The usage of insulated cables as the means to transmit power in HVAC is understandingly common. Nonetheless, offshore (submarine) applications have a different behavior that ultimately and most importantly, significantly reduce the acceptable distance of application. Limitations, such as high charging current and higher *Ferranti* effect [8], are widely known, the model must allow for the analysis of several scenarios, with real-time adjustment and performance assessment, still ensuring a less time-consuming computation of each one.

There are two main cable-sizing criteria, which are the rated voltage and admissible temperature [8] and the model is based on this simplification.

The nominal current is given directly by the rating of the wind farm whereas the fault current value is given at the HV OHL-bay at the onshore substation as it is the most significant contributor in case of short-circuit at the PoC. Both allow for an estimation of the minimum cable cross-section [7]:

$$I_N = \frac{P_N}{\sqrt{3}\,V_N \cos\varphi} = 262{,}43\ \text{A} \quad (1)$$

$$s_{min} = \frac{I_{CC}\sqrt{t}}{K_c} = 521{,}3\ \text{mm}^2 \quad (2)$$

Where *t* represents the fault-clearance time.

Having this as a reference, and given the cable standardization, a core section of 630mm^2 shall be selected. The OHL and cable will be selected having such as a reference. The upstream grid is not taken into consideration on the analysis (meaning the onshore PoC is assumed a PV-type node).

3. Software Implementation

3.1. Electrical Line-equivalent Model

When in comparison between lumped-sum or parabolic line-equivalent models, the differences are significant. In the case of OHL, the parabolic components of the equivalent are almost unitary, which allows for simplification and a lump-sum provides acceptable results [8].

In cable applications in general, the wave impedance is higher and as so the propagation constant decreases, resulting in non-unitary trigonometric components. These models compute the opposite-end results based on a linear and concentrated impedance section, the propagation speed is not taken into account (which drives from the simplification itself).

In order to proper translate the effects of submarine cable applications, the model has to take into account the influence of the propagation speed and the geometrical distance. An accurate model has to take effectively into account the distribution and variation of the parameters along the line, being therefore distance and transmission velocity- dependent (which lastly decreases for a higher cable length).

This knowledge is widely applied in very-fast transient analysis for atmospheric discharges or other high-velocity voltage and/or current variations on transmission lines. An *x* section of the line is presented in Figure 2.

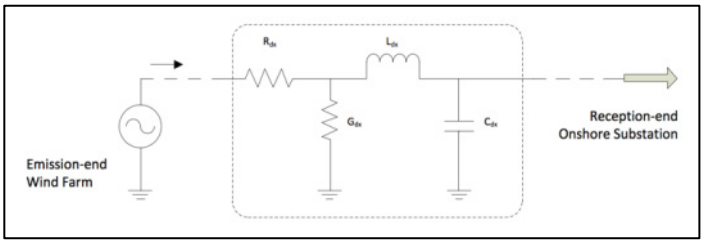

Figure 2. Infinitesimal section of the cable ([9], adapted)

As the results of that equivalent scheme are much more accurate, the respective equations (3) to (6) are used on the MATLAB model. These, on the first approach, provide a distance-based analysis of a given transmission link in regards to estimated voltage and current:

$$Z_L = (R + jX)\, l \text{ [ad]} \tag{3}$$

$$Y_T = (G + jB)\, l \text{ [ad]} \tag{4}$$

The voltage and current for *x* distance are given by:

$$V_x = V_1 \cosh(\gamma x) - Z_0\, I_1 \sinh(\gamma x) \text{ [kV]} \tag{5}$$

$$I_x = -V_1 \frac{1}{Z_0} \sinh(\gamma x) + I_1 \cosh(\gamma x) \text{ [A]} \tag{6}$$

All data shown on the GUI (hence plot options) are also based on a set of calculations detailed on the script. The calculations are performed for any given initial conditions, non-related to any previous tests – although a multi-set analysis can be provided, as shown on sections 4 and 5.

3.2. Model Design

The necessity to address a multitude of scenarios to draft earlier conclusions has led itself to the conclusion that a software, rather than casual calculation, had to be taken into practice. The development of a fast and custom-made tool to the analysis the design of HV transmission lines led the authors almost directly to the implementation of a GUI-based MATLAB model.

That allowed for the creation of a versatile and digital tool, which allows for a fast and straightforward verification, given a set of any initial conditions, if power transmission via a selected line (or power cable) is acceptable in technical terms. And, the model spans virtually to any range of, not only cables, but voltage, current, power factor or distance.

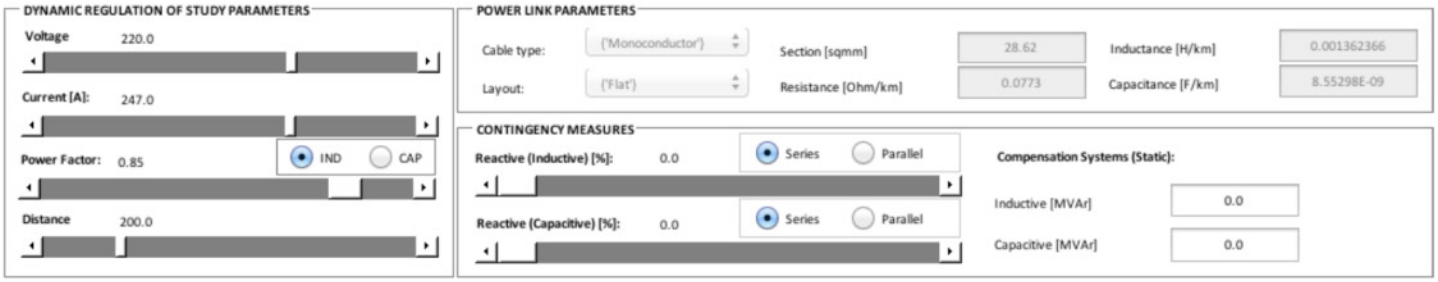
The possibility of checking a certain scenario in real-time and in on-hand is another plus, possible via the multitude of adjustments possible on the model itself, with instantaneous calculation and results. As the GUIDE is, basically, the user-friendly window of MATLAB C-based programming, also quite an user-friendly design was achieved.

In practical terms, the model operates by taking into account a set of transmission line conditions – stored on pre-loaded, yet adjustable .XLS sheet, of OHL and cables, then applies the equivalent model earlier addressed (section 3), and computes all the results that illustrate the steady-state operation of a given transmission "line". That includes voltage, current, no-load voltage & current, voltage drop, efficiency (losses evaluation), power factor, stability, surge impedance level (SIL) and model parameters (Z_L & Y_T).

3.3. Model Key Advantages

The segmentation and expandability of the model can be defined as two of the most important characteristics. All the information used and key features, aside from cables, are actually .XLS-based. The model starts and loads-up the majority of its functionalities with reference to the options and fields set on the configuration Excel sheets.

Features such as the stress parameters used for the calculation – further on shown – or the actual regulations, such as voltage or reactive power boundaries, can be adjusted with ease. The model also loads using acceptable and recommended voltage, current, power factor and distance values, further facilitating the usage. The plot section, on the other hand, allows for the simultaneous visualization of three different calculation windows, thus allowing the user do address a scenario in a much more complete manner.



Finally, the information provided has a key focus. As said, the ability to implement the line-equivalent is wide-spread in literature. The difference is to provide such information and the data outcomes in simpler yet much more complete manner. That information is provided to the user using overlay layers on the results plotted, and may include operational boundaries, compensation expectations, stress-range distance pin-pointing, or even, simultaneous calculation results – for example, for difference one-end power factors. The summary of the available results is shown on Table 3.

Table 3. Available Results of the Model

Ref	Description
1	Powerline Voltage
2	Powerline Current
3	No-load Current
4	No-load Voltage
5	Voltage Angle
6	Current Angle
7	Voltage Phase Displacement
8	Current Phase Displacement
9	Active Power
10	Reactive Power
11	Apparent Power
12	Transmission Losses
13	Transmission Efficiency
14	Voltage Drop
15	Power Factor
16	Tan-Phi
17	Stability Limits (Pe-Phi)
18	Voltage Drop (DV-PF)
19	SIL (impedance)
20	SIL (apparent power)
21	Longitudional Impedance
22	Transverse Admittance

The critical factors that guide the operational ranges are shown in Table 5. Generically (and, in fact changeable), the critical factors are presented based on two conditions: "C" (meaning Critical, for 80% of target) and "F" (for Failure, or 100% of target value). Other conditions may apply as mention on Table 5. The numbers refer to the references and 80/100 thresholds can be adjusted as the intention of the user with minor core programming adaptation.

Once again, model design is as simple yet flexible and expandable as possible. The majority of the reference and configuration-data is XLS-based and new features are easy to implement. The same can be done for the (line) data, as the routine reads any given organized sheet and performs the calculation. After the automated analysis is complete, the user can make a search, distance or variable-dependent, for a value-at-point or given location of the "line".

As observed in Figure 3, the real-time interface is possible via the adjustable sliders – which adapt the basic parameters. Re-calculation is done fast and automatically after any change on those. The advantages of a tailor-made GUI model span for other areas. The plotting windows included have been adapted to allow for the *online* setting of the units to be used: International system (SI) units, per-unit (P.U.) or %-based results.

The adjustment of the ranges and precision of the axis is adjusted directly on each respective axis line. Exporting is also made directly from the working plotting window, allowing for quick integration on written reports. This is, once more, allowed by a strong background interface with .XLS files, and further on, with facilities such as additional interfaces, adaptation, parameter-variation mode and export facilities, are all intricate on the model.

Table 4. Critical Factor References for Model

Ref	Variable Checked	Slope	Critical Value	Failure Value
1-4	Line Voltage	>=	REN regulations	
5-8	Line Voltage	<=	REN regulations	
9	Line Current	>=	Thermal limit of cable	
10-13	No-load Voltage	>=	REN regulations	
14-17	No-load Voltage	<=	REN regulations	
18	No-load Current	>=	50%	100%
19	Reactive Power	>=	40%	50%
20	Losses	>=	40%	50%
21-22	Voltage Angle	>=	±30º	±40º
1-4	Line Voltage	>=	REN regulations	
5-8	Line Voltage	<=	REN regulations	
9	Line Current	>=	Thermal limit of cable	
10-13	No-load Voltage	>=	REN regulations	
14-17	No-load Voltage	<=	REN regulations	

What is also worth mentioning is the ability to automatically see the stress ranges on a color-coded plot-overlay for any given calculation. These ranges are recognized and the maximum operating distances are identified. Ranges are loaded based on the Portuguese regulations (e.g. REN) and those can also be adjusted.

For a comparison to be made on different transmission solutions a simulation is made on a 220kV air-insulated single-circuit single-pole transmission line. The rated voltage is selected taking once again into account the grid topology at the PoC.

4. Evaluation of Air-Insulated Connection

4.1. Parameter Calculation

The overall manufacturer-issued characteristics of such cable, later on introduced on the MATLAB model, are shown on Table 5. The maximum active power output is stationed at 80MW (having a cos φ of 0,85 lag). The matrix therefore can be calculated as presented in equations (7) and (8).

Table 5. Characteristics of the simulated Overhead Line

U_N [MW]	r [mΩ/km]	L [mH/km]	C [nF/km]
220.0	77.3	1.362	8.553

$$Z_L = (R + jX)\, l = 10.381 + \text{j}26.3894 \text{ [ad]} \quad (7)$$

$$Y_T = (G + jB)\, l = \text{j}10.1 \times 10^{-3} \text{ [ad]} \quad (8)$$

These values are automatically calculated on the model.

4.2. Experimental Results

Computation is done assuming the reference data at the reception-end (onshore PoC). The simulation of the voltage and current at the emission-end of the line are shown on Figures 4 and 5. Ultimately, the results confirm the reliability of the model with existing accurate OHL-analysis data [9]. The calculation method is than transposed to an offshore (submarine) framework, as presented on section 5.

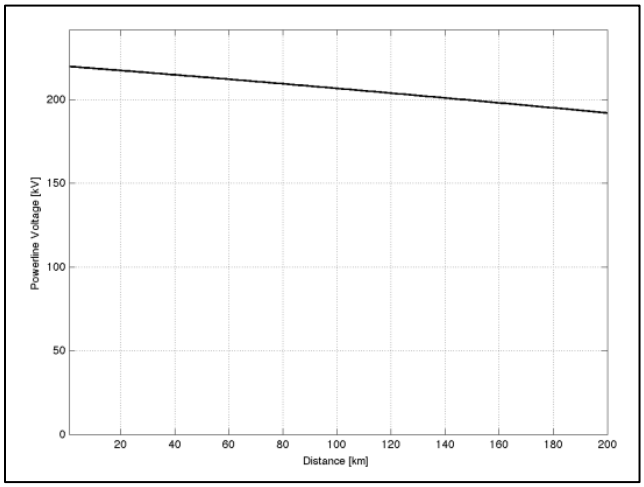


Figure 4. Powerline voltage simulation (220kV OHL)

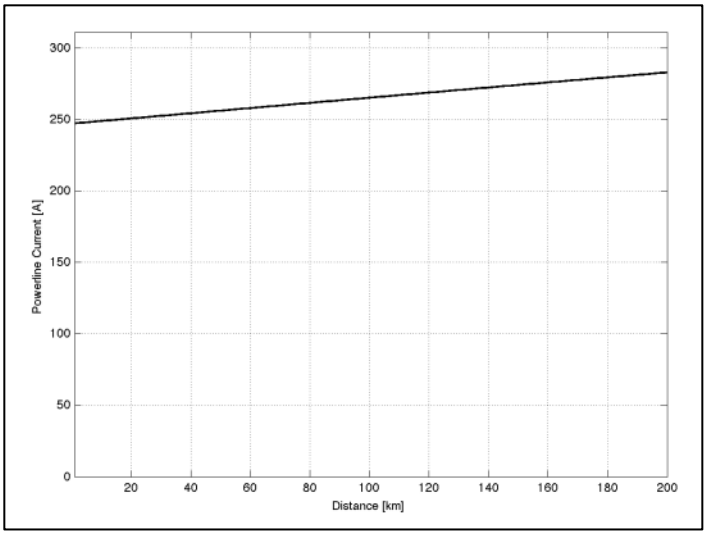

Figure 5. Powerline current simulation (220kV OHL)

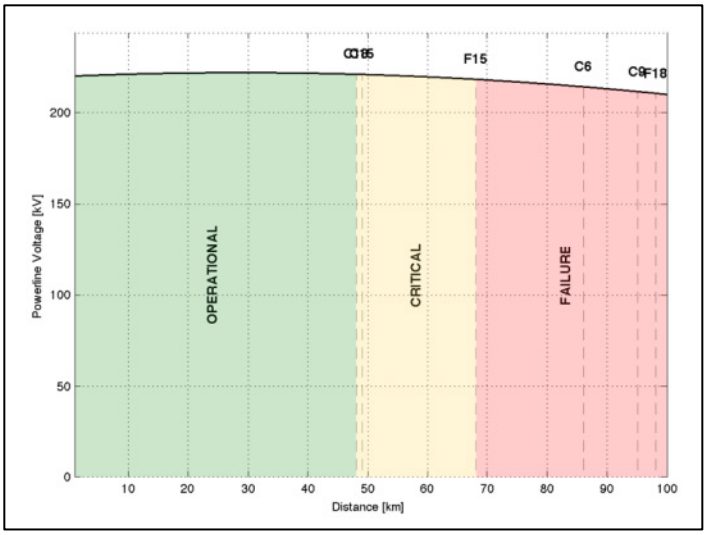

Figure 6. Powerline voltage simulation (220kV Submarine Cable)

The analysis of the submarine cable, being the focus, shall include much more significant data, however all being supported on the positive result of the voltage & current simulation shown on these two test plots.

5. Evaluation of Submarine Cable Connection

5.1. Parameter Calculation

The analysis of the submarine cable, hence parameter calculation, is done on the same basis as before. The cable data obtained from the manufacturer (ABB) is presented in Table 6. Cables are laid in a single pole linear and evenly distributed along the seabed.

Table 6. Characteristics of the simulated Submarine Cable

V_N [kV]	I_N [A]	Size [mm2]	R [Ω/km]	L [mH/km]	C [μF/km]
220	600	630	0.04935	1.4000	0.1600

$$Z_L = (R + jX)\text{l} = 9.87 + \text{j}87.9646\ [\text{ad}] \quad (9)$$

$$Y_T = (G + jB) = \text{j}10.1 \times 10^3 [\text{ad}] \quad (10)$$

Once again, these are automatically calculated on the model. Equations (5) and (6) apply for the calculation of all data plotted, including the calculation of the ABCD equivalent model parameters.

5.2. Voltage & Current Results

The operation, critical failure ranges can be seen on the figures shown. The reference for criticality/failure leads back to the REN regulations on the voltage boundaries. The same is shown on the current plot. A distance shorter than 100km is also sufficient to show the relevant information yet that range facilitates the condensation of data on the plot snapshot.

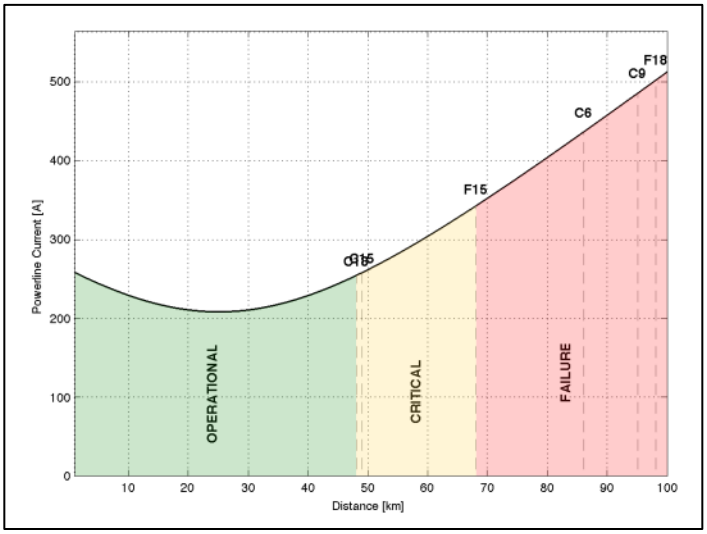

Figure 7. Powerline current simulation (220kV Submarine Cable)

The emission-end (WF) values are 210kV (Fig. 6) and 513A (Fig. 7). As it can be verified, the voltage drop reaches close to 5%. As for the current, it's final value is around two times the initial current value at the reception. This allows for an insight of one of the most important downsides of cables – the charging effect.

As far as the current values are concerned, the high capacitive characteristics of the submarine cable, lead to a significant increase of the line' current and emphasize the reactive power flow. This not only increases the power losses along the line but also confirms that cable solutions are not feasible after 30-50km [10] alongside theoretical information available.

5.3. Voltage Drop on Underground & Submarine Cables

As a basis of comparison, Figures 8 and 9 include the voltage drop along transmission cables using underground (8) and submarine (9) solutions. Evidently, as expected, the reduction of the voltage is much more significant on the second option.

The authors emphasize that, on both land and sea cables, the voltage drop encountered is actually a voltage rise along the line, due to the capacitive characteristics of the cables themselves. This has to be later on compensated on the WF-side, forcing the generators to operate under very low voltages.

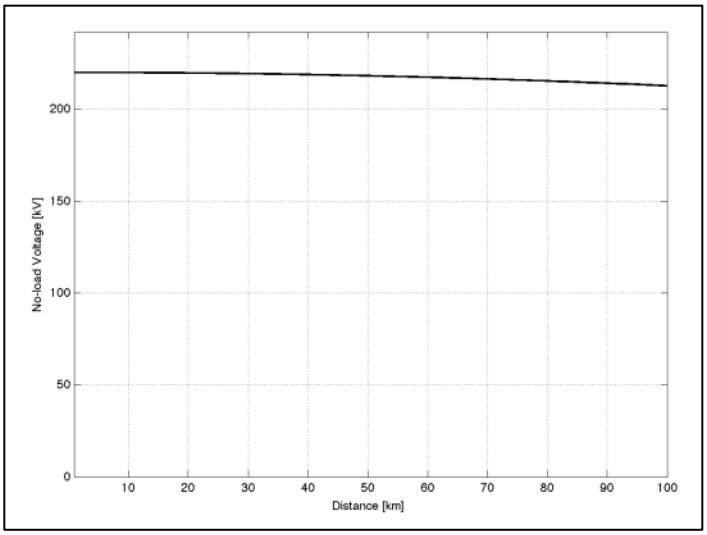

Figure 8. No-load voltage simulation (220kV Underground Cable)

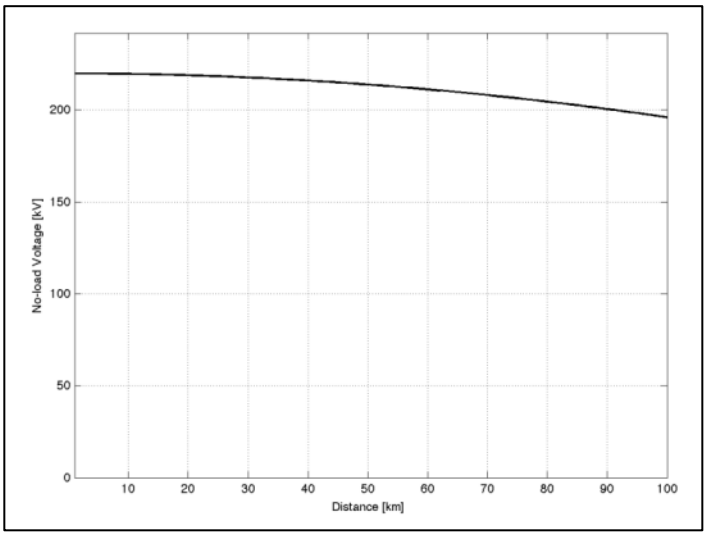

Figure 9. No-load voltage simulation (220kV Submarine Cable)

The inductance value has a tremendous influence on the voltage and current behaviour of the transmission line, but with more focus on the first one mentioned. Aside from the voltage decline – and as addressed earlier – with a higher impact, the charging and Ferranti effects are evaluated for this particular cable.

5.4. Charging Current & Ferranti Effect

The charging and Ferranti effects are the two most distinguishable plots which can be made from the behavior of insulated cables (both underground and submarine. The high capacitance of these cables leeds to a early increase on the current flow and therefore the transmittable power is severely restricted. No-load current, based on the F18 marker on the plot, is actually the failure cause of the cable under investigation.

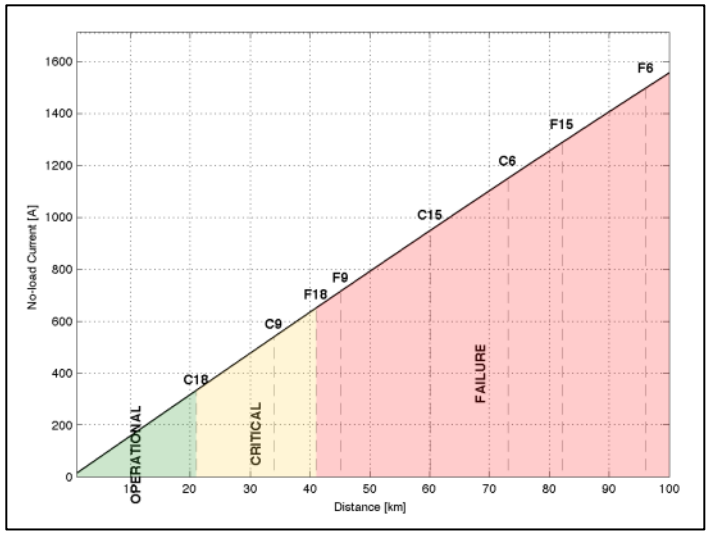

Figure 10. No-load current simulation (220kV Submarine Cable)

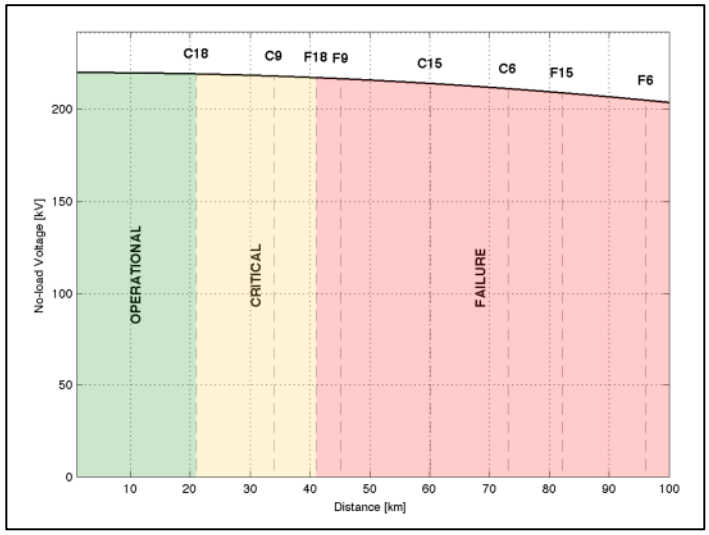

Figure 11. No-load voltage simulation (220kV Submarine Cable)

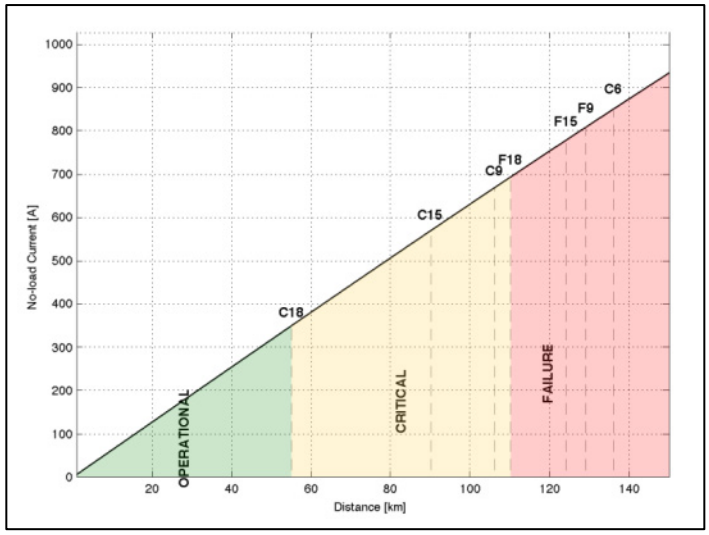

Figure 12. No-load voltage simulation (220kV Submarine Cable)

When compared to the equivalent underground cable included on the examples of the model, the differences are tremendous. The effect on the submarine option is almost 100% more. The operation of such "large capacitor" under no-load conditions also translates onto a voltage increase along the same cable – as shown previously on Figure 9.

5.5. Power Factor & Reactive Power Results

The behaviour of the power factor for a given section of the transmission cable is highly dependent on the initial conditions, especially the reception-end (PoC) power factor. For that reason, this section also includes a multi-scenario analysis, thus allowing for a better understanding of such impact.

A very high drop on the power factor is observed (close to 50% of the initial value), to a minimum of 0,44. Due to the increasing current, the active power still increases. However, it is the reactive power which increases the most, leading again to the failure of this setup for more than 70 kilometres (F15).

What is also verified is that, up to a certain distance, the capacitive characteristics of the line help to compensate for the inductive grade of the load (0,8 lag). Once the characteristics of the transmission line match the PoC, there is an inversion on the slope.

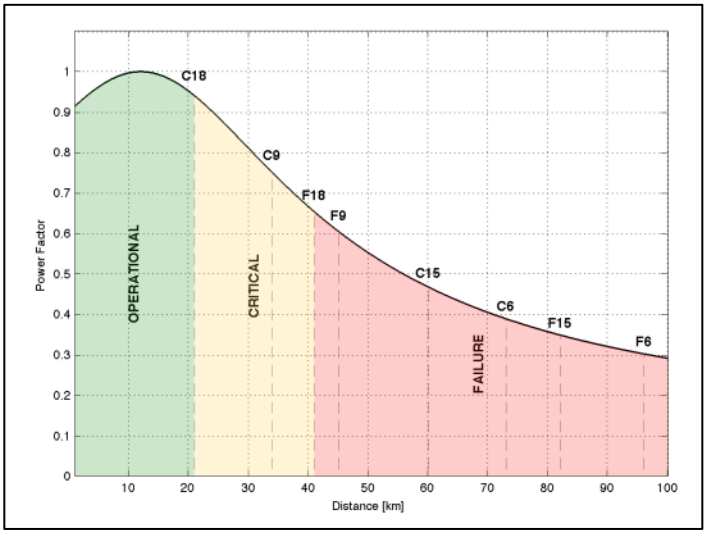

Figure 13. Power factor simulation (220kV Submarine Cable)

What is also verified is that, up to a certain distance, the capacitive characteristics of the line help to compensate for the inductive grade of the load (0,8 lag). Once the characteristics of the transmission line match the PoC, there is an inversion on the slope. After a certain distance (around 25km), the cable is actually acting as a reactive power provider. This fault is not triggered because, in percentage, it is still below the 50% threshold shown on Table 4.

What can also be understood from Fig. 8 is that the unitary power factor is obtained for a distance just under 15km. Despite failure only occurs after 40km (once more confirmed by literature), because the line has a significantly higher capacitance than the OHL, it acts much like a very large capacitor, consuming a highly capacitive current during operation. After 100km, the current required is about the same as the rating of the load (Figure. 7).

These results are quite conclusive on the balance that must be met. They also provide a further understanding on how much the compensation solutions must be tailor-made and real-time adjustible to proper ensure the safety of the link.

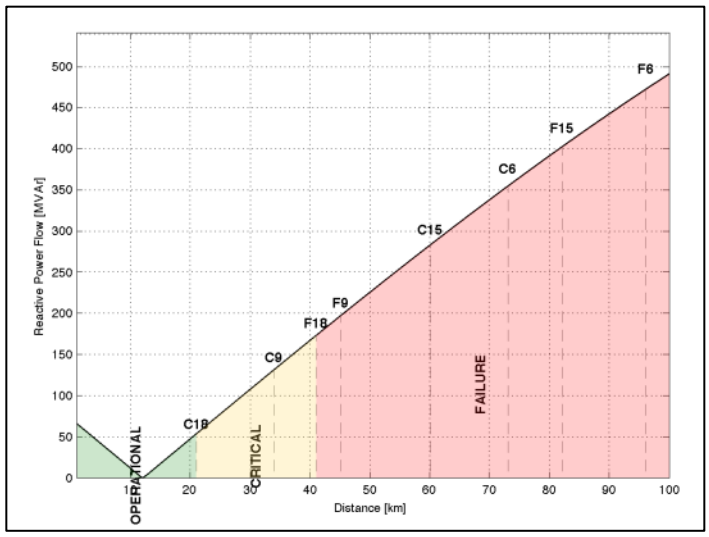

Figure 14. Reactive Power simulation (220kV Submarine Cable)

5.6. Losses & Efficiency

Losses are a significant part of the link evaluation. The model includes several paths to illustrate the losses. Two of the options are provided here: transmission efficiency and transmission (Joule) losses, plotted in Figures 15 and 16.

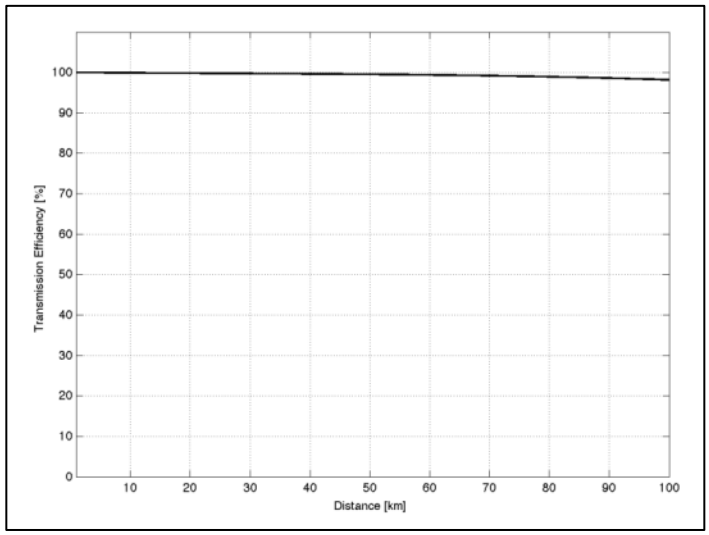

Figure 15. Transmission efficiency simulation (220kV Submarine Cable)

The efficiency remains under an acceptable range (above 90%). This easily confirms that the insulated cables have equivalent losses to the OHL, whereas the capacitive restrictions are the actual restrictions to the operation of these AC offshore links.

In a way, due to the higher inductance value, the capacitive current is not so high and Joule losses are slightly reduced. Nevertheless, the values commented are still very high and above acceptable boundaries. Losses are also similar to the equivalent land cable.

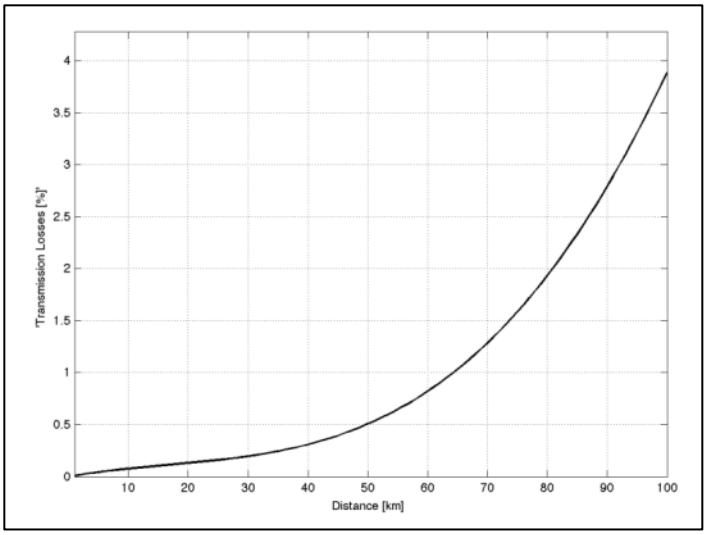

Figure 16. Transmission losses simulation (220kV Submarine Cable)

5.7. Voltage, Current & Displacement Angles

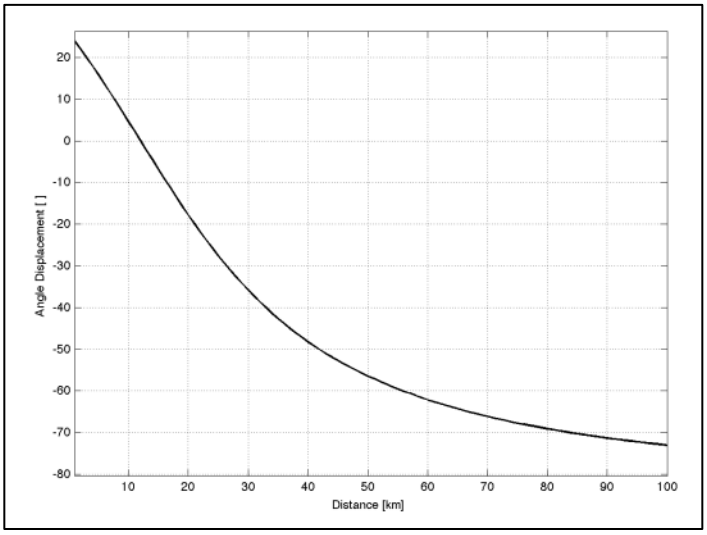

Figure 17. Angle displacement simulation (220kV Submarine Cable)

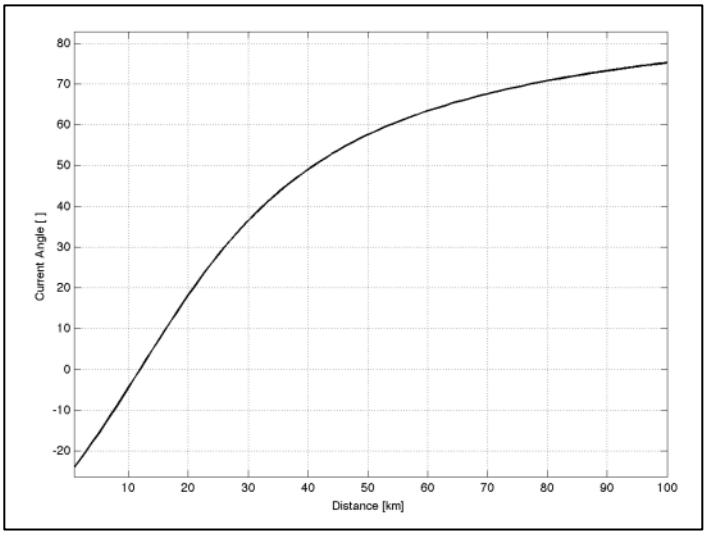

Figure 18. Current angle displacement simulation (220kV Submarine Cable)

The plot of the voltage and current angle displacements between the two ends of the cable is also a clear sign that, above the mentioned 40km, the cable is working under unacceptable operational conditions. The voltage is assuming a strongly capacitive characteristic. A comparison on the voltage angle variation for equivalent land and submarine cables is on Fig. 19.

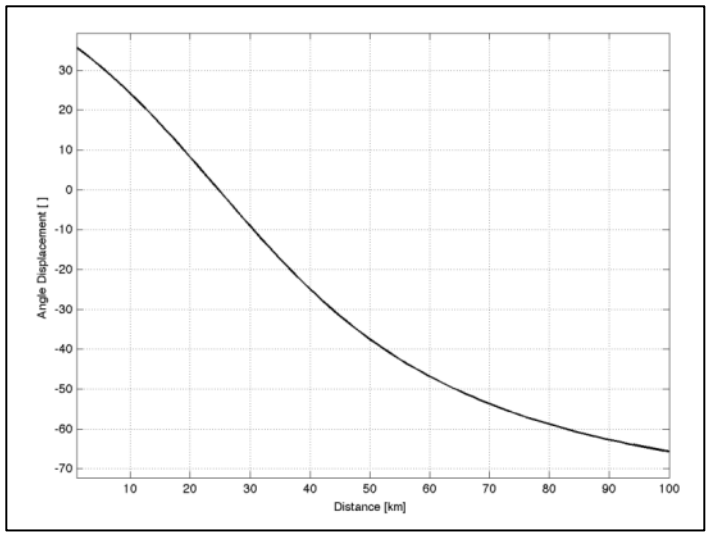

Figure 19. Angle displacement simulation (220kV Submarine Cable)

The angle and power factor values provide once more a good understanding path of the range of operation of the submarine link. The tendency of both curves is much alike the equivalent land cable. The power factor, here stated at 0,33 continues to be very low, inducing that the cable still behaves like a large capacitor. The analysis performed for the land cable, in order to assess the natural load and connectable distance is now demonstrated.

5.8. Variation of Cable Loading

With an inherit highlight of one of the additional major features of the model, this part presents the effects on the variation of the cable loading – current at the reception-end, once more, in regards to power factor and line current. The results are shown next. Hatches were disable to facilitate the visualization.

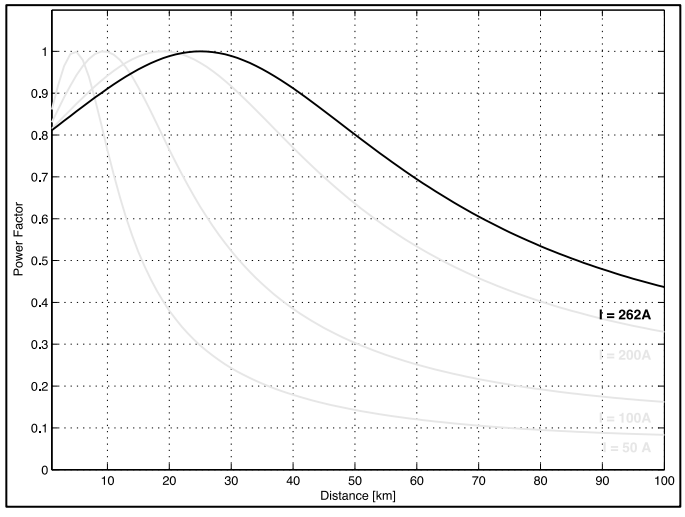

Figure 20. Power factor (load variation) simulation (220kV Submarine Cable)

If the impedance of the load is below the line's impedance, it means that the active power delivered is higher than the natural power for such voltage / cable. Land cables, which have a lower inductance and higher capacitance, are usually operated below their natural power [9], which is calculated, for this particular case, as follows:

$$Z_0 = \sqrt{\frac{L}{C}} = \sqrt{\frac{87.9646}{10.1 \times 10^{-3}}} = 93.32\ \Omega \tag{11}$$

$$P_n = \frac{V^2}{Z_0} = \frac{200 \times 10^3}{93.32} = 518.65\ MW \tag{12}$$

However, subsea cables are characterized to a much higher inductance value, thus changing that approach. With a higher rating yet under the thermal capabilities of the cable, such cable can operate and obtain better operational values.

Addressing the effect on the cable loading, both in terms of rated power, but also, in terms of power factor is crucial. The higher the current provided by the wind farm, a negative shift of the peak power factor occurs, thus leading to conclude that the cable has a wider operation range if the loading (current) is close to its rated value.

On the other hand, for an equivalent unitary capacitance, the sea cables have a much higher inductance, which for certain ranges and loads, it can help to compensate the power factor variation on the line.

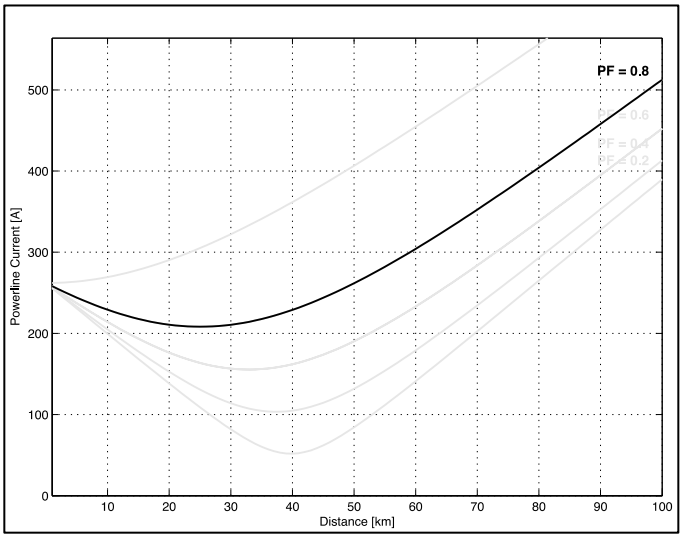

Figure 21. Current (load variation) simulation (220kV Submarine Cable)

As shown on Fig. 14, the lower the power factor of at the WF-side, the lower the current fed from the WF itself. On the other hand, the impact on the reference voltage is important. The voltage and current angles are also exposed to significant changes due to the variation of the initial power factor. The results are included on Figures 16 and 17.

This means that the lower the power factor (lag) is assumed, the voltage and current angles have smother slopes. This translates the mutual "compensation" between the power factor and the PoC and the capacitive characteristics of the long submarine cable.

For the current angle, the values at the end of scale (full distance) do not pose significant differences. But, if the center range of the angle curve is observed, it is clear that the acceptable operational boundary is improved with such power factor decrease.

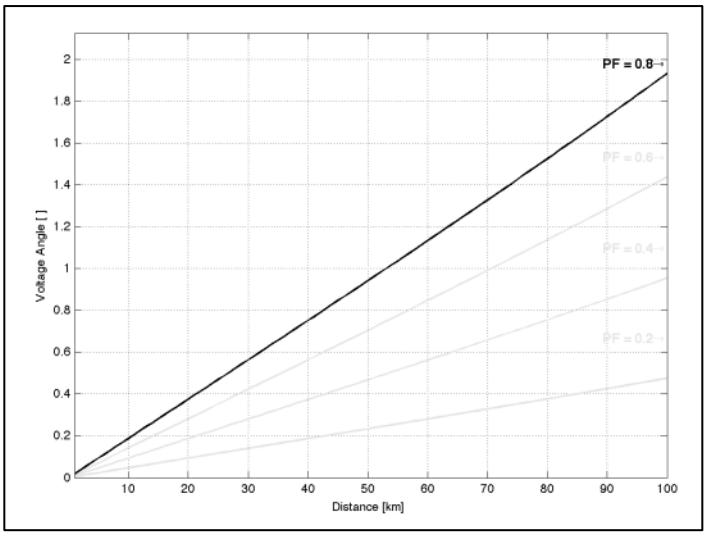

Figure 22. Voltage angle (load variation) simulation (220kV Submarine Cable)

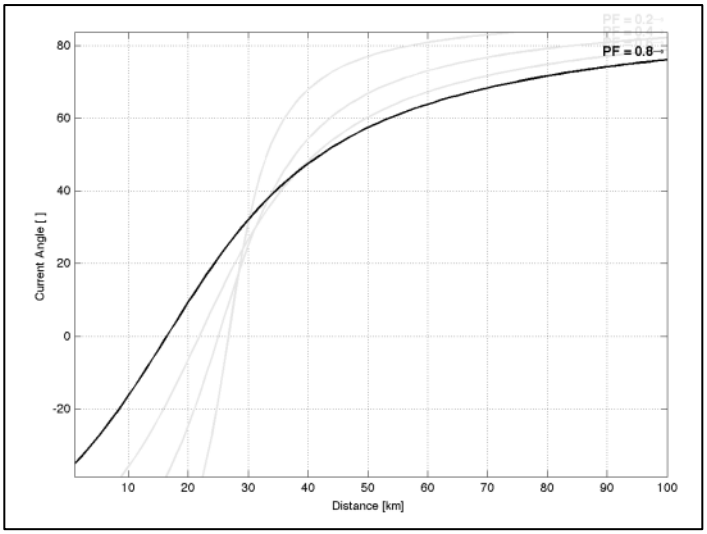

Figure 23. Current angle (load variation) simulation (220kV Submarine Cable)

Bearing in mind the purely academic approach for this – as cables used differ for distinct nominal voltages, what the model quickly provides is a framework on how an higher voltage can facilitate higher power flow. This is addressed via the SIL plot shown in Fig. 18.

The results on Fig. 16. further prove that model designed, as the conclusion, voltage increase allows for a higher SIL rating of the cable, which is aligned with the bibliography. The main result however is the easiness how this is selected on the GUI, by using the "Label" and "Freeze" capabilities. This allows the user to shown several identified scenarios {voltage, current, power factor, distance and compensation}.

Regardless, the what the authors conclude is that is now much easier, both in an academic or (risks measured) practical manner, to quickly assess the best conditions for which an AC offshore link should be designed. One route for the improvement of these results (links) is compensation.

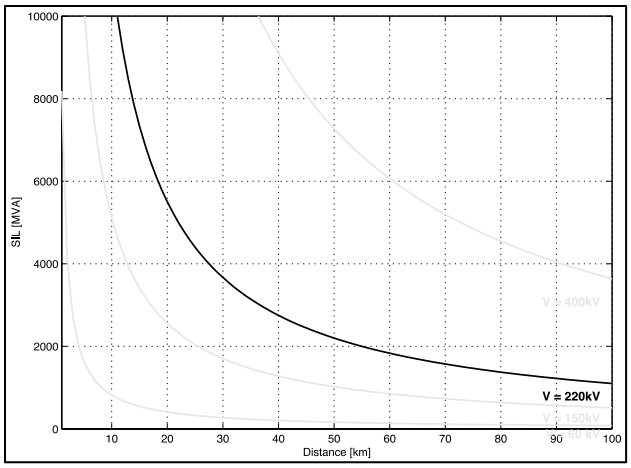

Figure 24. Current (load variation) simulation (220kV Submarine Cable)

6. MATLAB Compensated Results

The analysis of the compensated transmission cables is done still using the multi-scenario approach. As provided earlier, as the parameter changed in each scenario is automacally overlayd on the plot itself, concludes are easily drafted.

6.1. Estimation of Compensation

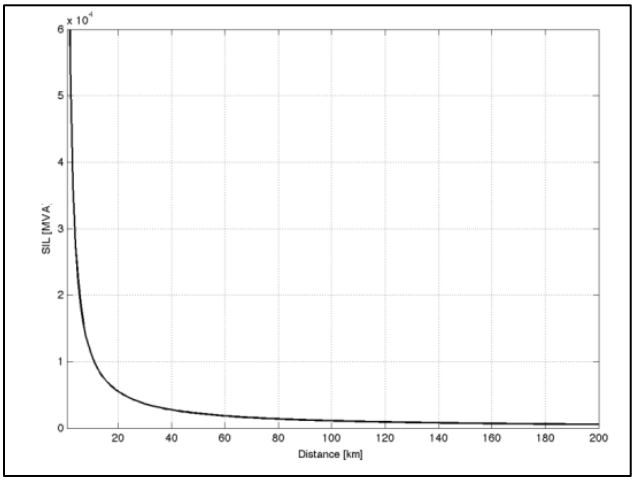

Figure 25. SIL simulation (220kV Submarine Cable)

Based on the results of the reactive power and considering a unitary power factor load, it is possible to estimate the rating of a shunt reactive compensation system – previously decided by the authors after execution a several scenario investigations using the same model. The reactive power is included in Figure 14 whereas the SIL (loading) evaluation is provided in Figure 25.

Given such and based on the experimental values shown on Fig. 16, 265MVAr was put into experiment. The effects on the voltage and power factor, two of the main images of the cable, are shown on the next section.

6.2. Voltage after Compensation

What is immediately observed is a shift of the stress (failure) point earlier identified, thus a clear improvement on the operational range. The reactive power at the emission, for nod distance, represents the full rating of the compensation.

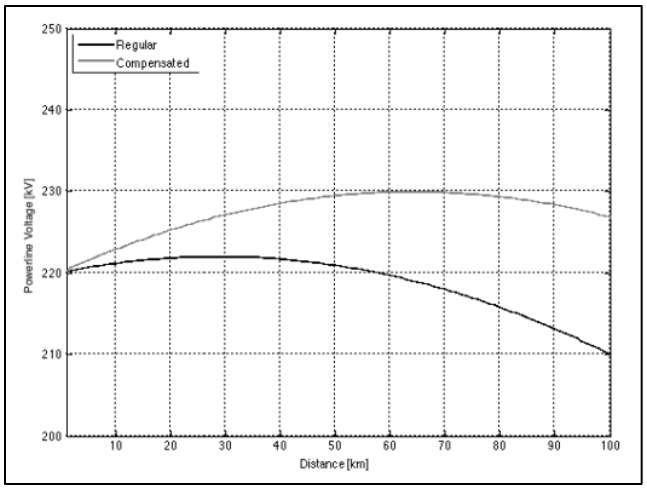

Figure 26. Voltage (after compensation) simulation (220kV Submarine Cable)

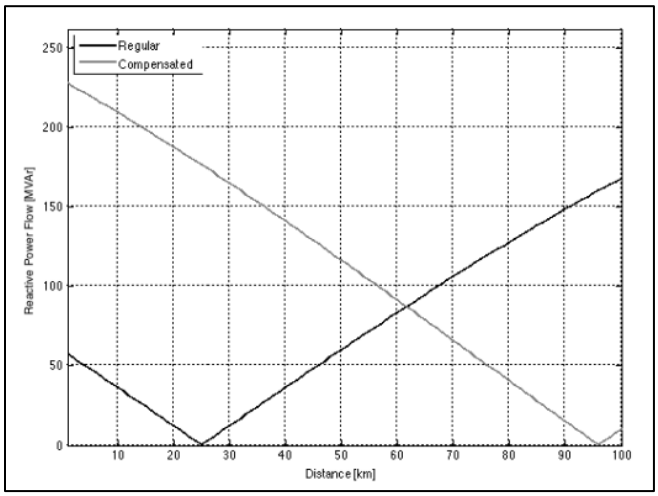

Figure 27. Current (after compensation) simulation (220kV Submarine Cable)

The GUI interface easily presents several scenarios, without going through a labour-intensive calculation routine. Taking once more the approach of adapting the cable loading (current at the reception-end), additional conclusions can be gathered (as provided on Figures 27 and 28).

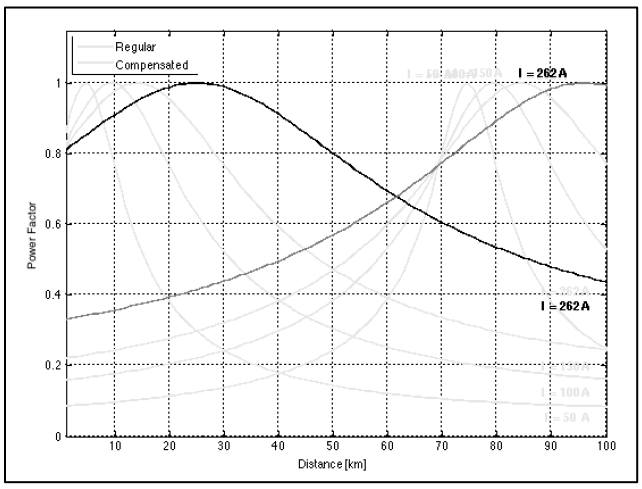

Figure 28. Power factor (load variation after compensation) (220kV Cable)

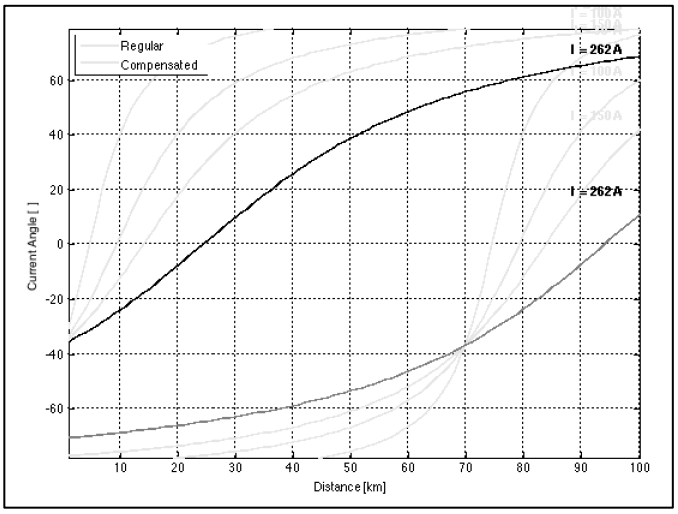

Figure 29. Current (load variation after compensation) (220kV Submarine Cable)

Voltage, reactive power and the power factor are now within perfectly acceptable boundaries, for the full 100km length. The power factor must be analysed depending on the point of connection of the compensation system, eventually using a split-off between the two ends.

Especially after the introduction of compensation, several loading scenarios have to be taken into account, once more, taking advantage of the GUI-model. For lower loading scenarios, the compensation system output has to be reduced or, eventually, taken out of service. Otherwise, what is identified in Figs. 19 and 20 is a clear overcompensation for a load drop (current). Nowadays, online FACTS systems effectively support the reactive power flow demanded by large-scale offshore wind farms. Although not addressed on this paper, once again, the model points to a quick rough estimation of a possible compensation solution.

7. Final Remarks & Conclusion

The authors firmly believe that this computational simulation tool is an important guide on the assessment of HVAC transmission links, especially for offshore applications such as wind farms.

As expected, the submarine cables presented the authors with the worst operational conditions from all the three options addressed on this document. The high inductance of such cables, mostly due to their type of insulation, introduces serious limitations, which translate in very short feasible distances. If this was the baseline for the investigation, the model as shown that the conclusions are obtained experimentally with ease.

The authors believe that the results shown before allow for a sufficient and accurate perception of the problematic associated with large HVAC transmission lines. The results were conclusive, with minor errors taking into consideration the objective proposed. So much more can be done in a further stage.

There is however still room for further improvement on the existing model, addressing topics such as different types of compensation of lines or introducing further characteristics of the line, of course, that can affect the line's behavior in some way.

The compensation system here studied also has some limitations, namely in terms of type (only fixed-step compensation is addressed) and in terms of distribution, eventually on several stages of the cable or transmission line. Future developments of the model should address this topic and allow for a more broad study of compensation effects.

The work can also extended and applied across other industries, such as Oil&Gas – for offshore energy supply to platforms and interplatform energy safety-grids. The goal of providing a safe and reliable tool, able to provide link estimations in a window of seconds to minutes was achieved.

Conflict of Interest

The authors declare no conflict of interest.

Acknowledgment

The authors thank EDP Distribution (the Distribution System Operator in Portugal). This work also has been once more partially supported by the Portuguese Foundation for Science and Technology under projects grants PEst-OE/ EEI/UI308/2014 and UID/EEA/00066/2013.

ABSTRACT

This paper investigates the efficiency benefits of replacing the Silicon diodes of a commercial IGBT module for the main inverter application of an electric vehicle with Silicon Carbide diodes, leaving the package, operating conditions and the system unchanged. This ensures that the comparison is directly between the chip technologies without any scope for discrepancies arising out of differences in the packaging, gate-driver circuit etc. A behavioral power loss calculation model is used to investigate the performance of the two modules for various drive cycles (Artemis, WLTP, NEDC). The behavioral power loss model is experimentally validated using two independent measurement methods, namely, power analyser based electrical input output method, and a calorimetric method which was developed especially for the low lossy light load condition. Furthermore, it is shown that the electrical method has close to 30% inaccuracy making it unsuitable for the main inverter applications, especially for comparing two different chip technologies, e.g., Silicon versus Silicon Carbide. The developed calorimetric method in contrast offers lower than 3% uncertainty.

1 Introduction

This paper investigates the efficiency benefits of replacing a Si IGBT based power module of an automotive traction inverter with a SiC Hybrid module, for public mission profiles such as NEDC, WLTP and Artemis. This paper is an extension of the work presented in [1] and [2], where the hybrid-Silicon Carbide (SiC) module was characterized and mission profile analysis was performed for public mission profiles. In this work, additionally, the inverter power loss model used for analysis will be experimentally validated using two independent methods, firstly with the input-output based electrical method, and secondly with the calorimetric method presented in [3], suitable for automotive main inverters which operate at light load conditions, i.e., less than a quarter of the nominal current more than 90% of the time.

2 Review of Literature and Motivation

A vast number of papers have been published in the last two decades investigating the advantages of SiC in automotive converters, especially by car makers like Toyota [4] and Ford [5] among others. While a vast majority of the publications have been on dc-dc applications with high switching frequency, one can find only a few papers addressing the traction inverter application which is generally a low switching frequency application (8 to 20 kHz). These papers that address the topic of SiC for automotive traction inverters often have one or more of the following drawbacks:

1. The considered switching frequencies are far higher than typical application requirements, e.g., [6] presents a full-SiC automotive inverter, but the switching frequency considered

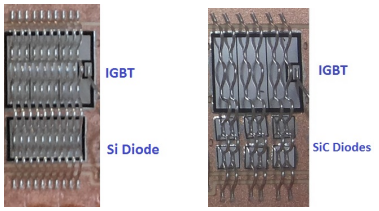
[*]Ajay Poonjal Pai, Infineon Technologies AG, Am Campeon 1-12, Neubiberg, Germany 85579 & AjayPoonjal.Pai@Infineon.com

https://dx.doi.org/10.25046/aj030140

is 50 kHz.

2. The considered devices are rated for low currents, in the range of 4 to 20 A, e.g., [7, 8, 9]. The resulting inverters are quite far from the typical application requirements of the traction inverter (above 100 A).

3. An impractical number of smaller devices are considered connected in parallel to meet the power ratings of a high power Insulated Gate Bipolar Transistor (IGBT) module. For example, [10] provides a comparison of SiC Junction gate Field Effect Transistors (JFETs) against Silicon (Si) IGBTs in traction inverter application for typical mission profiles. But in order to compare the 5 A SiC JFETs against a 300 A Si IGBT module, it is assumed that 60 JFETs are connected in parallel, which makes it an impractical and unfair comparison!



4. The devices and/or packages chosen for comparison are not suitable for mass production, but merely design studies, e.g., [11]. The constraints for a mass produced module can be quite different than for a design study module.

5. The compared Si and SiC chips are in completely different packages or application conditions, e.g., [12, 13, 14]. This makes it difficult to evaluate if the reported benefits of SiC are really coming from the advantages offered by the technology itself or simply due to the difference in package/operating conditions.

In short, a clear investigation of the efficiency benefits of using SiC as a direct replacement for a commercial Si- IGBT module at various boundary conditions, without giving any scope for discrepancies arising out of differences in the package, system, gate-driver circuit etc., is still missing in literature. This paper investigates the benefits of replacing a commercial Si IGBT module with a prototype Hybrid SiC module, as a first step, leaving the other components of the package and the system unchanged.

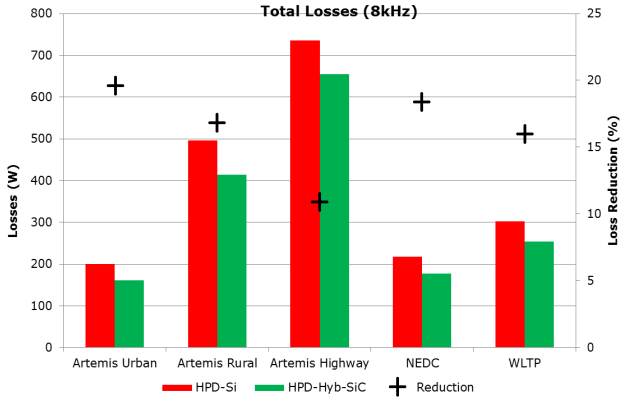
3 The Compared Modules

Infineon HybridPACK Drive [15] FS820R08A6P2B is chosen as the Si-IGBT module owing to its best-in-class low stray inductance (L_{sCE}=8nH) which makes it suitable for very fast switching applications. FS820R08A6P2 is an automotive qualified B6 bridge power module based on the new EDT2 Micro-pattern Trench-Field-Stop technology, with an implemented current rating of 820A per phase, and a blocking voltage rating of 750V. It has three IGBTs of 100 mm^2 each in parallel per switch (in total, A_I = 300 mm^2 per switch) and three anti-parallel diodes of 50 mm^2 each in parallel per diode (in total, A_D = 150 mm^2 per switch). Figure 1(a) shows an IGBT-diode pair of one switch. It comes with a Pin-Fin baseplate which is suitable for direct water cooling, and can operate up to T_j=175°C. It has one NTC per-phase integrated directly on the DCB which can be used for temperature sensing. For brevity, this module shall be referred to simply as "HPD" in this paper.

(a) With Si diode (b) With SiC diodes

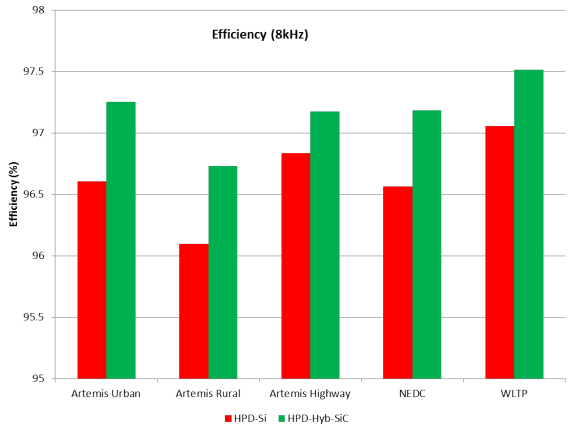
Figure 1: An IGBT-diode pair of HybridPACK Drive Module

For the purpose of evaluating the benefits of SiC, a prototype SiC Hybrid module has been produced by replacing the Si diodes of HPD with Generation-5 650V SiC Schottky diodes from Infineon [16]. The SiC diodes have a die size of 7.12 mm^2 and a nominal current rating of 40A. Each of the 50 mm^2 Si diodes are replaced by a parallel connection of six SiC diodes as seen from figure 1(b), leaving the remaining construction of the module as it is, for a direct evaluation of the SiC diodes vis-a-vis the Si diodes. This module shall be referred to as "HPD-Hyb-SiC" in this paper.



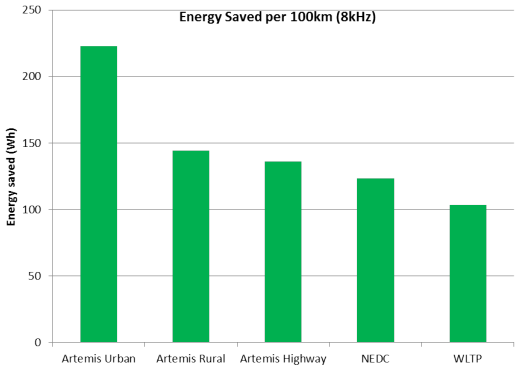
3.1 Inverter Power Loss Calculation Model

For a good comparison of the power loss performance of different chip technologies, it is imperative to have an accurate inverter power loss model. This model should offer an uncertainty significantly lower than the performance difference between the technologies compared. For example, it is meaningless to compare two different technologies which differ in loss performance by 20% with a model which suffers from 15% uncertainty, because it is not possible to ascertain if the apparent difference between the technologies is indeed because the technology is better than the other, or if it is merely due to the high uncertainty of the model used. Since this paper would compare Si and SiC technologies which usually differ by 10 to 20 percent, a model with an uncertainty of < ±5% presented in [17, 18] is used and the parameters A_{11}- E_{43} are determined for both the modules. The parameters for HPD can be found in [17, 18], and those for HPD-Hyb-SiC in [2].



4 Mission Profile Analysis

The model discussed in the previous section is used to compare the performance of the two modules for 5 different mission profiles, viz., Artemis-Urban, Artemis-Highway, Artemis-Rural, WLTP and NEDC.



For the mission profile investigation, a typical mid size sedan similar to Volkswagen Golf presented in [2] is chosen as the reference vehicle. The results at 8kHz are given in figure 2.

(a)

(b)

(c)

Figure 2: Results of Mission Profile Analysis for the modules

As a result of the higher average driving speed, the overall losses are the highest for Artemis Highway driving Cycle. Artemis Urban on the contrary, has the least average losses due to its low average speed. HPD-Hyb-SiC has about 10-20% lower losses compared to HPD-Si. The reduction in the losses is the highest for the Artemis Urban cycle, where the inverter operates in the low current regime. This is because, at low currents the switching losses (which are significantly lesser in the SiC diode compared to the Si diode) dominate over the conduction losses (which are higher in the SiC diodes than the Si diodes). Next, the study is repeated at different switching frequencies, 8-15kHz. The improvement in efficiency of the SiC module over the Si module is summarized in figure 3. Again, the highest benefit of increasing f_{sw} is for the Artemis Urban drive cycle, which sees more than 1.2% improvement in efficiency at 15kHz compared to about 0.7% at 8kHz. Artemis Rural and Artemis Highway cycles too are not far behind. This is because in all the artemis cycles, the switching losses dominate over the conduction losses, and the scope for improvement with SiC diodes is high. The NEDC and WLTP cycles are mostly dominated by conduction losses, and as a result the benefit of using SiC diodes is not high.

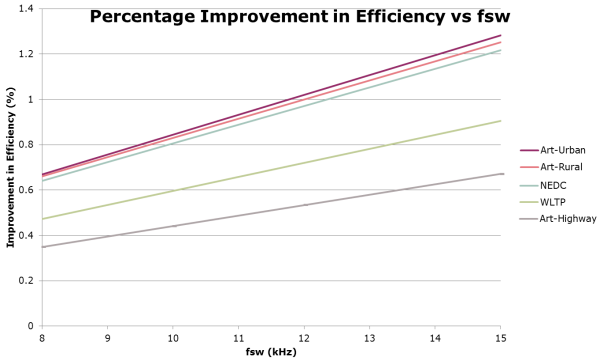


Figure 3: Mission Profile analysis at different f_{sw}

5 Experimental Validation of the Behavioral Power Loss Calculation Model

To have a good confidence level in the behavioral power loss calculation model used for mission profile analysis and to verify it experimentally, it is important to measure the inverter power losses at various operating points, preferably with two independent methods. Firstly, power loss measurements are performed at various inverter operating points with the power-analyser based input-output electrical method, which, being relatively easier to perform, is the most commonly used method for such applications. The sources of uncertainty are thoroughly analysed and it will be shown that this method has high uncertainty due to the switched nature of the output voltage waveform. A common solution to this problem is to add a sine output filter. However, the results include also the losses in the filter leading to wrong results, as will be shown in this paper. Thus, it is necessary to resort to the calorimetric method proposed in [3], which is nearly as easy to perform as the electrical method and is particularly suitable for low-lossy conditions.

This method does not require the use of an expensive calorimeter.

6 The Electrical Input-Output-based Method

6.1 Test Setup

A test platform is built as per the schematic in figure 4. The inverter (described in section 7) is connected to a 3-phase inductive load. The input dc current I_{dc} and output rms currents I_{rms} are sensed using high accuracy closed loop current transducers IT 200-S ULTRASTAB [19] and LF 510-S [20] respectively, which are then fed into a state-of-the-art precision Power Analyser WT1800 [21]. WT1800 has a high sampling frequency of 2 MHz with 16-bit resolution and a bandwidth of 5 MHz. It is also equipped with a digital line filter which can be set for frequencies from 100 Hz to 100 kHz. The impact of using this line filter on the accuracy will be also discussed later in this paper. The inverter is run in open-loop mode, and the desired output voltage is requested by setting the modulation index accordingly. The power analyser measures the input dc power P_{dc} and the output ac power P_{ac}, and the difference is equal to the power loss P_{loss}, from the basic definition, as per equation 1.

$$P_{loss} = P_{dc} - P_{ac} \tag{1}$$

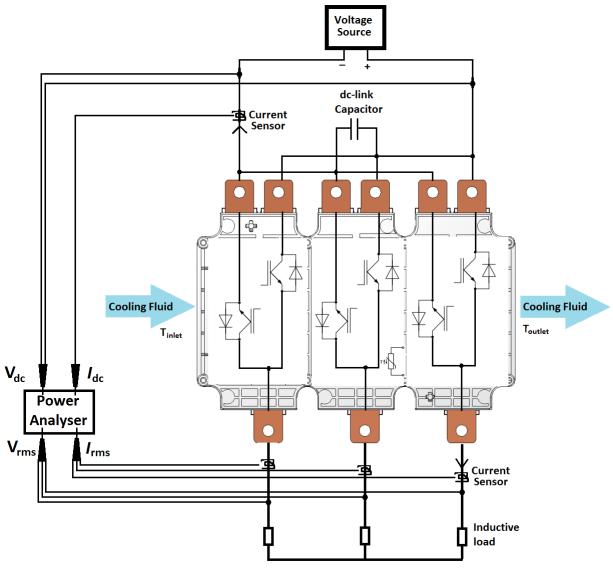

Figure 4: Schematic for measurement of power losses with the electrical method

6.2 Sources of Uncertainty

Uncertainties occur in this method, on account of the delays introduced by the probes and unintended phase-shifts between the different measured signals. In this section, the uncertainty involved in this method will be systematically derived. Out of the scope of this work are the errors introduced on account of the Radio Frequency Interference (RFI) and Electro Magnetic Interference (EMI) emanating from the high di/dt and dv/dt prevailing in hard switched power converters.

The uncertainty in the measurement of the power loss ΔP_{loss} from equation 1 can be derived using the Gaussian law of error propagation.

$$\frac{\Delta P_{loss}}{P_{loss}} = \sqrt{\left(\frac{\Delta P_{dc}}{P_{dc}}\right)^2 + \left(\frac{\Delta P_{ac}}{P_{ac}}\right)^2} \tag{2}$$

Equation 2 gives the uncertainty with a confidence value of about 68%. This will simply be referred to as *uncertainty* in the rest of this work. The upper bound for the uncertainty $\Delta P_{loss,max}$ can be simply calculated as

$$\frac{\Delta P_{loss,max}}{P_{loss}} = \frac{\Delta P_{dc}}{P_{dc}} + \frac{\Delta P_{ac}}{P_{ac}} \tag{3}$$

This will hence be referred to as the *maximum uncertainty*.

6.2.1 Uncertainty in P_{dc}

To calculate ΔP_{dc}, we have to go back to the fundamental equation of dc power, i.e.,

$$P_{dc} = V_{dc} \cdot I_{dc} \tag{4}$$

and the uncertainty can again be calculated by the Gaussian law described above as:

$$\frac{\Delta P_{dc}}{P_{dc}} = \sqrt{\left(\frac{\Delta V_{dc}}{V_{dc}}\right)^2 + \left(\frac{\Delta I_{dc}}{I_{dc}}\right)^2} \tag{5}$$

and the maximum uncertainty as:

$$\frac{\Delta P_{dc,max}}{P_{dc}} = \frac{\Delta V_{dc}}{V_{dc}} + \frac{\Delta I_{dc}}{I_{dc}} \tag{6}$$

From the reference manual of the power analyser [21], the uncertainties for the dc voltage measurement are given as a function of the set range $V_{dc,range}$ and the reading itself as follows

$$\Delta V_{dc} = 0.0005 \cdot V_{dc} + 0.001 \cdot V_{dc,range} \quad [V] \tag{7}$$

Additionally, it must be remembered that there is also a ripple in V_{dc} consisting mainly of a second harmonic of the fundamental frequency, and small magnitudes of harmonics of the switching frequency. These harmonics also contribute to the uncertainty, as will be covered in section 6.2.2. But, as the magnitude of this ripple is quite small, their contribution to the uncertainty can be neglected.

The uncertainties for the measurement of I_{dc} are similarly given as

$$\Delta I_{dc,analyser} = 0.0005 \cdot I_{dc} + 0.001 \cdot I_{dc,range} \quad [A] \tag{8}$$

$\Delta I_{dc,analyser}$, however, is the uncertainty of just the power analyser and since we are using an external LEM current transducer, we also have to take its uncertainty into account. From [19], the uncertainty

for the LEM transducer on the secondary side can be given as:

$$\Delta I_{\mathrm{dc,LEM,max,sec}} = I_{\mathrm{OE}} + \epsilon_{\mathrm{L}} \cdot I_{\mathrm{pry,range}} \cdot K_{\mathrm{N}} \quad [A] \quad (9)$$

and

$$\Delta I_{\mathrm{dc,LEM,sec}} = \sqrt{I_{\mathrm{OE}}^2 + (\epsilon_{\mathrm{L}} \cdot I_{\mathrm{pry,range}} \cdot K_{\mathrm{N}})^2} \quad (10)$$

where, $I_{\mathrm{OE}} = 80 \cdot 10^{-6}$A is the electrical offset current, $\epsilon_{\mathrm{L}} = 3 \cdot 10^{-6}$A is the linearity error, $I_{\mathrm{pry,range}}$=200A is range on the primary side and K_{N}=0.001 is the turns ratio. It is to be noted that, the effects due to self heating in the current transducer are neglected and it is assumed that the transducer is at a constant temperature of 25 °C. Since we are interested in the primary current for calculating P_{dc}, the absolute uncertainties get divided by the turns ratio as follows:

$$\Delta I_{\mathrm{dc,LEM}} = \frac{\Delta I_{\mathrm{dc,LEM,sec}}}{K_{\mathrm{N}}} \quad (11)$$

$$\Delta I_{\mathrm{dc,LEM,max}} = \frac{\Delta I_{\mathrm{dc,LEM,max}}}{K_{\mathrm{N}}} \quad (12)$$

Clubbing equations 8, 9 and 11/12, we obtain the effective uncertainty for I_{dc} as:

$$\frac{\Delta I_{\mathrm{dc}}}{I_{\mathrm{dc}}} = \sqrt{\left(\frac{\Delta I_{\mathrm{dc,analyser}}}{I_{\mathrm{dc,analyser}}}\right)^2 + \left(\frac{\Delta I_{\mathrm{dc,LEM}}}{I_{\mathrm{dc,LEM}}}\right)^2} \quad (13)$$

$$\frac{\Delta I_{\mathrm{dc,max}}}{I_{\mathrm{dc}}} = \frac{\Delta I_{\mathrm{dc,analyser}}}{I_{\mathrm{dc,analyser}}} + \frac{\Delta I_{\mathrm{dc,LEM,max}}}{I_{\mathrm{dc,LEM,max}}} \quad (14)$$

6.2.2 Uncertainty in P_{ac}

From the fundamental equation for the ac power for a line-line voltage of V_{rms}, line current I_{rms} and a power factor angle ϕ (in radians),

$$P_{\mathrm{ac}} = \sqrt{3} \cdot V_{\mathrm{rms}} \cdot I_{\mathrm{rms}} \cdot \cos\phi \quad (15)$$

and the uncertainty can again be calculated by the Gaussian law described above as:

$$\frac{\Delta P_{\mathrm{ac}}}{P_{\mathrm{ac}}} = \sqrt{\left(\frac{\Delta V_{\mathrm{rms}}}{V_{\mathrm{rms}}}\right)^2 + \left(\frac{\Delta I_{\mathrm{rms}}}{I_{\mathrm{rms}}}\right)^2 + (\Delta\phi \cdot \tan\phi)^2} \quad (16)$$

When ϕ is expressed in degrees, we have:

$$\frac{\Delta P_{\mathrm{ac}}}{P_{\mathrm{ac}}} = \sqrt{\left(\frac{\Delta V_{\mathrm{rms}}}{V_{\mathrm{rms}}}\right)^2 + \left(\frac{\Delta I_{\mathrm{rms}}}{I_{\mathrm{rms}}}\right)^2 + \left(\frac{\pi}{180} \cdot \Delta\phi \cdot \tan\phi\right)^2} \quad (17)$$

The calculation of uncertainty in the measurement of P_{ac} is less straightforward than that for P_{dc}. This is because, the inverter output voltages and currents used for determining P_{ac} are not pure sinusoids and contain a spectrum of various frequencies, and the uncertainties of the power analyser are differently defined for the spectral components of different frequencies. Moreover, the reference manuals for the power analyser define the uncertainties only for pure sine waves and do not explicitly describe how these spectral components have to be treated. One simplified approach, commonly adopted in literature, is to assume that the output voltage spectrum would be dominated by the fundamental output frequency f_{o} and then calculate the uncertainty as if the output voltage were a pure sine wave with f_{o}. However, as can be expected and as shall be shown later in this paper, such an approach results in a significant discrepancy in the estimation of uncertainty. Therefore, in this work, we propose the following spectrum-based approach.

Spectrum-based Approach to Calculating Uncertainty of Non-sinusoidal Signals

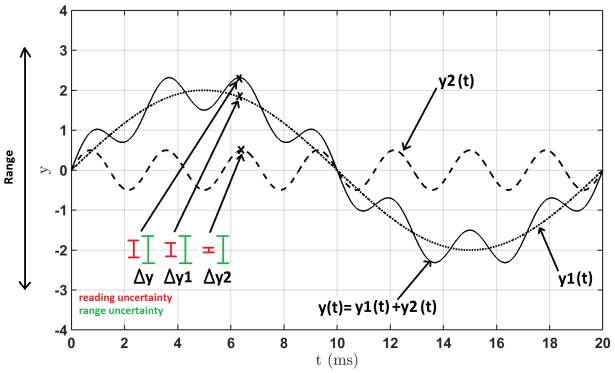

Figure 5: Reading- and range-uncertainties for a summation of signals

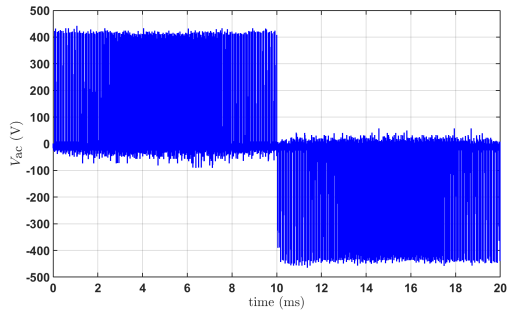
To understand how reading- and range- uncertainties should be calculated for a signal that is a combination of several signals, consider figure 5 which shows three signals, viz. $y_1(t)$ at 50 Hz, $y_2(t)$ at 350 Hz and $y(t)$= $y_1(t)$+$y_2(t)$. Lets assume that all the signals are measured with the same range r. Lets consider the points (t,y_1), (t,y_2) and (t,y) on the three signals respectively. The uncertainties for the three signals are also shown. The reading uncertainties $\Delta y_{1/2,\mathrm{reading}}$ can be calculated as follows:

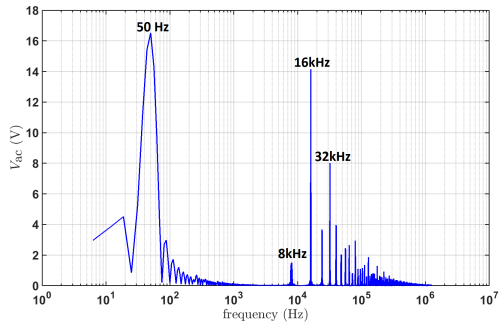
$$\Delta y_{1,\mathrm{reading}} = \epsilon_{\mathrm{reading}}(f)\Big|_{f=50Hz} \cdot y_1 \quad (18)$$

$$\Delta y_{2,\mathrm{reading}} = \epsilon_{\mathrm{reading}}(f)\Big|_{f=350Hz} \cdot y_2 \quad (19)$$



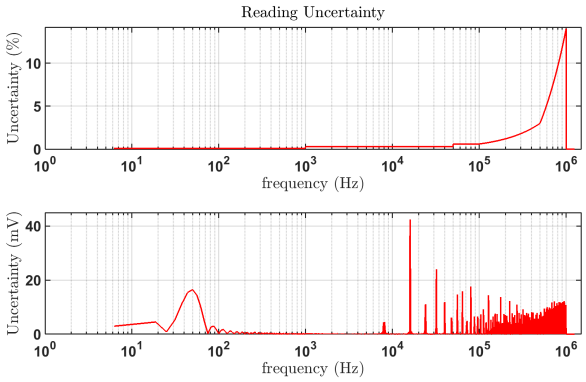
where, $\epsilon_{\mathrm{reading}}(f)$ is the frequency-dependent reading uncertainty coefficient normally specified in the reference manual. The range uncertainties $\Delta y_{1/2,\mathrm{range}}$ can be calculated as follows:

$$\Delta y_{1,\mathrm{range}} = \Delta y_{2,\mathrm{range}} = \epsilon_{\mathrm{range}} \cdot r \quad (20)$$



where, $\epsilon_{\mathrm{range}}$ is the uncertainty coefficient for the range, also specified in the reference manual. As the dependency of the range uncertainty on the spectral

components is small, it is assumed that ϵ_{range} is independent of f. The reading uncertainty $\Delta y_{\text{reading}}$ for the summed signal can be calculated simply by the sum of the reading uncertainties for the two signals as follows: The uncertainties for the three signals are also shown. The range uncertainties Δy_{range} can be calculated as follows:



$$\Delta y_{\text{reading}} = \Delta y_{1,\text{reading}} + \Delta y_{2,\text{reading}} \tag{21}$$

(a) A fundamental period of V_{ac} in time domain

(b) Spectral components

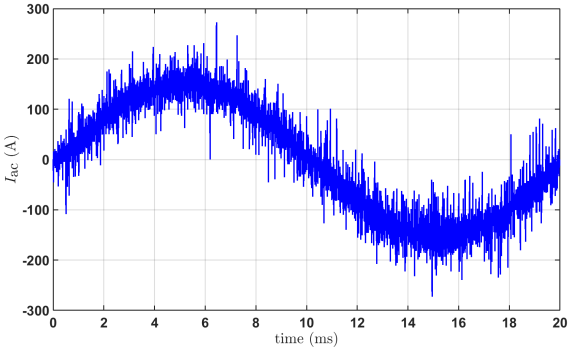
(c) Reading uncertainty for the spectral components

Figure 6: Measured output line-line voltage V_{ac} of a hard-switched inverter

The range uncertainty Δy_{range}, however, could be expected to be the same for Δy as for $\Delta y_{1/2}$ as we are using the same range. This means that, unlike in the case of the reading uncertainty, the range uncertainty for the sum of two signals is not equal to the sum of the range uncertainties for the two signals. Therefore, Δy_{range} is equal to that calculated by equation 20.

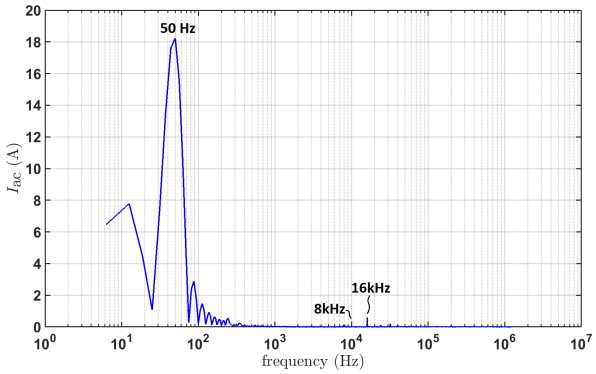
Let us now consider a practical example. Figure 6(a) shows one fundamental period of the measured waveform of a typical hard-switched inverter output line-line voltage V_{ac}. First, the measured voltage waveform is subject to a fourier transformation to decompose it into its spectral components, as shown in figure 6(b). It can be seen that apart from the fundamental frequency 50Hz, there is significant contribution at the switching frequency 8kHz and multiples thereof. The reading uncertainties for the different components are calculated using the respective equations in table 1, as defined by the reference manual. Figure 6(c) shows the calculated reading uncertainty, both absolute and percentage, as a function of the spectral frequency. The original spectrum taking into account the uncertainties is now transformed back into the time domain. The range uncertainty is calculated as described previously and is added to this time-domain signal to yield the required $V_{\text{ac}} + \Delta V_{\text{ac}}$.

Table 1: Definition of Uncertainty for different Spectral Components



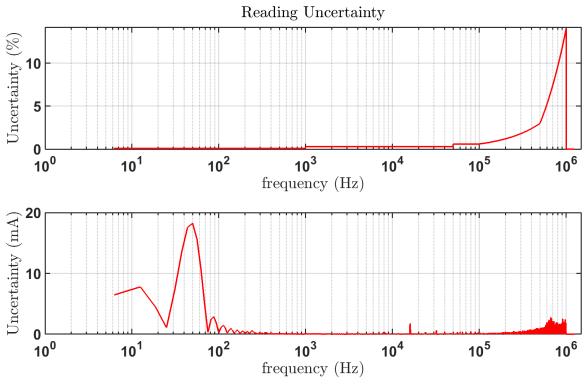
DC	$\Delta V_{\text{rms}} = 0.0005 \cdot V_{\text{rms}} + 0.001 \cdot V_{\text{rms,range}}$
0.1-10 Hz	$\Delta V_{\text{rms}} = 0.001 \cdot V_{\text{rms}} + 0.002 \cdot V_{\text{rms,range}}$
10-45 Hz	$\Delta V_{\text{rms}} = 0.001 \cdot V_{\text{rms}} + 0.001 \cdot V_{\text{rms,range}}$
45-66 Hz	$\Delta V_{\text{rms}} = 0.001 \cdot V_{\text{rms}} + 0.0005 \cdot V_{\text{rms,range}}$
66-1000 Hz	$\Delta V_{\text{rms}} = 0.001 \cdot V_{\text{rms}} + 0.001 \cdot V_{\text{rms,range}}$
1-50 kHz	$\Delta V_{\text{rms}} = 0.003 \cdot V_{\text{rms}} + 0.001 \cdot V_{\text{rms,range}}$
50-100 kHz	$\Delta V_{\text{rms}} = 0.006 \cdot V_{\text{rms}} + 0.002 \cdot V_{\text{rms,range}}$
100-500 kHz	$\Delta V_{\text{rms}} = (0.00006 * f) \cdot V_{\text{rms}} + 0.005 \cdot V_{\text{rms,range}}$
500-1000 kHz	$\Delta V_{\text{rms}} = (0.00022 * f - 0.08) \cdot V_{\text{rms}} + 0.01 \cdot V_{\text{rms,range}}$

This spectrum-based approach is also used to calculate the uncertainty for the current I_{ac}. The measured waveform is shown in figure 7(a). It can be seen that, unlike V_{ac}, I_{ac} is nearly sinusoidal which is on account of the inductance of the load. This can also be verified from the frequency spectrum shown in figure 7(b) where it can be seen that most of the energy is concentrated at the fundamental frequency. The contribution of the harmonics of the fundamental and the switching frequency is significantly lesser than in the case of V_{ac}. The calculated uncertainty as a function of the frequency spectrum is shown in figure 7(c).



The total uncertainties thus calculated for the rms values of V_{ac} and I_{ac} are tabulated in table 2[1]. The approximate approach underestimates the uncertainty in V_{ac} by a factor of three compared to the spectrum-based approach, due to the abundance of high-frequency content in the waveforms. For I_{ac}, on the other hand, both approaches result in nearly the same value, owing to the current waveform being nearly sinusoidal. Therefore, it can be summarized that the approximated approach is sufficient for calculating uncertainty in I_{ac}, but it is necessary to go to

[1] As with I_{dc}, we are using an external LEM current transducer for measurement and therefore, we must separately calculate the uncertainties $\Delta I_{\text{rms,analyser}}$ and $I_{\text{rms,LEM}}$ for the power analyser and the LEM transducer [20] respectively.



the more exact spectrum-based approach for calculating uncertainty in V_{ac}. Moreover, in applications with a higher switching frequency or a higher operating dc-link voltage V_{dc}, which is typical for a Silicon-Carbide-based application, the uncertainty in V_{ac} is higher respectively due to a wider distribution in the spectrum and a higher range that has to be chosen. In such applications, a higher deviation can be expected between the approximate and the spectrum-based approach which makes it more meaningful to use the spectrum-based approach.

(a) A fundamental period of I_{ac} in the time-domain

(b) Frequency spectrum

(c) Reading uncertainty for the spectral components

Figure 7: Measured line current I_{ac}

The uncertainty contribution due to the current transducer $\Delta I_{rms,LEM}$ can be calculated as follows:

$$\Delta I_{rms,LEM} = 0.005 \cdot I_{rms,nom} \tag{22}$$

where, the nominal current $I_{rms,nom}$=500A for the device used. The uncertainty ΔI_{rms} can be now written as

Table 2: Calculated measurement uncertainty for V_{rms} and I_{rms}

V_{rms}	ΔV_{rms}	
	Approximate	Spectrum-based
185.39 V	0.39 V (0.2 %)	1.11 V (0.6 %)
I_{rms}	$\Delta I_{rms,analyser}$	
	Approximate	Spectrum-based
106.158 A	0.181 A (0.17%)	0.203 A (0.19%)

$$\frac{\Delta I_{rms}}{I_{rms}} = \sqrt{\left(\frac{\Delta I_{rms,analyser}}{I_{rms,analyser}}\right)^2 + \left(\frac{\Delta I_{rms,LEM}}{I_{rms,LEM}}\right)^2} \tag{23}$$

and the maximum uncertainty as

$$\frac{\Delta I_{rms,max}}{I_{rms}} = \frac{\Delta I_{rms,analyser}}{I_{rms,analyser}} + \frac{\Delta I_{rms,LEM}}{I_{rms,LEM}} \tag{24}$$

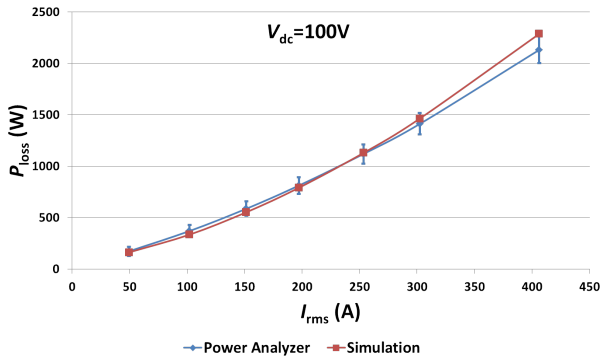
For WT-1800, $\Delta\phi$ is given as

$$\Delta\phi = \left(\left|\phi - \cos^{-1}\left(\frac{\lambda}{1.002}\right)\right|\right) + \sin^{-1}\left(0.001 \cdot V_{rms} \cdot I_{rms}\right) \tag{25}$$

where λ is the power factor. Lastly, it has to be remembered that the uncertainty of the power analyser depreciates over the passage of time from its recent calibration. For WT-1800, the uncertainty at one year is 1.5 times that at 6 months.

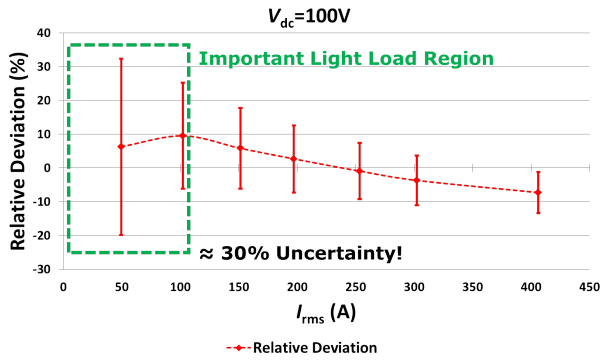
6.2.3 A Common Measurement Mistake while applying Line Filters in Power Analysers

Most state-of-the-art power analysers come equipped with digital line filters which can be used to attenuate spectral components in the measured signals with a frequency higher than a certain cut-off frequency (generally programmable individually for each input channels). These filters are meant to be used on measurement signals where there is high frequency noise due to the limitation of the measuring equipment. Let us suppose that such a filter is used on the I_{ac} signal with a cut-off fequency of, say, 1kHz. The high frequency components in I_{ac} are predominantly due to measurement noise as can be seen from figure 7(b) and table 2, and using such a filter would help in attenuating this noise, thereby making the measurements more meaningful. However, suppose we use the same filter, either intentionally or accidentally, on V_{ac} which inherently has a high-frequency content (see figure 6(b) and table 2), other than measurement noise. In such a case, the filter would attenuate not only the noise, but also these high frequency components. This would, in turn, result in a lower-than-real measured value for P_{ac} and therefore, a higher P_{loss}. Therefore, the line filter should be used only on signals which do not inherently have high frequency components, like V_{dc}, I_{dc} and I_{ac}, but not on signals



like V_{ac} which have a high frequency content. This is a common mistake while performing measurements incorporating such line filters, and will be demonstrated in the next section 6.3.

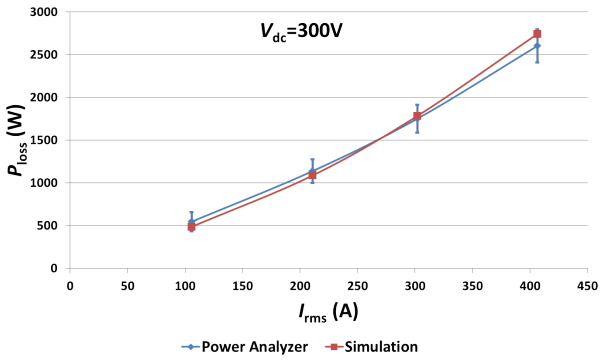
6.3 Measurement Results



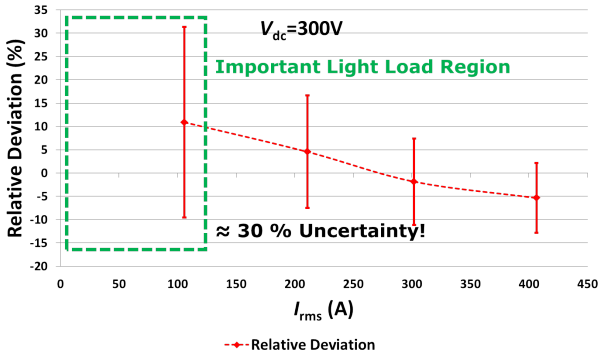
Figures 8-12 show the power losses measured with the electrical method for different application conditions. The uncertainties calculated for each of the measurements, using the spectrum-based approach described in the previous section, are shown as bars around the measurement points. Also shown are the simulated results based on the behavioral model discussed previously, and the relative deviation of the measured values from the simulation.

Figure 8(a) and 9(a) show P_{loss} measured for different output rms currents, I_{rms}, at V_{dc}=100V and 300V respectively. Across the entire range of the measured current, it can be seen that the simulations are within the tolerance of this state-of-the-art electrical input-output measurement approach, thereby validating the behavioral power loss calculation model.

In figures 10(a) and 11(a), the results are shown for different values of the gate resistances $R_{g,on}$ and switching frequencies f_{sw}. It can again be seen that the simulations are within the tolerance of this state-of-the-art input-output measurement approach.

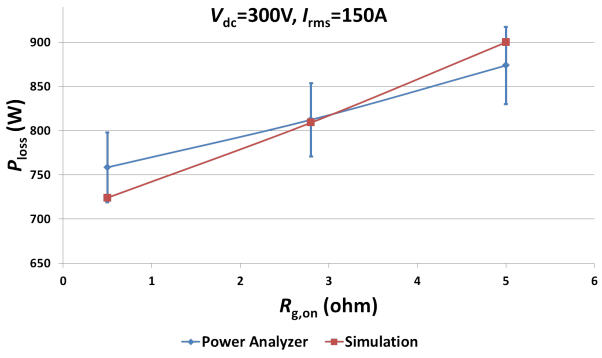


(a) P_{loss}

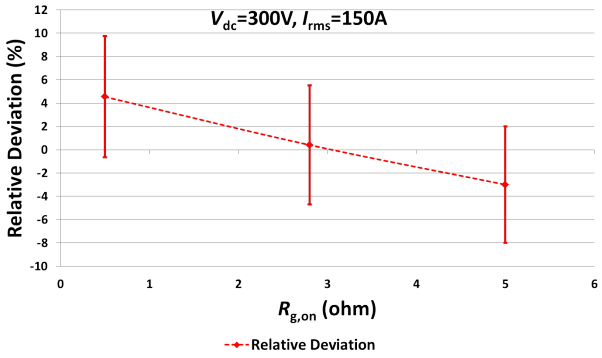


(b) Relative Deviation (%)

Figure 8: Comparison of the electrical method with simulations: P_{loss} vs. I_{rms} at V_{dc}=100V

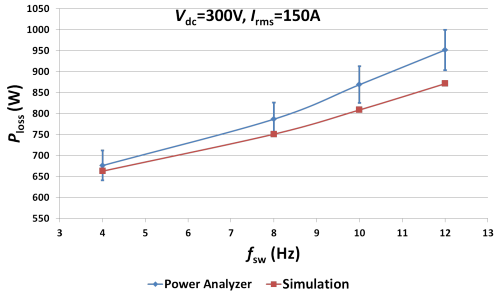


(a) P_{loss}

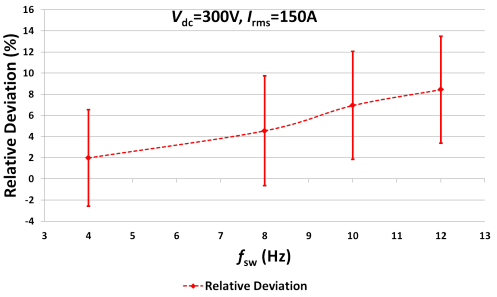


(b) Relative Deviation (%)

Figure 9: Comparison of the electrical method with simulations: P_{loss} vs. I_{rms} at V_{dc}=300V



(a) P_{loss}



(b) Relative Deviation (%)

Figure 10: Comparison of the electrical method with simulations: P_{loss} vs. $R_{g,on}$

Lastly, figure 12 shows the measurements performed with the line filter (cut-off frequency=1kHz) enabled for the output ac voltage V_{ac}, and compares them with the measurements without the filter. As explained in section 6.2.3, it can be seen that the losses measured are higher without the line filter because the measured P_{ac} is lower-than-real. This shows that enabling the line filter on V_{ac} can lead to wrong measurements. Overall, it must be observed that the electrical input-output based method has nearly 30% uncertainty in the light-load condition, making this method unsuitable for the main inverter application, especially when comparing different chip generations.

7 Calorimetric Measurement of Power Losses

A more accurate approach, compared to the electrical method, is to measure power losses with a calorimeter [22]. For applications such as the automotive main inverter which operate at less than a quarter of the inverter nominal current more than 90% of the time[17], the light-load low-lossy condition is of interest. With traditional calorimetric methods, however, a sufficient rise in the fluid temperature is hard to obtain at these conditions. To overcome this problem, without compromising on the accuracy, the inverter is subjected to a calorimetric method particularly suitable for low-lossy conditions. This method does not require the use of an expensive calorimeter and is presented in detail in [3]. A requirement for the test is that all the energy losses in the module must ideally go into heating up the baseplate, with no convection. Therefore, the module baseplate is thermally insulated with a layer of polystyrene as can be seen in figure 13. EVAL-6ED100HPDRIVE-AS, a 6-channel gate-driver board based on the EiceDriver 1EDI2001AS from Infineon, is connected on the top of the module. The gate-driver board is controlled by a micro-controller logic board connected on top of it. The logic board is connected to a computer through a CAN bus, and the parameters such as f_{sw}, m, f_{out} can also be controlled by software, in open loop or closed loop modes. Moreover, it is also possible to read the temperatures sensed by the NTCs and log them. The complete inverter system is shown in figure 14. This method comprises the following two stages.

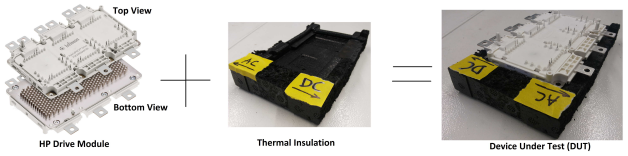

Figure 13: The DUT with the Thermal Package for the Calorimetric Test Bench

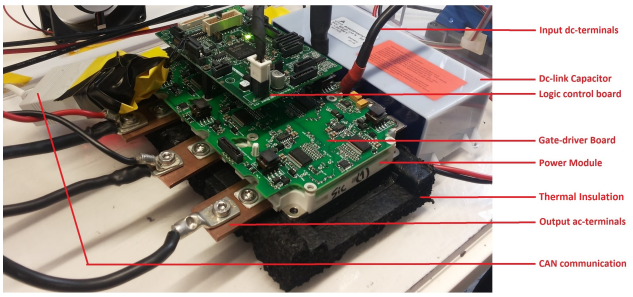

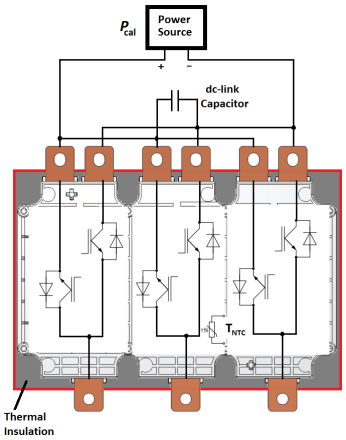

Figure 14: The Complete Inverter System in the Calorimetric Test Bench with the Thermally Isolated Baseplate

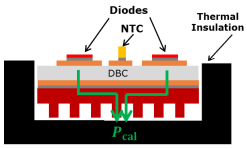


7.1 Calibration Stage

In this stage, the inverter system is connected to a dc source (with opposite polarity) with voltage sense pins capable of serving as a constant power source. The output ac terminals are disconnected as shown

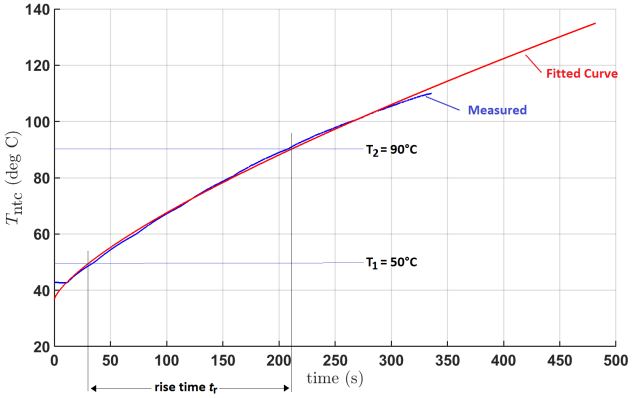
in the schematic in figure 15(a). A known amount of constant power P_{cal} is injected into the module through the diodes. As there is no output power, all the injected power is dissipated in the module as heat, which is trapped in the heatsink on account of the thermal insulation, as seen in figure 15(b). As the temperature of the diode increases, its voltage drop changes and the dc source must be capable of suitably adjusting the current to maintain the power constant. Due to the thermal insulation, and the absence of convection, almost all the heat is trapped in the capacitance of the baseplate, and goes on to increase its temperature exponentially as shown in figure 16(a).

(a) Schematic Diagram

(b) Thermal Stack

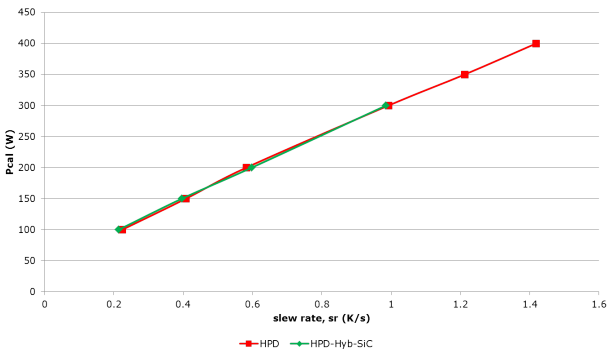
Figure 15: Calibration Setup

There is a small amount of heat that is radiated into the ambient, or leaves the modules through any surface other than the heatsink. However, this effect will be cancelled out and have no impact on the accuracy of this method if the test setup during the calibration and measurement stages is identical. The temperature sensed by the NTCs is recorded until it rises from $T_1 = 50°C$ to $T_2 = 90°C$[2], after which the dc source is switched off and the system is let to cool down to the ambient temperature. In order to filter out measurement noise, an exponential curve is fitted to the measurement. From this fitted curve, the time taken for the temperature to reach T_1 from T_2 is taken as the *rise time* t_r. The temperature *slew rate* s_r is calculated as



$$s_r = \frac{T_2 - T_1}{t_r} \tag{26}$$

This experiment is repeated at different values of injected power and P_{cal} is plotted against s_r as shown in figure 16(b) for both the modules and first order curves are now fitted to the two curves respectively, and the equations of the fitted curves are given below:



$$P_{loss} = 249.68 \cdot s_r + 48.655 \quad \text{[HPD Module]} \tag{27}$$

$$P_{loss} = 258.15 \cdot s_r + 45.905 \quad \text{[HPD-Hyb-SiC Module]} \tag{28}$$

As seen in figure 16(b), the calibration curves for the two modules match very closely, owing to the similar construction of the module. This is in line with the objective of this work to have minimum discrepancies arising out of differences in the packaging, for a fair comparison of Si and SiC. The slight difference seen between the curves can be attributed to the difference in the NTCs and the temperature measurement tolerances, which are cancelled out due to this method.

(a) NTC temperature at P_{cal} =100W

(b) Calibration Curve

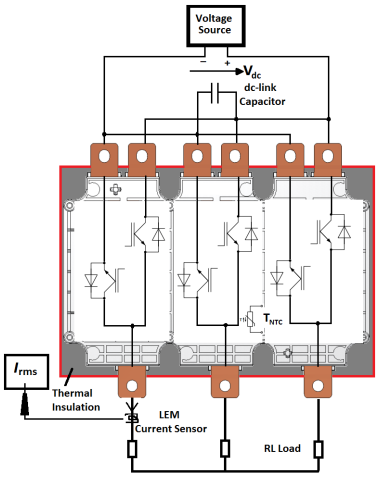
Figure 16: Calibration

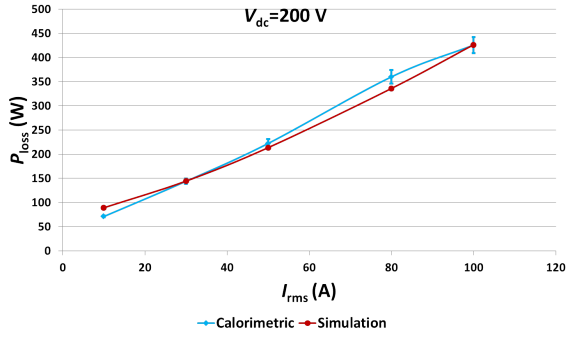
7.2 Measurement Stage

In this stage, the inverter is connected to a dc voltage-source (with normal polarity). Care must be taken to see that the setup, particularly the thermal insulation, is not disturbed between this stage and the calibration stage. The output ac terminals are connected to a three-phase star-connected passive load as shown in

[2]The choice of $T_1 = 50°C$ and $T_2 = 90°C$ is based on the observation that between these temperatures, the exponential curve is nearly linear. However, a different set of values may be chosen, provided that the temperature rise curve is nearly linear in this interval. But it must be ensured that the temperature limits chosen during calibration and measurement stages are the same.

figure 17 and the inverter is run in open-loop mode. A suitable rms current I_{rms} is established in the load, by adjusting m appropriately. As with the calibration stage, s_{r} is determined.





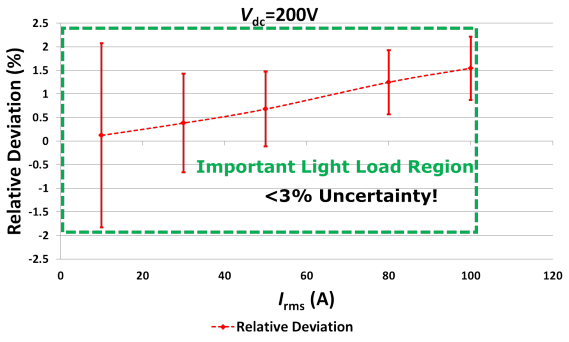


Figure 17: Measurement Stage

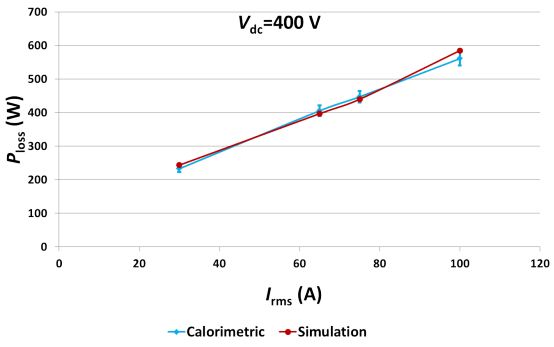
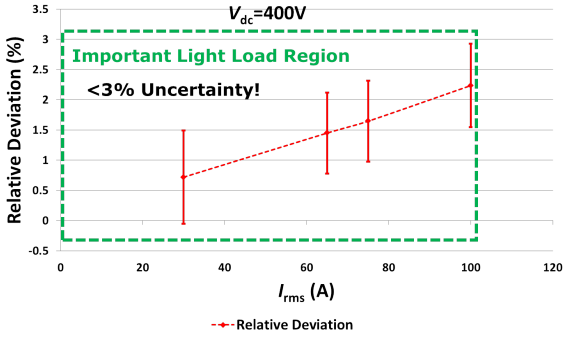


(a) P_{loss}



(b) Relative Deviation (%)

Figure 18: Comparison of the calorimetric method with simulations: P_{loss} vs. I_{rms} at V_{dc} = 200V

Now, the inverter losses can be obtained by substituting the measured s_{r} in equation 27 and 28 obtained from the calibration stage. The inverter power losses for different I_{rms} at two different working voltages 200 V and 400 V measured for HPD with the proposed calorimetric method are shown in figures 18(a) and 19(a). These are compared against simulations at the respective points. Also shown are the calculated uncertainties (this topic is described in [3]) for each of the points as bars around the measurement points. The relative deviation between the measurements and the simulations, expressed as percentage, is shown in figures 18(b) and 19(b). Across the entire range of measurement, it can be seen that the simulations are within the tolerance of the calorimetric approach, again validating the behavioral simulation model. Furthermore, in each of these cases, it can be seen that the uncertainty is well below 5%, especially at partial-load which makes the calorimetric method suitable for automotive main inverter applications, particularly for comparing chip technologies whose total power losses may differ in the range of 10-20%.

(a) P_{loss}

(b) Relative Deviation (%)

Figure 19: Comparison of the calorimetric method with simulations: P_{loss} vs. I_{rms} at V_{dc} = 400V

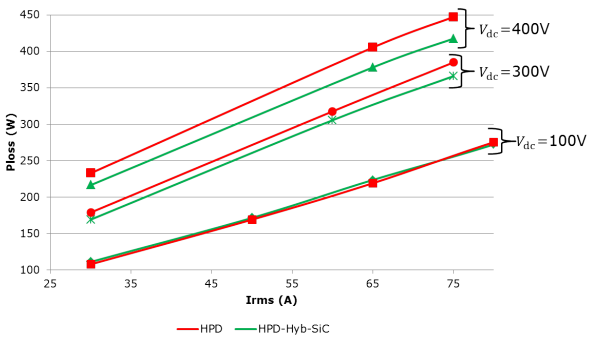


Figure 20: Measured Inverter Losses vs I_{rms} at various V_{dc} for HPD and HPD-Hyb-SiC

7.2.1 Comparison of Measured Inverter Losses for HPD versus HPD-Hyb-SiC

The tests are repeated for different operating points of V_{dc}, I_{rms} and f_{sw} for both the modules. Figure 20 shows a summary of the measured losses as a function of I_{rms} at different dc-link voltages. It can be seen that at V_{dc}=100V, the SiC module has almost the same losses as the Si module, offering no benefit. This is because at low V_{dc}, the switching losses do not contribute much to the total losses, and the conduction losses are dominant. As the conduction losses are higher in the SiC diodes as can be seen from the static curves presented in [2], HPD offers better overall performance than HPD-Hyb-SiC. At V_{dc}=300V, the benefits of SiC become prominent. At V_{dc}=300V, I_{rms}=75 A, there is about 5% reduction in the total losses. This gap widens as we increase V_{dc} as the switching losses become more dominant, and at V_{dc}=400V, 75A, we can see a reduction of around 7%.

8 Conclusions

In this paper, the benefits of replacing the Si diodes of a commercial automotive IGBT module with SiC diodes have been investigated for the main inverter application, maintaining the operating conditions, package and the rest of the system the same, to ensure a fair comparison of the devices without any external influence. A behavioral power loss model, suitable for mission profile analysis, is used to compare the performance of the two modules over several mission profiles. The highest benefit of using SiC diodes is seen for the Artemis Urban drive cycle, where the SiC diodes help reduce the overall losses by 20% at f_{sw}=8kHz. This translates to a saving of around 200Wh of battery energy per 100km. The behavioral model is experimentally verified by comparing it against two independent measurement methods, namely, electrical input output method and a calorimetric method. In each case, the simulation results are found to be within the tolerance of the measurements, thereby validating the simulation model used. At V_{dc} =400V, I_{rms} =75A, the inverter losses were found to be reduced by over 5% with the SiC module, due to the absence of reverse recovery in the unipolar SiC schottky diodes. This reduction is even better at higher dc-link voltages, due to the switching losses becoming more prominent.

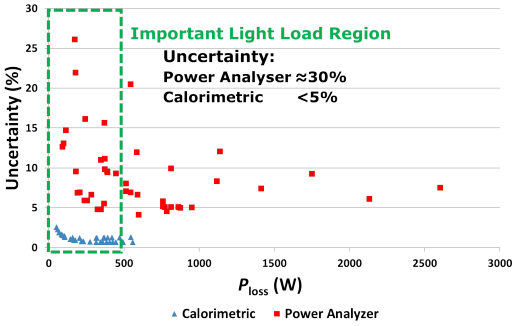

Figure 21: Scatter Plot of the uncertainties (%) at various measurement points for the two methods vs P_{loss}

Further, as summarized in figure 21, it can be concluded that the commonly used power analyser based electrical method has an uncertainty of nearly 30% in the light load condition, mainly due to delays and phase-shifts in the probes. It is to be noted that automotive traction inverters operate most of the time in the light-load condition, which means that the electrical method is not suitable for such applications. The developed calorimetric method outperforms the standard electrical input-output based method and achieves, especially in the important light-load region, a measurement uncertainty of lower than 5%. Furthermore, as the expensive calorimeter is not required for this method, it is nearly as easy to perform as the power-analyser based electrical method. This makes it ideal for comparing device technologies such as Si versus SiC in automotive main inverter applications.

9 Future Work

This work considered the advantages of replacing only the diodes with SiC. However, for higher benefits, it is desirable to replace the IGBTs with SiC MOSFETs, and it would be interesting to investigate the benefits they bring in terms of higher efficiency for different mission profiles. This will considered in a future publication.

ABSTRACT

Reliable operation of a power transformer with a certain load depends on the technical condition of individual construction parts and the ability to prevent defects that can cause a failure. During the lifecycle of a transformer, valuable data is constantly accumulated, which forms the basis for technical or risk assessment of the equipment. Therefore it also serves as a ground for the decisions on further operation, or repairs, or replacement. To achieve this goal, data need to be systematized. Since technical condition indexing allows combining various types of data including results of diagnostic tests is used within the framework of this research.

As part of a larger risk assessment methodology, algorithms for two indicators are proposed in this paper, and they are based on results of electrical measurements and analysis of oil parameters, respectively. The novelty of the algorithms for indicators introduced in this paper is based on analysis of features specific to the power system in Latvia such as large proportion of aged transformers, low loading level, significant variation in oil volumes, and statistics on typical faults. Proposed limits of parameters are verified with data from operation history. Taking into account the differences in the measurement periodicity, the indicator that is based on electrical measurements assesses the individual constructive parts of the transformer (windings and core, bushing and on-load tap changer) separately, whereas the other, indicator combines the results of oil parameters into a single assessment. These indicators were verified by using 30 transformers from the Latvian power system and the obtained results coincide well with the operation history.

1. Introduction

This paper is an extension of the results disseminated in the international conference paper relating to the development of risk indicator for power transformers based on electrical measurements [1]. This risk indicator is part of a condition indexing algorithm that allows categorizing a large volume of technical data obtained during operation and maintenance of a power transformer into discrete risk categories. It provides information in a fast and systematic way, so that transformers can be easily compared and critical ones can be selected for further investigation.

The main goal of this extended paper is to present an algorithm for determining the numerical value of the indicator based on results of electrical measurements (EM indicator), as well as for establishing the numerical value of the indicator based on results of oil parameters analysiss. The outcome for both indicators is the risk category derived on a scale from 1 (lowest risk) to 5 (highest risk, outage expected or immediate action necessary). The proposed indicators correspond to diagnostic tests regularly performed on power transformers in Latvian transmission system. However, significant differences in the periodicity of oil checks and electrical measurements determined the disparate structure of both algorithms and the mathematical methods selected.

The proposed indicators have been verified with 30 case studies. Results of diagnostic tests both from transformers that required repairing, and transformers in a normal operation condition were used. The authors express their gratitude to the Latvian Transmission System Operator (Augstsprieguma tikls, JSC) for providing data for the case studies.

Different approaches are applied to develop appropriate and efficient algorithms for technical condition index which includes such common power transformer parameters as oil characteristics, dissolved gas analysis and electrical measurements [2].

Artificial neural networks (ANN) and adaptive neuro-fuzzy inference system (ANFIS) models, for instance, are no longer limited just for diagnosing faults and aging of power transformers.

*Corresponding Author: Gints Poiss, Email: gints.poiss@edu.rtu.lv

These models can also be used to quantify the general condition of a power transformer [3], also as synthetic risk assessment methods [4] and fuzzy logic [5].

The different diagnostic tools and methods, periodicity and power system charchteristics are actually driving the need to develop a unique, expert-made assessment models for a certain power system. The novelty of the algorithms for indicators introduced in this paper is based on analysis of features specific to the power system in Latvia such as large proportion of aged transformers, low loading level, significant variation in oil volumes, and statistics on typical faults. Proposed limits of parameters are verified with data from operation history. The algorithms provide evaluation of the main constructive parts of a power transformer, and also the structure of indicator algorithms is planned as adjustable, if the amount of applied diagnostics tests is changed.

2. Technical Condition Index as a Part of Risk Matrix

Configurations of the risk matrix proposed for Latvian power system within the framework of this research is shown in Figure 1, and can be effectively used to evaluate each power transformer in the system, as well as to plan the maintenance or replacement of aged units. Risk matrix is divided into 3 parts, where green indicates a low-risk with no concern, blue indicates a moderate risk region or a transformer in a normal operation and technical condition, whereas the red region indicates a need for immediate action. The greatest attention will be paid to 4 cases depicted in Figure 1, that fall in the high-risk region.

In Figure 1, the ordinate axis of the risk matrix, shows operation characteristics and it is based on such important parameters as transformer age, load, maintenance history, the existence of monitoring system, importance in the system (as additional option). Three indicators are used to determine the technical condition index. Together with scoring and weighting factors it is depicted as a value on abscise axis of the risk matrix. Parameters used to determine the technical condition index are given in Table 1 and they correspond to diagnostic tests regularly performed on power transformers in Latvian transmission system.

The algorithm of the indicator based on dissolved gas analysis (DGA) is provided in [6]. It is based on assessment of 7 key gases shown in Table 1 and includes analysis of features specific to the power system in Latvia where power transformers are aged and variations in oil volumes are significant. Transformer loading, operation of the on-load tap changer (OLTC), and oil treatment are also taken into account in order to quantify this indicator.

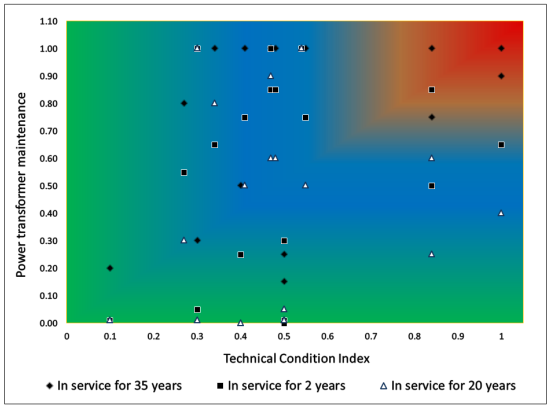

Figure 1. Proposed configuration of risk matrix

The indicator based on electrical measurements for technical condition indexing of a power transformer is developed by evaluating separately 3 main parts of a power transformer: windings, bushings and OLTC. A failure of any of these parts may be critical for a power transformer, the surrounding equipment, environment and even service personnel. The indicator based on analysis of oil parameters such as flash point, dissipation factor, acidity and moisture content is developed as a combined approach of binary and fuzzy logic which allows evaluating the risk on basis of several oil parameters as a single entity.

Both indicators are described in detail in the following chapters of this article.

Table 1. Indicators for technical condition indexing

Electrical measurements		
Windings and core	***Bushings***	***OLTC***
Power factor, PF	Power factor, PF	Static resistance, SR
Insulation resistance, R_m	Insulation resistance, R_m	Transition time & current ripple from dynamic resistance measurement (DRM)
Short-circuit impedance, Z_k	Capacitance, C1	
No-load losses, P_0		

Transformer oil	
Oil analysis	***DGA***
Dissipation factor	H_2, CH_2
Flash point	C_2H_4 C_2H_6
Moisture content	C_2H_2
Acidity	CO, CO_2

3. Development of Electrical Measurement Indicator

3.1. Winding and core

Power factor, insulation resistance and short-circuit impedance allow verifying the technical condition of transformer windings, whereas variations in no-load losses reflect the condition of a transformer core.

A flowchart of a multi-step algorithm is shown in Figure 2. where scoring system for windings and core as a part of the EM indicator is derived on a scale from T=1 (lowest risk) to T=5 (highest risk, outage expected).

The first step is input of measured parameter values from test reports: insulation resistance (R_m), power factor (PF), short-circuit impedance (Z_k), no-load losses (P_0), and winding temperature readings from a thermometer on a transformer.

Next step is data processing. As a reference point, it requires data from the factory test report for a particular power transformer, as well as background information such as age, rated voltage, etc. This information is stored in a specific technical file that is prepared for each transformer in the system. This file is also used for other condition indexing indicators. Since the technical file contains limits for the evaluation of parameters shown in Table 2, modifications are restricted.

During data processing the input data are modified into a suitable form for further analysis. PF values from the test report are calculated at base temperature of 20℃. Thus the limits proposed in Table 2 and stored in the technical file can be applied for risk evaluation (E1 indicates low risk, and E5 – high risk). PF limits are based on recommendations provided in the standard IEEE C57.152-2013. On basis of maintenance experience, additionally value for level E5 were specified. PF=1.5% at 20℃ is an effective parameter for detecting high risk since moisture and contamination of windings in this case in practice proved to be too high for reliable operation. Another parameter used for high risk detection is the D_t coefficient. It is a ratio between the measured resistance and rated voltage of high voltage winding (R_m/U_n). Coefficient D_t=1MΩ/kV at base temperature of 20℃ is set as the minimum insulation resistance limit [7]. For further analysis, values from the factory test report R_{fact} adjusted to base temperature are used as reference to evaluate if the decrease of measured R_m is acceptable.

Limits for evaluation of short-circuit impedance Z_k are based on [8] and given in Table 2. Two values of Z_k between phases should be within E4 of each other. Lager deviation can indicate on mechanical deformation of windings. A single-phase connection no-load losses P_0 measurement is a test that has been historically used for evaluating the magnetic system of power transformers in Latvia. A specific feature is that different test voltage is used (either 220V or 380V). It causes difficulties if evaluation is based on traditional comparative analysis to a factory test. In order to use results of a single measurement in this algorithm, limits based on statistical data and recommendations of [9] and performed study of measurement history of no-load losses from 100 transformers [1].

3.2. Bushings

Electrical measurement results can provide information about degradation of bushing insulation and help to avoid potential failures, such as bushing explosion and transformer winding deformation. Flowchart for bushing assessment is given in Figure 3, and evaluation process is similar to the windings assessment described before. Although a 3-level scoring system is proposed as more suitable for bushings as more polarizing. It starts with evaluation of results of PF measurements for bushings by applying respective limits from Table 2. for data from test reports are used for input. The input is followed by the next step – data processing where all data are modified in a suitable form just like in the algorithm for windings and the core part.

Table 2. Limits of parameters included in EM indicator

Parameter	Level			
	E1	E3	E4	E5
Windings and core				
PF, %, at 20℃	<0.5	0.5	1	≥1.5
$P_{0\ phase\text{-}phase}$, %		$P_{0\ A\text{-}B}$>40 $P_{0\ A\text{-}B}$<20 $P_{0\ A\text{-}C}$>4		
$Z_{k\ phase\text{-}phase}$, %			≥3	
Bushings				
PF, %, at 20℃	<0.5			≥1
On Load Tap Changer				
$SR_{ph\text{-}ph}$, %	<2		>2 (at least in 3 taps)	≥5
Transition time, t_t, ms	<100			≥200
$I_{N1,2}$, %			60	

If the measured PF value is above the limit E5 as it shown in Table 2 or the rated capacitance C1 of a bushing differs from factory measurement by more than 10 %, to reduce the risk of failure, it is advisable to remove the bushing from service [10].

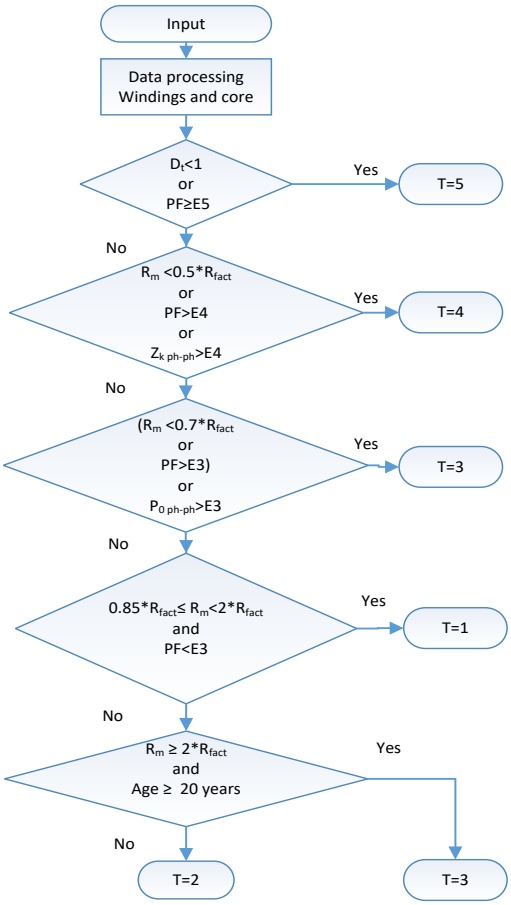

Figure 2. The algorithm of EM indicator for windings and core

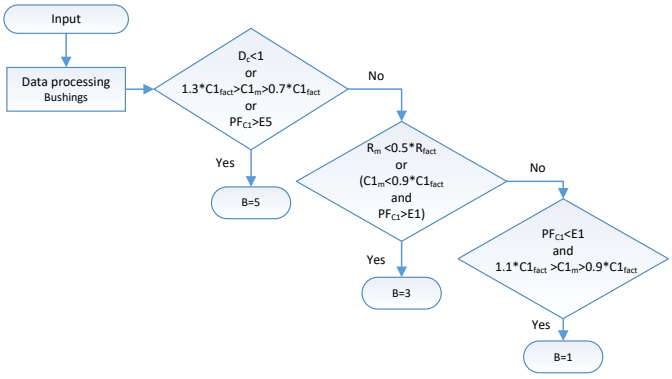

Figure 3. The algorithm of EM indicator for bushing

3.3. OLTC

The static resistance measurement (SRM) is an important tool in this industry and it is used to check for loose connections, broken strands, as well as high contact resistance in tap changer. For decades, SRM is performed for each tap in the tap changer for all power transformers in Latvia and the experience is significant. Therefore SRM is included in the OLTC algorithm as the exclusion rule which can only indicate if the risk is low or high.

For input in Figure 4, SRMs of all phases and all taps are assessed without the factory test report results; therefore the technical file is not needed.

In accordance with [11], the agreement with limit E5 indicates on high risk and it is an important signal to consider the need to repair tap changer immediately. If the SRM difference between phases is within the limit E1, it indicates on low risk. If resistance in 3 taps exceeds the limit E1, it should be investigated and TC=4 is assigned.

Dynamic resistance measurement (DRM) allows detecting defects caused by contact coking, contact wear, oil-film layer deposition, deviating transition times, contact timing problems, maintenance errors and damaged transition resistors. Therefore as additional criterion for the OLTC assessment – the dynamic resistance measurement (DRM) is proposed [1] evaluating two parameters form test report: transition time, ms, and current ripple change $I_{N1,2,}$ %. The proposed limit values E1 and E5 shown in Table 2 are assigned on basis of [12] research and were verified by authors with analysis of 76 test reports of DRM.

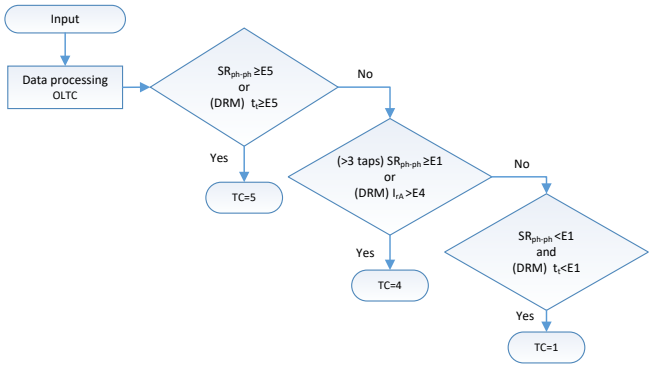

Figure 4. The algorithm of EM indicator for OLTC

4. Development of Oil Indicator

4.1. General description of oil indicator algorithm

Generally mineral transformer oil is used in power transformers in power system of Latvia. Regularly measured oil parameter are dielectric strength, moisture content, acidity, dielectric dissipation factor, interfacial tension, viscosity, flash point, and sludge content. Method for assessment of the measurement results described in the national standard involves comparison of data obtained in laboratory with the given assessments limits, and conclusions are obtained for each oil parameter separately rather than as a single entity. The standard does not provide guidance on how to obtain one conclusion based on multiple contradicting input parameters.

Fuzzy logic is widely applied for dissolved gas analysis (DGA) of power transformers [13, 14] since DGA contains relatively many input parameters. If binary logic is used a contradiction can occur, where some of the input parameters correspond with a good condition but others with a bad condition. Fuzzy logic can provide more detailed assessment of technical condition. For example, fuzzy logic based algorithm with acidity and interfacial tension of oil as input parameters is used to estimate remnant life of a power transformer [15]. Similar approach of data processing is described in [16] in which remaining service life of transformer in years is predicted based values of viscosity, resistivity, particle count, acidity and moisture content of oil. Another research [17] shows the possibility to combine measured values of moisture and acidity of oil, and the power factor of the winding to determine the type of transformer defect based on the physical and chemical condition of insulation in cases with contradicting input data values.

Therefore within the framework of this research fuzzy logic as data processing method is used to develop a technical condition indicator for a power transformer based on measurement results of oil parameters. Four independent oil parameters (flash point, dissipation factor, acidity and moisture content) and additional parameter (changes in flash point value in two subsequent measurements) are used as input data as shown in Figure 5. Limits shown in Table 3 are based on typical values observed for transformers installed in transmission network in Latvia. As a result, algorithm calculates the value of transformer oil indicator within limits from K=1 – (low risk) to K=5 (high risk, immediate actions required).

Flash point (FP) is the lowest temperature at which oil in certain conditions releases such amount of vapour that, together with air, creates a flammable mixture leading to fire hazard. Therefore, this parameter is proposed for indicating high risk. Based on practical experience in decision-making for transformer repairs dissipation factor (tanδ) is proposed as another parameter indicating high risk since it is sensitive to oil aging, moisture, as well as changes in contamination levels.

Table 3. Proposed Limits for Oil Parameters

Flash point, °C	Upper limit	Acidity, mgKOH/g	Moisture content, ppm	Tanδ, %
125 or ≥Δ5 in 2 subseqent measurements	Level 1	<0.05	<5	<1
	Level 2	≤0.075	≤10	≤2.5
	Level 3	>0.1	>15	>4

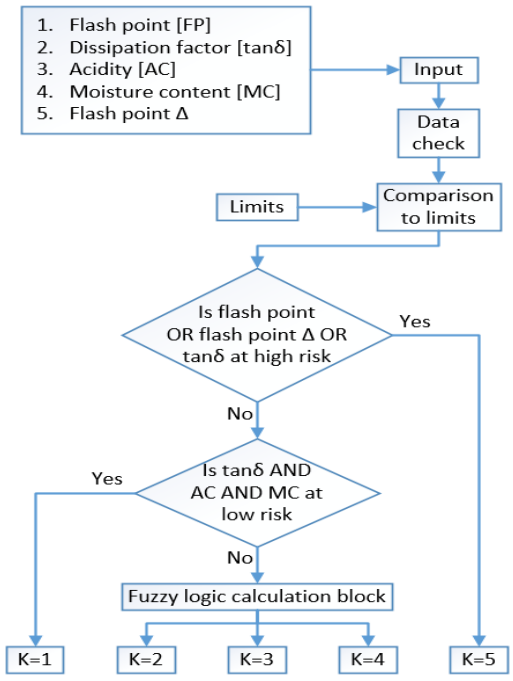

Figure 5. Overall flowchart of oil indicator algorithm

Dissipation factor tanδ along with acidity and moisture content are proposed as criteria for medium risk evaluation. In order to reach a unified conclusion regarding the correlation between these independent oil parameters, the use of fuzzy logic is suggested.

The operation of the algorithm begins with reading the input parameters, namely results from the most recent oil measurement which then are stored in technical file that is prepared for each transformer in the system for possible repetitive usage. If any of the necessary oil parameters have not been measured in this particular testing, the algorithm assumes the value of that parameter as in Level 2 (see in Table 3).

If the value of the parameter is repeatedly unknown, the approximation is performed in a logarithmic scale as shown in Figure 6 where approximated value aims for the Level 3, yet cannot reach it, since the difference from the maximum boundary is halved per iteration.

Figure 6. Assumed values for unknown parameter value

Next step of the proposed algorithm is the evaluation of exclusion cases indicating high risk (either flash point or changes in value of flashpoint or dissipation factor exceeds the limits of Level 3) or low risk (values of dissipation factor and moisture and acidity are all below limits of Level 1). Fuzzy logic calculation block activates if neither of the exception cases checks included in the algorithm is positive.

4.2. Fuzzification

Developed shape and slope for membership functions used within fuzzy logic calculation block of proposed algorithm is shown in Figure 7 originally, the selection of membership function shape and slope was carried out for each of the three oil parameters. Illustration of membership function for tanδ is shown in Figure 8. The triangle and trapeze forms were tested for M (medium risk) membership function, whereas slope was altered for L (low risk) and H (high risk) membership functions. All variations were tested by using the results of oil tests for 10 transformers with given maintenance history and different technical condition.

Results show that output values are not affected by the shape of M membership function, however, in some cases value changes were observed by alteration of the slope of L and H membership functions. After evaluation it was concluded that the combination of increased H membership function effect has the best correlation with technical condition based on maintenance history.

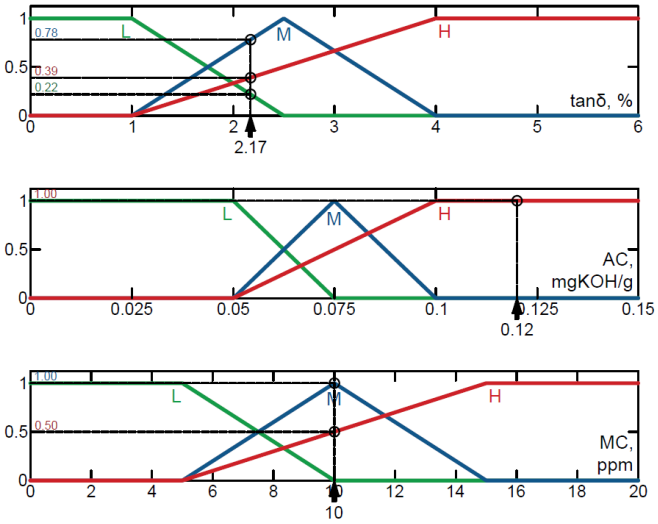

Figure 7. Membership functions of oil indicator

For obtaining corresponding output values, a rulebox is created as shown in Table 4. It contains all possible combinations. Altogether, there are 27 combinations, since for each of the 3 input parameters used in the fuzzy logic block 3 membership functions are assigned. The specific weight value is the minimum of all three membership values for a given combination. The specific weights are summed together for each result value and thus a fuzzified output is obtained. Afterwards, the gravitation centre of this output function is calculated. The obtained result is more precise, as more points are used for the calculation.

4.3. Fuzzy inference and defuzzification

An example is illustrated in Figure 7 with following values of oil parameters as input data from regular oil sample test of a particular 110 kV transformer: flash point, 139°C; changes in flash point value between two subsequent measurements, 2°C; dissipation factor tanδ, 2.17%; acidity, 0.12mgKOH/g; moisture content, 10 ppm. Since exception cases included in the algorithm are negative in this case fuzzy logic calculation block activates.

Table 4. Rulebox for fuzzy logic calculation block

#	Input Variables			Corresponding output	#	Input Variables			Corresponding output	#	Input Variables			Corresponding output
	tan δ	*AC*	*MC*			*tanδ*	*AC*	*MC*			*tanδ*	*AC*	*MC*	
1	L	L	L	2	10	H	M	L	3	19	L	M	H	3
2	M	L	L	2	11	H	L	M	3	20	M	M	H	3
3	L	M	L	2	12	H	M	M	3	21	H	H	L	4
4	L	L	M	2	13	L	H	L	3	22	H	H	M	4
5	M	M	L	2	14	M	H	L	3	23	H	L	H	4
6	M	L	M	2	15	L	H	M	3	24	H	M	H	4
7	L	M	M	2	16	M	H	M	3	25	L	H	H	4
8	M	M	M	2	17	L	L	H	3	26	M	H	H	4
9	H	L	L	3	18	M	L	H	3	27	H	H	H	4

The membership of dissipation factor is 0.78, 1 for acidity and 0.5 for moisture content. The specific weight is calculated as 0.5. This process is repeated for each matching combination. The gravitation centre of this output function is calculated, as well as the position of gravity centre on x axis is estimated as shown in Figure 9. The third of the position of gravity centre is the result and final output, in this case K=4 for oil indicator is obtained, which indicates a rather high operation risk.

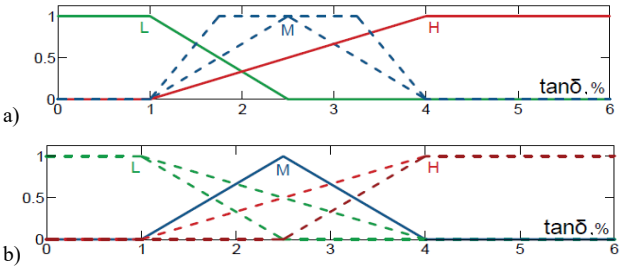

Figure 8. Selection of the shape and slope for membership functions for tanδ: a) shape for M membership function; b) slope for L and H membership function

	Membership function	Membership value
tanδ	L	0.22
	M	0.78
	H	0.39
AC	L	0
	M	0
	H	1
MC	L	0
	M	1
	H	0.5

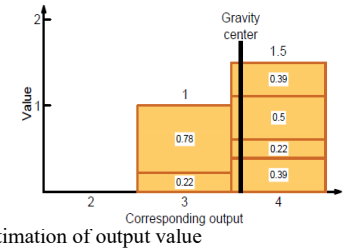

Figure 9. Estimation of output value

5. Verification of EM and Oil Indicator

Results of measurements within a time period of 8 years for 30 power transformers are used to verify both indicators and see how they complement each other. It has to be noted that the power transformer park in Latvia is aged and power transformers installed between 1967 and 2000 were used for verification with different technical condition, repairing plans and failure rate. Figure 10 shows numerical values of EM and oil indicator obtained for the latest available measurement set of each transformer. Since polarized score is used omitting the values 2 and 4 for bushings and 2 and 3 for OLTC the combined score 3&4 is allocated in a separate column. Mainly a numerical value of 1 was assigned to parameters OLTC and bushings which reflects timely scheduled repairs. In those two cases where score value of 5 is assigned for bushings immediate decisions to replace them have been made by system operator. Similarly OLTC is repaired immediately if there1 is a variation from normal operation or a problem is detected.

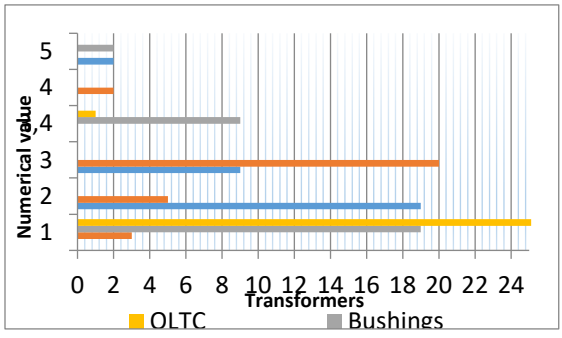

Figure 10. Numerical values of indicator parameters of 30 power transformers

Values 2 and 3 are obtained most frequently for oil analysis most showed result 2 and 3, which indicates either normal operation or marks out necessity for small maintenance works such as the change of silicagel in a thermosyphon. In two cases when score of 4 for winding and core is assigned result dramatic decrease of winding isolation resistance and increase of power factor therefore obtained results concise well with operation history.

For further analysis 4 cases from 30 were selected to illustrate how indicators together reveal the technical condition of a power transformer. Cases 1 to 3, plotted in Figure 11, depicts the latest measurements available for three different transformers. Case 2 reflects a transformer in an almost perfect technical condition. But in case 1, problems with OLTC can be noticed and analysis of measurement history revealed increased static resistance in 3 taps. Case 3 reveals bushing defect, caused by decreased insulation resistance in scheme C2 and increased power factor in scheme C1.

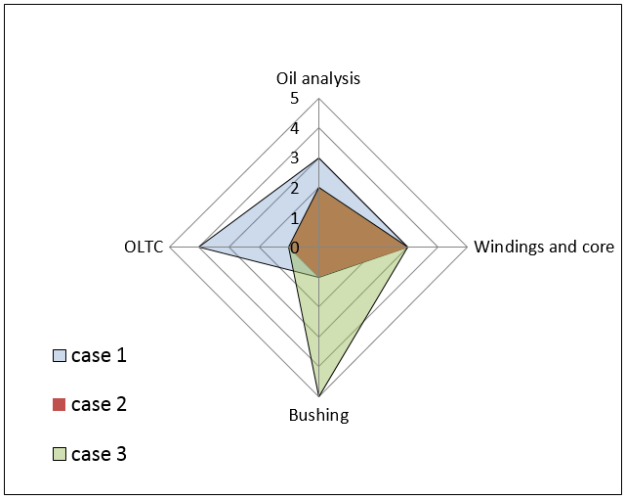

Figure 11. Case studies results

Since electrical measurements are performed on average once in four years EM indicator is more static. Case 4, plotted in Figure 12, illustrates the role of the oil indicator as the first implication of a possible fault in a transformer since its results are more dynamic. It can be observed that technical condition of this particular transformer has decreased due to increase in moisture level over the years.

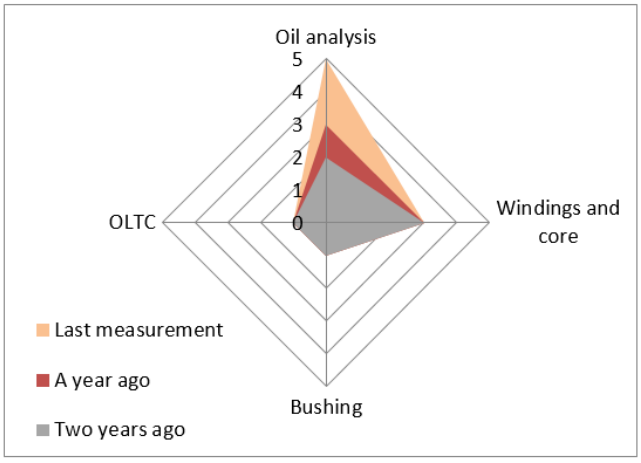

Figure 12. Oil analysis results

6. Conclusions

Literature review leads to a conclusion that methods for risk assessment of power transformers are mainly based on the results of performed diagnostic measurements and operation history. Since maintenance strategy may vary over the time and may depend on decisions by a particular transmission system operator the development of a modified risk matrix is a common global practice.

Configuration of risk matrix for power transformers in Latvian transmission network proposed within the framework of this research is composed of three regions indicating low risk, moderate risk and high risk the last one requiring immediate action. The place of a transformer within the risk matrix depends on its technical condition index (x-axis) and such parameters of operational history as transformer age, load, maintenance history, importance in the system (y-axis). Technical condition index is established by calculating the numerical values of the three indicators and applying a scoring and weighting factor.

To determine numerical values of the indicator based on oil analysis combined approach of binary and fuzzy logic proved to be successful since it allows evaluating risk based on several oil parameters as a single entity. Results from a verification confirm that higher output values are shown by transformers that have already attracted attention in practice. As oil analysis is done quite often, changes in values of this indicator are first indication of a possible defect in a transformer and they substantiate the necessity for further testing. However, an indicator based on results of electrical measurements more effectively serves to detect faulty constructive parts more effectively and can be used as a basis for decisions on replacement of a bushing or repairs of an OLTC.

ABSTRACT

In modern powers systems, one of the most considerable topics is economic load dispatch (ELD). ELD is non-linear problem and it became non-convex and non-smooth problem with some constraints such as valve point loading effect. ELD is very crucial for energy generation and distribution in power systems. For solving ELD problem, a lot of methods were developed and used at different power systems. Vortex search algorithm (VSA) is proposed and applied for solving ELD problem in this paper. VSA method was developed in the form of stirring liquids. Transmission line losses, valve point loading effect, ramp rate limits and prohibited zones constraints were used to make the results of ELD problem the closest to the truth. The results which are obtained from VSA compared with PSO, CPSO, WIPSO, MFO, GA and MRPSO techniques. It can be clearly seen that VSA gave minimum cost values with optimum generator powers so it is very effective and useful method and it gave the best solutions for ELD.

1. Introduction

This paper is an extension of work originally presented in 4th International Conference on Electrical and Electronics Engineering [1]. The purpose of this work is solving economic load dispatch problem with a lot of constraints through with new optimization technique Vortex Search Algorithm.

Economic load dispatch of a power system is very important in terms of control and planning of that power system. Main goal of ELD is distributed total demand power among the committed thermal generation units with minimum production cost by satisfying set of equality and inequality constraints. If ELD problem is not solved for thermal power plants, demand power may be generated very costly. ELD problem can be basically modeled second order (quadratic) function [2]. However, this function may became more complex, non-smooth and non-convex with some constraints such as valve point loading effect, ramp rate limits, transmission line losses and prohibited zones.

Economic load dispatch plays very big role for operated power plants. For this reason, a lot of researcher studied this issue. A number of optimization techniques developed and applied to ELD problem. Quadratic Programming [3], Linear Programming [4], Non-Linear Programming [5], Lambda Iteration Method [6] etc. techniques were used for solving ELD problem. These traditionally techniques gives good results for basic ELD problem but these techniques may poor results when constraints and complexity are increased.

Together with the advances in the computer sciences, a lot of random search optimization techniques developed and used [7]. Different Evolution [8], Particle Swarm Optimization [9], Genetic Algorithm [10], Artificial Bee Colony [11], Harmony Search [12], Bacterial Foraging Optimization [13], Firefly Algorithm [14], Ant Colony Optimization [15] etc. are some of these techniques. User defined parameters are necessary for these optimization techniques. If the parameters are not chosen properly, the results obtained from these techniques may not be good results.

The organization of this paper as follows: Economic load dispatch, main objective of ELD, constraints of ELD and mathematical express of ELD are described in Section 2. Vortex Search Algorithm and its mathematical model are described in Section 3. Using test system, its parameters, obtained results and

[*]Corresponding Author: Mustafa SAKA, Gazi University, Graduate School of Naturel and Applied Sciences, Ankara, TURKEY, msaka@gazi.edu.tr

figures are described in Section 4. Finally evaluation of this paper is briefed in Section 5.

2. Economic Load Dispatch

There are a lot of operating cost for thermal power plants such as fuel cost, personal fees etc.. In these costs the biggest share is fuel cost of thermal generation units. For this reason solving economic load dispatch problem for thermal power plants is necessity. Main objective of economic load dispatch is keep the total fuel cost as minimum level while meet the total demand power. Basically defined cost function of ELD as a quadratic function as follows:

$$F_i = a_i + b_i \times P_i + c_i \times P_i^2 \quad (1)$$

2.1. Valve Point Loading Effect

Due to opening stream valves at the power systems losses are increased. This effect is called valve point loading effect. Due to system losses are increased wit valve point loading effect, total cost value is increased. Above equation has sinusoidal terms due to valve point loading effect. This situation can be seen in Figure 1. This transformed equation is expressed as follows:

$$F_i = a_i + b_i \times P_i + c_i \times P_i^2 + |e_i \times \sin(f_i \times (P_i^{min} - P_i)) \quad (2)$$

F_i represents resulting fuel cost value, P_i represent power of thermal generator, a_i, b_i, c_i are cost coefficients and e_i, f_i are valve point loading coefficients of thermal generator unit i.

Total cost value of system is obtained by summed cost values of every thermal generation units.

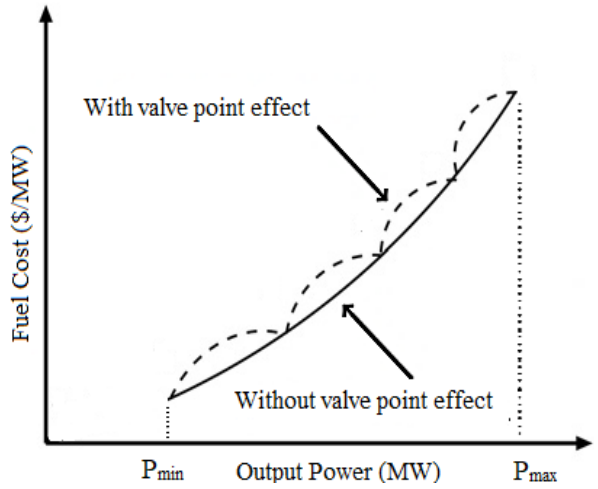

Figure 1 With and without valve point effect

2.2. Generators Limits

Thermal generators units must operate maximum and minimum power range. This power range can be different for different units:

$$P_{i,max} \geq P_i \geq P_{i,min} \quad (3)$$

Pi,min and Pi,max are represent minimum generator limit and maximum generator limit of unit i.

2.3. Power Balance

Total generated power at the thermal power plants meet the demand power by consumers. For this reason transmission line losses must be considered. The total generated power obtained sum of total demand power and total transmission line losses.

