Section 4 shows the execution of the decoder pipeline on the Zedboard platform. Finally, Some conclusion remarks and future directions are given in Section 6.

2. Overview of the HEVC Standard

Due to the complexity of multiprocessor systems, the probability of failure is all the more important that it requires special consideration. Indeed, during a failure, a part of the application state disappears and the application may pass in an inconsistent state that prevents it from continuing normal execution.

The HEVC [5,6] is the acronym of "High Efficiency Video Coding". This is the latest video-coding format used by JCT-VC. This standard is an improvement of the H.264 / AVC standard. It was created on January 2013 [7], when a first version was finalized. It was developed jointly by the ISO / IEC Moving Picture Experts Group (MPEG) & ITU-T Video Coding Experts Group (VCEG).

The main objective of this standard is to significantly improve video compression compared to its predecessor MPEG-4 AVC / H.264 by reducing bitrate requirements by as much as 50% compared to H.264/ AVC, with equivalent quality.

The HEVC supports all common image definitions. It also provides support for higher frame rates, up to 100, 120 or 150 frames per second.

Video coding standards have evolved mainly through the development of the well known ITU-T and ISO / IEC standards. ITU-T produced H.261 [8] and H.263 [9], ISO / IEC produced MPEG-1 [10] and MPEG-4 Visual [11], and the two organizations together produce H. 262 / MPEG -2 Video [12] and H.264 / MPEG-4 Advanced Video Coding (AVC) [13,14] standards.

The two standards that have been produced jointly have had a particularly strong impact and have found their way into a wide variety of products that become increasingly common these days. In the course of this evolution, efforts have been multiplied to increase the compression capacity and to improve other characteristics such as the robustness against data loss. These efforts take into account the capability of practical IT resources to be used in products at the time of the expected deployment of each standard.

The HEVC standard is intended to complement various objectives and to meet even stronger needs to encode videos with an efficiency more important than H.264 / MPEG -4. Indeed, there is a growing diversity of services such as ultra high definition television (UHDTV) and video with a higher dynamic range.

On the other hand, the traffic generated by video applications targeting peripherals and mobile tablets and transmission requirements for video-on-demand services impose serious challenges in current networks. An increased desire for quality and superior resolutions also occurs in mobile applications.

The HEVC standard defines the process of encoding and decoding the video. As an input, the encoder will process an uncompressed video. It performs the prediction, transformation, quantification and entropy coding processes to produce a bitstream conforming to the H.265 standard.

The decoding process is divided into four stages. The first stage is the entropy decoding for which relevant data such as reference frame indices; intra-prediction mode and coding mode are extracted. These data will be used in the following stages. The second is called reconstruction step, which contains the inverse quantization (IQ), inverse transform (IT) and a prediction process, which can be either intra-prediction or motion compensation (inter-prediction). In the third stage, a de-blocking filter DF is applied to the reconstructed frame. Finally a new filter called Sample Adaptive Offset (SAO) is applied in the fourth stage. This filter adds offset values, which are obtained by indexing a lookup table to certain sample values [14].

In HEVC, the coding structure is based on a quaternary tree representation allowing partitioning into multiple block sizes that

easily adapt to the content of the frames. Three units are defined to treat each frame. First, the Coding Unit (CU) that defined the frame‘s based size on pixels. It allows sizes ranging from 8x8 to 64x64 pixels to be adapted according to the application. Second, the Prediction Unit (PU) that defines the partitioning size according to predicts type (inter and intra). Finally, the Transform Unit (TU) defines the quantification and transforms size to be applied to a prediction unit. Four levels of decomposition are possible for this TU, which take sizes ranging from 4x4 to 32x32 pixels.

Three types of coding structures are defined; ALL intra or intra-only (AI), Low Delay (LD) and Random Access (RA). In the first structure, all pictures are encoded as intra, which yields very high quality, and no delay; this mode is mainly aimed for studio usage.

In the low delay one, the first is an intra frame while the others are encoded as generalized P or B pictures (GPB). This structure is conceived for interactive real-time communication such as video conferencing or real-time uses where no delay for waiting for future frames is permitted.

Finally, the random access structure is similar to hierarchical structure and intra pictures are inserted periodically, at the rate of about one per second. It is designed to enable relatively frequent random access points in the coded video data. This coding order has an impact on latency, since it requires frame reordering: for this reason the decoder might have to wait to have decoded several frames before sending them to output. This is the most efficient mode for compression but also requires the most computational power.

Each of these three modes has a low complexity variant where some of the tools are disabled or switched into a faster version. As an example low complexity uses CAVLC instead of CABAC

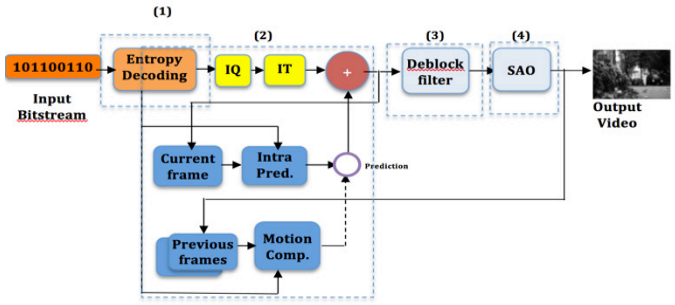

Figure 1. Functional structure of the HEVC decoder

3. Related works

HEVC includes several parallel specifications for many distributed multi-core systems. This allows division of each picture into several partitions that can be processed in parallel.

For these specifications, coarse grain communications levels are used. We cite the Group Of Pictures (GOP) level, the Slice Level, the Tile level and the wavefront parallel processing (WPP) level.

All these communication granularity has been justified by the small data dependency between processes acting on separate partition blocks.

For an embedded multiprocessor System on Chip (SoC) implementation, the communication granularity specified is not appropriate in all cases given the limited on-chip resources (memory, CPU frequency, bandwidth, …). For this, more fine grain communications granularities (CTU, TU, PU) are specified in HEVC standard based on a fine partition of a frame.

In [15], Authors carried out the analysis of parallel processing tools to understand the effectiveness of achieving the purpose for which they are targeted. In [16], an optimized method for MV-HEVC is proposed. It uses multi-threading and SIMD instructions implementation on ARM processors. The proposed method of MV-HEVC showed improvement in terms of processing speed on advanced RISC multi-core processors mobile platforms (ARM). In [17], Authors used the Wavefront Parallel Processing (WPP) coding and implemented it on multi- and many-core processors. The implemented approach is named Overlapped Wavefront (OWF), an extension of WPP tool that allows processing multiple picture partitions as well as multiple pictures in parallel with minimal compression losses. Results of her experimentations show that exploiting more parallelism by increasing the number of cores can improve the energy efficiency measured in terms of Joules per frame substantially. [18] discussed various methods in which the throughput of the video codec has been improved including at the low level in the CABAC entropy coder, at the high level with tiles, and at the encoder with parallel merge/skip tool. In [19], many optimizations are proposed to achieve HEVC real-time decoding on a mobile processor. These code optimizations include the adoption of single-instruction multiple-data (SIMD). An important speedup is accomplished with multiple threads assigned each one to a picture to be decoded. However, in the proposed solution, the SAO filter has not been implemented and optimized. Further, for the AI configuration, no additional speedup is achieved since no CPU resources are available anymore to decode a picture. In [20], a hybrid parallel decoding strategy for HEVC is presented. It combines task and data parallelism without any constraint or coding tools. The proposed approach aims to balance execution time of different stages, especially with SSE (Streaming SIMD Extensions) optimization. Another parallelism approach based on entropy slices is presented in [21]. This approach is not based on many slices because it can reduce the coding efficiency. It assigns one thread per LCU block to parallelize the HEVC decoder. Moreover, these threads are synchronized using the Ring-Line Strategy to maintain the wave front dependencies. This solution is great for high resolutions; however, it’s not the same for others.

4. Profiling of Test Model HEVC Decoder

In the specification and modelling phase of a co-design flow, the complete embedded system is written in a high level language such as C, C++, Java, Matlab and then the software is functionally verified. It will then be simulated on a host machine in order to understand its behaviour and measure the runtime performance of the program and eventually return feedback and performance statistics to the designer

This specification is an input to the profiling step, which consists in understanding the behaviour of the system in the various execution cases in order to deduce a clear representation of the various functions that represent it.

The behaviour of the system can be understood and mastered by following a parametric analysis of its execution in the different configurations and situations that the system is subject to.

This analysis can only be undertaken after having completed a detailed description of different functions of the system. The description can include the execution time of each function, its sizes, call graphs, dependencies between them and other information that can help designers to make the best decisions and technical choices. This process of identification and description is called profiling.

Once the profiling is done, designers can test the system with several configurations and estimate its performance parameters.

Several works dealing with performance estimation of embedded systems have been realized. In the case of the HEVC codec, performance estimation aims to test the ability of codecs to process video for real-time applications and to support new resolutions (HD, UHD, Full HD, 4k, 8k) and to measure footprint and the space occupied by the hardware components that make up the device.

In the work carried out by [22], a complete profiling of the encoder was carried out. The aim of this work is to present the different functions of the encoder, their execution times and the types of operations carried out in order to deduce the functions that are candidates for a hardware migration. The results are presented in terms of types of assembly level instructions in each encoder function. In [23], the authors propose a hybrid parallel decoding strategy for HEVC, which combines task level parallelism and data level parallelism. In [24], the authors use a performance estimation analysis to prove a power model based on bit derivations that estimates the energy required to decode a given HEVC coded bitstream. In [25], authors proposed a method to improve H.265/HEVC encoding performance for 8K UHDTV moving pictures by detecting amount or complexity of object motions.

4.1. Functions of the Test Model

HEVC HM Test Model is an open source project under BSD license. It is intended for the implementation of an efficient C++ HEVC decoder. The version used in this work was released from [4] and it is compliant with most of the HEVC standard. The code of the application is composed of C++ classes, and the main classes and functions are listed in the table 1.

The graph below (Figure 2) shows the most important classes in the decoding process and their associated functions. We note that the most significant classes are TComDataCU, TComTrQuant and TComSlice. The TComDataCU class represents the declaration of the CU data structure. The TComTrQuant class includes inverse transformation and inverse quantization, and the TComSlice class includes the decoder decompression process.

The optimization of the codes of the functions making up these classes can have a positive impact on the execution time and the footprint of the decoder.

As DecodeCTU, DecompressCtu called recursive function xDecompressCU which, in turn, decompresses each CU with the adequate prediction mode. When all CTUs in a frame are processed, the loop ends and the decoder performs both DF and SAO filters to correct artefacts.

Table 1: Main classes and principal functions of test model decoder

Main Classes	Principal functions	Size of code (Ko)
TDecGop	FilterPicture decompressSlice	8
TAppDecCfg	parseCfg	9
TAppDecTop	Decode x WriteOutput	21
TDecEntropy	decodePredInfo decodePUWise decodeInterDirPU	28
TdecTop	Decode Executeloopfilter	32
TComLoopFilter	xDeblockCU LoopFilterPic	35
TDecCU	decompressCtu decodeCtu xdecodeCU xcompressCU xReconInter xReconIntraQT	44
TComSlice	decompressSlice	126
TComTrQuant	partialBufferflyInverse32 partialBufferflyInverse16 partialBufferflyInverse8 xDeQuant	135
TComDataCU	initCu copySubCu	140

As shown in the diagram in Fig. 3, the process of decoding a frame is done by calling the DecompressCTU function of the TDecSlice class. This function executes a read loop of all CTUs in the current frame. Each CTU is decoded through the DecodeCtu function of the TDecCu class. The XdecodeCu function of the same class, recursively performs the decoding of all CUs in the same CTU. When decoding a CTU, the TDecSlice makes a second call to the DecompressCTU function of the TDecCu class. Like DecodeCTU, DecompressCtu call the recursive function xDecompressCU, which, in turn, decompresses each CU with the proper prediction mode. When all CTUs in a frame are processed, the loop ends and the decoder perform DF and SAO filters to correct the artefacts.

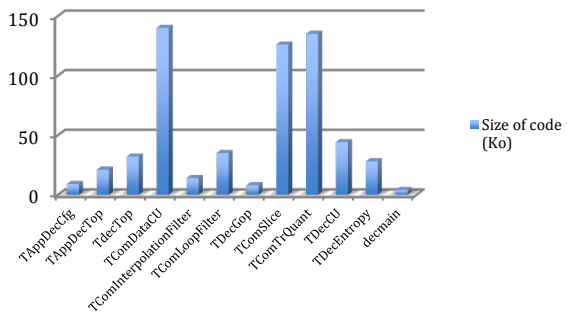

Figure 2. Main functions of Test Model Decoder

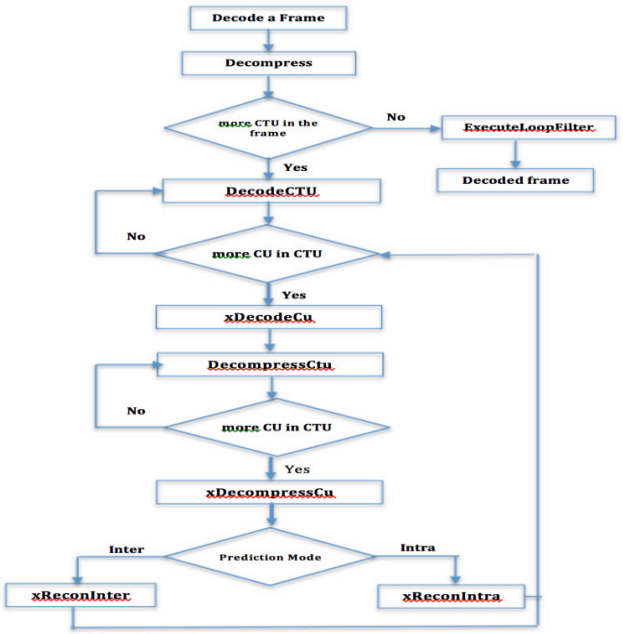

Figure 3. Frame decode Diagram of HM version

4.2. Call Graph functions of HM HEVC Decoder

Our goal in this step is to check the behaviour of the decoder described above, and to evaluate the performance of its various components in detail.

To achieve the profiling operation, we made use of profiling techniques based on code injection and also the use of tools such as gprof [26, 27] and Valgrind [28]. Gprof provides a flat profiling to give the execution time of each function of the decoder and also the number of times this function is called. Gprof can give us as a result, the call graph. This indicates for each function code, the number of times it was called, either by other functions or by itself. This information shows the relationships between the different functions and can be used to optimize certain code paths. Roughly, the results of profiling the performance generated by GProf revealed a runtime complexity of balance in terms of computing time in the functions Motion Compensation (36%) and ExecuteLoofilters of (16.7%).

Valgrind is a GPL licensed programming tool that can be used for profiling under the Linux operating system. It includes several tools, one of which is Callgrind. We used Callgrind to obtain the exact number of operations that were performed while decoding an entire video sequence. The results are separated in terms of classes, and in every class in terms of functions.

The resulting graph shows for each function, the execution time as a percentage of the total execution time (Valingring) and the functions to which they appealed. Normally, the graph shows that the most time-consuming functions are Motion Compensation and ExecuteLoofilters.

The aim of the profiling step is to understand the behaviour of the decoder described above and to evaluate the performance of its various components in detail.

To do so, we used profiling tools such as Gprof and Valgrind. These tools allow us to present the call graphs of the different functions and their execution times, and thus the state of the stack used. In order to have a complete profiling which includes the execution sequences in the different execution scenarios and configurations, a manual injection of code has been realized into significant functions.

The Gprof tool can give as a result, the call graph. This indicates for each function, the number of times it was called. This information shows the relationships between the different functions and can be used to optimize some code paths.

The profiling results generated by GProf revealed a computational complexity in terms of execution time in Motion Compensation (36%) and ExecuteLoofilters (16.7%) functions.

Valgrind is a GPL licensed tool. It includes several tools, one of which is Callgrind. We used Callgrind to get the exact number of operations performed when decoding a complete video sequence. The results are separated in terms of classes and in each class in terms of functions.

The resulting graph shows, for each function, the execution time as a percentage of the total execution time and the functions to which they appealed.

The graph shows that the most time-consuming functions are Motion Compensation and ExecuteLoofilters.

4.3. Profiling and functions Execution trace

As explained above, in order to determine the sequence of execution of the various functions of the decoder and the number of calls, a combination of code injection (manual code injection) and sampling profiling (using tools such as valgrind , Gprof, ...) has been made. The code injection in each function of the decoder has allowed us to locate called and calling functions. This also helps us to know the execution sequential order of different functions.

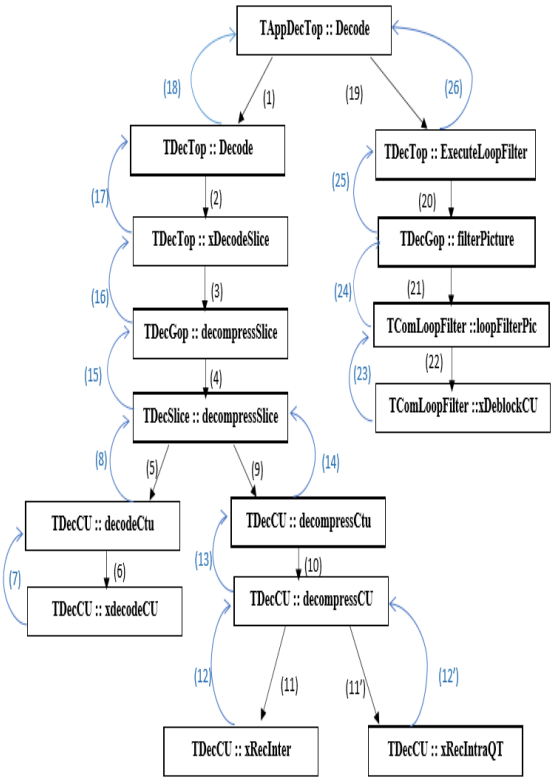

Figure 4. Functions execution Sequences

Values in parentheses indicate the execution order of decoder's functions.

The distribution of functions into groups is mainly based on three criteria: The first is to minimize communication between different groups of functions in order to have minimal inter-group communication and maximum intra-group communication. The second criterion is load balancing between the processors. Indeed, the target platform (Zedboard) is equipped with the two ARM V9 processors. To ensure optimal utilization of two processors, we must balance the charge of activity between the two cores. The third criterion is the execution parallelism. Indeed, we must ensure maximum parallel execution to minimize the average processing time of images.

Taking into account all the criteria, we came to the distribution of assigning the group functions 1, 2 and 4 to processor 0 (proc0) and functions of the group 3 to processor 1 (Proc1).

The calculations we have developed suggested the division mentioned above with the following performance data:

■ CPU.0:

Group 1: (1) (2) (3) (4) (15) (16) (17) (18) = 24.46%
Group 2: (5) (6) (7) (8) = 6.85%
Group 4: (19) (20) (21) (22) (23) (24) (25) (26) = 16.70%
Total activity time = 48.01%

■ CPU.1

Group 3: (9)(10)(11)(11') (12)(12')(13)(14)= 51.95%

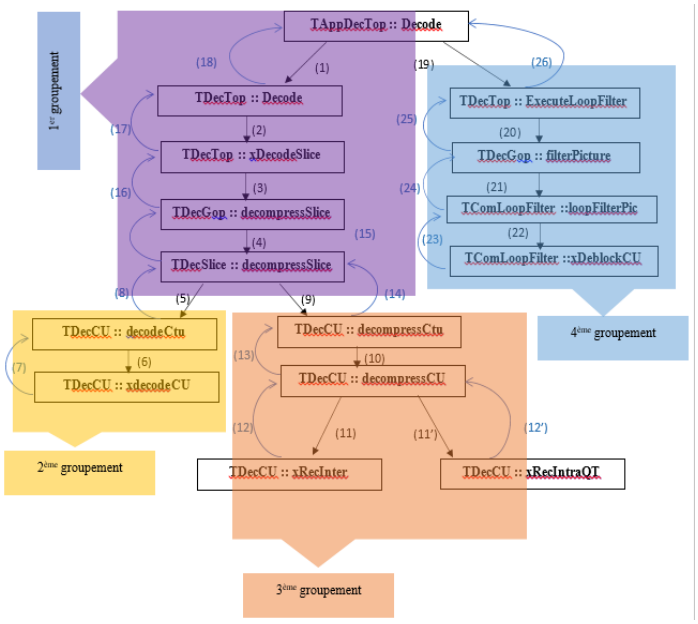

Figure 5. Grouping decoder functions

According to profiling procedure, we can divide the code on four main parts (Figure 4). The first contains the configurations functions. The second group represents the entropy decoding functions (decodeCTU and xdecodeCU). The third group is the reconstruction. Finally, the HEVC filters are grouped. We analyse their decoder's execution time in order to know its behaviour at runtime.

5. Experimental results

5.1. Test sequences

As an effort to carry out a good evaluation of the standard, the JCT-VC developed a document with some reference sequences and the codec configuration, which should be used with each one [29]. The sequences are divided into 6 groups (Classes) based on their temporal dynamics, frame rate, bit depth, resolution, and texture characteristics

A subset of six video sequences was selected from this list. These six video sequences were selected from three classes, such that two sequences from each class, namely Class A, Class C, Class F. Detailed descriptions of the sequences are given in Table II.

Table 2: Bitstreams used in the experimentations

Resolution (Sequence class)	Name	Frame rate	Frame number
2560x1600 (Class A)	*PeopleOnStreet*	30	150
	Traffic	30	300
832x480 (Class C)	*BQMall*	60	600
	PartyScene	30	500
1024x768 (Class F)	ChinaSpeed	50	500
	Slideediting	30	300

5.2. Zedboard Platform

Zedboard platform [30] (table III) is an evaluation platform based on a Zynq-7000 family [31]. It contains on the same chip two components. A dual-core ARM Cortex MPCore based on a high-performance processing system (PS) that can be used under Linux operating system or in a standalone mode and an advanced programmable logic (PL) from the Xilinx 7th family that can be used to hold hardware accelerators in multiple areas.

The two parts (PS and PL) interact between them by using different interfaces and other signals through over 3,000 connections [32]. Available four 32/64-bit high-performance (HP) Advanced eXtensible Interfaces (AXI) and a 64-bit AXI Accelerator Coherency.

Table 3: Zedboard technical specifications

Component	Characteristics
Processeur ZYNQ-7020 AP SOC XC7Z020-7CLG484CES	2 ARM Cortex A9 cores at 667 MHz
Memory	512 MB DDR3, 256 MB Quad-SPI Flash et SD Card
Communication	10/100/1000 Ethernet, USB OTG et USB UART
Extension	FMC (Low Pin Count) et 5 Pmod headers (2*6)
Display	HDMI output, VGA output et 128*32 OLED
Input / Output	8 switches, 7 push butons et 8 leds
Current and Voltage	3.0 A (Max) et 12V DC input
Certification	CE and RoHS certifier

In our experimentations, we have configured and compiled a custom Linux kernel downloaded from the official Linux kernel from Xilinx [31].

5.3. Pipeline execution approach

Since ZedBoard is based on Zynq chip that has dual cores, it is possible to distribute functions between the two cores.

Because of strict sequentially that we have seen in the functions execution of the HEVC decoder (HM Test Model version), the two processors will necessarily be in mutual exclusion of activity. To create parallel activity, we can transform the sequential video processing by a "pipelined" treatment.

If we refer to the grouping of functions explained above, we can consider that video sequence processing goes through four stages:

Stage 0: Download to a frame buffer (FB) the frame to be processed. This step corresponds to transition (1) in the graph (Fig. 5)

Stage 1: Decoding of the frame, corresponding to transitions (2, 3, 4, 5, 6, 7, 8). This stage corresponds to the Entropy decode process.

Stage 2: Decompression, corresponding to transitions (9, 10, 11-11 ', 12-12', 13, 14). This stage corresponds to the reconstruction process (that contains Inverse Transform, Inverse Quantification, Inter- prediction and Intra-prediction).

Stage 3: Filtering, which corresponds to transitions (15, 16, 17, 18, 19, 20, 21, 22, 23, 24, 25, 26). This stage corresponds to the Loop Filter process

A parametric analysis of the application has enabled to deduce that the overall execution time of Stages 0, 1 and 3 is approximately equivalent to the execution time of Stage 2. Therefore, we can affect stages 0, 1 and 3 in the first PROC0 processor and Stage 2 to the second processor PROC1.

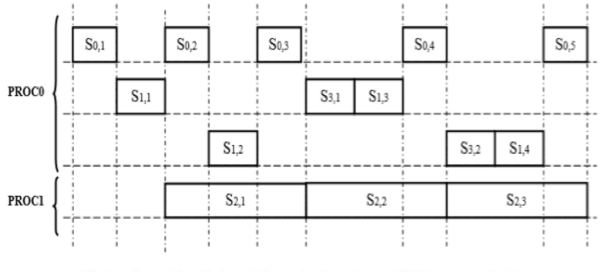

Figure 6. Pipeline execution based on dual cores Processor

Si,j represents the execution sequence of stage i applied to the frame number j. The first three rows reflect the sequencing of stage Si,j on the same processor PROC0:

Process P0, P1 and P2 support respectively the first, second and the third row.

The fourth row reflects the execution sequence of stage2 of the processor PROC1 applied to successive frames. A process P3 supports it.

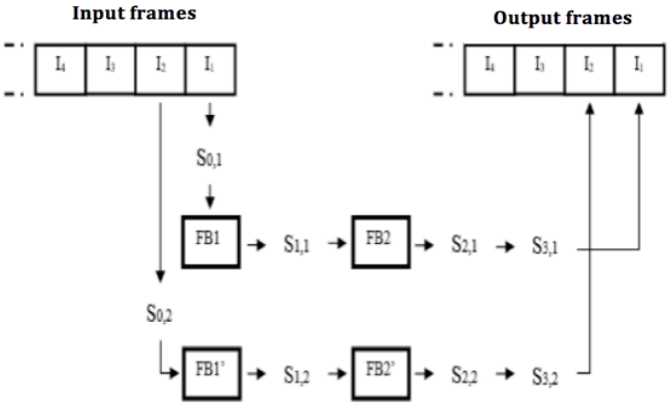

Figure 7. Sequence Process on two processors (cores)

Results obtained for the RA, AI and LD configurations are presentaed in tables IV, V and VI..

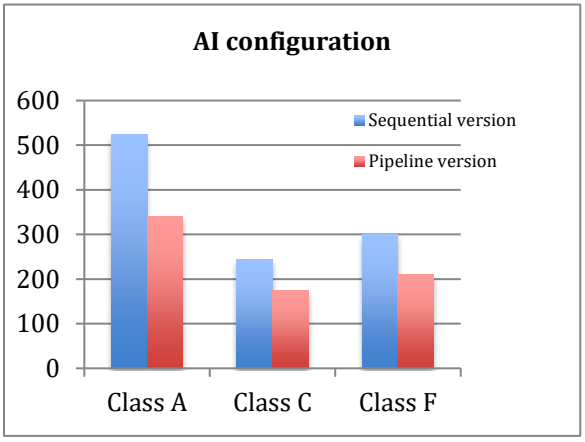

Figure 8. Execution time gain (AI configuration)

The experimental tests use reference sequences for the three configurations (AI, RA and LD) and with different quantification parameters (QPs). For the different configurations, results show a considerable gain compared to the sequential version (around 30%). We also note that class A frames have more processing time than the other classes (C and F) with a slightly more significant gain. This is logical since the resolution in this class is more important than for the other classes.

6. Conclusion

The objective of this article was to study the behaviour of the HEVC decoder represented by the reference application Test Model (HM). This study permitted us to discover the different functions of the decoder, their size, the call graphs, the percentage of CPU utilization and the number of instructions for each function.

Moreover, we have identified the most consuming functions in terms of CPU execution time and memory size, and then we have represented the execution trace of the functions by the use of an injection code technics. All these profiling results allowed us to divide the functions into groups. Once the regrouping is done, we proposed a parallelism approach based on the pipeline principle in order to run the application on the two cores of the Zedboard Platform. The experimental results found show an acceleration of about 30% compared to the sequential version.

Other technics can be added to improve this approach such as the increase of the number of processors or the implementation of hardware accelerators in the PL side.

Tumor Size; and Tumor Position

ABSTRACT

Brain tumor is such an abnormality of brain tissue that causes brain hemorrhage. Therefore, apposite detections of brain tumor, its size, and position are the foremost condition for the remedy. To obtain better performance in brain tumor and its stages detection as well as its position in MRI images, this research work proposes an advanced hybrid algorithm combining statistical procedures and machine learning based system Support Vector Machine (SVM) and Artificial Neural Network (ANN). This proposal is initiated with the enhancement of the brain MRI images which are obtained from oncology department of University of Maryland Medical Center. An improved version of conventional K-means with Fuzzy C-means algorithm and temper based K-means & modified Fuzzy C-means (TKFCM) clustering are used to segment the MRI images. The value of K in the proposed method is more than the conventional K-means. Automatically updated membership of FCM eradicates the contouring problem in detection of tumor region. The set of statistical features obtained from the segmented images are used to detect and isolate tumor from normal brain MRI images by SVM. There is a second set of region based features extracted from segmented images those are used to classify the tumors into benign and four stages of the malignant tumor by ANN. Besides, the classified tumor images provide a feature like orientation that ensures exact tumor position in brain lobe. The classifying accuracy of the proposed method is up to 97.37% with Bit Error Rate (BER) of 0.0294 within 2 minutes which proves the proposal better than the others.

1. Introduction

The brain controls all psychological and physiological activities of human body. These functional activities can be disrupted or damaged due to the abnormal cell division or growing tumor in our brain that causes miscellaneous problems to the malfunction of our body. A human brain is divided into several major areas and these major areas (see Fig. 1) are related to different functional part of our body. Especially, these major areas are known as frontal lobe (marked with 1), central lobe (marked by 2, 3, & 4), parietal lobe (marked by 5 & 6), occipital lobe (marked with 7), and temporal lobe (marked with 8). Frontal lobe functions to control our thinking, emotion, innovation, and other cognitive works. Central lobe is a part of the frontal lobe and this part controls our movement related functions. The temporal lobe is responsible for listening and it helps to avoid the uncertainty principle. Occipital lobe helps us to see or observe anything. Another major part that controls the speech processing through reading compression area, sensory speech area and motor speech area of Broca is parietal lobe. These major areas can be affected by tumors which are definitely threat to our normal living. Therefore, the proper detection is the first priority for the remedy. This paper presents an efficient method for the detection of the tumor size as well as the position with classified tumor stages from MRI images and this work is an extension of our conference paper [1] that was presented in ECCE-2017.

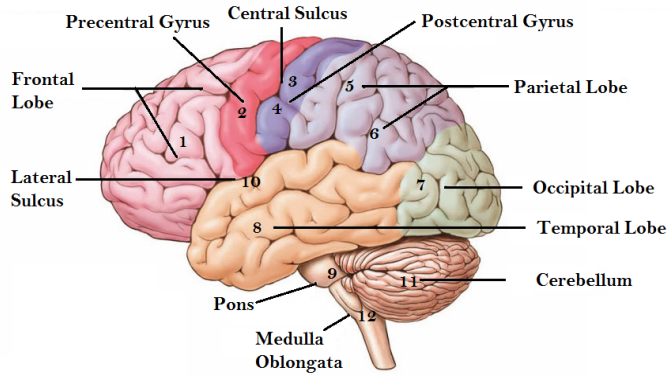

Figure 1: Major functional areas of human brain

In the recent era, there is a radical change in the field of medical science because it has experienced a great invention to the brain imaging. Previously it was predicted by the experts about brain hemorrhage on the basis of symptoms of a patient. But in recent decades the imaging techniques ease the way to detect any abnormality in the brain. There are several techniques of brain imaging like Magnetic Resonance Imaging (MRI), Computed Tomography (CT), Ultrasound Imaging, Positron Emission Tomography (PET), and so on. Among the aforementioned imaging techniques, MRI is a gold accepted modality by which the brain can properly be imaged avoiding any harm.

In case of imaging by MRI, water density in soft tissue is considered and we know that water density in brain tissue is comparatively high than other tissue like bone. Due to the inhomogeneity of brain structure, their contrast values differ randomly in MRI and that is why the proper detection of tumor or tumor size becomes often difficult for the general observer [2]. Recently, proficient brain detection has been a remarkable challenge for medical engineering science. In this case, MRI gets more attention because of its grayscale images. Though MRI provides good contrast value than the other techniques, a suitable segmentation of brain MRI image is ostensible for abnormality detecting from the brain. Since the brain structure is quite complicated, MRI image segmentation needs the sophisticated method and precise results [3]. The segmentation of an MRI image describes notable image regions to attain region(s) of interest (ROI's) like as tumors, edema, legions, necrotic tissues, etc. from brain MRI images [4].

In medical diagnosis, most of the doctors rely on MRI images due to its robustness and that is why the accuracy of the prediction algorithms is very important because the result is crucial for patient treatment. Region growing algorithm [3] is used to categorize brain tumor through statistical feature based brain MRI image classification. The results are attained through some predefined criteria such as intensity information and/or edges. Consequently, the connected regions of an image are being extracted. The primary limitation of this method is finding seed points through manual interaction. The principal component analysis (PCA) algorithm with K-means discussed in [4] can be used to define the tumor class on the basis of some correlated pixel of the MRI images. The increased number of features and samples cause more time to consume and increase inaccuracy in results of PCA based K-means algorithm [5].

The classification with K-means clustering is claimed for CT-Liver image. Along with experimental application in brain MRI explained that proper segmentation can be possible with exact thresholding [6]. Again the *K*-value does not exceed greater than 3 if there is any gray level intensity more than that. The research work presented in [7], has introduced a masking algorithm for the classification with the aid of any classifier algorithm. It is effective in finding automatic seed point and neighbors but the dimension of the mask is to change manually for different brain MRI images [7]. In [8]-[10], the Fuzzy C-means algorithm (FCM) was proposed for segmentation. After that, an expert system was introduced with predefined membership and clustered centroid to trace a landmark tissue comparing with a prior model. On the other hand, FCM is described in [8] has limitation due to its noise sensitivity and inadequacy in the detection of abnormality in brain MRI images like a tumor, edema, and cyst. One of the most acceptable and used techniques for brain MRI image classification is Artificial Neural Network (ANN). An ANN technique is discussed in [11] with convincing results. Nonetheless, the procedure of ANN actually requires a perfect pixel classifier, high dimensional training data, and long time to attain the results those are susceptible conditions for the acute patients.

Most of the methods mentioned above are good in some specific point of view like better accuracy but time-consuming or low accuracy with less time consumption. To enhance the overall performance there be requisite of hybridization of those methods in a way that can be able to overcome these limitations.

An advanced algorithm combining SVM and ANN for tumor classification is introduced in this research work. Brain MRI images with normal and abnormal behavior are firstly enhanced through some filter and preprocessing steps. Thereafter, for the detection and classification of the tumor in the brain, proposed segmentation processes namely temper based K-means and modified Fuzzy C-means (TKFCM) clustering algorithm is used. In this technique, the K-values vary from 1 to 8 those are limited to only 1 to 3 in conventional *K*-means and the automatically updated membership function eradicates limitation of FCM. Then, two kinds of features are extracted from these segmented images. One is used to classify the tumor with SVM as it is easy to classify two kinds of dataset in this method and another is used to classify tumor with ANN into five categories along with four malignant stages. Again, the extracted features provide the classification through ANN and the orientation of tumor define the exact position of the tumor in the lobe (i.e. right, left &center) of the brain.

This paper is structured to present that in section 2 conventional K-means and Fuzzy C-means algorithm is presented, the proposed algorithm is described step by step in section 3, the results and discussions are in section 4 and finally, total work is concluded with a few words in section 5.

2. State of the Arts

2.1. K-means clustering

The conventional K-means is discussed with proper explanation in [6] and based on that idea, in this section this method is represented with a slight modification concerning the proposed work. Suppose, a data set $\{x_1, \ldots, x_N\}$ contains N number of observations where x is D-dimensional Euclidian variable. The basic intention of K-means is to divide the data set into N numbers of clusters, where the value of K is given. Naturally, this can be considered that a cluster including a group of data points and their inner side distances are small compared to the outer sided distances

of the cluster. This concept can be formulated by familiarizing a set of D-dimensional vectors c_k, where k=1, …, K, in which c_k is an example related to the k^{th} cluster. Therefore, it is considered that c_k is representing the center of the cluster. Now it is consequence of the previous technique to find an assignment of those data points of clusters and a set of vectors $\{c_k\}$, in such an approach that the summation of the squares of each data point distance to its closest vector c_k could be minimum.

Now, it is suitable to define some symbolization to designate the assignment of data points to the clusters. For each data point x_n, a set of binary indicator variables $b_{nk} \in \{0,1\}$ can be introduced, where, k= 1, …, K represents the K clusters. The data point x_n is assigned to cluster k then b_{nk}=1 for $j \neq k$. This is recognized as the 1-of-k coding scheme. Consequently, definition of an objective function for distortion measurement [6] can be written as,

$$J = \sum_{n=1}^{N} \sum_{k=1}^{K} b_{nk} \left\| x_n - c_k \right\|^2 \quad (1)$$

The relation (1) represents the summation of the squares of each data point distance to its allotted vector c_k. The objective is to determine the values of $\{b_{nk}\}$ and $\{c_k\}$ so that the system can minimize J. It is usually determined through an iterative procedure in which each iteration comprises two successive steps related to successive optimizations regarding of the values of $\{b_{nk}\}$ and c_k. At first, some preliminary values of c_k are chosen and then the first phase J is being minimized with respect to the $\{b_{nk}\}$, maintaining the values of c_k, fixed. In second phase, J is to minimize in regard to the c_k, maintaining the values of $\{b_{nk}\}$, fixed. This two-stage optimization process is repeated until convergence. These two stages of updating $\{b_{nk}\}$ and c_k correspond respectively to the E (expectation) and M (maximization) steps of the EM algorithm in [12], and to emphasize this and EM is used the terms E step and M step in the context of the K-means algorithm.

Here, $\{b_{nk}\}$ is considered as first determination because J in (1) is a linear function of $\{b_{nk}\}$. This optimization is generally evaluated to offer a closed form solution. The values of n are independent and that is why this can be optimized for each n, separately. By selecting $\{b_{nk}\}$ as 1 gives the minimum value of $\left\| x_n - c_k \right\|^2$ for whatever the value of k. In other words, it can be merely allotted the n^{th} data point to the neighboring cluster center. More strictly, this can be stated as [12],

$$b_{nk} = \begin{cases} 1 & if\ k = \arg\ \min_a \left\| x_n - c_a \right\|^2,\ a = 1,...,k \\ 0 & otherwise \end{cases} \quad (2)$$

Consequently in this situation, it is to consider that the optimization procedure of the c_k with the values of $\{b_{nk}\}$ is occurred immovable. Here, J is the objective function which is actually quadratic function of c_k, and it is commonly minimized through setting its derivative regarding the values of c_k to be zero and this consideration gives the following mathematical relation given in (3).

$$2\sum_{n=1}^{N} b_{nk} (x_n - c_k) = 0 \quad (3)$$

From (3), the values of c_k can be easily evaluated as,

$$c_k = \frac{\sum_n b_{nk} x_n}{\sum_n b_{nk}} \quad (4)$$

The denominator of (4) is equal to the number of points allotted to the cluster k and subsequently this outcome has a simple explanation, explicitly set c_k equal to the mean of all the data points, x_n those are being assigned to the cluster k. Hence, this technique is recognized as the K-means algorithm.

2.2. Fuzzy c-means

The Fuzzy c-means (FCM) algorithm for image clustering with FORTAN code was first introduced in [14]. In this paper, we have presented FCM algorithm with an improvement of earlier clustering methods which actually followed by the explanation given in [13]. According the approach of this paper, suppose R is the set of real number where R^{P} and R^+ are the set of p tuples of real number and set of nonnegative real number, respectively. Here, W_{cn} is a matrix of order $c \times n$ which is called feature space where feature element, $x \in R^P$ & feature vector $x=(x_1, x_2, \ldots, x_p)$ is consists of p real numbers.

Delineation 1: If X is a subset of R^P and every function $u : X \to [0,1]$ is considered to be assigned to each $x \in X$, its grade of membership should be in the Fuzzy set u. The function u is termed a Fuzzy subset of X. It can be noted that there could be infinite Fuzzy sets related to the set X. It is anticipated to make "partition" X by the means of Fuzzy sets. Normally, it is executed by defining a number of Fuzzy sets on X such that for each $x \in X$. The summation of the Fuzzy memberships of x in the previously considered Fuzzy subsets is one.

Delineation 2: It is given that, a finite set $X \subseteq R^P$, $X = (x_1, x_2, ..., x_p)$, and an integer c $(2 \le c \le n)$ originate a Fuzzy c partition of X that can be represented by a matrix $U \in W_{cn}$ whose entries satisfy the following conditions:

i) The number of row i of U or $U_i = (u_{i1}, u_{i2}, ..., u_{in})$ exhibits the i^{th} membership function of X.

ii) The number of column j of U or $U_i = (u_{1j}, u_{2j}, ..., u_{cj})$ revelations the values of the c membership functions of the j^{th} data in X.

iii) The term, u_{ik} will be construed as u_i (x_k) which actually represents the value of the membership function of the i^{th} Fuzzy subset for the k^{th} data.

iv) The summation of the membership values for each x_k will be always one.

v) No Fuzzy subset will be empty.

vi) No Fuzzy subset will contain all elements of X.

M_{fc} denotes the set of the partitions of X in case of Fuzzy c. Here, the distinctive subset $M_c \subseteq M_{fc}$ of X in every u_{ik} is 0 or 1. In addition, the subset is the discrete set of non-Fuzzy c partitions of X. The solution space, M is for the conventional clustering algorithms. The Fuzzy c-means algorithm followed by this proposed work uses the iterative optimization method in order to approximating an objective function minimization which measures similarity on $R^P \times R^P$.

Delineation 3: Suppose that, $U \in W_{fc}$ is a Fuzzy c partition of X, and consider that v is the c tuple $(v_1, v_2, \ldots, v_c)$, $v_i \in R^P$. Therefore, $J_m : M_{fcd} \in R^P \rightarrow R^+$ is described by the following relation:

$$J_m = \sum_{k=1}^{n} \sum_{i=1}^{c} (u_{jk})^m (d_{ik})^2 \; ; \quad v = (v_1, v_2, ..., v_c) \in R^{cP} \tag{5}$$

Additionally, $v_i \in R^P$ is considered to be the cluster center or prototype of class i, $1 \leq i \leq c$, and consequently,

$$d_{ik}^2 = \|x_k - v_i\|^2 \tag{6}$$

Here, $\|.\|^2$ represents any inner product norm metric that defines the Euclidian distance [6], and $m \in [1, \infty]$. This distance calculates the distance from cluster centroid to each object. If we take the Euclidean distance with the distance matrix at null iteration, we get following relationship:

$$D = \begin{bmatrix} \alpha_1 & \beta_1 & \chi_1 & \delta_1 \\ \alpha_2 & \beta_2 & \chi_2 & \delta_2 \end{bmatrix} \begin{bmatrix} x \\ y \end{bmatrix} \tag{7}$$

Each column in D symbolizes the object. The first row of D relates to the distance of the each object to the 1st centroid and similarly, the second row of D is the distance of the each object to the 2nd centroid. As for example, distance from cluster center c= (x, y) to the first centroid $c_1 = (\alpha_1, \alpha_2)$ is $(x- \alpha_1)^2 + (y- \alpha_2)^2$, and its distance to the second centroid $c_2 = (\beta_1, \beta_2)$ is $(x- \beta_1)^2 + (y- \beta_2)^2$, and so on.

The FCM algorithm by the iterative optimization method produces a J_m Fuzzy C-partition of the data set $X=\{x_1, \ldots, x_n\}$. The basic steps to implement the algorithm can be represented by the following consecutive mathematical phases (followed the explanation given in [13]).

1) Fix the cluster numbers c, $2 \leq c \leq n$ where, n is the number of data items. Besides, it is to fix, m $(1 < m < \infty)$. Choose any inner product induced norm metric $\|.\|$ e.g., $A \in W_{pp}$.

2) Initialize the Fuzzy c partition $U^{(0)}$,

3) At step b, b=0, 1, 2, ...

4) Compute the c cluster for the centers $\{v_i^{(b)}\}$ with $U^{(b)}$ and the formula for the i^{th} cluster center is usually consider as the following relation:

$$v_{il} = \frac{\sum_{k=1}^{n} (u_{ik})^m x_{kl}}{\sum_{k=1}^{n} (u_{ik})^m}, \qquad (l = 1, 2, \ldots, p) \tag{8}$$

5) Bring up-to-date, $U^{(b)}$: determine the memberships in $U^{(b+1)}$ as the following steps a) & b). For k = 1, 2, 3, …, n.

a) Evaluate, I_k and $\tilde{I}_k$:

$$I_k = \{i \mid 1 \leq i \leq c,\ d_{ik} = \| x_k - v_i \| = 0\},$$
$$\tilde{I}_k = \{1, 2, ..., c\} - I_k, \tag{9}$$

b) For data item k, determine the new membership values so that,

i) if $I_k = 1$

$$u_{ik} = \left[\sum_{j=1}^{C} \left\{ \frac{d(x_k, v_i)}{d(x_j, v_k)} \right\}^{\frac{-2}{m-1}} \right] \tag{10}$$

ii) else, $u_{ik} = 0$ for all $i \in I_k$ and $\sum_{i \in I_k} u_{ik} = 1$, next k.

6) Compare $U^{(b)}$ and $U^{(b+1)}$ in a convenient matrix norm; if $\left\| U^{(b)} - U^{(b+1)} \right\| \leq \varepsilon$, (where $\varepsilon = \{0 \; to \; 1\}$) stop; otherwise, set b=b+1, and go to step 4.

The use of FCM algorithm necessitates the determination of several parameters, *i.e.*, $c \in m$, the inner product norm $\|.\|$, and a matrix norm. In addition to that, the set $U^{(0)}$ of initial cluster centers should have to be defined for sure. Although no necessary rules for choosing a good value of m are available in the literature. In most of the cases, the value of m is typically reported as the useful range of values as $1 \leq m \leq 5$. The objective of the algorithm mentioned above is to reduce the computational burden imposed by iterative looping between (9) and (10) when c, p, and n are large.

3. Methodology

3.1. MRI image collection

The data of brain MRI images are collected from internet public repository. The images of normal and tumorous brain with Lower Grade Glioma or Glioblastoma Multiforme are collected from the sources [15]-[17]. The number of the used data for each MRI image for classification of normal and tumor brain through SVM is of 39 images. There are 37 images for the classification of benign and malignant tumor stages.

3.2. Image processing

The enhanced images are achieved from the raw MRI images through some steps described as follow.

- **Image conversion and orientation setting**: The images MRI images are converted from *.mha* format and *.dicom* format into *.jpg* by using MATLAB conversion tools application. On the consequence of the conversion, the sizes and directions are reset. This step is conducted in order to have the same size and direction for all the MRI images. This process is performed automatically by using MATLAB with 256×256 pixels for the betterment of image usage.
- **Image enhancement:** The transformed images from the previous step, at first they are converted to L*a*b* images for the comparatively better view and quality. That is why the values of the luminosity of the images can be spanned with a range from 0 to 100 which should be scaled to [0 1] range (appropriate for MATLAB intensity images of class double) before applying the three contrast enhancement techniques like adjusted, adaptive thresholded, and histogram imaging. In this method, for smoothing the images hybridization of both weiner2 (image, [40, 40]) and median2 filter is assured and acquired good results.

3.3. Proposed TKFCM algorithm for tumor detection

In this segmentation process, K-means algorithm is used to segment MRI images on the basis of gray level. This gray level is selected depending on the temper of the image. Then the modified Fuzzy c-means algorithm which depends on the updated membership is applied to segment the temper based K-means segmented image. The membership of modified Fuzzy c-means is updated with the cluster distances from centroid defined by the features of the tumor MRI image. The TKFCM algorithm is the combination of the K-means algorithm and Fuzzy c-means algorithm with some important modifications. The temper is added in the proposed approach along with the conventional K-means algorithm which is identified by the temper or gray level intensity in the brain MRI images. Besides, the Fuzzy c-means membership and Euclidian distance are also modified by the image features.

Here, the coarse image $B(x_i, y_i)$ which is marked and describing the desired tempers for the *K*-means could be found through convolution of gray level based temper and image given as,

$$B(x_i, y_j) = \sum_{i=n+1}^{M+n} \sum_{j=n+1}^{N+n} P(x_i, y_j) \oplus T_{MN(resize)} \quad (11)$$

Temper based window is selected by T_{MN} that is calculated as,

$$T_{MN} = \sum_{i=n+1}^{M-n} \sum_{j=n+1}^{N-n} P(x_i, y_j) \quad (12)$$

In (12), there is presented a temper based matrix of image with a number of gray level intensities, *G* and number of bins, *S* those are used to detect the temper of the images P(x_i, y_j). Where *n* is defined as *n*= (*window Size*-1)/2. With exact value of the temper, row and column, the desired temper is obtained.

Separately temper based *K*-means and modified Fuzzy *c*-means clustering algorithm for segmentation can be written in equation as below:

$$J_k = \sum_{i=1}^{C} \sum_{j=1}^{K} B(x_i, y_j) \left\| x_i - c_j \right\|^2 \quad (13)$$

$$J_m = \sum_{j=1}^{N} \sum_{i=1}^{K} (U_{ij})^m (d_{ij})^2 \quad (14)$$

Here, *M* and *N* are the row and column of the binary coarse image matrix $B(x_i, y_j)$. The number of data points in clusters, centroid of the cluster, and number of clusters are defined by C, *N*, and *K*, respectively.

Then, from (13) and (14) the contour through which the exact location of tumor portion in any image can be find is

$$J_{km} = \oint_c \left(J_k, J_m \right) \quad (15)$$

The relation given in (15) shows a contour integral of temper based *K*-means image and updated membership based FCM image, where *c* is the contour value. The whole method that has been proposed for tumor detection from brain MRI image using Temper based K-means and modified fuzzy C-means is described by the flow chart given in Figure 2.

3.4. Feature extraction

The system extracts the first and second order statistical features as in [18]. The first order statistical features like contrast, correlation, entropy, energy, and Homogeneity are used to detect exact tumor and its position in the brain MRI image through SVM. On the other hand, second order region based statistical features provide area, eccentricity, and the perimeter is required for distinguishing the malignant and benign tumor. These second order feature values are used as the input of the ANN and provide desired tumor categories. The feature extraction procedure is mentioned step by step in Figure 2.

3.5. Methodology of combining SVM and ANN

In this proposed work, the combination of SVM and ANN is used to classify the tumor and its stages. The hybridization of the method is used firstly to classify normal and tumor dataset using Linear SVM Kernel and then classify the tumor data into different stages through ANN. In SVM there will be a hyperplane between the set of data points as the decision boundary. In this case, there are two classified data of normal and abnormal (Tumor) brain images and the hyper planes of SVMs are used to separate these classified data as normal data and tumor data. The input towards the ANN is the information of feature extraction; the first and second order statistic features. Then, the ANN will generate the output results as of benign and malignant I-IV tumors. The process of using ANN to attain the proposed goal of this research work is explained by the flow diagram presented in Figure 3.

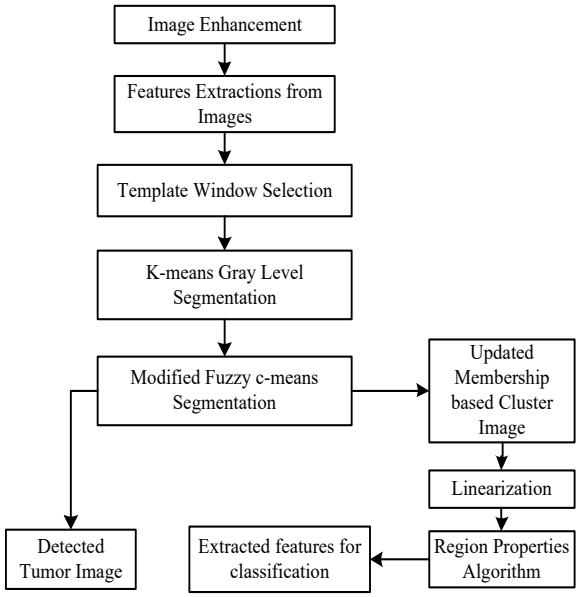

Figure 2: Methodology steps for proposed TKFCM algorithm in tumor detection

4. Results and Discussions

To implement the proposed methodology, first of all, a database of 46 multifaceted brain tumor images is created. It is aforementioned that, the images are collected from the sources of [15]-[17]. To make the quality of the images acceptable for the proposed methodology, some necessary steps were to do and the database was set for the network. To do so for the previous consequence, a thresholding method is applied with threshold level 0.8 and the morphological operation was performed. In addition to

that median and hybrid filters were used to remove the primary noises from the MRI images. The filtered MRI images are presented in Figure 4 (a) & 4(d).

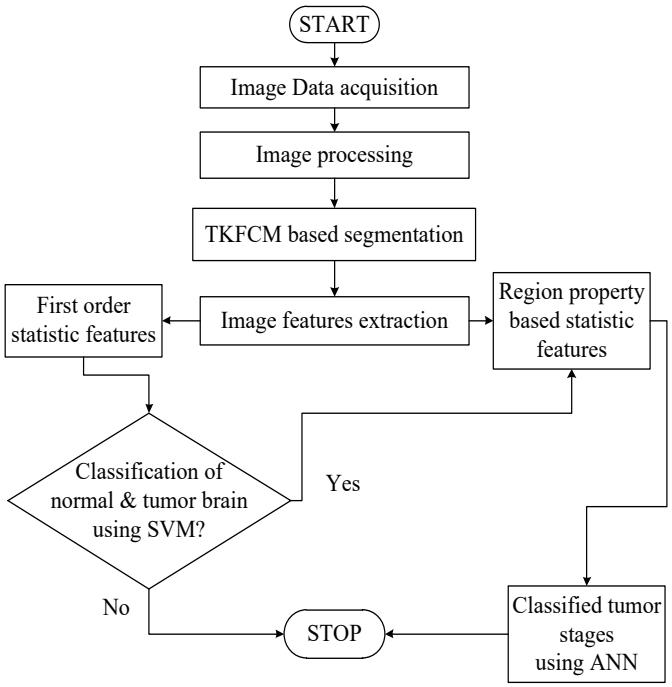

Figure 3: The methodology with their step by step description to implement the proposed hybridization of SVM & ANN algorithms in the filed tumor classification.

The preprocessing steps include filtration, increase of luminosity, and adjust of contrast. After the previous processing, all the images are segmented by the proposed TKFCM based segmentation process. The effects of this segmentation process on images are shown in Figure 4(b) & 4(e) and 4(c) & (f). Temper based K-means (TK) segmentation method shows 8-gray level intensity-based images in Figure 4(b) & 4(e). These figures describe that the input image is segmented by the combined effects of TK-segmentation and the modified approach of FCM algorithm.

The updated membership function with proper Euclidian distance for modified FCM represents the detected tumors in Figure 4(c) & 4(f). These are some examples of the optimum result that can differ this modified and hybrid TKFCM method from the conventional methods. The extracted tumors according to the proposed technique are marked with red color in Figure 4(c) & 4(f). Therefore, these segmented areas can be used to determine the region property based statistical features from the images.

In Figure 5, we presented ten images (given in Figure 5 (a) & (d)) as the input of classification by the proposed TKFCM scheme. These ten images are taken from the created database and used for the classification of the tumor and its area. The enhanced input images for TKFCM (shown in Figure 5(a) & 5(d)) are preprocessed by the steps described by the visual explanation in Figure 4. In Figure 5 (b) & 5(e), the detected brain tumor images marked as the red color those are the outcomes of the previous images by the application of the TKFCM method. Classified brain tumors through linearization of TKFCM are presented in Figure 5 (c) & 5(f). From which the region based features are obtained by the level thresholding, updated membership function, and region properties algorithm.

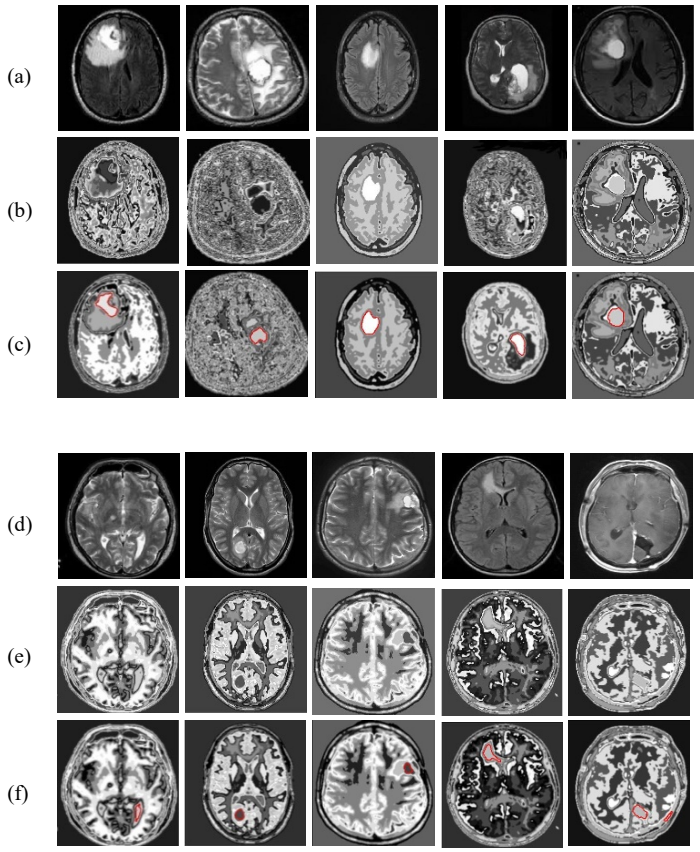

Figure 4: (a) & (d): Filtered images for TKFCM, 4(b & e): Temper based segmented images, 4(c & f): TKFCM based detected tumor images.

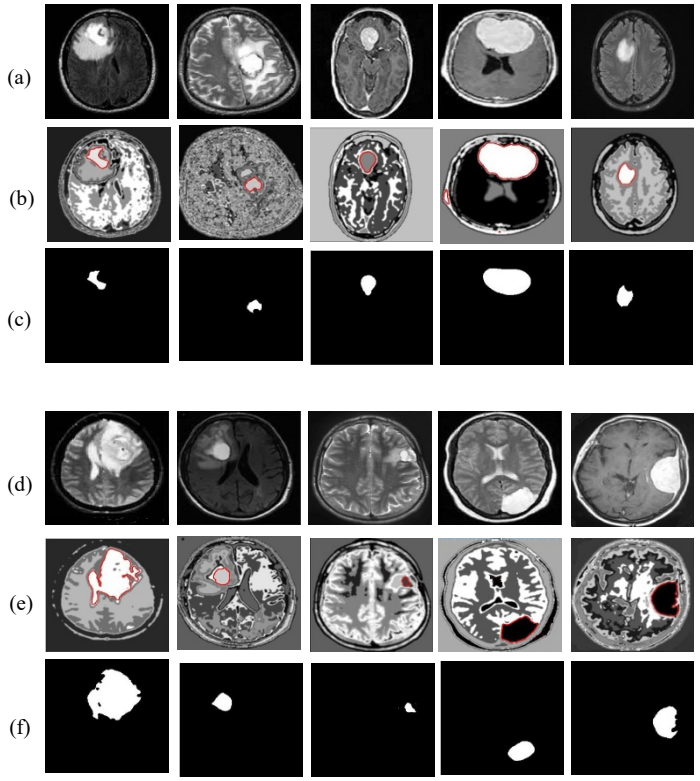

Figure 5: Enhanced Input images for TKFCM in 5(a & d), TKFCM based red marked tumor images in 5(b & e), and classified brain tumor through linearization of TKFCM in 5(c & f).

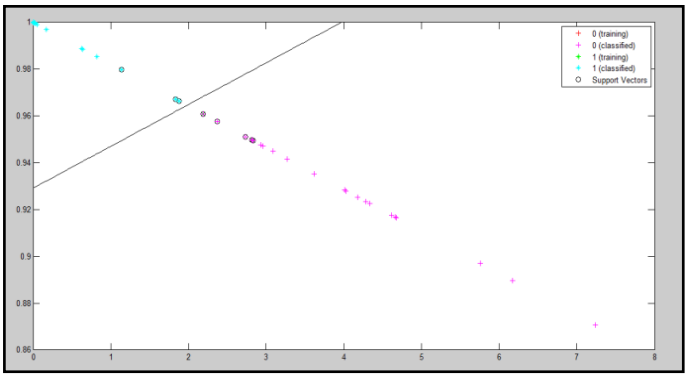
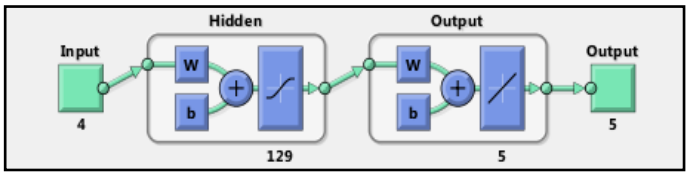
From the segmented image, two kinds of features are extracted: one is statistical features and other is region property based features. The first kind of statistical features *i.e.*, contrast, correlation, entropy, homogeneity, energy are used to classify whether there is any normal brain or tumorous brain using SVM. Therefore, SVM classifies the images into two categories- tumorous and normal. For this significance, two major kinds of MRI image data of normal and abnormal brain are fed to SVM network and the corresponding results of classification property of the SVM are presented in Figure 6(a). There are 46 images used to classify whether the system classified 37 tumor images, 8 normal images and rest 1 is misclassified. As a result, the accuracy of SVM method is 97.44% which is very convincing to move to the next step c.



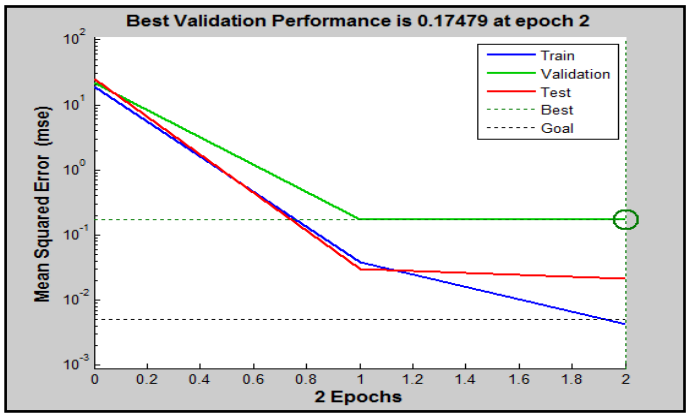
According to the previous approach the tumorous brains have to be classified into 5 defined categories. Due to implementing this classifying network, an ANN-based network was designed as the configuration given in Figure 6(b). The network consists of four input vector layers, one hidden layer with 129 neurons, and five output vector layers. The input feature vectors are evaluated as the second kind of features of MRI images which are acknowledged in this article by the region property based features.

The performances of training, validation, and testing of the proposed network are shown in Figure 6(c). The specifications of the achieved performances were 60 iterations with 0.05 increment order. Additionally, the minimum error was considered up to 0.5e-02, the gradient minima were approximately 1e-10, and the maximum validation check failure was taken 6. From the Figure 6(c), it is found that the desired performances are achieved between 8 and 9 iterations which indicate the less required time for the network compared to the 60 iterations. Best validation performance is 0.17479 at iteration 2 mentioned in Figure 6(c).



The second kind of features *i.e.*, area, eccentricity, perimeter, orientation are used to differentiate the tumor and different malignant stages of I to IV. The obtained features are denoted as input vectors of the proposed network. On this contrary, we acknowledged in this article that we have five categories of brain tumor those are I-IV malignant groups along with benign. Therefore, the results are given by the confusion matrix in Figure 6(d) are the output vectors or classified 5 groups. The network achieved 97.3% classifying accuracy given in Figure 6(d). This result is very convincing where it is found that there are 9 benign, 17 malignant I, 6 malignant II, 3 malignant III, and 1 malignant IV stages. The network misclassified 1 tumorous brain MRI images.

In Table 1, there are some feature values for classifying tumor categories as well as detecting exact tumor position in our brain lobe. The region-based features are used as input vector of ANN to classify the malignant and benign tumors. Beside one of the features mentioned as 'orientation' of the tumor defines the exact lobe position of the tumor in brain MRI images. These results of orientation by the proposed method provide the information about the position of the tumor either in left or right or center part of the brain.



Since the classification accuracy is not the only performance metric, some other performances of the classifier are necessary to be evaluated. Based on the value of true positive (TP), false positive (FP), true negative (TN), and false negative (FN) of the proposed network, some other performances like sensitivity, specificity, beat error rate (BER) can be calculated. In this step,

FCM	86.95	85.7	86.4	0.136	~5 min
SVM	96.2	66.67	90.44	0.0234	~4 min
K-means	75	92.85	83.7	0.160	~160-170 sec
TKFCM	88.9	100	91.89	0.055	~100 sec
Fuzzy Logic Method	96.3	100	96.667	0.018	~ 120 sec
Proposed SVM+ANN Method	**98**	**100**	**97.37**	**0.0294**	**~ 2 min**

*Image size=256x256, Software=MATLAB2014a, Processor= Core2duo, RAM=2GB, windows=7

these important estimations are performed by the following relations (16)-(19) and used for comparison purposed with other conventional methods [19].

$$Sensitivity = \frac{TP}{(TP+FN)} \times 100 \quad (16)$$

$$Specificity = \frac{TN}{(TN+FP)} \times 100 \quad (17)$$

$$Accuracy = \frac{(TP+TN)}{(TP+TN+FN+FP)} \times 100 \quad (18)$$

$$BER = \frac{1}{2}\left(\frac{(FN)}{(TP+FN)} + \frac{(FP)}{(FP+TN)}\right) \quad (19)$$

Comparisons of the proposed method with predictable techniques whose algorithms are coded to cope up with the same dataset are mentioned in Table 2. In this proposed technique, 37 brain tumor images are taken for the simulation. The sensitivity of 98%, specificity of 100%, the accuracy of 97.37%, and BER 0.0294, which are obtained by combining ANN and SVM. The results show that the proposed method is better than the conventional methods like thresholding, region growing, SVM, ANN, FCM, TKFCM, and K-means. The proposed algorithm that is actually combinations of several suitable techniques proves more effective than any other single method. Though the conventional ANN comprehends the value of accuracy of 95.07%, the computational time is so high. But the proposed technique shows less computational time with better accuracy than conventional ANN. So, it can be useful for both detecting tumors and be classifying tumor stages of brain MRI images for experts.

5. Conclusion

This work classified the images as normal and tumorous. In addition, the size of the tumor and its position in brain lobe were also identified by the proposed method from MRI image. To implement such an efficient and intelligent algorithm, a number of statistical and machine learning based algorithms like temper based *K*-means and modified Fuzzy *c*-means clustering, SVM, and ANN are combined. As a result, it is found that the previous limitations like less classifying accuracy, computational time requirement, unsatisfactory of BER, sensitivity, and specificity of conventional ideas has been overcome by this proposed algorithm. Other existing methods have some tradeoff among the performances. This method provides sensitivity 98%, specificity 100%, classifying accuracy 97.37%, BER=0.0294, and required less than 2 minutes to give the result. These results are too convincing to identify the brain tumor and its size, as well. In addition, this algorithm has provided the tumor position accurately. Considering all the performances, it can be concluded that the proposed algorithm is better than others like region growing, thresholding, and FCM compared to every parameter. On the other hand, in point of accuracy and

computational time the proposed method is better than ANN, SVM, and TKFCM. Eventually, we hope that this method can be very helpful for diagnosis of brain tumor.

Conflict of Interest

So far the knowledge, the authors declare no conflict of interest regarding this article.

Acknowledgment

Authors would like to thank Prof. Dr. Md. Abdur Rafiq, Dean, Faculty of Electrical and Electronic Engineering, Khulna University of Engineering & Technology (KUET), Khulna, Bangladesh, for his beautiful lectures on neural network- fuzzy logic and guidelines to implement it in this research work.

ABSTRACT

Metal housing has been used extensively on portable communication devices such as on mobile phones and tablets. The choice of metal housing ranges from metallic rim to metallic back cover. This metal housing tends to improve the outlook appearance of the mobile devices, and add mechanical strength towards the mobile devices. However, from the aspect of the communication antenna, the metal housing often posts great challenges towards the flexibility in antenna design and reduction in antenna performance. This paper presents an approach to overcome the challenges by integrating the metal housing of the mobile phone as part of the antenna, along with the introduction of tunable antenna concept to provide different forms of Aperture Tuning to the Cellular Main Antenna, to satisfy its wide frequency band coverages for the 2nd, 3rd and 4th Generation (2G, 3G and 4G) mobile network.

1. Introduction

Over the years, there had been a popular trend for mobile phones to be equipped with metal housing. The metal housing often comes in different forms, which examples are as shown in Figure 1. One form of metal housing is the Closed Metal Ring as shown in Figure 1(a), with a metal ring running around the edges of the mobile phone. Another type of metal housing, quite similar to the Closed Metal Ring, is the Broken Metal Ring (with open slot) as shown in Figure 1(b). In the Broken Metal Ring, there are slots cutting on the metal ring, dividing the metal ring into two or more sections. In recent years, there is another type of metal housing that has been becoming popular. This metal housing comes in the form of a Metallic Back Cover as shown in Figure 1(c). The use of metal housing on mobile phone tends to improve the outlook appearance of the mobile phone. Apart from that, the robustness of the metal housing tends to add mechanical strength to the mobile phone. However, the use of metal housing on mobile phone often post disadvantages towards the mobile phone antenna. These disadvantages include introducing unwanted coupling towards the antenna, creating a shielding effect over the antenna hence reducing the sensitivity of the antenna etc. Additionally, maintaining the aesthetics of the metal housing on the mobile phone comes with an antenna design flexibility cost.

(a) (b) (c)

Figure 1. Different forms of metal housing: (a) Closed Metal Ring; (b) Broken Metal Ring (with open slot); (c) Metallic Back Cover;

This paper serves as an extension of work originally presented in 2017 11th European Conference on Antennas and Propagation (EuCAP2017) [1]. This paper presents a flexible Aperture Tuning solution [2 – 4] for the cellular Main Antenna in a Metallic Back Cover mobile phone, to provide coverage for multi frequency bands in the frequency range of 700MHz to 960MHz (LTE700, GSM850, GSM900), 1710MHz to 2170MHz (DCS1800, PCS1900, WCDMA2100) and 2300MHz to 2690MHz (LTE2300, LTE2600). The flexible Aperture Tuning solution as proposed in this paper aims to overcome the disadvantages post by the metal housing as mentioned above. In the earlier paper [1], the flexible Aperture Tuning solution for the cellular Main Antenna has been briefly introduced, along with the Free-Space passive measurement data of the Main Antenna's Reflection Coefficient S11 and Total Efficiency. This paper will further elaborates on the concept of the different Aperture Tuning solutions that are deployed at different parts of the Main Antenna for tuning the antenna's Low (700 – 960MHz) Band, Mid (1710 – 2170MHz)

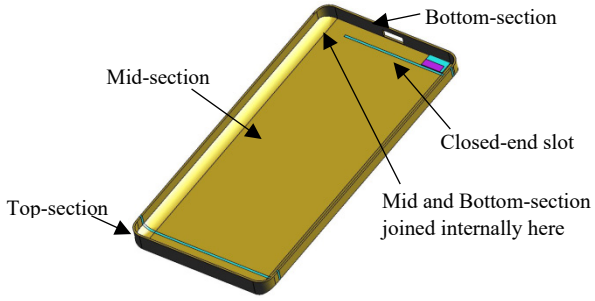
Band and High (2300 – 2690MHz) Band. Besides the Free-Space passive measurement data, this paper also presents the active measurement data (Total Radiation Power TRP) taken with the mobile phone mockup in the Free-Space and Phantom Head & Hands conditions.



2. Metallic Back Cover Mobile Phone Mockup

2.1. Metallic Back Cover

The metal housing for the mobile phone presented in this paper takes the form of a Metallic Back Cover, as mentioned in Figure 1(c). Figure 2 shows pictures illustrating the exterior and interior appearance of the Metallic Back Cover. From the exterior appearance shown in Figure 2(a), the Metallic Back Cover seems to be divided into three sections, namely Top-section, Mid-section and Bottom-section. In between each section, there is a plastic slot (at 1mm wide) running across the Metallic Back Cover. However, from the interior appearance shown in Figure 2(b), it can be seen that the Mid-section and Bottom-section of the Metallic Back Cover are actually joined together internally. This makes the slot at the Bottom-section more like a Closed-end slot instead of a through slot as seen at the Top-section. The overall dimension of the Metallic Back Cover is 144mm by 70mm by 6.5mm, which is suitable for mobile phone with 5.5inch display.

(a) Exterior appearance

(b) Interior appearance

Figure 2. Metallic Back Cover

In this proposed solution, the Main Antenna is located at the bottom section of the mobile phone. The entire Bottom-section metallic cover and partial of the Mid-section metallic cover are integrated as part of the Main Antenna design. Figure 3 shows pictures mainly highlighting the interior appearance at the bottom section of the Metallic Back Cover. There is a Capacitive Feed Patch located near the bottom left corner of the Metallic Back Cover. This Capacitive Feed Patch is a thin layer of conductive rectangular patch, separated from the inner surface of the Metallic Back Cover by a thin layer of plastic substrate with thickness of 0.5mm. The Capacitive Feed Patch is positioned on the Bottom-section side of the Metallic Back Cover in a way such that the edge of the Capacitive Feed Patch will align well with the edge of the Closed-end slot, as can be seen in Figure 3. Figure 3 also highlights the installation of a Tuner Board on the inner surface of the Metallic Back Cover. The Tuner Board is a tiny piece of Printed Circuit Board (PCB) that is used to house a Tunable Capacitor TC1. The Tuner Board is fully grounded onto the Mid-section of the Metallic Back Cover, positioned just by the edge of the Closed-end slot. The output of the Tunable Capacitor TC1 is bridged across the slot and get into direct contact with the Bottom-section of the Metallic Back Cover.

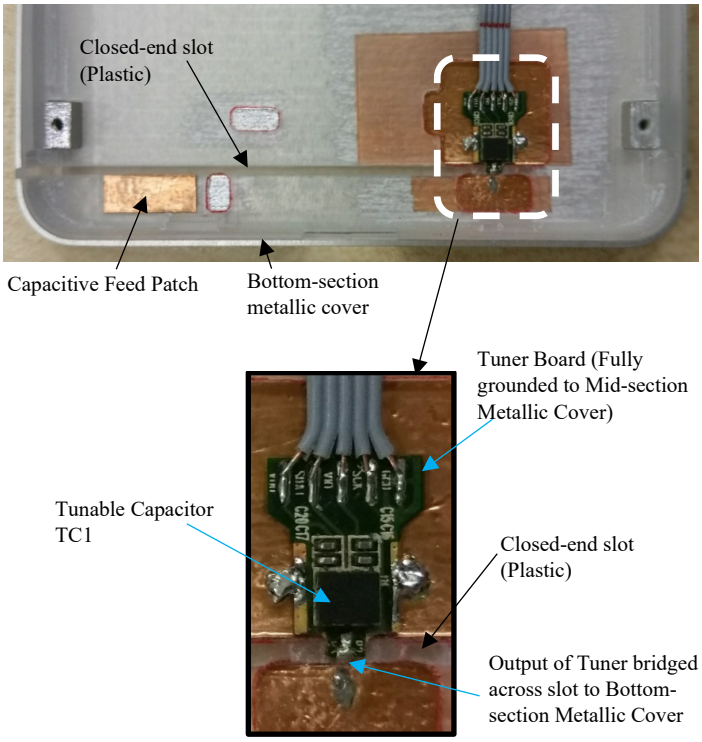


Figure 3. Capacitive Feed Patch and Tuner Board on Metallic Back Cover

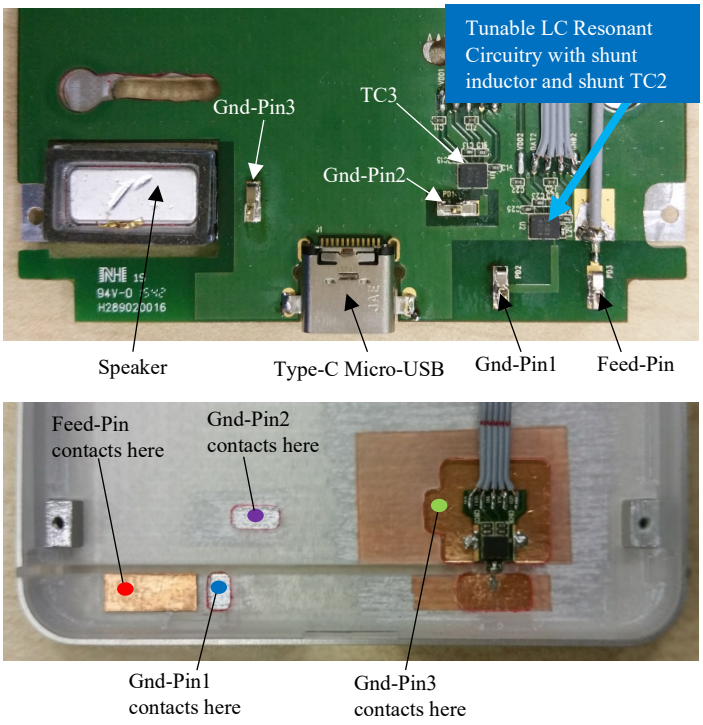
2.2. Main Antenna Printed Circuit Board (PCB)

Figure 4 shows partial of the Main Antenna Printed Circuit Board (PCB) used in the mobile phone mockup, mainly highlighting the environment in the Main Antenna region at the bottom section of the mobile phone. The PCB is equipped with a Type-C Micro-USB and a speaker which are components that are commonly found at the bottom section of mobile phone. On the PCB, there is a Feed-Pin that is traced to the source of the Main Antenna. The Feed-Pin can be in the form of a pogo-pin or spring contact to establish a direct connection with the Capacitive Feed Patch at the location (red-dot) as highlighted in Figure 4. Located next to the Feed-Pin is Gnd-Pin1, which is traced to a Tunable LC Resonant Circuitry, with reference to the common ground. This Tunable LC Resonant Circuitry is made up of a shunt inductor in parallel with a shunt Tunable Capacitor TC2, to provide Aperture Tuning to the Main Antenna. The Gnd-Pin1 can be in the form of a pogo-pin or spring contact to make direct contact with the Bottom-section metallic cover at the location (blue-dot) as indicated in Figure 4. Located above Gnd-Pin1 on the PCB is Gnd-Pin2 which is traced to a standalone Tunable Capacitor TC3 connecting to the reference ground. This standalone Tunable Capacitor is meant for providing Aperture Tuning to the Main Antenna. The Gnd-Pin2 makes direct connection with the Mid-

section of metallic cover at the location (purple-dot) as indicated in Figure 4. To the left of Gnd-Pin2, located near the speaker is Gnd-Pin3 which is connected directly to the reference ground. Gnd-Pin3 on the PCB is meant to make direct connection with the Mid-section of metallic cover at the location (green-dot) next to the Tuner Board as shown in Figure 4. This arrangement of the grounding connections between the respective ground pins (Gnd-Pin1, Gnd-Pin2 and Gnd-Pin3) on PCB and the Metallic Back Cover has integrated the Metallic Back Cover as part of the Main Antenna design. The three Tunable Capacitors (TC1, TC2 and TC3) as mentioned above on the Metallic Back Cover and Main Antenna PCB are Micro-Electro-Mechanical Systems (MEMS) based variable capacitors. Each capacitor has 16 different states of capacitance value ranging from 0.3pF to 2.97pF programmed in its register. The proposed tunable solution for the Main Antenna in this paper is not limited to the technology or type of the Tunable Capacitor.



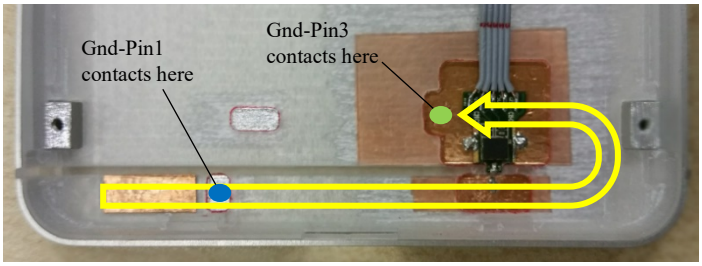


Figure 4. PCB layout for the Main Antenna and integrating the Metallic Back Cover as part of the Main Antenna design

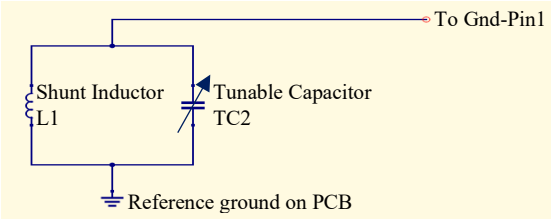
3. Flexible Aperture Tuning Solution for Main Antenna



The Main Antenna of the mobile phone has operating frequency bands that are divided into the Low Band, the Mid Band and the High Band. The Low Band covers frequency range from 700MHz to 960MHz, the Mid Band covers frequency range from 1710MHz to 2170MHz and the High Band covers frequency range from 2300MHz to 2690MHz. These ranges of frequency bands are sufficient to provide coverage for the 2G, 3G and 4G network. The Aperture Tuning of the Main Antenna as proposed in this paper will be broken down to sections with respect to the following bands: Low Band, Mid Band and High Band.

3.1. Low Band Tuning (700MHz to 960MHz)

The proposed Main Antenna solution is fed using the Capacitive-Fed Coupling Technique [5 – 6] to the Bottom-section metallic cover via the Capacitive Feed Patch as mentioned above in Figure 3. Energy from the Capacitive Feed Patch is coupled onto the Bottom-section metallic cover. Current on the Bottom-section metallic cover will then flows in the direction as indicated by the yellow-coloured arrow (as shown in Figure 5(a)) to Gnd-Pin3 on the Main Antenna PCB. This forms a Loop Antenna for the Low Band of the Main Antenna. Aperture Tuning is applied to this Loop Antenna at Gnd-Pin1, via the Tunable LC Resonant Circuitry [2 – 4] (as mentioned in Figure 4) which equivalent circuit is as shown in Figure 5(b). The resonance at the Low Band of the Main Antenna can be made to shift within the frequency range of 700MHz to 960MHz by tuning the capacitance value of the Tunable Capacitor TC2 on the PCB. In tuning the Low Band of the Main Antenna, the capacitance value of the Tunable Capacitor TC1 on the Metallic Back Cover and the Tunable Capacitor TC3 at Gnd-Pin2 on the PCB are kept constant at 2.97pF and 0.66pF respectively.

Figure 5. Low Band Tuning of Main Antenna

Figure 6 shows plots of the passive measurement result for the Low Band Tuning of the Main Antenna, in Free-Space condition. Figure 6 (a) is the Reflection Coefficient S11 of the Main Antenna measured using a Network Analyzer. Figure 6(b) shows plots of the Total Efficiency of the Main Antenna in the Low Band region, measured in an Anechoic Over-the-Air (OTA) Chamber. From the two plots shown in Figure 6, it can be seen that three different

(a) Reflection Coefficient S11 in Low Band region

(b) Total Efficiency in Low Band region

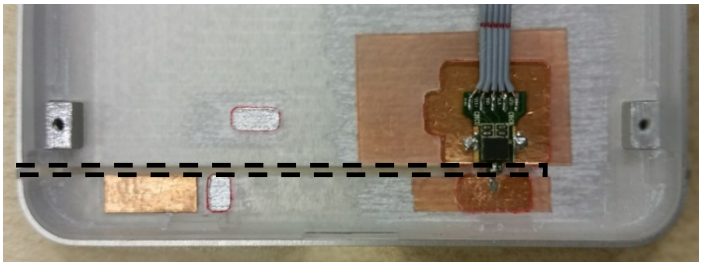

Figure 6. Passive measurement results in Low Band region

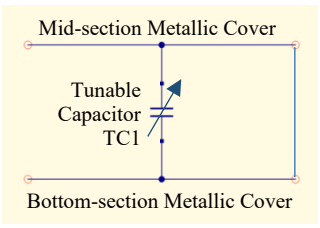
capacitance value of TC2 (at 0.48pF, 1.9pF and 2.97pF) are used to shift the Low Band resonance across the Low Band region of 700MHz to 960MHz. This shift in the Total Efficiency plot (as seen in Figure 6(b)) helps to maintain the Total Efficiency in the Low Band region at above 20%.



3.2. Mid Band Tuning (1710MHz to 2170MHz)

The Mid Band of the Main Antenna is resulting from a Slot Antenna form on the Metallic Back Cover by the Closed-end slot, as highlighted with the black-dotted line in Figure 7(a). The Tunable Capacitor TC1, which output is bridged across the Closed-end slot on the Metallic Back cover, is being used to provide Aperture Tuning to this Slot Antenna. The configuration of having the Tunable Capacitor TC1 across the Closed-end slot can be best described by the equivalent circuit as shown in Figure 7(b). Hence, by tuning the capacitance value of Tunable Capacitor TC1, the wavelength of the Slot Antenna will change accordingly, shifting the Mid Band resonance within the frequency range of 1710MHz to 2170MHz. In tuning the Mid Band of the Main Antenna, the capacitance value of both the Tunable Capacitor TC2 and TC3 on the Main Antenna PCB are kept constant at 2.97pF.

Figure 8 shows plots of the passive measurement result for the Mid Band Tuning of the Main Antenna, in Free-Space condition. Figure 8(a) is the measured Reflection Coefficient S11 of the Main Antenna and Figure 8(b) shows plots of the measured Total Efficiency of the Main Antenna in the Mid Band region. From the two plots shown in Figure 8, it can be seen that the Mid Band resonance can be made to shift across the Mid Band region of 1710MHz to 2170MHz by tuning the capacitance value of TC1 at 1.55pF, 1.9pF, 2.44pF and 2.97pF respectively. This shift in the Total Efficiency plot (as seen in Figure 8(b)) helps to maintain the Total Efficiency in the Mid Band region at above 20%.

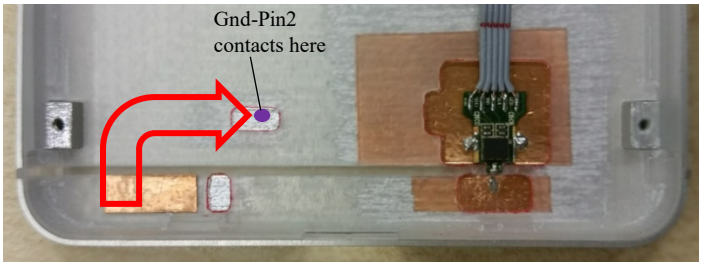
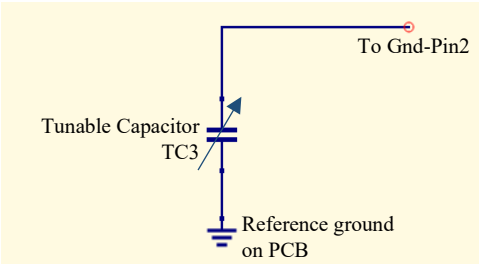
(a) Reflection Coefficient S11 in Mid Band region



(b) Total Efficiency in Mid Band region

Figure 8. Passive measurement results in Mid Band region



3.3. High Band Tuning (2300MHz to 2690MHz)

In High Band Tuning of the Main Antenna, the energy from the Capacitive Feed Patch on the Bottom-section metallic cover is coupled across the Closed-end slot to the Mid-section metallic cover. Current on the Mid-section metallic cover will then flows in the direction as indicated by the red-coloured arrow to Gnd-Pin2 on the Main Antenna PCB, as shown in Figure 9 (a). This actually forms a small Loop Antenna for the High Band of the Main Antenna. Aperture Tuning is applied to this small Loop Antenna at Gnd-Pin2, via the Tunable Capacitor TC3, which equivalent circuit is as shown in Figure 9 (b). The resonance at the High Band of the Main Antenna can be made to shift within the frequency range of 2300MHz to 2690MHz by tuning the capacitance value of the Tunable Capacitor TC3 on the PCB. In tuning the High Band of the Main Antenna, the capacitance value of the Tunable

Capacitor TC1 on the Metallic Back Cover and the Tunable Capacitor TC2 in the Tunable LC Resonant Circuit on the PCB are both kept constant at 2.97pF.

Figure 10. Passive measurement results in High Band region

Figure 10 shows plots of the passive measurement result for the High Band Tuning of the Main Antenna, in Free-Space condition. Figure 10 (a) is the measured Reflection Coefficient S11 of the Main Antenna and Figure 10 (b) shows plots of the measured Total Efficiency of the Main Antenna in the High Band region. From the two plots shown in Figure 10, it can be seen that two-different capacitance value of TC3 (0.3pF and 2.97pF) are used to shift the High Band resonance across the High Band region of 2300MHz to 2690MHz. This shift in the Total Efficiency plot (as seen in Figure 10(b)) helps to maintain the Total Efficiency in the High Band region at above 40%.

4. Mobile Phone Mockup in Active Phone Condition

In this section, the Metallic Back Cover mobile phone mockup as reported above is configured to be an active phone. Figure 11 shows a picture illustrating the Metallic Back Cover mobile phone mockup in its active phone configuration. The mockup is equipped with an in-house designed Main PCB which is used to house a Long-Term Evolution (LTE) module for conducting active Total Radiated Power (TRP) measurement in an Anechoic OTA Chamber. The Main PCB is equipped with power contact points to draw power from a mobile phone battery, to power up the LTE Module as well as the Tunable Capacitors (TC1, TC2 and TC3 mentioned above in section 2 and 3) during the active measurement.

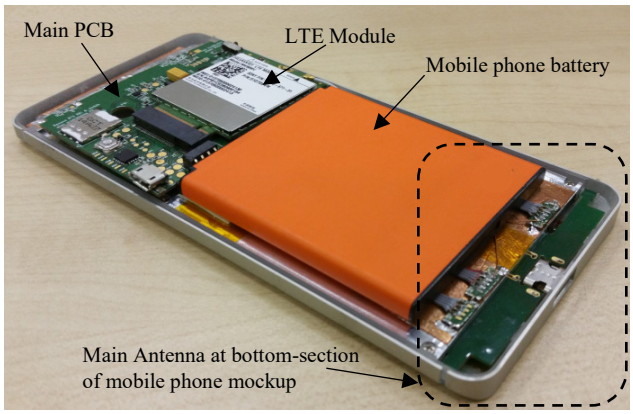

Figure 11. Mobile phone mockup in active condition

4.1. Measurement in Free-Space

The active TRP measurement in the Free-Space condition was conducted in an Anechoic OTA Chamber, for four different 3G bands and five different 4G LTE bands. These bands are WCDMA Band 1, 2, 5 and 8 in the 3G network, and FDD LTE Band 1, 4, 7, 8 and 13 in the 4G LTE network. Table 1 tabulates the active TRP measurement results of the Main Antenna, with the metallic cover mobile phone mockup in Free-Space condition. The first column in Table 1 lists the respective nine frequency bands in the 3G and 4G network. The second column displays the mid channel for each band respectively, and the third column lists the frequency (in MHz) corresponding to respective mid channel in the second column. As can be seen from the third column, this measurement covers the various frequencies which fall within the Low (700MHz to 960MHz), Mid (1710MHz to 2170MHz) and High (2300MHz to 2690MHz) Band regions of the Main Antenna. The fourth column in Table 1 lists the measured Conducted Power (in dBm) of the LTE Module, transmitting at the respective frequencies listed in the third column. And lastly, the measured Free-Space TRP (in dBm) of the Main Antenna on the Metallic Back Cover mobile phone mockup is as listed in the fifth column. From Table

1, the Conducted Power of the LTE Module is ranging from 20 to 23dBm, and the Free-Space TRP ranges from 14 to 20dBm.

Table 1. Active TRP measurement results in Free-Space

Band	Channel	Frequency (MHz)	Conducted Power (dBm)	Free-Space TRP (dBm)
WCDMA Band5	4182	836.6	22.3	17.8
WCDMA Band8	2787	897.6	22.2	16.7
WCDMA Band2	9400	1880.0	22.9	15.1
WCDMA Band1	9750	1950.0	22.4	14.1
FDD LTE Band13	23230	782.0	22.0	16.9
FDD LTE Band8	21625	897.5	21.2	16.6
FDD LTE Band4	20175	1732.5	21.8	15.7
FDD LTE Band1	18300	1950.0	21.7	13.8
FDD LTE Band7	21100	2535.0	20.2	19.7

4.2. Measurement with Phantom Head & Hands

To study the user effect towards the Main Antenna solution on the metallic cover mobile phone mockup, the active TRP measurement was further extended to the Phantom Head & Hands configuration. Figure 12 shows an example of the setup of the Phantom Head + Right Hand (BHHR) in the talk mode configuration. In this setup, the metallic cover mobile phone mockup will be gripped by the Hand, and placed beside the Phantom Head, as according to the CTIA Test Plan [7]. Two Phantom configurations had been considered in this measurement: Phantom Head + Left Hand (BHHL) and Phantom Head + Right Hand (BHHR). This active TRP measurement of the Main Antenna, with the mobile phone mockup on the Phantom Head & Hands was conducted in an Anechoic OTA Chamber, for four different 3G bands (WCDMA Band 1, 2, 5 and 8). Table 2 tabulates the active TRP measurement results of the Main Antenna, with the mobile phone mockup on the Phantom Head & Hands (BHHL and BHHR) talk mode configuration. The first three columns in Table 2 list the frequency bands, its mid channel and the corresponding frequency in the 3G network respectively. The fourth and fifth column in Table 2 list the measured TRP (in dBm) of the Main Antenna, in the BHHL and BHHR configuration respectively. From the BHHL TRP and BHHR TRP results listed in Table2, it can be clearly seen that the left hand has a greater influence on the Main Antenna performance as compared to the right hand. This is likely due to the hand is covering the opening of the Closed-end slot on the Metallic Back Cover in the BHHL configuration. The variation in TRP between BHHL and BHHR is between 1 to 3.3dBm, with the worst case scenarios taking place at WCDMA Band 2 (1880MHz). A comparison between the Free-Space TRP (in Table 1) and BHHL TRP (in Table 2) shows a reduction in the antenna performance in the latter case with variation of between 5.9 to 9.6dBm, and the worst case scenarios taking place at WCDMA Band 8 (897.6MHz). The comparison between the Free-Space TRP and BHHR TRP also shows a reduction in the antenna performance in the latter case, with variation of between 4.6 to 8.4dBm, and the worst case scenarios taking place at WCDMA Band 5 (836.6MHz).

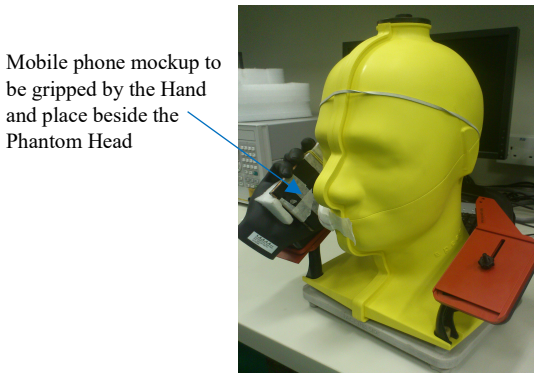

Figure 12. Phantom Head + Right Hand (BHHR) in talk mode setup

Table 2. Active TRP measurement results in BHHL and BHHR

Band	Channel	Frequency (MHz)	BHHL TRP (dBm)	BHHR TRP (dBm)
WCDMA Band5	4182	836.6	8.3	9.3
WCDMA Band8	2787	897.6	7.1	9.6
WCDMA Band2	9400	1880.0	7.0	10.3
WCDMA Band1	9750	1950.0	8.2	9.5

5. Conclusion

It has always been challenging in providing solution for antennas on mobile phones with metal housing. The metal housing often introduces unnecessary coupling, shielding effect towards the antennas as well as reducing the flexibility in designing the antenna. In this paper, a tunable solution has been proposed for the cellular Main Antenna of a mobile phone with metal housing in the form of metallic back cover. The proposed solution demonstrates the integration of the metal housing as part of the antenna design, along with the use of different Aperture Tuning circuitries at different parts of the Main Antenna, to allow flexible tuning of the antenna's Low, Mid and High Band. In an attempt to study the user effect towards the Main Antenna on the metallic cover mobile phone, the measurement results suggested that the Left Hand influence on the antenna is greater as compared to the Right Hand. In the comparison between Free-Space and BHHL/BHHR condition, the antenna performance sees a reduction of less than 10dBm.

ABSTRACT

Quality assurance of modern-day safety-critical systems is continually facing new challenges with the increase in both the level of functionality they provide and their degree of interaction with their environment. We propose a novel selection method for black-box regression testing on the basis of machine learning techniques for increasing testing efficiency. Risk-aware selection decisions are performed on the basis of reliability estimations calculated during an online training session. In this way, significant reductions in testing time can be achieved in industrial projects without uncontrolled reduction in the quality of the regression test for assessing the actual system reliability.

1 Introduction

Reliability assessment of safety-critical systems is becoming an almost insurmountable challenge. In the near future, the engineering of new applications for vehicles such as driving assistance functions or even autonomous driving systems will inevitably incur significantly increased engineering sophistication and longer test cycles. Thus, in the automotive domain, functional safety continues to be ensured on the basis of the international ISO 26262 standard. As both the levels of functionality such systems provide and their degree of interaction with their environment increases, an adequate increase in system safety assessment capabilities is required.

This paper is an extension of work originally presented at the 10th IEEE International Conference on Software Testing, Verification and Validation (ICST 2017) [1] and describes a methodology for efficiently assessing system safety. The focus of the paper is on regression testing of safety-critical systems consisting of black-box components. This scenario is common for automotive electronic systems, where testing time is expensive and should be reduced without an uncontrolled reduction in reliability.

The work reported here correspondingly seeks to increase testing efficiency by reducing the number of selected test cases in a regression test cycle. When a selection decision is made, the following two types of errors are possible:

- a test case is selected but would pass (type-I-error, false-positive case) and
- a test case is not selected but would fail (type-II-error, false-negative case).

Accordingly, we model a classifier $\hat{H}$ for solving the following optimization problem.

$$\begin{aligned} &\min\ p_{FP} = P(\hat{H} = H_1|H_0) \\ &\text{subject to } p_{FN} = P(\hat{H} = H_0|H_1) \leq p_{FN,MAX} \end{aligned} \tag{1}$$

A good standard of test efficiency calls for the avoidance of false-positives. This requires minimization of the probability of mistakenly assuming the rival hypothesis (H_1 : test case fails) even though the null hypothesis (H_0 : test case passes) is correct. Conversely, false-negatives mean that system failures remain undetected; the occurrence of this type of error must therefore be avoided with very stringent requirements. Thus, a predefined limit $p_{FN,MAX}$ for the probability of a false-negative is defined.

[1] proposed a concept for the selection of test cases based on a stochastic model. However, this paper proposes a holistic optimization framework for the safety assessment of safety-critical systems based on machine learning optimization techniques. We

[*]Corresponding Author: Ibrahim Alagöz, Hornstr. 1 85051 Ingolstadt, ibrahim.alagoez@gmail.com

https://dx.doi.org/10.25046/aj030107

suggest an incrementally and actively learning linear classifier whose parameters are estimated on the basis of Bayesian inference rules. As a result, our novel approach for modeling a linear classifier outperforms other machine learning approaches in terms of sensitivity.

Furthermore, this paper deals with the following fundamentally important research question: The machine learning approach is trained with data (test evaluations) obtained during a concurrently running regression test. How much training data is enough? When does regression test selection actually start?

We extend the proposed selection method [1] by introducing suitable test case features that are used in the machine learning approach for increasing performance (see [2]). Therefore, each feature introduced increases the complexity of the optimization problem (cf. Eq. 1) as a new dimension for optimization is introduced. Thus [3] and [4] suggest that high dimensional optimization problems can be solved in reasonable timeframes by using evolutionary algorithms instead of a (grid)search-based approach as given in [1]. Accordingly, we propose an evolutionary optimization approach for increasing testing efficiency.

Further extensions, such as the introduction of a prioritization strategy for test cases in order to select higher-priority test cases, will also be presented within this paper. In our novel approach, a linear classifier is trained in an online session; the ordering of the training data on the basis of a prioritization strategy therefore has the potential to improve our classifiers' performance.

We also provide an industrial case study to show the advantages of the suggested selection method. The study uses data from several regression test cycles of an ECU of a German car manufacturer, showing how test effort can be reduced significantly whereas the rates of both false-negatives and false-positives can be kept at very low values. In this example, we can quadruple test efficiency by keeping the false-negative probability at 1%.

We first discuss related work in Sec. 2 and explain basic definitions in Sec. 3. Accordingly, we motivate our research topic in Sec. 4 by giving some background information on regression tests and referring to the challenges. In Sec. 5, we give a brief overview of known machine learning methods' performance in solving safety-critical binary classification tasks. The concept of our novel machine learning approach is presented in Sec. 6. Sec. 7 discusses optimization strategies, and Sec. 8 focuses on the importance of the learning phase for the success of our approach. An industrial case study with real data is then given in Sec. 9. Finally, Sec. 10 presents the paper's conclusions.

2 Related Work

The automotive industry is currently engaged in a laborious quality assessment process around new engineered driver assistance and active and passive safety functions, while functional safety is ensured according to the international ISO 26262 standard [5]. Reliability assessment of systems is therefore, possible through both model-checking and testing.

Model-checking is used for verifying conditions on system properties. Thus [6] states that system requirements can also be validated by model-checking techniques. The idea is to check the degree to which system properties are met and to deduce logical conclusions on the basis of the satisfaction of system requirements. Model-checking has therefore gained wide acceptance in the field of hardware and protocol verification communities [7]. Motivated by the fact that numerical model-checking approaches cannot be directly applied to black-box components as a usable formal model is not available, we focus on model-checking driven black-box testing [6] and statistical model-checking techniques [8]. However, there exist some approaches for interactively learning finite state systems of black-box components (see [9] and [10]), which are proposed as *black box checking* in [11]. Learning a model is an expensive task, as the interactively learned model has to be adapted due to inaccuracy reasons. Nevertheless, some assumptions about the system to be checked, such as the number of internal states, are necessary; furthermore, conformance testing for ensuring the accuracy of the learned model has to be iteratively performed [9].

Therefore, [8] outlines the advantages of statistical model-checking as being simple, efficient and uniformly applicable to white- and even to black-box systems. [6] motivates on-the-fly generation of test cases for checking system properties; here, a test case is generated for simulating a system for a finite number of executions. All these executions are used as individual attempts to discharge a statistical hypothesis test and finally for checking the satisfaction of a dedicated system property.

Model-checking driven testing, or even simply testing a system in order to validate its requirements, is an expensive task, especially where safety-critical systems are concerned. However, the focus is on regression testing, which means that the entire system under test has already been tested once but has to be tested again due to system modifications that have been carried out. The purpose of regression testing is to provide confidence that unchanged parts within the system are not affected by these modifications [12]. White-box selection techniques have been comprehensively researched [13, 14]. However, we are here considering black-box components, and hence selecting test cases that only check modified system blocks gets difficult.

Since the implementation of black-box systems and moreover, the information on performed system modifications is not available [12], reasonably conducting a regression test becomes impossible.

Accordingly, regression testing of safety-critical black-box systems ends up in simply executing all existing test cases; this is a *retest-all* approach [12].

This is also motivated by the fact that in the au-

tomotive industry, up to 80% of system failures [1] that are detected during a regression test have not occurred previously. The reason behind this fact is that often many unintended bugs are introduced during a bug-fixing process. So between two system releases many new unknown errors are often introduced.

For reducing the overall test effort, we apply a test case selection method [1] based on hypothesis tests. Those test cases that are assumed to fail on their executions are accordingly selected. However, type errors while performing hypothesis tests are possible, as, for instance, in statistical model-checking.

We extend the proposed selection method into a holistic machine learning-driven optimization framework that utilizes suitable test case features for increasing testing efficiency (see [2]). Machine learning methods are often trained in so-called *batch* modes. Nevertheless, many applications in the field of autonomous robotics or driving are trained on the basis of continuously arriving training data [15]. Thus, incremental learning facilitates learning from streaming data and hence is exposed to continuous model adaptation [15]. Especially handling non-stationary data assumes key importance in applications like voice and face recognition due to dynamically evolving patterns. Accordingly, many adaptive clustering models have been proposed, including incremental K-means and evolutionary spectral clustering techniques [16].

Furthermore, labeling input data is often awkward and expensive [17] and hence accurately training models can be difficult. Therefore, semi-supervised learning techniques are developed for learning from both labeled and unlabeled data [17]. Motivated by these techniques, we propose a similar approach for effectively learning from labeled data. Hence, we cluster binary labeled data in more than two clusters for improving a classifier's learning capability due to the optimization of an objective function. Our optimization framework thus utilizes evolutionary optimization algorithms for handling the optimization complexity. Minimization of labeling cost on the basis of active learning strategies [18, 19] will also be dealt with in this paper.

3 Basic Definitions

We define the test suite $T = \{t_i \mid 1 \leq i \leq M\}$ consisting of a total of M test cases. $T_{Exec} \in T$ and $T_{\overline{Exec}} \in T$ are subsets of T that contain test cases that are executed and deselected in a current regression test respectively. Based on the test case executions ($\forall t_i \in T_{Exec}$), a system's reliability is actually learned, and thus the machine learning algorithm is trained.

The focus in supervised learning is on understanding the relationship between feature and data (here test case evaluation) [4]. Therefore, a test case needs to code a feature vector so that the indication of the coded features for a system failure can be learned in a supervised fashion. Such an indication is not just a highly probable forecast of an expected system failure, it is rather a particular risk-associated recognition.

First of all, a feature can be any individual measurable property of a test case. The data type of a feature is mostly numeric, but strings are also possible. However, such features need to be informative, discriminative and independent of one another if they are to be relevant and non-redundant The definition of suitable features increases the classifier performance [20]. In our application, a feature can be varied, such as a

- subjective ranking of a test case based on expert knowledge. Such rankings can hint at the error susceptibility of verified parts of the system;
- verified function's safety integrity level, known as the *ASIL* in automotive applications [5];
- name of a function whose reliability is assured;
- reference to any hardware component of a circuit board that is being tested in a hardware-in-the-loop (HiL) test environment;
- number of totally involved electronic control units during the testing of a networked functionality; Such a number can hint at the complexity of the networked functionality and hence at its error susceptibility.

We define the entire set of features $\Phi = \{\phi_f \mid 1 \leq f \leq F\}$ of test cases that might be relevant for understanding the behavior of test cases. Thus, features may be e.g. $\phi_1 = \{'QM','A','B','C','D'\}$ ($ASIL$) or $\phi_2 = \{f_1, f_2, f_3\}$ (function name). Hence, a test case can verify a function f_3 that has an *ASIL* A.

The following passages discuss the selection of suitable features, which is an important strategy for improving a classifier's performance.

- Sometimes less is more - If the defined set Φ is too large it can cause huge training effort, high dimensionality of the optimization problem and overfitting. Thus we define a selection mask $\boldsymbol{b}_s = \begin{bmatrix}1 & 0 & 0 \cdots 1\end{bmatrix}$ of length F for selecting relevant features Φ_s. If the $f-th$ matrix entry of $\boldsymbol{b}_s$ is greater than or equal to 1, then the corresponding feature $\phi_f \in \Phi$ is selected and added to Φ_s, otherwise not.
- The set of main features $\Phi_m \subseteq \Phi_s$ is coded as follows: If the $f-th$ matrix entry of $\boldsymbol{b}_s$ is equal to 2, then the corresponding feature $\phi_f \in \Phi_s$ is at the same time a main feature $\phi_f \in \Phi_m$, otherwise not. The main features are used to establish the overall training data set: The training data is adapted to each test case, and thus it is $T_{t_i} = \{t_j \mid t_j \in T_{Exec} \wedge t_i \overset{\Phi_m}{\equiv} t_j\}$. Hence, we define that two test cases t_i and t_j are equivalent $t_i \overset{\Phi}{\equiv} t_j$ if their features $\forall \phi_f \in \Phi$ have identical values.

Additionally, a cross-product transformation of features $\forall \phi_f \in \Phi_s \setminus \Phi_m$ is performed. Thus we define $\Psi = \phi_{f_1} \times \phi_{f_2} \times ... \times \phi_{f_h} \times ... \times \phi_{f_H}$ with $\phi_{f_h} \in$

$\Phi_s \setminus \Phi_m, 1 \leq h \leq H = |\Phi_s \setminus \Phi_m|$ consisting of features ψ_l that represent individual combinational settings for features $\phi_f \in \Phi_s \setminus \Phi_m$. In simple terms, the cross-product of our sample features is $\phi_1 \times \phi_2 = \{('QM', f_1), ('QM', f_2), ('QM', f_3), ('A', f_1), ...\}$ Finally, a Boolean function $check : T \times \Psi \rightarrow \mathbb{B}$ with $check(t_i, \psi_l) = \begin{cases} 0, & \text{if } t_i\text{'s features are given by } \psi_l \\ 1, & otherwise \end{cases}$ is defined.

In addition, the function $state$: $T \times R \rightarrow S$ is defined; it returns the state of a dedicated test case in a concrete regression test. The state has to be either 'Pass' or 'Fail', except for cases where the test case has not been executed so that its state is undefined. Therefore, $S = \{'Pass', 'Fail', 'Undefined'\}$ defines the set of possible states. Furthermore, the set $R = \{r_k \mid 0 \leq k \leq K\}$ includes r_0 which is the current regression test and older regression tests starting from the last regression r_1 to the first considered regression r_K. Lastly, we define the tuple $history(t_i) = \{state(t_i, r_1), ..., state(t_i, r_K)\}$ containing t_i's previous test results.

4 Motivation

In practice, finding suitable features is a difficult task. Since we focus here on black-box systems, system-internal information is not available that might be useful for understanding the system behavior. As a reason, we can only define the above listed features, which might be too high-level for classifying system failures. To illustrate this fact, Fig. 1 a) shows a typical situation: The behavior of test cases in relation to arbitrarily defined features ϕ_1 and ϕ_2 is given. Passed and failed test cases are presented by green squares and red diamonds respectively, and white circles stand for test cases yet to be executed.

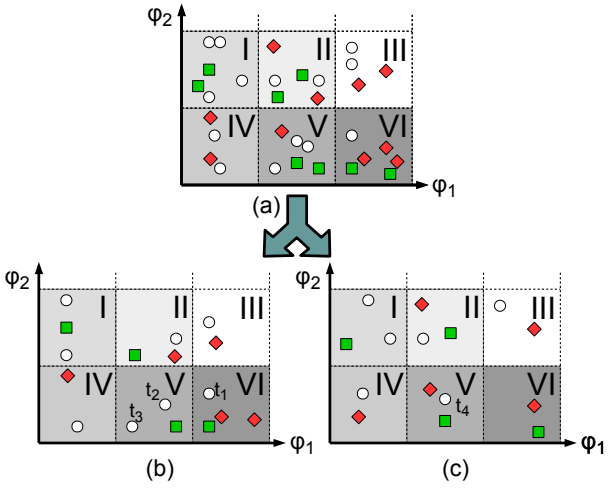

Figure 1: An artificial regression test with test cases.

We can see that the green squares and the red diamonds are widely scattered. Thus, defining a hyperplane in order to set two acceptance regions for passing and failing test cases is no easy matter. In order to solve this complex task, we develop a novel approach that is basically motivated by the following thought experiment: All test cases that are represented in Fig. 1 a) are now either assigned to 1 b) or 1 c) according to a certain mapping. The individual mappings of test cases will be discussed later, in Sec. 6. In the next step, a cross-product transformation is performed in order to group test cases into sub-regions (we refer these later as sub-clusters). In our example, we create six sub-regions. Table 1 lists the empirical failure probabilities of each sub-region.

In order to keep our thought experiment very simple, we will neglect statistical computations for now and focus only on the main idea of our novel approach. The introduction of Bayesian networks and hence the derivation of weights for linear classifiers will be discussed later, in Sec. 6. We assume for now that the calculated failure probabilities of test cases in Fig. 1 b) and Fig. 1 c) are correlated. So our example remains very simple, we also require that the failure probabilities of the corresponding sub-regions are equal. This assumption reduces the complexity of the following classification task enormously. We will classify the following test cases t_1, t_2, t_3 and t_4 in accordance with whether a selection is necessary or not.

Table 1: Failure probability of each sub-region.

$P(H_1)$	I	II	III	IV	V	VI
Fig. 1 a)	0	0.5	1	1	1/3	3/5
Fig. 1 b)	0	0.5	1	1	0	2/3
Fig. 1 c)	0	0.5	1	1	0.5	0.5

Only if t_1 passes will the failure probability of sub-region VI in Fig. 1 b) be equal to the failure probability of sub-region VI in Fig. 1 c). According to this fact, t_1 is assumed to pass, and hence it is deselected. Furthermore, t_2 will be selected as a fail of a test case inside sub-region V is expected. However, t_2 passes, and, based on the same consideration, t_3 is also selected and finally fails. Since now a failure probability of 1/3 is expected in sub-region V, t_4 is assumed to pass, and therefore it does not need to be selected. Table 2 summarizes all decisions executed.

Table 2: Test case states and algorithm decisions.

Test Case	State	Decision	Type of Decision
t_1	Pass	Deselected	True-Negative
t_2	Pass	Selected	False-Positive
t_3	Fail	Selected	True-Positive
t_4	Pass	Deselected	True-Negative

So our novel approach for solving binary classification tasks is based on calculated empirical probabilities and empirically evaluated correlations among those probabilities. The behavior of test cases can be

precisely estimated on the basis of the calculated correlations. In practice, the failure probabilities of same sub-regions in Fig. 1 b) and Fig. 1 c) is often not exactly equal, but these failure probabilities are correlated. So the main task is to find *good* sub-regions for maximizing the empirically evaluated correlations and thus for precisely estimating the behavior of test cases. A more detailed explanation of our novel approach will follow in Sec. 6.

5 Performance of Known Machine Learning Methods

We have already indicated, by showing the example regression test in Sec. 4 (see Fig. 1), that according to the distribution of the input data, many machine learning methods cannot be reasonably applied for solving the constrained optimization problem (cf. Eq. 1). We will now demonstrate briefly that training linear classifiers in the classical sense by minimizing a loss function cannot perform well for solving safety-critical binary classification tasks. The situation is that only a small percentage of the data is actually labeled with one ('Fail'). Furthermore, failed and passed test cases are widely scattered in the feature space, which means detecting failing test cases becomes impossible. Additionally, the performance of deep neuronal networks is validated in the following.

The evaluation results (precision/recall) of these machine learning methods are given in Table 3. Each machine learning method is trained in the *batch* mode. The training data consists of all obtained test evaluations of a special regression test that will also be analyzed in our industrial case study in Sec. 9. For evaluating the machine learning methods, we used the training data first for training and later for testing (training data = test data). Even so, the sensitivity of both machine learning methods is zero, and thus we propose a novel approach for determining a linear classifier's parameters in Sec. 6.

Table 3: Performance of known machine learning methods in solving safety-critical binary classification tasks.

Machine Learning	Precision	Recall / Sensitivity
Linear Classifier (Trained by Minimizing a Loss-Function)	0	0
Deep Neuronal Network	0	0

6 Concept

The concept of our novel approach is shown in Fig. 2. We start with specifying a feature set Φ, and taking its subset Φ_s and finally constitute a cross-product feature transformation to obtain the set Ψ. Based on Ψ and by applying the *check*-function on T_{Exec}, test cases can be grouped. If we look back to the example where we grouped test cases in Fig. 1 a), then we will see that there is a relationship between test cases' features and their assignments to sub-regions.

Correspondingly, we introduce the definitions of clusters and sub-clusters of test cases. In the first step, test cases $\forall t_k \in T_{t_i}$ are assigned to clusters based on their history-tuples. A cluster is basically a partition of T_{t_i} and consists of test cases that have the same history-tuples. Accordingly, the number of distinct history-tuples N determines the total number of clusters. This is the step that has already been shown in Sec. 4, where test cases inside Fig. 1 a) were individually mapped into Figs. 1 b) and 1 c). In this way, already executed test cases depicted in Fig. 1 b) belong to one cluster and, analogously, those executed test cases that are depicted in Fig. 1 c) belong to another cluster.

In the next step, each cluster C_n is subdivided into L sub-clusters. A test case $t_k \in C_n$ is an element of the l-th sub-cluster $C_{n,l}$ if $check(t_k, \psi_l)$ is true. We originally introduced the terminology of sub-regions in Sec. 4. However, we focus in what follows on discrete valued features, which means that grouping test cases into sub-clusters is more appropriate. By introducing the function $eval : T_{Exec} \rightarrow \{0, 1\}$ that is defined as follows

$$eval(t_i) = \begin{cases} 0, & \text{for } state\{t_i, r_0\} = \text{'Pass'} \quad (2) \\ 1, & \text{for } state\{t_i, r_0\} = \text{'Fail'} \quad (3) \end{cases}$$

the calculation of failure probabilities can be given in Eq. 4.

$$p_{n,l} = \frac{1}{|C_{n,l}|} \sum_{\forall t_i \in C_{n,l}} eval(t_i) \quad (4)$$

The given selection decisions in our example in Sec. 4 (cf. Fig. 1) were taken based on calculated failure probabilities. Additionally, the correlations between the failure probabilities were considered. Accordingly, we need a stochastic model for estimating the classifier's sensitivity and specificity. We propose a univariate and also a multivariate stochastic model. The short-comings of the univariate stochastic model for solving the optimization problem (cf. Eq. 1) will be discussed later to motivate the introduction of a multivariate stochastic model. First of all, the next step introduces a multidimensional Gaussian distribution that constitutes a distribution for the failure probabilities of test cases. Based on this distribution, two distinct Bayesian Belief networks for both stochastic models will be introduced.

In the following, we interpret $p_{n,l}, 1 \leq l \leq L$ as realizations of a random variable X_n. X_n is Gaussian distributed based on the following assumption:

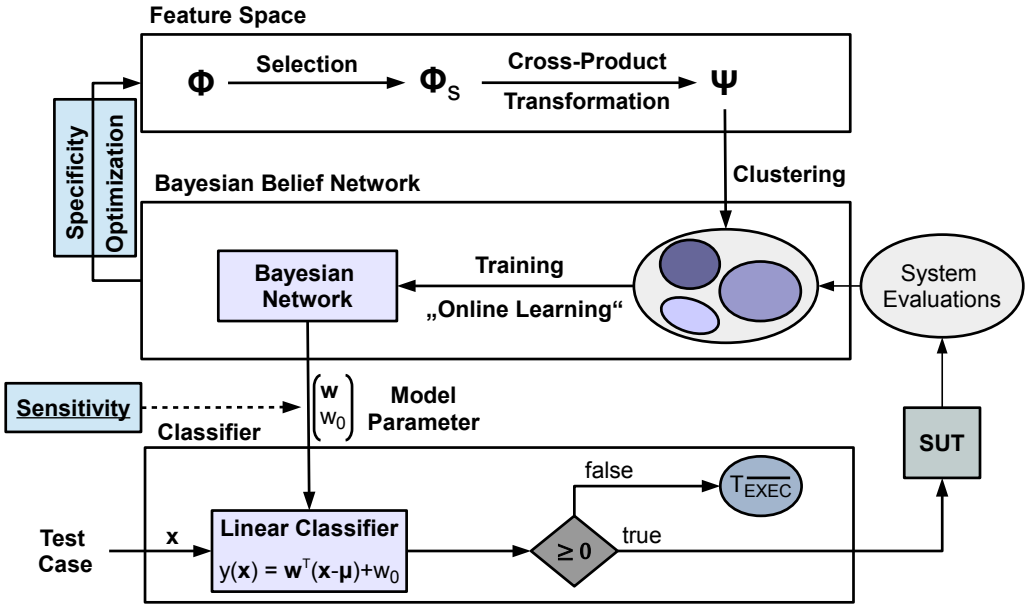

Figure 2: Determining the weights of a linear classifier for maximizing its specificity under the constraint of a specific sensitivity.

Since each test case evaluation is a binary experiment with two possible outcomes ('0' or '1'), it can be regarded as a realization of a binary random variable. As the sum of independent random variables results into a Gaussian random variable according to the central-limit theorem [21], considering test case evaluations as independent random experiments justifies X_n's assumed distribution. However, test cases are executed on the same system and there may be some dependencies between test case evaluations that cannot be directly validated by such means as performing code inspections. As a result, we assume a mix of dependent and independent test case evaluations, and hence the Gaussian assumption is still valid. The moments of X_n are $E[X_n] = \mu_n = \frac{1}{L}\sum_{l=1}^{L} p_{n,l}$ and $E[(X_n - E[X_n])^2] = \sigma_n^2 = \frac{1}{L-1}\sum_{l=1}^{L}(p_{n,l} - E[X_n])^2$. As we introduced in total N Gaussian random variables, the moments of the multidimensional Gaussian distribution are $\boldsymbol{\mu} = E[\boldsymbol{X}] = [E[X_1], E[X_2], ..., E[X_N]]^T$ and $\Sigma = E[(\boldsymbol{X} - \boldsymbol{\mu})(\boldsymbol{X} - \boldsymbol{\mu})^T]$.

Since the constraint of the optimization problem (cf. Eq. 1) has to be fulfilled, an accurate sensitivity estimation has to be iteratively performed.

6.1 Sensitivity Estimation

The formula for calculating the classifier's false-negative selection probability is given in Eq. 5.

$$p_{FN} = \frac{N_{FN}}{N_{FN} + N_{TP}} \leq p_{FN,MAX} \tag{5}$$

However, $\hat{p}_{FN} = \frac{\hat{N}_{FN}}{\hat{N}_{FN}+N_{TP}}$ has to be estimated, since the number of mistakenly deselected failing test cases N_{FN} is unknown, and thus it is estimated by $\hat{N}_{FN}$. The number of already detected failing test cases is given by N_{TP}. Before a decision can be taken on whether a test case t_i can be deselected, the currently allowed risk of taking a wrong decision has to be estimated in advance. The estimation of $\hat{N}_{FN}$ has to be adjusted by the term $xP(\hat{H} = H_0|H_1)$, where x is the failure probability of t_i and $P(\hat{H} = H_0|H_1)$ is the estimated false-negative probability if t_i is deselected. Accordingly, the recursive formulation $\hat{N}_{FN,new} = \hat{N}_{FN,old} + xP(\hat{H} = H_0|H_1)$ is continuously updated whenever an arbitrary test case is deselected. As $\hat{p}_{FN} \leq p_{FN,MAX} \Leftrightarrow \frac{\hat{N}_{FN,new}}{\hat{N}_{FN,new}+N_{TP}} \leq p_{FN,MAX}$ is required, the maximum allowed false-negative probability for deselecting the next test case t_i is given in Eq. 6.

$$\begin{aligned} P(\hat{H} = H_0|H_1) &\leq \frac{\frac{N_{TP} \cdot p_{FN,MAX}}{1-p_{FN,MAX}} - \hat{N}_{FN,old}}{x} \\ &=: p_{FN,Limit} =: \frac{p_{FN,Bound}}{x} \end{aligned} \tag{6}$$

6.2 Univariate Stochastic Model

We model the Bayesian Network that consists of the random variables X, H and $\hat{H}$, in Fig. 3. In the univariate stochastic model, the focus is on modeling of only one failure probability distribution. Thus the random variable X stands for the previously defined X_1 and its realization x is given by $p_{1,l}$ where l is the index of that sub-cluster $C_{1,l}$ that fulfills $t_i \in C_{1,l}$.

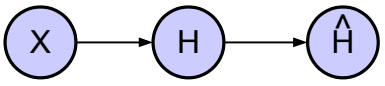

Figure 3: Bayesian Network consisting of the random variables X, H and $\hat{H}$.

H and $\hat{H}$ are binary random variables for modeling

test case states and classifier decisions. As the state of a test case t_i is a-priori unknown, it needs to be modeled by a corresponding random variable. According to the realization of X, a pass or a fail of the corresponding test case t_i, whose failure probability distribution is modeled by X, is expected. Finally, $\hat{H}$ takes a decision for t_i based on its failure probability x:

$$\hat{H}(x) = \begin{cases} H_0, & \text{if } x \in \mathcal{X}_0 = [0; p_{TH}[\quad (7) \\ H_1, & \text{if } x \in \mathcal{X}_1 = [p_{TH}; 1] \quad (8) \end{cases}$$

According to $\hat{H}$'s selection rule a very simple *hyperplane* $y(x) = x - p_{TH}$ is derived where in the case of $y(x) \geq 0$ a selection decision is taken. A particularly important factor is the definition of the threshold probability p_{TH}, as its setting determines the classifier's sensitivity and specificity. The common ways of estimating false-negative and false-positive probabilities are given in equations 9 and 10, respectively.

$$\hat{p}_{FN} = \int_{\mathcal{X}_0} p(X|H_1)dx \quad (9)$$

However, we could only estimate the probability density function (pdf) $p(X)$ in contrast to the conditional probability density functions $p(X|H_0)$ and $p(X|H_1)$. The reason for this is that pdf estimations are based on mean calculations of test case evaluations. Hence passing and failing test cases are both considered in calculating average failure probabilities. Thus, $p(X)$ is a distribution over failure probabilities of passing as well as failing test cases. Accordingly, $p(X|H_0)$ and $p(X|H_1)$ cannot be estimated and in conclusion, $\hat{p}_{FN}$ and $\hat{p}_{FP}$ cannot be estimated as in Eq. 9 and 10.

$$\hat{p}_{FP} = \int_{\mathcal{X}_1} p(X|H_0)dx \quad (10)$$

Fig. 4 shows the important probability distribution functions that are used for estimating $\hat{p}_{FN}$ and $\hat{p}_{FP}$.

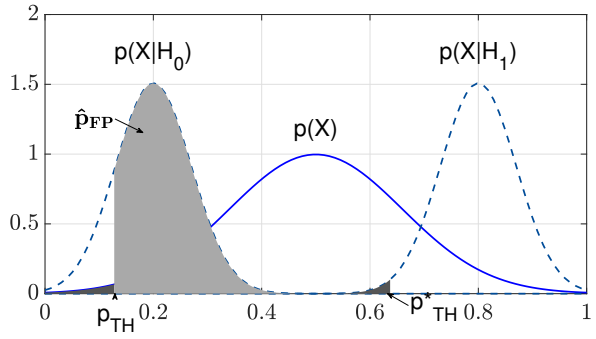

Figure 4: Considered probability distribution functions in the univariate stochastic model.

The threshold probability p_{TH} is calculated based on the estimation of $\hat{p}_{FN}$ as the following relation in Eq. 11 holds.

$$\hat{p}_{FN} = P(X < p^*_{TH}|H_1) \quad (11)$$

As Eq. 11 cannot be directly estimated, the following relation in Eq. 12 is used for estimating $\hat{p}_{FN}$ and finally for p_{TH}.

$$\hat{p}_{FN} = P(X < p_{TH}|H_1) \leq P(X < p_{TH}) \leq p_{FN,Limit} \quad (12)$$

$\hat{p}_{FN}$ is estimated in Eq. 12 according to the assumption that the quantiles of $p(X|H_1)$ are larger than the quantiles of $p(X)$. By solving Eq. 12 the threshold probability is computed as given in Eq. 13

$$p_{TH} = \text{erfinv}(2p_{FN,Limit} - 1)\sigma\sqrt{2} + \mu \quad (13)$$

with $\mu = E[X]$ and $\sigma = \sqrt{VAR(X)}$. As a result, the classifier's sensitivity is larger than $1 - p_{FN,Limit}$, since its false-negative selection probability is smaller than $p_{FN,Limit}$. Finally, the decision regions of the linear classifier are defined (cf. Eq. 7 and 8) by determining p_{TH}.

Furthermore, the minimization of the classifier's specificity is required by the definition of the constraint optimization problem (cf. Eq. 1). Accordingly, the classifier's false-positive selection probability is estimated as given in Eq. 14 and shown in Fig. 4.

$$\hat{p}_{FP} = P(X \geq p_{TH}|H_0) \quad (14)$$

However, $p(X|H_0)$ is not given and thus $\hat{p}_{FP}$ cannot reasonably be estimated. Furthermore, $\hat{p}_{FP}$ cannot be reasonably minimized as an optimization parameter is not defined; consequently, we need a so-called multivariate stochastic model for performing this. In the first instance, the idea of minimizing $\hat{p}_{FP}$ and hence gaining testing efficiency by regarding several distribution functions is explained.

6.3 Preliminaries

Let us assume that two dependent Gaussian random variables X and X' are given. The focus is again on estimating $\hat{p}_{FN}$ and $\hat{p}_{FP}$. Fig. 5 shows the probability distribution functions $p(X)$, $p(X|H_0)$ and $p(X|H_1)$ as in Fig. 4. Additionally, the a-posteriori failure probability distribution function $p(X|X')$ is shown.

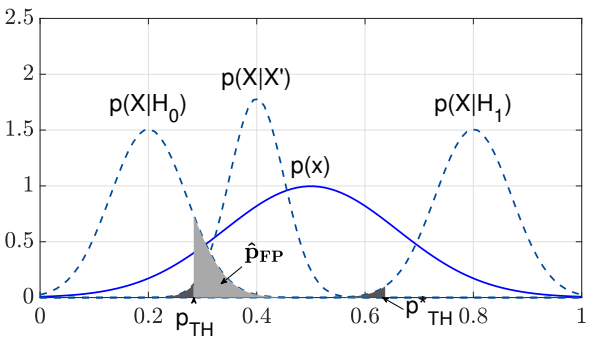

Figure 5: Qualitatively minimizing $\hat{p}_{FP}$ by introducing $p(X|X')$ and hence by using conditional informations.

The main idea is to use several observations of distinct dependent random variables to achieve a consid-

erably more representative a-posteriori failure probability distribution function that is relatively narrow within a certain range. So $p(X|X')$ is considered as the more representative distribution for the failure probabilities and hence $\hat{p}_{FN}$ and p_{TH} are estimated by using this distribution function. Comparing Figs. 4 and 5, it can easily be seen that $\hat{p}_{FP}$ is basically minimized, since the risk of a false-negative selection probability is computed based on $p(X|X')$, which allows a more representative risk estimation.

All in all, by regarding a set of dependent Gaussian random variables and by using the information about their observations, a more representative a-posteriori failure probability distribution function is achieved, which allows a more precise risk estimation. Accordingly, the probability of false-positive selection can be minimized. As a result, a multivariate stochastic model is created to exploit the dependency information between random variables for finally achieving testing efficiency.

6.4 Multivariate Stochastic Model

By using the dependency between the random variables $X_n, 1 \leq n \leq N$, a considerably more accurate estimation of $\hat{p}_{FN}$ is achieved and hence $\hat{p}_{FP}$ is minimized. Fig. 6 shows the modeled Bayesian network consisting of the random variables $X_n, 1 \leq n \leq N$, H and $\hat{H}$.

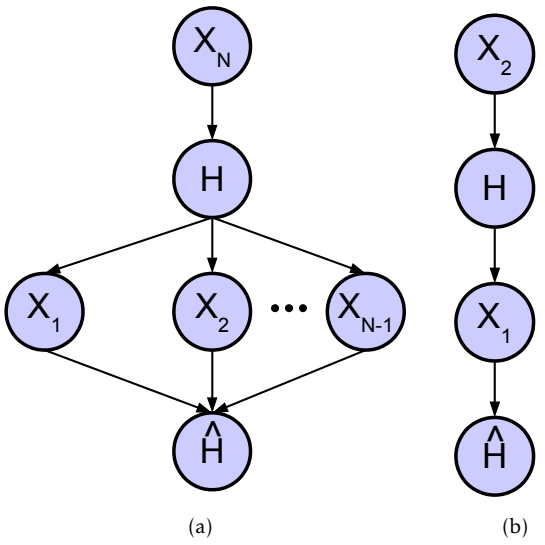

Figure 6: Bayesian Network consisting of an (a) indefinite and (b) definite number of random variables $X_n, 1 \leq n \leq N$.

The focus is on taking a selection decision for an arbitrary test case t_i. X_N now models the failure probability distribution of t_i. In our previous example, as shown in Fig. 1 c), the failure probability distribution of test case t_4 was calculated based on the empirically evaluated failure probabilities of test cases inside Fig. 1 c). Thus t_4 was an element of C_2 ($N = 2$), and its failure probability was modeled by X_2. Analogously, X_1 was defined by the empirically evaluated failure probabilities of test cases inside Fig. 1 b). In the interest of simplification, we always assume that the currently focused test case t_i is an element of cluster C_N and thus X_N models its failure probability distribution.

Furthermore, we can calculate the dependency among $X_n, 1 \leq n \leq N$. However, the Bayesian network in Fig. 6 models the statistical dependency between H and further random variables $X_n, 1 \leq n \leq N-1$. These dependencies cannot be calculated, but have to be modeled for estimating $\hat{p}_{FN}$ and $\hat{p}_{FP}$.

First of all, we model the classifier $\hat{H}(\cdot)$ as follows

$$\hat{H}(x_{ML}) = \begin{cases} H_0, & \text{if } x_{ML} \in \mathcal{X}_0 = [0; p_{TH}[\quad (15) \\ H_1, & \text{if } x_{ML} \in \mathcal{X}_1 = [p_{TH}; 1] \quad (16) \end{cases}$$

where $x_{ML} = \underset{x_N}{\operatorname{argmax}}\Big[\ln[\mathcal{L}(x_N|x_1,...,x_{N-1})]\Big]$ (consult [1]) is the maximum likelihood estimation. Accordingly, the likelihood estimation is a weighted sum as given in Eq. 17

$$x_{ML} =: \sum_{n=1}^{N-1} w_n(x_n - \mu_n) + \mu_N \tag{17}$$

with weights $w_n, 1 \leq n \leq N-1$ as given in Eq. 18.

$$w_n = -\frac{(\Sigma^{-1})_{n,N}}{(\Sigma^{-1})_{N,N}} \tag{18}$$

Further, p_{TH} has to be calculated based on a precise estimation of $\hat{p}_{FN}$. Thus we derive a calculation formula for $\hat{p}_{FN}$ for the case $N = 2$, but we will also provide a general calculation formula of $\hat{p}_{FN}$ for an arbitrary number N of random variables.

6.4.1 Derivation of probability distribution functions

In the following, some probability distributions are driven that are used for estimating $\hat{p}_{FN}$. First of all, the joint pdf $p(\hat{H}X_1HX_2)$

$$p(\hat{H}X_1HX_2) = p(\hat{H}|X_1)p(X_1|H)p(H|X_2)p(X_2) \tag{19}$$

and the conditional pdf $p(\hat{H}X_1H|X_2)$ are given in Eq. 19 and 20, respectively.

$$\begin{aligned} p(\hat{H}X_1H|X_2) &= \frac{p(\hat{H}X_1HX_2)}{p(X_2)} \\ &= \underbrace{p(\hat{H}|X_1)p(X_1|H)}_{p(\hat{H}X_1|H)}p(H|X_2) \end{aligned} \tag{20}$$

In the next step Eq. 21 is obtained by setting the equation $p(\hat{H}|X_1)p(X_1|H) = p(\hat{H}X_1|H)$ into Eq. 20.

$$p(\hat{H}X_1|H) = \frac{p(\hat{H}X_1H|X_2)}{p(H|X_2)} \tag{21}$$

Furthermore, the most important relation $p(\hat{H}|H) \leq \frac{p(\hat{H}|X_2)}{p(H|X_2)}$ is driven in Eq. 22.

$$p(\hat{H}X_1|H) \leq p(\hat{H}|H) \leq \frac{p(\hat{H}H|X_2)}{p(H|X_2)} \leq \frac{p(\hat{H}|X_2)}{p(H|X_2)} \tag{22}$$

Thus, the probability calculation $P(\hat{H} = H_0|H_1)$ can be estimated by using the relation in Eq. 22 as given in Eq. 23.

$$\hat{p}_{FN} = P(\hat{H} = H_0|H_1) \leq \frac{P(\hat{H} = H_0|X_2 = x_2)}{P(H_1|X_2 = x_2)} \tag{23}$$

Since $\hat{p}_{FN}$ cannot be directly estimated, as the conditional pdf $p(\hat{H}|H)$ is not given for performing the probability calculation $P(\hat{H} = H_0|H_1)$, the relation in Eq. 23 is used for estimating an upper bound for $\hat{p}_{FN}$. However, the linear classifier's actual false-negative deselection probability would be smaller than the calculated upper bound.

Since the constraint in Eq. 24 has to be fulfilled,

$$P(\hat{H} = H_0|H_1) \leq p_{FN,Limit} \tag{24}$$

we solve the inequality in Eq. 25.

$$\frac{P(\hat{H} = H_0|X_2 = x_2)}{P(H_1|X_2 = x_2)} \leq p_{FN,Limit} \tag{25}$$

As $x_2 = P(H_1|X_2 = x_2)$ holds, the following inequality is finally solved.

$$P(\hat{H} = H_0|X_2 = x_2) \leq p_{FN,Bound} \tag{26}$$

Eq. 26 is driven for the case $N = 2$ but in the general case, where the number of random variables $X_n, 1 \leq n \leq N$ is given by an arbitrary N, the following inequality has to be solved.

$$P(\hat{H} = H_0|X_N = x_N) \leq p_{FN,Bound} \tag{27}$$

By solving Eq. 27, the threshold probability

$$p_{TH} = -w_N(x_N - \mu_N) - w_0 + \mu_N \tag{28}$$

is obtained with weights

$$w_N = -\frac{e^{2I} - 1}{e^{2I}} \tag{29}$$

and

$$w_0 = -\frac{\sqrt{2}\sigma_N\sqrt{e^{2I} - 1}\,\mathrm{erfinv}(2p_{FN,Bound} - 1)}{e^{2I}} \tag{30}$$

Thus, the differential mutual information is defined in Eq. 31.

$$\mathcal{I} := \mathcal{I}(X_1, ..., X_{N-1}; X_N) \tag{31}$$

6.4.2 Conditional Independence

We have already motivated and introduced the following dependent random variables $X_n, 1 \leq n \leq N$. We have explained the fact that test case failure probabilities are correlated, since test cases are executed on the same system, and thus they show a dependent behavior.

However, the random variables $X_n, 1 \leq n \leq N$ are conditionally independent. This means that the information about a test case evaluation dominates such that a test case's originally calculated failure probability becomes irrelevant after observation of its state. Accordingly, the dependency among failure probabilities vanishes after observation of test case evaluations. This means that a fail of a test case t_m is actually expected based on the information about the evaluation of another test case t_n and no longer on t_n's originally calculated failure probability. Thus the remaining random variables $X_n, 1 \leq n \leq N-1$ become independent of the random variable X_N after observation of H's realization (cf. Fig. 6).

6.4.3 Specificity Estimation

The specificity is given by the term $1 - \hat{p}_{FP}$. As extensive mathematical derivations are needed for obtaining a calculation formula of $\hat{p}_{FP}$, these derivation steps are given in the appendix and in what follows here only the result is given.

Theorem 1 (False-Positive Probability Estimation)**.** *$\hat{p}_{FP}$ is estimated as given in Eq. 32*

$$\hat{p}_{FP} = P(Z \geq -w_0 + \boldsymbol{w}^T \Delta\boldsymbol{\mu}) = \frac{1}{2}\left[1 - erf\left(\frac{-w_0 + \boldsymbol{w}^T \Delta\boldsymbol{\mu}}{\sqrt{2}\sigma_Z}\right)\right] \tag{32}$$

with $\sigma_Z = [w_1 \cdots w_{N-1}]\Sigma_{1,1}[w_1 \cdots w_{N-1}]^T + w_N^2\sigma_N^2$ and $\Delta\boldsymbol{\mu} = \boldsymbol{\mu} - \boldsymbol{\mu}_{H_0}$. The conditional moment has the following definition $E[\boldsymbol{X}|H_0] = \boldsymbol{\mu}_{H_0}$

For the case $N = 2$, Eq. 32 can be simplified; after several calculation steps the following Eq. 54 results

$$\hat{p}_{FP} = \frac{1}{2}\left[1 - erf\left(\psi\right)\right] \tag{33}$$

with

$$\psi = \frac{\sqrt{e^{2\mathcal{I}} - 1}\,erfinv(2p_{FN,Bound} - 1) + \frac{\sqrt{e^{4\mathcal{I}} - e^{2\mathcal{I}}}}{\sigma_1\sqrt{2}}\Delta\mu_1 - \frac{\sqrt{e^{2\mathcal{I}} - 1}}{\sigma_2\sqrt{2}}\Delta\mu_2}{\sqrt{2e^{4\mathcal{I}} - 3e^{2\mathcal{I}} + 1}} \tag{34}$$

6.4.4 Small Dimension Validation

Fig. 7 shows five plots of $\hat{p}_{FP}$ for different values of displacements $\Delta = \mu_n - \mu_{n,H_0}$. Indeed, the actual value of Δ is unknown. However, the focus is on the minimization of $\hat{p}_{FP}$. Accordingly, $\hat{p}_{FP}$ decreases in each sub-figure of Fig. 7. The actual value of Δ only determines how fast $\hat{p}_{FP}$ decreases. So we can solve the optimization problem (cf. Eq. 1) by minimizing $\hat{p}_{FP}$. We considered two random variables X_1 and X_2, as in our example in Sec. 4 where we created two clusters. A very important factor here is the underlying strategy for clustering test cases. As the distribution of the random variables X_1 and X_2 is directly related to the clustering strategy the main focus is on the maximization of the differential mutual information $\mathcal{I}(X_1; X_2)$. Accordingly, $\mathcal{I}$ is an optimization parameter for effectively reducing $\hat{p}_{FP}$. Lastly, we chose the

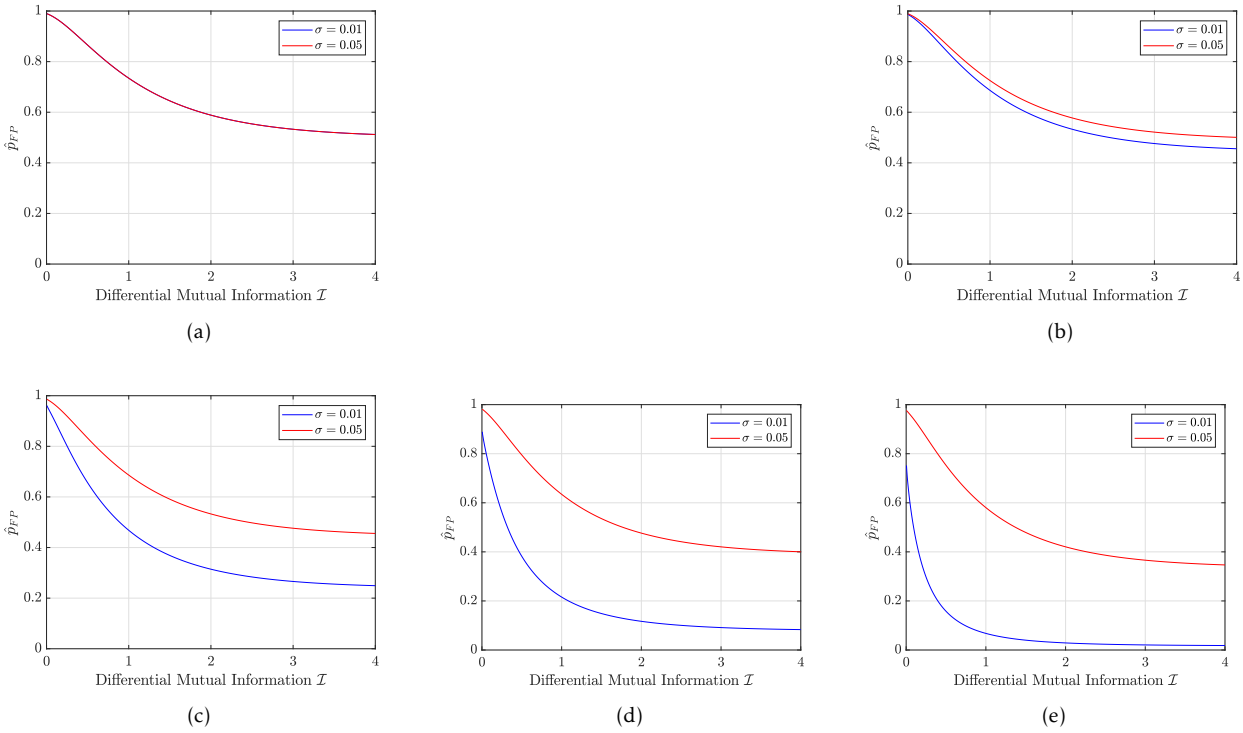

Figure 7: Estimation of $\hat{p}_{FP}$ for different values of $\boldsymbol{\Delta}$ and σ with $\boldsymbol{\Delta} = \alpha \cdot \boldsymbol{v} \cdot 10^{-3}$. The value of α is 0, 1, 5, 10 and 15 in Fig. 7 a), Fig. 7 b), Fig. 7 c), Fig. 7 d) and Fig. 7 e) respectively.

following values $\{0.01, 0.05\}$ for $\sigma = \sigma_1 = \sigma_2$ and selected the following displacements $\boldsymbol{\Delta} = \alpha \cdot \boldsymbol{v} \cdot 10^{-3}$ with $\alpha \in \{0; 1; 5; 10; 15\}$ and $\boldsymbol{v} = [1, -1]^T$.

7 Optimization

The first strategy is to optimize the feature selection. Optimal features are learned in an unsupervised learning session where an evolutionary optimization framework is applied to search for optimal features. The next strategy is to improve the labeling of test cases through an active learning strategy.

7.1 Evolutionary Optimization

Clustering (and sub-clustering) of test cases is performed based on features. Therefore, different clusterings for different selections of feature subsets (Φ_m, Φ_s) are possible. Accordingly, a different statistical model is obtained, as it reflects the failure frequencies in clusters. Furthermore, the differential mutual information (cf. Eq. 31) depends on the statistical dependencies and thus changes for different clusterings.

Sec. 6 proposed a calculation formula for the weights $w_n, 0 \leq n \leq N$, of a linear classifier. However, those formulas still depend on the differential mutual information I. A desired sensitivity has to be guaranteed, and thus the hyperplane is adjusted according to the value of I. It can be shown that for small values of I, the position of the hyperplane still guarantees a desired sensitivity but the false-positive selection probability increases. To minimize the false-positive selection probability, the differential mutual information has to be maximized, which is the final strategy for solving the constrained optimization problem (cf. Eq. 1).

First, clustering depends on the history-tuples of test cases as, for example, the length of the history-tuples determines the maximum number $|S|^K$ of clusters. Second, feature selection is optimized. All in all, we have summarized that K (number of considered previous regressions) is an optimization parameter and $\boldsymbol{b}_s$ (for coding selected and main features) is an optimization matrix. However, this is a large-scale high dimensional optimization problem, as there exist many possible settings for K and $\boldsymbol{b}_s$. Thus, [3] and [4] suggest that the high dimensional optimization problem can be solved in a reasonable time by using evolutionary algorithms. Accordingly, an evolutionary optimization framework is applied for solving the mentioned high dimensional optimization problem. As each setting for K and $\boldsymbol{b}_s$ is one possible solution for clustering test cases, which is the basis for derivation of a stochastic model, the fitness of this solution can be evaluated by calculating the extracted information $\mathcal{I}$ in Eq. 31. Thus, the optimal parameter and matrix setting with the best fitness will survive and will be returned by the evolutionary optimization algorithm.

Fig. 8 shows the overall flow chart of the evolutionary optimization framework. First of all, a new population consisting of several genotypes is initialized. Each genotype stands for a possible setting of K and $\boldsymbol{b}_s$. In the next step, the corresponding phenotypes of the genotypes are derived. Hence each phe-

notype encodes a stochastic model. Accordingly, the population is evaluated, wherein the fitness of each phenotype is calculated. However, a *bad* fitness is also possible due to *bad* statistical properties of the underlying stochastic model. This means that statistical calculations based on the stochastic model that a phenotype encodes cannot guarantee desired statistical confidence bounds. This will be explained in more detail in Sec. 8. Those phenotypes with *bad* fitness cannot survive and hence are eliminated.

Accordingly, remaining genotypes (phenotypes) are stochastically selected, and successively new genotypes are generated due to *crossover* and *mutation* operations. After a certain number of iterations, the phenotype with the best fitness will be selected, and this will be used in the selection algorithm. However, if the population is empty since all phenotypes were of *bad* fitness, then the training mode is activated, in which test cases are still executed without running the selection algorithm.

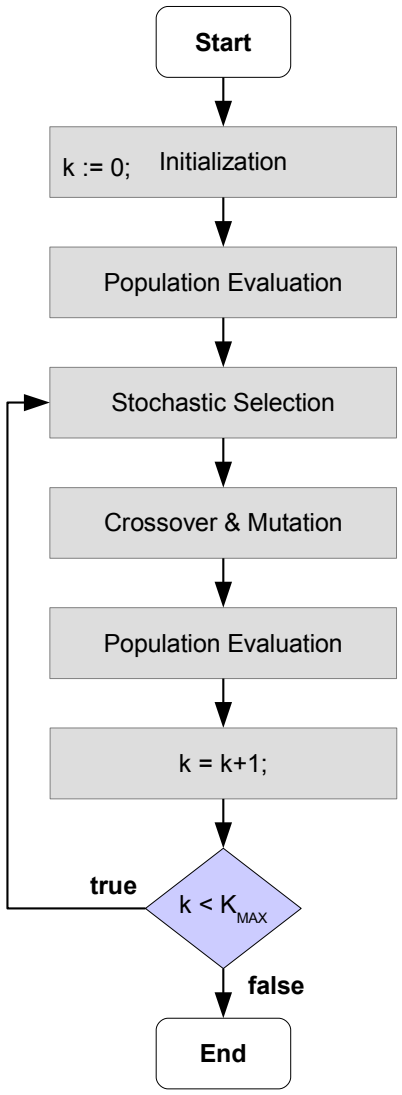

Figure 8: Evolutionary Optimization Framework.

7.2 Active Learning

Our classifier's conducted decisions can be regarded as *hard* or even as *soft* decisions. Once taken, *hard* decisions are never changed later on, in contrast to *soft* decisions. The test efficiency can be significantly increased by conducting *soft* decisions as opposed to *hard* decisions.

7.2.1 Hard Decision

[1] performs *hard decisions* since a selected test case is automatically executed and a once deselected test case is never selected again in the current regression test. In the following passages, the disadvantage of conducting *hard decisions* will be explained in detail in relation to classifier decisions.

The linear classifier's decision depends on the current estimation of $\hat{N}_{FN}$ as it calculates the allowed residual risk $p_{FN,Limit}$ (cf. Eq 6) of potentially taking a wrong decision. $\hat{N}_{FN}$ returns the number of supposedly unrevealed system failures that would be detected by those already deselected test cases that are elements of $T_{\overline{Exec}}$. Accordingly, the linear classifier's decision depends on the decisions it has already taken ($T_{\overline{Exec}}$) and hence it is memory driven.

Each deselected test case t_j has an individual additional contribution $\hat{N}_{FN,j}$ (cf. Eq. 36) to the overall estimation $\hat{N}_{FN}$ such that the relation in Eq. 35 holds.

$$\hat{N}_{FN} = \sum_{\forall t_j \in T_{\overline{Exec}}} \hat{N}_{FN,j} \tag{35}$$

$\hat{N}_{FN,j}$ is the product of t_j's failure probability x and the false-negative probability $P(\hat{H} = H_0|H_1)$ by deselecting t_j as given in Eq. 36.

$$\hat{N}_{FN,j} = P(H_1)P(\hat{H} = H_0|H_1) \tag{36}$$

Because of this fact, a deselection of an arbitrary test case can cause that the residual risk $p_{FN,Limit}$ reaches zero as $\hat{N}_{FN}$ increases (cf. Eq. 6). This means that no more risk ($p_{FN,Limit} = 0$) is allowed, and all remaining test cases have to be consequently selected.

Indeed, selecting test cases even if their deselection is allowed according to risk calculations is sometimes the better choice. In fact, this is the case if $p_{FN,Limit}$ is zero and thus it can be significantly increased by selecting and executing an already deselected test case in order to eliminate its risk. When this is done, $\hat{N}_{FN}$ decreases and hence $p_{FN,Limit}$ increases and thus a residual risk for further deselections is obtained.

However, the amount $\Delta\hat{N}_{FN}$ of how much $\hat{N}_{FN}$ can be decreased by selecting an arbitrary test case is significant. If later more than one test case can be deselected, and these deselected test cases add the same amount of expected unrevealed system failures $\Delta\hat{N}_{FN}$ to $\hat{N}_{FN}$ is in fact a gain in terms of reducing the regression test effort. So the strategy is to deselect primarily those test cases with fewer failure probabilities in order to increase testing efficiency.

As a result, the regression test efficiency can be increased. Therefore, the proposed selection method [1] is extended by a *soft decision* methodology. So each decision for deselecting a test case is now regarded as a *soft decision* that might be changed later. (We note here that the other way round is impossible since an already selected test case is automatically executed on the system under test and hence deselecting it later does not make sense).

7.2.2 Soft Decision

Fig. 9 shows the logic for managing soft selection decisions: Let us assume that t_i is the next test case that is analyzed by the linear classifier. If t_i is deselected, then it is queued into a priority queue whereby its priority is calculated as given in Eq. 37.

$$prio(t_i) = \hat{N}_{FN,i} = P(H_1)P(\hat{H} = H_0|H_1) \qquad (37)$$

In the other case, if t_i is selected then test cases deselected up to this point are analyzed to the end of improving the trade-off between the assumed risk and the total number of deselected test cases. As a consequence, the most probable failing test case t_j is obtained by taking the peek-operation on the priority queue. The priority of t_i and t_j is compared, and the test case with the higher priority is selected and executed on the system under test.

If t_j is executed, then it is removed from the set $T_{\overline{Exec}} \leftarrow T_{\overline{Exec}} \backslash t_j$ and added into the set $T_{Exec} \leftarrow T_{Exec} \cup t_j$. Furthermore, t_j's state is evaluated $eval(t_j)$ and accordingly the empirical failure probabilities of test cases are updated in algorithm 1. Since the calculated failure probabilities are averages of test case evaluations, the failure probabilities of those sub-clusters (see Eq. 4) have to be updated where t_j is an element of them. Accordingly, the failure probabilities of $\forall t_k \in T_{\overline{Exec}}$ are updated in algorithm 1.

Algorithm 1 Test case selection algorithm

```
procedure UPDATE STATISTICS(T_Exec_bar, t_j)        ▷ T_Exec_bar contains already deselected test cases; t_j is executed
    for each test case t_k ∈ T_Exec_bar do
        ∃!C_{n,l} ⟹ t_k ∈ C_{n,l}        ▷ Find sub-cluster of t_k and thus determine n and l
        if t_j ∈ C_{n,l} then
            p_{n,l} ← 1/|C_{n,l}| Σ_{∀t_i∈C_{n,l}} eval(t_i)        ▷ see Eq. 4
            P(H_1) ← p_{n,l}
            update t_k's priority: prio(t_k)        ▷ see Eq. 37
        end if
    end for
    if eval(t_j) == 1 then
        N_TP ← N_TP + 1
    end if
end procedure
```

The important point is that even the failure probability of t_i is computed again. In most cases, t_i would be deselected. Nevertheless, it could be possible that the execution of t_j has failed, such that a further system failure has been found. In such a case, even t_i's failure probability may have increased such that its deselection has to be checked again by the linear classifier.

All in all, testing efficiency can be significantly increased by performing *soft selection* decisions. The performance of both selection strategies (*hard decision* and *soft decision*) will be compared in Sec. 9.

8 Learning Phase

The learning phase is of essential importance due to the fact that during this phase, the system reliability is actually learned. Test case selection is a safety-critical binary classification task as probably system failures would remain undetected and hence, a corresponding quality measure of wrong decisions is required. Accordingly, risk estimations on probably undetected system failures due to deselection of test cases have to be as accurate as possible. The more the system is learned during a regression test, the more precise the risk estimations are. However, learning a system in terms of understanding its reliability is a costly process, as it requires test cases to be executed. The fundamentally important research question is how much training data is enough for safely selecting test cases with a desired sensitivity.

8.1 Statistical Sensitivity Estimation

We have already required a specific sensitivity in the constraint optimization problem (cf. Eq. 1). Accordingly, we define the following confidence level in Eq. 38, which is basically driven from the constraint of Eq. 1.

$$P\Big(\Psi \leq \gamma\Big) \geq 1 - \alpha \qquad (38)$$

Ψ is an estimator for the number of false-negatives $\hat{N}_{FN} = \sum_{t_i \in T_{\overline{EXEC}}} \hat{N}_{FN,i}$ and the bound is given as $\gamma = \frac{N_{TP} \cdot p_{FN,MAX}}{1 - p_{FN,MAX}}$. $\Psi = \sum_i \psi_i$ is composed of several random variables ψ_i standing for the distribution of each $\hat{N}_{FN,i}$. ψ_i's distribution is complex, since the individual contribution of a deselected test case t_i is given by $\hat{N}_{FN,i} = x_N \hat{p}_{FN}$ where x_N is t_i's failure probability and $\hat{p}_{FN}$ is the corresponding estimated false-negative probability: The following theorem is already proved in [1] and gives the formula for the false-negative probability estimation.

Theorem 2 (False-Negative Probability)**.** *For a given p_{th} the calculation formula of the false-negative probability $P(\hat{H} = H_0|H_1)$ has the form*

$$\hat{p}_{FN} = \frac{1}{2}\left(1 + erf\left(\frac{1}{\sqrt{2}} \frac{x_N - (x_N - p_{th})e^{2\mathcal{I}} - \mu_N}{\sigma_N \sqrt{e^{2\mathcal{I}} - 1}}\right)\right) \qquad (39)$$

where x_N is the failure probability of a test case, whereas μ_N, σ_N are parameters of the probability distribution function $\mathcal{N}(\mu_N, \sigma_N)$.

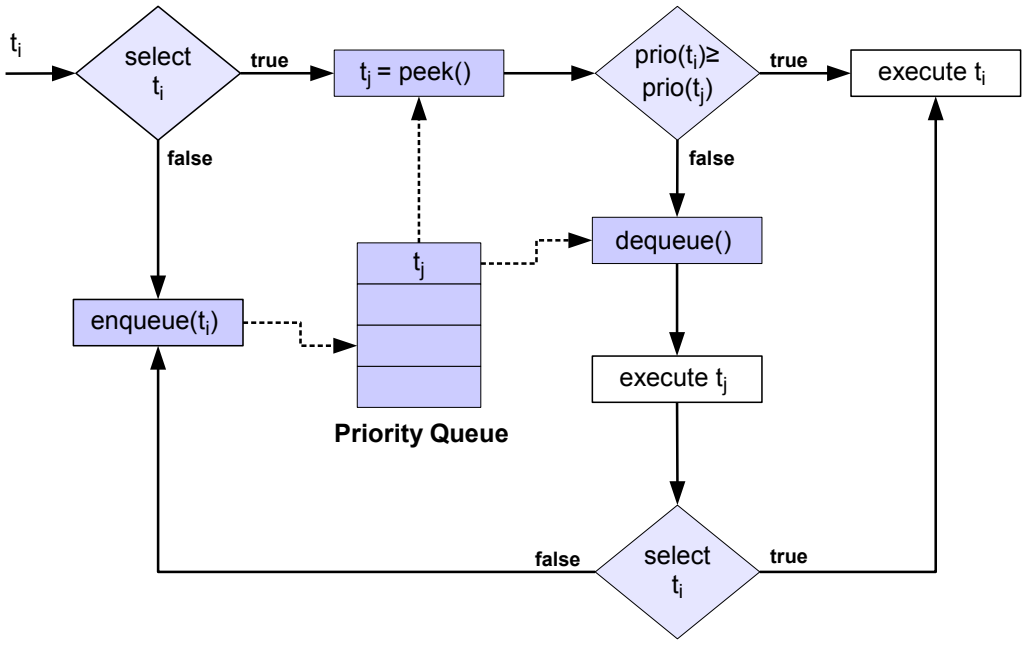

Figure 9: The extended concept for conducting soft decisions

These statistics are created on the basis of sample averages, such that the consideration of sample variances becomes inevitable during the estimation of confidence intervals. For instance, the false-negative probability estimation $\hat{p}_{FN}$ (see Eq. 39) is composed of the statistics x_N, μ_N, σ_N and I. Therefore, its variance depends on the individual variances of each statistic, including the sample variance of x_N. Especially the probability distribution of I is complex as it is nonlinearly composed of a set of multivariate distributed Gaussian random variables.

Therefore, we choose the following approach to solving Eq. 38. We simplify the definition of ψ_i as follows $\psi_i = \hat{p}_{FN} \cdot X_N$ where $\hat{p}_{FN}$ is assumed to be a constant value without any distribution. This step simplifies the calculation complexity of Eq. 38 significantly, as Ψ becomes simply a weighted sum of Gaussian random variables. However, the variance of $\hat{p}_{FN}$ is of course relevant and should not be easily neglected. Accordingly, we require a maximum confidence interval width for $\hat{p}_{FN}$ such that the estimated false-negative probability is quite accurate and hence can be assumed to be just like a constant value without any statistical deviation. We calculate the confidence interval $[\hat{p}_{FN}^{(l)}; \hat{p}_{FN}^{(u)}]$ and its width $\delta = \hat{p}_{FN}^{(u)} - \hat{p}_{FN}^{(l)}$ and require a maximal confidence interval width of δ_{max}.

The Wilson score interval [22] delivers confidence bounds for binomial proportions. Therefore, we calculate the following confidence intervals $[x_n^{(l)}; x_n^{(u)}]$ (confidence level: $1 - \alpha = 99\%$) for each failure probability estimation $x_n, 1 \leq n \leq N$. Each bound is consequently used for building the bounds of the composed statistics σ, Σ and I. By doing this, we obtain the following bounds: $\sigma^{(b)}$, $\Sigma^{(b)}$ and $I^{(b)}$ with $b = \{u, l\}$. Accordingly, we calculate $\hat{p}_{FN}^{(b)}$ by consequently inserting the bounds $\sigma^{(b)}$, $\Sigma^{(b)}$ and $I^{(b)}$ for the statistics σ, Σ and I respectively.

8.2 Criteria for Training

In order to guarantee a statistical bound on the sensitivity with a 99% confidence level, the following conditions have to be checked.

1. $\delta \leq \delta_{max}$
2. $P\left(\Psi \leq \gamma\right) \geq 1 - \alpha = 99\%$

If both conditions are fulfilled, then these risk calculations in the selection algorithm are reasonably accurate and hence selection decisions can be performed. However, if one condition is not fulfilled then the training mode is just active, such that test cases still have to be executed.

9 Industrial Case Study

A German premium car manufacturer constitutes each regression test as being a system release test, and thus the system test takes up to several weeks according to [5]. However, a first detected system failure makes a system release impossible so optimizing the current regression for achieving high efficiency in reducing the regression effort becomes justified.

It is often the case that close to the so-called start of production (SOP) of a vehicle, many electronic control units (ECU) have only some critical spots and thus each regression test is expected to be a system-release test. Since many test cases pass, a lot of time is spent in observing passing test cases. Therefore, reducing the number of executed passed test cases (since a system failure is detected and a system release

is no longer possible) and keeping the limited testing time back for fault-revealing test cases decreases the regression test effort significantly. In any case, a final regression test will succeed after further system updates have been conducted; this will be constituted as a final release-test that meets the high-quality standards of [5].

In our industrial case study, we applied our selection method to a production-ready controller that implements complex networked functionalities for the protection of passengers and other road users. Therefore its test effort is immense, and hence we apply our regression test selection method for accelerating its testing phase. In Fig. 10 the right-hand side of the well-known *V-Model* (see [23]) is shown, whereas the focus is on system testing in our case study.

A hardware-in-the-loop simulator (HiL) [24] is used for validating an ECU's networked complex functionalities as well as its I/O-interaction and its robustness during voltage drops, as it provides an effective platform for testing complex real-time embedded systems.

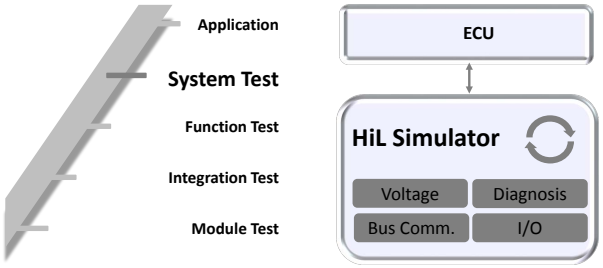

Figure 10: A HiL simulator is used for performing the system test.

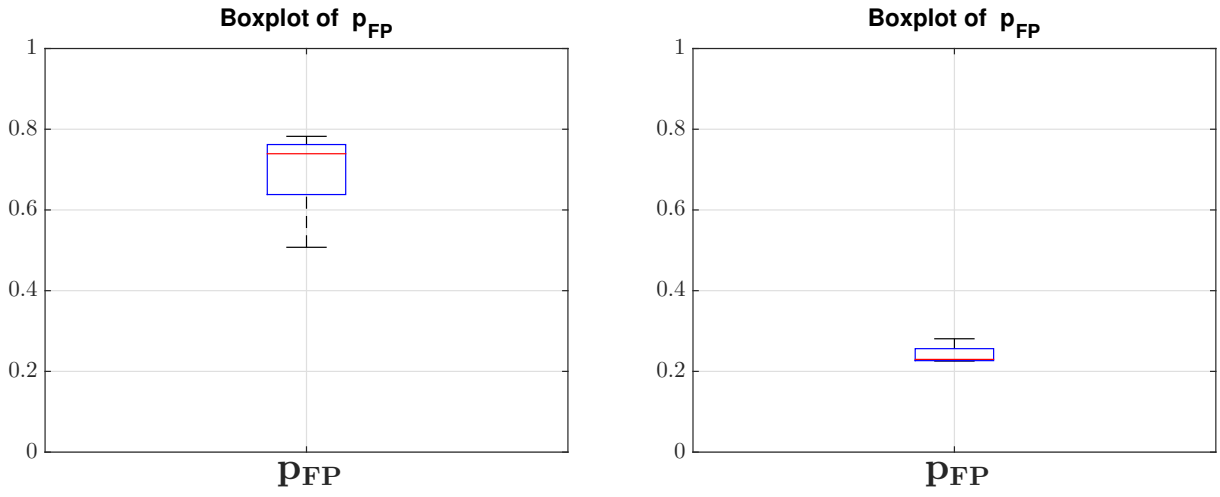
Further, we selected for the following test case features for training the machine learning algorithm:

- Name of verified system parts
- Name of a function for which reliability is assured
- Number of totally involved electronic control units during the testing of a networked functionality
- Error type (broken wire etc.) in hardware robustness tests
- Set of checked diagnostic trouble codes, *DTC*s
- Number of checked diagnostic trouble codes, *DTC*s

Since the quality of our selection decisions is hedged on a stochastic level, it can appear that during different runs of our selection method, a statistical deviation of the false-positive probabilities could occur. Therefore, we constitute several independent runs of a regression test, where we set $p_{FN,MAX} = 1\%$. The boxplots and the quantiles of the false-positive probabilities are given in Fig. 11 and in Table 4, respectively.