Transmission line losses is calculated as follows:

$$P_{loss} = \sum_{i=1}^{N} \sum_{j=1}^{N} P_i B_{ij} P_j + \sum_{i=1}^{N} B_{0i} P_i + B_{00} \quad (4)$$

Total generated power is calculated as follows:

$$\sum_{i=1}^{N} P_i = P_d + P_{loss} \quad (5)$$

N represent total thermal power plant. Pd and Ploss represent total demand power by consumer and total transmission line losses respectively. Bij, B0i and B00 are transmission loss coefficients.

2.4. Ramp Rate Limits

While a thermal generator unit is operating at a certain point, the operating point can only be increased to a certain level determined by the up ramp rate limit or decreased to a certain level determined by the down ramp rate limit.

This situation is shown as follows:

$$\max(P_i^{min}, P_i^0 - DR_i) \leq Pi \leq \min(P_i^{max}, P_i^0 + UR_i) \quad (6)$$

URi represents the up-ramp rate limit, DRi represent down ramp rate limit, is previous generated power and Pi present generated power of unit i.

2.5. Prohibited Zone

In some cases, thermal generation units do not worked and do not want to be worked some reasons such as mechanical corruption some particular power range (prohibited zone). These conditions can be expressed as follows:

$$P_i^{min} \leq Pi \leq P_{i,1}^{lowerbound} \quad (7)$$

$$P_{i,j-1}^{upperbound} \leq P_i \leq P_j^{lowerbound} \quad (8)$$

$$P_{i,ni}^{upperbound} \leq Pi \leq P_i^{max} \quad (9)$$

j represents number of prohibited zones of unit i and j=2, 3, 4 …ni. represents lower limit and represents upper limit of jth prohibited zone. Prohibited zone effect is shown in Figure 2.

3. Vortex Search Algorithm

Vortex search algorithm is a new optimization technique and inspired by stirring liquid materials.[17,18]. VSA is very influential and handy technique for solving economic load dispatch problem. problem. As a result of using an extensible step size modification arrangement a good balancing explorative and exploitative behavior of the search are obtained [18]. Vortex patterns can be represented in two dimensional space as a lot of nested circuits. The biggest and outer circuit is starting circuit of search space. The center of this circuit is calculated as follows:

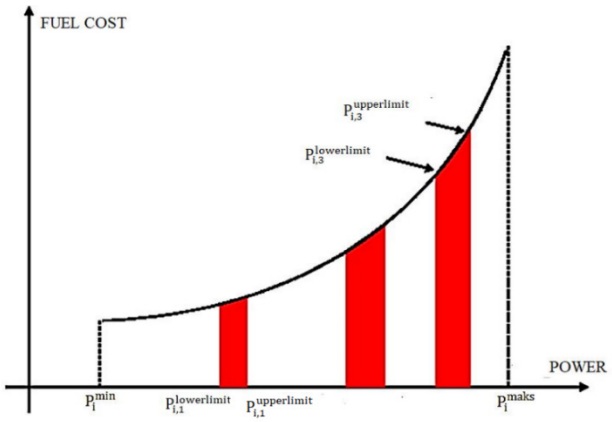

Figure 2 Shown of prohibited zones [16]

Upperlimit and lowerlimit are maximum and minimum constraints of the problem. A lot of candidate solutions are constituted into the outer circuit. The initial standard deviation is accepted as radius of this outer circuit and calculated as follows:

$$\mu_0 = (\text{upperlimit} + \text{lowerlimit}) / 2 \quad (10)$$

$$\sigma_0 = (\max(\text{upperlimit}) - \min(\text{lowerlimit})) / 2 \quad (11)$$

Generated candidate solutions must be controlled for ensure these solutions within the maximum and minimum limits of the problem. If these candidate solutions are not into the search space, they must be shifted into the search space. Some candidate solutions, which are not into the search space, shifted into the search space using equation as follows:

$$s_i^k = \text{lowerlimit}^i + (\text{upperlimit}^i - \text{lowerlimit}^i) \times \text{rand} \quad (12)$$

After this step a candidate solution, which is the best solution into the search space, is selected. This best solution is represented s'. This solution is memorized and current center μ0 is shifted to s'. New candidate solutions are constituted around this new center. All of candidate solutions are compared with previous best solution. If there is a better solution than s', it is selected as a new best solution [19]. This situation continues each iteration step. Radius of the circuits must be decreased every iteration. For this reason inverse gamma function (gammaincinv) is used and new radius is calculated every iteration as follows:

$$rt = \sigma 0 \times (1 / x) \times \text{gammaincinv}(x, a_t) \quad (13)$$

a_t is changeable parameter and it dependent a_0, t and MaxItr. This function shown as follows:

$$a_t = a_0 - (t / \text{MaxItr}) \quad (14)$$

Where t represents iteration number, MaxItr represents maximum iteration number. Due to cover the all search space a_0 is chosen 1. Outline flowchart of VSA method is shown in Figure 3:

4. Test System and Results

Vortex search algorithm was proposed and used for solving economic load dispatch problem. Six generation unit power system was selected. VSA algorithm was applied to this system considering various constraints. Each cases the number of iteration is limited to 1000 for obtained good solutions.

Case1 constraints are ramp rate limits and transmission losses;

Case2 constraints are ramp rate limits, prohibited zones and transmission losses;

Case3 constraints are transmission losses, valve point loading effect and ramp rate limits;

For every case transmission line losses coefficients are same and given as follows:

$B=10^{-4} \times$

0.17	0.12	0.07	-0.01	-0.05	-0.02

4.1. Case 1: ELD with Ramp Rate

For this case two different constraints, which are ramp rate limits and transmission line losses, applied to system. Cost coefficients, ramp rate limits data and maximum – minimum limits of generators are shown in Table 1. Results of VSA was given Table 2 with different optimization techniques. Convergence behavior of VSA for this case was shown Figure 4. For this case selected power is 1263MW.

According to given results from Table 6, proposed VSA method has better cost value when compared with the MFO, PSO, GA techniques from [21].

Figure 5 is shown convergence behavior of VSA for this case.

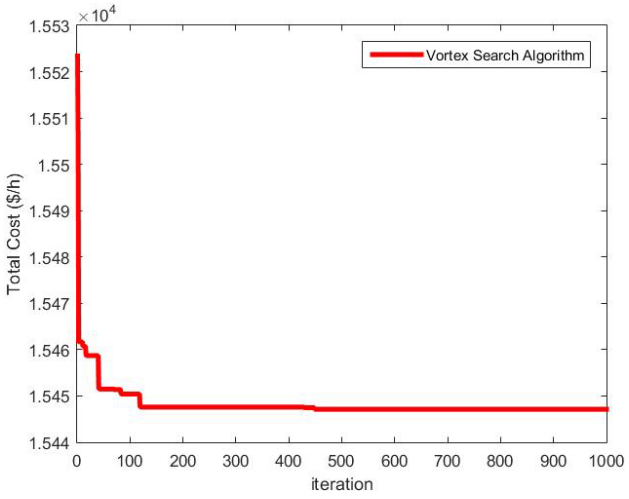

Figure 5 Convergence behavior of VSA for Case 2

4.3. Case 3: ELD with Valve Point Loading Effect

For this case three different constraints, which are transmission line losses, valve point loading effect and ramp rate limits, applied to system. Cost coefficients and valve point loading effect coefficients are given in Table 7. Obtained results were given in Table8 and compared with different methods. Convergence behavior of VSA for this case was shown Figure 6. 1263 MW power was selected for demand power.

Results of VSA and other techniques results was shown in Table 8. Maximum and minimum limits of generators are same with Table 4 and ramp rate limits are same with Table 5. Demand power is selected 1263 MW for this case.

Cost($)	15746	16372.9	16329.2	16327	16310.76

It is obviously seen that from the Table 8 VSA, method gave best cost value when compared with from PSO, CPSO, WIPSO and MRPSO techniques from [22].

Figure 6 is shown convergence behavior of VSA for this case

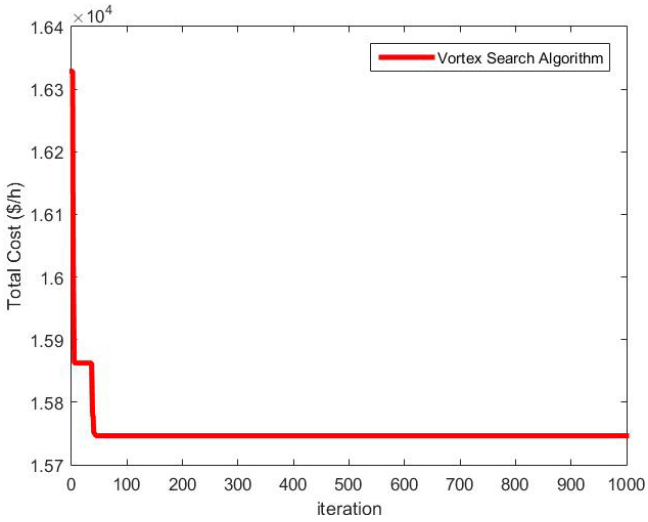

Figure 6 Convergence behavior of VSA for Case 3

5. Conclusion

In this paper vortex search algorithm was applied to six generator power system for solving economic load dispatch problem. ELD problem was became more complex and more difficult problem with valve point loading effect, ramp rate limits, transmission line losses and prohibited zones constraints. Three different situation were analyzed and for first case minimum cost value was found 15448 $, for second case minimum cost value was found 15447 $, for third case minimum cost value was found 15746 $. Obtained results from VSA compared with another techniques from the literature. These results clearly show that VSA is very capable,

feasible and effective method for solving non smooth and very complex economic load dispatch problem.

Tangent Delta
Frequency measurement

ABSTRACT

This paper is an extension of work originally presented in EIC-2017. It deals with influence of the supply frequency for dissipation factor measurements, mainly for tests under power frequency and low frequency. After a theoretical reminder, we present some experiments on single coils and stators of high voltage motors. Finally, we discuss the results and the desirability of choosing one or the other of these methods.

1. Introduction

Dissipation factor, or tan δ, is currently used for the insulation diagnostics. While the tan δ measurements are mainly performed at power frequency, some methods based on the frequency steps [1] and very low frequency have been developed. The methods using very low frequency have some advantages in term of portability, power requirement, etc. but it is interesting to see the impact of the frequency on the quality of measurement and, subsequently, of the diagnostic.

This paper presents the influence of the supply frequency on tangent delta measurement. The paragraph II reminds the theoretical bases. The paragraph III presents some experiments, firstly on single coil and secondly on a stator of high voltage motor. Test are performed at 0.1 Hz and 50 Hz. The analysis of the result presents some difference, especially on the sensitivity at relaxation phenomena. These differences are discussed, and we can define some interests on insulation diagnostic.

2. Theory reminder

Dielectric losses are currently measured and used for electrical machines diagnostics. To perform the dielectric loss measurement, the stator is considered as a capacitor and the theory supporting these measurements is based on the complex permittivity. Of course, this capacitor is imperfect.

It is schematized by the capacitance with a resistance in parallel, both in series with a resistance and an inductance, in our case, we can neglect Ls (fig. 1).

The real part of impedance is due to the series and parallel resistances Rs and Rp. Rs becomes important at high frequency when Rp has a dominating effect essentially at low frequency.

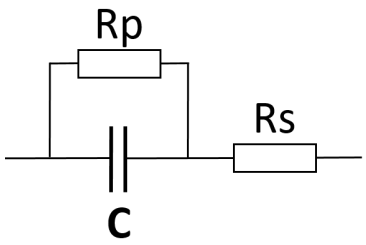

Fig. 1: Real capacitor model *(without Ls)*

*Cyrille CAIRONI, CAIRCY, 22, rue de Ceintrey 54160 Pulligny France Email : cyrille.caironi@caircy.org

Rp is the picture of the losses due to the dielectric polarization, the dielectric resistance, leakage current and also charge redistribution phenomena. All these phenomena are involved at low frequency especially at industrial frequencies and lower. De facto we currently use the model within resistance in parallel which excludes Rs (1).

$$\underline{I} = j\omega\underline{\varepsilon}C\underline{U} = \underline{I_{Rp}} + j\underline{I_C} \quad (1)$$

Due to the phenomena of relaxation and losses, the insulating materials permittivity is complex (2)

$$\underline{\varepsilon} = \varepsilon_0 \left(\varepsilon_r' - j\,\varepsilon_r''\right) \quad (2)$$

In this arrangement, ε_r' is the component which defines the capacitive current (3) and $\varepsilon_r''$is the component which defines the current I_{Rp} corresponding at the active losses in phase with the voltage (4).

$$\varepsilon_r' = \frac{\underline{I_C}}{j\omega C\underline{U}} \quad (3)$$

$$\varepsilon_r'' = \frac{\underline{I_{Rp}}}{\omega C\underline{U}} \quad (4)$$

The tangent delta, or dissipation factor is defined as (5):

$$tan\delta = \frac{\underline{I_{Rp}}}{\underline{I_C}} = \frac{\varepsilon_r''}{\varepsilon_r'} = \frac{1}{\omega CRp} \quad (5)$$

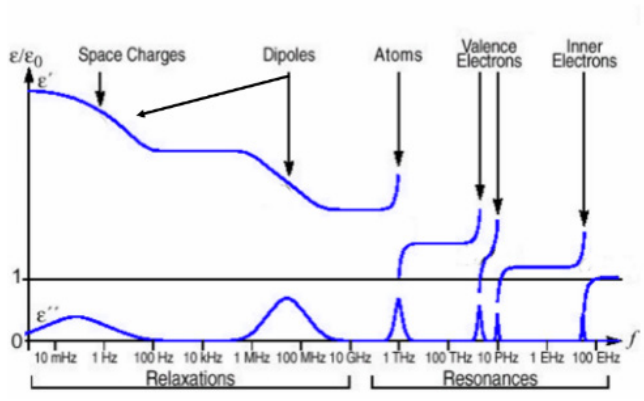

Fig. 2: effect of resonance and relaxation on permittivity *(source [2])*

Of course, we can see that the tangent delta is inversely proportional to the frequency. But the main interest of the low frequency is the physics of the material. The polarization and relaxation phenomena involved in dissipation of the insulation have different origins and each of them approximately can be linked to frequency (fig. 2) as presented in [2].

The electronic and ionic polarization have a high frequency level (around 10^{15} Hz for electronic polarization) this type of polarization is not interesting for the machine diagnostic in first approach. On the other hand, the relaxation phenomena linked to dipoles, space charges and interface charges are very interesting.

These relaxation phenomena enable us to check precisely details like pollution and polymerization, which are visible at lower frequencies (less than 1 Hz) by tan δ analysis.

Furthermore, the temperature influence is a particularly important factor as presented on figure 3 and figure 4 [3] and explained in [4].

It could be an advantage but also a risk because a variation on the temperature has a bigger impact at low frequency (less than 1 Hz) than at industrial frequency.

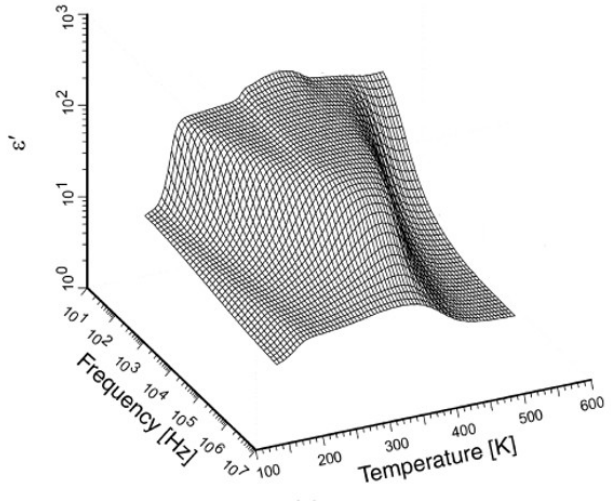

Fig. 3: Typical real part of the permittivity of porous glass versus frequency and temperature *(source [3])*

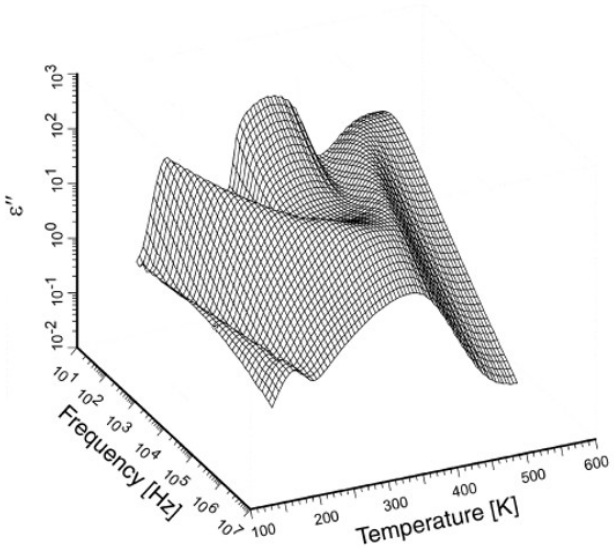

Fig. 4: Typical imaginary part of the permittivity of porous glass versus frequency and temperature *(source [3])*

3. Experimental studies

IEEE 433 recommends performing very low frequency tests at 0.1 Hz [5] and the monitoring present on the market uses this frequency. Therefore, the tests are performed at frequency of

0.1 Hz and 50 Hz, in accordance to IEEE 433 [5] and to IEC 60034-27-3 [6].

3.1. Experiments on coils

Tan δ measurements were performed on sample coils (7 kV rated) in steps of 1 kV from 1 kV to 9 kV. Measurements were performed successively at 0.1 Hz and 50 Hz.

These tests show higher tan δ values with a 0.1 Hz frequency supply than with a 50 Hz supply (fig. 5). Therefore, these measurements confirm some explanations of the theoretical reminder and they are also in accordance to the related literature and different diagnostic methods proposed in [1].

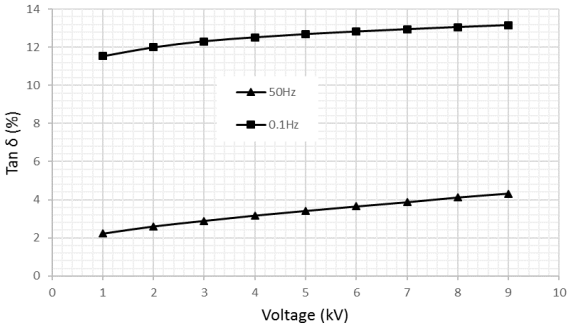

Fig. 5: tan δ versus voltage on single Coil

The difference of levels can be explained by a dielectric relaxation, which means a lowering of the dielectric losses with frequency, therefore 0.1 Hz is more sensitive than 50 Hz.

The underlying physical mechanism is usually related to the polymerization degree of the impregnating resin and interfacial polarization [4].

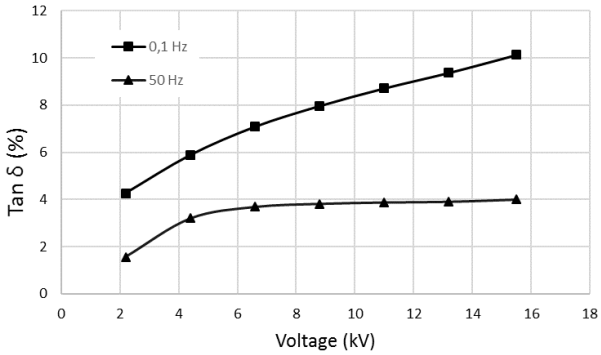
The voltage dependence of the losses of the sample is very similar for both frequencies. At this step, we could consider that the frequency just influences the level of tan δ. In fact, the influence is also on the behavior of the tan δ versus voltage.

3.2. Experiments on Stator

Measurements were performed on a 1.5 MW, 11 kV motor in accordance to IEC 60034-27-3 [6] and customer requirements (fig. 06).

Capacitance measurements at 50 Hz and 0.1 Hz have a similar behavior (fig. 08), on the other hand, the tan δ has a different shape at 50 Hz and 0.1 Hz (fig. 07)

As for a simple coil, the tan δ is higher at 0.1 Hz than at 50 Hz but of different shape (fig. 07). The measurement at 0.1 Hz shows a voltage dependence which is not present at 50 Hz.

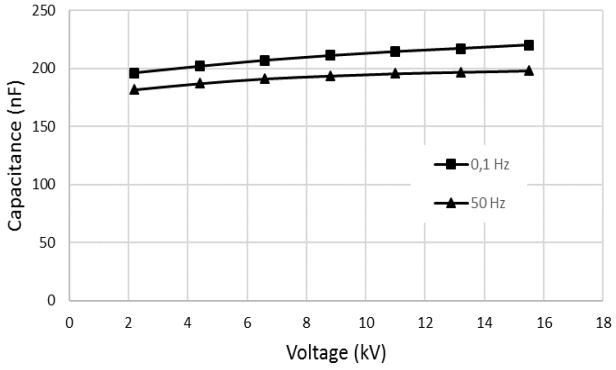


This nonlinear voltage dependences of rotating machine insulation properties typically stem from partial discharges and currents in endwinding corona protection.

Evidence of the structural influence on the dielectric properties is shown in [4] as mechanical losses and dielectric losses largely coincide. This indicates that the 0.1 HZ test method can provide information about insulation quality, e.g. brittleness, shrinkage and risk of resin cracking caused by post-polymerization

Partial discharges analysis, and especially PRPD, can complete the tan δ information. Of course, the tan δ and PRPD must be performed at the same frequency.

Fig. 6: VLF supply and measurement instrumentation on 11 kV Stator



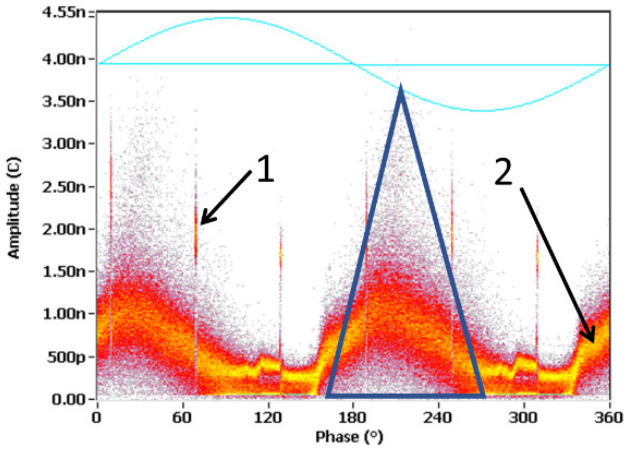


Fig. 8: capacitance versus voltage on 11 kV Stator

The patterns show solely the ionization phenomena and must be analyzed in accordance with the tan δ measurements. Furthermore, the noise phenomena have shown more important

using power frequency supplies. Phenomena linked to the noise can be solved by numerical tools presented in [7] and [8] especially in case of on-line PD monitoring.

Fig. 09 shows PRPD pattern at the network power supply and Fig. 10 shows PRPD pattern at 0.1 Hz. Despite differences, both patterns give similar information, but the 0.1 Hz can be easily compared to the tan δ.

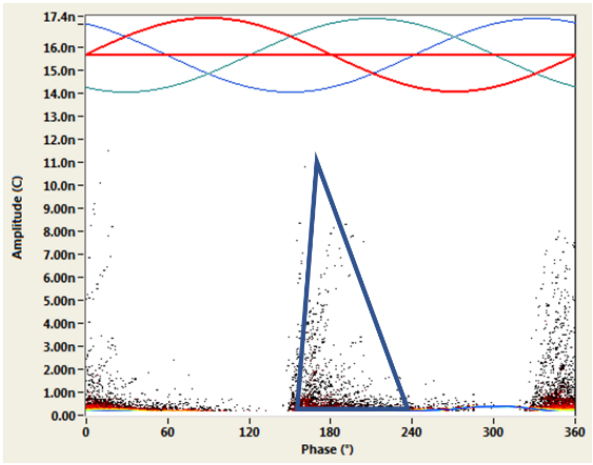

Fig. 10: PRPD at 0.1 Hz on 11 kV Stator

4. Extension to the Stator Insulation Diagnostic

The paragraph II confirms the theoretical reminder presented in paragraph I. Especially on complete stators, tan δ measurement allow to see some more phenomena at 0.1 Hz, being undetectable at 50 Hz.

In fact, the measurements at 0.1 Hz should be most efficient to the diagnostic phenomena linked to the complete insulation system [9]. Furthermore, the low frequency usage is not new. For example, measurements for CIGRE [10] was performed at 1Hz in 1990 in order to:

- do not have distortion of sinus wave (which is not perfect when it is provided by transformer at supply frequency)
- reduce the pulse pile-up
- have a cleaner PD pattern
- the higher sensitivity to the structural properties of the composite material allows to more sensitively follow the resin post-polymerization
- etc.

However, the low frequency usage was costly in the beginning of the 90th, which is not the case anymore and this off-line monitoring procedure can be easily implemented and could be interesting to complement on-line monitoring which is de facto happening at power frequency.

5. Conclusion

tan δ measurement. It reminds the theoretical bases before present two different cases: a coil and a stator. Measurement were performed on two frequencies: 50 Hz (power frequency) and 0.1 Hz.

If similar diagnostic results together with partial discharge measurements, different defects can be detected or identified at lower power frequency.

The low frequency measurements present some advantages. Especially the dielectric losses react more sensitive to structural changes.

However, while diagnostics can be improved using low frequencies, criteria must still be developed if the low frequency method should be used for acceptance testing. Indeed, most of the tan δ criteria are established for power frequency tests and we have to perform further research in order to define reliable acceptance criteria.

On the practical side, the instruments used by the authors have proven easily transportable, insensitive to noise and have very low power requirements in comparison to power frequency devices. So, that we feel, not only the enhanced diagnostic potential but also cost consideration, which justify more research efforts in that field.

ABSTRACT

The automotive industry has focused to use polymer materials in order to increase energy efficiency. So, the industry pays attention to use 3D printing technologies using several polymers. Among several 3D printer technologies, fused deposition modeling (FDM) is one of the popular 3D printing technologies due to an inexpensive extrusion machine and multi-material printing. FDM could use thermoplastics such as ABS, PLA, ULTEM so on. However, it has a problem related to the post-processing because FDM has relatively poor layer resolution. In this study, the mechanical properties of ABS parts fabricated by FDM were measured. The ABS parts were divided into one with vapor smoothing process and the other without the vapor smoothing process which is one of the post-processing methods. Using dynamic mechanical analysis (DMA) and dilatometer, temperature-dependent storage modulus and CTE for ABS specimens were measured. Based on the measured thermo-mechanical properties of ABS parts, finite element analysis was performed for an automotive bumper made of ABS. Moreover, response surface methodology was applied to study relationships among design parameters of thickness of the bumper, ambient temperature, and application of the vapor smoothing process. In result, a design guideline for a ABS product could be provided without time-consuming experiments

1. Introduction

The automotive industry has tried to increase energy efficiency for vehicles. In order to achieve the goal, one of ways is to reduce vehicle weight. If weight of the vehicle increases by 10%, fuel economy also increases by about 7% [1]. Therefore, researchers in the automotive industry have focused to use materials lighter than steel. One of the substitute materials is polymer. Currently, about 15% to 20% of total weight of a vehicle is in charge of polymer materials. The polymer materials are widely used for automobile parts including front ends, bumpers, fascia systems, grills, fenders, intake manifolds, engine mounts, door structures, panels, door impact beams, bonnet panels, under hood parts, pedal boxes, body structures, steering columns and so on [1]. Among several polymers, acrylonitrile butadiene styrene (ABS) is applied for bumpers, seats, dashboard, interior trim, exterior trim, and lighting and so on. This study focuses on ABS because fused deposition modeling (FDM), which is one of additive manufacturing techniques, could use ABS to make 3D printed structures.

Recently, additive manufacturing also known as 3D printing is considered as the key driver of the fourth industrial revolution. Compared to the conventional subtractive manufacturing such as turning, cutting, milling and grinding, 3D printing has unique advantages in design flexibility, personal fabrication, cost of geometry complexity, dimensional accuracy, time and cost efficiency in production run and so on [2]. Based on these merits, rapid development has been made in the several industrial areas such as aviation parts, manufacturing, and medical science [3]. However, the 3D printing has demerits of, scalability, trade-off between building and layer resolution, cost for mass manufacturing, material heterogeneity, need of anchor and support material, requirement for post-processing and so on [2]. So many researchers have solved the problems for the next generation of the 3D printing technique [2].

This study focuses on the post processing technique for the additive manufacturing. Additive manufacturing techniques have been classified into seven categories by ASTM international, which are shown in Figure.1.

Among them, FDM belongs to a category of material extrusion, which is an inexpensive and very popular 3D printing technique [2]. But FDM sometimes struggles with poor surface finish so that the post processing technique is necessary. The poor surface finish occurred by stair stepping effect could be treated by

*Corresponding Author: Sung-Uk Zhang, 82-51-890-1645, zsunguk@deu.ac.kr

polishing process such as sanding and vapor smoothing. The sanding may not be possible for tiny or complex geometries. On the other hand, the vapor smoothing could be effective for the complex shapes fabricated by 3D printing as shown in Figure. 2.

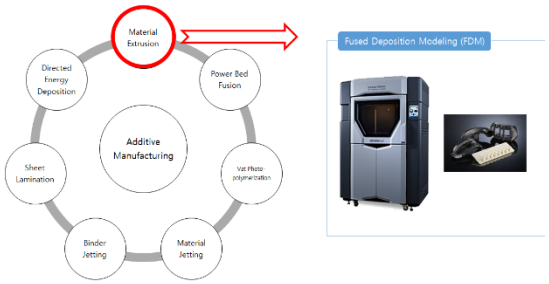

Figure.1. Seven categories for AM technologies

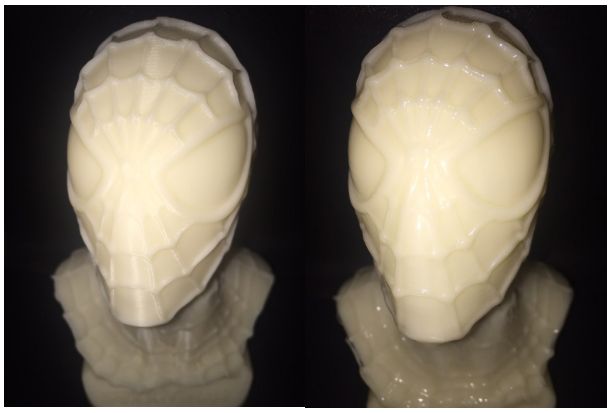

Figure.2. Vapor smoothing before and after

Many researchers have studied the vapor smoothing process and its effect in the mechanical properties. Kuo and Mao [4] developed an acetone-vapor smoothing system for ABS parts fabricated by FDM. They showed that surface roughness of the ABS parts could be significantly improved by using their system. Garg et al. [5] observed mechanical properties and surface roughness according to building parameters and vapor smoothing process for ABS specimens fabricated by FDM. In order to obtain the mechanical properties, they used ultimate testing machine (UTM). Singh et al. [6] studied vapor smoothing process for FDM parts. They had tried to improve the vapor smoothing process in term of surface roughness and dimensional accuracy by using DOE technique. Singh et al. [7] optimized building parameters of FDM and control parameters of vapor smoothing processes for hip joint as a biomedical application. They used Taguchi's method and response surface methodology to obtain the optimum level of process parameters. Cantrell et al. [8] measured mechanical properties of 3D printed ABS and PC parts with varying raster and building orientation of additive manufacturing. Gao et al. [9] investigates the impact of the vapor smoothing for 3D printed ABS parts in terms of the strength and elongation. They measured anisotropic mechanical properties of the ABS parts and showed that the material properties are affected by the length of process time for the vapor smoothing. Belter and Dollar [10] suggested a technique to strengthen 3D printed parts fabricated by FDM. They tried to remove voids in the printed parts by filling them with high-strength resins. They performed three-point bending test to obtain mechanical properties. Melenka et al. [11] evaluated mechanical properties and dimensional accuracy for 3D printed PLA parts fabricated by FDM. They used DOE technique to establish a relationship between building parameters and mechanical properties of the 3D printed parts.

In this study, temperature-dependent mechanical properties of 3D printed ABS parts fabricated by FDM and the acetone-vapor smoothing are measured by using dynamic mechanical analyzer (DMA) and dilatometer. Based on the measured data, finite element analysis and response surface methodology are performed in order to generate a design guideline for an automotive bumper made of ABS.

2. Methodology

The second section has four subsections. The first subsection includes geometry information of specimen for DMA and dilatometry. The second briefly explains about the vapor smoothing process. The third subsection describes about information measured by DMA and dilatometry. The last subsection introduces about finite element analysis and response surface methodology for an automotive bumper made of ABS.

2.1. Specimen fabrication for DMA and Dilatometry

Specimens for DMA and dilatometry were fabricated by using Fortus 3D printer which is based on Stratasys FDM technology. In modeler setup of Stratasys's software, building parameters were controlled, which are part interior style, visible surface style, and support style be set to sparse-low density, being enhanced, and being smart. The specimen for DMA has 27.8 mm length with 6.5 mm width and 2.0mm thickness and the size of specimen for dilatometry is 6 mm by 6 mm by 12 mm as shown in Figure. 3.

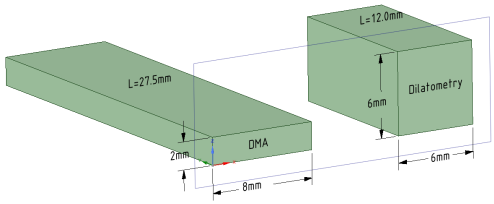

Figure.3. Geometry of the specimen for DMA and Dilatometer

2.2. Vapor smoothing process

Vapor smoothing process lets ABS plastic dissolve in acetone. So the secondary bonds between the ABS polymer chains is broken so that external layers of ABS 3D printed parts are softening. In result, this technique makes the surface finish of 3D printed parts be improved. A simple process for the vapor smoothing is shown in Figure. 4.

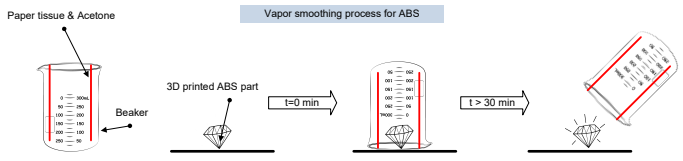

Figure.4. Vapor smoothing process

First of all, dust and debris from 3D printed ABS parts are removed. Small amount of acetone is poured on paper tissues. The tissues are attached inside of a beaker. Then, the 3D printed parts are covered with the beaker. Then, allow parts to be inside of the beaker for about 30 minutes. In this paper, amount of acetone was controlled from 5ml to 15ml in order to observe a relationship between the amount of acetone and mechanical properties of the 3D printed parts with the vapor smoothing.

2.3. Dynamic mechanical analyzer and Dilatometry

Dynamic Mechanical Analyzer (DMA), which known as DMA, is a powerful tool to characterize mechanical properties of a material as a function of temperature, time, frequency, stress, and so on. Q800 DMA was used, which is manufactured by TA instruments. Temperature-dependent storage modulus of ABS 3D printed parts could be observed by using DMA. As an applied mechanical load of DMA is a sinusoidal or oscillating force, complex modulus of E* could be obtained for polymer materials such as ABS, PLA, PC, and ULTEM, which consists of the storage modulus E' (real part) and the loss modulus E" (imaginary part) as follow

$$\mathbf{E}^* = E' + \mathbf{i}E'' \qquad (1)$$

$$\tan\delta = E''/E' \qquad (2)$$

where, tan δ is the ratio of loss modulus to storage modulus, which is an indicator of the energy lost. Figure.5 graphically shows temperature dependent storage modulus and tan δ measured by using DMA. In the graph of tan δ , the peak of tan δ indicates the glass transition temperature which means a midpoint between the glassy and rubbery states of a polymer.

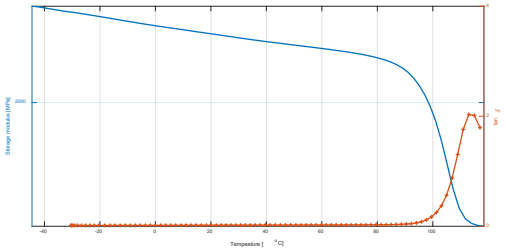

Figure.5.Temperature dependent storage modulus and tan δ obtained by using DMA

Moreover, a dilatometer is used to measure temperature dependent CTE of the polymer materials, which is an instrument to measure volume changes occurred by a physical or chemical event. In this study, the physical event is temperature change. The thermal expansion is expressed as

$$\alpha = \frac{1}{V}\left(\frac{\partial V}{\partial T}\right) \qquad (3)$$

where, α is a coefficient of thermal expansion (CTE), V is a volume, and T is a temperature. We used DIL-402C manufactured by NETZSCH. Using the dilatometry, we could obtain temperature dependent CTEs for ABS 3D printed parts.

2.4. Finite element analysis and response surface methodology for a 3D printed bumper made of ABS

A portion of a bumper is modeled and structurally evaluated by using finite element analysis as shown in Figure. 6 and Figure. 7. Fig 6 shows the geometry of the automotive bumper. Fig 7 graphically shows fixed boundary conditions, load boundary conditions, and body temperature condition on the geometry. In Figure. 7, the symbols of A, B and C mean boundary conditions of fixed support, pressures, thermal conditions.

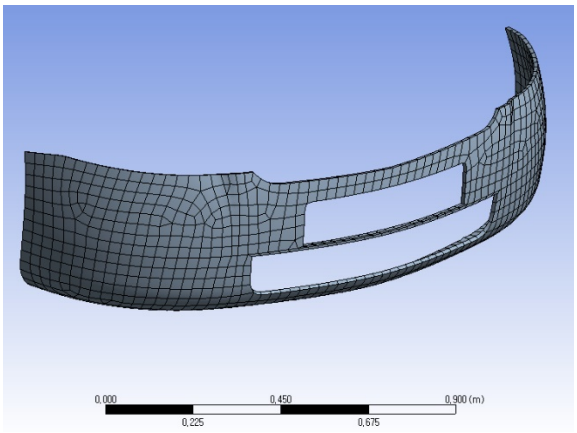

Figure.6. Finite element model for an automotive bumper

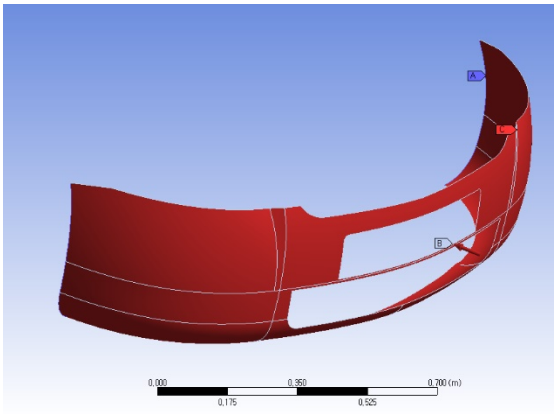

Figure.7. Boundary conditions for the finite element model

Input parameters for the response surface methodology were temperature, thickness of bumper, element size, and application of the vapor smoothing. The range of each parameter is shown in Table 1.

Table 1. The factor ranges for input parameters

Input parameter	[min, max]
Temperature [°C]	[-40, 70]
Thickness of Bumper [m]	[0.01,0.03]
Element Size [m]	[0.03,0.04]
Vapor smoothing	w/o, w/

Box-Behnken design was used for the response surface methodology. Design points were generated by using Minitab software as shown in Figure. 8. And the output parameter was a maximum of total deformation of the bumper.

3. Results and Discussion

The first describes thermo-mechanical properties of ABS specimens measured by DMA and dilatometry. The second subsection depicts numerical simulation for an automotive bumper made of ABS.

3.1. Thermo-mechanical properties of ABS specimens

Four different splits were measured, which were exposed to different amount of acetone vapor; 0ml, 5ml, 10ml and 15ml. Three specimens per each split were fabricated and measured in the same condition. Averaged thermo-mechanical properties of the

ABS specimens were obtained, which are the storage modulus and CTE as shown in Figure.9 and Figure.10.

Figure.8. Design points generated by Minitab software

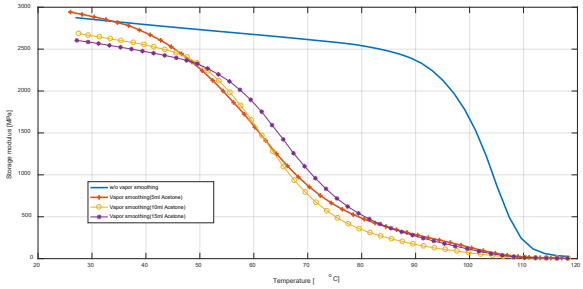

Figure.9. Average of temperature dependent storage moduli for four splits

Figure.9 graphically shows the difference between specimens without vapor smoothing process and ones with vapor smoothing process. The glass transition temperature of the specimens with the vapor smoothing process is much lower than one without the vapor smoothing process.

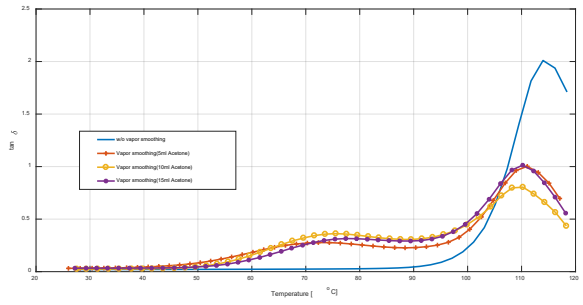

Figure.10. Average of tan δ for four splits

Figure.10 graphically shows the difference between specimens without vapor smoothing process and ones with vapor smoothing process in terms of tan δ. In the graph of first split, peak point of tan δ occurs at about 114ºC. However, the first peaks of the other specimens with the vapor smoothing are shown at 67ºC, 71ºC, and 74ºC. Figure.11 shows that CTEs vary as the temperature increases. CTE of the specimen without vapor smoothing is relatively constant.

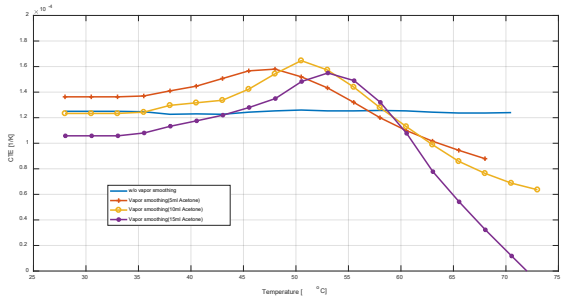

Figure.11. Average of the temperature dependent CTEs for four splits

However, CTEs of the others with vapor smoothing have large variations and have one peak between 45ºC and 60ºC. As the temperature increases more than 60ºC, CTEs of the samples with vapor smoothing decreases.

Figure.9, Figure.10 and Figure. 11 obviously shows which split does not have the vapor smoothing process. Figures represent that the vapor smoothing process weakens thermal stability of ABS 3D printed parts. However, above figures could not show any correlation between CTE and the amount of acetone vapor in the range of 5ml to 15ml.

3.2. Numerical evaluation for an automotive bumper made of ABS

The output parameter was the maximum value of total deformation of the automotive bumper as shown in Figure. 12. The maximum deformation occurs at the center of the bumper under the given boundary conditions.

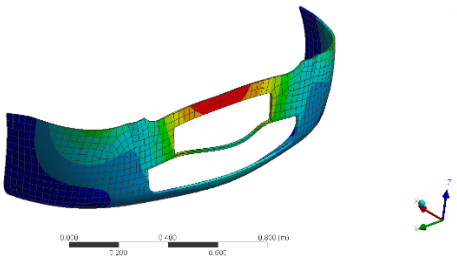

Figure.12. Total deformation of the automotive bumper

Using the response surface methodology and the finite element analysis, two regression equations with varying application of the vapor smoothing process were obtained as follow

$$D[m] = 0.1538 - 0.001126 \times T[C] - 5.97 \times Th[m] - 3.80 \times Elem[m] + 0.000006 \times T[C] \times T[C] + 108.4 \times Th[m] \times Th[m] + 51.7 \times Elem[m] \times Elem[m] - 0.01157 \times T[C] \times Th[m] + 0.02709 \times T[C] \times Elem[m] \quad (4)$$

$$D[m] = 0.182 - 0.000793 \times T[C] - 7.10 \times Th[m] - 3.81 \times Elem[m] + 0.000006 \times T[C] \times T[C] + 108.4 \times Th[m] \times Th[m] + 51.7 \times Elem[m] \times Elem[m] - 0.0116 \times T[C] \times Th[m] + 0.0271 \times T[C] \times Elem[m] + 0.2 \times Th[m] \times Elem[m] \quad (5)$$

where, D is the maximum deformation of the automotive bumper, T is the temperature, Th is the thickness of the bumper and Elem is the size of finite elements. When the vapor smoothing process is not applied, Equation (4) could be used. Otherwise, equation (5) could be used to estimate the maximum deformation of the bumper. R-square value of the response surface model was 81%. Two equations represent that the maximum deformation is

sensitive to the thickness of bumper and the temperature under given ranges. Based on two equations, contour plots were computed by using Minitab software as shown in Figure.12. According to the vapor smoothing process, two design guidelines could be obtained by using the response surface methodology, which might be useful information for bumper designers.

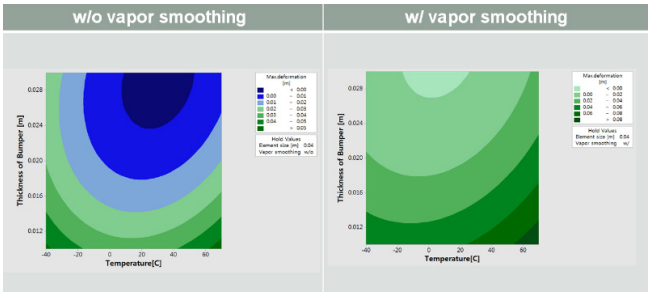

Figure.13. Contour plots according to the vapor smoothing process

4. Conclusion

In this study, the temperature-dependent mechanical properties of ABS parts were measured by used dynamic mechanical analyzer and dilatometry, which were fabricated by FDM and the vapor smoothing technique. The vapor smoothing process weakens thermal stability of ABS 3D printed parts. According to the temperature-dependent storage modulus of 3D printed ABS specimen, the glass transition temperature dramatically decreases by the process. The vapor smoothing process made relatively large variation in CTE of ABS 3D printed parts. Based on the measured thermos-mechanical properties of ABS specimen, finite element analysis and response surface methodology for an automotive bumper made of ABS were performed so that two design guidelines could be provided according to the vapor smoothing process.

ABSTRACT

The main target of this article is to perform the multidimensional analysis of multipath propagation in an indoor and outdoor environment at higher frequencies i.e. 15 GHz, 28 GHz and 60 GHz, using "sAGA" a 3D ray tracing tool. A real world outdoor Line of Sight (LOS) microcellular environment from the Yokusuka city of Japan is considered for the analysis. The simulation data acquired from the 3D ray tracing tool includes the received signal strength, power angular spectrum and the power delay profile. The different propagation mechanisms were closely analyzed. The simulation results show the difference of propagation in indoor and outdoor environment at higher frequencies and draw a special attention on the impact of diffuse scattering at 28 GHz and 60 GHz. In a simple outdoor microcellular environment with a valid LOS link between the transmitter and a receiver, the mean received signal at 28 GHz and 60 GHz was found around 5.7 dB and 13 dB inferior in comparison with signal level at 15 GHz. Whereas the difference in received signal levels at higher frequencies were further extended in an indoor environment due to higher building penetration loss. However, the propagation and penetration loss at higher frequency can be compensated by using the antenna with narrow beamwidth and larger gain.

1. Introduction

This article is an extension of research work originally presented at International Wireless Communication and Mobile Computing (IWCMC'17) conference [1]. In reference [1], studies were made at 15 GHz only, and only outdoor propagation was studied. However, in this article the radio propagation at millimeter wave frequencies i.e. 60 GHz is additionally studied. Furthermore, the research work of this article also includes indoor propagation analysis, which was not done earlier in [1].

Nowadays, the Fifth Generation (5G) of the mobile communication system is being actively discussed in both industry and academia [2-4]. Currently, various advanced wireless access technologies including High Speed Packet Access (HSPA), Long Term Evolution (LTE), and LTE-Advanced (LTE-A) are in operation. However, the ultimate solution for the ultra high capacity requirement of the future system is expected to be provided by the 5G. It is strongly believed that the higher frequency bands will play a vital role in meeting the capacity targets of the next generation of the cellular networks. The frequency bands between 700 MHz to 4 GHz are currently used by the mobile operators for radio transmission, and are already over loaded with current mobile technologies. Higher frequency bands offer wider spectrum. On the other hand, the higher path loss is also attributed with the higher frequency of operation [5]. The R&D organizations are extensively putting their effort for investigating the utilization of higher frequency bands for mobile communications [6]. The utilization of advanced antenna technologies such as Massive MIMO (MMIMO) and beamforming help in extending the coverage at higher frequencies.

It is important to understand the radio propagation characteristics in order to properly design and to efficiently optimize the system. Classical coverage prediction models do- not provide the insight information about the channel (environment). However, the deterministic ray tracing models provide the multidimensional characteristics of the radio propagation environment [7]. Multipath propagation is a complex phenomenon and involves several propagation mechanisms e.g. specular

reflection, diffraction from the corners, transmission, diffraction from the rooftops, and diffused scattering [8]. Ray tracing is a promising technique for finding the possible paths between the transmitter and receiver.

At reference [9], the NTT DOCOMO provides the field measurement results of 5G radio system operating at the frequency of 15 GHz in an outdoor and indoor microcellular environment. One of the core targets of this article is to provide the simulation result for the scenario considered in [9], so that a comparison between the measured and simulated data can be made. For this purpose, the sAGA ray tracing tool based on Image Theory (IT) algorithm is utilized for the simulations. The radio propagation properties such as received signal strength, Power Angular Spectrum (PAS), and Power Delay Profile (PDP) at higher frequencies are also provided in this article. The simulation results presented in this article highlight the difference of propagation at different considered frequencies i.e. 15 GHz, 28 GHz and 60 GHz, and also highlight the difference of propagation in an outdoor and indoor environment.

2. System Model and Environment

2.1. System Configuration

The Fifth Generation (5G) of the mobile communication system based on Time Division Duplex (TDD) operating at 15 GHz frequency is considered at reference [9]. The 5G communication system consists of four contiguous Component Carriers (CCs), and each CC is assumed to have 100 MHz bandwidth. Carrier Aggregation (CA) is employed to combine four component carriers. The transmission power per component carrier is set to 27.3 dBm, which makes a total transmission power of the transmitter equals 33.32 dBm for 400 MHz bandwidth. The base station is installed with a directional antenna at the height of 8 m. The transmitter is located on the wall of the building. The base station antenna has a horizontal Half Power Beamwidth (HPBW) of 90° and a vertical HPBW of 10.5° and has a maximum antenna gain of about 14.5 dBi. A mechanical downtilt of 13.5° is used to restrict the propagation in small cell environment. Whereas at the receiver end the MS is assumed to have an omni directional antenna with 0 dBi gain. As, the target of this paper was to provide the simulation results for the system and environment considered in [9], therefore the same set of parameters and environment are assumed in this paper.

2.2. Simulation Platform

The "sAGA" a MATLAB based three-dimensional ray tracing tool is used for the simulations. The sAGA tool is indigenously developed by the authors of this paper. Unlike other quasi 3D ray tracing tool, sAGA performs full three dimensional ray tracing. Multipath propagation involves several mechanisms of interactions e.g. reflection, diffraction, transmission, and scattering. The sAGA ray tracing tool uses Image Theory (IT) to find all the possible reflected, diffracted, ground reflected, and rooftop diffracted paths with the given number of reflections and diffractions [10-12]. In case of reflected paths, the loss in energy due to specular reflection is given by the reflection co-efficient and depends upon the incident and the reflected angle of path and material permittivity. Whereas for the diffracted paths the diffraction loss is given by Berg's recursive model [13]. The energy is scattered in the wide range of directions and the impact of scattering becomes significant at higher frequencies. Therefore, a concentric circle approach given at [14] is used to generate the scattering points on the walls of the building. Ray tracing requires detailed information about the simulation environment and provides accurate results. Three dimensional ray tracing requires 3D map of the simulation environment. The computational complexity of the ray tracing algorithm increases with the increase in the number of supported reflections and diffractions.

A. Simulation Environment

For simulations, a small area from the Yokusuka city of Japan is selected. The Google map view of the targeted area is shown in Figure 1. For outdoor microcellular environment simulation, the parking area of NTT DOCOMO R&D center in Japan is considered, and for indoor simulation the office building is considered in this article.

Figure 1. Google map view of targeted area.

Figure 2 illustrates the two dimensional simplified map of the considered area. The simplified map model consists of just five buildings. For outdoor coverage simulations, it is assumed that the MS is mounted on a vehicle at a height of 3.1 m. The MS is driven at the speed of 10 km/h along eight different routes (A1-A8) as shown in Figure 2. For indoor coverage simulations, two paths A9 and A10 are considered. The path A9 is close to the exterior wall of the building, and path A10 is 7 m away from the exterior wall of the building. The location of the transmitter is marked with the blue spot. The transmitter antenna has the azimuth angle of 90° (facing towards North). All the outdoor and indoor simulation routes have a clear LOS with the transmitter. Two outdoor location points are marked as Pt1 and Pt2, and one indoor location point is marked as Pt3 in Figure 2. These static points are selected for Power Angular Spectrum (PAS) analysis.

For PAS simulations, a directive antenna with 14° HPBW in the horizontal domain and 10.5° HPBW in the vertical domain with 20 dBi maximum gain is used. It is assumed that a directive antenna on a receiver side at a height of 1.65 m is rotated by 360° in the azimuth plane with a step size of 4°. For ray tracing, the reflected path with the maximum three reflections, and diffracted path with single diffraction were found. The scatterers are spread over the surface of the walls of the building. The general system simulation parameters are summarized in Table I.

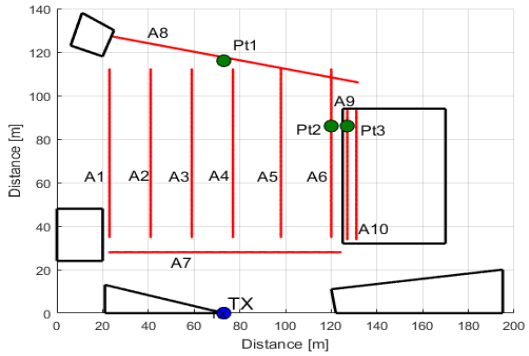

Figure 2. Illustration of simulation area and simulation routes.

Table I. General system simulation parameters for route simulations.

Parameters	Unit	Value
Frequency	GHz	15/28/60
Single carrier component (CC) bandwidth	MHz	100
System bandwidth (4 CCs)	MHz	400
Transmission power per CC	dBm	27.3
Total transmission power	dBm	33.32
Transmitter height	m	8
Antenna downtilt	°	13.5
MS height	m	3.1
Reflections		3
Diffractions		1
Diffuse scattering		Enabled

2.3. Building Penetration Loss (BPL)

The signal experiences a penetration loss while penetrating from the outdoor environment to the indoor environment. Outdoor to indoor penetration loss is generally termed as Building Penetration Loss (BPL). The building penetration loss is the function of frequency and depends heavily on the material characteristics of the building; therefore the BPL can be significantly different for different material types at different frequencies. Generally, the old houses are composed of plane standard glass windows and concrete wall, while the Infrared Reflective (IRR) glass windows are commonly used in the new modern energy saving houses. In reference [15], the old buildings are assumed to have 30 % of the standard glass windows and 70 % of the concrete wall. Similarly, the assumption for new modern building type corresponds to the 70 % of the IRR glass windows and 30 % of the concrete wall.

A simple model structure has been proposed in [15] to model a single material frequency dependent penetration loss. The penetration loss for different material types is provided at [16-20].

$$L_{\text{Single glass,dB}} = 0.1 * \text{Frequency}_{\text{GHz}} + 1, \quad (1)$$

$$L_{\text{Double glass,dB}} = 0.2 * \text{Frequency}_{\text{GHz}} + 2, \quad (2)$$

$$L_{\text{IRR glass,dB}} = 0.3 * \text{Frequency}_{\text{GHz}} + 23, \quad (3)$$

The penetration loss for the concrete wall as a function of frequency is modeled as

$$L_{\text{Concrete,dB}} = 4 * \text{Frequency}_{\text{GHz}} + 5, \quad (4)$$

As the buildings are composite of windows and concrete wall, the building penetration loss for old buildings and new buildings is modeled as shown in (5) and (6), respectively [21].

$$L_{\text{Old building,dB}} = -10\text{Log}_{10}\left[0.3 * 10^{\frac{-L_{\text{Double glass,dB}}}{10}} + 0.7 * 10^{\frac{-L_{\text{Concrete,dB}}}{10}}\right], \quad (5)$$

$$L_{\text{New building,dB}} = -10\text{Log}_{10}\left[0.7 * 10^{\frac{-L_{\text{IRR glass,dB}}}{10}} + 0.3 * 10^{\frac{-L_{\text{Concrete,dB}}}{10}}\right], \quad (6)$$

The building penetration loss as a function of frequency for different building types is shown in Figure 3.

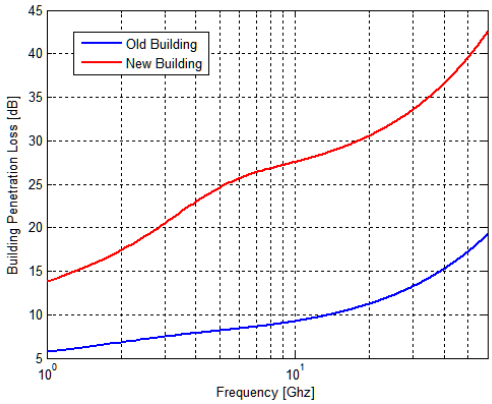

Figure 3. Building penetration loss as a function of frequency.

2.4. Indoor Propagation Loss

In an indoor environment, generally the indoor walls are made up of standard glass alternatively plaster. In [15], two different indoor wall loss models are presented as a function of the frequency assuming an average wall distance of 4 m. The Indoor Loss Model 1 assumes an indoor wall of standard glass, whereas Indoor Loss Model 2 is based on the measurements performed in [16]. Two indoor wall loss models are modeled as shown in (7) and (8). Indoor loss as a function of frequency for two different indoor wall loss models, expressed as dB/m is shown in Figure 4.

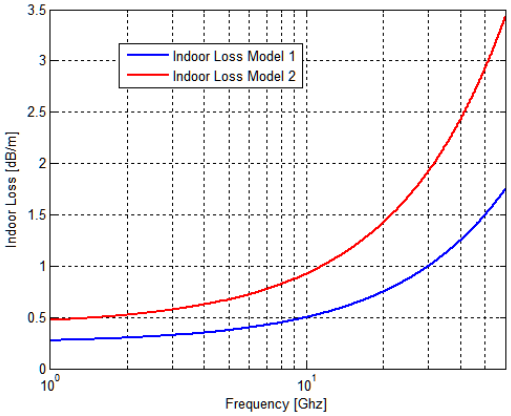

Figure 4. Indoor loss models as a function of frequency.

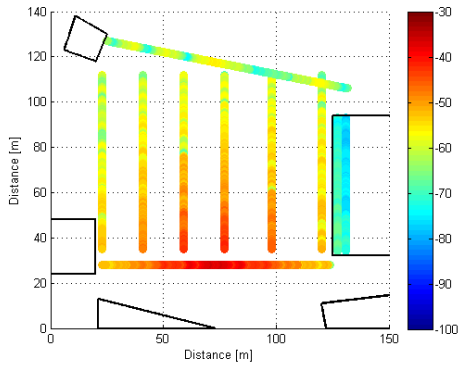
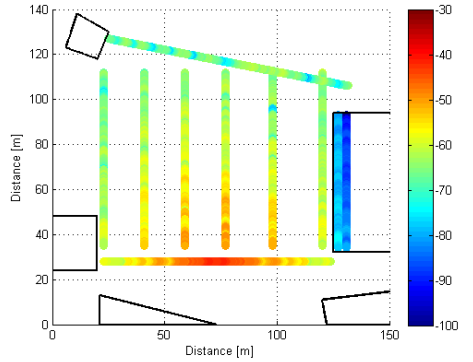


$$L^{(1)}_{\text{Wall loss,dB/m}} = L_{\text{Single glass,dB}}, \quad (7)$$

$$L^{(2)}_{\text{Wall loss,dB/m}} = 0.2 * \text{Frequency}_{\text{GHz}} + 1.7, \quad (8)$$



3. Simulation Results and Discussions

Figure 5 shows the received signal strength in dBm for eight outdoor and 2 indoor simulation routes. Figure 5(a), Figure 5(b) and Figure 5(c) shows the received signal strength along the paths at 15 GHz, 28 GHz and 60 GHz, respectively. It can be seen in Figure 5(a) that the maximum received signal strength of around -38 dBm is found in front of the BS antenna in the direction of the main lobe. However, the signal strength starts to degrade as the receiver starts to move away from the transmitter, and deviate from the direction of the main lobe of an antenna. The considered area for simulation was an open environment; therefore the LOS path always existed between the transmitter and receiver. Whereas there are signal fades along the routes due to the constructive and destructive addition of multipaths. The route A1 and A6, and path A2 and A5 are symmetrical and are at almost equal distance from the transmitter. It is interesting to see that the signal strength along the route A6 is better compared with A1 due to more reflected and scattered multipaths from the wall of the nearby building. As soon as the MS crossed the building in route A6, the signal degradation due to the absence of a reflected path is witnessed. The mean received signal level of path A6 is -57.01 dBm at 15 GHz. For indoor paths, old building type is considered. Path A9 is adjacent to path A6. However, due to building penetration loss the mean received signal level for path A9 is -69.78 dBm assuming old building type. The mean received signal level is further drops to -75.12 dBm in case of new building type which consists of IRR glass. Path A10 is located more deep inside the building, and due to additional indoor wall loss the signal strength degrades more rapidly in an indoor environment. The difference between the received signal level at 15 GHz and two other higher frequencies is clearly evident. However, the path loss at higher frequency can be compensated by using the antenna with higher gain.

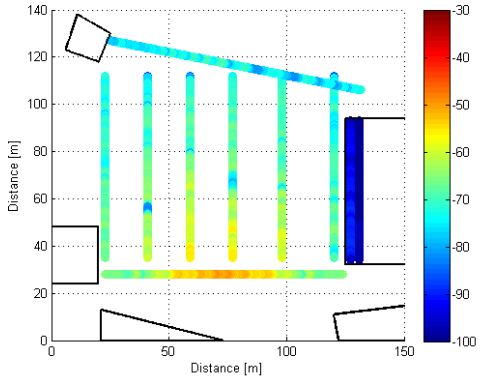


Table II presents the mean received signal level for the different simulation routes at 15 GHz, 28 GHz and 60 GHz. Considering the outdoor simulation routes, the mean path loss difference of around 5.7 dB and 13 dB was found between 15 GHz and 28 GHz transmission, and between 15 GHz and 60 GHz transmission, respectively. Similarly, for indoor simulation paths the mean path loss difference is around 10.57 dB and 27.82 dB between 15 GHz and 28 GHz transmission, and 15 GHz and 60 GHz transmission, respectively. As stated earlier, that the simulation routes A1 and A6 are symmetrical, however due to the presence of nearby wall for route A6 the mean received signal strength is around 1.25 dB and 1.43 dB better than A1 at 15 GHz and 28 GHz, respectively. Building penetration loss is the function of frequency and therefore the signal experiences higher penetration loss at higher frequencies. A significant difference was found between the received signal level of indoor user located in an old and new building type.

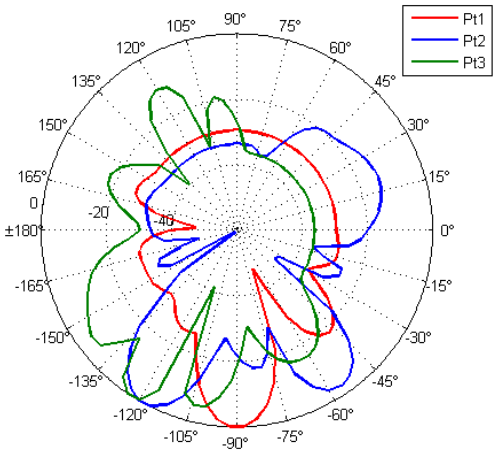
A10 (New building)	-93.94	-106.33	-127.73

Figure 6(a) and Figure 6(b) show the cluster of rays at 15 GHz reaching the outdoor location Pt1 and Pt2, respectively.

(a)



(b)

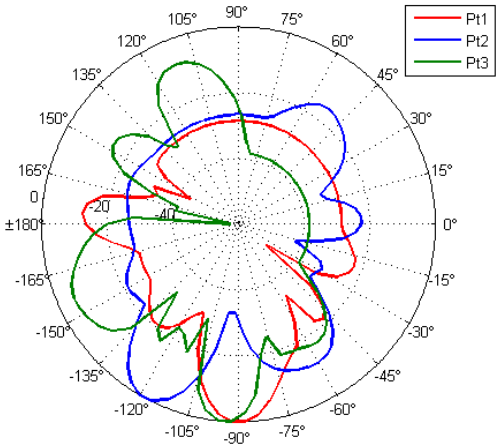


Figure 6. Multipath rays at 15 GHz from TX to (a) Pt1, and (b) Pt2.

The cluster of rays shown in Figure 6 includes wall reflected, ground reflected, diffracted and scattered paths. The impact of diffused scattering is clearly evident, and a considerable amount of energy at receiver points is coming through a large number of scattered paths. In Figure 6(a), the Pt1 is located in the middle of the simulation environment; therefore the walls of the building have clear visibility to the Pt1. Whereas, Pt2 is located closed to the wall of the nearby building, and the building on the right side of the TX does not have visibility to Pt2. Therefore, it can be seen in Figure 6(b) that there is no scattered path from the building on the right side of the transmitter.

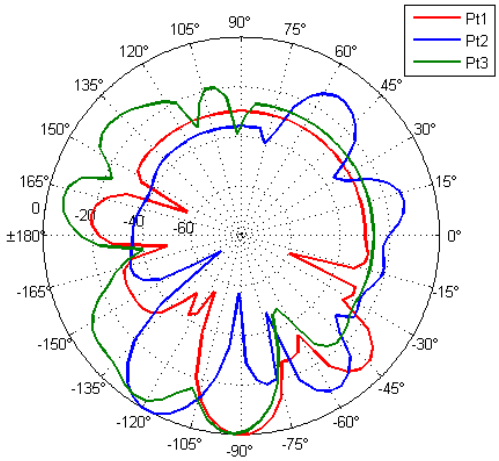

Figure 7(a), Figure 7(b) and Figure 7(c) shows the normalized power angular spectrum for location Pt1, Pt2, and Pt3 at 15 GHz, 28 GHz, and 60 GHz, respectively. The PAS shown in Figure 7 confirms that in the LOS condition the major contribution to the total received power comes through the LOS path, and through the specular reflected paths. However, at 28 GHz and 60 GHz the impact of diffused scattering is more significant than 15 GHz. An indoor environment has more scattering components due to nearby walls. It can be seen in Figure 7 that phenomenon of scattering has more significance at higher frequencies specifically in an indoor environment. The Pt1 is located at an azimuth angle of 90°, and therefore at Pt1 the strongest LOS path has a Direction of Arrival (DoA) of -90° as shown in Figure 7. The next strongest path is the reflected path with -44° of DoA.

(a)

(b)

(c)

Figure 7. Power angular spectrum for location Pt1, Pt2 and Pt3, (a) at 15 GHz, and (b) at 28 GHz.

The LOS path has a 3D path length of 116 m; whereas the reflected path has a path length of 156 m i.e. 40 m longer than the LOS path. Therefore, the strength of the reflected path is almost 17 dB and 22 dB less compared with the LOS path at 15 GHz and

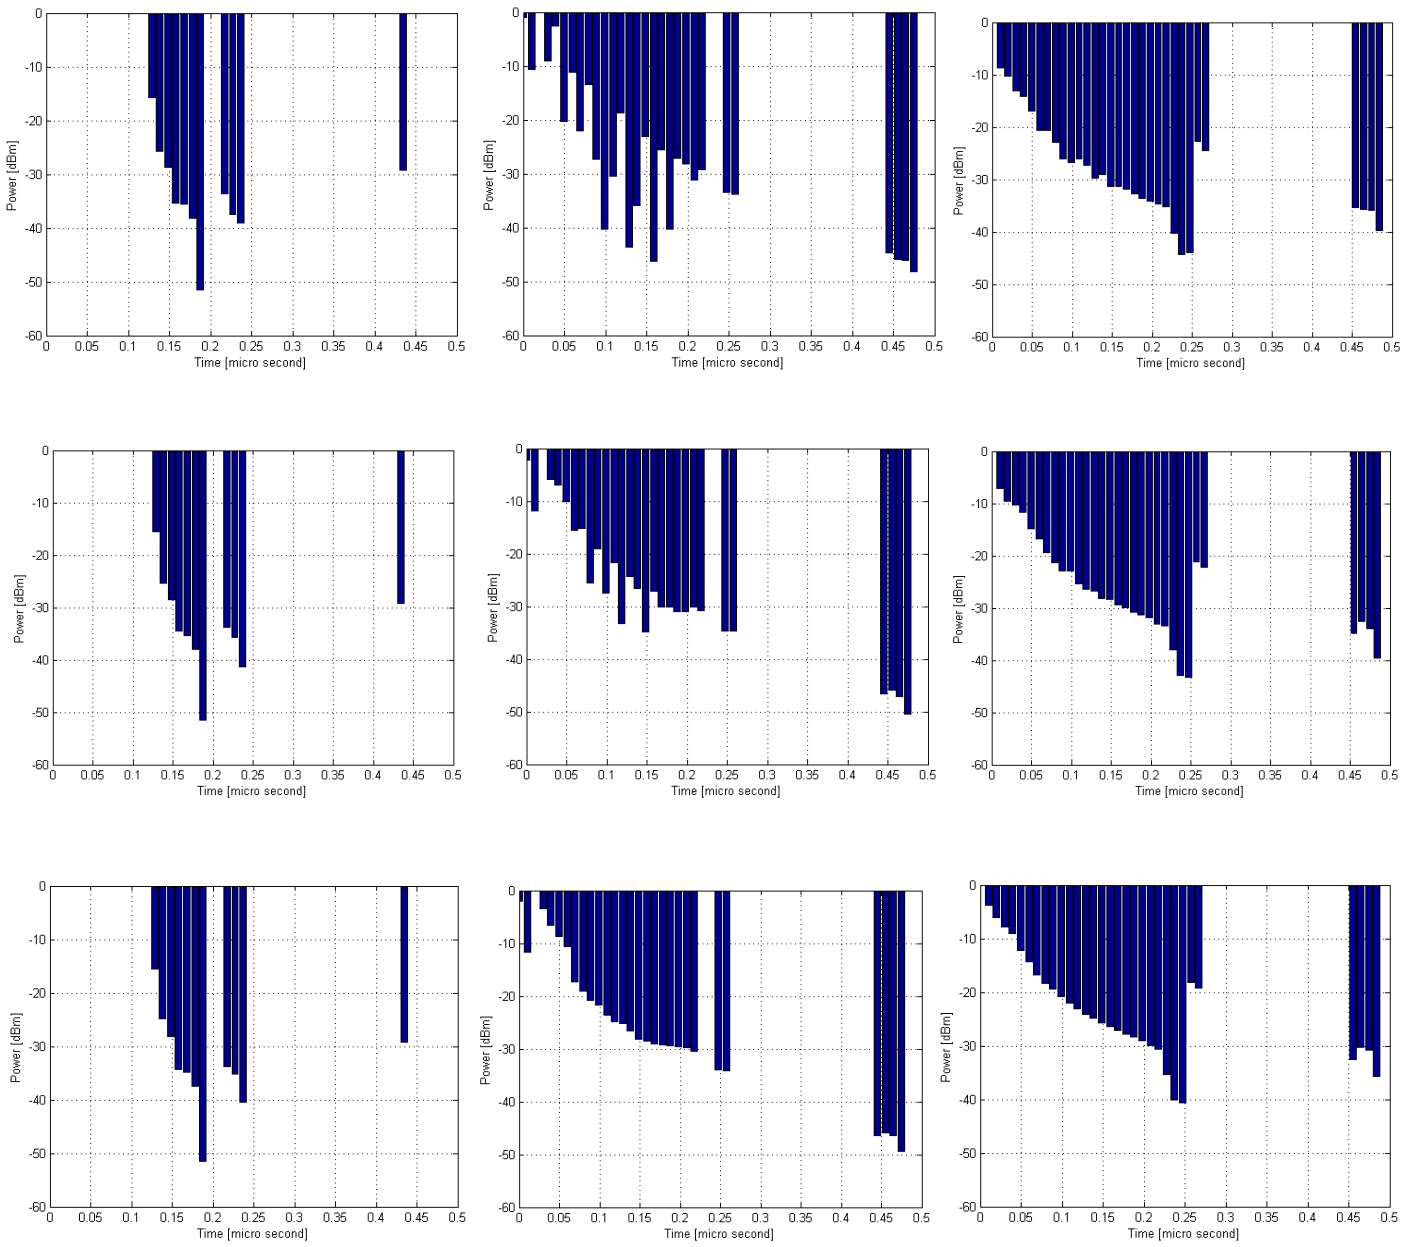

Figure 8. Power delay profile, (a) Pt1 (15GHz), (b) Pt2 (15GHz), (c) Pt3 (15GHz), (d) Pt1 (28GHz), (e) Pt2 (28GHz), (f) Pt3 (28GHz), (g) Pt1 (60GHz), (h) Pt2 (60GHz), and (i) Pt3 (60GHz).

28 GHz, respectively. However, at 60 GHz due to the presence of a large number of scattering components the composite strength of received signal components at -44° of DoA is almost 10 dB less compared with LOS direction. The Pt2 is located on the right side of the transmitter and has a valid LOS link with the transmitter

In Figure 7, the strongest path (LOS path) has around -120° of DoA and the other reflected path is reaching the receiver at -60°. At Pt2, the direct path has a path length of 98 m, and the reflected path has a path length of 104 m i.e. 6 m longer than the LOS path. Therefore, the strength of the reflected path is around 4 dB and 11 dB less compared with the LOS path at 15 GHz and 28 GHz, respectively. Also, the impact of diffused scattering from the wall at an angle of -60 ° at 28 GHz and 60 GHz is visible. The considered microcellular case is a simple environment, and not a multipath rich outdoor environment. Therefore, the most of the energy at the receiver points is coming from a narrow direction only. However, in an indoor environment, due to a rich indoor scattering environment the PAS of incoming multipath is wide spread, especially at higher frequencies i.e. 28 GHz and 60 GHz.

Figure 8 shows the Power Delay Profile (PDP) acquired through simulations of location Pt1, Pt2 and Pt3 at 15 GHz, 28 GHz and 60 GHz. For Pt1, the reflected path has 40 m longer path length therefore the reflected path reaches the receiver point with a delay of around 0.125 μs relative to LOS path, and the signal strength of the reflected path is around 16 dB less compared with LOS path. For Pt1, the power delay profile is almost identical at

15 GHz, 28 GHz, and 60 GHz. The Pt2 is located close to the wall of the building, and therefore the difference of path length between the reflected path and the LOS path is short. By comparing Figure 8(b), Figure 8(e), and Figure 8(h), it can be noted that the reflected path with slightly less signal strength than LOS path reaches the receiver point within a very short delay of 0.01 μs. Other diffracted and scattered paths from the nearby wall also reach the receiver Pt2 with a short delay period. The power delay profile of Pt2 got smoother at higher frequencies due to a large number of scattering paths at higher frequencies.

Indoor location Pt3 is located nearby the outdoor location Pt2. However, an indoor environment is a scattering rich environment and a larger number of scattering paths reach the receiver point with small delay. Therefore, the PDP of Pt3 is smoother compared with PDP of Pt2. It is interesting to find that the phenomenon of scattering becomes more prominent in higher frequencies, and the power of multipath components with short delay improves at 28 GHz and 60 GHz. The mean delay spread in nanoseconds for static location points are given in Table III.

Table III. Mean delay spread.

Location	Mean Delay Spread (ns)		
	15 GHz	28 GHz	60 GHz
Pt1	150	150	150
Pt2	109	107	106
Pt3	124	119	114

4. Conclusion

In this article, a multidimensional analysis of the multipath propagation in an outdoor and indoor microcellular environment has been carried out at higher frequencies i.e. 15 GHz, 28 GHz and 60 GHz, by means of a sophisticated ray tracing tool. The simulations are performed using a simplified 3D map of a small area from the Yokusuka city of Japan. The considered outdoor simulation routes and outdoor static points represent an open environment scenario with valid LOS link between the transmitter and the receiver in a microcellular environment. Indoor simulation routes and an indoor static point were also considered for studying indoor propagation at higher frequencies. The simulation results presented for different simulation routes at 15 GHz are in a close relationship with a measurement results presented in [9]. Similarly at 15 GHz for the selected static points the power angular spectrum (PAS) at receiver end acquired through simulations are in a satisfactory agreement with the measured PAS given at [9]. The power angular spectrum (PAS) at receiver shows the direction of arrival of LOS, specular reflected, diffracted and diffused scattered paths. It was found that mean received signal strength in an outdoor environment for the selected simulation routes at 15 GHz is almost 5.7 dB, and at 60 GHz the mean RX level is almost 13 dB inferior in comparison with the propagation at 15 GHz due to higher propagation loss at higher frequencies. The difference in a mean received signal in an indoor environment between 15 GHz and 28 GHz is extended to nearly 10. 5 dB, and the difference between the mean received signal in an indoor environment between 15 GHz and 60 GHz is further stretched to 28.5 dB due to extra building penetration loss at higher frequencies. However, the higher path loss at 28 GHz and 60 GHz can be compensated by using an antenna with higher gain. The power delay profile acquired through simulations was found helpful in distinguishing the multipath richness of the environment. The indoor was found more scattering rich environment compared with outdoor environment. The absolute values of performance results presented in this article may vary depending upon the modeling impairment, antenna radiation pattern, simulation parameters and simulation environment.

ABSTRACT

The paper shows a method of transforming an asynchronously feedbacked Mealy machine into a Moore machine. The transformation is done in dual-rail logic under the use of the RS-buffer. The transformed machine stabilizes itself and is safe to use. The transformation is visualized via KV-diagrams and calculated with formulas. We will present three use-cases for a better understanding. To underpin the stated transformation a simulation is also presented.

1 Introduction

A Synchronous circuits entail several benefits. Firstly performance advantages, e.g. faster system perfomance, no clock synchronization, fewer power consumption and fewer electromagnetic emission. Secondly asynchronous circuits also have safety advantages, e.q. no clock skew. Asynchronous circuits can also lead to simplicity, by connecting different parts modularly [1, 2]. On the other hand asynchronous circuits provide risks, such as faults like hazards, glitches and so on [3]. Therefore it is very important to design asynchronous circuits correctly, especially in safety critical applications such as in automotive, where human lives are at stake. To prevent faults like hazards, a mealy-to-moore transformation will be presented, which creates a function stable asynchronous machine. The Mealy machine with the state transfer function δ and the output function λ, see figure 1 be given. Each Mealy machine can be transformed into an equivalent Moore machine [3] for example by increasing the arity of δ by $|x|$ and coding it with x, $z' = (z,x)$ with $\delta'(z',x) \mapsto (\delta(z,x),x)$, and the output function is only dependent on the new state variable z' with $\mu : (z') \mapsto \mu(z')$.
By comparing the two machines the pros and cons can be shown. Therefore the idea of transforming the machines into each other to profit from the benefits of both is obvious. Mealy machines have the advantage of requiring less states since one state can produce a number of different outputs in combination with the input. A Moore machine's state on the other hand only produces one output. A Mealy machine is also faster by reacting directly to the input. This feature however is not always wanted, since it can lead to undesired outputs (e.g. hazards, glitches) when the input is variable. A Moore machine is more stable in this regard, since it only indirectly reacts to input changes. The output only changes when transferring into the next state. Transforming a Mealy machine into a Moore machine is therefore useful in case a direct dependence on the input is to be avoided [2].
In the paper the transformation of a Mealy machine into a Moore machine is presented. The machine will be designed under the use of dual-rail logic and the RS-buffer, and will stabilize itself. Firstly the transformation is made by breaking the feedback up and nesting it in the RS-buffer, secondly by encoding the inputs as states, so that the output function is only dependent on pseudo states. With the method presented in this article, function stable sequential circuit parts can be seen as combinational logic and moved over other blocks at will. With this method, individual machines can be strung together to realize complex circuits for safety relevant applications.

2 Theory

This paper describes the underlying theory of the transformation and provides an illustrative example.

Figure 1 shows a fully asynchronous Mealy machine. The branches entering a node in the graph should end reflexively, so that only transient states are allowed which are conscious and triggered from the outside [2]. To consider all branches of the Mealy machine as locally reflexively

*Corresponding Author: Mustafa Oezguel, mustafa.oezguel@fau.de

https://dx.doi.org/10.25046/aj020621

concluded, the feedback should be moved over λ, making the output y the feedback. In order to set the correct state z for the transfer function δ, a function λ^{-1} is realized. This function generates the reduced state $\underline{z}$ from the feedback y. This equivalent transformation is outlined in figure 2.

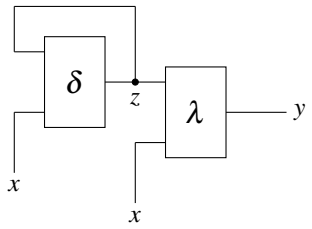

Figure 1: Fully asynchronous Mealy machine

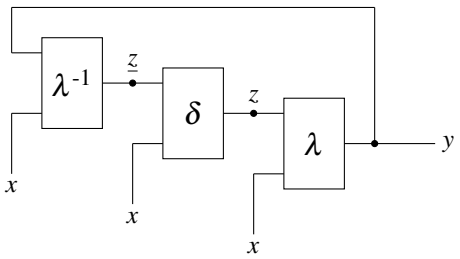

Figure 2: Equivalent transformation

The following applies:

$$\begin{aligned} \delta(\underline{z},x) &= \underline{z} \\ \delta\left(\lambda^{-1}(y,x),x\right) &= \lambda^{-1}(y,x) \\ \lambda\left(\delta\left(\lambda^{-1}(y,x),x\right),x\right) &= y \\ \text{mit } \lambda\left(\lambda^{-1}(y,x),x\right) &= y \end{aligned}$$

The next stage of transformation shows at first sight no feedback. Only the RS-buffer, which is in $\underline{\delta}$, has a nested feedback. This transformation is outlined in figure 3. Transient states can be triggered via the input, while state stable states are being held via the RS-buffer. In order to set the correct state $\underline{z}$ to μ, the function $\underline{\delta}$ must be well designed, which will be shown in the following sections.

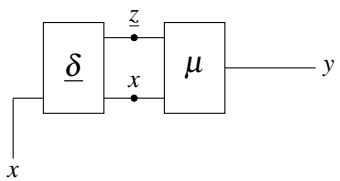

Figure 3: Moore transformation

The following applies:

$$\begin{aligned} \underline{\delta}(\underline{z},x) &= \underline{z} \\ \mu(\underline{z},x) &= y \end{aligned}$$

2.1 Dual-rail logic

For the implementation in dual-rail logic [4], the fully asynchronous circuit from figure 1 will be divided in the 1- and 0-share. This is done by partitioning the state transfer function and the output function, see figure 4.

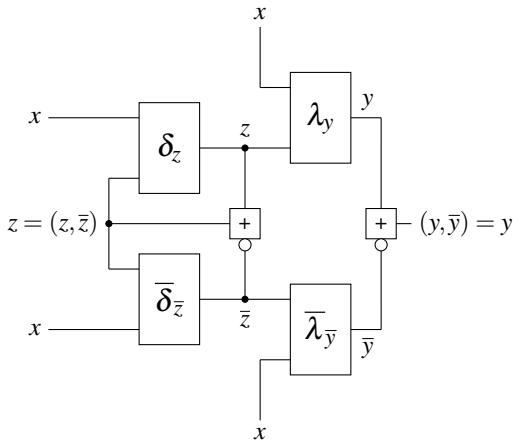

Figure 4: Mealy realized in dual-rail logic

The functions δ and λ are each w.l.o.g. realized in two blocks $\delta = (\delta_z, \overline{\delta}_{\overline{z}})$ and $\lambda = (\lambda_z, \overline{\lambda}_{\overline{z}})$. In order to guarantee this secure dual rail structure, RS-buffers are used. The mode of operation corresponds in a certain manner to the C-element [4, 5]. The function $\underline{\delta}$ of figure 3 will be designed by appropriate coding according to the RS-buffer, showing a general structure as outlined in figure 5.

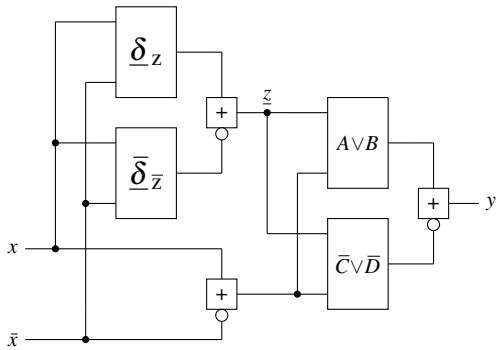

Figure 5: Transformed Moore

The stabilized 1-states, $\underline{\Lambda}_z \circ\!\!-\!\!\bullet \underline{z}$, are transformed into 1-outputs, $\Lambda_{\underline{y}} \circ\!\!-\!\!\bullet \underline{y}$. The corresponding Venn diagram of the stabilized 1-states in 1-outputs can be seen in figure 6. 1-states that appear as 0-outputs are declared as $\overline{\Lambda}_{\underline{z}}$, 0-states which appear as 1-outputs are declared as $\Lambda_{\overline{z}}$. The 1-partition is composed of:

$$\Lambda_{\underline{y}} \circ\!\!-\!\!\bullet \lambda_y(\underline{\delta}_z) + \lambda_y(\underline{\overline{\delta}}_{\overline{z}}) + \overline{\lambda}_{\overline{y}}(\underline{\delta}_z)$$

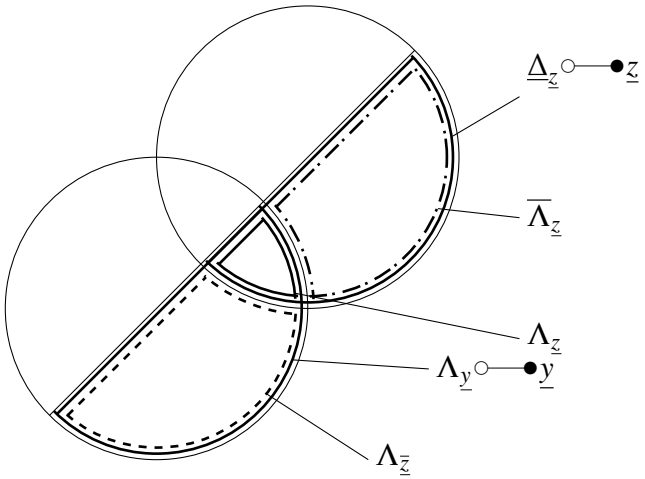

Figure 6: Venn diagram of 1-states in 1-outputs

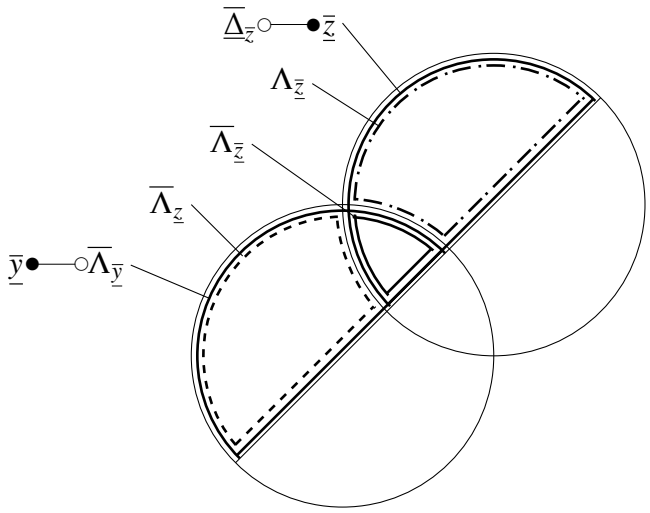

Figure 7: Venn diagram of 0-states in 0-outputs

The stabilized 0-states, $\overline{\underline{\Delta}}_{\overline{\underline{z}}} \circ\!\!-\!\!\bullet \overline{\underline{z}}$, are transformed into 0-outputs, $\overline{\Lambda}_{\overline{\underline{y}}} \circ\!\!-\!\!\bullet \overline{\underline{y}}$. The corresponding Venn diagram of the 0-states in 0-outputs is shown in figure 7. 0-states which appear as 1-outputs are declared as $\Lambda_{\overline{\underline{z}}}$, 1-states which appear as 0-outputs are declared as $\overline{\Lambda}_{\underline{z}}$. The 0-partition is composed of:

$$\overline{\Lambda}_{\overline{\underline{y}}} \circ\!\!-\!\!\bullet \overline{\lambda}_{\overline{y}}(\overline{\underline{\delta}}_{\overline{z}}) + \overline{\lambda}_{\overline{y}}(\underline{\delta}_{\underline{z}}) + \lambda_{y}(\overline{\underline{\delta}}_{\overline{z}})$$

To understand the coding, first the RS-buffer has to be understood.

2.2 RS-Buffer

The RS-Buffer used and its circuit symbol are represented in figure 8 and 9 and

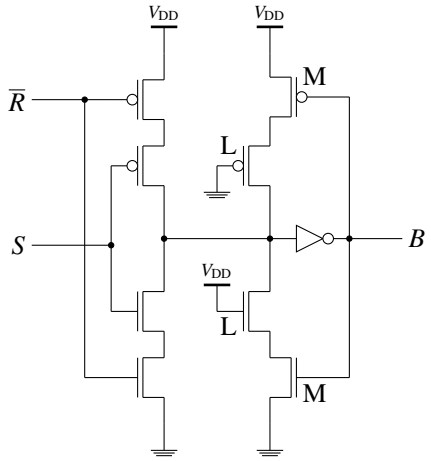

Figure 8: RS-Buffer (schematic)

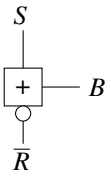

Figure 9: Circuit symbol of the used RS-Buffer

its truth table is specified in table 1.

R	0	0	1	1
S	0	1	0	1
B	B	1	0	B

Table 1: Truth table of the RS-Buffer

The RS-buffer is used to synchronize a dual-rail signal by only letting a state tranfer happen, if both incoming signals are disjoint (how it is desired) to each other. This means that there is no overlaying of signal, which could lead to fatal faults. The RS-buffer consists of the tri-state driver, which is the first state and the second stage the so called babysitter. The driving structure now provides 3 functions. Firstly the setting signal, which means the output is in the logical 1-state. Secondly the resetting signal, which means the output is in logical 0-state and least the hold state which holds the last state at the output by keeping the signal in the babysitter and having a high impedance state at the tri state. The babysitter consists of two complementary loops. The formula for the output B is therefore $B := \overline{R}(B \vee S) \vee S(B \vee \overline{R}) = \overline{R}S \vee \overline{R}B \vee SB$.

2.3 Design of the reduced state transfer function $\underline{\delta}$

As you can see the RS-buffer is coded via a 3-partitioning. There is the setting signal S=[1], the resetting signal R=[1] and the hold signal RS=[00]$\vee$[11]. The state transfer function of an automaton can in turn be split in 4 parts. Firstly

the transient 1-share, that means independent of the state the next state will be at logical 1, secondly the transient 0-share, that means output at logical 0 independent of the state, thirdly the state stable share of the state transfer function, that means the share, which is at constant input dependent on the value of the last state and the state instable state, which means a permanent change of the state at constant input, see figure 10. The resulting 3 parts, which are left, can now be easily compared to the 3-partitition of the RS-buffer. The transient 1-share $\underline{\delta}_z$ is realized by the setting signal of the RS-buffer, similar the transient 0-share $\overline{\underline{\delta}}_{\overline{z}}$ is realized by the resetting signal and the state stable share is realized by the hold signal of the RS-buffer.

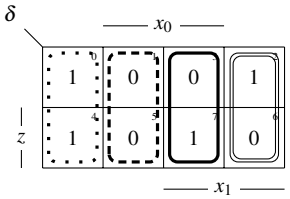

Figure 10: Parts of a state transfer function

To understand the transformation, first a few compositions must be defined:

$$
\begin{aligned}
{}_{z}\delta(z,x) &= \delta(z=1,x)\\
{}_{\overline{z}}\delta(z,x) &= \delta(z=0,x)\\
{}_{z}\overline{\delta}(z,x) &= \overline{\delta}(z=1,x)\\
{}_{\overline{z}}\overline{\delta}(z,x) &= \overline{\delta}(z=0,x)
\end{aligned}
$$

This work only concentrates on function stable machines, so that state instable parts are not allowed. State instable parts can be deduced via

$${}_{z}\overline{\delta} \wedge {}_{\overline{z}}\delta$$

Functions must not exhibit these parts. The other parts can be deduced by the following expressions

$$
\begin{aligned}
&\text{transient } 1: \underline{\delta}_z = {}_{z}\delta \wedge {}_{\overline{z}}\delta\\
&\text{transient } 0: \overline{\underline{\delta}}_{\overline{z}} = {}_{z}\overline{\delta} \wedge {}_{\overline{z}}\overline{\delta}\\
&\text{state stable}: {}_{z}\delta \wedge {}_{\overline{z}}\overline{\delta}
\end{aligned}
$$

This leads to the genereal formula for $\underline{\delta}_i$ for n states:

$$
\begin{aligned}
\underline{\delta}_{z_i} &= \underline{\delta}_{z_i} + \neg\overline{\underline{\delta}}_{\overline{z}_i}\\
&= ({}_{z_i}\delta_{z_i} \wedge {}_{\overline{z}_i}\delta_{z_i}) + \neg({}_{z_i}\overline{\delta}_{\overline{z}_i} \wedge {}_{\overline{z}_i}\overline{\delta}_{\overline{z}_i})\\
&= (\delta_{z_i}(z_i=1,x) \wedge \delta_{z_i}(z_i=0,x))\\
&+ \neg(\overline{\delta}_{\overline{z}_i}(z_i=1,x) \wedge \overline{\delta}_{\overline{z}_i}(z_i=0,x))
\end{aligned}
$$

with $i = 0...n-1$

2.4 Design of the output function

The detailed description of the Venn-diagrams given in figure 11 and 12 is reported in [6].

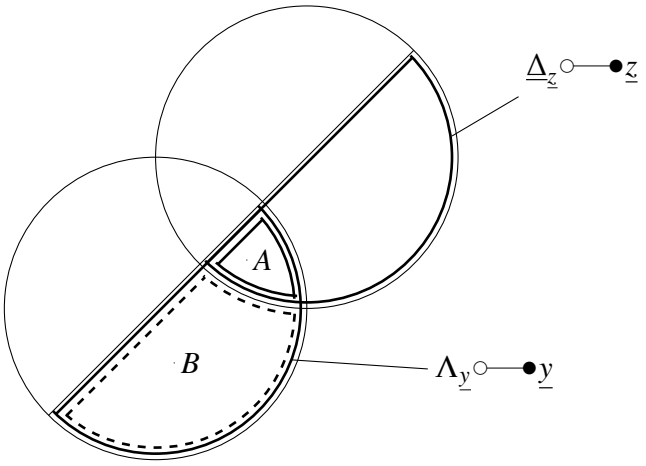

Figure 11: Venn-diagram of 1-states in 1-outputs

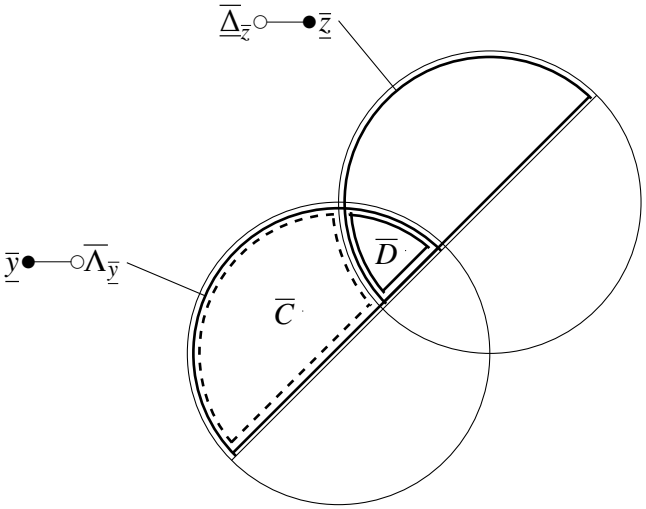

Figure 12: Venn-diagram of 0-states in 0-outputs

The coding of the parts A, B, $\overline{C}$ and $\overline{D}$ of the Venn-diagrams, see figure 11 and figure 12, is as follows:

$$
\begin{aligned}
&(z,y)\\
&(11) = A = \delta_z \wedge \lambda_y\\
&(01) = B = \overline{\delta}_{\overline{z}} \wedge \lambda_y\\
&(10) = \overline{C} = \delta_z \wedge \overline{\lambda}_{\overline{y}}\\
&(00) = \overline{D} = \overline{\delta}_{\overline{z}} \wedge \overline{\lambda}_{\overline{y}}
\end{aligned}
$$

The dual-rails y and $\overline{y}$ for y are now:

$$
\begin{aligned}
y &= A \vee B\\
\overline{y} &= \overline{C} \vee \overline{D}\\
y &= y + \neg\overline{y}
\end{aligned}
$$

The seperate parts of the machine have now been deduced and can simply be strung together to get the form of figure 5.

3 Use-Case

To get a better insight, three examples will be presented.

3.1 1-dimensional example

For $x = (x_1, x_0)$, $y = (y)$ and $z = (z)$ the transformation of the Mealy machine $(X, Y, Z, \delta, \lambda)$ with the state transfer function and output function

$$\delta(z,x) = x_1x_0 \vee z\overline{x}_1x_0 \qquad \lambda(z,x) = \overline{x}_1x_0 \vee z\overline{x}_1$$

will be executed. The automaton before the transformation can be seen in figure 13.

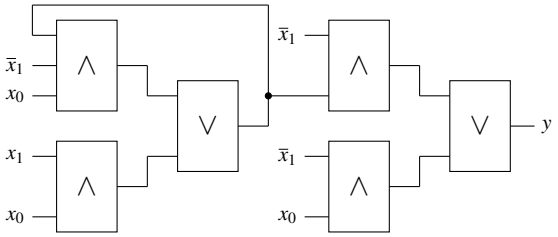

Figure 13: Mealy machine before the transformation

3.1.1 Design of $\underline{\delta}$

The KV-diagram of the state transfer function can be seen in figure 14.

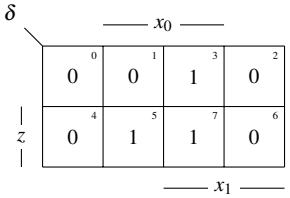

Figure 14: The state transfer function

To code the RS-buffer correctly, firstly the KV-diagram will be compacted, see figure 15.

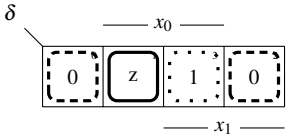

Figure 15: Compacted KV-diagram of δ

The parts of the state transfer function can easily be seen and the KV-diagrams for $\underline{\delta}_z$ and $\overline{\underline{\delta}}_{\overline{z}}$ can be deployed, see figure 16. For $\overline{\underline{\delta}}_{\overline{z}}$ 0 is coded as 1 and 1 is coded as 0 respectively, because of the dual-rail structure.

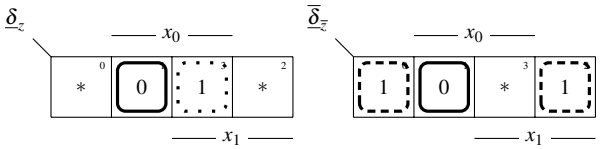

Figure 16: $\underline{\delta}_z$ and $\overline{\underline{\delta}}_{\overline{z}}$

For the next steps of the transformation, first the complement of δ has to be calculated:

$$\overline{\delta}(z,x) = \overline{z}\overline{x}_1 \vee \overline{x}_0$$

The parts of the state transfer function are:

$$\begin{aligned} {}_z\delta &= \delta(z=1,x) = x_0 \\ {}_{\overline{z}}\delta &= \delta(z=0,x) = x_1x_0 \\ {}_z\overline{\delta} &= \overline{\delta}(z=1,x) = \overline{x}_0 \\ {}_{\overline{z}}\overline{\delta} &= \overline{\delta}(z=0,x) = \overline{x}_1 \vee \overline{x}_0 \end{aligned}$$

It has to be checked, if there are any instable parts:

$${}_{\overline{z}}\delta_z \wedge {}_z\overline{\underline{\delta}}_{\overline{z}} = x_1x_0 \wedge \overline{x_0} = 0$$

${}_{\overline{z}}\delta \wedge {}_z\overline{\delta}$ is 0 means the function has no instable parts. The functions $\underline{\delta}_z$ and $\overline{\underline{\delta}}_{\overline{z}}$ can now be calculated via

$$\begin{aligned} \underline{\delta}_z &= {}_z\delta_z \wedge {}_{\overline{z}}\delta_z = x_1x_0 \\ \overline{\underline{\delta}}_{\overline{z}} &= {}_z\overline{\delta}_{\overline{z}} \wedge {}_{\overline{z}}\overline{\delta}_{\overline{z}} = \overline{x}_0 \end{aligned}$$

The coding for $\underline{\delta}$ of the RS-buffer is as follows:

$$\begin{aligned} &(r\ s) \\ \text{Set:} &(*1) = x_1x_0\ (\underline{\text{transient 1-share}}) = \underline{\delta}_z \\ \text{Reset:} &(1*) = \overline{x}_0\ (\underline{\text{transient 0-share}}) = \overline{\underline{\delta}}_{\overline{z}} \\ \text{Hold:} &(**) = \overline{x}_1x_0\ (\underline{\text{state stable share}}) \end{aligned}$$

Now $\underline{\delta}$ can be derived:

$$\begin{aligned} \underline{\delta} &= \underline{\delta}_z + \neg\overline{\underline{\delta}}_{\overline{z}} \\ &= x_1x_0 + \neg(\overline{x}_0) \end{aligned}$$

3.1.2 Design of λ

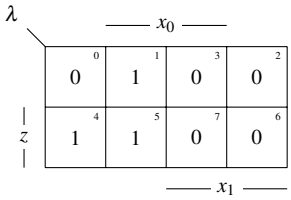

Figure 17: Output function λ

The stabilized state transfer function has now been designed, now the output function must be designed. Therefore the output function has to be layed over the state transfer function and the parts have to be specified:

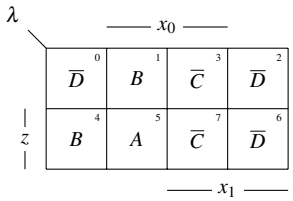

Figure 18: Parts of the output function

The parts are:

$$A(z,x) = z\overline{x}_1x_0$$
$$B(z,x) = \overline{z}\overline{x}_1x_0 \vee z\overline{x}_1\overline{x}_0$$
$$\overline{C}(z,x) = x_1x_0$$
$$\overline{D}(z,x) = x_1\overline{x}_0 \vee \overline{z}\overline{x}_0$$

This leads to the output function:

$$y = A \vee B = \overline{x}_1x_0 \vee z\overline{x}_1$$
$$\overline{y} = \overline{C} \vee \overline{D} = x_1 \vee \overline{z}\overline{x}_0$$
$$y = y + \neg\overline{y} = \overline{x}_1x_0 \vee z\overline{x}_1 + \neg(x_1 \vee \overline{z}\overline{x}_0)$$

The resulting automaton has the form of figure 19 with the determined functions $y = A \vee B$ and $\overline{y} = \overline{C} \vee \overline{D}$.

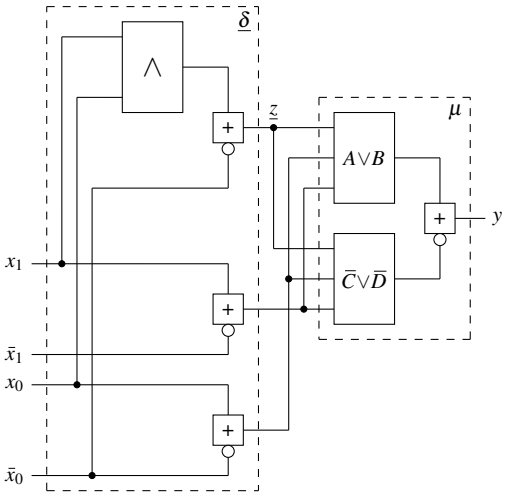

Figure 19: Transformed Moore

The truth table of the automaton:

#	z	x_1	x_0	δ	$\underline{\delta}_z$	$\overline{\underline{\delta}}_{\overline{z}}$	$\underline{\delta}$	λ	A	B	$\overline{C}$	$\overline{D}$	$A \vee B$	$\overline{C} \vee \overline{D}$	y
0	0	0	0	0	*	1	0	0	*	*	*	1	*	1	0
1	0	0	1	0	*	*	0	1	*	1	*	*	1	*	1

Table 2: Partial truth table of the resulting automaton

3.2 2-dimensional example

For $x = (x_1, x_0)$, $y = (y)$ and $z = (z_1, z_0)$ the transformation of the Mealy machine $(X, Y, Z, \delta, \lambda)$ with the state transfer functions and output function

$$\delta_{z_0}(z,x) = \overline{x}_0 \vee z_1x_1 \qquad \delta_{z_1}(z,x) = z_0x_1x_0 \vee z_1x_1\overline{x}_0$$
$$\lambda(z,x) = z_1x_1 \vee z_0\overline{x}_1\overline{x}_0$$

will be executed. The machine before the transformation is outlined in figure 20.

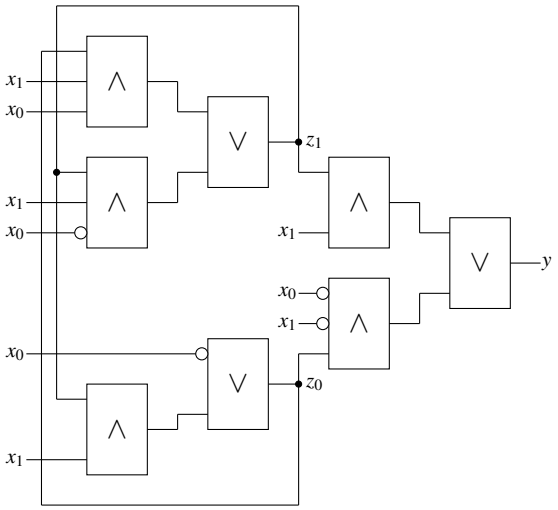

Figure 20: Automaton before the transformation

3.2.1 Design of $\underline{\delta}_{z_0}$

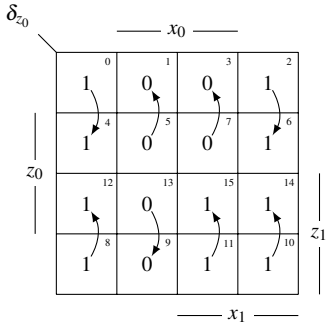

Figure 21: KV-diagram of δ_{z_0}

The KV-diagram of figure 21 will be lossless compacted given by the pointers in the diagram to the diagram of figure 22.

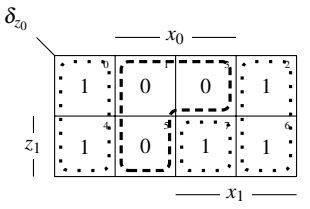

Figure 22: compacted KV-diagram of δ_{z_0}

With the compacted KV-diagram the RS-buffer for δ_{z_0} can be coded by specifying the functions $\underline{\delta}_{z_0}$ and $\overline{\underline{\delta}}_{\overline{z}_0}$, see

figure 23. The partial function $\underline{\delta}_{z_0}$ delivers the 1's of δ_{z_0} as 1's, while $\overline{\underline{\delta}}_{\bar{z}_{z_0}}$ delivers the 0's of δ_{z_0} as 1's. In this state transfer function, there is no state stable part only transient parts. Making the stable $\underline{\delta}_{z_0}$ a normal dual-rail structure.

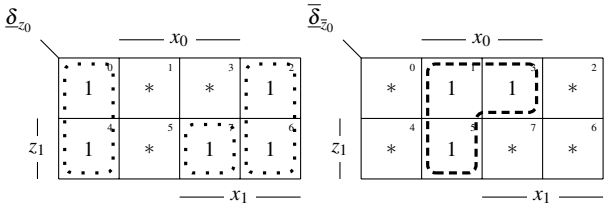

Figure 23: $\underline{\delta}_{z_0}$ and $\overline{\underline{\delta}}_{\bar{z}_0}$

State instable parts are not allowed in the state transfer function:

$$\bar{z}_0\delta_{z_0} \wedge_{z_0} \overline{\delta}_{\bar{z}_0} = (\bar{x}_0 \vee z_1x_1) \wedge (\bar{z}_1x_0 \vee \bar{x}_1x_0) = 0$$

Now the resulting $\underline{z}_0$ can be calculated:

$$\begin{aligned}
\underline{\delta}_{z_0}(z,x) &= {}_{z_0}\delta_{z_0} \wedge_{\bar{z}_0} \delta_{z_0} = \bar{x}_0 \vee z_1x_1 \\
\overline{\underline{\delta}}_{\bar{z}_0}(z,x) &= {}_{z_0}\overline{\delta}_{\bar{z}_0} \wedge_{\bar{z}_0} \overline{\delta}_{\bar{z}_0} = \bar{z}_1x_0 \vee \bar{x}_1x_0 \\
\underline{z}_0 &:= \underline{\delta}_{z_0} + \neg(\overline{\underline{\delta}}_{\bar{z}_0}) \\
\underline{z}_0 &:= \bar{x}_0 \vee z_1x_1 + \neg(\bar{x}_1x_0 \vee \bar{z}_1x_1)
\end{aligned}$$

3.2.2 Design of $\underline{\delta}_{z_1}$

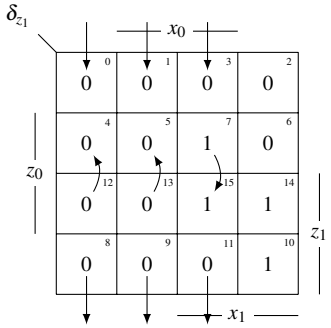

Figure 24: KV-diagram of δ_{z_1}

For $\underline{\delta}_{z_1}$ the same approach applies. First the KV-diagram, see figure 24, will be compacted:

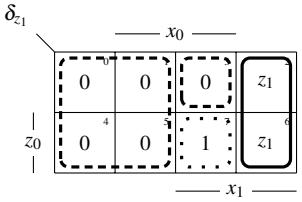

Figure 25: compacted KV-diagram of δ_{z_1}

Now the functions $\underline{\delta}_{z_1}$ and $\overline{\underline{\delta}}_{\bar{z}_1}$ can be deduced:

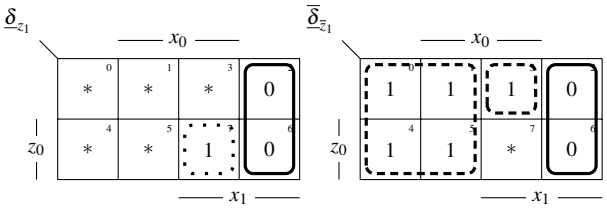

Figure 26: KV-diagrams for $\underline{\delta}_{z_1}$ and $\overline{\underline{\delta}}_{\bar{z}_1}$

First δ_{z_1} is checked for instable parts:

$$\bar{z}_1\delta_{z_1} \wedge_{z_1} \overline{\delta}_{\bar{z}_1} = z_0x_1x_0 \wedge (\bar{z}_0x_0 \vee \bar{x}_1) = 0$$

No instable parts, so the RS-buffer can be coded for δ_{z_1} by determining the functions $\underline{\delta}_{z_1}$ and $\overline{\underline{\delta}}_{\bar{z}_1}$:

$$\begin{aligned}
\underline{\delta}_{z_1}(z,x) &= {}_{z_1}\delta_{z_1} \wedge_{\bar{z}_1} \delta_{z_1} = z_0x_1x_0 \\
\overline{\underline{\delta}}_{\bar{z}_1}(z,x) &= {}_{z_1}\overline{\delta}_{\bar{z}_1} \wedge_{\bar{z}_1} \overline{\delta}_{\bar{z}_1} = \bar{x}_1 \vee \bar{z}_0x_0 \\
\underline{z}_1 &:= \underline{\delta}_{z_1} + \neg(\overline{\underline{\delta}}_{\bar{z}_1}) \\
\underline{z}_1 &:= z_0x_1x_0 + \neg(\bar{x}_1 \vee \bar{z}_0x_0)
\end{aligned}$$

3.2.3 Design of λ

The KV-diagram of λ can be seen in 27. Because of the two-dimensional state, λ has to be divided into eight parts. They exist as follows:

(z_1, z_0, y)	$(z_1, z_0, \bar{y})$
$(001) = A$	$(001) = \overline{E}$
$(011) = B$	$(011) = \overline{F}$
$(101) = C$	$(101) = \overline{G}$
$(111) = D$	$(111) = \overline{H}$

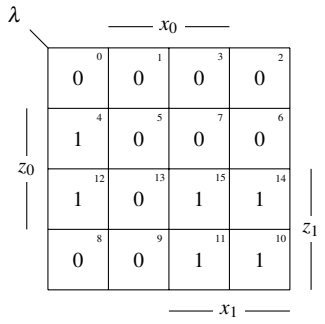

Figure 27: KV-diagram of λ

The parts of λ are set up in the KV-diagram, see figure 28.

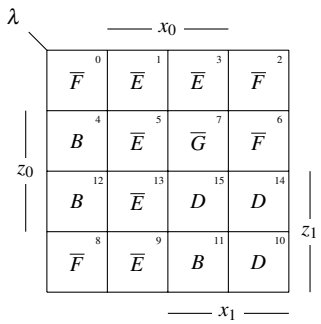

Figure 28: Parts of λ

The output functions y and $\bar{y}$ can be inferred from this:

$$
\begin{aligned}
y &= A \vee B \vee C \vee D \\
&= z_0\bar{x}_1\bar{x}_0 \vee z_1\bar{z}_0x_1x_0 \vee z_1x_1\bar{x}_0 \vee z_1z_0x_1 \\
&= z_1x_1 \vee z_0\bar{x}_1\bar{x}_0 \\
\bar{y} &= \overline{E} \vee \overline{F} \vee \overline{G} \vee \overline{H} \\
&= \bar{x}_1x_0 \vee \bar{z}_1\bar{z}_0x_0 \vee \bar{z}_0\bar{x}_0\bar{x}_1 \vee \bar{z}_1x_1\bar{x}_0 \vee \bar{z}_1\bar{z}_0\bar{x}_0 \vee \bar{z}_1z_0x_1x_0 \\
&= \bar{x}_1x_0 \vee \bar{z}_1x_1 \vee \bar{z}_0\bar{x}_1
\end{aligned}
$$

The resulting automaton can be seen in 30. As you can see in table 3, situation 7 leads to a cycle, by stepping to configuration 11, which steps back to configuration 7, and so on. So to have a state stable design in multistate machines, it is also necessary to regard the transitions between the states. A rule has to be found, to filter these race conditions. In the following transformation the auomaton of subsection b is stabilized, by changing δ_{z_1}.

3.3 Stable 2-dimensional example

The state transfer function δ_{z_1} has now been changed, to make it a stable automaton. For $x = (x_1, x_0)$, $y = (y)$ and $z = (z_1, z_0)$ the transformation of the Mealy machine $(X, Y, Z, \delta, \lambda)$ with the state transfer functions and output function

$$\delta_{z_0}(z,x) = \bar{x}_0 \vee z_1x_1 \qquad \delta_{z_1}(z,x) = z_0x_1x_0 \vee z_1x_1$$

$$\lambda(z,x) = z_1x_1 \vee z_0\bar{x}_1\bar{x}_0$$

will be executed. The machine before the transformation is outlined in figure 29.

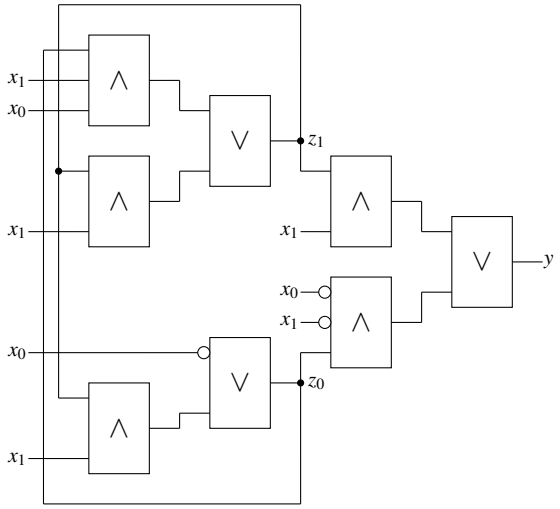

Figure 29: Automaton before the transformation

3.3.1 Design of $\underline{\delta}_{z_0}$

The KV-diagram of figure 31 will be lossless compacted given by the pointers in the diagram to the diagram of figure 32.

#	z_1	z_0	x_1	x_0	δ_{z_1}	δ_{z_0}	$\underline{\delta}_{z_1}$	$\overline{\underline{\delta}}_{\bar{z}_1}$	$\underline{\delta}_{z_1}$	$\underline{\delta}_{z_0}$	$\overline{\underline{\delta}}_{\bar{z}_0}$	$\underline{\delta}_{z_0}$	λ	A	B	C	D	$\overline{E}$	$\overline{F}$	$\overline{G}$	$\overline{H}$	y	$\bar{y}$	y

Table 3: Truth table of the transformed automaton

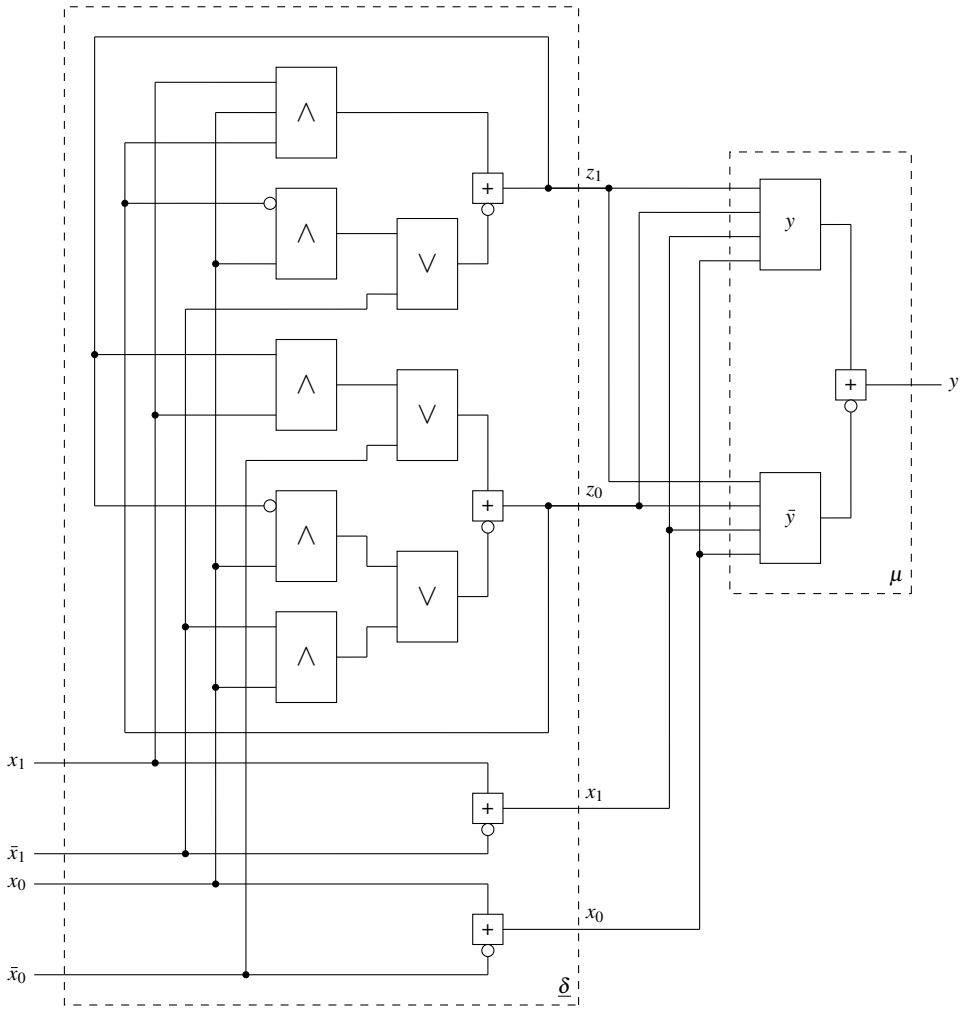

Figure 30: Resulting automaton

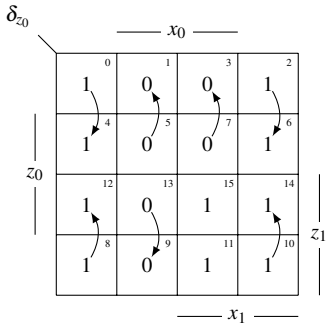

Figure 31: KV-diagram of δ_{z_0}

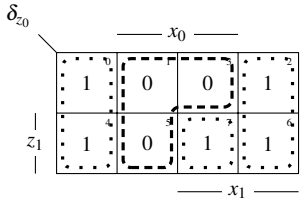

Figure 32: compacted KV-diagram of δ_{z_0}

With the compacted KV-diagram the RS-buffer for δ_{z_0} can be coded by specifying the functions $\underline{\delta}_{z_0}$ and $\overline{\underline{\delta}}_{\bar{z}_0}$, see figure 33.

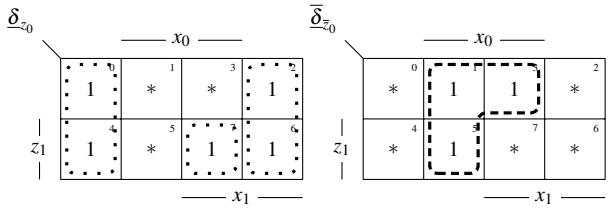

Figure 33: $\underline{\delta}_{z_0}$ and $\overline{\underline{\delta}}_{\bar{z}_0}$

State instable parts are not allowed in the state transfer function:

$$_{\bar{z}_0}\delta_{z_0} \wedge {}_{z_0}\overline{\delta}_{\bar{z}_0} = (\bar{x}_0 \vee z_1 x_1) \wedge (\bar{z}_1 x_0 \vee \bar{x}_1 x_0) = 0$$

Now the resulting $\underline{z}_0$ can be calculated:

$$\underline{\delta}_{z_0}(z,x) = {}_{z_0}\delta_{z_0} \wedge {}_{\bar{z}_0}\delta_{z_0} = \bar{x}_0 \vee z_1 x_1$$
$$\overline{\underline{\delta}}_{\bar{z}_0}(z,x) = {}_{z_0}\overline{\delta}_{\bar{z}_0} \wedge {}_{\bar{z}_0}\overline{\delta}_{\bar{z}_0} = \bar{z}_1 x_0 \vee \bar{x}_1 x_0$$
$$\underline{z}_0 := \underline{\delta}_{z_0} + \neg(\overline{\underline{\delta}}_{\bar{z}_0})$$
$$\underline{z}_0 := \bar{x}_0 \vee z_1 x_1 + \neg(\bar{x}_1 x_0 \vee \bar{z}_1 x_1)$$

3.3.2 Design of $\underline{\delta}_{z_1}$

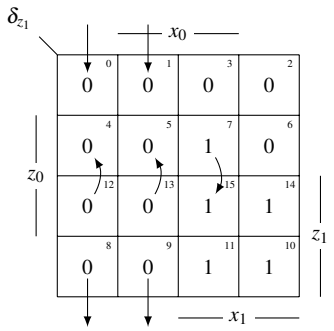

Figure 34: KV-diagram of δ_{z_1}

For $\underline{\delta}_{z_1}$ the same approach applies. First the KV-diagram, see figure 34, will be compacted:

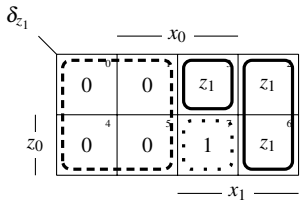

Figure 35: compacted KV-diagram of δ_{z_1}

Now the functions $\underline{\delta}_{z_1}$ and $\overline{\underline{\delta}}_{\bar{z}_1}$ can be deduced:

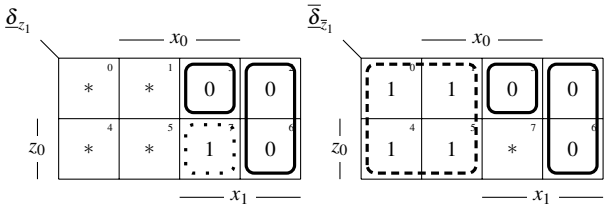

Figure 36: KV-diagrams for $\underline{\delta}_{z_1}$ and $\overline{\underline{\delta}}_{\bar{z}_1}$

First δ_{z_1} is checked for instable parts:

$$_{\bar{z}_1}\delta_{z_1} \wedge _{z_1}\overline{\delta}_{\bar{z}_1} = z_0x_1x_0 \wedge \bar{x}_1 = 0$$

No instable parts, so the RS-buffer can be coded for δ_{z_1} by determining the functions $\underline{\delta}_{z_1}$ and $\overline{\underline{\delta}}_{z_1}$:

$$\underline{\delta}_{z_1}(z,x) = _{z_1}\delta_{z_1} \wedge _{\bar{z}_1}\delta_{z_1} = z_0x_1x_0$$
$$\overline{\underline{\delta}}_{\bar{z}_1}(z,x) = _{z_1}\overline{\delta}_{\bar{z}_1} \wedge _{\bar{z}_1}\overline{\delta}_{\bar{z}_1} = \bar{x}_1$$
$$\underline{z}_1 := \underline{\delta}_{z_1} + \neg(\overline{\underline{\delta}}_{\bar{z}_1})$$
$$\underline{z}_1 := z_0x_1x_0 + \neg(\bar{x}_1)$$

3.3.3 Design of λ

The KV-diagram of λ can be seen in 37. Because of the two-dimensional state, λ has to be divided into eight parts. They exist as follows:

(z_1,z_0,y)	$(z_1,z_0,\bar{y})$
$(001) = A$	$(001) = \overline{E}$
$(011) = B$	$(011) = \overline{F}$
$(101) = C$	$(101) = \overline{G}$
$(111) = D$	$(111) = \overline{H}$

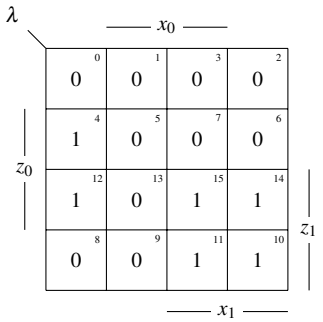

Figure 37: KV-diagram of λ

The parts of λ are set up in the KV-diagram, see figure 38.

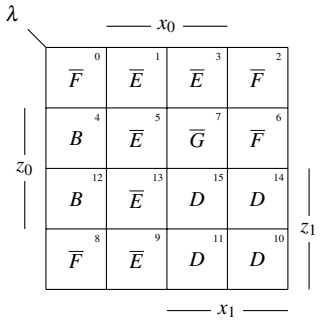

Figure 38: Parts of λ

The output functions y and $\bar{y}$ can be inferred from this:

$$\begin{aligned} y &= A \vee B \vee C \vee D \\ &= z_0\bar{x}_1\bar{x}_0 \vee z_1x_1 \\ \bar{y} &= \overline{E} \vee \overline{F} \vee \overline{G} \vee \overline{H} \\ &= \bar{x}_1x_0 \vee \bar{z}_1\bar{z}_0x_0 \vee \bar{z}_0\bar{x}_1\bar{x}_0 \vee \bar{z}_1x_1\bar{x}_0 \vee \bar{z}_1z_0x_1x_0 \\ &= \bar{x}_1x_0 \vee \bar{z}_1x_1 \vee \bar{z}_0\bar{x}_1 \end{aligned}$$

4 Test of Theory

To confirm the theory presented in the article, the state transfer function of the one dimensional example was analyzed making it a Medvedev. To simulate the circuit it was modelled with NAND gates and simulated in LT-Spice. The modeled NAND structure then was realized on the circuit board and the output was captured via an oszilloscope. The Medvedev machine $(X,Y,Z,\delta,1)$ with $x = (x_1,x_0)$, $y = (y)$ and $z = (z)$ with the state transformation function and output function be given:

The table and circuit:

#	z_1	z_0	x_1	x_0	δ_{z_1}	δ_{z_0}	$\underline{\delta}_{z_1}$	$\overline{\underline{\delta}}_{\bar{z}_1}$	$\underline{\delta}_{z_1}$	$\underline{\delta}_{z_0}$	$\overline{\underline{\delta}}_{\bar{z}_0}$	$\underline{\delta}_{z_0}$	λ	A	B	C	D	$\overline{E}$	$\overline{F}$	$\overline{G}$	$\overline{H}$	y	$\bar{y}$	y
0	0	0	0	0	0	1	*	1	0	1	*	1	0	*	*	*	*	*	1	*	*	*	1	0
1	0	0	0	1	0	0	*	1	0	*	1	0	0	*	*	*	*	1	*	*	*	*	1	0
2	0	0	1	0	0	1	*	*	0	1	*	1	0	*	*	*	*	*	1	*	*	*	1	0
3	0	0	1	1	0	0	*	*	0	*	1	0	0	*	*	*	*	1	*	*	*	*	1	0
4	0	1	0	0	0	1	*	1	0	1	*	1	1	*	1	*	*	*	*	*	*	1	*	1
5	0	1	0	1	0	0	*	1	0	*	1	0	0	*	*	*	*	1	*	*	*	*	1	0
6	0	1	1	0	0	1	*	*	0	1	*	1	0	*	*	*	*	*	1	*	*	*	1	0
7	0	1	1	1	1	0	1	*	1	*	1	0	0	*	*	*	*	*	*	1	*	*	1	0
8	1	0	0	0	0	1	*	1	0	1	*	1	0	*	*	*	*	*	1	*	*	*	1	0
9	1	0	0	1	0	0	*	1	0	*	1	0	0	*	*	*	*	1	*	*	*	*	1	0
10	1	0	1	0	1	1	*	*	1	1	*	1	1	*	*	*	1	*	*	*	*	1	*	1
11	1	0	1	1	1	1	*	*	1	1	*	1	1	*	*	*	1	*	*	*	*	1	*	1
12	1	1	0	0	0	1	*	1	0	1	*	1	1	*	1	*	*	*	*	*	*	1	*	1
13	1	1	0	1	0	0	*	1	0	*	1	0	0	*	*	*	*	1	*	*	*	*	1	0
14	1	1	1	0	1	1	*	*	1	1	*	1	1	*	*	*	1	*	*	*	*	1	*	1
15	1	1	1	1	1	1	1	*	1	1	*	1	1	*	*	*	1	*	*	*	*	1	*	1

Table 4: Truth table of the transformed automaton

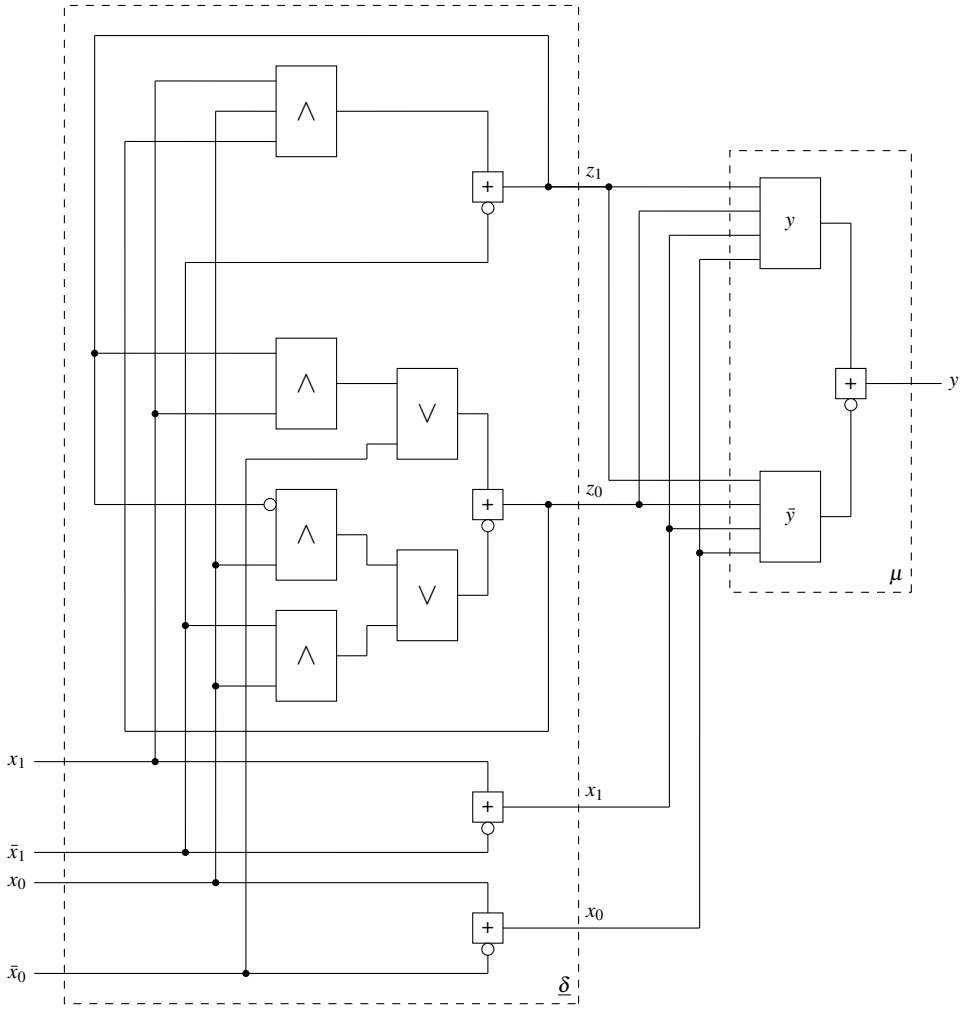

Figure 39: Resulting automaton

$$\delta(z,x) = zx_0\bar{x}_1 \vee x_1$$

The KV-Diagramm:

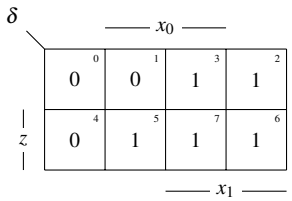

Figure 40: KV-diagram of δ

The table:

z	x_1	x_0	δ
0	0	0	0
0	0	1	0
0	1	0	1
0	1	1	1
1	0	0	0
1	0	1	1
1	1	0	1
1	1	1	1

Table 5: Truth table of the automaton

The graph of the automaton:

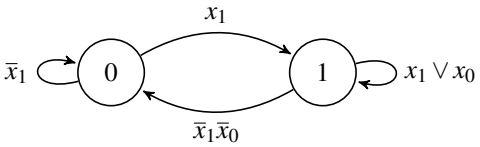

Figure 41: Graph of the automaton

NAND gates have been used to realize the structure. Therefore the DNF was transformed into a NAND strucutre by twice negating the DNF.

$$\delta(z,x) = \overline{\overline{zx_0\bar{x}_1 \vee x_1}} = \overline{\overline{zx_0\bar{x}_1} \wedge \bar{x}_1}$$

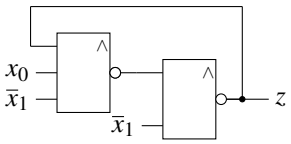

Figure 42: machine before the transformation

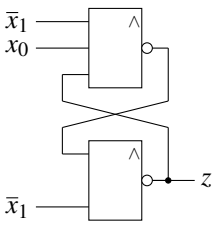

Figure 43: Different view of the automaton

Figure 43 shows two asynchronous feedbacks, which can lead to a race. On transition of x_1 from logical 1 to 0, while x_0 stays on logical 1, the feedback, which is first on logical 0, will make the other to a stable logical 1. Therefore on this transition, it can not be forecasted, whether the output will be on logical 1 or 0.

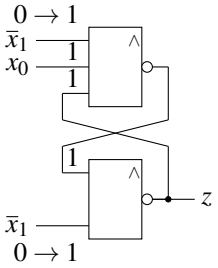

Figure 44: Race condition

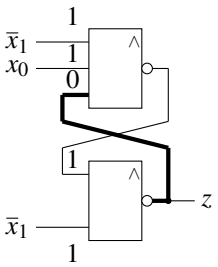

Figure 45: Race z = 0

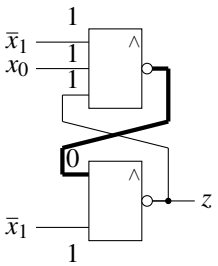

Figure 46: Race z =1

To simulate the race condition, the circuit was modelled and simulated in LT Spice. The simulation shows a race.

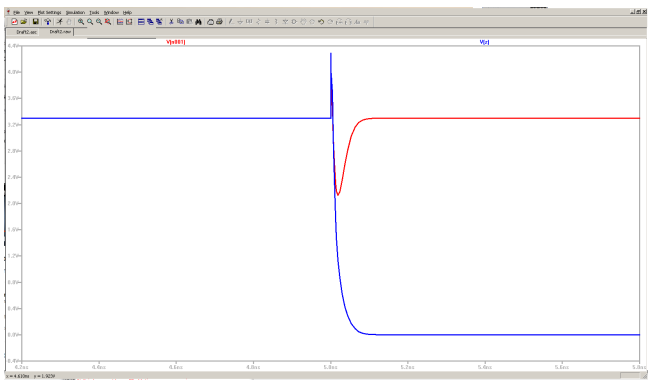

Figure 47: Simulated race situation

The circuit was realized in reality and the race was captured via an oscilloscope.

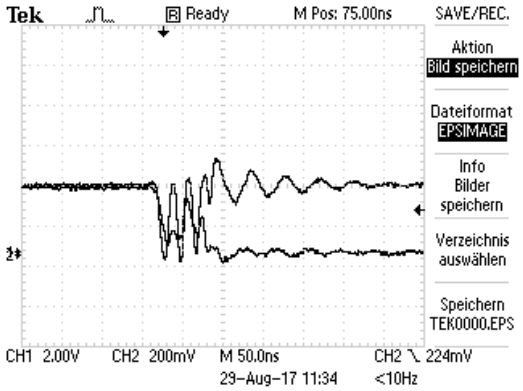

Figure 48: Race situation in reality

Then the transformation, which was presented in this journal, was made leading to the following structure, which does not have any contending feedbacks anymore. The only feedback this structure needs is nested in the RS-Buffer.

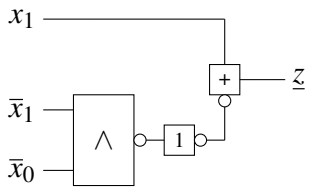

Figure 49: Transformed Moore

This structure does not show a race problem. To prove this statement the race condition of the old automaton has been set to the inputs. In figure 50 the state z and the rising edge of $\bar{x}_1$ is shown. It's clearly to see that the state doesn't change, not even a fluctuation of the signal can be recognized. Therefore the transformed machine is determined and stable.

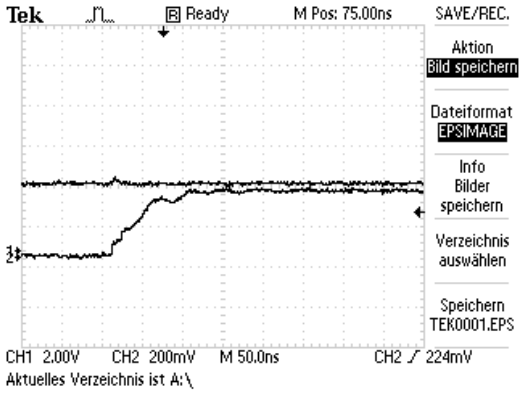

Figure 50: Race condition applied to the transformed automaton

5 Conclusion and Future Work

An asynchronous function stable Mealy was transformed into a state stable Moore under the use of the RS-buffer with suitable coding. The transformation provides general asynchronous design rules, e.q. the isolation of critical situations via the hold function. Due to the stabilisation by RS-buffer with the hold function, no races will be propagated through the circuit. In this journal three examples have been presented, a 1-dimensional and two 2-dimensional. Although the stable 2-dimensional transformation has produced an asynchronous feedback, this feedback leads either to a confirmation or a hold of the RS-buffer. The feedback has to be seen as a starting condition which gets triggered by the input and a change of the feedback will only affect the RS-buffer if the input changes. This design guideline can be used for all circuit designs, to create a stable, reliable system. The goal of the design is to remove the outer feedback and nest it in the RS-buffer. The inputs have been coded as pseudo states and stabilized via the RS-buffer. The output function has also been designed in dual-rail. This leads to a circuit, that looks at first sight as a combinational circuit. With this method you can simplify complex automata and combine them. The results have to be simulated to get a detailed look at the behavior of the transformed Moore. As it was shown, one dimensional machines get stabilized by this design, but for more dimensional machines it is necessary to design stable functions and regard the transitions between the states, not only concentrating on one state. So a rule has to be found, which can check for instabilities between states and stabilize machines in these constellations. Additionally the formula for the Transformation can be programmed, to create an automated process of transformation. Additionally the output function λ has to be checked for functional Hazards and addapted to guarantee that they are no longer existing.

Patient generated data, or personal clinical data, is considered an important aspect in improving patient outcomes. However, personal clinical data is difficult to collect and manage due to its distributed nature. For example, they can be located in multiple places such as doctors' offices, radiology centers, hospitals, or some clinics. Another factor that can make personal clinical data difficult to manage is that it can be heterogeneous data types such as text, images, charts, or paper-based documents. In case of emergencies, this situation makes personal clinical data retrieval very difficult. In addition, since the amount and types of personal clinical data continue to grow, finding relevant clinical data when needed is getting more difficult if no action is taken. In response to such scenarios, we propose an untethered patient health record system that manages personal health data by utilizing meta-data that enables easy retrieval of clinical data. We incorporate cloud-based storage for easy access and sharing with caregivers to implement continuity of care and evidence-based treatment. In emergency cases, we make critical medical information such as current medications and allergies available to relevant caregivers with valid license numbers only. Clinical data needs to be stored or made accessible from one place for easy sharing and retrieval. Well-managed personal cloud space could outlive the lifetime of personal health records system (PHRS) since the discontinuity of the service does not affect the data stored in the cloud space. In our approach, we separate the clinical data from applications in order to make the data independent from the application. Also, the users can have alternative applications for their clinical data. Such independence motivates users to use PHRS with flexibility.

1. Introduction

For most people, healthcare is considered important as there has been significant increase in chronic diseases such as heart disease, cancer, diabetes and asthma. This requires continuous treatment, reduces quality of life, and increases overall medical expenses (The Growing Crisis of Chronic Disease in the United States) [1]. According to the Centers for Disease Control and Prevention (CDC), in the U.S. about 610,000 people die of heart disease every year. In addition, 26 million people suffer from Type I or Type II Diabetes, around 14 million have severe chronic respiratory problems such as Chronic Obstructive Pulmonary Disease (COPD), and 68 million have been diagnosed with hypertension [2]. However, many of these diseases can be prevented and managed through early detection, physical activities, a balanced diet and treatment therapy. Adopting PHRS could help improve patient outcomes. Recently, there has been more focus on preventive care and proactive measures such as monitoring and controlling patients' symptoms. Nowadays, there are many mobile health applications and sensors such as blood pressure sensors, electrocardiogram sensors, blood glucose measuring devices, and others that are used for monitoring and controlling personal health. These apps and sensors produce personal health data that can be used for treatment purposes. If managed and handled properly, it can be considered patient-generated data. There are other types of personal health data that are available from various sources such as hospitals, doctor's offices, clinics, radiology centers or any other caregivers. Aforementioned health documents are deemed as a personal health record (PHR). According to American Health Information Management Association (AHIMA) [3], PHR can be defined as an electronic, lifelong resource of health information

[*]Mohammed Abdulkareem Alyami, Email: aljakman2006@hotmail.com

needed by individuals to make health decisions. However, it is not easy to collect all the relevant personal health data because of the fact that they are in different data types, available from different sources, and stored in different media and devices. To overcome such difficulties, it is desirable to have personal health data in one place where users have full control over their own clinical data. In order to be useful, the clinical data should be sharable when needed for diagnosis and treatment. Without proper clinical information (medical history, allergies, current medications, and adverse reactions) medical mistakes could occur when making medical decisions due to insufficient information. Even if a patient has a complete medical history and all the necessary clinical data, if it is not shared properly among caregivers at the time of need, discontinuity in care may occur. In order to meet the needs of such scenario, PHRS should have the following properties: robust and private storage, easy retrieval and maintenance, secure, sharable, and able to handle emergency situations.

There are two types of PHRS: untethered and tethered. Untethered PHR is an independent PHRS where patients have full control over their own personal health records. They can collect, manage, and share their health records. On the other hand, tethered PHRS are linked to a specific healthcare providers' EHR system, where the users typically gain easy access to their own records through secure portals and see their own clinical information such as test results, immunization records, family history, and other relevant information. They can also utilize secure messaging with their collaborating clinicians. The participating patients need to share the cost and the information with their care provider. However, these tethered records may not be complete since the information sources are from one provider only. Despite all the benefits PHRS provide, the adoption rate of PHR by the general public still remains low in the U.S. [4-6]. In our previous work [7], we identified six barriers (usability, ownership, interoperability, privacy and security, portability and motivation) that cause the slow adoption of PHRS. One of the main concerns for not having PHRS is the ownership issue. For example, one incident happened on January 1, 2012. Google Health™ System, one of the biggest PHRS providers, stopped its service and asked their registered customers to move their records to their computers or other PHRS vendors, which exacerbated ownership concerns by the public.

As an attempt to overcome some of the barriers, we propose an untethered PHRS that utilizes personal cloud storage, offers simplicity in organizing various kinds of clinical data by utilizing Dublin Core (DC) metadata, and provides easy access to emergency clinical data to paramedics or clinicians in case of emergency. DC metadata has been successfully applied in many areas, but since it is not specifically designed for clinical data, there are some limitations in its expressive power in the healthcare domain. In this research, we simplified the categorization of clinical data by human body part for easy retrieval of clinical data using DC, so users can manage their own clinical data without in-depth knowledge about clinical information. As a proof of our concept, we developed a system called My Clinical Record System (MCRS) to help users store, organize, retrieve, and share their clinical data with caregivers when needed, including in emergency situations. In an emergency situation, clinicians (e.g. physicians, paramedics, nurses, and others) can access patient's data using their license numbers and the patient's name and date of birth. Emergency information consists of current medication lists, known allergies, and side effects. By having complete medical history, MCRS users may be able to reduce medical errors and improve patients' outcomes. It also ensures continuity of care by sharing personal clinical data among healthcare providers when needed. The remainder of this paper is organized as follows: Section 2 discusses related work and in section 3 we focus on the clinical data's type and format. In Section 4, we discuss how to solve the data organization and retrieval issues using DC metadata to facilitate better and more accurate data retrieval. Section 5 discuses cloud-based storage. In section 6, we discuss the current situation in the healthcare industry (AS-IS). Section 7 uses a scenario as an example. Section 8 discusses the solution domain. In section 9, we introduce MCRS as a proof of concept and finally we conclude our study and discuss our future work in section 10.

2. Literature Review

In [8], Fearon defined Meta-data as structured information that describes, explains, locates, or otherwise makes it easier to retrieve, use, or manage an information resource. However, metadata standards have not been employed by many repositories and most of the meta-data was generally descriptive, rather than administrative or for preservation [9]. In [10], Greenberg investigated the ability of resource authors to create acceptable metadata in an organizational web site at the National Institute of Environmental Health Sciences in the U.S. The findings of their study indicate that resource authors can create better quality metadata when working with Dublin Core. In some circumstances, they may be able to create quality metadata better than a metadata professional. In [11], Talha developed their own metadata tool called Metadata Management System (MMS) to facilitate the creation, maintenance and storage of metadata. MMS supports two well-known metadata models, Dublin Core and SCORM 1.2 (IEEE Learning Object Metadata). The authors implemented their metadata tools in the Malaysia Grid for Learning (MyGfL). The results of the study indicate that MMS can substantially improve the discovery, retrieval management and control of web resources and learning objects in their MyGfL portal. In the healthcare domain, meta-data has been utilized as a method for confidentiality tags that indicate data sensitivity levels. This enables patients to give consent to the exchange of some parts of their health records (e.g. the medical diagnosis), while withholding consent for the exchange of other areas (e.g. a mental health counseling session) [12]. This work can help in increasing patients' privacy and allow them with some freedom in exchanging their health records. However, their work focused on EHR, but did not incorporate PHRS, which limited the scope of their study. Other researchers have adopted the ontology approach to quickly search and access relevant and meaningful information among large numbers of CDA documents within healthcare providers' systems (Electronic Health System), which in turn enables semantic interoperability[5, 13]. However, these studies were limited to one health data type (CDA), whereas health records include other data types such as images (e.g. x-rays, scanned documents, ultrasounds, and others), and observed symptoms noted by patients and clinical sensors' data. In [14] Patel developed a system called TrialX, on top of PHR, where patients not only can search by keywords, as in ClinicalTrials.gov, but also by demographics (e.g. age, gender, city and study site). This system enables patients to match their health condition to clinical trials. This system can accelerate and improve

the search results among health records. However, the authors did not take into account how to retrieve relevant clinical data since the amount and types of personal clinical data continue to grow, which makes it difficult to find such data. In [15], Appelboom reviewed the literature on smart wearable body sensors and found that these sensors are accurate and have clinical utility, but still are underutilized in the healthcare industry. These devices can be used to monitor physiological, cardiovascular and many other factors of health variables and transmit data either to a personal device or to an online storage site. The smart wearable body sensors are placed on different parts of the user's body based on the purpose of the sensor device. For instance, the physical therapy sensor is placed on the ankle; the cardiopulmonary sensor can be placed on the wrists, fingers, arms or thighs.

In [16], Zhang developed an application to apply meta-data efficiently on clinical trial data. The authors chose Microsoft Excel due to the wealth of built-in features (e.g. spell checking, sorting, filtering, finding, replacing, importing and exporting data capabilities), which contribute to the ease of use, power, and flexibility of the overall meta-data application. They focused on the analysis process in a drug development environment such as adverse clinical events (ACE), Electrocardiogram (ECG), laboratories (LAB), and vital signs (VITAL), where the raw data is stored in the clinical trial database and then the data can be manipulated.

Another study in [17], Teitz developed a website called HealthCyberMap with the goal of mapping Internet health information resources in novel ways for enhanced retrieval and navigation. They used Protégé-2000 to model and populate a qualified DC RDF meta-data base. They also extended the DC elements by adding quality and location elements. Also, the W3C RDFPic project extends the DC schema by adding its own elements such as camera, film, lens and film development date for describing and retrieving digitized photos. In [18], Ekblaw built a system (RedRec) to enable patients to access their medical health records across health providers (e.g. pediatrician, university physician, dentist, employer health plan provider, specialists, and others). Their system applies novel, blockchain smart contracts to create a decentralized content-management system for healthcare data across providers. RedRec governs medical records access while providing the patient with the ability to share, review, and post new records via flexible interface. The raw medical record content is kept securely in providers' existing data storage. However, when the patient wants to retrieve data from their provider's database, their Database Gatekeeper checks authentication. If it is approved, the Gatekeeper retrieves the relevant data for the requester and allows a sync with the local database.

In order to solve interoperability problems in exchanging clinical data, in [19], Dogac proposed archetypes to overcome the interoperability problems. They provided guidelines on how ebXML Registries can be used as an efficient medium for annotating, storing, discovering and retrieving archetypes. They also used ebXMLWeb services to retrieve data from clinical information systems. An archetype is defined as "a reusable, formal expression of a distinct, domain-level concept such as "blood pressure", "physical ex-amination", or "laboratory results", expressed in the form of constraints on data whose instances conform to some reference model"[19]. However, these studies are not comprehensive. Their limitations come from: focus only on one health data type, do not take into account PHR, lack of retrieving relevant clinical data, and overlook emergency access to medical records. Our proposed approach overcomes these limitations. Our study is comprehensive, which covers many different clinical and nonclinical documents such as images (e.g. x-rays, scanned documents, ultrasounds, and others), text (e.g. CDA, CCR, CCD, and others), and observed symptoms noted by patients and their clinical sensors' data. This can organize these various data types in a way that can help in storing and retrieving such data in an efficient way.

3. Clinical Data

In this section, we describe the types, formats, and sources of clinical data.

3.1. Measurements data from portable medical devices, sensors, or mobile application

One way to collect measurement data is through explicit clinical sensors. A clinical sensor is a device that responds to a physical stimulus and transmits a resulting impulse for interpretation or recording. Some sensors are designed to work outside the human body, while others can be implanted within the human body [20]. In this research, we are referring to clinical sensors for homecare settings, such as blood oxygen monitors, thermometers for body temperature, heart rate sensors, blood pressure sensors, and others. In addition to these textual data types, there can be non-textual data generated from sensors such as electrocardiogram measurement devices. The clinical sensors play a major role in healthcare, including early detection of diseases, diagnosis, disease monitoring and treatment monitoring.

Another method to collect measurement data is through mobile apps. For instance, most smartphones (e.g. Android or IOS) offer health and fitness apps that help users monitor their daily activities and health (e.g. track diet and nutrition calories, track vital signs, track fitness progress, share health data with their doctor electronically, and others). The data collected from these applications can be sent as a message or an email attachment to whom the users want to share it with. For interoperability, the collected data needs to be in standard format, such as HL7 CDA or in standard code such as SNOMED-CT.

3.2. Observed Symptoms

Patients sometimes experience particular symptoms (e.g. chest pain, nausea, vomiting, shortness of breath and others). If the patient notices such symptoms, they should be recorded and shared with their physician for proper treatment. If these symptoms are not shared with their physician, due to incomplete information, misdiagnosis could occur. When patients are recording, the observed symptoms should be described in standardized code such as SNOMED-CT. This will allow semantic interoperability, since the same symptoms can be described in multiple ways. Without codified descriptions, there can be discrepancies about the perceptions regarding symptoms between patients, nurses, or physicians [21].

3.3. Images

Most of the medical imaging machines produce standard image format called Digital Imaging and Communications in Medicine (DICOM). DICOM is defined as the international standard for medical images and related information (ISO 12052). There are two types of clinical data images: images that are based on DICOM standard (e.g. x-rays, Computed Tomography (CT), Magnetic Resonance (MR), and ultrasound devices) and scanned documents. The DICOM –format combines images and meta-data that describes the medical imaging procedure. Accessing data in DICOM files becomes as easy as working with TIFF or JPEG images [22]. On the other hand, the scanned documents (e.g. PDF/ JPEG) are difficult to retrieve because the content is not searchable. For example, some physicians write notes on clinical forms while diagnosing their patients and then type them on the computer. They also sometimes scan the notes and upload them to the patient records. Either way is time consuming, difficult to retrieve in a timely manner, and consumes relatively large storage space. In addition, the patient may have more than one doctor or may have been treated by many healthcare providers, which in turn fragments his/her records. So when patients obtain their records, they mostly receive them either printed out or sent as an email attachment. This makes it difficult to retrieve scanned documents because its content cannot be retrieved by computers. To alleviate such issues, we have utilized meta-data to describe such medical documents so computerized retrieval and systematic organization are possible.

3.4. Clinical Document

Clinical documentation (CD) is a computerized record describing a medical treatment, medical trial or clinical test, which can be exchanged among healthcare providers [23]. EHR data may be collected from healthcare providers. There are four types of clinical document formats: Continuity of Care Record (CCR), Clinical Document Architecture (CDA), Continuity of Care Document (CCD), and Consolidated CDA (C-CDA). All of which allow healthcare providers to exchange clinical information summary about a patient. However, CCR was excluded from the 2014 edition of EHR Certification, which is a standard certification criteria for EHRs that was established by The Centers for Medicare & Medicaid Services (CMS) and the Office of the National Coordinator for Health Information Technology (ONC), as a valid way to send summary of care documents. Hence, the content from a CCR was merged into a CDA format and called Continuity of Care Document (CCD). C-CDA includes nine different types of commonly used CDA documents such as CCD, consultation notes, discharge summary, imaging integration, DICOM diagnostic imaging reports, history and physical, operative note, progress note, procedure note, and unstructured documents. Each C-CDA Document Template was designed to satisfy a specific information exchange situation.

In the following subsection, we will discuss the difference between these formats (CCR, CDA, and CCR):

- CCR documents provide a snapshot of treatment and basic patient information such as diagnosis and reason for referral between healthcare providers. It also uses only specified XML code and does not support narrative text (free-text), which hinders physicians from writing notes if needed, and it is not electronically acceptable by all systems.
- CDA documents are a flexible standard which can be read by the human eye or processed by machine due to the use of XML language. It is based on the HL7 Reference Information Model (RIM), and uses HL7 V3 data types. CDA can be transported using different methods such as HL7 V2, HL7 V3, DICOM, MIME-encoded attachments, HTTP, or FTP. CDA documents can include text, images and even multimedia.
- CCD documents are not a complete medical history of the patient but it includes only the information critical to effectively provide continuity of care. Its primary purpose is exchanging patient information between different healthcare providers. It is based on XML standard and can be displayed on a web browser using style sheet. It also allows narrative text which is an advantage over other standards like CCR [24].

When using untethered PHRS, patients are responsible for collecting clinical data from their healthcare providers or from their own patient-generated measurement data and keeping it in their own personal cloud space. For example, CDA, CCR and CCD can be obtained from healthcare providers, X-rays can be obtained from the radiology department, and lab test results can be obtained from the test lab or doctor's office. Patients can share their health records with their clinicians by either electronically transmitting or granting access to their storage through the PHRS. If electronic sharing is not allowed, the patient may download the file and make hardcopies or store them in a USB, CD, or other mediums for sharing [25].

3.5. Meta-data

There are two different methods of storing meta-data. In the first method, meta-data can be embedded in the data (e.g. in the header of a digital file). The advantages of this option are ensuring that the meta-data will not be lost, eliminating the need for linking data and meta-data, and updating the data and meta-data together. In the second method, meta-data can be stored separately. The advantage of this option is that it can simplify the management of meta-data and can expedite the retrieval of the data [8]. In our approach, we employed the latter method to accelerate the retrieval of clinical data and to enhance expressive power. However, in this method, there can be inconsistencies between meta-data and clinical data. This can occur when transitioning to a new platform, integration between different systems or sharing data across multiple systems [12]. There are many meta-data formats that have been accepted internationally including: Dublin Core (DC), Federal Geographic Data Committee (FGDC), Encoded Archival Description (EAD), and Government Information Locator Service (GILS) [26]. Some of the metadata standards/schemas are generic, while others are domain-specific. For example , SCORM 1.2 (IEEE LOM) is used for educational approaches and rights management; Friend of a Friend (FOAF) is used for people and organizations; Simple Knowledge Organization (SKOS) is used for concept collections; Asset Description Metadata Schema (ADMS) is used for describing semantic interoperability assets; and Dublin Core is used for published material (text, images).

Generic metadata formats, such as Dublin Core, tend to be easy to use and widely adopted. In this study, we adopted DC metadata because it was developed for author-generated metadata, supports resource sharing and interoperability among information systems, has the broadest level of commonality of elements, extensibility, international acceptability and the flexibility it provides for extensions to the basic elements.

DC metadata solves one of the major issues in using meta-data among healthcare systems, which lacks interoperability [7]. Therefore, among these different metadata formats, DC metadata is the most appropriate format that aligns with our approach.

Meta-data benefits personal health record management in many ways. These benefits include the following:

- Consistency in definitions: properly defined tags provide structured information about the clinical data stored.
- Clarification of the relationships: meta-data can be used to clarify the relationships among the clinical items by defining categories and associated relationships within the category. We have defined each tag in DC for clinical purposes. When the data is uploaded or modified, the corresponding meta-data is required to update as well.

3.6. Meta-data Management

Meta-data management ensures that the data is associated with the datasets and utilized efficiently throughout and across organizations. Data governance is needed for successful meta-data implementation so it can provide trustworthy, timely and relevant information to decision makers, as well as personal users. For successful implementation, data governance must be aligned with the intended purposes of the users or organizations. This means that a data governance program starts by specifying its strategy, goals and the scope of its success. An organization needs to define the three data governance pillars including policies, people (and people skills), and processes. Once the above steps are in place, the organization can determine the best tools and technology to implement its data governance initiative [27].

3.7. Dublin Core Meta-data for Clinical Use

The DC Meta-Data Initiative (DCMI), is an open organization supporting innovation in meta-data design and best practices across the meta-data ecology. The DC Meta-data consists of 15 optional elements including: title creator, subject, description, publisher, contributor, date, type, format, identifier, source, language, relation, coverage and rights.

In this study, we defined the usage of DC Meta-data elements for clinical purposes to describe and retrieve clinical data efficiently as shown in Table 1. Some of the meta-data elements - title subject, description, type, data and resource - are required for the integrity of data. These elements must be present for every clinical data item. The optional fields can be skipped, but if it has been filled, the metadata quality will be increased.

Table 1: Meta-data schema for PHR

Entity	Description
DC. Title	The title of the document
DC. Creator	The author of the document
DC. Subject	Subject of the document
DC. Description	Description of the document
DC. Relation	- One of the body parts (Thorax, Abdomen, Heart, extremities, Integumentary, Head, Urinary or Reproductive) - This element is linked to the subject element
DC. Date	Date of meta data creation
DC. Type	Type will be used for lab tests (blood work, urinalysis, fecal sample, nasopharyngeal sample, oropharyngeal sample and others) or images (x-ray, cat scan/ CT, Ultrasound, Magnetic resonance/MR, Scanned Document, Electrocardiogram, EKG/ or ECG, CDA, C-CCD and others)
DC. Format	PDFs, Text, JPEGs , TIFFs, HL7 CDA, and others
DC. Identifier	Optional Document ID
DC. Language	English and other languages
DC. Coverage	Geographical and time-related information
DC. Rights	Copyright and access rights (secured or unsecured)
DC. Source	Data source

4. Healthcare Processes

4.1. AS-IS Healthcare Processes

Some of the issues that the current healthcare industry is having include discontinuity of care and unacceptably high rates of medical mistakes due to unavailable patient medical records at the time of need. Some of the factors that cause these issues are listed below and illustrated in the Figure 1. (the numbers listed below correspond to the numbers in the Figure 1)

- Personal clinical data is difficult to collect and manage because they are located over multiple places such as doctor's offices, radiology centers, hospitals, or some clinics (1).
- Heterogeneous data types such as text, images, charts, or paper- based documents (2) [8].
- Discontinuity of care due to lack of communication among caregivers. This is caused by distributed and fragmented medical information (3).
- Lack of evidence-based treatment due to limited access to medical records (4).
- Medical errors due to incomplete medical history or access to emergency health information (e.g. allergies, current medication list, side effects, and others) at the time of need (5). According to Sunyaev. [28], most PHRS do not offer built-in emergency access to the record, except through third-party services that are available for HealthVault. For example, Microsoft Health Vault provides users with

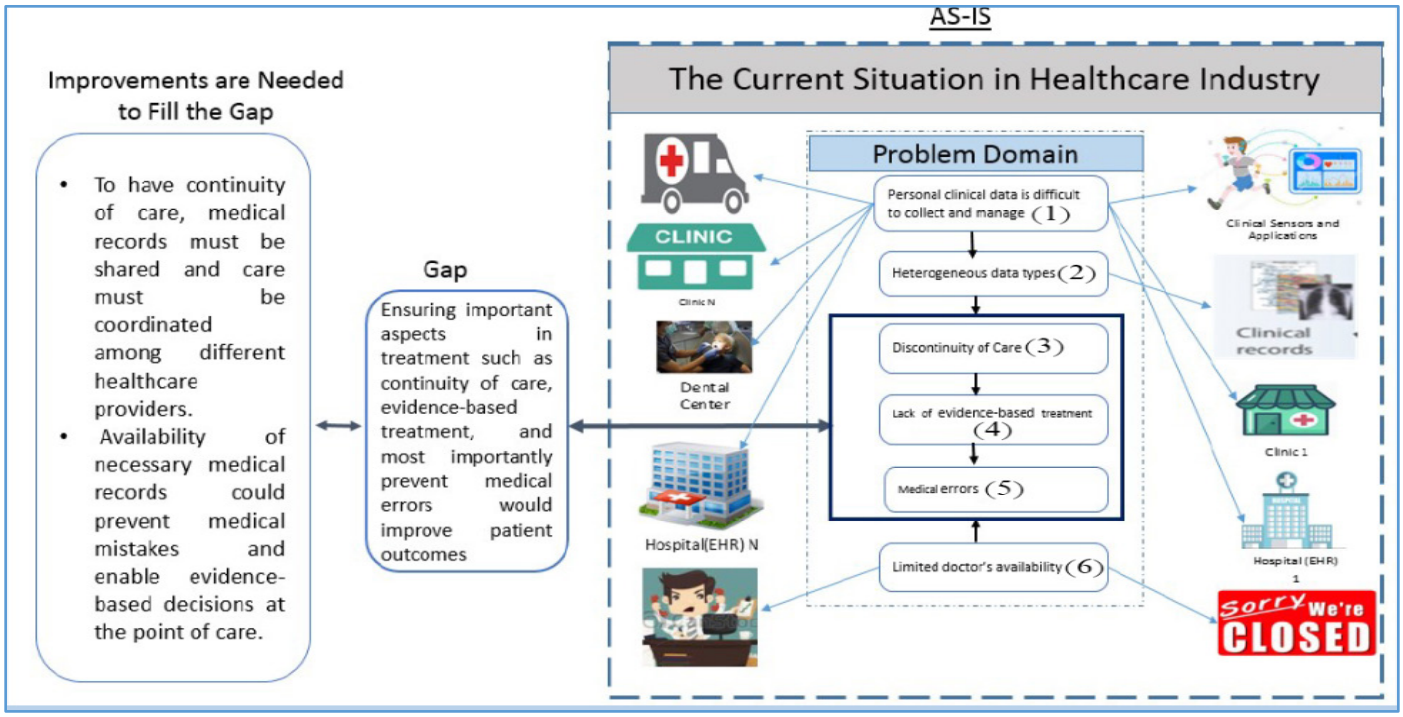

Figure 1: Problem Domain in the Current Healthcare Industry

access codes that can be given to emergency responders and other people they trust to allow access to the emergency information.

- Limited doctor availability. For instance, patients may need to be seen on the weekend or on a holiday when their doctor's office is closed (6).

4.2. Scenario for the Need of PHRS

John was suffering from tiredness and lack of energy for the past 4 weeks. He has several chronic conditions (type 2 diabetes, chronic kidney disease, chronic lower back pain, generalized anxiety disorder, depression, bipolar disorder, dyslipidemia, hypothyroidism, coronary artery disease and congestive heart failure) and is on multiple medications prescribed by his PCP, cardiologist, psychiatrist and pain management doctor. John had recently requested to become one of Dr. Smith's patients. After multiple attempts, Dr. Smith was able to obtain some of his previous medical records. Dr. Smith also was interested in reviewing his previous medical diagnoses and prior/current medications. Unfortunately, there was no integration of the records and medications taken. After several interviews with John and his wife, Dr. Smith was able to determine that the patient was using the same type of long-acting insulin twice a day because one had the generic name and the other the commercial or brand name. The patient was supposed to use this insulin once a day only. This patient's error kept his glucose at very low levels in blood which led to constant tiredness and lack of energy. Once the dose was corrected, the patient felt better. The immediate access to medical and prescription information would have allowed Dr. Smith to identify the error faster and provide him with the ability to take prompt corrective measures.

4.3. Solution Concept (TO-BE) Processes

To have continuity of care, medical records must be shared and care must be coordinated among different healthcare providers. Availability of necessary medical records could help prevent medical mistakes and enable evidence-based decisions at the point of care. It would be convenient to have clinical data stored in the same place for easy sharing and retrieval. Well-managed personal cloud space could outlive the lifetime of PHRS since clinical data is stored independently. In our approach, we separate the clinical data from applications to make the data independent from the application. Also, the users can have alternative applications to access their clinical data. Such independence helps clinical data outlive its applications. Our proposed solution concepts are illustrated in the Figure 2. In the Figure, the clinical data is separated from the application for data independence. The numbers in the Figure 2 correspond to the problems listed in the Figure 1.

5. My Clinical Record System (MCRS): A Proof of Concept

As mentioned in the introduction, there are a number of obstacles in collecting and maintaining personal health data. In an attempt to remove such obstacles, we developed a web-based system called My Clinical Record System (MCRS) that can help users to upload, organize, share, and retrieve relevant health data.

5.1. Overview of MCRS

Some of the main features of MCRS are listed below:

- Users can search their cloud storage not only by keyword, but also by any of the meta-data elements using document finder search features. They also can search by two elements such as subject and date in order to filter data by

showing more relevant data. Additionally, they can find a group of records based on a date range they specify.

- MCRS allows users to share their health records with their physicians using the share document feature as shown in the Figure 3.
- MCRS helps users to create meta-data for any documents (textual and non-textual data) and upload them to their cloud storage. For the non-textual data generated from sensors such as electrocardiogram (ECG) measurement devices, the users can scan them or take a picture and then upload them as an image or use a plotted number. Thus, the user will be able to include such data into their PHR and share it with their healthcare providers. MCRS also helps to retrieve those documents easily and can direct the users to its location if more information is needed.
- To overcome the ownership barrier, we separate the clinical data from applications, which will give the users more freedom by not limiting them to one provider or application. Also, their data is saved on their own storage, thus we do not have to store it in our system.
- To overcome the interoperability barrier, we used DC standards to describe any clinical data using our tag definition. The DC meta-data content for doctor visit summary document is shown in the Figure 4 and in the Figure 5.

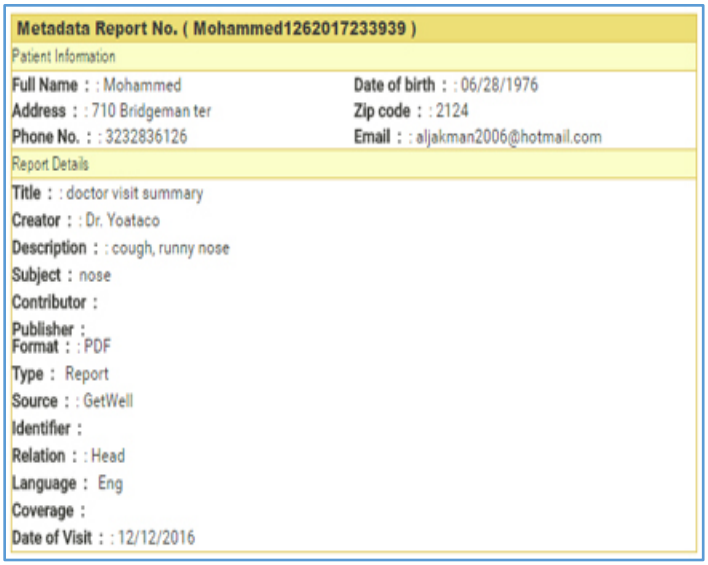

Figure 5: Visualization of the Meta-data

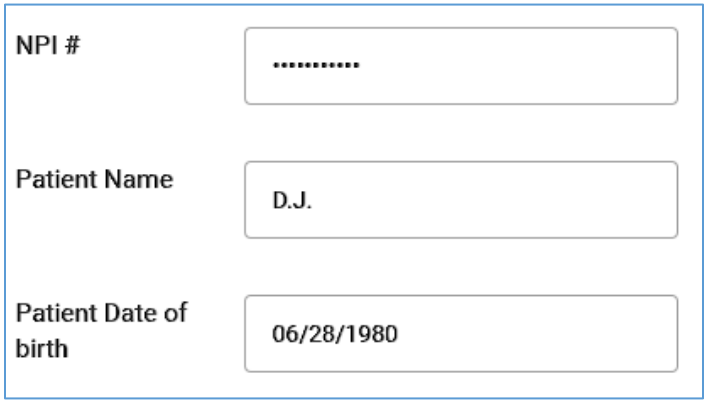

Figure 6: Emergency Access with Valid License Number

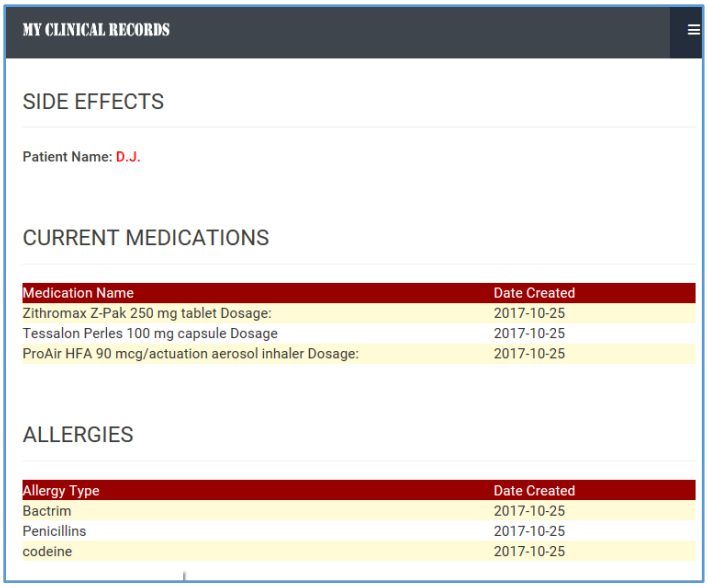

Figure 7: Emergency Information

- The easy access to users' health data and the ability to contribute to their record enhances users' motivation to use PHR.
- MCRS enables emergency clinical data access by emergency crew only with valid license number. We use the National Provider Identifier (NPI), patient name, and date of birth for the emergency medical information access as shown in the Figure 6. MCRS uses the Application Programming Interface (API) that was provided by NPPES NPI Registry in order to verify the NPI. Emergency information contains allergies, current medication list, and side effects. This information is updated regularly by patients as shown in the Figure 7. It also contains any references to the time of the last update.
    - Healthcare providers apply for NPI using the National Plan and Provider Enumeration System (NPPES) [29].
    - NPI can be validated through NPPES NPI Registry.

5.2. Using MCRS

We use patient's Dropbox access token to allow the connection between Dropbox and MCRS, so patients can have their own storage and have the ability to provide access to their storage through MCRS when needed. This allows users to keep their own data without binding to any specific application. MCRS contains no clinical data as they are stored in the patient's cloud storage. Patients need accounts for Dropbox and MCRS separately.

5.3. Personal Cloud Storage

Cloud storage is a place where users can store their data and access it anytime, from anywhere, and from any device via the Internet. It is maintained, managed and operated by cloud storage service providers such as Google, Amazon, or Microsoft Cloud storage services have many advantages such as cost savings, ease of use, ability to share data, accessibility, and sustainability. Personal Cloud Storage (PCS) is getting more popular because of the aforementioned convenience. Any cloud storage service provider may be used (SugarSync, Carbonite, IDrive, Dropbox, Google Drive, and others) – for storing personal clinical data as long as they provide required functionality and security. For testing purposes, we chose Dropbox™ as cloud storage. However, for practical use, secure cloud storage services that are HIPAA complaint can be used for privacy and security purposes, such as Dropbox (Business), Box, Google Drive, Microsoft OneDrive, and Carbonite [30]. The contents of each storage are described by DC meta-data for interoperability. In the case that data has embedded meta-data, we create another layer of meta-data so entire contents can be retrieved through our DC meta-data.

5.4. Managing Health Data

MCRS categorizes clinical data based on human body parts. There are eight categories: abdomen, heart, head, thorax, extremities, integumentary, urinary, and reproductive, as shown in Table 2. Any clinical data will be stored and linked based on these categories using the relation and subject tag elements of the DC meta-data. We kept the categories to a minimum so it can be simple enough to be used by patients. Users can specify the category (the human body part of interest) when searching for relevant clinical data, so it can show only the clinical documents (e.g. doctor visit summary, x-ray, and others) that are related to that part.

When using the relationships between the resource (DC subject) and target resource (DC relation), it is possible to combine the result to a greater scope, e.g. instead of eyes and ears, it can be categorized by head. This can be done by predefining each part of the human body and associating it with its related category in the system. Also, we have constrained the DC subject to a small core set that can be selected from a drop-down menu (all possible parts of the human body) to best describe the subjects (as shown in the Figure 8). When the users select the subject element, the DC relation field will be populated automatically with the associated part of its related category. For example, when a user searches by keyword (e.g. head) and chooses the element (e.g. relation), the search results will be filtered and show only all clinical documents that are relevant to the head (e.g. eyes, ears, brain, mouth, teeth, nose, and chin) as shown in the Figure 9. This is a less time-consuming method to filter the data instead of showing all documents as shown in the Figure 10. Also, the user can filter the search by date if they need to specify a period of time to find clinical documents.

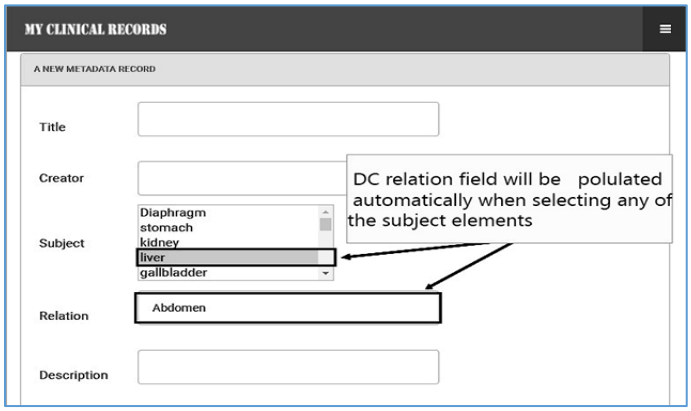

Figure 8: Create DC Meta-data

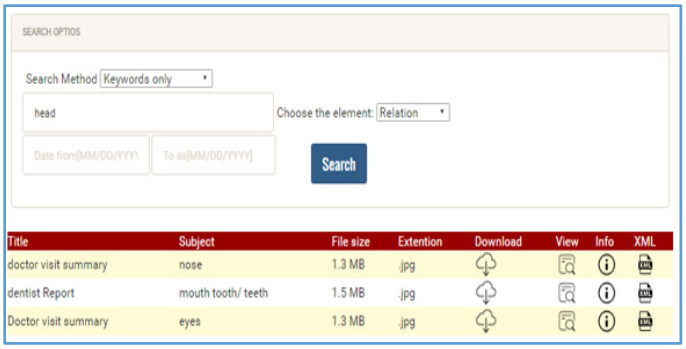

Figure 9: Example of Retrieving DC Meta-data for only Related Documents

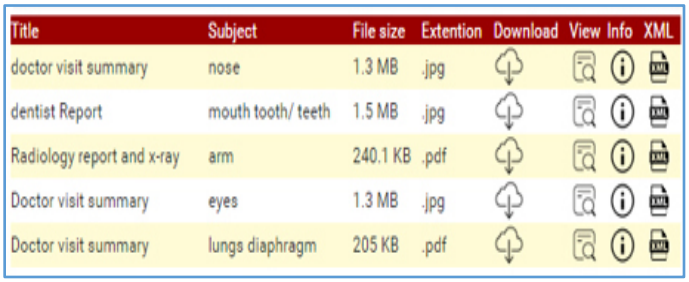

Figure 10: Example of DC Meta-data for all Documents

Table 2: Human Body Categories

Body categories	Body parts
The abdomen	Contains diaphragm, stomach, liver, gallbladder, pancreas, small intestine, large intestine, cava, spleen, and others.
Heart	Contains superior vena cava, pulmonary artery, pulmonary veins, pulmonic valve, tricuspid valve, inferior vena cava, right atrium, right ventricle, left ventricle, aortic valve, mitral valve, left atrium, aorta and others.
Head	Contains eyes, ears, brain, mouth, teeth, nose, chin, spinal cord, tonsil, uvula, gullet, meninges, pharynx and others.
Thorax	Contains lungs, diaphragm/pleura, nasopharynx/oral, cavity, trachea/Larynx, ribs, capillaries, bronchial tube, windpipe/trachea, chest, esophagus and others.
Extremities	Contains arms, elbows, hands, wrists, shoulders, hips/thighs, fingers, thumbs, legs, knees, toe, vertebral column, neck, ankles, breast, back pain, feet and others.
Integumentary	Skin and associated structures such as hair, nails, sweat glands, and oil glands
Urinary	Kidneys, ureters, urinary bladder, and urethra
Reproductive	Gonads (testes or ovaries) and associated organs; in females: uterine tubes, uterus, and vagina; in males: epididymis, ductus deferens, prostate gland, and penis

6. Conclusion

As the medical industry is going through a paradigm shift from clinician-centered to patient-centered, readily available complete personal medical history is becoming crucial. This will help ensure the three major goals in medical industry: evidence-based treatment, continuity of care, and prevention of medical mistakes. In this paper, we proposed an untethered personal health record system to help achieve such goals. Our proposed system, MCRS, provides a method to collect and organize heterogeneous personal health data using DC meta-data. The retrieval of the organized data was completed by the reorganized DC tags, which allowed the organization of clinical data by body parts for easy retrieval. Finally, we allowed access to personal emergency clinical data to emergency crew only by their license number at the time of need. In the future, we plan to expand the usage of clinical data collected from the application to analyze and identify the regional characteristics in health mapping to build better public policy for the nation. Our experiment was limited to one healthcare provider using the clinical data from that provider. Also, the data collection was limited due to the patient privacy regulations in the healthcare industry.

linear logic synthesis

ABSTRACT

The article considers linear algebra as an alternative mathematical tool of logic synthesis of digital structures to Boolean algebra and synthesis methods of digital electronic component base (ECB) on its ground. The methods of solving the applied problems of logic synthesis are shown, including the expansion of an arbitrary logic function by means of monotonic functions. The proposed mathematical apparatus actually provides the creation of digital structures on the principles of analog circuitry. It can find application in the design of multivalued digital ECB, specialized system-on-chip and analog-digital sensors with current output. The examples of synthesis of the combinational and sequential two-valued and multivalued digital devices are given. In conclusion, the advantages of linear algebra in comparison with Boolean algebra are formulated.

1. Introduction

This article is a continuation of the studies presented at the conference SIBCON-2017 [1].

Boolean algebra is known [2] as a leading mathematical tool for logic synthesis of two-valued digital structures. Almost all existing methods of logic synthesis are formed on its ground. The success of Boolean algebra is caused, among other things, by the fact that the Boolean representation of the realized logic function turned out to be rather technological: the circuit implementation of logic elements was relatively simple. TTL, C-MOS and ESL and other technologies occurred to be the most preferable for this purpose.

Despite this, the history of the development of digital microelectronics knows the attempts to replace both the approach to logic synthesis (the use of spectral representations [3 - 6] using the arithmetic polynomials [7 - 9]) and technological realization (I^2L, I^3L, ...).

The most significant contribution to the alternative theory of logic synthesis has been made by the threshold interpretation of Boolean algebra, called the threshold logic.

*Corresponding Author: Nikolay Prokopenko, Email: prokopenko@sssu.ru

Threshold logic related to one of the directions of synthesis of the digital structures [10], is constantly evolving. We know a significant number of publications devoted to this problem [11 – 14]. For two-valued functions, the threshold synthesis problems have already been solved beginning from the well-known papers of M. Dertouzos [10]. One of the advanced approaches of synthesis for the *k*-valued threshold functions is considered in this article [11].

The threshold logic was initially implemented in a two-valued version, but many publications on the multivalued threshold logic have recently appeared [14 - 17]. Why are they dedicated to the multivalued logic? The fact is that the multivalued logic is currently considered as a means of improving the quality characteristics of LSI (the ratio of "number of elements / number of links", "total area / real-estate" of the crystal, etc.), which doesn't require a drastic change in LSI technology. The authors of this article also follow this approach.

To develop this ideology we proposed an alternative approach to the logic synthesis of digital devices - the replacement of the mathematical tool of Boolean algebra by another body of mathematics - linear algebra. Such a replacement entailed fundamental changes in various aspects of the implementation of digital structures:

- the potential realization of Boolean logic was replaced by the current linear implementation;

- the key operating mode of the elements was replaced by the linear one;

- Boolean values of the variables took a quantitative form instead of the qualitative (logic) one;

- the value of logic was determined not by the scheme, but by the significance of signals;

- the output signal was presented by the difference of signals of two circuits operating in parallel, which improves the performance of digital structures.

Thus, the use of linear algebra as a mathematical tool of the logic synthesis ensured the development of alternative methods for the logic synthesis of current digital circuits and their practical implementations.

The authors published a number of papers [18-32] devoted to the synthesis of logic (nonthreshold) two-valued and multivalued digital structures. This paper considers the use of linear algebra as a mathematical tool for the logic synthesis of two-valued and multivalued, logic and threshold digital structures.

The fuzzy concept of the "threshold synthesis" can be interpreted in two ways:

- as a normal logic synthesis of digital structures with circuit implementation on threshold logic elements (any logic function can be implemented in this way);

- as a logic synthesis of threshold logic functions (an arbitrary logic function can be implemented by a network of threshold logic elements).

The purpose of this article is to propose logical and threshold current hardware components for constructing digital structures within the two specified areas. Within the framework of this goal, the authors' solutions for the following tasks are given below:

- since linear algebra is used as a mathematical tool for the logic synthesis of current logic structures, the article presents the main definitions and aspects of the practical use of linear algebra;

- as there is a close relationship between the threshold and monotonic functions, the article gives a definition of the monotonic function and explains the ways of representing arbitrary functions by monotonic linear functions;

- some versions of transformation of two-valued and multivalued monotonic functions into a threshold form in linear algebra are analyzed;

- versions of circuit implementation of linear threshold logic elements are considered.

2. Linear Algebra

A. Definition of linear algebra. Let $\boldsymbol{P} \to \langle P; +, \cdot, 0.1\rangle$ – field, $\langle A; +, \cdot, \theta\rangle$ – algebra with two binary operations and one nullary operation. The system $\boldsymbol{\Lambda} \to \langle A; +, \cdot, \theta, \mathbf{P}\rangle$ is called *linear algebra*, if the following conditions are met:

– the system $\boldsymbol{\Lambda} \to \langle A; +, \cdot, \theta, \boldsymbol{P}\rangle$ – linear (vector) space over the field $\boldsymbol{P}$;

– distributivities of operations + and ·

$$\forall(a, b, c \in A)\ (a + b)c = ac + bc \wedge c(a + b) = ca + cb;$$

– associativities of vector multiplication by elements of the field $\boldsymbol{P}$

$$\forall(a, b \in A) \wedge \forall(k \in P)\ k(ab) = (ka)b = a(kb).$$

B. Extension of linear algebra.

Let $\boldsymbol{A} \to \langle A; +, \cdot, \theta\rangle$ – vector space of linear algebra $\boldsymbol{\Lambda}$, $\boldsymbol{P} \to \langle P; \Omega = \{\omega_k | k \in P\}, 0.1\rangle$ – field of linear algebra $\boldsymbol{\Lambda}$, which contains the operations ω_k, which in general case do not necessarily coincide with the operations of linear space $\boldsymbol{A}$. Then the system $\boldsymbol{\Lambda'} \to \langle \{A; +, \cdot, \theta\}, \{P; \Omega, 0, 1\}\rangle$ is called *the extension of linear algebra* $\boldsymbol{\Lambda}$.

When interpreting this algebraic system in a certain way, we can obtain algebras with different properties. For example, interpreting A as a set of terms of Boolean functions $f(x_1,\ldots, x_n)$, the operations "+" and "·" - as $max(x_1,\ldots, x_n)$, $min(x_1,\ldots, x_n)$, we obtain algebra $\boldsymbol{A} \to \langle A; max, min, \theta; \boldsymbol{P}\rangle$. Similarly, leaving the semantics of operations in the original form (i.e., defining them as ordinary arithmetic operations), we can consider the reduced system as linear algebra on the set A of vectors in a linear space. The reduced algebraic system is considered below in this form.

C. Creation of bases. To form the bases from logic variables, it is possible to construct different constructions of linearly independent vectors with given properties. The choice of operations for creation of the bases is made independently on the operations of linear space and can be determined by various (mathematical, circuit, technological and other) requirements. In the applied plan, this allows obtaining the ideologically unified (based on operations of linear space) circuit solutions of functional elements (from different implementations based on field operations).

A basis is a system of m linearly independent vectors $\{F\} = \{\varphi_0, \varphi_1,\ldots, \varphi_{m-1}\}$, which enables to describe any vector $a \in \boldsymbol{A}$ in the linear form

$$a = \sum_{i=0}^{m-1} a_i \varphi_i\ , \qquad (1)$$

with respect to these vectors.

Each vector of the basis $\{F\} = \{\varphi_0, \varphi_1,\ldots, \varphi_{m-1}\}$ is uniquely determined by the set of coordinates $\varphi_i = \{\varphi_{i0}\ , \varphi_{i1},\ldots, \varphi_{i,m-1}\}$, with the help of which we can make a square matrix of order m:

$$F = \begin{bmatrix} \varphi_{10} & \varphi_{11} & \cdots & \varphi_{1,m-1} \\ \varphi_{20} & \varphi_{21} & \cdots & \varphi_{2,m-1} \\ \cdots & \cdots & \cdots & \cdots \\ \varphi_{m-1,0} & \varphi_{m-1,1} & \cdots & \varphi_{m-1,m-1} \end{bmatrix},$$

corresponding to the given basis {F}.

Two bases $\{F\} = \{\varphi_1, \varphi_2, \ldots, \varphi_{m-1}\}$ and $\{Y\} = \{\gamma_1, \gamma_2, \ldots, \gamma_{m-1}\}$, the matrices F and Y of which are inverse to each other, are reciprocal (dual). Besides,

$$F \cdot Y = E,$$

where E – diagonal matrix of order m with $\varepsilon_{ij} = 1$, when $i = j$ and $\varepsilon_{ij} = 0$, if $i \neq j$, which is an orthonormal basis $\{E\}$.

Since the resolution of an arbitrary vector a over the basis $\{F\}$ has the form

$$a = a_0\varphi_0 + a_1\,\varphi_1 + \cdots + a_{m-1}\,\varphi_{m-1},$$

then, multiplying both parts of this resolution by γ_i, $i = [0, m-1]$, we obtain:

$$a_i = a\cdot\gamma_i = a\cdot(Y\cdot\varepsilon_i) = a\cdot(F^{-1}\cdot\varepsilon_i).$$

Then the procedure for representing (i.e. obtaining the values of the expansion coefficients) of the arbitrary vector a in the given basis {F} is reduced to performing the following operations:

– construction of the basic matrix F;

– construction of the inverse basic matrix F^{-1};

– multiplication of the row-vector a by the column-vector of the matrix F^{-1} and computation of the expansion coefficients of the vector a over the basis $\{F\}$;

– writing of the expression for the vector a in the linear form (1) with respect to the basis $\{F\}$.

Example 1. Get a representation of the conjunction operation of two arguments $x_1\&x_2$ of the value 2 in the basis

$$F = \begin{bmatrix}1 & 1 & 1 & 1\\ 0 & 0 & 1 & 1\\ 0 & 1 & 0 & 1\\ 0 & 1 & 1 & 0\end{bmatrix},\quad (F)^{-1} = \frac{1}{2}\begin{bmatrix}2 & -1 & -1 & -1\\ 0 & 1 & -1 & 1\\ 0 & -1 & 1 & 1\\ 0 & 1 & 1 & -1\end{bmatrix}.$$

Solution.

a) we represent the sequence of values of the two-valued logic function by the row-vector

$$x_1\&x_2 = [0, 0, 0, 1];$$

b) we multiply the resulting row-vector by the columns of the inverse basic matrix $(F)^{-1}$ and obtain the row-vectors of the expansion coefficients of the represented logic function with respect to the given basis and the expression of the conjunction operation

$$x_1\&x_2 = [0, 0, 0, 1]\cdot\frac{1}{2}\begin{bmatrix}2 & -1 & -1 & -1\\ 0 & 1 & -1 & 1\\ 0 & -1 & 1 & 1\\ 0 & 1 & 1 & -1\end{bmatrix} =$$

$$= [0, 0, 0, 1]\cdot\frac{1}{2}[0, 1, 1, -1] = \frac{x_1 + x_2 - |x_1 - x_2|}{2}.$$

It is noteworthy that the last expression has been known since 1953 [3], but the author didn't describe the method of its obtaining (more precisely, it was described later).

The authors of this article propose three approaches to the creation of the basis vectors of linear bases, depending on the operations used for this purpose:

- based on Boolean operations ∨ , &, ⊕, ~, etc .;

- based on the truncated difference operation ∸;

- based on the comparison operation ≥.

When using Boolean operations, the upper and lower "cuts" [14, 18] of variables of different orders are used as operands for creating basis vectors:

– variables of the first order $x^{(i)} = x\&i,\ x_{(i)} = x \vee i$;

– variables of the second order

$$x^{(ij)} = x\&i - x\&j,\ x_{(ij)} = x \vee i - x \vee j$$

and so on.

When using the *truncated difference* operation

$$x_1 \dot{-} x_2 = \begin{cases} x_1 - x_2 & \text{when } x_1 \geq x_2;\\ 0 & \text{when } x_1 < x_2,\end{cases}$$

all logical operations are replaced by some combinations of this operation on variables involving operations of linear space. For example, the upper and lower "cuts" of the first and second orders are replaced by the expressions

$$x^{(i)} = i \dot{-} (i \dot{-} x) = x \dot{-} (x \dot{-} i);$$

$$x_{(i)} = i + (x \dot{-} i) = x + (i \dot{-} x);$$

$$x^{(ij)} = (x \dot{-} j) \dot{-} (x \dot{-} i);$$

$$x_{(ij)} = (i - j) \dot{-} (x - j).$$

Similarly, Boolean operations on two variables are replaced by the following expressions:

$$x_1\&x_2 = x_1^{(x_2)} = x_2 \dot{-} (x_2 \dot{-} x_1) = x_1 \dot{-} (x_1 \dot{-} x_2);$$

$$x_1 \vee x_2 = x_{1(x_2)} = x_2 + (x_1 \dot{-} x_2) = x_1 + (x_2 \dot{-} x_1);$$

$$x_1 \oplus x_2 = x_1 + x_2 - k\{1 \dot{-} [k \dot{-} (x_1 + x_2)]\};$$

$$x_1 \ominus x_2 = x_1 - x_2 + k\{1 \dot{-} [1 \dot{-} (x_2 \dot{-} x_1)]\};$$

and others.

When using the *comparison* operation, the above expressions are reduced to the following form

$$x^{(i)} = \sum_{j=0}^{i-1}(x > j);$$

$$x^{(i)} - x^{(j)} = \sum_{t=j}^{i-j}(x > t);$$

$$x_{(i)} = x + \sum_{j=0}^{i}(j > x) = i + \sum_{j=i+1}^{k-2}(x > j);$$

$$x_{(i)} - x_{(j)} = (i-j) - \sum_{t=j}^{i-1}(x > t).$$

It should be noted that the most interesting result of the studies is the fact of constructing logical structures based on *truncated difference* and *comparison* operations other than Boolean ones. Naturally, there are certain dependencies between the *truncated difference* and *comparison* operations, some of which are given below:

-"*truncated difference – comparison*":

$$x \dot{-} i = \sum_{j=i+1}^{k-1}(x > j);$$

$$i \dot{-} x = \sum_{j=1}^{i}(j > x);$$

$$j \dot{-} (x \dot{-} i) = \sum_{p=1}^{j}[(i+p) > x];$$

$$j \dot{-} (i \dot{-} x) = (j \dot{-} i) + \sum_{p=i-1}^{i \dot{-} j}(x > p);$$

- "*comparison - truncated difference*":

$$x \le i = 1 \dot{-} \{1 \dot{-} [(i+1) \dot{-} x]\};$$

$$x < i = 1 \dot{-} [1 \dot{-} (i \dot{-} x)];$$

$$x \ge i = 1 \dot{-} [1 \dot{-} (x \dot{-} i)];$$

$$x > i = 1 \dot{-} [(i+1) \dot{-} x];$$

$$x_1 > x_2 = 1 \dot{-} [1 \dot{-} (x_1 \dot{-} x_2)];$$

$$x_1 \ge x_2 = 1 \dot{-} \{1 \dot{-} [(x_1 \dot{-} x_2) + 1]\};$$

$$x_1 < x_2 = 1 \dot{-} \{1 \dot{-} [(x_2 \dot{-} x_1) + 1]\}.$$

3. Monotonic Logic Functions

Regarding the close connection between threshold and monotonic functions, we present some known results obtained in linear algebra in a simpler and more obvious way.

A. Construction of sequences of nondecreasing componentes. Suppose we have an arbitrary vector $a = (a_0, a_1, , \dots, a_{m-1}) \in Z^m$. We renumber the components of the vector with k-ary n-bit numbers. The vector a$\in$ Z^m is called monotonically increasing (decreasing), if for a bitwise comparison of k-ary number codes of the components a_i and a_j we have:

$$\forall (i, j \in Z^m) i \ge j \Rightarrow a_i \ge a_j \wedge i \le j \Rightarrow a_i \le a_j. \qquad (2)$$

The bitwise comparison of k-ary number codes of the components enables to single out the sequences of nondecreasing (nonincreasing) components.

The necessity to create these sequences is that for the monotonicity of the vector, condition (2) must be met in each sequence. Hence follows the first factor of simplicity of the analysis results in linear algebra: to verify the vector by monotonicity it is sufficient to establish its monotonicity within each sequence. This reduces the amount of computation and the overall complexity of the verification process.

The sequences of nondecreasing components are constructed as follows. The set G of components (constituents 1) of logic functions of the chosen number of n variables is divided into n groups $G = \{g_0, \dots, g_{n-1}\}$. Each group g_{it} includes the sequences of nondecreasing components with starting numbers t, $i \le t \le n-1$, determined by the following relation

$$k^i - k^{i-1} \le j \le k^{i+1} - k^i - 1,$$

in this case we take $(k^i - k^{i-1})\big|_{i=0} = 0$. The starting numbers are component numbers that should be compared with the values of the other elements in the sequence. Each sequence contains components with numbers the decimal equivalents of which are determined as $t + k^t, t + k^{t+1}, \dots, t + k^{n-1}$. As a result, the entire sequence generally takes on the form

$$g_{it} = \{g_t, g_t + k^t, g_t + k^{t+1}, \dots, g_t + k^{n-1}\}.$$

Thus, it is possible to construct the sequences of nondecreasing components for the given values of k and n. The sequence graphs of nondecreasing components for $k = 2$, $k = 3$ and $n = 3$ are shown in Figure 1. The digits in the circles denote the decimal numbers of the vector components, and the sequence itself includes a certain vertex and the nearest right vertexes connected with it by the lines.

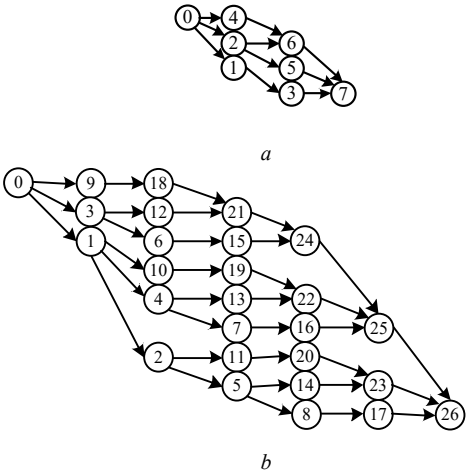

Figure 1: Sequence graphs of the nondecreasing components for $k = 2$, $k = 3$ and $n = 3$.

Example 2. Construct sequences of nondecreasing components for $k = n = 3$. Since $n = 3$, there are 3 groups of sequences with starting numbers 0, 1 and 2 for the initial data under consideration.

For group "0", the value of t_0 varies in the range

$$3^0 - 3^{-1} \le t_0 \le 3^1 - 3^0 - 1,$$

or $\quad 0 \le t_0 \le 1.$

Therefore, this group includes two sequences with the initial elements $t_{00} = 0$ and $t_{01} = 1$. The first sequence g_{00} of the group "0" contains the elements with numbers t_{00}, $t_{00} + 3^0$, $t_{00} + 3^1$, $t_{00} + 3^2$, i.e. 0, 1, 3, 9. The second sequence g_{01} of the group "0" comprises the elements with numbers t_{01}, $t_{01} + 3^0$, $t_{01} + 3^1$, $t_{01} + 3^2$, i.e. the elements with numbers 1, 2, 4, 10.

Similarly, for group 1, the value of t_1 is

$$3^1 - 3^0 \le t_1 \le 3^2 - 3^1 - 1,$$

or

$$2 \le t_1 \le 5.$$

Consequently, this group includes sequences with the initial elements $g_{1t} = 2 ... 5$, and each sequence of the group comprises the elements with numbers t_{1j}, $t_{1j} + 3^1$, $t_{1j} + 3^2$.

Finally, for group 2, the value of t_2 is

$$3^2 - 3^1 \le t_2 \le 3^3 - 3^2 - 1,$$

or

$$6 \le t_2 \le 17,$$

i.e. this group contains sequences with the initial elements $g_{2t} = 6 ... 17$, and each sequence includes the elements with numbers t_{2j}, $t_{2j} + 3^2$. Thus, we obtain the sequence structure of nondecreasing components in the form shown in Figure. 1*b*.

The monotonicity property of vectors from Z^m enables to obtain various representations of an arbitrary vector by means of monotonic vectors. Let's consider such representations in the following three variants:

– the difference of two monotonic vectors that have a value greater than the significance of the represented vector;

– the algebraic sum of monotonic vectors of the same value as the original vector;

– the algebraic sum of monotonic vectors of the value, the smaller value of the represented vector.

B. The problem of representing the logic function by the difference of two monotonic vectors of greater significance is solved by the following algorithm [18]:

Algorithm 1.

1. i=0. $b_0 = a_0$, $c_0 = b_0 - a_0$;

2. $1 \le i \le m - 1$.

$$b_i = \begin{cases} b_{i-1} \text{ when } a_i < a_{i-1} \\ b_{i-1} + a_i - a_{i-1} \text{ when } a_i \ge a_{i-1} \end{cases}, \quad c_i = b_i - a_i;$$

3. $i = m$, the end.

Here i and i–1 are neighboring indices of the elements in the sequence of nondecreasing components, $m = k^n$. The validity of the algorithm results from the following elementary arguments.

1. Let $b_0 = a_0$, then $c_0 = b_0 - a_0 = 0$.

2. Let the pair of components a_δ and a_γ satisfies the condition of monotonicity, i.e. $a_\delta \le a_\gamma$. In this case

$$a_\delta - a_\gamma \ge 0,$$

and, consequently, from the identity

$$b_\gamma = b_\delta + a_\gamma - a_\delta,$$

it follows that

$$b_\gamma \ge b_\delta,$$

i.e. b_γ also meets the monotonicity condition.

3. If the pair of components a_γ and a_δ doesn't fulfill the condition of monotonicity, i.e. $a_\delta \ge a_{\gamma\gamma}$, then, taking $b_\gamma = b_\delta$ we remain the monotonicity condition for the components of the vector b again.

Example 3. Construct a representation of the vector a = {0, 1, 1, 0, 1, 0, 0, 1, 1, 0, 1, 1, 1, 1, 1, 0} as a difference of two monotonic vectors for $k = 2$, $n = 4$, $m = k^n = 16$.

The sequence of nondecreasing components for this case has the following form:

Table 1

g	Sequences	Values of components
0	0, 1, 2, 4, 8	0, 1, 1, 1, 1
1	1, 3, 5, 9,	1, 0, 0, 0
2	2, 6, 10	1, 0, 1
	3, 7, 11	0, 1, 1
3	4, 12	1, 1
	5, 13	0, 1
	6, 14	0, 1
	7, 15	1, 0

We construct the components of the vectors b and c:

$$b_0 = 0 \qquad c_0 = 0$$
$$b_1 = b_1 + a_1 - a_0 = 1 \qquad c_1 = 0$$
$$b_2 = b_1 + a_2 - a_1 = 1 \qquad c_2 = 0$$
$$b_3 = b_1 = 1 \qquad c_3 = 1$$
$$b_4 = b_2 + a_4 - a_2 = 1 \qquad c_4 = 0$$
$$b_5 = b_1 = 1 \qquad c_5 = 0$$
$$b_6 = b_2 = 1 \qquad c_6 = 1$$
$$b_7 = b_3 + a_7 - a_3 = 2 \qquad c_7 = 1$$
$$b_8 = b_4 + a_8 - a_4 = 1 \qquad c_8 = 0$$
$$b_9 = b_5 + a_9 - a_5 = 1 \qquad c_9 = 1$$

$$b_{10} = b_6 + a_{10} - a_6 = 2 \qquad c_{10} = 1$$
$$b_{11} = b_7 + a_{11} - a_7 = 2 \qquad c_{11} = 1$$
$$b_{12} = b_8 + a_{12} - a_8 = 1 \qquad c_{12} = 0$$
$$b_{13} = b_9 + a_{13} - a_9 = 2 \qquad c_{13} = 1$$
$$b_{14} = b_6 + a_{14} - a_6 = 1 \qquad c_{14} = 1$$
$$b_{15} = b_7 = 2 \qquad c_{15} = 2$$

The described algorithm demonstrates one more fact, which confirms the simplicity of analysis in linear algebra.

As it can be seen from the example, when using the described algorithm in the general case, the value of the original vector does not coincide with the significance of the resolution vectors.

C. The expansion of the arbitrary logic function of n arguments into the algebraic sum of monotonic logic functions of the same value of the following form

$$f(\tilde{x}^{(n)}) = (-1)^i \sum_{i=0}^{p} \varphi_i(\tilde{x}^{(n)}),$$

where $p \le kn$, $\varphi_i(\tilde{x}^{(n)})$ – monotonic expansion functions with the property $\varphi_1 \supset \varphi_2 \supset \ldots$, are made in accordance with the following algorithm [18].

Algorithm 2.

1. We choose a minimal summation of the positive summands of the arithmetic-logical representation of the logic function $f(\tilde{x}^{(n)})$ covering (in the logical sense) all other positive summands, and combine it by the operation $\vee$. Thus, we form the first expansion function $\varphi_1(\tilde{x}^{(n)})$. To remain the equality, all possible logical products of summands from $\varphi_1(\tilde{x}^{(n)})$ with the signs defined as $(-1)^j$, where $1 < j < s$, s is a number of summands in $\varphi_1(\tilde{x}^{(n)})$, are added to $\varphi_1(\tilde{x}^{(n)})$. Then we reduce similar terms and represent the initial logic function $f(\tilde{x}^{(n)})$ in the following form $f(\tilde{x}^{(n)}) = \varphi_1(\tilde{x}^{(n)}) - f_1(\tilde{x}^{(n)})$, where $f_1(\tilde{x}^{(n)})$ is a remainder of the initial function after reduction of similar terms.

2. We repeat clause 1 for $f_1(\tilde{x}^{(n)})$. As a result, the initial logic function is represented in the following form

$$f(\tilde{x}^{(n)}) = \varphi_1(\tilde{x}^{(n)}) - \varphi_2(\tilde{x}^{(n)}) + f_2(\tilde{x}^{(n)}).$$

3. We repeat clause 2 until the remainder of the initial logic function becomes zero.

Since the number of arguments of the logic function is n, and the violation of monotonicity is possible in each of the k values of each argument, then, the maximum number of the expansion functions doesn't exceed $2n(k–1)$.

The process convergence follows from the fact that each successive resolution vector eliminates some violation of monotonicity in the original vector and doesn't introduce new monotonicity violations, since it is monotonic itself.

The problem of representing the arbitrary logic function by the algebraic sum of monotonic functions of the same value can be solved analytically. As is known [13], the minimal disjunctive normal form (DNF) of the monotonic logic function doesn't contain inversions over variables. Consequently, the given logic function must be reduced to the representation in the form of the algebraic sum of such functions. To do this, we must perform the following actions:

– conversion of the Boolean expression of the logic function into the linear one using the following identities

$$x_1 \vee x_2 = x_1 + x_2 - x_1 x_2;$$

$$\bar{x} = 1 - x;$$

– inverse transformation to the given (that doesn't contain inversions over variables) form.

Example 4. Obtain the two-valued logic function mapping of three arguments

$$f(\tilde{x}^{(3)}) = (0,1,1,0,1,0,0,1),$$

into the algebraic sum of monotonic logic functions.

Solution. The logic function is represented by a vector of values. Its linear representation has the following form

$$f(\tilde{x}^{(3)}) = x_1 + x_2 + x_3 - 2x_1x_2 - 2x_1x_3 - 2x_2x_3 + 4x_1x_2x_3.$$

Now we obtain the mapping of this function into the algebraic sum of monotonic functions. The first expansion function is formed from the first three summands, covering in aggregate all the remaining positive terms of sum:

$$f(\tilde{x}^{(3)}) = (x_1 \vee x_2 \vee x_3 + x_1x_2 + x_1x_3 + x_2x_3 - x_1x_2x_3) -$$
$$-2x_1x_2 - 2x_1x_3 - 2x_2x_3 - 4x_1x_2x_3 =$$
$$= \varphi_1(\tilde{x}^3) - x_1x_2 - x_1x_3 - x_2x_3 + 3x_1x_2x_3.$$

The subsequent expansion functions are obtained in the same way:

$$f(\tilde{x}^{(3)}) = \varphi_1(\tilde{x}^{(3)}) - (x_1x_2 \vee x_1x_3 \vee x_2x_3 + x_1x_2x_3 +$$
$$+x_1x_2x_3 + x_1x_2x_3 + x_1x_2x_3 - x_1x_2x_3) + 3x_1x_2x_3 =$$
$$= \varphi_1(\tilde{x}^{(3)}) - \varphi_2(\tilde{x}^{(3)}) + \varphi_3(\tilde{x}^{(3)}).$$

To obtain the threshold representation of the initial function, it suffices to transform the monotonic functions of the resulting expansion into the threshold form and to perform their algebraic addition.

Each conjunctive term of any logical expansion function is transformed into the threshold form in accordance with the following identical equation

$$x_i x_j \ldots x_s = P[(x_i + x_j + \cdots + x_s) > t - 1],$$

where t - a number of arguments in the term, P - the predicate symbol. Then all the terms are reduced to the common value of the right-hand side with the introduction of the corresponding

coefficients for the variables, then they are added together and the threshold value of the received sum is determined.

Let's explain the transformation of the monotonic logic function into the threshold form with the function from the previous example.

With the transformation of $\varphi_1(\tilde{x}^{(3)})$ everything is simple:

$$\varphi_1(\tilde{x}^{(3)}) = x_1 \vee x_2 \vee x_3 = P_1[(x_1 + x_2 + x_3) > 0];$$

The transformation of $\varphi_2(\tilde{x}^{(3)})$ looks somewhat more complicated:

$$\varphi_2(\tilde{x}^{(3)}) = x_1x_2 \vee x_1x_3 \vee x_2x_3 =$$
$$= P_2[(x_1 + x_2) > 1 + (x_1 + x_3) > 1 + (x_2 + x_3) > 1] =$$
$$P_2[(2x_1 + 2x_2 + 2x_3) > 2] = P_2[(x_1 + x_2 + x_3) > 1];$$

The transformation of $\varphi_3(\tilde{x}^{(3)})$ is produced just as easily as $\varphi_1(\tilde{x}^{(3)})$:

$$\varphi_3(\tilde{x}^{(3)}) = x_1x_2x_3 = P_3[(x_1 + x_2 + x_3) > 2].$$

Thus, to realize the considered logic function, three threshold logic elements are required. The simplicity of the transformations in linear algebra becomes obvious.

D. Representation of the arbitrary vector by the vectors of lower significance. This problem has many solutions. The variant considered below assumes the solution of this problem in two stages:

- obtaining a representation of the arbitrary vector from Z^m by the vectors of lower significance;

- transformation of the obtained representation into the representation by means of monotonic vectors.

Let us first consider the solution of the first stage of the problem. The representation of the arbitrary vector by the lower-valued vectors can be obtained by weighting (each resolution vector is included into the final representation with some weight coefficient) or unitary (each resolution vector is included into the final representation with a unitary weight coefficient) coding.

1. It is known from the theory of numbers [33] that any number a can be uniquely represented in the following form:

$$\sum_1^s a_{s-i}k^{s-i}, \qquad (3)$$

where $s = [\log_k a]$ – the closest integer to $\log_k a$, a_{s-i} – the values of the expansion coefficients of the number a in the k-valued number system. Due to the uniqueness, this relation determines the isomorphism between any number a and the described representation of this number.

The quantity a_{s-i} can be determined from the following relation:

$$a_{s-i} = \frac{a\,(mod\ k^{s-i+1}) - a\,(mod\ k^{s-i})}{k^{s-i}}.$$

This operation is linear

$$a + b = \sum_{i=1}^{s} a_{s-i}\,k^{s-i} + \sum_{i=1}^{s} b_{s-i}\,k^{s-i} =$$
$$= \sum_{i=1}^{s}(a_{s-i} + b_{s-i})\,k^{s-i};$$
$$\lambda a = \sum_{i=1}^{s} \lambda a_{s-i}\,k^{s-i} = \lambda \sum_{i=1}^{s} a_{s-i}\,k^{s-i},$$

thus, it is applicable to the vectors of the linear space. If now we associate the vector a to the number a in the linear space Z^m, and the weighted sums of the vectors a_{s-i} of the spaces K_1^m and K_2^m to the weighted sums $\sum_{i=1}^{s_1} a_{s_1-i}\,k^{s_1-i}$ and $\sum_{i=1}^{s_2} a_{s_2-i}\,k^{s_2-i}$ correspondingly, then the expression (3) is equivalent to the representation of the vector $a \in Z^m$ by the weighted sum of the vectors from K_1^m or K_2^m respectively. Since in both spaces the vector a is uniquely represented, both representations are isomorphic. Let's call such a representation by coding, and the corresponding linear operator - by *the encoding operator.*

Let the vector $a \in Z^m$ in the canonical basis be represented as

$$a = a_1e_1 + a_2e_2 + \cdots + a_me_m.$$

Using expression (3), we expand each coordinate of the vector a with respect to the bases *k1* and *k2*. As a result, we obtain its representation in the following form

$$a_i = \sum_{i=1}^{s_1} a_{i,s_1-i}\,k_1^{s_1-i},$$

or

$$a_j = \sum_{j=1}^{s_2} a_{j,s_2-j}\,k_2^{s_2-j},$$

where $a_{i,s-i}$ – the expansion components of the number a_i (i – e vector components a_i of the vector representation a).

Then the vector representation a in each of the spaces can be described in the following form

$$a = \left(a_{1,s-1}k^{s-1} + a_{1,s_1-2}k^{s-2} + \cdots + a_{1,0}k^0\right) +$$
$$+\left(a_{2,s-1}k^{s-1} + a_{2,s_1-2}k^{s-2} + \cdots + a_{2,0}k^0\right) + \cdots$$
$$+ \left(a_{m,s-1}k^{s-1} + a_{m,s_1-2}k^{s-2} + +a_{m,0}k^0\right),$$

or

$$a = \left(a_{1,s-1} + a_{2,s-1} + \cdots + a_{m,s-1}\right)k^{s-1} +$$
$$+\left(a_{1,s-2} + a_{2,s-2} + \cdots + a_{m,s-2}\right)k^{s-2} + \cdots$$
$$+\left(a_{1,0} + a_{2,0} + \cdots + a_{m,0}\right)k^0.$$

Thus, the arbitrary vector a can be written in the following form

$$a = \sum_{j=1}^{s}\left(\sum_{i=1}^{m} a_{i,s-j}\right)k^{s-j},$$

i.e. a is represented by the weighted sum s of the vectors from K_1^m or K_2^m

Example 5. Let $k_1 = 10$, $n = 1$. The problem is to represent the vector $a = \{0, 1, 3, 9, 7, 6, 9, 4, 3, 8\}$ by its k_2-weighted and k_2-unitary sums of the vectors when $k_2 = 3$.

Solution. Since $\lceil log_{k_2} k_1 \rceil = \lceil log_3 10 \rceil = 2$, then the vector a can be represented by the weighted sum of three vectors a_2, a_1 and a_0. The coordinates of the highest weight vector a_2 are determined as

$$a_2 = \frac{a\ mod 3^3 - a\ mod 3^2}{3^2} =$$

$$= \frac{(0139769348) - (0130760438)}{9} = (0001001000).$$

The components of the subsequent vectors a_1 and a_0 are determined similarly:

$$a_1 = \frac{a\ mod 3^2 - a\ mod 3^1}{3^1} =$$

$$= \frac{(0130760348) - (0100100102)}{3} = (0010220112);$$

$$a_0 = \frac{a\ mod 3^1 - a\ mod 3^0}{3^0} =$$

$$= \frac{(0100100102) - (0000000000)}{1} = (0100100102).$$

Thus,

$$a = \sum_0^3 a_i 3^i = (0001001000)3^2 + (0010220112)3^1 + (0100100102)3^0.$$

2. We now represent the arbitrary number a as follows:

$$a = \sum_{i=0}^{s-1}(a - \sum_{i=0}^{s-1} a_i)\ \&(k_2 - 1), \qquad (4)$$

where s - the nearest larger integer

$$s = \left\lceil \frac{k_1 - 1}{k_2 - 1} \right\rceil.$$

For the reasons stated above, this representation is also an isomorphism.

If we associate each coordinate of the vector a with its representation in form (4), we obtain:

$$a = \left[a_1\&(k_2 - 1) + \left(a_1 - a_{11}\&(k_2 - 1)\right) + \cdots + a_1 - \sum_{i+1}^{s-1} a_{1i}\right]\&(k_2 - 1) +$$

$$+ \left[a_2\&(k_2 - 1) + \left(a_2 - a_{21}\&(k_2 - 1)\right) + \cdots + a_2 - \sum_{i+1}^{s-1} a_{2i}\right]\&(k_2 - 1) + \cdots$$

$$+ \left[a_m\&(k_2 - 1) + \left(a_m - a_{m1}\&(k_2 - 1)\right) + \cdots + a_m - \sum_{i+1}^{s-1} a_{mi}\right]\&(k_2 - 1).$$

Thus,

$$a = \sum_0^{s-1} a_i,$$

where $a_i = (a - \sum_{i+1}^{s-1} a_i)\&(k_2 - 1)$, i.e. the arbitrary vector $a \in Z^m$ is represented by the k_2-unitary sum of vectors from Z^m.

Example 6. Present the original vector from the previous example using unitary coding.

Solution. Since under the same initial conditions $s = \left\lceil \frac{10-1}{3-1} \right\rceil = 4$, the vector a can be represented by the unitary sum of five vectors a_4, a_3, a_2, a_1 and a_0, where

$a_4 = a\&(3 - 1) = (0139769438)\&(3 - 1) = (0122222222)$;

$a_3 = (a - a_4)\&(3 - 1) = (0012222212)$;

$a_2 = (a - a_4 - a_3)\&(3 - 1) = (0002222002)$;

$a_1 = (a - a_4 - a_3 - a_2)\&(3 - 1) = [0002102002]$;

$$a_0 = (a - a_4 - a_3 - a_2 - a_1)\&(3 - 1) =$$

$$= [0001001000].$$

Thus,

$$a = \sum_0^3 a_i = (0122222222) + (0012222212) +$$

$$+(0002222002) + (0002102002) +$$

$$+0001001000.$$

The solution of the second stage of the problem, i.e. the transformation of the obtained representation into the representation by means of monotonic lower-valued vectors, can be obtained on the base of algorithm 2.

Thus, the body of the linear space theory determines easy-to-use means of representing arbitrary vectors of any given value by monotonic vectors of greater, similar or lesser significance, and also converting monotonic functions to the threshold form.

4. Synthesis of Logic and Threshold Elements

In linear algebra, the logic function is represented by a weighted algebraic sum of terms. As a whole the variables, terms and function take values from the set of numbers 0, 1, ..., k - 1. The algebraic sum is realized by operations of the linear space, and individual terms - depending on the choice made - by other operations chosen for technical, technological or operational reasons. In this article, *"Truncated Difference"* and *"Comparison"* are used as such operations. In the future, the developers of linear LSIs can be motivated to choose other operations. Thus, the process and the possibilities of logic synthesis will be further demonstrated on the bases based on the *truncated difference* and *comparison* operations.

To solve the problems of logic synthesis in linear algebra, first, it is necessary to solve the problem of the formation of bases.

In Boolean algebra, 17 previously defined functionally complete systems of logic functions of two arguments are known [34]. Selecting any of them, you can get its linear analog and

perform a logic synthesis of the circuit that implements the given logic function according to the established algorithm. Therefore, it is possible to construct bases as a mapping of Boolean functionally complete systems to a linear space. For *truncated difference* and *comparison* operations, the bases can be formed directly.

To form the bases, we need:

- a set of operations;

- a set of generating functions.

The following operation are considered as the basic ones:

- logical operations in their traditional understanding;

- operation *"truncated difference";*

- operation *"comparison".*

Constants 1, logical variables x_1, x_2, …, x_n and their totals subjected to the effect of basic operations are used as generators for the formation of bases.

The following methods of logic synthesis of digital structures are considered:

- direct synthesis in a given basis (logic synthesis in the linear space);

- synthesis with preliminary transformation of the value of the given function (for example, a multivalued two-digit implementation);

- synthesis with preliminary expansion of the given function into the algebraic sum of monotonic functions (threshold synthesis).

The first method is the most obvious and consists in the representation of the realized logic function in the chosen basis.

The second method presupposes a preliminary representation of the realized function in the form of an algebraic sum of logic functions larger, smaller or equal to the original value. The methods of this transformation have been described in the previous section.

Finally, the third method consists of the preliminary representation of the realized function by the algebraic sum of monotonic logic functions. In this case, each monotonic function is realized by a single threshold element.

Note that the synthesis of digital structures with increasing of their complexity, as usual, requires the involvement of methods of system engineering.

A. Basic operations of logic synthesis. The set of operations most often used to represent logic functions will be considered as basic operations of logic synthesis. In Boolean algebra, such operations can be considered as operations of the basic functional system AND (&), OR (∨), ($\bar{}$), and also the operations "modulo 2 sum" (⊕), "logic equivalence" (~) "dual stroke" (↓), "Sheffer stroke" (|), "prohibition with respect to x_1 (x_2)" $(x_1\bar{x}_2)$, "implication from x_1 to x_2)" $(x_1 \vee \bar{x}_2)$, majority operation $x_1 \# x_2 \# x_3$.

By *basic operations of linear algebra* we mean arithmetic operations (operations of the linear space), as well as operations used to form bases. We classify the current realizations of logical operations: the difference module, *the truncated difference*, the arithmetic sum and the difference, the multiplication by a constant coefficient, the operations of changing the sign to them. Perhaps there are other arithmetic operations suitable for the use in linear logic synthesis, but they are not considered in this article.

Since our task is logic synthesis in linear algebra, we start with the logic synthesis of basic operations of linear algebra.

Algebraic sum. The operation is realized by the assembly connection of conductors, over which the currents flow. The conditional graphic representation of the operation of the algebraic sum is shown in Figure 2.

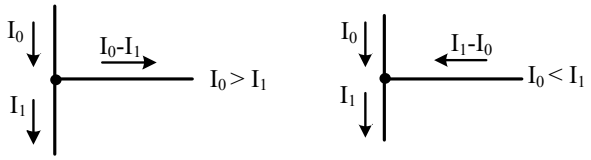

Figure 2: Conditional graphical representation of the algebraic addition of currents.

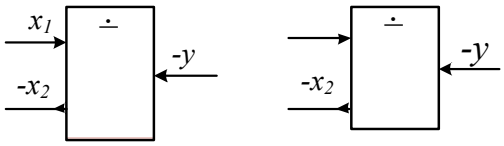
The arithmetic sum differs from the algebraic one in that in the latter case the signals of only one sign (i.e. only inflowing or only flowing out) are fed to the input of the element. From the output, the sum of the signals is removed. The positive direction of the input currents is the current direction to the connection point Σ_1, i.e. the positive current flowing into the connection point. The negative direction of the input currents is the direction of the current from the connection point of the conductors Σ_1, i.e. negative - the current flowing from the connection point. For the output (resulting) current, the positive direction is the direction from the connection point Σ_1, and the negative direction - to the connection point Σ_1,

The number of positive and negative inputs is determined by the function being implemented. Since the logical variables take values from the positive semi-axis of the numerical axis, when subtracting, it is necessary to meet the condition that the total sum of the negative summands (current quanta) doesn't exceed the total sum of the positive terms of the sum. Otherwise, instead of the algebraic sum, the *truncated difference* operation is performed, in which the subtraction from zero is a logical component of this operation and which carries the meaning of the *comparison* operation with zero (Figure 3)



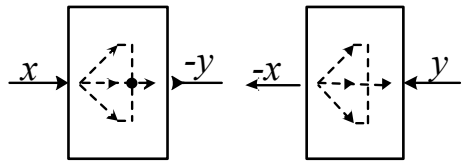


Figure 3: Conditional graphic representation o*f the truncated difference* operation.

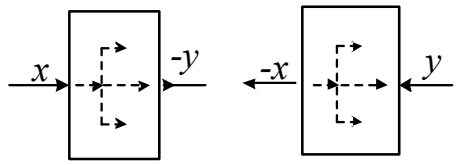
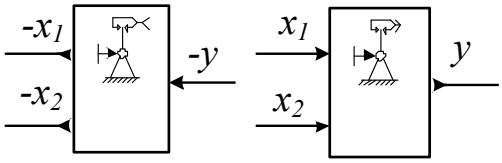


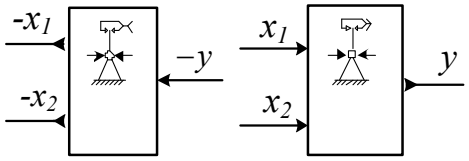
The operation of multiplying (dividing) by a constant coefficient consists in multiplying the input signal by several outputs and then combining the outputs of the multiplied signal (when multiplying) or outputting some part of the input signal (when dividing), as shown in Figure 4.

The comparison operation is used to determine the relationship between the compared variables. It can be performed in two forms: in the relative form, i.e. in the form of determining the difference in the values of the variables, or in the absolute form, i.e. in the form of the "more-less" comparison itself. The conditional graphic

symbols of the comparison elements in these forms are shown in Figure 5.

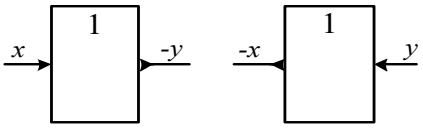


a



b

Figure 4: Conditional graphic representation of the operation of multiplication *(a)* and division *(b)*.



a

b

Figure 5: Conditional graphic representation of the *comparison* operation: relative *(a)* and absolute *(b)*.

The operation of *changing the sign* of terms allows changing the sign of the term, thereby transforming it from the summand to the subtrahend and vice versa. It is performed by the current inverter, the conditional graphic representation of which is shown in Figure 6.

a *b*

Figure 6: Conditional graphic representation of the operation of changing the sign.

The operation of changing the sign can functionally be combined with the operations of multiplication and division by the constant coefficient.

B. Formation of bases. The bases being formed are bases of the linear space, and according to the form they are sets of variables and their various combinations (terms) combined by the selected operations. We can approach to the formation of bases from different sides. For the two-valued synthesis, as it was shown above, it is possible, for example, to construct bases equivalent to 17 functionally complete systems (logical-arithmetic), and then create their analogs in linear algebra.

To form the multivalued bases, we can use the cuts of multivalued variables (10 combinations of such cuts are proposed in [18]), and then construct their analogs in linear algebra. Such a solution is also applicable for the two-valued bases. The problem of forming the bases is solved uniformly for the cuts of any type, so we demonstrate its solution on the basis of the upper cuts of the first level, which are analogs of the functionally complete system AND, NOT (OR, NOT).

The bases of this type for $k = 2$, $n = 2$ and $n = 3$, and for $k = 3$, $n = 2$ are given below. For each basis, the basic and inverse matrices are presented. Two-digit operations & and ∨ and their multivalued analogs $min(x_1x_2)$ and $max(x_1x_2)$ are used as generating operations. Therefore, the bases of this type are called logical-arithmetic.

The two-valued logical-arithmetic bases of two variables have the form:

- conjunctive (AND, NOT)

$$\&(\mathrm{B1},\mathrm{B1})^{(2)} = \begin{bmatrix} 1 \\ x_1^{(1)} \\ x_2^{(1)} \\ x_1^{(1)}x_2^{(1)} \end{bmatrix} = \begin{bmatrix} 1 \\ x_1 \\ x_2 \\ x_1\&x_2 \end{bmatrix} = \begin{bmatrix} 1 & 1 & 1 & 1 \\ 0 & 1 & 0 & 1 \\ 0 & 0 & 1 & 1 \\ 0 & 0 & 0 & 1 \end{bmatrix};$$

$$\left(\&(\mathrm{B1},\mathrm{B1})^{(2)}\right)^{-1} = \begin{bmatrix} 1 & -1 & -1 & 1 \\ 0 & 1 & 0 & -1 \\ 0 & 0 & 1 & -1 \\ 0 & 1 & 1 & 1 \end{bmatrix};$$

- disjunctive (OR, NOT)

$$\vee\,(\mathrm{B1},\mathrm{B1})^{(2)} = \begin{bmatrix} 1 \\ x_1^{(1)} \\ x_2^{(1)} \\ x_1^{(1)} \vee x_2^{(1)} \end{bmatrix} = \begin{bmatrix} 1 & 1 & 1 & 1 \\ 0 & 1 & 0 & 1 \\ 0 & 0 & 1 & 1 \\ 0 & 1 & 1 & 1 \end{bmatrix};$$

$$(\vee\,(\mathrm{B1},\mathrm{B1})^{2})^{-1} = \begin{bmatrix} 1 & 0 & 0 & -1 \\ 0 & 0 & -1 & 1 \\ 0 & -1 & 0 & 1 \\ 0 & 1 & 1 & -1 \end{bmatrix}.$$

The two-valued logical-arithmetic bases of three variables have the similar form:

$$\&(\mathrm{B1},\mathrm{B1},B1)^{(2)} = \begin{bmatrix} 1 \\ x_1 \\ x_2 \\ x_3 \\ x_1x_2 \\ x_1x_3 \\ x_2x_3 \\ x_1x_2x_3 \end{bmatrix} = \begin{bmatrix} 1 & 1 & 1 & 1 & 1 & 1 & 1 & 1 \\ 0 & 1 & 0 & 1 & 0 & 1 & 0 & 1 \\ 0 & 0 & 1 & 1 & 0 & 0 & 1 & 1 \\ 0 & 0 & 0 & 0 & 1 & 1 & 1 & 1 \\ 0 & 0 & 0 & 1 & 0 & 0 & 0 & 1 \\ 0 & 0 & 0 & 0 & 0 & 1 & 0 & 1 \\ 0 & 0 & 0 & 0 & 0 & 0 & 1 & 1 \\ 0 & 0 & 0 & 0 & 0 & 0 & 0 & 1 \end{bmatrix};$$

$$\left(\&(\mathrm{B1},\mathrm{B1},B1)^{(2)}\right)^{-1} = \begin{bmatrix} 1 & -1 & -1 & -1 & 1 & 1 & 1 & -1 \\ 0 & 1 & 0 & 0 & -1 & -1 & 0 & 1 \\ 0 & 0 & 1 & 0 & -1 & -1 & -1 & 1 \\ 0 & 0 & 0 & 0 & 1 & 0 & 0 & -1 \\ 0 & 0 & 0 & 1 & 0 & -1 & -1 & 1 \\ 0 & 0 & 0 & 0 & 0 & 1 & 0 & -1 \\ 0 & 0 & 0 & 0 & 0 & 0 & 1 & -1 \\ 0 & 0 & 0 & 0 & 0 & 0 & 0 & 1 \end{bmatrix};$$

$$\vee(\mathrm{B1},\mathrm{B1},B1)^{(2)}=\begin{bmatrix}1\\x_1\\x_2\\x_3\\x_1\vee x_2\\x_1\vee x_3\\x_2\vee x_3\\x_1\vee x_2\vee x_3\end{bmatrix}=\begin{bmatrix}1&1&1&1&1&1&1&1\\0&1&0&1&0&1&0&1\\0&0&1&1&0&0&1&1\\0&0&0&0&1&1&1&1\\0&1&1&1&0&1&1&1\\0&1&0&1&1&1&1&1\\0&0&1&1&1&1&1&1\\0&1&1&1&1&1&1&1\end{bmatrix};$$

$$\left(\vee(\mathrm{B1},\mathrm{B1},B1)^{(2)}\right)^{-1}=\begin{bmatrix}1&0&0&0&0&0&0&-1\\0&0&0&0&0&0&-1&1\\0&0&0&0&0&-1&0&1\\0&0&0&-1&0&1&1&-1\\0&0&0&0&-1&0&0&1\\0&0&-1&0&1&0&1&-1\\0&-1&0&0&1&1&0&-1\\0&1&1&1&-1&-1&-1&1\end{bmatrix}.$$

The three-valued logical-arithmetic analogs of these bases look like this:

- conjunctive

$$min(B1,B1)^{(3)}=\begin{bmatrix}1\\x_1^{(1)}\\x_1^{(2)}\\x_2^{(1)}\\min\left(x_1^{(1)},x_2^{(1)}\right)\\min\left(x_1^{(2)},2x_2^{(1)}\right)\\x_2^{(2)}\\min\left(2x_1^{(1)},x_2^{(2)}\right)\\min\left(x_1^{(2)},x_1^{(2)}\right)\end{bmatrix}=\begin{bmatrix}1&1&1&1&1&1&1&1&1\\0&1&1&0&1&1&0&1&1\\0&1&2&0&1&2&0&1&2\\0&0&0&1&1&1&1&1&1\\0&0&0&0&1&1&0&1&1\\0&0&0&0&1&2&0&1&2\\0&0&0&1&1&1&2&2&2\\0&0&0&0&1&1&0&2&2\\0&0&0&0&1&1&0&1&2\end{bmatrix};$$

$$\left(min(B1,B1)^{(3)}\right)^{-1}=\begin{bmatrix}1&-1&0&-1&1&0&0&0&0\\0&0&0&2&-2&0&-1&1&0\\0&0&0&-1&1&0&1&-1&0\\0&2&-1&0&-2&1&0&0&0\\0&0&0&0&2&-1&0&-1&1\\0&0&0&0&0&0&0&1&-1\\0&-1&1&0&1&-1&0&0&0\\0&0&0&0&0&1&0&0&-1\\0&0&0&0&-1&0&0&0&1\end{bmatrix};$$

- disjunctive

$$max(B1,B1)^{(3)}=\begin{bmatrix}1\\x_2^{(1)}\\x_2^{(2)}\\x_1^{(1)}\\max\left(x_2^{(1)},x_1^{(1)}\right)\\max\left(x_2^{(2)},2x_1^{(1)}\right)\\x_1^{(2)}\\max\left(2x_2^{(1)},x_1^{(2)}\right)\\max\left(x_2^{(2)},x_1^{(2)}\right)\end{bmatrix}=\begin{bmatrix}1&1&1&1&1&1&1&1&1\\0&0&0&1&1&1&1&1&1\\0&0&0&1&1&1&2&2&2\\0&1&1&0&1&1&0&1&1\\0&2&2&1&2&2&2&2&2\\0&0&0&0&1&1&0&2&2\\0&1&2&0&1&2&0&1&2\\0&1&2&2&2&2&2&2&2\\0&1&2&1&1&2&2&2&2\end{bmatrix};$$

$$\left(max(B1,B1)^{(3)}\right)^{-1}=\begin{bmatrix}1&0&0&0&-1&0&0&0&0\\0&0&0&0&2&0&0&-1&0\\0&-1&0&0&-1&0&0&1&0\\0&0&0&0&2&-1&0&0&0\\0&0&0&0&-2&1&0&1&-1\\0&2&-1&0&0&0&0&-1&1\\0&0&0&-1&-1&1&0&0&0\\0&0&0&2&0&-1&-1&0&1\\0&-1&1&-1&1&0&1&0&-1\end{bmatrix}.$$

To obtain linear analogs of the above logical-arithmetic bases, we can use the relations that establish the connection between logical operations, on the one hand, and with the operations used to form the bases of linear space, on the other hand. For the bases of the considered type these relations are as follows:

- logical operations - *truncated difference* operation

$$x^{(i)}=i\dot{-}(i\dot{-}x)=x\dot{-}(x\dot{-}i);$$

$$x^{(i)}-x^{(j)}=x^{(ij)}=(x\dot{-}j)\dot{-}(x\dot{-}i);$$

$$min(x_1,x_2)=x_1\dot{-}(x_1\dot{-}x_2)=x_2\dot{-}(x_2\dot{-}x_1);$$

$$max(x_1,x_2)=x_1+(x_2\dot{-}x_1)=x_2+(x_1\dot{-}x_2).$$

- logical operations - *comparison* operation

$$x^{(i)}=\sum_{j=0}^{i-1}(x>j);$$

$$x^{(i)}-x^{(j)}=x^{(ij)}=\textstyle\sum_{t=1}^{i-j}P_t(x>t);$$

$$min(x_1,x_2)=P\{[(x_1>0)+(x_2>0)]>1\}+$$
$$+P\{[(x_1>1)+(x_2>1)]>1\};$$

$$max(x_1,x_2)=P\{[(x_1>0)+(x_2>0)]>0\}+$$
$$+P\{[(x_1>1)+(x_2>1)]>0\}.$$

Using the above relations, we can easily obtain linear analogs of the above bases:

- conjunctive $k = 2$, $n = 2$ and $n = 3$

$$\&(\mathrm{B1},\mathrm{B1})^{(2)}=\begin{bmatrix}1\\x_1^{(1)}\\x_2^{(1)}\\x_1^{(1)}x_2^{(1)}\end{bmatrix}=\begin{bmatrix}1\\x_1\\x_2\\(x_1+x_2)\dot{-}1\end{bmatrix}=\begin{bmatrix}1&1&1&1\\0&1&0&1\\0&0&1&1\\0&0&0&1\end{bmatrix};$$

$$\left(\&(\mathrm{B1},\mathrm{B1})^{(2)}\right)^{-1}=\begin{bmatrix}1&-1&-1&1\\0&1&0&-1\\0&0&1&-1\\0&1&1&1\end{bmatrix};$$

$$\&(\mathrm{B1},\mathrm{B1},B1)^{(2)}=\begin{bmatrix}1\\x_1\\x_2\\x_3\\x_1x_2\\x_1x_3\\x_2x_3\\x_1x_2x_3\end{bmatrix}=\begin{bmatrix}1\\x_1\\x_2\\x_3\\(x_1+x_2)\dot{-}1\\(x_1+x_3)\dot{-}1\\(x_2+x_3)\dot{-}1\\(x_1+x_2+x_3)\dot{-}2\end{bmatrix}=$$

$$=\begin{bmatrix}1&1&1&1&1&1&1&1\\0&1&0&1&0&1&0&1\\0&0&1&1&0&0&1&1\\0&0&0&0&1&1&1&1\\0&0&0&1&0&0&0&1\\0&0&0&0&0&1&0&1\\0&0&0&0&0&0&1&1\\0&0&0&0&0&0&0&1\end{bmatrix};$$

$$\left(\&(\mathrm{B1},\mathrm{B1},B1)^{(2)}\right)^{-1} = \begin{bmatrix} 1 & -1 & -1 & -1 & 1 & 1 & 1 & -1 \\ 0 & 1 & 0 & 0 & -1 & -1 & 0 & 1 \\ 0 & 0 & 1 & 0 & -1 & -1 & -1 & 1 \\ 0 & 0 & 0 & 0 & 1 & 0 & 0 & -1 \\ 0 & 0 & 0 & 1 & 0 & -1 & -1 & 1 \\ 0 & 0 & 0 & 0 & 0 & 1 & 0 & -1 \\ 0 & 0 & 0 & 0 & 0 & 0 & 1 & -1 \\ 0 & 0 & 0 & 0 & 0 & 0 & 0 & 1 \end{bmatrix};$$

- disjunctive $k = 2$, $n = 2$ and 3

$$\vee(\mathrm{B1},\mathrm{B1})^2 = \begin{bmatrix} 1 \\ x_1^{(1)} \\ x_2^{(1)} \\ x_1^{(1)} \vee x_2^{(1)} \end{bmatrix} = \begin{bmatrix} 1 \\ x_1 \\ x_2 \\ x_1 + (x_2 \div x_1) \end{bmatrix} =$$

$$= \begin{bmatrix} 1 & 1 & 1 & 1 \\ 0 & 1 & 0 & 1 \\ 0 & 0 & 1 & 1 \\ 0 & 1 & 1 & 1 \end{bmatrix},$$

$$(\vee(\mathrm{B1},\mathrm{B1})^2)^{-1} = \begin{bmatrix} 1 & 0 & 0 & -1 \\ 0 & 0 & -1 & 1 \\ 0 & -1 & 0 & 1 \\ 0 & 1 & 1 & -1 \end{bmatrix},$$

$$\vee(\mathrm{B1},\mathrm{B1},B1)^{(2)} = \begin{bmatrix} 1 \\ x_1 \\ x_2 \\ x_3 \\ x_1 \vee x_2 \\ x_1 \vee x_3 \\ x_2 \vee x_3 \\ x_1 \vee x_2 \vee x_3 \end{bmatrix} = \begin{bmatrix} 1 \\ x_1 \\ x_2 \\ x_3 \\ 1 \div [1 \div (x_1 + x_2)] \\ 1 \div [1 \div (x_1 + x_3)] \\ 1 \div [1 \div (x_2 + x_3)] \\ 1 \div [1 \div (x_1 + x_2 + x_3)] \end{bmatrix} =$$

$$= \begin{bmatrix} 1 & 1 & 1 & 1 & 1 & 1 & 1 & 1 \\ 0 & 1 & 0 & 1 & 0 & 1 & 0 & 1 \\ 0 & 0 & 1 & 1 & 0 & 0 & 1 & 1 \\ 0 & 0 & 0 & 0 & 1 & 1 & 1 & 1 \\ 0 & 1 & 1 & 1 & 0 & 1 & 1 & 1 \\ 0 & 1 & 0 & 1 & 1 & 1 & 1 & 1 \\ 0 & 0 & 1 & 1 & 1 & 1 & 1 & 1 \\ 0 & 1 & 1 & 1 & 1 & 1 & 1 & 1 \end{bmatrix},$$

$$\left(\vee(\mathrm{B1},\mathrm{B1},B1)^{(2)}\right)^{-1} =$$

$$= \begin{bmatrix} 1 & 0 & 0 & 0 & 0 & 0 & 0 & -1 \\ 0 & 0 & 0 & 0 & 0 & 0 & -1 & 1 \\ 0 & 0 & 0 & 0 & 0 & -1 & 0 & 1 \\ 0 & 0 & 0 & -1 & 0 & 1 & 1 & -1 \\ 0 & 0 & 0 & 0 & -1 & 0 & 0 & 1 \\ 0 & 0 & -1 & 0 & 1 & 0 & 1 & -1 \\ 0 & -1 & 0 & 0 & 1 & 1 & 0 & -1 \\ 0 & 1 & 1 & 1 & -1 & -1 & -1 & 1 \end{bmatrix}.$$

Similarly, we obtain linear analogs of multivalued bases:

- conjunctive, $k = 3$, $n = 2$

$$min(B1,B1)^{(3)} = \begin{bmatrix} 1 \\ 1 \div (1 \div x_1) \\ x_1 \\ 1 \div (1 \div x_2) \\ [1 - (1 \div x_1)] - (1 \div x_2) \\ x_1 \div 2(1 \div x_2) \\ x_2 \\ 2[1 - (1 \div x_1)] - (2 \div x_2) \\ x_1 \div (x_1 \div x_2) \end{bmatrix} =$$

$$= \begin{bmatrix} 1 & 1 & 1 & 1 & 1 & 1 & 1 & 1 & 1 \\ 0 & 1 & 1 & 0 & 1 & 1 & 0 & 1 & 1 \\ 0 & 1 & 2 & 0 & 1 & 2 & 0 & 1 & 2 \\ 0 & 0 & 0 & 1 & 1 & 1 & 1 & 1 & 1 \\ 0 & 0 & 0 & 0 & 1 & 1 & 0 & 1 & 1 \\ 0 & 0 & 0 & 0 & 1 & 2 & 0 & 1 & 2 \\ 0 & 0 & 0 & 1 & 1 & 1 & 2 & 2 & 2 \\ 0 & 0 & 0 & 0 & 1 & 1 & 0 & 2 & 2 \\ 0 & 0 & 0 & 0 & 1 & 1 & 0 & 1 & 2 \end{bmatrix};$$

$$\left(min(B1,B1)^{(3)}\right)^{-1} =$$

$$= \begin{bmatrix} 1 & -1 & 0 & -1 & 1 & 0 & 0 & 0 & 0 \\ 0 & 2 & -1 & 0 & -2 & 1 & 0 & 0 & 0 \\ 0 & -1 & 1 & 0 & 1 & -1 & 0 & 0 & 0 \\ 0 & 0 & 0 & 2 & -2 & 0 & -1 & 1 & 0 \\ 0 & 0 & 0 & 0 & 2 & -1 & 0 & -1 & 1 \\ 0 & 0 & 0 & 0 & 0 & 1 & 0 & 0 & -1 \\ 0 & 0 & 0 & -1 & 1 & 0 & 1 & -1 & 0 \\ 0 & 0 & 0 & 0 & 0 & 1 & 0 & 1 & -1 \\ 0 & 0 & 0 & 0 & -1 & 0 & 0 & 0 & 1 \end{bmatrix};$$

- disjunctive

$$max(B1,B1)^{(3)} = \begin{bmatrix} 1 \\ 1 \div (1 \div x_1) \\ x_1 \\ 1 \div (1 \div x_2) \\ 1 \div (x_1 + x_2) \\ x_2 + \{2[1 \div (1 \div x_1)] \div x_2\} \\ x_2 \\ x_1 + \{2[1 \div (1 \div x_2)] \div x_1\} \\ x_1 + (x_2 \div x_1) \end{bmatrix} =$$

$$= \begin{bmatrix} 1 & 1 & 1 & 1 & 1 & 1 & 1 & 1 & 1 \\ 0 & 1 & 1 & 0 & 1 & 1 & 0 & 1 & 1 \\ 0 & 1 & 2 & 0 & 1 & 2 & 0 & 1 & 2 \\ 0 & 0 & 0 & 1 & 1 & 1 & 1 & 1 & 1 \\ 0 & 1 & 1 & 1 & 1 & 1 & 1 & 1 & 1 \\ 0 & 1 & 2 & 2 & 2 & 2 & 2 & 2 & 2 \\ 0 & 0 & 0 & 1 & 1 & 1 & 2 & 2 & 2 \\ 0 & 2 & 2 & 1 & 2 & 2 & 2 & 2 & 2 \\ 0 & 1 & 2 & 1 & 1 & 2 & 2 & 2 & 2 \end{bmatrix};$$

$$\left(max(B1,B1)^{(3)}\right)^{-1} =$$

$$= \begin{bmatrix} 1 & 0 & 0 & 0 & -1 & 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 & 2 & -1 & 0 & 0 & 0 \\ 0 & 0 & 0 & -1 & -1 & 1 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 & 2 & -1 & 0 & -1 & 1 \\ 0 & 0 & 0 & 0 & -2 & 2 & 0 & 1 & -2 \\ 0 & 0 & 0 & 2 & 0 & -1 & 0 & 0 & 1 \\ 0 & -1 & 0 & 0 & -1 & 1 & 0 & 1 & -1 \\ 0 & 2 & -1 & 0 & 0 & -1 & 0 & -1 & 2 \\ 0 & -1 & 1 & -1 & 1 & 0 & 0 & 0 & -1 \end{bmatrix}.$$

C. Logic synthesis of basic functions. The resulted conditional graphic designations of operations of the linear space can be used for graphic representation of basic Boolean logic operations in linear algebra and construct functional schemes of logic elements on their base. For this it is sufficient:

- to choose the basis from the listed above;

- to use the previously described technique of logic synthesis in linear algebra.

We choose a conjunctive version of the chosen basis as an object of logic synthesis in which we perform a logic synthesis of the two-valued and three-valued functions of circular shift

$$(x_1 \& x_2) \oplus 1 = [1\ 1\ 1\ 0],$$

and

$$min(x_1, x_2) \oplus 1 = [1\ 1\ 1\ 1\ 2\ 2\ 1\ 2\ 0],$$

and

$$min(x_1, x_2) \ominus 1 = [2\ 2\ 2\ 2\ 0\ 0\ 2\ 0\ 1].$$

In accordance with the above, the first action is to obtain the expansion vector of the value vector of the function in terms of the basis. Multiplying the vectors written above by the columns of the inverse matrix of the bases $\&(\mathrm{B1}, \mathrm{B1})^{(2)}$ and $min(B1, B1)^{(3)}$ results in the following:

$$w[(x_1 \& x_2) \oplus 1] = [0\ 1\ 1\ -2];$$

$$w[min(x_1, x_2) \oplus 1] \Rightarrow [1\ 0\ 0\ 0\ 3\ 0\ 0\ 0\ -2];$$

$$w[min(x_1, x_2) \ominus 1] \Rightarrow [2\ 0\ 0\ 0\ -3\ 0\ 0\ 01].$$

Weighing the basis vectors with respect to the obtained coefficients, we obtain expressions of the logic functions in the given basis

$$(x_1 \& x_2) \oplus 1 = 1 - (x_1 + x_1 - 2x_1 \& x_1);$$

$$min(x_1, x_2) \oplus 1 = 1 + 3min\left(x_1^{(1)}, x_2^{(1)}\right) - 2min\left(x_1^{(2)}, x_2^{(2)}\right);$$

$$min(x_1, x_2) \ominus 1 = 2 - 3min\left(x_1^{(1)}, x_2^{(1)}\right) + min\left(x_1^{(2)}, x_2^{(2)}\right).$$

The functional schemes corresponding to these expressions are shown in Figure 7 *a, b, c.*

To obtain the equivalent expressions of the functions in linear analogs of the logical-arithmetic basis under consideration, one can proceed in two ways:

- replace the used basis vectors with their linear analogs in the expressions obtained;

- use the above relations between logic and linear operations and convert the expressions written above into the linear form.

In all three cases, we obtain the following results:

$$(x_1 \& x_2) \oplus 1 = 1 - \{x_1 + x_1 - 2[(x_1 + x_1) \div 1]\};$$

$$min(x_1, x_2) \oplus 1 = 1 + 3\{[1 \div (1 \div x_1)] \div (1 \div x_2)\} - -2\{[(x_1 \div 1) + (x_2 \div 1)] \div 1\};$$

$$min(x_1, x_2) \ominus 1 = 2 - 3\{[1 \div (1 \div x_1)] \div (1 \div x_2)\} + +\{[(x_1 \div 1) + (x_2 \div 1)] \div 1\}.$$

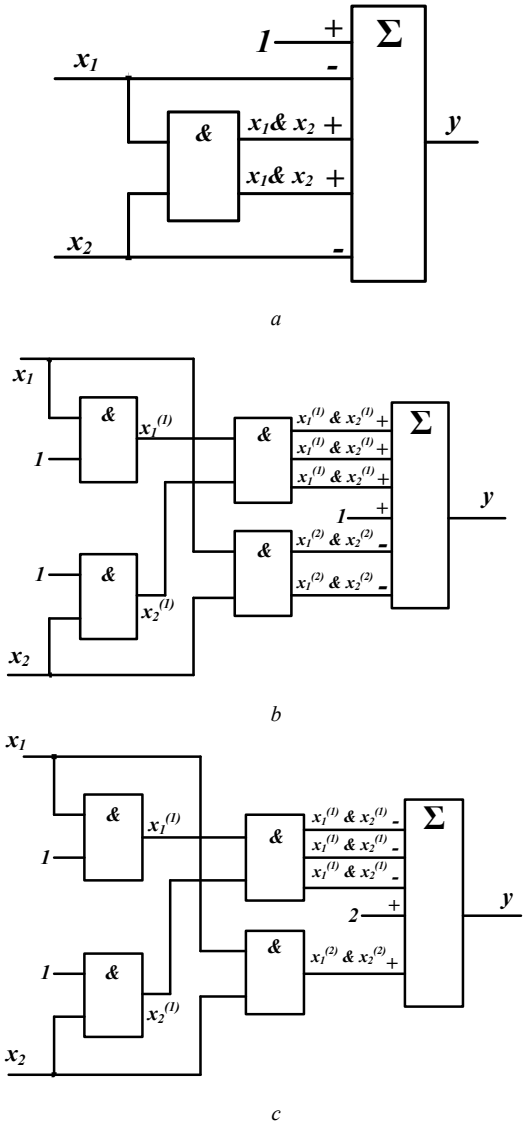


Figure 7: Functional schemes of the logical-arithmetic realization of the circular shift operation: a - two-valued, b - three-valued with a shift to the right, c - three-valued with a shift to the left.

The functional schemes corresponding to these expressions are shown in Figure 8, *a, b, c.*

The difference between the linear representations obtained from the arithmetic-logical representation is the possibility of physical realization. The authors of the article have obtained more than 25 patents for the circuit implementation of two-valued and three-valued logic circuits.

D. Expansion of the arbitrary function into the algebraic sum of monotonic functions of the same value. To obtain the representation of the functions under consideration by the algebraic sum of monotonic functions, we expand them into the algebraic sum of monotonic functions within each value. For the two-valued function, the sequence graph of nondecreasing components has the form shown in Figure 9.

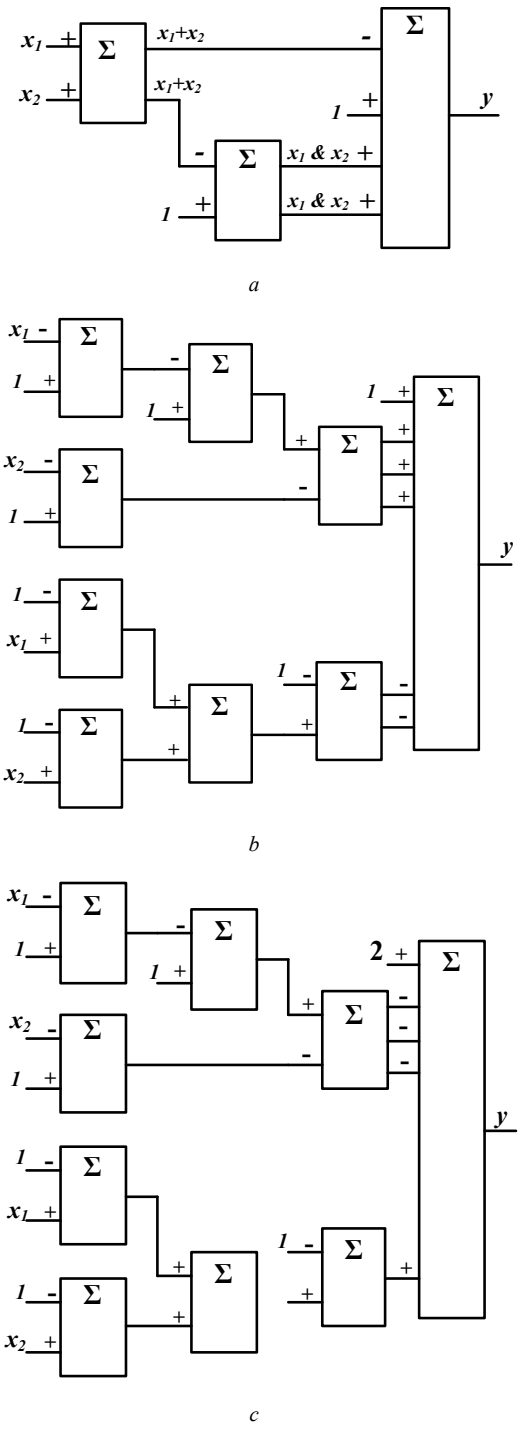

Figure 8: Functional schemes of the linear realization of the circular shift operation based on the *truncated difference*: *a* - two-valued, *b* - three-valued with a shift to the right, *c* - three-valued with a shift to the left.

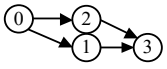

Figure 9: Sequence graph of nondecreasing components of the two-valued functions of two variables.

The structure of the expansion function of the equivalence $\bar{x}_1\bar{x}_2 \vee x_1x_2 = (x_1\&x_2) \oplus 1$ into the algebraic sum of monotonic functions is given in Figure 10.

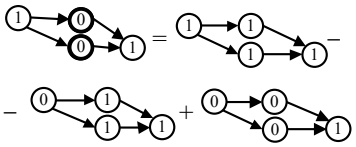

Figure 10: The structure of the expansion of the two-valued function $\bar{x}_1\bar{x}_2 \vee x_1x_2$ into the algebraic sum of monotonic functions.

Here and below, the double circle marks the terms the values of which violate the monotonicity of the function.

It follows from the structure of the expansion that the representation of the function under consideration by the algebraic sum of monotonic functions has the following form

$$f(\tilde{x}^{(2)}) = (x_1\&x_2) \oplus 1 = 1 - x_1 \vee x_2 + x_1\&x_2.$$

Carrying out the similar transformations for the three-valued functions, the sequence graph of nondecreasing components of which is shown in Figure 11.

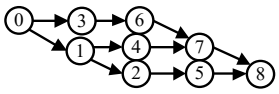

Figure 11: Sequence graph of nondecreasing components of the three-valued functions of two variables.

we obtain the following representations of the functions under consideration by the algebraic sum of monotonic functions:

- for $min(x_1, x_2)\oplus 1$.

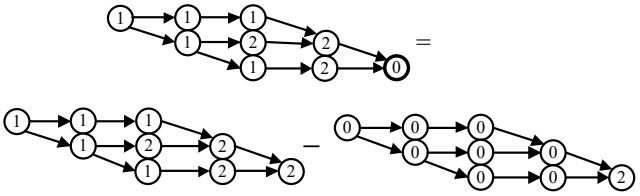

Figure 12: The structure of the expansion of the three-valued function $min(x_1, x_2)\oplus 1$ into the algebraic sum of monotonic functions.

$$min(x_1, x_2)\oplus 1 = 1 - min\left(x_1^{(1)}, x_2^{(1)}\right) -$$
$$-2min\left(x_1^{(2)}, x_2^{(2)}\right) + min\left(x_1^{(1)}, x_2^{(1)}\right);$$

– for $min(x_1, x_2) \ominus 1$.

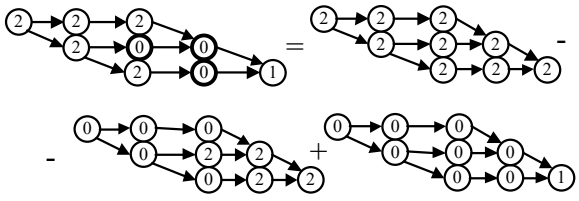

Figure 13: The structure of the expansion of the three-valued function $min(x_1, x_2) \ominus 1$ into the algebraic sum of monotonic functions.

$$min(x_1, x_2) \ominus 1 = 2 - 2min\left(x_1^{(1)}, x_2^{(1)}\right) +$$
$$+min\left(x_1^{(2)}, x_2^{(2)}\right).$$

To obtain the equivalent representations of the expansion functions in linear analogs of the basis under consideration, we can proceed in the same way as with the functions themselves.

Expansion of the arbitrary function into the algebraic sum of smaller value.

We consider this operation with the help of the above transformation of the three-valued function $min(x_1, x_2)\oplus 1$, by unitary and weighted coding of the values of variables and functions.

In these cases, the encoding of variables and functions looks like this:

- unitary coding

x	x_2	x_1
0	0	0
1	0	1
2	1	1

Hence, it follows that for the unitary coding

$x = x_1 + x_2;$

– weighted coding

x	x_2	x_1
0	0	0
1	0	1
2	1	0

It follows that at the weighted coding

$$x = x_1 + 2x_2.$$

Using the basic and its inverse matrix, we obtain the expressions for the two-valued expansion functions from the multivalued arguments:

- for the unitary coding

$$f_1 = 1 + min\left(x_1^{(1)}, x_2^{(1)}\right) - min\left(x_1^{(2)}, x_2^{(2)}\right);$$

$$f_2 = 2min\left(x_1^{(1)}, x_2^{(1)}\right) - min\left(x_1^{(2)}, x_2^{(2)}\right);$$

$$f = f_1 + f_2;$$

- for the weighted coding

$$f_1 = 1 - min\left(x_1^{(1)}, x_2^{(1)}\right);$$

$$f_2 = 2min\left(x_1^{(1)}, x_2^{(1)}\right) - min\left(x_1^{(2)}, x_2^{(2)}\right);$$

$$f = f_1 + 2f_2.$$

The representation of the three-valued function $min(x_1, x_2)\oplus 1$ by the two-valued ones for both versions of coding is given in Table 2.

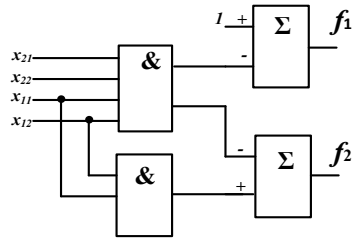
Table 2 – The expansion of the three-valued function $min(x_1, x_2)\oplus 1$ into the sum of the two-valued ones

x_2	x_1	Unitary		Weighted	
		f_2	f_1	f_2	f_1
0	0	0	1	0	1
0	1	0	1	0	1
0	2	0	1	0	1
1	0	0	1	0	1
1	1	1	1	1	0
1	2	1	1	1	0
2	0	0	1	0	1
2	1	1	1	1	0
2	2	0	0	0	0

Replacing the three-valued variables with the two-valued ones in accordance with the rules given above, we obtain the two-valued expansion functions in the following form:

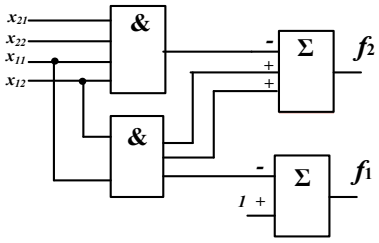
- for the unitary coding

$$f_1 = 1 - x_{11}x_{12}x_{21}x_{22};$$



$$f_2 = x_{11}x_{21} - x_{11}x_{12}x_{21}x_{22};$$

- for the weighted coding



$$f_1 = 1 - x_{11}x_{21};$$

$$f_2 = 2x_{11}x_{21} - x_{11}x_{12}x_{21}x_{22}.$$

The functional schemes of the linear realization of the circular shift operation by the expansion into the sum of the two-valued functions are shown in Figure 14.

a

b

Figure 14: Functional schemes of linear realization of the circular shift operation by the expansion into the sum of the two-valued functions: *a* - on the basis of the unitary coding, *b* - on the basis of the weighted coding.

For the threshold representation and the subsequent threshold realization, it suffices to transform the equations obtained above into the threshold form. After completing this transformation, we get:

- for the unitary coding

$$f_1 = 1 > [(x_{11}+x_{12}+x_{21}+x_{22}) > 3];$$

$$f_2 = [(x_{11}+x_{21}) > 1] - [(x_{11}+x_{12}+x_{21}+x_{22}) > 3];$$

- for the weighted coding

$$f_1 = 1 - [(x_{11}+x_{21}) > 1];$$

$$f_2 = 2[(x_{11}+x_{21}) > 1] - [(x_{11}+x_{12}+x_{21}+x_{22}) > 3].$$

The functional schemes shown in Figure 15 correspond to these equations.

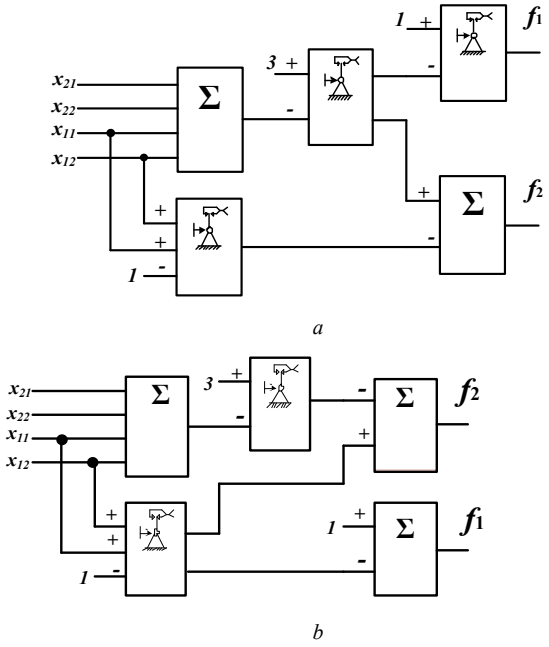


Figure 15: Functional schemes of linear realization of the circular shift operation by the expansion into the sum of the threshold two-valued functions: *a* - on the basis of the unitary coding, *b* - on the basis of the weighted coding.

The considered complex of transformations of logic functions in linear algebra proves useful in the design of digital structures for various applications.

5. Circuitry of the Linear Logic and Threshold Elements

A. Basic functional nodes of digital logic elements. The implementation of the mathematically predetermined set of linear operations over the current signals requires the corresponding set of hardware. The circuit implementation of digital signal transformation functions based on the mathematical tool of linear algebra can be reduced to performing a relatively simple set of operations over the current signals. These operations include:

- conversion of the standard logic signals into the binary current signals matched with a reference current quantum I_0;

- formation of the multivalued (non-binary) algebraic sums of current signals;

- performing the *comparing* operations of the received sums with the given levels of the reference currents.

These operations are typical for analog microcircuitry, therefore the main nodes of various functional elements can be constructed on the basis of the widely used analog structures. In addition, TTL circuitry and CMOS circuitry of these operations completely coincide.

The reference signal driver. It is designed to generate voltages that provide operational modes of elements of digital circuits synthesized in linear algebra. The schematic configuration of the driver is shown in Figure 16.

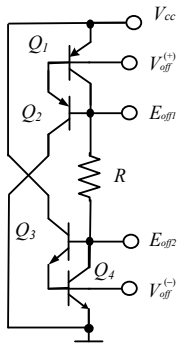

Figure 16: Reference signal driver.

The symmetric structure of the reference signal source is necessary for realizing the operations of converting "inflowing" and "flowing out" currents when creating the algebraic sums of variables in the mathematical tool of linear algebra. The only current-stabilizing two-terminal network, in particular case the resistor *R*, determines the levels of all reference signals. $V_{off}^{(+)}$ and $V_{off}^{(-)}$ are reference for setting the operating modes of current mirrors, and E_{off1} and E_{off2} - for setting the offset in the comparators of the currents. It can also be replaced by some semiconductor structure, and then the circuit becomes completely homogeneous and highly technological. It is also possible to make the two-terminal network *R* as an external element, which will allow changing the power consumption and the associated characteristics of the LSI during the debugging process.

The reference current source (RCS, Figure 17). The operating mode of the RCS is set by the reference voltages $V_{off}^{(+)}$ for the current sources and $V_{off}^{(-)}$ for the current sinks. The problem of constructing the RCS for digital circuits synthesized in linear algebra is completely similar to their problems in analog circuitry.

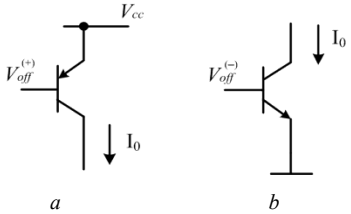

Figure 17: RCS of: a – the current current, b – the current sink.

The current follower (logic interpretation - direction converter). It is intended for the coordination of current directions at their algebraic summation. The schematic configurations of some versions of current followers in TTL circuitry are shown in Figure 18.

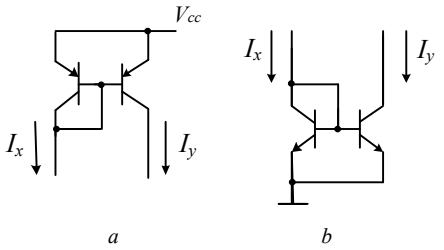

Figure 18: Current direction converter of: *a* – the sink current, *b* - the source current.

Circuitry of CMOS converters of the current direction is similar.

Algebraic current adder. It is an wired pack of the outputs of current mirrors with current directions determined by the mathematical representation of the realized logic function. To agree the operating modes of subsequent elements, it is provided with a buffer stage. The schematic configuration of the algebraic adder is shown in Figure 19.

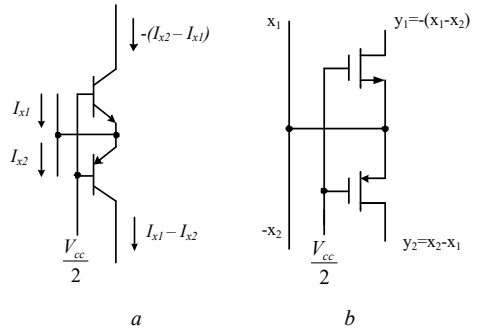

Figure 19: Algebraic current adder:
a - TTL circuit, *b* - CMOS circuit.

Current comparators. They are designed to determine the excess value of one of the input currents over the other. The schematic configurations of current comparators are given in Figures 20 and 21.

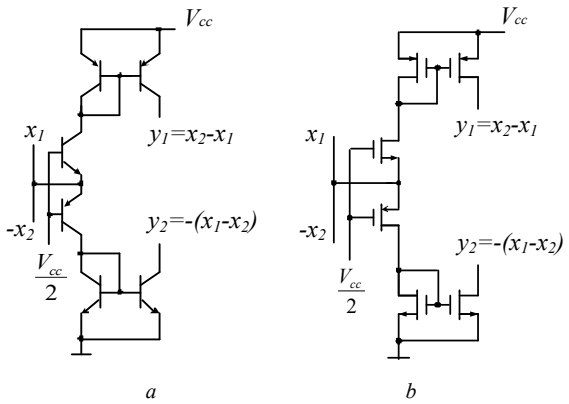

Figure 20: Comparator based on the *truncated difference*:
a - bipolar circuit, *b* - CMOS circuit.

In the circuit in Figure 21, the excess of one of the input currents (I_{x1}) over the other (I_{x2}) is determined by subtracting the second current from the first. One of the compared currents must be a source current and the second one – a current sink. Such a comparator is applicable for any logic value.

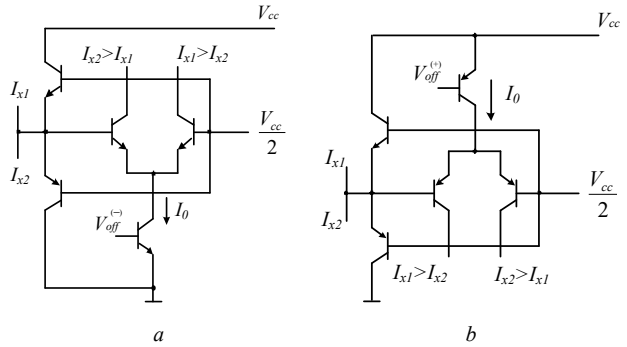

Figure 21: Current comparator based on the comparison: *a* - for current sinks, *b* - for source currents.

In the circuit of Figure 21, *a* at $I_{x1} > I_{x2}$ the left-hand transistor of the differential stage (DS) is closed and the current of the current mirror "leaves" through the right transistor of the DS. At $I_{x1} < I_{x2}$, the right transistor of the DS is closed and the current of the current mirror "goes" through the left transistor. The output current of the DS I_0 is the current sink.

In the circuit in Figure 21, *b* everything appears in a similar way, but with other current directions. Such a scheme is applicable for implementation of the two-valued digital structures.

In the previous section, the difference between the two-valued and multivalued implementations of the *comparison* operation is shown. In the latter case, it is possible to determine not only the fact, but the magnitude of the excess of one input signal over another one. In Figure 22 there is a circuit of the three-valued comparator performing such a modified *comparison* operation.

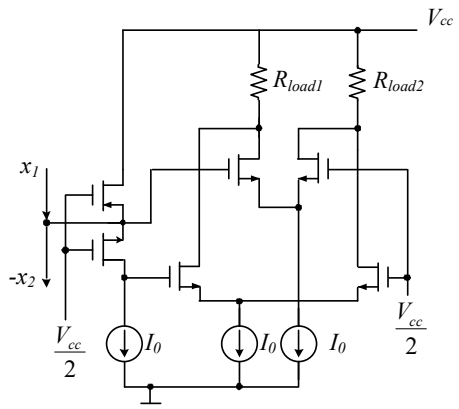

Figure 22: Modified multivalued comparator based on the comparison.

Such a scheme can be constructed for any value, increasing accordingly the number of parallelly operating DSs available to work with different values of currents.

Logic elements AND, OR, NOT. The representations of the operations of the two-valued basic functionally complete system in linear algebra using the *truncated difference* have the following form

$$x_1 \& x_2 = (x_1 + x_2) \div 1;$$

$$x_1 \vee x_2 = 1 \div [1 \div (x_1 + x_2)];$$

$$\bar{x} = 1 - x.$$

The schematic configuration of these elements are shown in Figures 23, 24 and 25, correspondingly.

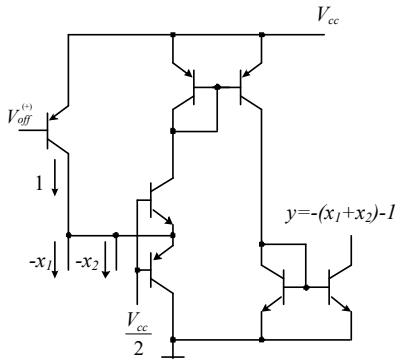

Figure 23: Schematic configuration of the element AND.

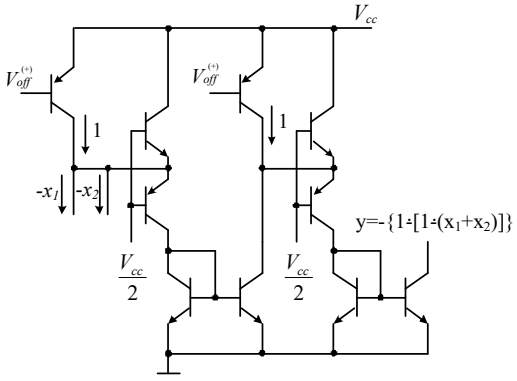

Figure 24: Schematic configuration of the element OR.

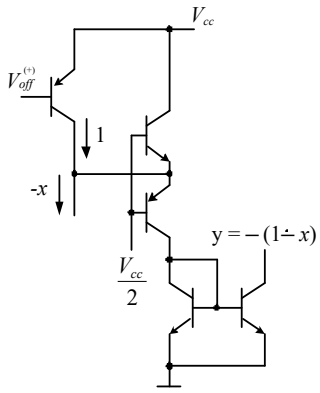

Figure 25: Schematic configuration of the element NOT.

Comparing the schemes shown in Figures 24 and 25, it is easy to see that removing the circuit of in Figure 25 from the scheme of Figure 24, we obtain the OR-NOT element.

Logic element "Inhibition". The representation of the two-valued operation in linear algebra using the *truncated difference* has the following form

$$x_1 \& \bar{x}_2 = x_1 \div x_2.$$

For the multivalued version, the two-valued inversion operation (in accordance with the accepted generalization ideology) should be replaced with the direct $min(x_1, x_2 \oplus 1)$, or inverse min $min(x_1, x_2 \ominus 1)$ cycle operation, or left unchanged; i.e. in the following form $min(x_1, 1 \div x_2)$. Other ideologies of generalization are also possible.

When using the *comparison* operation, the above expressions for operations of the functionally complete system take the following form

$$x_1 \& x_2 = (x_1 + x_2) > 1;$$

$$x_1 \vee x_2 = (x_1 + x_2) > 0;$$

$$\bar{x} = 1 > x.$$

The implementation of these functions on the basis of the *comparison* operation can be performed with the help of the universal logic element (ULE), the schematic configuration of which is shown in Figure 26.

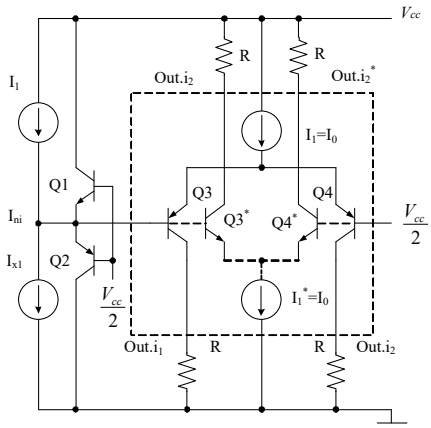

Figure 26: Basic scheme of the universal logic element.

At the inequality $I_1 < I_{x1}$, the source difference current is generated at the node In.i of the ULE. It will "go" to the emitter of the transistor Q1, increasing the voltage at the first input (In.1) of the voltage comparator up to the value $V_{OFF} + U_{be1}$, where $U_{be1} \approx 0.7V$ - voltage of the open emitter junction of the transistor Q1. In this case, the input transistors Q3 and Q4 of the voltage comparator (VC) switch to the inverse states - the collector current of the transistor Q3 becomes zero, and the transistor Q4 starts to transmit the current of the reference current source $I_2 = I_0$ to the second current output (Out.i_2) of the ULE.

Thus, depending on the difference in the numerical values of the currents I_1 and I_{x1}, the output currents of the ULE take one of two values: either it is the current of the reference current source $I_1 = I_0$ or "zero" (no current). Since the current I_1 (I_1^*) is equal to the current quantum I_0, then in one of the current outputs of the voltage comparator a standard current signal I_0 of one of the logic levels is generated, and in its second output - an inverse logic level signal. Depending on the numerical values of I_1 ($I_1 = 0{,}5I_0$, $I_1 = I_0$, $I_1 = 1{,}5I_0$) and the methods of forming the input current signals of the ULE (Figure 26), various logic functions can be performed, for example

– $\bar{x} = 1 - x$ at $y_1 = \begin{cases} I_0 \; at \; I_1 > I_x \\ 0 \; at \; I_1 \le I_x \end{cases}$;

– $x_1 \& x_2 = (x_1 + x_2) > 1$ when $y_1 = \begin{cases} I_0 \; at \; 1{,}5I_1 > I_x \\ 0 \; at \; 1{,}5I_1 \le I_x \end{cases}$;

– $x_1 \vee x_2 = (x_1 + x_2) > 0$ if $y_1 = \begin{cases} I_0 \; at \; 0{,}5I_1 > I_x \\ 0 \; at \; 0{,}5I_1 \le I_x \end{cases}$.

In the last two expressions $I_x \equiv x_1 + x_2$.

The element considered above can be used as a logic element, or as a threshold one; i.e. the generalization of the ordinary and threshold logics in the linear representation is very close. In the first case, unitary variables are fed to the inputs of the element. Besides, the number of inputs must correspond to the number of the variables. In the second case, the weighted sum of the variables should be fed to the "positive" input, and the constant equal to the calculated threshold value should be fed to the "negative" input. It is noteworthy that the described element can serve as an element of the homogeneous matrix, which can be used for matrix synthesis of the current digital structures. In addition, it is possible to construct universal current logic modules on its basis.

Similarly, the Ban operation can be expressed in terms of the *truncated difference* as

$$min(x_1, \{x_2 + 1 \dot{-} k[1 \dot{-} (x_2 \dot{-} 1)]\});$$

$$min(x_1, \{x_2 - 1 + k[1 \dot{-} x_2]\}),$$

and through the *comparison* - as

$$min(x_1, [x_2 + 1 \dot{-} k(x_2 > 2)]);$$

$$min(x_1, \{x_2 - 1 + k[1 > x_2]\}),$$

Cut formers. In fact, the cut former is an input signal limiter at the given level. As a former, the schemes that implement the operations $min(x_1, x_2)$ (upper cuts) and $max(x_1, x_2)$ (lower cuts) can be used.

Buffer output stage. The combination of the algebraic adder and the current follower (converter) can be applied as a buffer output stage. With the help of the latter, the given number of the output circuits can be arranged to provide the required output branching factor.

B. The synthesis of logical schemes. Let's consider it through the example of the two-valued and multivalued circular shift elements discussed above. They can be represented as a *single operation* in the form $min(x_1, x_2 \oplus 1)$ or $m(x_1, x_2 \ominus 1)$, or as a *compound operation*, i.e. as the sequential combination of operations working on one another $min(x_1, x_2)$ or $max(x_1, x_2)$ and operations $\oplus 1$ or $\ominus 1$, that is, in the form $min(x_1, x_2) \oplus 1$ or $min(x_1, x_2) \ominus 1$. We confine ourselves to the synthesis of the circuits using the operation $min(x_1, x_2)$.

In accordance with [17-32], the synthesis of the functional scheme corresponding to any logic function consists in multiplying the row-vector of the values of the function by the inverse basic matrix and obtaining the expansion vector of the function from the selected basis, and then recording the representation of the function as a weighted sum of the basis vectors. We perform the synthesis of the selected schemes using the basis presented below.

In the two-valued case, the element AND-NOT has an arithmetic-logical representation, described by the expression

$$\overline{x_1 \& x_2} = 1 - x_1 \& x_2,$$

which can be represented by the *truncated difference* in the following form

$$\overline{x_1 \& x_2} = 1 - [(x_1 + x_2) \dot{-} 1],$$

and by *comparison* - in the following form

$$\overline{x_1 \& x_2} = 1 > [(x_1 + x_2) > 1].$$

The schematic configurations of the elements can be constructed directly according to these expressions. Figure 27 shows an element scheme based on the *truncated difference*.

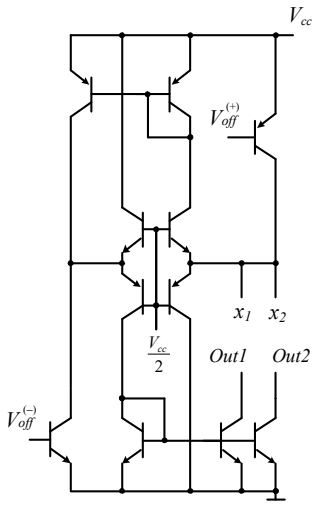

Figure 27: Schematic configuration of the element of AND-NOT based on the *truncated difference.*

We proceed similarly for the three-valued schemes in the first case (by the single operation). Using the basis

$$min(B1, B1)^{(3)} = \begin{bmatrix} 1 \\ 1 \dot{-} (1 \dot{-} x_1) \\ x_1 \\ 1 \dot{-} (1 \dot{-} x_2) \\ [1 - (1 \dot{-} x_1)] - (1 \dot{-} x_2) \\ x_1 \dot{-} 2(1 \dot{-} x_2) \\ x_2 \\ 2[1 - (1 \dot{-} x_1)] - (2 \dot{-} x_2) \\ x_1 \dot{-} (x_1 \dot{-} x_2) \end{bmatrix} =$$

$$= \begin{bmatrix} 1 & 1 & 1 & 1 & 1 & 1 & 1 & 1 & 1 \\ 0 & 1 & 1 & 0 & 1 & 1 & 0 & 1 & 1 \\ 0 & 1 & 2 & 0 & 1 & 2 & 0 & 1 & 2 \\ 0 & 0 & 0 & 1 & 1 & 1 & 1 & 1 & 1 \\ 0 & 0 & 0 & 0 & 1 & 1 & 0 & 1 & 1 \\ 0 & 0 & 0 & 0 & 1 & 2 & 0 & 1 & 2 \\ 0 & 0 & 0 & 1 & 1 & 1 & 2 & 2 & 2 \\ 0 & 0 & 0 & 0 & 1 & 1 & 0 & 2 & 2 \\ 0 & 0 & 0 & 0 & 1 & 1 & 0 & 1 & 2 \end{bmatrix}$$

with the inverse matrix

$$\left(min(B1,B1)^{(3)}\right)^{-1} =$$

$$= \begin{bmatrix} 1 & -1 & 0 & -1 & 1 & 0 & 0 & 0 & 0 \\ 0 & 2 & -1 & 0 & -2 & 1 & 0 & 0 & 0 \\ 0 & -1 & 1 & 0 & 1 & -1 & 0 & 0 & 0 \\ 0 & 0 & 0 & 2 & -2 & 0 & -1 & 1 & 0 \\ 0 & 0 & 0 & 0 & 2 & -1 & 0 & -1 & 1 \\ 0 & 0 & 0 & 0 & 0 & 1 & 0 & 0 & -1 \\ 0 & 0 & 0 & -1 & 1 & 0 & 1 & -1 & 0 \\ 0 & 0 & 0 & 0 & 0 & 1 & 0 & 1 & -1 \\ 0 & 0 & 0 & 0 & -1 & 0 & 0 & 0 & 1 \end{bmatrix},$$

we obtain the following results for the *single operation*:

- resolution vectors

$$w(min(x_1,x_2)\oplus 1) = [1\ 0\ 0\ 0\ 3\ 0\ 0\ 0\ -2];$$

$$w(min(x_1,x_2) \ominus 1) = [2\ 0\ 0\ 0\ -3\ 0\ 0\ 0\ 1];$$

- linear expressions of the functions

$$min(x_1,x_2) \oplus 1 = 1 + 3[1 - (1 \div x_1) - (1 \div x_2)] -$$

$$-2[x_1 \div (x_1 \div x_2)] .$$

$$min(x_1,x_2) \ominus 1 = 2 - 3[1 - (1 \div x_1) - (1 \div x_2)] +$$

$$+[x_1 \div (x_1 \div x_2)].$$

The schematic configuration of the element of the right circular shift, synthesized directly from the above expression, is shown in Figure 28.

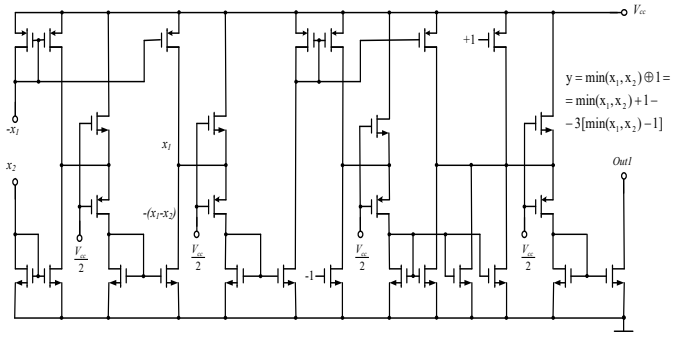

Figure 28: CMOS element of the right circular shift.

The schematic configuration of the element of the left circular shift, synthesized directly from the expression given above, is given in Figure 29.

Similarly, for the *compound operation*:

- the resolution vector $min(x_1,x_2)$

$$w\big(min(x_1,x_2)\big) = [0\ 0\ 0\ 0\ 0\ 0\ 0\ 0\ 1],$$

- linear expression of the function $min(x_1,x_2)$

$$min(x_1,x_2) = x_1 \div (x_1 \div x_2). \quad (5)$$

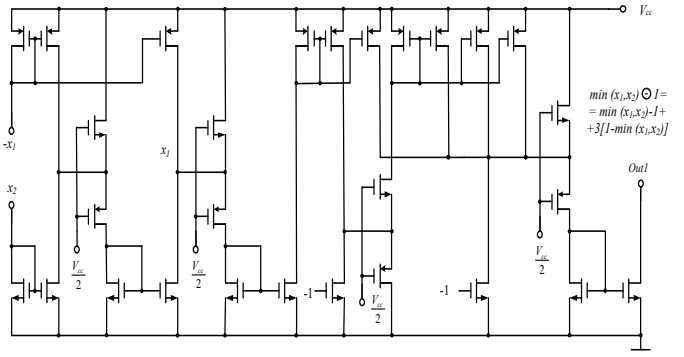

Figure 29: CMOS element of the left circular shift.

Similarly, for the *compound operation*:

- the resolution vector $min(x_1,x_2)$

$$w\big(min(x_1,x_2)\big) = [0\ 0\ 0\ 0\ 0\ 0\ 0\ 0\ 1],$$

- linear expression of the function $min(x_1,x_2)$

$$min(x_1,x_2) = x_1 \div (x_1 \div x_2). \quad (5)$$

- resolution vectors of the operations $x\oplus 1$ or $x \ominus 1$:

$$w(x\oplus 1) = [1\ 3\ -2];$$

$$w(x \ominus 1) = [2\ -3\ 1].$$

- linear expressions of the functions:

$$x \oplus 1 = 1 + [1 \div (1 \div x)] - 2x;$$

$$x \ominus 1 = 2 - 3[1 \div (1 \div x)] + x.$$

The schematic configuration of the element $min(x_1,x_2)$, synthesized directly from expression (5) discussed above, is shown in Figure 30.

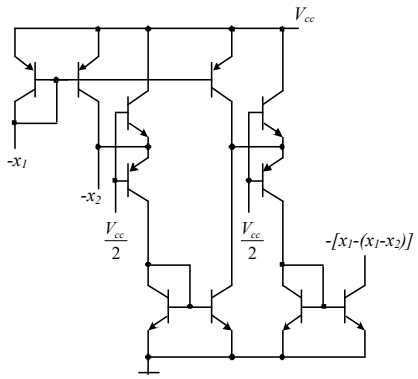

Figure 30: Schematic configuration of the element $min(x_1,x_2)$.

The schemes of the elements of the left and right cycles are shown in Figures 31 and 32.

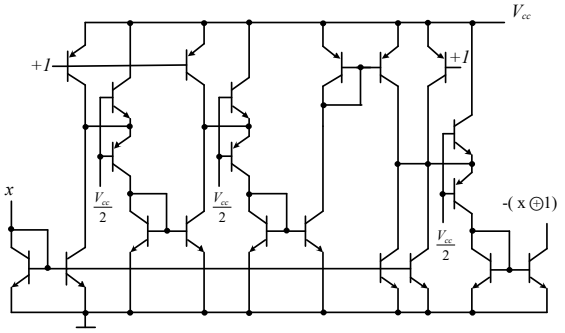

Figure 31: Element of the right cycle.

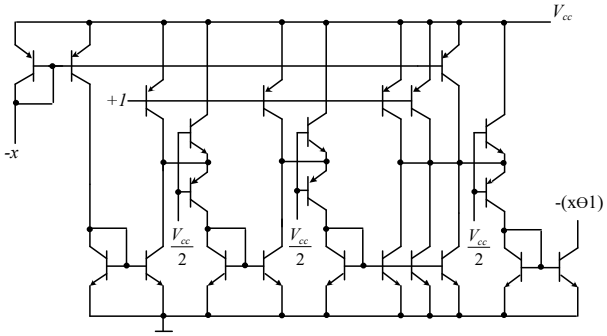

Figure 32: The element of the left cycle.

To obtain the final expression in the procedure for synthesizing a particular logic element, it is sufficient to substitute $min(x_1, x_2)$, for x in the last expression, and for the circuit implementation, - use the above implementation of the function $min(x_1, x_2)$, then connect the circuit $(x \oplus 1)$ or $(x \ominus 1)$ to its output.

C. To demonstrate the possibilities of the *sequential circuit synthesis*, we use the results of the logic element synthesis obtained above.

Boolean approach to the logic synthesis of triggers consists in supplying the memory element with a control circuit that provides a specified law for the operation of a specific type of the trigger. In the two-valued case, the memory element is a scheme of two 2AND-NOT elements covered by the positive feedback (Figure 33):

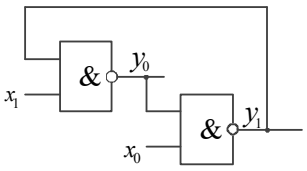

Figure 33: Two-valued trigger (memory element).

The linear synthesis of the two-valued triggers in linear algebra does not differ fundamentally from Boolean synthesis [17]. The schematic configuration of the trigger can be constructed in the same way as it is done in Boolean logic (for example – Figure 34):

When moving to higher values while remaining the general idea of synthesis, it is necessary to use the elements and operations that are a generalization of the two-valued operations and logic elements. The operations *min* (x_1,x_2) and *max* (x_1,x_2) are generalization of the operations & and ∨ is. As for the inversion operation, to generalize it for a multi-valued case it is convenient to represent it in the form of $\bar{x} = x \oplus 1 = x \ominus 1$ and generalize it by a circular shift of Post (left or right). The general functional configuration of the memory element based on three-valued elements of the direct circular shift is shown in Figure 35.

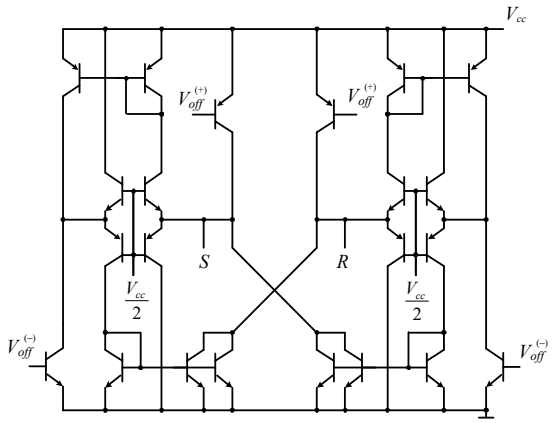

Figure 34: Two-valued RS-flip-flop in the studied basis based on the *truncated difference.*

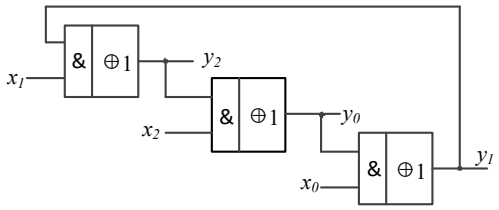

Figure 35: Three-valued trigger on the elements of the direct circular shift.

The general functional configuration of the memory element based on the three-valued elements of the inverse circular shift is given in Figure 36.

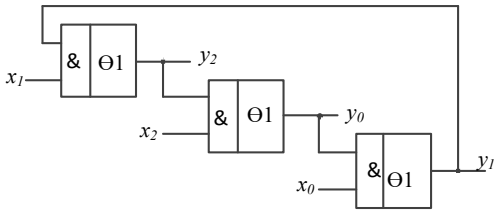

Figure 36: Three-valued trigger on the elements of the inverse circular shift.

The functional schemes of the memory elements of higher significance look similar.

Thus, to construct any multivalued memory element, it is necessary to synthesize the elements of direct and inverse circular shifts. To create a trigger of the given type (D-, RS-, JK-, etc.), it is required to equip the memory element with the corresponding control circuit.

The control circuits of the memory elements are constructed on the base of the verbal description of the operation of a specific type of the trigger. The result of the analysis of this description is the detection of logic control functions for each input of the memory element.

For example, the RS-flip-flop operates according to the following algorithm:

- the values of the input signals $S = R = k-1$ correspond to the storage mode;

- the signal *S* increases the trigger state index relatively to the current state towards the state *k*-1, and the signal R reduces the state index towards the state "0";

- the value of the state index change is equal to the value of the input signal: the signal equal to 1 can increase (or decrease) the current state index by 1, the signal equal to 2 - by 2, etc .; besides, the signal S increases the trigger state index to the state *k*-1, and the signal *R* reduces the state index to "0"; the state change on the cycle is impossible (we leave this for the universal triggers!);

- to change the trigger state index relatively to the current state *i*, the signal *S* can take values from 1 to *k*-1-*i* (larger values are equivalent to the value of *k*-1-*i*). Similarly, the signal *R* can take the values from 1 to *i* -1 (larger values are equivalent to the value *i* -1);

- all combinations are inhibited combinations of values of the input signals, except 0 – *k*-1, 1 – *k*-1, *k*-2 – *k*-1, *k*-1 – *k*-1, *k*-1 – 0, *k*-1 – 1, …, *k*-1– *k*-2.

Now it is possible to synthesize the logic function of the control circuit of the *RS*-flip-flop. Its output signal is a multi-valued signal *x* that sets the next state of the memory element, and the input signals are multivalued signals *S* and *R*, as well as the current trigger state index.

The truth table of the control functions of the three-valued RS-flip-flop, compiled on the basis of this description, has the following form:

S	R	Q_{t+1}	x_0	x_1	x_2
0	2	Q_2	0	1	1
1	2	Q_1	1	0	1
2	2	Q_t	1	1	1
2	1	Q_1	1	0	1
2	0	Q_0	1	1	0

From the last table it follows that the logic functions for controlling the state of the memory element are described as follows:

$$x_0 = P(S > 0) = 1 \div (1 \div S);$$

$$x_1 = 1 > [1 > (1 > S)] > [1 > (1 > R)] =$$

$$= 1 \div [1 \div |1 \div S|] \div [1 \div |1 \div R|];$$

$$x_2 = P(R > 0) = 1 \div (1 \div R).$$

The combination of the memory element circuit and the control circuit results in the implementation of the trigger of the given type.

Similarly, arguing, we can obtain the logical control functions of the three-valued D-flip-flop:

$$x_0 = (1 \div C)\&(1 \div D) = 1 \div [(1 \div D) \div C] =$$

$$= 1 \div [(1 \div C) \div D];$$

$$x_1 = (1 \div C)\&[D \div 2(D \div 1)] = 1 \div \{D \div [2(D \div 1) \div C]\} =$$

$$1 \div [1 \div (|D \div 1| + C)];$$

$$x_2 = (1 \div C)\&(D \div 1) = 1 \div [(D \div 1) \div C] =$$

$$= D \div [(1 \div C) \div 1].$$

In the same way, we can obtain the description of the control system of any other multivalued trigger, the number of types of which is certainly greater than the two-valued one.

Combining the control circuit and the memory element in series, it is possible to obtain the schematic configuration of the trigger of any type and any value.

6. Conclusion

1. The mathematical tool of linear algebra can be newly applied in problems of logic synthesis and circuit implementation of the current digital structures.

2. Linear algebra:

- enables to create not only a two-valued, but also a really properly functioning multivalued element base for digital signal processing devices;

- conduces the design of the digital element base with the improved technological, technical and operational characteristics (in comparison with the potential logic based on Boolean algebra);

- can serve as a basis for creating LSI on the basis of matrix fields of homogeneous elements (as in modern Altera design systems, etc.);

- improves the reliability of current digital LSIs synthesized on its basis, under extreme operating conditions (temperature, radiation, in-phase interferences, etc.).

3. Two-valued and three-valued triggers based on cyclic shift elements are considered. It is shown that in the transition to greater significance, while preserving the general idea of synthesis, it is necessary to use operations that are generalizations of two-valued operations and the corresponding logical elements.

4. The presents a basic set of current logic elements for the devices of automation, which allows solving the problems of transformation of the current signals in a different and more efficient way.

5. In the schemes of the developed class is provided a differential representation of the output signal that minimizes the effect of temperature and radiation on their basic parameters.

Conflict of Interest

The authors declare that there is no conflict of interests regarding of publication of this paper.

ABSTRACT

Tenants associated with a cloud-hosted application seek to reduce running costs and minimize resource consumption by sharing components and resources. However, despite the benefits, sharing resources can affect tenant's access and overall performance if one tenant abruptly experiences a significant workload, particularly if the application fails to accommodate this sudden increase in workload. In cases where a there is a higher or varying degree of isolation between components, this issue can become severe. This paper aims to present novel solutions for deploying components of a cloud-hosted application with the purpose of guaranteeing the required degree of multitenancy isolation through a mathematical optimization model and metaheuristic algorithm. Research conducted through this paper demonstrates that, when compared, optimal solutions achieved through the model had low variability levels and percent deviation. This paper additionally provides areas of application of our optimization model as well as challenges and recommendations for deploying components associated with varying degrees of isolation.

1. Introduction

Designing and planning component deployment of a cloud-hosted application with multiple tenants demands special consideration of the exact category of components that are to be distributed, the number of components to be shared, and the supporting cloud resources required for component deployment. [1] This is because there are different or varying degrees of multitenancy isolation. For instance, in components providing critical functionality, the degree of isolation is higher compared to components that only require slight re-configuration prior to deployment [2].

A low degree of isolation actively encourages tenants to share resources and components, resulting in lower resource consumption and reduced operating costs, however, there are potential challenges in both security and performance in the instance where one component sees a sudden workload surge. A high degree of isolation tends to deliver less security interference, although there are challenges instigated by high running costs and resource consumption in view that these tenants are not sharing resources [2]. Consequently, the software architect's main challenge is to first identify solutions to the opposing trade-off of high degrees of isolation (including excessive resource consumption issues and high operating costs), versus low degrees of isolation (including performance interference issues).

Motivated by these key challenges, this paper presents a model for the deployment of components which provides exemplary solutions specific to cloud-based applications and aims to do so in a way that secures the segregation of multitenancy. The approach for this research includes creating an optimization model which is mapped to a Multichoice Multidimensional Knapsack Problem (MMKP) before solutions are tested using a metaheuristic. The approach is analysed through comparing the different optimal solutions achieved which then collectively compose an exhaustive search tool to analyse the solutions capacity specifically for minor problem occurance, in its entireity.

This paper and its research questions: "***How can we optimize the way components of a cloud-hosted service is deployed for guaranteeing multitenancy isolation?***". It is possible to guarantee the specific degree of isolation essential between

[*]Laud Charles Ochei, Aberdeen, United Kingdom. l.c.ochei@rgu.ac.uk

tenants, whilst efficiently managing the supporting resources at the same time through component deployment optimization of the cloud-based application.

This paper expands on the previous work conducted in [3]. The core contributions of this article are:
1. Mathematical optimization model providing optimal component deployment solutions appropriate for cloud-based applications to guarantee multitenancy isolation.
2. Mathematical equations inspired by open multiclass queuing network models to determine the average request totals for granting component and resource access.
3. Variants of metaheuristic solutions to deliver optimization model resolutions attributed to simulated annealing.
4. Guidelines and recommendations for component deployment in cloud-hosted applications seeking to guarantee required levels of multitenancy isolation.
5. Application areas of a cloud-hosted service where it is possible for the optimization model to be directly applied to component deployment with the aim to guarantee required degree of multitenancy isolation.

The remainder of this paper is structured as outlined below: Section II focuses on the challenge of identifying and delivering near-optimal component deployment solutions specific to cloud-hosted applications that guarantee the essential levels of multitenancy isolation; Section III presents the Optimisation Model; the following section presents the Metaheuristic Solution; Section V considers the Open Multiclass Queuing Model; Section VI evaluates the results and presents the experimental setup; Section VII discusses the results; Section VIII discusses the model's application areas for the model; and Section IX conclude with recommendations of future work.

2. Optimising the Deployment of Components of Cloud-hosted Application with Guarantee for Multitenancy Isolation

This section examines multitenancy isolation, the conflicting trades-offs in delivering optimal deployment influenced by the varying degrees of multitenancy isolation, and other associated research on cloud resources and optimal allocation of such resources.

2.1. Multitenancy Isolation and Trade-offs for Achieving Varying Degrees of Isolation

In a multitenant architecture (also referred to as *multitenancy*), multiple tenants are able to access a single instance of a cloud service. These tenants have to be isolated when there are changes in workload. In the same way that it is possible to isolate multiple tenants, it is also possible to isolate multiple components of a cloud-hosted application.
In this paper, we define "Multitenancy Isolation" as a way of ensuring that other tenants are not affected by the required performance, stored data volume, and access privileges of one of the tenants. accessing the cloud-hosted application [3] [4].

A high degree of isolation is achieved when there is little or no impact on other tenants when a substantial increase in workload occurs for one of the tenants, and vice versa. The three cloud patterns that describe the varying degrees of multitenancy isolation are:
(i) Dedicated Component: tenants cannot share components; however, a component may be associated with one or more tenants or resources;
(ii) Tenant-isolated Component: tenants can share resources or components, and isolation of these is guaranteed; and
(iii) Shared Component: tenants can share resources or components, but these remain separate from other components.

If components required a high degree of isolation between them, then each tenant requires that each component is duplicated. This can be expensive and also lead to increased resource consumption. On the other hand, there could also be a need for a low degree of isolation which could, in contrast, reduce cost and resource consumption. However, any changes in workload levels that the application cannot cope with risk interference [4]. The question, therefore, is how optimal solutions can be identified to resolve trade-offs when conflicting alternatives arise.