Fig. 11 shows the overall boxplots of the false-positive probabilities achieved during the regression test replications. To compare the *hard* with the *soft decision* strategy we performed distinct regression test replications where we disabled and enabled the parameter for *'soft decision'*, respectively.

It can be seen from Fig. 11a) and Fig. 11b) that the average false-positive probability is about 74% and 23% for *hard* and enabled *soft decisions* respectively. As already mentioned, conducting *hard decisions* does not allow for global optimization of the trade-off between an already assumed risk and the corresponding number of totally deselected test cases. Global optimization hence requires the analysis of all test cases deselected thus far over and over again, and, if necessary, the selection of an already deselected test case. Therefore, test cases with a higher failure probability should be considered again for eventual selection in an ongoing regression test in order to potentially deselect further less risky test cases. As a result, the regression test effort can be reduced much more by applying *soft decisions*.



Furthermore, the condition in Eq. 40 on the false-negative probability p_{FN} or on the number of actually occurring false-negatives N_{FN} was fulfilled in all conducted regression test replications.

$$\begin{aligned} &p_{FN} \leq p_{FN,MAX} = 1\% \text{ or} \\ &N_{FN} \leq 1 \end{aligned} \tag{40}$$

Our implemented algorithm for selecting test cases runs on a desktop CPU that is specified in Table 5. We decided to conduct a multithreaded execution of the evolutionary algorithm such that the fitness of all phenotypes in a population is computed in a multithreaded manner (in total 32 threads). Thus the average CPU load is approximately 95% and the maximum memory allocation is about 4GB. We need a mean analysis time of 0.9s for deciding whether a test case should be selected or not.

10 Conclusion and Future Work

We proposed a holistic optimization framework for the safety assessment of systems during regression testing. To this end, we designed a linear classifier for (de-) selecting test cases according to a classification due to a risk-associated recognition. Therefore we defined an optimization problem, since the classifier's specificity has to be maximized whereas its sensitivity still has to exceed a certain threshold $1 - p_{FN,MAX}$. Accordingly, we developed a novel method for determining the weights of a linear classifier that solves the above optimization problem. We have theoretically shown that the classifier performance is directly interrelated with the success of selected relevant features of test cases. Lastly, we applied our method to a production-ready controller and analyzed the overall regression test effort subject to an active learning strategy. We have demonstrated that, in the regression testing of safety-critical systems, significant sav-

(a) hard decision

(b) soft decision

Figure 11: Boxplots of false-positive probabilities in case of a) hard and b) soft decisions

Table 4: Quantiles of the false-positive probabilities in each replicated regression test

	Quantiles of False-Positive Probability				
	0.025	0.25	0.5	0.75	0.975
Hard Decision	50.8%	63.8%	73.9%	76.2%	78.2%
Soft Decision	22.6%	22.7%	23%	25.6%	28.1%

ings can be achieved. As feature selection is a complex task, and thus an evolutionary optimization supposedly finds local optima, more thorough research in this field may indeed allow higher-order reductions of the classifier's false-positive selection probability.

11 Appendix

In the following, a detailed proof of Theorem 1 is given, relating to the proofs given in [1].

Proof of Theorem 1

Proof. According to [1], the maximum likelihood estimation $x_{N,ML}$ (abbreviated x_{ML} in the following) is given in Eq. 41.

$$x_{ML} = \mu_N - \frac{(\boldsymbol{x}_D - \boldsymbol{\mu}_D)^T \boldsymbol{\Phi}\boldsymbol{\Lambda}^{-1}\boldsymbol{\phi}^T}{\boldsymbol{\phi}\boldsymbol{\Lambda}^{-1}\boldsymbol{\phi}^T} \tag{41}$$

As $\boldsymbol{\Phi}\boldsymbol{\Lambda}^{-1}\boldsymbol{\phi}^T = P_1\Sigma^{-1}P_2^T$ and $\boldsymbol{\phi}\boldsymbol{\Lambda}^{-1}\boldsymbol{\phi}^T = P_2\Sigma^{-1}P_2^T = \left(\Sigma^{-1}\right)_{N,N}$ holds (consult Proof of Theorem 3 in [1]) x_{ML} can be written as given in Eq. 42.

$$x_{ML} =: \sum_{n=1}^{N-1} w_n(x_n - \mu_n) + \mu_N \tag{42}$$

with $w_n = -\frac{\left(\Sigma^{-1}\right)_{n,N}}{\left(\Sigma^{-1}\right)_{N,N}}$. Furthermore, the threshold probability p_{th} was calculated in [1] as given in Eq. 43.

$$p_{th} = x_N + \frac{\sqrt{2}\sigma_N\sqrt{e^{2\mathcal{I}}-1}\,\mathrm{erfinv}(2p_{FN,Bound}-1) + \mu_N - x_N}{e^{2\mathcal{I}}} \tag{43}$$

By introducing the definitions of the weights $w_0 := -\frac{\sqrt{2}\sigma_N\sqrt{e^{2\mathcal{I}}-1}\,\mathrm{erfinv}(2p_{FN,Limit}-1)}{e^{2\mathcal{I}}}$ and $w_N := -\frac{e^{2\mathcal{I}}-1}{e^{2\mathcal{I}}}$ the threshold probability can be written as $p_{TH} = -w_0 + \mu_N - w_N(x_N - \mu_N)$.

Eq. 44 derives the final definition of the hyperplane $y(\boldsymbol{x})$ and the acceptance region of the rival hypothesis H_1 by putting the definitions of x_{ML} and p_{TH} together.

$$\begin{aligned} x_{ML} &\geq p_{TH} \\ \mu_N + \sum_{n=1}^{N-1} w_n(x_n - \mu_n) &\geq -w_0 + \mu_N - w_N(x_N - \mu_N) \\ w_0 + \sum_{n=1}^{N} w_n(x_n - \mu_n) &\geq 0 \\ \underbrace{w_0 + \boldsymbol{w}^T(\boldsymbol{x} - \boldsymbol{\mu})}_{y(\boldsymbol{x})} &\geq 0 \end{aligned} \tag{44}$$

The estimation of the false-positive probability is

Table 5: Computational/memory requirements and algorithm performance

performed by calculating $\hat{p}_{FP} = P(\hat{H} = H_1|H_0)$. However, as already explained in Sec. 6, the conditional pdf $p(\hat{H}|H)$ is not given and therefore $\hat{p}_{FP}$ cannot be directly estimated. Thus, we assume that the conditional pdf $p(\hat{H}|H)$ is of a Gaussian distribution with mean $E[\boldsymbol{X}|H_0] = \boldsymbol{\mu}_{H_0}$ and covariance matrix $E[(\boldsymbol{X} - \boldsymbol{\mu}_{H_0})(\boldsymbol{X} - \boldsymbol{\mu}_{H_0})^T|H_0] = \Sigma$. However, $\boldsymbol{\mu}_{H_0}$ is an unknown parameter vector; additionally, the second-order moments are assumed to be invariant of an event H_0. We will calculate $\hat{p}_{FP}$ in dependency on the unknown vector $\boldsymbol{\mu}_{H_0}$ and will qualitatively show that $\hat{p}_{FP}$ can be minimized independently of $\boldsymbol{\mu}_{H_0}$ due to an optimization strategy. In showing this, we demonstrate that the concept of our work is validated and mathematically proved.

First of all, Eq. 44 is given in Eq. 45 with an additional term.

$$\begin{aligned} w_0 + \boldsymbol{w}^T(\boldsymbol{x} - \boldsymbol{\mu}) &\geq 0 \\ w_0 + \boldsymbol{w}^T(\boldsymbol{x} - \boldsymbol{\mu} + \boldsymbol{\mu}_{H_0} - \boldsymbol{\mu}_{H_0}) &\geq 0 \end{aligned} \tag{45}$$

Furthermore, by introducing the definition $\Delta\boldsymbol{\mu} = \boldsymbol{\mu} - \boldsymbol{\mu}_{H_0}$ Eq. 45 can be written as given in Eq. 46.

$$\boldsymbol{w}^T(\boldsymbol{x} - \boldsymbol{\mu}_{H_0}) \geq -w_0 + \boldsymbol{w}^T\Delta\boldsymbol{\mu} \tag{46}$$

Accordingly, $\hat{p}_{FP}$ is estimated as given in Eq. 47.

$$\hat{p}_{FP} = P\Big(\boldsymbol{w}^T(\boldsymbol{X} - \boldsymbol{\mu}_{H_0}) \geq -w_0 + \boldsymbol{w}^T\Delta\boldsymbol{\mu}\Big|H_0\Big) \tag{47}$$

By substituting $U := \sum_{n=1}^{N-1} w_n(X_n - \mu_{n,H_0})$ and $V := w_N(X_N - \mu_{N,H_0})$ with $\mu_{n,H_0} = \left(\boldsymbol{\mu}_{H_0}\right)_n$ the false-positive estimation is given as follows.

$$\hat{p}_{FP} = P\Big(U + V \geq -w_0 + \boldsymbol{w}^T\Delta\boldsymbol{\mu}\Big|H_0\Big) \tag{48}$$

Based on that fact, that H_0 is given U and V are conditionally independent (see explanation in subsection 6.4.2) of each other and hence the random variable $Z := U + V$ has the mean $E[Z] = E[U] + E[V]$ and the variance $\sigma_Z^2 = \sigma_U^2 + \sigma_V^2$. Since $E[X_n|H_0] = \mu_{n,H_0}$ holds the mean of U and V is zero ($E[U] = 0$; $E[V] = 0$).

The variances of U and V are given in Eq. 49

$$\sigma_U^2 = [w_1 \cdots w_{N-1}]\Sigma_{1,1}[w_1 \cdots w_{N-1}]^T \tag{49}$$

and Eq. 50 respectively.

$$\sigma_V^2 = w_N^2\sigma_N^2 \tag{50}$$

As $[w_1 \cdots w_{N-1}]^T = -\frac{\boldsymbol{\Phi}\boldsymbol{\Lambda}^{-1}\boldsymbol{\phi}^T}{\boldsymbol{\phi}\boldsymbol{\Lambda}^{-1}\boldsymbol{\phi}^T}$ holds and by substituting $\beta := \boldsymbol{\Phi}\boldsymbol{\Lambda}^{-1}\boldsymbol{\phi}^T$ the term $\beta^T\Sigma_{1,1}\beta$ can be simplified in Eq. 51 as already explained in the proof of Theorem 3 in [1].

$$\boldsymbol{\beta}^T\Sigma_{1,1}\boldsymbol{\beta} = -\frac{\det(\Sigma_{1,1})}{\det(\Sigma)} + \sigma_N^2\left[\frac{\det(\Sigma_{1,1})}{\det(\Sigma)}\right]^2 \tag{51}$$

It can easily be seen that the variance of U is equal to $\sigma_U^2 = \frac{\beta^T\Sigma_{1,1}\beta}{\left[\left(\Sigma^{-1}\right)_{N,N}\right]^2}$. Furthermore, $\left(\Sigma^{-1}\right)_{N,N} = \frac{\det(\Sigma_{1,1})}{\det(\Sigma)}$ holds and thus the variance is further simplified and is given in Eq. 52.

$$\sigma_U^2 = -\frac{\det(\Sigma)}{\det(\Sigma_{1,1})} + \sigma_N^2 \tag{52}$$

Finally, the false-positive probability is estimated as follows:

$$\hat{p}_{FP} = P(Z \geq -w_0 + \boldsymbol{w}^T\Delta\boldsymbol{\mu}) = \frac{1}{2}\left[1 - \mathrm{erf}\left(\frac{-w_0 + \boldsymbol{w}^T\Delta\boldsymbol{\mu}}{\sqrt{2}\sigma_Z}\right)\right] \tag{53}$$

For the case $N = 2$, Eq. 53 can be simplified and after several calculation steps the following Eq. 54 results

$$\hat{p}_{FP} = \frac{1}{2}\left[1 - \mathrm{erf}\Big(\psi\Big)\right] \tag{54}$$

with

$$\psi = \frac{\sqrt{e^{2\mathcal{I}} - 1}\,\mathrm{erfinv}(2p_{FN,Bound} - 1) + \frac{\sqrt{e^{4\mathcal{I}} - e^{2\mathcal{I}}}}{\sqrt{2}\sigma_1}\Delta\mu_1 - \frac{\sqrt{e^{2\mathcal{I}} - 1}}{\sqrt{2}\sigma_2}\Delta\mu_2}{\sqrt{2e^{4\mathcal{I}} - 3e^{2\mathcal{I}} + 1}} \tag{55}$$

ABSTRACT

The Internet of Things (IOT) is a revolutionary communication technology which enables numerous heterogeneous objects to be inter-connected. In such a wireless system, interference management between the operating devices is an important challenge. Cognitive Radio (CR) seems to be a promising enabler transmission technology for the 5G-IOT system. The "sense-and-adapt" smart transmission strategy in CR systems can help to overcome the problem of multiple access interference (MAI) in IOT systems. In this paper, a 5G-IOT smart infrastructure system is arranged in the form of CR based virtual antenna array (VAA) system. In VAA based wireless system, knowledge of users' locations can help the transmitter to achieve interference avoidance by steering the main beam towards the intended recipient. This idea has been applied to the VAA-IOT system, where smart antenna array based location aware beamforming are applied at both transmitter and receiver cluster of smart sensors with the help of spatial modulation principle. The waveform of choice for the CR-IOT clusters is Generalized Frequency Division Multiplexing (GFDM) while corresponding waveform for the primary user (PU) cluster is conventional Orthogonal Frequency Division Multiplexing (OFDM). Computer simulation shows that under multipath fading conditions, the implemented system can reduce the interference to the primary user (PU) system, leading to better coexistence.

1. Introduction

This paper is an extension of work originally presented in 2017 International Conference of Applied System Innovation, held at Sapporo, Japan [1]. In this work, a beamforming scheme is presented which is based on transmitter activation by spatial modulation (SM) technique. Spatial Smoothing (SS) based Multiple Signal Classification (MUSIC) algorithm is applied for direction of arrival (DOA) estimation of the PU. Based on the DOA data, the combined spatial modulation-beamforming scheme is designed for avoiding interference to the PU. In [1], an overview of the methodology was presented. However, in this work, details about application of the SS-MUSIC as well as receiver side data detection are presented. Computer simulations are performed to demonstrate the effectiveness of the designed scheme for better interference avoidance in CR scenario.

Increasing demand for higher data rate and quality of mobile communications has led to the development of advanced multicarrier signaling schemes such as OFDM and GFDM among others. GFDM is a recently proposed non-orthogonal multicarrier waveform which is a potential candidate for 5G wireless technology. Its benefits are flexible carrier aggregation and low out-of-band (OOB) radiation [2-4]. Due to its flexibility in subcarrier allocation, the GFDM based user can sense the spectral bands in a CR environment and intelligently allocate the subcarriers to the bands where the interference temperature threshold can be satisfied. Apart from frequency bands, space and angle dimensions can be exploited too with the recent advances in multiple antenna technologies. In such a smart heterogeneous infra-structure, multi-antenna based GFDM system can lead to enhanced system performance and low cross-tier interference. This can be achieved with the application of beamforming technology at the Femto-Cell transceiver system. Moreover, cognitive radio technology can be combined with beamforming at

*Jayanta Datta, 1, Section 3, Zhongxiao Xinsheng, Taipei City 10608, Taiwan, +886-0988354648, Email: jdatta1@iit.edu

the Femto-Cell network enabling it to become a self-aware entity [5, 6]. The cognitive Femto-Cell system can use spatial modulation principle to encode the location estimates of the Macro-Cell PUs and select the Femto-Cell users closest to the Femto-Cell SU receiver system. The selected SU transmitters can perform null-steering based beamforming to avoid cross-tier interference by directing nulls towards Macro-Cell PUs. In this work, the CR-IOT [7-9] system is considered as a cognitive Femto-Cell under-laid with an existing main Macro-Cell infrastructure. This kind of cognitive interference management strategy can maximize Femto-Cell CR-IOT system performance while minimizing interference on the Macro-Cell PU system, leading to better spectral coexistence between the primary Macro-Cell user and the secondary Femto-Cell CR-IOT user.

2. System Model

It is assumed that the primary Macro-Cell and secondary Femto-Cell use the same uplink and downlink frequencies and the same bandwidth. The Macro-Cell uses OFDM for transmission, while the Femto-Cell uses GFDM as its signaling scheme. Figure 1 shows the system model.

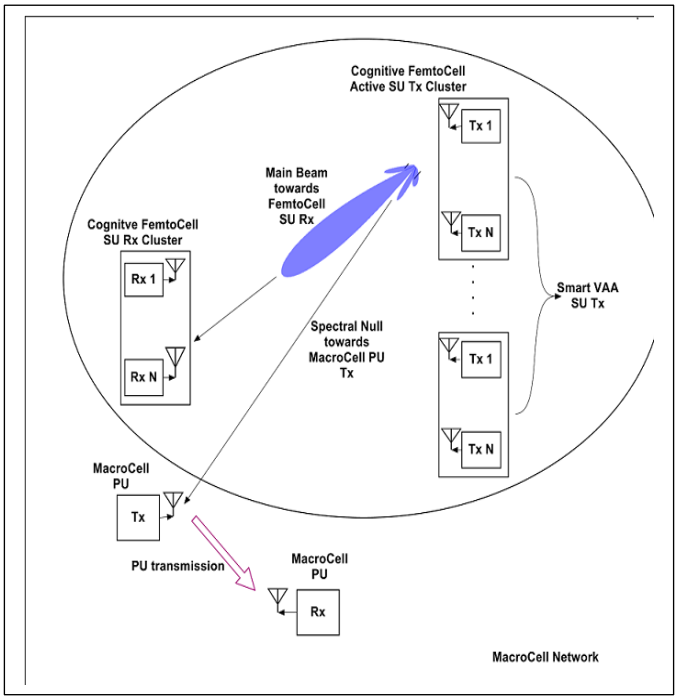

Figure 1. CR-IOT Femto-Cell VAA system under-laid with Macro-Cell PU system

The Femto-Cell based CR-IOT transmitter system is divided into multiple clusters. Each cluster contains a number of low power single antenna terminals arranged in the form of virtual antenna array (VAA) [10, 11]. The VAA based Femto-Cell CR-IOT system collects DOA information about the Macro-Cell PU and performs null-steering based beamforming to transmit its data. It uses spatial modulation principle to encode the DOA information of the PU in the form of bit blocks. This bit-block is used to identify a suitable transmit cluster which is then activated. The terminals in the active SU cluster transmit data to the SU receiver using null-steering based beamforming.

3. Transmitter Side Processing

Let there be 'N_c' SU transmitter clusters in total. Let there be 'N' terminals within each cluster. A central controller acts as the cluster head. The central controller has the role of the cognitive engine (CE). It is responsible for analyzing the received signal parameters and taking decisions on spectrum band occupancy status and estimated locations of the PUs and SUs. The transmit side processing operation can be divided into 2 phases, namely sensing phase and transmission phase.

3.1. Sensing Phase

The sensing phase operations performed at the SU transmitter side can be pictorially depicted as in Figure 2 below.

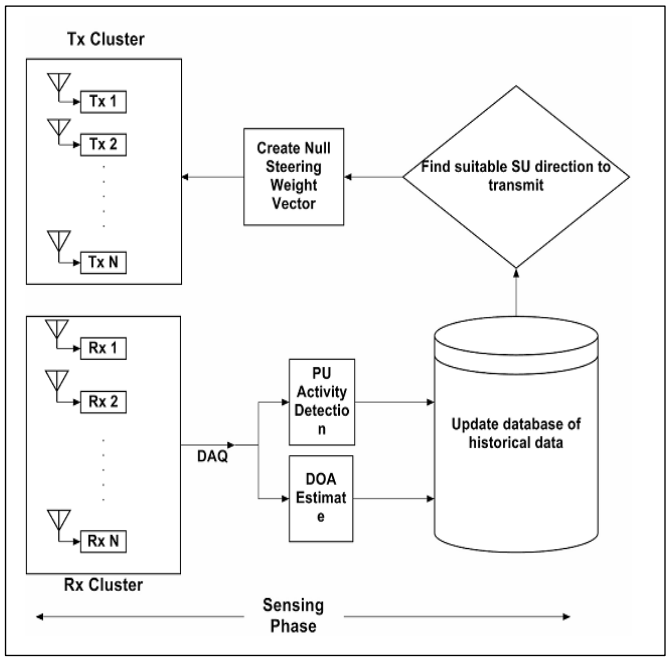

Figure 2. Sensing Phase at the Femto-Cell based CR-IOT transmitter cluster

1. PU parameters like Interference Temperature (IT), PU transmission power, available spectrum hole, PU location estimates (for e.g. DOA of received PU signal) etc. are collected and forwarded to the central controller, by the SU clusters.
2. Based on received parameters, the central controller calculates the distance of the clusters from the receiver SU. This can be achieved by localization algorithms like angle of arrival (AOA), received signal strength (RSS) estimation etc.
3. The central controller maintains a database of possible location estimates of the SU receiver clusters and PU terminals, as well as channel occupancy status within the spectrum band. The DOA estimates are matched with the database entries to verify the presence of PU activity at that location.

Based upon DOA estimation result of the received signal, the central controller creates a null-steering based beamforming weight vector. This is applied to the transmit signal during the transmission phase to steer spectral nulls towards the PU transmitter in order to avoid interference, whereas the main beam is steered towards the SU receiver cluster.

3.2. DOA Estimation by Spatial Smoothing MUSIC

SS-MUSIC [12, 13] is chosen for DOA estimation of the incoming signal under multipath propagation. Let the PU-OFDM signal be denoted by $x_{PU_OFDM}(t)$.

$$\boldsymbol{x_{PU_OFDM} = W^H . s} \tag{1}$$

In the above equation, 'W' indicates the discrete Fourier transform (DFT) matrix. 'W^H' indicates the inverse discrete Fourier transform matrix. The term's' indicates the data subcarriers which can be *M*-ary QAM or *M*-ary PSK modulated symbols. In general for an antenna array with N terminals, the received signal at all elements of the array can be expressed by the following mathematical equation:

$$\boldsymbol{r(t) = [r_1(t)\, r_2(t) \ldots\ldots r_N(t)]^T}$$

$$\boldsymbol{= \left[1\, e^{-j\omega\frac{dsinf}{c}} \ldots\ldots e^{-j\omega\frac{(N-1)dsinf}{c}}\right]^T . \left(H \otimes x_{PU_{OFDM}}(t)\right)}$$

$$\boldsymbol{= a(f).y(t), where\ y(t) = (H \otimes x_{PU_{OFDM}}(t))} \tag{2}$$

Suppose the antenna array comprising 'N' terminals be divided into 'L' overlapping sub-arrays. Each sub-array contains 'M' terminals, with M>K, K being the number of source directions. Then, N=M+L-1.

Let $x_i(t)$ be the received signal vector at the i^{th} sub-array. Let $a_M(\phi)$ be the steering vector associated with each sub-array.

$$\boldsymbol{x_i(t) = e^{-j\frac{\omega(i-1)dsinf}{c}} . a_M(f).y(t)\ , i = 1, 2, \ldots, M} \tag{3}$$

With 'K' DOAs, the received signal '$x_i(t)$' for the *i*th sub-array can be expressed by the following mathematical equation:

$$\boldsymbol{x_i(t) = [a_M(f_1) \ldots\ldots a_M(f_K)].\begin{bmatrix} e^{-j\frac{\omega(i-1)dsinf_1}{c}} & 0 & \cdots & 0 \\ \vdots & . & \ddots & \vdots \\ 0 & . & \cdots & 0 \\ 0 & . & . & e^{-j\frac{\omega(i-1)dsinf_K}{c}} \end{bmatrix} . y(t)} \tag{4}$$

$$\boldsymbol{A_M = [a_M(f_1) \ldots\ldots\ldots a_M(f_K)]} \tag{5}$$

$$\boldsymbol{D(i) = \begin{bmatrix} e^{-j\frac{\omega(i-1)dsinf_1}{c}} & 0 & \cdots & 0 \\ \vdots & . & \ddots & \vdots \\ 0 & . & \cdots & 0 \\ 0 & . & . & e^{-j\frac{\omega(i-1)dsinf_K}{c}} \end{bmatrix}} \tag{6}$$

$$\boldsymbol{x_i(t) = A_M . D_i . y(t)} \tag{7}$$

The correlation matrix at each sub-array can be computed as follows:

$$\boldsymbol{R_{x_i} = E\{x_i(t).x_i^H(t)\}}$$

$$\boldsymbol{= A_M . D_i . R_y . D_i^H . A_M^H + \sigma_0^2 . I}$$

$$\boldsymbol{= A_M . D_i . E\{y(t).y^H(t)\}. D_i^H . A_M^H + \sigma_0^2 . I} \tag{8}$$

The average of all the correlation matrices at all the sub-arrays can be expressed as follows:

$$\boldsymbol{R_{x_{avg}} = \frac{1}{L} . \sum_{i=1}^{L} E\{x_i(t).x_i^H(t)\}}$$

$$\boldsymbol{= A_M . [\frac{1}{L} . \sum_{i=1}^{L} D_i . R_y . D_i^H] . A_M^H + \sigma_0^2 . I} \tag{9}$$

The conventional MUSIC [12] algorithm can be applied on the matrix 'R_{x_avg}' to obtain the DOA estimate of the incoming PU-OFDM signal. The dimension of the matrix 'A_M' is M-by-M. The dimension of the matrix within square brackets is K-by-K. Hence, it is evident that the dimension of 'R_{x_avg}' is M-by-M.

By calculating the eigen-values of R_{x_avg}, 2 disjoint eigen-spaces can be identified. One is the signal subspace, and it consists of signal eigen-vectors on which noise is overlapped. The other one is the noise subspace which comprises eigen-vectors only due to noise. The signal eigen-vectors correspond to the 'K' (with K≤M-1) greatest eigen-values. The noise eigen-vectors correspond to the other (M-K) eigen-values. The MUSIC algorithm then searches for those steering vectors which are orthonormal to the noise subspace.

Let u_i be the *i*th eigen-vector of R_{x_avg} corresponding to the eigen-value σ_i^2.

Step 1: We perform eigen-decomposition of the M-by-M matrix 'R_{x_avg}'.

$$\boldsymbol{R_{x_{avg}} . u_i = \left[A_M . R_{s_{avg}} A_M^H + \sigma_0^2 . I\right] . u_i = \sigma_i^2 . u_i, i = 1, 2, \ldots, M}$$

$$\boldsymbol{where\ \sigma_i^2 > \sigma_0^2, i = 1, 2, \ldots, K; \sigma_i^2 = \sigma_0^2, i = K+1, \ldots, M} \tag{10}$$

Step 2: The above expression can be re-expressed as follows:

$$\boldsymbol{A_M . R_{s_{avg}} . A_M^H . u_i = (\sigma_i^2 - \sigma_0^2) . u_i; i = 1, 2 \ldots K}$$

$$\boldsymbol{= 0 \quad ; i = K+1, \ldots, M} \tag{11}$$

Step 3: We partition the M-dimensional vector space into signal subspace U_s and noise subspace U_n:

$$[\boldsymbol{U_s}\ \boldsymbol{U_n}] = [\boldsymbol{u_1} \dots \dots \dots \boldsymbol{u_K}\ \boldsymbol{u_{K+1}} \dots \dots \boldsymbol{u_M}],$$

$$\boldsymbol{where}\ \boldsymbol{U_s} = [\boldsymbol{u_1} \dots \dots \dots \boldsymbol{u_K}] : \boldsymbol{\sigma_i^2, i = 1, 2, \dots, K}$$

$$\boldsymbol{and}\ \boldsymbol{U_n} = [\boldsymbol{u_{K+1}} \dots \dots \dots \boldsymbol{u_M}] : \boldsymbol{\sigma_i^2, i = K+1, 2, \dots, M} \quad (12)$$

Step 4: The steering vector associated with the DOA of the PU-OFDM signal is in the signal subspace, the latter being orthogonal to the noise subspace. Hence, the MUSIC algorithm searches through all the angles 'ϕ' and plots the spatial spectrum given by the following equation:

$$\boldsymbol{P(f)} = \frac{\boldsymbol{1}}{\boldsymbol{a^H(f).U_n}} \quad (13)$$

Whenever the scanned angle $\phi=\phi_i$, the DOA of the PU-OFDM signal, the MUSIC spatial spectrum will exhibit a peak, providing an estimate of the DOA of the PU-OFDM signal.

3.3. Data Transmission Phase

This phase consists of 2 sub-phases, namely VAA cluster index modulated CR-IOT transmit signal generation and null-steering based transmit side beamforming.

i. VAA cluster index modulated CR-IOT transmit signal generation

Multiple-antenna techniques constitute a key technology for modern wireless communications, which trade-off superior error performance and higher data rates for increased system complexity and cost. The basic idea of SM-Beamforming is to map a block of information bits into information carrying units. Each information carrying unit comprises a symbol chosen from a complex constellation diagram and a unique cluster index that is chosen from a set of transmitter clusters. Each transmitter cluster contains a VAA of transmitters arranged in the form of a uniform linear array (ULA). As a consequence, we have a hybrid modulation and MIMO technique [14, 15], in which the modulated signal belongs to a tridimensional constellation diagram [15-17], which jointly combines signal and spatial information (cluster index). At the transmitter side, the bit-stream emitted from the central controller is divided into blocks containing ($\log_2 N_c + N_M.\log_2 M$) bits each, with $\log_2 N_c$ and $\log_2 M$ being the number of bits needed to identify a transmitter cluster and a transmitter symbol from the symbol constellation diagram respectively. Here, 'N_M' denotes the total number of information symbols to be transmitted for a particular time slot. Each block is then processed by a SM mapper, which splits each of them into two sub-blocks of $\log_2 (N_c)$ and $N_M.\log_2 (M)$ bits each. The spatial mapper comprises 2 separate tables, namely active cluster index (ACI) mapping table and information symbol mapping table. The ACI mapping table contains a list of the angular locations of the SU transmitter clusters, and bit combinations of size $\log_2 (N_c)$ corresponding to each transmitter cluster. The incoming bit sub-block of size $\log_2 (N_c)$ selects that SU transmitter cluster index which is nearest in distance to the SU receiver. It is assumed that the CE already has prior knowledge of the distances based on prior location estimation. The other bit sub-block of size $N_M.\log_2 (M)$ selects N_M symbols according to the information symbol mapping table. The ACI mapping table is depicted in Table 1 below:

Table 1. Active Cluster Index (ACI) Mapping Table.

SU Tx Cluster Index	SU Tx Cluster Locations	Bit Pattern
1	30 degrees	00
2	45 degrees	01
3	60 degrees	10
4	75 degrees	11

The information symbol mapping table is shown in Table 2 below:

Table 2. Information Symbol Mapping Table.

Symbol	Bit Pattern
1+j	00
1-j	01
-1+j	10
-1-j	11

According to the above scheme, only one cluster of SU transmitters is activated at a particular frame instant while the other clusters remain silent. This helps to avoid the inter-cluster interference. In other SM schemes [15-18], only one transmitter antenna is active at a particular time instant, thereby transmitting only one constellation symbol per instant. However in our proposed transmission scheme, multiple information symbols are transmitted by the antenna array leading to improved spectral efficiency.

The cluster index modulated symbol stream is passed through the GFDM modulator, after which null-steering based beamforming is performed by the array of SU terminals within the activated cluster. The process can be pictorially depicted in Figure 3 below:

Details of baseband GFDM transceiver implementation can be obtained from [2].

i. *Null-Steering Transmit Side Beamforming*

The digital baseband signal snapshots $x=[x_1, x_2 \dots x_N]^T$ in a transmit beamforming cluster with N single antenna sensors (virtual antenna array) can be represented by the following equation:

$$\boldsymbol{x} = \boldsymbol{w}(\emptyset_{SU}).\boldsymbol{x}_{SU_GFDM} \quad (14)$$

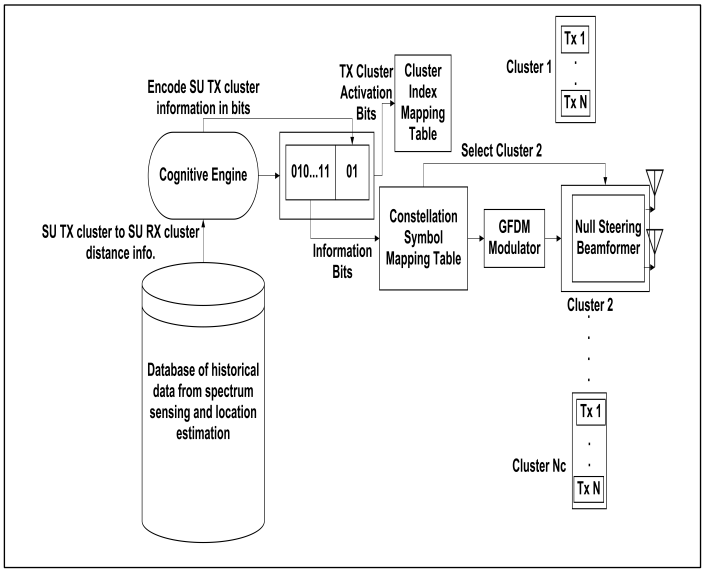

Figure 3. SM-Beamforming operation in CR-IOT GFDM Transmitter

In the above equation, $w(\phi_{SU}) = [w_1(\phi_{SU}), w_2(\phi_{SU}), \ldots.., w_N(\phi_{SU})]^T$ represents the beamforming weight vector under a specific optimization criteria towards the desired direction ϕ_{SU} [19],[20]. In other words, ϕ_{SU} is the direction in which the intended SU receiver is located. 'x_{SU_GFDM}' refers to the spatially modulated symbol transmitted by the activated SU cluster. It is assumed that the sensors within each transmit cluster are closely spaced. Under this assumption, the effective channels between the different transmit antennas inside the cluster and the receiver antenna differ by phase shift included in the steering vector of the transmit cluster. The steering vector for ULA in direction 'ϕ' can be represented by the following equation [21]:

$$\boldsymbol{a}(\emptyset) = [1, e^{j.d.k.cos\emptyset}, e^{j.2d.k.cos\emptyset}, \ldots.., e^{j.(N-1)d.k.cos\emptyset}]^T \quad (15)$$

In the above equation, the constant 'k'=2π/λ, where λ is the wavelength of the RF signal frequency. The distance between the elements of the cluster is expressed as'd'. The received snapshot of the signal received at a direction 'ϕ' is represented by the following equation:

$$\boldsymbol{y}(\emptyset) = \boldsymbol{a}^H(\emptyset).\boldsymbol{w}(\emptyset_{SU}).\boldsymbol{x}_{SU_GFDM} + \boldsymbol{n} \quad (16)$$

Suppose there is 'M' number of PUs operating in the same frequency band as the SU transmitter. Let the angles of the PUs from the SU transmitter be denoted by $\phi_{PU,1}$, $\phi_{PU,2}$,…., $\phi_{PU,M}$. Let the null-steering matrix be denoted by 'A'. Then the matrix 'A' consists of the steering vectors to all the PU directions.

$$\boldsymbol{A} = [\boldsymbol{a}(\emptyset_{PU,1}), \boldsymbol{a}(\emptyset_{PU,2}), \ldots\ldots\ldots, \boldsymbol{a}(\emptyset_{PU,M})] \quad (17)$$

The N-by-N matrix, P_A, refers to the orthogonal projection matrix onto the subspace spanned by the columns of A. It is expressed mathematically as follows:

$$\boldsymbol{P}_A = \boldsymbol{A}.[\boldsymbol{A}^H.\boldsymbol{A}]^{-1}.\boldsymbol{A}^H \quad (18)$$

Conventional null-steering beamforming problem can be formulated as follows [19]:

$$max_H |\boldsymbol{w}^H.\boldsymbol{a}(\emptyset_{SU})|^2 \; subject\; to\; \boldsymbol{w}^H.\boldsymbol{A} = 0 \; and \; \boldsymbol{w}^H.\boldsymbol{w} = c\,,$$

$$c: constant\; value \quad (19)$$

The solution to the above optimization problem is given as follows [19]:

$$\boldsymbol{w}(\emptyset_{SU}) = \frac{c}{||(\boldsymbol{I}-\boldsymbol{P}_A).\boldsymbol{a}(\emptyset_{SU})||}.(\boldsymbol{I}-\boldsymbol{P}_A).\boldsymbol{a}(\emptyset_{SU}) \quad (20)$$

In the above equation, 'I' refers to N-by-N identity matrix. The radiation pattern of the activated SU cluster represents the spatial response of the VAA performing the null-steering beamforming with the derived beamforming weights 'w (ϕ_{SU})'. Mathematically it can be expressed as follows:

$$\boldsymbol{R}(\emptyset) = |\boldsymbol{a}^H(\emptyset).\boldsymbol{w}(\emptyset_{SU})|^2 \quad (21)$$

4. Receiver Side Processing

4.1. Spatial Signature based Matched Filtering

In general, the wireless channel impulse response between the i^{th} terminal in the s^{th} SU transmitter cluster and the j^{th} terminal in the receiver cluster can be represented by the following mathematical equation [22]:

$$h_{s,i,j}(t,\tau) = \sum_{l=0}^{L_i(t)} \alpha_{i,l}(t).\delta(t-\tau_{i,l}(t)) \quad (22)$$

In the above equation, '$\alpha_{i,l}(t)$' denotes the complex channel amplitude. The number of multipath components is denoted by 'L_i (t)'.The path delay of the l^{th} multipath component is denoted by '$\tau_{i,l}(t)$'.Let '$H_{s,i,j}$' denote the frequency domain channel coefficients between the i^{th} transmitter antenna of the s^{th} SU transmitter cluster and j^{th} receiver antenna.

Let '$H^{diag}{}_{s,i,j}$' denote a diagonal matrix containing the elements of '$H_{s,i,j}$' along the main diagonal.

$$H_{i,j}^{diag} = \begin{bmatrix} H_{i,j}(1) & 0 & 0 & \cdots & 0 \\ \vdots & H_{i,j}(2) & 0 & \ddots & \vdots \\ . & . & . & . & . \\ . & . & . & . & 0 \\ 0 & 0 & 0 & \cdots & H_{i,j}(N_{sub}) \end{bmatrix} \quad (23)$$

Let '$\mathbf{x}^i{}_{SU_GFDM}$', i=1, 2…N_T , denote the transmitted GFDM signal from the i^{th} transmitter antenna, before application of the null-steering beamforming weight vector. Its mathematical expression is same as that for baseband GFDM signal shown in [2]. Let

'$\mathbf{S}^{i}_{SU_GFDM}$', i=1, 2…N_T , denote the pre –IFFT GFDM signal as expressed below. As mentioned earlier, details of the mathematical expression for '$\mathbf{x}^{i}_{SU_GFDM}$' can be found in [2].

$$\boldsymbol{S}^{i}_{SU_{GFDM}} = \boldsymbol{W}_{N_{sub}}.\boldsymbol{x}^{i}_{SU_{GFDM}}$$
$$= \boldsymbol{W}_{N_{sub}}.\left\{\boldsymbol{W}^{H}_{N_{sub}}.\sum_{k=1}^{K}\boldsymbol{P}_k.\boldsymbol{\Gamma}_{diag}.\boldsymbol{R}^{L}.\boldsymbol{W}_M.d_k\right\}$$
$$= \sum_{k=1}^{K}\boldsymbol{P}_k.\boldsymbol{\Gamma}_{diag}.\boldsymbol{R}^{L}.\boldsymbol{W}_M.d_k\ ; i = 1,2,\dots,N_T \quad (24)$$

Further, '$\mathbf{S}^{i}_{SU_GFDM}$' can be represented by the column vector as shown below:

$$\boldsymbol{S}^{i}_{SU_GFDM} = [S^{i}_{SU_{GFDM}}(1)\ S^{i}_{SU_{GFDM}}(2)\ \dots\dots\ S^{i}_{SU_{GFDM}}(N_{sub})]^T \quad (25)$$

It is assumed that the cyclic prefix (CP) is longer than the maximum delay spread of the channel. So after removal of the CP, the channel appears circular to the symbols. As such, application of FFT converts the circulant channel matrix to diagonal matrix, with frequency domain channel coefficients along the main diagonal.

The null-steering weight vector can be expressed as a column vector as follows:

$$w(\emptyset_{SU}) = [w^{(1)}(\emptyset_{SU})\ w^{(2)}(\emptyset_{SU})\ \dots\dots\dots w^{(N_T)}(\emptyset_{SU})]^T \quad (26)$$

The received signal at the *j*th receiver antenna can be expressed as follows:

$$\boldsymbol{y}_j = \left[\boldsymbol{H}^{diag}_{1,j}\ \boldsymbol{H}^{diag}_{2,j}\ \dots\dots\dots\boldsymbol{H}^{diag}_{N_T,j}\right].\begin{bmatrix} w^{(1)}(\emptyset_{SU}).\boldsymbol{S}^{1}_{SU_GFDM} \\ w^{(2)}(\emptyset_{SU}).\boldsymbol{S}^{2}_{SU_GFDM} \\ \vdots \\ w^{(N_T)}(\emptyset_{SU}).\boldsymbol{S}^{N_T}_{SU_GFDM} \end{bmatrix} + \boldsymbol{N} \quad (27)$$

The above equation can be re-expressed as:

$$y_j = \left(\boldsymbol{w}(\emptyset_{SU}) \odot \left[\boldsymbol{H}^{diag}_{1,j}\ \boldsymbol{H}^{diag}_{2,j}\ \dots\dots\boldsymbol{H}^{diag}_{N_T,j}\right]\right).\begin{bmatrix} \boldsymbol{S}^{1}_{SU_GFDM} \\ \boldsymbol{S}^{2}_{SU_GFDM} \\ \vdots \\ \boldsymbol{S}^{N_T}_{SU_GFDM} \end{bmatrix} + \boldsymbol{N}$$
$$= \left(\boldsymbol{w}(\emptyset_{SU}) \odot \left[\boldsymbol{H}^{diag}_{1,j}\ \boldsymbol{H}^{diag}_{2,j}\ \dots\dots\boldsymbol{H}^{diag}_{N_T,j}\right]\right).\boldsymbol{S}^{all}_{SU_GFDM} + \boldsymbol{N}$$
$$\boldsymbol{where}\ \boldsymbol{S}^{all}_{SU_GFDM} = [\boldsymbol{S}^{1}_{SU_GFDM}\ \boldsymbol{S}^{2}_{SU_GFDM}\ \dots\dots\boldsymbol{S}^{N_T}_{SU_GFDM}]^T \quad (28)$$

In (28), the sign 'Θ' indicates element-wise multiplication.

Let 'b_j' denote the spatial signature of the *j*th receiver antenna.

$$b_j = \boldsymbol{w}(\emptyset_{SU}) \odot [\boldsymbol{H}^{diag}_{1,j}\ \boldsymbol{H}^{diag}_{2,j}\ \dots\dots\boldsymbol{H}^{diag}_{N_T,j}] \quad (29)$$

Let '**b**' denote the matrix of spatial signatures at all the receiver antennas.

$$\boldsymbol{b} = [b_1\ b_2\ \dots\dots b_{N_R}]^T \quad (30)$$

Then, the received signal at 'N_R' receiver antennas can be expressed in terms of the transmitted signal and spatial signature associated with each receiver antenna as follows:

$$\boldsymbol{y} = [y_1\ y_2\ \dots\dots y_{N_R}]^T = \boldsymbol{b}.\boldsymbol{S}^{all}_{SU_GFDM} + \boldsymbol{N} \quad (31)$$

It is assumed that the channel is temporally slowly fading and that each post-FFT sample of the received GFDM signal encounters independent and identical Rayleigh distribution. Moreover, the channel stays constant over a number of symbols and the receiver has perfect knowledge of the slowly varying channel. The receiver computes the pseudo-inverse of the spatial signature matrix '**b**' to recover the transmitted spatially modulated GFDM signal.

4.2. Active Transmitter Cluster Index Estimation

While it is assumed that the receiver has perfect knowledge of the spatial signatures, the receiver does not have knowledge which transmitter cluster is active for that particular frame instant. The receiver performs spatial signature based matched filtering on the received signal using spatial signature belonging to each SU transmitter cluster and stores the result in vector form in a buffer. Next, the receiver computes the squared absolute value of each stored vector in the buffer and compares the result to find out the maximum value. The index of the maximum value gives an estimate of the active transmitter SU cluster.

The procedure is tabulated in Table 3 below:

Table 3. Spatial Signature based Matched filtering

Inputs:
Received Signal: y, Spatial Signature of s^{th} transmitter cluster: b_s ; s=1,2,……..,N_c
Output:
Index of Active Transmit SU cluster: s
(i) $\boldsymbol{y}^{matched}_{s} = (\boldsymbol{b}^{H}_{s}.\boldsymbol{b}_s)^{-1}.\boldsymbol{b}^{H}_{s}.\boldsymbol{y}, s = 1,2\dots., N_c$

(ii) $a_s = ||\boldsymbol{y}_s^{matched}||^2, s = 1,2,\dots,N_c$

(iii) $s = \arg max_s\, a_s, s = 1,2,\dots.,N_c$

5. Simulation Results and Analysis

In this section, simulation results are provided to evaluate the performance of the proposed system under multipath Rayleigh fading channel environment. It is assumed that the clusters are closely spaced. Inter-element distance within each cluster is d=0.5λ, where 'λ' is the wavelength. Cluster elements are arranged in the form of ULA. The center frequency of operation of both the CR-IOT Femto-Cell and primary Macro-Cell is f_c=2.3 GHz. The number of transmitter and receiver terminals within each cluster in the CR-IOT Femto-Cell network is 16. The multicarrier signaling scheme chosen for the Femto-Cell CR-IOT system is GFDM, which uses *M*-ary QAM constellation. The Macro-Cell PU system uses OFDM waveform, which also uses *M*-ary QAM constellation. The PU-OFDM transmitter is assumed to be at 45 degrees.

The following table shows the specifications of the Femto-Cell CR-IOT GFDM waveform.

Table 4. GFDM system parameters

Simulation Parameters for SM-beamformer GFDM system	
Total number of time slots	5
Active Subcarrier Indices 100:200	
Pulse Shaping Filter	RRC
RRC Overlap Factor	0.1
Number of SU Tx clusters	4
Number of SU Tx terminals per cluster	16
Number of SU Rx clusters	1
Number of SU Rx terminals per cluster	16

In Figure 4 showing antenna array pattern, null is steered at 45 degrees which is the Macro-Cell PU-OFDM transmitter's location. The SS-MUSIC algorithm provides the DOA estimate of the PU-OFDM transmitter, which helps to steer null towards the PU location. As evident from Figure 4, the red dotted line at 45 degrees indicates the direction of the Macro-Cell PU-OFDM transmitter.

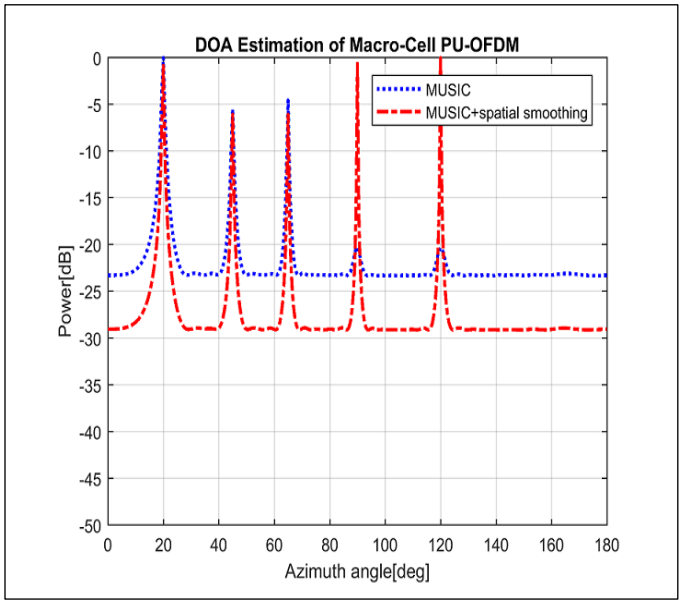

Figure 4. Cognitive Null Steering towards Macro-Cell PU-OFDM user

SS-MUSIC is preferred over conventional MUSIC primarily because of the fact that under multipath propagation, the latter does not perform well in identifying all the sources. This is because under multipath propagation environment, 2 or more DOAs might belong to the same source .i.e. for 'K' number of DOAs, actually the number of sources might be less than 'K' under multipath environment.

Figure 5 shows DOA estimation performance comparison between SS-MUSIC and conventional MUSIC for 2 sources arriving at the receiver from different directions, under multipath propagation conditions.

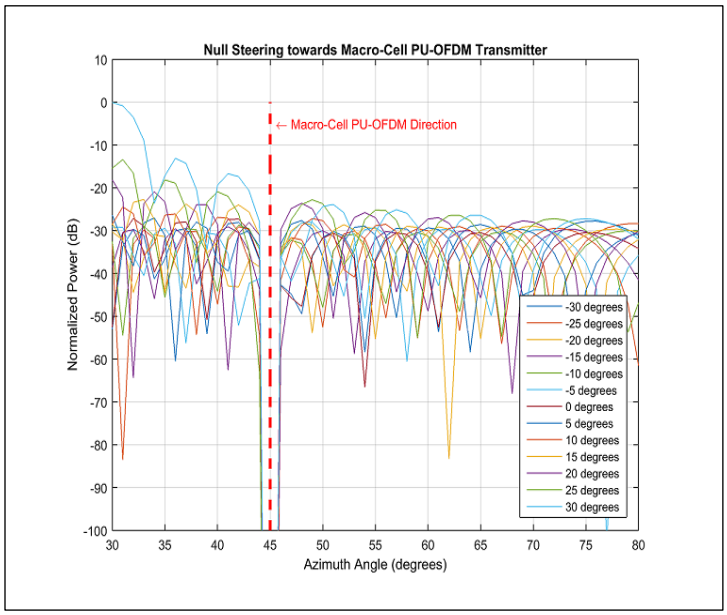

Figure 5. SS-MUSIC vs conventional MUSIC

As evident from Figure 5, for signals with multipath components too close to the main direction, the estimation capability of SS-MUSIC is better due to the application of the smoothing procedure. In the above figure, resolution of the main DOA (45º) and the multipath DOAs (20º, 65º, 90º and 120º) by the SS-MUSIC is better than that with MUSIC.

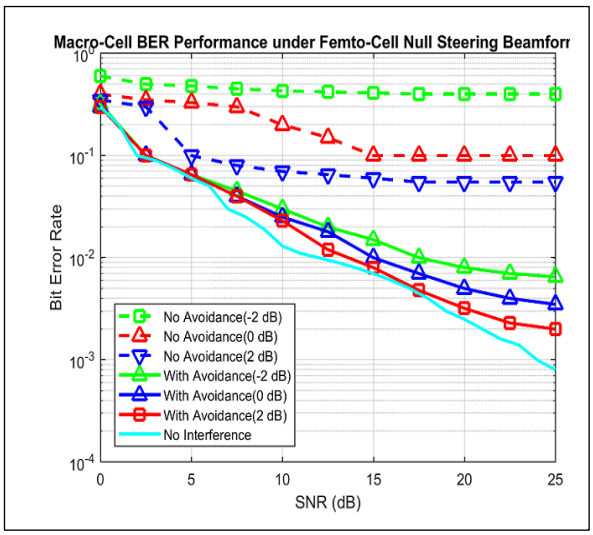

Figure 6. BER performance of Macro-Cell based PU-OFDM

Figure 6 compares the BER curves as a function of SNR for different signal-to-interference ratio (SIR) values for the Macro-Cell PU-OFDM user under conditions of no interference avoidance and with interference avoidance. As evident from the above figure, the Macro-Cell PU suffers significant performance loss under no interference avoidance scenario; however considerable performance improvement is achieved with the application of the cognitive null-steering based beamforming at the Femto-Cell CR-IOT GFDM transmitter.

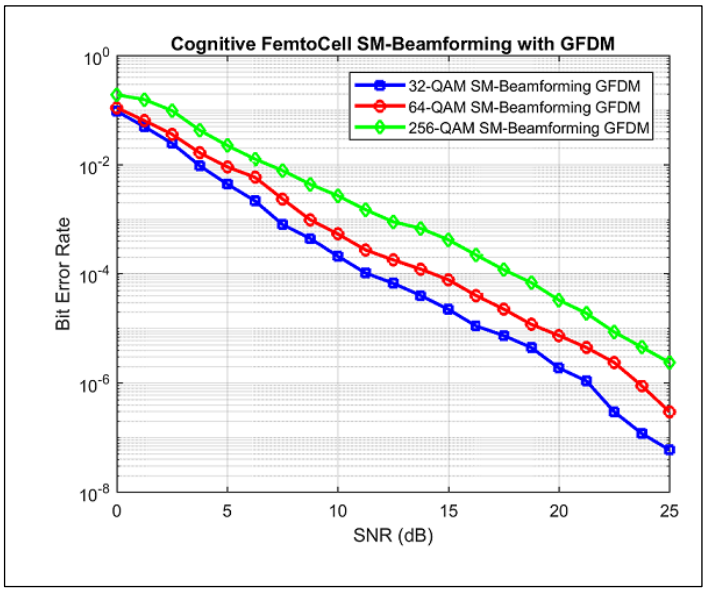

Figure 7. BER performance of Femto-Cell based CR-IOT GFDM

The proposed SM-beamforming system is very well capable of avoiding interference to the PU system for signal-to-noise ratio (SNR) less than or equal to 15 dB. At higher SNR values, it is observed that there is presence of residual interference. This happens due to imperfect steering of nulls at higher SNRs, for different SIR values.

Figure 7 shows the BER performance of the Femto-Cell based CR-IOT GFDM employing SM-beamforming scheme. As expected, BER for 256-QAM system is higher than that of 32-QAM and 64-QAM system under multipath Rayleigh fading channel conditions.

6. Conclusion

This paper introduces the application of SM based null-steering beamforming in VAA based CR-IOT system, under multipath fading channel conditions. Computer simulation results show that the proposed scheme can lead to good BER performance of the PU system by appropriate design of the null-steering beam-former. Moreover, the application of beamforming at the spatial modulation based SU transmitter also provides good BER performance of the SU system under multipath channel conditions. Spatial Smoothing based MUSIC is selected for DOA estimation due to its superiority over conventional MUSIC under multipath propagation. However, performance analysis of other DOA estimation algorithms needs to be evaluated for multicarrier signaling case. As a future work, transmit-receive beamforming schemes with DOA estimation will be investigated under full duplex spatial modulation based transmission conditions.

Conflict of Interest

The authors declare no conflict of interest.

Hammerstein model
Separate nonlinearity
Quadruple-tank process

ABSTRACT

A new coupled structure identification of Multi-Input Multi-Output (MIMO) Hammerstein models with separate nonlinearities is proposed. It is based on the use of the Recursive Least Squares (RLS) algorithm. A comparative study between a decoupled and coupled structures identification of MIMO Hammerstein models is discussed. A quadruple-tank process is used to illustrate the e ectiveness of the new structure.

1 Introduction

This paper is an extension of work originally presented in Conference on Science of Electronics, Technologies of Information and Telecommunications (SETIT 2016) [1].
The latter work presented two methods of parametric identification of decoupled multivariable Hammerstein model.
It consists of one nonlinear static block and one linear dynamic block. Many process (chemical and biological process, signal processing, *etc.*) have this structure, for example: pH neutralization processes [2], polymerization reactor [3], distillation columns [4] and dryer process [5].
Many system identification methods have been used to identify the single-input single-output (SISO) model. They can be divided into stochastic methods [6,7], iterative methods [8], over-parameterization methods [9], separable least squares methods [10,11], blind identification methods [12] and frequency domain methods [13].
It is possible to transform the SISO Hammerstein model to MISO and MIMO model which is linear in the parameters [14]. Serval approches have been proposed to identify MIMO Hammerstein model. In [15,16,17], neuronal networks and fuzzy logic have been used to deal with more general nonlinearities. An approach based on multivariable cardinal cubic spline functions to model the static nonlinearities have been proposed in [18]. The Least Squares Support Vector Machines (LS-SVMs) have been presented in [19,20]. A generalized Hammerstein model consisting of a static polynomial function in series with time-varying linear model is developed in order to model the Hammerstein-like multivariable processes whose linear dynamics vary over the operating space in [21]. In this work, we propose a new coupled structure identification of MIMO model with separate nonlinearities. It is organized as follows: SISO Hammerstein system is presented in part 1 of section 2. A new coupled structure for MIMO Hammerstein system is developed in part 2 of section 2. Simulation results of a quadruple-tank process is given in section 3. Finally, a conclusion is made.

2 Parametric identification of Hammerstein model

2.1 Parametric identification of SISO Hammerstein model

Assume that the Hammerstein model of Figure 1 is composed of a nonlinear block $F(.)$ associated with a linear sub-system $\frac{B(q^{-1})}{A(q^{-1})}$. It is described by:

$$\begin{cases} y_k = \frac{B(q^{-1})}{A(q^{-1})} v_k + w_k \\ v_k = F(u_k) \end{cases} \quad (1)$$

https://dx.doi.org/10.25046/aj020607

with:

$$A\left(q^{-1}\right) = 1 + a_1 q^{-1} + a_2 q^{-2} + \ldots + a_{n_A} q^{-n_A}$$

$$B\left(q^{-1}\right) = b_1 q^{-1} + b_2 q^{-2} + \ldots + b_{n_B} q^{-n_B}$$

$$v_k = \lambda_1\, u_k + \lambda_2\, u_k^2 + \ldots + \lambda_N\, u_k^N$$

q^{-1} delay operator, u_k input of the system, y_k output, v_k the unmeasurable internal signal and w_k represents the modeling error, external disturbances, *etc*.

In order to have a unique parameterizations of the Hammerstein model structure, the first coefficient of the nonlinear function $F(.)$ equals to 1, $\lambda_1 = 1$ [11,22].

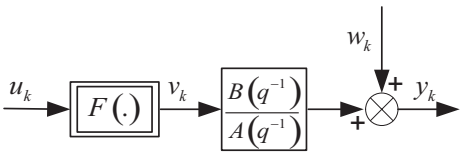

Figure 1: SISO Hammerstein model

The output y_k is given by:

$$y_k = -\sum_{i=1}^{n_A} a_i\, y_{k-i} + \sum_{i=1}^{n_B} b_i \left(u_{k-i} + \sum_{\rho=2}^{N} \lambda_\rho\, \mathrm{u}^\rho{}_{k-i} \right) + w_k \quad (2)$$

Equation (2) can be written in the following form:

$$y_k = \Phi_k^T\, \theta_k + w_k \quad (3)$$

with:

$$\Phi_k = \begin{pmatrix} Y_k \\ U_k \end{pmatrix},\ \theta = \begin{pmatrix} a \\ b \\ s \end{pmatrix},$$

Φ_k and $\theta_k \in R^{n_R}$ where $n_R = n_A + N\, n_B$,

$Y_k = \begin{pmatrix} -y_{k-1}, -y_{k-2}, \ldots, -y_{k-n_A} \end{pmatrix} \in R^{n_A}$,

$U_k = \begin{pmatrix} U_{1k}, U_{2k}, \ldots, U_{Nk}, \end{pmatrix} \in R^{N n_B}$,

$U_{j_k} = \begin{pmatrix} u^j{}_{k-1}, u^j{}_{k-2}, \ldots, u^j{}_{k-n_B} \end{pmatrix} \in R^{n_B}$,

for $j = 1, 2, \ldots, N$

$a = \begin{pmatrix} a_1, a_2, \ldots, a_{n_A} \end{pmatrix} \in R^{n_A}$,

$b = \begin{pmatrix} b_1, b_2, \ldots, b_{n_B} \end{pmatrix} \in R^{n_B}$,

$s = \begin{pmatrix} \lambda_2 b, \lambda_3 b, \ldots, \lambda_N b \end{pmatrix} \in R^{N n_B}$.

The parameter vector θ can be estimated using the RLS algorithm. It is described by the following equations:

$$\begin{cases} \hat{\theta}_k = \hat{\theta}_{k-1} + P_k\, \Phi_k\, \varepsilon_k \\ P_k = P_{k-1} - \frac{P_{k-1}\, \Phi_k\, \Phi_k^T\, P_{k-1}}{1 + \Phi_k^T\, P_{k-1}\, \Phi_k} \\ \varepsilon_k = y_k - \hat{\theta}_{k-1}^T\, \Phi_k \end{cases} \quad (4)$$

where P_k is the adaptation gain matrix, Φ_k is the observation vector and θ_k is the parameters vector.

2.2 Parametric identification of MIMO Hammerstein model

Two structures are used to identify MIMO Hammerstein models in the literature: with separate nonlinearities [21] or with combined nonlinearities [23]. The second case is the most general, but it can cause a very challenging parameter estimation problem because of the large number of parameters to be estimated.

In this paper, we developed a new coupled structure for MIMO Hammerstein model with separate nonlinearities. They are presented in Figure 2 and 4 where u_j, $v_{i,j}$, y_i for $i = 1, 2, \ldots, p$ and $j = 1, 2, \ldots, m$ are the system input, internal signal and system output. $F_{i,j}(.)$ are nonlinear function.

2.2.1 A decoupled structure identification of MIMO Hammerstein model

The decoupled structure of MIMO Hammerstein model is given in Figure 2. Each output $y_{i,k}$, $i = 1, 2, \ldots p$, of the multivariable system corresponds to a linear model, which at its input are introduced a nonlinear functions, Figure 3.

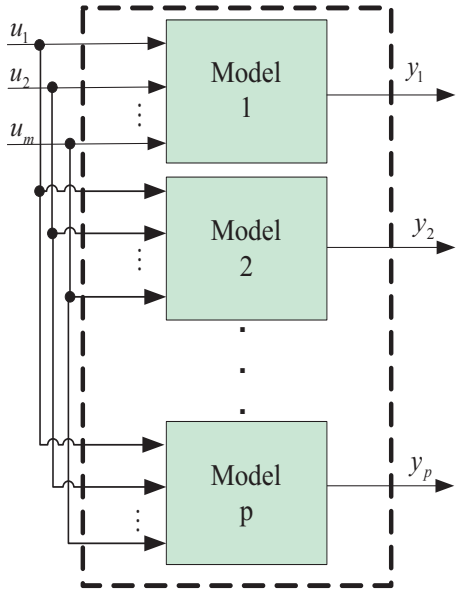

Figure 2: Decoupled structure of MIMO Hammerstein model

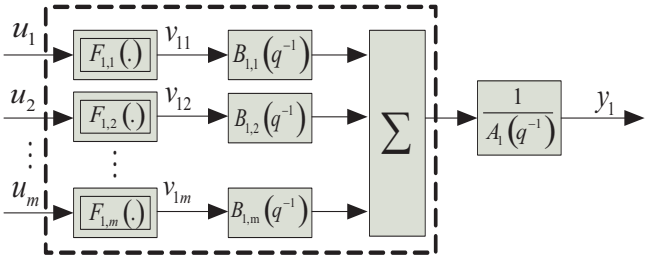

Figure 3: Structure of first model

Each output $y_{i,k}$, $i = 1, 2, \ldots p$, of the MIMO Hammerstein model is proposed as:

$$\begin{cases} A_i\left(q^{-1}\right)y_{i,k} = \sum_{j=1}^{m} B_{i,j}\left(q^{-1}\right)v_{j,k} \\ v_{i,j,k} = F_{i,j}\left(u_{j,k}\right) = u_{j,k} + \sum_{\rho=2}^{N} \lambda_{i,j,\rho}\, u_{j,k}^{\rho} \end{cases} \quad (5)$$

with:

$A_i\left(q^{-1}\right) = 1 + a_{i,1}q^{-1} + a_{i,2}q^{-2} + \ldots + a_{i,n_{A_i}}q^{-n_{A_i}}$

$B_{i,j}\left(q^{-1}\right) = b_{i,j,1}q^{-1} + b_{i,j,2}q^{-2} + \ldots + b_{i,j,n_{B_{i,j}}}q^{-n_{B_{i,j}}}$

System (5) can be rewritten as:

$$\begin{aligned} y_{i,k} = &-\sum_{\tau=1}^{n_{A_i}} a_{i,\tau}\, y_{i,k-\tau} + \sum_{j=1}^{m}\sum_{\tau=1}^{n_{B_{i,j}}} b_{i,j,\tau}\, u_{j,k-\tau} \\ &+ \sum_{j=1}^{m}\sum_{\tau=1}^{n_{B_{i,j}}}\sum_{\rho=2}^{N} b_{i,j,\tau}\,\lambda_{i,j,\rho}\, u_{j,k-\tau}^{\rho} \end{aligned} \quad (6)$$

then:

$$\begin{aligned} y_{i,k} = &-\sum_{\tau=1}^{n_{A_i}} a_{i,\tau}\, y_{i,k-\tau} + \sum_{j=1}^{m}\sum_{\tau=1}^{n_{B_{i,j}}} b_{i,j,\tau}\, u_{j,k-\tau} \\ &+ \sum_{j=1}^{m}\sum_{\tau=1}^{n_{B_{i,j}}}\sum_{\rho=2}^{N} s_{i,j,\tau,\rho}\, u_{j,k-\tau}^{\rho} \end{aligned} \quad (7)$$

Equation (7) can be written in the following form:

$$y_{i,k} = {\Phi_{i,k}}^{T}\ \theta_i \quad (8)$$

with:

$$\Phi_{i,k} = \begin{pmatrix} Y_{i,k} \\ U_k \\ \varphi_k \end{pmatrix},\ \theta_i = \begin{pmatrix} A_i \\ B_i \\ S_i \end{pmatrix}$$

$\Phi_{i,k}$ and $\theta_i \in R^{n_R}$; $n_R = n_{A_i} + \sum_{j=1}^{m} N n_{B_{i,j}}$

$$Y_{i,k} = \left(-y_{i,k-1},\ -y_{i,k-2},\ \ldots,\ -y_{i,k-n_{A_i}}\right) \in R^{n_{A_i}}$$

$$U_k = (U_{1,k},\ U_{2,k},\ \ldots,\ U_{m,k}) \in R^{m\times n_{B_{i,j}}}$$

$$U_{j,k} = \left(u_{j,k-1},\ u_{j,k-2},\ \ldots,\ u_{j,k-n_{B_{i,j}}}\right) \in R^{n_{B_{i,j}}}$$

$$\varphi_k = (\varphi_{1,k},\ \varphi_{2,k},\ \ldots,\ \varphi_{m,k}) \in R^{(N-1)\times m\times n_{B_{i,j}}}$$

$$\varphi_{j,k} = \left(\varphi_{j,1,k},\ \varphi_{j,2,k},\ \ldots,\ \varphi_{j,n_{B_{i,j}},k}\right) \in R^{(N-1)\times n_{B_{i,j}}}$$

$$\varphi_{j,\tau,k} = \left(u_{j,k-\tau}^{2},\ u_{j,k-\tau}^{3},\ \ldots,\ u_{j,k-\tau}^{N}\right) \in R^{(N-1)}$$

$$A_i = \left(a_{i,1},\ a_{i,2},\ \ldots,\ a_{i,n_{A_i}}\right) \in R^{n_{A_i}}$$

$$B_i = (B_{i,1},\ B_{i,2},\ \ldots,\ B_{i,m}) \in R^{m\times n_{B_{i,j}}}$$

$$B_{i,j} = \left(b_{i,j,1},\ b_{i,j,2},\ \ldots,\ b_{i,j,n_{B_{i,j}}}\right) \in R^{n_{B_{i,j}}}$$

$$S_i = (S_{i,1},\ S_{i,2},\ \ldots,\ S_{i,m}) \in R^{(N-1)\times m\times n_{B_{i,j}}}$$

$$S_{i,j} = \left(S_{i,j,1},\ S_{i,j,2},\ \ldots,\ S_{i,j,n_{B_{i,j}}}\right) \in R^{(N-1)\times n_{B_{i,j}}}$$

$$S_{i,j,\tau} = \left(s_{i,j,\tau,2},\ s_{i,j,\tau,3},\ \ldots,\ s_{i,j,\tau,N}\right) \in R^{(N-1)}$$

$$s_{i,j,\tau,\rho} = b_{i,j,\tau}\,\lambda_{j,\rho}$$

for $i = 1, 2, \ldots, p$, $j = 1, 2, \ldots, m$, and $\tau = 1, 2, \ldots, n_{B_{i,j}}$

The steps of the identification scheme are summarized as follows:

1. choosing an initial values for the adaptation matrix,
2. acquiring the input and output of the system and form the vector data as shown in (11) using the present and past values of the input u, output y, and u power,
3. solving the estimate parameter A_i, B_i and S_i using the algorithm RLS,
4. solving $\lambda_{i,j,\rho}$ using the estimated values $b_{i,j,\tau}$ and $s_{i,j,\tau,\rho}$ as:

$$\lambda_{i,j,\rho} = \left(\sum_{\tau=1}^{n_{B_{i,j}}} b_{i,j,\tau}^{2}\right)^{-1}\left(\sum_{\tau=1}^{n_{B_{i,j}}} b_{i,j,\tau}\, s_{i,j,\tau,\rho}\right) \quad (9)$$

2.2.2 A new coupled structure identification of MIMO Hammerstein system

The structure of this method is given in Figure 5. Each output of the system is depended on inputs and all other system outputs, Figure 4.

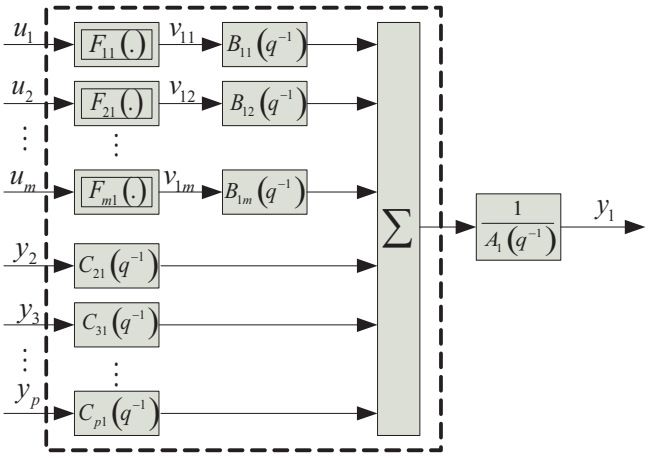

Figure 4: Structure of first model

Each output $y_{i,k}$, $i = 1, 2, \ldots p$, of the MIMO Hammerstein model is described by:

$$\begin{cases} A_i\left(q^{-1}\right)y_{i,k} = \sum_{j=1}^{m} B_{i,j}\left(q^{-1}\right)v_{j,k} + \sum_{\substack{l=1 \\ l\neq i}}^{p} C_{i,l}\left(q^{-1}\right)y_{l,k} \\ v_{i,j,k} = F_{i,j}\left(u_{j,k}\right) = u_{j,k} + \sum_{\rho=2}^{N} \lambda_{i,j,\rho}\, u_{j,k}^{\rho} \end{cases} \quad (10)$$

with:

$$A_i\left(q^{-1}\right) = 1 + a_{i,1}q^{-1} + a_{i,2}q^{-2} + \ldots + a_{i,n_{A_i}}q^{-n_{A_i}}$$
$$B_{i,j}\left(q^{-1}\right) = b_{i,j,1}q^{-1} + b_{i,j,2}q^{-2} + \ldots + b_{i,j,n_{B_{i,j}}}q^{-n_{B_{i,j}}}$$
$$C_{i,l}\left(q^{-1}\right) = c_{i,l,1}q^{-1} + c_{i,l,2}q^{-2} + \ldots + c_{i,l,n_{C_{i,l}}}q^{-n_{C_{i,l}}}$$

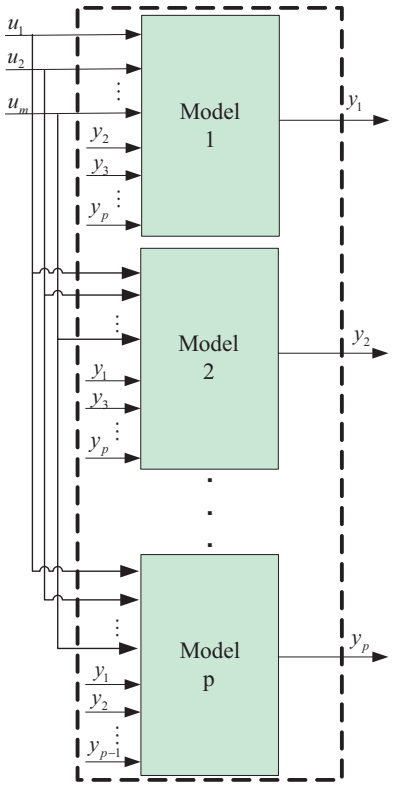

Figure 5: A proposed structure of MIMO Hammerstein model

System (10) can be rewritten as:

$$y_{i,k} = -\sum_{\tau=1}^{n_{A_i}} a_{i,\tau}\, y_{i,k-\tau} + \sum_{j=1}^{m}\sum_{\tau=1}^{n_{B_{i,j}}} b_{i,j,\tau}\, u_{j,k-\tau} + \sum_{j=1}^{m}\sum_{\tau=1}^{n_{B_{i,j}}}\sum_{\rho=2}^{N} b_{i,j,\tau}\,\lambda_{i,j,\rho}\, u_{j,k-\tau}^{\rho} + \sum_{\substack{l=1\\ l\neq i}}^{p}\sum_{\tau=1}^{n_{C_{i,l}}} c_{i,l,\tau}\, y_{l,k-\tau} \tag{11}$$

then:

$$y_{i,k} = -\sum_{\tau=1}^{n_{A_i}} a_{i,\tau}\, y_{i,k-\tau} + \sum_{j=1}^{m}\sum_{\tau=1}^{n_{B_{i,j}}} b_{i,j,\tau}\, u_{j,k-\tau} + \sum_{j=1}^{m}\sum_{\tau=1}^{n_{B_{i,j}}}\sum_{\rho=2}^{N} s_{i,j,\tau,\rho}\, u_{j,k-\tau}^{n} + \sum_{\substack{l=1\\ l\neq i}}^{p}\sum_{\tau=1}^{n_{C_{i,l}}} c_{i,l,\tau}\, y_{l,k-\tau} \tag{12}$$

Equation (12) can be written in the following form:

$$y_{i,k} = \Psi_{i,k}^{T}\theta_i^{new} \tag{13}$$

with:

$$\Psi_{i,k} = \begin{pmatrix} Y_{i,k} \\ U_k \\ \varphi_k \\ Y_{L,k} \end{pmatrix},\quad \theta_i^{new} = \begin{pmatrix} A_i \\ B_i \\ S_i \\ C_i \end{pmatrix}$$

$$\Phi_{i,k} \text{ and } \theta_i \in R^{n_R};\ n_R = n_{A_i} + \sum_{j=1}^{m} N n_{B_{i,j}} + n_{C_{i,l}} \times (p-1)$$

$$Y_{\substack{L,k\\ L\neq i}} = \left(Y_{1,k},\ Y_{2,k},\ \ldots, Y_{p,k}\right) \in R^{(p-1)\times n_{C_{i,l}}}$$

$$Y_{l,k} = \left(-y_{l,k-1},\ -y_{l,k-2},\ \ldots,\ -y_{l,k-n_{C_{i,l}}}\right) \in R^{n_{C_{i,l}}}$$

$$C_i = \left(C_{i,1},\ C_{i,2},\ \ldots,\ C_{i,p}\right) \in R^{(p-1)\times n_{C_{i,l}}}$$

$$C_{i,j} = \left(c_{i,j,1},\ c_{i,j,2},\ \ldots,\ c_{i,j,n_{C_{i,l}}}\right) \in R^{n_{C_{i,l}}}$$

for $i = 1, 2, \ldots, p$, $j = 1, 2, \ldots, m$, and $\tau = 1, 2, \ldots, n_{B_{i,j}}$, and $l = 1, 2, \ldots, p$, such as $l \neq i$.

Parametric identification consists to determine the parameters of the system based on vectors of inputs and outputs, using the recursive least squares algorithm.

3 Application: quadruple-tank process

A quadruple-tank process is used to illustrate the performance of the proposed structures of the MIMO Hammerstein model.

3.1 System description

The system setup is a model of a chemical plant fragment. Very often tanks are coupled through pipes and the reactant level and flow has to be controlled. The type of the experiments was performed on the 33-041 Coupled Tanks System of Feedback Instruments [24]. This plant, a variant of the quadruple tank process originally proposed in [25], is a model of a fragment of a chemical plant, Figure 6.

Figure 6: Plant of four coupled tanks [26]

The line diagram of the reservoir system is shown in Figure 7. The coupled tanks unit consists of four tanks placed on a rig. Another reservoir tank is placed at the bottom. In the reservoir two submersible pumps are placed, which pump the water on command to the tanks. The water flows freely to the bottom tanks through the configurable orifice. The way

the water flows through the setup can be configured in many ways with manual valves label led (MVA, MVB, MVC, MVD, MVE, MVF, MVG, MV1, MV2, MV3 and MV4).

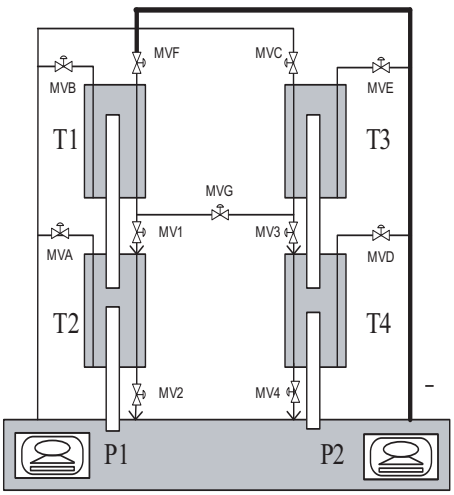

Figure 7: Line diagram for quadruple-tank process

3.2 Mathematical modelling

The quadruple-tank process admits the following nonlinear model [25] which has been assembled in simulink:

$$\begin{cases} \dot{h}_1(t) = \eta v_1(t) - \frac{a_1}{A}\sqrt{2gh_1(t)} - \frac{a_{13}}{A}\sqrt{2g(h_1(t)-h_3(t))} \\ \dot{h}_2(t) = \frac{a_1}{A}\sqrt{2gh_1(t)} - \frac{a_2}{A}\sqrt{2gh_2(t)} \\ \dot{h}_3(t) = \eta v_2(t) - \frac{a_3}{A}\sqrt{2gh_3(t)} - \frac{a_{13}}{A}\sqrt{2g(h_1(t)-h_3(t))} \\ \dot{h}_4(t) = \frac{a_3}{A}\sqrt{2gh_3(t)} - \frac{a_4}{A}\sqrt{2gh_4(t)} \end{cases} \quad (14)$$

where h_i, for $i = 1,2,3,4$, denote the water level in the corresponding tank and v_i, for $i = 1,2$, are voltages applied to the pumps. a_i, for $i = 1,2,3,4$, are the outlet area of the tanks, a_{13} is the outlet area betwixt tanks 1 and 3; η constant relating the control voltage with the water flow from the pump, A is the cross-sectional area of the tanks and g is the gravitational constant.

3.3 Simulation and results

The proposed structures has been tested with the model parameters presented in table 1.

	Value	Unit	Description
h_i	$0-25$	cm	Water level of tank i
v_i	$0-5$	V	Voltage level of pump i
S	0.014	m^2	Cross-sectional area
a_i	$5e-5$	m^2	Outlet area of tank i
a_{13}	$5e-5$	m^2	Outlet area betwixt $T1$ and $T3$
η	$2e-3$	$\frac{m^3}{V.s}$	Water level of tank i
g	9.81	m^{-2}	Gravitational constant

Table 1: Parameters of the plant

The inputs u_1 and u_2 are show in Figure 8. They are set to $[0\ldots+5V]$. The sample time used for all simulations is $T_e = 1s$.

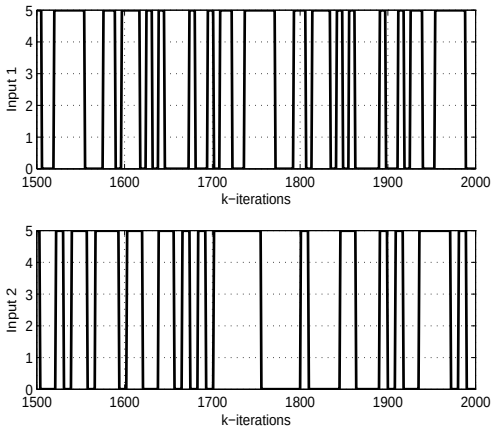

Figure 8: Inputs u_1 and u_2

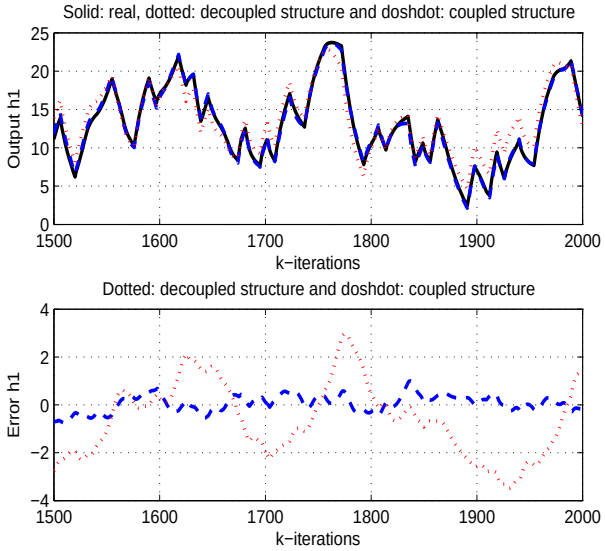

Figure 9: Response of the real and estimated h_1

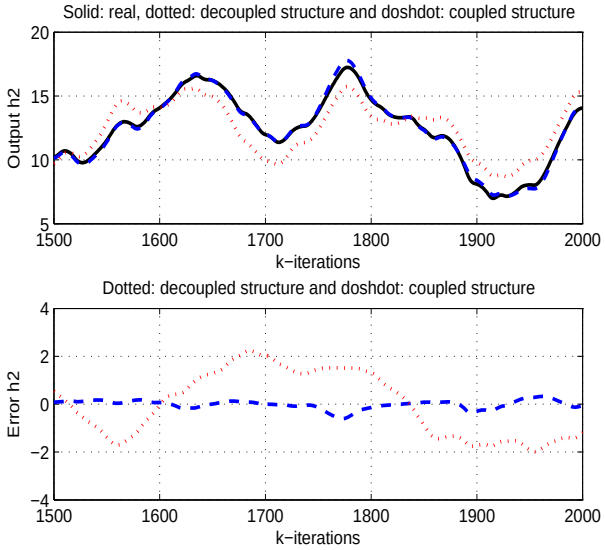

Figure 10: Response of the real and estimated h_2

Figures 9 to 12 show the results of the experiments with two method from a comparative point of view. Each of them shows a superposition of the actual output and the two outputs estimated as their two error curves. Solid line represents the real output, dotted line represents the estimated systems output signals with the decoupled structure and the dash dot lines represent the estimated systems output signals with the coupled structure in all four graphs. The responses of the original system and the results of the proposed method are very similar. It is clear that the error corresponds to the proposed structure is smaller than that corresponding to the decoupled structure. On inspection, the proposed structure is seen to work better than the decoupled structure. Thus, the feasibility and superiority of this proposed identification method are validated.

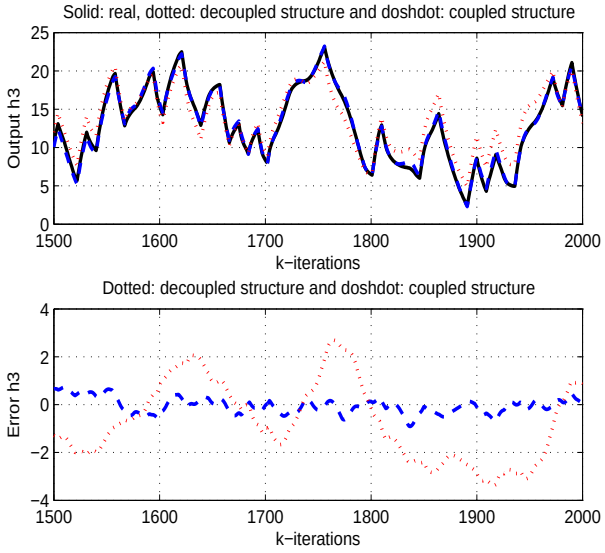

Figure 11: Response of the real and estimated h_3

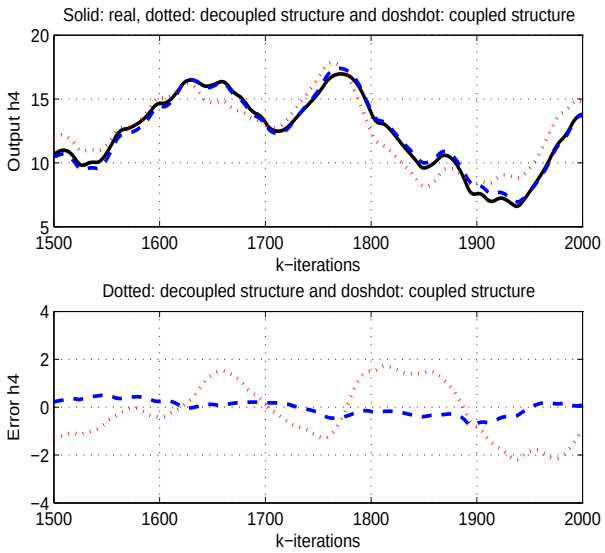

Figure 12: Response of the real and estimated h_4

4 Conclusion

In this study, a new coupled structure identification of MIMO Hammerstein model with separate nonlinearities has been developed. The method is based on RLS algorithm. A comparative study using simulation results for quadruple-tank process, between the proposed structure and the decoupled structure is discussed. Simulation results reveal the performance and effectiveness of the proposed method.
As a perspective, we will judge the performance of the method used in the presence of perturbations

Ray tracing

ABSTRACT

The main target of this article is to study the provision of indoor service (coverage) using outdoor base station at higher frequencies i.e. 10 GHz, 30 GHz and 60 GHz. In an outdoor to indoor propagation, an angular wall loss model is used in the General Building Penetration (GBP) model for estimating the additional loss at the intercept point of the building exterior wall. A novel angular wall loss model based on a separate incidence angle in azimuth and elevation plane is proposed in this paper. In the second part of this study, an Extended Building Penetration (EBP) model is proposed, and the performance of EBP model is compared with the GBP model. In EBP model, the additional fifth path known as the "Direct path" is proposed to be included in the GBP model. Based on the evaluation results, the impact of the direct path is found significant for the indoor users having the same or closed by height as that of the height of the transmitter. For the indoor users located far away from the exterior wall of building, a modified and enhanced approach of ray tracing type is proposed in this article. In the light of acquired simulation results, the impact of a modified ray tracing approach is emphasized.

1. Introduction

This article is an extension of research work originally presented at International Wireless Communication and Mobile Computing (IWCMC'17) conference [1]. In reference [1], studies were made at 10 GHz only; whereas in this article the impact of different propagation models is also analyzed at 30 GHz and 60 GHz. Additionally, two different ray tracing approaches are also analyzed in this article.

Outdoor to indoor propagation in a small cell environment involves Line of Sight (LOS) and Non-LOS (NLOS) propagation. It includes path loss computation, determination of reflection and diffraction loss, penetration loss, and other indoor losses. The penetration loss can be divided into four major categories i.e. building exterior wall penetration loss also known as building penetration loss, floor (ceiling) penetration loss, indoor propagation (room penetration) loss, and angular wall loss [2]. Several propagation models are given in literature e.g. General Building Penetration (GBP) model provides and evaluates the candidate paths, Berg's recursive method for micro cell path loss [3], and the linear attenuation model for indoor propagation. The frequency dependent penetration loss models are presented at [4].

The angular wall loss model presented in [2] and used in [4] depends on a single three-dimensional incidence angle. This paper presents a new angular wall loss model based on a separate incidence angle in azimuth and elevation plane. An Extended Building Penetration (EBP) model is proposed in this article. Path gain is used as a metric to compare the performance of different angular wall loss models and building penetration loss models. Section II provides the details about the GBP model, frequency

dependent penetration models, angular wall loss model, and ray tracing. Whereas Section III explains the proposed angular wall loss model and extended building penetration model. Section IV gives the description of the simulation environment and provides the details about the assumptions and simulation parameters. Section IV discusses the results in detail. Finally, Section V concludes the paper.

2. Background Theory

2.1. General Building Penetration (GBP) Model

The General Building Penetration (GBP) model is based on the COST231 building penetration model presented at [2]. The model considers a path from each exterior wall of the building. A top view of a single building scenario with a Transmitter (TX) located in an outdoor environment is shown in Figure 1. For each Receiver (RX) point located inside the building, there exist four candidate paths. A path coming from the front face of the building without any diffraction is called the "LOS path", and the paths which are reaching the receiver point after diffracting from the corners of the building are known as "NLOS paths". For the NLOS paths, the Berg's recursive model is used to capture the additional path loss due to the diffraction around the building, before entering the building, whereas the outdoor to indoor and other indoor losses are determined from the COST231 building penetration model as done in [4]. Each multipath has two propagation parts; the first part comprises free space propagation between the transmitter and the building's exterior wall intercept point. The second part is the propagation of a path in an indoor environment after penetrating through the exterior wall to the receiver point.

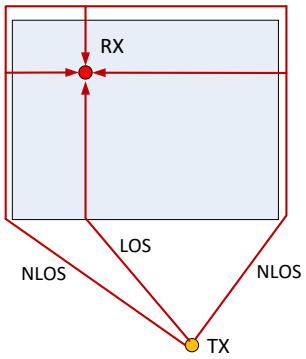

Figure 1. Illustration of propagation paths from outdoor base station to indoor location (top view).

A well-known Friis free space path loss model is used to find the path loss in the first free space propagation part. For the second part of the propagation path, along with the free space path loss model, the building penetration loss model, an indoor wall loss model, and an angular wall loss model is used to compute the additional loss due to indoor propagation. The received signal strength at the receiver location inside the building is the sum of four paths as shown in Figure 1.

Figure 2 shows the side view of the paths entering the building for the two receiver points RX1 and RX2 located on the Floor 1 and Floor 4, respectively. The signal path intercepts the building wall at the same height as that of a receiver height; therefore the ceiling penetration loss is not taken into account. It is important here to mention that in GBP model both the LOS path and NLOS paths do not penetrate through the ceiling.

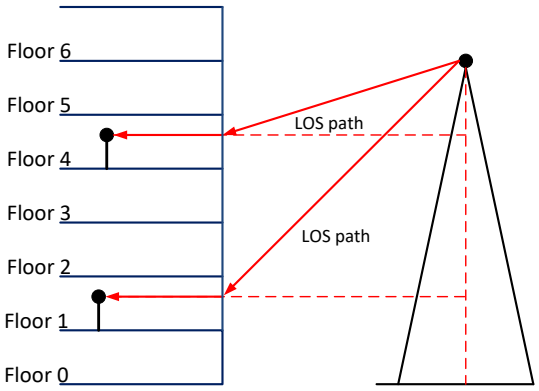

Figure 2. Illustration of LOS paths entering the building (side view).

2.2. Building Penetration Loss (BPL)

The signal experiences a penetration loss while penetrating from the outdoor environment to the building. Outdoor to indoor penetration loss is generally termed as Building Penetration Loss (BPL). The building penetration loss relies heavily on the frequency and on the material characteristics of the building; therefore the BPL can be significantly different for different material types at different frequencies. Generally, the old houses are composed of plane standard glass windows and concrete wall, while the Infrared Reflective (IRR) glass windows are commonly used in the new modern energy saving houses. In reference [4], the old buildings are assumed to have 30 % of the standard glass windows and 70 % of the concrete wall. Similarly, the assumption for new modern building type corresponds to the 70 % of the IRR glass windows and 30 % of the concrete wall.

A simple model structure has been proposed in [4] to model a single material frequency dependent penetration loss. The penetration loss for different material types is provided at references [5-9].

$$L_{\text{Single glass,dB}} = 0.1 * \text{Frequency}_{\text{GHz}} + 1, \quad (1)$$

$$L_{\text{Double glass,dB}} = 0.2 * \text{Frequency}_{\text{GHz}} + 2, \quad (2)$$

$$L_{\text{IRR glass,dB}} = 0.3 * \text{Frequency}_{\text{GHz}} + 23, \quad (3)$$

The penetration loss for the concrete wall is modeled as

$$L_{\text{Concrete,dB}} = 4 * \text{Frequency}_{\text{GHz}} + 5, \quad (4)$$

As the buildings are composite of windows and concrete wall, the building penetration loss for old buildings and new buildings is modeled as shown in (5) and (6), respectively [10].

$$L_{\text{Old building,dB}} = -10\text{Log}_{10}\left[0.3 * 10^{\frac{-L_{\text{Double glass,dB}}}{10}} + 0.7 * 10^{\frac{-L_{\text{Concrete,dB}}}{10}}\right], \quad (5)$$

$$L_{\text{New building,dB}} = -10\text{Log}_{10}\left[0.7 * 10^{\frac{-L_{\text{IRR glass,dB}}}{10}} + 0.3 * 10^{\frac{-L_{\text{Concrete,dB}}}{10}}\right], \quad (6)$$

The building penetration loss as a function of frequency for different types of building is shown in Figure 3.

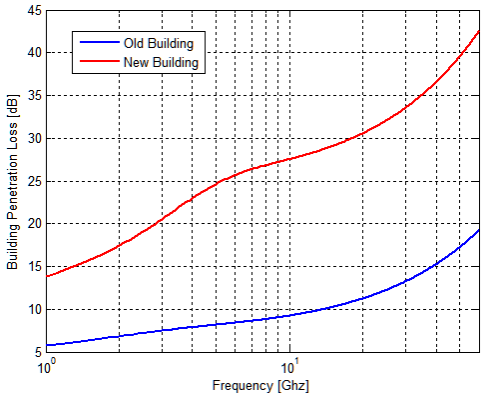

Figure 3. Building penetration loss as a function of frequency.

2.3. Indoor Propagation Loss

In an indoor environment, generally the indoor walls are made up of standard glass alternatively plaster. In [4], two different indoor wall loss models are presented as a function of the frequency assuming an average wall distance of 4 m. The Indoor Loss Model 1 assumes an indoor wall of standard glass, whereas Indoor Loss Model 2 is based on the measurements performed in [5]. Two indoor wall loss models are modeled as shown in (7) and (8).

$$L^{(1)}_{\text{Wall loss,dB/m}} = L_{\text{Single glass,dB}}, \quad (7)$$

$$L^{(2)}_{\text{Wall loss,dB/m}} = 0.2 * \text{Frequency}_{\text{GHz}} + 1.7, \quad (8)$$

Indoor loss as a function of frequency for two different indoor wall loss models, expressed as db/m is shown in Figure 4.

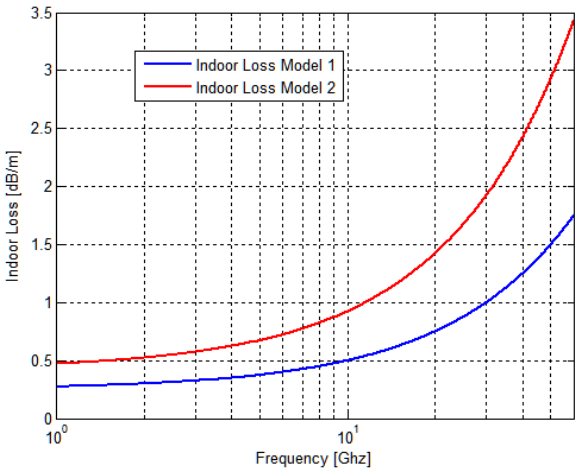

Figure 4. Indoor loss models as a function of frequency.

2.4. Body Loss as Function of Frequency

In reference [10], the frequency dependency of the body loss is modeled as given in (9).

$$L_{\text{Body,dB}} = \frac{\text{Frequency}_{\text{GHz}}}{60} + 3, \quad (9)$$

Equation (9) shows that frequency has a negligible impact on a considered body loss model at 10 GHz or lower frequencies, as traditionally the body loss is assumed to be 3 dB. However, equation (9) gives additional 0.5 dB and 1 dB body loss at 30 GHz and 60 GHz, respectively.

2.5. Angular Wall Loss Model Based on a Single Three-dimensional Incidence Angle

In addition to the building penetration loss and indoor wall loss, there exists an angular wall loss. An angular wall loss model presented at [2, 4] is used to include the angular loss that can be experienced at the building's exterior wall intercept point. The angular wall loss model is given by (10),

$$L_{\text{angular,dB}} = 20 * [1 - \text{Cos}(\theta_i)]^2, \quad (10)$$

where θ_i is the single three-dimensional incidence angle.

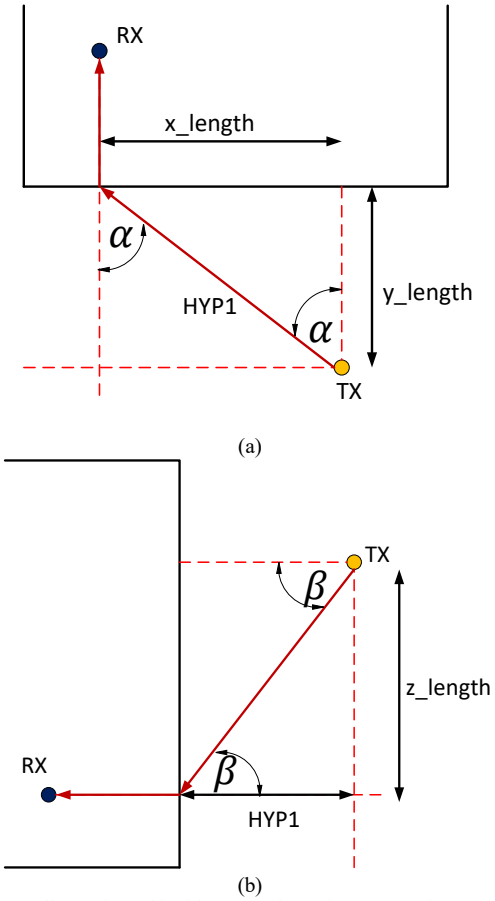

Figure 5. Illustration of incidence angles at intercept point on wall in, a) Azimuth (horizontal) plane, and b) Elevation (vertical plane).

To understand the geometry and the computation of θ_i, consider an example scenario in an azimuth plane (top view) as shown in Figure 5(a). The receiver point is located inside the

building and the transmitter is located in an outdoor environment. The distance between the transmitter and the receiver point along the x-axis and the y-axis is given by x_length and y_length, respectively. HYP1 is the distance between the transmitter and the incidence point on the wall, and is given in (11).

$$\mathrm{HYP1} = \sqrt{\mathrm{x_length}^2 + \mathrm{y_length}^2}, \tag{11}$$

In Figure 5(b), z_length is the difference of height between the transmitter and the receiver point, and HYP2 is the three dimensional distance between the transmitter and the wall intercept point. HYP2 is calculated as follows:

$$\mathrm{HYP2} = \sqrt{\mathrm{HYP1}^2 + \mathrm{z_length}^2}, \tag{12}$$

The single three-dimensional incidence angle θ_i can be computed as

$$\theta_i = \cos^{-1}\left(\frac{\mathrm{y_length}}{\mathrm{HYP2}}\right), \tag{13}$$

Considering the geometry shown in Figure 5, the equation given in (13) can also be re-written in a simplified form as

$$\mathrm{L_{angular,dB}} = 20 * \left[1 - \frac{\mathrm{y_length}}{\mathrm{HYP2}}\right]^2, \tag{14}$$

2.6. Ray Tracing (RT)

Ray tracing techniques can be used for estimating the received signal level and for the characterization of the radio propagation environment. Finding the multipath components between the transmitter and receiver is the first step towards the computation of the received electric field or power at the receiver point. By using Image Theory (IT) algorithm, all multipaths with the given finite number of reflections and diffractions can theoretically be found between the transmitter and receiver. An Image theory algorithm shows a high level of accuracy and precision. Determination of multipath components by image based ray tracing technique may require large computation time. The complexity and the computational time of the ray tracing algorithm increases with the increase in number of supported reflections and diffractions [11-13]. Reflection losses are determined by reflection coefficients. The reflection coefficient depends upon the polarization and on the material permittivity. For perpendicular and parallel polarization, the reflection coefficients are given in (15) and (16), respectively. β is the angle between the incident ray and the reflected surface, and ε_r is the material permittivity of the reflecting surface.

$$|\Gamma_\perp| = \frac{\mathrm{Sin}(\beta) - \sqrt{\varepsilon_r - \mathrm{Cos}^2(\beta)}}{\mathrm{Sin}(\beta) + \sqrt{\varepsilon_r - \mathrm{Cos}^2(\beta)}} \tag{15}$$

$$|\Gamma_\parallel| = \frac{-\varepsilon_r\,\mathrm{Sin}(\beta) + \sqrt{\varepsilon_r - \mathrm{Cos}^2(\beta)}}{\varepsilon_r\,\mathrm{Sin}(\beta) + \sqrt{\varepsilon_r - \mathrm{Cos}^2(\beta)}} \tag{16}$$

There are several ways for computing the diffraction loss; however a recursive method proposed in [14] is used in this article to compute the diffraction loss.

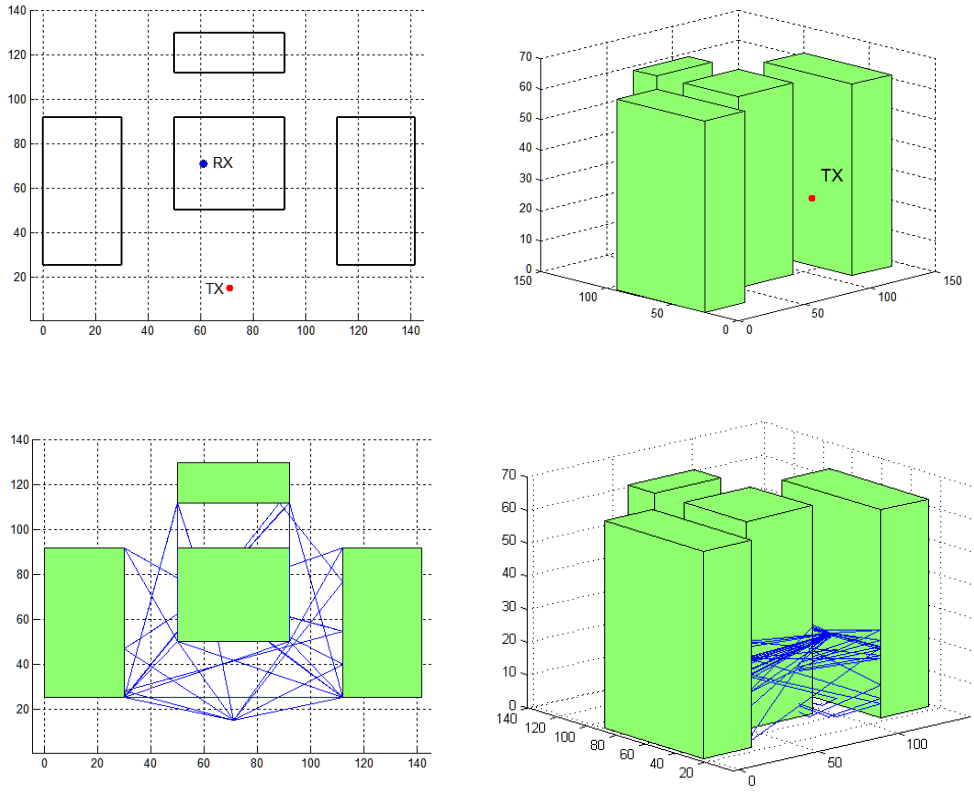

Figure 6. Illustration of ray tracing, (a) Two dimensional view of sample building scenario, (b) Three dimensional view of sample building scenario, (c) Two dimensional view of ray tracing, and (d) Three dimensional view of ray tracing.

Figure 6(a) shows the sample building scenario in two-dimensional environment with transmitter and receiver locations marked with TX and RX, respectively. Figure 6(b) shows the three-dimensional view of a sample scenario with TX height at 31.5 meter. The receiver point is located inside the central building at the height of 10.5 m. Figure 6(c) illustrates the ray tracing in two-dimensional view, whereas Figure 6(d) shows the three-dimensional view of ray tracing. Blue lines show different propagation paths with finite number of reflections and diffractions, and LOS path.

3. Proposed Models

3.1. Angular Wall Loss Model based on Separate Incidence Angle in Azimuth and Elevation Plane

In this article, a novel angular wall loss model based on a separate incidence angle in azimuth and elevation plane is proposed. It is proposed to compute the total angular loss as a sum of the angular loss in an azimuth and elevation plane. Unlike the single three-dimensional angle, in this proposed approach the incidence angle in the horizontal plane and vertical plane should be computed separately. The azimuth angular loss and elevation angular loss is given in (17) and (18), respectively.

$$L_{\text{Azimuth ang,dB}} = 10 * [1 - \text{Cos}(\alpha)]^2, \quad (17)$$

$$L_{\text{Elevation ang,dB}} = 10 * [1 - \text{Cos}(\beta)]^2 \quad (18)$$

The angles α and β used in (17) and (18), respectively, are shown in Figure 5. The angles α and β are the incidence angles computed separately in an azimuth and elevation plane. Now, the total angular loss is given by (19).

$$L_{\text{angular,dB}} = L_{\text{Azimuth ang,dB}} + L_{\text{Elevation ang,dB}} \quad (19)$$

While considering a fixed x_length of 50 m for a geometry shown in Figure 5, the Figure 7 shows the angular loss based on a single three-dimensional incidence angle as a function of y_length and z_length.

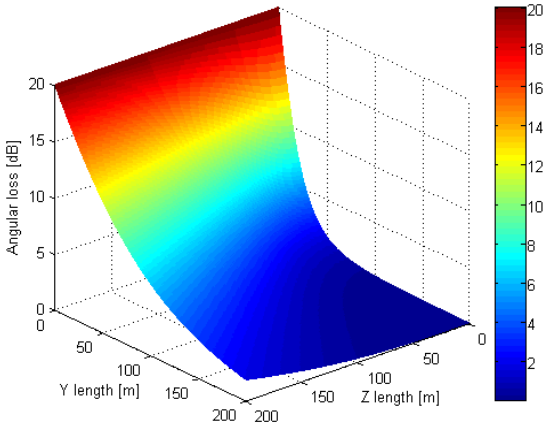

Figure 7. The angular loss based on single 3D incidence angle.

Figure 8 shows the angular loss based on a separate incidence angle in azimuth and elevation plane. The first approach of the angular wall loss model based on a single three-dimensional incidence angle gives higher angular loss at the lower values of y_length and z_length. The angular wall loss model based on a separate incidence angle in azimuth and elevation plane considers the change of angle of an incident ray in both domains separately, and therefore it can be seen in Figure 8 that the angular loss increases with the increase in z_length which is not the case in Figure 7. The impact of change of z_length especially at the lower values of y_length, is minimal on the angular loss based on a single three-dimensional approach, whereas Figure 8 shows that dual-angle model has greater dependency on the change of angle in the elevation plane compared with the single three-dimensional angle approach.

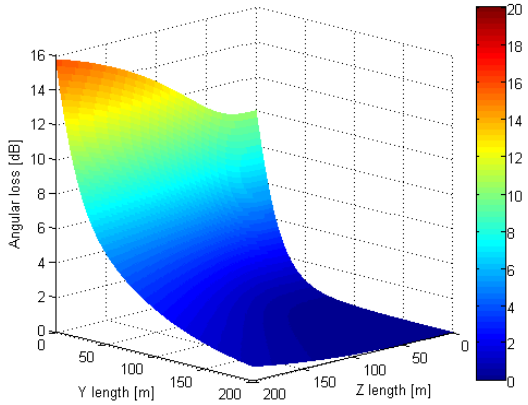

Figure 8. The angular loss based on separate incidence angle in an azimuth (horizontal) and elevation (vertical) plane.

3.2. Extended Building Penetration (EBP) Model

The extended building penetration model is the extension of the general building penetration model. In this model, the additional fifth path known as the "Direct path" is proposed to include as shown in Figure 9. In 3D environment, the direct path is the shortest path between the transmitter and the receiver and it can penetrate through the building wall and through the ceilings of the floors. Figure 10 shows two receiver points RX1 and RX2 located inside the building at Floor 1 and Floor 4, respectively.

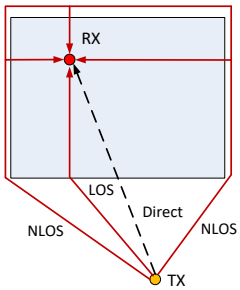

Figure 9. Illustration of direct path along with other paths (top view).

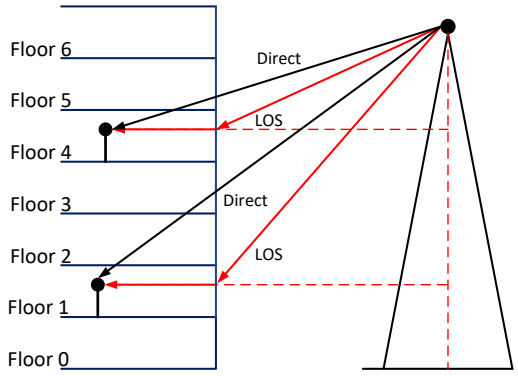
In Figure 10, the LOS paths are shown with the red arrows and the direct paths are shown with the black arrows. It can be seen that the direct ray follows the shortest path between the transmitter and the receiver, and intercepts the building wall at different height compared with that of a receiver height. In Figure 10, it can also be seen that the direct path to RX1 penetrates through the single ceiling, whereas the direct path to RX2 penetrates through the ceilings of two floors. Therefore, the ceiling penetration loss needs to be taken in to account for the direct path.



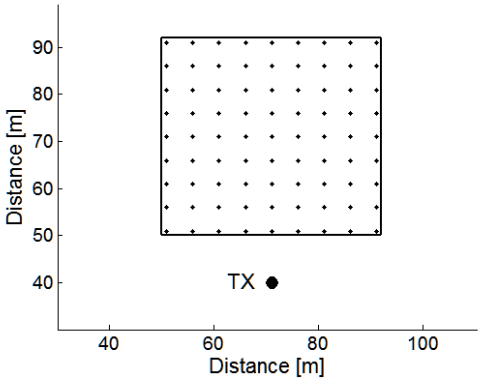


Figure 10. Ray path entering the building while penetrating through the ceiling (side view).

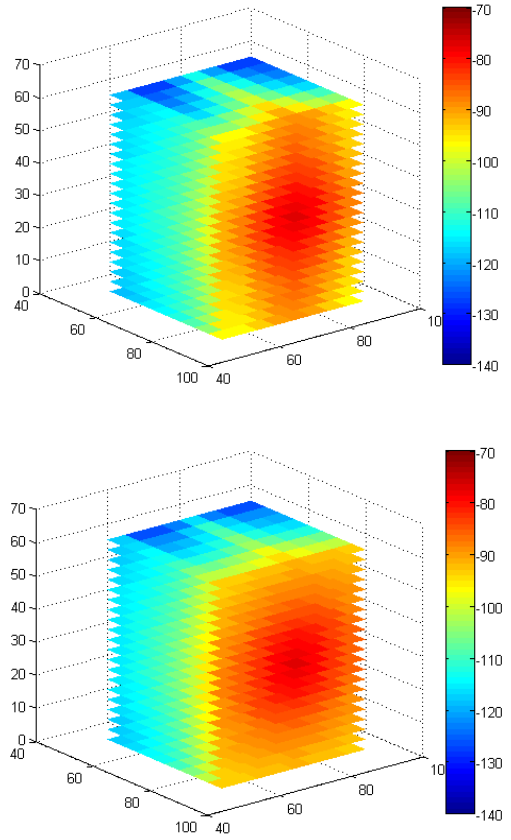
Generally, the ceilings are made up of concrete. Therefore, the ceiling penetration loss model is assumed to follow the concrete penetration loss model as given by (20). The given ceiling penetration loss model provides the ceiling penetration loss of 45 dB, 85 dB, and 125 dB at 10 GHz, 30 GHz and 60 GHz, respectively.

$$L_{Ceiling,dB} = 4 * Frequency_{GHz} + 5, \quad (20)$$

4. Simulation Environment and Simulation Results

For the first and second part of research work, a single twenty-one stories building with an average floor height of 3 m is considered for simulation as shown in Figure 11. An outdoor base station is located at a distance of 10 m away from the building as shown in Figure 11.



(a)

Figure 11. Two-dimensional map of a single building scenario with transmitter 10 m away from the building.

The transmission power and the height of the base station antenna are 33 dBm and 31.5 m, respectively. The simulations are performed at the frequency of 10 GHz. The indoor location points are placed on each floor with the separation of 5 m among them. An old building type was assumed with indoor wall loss model 1.

In the first part of this research work, the impact of angular wall loss models is analyzed. In case of an angular wall loss model based on a single three-dimensional incidence angle, the incidence angle θ_i was set to 60° for the NLOS paths. Similarly, in case of an angular wall loss model based on a separate incidence angle in azimuth and elevation plane, the incidence angle in an azimuth plane 'α' and the incidence angle in an elevation plane 'β' were also set to 60° for NLOS paths. Therefore, both models give similar results for NLOS paths.

(b)

Figure 12. Path gain, a) Angular wall loss model based on single three-dimensional incidence angle, and (b) Angular wall loss model based on separate incidence angle in azimuth and elevation.

Figure 12 shows the heat map of a path gain achieved with two angular wall loss models. The difference between the two angular wall loss models is evident and visible. In Figure 12(b) as we move away from the centre point of the building wall, the path gain starts to fade (deteriorate) in a perfect circular pattern. However, in Figure 12(a) the change of the path gain with the change in an azimuth and elevation angle is not in a perfectly circular way.

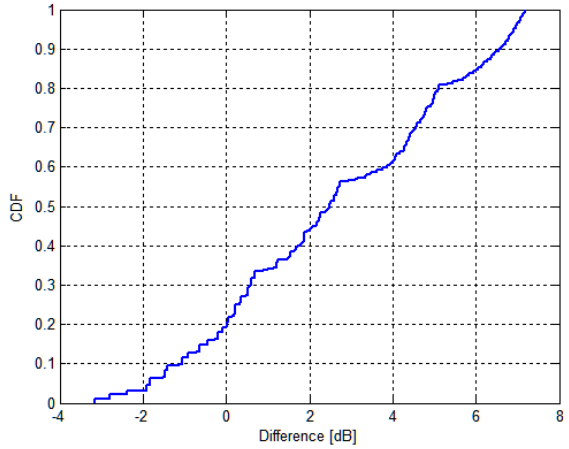


Figure 13. Difference of angular wall loss models.

The difference between the two angular wall loss models is computed by subtracting the received signal power at each point using angular loss model based on separate incidence angle in azimuth and elevation plane from the received signal power calculated using angular wall loss model based on a single three-dimensional incidence angle. The difference was computed assuming only LOS path. The NLOS paths were neglected for calculating the difference, as both models show similar results for NLOS paths. Figure 13 shows the CDF plot of difference between the two angular wall loss models. It can be seen in Fig. 10 that the difference between the two angular wall loss models has values up to 7 dB. The CDF curve with the large number of positive values shows that the angular wall loss model based on a single three-dimensional angle provides aggressive angular loss compared with the dual-angle based angular loss model.

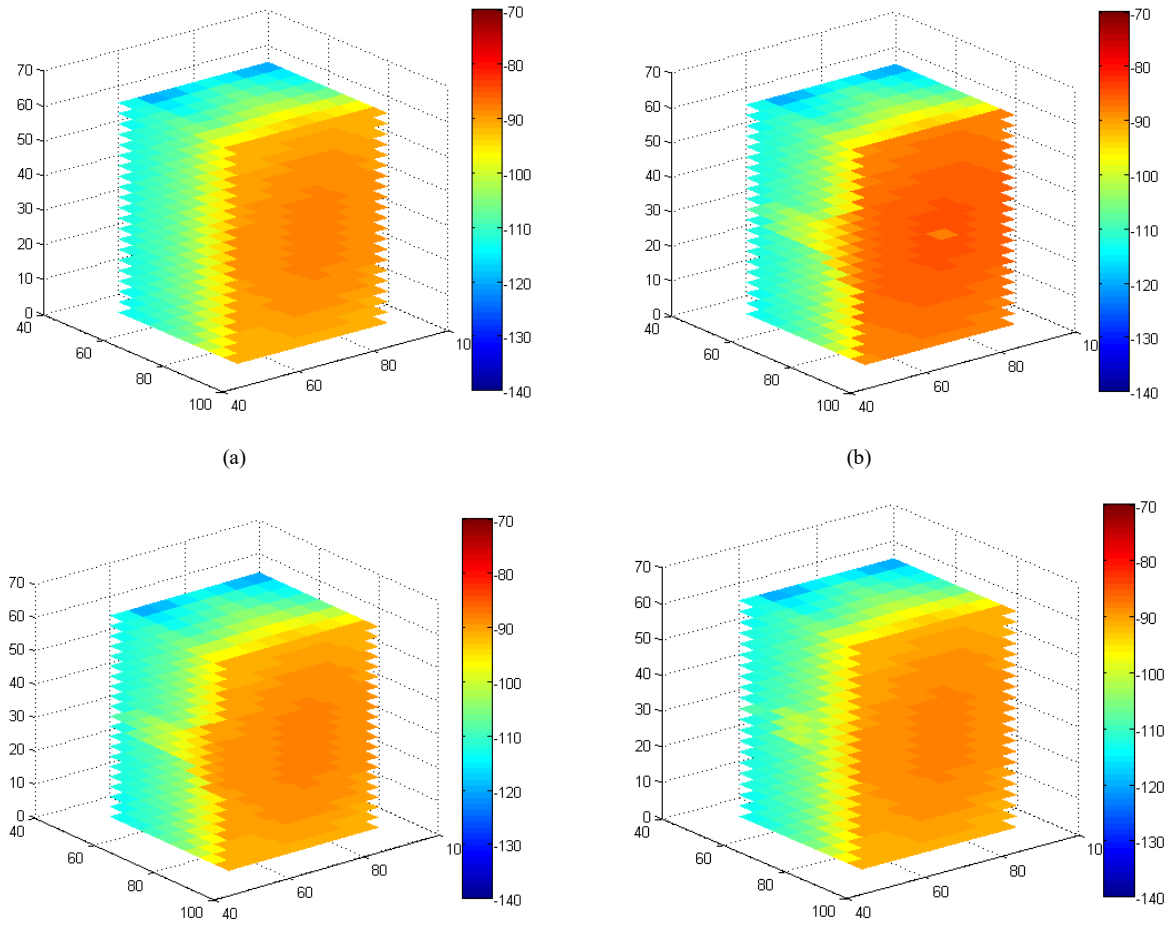

Figure 14. Path gain at 10 GHz, a) GBP model, (b) EBP model without any filter, (c) EBP model with 3 dB filter, and (d) EBP model with 7 dB filter.

In the second part of this research work, the impact of the direct path in the extended building penetration model is analyzed, and the performance of the general building penetration model is compared with the extended building penetration model. The angular wall loss model based on a separate incidence angle in horizontal and vertical plane is assumed, and the separation between the building wall and transmitter is set to 35 m.

Figure 14 shows a heat map of path gain for different cases. Figure 14(a) shows a path gain for GBP model, and while going from front to the back of the building an almost similar path gain is achieved on all the floors of the building. In Figure 14(b), a direct path is included. Now, due to an additional path a higher path gain is obtained. It is interesting to see that an additional direct path improves the received signal level of the users located on the floors which are close to the height of the outdoor transmitter

It can be seen in Figure 14(b) that due to higher ceiling penetration loss at higher frequency, the impact of a direct path diminishes as the difference between the outdoor antenna height and the user height increases. However, the impact of a direct path is clearly evident to the users located deep inside the building at the same floor height as an outdoor antenna, or on one floor above and below. On the other hand, it can also be observed that in Figure 14(b) the path gain is overestimated at the front face of a building, as the “LOS path” and the “Direct path” are almost identical, and they are both included in the modeling. Therefore, a filtering threshold of 3 dB is used in Figure 14(c) to filter out the direct path if the difference between the LOS path and the direct path is less than or equal to 3 dB. An impact of simple 3 dB filter can be seen in Figure 14(c) as the front face of a building is showing now almost similar results as in Figure 14(a). Similarly, a filtering threshold of 7 dB was used in Figure 14(d). The direct path has quite significant impact on the floors close to the outdoor antenna

height even with 3 dB filtering threshold. Therefore, it will improve the model of outdoor to indoor propagation by including a direct path along with the certain filtering threshold, as we have used in this study.

For ray tracing simulations in order to acquire reflected and diffracted multipaths a multiple building scenario is considered as shown in Figure 15.

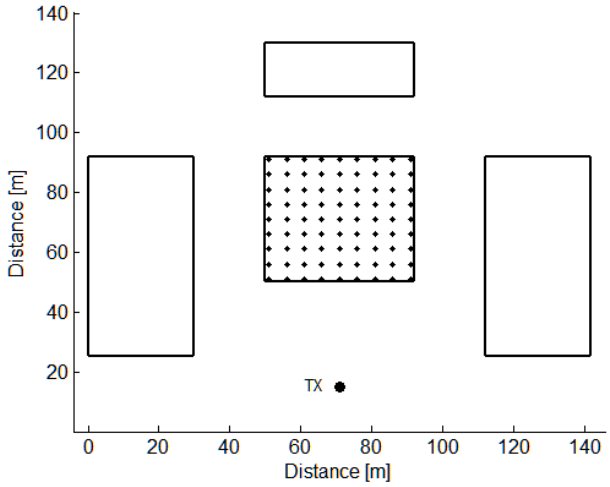

Figure 15. Two-dimensional map of a multiple building scenario with transmitter 35 m away from the building.

In this scenario, a single twenty stories building surrounded by four other buildings of the same height are considered. However, the focus area is the central building, and therefore indoor location test points are distributed in the central building only. An outdoor base station is located at a distance of 35 m away from the central building as in the case of a single building case.

In the third part of this research work, two different ray tracing approaches are considered for the indoor users:

Ray tracing type 1 (RT type 1): In this case, an Image Theory (IT) based ray tracing technique is used to find the propagation paths between the outdoor transmitter and the indoor receiver point. A smooth building surface is assumed, which acts as a perfect reflecting surface. For the transmitter and the receiver points at different heights, the incidence ray path does not intercept the building wall at receiver height. Therefore, for the paths which pass through the ceiling of a floor as shown in Figure 10, the ceiling penetration loss model is used to include the ceiling penetration loss.

Ray tracing type 2 (RT type 2): It is the modified approach of ray tracing type 1. In this case, the propagation paths between the transmitter and receiver in an azimuth plane are found by using the image theory. However, in an elevation plane for the transmitter and receiver at different heights the incidence ray path "always" intercepts the building wall at receiver height. It means that the ray path would never penetrate through the ceiling of a floor. Therefore, the ceiling penetration loss model is not used in this case.

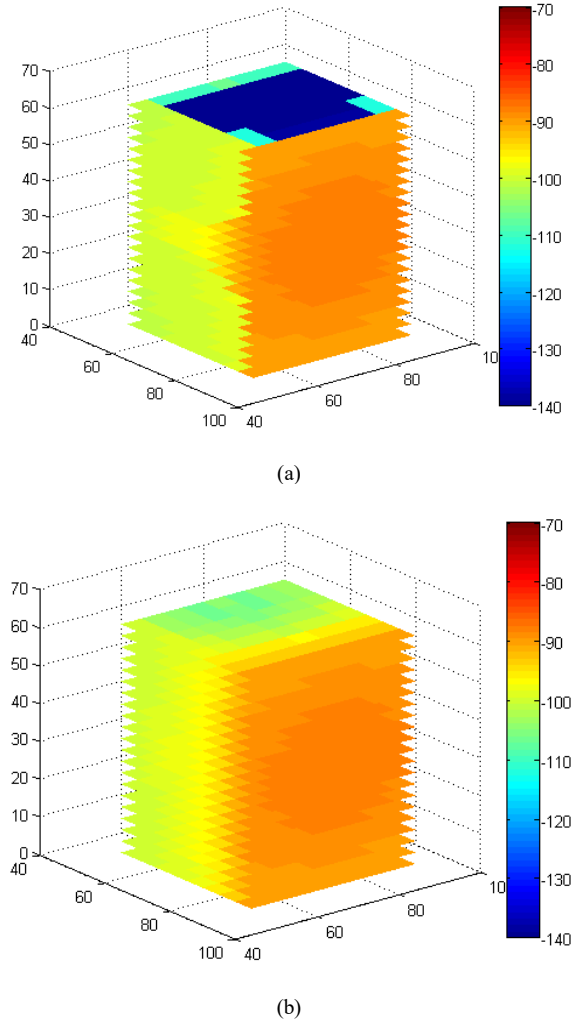

Figure 16. Path gain at 10 GHz, a) Ray tracing type 1, (b) Ray tracing type 2.

Figure 16 shows a path gain map for different cases. It is interesting to see the results obtained by ray tracing type 1. In Figure 16(a), the acquired results from ray tracing type 1 for the indoor users located 6 m or more deep inside the building are quite pessimistic in comparison with the results obtained with ray tracing type 1. As explained earlier, that in case of ray tracing type 1 approach, the ray path entering the building intercepts the building wall at different height compared with that of a receiver height. For the users located deep inside the building the most of the ray paths reach at the receiver point after penetrating through a single or through the multiple ceilings of the floor. Due to high ceiling penetration loss, the signal power attenuates significantly after passing through the ceilings.

Therefore, the ray tracing type 1 is found not suitable for the indoor users located far away from the exterior wall of the building. However, the results obtained with ray tracing type 2 seem more optimistic and realistic in comparison with the ray tracing type 1. It is critical here to mention that in ray tracing type 2, the incident ray always intercepts the building wall at the same height as that of a receiver height, and therefore the ceiling penetration loss is ignored in ray tracing type 2.

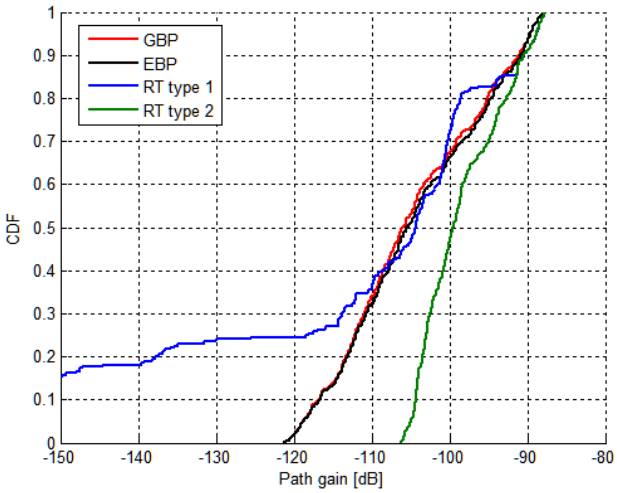

Figure 17. CDF plot of path gain for different propagation models at 10 GHz.

Figure 17 shows the CDF plot of path gain for different considered cases. For an extended building penetration model, a 3 dB filtering threshold was used. For the top nearly 14.5 % of the samples, the ray tracing type 1 shows an almost identical result as ray tracing type 2. Those 14.5 % of the samples mainly represent the receiver locations from the front row and few from the second row i.e. receiver points at the front face of the building. Again, for the same top 14.5 % of the samples the general building penetration model provides an almost similar result like that of an extended building penetration model and other ray tracing approaches. Then, the path gain starts to drop significantly for the receiver points located deep inside the building. A large portion of samples have the extremely pessimistic values of the path gain with a ray tracing type 1. For the considered cases, the ray tracing type 2 was found the most optimistic approach. For ray tracing simulations, all the possible ray paths with two reflections and two diffractions were considered.

Therefore, there is a large number of considered ray paths in case of ray tracing compared with the GBP and EBP. The results provided in Figure 14 and Figure 16 reveal that ray tracing type 2 is a better and realistic approach compared with ray tracing type 1 for estimating the received signal level, especially for the indoor users located deep inside the building.

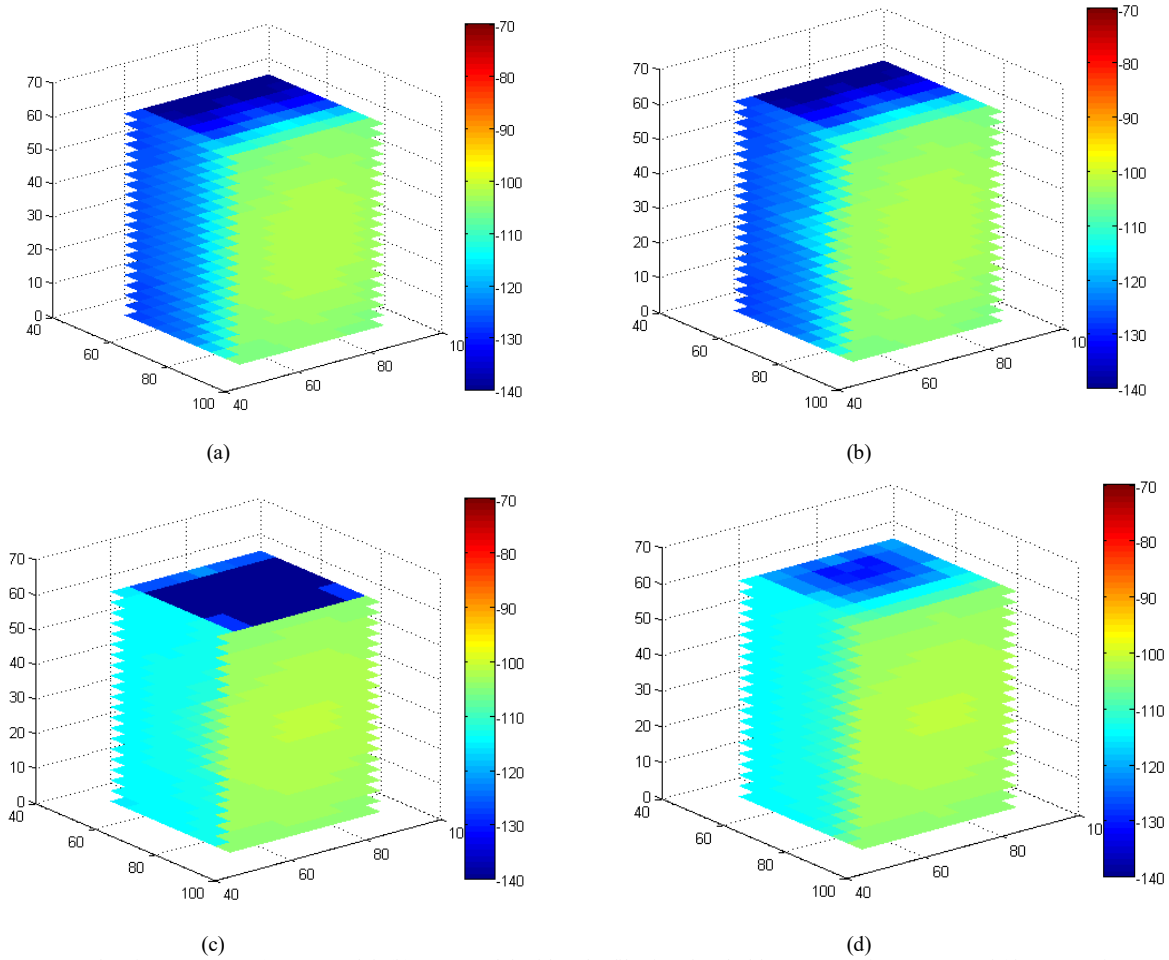

Figure 18. Path gain at 30 GHz, a) GBP model, (b) EBP model with 3 dB filtering threshold, c) Ray tracing type 1, and (d) Ray tracing type 2.

Figure 18 shows a heat map of path gain for different models assuming old building type at 30 GHz and indoor wall loss model 1. Path gain is the function of frequency and a significant impact of frequency of operation can be seen between the results presented in Figure 16 (at 10 GHz) and Figure 18 (at 30 GHz). In Figure 18(b), the path gain for EBP model with 3 dB filtering threshold is shown, and the impact of the direct path is even

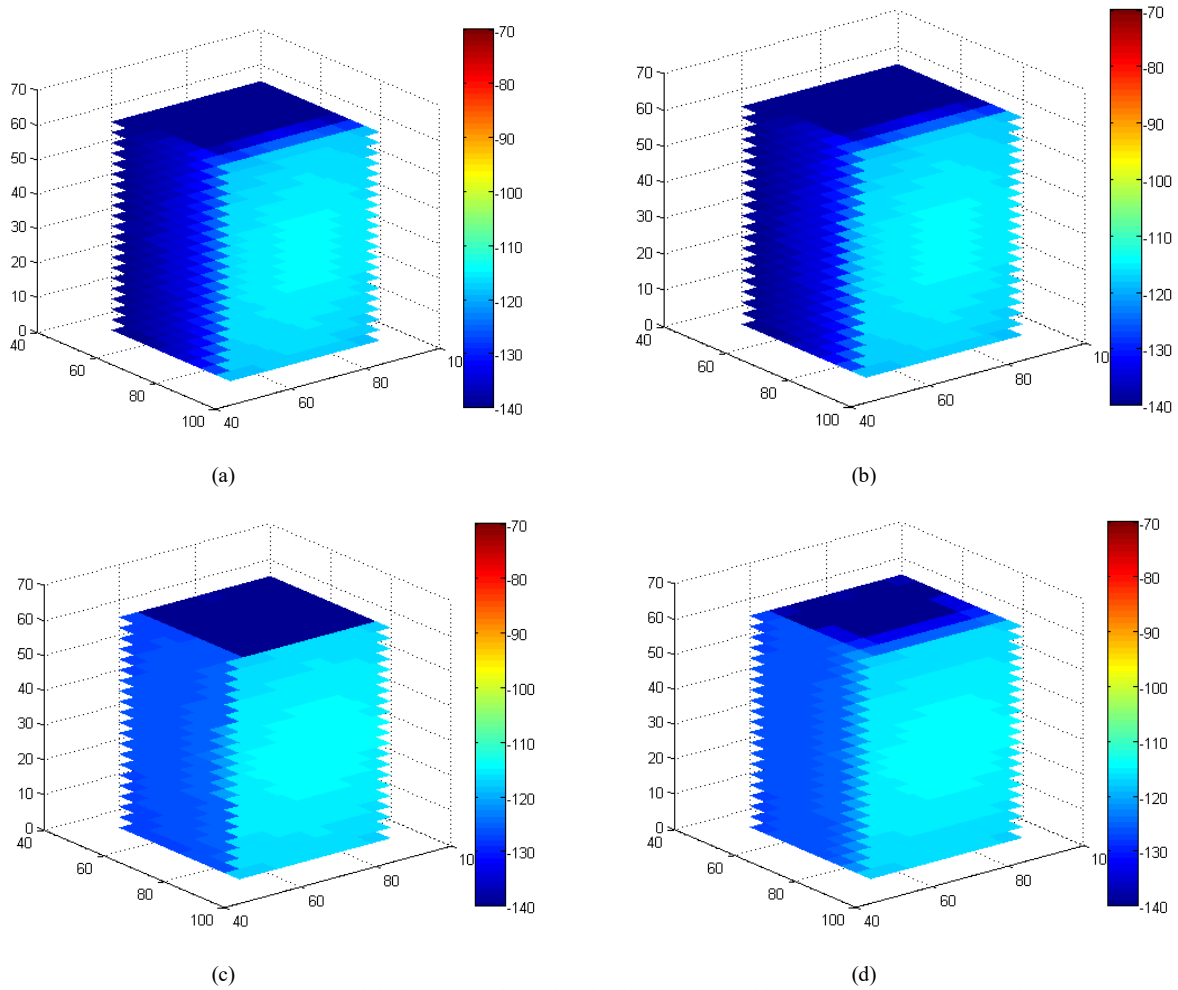

Figure 19. Path gain at 60 GHz, a) GBP model, (b) EBP model with 3 dB filtering threshold, c) Ray tracing type 1, and (d) Ray tracing type 2.

visible at 30 GHz frequency for the center floors. The impact of a direct path is not prominent in overall results. Again, the ray tracing type 1 is found as an inadequate approach for estimating the path gain, and it provides the extremely low values of path gain at 30 GHz. However, it is interesting to see the results acquired with ray tracing type 2. It is fascinating to compare the results of two ray tracing approaches, as ray tracing type 1 clearly shows lack of indoor coverage with the outdoor base station except the front wall of the building. On the other hand, the simulation results of ray tracing type 2 show that the low indoor coverage can be provided with the outdoor base station. Similarly, GBP and EBP models show lack of indoor coverage at 30 GHz. These results leave an open discussion that the results acquired from the ray tracing type 2 are more realistic or the results acquired with ray tracing type 1 are more realistic. As we don't have any measured reference data therefore it is hard to make a clear statement.

Figure 19 shows a heat map of path gain for old building type at 60 GHz assuming indoor wall loss model 1. At 60 GHz, all of the considered propagation models show that due to high propagation and penetration losses the indoor coverage cannot be provided with the outdoor base station. Higher antenna gain at higher frequencies can compensate the high penetration and propagation losses. Otherwise, an indoor coverage with the outdoor base station at 60 GHz can be provided if new buildings are constructed with the material having better signal penetration properties.

5. Conclusion

In this paper, the outdoor to indoor propagation at higher frequency is studied. Furthermore, a novel angular wall loss model based on a separate incidence angle in azimuth and elevation plane is proposed. In the proposed angular wall loss model, the total angular loss is the sum of loss due to the change of angle of an incident ray in both azimuth and elevation plane. The simulation results show that the angular wall loss model based on a single three-dimensional angle provides aggressive angular loss compared with the proposed dual-angle angular wall loss model. In the second part of this study, an Extended Building Penetration (EBP) model is proposed, and the performance of EBP model is compared with the COST231 building penetration model. In an extended building penetration model a fifth path known as a "Direct path" is added. Through the simulation results, it is shown that the direct path has a significant impact on the indoor receiver points located close to the height of the transmitter. Therefore, the extended building penetration model can be considered as a better

approach for modelling the outdoor to indoor propagation at higher frequencies.

The ray tracing is a promising and precise technique for estimating the received signal level and for channel modeling. In this study, a performance comparison between the general building penetration model and the ray tracing model is done. It was found that the traditional ray tracing technique provides good approximation for the users located close to the wall of the building. However, the traditional ray tracing approach was found in-efficient for modeling the outdoor to indoor propagation especially for the indoor users located far away from the exterior wall of the building. A new approach of ray tracing is also proposed in this study. The simulation results show that ray tracing performance is significantly improved by the proposed recommendation. With the proposed ray tracing approach the results of a path gain were fairly better compared with the other models. Later, the performance of different propagation models was compared at 10 GHz, 30 GHz and 60 GHz frequency of operation. It was found that for the considered simulation scenario the adequate coverage can be provided for the indoor users with the outdoor base station at 10 GHz. However at 30 GHz, the general penetration model clearly showed the lack of indoor coverage. Whereas the proposed ray tracing type 2 approach showed a fair indoor coverage at 30 GHz. The propagation and building penetration losses were quite high at 60 GHz; therefore the simulation results show no indoor service at 60 GHz.

Spatial Telemetry

ABSTRACT

This paper deals with the design of a new reconfigurable beam antenna used to improve the efficiency of spatial telemetry links on Nano-Satellite. This agile beam antenna is not built on the well-known array concept AESA (Agile Electronically Scanned Array) but using a new one called ARMA (Agile Matrix Radiating Antenna); MARPEM in French. In this paper there is the design of the circularly polarized matrix antenna, the generation of two beam forming modes, the design of the distribution circuit and the polarization circuits.

1. Introduction

The needs in high data rate of future Nano-satellite missions are incompatible with telemetry applications in VHF or S bands unlike the X-band. Moreover, most of applications require earth wide angle coverage in addition to a long time visibility, implying a theoretical isoflux radiation pattern particularly for LEO satellites. But this theoretical limited gain radiation pattern in nadir direction reduces the global efficiency of the PDTM (Payload Data Telemetry). A solution to maximize the PDTM is to use an agile beam antenna to increase the data rate efficiency by introducing several kinds of radiation patterns depending on the satellite position.

These links are produced by beams of various shapes delivered by an agile antenna working on several radiation modes. To limit the complexity of the architecture and to be accommodated on a Nano-satellite, these requirements lead to a dual mode circularly polarized antenna: one mode characterized by isoflux earth coverage and another one introducing high gain directive beam around the axial direction (nadir). To realize this PDTM link in X-band, a very compact antenna using dual mode radiation pattern has been developed with the following requirements:

- [8 – 8.4]GHz.
- To be accommodated on a 100mm x 100mm surface.
- Gain > 2dB for θ [-60°: 60°] and φ [-180°:180°].
- Axial Ratio < 4dB for θ [-60°:60°] and φ [-180°:180°].

The beam forming procedure and the switching process between two or more working modes need to use agile beam antennas. There are two kinds of electronically agile beam antennas; the first one is the well-known AESA (Agile Electronically Scanned Array) technique and the second, a new one, called ARMA (Agile Radiating Matrix Antenna) which introduces some advantages for such applications [1], [2] as larger angles beam scanning, higher power balance, side lobes minimization [3]-[6], lower couplings between adjacent elements and high gain solutions [7], [2] with smaller number of elements and less feeding network complexity.

In the context of this paper, the new ARMA concept is defined and the circularly polarized pixel with the polarization circuits design is presented. Then the ARMA matrix with circular polarization is used to generate two beams, the wide Isoflux and the high gain axial beams. Beam forming law is optimized to solve

the problem of Isoflux dissymmetry in the different azimuthal planes,

2. The ARMA Concept

ARMA principle introduces new sampling procedure for the radiating surface of the antenna that is sampled or pixelated using the pixel. Brief comparison of AESA and ARMA principles is found in [3]. ARMA approach uses jointed pixels as shown in Figure 1 to sample the radiating surfaces instead a lot of punctual sources for the array technique [4]. Each pixel generates a uniform radiating surface that never overlaps outside its dimensions [3].

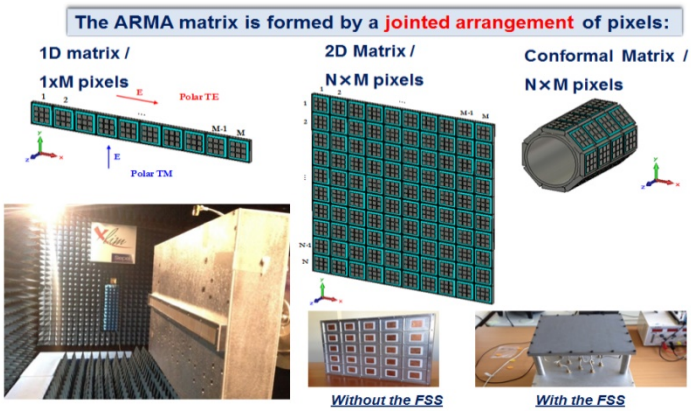

Figure 1. ARMA antennas architectures.

The most important point in ARMA approach is to be able to design a pixel which can generate a uniform *EM* field on its surface. This technique, deduced from the knowledge of EBG antennas properties, was extensively developed and validated in many papers [8]-[11] for linear polarization; it is the key point of the ARMA solution. Example of a pixel with one feeding probe is shown in Figure 2 with the corresponding radiating surface on the top.

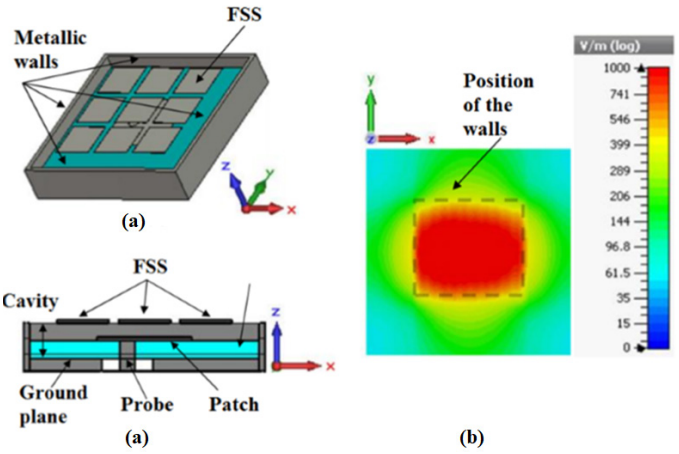

Figure 2. Pixel design: (a) FSS on top, patch inside the cavity and metallic walls, (b) the corresponding radiating surface.

For low profile antennas, a planar radiating surface *S* is built with pixels with a square radiating surfaces as shown in Figure 3.

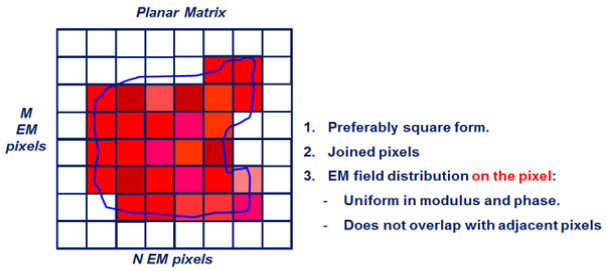

Figure 3. Radiating surface sampled by jointed square pixels.

3. Circularly Polarized Pixel Design

3.1. Pixel Design and Axial Ratio

For circular polarization (two orthogonal linear polarizations), the EBG cavity is usually fed by a patch probe generating a local circularly polarized field in the cavity. A good circular polarization can be obtained by two or four ports feeding circuit, shown in Figure 4. Of course, for a pixel considered alone, the axial ratio is better [12] [13] with the four ports technique (Figure 5 and Figure 6), but with higher manufacturing complexity and price.

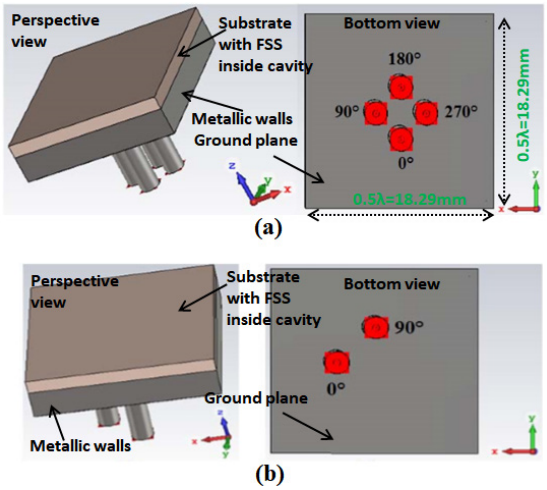

Figure 4. Pixel with two and four feeding ports for circular polarization generation.

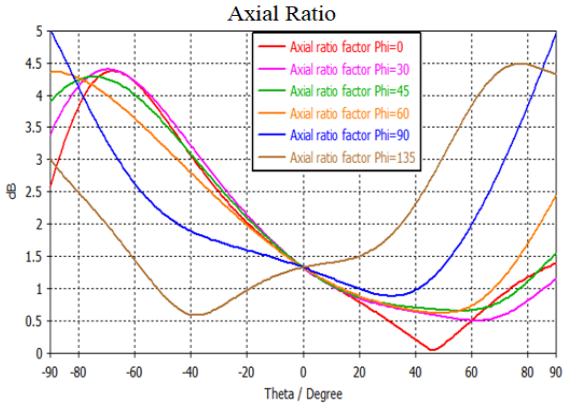

Figure 5. Axial ratio comparison obtained with a 2 ports ideal feeding procedure.

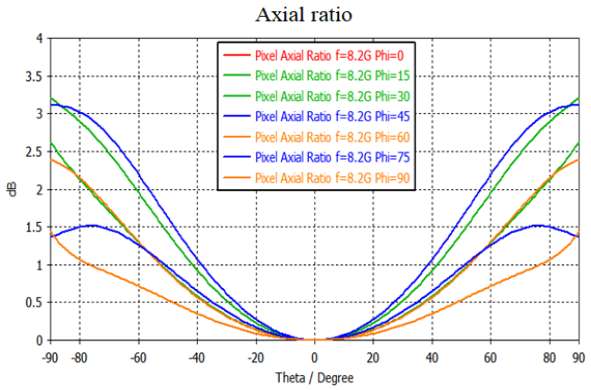

Figure 6. Axial ratio comparison obtained with a 4 ports ideal feeding procedure.

3.2. Polarization Circuits and Area Limitations

The main limitation in the design of the polarization circuit is the small area behind the pixel which is 18.29mmx18.29mm (0.5λx0.5) (Figure 4). This small area must include also the pad to solder the connector for the input power. For that the substrate TMM10i with permittivity 9.8 and thickness 0.381mm was used to print the circuit on it. The results of the axial ratio are not very modified by introducing the circuit to the pixel design: one hybrid coupler for the two ports case and 3 hybrid couplers for the 4 ports case as shown in Figure 7 and Figure 8.

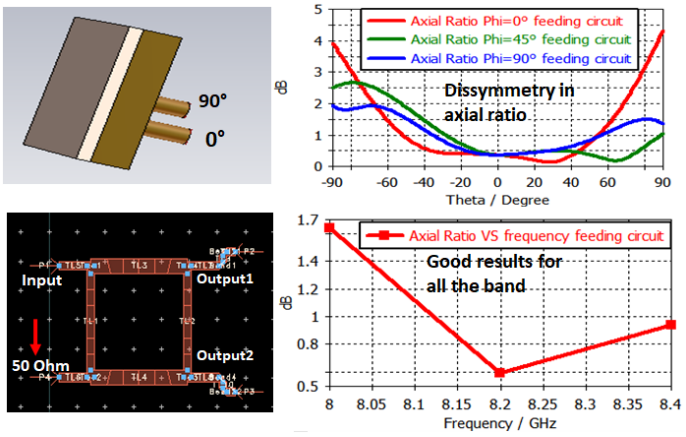

Figure 7. Axial ratios obtained with a one hybrid coupler for the two ports.

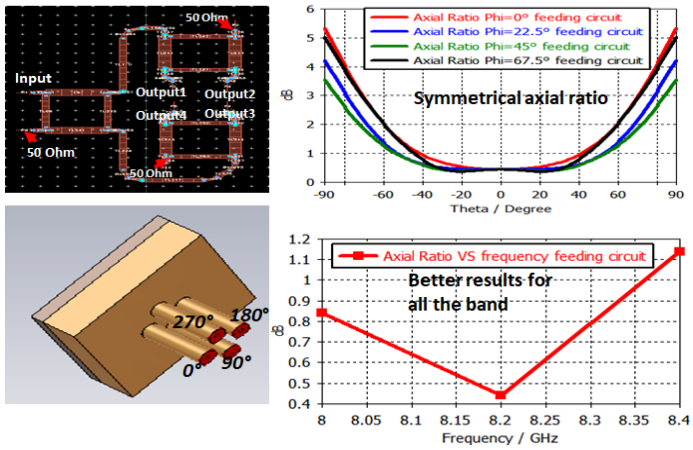

Figure 8. Axial ratios obtained with a d a 3 hybrid couplers for the 4 ports.

4. PDTM Application

4.1. Antenna Design

On this way, a square low profile ARMA antenna was built with 25 pixels where only nine are fed (Figure 9) by the BFN (Beam Forming Network); the other ones, located at the edges of the antenna, are only used to keep a good axial ratio for the whole matrix antenna.

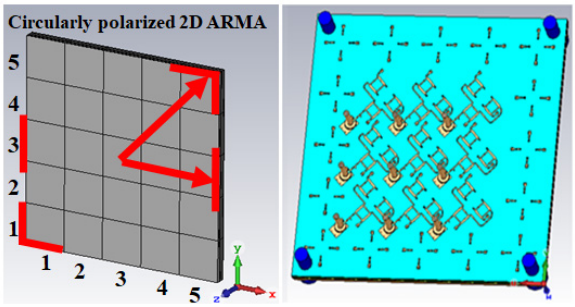

Figure 9. 25 pixels matrix antenna (left) with nine feeding ports and nine circular polarization circuits (Right).

4.2. Isoflux Pattern and Dissymmetry Problem

The isoflux coverage (first mode) is obtained by feeding the pixels with a weighting law deduced from a Sinc (sinus cardinal) function [14] [15]. This approach leads to weighting tables and to the corresponding matrix radiation patterns and axial ratios shown in Figure 10 and Figure 11.

Table of amplitudes $A_{i,j}$

	1	2	3	4	5
1	0	0	0	0	0
2	0	0.03	0.18	0.03	0
3	0	0.18	1	0.18	0
4	0	0.03	0.18	0.03	0
5	0	0	0	0.002	0

Table of $\varphi_{i,j}$

	1	2	3	4	5
1	0	0	0	0	0
2	0	180°	180°	180°	0
3	0	180°	0°	180°	0
4	0	180°	180°	180°	0
5	0	0	0	0	0

Figure 10. Sinc circular feeding law.

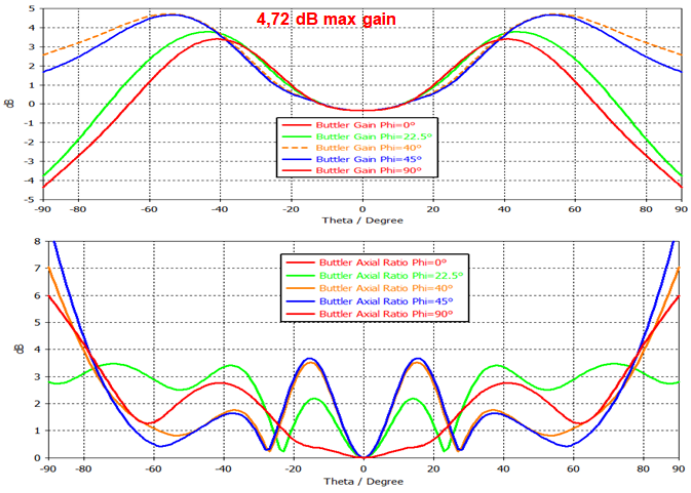

Figure 11. Gain an axial ratio patterns.

The pattern in Figure 11 shows a dissymmetry in the isoflux maximum gain positions (e.g. planes φ=0° and φ=45°); this is due to the non-symmetrical physical structure of the matrix antenna, where the distance from the center to the edges is not the same for all directions (Figure 9).

4.3. Feeding Law Optimization for Symmetrical isoflux

To compensate the dissymmetry resulted from the square matrix structure, the feeding law is optimized to modify the isoflux radiation pattern [15]. The value "A" is the weight applied on each pixel surrounding the central one, "A" is changed as shown in Figure 12, Figure 13 and Figure 14. This procedure, called Sinc-circular symmetrical, will be very useful to match easily the two modes together. It is also important to notice that the part of the following curves located between θ=±20° is not useful in the isoflux mode because for theses directions the matrix is working on the axial mode.

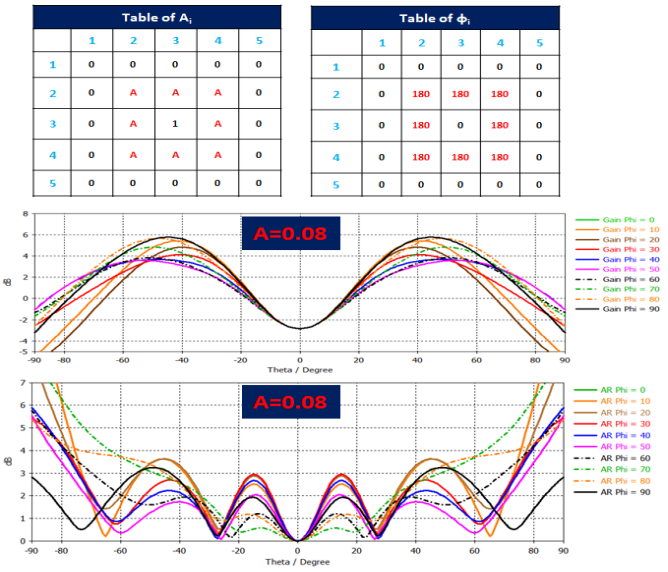

Figure 12. Gain and axial ratio evolution as a function of the elevation angle "θ" for different azimuth planes with A = 0.08.

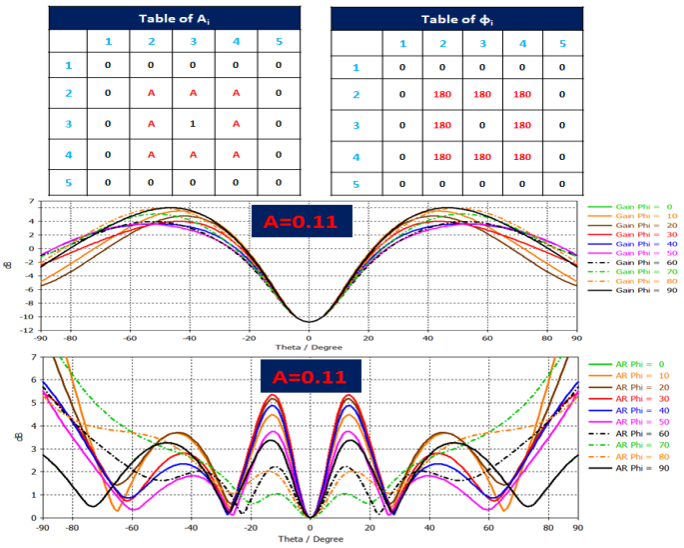

Figure 13. Gain and axial ratio evolution as a function of the elevation angle "θ" for different azimuth planes with A = 0.11.

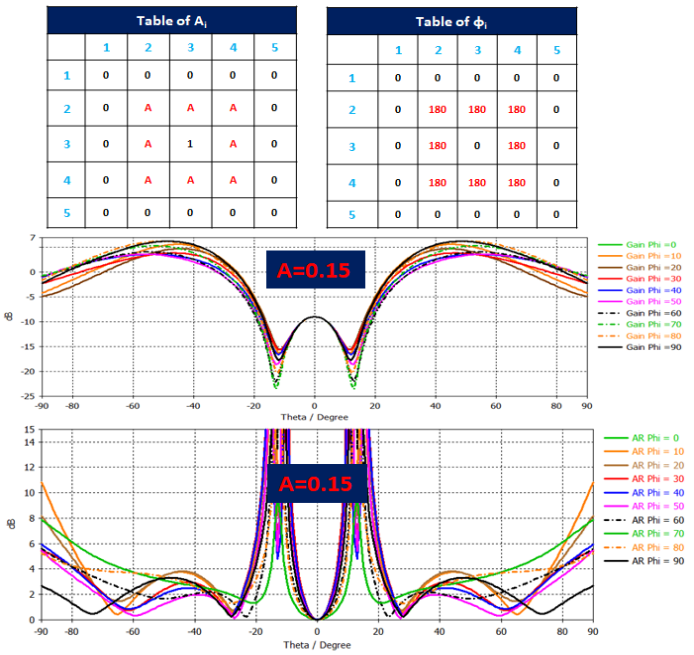

Figure 14. Gain and axial ratio evolution as a function of the elevation angle "θ" for different azimuth planes with A = 0.15.

Then with this symmetrical feeding solution the Isoflux gain pattern is more symmetrical with the position of the maximum gain located in the worst case at θ=±50° for the solution with A=0.15 (Figure 14). The axial ratio in this case is going very high for θ around ±20°, but these directions are not useful in this mode as mentioned above.

5. Directive Beam

The directive beam around the axial direction (second mode) is easy to obtain with the highest gain with all the weights equal to 1 (Figure 15). But, like for an array, it is also possible to optimize the radiation pattern and the axial ratio by modifying theses weights.

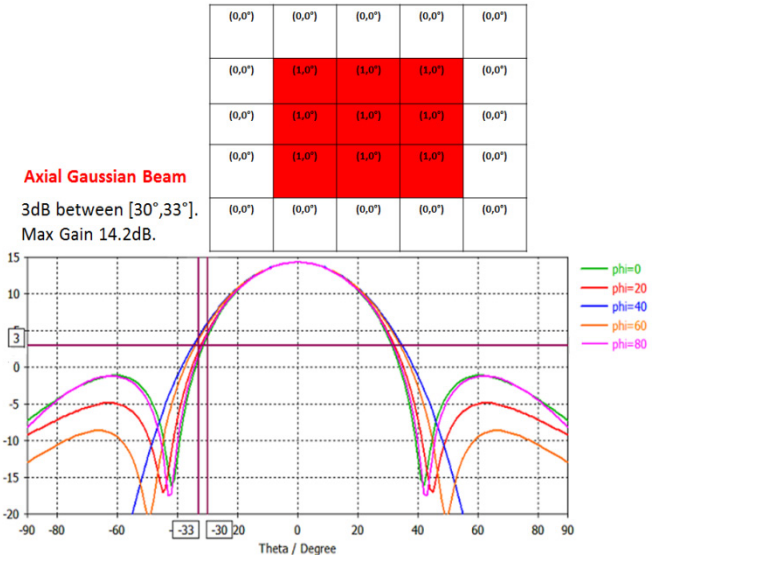

Figure 15. Radiation pattern of the axial mode as a function of the elevation angle θ for different azimuth planes φ.

6. Junction between Two Modes

The BFN (Beam Forming Network) architecture used to switch between the two modes is presented in Figure 16 for a 1D ARMA antenna.

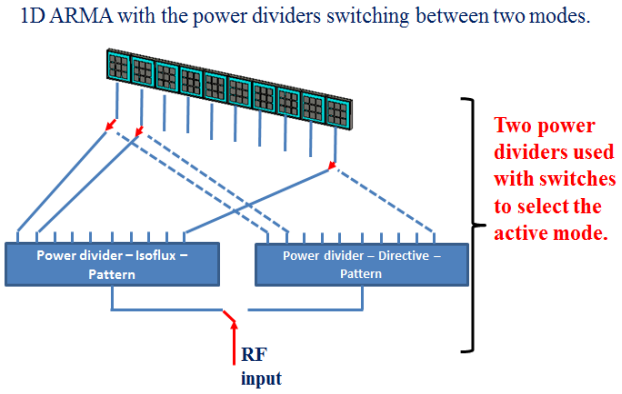

Figure 16. Switching procedure between the two modes.

The switching procedure [16] between the 2 modes can be easily performed for the elevation angle and the gain values expected by the users. For example it can be chosen to keep the gain above 3dB between -60° and +60° as shown in Figure 17.

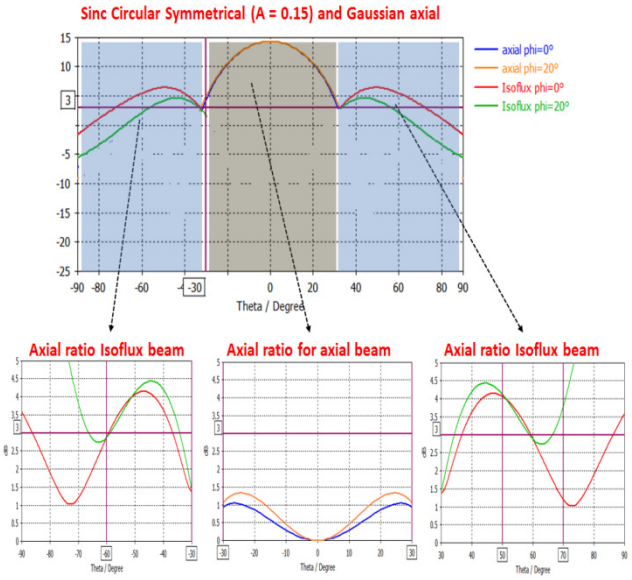

Figure 17. Two modes radiation patterns and axial ratios for the whole agile antenna for φ = 0° and φ = 20° planes.

7. Power Divider Design for Isoflux

The symmetrical feeding law with A=0.15 is considered for the Isoflux beam forming. To achieve this law a power divider was designed with one input and nine outputs as shown in Figure 18. The port labeled 5 is to be connected to the central pixel in the matrix antenna; the other output ports (1, 2, 3, 4, 6, 7, 8 and 9) will be connected to the other pixels around the central one. The return loss at the input of the power divider is shown in Figure 19. Using of the hybrid couplers at the outputs insure good matching (50Ω) when connecting the power divider to the polarization circuits that feed the patches inside the pixels cavities.

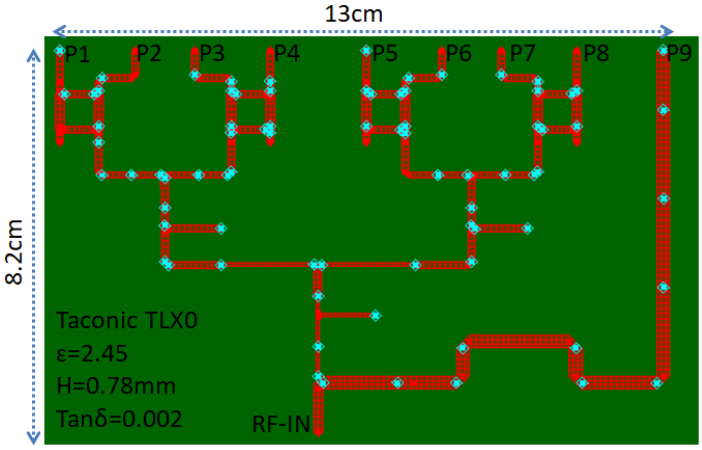

Figure 18. Power divider Momentum design for Isoflux beam forming.

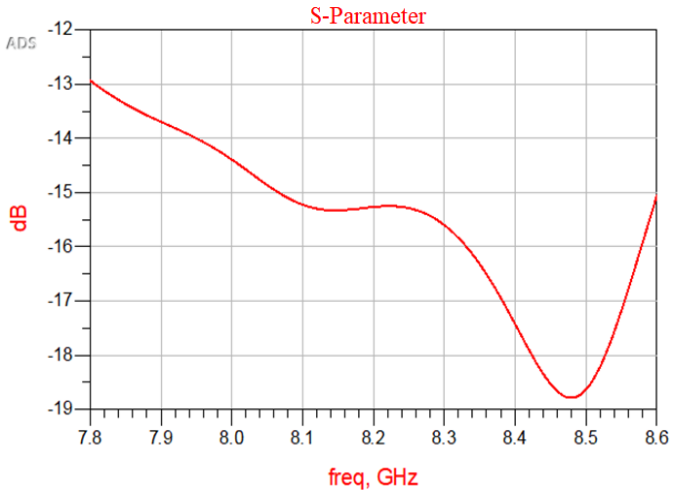

Figure 19. Return loss at the input of the power divider.

The output weights in magnitude and phase at 8.2GHz is presented in the table of Figure 20. These magnitudes are taken normalized with respect to the central port5 and the phases are the phase shift with the phase of port 5.

Port	P1	P2	P3	P4	P5	P6	P7	P8	P9
Magnitude	0.154	0.152	0.157	0.158	1	0.158	0.157	0.152	0.155
Phase	181°	182°	184°	181°	0°	181°	184°	182°	181°

Figure 20. Outputs of the power divider at 8.2GHz.

8. Pattern of the Whole Matrix

Polarization circuits and the power divider results files are taken from Momentum software and connected to the matrix antenna in CST (Figure 21). The realized gain and the axial ratio patterns are shown in Figure 22 at 8.2GHz. The position of the isoflux maximum is attained at approximately at fixed elevation angles and the difference in the gain between the different azimuth planes is 2.9dB.