2.2. Related Work on Optimal Deployment and Allocation of Cloud Resources

Research on optimal resource allocation in the cloud is quite significant, however, much fewer studies focus on optimal solutions in relation to component deployment across cloud-based applications in a way which guarantees the required degree of multitenancy isolation. Researchers in [5] and [6] aim to keep cloud architecture costs to a minimum by implementing a multitenant SaaS Model. Other authors [7] concentrated on bettering execution times for SaaS providers whilst reducing resource consumption using evolutionary algorithms opposed to traditional heuristics. A heuristic is defined in [8] for the capacity planning purposes for the SaaS inspired by a utility model. The aim of the utility model was to generate profit increases and so it largely concentrated on business-related aspects of delivering the SaaS application.

It is explained in [9] how optimal configuration can be identified for virtual servers, such as using certain tests to determine the required volumes of memory for application hosting. Optimal component distribution is discussed and analyzed by [10] in relation to virtual servers. Research conducted in [11] is of a similar nature to this paper in that it attempts to reduce costs (using a heuristic search approach is inspired on hill climbing), specifically in relation to the use of VMs from an IaaS provider with limitations around SLAs response time.

The studies noted above predominantly focus on scaling back costs associated with cloud architectural resources. The use of metaheuristics is not considered in these studies in delivering optimal solutions that can guarantee the required degree of multitenancy isolation. Additionally, previous research involving

optimization models have operated with one objective; an example is where [11] look to minimize VM operational costs. For this paper's model, a bi-objective case is used (i.e., maximising the required degree of multitenancy isolation and number of requests permitted to access a component). Thereafter, a modern metaheuristic inspired by simulated annealing is used to solve the model.

3. Problem Formalisation and Notation

This section defines the problem and explains the process of mapping it to a Multichoice Multidimensional Knapsack Problem (MMKP).

3.1. Description of the Problem

Assuming a tenant has multiple components associated with the same supporting cloud infrastructure. A team may represent a team or department, a company with a responsibility to design a cloud-based application, its components, and underlying processes. Components varying in size and function has to integrate with their cloud-hosted application to achieve effective deployment in a multitenant style. It is also possible to define component categories based on different features, such as function, for example, processing or storage. Within these categories, different components are likely to have differing degrees of isolation enabling some components to deliver the same function which can hence be accessed and used by multiple tenants, opposed to other components which may be solely allocated to certain tenants or departments.

Every component within an application needs a particular allocation of resources from the cloud infrastructure in order to support the volume of requests received. In instances where one component in the application experiences surges in workload, then it must be considered how the designer can choose components to deliver optimal deployment to effectively respond to the sudden changes in such a manner that: (i) maximises component degrees of isolation through ensuring they behave in the same way as components of other tenants, thus, isolating against one and other; and (ii) maximises the total requests permitted to access and use each components.

3.2 Mapping the Problem to a Multichoice Multidimensional Knapsack Problem (MMKP)

The above mentioned optimal component deployment problem can be closely linked to a 0-1 Multichoice Multidimensional Knapsack Problem (MMKP). An MMKP is a variant of the Knapsack Problem commonly depicted as a member of the NP-hard class of problems. For the purpose of this paper, the problem of focus can be formally defined as:

Definition 1 (Optimal Component Deployment Problem): Consider that there are N groups of components ($C_1,\ldots,C_N$) with each group having a_i ($1 \le i \le N$) components useful for designing (or integrating with) a cloud-hosted application. Each component of the application is affiliated with: (i) the degree of isolation that is required between components (I_{ij}); (ii) the rate at which requests arrive to the component λ_{ij}; (iii) the service demand of resources required to support the component D_{ij}; (iii) the average request totals permitted to access the component Q_{ij} and (iv) resources for supporting the component, $r_{ij} = r_{ij}^1, r_{ij}^2, \ldots, r_{ij}^n$. For the cloud to properly support all components, a certain volume of resources are required; the total number of resources needed can be calculated as $R = (R^1, R^2, \ldots, R^n)$.

The aim of an MMKP is to choose one component present in each category for deployment to the cloud in a manner that ensures that if one component sees sudden increases in load, then the: (a) the degree of isolation of other components is maximized; (b) the total requests permitted to access the component and application is maximised without using more resources than are actually available.

Definition 1 identifies two objectives within the problem. An aggregation function is used to convert the multi-objective problem into a single-objective because of merging the two objective functions merge (i.e., g1=degree of isolation, and g2=number of requests) into one single objective function (i.e., g=optimal function) in a linear way. Because the optimal function of this study is linear, a *priori single weight* strategy is employed to aid defining the weight vector selected based on the decision maker's individual preferences [12]. This paper also adopts the approach discussed in [12] for computing the absolute percentage difference (see section 7.1), the target solutions used to compare against the optimal solution (see section 7.2), and the use of the number of optimal function evaluations as an alternative to measuring the computational effort of the metaheuristic.

Therefore, the purpose is redefined as follows: to deliver a near-optimal solution for component deployment to the cloud-based application that also fulfils system requirements and achieves the best value possible for optimal function, G.

Definition 2 (Optimal Function): For a cloud-hosted application architect, the main issues impacting the optimal deployment of components are changes to workload, which can be expressed as:

$$\sum_{i=1}^{N} \sum_{j \in C_i}^{n} g_{ij} . a_{ij}$$

Subject to:

$$\sum_{i=1}^{N} \sum_{j \in C_i}^{n} r_{ij}^{\alpha} . a_{ij} \le R^{\alpha} (\alpha = 1, 2, \ldots, N) \quad (1)$$

$$\sum_{j \in C_i}^{N} a_{ij} = 1$$

$a_{ij} \in 0,1$ (i = 1, 2 ,…, N), j $\in C_i$

where (i) a_{ij} is fixed at 1 if component j is chosen from group C_i and 0 otherwise; (ii) g_{ij} is determined by a weighted calculation of parameters involving the degree of isolation, average requests permitted to access a component, and penalty for constraint violations.

$$g_{ij} = (w1 \times I_{ij}) + (w2 \times Q_{ij}) - (w3 \times P_{ij}) \quad (2)$$

Specific weight values are allocated to w1, w2, and w3; namely 100, 1 and 0.1 respectively. The allocation of weights is done using a method that provides preference to the required degree of isolation. The penalty, P_{ij}, imposed for components that surmount resource cap is expressed as:

$$P_{ij} = \sum_{i=0}^{n} max\left\{0, \left(\frac{R^k - R^k_{max}}{R^k_{max}}\right)\right\}^2 \quad (3)$$

For every component ($\boldsymbol{g}$), the degree of isolation, I_{ij}, is assigned either 1, 2, or 3 indicating either shared, tenant-isolated or dedicated components, respectively. The sum described as: $r_{ij} = r^1_{ij}, r^2_{ij}, \ldots, r^n_{ij}$ refers to the resource consumption in group C_i. for each individual application component j. Total resource consumption r^{α}_{ij} for all application components needs to be lower than the total available resources in the cloud infrastructure $R = R^{\alpha}, (\alpha = 1,\ldots,m)$.

It is presumed that the service demands at the CPU, RAM, Disk I/O, and the supporting bandwidth of each component can be identified and/or measured readily by the SaaS supplier or customer. This assumption enables us to calculate the number of requests, Q_{ij} that may be permitted access for each component through analysis of an open multiclass QN Model [13]. The following section expands further on the open multiclass network.

4. Queuing Network (QN) Model

Queueing network modelling is one modelling approach through which the computer system is depicted as a network of queues that can be solved in an analytic fashion. In its most basic form, a network of queues is an assembly of service centers representative of system resources, and customers representative of business activity, such as transactions [13]. Service centers are basically supporting resources for the components, such as CPU, RAM, disk and bandwidth.

Assumptions: For the purpose of this paper, the following component assumptions are made:
(i) components cannot support other applications or alternative system requirements, and is therefore exclusively deployed to one cloud-application;
(ii) component arrival rates are separate to the main system state and so component requests may have significantly varied behaviours.
(iii) it is possible to identify and effortlessly measure the service demands at the CPU, RAM, Disk, and Bandwidth supporting each component by both the SaaS provider and/or customer.
(iv) sufficient resource is available to support each component during changes to workload, particularly during significant surges of new incoming requests. Ensuring sufficient resource means that there are no overloads during peak times where all components are operating.

The assumptions noted above allow the study to utilise an open multiclass queuing network (QN) model for the purpose of calculating average requests permitted to reach the component, whilst simultaneously ensuring the required degree of isolation, as well as system requirements. The magnitude and intensity of workload volume in an open multiclass QN is determined by request arrival rates. The arrival rate is not typically reliant on the system state, and so is not reliant on the volume of other tenants in the system either [13].

Definition 3 (Open Multiclass Queuing Network Model): Assuming there is a total of N classes, where every class c is an open class with arrival rate λ_c. The arrival rates are symbolised as a vector by $\vec{\lambda} = (\lambda_1, \lambda_2, \ldots \lambda_N)$. The use of each component in class c at the center k is given by:

$$U_{c.k}(\vec{\lambda}) = \lambda_c D_{c.k} \quad (4)$$

To solve the QN model, assumptions are made, such as that a component stands for a single open class system hosting four service centers otherwise referred to as supporting resources, such as CPU, RAM, disk capacity and bandwidth. At any one service center (e.g., CPU), the average request totals for a specific component is:

$$Q_{c,k}(\vec{\lambda}) = \frac{U_{c.k}(\vec{\lambda})}{1 - \sum_{i=1}^{N} U_{i.k}(\vec{\lambda})} \quad (5)$$

Consequently, to determine the average amount of requests accessing the particular component, the length of the queue of all requests reaching all service centers (i.e., components' supporting resources such as CPU, RAM, disk capacity and bandwidth) would be totaled.

$$Q_c(\vec{\lambda}) = \sum_{i=0}^{n} Q_{c,k}\ \vec{\lambda} \quad (6)$$

5. Metaheuristic Search

The optimisation problem as explained in the section before is an NP-hard problem renowned for its feasible search capacity and exponential growth [14]. The number of potential and feasible solutions that may achieve optimal component deployment and solve the problem can be determined using this equation:

$$\left\{\binom{n}{r}\right\}^N \quad (7)$$

The above equation, Equation 4, signifies the different ways one or more (**r**) components can be chosen from each group (comprising of **n** components) from a pool of numerous (N) groups of components, for the purpose of creating and integrating them into a cloud-hosted application upon receipt of updates or changes to workload by the component. Thus, to manage such changes to workloads, the specific number of different ways that one component can be selected (i.e., r=1) from each of the 20 different groups (i.e., N=20), comprising of 10 items per group (i.e., n=10), approximately 10.24 x 10^{12} possible solutions can be identified. Contingent on the number of changes to workload and also the regularity of these, a cloud-hosted service quite large in size could experience a much greater volume of possible solutions.

Therefore, to obtain an optimal solution for the identified optimisation problem, it is essential to use an efficient metaheuristic. In addition, this should be done in real-time with the SaaS customer or cloud architect. Two versions of a simulated annealing algorithm are implied: (i) *SAGreedy*, incorporates greedy principles in conjunction with a simulated annealing algorithm; (ii) *SARandom*, employs randomly propagated solutions in conjunction with a simulated annealing algorithm. Both of these versions can be effectively utilised to achieve near-optimal solutions for component deployment. Additionally, an algorithm was developed for this study to generate an extensive search of the full solution area for a small problem size. Algorithm 1 includes the algorithm for *SA(Greedy)*. However, SA(Random) only needs a minor change to this algorithm, which will be described further in the following section. An extensive breakdown of Algorithm 1 can be viewed below:

Algorithm 1 SA(Greedy) Algorithm

```
1:  SA (Greedy) (mmkpFile, N)
2:  Randomly generated N solutions

18: end for
19: optimalSoln = bestSoln
20: Return (optimalSoln)
```

5.1. The SAGreedy for Near-optimal Solution

The first algorithm is a combination of simulation annealing and greedy algorithm which is used to obtain a near-optimal solution for the optimisation problem modelled as an MMKP. First, the algorithm extracts the key details from the MMKP problem instance before populating the encompassing variables (i.e., collections of different dimensions storing isolation values of isolation; average request totals; and the resource consumption of components). A basic linear cooling schedule is used, where $T_{i+1} = 0.9Ti$. The method for prescribing and fixing the preliminary temperature T_0 will be to randomly generate an optimal solution whose number is equivalent to the total number of groups (n) in the problem instance, multiplied by the number of iterations (N) used in the experimental settings before running the simulated annealing element of the algorithm.

When the problem instance and/or the total iterations is low, the magnitude of optimal solutions created may be limited by the number of groups (n) in the problem instance, multiplied by total iterations (N) used in the experimental settings. Next, the initial temperature T_0 is determined for the standard deviation of all optimal solutions (Line 2-3) through random generation. The algorithm then uses the greedy solution as the preliminary solution (Line 4) which is assumed as the best current solution. The simulated annealing process enhances the greedy solution further providing a near-optimal solution for cloud component deployment.

The execution of the algorithm in its most basic form for the instance C(4,5,4) is explained as follows: let us imagine that the total number of iterations is 100, 400 (i.e., 4 groups x 100 iterations) optimal solutions are randomly generated before calculating the standard deviation for all solutions. Assuming a value of 50.56, T_0 is identified as 50. It is also assumed that the algorithm creates a foremost greedy solution with $g(a^1) = 2940.12$, before a current random solution with $g(a^2) = 2956.55$. The solution a^2 will substitute a^1 with probability, P =exp(-16.43/50)=0.72, because $g(a^2) > g(a^1)$. In lines 14 to 16, a random number (rand) is generated between 0 and 1; if rand <0.72, a^2 replaces a^1 and we proceed with a^2. Alternatively, the study continues with a^1. Now, the temperature T is reduced providing $T_1 = 45$ (Line 17). Iterations continue until N (that is, the identified number of iterations set to enable the algorithm to function), is reached, thus the search converges with a high probability of near-optimal solution.

5.2. The SA(Random) for Optimal Solutions

Considering the SA(Random) metaheuristic version, a solution is also randomly generated before being encompassed within the simulated annealing process to provide a preliminary solution. It can be seen in Line 4 that rather than creating a greedy solution, a random solution is created. An optimal solution representative of a set of components with the highest total isolation value and number of requests permitted to reach the component access is

then output by the algorithm. Every time a variance in workload is experiences, the optimal solution alters to respond to this.

6. Evaluation

We describe in the section how each instance was generated as well as the process, procedure and set up of the experiment.

6.1. Instance Generation

Reflective of different capacities and sizes, a number of problem instances were randomly generated. Instances were divided into two categories determined by those cited frequently in current literature: (i) OR benchmark Library [15] and other standard MMKP benchmarks, and (ii) the new irregular benchmarks used in [16]. All these benchmarks were used for single objective problems. This study edited and modified this benchmark to fit into a multi-objective case through assigning each component with one of two profit values: isolation values and average number of requests [17].

The values of the MMKP the instance, were produced as follows: (i) random generation of isolation values in the interval [1-3]; (ii) values of component consumption of CPU, RAM, disk and bandwidth (i.e., the weights) were generated in the interval [1-9]; (iii) individual component resource limits (i.e., knapsack capacities for CPU, RAM, disk and bandwidth) were created by halving the maximum resource consumption possible (see Equation 7).

$$c_k = \frac{1}{2} \times m \times R \tag{8}$$

An identical principle has been employed to create instances for OR Benchmark Library, as well as for instances used in [18] [19]. This research considers the total resources/constraints as four (4) for each group, which reflects the minimal resource requirement to deploy a component to the cloud. The notation for each instance is: C(n,r,m), representing the number of groups, the amount of components in each group, and resource totals.

6.2. Experimental Setup and Procedure

For consistency, all experiments were set up and operated using Windows 8.1 on a SAMSUNG Laptop with an Intel(R) CORE(TM) i7-3630QM at 2.40GHZ, 8GB memory and 1TB swap space on the hard disk. Table I outlines the experimental parameters. The algorithm was tested using different sized instances of different densities. In relation to large instances, it was not possible to conduct an exhaustive search due to a lack of memory resource on the machine used.

As a result of this limitation, the MMKP instance was implemented first, C(4,5,4), to provide a benchmark for analysis to enable algorithm comparison.

Table 1. Parameters used in the Experiments

Parameters	**Value**
Isolation Value	[1,2,3]
No. of Requests	[0,10]
Resource consumption	[0,10]
No. of Iterations	N=100 (except Table 4)
No. of Random Changes	5
Temperature	T_0 = st.dev of N randomly generated solns.
Linear Cooling Schedule	$T_{i+1} = 0.9Ti$

7. Results

Section 7 discusses the experiment results.

7.1 Comparison of the Obtained Solutions with the Optimal Solutions

The results delivered by algorithms SA(Greedy) and SA(Random) were initially compared with the optimal solutions generated by an exhaustive search for a small problem instance in the entire solution space (i.e., C(4,5,4)). Table 2 and Table 3 portray the findings. The instance id used is noted in Column 1 of Table 2. The second, third and fourth columns respectively highlight the optimal function variables as (FV/IV/RV), representing the optimal function value, isolation value, and number of permitted requests, for Optimal, SA(Random) and SA(Greedy) algorithms. The first and second columns of Table 3 depict a proportion of the optimal values for SA(Random) and SA(Greedy) algorithms, respectively. The final two columns note the absolute percentage difference, indicative of the solution quality, for SA(Random) and SA(Greedy) algorithms, which is measured as follows:

$$\frac{|f(s) - f(s^*)|}{f(s^*)} \tag{9}$$

where s is the obtained solution and s* is the optimal solution generated by the exhaustive search.

It is clear that SA(Greedy) and SA(Random) provide very similar results. Solutions identified for SA(Random) are almost 100% close most of the time to their optimal solution, and over 83% in a smaller proportion of cases whilst in just one occurrence it was below 66%. SA(Greedy) also delivered nearly 100% close solutions created to the optimal solution in a considerable number of cases, and more than 83% in others. Overall, SA(Greedy) delivered better results than SA(Random) when considering percent deviation from the optimal solution.

7.2 Comparison of the Obtained Solutions to a Target Solution

It was not possible to run instances greater than C(4,5,4) because of hardware limitations (i.e., CPU and RAM).

Consequently, the results were compared to a target solution. The target solution for percent deviation and performance rate was determined as (n x max(I) x w1) and ((n x max(I) x w1) + (0.5 x (n x max(Q) x w2))), respectively. So, for instance C(150,20,4), the target solution for computing percent deviation sit at 45,000.

Table III, IV, and V demonstrates average solution behaviour: (i) on a significant selection of varied instances using the same parameters; (ii) over various runs on the same instance (with differing quantities of optimal evaluation); and (iii) over different runs on the same instance. The robustness of solutions in relation to their behaviour on varying types of instances using the same parameters was measured. Table III shows this measure and that solutions are strong when considering average deviation of solution behaviour for both the SA(Greedy) and SA(Random), as implied through their low variability scores.

The average percent deviation and standard deviation (of the percent deviations), for SA(Greedy) is marginally greater than SA(Random) as a result of the significant absolute difference between some solutions and the reference solution. For example, the percent deviations of SA(Greedy) for the instances C(100,20,4) and C150,20,4) are higher than SA(Random). The results show how SA(Random) performs much better than SA(Greedy) in reference to small instances up to C(80,20,4).

Table IV compares solution quality with optimal function evaluations. It can be determined that the overall solution quality is good when both algorithms are tested on large instances. Once again, the standard deviation for SA(Greedy) is notably lower than SA(Random) in addition to great percent deviation stability. Table V highlighted that SA(Greedy) is stronger than SA(Random) evidenced by the average optimal values and low solution variability. The performance rate (PR) was computed by determining the reference solution as a function of the quantity of optimal evaluations. The PR of SA(Greedy) is marginally higher than SA(Random).

Figure I depict the relationship of solution quality relating to optimal values (i.e., fitness value) and the volume of optimal function evaluations. It can be seen from the diagram that SA(Greedy) benefited a little from the preliminary greedy solution more than SA(Random) when optimal function evaluations are few. Nonetheless, solution quality for both algorithms are better as iterations increase. Once 100 optimal evaluations are reached, the optimal solution stabilizes, but thereafter fails to show any further noticeable improvement.

Figure 2 portrays correlations between solution quality relating to percent deviation and the total function evaluations. In line with expectations, SA(Random) reported a smaller percent deviation than SA(Greedy) in the majority of results, particularly in instances where function evaluations are few. An explanation for this could be the low function evaluation total used in the study. However, percent deviation for SA(Greedy) showed greater stability despite being greater than SA(Greedy)'s results.

Table 2. Comparison of SA(Greedy) and SA(Random) with the Optimal Solution

Inst-id	Optimal (FV/IV/RV)	SA(R) (FV/IV/RV)	SA(Greedy) (FV/IV/RV)

8. Discussion

In Section 8 the implication of the results is discussed further and recommendations for component deployment of a cloud-hosted application that guarantees multitenancy isolation are considered and presented.

8.1 Quality of the Solutions

Solution quality was measured encompassing percent deviation from either the optimal or reference solution. Tables II,

III and IV note solutions generated by SA(Greedy) which demonstrate a low percent deviation. The results also indicate that SA(Greedy) performs efficiently for large instances. However, Table III clearly evidences SA(Random) outperforming SA(Greedy) on small instances, that is, from C(5,20,4) to C(80,20,4).

Table 3. Computation of a Fraction of the Obtained Solutions with the Optimal Solution.

8.2. Computational Effort and Performance Rate of Solutions

Hardware limitations of the computer used for the study restricted evaluation and full consideration of computational effort for metaheuristics. On the other hand, it was still possible to compute algorithm performance rates as a function of optimal evaluation totals. Typically, the number of optimal evaluations is considered a computational effort indicator that is independent to the utilised computer system. Table V indicates that the performance rate of SA(Greedy) is marginally higher than SA(Random) when we put into consideration the total reference solutions achieved.

Table 5. Comparing Solution Quality vs. No. of Optimal Evaluations

Average	45632.46	45787.61	0.34	0.08
STD	439.77	5.07	0.93	0.01

8.3. Robustness of the Solutions

Low variability was seen from the SA(Greedy) algorithm particularly when run with large instances, therefore suggesting it delivers stronger solutions than SA(Random) making SA(Greedy) the most suitable algorithm for real-time use in a fast-paced environment experiencing regular changes to workload levels. Figure 1 demonstrates instability in SA(Random) for a small amount of evaluations, although following 1,000 evaluations it was seen to converge eventually at the optimal solution. In contrast, the SA(Greedy) showed steady improvement as evaluations increased.

8.4. Required Degree of Isolation

The study's optimisation model assumes that each component for deployment (or group of components) is linked to certain degree of isolation. By mapping the problem to a Multichoice Multidimensional Knapsack Problem linking each component to a profit values: either isolation value; or number of requests permitted to access a component, this was achieved. As a result of this, it was possible to monitor each component separately and independently, responding to each of their unique demands. Where limitations are faced, such as through cost, time or effort used to tag each component, a different algorithm could enable us to perform this function dynamically. In our research prior to this [20], an algorithm capable of dynamically learning the properties of current components in a repository was developed with this

information then used to associate each component with the required degree of isolation.

Table 6. Robustness of Solutions over Different Runs on the Same Instance.

Runs	SA(R)	SA(G)	%D SA-R	%D SA-G

9. Application Areas for Utilizing the Optimization Model

In this section, we discuss the various areas where our optimization model can be applied to the deployment components of a cloud-hosted service for guaranteeing the required degree of multitenancy isolation.

9.1. Optimal Allocation in a resource constrained environment

Our optimization model can be used to optimize the allocation of resources especially in a resource constrained environment. or where there are frequent changes in workload. This can be achieved by integrating our model into a load balancer/manager. Many cloud providers have auto-scaling programs (e.g., Amazon Auto scaling) for scaling applications deployed on their cloud infrastructure, usually based on per-defined scaling rules. However, these scaling programs do not have a functionality to provide for guaranteeing the isolation of tenants (or components) associated with the deployed service. It is the responsibility of the customer to implement such a functionality for individual service deployed to the cloud. In an environment where there are frequent workload changes, there would be a high possibility of performance interference. In such a situation, our model can be used to select the optimal configuration for deploying a component that maximizes the number of request that can be allowed to access the component while at the same maximizing the degree of isolation between tenants (or components).

9.2. Monitoring Runtime Information of Components

Another area where our model can be very useful is in monitoring the runtime information of components. Many providers offer monitoring information on network availability and utilization of components deployed on their cloud infrastructure based on some pre-defined configuration rules. However, none of this information can assure that the component is functioning efficiently and guarantees the required degree of multitenancy isolation on the application level. It is the responsibility of the customer to extract and interpret these values, adjust the configuration, and thus provide optimal configuration that guarantees the required degree of multitenancy isolation.

Our model can be implemented in the form of a simple web service-based application to monitor the service and automatically change the rules, for example, based on previous experiences, user input, or once the average utilization of resources exceeds a defined threshold. This application can be either be deployed separately or integrated into different cloud-hosted services for monitoring the health status of a cloud service.

9.2. Managing the Provisioning and Decommissioning of Components

The provisioning and decommissioning of components or functionality offered to customers by many cloud providers is through the configuration of pre-defined rules. For example, a rule can state that once an average utilization of a system resource (e.g., RAM, disk space) exceeds a defined threshold then a component shall be started. When runtime information of components is extracted, and made available as stated earlier, they can be used to make important decisions concerning the provisioning of required components and decommissioning of unused components.

10. Conclusion and Future Work

Within this research, to provide a further contribution to the current literature on multitenancy isolation and optimized component deployment, we have developed an optimisation model alongside a metaheuristic solution largely inspired by simulated annealing for the purpose of delivering near-optimal component deployment solutions specific to cloud-based applications that guarantee multitenancy isolation. First, an optimisation problem was formulated to capture the implementation of the required degree of isolation between components. Next, the problem was mapped against an MMKP to enable early resolution through the use of a metaheuristic.

Results show greater consistency and dependability from SA(Greedy), particularly when functioning on large instances, whereas SA(Random) operates sufficiently on small instances. When considering algorithm strength, SA(Greedy) portrayed low variability and thus generates higher quality solutions in dynamic environments experiencing regular changes in workload levels. SA(random) appears to have greater sensitivity and instability to small deviations of input instances compared to SA(Greedy), more so in relation to large instances.

We intend on testing the MMKP problem instances further using various metaheuristic types (e.g., genetic and estimated distribution algorithms) and combinations (e.g., simulated

annealing merged with genetic algorithm) with the aim of identifying the most efficient metaheuristic to generate optimal solutions to operate in a variety of cloud deployment situations. For future research, a decision support system will be developed capable of creating or integrating an elastic load balancer for runtime information monitoring in relation to single specific components in order to deliver near-optimal component deployment solutions specific to responses required from cloud-hosted applications to changes in workload. This would be of immense value to cloud designers and SaaS customers for decision making around the provision and decommission of components.

Conflict of Interest

The authors declare no conflict of interest.

ABSTRACT

When we drive a car, we often want to know the circumstances of roads between the current location and the destination. Ishihara et al. proposed a Vehicular ad-hoc NETworks (VANET) -based information sharing system, called the Real-Time Visual Car Navigation System, in which a driver can obtain Location-Dependent Information (LDI), such as photographs or videos of his/her Point of Interest (PoI), by telling the onboard device, e.g., a car navigation device, the PoI. The simplest way to provide LDI to vehicles is to flood the LDI to all vehicles, but unneeded LDI may be disseminated, and network resources may be wasted. To disseminate LDI to many vehicles that demand it with low communication traffic, we have proposed a data dissemination scheme based on Demand maps (Dmaps). In this scheme, each vehicle has a Dmap, a data set representing the geographical distribution of the strength of demands for LDI. To keep the Dmap up to date, each vehicle exchanges a subset of data constituting a Dmap (Dmap Information: DMI) with other vehicles. Vehicles preferentially send new LDI or forwarded LDI strongly demanded to the area where the LDI is frequently demanded based on Dmaps. If vehicles frequently send DMI, the accuracy of the Dmap becomes high, however, communication traffic becomes large. In this paper, we propose strategies for controlling the frequency of sending DMI and strategies for selecting DMI to be sent to improve the Dmap accuracy with low communication traffic. Simulation results show that one of the proposed strategies, the LDI Transfer Zone (LTZ) strategy, achieves highly accurate Dmaps with a small amount of communication traffic.

1 Introduction

If a driver can visually know the current circumstances of roads on a route to his/her destination, such as traffic jams, roadwork, accidents, and beautiful sights, he/she may select a better (faster, easier, or more fun) route to the destination. Currently, there are some applications that inform a driver of traffic information to make driving more comfortable, such as Google maps and ETC2.0 [1] in Japan, etc. In addition, Pioneer has provided a cellular network-based system that allows a driver to visually know the current circumstances of roads predefined by the system [2]. However, to the best of our knowledge, there is no application that visually informs a driver of the current circumstances of roads that are designated by the driver.

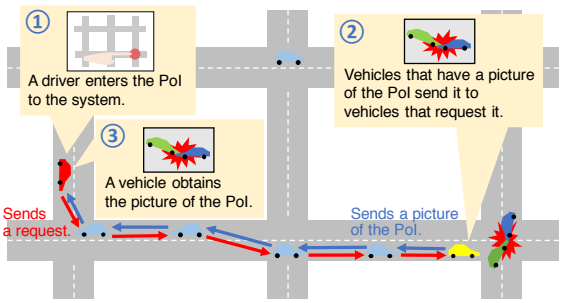

Figure 1. Real-Time Visual Car Navigation System

[*]Corresponding Author: Akihiro Yamada, Shizuoka University, 3-5-1 Johoku, Naka-ku Hamamatsu, Japan, akihiro@ishilab.net

Ishihara et al. proposed a Vehicular Ad-hoc NETworks (VANET)-based road traffic information sharing system, called the *Real-Time Visual Car Navigation System* [3–5]. This system allows driver to obtain photographs/videos of his/her Point of Interest (PoI) that is inputted to an onboard device, e.g., a car navigation device. In this system, when a driver inputs his/her PoI to an onboard device, the vehicle sends a request message to vehicles in the vicinity of the PoI. Then, vehicles that have a photograph/video of the PoI send it to the requesting vehicle (Figure 1).

In this system, we assume that vehicles use only VANET to send request messages to vehicles in the vicinity of a PoI and to send photographs/videos of PoI to requesting vehicles. If we use a simple pull-based strategy for sending the photographs/videos in the *Real-Time Visual Car Navigation System*, a requesting vehicle sends request messages to vehicles in the vicinity of a PoI, and vehicles that received a request message respond by sending photographs/videos of the PoI to the requesting vehicle. With this strategy, it is difficult for vehicles to certainly send the photographs/videos to the requesting vehicles with low latency because the connectivity between vehicles is intermittent due to the high mobility of vehicles. Furthermore, if multiple vehicles that are close together demand photographs/videos of the same PoI at the same time, the same data and the same request messages are repeatedly sent to the same location at the same time. Consequently, network resources may be wasted. Cooperative caching techniques such as ones proposed in [6] can be used to mitigate this problem. Another problem of pull-based schemes is that it is difficult to constantly deliver newly generated Location-Dependent Information (LDI) of PoI items to vehicles having interest in the PoI.

On the other hand, if all vehicles that have photographs/videos of the PoI send them based on a simple push-based strategy for certainly sending the photographs/videos to requesting vehicles, all vehicles send the photographs/videos whenever vehicles receive or generate them. Thus, unneeded data may be disseminated and limited network resources are wasted.

To ensure that newer LDI is sent to requesting vehicles with low communication traffic, Ishihara et al. have proposed a data dissemination scheme based on *Demand maps* (Dmaps) [4]. A Dmap is a data set representing the geographical distribution of the strength of demands for LDI. This scheme assumes that every vehicle has a Dmap. Vehicles grasp the geographical distribution of the strength of demands for LDI using a Dmap, and they send LDI to areas where it is strongly demanded via an efficient route. To keep Dmaps on vehicles up to date, each vehicle broadcasts several data constituting its Dmap (Dmap Information: DMI) with a beacon that it sends periodically. When vehicles receive other DMI, they update their Dmap by merging the received DMI with their own.

Since vehicles send LDI in accordance with Dmaps, the accuracy of Dmaps, i.e. the reproducibility of real geographical distribution of the strength of demands in Dmaps, should be high. Each vehicle should frequently update its Dmap by frequently exchanging DMI with other vehicles to make the accuracy of Dmaps high. However, if each vehicle frequently sends DMI, communication traffic becomes high. Therefore, strategies to increase the accuracy of Dmaps and control communication traffic are needed. In [4], Ishihara, et al. design the basic specification of Dmap-based data dissemination, however, they did not design the details of how to send DMI.

In this paper, to solve the tradeoff between Dmap accuracy and communication traffic, we propose strategies that control the frequency of sending DMI and strategies that each vehicle selects DMI to be sent. In addition, we evaluate the accuracy of Dmaps and communication traffic in the case that vehicles use the proposed strategies through simulations.

The contributions of this paper are summarized as follows.

1. We propose a strategy for controlling the frequency of broadcasting DMI. In this strategy, each vehicle determines whether it sends DMI based on the frequency of updating its DMI.

2. We propose three strategies for selecting DMI to be sent: i) the Recently Update First (RUF) strategy, which considers how new each DMI is, ii) the LDI Transfer Zone-based (LTZ) strategy, which considers the relation between each PoI and each location where requests occur, and iii) a hybrid strategy.

3. We evaluated the effectiveness of the proposed strategies through simulations and confirmed that the LTZ strategy most effectively reduces communication traffic and makes the accuracy of Dmaps high.

This paper is an extension of work originally presented in 2017 IEEE 31st International Conference on Advanced Information Networking and Applications (AINA) [7]. In this paper, we conduct simulations with more appropriate parameters, and provide a more detailed explanation of the proposed strategies and Dmap-based data dissemination. In addition, we improve the implementation of our proposed strategies in an existing simulator, and obtain more reliable simulation results. The description of related work is updated.

The remainder of this paper is composed as follows. In the next section, we review related work. In Section 3, we recapitulate the data dissemination scheme based on Dmaps and introduce the data structure of Dmap based on soft-state sketches. In Section 4, we propose strategies for sending DMI to improve the accuracy of Dmaps with low communication traffic. Then, in Section 5, we evaluate the effectiveness of the proposed strategies. Finally, we conclude this paper in Section 6.

2 Related Work

In Dmap-based data dissemination, we assume that a vehicle that has generated LDI appends the location where it generated the LDI. In addition, vehicles can know locations where the LDI is demanded based on their Dmap. Vehicles carry out the routing of LDI by referring to a location where the LDI is generated and locations where the LDI

is demanded. This concept is similar to Named Data Networking (NDN). In NDN, vehicles give a name, e.g. a location where data item is generated, to each data item and deliver the data item to vehicles requesting the data item associated with that name.

In [8], Grassi et al. proposed Navigo, an interest forwarding scheme in NDN. In Navigo, each vehicle that has received or generated an interest forwards it based on the shortest path between the location where it exists and the location where many vehicles having the demanded data exist. This scheme aims to deliver interests to locations where many vehicles having the required data are. In Navigo, vehicles send requests (interests) to many vehicles having the required data by sending the requests to the locations of these vehicles. In the Dmap-based scheme, vehicles register their requests to their Dmap instead of sending requests to the PoIs. In addition, vehicles having LDI can know not only a request for the LDI, but also the geographical distribution of the strength of demands for the LDI, and utilize this information for efficiently routing the LDI.

In [9], Ahmed et al. proposed CODIE as a data dissemination scheme using NDN. In CODIE, vehicles that forward an interest append the hop count of the interest from the requesting vehicle, and vehicles having the required data forward the data in accordance with the hop count. In this scheme, the same LDI may be disseminated to the same region at the same time, and network resources may be wasted. On the other hand, in the Dmap-based scheme, each vehicle grasps regions where each LDI is highly desired as well as its distribution. Therefore vehicles may be able to disseminate demanded LDI to many vehicles with a small number of the LDI transfers. In addition, Bian et al. introduced the NDN architecture to VANETs and proposed forwarding and caching schemes [10].

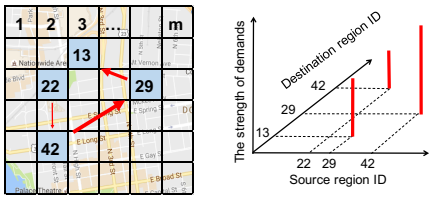
In Dmap-based data dissemination, requesting vehicles register their requests to their Dmaps. In the publish/subscribe (pub/sub)-based approach [14], e.g. [15] and [16] , requesting vehicles register their interests and their IDs to broker nodes. We regard that Dmap-based data dissemination is a kind of pub/sub based approach. A Dmap can be regarded as information on subscription and subscriber, and locations where requesting vehicles exist can be regarded as subscribers. In the Dmap-based scheme, each requesting vehicle does not register their IDs to a Dmap. However, locations where it requests LDI and locations where the LDI is generated are registered to a Dmap when it demands LDI. By disseminating LDI based on locations where requesting vehicles exist, the Dmap-based scheme can efficiently disseminate LDI to requesting vehicles compared with disseminating LDI based on IDs of requesting vehicles.

In our scheme, each vehicle sends DMI with a beacon that is sent periodically. In this paper, we discuss controlling the frequency of sending DMI. Many schemes for controlling the frequency of sending beacons have been proposed for sharing traffic information with low communication traffic. Dynamic beaconing (DynB) [11], UV-CAST [12], and DV-Cast [13] control the frequency of sending beacons adaptively to the density of vehicles and communication condition. In this paper, we propose a strategy that vehicles control the frequency of sending DMI adaptively to the relationship between the frequency of updating their DMI and the frequency that neighboring vehicles update their DMI and sharing a Dmap with low communication traffic. Strategies that use density of vehicles and communication condition, such as DynB, UV-CAST, and DV-Cast can be applied to our strategy.

Dmap-based data dissemination proposed in [4] and [17] can be categorized into a kind of data dissemination system for sharing Location-Dependent Information (LDI) in VANETs. Traffic information is typical LDI treated in VANETs. Various applications for sharing traffic information in VANETs, such as SOTIS [18], Trafficview [19], CASCADE [20], and Zone Flooding [21] have been proposed so far. They have a function for aggregating LDI obtained in a distributed manner. For example, in SOTIS, vehicles periodically broadcast a packet including traffic information, e.g. their location, velocity, and direction. When a vehicle receives information from other vehicles, it aggregates all the known information on each road segment to one average value. In those applications, unneeded information may be sent because vehicles broadcast traffic information without considering how strongly the traffic information is required. On the other hand, Dmap-based data dissemination aims to reduce redundant information dissemination by disseminating strongly required information in accordance with a Dmap.

In this work, a Dmap is represented with soft-state sketches proposed in [22]. A soft-state sketch is a data structure to stochastically estimate the number of unique data for aggregating data and reducing communication traffic. A soft-state sketch is represented by an array of non-negative values. In [22], soft-state sketches are used for counting the number of available parking spaces every load segment and sharing this information among vehicles. Vehicles use a set of soft-state sketches for estimating the number of available parking spaces in a load segment. In [22], each vehicle has a set of soft-state sketches every load segment. When each vehicle finds available parking spaces, it inputs the initial TTL of available parking spaces information to a soft-state sketch corresponding to the load segment where the vehicle exists. In addition, vehicles append sets of soft-state sketches to a beacon that is sent periodically, and update their information by merging their own soft-state sketches with received ones.

On the other hand, in this paper, we use soft-state sketches for counting the number of demands for LDI and sharing this information among vehicles. In our scheme, each vehicle has a set of soft-state sketches for every pair of each location where LDI is generated and each location where LDI is required. Then, each vehicle inputs the initial TTL to a soft-state sketch corresponding to its request when it requests LDI, and sends sets of soft state sketches as DMI with a beacon.



In [22], to reduce communication traffic for sending sets of soft-state sketches, a method for compressing soft-state sketches is proposed. However, we aim to reduce communication traffic by controlling the frequency of sending sets of soft-state sketches and selecting sets of soft-state sketches that vehicles should send.

3 A data dissemination scheme based on Demand map

In this section, we describe the details of the data dissemination scheme based on a Demand map (Dmap). In this scheme, each vehicle has a Dmap, which is a data set representing the geographical distribution of the strength of demands for LDI. Each vehicle forwards strongly demanded LDI items preferentially in accordance with its Dmap.

3.1 Demand map (Dmap)

A Dmap represents the geographical distribution of the strength of demands for LDI. We assume that the strength of demands for LDI is measured by the number of demands generated by vehicles. If multiple vehicles in geographically distant locations demand LDI of the same PoI, e.g. vehicles in the east end of a city and vehicles at the west end of the city require LDI of the city center, the routes for delivering the LDI to the vehicles in distant locations will be different. Thus, we divide an area into multiple regions, and a Dmap manages the strength of demands for LDI of each region every each region where demands are generated.

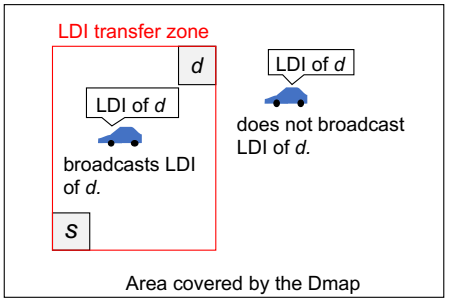
(a) Regions in a Dmap (b) Concept of a Dmap

Figure 2. Demand map

A Dmap is created as follows. Vehicles divide an area supported by their Dmap into multiple small regions and give a unique ID to each small region as shown in Figure 2 (a). We refer to a region where a requesting vehicle exists as a source region, and refer to a region where the requested LDI is generated as a destination region. For instance, in Figure 2, if a vehicle in region 29 requires LDI of region 13, we call region 29 a source region and call region 13 a destination region. A Dmap records the number of demands, i.e. the strength of demands, every pair of each source region and each destination region. For instance, in Figure 2 (a), if the start point of an arrow is a source region, and the end point of an arrow is destination region, and width of an arrow indicates the strength of demands corresponding to the arrow, a Dmap is represented as shown in Figure 2 (b).

3.2 How vehicles use a Demand map for disseminating Location-Dependent Information (LDI)

A Dmap on each vehicle is used for decision of routing of LDI. When a Dmap is updated or each vehicle generates new LDI or receives LDI, each vehicle refers to its Dmap and knows the number of demands per pair of a source region and a destination region. In addition, the vehicle refers to LDI time stamps, and it preferentially selects LDI that was required many times from sets of LDI that are current. If vehicles that are far from a source region send LDI, it may become outdated during delivery, even though LDI should be new. Therefore, vehicles that are far from the source region do not send LDI.



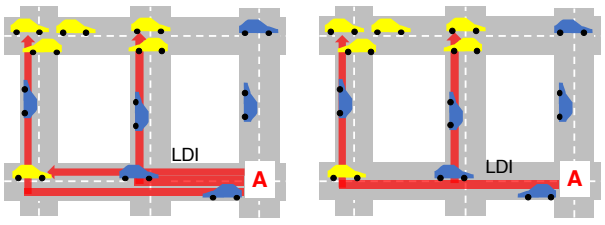


Figure 3. Disseminating LDI of s to d in accordance with a Dmap

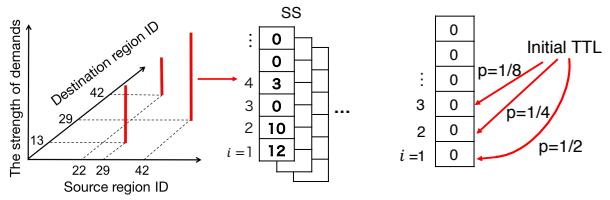
In addition, LDI should be delivered from the destination region to source regions via a route as short as possible. To realize this, we defined a zone where LDI is delivered as an LDI Transfer Zone (LTZ). An LTZ is a rectangular zone that consists of a diagonal whose ends are a source region and a destination region (Figure 3). When a vehicle sends LDI, it determines whether it sends the LDI based on whether it is in the LTZ corresponding to the LDI. A vehicle sends an LDI item only when it is in the LTZ corresponding to the pair of the destination region and the source region of the LDI (Figure 3). If the vehicle is in one of the LTZs corresponding to LDI that is strongly demanded from many source regions, it aggressively broadcasts the LDI item.

LDI is delivered via many source regions. Thus, in the case that LDI is demanded from multiple source regions at the same time, if duplicate routes exist, LDI is not passed through the duplicate route multiple times, and redundant dissemination may be reduced compared with simple pull-based strategy. For instance, in Figure 4 (a), if yellow cars request LDI of A, the LDI is sent via routes represented by red arrows multiple times and duplicate dissemination occurs. However, in Figure 4 (b), if all cars have the same content of a Dmap, the LDI is sent via a route represented by red arrows once, then, duplicate disseminations do not occur.

(a) Simple pull-based strategy (b) Dmap-based strategy

Figure 4. Comparison of Dmap-based strategy and simple pull-based strategy

We assume that vehicles send new LDI demanded by many vehicles to the area where the demanding vehicles exist so that the LDI can be delivered via a route satisfying the aforementioned requirements. A routing strategy based on a propagation function proposed in [23] can be used for



this purpose.

By this operation, vehicles that want the LDI will be able to obtain the LDI with a low data delivery delay and a small amount of traffic. For achieving high reliability and low data traffic for delivering LDI, the behavior of neighboring vehicles that have the same LDI and potentially broadcast the LDI should be considered. The detailed design of data forwarding algorithms based on a Dmap and behavior of the neighboring vehicles is beyond the scope of this paper.

3.3 Data structure of Demand map

One main scheme to create a Dmap is to collect all log data concerning demands that are generated by all vehicles, e.g. source region ID, destination region ID, car ID, and Time to Live (TTL) of demands, etc. However, if vehicles create their Dmap in accordance with this main scheme, all vehicles broadcast all log data concerning demands, and data size that vehicles have to broadcast and manage in their local storage increase in proportion to the number of demands and the number of vehicles.This leads to low scalability. To reduce the required communication traffic for maintaining Dmaps and the required storage on vehicles, a Dmap should be represented by a suitable data structure and needs algorithms to handle the data that can aggregate many demands generated by different vehicles in different locations.

Therefore, in [4] and [17], Ishihara et al. proposed to represent a Dmap by using soft-state sketches proposed in [22], a data structure to aggregate data and stochastically count the number of unique data. In [22], soft-state sketches are used for managing observation of free parking spaces in the same area by multiple vehicles. Meanwhile, we use soft-state sketches for counting the number of demands for the same pair of source region and destination region.

(a) Dmap with soft-state sketch (b) Putting TTL

Figure 5. Soft-state sketches in a Dmap

To manage a Dmap, each vehicle has a set of h ($h \geq 1$) sketches for a pair of source region and destination region (Figure 5 (a)). A sketch is an array of non-negative integers as shown in Figure 5 (a). Hereafter, we refer to a set of sketches as an SS for simplicity. Since an SS is used for representing DMI for a pair of source region and destination region, we will use these words interchangeably.

When a vehicle requires LDI of a PoI, it randomly selects a sketch from the SS corresponding to the pair of the vehicle's current region, i.e. the source region of the demand, and PoI, i.e. the destination region of the demand (Figure. 6). Then, it puts the initial TTL for the demand into i-th element from the smallest index of elements in the selected sketch with a probability of $1/2^i$ (Figure 5 (b)). The TTL value in each element is decremented as time progresses until the TTL value becomes 0. Since the probability that the TTL value is put into an element with a small index i is high and the probability that the TTL value is put into an element with a large index i is low, elements with a small index easily have non-zero values, but ones with a large index are hardly filled with a non-zero value. Therefore, the more demands occur, the more easily elements with large indexes are filled with non-zero values and the longer the run length of non-zero values from an element with the smallest index of a sketch is. Thus, the number of generating demands for a pair of source region and destination region, i.e. the strength of demands for the pair, is estimated based on the run length of non-zero values from an element with the smallest index of each sketch in an SS for the pair.

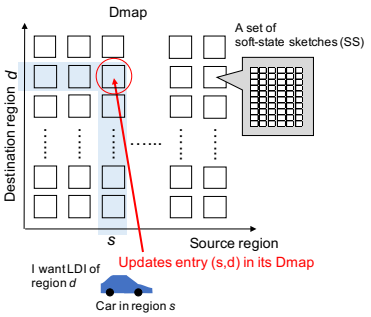


Figure 6. Behavior of a vehicle when it demands LDI

To keep Dmaps on vehicles up to date and share Dmaps among vehicles, each vehicle selects several SSs and sends them with a beacon that is sent periodically. When a vehicle receives SSs from another vehicle, it merges each of the received SSs with a corresponding SS in its Dmap. To merge the received SSs with the corresponding SSs in a local Dmap, the vehicle selects a larger value in the same element of the same index of sketches in each of received SSs and the corresponding SS in the local Dmap. Then the selected value is set to the element of the sketch of the SS in the receiver vehicle's Dmap as shown in Figure 7.

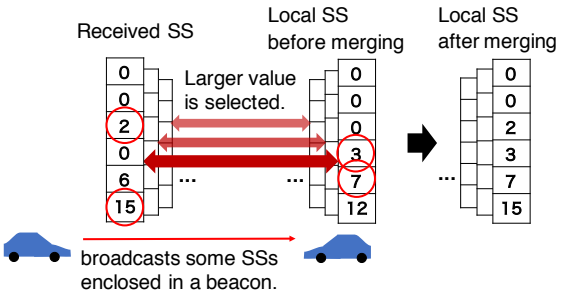

Figure 7. Merging with local SSs and other's

The number of demands for a pair of a source region and a destination region recorded in an SS consisting of m sketches $(S_1, \ldots, S_m)$ is estimated by the following formula presented in [22],

$$C(S_1, \ldots, S_m) := m \cdot \frac{2^{\sum_{j=1}^{m} Z(S_j)/m} - 2^{-\kappa \cdot \sum_{j=1}^{m} Z(S_j)/m}}{\varphi}, \quad (1)$$

with $\kappa \sim 1.75$, $\varphi \sim 0.77351$. S_j is a sketch in an SS, and m is the number of sketches composing an SS. $Z(S_j)$ is the run length of non-zero values from an element with the smallest index in S_j. In addition, the standard error of the estimate is $0.78/\sqrt{m}$. Therefore, the larger the number of sketches that compose an SS, the higher the accuracy of the estimate. However, data size that each vehicle has and sends increases in proportion to the number of sketches that compose an SS.

4 Strategies for efficiently sending DMI

In this section, we propose a strategy that controls the frequency of sending DMI and strategies that select DMI that vehicles should send for sending DMI with making the accuracy of Dmap high and making communication traffic low. To reflect current demands in a Dmap certainly, i.e. to improve the accuracy of a Dmap, it is desirable for each vehicle to frequently receive SSs for all pairs of all source regions and all destination regions from many vehicles and make its local Dmap up to date. However, if all vehicles frequently send all SSs that they have, the communication resource will be wasted because unneeded SSs may be sent and vehicles may send duplicate SSs. Therefore, we propose strategies for making the accuracy of Dmap high with low communication traffic.

4.1 Strategy controlling the frequency of sending DMI — Frequent strategy

We propose *selecting frequently updating vehicles* strategy, a strategy that controls the frequency of sending DMI (= SSs), to reduce the communication traffic for sending SSs without deteriorating the accuracy of Dmaps. Hereafter, we refer to this strategy as *Frequent* strategy for simplicity. Based on this strategy, when a vehicle sends a beacon, it determines whether it sends SSs with a beacon. The key idea of this strategy is that vehicles that frequently receive and update SSs may have SSs that certainly reflect the actual number of demands. On the other hand, vehicles that rarely receive and update SSs may have SSs that incorrectly reflect the actual number of demands. In addition, vehicles that frequently generate demands and update their SSs may have many SSs that are still not reflected in the SSs of other vehicles. Therefore the vehicles should send their SSs frequently. Therefore, in the Frequent strategy, vehicles that frequently update their SSs have a high priority to send SSs. Here, *updating* an SS means that one of the elements in a sketch of the SS is overwritten by putting a larger value due to a new demand generation or receiving a corresponding SS that has at least one larger value for any of elements in sketches in the receiver vehicle's SS from a neighboring vehicle.

In this strategy, each vehicle counts the total number of updates to its SSs during a certain past period, τ_u. We refer to the number as the Total Count of Updating Sketches (TCUS), for simplicity. In this strategy, vehicles whose TCUS is large are regarded as vehicles that frequently update their SSs. Vehicles whose TCUS is larger than one of their neighbor vehicles have a higher priority to send their SSs.

The operation of vehicles in this strategy is summarized follows. Each vehicle sends its TCUS with a beacon periodically. When a vehicle receives a beacon from another vehicle, it stores the received TCUS with the ID of the vehicle that has sent the TCUS. When a vehicle sends a beacon, it sorts TCUSs received from vehicles in the vicinity and its TCUS in descending order. Then, if its TCUS is in the top-k group of TCUSs, it decides to send SSs with a beacon (Figure 8). Otherwise, it does not send any SSs.For instance, as shown in Figure 8, if TCUS of car A is 4th from the largest TCUS and $k > 4$, car A sends SSs.

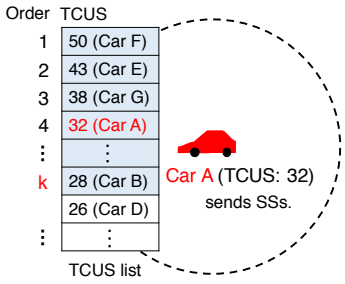

Figure 8. Frequent strategy

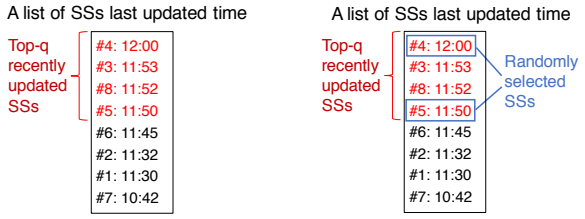
4.2 Strategies for selecting DMI that vehicles send

Each vehicle should select SSs to send so that Dmaps on vehicles, including itself, can achieve high accuracy with low communication traffic by eliminating redundant information that will not update the SSs of other vehicles. To achieve this, we propose three strategies, the Recently Updated First (RUF) strategy, the LDI Transfer Zone (LTZ) strategy, and the RUF + LTZ Hybrid strategy.

4.2.1 Recently Updated First (RUF) strategy



Recently updated SSs may have a large TTL value and may update SSs on vehicles that receive them, while SSs that are updated long ago may have a small TTL value and may not update SSs of the receiver vehicles. Sending SSs that will not update SSs of other vehicles wastes limited communication resources.

Therefore, in the RUF strategy, we give a high priority to recently updated SSs. When a vehicle updates an SS, it records the current time with a pair of a source region ID and a destination region ID. If a vehicle decides to send SSs with a beacon, it selects top-q recently updated SSs from its local SSs that have been updated so far (Figure 9 (a)).

However, if each vehicle selects SSs only based on the last update time of them, SSs that have the same pair of source region and destination region may frequently be sent and SSs that have other pairs will lose a chance to be sent. For instance, if an SS for a pair of source region s and destination region d is the most recently updated SS in a vehicle, the vehicle sends the SS. Then, when neighbor vehicles receive and update the SS, the SS for a pair of s and d becomes the most recently updated SS in the vehicles and the

vehicles will send it. The SS for a pair of s and d is repeatedly sent and SSs for other pair are rarely sent. Consequently, for some pairs of a source region and a destination region, the transition of the number of demands on a vehicle may not be reflected in SSs, and the Dmap accuracy may become low.

To provide the opportunity for not only the most recently updated SSs to be sent, in this strategy, each vehicle randomly selects up to n SSs from the top-q recently updated SSs and sends them (Figure 9 (b)).

(a) Selecting recently updated SSs (b) n SSs from the top-q SSs

Figure 9. RUF strategy

4.2.2 LDI Transfer Zone (LTZ) strategy

In Dmap-based data dissemination, we assume that vehicles send LDI for a pair of source region s and destination region d only when they are in the LTZ corresponding to s and d, as mentioned in Section 3.2. Therefore, vehicles in the LTZ corresponding to s and d should certainly know the number of demands for LDI for the pair of s and d. On the other hand, vehicles that are not in the LTZ do not have to know the number of demands for LDI. If the SSs for the pair of s and d are sent by only vehicles in the LTZ corresponding to s and d, the SSs are exchanged among only vehicles in the LTZ. As a result, the accuracy of the number of demands only for a pair of s and d composing an LTZ containing a vehicle holding the Dmap becomes high because noisy unneeded SSs are not sent and SSs that affect other vehicles SSs for a pair of s and d composing the LTZ are sent.On the other hand, exchanging SSs among vehicles outside the LTZ is not effective because vehicles do not need SSs that they will not use when they disseminate LDI.

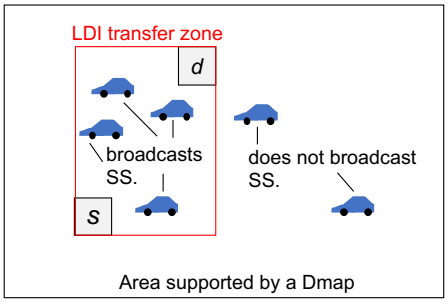


Figure 10. LTZ strategy

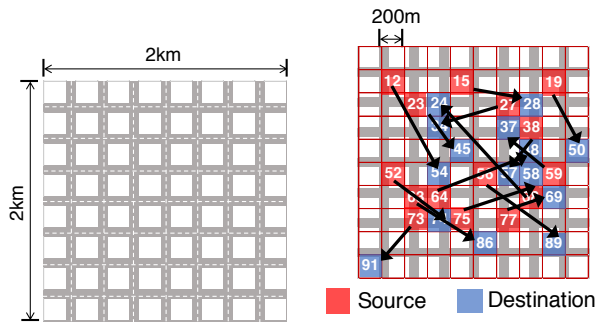
In the LTZ strategy, vehicles send SSs for the pair of s and d only when they are in the LTZ corresponding to s and d, and vehicles do not send the SSs when they are not in the LTZ. To this end, when each vehicle decides to send SSs, it first selects only SSs whose pair of source region s and destination region d satisfies $P \in A_{s,d}$. Here, P denotes the vehicle's current region, and $A_{s,d}$ denotes the LTZ for the pair of s and d (Figure 10). If the number of selected SSs is larger than the maximum number of SSs that can be included in a beacon packet, the vehicle randomly selects up to n SSs from the selected SSs.

4.2.3 RUF + LTZ Hybrid strategy

To leverage the advantages of both the RUF and LTZ strategies, we propose the RUF + LTZ Hybrid strategy. In this strategy, each vehicle sends more recently updated SSs only when it is in the LTZ corresponding to the SSs. Each vehicle selects and sends SSs as described below. If a vehicle v decides to send SSs with a beacon, it selects the top-q recently updated SSs from its local SSs that have been updated so far, like in the RUF strategy. Note that a vehicle selects SSs only based on whether SSs are more recently updated in this phase. We refer to the set of these SSs as $\boldsymbol{L}_v$. Then, it selects SSs whose pair of source region s and destination region d satisfies $P \in A_{s,d}$ from $\boldsymbol{L}_v$. We refer this set of selected SSs as $\boldsymbol{L}'_v$. Finally, v randomly selects up to n SSs from $\boldsymbol{L}'_v$ and broadcasts them. This algorithm is shown in Algorithm 1.

Algorithm 1 RUF + LTZ strategy

When vehicle v attempts to send some sets of sketches
$\boldsymbol{L}_v, \boldsymbol{L}'_v \leftarrow \phi$
$\boldsymbol{L}_v \leftarrow$ top q recently updated sets of sketches on v
for all (s,d) of a set of sketches in $\boldsymbol{L}_v$ **do**
  if $P_v \in A_{s,d}$ **then**
    add $S_{v,s,d}$ to $\boldsymbol{L}'_v$
  end if
end for
select n items randomly from $\boldsymbol{L}'_v$



5 Evaluation of strategies for efficiently sending DMI

In this section, we evaluate the effectiveness of the proposed strategies through simulations. We focus on the accuracy of Dmaps and communication traffic required for sending DMI in this evaluation.

5.1 Simulation settings

5.1.1 Simulation scenario

In each scenario of our simulations, each vehicle broadcasts SSs to update and to share their Dmap using only VANET. We used Scenargie [24], a network simulator developed by Space-Time Engineering, and we implemented our proposed strategies and comparative strategies described later. In our scenarios, there are 14 double lane roads in a square area that has 2 km on each side as shown in Figure 11 (a). All intersections have traffic lights.

(a) Simulation area (b) Regions in Dmap

Figure 11. Simulation area and regions for a Dmap

All vehicles move on the roads in the simulation area by a mobility log generated using the SUMO road traffic simulator [25]. In addition, we conducted simulations of vehicle mobility by changing the inter-vehicle arrival rate. These vehicle mobility simulation logs are used for evaluating how the density of vehicles affects the accuracy of Dmaps and the effectiveness of the proposed strategies.

Table 1. Pairs of source region ID and destination region ID of demands generated in the simulations

Source	Destination	Source	Destination
12	54	23	45
19	50	15	28
52	74	63	86
56	89	27	34
38	57	73	91
75	58	77	69
59	37	64	48
68	24		

Table 2. Simulation parameters

Parameters	Values
Inter-vehicle arrival rate [/h·lane]	100, 300
Interval of sending beacons [sec]	1
Tx power [dBm]	10
Interval of generating demands [sec]	1
The effective period of a demand	63
Simulation time [s]	900
MAC Protocol	IEEE802.11p
Propagation model	ITU-R P.1411
App. max. data size [bytes]	500
Size per SS [bytes]	192
τ_u	30
k	10, 17
q	7
n	2
p	0.8

We divided the simulation area into small square regions 200×200m^2 and gave an ID to each small region for creating a Dmap of each vehicle Figure 11 (b). In Figure 11 (b), vehicles in blue regions demanded LDI of red regions corresponding to the blue regions. Table 1 also summarizes pairs of a source region and a destination region of demands that vehicles generated in the simulations. Vehicles in each source region shown in Table 1 demanded LDI of the destination region corresponding to the source region every second when they were moving towards the direction of the destination region. For instance, a vehicle in region 12 demanded LDI of region 54 every second only when it was moving eastbound or southbound.

We repeated simulation runs ten times with different random number seeds. Table 2 summarizes parameters used in the simulations. We determined the values of n, k and the interval of sending beacons based on preliminary simulations. We selected values of these parameters so that communication traffic could be as small as possible and the reproducibility of real demands in Dmaps (the ratio of coincidence described later) could be high based on the results of the preliminary simulations using the same scenarios.

5.1.2 Comparative strategies

To evaluate the effectiveness of proposed strategies, we used three comparative strategies, the *All* strategy, the *Random Timing* (RandT) strategy, and the *Random Selecting* (RandS) strategy. The All strategy and RandT strategy are for controlling the frequency of sending SSs and used for evaluating the effectiveness of the Frequent strategy. The RandS strategy is for selecting SSs to be sent, and used for evaluating the effectiveness of the LTZ strategy, RUF strategy, and RUF + LTZ Hybrid strategy.

In the All strategy, all vehicles do not control the frequency of sending SSs and send SSs with every beacon. In the RandT strategy, each vehicle decides to send SSs with a probability of p when it sends a beacon. In the RandS strategy, vehicles that send SSs randomly select n SSs to send from SSs that have been updated so far.

5.2 Simulation metrics

We evaluated the performance of the proposed strategies focusing on the accuracy of a Dmap in each vehicle and communication traffic required for sending DMI (= SSs). Here, the accuracy of a Dmap means the reproducibility of the actual number of demands in the Dmap. Since vehicles send LDI based on the estimated number of demands given by the Dmap, the reproducibility of the actual number of demands in the Dmap should be high. The reproducibility of the actual number of demands should be evaluated by using a relative metric because the influence of the error is different according to how the actual number of demands is. Therefore, for evaluating the accuracy of Dmaps, we use the ratio of coincidence between the actual number of demands and the estimated number of demands in Dmaps, M.

M for a pair of source region and destination region is defined as follows.

$$M = 1 - \min\{1, |R - D|/R\} \quad (0 \le M \le 1). \qquad (2)$$

where D denotes the estimated number of valid demands (TTL > 0) that are generated in a source region for a destination region, and R denotes the actual number of valid demands for the same combination of a source region and a destination region as D. In addition, we assume that R is not 0 in this formula. The closer M is to 1, the higher the accuracy of the Dmap. As mentioned above, only vehicles in an LTZ for the pair of source region s and destination region d should surely know the number of demands for LDI for the pair of s and d because we assume that vehicles send

the LDI only when they are in LTZ corresponding to s and d. Therefore, we evaluated M for the pair of source region s and destination region d in a Dmap in only vehicles that are in the LTZ for the pair of s and d at the time point of the data analysis.

We also evaluated the communication traffic required for sending SSs. It is the average value of the product of the data size of an SS and the total number of broadcasted SSs in each simulation.

5.3 Simulation results

5.3.1 The ratio of coincidence M

Figure 12 shows the CDF of M calculated 800 seconds after the start of the simulation with vehicle traffic of 300 vehicles/lane·hour when the All strategy is used for controlling the frequency of sending SSs, and we evaluated the performance of the proposed strategies for selecting SSs. The vertical axis is the ratio of vehicles that have an SS representing M below each M on the horizontal axis. Each curve in the graph corresponds to a pair of a source region and a destination region of demands shown in Table 1.

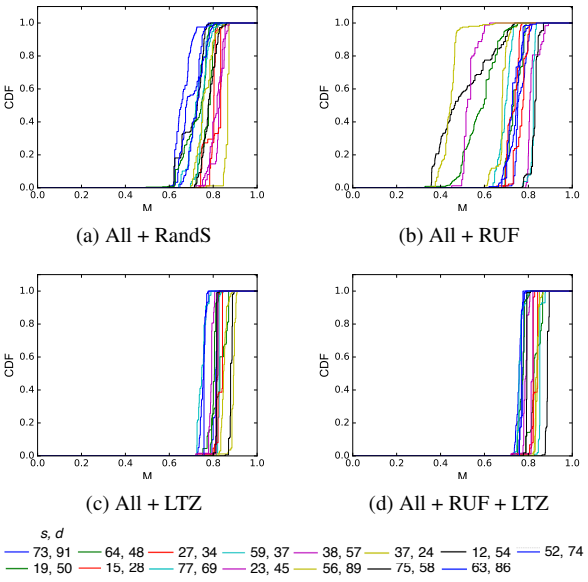


Figure 12. CDF of the Dmap accuracy (M) at 800 sec (inter-vehicle arrival rate: 300 vehicles/lane·hour)

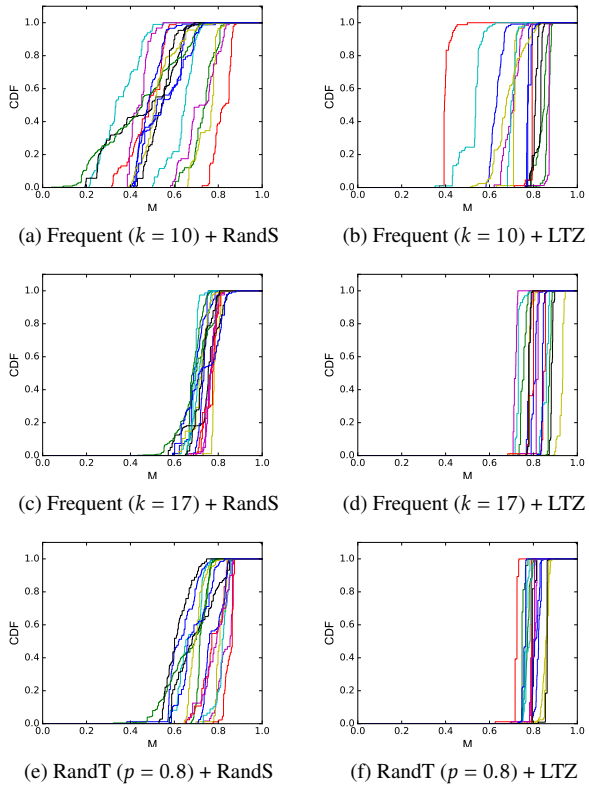
As shown in Figure 12, the LTZ strategy and the RUF + LTZ strategy outperform the other strategies. When the RandS strategy is used, M of pairs of s and d (Hereafter, we call them sd-pairs) ranges from 0.6 to 0.86. With the LTZ strategy and the RUF + LTZ strategy, M of sd-pairs is improved compared with M when the RandS strategy is used. M of sd-pairs when the LTZ strategy or the RUF + LTZ strategy is used ranges from 0.7 to 0.86. This is because SSs for the pair of s and d are preferentially sent in LTZ corresponding to the SSs. The reason why M in the LTZ strategy is similar to M in the RUF + LTZ strategy is summarized as follows. SSs are frequently sent in their corresponding LTZ if the LTZ strategy is used, then the time stamp of the SSs on vehicles in the LTZ is frequently updated. Therefore, SSs are frequently sent in the LTZs when vehicles select recently updated SSs in RUF + LTZ strategy. Therefore, similar SSs are selected both in the LTZ strategy and the RUF + LTZ strategy. Consequently, M in the LTZ strategy is similar to M in the RUF + LTZ strategy. On the other hand, when only the RUF strategy is used for selecting SSs, M is deteriorated. The reason is that SSs of the same sd-pairs tend to be sent repeatedly and transmission of SSs of other sd-pairs is suppressed.



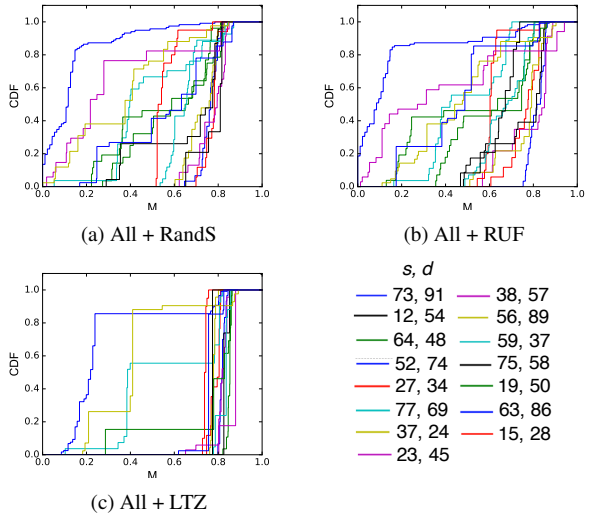


Figure 13. CDF of the Dmap accuracy (M) at 800 sec (inter-vehicle arrival rate: 300 vehicles/lane·hour)

Figure 13 shows the CDF of the Dmap accuracy (M) when the Frequent strategy and the RandT strategy were used for controlling the frequency of sending DMI (= SSs) with the RandS strategy or the LTZ strategy for selecting SSs. When vehicles use the RandT strategy and the RandS strategy, M is deteriorated compared to that in the case when the All strategy and the RandS strategy are used. This is simply because the number of exchanged SSs is decreased. However, when vehicles use the RandT strategy and the LTZ strategy, M is similar to one in the case when the All strategy and the LTZ strategy are used. The reason is that SSs are frequently exchanged in LTZ corresponding to them when the LTZ strategy is used even if the small number of vehicles send SSs. When the Frequent strategy with $k = 10$ is used, M is more deteriorated than that in the case when the RandT strategy is used. The reason is that the number of vehicles that send SSs is excessively restrained in the Frequent strategy with $k = 10$. On the other hand, when the Frequent strategy with $k = 17$ is used, M approximated M in the cases when the All strategy is used because the number of vehicles that send SSs was hardly not restrained.

Figure 14 shows CDF of M calculated at 800 seconds from the start of the simulation with 100 vehicles/lane·hour

vehicle traffic. Compared with Figure 12 (a)–(c), we can see that M is deteriorated when the vehicle density is low. This is because a sufficient number of SSs is not exchanged due to lack of connectivity between vehicles. Interestingly, even with poor connectivity, the LTZ strategy outperforms other strategies and most of the sd-pairs achieve high M around 0.8. The reason is that SSs are easily updated in LTZ corresponding to the SSs because SSs are frequently sent in the LTZ.

(a) All + RandS (b) All + RUF

(c) All + LTZ

Figure 14. CDF of M at 800 sec (inter-vehicle arrival rate: 100 vehicles/lane·hour)

5.3.2 Communication traffic

Figure 15 shows communication traffic in each combination of strategies when vehicle traffic is 300 vehicles/lane·hour. We can see that the LTZ strategy most effectively reduces communication traffic among strategies for selecting SSs. The reason is that each SS is sent only in the LTZ corresponding to the SS and is not sent outside the LTZ.

Concerning strategies for controlling the frequency of sending SSs, the Frequent strategy ($k = 10$) most effectively reduces the communication traffic. However, when the Frequent strategy (k=10) is used, M becomes low as shown in Figure 13 (a), (b) because SSs are rarely updated due to the limited chance to send SSs.

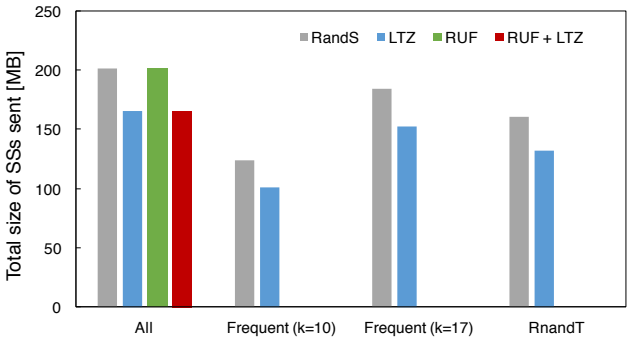

Figure 15. Communication traffic (Inter-vehicle arrival rate: 300 vehicles/lane·hour)

Summarizing the simulation results of the ratio of coincidence M and communication traffic, we can conclude that the LTZ strategy is the most useful to improve both the Dmap accuracy and communication traffic needed for exchanging SSs. The reason is that this strategy increases the frequency of SS exchange in their corresponding LTZ and reduces the frequency of exchanging them outside the LTZ. Concerning strategies for controlling the frequency of sending SSs, the Frequent strategy reduces the communication traffic. However, it deteriorates the Dmap accuracy. Therefore, the Frequent strategy does not solve the tradeoff between the Dmap accuracy and communication traffic. In addition, when both the LTZ strategy and RandT strategy are used, communication traffic and the Dmap accuracy is most effectively improved.

6 Conclusions

In this paper, we proposed a strategy for controlling the frequency of sending DMI (SSs) and strategies for selecting SSs that vehicles should send for improving the accuracy of a soft-state sketch-based Dmap on vehicles used for Dmap-based location dependent data dissemination services on VANETs, such as a real-time visual car navigation system. The simulation results revealed that one of the proposed strategies for selecting SSs, the LTZ strategy, effectively reduces communication traffic and achieves high Dmap accuracy, i.e. the reproducibility of the actual number of demands in Dmaps. The key feature of the LTZ strategy is that it is designed in consideration of where the exchanged information, i.e. SSs, may be used. In this strategy, vehicles send SSs in only locations where SSs may be used and do not send SSs in locations where SSs may not be used. Thus, it can reduce communication traffic and improve the accuracy of SSs in locations where SSs is used. On the other hand, the strategy for controlling the frequency of sending SSs, the Frequent strategy, which gives a high priority to vehicles frequently updating SSs, deteriorates the Dmap accuracy, while it drastically reduces communication traffic required for exchanging SSs.

The demand generation patterns used in the evaluation in the paper is limited. Thus, the performance evaluation of various demand generation patterns and realistic demand generation patterns are needed because there are many demand generation patterns in real life. For example, a demand generation pattern that frequency of demands change as time progress or change depending on a distance between a source region to a destination region should be considered. The mobility pattern of vehicles will also affect the performance of sharing Dmap information. For example, if an isolated vehicle has important Dmap information of a distant area, giving a high priority to exchanging the important Dmap information will contribute to that many vehicles knowing the distributions of demands for LDI. If many vehicles in the distant area want to obtain LDI of an area that has low connectivity from them in terms of store-carry-forward-based data delivery, such demand information will be carried by isolated vehicles.

For delivering LDI based on Dmaps, additional information is needed for each vehicle to determine whether it forwards an LDI item or not. For example, if its neighboring vehicle has sent the same LDI item recently, it should

not forward the LDI item to reduce the redundant data transmission without loss of the reliability of data delivery. Besides, if there are multiple isolated routes between the PoI and the destination of the LDI item, whether selecting one of the routes or using all the routes will affect the reliability of the LDI data delivery. In addition, we should design a criterion for selecting LDI that vehicles send, a method for calculating efficient forwarding routes based on Dmaps, etc. Our proposed strategies are important factors in the routing of LDI because vehicles disseminate LDI based on Dmaps in Dmap-based data dissemination. The design of a data forwarding algorithm based on Dmaps and additional information remains as our future work.

A B S T R A C T

This paper deals with the problem of Fault Tolerant Control (FTC) using PID-type Fuzzy Logic Controller (FLC) for an Electronic Throttle Valve (ETV) described by a switched discrete-time systems with input disturbances and actuator faults. In order to detect the faults, Unknown Input Observers (UIOs) are designed and formulated in terms of Lyapunov theory and Linear Matrix Inequalities (LMIs). This approach is designed in order to minimize the error between the desired flat trajectory generated using the flatness property and the estimated state provided from differents UIOs and to maintain asymptotic stability under an arbitrary switching signal, even in the presence of actuator faults. The simulation results have shown the effectiveness of the proposed approach.

1 Introduction

Actuator faults may cause undesired system behaviour and sometimes lead to instability, hence it is necessary to develop Fault Tolerant Control (FTC) methods against actuator faults of uncertain nonlinear systems. In the past decades some FTC design methods have been proposed for several classes of nonlinear systems with actuator faults [1-3]. It consists in computing control laws by taking into account the faults affecting the system in order to maintain acceptable performances and to preserve stability of the system in the faulty situations [4]. From the point of view of FTC strategies, the literature considers two main groups of techniques: passive and active ones. In passive FTC, the faults are treated as uncertainties. Therefore, the control is designed to be robust only to the specified faults [4]. Active FTC techniques consist in adapting the control law using the information given by the Fault Detection and Isolation (FDI) block [5]. The informations issued from the FDI block are used by the FTC module to reconfigure the control law in order to compensate the fault and to ensure an acceptable system performances.

The study of this problem was extended to switched systems in [6-8]. In [7], a switched discrete-time system with state delay has been considered. The design method is based on the construction of a filter and a fault estimation approach. In [8], an adaptive fuzzy tracking control method for a class of switched nonlinear systems with arbitrary switchings and with actuator faults has been proposed. The proposed control scheme guarantee the stability of the whole switched control system based on the common Lyapunov function stability theory and attenuate the effect of the actuator faults on the control performance by designing a new fuzzy controller to accommodate uncertain actuator faults. In [9], an observer has been built to detect the fault when it occurs. The problem of FTC for switchied linear systems is addressed by using a nominal control law designed in the absence of any fault, associated with fault detection, localization and reconfiguration techniques to maintain the stability of the system under an arbitrary switching signal in the presence of sensor faults. A state trajectory tracking has been proposed in [4] for actuator faults and observer bank based on controllers with switching mechanism for sensor faults has been also presented in [10]. A nonlinear observer based controller, adopting the so-

https://dx.doi.org/10.25046/aj020623

called parallel distributed compensation structure, has been designed to choose an adequate state estimate to compensate the effects of the faults on the system in [11]. Switched systems are dynamical systems consisting of a collection of continuous-time subsystems. Switched systems have attracted more attention due to their significance in the modelling of many engineering applications, such as chemical processes, robot manipulators and power systems. Stability analysis and synthesis of switched systems have been made using Lyapunov function to ensure stability of the switched systems such in [12].

In this paper, in order to acheive the FTC for a switched discrete-time systems, a set of PID-type Fuzzy Logic Controller (FLC) is implemented to minimize the error between the desired flat trajectory and the estimated state and to maintain the stability of the system in the presence of actuator faults. The estimated state is provided from an Unknown Input Observer (UIO). Based on residual analysis, a switching strategy using stateflow is then designed. The global stability for the switched systems is studied by Lyapunov theory and expressed as a Linear Matrix Inequalities (LMIs).

The paper is organized as follows. In Section 2, the FTC problem statement is formulated. In Section 3, the fault detection method using UIO is introduced. In Section 4, the PID-type FLC is described. Section 5 deals with the flatness property. The proposed approach is applied to an ETV in Section 6. Finally, the conclusion is drawn in Section 7.

2 FTC problem statement

Consider the discrete time switched system, which can be formulated such that

$$x(k+1) = A_j x(k) + B_j u(k) + E_j d(k) + B_j f_a(k) \quad (1)$$

$$y(k) = C_j x(k)$$

$x(k) \in \mathbb{R}^n$ is the state vector, $u(k) \in \mathbb{R}^p$ the control input, $y(k) \in \mathbb{R}^o$ the measured output, $d(k) \in \mathbb{R}^p$ the unknown disturbance input and $f_a(k) \in \mathbb{R}^p$ the actuator faults. $A_j \in \mathbb{R}^{n\times n}$, $B_j \in \mathbb{R}^{n\times p}$, $C_j \in \mathbb{R}^{o\times n}$ and $E_j \in \mathbb{R}^{n\times p}$ are the known constant matrices for $j \in \psi = \{1,2,...,m\}$ and m the number of models, $m > 1$.

In this paper, a FTC structure based on PID-type FLC, given by Figure 1, is proposed to maintain the trajectory tracking and to preserve stability of ETV in the presence of both input disturbance $d(k)$ and actuator faults $f_a(k)$.

According to this structure, the FTC approach needs to detect actuator faults firstly and then to design the j^{th} control law, denoted $u_j(k)$ given by (2), in order to minimize the error between the desired flat trajectory, generated using the flatness property and the estimated state, provided from the j^{th} UIO.

$$u_j(k) = -K_{c,j}\hat{x}_j(k) + y_j^d(k) \quad (2)$$

$K_{c,j}$ is the j^{th} gain control law.

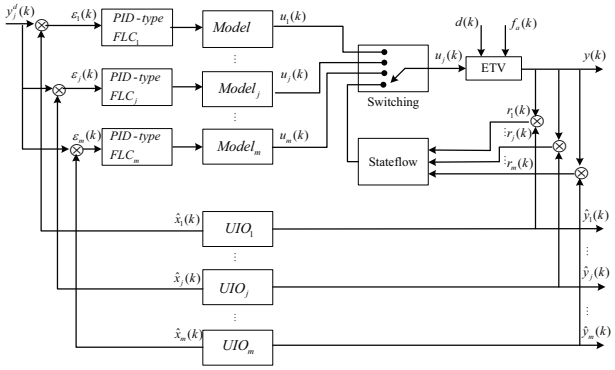

Figure 1: Proposed structure of FTC approach

In this case, LMI-based UIOs for the switched system (1) are designed using Lyapunov function for arbitary switching signal. Then, residuals $r_j(k)$ are determined by the UIOs and employed to achieve actuator faults detection.

3 Unknown input observers design and stability analysis

In this section, let us consider $f_a(k) = 0$, then the model (1) becomes

$$x(k+1) = A_j x(k) + B_j u(k) + E_j d(k) \quad (3)$$

$$y(k) = C_j x(k)$$

$j \in \psi$ denotes the j^{th} model. The structure of full rank UIOs can be formulated by

$$z(k+1) = F_j(k) + T_j B_j u(k) + K_j y(k) \quad (4)$$

$$\hat{x}(k) = z(k) + H_j y(k)$$

where $\hat{x}(k)$ is the estimated state vector $x(k)$, $z(k)$ is the state vector of full rank UIOs. F_j, T_j, K_j and H_j are unknown matrices which need to be designed.

Lemma: [13] Equation (4) is UIO of the switched system (3), if and only if the following conditions are satisfied

- $rank(C_j E_j) = rank(E_j)$
- $(C_j A_{j1})$ is observable

with

$$A_{j1} = A_j - E_j\left[(C_j E_j)^T C_j E_j\right]^{-1}(C_j E_j)^T C_j A_j \quad (5)$$

According to the above, the formulation of UIOs is constructed for each subsystem. In the next part, the multiple Lyapunov function will be used to realize the design of parameters for UIOs of switched system.

Theorem: [14] In the condition of arbitrary switching signal, for the system (3), if

$$(H_j C_j - I)E_j = 0 \quad (6)$$

$$T_j = (I - H_j C_j)$$

$$F_j = (A_j - H_j C_j A_j - K_{j1} C_j)$$
$$K_{j2} = F_j H_j$$

hold, and there exist symmetric matrices $P_j > 0$, $\forall j \in \psi$ such that

$$\begin{bmatrix} -P_j & P_j F_j \\ F_j^T P_j & -P_j \end{bmatrix} \leqslant 0, \ \forall j \in \psi \tag{7}$$

then the parameters of UIOs can be designed.

Proof: Define the state estimation error as $e(k) = x(k) - \hat{x}(k)$, the dynamic equation can be derived as

$$\begin{aligned} e(k+1) &= (A_j - H_j C_j A_j - K_{j1} C_j) e(k) \\ &- \left[F_j - (A_j - H_j C_j A_j - K_{j1} C_j)\right] z(k) \\ &- \left[K_{j2} - (A_j - H_j C_j A_j - K_{j1} C_j) H_j\right] y(k) \\ &- \left[T_j - (I - H_j C_j)\right] B_j u(k) - (H_j C_j - I) E_j d(k) \end{aligned} \tag{8}$$

with

$$K_j = K_{j1} + K_{j2} \tag{9}$$

In order to make the error decoupled from known control input $u(k)$, measured output $y(k)$ and unknown input $d(k)$, we should let

$$(H_j C_j - I) E_j = 0 \tag{10}$$

$$T_j - (I - H_j C_j) = 0$$
$$F_j - (A_j - H_j C_j A_j - K_{j1} C_j) = 0$$
$$K_{j2} - (A_j - H_j C_j A_j - K_{j1} C_j) H_j = 0$$

It can be concluded that

$$H_j = E_j \left[(C_j E_j)^T C_j E_j \right]^{-1} (C_j E_j)^T \tag{11}$$

$$A_{j1} = A_j - E_j \left[(C_j E_j)^T C_j E_j \right]^{-1} (C_j E_j)^T C_j A_j \tag{12}$$

$$F_j = A_j - H_j C_j A_j - K_{j1} C_j = A_{j1} - K_{j1} C_j \tag{13}$$

and the error dynamics is given by

$$e(k+1) = F_j e(k) \tag{14}$$

Equation (4) is UIOs of the switched system (3) if the estimation error tends asymptotically to zero despite the presence of an unknown input $d(k) \neq 0$.

Consider the following Lyapunov function

$$V_j(e(k)) = e(k)^T P_j e(k) \tag{15}$$

For $P_j = P_j^T > 0$, then, $V_j(e(k)) > 0$ holds, the ΔV given by (16) is negative

$$\begin{aligned} &V_i(e(k+1)) - V_j(e(k)) \\ &= e(k)^T F_j^T P_i F_j e(k) - e(k)^T P_j e(k) \\ &= e(k)^T (F_j^T P_i F_j - P_j) e(k); (i \in \psi, j \in \psi, i \neq j) \end{aligned} \tag{16}$$

if the following inequalities are satisfied

$$F_j^T P_i F_j - P_j \leqslant 0 \tag{17}$$

Thus, the error system (14) is stable asymptotically.

According to Schur complement lemma, the inequalities (17) can be rewritten as

$$\begin{bmatrix} -P_i & P_i F_j \\ F_j^T P_i & -P_j \end{bmatrix} \leqslant 0 \tag{18}$$

By substituting $F_j = A_{j1} - K_{j1} C_j$, the above matrix inequalities become

$$\begin{bmatrix} -P_i & P_i (A_{j1} - K_{j1} C_j) \\ (A_{j1} - K_{j1} C_j)^T P_i & -P_j \end{bmatrix} < 0 \tag{19}$$

and

$$\begin{bmatrix} -P_i & (P_i A_{j1} - W_{ij} C_j) \\ (P_i A_{j1} - W_{ij} C_j)^T & -P_j \end{bmatrix} < 0 \tag{20}$$

for $W_{ij} = P_i K_{j1}$.

Since $K_{j1} = P_j^{-1} W_{ij}$, we can obtain the value of K_{j1} then F_j, K_{j2} and $K_j = K_{j1} + K_{j2}$ from P_j and W_{ij} solutions of LMIs.

The aim of fault detection is to generate a residual signal $r_j(k)$, given by (21), which is sensitive to $f_a(k)$ in the presence of actuator faults which is the purpose of [15].

$$r_j(k) = y(k) - C_j \hat{x}_j(k) \tag{21}$$

4 PID-type fuzzy logic controller design

In this study, the FTC approach is based on PID-type FLC. To adjust the input and the output scaling factors of this controller, Genetic Algorithm (GA) optimization technique has been proposed in order to improve the performance of the controller.

4.1 PID-type fuzzy logic controller description

We consider a PID-type FLC structure as shown in Figure 2, [16], where $K_e \in \mathbb{R}^+$ and $K_d \in \mathbb{R}^+$ are the input scaling factors, $\alpha \in \mathbb{R}^+$ and $\beta \in \mathbb{R}^+$ the output scaling factors.

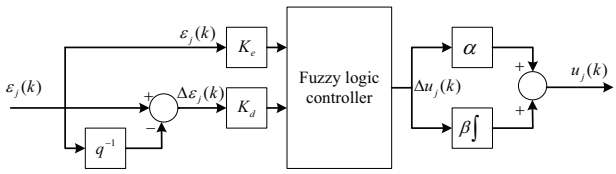

Figure 2: The PID-type FLC

The FLC inputs variables, the error $\varepsilon_j(k)$ between the desired flat trajectory $y_j^d(k)$ and the estimated state $\hat{x}(k)$, and error variation $\Delta\varepsilon_j(k)$ are given by the equations (22) and (23) where T_e is the sampling period.

$$\varepsilon_j(k) = -K_{c,j} \hat{x}(k) + y_j^d(k) \tag{22}$$

$$\Delta\varepsilon_j(k) = \frac{\varepsilon_j(k) - \varepsilon_j(k-1)}{T_e} \tag{23}$$

The output variable $\Delta u_j(k)$ of a such controller is the variation of the control law signal $u_j(k)$ which can be defined as (24).

$$\Delta u_j(k) = \frac{u_j(k) - u_j(k-1)}{T_e} \tag{24}$$

The output of the PID-type FLC is given by (25), [17]

$$\begin{aligned} u_j(k) &= \alpha \Delta u_j(k) + \beta \int \Delta u_j(k)\ \mathrm{d}t \\ &= \alpha(A + QK_e u_j(k) + DK_d \Delta u_j(k)) \\ &+ \beta \int (A + QK_e u_j(k) + DK_d \Delta u_j(k))\ \mathrm{d}k \\ &= \alpha A + \beta Ak + (\alpha K_e Q + \beta K_d D) u_j(k) \\ &+ \beta K_e Q \int u_j(k)\ \mathrm{d}k + \alpha K_d D \Delta u_j(k) \end{aligned} \tag{25}$$

where the terms Q and D are given by (26) and (27), [10].

$$Q = \frac{\Delta u_{(i+1)j} - \Delta u_{ij}}{\varepsilon_{i+1} - \varepsilon_i} \tag{26}$$

$$D = \frac{\Delta u_{i(j+1)} - \Delta u_{ij}}{\Delta\varepsilon_{j+1} - \Delta\varepsilon_j} \tag{27}$$

The fuzzy controllers with product−sum inference method, centroid defuzzification method and triangular uniformly distributed membership functions for the inputs and a crisp output proposed in [18], are used, in our study.

The linguistic levels, assigned to the variables $\varepsilon_j(k)$, $\Delta\varepsilon_j(k)$ and $\Delta u_j(k)$, are given in Table 1 as follows: NL: Negative Large; N: Negative; ZR: Zero; P: Positive; PL: Positive Large.

$\varepsilon_j(k)$ / $\Delta\varepsilon_j(k)$	N	ZR	P
N	NL	N	ZR
ZR	N	ZR	P
P	ZR	P	PL

Table 1: Fuzzy rules-base

4.2 Optimization of scaling factors using genetic algorithm

To adjust the input and the output scaling factors (K_e, K_d) and (α, β), GA is used in order to obtain their optimal values.

At first, an initial chromosome population is randomly generated. The chromosomes are candidate solutions to the problem. Then, the fitness values of all chromosomes are evaluated by calculating an objective function. So, based on the fitness of each individual, a group of the best chromosomes is selected through the selection process. The genetic operators, crossover and mutation, are applied to this 'surviving' population in order to improve the next generation solutions. Crossover is a recombination operator that combines subparts of two parent chromosomes to produce offspring. This operator extracts common features from different chromosomes in order to achieve even better solutions. Mutation is an operator that introduces variations into the chromosome. The modifications can consist of changing one or more values of a chromosome. Through the mutation operator the search space is explored by looking for better points. The process continues until the population converges to the stop criterion.

The most crucial step in applying GA is to choose the objective function that is used to evaluate the fitness of each chromosome. In this paper, the method of tuning PID-type FLC parameters using GA is based on minimizing the Integral of the Squared Error (ISE) used in [18].

5 Flatness and trajectory planning

The flatness approach is used in a discrete-time framework for system (1). Let the studied dynamic linear discrete system described by (28)

$$D_j(q) y_j(k) = N_j(q) v_j(k) \tag{28}$$

q is the forward operator, $v_j(k)$ and $y_j(k)$ are, respectively, the input and the output signals and $D_j(q)$ and $N_j(q)$ the polynomials defined by

$$D_j(q) = q^n + a_{j,n-1} q^{n-1} + \ldots + a_{j,1} q + a_{j,0} \tag{29}$$

$$N_j(q) = b_{j,n-1} q^{n-1} + \ldots + b_{j,1} q + b_{j,0} \tag{30}$$

where the parameters $a_{j,l}$ and $b_{j,l}$ are constants, $l = \{0, 1, ..., n-1\}$.

The system is considered as linear and controllable, consequently it is flat, [16].

The flat output $z_j(k)$, on which depend the output $y_j(k)$ and the control $v_j(k)$, can be seen as being the partial state of a linear system, [19]

$$v_j(k) = D_j(q) z_j(k) \tag{31}$$

$$y_j(k) = N_j(q) z_j(k) \tag{32}$$

The open loop control law can be determined by the following relations, [18]

$$v_j^d(k) = f(z_j^d(k), ..., z_j^{d^{(r+1)}}(k)) \tag{33}$$

$$y_j^d(k) = g(z_j^d(k), ..., z_j^{d^{(r)}}(k)) \tag{34}$$

f and g are vectorial functions and $z_j^d(k)$ is the desired trajectory that must be differentiable at the $(r+1)$ order.

In order to plan the desired flat trajectory $z_j^d(k)$, the polynomial interpolation technique is used.

Let consider the state vector: $Z_j^d(k) = (z_j^d(k)\ z_j{}^{d^{(1)}}(k)\ \ldots\ z_j^{d^{(r+1)}}(k))^T$ containing the desired flat output and its successive derivatives, [18].

The expression of $Z_j^d(k)$ can be given as following where k_0 and k_f are two moments known in advance.

$$Z_j^d(k) = M_{j,1}(k - k_0) c_{j,1}(k_0) + M_{j,2}(k - k_0) c_{j,2}(k_0, k_f) \tag{35}$$

such that

$$M_{j,1} = \begin{pmatrix} 1 & k & \cdots & \frac{k^{n-1}}{(n-1)!} \\ 0 & 1 & \cdots & \frac{k^{(n-2)}}{(n-2)!} \\ \vdots & \ddots & \ddots & \vdots \\ 0 & \cdots & 0 & 1 \end{pmatrix} \tag{36}$$

$$M_{j,2} = \begin{pmatrix} \frac{k^n}{n!} & \frac{k^{n+1}}{(n+1)!} & \cdots & \frac{k^{2n-1}}{(2n-1)!} \\ \frac{k^{n-1}}{(n-1)!} & \frac{k^n}{n!} & \cdots & \frac{k^{(n-2)}}{(n-2)!} \\ \vdots & \ddots & \ddots & \vdots \\ k & \cdots & \frac{k^{n-1}}{(n-1)!} & \frac{k^n}{n!} \end{pmatrix} \quad (37)$$

$$c_{j,1} = Z_j^d(k_0) \quad (38)$$

$$c_{j,2} = M_{j,2}^{-1}(k_f - k_0)(Z_{j^d}(k_f) - M_{j,1}(k_f - k_0)Z_j^d(k_0)) \quad (39)$$

After planning a desired flat trajectory in discrete-time framework, the real output $y_j(k)$, to be controlled, follows the desired trajectory $y_j^d(k)$ such that (40), [18].

$$y_j^d(k) = N_j(q)z_j^d(k) \quad (40)$$

6 Application of an electronic throttle valve

6.1 Electronic throttle valve modeling

The proposed approach is applied here for the case of the electronic throttle valve, Figure 3, [15].

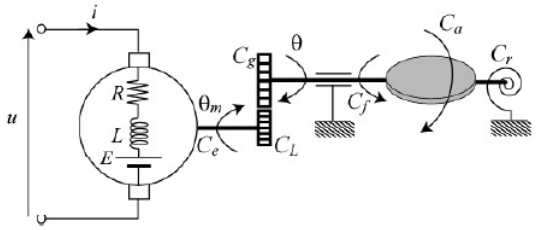

Figure 3: Electronic throttle system

The electrical part of this system is modeled by (41), [20,21].

$$u(t) = Ri(t) + L\frac{d}{dt}i(t) + k_v\omega_m(t) \quad (41)$$

L is the inductance, R the resistance, $u(t)$ and $i(t)$ the voltage and the armature current respectively, k_v a constant electromotive force and $\omega_m(t)$ the motor rotational speed.
The mechanical part of the throttle is modeled by a gear reducer, characterized by its reduction ratio γ such as (42)

$$\gamma = \frac{C_g}{C_L} \quad (42)$$

C_L is the load torque and C_g the gear torque.
The mechanical part is modeled according to (43) and (44), such that, [20,21]

$$J\frac{d}{dt}\omega_m(t) = C_e - C_f - C_r - C_a \quad (43)$$

$$\frac{d}{dt}\theta(t) = (180/\pi/\gamma)\omega_m(t) \quad (44)$$

$\theta(t)$ is the throttle plate angle, C_e the electrical torque, C_f the torque caused by mechanical friction, C_r the spring torque, C_a the torque generated by the airflow and J the overall moment of inertia.
The electrical torque is defined by

$$C_e = k_e i(t) \quad (45)$$

where k_e is a constant.
The electronic throttle valve involves two complex nonlinearities due to C_r and C_f, given by their static characteristics, [15]

- a dead zone in which the control voltage signal has no effect on the nominal position of the valve plate,
- two hysteresis combined with a saturation, due to the valve plate movement, limited by the maximum and the minimum angles.

The static characteristic of the nonlinear spring torque C_r is defined by

$$C_r = \frac{k_r}{\gamma}(\theta - \theta_0) + D\,\mathrm{sgn}(\theta - \theta_0) \quad (46)$$

for $\theta_{\min} \leqslant \theta \leqslant \theta_{\max}$, k_r is the spring constant, D a constant, θ_0 the default position and sgn (.) the following signum function

$$\mathrm{sgn}\,(\theta - \theta_0) = \begin{cases} 1, \text{ if } \theta \geqslant \theta_0 \\ -1, \text{ else} \end{cases} \quad (47)$$

The friction torque function C_f of the angular velocity of the throttle plate can be expressed as

$$C_f = f_v\omega + f_c\,\mathrm{sgn}(\omega) \quad (48)$$

where f_v and f_c are two constants.
By substituting in equation (43), the expressions C_e, C_f and C_r and by neglecting the torque generated by the airflow C_a, the two nonlinearities $\mathrm{sgn}(\theta - \theta_0)$ and $\mathrm{sgn}(\omega)$ and the two constants $\frac{k_r}{\gamma}\theta_0$ and f_v, the studied system is linear then it can be modelized by the following transfer function $H(s)$ (49), [21]

$$H(s) = \frac{(180/\pi/\gamma)k_e}{JLs^3 + JRs^2 + (k_ek_v + Lk_s)s + Rk_s} \quad (49)$$

with $k_s = (180/\pi/\gamma^2)k_r$ and s the Laplace operator; the identified parameters of this system are given in Table 2 at $25°C$, [20].

Parameters	Values	Units
R	2.8	Ω
L	0.0011	H
k_e	0.0183	$N.m/A$
k_v	0.0183	$v/rad/s$
J	4×10^{-6}	$kg.m^2$
γ	16.95	-

Table 2: Model's parameters

Recent work has shown that the ETV can be modeled by two linear models identified from the default position of the throttle plate for two values of the parameter k_s and for the sampling period $T_e = 0.002s$, [21]

- a model representing the position of the plate above the position by default for: $k_s = 1.877 \times 10^{-4} kg.m^2$, then the corresponding discrete-time transfer function $H_1(q^{-1})$ given by (50),

$$H_1(q^{-1}) = \frac{0.007480q^{-1} + 0.01334q^{-2} + 0.0007376q^{-3}}{1 - 1.948q^{-1} + 0.954q^{-2} - 0.006152q^{-3}} \tag{50}$$

- a model representing the position of the plate below the position by default for: $k_s = 1.384 \times 10^{-3} kg.m^2$, then the corresponding discrete-time transfer function $H_2(q^{-1})$ given by (51),

$$H_2(q^{-1}) = \frac{0.007479q^{-1} + 0.01333q^{-2} + 0.0007376q^{-3}}{1 - 1.946q^{-1} + 0.954q^{-2} - 0.006152q^{-3}} \tag{51}$$

6.2 Simulation results

In order to test the proposed fault tolerant control approach, tow models of an ETV in actuator fault and an unknown disturbance case are given as state space formulation as

$$x(k+1) = A_j x(k) + B_j u(k) + E_j d(k) + B_j f_a(k) \tag{52}$$

$$y(k) = C_j x(k)$$

where the parameter matrices and vectors of each model are given as

$$A_1 = \begin{pmatrix} 1.948 & -0.954 & 0.006152 \\ 1 & 0 & 0 \\ 0 & 1 & 0 \end{pmatrix} \tag{53}$$

$$A_2 = \begin{pmatrix} 1.946 & -0.954 & 0.006152 \\ 1 & 0 & 0 \\ 0 & 1 & 0 \end{pmatrix} \tag{54}$$

$$B_1 = B_2 = \begin{pmatrix} 1 & 0 & 0 \end{pmatrix}^T \tag{55}$$

$$C_1 = \begin{pmatrix} 0.007480 & 0.01334 & 0.0007376 \end{pmatrix} \tag{56}$$

$$C_2 = \begin{pmatrix} 0.007479 & 0.01333 & 0.0007376 \end{pmatrix} \tag{57}$$

$$E_1 = E_2 = \begin{pmatrix} 1 & 1 & 1 \end{pmatrix}^T \tag{58}$$

The studied system fulfills the conditions of Lemma 1.

$$\begin{cases} rank(C_1 E_1) = rank(E_1) = 1 \\ rank(C_2 E_2) = rank(E_2) = 1 \end{cases} \tag{59}$$

then $(C_1 A_{11})$ and $(C_2 A_{21})$ are both observable.
By applying Theorem, the system is stable asymptotically for any switching signal for symmetric matrice P definite positive given by (60).

$$P = \text{e - 010} \begin{pmatrix} 0.1429 & -0.0857 & 0.1903 \\ -0.0857 & 0.5085 & 0.0494 \\ 0.1903 & 0.0494 & 0.4251 \end{pmatrix} \tag{60}$$

Then, the rest parameters of UIOs are calculated as below

$$F_1 = \begin{pmatrix} -0.0266 & 0.8566 & -1.5415 \\ -0.0078 & 0.1954 & -0.3515 \\ 0.0165 & -0.4329 & 0.7788 \end{pmatrix} \tag{61}$$

$$F_2 = \begin{pmatrix} -0.0233 & 0.8717 & -1.5349 \\ -0.0071 & 0.1998 & -0.3515 \\ 0.0148 & -0.4384 & 0.7715 \end{pmatrix} \tag{62}$$

$$T_1 = \begin{pmatrix} 0.9657 & -0.6187 & -0.3470 \\ -0.0343 & 0.3813 & -0.3470 \\ -0.0343 & -0.6187 & 0.6530 \end{pmatrix} \tag{63}$$

$$T_2 = \begin{pmatrix} 0.9672 & -0.6196 & -0.3476 \\ -0.0328 & 0.3804 & -0.3476 \\ -0.0328 & -0.6196 & 0.6524 \end{pmatrix} \tag{64}$$

$$K_1 = \begin{pmatrix} 0.0002 \\ 0.0031 \\ -0.0056 \end{pmatrix}, K_2 = \begin{pmatrix} 0.0182 \\ 0.0208 \\ -0.0389 \end{pmatrix} \tag{65}$$

$$H_1 = \begin{pmatrix} 46.3945 \\ 46.3945 \\ 46.3945 \end{pmatrix}, H_2 = \begin{pmatrix} 46.4707 \\ 46.4707 \\ 46.4707 \end{pmatrix} \tag{66}$$

In this study, the method of tuning PID-type FLC parameters using GA is based on minimizing the ISE. If $y_j^d(k)$ is the desired flat trajectory and $\hat{x}_j(k)$ the estimated state, then we have

$$\varepsilon_j(k) = -K_{c,j}\hat{x}_j(k) + y_j^d(k) \tag{67}$$

For the ISE defined by

$$ISE = \int_0^t \varepsilon_j^2(k)dt \tag{68}$$

In this paper, the considered fitness function is taken as inverse of this error, i.e. the following performance index

$$fitness\ value = \frac{1}{ISE} \tag{69}$$

Then, the obtained optimum values of the input/output scaling factors $(K_e, K_d, \alpha, \beta)$, using genetic algorithm are given as follows: $K_e = 0.2006$, $K_d = 0.8071$, $\alpha = 0.1146$ and $\beta = 0.2063$.
The desired discrete time flat trajectory $z_j^d(k)$, with $j = \{1, 2\}$ can be computed according to the following polynomial form

$$z_j^d(k) = \begin{cases} \frac{cst1}{B_j(1)}, \text{ if } 0 \leqslant k \leqslant k_0 \\ Poly_{1,j}(k), \text{ if } k_0 < k \leqslant k_1 \\ \frac{cst2}{B_j(1)}, \text{ if } k_1 < k \leqslant k_2 \\ Poly_{2,j}(k), \text{ if } k_2 < k \leqslant k_3 \\ \frac{cst1}{B_j(1)}, \text{ if } k > k_3 \end{cases} \tag{70}$$

where $cst1$ and $cst2$ are constant parameters, $k_0 = 3s$, $k_1 = 6s$, $k_2 = 10s$ and $k_3 = 15s$ are the instants of transitions, $B_j(1)$ is the static gain between the flat output $z_j(k)$ and the output signal $y_j(k)$ for each model and $Poly_{1,j}(k)$ and $Poly_{2,j}(k)$ are polynomials calculated using the technique of polynomial interpolation.
The desired trajectories $y_1^d(k)$ and $y_2^d(k)$ are then given in Figure 4.

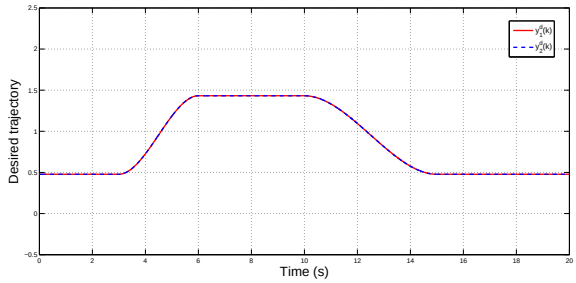

Figure 4: Desired trajectories $y_1^d(k)$ and $y_2^d(k)$

Let us consider the fault vector

$$f_a(k) = \begin{bmatrix} f_{a1}^T(k) \\ f_{a2}^T(k) \end{bmatrix} \tag{71}$$

such as $f_{a2} = 0$ and f_{a1} defined as follows

$$f_{a1}(k) = \begin{cases} 0, & k \in [0, 10] \\ -0.1\sin(0.314k), & k \in]10, 13] \\ 0, & k \in]13, 20] \end{cases} \tag{72}$$

The simulation results illustrated in Figure 5 and Figure 6, show some oscillations for the outputs signals and for the tracking error due to the unknown input. We remark that the system's responses with and without FTC track desired trajectories with disturbances rejection.

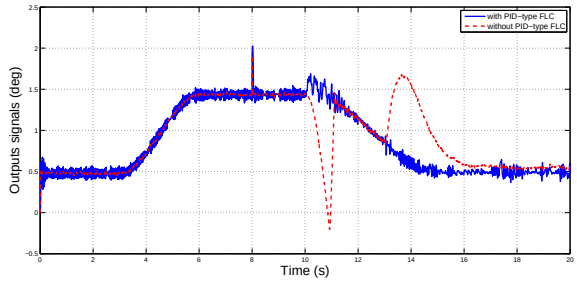

Figure 5: System outputs in actuator fault case with and without PID-type FLC

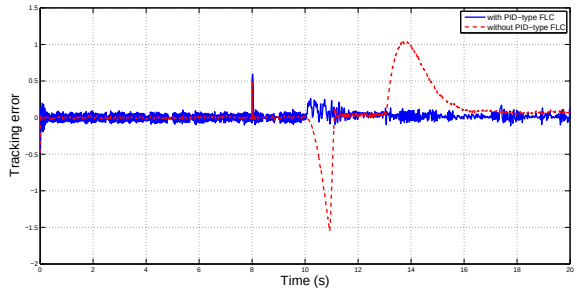

Figure 6: Tracking error in actuator fault case with and without PID-type FLC

At the time of actutor faults occurrence $k = 10s$, the system's behavior was changed. The system without FTC becomes unstable, whereas for the same reference input and by using the FTC, the system remains stable and the tracking error have a small deviation from zero which shows the effectiveness of the proposed FTC approach.

Figure 7, Figure 8 and Figure 9 show the residual values generated using UIOs and the switched signal. The switching between the two models is acheived based on residual values comparision.

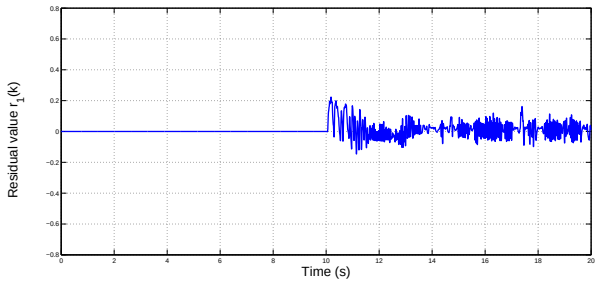

Figure 7: Residual value $r_1(k)$ in actuator fault case with PID-type FLC

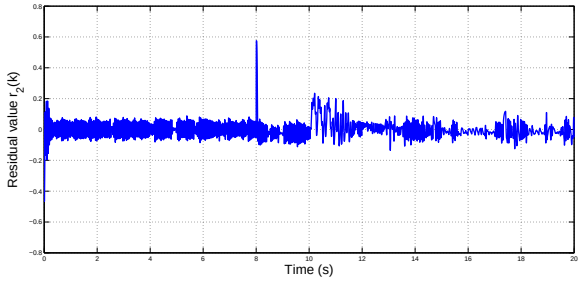

Figure 8: Residual value $r_2(k)$ in actuator fault case with PID-type FLC

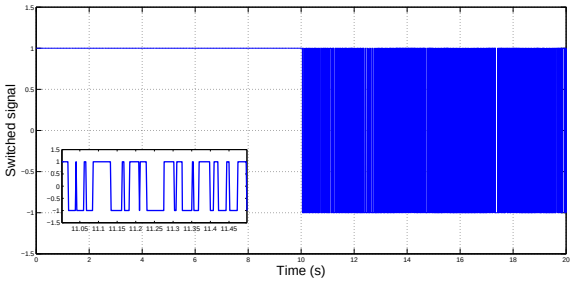

Figure 9: Switched signal in actuator fault case with PID-type FLC

7 Conclusion

In this paper, a new fault tolerant control law based on PID-type FLC is designed for the nonlinear complex system ETV, modelized by a multimodel structure. The approach is based on the use of a reference

model generated using the flatness property. The proposed control law is, then, designed to minimize the error between the desired flat trajectory and the estimated state, generated using UIOs, even in the presence of actuator faults based on minimizing the ISE.

ABSTRACT

Radio frequency Identification (RFID) is currently considered as one of the most used technologies for an automatic identification of objects or people. Based on a combination of tags and readers, RFID technology has widely been applied in various areas including supply chain, production and traffic control systems. However, despite of its numerous advantages, the technology brings out many challenges and concerns still not being attracting more and more researchers especially the security and privacy issues. In this paper, we review some of the recent research works using RFID solutions and dealing with security and privacy issues, we define our specific parameters and requirements allowing us to classify for each work which part of the RFID system is being secured, the solutions and the techniques used besides the conformity to RFID standards. Finally, we present briefly a solution that consists of combining RFID with smartcard based biometric to enhance security especially in access control scenarios. Hence the result of our study aims to give a clear vision of available solutions and techniques used to prevent and secure the RFID system from specific threats and attacks.

1. Introduction

This paper is an extension of work originally presented in Wireless Technologies, Embedded and Intelligent Systems (WITS) [1]. It concerns the security in Radio Frequency Identification (RFID) systems. The implementation of this technology in many industrial fields has recently attracted a lot of attention. Due to its important role of identifying people as well as objects, and data tracking, RFID is becoming more and more popular as an important topic of research. In particular, with the emergence of the Internet of things (IoT) paradigm that refers to a kind of networks that links physical objects to the internet to exchange data [2] and where RFID plays a key role. Besides, RFID is considered to be the next generation of barcode technology which is the case in many countries [2]. The use of RFID technology in several domains including supply chain, healthcare, transportation, education and many other fields have significant advantages including the flexible way of deployment with low cost, the possibility of integration and cooperation with Wireless Sensor Network nodes [2]. However, despite its numerous advantages, RFID technology still brings out many challenges including technical problems, customer privacy issues, coexistence of heterogeneous RFID standards [3] and more importantly security and privacy concerns. In fact, an RFID system consists of tags that store the data, readers interacting with the tags and transmitting information to backend servers and finally a network canal that manages this communication [4]. This architecture multiplies the sources of security problems and threats.

Several types of attacks can target the RFID system depending on each part is more vulnerable to the attacker. For example, the modification of the data, Cloning technique, and impersonation can be applied at level tags, whereas the reverse engineering, Eavesdropping Side Channel Attacks can affect the communication between backend servers, readers and tags [5].

In the research field, many of solutions and techniques assuring security and privacy come with processing and cryptographic algorithms such as Elliptic Curve Cryptographic (ECC) technique or mutual authentication mode between all RFID system parts. Most of these techniques remain far from being implemented in practice due to the limited resources of storing in tags and the low capacity of processing and executing complex operations. Furthermore, RFID customers require some guaranties that data contained in tags or exchanged remain private and highly protected against tracking and customer identity reconnaissance. A guarantee must be provided to customers aiming to adopt RFID in their own goals by ensuring that their private data stored in the tags will remain private and protected against spying and tracking

This work presents a clear vision about the concerns of security and privacy in an RFID system. Precisely we compare recent works dealing with security and privacy in an RFID system according to which layer the author is aiming to secure. To achieve this goal, we define some parameters and requirements such as CAI (Confidentiality, Availability and Integrity) based on the information suggested in [6]. We present for each work the category and the technique of solution used to deal with a typical defined attack. In addition, we verify for each work the application of RFID standards. Finally, we propose a device added scheme solution that we have used to enhance security in the access control scenario.

This paper is organized in 5 sections. The Section 2 summarizes the basics components of an RFID system, some examples of applications and a summarized review on most challenges and research directions where we concentrate on the problem of security. The section 3 presents our comparative study based on our parameters defining this study. The section 4 illustrates the smart card based biometrics solution to enhance RFID security and finally section 5 concludes this paper.

2. Background on RFID technology

In this part, we present the components of a typical RFID system, besides the related security challenges.

2.1. RFID Basics

An RFID system consists of 6 main components as shown in Figure 1:

- Tag: A tag is the data carrier and normally contains the ID number, and unique EPC code programmed into the tag.
- Reader & antenna: A reader captures the data provided by the tag when tags come in range of the area covered by the reader using its antenna.
- Middleware: The middleware can be a software as well as hardware dedicated to process data captured by the Reader, then dispatch this information to backend servers.
- Backend servers: The backend servers are the last station to make use of the data collected from RFID components. The information collected can be stored in database or sent to other systems for reporting and further analysis.
- Network infrastructure: Stands for the link between all RFID components which represents the main sources of RFID security and privacy threats.

2.2. Application domains

Animal tracking

RFID tagging systems are considered as powerful tools for animal identification management and tracking. Their benefits go beyond controlling the spread of diseases and ensuring quality-assured and safe food for consumers.
As an example of the application of RFID technology for animal tracking, an approach enabling an effective localization and tracking of small-sized laboratory animals was suggested in [7]

Logistics

The implementation of RFID technologies in logistics environments is increasingly attracting. The investment in this technology has shown that RFID is highly promising for identifying an object uniquely and providing the capability for "complete traceability" [8]. Moreover, it has been recognized as an effective solution to eliminate or reduce inventory inaccuracies [9].

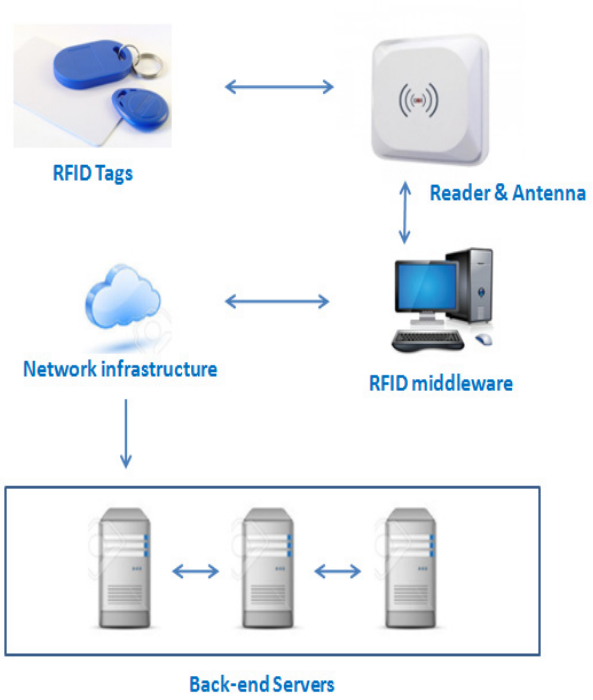

Figure 1. RFID system components

Intelligent transportation

The transport domain has widely benefited from the RFID adaptation due the ease of deployment of intelligence into each vehicle with a low cost approach [11].A vehicle emission inspection and notification system aiming to help daily monitoring of engine emissions through RFID devices was proposed in [12]. Also, a wireless system based on RFID technology was used to manage taxi fleets at the airports, train stations, bus terminals and all the taxis in cities [13]. RFID is also used in tolls collection as shown in Figure 2.

Healthcare

The use of RFID technology in the healthcare domain is making the patient's quality of care better. In fact, besides the collecting of information related to the patient as his presence inside a room and his health but also environment parameters can be detected such as temperature, humidity, and the presence of toxic gas [14].

In the same context, several efforts and research works have been made in this area. Exemplary, authors in [15] suggest a passive RFID platform for monitoring people during the night which deploys a long-range UHF RFID reader, wearable tags

integrated into clothes, and ambient tags dispersed in the environment, as well as a software engine for real-time processing and with warning modules [15].

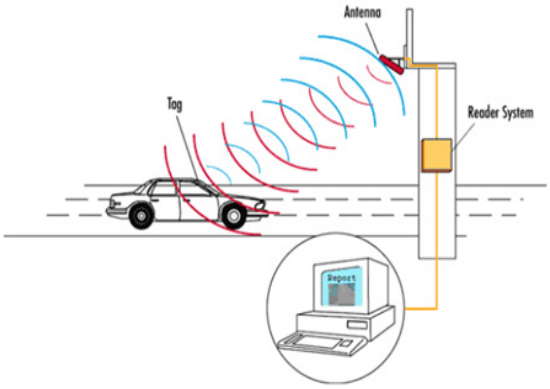

Figure 2. A toll collection using RFID [13]

2.3. RFID major issues

We address in this section some of the prominent issues related to RFID technologies and that still remain challenging topics of interest for a vast number of researchers.

Several works tried to study and gather the issues related the RFID to provide a baseline for researchers to understand the different sources as well as measures that can ensure the safety of sensitive data but more importantly to satisfy customers' needs and requirements in terms of efficiency, security and privacy. Among the most RFID challenges, we found technical problems, customer privacy issues and appliance to RFID standards [3]. In our work, we will focus on the last two problems which were taken into account in our comparative study (Section 3).

Technical problems

Among the biggest challenges during the implementation of an RFID system is studying the physical characteristics and capabilities of its components. In fact, the limited resource of storing information inside the tag, the low data processing and execution of complex operations can be a serious problem of performance and lack of mandatory features. In addition, due to the star architecture of the system, the reader can be the point of crush of the whole system, this problem occurs when a large number of items with RFID tags are energized by an RFID reader at the same time which leads to a confusion at the level of the reader and prevent it from tag scanning. A similar problem occurs when the coverage area of one RFID reader overlaps with another reader which leads to a signal interference and multiple reads of the same tag.

Standardization problems

Several efforts were dedicated to solve the problem of lacking of common RFID standards but the issue is still remaining in the industrial field. In fact, different standards coexist in parallel with divergent interests among which there is ISO 11784 that is utilized in the tracking of RFID cattle, the ISO 11785 for interface protocol, ISO 14443 for application of smart cards in payments and ISO 15693 that is applied to vicinity cards. The development of the electronic product codes (EPC) has been conceived to fill this need.

Obviously, the fact each of the existing standards is associated to a specific part of the RFID system make it different to deploy and protect data within an RFID system where tags standards can not comply with the communication standards for instance. Thus, it is of upmost importance to take into account the compliance to standards when implementing any RFID-based solution.

Security and privacy

Among the advantages of the deployment of RFID system is rendering the identification task automatically also gaining on performance and the ease of execution. All these benefits are not very useful is security and privacy are not guaranteed. For this reason, while designing an RFID system, many parameters should be taken into account to ensure a primary level of security, In fact, the data inside the tag, exchanged with the reader or dispatched to the back-end servers must be confidential, available and unchangeable (CIA characteristics). However, ensuring a full secure system which means keeping the whole system safe and operational, it remains a difficult task due to the several sources of attacks and threats that can coexist in parallel in some scenarios.

Table 1. RFID Typical attacks

Typical attack	The attack principle
Eavesdropping	This attack consists of listening to the network and sometimes recording for example all exchanges between tags and reader. The main goal of this attack is collecting data and taking advantage of the information gathered.
Denial of service	The denial of service consists of rendering equipment unavailable in the RFID system. An example of using this attack is spamming a reader with specific tags frequency requests which will make the reader out of service.
Cloning	The cloning attack is mainly to reproduce RFID tags. Using reverse engineering techniques to extract all the cart properties, precisely, the secrets keys, the tag can be modified and duplicated.
Tracking	The tracking attack consists of associating a tag to a person without his will and track his presence and movement as long as the attacker's reader is in range with the tag

During our research, many papers mentioned in their solutions some typical attacks that can take place in RFID systems, in the Table 1 below, we list some of most known attacks.

Many countermeasures and capabilities are proposed in literature to ensure security of the RFID system such as Pseudo-random based solution, Anonymous-ID scheme, symmetric and asymmetric cryptographic algorithms and others hashing based schemes [2].

Apart from the security aspect, the privacy is considered as a critical issue aiming to protect personal information. The expansion of the technology in several domains is not passing

without risks regarding the privacy the person since his identity information are associated to RFID chips that can be tracked and identified without his knowledge. As explained in table1 and due to the small size if RFID tags, they can be nested in personnel objects and clothes without being detected. The person movement and information are tracked and analyzed each time he come in range of the compatible reader area.

Some countermeasures and solutions were developed to protect personal data and reduce tracking capabilities. The table below illustrates the main techniques proposed in the literature studied for our classification.

Table 2. Some main countermeasures for privacy

Protection method	***How this technique improves privacy protection***
Delegation Tree	The principle of this method is delegating the control of reading tags depending on which privacy policy is assigned to each reader and tag. These specifications can be stored in database for example.
Protocol added *S*chemes	The technique consists of integrating a new coding scheme inside RFID tags and readers in order to create a specific protocol of communication; in this way, external readers cannot access to the network tags.
Tag killing	The tag killing method consists of destroying the content of tag after this one is no longer need to be used. The retailer can use the kill command after entering the right pin code. This technique can be used by the sellers after their products leave the store.
XOR encryption and PRNG	The XOR encryption and PRNG method is based on using a randomized protocol at each communication. This technique is powerful in the way to counter listening attacks such as Eavesdropping which will make the communication with tag a difficult task.
Blocker Tag	The Blocker tag technique aim to create an inductive field by the tag which will block communication between the tag and suspicious readers. Many occurrences of ID tag will be generated in order to hide the real one for the reader.

3. The comparative study

In this section, we will present the goal of our study besides the parameters defined for classification used to compare the selected academic works.

3.1. Motivation and design goal

Several levels of security can be applied to a typical RFID system, besides the nature of its architecture leads us to classify the solutions depending on each part of the system the attacks can take place. Furthermore, we refer to [6] to consider the three security main classes to classify the security threats in the reviewed works: Confidentiality, availability and integrity (CAI).

As defined in [6], the RFID system can be presented as three main layers: *1) RFID Edge Hardware Layer, 2) Communication Layer and 3) Backend Layer.* The possible threats and attacks related to each layer are mentioned based on CAI properties. In our work, besides classifying the attacks related to RFID security, we present also the solutions and techniques used to counter these problems. In [5], most of protection techniques can belong to specific categories as presented in Figure 3:

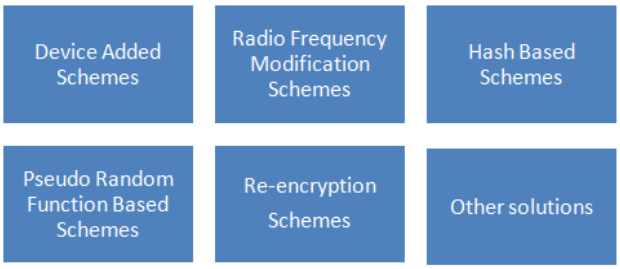

Figure 3. RFID security classes

In our study, we focus on recent works dealing with security and privacy, and we classify them according to the layers previously (attacks and solutions). In addition, we take into consideration other security requirements and parameters rather than CAI (untraceability, non-repudiation, forward secrecy, anonymity …).

Furthermore, we present the type of solutions and techniques dedicated for each layer and the attacks that can be related. At the end, we verify for each studied work the use and conformity to RFID standards. In this way, the following parameters are taken into account in our comparative study:

- *Privacy-focus / Security-focus*: Indicates whether the solution proposed take into account the security or consider privacy as the main concern.
- *Problem description and classification*: this parameter indicated which part of the system the problem can belong to. For this, we refer to the classification explained above.
- *Parameters of Security/Privacy considered:* Here we extract the security/privacy parameters considered by each author. Some papers focus on traditional security goals (confidentiality, integrity and availability) while other solutions take into account additional properties such as authorization, authentication, or forward secrecy.

Clearly, there are other properties to consider when authors focus in privacy as a main concern. These parameters include identity protection, anonymity and untraceability and. It is worth noting that these parameters are whether clearly cited in the paper or deducted.

- *Solution category*: As argued before, we have six mains classes of RFID solutions. For each of the twelve works studied we specify the class solution.
- *Techniques used:* For each class of solutions, we mention the techniques that have been exploited to ensure security and

privacy. Precisely, this includes cryptographic-based and no cryptographic-based methods.

- *Compliance to RFID standards?* Compliance to standards is considered as a primordial issue that need be highly highlighted. In this goal, for each studied work, we check the compliance to RFID or communication standards or if at least this issue is mentioned or an attention has been paid to by authors.
- *Examples of security attacks/ Threats considered:* this parameter indicates the security/ privacy attacks cited and treated in each paper. In the table below, the attack is defined for each part of the system it can occur and the solutions proposed to secure the system form this type of threats.

The objective of our comparative study as shown in Table 3, is not only presenting and classifying the security solutions and techniques regarding each of the recent studied paper but also making visible for researches and companies aiming to adopt an RFID system what are threats and attacks that should be taken into accounts while designing their systems.

As described before, the classification-based layer level helped us to locate the scope of each solution. Furthermore, during the study of the twelve works, we found that additional security / privacy parameters are considered rather than the traditional ones (CAI) in order to identify the several security/privacy threats. For Example, scalability is a primordial while aiming to enhance the system dimensions; some papers such as [24] consider scalability as a first topic while designing their solution. In fact, as mentioned in [22], this parameter remains among the real constraints of the majority of security solutions. Many techniques can be deployed to achieve scalability such as Checks handoff technique. As described in [24], this method was deployed to design a secure protocol supporting IoT.

Concerning techniques used, mutual authentication has taken more focus by authors as indicated in the works [20,16, 24] since, this security method is not only used in server's part but also between the reader and tags.

Concerning the security/privacy focus, many works try to ensure customer's privacy in their secured developed solutions and protocols. For instance, in [17, 20] intractability and an anonymous communication are taking into account to protect users' privacy. Thus, we noticed from the works presented in Table 3 that most of the solutions do not only focus on security or on privacy individually but these two concepts should be both take into consideration.

The second conclusion, we have subtracted from the Table 3 was that several works does not focus only on a single part of the system but they try to cover the whole layers (physical layer, communication layer, Back-end layer) that we have described in the section before.

For instance, authors in [18], propose two algorithms implemented by the Back-End server and a two-party protocol between the Back-End Server and a tag. In this way, two security methods were suggested in [20], the first contribution covers the backend layer by proposing two authentication (mutual and collaborative) schemes for both fixed and mobile readers, and the second contribution consisted at defining a secure channel between the reader and server in the communication layer. The main idea that we try to highlight is to not only paying attention to the data stored into tag or only securing communication between tags and reader but all the whole trajectory of data from data collecting to data storing in backend server.

As presented in Table 3, very few works we have studied focus on the device added schemes solution category. As an example, authors in [19] propose a solution that consist of changing the physical architecture of the RFID reader by dividing it into two different devices, an RF activator and a trusted shield device (TSD) playing an intermediary role between tags and reader for a secure communication [16].

In this way, the authors in [22] used the Physically Unclonable Functions (PUF) to secure data at level of tags (PUF is a security technology that seeks to introduce physical variation into individual devices taking part in cryptographic protocols [26]).

It is of upmost importance to tackle the issue of the RFID standardization. Indeed, and as illustrated in our comparative study, some works take into consideration the conformity of their solutions to RFID standards [12, 18, 19, 20, 20, 23, 24]. Intuitively, before designing any secure RFID solution it is crucial to verify whether this solution respects RFID standards or not.

Table 3: A comparative study of some security/privacysolutions in RFID systems

Characteristics / **Proposed Solution**	**Privacy-focus / Security -focus**	**Problem description and classification (Layer)**	**Parameters of Security/Privacy considererd**	**Solution category**	**Techniques used**	**Compliance to RFID standards?**	**Examples of security attacks/ Threat considered**
RFID-Tate: Efficient Security and Privacy Protection for Active RFID over IEEE 802.15.4 [16]	Both	Communication: A protocol for mutually authenticated (tag, reader) communication is suggested.	-Confidentiality -Availability - Authentication	Re-encryption	-Identity-based Encryption (IBE)	Yes : communication is performed over the standard IEEE 802.15.4f	- Cloning attacks. - Tag emulating, - Collision attack. - Spoofing - Replay attack -Sybil attack
A Secure Supply-Chain RFID System that Respects Your Privacy [17]	Both	Commiucation :p-Authors suggest a protocol between the reader and an individual tag	- Confidentiality - Integrity	Re-encryption	Public Key cryptography	Yes: (EPC tags standards)	-Reverse engineering

Secure Tag Search in RFID Systems Using Mobile Readers [18]	Both	Back-End: This paper suggests a search tag protocol; target backeEned Servers	- Confidentiality - Integrity - Anonymity - authorization	Pseudo-random based solution	XOR and 128bit PRNG operations	Yes : (EPC C1G2 compliance)	-Desynchronization, DoS attacks. -Side Channel Attacks: - Eavesdropping
Scalable RFID Security Framework and Protocol Supporting Internet of Things [24]	Security-Focus	Communication: A secure communication protocol and a framework supporting IoT	-Authentication. - Scalability - Confidentiality -Identity pretection -Adaptability	Other	Checks handoff (SCH) technique	Yes: EPCglobal standard	-Malware (Example SQLIA)
A New Security and Privacy Framework for RFID In Cloud Computing [25]	Both	Backend: A security and privacy model for RFID technology integrated to the Cloud computing (Servers) Was suggested.	- Confidentiality - Authentication	Re-encryption	Symmetric-key Cryptography	Not mentioned	No specified attacks was mentionned.
A secure ECC-based RFID authentication scheme integrated with ID-verifier transfer protocol [2]	Both	Both : Back-End: Two algorithms implemeted by the Back-End server are defined. Communication: A two-party protocol between the Back-End Server and a tag is proposed.	-Confidentiality - Availability - Forward security. -Anonymity Authorization, Authentication	Re-encryption	Public Key cryptography Elliptic curve cryptosystem	Mentioned but not applied	-Tag cloning attack. - Eavesdropping. - Replay attack. - Tag masquerade attack. -Denial-of-Service - Location tracking attack. - Server spoofing attack.
A Novel Coding Scheme for Secure Communications in Distributed RFID Systems [19]	Privacy-Focus	Physical Layer	Confidentiality - Integrity Anonymity	Device added scheme	- Reader changes architecture (New) Random Flipping and Random Jamming (RFRJ)	Only mentioned	- Random guessing attack. - Correlation attack. - Ghost-and-leech attack. - Eavesdropping.
A minimum disclosure approach to authentication and privacy in RFID systems [20]	Both	Both BackEnd: Two authentication (mutual and collaborative) schemes for both fixed and mobile reader are suggested. Communication: The channel between the reader and server is protected against attacks.	- Confidentiality - Untraceability Anonymity, Authentication, Forward secrecy	Pseudo-random based solution	Redundancy check (CRC) Pseudo random number generator (PRNG)	Yes (Conforme to EPC Class-1 Gen-2 spec-Ifications).	- Replay attack - Tag impersonation - Desynchronisation attacks.
Secure ownership transfer for multi-tag multi-owner passive RFID environment with individual-owner-privacy [12]	Both	Communication: Authors suggests multi-owner, multi-tag transfer protocol that achieves privacy-among-owners.	Confidentiality - Forward Untraceability Anonymity, Forward secrecy	Pseudo-random based solution	XOR and 128-bit pseudo-random number generators (PRNG)	Yes: complies EPC Global Class-1Gen-2 (C1G2)	-Tracking attacks - Replay Attacks - Denial of Service - Tag/Reader/Server Impersonation.
A Robust Grouping Proof Protocol for RFID EPC C1G2 Tags [21]	Security-focus	Communication: A grouping proof protocol ensuring a high level of security between tags and readers.	-Inegrity -Anonymity -Forward secrecy -Confidentiality	Pseudo-random based solution	(XOR) encryption and 128-bit pseudorandom number generators,	Yes: Complies EPC Global Class-1Gen-2 (C1G2)	-Replay Attacks -Denial of Service (DoS) Reader/Tag/Server impersonation Attack. -Active Attacks
Providing destructive privacy and scalability in RFID systems using PUFs [22]	Privacy-Focus	Communication: A private authentication protocol allowing a reader/tag communication.	- Confidentiality - Integrity - Authentication - Forward secrecy	Other	Physically Unclonable Functions (PUFs)	Not mentioned	- Compromising attack - Side-channel attacks
Computational Cost Analysis on Securing RFID Protocols Conforming to EPC Class-1 Generation-2 Standard [23]	Security-Focus	Both : A mutual authentication protocol seeking to achieve higher security level was proposed	-Confidentiality -Authentication - Forwad secrecy	Pseudo-random based solution	Pseudo-random number generators (PRNG)	Yes : Conform to EPC Class-1 Generation-2 standard (ISO 18000-6).	- DoS attacks - Reply attacks

4. RFID combining solution

4.1. Motivation

The comparative study presented in section 3, has shown many robust solutions and techniques that may counter several attacks, most of the techniques are based on cryptographic schemes and deal with direct attacks on physical layer of the RFID system components such as the tag and reader, whereas other techniques focus on the communication between readers and tags or reader and the backend servers to prevent the system from network attacks such as eavesdropping, man-in-the middle or desynchronization attacks.

Aiming to apply the RFID in the campus environment, we found that some scenarios are not totally secured. So, we propose to combine the RFID technology with other technologies to enhance security in the whole system.

4.2. Smart card based biometrics solution design

The RFID technology can be applied in many areas inside the university campus as shown below, in our work we focus on access control to exams rooms and sensitive areas like laboratories.

- Exams room
- Campus
- Research laboratories
- Library
- Staff offices
- Computer room

For instance, if we take the example of accessing to laboratories, the identity check must be verified before allowing the person access to the area. Based on the solutions proposed in Table 3, a cryptographic technique can be deployed in the inside the tag and the reader to secure the tag reading. However, the two main problems in our case are indicated in Figure 4.

For this reason, our method consists of enhancing the RFID technology by using smart card based biometrics solution. In fact, the RFID technology is seen as the fast-automatic technique of identification, whereas, the smart card check can support complex operations of cryptographic check as indicated in [27]. In addition, the biometric fingerprint will help us to check the true identity of the person aiming to access to the secured area. In Figure 5, we present the proposed system combining RFID with the smart card-based biometrics verification.

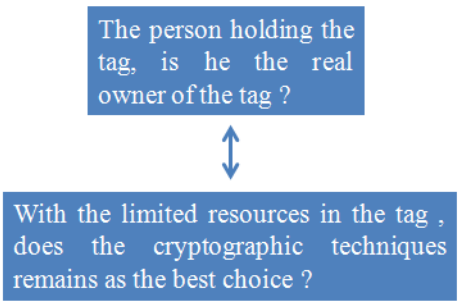

Figure 4. Access control issues in RFID system

As detailed in [27]. The step one consists of reading the RFID tag when it comes in range with the RFID reader. After that, in the step 2, the person's tag is sent to the local database to check if it belongs to the person's tags allowing him access the secure area. Once validated, the person inserts his smartcard and puts his fingerprint for validation. In this case, a first match-on-card is established comparing the user fingerprint with the other one stored in the smartcard. If the check is performed successfully, the fingerprint is sent to the database to verify that no changes were made on the couple (fingerprint, Tag ID). Finally, the door is opened if all the conditions are satisfied.

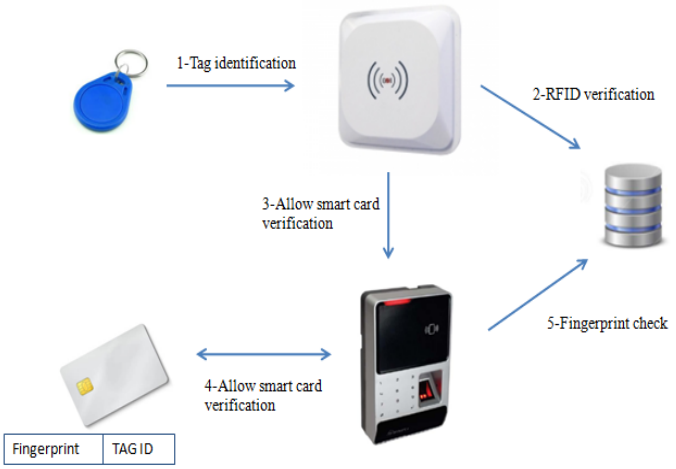

Figure 5. Components of the proposed system

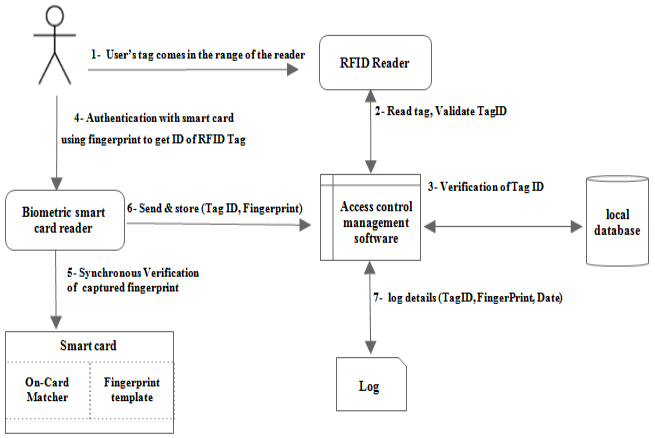

Figure 6. Flowchart of the access control system in sensitive areas [27]

In the proposed solution, we have chosen to combine smart card biometrics solutions with RFID in order to respect the limited resources and capabilities inside the tag for performing complex operations. Furthermore, even if the smart card is falsified or the person ask for authentication with a borrowed RFID tag, the verification explained above based multi-level of security will deny his access to the secured room. The flowchart in Figure 6 summarizes the sequence of actions during the authentication process. The system presented above meets the need presented in Figure 4 which are not guaranteed in the solutions presented in section 3.

5. Conclusion

In this paper, we have presented some recent works aiming to ensure security and Privacy in RFID systems. In particular, we tried to classify these solutions in order to provide a clear understanding of the different threats and risks related to security and privacy.

To achieve this goal, we compared some solutions according to the traditional security and privacy objectives. Also, we mentioned that additional parameters such as scalability and efficiency should be taken into account besides the traditional security and privacy objectives.

In addition, we proposed a combined solution using RFID and smartcard based biometrics to ensure performance and cover some security gaps detected while designing our RFID system. As future work, we plan to develop our device added scheme solution, by studying more the technical possibilities of its implementation inside the campus.

Conflict of Interest

The authors declare no conflict of interest.

Acknowledgment

This research is performed inside the MATSI Lab., ESTO, University Mohammed First, Oujda (Morocco).

Organizational structure

ABSTRACT

Excellence in hospitals supply management results in better quality, best prices, and good deliveries. One of the questions that come up as healthcare organization to capture the economies of scale in purchasing prices and process costs is whether their purchasing activities should be centralized or decentralized. In most cases, centralization strategy usually gives good supplier's service with a lower cost, but the consideration of supplier's cost in the hospital sector are mainly limited to visible ones. The high levels of hidden quality costs generated by suppliers and their unknown presence have serious consequences on the decisions made by the managers. However, the existence of this kind of costs has not been considered yet. Therefore, the main objective of this paper is to propose a decision-making-approach, integrating a new method of measuring supplier's hidden quality costs, in order to help managers to choose the appropriate purchasing organizational structure in the hospital sector.

1. Introduction

In Morocco, the ministry of health has undertaken several actions to make medicines and medical devices available and accessible to the population. It has a national list of medicines and essential medical devices, according to the last revision which was carried out at the end of 2011. The pharmaceutical products covered by this list benefit from an annual budget allocated by the ministry of health, to ensure their availability at the level of public hospitals and basic health care facilities. This budget increased by 67% between 2002 and 2012, reaching the sum of 1.6 billion Dirham [1-3]. Despite efforts made by the ministry, the access to medicines and medical devices in hospitals remains insufficient [2] [4]. The main factor that reduces the availability of medicines is a failure to achieve a good supplier's quality. Experiences have shown that it is possible to improve access to these products by making the best use of resources and streamlining management processes. Indeed, it is necessary to highlight the organizational purchasing structure, and improve the supplier's quality [5-7]. In this perspective, it is mandatory to study the relationship that exists between non-quality, costs and organizational structure. In fact, a change in an organizational structure impacts the entire system including customers, suppliers, and competitors. In the healthcare system, the suppliers are considered as the main stakeholders contributing to the improvement of the hospital's performance. The demand continues to support the growing supplies, which has changed the behavior of organizations to achieve good quality. This change includes both simple corrections and more complex changes for suppliers, at the level of their attitudes and their performances. The particularity of healthcare facilities is that the patient receives its service in real time. Though, the impact of the structure on the supplier's performance affects the quality of care and purchaser's satisfaction, this dissatisfaction could be estimated by a cost, which is considered as a hidden cost. Theses hidden quality costs may increase or decrease depending on the choice of the organizational structure.

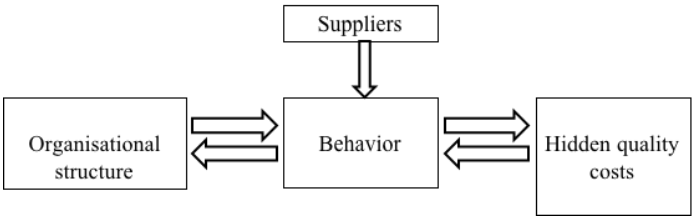

Figure 1. Relationship that exists between organizational structure and hidden costs

In light of the importance of hospital logistics, we propose in this paper to consider the supplier's hidden quality costs as one of the

*JENOUI Kaoutar, Email : k.jenoui@gmail.com

principle criteria to be based on for deciding the right purchasing strategy. This paper is an extension of a work originally presented in Logistiqua'17 conference [1]. It's organized as follows: Section II presents some definitions of the hospital sector, followed by section III that describes the problematic, and section IV that provides a literature review. In section V a deciding-making-approach is proposed and validated through a practical case study in section VI. Finally, section VII concludes the paper and states future work.

2. Hospital pharmacy presentation

This section provides important definitions that describe hospital pharmacy services, as well as the requirements for providing pharmaceutical care.

2.1. The hospital, hospital pharmacy and SEGMA hospital definition

The hospital is a healthcare unit composed of specialized scientific equipment, and certified healthcare professionals, working as a team for the common purpose of providing medical services to the population. While the hospital pharmacy defined as a department in a hospital, which is responsible for the supply of medical products, and headed by professionally competent and qualified pharmacist who directly supervises and ensures compounding and distribution of medication to in and out patients [8].

The status SEGMA stands for "State service managed in an autonomous way" and is defined as the services of the state whose expenses operations are executed by a head of the department attached to the superior accountant of the kingdom. In 2004, there was 38.4% of the total number of services dedicated to hospital care with SEGMA status. Currently 63% of the number of hospitals obtains the SEGMA status [9].

2.2. Goals of hospital pharmacy

The hospital pharmacy aims to provide safe and effective pharmaceutical care and services to users and health care facilities, through a global professional and ethical standards. Pharmaceutical services components are responsible for three main missions. Firstly, it's responsible for the procurement, distribution and control of pharmaceutical products, secondly, the evaluation and dissemination of comprehensive information about medical products and their use to the institution's employees and patients. And finally, it's responsible for the supplier's monitoring, evaluation, and assurance of the quality of drugs [8].

2.3. Hospital's pharmacy in Centralized and decentralized structure

Figure 2 shows the logistics flows for centralized and decentralized structure. The centralized structure aims to make orders for many hospitals independently when there is no grouping of commons orders. While decentralized structure is considered to refer to a practice model in which a pharmacist is responsible for orders purchasing and distribution services, including order validation and possibly order entry [5][8].

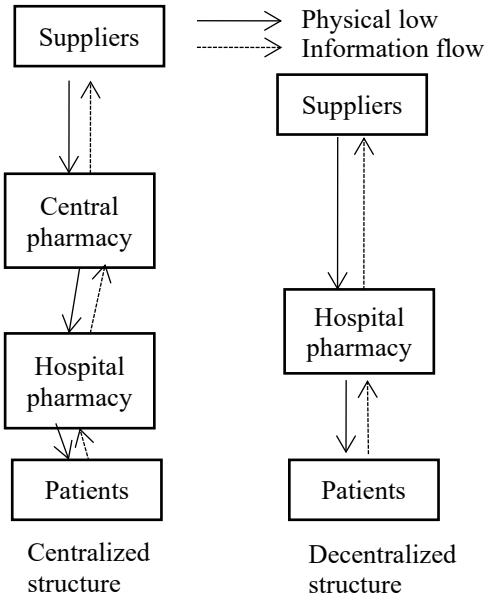

Figure 2. The information and physical flow in both structures

3. Problematic description

In 24 years, the Moroccan health care system switched many times between centralized and decentralized structure [9]. (See table 1)

In face of all these changes and developments of the organizational structure, Moroccan hospitals still suffer from inadequate quality, the insufficient availability of products and the increased costs [3].In decentralization structure, centers of storage and distribution cost up to one billion Dirhams per year, and operated by 200-250 people [1-4].Also, storage and distribution of medicines in Morocco cost the ministry of health over 30 million Dirhams per year. While in centralization structure, the rate of obsolescence of medicines decreased by 8% at the end of 2002, and the purchase prices of medicines through the centralized system in 2001 were lower than the prices paid in the decentralized system. This drop in prices allowed buying 50% more products. All these data show the supplier's bad quality and the inappropriate choice of the organizational structure, which indicates the importance of estimating poor quality costs generated by suppliers, also called hidden costs. Therefore, in this paper we propose a decision-making-approach, integrating a new method of measuring supplier's hidden quality costs, in order to help the managers to choose the appropriate purchasing organizational structure in the hospital sector.

4. Literature review

To discuss the literature related to this subject, this review will cover three principle topics, and we will start by a brief review of each of them:

4.1. Organizational structure

Decision-making can be performed in a centralized or a decentralized structure. In a centralized one, there exists a central responsibility for decision-making, whereas in a decentralized structure the individual entities can make their own decisions. In practice, each approach has its advantages and disadvantages. Most commonly, the strategic decisions are usually made centrally while operation decisions are decentralized. The performance of each approach depends on specific environment and particular decisions [9] [10]. Many researchers studied the effects of centralization and decentralization on the multi-item replenishment problem in a two-echelon supply chain. Chen et al. proposed both centralized and decentralized decision models and proved the optimal properties of both models to minimize costs [11] [12]. They found that it is beneficial to adopt centralized control and proposed a mechanism to coordinate the decentralized system so that each player in the chain benefit from it. Behdani et al. studied disruptions in a multi-plant company and considered alternative policies for coping with them. To model this complex system, they used an agent-based simulation model [13].

Table1. A brief history of the health care supply system

1980	Decentralization	With many difficulties faced by the central pharmacy, there has been an introduction of direct delivery system
1985-1986	Centralization	Worsening problems due to the small size of premises and storage spaces, implies return to centralization. There was also a need of the implementation of a new unit, and the improvement of the central pharmacy program, followed by a progressive implementation of semi-autonomous management for the regional hospitals which directly procure themselves.
1994	Decentralization	Establishment of the procurement division, reporting directly to the general secretariat of the ministry.
1995	Centralization	Commissioning of the storage unit to centralize procurement for medicines.
1997	Decentralization	Decentralization purchasing for SEGMA hospitals
2001	Centralization	Centralized purchasing (procurement, storage, distribution) for SEGMA regional hospitals by the procurement division.
2003	Decentralization	In view of difficulties of regular supply, it is envisaged to decentralize the supply of SEGMA hospitals.

However, no one has considered the hidden costs generated in each strategy. In our study, we will focus on this objective in a particular way.

Hidden quality cost:

In traditional systems, quality losses occur when the product deviates beyond the specification limits, and becomes unacceptable [14]. Taguchi proposed a narrower view of characteristic acceptability to indicate that any deviation from a characteristic's target value results in a loss, and that a higher quality measurement results in minimal variation from the target value [21-22]. Other authors analyze different aspects related to hidden quality cost in the construction business, and highlight the following examples of hidden quality costs: schedule delays, litigation and claims, loss of reputation and the subsequent impact on future business opportunities, loss of schedule and productivity, low operational efficiency, work inactivity from waiting or idle time, etc. [15-19]. Taguchi loss functions have been recently used for non-manufacturing applications. They were implemented to evaluate product quality as an aid to the selection of suppliers, been based on quantitative quality characteristics. These products are used for evaluation, comparison, and ranking process. There are several methods for the estimation of hidden costs [23-25]. However, none of them considers the quantification of hidden costs associated to qualitative criteria that presents subjectivity and uncertainty. The question which arises while measuring the cost associated to qualitative criteria is how to determine the target value, and the particular value specification that characterize the performance of each element.

4.2. Multi attributes decision making technique

There are many techniques developed for the supplier evaluation problem. Some of these techniques are categorical method, weighted point method [26], matrix approach [27], vendor performance matrix approach [28], vendor profile analysis (VPA) [29], analytic hierarchy process (AHP) [30-31], analytic network process (ANP) [32], mathematical programming [33-34] and multiple objective programming (MOP) [35-37]. However, most of these methods are more adapted to precise data. They don't have enough influence on factors such as imprecision preferences, qualitative criteria and incomplete information. The Technique for Order of Preference by Similarity to Ideal Solution (TOPSIS) is a multi-criteria decision analysis method based on the concept that the chosen alternative should have the shortest geometric distance from the positive ideal solution, and the longest geometric distance from the negative ideal solution [7]. Therefore, TOSPIS method is more appropriate to overcome problems in estimating hidden costs associated to qualitative characteristics. To sum up, the main contribution of this paper is the development of a method for the quantification of hidden quality costs based on Taguchi loss function and TOPSIS method, included in a decision-making-approach. We also compare the behavior of medicines suppliers under the centralized and decentralized strategies based on hidden quality costs. The suitability of the two strategies under two different scenarios is explored through a real case study in a Moroccan hospital.

5. The proposed deciding-making-approach

Based on the review of previous works and field interview with suppliers in Morocco, the organizational structure applied to purchase medical products for hospitals, helps to evolve the supplier's chain performance to flourish and vice versa. As indicated in figure 3, the organizational structure in the healthcare supply system is a critical component for any supplier's system improvement, and the decision to centralize or decentralize purchasing should be based on studies that focus on the actual supplier's hidden quality costs for each structure.

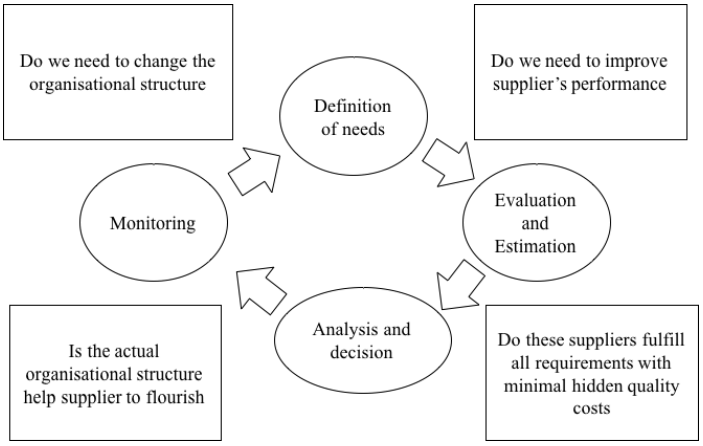

Figure 3. Deciding-making-approach lifecycle

5.1. Definition of needs

As indicated in the figure, targets of change include improving effectiveness at two principle levels: Supplier's performance and organizational structure. There is a strong relationship between these two elements that helps ensure solid communication. Therefore, in this phase, we should:

- Define the needs regarding supplier's specifications, functional and technical requirements.
- Recognize the problems inherent in managing the actual organizational structure and obstacles that overcome.
- Discover whether the actual resources and capabilities help increase hospital's ability to create value.

5.2. Evaluation and estimation of supplier's hidden quality costs

In this phase, the full capabilities of suppliers are being gauged against defined requirements. We believe that the supplier's quality loss occurs when his performance deviates from a target, the higher the deviation is, the worst the service is rendered, and the higher the purchaser is dissatisfied. This dissatisfaction could be estimated by a cost. According to Taguchi, as indicated in figure 4, the variation of this cost is represented by a quadratic curve. The curve is centered on the target value, which represents the best performance, and determining this best value is not usually a simple task.

Three types of loss functions have been presented in the Taguchi loss function [19], nominal the better (NTB), larger the better (LTB); and smaller the better (STB). Firstly, It is necessary to determine the criteria to be based on to estimate the supplier's hidden cost, the target value, then the upper and lower specification limits.

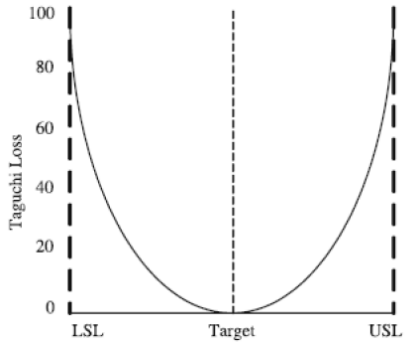

Figure 4. Two-sided loss function with specification preference

5.2.1. Supplier's hidden costs for quantitative quality characteristic

In this work, we adopt the form NTB for the quantitative quality characteristics which means that the nominal value is the best value. The loss function is given by Eq. 1.

$$L(y_i) = k(T-y_i)^2 \quad (1)$$

Where k is the loss coefficient, whose value is constant depending on the cost at the specification limits and the width of the specification, y_i is a particular value specification, that presents the value of the product characteristic, and $L(y_i)$ is the loss associated to y_i [19].

5.2.2. Supplier's hidden costs for qualitative quality characteristic

For qualitative criteria, we use a one-sided minimum (smaller-is-better) loss function of the form:

$$L(y_i) = k.(y_i)^2 \quad (2)$$

where the meanings of $L(y_i)$, y_i and k are the same as in equation 1. As indicated in figure 5, our philosophy aims to consider that the target value is presented as the best supplier's profile, which is characterized by the highest performance level at all quality attributes, and where the loss is equal to zero. Any supplier's distance from the ideal profile generates a cost; the smaller the distance, the lower the hidden cost is. This cost is estimated using TOPSIS method. This method measures this distance based on the supplier's performance level. It hypothesizes two artificial alternatives: The Ideal alternative that has the best level for all attributes considered, and the negative ideal alternative that has the worst attribute values [28]. TOPSIS allows determining the alternative that is the closest to the ideal solution and farthest from negative ideal alternative.

Let assumes that we have m alternatives, and n criteria. We have the score of each option with respect to each criterion. The supplier's distance from the ideal profile is calculated according to the following steps:

Let x_{ij} be the score of option i with respect to criterion j. We have a matrix X = (x_{ij}) with dimension m×n. Let J be the set of benefit attributes or criteria (LTB), and let J' be the set of negative attributes or criteria (SMB).

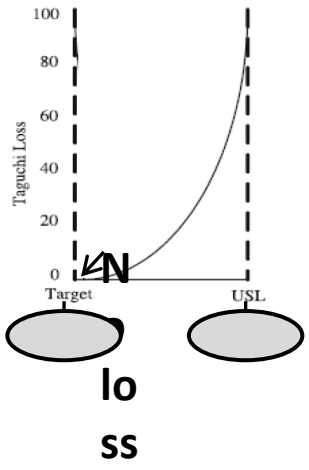

Figure 5. Loss function in case of qualitative criterion

Step 1: We construct normalized decision matrix

This step transforms various attribute dimensions into non-dimensional attributes, which allows comparisons across criteria. Scores or data are normalized as follows:

$$r_{ij} = x_{ij} / (\Sigma\, x^2_{ij}) \quad \text{for } i = 1, \ldots, m;\ j = 1, \ldots, n \tag{3}$$

Step 2: We construct the weighted normalized decision matrix.

In this step, we assume that we have a set of weights for each criteria w_j for j = 1,…,n. We multiply each column of the normalized decision matrix by its associated weight. An element of the new matrix is:

$$v_{ij} = w_j r_{ij} \tag{4}$$

Step 3: We determine the ideal and negative ideal solutions.

Ideal solution:

$$A^* = \{v_1^*, \ldots, v_n^*\}, \tag{5}$$

Where $v_j^* = \{ \max (v_{ij}) \text{ if } j \in J ;\ \min (v_{ij}) \text{ if } j \in J' \}$

Negative ideal solution:

$$A' = \{ v_1', \ldots, v_n' \}, \tag{6}$$

Where $v' = \{ \min (v_{ij}) \text{ if } j \in J ;\ \max (v_{ij}) \text{ if } j \in J' \}$

Step 4: We calculate the separation measures for each alternative.

The separation from the ideal alternative is:

$$S_i^* = [\Sigma (v_j^* - v_{ij})^2]^{1/2} \qquad i = 1, \ldots, m \tag{7}$$

Similarly, the separation from the negative ideal alternative is:

$$S'_i = [\Sigma (v_j' - v_{ij})^2]^{1/2} \qquad i = 1, \ldots, m \tag{8}$$

Step 5: We calculate the relative closeness to ideal solution y_i^*

$$y_i^* = S_i^* / (S_i^* + S'_i),\ 0 < y_i^* < 1 \tag{9}$$

The supplier's distance from the ideal profile determines *yi*, which allows calculating the loss occurred by equation (2).

5.3. Analysis and decision

There are significant costs associated with organizational structure management and supplier's performance. The choice of centralization or decentralization structure may reduce supplier's flexibility and therefore makes it difficult to be responsive to changing purchasing management. Furthermore, the structure chosen changes the distance and the number of touch points between hospitals entry and suppliers. Poor planning and oversight in such a highly complex demand leads to unnecessary expenses. For example, when many "hands" are involved, the right products in the right mix and volumes may not be in the right places at the right time. Therefore, this method allows us to evaluate our satisfaction with supplier's quality in the current structure, and to be taken into account before taking any decision of change.

5.4. Supplier's Monitoring

The movement of the healthcare system organization from one form to another often requires change within the organization itself. Therefore, the organization shall operate procedures for approval and continued monitoring of all its suppliers whose products or services may affect product safety. Monitoring a supplier's performance will provide an indication of changes within the suppliers' systems and procedures that could lead to potential issues. The results of evaluations and follow-up actions shall be recorded, for future decisions.

6. Practical case study: Military hospital of Rabat

We choose in this study the Mohamed V Military Hospital of Rabat/Morocco. This hospital carries the SEGMA status, and has been subject to the change of the structure from centralization to decentralization many times from the year 2000. The objective of this study is to report the experience of this hospital in the involvement of different types of structure in the management of medical products, materials and methods from 2001 to 2003. Taking into account the total number of suppliers who participated during this period, as shown in figure 6, we find that 47% of these suppliers participated during the decentralization period, 36% of them participated during centralization, and only 17% participated in both strategies. Our study will be focused on the estimation of hidden quality costs of suppliers, who have been involved in the purchase of medical products, in both strategies: centralization in 2001, and decentralization in 2003, in order to study the impact of organizational structure on supplier's behavior.

6.1. Definition of needs

As a result of the team efforts, and as recent data are confidential, we accessed to the suppliers' evaluation data in 2001 (centralization), and those in 2003 (decentralization). We highlight that old data will not have a significant impact on our

approach. In 2001, the hospital suffered from the unavailability of medical products, and the poor quality delivered by the suppliers, which was evaluated on several bases (see figure 7). The question which arises when changing the organizational structure from centralization to decentralization is whether this change will help suppliers to improve their performance or to get it worse. Therefore, in this section we will estimate the hidden quality cost behind the non-quality provided by suppliers in both strategies.

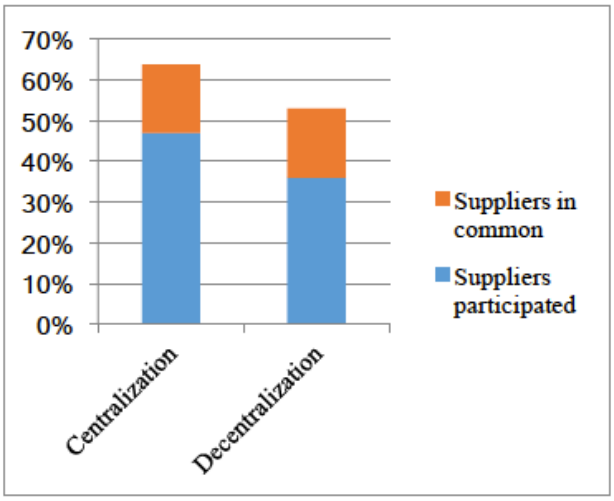

Figure 6. Suppliers participated in the period 2001-2003

6.2. Evaluation and estimation

6.2.1. Principle criteria for supplier's hidden quality costs

For the purpose of estimating supplier's hidden quality costs in the case of this hospital, we select three principle criteria: the delivery, the validity period as a single quantitative criterion, and quality as a multiple qualitative criterion, which is subdivided into five sub attributes. The objective is to estimate the supplier's hidden quality costs in seven cases as presented in the table 2.

6.2.2. Estimation of supplier's hidden quality costs

To apply the existing Taguchi loss function for quantitative quality characteristic, and the developed method for qualitative quality characteristic, we develop a purchasing model, in which we assume that the purchaser only knows the prices that might have different impacts on product quality and delivery. We estimate the loss associated to 7 suppliers according to these seven criteria.

- Quantitative quality characteristic

To calculate the loss associated to the quantitative criteria, we first need to specify the upper specification limit and lower specification limit for each criterion. For the case of this hospital, they are determined as follow:

- The maximum acceptable delivery and the minimum acceptable delivery are 7 days.
- The minimum period of validity is 18 months.

The average price of the market is 80.

As shown in table 3, we assume that the effect of price on delivery and validity period follows an exponential function, where delta price term shows the difference between the supplier price and the minimum price showed in the market. Then the estimation of the loss occurred in both structures, is determined in table 4 and 5.

- Qualitative quality characteristic

To estimate the loss associated to the quality criterion for each supplier, we suppose that: The maximum deviation from the ideal profile is 40%

- For the purchaser's orientation, the weight for each sub-criterion in the quality criterion is 0.2

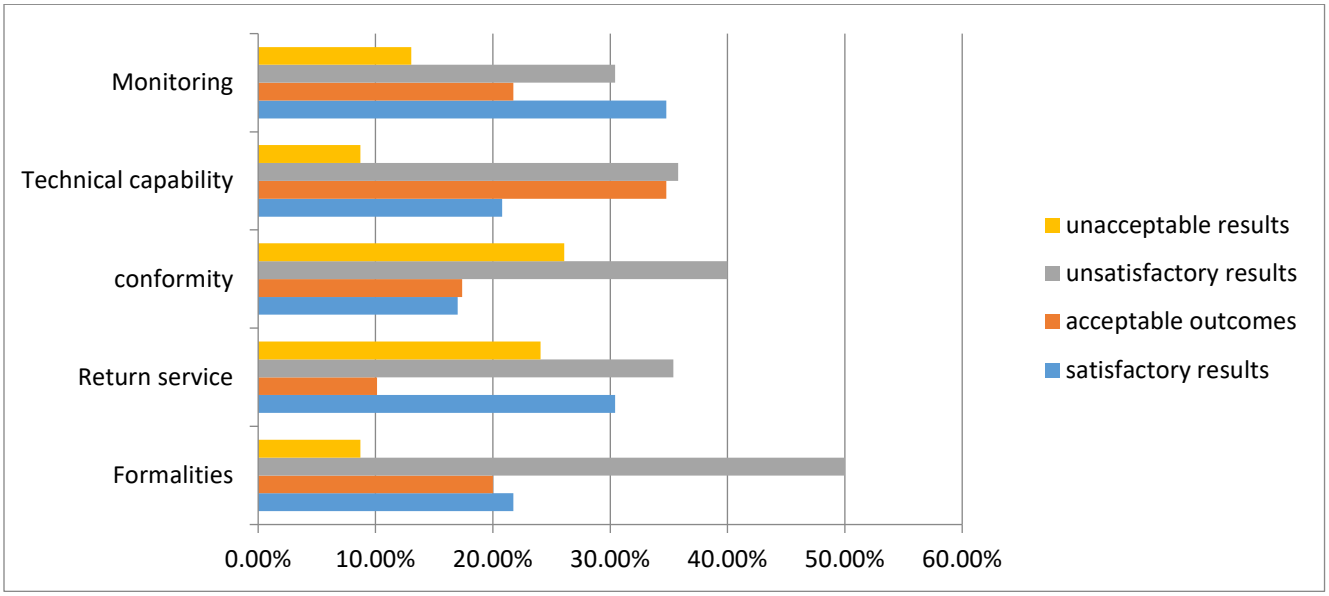

Figure 7. Supplier's evaluation criteria

Table 2. Criteria for supplier's hidden quality costs and their determination

Quantitative quality characteristic	1. Delivery		Costs to catch up the purchase unavailability as consequence of the supplier's delay or to pay extra fees to store the command for later use as a result of an order delivered in advance.
	2. Period of validity		Costs generated by expired medications due to suppliers that do not respect the validity period.
Qualitative quality characteristic	3.Quality	3.1. Monitoring	Costs to unlock the logistics problem in the hospital's upstream supply chain, generated by supplier's bad manufacturing practices, which include criteria for personnel, facilities, equipment, materials, manufacturing operations, labeling, packaging, quality control and, stability testing. These costs imply a supplier's bad conformity.
		3.2. Technical capability	Costs to maximize the return potential of the hospital's pharmacy generated by suppliers who have a bad experience in pharmaceutical returns service, and also to generate the minimum return credit for the hospital's outdated pharmaceuticals.
		3.3. Conformity	Costs to avoid unavailability of medicines in the pharmacy, and to monitor and check the supplier ongoing process of reviewing the degree to which programmed activities are completed and objectives are being met.
		3.4. Return service	Costs related to small errors of medications structure which can cause patients death. Hospital pharmacy policy requires providers to establish a continuous, systematic, and criteria-based evaluation system, such as the form and dose of drug use, that will help ensure the appropriate use of drugs.
		3.5.Formalities	Costs to assure continuity of hospital's supply and reliability of medicines quality, due to a supplier's bad technical capability. Hospital's pharmacy analysis confirms the reasonableness of the type and amount of resources proposed by the supplier. This analysis covers the proposed types and quantities of materials, labor, processes, special tooling, facilities, the reasonableness of scrap and spoilage, and other factors set forth in the supplier's proposal.

Table 3. Functions used to describe the effects of price on delivery and loss coefficients values.

	Delivery in advance	Late delivery	Period of validity in advance
Impact of price	High	Medium	Medium
Price function	$e^{\Delta price/-300}$	$e^{\Delta price/-200}$	$e^{\Delta price/-100}$
K	333.3	222.22	111.1

First, we have to determine for each supplier the independent variable y_i in equation 2. For this purpose, we rate each attribute of each alternative in the form of a matrix. To study the impact of these matrices values on final results, we assume that we have 2 experts; each one of them is assigned with the task of evaluating each supplier against each sub-criterion in each strategy. Then we determine the ideal solution, the ideal negative solution, and consequently the relative closeness to the ideal solution according to each expert (See table 6).

To get the values of k, we first need to specify the upper specification limit for each measure. As mentioned earlier, a loss of 100% will take place if a supplier image is 40% far away from the ideal profile. The other numerical measure that we need to model is how price affect quality characteristics. The expert might have different priorities regarding these criteria. For instance, one expert might be interested in high quality, while another in on-time delivery. For this reason, we assume that price effect is considered as medium or high in both centralized and decentralized structure. We use an exponential function to model the price effect for all experts.

Substituting these values in equation 2, we obtain the following loss coefficient values k, as shown in Table 7.

Table 4. Loss function results for delivery criterion

6.3. Analysis and decision

We assume that the effect of price on delivery and validity

period is the same in both centralization and decentralization strategies. However, there is a big change at the level of the supplier's hidden costs. The figure 8 indicates that loss results for the delivery criterion are much greater in the case of decentralization. The purpose of having several suppliers allows to benefit from the specific superiorities of each supplier in his specialty and to spread their risks. However, a purchase in small quantity leads to less favorable price and costs relationship. This decreases the chance of negotiating effectively the delivery deadlines, and does not help to put pressure on suppliers to meet the delivery date. The figure 9 shows that for most of suppliers, the cost relative to period of validity is high in the case of centralization. In fact, most of suppliers have medicines on stock whose period of validity have been already started, which constitutes a loss to the organization as long as they are stored. In one hand, the supplier tries to get the maximum profit, by lowering the unit purchase price to encourage the buyer. In other hand, the buyer is mainly based on maximizing the cost criterion, and does not pay enough attention to the period of validity. As a result, the buyer procures to optimize purchasing costs; but, in return the stocks in the hospital pharmacy hides a huge loss.

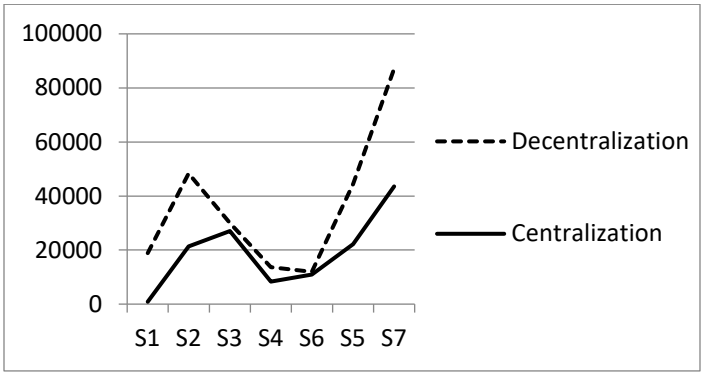

Figure 8. Loss results for delivery criterion in both structures

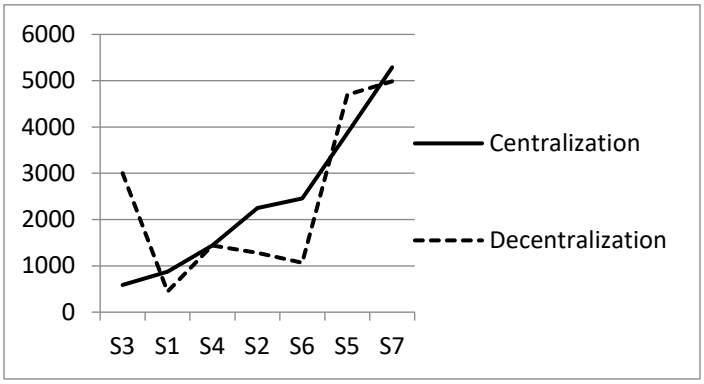

Figure 9. Loss results for period of validity criterion in both structures

In figure 10, the results determining the closest supplier to the best profile differ from one expert to another. In centralization strategy, the first expert indicates that S1 is the closest one, the second expert marks S3, while both experts' opinion answers for the decentralization strategy coincide at the same level for S6, which explains that experts' experiences bring different points of view on suppliers' evaluation.

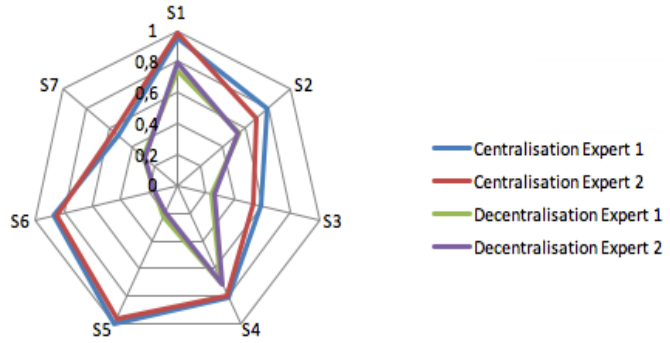

Figure 10. Expert's evaluation results

There are two parameters that might impact the supplier's loss function results: the value y, and the loss coefficient k. In one hand, the value y is influenced by the experts' evaluation (figure 11 shows that although both curves are almost symmetric for each strategy and follow the same trend, the maximum difference value is up to 5,6% in centralization strategy). In other hand, the loss coefficient is influenced by the determination of the impact of price on quality criterion, which is different from an organizational structure to another. As indicated in Figure 12, an increase in the loss coefficient results in an increase of the loss function, whose variation presented in an offset curve with a huge difference that comes to a maximum of 40%. Relatively speaking, the difference between experts' evaluations in centralization and decentralization strategy doesn't have a big impact on the variation of supplier's loss function in both structures which shows the effectiveness of our method.

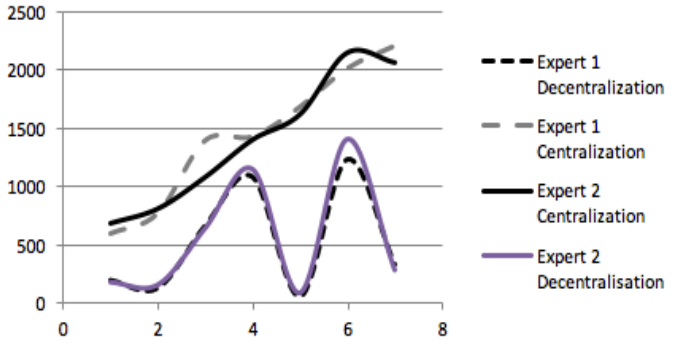

Figure 11. Variation of loss function in the case of medium impact of price on quality in both strategies

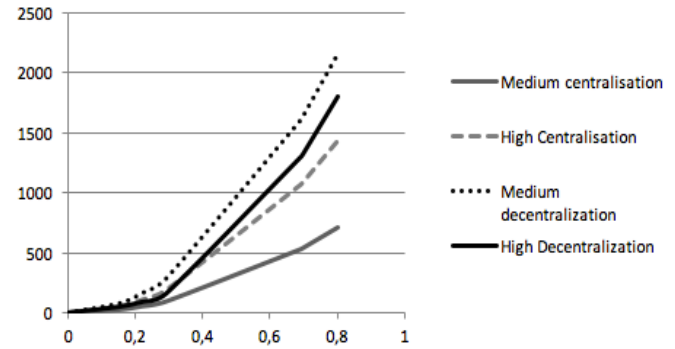

Figure 12. Variation of loss function in the case of first expert in both strategies

As shown in table 9, supplier's hidden quality costs are higher in the case of centralization, and this is due to:

- Centralization avoids sharing the responsibilities that can lead to coordination difficulties, and promotes decision-making consistent with the defined strategy.
- The centralized purchasing team may lack expertise on certain products, and their distance from user expectations may cause dissatisfaction.
- An error on a purchase will have multiple consequences, to the extent that the volumes purchased are more important, whether in terms of quality or delivery.
- Communication problems may occur between the various hospitals and the centralized purchasing site.
- Increased risk of dependence on suppliers as there is a risk of having too many purchases from few suppliers.

Table 9. Supplier's hidden quality costs in both organizational structures

	Centralization	Decentralization	Gain (C - D)/ C
S1	2889,2396	19226,7289	0,13190022

7. Conclusion

The purchasing organizational structure is considerably changed according to many factors. However, this change doesn't take into account its impact on supplier's hidden quality costs. In this study, a deciding making approach is elaborated for the hospital sector. Regarding to this new approach, a new method of measuring supplier's hidden quality costs is developed. The idea is to use improved Taguchi quality loss function in order to measure the loss associated to supplier's bad quality and help the manager to take an appropriate decision regarding the purchasing structure. Based on this work, we conclude that an erroneous value of the loss coefficient can result in misallocation of the loss function value in centralization and decentralization strategy. Therefore, future research needs to address this coefficient, which represents the impact of price on quality, differs from a structure to another and which is considered as an important component of quality loss function.

ABSTRACT

This paper presents an analysis of a parallel connection of one synchronous generator and one self-excited induction generator that feeds a resistive load and an Induction Motor. The system voltage and frequency are controlled by a voltage control loop and a speed control loop connected to synchronous generator. The induction generator speed is controlled by its primary machine that is fed by an autotransformer and a diodes bridge. Through by voltages applied by an adjustable tap autotransformer connected to induction generator's primary machine, it is possible widen the range of its shaft speed if compared with the shaft speed caused by only field flux variation method. Then, by the autotransformer method is possible to widen the speed and power limits from the induction generator what increases the induction generator contributions and relieves the power supply from synchronous generator. Analysis of generators power supply and its interactions in various operational scenarios are shown. The results enable comparisons of the two methods of induction generator speed control, either by auto-transformer method or by field flux variation method. The first results in larger range of speed and power from the induction generator. Therefore, it has more representative features of actual field conditions.

Nomenclature and Abbreviations

V_{SG}	Synchronous generator voltage
I_{SG}	Synchronous generator current
f_{SG}	Synchronous generator frequency
$I_{fieldSG}$	Synchronous generator field current
n_{SG}	Synchronous generator speed
DCM_{IG}	Direct current motor coupled with induction generator
DCM_{SG}	Direct current motor coupled with synchronous generator
DCG_{SG}	Direct current generator coupled with synchronous generator
I_{aDCMSG}	Armature current of direct current motor coupled with synchronous generator
I_{fDCMSG}	Field current of direct current motor coupled with synchronous generator
V_{IG}	Induction generator voltage
f_{IG}	Induction generator frequency
I_{IG}	Induction generator current
n_{IG}	Induction generator speed
I_{aDCMIG}	Current of direct current motor coupled with induction generator
I_{fDCMIG}	Field current of direct current motor coupled with induction generator
I_c	Capacitor bank current
I_{loadR}	Resistors banks current
Q	Reactive power
pF, cosϕ	Power factor
Xc	Capacitive reactance
SG	Synchronous generator
IG	Induction generator
PIG	Induction generator power
PSG	Synchronous generator power
P_{DCMSG}	DCM power input coupled with synchronous generator
P_{DCMIG}	DCM power input coupled with induction generator
I_{WSG}	SG active current
I_{WIG}	IG active current
Va_{DCMIG}	DCM armature voltage coupled with IG
Va_{DCMSG}	DCM armature voltage coupled with SG
Ra	Armature resistance

C	Conjugate
Xs	Synchronous reactance
E	Back electromotive force
V_{pn}	Phase neutral voltage
FPSO	Floating production storage offloading
IM	Induction Motor
IdwMT	Motor reactive current
IwMT	Motor active current

1. Introduction

This paper is an extension of work originally presented in PEDG conference [1].

The use of induction generators in generation systems is usual in wind plants [2-4] or eventually in small hydroelectric generation units [5]. Otherwise, from studies started in [1], it is shown a new knowledge border which consider the use of IG in parallel of SG in an isolated electric system. The first results and behavior of this kind of generation system were shown in [1] and are followed by this current article with original and deeper analysis.

Then, this work is composed of analysis over an expanded system that includes an induction motor, a resistive load, an autotransformer connected to a diodes bridge to feed the DCM_{IG} armature and then permits to increase manually the output electric power limits if compared to flux variation method (3) presented in [1]. Therefore, this article shows the IG supplying more active power and the induction motor inserted in experiment what enables a novel analysis of the system behavior.

This paper presents results that show additional remarkable characteristics by operation in parallel mode among one SG and one IG. Some characteristics, such as reduced weight and size, easier maintenance, and shorter manufacturing and delivery time are more associated with induction generators and are relevant to oil platforms or offshore installation concerns. Besides, it has absence of dc supply for excitation and better transient performances [5].

One of the potential motivation for this study is to develop a potential alternative capable of optimizing the main electric system currently adopted in oil platforms and floating production storage and offloading (FPSO) ships to become cheaper, simpler, lighter, and more efficient.

The potential application of this study is the replacement of one or two synchronous generators by one or two induction generators in oil offshore platforms or FPSO. A typical offshore electric system uses three or four turbo-generators in 13800 V, 60 Hz, driven by dual fuel (fuel gas or diesel oil) turbines. In typical operation, three main turbo-generators operate and can supply all unit consumers with the fourth in standby. During the peaks of load, the fourth main turbo-generator may be required to meet the demand. Therefore, the whole electric system shall be suitable for this operational condition.

Therefore, the study target is to analyze various aspects of topology and operating involving an induction generator in parallel with a synchronous generator for application in an isolated electric system, and to establish the operational viability, advantages and challenges.

2. Isolated Electric System

The isolated electric system was sized as shown in the following equations and data. The automatic controls of the system consist of a voltage control loop and a speed control loop. Both are inserted in the SG scheme as shown in Figure 5 and Figure 6. The dataplates of the principal equipment are shown in Tables 1 to 6.

The parameterization used in both electronic control boards is indicated in [1], except for the references of voltage and speed for each of the control loops which are respectively 65.5 and 65.2 as shown in Figure 9.

2.1. Dataplate

In tables 1 to 4 are shown the main equipment's dataplates and the tables 5 to 6 are shown the load's dataplates used in the experiments along this work.

Table 1: DMC_{IG} Dataplate

Direct Current Motor $_{IG}$				
220 V	7.72 A	1.7 kW	1500 rpm	600 $mA_{fieldmax}$

Table 6: Load, Induction Motor Dataplate

Induction Motor			
0.37 kW	1715 rpm	Cos ϕ: 0.71	60 Hz

2.2. Equations - Part I

Follow the main equations for analysis comprehension and to establish a studies base:

- Direct Current Motor

$$n = \frac{E}{k * \emptyset} \quad (1)$$

$$n = \frac{Ua - (\sum Ra) * Ia}{k * \emptyset} \quad (2)$$

$$C_{conjugate} = k * \emptyset * Ia \quad (3)$$

- Synchronous Generator

$$\dot{E} = \dot{U}a + (Ra + jX_s) * \dot{I}_a \quad (4)$$

- Induction Generator

$$S_{slip}\% = \frac{n_s - n_{IG}}{n_s} * 100 \quad (5)$$

$$n_s = \frac{120 * f_{SG}}{P_{number\ of\ poles}} \quad (6)$$

2.3. Capacitor Bank Sizing

As informed at the IG dataplate

$$\cos\phi = 0.8, \text{then } \sin\phi = 0.6$$

The reactive power is calculated to attend the reactive demand of the Induction Machine:

$$Q = \sqrt{3} * V * I * sen\phi \quad (7)$$

$$Q = \sqrt{3} * 220 * 7.5 * 0.6 => 1714.7 \text{ VAr}$$

$$Q_{generated} = Fc * Q \quad (8)$$

Fc =1.2 [6]

For the machine coupled at a resistive load which requires 7.5A, it is necessary for the reactive power generation to be approximately 2057.6 VAr as demonstrated below.

$$Q_{generated} = 1.2 * 1714.7 => 2057.6 \text{ VAr} \quad (9)$$

$$Q = \frac{3*V^2}{X_c} \quad (10)$$

$$Q = \frac{3*220^2}{X_c} => X_c = \frac{3*220^2}{2057.6} = 70.6\ \Omega \quad (11)$$

$$X_c = 70.6\ \Omega$$

$$X_c = \frac{1}{2*\Pi*f*C} = \frac{1}{2*\Pi*50*C} => \quad (12)$$

$$C = \frac{1}{2*\Pi*50*70.6} \cong 40\mu F \text{ per phase} \quad (13)$$

2.4. Resistive Divider Sizing:

- Field Control Loop Resistive Divider as in Figure 5 and Figure 6.

$$(1\ k\Omega + r_1) \rightarrow 300\ V_{(brigge\ output\ voltage)} \quad (14)$$

$$r_2(1\ k\Omega) \rightarrow 4V_{(MP\ 410T\ voltage\ limit)} \quad (15)$$

$$r_1 = 74\ k\Omega\ and\ r_2 = 1k\Omega \quad (16)$$

- Resistor Power Sizing:

$$P_{power} = {300^2}/{(75 * 10^3)} = 1.2\ W \quad (17)$$

- The resistors that were selected based on the sized resistor, were:

$$r_1 = 79.1\ k\Omega\ and\ r_2 = 947\Omega \quad (18)$$

- Speed Control Loop Resistive Divisor as in Figure 5 and Figure 6.

$$(1\ k\Omega + r_1) \rightarrow 36\ V_{(tacho\ generator\ output\ voltage)} \quad (19)$$

$$r_2(1\ k\Omega) \rightarrow 4V_{(MP\ 410T\ voltage\ limit)} \quad (20)$$

$$r_1 = 8\ k\Omega\ and\ r_2 = 1k\Omega \quad (21)$$

- Resistor Power sizing:

$$P_{power} = {36^2}/{(9 * 10^3)} = 1.14\ W \quad (22)$$

- The resistors chosen, based on the sized resistor, were

$$r_1 = 8{,}3\ k\Omega\ and\ r_2 = 947\Omega$$

2.5. Equations - Port II

Follow the system equations base to calculate the power and efficiencies shown in Table 7 and Table 8 for each generator and entire group of machines.

$$I_{SG}{}^2 = Iw_{SG}{}^2 + Ic_1{}^2 \quad (23)$$

$$I_{IG}{}^2 = Iw_{IG}{}^2 + Ic_2{}^2 \quad (24)$$

$$Ic - IdwMT = Ic_1 + Ic_2 \quad (25)$$

$$I_{wloadR} + IwMT = Iw_{SG} + Iw_{IG} \quad (26)$$

As I_{SG}, I_{IG}, Ic and I_{wloadR} are measured values, shown in Table 7 and Table 8, IdwMT(Motor's reactive current) and IwMT(Motor's active current) are values calculated in appendix 1. Then, the system has 4 four variables and 4-four equations. Then, for each scenario, the four variables Iw_{SG}, Ic_1, Iw_{IG} and Ic_2 were calculated by Matlab software and are shown in Table 7 and Table 8.

The entire group efficiency and the efficiency of each subgroup were calculated based on PIG, PSG, PDCMSG, and PDCMIG, as follows:

$$P_{SG} = \sqrt{3} * V_{SG} * Iw_{SG} \quad (27)$$

$$P_{IG} = \sqrt{3} * V_{IG} * Iw_{IG} \quad (28)$$

$$P_{DCMSG} = Va_{DCMSG} * Ia_{DCMSG} \quad (29)$$

$$P_{DCMIG} = Va_{DCMIG} * Ia_{DCMIG} \quad (30)$$

$$\eta_{group}\% = \frac{P_{SG}+P_{IG}}{P_{DCMSG}+P_{DCMIG}} * 100 \quad (31)$$

$$\eta_{SG}\% = \frac{P_{SG}}{P_{DCMSG}} * 100, \quad (32)$$

$$\eta_{IG}\% = \frac{P_{IG}}{P_{DCMIG}} * 100 \quad (33)$$

2.6. Equations - Part III

The equations e calculus used to determined the IM parameters and IM equivalent circuit as primary, secondary

impedances and currents, including IM currents showed in Table 8 are calculated in item 5 of appendix 1.

2.7. The Experiment and Schemes

The experiment was mounted in the laboratory as shown in Figure 1 and Figure 2. The detailed circuit is shown in Figure 6. Figure 2 shows another experiment view, including the taco generator and its connections. The detailed circuit is shown in Figure 6. Figure 3 shows the typical connections of both circuit board MP 410T which are implemented in this experiment for the voltage loop and speed loop. They are also indicated in Figure 5 and Figure 6.

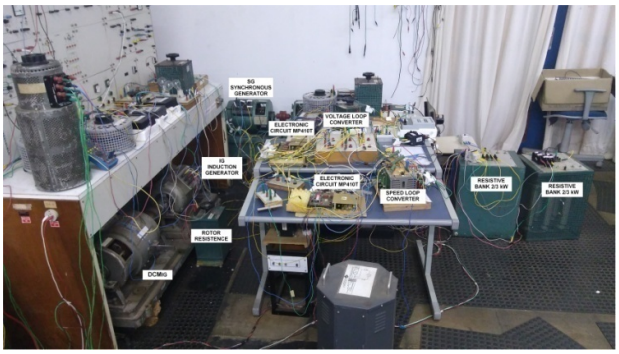

Figure 1 Laboratory assembly

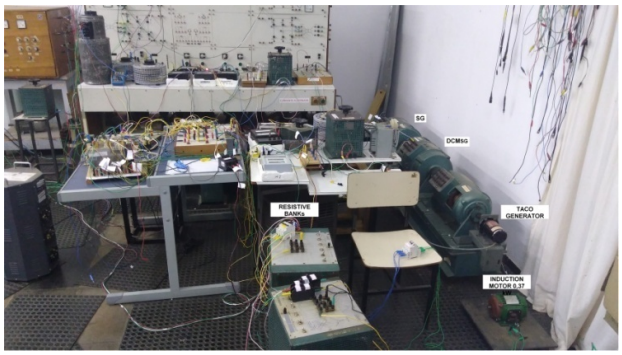

Figure 2 Another view of laboratory assembly

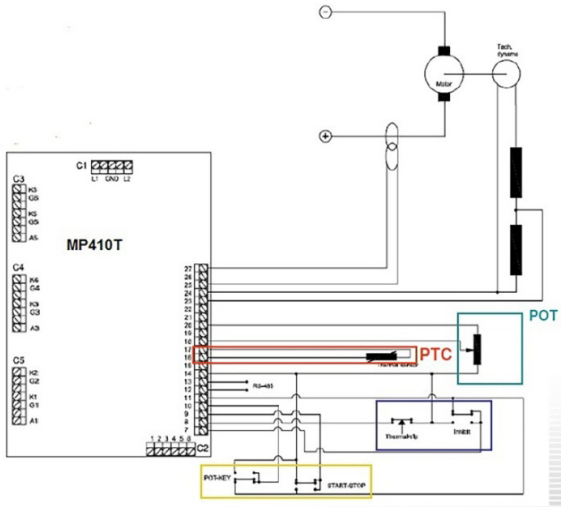

Figure 3. Connections arrangement of MP410T and devices

Figure 4 shows the 1B6C configuration used for the two thyristor converter bridges which were used in the control loops.

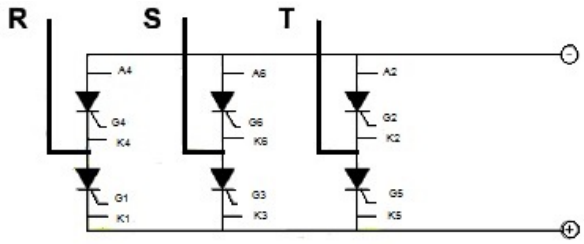

Figure 4. Converters configuration used in voltage and speed loops

As seen in [1], the power from IG, PIG, was limited because the I_{fDCMIG} reached the maximum viable value in accordance with DCM_{IG} current specifications. This limited speed from DCM_{IG} was a challenge because it was not showing a representative contribution from PIG. It was necessary to elevate the DCM_{IG} speed, n_{IG}.

Then, the methodology consists of implementing the comparative analysis of the power and efficiencies, starting with an analysis between the PIG from the scheme in [1] and PIG from the scheme in Figure 5 and Figure 6, covering the scenarios shown in Table 7 related to Figure 5 and Table 8 related to Figure 6. Finally, a comparative efficiency analysis was conducted for two subgroups, one composed of IG and DCM_{IG} and the other composed of SG and DCM_{SG} in scenarios related to the scheme in [1] and the schemes in Figure 5 related to Table 7 and Figure 6 related to Table 8.

Thus, the increase of DCM_{IG} speed, increase of PIG contributions and improvement of IG subgroup efficiencies are shown in results.

Figure 6 shows the scheme implemented in the laboratory to overcome the challenge related to limitation of IG speed [1] and bring the experiment closer to actual offshore conditions, taking into advantages of IG power capacity. It was used as an autotranformer connect to a diodes bridge to vary the voltage applied on the DCM_{IG} armature circuit and obtain a higher speed and PIG.

2.8. Voltage and Speed Control Loops

The Figure 7 and Figure 8 show the closed control loop used to control the SG speed and voltage via circuit boards.

Figure 9 (a) and Figure 9 (b) show the circuit boards with the respective working point or reference points defined during parameterization for the speed control loop, 65.2 and the voltage control loop, 65.5.

As [1], the master and slave behavior were verified by the generators, considering that SG is the master and IG is the slave. The frequency and voltage are determined by SG, while active power consumed at load is controlled by IG.

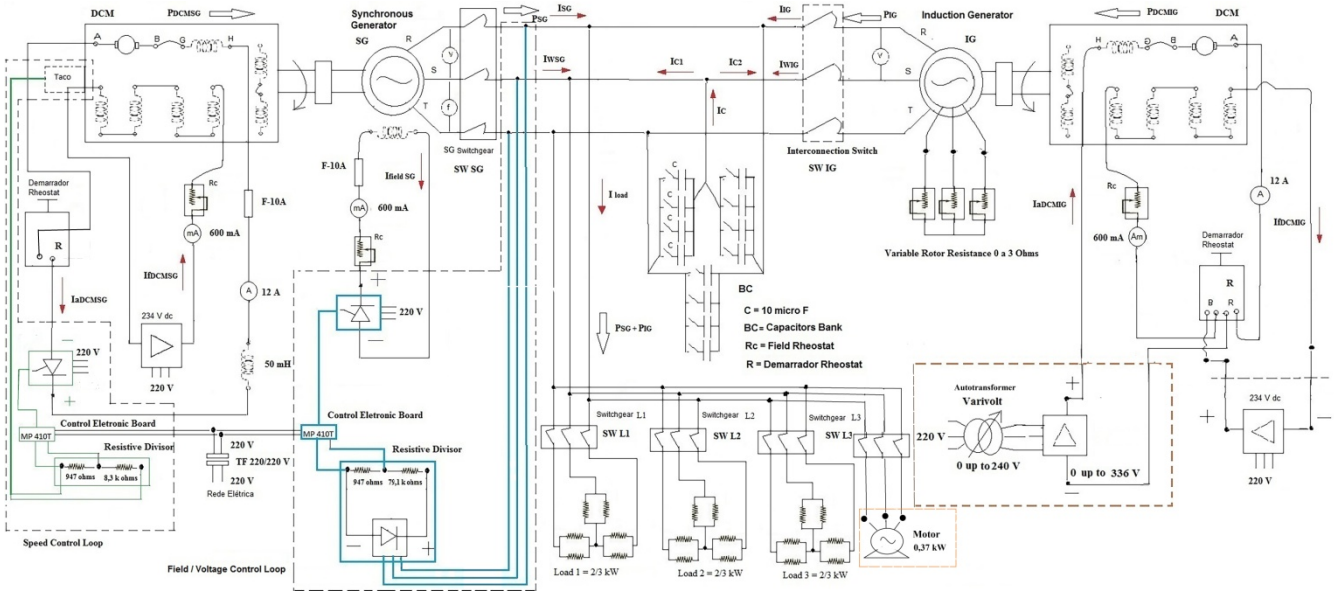

Figure 6: Synchronous generator in parallel with induction generator and its dc Motors _ Vdc variable source for DCM_{IG}

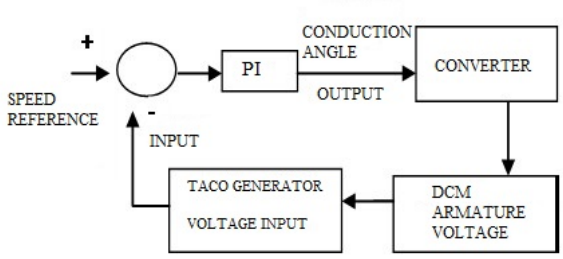

Figure 7. Speed Control Loop

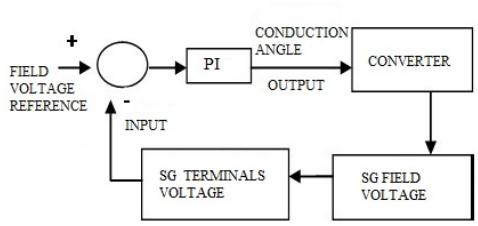
Note: For both regulators, the proportional gain P was experimentally set at 0,010 and, in the same manner, the time constant was set at 0,04 s as in [1].

3. Experiment Data and Results

3.1. Experiment Data

The experimental data obtained in the laboratory are shown in Table 7 and Table 8. The Table 7 is referred to scheme in Figure 5 and Table 8 is referred to scheme in Figure 6. The unique difference is the presence of IM as additional load presented in Figure 6 scheme. Then, the Table 7 and Table 8 shows the data obtained from the scheme shown respectively in Figure 5 and Figure 6 which are similar to scheme shown in [1], except for the presence of an autotransformer in the DCM_{IG} field circuit for Figure 5 and Figure 6 and an IM as additional load in Figure 6.



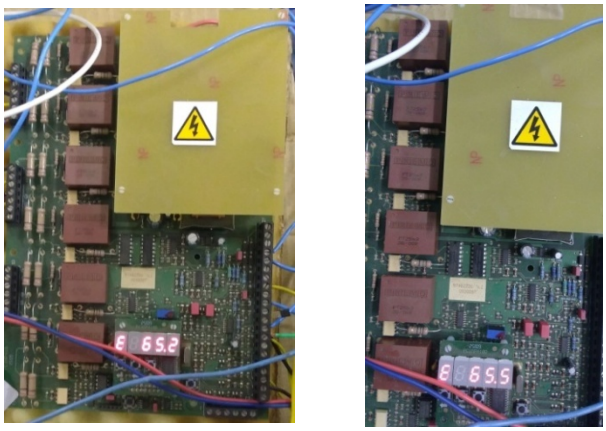


Figure 8. Field voltage control loop

(a) Speed Control Loop (b) Voltage Control Loop

Figure 9. Circuit boards MP410T used to implement the control loops

The autotransformer is responsible for applying a voltage range directly on the DCM_{IG} armature to obtain a larger speed range of the DCM_{IG} and to push more power to the IG, keeping the DCM_{IG} parameters into the rated values. Hence, the elevation of IG speed and power depend on just V_{aDCMIG}, it means this method is different from the scheme presented in [1] that depends on the DCM_{IG} field flux. Both V_{aDCMIG} and the DCM_{IG} field flux are adjusted manually. In summary, the [1] shows the data obtained from the scheme that has the 234Vdc steady source, Table 7 and Table 8 shows the data obtained from the schemes shown in Figure 5 and Figure 6, that has an autotransformer and a diodes bridge as substitute of the 234 Vdc steady source.

The data presented in Table 8 related to Figure 6 system performance results are compared to data obtained from Table 7 related to scheme in Figure 5 and also compared to data obtained from [1]. The scheme in Figure 5 and Table 7 shows the performance of the isolated electric system that considers the voltage application range on the DCM_{IG} armature by an autotransformer and an diodes bridge. The scheme in Figure 6 and Table 8 shows the performance of the isolated electric system that considers the same scheme presented in Figure 5 added by a induction motor, IM, as an additional load.

4. Results

The results and comparative analysis from experiments shown in Figure 5, Figure 6 and the results obtained in [1] are presented in the following.

The results show graphs and analysis of system configurations presented in Figure 5 and Figure 6, data obtained in [1] and analysis of contribution from each generator for each arrange of load, that, in this case, is ether just resistive banks or resistive banks added with an induction motor IM. It is noted that for all graphs obtained from [1] is related to a set system frequency of 55 Hz.

Obs.: 1- Italic and bold text: calculated values by equations 23 to 33
2- Frequency was chosen based on the average between the SG and IG rated frequency
3- n.a: not applicable

For all experiments shown in this paper, the system frequency is 60 Hz. Then, the synchronous speed for the experiments in [1] is 1650 rpm (6) and 1800 rpm for the experiments shown in this paper.

To highlight the contributions from autotransformer and diodes bridge in the experiments in relation to the experiments without these devices, it will be presented some analysis based on graphs and experiment results.

Figure 10 shows that the PIG was limited to 1164 W [1] in scenario 2 [1] because the over current of I_{aDCMIG} 9.8 A [1] is a value greater than the rated I_{aDCMIG} of 7.72 A as Table 1. To overcome this barrier, an autotransformer and a diodes bridge were installed to widen the voltage range applied over the DCM armature, as shown in Figure 5 and Figure 6. The armature voltage range with the autotransformer and diodes bridge can vary from 0 to 336 Vdc. This range is greater than the previous V_{aDCMIG} of 234 Vdc. As the DCM_{IG} speed, n_{IG}, is directly proportional to V_{aDCMIG}, as shown in (2), the n_{IG} is elevated proportionally with the V_{aDCMIG} as shown in scenarios 2 to 8, in Table 7 and Table 8. Then, in this latter method, I_{aDCMIG} variation depends on the load conjugate variation only; as long as I_{aDCMIG} decreases, I_{aDCMSG} rises because of the load distribution to the generators, whereas the DCM_{IG} flux, ϕ, remains constant as (3).

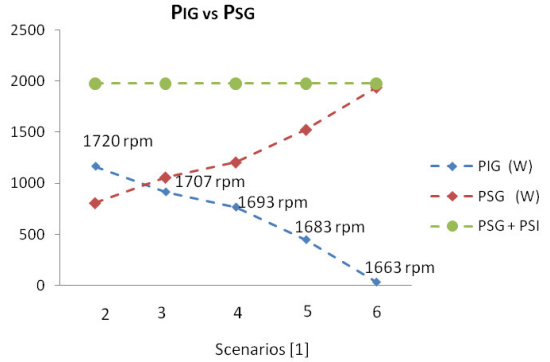

Figure 10. PIG vs PSG with DCM_{IG} field flux variation and V_{aDCM} kept constant

Figure 11 and Figure 12 shows that the power range supplied from IG, PIG, through the autotransformer method, is greater than PIG of 234 Vdc through the steady source method. Consequently, the power complement from SG is

lower than the PSG from 234 Vdc steady source method. Both methods feed the entire resistive load in Figure 10 and Figure 11, and resistive and motor load as shown in Figure 12.

In Figure 13, Figure 14 and Figure 15 shows the comparative results of IG and SG primary machine output power, P_{DCMIG} vs P_{DCMSG}. These performances are similar to PIG and PSG performances shown in Figure 10, Figure 11 and Figure 12. The P_{DCMIG} in Figure 13 elevates because the flux decreases and V_{aDCMIG} is kept constant [1] The P_{DCMIG} in Figure 14 and Figure 15 elevates because of the V_{aDCMIG} increases, which is manually adjusted by the autotransformer shown in Figure 5 and Figure 6.

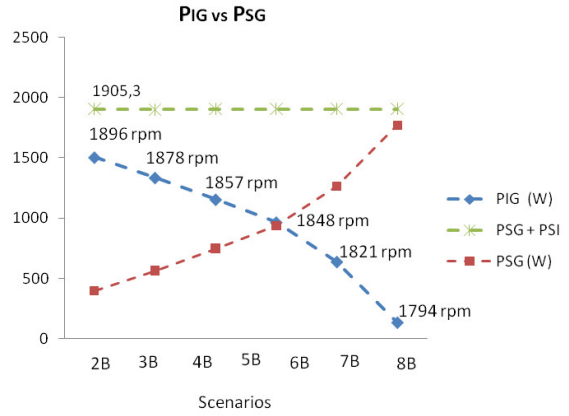

Figure 11. PIG vs PSG with V_{aDCMIG} variation and field flux kept constant (Only resistive load)

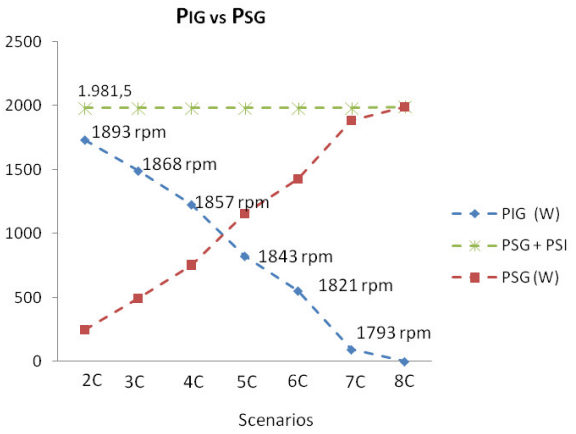

Figure 12. PIG vs PSG with V_{aDCMIG} variation and field flux kept constant (Resistive load plus IM)

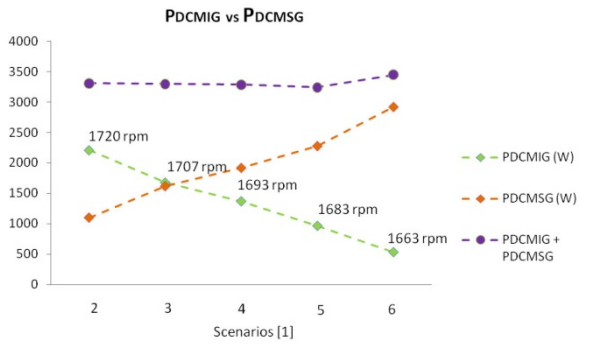

Figure 13. P_{DCMIG} vs P_{DCMSG} with DCM_{IG} field flux variation and V_{aDCMIG} kept constant

The efficiency results shown in Figure 16, Figure 17 and Figure 18 present each subgroup efficiency for each scenario and load conditions. Each subgroup efficiency is resulted from relation between a generator and a DCM as shown in (32) and (33). In summary, the target scenarios are: 2 to 7 (without autotransformer) as in [1], scenarios 2B to 8B (with autotransformer and just resistive load) and scenarios 2C to 8C (with autotransformer, resistive load and induction motor).

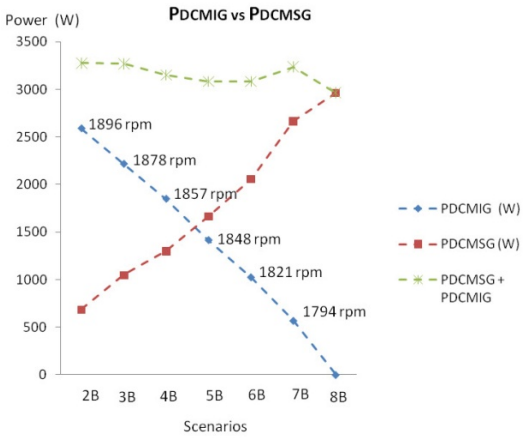

Figure 14. P_{DCMIG} vs P_{DCMSG} with V_{aDCMIG} variation and field flux kept constant (Only resistive load)

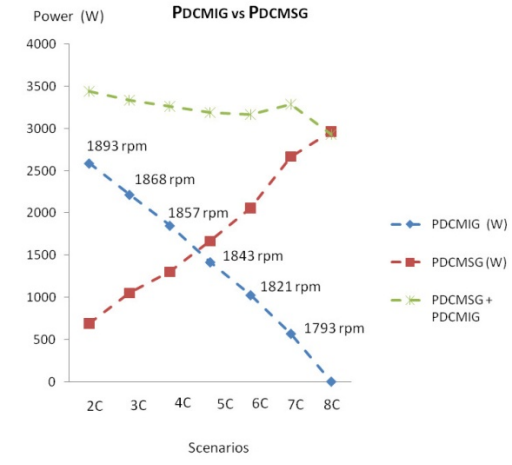

Figure 15. P_{DCMIG} vs P_{DCMSG} with V_{aDCMIG} variation and field flux kept constant (Resistive load plus IM)

The IG subgroup efficiencies shown in Figure 17 and Figure 18 are bigger than IG subgroup efficiencies from similar scenarios in Figure 16. Moreover, the elevation of power from IG due to the increase of DCM_{IG} speed, n_{IG}, is more representative of actual offshore conditions. The turbines can assume whatever speed required from generators in offshore platforms.

The reduction of losses contributed to increased IG subgroup efficiency as shown in Figure 17 and Figure 18. Fig. 16 shows the machine's efficiencies when the I_{fDCMIG} decreases to elevate the speed. The efficiency improves when the V_{aDCMIG} elevation method is applied as shown in Figure 17 and Figure 18.

The Figure 17 and Figure 18 are higher than the efficiency presented in Figure 16 considering that the Figure 16 indicates a DCM_{IG} speed range is more restricted as already clarified in [1].

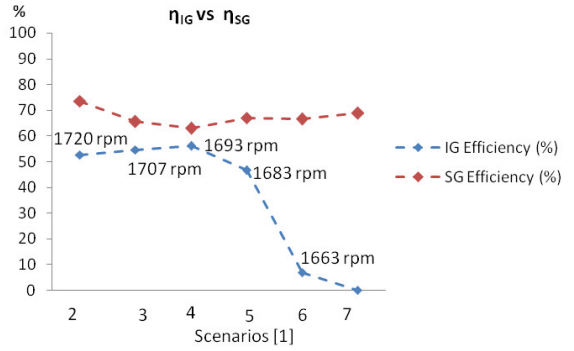

Figure 16. η_{IG} vs η_{SG} with DCM_{IG} field flux variation and V_{aDCMIG} kept constant

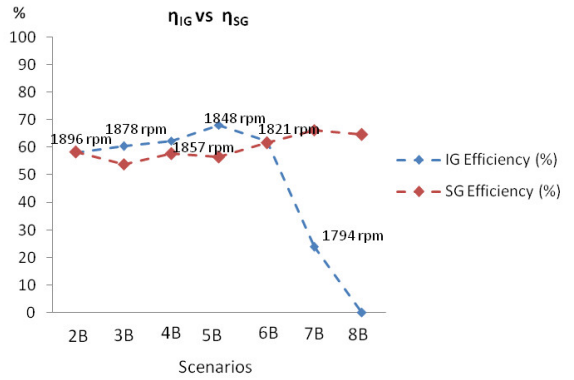

Figure 17. η_{IG} vs η_{SG} with V_{aDCMIG} variation and field flux kept constant (Only resistive load)

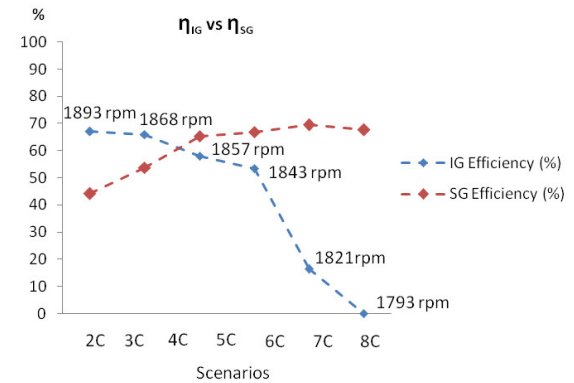

Figure 18. η_{IG} vs η_{SG} with V_{aDCMIG} variation and field flux kept constant (Resistive load plus IM)

5. Conclusion

The cited electric system shows voltage and frequency regulation for each scenario transition as demonstrated by results and respective analysis.

As it happened in [1], it was realized the master and slave behaviors to respectively SG and IG. SG controls the system voltage and frequency and IG follows the voltage and frequency defined by SG. The IG establishes the active power supplied to the system and the SG complements the rest of active power and reactive power required. The PIG depends on the IG shaft speed imposed by DCM_{IG}. The PSG and the system voltage and frequency are controlled by voltage and speed control loops presented in Figure 5 and Figure 6.

It was realized a greater PIG range in the scenarios in Table 7 and in Table 8, than the scenarios from [1] due to V_{aDCMIG} elevation method. The PSG complemented the PIG manually set to attend the load.

The V_{aDCMIG} elevation method resulted in increase of P_{DCMIG} and PIG and higher IG subgroup efficiency than the I_{fDCMIG} reduction method[1]. The increase of P_{DCMIG} and PIG were results of IG speed increase, $n_{IG,}$ that was obtained by elevation of V_{aDCMIG} as shown in Figure 11, Figure 12 and Figure 14. The use of V_{aDCMIG} range instead of Vdc steady source enables to reach the I_{aDCMIG} limit of 8,0 A and 1893 rpm shaft speed, it is 5,16% higher than synchronous speed. It is higher than Vdc steady source method limit that reached just 4,24% higher than synchronous speed, Figure 16 and [1].

The efficiencies from the V_{aDCMIG} elevation method were greater than efficiencies from the scheme with Vdc steady source [1], as shown in Figure 17 and Figure 18. V_{aDCMIG} elevation method does not have the additional current losses of Vdc steady source method. When the field flux ϕ, I_{fDCMIG}, is decreased, I_{aDCMIG} is increased by (3) and IG speed, $n_{IG,}$ is increased by (2). The main losses for the Vdc steady source method are related to higher I_{aDCMIG} elevation, $P(w)=Ra* I_{aDCMIG}^2$. Then, by the Vdc steady source method, besides I_{aDCMIG} be elevated due to the rise of PIG, I_{aDCMIG} is also elevated due to reduction of I_{fDCMIG}. Higher I_{aDCMIG} result in higher losses and lower efficiencies.

As shown in power performance graphs related to the V_{aDCMIG} elevation method, Figure 11, Figure 12, Figure 14 and Figure 15, the PIG and P_{DCMIG} are more representative of actual operation conditions in offshore platforms.

In continuation of this content, a study of load and generation transients has been done and submitted to publication in COBEP, Brazilian Power Electronic Conference that took place in November, 2017.

In the next stage of this work, it will be studied energy regeneration and ballast load as a additional way to the system regulation.

Conflict of Interest

The authors declare no conflict of interest.

Acknowledgment

The authors would like to thank the UNIFEI and PETROBRAS for the general support along the study.

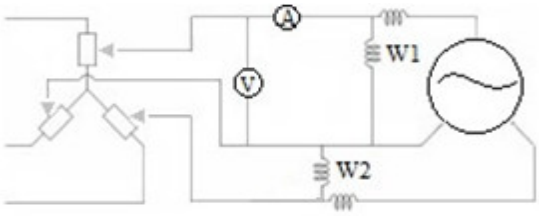
Appendix 1_ Induction Motor Parameters

The follow calculus were developed on base in [7].

1. No Load and Locked Rotor Tests

The Figure 1 shows the circuit implemented in laboratory to no load test and locked rotor test.

The temperature during the test= 26ºC.



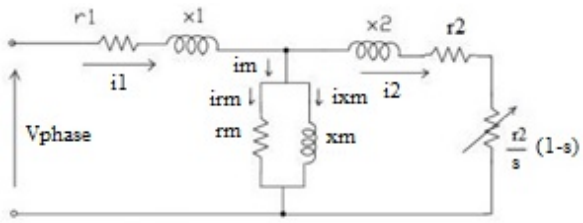


Figure 1: No load test and locked rotor test circuit

Figure 2: Induction Motor Equivalent Circuit

The Figure 2 shows the induction motor IM equivalent circuit.

5.1. No Load Test

In this section, it will be presented the no load test and locked rotor test to calculus the IM parameters such as impedances, currents, losses and efficiency

The Table 1 presented the no load test measurements.

Table 1: No load Test

Vapply (V)	W1 (W)	W2 (W)	V (V)	A (A)	W1+W2(W)
240	-120.0	+220.0	240.2	1.50	100.0
220	-100.0	+170.0	220.8	1.35	70.0
200	-70.0	+130.0	200.3	1.15	60.0
180	-60.0	+110.0	180.3	1.00	50.0
160	-40.0	+80.0	160.0	0.90	40.0
140	-30.0	+60.0	140.0	0.75	30.0
120	-20.0	+45.0	120.0	0.65	25.0
100	-15.0	+30.0	100.1	0.55	15.0
80	-10.0	+20.0	80.0	0.50	10.0
60	-4.0	+12.5	60.0	0.25	8.5
40	0.0	+5.0	40.0	0.15	5.0
20	0.0	+2.0	20.1	0.05	2.0
0	0.0	0.0	1.99	0.0	0.0

Figure 3 shows the curve of voltage applied and power measured by wattmeter (w1) and (w2). Note that the cross of curve and vertical axe result in estimated attrition and ventilation losses (*Pav*). In this case *Pav* is 1 W as demonstrated.

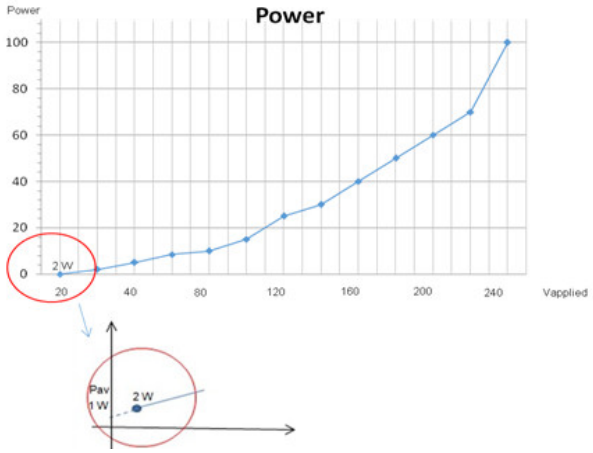

Figure 3: Results of no load test: W1+W2 vs Voltage applied

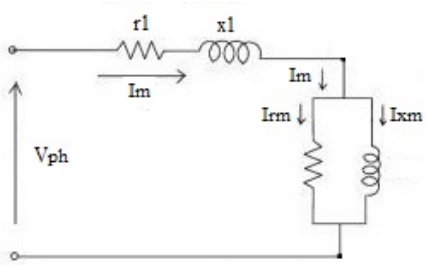

Figure 4: Equivalent circuit - No load test

- Magnetization Current

Im = Magnetization Current

Im= 1.35 A as shown in Table 1.

5.2. Locked Rotor Test

The Table 2 shows the locked rotor test measurements.

Table 2
Locked Rotor Test

W1 (W)	W2 (W)	V (V)	In (A)	W1+W2 (W)
20	65	39.34	1.80	85

- Rated Current

In = Rated Current

$$in = {}^{P}/_{\sqrt{3} * Vpp * cos\emptyset * \eta} \quad (1)$$

$$in = {}^{370}/_{\sqrt{3} * 220 * 0.71 * 0.76}$$

$$in = 1.80\ A \quad (2)$$

The Figure 3 shows the induction motor IM equivalent circuit during locked rotor test

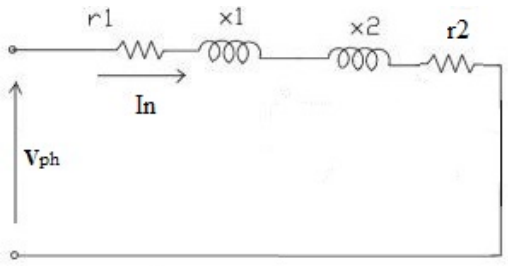

Figure 5: Equivalent circuit _ Locked rotor test

5.3. Magnetization Branch Parameters

Rm= Motor Average Measured Resistance
ry= Phase resistance in star connection
rd= Phase resistance in delta connection

Table 3:
Average Resistance

$R_{AA'}$	$R_{BB'}$	$R_{CC'}$
10.1	10.3	10.16

$$R_m = {(10.1 + 10.3 + 10.16)}/{3} = 10.16\ \Omega \quad (3)$$

- r1 Calculus

Follow the calculus memory of stator winding resistor r1.

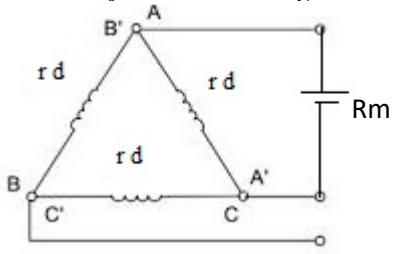

Figure 6: IM winding connection

$$R_m = {rd * 2rd}/{3rd} \quad (4)$$

$$R_m = {2}/{3}\,rd \quad (5)$$

$$rd = {3}/{2}\,rm \quad (6)$$

$$ry = {1}/{3}\,rd \quad (7)$$

(5) in (6)

$$ry = {Rm}/{2} = {10.16}/{2}$$

$$r1 = 5.08\ \Omega \quad (8)$$

- r2 Calculus

From Table XI, $W1 + W2 = 85\ W$

$$W1 + W2 = 3 * (\mathrm{r1} + \mathrm{r2}) * \mathrm{in}^2 \quad (9)$$

$${85}/{(3 * 1.8^2)} = 5.08 + r2$$

$$r2 = 3.66\ \Omega \quad (10)$$

- Reactive Power

$$Q = \sqrt{3} * Vpp * IdwMT * sen\emptyset = \sqrt{3} * (W2 - W1) \quad (11)$$

From Table XI, W2-W1=45

$$Q = \sqrt{3} * (65 - 20) = 77.94\ Var \quad (12)$$

$$Q = 3 * (x1 + x2) * In^2 \quad (13)$$

(13)and (2) in (14)

$$77{,}94 = 3 * (x1 + x2) * 1.8^2 \quad (14)$$

$$(x1 + x2) = 8.01\ \Omega \quad (15)$$

$$\begin{cases} x1 \rightarrow x2 \\ r1 \rightarrow r2 \end{cases} \quad [8] \quad (16)$$

(8) and (10) in (16)

$$\begin{cases} x1 \rightarrow x2 \\ 5{,}08 \rightarrow 3.66 \end{cases}$$

$$x1 = {r1 * x2}/{r2} \quad (17)$$

$$x1 = {5{,}08 * x2}/{3.66} \quad (18)$$

From (15) and (18), result in

$$5{,}08 * x2 + x2 * 3.66 = 29.32 \quad (19)$$

$$x2 * 8{,}74 = 29.32 \quad (20)$$

$$x2 = 3.35\ \Omega \quad (21)$$

(21) in (18), result in

$$x1 = {5{,}08 * 3.35}/{3.66} \quad (22)$$

$$x1 = 4.65\ \Omega \quad (23)$$

2. Power and Losses Calculus

The Pav was defined in Figure 3 and consist in 1 W and Pnl (no load losses) is no load test for 220 V, it resulted in 70 W (W1 +W2).

- Stator Joules Losses

$$\text{Pjstator26º= Stator Joule Losses} = 3 * r1 * im^2 \quad (24)$$

$$\text{Pjstator26º} = 3 * 5.08 * 1.35^2 \quad (25)$$

$$\text{Pjstator26º} = 27.77\ \text{W} \quad (26)$$

- Phf_ histerese and foucault losses

$$P_{hf} = (W1 + W2) - 3 * r1 * im^2 - Pav \quad (27)$$

$$P_{hf} = 70 - 3 * 5.08 * 1.35^2 - 1 \quad (28)$$

$$P_{hf} = 41.23\ W \quad (29)$$

5.4. No Load Reactive Power

$$Q_o = \sqrt{3} * (W2 - W1) \quad (30)$$

From Table 1, $W2 - W1 = 270W$

$$Q_o = \sqrt{3} * 270\ \text{W}$$

$$Q_o = 467.65\ \text{Var} \quad (31)$$

5.5. Magnetization Branch

- No load Reactive Power in Magnetization Branch

$$Q_m = Qo - 3 * X1 * io^{\,2} \quad (32)$$

$$Q_m = 467.65 - 3 * 4.66 * 1.35^{\,2} \quad (33)$$

$$Q_m = 442.23\ Var \quad (34)$$

- Magnetization Branch Power Factor Angle

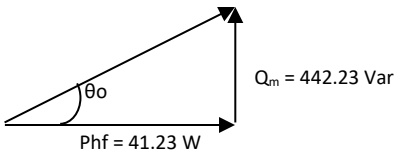

Figure 7: Magnetization branch power factor

$$\theta o = arctg\ {}^{442.23}/_{41.23} \quad (35)$$

$$\theta o = 84.67^{o} \quad (36)$$

- Magnetization Branch Currents

$$\text{Irm} = \text{Im} * \cos\theta o \quad (37)$$

$$\text{Irm} = 1.35 * \cos 84.67^{o} \quad (38)$$

$$\text{Irm} = 0.1254\ A \quad (39)$$

$$\text{Ixm} = \text{Im} * \text{sen}\theta o \quad (42)$$

$$\text{Ixm} = 1.35 * \text{sen}84.67^{o} \quad (40)$$

$$\text{Ixm} = 1.34\ \text{A} \quad (41)$$

- Magnetization Branch Resistance

$$\text{rm} = {}^{\text{Phf}}/_{(3 * \text{Irm}^2)} \quad (42)$$

$$\text{rm} = {}^{41.23}/_{(3 * 0.1254^2)} \quad (43)$$

$$\text{rm} = 873.97\ \Omega \quad (44)$$

- Magnetization Branch Reactance

$$\text{xm} = {}^{\text{Qm}}/_{(3 * \text{Ixm}^2)} \quad (45)$$

$$\text{xm} = {}^{442.23}/_{(3 * 1.34^2)} \quad (46)$$

$$\text{xm} = 82.10\ \Omega \quad (47)$$

3. Parameters of Induction Motor

Figure 8 shows all IM parameters calculated as resistors, reactance and currents as data obtained during experiment, without temperature correction because the motor operated no load.

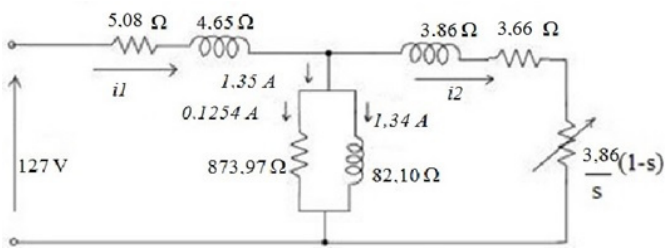

Figure 8: Parameters of Induction Motor _IM

4. Induction Motor Efficiency

It will be calculated the temperature correction factor, corrected resistences to 40ºC, corrected winding losses, Pwind40ºC, and total losses, Ptl, before induction motor efficiency calculus.

5.6. Temperature Correction Factor and Resistence Correction

- Temperature Correction Factor Kt 40ºC

$$\text{Kt } 40^{o} = {}^{234.5 + 40}/_{(234.5 + 26)} \quad (48)$$

$$\text{Kt } 40^{o} = 1.054 \text{ to r1 and r2} \quad (49)$$

- Resistence Correction

$$\text{r1 } 40^{o} = \text{r1 } 26^{o} * 1.054 \quad (50)$$

$$r1\ 40^{o} = 5.08 * 1.054 \quad (51)$$

$$r1\ 40^{o} = 5.35\ \Omega \quad (52)$$

$$r2\ 40^{o} = r2'26^{o} * 1.054 \quad (53)$$

$$r2\ 40^{o} = 3.66 * 1.054 \quad (54)$$

$$r2\ 40^{o} = 3.86\ \Omega \quad (55)$$

5.7. Corrected Winding Losses and Total Losses

- Winding Losses

The winding losses, Pwind, measured in locked rotor test, Table 2, need to be corrected to 40ºC. Follow the corrected winding losses.

$$Pwind40^{o} = kt\ 40^{o} * Pwind26^{o}\ (\text{locked rotor test}) \quad (56)$$

$$Pwind40^{o} = 1.054 * 85W \quad (57)$$

$$Pwind40^{o} = 89.59\ W \quad (58)$$

- Total Losses

The total losses, Ptl, calculus:

$$Ptl = Phf + Pav + Pwind40^{o} \quad (59)$$

$$Ptl = 41.23W + 1W + 89.59W \quad (60)$$

$$Ptl = 131.82\ W \quad (61)$$

5.8. Rated Motor Efficiency Estimate

Pout = Motor output power (Motor dataplate_Table 6)
Pin=Motor Input power

$$\eta = {Pout}/{Pin} \quad (62)$$

$$Pin = Pout + losses \quad (63)$$

$$Pin = 370\ W + 131.82\ W \quad (64)$$

$$Pin = 501.82\ W \quad (65)$$

$$\eta = {370}/{501.82} \quad (66)$$

$$\eta = 73.73\ \% \quad (67)$$

5. Induction Motor Currents

Follow the calculus of IM reactive and active currents (IdwMT and IwMT). This values are shown in Table 8 for all scenarios tested.

- Reactive Current

$$Q = \sqrt{3} * 220 * IdwMT = \sqrt{3} * (W2 - W1) \quad (68)$$

$$\sqrt{3} * 220 * IdwMT = 467.65 \quad (69)$$

$$IdwMT = 1.23\ A\ ** \quad (70)$$

** The difference between IdwMT and Ixm is perfectly acceptable. The difference close to 0,1 A between expected and found values is due to small measurements errors and instruments precision and accuracy errors. It does not impact the presented modeling. Therefore, the results and modeling continue valid.

- Active Current

$$P = (W1 + W2) = 70.0\ W \quad (71)$$

$$Q = \sqrt{3}(W2 - W1) = 467.6\ W \quad (72)$$

$$S = \sqrt{70.0^2 + 467.6^2} = 472.86\ VA \quad (73)$$

$$\cos\emptyset = {P}/{S} = {70}/{472.86} \quad (74)$$

$$\cos\emptyset = 0.148 \quad (75)$$

$$IwMT = Io * \cos\emptyset = 1.35 * 0.148 \quad (76)$$

$$IwMT = 0.20\ A \quad (77)$$

In Figure 9 are shown resistor banks current and no load IM current.

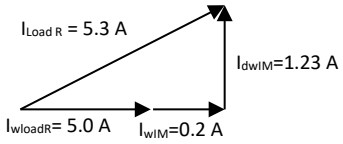

Figure 9: Resistors bank and IM currents in scenarios C

Actuator

ABSTRACT

This paper is the extended reflection of work originally presented in conference of Electrical, Computer and Communication Engineering (ECCE)-CUET 2017, entitled "Automated Anti Collision System for Automobiles". Automated collision avoidance system is a trending technology of science in automobile engineering. The aim of this paper is to design a system which will prevent collision from the front as well as the back for automobiles. This paper gives an overview of secure and smooth journey of car (vehicles) as well as the certainty of human life. This system is controlled by microcontroller ATMEGA32. Two Sharp distance sensors are used to detect object within the danger range where one is for front detection and other is for back detection. A crystal oscillator is used to produce the oscillation and generates the clock pulse of the microcontroller. An LCD and a GLCD are used to give information about the safe distance for front and rear respectively, and a buzzer is used as alarm. An actuator is used as automatic brake and inside the actuator there is a motor driver that runs the actuator. For coding "microC PRO for PIC" is used and "Proteus Design Suite Version 8 Software" is used for simulation.

1. Introduction

All of the greatest achievement of the science, automobile is the most probably the one, which significantly changed human life. A collision avoidance system is a current emerging technology in the field of automobile. It is also known as pre-crash system, forward collision warning system or collision mitigating or car anti-collision system. An automated car anti-collision system is an automobile safety system design to reduce the accidents as road traffic accidents are the largest cause of injury-related deaths worldwide .When driver himself is not concentrating on driving or any other parameters, that time it may cause damage to vehicle (car) as well as a life, that time automated ant-car collision device can play an effective role regarding the danger ahead. An automated anti-collision system device is placed within a car to warn its driver of any dangers that may lie ahead on the road. Once the detection is done this system either provide a warning to the driver when there is an imminent collision or take action autonomously without any driver command (by braking or steering both). This system runs by microcontroller that detects obstacle with speed sensor and stops the vehicle by giving instruction to the actuator. [1].

2. Literature Review

In 2003, Honda introduced the first pre-crash system with autonomous braking. In 2003 Toyota added an "automatic partial pre-crash braking system" to the Celsior36. In 2006 Audi introduced "Braking guard" radar-assisted forward collision warning on AudiQ7. But these could not put a satisfactory performance. These all were not fully automated. In 2009, the U.S. National Highway Traffic Safety Administration (NHTSA) had begun studying to make frontal collision warning systems and lane departure warning systems. In 2012 a research by the Insurance Institute for Highway Safety examined how particular features of crash-avoidance systems affected the number of claims under various forms of insurance coverage. This indicates that two crash-avoidance features provide the biggest benefits; these are (a) autonomous braking that would brake on its own when the driver would not alert to avoid a forward collision and (b) adaptive headlights that would shift the headlights in the direction to the driver steers. At the circa 2012 stage of development, it has found from this research that lane departure systems is not helpful and perhaps harmful. Periodically anti-car collision features are rapidly making their way into the new vehicle fleet. Many car companies like BMW, Audi, Mercedes- Benz , Ford, Toyota, Volvo developed vehicle collision avoidance system from 2003-2009, but not necessarily they were all time effective.[1] Few years back,

some research were carried out on car anti-collision system device using ad hoc wireless network, V2V communication, GPS and radar implementation but all this effort were informatory in type which would give signal to the driver or produced some buzzes or sounds only but finally action would be taken by the driver own self in which there were quite chances of the collision. [2] Since the emergence of mechanical vehicles, road safety has been a major concern, the automated anti-car collision system has gained increasing attention in the last three years. As a result, various automated anti car collision system have originated for assuring safety than the existing system. Research of the Queensland department of Transport and Main Roads has revealed that installation of anti-collision technology could reduce 20 to 40 percent in terms of number and severity of fatal crashes and 30-50 percent of all injuries. Thus it is the main aim to ensure the safety of human life during the collision, the U.S National High Way Traffic Safety Administration has decided to make the pre-crash system mandatory for vehicles. In similar way all new vehicles in Europe will have advanced emergency automated braking system installed by November,2015. A group of automakers and suppliers companies including General Motor(GM), Ford Motor, Nissan Motor are doing research of this automated vehicles collision avoidance system at the University of Michigan. General Motor company has a plan to install this automated vehicles avoidance system in their cars by next two years. Toyota has already given an official announcement that they are going to give this automated vehicles avoidance system in their Toyota and Lexus models by 2017. On the other hand, BMW has already introduced satisfactory and effective anti-car collision system on BMW 7series in 2012. Volvo company has launched this system in Volvo FH by February 2013. Also car company Renault introduced automated active braking system on Renault EspaceV, in October 2014 as well as Volkswagen Passat introduced too on Volkswagen Passat/B8 in 2014. [2] [3] Today, automated anti car collision system generally has camera sensor, distance sensor, actuator, buzzer to detect and warn the drivers of any danger lie ahead on the road, it could be a car, human, pedestrian or any stationary object just as tree or pole etc.

3. System Overview

The block diagram of proposed system is given in Fig.1.Advantage of proposed block diagram over existing technologies is, this system will provide forward collision protection as well as helps to avoid rear collision by displaying messages to the vehicles coming from the back regarding to slow down their vehicle. Here microcontroller does the prime work and it controls the entire task. Two distance sensors are connected to the microcontroller. A LCD, A GLCD and an alarming device are also connected to the microcontroller. A Motor Driver is connected with micro controller to operate an actuator, as actuator needs high current to turn on and microcontroller can't provide this amount of current so motor driver will provide high current to actuator to turn on when it's needed. Distance sensors will be placed in front and back side of a car. They will sense the distance of vehicle in front and rear of the car and send this information to microcontroller. Microcontroller will compare this distance with some preset distances. If the measured distance from the front distance sensor crosses the preset safe distance value, microcontroller will send command to LCD to display close distance and also to write value of that exact distance, At the same time microcontroller will send a pulsating signal to buzzer and buzzer will be buzzed according to that signal. If the measured distance by the front distance sensor crosses the preset value of close distance in microcontroller, microcontroller will tell LCD to show critical distance and the value of that corresponding distance measured by the sensor.

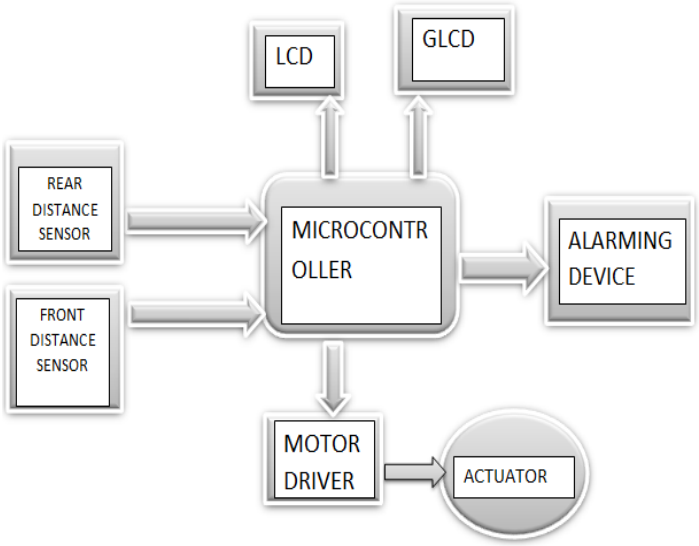

FIG.1. Block diagram of forward and back collision avoidance system for automobiles

At the same time a continuous signal will be send to buzzer and it will buzz continuously to notify the driver that vehicle is exceeding close distance and it's forwarding towards critical distance. Whenever vehicle crosses critical distance and entered into the distance at which collision is must if the car isn't slow down, that moment microcontroller will send signal to motor driver to turn on the actuator and it will stop the car automatically, at the same time LCD will "show actuator on" with distance information. Here, actuator itself works as a brake. For rear distance sensor it will sense the distance of the incoming vehicle and it will sent information to micro controller, if the distance exceed the safe distance value microcontroller will instruct GLCD to display slow down along with distance information, and if the incoming vehicle crosses critical distance microcontroller will instruct GLCD to display "Emergency! Stop" along with distance information to the driver of the incoming vehicle from the back. GLCD could be placed at the rear glass or just above the registration plate of the car containing this proposed safety technology.

4. Preparation to Proteus model

In this section components that were used for simulation and connection diagram has been explained.

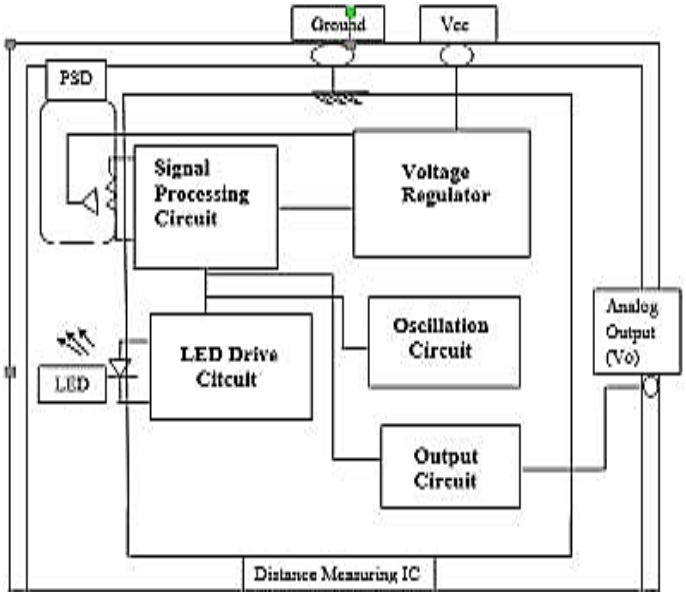
4.1. ATMEGA32

ATMEGA32 is the high-performance, low-power Microchip 8-bit AVR RISC-based microcontroller combines 32KB ISP flash memory with read-while-write capabilities, 1KB EEPROM, 2KB SRAM, 54/69 general purpose I/O lines, 32 general purpose working registers, a JTAG interface for boundary-scan and on-chip debugging/programming, three flexible timer/counters with

compare modes, internal and external interrupts, serial programmable USART, a universal serial interface (USI) with start condition detector, an 8-channel 10-bit A/D converter, programmable watchdog timer with internal oscillator, SPI serial port, and five software selectable power saving modes. The device operates between 1.8-5.5 volts. By executing powerful instructions in a single clock cycle, the device achieves output through approaching 1 MIPS per MHz, balancing power consumption and processing speed. [4]

4.2. Sharp Distance Sensor: Model (GP2Y0A21):

A sensor is an electrical device which is used to measure physical properties and gives corresponding electrical output which is a transmitting impulse as for measurement or control for operation. In this model for measuring the distance of a vehicle Sharp Distance Sensor (GP2Y0A21) is used. Sharp Distance sensor follows triangulation measuring method for measuring distance of an object in front of it, It transmits an IR (Infrared Ray), if any obstacle is present in the path of that IR ray it will bounces back to the sensor and that's how distance is measured. Output of this sensor is analog and this output varies a range from 3.1V at 10cm to 0.4V at 80cm.



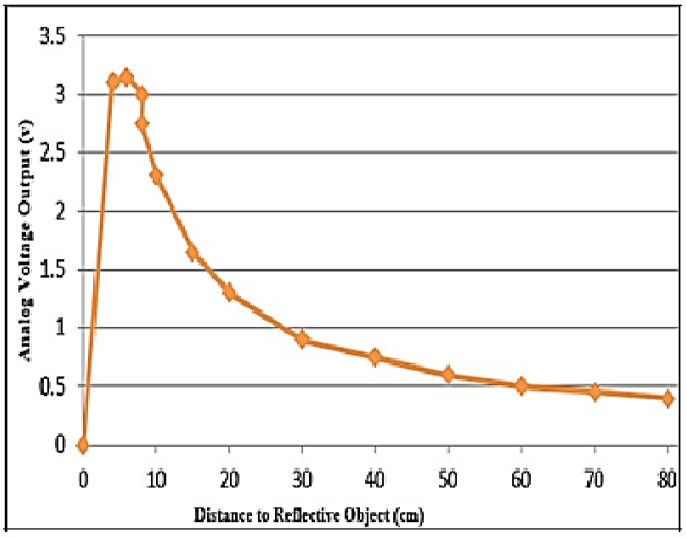


FIG.2.Internal Block Diagram of Sharp Distance Sensor [1]

FIG.2. indicates that this sensor contains IR LED armed with lens which discharges narrow light beam, after reflecting from the object, the beam will be directed through the second lens on a position-sensible photo detector (PSD) and the conductivity of PSD depends on the point where the beam falls, finally conductivity converts to voltage and voltage digitalizes by Analog to digital converter (ADC) [5]. Sharp Distance sensor utilize following equations to convert Distance into digitalized voltage with the help of ADC, and the relation between distance and the Voltage is

$$1 / (d + k) = a * ADC + b \qquad (1)$$

Where, distance is in centimeters.
k is corrective constant (fund using tial-and-error method)
ADC is digitalized value of voltage.
A is linear member (value is determined by the trend line equation)
b is free member (value is determined by the trend line equation).
So, distance d can be expressed from the formula [6]:

$$d = (1 / (a * ADC + B)) – k \qquad (2)$$

If a graph is plotted using equation (2) it will look like FIG.3. After analyzing this graph it can be concluded that the output voltage of the Sharp distance sensor is decreasing with the increased distance, which indicates an inversely proportional relation between distance and output voltage of sharp distance sensor.

4.3. Linear Actuator:

Linear actuator is a device which converts circular motion produced by a conventional electric motor into linear motion. Linear actuators are used in machine tools and industrial machinery, in computer peripherals such as disk drives and printers, in valves and dampers, and in many other places where linear motion is required. Hydraulic or pneumatic cylinders inherently produce linear motion. Many other mechanisms are used to generate linear motion from a rotating motor. In the majority of linear actuator designs, the elementary principle of operation is an inclined plane. The threads of a lead screw act as a continuous ramp that consents a small rotational force to be used over a long distance to complete the movement of a large load over a short distance. The system converts rotary motion (in the form of an electric motor) to linear motion. When an electrical source is applied to the motor, the thread shaft is driven and the nut rides up and down the shaft in the corresponding direction. This action delivers an extension and retraction capability for tasks requiring a linear displacement. Note that in this example the nut and red tube do not rotate, merely "ride" the threads on the spinning shaft up and down. [7]

4.4. Crystal Oscillator (16 MHz):

A crystal oscillator is an electronic oscillator circuit which uses in the mechanical resonance of a vibrating crystal of piezoelectric material to create an electrical signal with a very precise frequency and this frequency is usually used to keep track of time (as in quartz wristwatches), to provide a stable clock signal for digital integrated circuits, and to alleviate frequencies for radio transmitters and receivers, The most common type of piezoelectric resonator used is the quartz crystal, so oscillator circuits incorporating them became known as crystal oscillators but other piezoelectric materials including polycrystalline ceramics are used in similar circuits. [8]. A crystal is a solid in which the constituent atoms, molecules, or ions are packed in a repeatedly ordered, repeating pattern extending in all three spatial dimensions. Almost any object made of an elastic material could be used like a crystal, with appropriate transducers, since all objects have natural resonant frequencies of vibration. For example, steel is very elastic and has a high speed of sound. It was often used in mechanical filters before quartz. The resonant frequency depends on size, shape, elasticity, and the speed of sound in the material. High-frequency crystals are typically cut in the shape of a simple, rectangular plate. Low-frequency crystals, such as those used in digital watches, are typically cut in the shape of a tuning fork. For applications not needing very precise timing, a low-cost ceramic resonator is often used in place of a quartz crystal. When a crystal of quartz is suitably cut and mounted, it can be made to distort in an electric field by applying a voltage to an electrode near or on the crystal. This property is accepted as electrostriction or inverse piezoelectricity. When the field is removed, the quartz will generate an electric field as it returns to its previous shape, and this can generate a voltage. The result is that a quartz crystal behaves like a circuit composed of an inductor, capacitor and resistor, with a precise resonant frequency. Quartz has the further advantage that its elastic constants and its size change in such a way that the frequency dependence on temperature can be very low. The specific characteristics will depend on the mode of vibration and the angle at which the quartz is cut (relative to its crystallographic axes. Therefore, the resonant frequency of the plate, which depends on its size, will not change much, either. This means that a quartz clock, filter or oscillator will remain accurate. For critical applications the quartz oscillator is mounted in a temperature-controlled container, called a crystal oven, and can also be mounted on shock absorbers to prevent perturbation by external mechanical vibrations and oscillation.[8] In this design crystal oscillator is for to activate micro controller internal clock operating circuit.

4.5. Motor Driver (L293D):

L293D is a dual H-bridge motor driver integrated circuit (IC). Motor drivers act as current amplifiers since they take a low-current control signal and provide a higher-current signal. This higher current signal is used to drive the motors.L293D contains two inbuilt H-bridge driver circuits. In its common mode of operation, two DC motors can be driven simultaneously, both in forward and reverse direction. The motor operations of two motors can be controlled by input logic at pins 2 and 7 and 10 and 15. Input logic 00 or 11 will stop the corresponding motor. Logic 01 and 10 will rotate it in clockwise and anticlockwise. Enable pins 1 and 9 (corresponding to the two motors) must be high for motors to start operating. When an enable input is high, the associated driver gets enabled. As a result, the outputs become active and work in phase with their inputs. Similarly, when the enable input is low, that driver is disabled, and their outputs are off and in the high-impedance state. [9]

4.6. LCD Display (16x2):

LCD (Liquid Crystal Display) screen is an electronic display module and find a wide range of applications. A 16x2 LCD display is very elementary module and is very usually used in various devices and circuits. These modules are preferred over seven segments and other multi segment LEDs. The reasons is LCDs are economical, easily programmable, have no limitation of displaying special and even custom characters (unlike in seven segments), animations and so on. A 16x2 LCD means it can display 16 characters per line and there are 2 such lines. In this LCD each character is displayed in 5x7 pixel matrix. This LCD has two registers, namely, Command and Data. The command register stores the command instructions given to the LCD. A command is an instruction given to LCD to do a predefined task like initializing it, dissipating its screen, setting the cursor position, controlling display etc. The data register stores the data to be displayed on the LCD. The data is the ASCII value of the character to be displayed on the LCD. [10]

4.7. GLCD (AMPIRE128x64):

GLCD is a graphic liquid crystal display. AMPIRE (128*X*64) graphic LCD contains 128 coulombs and 64 rows. It can display data in (128x64) matrix. Graphical LCDs are different from the ordinary alphanumeric LCDS, like (16x1), (16x2), (16x4), (20x1), (20x2) etc. They (ordinary) can print only characters or custom made characters. They have a fixed size for displaying a character normally (5x7) or (5x8) matrix. Where as in graphical LCD we have 128x64=8192 dots each dot can be lit up as per coding or can make pixels with 8 dots that is 8192/8=1024 pixels, graphical LCD is controlled by two KS0108 controllers. A single KS0108 controller is capable of controlling 40 characters so for controlling a graphical LCD we need two KS0108 controllers and the 128x64 LCD is divided into two equal halves with each half being controlled by a separate KS0108 controller. [11] Special types of shapes or picture can be drawn in GLCD by exciting it DOTS.

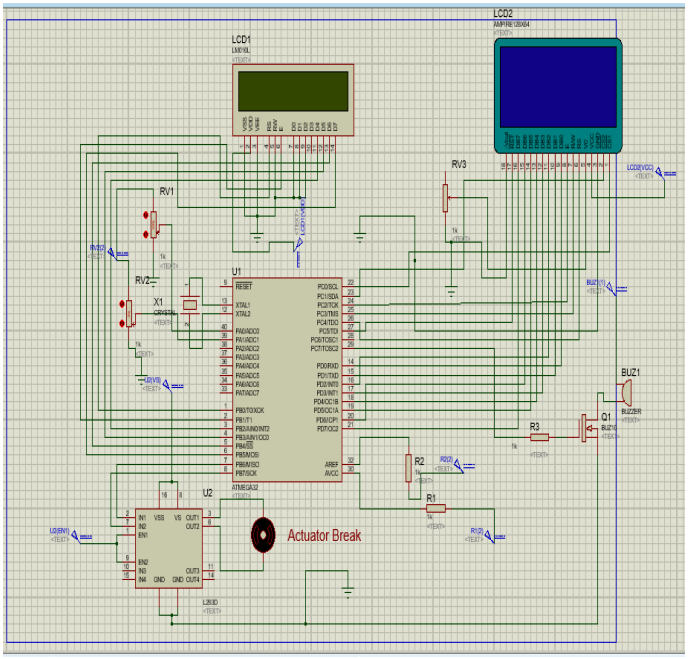
4.8. MOSFET:

MOSFET is a three terminal semi-conductor device it consists of gate drain and source. It works in three region such as cutoff active and saturation. To use MOSFET as a switch it need to operate in active region and for amplification any input signal it will work in saturation region. Whenever a signal will be given in its gate it will activate. In this model MOSFET is used as a switch for alarming circuit (buzzer circuit). It's used in a way that voltage across its drain to source is close to zero to make it work as a switch.

4.9. Proteus Model:

FIG.4 is the proteus model of an automatic forward and backward collision avoidance system. This microcontroller works within 20nsec. Its operating voltage range is: 2.0V to 5.5V. Two

sharp distance sensors are used to measure the distance of the obstacle for front and rear respectively, crystal oscillator is also connected to the microcontroller, it produces the oscillation and generates the clock pulse of the microcontroller. There is a buzzer used as alarm and it is controlled by a MOSFET, microcontroller turns on the MOSFET which work as a switch for buzzer. A motor driver L293D is used for controlling the actuator. Actuator will be connected to the car braking system.



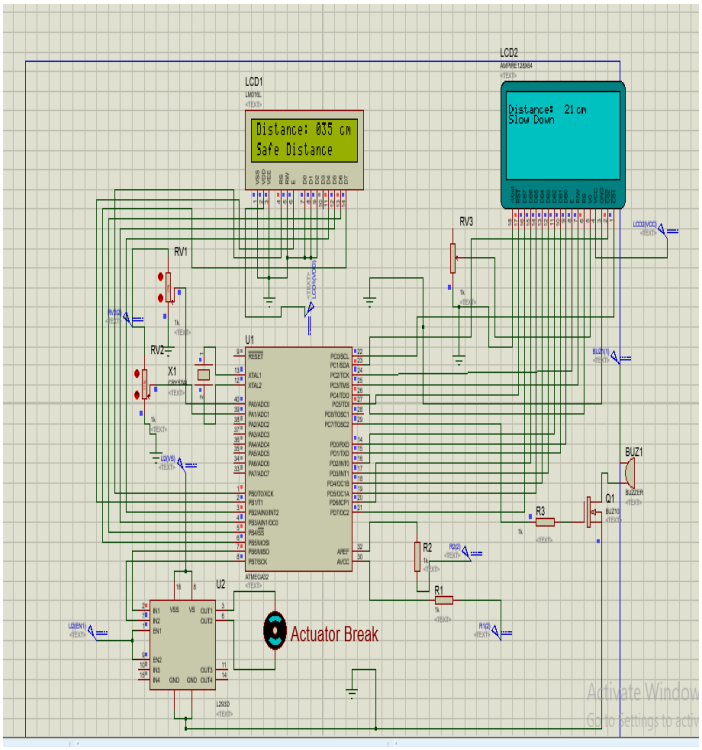


FIG.4. Proteus model of the system

From FIG.4 it is found that microcontroller pin7 (PB6/MISO) and pin8 (PB7/SCK) is connected to motor driver pin2 (IN1) and pin7 (IN2). From this connection of the configuration, motor driver gets command from microcontroller. 1k ohm resistors are connected to microcontroller pin30 and 32 with constant 5V DC for operating of microcontroller and ADC comparison respectively. ADC comparison is used in microcontroller because it will help microcontroller to process the measured distance by distance sensor in digital format. Microcontroller pin30 and 40 are connected to sharp distance sensors but there is no distance sensor device in Proteus so potentiometers are used instead of it. The highest readings of these potentiometers are 5k ohm and operating voltage +2.5V. Two port of actuator is connected to motor driver pin3 (OUT1) and pin6 (OUT2) A DC gear motor is used as an actuator in simulation for analyzing the motor driver behavior to actuator due to absence of an actuator in proteus model. Two ports of crystal oscillator are connected to microcontroller pin13 and pin12 is used for generating clock pulse of microcontroller. Here is a LCD display which pin11 (D4), pin12 (D5), pin13 (D6), pin14 (D7) are connected to microcontroller pin3 (PB2), pin4 (PB3/PGM), pin5 (PB4), pin6 (PBS) respectively, so that, LCD display can get signal from microcontroller and gives information about the obstacle.

Microcontroller pin29 (PC7) is connected to a MOSFET by a 1kohm resistor R2. Microcontroller itself cannot turn the buzzer on for this reason a MOSFET has been used. Microcontroller gives instruction to the MOSFET to turns the buzzer on and it operates at +12V. GLCD pin9-16 (DB0-DB7) is connected with microcontroller pin14-21 (PD0-PD7) which will give information regarding rear obstacle distance. GLCD control pins, 1(CS1), 2(CS2), 6(RS), 7(RW), 8(E), 17(RST) is connected to microcontroller pin22 (PC0),pin23 (PC1), pin26 (PC4),pin25 (PC3), pin24 (PC2),pin27 (PC5) respectively, so that GLCD can get signal from microcontroller and gives information about the distance which should be kept to avoid collision, or to stop to avoid collision towards the car approaching from the back. A program is written in MIKROC software, which is the instruction for microcontroller action and HEX file of that program is used for simulation.

5. Simulation and Result

From FIG.5.we can conclude that if there is a vehicle in front of a car containing this collision avoidance system at a distance of 35 cm microcontroller will command LCD to Display “safe distance “to the driver of the car, and at the same time if there is a vehicle approaching from rear and if it’s distance is 21 cm micro controller will instruct GLCD to display the distance information along with the message “Slow Down’’ to the incoming car from the back.

From FIG.6. we can conclude that if there is a vehicle in front of a car containing this collision avoidance system at a distance of less than 26 cm microcontroller will command LCD to Display “Close Distance” to the driver of the car and microcontroller will send activation signal towards buzzer circuit, and at the same time if there is a vehicle approaching from rear and if it’s distance is less than 15 cm micro controller will instruct GLCD to display the distance information along with the message “Emergency! Stop’’ to the incoming car from the back.

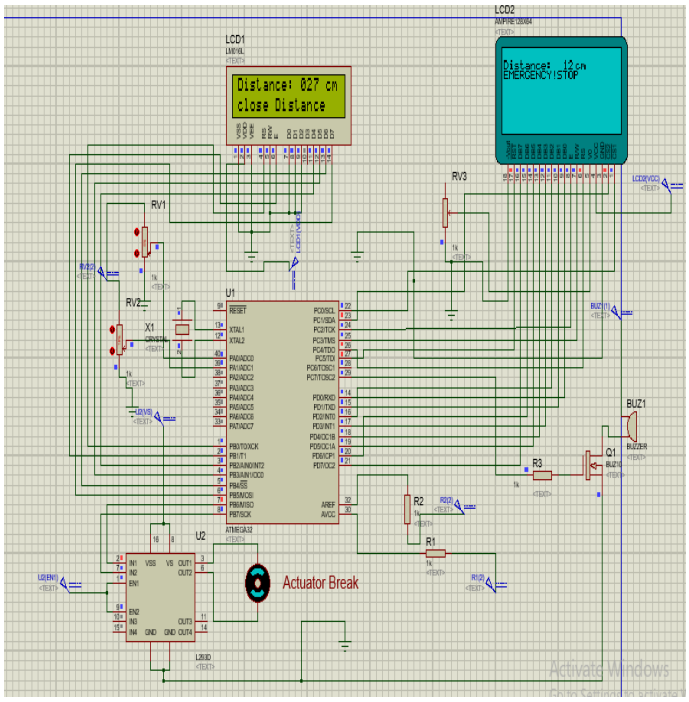

FIG.6. Result for close distance for front and emergency stop distance for rear

From FIG.7. shows that if there is a vehicle in front of a car containing this collision avoidance system at a distance of 18 cm microcontroller will command LCD to Display "Critical Distance" to the driver of the car and microcontroller will send activation signal towards buzzer circuit, and at the same time if there is a vehicle approaching from rear and if it's distance is27 cm micro controller will instruct GLCD to display the distance information along with the message "Maintain This Distance'' to the incoming car from the back.

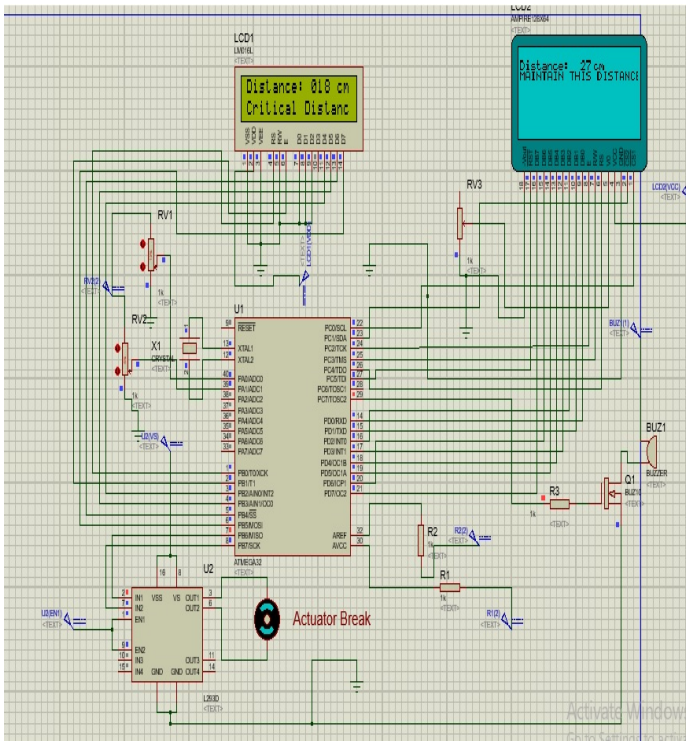

FIG.7. Result for critical distance for front and safe distance for rear

From FIG.8. we can conclude that if there is a vehicle in front of a car containing this collision avoidance system at a distance of 13 cm microcontroller will command LCD to Display "Actuator On" to the driver of the car and microcontroller will instruct motor driver to activate actuator, motor driver will send high current towards actuator which will cause actuator to turn on and this actuator will automatically press the brake of the car to stop. If there is a vehicle approaching from rear and if it's distance is less than 19 cm micro controller will instruct GLCD to display the distance information along with the message of "TENT TO COLLISION'' to the incoming car from the back.

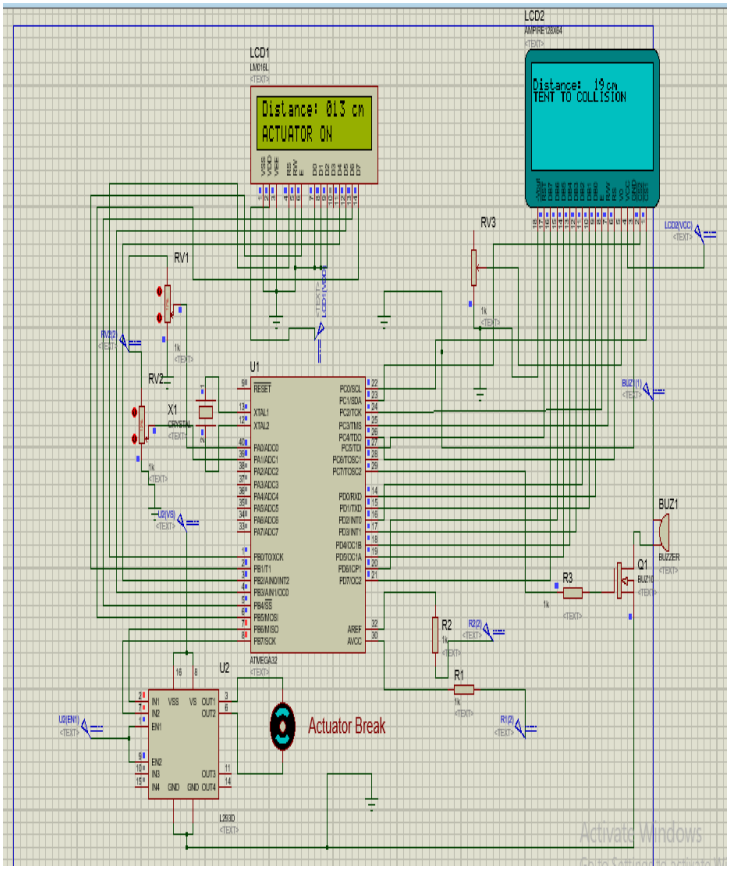

FIG.8. Result for Actuator On distance for front and tent to collision distance for rear

6. Result analysis:

During simulation distance was taken in small scale as in cm. For forward collision prevention system instruction for microcontroller was set in a way if measured distance by distance sensor is above 30 cm it will consider this distance to safe distance and it will instruct LCD to display to show the message safe distance along with that distance value. If the value of distance varies from 20 cm to 29 cm microcontroller will instruct LCD to show Close distance along with the value of the distance measured by the sharp distance sensor, further more microcontroller will send a pulsating signal to buzzer and buzzer will be turn on, this pulsating signal will cause change in the sound frequency of that buzzer. And if distance ranges from 15cm to 19 cm micro controller will instruct LCD to display the message "critical distance along with the measured distance "at the same time microcontroller will send a continuous signal to the buzzer and it

will buzzed, this buzzing frequency will be different from the previous one. And any distance less than 15 cm microcontroller will instruct motor driver to turn on the actuation system to stop the car. At the same time LCD will display "Actuator on along with distance information". From the simulated result, which were shown in the previous section; it is seen that when sharp distance sensors measure a distance of 35 cm LCD shows the message of safe distance which is larger than 30 cm. When measured distance by sensor was found 27 cm LCD shows the messages that this distance is close distance and at the same time a pulsating signal was sent to buzzer circuit. This measured distance was less than 29 cm. When distance was found about 18 cm LCD display message that this distance is critical distance, which was less than 20 cm. At the same time buzzer circuit will be turn on as micro controller sends a continuous signal to buzzer. From FIG.7 it can be seen that a red dot is appearing in front of the R3 resistor and which was connected with the microcontroller PC7 port and same red dot is appearing in that particular pin which indicates that microcontroller sending continuous signal to buzzer to buzz. Finally when distance was measured 13 cm which is less than 15 cm LCD displays the message that actuator on along with the measured value of distance in cm. From FIG.8 it is seen that there were two red dots in pin 2 and 7 of the motor driver which were connected to microcontroller pin 7 and pin 8 and same dots appear across those pins, which indicates microcontroller is sending high signal to motor driver to turn on the actuator or the motor of the actuator system. As motor driver needs high or low logic in its both pin to stop the motor of actuating signal and microcontroller is sending high signal to that motor driver is evidence that microcontroller is actually control the braking system of the vehicle and it will cause the car to stop.

For back collision avoidance system, the set of instruction for microcontroller was if measured distance is above 25cm it will be considered as a safe distance and GLCD will show "Maintain this distance" along with measured distance. Any distance less than 25 cm and greater 20 cm microcontroller will instruct GLCD to show "slowdown" along with measured distance value. Any distance ranges 19 cm to 15 cm microcontroller will instruct GLCD to display "tent to collision" along with the distance that was measured by sharp distance sensor. Finally any distance measured by the sharp distance sensor less than 15 cm microcontroller will instruct GLCD to display "Emergency! Stop". FIG.5 to FIG.8 in the simulation and result section it's seen that the measured distance by rear sharp distance sensor was 21cm, 12c m, 27 cm, 19 cm respectively, this distances follow the ranges that were mentioned above . And GLCD is displaying same sort of the message for that particular range of distances. From the above discussion it can be concluded that microcontroller is executing its instruction perfectly as it was given to it by a program which was written in MIKROC PRO for AVR, which results in that proposed design system is perfectly working during simulation. But when this system will be practically implemented for vehicle this distance range wouldn't be applicable, virtually all vehicles' or cars' road braking performance test indicate stopping distances for 60 mph are typically 36m to43m [12]. So when this system will be implemented in reality only the set of instructions will need to be changed which will be loaded in microcontroller.

7. Implemented forward collision system

The design of the research work in this paper is the extended design of the implementation of *"Automated Anti Collision System for Automobiles"* [1] which has been implemented successfully in practical by prototype prior, where a Sharp distance sensor, microcontroller PIC16f876a, motor driver, linear actuator alarming device and LCD display were used. From following figures we will see the complete view of previously implemented prototype device along with its distance ranges.

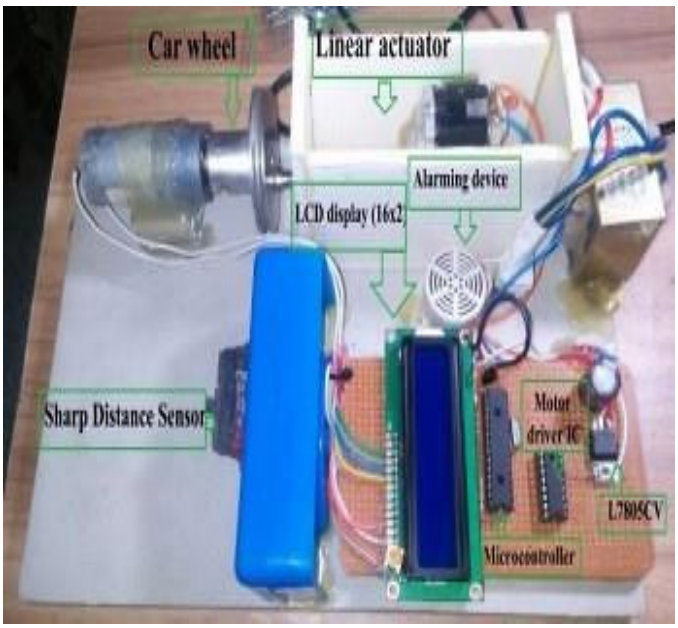

FIG.9: Implemented Prototype Device

From FIG.9.we can see the complete view of previously implemented prototype device.

FIG.10. Safe distance of the prototype device

From FIG.10.we can see the distance is 30 cm which was considered as safe distance and the actuator did not work. In FIG.11.and FIG.12.we can see distances as follow 24 cm and 09 cm whereas, 21 cm gave alarm to the actuator and in 09 cm, and actuator started working. In addition, the research of this paper has been done with the back collision avoidance system along with this mentioned forward collision avoidance system. Also more progress has been done about the forward obstacles detection distance ranges. Due to shortage of time this recent extended research work prototype was not possible to implement.

8. Application and Improvement plan of the system

Proposed system which is described in this paper will be implemented by prototype practically very soon. Near future, during manufacture it can be implanted in motor bikes taxi-cab, car, and truck even in aircraft system. In winter when roads might be rarely seen due to fogs this system will notify the person who will be in control of that vehicle about other vehicles or any other obstacles ahead of his vehicle. Which will help him drive safely his vehicle, and it will make him feel comfortable while driving and it will also extinguish his fear. This will reduce terrifying collision of the vehicles and not only the winter, in other season it will notify driver to maintain a safe distance by alarming sound or showing distance information in LCD. If driver begin to avoid the alarming sound and start to drive recklessly system will forcefully stop the car to avoid accident. Researchers of this paper has some future improvement plan for making this system more convenient and add other features to make this system more accurate. For improving this system sonar system will be implemented due to its long range detection, Emergency light or special kind of alarm will be used to notify the vehicle to maintain safe distance, graphical symbols will be added along with messages in GLCD. Wireless Fidelity (Wi-Fi) technology can be used for transferring information between successive vehicle about the distance and what speed should the kept for safety, furthermore, Dual Infra-Red Obstacle Detector (DROD40) can be used in this system to determine obstacle in every side such as left, right and ahead distinctly. In future, researchers of this paper have plan to design a system which will monitor driver health condition to judge his fitness for driving if he isn't fit, vehicle will not start. So, this will reduce almost 60% of accident.

Conclusion

Technologies, new inventions and transport system play an important role in human lives. Mankind is becoming habituated to these new inventions. Especially transport system without this mankind even think about their daily activities and even can step outside from their home. As every other invention this transport system has adverse effect too, and as usual mankind is responsible for this kind of adverse effect. People are always in rush to reach their destination as early as possible to save their time or to reach their destination on time without thinking about their lives value, what would happen if they met up with an accident which means colliding with other vehicle for their tendency to go somewhere within a flash. This results in injury or loses of their lives. The prime motive of the design is to reduce these accidents. In other words it can be concluded that this design is used to save human lives from the loss due to accident and also to ensure safe and comfortable journey.

Acknowledgment

First and foremost, we want to express our gratitude towards Almighty creator for his blessings without which it would not be possible to complete this work successfully afterwards want to acknowledge the constant support received from our family. It is an honor to express our heartiest gratitude to MS. Muhit, Assistant Professor, Faculty of Electrical and Electronic Engineering, AIUB, for his immense support and encouragement to improvise this designed system. And finally especial gratitude to honorable Mr. Chowdhury Akram Hossain, Assistant Professor, Faculty of Electrical and Electronic Engineering, AIUB. Without his motivation this work wouldn't be possible to advance so far. Finally, any errors are our own and should not tarnish the reputations of these esteemed persons.

ABSTRACT

This application developing for the project OCEMA comes as result of architecture building in Android, then the development of a professional modeling in Talend Open Studio for Big Data, which enabled the integration of data from many data sources. One of its uses is the quick identification of people found in areas affected by natural disasters. The application identifies the persons who do not have an ID card, or another identification document, by using identification through fingerprint or personal number. OCEMA Application has access to all the agencies involved in natural disasters managing, such as ISK, HMIK, MIK, FSK and CRA. This application is developed to connect to web applications as well, such as applications, which gather real time information on earthquakes and weather in the world.
The study of literature and the actual work with these systems has shown some important components of success for DWH systems, DataMart and mobile application development.

1. Introduction

In the year 2002 alone, disasters affected a staggering 680 million people worldwide. Natural disasters include bring earthquakes, flooding, droughts, heat waves, cold spells and events that destroy countries, businesses and individual property and well-being.
The goal of this study is to investigate the adoption of cell phones as preparedness efforts during the natural disaster seasons in a developing country. Since Kosovo is a country vulnerable to natural disasters, the present study aims to investigate the adoption of cell phones for natural disaster preparedness [1]

OCEMA applications initially are secured by a username and password, and then divided in 5 buttons, such as: ISK, CRA, HMIK, MIK and FSK. This application enables access to real time information, such as in the case of the agency of civil register, offering two possibilities to identify the victims of natural disasters.

It uses the identification through personal number, but in cases where there is no ID card, the identification can be done using the fingerprints. Part of this application is access to institutions such as the Institution of Seismology, the Medical Institution, the Hydro meteorological Institution and the Firefighter's Service.

These institutions have updated information. Beside this, the OCEMA application has the possibility to access important web pages in order to monitor climate and seismic conditions in world level.

2. Mobile Platforms

The four most common smart phone operating systems, by market share in the third quarter of 2013 (IDC 2013) are:
•Android by Google, with a distinct dominance at 81 %,
•iOS, on Apple's iPhone, at 12.9 %,
•Windows Phone by Microsoft at 3.6 %
•and BlackBerry at 1.7 %.

There are many significant differences between these platforms. Some are visible to the users such as availability of specific features or design of the user interface (UI), and some are invisible to the users but affect the developers of mobile applications.

2.1. Android architecture

Starting from the bottom we have Linux Kernel, Android is built up on the Linux Kernel. Linux is already being used extensively from so many years and its kernel had received so many security patches. Linux Kernel provides basic system functionality like

[*]Zijadin Krasniqi, Tax Administration of Kosovo, zijadinkrasniqi@hotmail.com

process management, memory management, device management like camera, keypad, display etc.

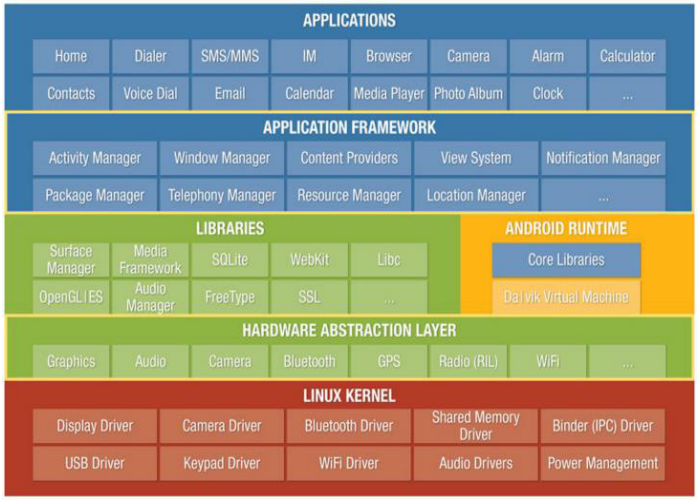

Figure 1: Android Architecture [2]

As the base for a mobile computing environment, the Linux kernel provides Android with several key security features, including:

- A user-based permissions model
- Process isolation
- Extensible mechanism for secure IPC
- The ability to remove unnecessary and potentially insecure parts of the kernel.

As a multiuser operating system, a fundamental security objective of the Linux kernel is to isolate user resources from one another. The Linux security philosophy is to protect user resources from one another [2]

Taking into consideration the Android as a target platform for application comes as the result of reviewing various works using Android technology.

The Android SDK allows application development with great ease. There are many inbuilt features and tools in an Android device, which can be integrated and programmed to be used as and when required from within the application [3]

3. Case study: SQLite_OCEMA database integration can be implemented in Android mobile devices

The operational Centre of the Emergency Management Agency requires analysis in daily, weekly and monthly bases. What is most important is the capability of real time data analysis. Therefore, this increases the need for data collection and data integration in a single database. The scope is to be able to analyze possible problems faced during emergency situations and natural hazards and then determine the highest levels of entities from which we can collect data.

The following data form the bases of the conceptual model of OCEMA database, which we are going to build.

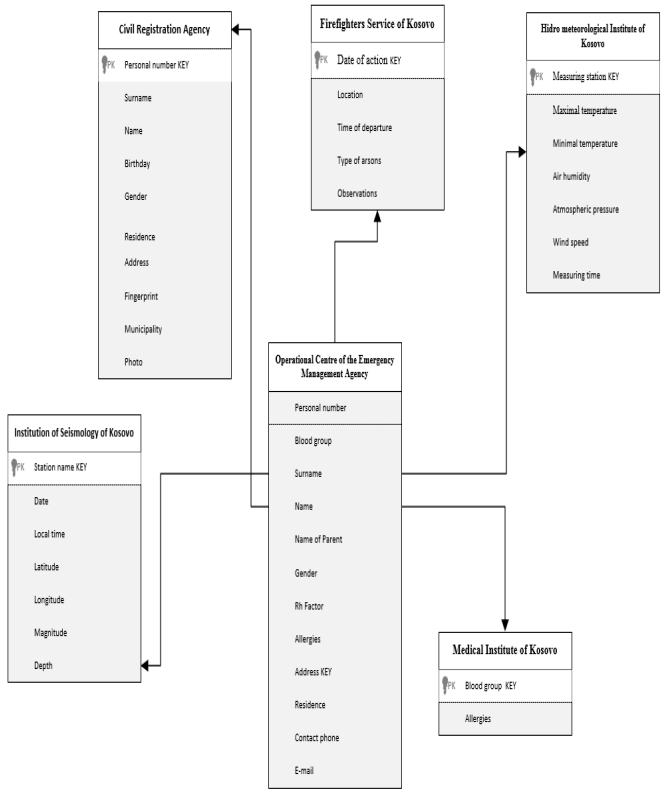

Figure 2: The Entity Relationship diagram of OCEMA database

We start with the description of the entities used in the OCEMA database.

The entity named Medical Institute of Kosovo is composed of the following data: Blood group for the patients and the eventual allergies present in the population. Entry data from MIK are an important information source at national level as far as the health of the population is concerned.

The entity named Civil Registry Agency includes several fields involving records on entry data regarding the civil registration at a national level, among them including the following characteristics: personal number, surname, name, date of birth, residence, address, fingerprints, district and photo.

All these attributes of the CRA entity include the population's records. In our study, the principal searching attributes on individuals will be the personal number and the fingerprints.
The entity named Institute of Seismology of Kosovo includes the following attributes: name of the weather station from where we get the real time data on seismic waves and information from the instruments of online monitoring of seismic waves.

Then in this entity we include: the date of seismic waves, local time, latitude, longitude, magnitude and seismic depth.
The data entity generated by the Hydro meteorological Institute of Kosovo includes a very significant dynamics of available data aiming the comprehensive real time monitoring in order to prevent flooding from rainfall, snow and also extreme draught caused by extreme maximal temperatures.

This entity includes the following attributes: the weather measuring station, maximal temperature, minimal temperature, air humidity, atmospheric pressure, wind speed, measuring time. It is very important to keep under control the continuous monitoring and observation of many factors, which affect arsons, such as the case of arsons involving homes, forests and pastures.

The entity of Firefighters Service is composed of the following attributes: date of action, location, time of departure, type of arsons, observations. All of these offer a very good opportunity to get information from this very important institution.

4. Data integration in SQLite_OCEMA through Talend Open Studio for Big Data

We have chosen SQLite as the main database, where we will integrate the tables from Oracle SQL, such as: CRA, HMIK, MIK, ISK and FSK. Most of the enterprise companies use Oracle in their applications in order to load data. In the case of data loading in SQLite_OCEMA, we have built the following job in Talend Open Studio for Big Data, as shown in the Figure below:

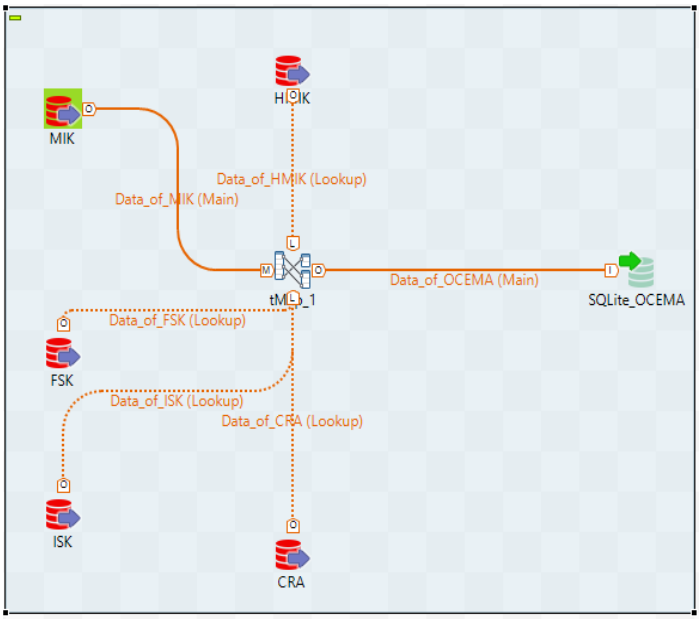

Figure 3: Talend's Job for data loading from the ORACLE SQL tables in SQLite_OCEMA

These heterogeneous data sources, HMIK, MIK, FSK, ISK and CRA, then will be stored in SQLite_OCEMA databases, as shown in the TOS schema.

An important step in ensuring the job developing with ETL is the successful connection between TOS and SQLite_OCEMA database.

4.1. Projecting the SQLite _OCEMA database

Unlike most RDBMS products, SQLite does not have client/server architecture. Most large-scale database systems have a large server package that makes up the database engine.

The database server often consists of multiple processes that work in concert to manage client connection, I/O files, caches, query optimization and query processing. A database instance typically consists of a large number of files organized into one or more directory trees on the server's file system.

In order to access the database, all the files must be present and correct. This can make it somewhat difficult to move or reliably back up a database instance. To access the database, client software libraries are typically provided by the database vendor. These libraries must be integrated into any client application that wishes to access the database server.

These client libraries provide APIs to find and connect to the database server, as well as set up and execute database queries and commands. The Figure 4 below shows how everything fits together in a typical client/server RDBMS.

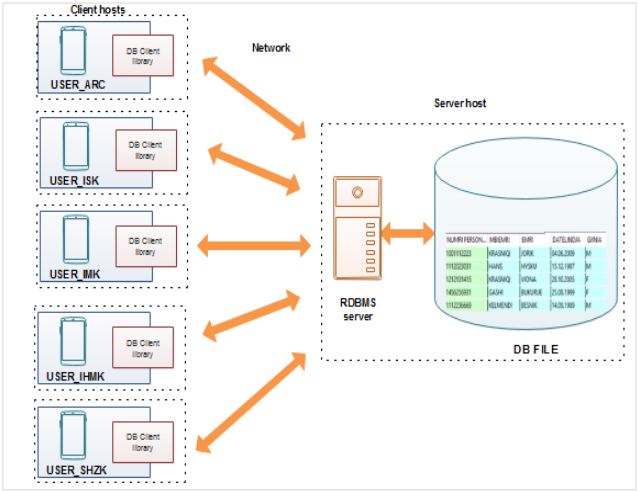

Figure 4: Client/server RDBMS architecture [4]

In contrast, SQLite does not have a separate server. The entire database engine is integrated into whatever application needs to access a database.

The only shared resource among applications is the single database file as it sits on disk. If we need to move or back up the database, we can simply copy the file. Below, in the Figure 5, we will see the SQLite architecture.

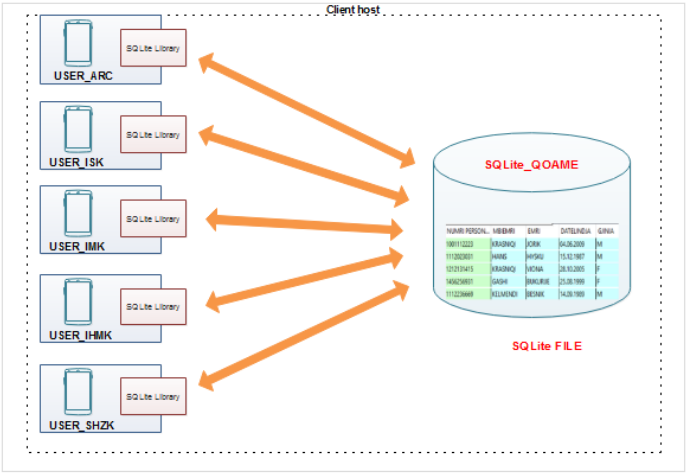

Figure 5: The SQLite server architecture [4]

By eliminating the server, a significant amount of complexity is removed. This simplifies the software components and nearly eliminates the need for advanced operating support. Unlike a traditional RDBMS server that requires advanced multitasking and high performance inter-process communication, SQLite requires little more than the ability to read and write to some type of storage.SQLite is designed to be integrated directly into an executable. This eliminated the need for an external library and simplifies distribution and installation. Removing external dependencies also removes most versioning issues.

If the SQLite code is built right into the application, we never need to worry about linking to the correct version of a client library or that the client library is version-compatible with the database server. Eliminating the server imposes some restrictions. SQLite is designed to address localize storage needs, such as a web server accessing the local database. This means it isn't well suited for situations where multiple client machines need to access a centralized database. That situation is more representative of client/server architecture and is better serviced by a database system that uses the same architecture. [4]

4.2. SQLite_OCEMA database-the case of android application for CRA

Android uses the SQLite database system, which is an open-source, stand-alone SQL database, widely used by many popular applications.

SQLite is a lightweight transactional database engine that occupies a small amount of disk storage and memory, thus, it is a perfect choice for creating databases on many mobile operating systems such as Android and iOS [2]

The Android platform offers full support for SQLite databases. The created database will be accessible by name from each of the classes inside the application, not those from outside. In our case, when we are searching the data from the Civil Registration Agency in case of emergencies and natural disasters, we have the possibility to search for missing people during lifesaving operations and also in the warning period of natural hazards.

Thus, we use the personal number identification method to find people struck there where the natural disaster happened. If we take the Civil Registration Agency table of the SQLite_OCEMA database as in the following Table 1:

Table 1: Civil Registration Agency data table in the SQLite_OCEMA database.

5. Searching the SQLite_OCEMA data using the personal number

If we set as criteria the searching of data using the personal number method from the SQLite _OCEMA database and we use the recommended methods to create a new SQLite database.

When a database has been successfully opened, the SQLite Open Helper will cache it, so you can (and should) use these methods each time you query or perform a transaction on the database, rather than caching the open database within your application.

A call to getWritableDatabase can fail due to disk space or permission issues, so it's good practice to fall back to getReadableDatabase method for database queries if necessary. In most cases this method will provide the same, cached writeable database instance as getWritableDatabase [5]. An example is shown in the Figure 6.

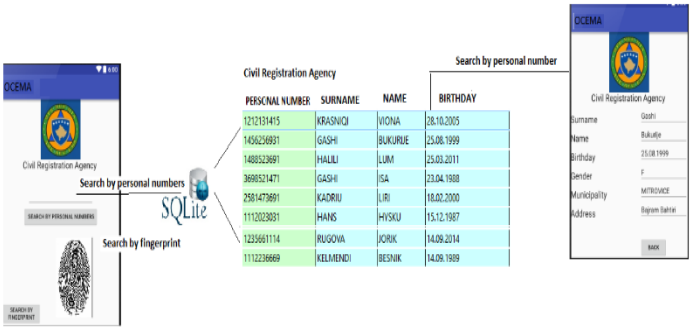

Figure 6: Searching by personal number in SQLite_OCEMA database [6]

This is a part of the application development. In this part, we search for people struck by natural disasters and emergency situations by using the fingerprint method, as shown in the Figure.

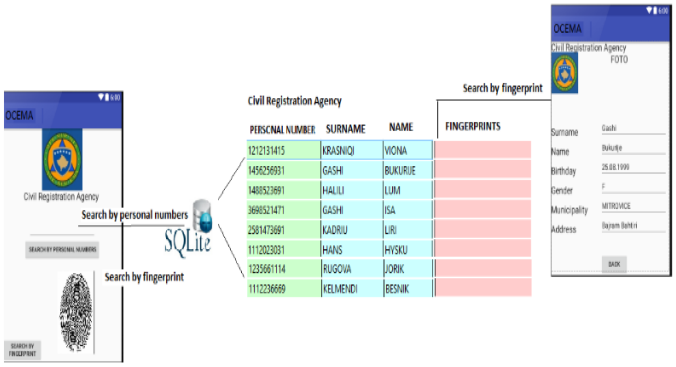

Figure 7: Searching by using the fingerprints in SQLite_OCEMA database.[6]

This result is displayed every time the user launches the matching activity from our proposed application, by comparing the initial fingerprint with the ones stored in database.

One utility of the proposed application consists in quick identification of the people struck in areas hit by natural hazards or emergency operations, in the quick identification of those people who do not have an ID card or another document of identification, by using the fingerprints identification method.

Also, the application could be deployed in the access systems of the public institutions like schools, libraries, hospitals and so on[7]

6. SQLite_OCEMA database- the case of android application for ISK

The Institution of Seismology has a large number of weather measuring stations across the territory of Kosovo. These stations transmit their data to the institute on daily, weekly and monthly bases. Upon creating and building the SQLite_OCEMA database, these data can be reported in a shorter time, better to say in real time across all the weather measuring stations.

By clicking on the ISK (Institute of Seismology of Kosovo) button in the OCEMA basic application, we gain access to search the latest updated ISK data, as shown below in the Figure 8.

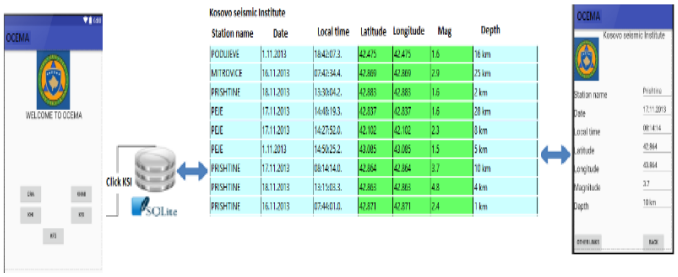

Figure 8: Access to the data of Institute of Seismology of Kosovo. [6]

After the creation of the Institution of Seismology of Kosovo table in the SQLite_OCEMA database, we can click on the ISK button to search the latest updated data of this institution, including magnitude of seismic waves, seismic depth, geographical position, latitude-longitude, date and time of the seismic wave.

7. SQLite_OCEMA database, the case of Android application for HMIK

The Hydro meteorological Institute of Kosovo has a large number of weather measuring stations across the territory of Kosovo. These stations transmit their data to the institute on daily, weekly and monthly bases. Upon creating and building the SQLite_OCEMA database, these data can be reported in a shorter time, better to say in real time across all the stations, including data from the river flows, data from sensors placed in locations where there is more snow.

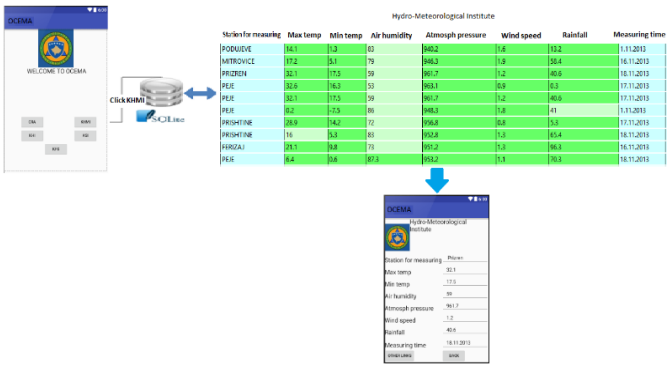

Figure 9: Data from SQLite database for the HMIK case [6]

Thanks to this application we have been able to get detailed information from all the weather measuring stations in the territory of Kosovo, which provide a representation of warnings in case of flooding from atmospheric precipitations, wind speed, air humidity and the maximum and minimum temperatures.

8. Conclusion

Mobile technology has shown a considerable impact on society over the past few years. Gradually, this technology has become part of every person's life and is the easiest mode to deliver information. The development of application OCEMA for the doctoral project comes as a result of building architecture in Android Platform, then a professional model in Talend Open Studio for Big Data, which enabled the data integration from multiple data sources. Then we have developed the applications in Android Platform using the Java programming language. We have made it possible to reach near real time representation of the sources.

It is widely known that during natural disasters and emergencies, we do not have all the information available, but in those moments, everything is important, above all the information related to the human factor. EMA should be aware of these kinds of situations and precede the capacity building in systems communication and developing applications for the management of emergencies and natural disasters.

Intrinsic layer

ABSTRACT

CdTe-based photovoltaic (PV) cells provide the lowest EBPT (energy payback time) and emit less amount of GHG (green house gases) among different types of PV cells. Thus, it is very essential to enhance the efficiency of CdTe-based solar cells. A high efficiency CdTe/CdS p-i-n heterostructure solar cell is designed and the performance of the cell is investigated. All the simulations have been done using AMPS 1D (Analysis of Microelectronic and Photonic Structures) simulator. The cell consists of a transparent conducting oxide (TCO) layer (ZnO), a window layer (n-type CdS), an intrinsic layer (CdTe), an absorber layer (p-type CdTe) and a highly doped CdTe and Si as back surface field (BSF) layer. After the optimization of layer thicknesses and doping densities of different layers, we obtained a conversion efficiency of 26.01% for a total cell thickness of 1.8 μm. It is also found that the conversion efficiency can be increased by simply increasing the thickness of intrinsic layer. At 1.5 AM solar irradiance, the proposed cell structure attained a V_{oc} of 1.09 V, a J_{sc} of 26.78 mA/cm^2, and a fill factor of 89%, reaching an overall conversion efficiency of 26.01% with CdTe as BSF layer.

1. Introduction

This paper is an extension of our previous work presented in *ICAEESE 2016* [1]. The rapidly rising demand of world energy supply and the depletion of fossil fuel impose crucial challenges concerning today's energy requirement context. It is also worth mentioning that, the surfeit burning up of fossil fuels renders threatening global warming emissions (GWE) ascribing alarming rise of terrestrial temperature while imposing serious environmental pollutions by particulate materials [2]. These aforementioned issues necessitate the blooming of alternatively dependable, affordable-cost consistent energy sources. To meet these requirements various plausible renewable energy technologies have been thriven so far. Among these alternative technologies solar photovoltaic (PV) is thought to be as one of the most potential and reliable green energy concepts that assures the direct conversion of incident solar irradiation into electrical energy. The power extracted from PV architectures is popularly being adopted and deployed in the remote areas while ensuring the minimization of electrical power transmission losses. PV power can also be potentially applied in vehicular transportation that can ensure the diminishing of global warming emissions in near future. From purely economic point of view, the flourishing market of PV is generating a shortfall in the storage of highly cost silicon wafers which takes almost 50% of the total manufacturing cost. Therefore, it fosters an opportunity for thin film solar technology to create credentials in the market of PV modules because of its moderate cost. Among different types of thin film based modules, CdS/CdTe thin-film solar cells reveals significant suitability owing to its distinctive characteristics encompassing the following aspects. Firstly, the energy bandgap of CdTe is 1.45 eV, which is favorably well-matched to the spectrum of solar radiation. It also lies in the category of direct bandgap semiconductor guiding to fairly strong light absorption with reduced generation of heat. Besides, the doping of CdTe as p-type semiconductor film as well as the formation of p-n heterojunction with the inclusion of CdS is found to be much easier. Moreover, CdS exhibits wide energy-gap of 2.4 eV and can be fabricated as n-type adopting undemanding usual techniques of film deposition [3-5]. In the meanwhile, various less-costly and manageable atomic congregation techniques have been developed for the growth of CdS/CdTe solar cells [6-7]. Also it should be mentioned that, a thickness of around 4 microns absorber layer of CdTe is almost appropriate for capturing the entire solar spectrum due to acceptable range of absorption coefficient [8-9] of CdTe (~10^5 cm^{-1}) in the visible solar spectrum. All these properties

*M. Mofazzal Hossain, Aftabnagar, Dhaka-1212, Bangladesh, +8801796587888 & Email: dmmh@ewubd.edu

of CdTe attribute to quite less material cost of the cell if compared with cells based on Si-wafers. In addition, from various respective studies, it is revealed that the energy-payback-time (average) of thin film CdS/CdTe solar cell is around 1.4 years [10] that is found to be as the rock-bottom among all PV technologies. Moreover, CdTe solar cell generates the lowest amount of GWE for per kWh electrical energy compared to other PV technologies [10].

In CdS/CdTe thin film solar cell, irrespective of superstrate or substrate configurations, light enters into the cell through the TCO and CdS (n-type) window layers. From the earlier attempts, the experimental efficiency of single junction CdS/CdTe solar cell has been reported so far around 17% [11-13]. Approximately 18.6% conversion efficiency from a CdS/CdTe solar cell incorporating complex BSF and TCO layers has been reported by Amin et al [14].

In this work, we explore the possibilities and chances of enhancing the efficiency of CdS/CdTe heterojunction solar cell with the insertion of an intrinsic layer of CdTe. Additionally, a back surface field (BSF) layer of highly doped CdTe (p^+ layer) and Si (p^+ layer) are sandwiched between back contact and the absorber layer of p-CdTe in order to diminish the recombination loss and thereby, magnifying the conversion efficiency. In this proposed structure as depicted in Figure 1, a TCO layer of ZnO is inserted to enhance the level of V_{oc} by minimizing the series resistance of the cell.

2. Methodology

In this work the proposed cell is simulated in AMPS 1D simulator to optimize the layer thicknesses of TCO, window, absorber, intrinsic and BSF layers, and the doping density of BSF layer to achieve the maximum possible conversion efficiency under 1.5 AM solar irradiance. The properties of n-CdS, p-CdTe, a-Si and n-ZnO, those are given in Table 1, are taken from [13-15].

Table 1 Material Properties

Parameters	a-Si	CdTe	CdS	ZnO
ε_r	11.9	9.4	9.0	9.0
μ_n ($cm^2.V^{-1}.s^{-1}$)	20	500	350	100
μ_p ($cm^2.V^{-1}.s^{-1}$)	2	60	50	25
E_g (eV)	1.72	1.45	2.42	3.0
N_C (cm^{-3})	2.5×10^{20}	8×10^{17}	2.4×10^{18}	2.2×10^{18}
N_V (cm^{-3})	2.5×10^{20}	1.8×10^{19}	1.79×10^{19}	1.8×10^{19}
χ (eV)	3.8	4.28	4.5	4.35

3. Function of Intrinsic Layer

To comprehensively explain the function of intrinsic layer the simplified energy band diagram for thermal equilibrium condition is shown in Figure 2. It is worth mentioning that while depicting the energy band diagram, gradient of the quasi-Fermi level has not been shown for simplicity. Literally, when light falls and photo-voltage is generated it biases the p-n junction in forward bias mode and therefore the Fermi level should not be continuous throughout the junction of cell. However, it is evident from this diagram that, the inclusion of intrinsic layer increases the width of depletion layer where mainly the photons are absorbed and electron-hole pairs are generated. From Figure 2, it is clear that the generated electrons can move easily towards the TCO layer (left to n-CdS) due to the slope of electron energy and the effect of tunneling. Similarly photo-generated holes can move towards the back contact layer (right to BSF layer) due the slope of holes energy.

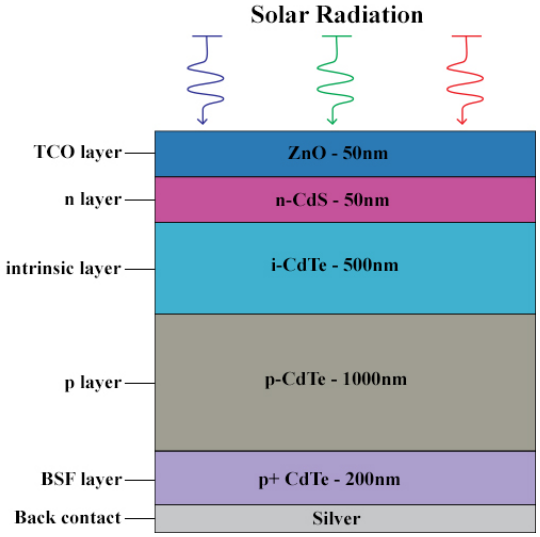

Figure 1The structure of the proposed p-i-n CdS/CdTe solar cell

4. Results and Discussion

In this work, using AMPS 1D simulator we have optimized the thickness of different layers of the cell in order to improve the efficiency. Throughout the simulation, the thicknesses of window layer (n-CdS) and absorber layer (p-CdTe) are kept constant at 50 nm and 1000 nm respectively (as shown Figure 1). We only explored the possibilities of enhancing the conversion efficiency of the cell by optimizing the thicknesses of BSF and intrinsic layers. The proposed structure is simulated in AMPS 1D environment and the I-V characteristics of the cell under 1 sun illumination is extracted from AMPS 1D simulator which is exemplarily shown in Figure 3. After simulation under different doping densities and thicknesses we obtained several figures and results from which we extracted the cell efficiency for desired doping density and thickness.

We explored the effects of doping density of p-CdTe BSF layer on the conversion efficiency for a BSF layer thickness of 50 nm and the results are shown in Figure 4. From Figure 4 it is found that beyond doping density of 2×10^{18} cm^{-3}, the conversion efficiency increases exponentially. The effects of the insertion of amorphous Si (a-Si) and CdTe as BSF layer on the efficiency are also investigated.

Figure 5 and Figure 6 depict the effects of BSF layer thickness (highly doped p-Si and p-CdTe) on the conversion efficiency without the inclusion of intrinsic layer. For this analysis, the doping density of a-Si and CdTe are considered as 6.0×10^{17} cm^{-3} and 1.0×10^{19} cm^{-3} respectively . At a BSF layer thickness of 200 nm, the maximum efficiencies for a-Si and CdTe are attained to be 23.0% and 24.46% respectively. It is observed that beyond 200 nm thickness of BSF layer, in case of a-Si the efficiency becomes

saturated whereas in case of CdTe the efficiency increases almost linearly. From Figure 5 and 6 it is also noticed that in the proposed CdS/CdTe solar cell, CdTe outperforms a-Si as a BSF layer.