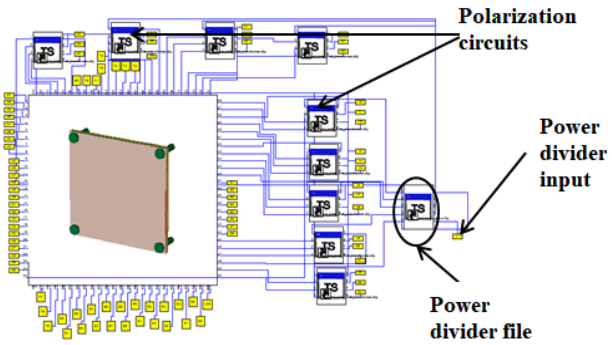

Figure 21. Matrix antenna with the polarization circuits and power divider.

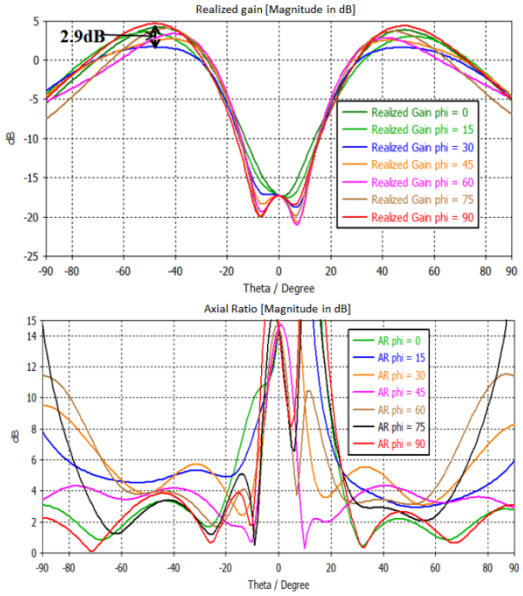

Figure 22. Realized gain and axial ratio patterns at 8.2GHz (whole antenna).

9. Testing the Antenna with the Nano-Satellite Support

The antenna is placed on the top of the Nano-satellite, so to check the effect of the satellite support the antenna was placed on the top of a metallic cube in CST (Figure 23) (cube with 130mm height and 100mm surface). In this case the antenna is tested as the real case for the satellite to be placed on it. Results of the antenna with and without the cube support show no significant modifications in the gain and axial ratio patterns (Figure 24).

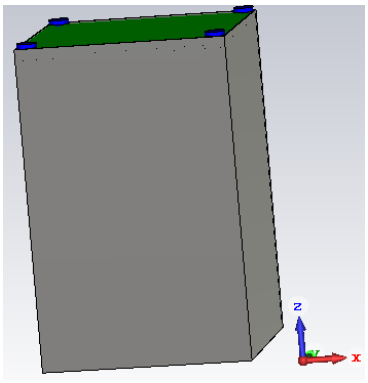

Figure 23. Antenna placed on the cube-sat support.

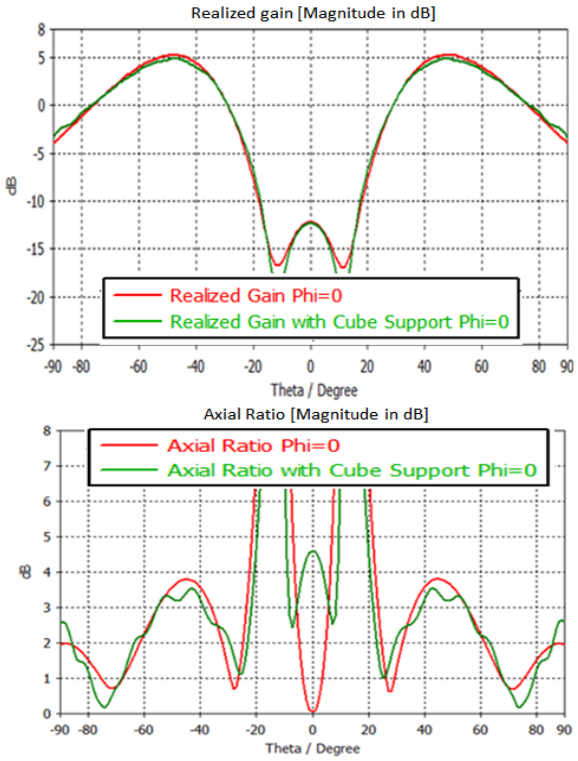

Figure 24. Realized gain and axial ratio patterns with and without cube-sat support.

10. Conclusion

A dual mode agile antenna based on the ARMA principle [1] [2] was presented in this paper. A prototype is under manufacturing and will be tested next month. The pixel with four ports with insures high stability of the axial ratio over wide elevation angles using the polarization circuit build by hybrid couplers. This pixel also insures the uniformity characteristics that are the basis of the new ARMA sampling procedure. The matrix ARMA was used to generate two different beams with and axial ratio for both below 3dB in their interesting regions. Also the antenna is tested on the Nano-satellite support with no problems.

ABSTRACT

The uncertain nonlinear systems can be modeled with fuzzy differential equations (FDEs) and the solutions of these equations are applied to analyze many engineering problems. However, it is very difficult to obtain solutions of FDEs.
In this paper, the solutions of FDEs are approximated by utilizing the fuzzy Sumudu transform (FST) method. Here, the uncertainties are in the sense of Z-numbers. Important theorems are laid down to illustrate the properties of FST. The theoretical analysis and simulation results show that this new technique is effective to estimate the solutions of FDEs.

1. Introduction

This paper is an extension of work originally presented in [1]. In many physical and dynamical processes, mathematical modeling leads to the deterministic initial and boundary value problems. In practical the boundary values may be different from crisp and displays in the form of unknown parameters [2]. When the parameters or the states of the differential equations are uncertain, they can be modeled with FDE. In recent days, many methods have used FDE for modeling and control of uncertain nonlinear systems [3-5]. The basic idea of the fuzzy derivative was first introduced in [Chang]. Then it is extended in [6]. The first-order fuzzy initial value problem, as well as fuzzy partial differential equation, have been studied in [7]. By generalizing the differentiability, [6] gave an analytical solution. The Lipschitz condition, as well as the theorem for existence and uniqueness of the solution related to FDEs, are discussed in [10-12]. In [13], the analytical solutions of second order FDE are obtained. The analytical solutions of third order linear FDE are found in [14]. By the interval-valued method, [15] examined the basic solutions of nonlinear FDEs with generalized differentiability.

A novel technique in order to solve FDEs is laid down based on the Sumudu transform. Sumudu transform along with broad applications has been utilized in the area of system engineering and applied physics [16-18]. In [19], some simple and deeper fundamental theorems, as well as properties of the Sumudu Transform, were generalized. In [20], Sumudu transform is applied to the system of differential equations. In [21], Sumudu transform is used in order to find the solution of the fuzzy partial differential equation. In [22], Sumudu transform has been used to solve fractional differential equations.

In this paper, we use FST to approximate the Z-number solutions of the FDEs. The FST reduces the FDE to an algebraic equation. A very important property of the FST is that it can solve the equation without resorting to a new frequency domain. The procedure of switching FDEs to an algebraic equation is cited in [10] and is stated as an operational calculus. We extend our previous work [1] by generating more theorems for describing the properties of FST and displaying the uncertainties with Z-numbers. The Z-number is a new concept that is subjected to a higher potential to demonstrate the information of the human being as well as to utilize in information processing [23]. Z-numbers can be regarded as to answer questions and carry out the decisions [24]. There exist few structure based on the theoretical concept of Z-numbers [25]. [26] gave an inception, which results in the extension of the Z-numbers. [27] generated a theorem to convert the Z-numbers to the usual fuzzy sets.

In this paper, initially, some preliminary definitions along with properties related to FST are demonstrated. After that, solving FDEs by using the methodology of FST has been discussed. At the end, two examples along with comparisons are utilized in order to demonstrate the effectiveness of our proposed method.

2. Preliminaries

Prior to the introduction of the FST, some concepts related to the fuzzy variables and Z-numbers are laid down in this section [28, 29].

Definition 1: A fuzzy number B is a function of $B \in E : R \to [0,1]$, in such a manner, 1) B is normal, (there exists $a_0 \in R$ in such a manner $B(a_0) = 1$; 2) B is convex, $B(\gamma a + (1-\gamma)c) \geq \min\{B(a), B(c)\}$, $\forall a, c \in R, \forall \gamma \in [0,1]$; 3) B is upper semi-continuous on R, i.e., $B(a) \leq B(a_0) + \varepsilon$, $\forall a \in N(a_0)$, $\forall a_0 \in R$, $\forall \varepsilon > 0$, $N(a_0)$ is a neighborhood; 4) The set $B^+ = \{a \in R, B(a) > 0\}$ is compact.

Definition 2: The r-level of the fuzzy number B is defined as follows

$$[B]^r = \{a \in R : B(a) \geq r\} \tag{1}$$

where $0 < r \leq 1$, $B \in E$.

Definition 3: Let $B_1, B_2 \in E$ and $\xi \in R$, the operations addition, subtraction, multiplication and scalar multiplication are defined as

$$[B_1 \oplus B_2]^r = [B_1]^r + [B_2]^r = [\underline{B}_1^r + \underline{B}_2^r, \overline{B}_1^r + \overline{B}_2^r] \tag{2}$$

$$[B_1 ? B_2]^r = [B_1]^r - [B_2]^r = [\underline{B}_1^r - \underline{B}_2^r, \overline{B}_1^r - \overline{B}_2^r] \tag{3}$$

$$[B_1 ? B_2]^r = \begin{pmatrix} \min\{\underline{B}_1^r \underline{B}_2^r, \underline{B}_1^r \overline{B}_2^r, \overline{B}_1^r \underline{B}_2^r, \overline{B}_1^r \overline{B}_2^r\} \\ \max\{\underline{B}_1^r \underline{B}_2^r, \underline{B}_1^r \overline{B}_2^r, \overline{B}_1^r \underline{B}_2^r, \overline{B}_1^r \overline{B}_2^r\} \end{pmatrix} \tag{4}$$

$$[\xi B_1]^r = \xi [B_1]^r = \begin{cases} (\xi \underline{B}_1^r, \xi \overline{B}_1^r), & \xi \geq 0 \\ (\xi \overline{B}_1^r, \xi \underline{B}_1^r), & \xi \leq 0 \end{cases} \tag{5}$$

Definition 4: The Hausdorff distance between two fuzzy numbers B_1 and B_2 is defined as [30,31]

$$D(B_1, B_2) = \sup_{0 \leq r \leq 1} \{\max(|\underline{B}_1^r - \underline{B}_2^r|, |\overline{B}_1^r - \overline{B}_2^r|)\} \tag{6}$$

$D(B_1, B_2)$ has the following properties

(i) $D(B_1 \oplus u, B_2 \oplus u) = D(B_1, B_2)$, $\forall B_1, B_2, u \in E$

(ii) $D(\xi B_1, \xi B_2) = |\xi| D(B_1, B_2)$, $\forall \xi \in R, B_1, B_2 \in E$

(iii) $D(B_1 \oplus B_2, u \oplus v) \leq D(B_1, u) + D(B_2, v)$, $\forall B_1, B_2, u, v \in E$

(iv) (D, E) is stated as complete metric space.

Definition 5: The function $\psi : [a_1, a_2] \to E$ is integrable on $[a_1, a_2]$, if it satisfies in the below mentioned relation

$$\int_{a_1}^{\infty} \psi(x)dx = \left(\int_{a_1}^{\infty} \underline{\psi}(x,r)dx, \int_{a_1}^{\infty} \overline{\psi}(x,r)dx\right) \tag{7}$$

If $\psi(x)$ be a fuzzy value function, as well as $q(x)$ be a fuzzy Riemann integrable on $[a_1, \infty]$ so $\psi(x) \oplus q(x)$ can be a fuzzy Riemann integrable on $[a_1, \infty]$. Therefore,

$$\int_{a_1}^{\infty} (\psi(x) \oplus q(x))dx = \int_{a}^{\infty} \psi(x)dx \oplus \int_{a}^{\infty} q(x)dx \tag{8}$$

According to the fuzzy concept or in the case of interval arithmetic, equation $B_1 = B_2 \oplus s$ is not equivalent with $s = B_1 ? B_2 = B_1 \oplus (-1)B_2$ or to $B_2 = B_1 ? s = B_1 \oplus (-1)s$ and this is the main reason in introducing the following Hukuhara difference (H-difference).

Definition 6: The definition of H-difference [32,9], is proposed by $B_1 ?_H B_2 = s \Leftrightarrow B_1 = B_2 \oplus s$. If $B_1 ?_H B_2$ prevails, its r-level is $[B_1 ?_H B_2]^r = [\underline{B}_1^r - \underline{B}_2^r, \overline{B}_1^r - \overline{B}_2^r]$.

Precisely, $B_1 ?_H B_1 = 0$ but $B_1 ? B_1 \neq 0$.

Definition 7: Suppose $\psi : [a_1, a_2] \to E$ and $x_0 = [a_1, a_2]$. ψ is strongly generalized differentiable at x_0, if for all $k > 0$ adequately minute, $\psi'(x_0) \in E$ exists in such a manner that (i) $\exists$ $\psi(x_0 + k) ?_H \psi(x_0)$, $\psi(x_0) ?_H \psi(x_0 - k)$ and

$$\lim_{k \to 0^+} \frac{\psi(x_0+k) ?_H \psi(x_0)}{k} = \lim_{k \to 0^+} \frac{\psi(x_0) ?_H \psi(x_0-k)}{k} = \psi'(x_0)$$

or (ii) $\exists\ \psi(x_0) ?_H \psi(x_0 + k)$, $\psi(x_0 - k) ?_H \psi(x_0)$ and

$$\lim_{k \to 0^+} \frac{\psi(x_0) ?_H \psi(x_0+k)}{(-k)} = \lim_{k \to 0^+} \frac{\psi(x_0-k) ?_H \psi(x_0)}{(-k)} = \psi'(x_0),$$

or (iii) $\exists\ \psi(x_0 + k) ?_H \psi(x_0)$, $\psi(x_0 - k) ?_H \psi(x_0)$ and

$$\lim_{k \to 0^+} \frac{\psi(x_0+k) ?_H \psi(x_0)}{k} = \lim_{k \to 0^+} \frac{\psi(x_0-k) ?_H \psi(x_0)}{(-k)} = \psi'(x_0)$$

or (iv) $\exists\ \psi(x_0) ?_H \psi(x_0 + k)$, $\psi(x_0) ?_H \psi(x_0 - k)$ and

$$\lim_{k \to 0^+} \frac{\psi(x_0) ?_H \psi(x_0+k)}{(-k)} = \lim_{k \to 0^+} \frac{\psi(x_0) ?_H \psi(x_0-k)}{k} = \psi'(x_0)$$

Remark 1:It is clear that case (i) is H-derivative. Furthermore, a function is (i)-differentiable only when it is H-derivative. *Remark 2*: It can be concluded from [32] that, the definition of differentiability is noncontradictory [33].

Let us consider $\psi : R \to E$ where $\psi(t)$ has a parametric form as $[\psi(t,r)] = [\underline{\psi}(t,r), \overline{\psi}(t,r)]$, for all $0 \le r \le 1$, thus (i) If ψ be (i)-differentiable, so $\underline{\psi}(t,r)$ and $\overline{\psi}(t,r)$ are differentiable functions, moreover $\psi'(t) = (\underline{\psi}'(t,r), \overline{\psi}'(t,r))$. (ii) If ψ be (ii)-differentiable, so $\underline{\psi}(t,r)$ and $\overline{\psi}(t,r)$ are differentiable functions, moreover $\psi'(t) = (\overline{\psi}'(t,r), \underline{\psi}'(t,r))$. Suppose $f : (a_1, a_2) \to R$ is differentiable on (a_1, a_2), furthermore ψ' has finite root in (a_1, a_2), and $m \in E$, therefore, $\psi(x) = mf(x)$ is strongly generalized differentiable on (a_1, a_2) along with $\psi'(x) = mf'(x)$, $\forall x \in (a_1, a_2)$.

Theorem 1: [9] Assume $\psi : R \times E \to E$ is taken to be a continuous fuzzy function. If $x_0 \in R$, the fuzzy initial value constraint

$$\begin{cases} \phi'(t) = \psi(x, \phi) \\ \phi(x_0) = \phi_0 \end{cases} \tag{9}$$

is incorporated with two solutions: (i)-differentiable, also (ii)-differentiable. Hence the successive iterations

$$\phi_{n+1}(x) = \phi_0 + \int_{x_0}^{x} \psi(t, \phi_n(t))dt, \qquad \forall x \in [x_0, x_1] \tag{10}$$

and

$$\varphi_{n+1}(x) = \varphi_0 \,?_H (-1) \int_{x_0}^{x} \psi(t, \varphi_n(t))dt, \qquad \forall x \in [x_0, x_1] \tag{11}$$

approaches towards the two solutions sequentially.

Definition 8: A Z-number has two components $Z = [B(a), \tilde{p}]$. The primary component $B(a)$ is restriction on a real-valued uncertain variable a. The secondary component $\tilde{p}$ is a measure of the reliability of B. $\tilde{p}$ can be reliability, the strength of belief, probability or possibility. When $B(a)$ is a fuzzy number and $\tilde{p}$ is the probability distribution of a, the Z-number is stated as Z^+-number. When $B(a)$ as well as $\tilde{p}$ are fuzzy numbers, the Z-number is stated as Z^- -number.

The Z^+ -number carries more information when compared with Z^- -number. In this paper, we utilize the definition of Z^+ -number, i.e., $Z = [B, \tilde{p}]$, B is a fuzzy number and $\tilde{p}$ is a probability distribution.

To express the fuzzy number the most common membership functions are utilized in this paper. The popular membership functions are the triangular function

$$\mu_B = F(\lambda_1, \lambda_2, \lambda_3) = \begin{cases} \frac{a-\lambda_1}{\lambda_2-\lambda_1} & \lambda_1 \le a \le \lambda_2 \\ \frac{\lambda_3-\zeta}{\lambda_3-\lambda_2} & \lambda_2 \le a \le \lambda_3 \end{cases} otherwise \mu_B = 0 \tag{12}$$

and trapezoidal function

$$\mu_B = F(\lambda_1, \lambda_2, \lambda_3, \lambda_4) = \begin{cases} \frac{a-\lambda_1}{\lambda_2-\lambda_1} & \lambda_1 \le a \le \lambda_2 \\ \frac{\lambda_4-a}{\lambda_4-\lambda_3} & \lambda_3 \le a \le \lambda_4 \\ 1 & \lambda_2 \le a \le \lambda_3 \end{cases} otherwise \mu_B = 0 \tag{13}$$

The probability measure is defined as

$$\tilde{P} = \int_R \mu_B(a)\tilde{p}(a)da \tag{14}$$

where $\tilde{p}$ is the probability density of a, also R is the restriction on $\tilde{p}$. For discrete Z-numbers

$$\tilde{P}(B) = \sum_{i=1}^{n} \mu_B(a_i)\tilde{p}(a_i) \tag{15}$$

Definition 9: The r -level of the Z-number $Z = (B, \tilde{P})$ is illustrated as

$$[Z]^r = \left([B]^r, [\tilde{p}]^r\right) \tag{16}$$

where $0 < r \le 1$. $[\tilde{p}]^r$ is computed by the Nguyen's theorem

$$[\tilde{p}]^r = \tilde{p}([B]^r) = \tilde{p}([\underline{B}^r, \overline{B}^r]) = \left[\underline{\tilde{P}}^r, \overline{\tilde{P}}^r\right] \tag{17}$$

where $\tilde{p}([B]^r) = \{\tilde{p}(a) \mid a \in [B]^r\}$. So $[Z]^r$ can be demonstrated as the form r -level of a fuzzy number

$$[Z]^r = \left(\underline{Z}^r, \overline{Z}^r\right) = \left(\left(\underline{B}^r, \underline{\tilde{P}}^r\right), \left(\overline{B}^r, \overline{\tilde{P}}^r\right)\right) \tag{18}$$

where $\underline{\tilde{P}}^r = \underline{B}^r \tilde{p}(\underline{a_i}^r)$, $\overline{\tilde{P}}^r = \overline{B}^r \tilde{p}(\overline{a_i}^r)$, $[a_i]^r = (\underline{a_i}^r, \overline{a_i}^r)$.

Similar with the fuzzy numbers, the Z-numbers are also incorporated with three primary operations, addition, subtraction, and multiplication. The operations in this paper are different definitions with [34]. The r -level of Z-numbers is applied to simplify the operations.

Suppose $Z_1 = (B_1, \tilde{p}_1)$ and $Z_2 = (B_2, \tilde{p}_2)$ be two discrete Z-numbers expressing the uncertain variables a_1 and a_2, $\sum_{\iota=1}^{n} \tilde{p}_1(a_{1\iota}) = 1$, $\sum_{\iota=1}^{n} \tilde{p}_2(a_{2\iota}) = 1$. The operations are displayed as

$$Z_{12} = Z_1 * Z_2 = (B_1 * B_2, \tilde{p}_1 * \tilde{p}_2) \tag{19}$$

where $* \in \{\oplus, ?, ?\}$.

For all $\tilde{p}_1 * \tilde{p}_2$ operations, we use convolutions for the discrete probability distributions

$$\tilde{p}_1 * \tilde{p}_2 = \sum_i \tilde{p}_1(a_{1,i})\tilde{p}_2(a_{2,(n-i)}) = \tilde{p}_{12}(a) \tag{20}$$

The above definitions satisfy the Hukuhara difference [35],

$$\begin{aligned} Z_1 \,?_H Z_2 &= Z_{12} \\ Z_1 &= Z_2 \oplus Z_{12} \end{aligned} \tag{21}$$

If $Z_1 ?_H Z_2$ prevails, the r -level is

$$[Z_1 ?_H Z_2]^r = [\underline{Z}_1^r - \underline{Z}_2^r, \overline{Z}_1^r - \overline{Z}_2^r] \quad (22)$$

Obviously, $Z_1 ?_H Z_1 = 0$, $Z_1 ? Z_1 \neq 0$.

Also the above definitions satisfy the generalized Hukuhara difference [7]

$$Z_1 ?_{gH} Z_2 = Z_{12} \Leftrightarrow \begin{cases} 1)\ Z_1 = Z_2 \oplus Z_{12} \\ 2)\ Z_2 = Z_1 \oplus (-1)Z_{12} \end{cases} \quad (23)$$

It is easy to display that 1) and 2) in combination are genuine if and only if Z_{12} is a crisp number. With respect to r -level we have

$[Z_1 ?_{gH} Z_2]^r = [\min\{\underline{Z}_1^r - \underline{Z}_2^r, \overline{Z}_1^r - \overline{Z}_2^r\}, \max\{\underline{Z}_1^r - \underline{Z}_2^r, \overline{Z}_1^r - \overline{Z}_2^r\}]$

and If and subsist, $Z_1 ?_H Z_2 = Z_1 ?_{gH} Z_2$. The circumstances for the inerrancy of $Z_{12} = Z_1 ?_{gH} Z_2 \in E$ are

$$1)\begin{cases} \underline{Z}_{12}^r = \underline{Z}_1^r - \underline{Z}_2^r and \overline{Z}_{12}^r = \overline{Z}_1^r - \overline{Z}_2^r \\ with\ \underline{Z}_{12}^r increa\sin g,\ \overline{Z}_{12}^r decrea\sin g,\ \underline{Z}_{12}^r \leq \overline{Z}_{12}^r \end{cases}$$
$$2)\begin{cases} \underline{Z}_{12}^r = \overline{Z}_1^r - \overline{Z}_2^r and\ \overline{Z}_{12}^r = \underline{Z}_1^r - \underline{Z}_2^r \\ with\ \underline{Z}_{12}^r increa\sin g,\ \overline{Z}_{12}^r decrea\sin g,\ \underline{Z}_{12}^r \leq \overline{Z}_{12}^r \end{cases} \quad (24)$$

where $\forall r \in [0,1]$

If B is a triangular function, the absolute value of the Z-number $Z = (B, \tilde{p})$ is defined as

$$|Z(a)| = (|\lambda_{11}| + |\lambda_{12}| + |\lambda_{13}|, \tilde{p}(|\lambda_{21}| + |\lambda_{22}| + |\lambda_{23}|)) \quad (25)$$

If B_1, as well as B_2 are triangular functions, the supremum metric for Z-numbers $Z_1 = (B_1, \tilde{p}_1)$ and $Z_2 = (B_2, \tilde{p}_2)$ is illustrated as

$$D(Z_1, Z_2) = d(B_1, B_2) + d(\tilde{p}_1, \tilde{p}_2) \quad (26)$$

in this case $d(\cdot,\cdot)$ is defined as the supremum metrics with fuzzy sets [3]. $D(Z_1, Z_2)$ is incorporated with the following possessions

$$D(Z_1 + Z, Z_2 + Z) = D(Z_1, Z_2)$$
$$D(Z_2, Z_1) = D(Z_1, Z_2)$$
$$D(\zeta Z_1, \zeta Z_2) = |\zeta| D(Z_1, Z_2)$$
$$D(Z_1, Z_2) \leq D(Z_1, Z) + D(Z, Z_2)$$

where $\zeta \in R$, $Z = (B, \tilde{p})$ is Z-number and B is triangle function, for proof refer to [36].

Definition 10: Suppose $\hat{Z}$ demonstrates the space of Z -numbers, then the $r-$ level of Z -number valued function $\Psi : [a_1, a_2] \to \hat{Z}$ is defined as

$$\Psi(\phi, r) = [\underline{\Psi}(\phi, r), \overline{\Psi}(\phi, r)]$$

where $\phi \in \hat{Z}$, and $r \in [0,1]$.

Based on the definition of Generalized Hukuhara difference, the gH-derivative of Ψ at ϕ_0 is defined as

$$\Psi'(\varphi_0) = \lim_{h \to 0} \frac{1}{h} [\Psi(\varphi_0 + h) ?_{gH} \Psi(\varphi_0)] \quad (27)$$

In (27), $\Psi(\phi_0 + h)$ and $\Psi(\phi_0)$ represents similar style with Z_1 and Z_2respectively defined in (laiop).

By implementing the $r-$ level (16) to initial value problem, $\phi'(t) = \psi(t, \phi(t))$, we generate two Z-number valued functions: $\underline{\psi}[t, \underline{\phi}(a,r), \overline{\phi}(a,r)]$ and $\overline{\psi}[t, \underline{\phi}(a,r), \overline{\phi}(a,r)]$.

The initial value problem can be equivalent to the following relation

$$i)\begin{cases} \underline{\phi}' = \underline{\psi}[t, \underline{\phi}(a,r), \overline{\phi}(a,r)] \\ \overline{\phi}' = \overline{\psi}[t, \underline{\phi}(a,r), \overline{\phi}(a,r)] \end{cases}$$
$$ii)\begin{cases} \underline{\phi}' = \overline{\psi}[t, \underline{\phi}(a,r), \overline{\phi}(a,r)] \\ \overline{\phi}' = \underline{\psi}[t, \underline{\phi}(a,r), \overline{\phi}(a,r)] \end{cases} \quad (28)$$

3. Fuzzy Sumudu transform

Fuzzy initial and boundary value problems can be resolved by utilizing fuzzy Laplace transform [10]. In this paper, the FST methodology for Z-number is illustrated, furthermore the properties of this methodology is stated. By applying the FST methodology, the FDE based on Z-number is reduced to an algebraic equation. The main advantage of the FST is that it can resolve the equation without resorting to a new frequency domain. The methodology of converting FDEs to an algebraic equation is expressed in [10].

Definition 11: Suppose $\psi(t)$ be a continuous Z-number valued function, also, $\psi(Bt) ? e^{-t}$ be an improper Z-number Riemann integrable on $[0, \infty)$. Accordingly, $\int_0^\infty \psi(Bt) ? e^{-t} dt$ is expressed as FST and it is defined by $\Omega(B) = \mathbf{S}[\psi(t)] = \int_0^\infty \psi(Bt) ? e^{-t} dt$, where $0 \leq B < K$, $K \geq 0$, also e^{-t} is a real-valued function. Based on the Theorem 3 we have the following relation

$$\int_0^\infty \psi(Bt) ? e^{-t} dt = (\int_0^\infty \underline{\psi}(Bt, r) e^{-t} dt, \int_0^\infty \overline{\psi}(Bt, r) e^{-t} dt) \quad (29)$$

Let

$$\mathbf{S}[\underline{\psi}(t,r)] = \int_0^\infty \underline{\psi}(Bt, r) e^{-t} dt$$
$$\mathbf{S}[\overline{\psi}(t,r)] = \int_0^\infty \overline{\psi}(Bt, r) e^{-t} dt \quad (30)$$

hence we obtain the following relation

$$\mathbf{S}[\psi(t)] = (\mathbf{S}[\underline{\psi}(t,r), \mathbf{S}\overline{\psi}(t,r)]) \quad (31)$$

Theorem 2: Suppose $\psi'(t)$ be a Z-number valued integrable function, as well as $\psi(t)$ be the primitive of $\psi'(t)$ on $[0,\infty)$. Therefore,

$$\mathbf{S}[\psi'(t)]=\frac{1}{B}?\mathbf{S}[\psi(t)]?(\frac{1}{B}?[\psi(0)]) \tag{32}$$

where is considered to be (i)-differentiable, or

$$\mathbf{S}[\psi'(t)]=\frac{-1}{B}?[\psi(0)]?(\frac{-1}{B}?\mathbf{S}[\psi(t)]) \tag{33}$$

where ψ is considered to be (ii)-differentiable.

Proof. For arbitrary fixed $r\in[0,1]$ we have

$$\begin{aligned}&\tfrac{1}{B}?\mathbf{S}[\psi(t)]?(\tfrac{1}{B}?\psi(0))\\&=(\tfrac{1}{B}\mathbf{S}[\underline{\psi}(t,r)]-\tfrac{1}{B}\mathbf{S}[\underline{\psi}(0,r)],\tfrac{1}{B}\mathbf{S}[\overline{\psi}(t,r)]-\tfrac{1}{B}\mathbf{S}[\overline{\psi}(0,r)])\end{aligned} \tag{34}$$

We have the following relations

$$\begin{aligned}\mathbf{S}[\overline{\psi}'(t,r)]&=\tfrac{1}{B}\mathbf{S}[\overline{\psi}(t,r)]-\tfrac{1}{B}[\overline{\psi}(0,r)]\\\mathbf{S}[\underline{\psi}'(t,r)]&=\tfrac{1}{B}\mathbf{S}[\underline{\psi}(t,r)]-\tfrac{1}{B}[\underline{\psi}(0,r)]\end{aligned} \tag{35}$$

Hence, we obtain

$$\frac{1}{B}?\mathbf{S}[\psi(t)]?(\frac{1}{B}?\psi(0))=(\mathbf{S}[\underline{\psi}'(t,r)],\mathbf{S}[\overline{\psi}'(t,r)]) \tag{36}$$

If is considered to be (i)-differentiable, so

$$\frac{1}{B}?\mathbf{S}[\psi(t)]?(\frac{1}{B}?\psi(0))=\mathbf{S}[\psi'(t)] \tag{37}$$

Let is (ii)-differentiable. For arbitrary fixed $\alpha\in[0,1]$ we obtain

$$\begin{aligned}&\tfrac{-1}{B}?[\psi(0)]?(\tfrac{-1}{B}?\mathbf{S}[\psi(t)])\\&=(\tfrac{-1}{B}\overline{\psi}(0,r)+\tfrac{1}{B}\mathbf{S}[\overline{\psi}(t,r)],\tfrac{-1}{B}\underline{\psi}(0,r)+\tfrac{1}{B}\mathbf{S}[\underline{\psi}(t,r)])\end{aligned} \tag{38}$$

The above equation can be written as the following relation

$$\begin{aligned}&\tfrac{-1}{B}?[\psi(0)]?(\tfrac{-1}{B}?\mathbf{S}[\psi(t)])\\&=(\tfrac{1}{B}\mathbf{S}[\overline{\psi}(t,r)]-\tfrac{1}{B}\overline{\psi}(0,r),\tfrac{1}{B}\mathbf{S}[\underline{\psi}(t,r)]-\tfrac{1}{B}\underline{\psi}(0,r))\end{aligned} \tag{39}$$

We obtain

$$\begin{aligned}\mathbf{S}[\overline{\psi}'(t,r)]&=\tfrac{1}{B}\mathbf{S}[\overline{\psi}(t,r)]-\tfrac{1}{B}\overline{\psi}(0,r)\\\mathbf{S}[\underline{\psi}'(t,r)]&=\tfrac{1}{B}\mathbf{S}[\underline{\psi}(t,r)]-\tfrac{1}{B}\underline{\psi}(0,r)\end{aligned} \tag{40}$$

So, we have

$$(\frac{-1}{B}\psi(0))?(\frac{-1}{B}?\mathbf{S}[\psi(t)])=(\mathbf{S}[\overline{\psi}'(t,r)],\mathbf{S}[\underline{\psi}'(t,r)]) \tag{41}$$

Hence

$$(\frac{-1}{B}\psi(0))?(\frac{-1}{B}?\mathbf{S}[\psi(t)])=\mathbf{S}([\overline{\psi}'(t,r)],[\underline{\psi}'(t,r)]) \tag{42}$$

Since ψ is (ii)-differentiable, therefore,

$$(\frac{-1}{B}\psi(0))?(\frac{-1}{B}?\mathbf{S}[\psi(t)])=\mathbf{S}[\psi'(t)] \tag{43}$$

Theorem 3: Taking into consideration that Sumudu transform is a linear transformation, so if $\psi(t)$ and $\vartheta(t)$ be continuous Z-number valued functions, moreover k_1 as well as k_2 be constant, therefore the following relation can be obtained

$$\mathbf{S}[(k_1?\psi(t))\oplus(k_2?\vartheta(t))]=(k_1?\mathbf{S}[\psi(t)])\oplus(k_2?\mathbf{S}[\vartheta(t)]) \tag{44}$$

Proof. We have

$$\begin{aligned}&\mathbf{S}[(k_1?\psi(t))\oplus(k_2?\vartheta(t))]\\&=\textstyle\int_0^\infty(k_1?\phi(Bt)\oplus k_2?\vartheta(Bt))?e^{-t}dt\\&=\textstyle\int_0^\infty k_1?\psi(Bt)?e^{-t}dt\oplus\int_0^\infty k_2?\vartheta(Bt)?e^{-t}dt\\&=k_1?(\textstyle\int_0^\infty\psi(Bt)?e^{-t}dt)\oplus k_2?(\int_0^\infty\vartheta(Bt)?e^{-t}dt)\\&=k_1?\mathbf{S}[\psi(t)]\oplus k_2?\mathbf{S}[\vartheta(t)]\end{aligned} \tag{45}$$

Therefore, we conclude

$$\mathbf{S}[(k_1?\psi(t))\oplus(k_2?\vartheta(t))]=(k_1?\mathbf{S}[\psi(t)])\oplus(k_2?\mathbf{S}[\vartheta(t)]) \tag{46}$$

Lemma 1: Assume that $\psi(t)$ is a continuous Z-number value function on $[0,\infty)$, also $\gamma\geq 0$, thus

$$\mathbf{S}[\gamma?\psi(t)]=\gamma?\mathbf{S}[\psi(t)] \tag{47}$$

Proof. Fuzzy Sumudu transform $\gamma?\psi(t)$ is defined as

$$\mathbf{S}[\gamma?\psi(t)]=\textstyle\int_0^\infty\gamma?\psi(Bt)?e^{-t}dt \tag{48}$$

furthermore, we have

$$\textstyle\int_0^\infty\gamma?\psi(Bt)?e^{-t}dt=\gamma?\int_0^\infty\psi(Bt)?e^{-t}dt \tag{49}$$

therefore,

$$\mathbf{S}[\gamma?\psi(t)]=\gamma?\mathbf{S}[\psi(t)] \tag{50}$$

Lemma 2: Assume that $\psi(t)$ is a continuous Z-number valued function, and $\vartheta(t)\geq 0$. Furthermore, if we suppose that $(\psi(t)?\vartheta(t))?e^{-t}$ is improper Z-number Reiman integrable on $[0,\infty)$, then

$$\begin{aligned}&\textstyle\int_0^\infty(\psi(Bt)?\vartheta(Bt))?e^{-t}dt\\&=(\textstyle\int_0^\infty\vartheta(Bt)\underline{\psi}(Bt,r)e^{-t}dt,\int_0^\infty\vartheta(Bt)\overline{\psi}(Bt,r)e^{-t}dt)\end{aligned} \tag{51}$$

Theorem 4: Suppose $\psi(t)$ is a continuous Z-number valued function, also $\mathbf{S}[\psi(t)]=D(B)$, therefore,

$$\mathbf{S}[e^{a_1t}?\psi(t)]=\frac{1}{1-a_1B}D(\frac{B}{1-a_1B}) \tag{52}$$

where e^{a_1t} is considered to be a real value function, also $1-a_1B>0$.

Proof. We have the following relation

$$\begin{aligned}&\mathbf{S}[e^{a_1 t}\,?\,\psi(t)]=\int_0^{\infty}e^{a_1 Bt}e^{-t}\psi(Bt)dt\\&=(\int_0^{\infty}e^{-(1-a_1B)t}\underline{\psi}(Bt,r)dt,\int_0^{\infty}e^{-(1-a_1B)t}\overline{\psi}(Bt,r)dt)\end{aligned}\tag{53}$$

Let us consider $z=1-a_1Bt$, then

$$\begin{aligned}&\mathbf{S}[e^{a_1 t}\,?\,\psi(t)]\\&=\tfrac{1}{1-a_1B}(\int_0^{\infty}\underline{\psi}(\tfrac{Bz}{1-a_1B},r)e^{-z}dz,\int_0^{\infty}\overline{\psi}(\tfrac{Bz}{1-a_1B},r)e^{-z}dz)\\&=\{\tfrac{1}{1-a_1B}\underline{D}(\tfrac{B}{1-a_1B}),\tfrac{1}{1-a_1B}\overline{D}(\tfrac{B}{1-a_1B})\}=\tfrac{1}{1-a_1B}D(\tfrac{B}{1-a_1B})\end{aligned}\tag{54}$$

4. Solving fuzzy initial value problem with fuzzy Sumudu transform method

Consider the following fuzzy initial value problem based on Z-numbers

$$\begin{cases}\phi'(t)=\psi(t,\phi(t)),\\\phi(0)=(\underline{\phi}(0,r),\overline{\phi}(0,r)),\qquad 0<r\le 1\end{cases}\tag{55}$$

where $\psi(t,\phi(t))$ is a Z-number function. By utilizing FST method for Z-numbers, we obtain

$$\mathbf{S}[\phi'(t)]=\mathbf{S}[\psi(t,\phi(t))]\tag{56}$$

The solving process of Eq. (56) is based on the following cases.

Case 1: Assume that $\phi'(t)$ is (i)-differentiable. Base on the Theorem 3 we extract

$$\phi'(t)=(\underline{\phi}'(t,r),\overline{\phi}'(t,r))\tag{57}$$

$$\mathbf{S}[\varphi'(t)]=(\frac{1}{B}?\mathbf{S}[\varphi(t)])?\frac{1}{B}\varphi(0)\tag{58}$$

Eq. (58) can be displayed as the following relation

$$\begin{cases}\mathbf{S}[\underline{\psi}(t,\phi(t),r)]=\frac{1}{B}\mathbf{S}[\underline{\phi}(t,r)]-\frac{1}{B}\underline{\phi}(0,\alpha)\\\mathbf{S}[\overline{\psi}(t,\phi(t),r)]=\frac{1}{B}\mathbf{S}[\overline{\phi}(t,r)]-\frac{1}{B}\overline{\phi}(0,r)\end{cases}\tag{59}$$

where

$$\begin{cases}\underline{\psi}(t,\phi(t),r)=\min\{\psi(t,B)\mid B\in(\underline{\phi}(t,r),\overline{\phi}(t,r))\}\\\overline{\psi}(t,\phi(t),r)=\max\{\psi(t,B)\mid B\in(\underline{\phi}(t,r),\overline{\phi}(t,r))\}\end{cases}\tag{60}$$

Accordingly, Eq. (60) can be resolved on the basis of the following assumptions

$$\mathbf{S}[\underline{\phi}(t,r)]=U_1(B,r)\tag{61}$$

$$\mathbf{S}[\overline{\phi}(t,r)]=U_2(B,r)\tag{62}$$

where $U_1(B,r)$, as well as $U_2(B,r)$ are the Z-number solutions of the Eq. (60). By applying inverse Sumudu transform, $\underline{\phi}(t,r)$ as well as $\overline{\phi}(t,r)$ are computed as

$$\underline{\phi}(t,r)=\mathbf{S}^{-1}[U_1(B,r)]\tag{63}$$

$$\overline{\phi}(t,r)=\mathbf{S}^{-1}[U_2(B,r)]\tag{64}$$

Case 2: Assume that $\phi'(t)$ is (ii)-differentiable. Based on the Theorem 3 we extract

$$\phi'(t)=(\overline{\phi}'(t,r),\underline{\phi}'(t,r))\tag{65}$$

$$\mathbf{S}[\varphi'(t)]=(\frac{-1}{B}?\varphi(0))?(\frac{-1}{B}?\mathbf{S}[\varphi(t)])\tag{66}$$

Eq. (66) can be displayed as the following relation

$$\begin{cases}\mathbf{S}[\underline{\psi}(t,\phi(t),r)]=\frac{1}{B}\mathbf{S}[\underline{\phi}(t,r)]-\frac{1}{B}\underline{\phi}(0,r)\\\mathbf{S}[\overline{\psi}(t,\phi(t),r)]=\frac{1}{B}\mathbf{S}[\overline{\phi}(t,r)]-\frac{1}{B}\overline{\phi}(0,r)\end{cases}\tag{67}$$

where

$$\begin{cases}\underline{\psi}(t,\phi(t),r)=\min\{\psi(t,B)\mid B\in(\underline{\phi}(t,r),\overline{\phi}(t,r))\}\\\overline{\psi}(t,\phi(t),r)=\max\{\psi(t,B)\mid B\in(\underline{\phi}(t,r),\overline{\phi}(t,r))\}\end{cases}\tag{68}$$

Accordingly, Eq. (68) can be resolved on the basis of the following assumptions

$$\begin{aligned}&\mathbf{S}(\underline{\phi}(t,r)=V_1(B,r)\\&\mathbf{S}(\overline{\phi}(t,r)=V_2(B,r)\end{aligned}\tag{69}$$

where $V_1(B,r)$, and $V_2(B,r)$ are the Z-number solutions of the Eq. (68). By applying inverse Sumudu transform, $\underline{\phi}(t,r)$ as well as $\overline{\phi}(t,r)$ are computed as

$$\begin{aligned}&\underline{\phi}(t,r)=\mathbf{S}^{-1}[V_1(B,r)]\\&\overline{\phi}(t,r)=\mathbf{S}^{-1}[V_2(B,r)]\end{aligned}\tag{70}$$

5. Examples

The following examples have been used to narrate the methodology proposed in this paper.

5.1. Example 1

A tank with a heating system is displayed in Figure 1, where $\widetilde{R}=0.5$, the thermal capacitance is $\widetilde{C}=2$ also the temperature is ψ . The model is formulated as follows[10, 37],

$$\begin{cases}\phi'(t)=-\frac{1}{\widetilde{R}\widetilde{C}}\phi(t),\qquad 0\le t\le T\\\phi(0)=[(\underline{\phi}(0,r),\overline{\phi}(0,r)),p(0.8,0.9,1)]\end{cases}\tag{71}$$

By utilizing the FST method based on Z-number we obtain

$$\mathbf{S}[\phi'(t)]=\mathbf{S}[-\phi(t)]\tag{72}$$

$$S[\phi'(Bt)]\odot e^{-t}dt\tag{73}$$

where $0\le B<K$. By considering case 1 for Z-numbers the following relation is obtained

$$\mathbf{S}[\varphi'(t)]=\frac{1}{B}?(\mathbf{S}[\varphi(t)]?\varphi(0))=\frac{1}{B}\mathbf{S}[\varphi(t)]?\frac{1}{B}\varphi(0) \quad (74)$$

Therefore

$$-\mathbf{S}[\varphi(t)]=\frac{1}{B}\mathbf{S}[\varphi(t)]?\frac{1}{B}\varphi(0) \quad (75)$$

Based on the Eq. (59), we have

$$\begin{cases}-\mathbf{S}[\bar{\phi}(t,r)]=\frac{1}{B}\mathbf{S}[\underline{\phi}(t,r)]-\frac{1}{B}\underline{\phi}(0,r)\\ -\mathbf{S}[\underline{\phi}(t,r)]=\frac{1}{B}\mathbf{S}[\bar{\phi}(t,r)]-\frac{1}{B}\bar{\phi}(0,r)\end{cases} \quad (76)$$

Therefore, the Z-number solution of Eq. (76) is extracted as $[(\mathbf{S}[\bar{\phi}(t,r)],\mathbf{S}[\underline{\phi}(t,r)]),p(0.8,0.94,1)]$ where

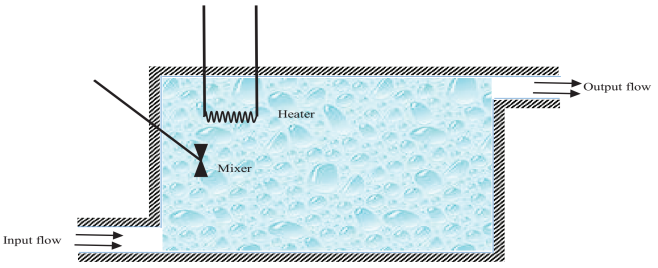

Fig. 1. A tank with a heating system

$$\begin{cases}\mathbf{S}[\bar{\phi}(t,r)]=(\frac{-1}{B^2-1})\bar{\phi}(0,r)+(\frac{B}{B^2-1})\underline{\phi}(0,r)\\ \mathbf{S}[\underline{\phi}(t,r)]=(\frac{-1}{B^2-1})\underline{\phi}(t,r)+(\frac{B}{B^2-1})\bar{\phi}(0,r)\end{cases} \quad (77)$$

By utilizing the inverse Sumudu transform for Z-numbers, we have

$$\begin{cases}\mathbf{S}[\bar{\phi}(t,r)]=\bar{\phi}(0,r)\mathbf{S}^{-1}(\frac{-1}{B^2-1})+\underline{\phi}(0,r)\mathbf{S}^{-1}(\frac{B}{B^2-1})\\ \mathbf{S}[\underline{\phi}(t,r)]=\underline{\phi}(0,r)\mathbf{S}^{-1}(\frac{-1}{B^2-1})+\bar{\phi}(0,r)\mathbf{S}^{-1}(\frac{B}{B^2-1})\end{cases} \quad (78)$$

where

$$\begin{cases}\bar{\phi}(t,r)=e^{t}(\frac{\bar{\phi}(0,r)-\underline{\phi}(0,r)}{2})+e^{-t}(\frac{\bar{\phi}(0,r)+\underline{\phi}(0,r)}{2})\\ \underline{\phi}(t,r)=e^{t}(\frac{\underline{\phi}(0,r)-\bar{\phi}(0,r)}{2})+e^{-t}(\frac{\underline{\phi}(0,r)+\bar{\phi}(0,r)}{2})\end{cases} \quad (79)$$

By considering case 2 for Z-numbers the following relation is obtained

$$\mathbf{S}[\varphi'(t)]=(\frac{-1}{B}\mathbf{S}[\varphi(t)])?(\frac{-1}{B}\varphi(0)) \quad (80)$$

Hence

$$-\mathbf{S}[\varphi(t)]=(\frac{-1}{B}\mathbf{S}[\varphi(t)])?(\frac{-1}{B}\varphi(0)) \quad (81)$$

Based on the above relations, Eq. (71) is illustrated as

$$\begin{cases}-\mathbf{S}[\underline{\phi}(t,r)]=\frac{1}{B}\mathbf{S}[\underline{\phi}(t,r)]-\frac{1}{B}\underline{\phi}(0,r)\\ -\mathbf{S}[\bar{\phi}(t,r)]=\frac{1}{B}\mathbf{S}[\bar{\phi}(t,r)]-\frac{1}{B}\bar{\phi}(0,r)\end{cases} \quad (82)$$

So, the Z-number solution of Eq. (82) is displayed as $[(\mathbf{S}[\underline{\phi}(t,r)],\mathbf{S}[\bar{\phi}(t,r)]),p(0.8,0.9,1)]$ where

$$\begin{cases}\mathbf{S}[\underline{\phi}(t,r)]=\underline{\phi}(0,r)(\frac{1}{B+1})\\ \mathbf{S}[\bar{\phi}(t,r)]=\bar{\phi}(t,r)(\frac{1}{B+1})\end{cases} \quad (83)$$

By utilizing the inverse Sumudu transform for Z-numbers, we have

$$\begin{cases}\underline{\phi}(t,r)=\underline{\phi}(0,r)\mathbf{S}^{-1}(\frac{1}{B+1})\\ \bar{\phi}(t,r)=\bar{\phi}(0,r)\mathbf{S}^{-1}(\frac{1}{B+1})\end{cases} \quad (84)$$

where

$$\begin{cases}\underline{\phi}(t,r)=e^{-t}\underline{\phi}(0,r)\\ \bar{\phi}(t,r)=e^{-t}\bar{\phi}(0,r)\end{cases} \quad (85)$$

If the initial condition is taken to be a symmetric triangular Z-number as $\phi(0)=[(-a(1-r),a(1-r)),p(0.8,0.9,1)]$, so

Case 1 :

$$\begin{cases}\underline{\phi}(t,r)=e^{t}(-a(1-r))\\ \bar{\phi}(t,r)=e^{t}(a(1-r))\end{cases} \quad (86)$$

Case 2:

Table 1. Approximation errors based on Z-numbers

α	FST	Average Euler
0	[(0.0078,0.0195),p(0.8,0.86,0.94)]	[(0.0138,0.0215),p(0.7,0.8,0.87)]
0.2	[(0.0085,0.0169),p(0.75,0.8,0.9)]	[(0.0188,0.0286),p(0.7,0.8,0.87)]
0.6	[(0.0058,0.0115),p(0.8,0.9,1)]	[(0.0182,0.0198),p(0.7,0.8,0.92)]
0.8	[(0.0091,0.0123),p(0.7,0.75,0.8)]	[(0.0148,0.0189),p(0.6,0.7,0.8)]
1	[(0.0132,0.0132),p(0.7,0.8,0.9)]	[(0.0710,0.0710),p(0.6,0.75,0.87)]

$$\begin{cases}\underline{\phi}(t,r)=e^{-t}(-a(1-r))\\ \bar{\phi}(t,r)=e^{-t}(a(1-r))\end{cases} \quad (87)$$

Approximation errors based on Z-numbers are shown in Table 1. These errors are the differences between the exact and the approximation solutions, for two different methods: FST and Average Euler method [38].

The following formula is utilized to transfer the Z-numbers to fuzzy numbers,

$$\sigma=\frac{\int\phi\pi_P(\phi)d\phi}{\int\pi_P(\phi)d\phi}$$

By taking in to consideration $Z=(B,\tilde{p})=[(0.0078,0.0195),p(0.8,0.86,0.94)]$, we obtain $Z^{\sigma}=[0.0078,0.0195;0.86]$ accordingly $Z'=[\sqrt{0.86}\,0.0078,\sqrt{0.86}\,0.0195]$. Approximation errors based on fuzzy numbers are shown in Table 2.

Figure 2 shows the corresponding error plots based on fuzzy numbers. FST is more accurate than the Average Euler method. Figure 3 and Figure 4 demonstrate the corresponding solution plots based on fuzzy numbers.

By implementing Z-numbers the degree of reliability of the information can be increased [39, 40]. The comparison between the Z-number $Z=[(0.0078,0.0195),p(0.8,0.86,0.94)]$ and fuzzy number $[0.0072,0.0180]$ is displayed in Figure 5. It can be seen that the Z-number incorporates with several information, also the solution related to the Z-number is more precise. The membership function regarding the restriction in the Z-number is considered to be $\mu_{B_Z}=[0.0078,0.0195]$. It can be in probability form.

Table 2. Approximation errors based on fuzzy numbers

α	FST	Average Euler
0	[0.0072,0.0180]	[0.0123,0.0192]
0.2	[0.0076,0.0151]	[0.0168,0.0255]
0.6	[0.0055,0.0109]	[0.0162,0.0177]
0.8	[0.0078,0.0106]	[0.0123,0.0158]

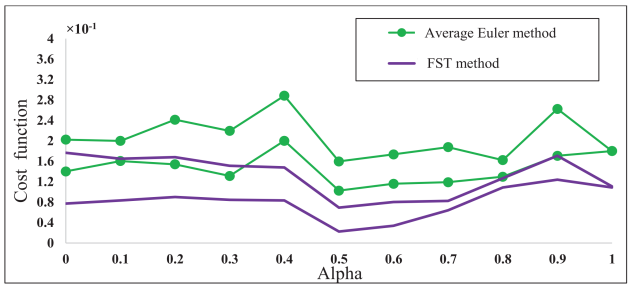

Fig. 2. The lower and upper bounds of absolute errors based on fuzzy numbers

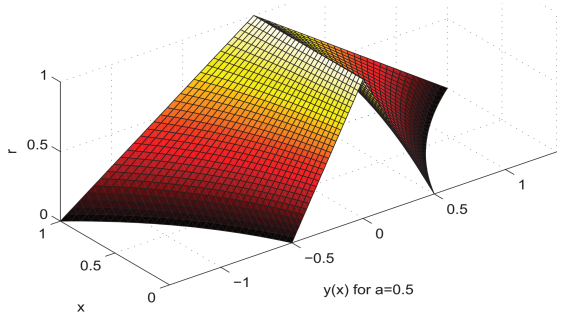

Fig. 3. The solution of FDE under case 1 consideration based on fuzzy numbers

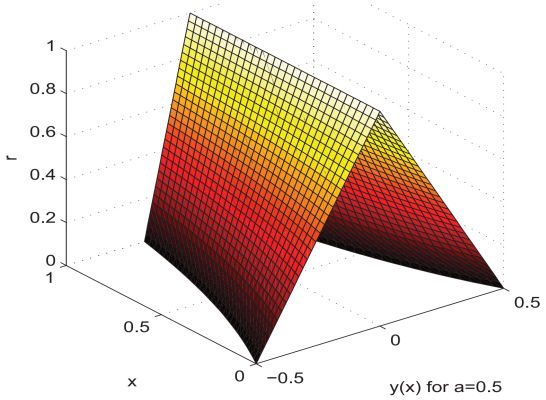

Fig. 4. The solution of FDE under case 2 consideration based on fuzzy numbers

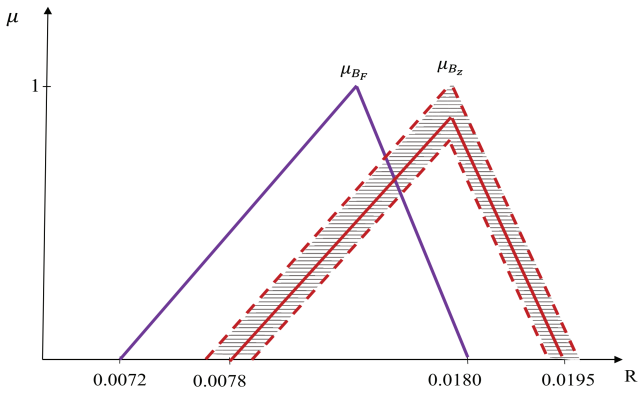

Fig. 5. The comparison between the Z-number and fuzzy number

5.2. Example 2

A tank system is displayed in Figure 6. Suppose $I=t+1$ is inflow disturbances of the tank that generates vibration in liquid level ϕ, also $H=1$ is the flow obstruction, which can be curbed utilizing the valve. $Q=1$ is the cross-section of the tank. The liquid level is illustrated as following relation [41, 42],

$$\begin{cases} \phi'(t)=-\frac{1}{QH}\phi(t)+\frac{I}{Q}, & 0\le t\le T \\ \phi(0)=[(\underline{\phi}(0,r),\overline{\phi}(0,r)),p(0.85,0.91,1)] \end{cases} \quad (88)$$

By utilizing the FST method based on Z-number we obtain

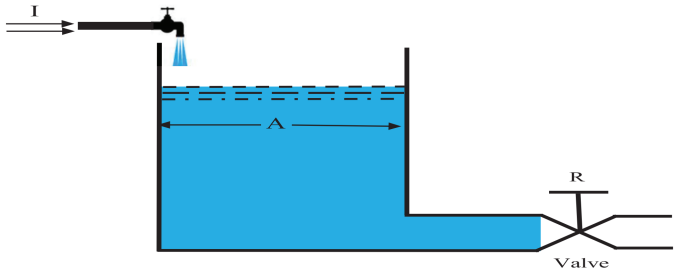

Fig. 6. Liquid tank system

$$-\mathbf{S}[\varphi(t)]=(\frac{1}{B}?\mathbf{S}[\varphi(t)])?(\frac{1}{B}\mathbf{S}[\varphi(0)]) \quad (89)$$

$$\mathbf{S}[\phi'(t)](\int_{a_1}^{\infty}\phi(Bt)e^{'-t}dt \quad (90)$$

By considering case 2 for Z-numbers the following relation is obtained

$$\mathbf{S}[\varphi'(t)]=(\frac{-1}{B}?\mathbf{S}[\varphi(t)])?(\frac{-1}{B}\mathbf{S}[\varphi(0)]) \quad (91)$$

So

$$-\mathbf{S}[\varphi(t)]+\mathbf{S}[t]+\mathbf{S}[1]=(\frac{-1}{B}?\mathbf{S}[\varphi(t)])?(\frac{-1}{B}\mathbf{S}[\varphi(0)]) \quad (92)$$

Based on the Eq. (59), we have

$$\begin{cases} -\mathbf{S}[\underline{\phi}(t,r)]+\mathbf{S}[t]+\mathbf{S}[1]=\frac{1}{B}\mathbf{S}[\underline{\phi}(t,r)]-\frac{1}{B}\underline{\phi}(0,r) \\ -\mathbf{S}[\overline{\phi}(t,r)]+\mathbf{S}[t]+\mathbf{S}[1]=\frac{1}{B}\mathbf{S}[\overline{\phi}(t,r)]-\frac{1}{B}\overline{\phi}(0,r) \end{cases} \quad (93)$$

Therefore, the Z-number solution of Eq. (93) is extracted as

$$\begin{cases} \mathbf{S}[\underline{\phi}(t,r)]=\mathbf{S}[t]+\mathbf{S}[1]+\frac{-1}{B}\mathbf{S}[\underline{\phi}(t,r)]-\frac{1}{B}\underline{\phi}(0,r) \\ \mathbf{S}[\overline{\phi}(t,r)]=\mathbf{S}[t]+\mathbf{S}[1]+\frac{1}{B}\mathbf{S}[\overline{\phi}(t,r)]-\frac{1}{B}\overline{\phi}(0,r) \end{cases} \quad (94)$$

hence,

$$\begin{cases} \mathbf{S}[\underline{\phi}(t,r)]=(\frac{1}{B+1})\underline{\phi}(0,r)+B \\ \mathbf{S}[\overline{\phi}(t,r)]=(\frac{1}{B+1})\overline{\phi}(t,r)+B \end{cases} \quad (95)$$

By utilizing the inverse Sumudu transform for Z-numbers, we obtain

$$\begin{cases} \underline{\phi}(t,r)=\underline{\phi}(0,r)\mathbf{S}^{-1}(\frac{1}{B+1})+\mathbf{S}^{-1}(B) \\ \overline{\phi}(t,r)=\overline{\phi}(0,r)\mathbf{S}^{-1}(\frac{1}{B+1})+\mathbf{S}^{-1}(B) \end{cases} \quad (96)$$

Where $$\begin{cases} \underline{\phi}(t,r)=e^{-t}\underline{\phi}(0,r)+t \\ \overline{\phi}(t,r)=e^{-t}\overline{\phi}(0,r)+t \end{cases} \quad (97)$$

If the initial condition is taken to be a symmetric triangular Z-number as $\phi(0)=[(-a(1-r),a(1-r)),p(0.85,0.9,1)]$, , so

$$\begin{cases} \underline{\phi}(t,r)=e^{-t}(-a(1-r))+t \\ \overline{\phi}(t,r)=e^{-t}(a(1-r))+t \end{cases} \quad (98)$$

Approximation errors based on Z-numbers are shown in Table 3. These errors are the differences between the exact and the approximation solutions, for two different methods: FST and Max-Min Euler method [38]. Figure 7 shows the Corresponding solution plot based on fuzzy numbers.

Table 3. Approximation errors based on Z-numbers

α	FST	Max-Min Euler
0	[(0.0053,0.0128),p(0.8,0.85,0.9)]	[(0.0108,0.0195),p(0.8,0.9,1)]
0.2	[(0.0019,0.0127),p(0.7,0.81,0.9)]	[(0.0072,0.0138),p(0.6,0.7,0.8)]
0.4	[(0.0031,0.0089),p(0.8,0.9,1)]	[(0.0113,0.0123),p(0.7,0.8,0.91)]
0.6	[(0.0008,0.0027),p(0.8,0.9,1)]	[(0.0043,0.0078),p(0.7,0.8,0.9)]
0.8	[(0.0049,0.0079),p(0.7,0.8,0.86)]	[(0.0069,0.0099),p(0.6,0.7,0.8)]
1	[(0.0109,0.0109),p(0.7,0.8,0.9)]	[(0.0587,0.0587),p(0.6,0.75,0.8)]

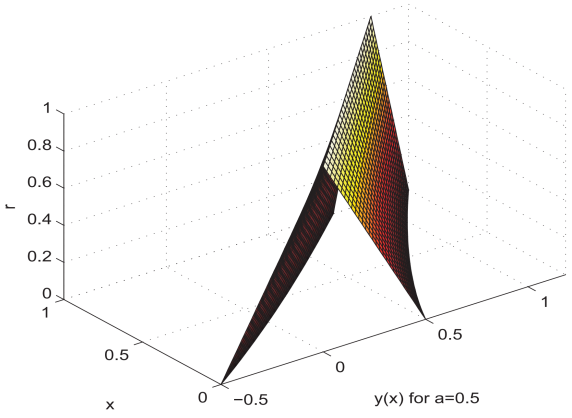

Fig. 7. The solution of FDE under case 2 consideration based on fuzzy numbers

6. Conclusion

In this paper, a novel method based on the FST is proposed in order to find the solution of the first order FDEs on the basis of the Z-numbers. The new method is clarified by utilizing the concept of strongly generalized differentiability. By using the FST method, the FDE converts to an algebraic problem. Some essential theorems are laid down in order to demonstrate the properties of the FST. Two real examples are applied to demonstrate the effectiveness of the proposed technique. This work has a significant contribution in initializing a superior starting point for such extensions.

ABSTRACT

Probabilities topic models are active research area in text mining, machine learning, information retrieval, etc. Most of the current statistical topic modeling methods, such as Probabilistic Latent Semantic Analysis (pLSA) and Latent Dirichlet Allocation (LDA). They are used to build models from unstructured text and produce a term-based representation to describe a topic by choosing single words from multinomial word distribution. There are two main weaknesses. First, popular or common words are different topics, often causing ambiguity for understanding the topics; Second, lack of consistent semantics for single words to be represented correctly. To address these problems, this paper proposes a model (A Two-Phase Method for Constructing Topic Model, TPMTM) that combines statistical modeling (LDA) with frequent pattern mining and produces better presentations of rich topics and semantics. Empirical evaluation shows that the results of the proposed model are better than LDA.

1. Introduction

Topic models are Bayesian statistical models that are structured in accordance with a hidden theme, usually called unstructured data in a set of textual documents, topics with multiple distributions of words. Due to a collection of unstructured text documents, the topic model assumes that the collection of documents (corpus) has a certain number of hidden topics and that each document contains more than one topic in different sizes. Researchers have developed several topic models such as Latent Semantic Indexing (LSA) [1], Probability Latent Semantic Analysis (PLSA) [2] and Latent Dirichlet Allocation (LDA) [3]. Topic modeling automatically selects topics from the text and identifies topics over time [4], explores the connection between topics[5], supervised the topics [6], recommendation [7], and so on.

LDA or unsupervised generation probabilistic methods for modeling the document collection (corpus), is the most commonly used topic modeling method. The LDA, each document can be described as a probabilistic distribution for latent topics, and that the topic distribution of all documents is distributed a common Dirichlet prior. Within each topic in the LDA model is described as a probabilistic distribution over-represented as a probabilistic distribution of words and words distributions of topics distribute the same Dirichlet prior. Each latent topic in the LDA model is also distributions of topics distribute a common Dirichlet prior as well. A corpus D consists of M documents, with document d having N_d words ($d \in \{1,..., M\}$), LDA models D as stated in the following process[8].

LDA concludes the following generative process for each document w in a D corpus:

1. Choose N ~ Poisson (ξ).

2. Choose θ ~Dir (α).

3. For each of the N words w_n:

(a) Choose a topic z_n~ Multinomial (θ).

(b) Choose a word w_n from $p(w_n|z_n.\beta)$, a multinomial probability conditioned on the topic Z_n.

The discovered variables are words in documents although others are hidden variables (θ and ϕ) and hyperparameters (β and α).To provide hyperparameters and hidden variables, the probability of discovered data D and maximized as follows:

$$p\,(D|\alpha,\beta)= \prod_{d=1}^{M} \int p(\theta_d\,|\alpha)\Big(\prod_{n=1}^{N_d} \sum_{z_{dn}} p(z_{dn}|\theta_d)p(\omega_{dn}|z_{dn},\beta)\Big)d\theta_d \quad (1)$$

The LDA model has three levels of the representation. In corpus level, there are two parameters (α and β) that are involved

[*]Corresponding Author: Than Than Wai, Web mining, University of Computer Studies, Mandalay, ZIP Code 05071, Myanmar | Email: thanwai85@gmail.com

in the process of building a corpus. Document-level variables are the variables θ_d, which are sampled once per document. Finally, word-level variables $z_{d,n}$ and $w_{d,n}$ are the variables that are collected for each word in each document. The current statistical topic modeling techniques make multinomial distributions in words to represent topics in a given collection of texts. For example, Table 1 displays a sample of multinomial distributions used to describe the three themes of a scientific collection of publications.

Table 1: A Sample of Topic Presentation on AAAI Dataset

TopicId	Words
7	problem, result,order ,solver, present
12	algorithm,show, state,find,result
18	behavior ,system ,agent, develop ,result

From the above results in Table1, a sample of word distributions used to present three themes of a scientific paper collection of AAAI dataset. The term "result" is a general term and very general term in showing research papers in all different fields. The general words cause ambiguous to the topic presentation. So, a new model is required to solve these problems. The new method should take higher special representations and explore latent associations under multinomial word distributions.

The LDA and other topic models are portions of the better field of probabilistic modeling. Generative probabilistic topic modeling is a method for unsupervised classification of documents, by modeling each document as a mix of themes and each theme as a mix of words. But there exist the problems of word uncertainty and semantic integrity [8].

Text mining is a technique that supports users' assets effective information from a variety of digital documents. Most text mining methods are keyword-based strategies that need single words to show the documents. Based on the theory that the phrase may have more linguistic meaning than the keyword, strategies for using phrases instead of keywords are also suggested. However, surveys have shown that phrase-based techniques are not always better than keyword-based techniques [9, 10]. Many strategies in the field of data mining are used in patterns to mine useful documents that yield encouraging results [11, 12].

Topic modeling provides a convenient way to analyze large classified text collections while extracting interesting features to express collections in text mining. Thus, it advances the proposed model to improve the accuracy and relevance of the topic's representations by using the techniques of text mining, especially frequent itemset mining techniques.

In this model, Latent Dirichlet Allocation (LDA) is integrated into data mining techniques and achieves successful accuracy for the collection documents (corpus). The proposed model is composed of two phases: 1) LDA is applied to accomplish first topic models and 2) the frequent itemset (pattern) mining method is applied to obtain further particular patterns to produce topics of the document collections. Furthermore, the frequent itemsets (patterns) often explain information about the structure of the relationship between words that provide topics that are understandable, relevant and broad.

2. Related Work

Probabilistic topic modeling is expanded to capture more interesting features [13], but they show topics through the distribution of multinomial words. The papers [14, 15] are a widespread way to express the linguistic meaning of the topics as mentioned in the introduction. The authors [16] show a way to calculate the similarities between given themes and a known hierarchy then select the most grant labels to show the topics. But, the weakness of existing methods is that they are strictly limited to resource candidates and are limited to linguistic coverage. The proposed model is a work extension originally presented at 16th IEEE/ACIS International Conference on Computer and Information Science, [17]. This paper [18] discusses the topic-related model phrase by Markov dependencies in word order based on LDA structure, related to this paper. The results provided on [19, 20, 21] show that the topics described by the phrases are easier to interpret than their LDA. But phrases may contribute low-level events in documents, which cannot be accomplished with efficient retrieval performance.

3. Phase1: Topic Presentation Propagation Using LDA

The Latent Dirichlet Allocation is an algorithm that automatically detects the themes that are present in the collection of documents. At the LDA, each document can be viewed as a mix of different topics. The LDA provides the topic using word distribution and representation of the document using the topic distribution. The description of the topic means which words are important to which the topic and representation of the document in which topics are important in the documents [22-26].

Let $D = \{d_1, d_2, ..., d_M\}$ be a corpus. Each document is considered as a mixture of themes and each theme can be defined as a distribution over frozen vocabulary words composed of documents using (1). In general, the proposed model has $\theta=\emptyset_1, \emptyset_2, \dots, \emptyset_V$ for all topics.

Example results of LDA, the topic presentation is shown in Table 2. At document level, table 3 shows LDA's example results, document representation and Table 4 also shows word-topic assignments results of LDA's example.

Table 2: Topic representations – probability distribution over words

Topic	θ
$\emptyset_7$	problem:$\frac{1}{3}$, result:$\frac{4}{12}$,order: $\frac{2}{12}$,solver$\frac{2}{12}$, present : $\frac{2}{12}$
$\emptyset_{12}$	algorithm$\frac{2}{15}$,show : $\frac{4}{15}$, state: $\frac{1}{3}$,find: $\frac{2}{15}$,result : $\frac{2}{15}$
$\emptyset_{18}$	behavior : $\frac{4}{15}$,system : $\frac{2}{15}$,agent : $\frac{1}{15}$, develop: $\frac{2}{15}$, result: $\frac{2}{15}$

LDA contributions are the representation of the topic that uses the word distribution that the words are important to what the topic matter is, and the representation of the document by distributing the topic which themes are important for a particular document. These representations are used for obtaining information, document classification, text mining, machine learning, etc.

Table 3: Document representation-probability distribution over topics

Document	z_7	z_{12}	z_{18}
d_7	0.385	0.123	0.108
d_{12}	0.464	0.118	0.073
d_{18}	0.305	0.11	0.098

Then, specified topics also indicate which words are important in which topics, similar to the representation on the subject. The proposed model performs word-topic emphasis on the LDA for more precise or more specific topic presentation for a given corpus.

4. Phase2: Topic Presentation Expansion

Words with high probability in topic distributions are selected to represent topics in most LDA based applications. For example, the top 5 words for the 3 topics, as shown in Table 2, are: problem, result, order ,solver, present for topic 7, algorithm, show, state, find, result for topic 12 and behavior ,system ,agent, develop ,result for topic 18. So, they are likely to represent the general concepts or common concepts of the three topics and can not describe the three topics that are noteworthy. Furthermore, the words in representations on the topics formed by the LDA are individual single words. Single words provide very little information about relationships between words and very limited language definitions to make the topic matter clear.

In this section, we propose a method based on frequent patterns (itemset) mining techniques, detailed in the following sub-sections, aimed at reducing the above-mentioned problems.

4.1. Frequent Itemsets based on LDA

The frequent itemset mining is the method of mining data in a set of items or words in large data sets. These patterns are usually described in various forms such as frequent itemsets, sequential patterns, or substructures.

In this paper, the proposed model uses frequent itemsets. Typical itemset generally indicates that a set of items often happens together in a transaction dataset. The methods of using frequent itemsets are categorized into three basic skills: horizontal data format, vertical data format, and expected database strategy.

We use the vertical data format in the mine frequent itemsets in this paper and believe that frequent pattern mining based representation can be more meaningful and more accurate to describe topics. In addition, frequent pattern based representations contain structural information that shows the relationship between the words.

Create Transactional Dataset: The aim of the proposed frequent pattern-based method is to discover related words (i.e., frequent itemsets) from the words assigned by LDA to the topics. From this purpose, we build a set of words from each word-topic assignment instead of using the order of words, because, for frequent pattern mining, the frequency of a word within a transaction is less important. A topical document transaction is a set of words without any duplicates. Let $D=\{d_1,d_2,\ldots,d_M\}$be the original document collection, the transactional dataset for topic Z_j is defined as T_j .

For the topics in D, we can develop V transactional datasets. An example of the transactional datasets is described in Table 5, made from the example in Table 4.

Generate Frequent Pattern-based Representation: The basic idea of the proposed method is to reduce frequent itemsets generated from each transactional dataset T_j to represent Z_j. Here the frequent items in each transactional dataset are taken. Then documents associated with each item are converted into the vertical format and a number of documents containing each item are counted. Items are sorted according to their number of hits (i.e. number of documents of each item). Removing noise items that the number of hits is greater than the user provided threshold. If document-set is a subset of another documents-sets in each transactional dataset then items are merged into enhanced frequent itemsets. For example, $w_1{:}d_1d_2{:}3$, $w_2{:}d_1d_3{:}2$, $w_3{:}d_1d_4{:}3$, $w_1{:}d_2d_3{:}2$, $w_8{:}d_1d_2d_3{:}2$, $w_7{:}d_1d_2d_4{:}3$ can be compressed as the enhanced frequent itemsets $w_1,w_2,w_8{:}d_1d_2d_3{:}2$, w_1,w_3, $w_7{:}d_1d_2d4{:}3$ (format - "items" : "document" : "topic (transactional dataset)"). Such meaningless itemsets may harm document filtering tasks using frequent itemsets because it has duplicates the same frequent itemsets. So, we can regard the proposed method as lossless compression because we can cover all the removed frequent itemsets with the exact topic and it can effectively filter out the redundant itemsets. Finally, frequent itemsets in each transactional dataset are reconstructed. ("itemset" and "pattern" are interchangeable in this thesis). Frequent itemsets are the most widely used patterns created from transactional datasets to illustrate useful or interesting patterns. The main idea of the proposed frequent itemset method is to use of frequent patterns generated from each transactional dataset to represent topic Zj. For a given minimal support threshold δ, and itemset p in T_j is frequent if supp (p) >= δ where supp(p) is the support of p where the number of transactions containing p. Take T_7 as an example, which is the transactional dataset for topic Z_7. For a minimal support threshold δ = 2, all the frequent itemsets generated from are given in Table 6. Patterns represent words related to specific and recognizable meanings.

Table 6: The Frequent Itemsets Explored from T_7

Frequent Patterns	minimal support threshold δ
<result>	3
<algorithm,show,state,find>	2

5. Evaluation

We made experiments to evaluate the performance of the proposed method. In this section, we show the results of the evaluation.

5.1. Datasets

Two datasets are used in experiments, containing abstracts of papers published in the AAAI from 2013 to 2014 and NSF from 1990 to 2003. The two datasets contain 548 and 129000 abstracts. The abstracts are obtained from UCI Machine Learning Repository (http://archive.ics.uci.edu/ml) and by using Porter's stemmer in Java (http://www.tartarus.org/~martin/PorterStemmer).

Table 4: Word-topic Assignments

Document	z_7		z_{12}		z_{18}	
	Proportion of Topic	***Terms***	***Proportion of Topic***	***Terms***	***Proportion of Topic***	***Terms***
d_7	0.385	problem, result, order ,solver, present	0.123	algorithm ,state, find ,algorithm	0.108	behavior , system ,agent
d_{12}	0.464	algorithm,show, state,find,result	0.118	spars ,distribute ,find	0.073	class, complex
d_{18}	0.305	algorithm,show, state,find,result	0.11	algorithm, state	0.098	behavior, system ,system

Table 5: Transactional datasets

Document	$z_7(T_7)$		$z_{12}(T_{12})$		$z_{18}(T_{18})$	
	Proportion of Topic	***Terms***	***Proportion of Topic***	***Terms***	***Proportion of Topic***	***Terms***
d_7	0.385	problem, result, order ,solver, present	0.123	algorithm,state, find	0.108	behavior , system ,agent
d_{12}	0.464	algorithm,show, state,find,result	0.118	spars,distribute, find	0.073	class, complex
d_{18}	0.305	algorithm,show, state,find,result	0.11	algorithm,state	0.098	behavior, system

5.2. Settings

Firstly, we are preparing datasets from the UCI Machine Learning Repository and preprocessing of all documents by removing stop and stemming words.

Secondly, we apply the LDA model to construct a topic model with V = 20 topics for each data collection, using the MALLET topic modeling toolkit (http://mallet.cs.umass.edu//index.php). Our experiments show that an inadequate number of topics will mainly lead to abundant expanded patterns in the topic model. We run Gibbs sampling for 1000 iterations, the LDA hyperparameters are α = 50 / V and β = 0.01.

Thirdly, topical transaction datasets for optimizing topic representations are developed.

Finally, frequent itemsets based on topic representations using the proposed method presented in Section 4 are developed. We used 10% of the documents for testing purpose and trained the resting model at 90%.

5.3. Baseline Model

In order to compare the suggested method, the LDA chose the baseline model in the experiments. Examples of the results of the two models (the LDA model and the frequent itemset based on model) are shown in Table 7. The top 10 terms or frequently itemsets in each of the topic presentations produced by two models are shown in Table 7.

Table 7: Topic Presentations of All Models Using the AAAI Dataset

Topic8		**Topic4**	
LDA	***Frequent itemsets***	***LDA***	***Frequent itemsets***
change	algorithm,method	parallel	markov
system	gener	semant	agent
data	differ	complex	popular,demonstre
unsupervise	propos	algorithm	analyze,learn
input	mani	mathemat	design
compact	consid	condit	relationship,topic
benefit	effici	represent	tempor
superior	sever,train	tool	recommend,exploit
state	imag	regular	adapt
trust	target,problem	improve	time

5.4. Results

The objective of the proposed approach and other current topic modeling methodologies is to show the topics of a collection of documents as specific potential. For existing topic modeling methods and the proposed methodology, the topic representations are word distributions or patterns with probabilities. The more specific selected words or patterns are in the representation of the topic, the more precise representation of the topic matter becomes. The performance of the proposed method is evaluated by the use of information entropy. The higher the entropy, the more the proposed model is disordered.

Table 8: Comparison of All Models in Information Entropy Using a collection of documents of AAAI and NSF

Datasets	**Latent Dirichlet Allocation**	**Frequent Itemsets (patterns)**
AAAI	4.86159	2.68171
NSF	28.3747	20.7532

From the above results in Table 8, the suggested method based on frequent itemsets has lower entropy rates than the baseline model. Thus, it can make more exact presentations of the topics of a corpus.

6. Conclusion

This paper proposes a model to produce more discriminative and semantic rich representations for modeling topics in a given collection of documents. The main contribution of this paper is the novel approach of incorporating the pattern mining method and topic modeling method (Latent Dirichlet Allocation) to produce representations based on the pattern for modeling the topics. The test results show that representations based on patterns are more specific than representations developed by the Latent Dirichlet Allocation. In the future, we will examine the structure of the patterns and discover the relationship between words that represent topics at a more granular level.

Real estate pressures in modern electronics have resulted in the need for electrically small antennas, which have subsequently garnered interest amongst researchers and industry alike. These antennas are characterized by their largest dimensions translating to a fraction of the operating wavelength; such a diminutive size comes at the expense of reduced gain and efficiency, and a worse overall match to a corresponding power source. In order to compensate for this deterioration in performance, antenna designers must turn towards increasingly complex and voluminous geometries, well beyond the capabilities of traditional manufacturing techniques. We present voluminous metal antennas, based on a novel inverted-F design, and fabricated using the emergent selective electron beam melting manufacturing technique, a type of powder bed fusion process. As predicted by small antenna theory, simulation results presented show in increase in the antenna's efficiency as it is voluminously expanded into the third dimension. Measurement results illustrate that key trends observed from simulations are upheld; however, further understanding of the electromagnetic properties of raw materials, in particular how these change during the printing process, is needed. Nevertheless, this type of additive manufacturing technique is suitable for rapid prototyping of novel and complex antenna geometries, and is a promising avenue for further research and maturation.

1. Introduction

With the continued trend of miniaturization in the design and manufacture of modern, 'smart' electronics, antenna designers are challenged with delivering compact, low-cost, and easy to fabricate antennas, often operating at wavelengths many times their largest dimension. A further key requirement is that these antennas are made efficient, so as to prolong battery life. This paper is an extension of work originally presented in the 2017 International Workshop on Antenna Technology in Athens, Greece [1]. The discourse on additively manufactured (AM) voluminous antennas is expanded to provide an overview of electrically small antennas (ESA) in literature fabricated using novel techniques, the three-dimensional (3D) powder bed fusion (PBF) printing process, the antenna design process, as well as the implications of simulated and measured results on practical antenna design.

Formally, an antenna is classed as electrically small if the product of the wavenumber, k (= $2\pi/\lambda$), and the radius of an imaginary sphere circumscribing the maximum dimension of the antenna, a, is less than or equal to 0.5; note that the parameter ka is unit-less [2-4]. It is widely accepted that as the electrical size of an antenna is reduced, its performance (in terms of gain, efficiency, and bandwidth) deteriorates. Generally, the radiation resistance decreases, while the reactive component of its impedance increases, leading to a poor match with the feed line or network. As such, there is a compromise between miniaturization and performance; small antenna theory dictates that a favourable compromise is reached when the antenna fully occupies a volume defined by the radius a [2-8]. Consequently, there is tremendous potential in the successful manufacture of novel, 3D antenna geometries – hitherto too complex to fabricate with traditional processes – using emergent technologies such as holographic photolithography, 3D printing, direct-write printing, direct transfer patterning, thermal transfer printing, and aerosol jet printing [9-18].

[*]Saad Mufti, Department of Electronic and Electrical Engineering, University of Sheffield, S10 2TN, UK, Email: saadmuftism@sheffield.ac.uk

PBF-AM is a particularly attractive technology, as it has the capability to print with metallic raw materials, simplifying the production line compared to some of the other additive techniques cited above. Techniques such as stereolithography and aerosol jet printing entail first printing a plastic or ceramic component, and then subsequently coating it with a layer of metal. Direct-write techniques are serial in nature, and thus slower and unsuitable for mass manufacture. Patterning techniques are suspect to wear and tear of the mechanical stamping parts. All of these processes require a substrate for subsequent metal patterning, whereas no such limitation applies to PBF-AM.

Simulated results for radiation efficiency are presented for a type of planar inverted-F antenna (PIFA), introduced in [19], as it is voluminously extended into the 3rd dimension. The results are validated with three PBF-AM fabricated antennas: flat, part-spherical (~66% fill-factor), and full-spherical (~100% fill-factor), using the Wheeler cap method [20-22]. Radiation pattern measurements are provided for two full-spherical prototypes to compare the effects of fabrication tolerances. The main aims of this research are to present measurement results on pioneering 3D antennas fabricated using AM, and to assess the viability of this emergent technique, in its current state, as a possible fabrication method for inherently 3D antennas. In particular, two popular PBF-AM techniques – which make use of a laser and an electron beam as the heat source, respectively – are compared and the relative strengths and weaknesses assessed.

2. Background on Additive Manufacture

Additive manufacture, also known as 3D printing, is the umbrella term given to a range of processes where raw materials are formatively shaped, layer by layer, to form a desired object or part [23, 24]. A generic illustration of a PBF printer is provided in Figure 1; the technology can be used on a wide range of plastics and metals, and has the obvious advantages of speed, reduced waste, and greatly simplified production lines. In particular, PBF-AM is an attractive technology for antenna manufacture as it is one the few subcategories of 3D printing which can handle metallic raw materials. Compared to other AM techniques, PBF is also advantageous with respect to operating costs, albeit at the expense of higher power consumption and lower build volumes. Two common heat sources used in PBF are lasers and electron beams, leading to the respective processes termed as selective laser melting (SLM) and selective electron beam melting (SEBM).

For this research, the laser based Renishaw AM250 and the electron beam based Arcam A2 printers were used. The difference in heat source leads to some inherent differences in the printing process. In an SLM printer, the chamber is typically filled with inert gas in order to minimize oxidation and degradation of the powdered material. A pressurized vacuum environment is necessary in the SEBM printer, otherwise the bombarded electrons would interact with atoms in the gas and thus get deflected. The electron beam can also be moved a lot faster than the laser, leading to shorter build times. Energy delivered by the electron beam is, however, more diffuse than a laser, leading to a greater area affected by the heat. Consequently, the minimum feature size, resolution, and surface-finish of the SEBM process are typically worse off compared to SLM.

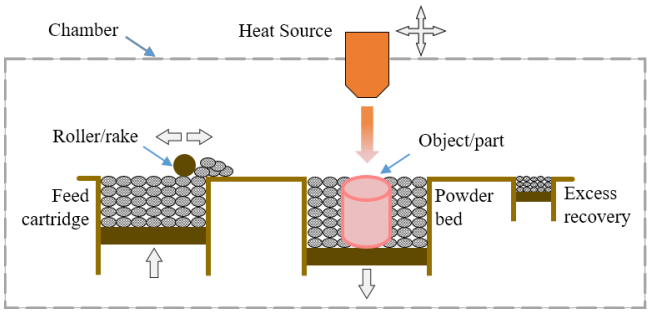

Figure 1. Illustration of generic PBF-AM printer.

In both processes, the powder in the build platform is maintained at an elevated temperature, typically just below its melting point and/or glass transition temperature; the build platform itself may be heated with the help of resistive heaters. For SLM, this elevated temperature allows for lowering the power rating of the laser, and prevents faults that might arise due to non-uniform thermal expansion and contraction. In the SEBM process, the powder is further heated to slightly sinter the particles prior to bombardment from the electron beam. This is done primarily to increase conductivity throughout the powder, to allow the negatively charged electrons to swiftly affect the desired object region. This eliminates the need for any sacrificial support structures under overhanging features, which are sometimes required in SLM printers.

3. Experimental Procedure

3.1. Antenna Design

Figure 2 shows the front profile view of the PIFA variant, based on the original design reported in [19]; the metallization is approximately 0.7 mm thick, resting on a hollow substrate with the same wall thickness, with the entire back side metallized to form the 'ground plane'. The centrally placed digitated structure contributes to a lowering of the resonance frequency of the antenna through additional capacitance and inductance. In fact, there are two current paths on this structure, contributing to orthogonally polarized modes, which may be tuned closer together with the relative positioning of the feed point and shorting pin, thereby increasing the effective bandwidth of the antenna. However, this was not a focus of the current research, as uncertainties in material properties and manufacturing tolerances meant that the focus was shifted purely to comparative efficiency measurements. Note than an extensive parametric study on antenna design and performance is presented in the reference [19], and is applicable to the voluminous antennas presented here.

This template is used for three variations of antennas with different voluminous expansions: flat, part-spherical, and full-spherical, as shown in Figure 3. For each antenna, the maximum radius, and parameter a, is 15.0 mm. Simulated results for the resonance frequency and efficiency as a function of the parameter h (as described in Figure 3) are provided in Figure 4 and Figure 5, respectively. It can be seen from Figure 5 that the 2nd resonance varies more as a function of the voluminous expansion, h, as compared to the 1st resonance, with the general trend that the respective resonance frequencies reduce as h increases, since the currents have a longer effective length on a more curved surface. The corresponding radiation efficiency at resonance also exhibits

a general trend, where the efficiency increases as h is increased and the antenna occupies more and more of the Chu sphere. For the 2nd resonance, the radiation efficiency of the flat antenna is 14%, increasing to 68% for the full-spherical antenna. Establishing an overall trend for this particular antenna geometry, at the dimensions specified, a unit (1 mm) change in height h results in an increase in radiation efficiency of 1.6 percentage points. Thus, the PIFA based antennas may be made more efficient, subsequently delivering power savings in appliances, at the cost of increased cross-sectional profile.

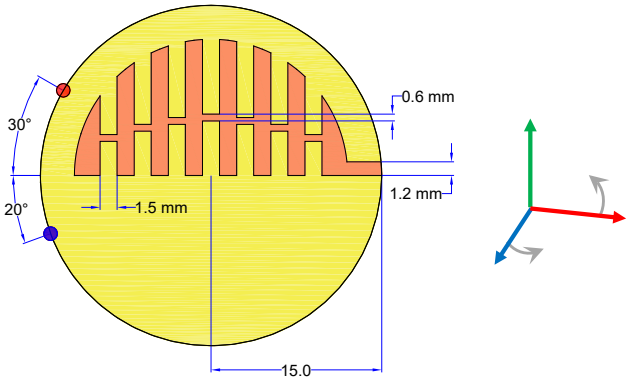

Figure 2. Schematic of top metallization for flat profile. Red dot is feed point; blue dot is shorting point. Back is fully metallicized.

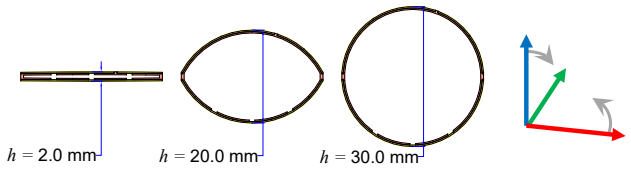

Figure 3. Cross-sectional view of CAD models simulated in CST Microwave Studio ®, for progressively greater voluminous expansion.

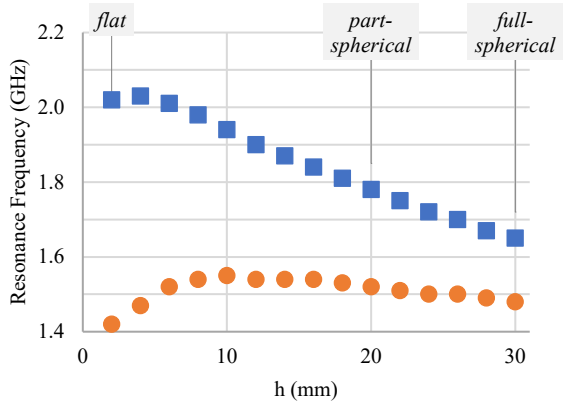

Figure 4. Simulated resonance frequency of (orange) 1st and (blue) 2nd resonances as a function of h. Fabricated antennas are annotated.

3.2. Fabricated Prototypes

The SLM process was trialed first, on a Renishaw AM250 printer, in order to take advantage of its superior surface finish. However, the process is much less capable of manufacturing overhanging features such as the centrally populated digits. Where this limitation is usually overcome with the use of sacrificial support structures analogous to scaffoldings used in building construction, the removal of such structures proved too damaging to the delicate digits.

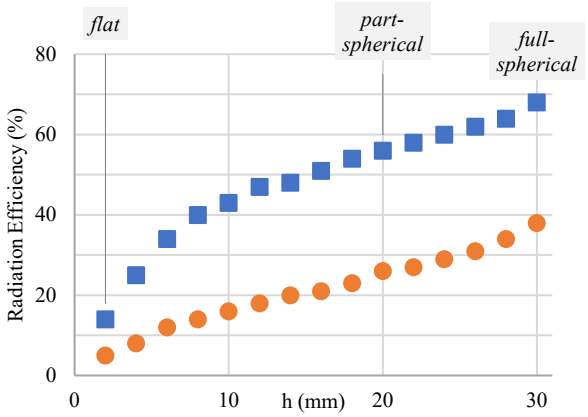

Figure 5. Simulated radiation efficiency of (orange) 1st and (blue) 2nd resonances as a function of h. Fabricated antennas are annotated.

A photograph of an antenna part fabricated with SLM is shown in Figure 6a, with the support structures partly removed. To alleviate this limitation, the antenna parts were subsequently fabricated using the SEBM based Arcam A2 printer. There is no need for support structures in this technique, as the metallic powder is pre-sintered before being melted by the electron beam. However, the poorer surface finish is evident from the photograph in Figure 6b. This is due to the use of coarser powder layers with the SEBM process (40-105 µm compared to 15-45 µm for the laser process), and the comparatively larger area affected at any one time by the electron beam compared to a heating laser.

(a) (b)

Figure 6. Photographs of metallic antenna parts fabricated using (a) SLM, and (b) SEBM.

In total, three variations of the same antenna design were fabricated: flat, part-spherical, and full-spherical; two of these are pictured in Figure 7. The antenna radiator and ground plane were fabricated separately using a Titanium alloy, Ti-6Al-4V ($\sigma \approx 10^5$ Sm^{-1}). Hollow plastic substrates fabricated from the plastic nylon12 were used to provide support. Copper tape was subsequently used to short the top metallization to the ground plane, and to provide contact pads for soldering Sub Miniature version A (SMA) connectors for interfacing to a power source. For this batch of antennas, a total of 18 parts were printed in just under two and a half hours; the build specifications for these antennas using the Arcam A2 printer are as follows:

- the printer was run under a vacuum of about 0.0001 mbar, with a slight amount of helium inserted into the chamber to help dissipate excess charge induced into the powder bed by the electron beam,
- a stainless-steel base plate was heated to 730 °C by the electron beam before any powder was deposited,
- for each layer of powder deposited (50 µm thick), the beam was first defocused and scanned across the layer at a high speed (30 ms^{-1}) with 2.3 kW power, for around 15 seconds, to sinter the powder,
- each part area was subsequently melted using a focused beam with a back and forth raster pattern at a speed of around 0.35 ms^{-1} with 300 W power,
- thereafter, successive powder layers were deposited and the previous sintering and melting steps repeated until the antenna parts were fully realized.

(a) (b)

Figure 7. Photographs of SEBM PBF-AM fabricated antenna prototypes, shown assembled; (a) flat, and (b) full-spherical.

4. Results and Discussion

Return loss measurements for the flat, part-spherical, and full-spherical antennas were conducted using the Agilent E5071B vector network analyser. Radiation efficiency (for 20 MHz bandwidth) was subsequently computed using the using the constant-loss-resistor Wheeler cap method described in [22]. Note that efficiency results were computed for the second resonance only as this is the dominant resonance from measurements, and that repeat measurements per prototype exhibit an error margin of ±10 %.

The corresponding simulations were carried out using CST Microwave Studio ®, using the frequency-domain solver. The titanium alloy was approximated using copper (Cu) metal properties in the CST material library, with reduced conductivity, σ. A notable limitation of using PBF-AM for manufacturing antenna parts is the relative lack of knowledge regarding the electromagnetic properties of the raw materials; this is in fact an active area of current research in the AM community [23, 25-27]. As such, these were iteratively refined in simulations. However, the general trends in performance observed can be interpreted as a validation of small antenna theory, as well as the usefulness of AM techniques in the swift prototyping of non-conventional antenna geometries.

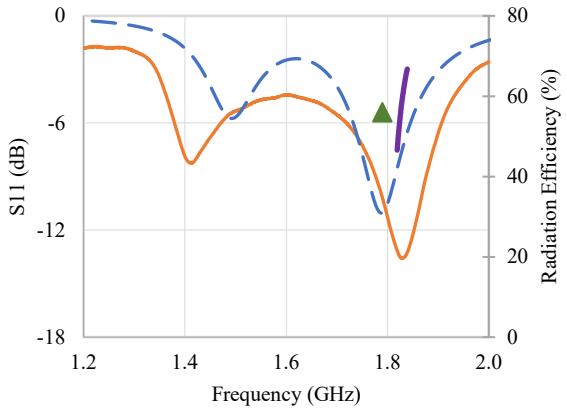

Figure 8. S_{11} results for PBF-AM part-spherical prototype; (orange) measured, (blue) simulated. Radiation efficiency at respective resonance frequencies, for the 2nd resonance; (purple) measured, (green) simulated.

Figure 9-11 compare the measured and simulated S_{11} parameter for the flat, part-spherical and two full-spherical prototypes, respectively. Note that S_{11} is the scattering parameter as obtained from a vector network analyser and is relatable to other reflectivity figures of merit such as return loss and reflection coefficient, and is typically presented in decibels (dB) [28]. Simulated efficiency at resonance and measured efficiency for 20 MHz bandwidth about the resonance frequency are also displayed. Despite differences in the absolute values for S_{11} and radiation efficiency, it can be seen that general trends are corroborated, as expected from small antenna theory. Computed radiation efficiency values for the 2nd resonances exhibit an increase as the voluminous expansion of the PIFA is increased.

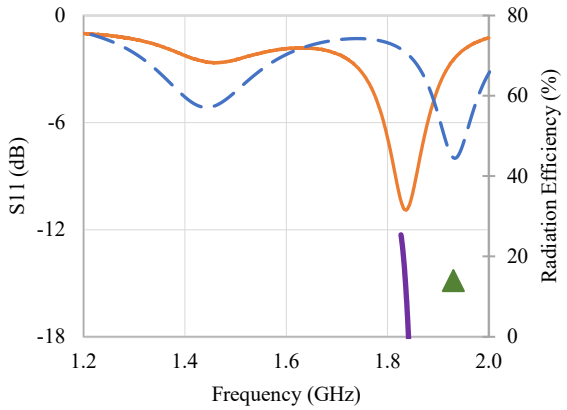

Figure 9. S_{11} results for PBF-AM flat prototype; (orange) measured, (blue) simulated. Radiation efficiency at respective resonance frequencies, for the 2nd resonance; (purple) measured, (green) simulated.

For the two full-spherical prototypes, despite the S_{11} curves following a similar curve, there is a difference of 50 MHz in the 2nd resonance. The mean radiation efficiency at resonance for the two prototypes is 68 %, with a discrepancy of 16 percentage points. Again, these differences are primarily due to inherent manufacturing differences in the antenna parts, as well as manual tolerances for the application of solder and copper tape contact pads. The differences in absolute values between simulations and measurements can be attributed to a number of factors, including

unknown changes in material properties during the printing process, the presence of solder and copper tape for electrical contact to the SMA connector, as well as the rough surface finish on the antenna parts.

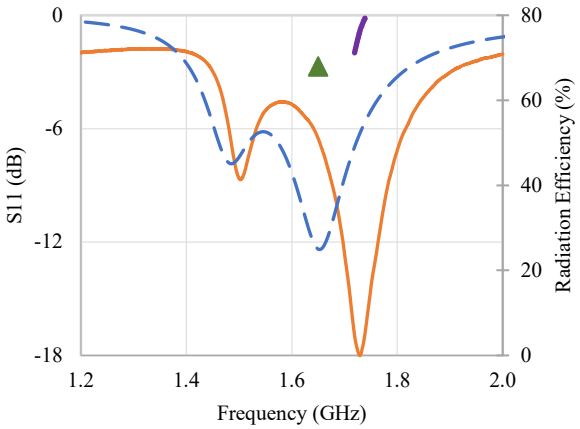

Figure 10. S_{11} results for PBF-AM full-spherical prototype-A; (orange) measured, (blue) simulated. Radiation efficiency at respective resonance frequencies, for the 2nd resonance; (purple) measured, (green) simulated.

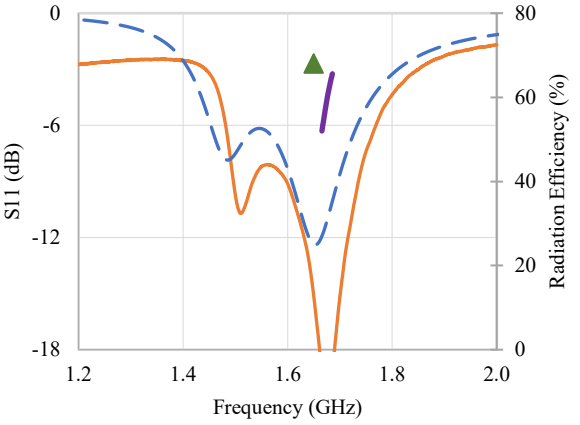

Figure 11. S_{11} results for PBF-AM full-spherical prototype-B; (orange) measured, (blue) simulated. Radiation efficiency at respective resonance frequencies, for the 2nd resonance; (purple) measured, (green) simulated.

Lastly, the realized gain for the full-spherical antenna prototypes was measured in an anechoic chamber, with an Agilent E5071C vector network analyser. Due to the particular feed location for this antenna, partial power gains were measured with respect to vertical and horizontal polarizations, and the gain transfer method [29] used subsequently to compute the total realized gain. Fig 6 and Fig. 7 plot the results for azimuth and elevation planes, respectively, measured at 1.7 GHz; the absolute gain is presented here in units of decibels-over-isotropic (dBi). It can be seen from these plots that simulation and measurement results largely agree, and are expectedly low directivity; there are some artifacts due to the setup (antenna holder) in the azimuth plane towards the rear of the antenna. Key results for the 2nd resonance of each antenna are summarized in Table 1.

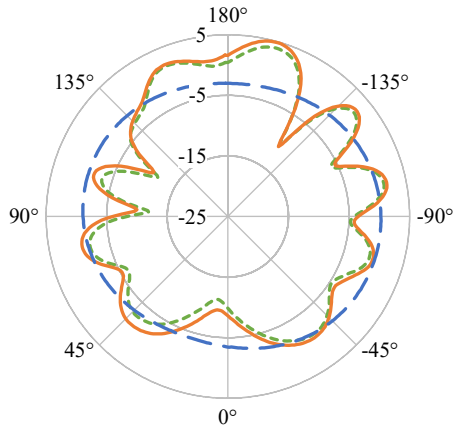

Figure 12. Realized gain (dBi) for the full-spherical ESA at 1.7 GHz; (orange) measured – sample A, (green) measured – sample B, (blue) simulated; azimuth (*z-x*) plane. Combined absolute gain (*φ and θ* components).

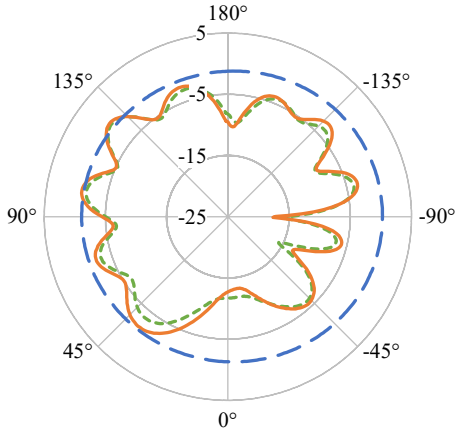

Figure 13. Realized gain (dBi) for the full-spherical ESA at 1.7 GHz; (orange) measured – sample A, (green) measured – sample B, (blue) simulated; elevation (*x-y*) plane. Combined absolute gain (*φ and θ* components).

Table 1. Simulated and measured resonant frequency and radiation efficiency at 2nd resonance for PBF-AM fabricated antennas. Measured and simulated gain at 1.7 GHz is provided for the two full-spherical antennas.

	Flat	*Part-spherical*	*Full-spherical (A)*	*Full-spherical (B)*
Simulated frequency (GHz)	1.93	1.79	1.65	-
Measured frequency (GHz)	1.84	1.83	1.73	1.68
Simulated efficiency (%)	14	56	68	-
Measured efficiency (%)	11	59	76	60
Simulated average gain; azimuth plane (dBi)	-	-	–1.7	-
Measured average gain; azimuth plane (dBi)	-	-	–2.2	–3.2
Simulated average gain; elevation plane (dBi)	-	-	–0.8	-
Measured average gain; elevation plane (dBi)	-	-	–5.9	–6.4

5. Conclusions and Future Work

This paper presents work done on voluminous, additive manufactured antennas based on a novel PIFA design. Measured results for return loss, radiation efficiency, and radiation pattern are presented for four prototypes manufactured using the SEBM based Arcam A2 printer. The metallization was realized from a Titanium alloy, Ti-6Al-4V, and hollow support substrates printed from nylon12. Copper tape was subsequently used to solder SMA connectors, and to short the top metallization to the respective antenna ground planes.

Radiation efficiency results corroborate the trends expected from simulations and small antenna theory. The mean radiation efficiency of 68% for the full-spherical antennas represents an improvement of 57 percentage points over their flat counterpart. The next stage of this project is to obtain an improved understanding of the material properties of metallic powders used in the printing process, as it has been demonstrated that the PBF-AM technique is viable for quick prototyping of complex and voluminous antenna geometries too difficult to realize using traditional fabrication techniques. Finally, the use of laser as the heat source would greatly improve the surface finish, but comes at the cost of limitations on the complexity of antenna geometry

ABSTRACT

The research reported in this paper proposes an Advanced Process Control system, denoted "i.Process | Steel – RHF", oriented to energy efficiency improvement in a pusher type billets reheating furnace located in an Italian steel plant. A tailored control method based on a two-layer Model Predictive Control strategy has been created that involves cooperating modules. Different types of linear models have been combined and an overall furnace global linear model has been developed and included in the controller formulation. The developed controller allows handling all furnace conditions, guaranteeing the fulfillment of the defined specifications. The reliability of the proposed approach has been tested through significant simulation scenarios. The controller has been installed on the considered real plant, replacing local standalone controllers manually conducted by plant operators. Very satisfactory field results have been achieved, both on process control and energy efficiency improvement. Optimized trade-offs between energy saving, environmental impact decreasing, product quality improvement and production maximization have been guaranteed. Consequently, Italian energy efficiency certificates have been obtained. The formulated steel industry reheating furnaces control method has been patented.

1. Introduction

Process industries were recently observing significant changes, due to the need to increase the automation features. This requirement is strictly related to the increasingly stringent environmental and pollution standards that are connected to the need to improve the energy efficiency level [1]. For this purposes, Advanced Process Control (APC) solutions are receiving the attention of process engineers [2]. Significant benefits can be obtained with respect to standalone controllers, both from process control and energy efficiency achievement and improvement point of view [3,4]. The magnitude of these results is directly tied to the amount of energy required for the considered processes.

Steel industry represents a high-energy intensive process industry: it is characterized by different complex phases that have to be carefully managed. Figure 1 briefly depicts the production chain of a steel industry [5]. Initially, raw materials (e.g. waste materials) are processed (Figure 1, *Raw Materials Processing Phase*) in order to obtain steel bars at an intermediate stage of manufacture, e.g. *billets*. Billets are then introduced in a reheating furnace in order to be suitably reheated (Figure 1, *Reheating Phase*). There are different typologies of reheating furnaces, distinguished by the furnace movement methodology: for example, in a *pusher type* reheating furnace, billets are moved along the furnace through the action of pushers. Billets can enter the furnace at different temperatures. In the case study that will be proposed in the present paper, i.e. a pusher type billets reheating furnace located in an Italian steel plant, the billets inlet temperature range is 20 [°*C*] – 700 [°*C*]. Through the combustion reactions triggered by some burners, i.e. air/fuel burners, billets are exposed to heating reactions during their path along the furnace. The billets must be reheated in order to fulfill the specifications required for the subsequent plastic deformation phase (Figure 1, *Rolling Phase*). In the proposed case study, a range example for billets discharge (furnace outlet) temperature is 1000 [°*C*] – 1100 [°*C*]. From the final phase, the finished products, e.g. iron rods or tube rounds, are obtained.

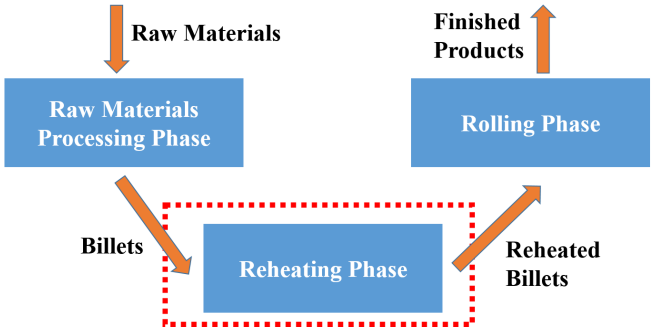

Figure 1. General production chain of a steel industry.

In a steel industry, the previously described *Reheating Phase* represents a crucial phase from an energy efficiency and products quality point of view [6]. In order to guarantee the desired trade-offs between the conflicting challenges of the steel industry *Reheating Phase*, i.e. energy saving and environmental impact decreasing versus product quality and production maximization, different approaches have been proposed in the control literature, ranging from classic to innovative techniques. In [7], a nonlinear optimization problem is formulated through a genetic algorithms approach; the minimization of fuel cost and the satisfaction of a desired discharge temperature represent the control objectives. In [8], two models and two related tracking control systems are proposed. In [9], a mixed neural network/heat transfer model approach is exploited, achieving an integrated intelligent control method. In [10], a nonlinear predictive approach is exploited for controlling a steel slabs continuous reheating furnace. A first principles mathematical model is developed that allows the controller to define the appropriate local furnace temperatures required for the achievement of the desired slabs discharge temperatures. The enormous potential of model-based control and optimization for steel reheating furnaces is described in [11], where one of the proposed control approaches is based on a transient nonlinear furnace model.

This paper is an extension of work originally presented in the 2017 6th International Symposium on Advanced Control of Industrial Processes (AdCONIP) [12]. In [12], the authors have presented an APC framework for the optimization of a pusher type billets reheating furnace (*Reheating Phase*) located in an Italian steel plant. Some details about the process features, the controller formulation and field results have been provided, highlighting the achieved benefits with respect to the previous control system, based on local temperature controllers managed by plant operators. In this paper, in addition to the previously reported literature analysis, additional aspects about the process modellization are provided. Furthermore, more details on simulation results are given through specific scenarios. Finally, results related to the installation of the developed APC system, denoted "i.Process | Steel – RHF", on the Italian industrial plant are depicted and discussed, analyzing process control and energy efficiency aspects.

The paper organization is the following: Section 2 details the main process features, focusing on the control specifications and on the formulated process model. Details on the obtained relationships between the main process variables are provided. Section 3 depicts the control architecture, detailing the formulation of the two MPC modules. A significant plant scenario is reported in Section 4, where a typical condition is simulated and managed with the activation of the developed APC system. In Section 5, results related to the installation on the Italian steel industry are reported, focusing on process control performances and on energy efficiency evaluation with respect to the computed baseline. Section 6 reports the conclusions.

2. Process description and modellization

This section reports the description of the considered case study, i.e. a pusher type billets reheating furnace located in an Italian steel plant. Furthermore, the formulated process model is described.

2.1. Pusher Type Reheating Furnace

As previously described, a pusher type billets reheating furnace located in an Italian steel plant represents the case study that is proposed in this paper for the illustration of the main peculiarities of "i.Process | Steel – RHF" APC system. Figure 2 reports a synoptic of the developed Graphical User Interface (GUI) where a schematic representation of the considered reheating furnace is given. Note the three furnace areas: *Preheating Area* (green rectangle), *Heating Area* (yellow rectangle), *Soaking Area* (red rectangle). The main features of the furnace areas have been reported in Table 1. The furnace billets capacity is 136 (m_b=136); the billets are moved along the furnace based on the defined furnace production rate (up to 120 [*t/h*]). Billets enter the furnace through the *Preheating Area* (Figure 2, left side). In their path along this furnace area, they cross a unique zone (*tunnel*, 4.733 [*m*] length) that is not equipped with an own burners set. Subsequently, billets are moved towards the *Heating Area* that is constituted by zone 6 (3.477 [*m*] length), zone 5 (6.4 [*m*] length), and zone 4 (3.2 [*m*] length). All these furnace zones have air/fuel burners (Figure 2, yellow circles). Finally, billets enter the last furnace area, i.e. *Soaking Area* (Figure 2, right side). Three zones constitute this furnace area, characterized by an own burners set (Figure 2, red circles): zone 3 (4.546 [*m*] length), zone 2 (3.2 [*m*] length), and zone 1 (3.2 [*m*] length). Zone 2 and zone 1 are vertically disposed. Table 2 contains some billets features related disposed. Table 2 contains some billets features related to the considered case study.

Flowmeters detect air and fuel (natural gas) flow rates. The furnace zones temperatures are measured through thermocouples. Furnace and air pressures are measured by manometers placed near the furnace inlet. Billets temperature is measured by optical pyrometers only at the furnace inlet and after the billets furnace discharge (in the rolling mill area). Before the installation of "i.Process | Steel – RHF" APC system, no information was available about billets heating profile within the furnace. Plant operators managed the local Proportional Integral Derivative (PID) temperature controllers; they try to ensure the desired billets discharge temperature exploiting their experience and skills. However, due to the multivariable, nonlinear and time- varying characteristics of the considered process, the observed billets furnace discharge temperature was often higher than the minimum required temperature.

Through deepened process preliminary studies, significant energy efficiency margins (fuel specific consumption minimization) have been identified. For this reason, an APC

Inlet Temperature	20 [$°C$] – 700 [$°C$]
Discharge Temperature	1000 [$°C$] – 1100 [$°C$]

system customized for the analyzed process has been developed. In particular, as it will be described in Section 3, a Model Predictive Control (MPC) strategy based on linear models has been formulated [13-15].

2.2. Process Modellization

In order to design an APC system, the availability of billets temperature estimations during their path within the furnace has been evaluated as a crucial milestone to satisfy. For this purpose, a virtual sensor has been developed [16]. The virtual sensor implements, for each billet that at each control instant lies in the furnace, a first principles adaptive nonlinear model. In this model, the involved heat phenomena and the billets movement information have been included. The inputs of the model are represented by the temperatures of the five furnace zones that are closer to the furnace inlet (tunnel, zone 6, zone 5, zone 4, and zone 3) and by the mean ($TempM_{21}$ [$°C$]) of the temperatures related to the two furnace zones that are closer to the furnace outlet (zone 2 and zone 1). The developed model has been based on the conduction model:

$$\dot{Q}_{cond} = -\lambda A \frac{dT}{dx} \quad [W] \tag{1}$$

In (1), A [m^2] represents the area related to the billet section that is normal to the heat transfer direction, λ [$W/(m \cdot K)$] is the billet thermal conductivity and dT/dx [K/m] is the temperature variation along the considered layer direction. The model reported in (1) can be customized with the needed number of billet layers. The convection and radiation phenomena have been considered through the following equations [17]:

$$\dot{Q}_{conv} = hA(T_{bill} - T_{env}) \quad [W] \tag{2}$$

$$\dot{Q}_{rad} = \varepsilon\sigma A(T_{bill}^4 - T_{env}^4) \quad [W] \tag{3}$$

In (2)-(3), A [m^2] represents the area related to the exposed surface, h [$W/(m^2 \cdot K)$] is the convection heat transfer coefficient, T_{bill} [K] is the billet temperature and T_{env} [K] is the environment temperature of the fluid around the billet. σ is the Stefan-Boltzmann constant and ε is the emissivity coefficient [17].

Through the equations reported in (1)-(3), a discretized model has been formulated for each billet that, at each considered sampling instant, lies in the reheating furnace. An important remark is the lack of an exact knowledge of the involved heat transfer coefficients. Online adaptation procedures for them have been included, based on customized constrained optimization problems that have been formulated exploiting feedback information. Figures 3-5 show an example of the virtual sensor field results related to October 2016. In Figure 3, blue stars indicate the measurements provided by the optical pyrometer in the rolling mill area; green stars represents the related virtual sensor temperature estimations. In Figures 4-5, trends related to the inputs of the virtual sensor model and related to the furnace production rate have been reported, respectively. Using the Root Mean Square Error of Prediction (RMSEP) as a performance indicator for the virtual sensor estimation, an RMSEP less than 10 [$°C$] has been detected (about 1 [$\%$] of an optical pyrometer measurement range). In Figure 4, examples of zone temperatures ranges can be observed. Note the increasing monotonicity of the temperatures according to the proximity to the furnace outlet.

The virtual sensor nonlinear model has then been linearized, in order to include billets temperatures estimations within an MPC strategy based on linear models. A Linear Parameter-Varying (LPV) model has been obtained [18]. The billets temperatures have been included in an ad hoc group of Controlled Variables (CVs), denoted as bCVs (b) group. In the considered case study, the bCVs group is composed by 136 elements (m_b=136). All terms involved in the inputs vector related to the bCVs model, i.e. the temperatures of all furnace zones, have been included in an own group, called as *zones* Controlled Variables (zCVs, y) group. This group also includes temperature differences between adjacent furnace zones, smoke-exchanger temperature (T_{SE}, [$°C$]), and fuel valves opening position [12]. As typical in industrial APC applications, other two categories of measured input process variables have been defined: Manipulated Variables (MVs, u) and Disturbance Variables (DVs, d). The MVs group includes the six fuel flow rates ($Fuel_i$ (i=1-6), [Nm^3/h]) and the six stoichiometric ratios (R_i (i=1-6), []) related to the furnace zones equipped with an own burners set. In DVs group,

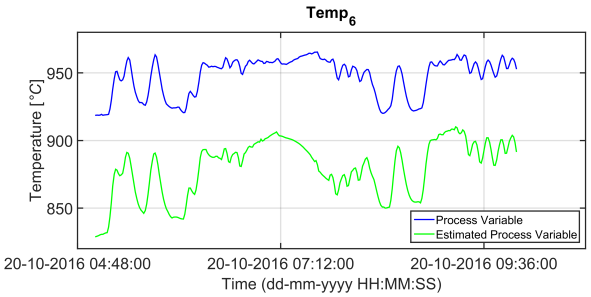

Figure 6. Zone 6 temperature model performances.

the furnace production rate (*Prod*, [*t/h*]), the furnace pressure (*FurnPress*, [*mmH2O*]) and the air pressure (*FurnPress*, [*mbar*]) have been included. The zCVs-MVs/DVs relationships have been modelled through asymptotically stable linear time invariant models without delays on the input-output channels. Steady-state gain signs related to some zCVs-MVs/DVs models have been reported in Tables 3-4. The empty boxes indicate the absence of a relationship.

Note, in Table 3, that the temperatures of the furnace zones located closer to the furnace inlet are influenced by the fuel flow rates of the downstream zones. Figures 6-7 report examples of the performances of the models related to zone 6 and zone 5 temperatures. Green lines represent the model prediction while blue lines represent the field process variables. The depicted trends refer to the same period taken into account in the scenario proposed in Figures 3-5.

3. "i.Process | Steel – RHF" APC system

In this section, "i.Process | Steel – RHF" APC system technology is described, focusing on the optimization problems solved by the two MPC modules and on tuning procedures.

3.1. APC Architecture Description

Figure 8 schematically describes "i.Process | Steel – RHF" APC system architecture. At each control instant *k*, a Supervisory Control and Data Acquisition (*SCADA*) system provides updated data; note the location of the developed billets temperature estimation virtual sensor. A *Data Conditioning & Decoupling Selector* (DC&DS) block receives updated process variables values (Figure 8, right side, *u(k-1), d(k), y(k), b(k)*). Furthermore, DC&DS block exploits other information, i.e. local control loops conditions (Figure 8, *Plant Signals & Parameters*), status information related to the selected process variables (Figure 8, right side, *u-d-y-b Status*), and control requirements related to MVs manipulation (Figure 8, right side, *Decoupling Matrix*) [19,20]. The status information related to the selected process variables defines which process variables have to be included in the MPC problem at each control instant. The *Decoupling Matrix* defines which MVs have to be moved by MPC strategy for the satisfaction of the specifications related to the zCVs. Table 5 shows the initial *Decoupling Matrix* provided to DC&DS block. For example, considering the zone 6 temperature, this zCVs is tied to all fuel flow rates (see Table 3); for this reason, without any expedients, all fuel flow rates could be moved by MPC system for the satisfaction of the zone 6 temperature specifications. According to some additional specifications that have been defined for the considered case study, only zone 6 fuel flow rate should be moved for the cited zCV. With regard to this aspect, observe the second row of Table 5 (related to zone 6 temperature): the "0" value indicates the MVs to be inhibited for its control [20].

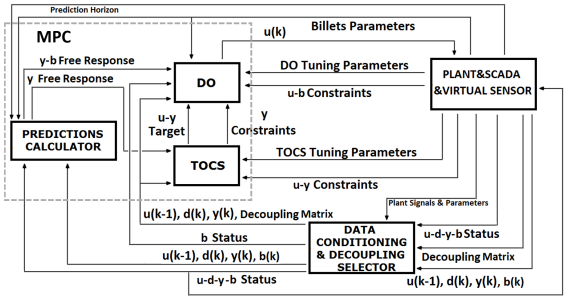

Figure 8. "i.Process | Steel – RHF" architecture.

Table 5: zCVs-MVs models: initial decoupling matrix

Acronym	$Fuel_6$	$Fuel_5$	$Fuel_4$	$Fuel_3$	$Fuel_2$	$Fuel_1$

Based on the received information, DC&DS block performs different operations and checks, e.g. bad detection and data conditioning. From this phase, the possibly modified process variables values (Figure 8, left side, *u(k-1), d(k), y(k), b(k)*), the final status values for process variables (Figure 8, left side, *u-d-y-b Status*) and the final *Decoupling Matrix* (Figure 8, left side, *Decoupling Matrix*) resulted. The final *Decoupling Matrix* contains information about process variables final status values and about MVs action inhibition specifications [20].

MPC block, based on all the detailed parameters and information, computes the current optimal input to be applied to the plant (Figure 8, *u(k)*). *MPC* block has been based on a two-layer scheme formulated on linear models, constituted by an upper layer module called as Targets Optimizing and Constraints Softening (Figure 8, *TOCS*) and by a lower layer module called as Dynamic Optimizer (Figure 8, *DO*). A *Predictions Calculator* module cooperates with the two-layer scheme.

3.2. Two-Layer MPC Scheme

The MPC scheme exploits process variables predictions on a prediction horizon H_p. The zCVs and bCVs *free response* ([13]) is computed by *Predictions Calculator* module (Figure 8, *y Free Response* and *y-b Free Response*).

At the upper layer of the proposed MPC scheme, *TOCS* module solves a Linear Programming (LP) problem. A linear cost function is minimized, subject to linear constraints:

$$V_{TOCS}(k) = {c_u}^T \cdot \Delta\hat{u}_{TOCS}(k) + {\rho_{y_TOCS}}^T \cdot \varepsilon_{y_TOCS}(k) \qquad (4)$$

subject to

$$\begin{aligned} &\text{i. } lb_{du_TOCS} \le \Delta\hat{u}_{TOCS}(k) \le ub_{du_TOCS} \\ &\text{ii. } lb_{u_TOCS} \le \hat{u}_{TOCS}(k) \le ub_{u_TOCS} \\ &\text{iii. } lb_{y_TOCS} - \gamma_{lby_TOCS} \cdot \varepsilon_{y_TOCS}(k) \le \hat{y}_{TOCS}(k) \le \\ &\qquad \le ub_{y_TOCS} + \gamma_{uby_TOCS} \cdot \varepsilon_{y_TOCS}(k) \\ &\text{iv. } \varepsilon_{y_TOCS}(k) \ge 0 \end{aligned} \qquad (5)$$

In the LP problem represented by (4)-(5), minimization or maximization directions for MVs can be preferred through c_u term that multiplies the MVs steady-state move $\Delta\hat{u}_{TOCS}(k)$. $\Delta\hat{u}_{TOCS}(k)$ is constrained by lb_{du_TOCS} and ub_{du_TOCS}; with regard to MVs, the steady-state value $\hat{u}_{TOCS}(k)$ is constrained by lb_{u_TOCS} and ub_{u_TOCS}. zCVs steady state value $\hat{y}_{TOCS}(k)$ is constrained by lb_{y_TOCS} and ub_{y_TOCS}. *TOCS* MVs constraints have been considered as *hard* constraints: they can never be violated and their feasibility has been suitably imposed. On the other hand, *TOCS* zCVs constraints have been considered as *soft* constraints: they can be violated thanks to the slack variables contained in $\varepsilon_{y_TOCS}(k)$ term. This term contains two nonnegative slack variables for each zCV; it has been introduced in (4) through ρ_{y_TOCS} term and in (5) through γ_{lby_TOCS} and γ_{uby_TOCS} terms.

In Figure 8, lb_{du_TOCS}, ub_{du_TOCS}, lb_{u_TOCS}, ub_{u_TOCS} are among *u-y Constraints*. c_u, ρ_{y_TOCS}, γ_{lby_TOCS} and γ_{uby_TOCS} terms are among *TOCS Tuning Parameters*.

TOCS module formulation exploits zCVs-MVs/DVs models and predictions at the end of the prediction horizon H_p. Solving its LP problem, *TOCS* module computes MVs and CVs steady-state

targets (Figure 8, *u- y Target*) and zCVs constraints (Figure 8, *y Constraints*); these terms are provided to *DO* module [19,20].

At the lower layer of the proposed MPC scheme, *DO* module computes the H_u (H_u is denoted as control horizon [13]) optimal MVs moves, solving a Quadratic Programming (QP) problem. These moves are included in a $\Delta\hat{u}(k+M_i|k)$ vector ($i = 1,\dots,H_u$). M_i represent the MVs movement instant ($M_1 = 0$; $M_i < H_p$) [12]. A quadratic cost function is minimized, subject to linear constraints:

$$\begin{aligned} V_{DO}(k) = & \sum_{i=0}^{H_p-1} \|\hat{u}(k+i|k) - u_t(k+i|k)\|^2_{\mathcal{S}(i)} + \\ & + \sum_{i=1}^{H_p} \|\hat{y}(k+i|k) - y_t(k+i|k)\|^2_{Q(i)} + \\ & + \sum_{i=1}^{H_u} \|\Delta\hat{u}(k+M_i|k)\|^2_{\mathcal{R}(i)} + \left\|\varepsilon_y(k)\right\|^2_{\rho_y} + \\ & + \sum_{j=1}^{m_b} \left\|\hat{b}_j(k+e_j|k) - lb_{b_DO_j}\right\|^2_{T_j} + \|\varepsilon_b(k)\|^2_{\rho_b} \end{aligned} \quad (6)$$

subject to

$$\begin{aligned} & \text{i. } lb_{du_DO}(i) \le \Delta\hat{u}(k+M_i|k) \le ub_{du_DO}(i), i = 1,\dots,H_u \\ & \text{ii. } lb_{u_DO}(i) \le \hat{u}(k+M_i|k) \le ub_{u_DO}(i), i = 1,\dots,H_u \\ & \text{iii. } lb_{y_DO}(i) - \gamma_{lby_DO}(i)\cdot\varepsilon_y(k) \le \hat{y}(k+i|k) \le \\ & \qquad \le ub_{y_DO}(i) + \gamma_{uby_DO}(i)\cdot\varepsilon_y(k), i = 1,\dots,H_p \\ & \text{iv. } lb_{b_DO_j} - \gamma_{lbb_DO_j}\cdot\varepsilon_{b_j}(k) \le \hat{b}_j(k+e_j|k) \le \\ & \qquad \le ub_{b_DO_j} + \gamma_{ubb_DO_j}\cdot\varepsilon_{b_j}(k), j = 1,\dots,m_b \\ & \text{v. } \varepsilon_y(k) \ge 0;\ \varepsilon_b(k) \ge 0 \end{aligned} \quad (7)$$

In the QP problem represented by (6)-(7), tracking errors over H_p between MVs and zCVs reference trajectories ($u_t(k+i|k)$ and $y_t(k+i|k)$) and the related predicted values ($\hat{u}(k+i|k)$ and $\hat{y}(k+i|k)$) are weighted by $\mathcal{S}(i)$ and $Q(i)$ positive semidefinite matrices. $\hat{u}(k+i|k)$ and $\hat{y}(k+i|k)$ are constrained by lb_{u_DO}, ub_{u_DO}, lb_{y_DO} and ub_{y_DO}. *DO* MVs moves are weighted in (6) by positive definite matrices $\mathcal{R}(i)$ and they are constrained in (7) by lb_{du_DO} and ub_{du_DO}. *DO* MVs constraints have been considered as *hard* constraints: they can never be violated and their feasibility has been suitably imposed. On the other hand, *DO* zCVs constraints have been considered as *soft* constraints: they can be violated thanks to the slack variables contained in $\varepsilon_y(k)$ term. This term contains a nonnegative slack variable for each zCV; it has been introduced in (6) through ρ_y term and in (7) through γ_{lby_DO} and γ_{uby_DO} terms.

In Figure 8, lb_{du_DO}, ub_{du_DO}, lb_{u_DO}, ub_{u_DO} are among *u-b Constraints*. lb_{y_DO} and ub_{y_DO} terms are among *y Constraints*. $\mathcal{S}(i)$, $Q(i)$, $\mathcal{R}(i)$, ρ_y, γ_{lby_DO} and γ_{uby_DO} terms are among *DO Tuning Parameters*.

Taking into account the just described terms related to MVs and zCVs, and exploiting zCVs-MVs/DVs models, a first "i.Process | Steel – RHF" APC system control mode has been formulated, denoted *zones* APC mode.

Including terms related to bCVs in the *DO* QP problem represented by (6)-(7), a second control mode for "i.Process | Steel – RHF" APC system has been obtained, denoted *adaptive* APC mode. It constitutes the main control mode and it exploits, besides zCVs-MVs/DVs models, also first principles bCVs LPV model and billets virtual sensor information. In this way, an adaptive two-layer MPC strategy has been formulated. In (6)-(7), for the generic billet that lies on the j ($j = 1 \dots m_b$) furnace place at the current control instant k, its predicted furnace discharge instant is computed (e_j) taking into account the furnace production rate. The billets temperature predictions ($\hat{b}_j(k+e_j|k)$) at the related furnace discharge instants e_j ($j = 1 \dots m_b$) are constrained in (7) by $lb_{b_DO_j}$ and $ub_{b_DO_j}$ (Figure 8, *u-b Constraints*). These constraints have been considered as *soft* constraints: they can be violated thanks to the slack variables contained in $\varepsilon_b(k)$ term. This term contains a nonnegative slack variable for each bCV; it has been introduced in (6) through ρ_b term and in (7) through γ_{lbb_DO} and γ_{ubb_DO} terms (Figure 8, *DO Tuning Parameters*). Tracking option of desired values ($lb_{b_DO_j}$) for bCVs has been included in *DO* cost function (6), exploiting T_j nonnegative scalars.

3.3. Tuning Details

Tailored tuning methods have been developed for optimizing the controller performances in the two defined control modes. The control moves are computed by the APC system once a minute, according to the formulated process model.

With regard to the choice of the prediction horizon H_p, it varies based on the control mode that has to be exploited. Consequently, also the control horizon H_u and the MVs movement instants M_i are adapted. For example, in the simulation example that will be proposed in Section 4, the *adaptive* APC mode will be activated. In this case, a furnace movement time equal to about 95 [s] is assumed, which corresponds, for the present case study, to a furnace production rate equal to about 85 [t/h]. Accordingly, in order to guarantee the predicted reaching of the furnace outlet to the billet closer to the furnace inlet, a prediction horizon H_p of 216 [min] is set. In a parametric way, the control horizon H_u is set equal to 44 moves suitably spaced over the prediction horizon H_p.

In *TOCS* module formulation, the elements of c_u have been set as positive, in order to prefer, within the process variables defined constraints, minimization directions for fuel flow rates and stoichiometric ratios. Furthermore, ρ_{y_TOCS}, γ_{lby_TOCS} and γ_{uby_TOCS} terms have been set in order to guarantee the desired priority on constraints satisfaction. For example, constraints related to smoke-exchanger temperature are more important than those related to zones temperature: the related ρ_{y_TOCS},γ_{lby_TOCS} and γ_{uby_TOCS} terms have been set accordingly to this specification, taking into account also the magnitude of the involved process variables.

In *DO* module formulation, common tuning aspects between the two formulated control modes have been proposed. The priority of the soft constraints terms (if these constraints are included in the controller setup) ρ_y, γ_{lby_DO} and γ_{uby_DO} is guaranteed; furthermore, zCVs constraints are always present within *DO* module formulation. The option of tracking desired reference trajectories related to MVs is another similar tuning aspect, together with the need to take into account the magnitude of MVs moves. In *DO* module formulation related to the *adaptive* APC mode, billets (tracking and/or constraints satisfaction) specifications can be considered; optimal trade-offs between control and energy efficiency specifications must be ensured.

4. Simulation Results

This section proposes some simulation results related to "i.Process | Steel – RHF" APC system. In particular, a simulation scenario where the *adaptive* APC mode is activated is described.

4.1. A Simulated Scenario

The *adaptive* APC mode performances are shown through a simulated scenario: the zCVs-MVs/DVs plant model exploits the identified zCVs-MVs/DVs model and no measurement noise is assumed. The plant model for simulating the relationships between billets temperature and furnace zones temperature is based on the developed billets temperature nonlinear model that is exploited by the virtual sensor.

At the initial control instant of the proposed simulation, the *adaptive* APC mode is requested to be activated. The virtual sensor estimation gives reliable results and bCVs (billets temperature) can be included in the control problem. The zCVs reported in Table 1, the temperature differences between the bCVs model inputs and all fuel flow rates represent the other process variables that are considered in the simulation. The other MVs and all DVs are considered constant, so not influencing the proposed simulation scenario. Constraints related to zCVs and fuel flow rates have been reported in Tables 6-7. The temperature differences between the bCVs model inputs are constrained so as to ensure an increasing monotonicity of the temperatures along the furnace. As mentioned in Subsection 3.3, the furnace production rate is equal to about 85 [*t/h*]; the temperature of the 136 billets that initially lie within the furnace is in the range 20 [°*C*] - 1140 [°*C*], while the billets that will enter the furnace during the simulation are characterized by a temperature of about 550 [°*C*]. The *Rolling Phase* specifications require that the billets temperature in the rolling area must be in the range 1030 [°*C*] - 1045 [°*C*]. This specification can be converted in a temperature range of about 1051 [°*C*] - 1066 [°*C*] at the furnace outlet. The "i.Process | Steel – RHF" *adaptive* APC mode ensures that the billets temperature detected by the optical pyrometer in the rolling mill area converges towards the minimum required temperature (1030 [°*C*]), as can be observed in Figure 9.

Table 6: Simulation scenario: zCVs constraints

The cooperative action between *TOCS* and *DO* modules, that exploits virtual sensor information and billets temperature LPV model ensures a coordinated management of the furnace zones temperature (Figure 10) that is directly tied to the manipulation of the fuel flow rates (Figures 11-16). Consequently, a more profitable plant configuration is guaranteed that, at the same time, respect all the defined specifications. For example, in Figure 10, note the increasing monotonicity of the temperatures along the furnace.

5. Field Results

The study and design phases of the project related to the considered process began in January 2015 and ended in May 2015. The APC system has been installed on the considered Italian steel plant in early June 2015, substituting the local PID temperature controllers managed by plant operators. This section shows a plant scenario under the control of "i.Process | Steel – RHF" APC system and some results about the obtained fuel specific consumption.

5.1. A Plant Scenario

Figures 17-26 show a field scenario where "i.Process | Steel – RHF" APC system is active. A four hours period is taken into account. Figure 17 shows the bCVs trends: virtual sensor estimation and optical pyrometer measurements are depicted, together with the defined constraints in the rolling mill area (1125 [°*C*] - 1065 [°*C*]). The furnace production rate is shown in Figure 18, while the billets furnace inlet temperature is shown in Figure 19. The inputs related to the bCVs model are depicted in Figure 20 and Figures 21-26 show the fuel flow rates. Note the fuel flow rates trends (Figures 21-26, blue line) and the defined constraints (Figures 21-26, red lines). All MVs and DVs are considered in the control problem, together with some zCVs (furnace zones temperatures, temperature differences between adjacent furnace zones, smoke-exchanger temperature) and the bCVs (some process variables have not been shown for brevity). Examples of the constraints defined for the furnace zones and smoke-exchanger temperatures have been reported in Table 8. The 136 billets that are already present in the furnace at the beginning of the considered plant scenario are characterized by temperatures in the range 55 [°*C*] – 1100 [°*C*] and the inlet temperature of the billets that will enter the furnace is in the range 40 [°*C*] – 105 [°*C*] (Figure 19). Besides the inlet temperature of the billets, also the furnace production rate is not constant (Figure 18): it assumes a

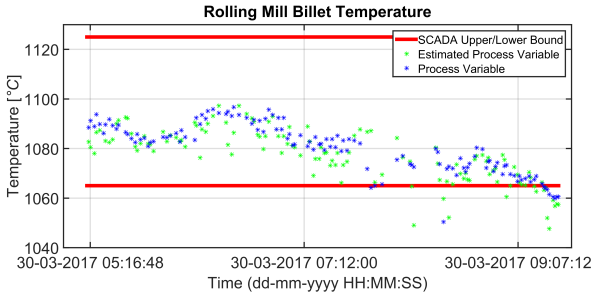

Figure 17. Field results: bCVs trends.

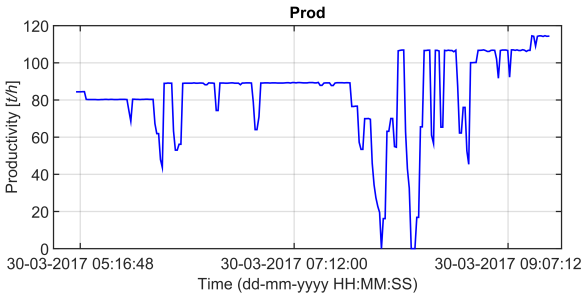

Figure 18. Field results: furnace production rate trends.

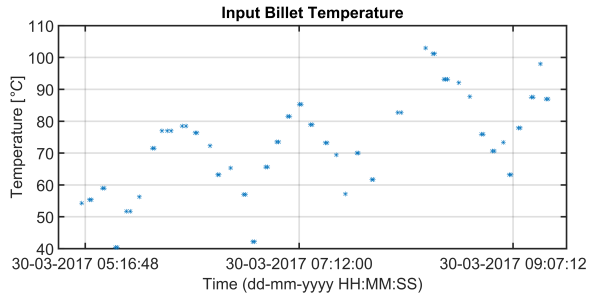

Figure 19. Field results: billets furnace inlet temperatures trends.

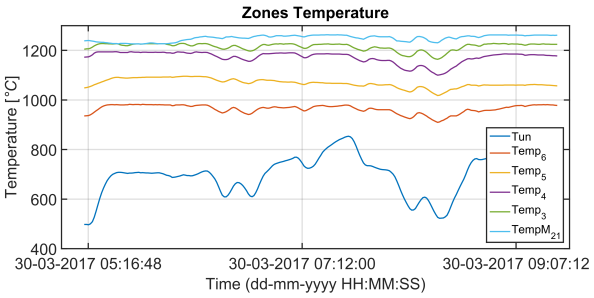

Figure 20. Field results: bCVs model inputs trends.

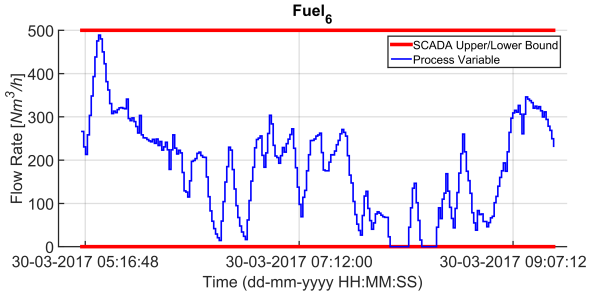

Figure 21. Field results: *Fuel*$_6$ trends.

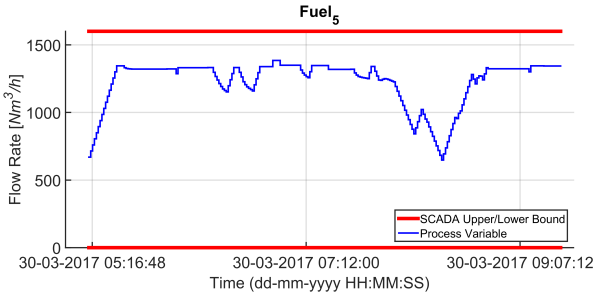

Figure 22. Field results: *Fuel*$_5$ trends.

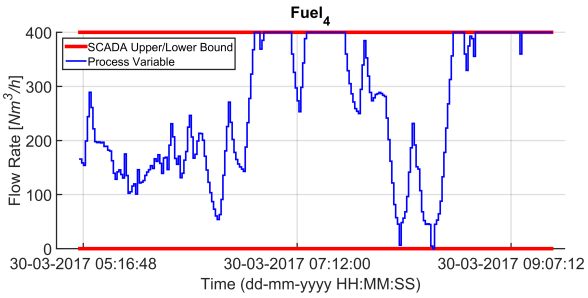

Figure 23. Field results: *Fuel*$_4$ trends.

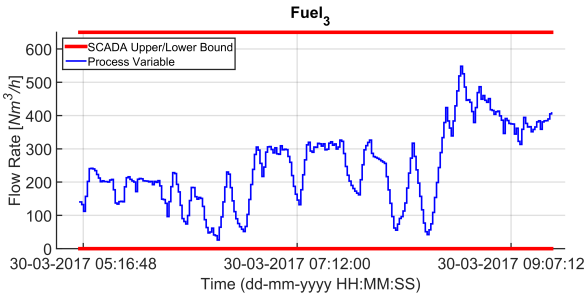

Figure 24. Field results: *Fuel*$_3$ trends.

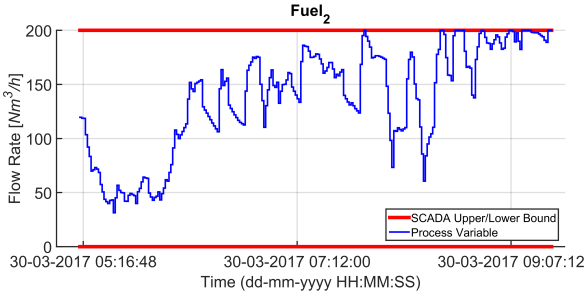

Figure 25. Field results: *Fuel*$_2$ trends.

maximum value that is equal to about 120 [*t/h*]. The furnace pressure and the air pressure (DVs) are about 0.9 [*mmH2O*] and 84 [*mbar*], respectively.

As can be observed in Figure 17, "i.Process | Steel – RHF" APC system ensures that the billets temperature detected by the optical pyrometer in the rolling mill area converges towards the minimum required temperature (1065 [°*C*]). The *TOCS-DO* cooperative action, exploiting virtual sensor information and billets temperature LPV model, ensures a profitable management of the furnace zones temperature (Figure 20) that is directly tied to the manipulation of the fuel flow rates (Figures 21-26). All the imposed constraints and specifications are fulfilled, despite a not constant furnace production rate (Figure 18) and a not constant billets furnace inlet temperature (Figure 19). The benefits deriving from the proposed multivariable predictive approach led the controller to conduct the plant to very profitable operating regions, but, at the same time, all the control specifications are satisfied. As it will be shown in the next subsection, an energy efficiency

Table 8: Field scenario: zCVs constraints

improvement has been obtained with the developed APC system, with respect to the previous furnace conduction.

5.2. Fuel Specific Consumption Results

The installation of the developed controller on the real industrial plant has guaranteed an improvement on the process control that has directly influenced the fuel specific consumption. The fuel specific consumption, that takes into account the fuel usage and the furnace production rate, represents a very significant indicator for the evaluation of the energy efficiency performances of "i.Process | Steel – RHF". A project baseline for the fuel specific consumption has been computed, that varies with the furnace hot charge.

Figure 27 shows a subpart of a synoptic of the developed GUI: the daily fuel specific consumption ([Sm^3/t]) is depicted. The "i.Process | Steel – RHF" APC system daily specific consumption

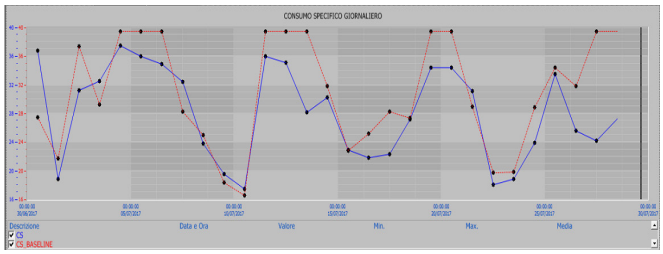

Figure 27. Field results: comparison between daily baseline and daily official specific consumption.

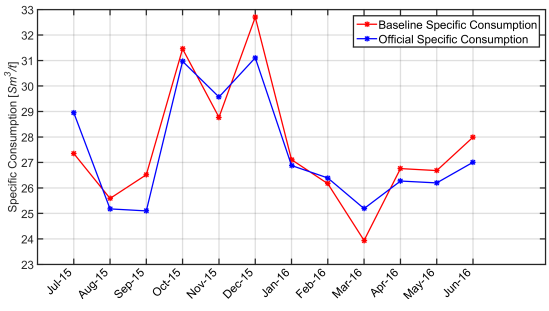

Figure 28. Field results: comparison between monthly baseline and monthly official specific consumption.

related to July 2017 is represented though a blue line, while the defined daily project baseline is shown through a red line. This page can be online monitored by plant operators; in this way, they can practically evaluate the controller performances from an energy efficiency point of view.

Figure 28 shows the monthly fuel specific consumption ([Sm^3/t]) related to the first year of "i.Process | Steel – RHF" APC system performances. The specific consumption is represented though a blue line, while the defined project baseline is shown through a red line. After about two years from the installation of "i.Process | Steel – RHF" APC system on the described pusher type billets reheating furnace, about 2 [%] reduction of the fuel specific consumption with respect to the defined project baseline has been achieved. A controller service factor about equal to 95 [%] has been observed.

6. Conclusions

In this paper, an Advanced Process Control system aimed at optimizing a pusher type billets reheating furnace located in an Italian steel plant has been proposed. The control system, denoted "i.Process | Steel – RHF", has been based on two-layer Model Predictive Control strategy formulated with linear models. The two-layer predictive controller also interacts with additional functional blocks.

Simulation and field results have demonstrated significant performances improvements guaranteed by the developed controller with respect to the previous control system based on Proportional Integral Derivative (PID) temperature controllers managed by plant operators. Thanks to the multivariable predictive approach, "i.Process | Steel – RHF" recognizes efficient operating zones and allows the process reaching them; in this way, process control and energy efficiency improvements have been guaranteed. Specifications related to the billets reheating are fulfilled and, at the same time, optimal configurations of the manipulated variables are reached. The developed control method has been patented [16].

After about two years from the installation of "i.Process | Steel – RHF" APC system on the described pusher type billets reheating furnace, about 2 [%] reduction of the fuel specific consumption with respect to the defined project baseline has been obtained, together with a controller service factor about equal to 95 [%].

ABSTRACT

Microelectromechanical Systems (MEMS) are devices made up of several electrical and mechanical components. They consist of mechanical functions (sensing, thermal, inertial) and electrical functions (switching, decision making) on a single chip made by microfabrication methods. These chips exhibit combined properties of the two functions. The size of system has characteristic dimensions less than 1mm but more than 1μm. The configuration of these components determine the final deliverables of the switch. MEMS can be designed to meet user requirements on any level from microbiological application such as biomedical transducers or tissue engineering, to mechanical systems such as microfluidic diagnoses or chemical fuel cells. The low cost, small mass and minimal power consumption of the MEMS makes it possible to readily integrate to any kind of system in any environment. MEMS are faster, better and cheaper. They offer excellent electrical performances. MEMS working at Radio frequencies are RF MEMS. RF-MEMS switches find huge market in the modern telecommunication networks, biological, automobiles, satellites and defense systems because of their lower power consumptions at relatively higher frequencies and better electrical performances. But the reliability is the major hurdle in the fate of RF MEMS switches. Reliability mainly arises due to the presence of residual stresses, charging current, fatigue and creep and contact degradation. The presence of residual stresses in switches the S-Parameters of the switches are affected badly and the residual stress affects the final planarity of the fabricated structure. Design and simulation of an RF-MEMS switch is proposed considering the residual stresses in both on and off state. The operating frequency band is being optimized and the best possible feasible fabrication technique for the proposed switch design is being analyzed. S-Parameters are calculated and a comparison for the switches with stress and without stress is performed in FEM based HFSS software.

1. Introduction

MEMS technologies are faster, better, and cheaper. They have reduced size and weight, means fewer power consumption and there are lower component counts. MEMS promises superior electrical performances and are built with low cost [1]. They can be produced at massive level. They have advanced functionality and superior reliability. They have new functionality and better system capability.

The ultimate goals of MEMS are to reduce size, cost, weight, power consumptions by increasing the performance of existing macroscopic devices [2]. To make devices never before possible at macroscopic scale. Easy to integrate into systems or modify. They have Small thermal constant and they can be highly resistant to vibration, shock and radiation. MEMS are Microelectro-mechanical system in which the device and structures are fabricated at micro levels using the micro level fabrication process [3]. It is basically an integrated micro devices or systems

combining electrical and mechanical components fabricated using Integrated Circuit (IC) compatible processing technique and it range from micron to millimeter [4].

MEMS structures can be a simple system with all static elements or large complicated system with some parts moving and some static elements. Chief concept of MEMS is that there is at least one moving element [5]. MEMS most important elements are micro sensors and micro actuators. Basically these are the transducers that convert electrical to mechanical and vice versa. Micro actuators and micro sensors are widely used in the integrated circuits industry due to low per device cost and other benefits.

2. Radio Frequency MEMS

2.1. Maintaining the Integrity of the Specifications

MEMS can be classified into different types depending upon their mean of actuation. These include acoustic MEMS, optical MEMS and Radio Frequency MEMS (RF-MEMS) [6]. RF MEMS operate in the electromagnetic wave frequencies in the 3 kHz - 300 GHz range [7-8]. This frequency provides maximized efficiency in the circuitry and ability to flow through paths containing insulating material, such as the dielectric insulators of capacitors.

3. Microfabrication of RF-MEMS Switch and Thermal Induction of Residual Stress

In Trento Italy; at ITC-IRST research center; using gold electroplating a process was carried out on micro bridge and RF MEMS; which resulted in obtaining suspended microstructure by photoresist of 3micrometer thickness [2].

3.1. RF Switch Surface (RFS) Micromachining

The RF-MEMS STS whose design is considered in this study is realized through the gold electrodeposition microfabrication

1. At 975C in a wet atmosphere silicon wafer came in contact with thermal oxide of 1000nm thickness and then with nitrogen. Resistors and lines are formed by polysilicon while pattern is formed by dry ditching
2. At 718C silicon oxide is placed with wafer and after that applied to photolithography.
3. A metal is spitted for signal line generation. The general temperature is 400C but when LPCVD oxide is deposited temperature rises by 30C. The area which was free from photoresist; for electrical contact oxide is removed by dry etching then wafer is washed.
4. Wafer is now wet etched and floating metal (Cr/Au) layer is evaporated. 3micrometer thickness of Cr is placed between oxide layer and Au.
5. At 52C electroplating of gold on seed layer is done.
6. At 52C; gold layer is used for strengthen the structure. It's left for 30 minutes a 190C. Finally at 200C structure comes in contact with plasma oxygen for removing extra layers.

3.2. Mechanisms contributing to Residual Stress Induction

For residual stress following steps are made: -

1. Stress In this process; Cr-Au PVD is deposited on photoresist. Seed layer is used for ensuring adhesive property of Au. Although due to thermal instability chromium oxide is formed along with residual stress.
2. Gradient happens due to difference in thermal coefficient of gold and seed layer. Seed layer expands more rapidly and results in tensile residual stress. However micro beams get deformed due to release of Au.
3. Oxygen Plasma ashing helps in avoiding sticking but temperature changes too rapidly forming residual stress. Temperature is maintained at 200C so that Au reached even the narrow paths.

4. Design of RF-MEMS Symmetric Toggle Switches

4.1. On State without stress

The simply designed switch in HFSS is the extension of work presented in "Simulating the Electromagnetic Effects of Thermally Induced Residual Stresses in RF-MEMS Switches". This RF-MEMS switch is designed in FEM based HFSS software. In this switch, (Figure 1) simply a suspended type bridge was designed over the coplanar waveguide transmission line, the design of the switch is as follow. The gold material was assigned to the bridge, this switch was designed just to ensure the results validity with the already present standards in the literature.

Similarly, when the stress was induced in the switch, (Figure 2) the central bridge of the switch deflected upward, which ultimately affected the overall electromagnetic performance of the switch.

4.2. Identify the Headings Design of a simple RF-MEMS Switch in off-state without stress

When the switch is in the off state, the bridge deflects downwards at the center just over the dielectric layer of signal CPW (Figure 3). The side conductors of the CPW are grounded while the signal pass through the central conductor of CPW

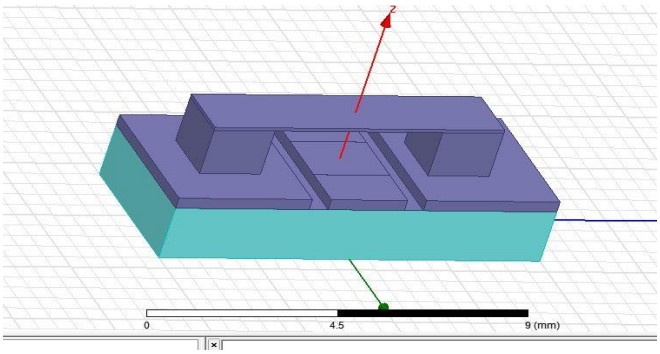

Figure 1: Design of a simple RF-MEMS Switch without stress and excitation

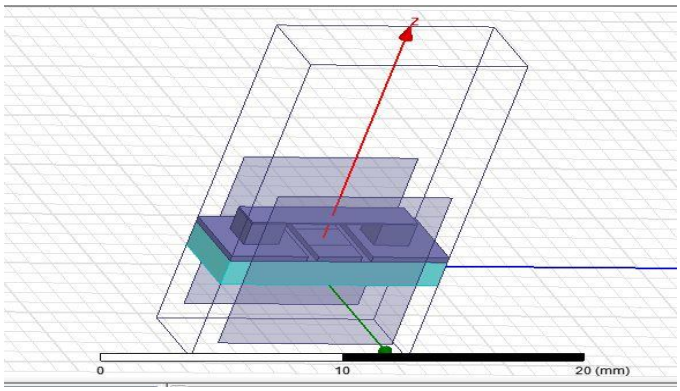

Figure 2: Design of a simple RF-MEMS Switch without stress and excitation and air box

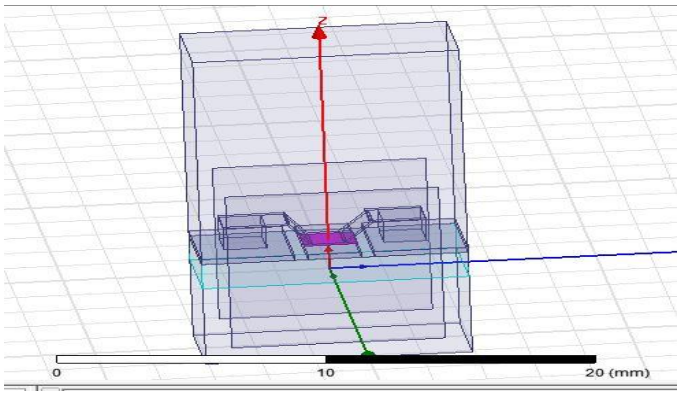

Figure 3: Design of a simple RF-MEMS Switch in off-state without stress

The excitation of the switch is applied through waveport excitations and it is shown in the figure as red shaded side conducting sheet. The waveport connects the central conductor of the CPW with the side conductors, and are used to supply the signal through the switch (Figure 4).

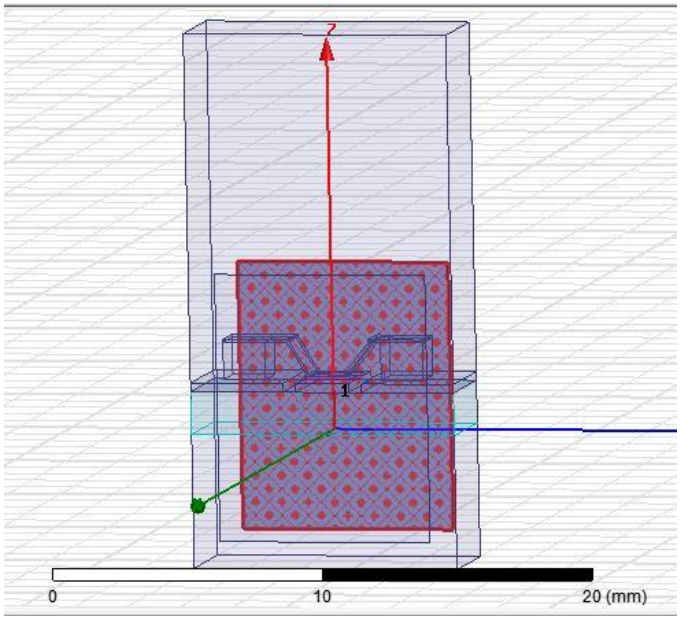

Figure 4: Design of a simple RF-MEMS Switch in off-state without stress with the excitation shown

5. Comparison of simply designed switch with the results already present in literature

5.1. Return Loss of On State

Per the Rangra at Kamal and Jacobi [9], the reflection coefficient of the switch during the on state must be always less than -10 dB, which ensures better switch performances. When we designed a simple switch RF-MEMS switch in HFSS software, the result of reflection coefficient was ascending curve along the X-axis. The result of this switch (Figure 5) is exactly in accordance with existing standards of literature [10, 11] which ensures that our approach was accurate.

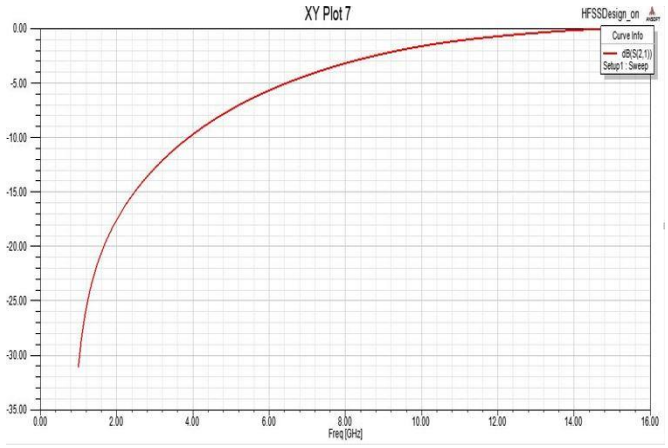

Figure 5: Simulated results of on state return loss

As shown in the graph above, at lower frequencies like between 1.5 GHz to 4 GHz, the reflection was good. Later as the operating frequency range increased, the switch moved to lesser matching or the reflection of the power from the switch increased. From the frequency range of 8GHz to 16 GHz, the switch was not in ideal conditions i.e. the refection increased at higher frequencies. The result already stated in literature (Figure 6) also showed the same trend as shown below [10, 12]. The reflection increased as we move on to higher frequencies.

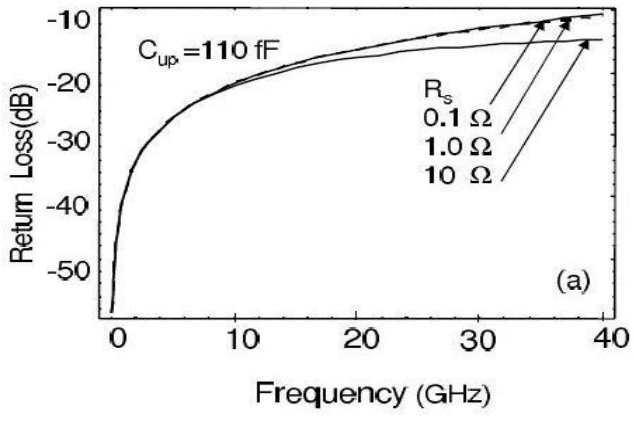

Figure 6: Literature results of on state return loss [2, 10]

5.2. Insertion loss of on state

Ideally, the switch during the on state should have minimum insertion loss, i.e. the value of transmission coefficient should be zero or close to zero. The results which we obtained for a simple RF-MEMS switch in the on state are shown in the graph below, here as the frequency increases, the value of transmission coefficient increases, which predicts lower or poor insertion loss (Figure 7). Ideally the transmission coefficient should be zero as state hypothetically in the literature (Figure 8), but in actual it is not possible to have perfectly zero transmission coefficient [2, 10]. But as the frequency increases, overall there is a decline in the value of transmission coefficient. Which means that at higher frequencies the transmission reduces [13].

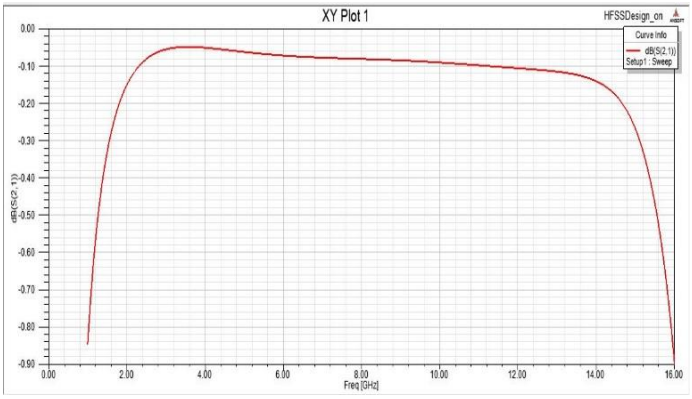

Figure 7: Simulated results of on state Insertion loss

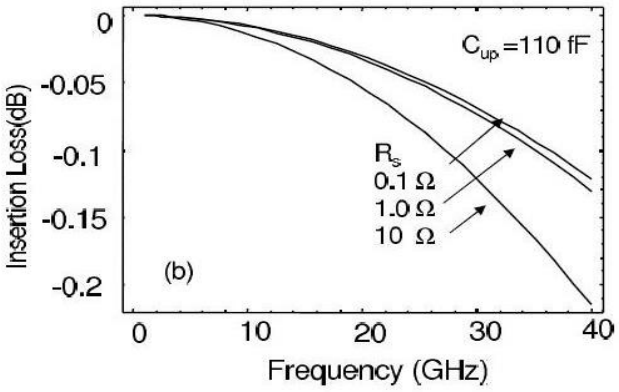

Figure 8: Literature results of on state Insertion loss [2, 10]

5.3. Return Loss of Off-State

Now when the switch is in off-state, the value of reflection coefficient should be greater than -10 dB because at the off-state, switch is not in the working conditions. Maximum power which is incident to the switch gets reflected back [14]. So as the literature predicts, if the operating frequency is taken on X-axis and the transmission coefficients along Y-axis, then the graph should be an ascending curve. So our results of a simple RF-MEMS switch (Figure 9) were found to be exactly similar to those, which were mentioned in the literature (Figure 10). The slight difference in the curve can be explained in terms of the operating frequency ranges i.e. in our graph the limit was between 0 GHz to 16 GHz, whereas in the standard the limit was between 0 GHz to 40 GHz.

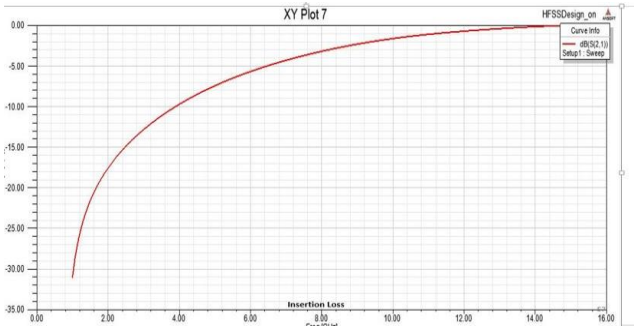

Figure 9: Simulated results of off state return Lost

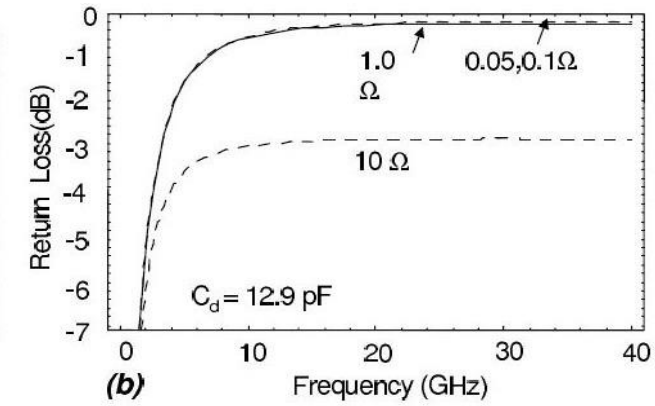

Figure 10: Literature results of off state return Loss. [2, 10]

5.4. Result of Isolation in Off State

According to the set standards, the isolation should be maximum in the off-state. Due to higher isolation, the leakage of power during off-state is minimum [15]. The S_{21} represents the isolation in the off-state. So, here the curve according to the set standard is descending curve, followed by a dip at nearly 15 GHz, and then a gradually ascending curve, after 15 GHz. So, our results of the simple RF-MEMS switch (Figure 11) are in accordance with the pre-defined standards (Figure 12). So, maximum isolation was observed at off-state nearly at 15 GHz.

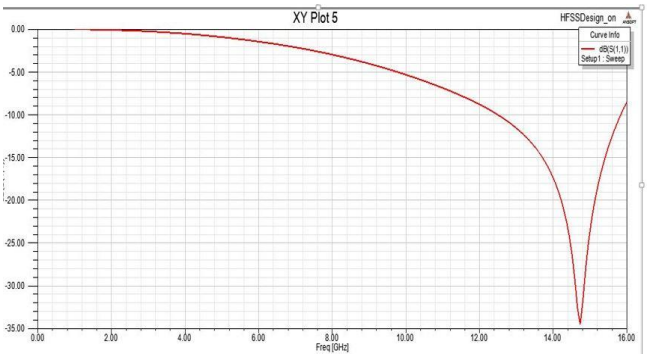

Figure 11: Simulated results of off state Isolation

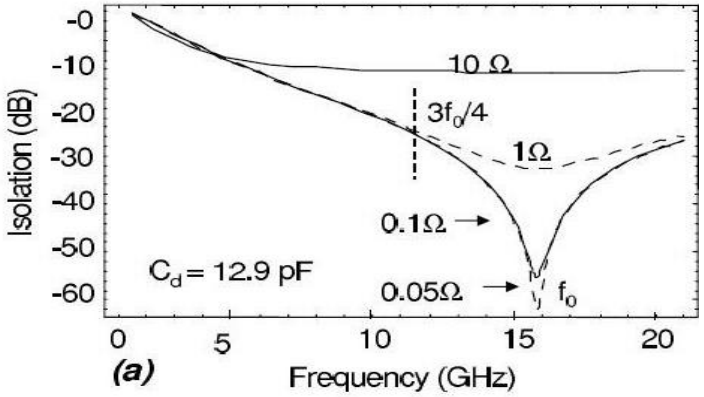

Figure 12: Literature results of off state Isolation. [2, 10]

6. ANALYSIS OF RESULTS

6.1. Without stress

The value of return loss S_{11} in the RF-MEMS switch without stress, shows excellent results. The value of reflection coefficients is much less than -10 dB, which indicates the best matching in the sense of transmitting power. The value of S_{11} lies between -58 dB to -42 dB, which indicates the very less power is reflected. As the value is much lesser than -10 dB, so we can say that switch is having excellent matching or very good reflection loss [16, 17]. Ideally any operating switch must have, reflection loss less than -10 dB, then it is assumed that the electrical performance of the switch is better. If any switch does not have this predefined reflection coefficient, then it means that maximum of the power is wasted or reflected back rather than transmitting through the switch [18]. So, the designed switch in HFSS software, which was already fabricated showed excellent electrical performance in the on state. Their electromagnetic performances are good for the frequency ranges between 2GHz to 16 GHz but, are best between the frequencies of 1.5 GHz to 8GHz. Similarly, the value of transmission coefficient is near 0dB, which means that overall transmission through the switch is excellent. The logic behind stating this is that as we know 0dB is actually equal to 1. It means when the value of transmission is or close to 0dB then the transmission through the switch will be excellent. Again, the operating frequency ranges between 1GHz to 8GHz. Because as the frequency increases, the transmission decreases.

6.2. With Stress

Due to the generation of residual stresses in the RF-MEMS switch, the reflection of the switch is badly affected. The reason is that due to generation of stresses, the bridge deflects upward at the center. Now the air gap between the top central bridge and the ground dielectric increases [19, 20, 21]. Due to rise in air gap the up-state capacitance of the switch is decreased now. As we already explained in the design aspect of RF-MEMS switch that S-parameters are dependent upon the up and down state capacitances. Reflection is dependent upon the up-state capacitances while the isolation is affected by down state capacitances [22, 23, 24]. The results of return loss with stress are shown in Figure 13.

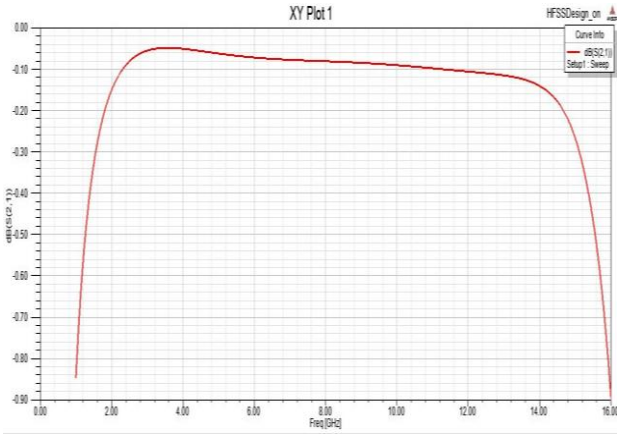

Figure 13: Simulated results of return loss with stress

Similarly, the results for insertion loss are shown in Figure 14.

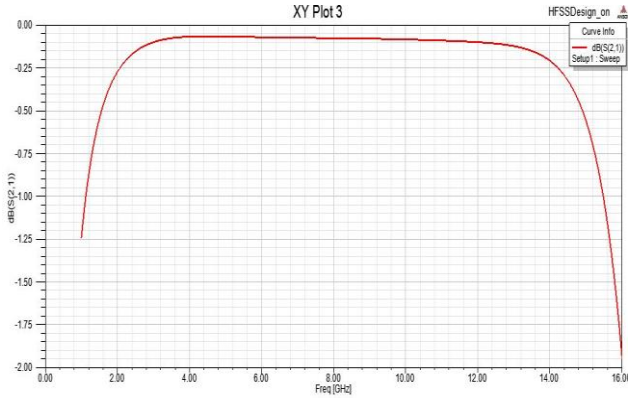

Figure 14: Simulated results of insertion loss with stress

7. Conclusion

So we can conclude that switch was operating efficiently when there were no residual stresses but due to the generation of residual stresses, not only the final planetary of the switch was affected but also the electrical performance of the switch was affected badly. Future work can be done on how to reduce the residual stresses in RF-MEMS switch during microfabrication when the temperature is changed abruptly. Some research can also be produced in the domain of improving reliability of RF-MEMS switches by reducing the effects of charging of dielectric, the effects of creep and fatigue along with the contact degradation. So that it may help to improve the overall efficiency of the RF-MEMS switch.

ABSTRACT

This paper proposes extended-range high-speed control for an IPMSM drive system. A simple real-time tuning flux-weakening control algorithm is proposed and implemented to control an IPMSM drive system in a wide variable speed range, from 3 r/min up to 2700 r/min. This flux-weakening control algorithm does not require any motor parameters and only needs simple mathematical computations. The proposed drive system adjusts the angle between the d-axis and q-axis current to reach flux-weakening control. In addition, a multiple sampling predictive controller is implemented to enhance the dynamic responses of the proposed drive system, which yields improved overall transient responses, superior load responses, and good tracking responses. A detailed analysis of the proposed drive system's stability is discussed as well. A 32-bit digital signal processor, TMS-320F-28335, is used to execute the predictive controller and the flux-weakening control algorithm for the IPMSM drive system. Experimental results can validate the theoretical analysis.

1. Introduction

Use of the interior permanent magnet synchronous motor (IPMSM) has greatly increased due to its advantages over other motors, which include high efficiency, wide operating speed range, high power density, and robustness. The IPMSM has two different torque components: electromagnetic torque and reluctance torque. By strategically controlling the d-axis and q-axis currents, the maximum torque per ampere (MTPA) control or flux weakening control can be achieved at different operating speeds.

This paper is an extension of work originally presented in 2017 IEEE 26th International Symposium on Industrial Electronics (ISIE) Conference [1]. Several researchers have proposed different flux-weakening control methods to increase the high-speed operating range of an IPMSM. For example, Bolognani et al. proposed an adaptive flux-weakening controller for an IPMSM drive system. The adaptation algorithm, however, is very complicated to implement [2]. Zhu et al. implemented a flux-weakening control for a PMSM drive system [3]. The proposed method accounted for resistance voltage drop and inverter nonlinearities. This method, however, is only suitable for a PMSM drive system, not an IPMSM drive system. Kwon et al. proposed a flux-weakening control for an IPMSM with quasi-six-step operation [4]. A feed-forward path, which consists of a one dimensional look-up table, is required. Pan et al. proposed a robust flux-weakening control strategy for a surface-mounted permanent-magnet motor drive [5]. A closed-form solution of the maximum available torque-producing current is generated to achieve both fast responses and real-time tuning flux-weakening control. This method, however, is suitable for a surface mounted PMSM but not an IPMSM. Uddin et al. proposed an on-line parameter-estimation-based high-speed control of an IPMSM drive. The method of estimating the d-axis inductance, q-axis inductance, and external load, however, is very complicated [6]. Pan et al. proposed a voltage-constraint-based flux-weakening control of an IPMSM drive system [7]. The method requires a d-axis current command and q-axis current command generator, which is rather complicated. Jung et al. proposed a hexagonal voltage limit to increase the voltage amplitude and to improve the DC-link voltage utilization in an IPMSM drive system. A torque control method based on the voltage angle was investigated. The idea is very good; however, the voltage vector selection algorithm is very complicated [8]. Chaithongsuk et al. proposed an optimal design of permanent magnet motors to improve flux-weakening performance in variable speed drives. It was shown that a salient-pole motor performed better at high speeds than a non-salient pole motor [9]. Kim proposed a novel magnetic flux-weakening method for permanent magnet synchronous motors in electric vehicles [10]. By adjusting the air gap between the stator and rotor, an increased maximum speed and maximum output power could be

*Corresponding Author: Tian-Hua Liu, Mobile: +886-22737-6108
Email: Liu@mail.ntust.edu.tw

obtained. This method, however, requires very complicated motor modifications. Jevremovic et al. proposed a simple robust integral controller to achieve field weakening control for a PMSM [11]. Harnefors et al. used a systematic analysis to determine the parameters of the current and speed combined controller to reduce the complicity [12]. To improve the performance of field weakening control, Wallmark et al. [13] and Bedetti et al. implemented a voltage regulator to achieve flux-weakening control for an electric vehicle and an IPMSM [14].

In this paper, a simple flux-weakening control method is proposed. This method has several advantages over previously proposed flux-weakening methods [1]-[14]. For one thing, the parameters of the IPMSM are not required. Also, the computations for the flux-weakening control are very simple. For example, only square root, multiplication, and addition are used. In addition, to achieve fast responses and good load disturbance rejection capability from the low-speed range to high-speed range, a predictive controller is employed. In contrast to previous research on predictive control [15]-[16], this paper proposes a multiple-loop predictive control motor drive system. The sampling interval of the current-loop is 100 , and the sampling interval of the speed-loop is 1 ms. Due to the quick current regulation, the proposed system has better performance than previous one-loop predictive control drive systems [15]-[16]. Unlike previous methods of flux-weakening control without using motor parameters [2], [16]-[17], the proposed method provides a simple control algorithm for voltage regulation without an adaptive controller or PI controller. To the authors' best knowledge, the proposed flux-weakening control method is a new idea. In addition, the idea of the predictive controller applied in the simplified flux-weakening control of an IPMSM is original.

2. Predictive Controller Design

The theory of predictive control was first proposed in the 1970s, and predictive controllers have been used in chemical and steel processing for more than 40 years. Recently, predictive control has been applied in motor drives due to the fast computation ability of the digital signal processor (DSP). The design objective of a predictive controller is to compute the control input u to optimize the future dynamic behavior for the output y of the plant. This optimization must be performed within a limited time window. Several researchers have investigated predictive control for motor drives. For example, Pacas et al. proposed a predictive direct torque control for PMSMs, which yielded a faster torque settling time than the classic field-oriented control with a PI controller [15]. Bolognani et al. investigated the design and implementation of model predictive control for electric motor drives [16]. Fuentes et al. implemented a predictive speed control for a two-mass system driven by a PMSM. Their proposed method allowed feedback of all the mechanical and electrical state variables into a single control input and provided a higher bandwidth closed-loop speed control [18]. Siami et al. proposed an improved predictive current control using prediction error correction for PMSMs [19]. Tarczewski et al. implemented a constrained state feedback speed control for PMSMs, which calculated the boundaries of control signals to provide permissible values of the future state variables [20].

In this paper, a systematic predictive controller design is proposed for an IPMSM drive system. The proposed predictive controllers, including a predictive current controller and a predictive speed controller, provide a multiple sampling rate control system and a closed-loop speed-control block diagram that are different from the predictive controllers proposed in previously published papers [15]-[16], [18]-[20].

The design of a predictive controller requires the following. First, a model of the uncontrolled drive system is developed. Next, a cost function that represents the desired behavior of the system is defined. Finally, a predictive controller for the motor drive system is derived.

2.1. Predictive Current Controller

The state-variable equation of an IPMSM can be expressed as

$$\frac{d}{dt}\begin{bmatrix} i_d \\ i_q \end{bmatrix} = \begin{bmatrix} \frac{-r_s}{L_d} & 0 \\ 0 & \frac{-r_s}{L_q} \end{bmatrix}\begin{bmatrix} i_d \\ i_q \end{bmatrix} + \begin{bmatrix} \frac{1}{L_d} & 0 \\ 0 & \frac{1}{L_q} \end{bmatrix}\begin{bmatrix} v_d \\ v_q \end{bmatrix} + \begin{bmatrix} \frac{1}{L_d} & 0 \\ 0 & \frac{1}{L_q} \end{bmatrix}\begin{bmatrix} \omega_{re} L_q i_q \\ -\omega_{re}(L_d i_d + \lambda_m) \end{bmatrix} \quad (1)$$

Where d/dt is the differential operator, i_d and i_q are the d-axis and q-axis stator currents, r_s is the stator resistance, v_d and v_q are the d-axis and q-axis stator voltages, L_d and L_q are the d-axis and q-axis self-inductances, λ_m is the permanent magnetic flux leakage, and ω_{re} is the electric motor speed.

After transferring the continuous-time domain into the discrete-time domain, (1) can be expressed as

$$i_d(z) = \frac{\beta_{cd} z^{-1}}{1-\alpha_{cd} z^{-1}}(v_d - \omega_{re} L_q i_q) \quad (2)$$

and

$$i_q(z) = \frac{\beta_{cq} z^{-1}}{1-\alpha_{cq} z^{-1}}(v_q - \omega_{re}(L_d i_d + \lambda_m)) \quad (3)$$

The related parameters in (2) and (3) are shown as follows

$$\alpha_{cd} = e^{\frac{-r_s T_{cur}}{L_d}} \quad (4a)$$

$$\beta_{cd} = \frac{1}{r_s}(1-\alpha_{cd}) \quad (4b)$$

$$\alpha_{cq} = e^{\frac{-r_s T_{cur}}{L_q}} \quad (4c)$$

$$\beta_{cq} = \frac{1}{r_s}(1-\alpha_{cq}) \quad (4d)$$

where T_{cur} is the sampling interval of current-loop control. Because the sampling time interval is shorter than the time constant of the stator current-loop, Euler approximation can be used here. As a result, the parameters shown in (4a)-(4d) can be described as follows

$$\alpha_{cd} \approx 1-\frac{r_s T_{cur}}{L_d} \tag{5a}$$

$$\beta_{cd} \approx \frac{r_s T_{cur}}{L_d} \tag{5b}$$

$$\alpha_{cq} \approx 1-\frac{r_s T_{cur}}{L_q} \tag{5c}$$

and

$$\beta_{cq} \approx \frac{r_s T_{cur}}{L_q} \tag{5d}$$

Then (2) and (3) can be rewritten as follows

$$X_{cur}(k+1) = A_{cur}X_{cur}(k) + B_{cur}U_{cur}(k) + B_{cur}F_{cur}(k) \tag{6}$$

and

$$X_{cur}(k) = \begin{bmatrix} i_d(k) & i_q(k) \end{bmatrix}^T \tag{7a}$$

$$F_{cur}(k) = \begin{bmatrix} \omega_{re}(k)L_q i_q(k) & -\omega_{re}(k)\left(L_d i_d(k) + \lambda_m\right) \end{bmatrix}^T \tag{7b}$$

$$U_{cur}(k) = \begin{bmatrix} v_d(k) & v_q(k) \end{bmatrix}^T \tag{7c}$$

$$A_{cur} = \begin{bmatrix} 1-\frac{r_s T_{cur}}{L_d} & 0 \\ 0 & 1-\frac{r_s T_{cur}}{L_q} \end{bmatrix} \tag{7d}$$

$$B_{cur} = \begin{bmatrix} \frac{T_{cur}}{L_d} & 0 \\ 0 & \frac{T_{cur}}{L_q} \end{bmatrix} \tag{7e}$$

According to (6), the (k+1)-th predictive current can be expressed as

$$\hat{X}_{cur}(k+1) = A_{cur}X_{cur}(k) + B_{cur}\left(U_{cur}(k) + F_{cur}(k)\right) \tag{8}$$

The performance index of the d-axis current control is defined as

$$J_{cur} = \left[\hat{i}_d(k+1) - i_d^*(k+1)\right]^2 \tag{9}$$

The following equation is the partial differential of (9) manipulated to equal zero.

$$\frac{\partial J_{cur_d}}{\partial U_d} = \frac{\partial\left(\hat{i}_d(k+1) - i_d^*(k+1)\right)^2}{\partial v_d(k)} = 0 \tag{10}$$

Substituting (8) into (10), we can obtain

$$\frac{\partial J_{cur_d}}{\partial v_d(k)} = \frac{\partial\left((1-\frac{T_{cur}r_s}{L_d})i_d(k) + (\frac{T_{cur}}{L_d})\left(v_d(k) + \omega_{re}(k)L_q i_q(k)\right) - i_d^*(k+1)\right)^2}{\partial v_d(k)}$$
$$= 2\left((1-\frac{T_{cur}r_s}{L_d})i_d(k) + (\frac{T_{cur}}{L_d})\left(v_d(k) + \omega_{re}(k)L_q i_q(k)\right) - i_d^*(k+1)\right)\left(\frac{T_{cur}}{L_d}\right) = 0 \tag{11}$$

After arranging the above, it is not difficult to obtain

$$\left((1-\frac{T_{cur}r_s}{L_d})i_d(k) + (\frac{T_{cur}}{L_d})\left(v_d(k) + \omega_{re}(k)L_q i_q(k)\right) - i_d^*(k+1)\right)$$
$$= \left((\frac{L_d}{T_{cur}} - r_s)i_d(k) + \left(v_d(k) + \omega_{re}(k)L_q i_q(k)\right) - \frac{L_d}{T_{cur}}i_d^*(k+1)\right) = 0 \tag{12}$$

Finally, from (12), we can derive the d-axis voltage command as

$$v_d^*(k) = r_s i_d(k) + \frac{L_d}{T_{cur}}\left(i_d^*(k+1) - i_d(k)\right) - \omega_{re}(k)L_q i_q(k) \tag{13}$$

By using the same principle, we can derive the q-axis voltage command as follows

$$v_q^*(k) = r_s i_q(k) + \frac{L_q}{T_{cur}}\left(i_q^*(k+1) - i_q(k)\right) + \omega_{re}(k)\left(L_d i_d(k) + \lambda_m\right) \tag{14}$$

2.2. Predictive Speed Controller

The differential equation of an IPMSM is

$$\frac{d}{dt}\omega_{rm} = \frac{1}{J_m}(T_e - T_L - B_m\omega_{rm}) \tag{15}$$

Where J_m ω_{rm} is the mechanical speed, $\frac{d}{dt}$ is the differential operator, T_e is the total output torque, T_L is the external load, and B_m is the viscous frictional coefficient.

According to (15) and assuming $T_L = 0$, the speed can be expressed as

$$\omega_{rm}(s) = \frac{T_e}{J_m s + B_m} \tag{16}$$

By converting (16) into discrete form, one can obtain

$$\begin{aligned}\omega_{rm}(k+1) &= e^{-(B_m/J_m)T_{sp}}\omega_{rm}(k) + \frac{1}{B_m}(1-e^{-(B_m/J_m)T_{sp}})T_e(k) \\ &= a_1\omega_{rm}(k) + b_1 u(k)\end{aligned} \tag{17}$$

and

$$a_1 = e^{-(B_m/J_m)T_{sp}} \tag{18}$$

$$b_1 = \frac{1}{B_m}(1-e^{-(B_m/J_m)T_{sp}}) \tag{19}$$

$$u(k) = T_e(k) \tag{20}$$

where T_{sp} is the sampling interval of the speed-loop control. Next, by setting the predictive window as 1 and the predictive control as 1, the performance index J_{sp} is expressed as

$$\begin{aligned}J_{sp} = \sum_{i=1}^{1}\left[P(z)\hat{\omega}_{rm}^{pre}(k+i) - P(1)\omega_{rm}^{*}(k+i)\right]^2 \\ + \rho\sum_{i=1}^{1}\left[Q(z)u(k+i-1)\right]^2\end{aligned} \tag{21}$$

where $\hat{\omega}_{rm}^{pre}$ is the predictive speed, $P(z)$ and $Q(z)$ are polynomials of z, and ρ is the weighting factor. By computing $\frac{\partial J_{sp}}{\partial u(k)}$, one can obtain

$$\begin{aligned}\frac{\partial J_{sp}}{\partial u(k)} = 2\frac{P(z)\partial\hat{\omega}_{rm}^{pre}(k+1)}{\partial u(k)}[P(z)\hat{\omega}_{rm}^{pre}(k+1) \\ - P(1)\omega_{rm}^{*}(k+1)] + 2\rho Q^2(z)u(k) = 0\end{aligned} \tag{22}$$

Substituting (17) into (22), one can derive

$$\begin{aligned}P(z)b_1\left(P(z)\left(b_1u(k) + a_1\omega_{rm}(k)\right) - P(1)\omega_{rm}^{*}(k+1)\right) \\ + \rho Q^2(z)u(k) = 0\end{aligned} \tag{23}$$

The speed command at (k+1)th sampling interval can be expressed as a fixed command Sp and then can be defined as

$$\omega_{rm}^{*}(k+1) = S_p \tag{24}$$

By substituting (24) into (23), we can obtain

$$(P(z)b_1)^2u(k) + \rho Q^2(z)u(k) = P(z)b_1P(1)S_p - P^2(z)b_1a_1\omega_{rm}(k) \tag{25}$$

The control input can be expressed as

$$u(k) = R(MS_p - N\omega_{rm}(k)) \tag{26}$$

and

$$M = \frac{P(1)}{b_1P(z)} \tag{27}$$

$$N = \frac{a_1}{b_1} \tag{28}$$

$$R = \frac{1}{1 + \frac{\rho}{b_1^2}(\frac{Q(z)}{P(z)})^2} \tag{29}$$

The predictive controller is shown in Figure 1. The block diagram of the predictive control includes a command gradation M(z), a controller R(z), a plant P(z), and a feedback gain N. The structure is very similar to a standard control system; however, the parameters can be systematically derived. Unlike [16], this paper outlines a systematic closed-loop block diagram of the predictive controller, which provides a clear feedback control structure for an IPMSM drive system. This is an unprecedented method of predictive control and also a major aspect of this paper.

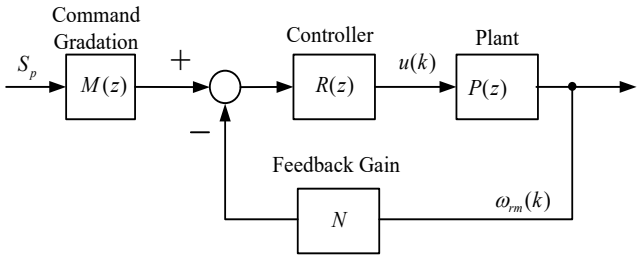

Figure 1 Block diagram of predictive speed-loop control.

2.3. Stability Analysis of the Proposed Drive System

The desired torque command of an IPMSM can be generated by the following equation

$$\frac{d}{dt}\omega_{rm}^{*} = \frac{1}{J_m}(T_e^{*} - T_L - B_m\omega_{rm}^{*}) \tag{30}$$

In the real world, there are parameter variations of the IPMSM and the external load measuring error. To compensate for that, the total equivalent load with uncertainty can be expressed as T_D, which includes the summation of the external load, the load influenced

by the parameter variations, torque tracking errors of both MTPA and flux weakening, and external load measuring error. Then (30) can be rewritten as

$$\frac{d}{dt}\omega_{rm}^{*} = \frac{-B_m}{J_m}\omega_{rm}^{*} + \frac{1}{J_m}T_e - T_{\mathrm{D}} \tag{31}$$

and

$$T_D = \frac{1}{J_m}(\Delta J_m \frac{d}{dt}\omega_{rm}^{*} + \Delta B_m \omega_{rm}^{*} + T_L) \tag{32}$$

where T_D is the total load disturbance, ΔJ_m is the variation of inertia, and ΔB_m is the variation of the viscous coefficient. Next, the dynamic speed equation of the IPMSM is

$$\frac{d}{dt}\omega_{rm} = \frac{-B_m}{J_m}\omega_{rm} + \frac{1}{J_m}T_e - \hat{T}_D \tag{33}$$

Where $\hat{T}_D$ is the estimated total load disturbance, which includes the influence of the motor parameters' uncertainty. The tuning step of the θ_{adv}, which is 0.18°, creates a varying torque that is less than 1% of the output torque T_e. As a result, the influence of the uncertainty is bound. The speed error, which is the difference between the speed command and the real speed, can be expressed as

$$e = \omega_{rm}^{*} - \omega_{rm} \tag{34}$$

Taking the differential of the speed error, one can obtain

$$\dot{e} = \frac{d}{dt}(\omega_{rm}^{*} - \omega_{rm}) = \frac{d}{dt}\omega_{rm}^{*} - \frac{d}{dt}\omega_{rm} \tag{35}$$

Subtituting (31) and (33) into (35), one can obtain

$$\begin{aligned}\dot{e} &= (\frac{-B_m}{J_m}\omega_{rm}^{*} + \frac{1}{J_m}T_e - T_{\mathrm{D}}) - (\frac{-B_m}{J_m}\omega_{rm} + \frac{1}{J_m}T_e - \hat{T}_D) \\ &= \frac{-B_m}{J_m}(\omega_{rm}^{*} - \omega_{rm}) - \tilde{T}_D\end{aligned} \tag{36}$$

We can define the load estimation error as $\tilde{T}_D = T_D - \hat{T}_D$. Assuming the external load changes slowly when compared to the quick responses of the speed control loop, it is possible to let $\dot{T}_D = 0$. The differential of the estimated load, therefore, can be expressed as follows

$$\dot{\tilde{T}}_D = -\dot{\hat{T}}_D \tag{37}$$

Define a lyapunov function as

$$V = e^2 + \frac{1}{k_1}(\tilde{T}_D)^2 \tag{38}$$

where k_1 is a weighting factor. By taking the derivative of the Lyapunov function, one can derive

$$\dot{V} = 2e\dot{e} + \frac{2}{k_1}\tilde{T}_D\dot{\tilde{T}}_D \tag{39}$$

Substituting (36) into (39), one can obtain

$$\dot{V} = 2e(\frac{-B_m}{J_m}e - \tilde{T}_D) + \frac{2}{k_1}\tilde{T}_D\dot{\tilde{T}}_D = 2\frac{-B_m}{J_m}e^2 + 2\tilde{T}_D(\frac{1}{k_1}\dot{\tilde{T}}_D - e) \tag{40}$$

According to (40), it is possible to choose an adaption law as follows

$$\dot{\hat{T}}_D = k_1 e \tag{41}$$

Substituting (41) into (40), we can obtain the differential of Lyapunov function as

$$\dot{V} = 2\frac{-B_m}{J_m}e^2 \le 0 \tag{42}$$

From (42), the differential of Lyapunov function is negative semi-definite. Then, Barbalet lemma can be applied. First, a function y_1 is set, which is equal to $\dot{V}$. Next, by integrating the y_1, we can obtain

$$\int_0^{\infty} y_1(\tau)d\tau = V(0) - V(\infty) < \infty \tag{43}$$

From (43), we can conclude

$$\lim_{t\to\infty} y_1(t) = 0 \tag{44}$$

According to (44), the speed error converges to zero as time approaches infinity.

3. MTPA Control and Flux-weakening Control

3.1. Basic Principle

The dynamic d-q axis voltages of an IPMSM can be expressed as

$$v_d = r_s i_d + L_d\frac{di_d}{dt} - \omega_{re}L_q i_q \tag{45}$$

and

$$v_q = r_s i_q + L_q \frac{di_q}{dt} - \omega_{re} L_d i_d + \omega_{re} \lambda_m \quad (46)$$

The total output torque of an IPMSM is

$$T_e = \frac{3}{2}\frac{P}{2}[\lambda_m + (L_d - L_q)\ i_d]\ i_q$$
$$= \frac{3}{2}\frac{P}{2}[\lambda_m i_q - (L_d - L_q)\sqrt{I_s^{\ 2} - i_q^{\ 2}}]i_q \quad (47)$$

Where I_s is the current amplitude. Two major control algorithms can be derived from (47) and can be used to adjust the torque of an IPMSM: field-oriented control and MTPA control. The field-oriented control sets a fixed d-axis current and adjusts the q-axis current to obtain linear proportional torque. The MTPA control sets a variable d-axis current, which is related to the q-axis current, to obtain maximum torque/ampere. The method can generate more torque than field-oriented control. However, the method creates a nonlinear relationship between the torque and q-axis current [3], which is a disadvantage of MTPA control. While it is a fact that MTPA's influence on torque linearity is a drawback, achieving maximum torque is a greater benefit that outweighs that disadvantage. The issue will be researched further by the authors of this paper.

Taking $\frac{d}{di_q} T_e = 0$ and substituting it into (47), we can obtain

$$\frac{3}{2}\frac{P}{2}[\lambda_m + (L_d - L_q)i_d - (L_d - L_q)i_q^2 \frac{1}{i_d}] = 0 \quad (48)$$

From (48), the d-axis current under MTPA control can be expressed as

$$i_d|_{MTPA} = \frac{-\lambda_m}{2(L_d - L_q)} - \sqrt{\frac{\lambda_m^2}{4(L_d - L_q)^2} + i_q^2} \quad (49)$$

The advance angle under MTPA control is

$$\theta_{MTPA} = \sin^{-1}\frac{i_d\ |_{MTPA}}{I_s} \quad (50)$$

and the current amplitude I_s is expressed as

$$I_s = \sqrt{i_d^2 + i_q^2} \quad (51)$$

In steady-state and neglecting the voltage drops of the resistance and inductance, it is not difficult to obtain

$$v_d = -\omega_{re} L_q i_q \quad (52)$$

and

$$v_q = \omega_{re} L_d i_d + \omega_{re} \lambda_m \quad (53)$$

The voltage amplitude is

$$v_s = \sqrt{(v_d^2 + v_q^2)} \quad (54)$$

If V_{om} is the maximum voltage amplitude, the voltage constraint can be shown as

$$(L_q i_q)^2 + (L_d i_d + \lambda_m)^2 = (\frac{V_{om}}{\omega_{re}})^2 \quad (55)$$

The maximum current amplitude I_{sm} can be expressed as

$$i_d^2 + i_q^2 = I_{sm}^2 \quad (56)$$

From (56), it is easy to obtain

$$i_q = \sqrt{I_{sm}^2 - i_d^2} \quad (57)$$

Combining (49), (54), and (57), the constraints of the IPMSM drive system can be obtained. The drive system operates under MTPA control when the motor speed is below the rated base-speed. After the drive system reaches its base speed, there are two constraints: the current constraint of the maximum amplitude, I_{sm}, and the voltage constraint of the maximum voltage amplitude, V_{om}. However, the $\frac{V_{om}}{\omega_{re}}$ is decreased as the motor speed increases, which is shown in Figure 2. As a result, the axes of the ellipse are reduced when the motor speed increases. When $\omega_{re} < \omega_{base}$, the motor operates under MTPA control, which is indicated as OCBA in Figure 2. When $\omega_{base} < \omega_{re} < \omega_c$, the motor operates in region II, in which the motor can operate either under MTPA control or flux-weakening control. If $i_d < i_d\ |_{MTPA}$, MTPA control is used; on the other hand, if $i_d > i_d\ |_{MTPA}$, flux-weakening control is used. When $\omega_c < \omega_{re}$, the motor operates in region III, in which only flux-weakening control can be used.

3.2. Proposed Real-Time Flux-weakening Control

In the real world, flux-weakening control is very complicated because it requires λ_m, L_d, and L_q, which are very difficult to measure [15].

To solve this difficulty, in this paper, a real-time tuning flux-weakening control is proposed. First, the voltage amplitude of the IPMSM, v_s, which is expressed in (54) is compared to the maximum voltage amplitude, V_{om}. The θ_{FW}, which is shown in Figure 3(a), is tuned as follows

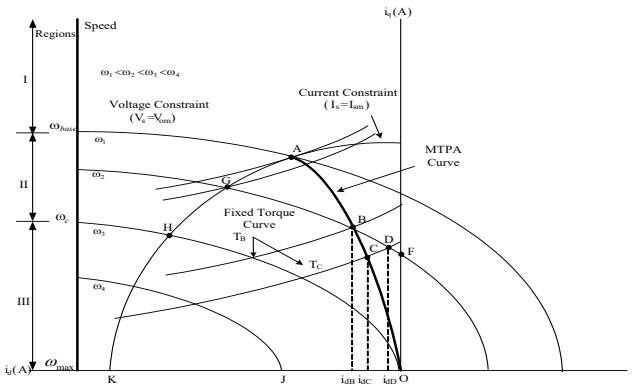

Figure 2 Operating regions of an IPMSM.

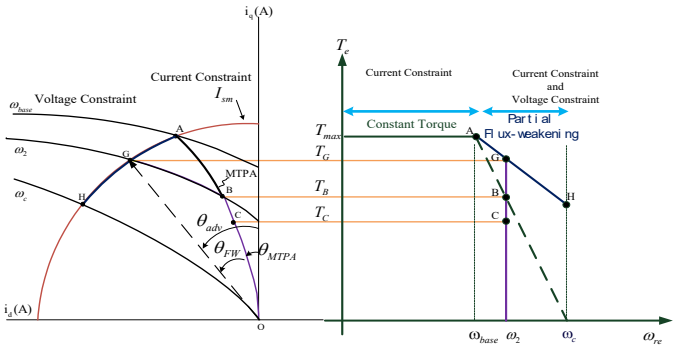
$$\theta_{FW}(\mathrm{k}) = \theta_{FW}(\mathrm{k}-1) + \alpha \cdot \mathrm{sgn}(v_s - V_{om}) \tag{58}$$



and

$$\mathrm{sgn}\ (v_s - V_{om}) = -1 \qquad \text{when } (v_s - V_{om}) < 0 \tag{59a}$$

and

$$\mathrm{sgn}\ (v_s - V_{om}) = 1 \qquad \text{when } (v_s - V_{om}) \geq 0 \tag{59b}$$

where α is the step size of the real-time tuning control. By using (58), (59a), and (59b), the θ_{FW} can be real-time tuned, as shown in Figure 3(a)(b). Finally, a block diagram of the proposed real-time tuning flux-weakening control is shown in Figure 4. First, the amplitude of the desired output voltage v_s is calculated. Next, the desired output voltage, v_s, is compared with the measured output voltage, V_{om}. After that, (58) is used to compute the $\theta_{FW}(k)$. Similar to previous research [2]-[5], [21], the proposed flux-weakening control method reduces the torque at high-speed operating range, and is not guaranteed the torque linearity. This is a common characteristic of flux-weakening control algorithms. However, the stability analysis of the whole drive system is discussed in the previous section of this paper.

(a) (b)

Figure 3 Operating curves and torque-speed curves of an IPMSM
(a) operating curves (b) torque-speed curves.

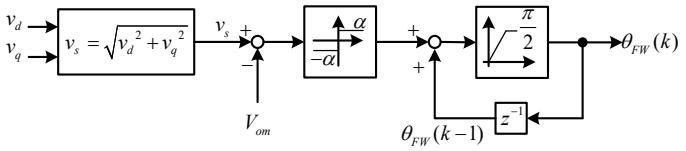


Figure 4 Block diagram of the proposed flux-weakening control.

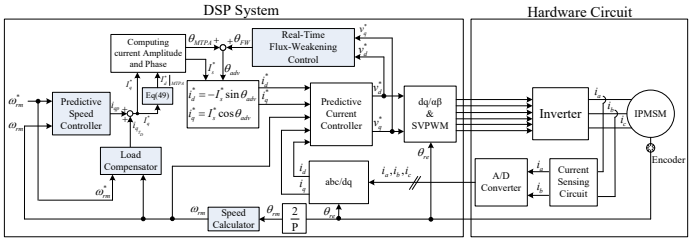
4. Implementation

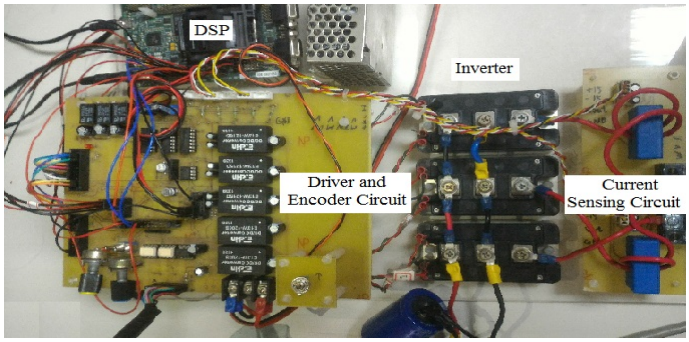
The implemented IPMSM drive system is shown in Figure 5(a) and (b). Figure 5(a) is a block diagram of the proposed IPMSM. The system consists of two main parts: the DSP system and the hardware circuit. The DSP system uses a TMS-320F-28335, which is a 32-bit, digital signal processor manufactured by Texas Instruments. The sampling interval of the current-loop control is 100 μs, while that of the speed-loop control is 1 ms.

Taking the MTPA operating region as an example, the controller works as follows. First, as shown in Figure 5(a) and based on the predictive speed controller, after the speed command is input and the motor speed is feedback, the q-axis current control i_{qp} is computed. Second, the load compensator compensates for the load disturbance $\hat{T}_D$ and then generates the compensation current $i_{q_{\hat{T}_D}}$. Then the total q-axis current command, which is the summation of the i_{qp} and $i_{q_{\hat{T}_D}}$, is computed and expressed as i_q^*. Next, the d-axis current is computed through (49) when the motor is operating in the MTPA region. After that, the advance phase angle θ_{MTPA} and stator current amplitude I_s^* are computed by using (50) and (51). Finally, the flux-weakening is obtained by adding θ_{FW}.



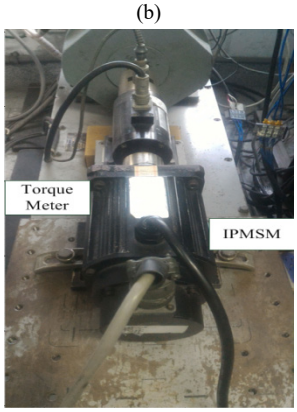
By using the MTPA table and the real-time tuning flux-weakening control, the advance angle of the current can be obtained. After that, the d-axis current command i_d^* and the q-axis current command i_q^* are calculated. A current regulated control and a space vector PWM modulation are executed. Finally, the switching states of the inverter are determined and output. A closed-loop system can thus be obtained. A DC motor is coupled with the IPMSM. The motor parameters are: $L_q = 31\ mH$, $L_d = 15\ mH$, $\lambda_m = 0.227\ v.\mathrm{sec}/rad$, and $R_s = 1.9\ \Omega$. The motor is 4-pole, 1-HP, and rated at 1500 r/min.

Figure 5(b) shows a photograph of the entire hardware circuit, which includes a DSP, gate drivers, peripheral devices, current sensing circuits, and an inverter. Figure 5(c) shows a photograph of the implemented IPMSM drive system, including an IPMSM and a dynamometer.



5. Experimental Results

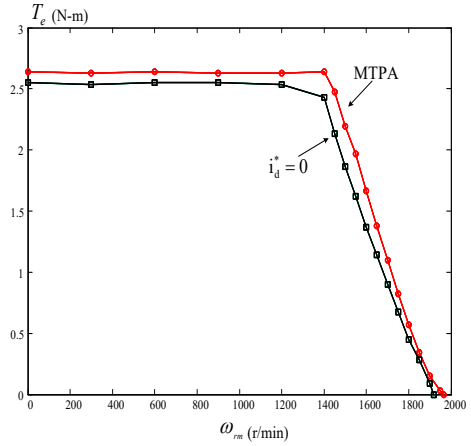
The performance of the proposed flux-weakening control for an IPMSM drive system was evaluated according to experimental results. Figure 6(a) shows the measured steady-state torque-speed curves using the zero d-axis current control and the MTPA control. Figure 6(b) shows measured steady-state torque-speed curves



using the MTPA control and the hybrid control, which is a combination of the MTPA control and the flux-weakening control.

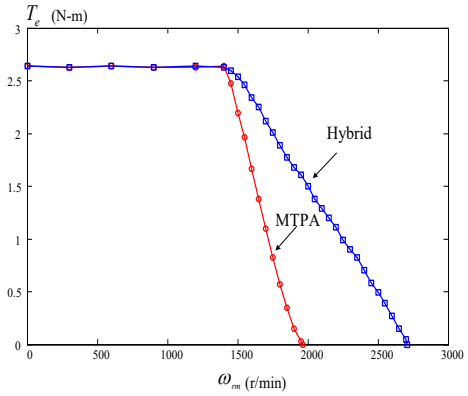
(a)

(b)



(c)

Figure 5 The implemented IPMSM drive system
(a) block diagram (b) hardware circuit (c) motor and dynamometer.



As you can observe, the hybrid control has better performance than the MTPA control. Figure 6 (c) shows the q-axis current to the d-axis current trajectory when the IPMSM is operating from the MTPA control region to the flux-weakening control region. The d-axis current increases slightly in the MTPA region; however, the d-axis current increases significantly in the flux-weakening region.

Figure 7(a)(b) and (c) show the measured waveforms of the IPMSM operating at 1800 r/min under loads of 0.57 N-m and 1.89 N-m. Figure 7(a) is the amplitude of the stator current I_s . Figure 7(b) shows the relative measured d-axis and q-axis currents. Figure 7(c) shows the measured advance angle θ_{adv} that is the sum of the θ_{FW} and θ_{MTPA}, which are the measured flux-weakening angle and the measured MTPA control angle. The delay of the measured responses is due to the lag between the load command and the external load that is generated by the dynamometer. Figure 8(a) shows the load disturbance responses when using the proposed predictive controller, the previous predictive controller that was proposed by [21], and the PI controller. The parameters of the PI controller are obtained by using the pole assignment technique. The locations of the desired poles for the closed-loop drive system are assigned as -4.06+j0.13 and -4.06-j0.13, respectively. The proposed predictive controller performs better than the previous predictive controller and the PI controller. At this 2000 r/min high speed, the field weakening algorithm is applied. The maximum allowed external load at this operating speed is 1.6 N.m. Experimental results show the proposed predictive controller performs the best. Figure 8(b) shows the repetitive 1.6 N.m load disturbance responses. The proposed predictive controller performs well again.

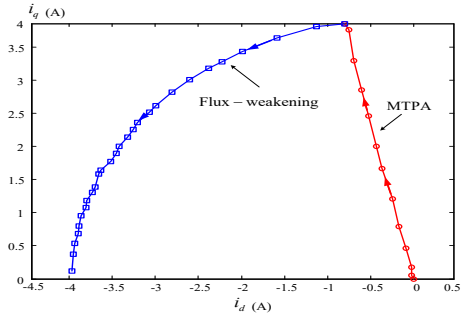


Figure 9(a) shows the measured step-input transient speed responses at the maximum speed, 2700 r/min. In this paper, the rated speed is 1500 r/min. The measured responses show the proposed predictive controller has a quicker rise time than the previous predictive controller proposed by [16] and the PI controller. Figure 9(b) shows the measured step-input transient speed responses at 3 r/min, which is the minimum operating speed. According to Figure 9(a) and Figure 9(b), we can conclude that the adjustable speed ratio of the maximum speed to minimum speed is 900:1. Figure 10 (a)(b)(c)(d) shows the current command and measured current errors using different controllers. Again, the proposed predictive controller has the smallest tracking errors. Figure 11(a)(b)(c) show the measured dynamic responses of the proposed flux-weakening control at 1800 r/min. A 5V step input at V_{om} is injected for every 1 second. The real voltage amplitude of the motor, which is expressed as v_s can track the voltage command V_{om} well. The rise time of the voltage control is about 50 ms. Figure 11(a), Figure 11(b) and Figure 11(c) show the responses of speed, voltage amplitude, and controlling angle θ_{FW} respectively. Figure 12(a) shows the measured efficiency of the whole drive system. The proposed method has higher efficiency than the linear flux-weakening method that was proposed by [21]. The major reason is that the proposed method provides greater output torque at the same motor speed. Figure 12(b) and (c) show the measured speed responses as the inertia of the drive system is increased to 5 times. The proposed predictive controller can provide a lower overshoot and a shorter settling time as the inertia increases.

6. Conclusions

In this paper, an MTPA control and a real-time flux-weakening control drive system using a predictive controller is proposed to improve the adjustable speed range and dynamic responses of an IPMSM. Experimental results show that the proposed drive system has good performance, including fast transient responses, good load disturbance rejection capability, and good tracking responses. Furthermore, the proposed method is easily implemented by using a DSP. Experimental results validate the theoretical analysis.

Keywords :
experimental development ecosystem, team entrepreneurship, team learning

ABSTRACT

The background of the article lies in South Eastern Finland, in Lappeenranta, where an active University campus has attracted a group of ICT startups as well as SME's in the field to collaboration. The novel education approach also has another remarkable role as a developer and source of innovation. An experimental development ecosystem (EDE), where learning of knowledge, skills and character are combined, is presented in the article. Also future paths of the EDE are discussed. Companies in the ICT field worldwide are in constant need of competent experts who are ready to adopt the new tools and, at the same time, have an entrepreneurial mindset. We argue that inspiring students to learn through appropriate learning methods and providing them with a modern learning environment comes first. ICT tools, applications and systems to support learning objectives come second. The model presented in the article has been studied for some years as action research. The learning methods that have been found beneficial in IT and marketing bachelor education have been spread to other bachelor and master study programs as well. Results from the data show that students who study as team entrepreneurs have learned content knowledge, meta-skills and reflection skills via the learner-centric methods used in EDE. They have also been inspired to employ new ICT tools and applications to support their learning and project work.

1. Introduction

This article is an extension of the work originally presented in Educon 2017 in Athens in April 2017 [1].

The change in digitalization has been rapid and the change speed has been increasing during the recent decade. Since Facebook, we have seen plenty of new platform business models. Only some of them have succeeded and have been able to capture value for themselves. However, those who have succeeded have been able to capture themselves almost the whole market.

At the same time, many conventional businesses have run into severe challenges caused by rapid digitalization. To give an example, The Finnish Posti – a post delivery company owned by the government – has in recent years laid off employees due the diminishing amount of traditional mail deliveries. At the same time, agile delivery companies have challenged the Finnish Posti by offering customers faster delivery and several add-on services. The Finnish Posti has tried to find new business elsewhere, e.g. from lawn moving services to offering basic health care services.

Another example is the Finnish national railway company VR Group, which has held a monopoly for a long time (over 150 years). During the recent years, discussion about free competition in railway traffic has increased, and current plans may be deployed in the 2020s. Already, these plans have caused major reorganizations and layoffs within the VR Group.

There are more such examples found elsewhere in the world, e.g. Eastman/Kodak. When we consider what will happen in higher education, we can foresee what is going to happen in the future. How will platforms such as Khan Academy, Coursera and Udemy, and other more sophisticated platforms developed after them, change the current education systems? How many teachers will be needed in future to teach basic principles of programming, for example, when high-quality content can be freely loaded via learning platforms?

For us as educators and researchers an important question is: Are we going to build a shelter and try to resist the change, or would it be wiser to build a windmill and try to utilize the winds of change as well as possible?

*Corresponding Author: Pasi Juvonen, Email: pasi.juvonen@saimia.fi

In the world of today, there is plenty of information available. Thus, one has to be able to think critically, have skills to synthesize and put the information into action in a wise way. According to Fadel et al. [2], in order to deepen the learning process in the three essential dimensions – knowledge, skills and character qualities – an important dimension is needed – meta-learning. This means that there are some internal processes required for our learning, namely reflection and adaptation of our learning. Figure 1 presents the framework for the 21st century learner and for the curriculum redesign that tries to answer to these needs.

Our practical experiences with the same philosophy started several years ago. We – a group of lecturers - decided to start building a learning environment which would enable utilizing knowledge gained from different sources, combine theory, learning by doing and reflection, and make rapid changes possible when learning needs a change, without rethinking and redesigning the whole curriculum. This learning environment also provides practical measures to show students' progress.

The current curriculum (presented in section 2.1) is a result from coaching altogether 11 student teams comprising altogether more than 150 students from two areas of specialization - information technology and marketing. The development of the curriculum took place in 2009 - 2016. Since its early steps in 2009, this learning environment has expanded into a learning ecosystem that we call Experimental Development Ecosystem (EDE). This article describes the ecosystem and its pedagogical background, how the learning is organized within it, and the operational level practices that enable it. In this article, we present and discuss our current state of the art with the EDE, ongoing development activities as well as future development paths.

The article is organized as follows. Chapter 2 presents the results from a literature study about the requirements in bachelor education in Finland and in the OECD context. It also presents the current state of the art with the Experimental Development Ecosystem. Chapter 3 discusses data collection and data analysis. Chapter 4 lists some observations based on the data, and finally, Chapter 5 summarizes the findings and discusses our probable future paths on the subject.

2. Rapid changes will require rearrangements in organizing learning environments

Discussion on a right balance between studying explicit content that will, depending on the subject, easily become out-of-date, and meta-skills that are useful but, at the same time, may leave learners with an experience of not learning anything specific has been going on for a long time. Skills that are easy to teach and learning that is easily measured involve skills that are easily automated [3]. We are, to a certain extent, educating young people for future professions that do not exist when decisions about students' curricula are made. These new professions emerge (and some others disappear) while students are studying for their diploma.

Learning is less about reproducing content knowledge. It is more about extrapolating what we know in novel situations [3]. In future, more employees with versatile skills are needed and, at the same time, fewer specialists with deep expertise in one subject are needed. Communal learning skills and team working in multidisciplinary working groups or teams are important [3].

The demands presented for undergraduate education are versatile. Based on a study of literature [3-10], an undergraduate student needs at least the following skills:

- team working
- communal learning
- problem solving
- creativity and innovativeness
- critical thinking
- decision making
- leadership and self-leadership
- shared expertise
- reflection on one's values, and social and emotional skills.

At the same time, learning environments built for supporting learning should

- offer versatile methods for learning
- diminish teacher-led methods
- provide coaching for the constantly changing world
- foster entrepreneurship
- enable running pilots (e.g. establishing cooperatives).

[3-10].

To get an overall picture of what should be considered when organizing higher education in 2017, we looked for a framework for identifying knowledge, skills, meta-level skills and methods. We also wanted to make a cross-section of the EDE compared to other frameworks. The framework we chose is presented in Figure 1.

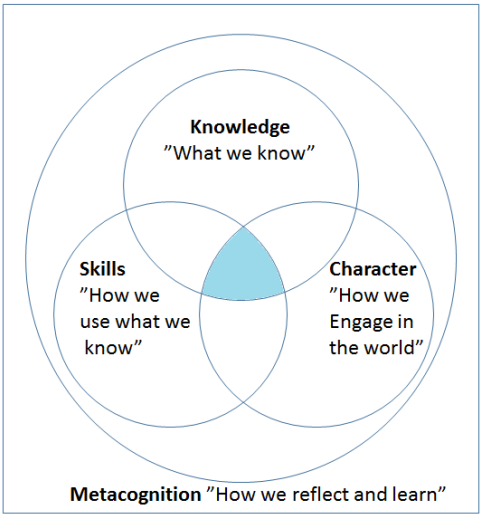

Figure 1. The framework for 21st century education by Centre for Curriculum Redesign [2].

According to [8], there are four forces that lead the learners towards new ways of learning for life in the 21st century. These forces are:

1. Knowledge work – employees who use brain power as well as digital tools for creating new solutions collaboratively in teams

2. Thinking tools – knowledge workers use a set of digital tools, devices and services
3. Digital lifestyles – today's student generations are born into the digital society, and grow up with the digital devices
4. Learning research – the latest research on learning during the last three decades has deepened the understanding of learning processes (See [34 – 37], [39-40], and [51-60] for more)

2.1. State of the art at our UAS – Experimental Development Ecosystem (EDE)

Since 2009 we have been developing a new learning environment, combining studying content knowledge (theory), learning by doing (practice), and employing dialogue [11, 12] in knowledge sharing, knowledge creation and reflection. Together with several local companies and municipalities, we have been able to build the Experimental Development Ecosystem. The current ecosystem offers our undergraduate students an excellent platform for both studying content knowledge, applying this knowledge in real customer projects, and reflecting what has been learned by doing with other team members and the team coach.

Since 2013 we have been developing the EDE in parallel with several RDI projects supported by the Finnish Funding Agency for Innovation (TEKES), Saimaa UAS and LUT University. An "easy-to-start" cooperation between stakeholder groups with little or no thresholds has been a cornerstone for the further development of the EDE.

The EDE was originally created and developed as a social innovation; it is a novel way to organize bachelor education for IT and Business Administration students specializing in marketing at Saimaa UAS. Tiimiakatemia [13] in Jyväskylä and Proakatemia [14] in Tampere were studied as models of how the core structures of team learning can be established. Both of the above academies are specialized in entrepreneurship. An extensive study of how team learning and team entrepreneurship has been organized at Saimaa UAS with IT students to support entrepreneurship education was carried out by Juvonen in 2014 [15].

In 2014 there was no other learning environment designed to support entrepreneurship education in IT Bachelor education [15]. The current employment of the EDE seems to be the only implementation of team entrepreneurship where a student can specialize in marketing (other deployments focus on entrepreneurship overall) and study as a team entrepreneur combining theory, practice and reflections within the EDE.

Studies on learning environments designed for supporting entrepreneurship education in higher education [16- 31], focus on promoting entrepreneurship by fostering either the mindset or skills needed in entrepreneurship, or focus on increasing the status of entrepreneurship as a career choice. Most of the studies we found from Scopus and Science Direct databases (from year 2010 until now) had a narrow focus either on a single course or group of students or a certain technique to foster entrepreneurial skills or thinking. We summarized these studies as follows:

- Applications, tools and methods for fostering entrepreneurial mindset, skills or intentions [19 – 25]
- Evaluation of entrepreneurship education programs overall [26, 27], perceived of value of entrepreneurship education program [27], evaluation of methods used in entrepreneurship education [28]
- How demand and supply meet on entrepreneurship education [30 - 32]
- Student entrepreneurship [33]

Applications with quite a similar approach than the EDE described in this study were found only at Lund University in Sweden and at University of Southern Denmark [18]. At Lund University, practice-based courses and projects are offered, and best practices are spread within an entrepreneurial ecosystem. At the University of Southern Denmark, there are many entrepreneurship education related courses, where different learning methods are used. Most of them are extra-curricular courses, which complicates student participation. Furthermore, basic concepts are taught in a conservative way and practical issues are learned via intensive courses, or via "real entrepreneurs" as visiting lecturers. An active reflection process has been found effective to unleash creative and innovative thinking potential [18].

Students in these two applications are not studying as team entrepreneurs, so they are not running and developing their own enterprise while they are studying. Rather they are participating in a series of teacher-led courses. Based on these differences, the current deployment of the EDE described in this study is considered as a novel approach to entrepreneurship education.

Also concepts of transformational learning [34] have been applied to service-learning while performing service work in [35]. The EDE is more than a team learning environment (Figure 2).

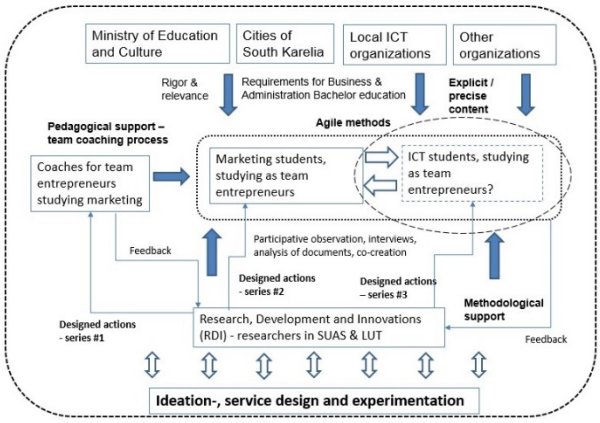

Figure 2. The Experimental Development Ecosystem. Adapted from [36].

The novelty of our approach (the EDE) is in combination of several factors. At the same time this combinations derives the EDE from the approaches found in literature. These factors are as follows:

- Students learn as team entrepreneurs by running a company (a cooperative) they own by themselves
- Focus for students is on specializing in learning marketing in versatile ways
- Experimental learning is emphasized - theory, practice and reflection is involved all the time

- A team coaching process where team development, team performance, and team leadership body of knowledge is applied to support learning
- Several stakeholder groups are involved in the implementation of the EDE
- Continuous cooperation between team entrepreneurs, team coaches, and researchers
- The curriculum has been rebuild to support the team learning and team entrepreneurship and it is further developed based on the experiences gained

Currently, Business Administration students who choose to specialize in marketing study their first year in a conventional way, enrolling on conventional study courses. After choosing the specialization in marketing, they continue their studies for two and half years as team entrepreneurs (Figure 3).

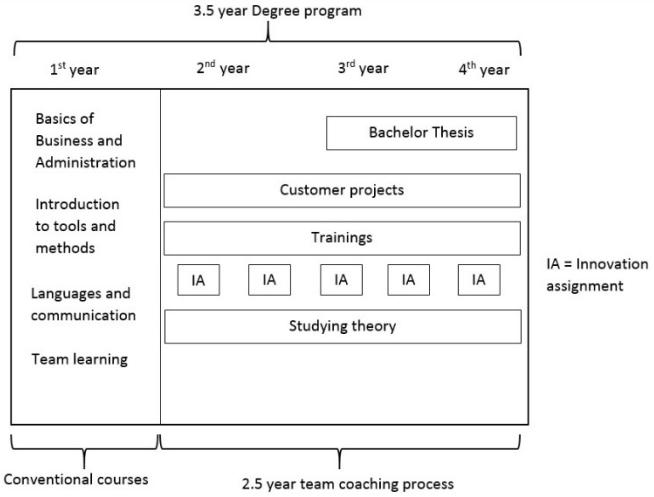

Figure 3. Overview of the curriculum for marketing students studying as team entrepreneurs.

The students who choose to specialize in marketing establish a team enterprise (in the form of a cooperative) and run its operations together during their studies. Their studies consist of studying theory (reading books and articles), carrying out customer projects for real customers for real money, and trainings, where a team coach (personnel of Saimaa UAS) coaches the team members and the team enterprise for team development and performance.

Progress of the team entrepreneurs' studies is measured by five practical measures. Four of these measures show the balance between theory, learning by doing, and sharing knowledge, and reflection. These measures are:

- amount of book points (3 book points equal to 1 ECTS point)
- amount of trainings (in hours, 133 hours equal to 5 ECTS points)
- amount of projects (in hours, 80 hours equal to 3 ECTS points)
- amount of innovation assignments (in hours, 80 hours equal to 3 ECTS points).

To give an example, when a team entrepreneur participates in every training session, which take place twice a week, she will get 5 ECTS points for trainings in a half year. Furthermore, when a team entrepreneur works for 16 hours per week in projects, she gets about 6 ECTS points for projects in a half year. Innovation sessions are held at least twice a year, and participating in them increased the ECTS points. The amount of book points is the only individual measure for the team entrepreneurs. Every team entrepreneur has to complete at least 102 book points, which equals 34 ECTS points. This means that every team entrepreneur has to read at least two business books per month. Book trainings are held twice a month, and those who have read a book and returned a book essay before a book training session are allowed to participate.

The measures described above produce the overall results that are monitored at Saimaa UAS, i.e. the numbers of students who complete at least 55 ECTS points per academic year (1.8 – 31.7). This measure is used by the Finnish Ministry of Education and Culture to monitor study progress in every university of applied sciences in Finland.

The team entrepreneurs are an important element of the ecosystem as collaboration partners and as a scalable source of creativity and innovativeness. Several team entrepreneurs have been recruited already during their studies by local companies. When a company and a team entrepreneur start cooperation on a customer project and continue cooperating on an internship scheme and/or Bachelor's thesis project, it is common, based on our experiences, to continue cooperation after the student has graduated.

The curriculum has been adjusted to make close cooperation with local companies and other organizations possible and fluent. When local companies and other organizations are not able to produce the knowledge they need on their own, they can ask team enterprises for help. A usual method of helping the local organizations is an innovation assignment (IA in Figure 2), where new knowledge is produced within a 12- or 24-hour time limit. Methods of experimental development are used in these assignments in order to create fast, concrete and applicable development ideas based on companies' current needs.

Innovation assignments serve several purposes. For local organizations, they function as a method of rapidly testing their assumptions on a certain topic. For team entrepreneurs, they provide an environment to develop problem-solving skills. Moreover, the assignments function as a measure of team development and substance skills. For all parties, the innovation assignments make it possible to find further cooperation opportunities. In most cases, the organizations participating in an IA will become cooperation partners in the EDE. Sometimes they also take part in RDI projects. Prototypes and/or concepts are usual outcomes of IA's, and prototyping is an important step in an experimental development process. This is the phase that can make a difference in comparison to the traditional workshops where the ideas are easily forgotten after the workshop. It is also easier for the client company to understand the idea and its possibilities for the company after seeing the prototype.

Also research, development, and innovation (RDI) projects support the current EDE model by offering team entrepreneurs

opportunities to work as research assistants. As research assistants, they learn about research methods, gain an understanding of organizing research processes and ways of producing value for local companies [15]. Acting as research assistants in an RDI project has led to employment via internships and/or Bachelors' thesis projects.

2.2. Pedagogics used in the Experimental Development Ecosystem (EDE)

The pedagogics used in the EDE follow ideally the cycle of learning as described by Kolb [37], where learning is described as a process: Firstly, concrete experience is gained, and as the next step in the process, the experience is reflected on. After that comes learning from the experience through abstract conceptualization, and finally testing the newly adopted knowledge and skills through active experimentation.

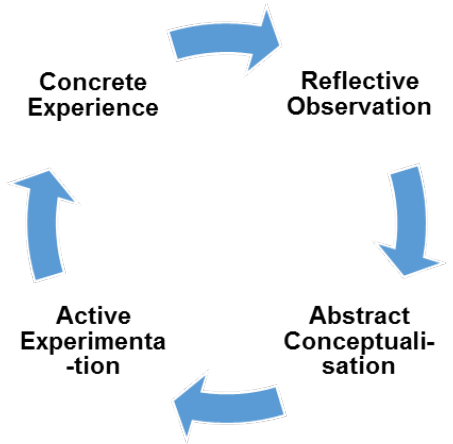

Figure 4. Cycle of learning, adapted from [35].

In constructivism, the learning of a human being is understood as a constant process where individuals are learning or creating their own understanding based on interaction between what they already know and believe, and ideas and knowledge with which they come into contact [38]. Constructivist learning involves at least the following five areas: 1) the educator's attention to the learners, the students and their backgrounds, 2) dialogue facilitation with the group with the purpose of creating a shared understanding of the topic, 3) planned or unplanned introduction of formal theory into the discussion, 4) creating opportunities for the students to challenge or change the existing beliefs and conceptions by using tasks that are structured in a way that makes this possible, and 5) developing students' awareness of their level of understanding and the learning process [39]. In addition to constructivism, team learning, as well as open and honest dialogue, are proven to support the learning objectives.

In the EDE pedagogics, the complexity of companies' operating environments can be learned via concrete experience. At the same time, the theories learned are linked to the reality. Here the principles of building an innovative learning organization are utilized [40]. When considering the current needs of the ICT field, ICT students require more insight into business operations, and practicing business. One way of supporting this is working together in shared projects with team entrepreneur students. Working in multi-disciplinary and heterogeneous project groups is analogous to working life experience, as project teams consist of experts from different fields. Reflection is an elemental part of the learning process and reflective dialogue is used as a pedagogical tool for deepening the learning experience. The researchers working in the ecosystem support the learning process, as they help the students in abstract conceptualization of the phenomena learned. The persons working in the ecosystem need coaching skills that can be applied to the EDE's needs as is required.

These modern thoughts about higher education will also require new skills from those who are employing the system with students. Instead of transferring information to the team entrepreneurs, the emphasis in the team coach's work is rather on helping the process of team development and facilitation of the learning of the information and skills that the team members need for their collaboration and learning (see [41] for more). These teamwork skills and competencies include adaptability, shared situational awareness, performance monitoring and feedback, leadership and team management, interpersonal relations, coordination, communication, and decision making. When these are managed with success, high commitment to learning can be achieved. High commitment usually leads to high performance [42].

A team coach should also make oneself familiar with different styles of consultation. These styles include acceptant, catalytic, confrontational, and prescriptive styles [43]. In the acceptant style, feelings are involved, and this style can be described as emphatic listening. The catalytic style helps the coachee to make decisions. In the confrontational style, the team coach points out what will follow if the coachee continues with her current behavior. The prescriptive style is common in conventional pedagogics. It gives direct advice; however, it does not offer the coachee any opportunity for growth. All these styles are needed in team coaching.

3. Data collection and analysis

The research framework for investigating all the development activities concerning the Experimental Development Ecosystem has been action research [44, 45]. During September 2015 – September 2017 there were several mini-cycles where designed development activities were carried out in different parts of the EDE, and the team entrepreneurs were active participants in many of these development activities.

The outcome of these development activities was monitored through participative observation. The team coaches are active agents for change when they act with student team entrepreneurs. By choosing to use qualitative methods of inquiry, the authors have, at the same time, committed themselves to continuous reflection of their own values and how they affect the research.

The field notes have provided valuable qualitative data, which has been analyzed with other researchers. Two other team coaches have been involved in the sense-making process of how to utilize

the current EDE in ICT education and how to foster cooperation between team entrepreneurs specialized in marketing and ICT bachelor students.

Survey and theme-based interviews during a one-year period between 10/2016 - 9/2017, followed by participative observation, have served as the main data collection methods for the study. An overview of the collected data for the study is presented in Table 1.

Table 1: Overview of the data.

Data collection method	Amount	Timeline	More information
Theme-based interviews	12	10/2016	13 specialists in 12 interviews, from different stakeholder groups involved with the EDE, were interviewed to find out development targets for the EDE.
Participative observation sessions	Over 50	Training sessions, four hours twice a week between 9/2016 – 9/2017	Team coach acts as an active agent for development and provides examples of digital tools for team entrepreneurs.
Theme-based interviews	34	3/2016 – 9/2017, lasted 15 – 40 minutes	Evaluation of the role of the ICT / Digital tools and reflections on why and how team entrepreneurs have been deploying them.
Survey	14 replies	8/2017 – 9/2017	E-mail survey followed by interviews as a part of development discussions.

Methodologically, this article is a partly descriptive and partly explorative case study [46, 47]. It presents the current implementation of the EDE, explores its possible development paths, and finally describes how the ICT Bachelor curriculum could benefit from it.

The basic assumption of the authors is that every research is value-laden and biased. By choosing to use qualitative methods for the inquiry, the authors have, at the same time, committed themselves to continuous reflection on their own values and how they affect the research. In this study, the objective has been the further development of the current EDE and integration of the ICT Bachelor education into it at some level. Therefore, there is an inbuilt bias in the observations and interventions made. However, the authors present the interpretation based on the analysis and the process of conducting research transparently and leave judgement of the validity of study to the reader.

The results of the study have been discussed with three team coaches and two researchers. Luckily, the team coaches share an office at the campus. This has helped to test inner validation of the observations made based on the interviews. The data for the article consists of qualitative interview material (12 specialist interviews with open-ended questions, notes on direct and participative observations, 10+ steering group meetings, researcher workshops, other workshops and meetings), and several unofficial discussions with colleagues and administrative staff at the Saimaa UAS campus and elsewhere where the authors have been actively involved in development activities.

Multiple sources of data and close cooperation between the two authors made it possible to utilize both investigator triangulation and data triangulation [48]. The triangulation of data and researchers has helped to test inner validation of the observations made based on the interviews and participative observation sessions. The data was analyzed applying the principles of grounded theory [49, 50]. The grounded theory analysis includes three main phases: open coding, axial coding, and selective coding [49], and the method requires the researcher theoretical sensitivity [51]. The researcher cannot force the data, but instead she has to let the data "speak". Naturally, this phase is extremely hard in cases where interviewers have a lot of pre-existing knowledge about the subject studied. The process can be made easier by asking the same open-ended questions about the subject studied from all the interviewees and carefully listening to and reporting their expressions.

In the open coding phase, interesting phenomena in the data were highlighted. In this study, the interview notes were first gathered into one text file and then analyzed by the two researchers. In the axial coding phase, the interesting phenomena marked in the open coding phase were grouped and their relations (causal and other) were analyzed. In the selective coding phase, a lot of data was abandoned, the core of the results - "What is going on here?" - was taken, and the research reports were written. An example of axial coding phase where i.e. associations and causal relations were searched by visualizing interesting phenomena with Atlas.ti software is presented in figure 5.

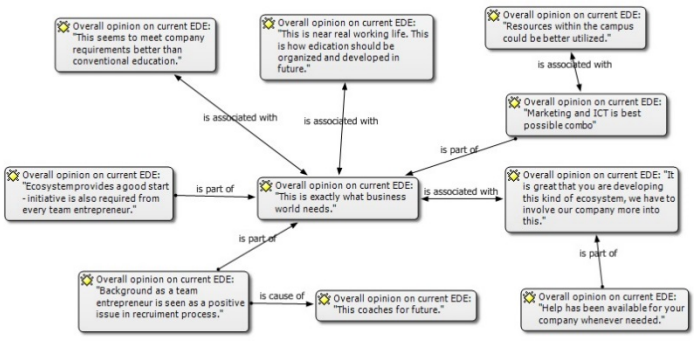

Figure 5. Axial coding with Atlas.ti code network view.

As mentioned above, the grounded theory analysis lets the data speak, and therefore no pre-existing theory is needed. In an ideal case, the grounded theory analysis is purely inductive. In practice, there always exists little or more pre-existing knowledge and bias related to the research subject. To be exact, a target to develop something is already a strong bias. Who defines development? Development for one stakeholder group may be stagnation for another group. When discussing values and biases, the best we can do as researchers is to be as open as possible about the motives we

recognize in ourselves. In this study, the researchers had a strong vision of how ICT Bachelor education should be organized in future. However, the interviewees were asked open-ended questions about the subject, and the results are presented as they are with no value-laden interpretations added.

Open coding and axial coding phases went on in parallel. During the open coding and axial coding phases, a constant comparative method and theoretical sampling [51, 52] were used. The use of the constant comparative method meant that when an interesting phenomenon was found later during data collection, all the earlier data was screened again to see if the phenomenon was found there, too. Theoretical sampling was used to collect more data on phenomena where more explanation was needed. The data was collected until a theoretical saturation was achieved. The use of the constant comparative method and theoretical sampling increased the researchers' interaction with the data. The selective coding phase also started early and parallel with the axial coding phase. The saturation of the new data [51] took place early, which meant that there was no need for extra interviews on that subject. A new tool for making word clouds was used to visualize part of the data (see Figure 4 for more details).

During the first round of interviews made with stakeholder groups, two seed categories [52] emerged during the open coding phase: 1) creating interdisciplinary interaction during ICT education, and 2) entrepreneurial mindset and its value. Based on an analysis of these seed categories and combined with the analysis of the new field notes (including memos, emails, book essays, and observation data) between January 2016 and mid November 2016, a pattern of "Where should we be heading?" was written. The results were published in a conference article in the Educon 2017 conference in Athens, Greece on 27th April 2017.

At the same time when employing designed actions to the Experimental Development Ecosystem learned from the previous study, two new research questions were chosen for this study:

1. *What are the learning experiences when dialogue is used as learning method?*
2. *How new ICT tools and applications have been utilized by team entrepreneurs during the first year?*

Between mid of November 2016 and mid November 2017, plentiful new data was gathered and analyzed. This data collection comprised two interview rounds as part of the team entrepreneurs' development discussions, over 50 training sessions (where team entrepreneurs and the team coach were present), and a survey. The survey was presented to the team entrepreneurs face to face and they were able to ask further questions about the purpose of reflecting on these issues. The team entrepreneurs were asked to evaluate their dialogue skills, make observations on dialogue in other groups they had visited, and describe how they had employed ICT tools in their project work. The expressions made by 14 interviewees were later observed in training sessions, project reflection sessions, and finally by end products made with the ICT tools that had been utilized.

4. Observations based on the data

In general, the majority of the interviewees within our stakeholder groups shared the opinion that the ecosystem model (EDE) in modern education is a response to many challenges in the employment of the newly graduated, and at the same time it is a way to pave the way to embarking the working career smoothly after studies. The students' early adoption of an open view of the real business life was generally seen as a positive and novel way of educating experts for the business world, where the described individual capabilities are appreciated by employees.

Entrepreneurial mindset and thinking as a driving force for students was seen as a positive feature to be maintained in education. The necessity of establishing a cooperative and working as team entrepreneurs was seen differently among the interviewees. Some of the interviewees from Saimaa UAS did not see that learning to run an enterprise would bring much value to ICT students. The interviewees from industry, however, saw that learning to think and operate as entrepreneurs would be one of the most important topics to learn overall.

As the most promising pathways, the interviewees saw the possibilities of interdisciplinary interaction between marketing and ICT students, who all are familiarized with the ICT business and the ICT customers' businesses. During the studies, the two student groups could make use of each other's specialty areas by participating in shared projects either in RDI or in business collaboration projects. As the study aims at understanding the future requirements for a competent ICT education, several ICT company representatives were interviewed. As a way to prepare competent future employees for the ICT field, the interviewed ICT companies mentioned a possibility to participate directly in the education of ICT students via both direct education activities and placement opportunities or shared customer projects in RDI, for example. This would create a firm an efficient recruitment process with less need for training the newly recruited personnel.

The interviewees that have graduated from the team entrepreneurship ecosystem or are currently studying marketing in that environment had positive experiences of this type of an education system. The most important and positive feature mentioned was learning through real business cases. The most valuable part in the model was the early networking with businesses. After graduation, it has been easy to find a job relating to the field of studies. At least, this different form of studies in a cooperative has proven a positively differentiating factor in job applications.

ICT business is mostly a project-based business where experience and an entrepreneurial mindset are a benefit as such. The current marketing team entrepreneurs have started to build also cooperation with students from different sectors of education within Saimaa UAS to be able to expand their domain knowledge. Making oneself familiar with different contexts where marketing activities (and ICT) are carried out is another example of a positively differentiating factor for the job applicant.

The ICT education ecosystem and ICT education in general need to respond to the changing skill requirements in the industry. In the EDE this can be promoted by involving the ICT sector in the constant development of the study programme and in the education activities in special projects. This would ideally result in long-term interaction between the ICT industry and the Saimaa University of Applied Sciences (SUAS) and the students. In some cases, even weekly co-operation between the ICT companies and the coach

and students would form a mutually beneficial cooperation model supporting a high level of motivation among both the students and the ICT companies. When mutual benefits exist and the captured value will be fairly shared between the parties, the cooperation will sustain itself.

There were some concerns towards the coached team learning and team entrepreneurship model raised in the interviews. In general, the team coaches have a key role and they are responsible for ensuring that the students are provided with the basic capabilities required in the education programme at a University of Applied Sciences. It was also stated that this type of a learning method is not ideal for students who still have to grow in order to mature for the responsibility and self-leadership skills that are required by the learning style. The entrance examination for the students was seen as one important step in this process. Also, the new ICT education should be marketed as a more interdisciplinary education program that is not too much technically oriented in order to lure the business oriented people with a high motivation for fast career building.

As the student teams operate in groups or as working teams, it would be beneficial if the different team roles could be consciously tested by each student. This would help the young students safely test their own personal strengths, which would be a supporting factor in building the students' professional self-esteem. As all companies, also the student teams have to set goals for their actions and all the steps during the studies should be taking the team towards the goals. It is not enough to act as active since that does not suffice to develop the situation. Supporting the building of students' versatile knowledge base requires a broad scale of practical learning projects, which has to be ensured during the studies. Here, the role of the team coach is emphasized again. A frequent presentation discussion of the learning goals and how they have (or have not) been achieved is crucial.

In the Business Administration degree program, the number of students who complete 55 ECTS points per year has been monitored since 2014 when criteria for funding University of Applied Sciences was changed. However, the measuring criteria were changed again in 2016, so we do not yet have enough new data to be able to make valid arguments about overall results. In the academic year 2015 – 2016, the overall result in achieving 55 ECTS points in the Business Administration and International Business degree programs (measured together) was 57.1 % (68.1 % with team entrepreneurs). In the academic year 2016-2017, the figures were 61.3 % (58.7%) respectively. The measuring system is now being updated to be able to provide more accurate data in future.

Even though we do not have enough performance data yet from team entrepreneurs' studying within the EDE, we are able to argue something. One of the biggest worries at the beginning of team learning and team entrepreneurship was how the increased freedom of students in choosing what they study and when will affect the performance measured in ECTS points. With this small amount of data we are able to argue that the pedagogics used with the EDE is working and no one has to worry about the performance metrics.

Two of the interviewees strongly emphasized that in future the EDE should emphasize the role of internationalization of students and companies cooperating in the EDE. This kind of organization of learning, development, and research activities is not familiar elsewhere and therefore the EDE ideas should be exported to other countries as well. The main strengths that this kind of ICT education would offer include the digital thinking of "Digi-native" generations together with marketing capabilities. These make a combination that a successful and competitive international business requires. The students would also, right from the beginning, start to understand that their future work will be part of someone's business – if not their own.

4.1. Towards a perfect ecosystem of learning

The key findings, as also described in pedagogic research literature that have proved to be successful in the researched EDE model are the following: authentic learning, mental model building, internal motivation, multiple intelligences as well as social learning. The curriculum applied in Saimaa UAS, as well as the piloted methodology applied on certain study courses, aims at developing skills needed when coping with the complexities of the 21st century: team working skills, communal learning skills, problem solving skills, leadership and self-leadership skills as well as innovativeness, shared expertise, and ability to reflect on one's own values and attitude.

These suggestions follow the advice from studies on how to build great teams. They suggest that energy (how team members contribute to a team as a whole), engagement (how team members communicate with one another), and exploration (how teams communicate with one another) are crucial factors for teams' success [53]. Furthermore, when quality of communication includes balance of advocacy and inquiry, a lot of positive feedback and true interest in others' opinions [54], there are many of the required elements available to develop great teams. Applications selected should support the objectives listed here, and this means they cannot be selected from a teacher-centric viewpoint.

Students' experiences from learning dialogue skills are proving that practicing dialogue in a safe environment gives them valuable communication exercise. It also supports the readiness for dialogue of the future company developers. Within one year's time every respondent said that there is development gained in one's own dialogue skills. Several respondents stated that they already are good at listening to other students. Several stated that they have learned to express their own opinions in the group. Based on external working life experiences, some students also had noticed that in many companies the leadership culture does not encourage dialogue at all. These future employees will be motivated as well as committed when they are part of a team where dialogue exists.

4.2. Where there's a will there's a way – A practical view of communication technologies and platforms.

A framework for making interpretations based on the qualitative data analysis for research question 2 had four phases:

1. Notes from interview data (What tools were said to be employed?)
2. Direct and participative observation in training sessions (What tools were actually employed in practice and by who?)

3. Reflection of what was learned (Who actually participated to implementation of new tools? How tools were selected? Why tools were abandoned?)
4. What outputs were done for customers (Videos, web-sites, etc.) with the ICT tools employed?

These phases helped to validate our findings. When a team entrepreneur expressed in an interview (1) that she was interested to learn a new tool for making videos, later discussed in training session (2) about utilizing the tool in a customer project, reflected the use of same tool when a project was completed (3), and finally the a video was publicly available (4) in social media platform – we were able to validate integrity of our chain of making interpretations. An example of how these 14 cases were analyzed is presented in figure 6.

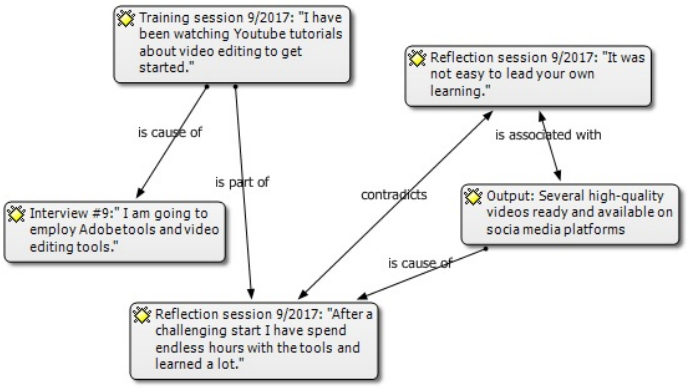

Figure 6. An example of qualitative data analysis, case #9

Based on our current experience, better utilization of tools and applications is not limited by availability of ICT tools and applications. Rather, it is limited by individual differences in the will to share information about one's working. Sharing work-related information is a much more sensitive issue than it is usually expected to be. This very same phenomenon limits the use of many other ICT systems as well. Every time when there is competition of projects within teams or departments of the same organization, openness in sharing information is limited. Only part of the employees are willing to share their business contacts via the company-wide CRM system, for example. A better understanding of the benefits of balance between individual work and team work (see [55] for more details) is needed to better utilize ICT systems. Cui bono (Who benefits?) question has to be answered clearly when new systems are employed.

Adopting the use of some practical IT tools while learning in projects is important. To facilitate communications between learners and to support project management, a broad selection of "free to use" tools have been applied within the EDE. The student respondents in the study in August 2017 stated that they had learned to use 4 - 5 new IT tools, applications or platforms on average during one year's time. Some of these tools had been presented by the team coach or a visiting company representative. Currently, also learners find and introduce new tools to the community on a regular basis. The list of the tools, applications and platforms used is long, including the following ones that were mentioned the most frequently: Trello, Slack, Skype, Doodle, WhatsApp, Moodle, Dropbox, Google Drive, Canva, Mention, Facebook, Twitter, and Instagram. Naturally, email, SMS messages and other conventional communications tools are used as well.

The most frequently used tools in project management were Google Drive, Google Sheets and Trello. In a brief unofficial discussion with the team entrepreneurs from other teams, the same tools were mentioned as the most popular ones in other teams as well.

According to our experiences, it is rather simple for the students to start using new digital tools when working on projects. This also helps students to quickly gain valuable experiences with different tools and platforms and their usability in different tasks. Sometimes students want to challenge themselves by learning to use a new tool, and harness it into the use of their cooperative. There is no need to teach the system itself, but rather act as an example and invite students to use the system. That way they will learn how the real work processes can make use of different technologies.

Though learners are using several tools and applications to support their learning in projects and to facilitate their communication, we are still in the early stages of truly benefitting from digitalization. Technology is not a limitation anymore. The real limitations are found in normal human behavior. To pick an example, a project manager and team members would benefit from knowing what tasks other team members currently have, who might need more tasks do to or who would need help. This data could easily be entered in a Trello table and shared to every team member.

4.3. Objectives first, systems to support productivity second

Making experiments and building prototypes [56, 57], associating different types of knowledge [58 - 60], and sharing knowledge of learning experiences [60 - 62] are part of the innovation management concept of the EDE. The team entrepreneurs experiment with different types of tools, applications, systems and platforms to find the ones that are appropriate and useful for their purposes.

Our target with the EDE is to help a new culture of agile methods, applications, and practices to emerge. The easiest way so far has been to start with the team entrepreneurs by introducing new applications to them and just starting using them in project management and communications, when students can directly see the benefit of the systems. So far, the results have been promising.

Experimental development is inbuilt in the EDE, in the form of innovation assignments mentioned before. Also the learning by doing approach, supported by reflection on what was learned, creates confidence in the cooperatives and students' own skills. Dedicating time for reflections is an important learning outcome on the way of becoming a professional in one's own area [63].

5. Discussion and summary

Combining and analyzing all data from the stakeholder groups of the EDE and from the team entrepreneurs studying within the ecosystem, we can clearly identify three steps we have to take next:

1) to leverage lessons learned so far in the ICT bachelor curriculum and master study curricula 2) to re-evaluate how extensively the use of new ICT tools has to be taught, and 3) to set objectives for further studies on the topic.

The current Experimental Development Ecosystem offers a pedagogically solid, tested, experimentally developed, and continuously evolving basis for supporting bachelor education in higher education. Also, the use of digital tools and applications to support learning by doing in projects and to facilitate communications within and between teams has been increasing rapidly.

5.1. Probable future for the EDE

Professional development should not focus on educating students about how current professions are executed [64]. As suggested, professional education should rather be focused on developing professions in cooperation between educational institutes and companies. Underneath these suggestions lies the activity theory [65, 66]. The ultimate goal is to help school and work life to collaborate in a better way. In times of rapid changes, educational arrangements including theory, practice and reflection repeat themselves in a continuing manner.

- International partners are needed to serve both education and business requirements. Companies who are interested in internationalizing their operations will benefit from opportunities for rapid experimentation in two or more locations.
- ICT students need a balanced amount of core ICT skills and business skills. This could be achieved by working with team entrepreneurs studying marketing with the EDE.
- ICT and marketing students should be put in mixed teams for sharing knowledge, and especially for creating new knowledge together. More cross-fertilization is needed for more learning and more versatile ideas.

There is also a lot of work to be done to better integrate the competencies of Saimaa UAS staff into the coaching process of marketing team entrepreneurs and/or ICT students, whether they study as team entrepreneurs or conventional students. This will require a more adaptive attitude towards how learning is organized from all the parties involved: teachers, administration, and team entrepreneurs.

In the beginning, this will require a lot of encouragement because even though higher education teachers may have extensive experience in teaching, they might lack competencies in learner-centric pedagogy and its methods, the mindset required for experimental development, or even both. Changing methods will also require teachers to accept that employing these methods means that they will frequently face situations that are novel to everyone. If someone has a strong routine of teaching, there might not be much interest or will to change it.

When the courage to experiment new methods to support learning is found (usually with support of colleagues or appropriate further education), at the beginning the change of habits will raise anxiety among teachers and learners. Teachers are used to acting as specialists providing answers and at the same time learners have been passive listeners. When tables are turned, both parties feel uncomfortable and the temptation to go back to old habits is strong. If this happens, it will return the potential of learners taking responsibility and teachers role of not giving easy answers to learners directly to zero. During the process of change we have gone through we have seen this phenomenon take place several times.

Very soon teachers, however, usually find out that with longer experience in life in general and operating in different types of situations helps to coach others to find means of how to solve them. Teachers are usually very good at abstracting and conceptualizing what has been learned. By reflecting on the learned skills and discussing how they can be applied in other contexts will help transfer the learning outcomes.

5.2. How teachers, lecturers and team coaches are able to benefit from the changes

At the beginning, creating a learning environment required in the 21st century will take more time than is usually used when organizing courses in higher education. After a two or three years' time, a new culture of students' responsibility for their own learning process will start to emerge and strengthen. At this tipping point, a team coach will recognize that there will be time for tactical and strategic thinking again.

5.3. Summary

By combining and analyzing the versatile data we collected, we were able to answer the research questions:

1. *What are the learning experiences when dialogue is used as learning method?*

2. *How new ICT tools and applications have been utilized by team entrepreneurs during the first year?*

This data shows that dialogue as a learning method was appropriate to support the professional development of the team entrepreneurs. Various new tools for project management, communication, and marketing and sales were employed in practice. It is noteworthy that these ICT tools, applications or systems were not taught. The dialogue and presentation of the tools was enough to inspire action.

The higher education institutes should foster creation of such ecosystems where knowledge, skills and character are combined. The learning environments should provide learner-centric methods, and acknowledge the importance of metacognition. Focusing mainly on content is not enough.

The systems (tools, applications, platforms) needed to support the ecosystem are nowadays mostly free to use and easy to use, meaning that most of them can be applied to practice at a fast pace. These are used in several visionary companies and they should be applied also in higher education institutes if they are not in use yet. The authors warmly welcome new partners to write and discuss the topics covered in this article.

Acknowledgments

This article has been written as a part of the Digikaappaus project, which is funded by Saimaa University of Applied Sciences,

Lappeenranta University of Technology, Tekes – the Finnish Funding Agency for Innovation, and by 11 Finnish organizations.

ABSTRACT

On-ramping is being widely used as e method to increase the freeway operational efficiency. The main traffic parameter that must be taken in consideration for the implementation of the feedback control strategies for the on-ramp metering is density on the main section of road. In this paper is given discretized model of traffic which is then improved by a recursive technique called Kalman-Filter with the aid of which is possible to predict the density, by only having the traffic flow measured on the start and end road section. Kalman Filter is based on linear relationship of flow and density. By minimizing the square of error between of the measurements and the estimated values of flows, a gain is derived which then is applied to the densities of the model in order to obtain the greatest accuracy of these values.

1. Introduction

The increasing demand of motorized vehicles is becoming one of the major problems that face the developed world places in nowadays. Based on some statistics in Great Britain, 90% of the journeys are by road, during the last decade, and for more the road distances travelled, have increased by over 1000% on the last sixty years. [1]

On-ramp metering [2] is being widely used as e method to increase the freeway operational efficiency by regulating the traffic interruption by minor roads, while maintaining the right of way on the major section until it reaches me critical densities, which assure the maximal flow [3]. Measure of the density on the major road is difficult to measure. In this paper is proposed a discretized traffic model (CTM) to obtain traffic densities which then will be accurate through Kalman Filter [4, 5 and 6].

2. CTM model of a Highway with three cells

If we denote with ρ_i (k) the density of a cell (uniform or non-uniform length), instead of the number of vehicles n_i on the a unit length cell, then we can bring equation *(1.1)*[6].

for density $\rho_i(k+1)$ of the cell i updated time step in *(k+1),* where T_s is the discrete time unit in seconds.

$$\rho_i(k+1) = \rho_i(k) + \frac{T_s}{L}(q_i(k) - q_{i+1}(k)) \quad (1.1)$$

Analyzing a highway partitioned in three cells (for the sake of simply illustration) with an on ramp and an off ramp, by assuming that the belonging cells can be in the free flow either in congested mode the densities on each cell can be written as in equations (*1.2, 1.3, 1.4*).

The densities on each cell are:

$$\rho_{i-1}(k+1) = \rho_{i-1}(k) + \frac{T_s}{L}(q_{i-1}(k) - q_i(k) + r(k)) \text{ or}$$
$$\rho_1(k+1) = \rho_1(k) + \frac{T_s}{L}(q_1(k) - q_2(k) + r(k)) \quad (1.2)$$

$$\rho_i(k+1) = \rho_i(k) + \frac{T_s}{L}(q_i(k) - q_{i+1}(k)) \text{ or}$$
$$\rho_2(k+1) = \rho_2(k) + \frac{T_s}{L}(q_2(k) - q_3(k)) \quad (1.3)$$

$$\rho_{i+1}(k+1) = \rho_{i+1}(k) + \frac{T_s}{L}(q_{i+1}(k) - q_4(k) - f(k)) \text{ or}$$
$$\rho_3(k+1) = \rho_3(k) + \frac{T_s}{L}(q_3(k) - q_4(k) - f(k)) \quad (1.4)$$

With the elaboration of the inter-cell flow law can be defined the expressions for the inter cell flows q_1, q_2 and q_3 in the above equations (*1.1, 1.2 and 1.3)*. Before the inter cell flows elaboration is given, a reasonable description of the congestion must be given further, since as we assumed above, the cells can be in either free

[*]Arlinda Alimehaj Rrecaj, Email: arlinda.alimehaj@uni-pr.edu

or congested mode. Congestion is defined as the state of the traffic with high density rates, or with other words the density of that part of the highway expressed in cell is equal or higher than the critical density based on the fundamental diagram of relationship of flow and density. Referred to the mentioned diagram, can be noticed that the congested flow belongs to higher values of the density, above the critical density values where the flow drops down. That can be described with enormous number of vehicles travelling at low speeds and with short distance spaces between each other.

The common modes, used in analysis of researchers are the fully congested mode when the three cells are congested, denoted by *CCC* mode, and free flow mode when the three cells are in free flow mode, denoted by *FFF* mode. The other middle modes that are out of the scope of this paper are those with last one and two cells in congested mode, written by *FCC* and *FFC*, respectively. To emphasize the modes, the congested cells are highlighted further.

Now, for the *FFF* mode, the densities of the cells are lower than the critical density and the inter cell flows are as follows:

$$q_i(k) = \min\left(v_{fi-1}.\rho_{i-1},\ Q_{i-1}\ w_i(\rho_J - \rho_i)\right) or$$

$$q_2(k) = \min\left(v_{f1}.\rho_1,\ Q_1\ w_2(\rho_J - \rho_2)\right) = v_{f1}.\rho_1 \quad (1.5)$$

$$\left| q_{i+1}(k) = \min\left(v_{fi}.\rho_i,\ Q_i\ w_{i+1}(\rho_J - \rho_{i+1}),\right)\right.$$

$$q_3(k) = \min\left(v_{f2}.\rho_2,\ Q_2\ w_3(\rho_J - \rho_3)\right) = v_{f2}.\rho_2 \quad (1.6)$$

In *CCC* mode, the densities of the cells are higher that the critical density, and the inter cell flows are:

$$q_i(k) = \min\left(v_{fi-1}.\rho_{i-1},\ Q_{i-1}\ w_i(\rho_J - \rho_i)\right) or$$

$$q_2(k) = \min\left(v_{f1}.\rho_1,\ Q_1\ w_2(\rho_J - \rho_2)\right) = w_2(\rho_J - \rho_2) \quad (1.7)$$

$$q_{i+1}(k) = \min\left(v_{fi}.\rho_i,\ Q_i\ w_{i+1}(\rho_J - \rho_{i+1}),\right)$$

$$q_3(k) = \min\left(v_{f2}.\rho_2,\ Q_2\ w_3(\rho_J - \rho_3)\right) = w_3(\rho_J - \rho_3) \quad (1.8)$$

After subtracting the expressions for inter cell flows (1.5 *and 1.6*) in the equations of densities *(1.2, 1.3* and *1.4),* for the *FFF* mode, we have:

$$\rho_1(k+1) = \rho_1(k) + \frac{T_s}{L}(q_1(k) - v_{f1}.\rho_1(k) + r(k)) \quad (1.9)$$

$$\rho_2(k+1) = \rho_2(k) + \frac{T_s}{L}(v_{f1}.\rho_1(k) - v_{f2}.\rho_2(k)) \quad (1.10)$$

$$\rho_3(k+1) = \rho_3(k) + \frac{T_s}{L}(v_{f2}.\rho_2(k) - q_4(k) - f(k)) \quad (1.11)$$

And after subtracting the expressions for inter cell flows (*1.7* and *1.8*) in the equations of densities (*1.2, 1.3* and *1.4*), for the *CCC* mode, we have:

$$\rho_1(k+1) = \rho_1(k) + \frac{T_s}{L}(q_1(k) - w_2\left(\rho_J - \rho_2(k)\right) + r(k)) \quad (1.12)$$

$$\rho_2(k+1) = \rho_2(k) + \frac{T_s}{L}(w_2(\rho_J - \rho_2(k)) - w_3(\rho_J - \rho_3(k))) \quad (1.13)$$

$$\rho_3(k+1) = \rho_3(k) + \frac{T_s}{L}(w_3(\rho_J - \rho_3(k)) - q_4(k) - f(k)) \quad (1.14)$$

3. State-Space presentation of CTM Model

The state space presentation (particularly the state space, eq.*1.17*) of *CTM* based traffic densities of a highway segment in *FFF* mode differs from that of *CCC* mode. [7].

What it characterizes the state space model of the traffic density based on *CTM* model, is implication of some other extension parts of the state space, B_q which is the input matrix of upstream and downstream flows q_1 and q_4 respectively, B_r the input matrix for on ramp and off ramp flows, r and f respectively that are applicable on the *FFF* mode and input matrices, B_w which takes into consideration the backward waves w_2 and w_3 and B_J the input matrix of the jam density that are applicable on the state space model of the *CCC* mode. (1.17) and (1.18)

$$\rho_{(k+1)FFF} = A\rho_{(k)} + B_u q_{(k)} + B_{r,f}(r,f)_{(k)} + Bw_{(k)} \quad (1.17)$$

$$\rho_{(k+1)CCC} = A\rho_{(k)} + B_u u_{(k)} + B_{r,f}(r,f)_{(k)} + B_J\rho_{J(k)} + Bw_{(k)} \quad (1.18)$$

Where: *x (k+1)* is the system state vector and in this paper, according to the *CTM* model, corresponds to the density in cell of cell *i.*

A is the state matrix, *B* is the input matrix, *u(k)* is the input or control and w_k represents the process noise.

They are assumed to be independent (of each other), white, and with normal probability distributions (Gaussian) as:

$p(w) \tilde{} N(0, Q)$ *and* $p(v) \tilde{} N(0, R)$.

From the system of equations in (*3.12, 3.13* and *3.14*) can be drawn (after some regulations finding partial derivatives of the functions of densities to the parameters previous densities *ρ(k),* flows q_1 and q_4 and backward waves w_2 and w_3 which provide the elements of the respective matrices of the i^{th} row that correspond to density of i^{th} cell) the belonging matrices of the system matrices.

After bringing up together (eq. in *1.19* and *1.20* can be expanded to the form of state space: For *FFF* mode:

$$\begin{pmatrix}\rho_1\\ \rho_2\\ \rho_3\end{pmatrix}_{FFF}(k+1) = \begin{pmatrix}1 - v_{f1}\cdot\frac{T_s}{l_1} & 0 & 0\\ v_{f1}\cdot\frac{T_s}{l_2} & 1 - v_{f2}\cdot\frac{T_s}{l_2} & 0\\ 0 & v_{f2}\cdot\frac{T_s}{l_3} & 1\end{pmatrix}\cdot\begin{pmatrix}\rho_1\\ \rho_2\\ \rho_3\end{pmatrix}(k) +$$

$$\begin{pmatrix}\frac{T_s}{l_1} & 0 & 0\\ 0 & \frac{T_s}{l_2} & 0\\ 0 & 0 & \frac{T_s}{l_3}\end{pmatrix}\cdot\begin{pmatrix}q_1\\ 0\\ -q_4\end{pmatrix}(k) + \begin{pmatrix}\frac{T_s}{l_1} & 0 & 0\\ 0 & \frac{T_s}{l_2} & 0\\ 0 & 0 & \frac{T_s}{l_3}\end{pmatrix}\cdot\begin{pmatrix}r\\ 0\\ 0\end{pmatrix}(k) \quad (1.19)$$

By recalling the standard state space models in (*1.19*) and *(1.20*), for completely free flow mode FFF and congested mode CCC respectively, there can be derived other variants, by changing the outflow from which is considered to have congestion the density formula, that is dictated by the backward speed and jam density of the downstream cell.

For *CCC* mode:

$$\begin{pmatrix}\rho_1\\ \rho_2\\ \rho_3\end{pmatrix}_{CCC}(k+1)=\begin{pmatrix}1 & w_2\cdot\frac{T_s}{l_1} & 0 & 0\\ 0 & 1-w_2\frac{T_s}{l_2} & w_3\cdot\frac{T_s}{l_2} & \\ 0 & 0 & 1-w_3\cdot\frac{T_s}{l_3} & \end{pmatrix}\cdot$$
$$\begin{pmatrix}\rho_1\\ \rho_2\\ \rho_3\end{pmatrix}(k)+\begin{pmatrix}\frac{T_s}{l_1} & 0 & 0\\ 0 & \frac{T_s}{l_2} & 0\\ 0 & 0 & -\frac{T_s}{l_3}\end{pmatrix}\cdot\begin{pmatrix}q_1\\ 0\\ q4\end{pmatrix}(k)+\begin{pmatrix}\frac{T_s}{l_1} & 0 & 0\\ 0 & \frac{T_s}{l_2} & 0\\ 0 & 0 & \frac{T_s}{l_3}\end{pmatrix}\cdot\begin{pmatrix}r\\ 0\\ 0\end{pmatrix}(k)+$$
$$\begin{pmatrix}0 & -w_2\cdot\frac{T_s}{l_1} & 0\\ 0 & w_2\cdot\frac{T_s}{l_2}0 & 0\\ 0 & 0 & w_3\cdot\frac{T_s}{l_3}\end{pmatrix}\cdot\begin{pmatrix}\rho_{1J}\\ \rho_{2J}\\ \rho_{3J}\end{pmatrix}(k) \qquad (1.20)$$

4. A numerical example of the CTM model-Traffic density1.1.

For the purpose of the demonstration of the CTM model, in this paper is performed a numerical example which is described below. For the sake of simplicity, are chosen the approximately the same freeway segment partitioning characteristics as that in earlier sections in order to do an interconnection with the laid state space model of traffic density. The system of performance measurements of the traffic road networks of the Californian state *PeMs* is used for traffic collection data and is considered a freeway link for on the street "Broadway Avenue", Stockton/San Francisco. The freeway is consisted from three cells with different lengths with one on-ramp on the first cell. (*fig.1).*

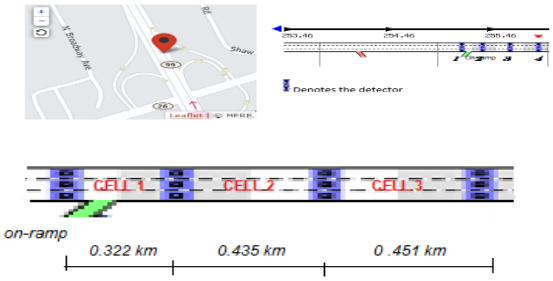

Fig. 1. Freeway segment with three cells

Calibrated parameters are given below [8].

Table 1. Summary of traffic parameters for three cells

	Q_M	*vf*	*ρcr*	*ρJ*	*w*	**FF/ /CC**
Cell 1	5580	84.8	65.8	248	30.6	FF
Cell 2	4176	96.8	43.1	248	20.3	FF
Cell 3	4268	106.7	40.0	248	20.5	FF

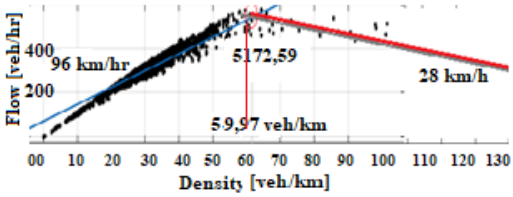

Fig.2. Calibrated parameters

5. Kalman Filter

Kalman filter-*KF* (*Kalman, 1960; Welch and Bishop 2001)* is a recursive data processing algorithm that uses only the previous time-step's prediction with the current measurement in order to make an estimate for the current state [4]. This means the *KF* does not require previous data to be stored or reprocessed with new measurements.

The building structure of the KF

The Kalman Filter consists of a set of mathematical equations that provides an efficient recursive computation to estimate the state of a process by minimizing the mean of the squared error. [4] The KF estimates the value of the variable x at any time (k+1), represented by a linear stochastic equation.

$$x_{k+1}=Ax_k+BX_k+w_k \qquad (1.22)$$

Where: A (k) is matrix which relates the state a time interval *k* with the state at current time interval *k+1. B (k)* is matrix which relates the current state to the control inputX_k.

The random variable *w* represents noise in modelling process. It is assumed to be within normal probability distributions with zero mean and variance Q (Gaussian) as: $p(w)\tilde{}\ N(0,Q)$

The system measurement equation describes the relationship between system states and measurements. Acknowledging that measurements inevitably contain noise, the output equation is expressed as follows:

$$\mathrm{Z(k+1)=H\cdot x(k)}, \qquad (1.23)$$

$\tilde{Z}(k)$ is the measurement variable (outflow of vehicles from cell 3-measured by loop detector 2) *H (k)* is the output matrix, and *v (k)* is the measurement noise variable. The errors in estimating *a priori* and *a posteriori* states are defined as follows:

$$P_k^-=x_k-\hat{x}_k^- \qquad (1.24)$$
$$\mathrm{P_k=x_k-\hat{x}_k} \qquad (1.25)$$

The *a priori* and a posteriori estimate covariance is given by:

$$P_k^-=E[e_k^-,e_k^{-T}]=AP_{k-1}\cdot A^T+Q \qquad (1.26)$$

$$P_k=E[e_k,e_k{}^T)=(I-K_kH)\cdot P_k^- \qquad (1.27)$$

The KF estimates a posteriori state of the process using a linear combination of a priori state and a weighted difference between the actual measurement and the model measurement of the state.

$$\hat{x}_k = \hat{x}^-_k + K(z_k - H \cdot \hat{x}^-_k) \quad (1.28)$$

$$K_k = P^-_k H^T (H P^-_k H^T + R)^{-1} \quad (1.29)$$

Based on the above equation, especially on (1.29), the *KF* process can be divided in two steps ore phases. The first step is the prediction step and the second step is the correction step.

6. Estimation with Kalman Filter

In this section are described in detail the applied matrices to the algorithm of the *CTM-KF* model. It is necessary to recall the equations state space of *CTM* model (Section V.1) first and then to do an interconnection of it with the *KF* algorithm equations. Since in our model, we are estimating the traffic densities of the three cells of the mentioned link, by the usage of the inputs values of the inflow q_1, output values q_4 and the flow from on ramp, then the state space vector of our algorithm are the densities $x=[x_1,x_2,x_3]= [\rho_1, \rho_2, \rho_3]^T$,the input vectors are

$$x_u= [q_1,0, q_4]^T; x_r=[qr,0,0]^T$$

$$x_{k+1} = Ax_k + BX_{Uk} + w_k$$

$$\begin{pmatrix}\rho_1\\ \rho_2\\ \rho_3\end{pmatrix} = A \cdot \begin{pmatrix}\rho_1\\ \rho_2\\ \rho_3\end{pmatrix} + Bu \cdot \begin{pmatrix}q_1\\ 0\\ -q_4\end{pmatrix} Br \cdot \begin{pmatrix}r\\ 0\\ 0\end{pmatrix} \quad (1.30)$$

On this paper we are going to use the measurement of the outflow from the cell three, that corresponds to the flow q_4 in the figure (3.1). Based on the fundamental diagram we model the traffic flow measurement through the densities on the last cell (ρ_3) and the free flow speed on cell 3 v_{f3} we will have $q_{out} = v_{f3} \cdot \rho_3$ that is consistent with the equation (6.2)

$$Z(k+1) = H \cdot x(k) \quad (1.31)$$

$$H = [0\ 0\ v_{f3}]\ and\ x = \begin{pmatrix}\rho_1\\ \rho_2\\ \rho_3\end{pmatrix}, q_{out} - [0\ 0\ v_{f3}] \begin{pmatrix}\rho_1\\ \rho_2\\ \rho_3\end{pmatrix}$$

Where*:* Q -the model error covariance matrix which elements standard deviations of the density variables. The off diagonal elements are equal to zero while R is the measurement or output error covariance. In this seminar paper, the matrices Q and R are assumed to be constant.[9]

$$Q = \begin{vmatrix} w & 0 & 0 \\ 0 & w & 0 \\ 0 & 0 & w \end{vmatrix}; R = \begin{vmatrix} 0 & 0 & 0 \\ 0 & 0 & 0 \\ 0 & 0 & v \end{vmatrix}$$

7. Results and Conclusion

Evaluation of the density values of cell is performed with discrete time intervals of $T_s=10$ seconds, where the initial values of the densities $\rho_0 = [\rho_{10}, \rho_{20}, \rho_{30}]^T$ and estimated covariance matrix P_o are assumed. T_s is chosen to be 10 second in order to fill the conditions $T<L/v_f$, for proper work with system matrices, otherwise there will be obtained negative values of density parameters. For the purpose of the results evaluation, measured traffic densities for five minute intervals are used for comparison with the estimated densities with *CTM* model. The performance of the model was quantified by calculating the Mean Absolute Percentage Error (*MAPE)* given in (*1.32).*

$$MAPE = [\frac{1}{n} \cdot \sum_{k=1}^{n} \left| 100 \frac{\rho_{mod}(k) - \rho_{meas}(k)}{\rho_{meas}(k)} \right] \cdot 100 \quad (1.32)$$

The MAPE results for CTM model for modes FFF -KF,

for Cell 1, Cell 2 and Cell3, 2 %, 0.6 % and 1 % respectively, nd for CCC-KF, 14% on the three cells. The results of the estimated values by CTM model against the measured values of traffic density are also graphically presented on the below figure (3-5).

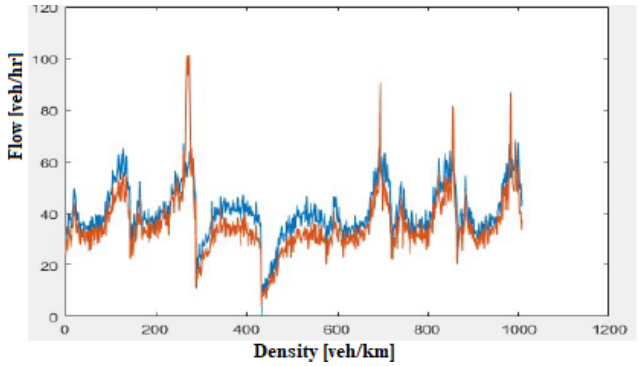

Fig.3. Graphic results densities of KF FFF and measurements- Cell 1

A B S T R A C T

The current advances in proteomic and transcriptomic technologies produced huge amounts of high-throughput data that spans multiple biological processes and characteristics in different organisms. One of the important directions in today's bioinformatics research is to discover patterns of genes that have interesting properties. These groups of genes can be referred to as functional modules. Detecting functional modules can be accomplished by the deep analysis of protein-protein interaction (PPI) networks, gene expression profiles, or both. In this work the focus will be on Human protein-protein interaction network and genes expression data that represents genes behavior in a group of diseases. Two of the most well-established clustering methods that target the interaction networks and the expression data will be used in this analysis. In addition, and to have more insights, genes molecular functionality will be studied. Finally, I will introduce the relation of the extracted modules on biological pathways. This study mainly illustrates the importance of including protein interaction activities as part of any study that aims at discovering meaningful knowledge about the biological scene where many actors play different roles.

1. Introduction

The current advances in proteomic and transcriptomic technologies produced huge amounts of high-throughput data that spans multiple biological processes and characteristics in different organisms. One of the important directions in today's bioinformatics research is to discover patterns of genes or genes products that have interesting characteristics that can be related to specific activities or functions inside the living organism. Researchers believe that those groups of genes are can give deeper insights of what is happening inside a living cell than studying individual genes in isolation. These groups of genes are called functional modules (patterns). Different approaches can be employed to discovering functional modules. One of the most important approaches is to focus on protein-protein interaction (PPI) networks and try to find well connected sub-networks. Another approach is to consider gene expression data and try to find modules that show similar behavior according to their expression levels by calculating correlations. The last approach is to integrate both the PPI and the expression data in a complementary effort because both PPI and expression data suffer from incompleteness and inconsistency problems [1].

However, for the expression profiles that are related to diseases in specific, most of the available data is in the form of genome-wide expression profiles that extracted from microarray measurements. A number of methods have been proposed to clarify the biological mechanisms from this expression data [2,3]. Most of those methods are based on individual genes ability to be used as a strong indication of the disease under consideration. However, considering only individual genes will give limited insights about the molecular mechanisms and biology of an organism under different disease conditions. On the other hand, studying groups of genes that show specific behavior related to some disease will help in grasping more comprehensive views about the disease itself and what molecular functionality those genes may have and can be involved in this disease. The reason for that is the fact that any biological process, such as a disease, occurring inside the living organism is affected and affects multiple and different biological components and pathways of that organism. Patterns of genes,

*Corresponding Author: Rami Alroobi, Magnolia, Ar 71753, 870-235-4295, Email: rmalroobi@saumag.edu

or functional modules, can be discovered in different ways. One approach is by applying clustering techniques on PPI networks to find patterns of well-connected genes. One of the most established methods used in this field is the stochastic flow-based clustering (Markov Cluster Algorithm, MCL) [4, 5]. The Markov cluster algorithm (MCL) uses a graph's natural transition probability matrix to cluster a graph by combining random walks with two alternating operations (expansion and inflation). With these operations, the algorithm iteratively simulates the dissipation and elimination of stochastic flow across the graph structure to produce a non-negative matrix representation of a graph clustering. In other words, the nodes of the graph are clustered with each other based on the strength of connections between these nodes. The MCL method has been shown to be significantly robust and superior to other network-based methods when used to cluster benchmarking biological networks [6].

Another approach is to use gene expression profiles to cluster genes that show similar behavior based on their expression levels that are extracted from microarray measurements. In this case, any clustering method can be used like K-means [7]. K-means and its variations are among the most popular iterative methods used for clustering data and can be easily applied to biological data. The general idea of K-means is that a number of centers are specified and a distance metric from these centers is used as a dissimilarity measure. The points are grouped towards the closest center based on the criteria used. For example, one of the widely used metrics is the Euclidean Distance. The Euclidean Distance [8] between values x_i and $x_{i'}$ can be defined as follows:

$$d(x_i, x_{i'}) = \sum_{j=1}^{p} (x_{ij} - x_{i'j})^2 = ||x_i - x_{i'}||^2$$

Then each of the points, genes in this case, will be assigned to cluster so that the distance between these points and the specified center is minimized. After that, a new set of centers are calculated and the assignment step is repeated. The process continues iteratively until the assignments stabilize so that no further assignments changes are possible.

2. Experimental Analysis

2.1 Datasets

In order to elucidate the work in this paper, a group of data sets were obtained and preprocessed in order to suite the setting required for this work. The following is a listing of the datasets used in the analysis.

- **Interaction Networks**
  The experiments were performed using Homosapiens (Humans) protein-protein interaction network. The Human network was obtained from the Human Protein Reference Database (HPRD), release 9 [9]. The Human PPI network has 9465 nodes with 37039 interactions.

- **Disease Gene profiles**
  In order to perform the planned analysis, gene expression profiles for 16 diseases were obtained from the GEO database [10]. Table 1 shows the names and identification numbers of these diseases.

- **OMIM dataset**
  The OMIM, Online Mendelian Inheritance in Man, database [11] was used to extract genes-disease data. The data includes 4022 different diseases. Each disease is represented by the genes causing it or in relation to that disease.

- **Human protein complexes**
  The human protein complexes are groups of proteins that have strong evidence that they are interact with each other. The protein complexes were extracted from HPRD (Human Protein Reference Database), release 9 [9]. This data set contains 1521 of manually curated protein complexes.

- **Molecular Functionality**
  For studying Molecular functions of the Human genes, the Molecular Functions from the GO annotation database were used (release date of the data base: 11/15/2011, version: 1.216) [12].

2.2 Performing Experiments

After obtaining all the datasets needed for this work, both MCL and K-means were employed to discover the interesting patterns.

Firstly, the MCL algorithm was applied to the HPRD interaction network. MCL uses a parameter that controls its operation. That parameter is called inflation. I used an inflation of 1.75 which is considered optimal according to [6]. I only considered the resulting patterns of sizes greater than or equal to 4 genes. The MCL produces connected modules when applied to the interaction network. The result contains 776 modules.

Table 1. Disease Datasets for expression profiles

GEO Series ID	GEO DataSet ID	Disease Name
GSE2503	GDS2200	Actinic keratosis
GSE1420	GDS1321	Adenocarcinoma of esophagus
GSE1297	GDS810	Alzheimer's disease
GSE5388	GDS2190	Bipolar disorder
GSE475	GDS289	Chronic obstructive lung disease
GSE1462	GDS1065	Chronic progressive ophthalmoplegia
GSE1629	GDS1850	Complex dental cavity
GSE3585	GDS2205	Congestive cardiomyopathy
GSE3365	GDS1615	Crohn's disease
GSE5370	GDS2153	Dermatomyositis
GSE2006	GDS1376	Essential thrombocythemia
GSE1751	GDS1331	Huntington's disease
GSE2018	GDS999	Lung transplant rejection
GSE3189	GDS1375	Malignant melanoma
GSE3868	GDS1746	Malignant neoplasm of prostate
GSE2549	GDS1220	Malignant pleural mesothelioma

2.3 Performing Experiments

After obtaining all the datasets needed for this work, both MCL and K-means were employed to discover the interesting patterns.

Firstly, the MCL algorithm was applied to the HPRD interaction network. MCL uses a parameter that controls its

operation. That parameter is called inflation. I used an inflation of 1.75 which is considered optimal according to [6]. I only considered the resulting patterns of sizes greater than or equal to 4 genes. The MCL produces connected modules when applied to the interaction network. The result contains 776 modules.

Secondly, the K-means algorithm was applied to the gene disease expression profile data. In order to have comparable number of modules to the one produced by the MCL, the number of modules resulting from the MCL was used as the number of K-means initial centers (clusters). Then, the analysis was performed with clusters of sizes greater than 4 genes (similar to what was done in MCL). K-means produced 1039 module of size ≥ 4 genes. The genes in these modules show similar behavior according to the disease expression data used in this study.

2.4 Human protien complexes

The following analysis was performed to assess the quality of the MCL and K-means produced modules in predicting known protein complexes. Those complexes are proved to have biological significance. Therefore, more matched complexes by the produced patterns means higher quality patterns from the biological point of view.

For assessing complex matching, I used the matching criteria introduced by [13]. The overlap score was computed by the formula $w = i^2/a*b$, where i is the size of the intersection set between the discovered patterns and the known complex, a is the size of the discovered protein pattern and b is the size of known protein complex. The overlap threshold between produced patterns and the protein complexes ranged from 0.1 to 1.0 with 0.1 increments; 1.0 implies a 100% match between the module and the protein complex. The range was chosen to make the overlapping abilities of the discovered patterns a tangible amount illustrating the quality of these patterns. Furthermore, we have not considered any overlap to be considered as a match which would may be seen as an overstatement of these results. More overlap indicates a better match with protein complexes, however knowing that more protein complexes are yet to be identified, even a lower match percentage can highlight some promising results. Figure 1 illustrates the MCL performance. While Figure 2 shows the performance of K-means prediction capability. Clearly, MCL has superiority over the K-means and was able to predict protein complexes even with higher overlap thresholds. This can be referred to the fact that many of the complexes are known to be well connected sub-graphs originally, and MCL aims at producing connected modules. Furthermore, K-means does not care about patterns connectivity. It is only concerned of expression similarity.

Another note about the results that I found interesting is that the larger the produced pattern the more penalty it will face in the complex matching process. This is because the average size of protein complexes is ≈ 5 genes and the criteria used for matching penalizes large patterns.

2.5 OMIM disease modules

The OMIM dataset provides a comprehensive collection of diseases that relates a large number of known diseases to the genes that are causing them or have a strong involvement in the cause and the mechanisms of the disease, in other words the Etiology and Pathogenesis of a disease. To evaluate the produced patterns and to have more insights that they can provide in the disease domain, both MCL and K-means produced patterns were tested against the OMIM disease dataset. This analysis aimed at discovering modules that might be related to known diseases.

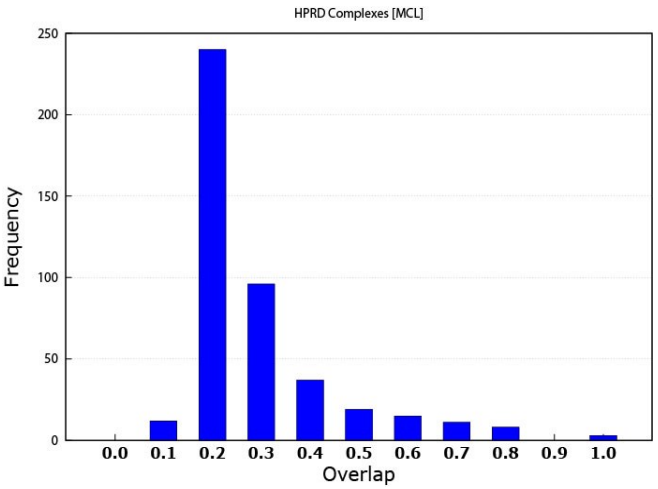

Figure 1. MCL protein complex prediction

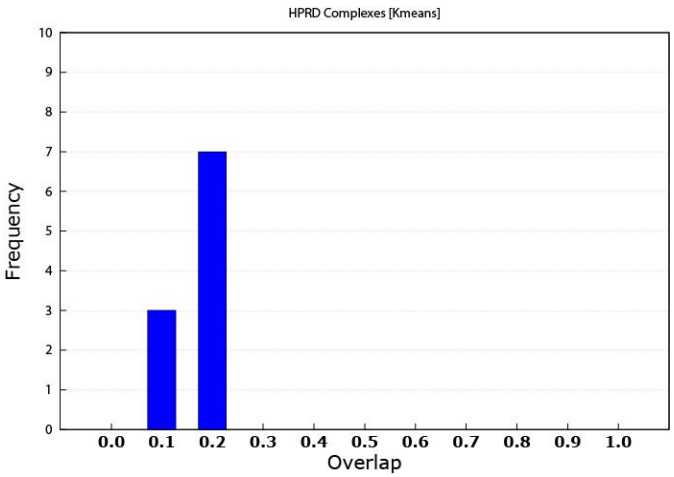

Figure 2. K-means protein complex prediction

As expected, the K-means slightly outperformed the MCL in this case. In this work, the patterns in the OMIM dataset are referred to as disease modules.

MCL produced patterns matched 68 disease modules while K-means matched 134 disease modules. The reason is that K-means patterns were originally based on data that is disease related. Some of the diseases that were used to create expression profile dataset were among the ones that were found from the OMIM dataset. As mentioned above, this study used only 16 diseases expression data, while the resultant matched diseases were multiples of that number. An explanation is that some genes can be involved in multiple diseases. This note means that some genes play the rule of a link between different diseases.

Thus, targeting these specific genes can illuminate hidden information that might lead interesting results; the cure for example. However, this statement needs more investigation by intensive research that is out of the scope of this work. In addition, a produced pattern can match more than one disease.

Figure 3 shows the performance of MCL when used with the OMIM dataset. Figure 4 is similar but for K-means. Table 2 and Table 3 show some of the disease matched by the MCL and K-means modules respectively. More specifically, Table 3 shows that some produced modules by K-means has matched multiple types of disease.

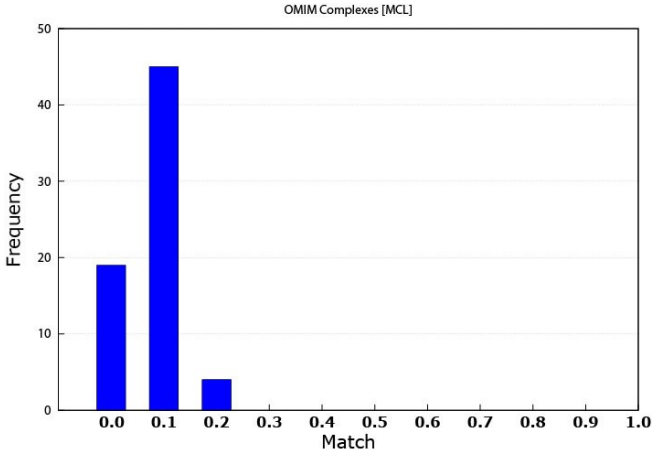

Figure 3. MCL matching performance against the OMIM data (0.0 means that the threshold is ≤ 0.1)

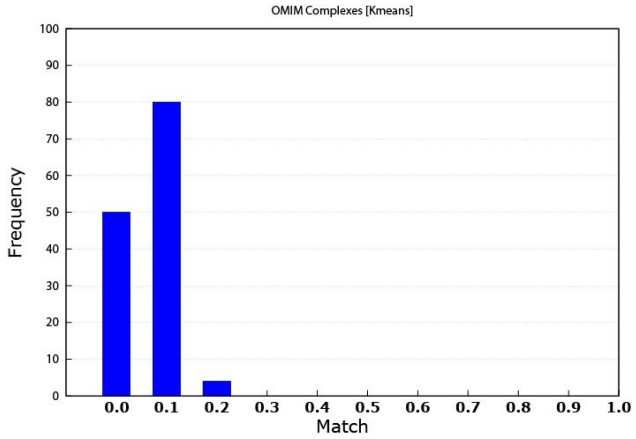

Figure 4. K-means matching performance against the OMIM data (0.0 means that the threshold is ≤ 0.1)

Table 2. Some of the MCL matched disease

Module's Genes	Related Disease

DHX9 SERPINB2 C6 MGEA5 PRPF8	Combined C6/C7 deficiency

3. Molecular functionality

As a further step, the Molecular Functionality (MF) of the genes can be considered as a useful source of information in many aspects. First, knowledge about the MF of the genes in the produced patterns is informative especially if some of the genes in the pattern are not well studied and their functions are not well known, but the association in the pattern may result in new data about these genes. Second, the combination between the MF of the patterns and the disease expression data can lead to meaningful indications about the disease mechanisms inside the living organism, the human in this case. Molecular Functions Gene Ontologies were extracted from the Gene Ontology project [12]. Studying the resulting modules showed that modules span multiple molecular functionalities and they did not show any tendency towards some particular biological processes. However, modules gene members have shown high similarities in what biological processes they share.

Table 3. Some of the K-means matched disease

Module's Genes	Related Disease
PKD2 IGBP1 TXNL4A NID1	Polycystic kidney disease
PKD2 IGBP1 TXNL4A NID1	Corpus callosum agenesis of with mental retardation ocular ,coloboma and micrognathia

Figure 5 has an example module that is enriched in a number of multiple molecular functions such as, GO:0008601: Modulation of the activity of the enzyme protein phosphatase type 2A. GO:0019888: Modulates the activity of a protein phosphatase, an enzyme which catalyzes of the removal of a phosphate group from a protein substrate molecule GO:0019208: Modulates the activity of a phosphatase, an enzyme which catalyzes of the removal of a phosphate group from a substrate molecule. GO:0005488: The selective, non-covalent, often stoichiometric, interaction of a molecule with one or more specific sites on another molecule. GO:0004512: Catalysis of the reaction: D-glucose 6- phosphate = 1D-myo-inositol 3-phosphate. This reaction requires NAD, which dehydrogenates the CHOH group to CO at C-5 of the glucose 6-phosphate, making C-6 into an active methylene, able to condense with the aldehyde at C- 1. Finally, the enzyme-bound NADH reconverts C-5 into the CHOH form. GO:0005515: Interacting selectively and non-covalently with any protein or protein complex. The above results were obtained using The Database for Annotation, Visualization and Integrated Discovery (DAVID) [14] [15].

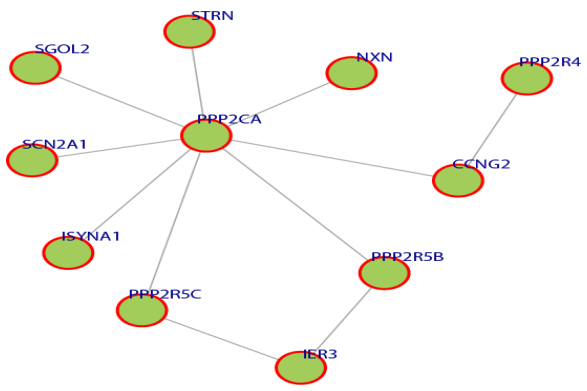

Figure 5. A module that was extracted from the network where all the genes have similar molecular functionality.

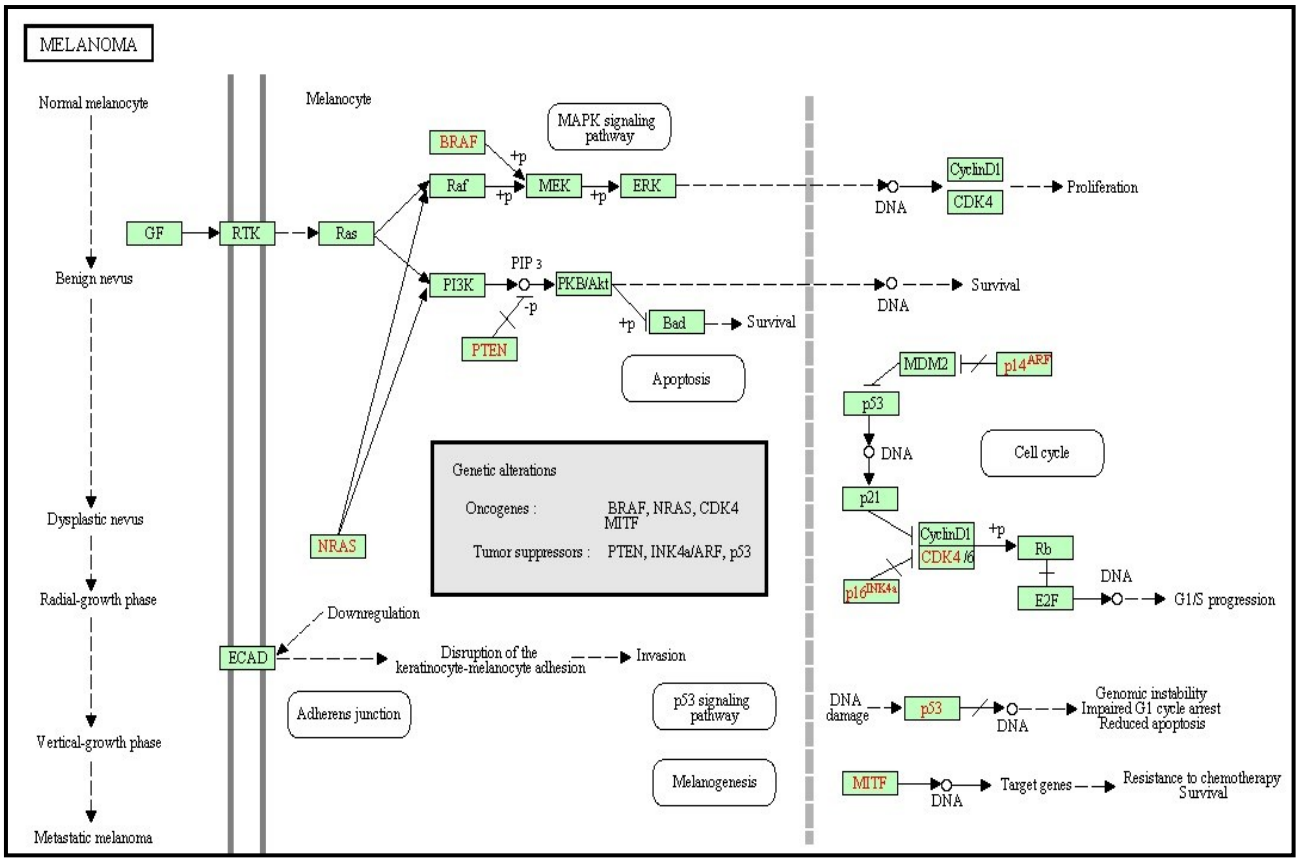

Figure 6. The prostate cancer pathway.

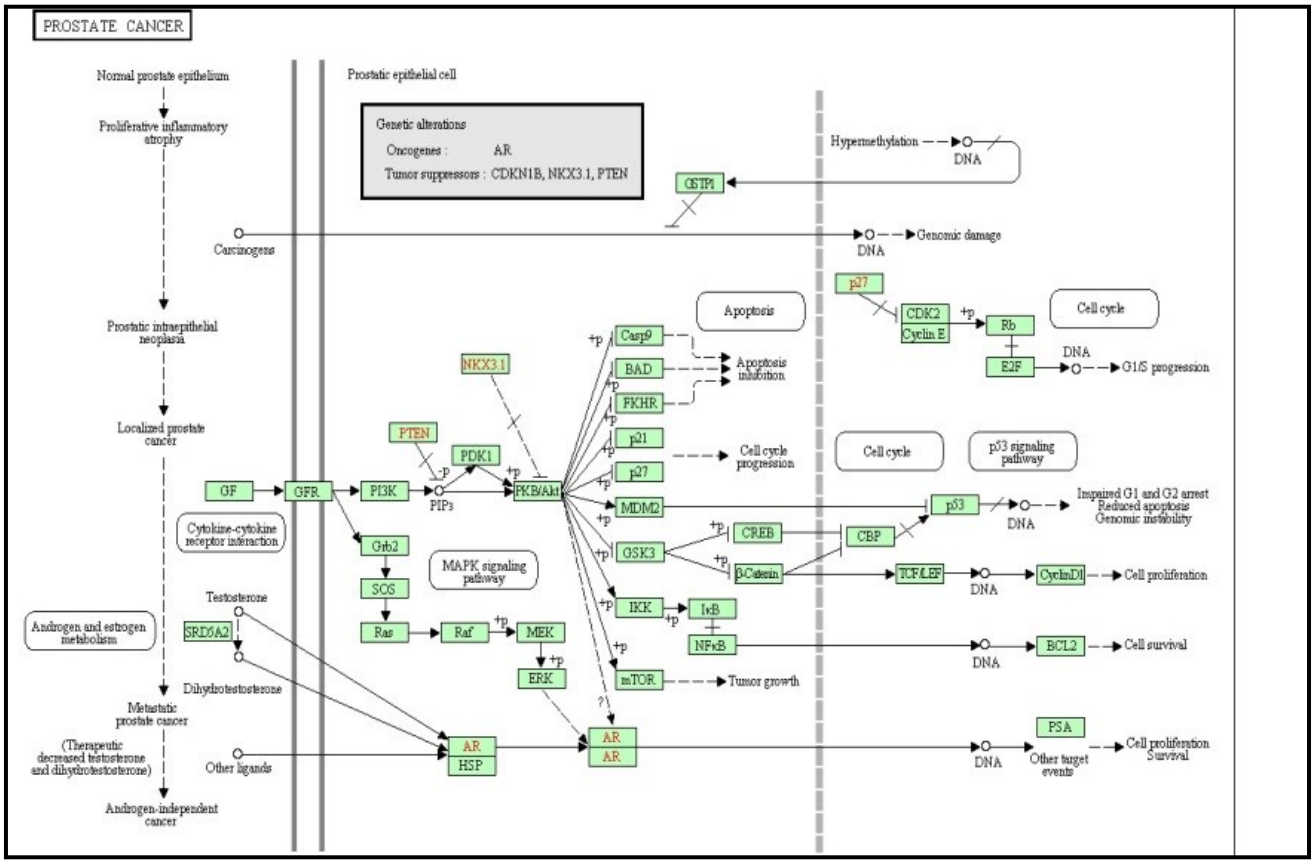

Figure 7. The Melanoma pathway.

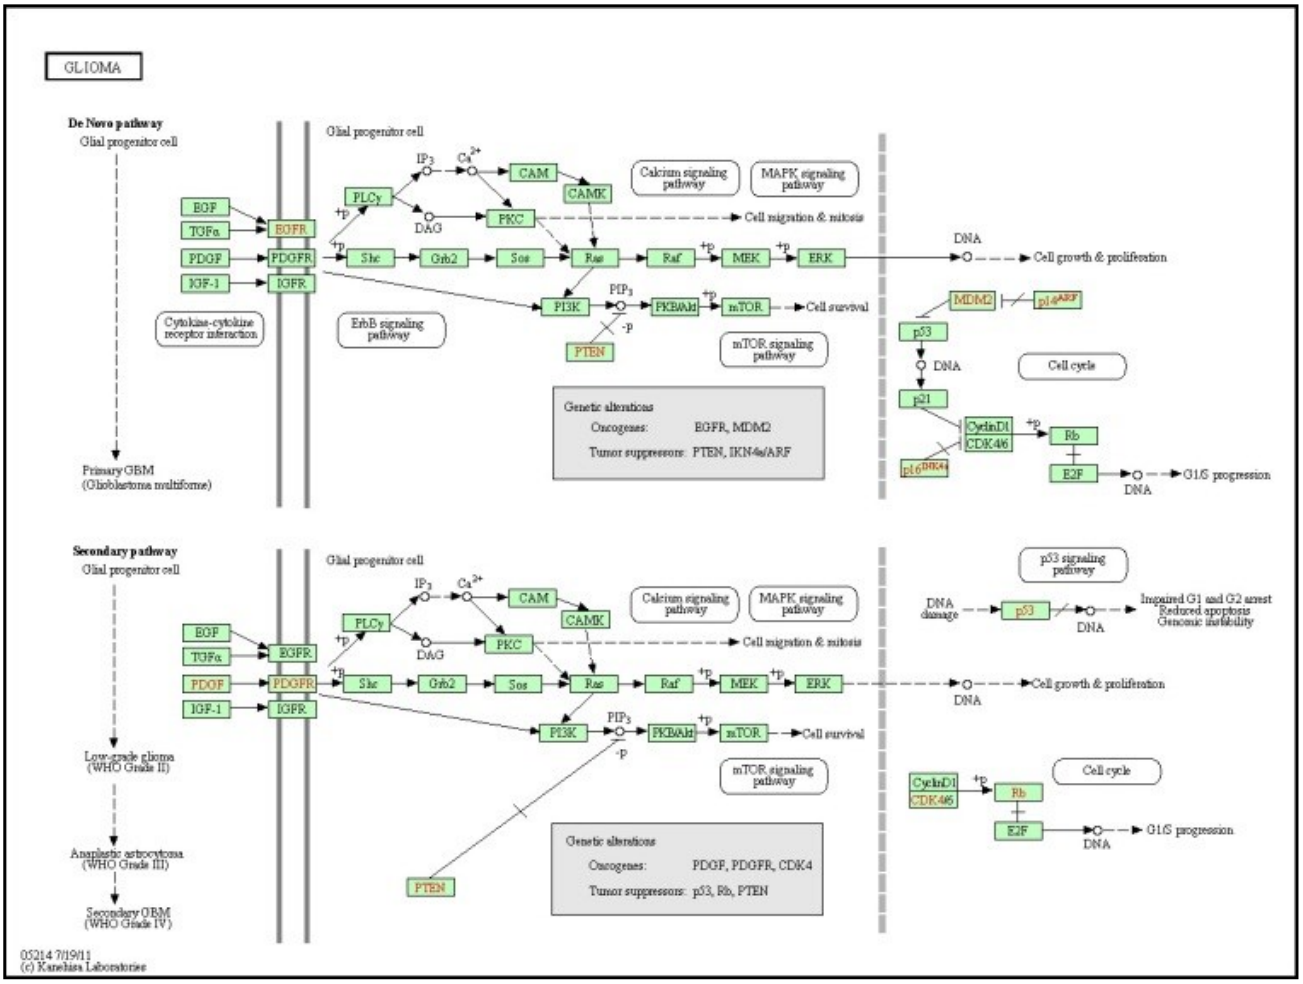

Figure 8. The Glioma pathway.

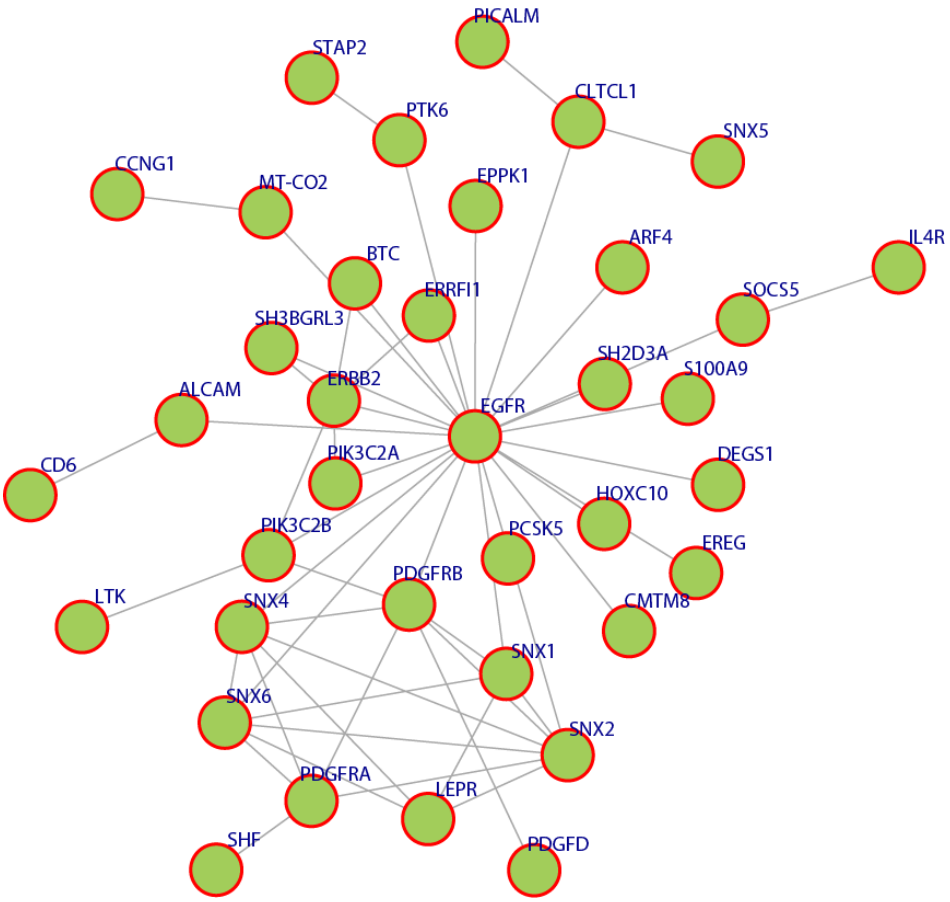

Figure 9. This discovered pattern above shows a module that is overlapped with multiple disease pathways

4. Pathways

Many of the discovered modules have biological pathways associations. Biological pathway is a group of actions that occur between the molecules in the cell that result in the formation of a new product or change in the cell. This association with pathways was checked against the Kyoto Encyclopedia of Genes and Genomes (KEGG) [16]. To illustrate the idea further, some example pathways chosen were very interesting in that they have a relation with different types of diseases. Figure 6, 7, 8, and 9 have some examples of disease-related pathways like: Prostate cancer pathway, Glioma pathway, and Melanoma pathway. In addition, another example (not shown here) matched the Notch Signaling Pathway. Notch signaling has been related to a number of malignancies including leukemia, lymphomas and carcinomas of the breast, skin, lung, cervix and kidneys [9]. It is clear from Figure 6, that one of the discovered modules has several genes that are highly incorporated in multiple disease pathways. Furthermore, we can see that not all of the module genes are present in those pathways; this raises an interesting question; can future research prove that those absent genes are related to the same pathway and therefore to the diseases because they were clustered with several of the pathway genes?

5. Conclusion

The availability of large amounts of microarray data in, both interaction networks and expression profiles, has been used to have deeper insights of what biological processes are taking place inside an organism. Much of this data is related to different aspects of the living cell activities. In addition, this expression data can be extracted from organism or tissues under a group of experimental, environmental, or any kind of stress conditions. Diseases expression data can be considered a very useful source of information regarding what genes are involved in or affected by them. In this study I tried to shed some lights about modules extracted from two separate sources of information and what relations they may have with known diseases and try to uncover some of new connections between genes and diseases. Both of the two methods employed here, MCL and K-means, have its strength sides and weakness sides. When it comes to interaction networks, MCL was superior. However, K-means has shown acceptable performance with expression profile data. The method has produced interesting patterns when they are tested against several biological concepts such as protein complexes, disease modules, molecular functionality, and biological pathways.

Conflict of Interest

The authors declare no conflict of interest.

Acknowledgment

I would like to thank the reviewers of this work for their help. This work was accomplished by the support of Southern Arkansas University, College of Science and Engineering.

Fault detection

ABSTRACT

Recently, the number of industrial accidents of chemical plants has been increasing in Japan. The fault detection system is required to keep chemical plant safely. In this study, a fault detection system for a chemical plants using agent framework and negative selection algorithm was proposed. The negative selection algorithm is one of artificial immune systems. The artificial immune system is an imitative mechanism of vital actions to discriminate self/nonself to protect itself. The method was implemented and applied to a complicated chemical plant—which is a boiler plant virtually operated using a dynamic plant simulator. The simulations of fault detection were carried out. And also the results of simulations are presented in this paper.

1 Introduction

This paper is an extension of work originally presented in 2017 6th International Symposium on Advanced Control of Industrial Processes (AdCONIP) [1].

Recently, it has been increasing the accidents of chemical plants. Figure 1 shows the annual numbers of the industrial accidents in Japan (the data is based on the summary of accidents in specified business facilities inside petrochemical complex in Japan, published by Fire and Disaster Management Agency, Ministry of Internal Affairs and Communications, Japan, posted on their official web site on May 2017, article in Japanese). The numbers of the industrial accidents in Japan—except accidents caused by earthquakes or tsunami—has been increasing from 45 in 1993 to over 250 in 2016. It is said that the remote causes of the rise of accidents in Japan are mass retirements of skilled engineers, insufficient technical tradition, labor-savings in production lines or plant operations, aged deterioration of productive facilities, or maintenance cost reduction in assertive ways. Therefore, effective fault detection system for chemical plants is required. In the general chemical plant operations, *plant alarm system* has been used to notify the process deviance to operators via warning lights or buzzers in the operation rooms, where the upper and lower thresholds of the measured values or the thresholds of their amounts of changes have been set to the sensors in the chemical plants. However, it is so difficult to determine the adequate values of thresholds (that is 'alarm setpoint') that if the alarm setpoints are too small, the alarm floods will be caused, if the setpoints are too large, missed detection of deviation will be caused. And also it is difficult to detect if the plant has normal and regular load fluctuations under both the normal and the abnormal situations. Therefore, a method is required that observes the relationship among several variables to detect faults in a complicated system. We focus on the Artificial Immune System.

Artificial Immune Systems—which are imitative mechanisms of vital actions of discrimination between self and nonself—have been proposed since 1990s. And a lot of methods have been proposed using various parts of artificial immune systems, for example, pattern recognition by B-cells for fault detection in gas lift oil well by Aguilar [2, 3], Natural Killer (NK) immune cells mechanisms by Laurentys [4], clonal selection algorithm for maintenance scheduling of power generators by El-sharkh [5], dendritic cell for failure detection of aircraft by Azzawi [6]. Also lots of applications have been proposed—Wada et al. [7] proposed an fault mode detection method for automotive exhaust gas treatment system, Inomo et al. [8] proposed an failure diagnosis method for water supply network by using immune system.

https://dx.doi.org/10.25046/aj030211

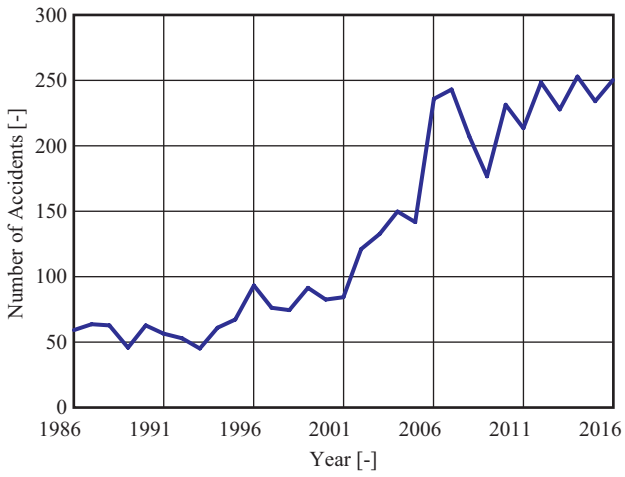

Figure 1: The annual numbers of the industrial accidents in Japan, data from FDMA, Japan.

In this study, we adopt a negative selection algorithm to detect faults in a chemical plant. Negative selection algorithm is an imitative method of mechanisms of differentiation and maturation, and discrimination of normal/abnormal. The algorithm was proposed by Forrest in 1994 [13] for the detection of computer virus. The negative selection algorithm has been applied to various domains—Dasgupta et al. [9] applied to aircraft fault detection, Gao et .al [10] applied to motor fault detection, Xiong et al. [11] and Prasad et al. [12] applied to fault detection in the Tennessee Eastman process.

In this study, we introduce detectors to detect faults based on the negative selection algorithm. The adopted method of the negative selection algorithm is mentioned in section 2. In order to utilize negative selection algorithm, we designed and implemented an agent based framework of fault detection system, mentioned in section 3. The target chemical process, the simulation conditions and the results are mentioned in section 4. And the conclusion in section 5.

2 Negative Selection Algorithm

Negative selection algorithm is one of the methods of the artificial immune systems inspired by the vital immune systems. Negative selection algorithm borrowed from the mechanism of T-cell generation in thymus. On T-cell generation in vital system, immature T-cells are randomly generated with various immunological types. And then some of T-cells are eliminated if they have high affinity with self-antigen to avoid response to "self". T-cells which are not self-affinitive can be matured to react with foreign antigen to protect itself.

In our system, detectors—correspond to mature T-cells in vital—can detect faults by recognizing the normal operational data of chemical processes which are assumed as *self* and the abnormal operational data which are assumed as *nonself*. In Figure 2(a)–(c), the steps of the generation phase of detectors are illustrated. Figure 2(a) illustrates that there are *self* regions in a 2-dimensional process variables space. And the rest area of the variables space are *nonself* regions. Figure 2(b) illustrates that detector candidates which indicated by plus(+) signs are generated with various position, where the radius is set as the minimum distance to the *self* region. In this study, we implement two steps of candidate generation. The first step is a grid-based generation. Place the detector candidates at every 0.1 of each axis—axis is normalized between [0.0, 1.0]—, therefore 121 (each axis divided into eleven) grid-based candidates are generated. The second step is a semi-randomly generation. Place a detector candidate at random position. Then check whether the new candidate is overlapped on the previously generated candidates. If it overlapped, the new candidate is eliminated in this step, if not, the new candidate is added to the candidates. And then, check the coverage of the detectors. If the coverage is over 90%, candidate generation will be terminated. From Figure 2(b) to (c), the elimination of some candidates which have affinity with "self" is carried out. Figure 2(c) illustrates that seven valid detectors are remained. Then the generation phase is finished.

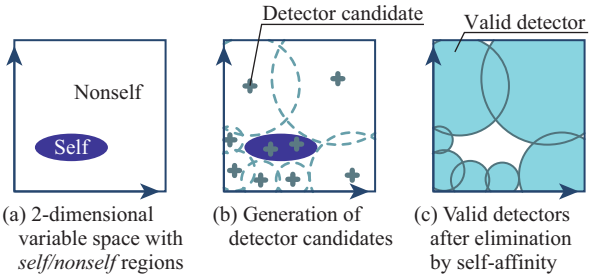

Figure 2: A schematic diagram of the detectors generation.

In the detection phase, a sample consists of the values of the current process variables—which are to be examined— is plotted into the variable space indicated by a 'star'. If the plotted sample is inside the detection area of at least one detectors, the sample is recognized as "abnormal" (Figure 3(a)). And if the sample is out of any detection area, the sample is recognized as "normal" (Figure 3(b)).

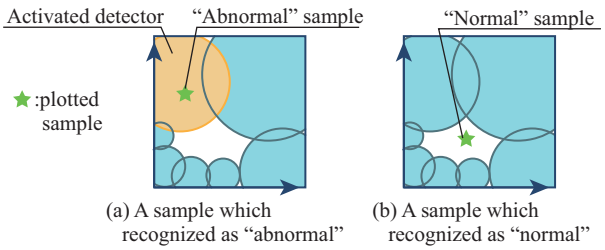

Figure 3: A schematic diagram of the detection by detectors.

3 Fault Detection System

A multiagent framework is adopted to implement a fault detection system using negative selection algorithm. In our system, there are *Detector Manager*, *Detector Leader(s)* and *Database Agent* illustrated in Figure 4. *Detector Manager* is an interface between human operator and the system. *Detector Leader(s)* have their own variable spaces to detect faults. These variable spaces represent relationships between two certain process variables. And there are a lot of detectors under the dominion of a *Detector Leader*. In order to avoid missing detection, some *Detector Leaders* with variety of combinations of the process variables are required. *Database Agent* have a database which stores operational database of the target process. All these agents can communicate with other agents via TCP/IP network connection.

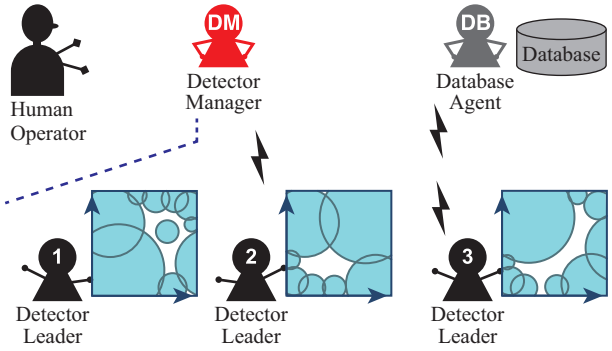

Figure 4: A schematic diagram of the detection by detectors.

4 Simulations and Results

4.1 Target Process

Figure 5 shows a boiler plant which is the target process of this study. It is an utility plant which supplies three steam headers—high pressure steam (HP), middle pressure steam (MP), and low pressure steam (LP) to the nearby plants by boiling pure water in a furnace. Due to the fluctuation of the steam demands from user plants, the boiler plant is always under unsteady operation. Therefore, it is difficult to detect faults by setting up the constant thresholds to some process variables of the boiler plant.

In this study, nine variables were selected from among 120 measured variables in the boiler plant. The selected nine variables are listed in Table 1 and also illustrated in Fig.5. The operational data was obtained by using dynamic plant simulator "Visual Modeler" (Omega Simulation Co., LTD).

4.2 Normal Operational Data

Data of a normal operation—in which the steam demands were stepwise changed without any malfunction—were obtained using the dynamic simulator. The data contain 7200 samples of the above-mentioned nine process variables and its sampling interval is one second. The trend graphs of PI1422 and TI1422 were indicated in Figure 6. These data were normal operational data which should be recognized as *self* in the artificial immune system even though the steam demands had increased at time 600 second.

4.3 Abnormal Operational Data

Abnormal operational data with three kinds of assumed malfunctions were obtained using the dynamic simulator. Table 2 shows the list of three assumed malfunctions. And Figures 8–10 illustrate the trend graphs of PI1422 and TI1422 when the one of malfunctions was occurred at time 600 second, but without any steam demand change during these 7200 seconds.

Table 1: Selected nine process variables of the boiler plant.

Variable name	Description
FI1422	Flow rate of the second extraction steam from the turbine
PI1422	Pressure of the second extraction steam from the turbine
TI1422	Temperature of the second extraction steam from the turbine
TC1423	Temperature of the low pressure steam from the desuperheater
PI1315	Pressure inside the furnace (upper)
GB401.pos	Valve position of the combustion air
PI1311	Pressure of the outlet of the forced draft fan
TI1310	Temperature of the exhaust gas at the gas air heater outlet
TI1308	Temperature of the combustion air at the gas air heater outlet

4.4 Generation of Detectors

Detectors were generated by using normal operational data for each of 36 combinations of 2-dimensional variable spaces—all the 2-dimensional variable spaces consists of two different process variables from the nine variables. Figure 7 illustrates the detectors in the variable space consisting of TI1422 vs. PI1422. The axes are normalized to the range of the normal operation occupies [0.05, 0.95] in the normalized axis respectively. In this figure, there are 261 detectors (118 grid detectors and 143 randomized detectors) which indicated as sky blue circles. In other words, it is recognized that there exist the normal operational data—which correspond "self" region—at

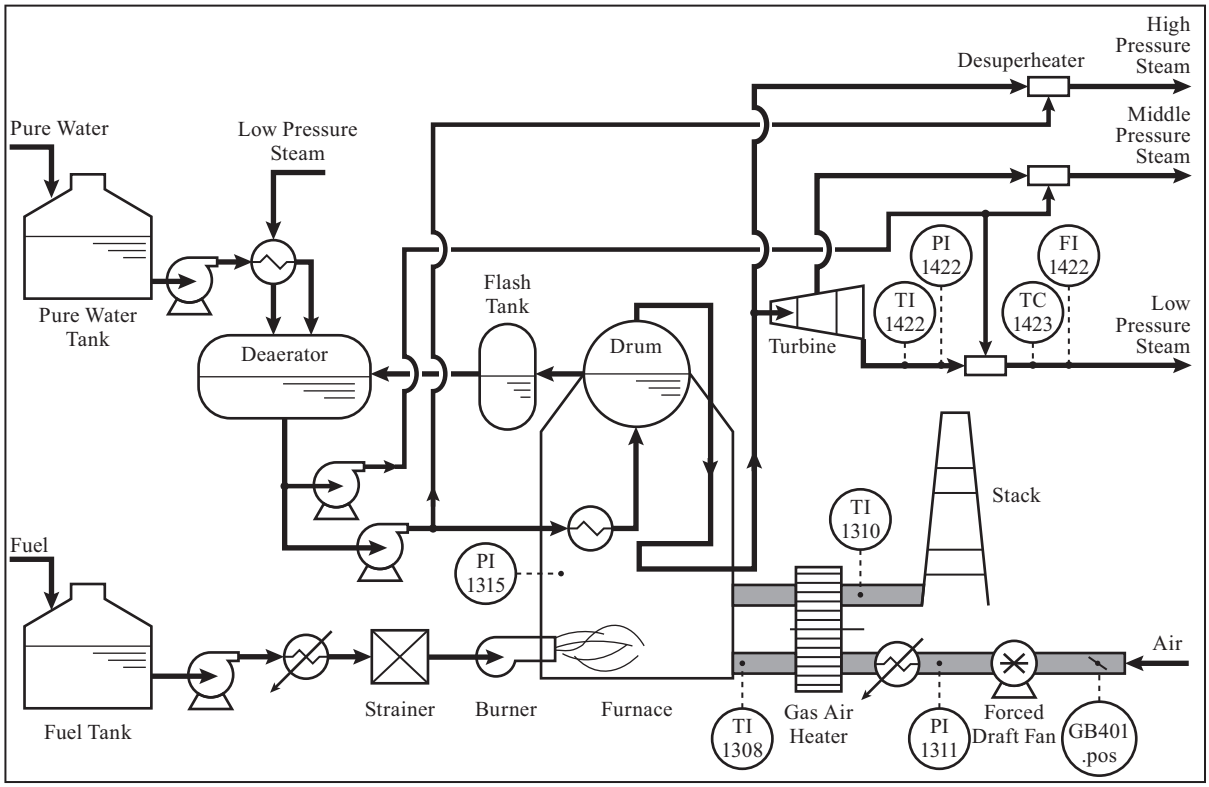

Figure 5: A schematic diagram of the boiler plant.

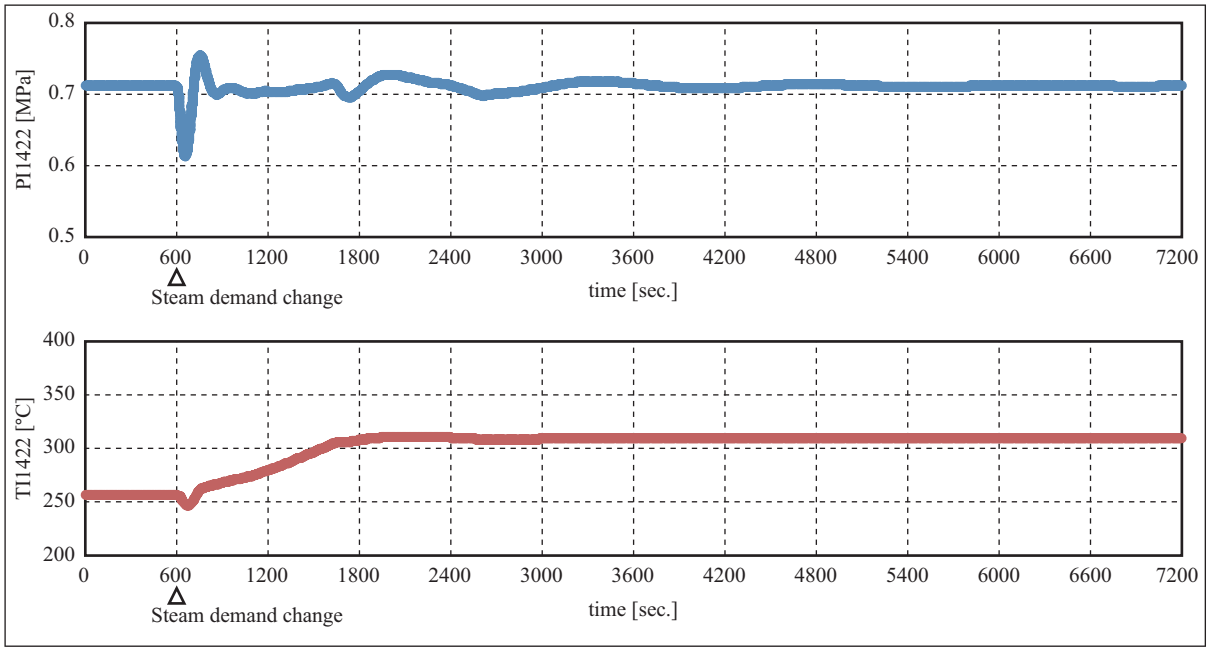

Figure 6: The trend graphs of PI1422 and TI1422 during normal operation with steam demands change at time 600 second.

the unpainted parts in Figure 7, and not exist the normal operational data—which correspond "nonself" region—at the painted sky blue parts. The sets of detectors were generated for the rest of variable spaces in the same way. The numbers of the detectors in each variable space were from 121 to 316 including both the grid detectors and randomized detectors.

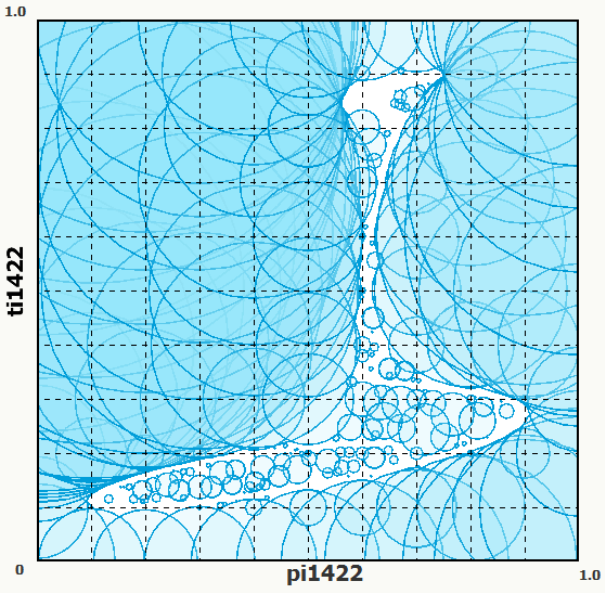

Figure 7: Generated detectors for a 2-dimensional variable space (TI1422 vs. PI1422).

The bold dashed lines in the trend graphs are the maximum and minimum values under the normal operation (Figure 6). We can find that it is impossible to detect fault using upper/lower thresholds of variable PI1422 and/or TI1422 when the malfunction BFO or GAH occurred, because the values of PI1422 and TI1422 have not exceeded the ranges under the normal operation. On the other hand, it may possible to detect at time 671 second by lower threshold of TI1422 when the malfunction FDFclose occured at time 600 second. TI1422 also exceeds upper threshold after time 1340 second, shown in Figure 10.

Table 2: Three assumed malfunctions in the boiler plant.

Malfunction ID	Description
BFO	Burner frame out
GAH	Gas air heater rotation failure
FDFclose	Forced draft fan inlet vane closure

4.5 Fault Detection using Detectors

Fault detections for the abnormal operational data were carried out. Figure 11 shows an outline of the fault detection in a 2-dimensional variable space consisting of TI1422 and PI1422 when malfunction BFO occurred. The axes and the detectors—indicated by sky blue circles— are the same as Figure 7. The sampling data were plotted by green dots on the 2-dimensional variable space after the normalization for every second serially. The blue dots are the normal operational data and the green dots are the sampling data to be examined by the detectors. These dots are moving in the variable space as time proceeds. If the green dots were placed on the unpainted region, they are recognized as "self"—where the values are similar to the normal operational data. If the green dots were placed over the sky blue region, they are recognized as "nonself"—in other words, a fault was detected in this variable space by detector(s).

In Figure 11, the painted orange circles indicate activated detectors—which have detected fault. Figure 12 shows the detection status through time. If the value is '1', at least one detector in this variable space detects fault, and if the value is '0', no detector detects fault at that time. The figure shows that the first detection was at time 630 second—which is 30 second after malfunction occurred—, and there are missing between time 897 and 904 second in this variable space. The detections using the sets of detectors in the rest of variable spaces were simultaneously carried out in the same way. Figure 13 shows the number of variable spaces whose detection status is '1'. The figure shows that there are 15 variable spaces detected at time 601 second, 30 variable spaces—which corresponds to 80% of 36 variable spaces—detected at time 604 second, and the number does not fall below the 80% after that time. Therefore it can be said that this system can detect malfunction BFO successfully.

Figure 14 shows the outline of the fault detection, Figure 12 shows the detection status through time when malfunction GAH occurred. The figures show that the fault was detected at time 666 second by the detectors. On the other hand, it have not been detected after time 1047 second in this variable space TI1422 vs. PI1422. However 16 shows that 21 variable spaces—which corresponds to 58% of 36 variable spaces—detected at time 602 second, and the number does not fall below 58% after that time. It can be said that this system can detect malfunction GAH successfully, although the variable space TI1422 vs. PI1422 could not detect after time 1047 second.

Figure 17 also shows the outline of the fault detection, Figure 18 shows the detection status through time when malfunction FDFclose occurred. The figures show that the fault was detected at time 630 second by the detectors. Although the detection status fluctuate between time 897–1102 second in the variable space TI1422 vs. PI1422, over 30 variable spaces detect after time 604 second and the number does not fall below the 80% of the 36 variable spaces after time 604 second. It can be also said that this system can detect malfunction FDFclose successfully.

5 Conclusion

We built up a fault detection system using negative selection algorithms which can focus on the relationships between process variables.

ABSTRACT

Feature extraction is taking a very vital and essential part of bio-signal processing. We need to choose one of two paths to identify and select features in any system. The most popular track is engineering handcrafted, which mainly depends on the user experience and the field of application. While the other path is feature learning, which depends on training the system on recognising and picking the best features that match the application. The main concept of feature learning is to create a model that is expected to be able to learn the best features without any human intervention instead of recourse the traditional methods for feature extraction or reduction and avoid dealing with feature extraction that depends on researcher experience. In this paper, Auto-Encoder will be utilised as a feature learning algorithm to practice the recommended model to excerpt the useful features from the surface electromyography signal. Deep learning method will be suggested by using Auto-Encoder to learn features. Wavelet Packet, Spectrogram, and Wavelet will be employed to represent the surface electromyography signal in our recommended model. Then, the newly represented bio-signal will be fed to stacked autoencoder (2 stages) to learn features and finally, the behaviour of the proposed algorithm will be estimated by hiring different classifiers such as Extreme Learning Machine, Support Vector Machine, and SoftMax Layer. The Rectified Linear Unit (ReLU) will be created as an activation function for extreme learning machine classifier besides existing functions such as sigmoid and radial basis function. ReLU will show a better classification ability than sigmoid and Radial basis function (RBF) for wavelet, Wavelet scale 5 and wavelet packet signal representations implemented techniques. ReLU will illustrate better classification ability, as an activation function, than sigmoid and poorer than RBF for spectrogram signal representation. Both confidence interval and Analysis of Variance will be estimated for different classifiers. Classifier fusion layer will be implemented to glean the classifier which will progress the best accuracies' values for both testing and training to develop the results. Classifier fusion layer brought an encouraging value for both accuracies either training or testing ones.

1. Introduction

Supervised learning is widely utilised in various applications. However, it is still quite limited method. The majority of applications need handcrafted engineering extraction of features by implementing different techniques. This means that the principal purpose is to represent the bio-signal by applying proper feature representation methods. Whenever significant features represent bio-signal, classification error should be anticipated to be lower than extracting features, which are not genuinely representing data. However, the general engineering handcrafted representation is still effortful and consumes a long time. Moreover, the standard feature extraction algorithm relies on researcher's experience. Many proposed feature learning methods may be implemented to improve feature representation automatically and save both effort and time. The primary evaluation of the behaviour of implemented feature learning method is the classification error. Deep learning is considered the

most common technique to implement feature learning. Rina Detcher was the first to introduce the fundamentals for both first and second order deep learning [1]. Deep learning is an essential division of machine learning that consists of a multilayer. The output of each layer is considered as features that will be introduced to the following cascaded layer [2]. Artificial neural networks use a hidden layer to implement each layer of multilayers that construct deep learning [3]. Fig.1 shows a simple architecture of deep learning steps. The learning technique is done in a hierarchal method starting from the lower layers to the upper ones [4]. Deep learning can be used for both supervised and unsupervised learning where it learns features from data and eliminates any redundancy that might be existing in the representation. Unsupervised learning recruitment brings more defy than supervised one. Unsupervised learning for deep learning was implemented by Neural history compressors [5]and deep belief networks[6].

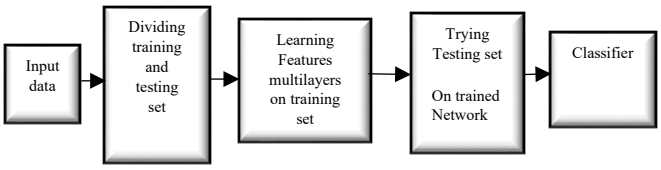

Fig.1. Traditional Deep Learning Steps

This paper is organised by presenting a brief study on previous work that has been done on classification finger movement and deep learning in different fields, then a review study on autoencoder including the main equation for Auto-Encoder will be introduced. The surface electromyography will be assimilated by Wavelet Packet, Spectrogram and Wavelet. We will compare our results by implementing three different classifiers, which will be Support vector machine, Extreme learning machine with three activation functions and Softmax layer.

The Analysis of Variance (ANOVA) will be calculated for different classifiers in Auto-Encoder deep learning method. Also, the confidence interval for Auto-Encoder will be implemented as well. At last, each of training and testing accuracy will be promoted by concatenating classifier fusion layer.