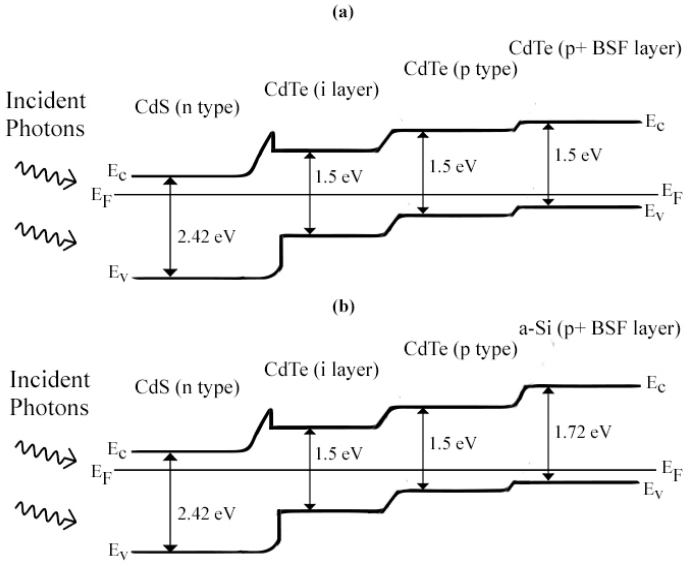

Figure 2 Simplified energy band diagram of proposed (a) p-i-n CdS/CdTe (BSF layer: CdTe) (b) p-i-n CdS/CdTe (BSF layer: a-Si) solar cells

Figure 7 and 8 show the effects of intrinsic layer (CdTe) thickness on the cell's conversion efficiency considering a-Si and CdTe as BSF layers separately. It is observed that in both cases the conversion efficiency increases linearly with the increase of intrinsic layer thickness. However, the maximum conversion efficiency at thickness 500 nm of intrinsic layer for CdTe and a-Si (as BSF layer) are found to be 26.01% and 24.51% respectively. The dependence of short circuit currents on the variation of intrinsic layer thickness for both CdTe and a-Si as BSF layers are also studied as depicted in Figure 9. From this comparison it is realized that CdTe as BSF layer provides larger short circuit current than that of a-Si.

5. Conclusions

An ultrathin (1.8 μm) p-i-n CdS/CdTe PV cell is designed and simulated using 1D AMPS simulator. The thicknesses of intrinsic layer and BSF layer and the doping density of BSF layer are optimized. It is found that CdTe outperforms Si as a BSF layer. The maximum conversion efficiency of the proposed solar cell is found to be 26.01% taking CdTe as BSF layer. Simulation results revealed that a highly doped p^+ CdTe layer (BSF layer) has significant contribution in achieving such a high efficiency. At 1.5 AM solar irradiance, the proposed cell structure with CdTe as BSF layer achieved an open-circuit voltage of 1.09 V, a short-circuit current density of 26.78 mA/cm^2, and a fill factor of 89% and the corresponding overall conversion efficiency of 26.01%. The same structure with Si as BSF layer achieved an open-circuit voltage of 1.06 V, a short-circuit current density of 26.66 mA/cm^2, and a fill factor of 87%, and the corresponding overall conversion efficiency of 24.51%. Compared to our previous work [1] the cell thickness is reduced by 30% with a sacrifice of 0.73% cell efficiency.

ABSTRACT

In remote measurements on large-sized objects main focus is on measuring deformations of bridge surfaces and determination of the dynamic amplification factor in particular. The proposed method estimates deflections of entire lower surface of a bridge due to placement of secondary radiators on this surface. Antenna array directivity pattern (ADP) is distorted during deflection of the bridge surface. ADP distortions contain the information about deflections of the individual points of the surface. Minimization of the distance in a functional space with a quadratic metric (the functional) between a distorted measured ADP and theoretical one allows us to determine these deflections. The main problem is measurement of the secondary radiators system ADP in far zone which often cannot be achieved for real bridges in practical situations. Therefore, a new method for determining surface deflections based only on field amplitude measurements in near-field zone of a secondary radiators system is considered in the article. This amplitude of field strength depends on the bridge surface deflection. The modulus of difference between the normalized amplitude distribution of the measured field at the outputs of the receiving array elements, which is created by the radiators system of an unloaded bridge, and the similar amplitude field distribution of a loaded bridge is minimized and deflection of the bridge at the points of the radiating elements placement is calculated.

1. Introduction

This paper is an extension of the work originally presented in the International Conference on Antenna Theory and Techniques [1].

In engineering practice, an important place is taken by measurements of surface deflections of large-sized objects. The dynamics of these deflections can serve as a basis for diagnosing the objects' state. Deflection measurements for lower part of the surface are one of the most important actions in maintenance of bridges. For this purpose, contact sensors are usually mounted directly on the lower part of the bridge. The installation of contact sensors and transducers interrupts traffic on the bridges and can be time-consuming. Non-contact measurements on bridges which are carried out remotely have recently become an alternative to the contact ones. The analysis of remote method for estimating bridge surface deflections was carried out in [1]. It is based on measurement of the antenna directivity pattern (ADP) distortion of the radiators which are installed on the lower surface of a bridge.

2. Modern Methods of Bridges Surface Deflections Measurement

Let us consider the methods of deflection measurements on bridge structures. The number of deflection measurement methods has increased essentially in the last decade. Bridge safety monitoring is based, in a great extent, on measurements of deflections that become indispensable for this aim. New technologies include intelligent robots that feature a high speed of measurement and precision, laser image deflection measurement, GPS satellite-surveying systems, electro-optical imaging deflection, wireless inclination sensor systems [2, 3] and techniques of digital image correlation between images of undeformed and deformed configurations [4]. In [5], for measuring deflection and vibration of bridges a ground-based interferometric radar is suggested. The maximum measurement range is equal to 1000 m and the errors of displacement radial component can reach

[*]Oleksandr Poliarus, Email : poliarus.kharkov@ukr.net

0.1 mm. Most of the proposed methods are expensive or very expensive.

The main characteristics of any bridge are dynamic amplification factor (DAF), bridge natural frequency and bridge acceleration [6]. The dynamic amplification factor can be evaluated as the maximum total load effect divided by the maximum static effect [7]

$$DAF = \frac{\varepsilon_{dyn}}{\varepsilon_{stat}}, \quad (1)$$

where ε_{dyn} – maximum dynamic response which is usually determined as vertical deflection of the bridge surface due to dynamic loads (for example, moving vehicles), ε_{stat} – maximum deflection under static loads (for example, immovable vehicles).

In [8], an optimal scheme for measuring DAF of a bridge using radar is proposed. This radar measures the phase of reflected electromagnetic wave in noisy environments. In its turn, the phase depends on deflections of the bridge surface.

Increased measurement accuracy can be provided by using measuring devices which operate on the different physical principles. An optimal scheme for determining bridge surface deflection by measuring it simultaneously with a mechanical sensor and radar has been developed in [9]. Practically, operation quality of such scheme does not depend on noise or interference. Since radar-based methods use phase measurements that are sensitive to moving both bridge and earth surfaces, seismic fluctuations of the earth surface reduce the accuracy of the deflections measurement due to traffic, for example. In addition, DAF estimation (1) involves measuring static and dynamic deflections that are separated in time due to technological reasons. This fact imposes strict requirements to stability of radar frequency that increases the cost of a measuring system.

Consequently, all modern measuring technologies for bridge structures can be divided into three groups. The first group includes the use of radar systems of millimeter and optical ranges of electromagnetic waves [10-15] for estimation of deformations and deflections of bridge elements, including stay-cables which support the buildings. For this purpose, in particular, phase interferometers with a high-resolution range are used. These systems measure dynamic characteristics of bridge structures at local points. The second group includes the use of opto-mechanical systems of technical vision [16-18] followed by image processing based on developed algorithms, which allows to analyze the dynamics of bridge structures in distributed areas. These methods do not determine the DAF. The third group is based on application of the algorithms for processing GPS data with Kalman filtration to obtain the value of the bridge DAF [19].

DAF measurement is performed at one point of the bridge structure. To measure it at another point, it is necessary to change the direction of the main maximum of the transmitting and receiving antennas directivity pattern. The existing measuring methods are not able to estimate the dynamics of deflection changes in the entire lower surface of the bridge. In order to fix that, a system for deflection measurements on the lower surface of a bridge by creating, on the surface, an equidistant linear antenna array that re-radiates the incoming electromagnetic wave was proposed in [1] (Figure 1). When the surface is bent due to the process of bridge loading, the radiators also move together with it and the ADP is distorted.

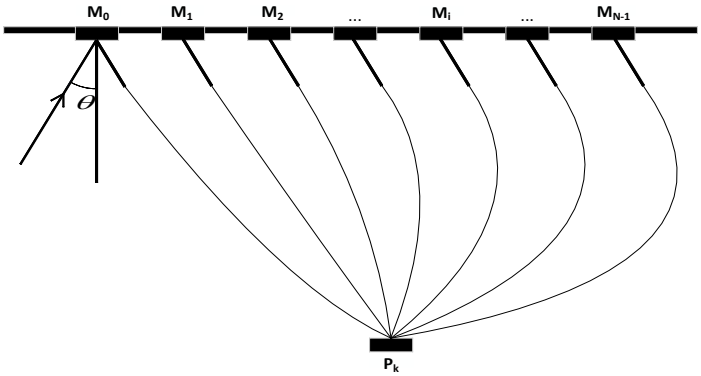

Figure 1: The system of secondary radiators on the lower part of a bridge surface

The antenna directivity pattern is measured in far zone of the antenna and then it is compared with the undisturbed one which was previously measured in the absence of deflections on the unloaded bridge. The integral of square of the difference between the two ADPs creates a functional which depends on the displacements of the secondary radiators at the deformed surface. Minimization of this functional by the method of global random search (using a genetic algorithm) leads to estimation of all the displacements of radiators and, consequently, the deviation of the points on the bridge surface. A similar method is used in [20] for antennas synthesis and even earlier in solving the inverse problem of measurement in linear inertial systems or systems with memory [21].

Let us consider this method. In [1], the authors have developed the functional,

$$J(s_0, s_1, ..s_{N-1}) = \int_{-\frac{\pi}{2}}^{\frac{\pi}{2}} \left(f_m(\theta) - \sum_{i=0}^{N-1} A_i \cdot e^{j\left[\phi_i + \frac{2\pi}{\lambda} l_i \cos\theta - \frac{2\pi}{\lambda} s_i \sin\theta\right]} \right)^2 d\theta, \quad (2)$$

in which s_i, $i = 1, 2, ... N-1$ is a deflection of the surface at the point of the secondary radiator placing, $f_m(\theta)$ – the measured ADP of the radiators system from which the theoretical ADP of the same system, that is described in (2), is subtracted.

For an unloaded bridge $s_i = 0$

$$J(s_0, s_1, ..s_{N-1}) \approx 0$$

$s_i \neq 0$, there may be a difference between the two ADPs of the radiators system. Minimization of the functional (2) using a genetic algorithm results in the determination of unknown deflections s_i. It should be known, however, that formula (2) is the only one and has N unknown deflections. Since the dependence of the functional (2) on the deflections in the N

space is complicated, it is possible to find a non-global, but a local minimum of (2) which leads to incorrect ("phantom") solutions of the deflections determination. One or more of them may have an abnormal meaning. Since the deflections were fixed during the simulation, the "phantom" solutions could easily be distinguished from the correct ones. As shown in [1], when the ratio of the distance d between the radiators to the wavelength λ exceeds 0.5, a certain probability of "phantom" solutions begins to appear. It may reach a value of 0.6 with an increase in the ratio $\frac{d}{\lambda}$ to one and more. The reason for this phenomenon is the appearance of array diffraction maxima and increased number of the local extrema in the search space of genetic algorithm. Consequently, "phantom" solutions can be almost completely eliminated by rational choice of the ratio $\frac{d}{\lambda}$ of the radiating antenna array. In addition, the use of a priori information about surface deflections reduces their probability significantly, even when the ratio $\frac{d}{\lambda}$ is large. This information is often known from previous bridge research or can be obtained by other methods, for example, using the measurements made by mechanical sensors.

It should be noted that instead of passive secondary reflectors, one can use the antenna array of active radiators located at the same points. However, the cost of such system is probably higher.

3. Results of Experimental Research

For experimental verification of this effect, a "Kredo" coherent-pulsed radar with an electromagnetic wave length of 1.8 cm and a pulse duration of 0.4 μs (Figure 2) was used. The experimental setup also included a digital oscilloscope DSO-2250, USB (analogue-digital converter (ADC) with a sampling frequency of 100 MHz) and a laptop. In Figure 2a, a photo of a radar sounding path is shown, in Figure 2b – the placement of the angle reflectors against the background of a reinforced concrete wall, and in Figure 2c – the experimental installation. At a distance of 0.7 m from a reinforced concrete wall and at a height of 1.5 m, the array of five secondary radiators in the form of triangular horns (Figure 2b) was constructed; the distance between horns was equal to 1.5 m. The length of the horn side was 30 cm, and its depth was 15 cm.

The analog radar signals reflected from the horns were received by a mirror antenna, converted to the intermediate frequency and arrived at the input of the amplitude detector. The signal from the output of this amplitude detector entered the ADC of the oscilloscope, was converted into a digital code, and then into a text file (file with extension .txt), which is available in various computer mathematical packages.

To estimate the amplitude of reflected signals, an informative signal (Figure 3) consisting of 200 points was cut out from a long signal (5000 points). It corresponded to the distances at which the angle reflectors were located. In Figure 3, a blanking signal (long, up to a distance of approximately 80 m) which corresponds to the duration of the sounding signal is displayed initially and then a signal (of a shorter duration), that describes the amplitude of the signal reflected from the horns, appears.

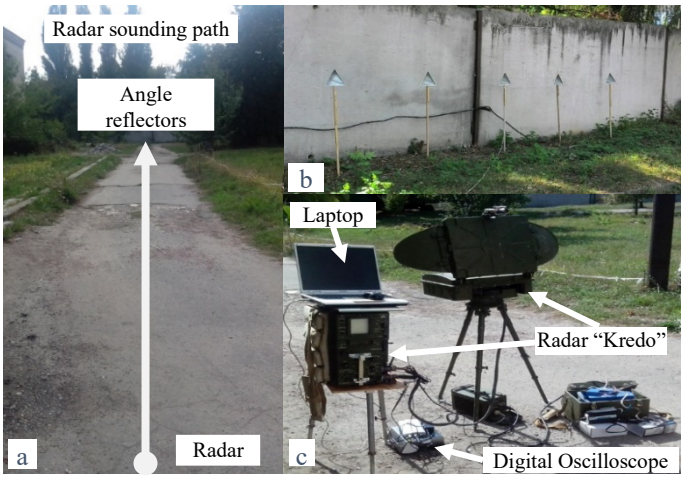

Figure 2: Photographic scheme of the experiment: radar sounding path (a); placement of the angle reflectors (b); general view of the experimental installation (c)

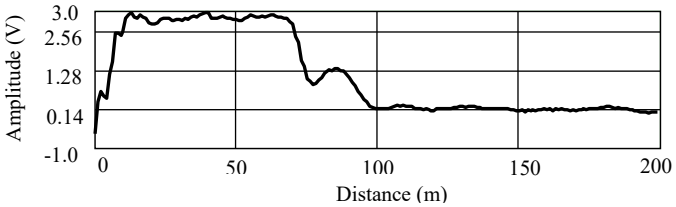

Figure 3: Distance distribution of amplitude of the signal received from angle reflectors

During the experiment the following positions of the angle reflectors were considered: a reinforced concrete wall without reflectors (variant 1); five reflectors on the same line (Figure 2b) (variant 2); one central reflector that was shifted forward by 20 cm (variant 3); two reflectors (central and next to the right) were shifted forward by 20 cm (variant 4); three reflectors (central and two next to the right) were shifted forward by 20 cm (variant 5); one reflector (rightmost) has been moved forward by 10 cm, two reflectors (central and next to it to the right) were shifted by 20 cm forward (variant 6); two rightmost reflectors were shifted forward by 10 cm, the central reflector was shifted by 20 cm forward (variant 7); three reflectors (central and two next to it to the right) were shifted forward by 10 cm (variant 8).

The reflected signals for the above-mentioned variants of the angle reflectors positions were recorded 10 times and then their values were averaged. The obtained experimental data were used to estimate the amplitude of the signals that were reflected from the angle reflectors with different placements relative to each other. The total field amplitude of secondary radiation of the horns at a range of 85 m was measured using the radar. The field amplitude at the radar receiver output was changed if any radiator was shifted in the radial direction (toward the radar location), that shows its sensitivity to movements of the radiators. For example, in the above-described variants, the experimental values in volt of the field amplitude were as follows: 1.16, 1.30, 1.39, 1.51, 1.39, 1.48, 1.40, 1.34. The shape of ADP of the secondary radiators system in experiments was not measured.

4. New Method for Estimating Bridges Surface Deflections

The problem of determination of the bridge surface deflections, described above, is technically complicated. The practical measurement of ADP for the secondary radiators system causes the greatest difficulty. First, we need to measure the field amplitude dependence on the angular coordinate, and it is not easy to do near a real bridge. Secondly, the measurements should be made in the far-zone of antenna at distance r_{fz}, calculated as two squares of antenna size L divided by the wavelength λ. For example, if $L = 30$ m and $\lambda = 30$ cm, then $r_{fz} \geq 6$ km and this value of far-zone distance is impossible for practice. Of course, with increasing wavelength and surface dimensions, whose deformation is measured, there are other problems associated with, for example, the efficiency of radiation of the passive elements of array. Consequently, practical application of the method presented in [1] is limited by the conditions of bridge sounding.

This problem can be solved on the basis of the amplitude-phase $(A_i,\ \phi_i)$ distribution measurement in the near-field zone of the antenna and obtaining the ADP of the radiators system on the basis of these measurements. Such problems were solved by many authors, for example, [22]. In practice, high-precision measurements of the amplitude and phase of the field in real weather and other conditions are complicated and expensive which reduces the value of this approach. Consequently, simpler methods of remote measurements of bridge surface deflections are required. This forces us to give up high-precision measurements of the amplitude and phase in the near-field zone of antenna.

The main idea of this article is to use only amplitude measurements in the near-field zone of the radiators system. The obtained data do not allow to determine the ADP but our task is to estimate only the bridge surface deflections. In this case, there is no need for complex operations of ADP measuring. Instead of these operations, we use a linear receiving antenna consisting of Q receiving elements, for example, horns located at points $P_q, (q = 1, 2, .., Q)$ (Figure 4) at the same distance δ from each other.

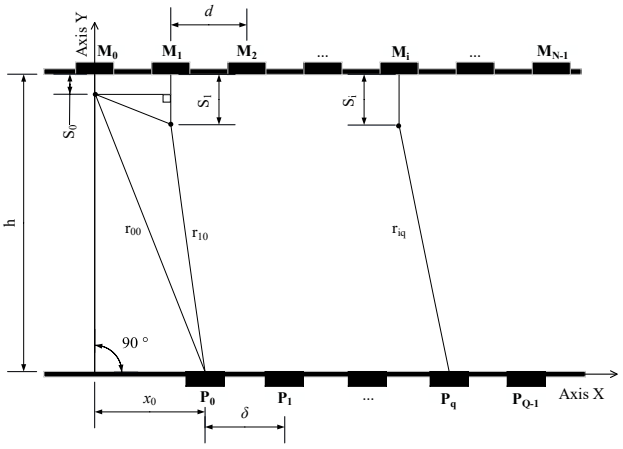

Figure 4: The layout of the receiving antenna array elements (points P_q) relative to the radiating elements position (points M_i)

The receiving element P_q is located from the transmitting element M_i at a distance which is easily determined from the geometry of Figure 4:

$$r_{iq} = \sqrt{(h - S_0)^2 + (x_0 + \delta \cdot q)^2 + (d \cdot i)^2 + (S_i - S_0)^2 - 2\Lambda_{iq} \cdot \Upsilon_{iq}}, \quad (3)$$

where $\Lambda_{iq} = \sqrt{(h - S_0)^2 + (x_0 + q \cdot \delta)^2}\sqrt{(d \cdot i)^2 + (S_i - S_0)^2}$,

$$\Upsilon_{iq} = \cos\left(\frac{\pi}{2} - \operatorname{arctg}\left(\frac{x_0 + q \cdot \delta}{h - S_0}\right) - \operatorname{arctg}\left(\frac{S_i - S_0}{d \cdot i}\right)\right),$$

h – distance between the lower surface of a bridge and array of receiving elements placed in parallel to the transmitting array;

S_i – amplitude of a bridge surface deflection at the points M_i, i. e. in locations of radiators;

x_0 – distance between the origin of the coordinates and the first in order of the receiving element P_0.

The complex amplitude of field strength at the output of each q receiving element is the sum of the fields created by all transmitting elements and is determined by the known formula [23] which for this case has the following form

$$\dot{E}_q = \sum_{i=0}^{N-1} \frac{\dot{A}_i}{r_{iq}} e^{-j\frac{2\pi}{\lambda} r_{iq}}, \quad (4)$$

where $\dot{A}_i = A_i e^{j\phi_i}$; A_i, ϕ_i – amplitude and phase of the field, which is created by the i radiator (further, for simplicity, initial phase field is taken equal to zero, i. e. $\phi_i = 0$).

We believe that all secondary radiators ADPs are equal and wide so that the extreme elements of the transmitting array irradiate all elements of the receiving array by energetically equivalent waves. The amplitude A_i of the field in the simulation was the same. Thus, the distance (3) makes the largest contribution to the total amplitude distribution of field strength. The amplitude of the field created by the secondary radiators at an unloaded bridge is determined similarly (4)

$$\dot{E}^0_q = \sum_{i=0}^{N-1} \frac{\dot{A}_i}{r^0_{iq}} e^{-j\frac{2\pi}{\lambda} r^0_{iq}}, \quad (5)$$

where the upper index "0" indicates variables describing the position of radiators on an unloaded bridge, the surface shape of which is not necessarily a plane. These variables are easy determined before carrying out measurements. Due to the specificity of the problem geometry (Figure 4), the amplitudes of field strength will be different at the output of every receiving element. After the bridge loading the deflections s_i

λ

elements E_q depend only on the distances r_{iq} containing the deflections. The simulation was carried out in several stages:

- Determination of the field amplitudes E_q^0 at the outputs of the receiving elements of the array for an unloaded bridge, provided that the distances r_{iq} are given;
- Measurement of deflections s_i by mechanical sensors. In this article the typical values of bridge deflections were set by authors;
- Determination of the field amplitudes E_q at the outputs of the array receiving elements for a loaded bridge, provided that the distances r_{iq} and the deflections s_i are specified.

Thus, amplitudes of the field at the outputs of receiving elements of the array for an unloaded bridge and a loaded one were obtained in the simulation process for different conditions. It was further assumed that the deflections S_i, which were previously given, are now unknown. To determine these deflections and compare them with the given ones or for this case with reference deflections, a functional was composed:

$$J(s_0, s_1, ..s_{N-1}) = \left| E_q^0 - E_q \right| \Rightarrow \min \qquad (6)$$

It is minimized with the help of a genetic algorithm by variations on S_i. As a result, the "unknown" values of the bridge surface deflections were determined.

5. The Simulation Results

In Figure 5, 6 normalized field amplitudes at the outputs of the receiving antenna array elements located at distances $h = 10$ m (Figure 5) and $h = 50$ m (Figure 6) from the lower surface of a bridge are presented. The length of the electromagnetic wave was $\lambda = 20$ cm. Similar figures for the wavelength $\lambda = 5$ cm are shown in Figures 7, 8.

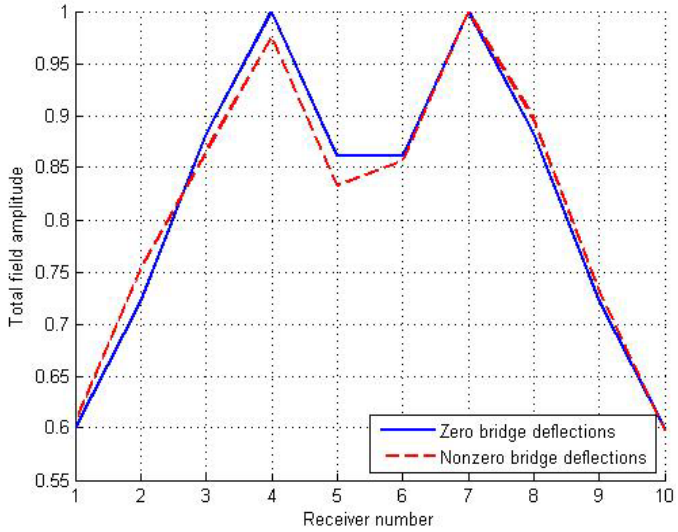

Figure 5: Normalized field amplitude at the outputs of the array receiving elements for an even (solid line) and deformed (dotted line) bridge surfaces for $\lambda = 20$ cm, h=10 m

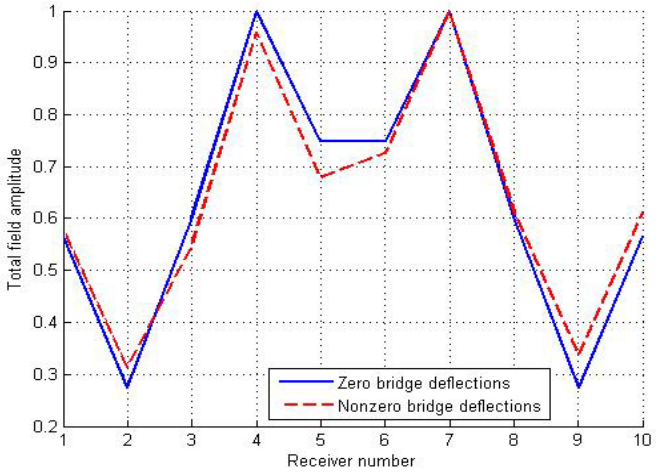

Figure 6: Normalized field amplitude at the outputs of the array receiving elements for an even (solid line) and deformed (dotted line) bridge surfaces for $\lambda = 20$ cm, h=50 m

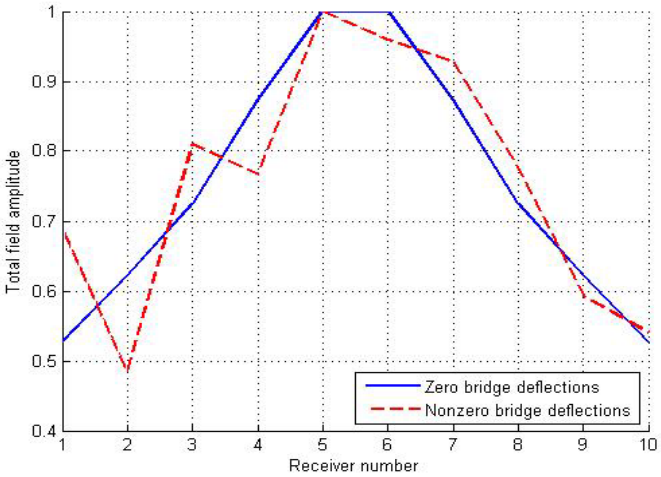

Figure 7: Normalized field amplitude at the outputs of the array receiving elements for an even (solid line) and deformed (dotted line) bridge surfaces for $\lambda = 5$ cm, h=10 m

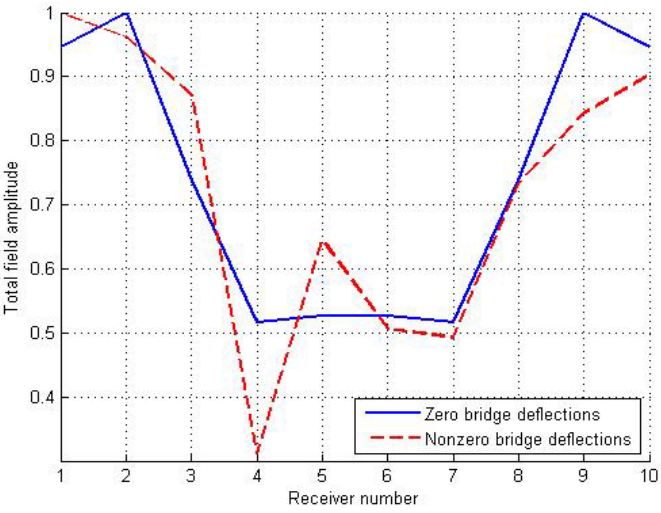

Figure 8: Normalized field amplitude at the outputs of the array receiving elements for an even (solid line) and deformed (dotted line) bridge surfaces for $\lambda = 5$ cm, h=50 m

The genetic algorithm in the process of its work "deforms" the dotted line in such a way that it takes a place of the continuous line. Since the latter is obtained for an unloaded bridge, the algorithm actually reduces existing deflections s_i almost to zero and at the same time determines their absolute values. In this case, the errors of these deflections determination arise. For modeling, the bridge surface deflections in millimeters were selected by authors as follows: $s_0 = 0$, $s_1 = 5$, $s_2 = 4$, $s_3 = 7$, $s_4 = 6$, $s_5 = 4$, $s_6 = 2$, $s_7 = 3$, $s_8 = 4$, $s_9 = 2$. The profiles of the deformed bridge surfaces and the profiles of the reconstructed surfaces that were determined by the genetic algorithm, are shown in Figure 9. Between them, there is some discrepancy which was interpreted as an error of deformed surface restoration.

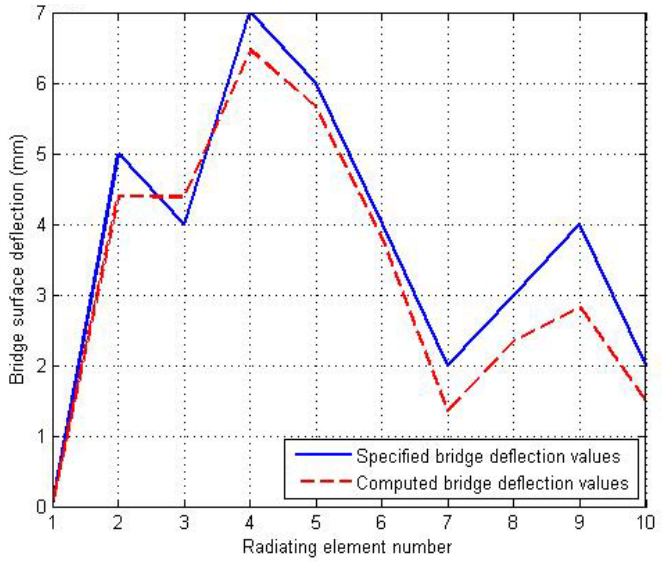

Figure 9: The profile of the deformed bridge surface (solid line) and the profile of the surface that was determined by genetic algorithm (dotted line)

The dependence of relative errors of surface profile restoration on the number of receiving elements in array for different wavelengths is shown in Figure 10.

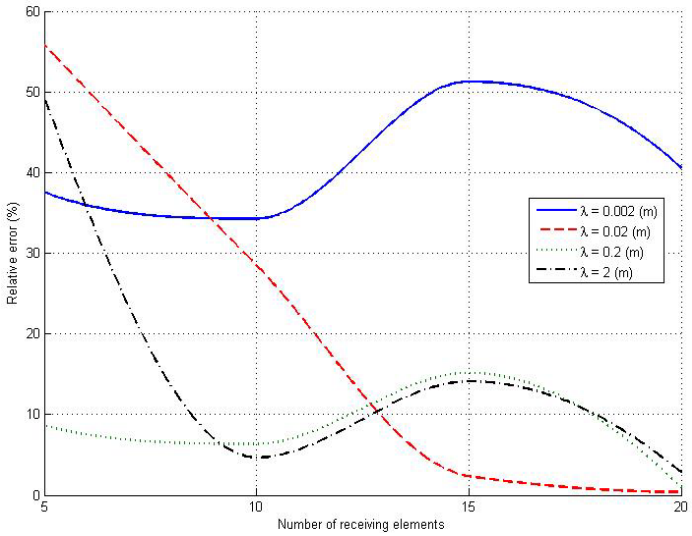

Figure 10: Dependences of the relative errors of the bridge deformed surface profile restoration on the number of receiving elements in array for different wavelengths

In the centimeter and decimeter range of wavelengths the relative errors of bridge surface profile determination are decreased with the increase in array receiving elements number and when the number 10 of receiving elements is exceeded, these errors are less than 10%. This quantity is limited in practice by reception conditions, because the method requires that all elements must receive the radiation from all transmitting elements. Relative error also depends on the wavelength which is used for radiation (Figure 11). The number of receiving elements is equal to 10.

For each bridge the dependence (Figure 11) will be different but there always is a wavelength range which provides the minimum error of the bridge surface deflection determination.

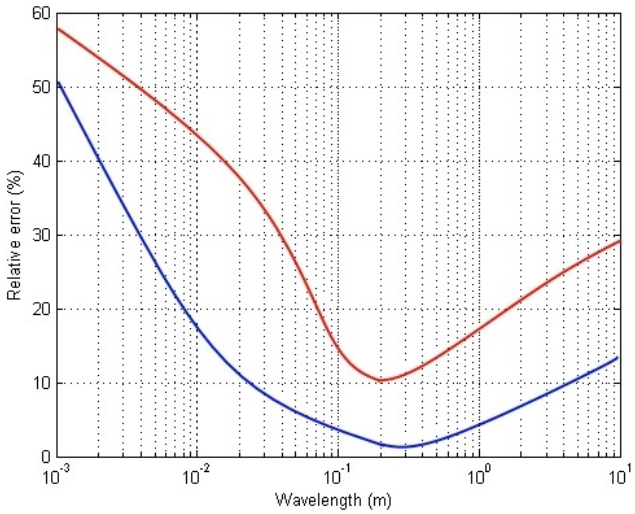

Figure 11: Dependences of the relative errors of the bridge deformed surface profile restoration on the wavelength: blue line – $h = 50$ m, $\delta = 3$ m; red line – $h = 100$ m, $\delta = 2$ m

Dependence of the relative errors of the bridge surface profile restoration on signal / noise ratio is represented in Figure 12. A deterministic signal describing the field amplitude and a white noise of different intensity were added in simulation. In this case the work of the genetic algorithm for finding the global minimum became more complicated.

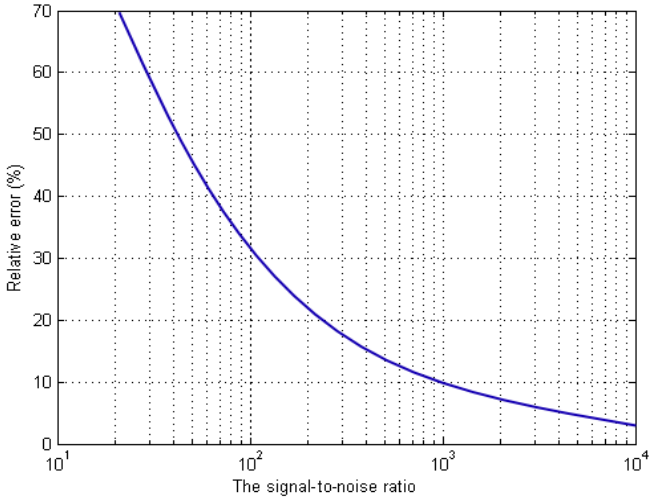

Figure 12: Dependence of the relative error of the bridge deformed surface restoration on the signal-to-noise ratio

The dependence of the "phantom" solutions probability on the ratio $\frac{d}{\lambda}$, that is, on the electrical distance between the radiators, is shown in Figure 13. Figure 14 demonstrates similar dependence on the number of receiving elements. The wavelength was 20 cm, and the distance between the lower surface of the bridge and the receivers was 50 m.

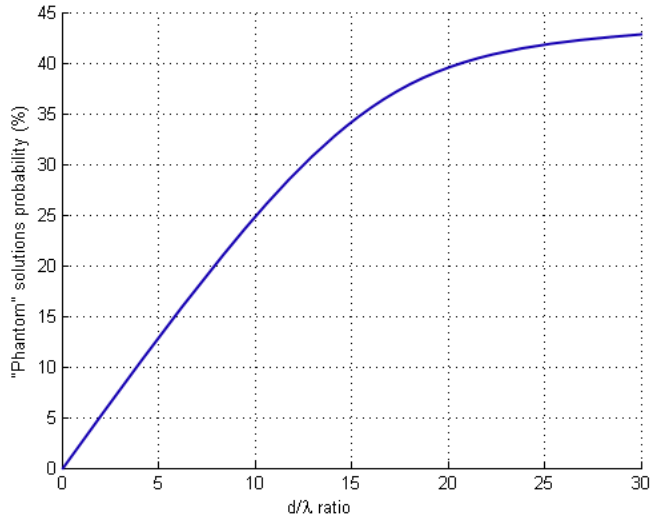

Figure 13: Dependence of "phantom solutions" probability on the ratio $\frac{d}{\lambda}$

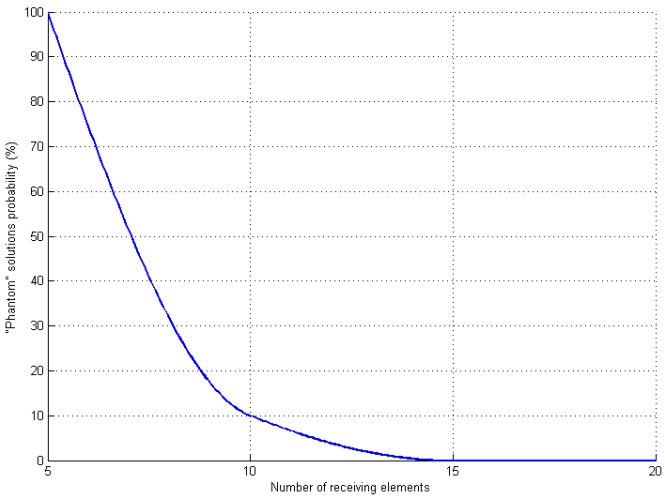

Figure 14: Dependence of "phantom solutions" probability on the number of receivers

The solution was considered as "phantom" one if the error of the bridge deformed surface restoration exceeded 10%. Figures 13 and 14 impose requirements for the number of radiators and receiving elements of the appropriate antenna arrays. Increased number of secondary radiators not only improves the quality of the curved surface profile measurement, but also significantly reduces the probability of the "phantom" solutions.

In the article, the problem of bridge surface deflections determination was solved for simplified conditions in the absence of radio waves reflection from the concrete part of the bridge surface and other parts, neglecting the influence of the steel elements of the reinforced concrete structure, etc. However, one should expect that the approach proposed in the article will not change. Indeed, in the process of the field amplitude measuring at the outputs of receiving elements of the array at an unloaded bridge, all the influencing factors which remain at a loaded bridge, will be taken into account. The difference between these fields appears only in the presence of bridge deflections in the second case. Hence the functional (6) will probably remain the same, that is, the method is expedient to implement in real conditions, too. However, the errors estimation for bridge surface deflections restoration in such conditions remains a challenging problem.

6. Conclusions

New methods for measuring surface deflection of bridges and other large objects were discussed in the paper. It is based on the processing of measurement information about the electromagnetic field amplitude which can be obtained from systems of secondary (passive) radiators (reradiators) or active radiators installed on the lower part of the bridge. The measuring information is obtained at the output of the receiving elements of a linear antenna array which can be installed at any convenient distance from the lower part of the bridge. Minimization of the functional developed in the study allows us to obtain numerical data on the movement of radiators, as well as the deflection of the entire surface of the bridge respectively. The paper defines the conditions under which the errors of deflections restoration in the process of the functional minimizing do not exceed the permissible ones. They depend on the electromagnetic wave length, the geometry of placement of the radiators and receiving elements, as well as on the level of noise in the measurement location. The application of a global random search of the functional extremum (using genetic algorithms) for the global minimum determination in certain situations leads to appearance of wrong ("phantom") solutions when the genetic algorithm finds the minimums that are not global. Recommendations to limit the probability of obtaining "phantom" solutions to a value of zero were also discussed. A mathematical model of electromagnetic waves scattering was made according to a simplified scheme, which did not take into account the reflection from the concrete surface of the bridge and other elements. The consideration of these factors will not make any significant changes to the principle of surface deflection determination, since in any case surface deflections certainly lead to a change in the field amplitude in the observation point, and these changes are the basis for determining deflections. The sensitivity of the field amplitude to the displacement of secondary radiators is proved in the paper experimentally. The proposed method can be used for determination of deflections of other large objects.

Conflict of Interest

The authors declare no conflict of interest.

Sentiment analysis is one of the most popular information extraction tasks both from business and research prospective. From the standpoint of research, sentiment analysis relies on the methods developed for natural language processing and information extraction. One of the key aspects of it is the opinion word lexicon. Product's feature from online reviews is an important and challenging task in opinion mining. Opinion Mining or Sentiment Analysis is a Natural Language Processing and Information Extraction task that identifies the user's views or opinions. In this paper, we developed an approach to extract domain independent product features and opinions without using training examples i.e, lexicon-based approach. Noun phrases are extracted using not only dependency rules but also textblob noun phrase extraction tool. Dependency rules are predefined according to dependency patterns of words in the sentences. StandfordCoreNlp Dependency parser is used to identify the relations between words. The orientation of words is classified by using lexicon-based approach. According to the experimental results the system gets good performance in six different domains.

1. Introduction

Sentiment analysis is one of the most popular information extraction tasks both from business and research prospective. It has numerous business applications, such as evaluation of a product or company perception in social media [1]. From the standpoint of research, sentiment analysis relies on the methods developed for natural language processing and information extraction. One of the key aspects of it is the opinion word lexicon. Opinion words are such words that carry opinion. Positive words refer to some desired state, while negative words to some undesired one. For example, "good" and "beautiful" are positive opinion words, "bad" and "evil" are negative [2].

Opinion phrases and idioms exist as well. Many opinion words depend on context, like the word "large". Some opinion phrases are comparative rather than opinionated, for example "better than". Auxiliary words like negation can change sentiment orientation of a word[3].

[*]Corresponding Author: Sint Sint Aung, Email: ssaung@gmail.com

Opinion words are used in a number of sentiment analysis tasks. They include document and sentence sentiment classification, product features extraction, subjectivity detection etc. [4]. Opinion words are used as features in sentiment classification. Sentiment orientation of a product feature is usually computed based on the sentiment orientation of opinion words nearby [5]. Product features can be extracted with the help of phrase or dependency patterns that include opinion words and placeholders for product features themselves. Subjectivity detection highly relies on opinion word lists as well, because many opinionated phrases are subjective in [6]. Thus, opinion lexicon generation is an important sentiment analysis task. Detection of opinion word sentiment orientation is an accompanying task.

Opinion lexicon generation task can be solved in several ways. The authors of [7] point out three approaches: manual, dictionary-based and corpus-based. The manual approach is precise but time-consuming. The dictionary based approach relies on dictionaries such as WordNet. One starts from a small collection of opinion words and looks for their synonyms and antonyms in a dictionary [8]. The drawback of this approach is that the dictionary coverage

is limited and it is hard to create a domain-specific opinion word list. Corpus-based approaches rely on mining a review corpus and use methods employed in information extraction. The approach proposed in [9] is based on a seed list of opinion words. These words are used together with some linguistic constraints like "AND" or "OR" to mine additional opinion words.

Clustering is performed to label the mined words in the list as positive and negative. Part of speech patterns are used to populate the opinion word dictionary in and Internet search statistics is used to detect semantic orientation of a word. In [10], the authors extend the mentioned approaches and introduces a method for extraction of context-based opinion words together with their orientation. Classification techniques are used in [11] to filter out opinion words from text. The approaches described were applied in English. There are some works that deal with Russian. For example, in [12], the author proposed to use classification. Various features, such as word frequency, weirdness, and TF-IDF are used there.

Most of the research done in the field of sentiment analysis relies on the presence of annotated resources for a given language. However, there are methods which automatically generate resources for a target language, given that there are tools and resources available in the source language. Different approaches to multilingual subjectivity analysis are studied and are summarized in [13].

In one of them, subjectivity lexicon in the source language is translated with the use of a dictionary and employed for subjectivity classification. This approach delivers mediocre precision due to the use of the first translation option and due to word lemmatization. Another approach suggests translating the corpus. This can be done in three different ways: translating an annotated corpus in the source language and projecting its labels; automatic annotation of the corpus, translating it and projecting the labels; translating the corpus in the target language, automatic annotation of it and projecting the labels. Language Weaver 1 machine translation was used on English-Roman and English-Spanish data. Classification experiments with the produced corpora showed similar results. They are close to the case when test data is translated and annotated automatically. This shows that machine translation systems are good enough for translating opinionated datasets. In [14], the authors also confirmed when they used Google Translate 2, Microsoft Bing Translator 3 and Moses 4.

Multilingual opinion lexicon generation is considered in [that presents a semi-automatic approach with the use of triangulation. The authors use high-quality lexicons in two different languages and then translate them automatically into a third language with Google Translate. The words that are found in both translations are supposed to have good precision. It was proven for several languages including Russian with the manual check of the resulting lists. The same authors collect and examine entity-centered sentiment annotated parallel corpora [15].

The process of automatic extraction of knowledge by means of opinion of others about some particular product, topic or problem. Opinion mining is also called sentiment analysis due to large volume of opinion which is rich in web resources available online. Analyzing customer review is most important, it tend to rate the product and provide opinions for it which is been a challenging problem today. Opinion feature extraction is a sub problem of opinion mining, with the vast majority of existing work done in the product review domain. Main fields of research in sentiment analysis are Subjectivity Detection, Sentiment Prediction, Aspect based Sentiment Summarization, Text summarization for opinions, Contractive viewpoint, Summarization, Product Feature Extraction, Detecting opinion spam [16].

2. Related Works

Many researchers have addressed the problem of constructing subjective lexicon for different languages in recent years. In [17] to compile a subjective lexicon, the author investigated three main approaches and they are outlined in this section.

knowledge to extract the domain-specific sentiment lexicon based on constrained label propagation. According to [18], the authors had divided the whole strategy into six steps. Firstly, detected and extracted domain- specific sentiment terms by combining the chunk dependency parsing knowledge and prior generic sentiment lexicon. To refine the sentiment terms some filtering and pruning operations were carried out by others. Then they selected domain-independent sentiment seeds from the semi-structured domain reviews which had been designated manually or directly borrowed from other domains. As the third step, calculated the semantic associations between sentiment terms based on their distribution contexts in the domain corpus. For this calculation, the point-wise mutual information (PMI) was utilized which is commonly used in semantic linkage in information theory. Then, they defined and extracted some pair wise contextual and morphological constraints between sentiment terms to enhance the associations. The conjunctions like "and" and "as well as" were considered as the direct contextual constraints whereas "but" was referred to as a reverse contextual constraint. The above constraints propagated though out the entire collection of candidate sentiment terms. Finally, the propagated constraints were incorporated into label propagation for the construction of domain-specific sentiment lexicon. In [19], the authors proposed approach showed an accuracy increment of approximately 3% over the baseline methods. Opinion analysis has been studied by many researchers in recent years. Two main research directions are sentiment classification and feature-based opinion mining. Sentiment classification investigates ways to classify each review document as positive, negative, or neutral. Representative works on classification at the document level include. These works are different from ours as we are interested in opinions expressed on each product feature rather than the whole review.

In [20], ssentence level subjectivity classification is studied, which determines whether a sentence is a subjective sentence (but may not express a positive or negative opinion) or a factual one. Sentence level sentiment or opinion classification is studied in. Our work is different from the sentence level analysis as we identify opinions on each feature. A review sentence can contain multiple features, and the orientations of opinions expressed on the features can also be different, e.g., "the voice quality of this phone is great and so is the reception, but the battery life is short." "voice quality", "reception" and "battery life" are features. The opinion on "voice quality", "reception" are positive, and the opinion on

"battery life" is negative. Other related works at both the document and sentence levels include those in [21].

Most sentence level and even document level classification methods are based on identification of opinion words or phrases. There are basically two types of approaches: (1) corpus-based approaches, and (2) dictionary-based. approaches. Corpus-based approaches find co-occurrence patterns of words to determine the sentiments of words or phrases, e.g., the works in [22].

In [23], the authors proposed the idea of opinion mining and summarization. It uses a lexicon-based method to determine whether the opinion expressed on a product feature is positive or negative. In [24] and [25]. these methods are improved by a more sophisticated method based on relaxation labeling. We will show in Section 5 that the proposed technique performs much better than both these methods. In [26], a system is reported for analyzing movie reviews in the same framework. However, the system is domain specific. Other recent work related to sentiment analysis includes in. In [27], the authors studied the extraction of comparative sentences and relations, which is different from this work as we do not deal with comparative sentences in this research.

Our holistic lexicon-based approach to identifying the orientations of context dependent opinion words is closely related to works that identify domain opinion words . In [28], the authors used conjunction rules to find such words from large domain corpora. In [29], the conjunction rule basically states that when two opinion words are linked by "and" in a sentence, their opinion orientations are the same. For example, in the sentence, "this room is beautiful and spacious", both "beautiful" and "spacious" are positive opinion words. Based on this rule or language convention, if we do not know whether "spacious" is positive or negative, but know that "beautiful" is positive, we can infer that "spacious" is also positive. Although our approach will also use this linguistic rule or convention, our method is different in two aspects. First, we argue that finding domain opinion words is still problematic because in the same domain the same word may indicate different opinions depending on what features it is applied to. For example, in the following review sentences in the camera domain, "the battery life is very long" and "it takes a long time to focus", "long" is positive in the first sentence, but negative in the second. Thus, we need to consider both the feature and the opinion word rather than only the opinion word as in [30].

Opinion target and opinion word extraction are not new tasks in opinion mining. There is significant effort focused on these tasks. They can be divided into two categories: sentence-level extraction and corpus-level extraction according to their extraction aims. In sentence-level extraction, the task of opinion target/word extraction is to identify the opinion target mentions or opinion expressions in sentences. Thus, these tasks are usually regarded as sequence-labeling problems. Intuitively, contextual words are selected as the features to indicate opinion targets/words in sentences. Additionally, classical sequence labeling models are used to build the extractor, such as CRFs and HMM. In [31], the authors proposed a lexicalized HMM model to perform opinion mining. In [32], the authors used CRFs to extract opinion targets from reviews. However, these methods always need the labeled data to train the model. If the labeled training data are insufficient or come from the different domains than the current texts, they would have unsatisfied extraction performance. Although in [33], the authors proposed a method based on transfer learning to facilitate cross- domain extraction of opinion targets/words, their method still needed the labeled data from out-domains and the extraction performance heavily depended on the relevance between in-domain and out-domain.

Although many target extraction methods exist, we are not aware of any attempt to solve the proposed problem. According to [34], although in supervised target extraction, one can annotate entities and aspects with different labels, supervised methods need manually labeled training data, which is time-consuming and labor-intensive to produce. Note that relaxation labeling was used for sentiment classification in, but not for target classification.

3. Proposed method

This section presents the detailed of step by step process about the system.

3.1. Preprocessing the Input sentences

Input sentences with xml file are prepared before parsing to the StanfordCoreNLP parser. Xml tag are removed. ASCII code characters are replaced with Unicode characters because StanfordCoreNLP cannot process non-Unicode characters.

3.2. Rules for Features and Opinions Extraction

In this section, we describe how to extract opinion and product features using extraction rules. They are the most important tasks for text sentiment analysis, which has attracted much attention from many researchers. Based on the relations between features and opinions, there are four main rules in the double propagation;

1. extracting features using opinion words
2. extracting features using the extracted features
3. extracting opinion words using the extracted features
4. extracting opinion words using both the given and the extracted opinion words

In the following extraction rules, O is opinion word, H is the third word, {O} is a set of seed opinion lexicon, F is product feature, and O-Dep is part-of-speech information and dependency relations. {JJ}, {VB} and {NN} are sets of POS tags of potential opinion words and features, respectively. And {DR} contains dependency relations between features and opinions such as mod, pnmod, subj, s, obj, obj2, conj. We used rule 1 and 2 to extract features, and rule 3 and 4 use to extract opinion words. Moreover, we also used some additional patterns to extract features and opinions.

R11: If a word F whose POS is NN is directly depended by an opinion word O through one of the dependency relations mod, pnmod, subj, s, obj and obj2, then F is a feature. It can be defined as follows;

$$O \rightarrow O\text{-}Dep \rightarrow F$$

$$F \rightarrow F\text{-}Dep \rightarrow O$$

such that O ∈ {O}, O-Dep and F-Dep ∈ {DR}, where {DR} = {mod, pnmod, subj, s, obj, obj2, desc} and P OS (T) ∈ {N N}. For eg. Overall a sweet machine.

R12: If an opinion word O and a word F, whose POS is NN, directly depend on a third word H through dependency relations except conj, then F is a feature. It can be expressed as follows;

$$O \rightarrow O\text{-}Dep \rightarrow H \leftarrow F\text{-}Dep \leftarrow F$$

such that O ∈ {O}, O-Dep and F-Dep ∈ {DR}, POS(F) ∈ {NN}. For eg. Canon is the great product.

R13: If a word F whose POS is NN is indirectly depended by an opinion word O through another word H through two dependency relations dobj and amod or nmod:poss, then F is a feature. It can also be expressed as follows;

$$O \rightarrow O\text{-}Dep \rightarrow H \rightarrow F\text{-}Dep \rightarrow F$$

$$O \leftarrow O\text{-}Dep \leftarrow H \leftarrow F\text{-}Dep \leftarrow F$$

such that O ∈ {O}, O-Dep ∈ {DR}, F-Dep ∈ {DR}, POS(F) ∈ {NN}. For eg. I like the computer’ s battery.

R21: If a word Fj, whose POS is NN, directly depends on a feature Fi through conj, then Fj is a feature. It can also be expressed as follows;

$$Fi \rightarrow Fi - Dep \rightarrow Fj$$

such that Fi ∈ {F}, Fj-Dep ∈ {CONJ}, POS(Fj) ∈ {NN}. For eg. Overall, I like the system features and performance.

R22: If a word Fj, whose POS is NN, and a feature Fi, directly depend on a third word H through the same dependency relation, then Fj is a feature. It can also be expressed as follows;

$$Fi \rightarrow Fi\text{-}Dep \rightarrow H \leftarrow Fj\text{-}Dep \leftarrow Fj$$

such that Fi ∈ {F}, Fi-Dep ∈ {DR}, Fj-Dep ∈ {DR}, POS(Fj) ∈ {NN}. For eg. Canon has done an excellent job.

R31: If a word O whose POS is JJ or VB directly depends on a feature F through one of the dependency relations mod, pnmod, subj, s obj, obj2 and desc, then O is an opinion word. It can also be expressed as follows;

$$O \rightarrow O\text{-}Dep \rightarrow F$$

$$F \rightarrow F\text{-}Dep \rightarrow O$$

such that F ∈ {F}, O-Dep and F-Dep ∈ {DR}, POS(O) ∈ {JJ, VB}. For eg. Overall a sweet machine.

R32: If a word O whose POS is JJ or VB and a feature F directly depend on a third word H through dependency relations except conj, then O is an opinion word. It can also be expressed as follows;

$$O \rightarrow O\text{-}Dep \rightarrow H \leftarrow F\text{-}Dep \leftarrow F$$

such that F ∈ {F}, O-Dep and F-Dep ∈ {DR}, POS(O) ∈ {JJ, VB}. For eg. Canon is the great product.

R33: If a word O whose POS is JJ or VB indirectly depends on a feature F through another word H through dependency relations dobj, amod and nmod:poss, then O is an opinion word. It can also be expressed as follows;

$$O \rightarrow O\text{-}Dep \rightarrow H \rightarrow F\text{-}Dep \rightarrow F$$

$$O \leftarrow O\text{-}Dep \leftarrow H \leftarrow F\text{-}Dep \leftarrow F$$

such that F ∈ {F}, O-Dep and F-Dep ∈ {DR}, POS(O) ∈ {JJ}. For eg. I like the computer’ s battery.

R41: If a word Oj, whose POS is JJ or VB, directly depends on an opinion word Oi through dependency relation conj, then Oj is an opinion word. It can also be expressed as follows;

$$Oi \rightarrow Oi\text{-}Dep \rightarrow Oj$$

such that Oi ∈ {O}, Oi-Dep ∈ {CONJ}, POS(Oj) ∈ {JJ, VB}. For eg. Nice and compact.

R42: If a word Oj, whose POS is JJ or VB, and an opinion word Oi, directly depend on a third word H through the same dependency relation, then Oj is an opinion word. It can also be expressed as follows;

$$Oi \rightarrow Oi\text{-}Dep \rightarrow H \leftarrow Oj\text{-}Dep \leftarrow Oj$$

such that Oi ∈ {O}, Oi-Dep == Oj-Dep, POS(Oj) ∈ {JJ, VB}. For eg. The screen size and screen quality is amazing.

3.3. Features and Opinion Extraction

In this section This system takes raw data as input and xml tag and ascii code characters are removed. After that, word tokenization, part-of speech tagging and dependency identification between words are done by using StandfordfordCoreNLP dependency parser. We used the algorithm also from [17]. Table 1 shows some examples of English stop word list.

Table 1. Some English Stopwords List

to	Of	I	Me	My
Mine	You	At	They	In
Which	With	On	Under	Below
Above	Thing	Things	Some	Someone
Sometime	Something	Somebody	No one	nobody

To start the extraction process, a seed opinion lexicon, a list of general words, review data and extraction rules are input to the proposed algorithm. The extraction process uses a rule-based approach using the relations defined in above. The system assumed opinion words to be adjectives, adverbs and verbs in some cases. And product features are nouns or noun phrases and also verbs in some cases.

Its primary idea is that opinion words are usually associated with product features in some ways. Thus, opinion words can be recognized by identified features, and features can be identified by known opinion words. So, the extracted opinion words and product features are used to identify new opinion words and new product features. The extraction process ends when no more opinion words or product features can be found.

Table 2. Some Unigram Features

Price	System	Computer	Laptop	Reviews
Customer	Battery	Camera	Power	Screen
Staff	Food	Wine	Window	Notebook
Work	Use	Download	Connection	Cost
D-link	Device	Feature	Model	quality

Moreover, textblob is used to extract ngram noun phrase words from the sentences that are not covered with extraction rules. It can increase the performance of the system in term of precision, recall, and f1-score. In order to increase the accuracy, stop words and some general words are removed during the extraction time. Table 2, 3 and 4 describe some extracted of unigrams, bigrams, trigrams and n-gram words from the system.

Table 3. Some Bigram Features

Picture quality	Battery life	Tech support	Screen quality
Power supply	Printer sharing	Return policy	Set up
Security setting	Service tech	Setup software	Mac support
Guest feature	8GB RAM	web cam	charger unit
connect quality	cooling system	cordless mouse	data rate
Window 7	Cd drive	Hard drive	Service tech

The system constructs n-gram dictionary to refine the noun phrase extraction. If the phrase contains in this dictionary, the system extracts it as a feature. Otherwise, remove it.

Table 4. Sme N-gram Features

D-Link support crew	customer service agents
cover for the DVD drive	Dell's customer disservice
D-Link support crew	extended life battery
Garmin GPS software	sound quality via USB
customer service center	design based programs
direct Electrical connectivity	built it web cam
fingerprint reader driver	technical service for dell

4. Classifying Polarity Orientation

Opinions are classified by using Vader lexicon and qualitative analysis techniques developed by C.J. Hutto and Eric Gilbert, 2014. This deep qualitative analysis resulted in isolating five generalizable heuristics based on grammatical and syntactical cues to convey changes to sentiment intensity. They incorporate word-order sensitive relationships between terms:

Punctuation, namely the exclamation point (!), increases the magnitude of the intensity without modifying the semantic orientation.

Capitalization, specifically using ALL-CAPS to emphasize a sentiment relevant word in the presence of other non-capitalized words, increases the magnitude of the sentiment intensity without affecting the semantic orientation

Degree modifiers (also called intensifiers, booster words, or degree adverbs) impact sentiment intensity by either increasing or decreasing the intensity.

The **contrastive conjunction** "but" signals a shift in sentiment polarity with the sentiment.

By examining the **tri-gram** to deeply analyze the intensity of sentiment orientation.

Table 5. shows some example of polarity classification. Polarity score included negative sign (-) indicates negative opinion. And, score with positive sign (+) indicates positive opinion.

Table 5. Polarity Classification of the System

Words	Polarity Score	Polarity Label
Set up	0.4404	positive
excellent	0.5719	positive
work	0.7264	positive
installation disk	-0.296	negative
problem	-0.4019	negative

5. Experimental Results

For experiment, we use core i7 processor, 4GB RAM and 64-bit Ubuntu OS, And, we implement the proposed system with python programming language (PyCharm 2016.3 IDE for python).

Table 6. Dataset Used in the System

Dataset	no of sentences	no of features
ABSA15 restaurant	1083	1193
ABSA15 Hotel	266	212
Router	245	304
Speaker	291	435
Computer	239	346
iPod	161	293
Linksys Router	192	375
Nokia 6000	363	633
Norton	210	302
Diaper Champ	212	239

In this paper, 10 product review datasets are collected and evaluated in term of precision, recall and f1-score. Table 6 shows the domains according to their names, the number of sentences

and the number of features. For performance evaluation on product feature extraction, the comparative results between the proposed approach and Qiu's approach are also analyzed. Precision, recall and f1-score of both are described in figure 1, 2 and 3.

From figure 1, we can see that the proposed approach has higher precision in 6 datasets, dropped in 3 datasets and nearly the same in 1 dataset over Qiu's approach. The proposed approach relies only on the review data itself and no external information is needed.

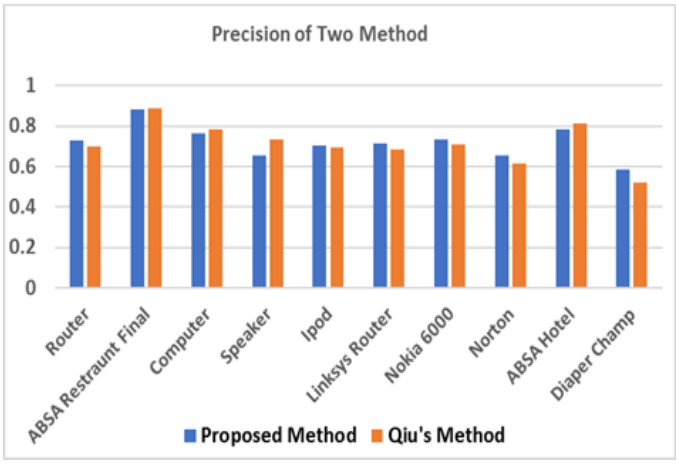

Figure 1: Comparison of Precision on Feature Extraction between Two Approaches

According to the experimental results, the highest precision 0.8819 (88%) are achieved in ABSA Restaurant dataset. In this dataset, the precision, recall and f1-score are nearly the same because there are no verb product features in this dataset.

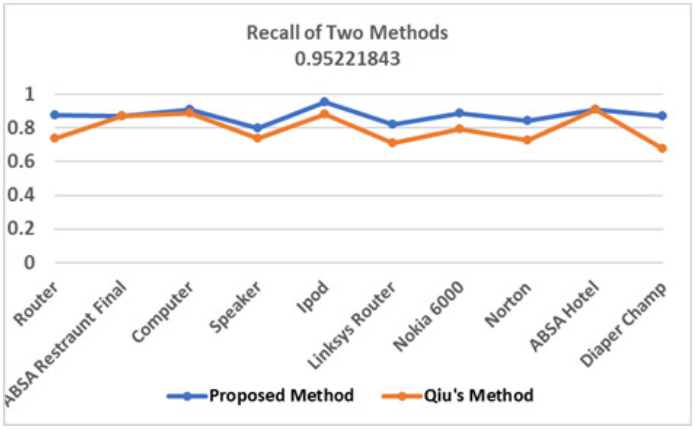

Figure 2: Comparison of Recall on Feature Extraction between Two Approaches

Figure 2 shows that proposed approach outperforms all the other approaches in recall except ABSA Restaurant dataset and ABSA Hotel dataset. The proposed approach has about 14% improvement in Router dataset, about 3% in Computer dataset, about 6% in Speaker dataset, about 7% in iPod dataset, about 10% in Linksys Router dataset, about 9% in Nokia 6000 dataset, about 12% in Norton dataset, about 20% in Diaper Champ dataset. In ABSA Restaurant and ABSA Hotel datasets, the recall of the two approaches are the same. So, to sum up, the proposed approach outperforms over the Qiu's approach according to the recall.

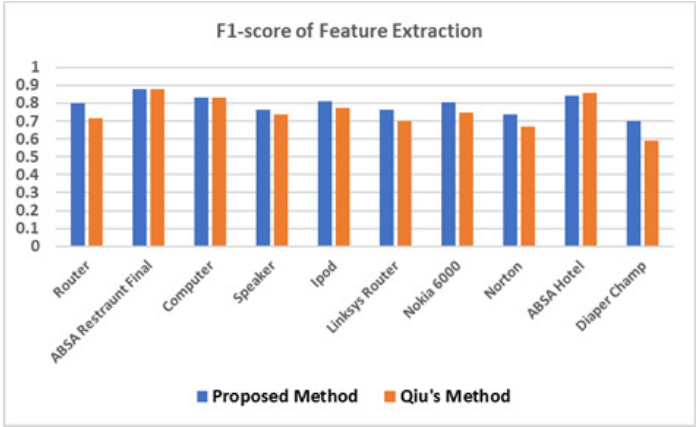

Figure 3: Comparison of F1-score on Feature Extraction between Two Approaches

The comparative results of f1-score in feature extraction are shown in figure 3. According to the experimental results, the proposed approach has higher f1-score (about 7%) in 7 datasets and about 0.003% drop in ABSA Restaurant and Computer datasets and 1% drop in ABSA Hotel dataset

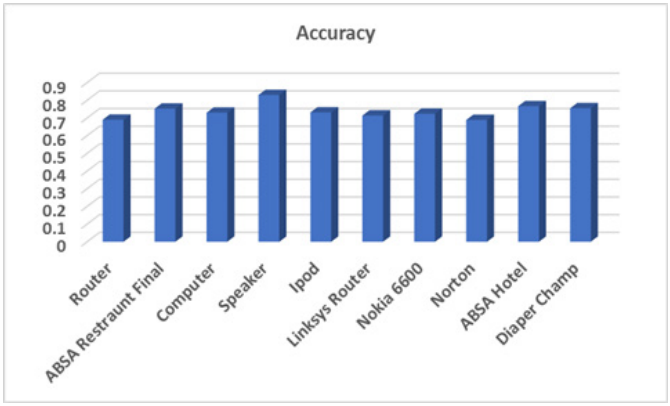

Figure 4 Experimental results of Polarity Classification

The performance analysis of polarity classification of the proposed system is evaluated in all datasets. Figure 4 shows the experimental results of polarity classification in all datasets. The system achieves Highest accuracy 83% in speaker dataset.

6. Conclusion

Opinion mining and sentiment classification are not only technically challenging because of the need for natural language processing. In this work, an effective opinion lexicon expansion and feature extraction approach is proposed. Features and opinions words are extracted simultaneously by using proposed algorithm based on double propagation. So, unlike the existing approach, context dependent opinion words are extracted and domain independence. According to experimental results, the proposed system works well in all datasets and get domain independency without using training examples. As the future extension, we will analyze the performance of the proposed system with more different datasets from SemEval research group.

And we will apply more dependency relations in extraction process.

ABSTRACT

This paper is an extension of work originally presented in 2016 IEEE Asia-Pacific Conference on Applied Electromagnetics (APACE). A 2×1 microstrip patch array antenna integrated with photonic bandgap (PBG) and stubs is designed and analyzed. The performance of the PBG and stubs structure are explained and analyzed in terms of the elimination of the resonance at the harmonic frequencies of the antenna. The proposed antenna is designed on FR-4 substrate with thickness of 1.6 mm and operated at 2.45 GHz frequency suitable for rectenna design application. From the simulated result, the first harmonic frequency (5.4 GHz), the second harmonic frequency (6.6 GHz) and the third harmonic frequency (7.8 GHz) are successfully suppressed. For instance, the radiation to the forward of the stubs-PBG antenna is suppressed at more than 15 dB at the second and third harmonic frequencies.

1. Introduction

The term rectenna is commonly denoted as rectifying antenna at microwave power transmission system. It is a combination of the antenna and high efficient rectifier circuit. The ability of the wireless power transmission system is very important and it depends on the ability of each process; the conversion of signal DC-to-RF at the transmitter, at the transmission and at the conversion of signal RF-to-DC at the receiver. Hence, the receiving antenna is one of the main elements in the rectenna system development.

One of the most popular types of receiving antenna that is used for rectenna application is the microstrip patch antenna [1 - 4]. Some of the advantages of employing this type of antenna is low profile, low cost, light-weight and suitable if integrated with RF devices. However, it also exhibits disadvantages such as the excitation of surface waves that exist in the substrate layer. Surface waves are exceptionable because when a patch antenna radiates, a part of the total available radiated power becomes trapped along the surface of the substrate. It will diminish the total available power for radiation to space wave, and the harmonic frequency is produced. In addition, for arrays antenna, surface waves have a significant impact on the mutual coupling between array elements [5]. Moreover, in rectifying circuit, diode that used to convert the RF signal to DC power supply also generates the unwanted radiation of harmonic frequencies. Thus, the rectenna cannot operate well and will disturb the overall performance of the system.

Several design methods have been proposed in the past in order to overcome these unwanted generated harmonic problems. One of the most popular methods is called the photonic band gap (PBG) or electromagnetic band gap (EBG) [6 - 8] and defected ground structure (DGS) [9 - 11]. Several other techniques for instance antenna with slit and stub structure [12], circular sector patch antenna [13], slot antenna and notch antenna [14], Low Pass Filter (LPF) [15 - 17] also have been discussed earlier as a one of the method to suppress the harmonic frequencies.

According to that, a harmonic suppression microstrip array patch antenna is proposed in order to improve the system performance. In this paper, the 2x1 microstrip patch array antenna integrated with stubs and two-dimensional (2-D) PBG pattern in the ground plane beneath the square patch, is proved experimentally and the capability of the stubs and PBG structure for the suppression of the harmonics are discussed [18].

2. Antenna design procedure

2.1. Numerical method

The structure of the microstrip patch array antenna with PBG substrate (PBG antenna) is presented in Figure 2. A 2x1 array antenna is fabricated on the FR-4 substrate with dimensions of 143 x 52 x 1.6 mm^3 and the relative permittivity of $\varepsilon r = 4.4$. The source signal is fed directly to the antenna by the 50Ω microstrip line with

*Nur Aisyah Amir: Universiti Tun Hussein Onn Malaysia, 01127865561, aisyahamir91@gmail.com

width length (Wd2) = 4.13 mm. The rectangular inset feed antenna dimensions are calculated prior to designing the array antenna by using [19]:

$$w=\frac{c}{2f_0\sqrt{\frac{(\varepsilon_r+1)}{2}}} \quad (1)$$

$$\varepsilon_{eff}=\frac{\varepsilon_r+1}{2}+\frac{\varepsilon_r-1}{2}\left(1+12\frac{h}{w}\right)^{-\frac{1}{2}} \quad (2)$$

$$L_{eff}=\frac{c}{2f_o\sqrt{\varepsilon_{eff}}} \quad (3)$$

$$\Delta L=0.412h\frac{(\varepsilon_{eff}+0.3)\left(\frac{w}{h}+0.264\right)}{(\varepsilon_{eff}-0.258)\left(\frac{w}{h}+0.8\right)} \quad (4)$$

$$L=L_{eff}-2\Delta L \quad (5)$$

Where:

W = Width of the patch
L = Length of the patch
Ɛr = Dielectric constant of substrate
Ɛreff = Effective dielectric constant of substrate
c = Speed of light
f_0 = Frequency reference
h = Height of dielectric substrate

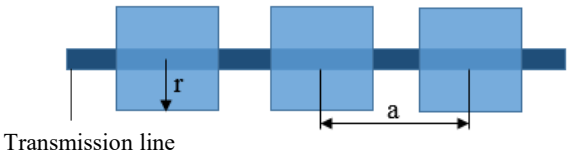
There are advantages of PBG structure which are increasing the antenna's performance in terms of the gain and radiation pattern and also react as a filter to suppress the harmonic frequency. The PBG structure is designed based on the formula [20]:

$$\lambda=\frac{c}{f_o\sqrt{\varepsilon_r}} \quad (6)$$

$$r=\lambda/8 \quad (7)$$

$$a=\lambda/2 \quad (8)$$

After calculation, the 9 x 5 squares with the dimensions 7 x 7 mm^2 are etched in the ground plane at the period (g_b) of 15 mm as shown in Figure 1.



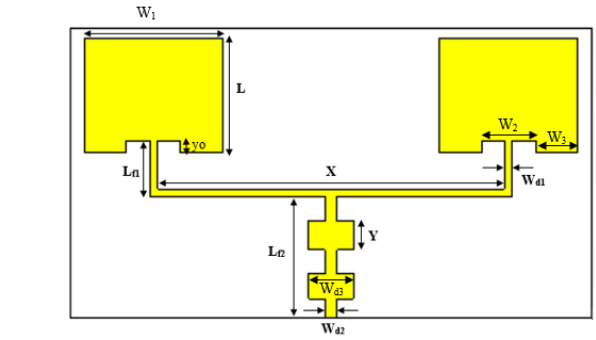


Figure 1: PBG structure at ground plane

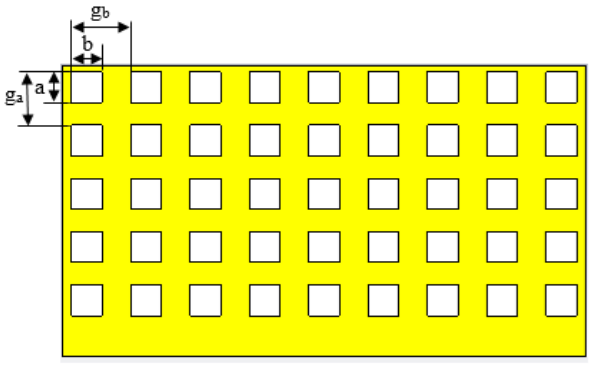

2.2. Design simulation

By using CST microwave software, the rectangular inset feed antenna is designed and simulated to get the operating frequency at 2.45 GHz. Some enhancement are made to obtain the best performance of the antenna. After completing the single element geometry, a 2x1 array antenna is designed. The parameters of the feed line network can be chosen by setting the feed line impedance to 50 Ω (Z1 = 50 Ω), which splits into two 100 Ω (Z2 = 100 Ω) [21]. Similarly, some optimization is done in order to get the greatest achievement of the array antenna.

After done with the conventional microstrip patch array antenna design, the 9 x 5 PBG square are etched at the ground plane. However, some size optimization of PBG square size is done in order to match with the 2x1 array patch antenna design.

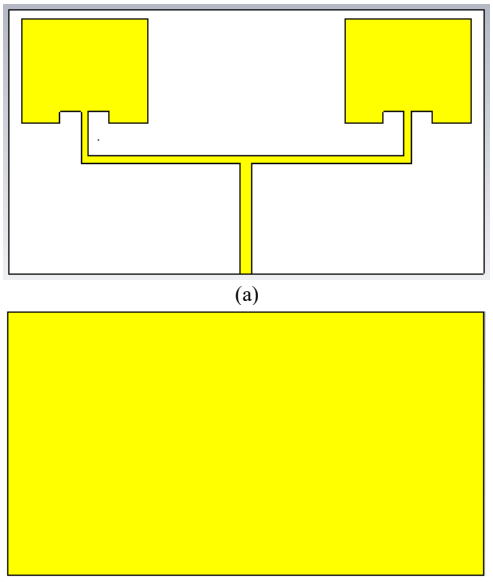
W_2	10	**Y**	5
W_3	13.805	**a**	7
L_{f1}	5.5	**b**	7
L_{f2}	15.7	**g_a**	15
W_{d1}	0.71	**g**	15
W_{d2}	4.13		



3. Result and discussion

This proposed antenna is divided into three parts which are normal array patch antenna, PBG array antenna and array patch antenna with PBG and stub structure. Each part is discussed and analyzed according to their characteristics.

3.1. Normal array patch antenna

The normal patch antenna without PBG structure shows in Figure 3 is simulated and measured for the comparison of the basic

characteristics. The resonant frequency of the fundamental is adjusted to be 2.45 GHz for the antenna. The simulated and measured S-parameter (return loss) result of the array antenna without stubs and PBG structures are shown in Figure 4. As can see, the return loss is at -13 dB and has a few harmonic frequencies which are not good for an antenna.

(a)

(b)

Figure 3: 2x1 rectangular inset feed array antenna (a) front view (b) back view

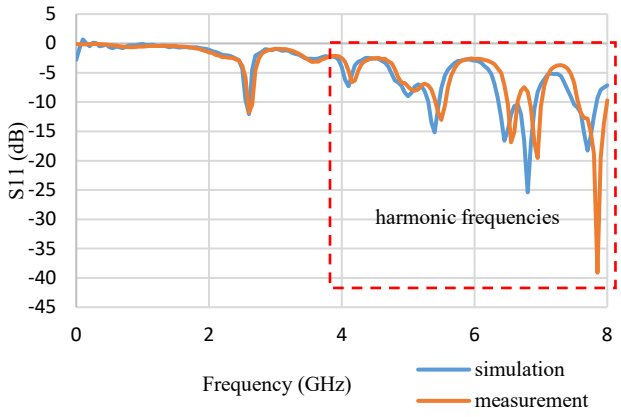


Figure 4: Simulated and measured result for S-parameter (return loss) of 2x1 rectangular inset feed array antenna

3.2. PBG structure

As can see in Figure 4, there are a lots of harmonic frequencies produces above 4 GHz. Hence, PBG structure is beneath at the ground in order to suppress the harmonic frequencies. At the same time, the gain of the antenna also can be improved. Figure 5 shows the PBG structure at ground plane. This arrangement of the PBG lattice produces the band pass characteristics of the transmission parameter at more than -20 dB from 4.6 GHz to 8 GHz shown in Figure 6 (a) when the uniform microstrip line is fabricated on this substrate instead of the patch antenna. The effect of the PBG can be seen by observing the S-parameter (return loss) in Figure 6 (b). It shows that the harmonic frequencies above 4.6 GHz is successfully suppressed when the S-parameter of PBG structure is compare with return loss of 2x1 rectangular inset feed array antenna with and without PBG structure. While Figure 7 shows the comparison of return loss of 2x1 rectangular inset feed array antenna with PBG structure only between simulation and measurement.

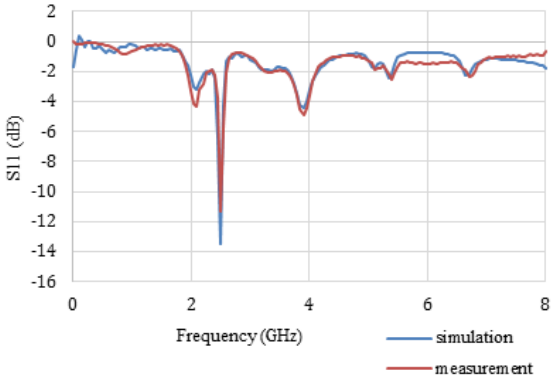

Figure 7: Simulated and measured result for return loss of 2x1 rectangular inset feed array antenna with PBG structure only

3.3. Array patch antenna with PBG and stub structure

The final design is combination of normal array patch antenna with PBG and stubs structure as shown is Figure 8. The S-parameter (return loss) of the array antenna with PBG and stubs structure, and the array antenna without PBG and stubs structure are shown in Figure 9.

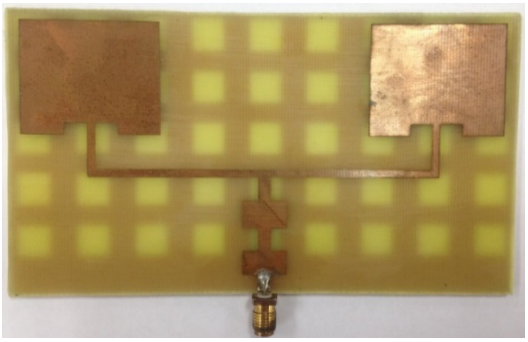

Figure 8: Prototype of 2x1 rectangular inset feed array antenna with PBG structure and stub

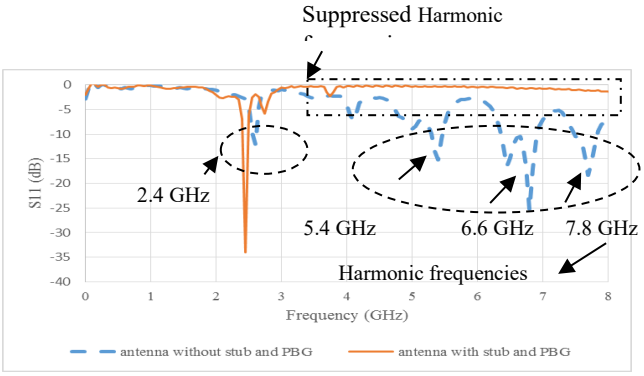

Figure 9: Measured S-Parameter (return loss) of the proposed array antenna. Graph of the comparison for antenna with and without stubs and PBG

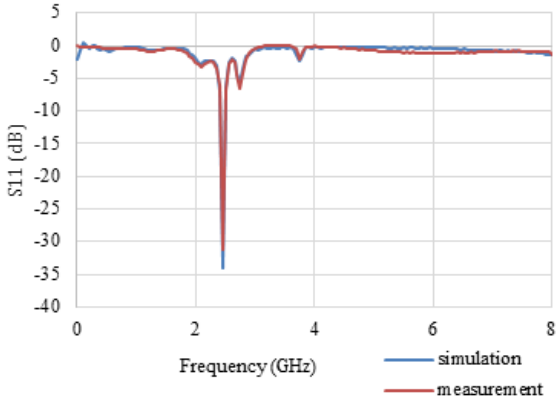

Figure 10: Comparison of return loss between simulation and measurement for 2x1 array patch antenna with PBG and stub structure

Figure 9 shows, a comparison between conventional array antenna with array antenna with PBG and stubs structure indicates that the harmonic frequencies are indeed suppressed. According to the theoretical design, the return loss is observed at 2.45 GHz. However from measurement result, the S-Parameter (return loss) is observed at 2.6 GHz for conventional antenna while for stubs-PBG antenna is at 2.45 GHz. Through observation, the antenna performances are increased. The return loss is revised from -12.05 dB to -34.99 dB after the stub and PBG is added. Besides, based on to the characteristic of PBG, it also can suppress the surface wave in the band-gap. A periodic structure surrounding the patches in addition to one underneath the patches is essential for effective suppression of the harmonic and surface wave. Figure 10 depicts the comparison between simulated and measured return loss of the proposed array antenna.

3.4. Gain

As mentioned before, besides suppressing the harmonic frequency, PBG structure also can increase the performance of the antenna in terms of gain. As can be seen in Figure 11 (a) and (b), there are comparison antenna's gain between simulation and measurement for normal array patch antenna and PBG array patch antenna.

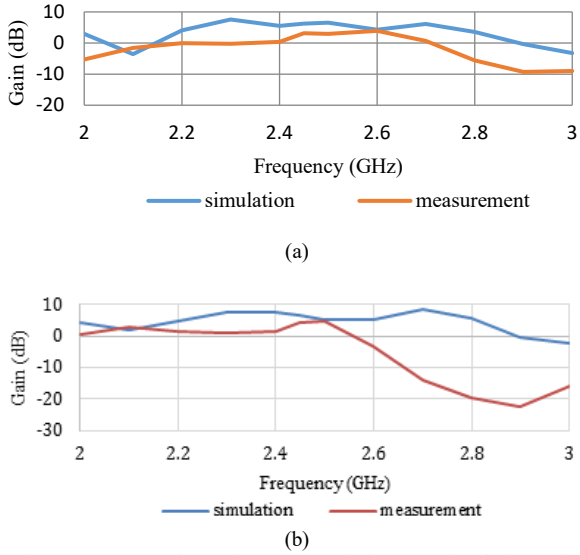

Figure 11: Comparison of antenna's gain between simulation and measurement (a) normal array patch antenna (b) PBG array patch antenna

Figure 11 (a) shows the gain comparison between simulation and measurement for normal array patch antenna. From the graph, the gain for 2.45 GHz is 6.263 dB for simulation while 3.15 dB for measurement. The gain increases to 6.436 dB when the PBG structure is added as shows in Figure 11 (b). While for measurement, the gain is 4.31 dB.

In Table 2, due to the effective suppression of the harmonic and the surface wave, and changes in the current distribution, the antenna array with stub and PBG has higher gain compared to the normal array antenna. The gain increase about 82.41% which is from 3.156 dB to 5.757 dB. While for normal array antenna and array antenna with PBG structure, the result shows a minimal gain increase by 36.66%. Thus, it shows that with the addition of stub structure at the feed line, the gain's performance will improve more. Moreover, the mixed current distribution is useful for diminishing the mutual coupling between the patches and decreasing the maximum side-lobe level.

Table 2: Measured antenna gain base on structure added

Antenna structure	Gain (dB)
Array antenna without PBG and stub	3.156
Array antenna with PBG	4.313
Array antenna with PBG and stub	5.757

4. Conclusion

2x1 microstrip patch array antenna has been presented in this effort. The proposed structure is integrated with two-dimensional PBG pattern in the ground plane under the square patch and stubs. The effectiveness of the PBG and stubs structure for harmonic suppression are analyzed. The simulation and measurement works verified that the combination of the array antenna with PBG and stubs is efficient in eliminating unwanted frequencies. Moreover, the performances of the antenna in term of gain also increase.

Acknowledgment

The authors would like to thank the Centre Graduate Study UTHM for supporting this study. Much appreciation also goes to the Electromagnetic Compability Lab (EMC Centre), Universiti Tun Hussein Onn Malaysia for providing the measurement facilities.

ABSTRACT

Two technology trends - a move toward software defined capabilities and toward networked devices – support both unprecedented innovations and requirements for security. A fundamental aspect of security is user authentication, which allows devices and software applications to establish their user's identity and identity is in turn used to establish which of its capabilities the user is authorized to access. While multiple authentication steps, known as multifactor authentication, are being used more widely throughout the military, government, businesses, and consumer sectors, the selection and implementation of which authentication factors to require is typically defined by security policy. Security policy is in turn typically established by a security organization that may have no formal metrics or means to guide its selection of authentication factors. This paper will present a taxonomy for describing authentication factors including important attributes that characterize authentication robustness to aid in the selection of factors that are consistent with the user's mission. One particular authentication factor that I have developed will be discussed in the context of this taxonomy to motivate the need to broaden current definitions and security policies. The ultimate goal of this paper is to inspire the development of standards for authentication technologies to both support mission aware authentication innovation and to inform decision making about security policies concerning user authentication and authorization. Further, this paper aims to demonstrate that such an approach will fundamentally enhance both security and usability of increasingly networked, software-defined devices, equipment and software applications.

1. Introduction

Mobile devices, such as cell phones and tablets, can be extremely useful for military personnel, security personnel, employees, and consumers in performing an entire gambit of tasks from routine day to day tasks to time critical emergency response. Current cybersecurity best practices encourage the use of user authentication in order for these devices to be accessed. Increasingly, equipment that was once thought of as hardware, is becoming essentially software defined. This includes military radios, medical devices, and autonomous cars. This trend supports the possibility of requiring users to authenticate with their cars, medical devices, and radios, for example, before gaining access to their functionality, thereby enhancing security and discouraging theft and/or hacking. Further, Internet of Things (IoT) devices are becoming pervasive throughout homes and industries, and security policies for IoT device access have not consistently been established and implemented.

This paper is an extension of work originally presented in [1], where a method for continuous secondary factor authentication for military or security personnel required to perform missions while in harm's way was motivated and described. Specifically, this paper will use the Concept of Operation (ConOps) and method discussed in [1] and related ConOps to motivate the need for mission aware authentication factors and in turn to describe and validate authentication factors so that appropriate ones can be selected. This paper will further argue that standards and/or specifications and a means of validating compliance is crucial to support innovation and transition to productization.

In [2], the National Institute of Standards and Technology (NIST) defines multifactor authentication as "Authentication

* Corresponding Author: Susan Gottschlich, susan.gottschlich@raytheon.com

using two or more different factors to achieve authentication. Factors include: (i) something you know (e.g., password/PIN); (ii) something you have (e.g., cryptographic identification device, token); or (iii) something you are (e.g., biometric)." When only two factors are used, this is referred to two factor or dual factor authentication. Dual factor authentication is currently a requirement for NIST's Risk Management Framework (RMF). RMF compliance is a requirement being levied on all military information systems.

Continuous authentication is an emerging authentication factor methodology that implements authentication as a process rather than a simple event such as entering a user name and password. The idea is that once a user establishes his or her identity through another authentication factor or as an initialization step in a continuous authentication factor, the user is continuously monitored by some means so that their identity is continuously established.

Continuous authentication can enhance usability by alleviating the need for a user to re-authenticate, for instance, if they allow their authenticated session to become idle for longer than some inactivity period prescribed by security policy. Continuous authentication can also enhance security by potentially detecting instantaneously when a user may have lost control of his or her device or software application session, eliminating the need for security policies to establish arbitrarily the length of inactivity periods allowed before re-authentication is required.

This paper argues that in order to enhance both security and usability, user authentication should be pervasively implemented on software-defined networked or stand-alone devices or software applications, but that the factors used in authentication should be selected to be consistent with the user's underlying mission and/or need for using the device or application. Thus, the factors employed may be far different than current approaches that typically involve entering a user name and password and/or pin along with a secondary factor (something the user is or has).

Section II will present background on current work on authentication factors and on biometrics which are increasingly being used to support 'something you are' authentication factors.

2. Background

Until recently, user authentication has pervasively been implemented via the use of a password or pin as a primary factor (something you know). If a secondary factor is warranted, several options for 'something you have' have been implemented including an RSA key, a CAC card, an email account, or a token. Alternatively biometric factors (something you are) such as finger prints, iris scans or voice spectrograms have been used. Section 4 will review ConOps examples where such approaches might not be practical given the user's mission.

Various implementations of an emerging authentication approach – continuous authentication – are beginning to emerge. Some of these implementations are described in industry publications [3, 4], and in conference proceedings [5]. Continuous authentication is the idea that a user is monitored in such a way that they are being continuously authenticated. An approach presented in [5], for instance, uses a combination of color information of users' clothing and face information in order to robustly monitor a user who may not always be facing the computer being used. Other continuous authentication approaches presented in [3, 4] use behavior recognition, such as keystroke patterns (e.g. typing rhythm, mouse movement) potentially used in combination with other biometric factors such as iris patterns.

Continuous authentication can bring about more secure authentication that is also more usable than current pervasive security policies implement. For instance, if a user who is not being continuously authenticated walks away from his or her computer briefly, a nefarious agent can assume this user's computer session. Locking computer sessions during inactivity periods is meant to counter this possibility but if the inactivity period is too short, it can become extremely counterproductive for a user who must frequently re-authenticate.

Alternatively, allowing for a lengthy inactivity period negatively impacts the security posture of the computer session. Continuous authentication is theoretically more secure because it tracks the user continuously, thus no timeout or inactivity period need be implemented. It may also be considered more user friendly because users do not need to re-authenticate.

An important thing to note about continuous authentication implementations is that they are generally tied to the type of device being used. For instance, key stroke and mouse behavior monitoring applies to computers but not necessarily cell phones or IoT devices. Further, they are often dependent on a user's mission or role. Tracking clothing, irises, and keyboard behavior are certainly appropriate for office and home environments. They may be less appropriate in environments where users are wearing uniforms (clothing is always the same color across users and days) and protective eyewear, using their devices occasionally while they perform other challenging tasks (e.g. driving, patrolling), or put into high stress situations that may alter their behavior or voice substantially.

In [1] I presented an approach that I developed that uses a fitness tracking device paired with a mobile device to continuously monitor a user performing potentially hazardous missions. This approach locks the mobile device if conditions suggest that the user is under severe duress (possible captured), dangerously wounded or killed. In other words, this approach monitors the user and when it detects that the user may have lost control of his or her device, it fails the user's authentication with the device. Otherwise, it allows a user persistent uninhibited access to the mobile device.

The novelty of the approach is based on the recognition that all of the conditions that suggest a user has lost control of his or her device will bring about a sudden change in the user's biometrics as monitored by the fitness tracking device. Because this is the case, the various biometric sensors can be monitored

using Kalman filters which can detect jump (or sudden) changes in a biometric variable.

In [1] I describe experiments conducted with this continuous monitoring approach. The experimental results, which were derived from live experiments with 'normal' conditions but simulated experiments with dangerous conditions, confirm the approach's ability to provide strong authentication under the assumed user conditions.

As far as I am aware, this is only continuous authentication approach published that considers how to detect and lock down a device when conditions suggest that the user has lost control of his or her mobile device.

While this is generally not a concern for office workers or personal device users, it may be an important concern for military and security users. This differentiation further suggests the need for selecting mission-aware authentication factors.

When contrasted against NIST's definition of authentication factors, the fitness tracking device might be considered both something you have and a means to identifying something you are. In addition to tracking biometric readings, the fitness tracker's API also allows the authentication software to monitor band contact, so it is possible to detect when the user is no longer wearing the device or the tracker is no longer communicating. This paper will argue that combination factors and other innovations will be encouraged if security organizations are given the tools to evaluation their effectiveness.

Further, I submit that the emergence and commercialization of many new technologies including biometric feature sensing and recognition, wearable technologies, and machine learning (ML) will support more innovative and specialized approaches to user authentication.

There is substantial related literature on the biometric readings that might be drawn from in order to help assess the strength and risks associated with a biometric factor. In his Ph.D. dissertation, Gari D. Clifford discusses heart rate variability (HRV) and its causes [6]. Clifford shows that a person's heart rate is variably by nature. For instance, Circadian rhythms will drive variability throughout the day and factors such as general stress level and caffeine intake will cause day to day variations.

Several publications, including [7, 8, 9] consider heart rate variability, Galvanic skin response (which can be measured with some currently available fitness trackers), and other factors in analyzing what happens during exercise, duress, and the differences between the two. Based upon the research presented in [6-9], I developed rules presented in [1] to differentiate conditions that result in an increased heart rate.

Note that all of the biometric factors used in the algorithm in [1] can be measured by the Microsoft® Band 2, which was used in the experiments that were described. Skin conductance delta (also known as Galvanic skin response), for instance, supports the estimate of duress, but other factors can be used in differentiation. My research indicates that conditions resulting in a sudden decrease in heart rate (e.g. extreme cold, cardiac arrest) generally indicate the user is severely stressed by health or environmental issues, rather than an explicit threat.

Research presented in [10] performed a case study on students under stress due to a university examination. In [11] the use of wearable sensors is compared to electrocardiograms and concluded that the former is sufficient for detecting stress conditions.

Much of the research on heart rate measurements are focused on detecting an abnormal condition that may occur during a medical procedure such as surgery. The approaches discussed in such research generally involve preprocessing the measurement signal and performing machine learning (ML) techniques.

The algorithmic approach presented in [1] rejected the application of a pure ML techniques because measurable biometrics, such as heart rate, will vary from day to day due to many factors such as time of day, intake of caffeine or other drugs, and the user's current activity, and it is not practical to control for these factors.

Rather, the algorithm focuses on detecting jump changes in biometric measurements so that normal variances in measurements are implicitly handled.

The work in [12] describes the use of Electroencephalogram (EEG) for authentication. When mature, this technology may be trusted to uniquely authenticate an individual as a single factor (e.g. as opposed to dual factor or multifactor authentication). An unanswered question is how well these approaches work under high stress and maybe duress situation.

The work in [13] addresses biometric recognition techniques, including facial recognition, voice recognition, finger print recognition and iris recognition, being applied to authentication. It further describes how to assess biometric characteristics in terms of five qualities: robustness, distinctiveness, availability, accessibility and acceptability. The work further developed a taxonomy of uses. The focus of this work, however, is in 'snapshot' authentication – authenticating a user at a particular point in time using a snapshot reading (finger print, facial image, etc.) as opposed to the continuous streams of readings I proposed using in [1].

Nevertheless the discussion in [13] can easily be extended into the continuous monitoring domain if it can be assumed that there are mechanisms to continuously take snapshots of the discussed biometric factors.

In the following I will first propose a taxonomy for authentication factors that expands on the work presented in [13] in Section III. Specifically, I decompose the qualities presented in [13] into measurable and verifiable attributes. Further, these attributes are intended to support a broad array of potential authentication methodologies.

In Section IV, I present three ConOps to consider with regards to the taxonomy. I will conclude with a discussion of next steps.

3. Authentication Factor Taxonomy

The purpose of this section is to present a draft taxonomy for authentication factors and the user's that they are designed to identify and authorize. The goal is to motivate the development of industry and government standards organization that develops and maintains taxonomies and related standards that can be utilized by manufacturers of authentication devices and/or algorithms as well as security organizations or home users who must ultimately determine authentication policy. This draft has been developed informally as a means to motivate a formal taxonomy following a research methodology, for instance, as described in [14, 15].

The draft ontology is decomposed into three related groups of attribute/value pairs for describing authentication factors, user missions, and security policy.

Table I provides a list of key attribute/value pairs that can be used to provide specifications for an authentication factor. It is anticipated to be used by suppliers of authentication factors to provide an unambiguous description of the level of security a given authentication factor offering is able to support. It is also anticipated to be used by security organization to specify policy for the conditions under which a given methodology can be used.

This taxonomy can be seen as an extension of the characterization described in [13] because it encompasses the full range of authentication factors and it including attributes that might be used in a risk analysis (e.g. some connection protocols may be considered to be less secure than others). It further attempts to decompose the qualities into attributes that are measurable and verifiable.

This taxonomy strives to address current and emerging authentication methodologies. It is understood that future innovations may bring about methodologies that will require a further extension in the taxonomy. Nevertheless it is quite possible that future innovations will not change the attributes in the taxonomy but instead extend the range of potential values associated with each attribute.

It is the only taxonomy that I am aware of that is meant to model emerging authentication factor technology including continuous authentication and combination factors (e.g. something you have and something you are). I believe that research aimed at characterizing authentication factors is essential to promote innovation in authentication factor offerings. Without such a mechanism, innovators may have a hard time determining whether or not a proposed authentication concept will, if developed, be acceptable by security organizations and users, and thus less likely to expend resources developing innovative authentication approaches.

The first attribute, category, provides a high level simple characterization. Security policies may use this characterization to structure the definition of acceptable authentication factors. In turn, users may use it to determine the best factor(s) to implement their ConOps.

Table 1: Authentication factor definition

ATTRIBUTE	VALUE
Category (structure which provides high level distinctions to support policy definition)	-Discrete, continuous, or continuous with initial discrete authentication factor -Something you know, something you are, something you have, or a combination factor.
Strength (structure that varies depending on the underlying factor)	-Something you know: number of characters, special characters (for single entry), number of questions (for security question knowledge based authentication) -Something you have: restrictions on how the device is obtained, if/when it expires, policies for how lost, stolen, or damaged devices are replaced - Something you are: frequency of interrogation
False Acceptance Rate	Expressed as a percentage. May be calculable based on strength settings.
False Rejection Rate	Expressed as a percentage. May be calculable based on strength settings.
Validation Approach	The approach used to validate strength, false acceptance rate and false rejection rate established.
Connections required (something you have, something you are)	Wired interfaces including: USB, DS-101. Wireless interfaces including: WiFi, Bluetooth, ZigBee (IoT), Proximity card, Near-Field Communications (NFC)
Acceptable user conditions	A list of well-defined conditions including: Continuous use, continuous use with occasional interruptions, wearable-occasional use, pocketed-occasional use, protective face equipment, protective eye equipment, protective hand equipment, protective finger equipment, exertion-tolerant, stress-tolerant, voice use, covert use.
Authenticated devices and applications	A list of well-defined devices, including computer (keyboard, mouse, camera), tablet, phone, software defined equipment, IoT device, etc.as well as applications that the factor can support.
Acceptable devices for authentication factor (if required)	Varies depending on the factor (e.g. USB token, wearable device, software algorithm to run on device for use).
Additional events detected	A list of well-defined events including: duress, medical issue, fatigue, theft, tamper.

The next three attributes – strength, false positive rate and false negative rate – aim to support objective measurable specifications that address the 'robustness' and 'distinctiveness' qualities described in [13]. The strength attribute represents methods by which an authentication factor can be configured (from a supplier's point of view) or must be configured (from a security policy point of view). The strength attribute is particularly important for something that you know factors (e.g. passwords). For continuous factor authentication, strength may be described in terms of the sampling rate (how frequently classification/recognition is performed). For knowledge-based authentication (e.g. answering security questions), strength may be described in terms of the number of questions required to authenticate. The strength attribute is usually configurable.

False acceptance rate and false rejection rate are important for biometric and continuous authentication factors. They are specialized from the universally accepted receiver operating characteristic (ROC) curve mechanism for statistically characterizing the sensitivity and specificity of a binary classifier (for instance see [16]).

In the realm of user authentication, these measures are intended to capture statistically how likely a false user successfully authenticates or a true user fails to authenticate. This occurs because biometric recognition technologies (face recognition, voice recognition, etc.) are not perfect. Specifically, distinctiveness is addressed by false acceptance rate. A low false acceptance rate suggests that the underlying algorithm is able to distinguish a true user from false users.

These attributes are extremely important in helping to select which of perhaps many similar technologies is appropriate for a given application. They may not, however, be meaningful for more traditional authentication factors (e.g. something that you know) such as passwords as there is virtually no way for these factors to be misrecognized.

False acceptance and rejection rates are usually not directly configurable. However, it is frequently possible to tune them. For instance, lower false acceptance rates may be achievable by tuning algorithmic parameters in such a way that the false rejection rate increases as a result. Other factors, possible tied to strength, might also be tuned to decrease these rates. For instance, acceptance rates may increase or decrease depending on the frequency of classification/recognition.

The validation approach attribute is important in specifying how strength and acceptance rate specifications are validated. False acceptance rates and false rejection rates quotations may be very low if, for instance, statistical validation is performed using a small homogeneous sample set. Further, the validation approach may help a security organization determine under which conditions an authentication factor may be useful. For instance, voice recognition technologies may be robust in quiet lab environments but less so in outdoor public environments. This attributes addresses, in part, the acceptability and accessibility qualities from [13].

The connections requirement is particularly important for security organizations that need to perform a vulnerability analysis. Any connection interface is potentially vulnerable to exploitation, spoofing and/or denial. Further, organization may have implemented mechanisms for minimizing vulnerability for given connection types and thus prefer some technologies over others. Note that this attribute may not be relevant to 'something you know' authentication. This attribute addresses, at some level, the availability, accessibility, and acceptability qualities from [13].

The acceptable user conditions attribute supports the acceptability and accessibility qualities. Emerging authentication factors will likely be specialized for a given user condition or situation in order to support appropriate robustness while also maximizing convenience. For instance, continuous authentication based on facial recognition is only appropriate in situations where the user is expected to always be facing the face image capture component of the authentication factor. This may be appropriate for continuous use of a computer in an office environment, but may be less appropriate for occasional use devices that are frequently pocketed.

The next two attributes Authenticated devices and applications and Acceptable devices for authentication factor are simply characterizations of the equipment/software that a factor is intended to authenticate (e.g. computer, bank account session) and equipment used to perform the authentication. These attributes anticipate that suppliers may want to provide software-based solutions that can run on a variety of equipment. For instance, a factor that involves the use of a fitness tracker could potentially run on a variety of commercially available trackers. Thus, this attribute addresses the 'accessibility' quality discussed in [13].

Finally, the additional events detected attribute formalizes the concept that many potential authentication factors may have applications well beyond that of simple authentication. In particular, continuous biometric authentication factors may be able to detect events not directly related to authentication or security such as health events or fatigue. This attribute addresses the 'acceptability' quality from [13]. In particular, an organization may be more willing to invest in an authentication factor approach if it may bring additional benefits beyond robust authentication.

It should be noted that Table I is used to describe 'opt in' technologies where the user has opted to use an authentication factor in order to identify themselves. In biometric recognition and related areas, 'opt out' technologies are used to identify individuals without their direct compliance. While opt out technologies define an important research area, I do not believe that they are appropriate for authentication factors as most current uses for authentication implicitly involve users opting in in order to utilize the equipment or service being secured.

To achieve security policies that are appropriately flexible while maintaining a strong security posture, it is important to take into account a user's mission. In many situations today, security policies only allow a single combination of authentication factors. The result is that users may not use equipment or services that is too onerous to access, may seek

mechanisms to subvert the security policies decreasing the security posture, or may put up with the inconveniences reducing their overall effectiveness and safety. Future security policies might allow a user community to select their own factors and instead provide guidance on how the selected factors must be configured and used in order to be allowable.

Toward this end, Table II provides a draft taxonomy for users in the context of the mission they are performing and for which they need devices and applications authenticated. It is anticipated to be used by a mission leader. The first attribute, mission class, is intended to be a high level characterization to simplify selection and guidance of authentication factors.

Table 2: User (Mission) Definition

ATTRIBUTE	VALUE
Mission Classes	A list of well-defined mission classes including: Desk worker, Office worker not at desk, Factory worker, Home indoor user, home outdoor user, tactical user in hazardous situations, tactical user not likely in hazardous situations, tactical user in extreme environments, etc.
Anticipated session duration	Varies but used to help determine how often a user might be required to re-authenticate
False Acceptance Rate tolerance	Taken together these might be used to select appropriate factors and/or their configurations. For instance, a factor may be configured for extremely low acceptance rate while allowing higher rejections rates (possibly forcing user re-authentication)
False Rejection Rate tolerance	
Acceptable user anomalies	A list of well-defined conditions that are acceptable for a user to exhibit during a valid authentication session including: Stress, strenuous activity, covert use, extreme environmental conditions, etc.
Mission restrictions and conditions	A list of well-defined restrictions and conditions including: outdoor use, wired and wireless restrictions, etc.
Devices and/or applications requiring authentication	A list of devices or applications including computer, tablet, phone, software defined equipment, IoT devices and web site account sessions.
Authentication factor limitations	A list of well-defined restrictions including: no-keyboard requirement, no carry requirement

The second attribute, expected duration, is important in selecting technologies and methods. For instance, more rigorous initialization and/or calibration steps may be more acceptable for long duration uses. If the duration is anticipated to span multiple days then authentication approaches must deal with users sleeping and bathing. For some technologies, expected battery life on equipment is an important consideration.

False acceptance and rejection rate tolerances are important in helping mission leaders specify acceptable risks. For instance, a mission leader may need to consider the risk of an authenticated device falling into an adversary's hands. To the extent that recognition algorithms are tunable, a mission leader may insist on a tuning that is either very conservative for false acceptance rate or very conservative for false rejection rate.

Mission restricts and conditions are important for helping users consider what authentication technologies may be acceptable. Outdoor usage suggests weatherproofing and often battery operation. Wireless transmissions are ultimately observable and/or disruptable by an adversary, but some are less so than others.

Listing all of the equipment or services that a user might authenticate with in order to carry out their mission may spur the usage of authentication factors that can be applied to multiple devices simultaneously. For instance, a wearable device may potentially interface with all of the equipment a user may need to use during a given mission so that they are less encumbered by individual specific authentication processes.

Authentication device restrictions may be used to reject authentication factors. Something you have factors such as tokens or cards are problematic if a user damages, loses or forgets to bring them, particularly where there may be no viable back up options. This case may suggest a 'no carry' restriction. Users wearing protective hand gear may reject any approach requiring a keyboard or keypad.

Table III is intended to allow a mission leader to work with a security organization to develop appropriate security policies and to allow the mission leader to determine how best to perform his or her mission given acceptable risks. A security policy may allow a variety of primary factors to be used as long as they meet requirements spelled out in the security policy. The same should be possible for secondary factors. A supplier offering an authentication factor that is intended as a secondary factor might provide appropriate interfaces to a variety of primary factors in order to facilitate integration.

As wearable devices and biometric recognition algorithms become more capable, I believe that it should be possible to develop an authentication factor that can be used to 'unlock' a number of devices or services. In particular, software defined equipment could interface with other equipment to obtain authenticated user credentials providing a stronger security posture without placing additional requirements on the user.

Thus, future security policies should define to what degree they will allow multiple simultaneous devices and/or applications to be authenticated by a given authentication factor or combination of factors. Today, a similar concept is in common use, referred to as single sign on, where once a user authenticates with their computer, for instances, their credentials

are made available to software applications (avoiding the need to re-authenticate).

Table 3: Authentication Policy definition

ATTRIBUTE	VALUE
Primary factor requirements	Restrictions on the primary authentication factor. These requirements should specify restrictions on strength and mechanisms for re-authentication if 'something you know' is forgotten or 'something you have' is misplaced, forgotten, or damaged. It may further provide restrictions on secondary factors paired with it.
Secondary factor(s) requirements	Restrictions on the secondary factor(s) (can be more than one). Includes re-authentication mechanisms, restrictions on strength
Acceptable devices or services for use	A list of devices or services that can be simultaneously authenticated via a single (multifactor) authentication.
Anomaly policy	A list of well-defined actions to be taken including logging, notification, etc.
Rejection policy	A description of what happens when user authentication is rejected including logging, notification, locking session, etc.
Recovery policy	A description of how a valid user 'recovers' from authentication factor issue including forgetting information, losing, damaging or forgetting tokens, biometric measurement issues, etc.

Anomaly policy provides guidance on what actions are taken if anomalies are detected. For instance, an anomaly on a user's tablet might trigger a notification to the mission leader that might help the leader decide whether or not to take action.

Finally, rejection policies in the future may be more flexible than they are today. If a user loses control of their device, it may make sense to lock or even zeroize the device. However, if the possibility exists for them to regain control, a policy that might allow partial access to emergency features (e.g. ability to send emergency requests to a mission leader) or re-authentication features.

Note that Table I-III are not meant to be completely exhaustive. Rather their intent is to trigger discussions about how to completely define authentication technologies vis a vis user missions and security policies so that standards and/or specifications can be developed that are inclusive of a wide range of authentication technologies.

While the scope of situations for which this taxonomy is intended to address is extremely wide, Table IV attempts to outline a potential approach to using the three part taxonomy presented in this section to select an appropriate authentication methodology for a given mission.

4. ConOps and Authentication Limitations

To better motivate the need for innovation and flexibility in authentication factors and the security policies used to provide restrictions and requirements for them, this section will describe 2 ConOps for which currently acceptable assumptions made about authentication implementations may not hold and 1 for which they do.

The first ConOps was originally presented in [1]. Here a tactical user, such as a soldier, Marine, law enforcement officer, guard or emergency responder, uses a network-enabled cell phone or tablet to support their operations. The user's device might be of critical importance in helping them identify and locate persons of interests or threats, send out requests for back up or exfiltration, or report back relevant intelligence and observations.

The challenge here is that user authentication is extremely important to insure that if the user's device or they themselves are captured by a red force actor (enemy combatant, criminal, or other threat) that the red force actor is not able to exploit the device to gain access to critical information and/or intelligence. On the other hand, the user authentication should allow the tactical user uninhibited access to the device up until the moment that the tactical user loses control of it.

A fundamental assumption that we made in pursuing this work is that the target user community can be characterized by the following constraints:

- The user needs to access their device even when they are in harm's way and there is a possibility that the device may fall into the hands of adversaries including insider threats.
- The user will need to access their device while performing other tasks that will take precedence over device interaction.
- These may include driving, surveilling or monitoring, or physically interacting with civilians, criminals or other red force actors.
- Thus, authentication factors tied to inactivity periods are not practical as the tactical user may be inactive, vis a vis the device, throughout the majority of their tactical mission.
- The user may want to be able to access sensitive data and applications covertly (for instance, if they are undercover).
- This implies the use of commonly available devices, not specialized restricted equipment.

Table 4: Selecting Authentication Methodology for a Given Mission

CONSIDERATION	TAXONOMY RELEATIONSHIP	COMMENTS
What devices and/or applications are required for the mission and do they need to be protected?	Table II – Mission class, expected duration, devices and/or applications requiring authentication	Include the following: • Software defined equipment (e .g. radios, networks, sensors) • Applications running on computing devices such as computers, tablets, phones Consider if it is possible to implement authentication directly into the device or application: • Can authentication be added to or credentials shared with software defined equipment? • Can authentication be added to applications? Consider if alternative mechanism to protecting devices is possible: • Physical device not require protection but cloud based applications running on them do need to be protected. Is there an effective mechanism for authentication on the cloud? • Software defined equipment does not need to be protected as long as the infrastructure that it integrates with is able to provide protections
Risk of false acceptance	Table II - False Acceptance Rate tolerance	If a red force actor gains access to mission devices and/or applications, what are the risks (critical information access, ability to reengineer underlying technology, ability to perform malicious actions with capture devices and/or applications)? Are there other mechanisms to mitigate the risks?
Risk of false rejection	Table II - False Rejection Rate tolerance	If a user can no longer access their devices and/or applications, what are the issues (inability to communicate with teammates, inability to navigate mission area, loss of knowledge access critical to perform mission, inability to perform actions required for mission). Are there other mechanisms to mitigate the loss of access?
Restrictions on authentication factors	Table II - Authentication factor limitations	Consider if a user can use their fingers at all times that device interaction is required. Consider if a user can wear a device and where (wrist, finger, around neck). Consider if a user may forget something they know. Consider if a user may loss, damage, or forget something they have. Consider if a biometric feature will be available to measure (iris scan, finger prints).
What category(s) of authentication methodology are acceptable	Table I – Categories	Work with Security organization to find categories for which policies exist or develop new policies for given category.
What is the best authentication implementation?	Table I – Remaining attributes	Work with Security organization to select authentication factors and configurations to meet mission requirements and provide appropriate protection.
How to implement security policy?	Table III all attributes	Work with Security organization to determine how best to implement policy to provide appropriate protection and mission flexibility.

- The user's organization does not wish to waive cybersecurity controls associated with identification and authentication because the cybersecurity risk of the waiver is considered higher than is acceptable.

To support this ConOps, we developed a continuous authentication algorithm for monitoring the availability of a fitness tracker, worn by the user, and connected to the device via a consented Bluetooth wireless connection. The algorithm further estimating a user's health status based on biometric sensor readings read from the fitness tracker. In particular, we implemented the algorithm using both a Microsoft® Band 2 and Microsoft® Band 1 fitness tracker connected to a Microsoft® Surface tablet.

While the ultimate use of the proposed algorithm must be determined by the security policies of the organization responsible for managing the mobile devices, the proposed use of the algorithm is to provide a continuous stream of user health status estimations to be used as a secondary authentication factor. Certain statuses, when they are identified, will cause the device to lock and/or wipe sensitive data depending on organizationally defined procedures. In particular, the following situations may indicate authentication failure or partial failure limiting device access, especially to sensitive data:

- The fitness tracker loses contact with the wearer or the connection with the device implying that the user may no longer have his or her device and/or fitness tracker.
- The tactical user is under extreme duress implying that the user may no longer be in full control of the device or may be being manipulated by the threat.
- The tactical user may be dead or their health may be extremely compromised indicating that the user is unable to maintain control of the device.

In [1] we presented a jump Kalman filter (JKF) that continuously monitors the fitness tracker sensor readings looking for 'jump' discontinuities that might indicate one of the above three situations. Jump discontinuities are required to differentiate between, for example, duress and extreme physical exertion, the latter being an acceptable and even expected situation for the tactical user.

The benefit of using JKFs over explicit ML techniques is that JKFs are always using recent history to predict a user's next biometric reading. As long as the biometric readings do not change suddenly, the JKF's estimates will be very close to the actual readings. At times when the variability of the readings is high, the estimated covariance is high, so the allowable difference between the estimates and actual readings is increased. It is only when a true discontinuity in readings is observed that a jump is identified. This means that regardless of what a user's health state is after the user is initially authenticated by whatever means, as long as it does not change suddenly during the continuous monitoring, the JKF does not recognize a duress or other disqualifying condition. See [17,18] for other work related to JKF algorithms.

ML techniques can be very powerful, but many will require an initial training period. This may require retraining during every authentication session when using sensor readings or outputs that change a lot over time, e.g. from day to day. Of course, if the degree of difficulty involved in retraining is low, ML techniques might be very useful.

The implementation of the JKF algorithm and its configuration can be used to illustrate important considerations in user authentication. Ultimately, for a security organization to trust such an algorithm, they should require objective metrics on its performance in all relevant conditions. These include probability of false acceptance and probability of false rejection. Ideally such metrics might be computed by a supplier of this kind of authentication factor but then an important question is how these metrics are collected. Ultimately, it may be difficult for a commercial organization to thoroughly vet such an algorithm with actual users because it might require putting users into, at least convincingly, dangerous situations.

Further, this algorithm performs best when calibrated. Kalman filters normally are calibrated by simply collecting a small amount of history at the beginning of a session. In [1] we used 10 seconds of history to calibrate the JKFs. Jumps were recognized by the difference between actual and predicted readings exceeding the filter's covariance by greater than a predetermined constant factor:

$$|\boldsymbol{x_k} - \boldsymbol{z_k}| > C\ {\sigma_z}^2 \quad (1)$$

where $\boldsymbol{z_k}$ is the measurement, $\boldsymbol{x_k}$ the prediction, ${\sigma_z}^2$ the covariance, and C is a predetermined constant factor. One potential use of ML in conjunction with a JKF is in establishing the value of C, which may or may not be a constant. For instance, it is possible to imagine that the value of C may be best expressed as a function of other variables including the covariance. Ultimately, rigorous calibration mechanisms that are not unduly onerous for the user community are needed and security organizations need confidence in these mechanisms.

It should be noted that in addition to supporting user authentication, the approach presented in [1] supports a host of auxiliary requirements and features, including enhanced situation awareness of tactical users' status, early indicators of conflict or environmental hazards, and possibly early warning of health related issues (e.g. experiencing duress when not in a hazardous situation). It is likely that many of the other approaches being invented for user authentication might also be capable of supporting ancillary features.

A second ConOps is that of a tactical user, such as an Airman conducting an airborne mission. In such missions, physical access to mission aircraft is heavily restricted by armed guards. Because of this, in the past, authentication requirements may have been waived. In recent times, however, concern over insider threats, which may be inadvertent, accidental or deliberate, have forced tactical users to perform dual factor authentication. User authentication both limits access to the aircraft systems to trusted users and enforces nonrepudiation – the concept that an authenticated user cannot perform an action and later deny it.

An issue with requiring 'something you have' such as a token as a secondary authentication factor in such situations, is that if a user forgets, losses, or damages the card it may be necessary to scrub the mission.

Biometric factors may be complicated by the requirement to wear personal protective equipment. A further concern with biometric factors, such as finger prints, is that a red force actor can physically force a user (conscious or unconscious) to provide a reading to the authentication system.

One authentication approach for the tactical user that I believe will support strong security while alleviating concerns over authentication factor requirements involves a continuous authentication factor. Similar to the approach presented in [1], a continuous authentication factor tied to something that a tactical user may normally be wearing, such as a fitness tracker, may be used to establish and maintain the user's identity.

Further, this wearable device may be used to establish connections with all of the devices, such as radios and mission computers that the user needs to interact with in order to conduct their mission. The user could be automatically authenticated to all devices as long as the continuous authentication and connection to the devices remains viable. The continuous

authentication algorithm used to establish the user's identity and continually monitor the user may be changed to reflect different aspects of the mission than the one described in [1].

Wireless technologies are frequently disallowed in classified environments which may include mission aircraft. In order to use a continuous monitoring approach such as the one suggested, either a wired device would be required to monitor the user, or a wireless protocol that is not considered vulnerable must be utilized. Bluetooth, ZigBee (utilized in IoT devices), or Near Field communications (NFC) protocols are probably the most practical for such situations but they may require further encryption or other restrictions before they are allowed in a classified environment.

A third ConOps to consider is one that is implicitly addressed in much of the literature involving continuous authentication. It is that involving a knowledge worker who is usually using a computer or tablet. During the course of a normal day's work the worker would not be expected to undergo severe stress or duress. Any such situation would be considered abnormal and would warrant locking the worker out of their session until he or she reestablishes it via more traditional means such as requiring the entry of a password or PIN or calling a help desk. In this situation, video analytics using the computer or tablet camera, keystroke behavior, or a variety of other factors are likely practical to support strong and usable security.

5. Next Steps

This paper has sought to demonstrate that an increasingly networked software-defined technology footprint in our work and leisure environments is expanding the need and/or opportunity for user authentication before allowing access to computers, phones, IoT devices, services, and general equipment. At the same time, technology advances in wearable devices, biometric sensors, behavior analytics and a host of other fields is supporting the potential for more secure and less onerous authentication methodologies. Developing innovative new authentication factors to the point of productization and mass production, however, will be accelerated if inventors, investors, and manufacturers understand that security organizations and even home users will accept alternative authentication factor technologies to the relatively simplistic ones commonly utilized today.

Toward this end, this paper has attempted to motivate the formation or expansion of a standards body concerning user authentication technologies and policies. The taxonomy presented in Section III is primarily meant to provide early talking points in the formulation of a standards or specification body.

In one somewhat related example of how standards bodies can spur innovation and technology development, the U.S. National Security Agency (NSA) developed and published the Commercial Solutions for Classified Program (CSfC) specification [19]. Manufacturers and solution providers have used this specification to develop capability sets that they in turn have been able to have registered with NSA after providing evidence of compliance with the CSfC specification. This allows third parties to purchase and integrate compliant capability sets into their environments. In the end, the overall process of getting a classified environment certified by NSA has become far more flexible, affordable, and expedient because of the specification and associated registration process.

A similar approach applied to user authentication may ultimately support stronger and less onerous user authentication, and it may further support the expansion of user authentication and access restriction's use within an overall cybersecurity plan further enhancing security and usability at an enterprise level. For instance, if all equipment in a factory, office, or military platform required user authentication to read and/or modify equipment settings and/or to use the equipment, it may be much more difficult for the equipment to be 'hacked' because network penetration alone does not provide access to the equipment and software running on it.

While such an approach may seem unacceptable today, acceptance of emerging authentication methodologies will increase within security organizations as their strength and acceptance rates are proven and their risks are understood and mitigated. Further, acceptance within user communities will increase as authentication processes become simpler and less prone to error.

Similarly, user authentication techniques that are easy to understand and utilize might be used to enhance home security in a consistent and predictable fashion reducing deliberate and/or inadvertent actions causing harm to occupants and/or damage to or loss of property.

Conflict of Interest

The author declares no conflict of interest.

Velocity obstacles

ABSTRACT

This paper addresses the motion planning problem of Reeds-Shepp-type car-like mobile robots moving among static and dynamic obstacles. If the positions and the velocity vectors of the obstacles are known or well estimated, the Velocity Obstacles (VO) method and its non-linear version (NLVO) can be used to plan a collision-free trajectory for a robot in the dynamic environment. VO and NLVO algorithms determine a velocity vector for the robot which corresponds not necessarily to the orientation of the robot, hence a nonholonomic car-like mobile robot cannot apply it exactly. Previously, the NLVO method was adopted for Dubins-like mobile robots, which are able to move forward only. In this paper, a method similar to NLVO is presented, but it results motions feasible for Reeds-Shepp-type robots, which are able to drive both forward and backward. Longitudinal velocities and curvatures of turning circles are calculated, which ensure collision-free motion if the arbitrary movement of the obstacles are known for some time-horizon.

1. Introduction

This paper is an extension of work originally presented in the 25th Mediterranean Conference on Control and Automation [1].

One of the main tasks of autonomous mobile robots is to execute a safe motion in their workspace from the actual position to a desired goal configuration. In some applications, the environment is fix, i.e. the positions and velocities of the obstacles are known. Otherwise the robot has to use some sensors to be able to estimate this information. Robots should be able to plan their motions such that they will not collide with static or moving obstacles. The literature presents several path planning methods for the avoidance of static obstacles (see e.g. [2,3]).

There are two possibilities for motion planning among moving obstacles: 1, The planning can be done in two steps: geometric path planning and then velocity planning. 2, The geometry of the path and the velocity profile along it are determined simultaneously.

[*]Corresponding Author: Emese Gincsainé Szádeczky-Kardoss,
Email: szadeczky@iit.bme.hu

In the first case, the geometry of the path and its time distribution are calculated separately (e.g. [4,5]). At the path planning phase, the moving obstacles are disregarded. The planner calculates a path which ensures collision-free motion to the goal among the static obstacles. The motions of the obstacles influence only the velocity profile of the path.

The second possibility is to calculate both the path geometry and the velocity profile in one step (e.g. [6]). In this second case the shape of the path depends also on the positions and movements of the dynamic obstacles.

If the information about the obstacles (positions, velocities) are known, a global path planner can be applied. If the environment is unknown, a local reactive obstacle avoidance algorithm has to be used based on the sensory information (e.g. [7]).

Several motion planning methods in static environment can be extended to solve the dynamic problem as well. Some methods use the configuration space of the robot to find a feasible path among static obstacles (e.g. [3]). If the workspace of the robot contains moving obstacles as well, the configuration space should be

extended by a temporal dimension, and the motion should be searched in this extended space. Using this solution, one has to modify the distance metric to deal with the temporal dimension [5].

The Artificial Potential Field (APF) algorithm is a quite simple method which can be used for path planning in static environment [8]. Applying special potential force functions, one can solve the motion planning problem in case of moving target and obstacles using APF [9,10].

The Dynamic Window (DW) method is a local obstacle avoidance algorithm used in static environment [11]. The planning is done in the velocity space of the robot. Reachable and admissible velocity values are selected. Reachable values satisfy the kinematic and dynamic constraints of the robot and admissible values guarantee that the robot can stop before hitting an obstacle. An adaptation of DW can be used with moving obstacles as well [7].

The inevitable collision states (ICS) for robots are presented in [12]. If the robot is in an IC state, it surely collides with an obstacle independently from the future trajectory of the robot. If a state is non-ICS, there exists at least one motion possibility for the robot to avoid collision. Using the ICS concept, the motion planning problem in dynamic environment can also be solved [13].

The concept of velocity obstacles (VO) was introduced in [6] for such environments where the velocity vectors of the obstacles are supposed to be unchanged for some time-interval. Using VOs, an avoidance maneuver can be determined in the velocity space of the robot, based on the current positions and velocities of the robot and obstacles. Velocity obstacles represent the set of robot velocities that would result in a collision with a static or moving obstacle. The basic VO method was extended for obstacles moving along arbitrary trajectories (non-linear velocity obstacles – NLVO [14]).

The inverse version of NLVO (INLVO) can be used to plan the velocity profile for a robot along a path with fix geometry [15]. A modified VO method can be used to plan autonomous navigation for unmanned surface vehicles as well [16]. The hybrid reciprocal VO (HRVO) is a method to plan the motion of multiple mobile robots without central coordination [17].

Our conference paper [1] presented a modified version of VO to plan the motion for Dubins-like mobile robots (VOD - Velocity Obstacles for Dubins-like robots). These robots go only forward. VOD defined pairs of colliding velocity and turning radius.

In this paper, the goal is to define velocity obstacles for Reeds-Shepp-type car-like mobile robots, which are able to drive both forward and backward. The determination of colliding velocity and curvature pairs is discussed. In this paper, the curvature is used instead of turning radius, hence the graphical representation of the colliding pairs is easier. The method and the equations of [1] were modified to deal with negative velocities and to use curvature instead of turning radius.

The paper is organized as follows. Section 2 gives a short review of velocity obstacle methods. Section 3 presents the properties of Reeds-Shepp-type mobile robots. Section 4 describes how the 'velocity' of a car-like robot is represented in this work. In Section 5, the velocity obstacles for car-like mobile robots (VOCL) are presented. Some simulation results are given in Section 6. Finally, a short section concludes the paper.

2. A Short Review of Velocity Obstacles

VO method can be used to find a feasible velocity vector for the robot such that the robot is able to avoid static and moving obstacles. It is assumed that the position and velocities of the obstacles are known, and the obstacles follow a straight-line path for some time-horizon. The VO method uses circular representation of the robot and the obstacles with known radii.

Given are a robot A and some moving obstacles B_i ($i = 1 \dots n < \infty$), where n denotes the number of obstacles. (According to this concept, a static obstacle is a moving obstacle with zero velocity.) The velocity obstacle VO_i contains all the robot velocity vectors $\mathbf{v}$ which would result a collision with obstacle B_i:

$$VO_i = \{\mathbf{v} | \exists t: A(t, \mathbf{v}) \cap B_i(t) \neq \emptyset\} \quad (1)$$

where $A(t, \mathbf{v})$ denotes the robot at time t if velocity $\mathbf{v}$ was applied. The shape of VO_i is a cone (see Figure *1*). The union of the individual VO_i reads

$$VO = \cup_{i=1}^{n} VO_i. \quad (2)$$

Selecting a velocity vector outside VO guarantees that no collision will occur between the robot and the obstacles.

An example for a point robot A and two moving (B_1, B_2) and a static obstacle (B_3) is presented in Figure *1*.

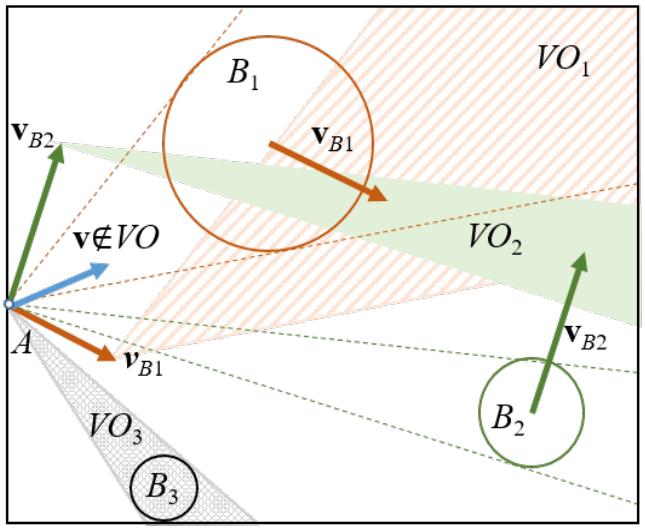

Figure 1. Velocity obstacles for a point robot A with two moving (B_1, B_2) and a static obstacle (B_3). $\boldsymbol{v}_{B1}, \boldsymbol{v}_{B2}$ are the velocities of the obstacles. VO_i denotes the velocity obstacle corresponding to obstacle B_i. A collision-free example is depicted for robot velocity: $\boldsymbol{v} \notin VO = \cup_{i=1}^{3} VO_i$.

2.1. Non-Linear Velocity Obstacles

The non-linear velocity obstacle (NLVO) defines the set of all linear robot velocities that would result a collision with obstacle B_i (t) moving along arbitrary known trajectory. At time instant t,

one can define robot velocity vectors which move the robot to a position during time $t - t_0$ such that a collision occurs with B_i:

$$NLVO_i(t) = \frac{c_i(t)+B_i}{t-t_0} \tag{3}$$

where $c_i(t)$ denotes the trajectory of the obstacle B_i. Considering all $t > t_0$, one gets

$$NLVO_i = \bigcup_{t>t_0} \frac{c_i(t)+B_i}{t-t_0}. \tag{4}$$

The shape of the non-linear velocity obstacle $NLVO_i$ is a warped cone with apex at A (see Figure 2). Similar to (2), the union of the individual $NLVO_i$ defines the set of all robot velocity vectors which result a collision for some $t > t_0$.

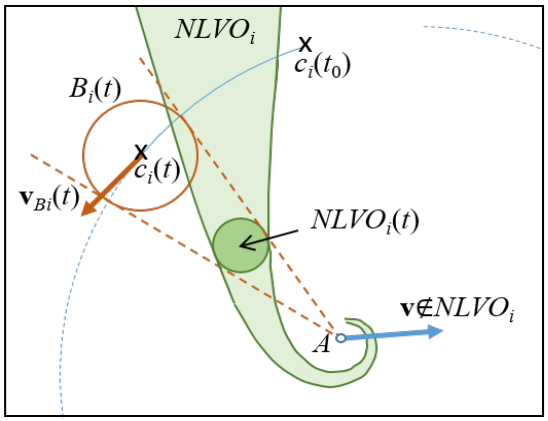

Figure 2. $NLVO$ for a point robot A with obstacle B_i moving along a circular path.

2.2. Generalized Velocity Obstacles

The concept of velocity obstacles was generalized to apply it for car-like robots [18]. The obstacle is defined in the control space of the robot:

$$GVO = \{u | \exists t: \|A(t,u) - B(t)\| < r_A + r_B\} \tag{5}$$

where u is the control input of the robot, $A(t,u)$ is the position of A if control u was applied up to t. r_A and r_B denote the radii of the circular robot and obstacle.

The controls are sampled, and for each control u, the minimum distance between A and B is determined numerically, if control u was applied to the robot. If the minimum distance is smaller than the sum of the radii, $u \in GVO$ and it means that a collision will occur between B and A for the control u.

2.3. Idea for Extension

In this paper, the velocity obstacles are applied to similar robots as presented in Subsection 2.2. This solution will not be restricted to sampled control inputs, as suggested by [18]. The presented method represents the velocity obstacles for car-like robots as a subset of a two-dimensional plane similar to the methods of VO and NLVO. In this work, this plane is determined by the velocity of the robot and the curvature of its path.

3. Reeds-Shepp-Type Car-Like Mobile Robots

A car-like mobile robot (see Figure 3) can move in a two-dimensional workspace. The state of the robot is defined by its position and orientation. The position is given by the (x, y) coordinates of the midpoint of its rear axle. The orientation of the robot is denoted by θ, and it is defined by the angle of the positive x axis of the coordinate system and the longitudinal axis of the robot. Ackermann-steering is supposed (see [19]), and the movement of the robot is described by the motion of a bicycle putting on the longitudinal axis of the robot. The inputs of the robot are the longitudinal velocity v and the angle of the front turning wheel (δ). Notice, that v is a scalar.

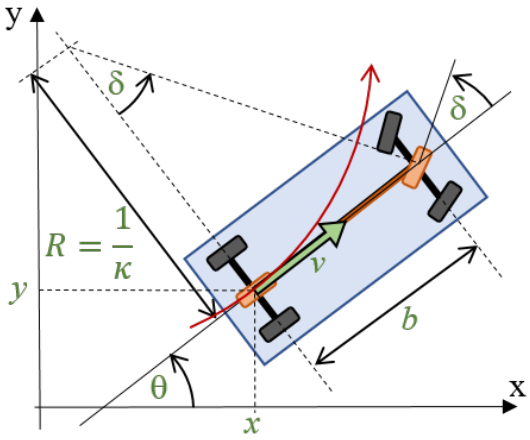

Figure 3. Car-like mobile robot.

The kinematics of the robot reads:

$$\begin{bmatrix}\dot{x}\\ \dot{y}\\ \dot{\theta}\end{bmatrix} = \begin{bmatrix}\cos\theta\\ \sin\theta\\ \frac{\tan\delta}{b}\end{bmatrix} v, \tag{6}$$

where b is distance between the front and the rear wheels. The turning angle δ of the front wheel determines the radius R of the turning circle of the robot: $R = \frac{b}{\tan\delta}$. The reciprocal of the turning radius is called curvature: $\kappa = \frac{1}{R} = \frac{\tan\delta}{b}$.

The turning radius R cannot be arbitrary small, since the turning angle δ of the front wheels is also limited. Depending on the limit of δ and the geometrical b parameter of the robot, a minimal turning radius can be determined: $R_{min} \leq |R|$. Similarly, the curvature is also limited: $|\kappa| \leq \kappa_{max}$.

The car-like mobile robot is a nonholonomic system since the direction of its velocity vector is constrained by the following equation:

$$\dot{x}\sin\theta - \dot{y}\cos\theta = 0. \tag{7}$$

There are different types of car-like mobile robots: Dubins-robots can only move forward (i.e. $v > 0$). It was proved that for given start and goal states the path with the minimal length consists of three segments: two or three circular segments with maximal

curvature (i.e. with minimal turning radius) and, if needed, a straight-line between two circles if no obstacles are presented in the workspace [20]. The Reeds-Shepp-type mobile robots are able to travel both forward and backward. It was also shown that the path with minimal length between given start and goal states contains (like Dubins-robots) circular segments with maximal curvature, and it may contain straight-lines and cusp points where the driving direction changes [21].

4. Velocity Representation for Car-Like Mobile Robots

A Reeds-Shepp-type mobile robot can move forward or backward on a circular path segment with constant curvature (κ), i.e. with constant radius ($R = \frac{1}{\kappa}$), or on a straight-line. The curvature may have negative values, which shows that the robot turns in the negative direction (i.e. clockwise). The straight-line motion can also be described by a zero curvature. The time-distribution along the path depends on the longitudinal velocity v of the robot. The sign of v shows the direction of motion. These imply that the actual motion of the robot can be described by the pair (v, κ).

If (v, κ) is constant for a time period Δt, one can calculate the displacement in position and in orientation for Δt, if the motion starts at $t_0 = 0$ from $[x_0, y_0, \theta_0] = [0,0,0]$ by integrating (6):

$$\begin{bmatrix} x(\Delta t) \\ y(\Delta t) \\ \theta(\Delta t) \end{bmatrix} = \begin{bmatrix} \frac{2}{\kappa} \sin\frac{\kappa v \Delta t}{2} \cos\frac{\kappa v \Delta t}{2} \\ \frac{2}{\kappa} \sin^2\frac{\kappa v \Delta t}{2} \\ \kappa v \Delta t \end{bmatrix}. \quad (8)$$

This works in the reverse direction as well: if a point (x, y) is given in the workspace of the robot, one can determine the constant curvature κ and the constant forward longitudinal velocity $v^f \geq 0$ and backward velocity $v^b < 0$, which can move the robot from $t_0 = 0$ and $[x_0, y_0, \theta_0] = [0,0,0]$ to this point during time Δt:

$$\kappa = \frac{2y}{x^2+y^2}, \quad (9)$$

$$v^f = \frac{x^2+y^2}{y\Delta t} \operatorname{atan}\frac{y}{x}, \quad (10)$$

$$v^b = \frac{x^2+y^2}{y\Delta t} \left(\operatorname{atan}\frac{y}{x} - sgn\left(\operatorname{atan}\frac{y}{x}\right)\pi\right). \quad (11)$$

Notice, that (10) (and (11)) has several solutions for given x and y. If the robot does not go more than ones around in a circle, (10) (or (11)) will have a single solution for v^f (or for v^b) with $-\pi < \operatorname{atan}\frac{y}{x} \leq \pi$.

If the robot goes straight, its motion is described by: $x = v\,\Delta t, y = 0, \kappa = 0, R = \infty, v = \frac{x}{\Delta t}$. In the sequel, the goal is to determine the (v, κ) (i.e. (v^f, κ) and (v^b, κ)) pairs which result a collision-free motion for the robot.

5. Velocity Obstacles for Car-Like Robots

Let the robot be at the $[x_0, y_0, \theta_0] = [0,0,0]$ initial state. First, such (v, κ) pairs are determined which result a collision with static obstacles. Then the collision with moving obstacles is also considered.

5.1. Collision with Static Obstacles

Suppose that a static obstacle is presented in the workspace of the robot. Let a circle represent the obstacle. Its position is given by the coordinates of its center: (x_o, y_o) and its radius is r_o. For the sake of simplicity, the robot is also represented by a circle with radius r_r. (A non-circular robot or obstacle can be approximated by one or more circles.) To examine the collision for a point-like robot, the radius of the obstacle should be enlarged by the radius of the robot: $r_o' = r_o + r_r$ similar to the method proposed in [6].

First, such circular motions (i.e. curvatures κ_g) are considered, where the robot grazes (touches) the obstacle. Geometrically, the problem is the following: given a point (position of the robot), a straight-line going through this point (line of the robot's orientation) and a circle (obstacle with enlarged radius r_o'), such a circle has to be found, which is tangential to the circle of the obstacle and grazes the line of orientation at the given point (robot's position).

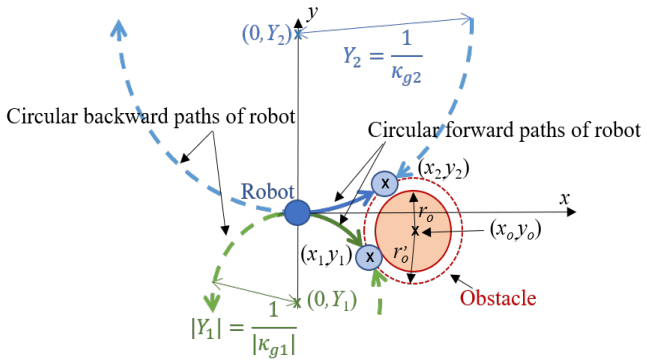

Figure 4. Grazing a static obstacle.

There are two possibilities (see Figure 4). In both cases the center of the turning circle lies on the y-axis (i.e. the x coordinate of the center of the turning circle is 0). The y coordinate of the center of the turning circle defines the radius of the circle. The two possible values for the curvatures (or for reciprocals of y coordinates of the center) are:

$$\kappa_{g1} = \frac{1}{Y_1} = \frac{2(y_o - r_o')}{x_o^2 + y_o^2 - r_o'^2}, \quad (12)$$

$$\kappa_{g2} = \frac{1}{Y_2} = \frac{2(y_o + r_o')}{x_o^2 + y_o^2 - r_o'^2}. \quad (13)$$

All curvatures between κ_{g1} and κ_{g2} will result in a collision with the static obstacle. More precisely, moving on a circle with curvature $\kappa_i \neq 0$ will cause a collision if

$$\min(\kappa_{g1}, \kappa_{g2}) < \kappa_i < \max(\kappa_{g1}, \kappa_{g2}). \quad (14)$$

$\kappa_i = 0$ can only cause a collision if

$$sgn(\kappa_{g1}) \neq sgn(\kappa_{g2}) \wedge sgn(x_o) = sgn(v). \quad (15)$$

The coordinates of the grazing points ((x_1, y_1) resp. (x_2, y_2)) can be calculated as well:

$$x_1 = \frac{x_o(x_o^2+y_o^2-r_o'^2)}{x_o^2+(y_o-r_o')^2}, \quad (16)$$

$$y_1 = \frac{(x_o^2+y_o^2-r_o'^2)(y_o-r_o')}{x_o^2+(y_o-r_o')^2}, \quad (17)$$

$$x_2 = \frac{x_o(x_o^2+y_o^2-r_o'^2)}{x_o^2+(y_o+r_o')^2}, \quad (18)$$

$$y_2 = \frac{(x_o^2+y_o^2-r_o'^2)(y_o+r_o')}{x_o^2+(y_o+r_o')^2}. \quad (19)$$

Consider now the time instant t. The (v, κ) input pairs can be determined, which cause collision with the static obstacle B_i at t. The velocity obstacle for a car-like robot (VOCL) is the union of these points (see Figure 5):

$$VOCL_i(t) = \{ (v, \kappa) | A(t, v, \kappa) \cap B_i \neq \emptyset \}, \quad (20)$$

where $A(t, v, \kappa)$ represents the robot at time-moment t moving from $t_0 = 0$ and from the origin on a circular path with radius $\frac{1}{\kappa}$ with velocity v. κ and v can be calculated from (x, y) position using (9)-(11).

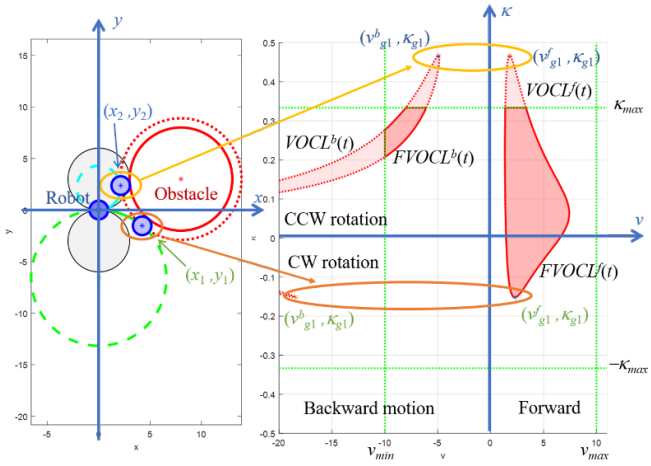

Figure 5. a. Robot and obstacle at a grazing case. b. Velocity obstacle $VOCL(t)$ and feasible VO $FVOCL(t)$ for time instant t

From the grazing points (x_1, y_1) and (x_2, y_2), one can determine the corresponding points in $VOCL_i(t)$. The curvatures κ_{g1} and κ_{g2} are used and the forward velocities v_{g1}^f, v_{g2}^f and backward velocities v_{g1}^b, v_{g2}^b can also be calculated if (x_1, y_1) or (x_2, y_2) should be reached on a circular path during time t.

(v_{g1}, κ_{g1}) and (v_{g2}, κ_{g2}) lie on the boundary of $VOCL_i(t)$. All other points on the boundary of $VOCL_i(t)$ correspond to a motion (i.e. (v, κ) values) which moves the robot during time t to a boundary point of the obstacle, but before or after the time instant t a collision occurs.

$VOCL_i(t)$ according to (20) may contain (v_j, κ_j) pairs, such that $|\kappa_j| > \kappa_{max}$ or $|v_j| > v_{max}$. These κ_j or v_j values are not feasible. Feasible VO ($FVOCL_i(t) \subseteq VOCL_i(t)$) contains only feasible curvature and velocity values:

$$FVOCL_i(t) = \{(v, \kappa) | A(t, v, \kappa) \cap B_i \neq \emptyset \wedge$$

$$|v| \leq v_{max} \wedge |\kappa| \leq \kappa_{max}\}. \quad (21)$$

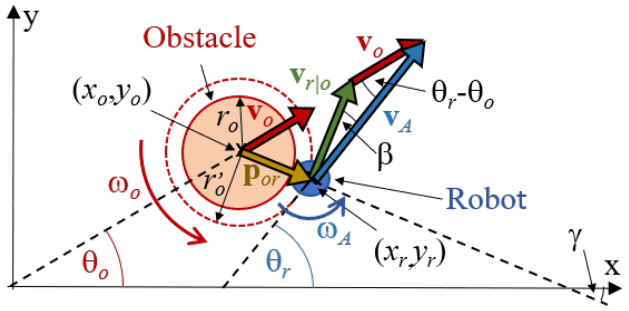
In Figure 5 $VOCL_i(t)$ is delimited by dotted line and $FVOCL_i(t)$ is bounded by solid line.

Taking time-moments in a time-interval $t \in [t_0, t_h]$ one can get $FVOCL_i$ for a static obstacle B_i:

$$FVOCL_i = \bigcup_{t \in [t_0, t_h]} FVOCL_i(t). \quad (22)$$

If the robot moves according to $(v, \kappa) \notin FVOCL_i$, the robot will not collide with the static obstacle B_i in the given time interval $[t_0, t_h]$.

Notice, that the selection of t_h influences the effectiveness and the computational demand of the method. If a small value was selected for t_h, a mobile robot may collide with a moving obstacle. On the other hand, a large time-horizon can result that VO includes almost the complete velocity space [13].



5.2. Calculating VOCL for Moving Obstacles

For a moving obstacle $B_i(t)$ the definition of $VOCL_i(t)$ for a given time-moment t is similar to (20):

$$VOCL_i(t) = \{ (v, \kappa) | A(t, v, \kappa) \cap B_i(t) \neq \emptyset \}. \quad (23)$$

$FVOCL_i(t)$ and $FVOCL_i$ can be determined as well, according to (21) and (22).

The main difference is the following: the grazing points in $VOCL_i(t)$ ((v_{g1}, κ_{g1}) and (v_{g2}, κ_{g2})) do not represent grazing cases any more if the obstacle is moving since the position of the grazing points depends on the motion of the obstacle.

To analyze VOCL and the grazing points, the following notations are used (see Figure 6):

- A time instant t_A is considered.
- The position of the moving obstacle at t_A is denoted by $(x_o(t_A), y_o(t_A))$. The angle between the positive x-axis and

the velocity vector $\mathbf{v}_o(t_A)$ of the obstacle is denoted by $\theta_o(t_A)$, the absolute value of the velocity is $v_o(t_A)$. $\omega_o(t_A)$ denotes the turning rate of the obstacle. The vector $\boldsymbol{\omega}_o(t_A)$ is parallel to the positive z-axis, if the direction of the rotation is positive, and to the negative z-axis in case of clockwise rotation.

- An input pair (v_A, κ_A) is selected.
- If a robot is moving with a velocity v_A on a circle with curvature κ_A for time t_A, its position $(x_r(t_A), y_r(t_A))$ and orientation $\theta_r(t_A)$ can be determined according to (8). The absolute value of the robot's velocity v_A remains unchanged during the circular motion, but the vector of the velocity $\mathbf{v}_A(t_A)$ changes, since the orientation of the robot is also modified. The turning rate of the robot is $\omega_A = \kappa_A\, v_A$. The direction of vector $\boldsymbol{\omega}_A$ is parallel to the positive z-axis, if $\omega_A > 0$, and to the negative z-axis if $\omega_A < 0$. The vector $\boldsymbol{\omega}_A$ is constant during the circular motion, since its direction and length (i.e. ω_A) are unchanged.
- The relative velocity of the robot and the obstacle at time moment t_A is denoted by

$$\mathbf{v}_{r|o}\,(t_A) = \mathbf{v}_A(t_A) - \mathbf{v}_o(t_A). \tag{24}$$

- The angle between the velocity vector $\mathbf{v}_A(t_A)$ of the robot and the relative velocity $\mathbf{v}_{r|o}(t_A)$ is:

$$\beta(t_A) = \operatorname{atan}\frac{v_o(t_A)\sin(\theta_r(t_A)-\theta_o(t_A))}{v_A - v_o(t_A)\cos(\theta_r(t_A)-\theta_o(t_A))}. \tag{25}$$

- $\mathbf{p}_{or}$ is a vector connecting the center of the obstacle to the center of the robot.
- The angle between the positive x-axis and $\mathbf{p}_{or}$ is:

$$\gamma(t_A) = \operatorname{atan}\frac{y_r(t_A)-y_o(t_A)}{x_r(t_A)-x_o(t_A)}. \tag{26}$$

The following two propositions follow directly from the definition of $VOCL_i(t)$.

Proposition 1:

$$\sqrt{\left(x_r(t_A)-x_o(t_A)\right)^2 + (y_r(t_A)-y_o(t_A))^2} \le r_o' \Leftrightarrow$$

$$(v_A, \kappa_A) \in VOCL_i(t_A). \tag{27}$$

If $|\kappa_A| \le \kappa_{max}$ and $|v_A| \le v_{max}$, then $(v_A, \kappa_A) \in FVOCL_i(t_A)$ is also true. Similar to [14], the boundary points of the set $VOCL(t)$ are denoted by $\delta VOCL(t)$.

Proposition 2:

$$\sqrt{\left(x_r(t_A)-x_o(t_A)\right)^2 + (y_r(t_A)-y_o(t_A))^2} = r_o' \Leftrightarrow$$

$$(v_A, \kappa_A) \in \delta VOCL_i(t_A). \tag{28}$$

For the grazing points (v_{g1}, κ_{g1}) and (v_{g2}, κ_{g2}) in case of a static obstacle still holds true that $(v_{g1}, \kappa_{g1}) \in \delta VOCL_i(t_A)$ and $(v_{g2}, \kappa_{g2}) \in \delta VOCL_i(t_A)$ where δ denotes the region boundary. But these points are not grazing points any more, if the obstacle is moving.

Theorem 3: (v_A, κ_A) is a grazing point in $VOCL_i(t_A)$ if

$$\theta_r(t_A) + \beta(t_A) - \gamma(t_A) = \frac{(2a-1)\pi}{2}, a \in \mathbb{Z}. \tag{29}$$

Proof: $\theta_r(t_A) + \beta(t_A)$ denotes the angle between the relative velocity $\mathbf{v}_{r|o}(t_A)$ and the positive x-axis. $\gamma(t_A)$ is the angle between the positive x-axis and $\mathbf{p}_{or}$ (the vector connecting the center of the robot and the obstacle). The condition for the grazing situation is that the relative velocity $\mathbf{v}_{r|o}(t_A)$ is perpendicular to $\mathbf{p}_{or}$ which is equivalent to the case where the relative velocity $\mathbf{v}_{r|o}(t_A)$ is tangent to the circle of the enlarged obstacle with radius r_o'.

Similar to [14], it can be proven that if $\mathbf{v}_{r|o}(t_A)$ is perpendicular to $\mathbf{p}_{or}$, the robot grazes the obstacle.