2. Previous Work

In this research, we will suggest a deep learning system that will be capable of providing essential features from the input signal without recourse to traditional feature extraction and reduction algorithms. The suggested system will be talented in assert the ten hand finger motions. The classification of different Finger motions was discussed earlier in many published scientific types of research. The early pattern recognition for finger movements was proposed in [7] where the researchers suggested using neural networks in analysing and classifying the introduced EMG pattern. They classified both finger movement and joint angle associated with moving finger. Later, in [8] the authors investigated and optimised configuration between electrode size and its arrangement to achieve high classification accuracy. Then, in [9] the researchers gave more attention to selecting the extremely discriminative features by employing Fuzzy Neighbourhood Preserving Analysis (FNPA) where the main purpose of this technique is to reduce the distance between the samples that belong to the same class and maximise it between samples of different classes. In the same year, other researchers explored the traditional machine learning well-known algorithm. Where, they used time domain features and implemented support vector machine, linear discriminate analysis and k-nearest neighbours as different classifiers then, they took advantage of Genetic Algorithm to search for redundancy in the used dataset and selected features as well [10]. In the same context, authors proposed an accurate finger movement classification system by extracting time domain-auto regression features, reducing features by using orthogonal fuzzy neighbourhood discriminant analysis technique and implementing linear discriminant analysis as classifier [11]. After that, other researchers suggested an accurate pattern recognition system for finger movement by extracting 16-time domain features to process the Electromyography signal and implementing two layers feed forward neural networks as classifiers [12]. In contrast, effort and time that are being wasted, as mentioned before, in feature extraction and reduction were the motivation behind introducing the concept of deep learning. Therefore, many researchers published valuable achievements in deep learning for the biomedical signal. An extensive review study was presented on different types of research that recalled deep learning in health field [13]. The common factor in each study was the recruitment of neural network to learn features from input bio-signal. In the same context, researchers proposed a model by using convolutional neural networks to convert the information which was given by wearable sensor into highly related discriminative features [14]. Another research presented a deep learning record system that predicted the future medical risk automatically after extracting essential features by implementing convolutional neural networks [15]. Also, researchers implemented a system that used to extract shallow features from wearable sensor devices then the features were introduced to convolutional neural networks and finally to the classifier layer [16]. Based on the above, we can conclude that deep learning is an initial step towards implementing self-learning system by using neural networks. In our proposed system, we will implement neural networks in the form of two stages autoencoder, which read represented bio-signal by either spectrogram, wavelet or wavelet packet. We will use different classifiers to evaluate our system behaviour. Finally, we will add classifier fusion layer, which will follow best local classifier methodology. Adding classifier fusion was a promising contribution to the accuracies. Moreover, both confidence interval and Analysis of Variance will be estimated for different classifiers.

3. Sparse Auto-Encoder

An Autoencoder is an extensively used technique to reduce dimensions [17]. Sparse autoencoder idea first started in [18]. Where it started to reduce the redundancy that may result from complex statistical dependencies. Building a neural network and train it by using sparse method penalty as mentioned in [19] and taking into account the number of hidden nodes in the developed neural network, is considered a straightforward factor but as crucial as choosing the learning algorithm [20].

Auto-Encoder is a feed-forward neural network that is used in unsupervised learning [21]. The implemented neural network is being trained to learn features and produce it as its output rather than generating classes in case of recalling the classification ability of the hired neural network [22]. The encoder input is the represented data while its output is the features learnt by autoencoder. The learnt features learnt from the autoencoder will be introduced to classifier to be used in the assort of the data into

predefined classes[23]. Lately, autoencoder is commonly employed to extract highly expressing features from data.

Unlabelled data can be used to train an autoencoder where training is mainly interested in optimising the cost function. The cost function is mainly responsible for estimating the miscalculation that may occur in calculating the reconstructed copy of input at the output and the input data.

Assume that we have an input vector $x \in R^{D_x}$. The autoencoder maps this input to a new vector $z \in R^{D^{(1)}}$.

$$z^{(1)} = h^{(1)}(W^{(1)}x + b^{(1)}) \quad (1)$$

Where the superscript (1) represents the first layer of the autoencoder. $h^{(1)}: R^{D^{(1)}} \rightarrow R^{D^{(1)}}$ represents the transfer function, $W^{(1)} \in R^{D^{(1)}}$ represents the weight matrix, and $b^{(1)} \in R^{D^{(1)}}$ represents the bias vector. Then the decoder transfers the encoded representation z as a reconstruction of the input x following the next equation

$$\hat{x} = h^{(2)}(W^{(2)}x + b^{(2)}) \quad (2)$$

Where the upper character (2) signifies the second layer of the autoencoder. $h^{(2)}: R^{D^{(2)}} \rightarrow R^{D^{(2)}}$ accounts for the transfer function, $W^{(2)} \in R^{D^{(2)}}$ represents the weight matrix, and $b^{(2)} \in R^{D^{(2)}}$ represents the bias vector.

The sparsity term can be introduced to autoencoder by adding an adapted cost function in the form of regularisation term. The regularisation function is estimated for each neuron i by averaging its activation function, which can be expressed as follows

$$\hat{\rho}_i = \frac{1}{n}\sum_{j=1}^{n} z_i^{(1)}(x_j) = \frac{1}{n}\sum_{j=1}^{n} h(W_i^{(1)T}x_j + b_i^{(1)}) \quad (3)$$

Where n is the number of training samples, x_j is the j^{th} training sample of input, $W_i^{(1)T}$ is the i^{th} row of the weight matrix transpose of the first layer, and $b_i^{(1)}$ is the i^{th} term of the bias vector for the neural network. The neurone is considered to be firing if its output activation function is high and in the case of having a low activation value, this means that the neurone is only responding to a small number of input samples, which in turn encourages the autoencoder to learn. Accordingly, adding a limitation term to activation function output $\hat{\rho}_i$ limits every neurone to learn from limited features. This motivates the other neurones to respond to only another small number of features, which initiates every neurone to be responsible for responding to individual features for each input.

Introducing a sparsity regularise value is considered as a measure of how far or close is the targeted activation value ρ from the actual activation output function $\hat{\rho}$. Kullback-Leibler divergence is a very well know the equation that describes the difference between two different distributions. This equation is shown as follows:

$$\Omega_{Sparsity} = \sum_{i=1}^{D^{(1)}} KL(\rho||\hat{\rho}_i) = \sum_{i=1}^{D^{(1)}} \rho \log\frac{\rho}{\hat{\rho}_i} + (1-\rho)\log(\frac{1-\rho}{1-\hat{\rho}_i}) \quad (4)$$

The cost function is decreased to initiate the two distributions $\hat{\rho}_i$ and ρ to be as close as possible. The cost function can be represented by a mean square error equation as follows:

$$E = \underbrace{\frac{1}{N}\sum_{n=1}^{N}\sum_{k=1}^{K}(X_{kn} + \hat{X}_{kn})^2}_{\text{Mean Square Error}} + \underbrace{\lambda * \Omega_{weights}}_{\text{L2 Regularisation}} + \underbrace{\beta * \Omega_{Sparsity}}_{\text{Sparsity Regularisation}} \quad (5)$$

Where L2 regularisation is a term to be added to the cost function to regulate and prevent the value of Sparsity Regularisation value of being small during the training due to the increase that may happen to the values of weights and decrease to the value of the mapped vector z

$$\Omega_{wights} = \frac{1}{2}\sum_{l}^{L}\sum_{j}^{n}\sum_{i}^{K}(w_{ji}^{(1)})^2 \quad (6)$$

L is the number of hidden layers, N is the number of input data samples, and K is the number of classes.

Autoencoder was hired in many research areas as a feature learning layer. Where its primary task, was to learn features from input data. A robust study was published to compare between many applications for autoencoder in deep learning field [24]. Autoencoder was implemented in [25] to learn incremental feature learning by introducing an extensive data set to denoising autoencoder. Denoising autoencoder provides an extremely robust performance against noisy data with a high classification accuracy [26, 27]. Another suggested autoencoder was a marginalised stacked one which showed a better performance, with high dimensional data, than the traditionally stacked autoencoder regarding accuracy and simulation time [28]. Denoising stacked autoencoder was hired to learn features from unlabeled data in a hierarchical behaviour [29] and was applied to filter spam by following greedy layer-wise to the implemented denoising stacked autoencoder [30].

In our proposed model, Auto-Encoder is a feed-forward neural network that is used in feature learning. The implemented neural network is being trained to learn features and produce it as its output rather than generating classes in case of recalling the classification ability of the hired neural network. Where, we implemented a stack autoencoder, which consists of two successive encoder stages. The input to the encoder is the data while the output is the features or representations. The classifier uses features produced from encoder as an input while; its output is the classes equivalent to input data [23]. Fig.2 demonstrates the steps that the surface electromyography signal moves through by using a sparse autoencoder.

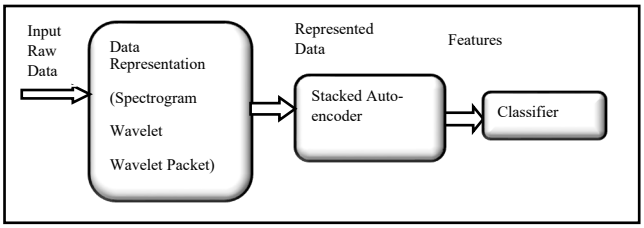

Fig.2. Procedures of Sparse Auto-Encoder signal representation

In the same context of feature learning, autoencoder will generate useful features at the output, rather than producing classes, by decreasing the dimension of the input data into a lower dimension. However, the new lower dimension data will be dealt with our features that contain essential and discriminative information on the data, which will help in better classification results. Sparse autoencoder enhances us to leverage the availability of data.

4. Bio Signal Representation

We suggested three signal representations be applied on raw biological data to ensure fidelity and precision of our bio signal. Moreover, introducing raw data directly to first auto-encoder stage resulted in accuracy less than 50%. The first data representation was the spectrogram for bio raw signal. The spectrogram is interpreted to be the illustration of the spectrum of frequencies of our surface electromyography signal in a visible method. Numerically, Spectrogram can be estimated by calculating the square of the magnitude of Short-Time Fourier Transform (STFT). It can be called short-term Fourier transforms rather than spectrogram. In short time Fourier transforms, the long-time signal is divided into equal length segments and shorter in time. Short time Fourier transforms is relevant to Fourier transform. Then, the frequency and phase for each segment to be estimated separately. Based on the above, we can deduce that spectrogram can be treated as Fourier transform but for shorter segments rather than estimating it from the full long signal at once[31].

Assume that we have a discrete time signal x with a finite duration (limited signal) and a number of samples N. The Discrete Fourier Transform (DFT) can be expressed as follows:

$$\hat{x}(k) = \sum_{n=0}^{N-1} x(n) e^{-i\frac{2\pi k}{N}n} \quad , k = 0, \dots\dots, N-1 \qquad (7)$$

Knowing that the Fourier transform is estimated at frequency $f = \frac{k}{N}$

The original signal x can be restored back from $\hat{x}$ by applying the inverse Discrete Fourier Transform as follows:

$$x(n) = \frac{1}{N}\sum_{k=0}^{N-1} \hat{x}(k) e^{-i\frac{2\pi k}{N}n}, \qquad n = 0, \dots\dots, N-1 \qquad (8)$$

The above-mentioned two equations can be rephrased as follows:

$$x = \frac{1}{N} F\hat{x} \qquad (9)$$

$$\hat{x} = \bar{F}x \qquad (10)$$

Where F is Fourier matrix of $n * n$ dimensions and $\bar{F}$ is its complex conjugate

$$F = \begin{bmatrix} 1 & 1 & 1 & \cdots & 1 \\ 1 & e^{i\frac{2\pi}{N}} & e^{i\frac{4\pi}{N}} & \cdots & e^{i\frac{2\pi(N-1)}{N}} \\ 1 & e^{i\frac{4\pi}{N}} & e^{i\frac{8\pi}{N}} & \cdots & e^{i\frac{2\pi 2(N-1)}{N}} \\ \vdots & \vdots & \vdots & \ddots & \vdots \\ 1 & e^{i\frac{2\pi(N-1)}{N}} & e^{i\frac{2\pi 2(N-1)}{N}} & \cdots & e^{i\frac{2\pi(N-1)^2}{N}} \end{bmatrix} \qquad (11)$$

Where the entries of $\hat{x}$ is expressed in terms frequencies coefficients

$$f = 0, {}^{1}/_{N}, {}^{2}/_{N}, \dots\dots {}^{(N-1)}/_{N} \qquad (12)$$

We need to calculate the spectrogram of the signal. Assume that we have a signal x of length N, which is divided into successive equal segments m. Where $m < N$. The matrix of successive equal segments can be expressed as X where $X \in R^{mx(N-m+1)}$. The first column of X matrix equals $[x[0], x[1], \dots\dots x[m-1]]^T$ and its second column equals $[x[1], x[2], \dots\dots x[m]]^T$. The spectrogram for a signal x with window size m can be annotated $\widehat{X}$. The columns which are composing matrix $\hat{X}$ is the discrete Fourier transform

$$\hat{X} = \bar{F}X \qquad (13)$$

$$X = \frac{1}{m} F\hat{X} \qquad (14)$$

The rows of the matrix $\hat{X}$ are representing the signal x in the time domain while its columns are representing the signal x in the frequency domain. So simply spectrogram is a time-frequency representation of the signal x.

The spectrogram was used in many applications especially for speech signal analysis wherein [32] the authors represented the speech signal by different representations like Fourier and spectrogram to conclude that the resolution is mainly dependent on used representations. In [33] the researchers estimated the time corrected version of rapid frequency spectrogram of the speech signal which showed a better ability to follow the alterations in the bio-signal than other published techniques.

The second signal representation used was wavelet of the signal. Wavelet is estimated by shifting and scaling small segmentations of the bio-signal. Fourier transform is an illustration of the signal in a sinusoidal wave by using various frequencies while wavelet is the illustration of the abrupt changes that happen to the signal. Fourier transform is considered a good representation of the signal in case of having a smooth signal. While wavelet is believed to be a better representation, than Fourier, for the sudden changing signal. Wavelet gives the opportunity to represent rapid variations of the signal and help the system extract more discriminative features. We implemented Haar wavelet for our proposed model.

So in brief, a wavelet is an analysis for time series signal that has non-stationary power at many frequencies [34]. Assume that we have a time series signal x_n with equal time spacing δt and $n = 0, \dots\dots N-1$ where the wavelet function is $\Psi_o(\eta)$ that depends on time η. The wavelet signal has zero mean and is represented in both time and frequency domain [35]. Morlet wavelet can be estimated by modulating our time domain signal by Gaussian as follows:

$$\Psi_o(\eta) = \pi^{\frac{-1}{4}} e^{i\eta\omega_o} e^{\frac{-\eta^2}{2}} \qquad (15)$$

Where ω_o is the frequency of the unmodulated signal. The continuous wavelet of a discrete signal x_n is the convolutional of x_n with scaled and shifted version of $\Psi_o(\eta)$

$$W_n(s) = \sum_{n'=0}^{N-1} x_{n'}\ \Psi^*\left[\frac{(n'-n)\delta t}{s}\right] \qquad (16)$$

Where * is the complex conjugate and s is the scale.

The wavelet transform was applied in several studies and different fields as in [36] where wavelet implemented in Geophysics field, in [37, 38] for climate, in [39] for weather, in [40] and many other applications. The above equation can be simplified by reducing the number of N. The convolutional theorem permits to estimate N convolutional in Fourier domain by implementing Discrete Fourier Transform (DFT). The Discrete Fourier Transform for x_n.

$$\hat{x}_k = \frac{1}{N}\sum_{n=0}^{N-1} x_n e^{-2\pi i k n/N} \quad (17)$$

Where $k = 0, \ldots, N-1$ which is representing the frequencies. For a continuous signal $\Psi(t/s)$ is defined as $\hat{\psi}(s(\omega)$. Based on the convolutional theorem, the inverse Fourier transform is equal to wavelet transform as follows:

$$\psi_n(s) = \sum_{k=0}^{N-1} \hat{x}_k \hat{\psi} * (s\omega_k) e^{i\omega_k n \delta t} \quad (18)$$

Where the angular frequency ω_k can be expressed as follows:

$$\omega_k = \begin{cases} \frac{2\pi k}{N\delta t} & : k \le \frac{N}{2} \text{ or} \\ \frac{-2\pi k}{N\delta t} & : k > \frac{N}{2} \end{cases} \quad (19)$$

An improved copy of wavelet algorithm was recalled in [41] where the authors presented two techniques. The first one used expansion factors for filtering while the other one is factoring wavelet transform. The researchers in [42] introduced the Morlet wavelet to vibration signal of a machine. The vibration signal of the low signal to noise ratio was represented by wavelet to grant fidelity to the signal and allow extraction better powerful features. This model was implemented in [43] where researchers used wavelet transform to predict early malfunction symptoms that may happen in the gearbox.

As a refinement act, we scaled the wavelet signal by five in wavelet, which in turn promoted the results as shown in Table I. As a comparative study, we utilised wavelet packet for the signal representation. The signal can be represented in both time and frequency domain simultaneously. This representation gains a fidelity to the signal due to its robust representation. Wavelet packet is one of the very widely used signal representation that produces the signal in both time and frequency domain [44]. The wavelet packet shows a very well acted for both nonstationary and transient signals [45-47]. Wavelet packet is estimated by a linear combination of wavelets. The coefficients of linear combination are calculated by recursive algorithm [48]. The wavelet packet estimation can be done as follows:

Assume that we have two wavelets type signal $h(n)$, $g(n)$ and two filters of length $2N$. Let us assume that the following sequence of functions is representing wavelet functions.

$$(W_n(x), n = 0,1,2, \ldots\ldots)$$

$$W_{2n}(x) = \sqrt{2}\sum_{k=0}^{2N-1} h(k) W_n(2x-k)$$

$$W_{2n+1}(x) = \sqrt{2}\sum_{k=0}^{2N-1} g(k) W_n(2x-k) \quad (20)$$

Where $W_0(x) = \varphi(x)$ is the scaling function, $W_1(x) = \omega(x)$ is the wavelet function.

$N = 1, h(0) = h(1) = \frac{1}{\sqrt{2}}$ and $g(0) = -g(1) = \frac{1}{\sqrt{2}}$

The above equations became

$$W_{2n}(x) = W_n(2x) + W_n(2x-1)$$

And

$$W_{2n+1}(x) = W_n(2x) + W_n(2x-1) \quad (21)$$

Where $W_0(x) = \varphi(x)$ is the scaling function, $W_1(x) = \omega(x)$ is the Haar wavelet function.

Many researchers implemented wavelet packet as in [49]. The authors used wavelet packet to create an index called rate index to detect the damage that may happen to the structure of any beam. In the same context authors of [50] employed wavelet packet and neural networks to detect a fault in a combustion engine. The implemented wavelet packet was six levels for sym10 at sampling frequency 2 kHz.

5. Classifiers

In the implementation of Auto-Encoder as feature learning algorithm, we applied three different classifiers, where the first was Softmax layer, the second was Extreme learning machine, and the third was Support Vector Machine (SVM). We measured the accuracy of Linear support vector machine, Quad support vector machine, Cubic support vector machine, Fine Gauss support vector machine, Medium Gauss support vector machine and Coarse Gauss support vector machine and elected the support vector machine classifier that resulted in the highest accurate result. Furthermore, the appending of classifier fusion layer to nominate best local classifier which in return endorsed the accuracy values. Fig.3 shows the block diagram for our implemented autoencoder feature learning proposed model

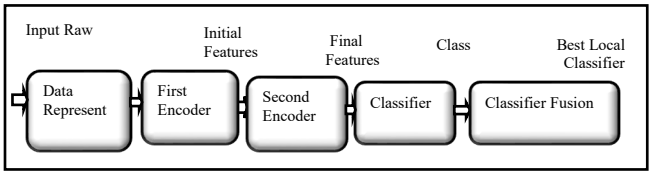

Fig.3. Scheme of proposed Model

Moreover, ANOVA for autoencoder different classifiers was implemented. Where, we assembled average testing accuracies for four signal representation techniques (Wavelet, Wavelet Scale5, Wavelet Packet and Spectrogram) that resulted in P value 0.7487. So as wavelet results should not be counted, due to its low accuracy values, so, we suggested a second trial which was to group average testing accuracies for three signal representing techniques (Wavelet Scale5, Wavelet Packet and Spectrogram) that resulted in P value 0.3405. Both P values showed that there was no sensible variation between any of the implemented three

classifiers as P value was higher than 0.05 in both cases. Fig.7 shows different P values for different classifiers.

In addition to the above, we estimated the confidence interval for each classifier. Our confidence interval was designed for confidence score 60%. Our assessed interval was bounded by higher and lower limit. In other words, we were confident or assured of any new accuracy by percentage 60% as long as it is located in the previously estimated interval.

6. Implementation

In this part, the data acquisition methods we followed will be expressed more extensively, and simulation outcomes will be exhibited and discussed.

6.1. Data Acquisition

The surface Electromyography signal was read by using FlexComp Infiniti™ device. Two sensors were placed on the forearm of the participant of type T9503M. The placement of two electrodes on participant's forearm is as shown in fig.4

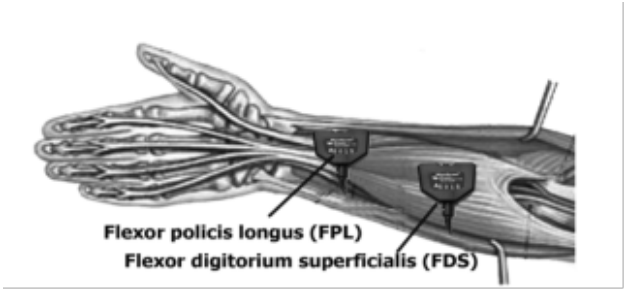

Fig.4. Placement of the electrodes

The Electromyography signal was collected from nine participants. Each participant performed one finger movement for five seconds then had a rest for another five seconds. Every finger motion was reiterated six times. The same sequence was repeated for the second finger activity. Amplification of the signal by 1000 was applied and a sampling rate of 2000 samples for each second was implemented.

The collected Electromyography signal was used to categorise between predefined ten finger motions, as shown in Fig.5 via using our suggested model. Three folded cross validation was applied on our collected Electromyography signal. Accordingly, 2/3 of the collected data was assigned to training set while remaining 1/3 to be used by testing set.

Our surface electromyography signal was filtered to ensure fidelity and removal of any noise that may be inserted into the collected bio-signal. The average training or testing accuracy was estimated by simulating our proposed model for every subject apart then summed the accuracies for all subjects and divided the result by the total number of subjects.

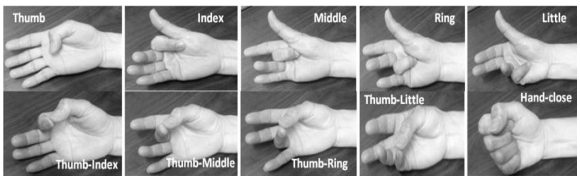

Fig.5. Targeted Ten different finger motions

6.2. Results

We implemented 400 nodes for the first layer of autoencoder and 300 nodes for the second one. As for the transfer function of the encoder, it was the pure linear type.

Table I shows autoencoder feature learning testing and training accuracy where the bio-signal was presented by spectrogram, wavelet, Wavelet scale 5 and wavelet packet. Three different classifiers were executed. The first was a SoftMax layer. While the second classifier was an extreme learning machine, we examined the performance of various activation functions for extreme learning machine classifier like sigmoid, the rectified linear unit and radial basis function. As that, the third classifier was support vector machine. We examined the performance of linear support vector machine, quadratic support vector machine, cubic support vector machine, fine gauss support vector machine, medium gauss support vector machine and coarse gauss support vector machine. Then, we selected the highest support vector machine that showed better classification ability to be our implemented support vector machine.

Table I. Auto Encoder Testing and Training Accuracy

Signal Representing	Average Training Accuracy	Average Testing Accuracy	Classification Algorithm	Simulation Time
Spectrogram	95%	73%	SoftMax Layer	830.93 Seconds
Spectrogram	95.5%	79.14%	ELM (Sigmoid)	379.10 Seconds
Spectrogram	95.5%	82.78%	ELM (ReLU)	379.54 Seconds
Spectrogram	97.237%	83.56%	ELM (RBF)	353.756 Seconds
Spectrogram	89.48%	77.27%	Cubic SVM	1000.409 Seconds
Wavelet	91.42%	45.71%	SoftMax Layer	210.04 Seconds
Wavelet	79.95%	59.88%	ELM (Sigmoid)	265.23 Seconds
Wavelet	83.62%	64.73%	ELM (ReLU)	276.149 Seconds
Wavelet	81.98%	62.70%	ELM (RBF)	257.83 Seconds
Wavelet	70.29%	52.29%	Linear SVM	341.57 Seconds
Wavelet (Scale 5)	98.85%	82.13%	SoftMax Layer	668.355 Seconds
Wavelet (Scale 5)	95.65%	85.416%	ELM (Sigmoid)	402.647 Seconds
Wavelet (Scale 5)	96.98%	86.827%	ELM (ReLU)	276.697 Seconds
Wavelet (Scale 5)	95.59%	85.58%	ELM (RBF)	444.067 Seconds
Wavelet (Scale 5)	96.55%	83.85%	Cubic SVM	495.124 Seconds
Wavelet Packet	98.69%	84.176%	SoftMax Layer	429.52 Seconds
Wavelet Packet	93.3%	86.79%	ELM (Sigmoid)	419.27 Seconds
Wavelet Packet	96.42%	89.41%	ELM (ReLU)	419.27 Seconds
Wavelet Packet	95.59%	87.78%	ELM (RBF)	540.22 Seconds
Wavelet Packet	98.16%	89.707%	Quad SVM	579.713 Seconds

outstanding in our application for all signal representation except for wavelet packet. Both quadratic support vector machine and extreme learning machine, with the rectified linear unit as an activation function, showed a very close performance for wavelet packet signal representation. Extreme learning machine was improved when we replaced sigmoid activation function by Radial basis function and the rectified linear unit. The rectified linear unit activation function for extreme learning machine presented a superior behaviour than radial basis function and sigmoid activation functions for wavelet, Wavelet scale 5 and wavelet packet. However, the rectified linear unit offered better performance than sigmoid and lower accuracy than radial basis function for spectrogram.

Cubic and Quad support vector machine started to result in a good testing accuracy for Wavelet scale 5 and wavelet packet only. Simulation time for support vector machine is relatively longer than other compared classification algorithms. SoftMax layer resulted in a very poor classification for wavelet signal representation, as the testing accuracy was less than 50%. Softmax started to prove its classification ability for Wavelet scale 5 and wavelet packet. Fig.6 shows different P values for different classifiers and Fig.7 shows confidence intervals for each classifier where it was calculated twice. The grey bars were calculated for different classifiers with three signal representation methods (Wavelet Scale5, Wavelet Packet and Spectrogram). While, yellow bars calculated for different classifiers with four signal representation methods (Wavelet, Wavelet Scale5, Wavelet Packet and Spectrogram). The narrowest interval was 2.53% for the extreme learning machine. While the widest one was 6.10% for support vector machine and softmax layer interval reached 5.77%.

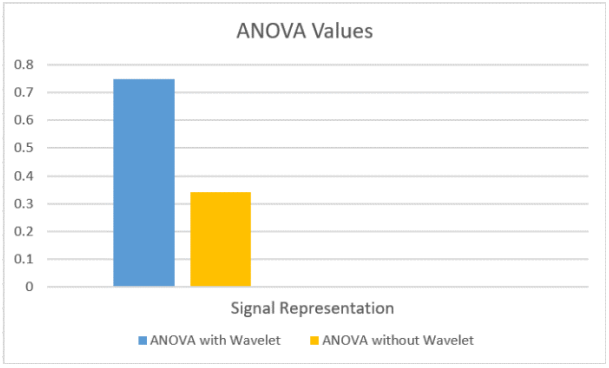

Fig.6. ANOVA values for different Classifiers

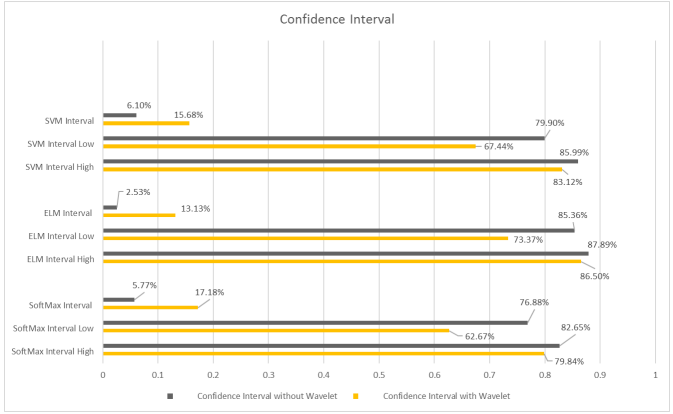

Fig.7. Confidence Intervals for used classifiers

We concatenated a layer of classifier fusion after classification layer. The function of this added layer is to nominate the best-implemented classifier based on the outcomes of accuracies values. This added classifier fusion layer in return enriched our accuracies as displayed in Table II. On the other side, adding classifier fusion layer relatively increased the simulation time than without fusion layer.

Table II: Auto Encoder Classifier Fusion Testing and Training Accuracy

Signal Representing	Average Training Accuracy	Average Testing Accuracy	Classification Algorithm	Simulation Time
Spectrogram	99.53%	91.05%	Classifier Fusion	2118.846 Seconds
Wavelet	96.99%	86.80%	Classifier Fusion	745.67 Seconds
Wavelet (Scale 5)	99.24%	89.02%	Classifier Fusion	1378.41 Seconds
Wavelet Packet	98.70%	92.25%	Classifier Fusion	1656.724 Seconds

7. Conclusion

Sparse autoencoder is just one hidden layer algorithm. Therefore, to establish the concept of deep learning, and take advantage of stacking more than a layer, as the testing set accuracy was less than 50% for one stage only of the autoencoder, we implemented stacked autoencoder that led to verifying deep learning concept and enriching the results accuracy. In addition, applying some signal representation like calculating spectrogram, wavelet and wavelet packet, instead of using raw signal, and introducing the output of these signal representation to the first stage of autoencoder enhanced the performance of the system. Extreme learning machine showed a satisfactory performance on the level of testing accuracy and simulation time. Softmax layer classification resulted in the most mediocre testing accuracy although it consumed longer simulation time than extreme learning machine. Support vector machine produced an excellent testing accuracy but consumed long simulation time. Applying signal representation like Spectrogram, wavelet or wavelet packet improved both training and testing accuracy a lot as both accuracies were much less than 50% when we fed first stage autoencoder by raw data. Multiplying wavelet scale by 5 enhanced the results a lot. As a conclusion, applying any signal representation either in the time domain, frequency domain, or both had a good impact on our training and testing accuracies. We introduced the rectified linear unit as an activation function for extreme learning machine besides already existing functions such as radial basis function and sigmoid. The rectified linear unit was superior in its testing accuracy than both radial basis function and sigmoid one for wavelet, Wavelet scale 5 and wavelet packet signal representation. Moreover, it resulted in a lower testing accuracy than radial basis function but better than sigmoid for spectrogram signal representation.

learnt, by itself, the best features suitable for the application under examination. In addition, since feature extraction and reduction methods varied according to the application so, feature extraction and reduction algorithms were not fixed and needed more experience. In other words, deep learning system should be adaptable to any set of data if the data was accurate and well represented. This brought a new challenge on the scene in regarding representing the data. The data should be represented in a high precision way to expect a good result from implementing deep learning technique.

ABSTRACT

This paper presents the modelling and analysis of permanent magnet synchronous generator (PMSG) which are used in direct driven small scale wind turbines. The 3 kW PM generator which is driven directly without gear system is analyzed by Ansoft Maxwell 2D RMxprt. The performance analysis of generator includes the cogging torque in two teeth, induced coil voltages under load, winding current under load, airgap flux density distribution and so on. The modelling analysis is based on the 2D finite element techniques. In an electrical machine, an accurate determination of the geometry parameters is a vital role. The proper performance results of 3kW PMSG in small scale wind turbine can be seen in this paper.

1. Introduction

In this century, wind power generation has become the most powerful influences in all over the world[1]. The variable speed wind turbines have been more popular in nowadays because it has some advantages compare to fixed speed wind turbines such as less mechanical stress, higher efficiency, higher power quality and so on[2].

The several advantages of variable speed wind turbines are reduced mechanical stress and optimized power capture.In variable speed wind turbines, two types of generators are usually employed in the small scale wind turbine such as induction generators (IGs) and permanent magnet synchronous generators (PMSGs)[3].

Recently, in the WTs, the PMSGs have been more attractive the IGs because of direct drive and high efficiency. Moreover, the PMSGs have the high torque density and the power factor characteristics. The direct-drive train wind power on system generation can be seen in Figure 1.Four main components are contained in this system and the PMSG connects to the grid through a back to back converter, converting the mechanical energy produced by the wind turbine to the electrical energy[4].

Two type of rotor position can be used in PMSG family such as outer rotor and inner rotor. In this study, the small outer rotor surface mounted generator is adopted for modelling and analysis because of the easier construction. In conventional machines, the magnetic field is in the radial direction. These types of machines are referred to as radial flux machines (RFM) whereas the magnetic field of axial flux machine (AFM) is in the axial direction [5].

The small scale generators can be used for remote areas. The American Wind Energy Association (AWEA) defines small scale wind generator as those whose power reaches up to 100 kW.

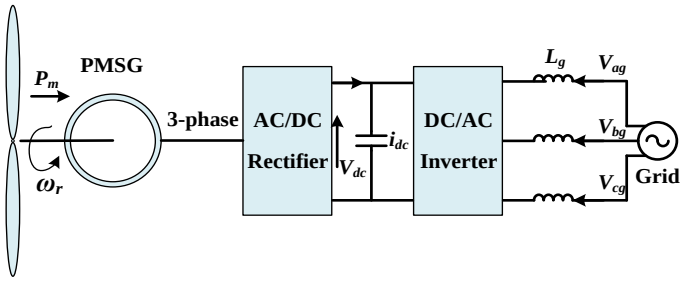

Figure 1. Configuration of a direct-drive PMSG system

The 2D analysis of outer rotor surface mounted PM generator is studied in this paper. The output power is 3 kW, rated

mechanical speed is 250 rpm and number of poles are 34, respectively.

2. Modelling of PMSG by Maxwell 2D RMxprt

2.1. The geometry model of PMSG

In this study, outer rotor radial flux surface mounted direct-driven PMSG are employed. The radial flux outer-rotor PMSG, 17 pole pairs, are considered. The advantages of outer rotor PMSG compared to inner-rotor PMSG is that the magnets are easily attached to the rotor surface.Permanent magnet synchronous generators (PMSGs) have two parts; stator and rotor. Rotor has permanent magnets to create constant magnetic field in electrical machine[6]. Other time and space varying magnetic field is created with the stator windings. The geometry model of outer rotor radial flux surface mounted PMSG is shown in Figure 2.

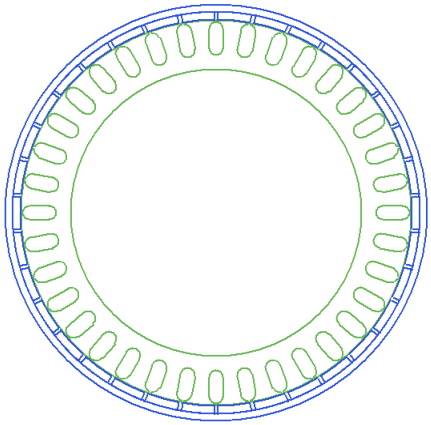

Figure 2. The geometry model of outer rotor PMSG

2.2. Maxwell 2D Model of PMSG

In this model, 3 kW small scale DDPMSG for wind turbine are designed. The main parameters of the DDPMSG are shown in Table 1.

Table 1: Major Parameters of DDPMSG

Parameters	Unit	Quantities
Rated output power	kW	3
Rated phase voltage	V	220
Control Type	-	AC
Rated power factor	-	0.9
Rated speed	rpm	250
Number of poles	-	34
Number of phases	-	3
Permanent magnet	-	NdFeB
Rotor Position	-	Outer Rotor

Parametrical analysis procedure are considered. Firstly, the stator steel type, rotor steel type and the magnet type should be determined from RMXprt library and the diameters of stator and rotor, the thickness of yoke and the airgap are roughly defined. And then, design calculations and modelling analysis are started. Table 2 represents the model design results of 3kW PMSG which are based on electrical machine theory.

Table 2: Design Results of DDPMSG

Parameters	Unit	Quantities
Phase		3
Pole		34
Stator Slot		36
Conductors per slot		24
Length of Rotor	mm	60
Outer Diameter of Rotor	mm	512
Inner Diameter of Stator	mm	358
Thickness of Magnet	mm	10
Rotor Pole Embrace	-	0.9

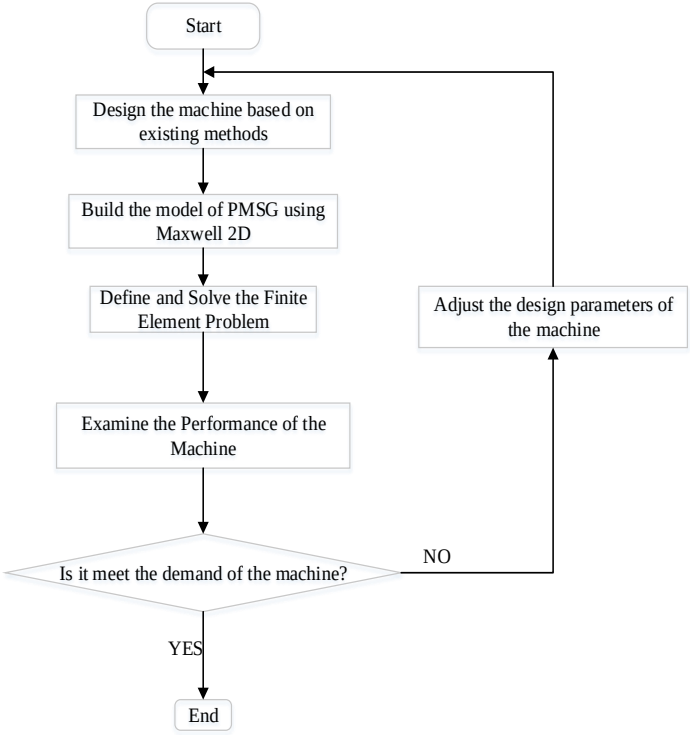

Figure 3. Design flow chart of the model for the PMSG

According to the proposed flow chart of the PMSG shown in Figure 3, a PMSG of 3kW is modelled. In this model, RMXprt (XG196/96) magnets are radially magnetized and are mounted on the surface of the rotor and the steel type of D21-50 is chosen for stator and rotor laminations. To reduce the risk of partial demagnetization, an accurate prediction of magnet loss at the design stage is an important role. It can not only give a better efficiency but also may prevent excessive temperature rise in magnets [6]. Considering the almost fixed magnetic field, the rotor core is made of solid steel and the stator core is made of electrical steel with 36 slots for three phase windings. The

prototype model of 3 kW DDPMSG in wind energy conversion system (WECS) can be seen in Figure 4.

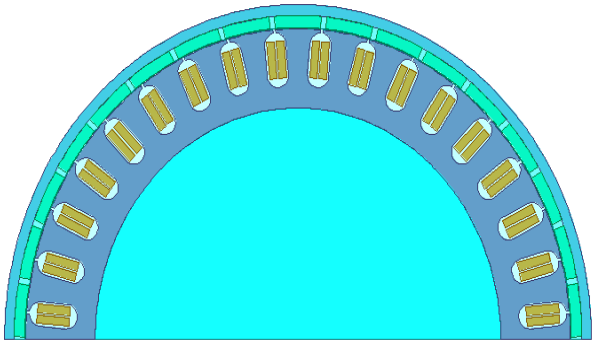

Figure 4. Maxwell 2D Model of PMSG Prototype

3. General Characteristics of PMSG

Nowadays, the DDPMSG is widely used in wind power application which has some advantages compare to other type of generators. The Maxwell 2D stator winding construction of this model is presented in Figure 5.

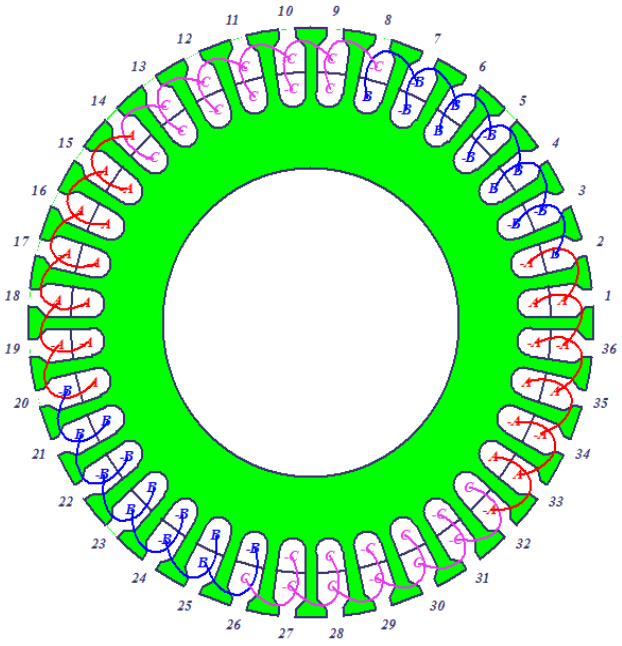

Figure 5. The stator winding connection of 3 kW PMSG

Moreover, the hysteresis (B-H) curves which express the relation between the flux density B and the magnetic field intensity H of the stator and rotor steel is an important characteristics of PMSG[7]. The stator and rotor steel type B-H curve of the FEM model is shown in Figure 6. Figure 7 represents the relationship between the flux density B and the magnetic field intensity H of magnet XG 196/96 from FEM analysis.

3.1. Magnetic Flux and Flux Density Distribution

With the application of high energy-product rare-earth PM to electric machines, many 2-D analytical models have been proposed for the direct driven PM machines and most of them focus on the field distribution and airgap flux density distribution. ANSYS Maxwell 2D RMxprt software is universal finite element analysis software of magnetic field calculation [8].

The model meshing plot of J vector can be seen in Figure *8. And* then, The Maxwell 2D analysis of the important parameters of PMSG such as the flux distribution, field distribution and magnetic flux density distribution are shown in Figure 9, Figure 10 and Figure 11, respectively.

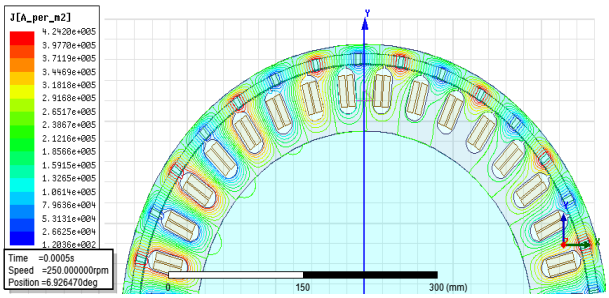

Figure 10. Field Distrubtion of J vector

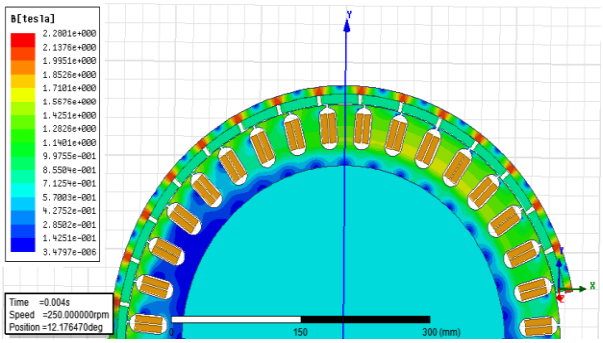

Figure 11. Magnetic flux density distribution of Maxwell 2-D

3.2. Mathematical Models of PMSG

Mathematical model of PMSG is usually given in rotating reference frame of machine. The quadrature (q) axis and the direct (d) axis PMSG equations are given below. Figure 12 and Figure 13 show equivalent circuit of PMSG in d-q frame [9].

$$v_{qs} = R_s i_{qs} + \frac{d\psi_{qs}}{dt} + \omega\psi_{ds} \quad (1)$$

$$v_{ds} = R_s i_{ds} + \frac{d\psi_{ds}}{dt} - \omega\psi_{qs} \quad (2)$$

$$\psi_{ds} = (L_{ld} + L_{md})i_{ds} + \psi_{mag} = L_{ds} i_{ds} + \psi_{mag} \quad (3)$$

$$\psi_{qs} = (L_{ld} + L_{mq})i_{qs} = L_{qs} i_{qs} \quad (4)$$

$$T_e = \frac{3}{2}\frac{P}{2}\psi_{mag} i_{qs} \quad (5)$$

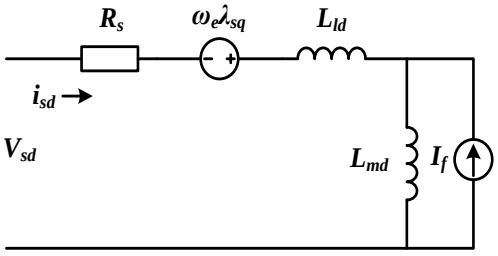

Figure 12. The d- axis equivalent circuit of PMSG

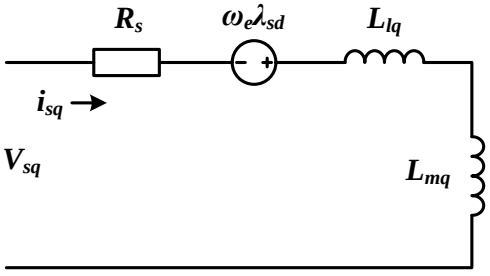

Figure 13. The q- axis equivalent circuit of PMSG

3.3. Finite Element Model Analysis

The two dimensional finite element model of the PMSG of 3kW with surface mounted PM is set up by using Maxwell 2D RMxprt. There are four main modelling processes such as inputting the data of the geometrical size of the PMSG, defining the stator, rotor, airgap, windings and PM properties, defining the boundary condition and generating finite element mesh.

After finishing these four steps, the proposed PMSG could be the modeled and solved though the FEA at different operation modes.

4. Performance Analysis of DDPMSG

The small scale wind turbine is directly connected to PMSG which receives wind turbine torque as a mechanical input and converts it into the electrical input; however, this electrical energy has a variable amplitude and frequency [10]. The FEA model of electromagnetic field is built by Ansoft Maxwell 2D and the simulation time is taken some hours [11]. To visualize magnetic fields and predict magnetic forces, Maxwell 2D program can be used.

The modelling analysis of 3 kW PM generator for wind energy conversion system is presented. The key characteristics of DDPMSG such as the cogging torque, air-gap flux density, induced coil voltage at rated speed and winding current under load are analyzed by Maxwell 2D RMxprt. Figure 14 shows the curve of cogging torque in two teeth. In PMSG, the cogging torque is generated by the sum of a series of cogging torque harmonics [12]. The cogging torque in PM machine can be expressed as:

$$T_c = \frac{1}{4\mu_0} L_{eff}(r_m^2 - r_s^2)\sum_{i=1}^{\infty} nNB_{nN}^2 \lambda_{nN}^2 \sin(nN\theta_r) \quad (6)$$

Where N is the least common multiple of the number of poles and stator slots of the PMSG. The cogging torque causes noise and vibration in PMSG at low speed and the direct drives applications. The frequency of cogging torque is the proportional to the least common multiple of the number of poles and the stator slots of the PMSG. The results obtained by using 2D Maxwell model provide sufficient accuracy with measured ones in a PMSG prototype.

In this FEM model, the proper simulation results of DDPMSG as shown in Figure 14 to Figure 19.The variation of cogging torque with respect to electrical degree can be seen in Figure 14 that generated the 3 kW FE model of Maxwell 2D.

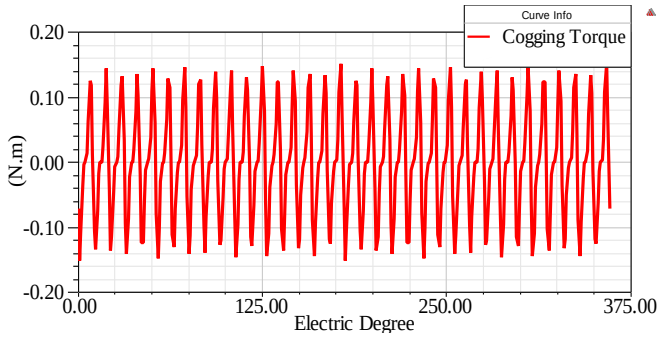

Figure 14. Cogging torque in two teeth of 3kW PMSG

The relationship between the winding voltage under load condition and electrical degree can be determined by the FEM analysis represented in Figure 15. The induced winding voltage of rated speed is shown in Figure 16.

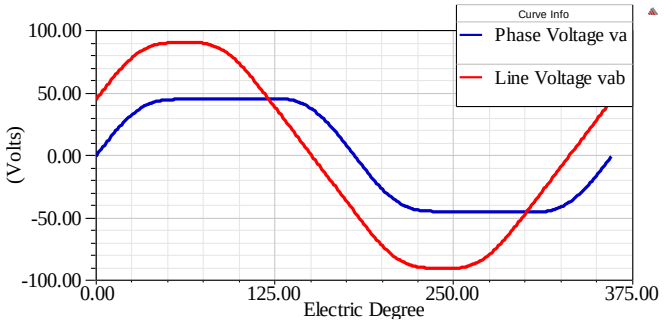

Figure15. Winding Voltage under Load

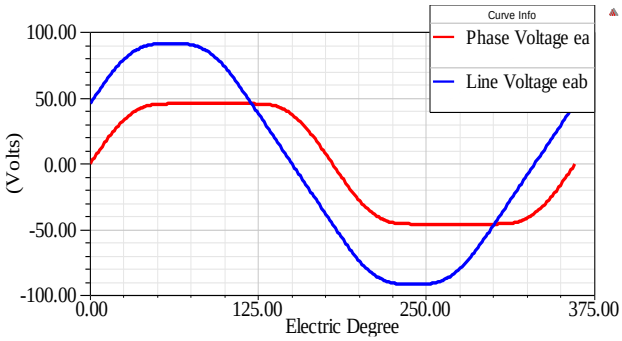

Figure 16. Induced Winding Voltage of Rated Speed

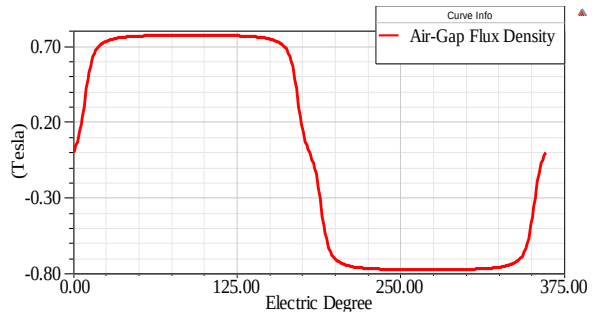

Figure 17. Air –Gap Flux Density

In this model, the maximum air-gap flux density distribution can be generated about 0.7 T by Maxwell 2D.The important parameter of air-gap flux density distribution of PMSG as shown in Figure 17. The performance curves of induced coil voltage at rated speed and the winding current under load are represented in Figure 18 and Figure 19,respectively.

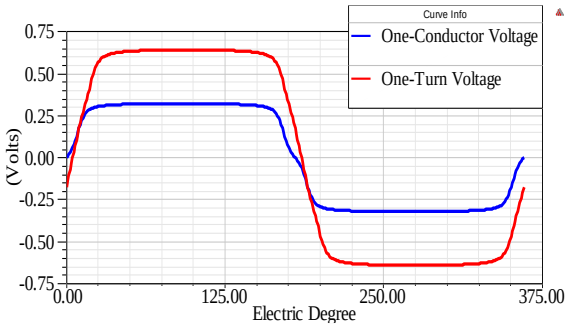

Figure 18. Induced Coil Voltage at Rated Speed

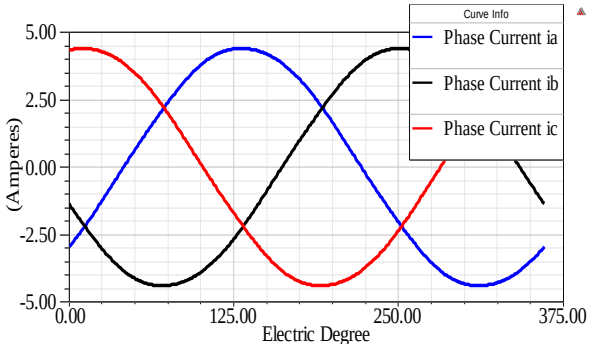

Figure 19. Wndinding Current under Load

Moreover, the transient analysis of 3 kW DDPMSG are discussed in this paper. The transient plots of main parameters in wind generator like the induced winding voltage of phase A,B and C,the comparison of solid losses and core loss,the moving torque of PMSG and the flux distributions in machine are generated by Ansoft Maxwell 2D RMxprt. All of the transient analysis curves are shown below.

5. Conclusions

The 2D modelling analysis of surface mounted PM generator in small scale wind turbine is studied in this paper. There are two main parts of the performance analysis in electrical machine such as the FEM performance curves and the transient curves. In this paper, the key machine parameters analysis are discussed by Ansoft Maxwell 2D RMxprt. To construct the machine model, Maxwell 2D RMxprt is to be a competent and valuable tool. Moreover, the analysis results obtained by using 2D finite element model provided sufficient accuracy with a PMSG prototype. According to the FEM modelling analysis and transient analysis, the design of 3 kW PMSG in this paper is suitable for small wind power applications.

Nomenclature

T_c	Cogging torque
L_{eff}	Effective length of the PMSG
r_m	Inner diameter of the magnet
r_s	Outer diameter of the stator
L_{mq}	Q-axis magnetizing inductance
L_{md}	D-axis magnetizing inductance
ω	Electrical angular speed
T_e	Electromagnetic Torque of PMSG
L_{ds}	D-axis stator inductance
L_{qs}	Q-axis stator inductance
R_s	Stator resistance
v_{qs}	Q-axis stator voltage
v_{ds}	D-axis stator voltage
ψ_{ds}	D-axis flux linkage
ψ_{qs}	Q-axis flux linkage
ψ_{mag}	Permanent magnet flux linkage
i_{ds}	D-axis stator current
i_{qs}	Q-axis stator current

ABSTRACT

A switched capacitor low-pass filter employing folded-cascode CMOS OP Amps with a dynamic switching bias circuit capable of processing video signals, which enables low power consumption, and operation in wide bandwidths and low power supply voltages, is proposed. In this filter, charge transfer operations through two-phase clock pulses during the on-state period of the OP Amps and a non-charge transfer operation during their remaining off-state period are separated. Through simulations, it was shown that the low-pass filter with an OP Amp switching duty ratio of 50 % is able to operate at a 14.3 MHz high-speed dynamic switching rate, allowing processing video signals, and a dissipated power of 68 % of that observed in the static operation of the OP Amps and a full charge transfer operation without separation of a cycle period. The gain below -31 dB in the frequency response, which is suitable, was obtained at over 6 MHz within a stop-band. Especially high attenuation in 5 MHz was achieved under the optimized condition of load capacitances (4 pF) of OP Amps.

1. Introduction

The switched capacitor (SC) techniques are appropriate for realizing various filters that can be integrated in monolithic ICs (Integrated Circuits) from using the CMOS (Complementary Metal-Oxide-Semiconductor) technology. In conventional active RC filters, monolithic ICs cannot be realized from using resistors. On the contrary, the CMOS SC techniques suitable for realizing analog signal processing ICs, have promising use in video signal bandwidth circuits in particular, because these can replace resistors to switched capacitor pairs with small capacitances. It has been demonstrated that SC techniques using CMOS operational amplifiers (OP Amps) are useful for implementing analog functions such as filtering [1-5]. Although CMOS OP Amps are suitable for such filter ICs, the use of several OP Amps results in large power consumption. Especially, the power consumption of OP amplifiers in high speed operation becomes large because they have wideband properties. Therefore, the use of them is currently limited to the use in low-frequency passband of at most a few hundred kHz (that is, applications of low speed signal processing, such as analog voice signals).

*Corresponding Author: Hiroo Wakaumi, Tokyo Metropolitan College of Industrial Technology, Tokyo, 140-0011 Japan
E-mail: wakaumi@metro-cit.ac.jp ; waka781420j@ab.auone-net.jp

Until now, several approaches have been considered to decrease the power consumptions of OP Amps, including the development of ICs that work at low power supply voltages [6]. A clocked current bias scheme for folded-cascade OP Amps suitable for achieving a wide dynamic range has typically been proposed to decrease the power consumption of the OP Amp itself [7, 8]. Because the circuit requires complicated four-phase bias-current control pulses and biasing circuits, it results in a large layout area and is not suitable for the high-speed operation. A control method using power supply switching has been proposed for audio signal processing as another approach in decreasing the power consumption of OP Amps [9]. Because large capacitors for the power supply terminals are intrinsically loaded, the switching speed is limited to a low speed of 1 MHz at most. Therefore, this type of control circuit is not suitable for application to video signal processing ICs, which are required to operate at over 10 MHz switching frequency.

Recently, the author proposed a folded-cascade CMOS OP Amp with a dynamic switching bias circuit (DSBFC OP Amp), of simple configuration, to provide low power consumption while maintaining high speed switching operation suitable for processing video signals [10]. However, low-power signal processing circuits such as wideband filters with such DSBFC OP

Amp, suitable for processing video signals, have not been developed yet.

In this paper, a configuration of SC Butterworth low-pass filter (LPF) with DSBFC OP Amps [11] as an example of application of the DSBFC OP Amp is proposed, which enables low power consumption and is suitable for achieving wide bandwidths and operation in low power supply voltages, and its availability is also evaluated for the performance of frequency response and power dissipation. Further, the effect of OP Amp load capacitances on the frequency response is evaluated. This paper is an extension of work originally presented in LASCAS 2017 [11].

2. SC Filter Theory

The discrete-time transfer function of second-order SC infinite impulse response (IIR) LPF is shown as follows using the z-transform.

$$H(z) = \frac{K\ (1+z^{-1})^2}{1+\sum_{k=1}^{2} b_k z^{-k}} \quad (1)$$

Here, K, b^k, and z^{-1} represent the gain constant, the filter coefficient in a recursive loop, and the one-step delaying operation, respectively. All of operation circuits are composed of active sampled data processing circuits with a sampling circuit, switching circuits and capacitors.

3. SC Filter Circuit Design

A second-order IIR LPF with the Butterworth frequency characteristic was designed because it is easy to design due to its flat gain characteristic in the passband. The Butterworth LPF is also superior to a Chebyshev filter for processing video signals owing to its ripple less characteristic within the passband. The filter order of second was selected to achieve a gain of -30 dB at a stop-band over 6 MHz. The other design condition was set as follows. That is, a sampling frequency fs=14.3 MHz, which is equal to four times as much as the NTSC color sub-carrier frequency 3.58 MHz, and a cutoff frequency fc=2 MHz, respectively, were chosen, that enable the LPF to process video signals. Under this condition, the inverted discrete-time transfer function is given by

$$H(z) = -\frac{0.1174(1+z^{-1})^2}{1-0.8252z^{-1}+0.2946z^{-2}} \quad (2)$$

The circuit configuration realizing this transfer function is shown in Figure 1. In order to enable easily to determine the capacitance value of each capacitor, the coefficient of A is set to be equal to that of B. Capacitors can be basically divided into two groups. In one group (C, D, E, and G), charges are supplied to OP Amp 1. In another group (A, B, and I), charges are supplied to OP Amp 2. Even if a capacitance of each capacitor group is multiplied by constant times, the transfer function does not change. Therefore, capacitances of integral capacitors B and D are here selected as a reference capacitance in each group and each coefficient of B and D is normalized to 1. At this time, 1 as every normalized coefficient of A, B, and D is obtained because A and B are the same coefficient. In Figure 1, when the coefficients of A, B, and D are normalized to 1, other coefficients are determined as follows.

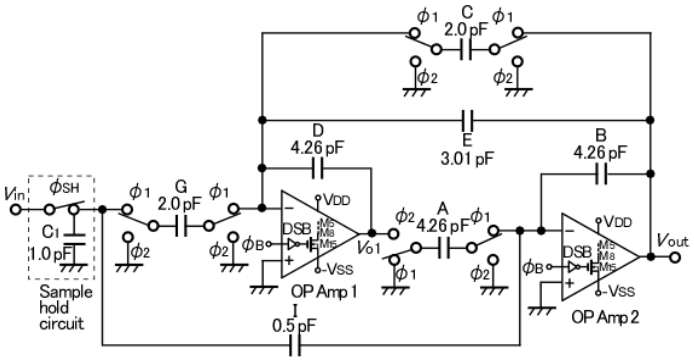

Figure 1: Configuration of the 2nd-order SC LPF with DSBFC OP Amps

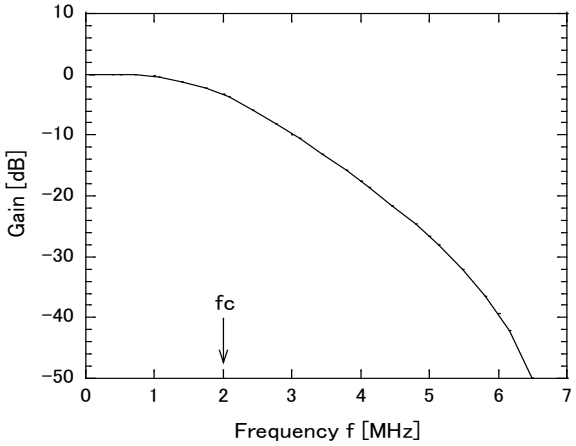

Figure 2: Theoretical frequency response of the 2nd-order SC Butterworth LPF

I=K=0.1174

G=2K+2I=0.4694

C=1+b_1+b_2=0.4694

E=1-b_2=0.7054

Here, b_1=-0.8252 and b_2=0.2946. When the smallest coefficient of I=0.1174 is replaced as a reference capacitance of 0.5 pF, each capacitance in the SC IIR LPF IC is set in proportion to the above coefficients as shown in Figure 1. Because its input signal is desirable to be maintained by a sample/hold circuit for stabilizing, this sampling circuit is also applied in the SC LPF. At this time, the transfer function is multiplied by the following zero-order hold function due to a sample-hold effect.

$$H_s(j\omega)=\frac{\sin(\omega T_s/2)}{(\omega T_s/2)} \quad (3)$$

Here, Ts represents a cycle period of sampling and switching pulses. Therefore, when the function of (2) is replaced using $z=e^{j\omega T_s}$, the magnitude of the transfer function of the second-order SC LPF considering the sample-hold effect is given by (4).

$$|H(j\omega)|=\frac{\sin(\omega T_s/2)}{(\omega T_s/2)} \cdot \frac{0.2347(1+\cos\omega T_s)}{\sqrt{1.7678-2.1368\cos(\omega T_s)+1.6513\cos(2\omega T_s)}} \quad (4)$$

The theoretical frequency response including the sample-hold effect is shown in Figure 2. The SC LPF configuration was designed referencing a SC biquad circuit with integrators in the

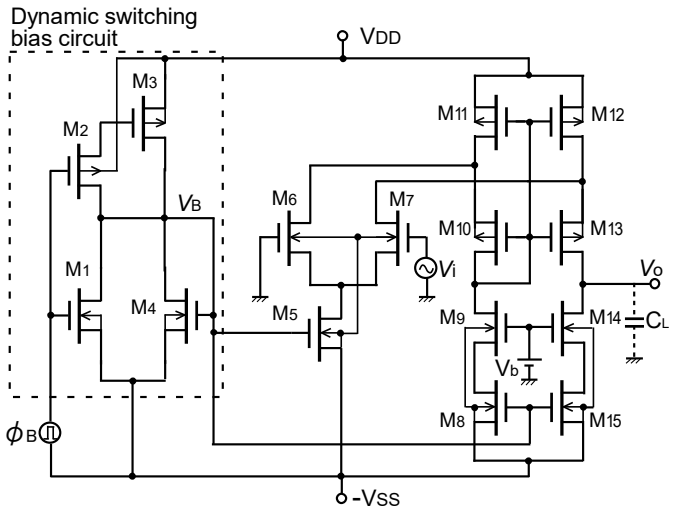

Figure 3: Configuration of the DSBFC OP Amp

reference [12]. It consists of a sample-hold circuit with a holding capacitor C_1 and a CMOS sampling switch controlled by ϕ_{SH}, CMOS switches ϕ_1, ϕ_2, capacitors A, B, C, D, E, G, and I, and two FC CMOS OP Amps with the DSB circuit (DSBFC OP Amps). A configuration of the DSBFC OP Amp enabling low power consumption, which is different from conventional ordinary OP Amps [10], is shown in Figure 3. With respect to the DSBFC OP Amps, the same CMOS channel width / length as that in the DSBFC OP Amp shown in the reference [10] was employed. The sampling switch was designed to a channel width / channel length W/L=35/2.5 (μm/μm) for each of p-MOSFET and n-MOSFET. The holding capacitor C_1 has a small capacitance of 1 pF. CMOS switches with a W/L=25/2.5 (μm/μm) are turned on and off by non-overlapping two-phase clock pulses ϕ_1 and ϕ_2, swinging from -2.5 V to 2.5 V. These sampling and CMOS switches are designed to have a balanced structure with each equal length and width of p-channel and n-channel MOSFETs (component of these CMOS switches) to delete a feed-through phenomenon, which is caused by gate clock pulses due to a capacitive coupling between gate and CMOS-switch output terminals. Major CMOS process parameters are given as a gate insulating film thickness t_{ox}=50 nm, an n-MOSFET threshold voltage V_{Tn}=0.6V, and a p-MOSFET threshold voltage V_{TP}=-0.6 V.

The operation principle of this LPF is simply described in the following. The output signal V_{o1} of OP Amp 1 is obtained as an additional output of an integrated signal of V_{in} using a negative integrator (D, G SC circuit, and OP Amp 1), an integrated signal of V_{out} using a negative integrator (D, C SC circuit, and OP Amp 1), and a signal multiplied V_{out} by E/D. The output signal V_{out} is an additional output of an integrated signal of V_{o1} using a positive integrator (A SC circuit, B, and OP Amp 2), and a signal multiplied V_{in} by I/B. V_{out} is basically fed back to an input of OP Amp 1 like this. V_{in} is also integrated twice and added after being decreased by an appropriate capacitance ratio. Due to these integration using positive / negative integrators, addition and feedback operations, the function of LPF is achieved.

The operation waveforms of the SC LPF are shown in Figure 4. In this SC LPF, charge transfer operations through the clock

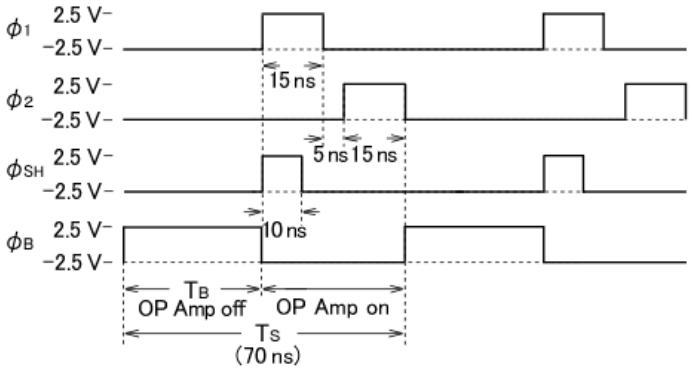

Figure 4: Operation waveforms of the 2nd-order SC LPF

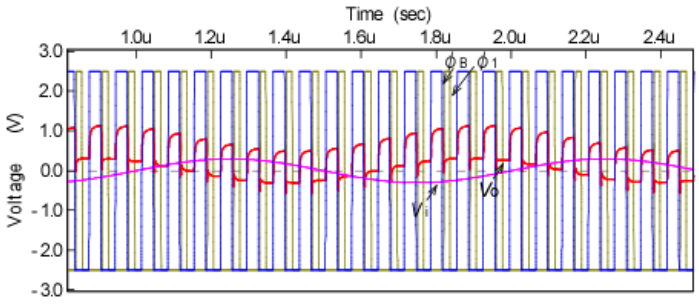
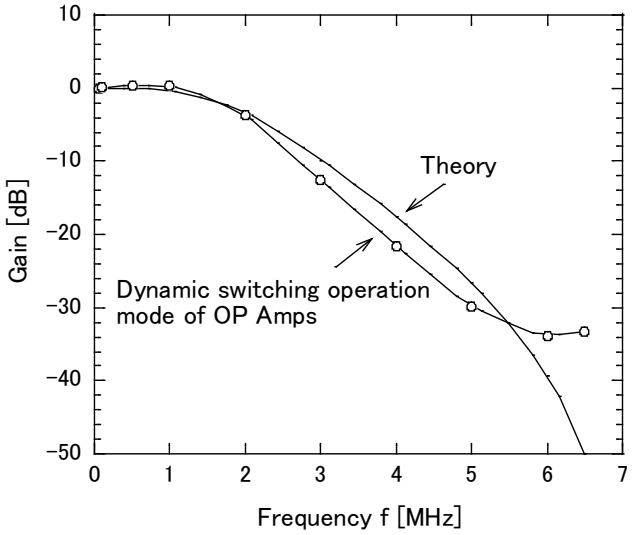
pulses ϕ_1 and ϕ_2 are achieved during the on-state period of the DSBFC OP Amps. The off-state period T_B (the remaining period of the one cycle period Ts) is separately provided to realize low power dissipation for the SC LPF. An input signal is sampled during the sampling phase of ϕ_{SH} (10 ns) and the first period of clock phase ϕ_1, while its corresponding charge is stored on the holding capacitor C_1, and is transferred to an output terminal V_{out}, charging all capacitors. The voltage at the off transition of ϕ_{SH} is kept on C_1 during the remaining period of clock phase ϕ_1. During subsequent clock phase ϕ_2, each charge of two capacitors C and G is discharged and each charge of remaining capacitors is redistributed. These charge transfer operations are achieved during the on-state period of the OP Amps. During this period, the OP Amps turn on by setting a bias voltage of V_B at an appropriate level enabling M3 and M4 to operate in the saturation region, and operate normally as operational amplifiers. ϕ_B is set to low just before ϕ_1 changes to high.

Subsequently, ϕ_B becomes 2.5 V at the off-state transition of the OP Amps, at the same time ϕ_2 is switched to off. During this off period T_B, the OP Amps turn off by setting V_B at nearly -2.5 V enabling M1 to operate in a low impedance and M3 in a high impedance. Therefore, during this off period, the OP Amps do not dissipate at all. When T_B is relatively long as compared to the one cycle period Ts, the power dissipation is expected to become lower than that observed in ordinary static operation for the SC LPF using conventional OP Amps. If half GB (Gain Bandwidth product) OP Amps for the SC LPF are used in the static operation (without DSB operation), rise and fall times to stable states of filter output signals will increase to much larger than twofold, because slowly changing transition occurs at the end of transition. Therefore, an expected proper filter performance will not be able to be obtained when such OP Amps are used.

4. Simulation Results

The performance of the SC LPF was investigated by simulation using the SPICE (Simulation Program with Integrated Circuit Emphasis) program package. Operation waveforms for an input signal of 1 MHz with an amplitude of 0.3 V and an output load capacitance of 1 pF are shown in Figure 5. For the passband frequency signal, the same level output signal as the input one was obtained. The frequency response of the SC LPF is shown in Figure 6 (a) in the dynamic switching operation of the DSBFC OP Amps and (b) in the on-state (static operation) of the DSBFC





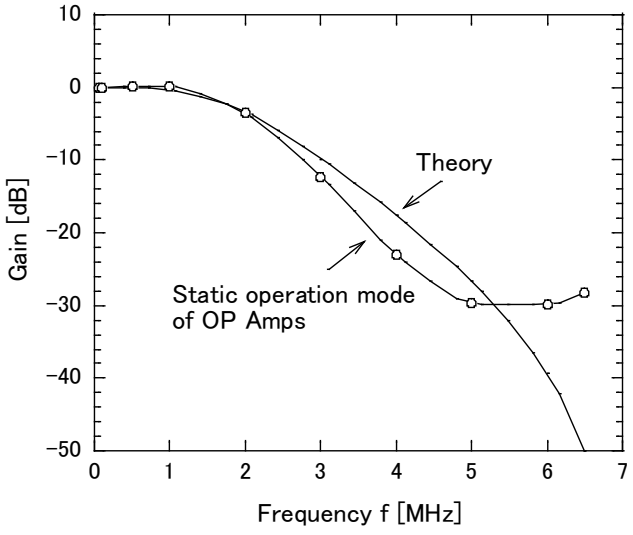


Figure 5: Simulation waveforms for the 2nd-order SC Butterworth LPF. Input signal=0.3 $V_{0\text{-}P}$, Input signal frequency $f$in=1 MHz

(a)

(b)

Figure 6: Frequency response of the 2nd-order SC Butterworth LPF. (a) Dynamic switching operation mode of the DSBFC OP Amps, T_B=35 ns, (b) Static operation mode of the DSBFC OP Amps, ϕ_B=-2.5 V

OP Amps at ϕ_B= -2.5 V. The uncertainty of gain characteristics in simulation is nearly 1 dB at the frequency of 6.5 MHz. The frequency responses in case of both modes are almost the same for the in-phase state, in which the maximum output signal is

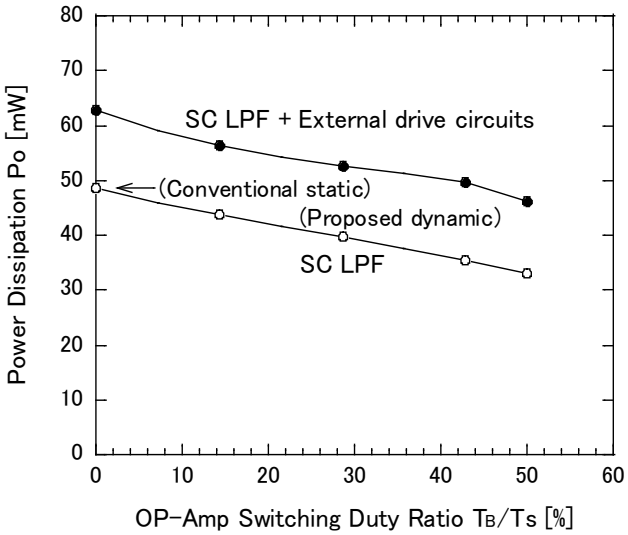

Figure 7: Power dissipation vs. OP Amp switching duty ratio in the 2nd-order SC LPF. $f$in=1 MHz. A constant pulse width of 15 ns for ϕ_1 and ϕ_2 was used

obtained depending on a phase between the input signal and the sampling pulse. The response was near the theoretical one from 100 kHz up to near 5 MHz, in the high frequency range over 6 MHz, it deteriorated due to a sampling phase effect. The gain below -33 dB was obtained at over 6 MHz within a stop-band. This was superior to that in the static operation. Therefore, it is thought that there is almost no gain deterioration caused by employing the DSB operation of the OP Amps. Though the stop-band gain in the second order LPF is not low enough as shown above, it is expected that the roll-off in the frequency response will become steeper by increasing the filter order, and so the stop-band gain will greatly decrease. Therefore, the achievement of a wide stop-band with a high attenuation will become possible.

Power dissipation vs. OP-Amp switching duty ratio with ϕ_1= ϕ_2=15 ns is shown in Figure 7. The power dissipation of the SC LPF itself excluding that of external drive circuits for ϕ_{SH}, ϕ_1, ϕ_2, and ϕ_B decreased in proportion to the off period T_B of the Op Amps as expected. In the operation mode of T_B=35 ns (=50 % switching duty ratio) and ϕ_1= ϕ_2=15 ns, the power dissipation of the SC LPF (32.9 mW) was decreased to 68 % as compared to that in the static operation of the OP Amps (48.5 mW). In the full charge transfer operation without separation of the one cycle period Ts (ϕ_1= ϕ_2=30 ns), the power dissipation of the LPF was 48.5 mW, the same as that in the static operation of the OP Amps with the above separated charge transfer mode. Most of the power dissipation of the SC LPF corresponds to total power consumption dissipated in the OP Amps themselves. The power consumption of the external drive circuits was nearly 13~14 mW. Thus, even when two DSBFC OP Amps are applied to the SC LPF, the dynamic operation of the DSBFC OP Amps enabling low power dissipation as compared to their static operation is also useful for reducing the power dissipation of SC LPF. When the SC LPF is operated at a lower dynamic switching rate, because it enables T_B/Ts to become larger than 50 %, the power dissipation of the SC LPF is expected to decrease in proportion to T_B still more. This means that the SC LPF with high-speed DSB operation OP Amps is advantageous compared to the SC LPF using static operation OP Amps with a lower GB.

Table 1: Performance comparison of SC LPFs with CMOS technology

Performance parameters	Fifth-Order SC LPF with CMOS OP Amps [13]	2nd-Order SC LPF with DSB CMOS OP Amps
Process technology	0.35 µm CMOS	2.5 µm CMOS
Power supply voltage	5 V	5 V
Sampling frequency fs	103.68 MHz (Double sampling)	14.3 MHz
Cutoff frequency fc	20 MHz	2 MHz
Power consumption	125 mW	32.9 mW (Dynamic : T_B/T_S=50 %)

When the filter order is increased, a SC LPF with DSB OP Amps uses OP Amps of the number of filter order. Therefore, the power dissipation of this SC LPF is expected to increase in proportion to its filter order. The power dissipation for the reported fifth-order SC LPF employing conventional CMOS OP Amps with a 5-V power supply and a 0.35-µm CMOS technology was 125 mW as shown in the performance comparison of Table 1 [13]. If a fifth-order SC LPF using the DSB OP Amps with the sampling frequency fs=14.3 MHz is achieved, its power dissipation will be estimated to be 82.3 mW. Considering that the power consumption of OP Amps parts in each LPF is dominant, a comparison between these values is possible. Obviously, the estimated power dissipation of a revised version of the proposed SC LPF with DSB OP Amps is much less than that of the above conventional fifth-order SC LPF.

5. Effect of Load Capacitances

Because the DSBFC OP Amp switches dynamically, its output becomes a quasi-floating state during the off-state period. In the off-state period of the OP Amp, though MOSFETs M5, M8, and M15 turn to the off-state completely, MOSFETs M11 and M12 become the on-state strongly because over the threshold voltage between each gate and source is applied. At this time MOSFETs M6, M7, M9, M10, M13, and M14 become the on-state weakly. The output terminal *Vo* of the OP Amp is set to a voltage depending on the load capacitance through the capacitive coupling between the drain and the gate of the MOSFET M13. Therefore, when a large output swing in *Vo* occurs at the off-state transition, there is a fear that the output voltage during the subsequent on-state period of the OP Amp suffers the influence of this transition. So, a dynamic offset voltage Voff (the difference of the on-state and the off-state output voltages of the OP Amp) at the off-state transition of the OP Amp vs. load capacitance C_L was tested and is shown in Figure 8. Obviously, the dynamic offset voltage depends on the load capacitance and decreases as its load capacitance becomes large because C_L compared to the drain-gate capacitance in M13 becomes large. The change of Voff against C_L of the SC LPF resembles to that of the OP Amp (Figure 9). This means that Voff of the SC LPF is mainly determined by the OP Amp's dynamic off-state transition. Gain vs. OP Amp load capacitance (of two OP Amps) for the SC LPF is shown in Figure 10. In this case, the phase between the input signal V_{in} and the sampling signal ϕ_{SH} was fixed to a constant value in each input signal to avoid the sampling phase effect. The gain became the minimum at a load capacitance of nearly 4~5 pF for the input signal frequency of 5 MHz. The reason is explained in the following. In small load capacitances, V_{off} is not only large, but also its variation is not negligible depending on the on-state output voltage. This phenomenon causes the on-state output voltage's difficulty to

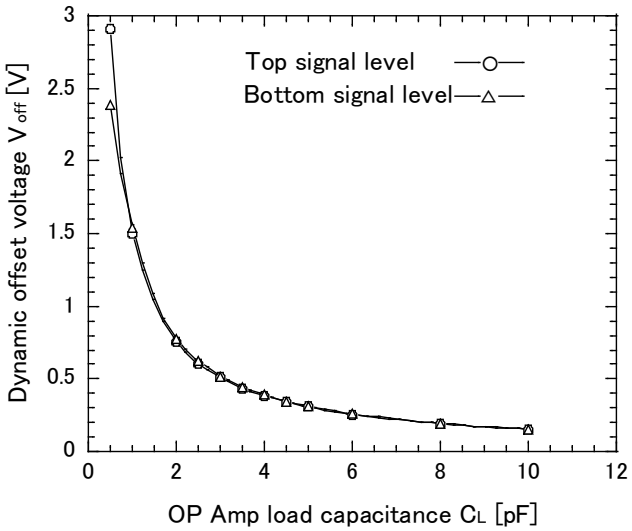

Figure 8: Dynamic offset voltage vs. load capacitance in the DSBFC OP Amp. Input signal=0.00085 $V_{0\text{-}P}$, Input signal frequency *f*in=0.5 MHz, Cutoff frequency *f*c at C_L of 1 pF =4.13 MHz

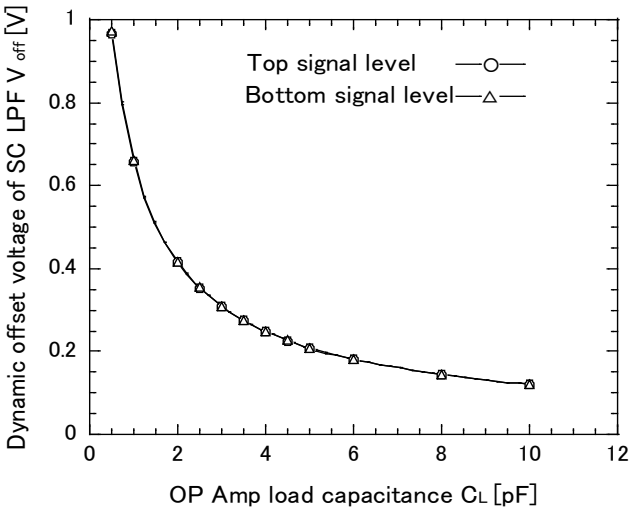

Figure 9: Dynamic offset voltage vs. OP Amp load capacitance in the SC LPF. Input signal *V*in=0.3 $V_{0\text{-}P}$, Input signal frequency *f*in=5 MHz

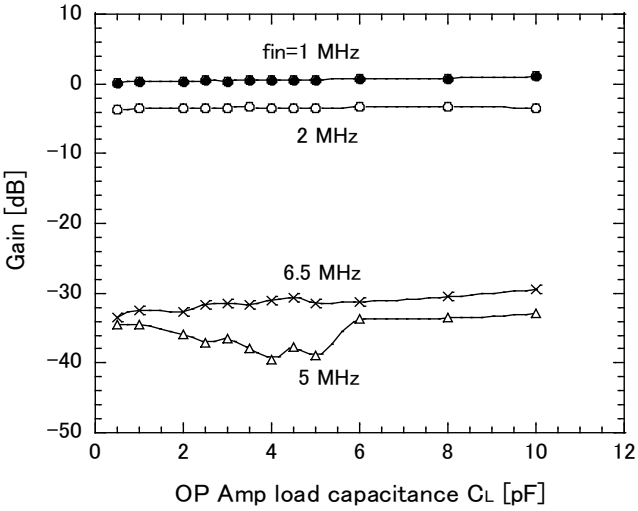

Figure 10: Gain vs. OP Amp load capacitance in the SC LPF

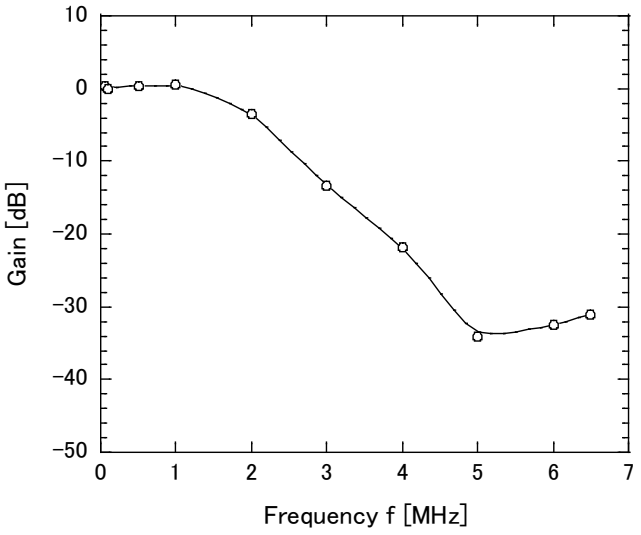

Figure 11: Frequency response of the SC LPF. OP Amp load capacitance C_L=4 pF

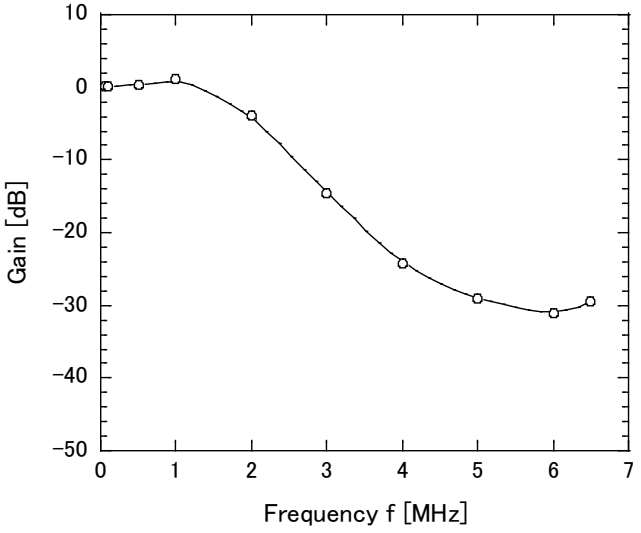

Figure 12: Frequency response of the SC LPF. OP Amp load capacitance C_L=10 pF

reach its steady state completely within the short time period of 15 ns (in ϕ_1 or ϕ_2), while permitting its output voltage to change slightly (bringing about the SC LPF gain's deterioration). In large load capacitances, it becomes also hard to reach its steady state within 15 ns (causing the gain's deterioration) due to OP Amp's bandwidth deterioration although V_{off} and its variation are very insignificant. However, at an optimum capacitance of nearly 4 pF, its gain deterioration becomes slight due to small offset transition with slight offset voltage variation and fast transition to the steady state. For other input signals of low frequencies (1, 2 MHz), the variation effect of V_{off} is negligible due to its large output signal (the change of gains is hardly seen) although its variation depending on the output signal voltage is relatively large in small load capacitances. Of course, since V_{off} and its variation for these low frequencies are negligibly small in large load capacitances, the change of gains with C_L is dominated by only OP Amp's bandwidth deterioration. For the 6.5 MHz input signal, though the gain is basically determined due to the sampling phase effect, it is slightly changing with C_L due to OP Amp's bandwidth deterioration.

Under the optimized load capacitance of 4 pF, the frequency characteristic of gain for the SC LPF was tested. As shown in Figure 11, its high frequency gain of near 5 MHz improved drastically (over 4.3 dB compared to the gain in the load capacitance C_L of 1 pF). Though its gain increased slightly (up to -31 dB) in 6.5 MHz, the amount of its gain increase is slight. On the contrary, when C_L is increased to 10 pF larger than the optimized value, the frequency response of the SC LPF deteriorated in high frequencies over 5 MHz (Figure 12). Thus we can see that the SC LPF gain characteristics can be improved by the optimization of load capacitances of DSB OP Amps. Typical characteristics are listed in Table 2.

Table 2: Typical characteristics of SC LPF with DSB OP Amps (V_{DD}=V_{SS}=2.5 V)

Performance parameters	Simulation results
Sampling and switching frequency fs	14.3 MHz
Input signal amplitude	0.3 $V_{0\text{-}P}$
Cutoff frequency fc	2 MHz
Gain at over 6 MHz within a stopband	<-31 dB (DSB mode)
	<-27 dB (Static mode)
Power consumption	48.5 mW (Conventional static)
	32.9 mW (Proposed dynamic: T_B/Ts=50 %)

Conclusions

A switched capacitor low-pass filter employing folded-cascode CMOS OP Amps with a dynamic switching bias circuit capable of processing video signals, which enables low power consumption, operation in wide bandwidths and low power supply voltages, was proposed and its performance was evaluated. In this SC LPF, charge transfer operations through two-phase clock pulses during the on-state period of the OP Amps and non-charge transfer operation during the remaining off-state period of the OP Amps were separated. Through SPICE simulations, it was shown that the SC LPF is able to operate at a 14.3 MHz high-speed dynamic switching rate, allowing processing video signals, and a dissipated power of 68% of that observed in the static operation of the OP Amps and the full charge transfer mode without separation of the one cycle period. The power consumption in the SC LPF body except for the external drive circuits was that of OP Amps. When rearranging these results, it became clear that a lower-dissipated-power SC LPF employing DSB folded-cascode CMOS OP Amps compared to conventional SC LPFs with static operation OP Amps can be realized. The gain below -31 dB in the frequency response, which is suitable, was also obtained at over 6 MHz within a stop-band. Especially high attenuation in 5 MHz was achieved under the optimized condition of load capacitances (4 pF) of OP Amps.

Thus, the dynamic charge transfer operation during the on-state period of the OP Amps and non-charge transfer operation during their off-state period is useful for high speed operation, and reducing the power dissipation of the SC LPF. This circuit should be useful for the realization of low-power wide-band signal processing ICs including over one of multi-order low-pass, high-pass and band-pass filters. The DSB circuit achieving such operation can be applied to not only folded-cascode but telescopic, two-stage, and rail-to-rail OP Amps.

A B S T R A C T

A bistatic radar breadboard for space surveillance has been developed by ONERA for the European Space Agency. This item was operated during the launch of the ExoMars mission on March 14th 2016. The spacecraft, attached to the Proton launcher, was well detected in real-time during its passage over South Europe. This paper presents the setting up of an experiment to detect this particular type of targets with the radar breadboard. The results of its operation as space surveillance system as well as a specific kinematic analysis of the ExoMars spacecraft as viewed from the radar.

1. Introduction

This paper is an extension of works originally presented in 2017 IEEE Radar Conference (RadarConf17) [1].

ABISS project (Antenna BIstatic for Space Surveillance) is relative to the breadboarding of a ground-based surveillance radar demonstrator for European Space Agency (ESA) [2]. This paper presents the setting up of an experiment to detect certain types of targets with this Space Surveillance radar demonstrator

The first section presents a description of the radar demonstrator and its principle of operation for Space Surveillance. Results obtained during the different campaigns of measurements are presented.

The second section is relative to the experiments which have been done during ExoMars launch in March 2016. A kinematic analysis of the radar parameters has been realized from the measurements of detection of this particular target.

2. Radar demonstrator

The European Space Surveillance radar breadboard is a bistatic system that is located on two separate sites in the northern part of France around Paris as shown in Figure 1.

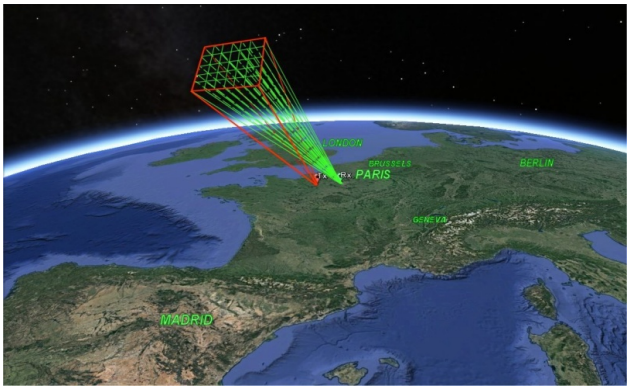

Fig.1. Bistatic radar configuration (*Tx*: transmitting site in red, *Rx*: receiving site in green)

This radar operates in L-band for the detection of space objects over a steerable Field of Regard (FoR) defined as 30° in azimuth by 25° in elevation oriented preferably to the South.

One of the advantages of such a system is its operation with a continuous wave (CW) signal, which is easier for spectral management as it is strictly limited to the carrier frequency.

*Stéphane Saillant, Email: stephane.saillant@onera.fr

The breadboard has been designed on the basis of simulations of performances, as a radar which should have a reference detection range at 500 km for a reference target of 0 dBm² as Radar Cross Section (RCS) for a revisit time of 10 seconds, meaning that the beam of the radar should revisit the same azimuth and elevation position within 10 seconds.

These are the reference values that have been used in the power budget computation for the design of the system. The principle of the detection for such radar is only based on Doppler measurement; there is no evaluation of the distance of the target.

The transmitting system (*Tx*, presented in figure 2 and figure 3) is constituted of one antenna array of surface area 1.5 m² with 49 radiating elements, and 49 CW solid state power amplifiers, controlled in both phase and gain, associated to each radiating element.

All electronics equipments for transmitting and control are in a shelter. The antenna array is set up under a radome on the roof oriented to the South. The positioner which hosts the antennas array can be steered in +/-90° in azimuth around a central position oriented in South direction, and 0° to 90° in elevation.

Fig.2. The transmitting system the shelters with the antenna on the roof under a radome)

Fig.3. Transmitting system (the shelters with the antenna on the roof without the radome)

The receiving site (*Rx*) is within ONERA centre in Palaiseau. The antenna panel, with a surface area of 10.5 m² and 64 receiving antennas, is installed on the roof of an office building as shown on Figure 4.

The antennas array can be steered in +/-90° in azimuth around a central position oriented in South direction, and it can be inclined from 0° to 90° in elevation. The receiving system is constituted of 64 analog front-edge stages in one cabinet, 4 digital receivers of 16 channels and a cluster of 10 PC servers to process the data.

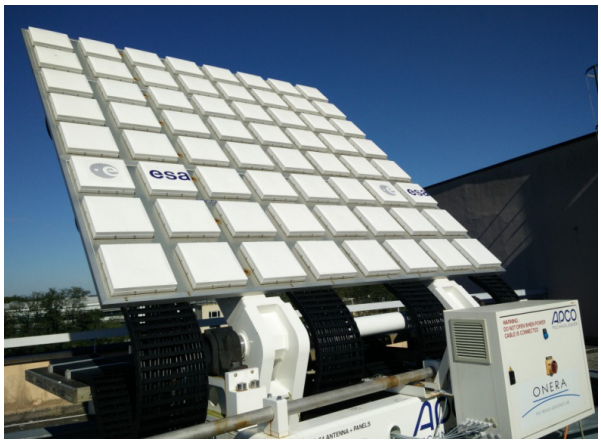

Fig.4. The receiving antenna panel in Palaiseau (ONERA centre)

In order to achieve the simulated detection performances, the whole Field of Regard of 30° in azimuth by 25° in elevation as shown in Fig.5, should be revisited every 10 seconds.

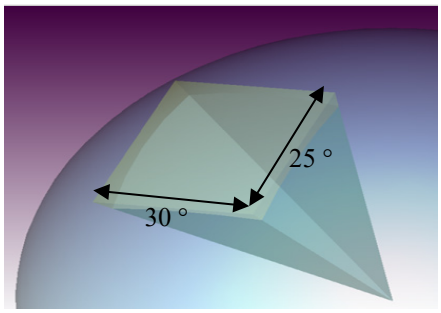

Fig.5. The Field of Regard (FoR) of the radar

According to simulations taking into account the geographical constraints and the maximization of objects detection, the difference of pointing between the two beams oriented South is few degrees between the two boresight directions.

The aperture of the transmitting beam plotted on Figure 6 is 11° azimuth by 11° elevation. Thus, the entire Field of Regard is covered by 10 scanning positions of this beam as presented on Fig.7.

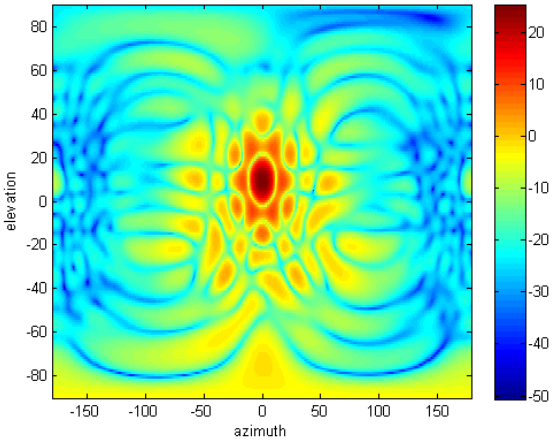

Fig.6. Pattern of the transmitting beam formed with transmitting array (11° aperture in azimuth and elevation).

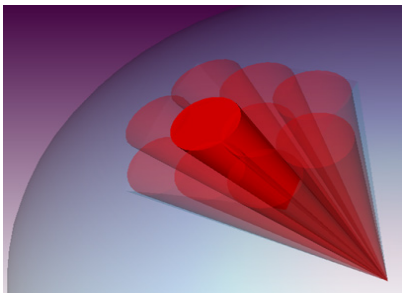

Fig.7. The 10 beams positions necessary to cover the Field of Regard

The Field of Regard is completely covered with an average gain greater than 22 dB as presented on Fig.8.

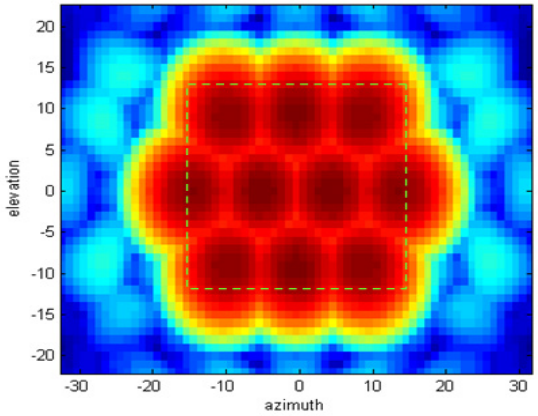

Fig.8. Optimization of the coverage of the Field of Regard for detection requirement

An evaluation of the number of receiving beams to form to cover each transmitting beam is done with an overlapping factor of 0.8 with a beam width of 4° (the aperture of receiving beam). The Figure 9 shows the results of the evaluation of receiving beams to form for extreme positions of the transmitting beam in the four corners and in the middle of the Field of Regard.

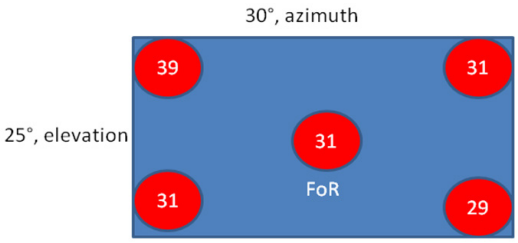

Fig.9. Number of *Rx* beams required in different locations of transmitting beam (Red areas) in the Field of Regard (Blue area: 30° azimuth x 25° elevation).

The most critical position which requires most of receiving beams to compute is when transmitting beam is focalized in the position corresponding to the upper left corner of the Field of Regard. Maximum number of beams to form for this steering direction of the transmitting beam is around 39, according to the following result represented on Figure 10 with a drawing which takes into account the distortion of the illuminated area.

The full receiving antenna array (including coupling and losses of materials) has been simulated. The global gain in the central boresight of the panel is 31.8 dB as shown in the 3 dimension display of the Figure 11.

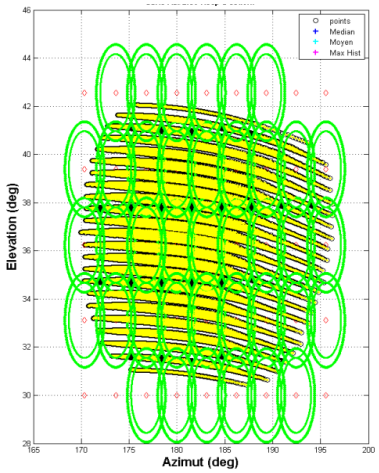

Fig.10. Transmitting beam deformed (yellow) and viewed from receiving site with the coverage of associated receiving beams (green)digitally formed

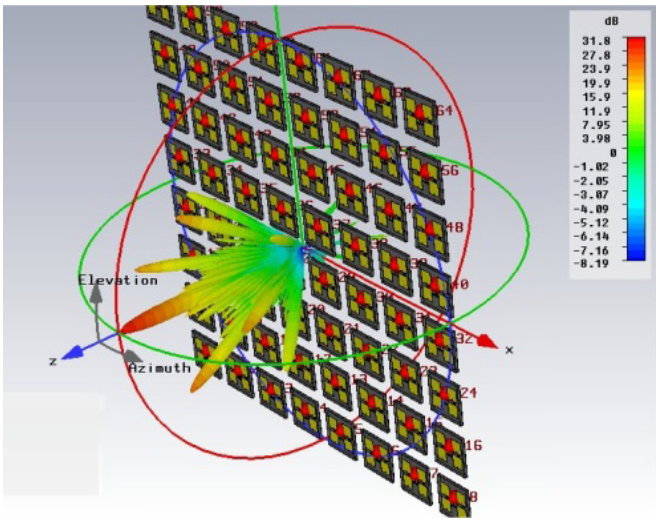

Fig.11. 3D simulation of the full receiving antenna panel (normal direction pointing)

The average gain has been evaluated over the whole Field of Regard of the radar. It is greater than 29.9 dB by computing all the beams formed for each of the 10 positions of the transmitting beam.

The signal processing implemented in the radar consists in Doppler/acceleration measurements (*i.e.*, speed estimation), detection and monopulse compression for precise direction finding. As the Field of Regard is covered by 10 positions of the transmitting beam in 10 seconds, one second of signal is analyzed at each position. Consequently, the coherent integration time is 1 second.

Thus, detections of objects that pass through the Field of Regard are characterized by Doppler traces versus time. The passage of one space object is signaled by a series of closely spaced radar plots as it can be observed on Fig.12.

Each extracted plot contains all measurements parameters, namely azimuth, elevation, Doppler (speed), radial acceleration and time of detection.

Tracking of a previously detected target is realized with consecutive plots using the Track-While-Scan (TWS) method, which combines both search and track functions. The orbital

trajectory can be built from the track from latitude and longitude positions of the transmitting site and receiving site of the radar.

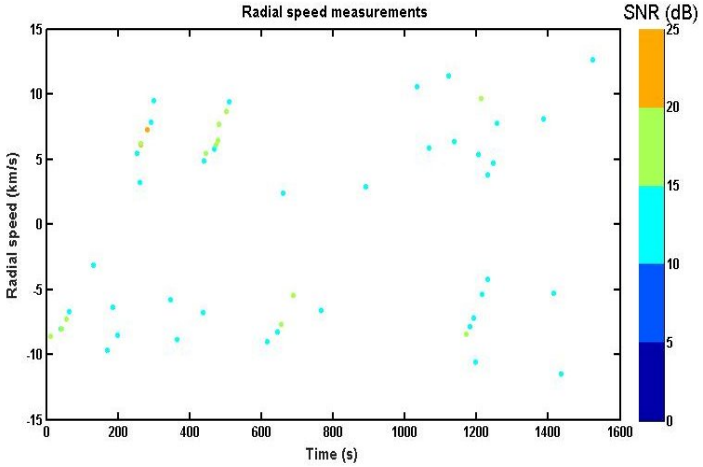

Fig.12. Doppler traces (speed) versus time (many traces of detected space objects are characterized by alignments of closed detected plots at 50 s, 250 s, 430 s, 620 s and 1200 s)

The breadboard radar has been regularly operating for more than one and half year.

Around 700 space objects have been detected and their associated tracks have been generated. The tracked objects are plotted as red dots over the Space track catalogue display on the Figure 13. More than 60% of detections are related to targets at least 3 meters in diameter at ranges less than 700 km. Objects tracked over 800 km to 1000 km are generally bigger (more or less 5 meters in diameter).

More than 40% of detections are identified as rocket debris.

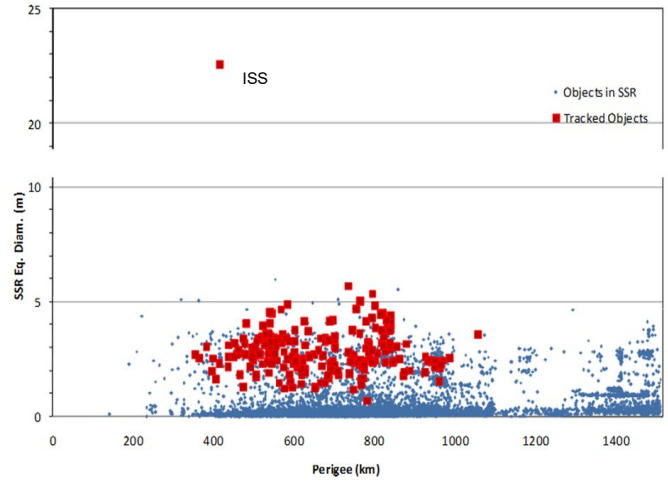

Fig.13. Estimated size of the detected objects with ABISS radar (Red) - Equivalent diameter (m) versus perigee (km) given by Space Track catalogue (Blue dots)

3. Operation of ABISS radar during ExoMars mission

The first ExoMars mission started with the launch of the spacecraft in collaboration with Russian agency Roscosmos. The launch is operated with a Proton rocket from Baikonur cosmodrome, Russian launch center.

Before separating from ExoMars, the Proton launcher vehicle needs three steps to place the spacecraft on its required Earth escape trajectory as shown on Figure 14:

- One first complete revolution around the Earth on a low parking orbit after the lift-off concluded by a boost to change its altitude,
- A second complete revolution on an intermediate eccentric orbit with a new burn to place the launcher on its transfer orbit just above North-West of Spain (in term of ground track),
- A third quasi-complete revolution with a final maneuver to eject the spacecraft on the way to Mars, above Central Africa.

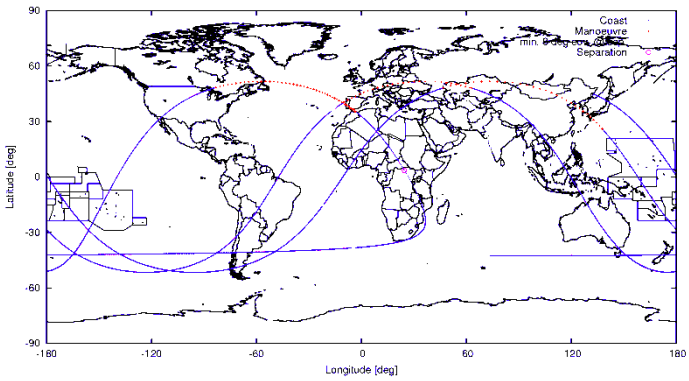

Fig.14. Estimate trajectory of the launcher (Maneuver sections in red, separation from ExoMars above Africa at magenta dot) (Sources: blogs.esa.int, http://www.russianspaceweb.com)

The maneuver to move from intermediate eccentric orbit to its transfer orbit during the second phase of the flight is exactly realized in the area where the Field of Regard of ABISS radar can be steered. The radar was set up to steer its Field of Regard so as to cover the area where this maneuver would take place as it can be seen on Figure 15.

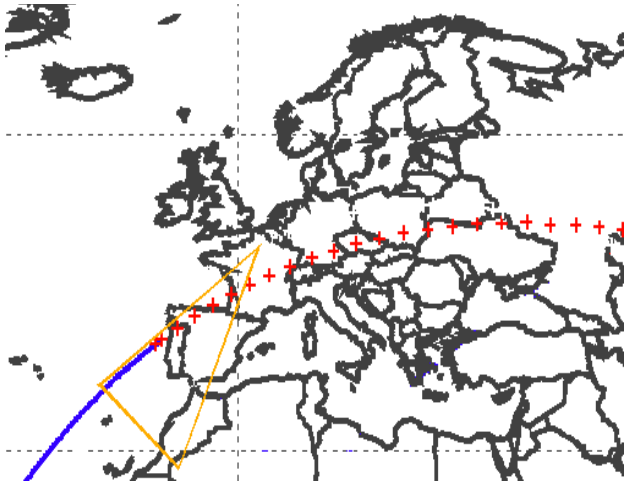

Fig.15. Trajectory of the launcher in the Field of Regard of ABISS radar (orange) during the second passage

The spacecraft was launched on March14th 2016 at 10:31 CET. The burn for this change of orbit was operated around 5 hours after lift-off.

The last stage of the launcher, with the ExoMars spacecraft, was detected by the radar approximately at the expected time when it passed through the Field of Regard [3]. At the beginning of the detection the object was just coming off the perigee of its second revolution and a new burn was operated to go on its transfer orbit.

Few plots were directly extracted from the signal processing but a corrected trajectory was calculated after a correlation with a refined trajectory. As the ExoMars launcher is a specific object in terms of kinematic behavior, we decided to have a detailed analysis of radar parameters concerning this detection [1].

Other space objects were detected during the measurements campaign for ExoMars observation. One of them is particularly useful because it appeared almost at the same time as the passage of the launcher as it can be observed on Fig.16. This space object has been identified by data processing as the rocket-debris named SL-14 R/B with a well-known actualized TLE (Two lines Elements).

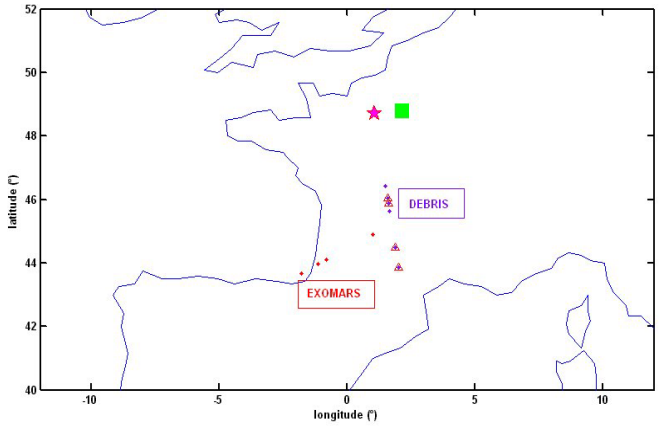

Fig.16. ExoMars launcher and rocket-debris SL-14 R/B detected simultaneously – 14th march 2016 – 10:31 CET – Triangles represent the confirmed positions of detected plots (dots)

Rocket-debris SL-14 R/B, which was detected just before ExoMars passage, is used as a calibration source for speed and acceleration measurements. The visualization of its trajectory in radar axis on Figure 17 shows the good correlation between the plots positions and the TLE of the object.

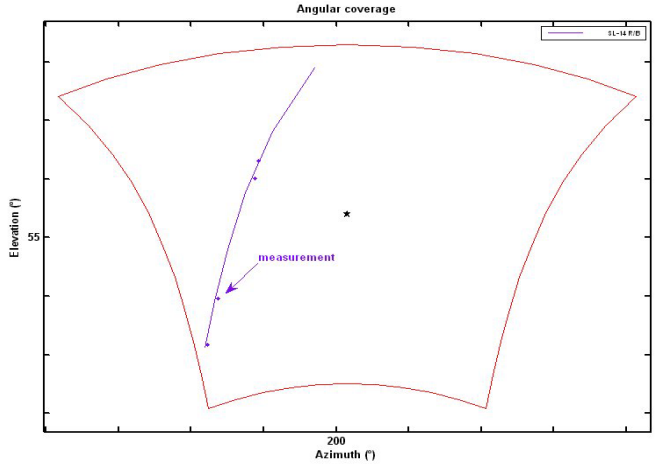

Fig.17. Rocket-debris SL-14 R/B passage in radar axis in UTC reference

As the passage of this object through the Field of Regard was confirmed by the successful tracking and approved by the identification process, the calibration of the radar was realized by evaluating the shift observed on radial speed ΔV (as shown in Fig.18) and radial acceleration parameters$\Delta\gamma$ (as shown in Fig.19) for each detected plot compared to TLE.

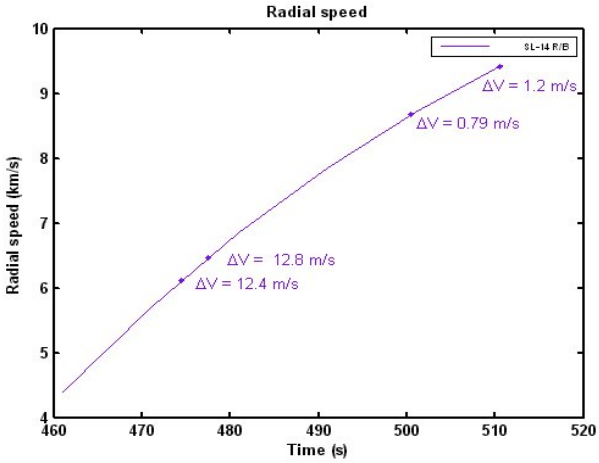

Fig.18. Rocket-debris SL-14 R/B radial speed and error margins

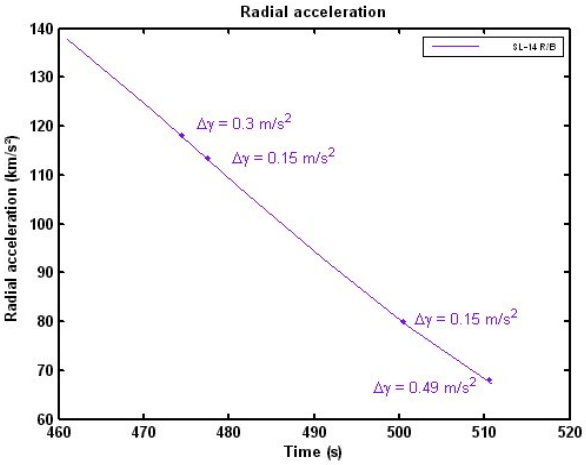

Fig.19. Rocket-debris SL-14 R/B radial acceleration and error margins

Measurements are in accordance with the parameters of movement of the target, no major bias can be observed in comparison with the values deduced from the TLE. The good correlation of acceleration versus speed confirms the synchronization of detections as presented in Fig.20. This could be used to estimate the time shift to apply for recalibration of ExoMars detections. Indeed, biases are expected to be observed along the trajectory of ExoMars because its orbit is not keplerian especially during the thrust phase for the change of altitude of the spacecraft.

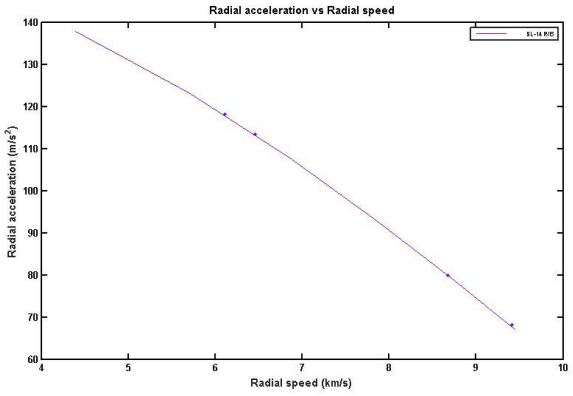

Fig.20. Radial acceleration versus radial speed of SL-14 R/B

Four detected plots of the ExoMars launcher appeared during the time window of the passage through the Field of Regard as spotted on Figure 21.

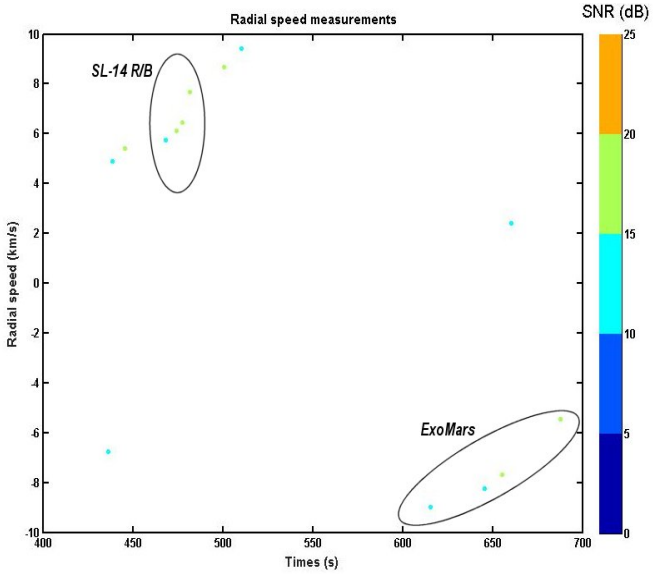

Fig.21. Detected plots around the time of ExoMars passage in the Field of Regard - Radial speed versus time (The two targets of interest have been circled - 4 plots characterize the passage of ExoMars)

The synchronization of these detections was obtained by shifting the reference time by +6 seconds (UTC + 6 s). Only two of them were matched to the estimated trajectory, especially for the beginning of the passage when the object is still in an eccentric orbit at its perigee around 600 km as shown with an estimated trajectory of classical orbit on Figure 22.

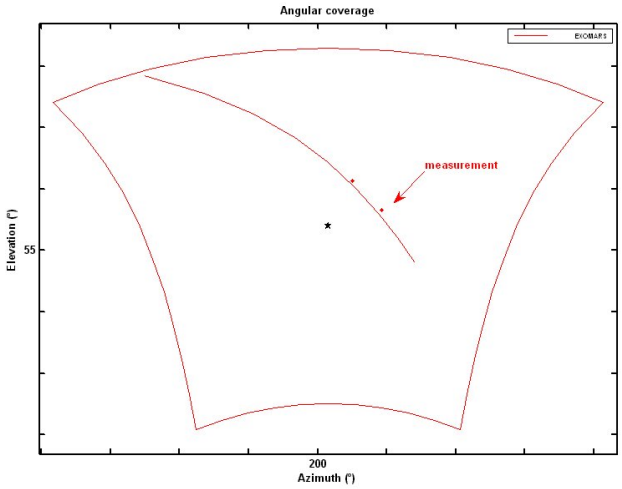

Fig.22. ExoMars launcher passage in the radar axis in UTC + 6 sec

The other two plots are not visible due to the thrust phase of the launcher (change from the second orbit to the third). The figure of radial acceleration ($\Delta\gamma$) versus radial speed (ΔV) for the two matched plots shows an important shift between measurements and predicted parameters from the TLE as observed on Figure 23.

These two biases measured on the parameters of radial speed and radial acceleration, are presented respectively on Figure 24 and Fig.25.

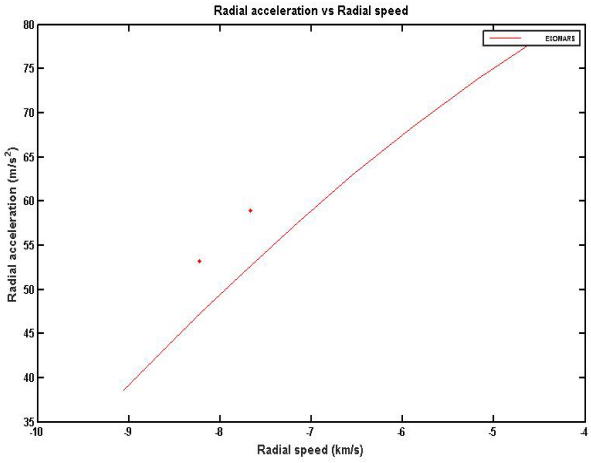

Fig.23. Radial acceleration ($\Delta\gamma$) versus radial speed (ΔV) of ExoMars

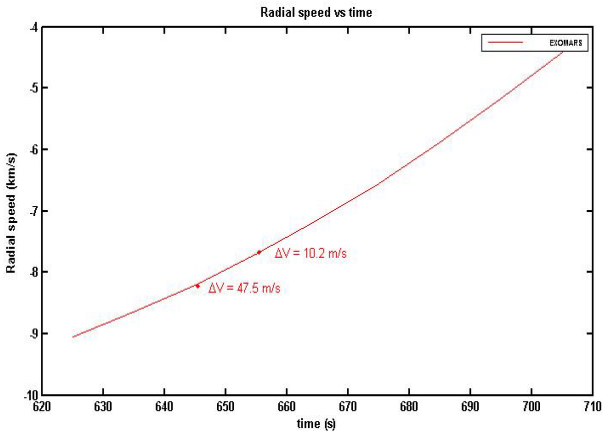

Fig.24. Radial speed of ExoMars for the first 2 detected plots

It can be noticed that the observation of the launcher was excellent during the thrust phase for orbit change, in accordance to the predicted trajectory. As shown on Fig.25, the two last plots of detection of the launcher are outside the limits of the coherence domain with a classical orbit consideration. This is due to the increase of the acceleration for the thrust.).

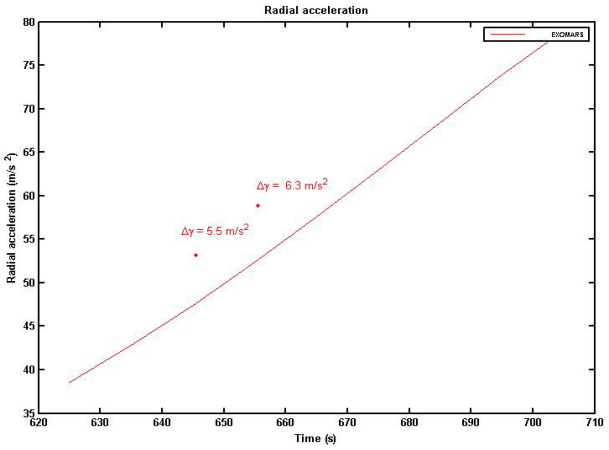

Fig.25. Radial acceleration of ExoMars for the last 2 detected plots

4. Conclusion

The challenge was to detect the ExoMars spacecraft still attached to the launcher during its passage of over South Europe with the demonstrator of Space surveillance radar ABISS. The results obtained during this campaign of experiments have shown that such a system has the capacity to detect as well as to match a specific target in the radar area of surveillance during its thrust phase as long as it stays within the domain of coherence of a classical orbit consideration in terms of kinematic.

Conflict of Interest

The authors declare no conflict of interest.

Bandwidth
Prediction

ABSTRACT

A new statistical approach to predict the gain bandwidth of Phoenix-cell based reflectarrays is proposed. It combines the effects of both main factors that limit the bandwidth of reflectarrays: spatial phase delays and intrinsic bandwidth of radiating cells. As an illustration, the proposed approach is successfully applied to two reflectarrays based on new Phoenix cells.

1. Introduction

This paper is an extension of work originally presented in the 11th European Conference on Antennas and Propagation (EuCAP) where a novel single layer stub-patch Phoenix cell is suggested as a broadband and easy solution to fabricate reflectarray (RA) elements [1].

The Phoenix cell concept was firstly introduced in [2] and many other Phoenix cells were derived later [3-8]. As their name suggests, Phoenix cells are characterized by rebirth capabilities, which means that their geometry comes back to its initial state after a complete 360° phase cycle. This guarantees a smooth evolution of cell geometries over the RA panel and prevents perturbations in the radiation pattern. Phoenix cells are also characterized by a quasi-linear phase response which classifies them as broadband RA cells. Nevertheless, as for other broadband cells, their phase response is still not totally perfect and the proper assessment of the residual phase error versus frequency is still missing in the literature.

In this paper, this last issue is addressed and a new statistical approach for estimating the bandwidth of RA based on Phoenix cells is proposed. The suggested approach relies on the standard deviation of phase errors over the RA panel and combines the effects of both bandwidth limiting factors: the dispersion of spatial phase delays with frequency [9] and the intrinsic limited bandwidth of cells themselves [10]. This standard deviation is shown to provide a promising figure of merit, better than those in [9, 10] where only the maximum phase error due to spatial delays is taken into account.

The paper is organized as follows. In section 2, the new statistical approach is defined. In sections 3 and 4, a bandwidth estimator for RA gain is derived. Finally, in section 5, it is validated by comparison with the simulated bandwidth of a test-case RA based on two different Phoenix cell topologies.

2. Statistical Bandwidth Estimator

Consider an *N*-cell circular RA of diameter *D* with a feeding antenna positioned at distance *F* normally above the array center. The phase of the wave radiated by cell *i* at central frequency f_0 is defined as:

$$\phi_i^{Rad}(f_0) = \phi_i^{Inc}(f_0) + \phi_i^{Sh}(f_0) \quad (1)$$

where $\emptyset_i^{Sh}$ is the phase-shift produced by the cell and $\emptyset_i^{Inc}$ is the phase of the incident wave defined as:

$$\phi_i^{Inc}(f_0) = -2\pi f_0 F\sqrt{1+(\rho_i/F)^2}/c \quad (2)$$

In these equations, ρ_i is the radial distance between the center of the array and cell *i* and *c* is the velocity of light in vacuum.

In order to produce a desired radiation pattern, the required radiated phases $\emptyset_i^{Rad}$ are usually specified at f_0 and the subsequent

*Hassan Salti, Department of Electrical Engineering, Australian College of Kuwait, P.O. Box 1411, Safat 13015, Kuwait, Email: h.salti@ack.edu.kw

phase-shifts $\emptyset_i^{Sh}(f_0)$ are directly deduced from (1) and (2). The cells are selected accordingly and appropriately distributed over the RA.

When the frequency is shifted to $f=f_0+\Delta f$, the phase radiated by cell i is changed by $\Delta\emptyset_i^{Tot}$ as:

$$\Delta\phi_i^{Tot}(f) = \Delta\phi_i^{Inc}(f) + \Delta\phi_i^{Sh}(f) \quad (3)$$

where $\Delta\emptyset_i^{Inc}$ is the predictable deviation of the phase of the incident wave defined as:

$$\Delta\phi_i^{Inc}(f) = -2\pi\Delta f F\sqrt{1+(\rho_i/F)^2}/c \quad (4)$$

while $\Delta\emptyset_i^{Sh}$ is the cell-dependent phase deviation due to the cell's dispersive phase response. At the RA level, these phase errors are responsible for a decrease of the gain at f, and thus for the limited bandwidth.

The bandwidth estimator we propose is derived from the standard deviation of the total phase error. Let $\Delta\emptyset^{Tot}(f)$, $\Delta\emptyset^{Inc}(f)$, and $\Delta\emptyset^{Sh}(f)$ be the statistical variables related to the total, incident and phase-shift errors at f respectively. $\sigma^{Tot}(f)$, $\sigma^{Inc}(f)$ and $\sigma^{Sh}(f)$ are the respective standard deviations. Using (3), the standard deviation of the total error $\sigma^{Tot}(f)$ can be expressed as:

$$\sigma^{Tot}(f) = \sqrt{[\sigma^{Inc}(f)]^2 + [\sigma^{Sh}(f)]^2 + 2\,\mathrm{cov}[\Delta\phi^{Inc}(f), \Delta\phi^{Sh}(f)]} \quad (5)$$

Assuming $\Delta\emptyset^{Inc}(f)$ and $\Delta\emptyset^{Sh}(f)$ are uncorrelated, which is the case when the synthesis process is done at f_0 only, as usually applied in the literature [11-15], the covariance term reduces to zero and $\sigma^{Tot}(f)$ reduces consequently to:

$$\sigma^{Tot}(f) = \sqrt{[\sigma^{Inc}(f)]^2 + [\sigma^{Sh}(f)]^2} \quad (6)$$

3. Bandwidth Estimator: Incident Phase Errors

3.1. Standard Deviation of Incident Phase Errors

Defining:

$$S_i = \sqrt{1+(\rho_i/F)^2} \quad (7)$$

(4) can be reformulated as:

$$\Delta\phi_i^{Inc}(f) = -2\pi\Delta f F S_i/c \quad (8)$$

Due to the mathematical properties of standard deviation, $\sigma^{Inc}(f)$ can be derived as:

$$\sigma^{Inc}(f) = 2\pi|\Delta f|F\sigma_S/c \quad (9)$$

where: $$\sigma_S = \sqrt{E[S^2] - (E[S])^2} \quad (10)$$

E[S] and *E[S²]* are the first statistical moments and can be calculated as:

$$\begin{aligned} E[S] &= (2/D)\int_0^{D/2}\sqrt{1+(\rho/F)^2}\,d\rho \\ &= 0.5\sqrt{1+(D/2F)^2} \\ &\quad + (F/D)\ln[(D/2F)+\sqrt{1+(D/2F)^2}] \end{aligned} \quad (11)$$

$$\begin{aligned} E[S^2] &= (2/D)\int_0^{D/2}[1+(\rho/F)^2]\,d\rho \\ &= 1+0.33(D/2F)^2 \end{aligned} \quad (12)$$

Note that σ_S does not depend on frequency but only on the dimensions of the RA, which is consistent with other criteria in the literature [10]. Note also that, in (11) and (12), a rectangular lattice is considered and ρ_i is consequently supposed to vary uniformly in the [0, D/2] range. In addition, though ρ_i is normally a discrete variable, it is assumed here to vary continuously. This assumption is reasonable since the inter-element spacing is usually a small fraction of λ_0 (which is much lower than D/2). Furthermore, as in [9] and [10] and for simplicity reasons, S_i and the resulting σ_S are calculated for a centered fed RA. Different expressions could easily be established for offset configurations.

3.2. Bandwidth Estimator

We now investigate how the gain deteriorates with respect to σ^{Inc}. To do so, we consider the gain at broadside for a test-case RA with 12mm spacing (i.e. $0.5\lambda_0$ at the center of the [11-14] GHz frequency band). Edge tapering is supposed to be -12dB and different antenna configurations are considered: F/D=0.6 and 0.8 with D varying from 0.28m≈ $12\lambda_0$ to 1m ≈ $42\lambda_0$. For each couple (F/D; D), the reflected field (phase and magnitude) in the aperture is calculated and the associated gain is derived using simple array theory (as in [16]). Simultaneously, $\sigma^{Inc}(f)$ is also computed as the standard deviation of all phase errors. Finally, Figure 1 gives the representation of the normalized simulated gain $G(f)/G(f_0)$ versus the corresponding standard deviation σ^{Inc}.

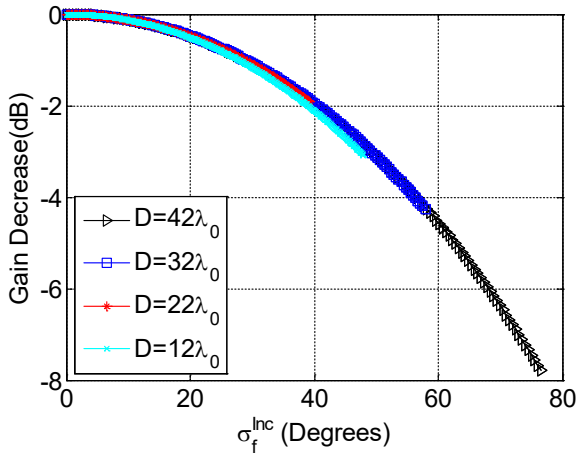

Figure 1. Simulated gain decrease with respect to the standard deviation of incident phase errors (F/D=0.8 or F/D=0.6).

An important conclusion from Figure 1 is that all curves superimpose whatever the particular values of *D, F* or *f*. This demonstrates that σ^{Inc} is a reliable estimator for the bandwidth since it directly reflects the gain decrease. Figure 1 also shows that a 1dB gain-drop approximately corresponds to σ^{Inc}=π/6. As a consequence, the upper frequency f_{max} of the -1dB bandwidth may be derived simply by replacing $\sigma^{Inc}(f)$ by π/6 in (9), leading to:

$$B_{Inc} = 2(f_{\max} - f_0)/f_0 = c/(6Ff_0\sigma_S) \qquad (13)$$

where

$$f_{\max} = f_0 + c/(12F\sigma_S) \qquad (14)$$

Equation (13) will thus be used as a bandwidth estimator. At this stage, it does not depend on any particular cell topology but only on the spatial phase delay error. As will be seen now, this initial estimator can advantageously be replaced by a more sophisticated one that also accounts for the phase dispersion of the used RA cells. In what follows, the case of cells with an ideal phase response is considered.

4. Bandwidth Estimator: Total Phase Errors

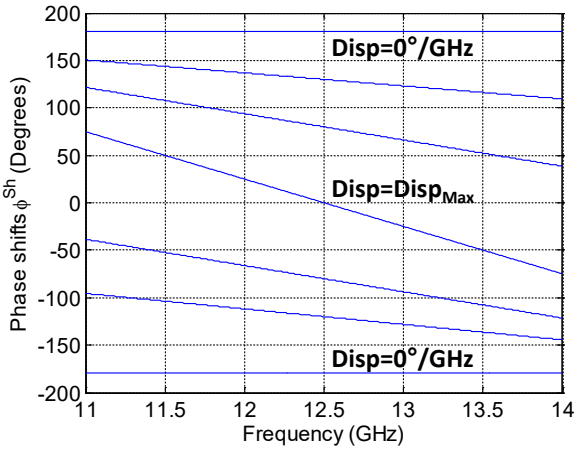

Figure 2. Linear phase response of an ideal Phoenix cell.

The ideal cell we suggest here is quite representative of Phoenix cells as will be shown in section 5. It is supposed to provide a phase range of at least 360° at f_0 and perfect linear variations with respect to frequency. Figure 2 shows the phase response versus frequency of the ideal cell. As such, the phase-shift error for cell *i* at frequency *f* can be expressed as:

$$\Delta\phi_i^{Sh}(f) = \phi_i^{Sh}(f) - \phi_i^{Sh}(f_0) = Disp_i.\Delta f \qquad (15)$$

where $Disp_i$ is the dispersion that is supposed to vary uniformly in the interval [0-$Disp_{max}$]. More specifically, $Disp_i$ is considered to be equal to 0°/GHz for phase-shifts $\emptyset_i^{Sh}(f_0)$= ±180° and to reach its maximum (i.e. $Disp_{max}$) when $\emptyset_i^{Sh}(f_0)$= 0°. Note that the perfect Phoenix cell is obtained when $Disp_{max}$= 0°/GHz as all its phase states would be perfectly parallel.

Assuming all phase-shifts are equally probable on the radiating aperture, $\sigma^{Sh}(f)$ can be expressed as:

$$\sigma_f^{Sh} = |\Delta f| Disp_{\max}/\sqrt{12} \qquad (16)$$

Using (9) and (16) in (6), a generalized bandwidth estimator $\sigma^{Tot}(f)$ accounting for both types of errors is derived:

$$\sigma_f^{Tot} = |\Delta f|\sqrt{(2\pi F\sigma_S/c)^2 + (Disp_{\max}/\sqrt{12})^2} \qquad (17)$$

Finally, $\sigma^{Tot}(f)$ is set to π/6 as already done in Part 3.2 to obtain the generalized bandwidth estimator:

$$B_{Tot} = B_{Inc}/\sqrt{1 + 0.75(Disp_{\max}.f_0B_{Inc}/180°)^2} \qquad (18)$$

To validate (18), the gain decrease simulation described in Section 3.2 is repeated (as in [16]), now accounting for both types of phase errors. The associated simulated -1dB gain bandwidth is then extracted and compared to the theoretical value predicted from (18). In this study, *F/D* is set to 0.8, *D* varies from 0.16m to 1m (i.e. ~7λ_0 to 42λ_0) and $Disp_{max}$ varies from 0°/GHz to 100°/GHz. Figure 3 shows that the difference between simulation and theory is less than 3%, even for the highest dispersion and the smallest diameter values.

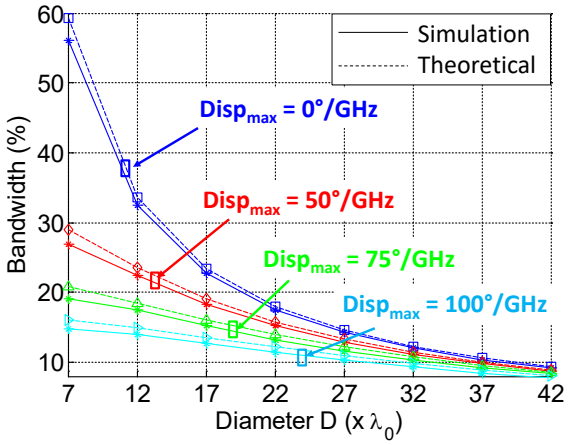

Figure 3. Total phase errors effects: simulated and theoretical bandwidths (F/D=0.8).

As a conclusion, (18) appears to be a reliable bandwidth estimator. In practice, it can be used to define the maximum acceptable cell dispersion for a given application. As an example, for a RA with *D*=22λ_0 and *F/D* = 0.8, the cell dispersion should be less than 50°/GHz to ensure a 15% bandwidth.

5. Practical Validation

In practice, the phase response of Phoenix cells is not purely linear as in the previously-used ideal cell model. Therefore, to assess the validity of our approach, the actual performance of two recently-proposed Phoenix cells is assessed and compared to those obtained using (18).

The two cells are designed to operate around a central frequency f_0 = 12.5GHz, with $\lambda_0/2$ spacing at f_0. Both cells are printed on a Duroïd substrate with 2.17 dielectric constant and backed by a ground plane. The substrate height is fixed to 4 mm.

This corresponds to approximately $\lambda_0/(4\sqrt{\varepsilon_r})$, which means the reflected phase is close to 0° if the cell is transparent.

To extract the phase responses, both cells are simulated using ANSYS-HFSS software assuming normal incidence and local periodicity. As Phoenix cells allow for smooth evolution of cell geometries over the RA panel, it is assumed that the phase responses obtained by simulation are valid for finite reflectarray configurations [2].

5.1. Cell 1: Slot – Patch Phoenix Cell

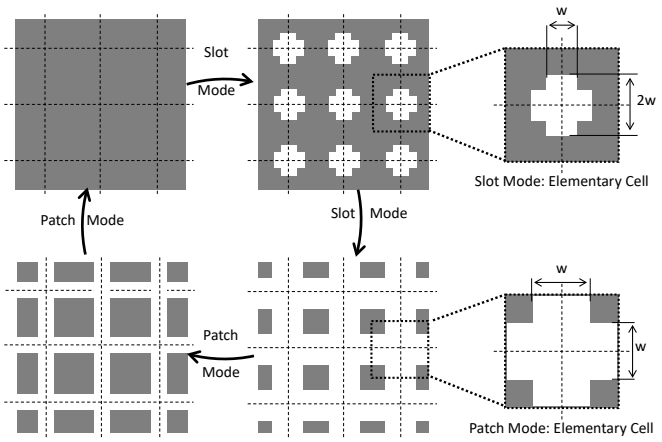

Figure 4. Slot-Patch Phoenix Cell: Rebirth cycle

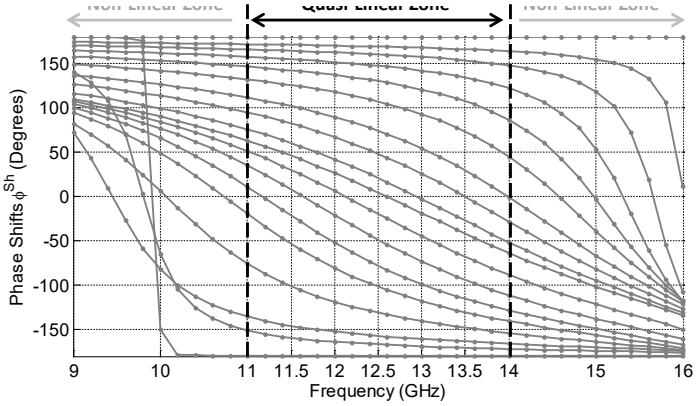

Figure 5. Slot-Patch Phoenix Cell: Phase response.

The first cell, the Slot – Patch Phoenix cell was initially introduced in [8] and its performance was improved in [7]. The cell cycle is illustrated in Figure 4. The initial cell consists of a ground plane providing a 180° phase shift, whatever the frequency. The first mode of operation, or slot mode, is obtained by opening a crossed-shaped slot with variable length and width in the ground plane. For simplicity reasons, the length of the cross is fixed as twice its width. The slot mode ends when the slot arms reach the borders of the cell, thus defining square patches. The operating mode then switches to a patch mode. In this second mode, the length of the pre-opened slot is frozen and only the width of the slot w is decreased. The patch mode ends when the slot vanishes, taking back the cell to its initial geometry and opening the door for a new cycle.

The obtained phase response is presented in Figure 5. At the central frequency, the slot mode provides phase shifts between 0° and 180° while the patch mode completes the remaining phase range between 0° and -180°. The use of complementary modes provides a phase response that is quasi-linear within a 24% bandwidth around 12.5GHz. The maximum dispersion is 53°/GHz. This phase response fits well with the ideal model used to derive (18), although the linearity is not perfect.

5.2. Cell 2: Stub – Patch Phoenix Cell

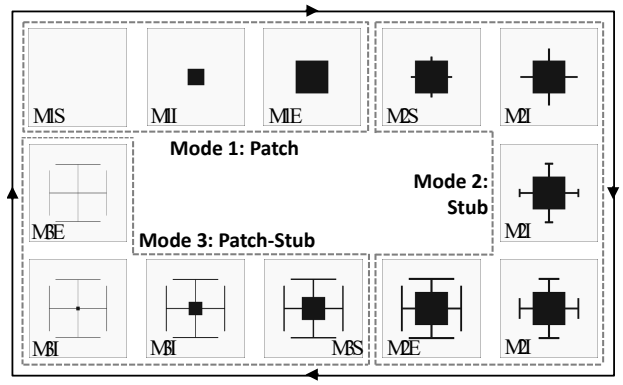

Figure 6. Patch-Stub Phoenix cell: Rebirth cycle (MαS: Mode α's Start; MαI: Mode α's Intermediate states; MαE: Mode α's End).

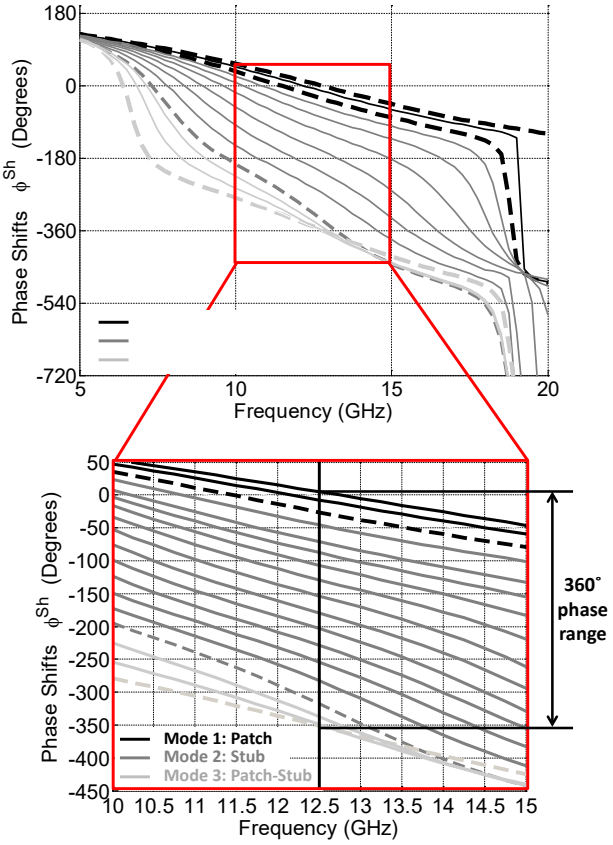

Figure 7. Patch-Stub Phoenix cell: Phase response.

The second cell, the Stub-Patch Phoenix cell was introduced recently in [1]. It improves the bandwidth further due to the three possible operating modes it offers: a patch mode, a stub mode, and a combined patch-stub mode.

As illustrated in Figure 6, the cycle starts with a pure Duroïd substrate backed by a ground plane providing an initial phase shift close to 0° at f_0. The first mode of operation, namely the patch mode, is obtained by inserting a square patch at the center of the cell (cf. Figure 6 – Mode 1). The phase shift produced by the cell is controlled by increasing the patch size until it reaches a maximum predefined value.

In mode 2, namely the stub mode, the patch size is frozen to this maximum value and four open-circuited stubs are grown perpendicularly to the patch from the center of its edges (cf. Figure 6 – Mode 2). A T-shape is used for the stubs when the total metal length approaches the limit allowable by the inter-element spacing. In this mode, the phase shift is thus controlled by the length of the stubs.

The mode then switches to mode 3, namely the patch-stub mode, during which the stub-loaded patch shrinks gradually until both patch and stubs disappear completely allowing the cell to rebirth and to start a new cycle (cf. Figure 6 – Mode 3). In this mode, the phase shift is controlled by the shrinking ratio.

The phase response of the suggested cell in all modes is summarized in Figure 7. Dashed curves represent the start/end of a mode (i.e. MαS/MαE) and continuous lines represent intermediate states (i.e. MαI). As can be noticed, a phase range of 360˚ is achieved at f_0. Within a frequency band ranging from 10 to 15GHz (40%), the phase response is almost linear. The maximum phase dispersion is obtained at the transition from mode 2 to mode 3 and is equal to 55˚/GHz. The minimum dispersion is obtained at the beginning of mode 1 and is equal to 21˚/GHz. Compared to cell 1, cell 2 exhibits a better linearity of phase response. On the other hand, its minimum dispersion is not zero as required by the previously-used ideal cell model. However, this model still applies if we replace the maximum dispersion by the relative maximum dispersion, defined as the difference between the maximum and minimum dispersions. For cell 2, it is then equal to 34˚/GHz.

5.3. Performance Evaluation and Comparison

The previously-described Phoenix cells are now consecutively used as the radiating element in our test-case RA (F/D=0.8, variable D). The bandwidth is calculated by simulations as in [16] and compared to that given by (18). For this theoretical study, the maximum dispersion $Disp_{max}$ in (18) is set to 53°/GHz for cell 1 and 34°/GHz for cell 2.

Figure 8 summarizes all theoretical and simulation results. The results show a remarkable agreement between simulation and theoretical curves for a given cell. The slight discrepancy is mainly due to the linearity assumption in the ideal model which is not fully respected by realistic Phoenix cells. It is less than 5% for cell 1 and 3% for cell 2. As expected, a smaller error is obtained for cell 2 as it offers a better linearity of phase response.

Formula (18) is hence a reliable bandwidth estimator, even for realistic phase-shifting cells, provided that they are characterized by a quasi-linear response. As a consequence, it can be advantageously used to define the maximum dispersion allowed for a Phoenix cell to comply with given bandwidth specifications or to predict a Phoenix cell's performance in a RA configuration.

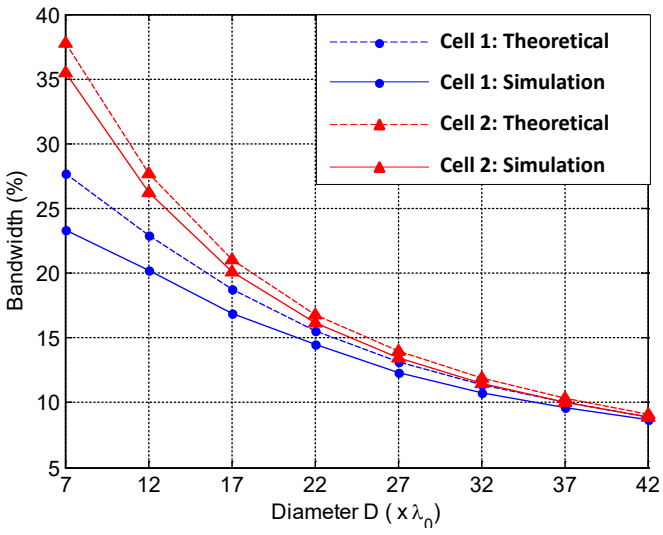

Figure 8. A Realistic study: simulated versus theoretical bandwidth of realistic Phoenix cells (F/D=0.8)

6. Conclusion

Bandwidth limitation of RA results from both the effect of various path delays between cells and source on one side, and intrinsic narrow bandwidth of cells themselves on the other side. The first phenomenon had been significantly investigated in the literature. For the second one, the usual solution relies on the use of broadband cells providing linear and parallel phase states. As this ideal characteristic is never met perfectly, this paper has defined a new approach to assess the effect of imperfection in the phase response of broadband RA cells.

We firstly proposed the standard deviation of phase errors over the array as an efficient criterion to predict RA's bandwidth when accounting for both its limiting phenomena. This criterion has then been formulated and validated for an ideal cell model with linear but non-parallel phase states. Finally, it has been successfully applied to realistic and novel Phoenix-cells. The suggested approach has thus been demonstrated as a powerful tool to help the designer in the selection of appropriate cells before entering the complex RA optimization process.

A B S T R A C T

The necessity of navigation in people and mobile robots (MR) through specific environments (indoors or outdoors) has become more and more relevant nowadays. For indoors, generally speaking, the positioning systems can be divided into 2D (two dimensions) or 3D (three dimensions) approaches, where Ultrasonic Local Positioning Systems (ULPS) are often a common solution for MRs in 2D. This work proposes the extension of an already developed 2D ULPS to a 3D ULPS, where the compact design and the suitable performance of the initial 2D ULPS have been maintained. The ultrasonic beacons have been re-arranged to avoid co-planarity, then improving the third coordinate estimation. Furthermore, this work proposes the use of up to four ULPSs together to cover the 3D region of interest. Two configurations have actually been considered, one involving three ULPSs and another based on four. A heuristic Position Dilution of Precision (PDOP) estimation has been carried out, by taking into account two ways of obtaining the 3D-position: a) all beacons from the three different ULPSs are processed simultaneously, so all measurements are considered in the same set of positioning equations; and b) every ULPS is detected and considered separately and, later, the different estimated positions are merged. The second option is more likely to happen in a real scenario and, furthermore, the fusion of the independent positions obtained from each one of the ULPS improves the final position accuracy.

1. Introduction

The necessity for positioning and navigating objects and people indoors and outdoors is expanding more and more every day. For outdoor environments, the Global Positioning System (GPS) is widely used. Nevertheless, whether there is a lack of RF signals, indoors or in constrained outdoor environments, other approaches have already emerged as a supporting and/or alternative technology, thus providing the so-called Local Positioning Systems (LPS). The demand for these LPSs, and in general terms for indoor positioning, has also become more relevant due to the worldwide spreading of smart devices, and their corresponding location applications.

Different sensory technologies have already been used in the development of LPS, such as Wi-Fi, infrareds (IR), ultrasounds (US) or radio-frequency (RF). The final decision on one technology or another is mainly related to the type of application, the environment, the required accuracy, as well as other secondary parameters [1] [2] [3]. Among them, ultrasounds-based approach is often considered whether the required accuracy is in the range of centimetres, not only for 2D but also for 3D deployments.

This work has been initially based on the previous LOCATE-US LPS (ULPS), firstly developed by the GEINTRA-US/RF Research Group from the University of Alcalá for 2D positioning [4]. A performance analysis of an ULPS is presented here when it is adapted for 3D positioning in a certain region. The proposal consists of using several ULPSs, which cover the area under scanning from different points of view in order to achieve an accurate estimation of the receiver's position in 3D. The main goal of the paper is the study of different configurations of these ULPSs (number and location in the environment) and compare them in terms of the accuracy obtained in a grid of test points that cover all the 3D region of interest. As the positioning accuracy depends on

[*]Khaoula Mannay, Email: khaoula.mannay@gmail.com

the position itself to be determined, for every particular configuration it is necessary to study the positioning errors in all the points for all the cases. The rest of the manuscript is organized as follows: Section 2 presents a general background about LPSs, their main characteristics and technologies; Section 3 describes the previous LOCATE-US LPS, whereas the proposed 3-D ultrasonic LPS (ULPS) is presented in Section 4; Section 5 explains the 3D positioning algorithm implemented for the ULPS; Sections 6, 7 and 8 shows some simulation results; Section 9 presents a short discussion; and, finally, conclusions are considered in Section 10.

2. LPS Background

Local Positioning Systems (LPS) try to position one or multiple mobile objects accurately in an indoor environment. They are often used in applications, such as environment monitoring, people tracking, robot localization, resource management, or location-based services. The moving object is usually equipped with a small receiver (or transmitter depending on each LPS design), which acquires the emissions coming from the beacons forming the LPS, in order to estimate its own position. The nature of the transmitted signals can be different, depending on the technology involved: IR, RF, US, etc. [5]. According to this, Fig. 1 shows a general scheme for a LPS, where the beacons are fixed in the environment and the receiver is moving and computing its own position.

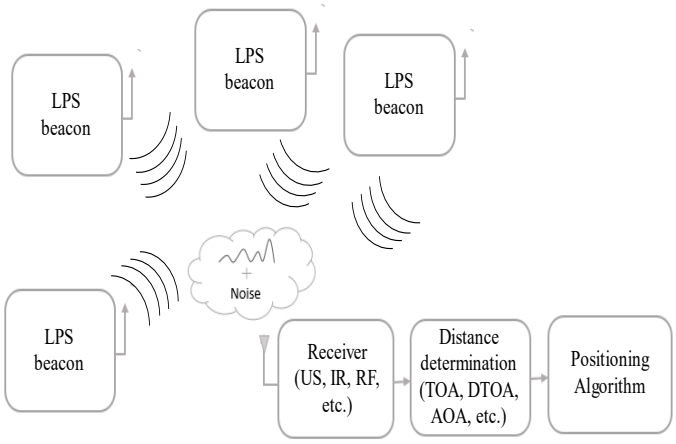

Fig. 1. General scheme of a LPS based on transmitting beacons and a moving receiver.

Furthermore, LPSs can also be classified into two groups: absolute for those where the mobile object is able to estimate its own position with respect to a reference point at any time; relative, when the mobile object can only know its position in a relative way to other receivers (or nodes) existing in the same coverage area [5].

Common LPS applications are those dedicated to 2D positioning and navigation of mobile robots and/or vehicles, as well as those focused on 3D positioning of smart devices and vehicles, such as smart phones, drones, etc. [7] [8]. Furthermore, Location-Based Services (LBS) are also potentially commercial applications for the market, not only to deliver context-dependent information accessible with a mobile device, but also to obtain information or navigate in the corresponding indoor environment. Finally, LPSs become particularly interesting in some emergency scenarios, such as positioning medical staff or equipment in hospitals, assisting rescue services in critical situations, or those proposals applied to intelligent transportation systems and/or industry manufacturing [9].

The final accuracy of a LPS in the position determination often depends on the system configuration, the sensory technology and the type and difficulty of the coverage area. Related to this, proposed LPSs are typically parametrized by the geometric dilution of precision (GDOP), where the distribution of the distance error between the estimated position and the true position is computed. Another key parameter is the range of coverage, where common values are between 5 meters and 50 meters. In this sense, for large coverage areas, scalability is key to guarantee an average positioning performance, as the positioning estimation degrades with the distance between the transmitters and receiver [10] [11] [12].

As far as the positioning algorithms are concerned, all of them are based on the determination of a variable from the beacon-receiver transmission. Some previous works based on ultra-wide band (UWB) have been recently proposed for indoor positioning by using the time differences of arrival (TDOA) from the RF transmissions between a reference beacon and the others. Typical accuracy values for these approaches are in the range of metres or even centimetres, although they present significant drawbacks, such as complexity or multi-path effects on the achieved accuracy [13] [14].

On the other hand, wireless local area networks (WLAN) have also been applied to indoor positioning [15]. Although they can also be based on TDOA, most cases deal with the received signal strength (RSS), reaching accuracies from 3m to 30m approximately [16] [17]. A similar case is the use of radio-frequency identification (RFID) [18]. In the case of infrareds, they often require a direct line-of-sight (LOS) communication between devices along a very short distance [19], where proximity, differential phase shift, and angle of arrival (AoA) are predominant.

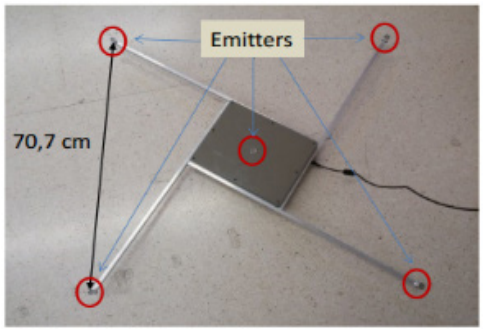
Finally, ultrasounds-based systems also deal with TDOA [20], when there is no synchronization between the beacons and the receiver, and, afterwards, a hyperbolic positioning algorithm allows the position of the receiver to be estimated. The global accuracy of ultrasonic LPS (ULPS) is high and the structure is simple, but they often present drawbacks, such as multipath effects, Doppler, etc. [21] [22] [23].

3. General view of LOCATE_US system

The 2D LOCATE-US ULPS, designed by the GEINTRA-US/RF Research Group from the University of Alcala [4] [24], is a compact, light and portable ultrasonic beacon architecture [5]. The ULPS is formed of five coplanar ultrasonic beacons (B_i, where i=1,2,…5), placed at the four corners of a 0.707m x 0.707m square and at the centre, as is shown in Fig. 2. The five beacons have the same orientation (usually the ULPS is placed in the ceiling) and they cover roughly the same area on the floor. As the emission pattern of transducers is 120º [5], the ULPS can cover an area of 40m² roughly for a height of 3.5m. Any receiver inside the coverage area (attached to smartphones, a mobile robot (MR), a drone, ...) can compute its position in an independent and autonomous way [4] [24].

In order to cover wide indoor areas, several ULPSs can be easily deployed. Particular calibration techniques have been proposed in [27] to facilitate this deployment.

The emitters in the ULPS use a code division multiple access (CDMA) and a time division multiple access (TDMA) protocols. Every emitter is encoded with a different code, with good auto-correlation properties and low mutual interference properties with the others. The ultrasonic transmissions of the different emitters can be configured in terms of sampling frequency, modulation schemes and code patterns to be emitted. The obtained accuracy for the measurement of distances is in the centimetre range (we assume a typical deviation of 1cm). The distances measured can be up to about 20m. All that is enough for MR applications in 2D spaces, and if extensive areas must be covered we can use a set of single ULPSs [4].



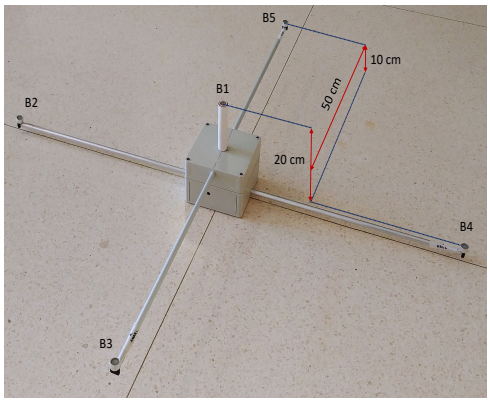


Fig. 2. General view of the 2D LOCATE-US LPS

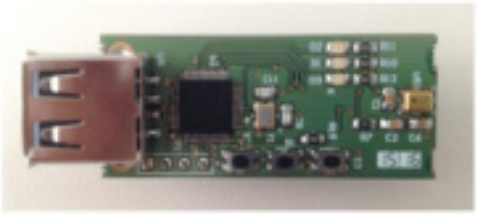
4. Proposed 3D ULPS



The 3D ULPS described hereinafter is an extension of the 2D LOCATE-US, so it is also formed by five ultrasonic beacons B_i placed at the four vertices of a 0.707m x 0.70 m square and at the centre, as is shown in Fig. 3.a). All of them present slight variations in the z coordinate to improve this coordinate estimation and to avoid co-planarity; but still keeping the same properties of the previous 2D ULPS, such as the common orientation and coverage area. The new beacon distribution is: B2 and B4 are in the base plane, B3 and B5 are 10cm high from the base plane, and finally B1 is placed at 20cm high from the base plane [24].

The ultrasonic beacons are wired-synchronized to enable simultaneous and periodic emission [4] [24]. The ultrasonic transmission are encoded with orthogonal 1023-bit Kasami sequences, in order to mitigate any effect coming from multiple access interference (MAI) as much as possible [25]. These codes have been selected due to their suitable auto-correlation and cross-correlation properties. For their transmission, a binary phase shift-keying (BPSK) modulation has been carried out, with a carrier placed at the central frequency of the transducer bandwidth, f_c=41.67kHz. Two carrier cycles per modulation symbol have been applied, and ultrasonic transmissions are carried out periodically every 50ms to reduce multipath effects.

The involved ultrasonic transducer is the Prowave 328ST160 [26], together with an ad-hoc front-end designed for this application. The five beacons B_i are managed by a FPGA-based system, in charge of controlling the global operation of the ULPS through an Ethernet link [24].The type of binary sequence and its length, the number of carrier periods, the type of carrier, and the time interval between different emissions can be configured by the PC. A digital pass-band filter with a 40 kHz central frequency and a 10 kHz bandwidth has been included to constrain information to the ultrasonic transducer bandwidth [26].

a)

b)

Fig. 3. a) General view of the 3D LOCATE-US LPS;
b) Designed ultrasonic receiver.

With regard to the reception, the moving device estimates its position asynchronously by hyperbolic trilateration from the TDOA measurements between a reference beacon and the others. To detect the TDOAs, the mobile device demodulates the received signal and correlates it with the corresponding emitted Kasami sequences, based on a generalized cross-correlation (GCC) of the received signal. A main lobe appears at the arrival instant for every Kasami sequence, so it is possible to calculate the associated TDOAs. Finally, a Gauss-Newton minimization method computes the position. Fig. 3.b) shows the general aspect of the used ultrasonic receiver [24].

5. 3D Positioning

In positioning systems, it is important to know the accuracy of the estimated position, which depends on the quality of measurements (ranging distances, signal strength, etc.), and on the geometry of the positioning system (beacons' geometry) with respect to the mobile node. The Position Dilution of Precision (PDOP) includes such dependencies and can be obtained empirically using (1).

$$PDOP \approx \frac{\sqrt{\sigma_x^2+\sigma_y^2+\sigma_z^2}}{\sigma_m} \qquad (1)$$

Where σ_x^2, σ_y^2 and σ_z^2 are the position variances in the three axes X, Y and Z, respectively; and σ_m is the standard deviation in the distance measurements (assumed to be 1cm hereinafter). As has been already mentioned, the technique used to position objects in 3D is based on the TDOAs, thus requiring synchronization between beacons (emitters), but not with receivers.

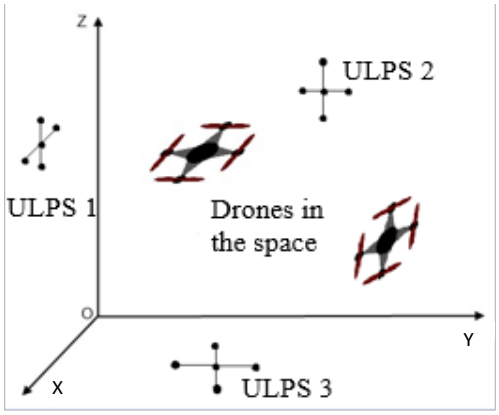


Fig. 4. Example of 3D configuration using three ULPSs and two receivers (drones).

In order to position a mobile target in a 3D space (see Fig. 4), a single ULPS is not enough to cover all the space with enough accuracy, assuming an 8x8x8m^3 volume. The setup with a single ULPS implies that the performance significantly degrades with the height variation, due to the poor Vertical Dilution of Precision (VDOP), which determines the performance by only taking into account the typical deviation in the *z* coordinate.

Thereby, the use of only one ULPS is not a suitable solution. As an example of that, Fig. 6 shows the case in which one ULPS is placed at the centre of the floor at coordinates (4m, 4m, 0m), whereas Fig. 8 depicts the case of one ULPS placed at the lower corner with coordinates (0m, 0m, 0m). Both Figs. represent the cloud of obtained position points, assuming the receiver in the X-Y plane (with steps of 1m in both axes), for three different heights: *z*=6m in the half upper volume of the room; *z*=4m in the middle of the room; and *z*=2m in the half lower volume of the room.

Additionally, Figs. 7 and 9 show the different PDOP values for the same X-Y planes and heights (*z*=2m, 4m, 6m). Note that the PDOP values are high in general terms (above 100). The contour map is a representation of the PDOP in planes at different height. The values of the PDOPs have been calculated for every point in the grid (according to the cloud of points with the estimated positions after the simulations).

Each color represent a particular value of PDOP; and the greater the PDOP the greater the positioning error in this point (even in the case that all the distances has been measured always with a typical deviation of 1 cm). With this representation one can have an idea about the error we can wait in each region of the environment in a real situation with a particular ULPS arrangement.

On the other hand, the receiver has been placed at every point in a 9x9x9 grid (8x8x8m^3 volume using 1m interval). At each point, a hundred simulations have been run by using an hyperbolic trilateration with the Gauss-Newton Positioning Method (GNPM) [10]; the standard deviation in the distance measurements is σ_m =1cm, which is consistent with ultrasonic measurements of distances.

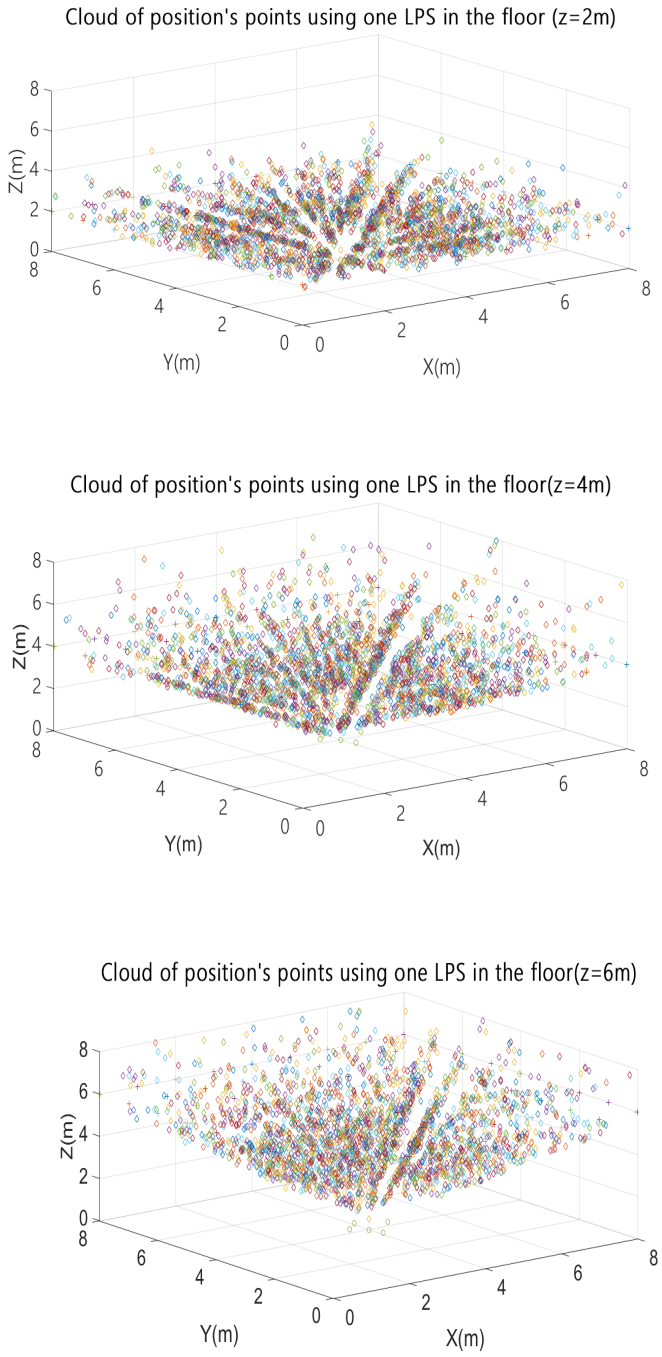

Fig. 6. Cloud of position points for one ULPS placed at the centre of the floor (4m,4m,0m) for X-Y planes at different heights (z=2m, z=4m, z=6m).

As can be observed in Fig. 7, the PDOP values differ from one plane to another, but, in general, it is smaller in the centre of every plan, and then it increases towards the sides of the room. For the first plane *z*=2m (lower half of the room), the PDOP varies from 100 to 900.

Whereas these values increase in the middle of the room (*z*=4m), where the PDOP is between 250 and 800; and, finally, they range from 450 to 850 in the third plane *z*=6m (upper half of the room).

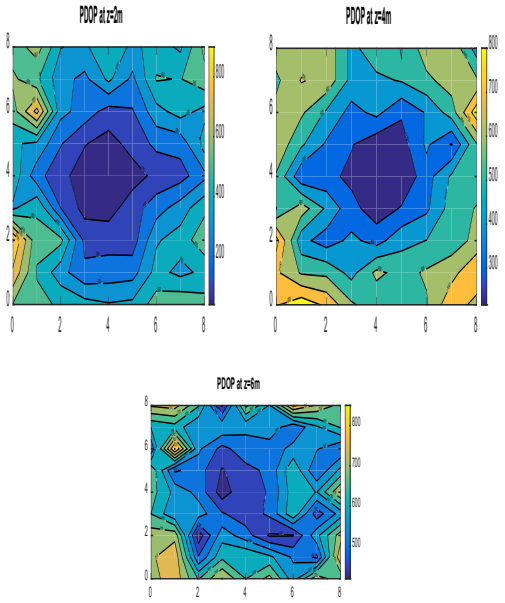

Fig. 7. Colour map of PDOPs for an ULPS placed at the centre of the floor (4m, 4m, 0m) for different X-Y planes (z=2m, z=4m, z=6m).

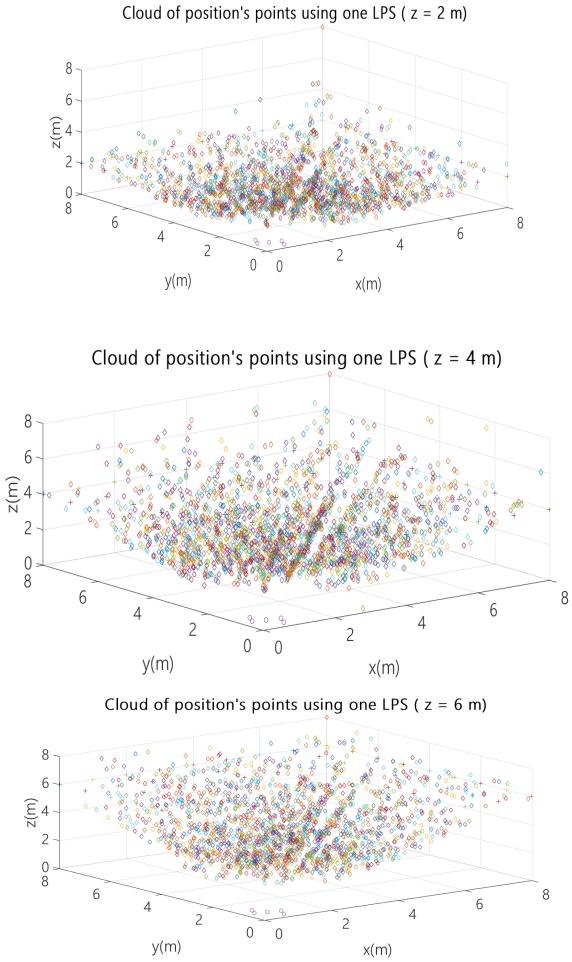

Fig. 8. Cloud of position points using an ULPS placed at (0m, 0m, 0m) corner for X-Y planes z=2m, z=4m and z=6m.

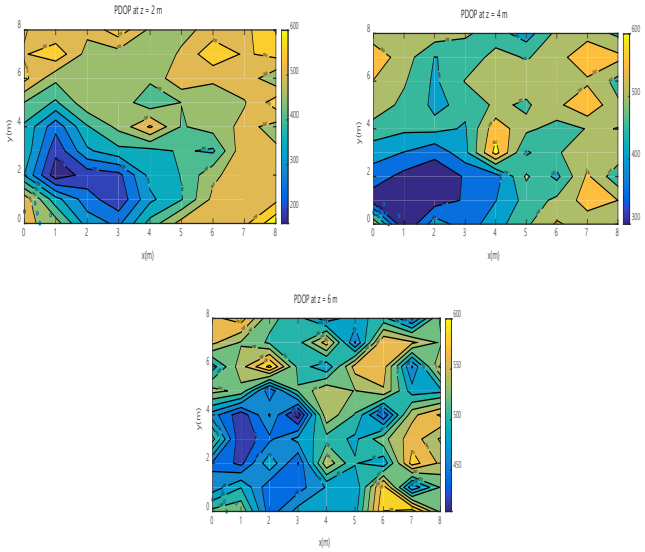

Fig. 9. Colour map of PDOPs for an ULPS placed at (0m, 0m, 0m) corner for X-Y planes (z=2m, z=4m, z=6m).

Similar conclusions can be derived from Fig. 9 with the LPS placed at corner (0m, 0m, 0m) and pointing at the centre of the room. For the first plane z=2m, the PDOP values are between 200 and 600; for z=4m, they are between 300 and 600; and between 420 and 600 for z=6m.

In order to improve these results, as well as to enhance the coverage area, the use of several ULPSs placed at different points of the room has been considered. These tests have been carried out by using two different configurations:

- Configuration A: three ULPSs placed at the centres of X-Y plane z=0m, Y-Z plane x=0m and X-Z plane y=8m, respectively. All these ULPS are emitting perpendicularly to the plane in which they are placed.
- Configuration B: four ULPSs placed at corners (0m, 0m, 0m), (8m, 8m, 8m), (0m, 8m, 0m) and (8m, 0m, 8m), respectively. Each LPS is emitting in the direction of the cube diagonal corresponding to the corner at which it is placed.

In practical situations, the 3D position can be computed with one or an array of microphones to cover all the incoming signals. In this way, two options have been considered here:

- Simultaneous measurements: all the distances (derived from TDOAs), from all the ULPSs that must be synchronized, are obtained at the same time, so the positioning algorithm involves as many equations as measured distances. For the three ULPSs configuration, the positioning algorithm requires fifteen equations, whereas, in the four ULPSs configuration, twenty equations.
- Independent measurements for each ULPS: whether five distances from one single ULPS are obtained at the receiver, it obtains a 3D position. In parallel, several 3D positions can be computed (one per every detected ULPS). To combine all these 3D positions, the Maximum Likelihood Estimation (MLE) is applied. In the case of having available three independent measurements q_1, q_2 and q_3 for a certain position q, provided that the positioning error may be modelled as $p(q_i|q)=N(q, \sigma_i)$, the

merged estimate q_{MLE} for position q can be obtained by following the procedure (2):

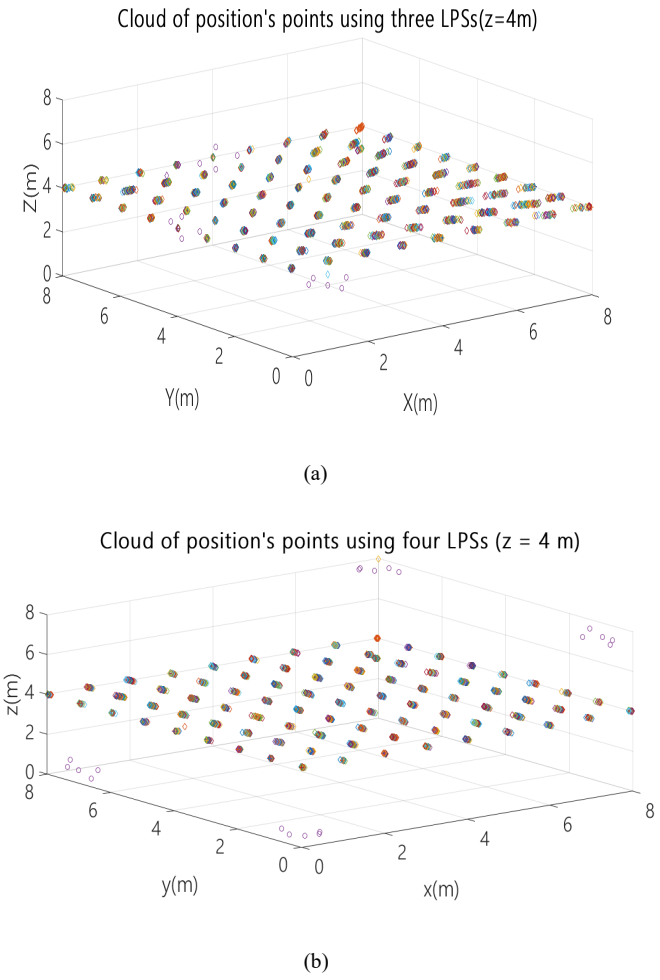

Fig. 10. Cloud of position points for the X-Y plane z=4m using: (a) configuration A with three ULPSs; (b) configuration B with four ULPSs.

$$q_{MLE} = \frac{\sigma_1^{-2} \cdot q_1 + \sigma_2^{-2} \cdot q_2 + q_3^{-2} \cdot z_3}{\sigma_1^{-2} + \sigma_2^{-2} + \sigma_3^{-2}} \qquad (2)$$

Where q_1, q_2 and q_3 are three independent measurements for position q in the case of detecting three different ULPSs. Since the statistical information is additive, the new standard deviation σ will be (3):

$$\sigma^{-2} = \sigma_1^{-2} + \sigma_2^{-2} + \sigma_3^{-2} \qquad (3)$$

Where σ_1, σ_2 and σ_3 are the standard deviations for the corresponding position measurements q_1, q_2 and q_3.

6. Results for configuration A (three ULPSs on the walls)

In order to compare the performance of each ULPS arrangement and the total number of distance measurements available, for both configurations A and B, one hundred simulations have been conducted at every point in the 3D grid (9x9x9m^3) with a step in x, y and z of 1m. The standard deviation considered in the distance measurements is σ_m=1cm.

6.1. Simultaneous measurements from all ULPSs

In this case, the 3D receiver position is estimated by the GNPM at each point, assuming there are available simultaneous measurements of TDOAs from all the ULPSs at the receiver. For configuration A, the space is covered by three ULPSs, as shown in Fig. 10. Two cases have been studied: only two of them are available; all the three are available.

6.1.1. Two ULPSs available

Firstly, in addition to the ULPS placed at the position (4m, 4m, 0m), a second ULPS has been placed at the centre of the wall y=8m, at position (4m, 8m, 4m). Figs. 11 and 12 show the cloud of positions obtained, as well as the PDOP for planes z=2m, z=4m and z=6m.

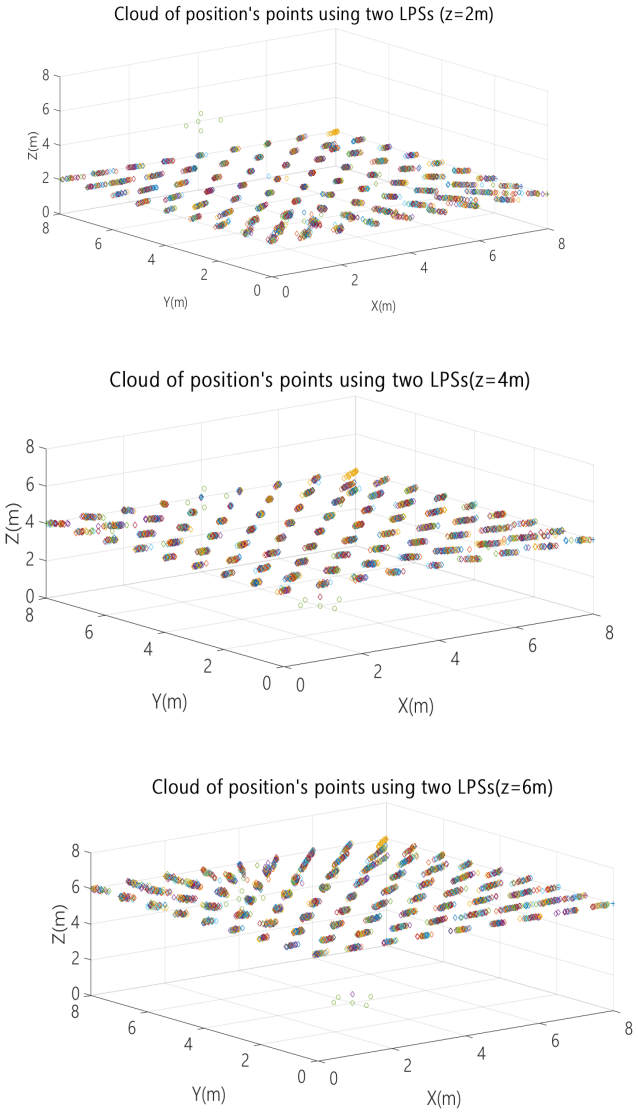

Fig. 11. Cloud of position points for two ULPSs: one placed at (4m, 4m, 0m) and the other at (4m, 8m, 4m), for different X-Y planes (z=2m, z=4m, z=6m).

Comparing with the previous results achieved with only one ULPS (Figs. 6 to 9), the improvement is clear: now the PDOP varies from 5 to 100, providing larger volumes with lower values. The lowest PDOP values are around the centre of the room.

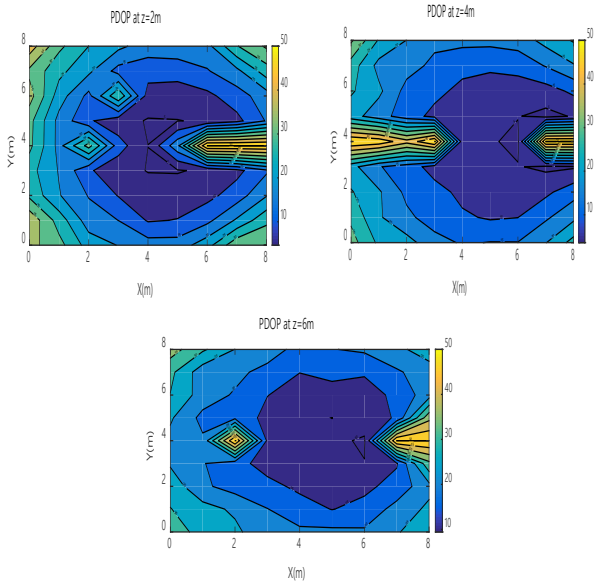

Fig. 12. Colour map of PDOP values for two ULPSs placed at (4m, 4m, 0m) and the other at (4m, 8m, 4m), for different X-Y planes (z=2m, z=4m, z=6m).

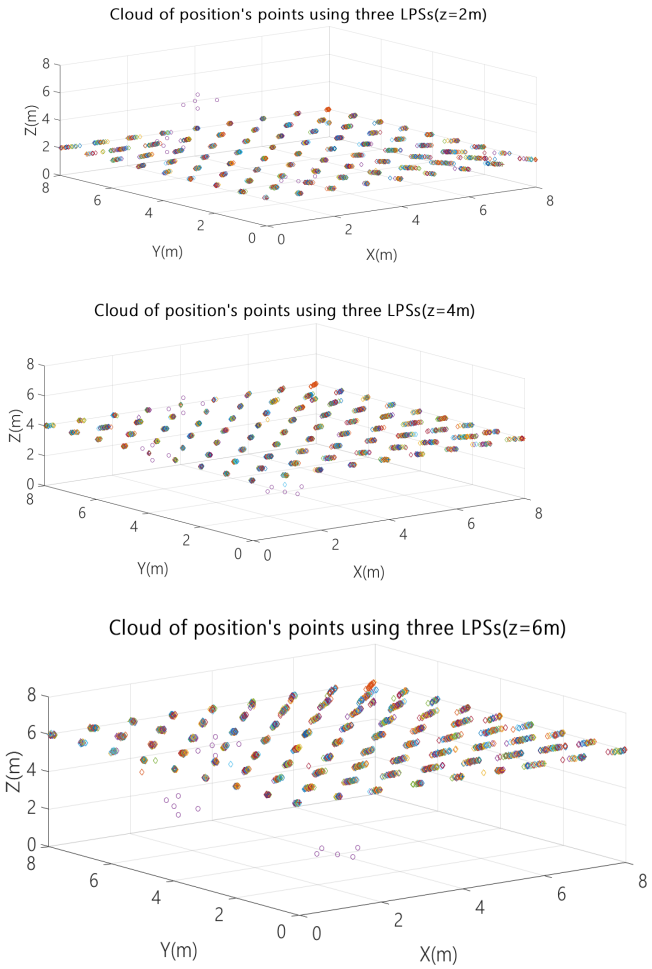

Fig. 13. Cloud of position points for three ULPSs placed at (4m, 4m, 0m), (4m, 8m, 4m) and (0m, 4m, 4m) for different X-Y planes (z=2m, z=4m and z=6m).

6.1.2. Three ULPSs available

A third ULPS has been added at coordinates (0m, 4m, 4m). Figs. 13 and 14 show the same clouds of points and PDOPs as before, for X-Y planes *z*=2m, *z*=4m and *z*=6m.

By adding the third ULPSs, the cloud of the 100 position points simulated is more accurate around the real positions considered in the grid. The PDOP values decrease below 30 in general terms, and below 15 in almost all the space, independently of the height.

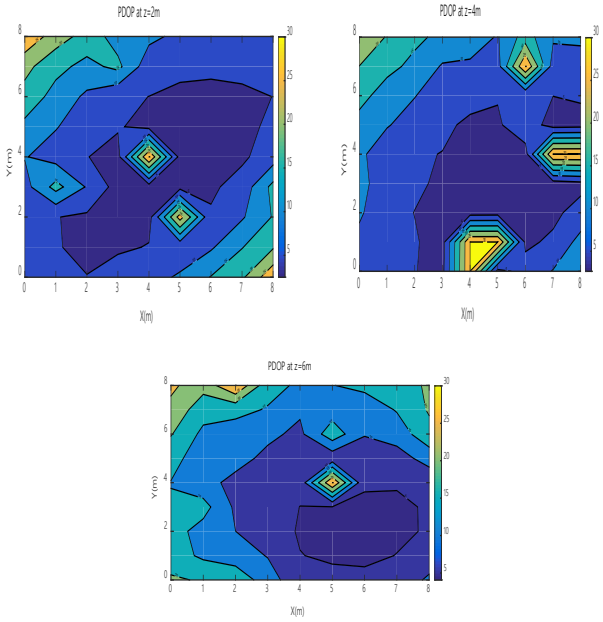

Fig. 14. Colour map of PDOP values for three ULPSs placed at (4m, 4m, 0m), (4m, 8m, 4m) and (0m, 4m, 4m) for different X-Y planes (z=2m, z=4m, z=6m).

6.2. Independent measurements for each ULPs

6.2.1. Fusion of two ULPSs

The configuration analysed here is the same as that one in Section 5.1.1. Now, the 3D positions from the two different ULPSs are obtained separately, and, afterwards, these positions are combined by using a MLE to estimate a final position. The process has been repeated a hundred times at each point in the aforementioned grid. The final PDOP values are shown in Fig. 15, varying from 5 and 100, also providing large areas with low values. It is worth noting that these results are similar to those in Fig. 12 for the case of simultaneous measurements.

6.2.1. Fusion of three ULPSs

When having a third ULPS placed at (4m, 0m, 4m), the PDOP values have been calculated for a hundred simulations at each point in grid, and they are shown in Fig. 16. Again, the distribution of the PDOP values with the MLE merging method are very close to the case when using simultaneous measurements (see Fig. 14).

In order to summarize the results for the case analysed in this section, for the whole volume under analysis the Cumulative Distribution Function (CDF) of the position error has been obtained, by taking into account all the points in the grid (100 simulations per each position). Fig. 17 shows the CDF for simultaneous (a) and independent (b) measurement approaches.

According to Fig. 17, for simultaneous measurements, in the 90% of the cases the error is below 0.7m when using only one ULPS, below 0.2m with two ULPSs, and below 0.1m for three ULPSs. On the other hand, for independent measurements, in the 90% of the cases the error is below 0.9m for one ULPS, 0.8m for the fusion of two LPSs, and 0.7m for the fusion of three ULPSs.

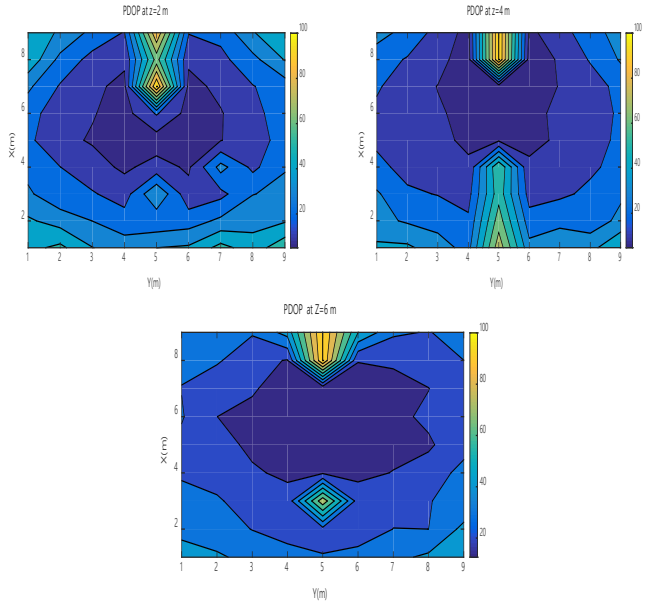

Fig. 15. Colour map of the PDOP values obtained by the MLE when using two ULPSs at (4m, 4m, 0m) and at (4m, 8m, 4m) for X-Y different planes (z=2m, z=4m, z=6m).

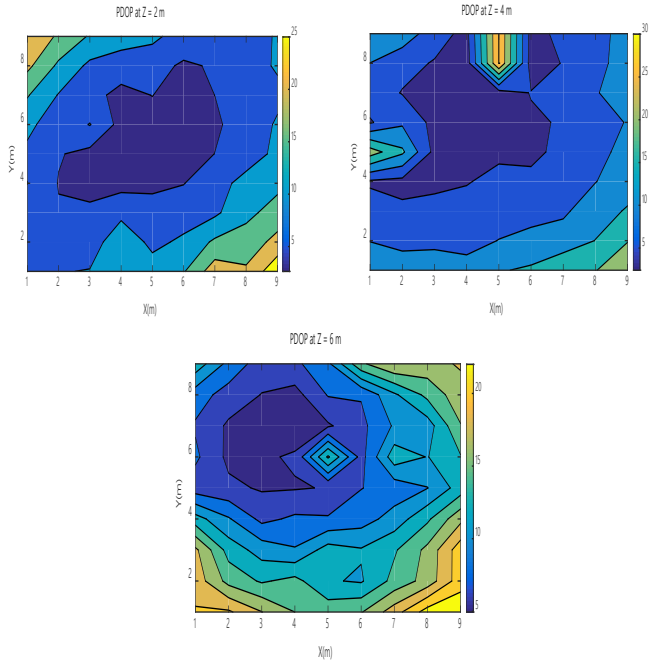

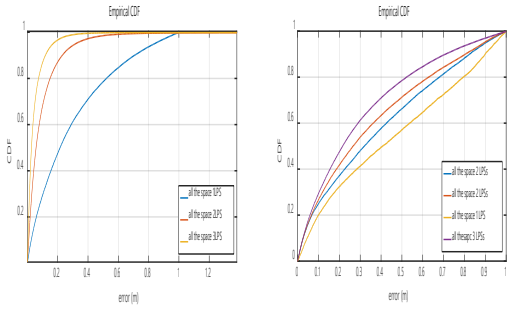

Fig. 16. Colour map of the PDOP values obtained by the MLE when using three ULPSs at (4m, 4m, 0m), (4m, 8m, 4m) and (0m, 4m, 4m) for X-Y different planes (z=2m, z=4m, z=6m).

(a) (b)

Fig. 17. CDF for the position error in the whole volume: a) using simultaneous measurements; and b) using independent measurements (and fusion).

7. Results for configuration B (with four ULPSs)

As has been already explained in Section 4, the whole volume is covered by four ULPSs in the configuration B. The goal is to improve the results presented in Figs. 8 and 9, where only one ULPS located at position (0m, 0m, 0m) was used.

7.1. Simultaneous measurements

7.1.1. Two ULPSs

Together with the ULPS located at (0m, 0m, 0m), a second one is added at the opposite corner, that is, located at (8m, 8m, 8m). The resulting clouds of points and PDOP after 100 simulations at each grid point are shown in Figs. 18 and 19, respectively, for planes z=2m, z=4m and z=6m.

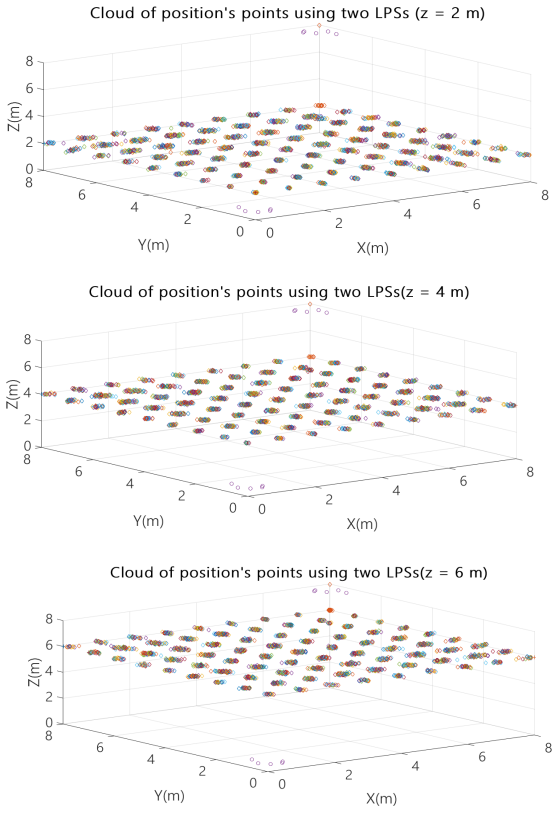

Fig. 18. Cloud of position points for two ULPSs at corners (0m, 0m, 0m) and (8m, 8m, 8m) for planes (z=2m, z=4m, z=6m).

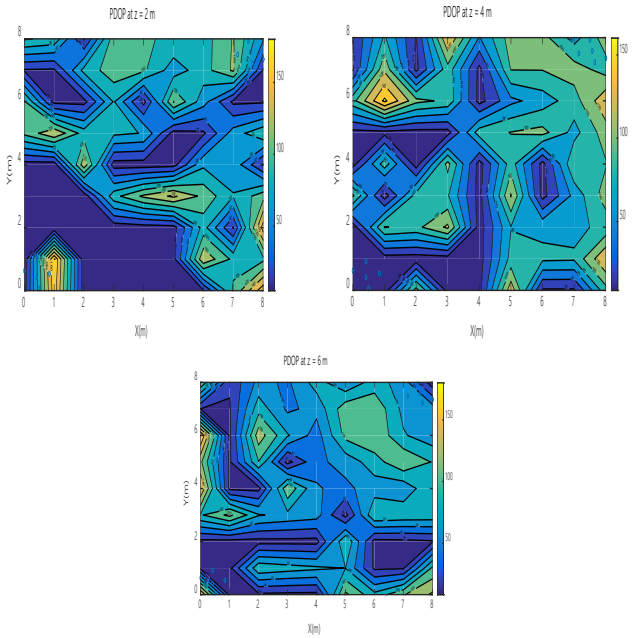

Fig. 19. Colour map of PDOP values for two ULPSs at (0m, 0m, 0m) and at (8m, 8m, 8m) for X-Y planes (z=2m, z=4m, z=6m).

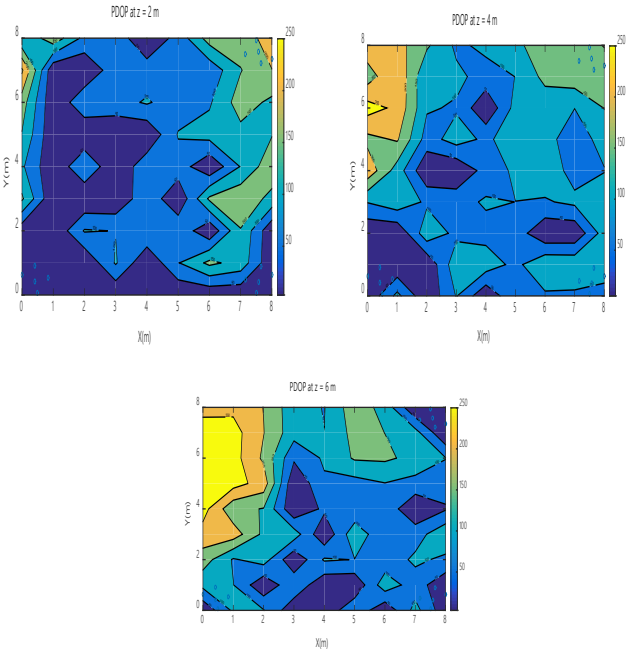

Fig. 21. Colour map of PDOPs for three ULPSs at (0m, 0m, 0m), (8m, 8m, 8m) and (8m, 0m, 8m) for X-Y planes (z=2m, z=4m,z=6m).

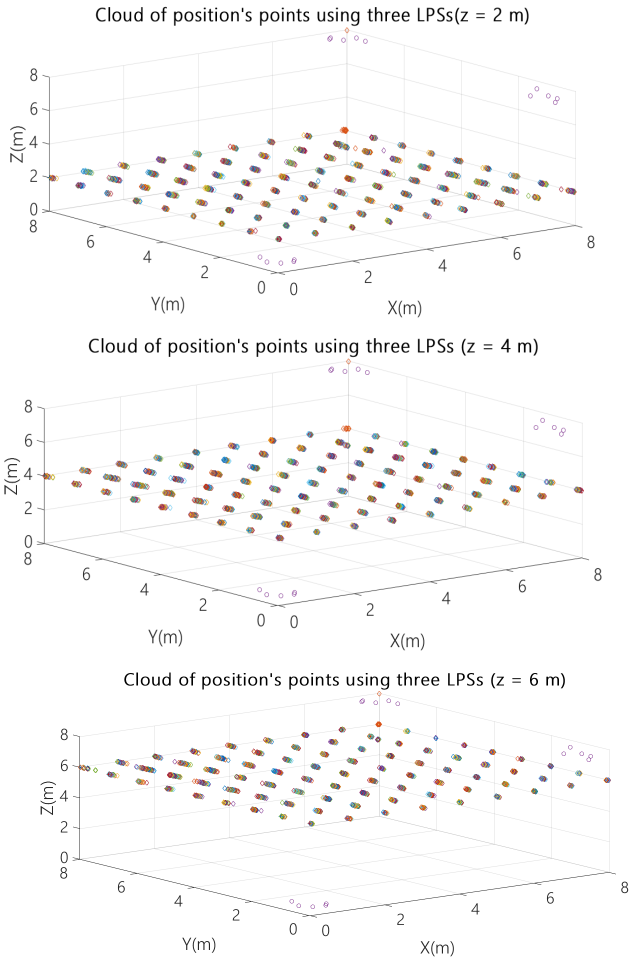

Fig. 20. Cloud of position points for three ULPSs, placed at (0m, 0m, 0m), (8m, 8m, 8m) and (8m, 0m, 8m) for X-Y planes z=2m, z=4m and z=6m.

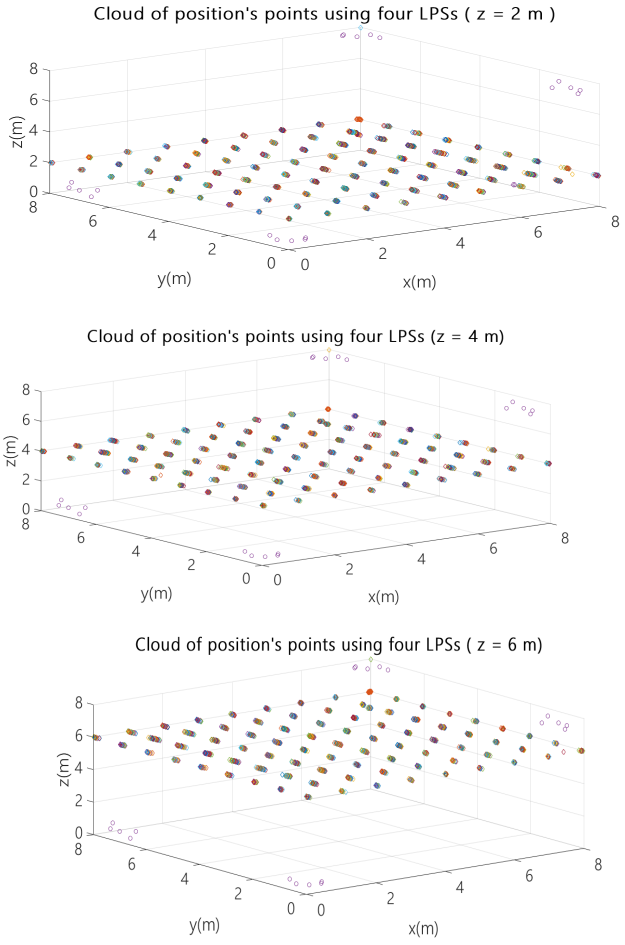

Fig. 22. Cloud of position points for four ULPSs at (0m, 0m, 0m), (0m, 8m, 0m), (8m, 0m, 8m) and (8m, 8m, 8m) for X-Y planes (z=2m, z=4m, z=6m).

It can be observed that there is an improvement in the error for all the grid points, compared to the case of only one ULPS, but still the PDOP values are in the interval from 10 to 180.

7.1.1. Three ULPSs

With a third ULPS placed at the corner (0m, 8m, 0m), the obtained results are shown in Figs. 20 and 21, also for the three planes *z*=2m, *z*=4m and *z*=6m.

The 3D positions are now more accurate, since the errors decrease especially in the neighbourhood of the ULPSs. The PDOP values are below 50 in large areas of the analysed planes.

7.1.2. Four ULPSs

Finally, a fourth ULPS is inserted at (0m, 8m, 0m), in addition to the previous three ones. The corresponding results are plotted in Figs. 20 and 21.

The errors have been considerably reduced with PDOPs between 5 and100, including large areas below 20.

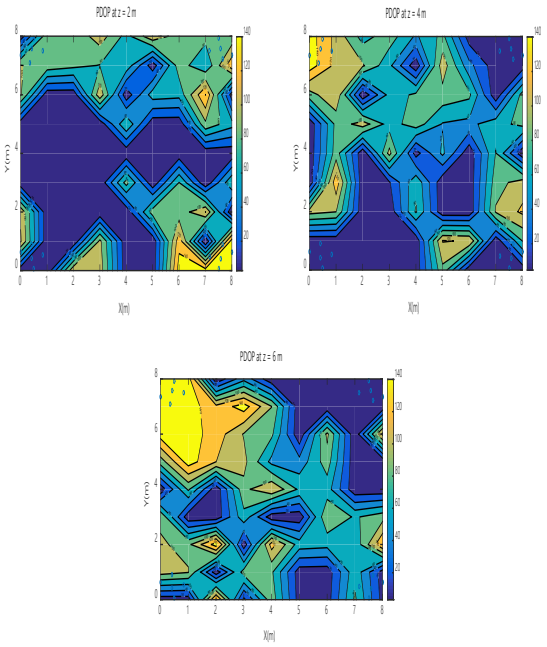

Fig. 23. Colour map of PDOP values for four ULPSs at (0m, 0m, 0m), (0m, 8m, 0m), (8m, 0m, 8m) and (8m, 8m, 8m) for X-Y planes (z=2m, z=4m, z=6m).

7.2. Independent measurements

In the second case analysed with the configuration B, each ULPS is considered independently. Figs. 24, 25 and 26 represent the PDOP values for two, three or four ULPSs,

respectively, after the fusion of the independent calculations for the positions.

Note that for two ULPSs the PDOP values are still as high as 420 in relatively large areas around the centre of the space. These areas are greatly reduced with three ULPSs (see Fig. 25) and even more with four ULPSs (see Fig. 26).

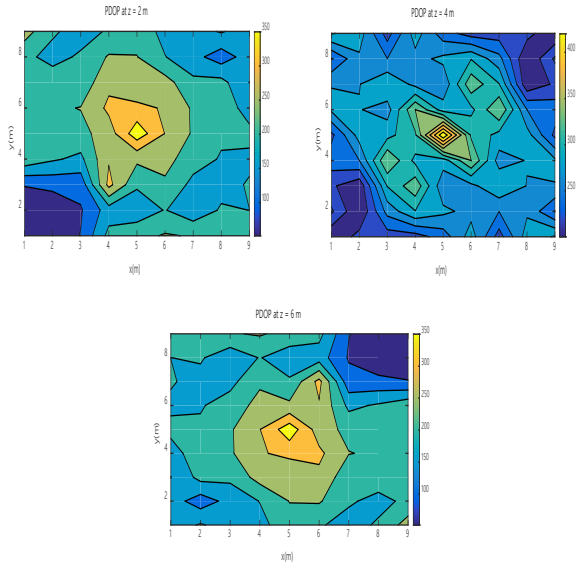

Figure 24. Colour map of the PDOP values obtained by the MLE when using two ULPSs placed at (0m,0m,0m) and (8m,8m,8m) for different X-Y planes (z=2m, z=4m, z=6m).

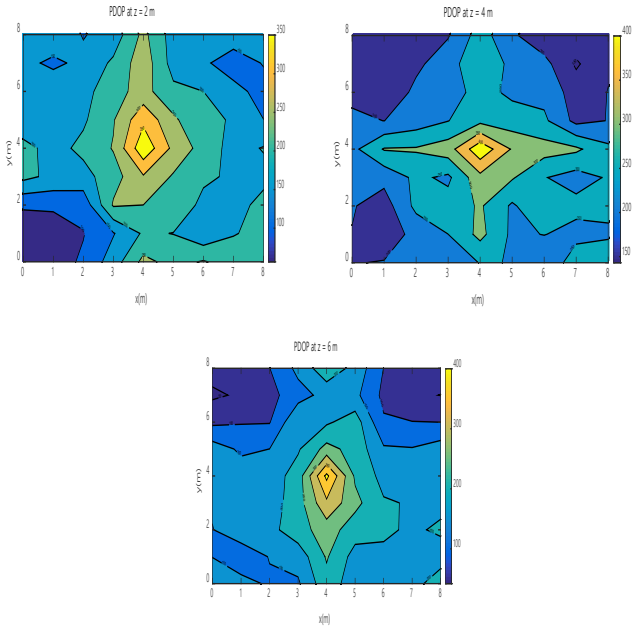

Figure 25. Colour map of the PDOP values obtained by the MLE when using three ULPSs placed at (0m,0m,0m), (8m,8m,8m) and (0m,8m,0m) for different planes (z=2m, z=4m and z=6m).

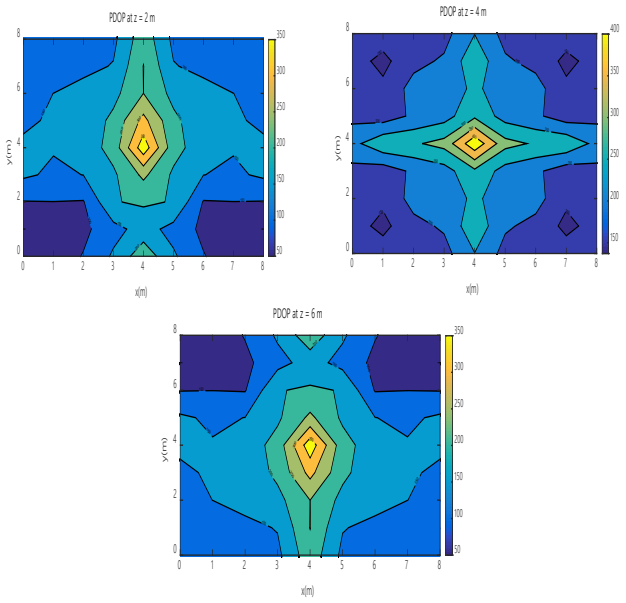
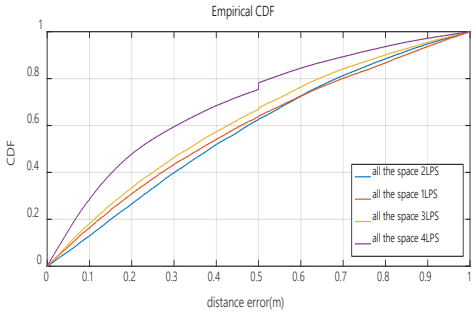
7.2.1. Error CDF

The error CDF, again obtained in all the points (and for a hundred simulations at each) for these distributions of ULPSs previously described, can be seen in Fig. 27. The upper plot considers simultaneous measurements, whereas the second one involves the fusion of independent measurements from each ULPS. In both, different CDF plots are shown for one, two, three and four ULPSs.

For the simultaneous emission, the errors for the 90% of the cases are below 0.75m using one ULPS, 0.15m for two ULPSs, 0.1m for three ULPSs and, finally, 0.07m for four LPSs (see Fig.

27.a). In case of fusion of data from independent ULPSs, these errors are below 0.85m for one ULPS and below 0.7m for four ULPSs (see Fig. 27.b).





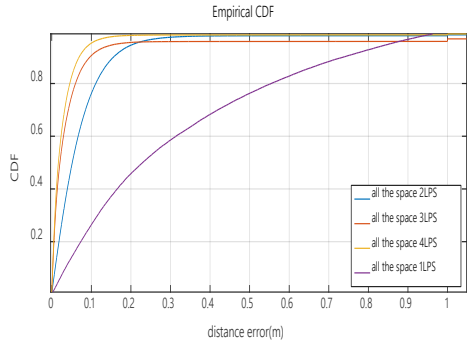


Figure 26. Colour map of the PDOP values obtained by the MLE when using four ULPSs placed at (0m,0m,0m), (8m,8m,8m), (8m,0m,8m) and (0m,8m,0m) for different X-Y planes (z=2m, z=4m, z=6m).

(a)

(b)

Figure 27. Error CDF in all the space, for 1, 2, 3 or 4 ULPSs and considering: a) simultaneous measurements with all the ULPSs; and b) independent measurements from each ULPS.

Finally, for the best case (simultaneous measurements with four ULPSs), the CDF has been split and represented in Fig. 28 for the points in every analysed plane *z*=0m, 1m, 2m …8m. Note that the error is quite similar in all the planes and, for the 90% of the cases, it is below 6-8 cm. That is, the performance of the system is similar in the whole volume.

8. Experiment results

In order to validate the proposal with real data, firstly, configuration A presented in Section 5 has been considered by using one ULPS. The tests have been carried out by positioning a receiver at each one of the 16 specific positions in a grid on the floor, as can be observed in Fig. 29. The ULPS is placed in the ceiling at a height of 3.5m. This workspace is not very complex and only the points of the corners of the grid have some problems due to signal attenuation and multipath.

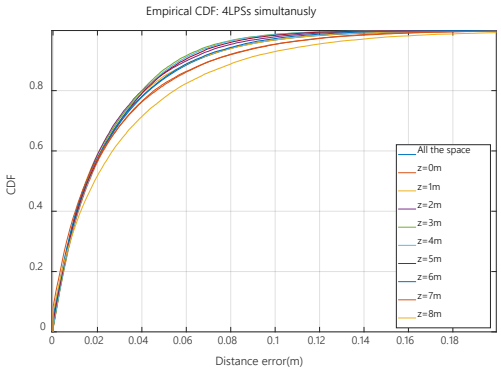

Fig. 28. Error CDF in every X-Y plane (z=1,2,…,8) for 4 ULPSs with simultaneous measurements.

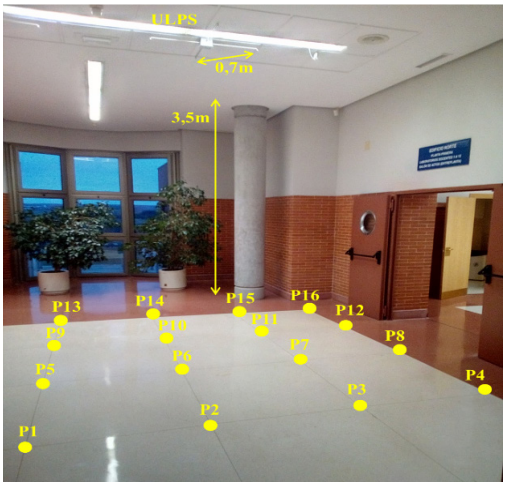

Fig. 29. Experimental setup formed by one ULPS placed in the ceiling at a height of 3.5m and the receiver placed at 16 points in a 4x4m² grid on the floor.

A set of 100 measurements have been carried out for every position, where the final estimated positions are represented by blue crosses in Fig. 30. On the other hand, the red circles are the real positions. An error ellipse containing the 95% of estimates has also been represented for every cloud of points. The green diamonds are the beacons' projections on the floor. It can be observed that the estimated positions at the test points below the beacons have a lower error than those further away. Nevertheless, all the positions are reasonably estimated.

Fig. 31 shows the error CDF obtained by simulating only one ULPS for the grid of points at z=3.5m. It can be observed that, for the 90% of cases, the positioning error is less than 1 cm. On the

other hand, Fig. 32 represents a similar CDF for experimental data, considering all the measurements or grouping them into two subsets: points P6, P7, P10 and P11 (placed at the center of the grid, just below the ULPS) and the rest of points. The differences between simulated and experimental data can be due to several factors: inaccuracies in the position of the receiver when tests were performed, and propagation effects not considered in simulations (attenuation, multipath, non-Gaussian noise, etc.).

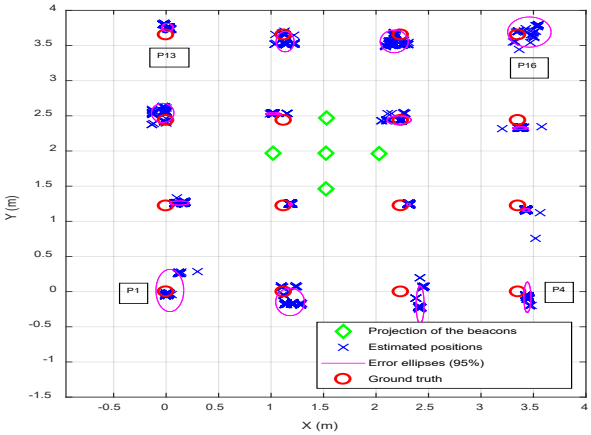

Fig. 30. Experimental test positions (red circles), estimated positions (blue crosses), and beacons' projections (green diamonds)

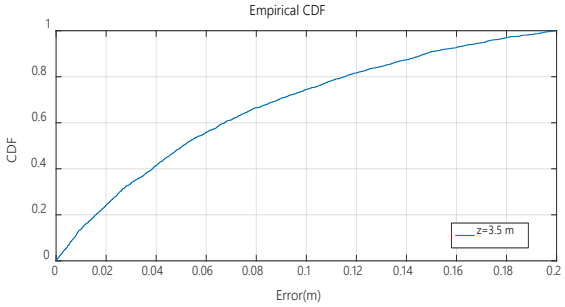

Fig. 31. Error CDF obtained by simulation for the X-Y plane (z=3.5m) using only one ULPS.

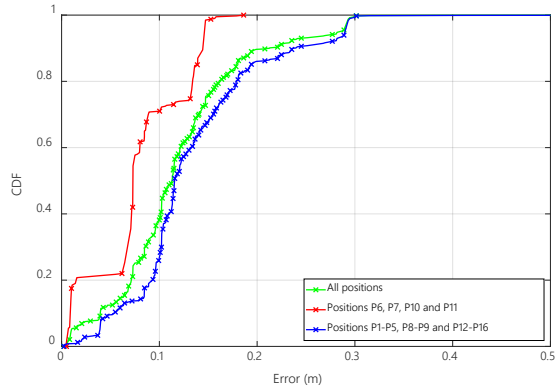

Fig. 32. Error CDF for the experimentally estimated positions in the X-Y plan (z=3.5m) using one ULPS.

Note that, according to the different CDFs in Fig. 32, the error is less than 20cm in the 90% of cases when considering all the test positions. This error is smaller (about 15cm) for those points just below the ULPS, whereas larger (in the range of 25cm) for the test positions that are far away from the ULPS' projection.

9. Discussion

When an ULPS is used in 2D, its final position can be fixed at the ceiling with all the beacons emitting downwards and the targets with receivers pointing upwards. In that case, the coverage area on the floor is a circle about 40m², assuming the ULPS is placed 3.5m high. For an extended 2D workspace, it is needed to add more ULPSs at the ceiling at different positions to cover a larger area on the floor. Anyway, these different ULPSs are always placed in the ceiling, they work independently and the obtained accuracy is similar for all the 2D floor positions considered.

Nevertheless, for a 3D positioning it is necessary to cover all the space and not only the floor surface. This is why a set of ULPSs must be placed at different positions and with different orientations (see Fig. 4) to cover all the space, thus having enough accuracy in all the volume of interest.

Two different configurations for 3D positioning in a cubical region of 8x8x8m^3 have been studied in this work. The first is the configuration A with three ULPSs pointing towards the centre of the cube and placed at the centres of the X-Y plane (z=0m), the Y-Z plane (x=0m), and the X-Z plane (y=8m). The second is the configuration B with four ULPSs pointing towards the centre of the cube and placed at corners (0m, 0m, 0m), (8m, 8m, 8m), (0m, 8m, 0m) and (8m, 0m, 8m).

Furthermore, two alternatives have been considered for each configuration:

- To have measurements from all the ULPSs simultaneously (with all the emitters synchronized). In this case, all the measured distances can be provided to the positioning algorithms.
- To have measurements independently for each ULPS (avoiding the need of synchronization among the different ULPSs). In this case, a position is estimated for every ULPS and afterwards all the results are merged.

The use of simultaneous measurements from different ULPSs is better in terms of the obtained accuracy, but it requires synchronization among ULPSs, as well as a wide receiver coverage that can be difficult in practical systems. On the other hand, with independent measurements for each ULPS, these issues can be avoided at the cost of reducing accuracy (that can still be enough for many applications).

10. Conclusions

The performance of a 3D ultrasonic positioning system (ULPS), firstly developed with a structure and characteristics for 2D positioning, has been studied and adapted to be deployed for 3D positioning. The study has covered the use of different ULPSs configurations, considering simultaneous or independent measurements. The comparison has been carried out and based on the estimation of the PDOP, by using a grid that covers all the space of interest (a cube of 8x8x8 m^3).

The achieved accuracy varies in the two cases analysed (case A and case B), depending on the number of ULPSs involved (1 to 4 ULPSs) and their positions/orientations (at the corners, in the ceiling, in walls....). Some preliminary experimental tests have also

shown the performance for a single ULPS. The positioning error is less than 20cm for the 90% of considered measurements. This centimetre accuracy is in accordance with other positioning systems based on ultrasounds as can be observed in [5], which also compares this technology with others also applied to this type of systems.

Acknowledgment

This work has been possible thanks to the Spanish Ministerio de Economía, Industria y Competitividad (TARSIUS, ref. TIN2015-71564-c4-1-R, and SOC-PLC, ref. TEC2015-64835-C3-2-R) and the University of Alcala (LOCATE-US, ref. CCG2016/EXP-078). Authors thank Dr. David Gualda for his support with experimental measurements.

ABSTRACT

In acronym Captology - Computers as Persuasive Technology, a persuasive component (lat. persuasibilibus - enticing) refers to the persuasive stimulation by intelligent technologies. Latter being transitive and interactive as intelligent systems, they have imposed, by their persuasivity, a 'cult of information', after which information has become a type of goods that as a utilitarian resource must be exploited quickly and efficiently. Such a widely accepted fact resulted as hype, presenting a perspective that the approach to a large amount of information and faster 'digestion' of their content will enable users to quickly get desired knowledge.

Recent investigations about persuasion processes have shown its dependence on intelligent technology factors (design, interactive computer products, web, desktop and others). Such technologies are also used to influence people's attitudes, beliefs, learning, and behaviour. Development strategies for global computer production and sales head in that direction and confirm latter statement with the promoted 3-P model: persuasive, permissive and pervasive components. Cognitive level of human integrated development is increasingly overshadowed by the contribution of artificial intelligence through its products, i.e. 'smart' creations, and by the array of shortcomings and problems that the same interactive technology brings. This paper presents a parallel between captological component of intelligent and interactive technologies on one side and illustrates examples of captological influences proved by confirmed trials within cognitive science through computer simulations of human thinking on the other side. Many studies have shown that the success of persuasion depends on the factors which have been exposed by cognitive cybernetics. Next to it, people's behavior system is transforming through the very development of society. Therefore, the influence of latter can be either positive or negative, while its extremes are already escalating in direction of a new trans-singularity and post humanism theories based on the principles of extropy.

1. Introduction

This article extends the work originally presented at 40th International Convention on Information and Communication Technology, Electronics and Microelectronics (MIPRO), Opatija, Croatia, May 2017, [1-4]. The presented paper confirmed how human mind development is being contributed by the 'smart' creations of intelligent technologies as artificial intelligence (AI) products. Researches have been devoted to methodological directions and developing concrete tools for self-analysis and synthesis, simultaneously providing exhaustive theories about human nature being experienced as a 'new philosophy', but also as an 'anti-philosophy', defined on a new scientific course called cognitive cybernetics.

Cognitive cybernetics is the expansion of the 'classical' cybernetics, which includes scientific comprehensions of cognitive control and regulation of artificially-technical and socio-technical systems, biological organisms, organizations, processes, structures etc. The cognitive aspect of all evaluated systems elaborates and applies cognitive models, cognitive-functional and procedural system implementation, problem-solving based on natural methods by analogue cognitive computer techniques and lastly, the realization of system solutions and their organization in the context of management approaches and methodologies. This work is based

on the cognitive development and implementation of ITK's (Ingenieurgesellschaft für Technische Kybernetik, Rülzheim, Germany) education modules in cooperation with National University of Vietnam, Hochschule Offenburg and Electrical Engineering Department at Zagreb University of Applied Sciences.

Cognitive Cybernetics recognize motivation as an internal state that excites, directs, and maintains the behavior of an individual. In education and training, motivation is especially important both for learning and for seeking the purpose and meaning. In academic activities or preferences, latter is described as meaningful and effort-worthy exertions, while tend to be realized and applied within importance of higher levels competences and skills. Those who are more motivated have a greater positive attitude on everything, and so on education; they persist longer in more difficult tasks, process information at a deeper level and excel in learning experiences. The classic distribution of motivation on intrinsic and extrinsic motivation in education is an incentive for activities which:

- represent the challenges of optimally assessed goals,
- can be controlled for goal achievement, which is emotionally fulfilling,
- establish the autonomy of action through the existence of feelings that can be controlled and have the effect on own development,
- encourage curiosity for the new, surprising experiences that increase the intrinsic motivation,
- include creativity and imagination where the motivation awareness is confirmed by imagination.

Approaches for defining motivation in education are:

- Behavioral approach in which understanding of motivation begins with a careful analysis of incentives and awards,
- Humanistic approach that emphasizes the understanding of the need for self-reliance through the stimulation of internal resources (sense of competence, self-esteem, and autonomy),
- The cognitivistic approach that accepts the fact peoples' activity and curiosity are inherent, and they seek information to solve relevant tasks.

An integrated approach for creation of education based on cognitive cybernetics foundation, considers:

- socio-cognitivistic focus on individual's behavior and potential interest for the impact on beliefs and expectations,
- the socio-cultural atmosphere created by participation in the community, in activities that maintain the identity of the community's interrelationships.

Therefore, motivation in the community is strengthened by the education to which it belongs and appreciates it. Specialist tutoring programs are the foundation for acquiring an expert status, where the very understanding of problem-solving is needed at that level, for which is necessary to gain the knowledge by understanding. Elementary forms of understanding are prescribed by the concept of objective mind or spirit, which guarantees the possibility of intersubjective communication at the basic level. 'Higher forms of understanding' occur when one internal difficulty or contradiction confronts with what is already known. It is then necessary to summon up and include the entire life structure, (establishing a relationship between life expression and its cognitive content), which can be found in its hermeneutical understanding, [5-8]. Research results show that understanding develops through information processing and modifies over a longer period. At a somewhat higher flexible cognitive level, it is possible to cognitively gain skills through which information is processed both intuitively and analytically. This knowledge, along with the persuasive context and information technology, closes the 'hermeneutic circle of artificial intelligence', Figure 1.

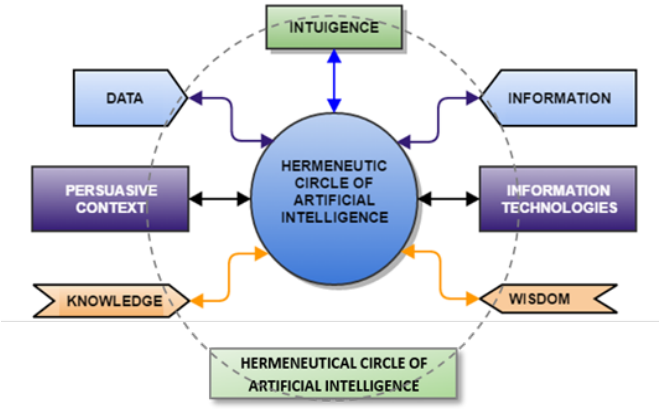

Figure 1 - Hermeneutical circle of artificial intelligence

2. Cognitive cybernetics – the future of education

Researches that deal with the captological components of intelligent and interactive technologies are confirmed by cognitive cybernetics through simulation examples of human thinking. Approaches to the study include analytical levels by evaluating the system almost in all technological branches and domains with the assumption of significant and dramatic advances in neuroscience, genomics, robotics, nanotechnology, computers and artificial intelligence with the help of other interdisciplinary studies, shown in Figure 2.

Studies and researches have further led to transhumanism extremes that advocates human body modification, including mental and psychological changes, all to control desires, mood and mental states. The everlasting fight against aging and illnesses is therefore not the only task of transhumanists, but also a try to improve the man at all levels, emphasizing simultaneous mental and physical advancements would be desirable.

If transhumanism associated with humanism is recognized as writing it as 'trans + humanism', then from the enlightened humanism comes the emphasis of a progress (its ability and desirability, not its inevitability), personal responsibility to create a better future and progress to a new society, but at the same time the awareness of accidents that can be caused by technology misuses in such society. For these reasons, it is necessary to differentiate the forms of meaning (i.e. primary and secondary), on which science assignments are based, and values that are recognized in the world, [9], addressed below in Figure 3.

Treatment by cognitive science has selected, among other things, certain factors of one's individual ability expectations to achieve desired goals and their value, respectively.

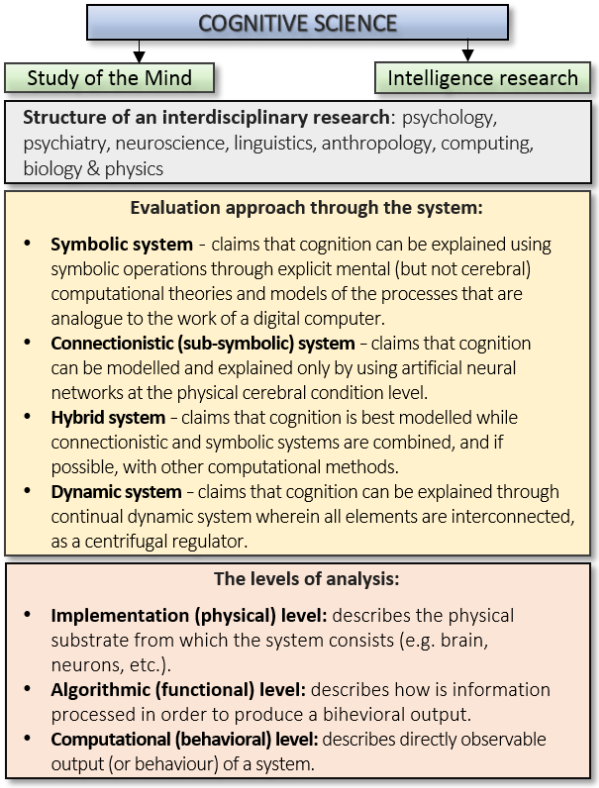

Figure 2 - Interdisciplinary study of the mind and intelligence through level analysis over the system

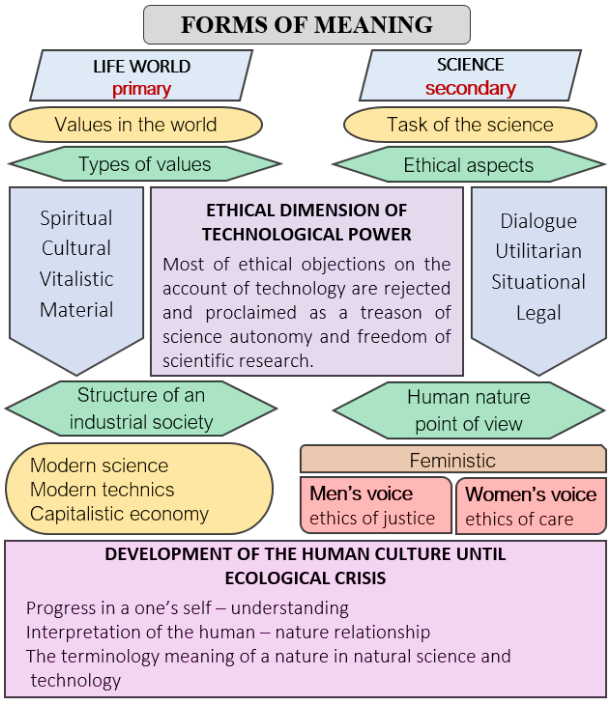

Figure 3 - Primary and secondary forms of meaning and ethical dimensions of technological power

Apart from this, it is accepted the fact that a man is a cognitive, reasonably-minded being, who accomplishes its own understanding at two levels. The first one is subjective level or the level of psychological participation, and the second is objective level or the level of intellectual participation. Hence, it is possible to conclude that hermeneutics is a universal theory of understanding in which no confusion is present because hermeneutic understanding is neither interpretation nor explanation. In this way, a differentiation between the objective understanding of the meaning on one side and subjective understanding of motives and intentions on the other side can be made. Theoretically, it is possible to attain adequate learning processes from the book, without producing any external signs of acceptance and application of such learned matter. The effects of learning efficiency, whose outcome must have been understanding, depend on many factors such as physical and biological states, prior knowledge, daily oscillations in the brain chemistry, peptide hormone levels, and ultimately – the captology. Therefore, in understanding the recognition of its either elementary or higher forms for the purpose of education system, it is important to point out the most important motivational variables, namely:

- needs,
- beliefs,
- goals as outcomes to be achieved,
- internal interest,
- emotions.

These variables are linked and processed through natural analogue systems, confirming the new concept in cognitive cybernetics – 'Brainware', [10].

2.1. Needs

Although there are many theories, all rely on the most famous one – the Maslow's hierarchy of needs that differentiates the needs of a lower order or the needs of lack - survival, security, affiliation, and self-esteem, and the needs of higher levels or the growth needs - intellectual success, aesthetic assessment, and self-realization. The latter needs can never be fully met, since when one desire is fulfilled, the other one immediately takes its place. Newer approaches to the motivation influenced by intelligent technologies focus on highlighting not only individual needs (a generated need to feel capability and competence), but also on interaction with the world, having the choice and feeling of controlling life, while at the same time on the challenge of connectedness through sustainability in the world. Such a theory, though seemingly presents the absurd paradigm because it reduces the basic human needs to autonomy, competence and connectivity, relies on the persuasion which is the second name for the captology present in cognitive cybernetics, Figure 4, [11].

2.2. Beliefs

Beliefs as a variable of cognitive cybernetic processing come down to the achievements of:

- knowledge,
- capabilities,
- causes and control,
- self - value.

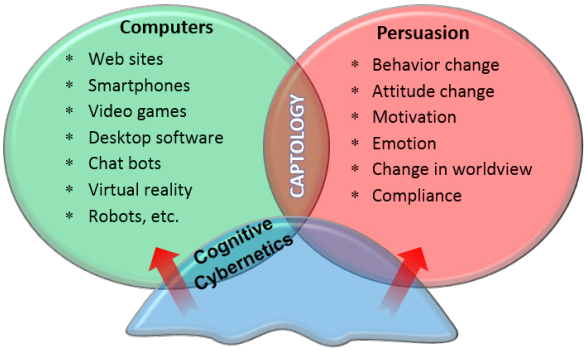

Figure 4 - The captology of cognitive cybernetics in computer persuasion, [11]

Knowledge beliefs are defined as beliefs about the structure, stability, and security of knowledge and as best ways of acquiring knowledge that influence learning strategies use.

Capability beliefs are one of the most powerful beliefs that affect motivation. There are two types of capability views: entity and incremental. The entity view refers to the belief that capability is a fixed characteristic and can not be changed. Although capabilities differ between individuals, their representation is potentially stable when acquired, but capability as a set of skills may change. By means of continuous work, learning and exercising, it is possible to increase one's knowledge and thus improve the capability.

Causes and control beliefs are based on attempt to understand the meaning of one's own and/or another peoples' behavior. This theory explains how individual explanations, justifications, and excuses about oneself and others affect motivation.

Self-value beliefs can be oriented to control or avoid failure. Orientation toward control seeks out the tendency of addressing value to achievement and the ability to set the attitude that achievement can be enhanced by targeting the goals. By mere control, one's own skills and abilities are being improved.

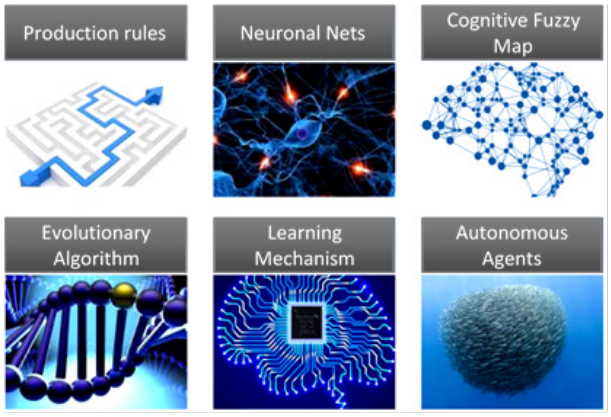

Figure 5 - Concept of cognitive solutions in environment, [11]

Orientation to avoid failure supports the entity's view of ability and sets further its goals related to performance. One can have a lack of strong ability sense and value separated from the performance, thus cognitive cybernetics serve as a simulation for technological and technical solutions (production rules, evolutionary algorithms, autonomous agents etc.), for the purpose of understanding and functioning of biological states (neural networks, learning mechanisms, cognitive fuzzy maps, etc.). In this way, mapped into education systems, strategies for avoiding failure are being worked out so they don't lead to a failure or to prevent the continuation of failure. Such strategies (shown in Figure 5) do not accept excuses or incapability, therefore the possibility to give up or accept a failure as a belief that problems arise due to low capabilities is not considered.

2.3. Goals

Goals are the outcomes or achievements to be attained and they enhance performance because they direct one's attention on the current tasks and divert from the distractors. Goals encourage devotion, for as the goal is as greater, such is the commitment. They increase perseverance, for when there is a clear goal, it is more difficult to give up. Furthermore, goals also encourage the development of new knowledge and strategies until they prove as successful ones.

Types of goals being set affect the extent of motivation that is needed to achieve them. Aims that are specific, moderately tough and likely to be achieved soon, often increase motivation and persistence. Just as goals, there are target orientations related to belief patterns about goals, also associated with achievements. Goals differ from the type of control, performing, avoiding the effort and social goals that need to be recognized for motivation.

The concept of cognitive solutions that today's civilizational environment treats as an agent systems by cognitive coverage of processes and programs, integrates human factors and machines (technologies) as inspirational cognitive goals, Figure 6.

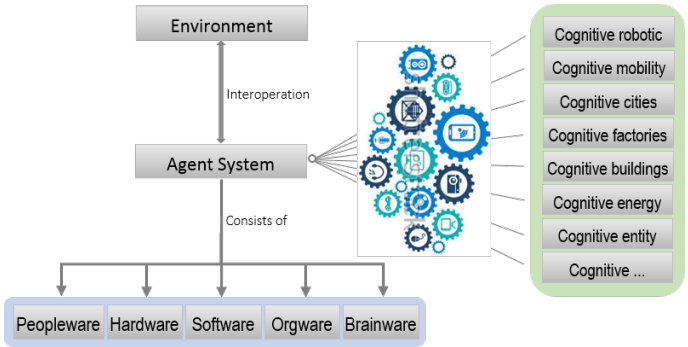

Figure 6 - Concept of environment cognitive solution set as cognitive goals, [11]

2.4. Internal interest

There are two kinds of interest: personal and situational. Personal interests relate to more persistent personal aspects, such as a long-term preference for the particular subject, while situational interests relate to short-term aspects of activity, such as a text or material that attract and retains attention. Interest in the education grows with a sense of competence, even if initially there was no interest in a certain activity. Cognitive industry, by

its evolution, is an inexhaustible source of interests, and as such through modern civilization imposing itself as a leading variable. Within cognitive cybernetics processing and understanding, interest is related to entities (synonym for the subject, article, individual, being, form of life, body, creature, organism etc.), which in ontological terms is connected with different and independent existence plus applicability, and is profiled as a cognitive entity platforms, entity ecosystems, browsers, entities, services, service portals, interoperability servers, maintenance portals, integrated server, entity application as a tool, etc., Figure 7.

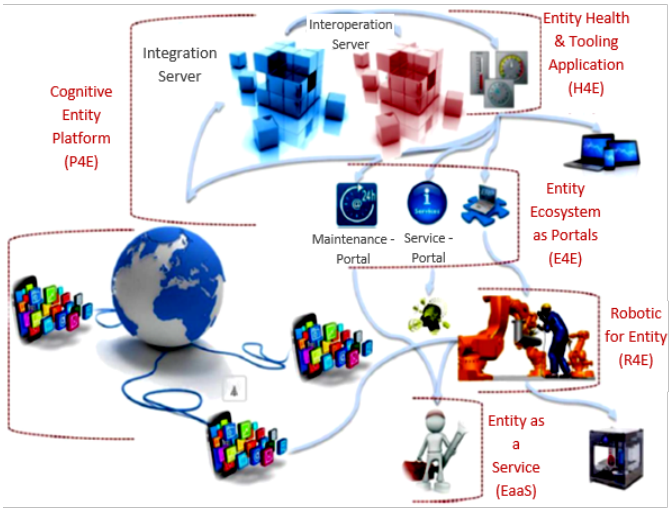

Figure 7 - Platforms of creating cognitive solutions as goal variables, [11]

2.5. Emotions

Emotions, especially pleasant ones, have very positive effects on ability beliefs (accepting an incremental view of ability), target orientation (associated with learning objectives), self-regulation, information processing (emotions are encoded with information), etc. Positive emotions encourage positive thoughts and memories, along with evaluation of education, hence such a positive effect is adequately treated for evaluation and performance of education based on the concepts of a system cognitive modelling.

In the beginning of education, emotions are very important, especially when it comes to the feelings of excitement, pleasure, fun, and curiosity, because these emotions can trigger a situational interest. It is only necessary to control them in order to prevent exaggerating effects which can lead to negative emotions, having a somewhat more complex relationship with motivation.

Additional stimulus to emotional motivation is the over-occupancy that refers to an intense form of intrinsic motivation in which an individual is in a state of profound insight, concentration and focus on the challenging activity. The experience of occupancy depends on autonomy. Intrinsic emotional motivation was often experienced in activities that were chosen willingly rather than imposed by others. Therefore, competence (skills and techniques) is so trained that it becomes automatic and is responsible for the optimal challenge (the optimal ratio of challenges and skills), creating a special emotional concentration that is not obscured with time and space.

3. Cognitive cybernetics in mystical artificial intelligence implosion

When artificial intelligence emerged in such terminology in the middle of the last century, it was the fastest growing scientific discipline. At the beginning of this century it started to be mystically missing in implosion, which can be attributed to a certain transformation. Development of artificial intelligence encompasses four periods of time, [10]:

- The period of enthusiasm and great expectations (1952 - 1969),
- The Age of Cognitive Reality (1966 - 1973),
- Knowledge-based Systems (1969-1979),
- The period of applicability (it begins in 1980s and continues as a process to date).

The fourth period is a process that goes through its five stages of transformation:

- The first stage is application of artificial intelligence in industry, from 1980s,
- The second stage is a transformation through neural networks, introduced in 1986,
- The third stage of transformation has placed artificial intelligence in the science, and is accepted since 1987,
- The fourth stage of transformation introduced super-intelligent agents, in 1990s,
- The fifth stage of transformation is the mystical implosion of artificial intelligence that is still ongoing.

Mysticism in this matter is trying to point out that implosion is a way in which artificial intelligence disappeared within itself, and at the same time in some certain connectedness, cognitive cybernetics emerges. In that mysticism lies the impossibility of terminological discernment and a clear access to technological level called 'Industry 4.0', as well as transition and emergence of the new era of 'Evolution Industry - Industry X.X.', in which cognitive cybernetics has been already implemented. Therefore, regarding such a rapid pace, it can be concluded this already 'is' the future so widely present as a subject of discussions.

Today, this future is also called the 'Society 5.0', (germ. 'Gesellschaft 5.0'). The Idea of Society 5.0. was launched from the 'Fifth Scientific and Technological Fundamental Development Plans' in Japan by the end of 2015. The idea is to bring digitalization closer to all segments of society through the creation of a so-called 'super-smart society', whose core is the social impact of technology and which is focused on cognitive cyber-products. Production processes and production itself of these cyber-products are created by developed and self-regulated autonomous cycles, partly realized through the very products.

Toward adoption of the Society 5.0 strategy, on CeBIT meeting in Hannover, 25th of January, 2017, the Japanese Prime Minister (presented Japan as the partner country) and the German chancellor agreed about opinions that although the market

prerequisites for further development brought by technology such as open borders, democratic values and a free trade, they stated: '*Millions of people do not know what to expect from the upcoming changes, and those who should change the policy and the digital sector in Europe which relies on cognitive cybernetics are often slow in key decisions*'.

3.1. Transformation approaches of cognitive cybernetics

The mystical disappearance of artificial intelligence presented above and characterized as an implosion, further shows that the emergence of cognitive cybernetics can be studied through three approaches to that transformation, as addressed below.

A. Anthropological approach

The anthropological approach of artificial intelligence into cognitive cybernetics transformation relies on the study of a human species development (life and culture), which looks at the presence and future of the human race, and links:

- nature and culture,
- past and present,
- the uniqueness of the human race through diversity of its forms.

The relationship between nature (biology) and culture defines the development of human species through cortex specialization, which enables understanding, communication, and learning. Thusly created (learned) content is called culture. As a fundamental concept of anthropology, culture is a set of behaviors that people learn and share in a given period and in a chosen natural and social environment.

The relationship between past and present although in the evolutionary sense compared to other beings follows the same natural rules, enriches people with extraordinary ability to learn and pass on the knowledge from generation to generation. This approach has accelerated the cultural evolution which has become faster than the biological evolution. In this sense, profound differences are being outlined, not only in terms of anatomy and physiology, but also in terms of the very habits so different that the essential unity of the human race is not seen anymore, and therefore the potential for innovation is harder to be recognized.

The uniqueness of human race through diversity of its forms is a consequence of the lifestyle difference not only in different times and areas, but also within the same society due to regional specialties based on the economy and different living conditions as entities. Within the same area, differences exist in the way of certain communities' lifestyle, not only immigrants' ones, but also among the sexes, ethnic, age and class groups. Responses about purposefulness inquiries given from anthropology are used to understand, create and inspire cognitive cybernetics.

B. Ontological approach

Ontological approach to the concept of cognitive cybernetics relies on strictly traditional philosophical discipline as the central branch of metaphysics that studies the being, if it is a being, as such. Modern analytical ontology is, above all, the theory of general categories such as object, attribute, event, etc. Ontology is a study of nature of the things we find in our environment, around the world, and what relationships are among them. In addition, it is related to existence, objective property of things, space, time, causality, and opportunities that result from all of this. Since cybernetics within science explains the general principles of the process management, regulation, obtaining, storing, transforming and transmitting information, both in living beings and in technical systems, therefore as a scientific discipline explores a dynamic self-regulating and self-organizing systems, while through ontologic patterns also defines system properties. In this way, accessibility is recognized in environment and by means, changes as responses within. Activity as operation is directed towards achieving the goal through takeover of the initiative. Socialization that works together with other systems and people to achieve goals also helps others in achieving theirs. Furthermore, mobility opens the possibility of acting in any environment and lastly, a learning ability based on understanding human intelligence and communicating with machines ensures exceptional availability.

Ontological approach enables expansion and connection with boundary theory areas of a system, management, information, coding, logic, formal languages and grammar, games, mathematical algorithms and programming, and robotics, which include all four existing types of cybernetics:

- Theoretical or general cybernetics,
- Applied or applicable cybernetics,
- Technical / technological cybernetics,
- Economic cybernetics.

Their most important features are the features of the system:

- a great complexity,
- stochasticity and
- auto-regulation.

Recognizing these cybernetic characteristics and features enables ontological observation through its theoretical, technical and economic views.

Theoretical point of view represents the logical structure of hypotheses, knowledge, discoveries, scientific facts, theories and laws. It involves observing, collecting, measuring and rendering data, and lastly, data experimentation, for ensuring optimal conditions under which data, information and knowledge can be obtained. The economic or organizational standpoint provides rational technology intended for further research in all essential elements.

C. Captological approach

The captological approach to cognitive cybernetics includes the cognitive character of persuasive technologies and as a superior scientific field introduces expansion limes on ethical principles. This approach to cognitive cybernetics through its purposefulness in industrial ecology, an emerging scientific interdisciplinary field, unites its development by combining natural, technical and social sciences into a unique system from

global to local level. Foundation of this concept is a cognitive captological integration based on analogy between intelligent technologies, processes in nature (biosphere) and processes in society (technosphere), Figure 8.

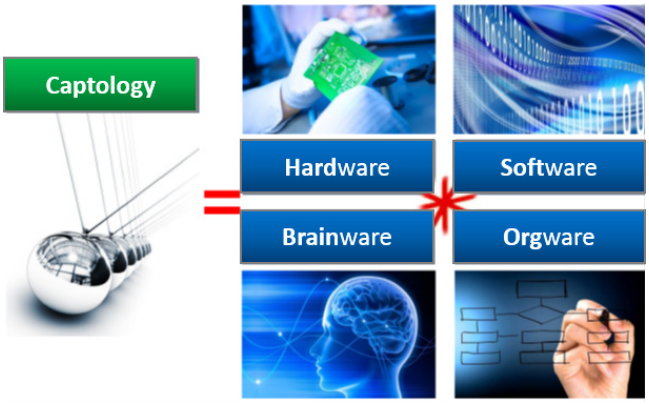

Figure 8 - Captology as a threat to innovation's access and openness

The biosphere, with its laws and principles, refers to coniferous life around the planet, summed up in earthly life as a whole in which all transformations take place. Technosphere is an artificial sphere of all kinds of technology around the planet (all technical and technological aids, creations and systems), with its own artificial time functions in which everything is immersed. Today, the ultimate development and application of intelligent technologies is experienced as a planetary intelligence system made by the Internet, mobile communications, applications and virtual structures of technological simulations. Cognitive cybernetics might enable the creation of awareness of innovations that will drive evolution of life on Earth only in a mental and spiritual direction, [12-15].

3.2. The role of human factors in cognitive cybernetics

Cognitive cybernetics has advanced to such a degree that it can do all the imaginable management and monitoring in a hardware sense. For its efficient application, education is needed to acquire special skills, knowledge and competences required for unerring behavior of decision-makers in approaches to accept innovations and consider scrupulosity. Herein come invaluable characteristics of the ability to use a 'common sense':

- Expressive abstraction and conceptual analysis for quick and successful problem solving in unexpected situations
- Unlimited flexibility.

Certain problems can be identified through persuasion perfidy in the context of treatment and understanding data and information. Research has confirmed that 'third-party tools for experiments on users from database software algorithms evaluate and rank all information accessed through the network - currently 95% for which an average educated user reaches!? Thus, it is not surprising fact that over 300 trials and about 200 signals are continually being run on a daily basis, watched and measured to help maintain 'freshness' and the speed of collection, securing, and transferring data. Although scarcely mentioned, but shows persuasion as useful, the captological arsenal is revealed as:

- Cognitive prejudices, (between more than 170 cognitive prejudices emphasize the 'unwillingness of taking risk in time deficit', and which has been led by persuasive message),
- The weapon of persuasion (this is about persuasive techniques that rely on the 'principle of scarcity' and the 'theory of authority acceptance'),
- Productivity laziness (confirmed by the fact of human mind laziness and the tendency to skip or careless reading which, due to the persuasive guidance, results in unwanted consequences),
- Decision-making fatigue, (associated with the user exhaustion by persuasive over-offerings that encourage the use of lower resistance paths).

The brain capacity for learning is enormous and created for more demanding intellectual activities than the ones commonly included into. The human brain possesses two mutually independent systems of receiving and thinking. The leading one is in the left half of the brain and it analyses, writes, reads, talks and receives logically. The main center for feelings in the right half of the brain is more complete, emotional and associative, or better said - intuitive. Selected activities of the left and right hemispheres of the brain help to its learning by the pairs model (challenges and feedbacks).

The right side of the brain is used for intuitive handling of problems based on two components:

- Simple provisional rules that exploit the proviso to hit the most important information but ignore everything else, hence allowing a quick reaction,
- Predispositions of evolved brain abilities - skills acquired by genetics and learning to transform predisposition into the ability.

As the human mind develops regarding to inexhaustible desire to try and change, not just by wanting to always follow only 'reliable' answers, the question is whether the brain can be stimulated to develop when captologies is not new but uniform, deadening situations.

3.3. Conducted trials

In addition to aforementioned persuasive addictions, the results of 'tests/exercises' can be joined from originally elaborated materials of the course Intelligent systems, conducted at the Zagreb University of Applied Sciences, Electrical Department. It is basically about mechanisms and elements of conclusion through knowledge bases and databases of an expert system. Conclusion is gained by applying acquired knowledge about distributed artificial intelligence in correlation with human intelligence and social predisposition. The task is precisely described by instructions each student receives in the envelope, and before starting, teacher reads the instructions aloud before all

students at the initial location of the exercise. The task is shared to two groups of students who, after receiving the instructions, go at two different locations. Students have drawn attention for having the opportunity to cooperate with each other, which is the goal of exercise, at last. There are five simple questions needed to be answered in manner that all students participate and create common, identical answers. The guideline text is divided into three parts (task description, approach to solving and solution guidelines). Conducting this exercise within four educational periods in three academic years, 148 students participated, and the task was successfully solved not even once.

The reason why such a simple task has not yet been solved lies in the hyper-offer of data (information). Students are mostly taught that use of information technology encourages rapid data inspection. By doing such, reading of the task is reduced to mere browsing and is very superficial, which makes easier overlook of the solving approach. Too much data drives away from deeper and more permanent entry into any single argument, fact or idea. An overwhelming number of information and characters nullify themselves. Students are apt to access the search by going to links (connections) irrelevant to problem solving, but seemingly interesting information is the very beginning of current potential termination of available concentration. This outwardly produces impatience, a lack of attention and the absence of co-operation, respectively. As in reviews and surveys of a vast data, users are prompted to quickly come and go; the same effect was achieved through the lumped text of this task. In this journey of a rapid collection and data transfer, the cognitive efficiency is lost, unfortunately. A lot of confusing information and attention-shifting parameters fragment, hinder and distort the flow of thoughts that end up as distraction. The use of mind is under influence of intelligent technology and therefore under the pressure. Part of the human mind in charge for critical thinking, analysis of reality and which should be used daily as a way of thinking in solving problems, but also in social interactions when it serves to connect with the outside world, doesn't come to the expression in this task, and there was no created understanding – mind is lost in captology for it does not follow the evaluation sequence.

A. An example of understanding when meeting other people

As an example of understanding, a study was conducted related to learning of understanding when meeting other people, already discovered by William Outhwaite, who had been looking at such situations through four categories:

1. The category of physical facts that can be noticed (how people look and what is the consequence of that). These are understandable phenomena in relevant sense, when being seen as a sign of something not physical from the past or something related to the mental state.
2. The category of mind states in others that can be identified now or can be inferred based on the previous comprehension.
3. The category of others' actions (by noticing what others do and what they consider to be doing) is described with three sub-categories:
   a) Recognizing an action by approaching from distance,
   b) Accepting of what is being said about on the same elemental level,
   c) Complex judgment of the real importance of what is being done or what is thought to be said;
4. The category of questions why certain things are being done, and what motivates people to do them.

Latter categories try to establish a difference (especially between the states of third and fourth category), or the differences between motives and the 'hermeneutic understanding'. Psychological understanding of the human mind mental states can be observed based on three conclusions about peoples' motives and their intentions, which are the following: a) visible signs, b) explicit statements, and c) knowledge of the 'situational facts', confirmed by the psychology of the situation that has been discussed since Aristotle, Figure 9. From the aforementioned examples a complexity of the understanding comprehension can be seen, which is theoretically evaluated; and people have a social process of meeting embedded in a sub-conscious algorithm operable in real-time.

B. An example of learning understanding while reading aloud

To confirm the conducted research, it is useful to consider the acquisition of understanding on research example of literacy development. Therein, it comes to conclusion that the central process of learning by reading is understanding the text and active search of meaning and purpose, as established by G. J. Whitehurst and C. J. Lonigan. The reading process or understanding what was read comes down to understanding of coding and decoding, like digital data transmission. This also presents the concept of an expert system functioning, which was followed herein for explanation and elaboration.

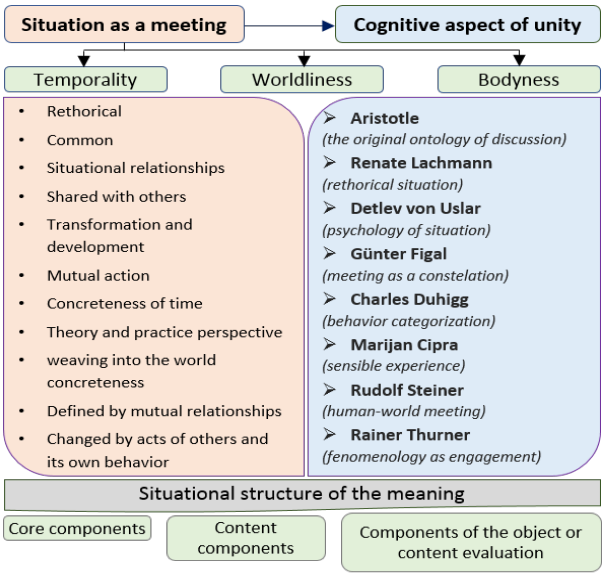

Figure 9 - Analysis of the situation psychology as a situational structure of significance

Researches on reading effects has set the groundwork for reading mechanisms evaluation, which are:

- a comparison,
- a recall from the memory,
- linking what is seen or heard, (or heard before),
- identifying essential data and rejection of redundant ones.

On these grounds, data processing while reading developed by R. J. Marzano and D. E. Paynter happens simultaneously with five concurrent processes, known as a 'Model of 5 babushkas', Figure 10, which comprises:

- Understanding the purpose of reading,
- Estimating the compliance of read data with the purpose,
- The meaning of the smallest thinking units (claims),
- Identifying the meaning of words,
- Recognizing the meaning of a read wholeness.

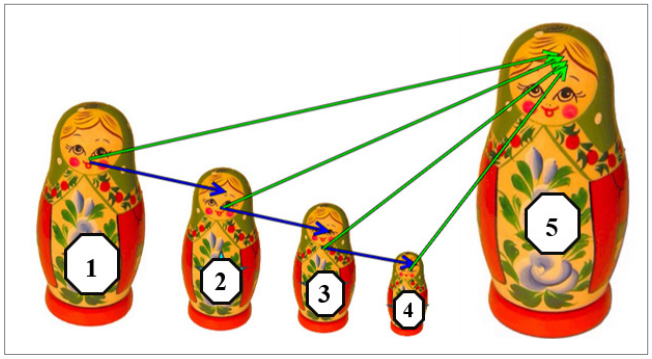

Figure 10 - Data processing while reading, (the model of 5 babushkas)

Reading, listening, watching and pronouncing are the ways of learning and each has a different contribution to learned matter. In accordance with learning mode, the left and right hemisphere along with emotional center of the brain are activated. Understanding the reading comprehension (reading aloud) is an understanding strategy that along with understanding, implies the voice sensitivity and motivation development. The above-mentioned examples, especially data processing while reading, is an important foundation for analyzing different types of reading, such as:

- mature reading,
- reading a linear text - a printed book,
- reading a linear text - e-book,
- reading by text search – a computer,
- reading hypertext – a computer,

and where reading should be distinguished from a mere search, under the influence of captology and turned into an addictive need, because it maintains a worthless dominance over digital information flow. The imposed 'Internet ethics' through different kinds of media results in persuasive addiction manifested by:

- encouraging and treating a 'thirst' for small and short-term information slots,
- curious dependence on a continuous data stream updated in the real-time; an 'updated status' which lost its purpose slightly after a few moments of release, and
- the desire to speed up the flow of information.

Aforementioned manifestations hold not any contribution to storage of learned, because nothing has been learned. Moreover, a disturbance has occurred, and no recognized brain cell nor emotional center has been activated, which today can be safely confirmed by psychometric investigations for more serious (i.e. legislative) use, still deliberately delayed, while minor trials so needed have not yet been clearly recognized and are ongoing through new researches.

C. An example of a thought material storage

In support of the researches conducted, there is also an example of storing thought material in the memory, which requires a careful and balanced information flow. An example can be visualized for the practical acceptance. It is easily possible by photography, Figure 11, to identify a chair (or chairs) that represents a thought material which can be carefully and permanently stored in a visualized mental space.

Figure 11 - The HAZU[1] revival hall, Opatička 18, Zagreb - an example with a careful and balanced storage of thought material

An example of a mess explains a fragmented, disturbed, and a ruined flow of thoughts that end up as a distraction. Hardly anyone will be able from the photos, (Figure 12 and Figure 13), to recognize the thought material at the glance, the 'seat', which should be stored in the permanent memory. Careful and balanced storing of thought material in a chaos is impossible, because from a visualized matter a particular psycho-culture is participated, lately projected in all spheres of life.

The term 'psycho-culture' comes from the culture (lat. *colere* - cultivate, nourish, *cultos* - processing, nourishing, cultivating), which represents an integrated system of attitudes, beliefs and behavior patterns characteristic for the members of society and which are not a result of biological heritage, but a social product created, transmitted and maintained through communication and

learning. The function and meaning of the culture are facilitation, extension and development of the human society.

Figure 12 - The courtyard of the house, Trešnjevka in Zagreb - an example of thought material storing represented by mess and chaos

Figure 13 - The environment of the building, Hrgovići settlement, Trešnjevka in Zagreb - an example of thought material storing represented by mess and chaos

Culture arises from the peoples' need to master the nature and to be free from animalistic life, so that man does not cultivate only external nature but also his own, thus achieving the process of humanization. Under various influences and so under the influence of intelligent technologies, culture is subjective to collective programming of the mind by which members of one community differ from others. Psycho-culture associated with Cicero's cultivation of the soul from ancient times (lat. *cultura anima*), I. Kant evolves and develops it through his 'categorical imperative' as a noble trait, but also recognizes the formation of a collective mentality in society achieved by a dominant ideology and which directs social and political processes. Each person has its own ideology, a system of values and life orientations that direct through life and determine the behavior influenced by intelligent technologies and intuigence (intuition + intelligence), [16-23]. Socio-cultural neuroscience provides better and better insights into complex interactions between socio-cultural and neuronal structures and processes, and thus within biological mechanisms that underpin socio-cultural phenomena and human behavior including all components of Kierkegaard's existentialism.

For these reasons it is useful to point out that the structure of neural network, part of the big brain cortex, represents the biological basis of our mental abilities. In adulthood, new knowledge and skills are easily adopted without changing the structure of the neural network. On the other side, educational, psychological, social and emotional environments during such development change the very structure of the neural network, especially in the brain parts crucial to adopt the most complex brain functions. This includes the affective modulation of emotional expression, the conceptualization of one's own mind, mentalization, cognitive flexibility and a work memory.

4. Continuation of research

The continuation of researches presented in the paper is based on the prepared teaching material, [24-28]. In the new education period part of the Intelligent Systems program is transformed into a new area, [29-34]. This new area will be presented at the 1st International Conference on Intelligent Human Systems Integration: Integrating People and Intelligent Systems (iHSI 2018), which will be held at the JW Marriott Marquis in Dubai, United Arab Emirates, January 7-9th, 2018.

Authors in their work have come up with recognizing:

I. Human Intelligence Systems, (HIS) - at the very beginning of the 1980s, researches in the field of artificial intelligence was focused on systems associated with human intelligence. Their goal was to incorporate the principles of human intelligence into intelligent platforms for data processing through artificial intelligent systems, which in turn resulted and actively contributed to the industry development and advancement of society, such as:
   a) advanced development and use of mechanical systems and devices in industrial production as intelligent autonomous robots,
   b) the introduction of humanoids into the social and palliative spheres of life.

II. Intelligent Human Systems, (IHS) - researches continued in the 1990s, conducted on already developed intelligent systems foundation with the intent of implementation in education, had included among others:
   a) developing and upgrading intelligent interactive technologies for use in systems with algorithms involving the principles of human thinking,
   b) scientific analysis of social activities and human intelligence through mathematical modelling, scientific brain research and cognitive sciences in general.

Such intelligent systems contain the knowledge of certain domains with sophisticated decision-making processes and the ability to explain their behavior. This feature shows the most important aspect of such systems - their ability to effectively interact with people in social environment, teaching, and assisting in availability and complex data manipulation. Furthermore, their use has resulted as a significant impact on human resources with the effect of increased demand for education, [35-40]. Knowledge (when considering Human Intelligence Systems / Intelligent

Human Systems) on the moral plane is designed to achieve what is achieved physiologically by asking the following questions:

1. How does consciousness, starting from the physical plane, finally reach the moral one?
2. How is physical balance a first step towards moral balance?
3. How is every controlled act the path towards improvement?
4. How are the rules of control also the rules of training?
5. How there is no discussion without calmness?
6. How does raising a will as a freedom and reasonable energy give man the freedom, right and task to choose between good and evil?

Although there are some suggestions today, it is more probable that in the near future answers to above questions need to be considered taking into account the parameters listed in Table 1, [41-45].

Table 1 - Parameters of the future considerations and justifications of Human Intelligence Systems / Intelligent Human Systems areas

Genetic neo-construction	Transhumanism	Ultra-Intelligence
Genetic Technology	Singularity	Super-Intelligence
	Extropy	
Biotechnics	Cyberpunk	Historical apokatastasis
Bionics		
Bioethics	Posthumanism	Human-biological planning
Biopolitics	The epoch of hypermodern	Spiritual programming
Bioconservatism	Nanotechnology	

5. Conclusion

Education for acquiring knowledge, skills and competencies will experience drastic changes in the near future because it will have to rely on cognitive cybernetics. In this paper, the results of research are presented as elaborated concepts of internationally recognized ITK institutions that launch new education programs with their partners. The Electrotechnical Department of Zagreb University of Applied Sciences is one of the partners since proven by its approach to educational standards formation and study programs alignment in polytechnic areas with the needs (existing and future) of the labor market, all in the context of globalization and technological development. Regarding to changes of higher education environment and the needs of labor market, it is necessary, as soon as possible, to harmonize them with the principles of cognitive cybernetics. This alignment must necessarily improve latter with introduction of new cognitive education modules because such activity of educational content should be a research for which human factors are at the same level of perfection and reliability as the available cognitive cyber-technology.

When information processing, problem-solving and decision-making are compared with expert system that contains human cognition and mental potential, it is possible to pull a parallel with intuition and intelligence.

The knowledge base is 'cognitively' dependent, associated with symbolic representation, and is identical to intelligence. Applying databases and knowledge bases, it would be useful to subject it to conclusion mechanism. This in biological sense of identifying with the human brain functioning (the way of thinking) suggests that purposeful use of intuition and intelligence require some sort of a skilled strategy – the intuigence, which has been confirmed by outputs of detailed researches carried out from 2008 to date, and which are presented in this paper.

When the education, psychological, social and emotional environment are linked to the presence and intimacy of intelligent systems and interactive technologies, the hypothesis of their multiple influences is confirmed; in a positive sense – through the knowledge of raising the level of integrated human mind development, and the negative one – the influence on people through neuropsychiatric disorders development. Biomedical and sociologically important concept is one of the main subjects of continuous discussion between advocates of selective theory against advocates of constructive theory of mental processing. Nowadays, the question about how to use the mind and intelligent technologies seems to be the same one. As one part of the human mind is in charge for critical thinking and reality analysis, it is used for problem solving but also in social interactions when it serves to connect with outside world. The second part of the mind is used for imagination and can only be triggered when the analytical opinion is excluded. The notion that imagination and analytical thinking are not treated as two opposing forms of thinking, but as two kinds of opinions with different functions, is the result of intelligent technologies impacts, for which human intelligence should set some directions and advices. For these reasons the question is set: does between cognitive cybernetics and captology exist a cooperation or the conflict?

Electrical Characterization

ABSTRACT

Through-Silicon-Vias (TSVs) are utilized for high density 3D integration, which induce crosstalk problems and impact signal integrity. This paper focuses on TSV crosstalk characterization in 3D integrated circuits, where several TSV physical and environmental configurations are investigated. In particular, this work shows a detailed study on the influence of signal-ground TSV locations, distances and their structural configurations on crosstalk. Embedded 3D testing circuits are also presented to evaluate the coupling effects between adjacent TSVs such as crosstalk induced delay and glitches for different crosstalk modes. Additionally, A 3D parallel Ring Oscillators testing structure is proposed to provide crosstalk strength coupling indicator between adjacent TSVs. Simulation results are conducted using a 3D electromagnetic field solver (HFSS) from Ansoft Corporation and a Spice-like simulator (ADS) from Keysight Technologies Corporation based on MIT 0.15µm 3DFDSOI process technology.

1. Introduction

3D Interconnect is the promising technology [1]-[4], which includes Through-Silicon-Vias (TSVs) to connect vertically stacked semiconductor chips with shortest paths, which means lowest inductance and conduction loss, to both signals and power supplies. In spite of these benefits, the signal integrity issues in TSVs become the major challenges in 3D designs [5-6]. The goal of TSVs or 3D Vias development is to acquire high chip density. Therefore, the density of the 3D Vias is also high. In this environment, a crosstalk problem appears between two adjacent signal 3D Vias (Aggressor and Victim). Studies show that the coupling problem is not negligible in TSVs because of the relatively large diameter and small pitch, which results in non-negligible TSV-to-TSV coupling that degrades significantly the 3D circuit performance. Hence, it becomes very essential to precisely model and evaluate the electrical characteristics of TSVs [7]-[9] to analyze signal integrity (SI), and crosstalk of adjacent TSVs under the conditions of various structures and configurations.

*Corresponding Author: Shadi MS. Harb, Intel Corporation, Hillsboro, OR 97124, USA | Email: shadiharb@ieee.org

In this paper, the electrical characteristics of 3D interconnect, based on our previous work [10], is presented to characterize signal integrity effects of 3D crosstalk for different TSVs placement and configurations. 3D Vias based on 0.15 µm 3DFDSOI process from MIT Lincoln lab [11] are used as a device under test (DUT) for crosstalk characterization where a 3D full wave simulator such as HFSS from Ansoft Corporation is used to extract and predict the electrical characteristics of TSVs in the frequency domain (S-Parameters) and a Spice-like simulator such as ADS from KEYSIGHT technologies to evaluate the TSVs transient response in the time domain (Eye-diagram). Additionally, embedded 3D testing applications are proposed to characterize the TSV's signal integrity effects and the impact of TSVs on the 3D circuit performance after fabrication. A 3D circuit test is presented to evaluate the coupling effects between adjacent TSVs such as induced-delay and glitches [12-13] for different crosstalk modes. Additionally, a consecutive triggered parallel Ring Oscillators (ROs) testing structure is proposed to provide a crosstalk coupling indicator between adjacent TSVs.

The paper is organized as follows: section 2 discusses the 3D Full wave modeling for TSV and the simulation setup. A detailed study of crosstalk for different physical and environmental TSVs configurations is given in Section 3. 3D Crosstalk embedded

testing applications are given in Section 4. Section 5 concludes the paper.

2. A 3D Full Wave Modeling for TSVs

In order to evaluate the electrical characteristics of a TSV depending on structural parameters such Via pitch, Via height, and Via size, the 3D interconnect based on MIT 0.15µm 3DFDSOI technology is used as DUT to model and characterize crosstalk in different testing configurations. The vertical connection in this technology is slightly different from the standard Through-Silicon-Via (TSV), which is a square shape via made from Tungsten material and fully surrounded by oxide; thus, it is simply called a 3D Via. The 3D Via pitch is around 3.325 µm (distance between the centers of two 3D Vias), 7.34 µm TSV height, 1.25 µm x 1.25 µm TSV size. The physical size of 3D Via after fabrication is estimated to be around 2 µm for the top dimension and 1 µm for the bottom dimension. The 3D Via was simulated using a 3D full wave simulator (HFSS from Ansoft Corporation), which generates the S-Parameters of the structural model of the Via and a Spice type simulator (ADS from Keysight Corporation) to predict the electrical characteristics of 3D Vias in the time domain (Eye-diagram). Figure 1 presents a pair of TSVs structure using the HFSS simulator.

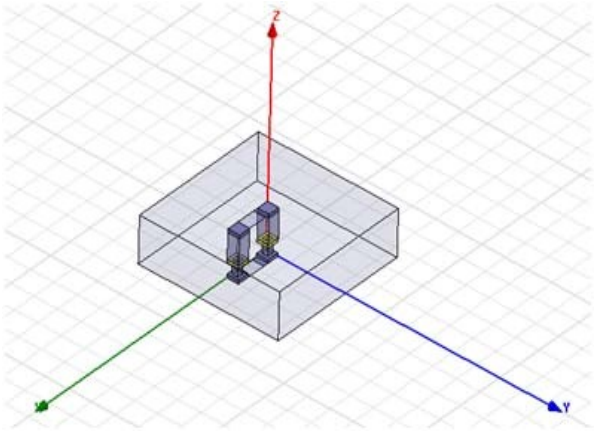

Figure 1. Physical Structure of a pair of TSVs using 3D full wave simulator

Usually, an interconnection line is characterized using S-Parameters. S11 and S21 are the S-parameters reflection and transmission coefficients respectively, which are typical characteristics of an interconnection. The evaluated S11 and S21 magnitudes for the electrical characteristics of a 3D Via based on the default parameters are shown in Figure 2.

The transmitted data stream through the 3D Via was simulated with the evaluated S-parameters from the 3D full wave simulator (HFSS). The Eye-diagram of the transmitted data stream was evaluated for 10^7-1 pseudo random bits sequence (PRBS) using the Spice type circuit simulator (ADS). The source for the simulation has 1.5 Vp-p and 50Ω source termination. The 3D Via is terminated by a shunt connected 50 Ω resistor and 1pF capacitor. The Eye-diagrams of 2 Gbps, and 10 Gbps PRBSs are shown in Figure 3. Also, all PRBSs were assumed that they have 10% rising and falling times

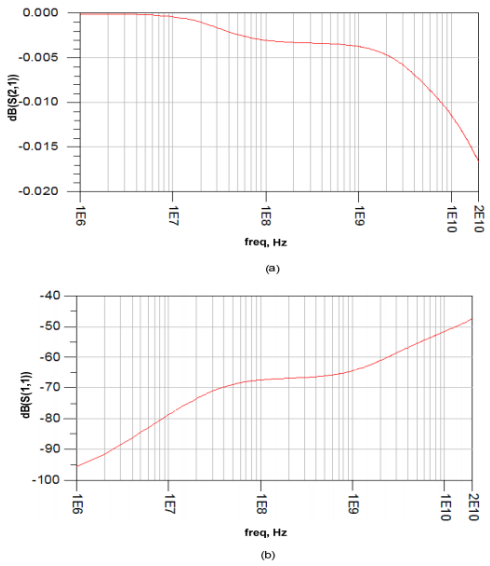

Figure 2. Evaluated S21 magnitude (a) and S11 magnitude (b) of 3D via using HFSS

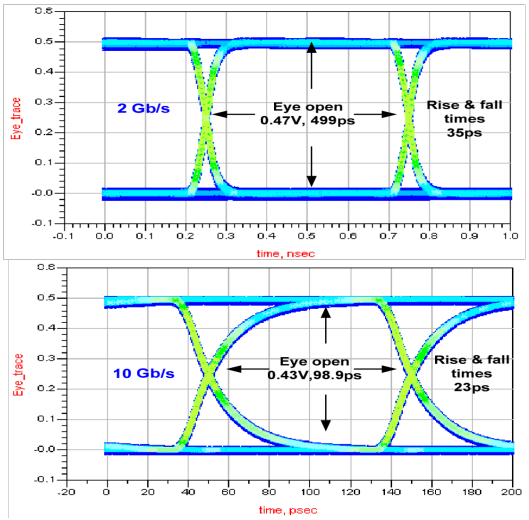

Figure 3. The simulated eye-diagrams of 2Gbps (a), and 10 Gbps (b) PRBSs after passing through the 3D Via

3. A Crosstalk between 3D Vias

3.1. The Influence of 3D Via Locations, and Distances on Crosstalk

Crosstalk is evaluated depending on the distance of two signal Vias and the location of two GND Vias as shown in Figure 4.

Five distances (4 µm, 8 µm, 16 µm, and 32 µm) based on SGSG configuration between the two signal Vias have been simulated. As expected, if the distance between the two signal 3D Vias is larger, the crosstalk level is going down as shown in Figure 5. The effect of the distance of GND Vias with respect to the signal via on the crosstalk is also evaluated as shown in Figure 6 with four distances: 4 µm, 8 µm, 16 µm, and 32 µm. The results show an increase in the magnitude of the crosstalk as the distance of the reference via (GND) increases. Also it is shown in Figure 7 that the crosstalk magnitude of SGGS (i.e. the cross locations of

the signal and ground Vias) configuration is smaller than that of SGSG configuration comparing two same distance cases. The difference of the two cases is almost 10dB. This is a very interesting point for 3D designers to keep in mind, because just changing the 3D Via role can reduce the crosstalk magnitude especially in high frequency applications, where crosstalk problem is very critical to obtain the maximum system performance.

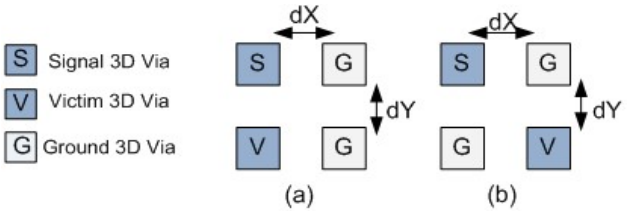

Figure 4. Location of signal Vias and GND Vias for crosstalk evaluation, (a) SGSG, (b) SGGS configurations

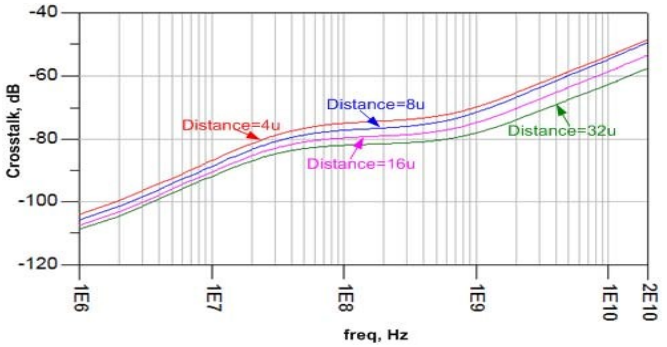

Figure 5. Comparison of five locations of 3D Vias. The distances 4 µm, 8 µm, 16 µm, and 32 µm between two signal Vias are associated to the graphs from top to bottom respectively

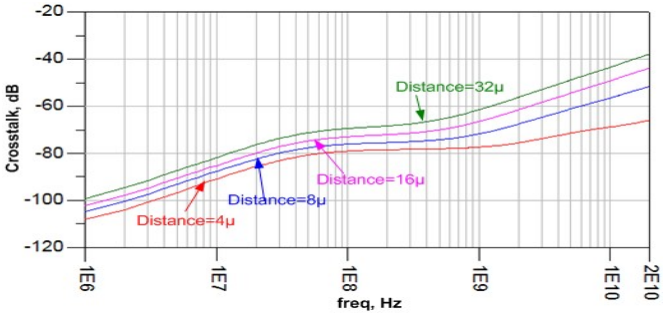

Figure 6. Comparison of three locations of GND Vias. The distances 4 µm, 8 µm, 16 µm, and 32 µm between two GND Vias are associated to the graphs from bottom to top respectively

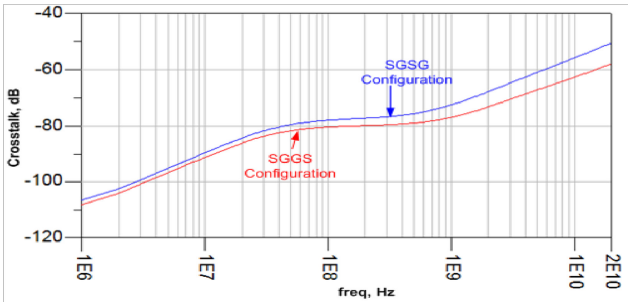

Figure 7. Comparison between SGSG and SGGS configurations for 10 µm distance, SGSG and SGGS are the top and bottom graphs respectively

3.2. 3D Via Crosstalk in Structures with Different Configurations

The geometry of the return current path may be one of the most efficient methods to affect the crosstalk between a signal and victim Via. Four different configurations have been investigated (1) Two Via pairs in a straight line (Figure 8(a)), (2) Two Via pairs placed opposite to each other (Figure 8(b)), (3) A signal Via with two reference via placed opposite to a victim Via with two ground Vias (Figure 8(c)), (4) A signal and victim via, each with three reference Vias as a return current path (Figure 8(d)).

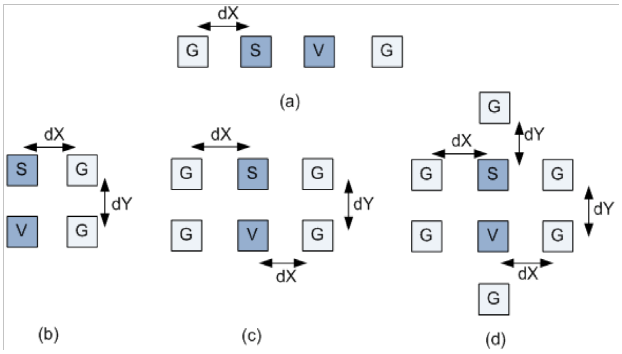

Figure 8. Comparison of three different configurations, (a) Configuration #1, (b) Configuration #2, (c) Configuration #3, and (d) Configuration #4

In configuration 2, the signal Via has a slightly lower inductance than it would in configuration 1 because the second Via is close enough to the signal Via to have a slight impact on its inductance. Configuration 4 has the lowest inductance because it has the most well defined return current path. This lowering of the inductance will also lower the near-end crosstalk as shown in Figure 9. Also it is shown that the highest crosstalk as predicted, comes from configuration 1. Only slightly lower is the crosstalk from configuration 2. Then, there is a significant decrease in crosstalk when the extra two reference Vias are added in configuration 3, and a slight decrease further when the third reference Via is added to the victim and signal Vias in configuration 4. The reduction in crosstalk from adding additional reference Vias is almost 4 dB.

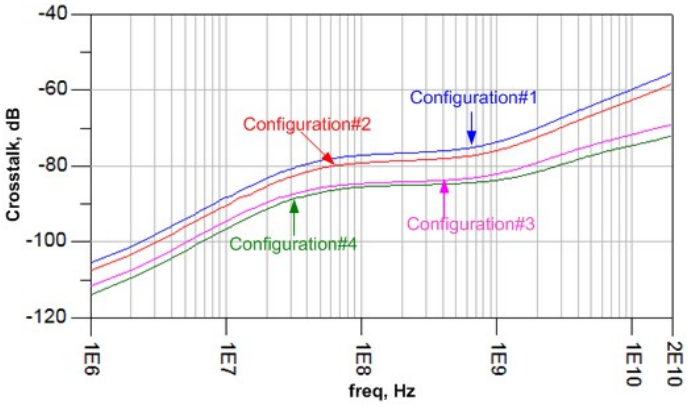

Figure 9. Crosstalk between four different configurations

Until this point, only isolated 3D Vias with respect to ground Vias have been considered. Potential coupling in the 3D Vias in the discontinuity between the 3D via and the transmission line may be an important effect to consider. In Figure 10, a new Ansoft HFSS model is presented that accounts for the discontinuity between the 3D via and the transmission line.

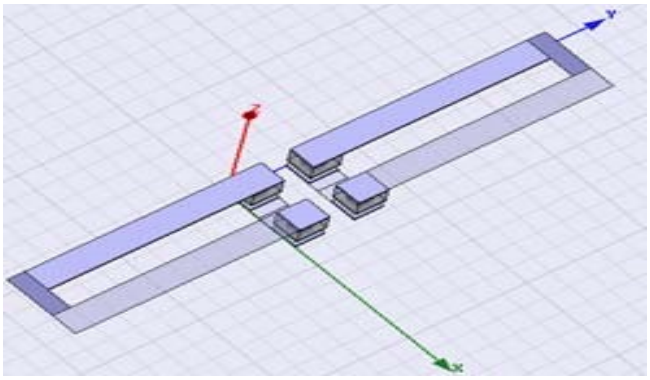

Figure 10. A TSV coupling model that includes the transmission lines

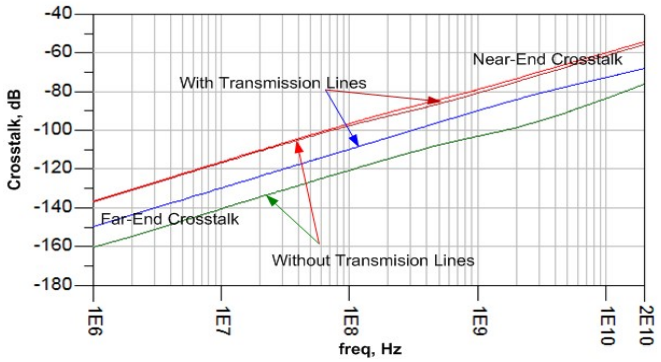

Figure 11. Comparison of crosstalk between TSVs with and without the inclusion of transmission lines

Figure 11 shows that, according to the full wave simulations, there is no measurable difference between the near-end crosstalk as a result of the discontinuity between the transmission lines and the 3D Vias. The difference between the two simulations is very small over the entire frequency range. However, the discontinuity between the transmission lines and 3D Vias will increase the far-end crosstalk. On the other hand, the far-end crosstalk is more minimal than the near-end crosstalk, less significant and never exceeds -50 dB as shown in the simulation.

4. 3D Embedded Crosstalk Test Applications

4.1. 3D Testing Circuit for Crosstalk Induced-Delay and Glitches

In this embedded test application, the coupling effects between adjacent TSVs such as induced-delay and glitches can be investigated for different crosstalk modes. As shown in Figure 12, high speed signals can be fired through three adjacent TSVs at each tier using a multi-edge delay generator circuit. A Mux and Tristate circuits are used to control which signals are active from which tier. The complementary signals are also generated from the delay generator to cover different crosstalk modes. In order to study the effect of phase shifting the aggressor signal on crosstalk induced-delay cancellation, the multi-edge delay generator is used to fine control the delay between adjacent signals.

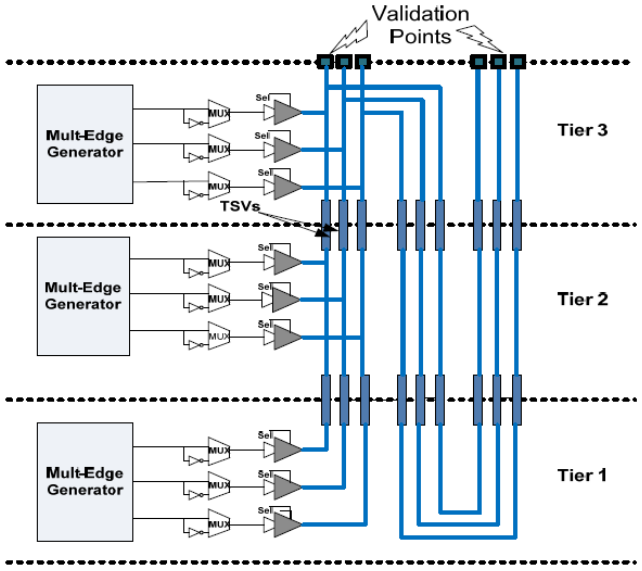

Figure 12. 3D Interconnect crosstalk induced-delay test

Figure 13 shows different crosstalk modes for studying crosstalk coupling on the victim edge. For example; -2X presents the case when both aggressors transition in the same direction as victim. -1X: when one aggressor transitions in same direction and other is quiet. 0X: when both aggressors are quiet or transition in opposite directions or the victim is quiet. +1X: when one aggressor transitions in opposite direction and other is quiet. +2X: when both aggressors transition in opposite direction as victim.

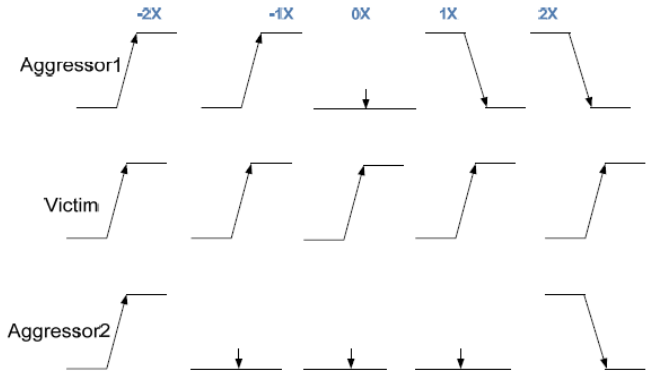

Figure 13. Different Crosstalk Patterns

Figure 14 shows simulated results for the induced-delay crosstalk with different patterns using ADS and 0.25 µm CMOS standard process. The middle graph is the victim line signal with no activity on both aggressor lines. The furthest right and left graphs are -2X and 2X cases respectively, which cause the worst case induced-delay effect. This induced-delay can be mitigated by phase shifting the aggressor signals using the multi-edge delay generator. Figure 15 shows an example of the crosstalk induced-delay cancellation effect after phase shifting the aggressor line 0.8ns for the case of +1X. As graphed, the induced delay due to crosstalk is almost cancelled and the signal aligns again with the 0X case (i.e. without crosstalk).

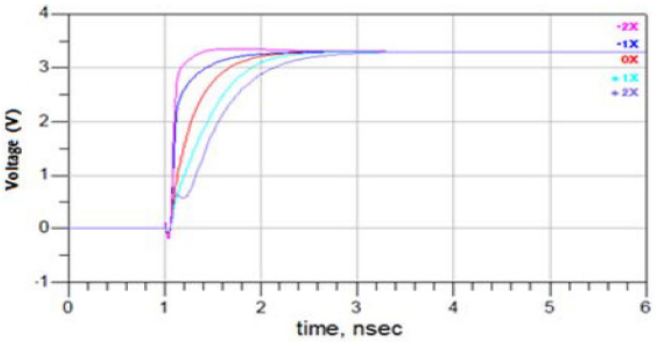

Figure 14. 3D interconnect induced-delay crosstalk for different crosstalk patterns

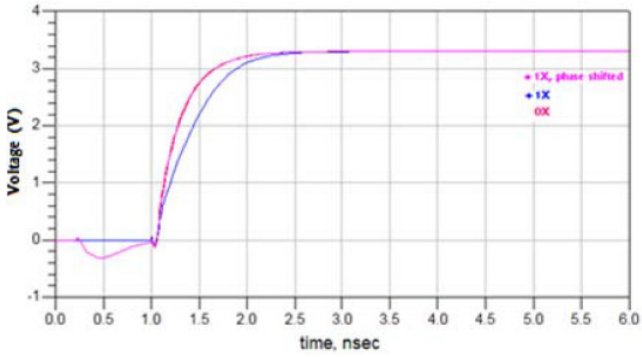

Figure 15. 3D interconnect induced-delay crosstalk cancellation

4.2. Ring Oscillators 3D Crosstalk Test

In this test, a consecutive triggered parallel Ring Oscillators (ROs) structure running same frequency is used to characterize the crosstalk effect between TSVs. Figure 16 shows four triggered oscillators; two oscillators are crosstalk-coupled and the other two are crosstalk-free. The proposed ROs parallel structure creates a delta phase shift difference between each consecutive triggered oscillators, which is equal to the time difference between the delay buffer chain and the oscillation time period of the triggered oscillators. 3D crosstalk detection can be achieved by observing the frequency of crosstalk-coupled oscillators, which is different from the frequency of the crosstalk-free oscillators.

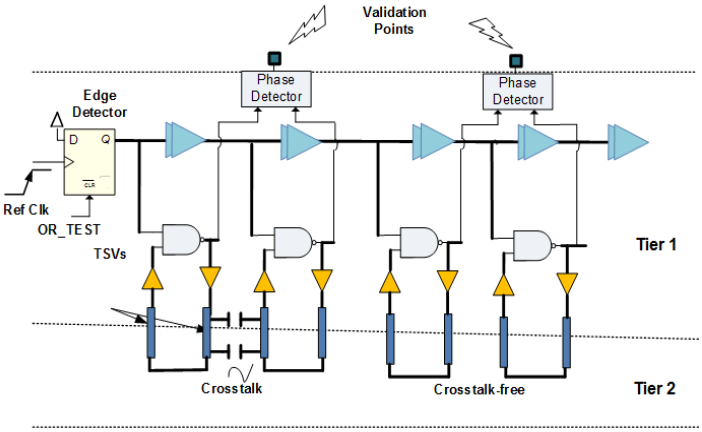

Figure 16: 3D Crosstalk Detection Scheme

Figure 17 shows the output frequency for both crosstalk-coupled (725 MHz) and crosstalk-free oscillators (667MHz).

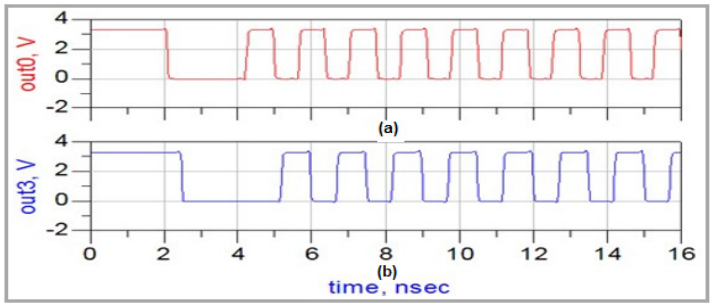

Figure 17: Output frequency for (a) Crosstalk-coupled and (b) Crosstalk-free oscillators

Interestingly, the two crosstalk-coupled triggered oscillators have less oscillation time delay (i.e. faster frequency) than the crosstalk-free oscillators, and the phase difference between the two crosstalk-coupled oscillators diminishes due to the coupling effect as shown in Figure 18. Phase detection at the output of the crosstalk-coupled triggered oscillators can be used as an indicator for strong coupling between TSVs. On the other hand, the edges of crosstalk-free oscillators are still separated by a deterministic phase shift dictated by the time difference between the delay buffer chain and the ring oscillation time period.

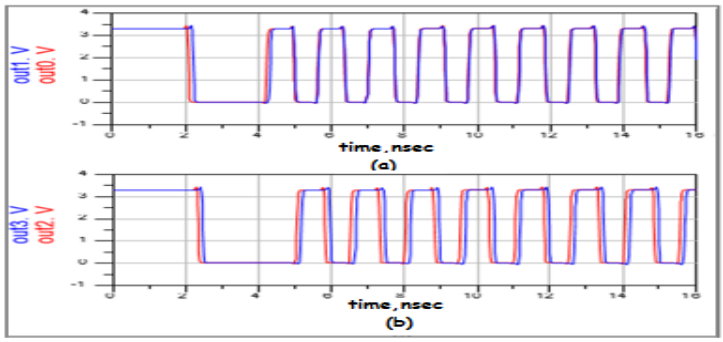

Figure 18: Simulated Results for 3D Interconnect Crosstalk (a) Crosstalk-coupled (b) Crosstalk free

5. Conclusion

In this paper, we presented the signal integrity effects of crosstalk in 3D stacked ICs. A detailed study of TSVs electrical modeling and characterization using HFSS and ADS simulators for frequency and time domains analysis respectively was presented. Simulation results were conducted based on 0.15µm 3DFDSOI process technology from MIT Lincoln lab which present the influence of 3D Vias distances, locations and their structural configurations on crosstalk. The study shows that increasing and decreasing distance of 3D Via signals and grounds respectively can mitigate significantly the effect of 3D crosstalk. In addition, adding more reference Vias and creating a well-defined return current paths have the most impact on mitigating crosstalk. Furthermore, it was shown that the discontinuity between 3D Via and transmission line has negligible impact on near-end crosstalk (NEXT), however; far-end crosstalk (FEXT) might increase but with less significant impact.

Furthermore, a 3D testing circuit application based on a multi-edge signal generator placed at different 3D stacked tiers was studied to evaluate the effect of crosstalk induced-delay and glitches. Additionally, a cross-coupled parallel ROs structure was

also presented to evaluate the crosstalk coupling strength effect compared to ROs structure with crosstalk-free TSVs.

The United Arab Emirates (UAE) is dedicated to establishing the best teaching and learning environment for students and staff across all higher education institutions. To heed this call, the engineering division adopted the Learning-by-Doing (LBD) pedagogical philosophy for 21st Century education at the heart of its strategic directions. This study intends to explore how LBD is understood and practiced in UAE colleges and how 21st Century skills can be explicitly incorporated into its engineering curriculum by using constructive alignment as a pattern for instructional design. This work intends to investigate the general question: "What constructively aligned Learning-by-Doing pedagogical model, with the incorporation of 21st Century skills, needs to be developed to effectively teach and prepare engineering students at the Higher College of Technology, UAE for successful long-term employment in the global working economy?". Using mixed method research design and input from its major stakeholders, student survey questionnaires, engineering instructors and dean structured interviews, overt class observation and syllabi examination have all been utilized for data triangulation. In conclusion, the study developed a collaborative LBD model tailor-fitted to the institution's engineering program and to UAE's culture.

1. Introduction

This study of students' and instructors' perception of the implementation of Learning-by-Doing and 21st Century skills was conducted in Higher Colleges of Technology, HCT, a tertiary education institution in the United Arab Emirates (UAE). This research is an extension of work presented at the 2017 Global Engineering Education Conference [1]. Additionally, the work is part of thesis work for doctoral studies. The 2003 Emiratisation program, developed for the purpose of training Emiratis to become competitive, has been strictly enforced by His Highness Shaikh Mohammad Bin Rashid Al Maktoum, the Vice President and Prime Minister of the UAE (2012) [2]. The Emiratisation program is aligned with the UAE Vision 2021[3], which aims to develop and train Emiratis for taking up jobs in the country. Among other things, Vision 2021 foresees higher education as an environment where students will "enrich their minds with the skills that their nation needs to fuel its knowledge economy" [3, p. 16]. Thus, it can also be observed that part of Vision 2021's directive is for the UAE universities to "listen closely to the needs of Emiratis and of their future employers" and to "balance their teaching to the demands of the workplace" [3, p. 16]. Teaching methods and approaches need to be aligned with this requirement of matching the students' learning with practical needs of jobs in future, and Learning-By-Doing is one method that is gaining a reputation for doing just that [4]. This study is therefore conducted in a tertiary educational institution in the United Arab Emirates (UAE), with the aim of evaluating the pedagogical approach in the context of the framework of 'Learning-By-Doing'.

The concept of a more authentic, relevant learning has been a focus for educators since the time of John Dewey in the early part of the last century. Dewey's concept of "learning by doing" was based on his understanding that people learn best when they are actively involved in tasks that have meaning and importance [4]. In this last century, education has also been shaped by our growing understanding of how people learn. Johnson, Johnson and Holubec [5] argued that the work of Vygotsky in the 1920s, Jean

Piaget's cognitive development stages, Bloom and his now famous taxonomy, Howard Gardner's multiple intelligences and other related research studies have deepened our understanding of human learning, which, as [4] advocated should involve all aspects concerning the mind, hands and heart. Additionally, the principle of Learning-By-Doing is manifested in many of today's learning theories. Experiential learning, under which falls-active learning (whose subsets include cooperative learning and collaborative learning) and service learning – all exemplify the principle of Learning-By-Doing [6]. According to Voogt and Roblin [7, p. 29], in order for students to be successful in the 21st century, not only are certain skills necessary but these specific skills also need to be taught through (and are best supported by) "specific pedagogic techniques, such as problem-based learning, cooperative learning, experiential learning, and formative assessment", which again is encompassed in the approach of Learning-By-Doing [6].

The study aims to answer the overarching research question: What constructively aligned Learning-by-Doing pedagogical model, with the incorporation of 21st Century skills, needs to be developed to effectively teach and prepare engineering students at the Higher College of Technology, UAE for successful long-term employment in the global working economy? The main objectives of the research are as follows:

- To analyze the current understanding of LBD from the viewpoint of the engineering college's dean and instructors.
- To identify what LBD practices are being successfully implemented in the engineering department, from the perspectives of instructors and students in HCT.
- To identify what 21st Century skills are intentionally or incidentally taught and assessed in the practice of LBD, from the perspectives of instructors and students in HCT.
- To identify what pedagogical model might best meet the needs of implementing LBD and 21st Century skills in the engineering faculty at HCT.

The following sub-questions were formulated to guide the two phases of the study and provide conclusions:

RQ1. What are the current understandings of LBD from the viewpoint of the engineering dean and the instructors?

RQ2. From the perspectives of engineering instructors and students, what LBD practices are successfully implemented in the engineering department?

RQ3. From the perspectives of instructors and students, what 21st Century skills are taught and assessed in the practice of LBD?

RQ4. What pedagogical model might best meet the needs of implementing LBD and 21st Century skills in the engineering division at HCT?

2. Research Locale and Participants

The UAE is identified by PISA (Programme for International Student Assessment) as one of the most rapidly improving education systems in the world [9]. The UAE government recognizes that in 21st century economies, knowledge and skills have become so essential that a high value is placed on building a world-class education system that nurtures the minds and hearts of the UAE citizens. The government of UAE plays a dominant role in education, for schools and universities. It typically controls curricula even at private schools [9]. Most instructors are government employees, and most education is publicly financed up to the degree level. There are several types of post-secondary institutions in the UAE. A university offers degrees in several disciplines and usually offers graduate studies, while university colleges focus on one major discipline and are mostly for bachelor degrees. Technical institutes offer two- or three-year diplomas and are common throughout most of the region, accounting for one-third of all post-secondary students.

The UAE has more than 30 foreign academic institutions. The establishment of those institutes is a manifestation of the globalization of higher education and an indication of some of the UAE's attempts to become a knowledge-based society. Public universities in the UAE have separate colleges for males and females, following Islamic traditions. Such is the case with HCT, the locale of the present study.

HCT is one of the public's higher education institutions in the UAE, established in 2006. All the engineering programs are internationally recognized by accrediting bodies specifically the American Accreditation Board for Engineering and Technology (ABET). Because the proposed model is specific to the engineering department of HCT, the participants are its stakeholders: the engineering dean, the instructors teaching major courses in engineering and the engineering students. Only the instructors who have signed an informed consent to participate in the research were interviewed and observed. Table I shows the number of participants who were invited and participated in the study.

Table I: Participants of The Study

Colleges	Year 1	Year 2	Year 3	Year 4	Instructors	Dean
MZC Colleges (women)	18	15	0	0	2	
RUC colleges (women)	31	16			3	
RUC colleges (men)	30	41	32	18	3	
Total	79	72	32	18	8	1

3. Significance of the Study

The researcher believe that while LBD may be translated into various strategies that call for student-centered activities, an explicit definition based on shared understanding, contextualized to how LBD should be applied in the HCT colleges, would make its practice more focused. This has the potential to greatly contribute to achieving the college's mission of providing educational experiences that will infuse its graduates with "the knowledge, skills, and attributes to effectively contribute to the nation-building process and to help them develop a sense of personal and social responsibility". (http://www.hct.ac.ae/about/learning-model).

Additionally, the researcher sees the viewpoints of HCT major stakeholders as vital in developing explicit foundational commitments from the college community in lieu of one solely determined by higher management and handed down to teachers

for mandated implementation. Hence, the researcher takes into account the teachers, the students, and the management's viewpoints. It is anticipated these findings will contribute to the development of an explicit model that will help the teachers focus methodologies, assessments, and other pedagogical activities not only to the principal elements that comprise LBD but also for the promotion of learned 21st Century skills developed amongst students.

4. Implications for the Present Research

Although the literature does not provide any explicit definition of LBD, it links it to a number of important elements that ultimately promote its philosophy. This gives a more definitive idea of what it involves and a basis for investigating how the HCT instructor individually understands and practices the philosophy of LBD under the guidance of the college. The following is an analysis of what LBD involves:

- Learning to do (skills) not just to know, [10] - [11];
- Learning that is experiential [11], [12], active [10], [1],[13], [14], collaborative and cooperative [15];
- Learning that occurs in the context of a goal that is relevant and interesting to the student [2], [16];
- Learning that is planned (not discovered) [16], [2];
- Learning that involves not only quality academic reflection[17], [18] but civic (global) and personal experiences as well [18];
- Learning that considers the students' cultural context [19], [20] and respects every student's experience and builds upon these [11], [16];
- Learning that involves practical experiences in the context of relevant tasks closely related to how students will use it outside the learning environment [1], [5];
- Learning that involves strategies such as presentation, reports, team building, online contact time with students, critical thinking, studio teaching, team projects, and open-ended problem solving [20], [21] - [22];

The literature reviewed leaves no doubt as to the importance of 21st Century skills in today's education, particularly to engineering education. The review has also shown that a number of 21st Century skills take their roots from Dewey's (1899) work, among others.

Also, as mentioned in the research reviewed, over and beyond foundation knowledge taught through content engineering courses, the following are deemed indispensable 21st Century skills applied to an engineering education. The researcher adopts Mishra and Kereluik's re-categorization of 21st Century skills in presenting these.

1. Meta knowledge
   - critical and self-critical abilities/problem solving, [23] - [25];
   - communication and collaboration, [23] - [26];
   - teamwork [23] - [27];
   - creativity/innovation [23];
2. Humanistic knowledge
   - life and job skills [23], [25], [26]
   - ethics and cultural knowledge [26];

Interestingly, the LBD elements as listed above align with a number of the 21st Century skills reflected in the HCT learning model. To fully explore the alignment between LBD elements and 21st Century skills necessary in engineering education as outlined in the learning outcomes of HCT, a brief analysis by the researcher is presented in Table 2.

Table 2: Alignment Between LBD Elements, 21st and HCT Learning Model

LBD elements	21st Century skills	HCT learning outcomes
• Learning to do (skills) not just to know (factual knowledge); experiential, active, cooperative, collaborative learning	creativity/innovation life and job skills/communication and collaboration teamwork	Critical and creative thinking Vocational competencies Communication literacy Teamwork and leadership
• Learning that occurs in the context of a goal that is relevant, meaningful and interesting to the student	life and job skills communication critical and self-critical abilities/problem-solving	Vocational competencies Communication literacy Critical and creative thinking Self-management and independent Learning
• Learning that is planned	all skills should be planned learning outcomes	HCT learning model mandate
• Learning that involves quality reflection	critical and self-critical abilities ethics and cultural knowledge	Self-management and independent learning Global awareness and citizenship
• Learning that considers culture	ethics and cultural knowledge	Global awareness and citizenship
• Learning that involves practical experiences in the context of relevant tasks closely related to how students will use it outside the learning environment	creativity/innovation life and job skills communication and collaboration teamwork	Critical and creative thinking Vocational competencies Communication literacy Teamwork and leadership Mathematical literacy
• Learning that involves strategies such as presentation, reports, team building, critical thinking, steam projects, and problem-solving	communication and collaboration teamwork critical and self-critical abilities	Critical and creative thinking Teamwork and leadership Communication literacy Mathematical literacy

Biggs [28] instructional design, constructive alignment, aside from fully supporting LBD as it espouses experiential learning, sees the usefulness of an LBD structured system of learning in engineering education [29], [30]. The researcher finds this significant in contributing directions on how to go about model construction, giving particular focus to Biggs' alignment of learning outcomes, teaching and learning activities, and assessment.

In developing the model which this study proses to do, the researcher should keep in mind that although LBD is mandated as the teaching principle of Higher Colleges of Technology and is promoted in Biggs' instructional design [28], conventional methods of teaching still have a place in the classroom [23], [31] - [33]. Hence, the researcher notes that some lessons can be taught through interactive, high-level psychological lectures and activities rather than behavioral, experiential ones.

Additionally, following Houghton [34] and Fung [29] propositions, criterion-based assessments will be looked into while keeping in mind Voogt and Roblin's recommendation that while summative and formative assessments are useful in assessing 21st Century skills, new forms of assessment should build on previous assessment practices and should be considered as a starting point.

5. Research Methodology

As mentioned, HCT has mandated the use of LBD and 21st Century skills learning, having adopted these at the heart of its strategic directions. At this point, it is important to delve into how LBD is implemented and how 21st Century skills are infused especially from the collective perspectives of the different stakeholders – students, instructors, and the dean.

Keeping in view the pragmatic stance that reflects the belief that human experiences are multifaceted, and that agreement concerning what is and what should be in any given situation is best negotiated among all concerned parties, the mixed method approach was selected as the best-suited method for this study. The selection of the mixed method approach was in keeping with the stance of Venkatesh, Brown, and Bala [35] who state that "such work can help develop rich insights into various phenomena of interest that cannot be fully understood using only a quantitative or qualitative method" (p. 21). Creswell and Plano Clark [36] claim that using both qualitative and quantitative methods enables the researcher to reach a more comprehensive response to the research questions, as opposed to the possible limitation of using only one method. Using the mixed methods design in this research has enabled reliable and valid data to be elicited, as it helped the researcher in obtaining data from different sources using different approaches – in-depth interviews, observations, quantitative surveys, and document analysis. Migiro and Magangi [37] state that there are three important advantages of this method:

(1) A researcher can use strengths of an additional method to overcome the weaknesses in another method by using both in a research study;

(2) Mixed method research can provide stronger evidence for a conclusion through convergence and corroboration of findings;

(3) Mixed method research can add insight and understanding that might be missed when only a single method is used (p. 3763).

Hussein [38] states that using multiple ways of data collection in the same study increases the credibility of the study (p. 1). He asserts that using mixed methods achieves more accurate and reliable findings with richer information.

The use of mixed methods is therefore grounded in the researcher's belief that findings from each set of participants (students, teachers, and the dean of engineering) will give not only a richer depiction of the findings but also a unique description of what LBD practices and 21st Century skills are currently implemented at HCT.

Quantitative Tools

Quantitative methods are often used in social science to acquire knowledge by manipulating data through sophisticated quantitative approaches, such as multivariate statistical analysis [22]. The engineering students were requested to repond using Likert-scale questions by employing an online survey framework that was used by the researcher. Keeping in mind participant fatigue, the questionnaires were divided into two sets: LBD elements and 21st Century skills. The sets were administered separately, a week after the other.

Qualitative Tools

The qualitative data collection was selected in order to offer the researcher an in-depth perspective regarding the personal experiences. Reference [23] provided a succinct definition that "qualitative research seeks to discover new knowledge by retaining complexities as they exist in natural settings." Reference [24] provides a description of a variety of data collection tools used in qualitative studies: interviews; data analysis; direct observations; and reporting. The choice of tool is influenced by the skill of the researcher, data collection strategy, the type of variable, the accuracy required, and the collection point [21].

Data Analysis

The following data analysis approach was shaped by the type and amount of data collected and made extensive use of description in addition to a number of statistical analyses of the quantitative data. The primary data sources, survey questionnaires, semi-structured interviews, content analysis and over classroom observations, were analysed and reported in terms of patterns in participants' responses in relation to the main and enabling research questions that guided the study.

1) Quantitative Data Analysis

To test whether the actual values are significantly different from the expected values, the chi-square test was applied to the LBD and 21st Century questionnaire. A null hypothesis signifies that there is no statistically significant difference and an alternate hypothesis states the opposite. Based on the results of the above

test, the researcher can either reject or fail to reject the null hypothesis. The techniques and methods used in this study encompass the following: The descriptive analysis by using the mean and standard deviations was conducted for the items determining the 21st Century skills.

2) Qualitative Data Analyses

To analyse the qualitative data, the audio recordings of the interviews and transcripts of the recordings were entered into nVivo software for coding and further analysis.

6. Data Analysis and Results

This section discusses the findings stemming from the quantitative and qualitative data collected. The quantitative methodology tools used are questionnaires given to one particular type of stakeholders, specifically the engineering students. A descriptive analysis was carried by using the frequencies and proportions. The Likert-scaled data of Learning-by-Doing items were tested for statistical significance by using a Chi-squared test. A descriptive analysis using the frequencies and proportions was conducted for the items determining the 21st Century skills. The qualitative methodology tools used are semi-structured, one-on-one interviews among the two sets of target participants: the engineering instructors and the dean.

A. Descriptive statistic Learning-by-Doing survey findings

The first questionnaire was administered to the engineering students seeking to understand how LBD is manifested inside the classroom. Students were given a set of 16 statements and then asked to rate the frequency of these statements. The statements were geared to correspond to LBD principles as opposed to LBD techniques. The survey questionnaire was administered to 184 engineering students. Students' ratings of each of the statements are listed in Table 3. Frequencies, Means, and Standard Deviation data analysis are shown. In addition, a graphical representation for the rating of LBD statement is shown in figure 1.

The first statement provides emphasis on activities done in the classroom which emphasizes collaboration as its main ingredient. Only 26% of the participants stated that this is always the case with 32% stating this is usually done. The second statement aims to find out whether there is a meaningful interaction between students and instructors during discussions. 32% stating this is always done. The third statement emphasizes reflection on activities conducted. This is one of the hallmarks of Learning-by-Doing. More than 50% of the students said it was done at least 4 times in six situations. The fourth and fifth statements are related to each other as they tackle the issue of learning "life skills," another characteristic of LBD. We can safely say more than 50% of students are saying these are being done 4 out of 6 situations. The 6th statement's aim was to ferret out whether "Active Learning" is happening in the classroom. This statement garnered the lowest number 5 rating (12%). The 7th statement refers to the use of simulation in the classroom. The results on this question are encouraging considering it has a high rate of "Usually" (38%). The demonstration of a concept is the emphasis of the 8th statement. Looking at the results, it can be seen that it has the highest points garnered in the data spectrum of "Always" (30%). The 9th statement belongs to the purview of "Active Learning," conducting drills and practice. The results show that this statement has the highest frequency number for the rate of "Usually," garnering a whopping 44%. The 10th statement is part of the reflection phase of LBD where students are supposed to retrospect on what they have learned. The combination of the "Usually" and "Always" frequency score however still ensures that more than 50% of the participants believe that this happens. The 11th statement touches the post-evaluative aspect. LBD encourages different ways of evaluation to encourage the participation of the learner or learners in this phase. We can still conclude that more than 50% of students believe that this happens 4 times out of 6 situations. The 12th statement is part of the real-life learning of LBD were activities that encourage more "learner" immersion is an integral part. Suggested by the statement itself are workshops and field trips. This statement got the highest "Never" and "Almost Never" frequency score. The 13th statement is still within the context of real-life learning. The 14th statement is within the purview of "Active Learning," with at least 50% of the participants believing that this occurs in 4 out of 6 situations. The 15th statement is within the coverage of post-evaluation and reflection. Students are asked to record their impressions on a phase by phase basis. Almost 60% of the participants believe that this happens in at least 4 out of 6 situations. The 16th statement focuses on hand-ons, kinesthetic activities. This statement got the highest "Occasionally" rate, having 40%.

Table 3: Summary of Results for Each LBD Statement

	LBD statements	Frequency %					Sample Size	Mean	SD.P
		Always	Usually	Occasionally	Almost never	Never			
1	There are classroom activities that require students to **collaborate** and learn with and from each other. Examples are **group projects** that emphasize **teamwork**.	26	32	26	12	4	184	20	10.2
2	Discussions in the classroom are **interactive** meaning students as well as the teacher contribute to the topic being discussed.	32	32	25	9	3	184	20	12.0
3	Questions and answers that focus o**n post-evaluation** of learning activities are conducted in the sessions.	25	33	27	10	5	184	20	10.7
4	Exam questions are focused on **scenarios** that require students to apply what they have learned and are not merely limited to ones that call for memorization, definitions, etc.	21	34	30	10	4	184	20	11.4
5	The teacher uses **real life** case studies as a means for teaching the content of the course.	20	32	33	11	5	184	20	11.1
6	Students are presented with **problem-based** questions where students either in group or individually will work out the solutions.	12	37	35	12	4	184	20	13.4
7	Teacher uses **simulation** either digital or manual as a means of teaching a concept.	22	38	30	7	3	184	20	13.3
8	Teacher **demonstrates** a required subject skill first then asks the students to follow suit.	30	35	26	7	2	184	20	13.1
9	Students **do drills and practice** as a means of learning and **mastering a skill** or a concept.	29	44	19	7	2	184	20	15.1
10	Students are encouraged to **reflect** on what they have learned and express this reflection either orally or in written format.	21	34	33	9	3	184	20	12.5
11	In assessing student's work, the teacher uses other means in addition to his/her own assessment. This other means can be **self-assessment or peer review.**	15	36	30	11	7	184	20	11.2
12	Teachers conduct activities that allow students to fully experience the topic. Examples of these type of activities are **field trips and workshops.**	16	29	33	14	8	184	20	9.4
13	The college provides programs that bring students to the **workplace** as part of the student's preparation for professional working life after graduation.	15	34	32	11	8	184	20	10.8
14	Classroom activities that ask the students to **model experiences** or concepts are conducted. Examples of these types of activities are **role-playing,** reenactment or walkthrough (From process to output)	17	33	35	9	5	184	20	12.2
15	Teachers encourage students to **record their impressions** on how they made the project on a **phase-by-phase** basis. This requirement is in addition to the required output of the project.	29	31	26	11	3	184	20	11.1
16	Classroom activities are formulated in such a way that students can be more **active and motivated** in their work. Examples of this type of activity are educational games and other hands-on means.	23	28	36	9	4	184	20	11.9

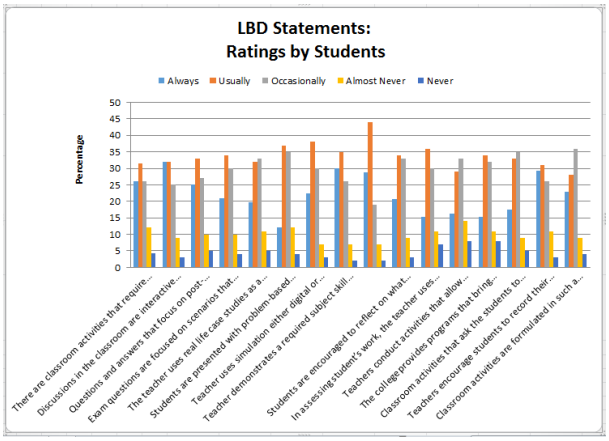

Figure 1. LBD Statements

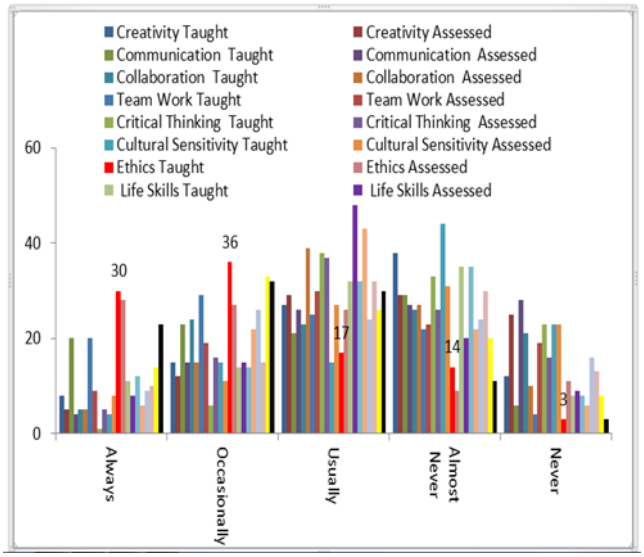
B. Chi-Square Test on Learning-by-Doing statements

In order to determine whether there is a significant difference between the opinions of the participants regarding the LBD statements, a chi-square test for equal proportions was applied. The null and alternate hypotheses are as follows:

Null hypothesis: There is no significant difference between the opinions of the participants regarding each statement.

Alternate hypothesis: There is a significant difference between the opinions of the participants regarding each statement.



Since the p-value is less than 0.05, we can conclude that there is little significant difference between the participants' opinions.

C. 21stCentury skills survey findings

To answer the 3rd question of the study, the student's point of view with regard to whether 21st Century skills are either intentionally or inadvertently taught or assessed in the classroom was addressed. The manifestation of the skills was established in the questionnaire to crystalize the concept in the mind of the students. Students rated each category based on a 1 to 5 frequency scale. Findings of the survey results are shown in Table 4.

Table 4: Summary of Findings for 21st Century Skills.

	21st Century Skills		Frequency %					Sample Size	Mean	SD.P
			Always	Occasionally	Usually	Almost Never	Never			
1	Creativity	Taught	8	15	27	38	12	132	20	11.0
		Assessed	5	12	29	29	25	132	20	9.8
2	Communication	Taught	20	23	21	29	6	132	19.8	7.6
		Assessed	4	15	26	27	28	132	20	9.3
3	Collaboration	Taught	5	24	23	26	21	132	19.8	7.6
		Assessed	5	15	39	27	10	132	19.2	12.3
4	Team Work	Taught	20	29	25	22	4	132	20	8.6
		Assessed	9	19	30	23	19	132	20	6.8
5	Critical Thinking	Taught	1	6	38	33	23	132	20.2	14.6
		Assessed	5	16	37	26	16	130	20	10.8
6	Cultural Sensitivity	Taught	4	15	15	44	23	128	20.2	13.3
		Assessed	8	11	27	31	23	132	20	9.0
7	Ethics	Taught	30	36	17	14	3	132	20	11.7
		Assessed	28	27	26	9	11	132	20.2	8.4
8	Life Skills	Taught	11	14	32	35	8	132	20	11.2
		Assessed	8	15	48	20	9	131	20	14.7
9	Problem Solving	Taught	12	14	32	35	8	130	20.2	11.1
		Assessed	6	22	43	22	6	129	19.8	13.6
10	Innovation	Taught	9	26	24	24	16	131	19.8	6.4
		Assessed	10	15	32	30	13	131	20	9.1
11	Computer Literacy	Taught	14	33	26	20	8	132	20.2	8.8
		Assessed	23	32	30	11	3	132	19.8	11.2

Creativity: It is observed that 50% of the students think creativity as a skill is being taught and assessed only once in 6 situations. It is interesting to note that about 54% of the participants graded 1 (never) or 2 (almost never) for they now think outside the box by exploring alternative ideas and solutions. It is interesting to note that creativity taught and assessed received 8% and 5% respectively. This shows very little emphasis is devoted to creativity in the classroom by the teachers.

Communication: Communication skills reached the 43% in terms of students believing that it happens 4 out of 6 times in the category of taught and assessed. It would seem that communication is another skill that is not well assessed with 55% of the students thinking that never/almost never done is happening here.

Collaboration: Looking at the taught and assessed categories, we can see that only 5% of the participants think this is done 6 times out of 6 situations and 44% think this is done 4 out of 6 situations. We can conclude that collaboration is not taught nor assessed in the classroom

Team work: Can also be considered as one of the top skills in terms of scoring as it has a more than 40% rating in the "Usually" and "Always" categories. Just like in the other skills it means 50% of the students believe it is happening 4 out of 6 times.

Critical thinking: This skill scored lowe in both categories. These results support the obtained data from the instructor interviews about the teaching and assessment of the critical thinking skill. It is observed that 56% of the students think critical thinking as a skill is being taught and assessed only 1 time in 6 situations.

Cultural sensitivity: This skill received the highest score of 44% for "Almost Never." This highlights that almost half of the participants think that cultural sensitivity is rarely being taught in class.

Ethics: Ethics is one of the top skills that the student consistently rated high. It has 30%, "Always" score based on the taught category, achieving the highest score among all the skills.

Life Skills: Life skills received an average score in both categories. In the taught category Life Skills received 14% in "Usually" and 11% in "Always."

Problem Solving: The problem-solving scores 12% in the taught and 14% that this happens 4 times out of 6 situations. This is surprising result given that most of the exercises in the engineering department require laboratory and math problems. It is observed that about 35% of the participants rated "Occasionally" for classroom activities that require students to examine different processes or paradigms and apply these to different types of problems.

Innovation: Similar to critical thinking and creativity, innovation received a low percentage in "Always." It has 9% in the taught category and 10% percent in assessed category.

Computer Literacy: In the category of "taught" alone, the combination of "Usually" and "Always" is 47% which means almost 50% of the participants agree that it happens at least 4 out of 6 times.

D. Learning-by-Doing as explained by participants

The study presents a discussion on the analysis of the results obtained from the primary research. The study aimed at evaluating the understanding of LBD at Higher Colleges of Technology (HCT). UAE has taken evident measures to enhance the quality of education, in order to prove its educational capabilities on the global platform. Hence, in order to assess if the government is successful in its endeavor, it was important to assess how HCT approaches and implements LBD and 21st Century skills. The research therefore aimed at understanding, from the perspectives of the teachers, students, and the dean of the Higher Colleges of Technology what constitutes of LBD and 21st Century skills, and which activities were in the process of implementation under LBD and 21st Century skills. This is part of primary research that was undertaken by conducting using semi-structured interviews (of teachers and the dean) and surveys (of students). In addition, eight classroom observations were also used to assess first-hand the activities employed in classroom and the approach of teachers while teaching. The classroom observations were then analyzed in conjunction with the interview and the survey findings. In addition, an exhaustive analysis of the HCT curriculum was also undertaken in order to review the LBD and 21st Century related content and activities present in it.

The participants' answers can be grouped into four different classifications; mainly, the practical aspect, real world impact, and definition of LBD. From the data gathered, it can be inferred that the participants have diverse views on Learning-By-Doing practices, and it is stated to have a different meaning depending upon the type of course(s) the faculty is teaching and prior professional experience of the participant educator. Table 5 reflects the answers of the participants when asked about their understanding of LBD.

In the concept of engineering, it was claimed by one of the participants that LBD is more about working on "analytical thinking, thinking and formulating a problem, and understanding the practical application of concepts." Another participant stated that, he looks at Learning-by-Doing as a "fairly permissive term and that it is primarily focused on experiential learning." The same view was shared by the engineering dean where he stated "my understanding on learning-by-doing is it's a fairly lenient term. So the first thing I would say is it hasn't got an exact definition."

Table 5. Summary of findings of LBD understanding

Findings	Occurrence
Different meanings in different context	1
Includes critical thinking	1
Laboratory work	1
Relevant learning experience	1
Embrace all other types of pedagogy	1
Hands on applicability	1
Old concept	1
Practical aspect of learning	4
Integral part of engineering	3
Supports theory	2
Relating to real world	4
Increase productivity of students	1
Involves careful design of activities that allows good foundation for knowledge.	1
Provides an opportunity to explore and develop new ideas.	1
Problem solving	1
Practical aspect	4
Real world	4
Impact of LBD	5
Definition of LBD	2

Almost all educator participants suggested during the interviews the need for a clearer and concise definition of LBD to be produced by the institution. Specifically, as one participant stated - "we need a more expansive definition of Learning-By-Doing that captures what distinguishes as well as what unites all members of engineering divisions in a shared educational enterprise." Table 6 captures the common understandings of LBD highlighted during the interviews.

Table 6. LBD defined

Findings	Frequency	Percentage
Experiential learning	2	25%
Life-long learning	1	12%
Problem solving	1	12%
Applying theoretical knowledge	3	37.5%
Apply learning to real life	3	37.5%
Project-based	1	12%

Almost all participants highlighted the importance of the union of theory and practice with an emphasis on the later. The view of marrying both theory and practice is not something new as it has been part of the LBD research literature tradition. For instance, Dewey [25] suggested the move from formal, abstract education to one that is more experienced-based. At the core of Dewey's LBD philosophy is action. Rather than merely thinking about abstract concepts, LBD involves a direct encounter with the phenomenon being studied. It utilizes actual experience with the phenomenon to validate a theory or concept [25]. It should be emphasized and pointed out that most of the participants believed that LBD is not a "stand-alone" philosophy or practice but instead intrinsically tied in with making the theory more relevant and understandable.

The experiential learning definition received the second highest percentage. This is well in agreement with widely

published literature on LBD and in its roots of formulation as a concept and action. Experiential learning and its subsets, cooperative learning and collaborative learning, exemplify the philosophy of LBD [26]. However, as verified in the interview and follow up questions, most of the participants understood experiential learning as a type of "hands-on" learning that does not really emphasize the promotion of discussion, critical thinking, reflection, introspection, and retrospection. In this aspect, the experiential learning that most of the participants subscribe to has something to do with involving the student in the learning experience in order for the learner to understand the concept, thus this is more akin to active learning [13].

Participants were asked, "What LBD activities do you do or have you done to teach your students?" Diverse practices were encountered in classrooms to achieve LBD. Table 7 summarizes these findings.

Table 7: LBD Practices

LBD Practices	Frequency	%
Laboratory activities/ experiment	5	21.7
Case study	1	4.3
Project-based	3	13
Building	1	4.3
Industry visit	2	8.6
Design process	1	4.3
Demonstration	5	21.7
Peer Demonstration	1	4.3
Exploration	1	4.3
Modeling and non-routine problems	1	4.3
Problem-based	2	8.6

The highest observed practices are laboratory activities and demonstration with 21.7% each. With respect to hands-on courses, the instructors are observed to assess the students and train them in LBD through practical experiments and labs. Certain other answers inferred that experiential learning is not only experiental or lab work. "I think having a reflective analysis and self-criticism or guided criticism of that experiential learning exercise is something that is often missed," the dean of engineering noted. It was also inferred that one of the biggest challenges is the understanding that pedagogy is the philosophy.

E. Participants view on 21st Centure practices

Participants were asked to answer several questions on how 21st Century skills were adopted in their classroom activities. The engineering dean said, "UAE engineering students need to possess them in order to survive in the current corporate world." He used the term "professional skills" for 21st century education to highlight those listed skills. Ongoing research findings reveal that to answer today's challenges, students must have the capacity to apply knowledge in practice by learning to adapt to new situations; critical and self-critical abilities; the ability to use teamwork and communication skills, with these being listed as the top three competencies needed by 21st century engineers [27]. The dean went on to highlight the opportunities and challenges of engineering education in the 21st century, contending that the new professional engineer not only needs to be knowledgeable in his own discipline but also needs a new set of professional skills. Table 8 summaries the 21st Century skills findings.

Table 8: 21st Century Skills Findings

Participant	21st Century skills understanding	21st Century skills used	Assessed
Dean	The participant has a clear understanding of 21st Century skills. He even defined some of the skills to include theirelements in the assessment of students.	50% of courses use the 21st Century skills.	Not really, but should be included with clear rubric during lesson and assessment.
Teacher 1	It seems that the interviewee is unsure of the definition of those skills. He struggles to distinguish between terms such as creativity and innovation.	Innovation, creativity, team work, problem-solving, communicati on, ethics.	It does not seem that the teacher is aware of how to assess his students on any 21st Century skills. None of these skills are clearly assessed.
Teacher 2	It seems the participant is unclear on the definition of 21st Century skills.	Team Work, collaboration , and cultural sensitivity.	Yes, informally. Not with a set of clear rubric.
Teacher 3	The participant was aware of the 21st Century skills and answered some questions about their definitions	Creativity, collaboration , teamwork, critical thinking, problem-solving and innovation.	Yes. In a rubric. Official rubric tool was supposed to be presented to the interviewees.
Teacher 4	"I don't understand what you mean by communication." She seems to understand all the other skills.	Problem-solving, critical thinking, teamwork, collaboration , and life-skills.	Not all are assessed. Problem-solving, critical thinking, teamwork, and collaboration are hard to assess. But others I do assess in LBD activities.
Teacher 5	Don't understand the cultural sensitivity. Some confusion about the definitions of some skills.	All skills are used in LBD activities.	All skills are assessed except ethics and critical thinking. No rubric is available.
Teacher 6	The participant is clear about the definition of the 21st Century skills.	Creativity, communicati on, collaboration , teamwork.	All are assessed. Some might have an indirect assessment. No rubric presented.
Teacher 7	The participant seems to understand 21st Century skills.	Teamwork, collaboration almost all of the 21st Century skills.	All indirectly assessed. No rubric is available.
Teacher 8	The participant was not aware of the distinction between innovation and creativity. Also, he did not understand the use of life skills in classrooms.	Collaboratio n, team work, ICT and life cultural sensitivity is used.	None of the skills are assessed directly.

It is obvious that not all participants understood what 21st Century skills are, let alone what the definition is or what the included activites are. This is despite the fact that a working definition of the skills was sent to them before they started teaching their courses at the beginning of the semester. While the participants understood the general meaning of the terms, they are at a loss when they are asked about them in the context of their inclusion in classroom activities and assessments. This is not surprising since most of the assessments of engineering subjects are technical in nature which means they usually use a quantitative approach. Skills such as collaboration, creativity, innovation, ethics, and cultural sensitivity would seem to require a qualitative evaluation framework in order to be assessed. 90% of the participants admitted that they do not include a majority of these skills as part of their assessment. When pressed with a follow-up question on the reason why, most of them simply said it was not required in the course outline. Some ventured to say it is difficult to assess these skills as they seem to be fraught with subjectivity which to them is a departure to the objective and clear type of assessment engineering students are used to having. However, not all 21st Century skills were unfamiliar to the participants. A clear majority of them stated that technological literacy, problem-solving, teamwork, ethics, and collaboration are mostly included in their assessment tools.

F. View of the participants towards incorporating the Learning-By-Doing and 21st Century skills better in the course outline

The participants also provided their views on how LBD and 21st Century skills were incorporated in the course outline. Mostly, it was stated that the course outline should include clear assessment guidelines for LBD activities and 21st Century skills. Two of the participants emphasized the core concepts and skills students needed to learn and cautioned to avoid unconnected topics which inhibit the development of critical thinking and other 21st Century skills. In addition, the participants also claimed that critical and creative thinking can be incorporated into the course outline, and on giving more importance to improving the communication abilities and promoting the spirit of teamwork and leadership. One of the participants specified four main skill areas that affect creativity and innovation in the current course outline: *fluency, flexibility, elaboration and originality*. Hence it was proposed that making these skills a part of the assessment strategy would better incorporate LBD and 21st Century skills in the course outline. The participants also claimed that the personal and social development of the students may be enhanced by developing their managerial and leadership skills, and by preparing them to implement complex skills such as planning, communicating, problem-solving, and decision-making.

Conclusion

This study reported on data gathered from instructors and the HCT dean's interviews and student questionnaire surveys. It has shown diverse views on the Learning-by-Doing understanding, practices, and definition. While most of the educator and student participants explained their understanding of LBD, the enumeration of the impact verifies the "incomplete" understanding of LBD. On the definition of LBD, participants viewed it as the second half of "theoretical" knowledge which is its application. This understanding is supported by LBD research literature. For instance, [7] suggested the move from formal education to one that is more experienced-based. As engineering is a skill-based field, it was no surprise for the participants to award high percentage for laboratory activities and experiments to be the most used LBD activities. The importance of 21st Century skills was highlighted by all participants during the educator participant interviews. But, most of them failed to use them in the context of their classroom activities. Creativity, critical thinking and innovation skills were highlighted as the most difficult to assess in engineering courses. The underlying theme of the findings from the students' point of view is that nearly 55% of the students believed the LBD is conducted and assessed in the classroom. The rest of the students, 45% seem to believe that LBD is not conducted in the classroom activities. The survey data used in this study was discussed along with other interviews and personal observation data to explore the results further in the construction of the LBD model.

ABSTRACT

Nowadays, text annotation plays an important role within real-time social media mining. Social media analysis provides actionable information to its users in times of natural disasters. This paper presents an approach to a real-time two layer text annotation system for social media stream to the domain of natural disasters. The proposed system annotates raw tweets from Twitter into two types such as Informative or Not Informative as first layer. And then it annotates again five information types based on Informative tweets only as second layer. Based on the first and second layer annotation results, this system provides the tweets with user desired informative type in real time. In this system, annotation is done at tweet level by using word and phrase level features with LIBLINEAR classifier. All features are in the form of Ngram nature based on part of speech (POS) tag, Sentiment Lexicon and especially created Disaster Lexicon. The validation of this system is performed based on different disaster related datasets and new Myanmar_Earthquake_2016 dataset derived from Twitter. The annotated datasets generated from this work can also be used by interested research communities to study the social media natural disaster related research.

1. Introduction

Today, online social networking sites like Twitter, YouTube Facebook and Weibo play the important news sources during mass emergencies. Among them, Twitter, the most popular social networking site, provides a wealth of information during a natural disaster. It is often the first medium to break important disaster events such as earthquakes often in a matter of seconds after they occur and more importantly. Recent observation proofs that some events and news emerge and spread first using this media channel rather than other the traditional media like online news sites, blogs or even television and radio breaking news.

People also used social media to share advice, opinions, news, moods, concerns, facts, rumors, and everything else imaginable. Corporations use social media to make announcements of products, services, events, and news media companies use social media to publish near real-time information about breaking news. However, due to questionable source, uncontrollable broadcasting, and small amount of informational tweets among large number of non-informational tweets, Twitter is hardly an actionable source of breaking news.

Tweets from Twitter are highly vary in terms of subject and content and the influx of tweets particularly in the event of a disaster may be overwhelming. It is impractical to generation of efficient features vector based on uniform vocabulary. Therefore, effective feature extraction is first challenge. It is infeasible to automatically classify these varied tweets by using particular annotated corpora for specific messages of every disaster events. Cross event classification is a major challenge.

Another challenge is occurred by the development of supervised learning based systems trained on a single corpus and able to achieve a good performance over a broad range of different events. The annotation of corpus of messages for every disaster by human annotators is obviously time-expensive and practically infeasible on real time manner. Therefore annotation of tweets corpora by human is additional challenge.

In summary, the proposed system is aimed to address these issues by using three main functions: 1. Create annotated disasters corpus of tweets with five labels for Informative tweets on real

[*]S. S. M. Win, U.C.S.M, Email: sisimarwin@gmai.com

time manner. 2. Competitive, easily implementable feature extraction method that act as a benchmark for automated accurate classification approaches for natural disaster related datasets by using natural disaster lexicon. 3. Creation of extended natural disasters lexicon based on publicly available annotated datasets and newly annotated corpus. This paper is an extension of the work originally presented in IEEE/ACIS 16th International Conference on In Computer and Information Science (ICIS) [1]. In the previous work, we identified the tweets into only three labels such as Informative, Not Informative and Other Information as single layer annotation. Therefore, we continue to identify the Informative tweets into more specific information types. Our annotation model in this paper is based on a more relevant and small set of features than our previous work.

The rest of the paper is organized as follow: Section 2 presents the overview of closely related work to this paper. Section 3 explains the methodology that we used in collecting, preprocessing, feature extraction, disaster lexicon creation, and classification scheme used for annotating the tweets. Section 4 describes the architecture of the proposed system. Section 5 expresses the datasets details, experiments and analysis performed. Section 6 summarizes the results from our analysis and highlights the implications of our results. In this section, we also describe the future work of the proposed system.

2. Related Work

This section presents the current state-of-the-art systems, algorithms and methodologies to access the social media data analysis. Social media allows users to exchange small digital content such as short texts, links, images, or videos. Although it is a relatively new communication medium compared with traditional media, microblogging has gained increased attention among users, organizations, and research scholars in different disciplines. There are several researches on social media mining for text based data for classification and prediction of informational posts in different domains.

Among them, the authors in [2] proposed Artificial Intelligence for Disaster Response (AIDR) system to annotate the posts from Twitter into a set of user defined categories such as damage, needs etc. by using hybrid unigram and bigram features. In AIDR system, the tweets were identified into Informative and Non-Informative types during Pakistan earthquake in 2013.