A point P is selected on the boundary of the robot. $\mathbf{p}_P$ is a vector which goes from the center of the robot to P. The velocity of the point P is:

$$\mathbf{v}_P(t_A) = \mathbf{v}_A(t_A) + \boldsymbol{\omega}_A \times \mathbf{p}_P. \tag{30}$$

Similarly, a point Q can be selected on the boundary of the obstacle. $\mathbf{p}_Q$ is a vector which goes from the center of the obstacle to Q. The velocity of Q reads:

$$\mathbf{v}_Q(t_A) = \mathbf{v}_o(t_A) + \boldsymbol{\omega}_o(t_A) \times \mathbf{p}_Q. \tag{31}$$

If the point P of the robot grazes point Q on the obstacle, vector $\mathbf{p}_{or}$ has to be parallel to $\mathbf{p}_Q$ and $-\mathbf{p}_P$. Moreover, grazing case can only occur, if the relative velocity of point P according to point Q is tangent to the circle of the obstacle, i.e. if it is perpendicular to $\mathbf{p}_{or}$ (and accordingly to $\mathbf{p}_Q$ and $\mathbf{p}_P$ as well). The relative velocity of P according to Q is:

$$\mathbf{v}_{P|Q}(t_A) = \mathbf{v}_P(t_A) - \mathbf{v}_Q(t_A) =$$

$$= \mathbf{v}_A(t_A) + \boldsymbol{\omega}_A \times \mathbf{p}_P - \mathbf{v}_o(t_A) - \boldsymbol{\omega}_o(t_A) \times \mathbf{p}_Q. \tag{32}$$

$\mathbf{v}_{P|Q}(t_A)$ is perpendicular to $\mathbf{p}_{or}$, if:

$$\mathbf{v}_{P|Q}(t_A) \cdot \mathbf{p}_{or} = 0$$

$$(\mathbf{v}_A + \boldsymbol{\omega}_A \times \mathbf{p}_P) \cdot \mathbf{p}_{or} - \left(\mathbf{v}_o + \boldsymbol{\omega}_o \times \mathbf{p}_Q\right) \cdot \mathbf{p}_{or} = 0. \tag{33}$$

Both $(\boldsymbol{\omega}_A \times \mathbf{p}_P) \cdot \mathbf{p}_{or}$ and $\left(\boldsymbol{\omega}_o(t_A) \times \mathbf{p}_Q\right) \cdot \mathbf{p}_{or}$ equal 0, hence one gets

$$\left(\mathbf{v}_A(t_A) - \mathbf{v}_o(t_A)\right) \cdot \mathbf{p}_{or} = 0, \tag{34}$$

which is equivalent to that $\mathbf{v}_{r|o}(t_A)$ is perpendicular to $\mathbf{p}_{or}$.■

Notice, that the obstacles can move on arbitrary paths with arbitrary velocity profiles. The algorithm only supposes that for every time moment $t_A \in [t_0, t_h]$ the positions and the velocity vectors of each obstacles are known.

5.3. Trajectories Avoiding Obstacles

If a goal position is given in the workspace of the robot, a motion should be planned which arrives to this point. During the motion, no collision should occur.

Fiorini and Shiller presented some heuristic search methods using Velocity Obstacles [6]. Applying these, one can easily select at each time moment a feasible velocity vector which moves the robot to the direction of the goal such that it avoids collisions with the obstacles. Using these heuristics alone does not guarantee to find an optimal solution. They designed an off-line global search method as well. A tree was generated for avoidance maneuvers using VO.

Shiller et al. presented avoidance maneuvers using NLVO [14]. These avoidance maneuvers can be used in a local or global motion planner as well.

The VOCL method can also be used in all above methods to plan the motion for car-like mobile robots to a given goal avoiding static and moving obstacles.

5.4. The Safest Solution

Another possibility for the selection of (v, κ) pair is to determine the safest motion. This method is called as the Safety Velocity Obstacles method (SVO).

The most important goal of the SVO method is to ensure the safest path for the robot during the motion.

This method checks, how far a possible $(v, \kappa) \notin FVOCL$ pair is from the nearest $FVOCL_i$ (name this distance VO_{dist}). If the distance is bigger than a predefined threshold d_{max}, then the value of VO_{dist} is set to this maximum distance.

Hence, a normalized distance can be defined:

$$VO_{norm} = \frac{VO_{dist}}{d_{max}} \tag{35}$$

where $VO_{norm} \in [0,1]$. After that the value of the cost can be defined as

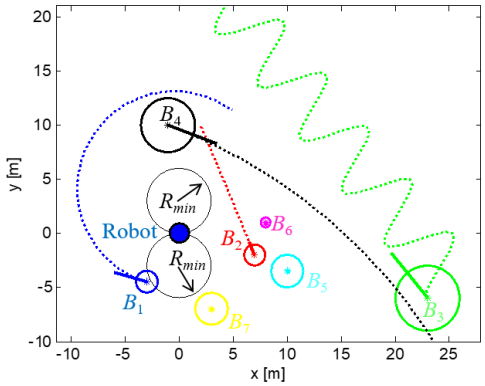
$$VO_{cost} = 1 - VO_{norm}. \tag{36}$$

If the selected (v, κ) pair is far from the nearest $FVOCL_i$, then the value of VO_{norm} will be a big number (near to 1). So, such (v, κ) pair has to be chosen for the robot, where the value of VO_{cost} is minimal.

So, with the SVO method one can plan the safest motion in dynamic environment.

6. Simulation Results

An example for VOCL is presented here. A circular robot with radius $r_o = 0.9\text{m}$ is given. Its minimal turning radius is $R_{min} = 3\text{m}$ (i.e. $\kappa_{max} = \frac{1}{3}\text{m}^{-1}$) and its maximal velocity is $v_{max} = 7\frac{\text{m}}{s}$. Seven circular obstacles with different radii are presented in the workspace (see Figure 7). Four obstacles move (B_1, B_2, B_3, B_4) and there are three static obstacles (B_5, B_6, B_7). The velocity vectors and the paths of the dynamic obstacles are also depicted in Figure 7. The VOCL and FVOCL for $t_h = 10\text{s}$ is given in Figure 8. White areas represent (v, κ) pairs which correspond to collision-free motion for t_h.



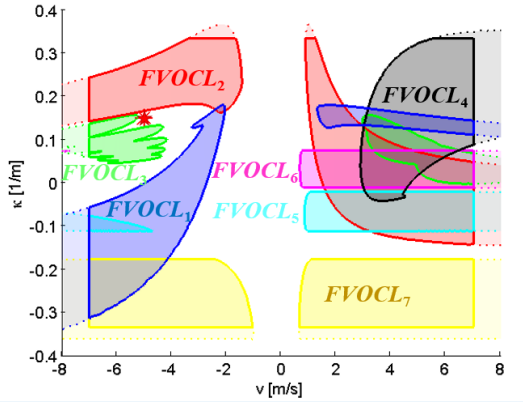


Figure 7. An example with seven obstacles at $t_0 = 0\text{s}$. The velocity vectors of dynamic obstacles are depicted by solid lines, the paths of the obstacles are denoted by dotted lines (with $t_h = 10s$).

A collision-free example is also presented here. $\kappa = 0.15\text{m}^{-1}$ ($R = 6.\dot{6}\text{m}$) and $v = -5\frac{\text{m}}{s}$ was selected. The corresponding (v, κ) point is depicted by a red star in Figure 8. The motion of the robot and the movement of the obstacles are depicted in Figure 9.

7. Conclusion

Velocity obstacles (VO) and non-linear velocity obstacles (NLVO) methods can be used to plan a collision-free motion for a planar robot moving among static and moving obstacles. VO supposes that the obstacles move on straight-lines with constant velocities. If the path of the obstacle is not a straight-line, NLVO can be applied. These methods determine a velocity vector for the robot, which results in a collision-free motion in a time-interval. Applying this velocity, the robot will move on a straight-line according to the direction of the selected velocity vector. Both methods assume that the position and the motion of the obstacles are known.

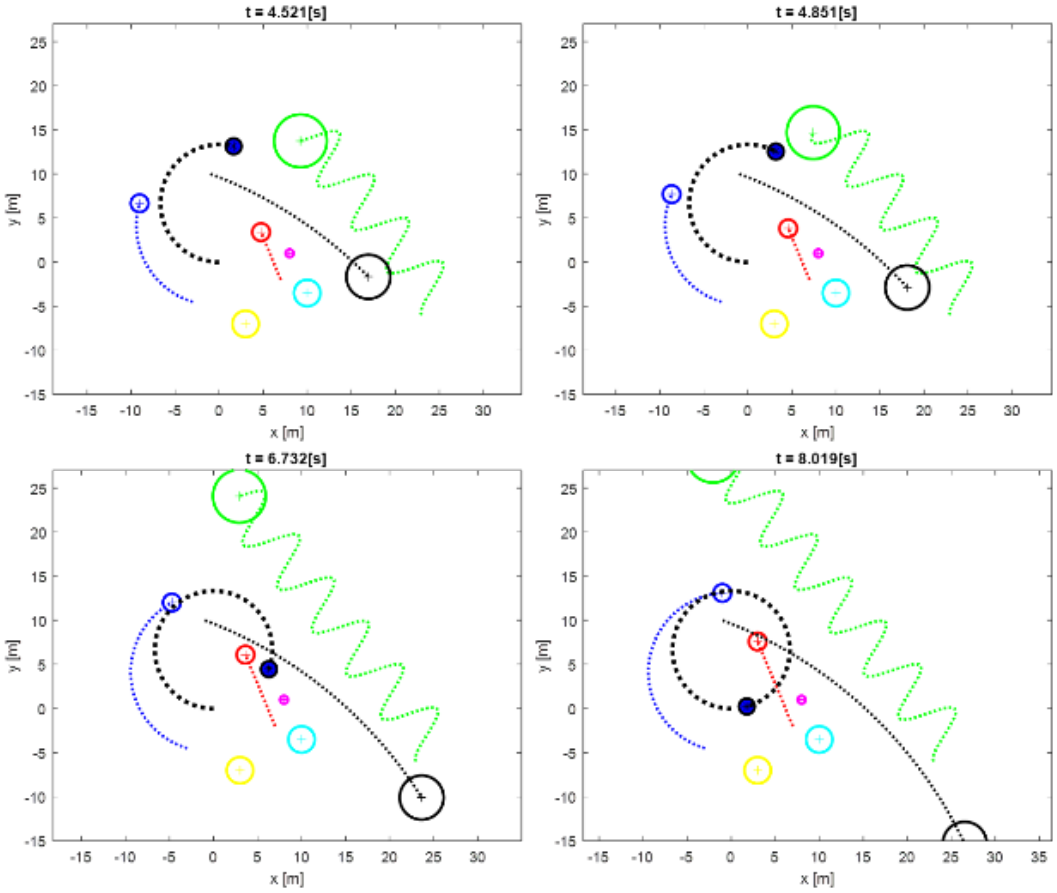

Figure 9. Motion of robot and obstacles in the example ($v = -5\frac{m}{s}$, $\kappa = 0.15m^{-1}$). The robot is depicted by a blue disc, and its path is shown by the thick black dotted line.

The method, presented in this paper is similar to NLVO but in this case the robot is a car-like mobile robot. This robot cannot move to arbitrary direction. The direction of its velocity vector is determined by its orientation. The robot can move on a straight-line according to its orientation or on a circular path. Hence, the presented VOCL method determines only the magnitude of the velocity vector and, additionally, the curvature of the circular path to follow to avoid collisions.

The next stage of this work is to implement the VOCL method for a car-like mobile robot, such that the collision-free motion is determined in real-time.

Our future goal is to take the non-circular shape of the robot (e.g. car-like rectangle) also into consideration during the construction of VOCL.

[22]. In this case a continuous curvature path could be determined. The drawback is that the computational complexity would be larger.

ABSTRACT

Currently the use of distributed energy resources, especially renewable generation, and demand response programs are widely discussed in scientific contexts, since they are a reality in nowadays electricity markets and distribution networks. In order to benefit from these concepts, an efficient energy management system is needed to prevent energy wasting and increase profits. In this paper, an optimization based aggregation model is presented for distributed energy resources and demand response program management. This aggregation model allows different types of customers to participate in electricity market through several tariffs based demand response programs. The optimization algorithm is a mixed-integer linear problem, which focuses on minimizing operational costs of the aggregator. Moreover, the aggregation process has been done via K-Means clustering algorithm, which obtains the aggregated costs and energy of resources for remuneration. By this way, the aggregator is aware of energy available and minimum selling price in order to participate in the market with profit. A realistic low voltage distribution network has been proposed as a case study in order to test and validate the proposed methodology. This distribution network consists of 25 distributed generation units, including photovoltaic, wind and biomass generation, and 20 consumers, including residential, commercial, and industrial buildings.

1. Introduction

The present paper is an extension of work originally proposed in *2017 IEEE Manchester PowerTech* [1]. The generation variation in Distributed Renewable Energy Resources (DRER) is a topic of introduction in a lot of research works, since they have a key role in nowadays power system [2]. By appropriate management on the consumption in demand side, energy efficiency and optimal energy usage should be addressed. Curtailment Service Provider (CSP), Virtual Power Player (VPP), and aggregator are entities that can provide reliable solutions for the management of consumption and generation resources, since these can be aggregated and represented as a unique resource in electricity markets [3-5].

In this context, an aggregator is responsible to optimally manage a certain number of resources in a region, and aggregate them as one resource. This simplifies the process of energy negotiation in electricity markets [6]. Moreover, if other players, such as Balance Responsible Parties (BRPs), exist in the network, the role of aggregator would be more efficient and important [7].

Nowadays, there are several European countries that employ the aggregator concept for electricity consumers [8]. As an example, France is one of these countries that accepted aggregated loads in every ancillary service program, and BRPs and aggregators have been reorganized based on [9], [10]:

- Performing electricity market negotiations, to calculate compensation costs by aggregator for BRP;
- Aggregator has no direct interaction with BRP, however, it establishes contract with an electricity supplier in order to have flexibility services.

In fact, an aggregator is accountable not only for DRERs, but also is responsible for Demand Response (DR) programs [10]. According to the Federal Energy Regulatory Commission (FERC) [11], DR program is referred as "Changes in electric use by demand-side resources from their normal consumption patterns in response to changes in the price of electricity, or to

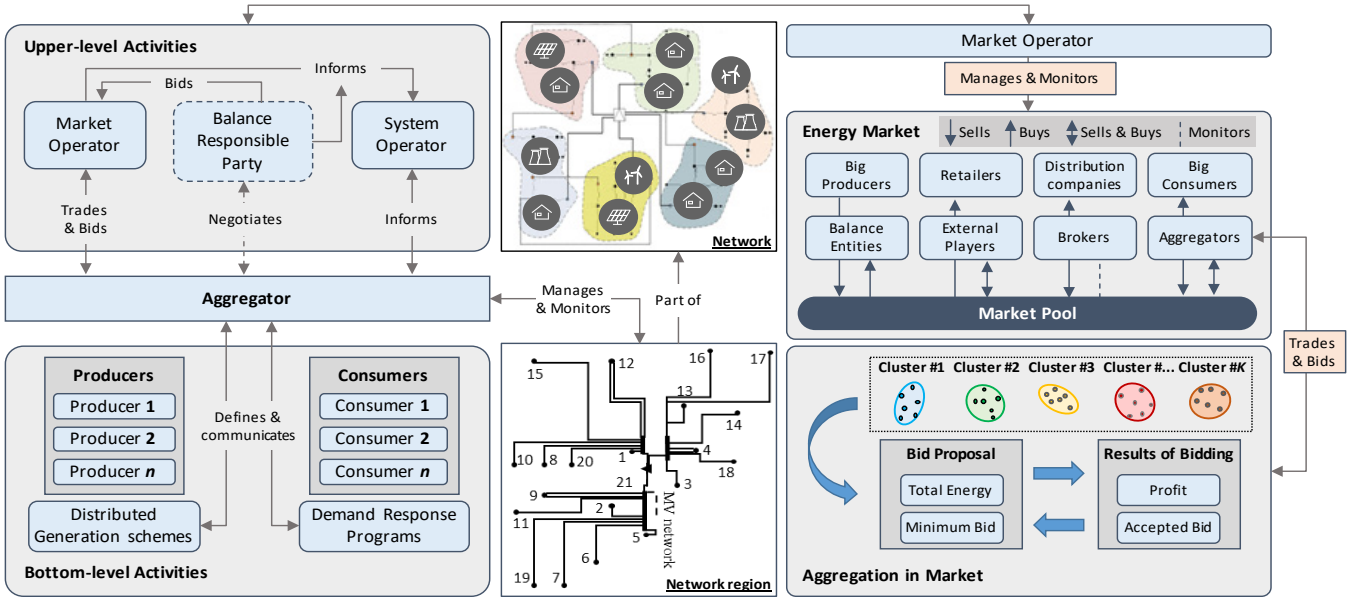

Figure 1. Overal architecture of the aggregation model.

incentive payments designed to induce lower electricity use at times of high wholesale market prices or when system reliability is jeopardized". The role of an aggregator in terms of DR programs is to gather all electricity consumer who can participate in DR programs, and present them as one. Therefore, it can be considered as a flexible player [12]. For this purpose, the aggregator can establish bidirectional contracts with end-users for DR programs to manage consumption resources, and consequently, to have flexibility in electricity market negotiations. In order to manage the generation of end-users, which are considered as prosumer (a consumer who is able to produce electricity), the aggregator can play the role of VPP, as [13]-[14] demonstrated before. It is clear that the generation capacity of these prosumers is not significant, thus, the network management would be difficult for system operators. Therefore, the need of a third party, namely an aggregator, is evident to gather all these small-scale consumption and generation resources, and participate in electricity market.

This paper represents an optimization based aggregation model for DRERs and DR programs managements, which enables small and medium resources to have active participation in the electricity markets. The aggregator controls demand-side customers by providing them several tariffs based DR programs, which brings flexibility in the electricity market negotiations. Moreover, this aggregator model gathers energy of resources and aggregated costs to be aware of available energy and minimum selling cost for defining remunerations, and also participate in the market with profit.

The rest of the paper is organized as follow. Section 2 details the aggregator model architecture considered for the aggregation. Section 3 describes the mathematical formulation considered for the optimization problem and aggregation process. Section 4 explains a case study that will test and validate the proposed method, and its results are expressed in Section 5. Finally, main conclusions of the work are proposed in Section 6.

2. Aggregator Model Architecture

This section focuses on how the presented aggregation model performs scheduling, aggregating and remuneration. The overall view of the presented model is illustrated by Figure 1. In this aggregation model, the consumption and generation resources are classified in several groups, where the output of the aggregation process will be the energy and cost of each group. As one can see in Figure 1 and also proposed in [15], the functionality of the aggregator is categorized in two sections of upper-level and bottom-level. In the upper level, the aggregator negotiates with players, such as market operator, BRP, and system operator; however, in the bottom level, it deals with demand-side users, namely small and medium scale consumers and producers.

The aggregator performs the scheduling process relying on external suppliers, Distributed Generation (DG) especially renewable resources, and DR programs. The customers who can execute DR programs would be able to establish contract with aggregator in three programs: load shifting, load reduction, and load curtailment. The load shifting model has been adapted from [16], and in this aggregation model it is considered as a free DR program. Load reduction and curtailment are the programs that aggregator takes them into account for scheduling and participating in the market. The aggregator considers a linear cost function for all external suppliers, DGs, load reduction and load curtailment. In this model, the aggregation process is done by K-Means Clustering algorithm by respect to the scheduled energy and its costs. In the aggregation process, only the resources that have been selected form the scheduling, are considered, and the rest that have no interaction in scheduling process, will not be considered. The aggregator categorizes the resources in several groups, and specifies a remuneration for each group, which called group tariff. This means the remuneration process should be calculated after the aggregation. The resources that are classified in a group, will be remunerated with same price. For this reason, the maximum price available in each group will be selected for group tariff. Therefore,

the cheapest resource in the group will be motivated to participate in aggregation, since the group tariff is greater than the price initially defined, and also the most expensive resource will be satisfied, since the group tariff is as same as the price that it proposed.

In this way, the aggregator is able to participate in the market with a bid for each group. In each bid, the aggregator deliberates the gathered energy from the resources and also the group tariff as the minimum rate. The energy in each group is related to the aggregation of scheduled resources of that related group, therefore, the aggregator can easily manage its activities. On the other hand, the aggregator will be able to have negotiation in the market by biding the available energy of each group with a certain price, where this price should be greater or equal to the group tariff for the aggregator to gain profits or at least obtain the amount expended for the resources.

3. Optimization problem

The mathematical formulation regarding the presented aggregation model, especially resource scheduling, will be presented in this section. The optimization problem developed for the aggregator scheduling contains several continuous and discrete variables, therefore, the problem is considered as a mixed-integer linear problem (MILP). The objective function considered for the aggregation model is to minimize its Operational Cost (OC) and is shown by (1). It should be noted that in this model it is supposed the technical verification of the network is the obligation of the network operator, and the aggregator is not responsible for this matter.

$$\begin{aligned} MinOC = & \sum_{s=1}^{S} P_{(s,t)}^{Sup} \cdot C_{(s,t)}^{Sup} + \sum_{p=1}^{P} P_{(p,t)}^{DG} \cdot C_{(p,t)}^{DG} \\ & + \sum_{c=1}^{Cs} \left[\begin{array}{l} P_{(c,t)}^{Red} \cdot C_{(c,t)}^{Red} + P_{(c,t)}^{Cut} \cdot C_{(c,t)}^{Cut} \\ + \sum_{d=1}^{T} P_{(c,t,d)}^{Shift} \cdot C_{(c,t,d)}^{Shift} \end{array} \right] \\ & \forall t \in \{1,...,T\} \end{aligned} \tag{1}$$

In this objective function, $P_{(s,t)}^{Sup}$ is purchased energy from external supplier, $P_{(p,t)}^{DG}$ denotes the attained energy from DG, $P_{(c,t)}^{Red}$ stands for DR load reduction, $P_{(c,t)}^{Cut}$ is for DR load curtailment, and $P_{(c,t,d)}^{Shift}$ represents DR load shifting.

There are several constraints that should be considered in the objective function. The first constraint stands for load balance, as (2) shows. In this equation, $P_{(c,t)}^{Load}$ presents the required demand of consumers.

Also, the technical limitations of all resources available in the proposed methodology should be considered. Therefore, (3) represents the generation limitations of external supplier in term of minimum and maximum ($P_{(s,t)}^{Sup\min}$, $P_{(s,t)}^{Sup\max}$), and (4) considers DG limitations ($P_{(p,t)}^{DG\min}$, $P_{(p,t)}^{DG\max}$).

$$\sum_{c=1}^{Cs} \left[\begin{array}{l} P_{(c,t)}^{Load} - P_{(c,t)}^{Red} - P_{(c,t)}^{Cut} \\ - \sum_{d=1}^{T} \left(P_{(c,t,d)}^{Shift} - P_{(c,d,t)}^{Shift} \right) \end{array} \right] - \sum_{s=1}^{S} P_{(s,t)}^{Sup} - \sum_{p=1}^{P} P_{(p,t)}^{DG} = 0 \quad \forall t \in \{1,...,T\} \tag{2}$$

$$P_{(s,t)}^{Sup\min} \le P_{(s,t)}^{Sup} \le P_{(s,t)}^{Sup\max} \quad \forall s \in \{1,...,S\}, \forall t \in \{1,...,T\} \tag{3}$$

$$P_{(p,t)}^{DG\min} \le P_{(p,t)}^{DG} \le P_{(p,t)}^{DG\max} \quad \forall p \in \{1,...,P\}, \forall t \in \{1,...,T\} \tag{4}$$

DR technical limitations, including load reduction, curtailment, shifting, are presented by (5)-(8).

$$P_{(c,t)}^{Red\min} \le P_{(c,t)}^{Red} \le P_{(c,t)}^{Red\max} \tag{5}$$

$$P_{(c,t)}^{Cut\min} \le P_{(c,t)}^{Cut} \le P_{(c,t)}^{Cut\max} \tag{6}$$

$$P_{(c,t)}^{Cut} = P_{(c,t)}^{Cut\max} \cdot X_{(c,t)}^{Cut}, \quad X_{(c,t)}^{Cut} \in \{0,1\} \quad \forall c \in \{1,...,C\}, \forall t \in \{1,...,T\} \tag{7}$$

$$P_{(c,t,d)}^{Shift\min} \le P_{(c,t,d)}^{Shift} \le P_{(c,t,d)}^{Shift\max} \tag{8}$$

Although load shifting may not be pleasant for end-users, it is an appropriate and practical tool for aggregator. Load shifting process may limit consumers use of devices in a certain period, however, it enables the aggregator to manage the consumption based on the offered generation capacity. For this purpose, the limitations of maximum energy that will be shifted out from a period ($P_{(c,t)}^{Shift_out}$), and enters to another period ($P_{(c,t)}^{Shift_in}$) are proposed in (9) and (10).

$$\sum_{d=1}^{T} P_{(c,t,d)}^{Shift} \le P_{(c,t)}^{Shift_out} \tag{9}$$

$$\sum_{d=1}^{T} P_{(c,d,t)}^{Shift} \le P_{(c,t)}^{Shift_in} \quad \forall c \in \{1,...,C\}, \forall t,d \in \{1,...,T\} \tag{10}$$

Moreover, (11) demonstrates the constraint regarding the groups tariff and their remuneration, which is the maximum price of group. The groups are separated based on the type of available resources (DG or DR).

$$\begin{aligned} & G_{(k,t)}^{DG} = max(C_{(p,t)}^{DG}) \\ & G_{(k,t)}^{DR} = max(C_{(c,t)}^{Red}, C_{(c,t)}^{Cut}), \forall c \in \{1,...,C\} \\ & \forall p \in \{1,...,P\}, \forall k \in \{1,...,K\}, \forall t \in \{1,...,T\} \end{aligned} \tag{11}$$

As a summary, the mathematical formulation for resources scheduling and their remuneration performed by the aggregator have been explained in this part. The methodology presented in this section will be employed in a case study in the next section.

4. Case Study

In order to examine the model represented in this paper, a case study is proposed. For this purpose, an low voltage distribution network of a university campus, in Porto, Portugal, is considered for the aggregator, which has been adapted from [17]. This distribution network is shown in the bottom of Figure 1 (Network region) and is considered as a part of main network. The network consists of underground electrical lines with 21 buses, where a MV/LV transformer in BUS #21, connects the campus network to the main network.

For this case study, we considered that there are 20 consumers, and 26 producers in the network. The consumers include 8 Residential (RE) buildings, 10 Commercial buildings in three scales of small (C-S), medium (C-M), and large (C-L), and 2 Industrial (IN) units, which are classified based on average daily consumption. Moreover, producers consist of renewable resources including 20 Photovoltaic (PV) units and 4 wind generators, 1 biomass, and external suppliers. The generation and consumption profiles of whole network considered for day-ahead scheduling in a winter day are shown on Figure 2.

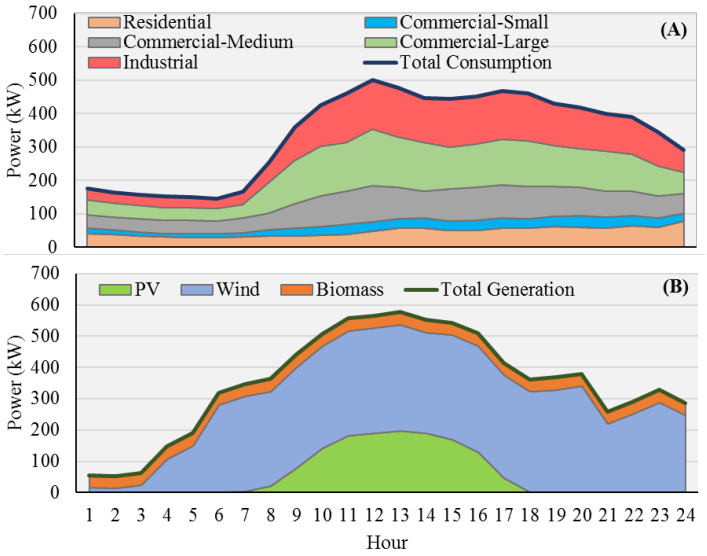

Figure 2. Day-ahead profiles of the network considered for case study: (A) Consumption, (B) Production.

As it can be seen in Figure 2 – (A), large commercial buildings and industrial units have occupied a huge part of consumption, and peak periods start from period #10 to #23. In this case study, it is presumed that the biomass production, and external suppliers have maximum capacity of 40 and 500 kW respectively. The external suppliers profile is not illustrated in Figure 2 – (B), since it is out of scope of figure and is a constant value during all periods. Moreover, it is considered that all producers would be able to contribute in the aggregation process, except external suppliers. Additionally, as you can see in Figure 2 – (B), since a winter day selected for the case study, PV producers have no significant generation, therefore, the aggregator should rely on wind, biomass, external suppliers and DR programs to prevent purchasing energy from the market. However, by comparing both parts of Figure 2, it is obvious that there are some periods that aggregator has more generation than consumption, therefore, it would be able to sell energy to the market and gain profits.

Regarding DR programs, Figure 3 demonstrates linear costs considered for each consumer based on its type. These costs are for load reduction and load curtailment, where 20% of the initial consumption is considered as maximum load reduction, and 15% for maximum load curtailment.

Furthermore, the linear costs considered for energy resources are shown on Figure 4. Each point in Figure 4 is the individual cost of each resource, where resource #1 to #20 are all PV, #21 to #24 are wind generators, #25 is biomass unit, and #26 illustrates external suppliers. It is should be mentioned that the costs demonstrated in Figure 4, are constant in all periods.

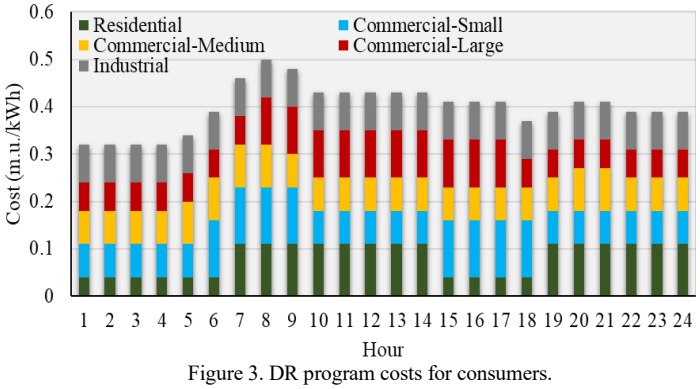

Figure 3. DR program costs for consumers.

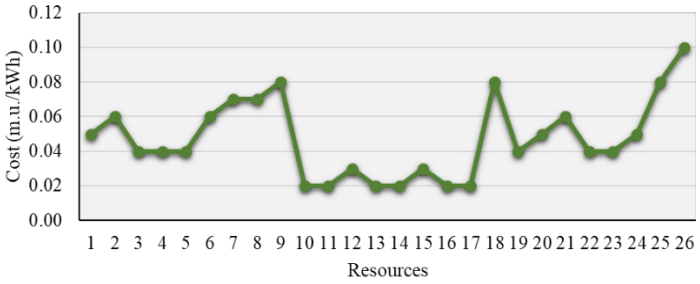

Figure 4. Individual cost for each energy resource.

Additionally, Figure 5 represents the day-ahead market prices considered for the aggregator in order to participate in market negotiations.

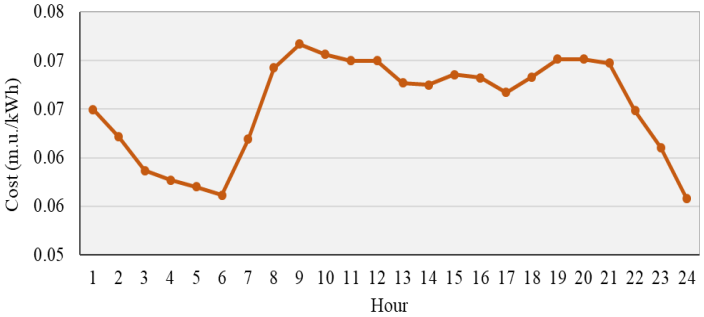

Figure 5. MIBEL market price for Portugues section in a winter day.

These prices are for a winter day in 2017 and have been adapted from Portuguese sector of Iberian Electricity Markets (MIBEL) [18]. In order to model the participation of the aggregator in the electricity markets, a market place should be taken into account, to guaranty its contribution in the competition. For this purpose, a market pool is an appropriate solution to ensure that third parties, such as aggregator, would be able to present energy bids.

5. Results

This section concerns the aggregation and scheduling results of the case study presented in the previous section. The optimization problem of aggregation and scheduling presented in this paper, has been solved through TOMLAB [19]. Additionally, the market negotiation results are represented, which shows how the aggregator utilizes these results for providing a bid. In the case study, we considered that the aggregator meets a drop from external suppliers in first four periods that can supply only 10% of their capacity. The reason of this lack of energy is considered as a fault or any other causes in the external suppliers. Figure 6 shows the network consumption before and after the scheduling of aggregator.

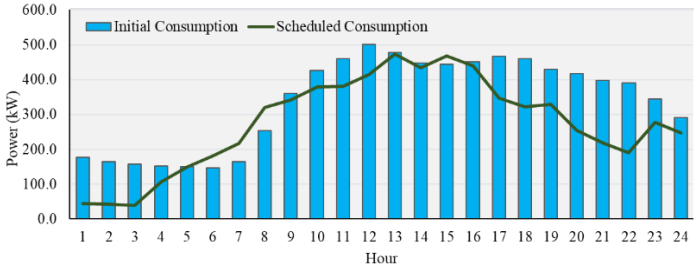

Figure 6. Total consumption of the network.

The scheduling results shown in Figure 6 are based on DG and available energy during each period. Additionally, there are several periods that scheduled consumption profile are greater or smaller than the initial profile. This is due to the utilization of DR programs by aggregator. With this in mind, Figure 7 illustrates more information regarding the generation and DR scheduling.

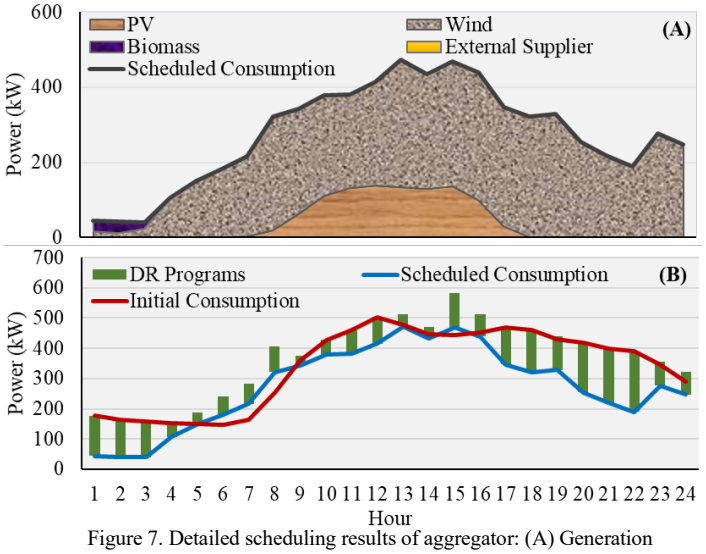

Figure 7. Detailed scheduling results of aggregator: (A) Generation scheduling, (B) DR scheduling.

As one can see in Figure 7 – (A), since the DG suppliers are considered as cheapest resources comparing with external suppliers, the aggregator utilizes the available DG energy, especially PV and wind, to supply the demand, and in the first four periods, it employs biomass generation to supply the loads. In other words, the aggregator reduced the consumption to the available DG energy in order to prevent purchasing energy from market for minimizing the costs. This means, in the periods that the DG generation is not adequate for the demand, aggregator applies DR programs to regulate the difference between the consumption and generation, as illustrated in Figure 7 – (B). The DR programs that aggregator employed to balance the network for each single period, are shown on Figure 8. The utilized DR programs include load reduction, load curtailment, and load shifting.

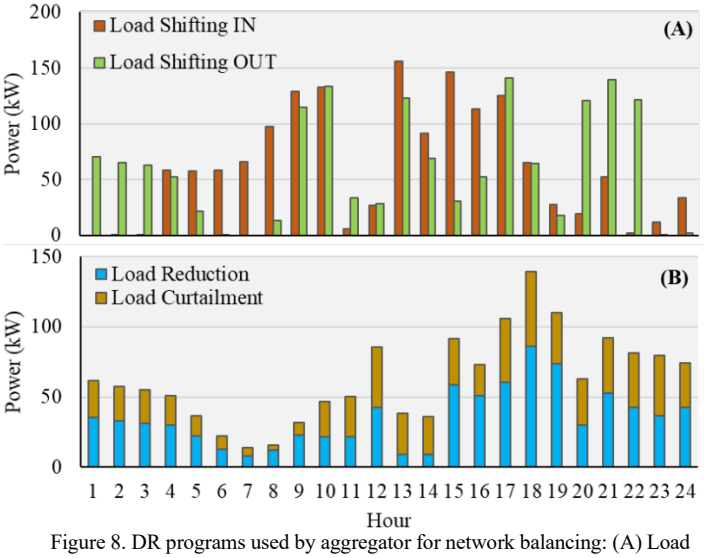

Figure 8. DR programs used by aggregator for network balancing: (A) Load shifting, (B) Load reduction and curtailment.

The incoming and outcoming consumption of each period during load shifting are shown on Figure 8 – (A), which occurred during low generation periods, and shifted to high generation periods. The load shifting enables the aggregator to manage the consumption and shift it to desired periods to prevent purchasing energy from the market, since it is more expensive comparing with DG resources.

Additionally, Table 1 shows the results of aggregation and remuneration processes for period number 12.

Table 1. Remuneration and aggregation results for a single period.

Group		1	2	3	4	5
DG	PV (kW)	0	36.23	19.64	37.54	43.86
	Wind (kW)	250.58	0	0	0	26.88
	Biomass (kW)	0	0	0	0	0
	tariff (m.u./kWh)	0.05	0.02	0.05	0.06	0.06
DR	Residential (kW)	0	0	0	0	0
	Commercial Small (kW)	0	0	0	0	10.09
	Commercial Medium (kW)	0	0	11.07	20.05	7.11
	Commercial Large (kW)	0	0	0	0	0
	Industrial (kW)	26.21	10.94	0	0	0
	tariff (m.u./kWh)	0.06	0.06	0.05	0.05	0.05
Total (kW)		500.18				

In Table 1, the total energy as well as the number of resources in each group have been calculated by aggregation computation, however, the group tariff has been indicated by remuneration calculation. Moreover, in order to calculate the profit of the aggregator after paying all resources, including DG and incentives for DR participation, (12) is proposed. This profit is the monetary benefit that aggregator gained after its operations.

$$Profit = C_{(t)}^{mcp} \cdot \left[\sum_{p \in k}^{P} P_{(p,t)}^{DG} + \sum_{c \in k}^{C} (P_{(c,t)}^{Red} + P_{(c,t)}^{Cut}) \right] - \left[G_{(k,t)}^{DG} \cdot \sum_{p \in k}^{P} P_{(p,t)}^{DG} + G_{(k,t)}^{DR} \cdot \sum_{c \in k}^{C} (P_{(c,t)}^{Red} + P_{(c,t)}^{Cut}) \right] \quad (12)$$

$$\forall k \in \{1,...,K\}, \forall t \in \{1,...,T\}$$

In (12), the $C_{(t)}^{mcp}$ denotes market clearing price, which is considered in this case study is equal to the market prices provided in Figure 5. The classification of the resources in the several groups enables the aggregator to provide lower group tariffs, comparing with the situation that all resources are in the same group. It is true that with classification of resources in several groups, high group tariff will be still remained, however, the chance of aggregator to reach some group tariff with lower rates will be increased. The financial profit gained by aggregator during period number 12, is shown on Table 2. In this single period, the aggregator has total energy of 500.18 kW, which has incoming of 35 monetary unit from the energy that sold to the market. However, it also paid 22.84 monetary unit for all resources, including DG units and DR incentives, and in total, 12.17 monetary unit will be the final profit of aggregator during period number 12.

Table 2. Gained profit by aggregator during market negotiations for one period.

Parameter	Value
Costs paid to all resources (m.u.)	22.84
Market clearing price (m.u./kWh)	0,0700
Income from market sell (m.u.)	35.00
Total aggregator profit (m.u.)	12.17

The profit of aggregator shown on Table 2, is for a single period (considered as one hour in a day in this case study), and even with a few number of consumers and generators, it could gain profit from market negotiations. This means that if the aggregator is responsible for a larger network He will be able to aggregate more energy capacity for clustering, and therefore, with great participation in market, which leads to obtain a satisfying amount of financial benefits. However, this profitability depends on the capabilities and offers of aggregator in market negotiations and existing competitions. Figure 9 demonstrates the financial results concerning the participation of aggregator in the electricity market for all periods of case study. These results are obtained after the scheduling and remuneration processes. It should be noted that only the resources that participated in these processes, are considered. The costs of each period in Figure 9 follows the same process represented in Table 2, which the gained profit is a subtract of costs paid to all resources and the income from market participation.

The last results of this section are related to a comparison that shows the impact of load shifting method for aggregator. For this purpose, it is considered that the aggregator is not capable to employ load shifting during scheduling process. The scheduling results, without load shifting, are illustrated in Figure 10. The results shown in Figure 10 (without load shifting) can be compared with the scheduling results demonstrated in Figure 7 (with load shifting).

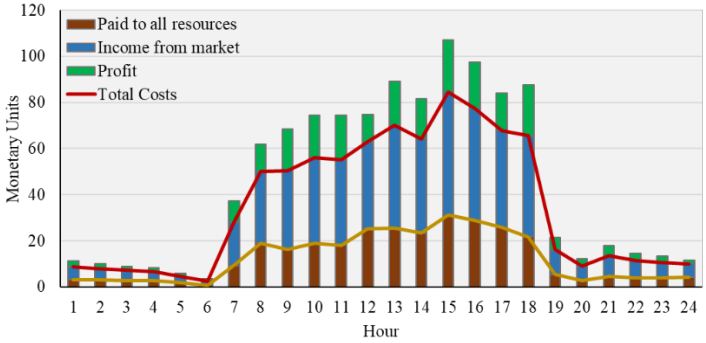

Figure 9. Detailed aggregator costs after scheduling and remuneration process for all periods.

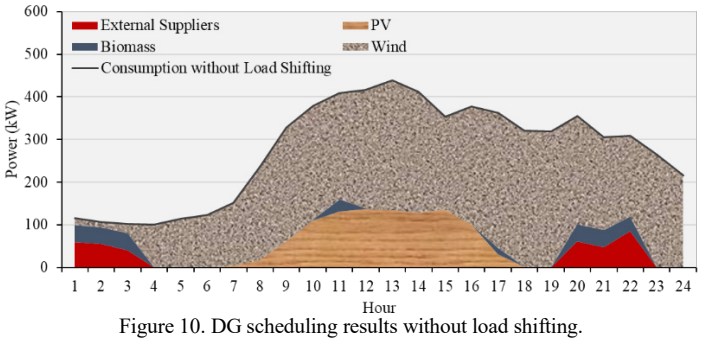

Figure 10. DG scheduling results without load shifting.

As one can see in Figure 10, in some periods the aggregator not only utilizes all available DG resources to supply the demand, but also, it is forced to use energy from external suppliers to feed all demand. By this way, since the electricity price of external suppliers are more expensive than the DG resources, the total costs of aggregator will be increased, and therefore, the gained profit will be decreased. However, as Figure 7 demonstrated, if the aggregator utilized load shifting scenario, and shift the load from the moments that there is no adequate DG energy, to the periods with high DG energy, its operational costs will be reduced, and obtained financial benefits will be increased.

6. Conclusions

This paper presented an aggregator model for distributed energy resource and demand response program management. The presented model considered the resources able to participate in electricity market negotiations through the aggregator. The aggregator has capability of demand-side flexibility by establishing several demand response contracts with consumers.

The main focus of the paper was given to a business model that aggregator utilized it to gather energy of resources and their costs, to define a fair remuneration tariff for all resources, as well as an affordable price for market participation. By this way, the aggregator guarantees that the small-scale resources, including distributed generation and demand response programs, will participate in the electricity market, and therefore, getting profits.

The results of case study demonstrate that the aggregator model is able to perform an optimal scheduling for distributed resources, in order to minimize the operational costs of the aggregator. This is done through implementing several DR programs. The final outcomes of aggregation and remuneration processes validated the proposed method, and proved that the aggregator can gain financial benefits from market negotiations, even by paying a fair tariff to all available resources.

Conflict of Interest

The authors declare no conflict of interest.

ABSTRACT

This paper presents various concepts related to the application of a microgrid pilot project in a residential condominium at Fortaleza / CE - Brazil, such as battery energy system, renewable and distributed generation, islanding recloser and all different units using interface based on power electronics. This papers main objective is to create information about microgrid operation and the interaction between its main equipment, such as power converters, utility energy distribution system and control units responsible for algorithms and changes in microgrids operation mode. This information is important for understanding the need for a test setup construction. To perform the test procedures, a temporary setup in a controlled environment within the microgrid is proposed. During the test periods, intentional power outages are required to evaluate the operating mode switching on each unit. The test setup described in this paper aims to mitigate the tests effects on other residential units inside the condominium.

1. Introduction

Typical electric power systems are known to operate by transmitting energy in bulk from large generating plants over long distances to large load centers. With the introduction of distributed generation and the growing evolution of power electronics for the renewable generation sources of electricity, such as solar and wind, this scenario of operation has been changing gradually, leaving behind the centralized form of generation and becoming now decentralized, producing energy closer to consumers [1, 2].

In this context, microgrids present a new concept of power generation and distribution. Microgrids are utility power grid subsystems composed of a set of distributed energy resources, controllable electric loads, energy storage elements and power control system. Microgrid main characteristic is the ability to operate in island conditions, i.e., operate isolated from the main electricity distribution grid preserving an energy quality for microgrid connected consumers [3-5].

In addition to both connected and islanded modes, this microgrid, under analysis, presents a third operation mode referred to as Maintenance Mode. This operation mode is activated when a fault, such as short circuit, happens inside the microgrid, and consequently making it impossible to operate islanded. Therefore, maintenance mode becomes essential while aiming towards a safe microgrid operation. Recent studies [6, 7] also described the importance of such mode and its benefits for microgrid operations.

While in maintenance mode, the microgrid cannot be powered by any of its distributed energy resources (DER), i.e., the central energy storage (grid-forming power converter) and its internal sources of distributed generation (grid-feeding power converter) are unable to generate energy. Maintenance mode is also triggered with a power distribution company request, followed by command from the operation center, due to maintenance in the local medium voltage distribution grid, as it is procedure to disable the microgrid and ensure a complete absence of power at the condominium internal distribution grid.

To perform real tests of the control system operation mode switching and interaction with the equipment, a test setup for the pilot microgrid is proposed, aiming to mitigate the impact on consumers loads. In this paper, the microgrid project in analysis will be presented first and then the proposed test setup and procedures.

2. Microgrid Architecture

This microgrid under study is located in a residential condominium at Fortaleza / CE – Brazil. The condominium is connected to the utility through medium voltage grid.

*Corresponding Author: Bruno Alberto Pacheco, CERTI Foundation, Email: bap@certi.org.br

The Microgrid is divided into several units according to their characteristics and devices. This unit delimitation allows a better understanding of microgrid operation. Those units are shown in Figure 1.

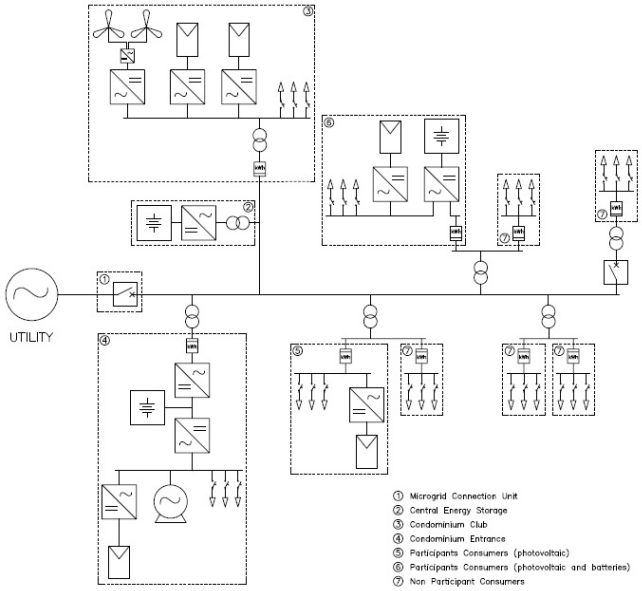

Fig. 1. Architecture of the real microgrid pilot project.

The main microgrid units are presented as it follows:

2.1. Central Energy Storage

This unit is composed by an energy storage system along with its power conversion and control devices. With a storage capacity of 105kWh and 250kW of power, this system is able to supply power for the microgrid while operating in islanded mode [8]. Figure 2 displays a simple electric diagram for this unit.

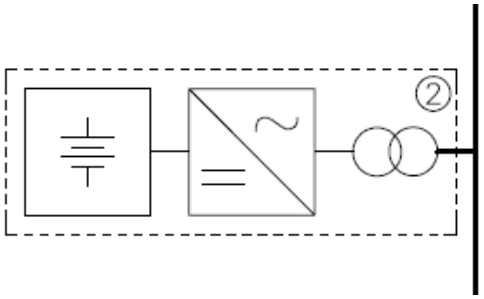

Fig. 2. Central Energy Storage.

The central storage system features a lithium-ion battery bank, grid-forming power converter, 380/13800 V power transformer, switchgear and their respective control and protection equipment.

During islanded mode, this unit function is to provide power for the loads and a voltage reference for all renewable distributed generation. While operation at connected mode, this unit is recharged and can also be discharged providing grid support services.

2.2. Consumers Units

Microgrids consumers are the systems main loads. They are strategically chosen residential consumers with distributed generation resources and some with local storage systems.

They are subdivided into Participant Consumers and Non Participant Consumers. Whilst operating in connected mode, both participant and non-participant act as loads for the system. During islanded operation, non-participant consumers are disconnected through smart meters. Therefore, only participant consumers remain connected at microgrid [8].

Figures 3 and 4 displays a simplified electrical diagram of those participant consumers. They are equipped with demand-response devices, solar generation, power inverters, smart meters, and some units are also equipped with a local storage system.

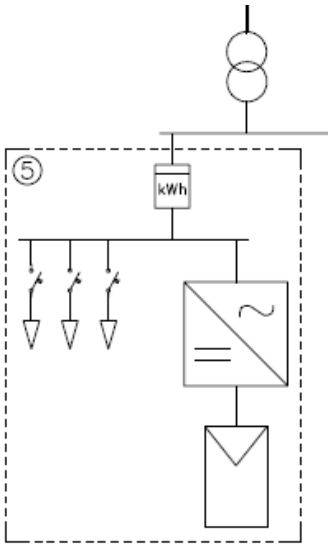

Fig. 3. Participant Consumers Units.

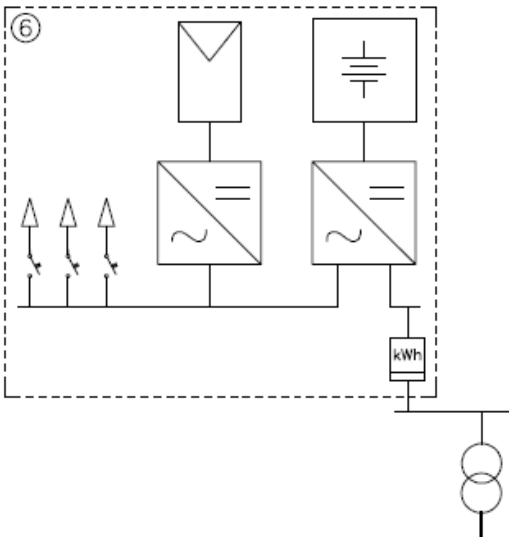

Fig. 4. Participant Consumers Units with a local storage system.

2.3. Club Unit

This residential condominium contains a club with common areas for its residents. The Club Unit (Figure 5) is also a microgrid consumer, however it has a larger distributed generations, composed with 24kWp of photovoltaic panels, as well as 7kW of wind generation.

Like the participating consumers, the Club is endowed with controllable loads through the demand-response devices. Another

important detail is that this unit is connected at microgrid in medium voltage and has its own substation.

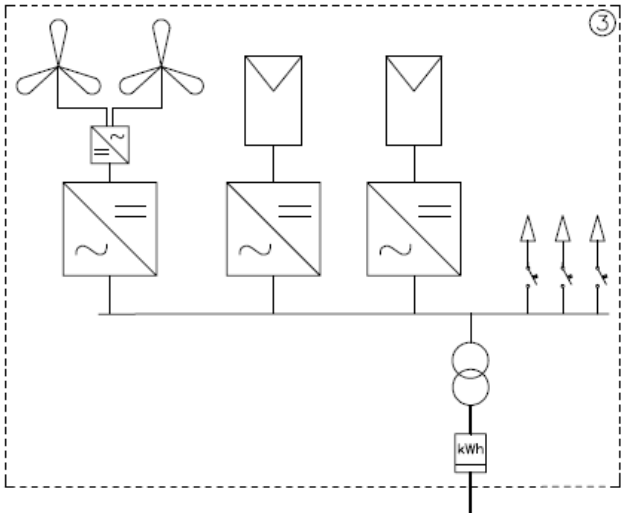

Fig. 5. Club Unit.

2.4. Condominium Entrance

This unit contains critical loads for condominium security and safety functions. Due to this fact, it is equipped with a diesel generator as a back-up unit.

A back-to-back converter is employed as a connection interface with the utility grid, allowing for smooth operation during power outage scenarios. Furthermore, this diesel generator can be used in a microgrid support scheme, relieving the system during a utility outage [8].

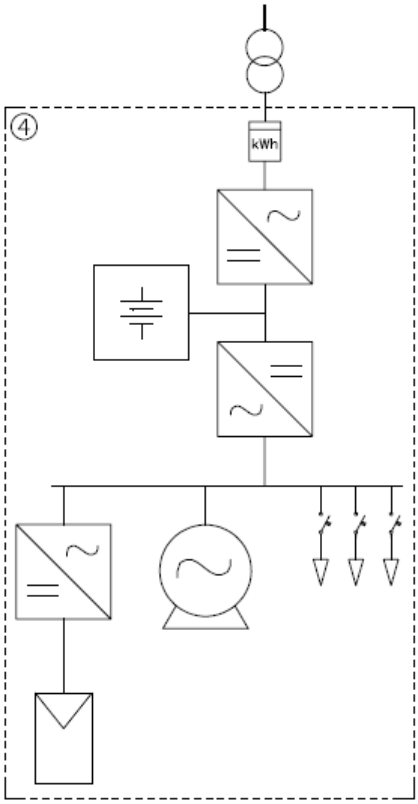

Fig. 6. Condominium Entrance.

This unit also has a solar generation system and controllable loads with demand-response devices as shown in Figure 6.

2.5. Microgrid Connection Unit

The Microgrid Connection Unit (Figure 7) consists of a medium voltage recloser and a set of control equipment for an energy outage detection in the distribution system, coordination of islanding and microgrid reconnection to the distribution system.

This unit is responsible for controlling the microgrid operation mode changes by informing other control units. It is also the communication interface with the utility grid SCADA (Supervisory Control and Data Acquisition) system.

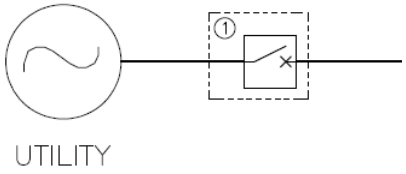

Fig. 7. Microgrid Connection Unit.

3. Microgrid Test Setup

In order to validate microgrid safe operation during its transitions through connected, islanded and maintenance modes, a power setup is proposed for conducting systemic tests (Figure 8).

The premise of this setup is to use the Club Unit area for real islanding, synchronization and reconnection microgrid tests. Since the Club Unit has a medium voltage connection, which is independent from the other condominium derivation line, any power supply interruption inside this area will not affect other microgrid units, reducing the inconvenience for all condominium residents.

As mentioned before, the Club unit has a larger amount of distributed generation and controllable loads. That can be used as a controlled test environment by simulating the residents homes energy consumption and generation. Thus, real tests of operation mode switching can be conducted in a safe way using the Club unit infrastructure.

In connected mode, the utility grid supplies the power for the loads and sets a voltage reference for the power electronics equipment of the generating units. The Central Energy Storage behaves like a grid-feeding power converter in this mode, only providing utility grid support when requested.

3.1. Islanding Tests

For islanding tests, the Microgrid Connection Unit (① in Figure 8) detects an outage in the distribution system due to under voltage protections. It then proceeds to disconnect the microgrid from the utility and sends a command to the Central Energy Storage, requesting a change in its mode of operation. The use of the temporary recloser (② in Figure 8) installed in the test setup input derivation is essential, in order to simulate an outage occurring when an intentional opening of this equipment is performed.

After disconnecting and receiving the command from the Microgrid Connection Unit, the Central Energy Storage operates as a grid-forming power converter, assuming the role of the main power supply of the microgrid and providing voltage reference for the generation interfaces.

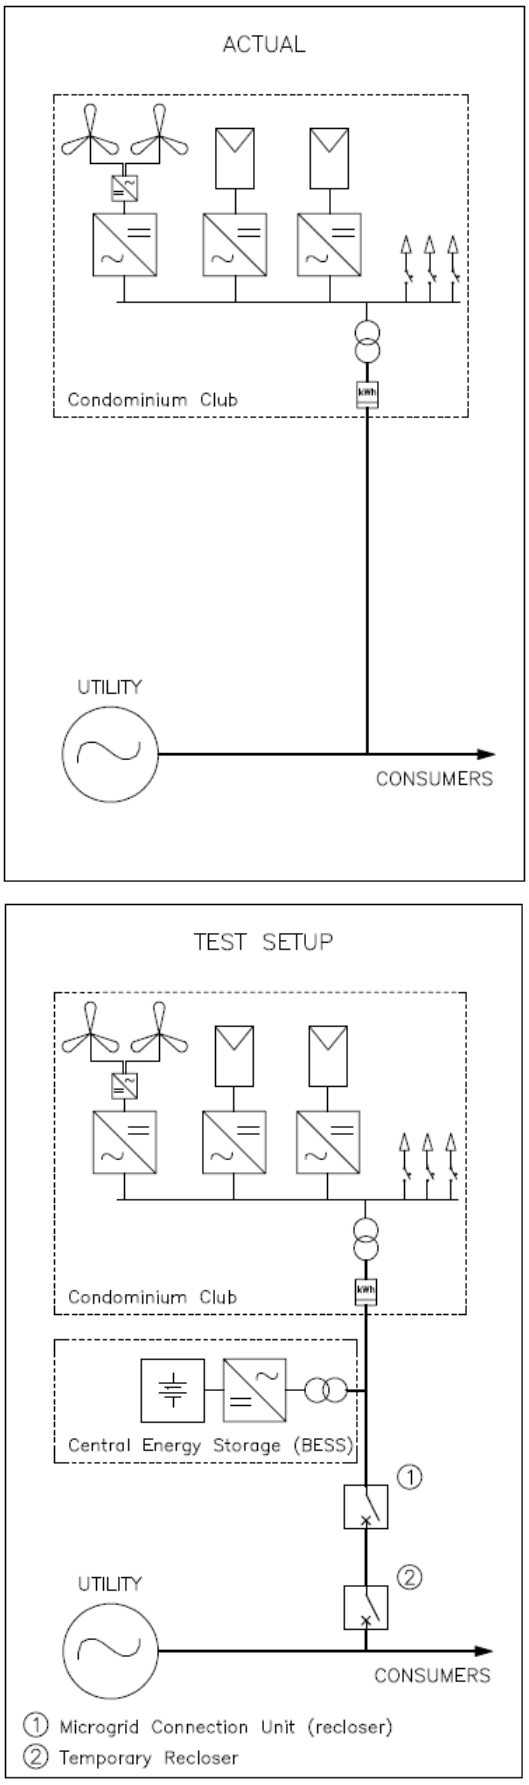

Fig. 8. Actual setup and Microgrid test setup.

3.2. Reconnecting Tests

When reconnecting the microgrid to the utility grid, the temporary recloser (② in Figure 8) is closed simulating the utility grid stable return after an outage.

The Microgrid Connection Unit detects the energy utility supply return while the Central Energy Storage synchronizes with the utility voltage reference. Microgrid is only reconnected to the main electricity distribution grid after synchronization is achieved.

Before the microgrid is connected to the utility grid, some of the indicators and parameters need to be checked, and the best time to close static switch should also be judged. This process is very important that can prevent the dangerous of transient phenomena during connecting the microgrid to utility grid. The good time to close the switch is when the voltage across the switch has to be very small (ideally zero), and the grid's frequency is higher than the microgrid's frequency. Because the current flowing through the switch is minimum, and the power flow direction is from utility grid to the microgrid in such a situation.

A safe and reliable grid-connection process will require to meet the following three conditions: a) the voltage through the static switch must be very small. b) microgrid operating frequency must be slightly smaller than the grid frequency. c) utility grid voltage must be ahead of the microgrid voltage [9].

3.3. Maintenance Tests

Maintenance mode is also tested in this setup with a request through utility operation center command. In such case, it must be verified that the Central Energy Storage is disconnected from the grid, not powering the microgrid when necessary.

Another advantage for this test setup is that all equipment employed will be used in the final installation. In this procedure it is possible to test the interaction between connected equipment in medium voltage, control system and power electronics interfaces. In addition, the Central Energy Storage is tested at its final installation place allows for other control and protection details to be verified.

4. Conclusions

In this work, the microgrid architecture on a pilot project at a residential condominium is presented, along with its main units, equipment and components according to its functionalities and technical characteristics.

Through the proposed test setup it is possible to obtain performance indicators on microgrid operating mode transitions and grid-forming power converter, as well as the integration between the control and protection equipment.

With the test setup execution, all operation modes shall be validated, along with transitions among them. The test results will improve the teams acknowledge around a correct microgrid functioning and a validation of its infrastructure and equipment.

Factorization theorem, Fundamental theorem

ABSTRACT

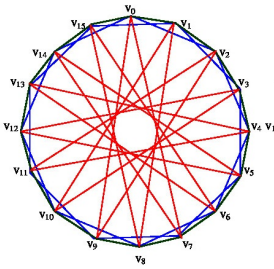
$C_n(R)$ denotes circulant graph $C_n(r_1, r_2, \ldots, r_k)$ of order n for a set $R = \{r_1, r_2, \ldots, r_k\}$ where $1 \leq r_1 < r_2 < \ldots < r_k \leq \left\lfloor \frac{n}{2} \right\rfloor$. Circulant graph $C_n(R)$ is said to have the Cayley Isomorphism (CI) property if whenever $C_n(S)$ is isomorphic to $C_n(R)$, there is some $a \in \mathbb{Z}_n^*$ for which $S = aR$. In this paper, isomorphic properties of circulant graphs that includes (i) Self-complementary circulant graphs; (ii) Type-2 isomorphism, a new type of isomorphism other than already known Adam's isomorphism of circulant graphs and (iii) Cartesian product and factorization of circulant graphs similar to the theory of product and factorization of natural numbers are studied. New abelian groups are obtained from these isomorphic circulant graphs. Type-2 isomorphic circulant graphs have the property that they are isomorphic graphs without Cayley Isomorphism (CI) property and thereby new families.

1 Introduction

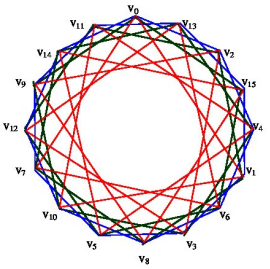
This paper is an extension of work originally presented in ICMSAO2017 [1] and covers the author's study on a few isomorphic properties of circulant graphs that includes (i) Existence of self-complementary circulant graphs; (ii) Type-2 isomorphism, a new type of isomorphism other than already known Adam's isomorphism of circulant graphs that helps to obtain graphs without CI-property and abelian groups and (iii) Cartesian product and factorization of circulant graphs similar to the theory of product and factorization of natural numbers.

Beauty comes out of symmetry as well as asymmetry. Investigation of symmetries/asymmetries of structures yield powerful results in Mathematics. Circulant graphs form a class of highly symmetric mathematical (graphical) structures. In 1846 Catalan (cf. [2]) introduced circulant matrices and properties of circulant graphs have been investigated by many authors [1-20]. An excellent account of circulant matrices can be found in the book by Davis [2] and circulant graphs in the article [11].

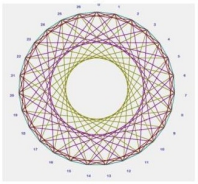
If a graph G is circulant, then its adjacency matrix $A(G)$ is circulant. It follows that if the first row of the adjacency matrix of a circulant graph is $[a_1, a_2, \ldots, a_n]$, then $a_1 = 0$ and $a_i = a_{n-i+2}$, $2 \leq i \leq n$ [15, 17].



Through-out this paper, for a set $R = \{r_1, r_2, \ldots, r_k\}$, $C_n(R)$ denotes circulant graph $C_n(r_1, r_2, \ldots, r_k)$ where $1 \leq r_1 < r_2 < \ldots < r_k \leq \left\lfloor \frac{n}{2} \right\rfloor$. Only connected circulant graphs of finite order are considered, $V(C_n(R)) = \{v_0, v_1, v_2, \ldots, v_{n-1}\}$ with v_i adjacent to v_{i+r} for each $r \in R$, subscript addition taken modulo n and all cycles have length at least 3, unless otherwise specified, $0 \leq i \leq n-1$. However when $\frac{n}{2} \in R$, edge $v_i v_{i+\frac{n}{2}}$ is taken as a single edge for considering the degree of the vertex v_i or $v_{i+\frac{n}{2}}$ and as a double edge while counting the number of edges or cycles in $C_n(R)$, $0 \leq i \leq n-1$. Generally, write C_n for $C_n(1)$ and $C_n(1, 2, \ldots, \left\lfloor \frac{n}{2} \right\rfloor)$ for K_n. We will often assume, with-out further comment, that the vertices are the corners of a regular $n-gon$, labeled clockwise. Circulant graphs $C_{16}(1,2,7)$, $C_{16}(2,3,5)$, $C_{27}(1,3,8,10)$, $C_{27}(3,4,5,13)$ and $C_{27}(2,3,7,11)$ are shown in Figures 1 - 5. Now, let us consider the following definitions and results that are useful in the subsequent sections.



Definition 1.1. [17] *Let n and r be positive integers with $n \geq 4$ and $r < \frac{n}{2}$. Then, clearly, $C_n(r)$ consists of a collection of cycles $(v_0 v_r v_{2r} \ldots v_0)$, $(v_1 v_{1+r} v_{1+2r} \ldots v_1)$, $\ldots$, $(v_{r-1} v_{2r-1} v_{3r-1} \ldots v_{r-1})$. If $d = gcd(n, r)$, then there are d such disjoint cycles, each of length $\frac{n}{d}$. We say that each of these cycles is of period r, length $\frac{n}{d}$ and rotation $\frac{r}{d}$.*



If $r = \frac{n}{2}$, then obviously $C_n(r)$ is just a $1-factor$. Since $C_n(R)$ is just the union of the cycles $C_n(r)$ for $r \in R$, we have a decomposition of $C_n(R)$.

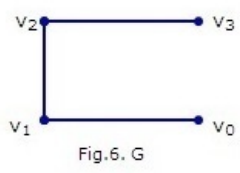
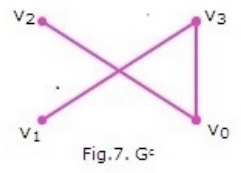
Theorem 1.2. [17] *Let $r \in R$. Then, in $C_n(R)$, the length of a cycle of period r is $\frac{n}{gcd(n,r)}$ and the number of disjoint periodic cycles of period r is $gcd(n,r)$.* □

Corollary 1.3. [17] *In $C_n(R)$, the length of a cycle of period r is n if and only if $gcd(n,r) = 1$, $r \in R$.* □

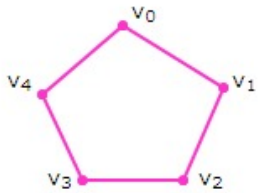
Remark 1.4. [17] *Let $|R| = k$. Then, the circulant graph $C_n(R)$ for a set $R = \{r_1, r_2, \ldots, r_k\}$ is $(2k-1)-regular$ if $\frac{n}{2} \in R$ and $2k-regular$ otherwise.* □



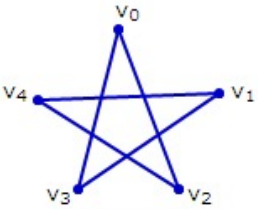
The following Lemmas are useful to obtain one-to-one mappings.



Lemma 1.5. [15] *Let A and B be two non-empty sets. Let $f : A \to B$ be a mapping. Then, f is one-to-one if and only if $f/_{A'}$ is one-to-one for every non-empty subset A' of A.* □



Lemma 1.6. [15] *Let A and B be non-empty sets and $A_1, A_2, \ldots, A_k$ be a partition of A (each A_i being non-empty, $i = 1, 2, \ldots, k$). Let $f : A \to B$ be a mapping. Then f is one-to-one if and only if $f/_{A_i}$ is one-to-one for every i, $i = 1, 2, \ldots, k$.* □



2 On self-complementary circulant graphs

In 1962, Horst Sachs [14] proved that the sufficient condition for the existence of a self-complementary circulant graph of order n is that every prime factor p of n should satisfy $p \equiv 1 \pmod 4$. He also conjectured that the sufficient condition is a necessary one. We have proved that the self-complementary circulant graph on n vertices does not exist if n has any prime factor which is not of the form $4m+1$, $m \in \mathbb{N}$. Thereby, we establish that the sufficient condition is also a necessary one. The proof is based on counting the number of disjoint cycles of a particular length in K_n and is given in this section [4, 17]. Graphs given in Figures 6 and 7 are self-complementary but not of circulant whereas graphs given in Figures 8 and 9 are self-complementary circulant graphs.

Fig.6. G

Fig.7. G

Fig.8. $C_5(1)$

Fig.9. $C_5(2)$

Theorem 2.1. [17] *If $C_n(R) \cong C_n(S)$, then there is a bijection f from R to S so that for all $r \in R$, $gcd(n,r) = gcd(n, f(r))$.*

Proof. The proof is by induction on the order of R. □

Theorem 2.2. [9] *If graph G of order n is self-complementary, then $n \equiv 0, 1 \pmod 4$.* □

Theorem 2.3. [17] *If $C_n(R)$ for a set $R = \{r_1, r_2, \ldots, r_k\}$ is self-complementary, then $n \equiv 1 \pmod 4$.*

Proof. Using Theorem 2.2, we get $n \equiv 0, 1 \pmod 4$. When n is even, a circulant graph is of even degree if and only if its complement is of odd degree since any circulant graph is a regular graph. Thus, self-complementary circulant graph of even order doesn't exist. Hence, we get the result. □

Theorem 2.4. [17] *If $C_n(R)$ for a set $R = \{r_1, r_2, \ldots, r_k\}$ is self-complementary, then $n = 4m+1$, $k = m$ and $|S_i|$ is even where $S_i = \{j : gcd(n,j) = gcd(n,i),\ 1 \le j \le \left\lfloor \frac{n}{2} \right\rfloor\}$, for all i, $i = 1, 2, \ldots, \left\lfloor \frac{n}{2} \right\rfloor$.*

Proof. Using Theorem 2.3, we get, $n = 4m+1$. This implies that the degree (of each vertex) of a self-complementary circulant graph of order $4m+1$ is $2m$ which implies $k = m$.

Let $C_{4m+1}(R)$ be a self-complementary circulant graph for $R = \{r_1, r_2, \ldots, r_m\}$. If it contains a cycle of period r (and of length $\frac{n}{gcd(n,r)}$, using Theorem 1.2), then its complement also contains a periodic cycle of period, say, s such that $\frac{n}{gcd(n,s)} = \frac{n}{gcd(n,r)}$, $1 \le r, s \le \left\lfloor \frac{n}{2} \right\rfloor$, using Theorem 1.2. This implies that $gcd(n,s) = gcd(n,r)$. Here we consider that the cycles of periods r_i and $n - r_i$ are the same in $C_n(r_1, r_2, \ldots, r_k)$, $1 \le i \le k$. Combining the above arguments, we get the result. □

Remark 2.5. *The above theorem states that if a self-complementary circulant graph of order n exists, then* $n = 4m+1$ *and so it is* $2m$*-regular and the number of periodic cycles of length* i *in* K_n *is always even for each* i, $1 \leq i \leq \left\lfloor \frac{n}{2} \right\rfloor$.

Theorem 2.6. [17] *Self-complementary circulant graph of order n doesn't exist when n has any prime factor of the form* $2(2m-1)+1$, $m \in \mathbb{N}$.

Proof. Using Theorem 2.3, $n = 4a+1$, $a+1 \in \mathbb{N}$.

Let $n = p_1^{n_1} p_2^{n_2} \dots p_j^{n_j}$ where $p_1, p_2, \dots, p_j$ are the (odd) prime factors of n. Let $p_i \neq 4m+1$ for at least one i, $1 \leq i \leq j$ and for any $m \in \mathbb{N}$. This implies, $p_i = 2(2q-1)+1$ for some $q \in \mathbb{N}$. Consider the circulant graph $C_{4a+1}(1, 2, \dots, 2a) \cong K_{4a+1} = K_n$. Let r be the natural number such that $r = \frac{n}{p_i}$.

Aim To find out all natural numbers lying between 1 and n such that g.c.d. of each one of them with n is exactly r.

Let $gcd(n, pr+s) = r$ where $p, s+1 \in \mathbb{N}$ such that $0 \leq s < r$ and $1 \leq pr+s \leq n = rp_i$. This implies that $s = 0$ and so $gcd(n, rp+s) = gcd(n, rp) = gcd(rp_i, rp) = r$ where $1 \leq pr \leq p_i r = n$. Thus we get $gcd(p, p_i) = 1$ where $p \leq p_i$ which is greater than 1. Therefore the possible values of p are $1, 2, \dots, p_i - 1$.

Thus $r, 2r, 3r, \dots, (p_i-1)r$ are the only numbers lying between 1 and n such that g.c.d. of n with each one of them is exactly r. This implies $r, 2r, 3r, \dots, (p_i-1)r$ are the possible periods of cycles of length p_i each, in $C_n(1, 2, \dots, \left\lfloor \frac{n}{2} \right\rfloor)$ since the length of a cycle of period rp in $C_n(1, 2, \dots, \left\lfloor \frac{n}{2} \right\rfloor)$ is $\frac{n}{gcd(n,rp)} = \frac{rp_i}{gcd(rp_i,rp)} = \frac{p_i}{gcd(p_i,p)} = p_i$ for $p = 1, 2, \dots, p_i - 1$, using Theorem 1.2.

In $C_n(1, 2, \dots, \left\lfloor \frac{n}{2} \right\rfloor)$,

the cycles of period r and $n - r(= (p_i-1)r)$ are the same,

the cycles of period $2r$ and $(p_i-2)r$ are the same,

...

the cycles of period $\frac{(p_i-1)r}{2}$ and $\frac{(p_i+1)r}{2}$ are the same.

Thus, there are $\frac{p_i-1}{2}$ number of possible distinct periodic cycles of (periods $r, 2r, \dots, \frac{p_i-1}{2}$ and) length p_i, each in $C_n(1, 2, \dots, \left\lfloor \frac{n}{2} \right\rfloor)$.

Now, $\frac{p_i-1}{2} = 2q-1$ is an odd number. This implies, any circulant graph of order n and its complementary circulant graph contain unequal number of periodic cycles of length p_i, each. This implies that self-complementary circulant graph of order n does n't exist when n contains any prime factor of the form $2(2q-1)+1$, $q \in \mathbb{N}$, by Remark 2.5. □

Thus, when $n = 9, 21, 33, 49, 57, 69, 77, 81, 93$, etc., self-complementary circulant graph doesn't exist on n vertices, by Theorem 2.6, even though in each case, $n \equiv 1 \pmod 4$.

Now, by combining Theorem 2.6 and the sufficient condition for the existence of a self-complementary circulant graph of order n, we get the following result.

Theorem 2.7. [17] *The necessary and sufficient condition for the existence of a self-complementary circulant graph of order n is that each prime factor p of n should satisfy* $p \equiv 1 (mod\ 4)$. □

3 On Isomorphism of Circulant Graphs

In this section, Type-2 isomorphism, a new type of isomorphism different from already known Adam's isomorphism of circulant graphs, main results related to it and families of new abelian groups obtained from isomorphic circulant graphs are presented. Type-2 isomorphic circulant graphs have the property that they are isomorphic graphs without Cayley Isomorphism (CI) property.

Definition 3.1. [12] *A circulant graph* $C_n(R)$ *is said to have the CI-property if whenever* $C_n(S)$ *is isomorphic to* $C_n(R)$, *there is some* $a \in \mathbb{Z}_n^*$ *for which* $S = aR$.

Lemma 3.2. [16] *Let S be a non-empty subset of* $\mathbb{Z}_n$ *and* $x \in \mathbb{Z}_n$. *Define a mapping* $\Phi_{n,x} : S \to \mathbb{Z}_n$ *such that* $\Phi_{n,x}(s) = xs$ *for every* $s \in S$ *under multiplication modulo n. Then,* $\Phi_{n,x}$ *is bijective if and only if* $S = \mathbb{Z}_n$ *and* $gcd(n, x) = 1$. □

Definition 3.3. [3] *Circulant graphs* $C_n(R)$ *and* $C_n(S)$ *for* $R = \{r_1, r_2, \dots, r_k\}$ *and* $S = \{s_1, s_2, \dots, s_k\}$ *are Adam's isomorphic if there exists a positive integer x relatively prime to n with* $S = \{xr_1, xr_2, \dots, xr_k\}_n^*$ *where* $< r_i >_n^*$, *the reflexive modular reduction of a sequence* $< r_i >$ *is the sequence obtained by reducing each* r_i *modulo n to yield* r_i' *and then replacing all resulting terms* r_i' *which are larger than* $\frac{n}{2}$ *by* $n - r_i'$.

Lemma 3.4. [16] *Let* $m, r, t \in \mathbb{Z}_n \in gcd(n, r) = m > 1$ *and* $0 \leq t \leq \frac{n}{m} - 1$. *Then the mapping* $\Theta_{n,r,t} : \mathbb{Z}_n \to \mathbb{Z}_n$ *defined by* $\Theta_{n,r,t}(x) = x + jtm$ *for every* $x \in \mathbb{Z}_n$ *under arithmetic modulo n is bijective where* $x = j + qm$, $0 \leq j \leq m-1$, $0 \leq q \leq \frac{n}{m} - 1$ *and* $j, q \in \mathbb{Z}_n$. □

Theorem 3.5. [16] *Let* $V(C_n(R)) = \{v_0, v_1, \dots, v_{n-1}\}$, $V(K_n) = \{u_0, u_1, \dots, u_{n-1}\}$, $r \in R$ *and* $gcd(n, r) = m > 1$. *Then the mapping* $\Theta_{n,r,t} : V(C_n(R)) \to V(K_n)$ *defined by* $\Theta_{n,r,t}(v_x) = u_{x+jtm}$ *and* $\Theta_{n,r,t}((v_x, v_{x+s})) = (\Theta_{n,r,t}(v_x), \Theta_{n,r,t}(v_{x+s}))$ *for every* $x \in \mathbb{Z}_n$, $x = j + qm$, $0 \leq j \leq m-1$, $0 \leq q, t \leq \frac{n}{m} - 1$ *and* $s \in R$, *under subscript arithmetic modulo n, for a set* $R = \{r_1, r_2, \dots, r_k, n - r_k, n - r_{k-1}, \dots, n - r_1\}$ *is one-to-one, preserves adjacency and* $\Theta_{n,r,t}(C_n(R)) \cong C_n(R)$ *for* $t = 0, 1, 2, \dots, \frac{n}{m} - 1$. □

Definition 3.6. [16] *For a given* $C_n(R)$ *and for a particular value of* t, $0 \leq t \leq \frac{n}{m} - 1$, *if* $\Theta_{n,r,t}(C_n(R)) = C_n(S)$ *for some* $S \subseteq [1, \frac{n}{2}]$ *and* $S \neq xR$ *for all* $x \in \Phi_n$ *under reflexive modulo n, then* $C_n(R)$ *and* $C_n(S)$ *are called Type-2 isomorphic circulant graphs w.r.t.* r, $r \in R$. *In this case, subsets R and S of* $\mathbb{Z}_n$ *are called Type-2 isomorphic subsets of* $\mathbb{Z}_n$ *w.r.t.* r.

Clearly, Type-2 isomorphic circulant graphs are circulant graphs without CI-property. We obtained the following results on Type-2 isomorphism.

Theorem 3.7. [16] *For $n \geq 2, k \geq 3, 1 \leq 2s-1 \leq 2n-1$, $n \neq 2s-1$, $R = \{2s-1, 4n-2s+1, 2p_1, 2p_2, \ldots, 2p_{k-2}\}$ and $S = \{2n-(2s-1),\ 2n+2s-1, 2p_1, 2p_2, \ldots, 2p_{k-2}\}$, circulant graphs $C_{8n}(R)$ and $C_{8n}(S)$ are Type-2 isomorphic (and without CI − property) where $gcd(p_1, p_2, \ldots, p_{k-2}) = 1$ and $n, s, p_1, p_2, \ldots, p_{k-2} \in \mathbb{N}$.* □

Theorem 3.8. [16] *For $R = \{2r-1, 2s-1, 2p_1, 2p_2, \ldots, 2p_{k-2}\}$, $n \geq 2, k \geq 3, 1 \leq t \leq [\frac{n}{2}], 1 \leq 2r-1 < 2s-1 \leq [\frac{n}{2}]$, $gcd(p_1, p_2, \ldots, p_{k-2}) = 1$ and $n, r, s, t, p_1, p_2, \ldots, p_{k-2} \in \mathbb{N}$, if $\Theta_{n,2,t}(C_n(R))$ and $C_n(R)$ are Type-2 isomorphic circulant graphs for some t, then $n \equiv 0\ (mod\ 8)$, $2r-1+2s-1 = \frac{n}{2}$, $t = \frac{n}{8}$ or $\frac{3n}{8}$, $2r-1 \neq \frac{n}{8}, 1 \leq 2r-1 \leq \frac{n}{4}$ and $n \geq 16$.* □

Definition 3.9. [1] *Let $Ad_n = \{\Phi_{n,x} : x \in \Phi_n\}$, $Ad_n(R) = \{\Phi_{n,x}(R) : x \in \Phi_n\} = \{xR : x \in \Phi_n\}$ and $Ad_n(C_n(R)) = T1_n(C_n(R)) = \{\Phi_{n,x}(C_n(R)) : x \in \Phi_n\} = \{C_n(xR) :\ x \in \Phi_n\}$ for a set $R = \{r_1, r_2, \ldots, r_k,\ n-r_k,\ n-r_{k-1}, \ldots, n-r_1\} \subseteq \mathbb{Z}_n$. Define '$\circ$' in $Ad_n(C_n(R))$ such that $\Phi_{n,x}(C_n(R)) \circ \Phi_{n,y}(C_n(R)) = \Phi_{n,xy}(C_n(R))$ and $C_n(xR) \circ C_n(yR) = C_n((xy)R)$ for every $x, y \in \Phi_n$, under arithmetic modulo n. Clearly, $Ad_n(C_n(R))$ is the set of all circulant graphs that are Adam's isomorphic to $C_n(R)$ and $(Ad_n(C_n(R)), \circ) = (T1_n(C_n(R)),\ \circ)$ is an abelian group and we call it as the Adam's group or Type-1 group on $C_n(R)$ under '$\circ$'.*

Definition 3.10. [1] *Let $V(C_n(R)) = \{v_0, v_1, \ldots, v_{n-1}\}$, $V(K_n) = \{u_0,\ u_1,\ \ldots,\ u_{n-1}\}$, $r \in R$, $m, q, t, t', x \in \mathbb{Z}_n$ such that $gcd(n, r) = m > 1$, $x = j + qm$, $0 \leq j \leq m-1$ and $0 \leq q, t, t' \leq \frac{n}{m} - 1$. Define $\Theta_{n,r,t} : \mathbb{Z}_n \to \mathbb{Z}_n$ and $\Theta_{n,r,t} : V(C_n(R)) \to V(K_n)$ such that $\Theta_{n,r,t}(x) = x + jtm$, $\Theta_{n,r,t}(v_x) = u_{x+jtm}$ and $\Theta_{n,r,t}((v_x, v_{x+s})) = (\Theta_{n,r,t}(v_x), \Theta_{n,r,t}(v_{x+s}))$ for every $x \in \mathbb{Z}_n$ and $s \in R$, under subscript arithmetic modulo n. Let $s \in \mathbb{Z}_n$, $V_{n,r} = \{\Theta_{n,r,t} : t = 0, 1, \ldots, \frac{n}{m} - 1\}$, $V_{n,r}(s) = \{\Theta_{n,r,t}(s) : t = 0, 1, \ldots, \frac{n}{m} - 1\}$ and $V_{n,r}(C_n(R)) = \{\Theta_{n,r,t}(C_n(R)) : t = 0, 1, \ldots, \frac{n}{m} - 1\}$. Define '$\circ$' in $V_{n,r}$ such that $\Theta_{n,r,t} \circ \Theta_{n,r,t'} = \Theta_{n,r,t+t'}$, $(\Theta_{n,r,t} \circ \Theta_{n,r,t'})(x)\ (= \Theta_{n,r,t}(\Theta_{n,r,t'}(x)) = \Theta_{n,r,t}(x + jt'm) = (x + jt'm) + jtm = x + j(t + t')m) = \Theta_{n,r,t+t'}(x)$ and $\Theta_{n,r,t}(C_n(R)) \circ \Theta_{n,r,t'}\ (C_n(R)) = \Theta_{n,r,t+t'}(C_n(R))$ for every $\Theta_{n,r,t}, \Theta_{n,r,t'} \in V_{n,r}$ where $t + t'$ is calculated under addition modulo $\frac{n}{m}$. Clearly, $(V_{n,r}(s), \circ)$ and $(V_{n,r}(C_n(R)), \circ)$ are abelian groups for every $s \in \mathbb{Z}_n$.*

$V_{n,r}(C_n(R))$ contains all isomorphic circulant graphs of Type-2 of $C_n(R)$ w.r.t. r, if exist. Let $T2_{n,r}(C_n(R)) = \{C_n(R)\} \cup \{C_n(S) : C_n(S)$ is Type-2 isomorphic to $C_n(R)$ w.r.t. $r\}$. Thus, $T2_{n,r}(C_n(R)) = \{C_n(R)\} \cup \{\Theta_{n,r,t}(\ C_n(R)) : \Theta_{n,r,t}(C_n(R)) = C_n(S)$ and $C_n(S)$ is Type-2 isomorphic to $C_n(R)$ w.r.t. $r,\ 0 \leq t \leq \frac{n}{m} - 1\} = \{\Theta_{n,r,0}(C_n(R))\} \cup \{\Theta_{n,r,t}(C_n(R)) : \Theta_{n,r,t}(C_n(R)) = C_n(S)$ and $C_n(S)$ is Type-2 isomorphic to $C_n(R)$, $0 \leq t \leq \frac{n}{m} - 1\} \subseteq V_{n,r}(C_n(R))$ and $(T2_{n,r}(C_n(R)),\ \circ)$ is a subgroup of $(V_{n,r}(C_n(R)),\ \circ)$. Clearly, $T1_n(C_n(R)) \cap T2_{n,r}(C_n(R)) = \{C_n(R)\}$. And $C_n(R)$ has Type-2 isomorphic circulant graph w.r.t. r if and only if $T2_{n,r}(C_n(R)) \neq \{C_n(R)\}$ if and only if $T2_{n,r}(C_n(R)) \cap \{C_n(R)\} \neq \Phi$ if and only if $|T2_{n,r}(C_n(R))| > 1$ [1].

Definition 3.11. [1] *For any circulant graph $C_n(R)$, if $T2_{n,r}(C_n(R)) \neq \{C_n(R)\}$, then $(T2_{n,r}(C_n(R)),\ \circ)$ is called the Type-2 group of $C_n(R)$ w.r.t. r under '$\circ$'.*

Theorem 3.12. [1] *Let p be an odd prime and $k \geq 3$. Then, for $i = 1$ to p, $d_i = (i-1)np + 1$ and $R_i = \{d_i,\ np^2 - d_i, np^2 + d_i, 2np^2 - d_i, 2np^2 + d_i, 3np^2 - d_i,\ 3np^2 + d_i, \ldots, (p-1)np^2 - d_i, (p-1)np^2 + d_i, np^3 - d_i, pp_1, pp_2, \ldots, pp_{k-2},\ p(np^3 - p_{k-2}),\ p(np^3 - p_{k-3}),\ \ldots,\ p(np^3 - p_1)\}$, circulant graphs $C_{np^3}(R_i)$ are Type-2 isomorphic (and without CI-property) where $gcd(p_1, p_2, \ldots, p_{k-2}) = 1$ and $n, p_1, p_2, \ldots, p_{k-2} \in \mathbb{N}$.* □

Theorem 3.13. [1] *Let p be an odd prime, $k \geq 3$, $1 \leq i \leq p$, $d_i = (i-1)np + 1$, $R_i = \{d_i,\ np^2 - d_i,\ np^2 + d_i,\ 2np^2 - d_i,\ 2np^2 + d_i,\ 3np^2 - d_i,\ 3np^2 + d_i,\ \ldots,\ (p-1)np^2 - d_i,\ (p-1)np^2 + d_i,\ np^3 - d_i,\ pp_1,\ pp_2,\ \ldots,\ pp_{k-2},\ p(np^3 - p_{k-2}),\ p(np^3 - p_{k-3}),\ \ldots,\ p(np^3 - p_1)\}$, $T2(R_i) = \{\Theta_{np^3,p,jn}(R_i) : j = 1, 2, \ldots, p\}$, $T2(C_{np^3}(R_i)) = \{\Theta_{np^3,p,jn}(C_{np^3}(R_i)) : j = 1, 2, \ldots, p\}$, $gcd(p_1, p_2, \ldots, p_{k-2}) = 1$ and $n, p_1, p_2, \ldots, p_{k-2} \in \mathbb{N}$. Then $T2_{np^3,p}(R_i) = T2(R_j)$, $T2_{np^3,p}(C_{np^3}(R_i)) = T2(C_{np^3}(R_j))$ and $(V_{np^3,p}(R_i), \circ)$, $(V_{np^3,p}(C_{np^3}\ (R_i)), \circ)$ and $(T2_{np^3,p}(R_i), \circ)$ are abelian groups, $1 \leq i, j \leq p$. Moreover, $(T2_{np^3,p}(C_{np^3}(\ R_i)), \circ)$ is the Type-2 group of order p on $C_{np^3}(R_i)$ w.r.t. $r = p$, $1 \leq i, j \leq p$.* □

Circulant graphs $C_{16}(1,2,7)$ and $C_{16}(2,3,5)$ are Type-2 isomorphic and $C_{27}(1,3,8,10)$, $C_{27}(3,4,5,13)$ and $C_{27}(2,3,7,11)$ are also. See Figures 1–5.

4 Cartesian Product and Factorization of Circulant Graphs

Just as integers can be factored into prime numbers, there are many results on decompositions of structures throughout mathematics [6]. The standard products - Cartesian, lexicographic, tensor, and strong - all belong to a class of products introduced by Imrich and Izbicki and called $B - products$ [8]. In this section, a few important results that are obtained in our study of Cartesian product and factorization of circulant graphs, similar to the theory of product and factorization of natural numbers, are presented (For details see [15]). Graphs $C_5 \square C_6$ and $C_{30}(5,6)$ are isomorphic and are given in Figures 12 and 13. One can see the difficulty of this study from this example.

Definition 4.1. [9] *The cross product or Cartesian product of two simple graphs $G(V, E)$ and $H(W, F)$ is the simple graph $G \square H$ with vertex set $V \times W$ in which two vertices $u = (u_1, u_2)$ and $v = (v_1, v_2)$ are adjacent if and only if either $u_1 = v_1$ and $u_2 v_2 \in F$ or $u_2 = v_2$ and $u_1 v_1 \in E$.*

Theorem 4.2. [15] *Let G be a connected graph of order n, $n > 2$. Then, $P_2 \square G$ is circulant if and only if $G \cong H$ or $P_2 \square H$ where H is a connected circulant graph of odd order.* □

Theorem 4.3. [15] *Let G be a connected graph of order $n \geq 2$. Then $C_4 \square G$ is circulant if and only if G is circulant of odd order.* □

Theorem 4.4. [15] *If G and H are connected graphs and $G \square H$ is circulant, then G and H are circulants.* □

Graphs $P_2 \Box C_3$ and $P_2 \Box C_4$ are given in Figures 10 and 11 and $C_5 \Box C_6$ and $C_{30}(5,6) \cong C_5 \Box C_6$ in 12 and 13, respectively.

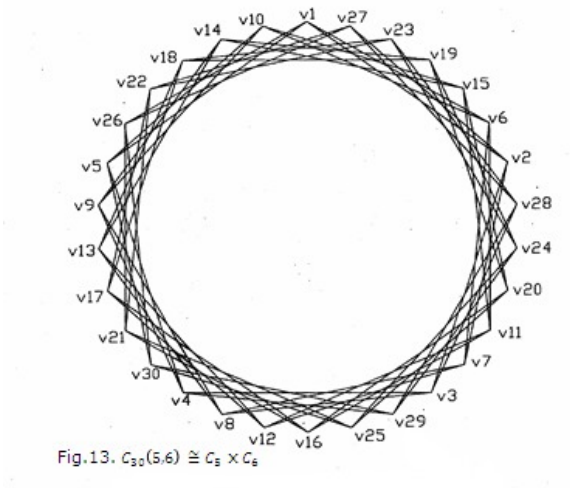

Fig.13. $C_{30}(5,6) \cong C_5 \times C_6$

Theorem 4.5. [15] *Let G and H be connected graphs, each of order > 2. Then $G \Box H$ is circulant if and only if G and H are circulants and satisfy one of the following conditions:*

(i) $G \cong C_m(R)$; $H \cong C_n(S)$ *and* $gcd(m,n) = 1$.

(ii) $G \cong C_{2m+1}(R)$; $H \cong C_{2n+1}(S)$, $P_2 \Box C_{2n+1}(S)$, $C_4 \Box C_{2n+1}(S)$ *or* $C_{2^k(2n+1)}(S)$ *and* $gcd(2m+1, 2^k(2n+1)) = 1$, $k \in \mathbb{N}$.

(iii) $G \cong P_2 \Box C_{2m+1}(R)$; $H \cong C_{2n+1}(S)$ *or* $P_2 \Box C_{2n+1}(S)$ *and* $gcd(2m+1, 2n+1) = 1$.

(iv) $G \cong C_{2^k(2m+1)}(R) \neq P_2 \Box C_{2^{k-1}(2m+1)}(T)$ *for any* $C_{2^{k-1}(2m+1)}(T)$; $H \cong C_{2n+1}(S)$ *and* $gcd(2^k(2m+1), 2n+1) = 1$, $k \in \mathbb{N}$.

(v) $G \cong C_4 \Box C_{2m+1}(R)$; $H \cong C_{2n+1}(S)$ *and* $gcd(2m+1, 2n+1) = 1$.

(vi) $G \cong C_{2^k(2m+1)}(R) \neq C_4 \Box C_{2^{k-2}(2m+1)}(T)$, $P_2 \Box C_{2^{k-1}(2m+1)}(U)$ *for any* $C_{2^{k-2}(2m+1)}(T)$ *and* $C_{2^{k-1}(2m+1)}(U)$; $H \cong C_{2n+1}(S)$ *and* $gcd(2^k(2m+1), 2n+1) = 1$, $k \in \mathbb{N}$, $k \geq 2$. □

Definition 4.6. [15] *A non-trivial graph G is said to be prime if $G = G_1 \Box G_2$ implies G_1 or G_2 is trivial; G is composite if it is not prime.*

Definition 4.7. [15] *If $C_m(R)$, $C_n(S)$ and $C_{mn}(T)$ are circulant graphs such that $C_m(R) \Box C_n(S) \cong C_{mn}(T)$, then we say that $C_m(R)$ and $C_n(S)$ are divisors or factors of $C_{mn}(T)$.*

Thus for any connected circulant graph, the graph and $C_1(\,) = K_1$ are always divisors and so we call them as *improper divisors* of the circulant graph. Divisors which are integer multiple of improper divisors also be called as improper divisors of the circulant graph. This doesn't arise since we consider divisors of connected graphs only. Divisor(s) other than improper divisors is called *proper divisor(s)* of the circulant graph.

Definition 4.8. [15] *A circulant graph whose only divisors are improper is called a prime circulant graph. Other circulant graphs are called composite circulant graphs.*

Theorem 4.9. [15] ***[Factorization Theorem On Circulant Graphs]***
Let m and n be relatively prime integers. If $R \subseteq [1, \frac{m}{2}]$, $S \subseteq [1, \frac{n}{2}]$ and $T \subseteq [1, \frac{mn}{2}]$ with $T = dnR \cup dmS$ for some d such that $gcd(mn, d) = 1$, then $C_{mn}(T) \cong C_m(R) \Box C_n(S)$. □

Theorem 4.10. [15] *If $n \neq 4$ and $1 \in R$, then $C_n(R)$ is a prime circulant.* □

Corollary 4.11. [15] *If $n \neq 4$ and R contains an integer relatively prime to n, then $C_n(R)$ is prime circulant.* □

Corollary 4.12. [15] *If n is a prime power other than 4 and $C_n(R)$ is connected, then $C_n(R)$ is prime circulant for all $R \neq \phi$.* □

Theorem 4.13. [15] ***[Fundamental Theorem of Circulant Graphs]***
Every connected circulant graph is the unique product of prime circulant graphs (uniqueness up to isomorphism). □

Remark 4.14. [13, 15] *If G is a connected graph such that $G \cong G_1 \Box G_2 \Box \ldots \Box G_k$, then the diameter of G, $dia(G) = \sum_{i=1}^{k} dia(G_i)$.*

Thus, we can find the diameter of any given circulant graph, provided diameters of its prime circulant graphs are known. Also the above relation helps to generate (circulant) graphs of bigger diameters.

Remark 4.15. [15]

1. *In prime factorization of connected circulants* $C_1(\ ) = K_1$ *and* $C_2 = P_2$ *act similar to* 1 *and* 2 *among the set of all natural numbers, respectively. Thus,* $C_1(\ )$ *is a unit, like* 1 *in number theory.*
2. *There exist two types of prime circulant graphs of order n, one with periodic cycle(s) of length n and the other without periodic cycle of length n.*
3. *The theory of factorization of circulants is similar to the theory of factorization of natural numbers and one of the very few well-known mathematical structures so vividly classified (expressed) in terms of prime factors. It can be applied in cryptography.*
4. *We developed VB programs POLY215.exe and POLY315.exe to show visually how the transformations* $\Theta_{n,r,t}$ *and* $\Phi_{m,n}$ *act on* C_n *and* $C_m \square C_n$*, respectively for different values of m and n,* $m, n \in \mathbb{N}$.
5. *An interesting problem is, for a given integer n, finding the number of prime (composite) circulant graphs of order either equal to n or less than or equal to n.*
6. *One can develop theories similar to the theory of Cartesian product and factorization of circulant graphs to the other standard products of circulant graphs.*

Conclusion This study covers a few isomorphic properties of circulant graphs. One can go for a similar study on Cayley graphs.

ABSTRACT

Log-periodic antennas have high electrical characteristics over a wide frequency range. The large length of the antennas is their significant disadvantage caused by the fact that each active region consisting of several radiators operates in a narrow frequency range. To extend this range, it is proposed to use radiators with concentrated capacitive loads, providing in-phase currents with a linear amplitude distribution law. An approximate calculation of the fields and directional characteristics of a complex multielement radiating structure is performed using a new method of electrostatic analogy based on the assumption that the ratio of emf in the radiator centers is equal to the charge ratio on the conductors of the electrically neutral system. The problem of optimization of considered antennas by methods of mathematical programming is formulated.

1. Introduction

The use of concentrated loads included along the axis of a linear antenna allows solving the synthesis problem, i.e., to obtain an antenna with required characteristics, more precisely with characteristics closest to required [1]. The special case of this problem - the creation of an antenna that provides a high level of matching in a wide frequency range and a maximum of radiation in a plane perpendicular to the axis of the radiator – has a great practical importance.

A conventional linear radiator does not satisfy these requirements. A reactive component of its input impedance is great everywhere except of a vicinity of a series resonance. When the length of a radiator arm is greater than 0.7λ (λ is a wavelength), the radiation in the plane perpendicular to its axis decreases, since anti-phase segments form on the current curve.

The task of creating a wide-range radiator is to determine the types and quantities of loads that provide high characteristics of the antenna in the operating frequency range. This task was solved by applying concentrated capacitive loads (capacitors) installed along the axis of the radiator and forming an in-phase current with a given law of the amplitude distribution along the antenna. The solution was based on an understanding of the advantages of in-phase current distribution and Hallen's hypothesis on the use of capacitive loads, the values of which vary along the radiator axis in accordance with a linear or exponential law. The chosen approach confirmed the Hallen's hypothesis and demonstrated the effectiveness of the proposed approximate methods of calculating capacitive loads: the method of impedance long-line and the method of a long-line with loads. The loads calculated by these methods were used as the initial values for numerical solution of the problem by methods of mathematical programming.

Since the placement of concentrated capacitive loads along the radiator allows to obtain not only a high level of matching of the antenna with the cable, but also high directional characteristics in a wide frequency range, the application of these loads had been considered in radiators – first in a linear antenna and then in directional one.

It should be emphasized that the optimization problem, as a rule, is solved in two stages. At the first stage an approximate method of analysis, based on physical representations about the nature of the problem, is developing. At the second stage, approximate results are used as initial values for the numerical solution of the problem by methods of mathematical programming.

The proposed method of an approximate analysis of antennas characteristics allowed us to calculate the directional patterns of radiators with a given current distribution and to compare performances of antennas, in which various laws of current distribution are realized. This is, firstly, the linear metal antenna with a sinusoidal current distribution along its axis, and secondly, the linear antenna with an in-phase current and with a linear or exponential law of an amplitude distribution. Calculations show that the use of linear antennas with capacitive loads makes it possible to obtain in the wide frequency band the desired shape of the radiation pattern, which provides a substantial increasing the communication distance.

*Boris Levin, Email: levinpaker@gmail.com

To evaluate this shape, a special parameter has been introduced - the pattern factor, equal to an average radiation level in a given range of vertical angles, for example, at angles θ from 60° to 90°. This parameter shows in fact what part of the signal is propagating along the earth's surface, i.e., it is useful for increasing the communication distance. With the help of the proposed method, it is shown that the in-phase current distribution in linear and V-radiators provides not only a high level of matching, but also the high directivity and smooth variation of this directivity over a wide frequency range [2].

For an approximate calculation of the fields of complex multielement radiating structures, the method of electrostatic analogy was proposed. It is based on the assumption that the ratio of emf in the radiators centers is equal to the ratio of the charges located on the conductors of electrically neutral system. This allows proposing a simple and effective procedure of calculating directional characteristics of director and log-periodic antennas with concentrated capacitive loads. The calculation results confirm the possibility of increasing the frequency range of the director antennas and decreasing the length of the log-periodic antennas.

The results of applying this method to calculating the directional characteristics of director antennas are given in [3]. They are compared with the characteristics of director antenna, described in [4] and consisting from four metal elements: active radiator, reflector and two directors. When optimizing the metal antenna, the mathematical programming method was used. The application of the approximate method of electrostatic analogy to a metal antenna confirmed the results obtained in [4]. With the help of the presented procedure, it was shown also that in-phase current distribution in radiators of the director antennas provides the higher directivity in a wide frequency range.

The remainder of this paper is organized as follows. In Section II, the proposed method of analysis is applied to the calculation of fields and directional characteristics of an active region of the log-periodic antenna. The numerical results obtained in Section III for such antennas with in-phase currents show that the number of such regions can be substantially reduced. The section IV contains conclusions, which emphasize a theoretical interest and practical benefits of the work.

2. Method of Analysis

In accordance with a well-known method of analysis of a log-periodic antenna [5], we consider an active region of this antenna, consisting of three radiators (Fig. 1), and find fields of these radiators when emf *e* is located in the center of the middle radiator. In accordance with Kirchhoff' law other generators must be short-circuited. As shown in [5], this means that emf's in the centers of other radiators and at the ends of sections of a two-wires distributive long line in the points of these radiators location are shorted also. We regard that the arm length of the middle radiator is $L_0 = \lambda/4$, the arm length of the left (longer) radiator is equal to $L_1 = \lambda/(4\tau)$, and the arm length of the right (shorter) radiator is $L_2 = \lambda\tau/4$, where τ is a denominator of a geometric progression, according to which the radiators' dimensions are changed. A magnitude σ is the other antenna parameter, equal to $\sigma = 0.25(1-\tau)\cot\alpha$, where α is an angle between an antenna axis and a line passing through radiators ends. The value σ is the number of wavelengths between the half-wave radiator and the smaller neighboring radiator: $b_2 = \sigma\lambda$.

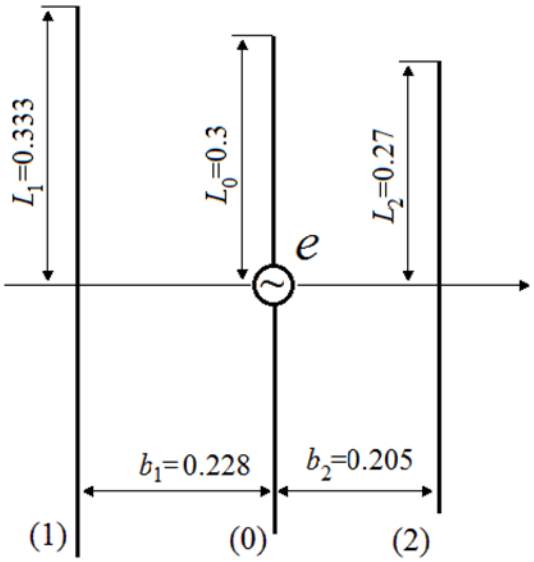

Figure 1: Antenna of three radiators

Respectively b_1 is equal to $\sigma\lambda/\tau$. As stated in [6], generalization of information in the literature leads to the conclusion that the minimum changes in the electrical characteristics of the log-periodic antenna with metal dipoles within the frequency range from f to $f\tau$ occur when $\sigma/\tau = 0.19$. We regard that this relation is valid for the considered antenna and that value τ for certainty is equal to 0.9. Then $L_1 = L_0/0.9 = 0.278\lambda$, $L_2 = L_0 \cdot 0.9 = 0.225\lambda$, $\alpha = 0.146$, $b_1 = 0.19\lambda$, $b_2 = 0.171\lambda$.

As already mentioned, we use the method of electrostatic analogy of two structures (of currents and charges), located on the same conductors, as an approximate method. We are assuming that the ratio of emf's in the radiator centers is equal to the ratio of charges located on these conductors. The positive charge, equal to Q_0, is placed on the conductor *0* (active radiator). The charges of other conductors *i* are negative. They are equal to $-Q_i$, and their sum is equal to $\sum_{i=1}^{2}(-Q_i) = -Q_0$, i.e., the sum of all charges is zero, and the conductors form an electrically neutral system. In this system

$$Q_i/Q_0 = C_{0i}\Big/\sum_{i=1}^{2} C_{0i}, \qquad (1)$$

where C_{0i} is the partial capacitance between conductors *0* and *i* (see, for example, [7]). From (1) it follows that the charges of the conductors *i* are directly proportional to the partial capacitances C_{0i} between these conductors and the conductor *0*. The mutual capacitance C_l per unit length of two parallel infinitely long conductors of the radius *a* is equal to

$$C_l = \pi\varepsilon/\ln(b/a), \qquad (2)$$

where ε b is the distance between the conductors. Multiplying this value into the conductor length,

we find in a first approximation the partial capacitance C_{0i} between these conductors.

We divide the active radiator (conductor *0*) into two parallel conductors (with numbers *01* and *02*), and the resulting structure of four conductors into two circuits: conductors with numbers *01* and *1* in the first scheme, and conductors with numbers *02* and *2* in the second scheme. In accordance with the method of electrostatic analogy of the two structures, i.e., in accordance with the physical content of the problem, we will assume that the ratio of the emf in the centers of the wires *01* and *02* is equal to the ratio of the partial capacitances C_{01} and C_{02}, i.e., $e_1 = 0.52e, e_2 = 0.48e$.

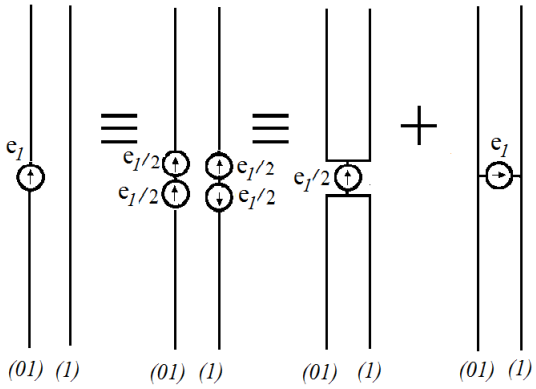

Figure 2: Successive transforming a structure of two parallel vertical conductors

Fig. 2 demonstrates a scheme for successive transforming a structure of two parallel vertical conductors (*01* and *1*), one of which is excited at the center, into a structure consisting of a two-conductor dipole and two open transmission lines. The scheme is based on the theory of a folded antenna (see for example, [1]). As can be seen from this figure, the current at the center of each dipole conductor and the current at the same point of each transmission line are respectively equal

$$J_{1d} = e_1/(4Z_{1d}), J_{1l} = e_1/(2Z_{1l}), \tag{3}$$

where Z_{1d} is the input impedance of this dipole, Z_{1l} is the input impedance of each long line. Accordingly, the current J_{01u} of the upper arm of the conductor *01* is equal to the difference of these currents, and the current of the lower arm of the conductor *01* - to the sum:

$$J_{01u} = J_{1d} - J_{1l}, J_{01l} = J_{1d} + J_{1l}. \tag{4}$$

The current J_{1u} of the upper arm of the conductor *1* on the contrary is equal to the sum of these currents, and the current J_{1l} of the lower arm of the conductor *1* – to their difference. The field amplitude and phase value of each radiator depend on its structure and location in an antenna. If the radiator arm is manufactured as the straight metallic wire, the current along it is distributed by the sinusoidal law

$$J(z) = J(0)\sin k(L - |z|). \tag{5}$$

Here z is a coordinate along the radiator axis, $J(0)$ is the current in its center, k is the propagation constant. In this case the far field of the radiator is equal to

$$E = \frac{AJ(0)}{Sin\theta}[\cos(kL\cos\theta) - \cos kL], \tag{6}$$

where $A = j\frac{60}{\sin kL}\cdot\frac{\exp(-jkR)}{R}$, R is the distance to the observation point. If concentrated capacitive loads located along the radiator axis allow realizing in it the in-phase current with an amplitude, distributed along this axis by the linear law,

$$J(z) = J(0)(L - |z|), \tag{7}$$

the far field of the radiator (see [2]) is equal to

$$E = \frac{AJ(0)\sin\theta}{\cos^2\theta}[1 - \cos(kL\cos\theta)]. \tag{8}$$

Consider an impact of the radiator location on the far field of the antenna by way of a specific example of the director antenna, shown in Fig. 1. The arm length of the middle (active) radiator is equal to 0.3 м, i.e., the wave length of the first (series) resonance is equal to 1.2 м. Radii of all conductors are the same and are equal to 0.001м. The magnitude τ is 0.9.

It is obvious that the maximal radiation of the antenna should be directed to the right, toward the radiator *2*. Since the radiator *1* is located from the left of the active radiator *0*, at a distance b_1 from it, its field lags behind the field of the active radiator, first on kb_1 in phase, that is by the time interval of the propagation of the signal from the active radiator to the passive radiator *1*, and, secondly, by $kb_1/\sin\theta$ in phase, i.e., by the time of the signal propagation in the opposite direction, from the radiator *1* to the active radiator (signal of the wire *1*, radiated at an angle θ, must come to the active radiator at the same angle θ, i.e., it must pass the distance $b_1/\sin\theta$, and not the distance b_1. The total change in phase is equal to $\psi_1 = -kb_1\cdot\frac{1+\sin\theta}{\sin\theta}$. Similarly, in the case of radiator *2*, this phase change is equal to $\psi_2 = -kb_2\cdot\frac{\sin\theta - 1}{\sin\theta}$.

The total field of the antenna structure shown in Fig. 1 with in-phase current distribution at angle θ on the base of aforesaid may be written in the form

$$E = \frac{AJ(0)\sin\theta}{2Z_{1d}\cos^2\theta}\sum_{i=1}^{2} e_i\{[1 - \cos(kL_0\cos\langle\theta - \theta_0\rangle)] + \exp(j\psi_i)[1 - \cos(kL_i\cos\theta)]\}. \tag{9}$$

The directivity magnitude is determined by the expression

$$D = |E(\pi/2)|^2 \Big/ \sum_{n=1}^{N}[|E(\theta_n)|^2\Delta\sin\theta_n], \tag{10}$$

where Δ is the interval between neighboring values θ_n, N is the number of these intervals between $\theta = 0$ and $\theta = \pi/2$.

3. Examples of Calcultations

The results of calculating the directivity magnitude for the structure, shown in Fig. 1, are given in Fig. 3 depending on an electrical length kL_0

$kL_0 = \pi$ to $kL_0 = 10\pi$.

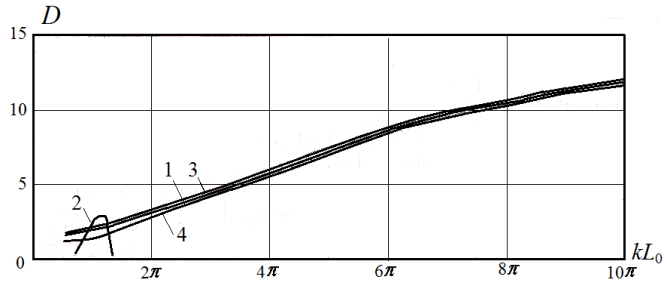

Figure 3: Directivity of structures of three radiators

Radiation of neighboring elements of log-periodic antenna with the arm length 0.27 m and 0.333 m respectively requires calculating fields in the structures presented in Fig. 4*a* and 4*b*. Results of these calculations are given in Fig. 3: curve 3 corresponds to Fig. 3*a*, curve 4 - to Fig. 3*b*. The directivity magnitudes in Fig. 3 for specific values kL correspond to the same frequencies, i.e., the same values of kL correspond to the elements of equal length in the all three schemes (for example, to the elements with the arm length 0.3 m). Fig. 3 shows that the directivity magnitudes at the same kL are close to each other. This is natural, since the directivity in each scheme increases slowly with increasing frequency. Small increasing the active radiator length causes at the same kL the small increase of the resonant wavelength, i.e., the small decrease of the resonance frequency and the directivity.

The obtained results show that each active radiator with in-phase current included in the structure of the log-periodic antenna provides high radiation directivity in a wide frequency range. Neighboring radiators have similar directivity magnitude. The direction of the radiation is the same. A signal propagates along the distributive line from short elements to the long dipoles (in Figures 1 and 4 to the left), the radiated signal propagates in the opposite direction. The total path difference is quite large. For example, for the signals radiated by a half-wave radiator and a smaller neighboring radiator it is equal to 0.38 λ, i.e., it is close to a half wavelength. Crossing wires of the distributive line in an interval between the elements permits to reduce dramatically this path difference.

Known log-periodic antenna with sinusoidal current distribution along the radiators have a property of automatic currents "cut-off", i.e., a separate antenna section (active region) radiates a signal in a narrow frequency band. Outside this band, outside the borders of the active region the signal decays rapidly. Wide frequency range is provided by a large antenna length, which is equal to the sum of the lengths of the active regions. Attempts to reduce the antenna length by disturbing a geometric progression and increasing a radiators number lead to a small dimension decrease and a sharp deterioration of electrical characteristics. The more effective methods are firstly a two-fold use of each active region by an application of linear-spiral radiators and secondly an employment of an asymmetrical log-periodic antenna with coaxial distribution line [6]. These methods allow decreasing the antenna length by 25-30%.

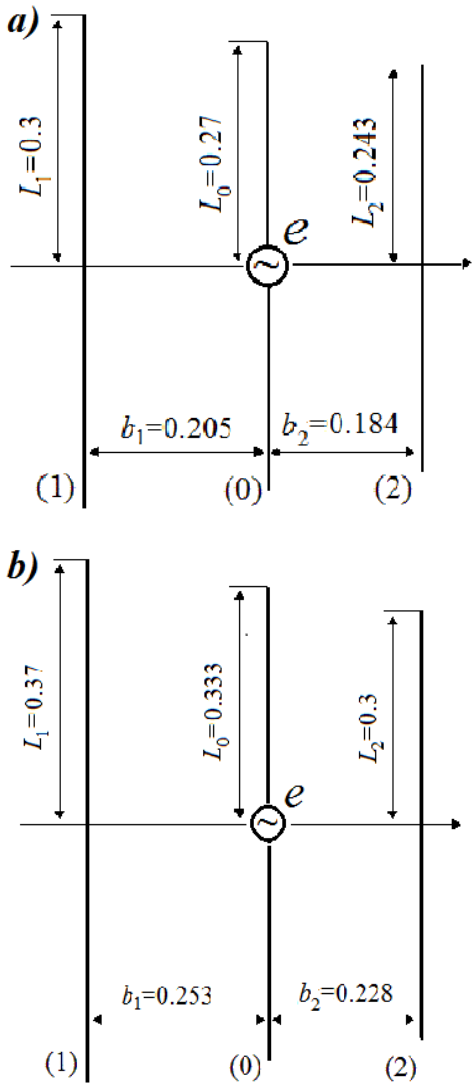

Figure 4: Structures of smaller (*a*) and greater (*b*) neighboring radiators

Replacement of the straight metal radiators by the radiators with concentrated capacitive loads allows obtaining a high directivity in a wide frequency range, using a simple structure of three radiators. Increasing the radiators number in the structure must allow to dramatically increasing its directivity.

4. Conclusion

In this work the following results are obtained:

1) The method of electrostatic analogy is proposed for calculating fields of complex multielement antennas. It is based on an assumption that a ratio of emf in radiators centers is equal to a ratio of charges located on conductors of an electrically neutral system. This method had been used for calculating directional characteristics of log-periodic antennas.

2) The given procedure permitted to compare the directional characteristics of log-periodic antennas with sinusoidal and in-phase current distribution in simple radiators. It was shown that replacement of the metal radiators by the radiators with concentrated capacitive loads allows providing, using a few

radiators, the high directivity in a wide frequency range, i.e., decreases sharply the antenna length. Increasing radiators number must allow increasing substantially the antenna directivity.

Results obtained by means of the method of electrostatic analogy may be used for solving optimization problem log-periodic antennas by methods of mathematical programming.

Porous media

ABSTRACT

The efficiency of a plasma-aided finishing process, namely capillary impregnation, can be predicted only by setting two basic parameters of the real wood porous surface and the actual impregnating solution – surface free energy and surface tension. In general, the following processing efficiency parameter was found and the rule is true: "The plasma aided or enhanced finishing of a porous media will be more successful and this media will be more susceptible to it as the difference between its surface free energy and the surface tension or the so-called penetration-spreading parameter is positive: PSP = $(\sigma_S - \gamma_L) > 0$. If not, wetting, wicking and finishing problems will occur.

1. Introduction

This paper is an extension of a work originally presented at the International conference on electrical machines, drives and power systems "*ELMA'17*" [1].

Dielectric-barrier discharges (DBD) have been known for more than a century – the first experimental investigations focused on ozone generation were reported by *Werner von Siemens* in 1857. In 1951, *Werner Eisby* founded his company *Vetaphone* on the patent of a new plasma surface technology, which he initially named *E-treatment* and later it was known worldwide as the *Corona technology*. In fact, *Corona* was a *Dielectric-barrier discharge* in air at atmospheric pressure. This high-frequency electric discharge was controlled by a dielectric barrier and organized in the *micro-discharge mode* – it created a pattern of streamers distributed over the whole surface. This *atmospheric pressure air-plasma* (APP) *pre-treatment* was necessary to obtain sufficient wetting and adhesion on plastic films or metallic foils before high-speed roll-to-roll converting processes to ensure perfect surface finishing - printing, laminating or coating. Adding a *Corona treater* on a blown film or cast film extrusion line was essential in order to obtain a perfect *surface free energy* (SFE) prior to the following converting process. This *plasma-aided finishing* has proved to be both highly effective, cost-effective and can take place in-line [2, 3].

In the 80s of the last century, the *APP pre-activation* came to facilitate the textile finishing. In textile manufacturing finishing refers to the processes, that convert the woven, non-woven or knitted cloth into a usable material or fabric to improve the aesthetic appearance and the functional characteristics of the finish textile. This *plasma-aided finishing* has proved to be both highly effective, cost-effective and can take place not only in-line, but also out-of-the-line. The finish textiles such as carpets, rugs, mats, curtains or clothing require the implementation of plasma-aided finishing *out of the production line* [3, 4].

At the beginning of this century, the *APP-activation* (APPA) was used to enhance the wood finishing. In wood manufacturing finishing refers to the process of refining or protecting wooden surfaces. Wood finishing is the final step of the manufacturing process that gives wood surfaces desirable characteristics, including enhanced appearance and increased resistance to moisture, to fire and to attack from destructive organisms such as fungi and insects. It is well known that the inactivated by hydrophobic contamination wood surface has low *SFE*. This *wood inactivation*, [5], leads to poor wetting, adhesion, and impregnation especially for water-based varnishes and printing inks, adhesives and coating substances, as well as flame retardant water solution. The plasma-aided finishing has proved to be both highly effective, cost-effective, [6, 7], and can take place not only in-line, but mostly out-of-the-line. The three-dimensional wooden buildings and structures require removal of the plasma-aided finishing "*in situ*" out of the production line [8].

The *APPA* is essential in surface finishing processes. Without plasma-chemical surface pre-treatment, the porous and non-porous substrates will not allow further finishing processes due to the low *SFE*. The *plasma surface activation* and *functionalization* are able

* Corresponding Author: Peter Dineff, Technical University - Sofia, Faculty of electrical engineering, 1756, Bulgaria, dineff_pd@abv.bg

to ensure that perfect finishing result we all want to see when looking at finish products. The objective of this kind of activation is to increase the *SFE* and subsequently the wettability, adhesion and wicking for laminating, printing, dyeing, gluing, impregnating and other finishing processes [9, 10].

Established *APPA* processes, such as plasma or flame activation, increase the *SFE* and decrease the contact angle, and therefore improve the processing characteristics. The *Sessile Drop Test* - a contact angle measurement technique, and the *Dine Test* - an ink test technique, were two widely used methods for *SFE* assessment and therefore for checking the *need for APPA* or the efficiency of such a pre-treatment processes [11, 12, 13].

The *SFE* of a solid cannot be measured directly because solids typically show no reaction to the exertion of *SFE*. Plasma, corona or flame treated and untreated surfaces are indistinguishable to the naked eye. Consequently, practical measurements of *SFE* involve the interaction of the solid with a test liquid to determine wetting surface tension as a measure of *SFE*. Standards such as DIN EN 828: 2013-04 (E) for adhesive finishing specify contact angle measurement as a method for determining the *SFE* of surfaces for checking the efficiency of cleaning or activating plasma pre-treatment processes.

The purpose of this paper is not only to collect new evidence and extend knowledge about the plasma-aided porous media finishing, especially *capillary impregnation,* with phosphorous flame retardant (FR) containing water solution for *flame retardancy* as finishing for wood, wooden and cellulosic materials, but also to provide a process efficiency assessment for the overall plasma enhanced process, not only for the *APPA pre-treatment*.

2. Assessment of plasma-activated finishing efficiency

2.1. Model of wetting-wicking theory and efficiency assessment

Plasma-aided technique was used to facilitate the surface finishing, more precisely the *surface impregnation* of porous media such as wood, wooden and cellulosic materials [1, 14-17].

Porous materials with low *SFE* (σ_S) were subjected to plasma-chemical surface pre-activation for increasing their *SFE* and enhance the finishing. The wetting phenomenon occurs in a different way on porous media. The surface curvature of a sessile liquid drop on a porous solid depends not only on wetting but also on wicking in depth. This is a phenomenon of wetting-wicking. Wicking and wetting are essential in porous media finishing, such as capillary impregnation for flame retardancy of wood, wooden materials,woven and non-woven textile Figure 1, [1].

Both wetting and wicking together determine the variation of the sessile drop curvature and the contact angle over time. This is the wetting-wicking and contact angle phenomenon. That is why it is imperative in the case of porous media to talk about *apparent contact angle* and *apparent surface free energy.* This process of contact angle change ends with the complete absorption of the flame retardant solution at almost constant value of the contact angle - *end contact angle*, much lower than the *initial contact angle,* Figure 2.

The "*wetting-wicking theory*", expressed in terms of the thermodynamic parameters, such as the *contact angle*, the *surface tension*, and the *surface free energy*, can be the most widely used approach to porous media in wetting science at future, also referred here as "*wetting-wicking phenomena*". Wetting-wicking is defined here as the ratio between the surface energies of the solid and the surface tension of the liquid [14].

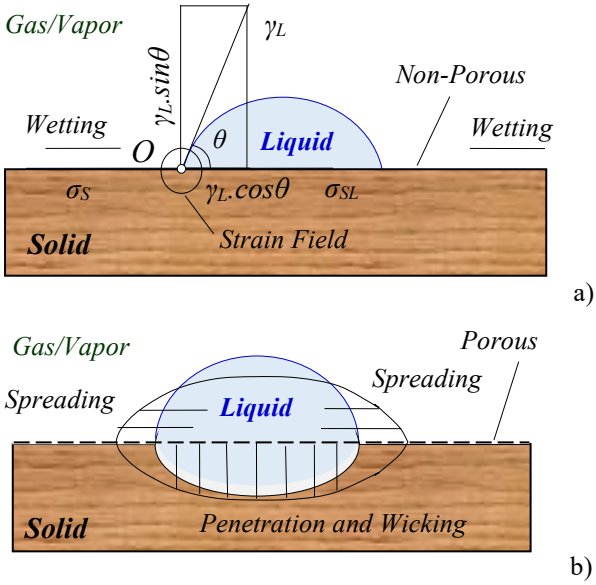

Fig. 1. Schematic illustration of two types of *wetting phenomena*: **a)** the *wetting phenomenon* on a *non-porous surface* when a liquid drop is placed on a smooth, non-porous and rigid solid, both exposed to gas/vapor, the system will not be in equilibrium and the liquid "wets out" or spreads over the solid, then the liquid exhibits a contact angle of zero against the solid (*Good,* 1993); **b)** *the wetting-wicking* or shortly *wicking phenomenon* on a *porous surface* can involve: *i* - spreading over the solid; *ii* - penetration or wicking into the porous solid (*Berg*, 1993).

According to *Young's equation*, which is proven since over 200 years (1805), there is a fundamental relationship between the *contact angle* θ, deg, the *surface free energy* (SFE) of the solid σ_S, mJ/m^2, the *surface tension* (SFT) of the liquid γ_L, mN/m, and the *interfacial tension* (IFT) σ_{SL} between liquid and non-porous or porous solid, mJ/m^2, Figure 1a, [1, 15]:

$$\sigma_S - \sigma_{SL} - \gamma_L \cos\theta = 0; \quad (1)$$

$$\Sigma = \gamma_L \cos\theta = \sigma_S - \sigma_{SL}, \quad (2)$$

where Σ is the *adhesion tension*, mJ/m^2; the adhesion tension reaches its maximum value at full wetting surface when the *IFT* reaches its minimum value: $\cos\theta = 1$ ($\theta = 0°$); $\sigma_{SL} = \sigma_S - \gamma_L$; and $\Sigma = \gamma_L$.

The liquid in porous materials is often pulled into surface pores and capillaries by *capillary action*. The capillary action or *capillarity* is defined as the movement of liquid within the spaces of a porous media due to the forces of adhesion, cohesion and surface tension. Capillarity manifests itself when the adhesion to the capillary walls is stronger than the cohesive forces between the liquid molecules. Its ability to fill-in defects, such as surface-breaking cracks, voids, pores and capillaries can be imputed to a great extent to penetration, sorption or wicking characteristics. In porous media, capillary pressure p_C is the force necessary to squeeze a droplet through a pore throat and to work against the *IFT* between solid and liquid phases. Capillary pressure p_C is proportional to the adhesion tension Σ and depends only on it at a certain characteristic pore size r [16]:

$$p_C = 2\,(\sigma_S - \sigma_{SL})/r = 2\,\Sigma/r, \quad (3)$$

where the capillary pressure p_C reaches its maximum value when the adhesion tension Σ reaches its maximum value at complete wetting: $cos\ \theta = 1$ ($\theta = 0°$); $\Sigma = \gamma_L$; and $p_C = 2\ \gamma_L/r$.

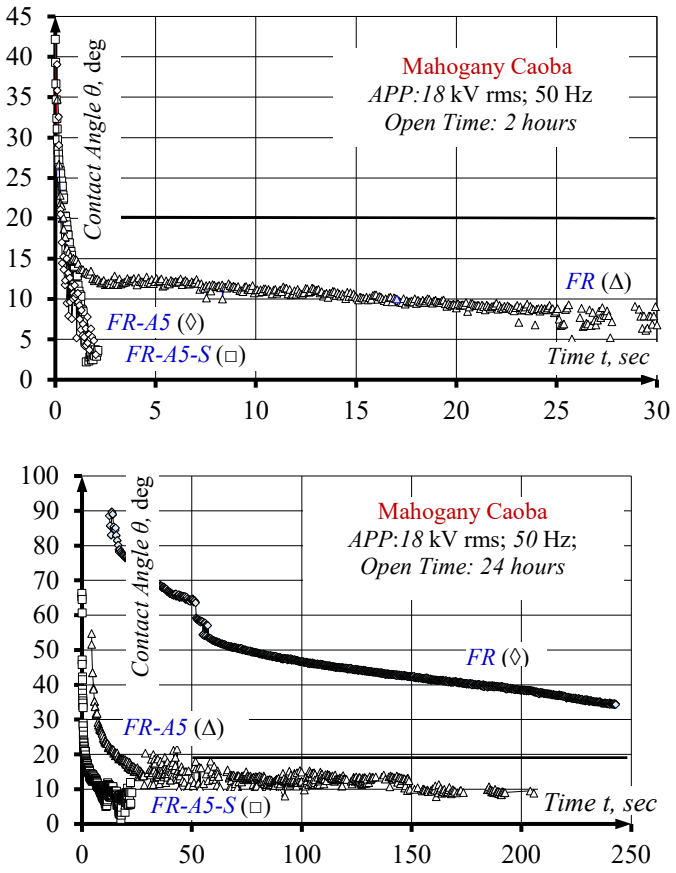

Fig. 2. Dynamics of change in *apparent contact angle* θ over time t depending on the used impregnating water solutions of phosphorous flame retardant with different surface tension: *FR* – 46.4 mN/m; *FR-A5* – 22.4 mN/m and *FR-A5-S* – 18.5 mN/m, and short and long aging time, 2 or 24 hours.

Sessile and pendant drop analyses allow *SFE* and *SFT* to be quantified and to propose two distinct relationships that illustrate in general this process in the wetting area, $\theta \in [0 \div 90]°$, – the *IFE* and adhesion tension Σ - proportional to capillary tension p_C, as a functions of the contact angle θ, Figure 3.

2.2. The best solution rule for finishing and plasma-aided finishing efficiency parameter

Both *SFE* and *SFT* are essential in porous media finishing phenomena, (1). *APPA* surface technique can be used to enhance surface finishing: materials with low *SFE* were subjected to oxidative *APPA* to increase it, Figure 3.

The difference between *SFE* of porous surface and *SFT* of impregnating solution was chosen as a finishing efficiency or *penetration-spreading parameter* (PSP) for a real porous solid such as wood: $PSP = (\sigma_S - \gamma_L)$. *Finishing* does not include evaporation of solution, dissolution or swelling of the solid by the water solution or any kind of chemical reaction between the solution and the solid substrate that changes the system composition. The higher the *SFE* of the solid, the better the finishing; the lower the *SFT*, the better the result of finishing. To sum up, large and positive difference between *SFE* and *SFT*: $\sigma_S - \gamma_L > 0$, (or $\sigma_S > \gamma_L$), will provide more effective porous surface finishing [1].

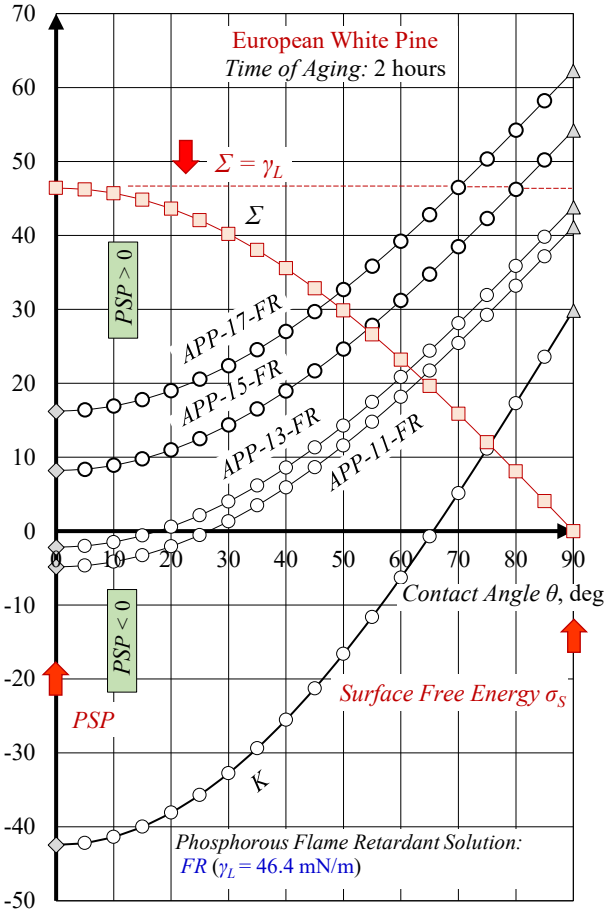

Fig. 3. Relationship between the "solid-liquid" interfacial energy σ_{SL} and the contact angle θ, measured by *Sessile drop technique*. Penetration-spreading parameter (*PSP*) is equal to the minimum *IFE* value at $cos\ \theta = 1$ ($\theta = 0°$): $PSP = \min \sigma_{SL}$. An effective finishing has a positive value of *PSP*: $PSP > 0$; a non-effective finishing has a value of less than or equal to zero: $PSP \leq 0$. Surface free energy σ_S is equal to maximum *IFE* value at $cos\ \theta = 0$ ($\theta = 90°$): $\sigma_S = \max \sigma_{SL}$.

Relationship between the adhesion tension Σ and the contact angle θ. The maximum adhesion tension Σ value is equal to the surface tension γ_L of the flame retardant water solution *FR*: $\gamma_L = 46.4$ mJ/m^2.

Atmospheric pressure plasma pre-activation at 50/60 Hz and different voltage: 11, 13, 15 and 17 kV rms: method – in situ; time of activation – 60 sec; glass barrier – 3 mm; air gap – 6 mm.

In general, the following processing efficiency parameter was found and the rule is true: "*The plasma aided or enhanced finishing of a porous media will be more successful and this media will be more susceptible to it as the difference between its SFE* σ_S *and the SFT* γ_L *or the so-called penetration-spreading parameter is positive*: $PSP = (\sigma_S - \gamma_L) > 0$. *If not, wetting, wicking and finishing problems will occur*" [1].

This new rule of processing efficiency is fully consistent with the well-known rule formulation: "*If the liquid has a dyne level (SFT) lower than the substrate dyne level (SFE),* $\gamma_L < \sigma_S$, *then the liquid will spread out over its entire surface in uniform wet layer. If the liquid dyne level is equal to or higher than a substrate dyne level,* $\gamma_L \geq \sigma_S$, *the liquid will become cohesive and tend to remain in droplets*" [18]:

$$\sigma_S > \gamma_L: \sigma_S - \gamma_L > 0 \text{ or } PSP > 0. \qquad (4)$$

According to *Young's equation*, there is a fundamental relationship between *IFE* and $PSP = (\sigma_S - \gamma_L)$:

$$\sigma_{SL} = (\sigma_S - \gamma_L) + \gamma_L (1 - \cos\theta) = PSP + \gamma_L - \gamma_L \cos\theta; \quad (5)$$

$$\min \sigma_{SL} = (\sigma_S - \gamma_L) = PSP;\ \theta = 0°: \cos\theta = 1, \quad (6)$$

or the minimum value of the "*solid-liquid*" *IFE* at $\theta = 0°$ is equal to the value of *PSP*: $\sigma_{SL} = PSP$, Figure 3, [1, 14].

Table 1. Contact angle, wetting and hydrophilicity change.

Contact angle θ, °	**0**	10	20	30	70	**90**
cos θ	1	$1 > \cos\theta > 0$				0
Interface free energy (*IFE*)	$\sigma_{SL} = PSP$					$\sigma_{SL} = \sigma_S$
Hydrophilicity / Hydrophobicity	Hydrophilicity				Hydro phobicity	
	Super-Hydrophilicity		Hydro philicity		Hydro phobicity	
Degree of wetting	*Spreading*	*Complete wetting*	*Wetting*	*Partial wetting*		*Incomplete wetting*
Wettability	*High wettability*					

The maximum value of the *IFE*, at $\theta = 90°$, is equal to the value of porous wood *SFE*: $\sigma_{SL} = \sigma_S$, Figures 3 and 4.

Therefore, the requirement for process efficiency finishing $PSP = (\sigma_S - \gamma_L) > 0$ can be transformed into a new requirement for effectiveness, Figure 3:

$$\sigma_S > \sigma_{SL} > PSP > 0, \quad (7)$$

which already refers directly to *IFE*: "*it is necessary for the entire range of variation of the static contact angle* ($0° \le \theta \le 90°$) in the area of the *high wetting*, *the value of the IFE to be greater than zero*: $\sigma_{SL} > 0$".

Plasma-aided capillary impregnation finishing will be more successful and the porous media will be more susceptible when the $PSP > 0$. This is the essence of the rule for obtaining effective plasma-enhanced capillary impregnation finishing.

Surface activation refers to the temporal increase of the *SFE* determined by the rise of the polar part of the *SFE*, Figure 4. This *APPA* process is based on the implantation of oxygen, leading to the formation of functional groups like *ether* (C-O), *hydroxyl* (C-OH), *carbonyl* (C=O), and *carboxyl* (O=C–OH). Such a plasma treatment enhances the affinity of the substrate for other substances and is especially needed for solids which typically have a low intrinsic *SFE*. This process is generally achieved using a standard *DBD* in open air and "in situ" or remote application Figure 5.

The *PS*-parameter depends only on two thermodynamic parameters of the finishing process – the *SFE* σ_S of the solid and the *SFT* γ_L of the liquid, which can be quantified individually using two well-known methods of contact angle measurement – the sessile drop and the pendant drop techniques [15, 16 and 17].

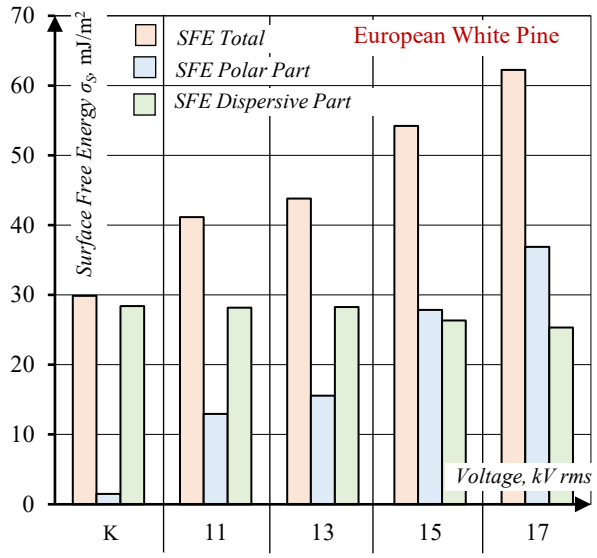

Fig. 4. Surface free energy σ_S and its dispersive and polar parts for *European white pine* after *APPA* and 2 hours of aging time and varied voltage: 11,13,15 and 17 kV rms, defined by Sessile drop technique and *theory of Wu*.

Working with the graphs and studying the relationship between the "*solid-liquid*" *IFE* σ_{SL} and *contact angle* θ in the area of high wettability, $0° \le \theta \le 90°$, it becomes clear that the graphs of the efficiency realizations of plasma-aided surface impregnation – *APP-15-FR* and *APP-17-FR* are located in the first quadrant above the abscissa, Figure 3.

One more graphic illustration has been brought about, Figure 5, depicting the efficiency parameter assessment of plasma-aided capillary impregnation with modified phosphorous *FR* solution by increasing the *SFE* and decreasing the *SFT* of the impregnating solution.

2.3. Aging, plasma activation durability and open time

It is very important to realize that the changes induced on the surface by an *APPA* are not permanent. There is aging, which is the effect of the *APPA* or *SFE* decreasing in time. Often, the activation effect will remain partially and a steady state will be reached after some hours, days or weeks. For *APPA*, the aging can be really an issue. Hence the typical *APPA* was performed "in-line", immediately before the finishing for which it is intended. Aging was usually regarded as an unwanted side-effect in plasma-aided finishing [17, 19].

The time of aging or *open time* is the period of time after an *APPA* has been applied, allowing for the finishing processes to take place – printing, bonding, painting, laminating and impregnating, during which an effective plasma-aided finishing can be achieved. Plasma pre-activation most often takes place "in-line" immediately prior to the onset of the finishing. The *time of aging* in this case is zero. The *time of aging* is different from zero when the plasma-aided capillary impregnation is applied "out-of-the-line", for example in the finishing of a wooden building construction, wood paneling, flooring or staircase. Most often, the entire surface is activated "*step by step*" for a certain time and then it is proceeded to capillary impregnation, Figure 6.

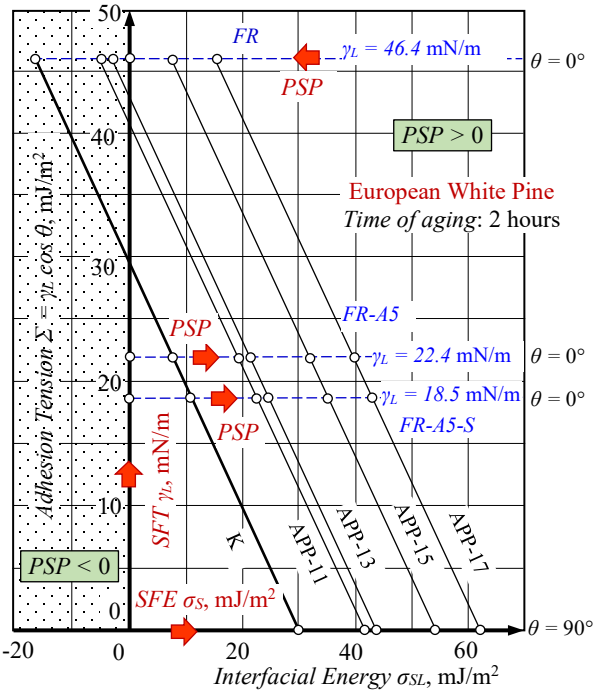

Fig. 5. Relationship between the adhesion tension Σ and the "solid-liquid" interfacial energy σ_{SL} that reveals at once the impact of: *i* – the variation of *SFE* as result of *APPA* and 2 hours of aging at varied voltage: 11, 13, 15 and 17 kV rms; *ii* – the variation of *SFT* as a result of *FR*-solution modification with surfactants: *FR-A5* – with micelle-forming anionic surfactant at 5 vol. % and *FR-A5-S* – with trisiloxane surfactant at 0.1 vol. %.

The industrialization of the plasma-aided finishing "out-of-the-line" during 2007÷09 allowed the empirical definition of two very important values for the time of aging – 2 hours or a short time of aging, allowing for successful finishing of large-scale wood wares such as paneling, flooring, wooden construction, and a day or 24 hours, a long time of aging, which is close to the *critical open time* when the effect of the plasma activation will be obliterated.

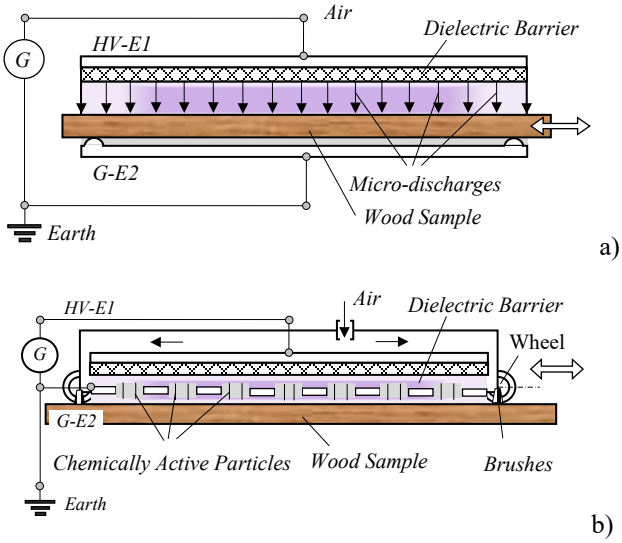

Fig. 6. Atmospheric pressure plasma pre-activation by dielectric barrier discharge in air: **a)** *APPA*, "in situ" activation where the sample is immersed in the cold plasma of the *DBD* (*V. Eisby*, 1951); **b)** *RAPPA*, remote activation where the sample interacts only with the chemically active particles produced by the *DBD* (*P. Dineff*, 2005).

HV-E1 – high-voltage electrode; *G-E2* – grounded electrode; *G* – AC electric generator (50/60 Hz).

Remember that the *SFE* level decay is extremely fast right after *APP*-activation "*in line*" – in fact an immediate loss of 10 mJ/m^2 is possible. This is due to the contact with process rolls, surface migration of additives and interfacial transfers between treated and untreated surfaces within the finished wound roll. Generally, the *SFE* of a film should be between 3 and 10 mJ/m^2 greater than the *SFT* of the ink or impregnating liquid in order to ensure acceptable performance, Figure 6, [11, 18].

The highest plasma-activation effect to the finishing, expressed by maximum *SFE* value increase, was observed with "*in situ*" *APPA*, "in line" application, Figure 6, [1, 18].

THE OBJECTIVE of this paper is to study the efficiency assessment of plasma-aided capillary impregnation as finishing for flame retardancy of wood at industrial frequency (50 Hz) and voltage of 15/18 kV rms, after short and long aging time, 2 and 24 hours, and the change of the wood impregnability monitored by the penetration-spreading parameter (PSP) and the processing efficiency rule: *PSP* > 0.

3. Experimental investigation

The development of a plasma-enhanced capillary impregnation finishing for wood flame retardancy goes through three stages:

- *The first stage* includes the selection of an effective *APPA* mode that provides the necessary high level of *SFE* after a short aging of 2 hours, Figures 3 and 9;
- *The second stage* includes the selection of an anionic micelle-forming water surfactant in a concentration to ensure the required low level of the *SFT*: 30 mN/m > γ_L > 20 mN/m, Figure 10;
- *The third stage* includes the selection of an effective *APPA* mode that will provide the necessary high level of *SFE* after a long time of aging, a day or 24 hours, and low level of *SFT,* by some adequate surfactants and concentrations, Figure 11.

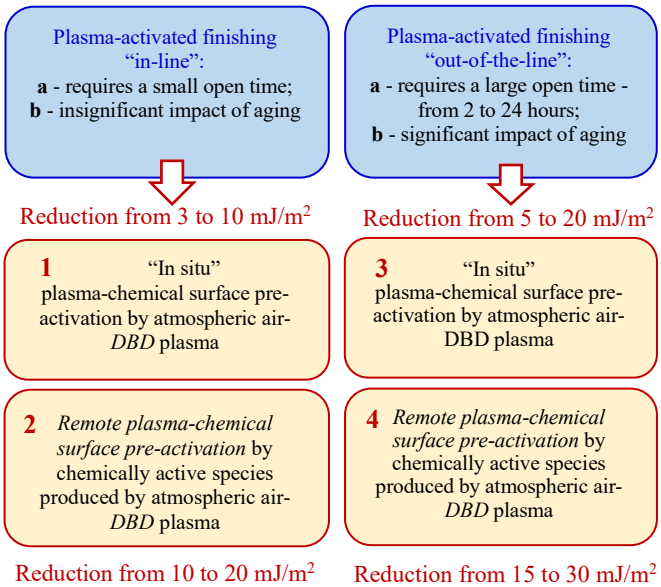

Fig. 7. Surface free energy reduction before finishing due to: *i* - contact with other non-activated surfaces, *ii* – aging after plasma activation, and *iii* – different modes of plasma surface activation provide different activation options: *APPA*, "in situ" activation immerced in cold plasma or *RAPPA*, remote activation with chemically active particles.

This experimental study was carried out on four kinds of wood samples: *European white pine* (*Pinus Sylvestris L.*) from Bulgaria and three woods from Mexican rain forest: *Tzalam* (*Lysiloma Bahamensis L.*), *Mexican white cedar* (*Cupressus lusitaca L.*), *Mahogany caoba* (*Swietenia mahogany L.*), according to the well-known method [1, 15-17]. The selected wood species form the following range of decreasing density, in kg/m^3: *Tzalam* – 780; *Mahogany caoba* – 650; *Mexican white cedar* – 470; *European white pine* – 371. There are two hard wood species with high density, $d > 540$ kg/m^3: *Tzalam* and *Mahogany caoba*, and two soft wood species with low density, $d < 540$ kg/m^3: *Mexican white cedar* and *European white pine*.

On the basis of our own former experience in plasma-aided capillary impregnation of wood and wooden materials, [9-12], an oxidative *APPA* has been applied on the test samples for 60 sec. This study employs a well-known experimental methodology, already used by us [1, 14-17].

All experimental studies pertain to *APPA* of the wood specimens in a specific burning mode of the air *DBD* at atmospheric pressure (~ 101 kPa) at the first peak of surface density of real power p_a = 26 W/m^2 and the second peak p_a = 8 W/m^2 in asymmetric rectangular coplanar electrode system with 6 mm air gap – mode *A* and *B* respectively, Figure 7.

The *APPA* was carried out with "*in situ*" application of *DBD* for 60 sec, Figure 5a. The effective operating modes of *DBD* at voltages above 13 kV rms (18.3 kV peak value) determine a surface density of real power above 4 W/m^2, Figure 7.

The aim of this study was to verify the possibility to evaluate the *PS*- efficiency parameter values for plasma and surfactant enhanced capillary impregnation trough calculation of *SFE* and *SFT* by drop shape analysis. *Drop shape analysis* is an image analysis method for determining the contact angle from the shadow image of a sessile drop and the *SFT* from the shadow image of a pendant drop. There are number of theories and models for *SFE* calculation with the help of contact angle data. The method according to *Wu* for calculating *SFE* and its two parts – polar and disperse, is suitable for high polar or plasma activated surfaces, Figure 4.

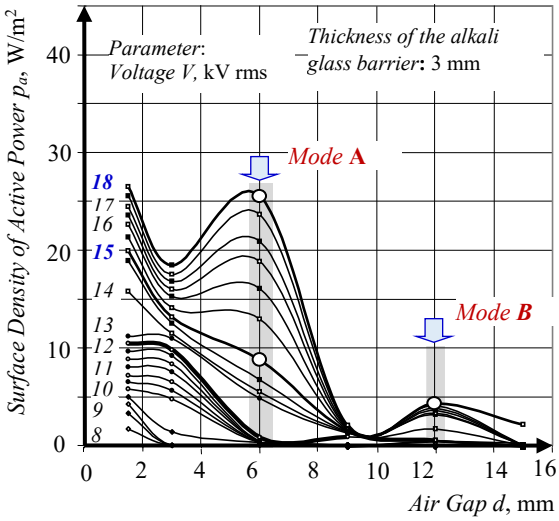

Fig. 8. Technological discharge characteristic "surface density of active power p_a – air gap size *d*" of non-equilibrium *DBD* burning at industrial frequency (50 Hz) in asymmetric rectangular coplanar electrode system with one glass barrier.