The authors in follow up study automatically and provided human annotated Twitter corpora for 19 different events that occurred between 2013 and 2015. They also experimented their corpora by using the similar features set [3].

The other authors also presented the Tweedr, twitter-mining tool, to retrieve actionable information from Twitter. They applied several different types of features for their CRF clustering. For each token in a tweet, they extracted capitalization, pluralization, whether it is numeric or includes a number, WordNet hypernyms, Ngrams, and part of speech tags to provide specific information about different classes of infrastructure damage, damage types, and casualties [4].

The authors in [5] used six types of features such as Tweet Meta-data Features, Tweet Content Features, User based Features, Network Features, Linguistic Features and External Resource Features for credibility analysis.

They also developed a real time web application, TweetCred, to provide the one of the seven credibility scores of user generated content on Twitter by using 45 features. They tested their application within three weeks period. Their result showed that high credibility tweets were 8% [6].

Moreover, hashtags have been effectively utilized as critical features for various tasks of text or social media analysis, including tweet classification system [7].

In [8], the authors studied the linguistic method to analyze the importance of linguistic and behavioral annotations. They applied the datasets of four crisis events such as Hurricane Gustav in 2008, the 2009 Oklahoma Fires, the 2009 and 2010 Red River Floods, and the 2010 Haiti Earthquake. They observed that the usage of specific vocabulary to convey tactical information on Twitter can achieve higher accuracy than the usage of bag of words (BOW) model for classification of context-aware tweets.

The classification of tweets into Credible or Not Credible was presented in [9]. However, most of the recent research focuses on the information extraction and detection of situational awareness during natural disasters, it is still needed to provide a cohesive pipeline that takes into consideration all of the facets of data extraction.

This system focuses on the content based features set such as Linguistic features, Disaster Lexicon based features, twitter specific features (hashtags and URLs), unigram POS tag features and other salient features from tweet content.

3. Methodology

At the core function of this system is the capability of annotating tweets into predefined information types in real time. We propose, implement and evaluate the approach for determining and assigning a label for each tweet, taking into account terms from the tweet itself and from disaster lexicon. For this study, we first collect the tweets from Twitter. And then we extracted content based features from the collected tweets.

3.1. Data Collection

This function works for tweets collection. It collects messages from Twitter for training and testing using the Twitter streaming API. At first, it collected different annotated datasets published by using annotated tweet_id from Imran et al. [3].

The new data collection process focuses on the exact matching of keywords to acquire tweets and build the query using user defined keywords or hashtags. Using the relevant keywords or hashtags for queries are the best way to extract the most relevant tweets during crisis or disasters. For example, #MyanmarEarthquake hashtag is applied to acquire the news of earthquake that struck in Myanmar.

3.2. Preprocessing

Firstly, this task removes the tweets which already contains the same text in the previous preprocessed tweets to reduce the redundancy and noise by using the cosine similarity.

Secondly, stop-words from tweets are removed to reduce dimensionality of the dataset and thus terms left in the tweets can be identified more easily by the feature extraction process. Stop-words are common and high frequency words such as “a”, “the”, “of”, “and”, “an” “in” etc. [10]. User mention and URLs are also eliminated.

Finally, we used lemmatization instead of stemming to convert all the inflected words present in the text into a base form called a lemma. For the purpose of lemmatization, the proposed system uses Stanford Core NLP.

3.3. Feature Extraction

The most important step in text analysis using supervised learning techniques is generating feature vectors from the text data or documents. This work is intended to build a real time system based on tweets from Twitter, feature extraction is therefore concerned with altering tweet contents into a simple numeric vector representation.

In our previous work, we used hybrid unigram and bigram, unigram Brown cluster, unigram part of speech (POS) tags, number of hashtags, number of URLs and two lexicon based features such as NRC hashtags lexicon and our disaster lexicon as our features set. We found these features outperform the neural word embeddings and only hybrid unigram and bigram features.

According to the constant vocabulary, hybrid unigram and bigram features outperforms the classification of same events (i.e. the training and test datasets are equal). However we need to annotate the unknown disaster events and the contents described for different events may have different vocabulary. Even the same type disaster events may contains the different language style.

The analysis of social media data is heavily rely on the ability to analyze text data. However, there are some unique considerations in the analysis of social media data that make it different than a normal text mining analysis. To overcome the informal social media data to be formal consideration, text in tweets are tokenized using ARK Tweet NLP [11]. This process receives the tweets from preprocessing step, it extracts the features by using ARK POS tagger and different lexicons. The features used in this work are only extracted from tweet contents.

To derive the most relevant feature, this work investigated the three types of feature extraction methods. The first one is BOW model with unigram and bigram based features used in AIDR. The second is the neural word embeddings (WE) model and the last one is the proposed content based features model.

This system proposes the features set based on the following observations:

1. Messages in tweets written by users for same disaster type may have composed of same terms. It is usually the case that the same disasters have the same terms such as shake, strike, magnitude for disaster earthquake.
2. Different natural disaster related tweets may have composed of same terms such as need, pray, pray for, damage, death, destroy, survivor, etc. and may have same syntactical style such as POS tag.
3. Similar words have similar distributions of words to their immediate left and right [11].
4. If a tweet contain more than two hashtags in its content, it may not be information tweet.
5. In crisis related tweets, hashtag may be assumed as topic word or keyword of these tweets.
6. Informative tweets may contain numerical word and URL.

Based on these observations 1 and 2, we decided to create and use Disaster Lexicon and word Ngrams. According to observation 3, we use Brown Word cluster. We also use number of hashtags and hashtag term, URL and numeral features due to the observation 4, 5 and 6. Ngrams POS features are used according to the observation 2. The proposed features used in this system are shown in Table 1.

Table 1. Features used in the proposed system

Feature	Explanation
Brown Cluster Ngrams	Unigram and Bigram of 1000 Brown clusters in Twitter Word Clusters made available by CMU ARK group
Count of disaster related terms	Number of disaster related terms as informative words in a created lexicon for disaster tweets.
Total PMI Score of disaster related terms	Total PMI scores of unigrams and bigrams words that occurred in the tweet and listed as strongly correlated with natural disaster in a disaster lexicon for tweets
Count of non-informational terms	Lexicon creation function of this system also identifies a set of terms which appear only in Not-Informative tweets across all natural disasters datasets.
Total PMI Score of non-informational terms	Total PMI Score for each set of unigrams, bigrams that mostly occur in the Not informative tweet.
Count of numerals	Expected to be higher in situational tweets which contain information such as the number of casualties, emergency contact numbers.
POS tag	Unigram part of speech tags that occur in the Tweet generated by CMU ARK POS-Tagger
Word Ngrams	Unigram and bigram of terms from Disaster Lexicon

To extract neural word embeddings (WE) features for baseline model, this system used Word2vec model in Deep Learning4J [12]. Word2Vec is the representations of words with the help of vectors in such manner that semantic relationship between words preserved as basic linear algebra operations. The following parameters were used while training for Word2Vec: 100 dimensional space, 10 minimum words and 10 words in context. After transforming 100 dimension feature vector of each word in the corpus, this system used t-Distributed Stochastic Neighbor embedding (t-SNE) technique to reduce from 100 dimensions of each feature vector to 10 dimensions feature vector.

3.4. Extended Disaster Lexicon Creation

This system creates the disaster lexicon which contains specific natural disaster related terms with a point wise mutual information (PMI) based score and frequency distribution of these terms based on the set of annotated disaster datasets. This lexicon creation

process follows the method of Olteanu et al. [13]. In this process, we exploit their natural disaster related datasets, the other available natural disaster related datasets [2] and newly annotated dataset such as Myanmar_Earthquake_2016 dataset which are collected by proposed system for lexicon expansion or keywords (disaster related terms) adaptation.

The disaster creation process consists of two main parts. At first, to obtain the most relevant disaster terms, we create various disaster lexicons based on different datasets of same disaster type. For example, this work uses all available earthquake datasets such as 2015_Neapl, 2014_Chile, 2014_Calfornia and 2016_Myanmar earthquakes for creation of Earthquake Lexicon. In this phase, we used equal number of Informative and Not informative tweets for each disaster datasets based on same disaster types.

At second, we combined the different disaster lexicons into one master disaster related lexicon with unique unigram and bigram terms. In this step, we calculate the mean PMI score for the terms which are contained in the two or more lexicons.

The score of a term could be calculated from the PMI value of a term t in an informative context PMI (t, informative) and the same term in a non-informative context PMI (t, non-informative) using the equation:

$$InfoScore = PMI\ (t, informative) - PMI\ (t, non\text{-}informative) \quad (1)$$

Here PMI (t, informative) and PMI (t, non-informative) are calculated using:

$$PMI\ (t, orientation\ ) = log_2 \frac{freq(t, orientation).N}{freq(t).\ freq(orientation)} \quad (2)$$

Where, freq (t) is the number of times term t appears in a tweet, while *N* is total number of terms in the tweet.

This automatically created lexicon is used in feature extraction process of the proposed system.

3.5. Feature Selection

Feature selection is an important problem for text classification. In feature selection, this work attempts to determine the features which are most relevant to the classification process. This is because some of the words are much more likely to be correlated to the class distribution than others. This system applied the information gain based feature selection method which is widely used for text classification.

Information gain (IG) measures the amount of information in bits about the class prediction, if the only information available is the presence of a feature and the corresponding class distribution. n this method, let P_i be the global probability of class *i*, and $P_i\ (w)$ be the probability of class *i*, given that the document contains the word w. Let *F(w)* be the fraction of the documents containing the word w. The information gain measure *I(w)* for a given word *w* is defined as follows:

$$I(w) = -\sum_{i=1}^{k} P_i\ .\log\ (P_i) + \ F(w).\sum_{i=1}^{k} P_i(\mathrm{w})\ .\log\ (P_i(w)) +$$

$$(1 - F(w)).\sum_{i=1}^{k}(1 - P_i(\mathrm{w}))\ .\log\ (1 - (P_i(w)) \quad (3)$$

The greater the value of the information gain *I(w)*, the greater the discriminatory power of the word *w*.

3.6. Annotation of Social Media Text

This system assess annotation of tweets by using supervised machine learning technique. This technique automatically classifies the information contained in tweets. To perform the annotation task, the proposed system trained a LIBLINEAR classifier operating on extracted features set. LIBLINEAR solves large-scale classification problems in many applications such as text classification. It is very efficient for training large scale. It takes only several seconds to train more than 600,000 examples while a Library for Support Vector Machines (LibSVM) takes several hours for same task [14].

Given a set of features and a learning corpus (i.e. the annotated dataset), the classifier trains a statistical model using the feature statistics extracted from the corpus and then annotates the tweets into Informative or Not Informative. This trained model is then employed in the classification of unknown tweets and, for each tweet, it assigns the probability of belonging to a class: Related and Informative as Informative, Not Related or Not applicable as Not Informative in first layer annotation. And then based on the Informative tweets, this system annotates again these informative into one of five types such as infrastructure damage, caution and advice, dead or injured people, needs and offer and Donations and volunteering as second layer annotation. The annotated datasets required by the system can be obtained from three sources such as AIDR, CrisisNLP which is the collection of tweets from 19 natural and man-made disasters and CrisisLexT26 which is the collection of tweets from 26 Crises [2, 3, 13]. This system uses datasets in English language only.

4. Architecture of the proposed System

The holy grail of text annotation is an automated system that accurately and reliably annotates very large numbers of cases using relatively small amounts of manually annotated training data. This work is intended to develop a two layer annotation system that automatically creates the different disaster datasets with annotated tweets. In this system, annotation is restricted to tweets in English language. Non-English tweets are not considered. Non-English tweets are not considered.

The system, illustrated in Figure, first collects the tweets from Twitter by using user desired query terms or target disaster related terms. After collecting the tweets, it removes the redundant tweets by using tweet_id and then it also eliminates the stop-words. In feature extraction, this system applies Linguistic features such as Brown cluster, Syntactic feature such as POS features, Lexical features using disaster lexicon and the other Twitter centric features such as Hashtags and URLs.

This system also analyzed which features are important in the data to annotation. It applied the annotated corpus to train a classifier that automatically annotates the tweets.

To improve model performance, the best set of 300 features were chosen by using Information gain theory based feature selection method.

In the ground truth annotation process, LIBLINEAR classifier uses these selected features subset for tweets categorization to create annotated corpus with Informative or Non-informative tweets and to provide informative tweets to the users.

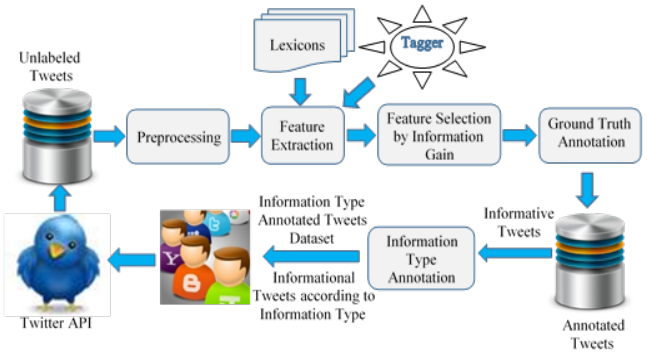

Figure 1: Architecture of the Proposed System

After annotating the collected tweets into one of the five information types, his system provides the informational tweets to users based on their desired type of information.

5. Experiments

This system performs a set of preliminary experiments to evaluate the effectiveness of feature extraction, feature selection model and classifier model on the performance of the proposed approach. For feature extraction, the proposed system applied three models such as neural word embedding, BOW with Unigram and Bigram model and the proposed model.

The final experiment is done under the best development settings in order to evaluate the classifier model with the best feature set. This section presents experiments and results for classification of four annotated datasets. The results along with the experimentation of different datasets are described based on accuracy, precision, recall, and F1 score of classifier model for feature extraction performance.

5.1. Datasets and Setting

In order to evaluate the effectiveness of the proposed social media text annotation strategies for identifying informative tweets during natural disasters events, the experiments of this system used people freely available 10 annotated natural disaster datasets . These datasets are already annotated with different information types.

To reduce the noise in training data, this system discarded all the following tweets.

1. The tweet where an information type clash is observed. An information type clash is a tweet that may happen two or more different type and may ambiguous in the dataset.

2. "Not labeled" tweets.

3. "Animal Management" are also eliminated.

The tweets with similar information types such as "Infrastructure damage" and "Infrastructure and utilities" are combined as "Infrastructure and utilities". "Injured or dead people", "missing or found people", "displaced people and evacuation" and "personal updates" tweets are combined as "Affected individuals" and "donation needs or offer volunteering services" and "Money" are also combined as "Donations and volunteering".

Before training the corpus for second layer annotation, the informative tweets with non-specific information type such as "Other Useful Information" are also discarded.

Detailed information of datasets is described in Table 2 and Table 3. In this table Type 1 refers to the information type "Affected individuals", Type 2 refers to "Infrastructure and utilities", Type 3 means "Donations and volunteering", Type 4 is "Caution and advice", and Type 5 refers to "Sympathy and emotional support".

Table 2. Natural disaster datasets details including disaster type, name, number of informative tweets, number of Not Informative tweets and total tweets.

Type	Disaster Name	Info	Not-Info	Total
Floods	2013_Queensland_floods (QF)	728	281	1009
Bushfire	2013_Australia_bushfire (AB)	691	261	952
Typhoon	2013_Typhoon_Yolanda (TY)	765	175	940
Wildfire	2012_Colorado_wildfires (CW)	685	247	932
Earthquake	2014_Chile_earthquake (ChiE)	1834	179	2013
Floods	2013_Colorado_floods (CF)	589	190	779
Earthquake	2014_Costa_Rica_earthquake (CE)	842	170	912
Floods	2014_Manila_floods (MF)	628	293	921
Floods	2012_Phillipines_Floods (PF)	761	145	906
Floods	2013_Alberta Floods (AF)	684	297	981
Floods	2014_India_floods (IF)	940	396	1336

Table 3. Natural disaster datasets statistics for five information types

Dataset	Type 1	Type 2	Type 3	Type 4	Type 5
QF	207	113	55	114	17
AB	199	65	35	70	33
TY	77	106	383	20	63
CW	44	128	62	69	25
NE	6	165	239	1215	458
IF	30	792	42	51	25
ChiE	55	3	70	14	58

The proposed system performed 10 fold cross validation to test the efficiency of the feature extraction and the model. In the experiments of classification, the proposed system used the set of tweets from five natural disasters such as 2013_Queensland_floods denoted by QF, 2013_Australia Bushfire as AB, the set of tweets for 2013_Typoon_Yolanda as

TY, 2012_Colorado_wildfires as denoted by CW, and the set of tweets from 2012_Costa_Rica_Earthquake as CE respectively.

5.2. Effectiveness of Feature Extraction

To choose the best classification model, we tested the extracted feature set on four different classifiers such as Random Forest, Sequential Minimal Optimization (SMO) which is the fast training algorithm for Support Vector Machine (SVM), Naïve Bayes and our LIBLINEAR classifier that are well known in text classification process. Due to the experiments on the previous work, the performance of Random Forest, Naïve Bayes and SMO was sensitive to the large number of features. Therefore, this system used LIBLINEAR classifier with Information Gain based feature selection method to get better performance and to reduce inconsistent features. This wok uses a well-known WEKA machine learning tools for implementation of Random Forests, Naïve Bayes, SMO, LIBLINEAR and Information Gain based feature selection methods [15]. The results of our previous work are described in [10]. Due to these results, we selected the LIBLINEAR classifier as our classification model.

In this work, the proposed feature extraction method and two baseline methods are evaluated by experiments on ten datasets. To compare the performance of the different feature-models (using LIBLINEAR classifier) under three scenarios such as (i) in-domain classification, (ii) cross event classification and (iii) cross-domain classification, where the classifier is trained with tweets of one event, and tested on another event are considered in this system.

5.2.1. In Domain Classification

In this type of classification, the classifier is trained and tested with the tweets of the same event. To evaluate the in-domain performance of each model, the proposed system followed a 10-fold cross validation process: each dataset was randomly split in 10 different non overlapping training and test sets. The Accuracy, Precision, Recall and F-Measure were calculated as the weighted average of these values over all the 10 test sets.

Table 4. Classification results in terms of Precision, Recall, F-Measure and Accuracy across Informative and Not Informative classes.

Test Data	Feature Extraction Model								
	Weighted Avg. P			Weighted Avg. R			Weighted Avg. F-M		
	BOW	P	WE	BOW	P	WE	BOW	P	WE

AB	**0.772**	0.754	0.567	**0.79**	0.765	0.753	0.768	0.758	0.647
TY	0.797	**0.802**	0.685	**0.825**	0.816	0.828	0.788	**0.807**	0.750
CW	0.813	**0.815**	0.676	0.818	**0.820**	0.714	0.711	**0.817**	0.633

Table 4 represents a summary of evaluation for in domain classification by weighted average Precision (P), Recall (R) and F-Measure (F-M) of the classification results on four datasets.

According to the results, BOW with hybrid unigram and bigram model would perform relatively well in in-domain classification, since the training event and test event share a common vocabulary. However, the performances of the proposed features model is as good as BOW method.

5.2.2. Cross Event Classification

In this type of classification, where the classifier is trained with tweets of one event, and tested on another event. The result is significant since it shows that good classification can be achieved even without considering the type of disasters.

Table 5, Table 6, Table 7 and Table 8 also show the cross event classification performance on AB, TY, CW and QF dataset as training and the remaining datasets as testing data using the features sets extracted by the baseline method, proposed method and neural word embeddings method. The results in these tables indicated that the proposed method yields a high accuracy by using the LIBLINEAR algorithm in predicting certain classes in cross event classification.

AB	0.772	**0.817**	0.76	0.727	**0.831**	0.60	0.743	**0.818**	0.62
TY	0.771	**0.76**	0.76	0.641	**0.793**	0.65	0.672	**0.755**	0.68
CW	0.759	**0.795**	0.75	0.73	**0.808**	0.62	0.741	**0.799**	0.64

According to the experimental results, the performance of the BOW (hybrid unigram and bigram) and WE models is significantly inferior to the proposed model for cross-event classification. This is because the training and testing datasets (related to two different disaster events) have very different vocabularies. On the other hand, the classifier based on the proposed features significantly out-perform these two models in all cases. This implies that the selected features can separate between Informative and not-Informative tweets irrespective of the vocabulary and linguistic style related to specific events. Thus, classifiers can be trained over these features extracted from past disasters, and then deployed to classify tweets posted during future events.

5.2.3. Cross Domain Classification

In cross domain classification, to assign one of the two classes for first layer annotation and one of the five predefined categories (e.g. Affected individuals, Infrastructure and utilities, Donations and volunteering, Caution and advice, Sympathy and emotional support etc.) for second layer annotation to the tweet, the classifier requires sufficient training examples to learn about each pre-defined category. The proposed system used multiple past disasters of various types to train the classifier to robustly identify the different types of tweets for future natural disasters. The experiment for two classes classification (i.e. Informative and Not Informative), the proposed system used the set of tweets from Philippines (PF), Colorado (CF), and Queensland floods (QF) as the training set, denoted by PCQ, the set of tweets for Manila floods as the development set, denoted by MF, and the set of tweets from Alberta and Sardinia floods as two independent test sets, denoted by AF and SF, respectively. The results of this experiment are shown in Table 9.

Table 9. Experiments performed using the combined 2012_Philipinnes_flood, 2013_Colorado_floods and 2013_Queensland_floods as training set

Train /Test	Accuracy	Precision	Recall	F-Measure
PCQ/MF	80.34%	0.8609	0.803	0.808
PCQ/AF	76.47%	0.754	0.76476	0.7414
PCQ/SF	66.58%	0.6463	0.66579	0.6121

In the other experiments over five classes or multi-classes classification, this system combined the three or four datasets of different disaster types as training and the other one for testing data. For example, taking Colorado floods, Costa-Rica-earthquake, Philippine floods, Pablo-typhoon and Australia-Bushfire (CCPPA) as training dataset and the other datasets as individual test data. The classification results are shown in Table 10. Table 11 shows the classification results over the five classes of LIBLINEAR with 10-fold cross validation for six datasets by using three feature models.

Table 10. Classification results in terms of Precision, Recall, F-Measure across all five classes.

Train /Test	Accuracy	Precision	Recall	F-Measure
CCPPA/MF	72.3%	0.7308	0.723	0.719
CCPPA/TY	64.9%	0.72	0.649	0.663
CCPPA/CW	86.4%	86.8%	0.864	0.862
CCPPA/ChiE	79.5%	0.8214	0.795	0.7908

Table 11. Classification results across five classes using (i) (BOW), (ii) Proposed (P) (iii) Word Embeddings (WE)

Test Data	Feature Extraction Model								
	Weighted Avg. P			Weighted Avg. R			Weighted Avg. F-M		
	BOW	P	WE	BOW	P	WE	BOW	P	WE
QF	0.56	**0.581**	0.25	0.56	**0.586**	0.415	0.549	**0.576**	0.287
AB	0.537	**0.583**	0.22	0.569	**0.607**	0.465	0.532	**0.582**	0.295
TY	0.694	**0.701**	0.36	**0.724**	0.713	0.596	0.695	**0.705**	0.445
CW	0.653	**0.67**	0.18	0.64	**0.681**	0.427	0.631	**0.666**	0.255
NE	**0.749**	0.712	0.67	**0.761**	0.726	0.681	**0.738**	0.713	0.666
CE	0.757	0.78	0.58	0.783	**0.79**	0.76	0.754	**0.78**	0.658

According to the results in Table 10 and 11, the performance of LIBLINEAR classifier with proposed feature model outperforms the BOW and WE models in most cases and it can identify informational tweets at 67% accuracy on average. The performance of BOW and WE models sometime close to less than 20 %. This indicates that lexical features are critical to solve the ambiguous of information types.

5.3. Effectiveness of Annotation

In this section, the validation of this system on a real disaster study by classifying the data of Myanmar earthquake collected by Twitter API. The 6.8 magnitude earthquake that struck Myanmar on August 24th , 2016 is among the strongest in recent Myanmar history. The shaking was clearly perceived in all Central and Northern Myanmar and caused 4 deaths and several damage to the Pagodas of the area of Bagan. This dataset is crawled for a three days period from August 24th to 26th , 2016 by using the hashtags (#Myanmar, #Bagan, #earthquake, #Myanmarearthquake). And then it was randomly selected 1,800 tweets and was manually annotated based on the available news media in Myanmar such as Myanmar Times, The Global New Light of Myanmar and The Mirror.

Table 12. First Layer Annotation Results of Proposed features by LIBLINEAR

Dataset	Precision	Recall	F1	Accuracy
AB	0.897	0.895	0.895	89.45%
TY	0,912	0,92	0,913	92,02%
IF	0.908	0.908	0.908	90.82%
NE	0.748	0.751	0.749	75.05%

Table 13. Second Layer Annotation Results of Proposed features by LIBLINEAR

Dataset	Precision	Recall	F1	Accuracy
AB	0.682	0.693	0.685	69.31%
TY	0.768	0.786	0.774	78.60%
NE	0.815	0.843	0.828	84.26 %
IF	0.731	0.782	0.755	78.18 %

Base on cross domain classification over all five classes where we train the classifier on one dataset and test on another dataset, the experimental results using 2012-Costa-Rika- and 2014_Chile Earthquake as training data and Myanmar Earthquake as test data confirmed the expected classification of this work.

Myanmar_Earthquake_2016 was successfully annotated with predefined two labels at 75% accuracy on average and five labels also 74 % which is pretty high. The results of each annotation layer for four datasets are shown in Table 12 and Table 13.

5.4. Real Time Annotation

We showed a proof of real time model which takes a direct stream of new tweets as input test set and takes manually annotated tweets from previous disaster as training set, and then uses automated techniques to annotate the new tweets.

In the first layer, this system annotated the tweets into Informative if the tweets contain the information about the target disaster and Not informative for the remaining tweets. In the second layer, each informative tweet from previous layer is annotated into one of the five information types with respect to the information that contained in it.

To do this, we developed and deployed a real time system in the form of a Web application using Java 2 Platform Enterprise Edition (J2EE) and Twitter API binding library (Twitter4j). We analyzed the deployment and usage activity of our application from 24th August, 2016 to 28th August, 2016 which was the day of earthquake and days after an earthquake in Myanmar. For analysis and statistics, we collected the annotated datasets of our system for only three days period since August 24th to August 26th. In real time annotation process, we used the combined 2014_Chile_Earthquake and 2015_Nepal_Earthquake as training set. The number of collection and annotation times per day is 6. Each collection time is 4 minutes for 2000 tweets and annotation time is only 1 minute for each layer. Among the collected tweets, 62% of tweets are retweets and half of them are redundant tweets. Most of them are similar in text. Although the number of tweets collected in each time was 2000, the number of tweets annotated by our system is at most 750 because of the tweet cleaning step in preprocessing. The tweets in annotated datasets from each day are also redundant. The total unique automatically annotated tweets over three days, are nearly 2000.

After manually annotating the tweets, we compared the automatically annotated tweets from our system with manually annotated tweets to obtain the performance of our real time system. The manual annotation process is described in the previous section. According to the analysis results, the annotation accuracy of new tweets by our system is 80% in first layer and 74 % on second layer annotation.

5.5. Findings and Discussion

As mentioned above this system used 10 datasets for training and testing for evaluating classifier models and feature extraction models. Another new dataset for testing again for overall performance of the proposed system. According to the initial experimental results of BOW and word embeddings were very sensitive and depend on the vocabulary. The results of three feature extraction methods, the proposed method always outperforms the other two methods. Therefore, the proposed feature extraction model with LIBLINEAR classifier was chosen for second layer annotation process for categorizing the tweets into five specific frequently found information type.

6. Conclusion

Social media mining for disaster response and coordination has been receiving an increasing level of attention from the research community. It is still necessary to develop automated mechanisms to find critical and actionable information on Social Media in real-time. The proposed system combines effective feature extraction using NLP and machine learning approach to obtain the annotated datasets to improve disaster response efforts. Expanded disaster lexicon is also used to extract the relevant disaster related lexical features for annotation.

The proposed feature extraction method significantly outperforms the standard bag of words model and neural word embeddings model. By using LIBLINEAR classifier based on the proposed method, this system successfully annotated five information types to the Myanmar Earthquake data at 74% accuracy on average. In future, we will investigate the specific variation of terms over different disasters to perform annotation on all disaster types. We hope to formalize disaster lexicon in more detail to improve cross domain classification accuracy.

ABSTRACT

This paper proposes the modeling and control of a Solid-State Transformer using a three-stage conversion topology. First, a rectification stage is used, where a three-phase high-voltage AC signal is converted to a DC level; this stage is then followed by a DC-DC converter, and finally an inverter is used to convert the DC into a three-phase low-voltage AC signal. The adopted topology is modeled using a simplified model for each stage, useful to design their controllers. Based on these models, the controllers are tuned to obtain a good performance to sudden load changes. This performance is tested through simulations.

1 Introduction

It is necessary to mention that this paper is an extension of work originally presented in [1]. This extension includes a detailed description of the proposed models and controllers. These models are used for tuning the controller parameters in order to obtain good performance in presence of sudden load changes.

Solid-State Transformers (SST) are emerging as a new technology capable of replacing power distribution transformers [2]. It is expected that the next generation of the power distribution transformers is based on power electronics semiconductor devices [3]. By using these semiconductors, it is possible to design an apparatus based on power converters with smaller and lighter high-frequency transformers. In this way, it is possible to obtain a smaller and lighter distribution transformer when compared with a traditional transformer of the same power rating. Roughly speaking, SSTs work as follows. In a first stage a sinusoidal signal of, typically, 50 or 60 Hz is converted to a high-frequency signal. Then, the amplitude of this signal is changed, by using a small high-frequency transformer, and finally in a third stage a new signal of the same frequency as the input signal but different amplitude is obtained.

Several topologies for the SST can be found in the literature, with their advantages and disadvantages [4]. In addition, it is possible to find some reviews dealing with the subject [5, 6]. Applications in transportation and smart grid can be found in [7]; whereas a topology based on SiC devices can be found in [8]. Also, a traditional transformer and an SST were compared in [9], and a procedure to obtain a detailed model of an SST topology can be found in [10].

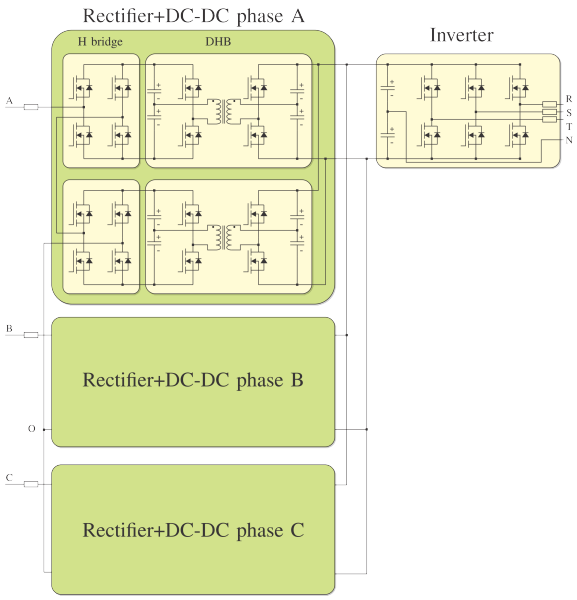

Figure 1: SST topology.

*Corresponding author, sebastian.gomezjorge@uns.edu.ar

A three-stage SST is considered in this paper [7]. Its topology is shown in Figure 1. The three stages are: a rectification stage, where a three-phase high voltage (HV) AC grid voltage is converted to a DC signal, a DC-DC converter stage (multiple stages in parallel) that provides isolation and performs the level adaptation, and finally, an inverter stage that converts the DC signal into a three-phase low voltage (LV) AC sinusoidal wave.

In this paper, simple models for each stage are proposed. Using these models, the required controllers are designed and their parameters are tuned to obtain a good performance in presence of sudden load changes. In order to test the performance of the proposed controllers, simulations results are introduced.

2 Proposed SST topology and model

Figure 2 shows a general diagram of the chosen topology. The SST is composed of a bidirectional multi-level HV three-phase converter, labeled Rectifier, six bidirectional isolated DC-DC converters, labeled DHB1 through DHB6, and a bidirectional LV three-phase converter with neutral, labeled Inverter. This topology has a great degree of modularity, allowing to consider the converters as decoupled systems and simplifying the design of the controllers [7].

Each converter and its simplified model is described below. Since the controllers are implemented using digital control techniques, the models are described in discrete time, assuming a sampling time T_s.

2.1 Rectifier

The rectifier is a three-phase AC-DC converter connected to the HV grid. As shown in Figure 2, the rectifier input port is modeled as a three-phase controlled voltage source $v_{rec} = [v_{reca}\ v_{recb}\ v_{recc}]^T$, coupled to the HV grid voltage $v_{hv} = [v_{hva}\ v_{hvb}\ v_{hvc}]^T$ through an inductor with current $i_{hv} = [i_{hva}\ i_{hvb}\ i_{hvc}]^T$. This coupling filter is modeled using complex vector notation (see Appendix). The zero order hold (zoh) discrete time model of the coupling filter results:

$$\vec{i}_{hv}[k+1] = \frac{T_s}{L_{rec}}\left(\bar{\vec{v}}_{hv}[k] - \vec{v}_{rec}[k]\right) + \vec{i}_{hv}[k], \qquad (1)$$

where $\bar{\vec{v}}_{hv}[k] = 0.5(\vec{v}_{hv}[k+1] + \vec{v}_{hv}[k])$ is the mean value of the HV grid voltage in the time interval $T_s k$, $T_s(k+1)$.

The output ports of the rectifier are modeled as current sources i_{iX}, with $X = 1 \ldots 6$. These currents are computed through power balance. Considering that both H bridges of each phase of the rectifier are given the same reference, it can be found that their currents are equal:

$$i_{i1}[k] = i_{i2}[k] = \frac{v_{reca}[k] i_{hva}[k]}{V_{busH1}[k] + V_{busH2}[k]}, \qquad (2)$$

$$i_{i3}[k] = i_{i4}[k] = \frac{v_{recb}[k] i_{hvb}[k]}{V_{busH3}[k] + V_{busH4}[k]}, \qquad (3)$$

$$i_{i5}[k] = i_{i6}[k] = \frac{v_{recc}[k] i_{hvc}[k]}{V_{busH5}[k] + V_{busH6}[k]}. \qquad (4)$$

Note that in this rectifier model, the independent variables (control inputs) are the three-phase components of $v_{rec}[k]$.

2.2 Dual Half Bridge (DHB)

Since there are six isolated DC buses in the rectifier, there are six DC-DC converters which are implemented using the DHB topology, which are modeled as current sources. The coupling between the output ports of the rectifier and the input port of each DHB is performed through a capacitor. The voltage across each of these capacitors is modeled through the difference equation:

$$V_{busHX}[k+1] = \frac{T_s}{C_H/2}\left(i_{iX}[k] - i_{oX}[k]\right) + V_{busHX}[k], \quad (5)$$

with $X = 1 \ldots 6$. The DHBs themselves are controlled using a phase shift strategy. Therefore, each converter can be modeled through the algebraic equation for their average power transfer [11]:

$$P_{dhbX}[k] = \frac{V_{busHX}[k]\ m V_{busL}[k] \delta_X[k] \left(\pi - |\delta_X[k]|\right)}{8\pi^2 L_d f_{sw}^{dhb}}, \quad (6)$$

where m is the DHB transformer relation, L_d is the total leakage of the transformer referred to the HV side, f_{sw}^{dhb} is the switching frequency of the DHB converter, and δ_X is the phase shift angle between the voltages generated at the HV and LV sides of the DHB under consideration. Dividing this power by $V_{busHX}[k]$, it results

$$i_{oX}[k] = \frac{m V_{busL}[k] \delta_X[k] \left(\pi - |\delta_X[k]|\right)}{8\pi^2 L_d f_{sw}^{dhb}}, \qquad (7)$$

which describes the relation between input port i_{oX} and the control action δ_X. The outputs of all the DHBs are connected in parallel, and feed the LV bus. The relation between the input signals and the output signals is obtained through power balance, as described in the following equation:

$$i_{dhbX}[k] = \frac{i_{oX}[k] V_{busHX}[k]}{V_{busL}[k]}. \qquad (8)$$

Note that in this DHB model, the independent variable (control input) for each DHB is δ_X.

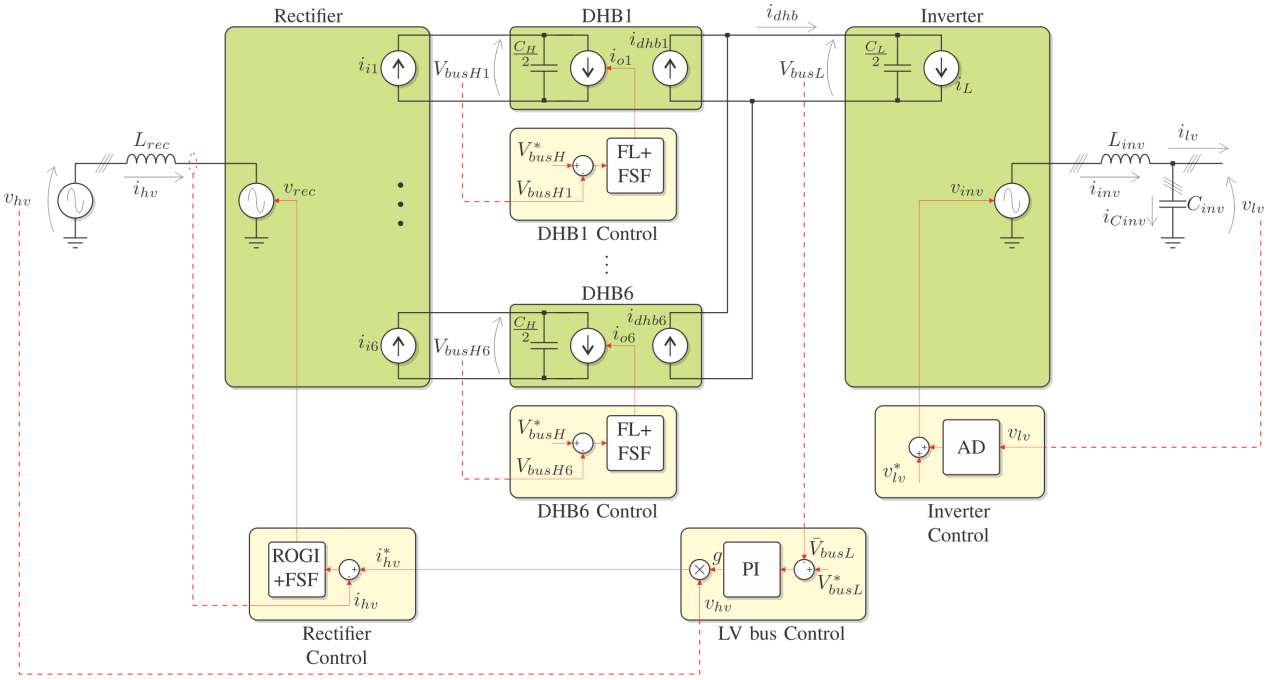

Figure 2: SST topology, model and general control scheme.

2.3 Inverter

The inverter is a three-phase DC-AC converter connected to the LV grid. The input port is modeled as a controlled current source i_L, and the output port is modeled as a three-phase controlled voltage source $v_{inv} = [v_{invr}\ v_{invs}\ v_{invt}]^T$. The load voltage and current are $v_{lv} = [v_{lvr}\ v_{lvs}\ v_{lvt}]^T$ and $i_{lv} = [i_{lvr}\ i_{lvs}\ i_{lvt}]^T$, respectively.

The coupling between the output ports of the DHBs and the input port of the inverter is performed through a capacitor. The voltage across this capacitor is modeled through the difference equation:

$$V_{busL}[k+1] = \frac{T_s}{C_L/2}\Big(i_{dhb}[k] - i_L[k]\Big) + V_{busL}[k], \qquad (9)$$

where

$$i_{dhb}[k] = \sum_{X=1}^{6} i_{dhbX}[k]. \qquad (10)$$

The coupling between the load and the output port of the inverter is performed by an LC filter. Since each leg of the inverter is controlled as a single phase converter, the zoh discretization of this filter is given for each phase of the inverter. This is denoted with subscript Y, which can be equal to r, s or t:

$$x_{invY}[k+1] = A_{inv}x_{invY}[k] + B_{inv}v_{invY}[k] + B_{inv1}i_{lvY}[k], \qquad (11)$$

where $x_{invY}[k] = [i_{invY}[k]\ v_{lvY}[k]]^T$,

$$A_{inv} = \begin{bmatrix} \cos\left(\frac{T_s}{\sqrt{C_{inv}L_{inv}}}\right) & -\sqrt{\frac{C_{inv}}{L_{inv}}}\sin\left(\frac{T_s}{\sqrt{C_{inv}L_{inv}}}\right) \\ \sqrt{\frac{L_{inv}}{C_{inv}}}\sin\left(\frac{T_s}{\sqrt{C_{inv}L_{inv}}}\right) & \cos\left(\frac{T_s}{\sqrt{C_{inv}L_{inv}}}\right) \end{bmatrix}, \qquad (12)$$

$$B_{inv} = \begin{bmatrix} \sqrt{\frac{C_{inv}}{L_{inv}}}\sin\left(\frac{T_s}{\sqrt{C_{inv}L_{inv}}}\right) \\ 1 - \cos\left(\frac{T_s}{\sqrt{C_{inv}L_{inv}}}\right) \end{bmatrix}, \qquad (13)$$

$$B_{inv1} = \begin{bmatrix} 1 - \cos\left(\frac{T_s}{\sqrt{C_{inv}L_{inv}}}\right) \\ -\sqrt{\frac{L_{inv}}{C_{inv}}}\sin\left(\frac{T_s}{\sqrt{C_{inv}L_{inv}}}\right) \end{bmatrix}. \qquad (14)$$

As in the previous converters, the relation between the input signals and the output signals is obtained through power balance, as described in the following equation:

$$i_L[k] = \frac{v_{inv}[k] \bullet i_{lv}[k]}{V_{busL}[k]}, \qquad (15)$$

where the $\bullet$ operator denotes scalar product. Note that in this inverter model, the independent variables (control inputs) are the three-phase components of $v_{inv}[k]$.

3 Converter controller description

Figure 2 shows the simplified block diagrams of the proposed controllers for each converter. In this figure, dashed lines represent measured signals, and solid lines in the controllers represent control signals. In what follows, each individual controller is described.

3.1 Rectifier control

This controller is tasked to make the HV grid current i_{hv} to copy the current reference i^*_{hv}. This is

achieved through a full state feedback (FSF) control with the addition of a reduced order generalized integrator (ROGI) [12]. The ROGI is added to achieve zero steady state tracking error, since the current reference is a grid frequency positive sequence three-phase signal. Considering a one sample time processing delay, typical in digital implementations, complex vector notation, and space vector modulation (SVM), the control action is

$$v_{rec}[k] = v^*_{recSVM}[k-1], \tag{16}$$

$$v^*_{recSVM}[k] = v^*_{rec}[k] - v_{mc}[k], \tag{17}$$

$$v_{mc}[k] = 0.5\,(\max(v^*_{rec}[k]) + \min(v^*_{rec}[k])), \tag{18}$$

where max and min functions are computed between the *abc* components of $v^*_{rec}[k]$. Also,

$$\vec{v}^*_{rec}[k] = -K_{rec}\begin{bmatrix}\vec{i}_{hv}[k] - \vec{i}^*_{hv}[k]\\ \vec{v}^*_{rec}[k-1]\\ \vec{r}_1[k]\end{bmatrix}, \tag{19}$$

$$\vec{r}_1[k+1] = j(1-e^{j\omega T_s})\left(\vec{i}_{hv}[k] - \vec{i}^*_{hv}[k]\right) + e^{j\omega T_s}\vec{r}_1[k], \tag{20}$$

with K_{rec} a 1×3 complex gain vector, and $\vec{r}_1[k]$ represents the state of a ROGI tuned at fundamental grid angular frequency ω. As described in [12], gain vector K_{rec} can be found using the linear quadratic regulator method, or by pole placement using Ackerman's formula, and the matrix description of the system:

$$x_{rec}[k+1] = A_{rec}x_{rec}[k] + B_{rec}\vec{v}^*_{rec}[k], \tag{21}$$

where $x_{rec}[k] = [\vec{i}_{hv}[k]\ \vec{v}^*_{rec}[k-1]\ \vec{r}_1[k]]^T$,

$$A_{rec} = \begin{bmatrix}1 & -\frac{T_s}{L_{rec}} & 0\\ 0 & 0 & 0\\ j(1-e^{j\omega T_s}) & 0 & e^{j\omega T_s}\end{bmatrix}, \tag{22}$$

$$B_{rec} = [0\ 1\ 0]^T. \tag{23}$$

The reference i^*_{hv} is the output of the LV bus controller, and it is related to the instantaneous HV grid voltage through

$$i^*_{hv}[k] = g[k]v_{hv}[k], \tag{24}$$

where g is a scalar variable signal. Therefore, depending on the sign of g and assuming v_{hv} sinusoidal with no harmonic distortion, the rectifier will source or sink a three-phase sinusoidal current to the HV grid, with unity power factor. In this paper the closed loop poles are chosen to achieve a settling time of 4.5[ms].

3.2 DHB control

The objective of the DHBs is to transfer the pulsating power of each of the H bridges of the rectifier to the LV bus, where the resulting power is non-pulsating. To achieve this objective, the controller of each DHB is designed to keep its instantaneous voltage V_{busHX} at its reference level V^*_{busH} (which is the same for all six DHBs). As shown by (7), the relation between current i_{oX} and phase-shift angle δ_X is non-linear. In order to be able to apply linear control techniques, a feedback linearization (FL) is implemented. Then, the resulting linear system is controlled through FSF.

Considering a one sample time processing delay, the control action is

$$\delta_X[k] = \delta^*_X[k-1], \tag{25}$$

where

$$\delta^*_X[k] = 0.5\pi\left(1 - \sqrt{1 - 32 f^{dhb}_{sw}\frac{|i^*_{oX}[k]|}{mV_{busL}[k]}}\right)sign(i^*_{oX}[k]), \tag{26}$$

is obtained from (7) and it is the FL equation for the system. Assuming that $V_{busL}[k] \simeq V_{busL}[k-1]$ (slow varying signal), it can be numerically verified that for a given value of $i^*_{oX}[k-1]$, evaluating (26) at $k-1$, and replacing the result in (25) and (7) yields $i_{oX}[k] \simeq i^*_{oX}[k-1]$. Therefore, the linearized system is modeled by (5) and

$$i_{oX}[k] = i^*_{oX}[k-1]. \tag{27}$$

Adding a discrete time backward Euler integrator to achieve zero steady state error, the control action for each DHB is computed as follows:

$$i^*_{oX}[k] = -K_{DHB}\begin{bmatrix}V_{busHX}[k] - V^*_{busH}[k]\\ r_0[k]\\ i_{oX}[k]\end{bmatrix}, \tag{28}$$

$$r_0[k+1] = T_s\left(V_{busHX}[k] - V^*_{busH}[k]\right) + r_0[k], \tag{29}$$

where K_{dhb} is a 1×3 gain vector, and $r_0[k]$ represents the state of the discrete integrator. Once (28) is computed, the phase shift angle δ^*_X is obtained through (26) and applied to the converter.

Gain vector K_{dhb} can be found using the linear quadratic regulator method, or by pole placement using Ackerman's formula, and the matrix description of the linearized system:

$$x_{dhb}[k+1] = A_{dhb}x_{dhb}[k] + B_{dhb}i^*_{oX}[k], \tag{30}$$

where $x_{dhb}[k] = [V_{busHX}[k]\ r_0[k]\ i_{oX}[k]]^T$,

$$A_{dhb} = \begin{bmatrix}1 & 0 & -\frac{T_s}{C_H/2}\\ T_s & 1 & 0\\ 0 & 0 & 0\end{bmatrix}, \tag{31}$$

$$B_{dhb} = [0\ 0\ 1]^T. \tag{32}$$

This scheme makes each DHB source power to the LV bus if its HV bus voltage is higher than V^*_{busH}, or sink power from the LV bus if its HV bus voltage is lower than V^*_{busH}. In this paper the closed loop poles are chosen to achieve a settling time of 1[ms].

3.3 LV bus control

This controller is tasked to keep the mean value of the LV bus voltage ($\bar{V}_{busL}$ in Figure 2) at the reference level V^*_{busL}. In order to do so, signal V_{busL} is filtered (filter not shown in the figure) and then a proportional integral (PI) controller is used. The output of this controller is the variable gain g. This gain is used to properly scale the measured HV grid voltage, and generate the current reference for the rectifier, defined in (24). For this reason, the dynamics of the rectifier control loop and the LV bus control loop must be decoupled. This is achieved by making the bus control loop significantly slower than the rectifier and DHB control loops.

The LV bus voltage is modeled by (9). Since there is no controlled current source directly connected to the LV bus, the design of the controller assumes that i_{dhb} is the control action. Once the control action i_{dhb} is computed, gain g is obtained through power balance:

$$g[k] = \frac{i_{dhb}[k]\bar{V}_{busL}[k]}{3V^2_{nomhv}}, \tag{33}$$

where V_{nomhv} is the nominal rms value of the HV grid voltage. As stated at the beginning of this section, this controller is slow. Therefore, both the processing delay and the dynamics of the filter used to obtain $\bar{V}_{busL}$ can be ignored without significant error. Considering this, and adding a discrete time backward Euler integrator to achieve zero steady state error, the control action is computed as follows:

$$i_{dhb}[k] = -K_{LV}\begin{bmatrix}\bar{V}_{busL}[k] - V^*_{busL}[k] \\ r_{0LV}[k]\end{bmatrix}, \tag{34}$$

$$r_{0LV}[k+1] = Ts\Big(\bar{V}_{busL}[k] - V^*_{busL}[k]\Big) + r_{0LV}[k], \tag{35}$$

where K_{LV} is a 1×2 gain vector, and $r_{0LV}[k]$ represents the state of the discrete integrator. Once (34) is computed, gain g is computed through (33), and used to generate the HV grid current reference i^*_{hv} through (24).

Gain vector K_{LV} can be found using the linear quadratic regulator method, or by pole placement using Ackerman's formula, and the matrix description of the system:

$$x_{LV}[k+1] = A_{LV}x_{LV}[k] + B_{LV}i_{dhb}[k], \tag{36}$$

where $x_{LV}[k] = [V_{busL}[k]\ r_{0LV}[k]]^T$,

$$A_{LV} = \begin{bmatrix}1 & 0 \\ T_s & 1\end{bmatrix}, \tag{37}$$

$$B_{LV} = [\frac{T_s}{C_L/2}\ 0]^T. \tag{38}$$

In this paper the closed loop poles are chosen to achieve a settling time of 100[ms].

3.4 Inverter control

This controller implements the active damping (AD) of the output LC filter resonance. The implementation of the AD requires to measure the current through C_{inv}. To avoid this measurement, an estimator through high pass filter derivation is used. This estimator only requires the measurement of v_{lv}, and only slightly increases the settling time of the control loop. The LV grid voltage reference v^*_{lv} is added to the control action of the AD. This voltage reference is a three-phase balanced sinusoidal signal, which can be generated internally, or can be obtained through a synchronization algorithm in synchronism with the HV grid voltage.

Since each leg of the inverter is controlled independently, there are three equal controllers. In what follows, they are described with subscript $Y = r$, s or t. Considering a one sample processing time, the control action for the active damping strategy is $v_{invY}[k] = v^*_{invY}[k-1]$, where

$$v^*_{invY}[k] = -K_{lv}\begin{bmatrix}\hat{i}_{CinvY}[k] \\ v_{lvY}[k] \\ v^*_{invY}[k-1]\end{bmatrix} + K^*v^*_{lvY}, \tag{39}$$

where K_{lv} is a 1×3 gain vector, K^* is a gain, and $\hat{i}_{CinvY}[k]$ is the estimated capacitor current, obtained from the zoh discretization of a high pass filter:

$$\eta_Y[k+1] = (e^{-\omega_c T_s} - 1)v_{lvY}[k] + e^{-\omega_c T_s}\eta_Y[k], \tag{40}$$

$$\hat{i}_{CinvY}[k] = C_{inv}\omega_c\Big(v_{lvY}[k] + \eta_Y[k]\Big), \tag{41}$$

with ω_c the cut off frequency of the high pass filter, and η_Y the state of the filter.

Gain vector K_{lv} is obtained by pole placement to damp the LC filter resonance using Ackerman's formula, and the matrix description of the system:

$$x_{lv}[k+1] = A_{lv}x_{lv}[k] + B_{lv}v^*_{invY}[k], \tag{42}$$

where $x_{lv}[k] = [i_{invY}[k]\ v^*_{invY}[k-1]\ v_{invY}[k]]^T$,

$$A_{lv} = \begin{bmatrix}A_{inv} & B_{inv} \\ 0\ 0 & 0\end{bmatrix}, \tag{43}$$

$$B_{lv} = [0\ 0\ 1]^T. \tag{44}$$

Finally, gain K^* is included to compensate the magnitude of the LV grid voltage reference, and is obtained evaluating:

$$TF = C_{lv}(z\,I - A^{CL}_{lv})^{-1}B_{lv}\Big|_{z=e^{j\omega T_s}}, \tag{45}$$

$$K^* = |1/TF|, \tag{46}$$

where $A^{CL}_{lv} = A_{lv} - B_{lv}K_{lv}$, I is the 3×3 identity matrix and $C_{lv} = [0\ 1\ 0]$. Note that the controllers for each phase use the same gain vector K_{lv} and gain K^*. In this paper the closed loop poles are chosen for optimal damping ($\zeta = 0.707$). This results in a settling time of approximately 2[ms].

4 Parameter selection criteria

This section gives criteria for choosing the values of the different parameters of each converter.

4.1 Rectifier coupling inductance L_{rec}

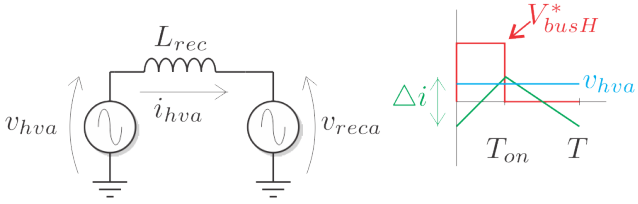

Figure 3: Rectifier phase a and switching interval variables.

The value of L_{rec} is chosen to obtain a desired current ripple $\triangle i$ when injecting zero current to the HV grid. Due to the 5-level structure of the rectifier and the use of unipolar modulation, the effective switching frequency applied to L_{rec} is $4f^{rec}_{sw}$ [1]. Also, this multilevel structure ensures that the voltage difference applied to L_{rec} will never be larger than V^*_{busH} (assuming all the HV buses are kept at that level).

Taking phase a as a reference, Figure 3 shows one switching interval. The current variation in this interval is

$$\triangle i = \frac{T_{on}}{L_{rec}}(v_{hva} - V^*_{busH}). \tag{47}$$

Since zero current injection is assumed, in this interval

$$v_{hva} \simeq V^*_{busH} d, \tag{48}$$

where $d = T_{on}/T$. Therefore, replacing this in (47),

$$\triangle i = \frac{V^*_{busH}}{L_{rec} 4f^{rec}_{sw}}(d^2 - d), \tag{49}$$

where $T = 1/(4f^{rec}_{sw})$ was used. The maximum $\triangle i$ occurs for $d = 0.5$, therefore for this condition, from (49),

$$L_{rec} = \frac{V^*_{busH}}{\triangle i 16 f^{rec}_{sw}}. \tag{50}$$

From Table 1, choosing the peak current ripple $\triangle i/2 = 0.1(\sqrt{2}I_{nomhv})$, the inductance results $L_{rec} = 190$[mH]. From an additional analysis not included in this paper, considering commercially available cores, $L_{rec} = 200$[mH] is chosen.

4.2 DHB transformer leakage inductance L_d

From (6), assuming $V_{busHX}[k] = V^*_{busH}$ and $V_{busL}[k] = V^*_{busL} = V^*_{busH}/m$ the maximum power transfer occurs for $\delta_X[k] = \pi/2$ and results

$$P_{dhbMAX} = \frac{(V^*_{busH})^2}{32 L_d f^{dhb}_{sw}}. \tag{51}$$

Under nominal operation conditions, each DHB will have to transfer a mean power $\bar{P}_{dhb} = S_{nom}/6$. Taking a safety margin of $P_{dhbMAX} = 2\bar{P}_{dhb}$ to catch any transients, and replacing this in (51), the leakage inductance results

$$L_d = \frac{3(V^*_{busH})^2}{32 S_{nom} f^{dhb}_{sw}}. \tag{52}$$

Using the necessary parameters from Table 1 to evaluate (52), it results $L_d = 8.44$[mH]. From an additional analysis not included in this paper, designing L_d considering commercially available cores, it results $L_d = 8.8$[mH] .

4.3 HV bus capacitor C_H

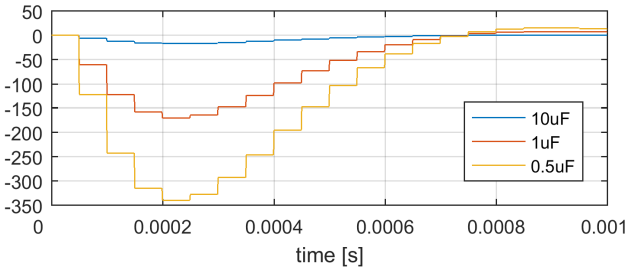

Figure 4: $\triangle V_{busH}$ [V] for a 10% HV grid voltage dip for different values of C_H.

During the event of dips or swells in the HV grid voltage v_{hv}, there will be a transient behavior in each of the HV buses. This can lead to unacceptable under/over voltages in V_{busHX}. The HV buses voltage variations during these transients are determined by the value of C_H, the settling time of each DHB control loop, and the magnitude of the dips or swells. Since the evaluation of these transients involves the DHB control loop, the process is iterative. For a given value of C_H, gain K_{dhb} must be computed. Then, the performance is evaluated through a simple simulation applying the desired dip or swell magnitude. Finally, the process is repeated until the desired performance is attained.

The evaluation is performed considering a step change in the magnitude of v_{hv}. In the following, the worst case scenario for V_{busH1} is analyzed, which is similar for the remaining buses.

The maximum instantaneous power variation in phase a occurs when the rectifier is sinking nominal current, and at the instantaneous peak of $v_{hva}[k]$ its magnitude changes $\triangle v_{hv}$ volts. From (1), assuming that previous to the step $\vec{v}_{hv} \simeq \vec{v}_{rec}$, the magnitude of the change in the HV grid current is

$$\triangle i_{hv} \simeq \frac{T_s}{L_{rec}} \triangle v_{hv}. \tag{53}$$

From (2), assuming that previous to the step $V_{busH1} = V_{busH1} = V^*_{busH}$, the variation in current i_{i1} is

$$\triangle i_i = \frac{\sqrt{2} V_{nomhv} \triangle i_{hv}}{2 V^*_{busH}} = \frac{T_s}{L_{rec}} \frac{\sqrt{2} V_{nomhv} \triangle v_{hv}}{2 V^*_{busH}}, \tag{54}$$

where (53) was used for the last equality. Now the effect of $\triangle v_{hv}$ in V_{busH1}, defined as $\triangle V_{busH}$, is evaluated simulating the closed loop response of the linearized DHB (30)-(32):

$$\triangle x_{dhb}[k+1] = A^{cl}_{dhb}\triangle x_{dhb}[k] + B^{i_i}_{dhb}\triangle i_i, \quad (55)$$
$$\triangle V_{busH}[k] = [1\ 0\ 0]\triangle x_{dhb}[k], \quad (56)$$

where $B^{i_i}_{dhb} = [\frac{T_s}{C_H/2}\ 0\ 0]^T$ and $A^{cl}_{dhb} = A_{dhb} - B_{dhb}K_{dhb}$. Figure 4 shows simulation results for this system for $C_H = 10$ [μF], 1[μF] and 0.5[μF] when a 10% dip is simulated ($\triangle v_{hv} = -0.1V_{nomhv}$) for the DHB control designed with a settling time of 1[ms]. From the results $C_H = 1$ [μF] is chosen, since it results in a 2.5% voltage variation.

4.4 LV bus capacitor C_L

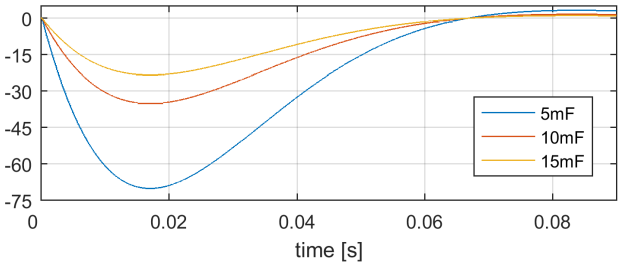

Figure 5: $\triangle V_{busL}$ [V] for a nominal load sudden connection and different values of C_L.

The value of capacitor C_L is chosen so that in the event of a sudden nominal load connection, the LV bus voltage does not go below the minimum value required for normal operation. The minimum LV bus voltage required for operation is

$$V_{busLMIN} = 2\sqrt{2}V_{nomlv} = 622V, \quad (57)$$

where the value is obtained from Table 1. Therefore, a conservative design criterion is to keep $V_{busL} > 700V$ when a nominal load is connected. This is equivalent to obtain a LV bus voltage variation $\triangle V_{busL} < 100V$.

To evaluate the LV bus voltage variation for different values of C_L, gain vector K_{LV} is computed for each given value, and then a simulation is performed. From (36)-(38), the following system is simulated:

$$\triangle x_{LV}[k+1] = A^{cl}_{LV}\triangle x_{LV}[k] + B^{cl}_{LV}\triangle i_L, \quad (58)$$
$$\triangle V_{busL}[k] = [1\ 0]\triangle x_{LV}[k], \quad (59)$$

where $A^{CL}_{LV} = A_{LV} - B_{LV}K_{LV}$, $B^{cl}_{LV} = -B_{LV}$ and $\triangle i_L = S_{nom}/V^*_{busL}$. Figure 5 shows simulation results for this system for $C_L = 5$ [mF], 10[mF] and 15[mF] when a nominal load is suddenly connected and the LV bus voltage control loop is designed with a settling time of 100[ms]. From the results all capacitor values meet the requirements, however $C_L = 10$ [mF] is chosen because of reduced ripple under unbalanced load conditions.

4.5 Inverter filter $L_{inv}C_{inv}$

The typical output impedance of a standard transformer is 2%-5% of its base impedance. Therefore, L_{inv} is chosen so that its impedance at angular frequency ω is 2% of the base impedance:

$$L_{inv} = 0.02\frac{3V^2_{nomlv}}{\omega S_{nom}} = 462\ [\mu H]. \quad (60)$$

On the other hand, capacitor C_{inv} limits the bandwidth of the output. Here, to obtain a fast transient response, the cut-off angular frequency of the output filter is chosen

$$\omega_{cut-off} = 20\omega. \quad (61)$$

Since the resonance frequency of the filter is approximately equal to the cut-off frequency,

$$\omega_{res} \simeq \omega_{cut-off} = \frac{1}{\sqrt{L_{inv}C_{inv}}}, \quad (62)$$

then

$$C_{inv} = \frac{1}{(20\omega)^2 L_{inv}} = 55\ [\mu F]. \quad (63)$$

5 Operation analysis of the control system and simulation results

This section presents simulation results of the proposed SST when a load is suddenly connected and disconnected. Additionally, results for sudden nonlinear load connection are included. The results are obtained using the switching models of all converters. The system parameter summary is shown in Table 1.

Table 1: System parameter summary

RECTIFIER AND LV BUS		
Param.	Value	Description
S_{nom}	20[kVA]	SST nominal power
V_{nomhv}	7621[Vrms]	HV nom. phase voltage
I_{nomhv}	0.875[Arms]	HV nom. phase current
f	50[Hz]	HV grid frequency
L_{rec}	200[mH]	HV filter inductance
V^*_{busL}	800[V]	LV bus reference
C_L	10[mF]	LV bus capacitor
f^{rec}_{sw}	8[kHz]	Switching frequency
DHB		
C_H	1[μF]	HV bus capacitor
C^{dhb}_L	56[μF]	LV DHB capacitor
L_d	8.8[mH]	DHB leakage ind.
V^*_{busH}	6000[V]	HV bus reference
m	7.5	Transformer relation
f^{dhb}_{sw}	20[kHz]	Switching frequency
INVERTER		
L_{inv}	461.2[μH]	LC filter ind.
C_{inv}	55[μF]	LC filter cap.
V_{nomlv}	220[Vrms]	LV phase voltage
f^{inv}_{sw}	20[kHz]	Switching frequency

The controllers were designed so that the rectifier control loop has a settling time of 4.5[ms], the DHB control loop has a settling time of 1[ms], and the LV bus voltage control loop has a settling time of 100[ms]. The settling time of the inverter AD loop is defined by the cutoff frequency of its LC output filter plus the estimation of the current through C_{inv}. This settling time results approximately 2[ms].

5.1 Sudden load connection

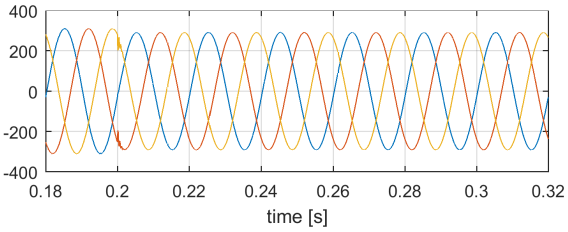

Figure 6: v_{lv} [V] sudden load connection.

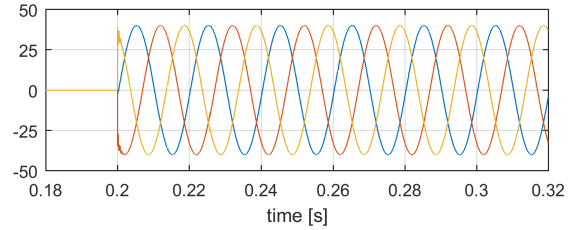

Figure 7: i_{lv} [A] sudden load connection.

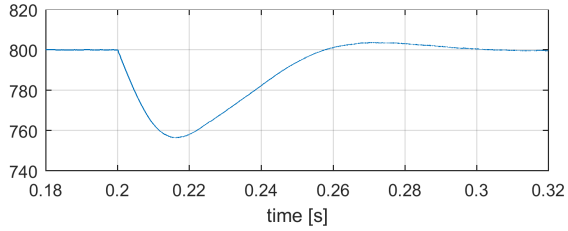

Figure 8: V_{busL} [V] sudden load connection.

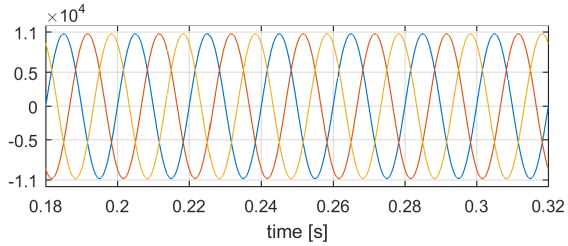

Figure 9: v_{hv} [V] sudden load connection.

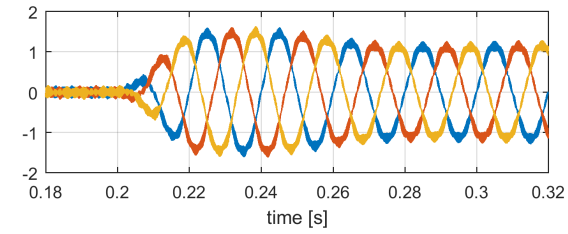

Figure 10: i_{hv} [A] sudden load connection.

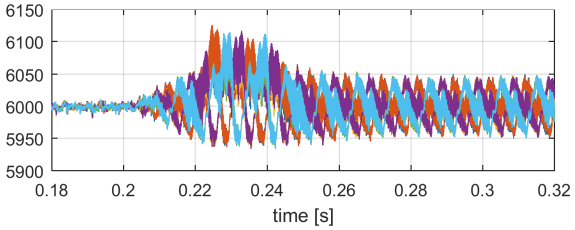

Figure 11: $V_{busH1} - V_{busH6}$ [V] sudden load connection.

The simulation results shown in Figures 6-11 start at $t = 0.18$[s] with the SST in steady state, with no load connected on the LV side. This means that the HV and LV buses start at their reference voltage levels and that a balanced three-phase sinusoidal voltage v_{lv} is generated without taking significant current i_{hv} from the HV grid.

At $t = 0.2$[s] a resistive nominal load is connected at the inverter output. The following sequence of events occurs (refer to Figure 2 for the definition of the variables):

- Figures 6 and 7 show v_{lv} and i_{lv}, respectively. As expected, when the load is connected v_{lv} has a short transient.
- Through power balance, current source i_L takes current from capacitor C_L, reducing voltage V_{busL} as shown in Figure 8. As can be seen, its settling time is approximately 100[ms], as designed.
- The LV bus voltage control loop detects the reduction of $\bar{V}_{busL}$, increasing in turn the value of g, resulting in $g > 0$. As a result, current reference i^*_{hv} magnitude increases.
- Commanded by its current controller, the rectifier sinks active power from the grid, with unity power factor. Figures 9 and 10 show v_{hv} and i_{hv}, respectively. Here the settling time of the current is tied to the settling time of g, defined by the LV bus control loop.
- Through power balance, the current source outputs of the rectifier charges capacitors C_H of the HV buses, increasing their voltage levels. The voltages of the HV buses is shown in Figure 11.
- The control loop of each DHB detects the increase in their respective HV bus voltage V_{busHX}. As a result, it commands each DHB to sink current i_{oX} in order to decrease the instantaneous value V_{busHX} to its reference value V^*_{busH} once again. This results in the short transient increase in the mean value of voltages V_{busHX} seen in Figure 11. Through power balance, each output current i_{dhbX} sources current to the LV bus, charging C_L to V^*_{busL} again, as shown in Figure 8.

By the end of this sequence, in steady state, the system is delivering power to the load and taking current with unity power factor from the HV grid.

5.2 Sudden load disconnection

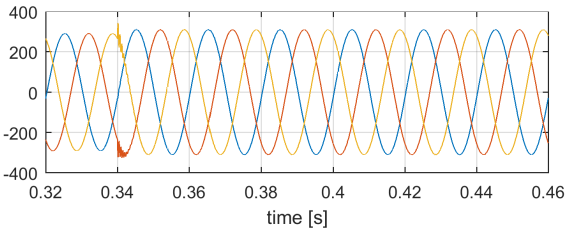

Figure 12: v_{lv} [V] sudden load disconnection.

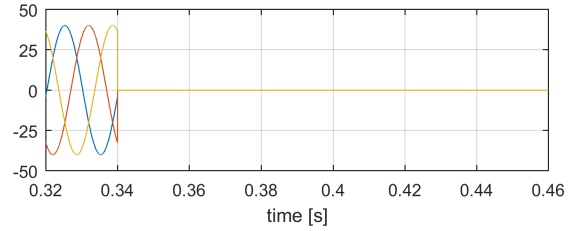

Figure 13: i_{lv} [A] sudden load disconnection.

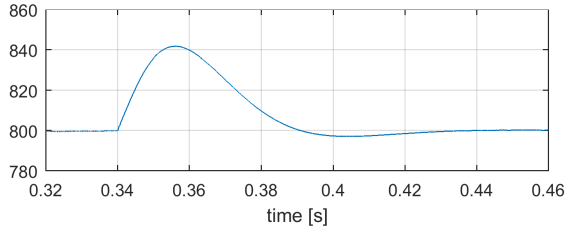

Figure 14: V_{busL} [V] sudden load disconnection.

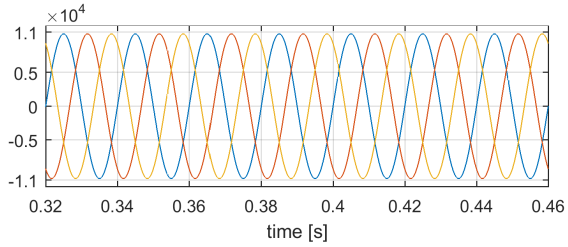

Figure 15: v_{hv} [V] sudden load disconnection.

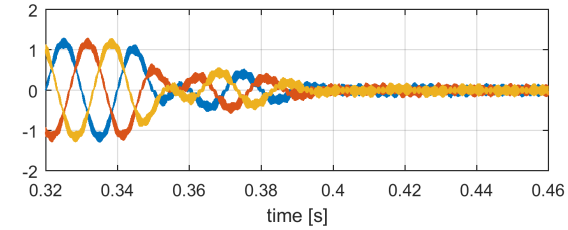

Figure 16: i_{hv} [A] sudden load disconnection.

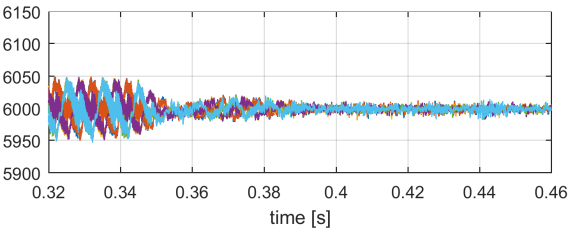

Figure 17: $V_{busH1} - V_{busH6}$ [V] sudden load disconnection.

Starting from the previous condition, if the load is now disconnected, the following sequence of events will occur:

- Figures 12 and 13 show v_{lv} and i_{lv}, respectively. As expected, when the load is disconnected v_{lv} has a short transient.
- Through power balance, current source i_L stops sinking current from capacitor C_L, which charges because the DHBs are still transferring power from the HV grid. This is seen in Figure 14.
- LV bus voltage control loop detects the voltage increase in $\bar{V}_{busL}$, decreasing in turn the value of g, resulting in $g < 0$. As a result, current reference i^*_{hv} magnitude decreases.
- Commanded by its current controller, the rectifier goes from sinking to supplying active power to the grid, with unity power factor. Figures 15 and 16 show v_{hv} and i_{hv}, respectively.
- Through power balance, the current source outputs of the rectifier discharge capacitors C_H of the HV buses, decreasing their voltage levels, as seen in Figure 17.
- The control loop of each DHB detects the decrease in their respective HV bus voltage V_{busHX}. As a result, it commands each DHB to source current i_{oX} in order to increase the instantaneous value V_{busHX} to its reference value V^*_{busH} once again. This results in the short transient decrease in the mean value of voltages V_{busHX} seen in Figure 17. Through power balance, each output current i_{dhbX} sinks current from the LV bus, discharging C_L to V^*_{busL} again, as shown in Figure 14.

By the end of this sequence, in steady state, the system has its buses at their reference values, and the inverter generates v_{lv} without sinking current i_{hv} from the HV grid.

5.3 Sudden non-linear load connection

The simulation of section 5.1 is repeated for the sudden connection of a balanced non-linear load. For each phase of the inverter, the load is composed of a single phase rectifier, feeding a 1[mH] inductor in series an RC load where R and C are in parallel (with R=19.5[Ω] and C=1[μF]). The results of this simulation are shown in Figures 18-23. As can be seen in these results, the proposed topology works well under highly non-linear load conditions.

5.4 Sudden non-linear unbalanced load connection

The simulation of the previous section is repeated, using the same non-linear load, but connecting these loads to only two of the three phases. The results of this simulation are shown in 24-29. As can be seen in these results, the proposed topology also works well for unbalanced non-linear loads.

6 Conclusions

In this paper a model and a control strategy for an SST topology is proposed. The analyzed SST is designed using three separate stages: a rectifier, a DC-DC converter and an inverter. The proposed design approach is to model each stage using simple models. These simple models help to design and tune the controllers for each stage. The main focus of the tuning procedure is to obtain good performance to sudden load connections. Criteria to choose the main parameters of the SST are also given.

To validate the proposed method, simulation results are presented. The results show that the proposed topology and control strategies perform as expected from design conditions. Moreover, the staged design of the SST allows to decouple the HV side from the LV side in regard to load disturbances, which is an additional feature of the SST when compared to traditional transformers. Simulations were performed for both linear and non-linear loads. Moreover, a non-linear unbalanced load was also tested, with good performance results.

Appendix

Given a three-phase signal $f = [f_a\ f_b\ f_c]^T$, its $\alpha\beta$ components are obtained through Clarke's transform:

$$\begin{bmatrix} f_\alpha \\ f_\beta \end{bmatrix} = \frac{2}{3}\begin{bmatrix} 1 & -0.5 & -0.5 \\ 0 & \sqrt{3}/2 & -\sqrt{(3)}/2 \end{bmatrix}\begin{bmatrix} f_a \\ f_b \\ f_c \end{bmatrix}. \quad (64)$$

Then, the complex vector $\vec{f}$ is defined as

$$\vec{f} = f_\alpha + j f_\beta, \quad (65)$$

where $j = \sqrt{-1}$.

ABSTRACT

This paper reports the results of an empirical, 3D full wave inversion (FWI) numerical analysis which provides an estimation of the performance of multi-static handheld ground penetrating radar (GPR,) compared to a bi-static system, for landmine detection using FWI imaging. The experiments are based on simulated data and provide a more realistic evaluation of the performance of multi-static handheld GPR for the landmine problem based on FWI, than previous studies based on a 2D analysis.. Furthermore, a novel method of estimating a parameter set that is closer to the global minimum for an iterative FWI optimization is introduced.

1. Introduction

This paper provides an extension of the work presented in [1], which is based on a sensitivity analysis of handheld GPR measurements, comparing bi-static and multi-static system performance using singular value decomposition (SVD). The results obtained confirmed the conclusions of a previous study conducted by Watson [2], which states that multi-static systems achieve greater subsurface information, for a landmine detection application using full wave inversion (FWI). The study in [2] also conducted a 2D FWI to verify the superior performance of multi-static arrays over a bi-static configuration, for handheld GPR. It concludes that the size of the multi-static array, or number of antenna elements, is insignificant. Furthermore, the acquisition system under test was simplistic and radio propagation properties such as the antenna cross-coupling, radiation pattern and geometry are neglected. Additionally, only a flat, homogenous domain was simulated for the 2D FWI analysis.

Nevertheless, a 2D FWI study is insufficient, as the landmine detection domain is a 3D, heterogeneous domain and a 3D analysis is required to produce a more realistic evaluation of the performance of bi-static and multi-static handheld GPR systems for the demining challenge. Here, an empirical FWI numerical analysis is reported for a 3D domain, which considers a homogenous as well as a heterogeneous or cluttered domain, using a derivative-free optimization algorithm. The bi-static and multi-static system performance are evaluated by comparing the estimated subsurface parameters obtained in each case with synthetic GPR data parameters. All the radio propagation effects are included with simulated experiments conducted in the CST STUDIO SUITE 3D electromagnetic (EM) environment. Finally, a novel method to determine an improved initial parameter set for the GPR FWI optimization, that is closer to the global minimum, is proposed. This is achieved by generating a database of prior forward problem solutions. The database is used with each measured GPR data to determine the least L2 norm objective function, whose parameters are considered as the initial parameter set for the actual FWI optimization.

2. FWI for Multi-static Handheld GPR

2.1. Gradient Based Method

The GPR FWI problem for landmine detection may be posed as a regularised least squares (LSQ) non-linear optimisation problem given by [2]

$$\mathbf{X}_{im} = \arg\min_{\mathbf{x}} \frac{1}{2}\left\|GPR(\mathbf{X}) - \mathbf{d}\right\|_2^2 + \lambda T(\mathbf{X}) \qquad (1)$$

where $\mathbf{X}_{im}$ is a vector of geometric and electrical parameters describing the ground, $\mathbf{d}$ is the GPR measured data, $GPR(\mathbf{X})$ is a forward model that returns the GPR measurement that would be made for a subsurface with parameter vector $\mathbf{X}$. The GPR inverse problem is ill-posed as arbitrarily large changes in $\mathbf{X}$ can have negligible effect on the error $\left\|GPR(\mathbf{X}) - \mathbf{d}\right\|_2^2$. The regularisation term

is required to control the size of components of $\mathbf{X}$ with little or no effects on GPR data. The function $T(\mathbf{X})$ introduces a penalty based on the size of these components and is a way to introduce prior information. For Tikhonov regularisation $T(\mathbf{X})=\|\mathbf{\Gamma X}\|^2$ and often $\mathbf{\Gamma}$ is chosen to be the identity matrix. The regularisation or Tikhonov factor $\lambda \geq 0$ is often adjusted dynamically during the iterative optimisation process to control convergence. Optimisation is posed as a LSQ problem as the error functional uses the L2 norm.

The GPR forward model is non-linear and so (1) is often solved by iterative linearization. Watson used an iterative, quasi Newton method called the limited memory Broyden-Fletcher-Goldfarb-Shannon (L-BFGS) nonlinear optimisation algorithm [3]. The solution requires a calculation of the gradients of the LSQ error function $\|GPR(\mathbf{X})-\mathbf{d}\|_2^2$. Due to the special form of the LSQ error function, these derivatives can be directly related to the derivatives of the forward model.

2.2. Derivative-free Method

The derivative-free method for solving the FWI problem is used because it is computationally expensive to estimate the derivatives required for derivative based methods. Derivative-free methods require less computation per iteration and are suitable for a limited number of variables, but may require more iterations. A range of non-derivative nonlinear optimization algorithms may be used to solve the FWI optimisation problem when gradients do not exist or are expensive to compute. Local direct search methods may be used when there are a small number of variables and the objective function is computationally cheap to evaluate. The Nelder-Mead simplex algorithm [4] is the most cited, robust and efficient of local direct search methods. The algorithm fundamentally relies on an initial number of points that create a simplex i.e. a set of points spanning a volume in the variable dimensionality considered. The objective function is evaluated at the vertices of the simplex during each iteration to determine the highest objective value, which is used to redefine another vertex that produces a new simplex. Additional new points are produced by moving the vertex with the highest objective value through a series of transformations using the centroid of the associated simplex that include reflection, expansion, internal and external contractions [5]. These steps are iterated until convergence is achieved. Convergence can occur for non-smooth objective functions even when the second derivative of the function is unobtainable [6]. The Nelder Mead simplex algorithm may be applied to the FWI optimisation problem, to estimate the uncertainty in parameter sensitivity of the handheld GPR bi-static and multi-static systems. The Nelder Mead Simplex algorithm is embedded in the CST STUDIO SUITE environment and so the 3D GPR forward model may be integrated with the optimization process on the same platform.

3. Modelling and Simulation

3.1. The GPR System Models and Experiments

The GPR system models are developed with linear antenna arrays positioned with dipoles at a fixed distance above the ground surface. The configurations are for a bi-static system, and multi-static system with two and four receive elements, driven in a single input multiple output (SIMO) sequence. The antennas are end-fed (coaxial) dipole antennas designed and optimised using the Antenna Magus software for a centre frequency of 2.5 GHz and frequency range of 1.75-3.25 GHz. Assuming the same offset of 20 cm used by Watson, an antenna element spacing of 5 cm was used in all configurations. Antenna cross-coupling losses are significant, given this spacing which is less than a wavelength. The antennas are placed initially at a height of approximately 3.76 cm above the ground surface. The transmitting element is at the extreme left end of the array and the time series measured at each receive antenna are concatenated into a single data vector **d**. The target object is placed under the centre of the array, based on the assumption that a metal detector (MD) has located a conducting part of the device.

To reduce the computational cost, the ground size for this study is reduced to a 31 cm by 29 cm box with a depth of 9cm. The subsurface parameters are the relative permittivity $\varepsilon_r^{soil}=2.53$ and loss tangent $\tan\sigma=0.0036$. The target is a single AP mine which is modelled as a typical plastic cylinder with relative permittivity $\varepsilon_r^{mine}=2.8$ (typical US M14 mine). The diameter and height are 7cm and 6cm respectively, closer to a Colombian military MN-MAP-1 mine [7]. The mine also contains a tetryl charge (US M14) with relative permittivity $\varepsilon_r^{tetryl}=2.163\ \left(1g/cm^3\right)$ and an air void of free space relative permittivity of one. Instead of ABC boundary conditions (used by Watson), perfectly matched layer (PML) boundary conditions are applied on all faces of the box (ground) for all models in this study with added space above the antennas on the top of box to simulate the antenna to antenna and antenna to ground propagation. ABC boundary conditions have been studied longer and are generally easier to implement, but the PML region achieves less boundary reflections [8].

For a heterogeneous ground (cluttered domain), we introduce a rough surface to the flat ground (box) surface. The ground surface roughness height is modelled in the form of a Gaussian distribution [9]. Therefore, the box planar surface is modelled with depressions and protrusions to simulate a ground surface with a random height, assuming a Gaussian distribution, normally distributed white noise and a mean value of zero [10]. Additionally, subsurface clutter sources are modelled as several 3D rectangular blocks, grouped into two clusters, with each set having a different relative permittivity. One has a relative permittivity, $\varepsilon_r=5$ and the other with a relative permittivity, $\varepsilon_r=4$. An example bi-static dipole system and target subspace is shown in Figure 1. A LSQ FWI regularised optimisation problem, as in (1), is the test problem. The goal value to be evaluated is the sum squared difference of the total simulated GPR data (time-series) and the total forward model data (time-series), which is given by $\|GPR_{meas}-GPR(\mathbf{X})\|^2$. Watson performed a similar study for dipole antennas in a simplified 2D, homogenous domain only. Here both 3D homogenous and heterogeneous domains are investigated for the FWI analysis.

The optimization is set to a maximum of 20 iterations, due to computational constraints. The hexahedral mesh used to produce

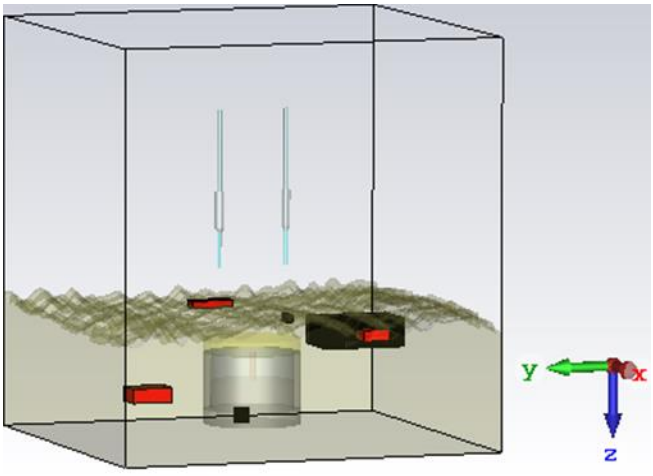

Figure 1: Bi-static dipole system for a heterogeneous ground

synthetic GPR measurements is different from the mesh used in the forward model within the FWI objective function. This avoids the spuriously good results that can be the inverse crime artefact [11] due to using the same mesh for both operations.

The parameter vector for the synthetic GPR data for the homogenous ground is given by

$$GPR_{initial} = [\varepsilon^T, \tan\sigma, \varepsilon^0, \varepsilon_r^m, \varepsilon_r^s] = [2.163, 0.0036, 1, 2.8, 2.53] \quad (2)$$

where ε^T = relative permittivity of tetryl charge

$\tan\sigma$ = loss tangent

ε_0 = relative permittivity of free space

ε_r^m = relative permittivity of plastic mine

ε_r^s = relative permittivity of dry sandy soil

Whereas the parameter vector for the synthetic GPR data for the heterogeneous ground is given by

$$GPR_{initial} = [\varepsilon^T, \varepsilon^{C1}, \varepsilon^{C2}, \tan\sigma, \varepsilon^0, \varepsilon_r^m, \varepsilon_r^s] = [2.163, 3.75, 6, 0.0036, 1, 2.8, 2.53] \quad (3)$$

where ε^{C1} = relative permittivity of first clutter source

ε^{C2} = relative permittivity of second clutter source

ε_0 = relative permittivity of free space

ε_r^m = relative permittivity of plastic mine

ε_r^s = relative permittivity of dry sandy soil

The initial subsurface parameter vector for the homogenous ground FWI is given by

$$GPR_{initial} = [\varepsilon^T, \tan\sigma, \varepsilon^0, \varepsilon_r^m, \varepsilon_r^s] = [2.363, 0.0046, 1.2, 3.01, 2.23] \quad (4)$$

Whereas the initial vector for the heterogeneous ground FWI is given by

$$GPR_{initial} = [\varepsilon^T, \varepsilon^{C1}, \varepsilon^{C2}, \tan\sigma, \varepsilon^0, \varepsilon_r^m, \varepsilon_r^s] = [2.363, 5, 4, 0.0046, 1.2, 3.01, 2.23] \quad (5)$$

3.2. FWI Numerical Analysis Results

To estimate the performance of the different antenna systems, we compare and consider the estimated parameter values approached by the FWI solutions for both models with their respective synthetic GPR data true parameter values. The error in the subsurface parameters for each system in the different ground conditions is estimated by determining the total sum squared difference between the GPR data vector parameters and the FWI solution vector parameters. The total estimated parameter errors are indicated in Tables 1 and 2 for the homogenous ground and heterogeneous ground respectively.

The 3D FWI data shows that for both ground domains, the conclusion that multi-static systems can achieve more subsurface information is achieved as the smallest subsurface error in both cases is recorded with a multi-static system. At this stage, we can confirm that the multi-static system performs better than the bi-static system in general. However, the subsurface parameter error is not monotonic for the number of antenna elements whereas it was found to be linear for a 2D FWI analysis. These results based on a 3D analysis are more realistic as the scattering on the soil surface and cylindrical mine introduce more degrees of freedom and complexity than a 2D numerical analysis.

For the homogeneous soil, the 4 receiver (RX) system FWI achieves a better performance than the two other systems though the difference between the bi-static system and 2 RX multi-static system is marginal. However, in the more realistic heterogeneous domain the 4 RX multi-static system yields the largest parameter uncertainty. The scattering and clutter signals are observed to be larger in the heterogeneous domain than the homogenous domain based on the larger subsurface parameter error and uncertainty figures that are estimated in the former. This is due to greater air-ground reflections from the rough ground surface and scattering from the buried clutter sources. In this case the clutter signal is much larger than the mine signal. Nevertheless, for both soils, particularly the heterogeneous soil, the parameterisation does not sufficiently describe the clutter and so the optimisation easily converges to the wrong solution. Some method is required to reduce the effects of the clutter signal. Therefore, better imaging with multi-static systems for a real GPR system and demining operation based on FWI is predicated on an optimised antenna design as well as clutter reduction.

Conversely, this analysis also shows that the multi-static system achieves only a small improvement over the bi-static system. A FWI optimization with actual GPR measurements or field evaluation data is expected to exhibit greater complexity and hence the improvement may only be marginal. This study has been limited to synthetic data and future studies may include further

validation of the results obtained with the use of measured GPR data.

Table 1: Summary of GPR and FWI solution parameter values for homogenous ground

Subsurface Parameters	GPR Data Parameter Values	FWI Solution Estimated Parameter Values		
		Bi-static	Multi-static (2RXs)	Multi-static (4RXs)
Charge relative permittivity	2.163	2.292	2.268	2.3
Loss tangent	0.0036	0.0026	0.0034	0.0069
Air void relative permittivity	1.0	1.49	1.5	1.45
Mine relative permittivity	2.8	3.069	3.185	3.032
Soil relative permittivity	2.53	2.2	2.2	2.6
Estimated parameter error	**-**	**1.219**	**1.320**	**0.892**

Table 2: Summary of GPR and FWI solution parameter values for heterogeneous ground

Subsurface Parameters	GPR Data Parameter Values	FWI Solution Estimated Parameter Values		
		Bi-static	Multi-static (2RXs)	Multi-static (4RXs)
Charge relative permittivity	2.163	2.4	2.388	2.314

Soil relative permittivity	2.53	2.27	2.33	2.2
Estimated parameter error	**-**	**3.869**	**3.048**	**4.734**

4. Improvement of the FWI Initial Parameter Set

The steepest descent and direct search methods for iterative nonlinear optimisation all require an initial parameter set which is updated iteratively according to the chosen method. The GPR FWI problem is also a local minimisation problem that is nonlinear as well as ill-posed. A good initial parameter set that is as close as possible to the true solution is desirable to ensure convergence to the global minimum and less computational expense. A more general approach would be to employ global optimization techniques prior to the local optimization. However, for the GPR problem this would be computationally prohibitive. We propose a compromise approach that involves solving the forward problem for several parameter sets within the bounded local domain or search space and using an L2 norm objective with the true solution or measured data, as the goal value. The forward model meshing or grid would be set to the lowest tolerance level as only a coarse analysis is required to avoid a high computational expense. A higher tolerance is set for the forward model grid for the actual optimization.

A database of the forward model solutions for a specific operation is generated and can be evaluated with data from each GPR measurement. The initial parameter vector for the FWI solution is chosen by interpolation from the database of parameter vectors and measured time-series. Hence a single database is generated during a single campaign but can be used repeatedly for GPR data from the same source environment or location. The database campaign could be done during the training phase of a demining operation prior to the actual clearance operation. The database can be generated for any chosen number of parameter combinations and sample space or bounded conditions. More forward model solutions would be expected to increase the probability of a better initial estimate of the parameter set. For this experiment, the 4 RX dipole system GPR model for a heterogeneous domain is utilised. Eleven forward model solutions are generated by arbitrarily choosing eleven different parameter sets for values between a minimum and maximum bound. This yields a database of eleven sets of A-scan data and the L2 norm objective value of each of these data for any measured GPR is determined. The parameter set for the time-series (A-scan) that achieves the lowest objective function value would be considered as the closest to the true solution or global minimum and selected as the initial optimization parameter set. Figure 2 presents the objective function value for all eleven forward problem solutions.

It can be determined from Figure 2 that the lowest objective function value is obtained at simulation run eight which corresponds to a value of 0.001708. The parameter set for this forward model measurement, GPR_F is given by

$$\begin{aligned} GPR_F &= [\,\varepsilon^T, \varepsilon^{C1}, \varepsilon^{C2}, \tan\sigma, \varepsilon^0, \varepsilon_r^m, \varepsilon_r^s\,] \\ &= [2.25, 5.75, 6.50, 0.0061, 1.35, 3.05, 2.55] \end{aligned} \quad (6)$$

Therefore, this parameter set given in (6) is selected as the initial parameter set for the iterative FWI solution, for the heterogeneous domain under test. The FWI optimization solution for this parameter set is then obtained for 20 iterations, due to computational constraints, and compared directly with the FWI solution for the initial parameter set in (3). The result is shown in Figure 3.

The comparison of the FWI solution for the original initial parameter set and the one derived from the database generation (Figure 3) shows that the latter does not achieve an improvement in the accuracy of convergence as the absolute error is marginally less than the original solution. However, the result does show that the database generated initial parameter FWI solution is closer to the true solution. This could potentially lead to a more efficient optimization using a more powerful algorithm. Derivative based methods would benefit from this improvement and achieve convergence with less computational expense and fewer iterations as a local minimum would be realised more efficiently. The procedure achieves the primary goal of improving the initial parameter estimation or guess. The CST integrated Nelder-Mead optimisation does not allow the user to specify the entire simplex and objective function values. If this had been the case, the initial 10 iterations exploring the simplex could have been entirely

avoided by selecting all the simplex points from the database. The performance of gradient based algorithms are expected to benefit from the database generated improved initial parameter set.

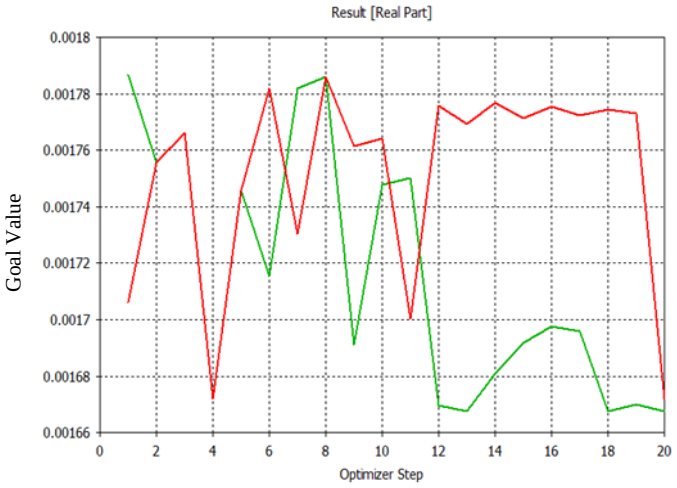

Figure 3: FWI solution result for 4 RX dipole a. original initial parameter set (GREEN) versus database selected parameter set (RED)

5. Conclusion

An empirical study has been undertaken to compare 3D FWI imaging using multi-static and bi-static systems in homogeneous and heterogeneous media. The results verify the possibility of multi-static systems to achieve greater subsurface parameter sensitivity and hence reliability of target detection than bi-static systems. In 2D, all multi-static systems outperformed the bi-static systems. However, a more realistic 3D analysis shows that the improvement in performance with increasing numbers of antennas is not simple or monotonic due to cross-coupling and antenna patterns. This underlines the need for optimisation of the antenna system configuration and size (number of elements), to achieve better performance than a bi-static system. Additionally, the effect of clutter significantly limits the accuracy of parameter estimation. Finally, a novel procedure has been proposed to determine the initial parameter vector for the FWI solution which yields an initial forward problem solution that is closer to the true GPR data solution. The procedure requires numerous forward problem solutions stored prior to a deeming campaign but has the potential to significantly reduce the computational expense of the FWI as well as the accuracy for an ideal local minimisation.

Threat estimation

ABSTRACT

Safety-critical systems are well documented and standardized (e.g. IEC 61508, RTCA DO-178B) within system design cycles. However in Defence and Security, systems that are critical to the success of a Mission are not defined within the literature nor are there any guidelines in defining criticality in their design or operational capabilities. When it comes to Vetronics (Vehicle Electronics), a mission-critical system, is a system with much complexity and mixed criticality levels that is a part of the overall platform (military vehicle) offering integrated system capabilities. In this paper, a framework is presented, providing guidelines in designing efficiently and effectively mission-critical systems considering principles of Interoperable Open Architectures (IOA), mission-critical integrity levels and following new standardization activities such as NATO Generic Vehicle Architecture (NGVA). A Defensive Aid Suite (DAS) system is used as a case study to illustrate how this framework can be exploited. The indention of this extension is to provide an approach to precisely estimate threats in order to de-risk missions in the very early stages.

1. Introduction

Modern military vehicles rely on mission-critical systems that enhance and guarantee successful mission capabilities. Currently, these mission-critical systems come as black boxes that are installed and maintained by the same manufacturer through the vehicle's life-cycle. These black boxes are built on proprietary technology that only the manufacturer has access to, thus limiting the choices of maintenance and upgrades. Furthermore, existing mission-critical systems are limited to communicating with other on-board systems resulting to a vehicle having multiple instances of the same equipment (e.g. GPS sensor). This presents a number of issues including having network complexity and reduced flexibility in vehicle systems configuration depending on operational requirements.

For this reason, there is a need for an innovative architecture approach that allows components from different manufacturers to be integrated, paying particular attention to the system's mission, safety, and security. When building a mission-critical system, the system designer should have the freedom to choose components that fit appropriately to the intended use as well as enable integration to any legacy mission-critical system or sensors/actuators that exist on-board the vehicle.

In this study, a thorough investigation is conducted offering a new open modular architectural approach on mission-critical systems including a case study on Defensive Aid Suites (DAS), aided to extract the necessary technical and functional requirements directly related to the system. This presented an opportunity to research a conceptual approach to the bespoke system whereby a constructive framework could be established with firm recommendations on a high level (abstracted) design so that a target platform can be equipped with a tailored mission-critical system to meet its specific requirements.

The novel mission-critical system architecture for military platforms adopts an open and modular design approach offering flexibility in configuration, upgradability, and integration. This enables a better operational and functional understanding of the mission-critical system, increasing integrated survivability capabilities [1].

Following the presented framework of this work, qualitative and quantitative results are extracted in order to provide mission

[*]Kyriakos Houliotis, Vetronics Research Centre, University of Brighton, BN2 4GJ, United Kingdom, +44 (0) 1273 642251, k.houliotis@vetronics.org

functional concepts based on mission-critical systems and threats. Additionally from the results, an early de-risking estimation can be observed, that could be beneficial for stakeholders, systems engineers and architects to decide the appropriate elements for designing mission-critical systems in the very early stages of the overall system's life-cycle. The rest of the paper is structured as shown below:

- Section 2 presents some representative key questions that offer the direction of designing mission-critical systems.
- Sections 3 and 4 provides a definition for mission-critical systems in line with standardisation activities around military vehicle architecture design approach.
- Section 5 offers the Generic Architecture Framework.
- Section 6 identifies some key considerations on safety and security in aligning and defining mission criticality levels.
- Section 7 provides an approach of calculating threats using numerical values and mathematical equations.
- Sections 8, 9, 10 and 11 present a case study on how the framework can be used to define a DAS Architecture including qualitative and quantitative results.
- Section 12 concludes the paper with some indication of next steps to this research.

This paper is an extension of work originally presented in International Conference on Military Technologies (ICMT) 2017 [2].

2. Key Questions

2.1. Modularity and Openness

What approaches are needed for a mission-critical system to be feasible and extract advantages such as modularity and openness?

2.2. Construction, Maintenance and Safety Certification

What are the benefits of using modules sharing specific functionalities on a mission-critical system and how efficient and effective can become?

2.3. Alongside benefits from the framework

How the framework's modularity extracts through the mission-critical system development benefits such as safety cases and certifications?

2.4. Low-cost tools

What are the necessary tools needed to accomplish a rapid prototyping testing and permitting software functionality and operation of a mission-critical system using low-cost components?

2.5. Migration of low cost to a safety-critical performance verification testbed

How to achieve a transition from a low-cost functional testbed to a more elaborated safety-critical performance verification testbed?

3. Mission-Critical Systems

In general, the mission is the formal summary of the aims and values of an activity. The activity can be achieved with specific mission-critical elements. Those mission-critical elements are defined as vital to the functioning of an activity. Meaning that, a successful mission can be achieved when only the right mission-critical elements are applied. There are two attributes that make the specific mission-critical elements to be applied and to be right.

First, is usually when there is maturity in the applied mission-critical elements. The maturity must reach into a level that is satisfactory in each of the involved disciplines. When this level is reached, the expected outcome is sufficient and hence, the mission can be considered successful.

The second attribute is when enough knowledge is accumulated to allow for the prediction of a mission outcome to be more accurate. To achieve this, consideration needs to be given to all possible factors involved on the specific mission. Those factors are usually known or unknown and could be anything related to the mission. The knowledge can be gained when those factors are asked and answered using three main engineering questions; "What", "Why" and "How". Once these answers are mature enough and understandable the mission-critical elements can be referred to as vital and therefore, provide success to the mission.

Today, the technology has been developed in such a way that many missions could be successfully completed with the aid of systems. Those systems are referred to as mission-critical systems. A general definition of a mission-critical system is [3]:

"*A system that is essential to the survival of a service, and whose failure or interruption significantly impacts the mission*".

A mission-critical system for a typical land military vehicle is:

"*A system that is essential to complete the mission successfully*".

A mission-critical system in land military platform is composed of many discrete Vetronics (vehicle electronics) sub-systems and components including sensors, actuators, effectors, radars and processing resources. Each of these sub-systems may contain further sub-systems and components including mechanical parts.

In Vetronics the mission can be designed, described and/or accomplished either in simple or complex terms. This differentiation resulted from the characteristics that a Vetronics system has. A simple mission for a Vetronics system is when not many factors are involved. It is also simple, when a clear and an easy step-by-step procedure is provided. For instance, a mission-critical system has to transmit data from node A to node B. That can be described as a simple mission since there is only one task to be completed and if the right mission-critical elements are used.

However, in Vetronics, for a data to be transmitted from one node to another in reality it is more complicated than the previous example. What makes the mission more complicated in Vetronics mission-critical systems is when a number of multiple disciplines, such as safety, security and survivability, are involved to achieve the mission. A more desirable, refined and detailed mission procedure is required.

Assume each of the aforementioned disciplines require to complete a specific goal on the same mission. The safety prioritises the safety of people and environment; the security prioritises the protection of data from various threats; and survivability prioritise the whole mission envelop. This makes the mission more difficult

to accomplish if there is neither enough maturity nor confidence on the applied mission-critical elements.

In conclusion, "mission in military applications cannot be specified or narrowed down into a single element that easily". Therefore, an innovative unified framework is required to define and guide Mission-Critical Systems development so as to enhance mission success.

4. IOA International Activities

Today within a modern military platform, land, naval and air force, have adapted the principles of the Interoperable Open Architecture (IOA) in their system design to speed up acquisition and upgrading alongside with reducing life-cycle costs through data modelling. Below a selection of significant activities in the area of architectures and standardisation with IOA is presented.

4.1. Generic Vehicle Architecture (GVA)

The Generic Vehicle Architecture is an approach taken by the UK Ministry of Defence (MOD) to the design of electronic and power architectures for military vehicles. The approach is based on establishing system engineering principles to define a generic architecture that requires open implementation standards, Def-Stan 23-009, to support cost-effective integration of sub-systems on land platforms, electronically, electrically and physically. Any equipment shall be integrated with the GVA military land platforms must be designed in the Land Data Model (LDM) which is a (sub)-system standardisation process [4].

4.2. NATO Generic Vehicle Architecture (NGVA)

The NGVA is an approach to ensure interoperability among military land vehicles equipment. The NGVA follows a similar line to the GVA, incorporating a new method of verification and validation and by maturing the NGVA Data Model concepts, focus and implementation can be achieved [5], [6].

4.3. Future Airborne Capability Environment (FACE)

The FACE approach is an aviation US government-industry software standard and business strategy for acquisition of affordable software systems that promotes innovation and rapid integration of portable capabilities across global defence programs. The main objective of this approach is to make military operations more robust, interoperable and secure using open standards [7].

4.4. Vehicle Integration for C4ISR/EW Interoperability (VICTORY)

VICTORY is a US army vehicle's open standard for physical and logical interfaces between systems and C4ISR/EW components. The VICTORY architecture targets to provide a clear picture between to the users and the developers. Throughout the usage of an open architecture, the platforms can accept upgrades without a significant impact on the design.

5. Generic Architecture Approach

Model Driven Architecture (MDA) is an approach that is used in the system engineering domain to improve product development and delivery. The approach was initially launched in 2001 by the Object Management Group (OMG) to support the model-driven engineering of software systems. The main objective of the MDA is to provide a set of specifications of system's functionality and behaviour expressed in models. Instead of writing the code manually, the MDA approach with the help of a data modelling tool it is possible to regenerate automatically an application code. Additionally, this approach reduces implementation and integration risks when an activity is designed.

In Figure 1 an illustration of the MDA process is presented. Initially, the system requirements can be defined and specified into a Platform Independent Model (PIM) model. Using a specific standard and specification, the model can be constructed in a formal way such as the Unified Modelling Language (UML). The objective of the PIM model is to specify data, operations, functions and modes of a system, independent of the platform in which it may be integrated. In order to organise and standardise the data as well as facilitate a long-term improvement in interoperability and upgradability within the model, a data model is essential. A Platform Specific Model (PSM) model contains elements of a specific software platform. It can be generated from the PIM model either manually or automatically if appropriate tools are used. The PSM embeds the chosen software architecture strategies which refine the PIM model based on specifications. The Platform Specific Implementation (PSI) embeds the chosen middleware technology and explains the usage of a specific platform.

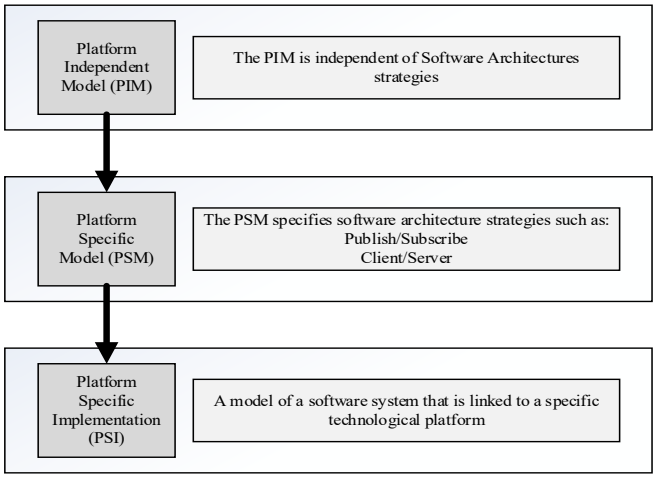

Figure 1. Model Driven Architecture Approach.

Each electronic device is developed to satisfy one or more specific task(s) thus, the devices can only generate or receive a set of specific data for their operation. Therefore, when these devices are integrated into an IOA architecture, the broadcasted data cannot be ensured if is critical or not. For instance, the real-time level cannot be defined just by the device itself but is needed to be declared from the designers. Below there is a brief explanation of the real-time levels.

Real-Time Level – In any electronic architecture there is a set of data or information it might be critical or noncritical. Real-time can enable non, soft and hard responsiveness depending on what level, prioritisation, and importance the data is designed for. In Vetronics different real-time levels are applied for satisfying different level processes or events. The definitions of real-time levels are:

- Non-Real-Time (**NRT**) - Best Effort Service with no time constraints.

- Soft Real-Time (**SRT**) - Relaxed time (latency) requirements.
- Hard Real-Time (**HRT**) - Fixed time requirements. [8]

Due to the different critical level of data in Vetronics, this paper proposes a novel framework to support the developers to design and decide whether the data is critical or noncritical. With the aid of a flowchart, Figure 2 demonstrates a modular framework that is aimed to accurately design a data for a mission-critical system. The designer must firstly define the data attribute and if is already existing on the model. When the data attribute is declared, the designer must decide in what level of real-time responsiveness the data is belonging to. The different levels the data can take are the Hard, Soft, and Non-Real-Time. This can be useful for the developers to choose the appropriate network communication technology. Next, the designer must declare the criticality level of the data by choosing between Mission, Safety, and Security Critical levels. The critical levels shown in the diagram are the most commonly used levels used in the Vetronics systems. The user has the freedom to add/remove other critical levels such as survivability or business critical.

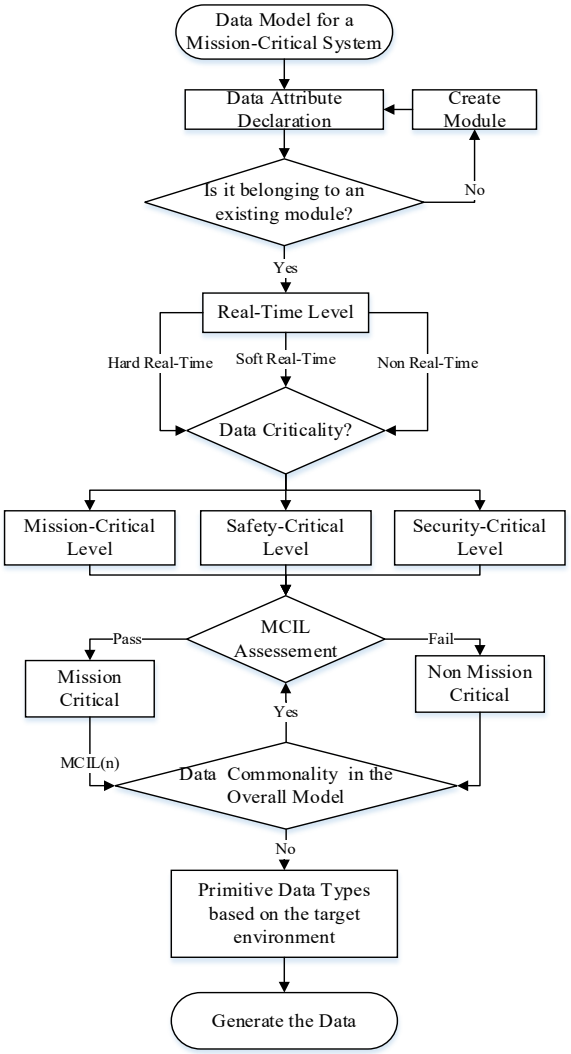

Figure 2. Mission-Critical Modelling Framework.

The next step is an assessment that is applied for the mission planning and goals based on risk assessments, a detailed explanation will be discussed in Sections 10 and 11. If the data fails the assessment is considered as non-mission-critical and if the data meets the requirements then is considered as mission-critical. In the mission-critical block, the data will be labelled with the Mission-Critical Integrity Level (MCIL). To ensure that the model is not polluted with data having similar attributes, a data commonality assessment is provided for addressing that issue. Finally, the data must have its own data type and must be checked whether the data type can be supported or not by the targeted programming language.

In a communication network, there are multiple connection points that are able to receive, store and send data across. These connection points are known as network nodes. Figure 3 depicts a generic network node which is divided into three elements, communication, processing, and application. The application element, is a computer program designed to perform a group of coordinated functions, tasks or activities for the benefit of the end user. The processing in a networked node, is a combination of machines, people, and processes that for a set of inputs produces a defined set of outputs. And the communication is the communication endpoint. The transmission of data from one computer to another is achieved by the communication device using various communication technologies [9].

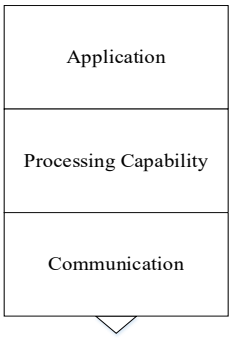

Figure 3. Network Node.

In the military vehicles, multiple (sub)-systems are integrated on a single platform. In a mission-critical system the most commonly used network nodes are sensors, actuators, effectors, processing nodes and so on. All the network nodes are interacting together through a virtual networking, as shown in Figure 4. A virtual network is capable of controlling one or more nodes over a logical or virtual networks that are decoupled from the underlying network hardware. This is used to ensure that the network nodes can efficiently integrate and perform on a single network. Common data sharing technologies used for military applications are the Data Distribution Service (DDS) and the Message Queuing Telemetry Transport (MQTT). The gateway block is integrated to support system legacy and allow different existing on-board systems to provide and receive services.

6. The need of Safety and Security

In land military platforms, there are other existing critical systems. These critical systems are for the safety and for the security of the platform and the crew. Safety critical systems are the systems whose failure may endanger human life, economics or the environment. Examples of safety critical systems in military

vehicles are the vehicle's steering and fire control. Security critical systems deal with the integrity and loss of sensitive data through theft or accidental loss [10].

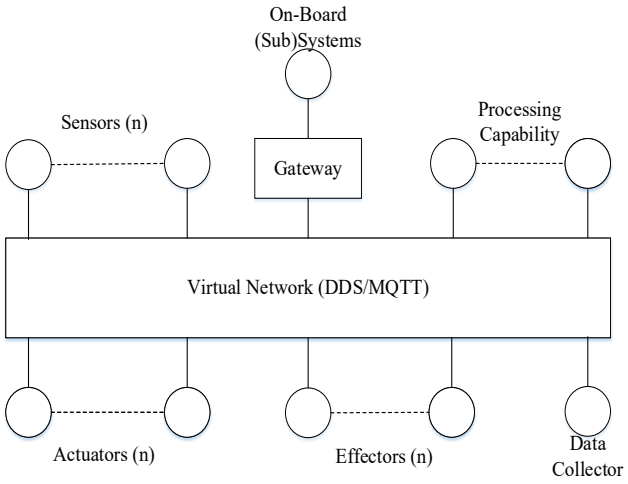

Figure 4. Virtual Network.

Safety and security critical systems can be used to extract logical capabilities, in which they can be mapped and used as the essentials of a successful mission-critical system. Considering safety and security capabilities on the development of a mission-critical system, it is possible to achieve a complete integrated survivability system [11]. It is vital to increase the dimensions and properties of safety and security in a mission-critical system to address issues such as intrusion detection, component fault/failure detection system behaviour, and restoring essential services in case of a security attack [12].

The developer must specify and approve the criticality level of each data. This can be varied depending on the application and technical specification related to user and system requirements. Although it is possible to declare and assess the data's mission-critical level using the Tables 1-4. The tables are essential to achieving a successful mission-critical system in which the mission goals are based on risk assessments. Risk assessments should be set and then that, the rigour of management and processes should be appropriate to meeting them.

Assume a civilian vehicle used for a military application; when the vehicle's passenger opens the vehicle's door some interior lights are switched on. The interior lights are designed to provide luminosity in the vehicle at night or in dark environments. During the day or at bright environments the light does not significantly impact any process thus the related data for the light can be categorised as negligible or MCIL4. During the night the light may provide luminosity to the passengers but it also indicates the vehicle's location. If the vehicle is used for a mission during night, it is likely the mission will fail, thus the corresponding data, for the light, can be categorised to as catastrophic or MCIL1. However, any data must be filtered and tested through the risk assessments before is integrated into the platform. Furthermore, the framework requires, that hazard and risk assessments be executed for the analysis of the likelihood of occurrence, consequences and detection levels provided by the tables below.

Table 1 Categories of likelihood of failure occurrence

Category	**Definition**	**Range (Mission Failure)**
Frequent	Many times in missions	$> 10^{-3}$
Probable	Several time in missions	10^{-3} to 10^{-4}
Occasional	Once in mission	10^{-4} to 10^{-5}
Remote	Unlikely in missions	10^{-5} to 10^{-6}
Improbable	Very Unlikely	10^{-6} to 10^{-7}
Incredible	Cannot believe that it could occur	$< 10^{-7}$

Table 2 Consequence categories

Category	**Definition**
Catastrophic	Complete mission failure
Critical	Impacts mission but not complete failure
Marginal	Major mission issues
Negligible	Minor mission issues

Table 3 Risk class matrix

Likelihood	**Consequence**			
	Catastrophic	***Critical***	***Marginal***	***Negligible***
Frequent	Class 1	1	1	2
Probable	1	1	2	3
Occasional	1	2	3	3
Remote	2	3	3	4
Improbable	3	3	4	4
Incredible	4	4	4	Class 4

The classification of the consequences are as follow:

- **Class 1**: Unacceptable in any circumstance
- **Class 2**: Undesirable: tolerable only if risk reduction is impracticable or if the costs are grossly disproportionate to the improvement gained.
- **Class 3**: Tolerable if the cost of risk reduction would exceed the improvement.
- **Class 4**: Acceptable as it stands, though it may need to be monitored.

Once the hazard and risk assessments are identified, each of the threats should also be assigned with a detection level, as given in Table 4, in order to provide a definition in which degree a threat can be detected.

Table 4 Detection Levels

Difficulty Level	Definition
No effort	Very likely to be detected
Very Easy	With almost no effort
Easy	Without great effort
Normal	Conforming to a standard
Hard	With a great deal or effort
Very Hard	Not likely to be detected

Mission-critical levels, see Table 5, offers the ability to attain in regards to mission-critical system development and related to the Classification Matrix given in Table 3. Throughout risk assessments the target MCIL can be identified and thus, it can be converted as a requirement for the mission-critical system. The derived requirements can provide an efficient data model development that can be used and ensure that the mission-critical system can succeed a mission.

Table 5 Mission-Critical Levels

Mission-Critical Integrity Level	Mission Failure Factor	Risk Classification
MCIL 4	100,000 to 10,000	Class 4
MCIL 3	10,000 to 1,000	Class 3
MCIL 2	1,000 to 100	Class 2
MCIL 1	100 to 10	Class 1

Safety (mission) critical applications, such as in [13] and [14], are using safety standards, such as the IEC 61508 and the RTCA DO-178B, in which are oriented for people's safety when a system is designed. The standards are intended to be a basic functional safety standard applicable to cover the safety management of electrical, electronic and programmable electronic systems throughout their lives. If the development of a mission-critical system involves human factors then the system should be considered as a safety critical system.

7. Threat Estimation

First, it is important to note that Tables 1, 2 and 4 are abbreviated as, Occurrence – O[n], Severity – SE[n], Detection – D[n] and threat estimation as T[n], with "[n]" representing a natural number [1] of each element or requirement. For example, if one threat is identified within the framework, then the threat will be assigned to as T[1]. If threat T[1] has sub-requirements, then it will be assigned to as T[1][n].

In order to evaluate or estimate the criticality of the identified threat T[n], the aforementioned tables and their elements must be assigned with numerical values, as depicted in Table 6. The idea behind the values is indicative (assumption), therefore, the maximum value of the threat T[n] can be roughly 99.9% and the lowest 0%. These values will indicate the probability of the threat affecting the mission.

Therefore, the threat level of the identified threat T[n], TL_T[n] can be calculated using the following expression,

$$TL_T[n] = O[n] + SE[n] + D[n] \quad (1)$$

Where,

TL_T[n]: The threat level of the identified threat.

O[n]: The occurrence value of the O[n].

SE[n]: The severity value of the SE[n].

D[n]: The detection value of the D[n].

In the event of having multiple threats or sub-threats, an estimation of an overall threat must be calculated in order to predict the probability of the mission success. A representation of this is shown in Table 7.

Where,

Req_core: The core requirement.

1st Sub: The first sub_core_requirement.

n Sub: Indicated the last sub-requirement.

n: Represents the real number.

i: Represents the sequential number of sub-requirements.

An approach on how to calculate the average value of two or more requirements of the same degree is as follows, (2),

Table 6 The Assigned Values for Calculating Threat T[n]

Occurrence – O[n]	Occurrence (%)	Severity – SE[n]	Severity (%)	Detection – D[n]	Detection (%)
Frequent	25	Catastrophic	≤50	Very Hard	25
Probable	20	Critical	~33.4[3.s.f]	Hard	20
Occasional	15	Marginal	~16.7[3.s.f]	Normal	15
Remote	10	Negligible	0	Easy	10
Improbable	5			Very Easy	5
Incredible	0			No Effort	0

Table 7 Requirement Sequence

Req	1st Sub	n Sub
	Req[1][1]	Req[1]…i…[1]
Req[1]	…	…
	Req[1][n]	Req[1]…i…[n]
	…	…
	Req[n][1]	Req[n]…i…[1]
Req[n]	…	…
	Req[n][n]	Req[n]…i…[n]

$$Req_core = \sum_{i=1}^{n} \frac{Req[i]}{n} \quad (2)$$

Where:

Req_core: The overall average value of the core requirement.

i: Lower limit number of requirement.

n: Upper limit number of requirement.

8. Case Study: Defensive Aid Suite (DAS) System

A most commonly used mission-critical system in the military platforms, is the Defensive Aid Suite (DAS) system. Is a survivability system, and can be used as a potential case study that addresses similar complexity issues to the aforementioned mission-critical systems and integration levels. A DAS is composed of sensors, effectors, algorithms and Human Machine Interfaces (HMI) that enhances the integrated survivability of a military vehicle. DAS also consists of different decoupling physical and logical capability networks applied for specific tasks or applications.

The DAS system can be a semi-autonomous or autonomous system that is capable of detecting, recognising and addressing threats. DAS elements are classified into two major categories Soft-Kill and Hard-Kill; other action categories are also possible where effective countermeasures can be deployed by other assets.

A **Hard-Kill** system engages and destroys threats. It creates an active fire zone of protection at a safe distance near the vehicle.

A **Soft-Kill** system is designed to avoid threats by confusing or re-directing the threats using jammers, decoys, and signature reduction measures.

An existing soft-kill DAS system from [14] has been selected for this case study, using existing DAS system components. In this DAS system various electronic components can be addressed, which are used in a Light Armed Vehicle (LAV) vehicle. A component such as the Long Range Passive Sensing (LRPS) sensor. The threat can be detected using optical systems with either Wide Field Of View (WFOV) or Narrowed Field Of View (NFOV) mounted on the platform. Each of the detected threats produces a signature identifying a potential threat that may be weapon systems such as guns and anti-tank rocket-propelled grenade launchers (i.e. M-712 and RPG-7). The detection range of the WFOV and NFOV optics are represented in Table 8. The table can be used as a message specification for a generic DAS system.

Table 8 Sensor Camera and Threats Attributes [15]

Anti-Armour Threats	***Threat, Calibre***	M-712, LSAH, 155mm	RPG-7, 80mm	Gun, 20mm, APDS
IR WFOV	***Distance, [m]***	400	470	5480
IR NFOV	***Distance, [m]***	3600	4200	340
LI/RG Camera	***Threat, [Pixels]***	1.3	42 x 42	0.8
	Target, [Pixels]	25x20	234 x 187	118 x 60
Threat Variables	***Dimensions, [m]***	0.155 dia.	0.18 dia.	2.1 dia.
	Range, [m]	14000	500	2000
	Velocity, [m/s]	255	255	815

9. Proposed DAS Architecture and Modules

This section presents a novel DAS system architecture that could be potentially used to satisfy the questions in Section II as presented earlier in this paper. For the system to facilitate a modular framework the Model Driven Architecture approach is used to construct modules that enable upgradability, maintainability and system legacy with technologies, devices and operational or functional capabilities. This proposed DAS architecture aims to fuse systems and software modelling and simulation capabilities, modular open system architectures and device integration techniques into a single package to enable rapid design, development, verification, certification and deployment of interoperable, platform portable and manoeuvre embedded mission criticality. The following sub-sections are classified as module models used for a DAS system and can also be applied for any mission-critical system.

9.1. Threats

Threats are all the known causes that can damage the platforms. Threats can be either external or internal; internal threats could be cyber-attacks, malfunction etc. External threats could be missiles or mines.

9.2. Sensors

Sensors module represents all the candidate sensors used for the DAS system. This module is for detecting and responding to any incoming threat from the physical environment. The specific input may be motion, heat, light or any of other environmental phenomena. The output is a signal that is converted into a format that is human readable or machine readable electronically transmitted over a network for exploitation and further processing.

The Sensors module can be directly connected to the DAS Sensor Processing Module to apply the safety, security, and performance on the indented design.

9.3. DAS Sensor Processing Module (DASSPM)

The DASSPM is the module that is capable of receiving the data/information from the DAS sensor. The DASSPM converts the data into a usable format that can classify, position and eventually eliminate or avoid the detected threat. The module will be able to detect also the attributes of the candidate DAS sensor in terms of type and capability if the appropriate message specification is constructed.

The DASSPM, therefore, receives the data/information from the candidate sensor and extra qualities can be added. Developers can customise the data and modify it into the corresponding real-time environment, criticality level, and mission-critical integrity level. The DASSPM will also communicate with the DASECM.

9.4. DAS Computer Module (DASCM)

The DASCM collects and processes the information from the DASSPM, to decide the best action for each available threat. This action may require user interaction or it can be fully automated. The modular design allows the system designer to use a single or multiple DASC that may deal with the same or different types of threats at the same time, providing fault tolerant and distributed design. Then the DASC communicated with the appropriate DAS Effector Control Module (DASECM), depending on the type of action decided. When there is no DASC available, the DASECM takes responsibility for the appropriate countermeasure action.

9.5. DAS Effector Control Module (DASECM)

The DASECM is responsible for controlling the DAS effectors according to the commands received from the DASCM. This module has many commonalities in data and functionality with the DASSPM. In the case of DASC failure, the DASECM can be actioned to directly deal with the threat. Additionally, it offers configuration options for the effector to achieve modularity and dynamic configuration.

9.6. Effectors

The Effectors Module is the representation of the all the candidate effectors. This module is constructed upon the available effectors needed to be installed on the platform. Each of the candidate effectors carries specific attribute thus, the module is using message specifications common to the overall architecture.

10. Top Level of a DAS Data Model

Due to the increased number of electronic components designed from different manufacturers who use different technologies, approaches, standards and architectures, the systems integration process becomes rather complex. A suggested approach to improve the vehicle's performance and survivability is to use, information management techniques. In this paper, the potential approach to such component's capability acquisition is proposed by structuring a set of message specifications and develop the DAS Data Model, represented in Figure 5.

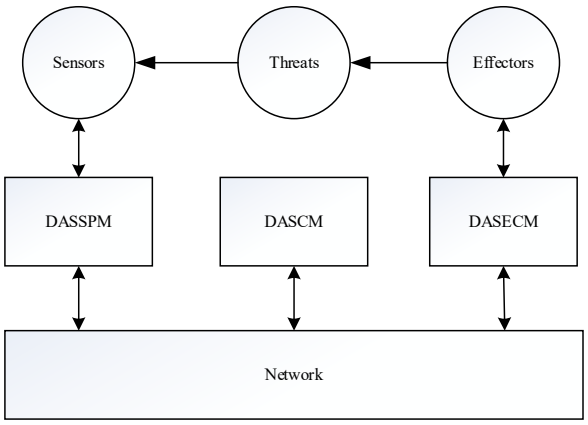

Figure 5. Top Level of DAS Architecture.

Following the proposed framework and the proposed DAS architecture and modules, the system will be able to use different battlefield scenarios, operational modes and different electronic devices from different manufacturers. With this development and the combination of the proposed approaches, the DAS Data Model will provide the different criticality levels and the different real-time environments that will be the essentials for a successful mission.

10.1. DAS PIM

Using the IBM Rational Rhapsody Developer for C++ tool, the message specification for the soft-kill DAS system sensors is represented in a UML model as shown in Figure 6. The tool is selected because it is the most commonly used for land vehicle electronic architectures, specifically in the GVA approach implementation [4]. This a PIM in which it has the ability to be redesigned when additional modifications are required during the development, or additional sensors are included in the DAS system. This PIM model is constructed using the attributes in Table 8 and with the usage of the proposed MCIL framework and DAS architecture, the mission-critical message specifications of a soft kill DAS can be created.

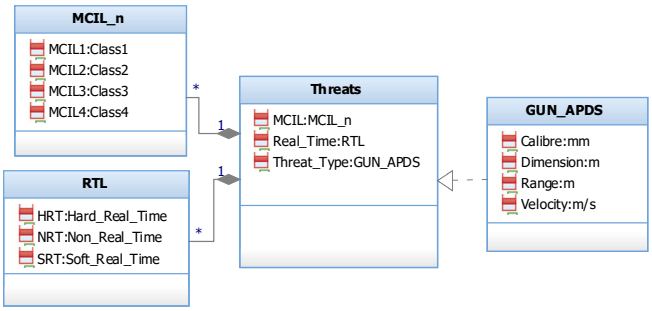

Figure 6. Threat PIM.

The message specification in Figure 6 has its own Mission-Critical Integrity Level (MCIL_n) and Real-Time (RTL) levels.

The developer will have the freedom to choose between the aforementioned levels when applying the paper's approaches. For instance, if the vehicle uses passive armour the specific threat is not lethal, therefore, the Mission-Critical Integrity level of the message can be classified as Class 4. If is a light armoured vehicle then the Mission Criticality Integrity level can be classified as Class 2. The same can be applied for the Real-Time responsiveness.

10.2. DAS PSM

Once the PIM model is designed and specified, the model can be translated into PSM for integration into a specific architecture. The middleware technologies that can be used are the Data Distribution Service (DDS) or Message Queue Telemetry Transport (MQTT). DDS is an OMG machine-to-machine middleware standard that offers scalability, real-time, Quality of Service (QoS), high performance and interoperability data exchange between data publishers and subscribers. Publish/Subscribe message patterns are used for sharing the DAS system data in order to minimise the impact of adding new sub-systems [16]. MQTT is a lightweight messaging protocol that offers bi-directional communication to nodes. Its design has been created to minimise network bandwidth that uses the messages in a reliable degree of delivery.

When each attribute in the PSM model has its own data type, it must be specified and validated from the supported primitive data types of each target environment of DDS. The message specification file is used to describe the software component's application in order to enable communication between software components from different programming languages. However, the PSM transformation can be translated into a PSI model for the simulations and apply case studies of any mission-critical environments.

11. Qualitative and Quantitative Results

Using the example in Figure 6 (Section 10.1) and applying the threat estimation procedure discussed in Section 7, the threat can be calculated and then estimate the effect level of the mission. The example stated the following, "if the vehicle uses passive armour the specific threat (see Figure 6) is not lethal, therefore, the Mission-Critical Integrity level of the message can be classified as Class 4. For a light armoured vehicle then the Mission Criticality Integrity level can be classified as Class 2". In this section an estimation of the effect level of the stated threat is presented using anticipated values for each element.

11.1. Case 1: Passive Armour Vehicle

Case 1: If the vehicle uses passive armour then threat is as depicted in Figure 7.

The occurrence O[1] of the potential cause can be occasional. Therefore, the occurrence selected from Tables 1 and 6 is,

Occurrence: **O[1]** – Occasional (15%)

Using Table 6, the O[1] is 15%.

Considering that the threat does not significantly impact the mission or the vehicle, the severity of the specified threat can be negligible. Using Tables 2 and 6,

Severity: **SE[1]** – Negligible (0%)

Assuming that the vehicle uses passive armour instead of active, the threat T[1] will be detected from the crew. Therefore, the detection might be considered to as hard to detect, and using Tables 4 and 6,

Detection: **D[1]** – Hard (20%)

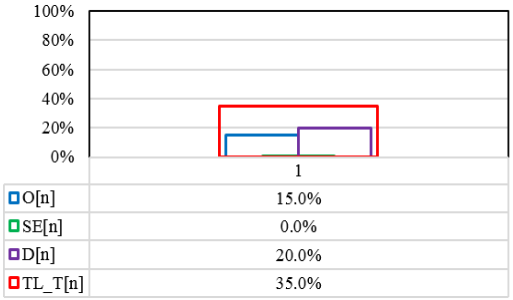

Figure 7 Case 1: T[n] Level

TL_T[1]: [(O[1]:15%)+(SE[1]:0%)+(D[1]:20%)= 35%

After the threat analysis of the specific threat for this case study, it has been identified to be 35% hazardous against the mission.

11.2. Case 2: Light Armoured Vehicle

Case 2: If the vehicle is a light armoured vehicle then the threat will be as in Figure 8. The occurrence O[1] of the potential cause can be occasional similar to the Case 1. Therefore, the occurrence selected from Tables 1 and 6 is,

Occurrence: **O[1]** – Occasional (15%)

Using Table 6, the O[1] is 15%.

Considering that the threat significantly impacts the mission or the vehicle then the severity of the specified threat can be catastrophic. Using the table 2 and 6,

Severity: **SE[1]** – Negligible (50%)

As aforementioned, the vehicle is a light armoured vehicle and assume that it has an integrated DAS system. Therefore, the threat T[1] to be detected can be categorised as easy. Using the Tables 4 and 6, detection is,

Detection: **D[1]** – Easy (10%)

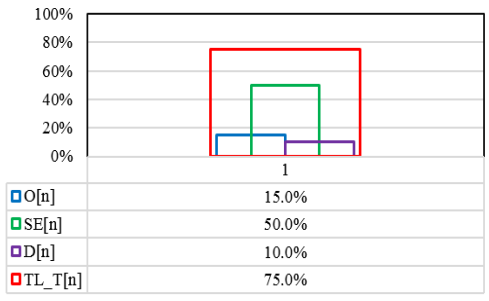

Figure 8 Case 2: T[n] Level

TL_T[1]: [(O[1]:15%)+(SE[1]:50%)+(D[1]:10%)= 75%.

The same threat as identified in Case 1 has being calculated to be 75% within this case study (2); whilst the same threat for a different mission scenario has increased in terms of threatening level. This in turn, elements that can be identified for a mission shall be re-used and analysed accordingly using this preliminary mission analysis at this early stage of a mission-critical system.

12. Conclusion and Future Work

At present there are no current development activities employed for mission-critical systems. In this paper, the importance of those activities is discussed. The objective of the proposed framework, is to enable system engineers achieve the mission development of any critical system's life-cycle, efficiently and effectively. This is achieved through a single package, using the three following main capabilities.

Firstly, a basic functional "mission standard" that enables the mission life-cycle development in a critical system; Secondly, the ability of mission interoperability for services and functionalities between systems and sub-systems built and procured in different times; and finally, the process that can support to define and analyse the mission data requirements of various critical systems.

The paper covered only the primary mission-critical attributes of a critical system, extracting the basic functional requirements. The scope of those requirements is paying particular attention on the mission, safety and security-critical attributes.

Furthermore, the extended part of this work, proposed an approach to estimate threats and their impact on a mission so as to early de-risk missions and systems (mission-critical) whilst in their design stages.

The next step is to further develop and refine the proposed using detail low level design case studies along with measures of performance.

ABSTRACT

In this paper, a hybrid system solar cell antenna was studied. Our contribution lies in the combination of both optical and radio-frequency signals in a solar cell antenna. Hence, we propose a new method to merge antenna and solar cell. The leaf- shaped patch solar cell antenna was dedicated at a time to the energy harvesting and the RF transmission. A performance analysis of the solar cell antenna was conducted using Advanced Design System (ADS) software. Simulation results showed a resonance at a frequency of 15.77 GHz with an effective return loss of -27.62dB and a gain of 5.77dBi.

1. Introduction

Solar energy was considered as one of the most renewable energy resources that could fill the shortage of energy needs. In fact, human beings used the solar energy to produce electricity. Although the photovoltaic (PV) cell was first employed to produce it, its efficiency remained limited [1]. Solar energy has become an attractive alternative for powering autonomous communication systems. Many communication systems, such as standalone systems like environmental monitoring system, vehicular communication and satellite systems [2] require electric energy for their operation and use. Solar powered communication systems have received considerable attention due to their ability to operate without the necessity of being connected to an electricity grid. This has become a significant challenge when it comes to powering communication systems in remote places where the electricity grid is not available. In order to address this challenge, the use of photovoltaic in communication systems has recently been the subject of many researches. The photovoltaic systems of power generation when combined with communication systems can provide compact and reliable autonomous communication systems, which can be used for many applications.

Traditionally, telecommunication antennas and solar cells do not mix. They must operate independently so as not to interfere. They compete for the available space on mobile and standalone systems which are generally limited in size. Furthermore they may be bulky and expensive and they limit the capabilities of product designs. In space applications for instance, both solar panels and communication system are major contributors to the overall size and weight of the satellites and combining these two systems could save real estate and cost. In urban areas, wireless communication infrastructures could be integrated into solar panels. Finally the integration of antennas and solar cell panels can be essential for the transportability of emergency autonomous communication stations [3-4] and [5-6].

In this paper, we describe the solar cell antenna in the second section; we detail the proposed approach as well as the effects of optical transparency on the antenna parameters. In the third section we explain the proposed solar cell antenna structure by giving a model of the mesh patch with optimized geometry. The simulations results of the solar cell antenna are presented. A solar cell antenna array has also been studied in this section by giving their parameters. The solar cell antenna equivalent circuit as well as the RF / DC decoupling circuit have been studied in order to eliminate the influence of the RF signal on the DC signal and to show that this hybrid system will be both for the recovery of a solar cell, energy and RF transmission. Finally, we conclude the paper.

2. Solar cell antenna

2.1. Approach

Several attempts to integrate solar cells with patch antennas have been studied, but they did not pay attention to the antenna patch when it is placed above a solar cell. To remedy the drawbacks, especially of limited surface area, encountered during the integration of patch antenna with a photovoltaic cell, we

* Chokri Baccouch, National Engineering School of Tunis, Tunis El Manar University, B.P. 37, Le Belvédère, 1002 SYS'COM Laboratory, Tunis, Tunisia,

propose here new types of antennas based on optically transparent photovoltaic cells with mesh patches.

Optically transparent mesh patch antennas are antennas that have a certain level of optical transparency. These transparent antennas, for example, are potentially suitable for integration with solar cells for small satellites. Traditional patch antennas used on small satellites compete with solar cells for the surface. However, a mesh patch antenna can be placed directly on the solar cells and solve the surface limitation problem. For such integration, a high optical transparency of the patch antenna is required from the solar cells point of view, since solar cells require sufficient sunlight to generate adequate electrical power. On the other hand, the antenna must have at least acceptable electrical properties at the same time so that it can radiate correctly and efficiently [7-8] and [9-11].

The hybrid system studied in this paper was devoted at a time to the energy harvesting and the RF transmission for satellite communication. This structure was made of a photovoltaic cell in which the front grid was designed to have a miniature antenna suited to the band transmission and to minimize the power loss of the cell devoted to energy conversion. The received electrical energy was used to operate the complete system.

2.2. Optical transparency effects on the antenna parameters

The openings in the conductor make it possible to pass the light while the mesh can still be conceived as an efficient radiator. Mesh patch antennas, compared to their solid counterparts, have a higher surface resistance due to much lower conductor coverage. Consequently, it is normal, when the optical transparency increases, to have a low performance of the antenna.

The antenna optical transparency is given most often by the ratio of the mesh patch surface to the patch total area (eq.1).

$$T = \left[1 - \frac{A_{conductor}}{A_{patch}}\right].100\% \qquad (1)$$

It has been demonstrated that, when the line width is fixed, we notice that during the patch transparency increase the frequency of resonance decreases. Since t the patch physical length is the main determinant of the resonance frequency as noted by Clasen [7], the increase in transparency introduces the possibility of minimizing the antenna design. Using the mesh patch increases the fringing fields; therefore, increase the antenna electrical length [12]. Also from Figure 1 one is able to see that increasing the transparency decreases the bandwidth. Bandwidth is defined by the following equation:

$$BW = \frac{f_h - f_l}{f_r} \qquad (2)$$

With f_h the highest frequency at which the voltage standing wave ratio (VSWR) is below 2, f_l the lowest frequency at which the VSWR is below 2, and f_r is the frequency of the minimum VSWR.

Also as seen in Figures.2, 3 and 4, the increase in transparency decreases the antenna efficiency, gain and directivity.

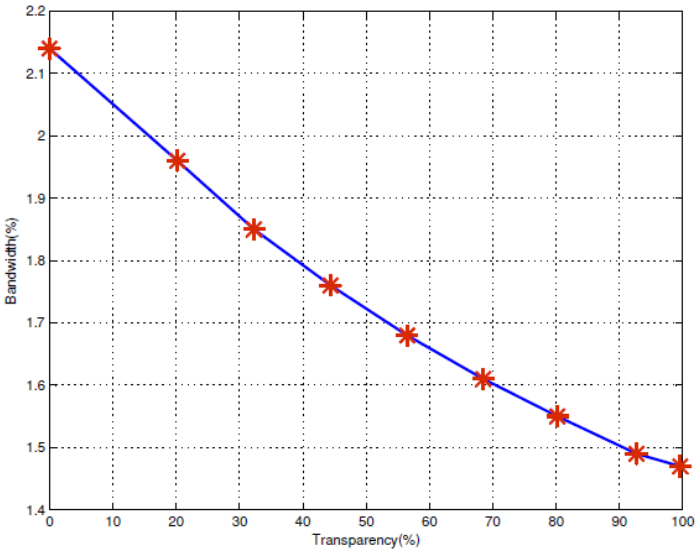

Figure 1: Bandwidth in terms of transparency

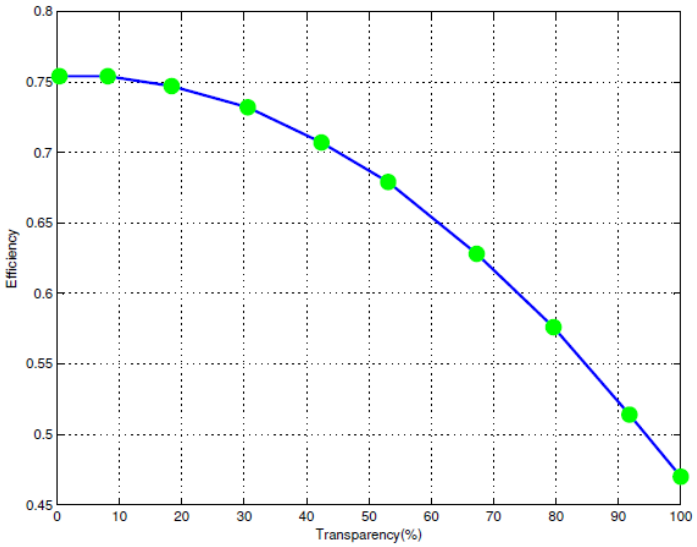

Figure 2: Efficiency in terms of transparency

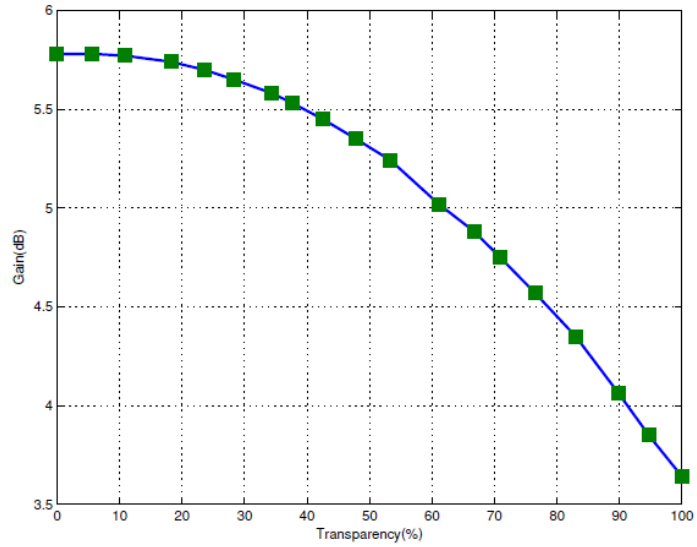

Figure 3: Gain in terms of transparency

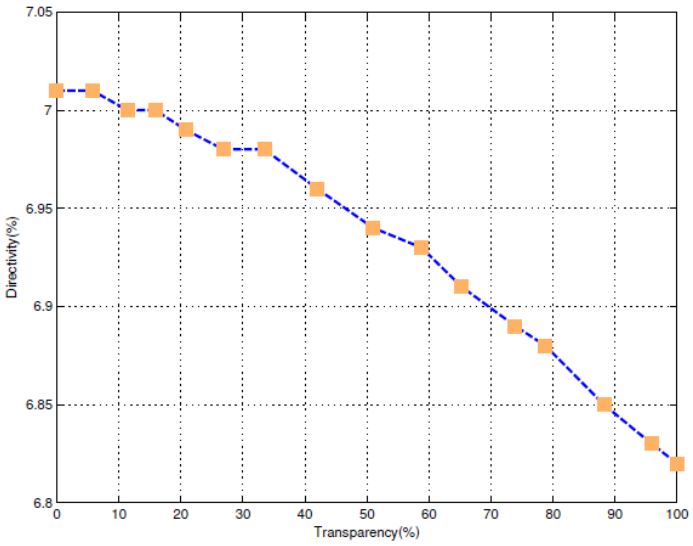

Figure 4: Directivity in terms of transparency

2.3. *Effect of the line width*

The study of optically transparent antennas is based essentially on the optimization of the mesh patch dimensions. In this paper, antennas with an optical transparency of 70%, 80% and 90% are generated. Each transparency depended of the line width and the number of mesh lines. Simulation results present the efficiency of the mesh antenna as a function of the line width for each transparency is plotted in figure 5. We interpret that for a given transparency, efficiency of a mesh antenna can be improved by refining the line width. From fabrication standpoint of view, the line width realization of 0.1 mm or more is simple. The efficiency and transparency are adequate for this hybrid system of solar cell antenna for satellite and terrestrial communications. From the simulation results (see Figure 5), we conclude that with a line width of 0.1 mm, it is possible to achieve more than 60% efficiency with an antenna of 90% transparency, 63% efficiency with an antenna of 80% transparency and 67% efficiency with an antenna of 70% transparency.

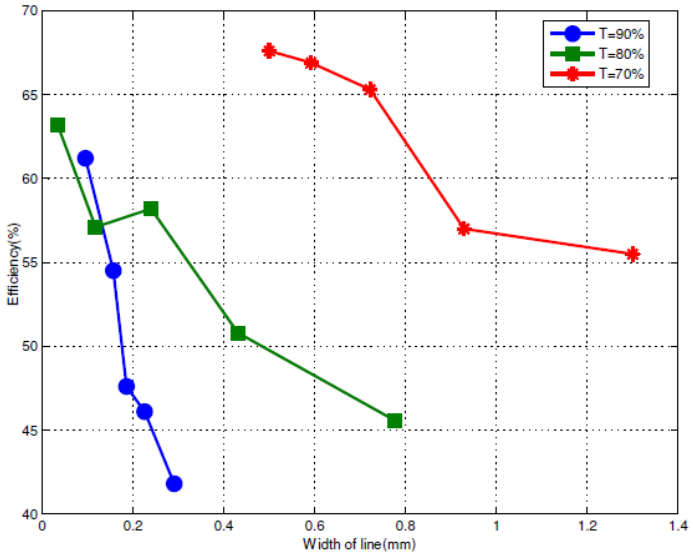

Figure 5: Efficiency in terms of width of line

Efficiency is inversely proportional with optical transparency, this is true because traditional patch antennas are more efficient but when they are integrated with solar cells they screen these and can reduce the collected electrical power. Our method allows us to propose a hybrid solar cell antenna system for energy harvesting and RF transmission for satellite and terrestrial communications.

3. Simulations results and discussions

3.1. *Structure of solar cell antenna*

We propose a solar cell antenna with mesh patch. A mathematical model that we have already studied to minimize the power losses of the solar cell antenna and improve the conversion efficiency as a solar cell [13-14]. Optimization of the maximum electrical power collected as a function of finger width was determined. The optimal width W_f has been used for the mesh patch design or front face collection grid.

Improving the performance of a solar cell depends not only on the materials and structure but also on the design of the metal grid front face.

With this mesh patch structure two types of waves can exist. The optical waves that will be absorbed by the silicon (semiconductor) and the RF waves that will be collected by the mesh patch metal whose width of fingers W_f is optimized. The structure designed was a solar cell antenna printed on a multi-layered substrate Figure 6.

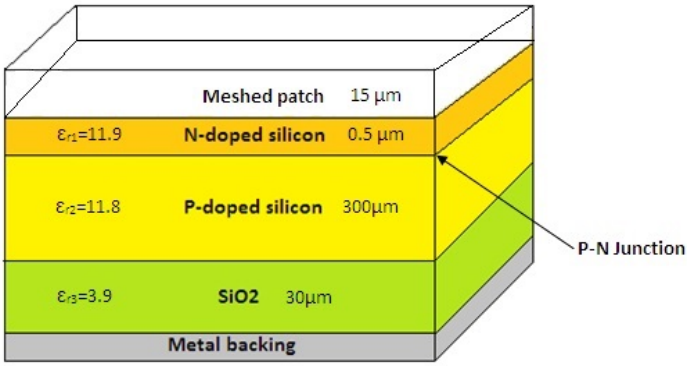

Figure 6: Multi-layered substrate of solar cell antenna

The silicon on an insulating layer SiO_2 confers to the components that are realized, a higher operating frequency, an ability to operate at low voltage and low power consumption and an insensitivity to the effects of ionizing radiation. When using a thin-film substrate we observe that the simulations are complex and time consuming. The meshed patch of solar cell antenna proposed is given in Figure 7. The dimensions of the proposed patch of solar cell antenna are given in the following table (Table 1).

Table 1: Dimensions of solar cell antenna

Parameters	Values
Width of busbars	W_b=0.5mm
Width of finger	W_f=60 µm
Length of feedline	L= 9.1 mm
Width of feedline	W=0.235 mm

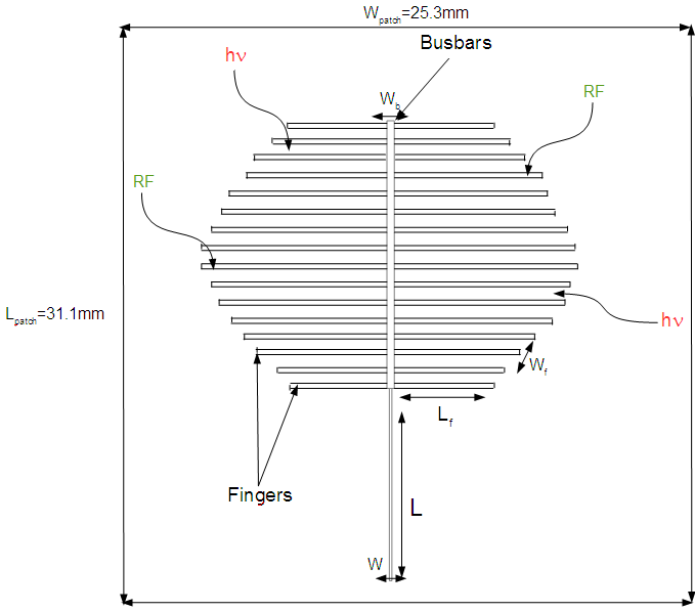

Figure 7: Meshed patch of solar cell antenna proposed

This antenna was excited by a microstrip line of characteristic impedance equal to 50 Ω. In this paper, the transparency of a patch is defined by the percentage of see-though area on the patch as shown below (see equation 3):

$$T = \left[1 - \frac{A_{conductor}}{A_{patch}}\right].100\% = \left[1 - \frac{W_b L_b + WL + \sum_{1}^{32} W_f L_f}{W_{patch} L_{patch}}\right].100\% \quad (3)$$

where W_f is the mesh line width, L_f length of each mesh line, W_b is the busbars line width, L_b the busbars length, W is the InsetFeed width, L is the InsetFeed length, W_{patch} is the patch width and L_{patch} is the patch length (see Figure7).

3.2. Antenna Parameters

As an antenna, the electromagnetic performances of the solar cell antenna were simulated by using the ADS software. The simulated S11 parameter was presented in Figure 8. An antenna should be perfect radiator, rather than perfect absorber. The amount of radiated power returned back through the port can be calculated for finding return loss at that resonating frequency. For the resonant frequencies the return loss should be less than -10dB i.e. S11<-10 dB. Simulation results show that the designed antenna can be used as a frequency antenna with an effective return loss of -27.62dB at 15.77GHz. To the normal scale $S11=10-2.762, ie only 0.17% of the emitted power will be reflected as well as the impedance Z_a=49.82 Ω which confirms the adaptation of the antenna. The adaptation of our antenna is substantiated by the return loss low value S11. Similarly, its operation can be assessed by the VSWR curve which is another performance measurement parameter at the input. It indicates the signal reflection due to a mismatch between the impedance of the antenna and that of the source. The reflected signal leads to the appearance of the standing wave voltage in the feed line which, in turn, destroys the reliability of the antenna. The ideal value of VSWR is 1 which means that 100% of the delivered power is accepted (no reflection). But, practically speaking, it is tolerable up to 2 [15]. The VSWR obtained for this antenna equal to 1.0036.

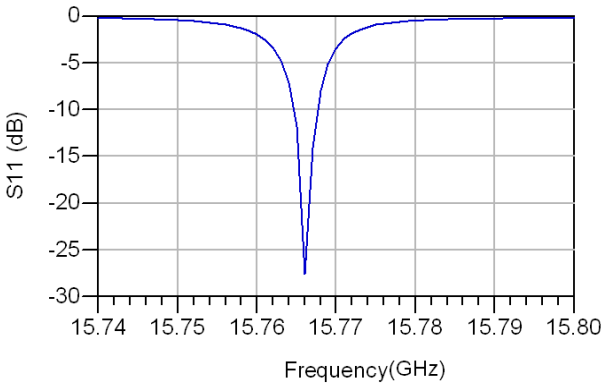

Figure 8: Reflection coefficient S11

The radiation of our antenna is gathered in the main lobes which have a wide beam width at -3 dB and whose amplitude is much higher than that of the side lobes. This reflects a very directive radiation by offering a total directivity equal to 7.26 dB at 15.77 GHz. The radiation pattern of this antenna at a frequency of 15.77GHz is shown in Figure 9. The polarization of the radiated field was linear.

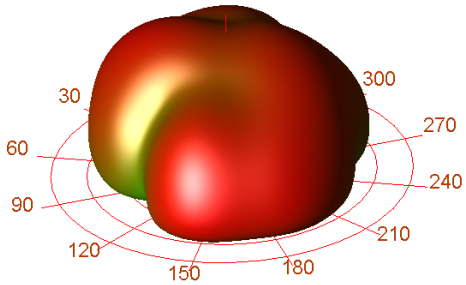

Figure.9: Radiation pattern

When designing an antenna, the gain must be taken into consideration as it is an important metric. The good values of S11 and VSWR are not enough to confirm a good radiation. Antenna gain describes how much power is transmitted in the direction of peak radiation to that of an isotropic source. The gain of this antenna was 5.77dBi.

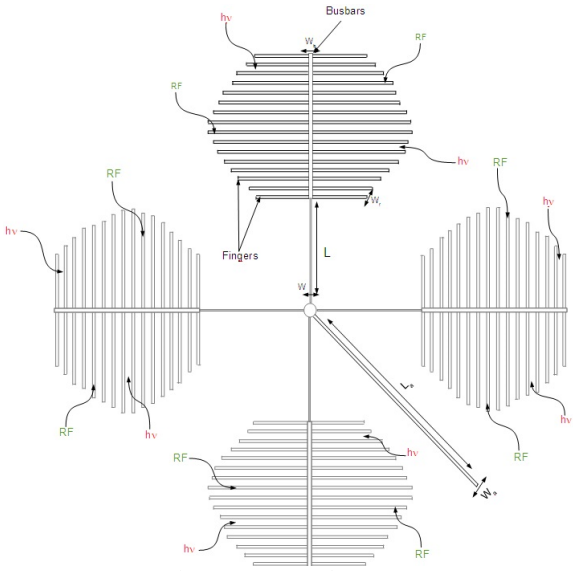

Figure 10: Array of antennas

3.3. Array of antennas

In order to increase the gain, we proposed an array of antennas shown in Figure 10. Simulation results of S11 parameter and radiation pattern are given, respectively, in Figures 11 and 12.

This array of antennas was excited by a microstrip line of La=16.82 mm in length and W_a=0.228 mm in width and of characteristic impedance equal to 50 Ω. S11 parameter shown in Figure 11 of a dual resonant frequency at 15.72GHz and 15.77 GHz with an effective return loss respectively of -20.18 dB and -22.81dB.

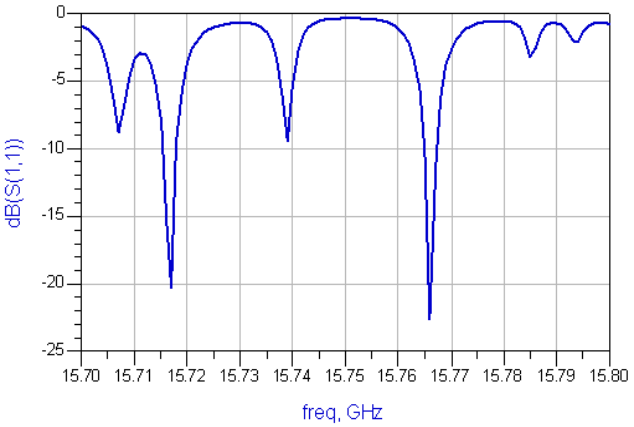

Figure 11: Reflection parameter S11 of array antennas

The radiation pattern of this array of antennas is shown in figure 12. It is gathered in the main four lobes. The gain at the resonance frequency of 15.77GHz is 9.76 dB and the directivity is 11.24 dB.

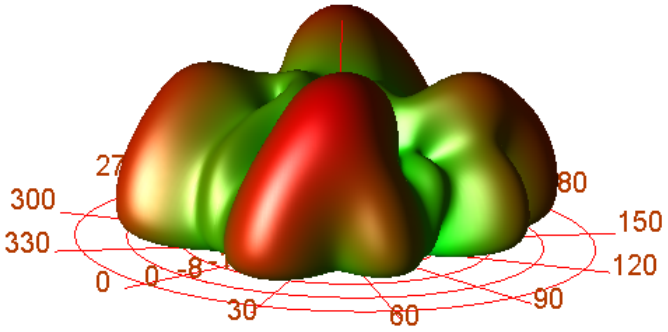

Figure 12: Radiation pattern of array antennas

The designed array antennas are showing excellent gain and directivity at the resonating frequencies with high radiation efficiency.

3.4. Equivalent circuit of solar cell antenna

Solar cell equivalent circuit is specially simulated in Advanced Design System for measuring power (P), current (I) and voltage (V). Microstrip antenna equivalent circuit is separately simulated and the same output is measured. Finally both microstrip and solar cell circuits are combined and output is measured. While comparing both outputs, combination of microstrip and solar cell equivalent circuit produces high voltage (V), current (I) and power (P). The simulation of SOLAN in ADS provides the following values of current (I) =872.8mA Voltage (V) =8.728mV and Power (P) =7.6177984mW were measured as shown in Figure 13.

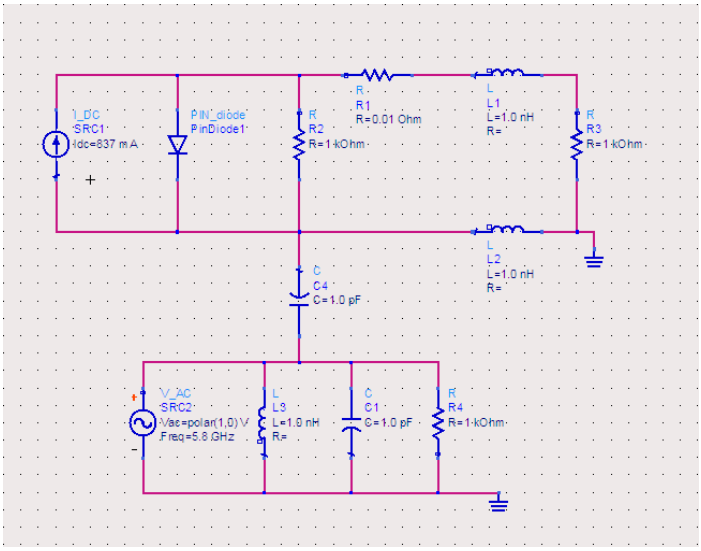

Figure 13: Equivalent circuit of solar cell antenna

3.5. Decoupling RF/DC in solar cell antenna proposed

Since the solar cell has a DC circuit, the direct current path must be decoupled from the RF signal path in such a way that the DC load has no influence on the RF properties of the antenna. The decoupling can be realized by means of concentrated reactive elements and distributed elements, respectively. In this case, we propose an inductive and capacitive RF/DC decoupling circuit shown in Figure 14.

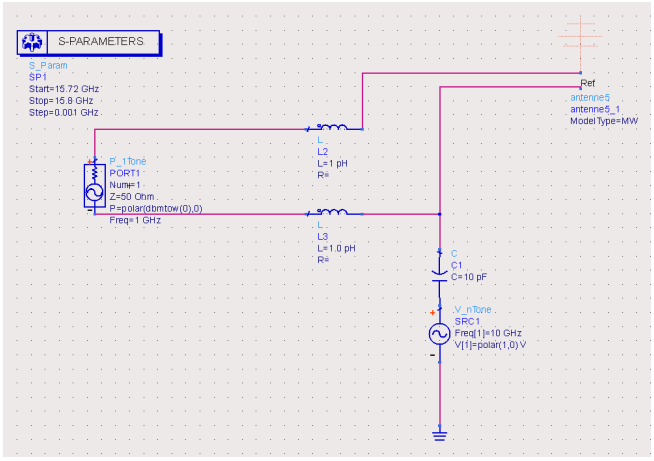

Figure 14: RF/DC decoupling circuit

The decoupling circuit was simulated (see Figure 15) and values are compared to the S11 parameter shown in Figure 8. The simulation of the reflection parameter S11 of decoupling circuit provides the same result of resonant frequency of the proposed solar cell antenna in Layout with a slight increase of return loss.

After RF/DC decoupling, this solar cell antenna can meet the purpose for which it is being studied energy harvesting for the relevant telecommunication system power supply and RF

transmission. Based on the simulations results obtained, the solar cell antenna proposed here can be used for ku band satellite communication. Figure 16 explains well the operation of this solar cell antenna.

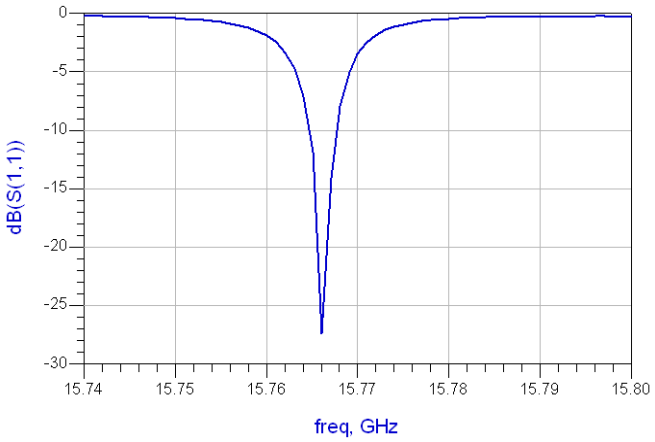

Figure 15: Simulation of RF/DC decoupling circuit

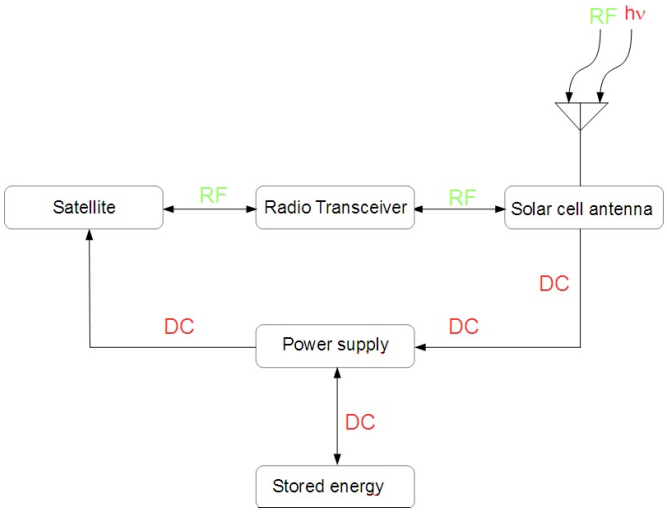

Figure 16: Self-contained wireless system with solar cell antenna

4. Conclusion

In this paper, we presented a solar cell antenna with leaf-shaped patch. This optically transparent antenna is particularly well adapted for energy harvesting and for the RF transmission in Ku band with a large gain. Good performances are obtained for this solar cell antenna, as a PV cell with its collected electrical power and as an antenna with its gain 5.77dBi and 9.76 dBi of array of antennas, directivity and efficiency. We conclude that the hybridized method where the patch element of a patch antenna has been replaced by a solar cell is more efficient than a simple integration where the patch antenna was placed directly on the solar cell is what which limited the available area of the cell and consequently a loss of electrical energy collected.

ABSTRACT

This article describes the modeling procedure of a direct resistive heat model of the molybdenum sheet and its simulation with electrodes made from various materials. The main characteristic of the proposed model is its dynamic behavior, because model considers the movement of the molybdenum sheet. The simulation results are mutually compared and the optimal material parameters are selected. The development of the model, in which the movement of molybdenum sheet is considered is used for determination of optimal movement speed of the molybdenum sheet in order to achieve requested temperature. The presented model can be also used for determination of optimal electrode materials and its geometrical properties/shape.

1. Introduction

This paper is an extension of work originally presented in Electrical Power engineering 2017 [1]. This article discusses the usage of finite element method for the development of a resistive heating model of the molybdenum sheet. The model is designed for the needs of the development of the equipment for the heating and shaping the molybdenum sheets into molds. The mentioned molds are used as containers for horizontal crystallization of the sapphire single crystal. Molybdenum is one of the few materials suitable for this purpose in a view of the long-term high-temperature load of the mold. The mold is exposed to the temperature gradient of up to 100 °C./ mm at the maximum temperature of 2150 °C. in the longitudinal direction of the container, where in one part is the melt and in the adjacent part is the corundum as an already growth product, i.e. single sapphire crystal. Based on the extreme conditions during the process, it is crucial to not decrease the mechanical abilities during the shaping process of the mold. For that purpose, the structural changes and possibilities of avoiding them by properly set pre-heating respectively heating/cooling system of Mo sheets need to be predicted. Currently, the molds are made of molybdenum sheet having a thickness of 0,5 mm, made by powder metallurgy technology, i.e. by plastic deformation and sintering procedure. Specifically, the molybdenum sheet Grade M1 corresponding to the American standard ASTM B386 or GB 3877, where the chemical composition is approximately the same. [2-5]

2. Basic simulation model

The simulation model is developed in COMSOL environment as a 3D model with the options for reconfiguration the mutual position of electrodes, the electrode material and the pressure on the electrodes. The model is composed of the molybdenum sheet and two electrodes. The molybdenum sheet is modeled as a block (domain) with a wanted width(a), depth(b) and thickness(c) and electrodes are modeled as cylinders with a wanted diameter(d), height(h) and distance(x) between them. The geometry (Fig.1.) is then complemented by physic setup. The Multiphysics "Joule heating (JH)" is used for the model. This Multiphysics is formed by the connection of "Electrical circuit (EC)" physic and "Heat transfer in solid (HTS)" physic. The physic "Electrical circuit" is used to set up the value of input current trough top boundary of one electrode and grounding through the top boundary of the other electrode. Within the EC module, the required contact pressure applied to the electrodes and the roughness of the contact between the electrode and Mo sheet can be adjusted. The HTS is used to set up parameters as initial temperature of the system and the method in which the temperature is transferred to the surrounding area. The proper function of the model is achieved by setting the spherical domain with a diameter of one meter, which is filled with air. All simulations are the set as time domain simulation, so we can determine the influence of studied materials on the speed of the heating of the Mo sheet. [6-9]

As it has been already mentioned, the model is reconfigurable, but for means of this paper the following geometrical parameters are set: Parameters of molybdenum sheet (based on manufactured molybdenum sheets [10,11]): **1000/300/1 (a/b/c) mm,** parameters

of electrodes: **20/50 (d/h) mm**, the electrodes distance: **100 (x) mm**. The electrodes are pressed to the Mo sheet with a pressure of **0.3 MPa.** For the electrode's material study, three classes of materials based on the electrical conductivity of the electrodes are defined (lower than Mo, Mo and higher than Mo). The electro-thermal parameters of the basic model are defined in TABLE I. The model needs to be particularly accurate in the molybdenum sheet domain. For that purpose, the temperature dependencies of electro-thermal parameters of molybdenum are implemented, specified by the manufacturer "PLANSEE" (Fig.2-4.).

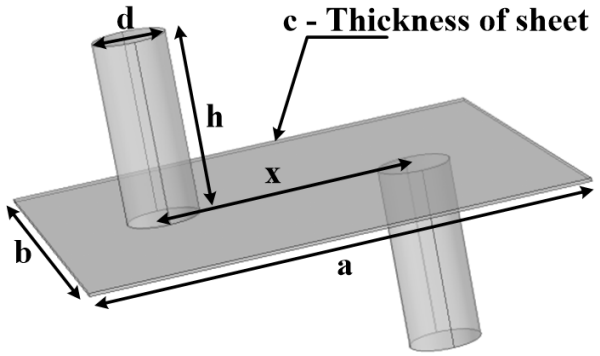

Fig. 1. Representation and definition of Mo sheet model

Table 1: Electro-thermal parameters used in simulations

Material	Parameter				
	Electrical cond. [S/m]	*Relative perm. [-]*	*Thermal cond. [W/(mK)]*	*Specific heat capacity [J/(kgK)]*	*Density [kg/m^3]*
Molybdenum (20 °C) (293.15 K)	17.9e6	1	142	254	10280
Class I. Lower El. Con.	$\sigma_{Mo}/10$	1	400	385	8700
Class II. Equivalent El. Con.	σ_{Mo}	1	400	385	8700
Class III. Higher El. Con.	$\sigma_{Mo}*100$	1	400	385	8700

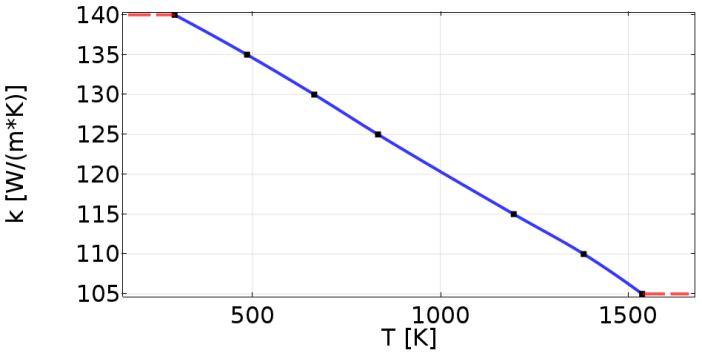

Fig. 2. Thermal dependence of thermal conductivity of molybdenum used in simulations

The mentioned JH module of the COMSOL environment uses well-known equations for modeling a heat transfer in solid materials (1).

$$\rho C_P \frac{\partial T}{\partial t} - \nabla \cdot (k \nabla T) = Q \qquad (1)$$

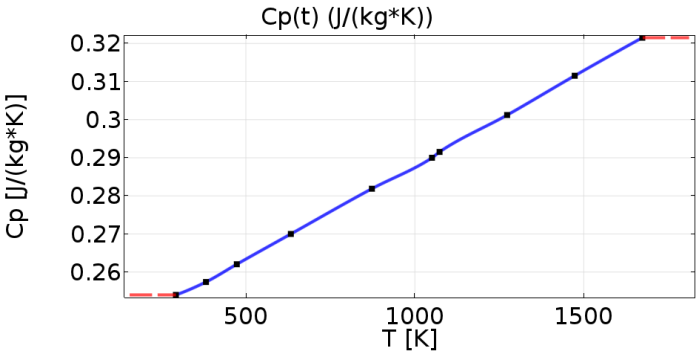

Fig. 3. Thermal dependence of specific heat capacity of molybdenum used in simulations

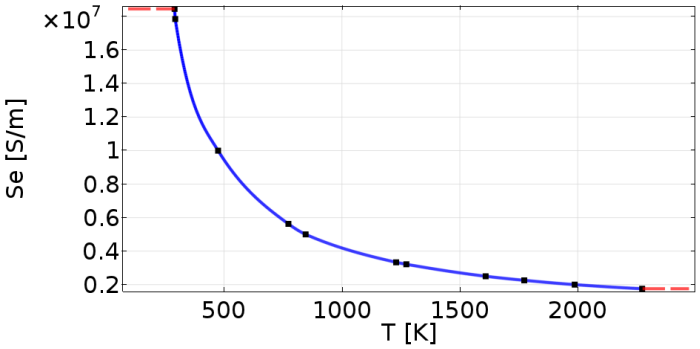

Fig. 4. Thermal dependence of electrical conductivity of molybdenum used in simulations

Where "ρ" is the density of the modeled material, "C_P" is specific heat capacity of the material, "k" is thermal conductivity of the material and "Q" is a heat source.

In this case, the heat source "Q" is determined by Joule-Lenz law of resistive loses in material structure due to the current flow through this structure.

3. Simulation results I.

Based on [6] the wanted temperature of Mo sheet is at a level between 1000 K to 1200 K. At those levels, the Mo sheet can be easily bendable. The simulation is done for before mentioned electrode's material classes (TABLE I.) not for specific material. The input current of the system is selected within the interval from 1000 A to 1400 A. The results are compared in a way of temperature distribution within Mo sheet domain and speed of the heating process. Fig.5. shows actual simulation model with geometrical parameters defined in the previous paragraph.

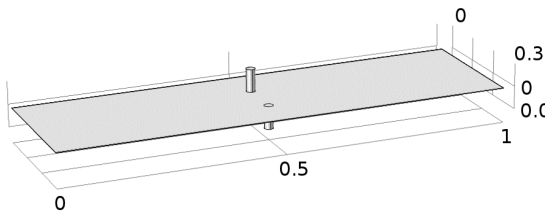

Fig. 5. Model of Mo heating with given geometrical parameters

The simulation is done with electrodes placed in the middle of the longer side of the sheet while the distance between electrodes is set to 100 mm. The following results are displayed as the temperature in the point in the middle of the sheet's volume and temperature distribution in the cutline between electrodes (middle of the Mo sheet) as can be seen at Fig.6.

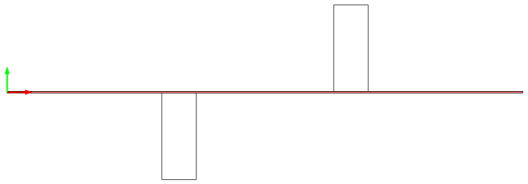

Fig. 6. Line for result extraction (Temperature distribution)

Fig.7. shows mentioned results for the first class of electrode's material, which has lower electrical conductivity than Molybdenum. The wanted temperature of 1000 K (Fig.7. up) was achieved in 75 s for lowest current (1000 A) and in 4 s for highest simulated current (1400 A). The wanted temperature interval is marked as black dashed lines in Fig.7,8,9 (up). The second part of the graph (Fig.7.middle) shows temperature distribution (based on Fig.6.) for different current values, while the time when the desired temperature value was achieved (1000 K) is considered. The last part of the graph shows temperature distribution within whole Mo sheet with the chosen current flow. Fig.8. and Fig.9. have the same purpose as Fig.7., but other material types are considered. For second electrode's material (Se=17.9e6 S/m) can be seen that wanted temperature was achieved in 95 s for current value of 1400 A.

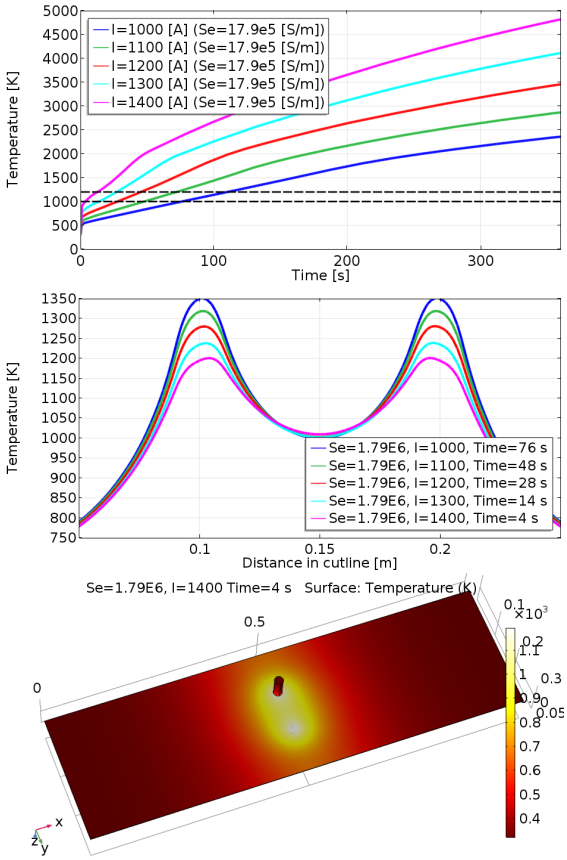

Fig. 7. Results for first electrodes material type (Se = 17.9e5 [S/m])

In case of third material the heating process was much slower (the major part of heat is produced through the direct resistive heating, while in first two cases there was also considerable influence of indirect resistive heating), wanted temperature was achieved in 164s for current 1400 A and it can be said that minimal current needed to achieve wanted temperature in given time is 1200 A.

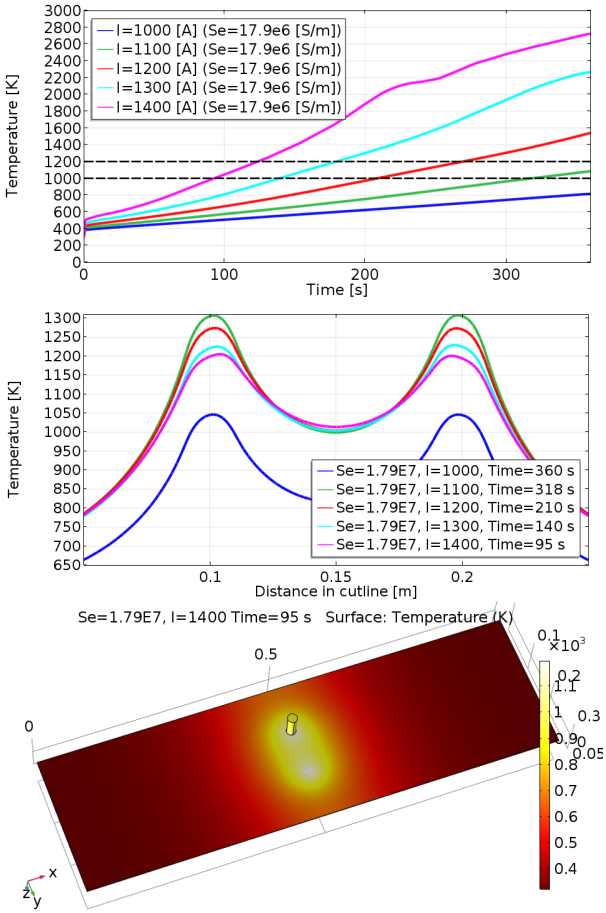

Fig. 8. Results for second electrede's material type (Se=17.9e6 [S/m])

4. Model of sliding molybdenum plate

For simulation of sliding molybdenum sheet the same settings of physics and geometry are used as within the basic model (previous part), but for the shift of the Mo sheet a special script in Matlab language is developed, which basically simulates the heating in a loop with the different initial position of electrodes. For the required temperature distribution, which is different for each step of the simulation, the molybdenum sheet domain is divided into subdomains (blocks) (Fig.10.). Within individual subdomains, the average temperature is defined (volumetrically) from previous simulation step and next simulation step is simulated with given electrodes shift. Each domain is within script defined as a 3D object with given length, width and height. These geometrical parameters are computed from geometrical parameters of whole Mo plate and from a wanted number of the subdomain in every direction of Mo plate. Mathematically, this model is described as the basic simulation model with equation 1 and by Joul-Lenz law for heat source of the modeled physic.

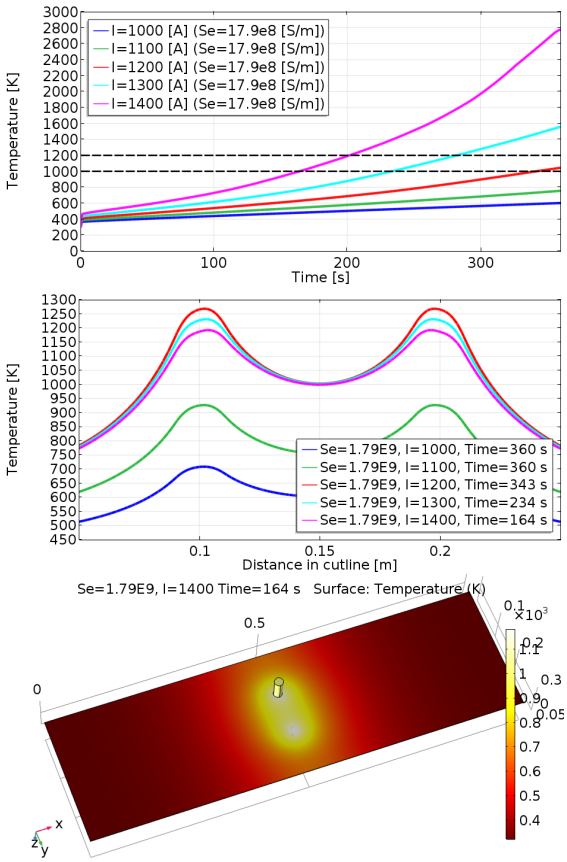

Fig. 9. Results for third electrode's material type (Se=17.9e8 [S/m])

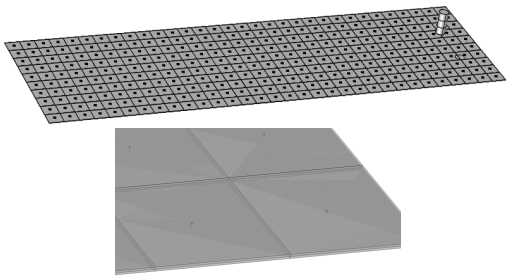

Fig. 10. Model of Mo heating with subdomains

5. Simulation results II.

The simulation is done for the second class of materials with electrical conductivity value close to Mo sheet, in which the temperature distribution was most uniform. Based on the optimal speed of the heating process and distribution of heat within Mo sheet, the input current of 1400 A is applied. It needs to be mentioned that this part of the model was created purely for verification of the proposed modeling process and thus, it does not consist any actual comparison with measurement. For that reason, a quite large (120 mm) electrodes shift is chosen for simulation. Model of the Mo sheet is composed of (32x10x2) subdomains and it is simulated in 5 steps with total electrodes shift of 600 mm in 100 s. The results shown in fig. 11 demonstrates the functionality of the proposed model (chapter 4), while each step of simulation is defined two times. The initial time (0 s) is representing initial temperature setting within each subdomain with new electrode position. The secondary time (20 s) is representing end time for each step and for the temperature distribution needed what is needed for next step's initial condition. Based on the results of the individual simulation steps, it can be said that the modeling process is suitable for this application and may be applied also in other cases/studies.

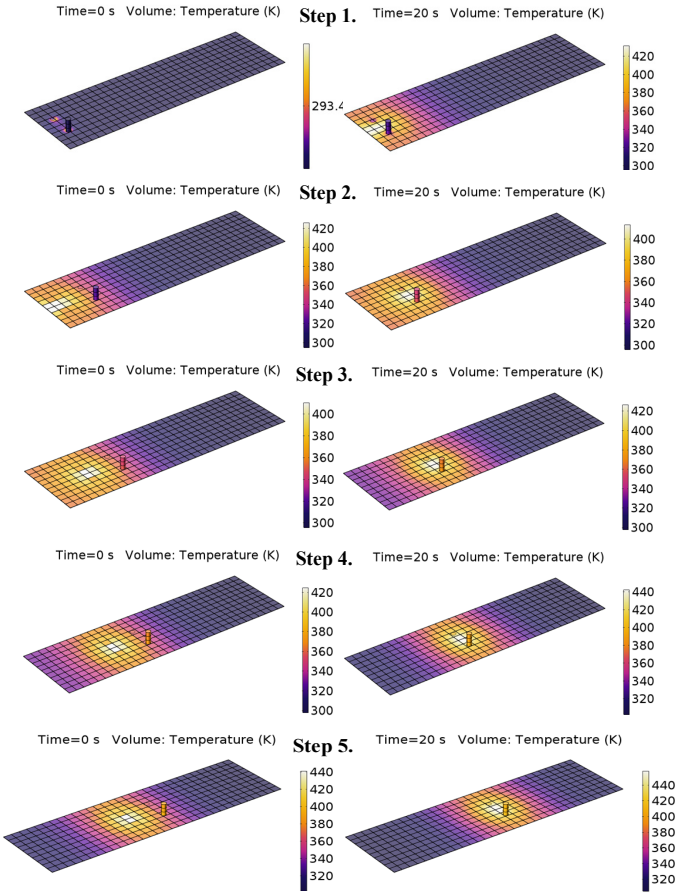

Fig. 11. Simulation results for given parameters

6. Conclusion

In this paper, the design of thermal finite element simulation model of Mo sheet was described. The main aim was to target exact modeling of thermal field in the structure of Mo sheet, while multiple material properties of heating electrodes where considered because resistive heating is considered within the proposed paper.

The presented model had the possibility of the reconfiguration of the electrode material, the electrodes distance, the electrode geometry as well as Mo sheet geometry. Also, Multiphysics is considered, whereby various values of electric current have been applied during experiments. For these purposes, several types of simulation models were developed. The main problem during the investigation is the proper definition of the material properties of Mo sheets. Each manufacturer has different material composition. Therefore, the simulation model has to have the possibility of reconfiguration in order to meet experimental results, which have been made within previous researchers. Consequently, the presented model shall serve for optimization procedures, because experimental investigation mostly acts as time-consuming. Based on investigated configuration it can be claimed that there are possibilities of improvement in speed of heating (point-heating)

as well as possibility of pre-heating (line-heating) by using electrodes from different materials.

Second approach o presented paper was focused on the design of the model, which will consider a dynamic change of the heated place within Mo sheet, i.e. translation move was applied. Various software products have limitations regarding the dynamic movement of the investigated sample, therefore special script in MATLAB environment was developed. With the use of this approach, each iteration of the simulation accepts previous results, which are repeatedly implemented within the computation solution.

Given proposal of the solution was required due to future works, which will be focused on the design of multi-physics simulation model of Mo sheet heating and molding system, where high-validity simulation models are expected to be used namely for further investigations of mechanical parameters and other molybdenum restrictions.

Conflict of Interest

The authors declare no conflict of interest.

ABSTRACT

This paper critically evaluates the operational perspective of Virtual Power Plants (VPP) in Germany by analyzing key factors to replace conventional power plants in the future power system. Therefore, its necessity for the secure operation as well as the technical and economic benefits for the German power system are pointed out. The single sections describe in detail how the requirements on technical functions and standardized communication can be reconciled with the increasing challenges on volatile generation. Furthermore, different operation concepts (profit maximization, intra-day schedule loyalty and system services maximization) are described with respect to their mathematical algorithms and their practical feasibility under consideration of given circumstances and future developments. The impact on the power system by the different possible VPP-operational concepts are exemplary pointed out in a case study with use of a medium voltage Cigre-Benchmark Network. The results indicate a high impact on hand-over points by VPP operational concepts.

1. Introduction

This paper is an extension of work originally presented in 14th International Conference on the European Energy Market (EEM) [1]. The goal of the German government to reduce CO2 emissions about 40 % until 2020 leads to a rising energy infeed fluctuation evoked by renewable energy sources in the German power system[2]. Due to a high percentage of volatile power infeed, the share of gross electricity generation in 2016 increased to 12.3 % from wind, 7.0 % from bio power plants and 5.9 % from photovoltaic (PV) [3]. The future share of renewable energy sources should rise up much more according to the German government. 45 % of the renewable power was installed in medium and low voltage level [4], so that a large percentage of uncontrolled generation is located in this area. Therefore, the electricity system requires intelligent power networks to secure a stable balance between generation and demand [5]. One part of this intelligent power network is a Virtual Power Plant (VPP) that provides centralized control for aggregated units. The future system shall provide advanced functionalities similar to real power plants aiming on economically sensible generation and increased reliability [6, 7]. Therefore, the individual functionalities of decentralized units are bundled up using suitable communication and control systems to entirely replace conventional power plants [7]. However, bundling up single functionalities of single generation unit's does not directly secure similar operation concepts to conventional power plants.

Therefore, this paper deals with the question how VPP can be integrated into the current German power system exploiting their advantageous characteristics like centralized control of small volatile renewable generation units. Included in this, current available technical VPP properties as well as available and economic reasonable operation concepts are checked under consideration of current market circumstances. For example, so far there is no operation concept for VPP that supports the elimination of critical situations in TSO and DSO voltage levels.

[6 – 8] present some investigations already dealt with corresponding optimization methods for operational concepts, but none of them addresses the overall system requirements in its entirety. For that reason, Figure 1 illustrates the system design of a VPP as well as the interaction of market and power system participants and components. All units are remotely accessible through a central energy management and control center, which calculates the optimal schedule by taking into account information from the electricity market and forecast data of the individual generation and load units.

The overall flexibility of decentralized power units could be improved by applying the concept of VPP's [6, 7, 9] but the German electricity market together with applicable regulations still

*Corresponding Author: André Richter, Email: andre.richter@ovgu.de

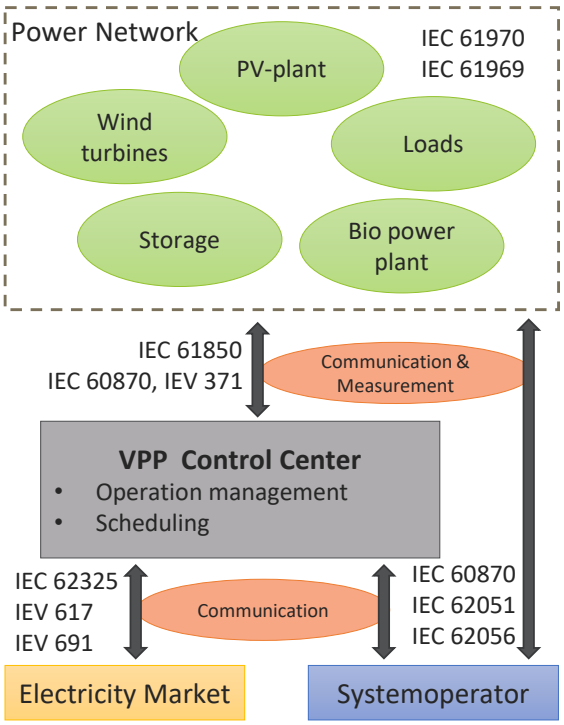

Figure 1. Components of the VPP and influencing factors

not provide the required incentives for a sustainable operation and consequently for a large-scale roll-out. Based on the identification of basic requirements, this paper points out different necessary presupposes for the operation of VPP's similar to conventional power plants. This includes different aspects like communication, generation and demand forecast as well as the German electricity market behavior and costs (*c*) for generation (**Error! Reference source not found.**).

Table 1: Costs of renewable generation without investment costs

	Variable costs in € /kWh	**Annual fix costs in € /kW**
Wind turbines [10]	0.0241 – 0.0268	56 – 61
PV plants [11, 12]	0.0000	13.00 – 35.00
Biopower plants [12]	0.0325	175.00

Furthermore, these presupposes are necessary to realize the new VPP operational concepts for taking part in network congestions elimination or control reserve contribution as well as intra-day schedule loyalty concerning the day-ahead planned generation unit operation. Therefore, not only the benefit for VPP owners and direct marketers is identified, but mainly the operational concpets are mathematically described. The paper presents an ongoing case study, where operational concepts are tested and evaluated according to the impact in a medium voltage CIGRE benchmark system. Thereby, the basic preconditions for the operation of Virtual Power Plants according to the German Market system are considered. Finally, the results and conclusion will indicate the high impact of small centralized controlled generation units as well as use cases where only small incentives are needed for the realization of the system supporting technical concpets. This paper differs strongly from the original paper in [1] by an extended definition of market restriction, in detail concerning the control reserve market and by presenting defined operational concepts and algorithms.

2. Basic Requirements of VPP's

2.1. Communication

Communication is a basic requirement for the operation of VPP as well of intelligent power networks in general. Therefore, it is necessary that generation units, controllable loads and all players offering power flow flexibility and aiming on benefits from variable tariffs can use a standardized and reliable communication system [5]. Based on this, there is a need for a standardized communication language and easy data exchange between all players [13]. Table II lists typical standards for communication in electric power systems, which can be applied in German power system. Furthermore all these standards are necessary for the operation of VPP and the communication with measurement systems, market and the system operator.

Table 2: Communication standards for intelligent power networks [14, 15]

Standard content	**Standard**
Telecontrol	IEC 60870, IEV 371
Communication systems in substations	IEC 61850
Interface for distribution management	IEC 61968
Energy market communication	IEC 62325
Data exchange with metering equipment / Electricity Metering	IEC 62051 /IEC 62056
Application in energy management system	IEC 61970 / 61969

Table II shows that various communication standards are applied to VPPs [16, 17]. According to [17] the IEC 61850 represents one of the most important communication standards for the operation and control of VPP with the integrated intelligent networks and distributed units. The innovative standard enables a secure and reliable communication and control using intelligent measurement systems like Phasor Measurement Units (PMUs) and control units like Remote Terminal Units (RTUs) [17 – 19]. Its necessity is based on the requirement to standardize data-models and furthermore to describe communication mechanisms and system management aspects. This standard is an extension to IEC 60870 resulting from adapted power system requirements. IEC 61850 has the advantage of defining data units through logical nodes with defined data structures (common data classes) [20]. The adressed protocol enables the control center to have direct data access and direct control to any physical unit of the VPP in the power network. Furthermore, the application of this standard combined with direct communication supplies the VPP operator with information about the physical location so that he is able to separate physical units according to accounting areas for instance.

2.2. Forecast-oriented power unit scheduling

For setting up an optimal power unit schedule, the VPP operator needs to distinguish the individual characteristics of the available resources. This information is not only necessary for an

optimal market participation, but also for enabling the system operator to make day-ahead and intra-day forecasts as well as to know the maximum controllable power for critical situations. The demand forecast for high numbers of small consumers can be realized using standardized load profiles. Bigger customers, like industry companies with bilateral contracts, require separate measurement systems in order to meet the requirements for providing dedicated demand side potential. In contrast, a larger percentage of units in the VPP are generation units and especially volatile ones like PV plants and wind turbines. Consequently, an exact forecast for those units is indispensable from the operator‘s point of view, e.g. for scheduling the secondary control reserve [21].

The forecast for wind and PV generation can be realized with different methods presented in Figure 2 and Figure 3. Thereby, the volatile factors are wind speed and solar radiation [19].

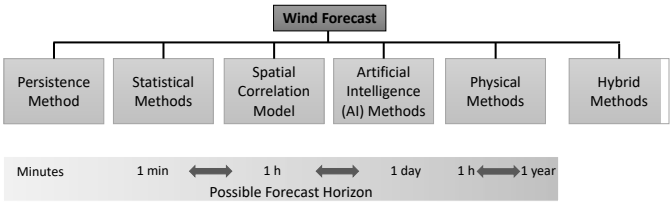

Figure 2. Overview of wind forecast methods and corresponding mathematical algorithms, [21 – 23]

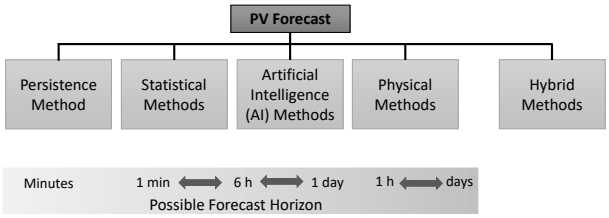

Figure 3. Overview of PV forecast methods and corresponding mathematical algorithms [25]

Wind forecast methods can be divided in six groups depending on its corresponding mathematical algorithms. Four methods (Persistence-, Statistical-, Artificial Intelligence method and Spatial Correlation model) are based on current wind measurement and statistical data as well as on learning approaches to predict wind generation. Depending on the applied method, the forecast horizon varies between a few minutes up to one day. To achieve an increase in accuracy and time horizon, it is necessary to use a physical or hybrid method. Both methods are based on meteorological and climate data and use the numerical weather prediction (NWP) for that purpose, but under the constraint of high computational effort. Regarding the methods and the forecast horizon the best accuracy (mean absolute error) varies between 5 % and 7 % for one to two hours forecast and increases for day-ahead forecast [21 - 24]. According to Figure 3, three of the shown methods (Persistence-, Statistical- and Artificial Intelligence Method) process current solar radiation and statistical data. This way utilizable data can be provided for a forecast horizon of a few minutes until one day. However, similar to wind forecast the accuracy rapidly decreases with the forecast horizon. Compared to wind forecast, PV forecast depends even more on the availability of information from weather stations and satellite data to detect clouds, high fog and other phenomena that effect solar radiation. Therefore, the physical method and the hybrid methods use NWP and Cloud Imagery for prediction with subsequent data post processing [25].

In consequence to the described uncertainties in generation forecast, the VPP operator has to deal with different impacts. In case of direct market participation, he has to expect sanctions from the power system operator or to participate in the Intra-Day market accepting possible high costs [26]. Besides using storage systems, there is a solution by using existing flexibilities from wind turbines pv, biomass plants and other technical solutions as in **Error! Reference source not found.**. Those technologies can provide power reserve if they are not operated at their maximum power output limit. However, since storage systems are still expensive and an appropriate market model involving positive and negative power capacity of wind and bio generation is not provided, more profit can be achieved by operating the units at its maximum power output level.

2.3. German Electricity Market

In this section, the German electricity market will be characterized focusing on VPP to identify possible operation behavior which influence system operation. Based on this, there are three possibilities to sell energy from renewable energy sources. The first possibility is to receive fixed payment, which is determined based on the German Renewable Energy Act (EEG). The other two possibilities are to participate in the Energy-Only-Market and to sell control reserves at the balancing market [26].

The electricity is traded in Germany either at the energy exchange or bilateral at the Over-the-Counter market. The European Energy Exchange (EEX) in Leipzig is the biggest market place for electricity produced in Germany. Electricity on the EEX can be traded either on the futures market or on the spot market (EPEX SPOT in Paris). The main difference between these markets is the electricity delivery time. Thus, the future markets provides contracts for long-term supply of electricity up to six years in the future [26]. The spot market is used as a trading platform for the short-term supply of electricity within 1-2 days, namely Day-Ahead and Intra-Day market [26, 28]. Thus, the day-ahead market is used to trade the electricity, that will be generated and consumed the next day. Because of the fact, that the day-ahead market is based on forecasted profiles (generation and consumption), an Intra-Day market is necessary to balance the forecasted errors. The contracts on the Spot market are mostly carried out physically, that means the physical electricity delivery to the fixed date [29]. According to (§11 EEG 2014), a system operator is obligated to transmit the renewable electricity and to sell it at the exchange. The operators of renewable power plants receive a fixed remuneration, which is supported by the EEG-apportionment. As a result, the renewable energy sources are always first at the merit-order, independently of the operation costs. Nuclear and lignite power plants follow, since they are usually used to cover the base load due to technical and economic advantages. Hard coal, gas and oil power plants are usually more expensive. Thus, renewable electricity has a great influence on the electricity price, because of its prior position. The operator of renewable energy sources can freely choose between a fixed EEG remuneration and the direct marketing at the beginning of each calendar year, §20 (1) EEG 2014. In addition, all systems with an installed power of more than 100 kW, which are set to operation from 1 January 2016, must be marketed directly (§ 21 EEG 2017). The benefit of direct trading in contrast to the fixed remuneration is that trader get the chance of higher profits by receiving market earnings plus a market premium. The market premium is lower

than the fixed remuneration but another governmental incentive to get a higher percentage of renewables in the market system. However, there are some technical limitations which restrict the operation of VPP at the market and in the power system. These are for example the lowest bid of 0.1 MW to participate in the Day-ahead and in the continous Intra-Day market. Furthermore, there are finacial requirements to participate in the spot market, in Germany [30]. The participation fee for Day-ahead market is about 10000 €/ a with additional 0.04 €/MWh (Day-Ahead auction) and 0.08 €/MWh (intra-day auction). Aditionally, there is a one-time participation fee to get into the spot market of about 25000 € for Day-Ahead market. These are costs that have to be covered by an optimal operational concept or new regulatory incentives.

The control reserve market in Germany is characterized by the fact that the German transmission system operator are responsible to keep the power system stable and the rated frequency of 50 Hz. There are 3 types of control reserves (primary control reserve, secondary control reserve as well as minute reserve). These types are differentiated according to activation speed and duration. The procurement of these control reserves is organized in a tender auction with participation of power plant operators and customers. One main fact is that pooling is still permitted to reach the market entry boundaries [31]. Main characteristics of the three control reserves are explained subsequently according to [32]:

Primary control reserve (PCR):

- full activation of PCR within 30 seconds
- incident period that have to be covered 0 <t <15 min
- automatic activation
- symmetrical (positive and negative PCR is not separated) bid of minimum +/- 1 MW
- the tender submission period is one week
- fixed power price

Secondary control reserve (SCR):

- energy balance of the control area and frequency control
- immediate automatic activation by the concerned TSO
- complete activation within 5 minutes
- automatic activation based on Merit-Order-List
- separated bid for negative and positive SCR is possible
- separation of SCR positive and negative in high tariff (HT, on Monday till Friday, 8 am til 8 pm) and low tariff (LT, weekend, national holidays and 8 pm til 8 am)
- minimum bid of 5 MW and an increment of 1 MW
- the tender submission period is one week
- fixed power price and energy price on call

Minute reserve (MR):

- automatic activation is based on a Merit-Order-List
- complete activation within 15 minutes
- incident period that have to be covered are t > 15 min to 4 quarter hours or up to severalhours in case several incidents
- separated bid for negative and positive MR is possible
- positive and negative MR, always with six 4-hour time slices
- minimum bid of 5 MW
- the tender submission period is one day
- fixed power price and energy price on call

Finally, the market regulatories and EEG incentives for the operation of single generation units are nowadays much higher, instead of VPP-operation with centralized controlled of small generation units. But there are ongoing changes in the market system which enable VPP for offering more system supporting functionalities. In [33] a change in the control reserve market system is already anounced. For instance, SCR and MR are intended for a daily (calendar) tender submission period with 4-hour time slices. Furthermore, exceptional rules that allow for minimum bids below 5 MW are introduced.

In conclusion, there are still no high financial and regulatory incentives to operate VPP in a way, which serves both areas – market and technical operation – at the moment. Because of this physical delivery of electricity remains uncertain with respect to a future power system including a higher share of renewables. Consequently, it will be indispensable to use the VPP benefits of generation unit aggregation and its aggregated central controlled flexibilities to have minimum system effecting controllable power. Therefore, some assumptions are made for the ongoing analyzes for a medium-term future VPP.

3. VPP -Operational concepts

One of the main challenges of VPP operators is the setup of the internal merit order, that defines which power unit shall be used to satisfy a certain power demand or infeed. This has to be done under consideration of type of generation unit, its technical capability and regulatory as well as economical restrictions. However, right now VPP operators maximize their profits by offering as much energy as possible in the markets aiming on the highest possible profit. As one result, VPP functionalities remain unused due to missing monetary or regulatory incentives, in particular the centralized control of aggregated small generation units. This causes a problem for the system operator: VPP operators sell energy based on the market premium at every point of time, even in case of congestions in the DSO or TSO network.

Therefore, this paper offers two main system supporting operational concepts and additonally an economical concept (see Figure 4). Each concept is explained in detail in the ongoing subsections 3.2 and 3.3.

1) Economical oriented (green): porift maximization, by optimal energy selling on the electricity market.
2) Technical oriented (orange): intra-day schedule loyalty and system service maximization including centriole reserve maximization and redispatch maximization.

3.1. Mathematical optimization problem

The operational concepts can be mathematically involved and expressed in terms of a maximization or minimization problem (objective function) with a given number of restricted goods (constraints). Therefore, this paper presents options to solve the optimization problems in MATLAB for day-ahead scheduling and intra-day schedule loyalty in intervals of 15 minutes. The development of schedules in day-ahead and intra-day planning rely on an optimization problem with an application-specific objective function. The restrictions are defined for technical characteristics of the system, electricity market restrictions and for current as well as predicted system states. Linear optimization method based on simplex algorithm is applied to solve the optimization problem. Linear optimization either minimizes or maximizes a linear

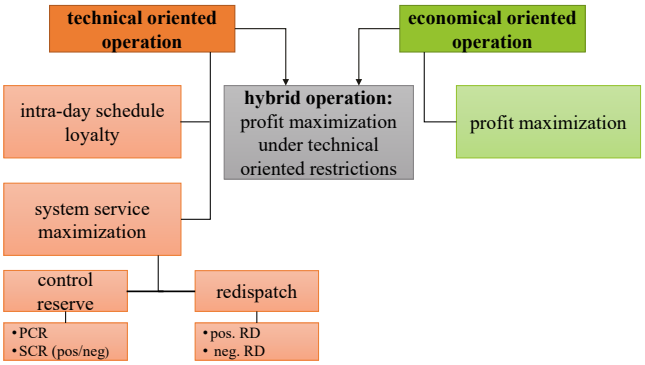

Figure 4. VPP operational concepts

objective function, taking into account linear constraints. The linear optimization contains only continuous variables, whereby benefitery short calculation times are realized. From the linear optimization, the mixed integer linear optimization can be distinguished. Mixed integer linear optimization (MILP) is the basis of the optimization problem for day-ahead and intraday optimization implemented in this paper. Unlike linear optimization, variables can be either continuous or integer or binary. Especially with binary variables it is possible to model logical conditions. The degree of detail of the optimization can be increased, but this is accompanied by an increase in the computational effort for the determination of the optimal solution. [34] The solver intlinprog is used to implement the scheduling problem in MATLAB. Firstly, the objective function is defined and implemented according profit maximization. Ongoing the different technical and economical upper and lower bounds as well as linear constraints were defined and implemented. Finally, the integer constraints have to be implemented. The solver finds a first less constraint starting solution by using linear optimization without integer constraints. The starting solution serves as a starting point for new solutions for the method branch and bound. The method branch and bound takes all constraints and inequaltities into account by generating subproblems and finally finds the best solution, if this solution is within a defined tolerance gap according to the other solutions.

3.2. Economical oriented operation

The main objective of a power plant operator and thus a VPP operator is always to maximize its profits, regardless of the system situation. The regulatory framework and the optimization skills always determine whether or in what amount the operator generates profit. Consequently, the composition of the VPP has a significant impact on potential profits. In the analysis of this concept for resource planning, an optimization based on today's market data for control reserve markets ($p_{\mathrm{PCR/\,SCR/\,MR}}$ / $P_{\mathrm{PCR/\,SCR/\,MR}}$), Day-Ahead auction (p_{auction} / $P_{\mathrm{wind/pv/bio,auc}}$) and continuous Intra-Day market ($p_{\mathrm{continous,IH,T}}$ / $P_{\mathrm{wind/pv/bio,continous,IH,T}}$) is made. The analysis assumes that both a fixed EEG allowance and a market premium for market participation through EEG plants are not paid out. Aim of this assumption is to analyze the VPP operation under perfect market conditions without any subsidies. This leads to the objective function where profit (p) should be maximized by optimal day-ahead generation unit schedule(P_{wind}, P_{pv} and P_{bio}). The optimal distribution of power to different selling options is limited to the forecast of renewables ($P_{\mathrm{wind/pv,\,forecast}}$), the installed power, various constraints and other secondary conditions which are described in (2) – (34).

$$\begin{aligned}\max f(p) = {} & p_{\mathrm{wind}}(t)\cdot P_{\mathrm{wind}}(t) + p_{\mathrm{pv}}(t)\cdot P_{\mathrm{pv}}(t) \\ & + p_{\mathrm{bio}}(t)\cdot P_{\mathrm{bio}}(t) \\ & + p_{\mathrm{auction}}(t)\cdot P_{\mathrm{wind,auc}}(t) \\ & + p_{\mathrm{auction}}(t)\cdot P_{\mathrm{pv,auc}}(t) \\ & + p_{\mathrm{auction}}(t)\cdot P_{\mathrm{bio,auc}}(t) \\ & + p_{\mathrm{continous,IH,T}}(t)\cdot P_{\mathrm{wind,continous,IH,T}}(t) \\ & + p_{\mathrm{continous,IH,T}}(t)\cdot P_{\mathrm{pv,continous,IH,T}}(t) \\ & + p_{\mathrm{continous,IH,T}}(t)\cdot P_{\mathrm{bio,continous,IH,T}}(t) \\ & + p_{\mathrm{PCR}}(t)\cdot P_{\mathrm{PCR}}(t) \\ & + p_{\mathrm{SCR,pos}}(t)\cdot P_{\mathrm{SCR,pos}}(t) \\ & + p_{\mathrm{SCR,neg}}(t)\cdot P_{\mathrm{SCR,neg}}(t) \\ & + p_{\mathrm{MCR,pos}}(t)\cdot P_{\mathrm{MCR,pos}}(t) \\ & + p_{\mathrm{MCR,neg}}(t)\cdot P_{\mathrm{MCR,neg}}(t)\end{aligned} \tag{1}$$

During the analyzes several constraints are considered. The main constraints are:

- The profit calculation based on revenue (r) is depending on the market selling option and the costs (c) (energy generation costs, spot-market selling).

$$p_{\mathrm{wind}}(t) = -c_{\mathrm{wind}} \tag{2}$$

$$p_{\mathrm{pv}}(t) = -c_{\mathrm{pv}} \tag{3}$$

$$p_{\mathrm{bio}}(t) = -c_{\mathrm{bio}} \tag{4}$$

$$p_{\mathrm{auction}}(t) = r_{\mathrm{auction}}(t) - c_{\mathrm{auction}} \tag{5}$$

$$p_{\mathrm{continous.IH,T}}(t) = r_{\mathrm{continous.IH,T}}(t) - c_{\mathrm{continous.IH}} \tag{6}$$

- Minimum possible generation for wind, PV and bio generation that can be used for optimization: The factors $f_{\mathrm{wind,min}}$ $f_{\mathrm{pv,min}}$ and $f_{\mathrm{bio,min}}$ set the lower bounds of minimum generation output. They define pre-process depending generation output especially for bio generation. The minimum for wind and PV is zero by default.

$$f_{\mathrm{wind,min}} \cdot P_{\mathrm{wind,forecast}}(t) \le P_{\mathrm{wind}}(t) \tag{7}$$

$$f_{\mathrm{pv,min}} \cdot P_{\mathrm{pv,forecast}}(t) \le P_{\mathrm{pv}}(t) \tag{8}$$

$$f_{\mathrm{bio,min}} \cdot P_{\mathrm{bio,inst}} \le P_{\mathrm{bio}}(t) \tag{9}$$

- Bio generation power ramping: The maximum rate of change of power ($f_{\Delta P\mathrm{bio,pos}}$, $f_{\Delta P\mathrm{bio,neg}}$) is limited, comparable with conventional power plants.

increase of power for t = 1:

$$P_{\text{bio}}(t) - f_{\text{bio,Start}} \cdot P_{\text{bio,inst}} \leq f_{\Delta P\text{bio,pos}} \cdot P_{\text{bio,inst}} \tag{10}$$

increase of power for t ≥ 2:

$$P_{\text{bio}}(t) - P_{\text{bio}}(t-1) \leq f_{\Delta P\text{bio,pos}} \cdot P_{\text{bio,inst}} \tag{11}$$

decrease of power for t =1:

$$f_{\text{bio,Start}} \cdot P_{\text{bio,inst}} - P_{\text{bio}}(t) \leq f_{\Delta P\text{bio,neg}} \cdot P_{\text{bio,inst}} \tag{12}$$

decrease of power for t ≥ 2:

$$P_{\text{bio}}(t-1) - P_{\text{bio}}(t) - \leq f_{\Delta P\text{bio,neg}} \cdot P_{\text{bio,inst}} \tag{13}$$

- Limitation of provision of control reserve (CR) by bio generation: Not every bio power plant is able to fulfill the technical requirements of PCR provision. Therefore, the proportion of bio generation units that can provide PCR can be limited with the factor $f_{\text{Bio,PCR}}$. Furthermore, the contribution of PCR and SCR has to be defined in constraints according to the technical requirements that PCR have to be provided in at least 30 s and SCR in at least 5 min. $f_{\text{d}P\text{bio,pos}}$ and $f_{\text{d}P\text{bio,neg}}$ describe the maximum possible rate of change of power in one minute so that the constraints for PCR and SCR are described as follows:

PCR contribution within 30 s, positiv and negative:

$$\text{d}P_{\text{bio,PCR,pos}}(t) \leq \frac{f_{\text{d}P\text{bio,pos}}}{2} \cdot f_{\text{bio,PCR}} \cdot P_{\text{bio,inst}} \tag{14}$$

$$\text{d}P_{\text{bio,PCR,neg}}(t) \leq \frac{f_{\text{d}P\text{bio,neg}}}{2} \cdot f_{\text{bio,PCR}} \cdot P_{\text{bio,inst}} \tag{15}$$

SCR contribution within 5 min, positiv and negative:

$$\text{d}P_{\text{bio,SCR,pos}}(t) \leq 5 \cdot f_{\text{d}P\text{bio,Pos}} \cdot P_{\text{bio,inst}} \tag{16}$$

$$\text{d}P_{\text{bio,SCR,neg}}(t) \leq 5 \cdot f_{\text{d}P\text{bio,neg}} \cdot P_{\text{bio,inst}} \tag{17}$$

- Maximum possible control reserve. The provision of control reserve is limited to the requirements described in section 2.3. These are the continuous availability of CR according to the defined periods (PCR-continuous over the day, SCR-LT, SCR-HT, MR-4 hour intervals) and under consideration of wind and PV forecast and the limited contribution of bio generation, respectively.

PCR positive and negative:

$$\begin{aligned} P_{\text{PCR}}(t) \leq\ & P_{\text{wind,forecast}}(t) - P_{\text{wind}}(t) \\ & + P_{\text{pv,forecast}}(t) - P_{\text{pv}}(t) \\ & + \text{d}P_{\text{bio,PCR,pos}}(t) \end{aligned} \tag{18}$$

$$\begin{aligned} P_{\text{PCR}}(t) \leq\ & P_{\text{wind}}(t) - f_{\text{wind,min}} \cdot P_{\text{wind,forecast}}(t) \\ & + P_{\text{pv}}(t) - f_{\text{pv,min}} \cdot P_{\text{pv,forecast}}(t) \\ & + \text{d}P_{\text{bio,PCR,neg}}(t) \end{aligned} \tag{19}$$

SCR positive and negative:

$$\begin{aligned} P_{\text{SCR,pos,HT}}(t) + P_{\text{SCR,pos,NT}}(t) \leq\ & P_{\text{wind,forecast}}(t) - P_{\text{wind}}(t) \\ & + P_{\text{pv,forecast}}(t) - P_{\text{pv}}(t) \\ & + \text{d}P_{\text{bio,SCR,pos}}(t) \end{aligned} \tag{20}$$

$$\begin{aligned} P_{\text{SCR,neg,HT}}(t) + P_{\text{SCR,neg,NT}}(t) \leq\ & P_{\text{wind}}(t) \\ & - f_{\text{wind,min}} \cdot P_{\text{wind,forecast}}(t) \\ & + P_{\text{pv}}(t) \\ & - f_{\text{pv,min}} \cdot P_{\text{pv,forecast}}(t) \\ & + dP_{\text{bio,SCR,neg}}(t) \end{aligned} \tag{21}$$

MR positive and negative:

$$\begin{aligned} P_{\text{MCR}}(t) \leq\ & P_{\text{wind,forecast}}(t) - P_{\text{wind}}(t) \\ & + P_{\text{pv,forecast}}(t) - P_{\text{pv}}(t) \\ & + P_{\text{bio,inst}} - P_{\text{bio}}(t) \end{aligned} \tag{22}$$

$$\begin{aligned} P_{\text{MCR}}(t) \leq\ & P_{\text{wind}}(t) - f_{\text{wind,min}} \cdot P_{\text{wind,forecast}}(t) \\ & + P_{\text{pv}}(t) - f_{\text{pv,min}} \cdot P_{\text{pv,forecast}}(t) \\ & + P_{\text{bio}}(t) - f_{\text{bio,min}} \cdot P_{\text{bio,inst}} \end{aligned} \tag{23}$$

- Avoidance of multiple use of power for control reserve provision: This constraint defines an upper limit for the sum of CR not exceeding the amount of available power. This is divided into positive and negative CR.

$$\begin{aligned} CR_{\text{pos}}(t) = & P_{\text{PCR}}(t) + P_{\text{SCR,pos,HT}}(t) \\ & + P_{\text{SCR,pos,NT}}(t) + P_{\text{MR,pos,4 h-slice}}(t) \end{aligned} \tag{24}$$

$$\begin{aligned} CR_{\text{pos}}(t) \leq\ & P_{\text{wind,forecast}}(t) - P_{\text{wind}}(t) \\ & + P_{\text{pv,forecast}}(t) - P_{\text{pv}}(t) \\ & + \text{d}P_{\text{bio,PCR,pos}}(t) \end{aligned} \tag{25}$$

$$\begin{aligned} CR_{\text{pos}}(t) \leq\ & P_{\text{wind,forecast}}(t) - P_{\text{wind}}(t) \\ & + P_{\text{pv,forecast}}(t) - P_{\text{pv}}(t) \\ & + P_{\text{bio,inst}} - P_{\text{bio}}(t) \end{aligned} \tag{26}$$

$$\begin{aligned} CR_{\text{neg}}(t) = & P_{\text{PCR}}(t) + P_{\text{SCR,neg,HT}}(t) \\ & + P_{\text{SCR,neg,NT}}(t) + P_{\text{MR,neg,4 h-slice}}(t) \end{aligned} \tag{27}$$

$$\begin{aligned} CR_{\text{neg}}(t) \leq\ & P_{\text{wind}}(t) - f_{\text{wind,min}} \cdot P_{\text{wind,forecast}}(t) \\ & + P_{\text{pv}}(t) - f_{\text{pv,min}} \cdot P_{\text{pv,forecast}}(t) \\ & + \text{d}P_{\text{bio,SCR,neg}}(t) \end{aligned} \tag{28}$$

$$\begin{aligned} CR_{\text{neg}}(t) \leq\ & P_{\text{wind}}(t) - f_{\text{wind,min}} \cdot P_{\text{wind,forecast}}(t) \\ & + P_{\text{pv}}(t) - f_{\text{pv,min}} \cdot P_{\text{pv,forecast}}(t) \\ & + P_{\text{bio}}(t) - f_{\text{bio,min}} \cdot P_{\text{bio,inst}} \end{aligned} \tag{29}$$

- Minimum bid and increment for control reserve provision, according to the market restrictions: The control reserve amount can be zero or or an integer

multiple of the increments, depending on size of minimum bid and minimum increment. The restriction is presented for PCR with analog constraints for SCR and MR. The factor $y(t)$ is a binary variable for the proof, if enough power is available for CR provision.

$$P_{\mathrm{PCR}}(t) - y_{\mathrm{PCR}}(t) \cdot P_{\mathrm{PCR,min}} \geq 0 \tag{30}$$

- Spot-market restriction: According to the spot-market options regarded in this paper, there are the possibilities to sell the energy in the Day-Ahead auction offered by hour or in the continuous Intra-Day market offered by 15 minutes. Because of the fact that this is a day-ahead planning process, Intra-Day market prices have to be assumed as forecasted values. A further constraint is that the available energy should be sold out under profitable conditions.

$$P_{\mathrm{wind}}(t) = P_{\mathrm{wind,auc}}(t) + P_{\mathrm{wind,continous,IH,T}}(t) \tag{31}$$

$$P_{\mathrm{pv}}(t) = P_{\mathrm{pv,auc}}(t) + P_{\mathrm{pv,continous,IH,T}}(t) \tag{32}$$

$$P_{\mathrm{bio}}(t) = P_{\mathrm{bio,auc}}(t) + P_{\mathrm{bio,continous,IH,T}}(t) \tag{33}$$

$$\begin{aligned} & P_{\mathrm{wind}}(t) + P_{\mathrm{pv}}(t) + P_{\mathrm{bio}}(t) \\ & = P_{\mathrm{wind,auc}}(t) + P_{\mathrm{wind,continous,IH,T}}(t) \\ & + P_{\mathrm{pv,auc}}(t) + P_{\mathrm{pv,continous,IH,T}}(t) \\ & + P_{\mathrm{bio,auc}}(t) + P_{\mathrm{bio,continous,IH,T}}(t) \end{aligned} \tag{34}$$

As a result of the economic optimization schedules are defined for wind, PV and bio generation. All presented constraints consider the figures presented in section 2. This methodology allows for an economically optimal day-ahead schedule, regardless of the size of the VPP (available generation units) and the impact on the electrical power system. In future systems with high penetration of RES, this can lead to unstabelizing effects and to a lack of system services. Therefore, the system itself and system operator need system supporting services to handle exemplary high volatility generation and forecast errors.

3.3. Technical oriented operation

Within this section, various new network-relevant VPP operating concepts are to be examined, which are intended to ensure stable grid operation in the future and also to minimize the effort of operational management for directly and indirectly connected grid operators. These different concepts thus represent the integration of network operator requirements into the operational planning. The new technical concepts meet the request of reliable schedules contributed by VPP and by renewable generation units in general. Furthermore, the presented concepts will enable a maximum of PCR and SCR contribution as well as redispatch. Therefore, the day-ahead maximization function in (1) with its constraints in (2) – (34) are applied. Changed or added objective functions and constraints for optimal day-Ahead scheduling will be presented according to the concepts. The intra-day schedule loyalty represents a further concept which was presented in general in [35].

3.3.1. Intra-day schedule loyalty

The objective of intra-day schedule loyalty is to minimize the schedule deviation, which is mainly based on forecasting errors related to renewable energy source (RES) infeed in the operational planning of the VPP control center. In this case, the power consumption or the power recovery from or into the higher-level network should be reduced, so that the higher-level network operator or the accounting area manager only has to make few or no interventions. If all VPP operators were capable of doing this in the future, day-ahead planning process of system operators can be optimized and network congestions may be avoided.

However, this requires a defined level of flexibility within the VPP and can also lead to curtailments of generation units. The intra-day loyalty operation must be preceded by a day-ahead optimization in which capacities are blocked in order to compensate intra-day schedule deviations. The consumption of control energy should be avoided, if possible. For this purpose, a high fictitious penalty of 1000 €/MW is initially assumed for the balancing energy consumption when positive balancing power ($p_{\mathrm{reBAP,pos}}(t)$) or negative balancing power ($p_{\mathrm{reBAP,pos}}(t)$) is consumed. If the day-ahead schedule can not be met without consumption of balancing energy, balancing energy can be received ($P_{\mathrm{reBAP,pos}}(t)$ and $P_{\mathrm{reBAP,neg}}(t)$). Therefore, the term of the balancing energy represents a measure of the deviation from schedule. Thereby, a main constraint is that a control reserve deviation ($P_{\mathrm{deviation,CR,pos}}(t)$ and $P_{\mathrm{deviation,CR,neg}}(t)$) is prohibited by use of fictitious penalty ($p_{\mathrm{deviation,CR}}$) about 10000 €/MW. The objective function is presented in (35) with the objective to minimize the deviation according to the planned market schedule.

$$\begin{aligned} \max f(p,P) = & \; p_{\mathrm{wind,intraday}}(t) \cdot P_{\mathrm{wind,intraday}}(t) \\ & + p_{\mathrm{pv,intraday}}(t) \cdot P_{\mathrm{pv,intraday}}(t) \\ & + p_{\mathrm{bio,intraday}}(t) \cdot P_{\mathrm{bio,intraday}}(t) \\ & + p_{\mathrm{reBAP,pos}}(t) \cdot P_{\mathrm{reBAP,pos}}(t) \\ & + p_{\mathrm{reBAP,neg}}(t) \cdot P_{\mathrm{reBAP,neg}}(t) \\ & + p_{\mathrm{deviation,CR}} \cdot P_{\mathrm{deviation,CR,pos}}(t) \\ & + p_{\mathrm{deviation,CR}} \cdot P_{\mathrm{deviation,CR,neg}}(t) \end{aligned} \tag{35}$$

This operational concept requires similar constraints, like fictitious penalties for CR deviation and the possible use of balancing power. But the most important point for this operational concept is the flexibility, which is used to fulfill the schedule. Therefore, it is needed to reduce the maximum available power output from bio-generation in the day-ahead planning process by a defined value (e.g. 5 %). This procedure has to be applied for wind and PV forecast as well. The day-ahead forecast has to be reduced by a factor to ensure intra-day flexibilities and intra-day schedule loyalty. The factor has to be optimized depending on forecast precision and VPP generation unit composition. Two further constraints are loyalty of generation units and observance of day-ahead and intra-day schedule. The constraint loyalty of generation units has the aim to consider optimized day-ahead generation unit schedules for wind, PV and bio under the changed intra-day

conditions for renewable infeed ($P_{\text{wind,intraday}}(t)$ and $P_{\text{pv,intraday}}(t)$). If this will not be possible, energy has to be bought according to positive balancing power ($P_{\text{reBAP,pos}}(t)$) or negative balancing power ($P_{\text{reBAP,pos}}(t)$). The constraint observance of day-ahead and intra-day schedule ensure that the schedules of generation units can be changed according to the failure in forecast of renewables. But the sum of generation and the planned amount of cumulated power in each time step for trading on Day-Ahead and Intra-Day market is as much as possible prohibited to change. Both constraints can be expressed as:

$$\begin{aligned} P_{\text{wind}}(t) + P_{\text{pv}}(t) + P_{\text{bio}}(t) = {} & P_{\text{wind,intraday}}(t) \\ & + P_{\text{pv,intraday}}(t) \\ & + P_{\text{bio,intraday}}(t) \\ & + P_{\text{reBAP,pos}}(t) - P_{\text{reBAP,neg}}(t) \end{aligned} \tag{36}$$

The result of this operational concept is a reliable schedule planning which supports system operator in systems with a high amount of RES to keep a stable system and avoid redispatch. The changed generation unit schedule depends on the quality of forecast and reserved capacity for intra-day flexibility and thus indirectly depending on the quality of the forecast.

Furthermore, this concept only needs small monetary or regulatory incentives, because the needed flexibility reserve not leads to high loss in profit. But there is a need of incentives for this operational concept.

3.3.2. Redispatch maximization

The concept of redispatch maximization is a mainly technical triggered concept, which currently has no regulatory or monetary incentives. But in medium-term and future systems there will be an incredible high need for system operators to handle congestions in a system with less controllable conventional power plants. VPP can provide those functions utilizing the concept of centralized control of RES. It has to be assumend that the VPP is either small, so that it feed in a defined network section like in one medium voltage network, or that the schedule for this concept is adaptable for defined network sections. This assumption has to be done to ensure the effectiveness of redispatch in the system. The objective function (37) is focused on the maximization of negative ($P_{\text{RD,neg}}(t)$) or positive ($P_{\text{RD,pos}}(t)$) available power for redispatch. Therefore, the monetary objective function (1) is extended with fictious positive ($p_{\text{RD,pos}}(t)$) and negative ($p_{\text{RD,neg}}(t)$) profit for redispatch. This profit has to be given a high constant value only. A benefit of the methodology of fictious profits to maximize technical needs is that minimum monetary incentives can be identified under given market circumstances, if there is an ambition to create and examine new market concepts for technical needs.

With the integration of redispatch, additional constraints have to be defined. These are the definition of lower bounds for available power, exceeding a defined minimum in (38) – (39) and the calculation of available power for redispatch in (40) – (41).

$$\begin{aligned} \max f(P_{\text{RD}}) = {} & p_{\text{Wind}}(t) \cdot P_{\text{Wind}}(t) + p_{\text{PV}}(t) \cdot P_{\text{PV}}(t) \\ & + p_{\text{Bio}}(t) \cdot P_{\text{Bio}}(t) \\ & + p_{\text{auction}}(t) \cdot P_{\text{Wind,auc}}(t) \\ & + p_{\text{auction}}(t) \cdot P_{\text{PV,auc}}(t) \\ & + p_{\text{auction}}(t) \cdot P_{\text{Bio,auc}}(t) \\ & + p_{\text{continous,IH,T}}(t) \cdot P_{\text{Wind,continous,IH,T}}(t) \\ & + p_{\text{continous,IH,T}}(t) \cdot P_{\text{PV,continous,IH,T}}(t) \\ & + p_{\text{continous,IH,T}}(t) \cdot P_{\text{Bio,continous,IH,T}}(t) \\ & + p_{\text{PCR}}(t) \cdot P_{\text{PCR}}(t) \\ & + p_{\text{SCR,pos}}(t) \cdot P_{\text{SCR,pos}}(t) \\ & + p_{\text{SCR,neg}}(t) \cdot P_{\text{SCR,neg}}(t) \\ & + p_{\text{MCR,pos}}(t) \cdot P_{\text{MCR,pos}}(t) \\ & + p_{\text{MCR,neg}}(t) \cdot P_{\text{MCR,neg}}(t) \\ & + p_{\text{RD,pos}}(t) \cdot P_{\text{RD,pos}}(t) \\ & + p_{\text{RD,neg}}(t) \cdot P_{\text{RD,neg}}(t) \end{aligned} \tag{37}$$

$$P_{\text{RD,pos}}(t) \geq P_{\text{min,RD,pos}}(t) \tag{38}$$

$$P_{\text{RD,neg}}(t) \geq P_{\text{min,RD,neg}}(t) \tag{39}$$

$$\begin{aligned} P_{\text{RD,pos}}(t) = {} & P_{\text{wind,forecast}}(t) - P_{\text{wind}}(t) \\ & + P_{\text{pv,forecast}}(t) - P_{\text{pv}}(t) \\ & + P_{\text{bio,inst}} - P_{\text{bio}}(t) \end{aligned} \tag{40}$$

$$\begin{aligned} P_{\text{RD,neg}}(t) = {} & P_{\text{wind}}(t) + P_{\text{pv}}(t) \\ & + P_{\text{bio}}(t) - f_{\text{bio,min}} \cdot P_{\text{bio,inst}} \end{aligned} \tag{41}$$

3.3.3. Control reserve maximization

Control reserve is one of the most needed products in systems with high volatile generation. CR is important for a global point of view for systems with increased percentage of renewables and decreased number of CR providing conventional power plants. VPP offers the possibility to fulfill market restriction for control reserve market by pooling small decentralized generation units. Depending on the size (amount of installed renewable capacity), VPP can provide only CR products most of the time. Therefore, this optimization maximizes the contribution of positive or negative SCR or the contribution of PCR. The only limiting factors are market restriction concerning minimum bid size and minimum increment, so that CR is maximized first and remaining energy is traded according to profit maximization. This optimization is again based on (1) extended by fictitious high profit for CR. The fictitious profit is chosen very high, depending on the maximization problem (PCR, pos. SCR and neg. SCR).

$$\begin{aligned}\max f(P_{CR}) = {} & p_{Wind}(t)\cdot P_{Wind}(t) + p_{PV}(t)\cdot P_{PV}(t) \\ & + p_{Bio}(t)\cdot P_{Bio}(t) \\ & + p_{auction}(t)\cdot P_{Wind,auc}(t) \\ & + p_{auction}(t)\cdot P_{PV,auc}(t) \\ & + p_{auction}(t)\cdot P_{Bio,auc}(t) \\ & + p_{continous,IH,T}(t)\cdot P_{Wind,continous,IH,T}(t) \\ & + p_{continous,IH,T}(t)\cdot P_{PV,continous,IH,T}(t) \\ & + p_{continous,IH,T}(t)\cdot P_{Bio,continous,IH,T}(t) \\ & + p_{PCR}(t)\cdot P_{PCR}(t) \\ & + p_{SCR,pos}(t)\cdot P_{SCR,pos}(t) \\ & + p_{SCR,neg}(t)\cdot P_{SCR,neg}(t) \\ & + p_{MCR,pos}(t)\cdot P_{MCR,pos}(t) \\ & + p_{MCR,neg}(t)\cdot P_{MCR,neg}(t)\end{aligned} \quad (42)$$

The only constraints which have to be added according to the day-ahead optimization are the definition of lower bounds (P_{min}) for minimum provision of control reserve. Further restrictions are still defined in section 3.2. The constraints are:

$$P_{PCR}(t) \geq P_{min,PCR} \quad (43)$$

$$P_{SCR,pos,HT}(t) \geq P_{min,SCR,pos,HT} \quad (44)$$

$$P_{SCR,pos,NT}(t) \geq P_{min,SCR,pos,NT} \quad (45)$$

$$P_{SCR,neg,HT}(t) \geq P_{min,SCR,neg,HT} \quad (46)$$

$$P_{SCR,neg,NT}(t) \geq P_{min,SCR,neg,NT} \quad (47)$$

The result of the control reserve maximization is a scheduling concept to provide system services and enables the transmission system operator to have stable and effective control. Furthermore, if the VPP is located in lower voltage levels, this concept supports the appropriate connection system operator with defined schedule information concerning possible control reserve activation for distribution system operator. This is a necessary information during the day-ahead planning process in case of expected congestions in the distribution system.

4. Case Study

The case study demonstrates the application of the presented concepts under consideration of a test network. The impact of the operational concepts on the power system are highlighted according to the case study. The test nework in Figure 6 is based on the CIGRE Benchmark System. The used medium voltage network represents areas of central city, suburb and country grid according to [36 – 39]. Furthermore, there is only a single hand-over point to the overlay 110 kV network. Renewable generation from PV, wind and bio mass are collected in the voltage levels HV/MV, MV, MV/LV and LV in this test network.

Based on the investigation in [40] a defined amount of load (9815 kW) and installed renewable generation were randomly distributed. The main amount of RES is installed in country and suburb area and the main installed load is in the central city. Load profiles are modelled with standardized load profiles for households, business and agriculture. The installed renewable power for the VPP operation is considered to be 339.25 kW bio generation, 2126.56 kW wind generation and 7279.39 kW photovoltaic (pv, mainly in low voltage). The case study represents a scenario with high wind and photovoltaic infeed time-series for one day in 15 minute values and the operational starting point for bio power plants were expected to be 50 % of nominal power output. Figure 5 shows the uncontrolled renewable energy infeed forecast in the VPP area.

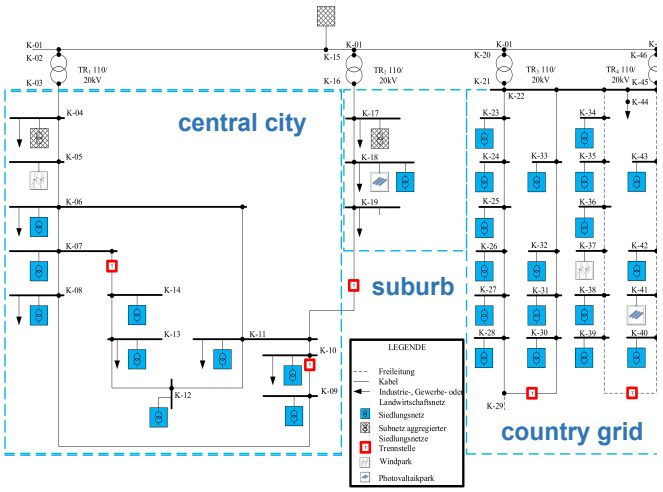

Figure 6. Medium voltage test network to [36 – 39]

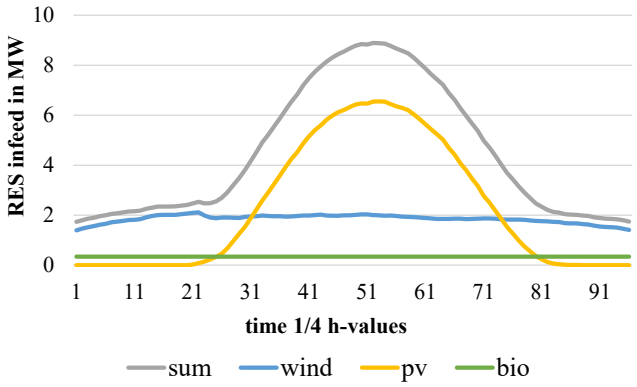

Figure 5. VPP generation day-ahead forecast

In the next step, the impact of the optimization is presented for the day-ahead planning process, with change of generation unit schedule in comparison to the uncontrolled renewable energy infeed (forecast). The test network with the implementation of load and generation as well as the according profiles offers the possibility to highlight the qualitative impact of the operational concepts on the 110 kV hand-over point exemplary. The impacts demonstrate the need of schedules and the impact of centralized controlled RES in low voltage levels. It is assumed that minimum bid and increment for control reserve is below 0.1 MW, because the case study only considers a small part of a network. The VPP itself can operate with more installed capacity of RES that is distributed in a bigger area and fulfill CR market requirements.

Furthermore, the technical oriented concepts will be exemplary represented by negative SCR contribution and negative redispatch contribution. Generation unit schedule is close to zero in case of maximum positive power provision for SCR and RD.

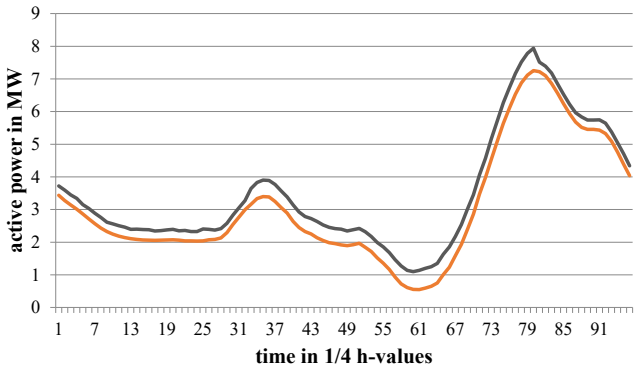

Figure 7. Active power demand of the medium voltage network with (grey) and without (orange) profit maximization

4.1. Economical oriented operation

The results of profit maximization are based on average prices for Day-Ahead market (blue) and Intra-Day market (green) as well as for CR participation (Figure 7). The revenue for PCR participation was assumed with 3646 €/MW and for SCR: 357 €/MW (pos. HT), 605 €/MW (pos. LT), 122 €/MW (neg. HT), 318 €/MW (neg. LT).

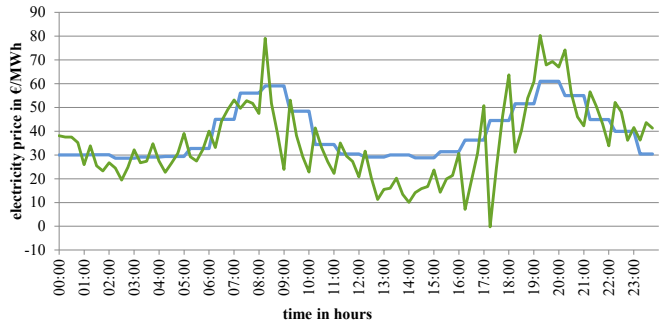

Figure 8. VPP generation unit scheduling for profit maximization

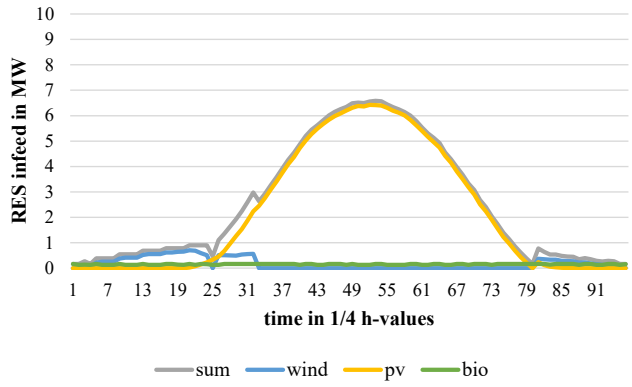

Figure 9. VPP generation unit scheduling for profit maximization

The overall expected profit for average spot-market prices of CR-market, Day-Ahead and Intra-Day market is about 1443.24 €. Most of the energy is planned to be traded on the Intra-Day market. Only less power is provided for positive SCR in low tariff with 1.563 MW and 2.297 MW in high tariff. The optimized generation unit schedule is reduced according to SCR provision (Figure 9).

Figure 7 demonstrate the impact of the profit maximization at the 110 kV hand-over point before profit maximization (orange) and after (grey). Due to the CR provision, the demand in this network area increases. It can be stated that the power demand of the network section is strongly reduced during the middle of the day, caused by a high PV infeed.

4.2. Technical oriented operation

The schedule loyalty is one of the basic needs for future system operation with high percentage of RES. The starting point for this concept is close to profit maximization, but the capacity for flexibilities has to be defined. Therefore, the day-ahead planning process is optimizing with only 95 % of forecast and a maximum of 90 % for bio generation. Therefore, the day-ahead schedule is set according to Figure 10. Furthermore, a random failure of maximum 5 % is assumed in each time step for wind and PV forecast. The Day-Ahead schedule expects a profit of about 1337.21 €, which lower compared to profit maximization. Most of the power is planned to be traded again in the Intra-Day market, but less power is provided for positive SCR in low tariff with 1.493 MW and 2.191 MW in high tariff.

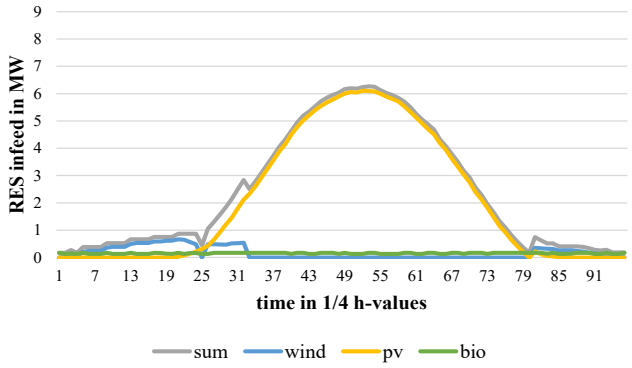

Figure 10. VPP day-ahead generation unit scheduling for schedule loyalty optimization

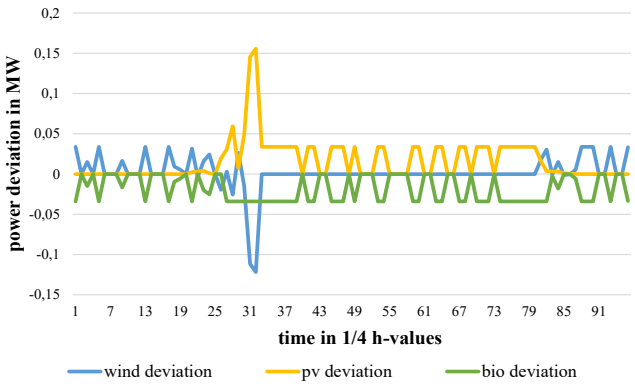

Figure 11. VPP intra-day deviation of generation in comparison to day-ahead schedule

The planned schedule can be fullfilled during the intra-day operation without any CR constraint violation and without any balancing power consumption. The intraday difference in generation unit operation is shown in Figure 11. The results demonstrate the functionality of this optimization concept. Furthermore, it was shown that the reduction of profit is relatively small in comparison to profit maximization, but the system benefit is enormous.

Eventually, the results for negative secondary control reserve and negative redispatch maximization are presented exemplary for all concepts of system service maximization. Both concepts represent the objective to maximize the power in within the planning horizon to provide maximum power that can be reduced by negative RD or negative SCR activation. Though results in generation unit schedule are the same, the reason of use is different. Figure 12 presents the day-ahead generation unit schedule. By considering the sum of generation, power output is maximized with repect to planned negative SCR and RD. In case of call of power reduction (RD) or negative SCR the maximum power is reduced. In particular at time step 25, there is a small reduction of wind caused by local weather conditions. It has a high impact on the maximization because PV infeed is low in the morning and the share of bio generation is small

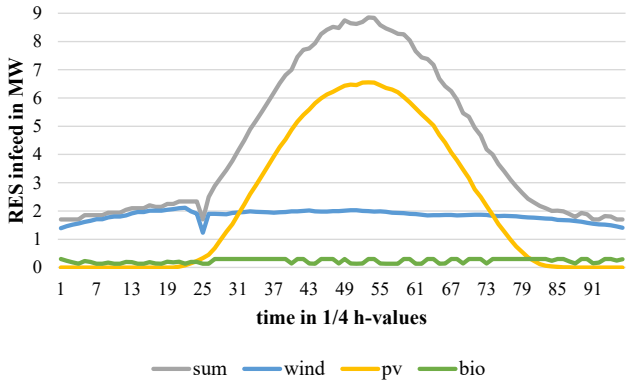

Figure 12. VPP generation unit schedule for maximization of negative SCR and negative RD

One main challenge and requirement for these concepts is the embodiment of incentives to support the system with these functionalities. On the other hand, is the concept of intra-day schedule loyalty. Schedule loyality is one of the best circumstances for system operatores point of view in terms of high voltilty during system operation. The concept of intra-day schedule loyalty needs only small incentives to be integrated in the german power system and leads only to small losses in profit. This concept can optimally be applied with controllable, forecast independent, generation or storage units. Otherwise, with a high amount of pv and wind it is necessary to make a day-ahead schedule with reduced forecast. But in the end this concept is main requirement for future system with high amount of RES and less conventionals to keep the system stable.

Figure 13 illustrate the change of power demand of the network at 110 kV hand-over point in case of call of negative SCR or negative RD (orange). The demand of active power before activation (grey) indicates a low load in comparison to the installed RES with times of power infeed in the 110 kV network. The activation of SCR or RD can almost double the demand during the middle of the day, depending on the high PV infeed.

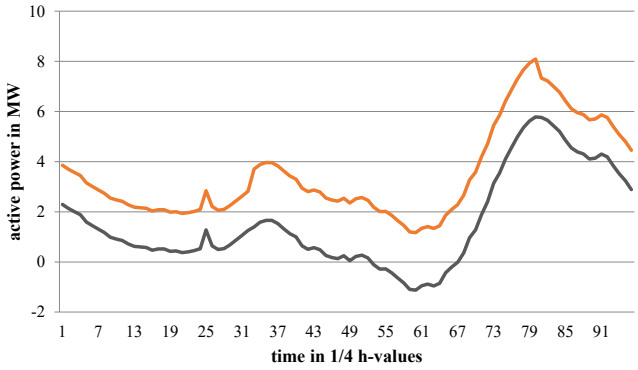

Figure 13. VPP intra-day deviation of generation in comparison to day-ahead schedule

5. Summary

The ongoing penetration of RES, especially in lower voltage levels, lead to a dramatically lack of needed system operation control funcitionalities as well as to enourmous increase of volatile generation. Therefore, this paper adresses their synergetic use in VPPs and their operational concepts. One basic advantage is the available schedule information for the system operator due to the centralized control for a defined network area. This can immensely optimize the DSO's and TSO's planning and operation process and enable generation process interventions (active and reactive power control) by involving the VPP control center, without having expensiv direct communication excess to each small unit. On top of that, it has been shown that the technical preconditions for the implementation of VPP in Germany are provided. Several suitable communication standards that meet the requirements of an intelligent power network and its decentralized generation units are already in use.Furthermore, the profit maximization concept indicates the generation of profit under currently given market conditions and without any renewable remuneration in the case study. But this result is without regarding costs for the operation of the VPP and this concept requires a sensitivity analysis to identify the minimum optimal number and kinds of generatin units to generate profit. However, there are many technical flexibilities like active and reactive power adjustments of decentralized generation units as well as storage systems, which can partly solve the uncertainty problem of demand and volatile generation forecast in particular as well as the contribution of system services. For this purpose, the concepts of intra-day schedule loyalty, control reserve maximization and redispatch maximization have been presented. The different concepts can be used in order to improve a stable and reliable system operation today and in the future. The presented technical concepts of CR and RD maximization algorithms are based on the profit maximization extended by fictious profits. This leads to the advantage that the algorithms enable the definition of needed monetary incentives to fulfill technical oriented operational concepts by optimal identification of fictious prices under changing market conditions. Furthermore, the case study demonstrates the importance of the information about location of generation units and day-ahead scheduling for CR and RD

maximization, where the call of system services can dramatically change the power demand at the hand-over point.

Eventually, the economical aspect is the most important one, especially from a VPP operator's point of view. As long as there is no sufficient level of monetary incentives, a reasonable support for the power system will not be provided. Under the given market conditions and the validity of the German Renewable Energy Act the profit for a single generation unit is much higher as for a VPP system compound, especially with regard to installation costs for a communication system and control center. Nevertheless, the future market will be dominated by renewable energy sources, so that the VPP concept will become more and more important for maintaining and improving a reliable and secure power system operation.

Limitations of the presented methods might be the computational time in case of increasing the number of constraints and by using MATLAB as the solver. For example, by defining individual technical and economical constraints for each generation unit in a VPP, the optimization complexity will increase dramatically, so that a more professional mathematical solver (e.g. Gurobi optimizer) is needed. Furthermore, the presented methods are day-ahead planning methods for a complete schedule over 96 time steps without any interruption in between two time steps. A further challenge can be to transfer the concepts of CR and RD into intra-day operation by taking system states of network frequency, line congestions and voltage stability into account [41], under consideration to calculate a new optimal solution for each next time step. By taking this aspects into account, the mathematical problem will rise strongly depending on the size of the network, size of VPP and the assumptions made.

Conflict of Interest

ABSTRACT

Combinatorial optimization is an area of great importance since many of the real-world problems have discrete parameters which are part of the objective function to be optimized. Development of combinatorial optimization algorithms is guided by the empirical study of the candidate ideas and their performance over a wide range of settings or scenarios to infer general conclusions. Number of scenarios can be overwhelming, especially when modeling uncertainty in some of the problem's parameters. Since the process is also iterative and many ideas and hypotheses may be tested, execution time of each experiment has an important role in the efficiency and successfulness. Structure of such experiments allows for significant execution time improvement by distributing the computation. We focus on the cloud computing as a cost-efficient solution in these circumstances. In this paper we present a system for validating and comparing stochastic combinatorial optimization algorithms. The system also deals with selection of the optimal settings for computational nodes and number of nodes in terms of performance-cost tradeoff. We present applications of the system on a new class of project scheduling problem. We show that we can optimize the selection over cloud service providers as one of the settings and, according to the model, it resulted in a substantial cost-savings while meeting the deadline.

1. Introduction

This paper is an extension of work originally presented in conference MIPRO 2017 [1].

Combinatorial optimization (CO) is a research field with many important real-world applications. Scheduling [2], auctions [3], and vehicle routing [4] are just a few notable examples. Combinatorial optimization is a subfield of mathematical optimization. It deals with problems where optimal selection needs to be done from a discrete feasible set. Exhaustive search evaluates all possible solutions before selecting the best one which is infeasible for realistic problem sizes. There are special classes of CO problems that can be solved with polynomial-time algorithms such as shortest paths, flows, spanning trees, and matching. However, many interesting problems are NP-complete and for these problems, unless P=NP, there are no computationally efficient solving algorithms. For such problems, different search or metaheuristic algorithms are created in order to get as good as possible performance in a realistic amount of time. Design of such algorithms is an intrinsically empirical process, guided by the experiments while the ranking of different design choices, hyperparameter values and algorithms depends on the results from experimental runs, often performed on benchmark test sets.

Each experiment consists of experiment units which denote the smallest indivisible executable unit. Experiment units are in the focus of this paper as they tend to be independent during the execution, which enables a high degree of parallelization. In deterministic CO problems all the parameters are deterministic. For them, each sampled instance of CO problem comprises an experimental unit. In stochastic and robust CO problems, some of the parameters are uncertain or unknown. In that case, each combination of sampled problem instance with its sampled parameter scenarios makes one experimental unit. For that reason, the number of experimental units in stochastic and robust problems can grow exponentially in the number of uncertain parameters. Additionally, the aforementioned set of experimental units is increased in Cartesian product with other experimental factors, as shown in Figure 1. Such factors include hyperparameter values, used algorithm, and algorithm design choices.

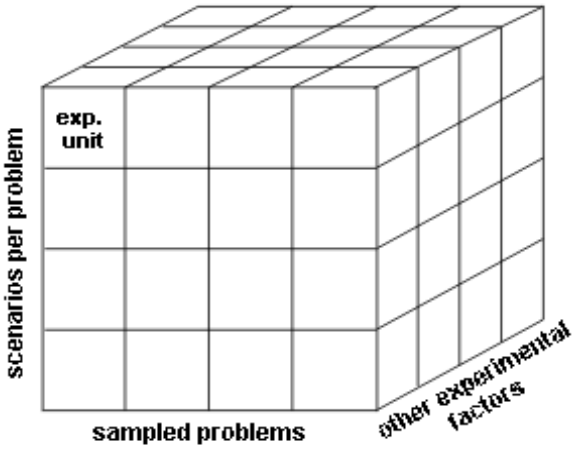

Figure 1. Exponential growth of number of experimental units with added factors which constitute independent dimensions

The experiment requires execution of all experimental units and empirical data must be recorded over those runs. This can be expensive operation, depending on the number of experimental units and the complexity of the underlying problem in each unit. However, as already mentioned, experimental units tend to be computationally independent and the process of experiment execution is inherently parallelizable over the units. In the current state-of-the-art combinatorial optimization, experimentation is mostly done on single computer. This was the case in stochastic variant of vehicle routing problem in [5] and project scheduling in [6]. There were applications where the problem was of such complexity that computer cluster had to be employed in order to make the algorithm practically usable. This was the case for fleet optimization in [7].

In this paper we present an architecture of a system for distributing extensive computational experiments over the cloud that takes advantage of the independence between experimental units to achieve inexpensive scalability in the cloud. This architecture can be implemented as a standalone system or it can use some of the frameworks and systems described in section 2 if the amount of reuse and alignment of the blueprint with the implemented functionalities in those systems can be achieved. The architecture was designed in a way to reduce the amount of communication to a minimum level while still enabling efficient load balancing. We explain the distributed design of data storage for the experimental results. The distributed design reduces the communication overhead which is a problematic aspect for high-performance computing (HPC) in the cloud. Storing rich experimental data is important for further analysis and also important as a mean of scientific scrutiny by enabling efficient sampling-based reproducibility. An optimization model is presented that describes the best choice of settings for running specific experiments. The model uses data from pilot runs which execute sampled subset of experiment units. Finally, the proposed architecture was applied on a specific problem of developing and validating algorithms for a new type of complex stochastic combinatorial optimization problem in project scheduling.

The paper is organized as follows: in section 2 we present the idea of high-performance computing in the cloud as an alternative to in-house grids. Section 3 lists the related work. Section 4 presents the general architecture of our system for distributed experimental runs. In section 5, a distributed design of the storage is described. Applications of the architecture on a real research problem are described in section 6. Section 7 drafts future research ideas and section 8 offers concluding remarks.

2. High-performance computing in the cloud

Distributed computing is unavoidable in high-performance computing (HPC) where job is divided between many available processors in order to significantly reduce the runtime with currently available hardware. Traditionally, dedicated in-house grids (super-computers) are used. They are difficult to setup, maintain and operate [8]. In this paper we shall deal with cloud computing as a flexible and cheap resource alternative that can be rented on demand instead of being owned the whole time – for a lower overall cost and a relatively small performance penalty. Studies have been conducted on the matter of using the cloud for high performance computing. In [9] and [10] authors concluded that there is a limit on a number of used computational nodes where coupled applications are competitive with in-house grids. Beyond that limit, overheads become overwhelming performance detractors. In [11] virtualization, latency and system noise are singled out as the biggest issues in comparison to dedicated supercomputers. They found that research groups with limited access to supercomputer resources and with varying demand might find cloud computing to be a beneficial choice. Latency is problematic due to used commodity equipment in most of the cloud infrastructure and network virtualization. Virtualization introduces performance penalties through network virtualization and other virtualization overheads while accessing physical resources. In [11], network virtualization was found to be the primary bottleneck of the cloud that increases latency, reduces bandwidth and interferes with processes. System noise affects the performance due to multi-tenancy which introduces resource sharing with virtual machines deployed on the same physical hardware. Service providers can manipulate the degree of multi-tenancy, which enables greater profit by overallocating resources to the users. The problems with HPC in the cloud were reiterated in [12] where authors have put the focus on necessary reductions in communication overhead and virtualization. For the former, they propose the implementation of better load balancing, and using bare-metal containers for the latter. Comparative study in [13] confirmed raw performance superiority of in-house grids to Amazon's Elastic Compute Cloud (EC2) cluster. However, waiting time in queue on HPC clusters plays a significant role when taking turnaround time into account . In such circumstances EC2 cluster could produce better turnaround times. The cost-effectiveness of running HPC application was observed as dependable on raw performance and scalability. Cloud computing enables utilizing available monetary resources to rent practically as many as possible identical processing instances. This identicality of processing instances is desirable in running experiments as it sets all runs in the identical environment. This keeps most of the variance in measurements related to designed experimental factors. The effect of system noise on experiment results can be reduced using effective randomization in the job balancing.

3. Related work

In the last decade, with advent of Big Data, usage of cloud computing became all-pervasive. Related to scientific

applications, authors in [14] presented a reproducible genome sequencing task that was run in the cloud for a small cost with a near linear scalability. In [15], a new artificial intelligence algorithm for complex control tasks has been created. It features linear speedups with over a thousand workers on a public cloud service to cut down on total execution time in comparison to other algorithms. Authors in [16] have created distributed architecture for deep neural networks in the cloud for sensor fusion and inference based on the data from multitude of end devices. The communication cost was reduced by a factor of over 20x compared to the alternative. All of the aforementioned applications intentionally achieved low communication requirements between subtasks, hence avoiding or mitigating problems related to the communication overhead in cloud computing. Distributed execution engines have been created to simplify parallelization of computationally intensive tasks. Ray [17] is a python-based example of such system which enables computations.

Existing tools that provide support in design and comparison of optimization algorithms are listed in this paragraph. Comparing Continuous Optimizers (COCO) [18] is a platform for continuous optimization, hence it does not cover combinatorial optimization. Nevertheless, it has many of the features needed in a tool for our needs. It has a library of standard benchmark problems on which optimizers can be compared. Experiments can utilize Shared Memory Parallelism (SMP), but grid computing is not utilized. For that reason, big-scale execution in the cloud is not standard feature of that platform. ParadisEO [19] is a white-box C++ framework for reusable design of parallel and distributed metaheuristics. It has features and components helpful for creating new algorithms. The intent of this framework is to simplify the design of topologies within a single running system, i.e. a single optimizer that can be distributed. However, it does not specify the efficient way of executing distributed experiments. Java Evolutionary Computation Toolkit (ECJ) [20] is an option similar to ParadisEO. Multi-Objective Evolutionary Algorithm (MOEA) [21] Java-based Framework deals with multi-objective optimization by combining the features of COCO, ParadisEO, and ECJ. We have pointed out that COCO covers only continuous optimizers, while other tools enable easier and faster algorithm design. The latter is achieved through reusability of common algorithmic components when the optimization problem and algorithm design have favorable features. These tools do not specify guidelines for distributing extensive computational experiments over the cloud.

Performance of executing the experiment in the cloud is an important issue. Predictions can be used in scheduling as well as in finding optimal settings of computational nodes. The focus of [22] is on comparing public cloud providers using measurements on specific applications. These measurements can inform the processes of provider selection and performance prediction. Performance prediction using machine learning for improving the quality of system management decisions has been investigated in [23]. Authors in [24] used machine learning to predict the execution time of computational fluid dynamics applications in the cloud. These predictions were used in scheduling algorithms. A system for efficient performance prediction for large-scale analytics on EC2 cloud has been created in [25]. It utilizes optimal experimental design in order to minimize the resources in building the model. The system is used to find the optimal configuration in number of instances. Our architecture uses simple statistical model for performance prediction in order to calculate cost-optimal instance-type and number of necessary instances in order to satisfy desired probabilistic level of satisfying the deadline. In our case, settings also include the cloud provider, hence combining the intents of aforementioned works: performance prediction and optimization of node-selection that takes into account the cloud provider as well.

4. Architecture

The intended use-case is inherently parallelizable task. This architecture is designed in a way to use those favorable features of the task in order to achieve low communication between the computational nodes. In that way, latency is not an issue and there is only occasional communication where bandwidth plays the main role. Communication between the nodes is necessary for creating the computational nodes, sending instructions for job chunks (that is, batches) to them, and during migration of the final results. Instructions for job chunks contain small amount of information. Chunks are sized in a way to keep the nodes occupied for some time. There is a tradeoff between achieving good job balancing and reducing communication overheads in relation to the amount of computation done on the node. Computational nodes keep all generated and logged experimental data locally in their part of distributed database. The results, raw or processed, can be pooled periodically, upon finalization of the assigned experiment chunk or at the end of node's part in the experiment. Aforementioned features make the problem suitable for cloud deployment as we can avoid communication-related detrimental effects on performance.

Our pipeline architecture includes five general stages in the experimental process:

1. Creation of experimental data, that is the data about experiment units in initial seed database.

2. Creation of node images populated with all the necessary data and optimized code for executing the experiment units, logging and storing the results.

3. Optimizing the settings of execution environment. Pilot runs are used on a small subset of experiment units for different settings of the nodes, including a service provider to inform the optimization procedure.

4. Executing the experiment on pre-calculated number of identical nodes with settings selected in the previous stage.

5. Collecting experimental data from computational nodes, conducting analysis and getting the results.

In the rest of this section, we shall describe each of the stages in more details. All steps are enumerated according to their corresponding figures.

4.1. Creation of the experimental data

The data needed for running an experiment is created in the first phase, which is depicted in Figure 2. This means creating all the data that sufficiently describes experiment units so that they can be created and executed.

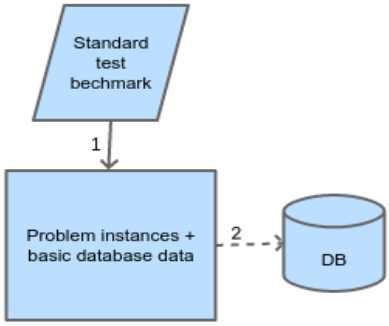

Figure 2. Preparing the seed database

The first step in this stage is optional. It uses standard test set as a source for creating problem instances. For many well-researched CO problems, such sets are shared within the community of the researchers to enable consistent ranking of algorithms. In case of new CO problems, maybe a standard test benchmark related to the problem can be found and used for creation of problem instances. Also, problem-instance generators are available for some problems and custom test set can be created. In this step, sampling and transformations of problem instances can be done to create our own set of problem instances that are going into an experiment.

Actually used test set is created at this point. The "seed" database is created and populated with the metadata necessary for experiment execution. Also, it is filled with all the data about experiment units needed for execution and result logging. Part of the data can be in the form of external files if that is more appropriate, but they must be linked from a database. In order to enable distributed execution, a database (and external data) is distributed over the nodes in such a way that each node has its independent, unsynchronized version of a database. Each such database is initiated from a singular seed database. Horizontal fragmentation of writeable relations is employed as a mean of data distribution over the nodes. Details of a database are given in section 5.

4.2. Creation of node images

One or more virtual machine (VM) images need to be created at this stage (shown in Figure 3). The exact number depends on the requirements in a phase of pilot runs. Each image contains a copy of a seed database and all the necessary code for running the experiment chunks on the node. Executable code is tuned to the intended hardware. After that, image is migrated to the cloud service from where it can be easily deployed for creation of the computational nodes.

4.3. Optimizing the execution environment

It is hard to know exactly in advance what settings of the computational node are efficient. For that reason we need an optimization phase of an experiment with regards to the settings of the experiment run. This is a stochastic combinatorial optimization problem as well and it can be stated as a problem of minimizing the monetary cost of renting cloud instances under a constraint of

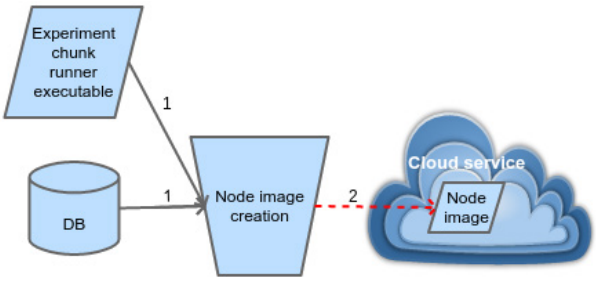

Figure 3. Creating the image for virtual machines in computational nodes

achieving desired probability of finishing before the selected deadline. The problem can be formulated and expressed as:

$$\min \mathbf{E} \sum_{x \in S} C_x(n_x) \quad (1)$$

with the constraints:

$$\sum_{x \in S} \delta_x = 1, \quad (2)$$

$$\mathbf{P}\{T_x(n_x) \leq D\} \geq \delta_x \cdot p, \ \forall x \in S, \quad (3)$$

$$\delta_x \in \{0,1\}, \ \forall x \in S, \quad (4)$$

$$n_x \in \mathbf{N}_0, \ \forall x \in S. \quad (5)$$

In the above formulation **E** is the expectation operator and **P** is a probability measure of the set. The above problem (1)-(5) has several parameters with values known prior to optimization: D is a desired deadline, S is a set of node-type options, and p is a desired probability of achieving the deadline. Also, C_x is a random cost of running the experiment on n_x instances of node-type x. The cost is random as it depends on the utilization durations of n_x nodes. T_x is a random experiment finish time when running it on n_x instances of node-type x. Decision variables are n_x and δ_x where n_x represents a number of instances of type x (5), and δ_x represents exclusive choice between the node-types (4). Randomness in this problem originates from the noise in execution due to hardware reasons and uncertainty in computational requirements of each experiment unit. That randomness is reflected in C_x and T_x. These functions can be created using statistical analysis or machine learning on the data from pilot runs. The objective function (1) is the expected value of total cost of the experiment. It sums the costs across all possible node-types but only one of those costs is going to be non-zero. The first constraint (2) ensures that only one node-type is selected. A set of chance-constraints (3) ensures that for selected node-type x a number n_x of nodes is selected so as to achieve a desired level of safety. All zero-valued δ_x make these constraints trivially satisfiable for all non-selected node-types x. For the selected node-type, a constraint enforces that a probability of finishing before the deadline must not be lower than the prescribed p.

We propose to make a parameter search over a set of node settings by running a simple and small experiment (using only a subset of experiment units) on each setting in S. A set of options should be small in order to reduce the cost of doing the pilot runs. That set can be composed by a careful pre-selection based on available data from previous general analyses such as [22] and based on analysis of the code for experiment execution as in [26].

The settings with the most impact are the selected cloud-service provider and cloud-instance type. The latter can be further customized across some set of subsettings, but usually the types are predefined less flexibly. The most important subsettings pertain to hardware components: CPU, disk size, RAM, etc. Pilot runs are identical to executing the experiment described in the following subsection. The difference from the latter is in the scale; in pilot runs just one experimental node per different setting is used , while many experimental nodes with identical settings are used during the experimental run. Collected data are analyzed by a procedure described in subsection 4.5. Based on the collected data and optimization model, economically most efficient node setting is chosen for the full experiment. Also, for that choice we get an estimate of the total experiment run time and cost by taking the summary statistics of T_x and C_x. Based on a desired due date, we infer the necessary number of computational instances N. N is the value of only non-zero n_x in optimal solution of the the optimization model.

4.4. Executing the experiment

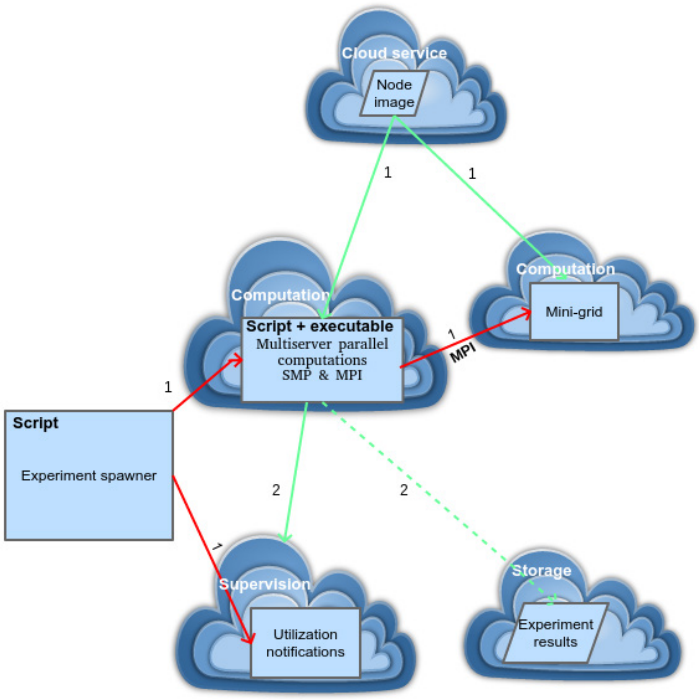

Figure 4. Execution of the experiment

The experiment is executed by distributing chunks across computational nodes (Figure 4). Experiment spawner is a script that balances the load between instantiated computational nodes. The experiment is partitioned into disjoint experimental chunks. Each chunk is a set of experiment units to be executed on a single computational instance.

1. Experiment spawner creates N cloud nodes and sends over network the parameters that define their workload chunks. These parameters constitute a small amount of information. Each experimental node runs a chunk runner which processes its assigned workload. Each runner, depending on the type of a problem, can instantiate additional computational nodes to form a mini-grid using Message Passing Interface (MPI). That is done if some of the algorithms require such execution architecture by design. SMP can be switched on by the parameters sent from the experiment spawner. Each node sets triggers for utilization alarms at the performance supervisor. Triggers improve the efficiency of a system by notifying the subscribers of different events. This information can be used for better, more prompt load balancing and it can reduce the renting costs.

2. At the end of processing a chunk, a computational node triggers supervisor's alarm when it can get another chunk to execute. When the node finishes with processing, it migrates its results to a permanent cloud storage and it gets terminated.

4.5. Result analysis

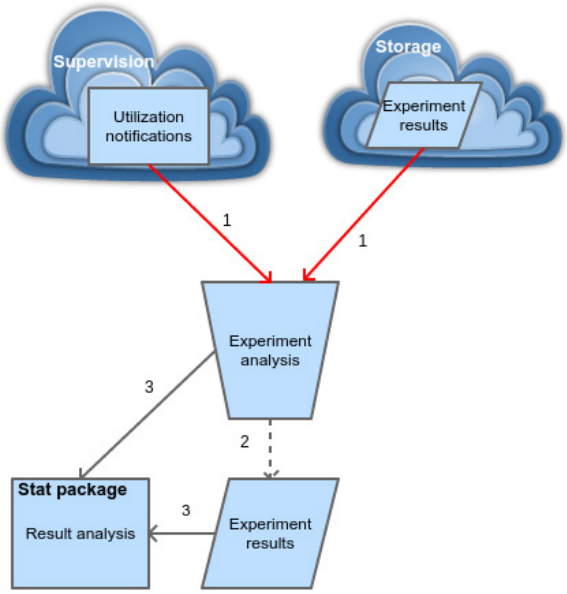

Figure 5. Analysis of experimental results

Users are notified by supervisor's alarm about the finalized jobs. A procedure is subscribed to notifications and reacts to them as shown in Figure 5. At first, the data is migrated from a computational node to some storage, locally or in the cloud. If the node has no more jobs to process, it is terminated to reduce costs. Analysis is done iteratively over the partial data as they pool to the storage. At the end of the process, with all the experimental results available, concluding results are created.

5. The database

The main objective of our system is to produce detailed experimental data as fast as possible. We have decided to store all the data into a database as it simplifies manipulations with overwhelming amounts of data.

It is assumed that running computational experiments is expensive both temporally and monetary. Storage, on the other hand, is much cheaper on both accounts. For that reason, as much data as possible should be stored for future analyses to avoid experiment re-runs.

Practicing scrutiny is important in science in order to prune mistakes and misconduct. Replication studies simply repeat experiments to check if the results match. In computer science, this

can be done by sampled replications that repeat small sampled set of experiment units. In each repetition, the same settings for pseudo-random number generators (PRNG), algorithms and problem instances should be used to create near-identical conditions as with the initial experiment. The results of replication study must match the stored values for everything except the execution time which includes incontrollable system noise. This is more efficient than replications of physical experiments where the exact conditions cannot be repeated and results should only statistically match. In the latter case, a greater number, if not all, of experimental units needs to be repeated in order to make conclusions. Also, executing experiment units in computational experiments is often cheaper than for physical experiments. The probability of non-matching results gets exponentially smaller with the size of randomly generated sample for replication.

5.1. Design

As described in section 2, communication overheads are serious performance detractors to scalability in the cloud in comparison to the in-house grids. Grids have tight interconnection and synchronization. For that reason, we have decided to minimize communication frequency between the cloud instances. All instances have their own database for storing results that springs from the initial seed database which is copied to all instances during creation of the node image as described in subsection 4.2. Seed database holds metadata and identification/replication data. The former defines all necessary structures to store the experiment data. The latter are the basic data necessary for identification of experiment units. Such data include the shared information for all instances of CO problems, used optimization algorithms, PRNG types and uncertainty scenarios in the case of stochastic or robust CO. Hence, all the data that define and describe experiment units (Figure 1) are present in a seed database.

Each node is created with a separate copy of a seed database. These copies make up a distributed database. The writeable relations, which record the experimental run data, are horizontally fragmented. Horizontal fragmentation keeps table schemas and distributes table rows across the nodes, as depicted in Figure 6.

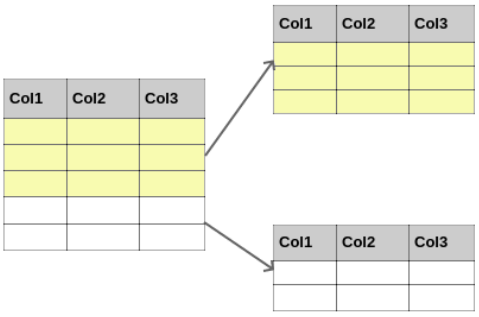

Figure 6. An illustrative example of horizontal fragmentation

During the experiment execution, each node saves two types of data: identification/replication data, and performance data. The former describe the settings of an executed experiment unit. This consists of the settings of the used optimization algorithm, PRNGs and other components that hold the key to replicating the execution of the experimental unit during replication studies. Performance data track decisions made during the execution and measurements of their effects. Quantitatively they make up the majority of generated and stored data, and the final conclusions are based on them.

Distributed data uses the identification scheme that combines together node-specific identification/replication information with shared information that originated from a seed database. That scheme makes data aggregation from all chunks unambiguous.

6. Application

The primary motivation for creating previously described architecture was a practical problem. As a result of different branch of research, we have worked with the new type of stochastic project scheduling problem, Cost-based Flexible Stochastic Resource Constrained Project Scheduling Problem (CBF-SRCPSP), defined in [27]. This problem deals with proactive-reactive project scheduling which makes the synchronization between project collaborators easier. It uses an agreed upon baseline schedule that stores the time-agreements for starting times of different project activities. Deviations of real start times from these agreements are penalized for inflexible, change-sensitive activities. The additional element in this model is that the changes to the baseline schedule can be profitable if they can be undertaken sufficiently far into the future. This extension to the features of baseline schedule makes the solution space much more complex due to the aforementioned proactive rescheduling operations. Searching the solution space becomes more time-consuming, though it pays off. We were lead empirically through the design and creation of optimization algorithms for CBF-SRCPSP.

The experimental set was created based on the standard Project Scheduling Problem Library (PSPLIB) set of instances for deterministic resource constrained project scheduling problems [28]. Cluster sampling was used to select sets of template instances from J30, J60, and J120 problem sets. The latter consist of projects that have 30, 60, and 120 project activities, respectively. The templates were expanded to fit CBF-SRCPSP model by modeling the stochasticity in activity durations with discretized beta distributions with a combination of selected and randomly generated distribution parameters. Additional parameters for each activity were randomly generated, according to the selected triangular distributions. After this procedure we ended up with 300 instances of each size which sprang up from template instances extended to fit the new model. The templates were instantiated according to the two experimental factors regarding to the project deadline: tightness of the deadline and bonus for early-finishing the project. For each instance, we generated 1000 activity duration scenarios from the discretized beta distributions. Activity durations were the only source of uncertainty. All of this data: project instances and uncertainty scenarios per each project were fed into a seed database. The used database was sqlite3 as it fit the needs of our experiment. Its simplicity trades-off well with its shortcomings in comparison to the more elaborate database management systems.

The seed database was also populated with the metadata about used PRNGs and CO algorithms. We have used two PRNGs: Mersenne twister with careful parameterization [29] and Threefry [30]. Several search algorithms were developed during the algorithm design. We had at our disposal implementations of optimization algorithms from the CO literature that were already

available in the used simulation library [26]. The final experiment included one benchmark CO algorithm from the literature and two selected newly-developed algorithms that were hypothesized to significantly outperform the benchmark. However, the analysis necessary for proving the hypothesis necessitated sufficient number of samples. The newly-developed algorithms were computationally expensive due to a search in more complex solution space than the benchmark.

The node images used Linux with gcc and necessary libraries. New algorithms were developed upon the C++ simulation library from [26]. This means that the most computationally intense parts, namely simulation-based experimentation and database logging were coded in C++ for better performance. The mini-grids were not used, since all the algorithms used only shared memory parallelization with two threads using OpenMP to speed up the search. This choice was based on the experiment in [26] regarding the parallel efficiency of the used simulation library. That also determined the number of computational cores per instance.

The total experiment was run on two occasions. The second experiment was done due to improvements to the developed algorithms and the results from the second study were used in the final experiment report. Here we shall cover both experiment runs as they utilized different experimental choices. In both cases, the raw results were downloaded locally using the python script. Statistical language R was used for results analysis. RSQLite R package was used to query the databases for the relevant data and to gather them together from all the sources.

6.1. The first experimental run

During the first experiment run we have selected Amazon Web Services (AWS) [31] as a service provider. Therefore, we did not use service provider as the experimental factor in pilot runs during the selection of the ideal instance type. We have used EC2 for computations, and have opted, after pilot runs, for c3.large instances with 2 dedicated physical cores of Intel Xeon E5-2680 v2 (Ivy Bridge) processors and 3.75 GiB of RAM. Simple Storage Service (S3) was used to store experimental results. The combination of CloudWatch (CW) and Simple Notification Service (SNS) was used for supervision and utilization notifications. Experiment spawner was coded in python, using the boto API [32] for accessing AWS and paramiko module [33] for controlling SSH2 connections.

Experiment consisted of 1.6 million experiment units. Experiment chunking was done across the problem instances. The chunk runner accepts parameters that describe chunk boundaries. These parameters are just several bytes in size and it is all the information needed for initiating the experiment execution on a computational instance. The total computational workload of the experiment was estimated based on running small sample of experiment units during the pilot run. It was estimated that the total workload is three and a half months of computational labor on the available hardware. The deadline was set to 7 days which we wanted to achieve with 90% probability. We calculated the necessary number of computational instances to satisfy this requirement. This resulted in using up to 26 cloud instances and reducing the total duration to 6 days. The database for each instance was migrated to S3 at the end of chunk execution and it awaited further analysis there. The cost of the first experiment was 445$.

6.2. The second experimental run

The second experiment was run on improved algorithms. The number of the most computationally expensive units was significantly increased, resulting in the total of 2.1 million experimental units. The optimization stage was used to select the node-type, also taking into account the service provider. We have used prior knowledge of the characteristics of our experiment runner - low working memory consumption (under 500MB) and high CPU utilization - to narrow down a range of instances. We tested the instances with 2 processors and as close as possible to 2GiB of memory. Market research was used to select the small set of service providers: Online Virtual Hosting (OVH), AWS (due to the use in the first experiment), and Linode. The selected instance-types are listed in Table 1.

Table 1. Members of alternative set *S* for optimization of execution environment

	OVH	**Amazon EC2**	**Linode**
instance-type	2vCores@ 2.4GHz 8GB RAM	c3.large 2vCores@ 2.8GHz 3.75GB RAM	2vCores@ 2.5GHz 4GB RAM
price	13.49$ (monthly)	0.105 $(hourly)	20$ (monthly)

The identical pilot run was used on all instance-types. Seven different types of experiment units were sampled into the pilot's unit set. The price of pilot runs in the optimization stage was 1.1$. The measurements were used to model execution durations for each combination of instance-type x and unit type u as Gaussian random variables $d_{x,u}$. Then, the total experiment duration for each instance-type is Gaussian random variable where w_u is the number of units of type u in our experiment. We approximated T_x by assuming that the total work modeled by d_x is simply equally divided among n_x computational instances.

It was estimated with the probability of 90% for the fastest option that the total workload is just above three years. The ranking and the necessary number of instances were calculated in order to satisfy the selected deadline of 30 days with the probability of 90%. The deadline was set to 30 days to take advantage of the monthly pricing. Figure 7 shows the optimal expected total costs for each option in Table 1. The results in Figure 7 were anonymized due to the legal concerns. Based on the available data, we have selected the C3 type instance as the most efficient with the estimated cost just below 500$. The experiment was run and it finished after 23 days of executing.

7. Future work

Possible future research ideas include improvement to the robustness of the total workload estimator. In our application, different simplifying assumptions were made and the error of their approximation effect should be investigated.

In order to reduce costs of the research community, general data about computational experiments (duration and prices) could be shared online with the public. This data can be useful for

creating promising and efficient alternative sets for optimizing the execution environment.

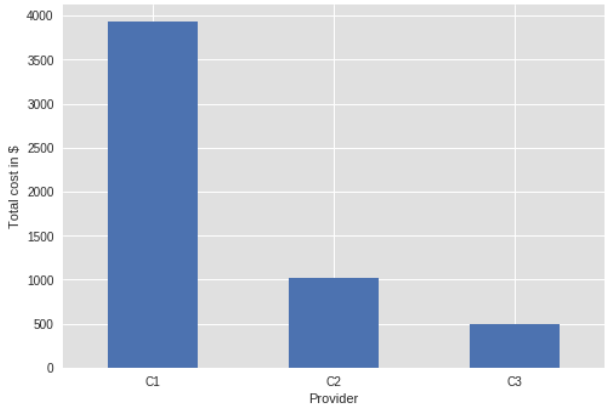

Figure 7 Estimates of total expected cost for anonymized permutation of options from Table 1

An automated tool for the composition of alternative sets could be utilized based on the experiment requirements. There is a potential in using pilot run on just one carefully selected instance type and then utilizing machine learning to find the best option and the number of necessary instances N for the desired target duration and the probability of achieving it. More advanced notions of risk and chance constraints can be used to account for the uncertainty in estimations and its economic effect. That can inform budget planning and the project management that undertakes the experiment.

Many parts of the architecture presented in section 4 are abstracted from the details of the particular experiments and can be reused in different settings. Component-based framework for general experimenting can be created. In that way, reuse of existing components can be increased and a code generator for repetitive parts can speed up the development, especially if the user does most of the manual process through an intuitive graphical user interface. Cloud costs can be reduced further by better node tracking and possibly using the cheaper spot instances for non-critical computations, especially during the algorithm design, prototyping and various pilot runs. The performance penalty in case of using such instances should be investigated in order to drive recommendations for configurations that utilize them.

8. Conclusion

Cloud computing is still not a simple and clear choice for high performance computing due to the issues pointed out in [11]: communication overhead, virtualization and system noise. The efficiency of cloud depends greatly on the specifics of the problem that we are trying to solve.

We have presented a system for distributing combinatorial optimization experiments over the cloud. Doing computational experiments for validation and guiding the design of CO algorithms has a specific property that it can be parallelized across experimental units that tend to be independent. This allows for low coupling between the simultaneous tasks and circumvents the issues related to the communication overhead.

Our system records rich data about the experimental runs in order to reduce the need for re-runs of experiments which may be computationally and monetarily expensive. In order to keep communication overhead to the minimum, distributed database with horizontal fragmentation was used. Each cloud node populates only the data related to its assigned disjoint experiment chunk. The unambiguity of the data across the system is, hence, kept without additional effort. When the tested algorithms use distributed computations in mini-grids, they should keep the grid size within the limits of recent studies, such as given in [11], to get the best performance benefits. It is expected that additional tuning and advances in cloud computing technology will increase the limits found by these studies.

We described two successful applications of our proposed system on the newly developed algorithms for complex stochastic combinatorial optimization problem, CBF-SRCPSP. Initial estimated sequential duration of several months to several years was reduced to under a month (the first experiment under a week) by distributing the execution. The optimization stage of our architecture finds the best settings for the execution environment. This enables the selection of the best instance-type across different cloud-service providers. In our case, that significantly reduced the cost of running the experiment.

Conflict of Interest

The authors declare no conflict of interest.

Feedback overhead

ABSTRACT

In this paper an efficient feedback quantization technic for beamforming in MIMO systems is presented. The proposed technic named time domain quantization TD-Q is based on the feedback of time domain parameters necessary for the reproduction of the beamforming matrix at the transmitter. This TD-Q presents the same performance than the conventional Givens rotation quantization GR-Q approach which is adopted in IEEE 802.11ac standardand. The performance and amount of feedback of the proposed TD-Q are studied and compared with the GR-Q in IEEE 802.11ac context.

1 Introduction

The combination of Multiple-Input Multiple-Output (MIMO) and Orthogonal Frequency Division Multiplexing (OFDM) technologies (MIMO-OFDM) is now adopted in several communication standards, including the 5^{th} generation of mobile communication network (5G) [1], the IEEE WLAN 802.11ac [2] and the IEEE 802.16 standards (WiMax)[3].

On the one hand, OFDM is a worthwhile tradeoff between bit-error rate performance and spectral efficiency. OFDM consumes part of the channel bandwidth, but it is robust to frequency selective fading environment. In addition, it enables the use of several advanced technics to further enhance the system throughput, as for instance the bit loading technic [4] and the subcarriers allocation in orthogonal frequency division multiple access (OFDMA) [5].

On the other hand, the MIMO system has the potential to improve the system capacity. In IEEE 802.11ac wireless local area network (WLAN) standard, there are five transmit and receive MIMO technics: Cyclic Shift Diversity (CSD), Space Time Block Coding (STBC), Spatial Division Multiplexing (SDM), Maximal Rotation Combining (MRC) and Transmit Beamforming (TxBF) [2]. Among these five technics, this is the Transmit Beamforming which can maximize the system capacity. Indeed, the Beamforming with precoding and postcoding eliminates the co-channel interferences (CCI) which are the fundamental problem faced by the practical MIMO system [6-8].

However, in beamforming technic the channel state information (CSI) must be available at the transmitter and the receiver. This CSI is estimated at the receiver and fed back to the transmitter. The CSI, which indicates amplitude and phase for each transmit antenna, receive antenna, and each OFDM subcarrier in the RF channel may reduce the overall throughput. To reduce the feedback amount, the receiver computes the beamforming matrix (precoding matrix) which is an unitary matrix and compresses it before sending back to the transmitter.

There are several proposals in the literature for the beamforming matrix compression. Many authors propose codebook based approach. In codebooks based technics, the channel distribution is taken into account during the codebook design. Instead of sending the precoding matrix, only the index of the selected precoding matrix (after channel estimation and SVD decomposition) is sent. Intrinsically, the codebook is restricted to have fixed cardinality. Thereby, the selected pre-coding matrix, which is the most similar is not necessarily the most optimal. Unfortunately, the codebook size has an impact on the system performance and requires high storage. For traditional MIMO systems, several codebooks have been proposed, such as Kerdock codebook [9], codebooks based on vector quantization [10], Grassmannian packing [11], discrete Fourier transform (DFT) [12] and quadrature amplitude modulation [13]. The coodbook principle is adopted in LTE [14]. In [15], the codebook was designed and optimized by selecting matrices having 8 phase-shift keying (PSK) entries and coping with a large range of propagation conditions. However the cost of this scheme is that the performance gain decreases dramatically due to the channel quantized er-

https://dx.doi.org/10.25046/aj030216

ror caused by the codebook feedback[16].

Another alternative is the Givens rotation (GR) approach. Here, Givens rotation is used to decompose the unitary beamforming matrix. After the decomposition, the receiver only feeds back the GR parameters necessary for the reproduction of the beamforming matrix by the transmitter [17]. The GR approach is adopted in IEEE 802.11ac standard for TxBF mode[2]. The compression ratio of the GR quantization is 75% for a MIMO 2×2 configuration [18]. However, this ratio decreases depending on the number of antennas. It then becomes necessary to find an alternative to the GR qunatization since the 802.11*ac* standard has adopted an 8×8 MIMO configuration which may reach $10Gbps$ and this number of antennas will undoubtedly increase due to the growing demand for bitrate.

This paper proposes a quantization approach named time domain quantization (TD-Q). Instead of the quantized precoder matrix as in GR, we propose the feedback of the quantized time domain channel coefficients. In addition, an optimization based on a metric updated during the channel estimation process and the MIMO channels impulse response is also proposed in order to further reduce the feedback overhead.

The rest of the paper is organized as follows. The section 2 presents the beamforming in MIMO OFDM systems. Section 3 is dedicated to the GR-Q which is adopted in the IEEE 802.11ac standard. Following that, the proposed TD-Q is presented in the section 4. Next, simulation results and comparison between GR-Q and TD-Q are shown in the section 5. Finally, the conclusion on the works presented in this paper is done in the section 6.

2 System Model

Consider a MIMO channel with N_t transmit antennas and N_r receiver antennas. In classical MIMO-OFDM context, for each subcarrier, the $N_r \times 1$ received signal y can be expressed as:

$$y = Hx + n \tag{1}$$

where H is the $N_r \times N_t$ frequency channel coefficients, x the $N_t \times 1$ transmitted signal and n the $N_r \times 1$ zero mean Gaussian noise vector.

By using singular value decomposition (SVD), the matrix H can be decomposed into:

$$H = UDV^H \tag{2}$$

where $U \in \mathbb{C}^{N_r \times R}$ and $V \in \mathbb{C}^{N_t \times R}$ are unitary matrix, $D \in \mathbb{C}^{R \times R}$ is diagonal, $(.)^H$ denotes the hermitian of $(.)$ and R the rank of the matrix H.

In MIMO-OFDM with beamforming context as in TxBF mode of IEEE 802.11ac, the received signal y is expressed this time by:

$$y = U^H HVx + U^H n = U^H UDV^H Vx + U^H n = Dx + U^H n \tag{3}$$

where V and U^H are used as a precoder matrix and a postcoder matrix respectively. The postcoder matrix U^H is an unitary matrix and thus the noise is neither colored nor enhanced.

Since D is exactly diagonal, there is no CCI and the MIMO channel matrix is reduced on R separate and independent SISO channels.

However, the precoder matrix V is needed at the transmitter. Two solutions are available in order to provide CSI at the transmitter. The first solution consists of exploiting the channel reciprocity in case of time division duplex (TDD) transmission modes. But, it is not straightforward due to the mismatch in the radio front end. The alternative, which is the most appropriate and that can be applied for both TDD and frequency division duplex (FDD) transmission modes, consists in using the reverse link to feed back the matrix V to the transmitter. Note that, for each subcarrier the unitary matrix V has to be quantized and fed back to the transmitter.

3 Givens Rotation Quantization and feedback compression ratio analysis

3.1 Givens Rotation Quantization principle

Givens Rotation Quantization GR-Q is proposed in [17]. The authors propose a reduction of the feedback overhead by exploiting the unitary property of the precoder matrix V. The idea is to represent the matrix V as a special form of Givens rotation with a complex diagonal matrix. Thereby, the $N_t \times R$ unitary matrix V can be factorized as follows.

$$V = \prod_{i=1}^{min(R,N_t-1)} [D_i \prod_{l=i+1}^{N_t} G_{li}^T(\psi_{li})] \times I_{N_t \times R} \tag{4}$$

where

$$D_i = \begin{bmatrix} I_{i-1} & 0 & 0 & \dots & 0 \\ 0 & e^{j\phi_{i,i}} & 0 & \dots & 0 \\ 0 & 0 & \dots & 0 & 0 \\ 0 & 0 & 0 & e^{j\phi_{N_t-1,i}} & 0 \\ 0 & 0 & 0 & 0 & 1 \end{bmatrix} \tag{5}$$

$$G_{li} = \begin{bmatrix} I_{i-1} & 0 & 0 & \dots & 0 \\ 0 & cos(\psi_{li}) & 0 & sin(\psi_{li}) & 0 \\ 0 & 0 & I_{l-i-1} & 0 & 0 \\ 0 & -sin(\psi_{li}) & 0 & cos(\psi_{li}) & 0 \\ 0 & 0 & 0 & 0 & I_{N_t-l} \end{bmatrix} \tag{6}$$

The matrix D_i is an $N_t \times N_t$ diagonal matrix, $I_{N_t \times R}$ is an $N_t \times R$ identity matrix and G_{li} is an $N_t \times N_t$ Givens rotation matrix.

According to the equations (4-6), the parameters to be determined to identify the precoder matrix V are:

$$\begin{array}{llllll} \psi_{li} & for & i = 1,2,\dots,m & and & i < l \leq N_t \\ \phi_{j,i} & for & i = 1,2,\dots,m & and & i < j \leq N_t - 1 \end{array} \tag{7}$$

where $m = min(R, N_t - 1)$.

Take a 3×3 unitary matrix V as an example, it can be expressed as:

$$V = D_1 \times G_{21}^T(\psi_{21}) \times G_{31}^T(\psi_{31}) \times D_2 \times G_{32}^T(\psi_{32}) \times I_{3\times 3} \quad (8)$$

The precoder matrix V can then be reconstructed through the six parameters $\psi_{21}, \psi_{31}, \psi_{32}, \phi_{1,1}, \phi_{2,1}$ and $\phi_{2,2}$.

Therefore, instead of all the elements of the matrix V, it is sufficient to considere the parameters ψ_{li} and $\phi_{j,i}$. These parameters can vary from 0 to 2π for ϕ and from 0 to $\pi/2$ for ψ.

Now, ψ and ϕ can be quantized according to equations (9) and (10) where $\widehat{\psi}$ and $\widehat{\phi}$ represent the quantized angles.

$$\widehat{\psi} = \frac{k\pi}{2^{nb_\psi+1}} + \frac{\pi}{2^{nb_\psi+2}} \quad (9)$$

where $k = 1, 2, \ldots, 2^{nb_\psi} - 1$ and nb_ψ the number of bits per angle ψ

$$\widehat{\phi} = \frac{k\pi}{2^{nb_\phi-1}} + \frac{\pi}{2^{nb_\phi}} \quad (10)$$

where $k = 1, 2, \ldots, 2^{nb_\phi} - 1$ and nb_ϕ the number of bits per angle ϕ

Finally, the receiver feeds back the quantized parameters $\widehat{\psi}_{li}$ and $\widehat{\phi}_{j,i}$ to the transmitter which can recover the quantized precoder matrix $\widehat{V}$ by using:

$$\widehat{V} = \prod_{i=1}^{min(R,N_t-1)} [\widehat{D}_i \prod_{l=i+1}^{N_t} \widehat{G}_{li}^T(\widehat{\psi}_{li})] \times I_{N_t \times R} \quad (11)$$

where

$$\widehat{D}_i = \begin{bmatrix} I_{i-1} & 0 & 0 & \ldots & 0 \\ 0 & e^{j\widehat{\phi}_{i,i}} & 0 & \ldots & 0 \\ 0 & 0 & \ldots & 0 & 0 \\ 0 & 0 & 0 & e^{j\widehat{\phi}_{N_t-1,i}} & 0 \\ 0 & 0 & 0 & 0 & 1 \end{bmatrix} \quad (12)$$

It is important to note that:

- The receiver has to feed back a precoder matrix $\widehat{V}$ for each subcarrier.
- The quantization error Σ with $\widehat{V} = V + \Sigma$ exists on each subcarrier.

Consider the equation (3) with the quantized error Σ and $\widehat{V}$ as a precoder matrix.

$$\begin{aligned} y &= U^H U D V^H \widehat{V} x + U^H n \\ &= U^H U D V^H (V + \Sigma) x + U^H n \\ &= Dx + \overline{D} V^H \Sigma x + U^H n \\ &= Dx + M_{CCI} x + U^H n \end{aligned} \quad (13)$$

The term $M_{CCI}x = (DV^H\widehat{V} - Dx$ is the corresponding CCI caused by the quantization error. However, in telecommunication standrd, one always chooses a number of quantization bits (nb_ψ and nb_ϕ) that allows the minimization of resulting CCI. This is the case of IEEE 802.11ac where $nb_\psi = nb_\phi = 10$.

Finally, the feedback overhead length (in bit) noted by N_{FGR} can be calculated using the formula $N_{FGR} = N_u * nb * N_t(N_t - 1)$ assuming that $N_r = N_t$, $nb_\psi = nb_\phi = nb$ and N_u the number of used subcarriers.

3.2 Feedback overhead length analysis in IEEE 802.11ac context

The bandwidth in IEEE802.11ac has increased from a maximum of 40 MHz with the old standard up to 80 or even 160 MHz. The number of subcarriers and used one according to the bandwidth are grouped in the Table 1.

Table 1: Number of used subcarriers according to the de bandwidth in IEEE 802.11ac

Bandwidths	N	N_u
20 MHz	64	52
40 MHz	128	108
80 MHz	256	234
160 MHz	512	486

Table 2 contains for any MIMO configurations and bandwidth:

- the feedback overhead length when no compression is performed,
- the feedback overhead length when GR quantization is performed,
- the compression ratio achieved by GR quantization.

As we can see, the GR quantization can reach a compression ratio up to 75% for a MIMO 2×2 configuration. This compression ratio decreases when the number of antennas becomes large. Because of the high demand in terms of transmission throughput, the number of antennas will increase in the evolution of IEEE 802.11 standard. The next WLAN generation will undoubtedly consider the massive MIMO concept which is more and more studied for WLAN [19-20]. In this context, it is necessary to find an alternative to the GR quantization because its compression ratio, as demonstrated by the equation (14), will be around 50%:

$$\lim_{N_t=N_r\to+\infty} \frac{N_t(N_t-1)}{N_t * N_t * 2} = \frac{1}{2} \quad (14)$$

4 Time domain quantization

4.1 Time domain quantization principle

Consider a MIMO channel with N_t transmit antennas and N_r receive antennas. The discrete time domain channel response between the transmitting antenna i

Table 2: Feedback overhead (in bit) with and without GR quantization for any configurations ($N_t \times N_r$ and bandwidth).

MIMO configuration	Number of GR parameters	feedback overhead N_{FGR} for GR				feedback overhead without quantization				Ratio
		20 MHz	40 MHz	80 MHz	160 MHz	20 MHz	40 MHz	80 MHz	160 MHz	
2x2	2	1040	2160	4680	9720	4160	8640	18720	38880	75%
3x3	6	3120	6480	14042	29160	9360	19365	42120	87480	66.67%
4x4	12	6240	12960	28080	58320	16640	34560	74880	155520	62.5%
6x6	30	15600	32400	70200	145800	37440	77760	169730	349920	58.33%
8x8	56	29120	60480	131040	271410	53248	110592	239616	622080	56.25%

and the receiving antenna j under the multipath fading environments can be expressed as:

$$h_{ij}(n) = \sum_{l=0}^{L-1} h_{ij,l}\delta(n - \tau_{ij,l}) \tag{15}$$

where L is the number of paths, $h_{ij,l}$ and $\tau_{ij,l}$ the complex time varying channel coefficient and delay of the l^{th} path.

Note that in practical OFDM system, in order to eliminate the intersymbol interference (ISI) between consecutive OFDM symbols, the maximum multipath delay is within the cyclic prefix, of length (CP) *ie* $L \leq CP$. Thereby, we propose, instead of the quantized precoder matrix V for each subcarrier, to feed back the quantized time domain channel coefficients for the entire system. The main goal of this proposition is to considerably reduce the feedback overhead because in this case, the feedback is composed at most by $N_t * N_r * CP$ complex coefficients. As can be seen, the number of OFDM subcarriers has no impact on the feedback overhead length. In addition, this proposed time domain quatization method can be performed jointly with the channel estimate.

4.2 Joint time domaine channel estimation and feedback quantization

In closed loop MIMO-OFDM systems, a preamble is inserted at the beginning of frames to facilitate the channel estimation. Comb-type pilot method can also be used on the rest of the frame (as in IEEE 802.11ac [2] or LTE [1]) to improve the accuracy of the channel estimation during the transmission. In this paper, we focus on time domain channel estimation (TD-CE). This technique is known to provide very good results by significantly reducing the noise on the estimated channel coefficients [21][22].

Firstly, without using any knowledge of the statistics on the channels, least square (LS) channel estimation can be performed at the receiver side using the demodulated pilots signal and the known pilots symbol in the frequency domain for each subcarrier.

Next assuming that $H_{ij,k}$ is the discrete LS estimated channel response on subcarriers k between the ith transmit antenna and the jth receive antenna, the CSI can be converted into the time domain by the inverse discrete fourier transform (IDFT) algorithm as:

$$\begin{aligned} h_{ij}(n) &= IDFT(H_{ij}) \\ &= \sqrt{\tfrac{1}{N_s}} \textstyle\sum_{k=0}^{N_s-1} H_{ij,k} e^{\frac{j2nk\pi}{N_s}} \end{aligned} \tag{16}$$

where N_s is the number of subcarriers and $n = 1, \ldots, N_s$.

Note that the LS method is widely used due to its simplicity and minimum requirements for the knowledge of channel statistics . However, the LS estimator does not consider the noise effect. That is why its performance is often degraded by the noise. By taking into account the equation (15) and the fact that $L \leq CP$, the time domain samples $h_{ij}(n)$ from ((16)) can be divided into two parts:

- the first CP samples in which are the paths of the channel,
- the other samples which are only composed by noise.

A smothing process which keeps only the first CP samples by eliminating the other one can considerably improve the accurate of the estimated channel [21]. However, it is possible to estimate a mean of the noise noted by $\overline{m}$ from the noise samples before its deletion.

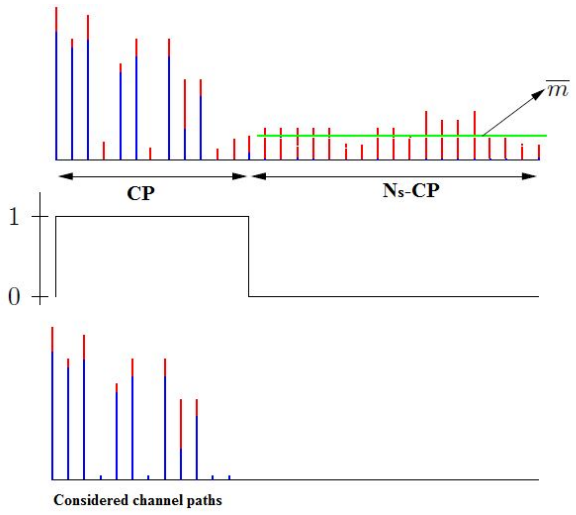

Figure 1: Mean Noise

This proposed process is illustrated in the figure 1. the metric $\overline{m}$ estimated from the noise samples allows to keep only the channel paths which are among the

first CP samples. As can be seen, all samples below the $\overline{m}$ were eliminated.

Now, the receiver have to do the two following actions:

- Perform a DFT of size N_s by considering only the remaining samples $h_{ij}(n)$. The resulting estimated channel frequency response is then more accurate than the LS one.

- Perform the feedback of the remaining samples $h_{ij}(n)$. To achieve this goal, each of the remaining samples $h_{ij}(n)$ whose number is lower than CP is expressed as:

$$h_{ij}(n) = \rho_{ij} e^{\phi_{ij,n}} = tan(\psi_{ij,n}) e^{\phi_{ij,n}} \qquad (17)$$

  where $n \leq CP$, $\psi_{ij,n}$ and $\phi_{ij,n}$ angles parameters can vary from 0 to $\pi/2$ and 0 to 2π respectively.

  After that, $\psi_{ij,n}$ and $\phi_{ij,n}$ is quantized and fed back to the transmitter according to equations (9) and (10) where $\widehat{\psi}_{ij,n}$ and $\widehat{\phi}_{ij,n}$ represent the quantized angles parameters.

Thus, the feedback overhead length (in bit) noted by N_{FTD} can be calculated using the formula $N_{FTD} = N_{rs} * 2 * nb * N_t^2$ assuming that $N_r = N_t$, $nb_\psi = nb_\phi = nb$ and N_{rs} the number of remaining samples.

Thanks to this feedback, the transmitter can reconstitute the accurate estimated channel. Thereby, the MIMO channel response is available both at the reciever and the transmitter side. Finally, transmitter and reciever perform SVD decomposition which allows it to respectively have the pre-coder and the post-coder.

5 Performance comparison in IEEE 802.11ac context

In this section, we compare the Givens rotation quantization GR-Q and the proposed time domain quantization TD-Q one in terms of feedback overhead and BER performance in IEEE 802.11ac context [2]. Note that the bandwidth in IEEE802.11ac has increased from a maximum of 40 MHz with the old standard up to 80 or even 160 MHz. For each bandwidth, the cyclic prefix length (CP) is equal to a quarter of the number of subcarriers (in Table 1). We consider in the similations MIMO 2×2, 3×3, 4×4, 6×6 and 8×8 with $4-QAM$ and $64-QAM$ modulations.

In the sequel, all simulations are performed using the ITU Channel Model for Outdoor to Indoor and Pedestrian Test Environment. Since the delay spread can vary significantly, the ITU recommendation specifies two different delay spreads for each test environment: low delay spread (channel model A), and medium delay spread (channel model B). The parameters of these channel's model are grouped in Table 3. In this paper we focus on the channel model B.

5.1 feedback overhead comparison

Figures 2 to 6 show the evolution of the total number of feedback complex coefficients of the proposed time domain quantization according to the signal to noise ratio (SNR) for MIMO 2×2, 3×3, 4×4, 6×6 and 8×8 configurations. For each MIMO configuration, simulations are performed for the 4 existing bandwidth of the IEEE 802.11 ac standard (20 MHz,40 MHz,80 MHz and 160 MHz). Note that the total number of feedback complex coefficients represents the sum of all the remaining samples and it can be calculated by $N_{rs} * N_t^2$ assuming that $N_r = N_t$.

As can be seen from these figures:

- whatever the MIMO configuration, the total number of feedback complex coefficients increases according to the bandwidth and the number of antennas.

- whatever the SNR, the plotted cumulative distribution function (CDF) shows that it is statistically possible for each MIMO configuration and bandwidth to know the maximum value of the total number of feedback complex coefficients. Following this study the total number of feedback complex coefficients for any configurations ($N_t \times N_r$ and bandwidth) in IEEE 802.11ac ontext are grouped in the table 4.

Therefore, according to equation (17) the feedback overhead length of the proposed time domaine quatization (in bit) noted by N_{FTD} can be calculated using $N_{FTD} = N_{rs} * 2 * nb * N_t^2$ and the number of remaining samples N_{rs} in the Table 4.

Except for MIMO 2×2 configuration and bandwidth $20MHz$, the feedback overhead of the proposed time domain quantization is much shorter than that of the Givens Rotation quantization. The compression ratio of the proposed time domain quantization compared to Givens Rotation quantization can be up to almost 70%.

The most important to note here is the fact that unlike the Givens Rotation quantization for which the compression ratio decreases when the number of antennas becomes large (see section 3.2), the proposed time domain compression becomes more efficient. This last remark makes the proposed time domain compression very interesting for the next WLAN generation which will undoubtedly consider the massive MIMO concept which is more and more studied for WLAN [19-20].

Table 3: ITU Channel Model for Outdoor to Indoor and Pedestrian Test Environment.

Tap	Channel A		Channel B

5.2 BER performance

In this subsection, we compare the beamforming with Givens rotation quantization (GR-Q) and that with the time domain quantization in terms of bit error rate (BER) performance. The considered simulation parameters are listed in Table 6.

Table 5: Feedback overhead (in bit) comparison between Givens Rotation quantization and the proposed time domain quatization for any configurations ($N_t \times N_r$ and bandwidth).

MIMO configuration	feedback overhead N_{FGR} for Givens Rotation quantization				feedback overhead N_{FTR} for the proposed time domain quatization				Ratio

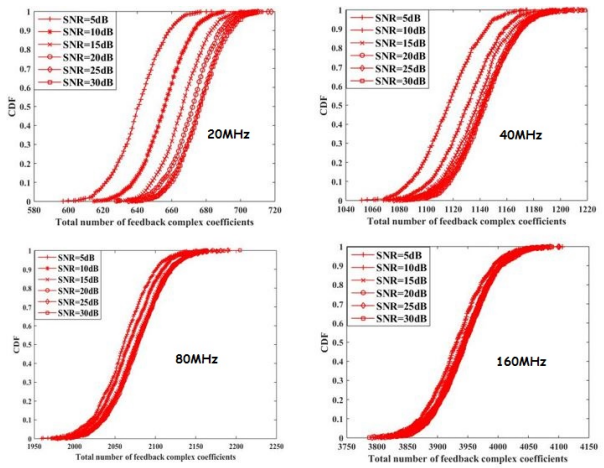

Figure 6: The Cumulative Distribution Function of the total number of feedback complex coefficients according to the Signal to Noise ratio and Bandwidth for MIMO 8×8 configutation

Table 6: Simulation Parameters

Channel Model	ITU Channel Model
Bandwidth	40MHz
Number of FFT points (N)	128
Number used subcarriers	108
Number of bits per angle	10
cyclic prefix	*Long ie* 32 samples
Number of $N_t \times N_r$ antennas	2×2 and 4×4
Modulation	QPSK and 64-QAM
FEC	Convolutional
Coding Rate	1/2

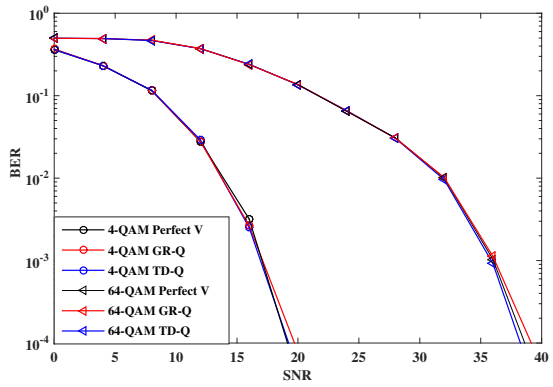

Figure 7: BER performance for perfect beamforming (Perfect V), beamforming with GR-Q and beamforming with the prposed time domain quantization (TD-Q) in MIMO 2×2 context. The ITU Channel Model is considered for simulations.

The BER performance is shown in Figures 7 and 8 for 4–QAM and 64–QAM in MIMO 2×2 and MIMO 4×4 context respectively. The number of bits per angle feedback is taken to 10. It can be seen that the proposed TD-Q presents the same performance, for all considered configurations in these simulations, than the GR-Q which is adopted in IEEE 802.11ac standard. As considered in the 802.11ac standard, the simulations confirm that 10 bits per angle feedback minimizes the quantization error and allows the quantized beamforming (GR-Q and TD-Q) to have the same performance than the perfect one.

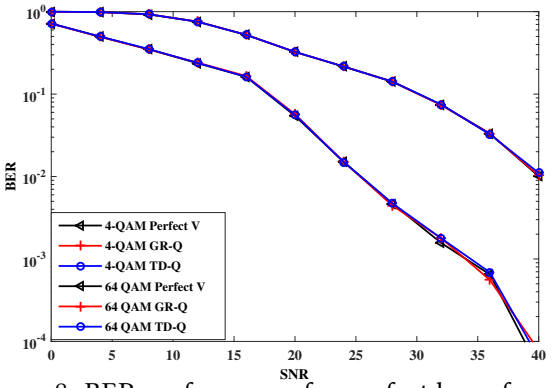

Figure 8: BER performance for perfect beamforming (Perfect V), beamforming with GR-Q and beamforming with the prposed time domain quantization (TD-Q) in MIMO 4×4 context. The ITU Channel Model is considered for simulations.

6 Conclusion

The proposed TD-Q requires less amount of feedback than the GR-Q one in IEEE 802.11ac TxBF mode. In addition, simulations in 802.11ac context with standard TGn channel model show that the TD-Q beamforming allows to have the same performance than the adopted GR-Q. The highlight of this proposal is that the proposed TD-Q can be considered as a credible alternative to the GR-Q for the IEEE 802.11ac evolution. The proposed quantization technic is not only for WLAN systems. It can be adapted for all SISO or MIMO system using closed loop beamforming.

Environmental Sound Recognition
Machine Learning

ABSTRACT

Environmental sound recognition (ESR) has become a hot topic in recent years. ESR is mainly based on machine learning (ML) and ML algorithms require first a training database. This database must comprise the sounds to be recognized and other related sounds. An ESR system needs the database during training, testing and in the production stage. In this paper, we present the design and pilot establishment of a database which will assists all researchers who want to establish an ESR system. This database employs relational database model which is not used for this task before. We explain in this paper design and implementation details of the database, data collection and load process. Besides we explain the tools and developed graphical user interface for a desktop application and for the WEB.

1. Introduction

This paper is an extension of work presented in 25th Signal Processing and Communications Applications Conference (SIU), 2017 [1]. The database design and implementation described in that paper was mainly for impulsive sound detection and the database was for a hazardous sound recognition application. Here the extended database is for all kinds of environmental sounds and it is aimed for all kinds of ESR applications.

Historically non-speech sound recognition has not received as much attention as automatic speech recognition (ASR). ASR has well established algorithms and databases while research has begun much earlier. Automatic ESR (AESR) is getting attraction since last two decades. We can list the following applications of AESR: In military, forensic and law enforcement domain there are studies on gunshot detection systems. In [2], a gunshot detection system is proposed. In [3], the gunshot blast is used to identify the caliber of the gun. In [4] and [5] ESR is used for robot navigation. ESR can be used for home monitoring. It can be used to assist elderly people living in their home alone [6], [7]. In [8], it is used for home automation. In [9] and [10], ESR is used for recognition of animal sounds. In the surveillance area, it is used for surveillance of road [11], public transport [12], elevator [13] and office corridor [14].designations. ESR system design is started with the training phase. How a sound database is used in training phase of an ESR system is explained in Figure 1.

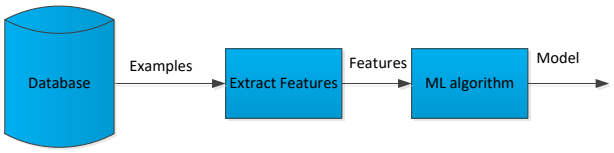

Figure 1: ESR system in training phase

During the development stage of an ESR system the desired ML algorithm must be trained with the sounds to be recognized. The database provides the sound clips to be recognized and other sound clips which are negative examples. After training, a model is developed and this model is used for testing. In Figure 1, the database provides positive and negative examples; features are inputs to the ML algorithm, ML algorithm using these features produce the model.

In Figure 2, testing phase of an ESR system is shown. In testing phase database provides the positive and negative examples, model produces the predictions about the examples provided and at last predictions are compared with the truth provided by the database and a performance rate is reached. According to this performance rate, ML algorithm or the feature set or other parameters of the ML algorithm may be needed to change. Then the whole training and testing phase start again. This process continues until an acceptable performance rate is reached.

After model creation and testing, this model is used in the production phase (Figure 3). In production phase, sounds come

*Yuksel Arslan, Ankara, Cankaya Ilkbahar Mah. Guneypark Kumeevleri A35/35 Turkey, Email: yuksel_arslan@yahoo.com

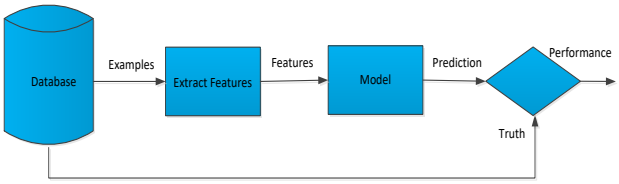

Figure 2: ESR system in testing phase

from the environment, model makes the predictions about the classes of sounds and we actually may not know the real truth. In production stage we may update sounds in database, update the model even we may change the ML algorithm. In each case we need the database.

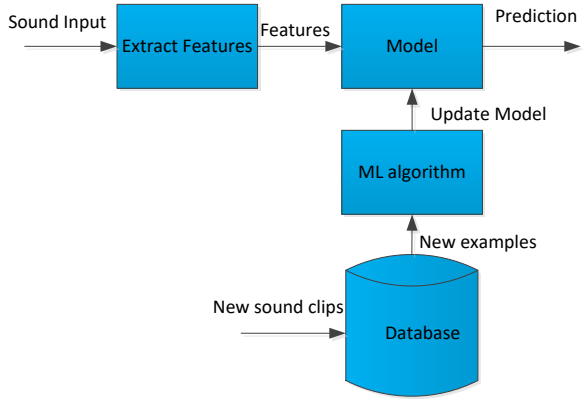

Figure 3: ESR system in production phase

This paper is organized as follows: In section II we will make a literature review of ESR databases. In section III a new relational database model for ESR systems will be explained. At the last, section IV, the contribution of this work and other planned activities will be explained.

2. Literature Review

In this section we will review the mostly referenced databases in ESR related papers. The structure of the databases will be explored; pros and cons of the structure will be argued if applicable.

One of the databases that have been mostly reverenced is Real World Computing Partnership's (RWCP) non-speech database [15]. Using a standard single microphone, acoustic signals of about 100 types of sound sources were measured in an anechoic room as the dry source. By using the impulse response of three kinds of rooms, convolution with the 48 kHz sampling signal was carried out to reconstruct the sound signal in respective rooms. The database structure (structure of directories) and navigation to sounds is explained and provided by an HTML page as shown in Figure 4 for dry sources. As an ESR developer we must examine the structure of HTML file and find the desired sound clips. Maintenance of the data and usage is not so easy with this kind of structure.

Detection and Classification of Acoustic Scenes and Events (DCASE) is an official IEEE Audio and Acousti Acoustic Signal Processing challenge. For challenge a database is prepared and it is also a resource for ESR researchers. DCASE 2016 challenge consists of four tasks [16]. The goal of Task-2 is to detect sound events for example "bird singing", "car passing by" that are present within an audio segment. To be prepared for the challenge two datasets, train and development are given. Train is used to create the model and development is to test the model.

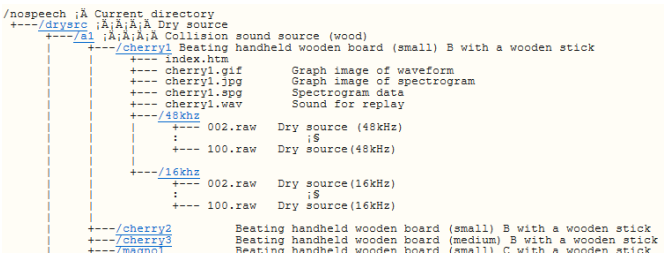

Figure 4: RWCP dry source sound clips structure

For training all sound files are in one directory and a readme file explains the details, such as sampling frequency, quantization bit depth, etc. For development dataset there is an annotation text file for each sound clip. Each .txt file contains information about the onset, offset, and event class for each event in the scene, separated by a tab.

DCASE 2017 Task-2 dataset contains ".yaml" files for annotations [17]. ".yaml" files (Figure 5) can be read by a Matlab command, so it is easy to work with these structured files.

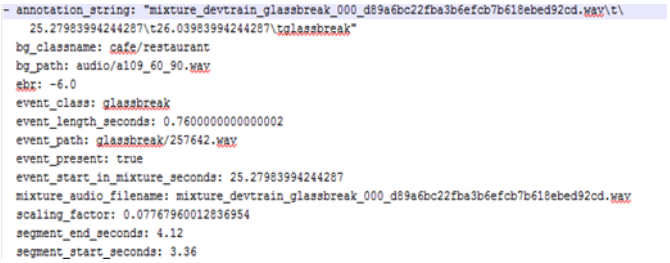

Figure 5 DCASE 2017 task-2 development dataset "yaml" file for glass break

Dataset for Environmental Sound Classification (ESC) contains two databases. There are 10 classes and each class has 40 clips in ESC-10 dataset. ESC-10 is subset of ESC-50 which contains 50 classes and each class has 40 clips. There is a readme file in which there is a line for each clip explaining the details of the clip for each dataset [18].

In [19], a dataset of annotated urban sound clips are recorded and taxonomy for urban sound sources is proposed. The dataset contains 10 sound classes with 18.5 hours of annotated sound event occurrences. The dataset contains a CSV file (Figure 6) explaining the details of each recording.

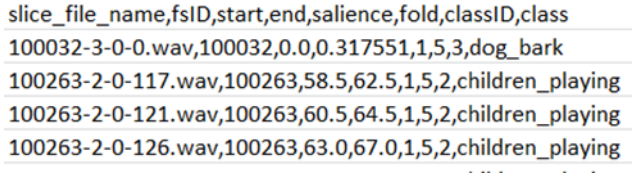

Figure 6: CSV file explaining Urbansound database

Another ESR database is http://www.desra.org. In [20], the aim of this database, details of the design and the sources used are

explained. It is designed as multi-purpose database. The database contains variety of sounds from different events with thorough background information for each sound file. It is accessible from the Internet (The database is not fully functional at the moment). The database was designed considering for admin tasks and general user level tasks. Web front end provides the functionality for user level tasks.

http://www.auditorylab.org is [21] another database. This database was constructed by Carnegie Mellon University to examine the human ability to use sounds to understand what events are happening in the environment. All the sounds in the database are recorded in a controlled way. The laboratory and the recording media used are technically detailed. In the construction of database sounds are grouped by the event that makes the sound. Sounds of events like impact, rolling can be downloaded from this database.

3. Database Design

The databases reviewed in Section 2 are prepared for just resources for the development of ESR applications. Many of them provide the data and the files for correctly handling the data. In this context they are valuable resources for all ESR researchers. Desra [20], provides extra tools such as a web graphical user interface for searching and testing.

In the development process of an ESR system, some main functions training, testing and production explained in Section I. During this development process, many sound clips are used; new sound clips may be added or deleted. We deal with many features extracted from these sound clips; we create models using different ML algorithms. Then we compare the models; try to find best features and best ML algorithms. This loop continues. Our first goal in this database design is to help researchers as much as possible to ease the burden of handling data. The second goal is to help maintenance of the data. Our data is sound clips, features, algorithms and models. Addition, deletion, searching, annotation, backup and restore can be thought as the maintenance task.

3.1 Taxonomy of Environmental Sounds

We need a taxonomy to be able to store, search and retrieve the data from the database. During literature review we see two kinds of taxonomy. In the first taxonomy, the sounds can be grouped by the event that makes the sound. In Figure 7, grouping of sounds defined in [21] is seen.

Figure 7: Grouping of sounds based on sound producing events [21]

Another hierarchical grouping is seen in Figure 8. This is also classified in the first taxonomy. This is the grouping defined in [22] based on sound producing events and the listeners' description of the sound. Second taxonomy is based on the sound source [19][23]. The subset of the taxonomy defined in [23] is taken into consideration for urban sounds given in [19].

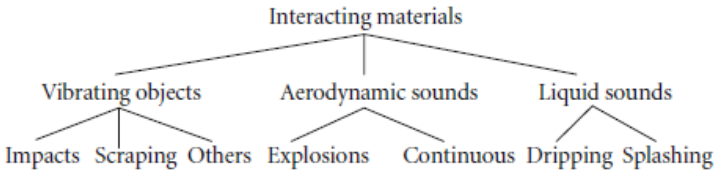

Figure 8: Grouping of sounds defined in [22]

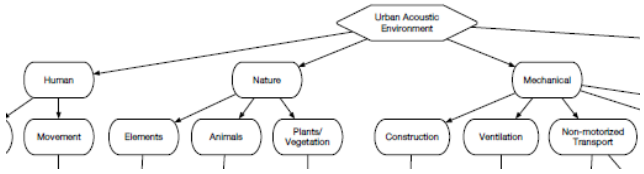

Figure 9 A part of the urban sound taxonomy defined in [19]

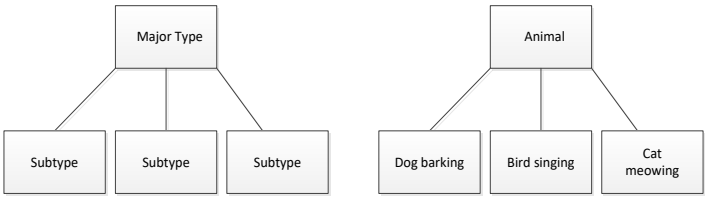

Figure 10: Environmental sounds grouping in the database

3.2 Non Functional Requirements of the Database

- There will be sound clips in the database. These sound clips will contain environmental sounds. Each sound clip can have more than one environmental sound. These environmental sound clips can belong to different major environmental sound types. Origin of these sound clips, such as own recording, from an internet site or from another database, should be entered to database. Recording details should be entered. Size, file type of sound clip and the path where the sound clips are recorded should be entered to the database.
- There should be major types, such as human, nature, animal, etc. There should be subtypes, such as dog bark, gunshot etc. and these must belong to major type. Start and end sample index or start/end time of these clips should be known.
- There will be environmental sound clips in the database. These clips should be extracted from sound clips defined in first paragraph. Each of these sound clips should have a subtype and it should be known from which sound clips it

is extracted. Extraction method should be entered. If it is extracted by an algorithm the algorithm name otherwise as "manual" should be entered to database.

- Recording details should be entered to the database such as, sampling rate, quantization bit, channel size, etc.
- Background clips should be entered to the database. Each background clip should have a type. Each background clip should also have file type, file size, recording detail and the path where it is recorded.

3.3 Functional Requirements

- There should be scripts which will take algorithms as arguments and extract the environmental sounds from sound clips. These extracted clips should be entered to the database as explained in 3.2.
- There should be scripts which will embed environmental sound into noise clips at desired Signal to Noise Ratio (SNR) level.
- There should be scripts which will extract features from environmental sound clips and store to the database.
- The scripts, their help files, paths should be stored in the database.

3.4 Graphical User Interface (GUI) Requirements

- Administrators can use the GUI for meta data entrance, deletion and update such as major types, subtypes, recording details.
- Administrators can use the GUI for data load manually or using the data loader script.
- Researchers can use the GUI for searching and downloading the desired environmental sounds.
- Researchers can load their features and models to the database.

3.5 Database Implementation

The implemented database will include some data which can be stored by way of data types found in the standard database software and also sound files. These sound files will not be stored to database instead they will be stored in the operating system file structure and the path to this file is just recorded in the database.

Microsoft SQL 2008 Database Server is used to create tables. The tables and the relationships between them are shown in Figure 11. The scripts providing functionality are coded in Matlab 2011a. The files are stored in "mat" type when required.

For functional requirements the following scripts are coded using Matlab.

- Environmental Sound Detector: This script is an interface between algorithms that extracts environmental sounds from the sound clips. Different algorithms can be used here for extraction of the environmental sounds. The algorithms must conform to this script interface definition. This script takes the algorithm name that will be started and the environmental sound types which will be searched are given as arguments.
- Environmental Sound Embedder: This script takes the type of the environmental sound, noise type, SNR level and at last the number of required record count to be created. The script merges the environmental sound clip with the noise clip at the desired SNR level and records it to the database table.
- Feature Extractor: This script acts as an interface between feature extractors. It takes the path of the feature extractor from the features table, feature name and the environmental sound type from command line. After extracting features, it is saved as a mat file.
- Data Loader: To load data from other databases this script is used to interface with data loading scripts.

The GUI is developed using Microsoft Visual Studio with C# language. GUI has admin utilities and end user tools. In Figure 12(a), it is seen the part of GUI providing admin operations. These admin operations are additions and deletions of major types, subtypes and sampling information. Besides the GUI provides the administrators load data one by one or using a script to load as a batch.

The GUI provides the users some tools. The tools are for searching the database and testing their algorithms on the sound clips given by the database. Users can search the database to see the sound clips with desired type.

End users can search the database with noise clip type, sound clip type and with SNR interval then select a clip and copy it to their own computer. After finding the start index of the embedded environment sound clip, by writing the start index of this environmental sound to the edit box on the GUI and by clicking the test button, they can test their algorithm correctness. The WEB GUI for end user tools is seen in Figure 12(b).

After database and scripts implementation we loaded the data from Urbansound [19] database. Now many operations on the database can be done either using GUI or an SQL command line.

4. Conclusion

The lack of common database for environmental sound recognition is an important obstacle in front of the researchers. The development of and ESR system is a tough process during which someone have to deal with lots of sound clips with different types, algorithms and models. In this paper we explained a relational database model which will make the data handling easier. The database developed is different from other counterparts which are just providing the data. The relational database model described here provides easy maintenance as well as easy usage.

Although our goal of designing this database is for ESR, other areas that deal with environmental sounds can use it.

By improving the database by adding data from general databases mostly used and by adding more functionality we aim it to be a common database for research activities of ESR.

Conflict of Interest

The authors declare no conflict of interest.

ABSTRACT

The energy marathon is becoming increasingly based on renewable sources, whereas the continuous decrease on the cost of energy production has supported in last decade, for instance, the development of large-scale offshore wind applications. The consistency and availability of the AC-working equipment portfolio is only limited by physical application boundaries, which are quite evident in this sort of accomplishments. The focus of this article is to present a tool developed under the MATLAB environment which allows for a quick and real-time analysis of HVAC links, assessing the impact of voltage, current, power factor or distance conditions. The conclusions are drawn directly by means of a stress-point and operational acceptance range.

1. Introduction

This paper is an extension of work originally presented in 2017, 11th IEEE International Conference on Compatibility, Power Electronics and Power Engineering (CPE-POWERENG) [1]. Offshore wind applications are clearly under the spotlight. The wind conditions, the ability to increase the rated power of the turbines and thus the size of the plant, in addition to the operational and technical advantages of having the units dispersed over the sea, provide the arguments to position it as one of the viable alternatives for the energy demands of the future [2]. However, there are known limitations for the Alternate Current (AC) Transmission Links.

As wind turbines now compete with gas turbines – in rated power – and the cost of production is consistently approaching the one of traditional carbon-based plants [3], innovation pushes the offshore power flow to the MW-unit level. That, added to the long distance the submarine cables should meet, reduces, in a sense, the reliability of traditional AC solutions [4]. This is the starting-point of this investigation. Would that information provide the basics, the goal is clear – the model aims to provide the operational range and the restrictions for any given AC link (meaning a set of initial conditions). Moreover, that was proven based on the results obtained shown later.

AC-based plant-to-shore links do not provide a one-size fits-all option and a careful analysis still is mandatory to ensure the proper conversion of the bulk wind onto usable power preferably with limited losses.

Although it is common knowledge that current HVAC Overhead Lines (OHL) can easily be deployed in distances in upwards of 100km, the same is not true for insulated-cable based lines, especially in offshore applications, which are based in submarine cables. For both of these cable types, their fabrication characteristics – hence the electromagnetic characteristics seriously restrict the application of AC on the offshore [5]. Once more, the goal of this paper is to present a model that allows for a reliable estimation of the maximum operational distance in such regard without requiring a time-consuming case-by-case investigation and still providing detailed results.

This paper divides in seven sections. The first part provides a description of the wind farm (WF) model under appreciation, which constitutes the baseline for the operation of the model. The intention is to provide a set of results, for equivalent air and cable-based lines, and ultimately, also to allow for an extrapolation for other configurations. The transmission-line equivalent and the GUI-based analysis models are presented in sections 2 and 3, respectively.

Sections 4 to 6 present the experimental results of the analysis performed, for standard OHL submarine cables, as well as, for

offshore compensated-cable solutions. The last chapter includes the conclusions.

2. Simplified Model of the Offshore Wind Farm

2.1. Characteristics of the Wind Farm

This section consists of two main parts; The first one aims to present the simplified model of the wind farm under consideration, whereas the second one introduces the line model, later on used on the MATLAB-based software (section 3). Based on actual available portfolio [5] and existing projects [6], a decision was made to assess the link of an 80MW offshore wind cluster, composed by ten 8MW turbines. The schematic of the model is shown on Figure 1.

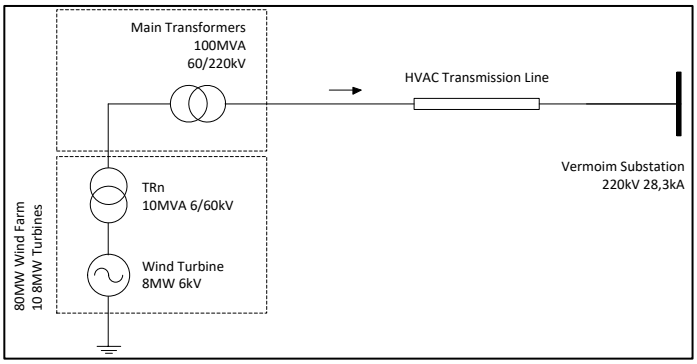

Figure 1. Layout of the Wind Farm

As shown on the figure above, the authors chose to use a 220kV link to the shore, given the rated power of the wind farm and the existing transmission infrastructure on that region. REN' Vermoim Substation located approximately 40km from the district capital Oporto was the onshore Point of Connection (PoC). The tables 1 and 2 present, respectively, the characteristics of the wind farm and the ratings at the given substation (at the 220kV busbar).

Table 1. Characteristics of the Wind Farm

Nr. Units	$S_{N\text{-}Turb}$ [MW]	$S_{N\text{-}Farm}$ [MW]	L_{Link} [km]
10	8	80	200

Table 2. Short-circuit ratings at Vermoim 220kV Busbar

$S_{CC\ MAX}$ [MW]	$S_{CC\ MIN}$ [MW]	$I_{CC\ MAX}$ [kA]	$I_{CC\ MIN}$ [kA]
10.7	8.3	28.3	21.7

2.2. Characteristics of the HVAC Link