All methods described are included in the KRÜSS Drop shape analysis programs. *Drop Shape Analyzer* (DSA100 and DSA30, KRÜSS GmbH, Germany) was used for the precise measurement of contact angle *SFE* and also for measurement of the *SFT* of liquids using the pendant drop method. Measuring range (referred to image analysis) for *Sessile drop technique*: contact angle – 1°÷180°; surface free energy – 0.01÷1 000 mJ/m^2; and for *Pendant drop technique*: surface tension – 0.01÷2000 mN/m. Measurement accuracy: contact angle – 0.3°; surface tension – 0.3 mN/m [7].

Modes of *APPA* for wood samples: *mode A* – cathode-directed streamer mode at air gap of 6 mm; *mode B* – anode-directed streamer mode at air gap of 12 mm, Figure 8.

A halogen-free, phosphorous and nitrogen containing flame retardant (FR) based on ortho-phosphorous acid, urea and ammonia has been produced and studied as water solution. The impregnating *FR* water solution was based on it: dry substance of 30 wt. %; phosphorus content of about 13 wt. %, pH = 7÷8 and density of 1.15÷1.14 g/cm^3.

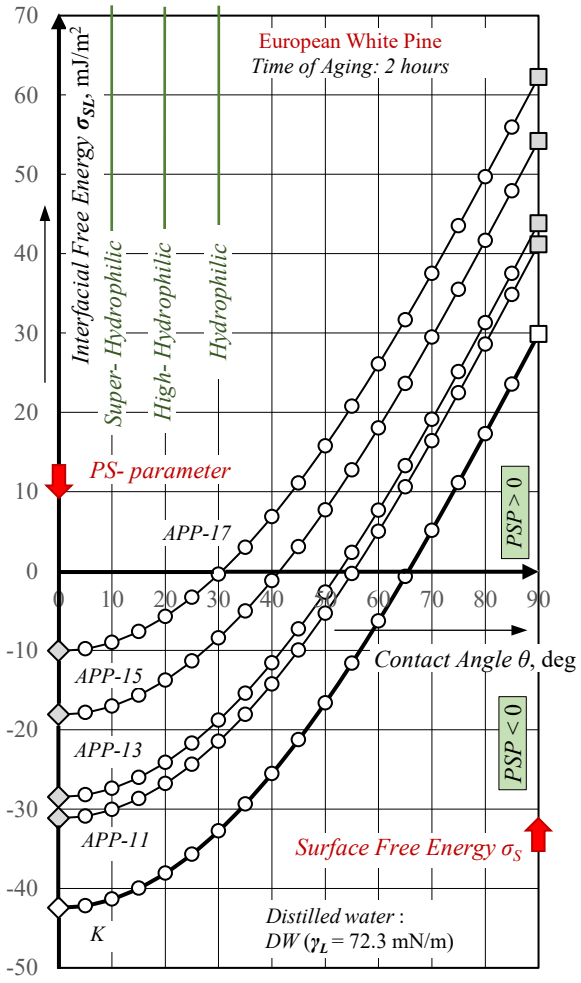

Fig. 9. The use of distilled water as a test-liquid with $SFT - \gamma_L = 72.3$ mN/m, does not carry adequate information on the efficiency of the finishing of *FR* capillary impregnation – no effective mode of *APPA* has been found at voltages up to 17 kV rms for *European white pine*: $PSP = \sigma_S - \gamma_L < 0$. All *SFE* values were determined according to the *method of Wu* for short aging time of two hours.

The non-equilibrium air (oxidative) *APPA* was combined with anionic micelle-forming (AS, "Anticrystalin A", *Chimatech, Ltd.*,

Bulgaria) and trisiloxane-ethoxylate surfactant (Y-17113, *Momentive Performance Materials* GmbH & Co. KG, Germany) enhanced capillary impregnation with well-known experimental methodology [10, 11, 12].

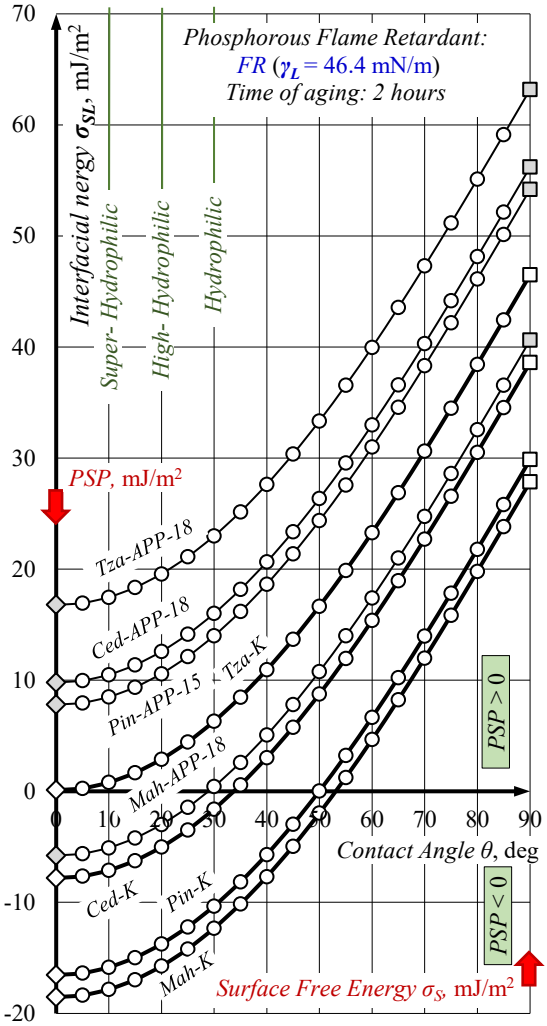

Fig. 10. Effective mode selection of *APPA* at an air gap of 6 mm and short aging time of two hours for plasma-aided capillary impregnation finishing was found only for *European white pine* (*Pin-LF-15*), *Mexican white cedar* (*Ced-LF-18*), and *Tzalam* (*Tza-LF-18*): *PSP* > 0. No steady *APPA* mode for *Mahogany caoba* (*Mah-LF-18*) was found: *PSP* = 0.1 mJ/m² ≈ 0. Plasma pre-activation modes provided trought the declared voltage – 15/18 kV rms, get the maximum *SFE* value for each species of studied woods.

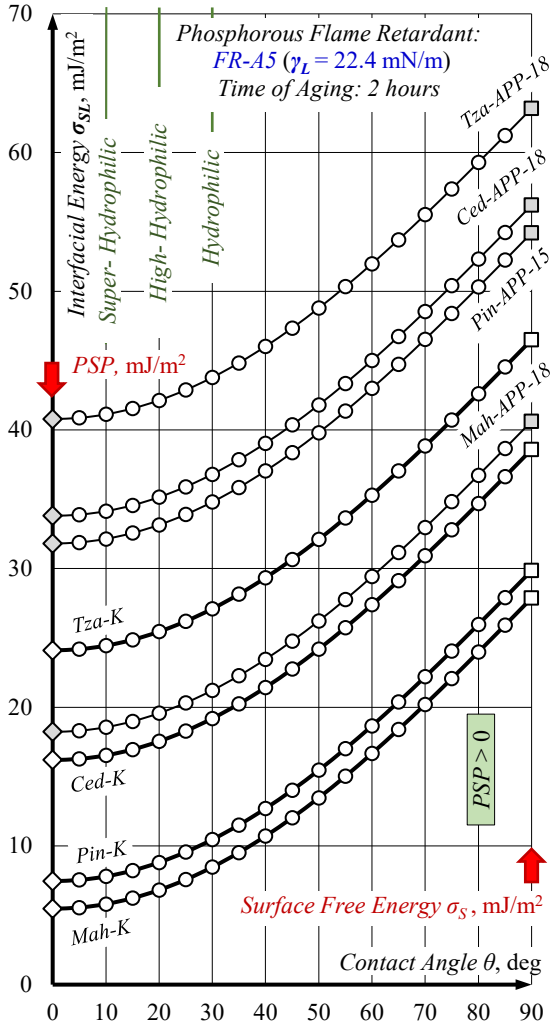

Fig. 11. Effective mode selection of *APPA* at an air gap of 6 mm and short aging time of two hours for plasma-aided capillary impregnation finishing was found for all wood species by decreasing the *SFT* of the basic phosphoric *FR* solution with *anionic micelle-forming water surfactant* at 5 vol. % (*FR-A5*): γ_L = 22.4 mN/m. The rule of processing efficiency was met for all applications of capillary impregnation – non-activated (*-K*) and *APP*-activated (*-APP-XX*) at different voltages: 11, 13, 15 and 17 kV rms: *PSP* > 0.

4. Experimental rezults and discusion

This study meets another issue which can be formulated as follows: "*is it possible a simple drop test with distilled water* (DW) *to adequately replace the entire PSP study conducted with a real impregnating FR-water solution*".

The answer can be found in the information provided in Figure 3 and 8. The use of distilled water as a test-liquid does not carry adequate efficiency assessment of the finishing – the plasma-aided capillary impregnation. The effective mode selection (*APP-XX*: *APPA* at 11, 13, 15, and 17 kV rms; 50/60 Hz) can be determined only by the use of *FR* solution – a basic *FR* water solution containing phosphor- and nitrogen flame retardant with *SFT*, γ_L = 46.4 < 72.3 mN/m, and the relationship between the "*solid-liquid*" *IFE* (σ_{SL}) and static contact angle θ measured by Sessile drop technique – *IFE* acquires a value equal to the *PS-Parameter* at *complete wetting*, i.e. contact angle equal to zero: $\sigma_{SL} = PSP$ ($\theta = 0$).

Distilled water has a too high *SFT*: γ_L = 72.3 > 46.4 >> 22.4 mJ/m². *APPA* cannot compensate it by increasing *SFE*, so a rule process efficiency should be enforced: $\sigma_S < \gamma_L$; *PSP* < 0, Figure 8. Normally, it fails to predict the efficiency of the plasma-aided finishing with modified γ_L = 22.4 mJ/m², or non-modified γ_L = 46.4 mJ/m², *FR*-solution, Figures 3 and 8.

All modes of *APPA* with a voltage higher than 13 kV rms (18.3 kV peak value) provide processing efficiency finishing of capillary impregnation: *PSP* > 0, Figure 3.

At the first stage, the *PSP*- testing indicates that the voltage of the *APPA* for European white pine samples should be 15 kV rms (σ_S = 54.2 kJ/m²) for a maximum processing efficiency of the *FR* (γ_L = 46.4 mJ/m²) impregnation finishing: max *PSP* = 7.8 mJ/m²

> 0, Figure 9.

The most effective voltage for the other studied species of wood was determined using the same procedure and it is 18 kV rms. They are arranged in order of decreasing *PS-parameter* according to their density, mJ/m^2: *Tzalam* – 16.78, *Mexican white cedar* – 9.8 and *European white pine* – 7.8. However, no steady *APPA* mode for *Mahogany caoba* was found: *PSP* = 0.1 mJ/m^2 ≈ 0. This result indicates that there are wood species for which a processing efficiency finishing – a capillary impregnation, cannot be applied, Figure 9.

At the second stage, the *PSP*- testing of the all studied wood species indicates that the modified *FR*- solution with less *SFT* γ_L = 22.4 mJ/m^2, performs the rule of processing efficiency after a short time of aging, *PSP* > 0, Figure 10.

At the third stage, the *PSP*- testing of all studied wood samples indicates that the *APPA* and the finishing of capillary impregnation with the modified impregnating *FR* solution (FR-A5), γ_L = 22.4 mJ/m^2, satisfy the rule of finishing processing efficiency: *PSP* > 0, Figure 11.

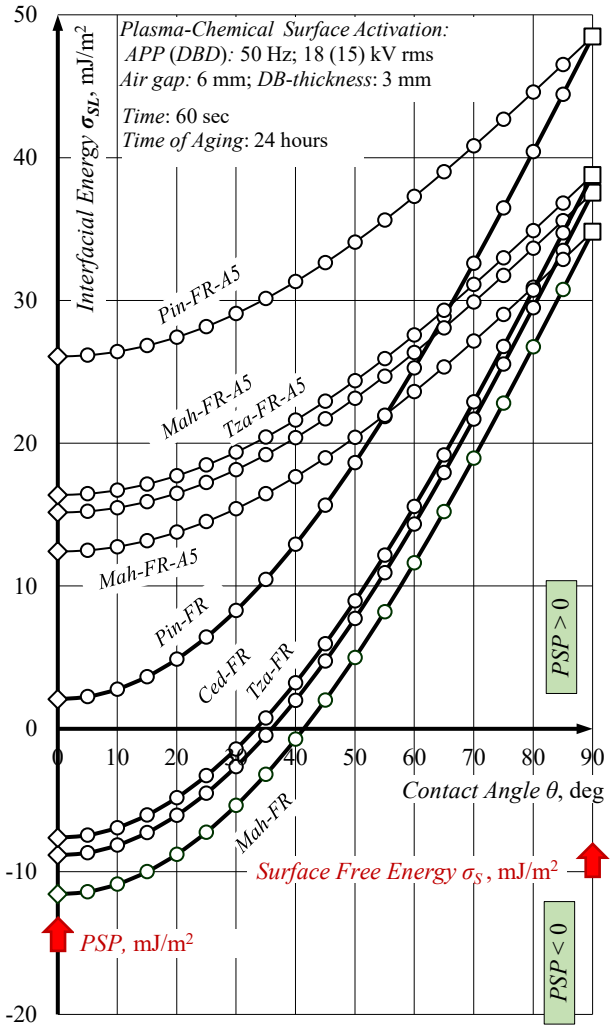

Fig. 12. Effective mode of *APPA* at air gap of 6 mm and short and long aging time - 2 and 24 hours, for plasma-aided capillary impregnation finishing was found for all studed wood samples by decreasing the *SFT* of the *FR* impregnating solution with anionic micelle-forming surfactant at 5 vol. % (*-FR-A5*): γ_L = 22.4 mN/m. The rule of processing efficiency was met for all applications of plasma-aided finishing with this modified solution: *PSP* > 0.

This study proves our claim that the plasma-aided capillary impregnation can be applied "out-of-the-process-line" after a long time of aging 24 hours, between *APPA* and the capillary impregnation finishing.

The plasma-aided capillary impregnation of porous woods has resulted in the formation of a *FR*-functional coating with a certain thickness, continuity and defect-free surface. In porous media, the *capillary pressure* p_C is proportional to the *adhesion tension* Σ and depends only on it at certain characteristic pore size, (3).

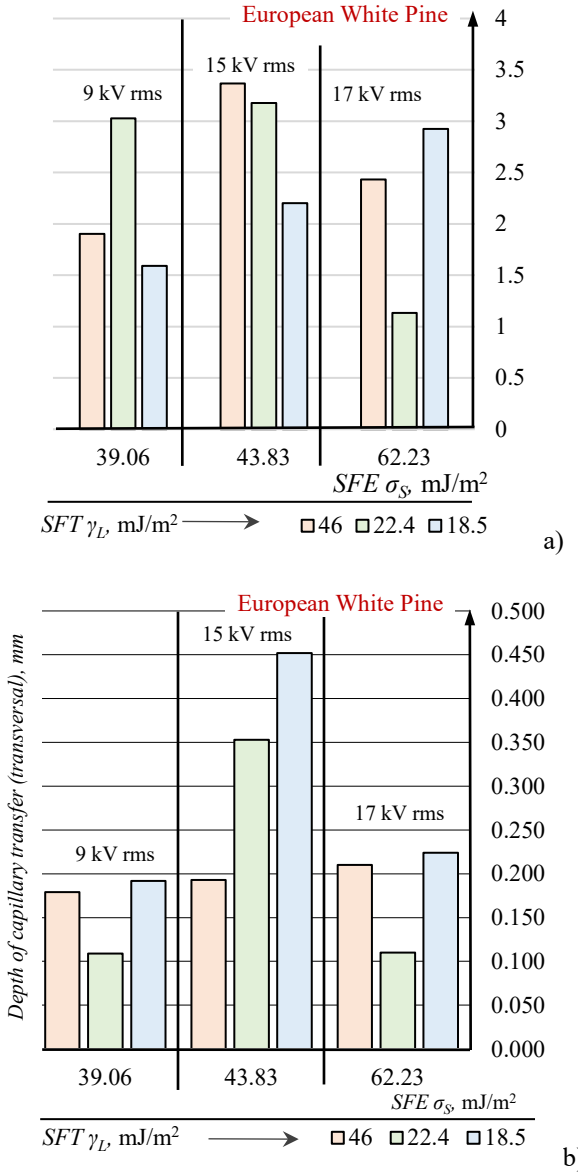

Fig. 13. Effect of *APPA mode* (voltage) – 9, 15 and 17 kV rms (50/60 Hz; air gap: 6 mm), the short time of aging – 2 hours, the used impregnating phosphorous *FR* solutions and consumption rate – constant rate: 0.139 l/m^2 (dm^3/m^2) on the depth of "capillary" transfer to the wood capillary direction: *longitudinal* – capillary displacement (**a**) and *transversal* – wicking through the capillary walls (**b**). The best quality of the plasma-aided capillary impregnation for flame retardancy of *European white pine* is at 15 kV rms.

It was expected that the largest *DBD* voltage of 17 kV rms should ensure greater depth of wicking transfer as the *SFE* and its greatest polar part, which determines greater value of *PS*-efficiency parameter. Although the *SFE* and its polar part are greater, Figure 4, just like the *PS*-parameter, Figure 3, the depth of

capillary transfer – longitudinal to the capillary structure and transversal to it, or through the capillary walls, is less than 15 kV rms, Figure 12. What is typical for this mode (15 kV rms) of plasma and surfactant enhanced capillary impregnation, is that the polar part of the *SFE* becomes greater than the dispersive part of *SFE*, Figure 4. The transition to more intensive mode of *APPA* (17 kV rms) does not give a positive result in spite of increasing *SFE* and its polar part, and *PS*-efficiency parameter.

Both the capillary displacement and the wicking through the capillary walls are two visible forms of maximum solution transfer, Figure 12. The maximum *capillary displacement* was determined by a maximum value of capillary pressure p_C or adhesion tension Σ respectively. This is determined by the maximum basic *FR* solution, Figure 5 and 13. On the contrary, the maximum *wicking through the capillary walls* was obtained at the minimum value of adhesion tension Σ; this is provided by the modified *FR-A5-S* solution. Wicking, however, is essential for the impregnation process. More extensive studies on different species of wood are needed to confirm this experimental fact, which has been observed only for European white pines so far.

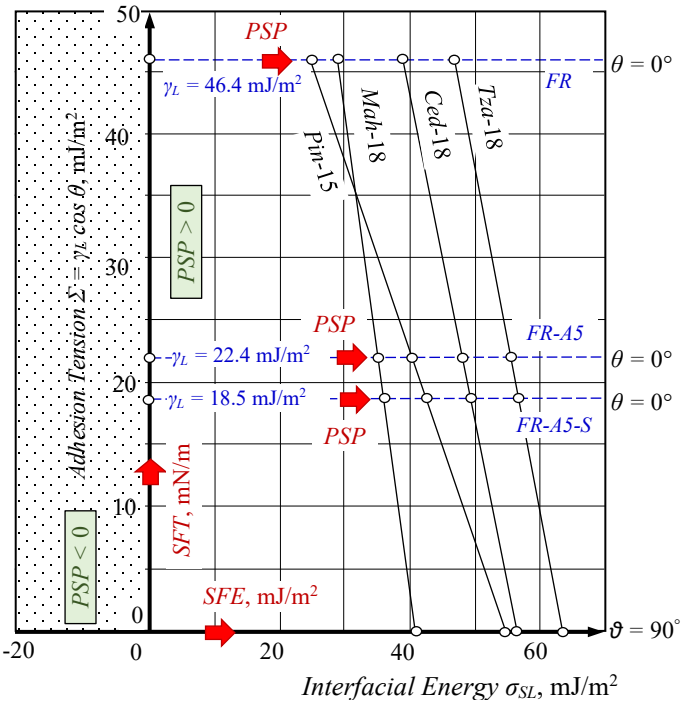

Fig. 14. Relationship between the *adhesion tension* Σ and the "*solid-liquid*" *interfacial energy* σ_{SL} that reveals at once the impact of: *i* – the variation of *SFE* as result of *APPA* at short time of aging (2 hours), air gap of 6 mm and voltage 15 kV rms; *ii* – the variation of *SFT* as a result of *FR*-solution modification with surfactants: *FR-A5* – anionic micelle-forming surfactant at 5 vol. %; *FR-A5-S* – trisiloxane neutral surfactant at 0.1 vol. %.

In conclusion, an attention has to be paid to the fact that the transfer of the *FR*-solution in depth is mainly carried out in the more complicated way through the capillary walls. The modification of the basic *FR*-solution through the combination of anionic micelle-forming and trisiloxane surfactant thus acquires a new meaning.

The graphical representation of the relationship between *adhesion tension* Σ and "*solid-liquid*" *IFE* σ_{SL} fully illustrates the two pathways for achieving the finishing efficiency *PSP* of plasma-aided capillary impregnation by increasing the *SFE* of porous media and reducing the *SFT* of the impregnating *FR* solution, Figures 5 and 13.

By selecting the voltage, the quality of the *APPA* expressed by the process efficiency parameter *PSP* was controlled: the *SFE* of the European white pine samples was increased; the *SFT* of the impregnating *FR* solution was decreased. The process efficiency parameter *PSP* meets the rule of plasma-aided finishing efficiency, *PSP* > 0, at and above 15 kV rms, Figure 5. For all wood species, the maximum process efficiency parameter *PSP* is at a voltage of 18 kV rms, Figure 13.

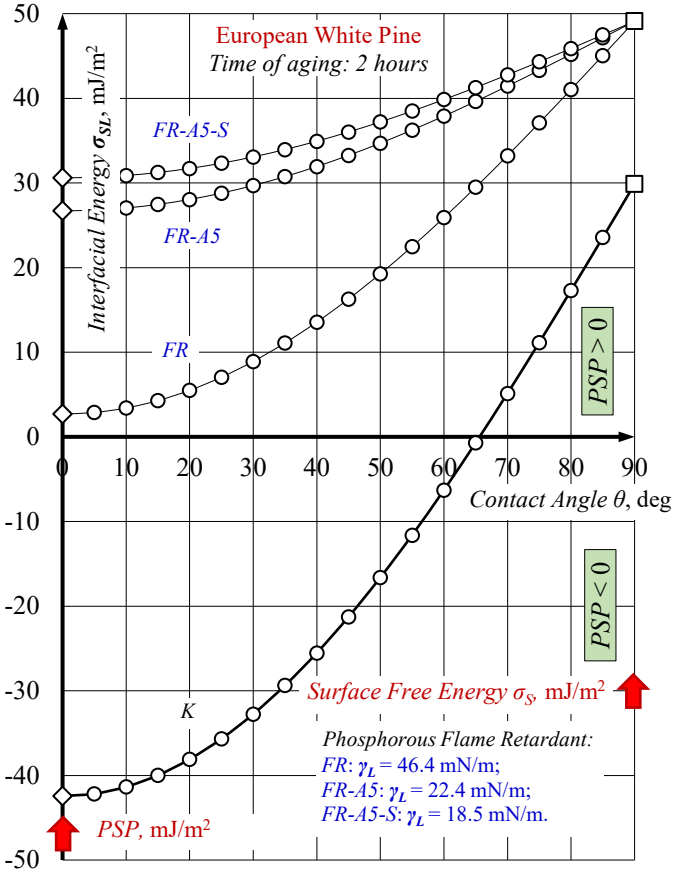

Fig. 15. Effective mode selection of plasma-aided capillary finishing of *European white pine* after two hours aging time from air *RAPPA* at air gap of 6 mm by a modification of the phosphoric *FR*-solution with an *anionic micelle-forming water surfactant* at 5 vol. % (*FR-A5*) and neutral trisiloxane surfactant at 0.1 vol. %. The rule of processing efficiency was met for all plasma-aided applications of capillary impregnation.

The new created plasma-aided finishing can find its wide application only if it can be envisaged and managed so as to observe the process efficiency rule: *PSP* > 0, Figure 15.

The prerequisite for this is the possibility for *SFE* measurement "*in situ*" out of the lab. We believe that this approach can be successful, as the market now has a technical device for measuring the *SFE* "in situ" – pocket goniometers, mobile or hand-held surface and contact angle analyzers.

There is also an innovative "mobile" analyzer with two test liquids using a dispenser with two parallel drops with "one click" for direct analysis of the static contact angles and the results obtained from the *SFE*.

Conclusion

Plasma, surfactant or plasma and surfactant aided finishing were used to enhance the finishing of capillary impregnation and thus the flame retardancy of wood: wood materials and constructions – timber, lumber, plywood, cardboard, paper, flooring, paneling, staircase and wooden structure with low *SFE* were subjected to *APPA* and *RAPPA* for increasing their *SFE*.

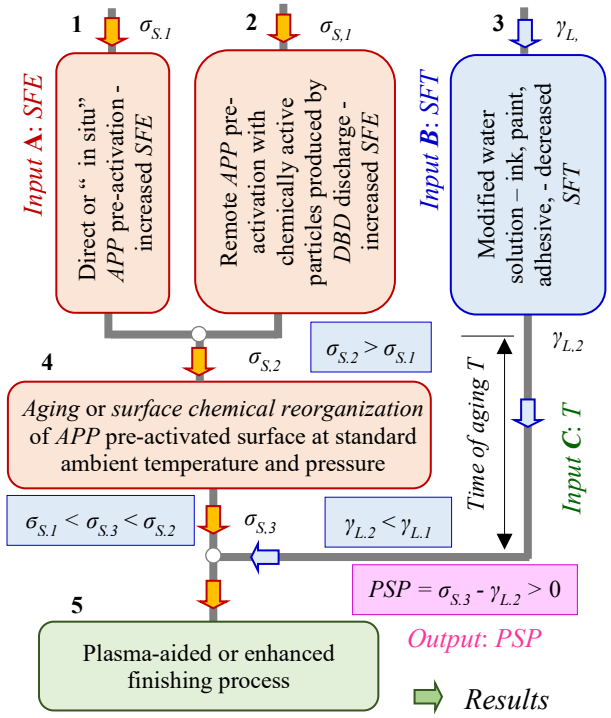

Fig. 16. Schematic representation of the plasma-aided impregnation finishing model – flow of information and processes involved in the processing efficiency and results to be obtained. Management of the plasma-aided finishing with two input factors – *SFE* of the porous solid and *SFT* of the liquid. The time of aging is set depending on the *APPA* and impregnation used technology.

In general, a processing efficiency parameter named *PSP* was found: "*Plasma, surfactant or plasma and surfactant enhanced finishing of capillary impregnation will be more successful and the material will be more susceptible when the PSP is positive: PS* > 0".

This process efficiency parameter was defined by the difference between the *SFE* of the porous wood and the *SFT* of the impregnation *FR*- solution: $PS = \sigma_S - \gamma_L$. This efficiency parameter is equal to the value that gets the *IFE* when the water solution wets the surface completely: $PS = \sigma_{SL}$, $\theta = 0°$ ($\cos\theta = 1$).

The efficiency of a plasma-aided impregnation finishing can be predicted only by setting both basic parameters of the real porous wood surface and the actual *FR*-impregnating solution – the *SFE* and the *SFT*. Successful plasma aided or enhanced finishing, including the capillary impregnation, can be expected if the process efficiency parameter takes a positive value, *PSP* > 0, after a prescribed aging time – 2 or 24 hours.

The evolution of plasma-enhanced wicking phenomena in time after *APPA* – the short and long-time aging of plasma activated surface, after 2 and 24 hours, was investigated for four species of wood by the *PS*-efficiency parameter change. All species of wood were ranked according to the plasma aided capillary impregnation process efficiency as per its *PSP*.

The existing methods and instruments for measuring the *SFE* of solids and *SFT* of liquids, including portable measurement systems, [20], allow this approach to determine the process efficiency of the plasma-enhanced finishing such as impregnation, printing, painting, laminating to be recommended for application "in-line" and "out-of-the-line".

Modifiability

ABSTRACT

Model driven development is an important role in software engineering. It consists of multiple transformation functions. This development is a paradigm for writing and implementing computer program quickly, effectively, at minimum cost and reducing development efforts because it transforms design model to object-oriented code. Our approach is rule-based model driven development in which textual Umple model is used as primary artifact and transformed to mobile applications. In this model driven development, evaluation of quality of transformation is critical. This paper has presented a set of metrics to assess the quality attribute of modifiability and evaluated using these object-oriented metrics. Results represent our approach achieves high efficiency in quality of modifiability.

1. Introduction

Changing with technology, mobile devices and mobile applications are necessary thing for every person and every sector. The burst on the availability of mobile devices is powering a growing mobile application. According to this fact, mobile applications, which are used in these devices, are critical in an industrial development. To fulfill the demand of these things, mobile application development preferably uses model-driven engineering than traditional software development process widely and effectively. It focuses on model for the development of software. There is lower the overall cost of building large internal applications, there is lower the risk of large application, speed time to build large applications and expand the pool of resources that can work on large application are main strategic objectives to use model driven development. Reduction of both direct and indirect development efforts, which enables scripters to contribute to enterprise development and enables task-oriented management of development are benefit of model driven development. It is a superset of model driven development because it goes beyond the traditional development.

In this case, the rule based model driven development of mobile application using Drool Knowledge-based Rule was presented in [1]. They also measured assessment of transformability using object oriented metrics. Drools Knowledge-based is a business rule management system with a forward and backward chaining inference based rules engines [2].

Moreover, this model-driven development is a development paradigm that uses model as the primary artifacts of the development process. It transforms source model to target model/code according to changing requirement and software reused more rapidly than traditional software development. A model transformation consists of multiple transformation functions. These transformation functions transform target language elements from the source language. Most of researchers concentrate on model to model transformation using intermediate meta-model or model to code transformation [3-6]. There is no quality, there is no efficiency in everything. Quality issue also change scale and become more important. The process transforms to new model or code related to quality of final software product and the quality of the model used to generate it. The consistency of source and target model and the assessment of quality of transformation is the critical issue in model transformation domains.

There are many attributes to evaluate quality in software engineering. Among them, most of these quality attributes can be applied to software artifacts in general. However, in [7] authors describe two quality criteria important in model transformation. They are transformability and modifiability. According to their

[*]Corresponding Author: Nwe Nwe, Email: nwenwemdy08@gmail.com

work, it is necessary to extend the assessment to other quality attribute of modifiability, maintainability and reusability using object-oriented metrics. Modifiability is the extent to which a model transformation can be adapted to provide different or additional functionality. The main reason for modifying a model transformation is changing requirements. Another reason is that the (domain specific) language in which the source and/ or target model are described which may be subject to changes. Modifiability captures the amount of effort needed to modify a model transformation. It is the combination of the modularity and reusability, an essential aspect of software engineering that promotes software maintainability. Moreover, it enables transform without affecting other parts of a program that are not directly connected to the changes. This paper is organized as follows: Section II explains the basic concepts of related work. Section III presents the contribution of rule based model transformation and quality attributes of modifiability. Section IV describes our experimental results and comparison results. Finally, section V concludes our approach and evaluation of modifiability using object oriented metrics.

2. Related work

There is increasing attention towards the generation of source code from modeling languages. Several researchers propose model driven approach for the different aspects of mobile applications. The model driven development of mobile applications using Drools knowledge-based Rule was describes in [1]. They developed mobile application by applying Drool rule based. Their work is closely related with JUSE4 android application [8,9]. Moreover, they attempted to address the consistency of source and target model and the assessment of transformability by measuring the accuracy of consistency between source and target model and assessing the transformability using object oriented metrics. According to their work, it is necessary to extend the assessment to other quality attributes of model driven development using object-oriented metrics. Authors performed a comparative study on C++, C# and Java programs using object-oriented metrics in [10]. It consists of class size, complexity, coupling cohersion, inheritance, encapsulation, polymorphism and reusability.

An evaluation of the quality of model transformation was defined in [11]. They made the quality of model transformation measurable. They presented the quality attributes and a set of metrics to assess these quality attributes. A calculation of metrics values using the same set of standard metrics for three software system of different sizes was described in [12].

In [5], authors presented quality goal in MDE and states that the quality of models is affected by the quality of modeling languages, tools, modeling processes, the knowledge and experience of modelers and the quality assurance techniques applied. In [3, 4], authors defined the meta-model and model transformation rule for model driven android application development. In [13], authors also defined ATLAS transformation rules for UML sequence diagram to generate enterprise java bean code (EJB). In [6], authors presented enhance code generation tool for android source code based on UML class and sequence diagram. In [14], authors specified meta-model with Ecore and transformation rules with Xpand templates for entity relationship diagram to generate android SQLite database model.

In model driven transformation, the approaches are quite different in their respective use of input model. Most of these approaches are based on graphical modeling or textual modeling languages. In contrast to our approach, the previous approaches applied pre-defined meta-modeling while our approach automatically parses and extracts syntax form input model of Umple [15]. Moreover, our approach has specified transformation rules in object pattern matching approach. JUSE4Android is also based on textual modeling languages. Unlike our approach, it is adding annotation into JUSE model and transform into android source according to the predefined meaning of annotation. Therefore, they generated source code contains some more files in their project. The authors [16, 17] have proposed the approach for empirical evaluation of model driven engineering in multiple dimensions. Their case studies include qualitative (expert judgements) and quantitative data (metrics) evaluations. They suppose that the productivity and defect detection rate are the popular metrics for measuring automation degree of MDD processes. Some quality goals such as well-establishment and precision are especially important in MDE [18 -20]. In [21], authors also developed open source tool aims to address quality measurement and prediction process to achieve automatically. In [22], authors presented the most recent challenges faced in the process to make model transformation more sophisticated. According to the literature, it is necessary to extend the assessment to other quality attribute of modifiability using object-oriented metrics. We conducted the comparative study for measuring the modifiability of MDD generated source code using object-oriented metrics. Therefore, we obtain more reliable findings.

3. Rule based model transformation framework

Model transformations become essential with the evolution of model driven development. It is a mechanism of automating the manipulation of models. A transformation is the automatic generation of a target model from source model using transformation definition. These transformations definition is a set of transformation rules that define how a model in the source language can transform into target language. These rules are descriptions of how one or more constructs in the source language can be transformed into one or more constructs in the target language.

In this section, we provide an overview of the framework and their underlying architecture. The proposed architecture is divided into three major parts corresponding to the main capabilities of the proposed framework. These components are parser, transformer and code generator. The parser receives an input model, written in Umple language, tokenizes it and passes it to the next component transformer. The transformer is a knowledge

based rule engines. It has received the tokens previously obtained and transforms them into internal representation consistent with target source code model using predefined set of Drools mapping rules. It is more correctly classified as a production rule system. It is a kind of Rule engine and also an Expert system, the validation and expression evaluation Rule Engines. It is declarative programming and allows to present what to do. The key advantage of rule engine is that using rules can make it easy to express solution to difficult problems and consequently have those solutions verified. The code generator translates the internal representation into target artifacts: source code as Java, XML and android activity class. Each component is tested independently to ensure that the input is processed correctly and the resulted output is validated [1]. Figure 1 describes the overall architecture of the proposed system. We have used Umple as input and transformed to mobile application. In this case of model transformation, we have applied Drool Rule based transformation.

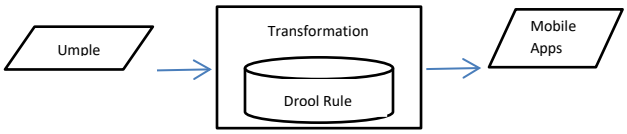

Figure 1 Overall Architecture of model transformation

3.1. Rule-based Inference System

In this system, we present a rule-based model driven approach to generate android application from text-based modeling language. Rule languages and inference engines incorporate reasoning capabilities are used in mobile application development system. A rule is made up of a collection of conditions associated with a sequence of actions to be applied to each collection of facts matching the rule condition. The proposed model transformation rules are based on Drools rule inference engine [2]. It is improved to reach the generation of mobile applications source code and introducing new concern in model driven mobile engineering. The core of the Drool suites and advanced Inference Engine using are improved Rete algorithm for object pattern matching. Rules are stored in the production memory, while facts are maintained in the working memory. The production memory remains the same during an analysis session, i. e, rules cannot be added or removed or changed. The contents of the working memory on the other hand can change. Facts may be modified, removed or added by executing rules or from external sources. After changing in the working memory, the inference engine is triggered and it works out which rules become "true" for the given facts. If there are multiple selected rules, their execution order will be managed via the Agenda, using a conflict resolution strategy.

3.2. Drools Transformation Rule

Drools rules are defined using Java-like language. It is a Business Logic integration Platform (BLiP). With the runtime, we create a working memory. The syntax of rule is shown as follows:

Rule
Rule <Rule Name>
When <Condition>
then <Action>

Rule: A rule is nothing but the logic that will be applied to incoming data. It has two main parts; when and then.

When: works out the condition on which Rule will be fired.

Then: the action; if the rules met the condition, they define what work this rule performs.

Step 1: Create a.drl (droolRule.drl)file where we will define the rules.

Step 2: Create Person POJO class.

The proposed rule engine consists three parts: umple2model, umple2view and umple2controller according to android model, view and controller perspective. Table 1 shows the sample form of Drools transformation rule for simple variable declaration for Account Title. Umple2Model.drl transforms incoming abstract syntax model (ASM) into plain java object (POJO). Umple2View.drl transforms ASM into android user interface XML file and Umple2Controller.drl transforms ASM into android activity class. The code generator receives the POJO model for model layer, XML model for view layer and android model for controller layer. The generator use the java development tool (JDT-core) to generate POJO class and android class source code. It is also used the JDOM to generate XML user interface file.

Table 1: Transformation Rule Sample

```
Umple          String AccountTitle;

Rule "VariableDeclaration"
Dialect "java"
when
$st : SyntaxTree(status==SyntaxTree.VAR_DECLARE)
then
TypeDeclaration type=AST2Android.Variable_Decl($st.getType());
CompilationUnit cu=$st.getCu();
$st.setStatus(SyntaxTree.ACTIVITY_CREATE);
$st.setType(type);
$st.setCu(cu);
update($st);
end
```

```
POJO (Model Layer) String AccountTitle;
PublicvoidsetAccountTitle(String at){
accountTitle=at;}
public String getAccountTitle(){
return accountTitle;}
}

XML (View Layer)
<EditText android:id=
"@+id/ txtaccountTitle"
android:layout_height=
"wrap_content"
android:layout_width=
"wrap_content"/>

Android (Controller Layer)
private EditText txtaccountTitle;
private String accountTitle;
txtaccount-
Title=(EditText)findViewById(R.id.accountTitle);
```

4. Experimental results and comparison

In model driven development, there are two important criteria to evaluate the quality of model transformation. They are transformability and modifiability. The consistency of source and target model and the assessment of transformability are evaluated in [1]. According to these results, we extend to evaluate the assessment of quality of modifiability in this model driven transformation.

4.1. Modifiability

Changes made for the requirements are rendered quality of the code in the models the code. This fact becomes challenges in quality of model driven development [quality]. To address these issues, this paper has proposed the evaluation of modifiability of model driven transformation using object oriented metrics. This modifiability is decomposed into traceability of model elements and well-designated or not being too complex. Moreover, the extent to which a model transformation can be adapted to provide different or additional functionality. The main reason for modifying a model transformation is changing requirements. Another reason is that the (domain specific) language in which the source and/ or target model is described which may be subject to changes. Modifiability captures the amount of effort need to modify a model transformation. It controls the visibility of system development. Such controls contribute to modularity, an essential aspect of software engineering that promotes software maintainability. In object-oriented programming, we note that these classes form the modules of programs. From the modularity perspective, modules should be as independent as possible with minimal coupling.

We have also performed a comparative study using both our proposed system and JUSE4 Android [8, 9] based on object oriented metrics. These metrics indicate quality of source code directly. We evaluate the quality of model driven for model transformation of generated source code quality and prior approach's generated source code quality. The results are used to evaluate a model is complete or suitable for automation or a modeling technique is appropriate for a target transformation. Therefore we have identified metrics to examine in this process.

4.2. Metrics

We describe the metrics for assessing the quality attributes for model transformation. Those metrics are applicable to language definition and characteristics of languages. For modifiability, we determine encapsulation, polymorphism and reusability as the quality criteria. These are described in table 2.

Table 2: Object oriented quality criteria

Quality of Criteria for Comparative Study				
No	Quality Criteria	Metrics	Acronyms	Desired Results
1	Encapsulation	Methods of hiding factor	MHF	High
		Attribute hiding factor	AHF	High
2	Polymorphism	Number of method overridden by a subclass	NMO	High
		Polymorphism factor	PF	High
3	Reusability	Reuse ratio	RP	High
		Specialization ratio	SR	High

A. Data Collection

To evaluate the modifiability of transformation, we have collected the metric values by using Eclipse metrics Plug-in [23]. It is an open source metrics calculation tools which measures various metrics and detects cycle in package and type dependencies. At first, we have generated the android application from different approaches of proposed and prior approach respectively. In the next step, we enable Eclipse Metrics Plug-in on each generate source code that give common solution. Finally, we extracted the mean, standard deviation and maximum metric values for each generate source code. In our comparative study, we have collected the average metric values from the proposed

and prior generated source code with respect to the quality criteria. Table 3 shows extracted metric values.

4.3. Encapsulation

It is the bringing together of a set of fields and methods into an object definition and hiding their internal working from the users of the object. By encapsulation, the way an object or its fields and methods are structured which is not visible to the users of the object. It is also facilitated by bundling and information hiding. It enhances the software maintainability. Encapsulation increases the cohesiveness of data and methods through bundling and reduces the strength of coupling between software components through information hiding. For encapsulation, we have measured method hiding factor (MHF) and attribute hiding factors (AHF) using the following equation 1 and 2. MHF and AHF are indicators to show how well methods and attributes are hidden inside classes. The results are presented in table 3. The comparisons of MHF values and AHF values of proposed system and prior systems are shown in the following figure 2 and 3 respectively. These metrics are measured at system level and high metric values are expected. The results are compared with prior approach and our proposed approach. This result means that we achieve the higher method hiding factor and attribute hiding factors.

Let V (M)= number of classes where the method M is visible, then

$$MHF= 1-\frac{\sum V(M)/(Total\ numbers\ of\ classes-1)}{Number\ of\ methods\ in\ all\ classes} \quad (1)$$

Let V (A) = number of classes where the attribute A is visible, then

$$AHF= 1-\frac{\sum V(A)/(Total\ numbers\ of\ classes-1)}{Number\ of\ attributrd\ in\ all\ classes} \quad (2)$$

By using the equation 1, we have calculated the MHF value. The result described that the ratio of number of classes where the visible method M is higher, the MHF value is lower.

By using the equation 2, we have calculated the AHF value. The result described that the ratio of number of classes where the visible attribute A is higher, the AHF value is lower.

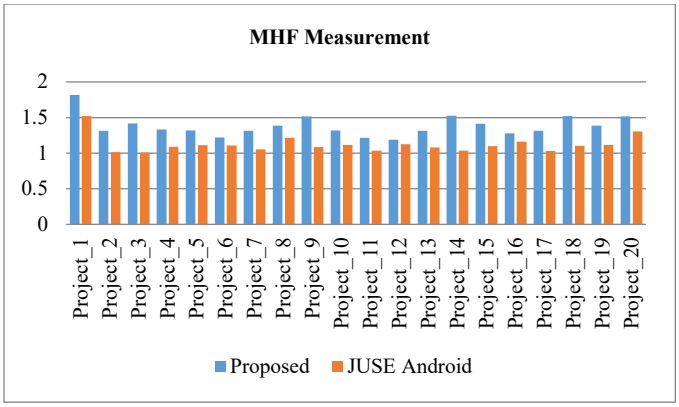

Figure 2 Comparison results of method of hiding factors

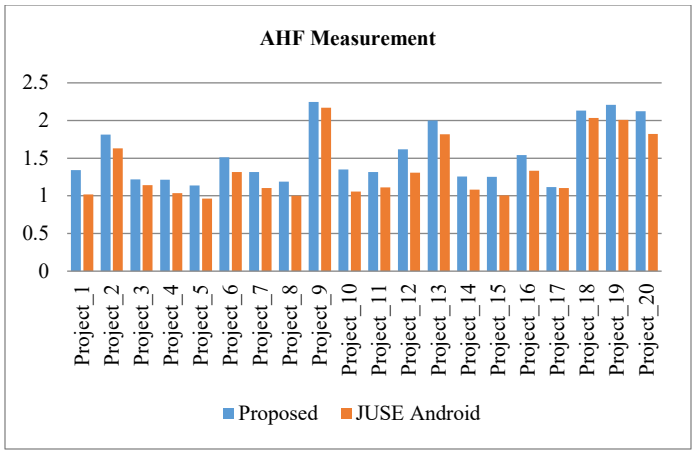

Figure 3 Comparison results of attribute hiding factors

4.4. Polymorphism

It is the ability of objects to respond to the same message but with the appropriate method based on their class definitions. For polymorphism, we have measured the number of method overridden by a sub class (NMO) and polymorphism factors (PF). Results are described in figure 4 and 5 respectively.

For NMO, we have determined the number of methods in a subclass overridden from its base class by using equation 3. Moreover, we determine the PF by using following equation 4. By using this equation 4, we present the PF value in table 3. To be specific, NMO is a class-level metric, which refers to the number of methods overridden by a single subclass, while PF is a system level metric, which measures the degree of method overriding in the whole type tree. These values are desired to be high. The results are compared with prior approach and our proposed approach. This result means that we achieve the higher number of methods overridden by a subclass and polymorphism factor.

NMO= the number of methods in a subclass overridden from its base class (3)

$$PF= \frac{\sum_{i=0}^{TC} M0(Ci)}{\sum_{i=0}^{TC}[(Mn\ Ci)x\ DC\ (Ci)]} \quad (4)$$

Where TC = the total number of classes

M_n (C_i)= Number of new methods of the class C_i

M_o (C_i)= Number of overriding methods of the class C_i

DC(C_i)= Number of Descendant of the class C_i

We have calculated the NMO value by using the number of methods in a subclass overridden from its base class and applying equation 3. They are presented in table 3.

We have calculated the PF value by using equation 4 and the results are described in table 3. The results present that number of overriding methods of the class is higher, the PF value is higher.

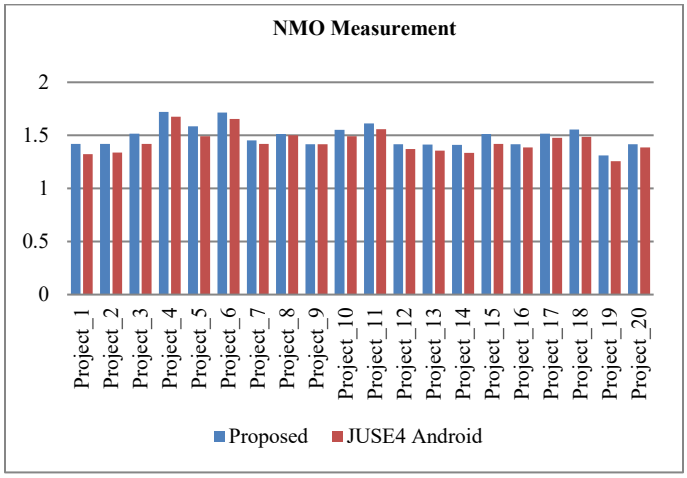

Figure 4 Comparison results of number of methods overridden by a sub class

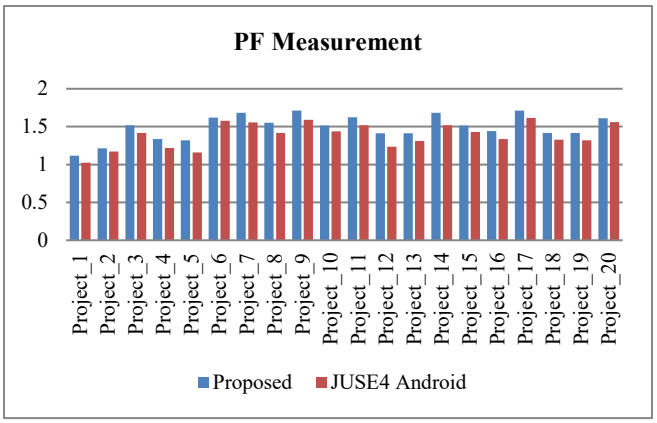

Figure 5 Comparison results of polymorphism factors

4.5. Reusability

Reusability is the extent to which a model transformation can be reused by other model transformations. It refers to as-is reuse. It is especially relevant for model transformations when a source model has to be transformed into different target models or vice versa. For reusability, we have measured reuse ratio (RR) and specialization ratio (SR) and results are presented in figure 6 and 7.

We have determined the RR and SR by using the following equation 5 and 6. RR and SR are both system level reusability metrics. They are calculated as the ratios of subclass to all classes and to super classes, respectively. The results are presented in table 3. We have expected to be highly reused, large reusability metrics values are desirable.

$$RR = \frac{(Total\ number\ of\ Super\ classes)}{(Total\ number\ of\ classes)} \quad (5)$$

$$SR = \frac{(Total\ number\ of\ Sub\ classes)}{(Total\ number\ of\ super\ classes)} \quad (6)$$

We have calculated the RR and SR values by applying equations 5 and 6 respectively. There are more subclasses, the higher the RR and SR values.

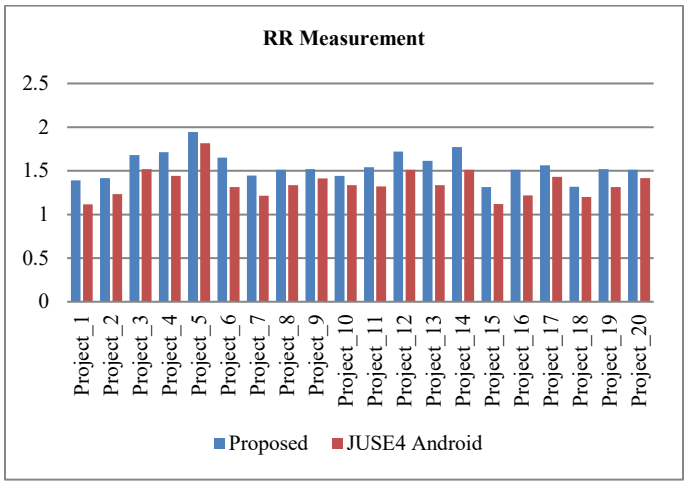

Figure 6 Comparison results of reuse ratios

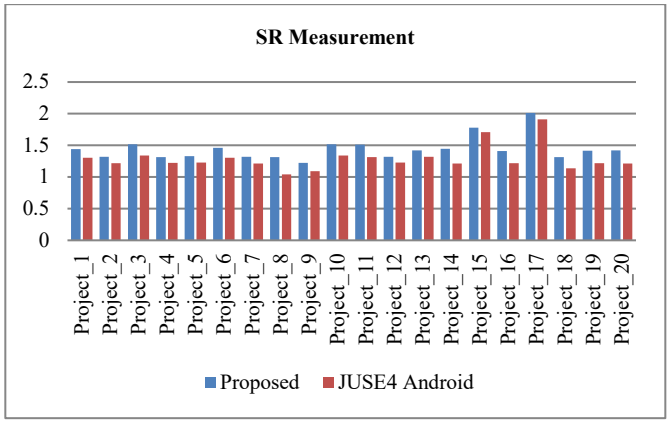

Figure 7 Comparison results of specialization ratios

5. Results and discussion

We have presented comparison results of our measurement. Expected results for our evaluation are shown in table 2. The larger a model transformation, the harder it is to understand and modify. Moreover, the number of signature and equations per function has a negative effect on consistency. If more similar signatures or equations have to be written, it is more likely that a different style is used.

The comparison results of our measurements are described in table 3. We have employed the result from MHF and AHF metrics for encapsulation, NMO and PF metrics for polymorphism and RR and SR for reusability to compare our approach and prior approach.

We have used private, protected and public keywords to control the accessibility to the method and attributes inside a class. According to these facts, we have planned quality attributes of our system to achieve higher modifiability.

By applying the experimental results, our approach has higher value than prior approach in encapsulation, polymorphism and reusability. Moreover, our expected result is that the high metric values are preferable.

These experimental results show how well methods and attributes are hidden inside classes. Therefore, our approach can help system develop methods and attributes which are hidden inside classes more efficiently. This means that our approach is more efficient than others. However, these results describes that they are a little bit higher than prior approach. By using these results, we will enhance our approach to achieve more efficiently and effectively model driven development process.

6. Conclusion

Model transformations become essential with the evolution of model driven development. It is an automatic generation of a target model from source model by using transformation definition. Modifiability is key issues in quality of this transformation. To address this issue, we have evaluated the modifiability of quality of model transformation using object oriented metric. This modifiability is decomposed into traceability of model elements and well-designated or not being too complex. Moreover, the extent to which a model transformation can be adapted to provide different or additional functionality. The main reason for modifiability of a model transformation is changing requirements. In this paper, we have performed the comparative study on our approach and prior approach to determine modifiability to develop more efficient mobile application system. We have determined the encapsulation, polymorphism and reusability as quality metrics. These metrics are measured at system level. We have used private, protected and public keywords to control the accessibility to the method and attributes inside a class. According to these facts, we have planned quality attributes of our system to achieve higher modifiability. The determination of experimental results represent that we achieve high score from comparison of our approach and prior approach. This means that our system is more traceability and

well-designated. Using these findings, we will enhance our approach to achieve higher efficiency and quality. In the future work, we will investigate more quality attribute for high accuracy of system development. Moreover, we will also evaluate the impact of transformation rules.

ABSTRACT

Constant Envelope Discrete Cosine Transform based Orthogonal Frequency Division Multiplexing (CE-DCT-OFDM) system with M-ary Pulse Amplitude Modulation (PAM) mapper is considered. In the system phase modulation is used to achieve constant envelope signals that have 0 dB Peak-to-Average-Power Ratio (PAPR). Transmission of such signals permit high power amplifiers in the system to operate with maximum power efficiency. The performance of CE-DCT-OFDM system is examined over Additive White Gaussian Noise (AWGN) and over fading channels. Closed-form expressions for Bit Error Rate (BER) over Ricean and Rayleigh channels are derived. The performances of CE-DCT-OFDM and conventional DCT-OFDM systems are compared as a function of Input power Back-Off (IBO) and Signal-to-Noise Ratio (SNR) for the Traveling-Wave Tube Amplifier (TWTA) model. Results show that CE-DCT-OFDM system offers superior BER performance compared to DCT-OFDM system and has other advantages as well.

1 Introduction

Fast Fourier Transform based Orthogonal frequency division multiplexing (FFT-OFDM) is widely adapted in a variety of communication standards due to its attractive properties such as high spectral efficiency and low complexity of the receiver, particularly, over multipath fading channels [2]. In an FFT-OFDM system, complex orthogonal exponential functions are used as basis functions. Instead, orthogonal cosinusoidal functions can be utilized as basis to create multicarrier system. Such a system utilizes Discrete Cosine Transform (DCT) [3] and is referred to as DCT-OFDM system. Several researchers have been investigating the use of DCT in OFDM system [4,5,6], as it has several advantages over conventional FFT-OFDM system. They are:

1. DCT is well known to have excellent spectral compaction and energy concentration properties. As a result, the channel estimation and also the system performance can be improved in noisy environments [7].
2. DCT is widely adopted in image/video coding standards (e.g. JPEG). Using IDCT for modulation and DCT for demodulation in an OFDM system, results in better integrated system design and reduced overall implementation cost are possible [8].
3. DCT uses real arithmetic compared to complex arithmetic in the case of FFT. This reduces signal processing complexity and power consumption, especially, when M-ary Pulse Amplitude Modulation (MPAM) mapper is used in DCT-OFDM system [7].
4. In the presence of frequency offset, due to the energy-compaction property of DCT, the inter-carrier interference (ICI) coefficients in DCT-OFDM system are concentrated around the main coefficient. As a result, DCT-OFDM system is robust to Carrier frequency offset (CFO) [7].
5. When MPAM mapper is used in DCT-OFDM system, it requires half of bandwidth required by an FFT-OFDM system, with the same number of subcarriers [9].

One of the major drawbacks of an OFDM system is

https://dx.doi.org/10.25046/aj030131

the high PAPR of transmitted signals in an FFT-OFDM system. When high PAPR signals are amplified using non-linear power amplifier, severe signal distortion will occur. Therefore, power amplifier with suitable power backoff is required in the system. Without appropriate power backoff, the system suffers from spectral broadening, intermodulation distortion, and, consequently, performance degradation. The problem can be mitigated by increasing the power backoff, but this results in poor power efficiency. In mobile devices with limited battery supply power efficiency is required to be as high as possible [10]. Several techniques have been suggested to mitigate the problem of high PAPR in an OFDM system such as coding, partial transmission sequences, clipping, tone reservation, and filtering [11,12,13]. These techniques offer a variety of trade-offs in terms of complexity, performance and spectral efficiency.

An alternative approach to completely eliminate the PAPR problem in an OFDM system is based on signal transformation. In this technique, signal transformation occurs at the transmitter prior to modulation and an inverse transformation at the receiver prior to demodulation. In [14,15,16,17] phase modulation and demodulation are considered in OFDM systems. Such systems are characterized by constant envelope signal with 0 dB PAPR, and hence suitable for power amplification close to the saturation level of nonlinear power amplifier. While FFT-OFDM systems with phase modulation have been extensively studied in the literature, DCT-OFDM system with phase modulation has not received much attention. In this paper, therefore, DCT-OFDM system with phase modulation referred to as CE-DCT-OFDM is presented and examined. The intent of this paper is to present a generalized model of CE-DCT-OFDM system that can be used to examine its performance. The BER analysis of CE-DCT-OFDM system in AWGN channel is presented and then the analysis is extended to the case of fading channel, as over practical communication channels signal fading is always present.

This paper is organized as follows. Section II describes the generation of DCT-OFDM signal. Section III introduces phase modulation in DCT-OFDM system. CE-DCT-OFDM system with MPAM mapper is described in Section IV, and its performance is analysed in AWGN channel. Section V deals with performance analysis of CE-DCT-OFDM system over fading channels. Finally, the paper is concluded in Section VI.

2 Baseband DCT-OFDM Signal

The process of generating DCT-OFDM signal is shown in Figure 1. The signal can be represented by

$$f(t) = \sum_{n=0}^{N-1} C_n \, \varphi_n(t), 0 \le t < T, \tag{1}$$

$$\varphi_n(t) = \begin{cases} \sqrt{\frac{2}{T}} cos 2\pi f_n t, & 0 \le t < T, \\ 0, & otherwise \end{cases} \tag{2}$$

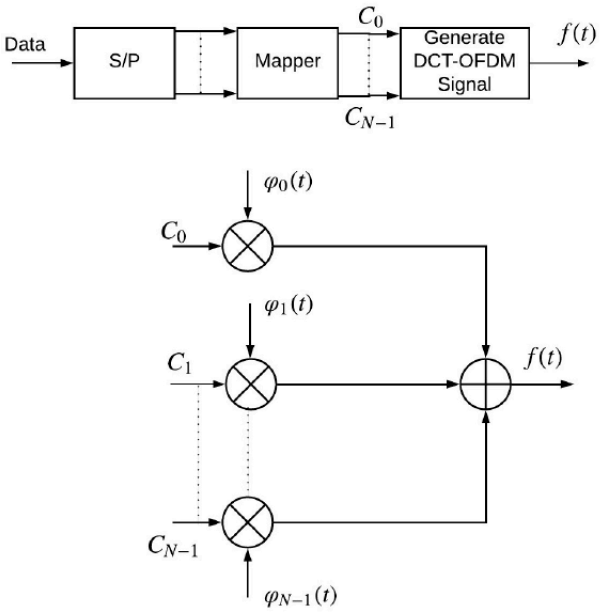

Figure 1: Block diagram of DCT-OFDM signal generator

The cosinusoidal function $\varphi_n(t)$ is the n^{th} orthogonal signal with frequency $f_n = n/2T$ and repersents the n^{th} subcarrier. The subcarrier spacing is $1/2T$. The subcarriers are orthonormal over $0 \le t \le T = NT_s$. That is,

$$\int_0^T \varphi_n(t)\varphi_k(t)dt \tag{3}$$

$$= \int_0^T \sqrt{\frac{2}{T}} cos 2\pi f_n t * \sqrt{\frac{2}{T}} cos 2\pi f_k t \, dt \tag{4}$$

$$= \begin{cases} 1 & n = k \\ 0 & otherwise \end{cases} \tag{5}$$

The time duration of the OFDM symbol is $T = NT_s$; T_s is the time duration of DCT-OFDM symbol. It is noted that $T_s = kT_b$ and $M = 2^k$. T_b denotes the bit duration. $C_n (n = 0, 1, .., N-1)$ are N independent data symbols obtained from MPAM signal constellation. The DCT-OFDM signal can thus be represented by

$$f(t) = \sqrt{\frac{2}{T}} \sum_{n=0}^{N-1} C_n \cos \pi nt/T, 0 \le t < T, \tag{6}$$

3 DCT-OFDM Signal with Phase Modulation

The phase modulated bandpass signal can be represented by

$$s(t) = A_c cos(2\pi f_c t + \phi(t)) \tag{7}$$

Where A_c and f_c are the carrier amplitude and frequency. The phase in (7) is proportional to $f(t)$ and is given by

$$\phi(t) = h_p f(t) \tag{8}$$

where h_p is the modulation index.

In DCT-OFDM system, $f(t)$ is real for MPAM mapper [9]. The advantage of DCT-OFDM system with phase modulation is that the transmitted signals have peak and average powers the same and hence, their PAPR is 0 dB. Figure 2 shows a comparison of instantaneous powers of DCT-OFDM and CE-DCT-OFDM signals.

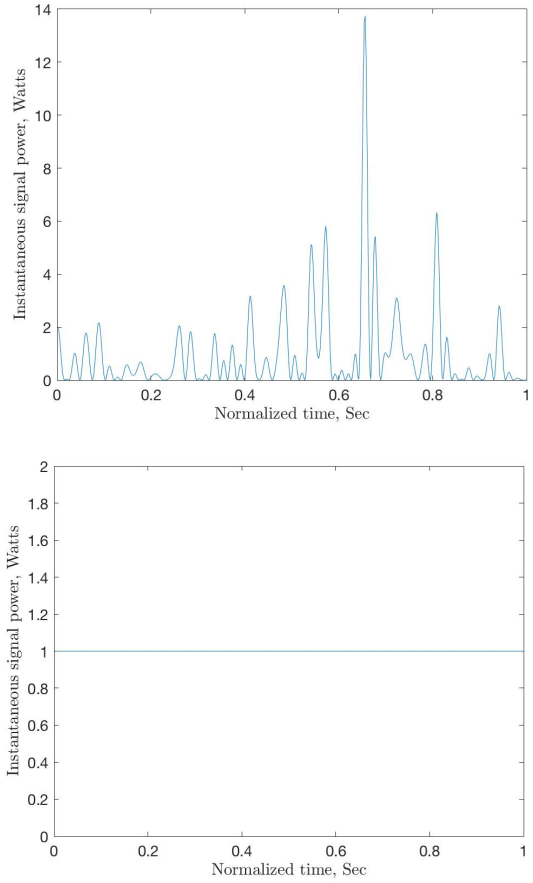

Figure 2: Instantaneous signal power: (a) DCT-OFDM signal and (b) CE-DCT-OFDM signal.

4 CE-DCT-OFDM Transmitter

The block diagram of CE-DCT-OFDM transmitter is shown in Figure 3. The output of the system can be written as:

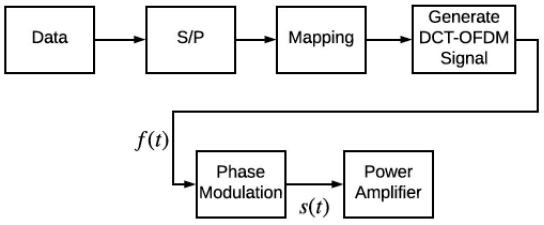

Figure 3: Block diagram of CE-DCT-OFDM transmitter

$$s(t) = A_c cos\left(2\pi f_c t + \sqrt{\frac{2}{T\sigma_s^2}} h_p \sum_{n=0}^{N-1} C_n cos(\pi nt/T)\right) \quad (9)$$

where $0 \le t \le T$, A_c is the signal amplitude and f_c is the carrier frequency. $\sigma_s^2 = (M^2-1)/3$ is the variance of the data symbols [16]. $\{C_n\}$ are MPAM data symbols, $C_n \in \{\pm 1, \pm 3, \cdots, \pm(M-1)\}$ for all n. The message signal is given by: $f(t) = \sqrt{2/T\sigma_s^2} \sum_{n=0}^{N-1} C_n cos(\pi nt/T)$. The average power of $s(t)$ is $P_s \left(= \int_0^T s(t)^2 dt/T = A_c^2/2\right)$ and the signal energy is $E_s = P_s T = A_c^2 T/2$. For k bits of information per symbol per transmission, the average bit energy is $E_b = A_c^2 T/2N \log_2 M = A_c^2 T/2Nk$.

4.1 Bandwidth Considerations

Phase modulated signals are complex to analyze for their bandwidth. However, simple observations can be used to get rough idea about the bandwidth of CE-DCT-OFDM signals. Using Maclaurin series, the PM signal described in equation (7) can be written as

$$s(t) = A_c(cos2\pi f_c t - h_p f(t) sin2\pi f_c t - \frac{h_p^2}{2!} f^2(t) cos2\pi f_c t + \cdots) \quad (10)$$

When h_p is small, the first two terms in the series are sufficient to represent CE-DCT-OFDM signal. That is,

$$s(t) \approx A_c cos2\pi f_c t - A_c h_p f(t) sin2\pi f_c t \quad (11)$$

This represents the narrowband case and the bandwidth of the signal is at least $2W$, where W is the bandwidth of $f(t)$. As h_p becomes larger, the bandwidth of the signal broadens. A useful expression for bandwidth of the signal is given by the root-mean-square (RMS) bandwidth [18] which is equal to $max(2h_p, 2)WHz$. The bandwidth of the message signal $f(t)$ is $W = (N/2T)Hz$

4.2 BER Analysis over AWGN Channel

The CE-DCT-OFDM receiver consists of a phase demodulator followed by the standard DCT-OFDM demodulator to recover the transmitted data symbols as shown in Figure 4. Each block will be analyzed below.

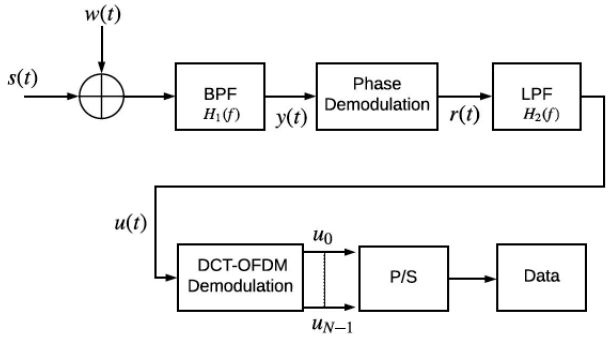

Figure 4: Block diagram of CE-DCT-OFDM receiver

4.2.1 Phase Demodulation

The noise $w(t)$ is modelled as additive white Gaussian with zero mean and power spectral density $N_0/2$. The received signal $s(t)+w(t)$ is fed to a BPF with transfer function $H_1(f)$ shown in Figure 5. The filter has a center frequency f_c and bandwidth B. It is noted that only a negligible amount of input signal power lies outside the frequency band $f_c - B/2 \leq |f| \leq f_c + B/2$. The bandwidth B is in excess of twice the message bandwidth W by an amount that depends on the deviation ratio of the signal $s(t)$. Thus, it is noted that the BPF allows the CE-DCT-OFDM signal without any distortion. The filtered narrow band noise $n(t)$ can be represented as

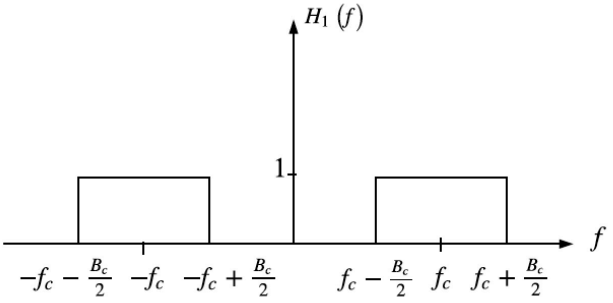

Figure 5: Ideal bandpass filter characteristic

$$n(t) = n_I(t)cos2\pi f_c t - n_Q(t)sin2\pi f_c t \quad (12)$$

where $n_I(t)$ and $n_Q(t)$ are the in-phase and quadrature components of the zero-mean filtered Gaussian noise. $n(t)$ can also be represented as

$$n(t) = x(t)cos[2\pi f_c t + \Psi] \quad (13)$$

where

$$x(t) = \sqrt{[n_I(t)^2 + n_Q(t)^2]} \quad (14)$$

and

$$\Psi = tan^{-1}(n_Q(t)/n_i(t)) \quad (15)$$

The bandpass filter output $y(t)$ can be written as:

$$y(t) = A_c cos[2\pi f_c t + \phi(t)] + x(t)cos[2\pi f_c t + \Psi(t)] \quad (16)$$

Equation (16) in polar form is given by:

$$y(t) = v(t)cos[2\pi f_c t + \theta(t)] \quad (17)$$

where $v(t)$ represents the envelope and $\theta(t)$ is the phase angle which can be written as [18,19]

$$\theta(t) = \phi(t) + \varepsilon(t) \quad (18)$$

where

$$\varepsilon(t) = tan^{-1}\left\{\frac{x(t)sin[\Psi(t)+\phi(t)]}{A_c + x(t)cos[\Psi(t)+\phi(t)]}\right\} \quad (19)$$

is the noise signal. With the assumption of a high Carrier-to-Noise Ratio (CNR), $A_c >> x(t)$, equation (18) becomes

$$\theta(t) \approx \phi(t) + \frac{x(t)}{A_c} sin[\Psi(t) - \phi(t)] \quad (20)$$

The output of the phase demodulator is given by

$$r(t) = k_p \theta(t) \quad (21)$$

where k_p is the gain constant. With the large CNR assumption and choosing $k_p = 1/h_p$, equation (21) becomes.

$$r(t) = f(t) + n_d(t) \quad (22)$$

where

$$n_d(t) = \frac{k_p x(t)}{A_c} sin[\Psi(t) + \phi(t)] \quad (23)$$

The power spectral density $S_{Nd}(f)$ of $n_d(t)$ is related to the power spectral density $S_{NQ}(f)$ of $n_Q(t)$. That is [19,20],

$$S_{Nd}(f) = \left\{\frac{k_p}{A_c}\right\}^2 S_{NQ}(f) \quad (24)$$

where

$$S_{NQ}(f) = \begin{cases} N_0, & |f| \leq \frac{B}{2} \\ 0, & otherwise \end{cases} \quad (25)$$

The phase demodulator output is applied to a low pass filter of bandwidth equal to message bandwidth W. It is used to pass the message signal and reject out-of-band noise from $n_d(t)$. The ideal transfer function of the filter is

$$H_2(f) = \begin{cases} 1, & |f| \leq W \\ 0, & otherwise \end{cases} \quad (26)$$

The output of the low pass filter can be written as

$$u(t) = f(t) + n_u(t) \quad (27)$$

The power spectral density $S_{Nu}(f)$ of output noise $n_u(t)$ at the output of low pass filter is given by

$$S_{Nu}(f) = \begin{cases} N_0 k_p^2 / A_c^2, & |f| \leq W \\ 0, & otherwise \end{cases} \quad (28)$$

and the average output noise power is

$$\int_{-W}^{W} \frac{N_0 k_p^2}{A_c} df = \frac{2WN_0 k_p^2}{A_c^2} \quad (29)$$

4.2.2 DCT-OFDM Receiver

The DCT-OFDM receiver, as depicted in Figure 4, is composed of two stages: a demodulator and a detector. The demodulator projects the incoming signal using orthonormal bases and generates a vector whilst the detector applies detection algorithm to estimate the transmitted information symbols.

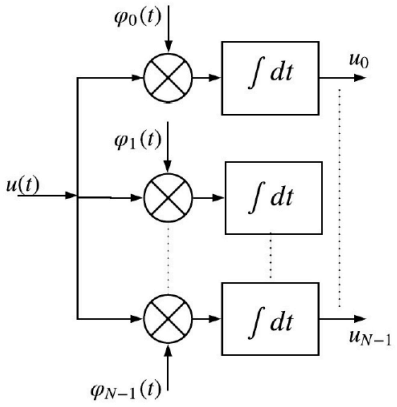

Figure 6: DCT-OFDM signal demodulation using correlators

The input to the bank of correlators (DCT-OFDM demodulator) in Figure 6 is the signal $u(t)$. The output of the demodulator is the vector $\bar{u}$. The j-th element of $\bar{u}$, can be expressed as:

$$u_j = \int_0^T u(t)\varphi_j(t)dt \tag{30}$$

$$= \int_0^T [f(t) + n_u(t)]\varphi_j(t)dt \tag{31}$$

$$= C_j/\sqrt{\sigma_s^2} + N_{uj}; j = 1, 2, .., N-1 \tag{32}$$

The mean of u_j is,

$$E[u_j] = E[C_j/\sqrt{\sigma_s^2} + N_{uj}] = E[C_j/\sqrt{\sigma_s^2}] = C_j/\sqrt{\sigma_s^2} \tag{33}$$

where $C_j \in \{\pm 1, \pm 3, ..., \pm(M-1)\}$. The mean is independent of the noise. However, the variance of u_j is dependent on noise and is given by:

$$Var[u_j] = \sigma_{uj}^2 \tag{34}$$

$$= E[(u_j - C_j)^2] \tag{35}$$

$$= E[(N_{uj})^2] \tag{36}$$

$$= E\left[\int_0^T n_u(t)\varphi_j(t)dt \int_0^T n_u(z)\varphi_j(z)dz\right] \tag{37}$$

$$= E\left[\int_0^T \int_0^T \varphi_j(t)\varphi_j(z) \cdot n_u(t)n_u(z)dtdz\right] \tag{38}$$

Taking the expectation operation inside the integrals, we can write

$$\sigma_{uj}^2 = \int_0^T \int_0^T \varphi_j(t)\varphi_j(z)E\left[n_u(t) \cdot n_u(z)\right]dtdz \tag{39}$$

$$= \int_0^T \int_0^T \varphi_j(t)\varphi_j(z)R_n(t,z)dtdz \tag{40}$$

where $R_{nu}(t,z)$ is the autocorrelation function of the noise process. The variance of u_j can be shown to be given by:

$$\sigma_j^2 = \frac{2WN_0k_p^2}{A_c^2}\int_0^T \varphi_j^2(t)dt \tag{41}$$

$$= \frac{2WN_0k_p^2}{A_c^2} \tag{42}$$

4.2.3 Probability of Bit Error

The symbol error rate (SER) can be shown to be given by [21]:

$$SER = \frac{M-1}{M}2P\left(N_{uj} > \frac{1}{\sqrt{\sigma_s^2}}\right) \tag{43}$$

$$= 2\frac{M-1}{M}\int_{1/\sqrt{\sigma_s^2}}^{\infty} \frac{1}{\sqrt{2\pi\left(2WN_0/A_c^2h_p^2\right)}} \tag{44}$$

$$e^{\left(-x^2/\left[2\left(2WN_0/A_c^2h_p^2\right)\right]\right)}dx$$

$$= 2\frac{M-1}{M}\int_{1/[2WN_0\sigma_s^2/A_c^2h_p^2]^{0.5}}^{\infty} \frac{1}{\sqrt{2\pi}}e^{-x^2/2}dx \tag{45}$$

$$= 2\left(\frac{M-1}{M}\right)Q\left(\sqrt{\frac{6h_p^2\log_2(M)E_b}{(M^2-1)N_0}}\right) \tag{46}$$

It is noted that for $h_p = 1$, (46) represents the SER for MPAM system [21]. For high CNR, the only significant symbol errors are those that occur at adjacent signal levels. The BER of CE-DCT-OFDM system, thus, can be approximated as [21]

$$BER \approx \frac{SER}{\log_2(M)}$$

$$\approx 2\left(\frac{M-1}{M\log_2(M)}\right)Q\left(\sqrt{\frac{6h_p^2\log_2(M)E_b}{(M^2-1)N_0}}\right) \tag{47}$$

The BER performance given by (47) is a function of E_b/N_0, signal-to-noise ratio, h_p, modulation index, and M, the number of amplitude levels in the MPAM mapper in the CE-DCT-OFDM system. The performance of CE-DCT-OFDM system with $h_p = 0.7$ for various values of M are illustrated in Figure 7, which shows that BER increases as M increases for fixed value of modulation index. For example at BER = 10^{-5} and $h_p = 0.7$, the SNR required for $M = 16$ is 14 dB more than that required for $M = 4$.

Figure 8 depicts BER performance of CE-DCT-OFDM system for 16-PAM mapper for $h_p = 0.3, 0.7$ and 1.2. It is observed that BER decreases as h_p increases for a fixed value of SNR. For example at BER = 10^{-5} the SNR required for $h_p = 0.3$ is 12 dB more than that required for $h_p = 1.2$. The BER performance of the system can be controlled by varying h and M as shown in Figure 9. For example, the system with $M = 16$ and $h_p = 1.7$ outperforms the system with $M = 4$ and $h_p = 0.2$ by nearly 9 dB at BER = 10^{-5}.

Figure 10 compares simulation results to theoretical BER given by (47) for CE-DCT-OFDM system using $N = 64$ subcarriers, and $M = 4$. For E_b/N_0 greater

than 15 dB, and for a small modulation index $h_p = 0.1$, simulation result is nearly the same as theoretical result. For large modulation index, for example $h_p = 0.8$, the theoretical BER is not as accurate as simulation result but still is within 1 dB of the former.

For the traveling-wave tube amplifier (TWTA) model, BER performance of CE-DCT-OFDM system is compared with that of DCT-OFDM system. The undesirable effects of TWTA nonlinearities can be reduced by increasing the input power backoff (IBO). For a given DCT-OFDM signal, we need to adjust the average input power so that the peaks of the signal are rarely clipped. That is, we will have to apply an IBO to the signal prior to amplification. Computer simulations are used to study the performance of the systems using nonlinear TWTA with various IBO levels. Figure 11 compares BER performance of 64 subcarrier 8-PAM CE-DCT-OFDM system and 8-PSK DCT-OFDM system with TWTA using IBO of 0 dB, 8 dB and 12 dB. At high SNR, CE-DCT-OFDM system provides significant performance improvement due primarily to the 0 dB backoff. The DCT-OFDM system with 0 dB IBO has an error floor at BER of 0.09. At the BER 10^{-3}, the IBO that results in the best DCT-OFDM system performance is 12 dB, with $E_b/N_0 = 16$ dB. However, the CE-DCT-OFDM system achieves this BER= 10^{-3} with $E_b/N_0 = 12$ dB which implies an advantage of 4 dB.

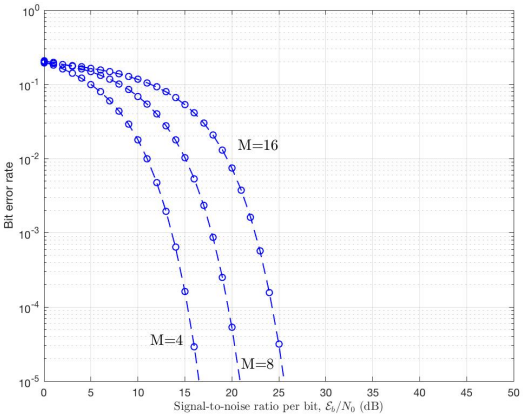

Figure 7: BER performance of CE-DCT-OFDM system over AWGN channel, as a function of M for $h_p = 0.7$

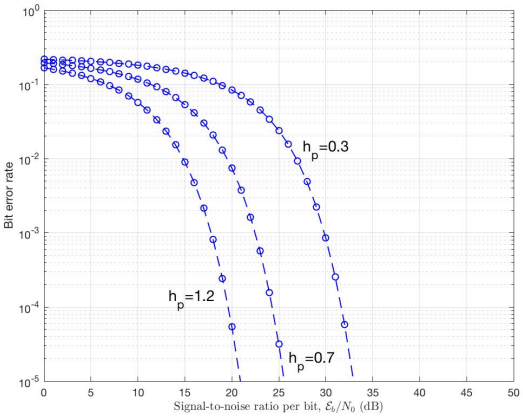

Figure 8: BER performance of CE-DCT-OFDM system over AWGN channel, as a function of h_p for $M = 16$.

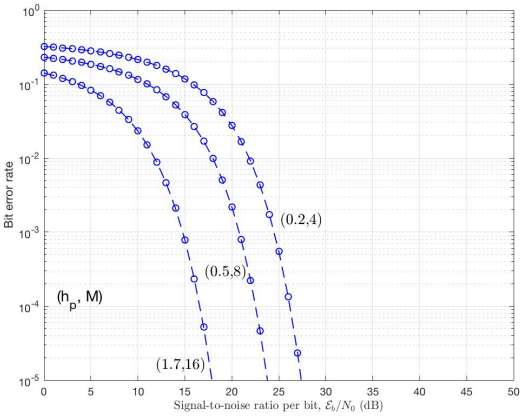

Figure 9: BER performance of CE-DCT-OFDM system over AWGN channel, as a function of (h_p, M).

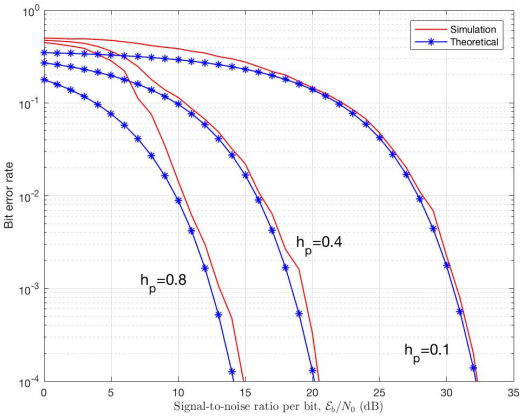

Figure 10: BER performance of 64 subcarrier CE-DCT-OFDM system with $M = 4$ over AWGN channel, as a function of h_p.

5 Performance over Fading Channels

The received CE-DCT-OFDM signal over a fading channel can be expressed as:

$$r(t) = h(t) * s(t) + n(t) \tag{48}$$

where $h(t)$ represents the impulse response of the fading channel given by $h(t) = \alpha\delta(t)$. The instantaneous

SNR per bit and the average SNR per bit can be represented as $\gamma = \alpha^2 E_b/N_0$ and $\bar{\gamma} = E\left\{\alpha^2\right\} E_b/N_0$, respectively. To obtain the bit error rate (P_b) of CE–DCT-OFDM system over such a fading channel, the conditional BER is averaged over the Probability Density Function (PDF) of γ and can be written as [22]:

$$P_b = \int_0^\infty P(\gamma) p_\gamma(\gamma) d\gamma \tag{49}$$

where $P_b(\gamma)$ is given by:

$$P_b(\gamma) = 2\left(\frac{M-1}{M\log_2(M)}\right) Q\left(\sqrt{D\gamma}\right) \tag{50}$$

where $D = \frac{6h_p^2 \log_2(M)}{M^2-1}$. It is noted that $Q(z)$ in (50) is the well-known Q-function and it can also be written as:

$$Q(z) = \frac{1}{\pi}\int_0^{\pi/2} exp\left(-\frac{z^2}{2sin^2(\theta)}\right) d\theta \tag{51}$$

5.1 Rayleigh Fading Channel

For Rayleigh fading channel, the PDF of γ is given by [22]:

$$p_\gamma(\gamma) = \frac{1}{\bar{\gamma}} exp\left(\frac{\gamma}{\bar{\gamma}}\right), \gamma \geq 0 \tag{52}$$

Using (50)-(52) in (49), the average BER over Rayleigh fading channel can be shown to be given by

$$P_b = 2\left(\frac{M-1}{M\log_2(M)}\right)\frac{1}{\pi\bar{\gamma}}\int_0^{\pi/2}\int_0^\infty exp\left(-\frac{D\gamma}{2sin^2(\theta)} - \frac{\gamma}{\bar{\gamma}}\right) d\gamma d\theta \tag{53}$$

Upon simplification (53) [23], we get:

$$P_b = \left(\frac{M-1}{M\log_2(M)}\right)\left[1 - \sqrt{\frac{D\bar{\gamma}/2}{1+D\bar{\gamma}/2}}\right] \tag{54}$$

The BER given by (54) for CE-DCT-OFDM system over Rayleigh fading channel is a function of h_p, modulation index, M, number of levels in MPAM, and E_b/N_0, signal-to-noise ratio. The BER of CE-DCT-OFDM system for $M = 4$ is plotted as a function of h_p, and E_b/N_0 as shown in Figure 12. It is observed that BER increases as h_p decreases for a fixed value of SNR. For example at BER = 10^{-5} the SNR required for $h_p = 0.7$ is 7 dB more than that required for $h_p = 1.5$.

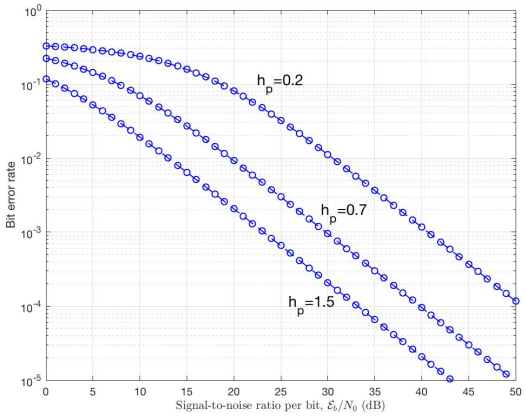

Figure 12: BER performance of CE-DCT-OFDM system over Rayleigh fading channel, as a function of h_p for $M = 4$.

5.2 Ricean Fading Channel

For the Ricean fading channel, the PDF of γ is given by [22]:

$$p_\gamma(\gamma) = \frac{(1+K)e^{-K}}{\bar{\gamma}} exp\left[-\frac{(1+K)\gamma}{\bar{\gamma}}\right] I_0\left[2\sqrt{\frac{(K+K^2)\gamma}{\bar{\gamma}}}\right], \gamma \geq 0 \tag{55}$$

Using (50), (51) and (55) in (49), P_b can be written as:

$$P_b = \frac{2}{\pi}\left(\frac{M-1}{M\log_2(M)}\right)\frac{(1+K)e^{-K}}{\bar{\gamma}}\int_0^{\pi/2}\int_0^\infty exp\left[-\frac{D\gamma}{2sin^2(\theta)} - \frac{(1+K)\gamma}{\bar{\gamma}}\right] I_0\left[2\sqrt{\frac{(K+K^2)\gamma}{\bar{\gamma}}}\right] d\gamma d\theta \tag{56}$$

Integrating (56) [23], BER of CE-DCT-OFDM system over Ricean fading channel can be written as:

$$P_b = \frac{2}{\pi}\left(\frac{M-1}{M\log_2(M)}\right)\int_0^{\pi/2}\frac{(1+K)sin^2(\theta)}{(1+K)sin^2(\theta)+D\bar{\gamma}/2} exp\left[-\frac{KD\bar{\gamma}/2}{(1+K)sin^2(\theta)+D\bar{\gamma}/2}\right] d\theta \tag{57}$$

The BER given by (57) is a function of h_p, M, K, Rice distribution parameter and E_b/N_0. The BER performance $K = 7$ dB and $M = 4$ is illustrated in Figure 13, are a function of h_p. It observed that there is improvement in BER as h_p increases, for example at BER = 10^{-5} the SNR required for $h_p = 1.5$ is 17 dB less than that required for $h_p = 0.2$.

The effect of parameter K on BER performance is illustrated in Figure 14, for $M = 4$ and $h_p = 0.5$. It is noted that the BER decreases as K increases, for example at BER = 10^{-5} and $h_p = 0.5$ the SNR required for $K = 2$ dB is 30 dB more than that required for $K = 18$ dB.

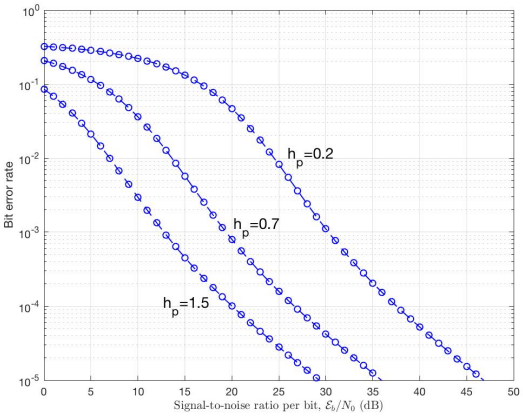

Figure 13: BER performance of CE-DCT-OFDM system over Ricean fading channel, as a function of h_p for $M = 4$.

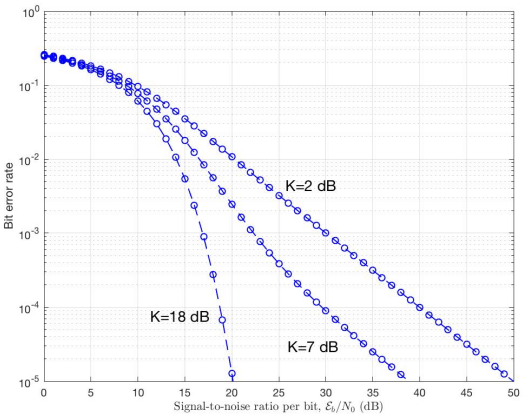

Figure 14: BER performance of CE-DCT-OFDM system over Ricean fading channel, as a function of K for $M = 4$ and $h_p = 0.5$.

6 Conclusions

A generalized description of CE-DCT-OFDM system is presented. In this system, phase modulation is used to eliminate the problem of PAPR. BER analyses of this system over AWGN and flat fading channels are presented and closed-form expressions for BER have been obtained. Improved BER performance is seen with increased value of modulation index at fixed transmission power. It is also observed that BER performance can be controlled by varying h_p and M as well. Simulation performance of CE-DCT-OFDM system over AWGN channel is also presented and compared with theoretical results. The results show that for a small modulation index, simulation result is nearly the same as theoretical result. With nonlinear the results show that CE-DCT-OFDM system has better BER performance than the conventional DCT-OFDM system when TWTA amplifier is used.

Conflict of Interest The authors declare no conflict of interest.

Voltage Stability

ABSTRACT

The aim of this paper is to develop a hybrid device for voltage stability enhancement using two kinds of FACTS (Flexible AC Transmission System) namely SVC (Static Var Compensator) and TCSC (Thyristor Controlled Series Capacitor). The idea behind the proposed method is to maintain safe and satisfactory power system operation in a lesser costing manner by taking advantage of the performances of SVC and TCSC at the same time. We propose to evaluate the efficacy of the combined device to UPFC, as it is a hybrid FACTS and it is the most versatile compensator. For purpose of identifying the placement of the devices, we opt for a heuristic based approach. The methodology is tested with the IEEE 14-Bus system using the software EUROSTAG, and the simulation results reveal the efficiency of the proposed method for enhancing voltage stability.

1. Introduction

Today's power system is more and more operating close to its stability limits due to the unceasing growing of the power demand [1, 2]. Therefore, transmission lines are prone to the overloading, especially when the system is unable to cope up with power transition [3]. In addition, in some cases, the transmission of the energy is a hard task because of the long distance between the generation station and the loads. This may increase power losses and threats to the voltage stability. Voltage stability is defined as the system's ability to retain voltages at all the buses in the whole network within the specified boundaries after a disturbed condition [4]. Several system collapses have been reported in recent years [5] making the need for rapid and accurate control systems more and more insistent [6]. As power electronics components continue to develop, a variety of control devices as FACTS (Flexible AC Transmission System) have been prospered [7, 8]. The introduction of such a technology in the power system provides the control of the transmission line impedance, the voltage magnitude, and the phase angle. UPFC, SVC, and TCSC are three of the main FACTS devices which have acquired a well-recognized term for higher and smoother controllability in power systems.

The use of FACTS technology for system stability support has been studied in a large number of works [9-11]. A. Motiebirjandi *et al.* [12] studied the impact of UPFC on damping oscillations of the generator rotor. For this purpose, authors proposed system critical modes and residue factor methods for the optimal placement. In addition, they applied particle swarm optimization (PSO) to optimize the parameters of the UPFC. Reference [13] proposed the use of SVC to improve power system transient stability and damp oscillations in case of three-phase short-circuit. In reference [14], the authors demonstrated the performance of UPFC compared to SVC, in terms of improving power system stability. In order to enhance transient stability, the authors in [15] compared the performances of UPFC to different FACTS devices, namely TCSC, STATCOM (Static Synchronous Compensator) and SVC. B. Bhattacharyya et al. [16] were interested in the cost implication and power loss of installing UPFC alongside with SVC and TCSC. After determining the optimal emplacement and parameters of the FACTS using specific algorithms, authors have reported the gain obtained when adding the hybrid compensator to the other FACTS. Likewise, authors in [17] discussed the use of SVC, TCSC, and UPFC in the improvement of dynamic and transient system stability. They compared the three FACTS based on their mathematical models and operation modes. It was found that UPFC provided the most rapid control and the highest performances in stabilizing the system. P. Pandey *et al.* [18] studied the contribution of the SVC and UPFC in enhancing the voltage profile of a grid connected distributed generation system. They demonstrated through simulations, the satisfactory operation of the two FACTS especially the hybrid device. Reference [19] presented the application of a heuristic based procedure to

*Hajer Jmii, University of Tunis, Tunis 1008, Tunisia, +21694014865, hajerjmii@yahoo.com

parameters, type and location problems of UPFC, SVC and TCSC. Simulations showed satisfactory results of the proposed method.

This paper is an extension of work initially published in the Proceedings of the International Conference on Sciences of Electronics, Technologies of Information and Telecommunications [20]. The aim of this work is to improve power system voltage stability by using a hybrid device composed of SVC and TCSC. The benefits of this idea are to achieve a safe and secure power system operation in a less costly way. We choose to compare the performance of the proposed device to UPFC, as it belongs to the family of hybrid FACTS and it is the most powerful tool in the current control systems. The placement of the devices is identified by applying a heuristic based approach and the proposed method is tested on the IEEE 14-Bus system via the software EUROSTAG.

Firstly, in section 2 we present statistics about FACTS devices. Second, the voltage instability phenomenon is explained mathematically. Then, the mathematical models and structures of the proposed FACTS are detailed. Section 5 outlines the proposed approach. In section 6, we focus on the case study and the discussion of simulation results. Finally, we summarize the main points of this paper in the conclusion.

2. Statistics about FACTS Devices

Since the development of power electronics, a great interest has been granted to FACTS devices. The research considers this technology as a substantial and a timely topic. For this reason, an important number of studies discussing the application of FACTS to power systems have been published. In power system stability field, the publications related to FACTS are also numerous as described in Figure 1. It was found that the interest to the flexible controllers is more and more increased which reflects the efficiency of such a solution for instability problems. According to reference [21], when looking at the statistics for SVC, TCSC and UPFC publications, we noted that they are dominant compared to the other FACTS. Nonetheless, SVC is reaping the major concern in researcher's studies with 114 publications until 2004.

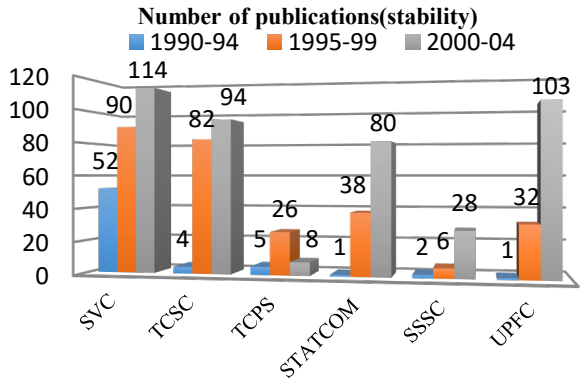

Figure 1. Statistics of the publications related to the FACTS

Actually, these statistics are reflecting the installed FACTS systems in the world. Reference [22] presented approximate results of a survey on worldwide integrated FACTS. It should be mentioned that SVC is the most exploited FACTS with a total power of 90.000MVA. While 2.000MVA are distributed on 10 incorporated TCSC into power systems, there are only 3 real networks equipped with UPFC with 250MVA of generated power.

To understand the reasons for the widespread use of SVC in comparison to the others FACTS particularly UPFC, we must look at system planner's choices. Recognizing that the investment cost is always a considerable constraint, economical solutions for power system instability are generally preferred. The cost of a FACTS device is highly dependent on the complexity of its model which is determined by the number of semiconductors used. Thereby, consisting of two voltage source converters, UPFC has the highest cost among the various FACTS [22]. According to reference [23], it is estimated at 0.33 million$ for 1MVAR generated power while the cost of SVC is approximately 0.19 million$ and the instrument and investment costs of TCSC are estimated at 0.22 million$ for 1MVAR generated power. Thus, when the network is already equipped with SVC, we can get well-improved stability by adding TCSC and at the same time economize 0.11million$ for each MVAR generated.

Otherwise, the cost-efficiency is not always to install the least costly FACTS device, but rather to choose the appropriate one based on the type of instability problem that we want to solve. As these problems are, on the one hand, unpredictable and on the other hand, closely linked, it is required to invest in equipment which can assure the control of more than one network parameter. Currently, UPFC has the potential to act on three parameters, namely: phase angle, line impedance, and bus voltage either simultaneously or separately. So, confronted with these constraints, we thought to find a solution for network instability, combining the economical side with the wide application area and efficiency side. Hence, our idea is to create an equivalent of UPFC by joining the action of TCSC, as a series FACTS, to that of SVC which assure the shunt compensation. With this approach, power system stability is enhanced at lower cost.

3. Voltage Instability

In power system stability field, a particular interest is accorded to the control of voltage and reactive power. The main issue is to avoid voltage instability which can result in a widespread problem known as voltage collapse [7]. For this purpose and in order to guarantee the reliability and the efficiency of power system operation, the following points must be respected in voltage and reactive power control:

- Voltages of all network buses must be within the permissible interval. According to reference [24], it is specified as [0.94pu; 1.06pu] for MV network.
- The reactive power flow in transmission lines must be minimized as much as possible. This leads to reducing line losses: RI^2 and XI^2.

We can illustrate the voltage instability by considering the system of Figure 2. This 2-bus network consists of a voltage source supplying a load through a transmission line.

The apparent impedance at bus 2 is expressed by:

$$S_2 = P_2 + jQ_2 = V_2 I^* \quad (1)$$

Where:

$$\bar{I} = \frac{\overline{V_1} - \overline{V_2}}{jX}$$

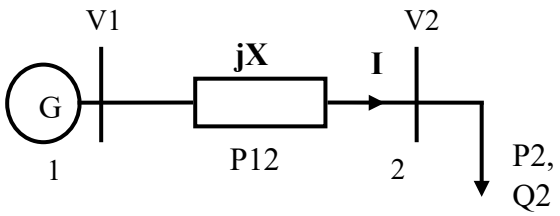

Figure 2. Equivalent model of a 2-bus system

Therefore equation (1) may be expressed as :

$$S_2 = V_2 \times \frac{V_1 \cos(\delta) + jV_1 \sin(\delta) - V_2}{jX} \quad (2)$$

$$S_2 = \frac{V_1 V_2 \sin(\delta)}{X} + j\frac{V_1 V_2 \cos(\delta) - V_2^2}{X} \quad (3)$$

The active and reactive powers supplied to the load are :

$$P_2 = \frac{V_1 V_2 \sin(\delta)}{X} = P_{\max} \sin(\delta) \quad (4)$$

$$Q_2 = \frac{V_1 V_2 \cos(\delta) - V_2^2}{X} \quad (5)$$

From equations (4) and (5) and using: $\cos^2(\theta) + \sin^2(\theta)$, we obtain:

$$P_2^2 + (Q_2 + \frac{V_2^2}{X})^2 = \frac{V_1^2 V_2^2}{X^2} \quad (6)$$

Therefore the voltage at bus 2 can be extracted as:

$$V_2^2 = \frac{1}{2}\left[V_1^2 - 2Q_2X \pm V_1(V_1^2 - \frac{4P_2^2X^2}{V_1^2} - 4Q_2X)^{1/2}\right] \quad (7)$$

Where :

V_1 : Busbar 1 voltage

V_2 : Busbar 2 voltage

I : Line current

X: Line reactance

δ : Generator internal angle

P_2 and Q_2 : Active and reactive powers supplied to the load.

Equation (7) describes the evolution of the voltage at bus 2 in function of the load increase at the same bus. We can deduce that in addition to the active and reactive powers, bus 2 voltage depends on the line reactance.

4. FACTS Models

In order to compare the performances of the FACTS devices, it is required to describe their functionalities supported with mathematical models and equivalent schemes. That is what we are going to present in this subsection.

4.1. TCSC

TCSC is one of the most important FACTS equipment, which has been used to modify the series impedance of the transmission line in order to improve system stability. Typically, it consists of a thyristor-controlled reactor in parallel with a fixed capacitor, which is equivalent to an adjustable reactance [25, 26]. The reactance of a transmission line equipped with a TCSC is expressed as follows:

$$X_{jk} = X_{jk}^{line} + X_{jk}^{TCSC} \quad (8)$$

Figure 3 shows a TCSC integrated between bus j and bus k with its equivalent model while Figure 4 describes the configuration of the series FACTS.

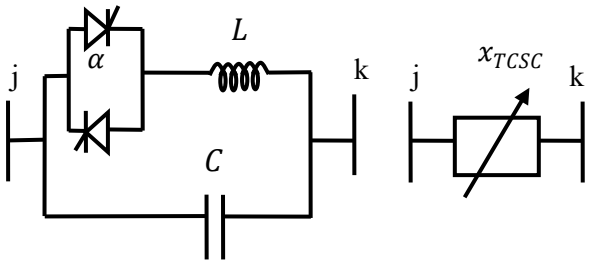

Figure 3. TCSC configuration

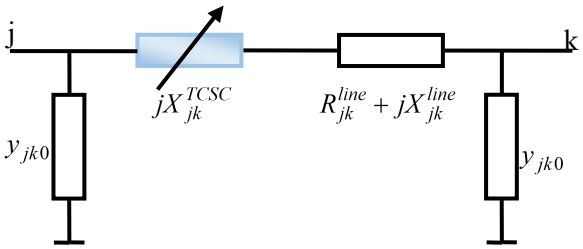

Figure 4. Equivalent model of TCSC

Before the integration of the TCSC in the transmission line jk, the admittance matrix Y is given by equation (9) [27]:

$$Y = \begin{pmatrix} \underline{y}_{jk} + \frac{\underline{y}_{jk0}}{2} & -\underline{y}_{jk} \\ -\underline{y}_{jk} & \underline{y}_{jk} + \frac{\underline{y}_{jk0}}{2} \end{pmatrix} \quad (9)$$

Where:

$$y_{jk} = G_{jk} + jB_{jk} \quad (10)$$

$$G_{jk} = \frac{R_{jk}^{line}}{(R_{jk}^{line})^2 + (X_{jk}^{line})^2} \quad (11)$$

$$B_{jk} = -\frac{X_{jk}^{line}}{(R_{jk}^{line})^2 + (X_{jk}^{line})^2} \quad (12)$$

The addition of the TCSC modifies the admittance matrix as follows:

$$Y' = \begin{pmatrix} \underline{y}'_{jk} + \frac{\underline{y}_{jk0}}{2} & -\underline{y}'_{jk} \\ -\underline{y}'_{jk} & \underline{y}'_{jk} + \frac{\underline{y}_{jk0}}{2} \end{pmatrix} \quad (13)$$

Where:

$$y'_{jk} = G'_{jk} + jB'_{jk} \quad (14)$$

$$G'_{jk} = \frac{R_{jk}^{line}}{(R_{jk}^{line})^2 + (X_{jk})^2} \quad (15)$$

$$B'_{jk} = -\frac{X_{jk}}{(R_{jk}^{line})^2 + (X_{jk})^2} \quad (16)$$

On EUROSTAG, to model a series and variable admittance, we must create two fictive buses in a transmission line and insert a current injector to each bus, as described in Figure 5. The two fictive buses must be connected to the network by lines with high reactance value to avoid injector shutdown in case of an opening line.

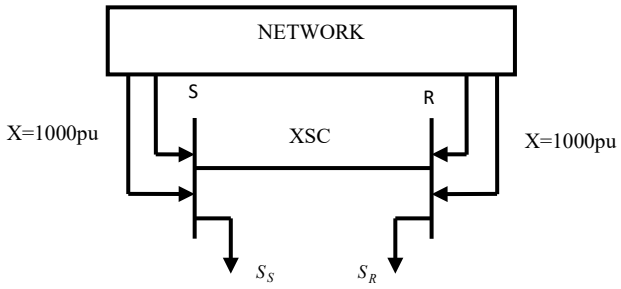

Figure 5. TCSC model on EUROSTAG

4.2. SVC

SVC is a static reactive power compensator whose output is adjusted for exchanging a capacitive or inductive current with the network to typically control bus voltage [28, 29]. In the steady state as well as in transient regime, this device is able to maintain voltage within the desired limits. Figure 6 shows the dynamic model of SVC. It can be modeled as variable shunt admittance with a thyristor controller. However, by neglecting the losses of SVC, we can consider it as ideal, so the admittance is purely imaginary and is described by the equations (17) and (18):

$$G_{SVC} = 0 \quad (17)$$

$$y_{SVC} = jB_{SVC} \quad (18)$$

The susceptance can be capacitive or inductive. Indeed, in the case of reactive power excess, SVC absorbs the increased amount through the inductor and in the opposite case; the capacitor covers the reactive demand.

The capacitive power injection model of SVC at the rated voltage is given by equation (19) [30]:

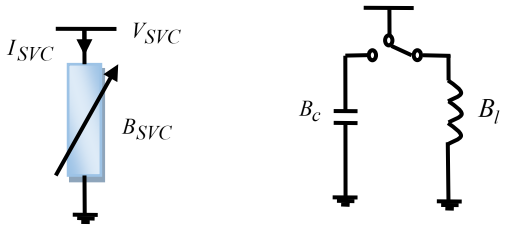

Figure 6. SVC model

$$Q_{SVC} = -V_N{}^2 B_{SVC} \quad (19)$$

Where B_{SVC} must be controlled according to equation (20):

$$B_{SVC}{}^{\min} \le B_{SVC} \le B_{SVC}{}^{\max} \quad (20)$$

$B_{SVC}^{\max}$ designates the capacitive limit state while $B_{SVC}^{\min}$ designates the inductive one. If SVC susceptance reaches its limits without maintaining the voltage of the bus where it is connected, it loses the capability of voltage control and it becomes similar to a fixed susceptance.

The connection of SVC to a bus j, as illustrated in Figure 7, changes the admittance matrix only at the element Y'_{ii}, in fact, the admittance of the compensator is added according to the following equation:

$$Y'_{ii} = Y_{ii} + y_{SVC} \quad (21)$$

The admittance matrix is so expressed by equation (22).

$$Y = \begin{pmatrix} y_{ij} + \frac{y_{ij0}}{2} + y_{SVC} & -y_{ij} \\ -y_{ij} & \frac{y_{ij0}}{2} + y_{ij} \end{pmatrix} \quad (22)$$

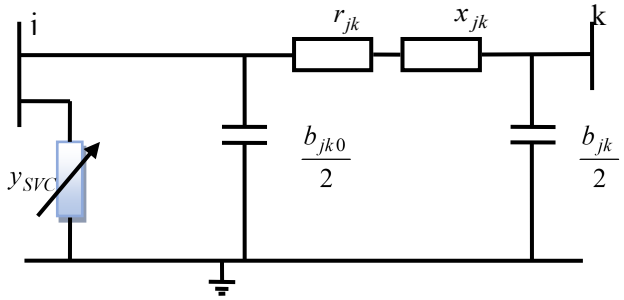

Figure 7. SVC connected to a bus

EUROSTAG adopts the model of Figure 8 and represents SVC as an impedance injector connected to a bus of the electrical network.

4.3. UPFC

UPFC is the most recognized hybrid compensator, it is the third generation of FACTS devices, it is the first and only device that has the ability to control simultaneously or separately voltage, line impedance and the phase shift of the bus voltage. UPFC consists

of two transformers, one connected in series and the other in shunt with the transmission line as shown in Figure 9 [31].

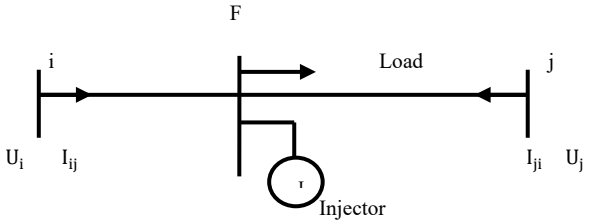

Figure 8. SVC model on EUROSTAG

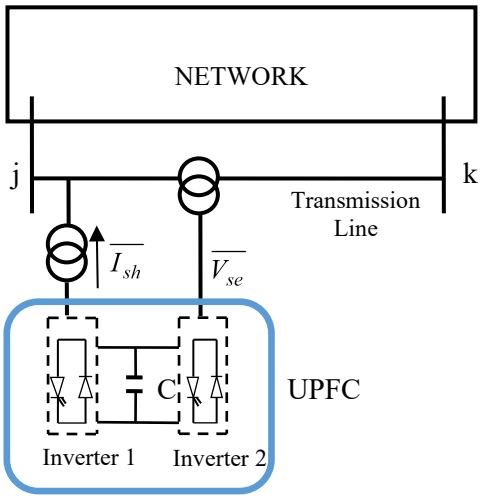

Figure 9. UPFC inserted in a power system

The inverter 2 injects the voltage $\overline{V}_{se}$ which is controllable in amplitude and in phase so that it can perform the serial compensation function of the active power. On the other hand, the inverter 1 is used, through the continuous connection, to provide the active power required for the inverter 2, it serves to compensate the reactive power since it can absorb or inject the active power into the network. Indeed, UPFC allows both the active power control and the line voltage control. It can switch from one to the other function instantaneously by changing the control of the inverters separated by a capacitor.

The equivalent circuit of UPFC is represented in Figure 10 [32]. From this scheme, we can extract the active and reactive power flows of the shunt and series converters which are expressed by the equations (23) - (25).

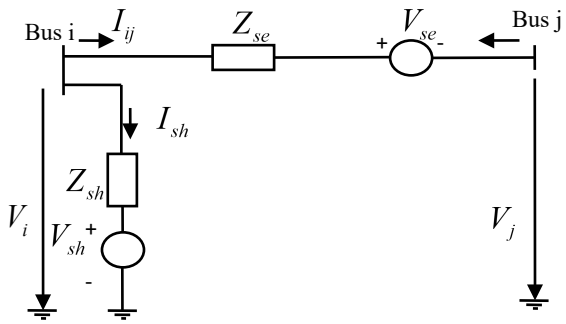

Figure 10. Equivalent circuit of UPFC

$$P_{sh} = V_i^2 g_{sh} - V_i V_{sh}(g_{sh}\cos(\theta_i - \theta_{sh}) + b_{sh}\sin(\theta_i - \theta_{sh})) \quad (22)$$

$$Q_{sh} = -V_i^2 b_{sh} - V_i V_{sh}(g_{sh}\sin(\theta_i - \theta_{sh}) - b_{sh}\cos(\theta_i - \theta_{sh})) \quad (23)$$

$$P_{ij} = V_i^2 g_{ij} - V_i V_j(g_{ij}\cos\theta_{ij} + b_{ij}\sin\theta_{ij}) - V_i V_{se}(g_{ij}\cos(\theta_i - \theta_{se}) + b_{ij}\sin(\theta_i - \theta_{se})) \quad (24)$$

$$Q_{ij} = -V_i^2 b_{ij} - V_i V_j(g_{ij}\sin\theta_{ij} - b_{ij}\cos\theta_{ij}) - V_i V_{se}(g_{ij}\sin(\theta_i - \theta_{se}) - b_{ij}\cos(\theta_i - \theta_{se})) \quad (25)$$

Where:

$$g_{sh} + jb_{sh} = \frac{1}{Z_{sh}}$$

$$g_{ij} + jb_{ij} = \frac{1}{Z_{se}}$$

$$\theta_{ij} = \theta_i - \theta_j$$

V_i and V_j: voltages at buses i and j

P_{sh} and Q_{sh}: active and reactive power flows of the shunt inverter

P_{ij} and Q_{ij}: active and reactive power flows of the series inverter

V_{sh} and V_{se}: shunt and series voltage sources

Z_{sh} and Z_{se}: shunt and series coupling transformer impedances.

The modeling of the UPFC shunt part on EUROSTAG is simple; it is represented by a current injector. As for the modeling of the series part, we must open the line where we want to insert UPFC and place at its extremities two current injectors (Figure 11). The opening of the line is assured by a high reactance value.

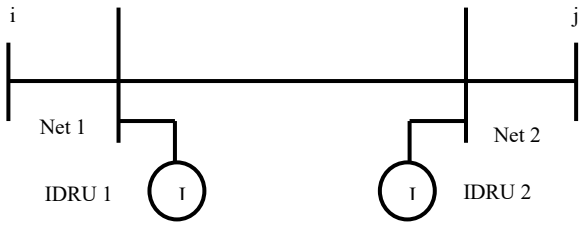

Figure 11. UPFC model on EUROSTAG

5. Proposed Approach

The main purpose of our paper is to find an economical and efficient way for sustaining voltage stability by comparing the performances of SVC-TCSC to those of UPFC. In order to achieve

this, it is important to take into consideration the identification of the proper placement of the FACTS in the system.

There is a variety of methods for finding optimal solutions [19, 33]. However, in practice, the time factor is more important than optimally solving the problems so that engineers and system planners often resort to heuristic methods. Heuristic methods known also as approximate methods are used for the resolution of optimization problems. These methods guarantee to find in a polynomial time at least a good and a feasible solution, but not necessarily the optimal one [34].

There are different types of heuristic algorithms, as shown in Figure 12, among which we are interested in reduction heuristics. The principle of such a method is to simplify the problem and to reduce the domain of the solutions. This implies to define the boundaries of the problem by identifying the properties that must satisfy a good solution.

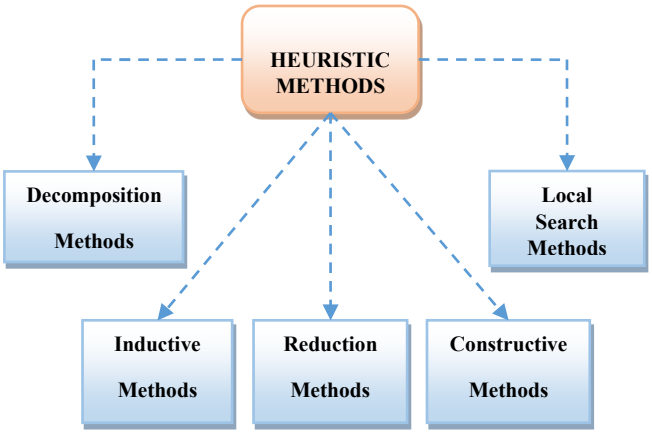

Figure 12. Types of heuristic algorithms

Figure 13 shows the flowchart of the proposed method. The normal state of the system must be obtained first of all so that we can analyze the load flow results and determine the weakest zone of the system that needs to be compensated. In this way, the location problem is simplified and the domain of solutions is reduced to the weakest zone. Based on the load flow analyses, a preliminary selection of the FACTS placement is made. Then, the system with the FACTS devices is executed. The evaluation of the selected location is performed by comparing the voltage magnitude to the specified lower and upper boundaries. A proper FACTS placement must maintain the voltage of all the buses within the permissible limits. If this criterion is not respected, another location has to be considered, and the evaluation based on the defined boundaries is repeated. Once the best location of the devices is identified, the next step is to perform the comparison between the proposed FACTS. The comparison takes into consideration the voltage magnitude, the oscillations, and the power flows.

With this method, we can get satisfactory results and avoid complicated and slow routines of the optimization methods.

6. Simulation

6.1. Test System

The proposed case study is the classical system IEEE 14-bus network, it consists of:

- Two generator buses and eleven load buses.
- Fifteen transmission lines.
- A three-winding transformer and two step-up transformers with two windings.
- Three synchronous compensators connected to buses 3, 6 and 8.

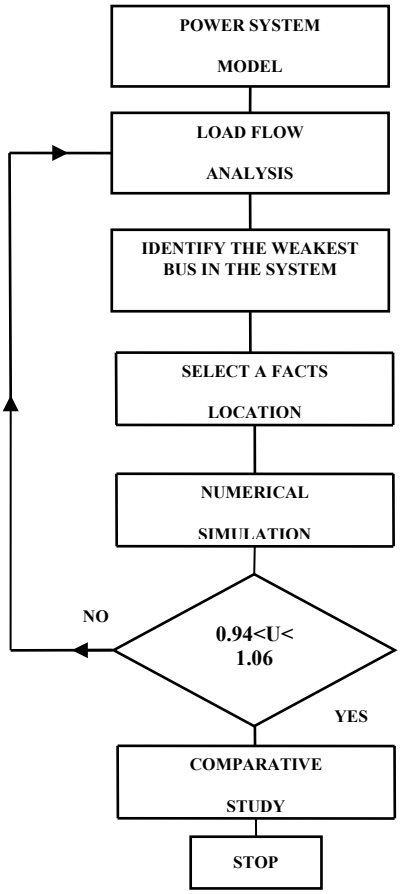

Figure 13. Flowchart of the proposed method.

All data relating to this test network are extracted from reference [32] and we used EUROSTAG software package [35] for the simulations. This software is a powerful tool dedicated to dynamic simulations. Its major advantage is the high rapidity of its algorithm. Irrespective of the nature of the disturbance and the system size, it can rapidly visualize the behavior of the network until it returns to an equilibrium state. Furthermore, this simulation is not accompanied by any deterioration in the accuracy of the calculations. In addition, it gives the possibility to define the modeling level adapted to the type of the performed study.

6.2. Simulation Results

6.2.1. Identification of FACTS Location

To compare the performances of UPFC and the proposed SVC-TCSC, first of all, it is mandatory to identify the appropriate placement of the FACTS. This step has to provide a firm basis for comparison. Therefore, we plan a step change in load at time t= 200s from 5% of the initial load by a step of 5%. The procedure

continues until reaching the maximum loading capability of the system.

The results of the base state signaled that bus 14 has got the lowest voltage amplitude as shown in Figure 14; hence we summarized the voltage levels of bus 14 during various step changes in Table 1.

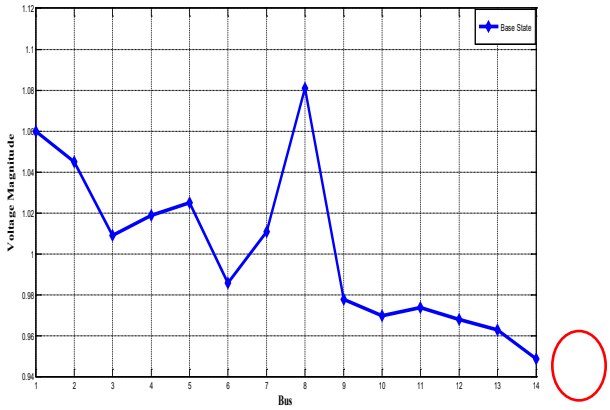

Figure 14. Voltage profile of IEEE 14-bus system in normal state

Table 1. Network behavior under incremental load increase.

Network Settings	Load Increase in %					
	5%	*10%*	*20%*	*25%*	*30%*	*33%*
U14 (pu)	0.966	0.962	0.952	0.948	0.946	Voltage collapse
State System	Stable					

We note the occurrence of a voltage dip in bus 14, which is increased as more the loads are augmented. The voltage level is still acceptable and the network is maintaining its stability until 32% of load increase. When reaching the case of 33%, EUROSTAG fails to execute the simulation which means that the system is collapsing.

After identifying the weakest bus of the system, we make a preliminary selection of the FACTS location. Hybrid or series controller both must be integrated through a transmission line. According to the network architecture, as schematized in Figure 15, bus 14 is related to bus 13 and bus 9, so we have two possibilities to place the device.

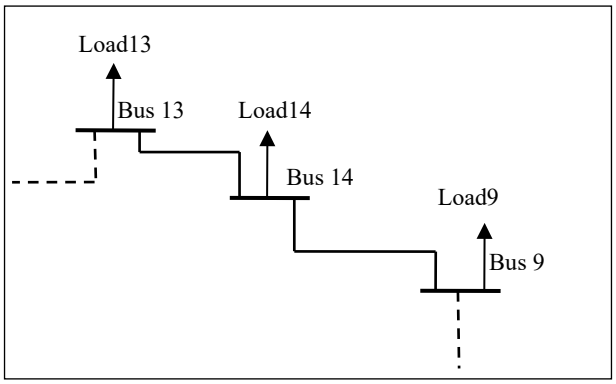

Figure 15. Scheme of the architecture of the IEEE 14-bus system

First of all, we integrate UPFC in the middle of line 13-14. Then, we apply an increase of 20% of the total load of the system. As shown in Figure 16, there is no improvement in the magnitude of bus 10 voltage. In addition, lower amplitudes equal to 0.925pu and 0.977pu are obtained respectively in bus 14 and bus 9, compared to the uncompensated system. Thus, it is concluded that line 13-14 is not a good location for the FACTS to perform the comparative study.

Now, we integrate UPFC through line 9-14 and we rerun the system. A meaningful improvement of the voltage magnitude is observed. According to Figure 16, UPFC has increased the voltage amplitude of bus 14 from 0.952pu to 0. 1.007pu with less severe oscillations, bus 10 from 0.976pu to 0.985pu and bus 9 from 0.982pu to 0.991pu. As we have got satisfactory results, the line 9-14 is retained as a good placement to insert the proposed FACTS and then to compare their potentialities.

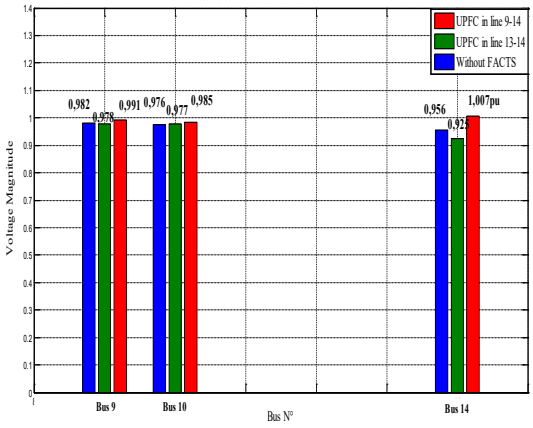

Figure 16. Voltage profile with different UPFC locations.

6.2.2. *Performance comparison between the FACTS*

We connect UPFC and SVC-TCSC to the network, separately. Firstly, UPFC was integrated into the middle of line 9-14 with a capacity of 60MVAR for each one of its inverters, and then, with keeping the same dimensions, we inserted TCSC through the line 9-14 and SVC to bus9.

Based on the results of the prior section, we apply a total load increase of 30% of the initial load. In this case, the test network is under heavy loaded conditions.

We are interested in the comparison, to the evolution of bus voltage as well as the active and reactive power flows in transmission lines.

Taking bus 14 as an example as shown in Figure 17, it can be seen that both UPFC and SVC-TCSC have a bearing on the voltage magnitude by increasing it significantly, while it was under the minimum acceptable value before compensation. However, UPFC showed a higher capability of enhancing voltage level, from 0.90pu to 0.96pu. In addition, we obtained a rapid damping of oscillations after only 7s either by UPFC or SVC-TCSC.

The impact of the FACTS on the oscillatory regime is clearer in the voltage curve of bus1, plotted in Figure 18. Nonetheless, we note that the damping action of SVC-TCSC is more

considerable compared to that of UPFC, in fact, it reduced the highest oscillation from 1.08pu to 1.071pu and rapidly established the steady state with well-amortized oscillations.

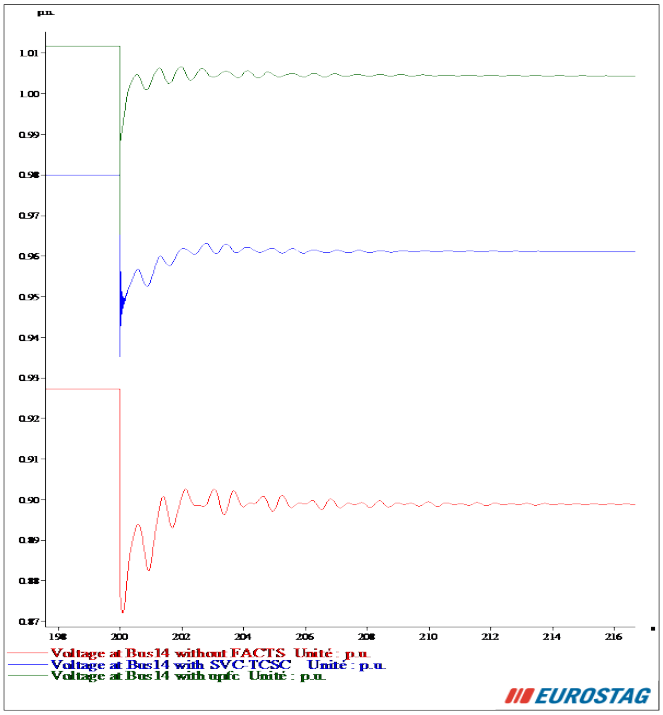

Figure 17. Voltage of bus14 with and without FACTS.

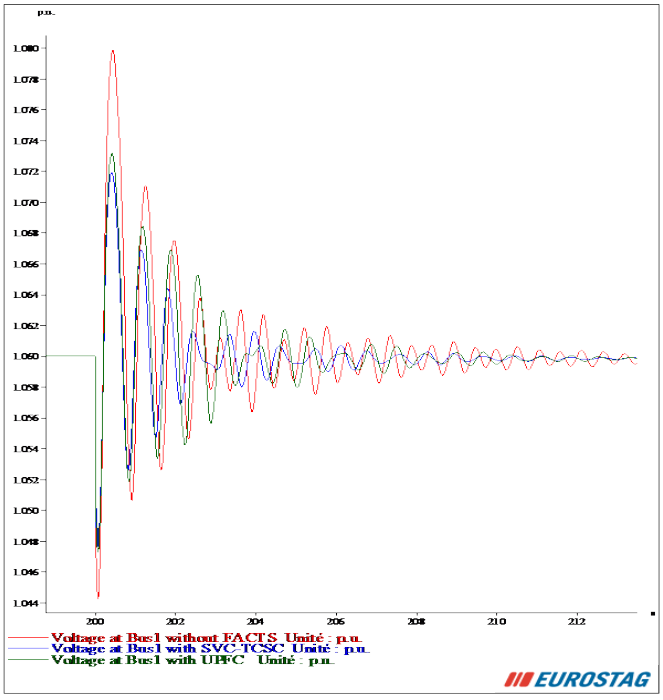

Figure 18. Voltage of bus1 with and without FACTS.

According to the results of Table 2, an excellent enhancement in the active power has been observed with the action of UPFC. However, we didn't note any important change in its level when used SVC-TCSC. As for the reactive power flow, it encountered a considerable decrease by using UPFC; it was decremented from 5.7 MVAR to 2.5MVAR through the line 9-10 as an example. This was observable also when introducing the combination SVC-TCSC. The amount of reactive power in line 6-12 is reduced by about 12% and in line 1-2, from 20MVAR to 19.2MVAR. Nevertheless, we recorded an increase of 10.5% in the transmitted MVARs across line 9-10.

Figure 19 shows the active power transmitted in line 1-2 with and without FACTS. When focusing on the transient regime, it must be mentioned that even in the temporal evolution of powers, the damping action of SVC-TCSC is more efficient; it gives more attenuated oscillations and joins the stable state in a shorter time.

Table 2. Active and reactive power flows with and without FACTS.

Simulation case	Line 9-10		Line 1-2		Line 6-12	
	Active Power MW	*React. Power MW*	*Active Power MW*	*React. Power MW*	*Active Power MW*	*React. Power MW*
Without FACTS	8.3	5.7	209	20	9.8	3.4
With SVC-TCSC	8.3	6.3	209	19.2	10	3
With UPFC	9.2	2.5	216	18.1	10.8	1.5

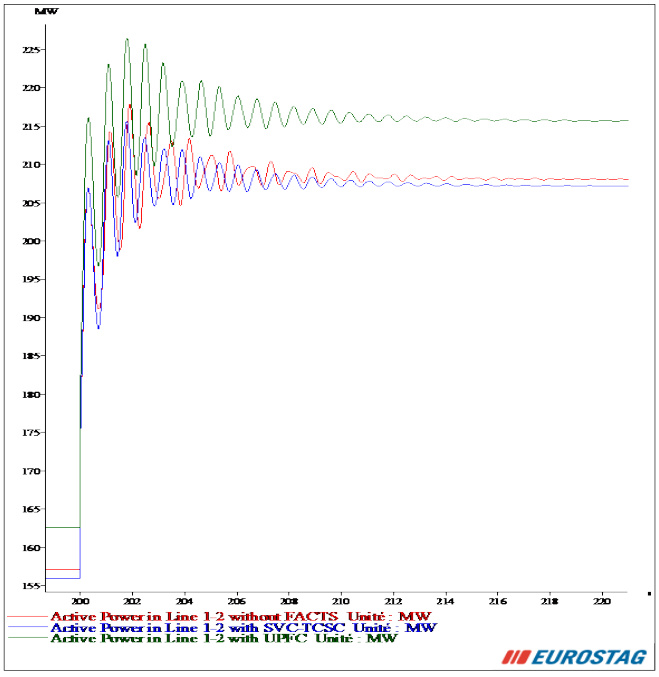

Figure 19. Active power flow in line 1-2 with and without FACTS.

Conflict of Interest

The authors declare that there is no conflict of interests regarding the publication of this paper.

7. Conclusion

This paper presented a hybrid method for voltage stability enhancement using SVC and TCSC. The advantage of the proposed approach is the lesser cost of achieving a safe power

system operation. The IEEE 14-bus system was utilized to test the performance of the combination SVC-TCSC and compare it to the UPFC, the most pricey and multi-functional FACTS. The identification of the best placement of the FACTS devices was performed using a simple heuristic method. The simulation results demonstrated that the hybrid FACTS based on SVC and TCSC is able to significantly improve the voltage profile of the whole network in addition to the satisfactory action in amortizing the oscillations. The findings are encouraging to rather improve the performance of the SVC-TCSC in controlling power flow in lines and introduce other techniques for optimal location.

Voltage Stability

ABSTRACT

This paper proposed the identification of the proper placement of UPFC (Unified Power Flow Controller) using a series of methodological numeric simulations to improve voltage stability. For this purpose, the critical zone of the system is determined, then, comparative analyses depending on different emplacements of UPFC are performed. The dynamic model of UPFC and the proposed method are tested on the IEEE 14-bus system. The finding shows that the proper location of UPFC helps in improving voltage profiles and increasing the maximum loading capacity.

1. Introduction

Power systems have been forced to operate close to their stability limits and around their full capacities. This is due to the economic and environmental pressures imposed on the power generation and the construction of new transmission lines [1-4]. On the other hand, the amount of power transmitted across transmission lines is limited for safety and stability considerations. The system is prone to be collapsed when the power flowing exceeds the limits in case of an arbitrary incident [5]. System planners are so more and more focusing on how to manage the obstacles facing the power transmission.

Over the last decades, FACTS (Flexible AC Transmission Systems) devices have opened new perspectives for managing the transmission of the power [6]. Different types of FACTS controllers are available for this aim, but the most powerful and prominent one is UPFC. UPFC is able to control the three parameters of the transmission system: phase angle, impedance, and voltage. In addition, it provides voltage support, improves transient stability and amortizes oscillations [7, 8].

However, according to references [9, 10], the major disadvantage of UPFC is the expensive cost of installation and reactive power generation which is due to the great efforts of its voltage source converters. Therefore, an optimal location of the device helps in achieving good performances and enhancing power system stability with a reduced investment cost [11].

Previous studies have been focused on the optimal placement of UPFC and the evaluation of its impact on system stability using various methods and techniques [12-14]. The authors in reference [15] presented an evolutionary algorithm-based approach to identify the optimal placement and settings of the hybrid device. Reference [16] has investigated the use of UPFC to increase the load ability margin and improve the system stability. The emplacement of the FACTS is decided by the stability indices which determine the critical line, the appropriate line for introducing UPFC. In reference [17], H. Wang investigated the impact of UPFC on the stability of a multi-machine power system. A. Ray *et al.* [18] studied the application of UPFC for controlling power flow in the transmission line and improving the voltage profile. They computed the VSI (Voltage Stability Index) for each line to integrate UPFC into the line which has got the highest VSI value. In reference [19], authors opted for the CPF (Continuation Power Flow) and LSI (Line Stability Index) for the identification of the suitable location of UPFC. Through simulation results, it was demonstrated that optimal placement of the hybrid FACTS improves the static and transient stability of power system when subjected to large disturbances. S. Lee *et al.* [20] addressed the determination of UPFC location and rating for voltage stability improvement using the analysis of the Jacobian matrix. Intelligent techniques were applied in reference [21] for the optimal position of UPFC along with series FACTS to minimize the operation cost of the power system. In [22], authors proposed two evolutionary optimization techniques to optimally place and size the hybrid controller in view of reducing the active power losses.

This paper is an extension of work initially published in the Proceedings of the International Conference on Control Engineering &Information Technology [23]. In this work, we proceed with an efficient method for the identification of the proper placement of UPFC, for the purpose of improving voltage

*Hajer Jmii, University of Tunis, Tunis 1008, Tunisia, +21694014865, hajerjmii@yahoo.com

stability. We plan a series of methodological dynamic simulations to find the critical zone of IEEE 14-bus case study. The zone having the lowest voltage magnitudes is taken as the best location of UPFC. Then, we perform comparative studies to justify the placement selected. The dynamic model of UPFC and the numerical simulation method are implemented within the software EUROSTAG.

2. Necessity of FACTS devices

Consider a single machine infinite bus system interconnected through a transmission line having reactance X, as shown in Figure 1. The power transferred across the transmission line is given in equation (1) [24, 25].

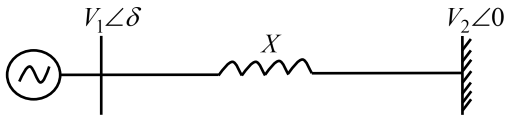

Figure 1. Single machine infinite bus system

$$P = \frac{V_1 V_2}{X}\sin\delta \quad (1)$$

V_1 and V_2 are the voltages of the synchronous generator and the infinite bus respectively where: $V_1\angle\delta$ and $V_2\angle 0°$.

The power variation is a sinusoidal function of the difference between the two voltage angles as shown in Figure 2. The maximum power that can be transmitted across the line corresponds to $\delta = 90°$ and by considering $V_1 = V_2 = V$, it is given by:

$$P_{\max} = \frac{V_2}{X} \quad (2)$$

$P_{\max}$ depends on the value of the reactance X which imposes the theoretical limit of the steady state transmitted power. However, the line resistance R creates power losses quantified by RI^2 and thus sets the practical limit of the line. The physical characteristics of the conductor could also limit the power transmission, which is known as the thermal limit.

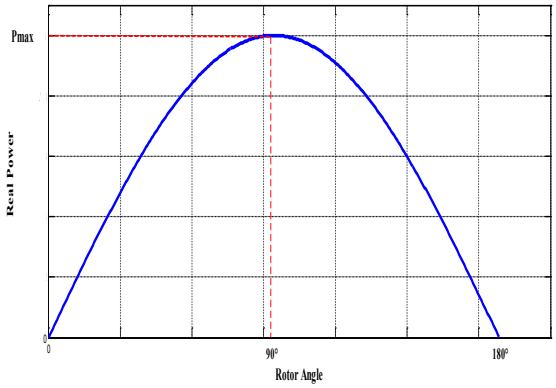

Figure 2. Power-angle curve

From equation (1), we note that the power can be controlled by two parameters; it can be enhanced by increasing the voltage magnitude of the synchronous machine and the infinite bus or by increasing the angular difference of the voltages. However, there are limits imposed on either the voltage magnitude or the angular difference, which have to be considered. The voltage variation must not exceed $\pm 5\,\%$ of the nominal voltage while the difference between the angles is limited to less than $30° - 35°$ to maintain the transient stability [26, 27].

Therefore, it is inferred that the power transmission is limited by:

- Thermal limitations.
- Physical limitations.
- Stability.

It is possible to deal with the thermal limitations by renovating the transmission lines and opting for a higher current rating conductor. Nonetheless, this solution does not necessarily guarantee voltage within the acceptable boundaries or the flow and the controllability of the power, but it is feasible by line compensation. Electro-mechanical devices used for line compensation cannot achieve rapid compensation and are prone to the wear quicker than the static equipments. The solid-state based technology, FACTS, provides the control of one or more parameters to magnify the loading capability and to develop controllability. As the current in a transmission line has the property to be controlled, it is possible to use a FACTS device for flowing power across the line during normal or disturbed conditions. This returns to the ability of FACTS devices to control all power flow parameters, namely phase angle, bus voltage and line impedance. In other words, the FACTS technology gives the possibility to maintain acceptable voltage magnitude and power flow.

3. UPFC

The UPFC is a hybrid device consisting of two voltage source converters interconnected through a common DC link capacitor, as shown in Figure 3 [28-30]. The inverter 1 is connected in shunt with the transmission line while the inverter 2 is series connected. It injects a series connected. It injects a series voltage controllable in phase and magnitude. The decomposition of this voltage leads to a quadrature component responsible for controlling the real power and an in-phase component which controls the reactive power in the line. Similarly, the injected shunt voltage is decomposed into two components. The quadrature component regulates the voltage of the DC link as for the in-phase component; it controls the exchange of the reactive power with the system.

The model of UPFC is represented in Figure 4 [30, 31]. From this scheme, we can extract the active and reactive power flows of the series and shunt converters which are expressed by the equations (3) - (6).

$$P = \frac{VV_k}{(1+K)X}\sin(\theta_{jk} + \theta) \quad (3)$$

$$Q = \frac{1}{(1+K)^2 X}[V^2 - VV_k\cos(\theta_{jk} + \theta)] \quad (4)$$

$$-\frac{1}{(1+K)^2 X}[{V_k}^2 - VV_k\cos(\theta_{jk} + \theta)]$$

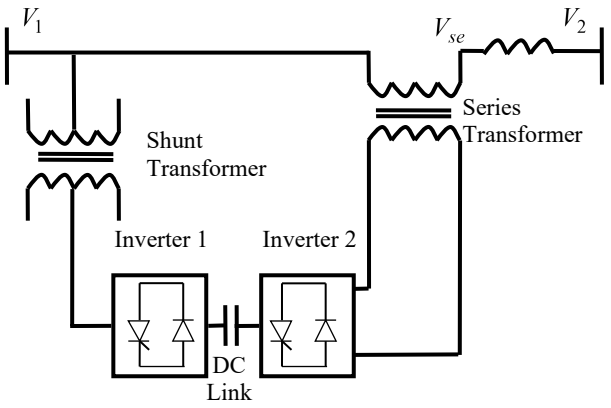

Figure 3. UPFC incorporated in a power system

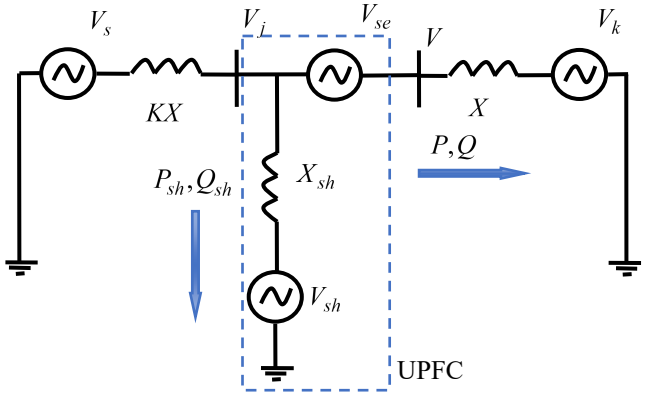

Figure 4. Model of UPFC

Where:

$$V^2 = V_j^2 + V_{se}^2 + 2V_jV_{se}\cos\phi_{se}\ \ \phi_{se} = \tan^{-1}\frac{\gamma}{\beta},\ \ \theta = \tan^{-1}\frac{\gamma}{1+\beta}$$

Similarly, the active and reactive powers of the shunt inverter are expressed by:

$$P_{sh} = \frac{V_jV_{sh}}{X_{sh}}\sin\varepsilon \quad (5)$$

$$Q_{sh} = \frac{V_j^2}{X_{sh}} - \frac{V_jV_{sh}}{X_{sh}}\cos\varepsilon \quad (6)$$

Where: $\varepsilon = \tan^{-1}\frac{\xi}{1+\eta}$ and $V_{sh}^2 = (1+\eta)^2V_j^2 + \xi^2V_j^2$

KX: Short circuit level;

$\phi(x)$: Gaussian function

γ : Relative quadrature series voltage;

β : Relative in-phase series voltage;

ξ : Relative quadrature shunt voltage;

η : Relative in-phase shunt voltage;

V : Right YPFC voltage;

V_{se} : Series voltage;

V_{sh} : Shunt voltage;

P : Real power;

Q : Reactive power;

P_{sh} : Shunt real power;

Q_{sh} : Shunt reactive power.

The modeling of the UPFC shunt part on EUROSTAG is simple; it is represented by a current injector. As for the modeling of the series part, we must open the line where we want to insert UPFC and place at its extremities two current injectors (Figure 5). The opening of the line is assured by a high reactance value.

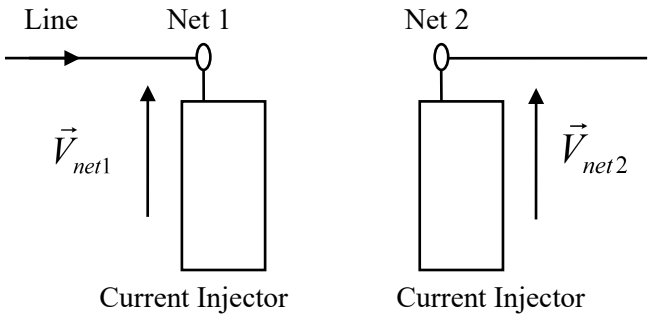

Figure 5. Model of UPFC in EUROSTAG

4. Simulation

4.1. Case Study

To test the proposed method, we used the IEEE 14-bus test system. This system contains two generators each one is equipped with voltage and speed regulators and three synchronous compensators to produce reactive power. It also has two transformers with two windings, a three-winding transformer, fifteen transmission lines and eleven loads. The data of the above mentioned system are taken from reference [31].

EUROSTAG [32] adopts the model considering the voltage behind transient reactance for representing all the generators and constant impedance to model loads and transformers.

4.2. Simulations Results

4.2.1. Identification of the Critical Zone:

The IEEE 14-bus network can be decomposed into a transmission system (69 KV) referred by « zone A » and a distribution one (13.8 KV) referred by « zone B » interconnected through three step-down transformers. To identify the critical zone, we proceeded by an incremental load increase of each zone separately. The part of the network experiencing voltage collapse rapidly is considered as the critical zone.

According to the steady state, we noted that bus 14 is the most insecure bus; it has got the lowest magnitude compared to the other buses. For this reason, we choose to adopt this bus as an index for voltage stability assessment.

Figure 6 shows the main results of increasing load. In zone A, the voltage of bus 14 underwent a progressive decrease of 0.002pu from one case to another until collapsing in the case of 49%. As for zone B, it could not withstand over than 39% of load increase where bus 14 has got the limit voltage amplitude. While the increase of the total system load leads to a severe voltage drop which ends with a collapse when reaching 25%.

Noteworthy that distribution system is the critical zone. All thanks to voltage and speed regulators of synchronous machines which reinforce transmission system stability.

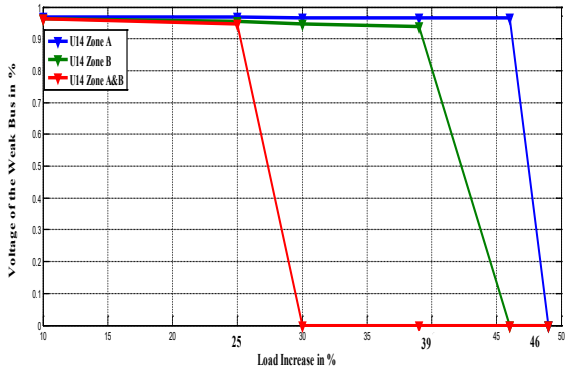

Figure 6. Identification of the critical zone of IEEE 14-Bus system.

4.2.2. UPFC Application:

Having identified the critical zone, we placed UPFC between buses 9 and 14, sized at 60MVAR for each one of its converters. Line 9-14 is close to the weakest bus so that we expect satisfying results when introducing UPFC into it. To evaluate the contribution of the controller, we rerun the system under 20 % of load increase at time t=250s.

As we can see in Figure 7, UPFC was able to considerably increase bus14 voltage amplitude just after perturbation and with well-damped oscillations compared to the uncompensated system. This result indicates the voltage support supplied by the UPFC. Note that we obtained similar results for the other buses of the network.

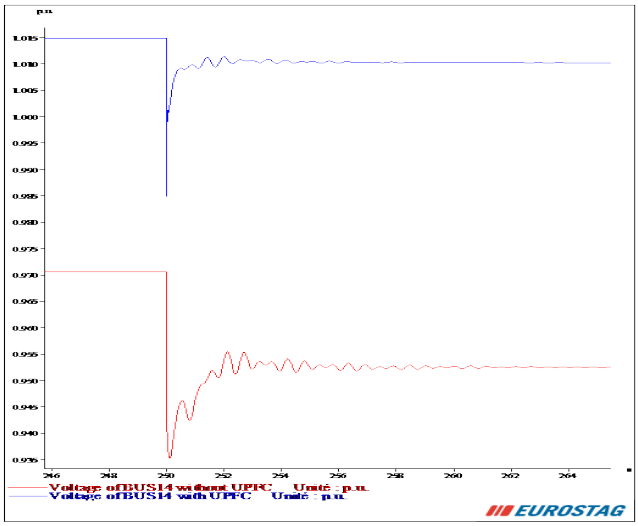

Figure 7. Temporal evolution of voltage at bus14 for 20 % of load increase with and without UPFC

The test network along with UPFC at different locations is tested now for comparison purpose. In addition to line 9-14, we choose two placements in the transmission system: lines 1-2 and 2-3 which are intended for transmitting the highest amount of reactive and active powers. Thereby, enhancing power flowing in these lines can be effective in improving voltage stability of the whole network. Figure 8 and Figure 9 illustrate the temporal evolution of voltage at bus1 and bu2 respectively. It should be noted that the implementation of UPFC in line 1-2 has considerably damped voltage oscillations compared to the other cases. While, this location had no effect on the voltage magnitude as shown in Figure 10. UPFC in line 9-14 gave best voltage levels at all network buses than when it is incorporated in line 2-3, where we obtained the lowest voltage magnitudes.

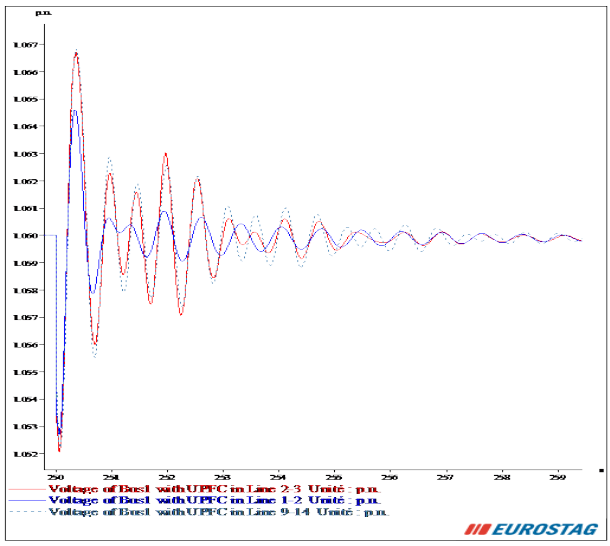

Figure 8. Temporal evolution of voltage at bus 1 for 20% of load increase with different locations of UPFC.

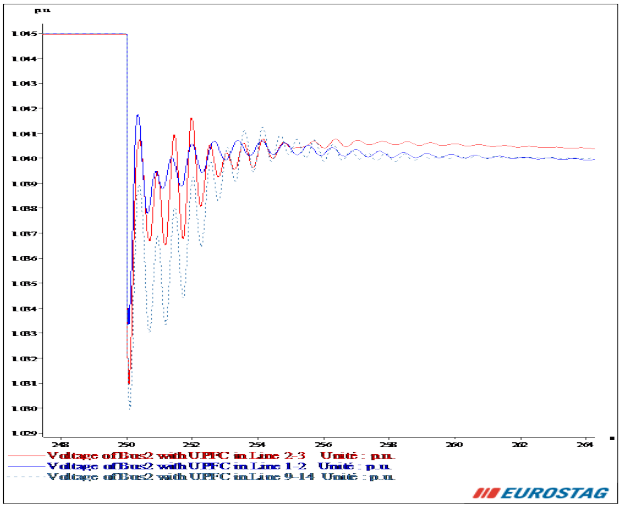

Figure 9.Temporal evolution of voltage at bus 2 for 20% of load increase with different locations of UPFC.

Figure 11 illustrates the active power losses of the system. It is clearly observable that the active power losses had the lowest value in the case of UPFC inserted through line 9-14, it is about 13.5MW. However, a large amount of active losses is detected with line 2-3 placement and about 14 MW in line 1-2 case.

Now, we evaluate the impact of UPFC location on the loadability margin of the power system. From Table 1, we can note that the contribution of the controller in improving the maximum loading capability was very meaningful when installing in the distribution system. In fact, it was able to increase the loadability margin in zone A from 48% to 59% and from 39% to 70% in zone B. As for the whole network, it became able to

maintain a stable state up to 33.5% of load increase while its maximum loadability was about only 25% before compensation. Nevertheless, when introduced in the transmission system, UPFC was less effective in increasing loadability margin. That was observable notably in line 2-3, where only the loading capacity of zone A; reached a higher percentage compared to the case without UPFC.

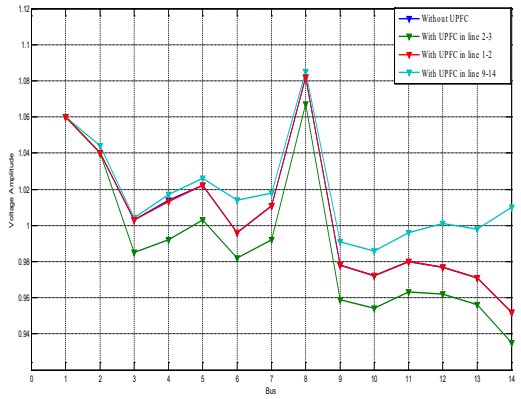

Figure 10.Voltage profiles of IEEE 14-Bus system for 20% load increase with different locations of UPFC

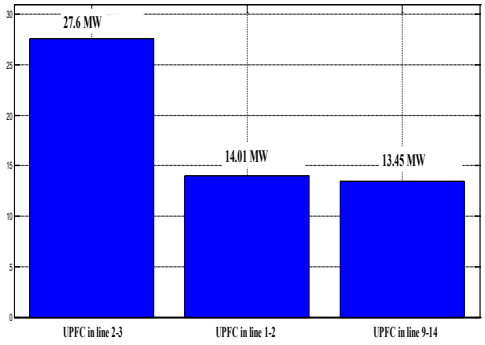

Figure 11. Active power losses for 20% load increase with Different UPFC Locations.

Table 1. Load ability Margins with Different Locations of UPFC.

Network Zone	Loadability Margin in %			
	Without UPFC	With UPFC in line 2-3	With UPFC in line 1-2	With UPFC in line 9-14
Zone A	48	52	55	59
Zone B	39	39	39	70
Zones A&B	25	25	32	33.5

Conflict of Interest

The authors declare that there is no conflict of interests regarding the publication of this paper.

5. Conclusion

In this paper, the impact of the proper installation of UPFC on improving voltage stability has been investigated. The placement of UPFC is done by using a numerical simulation based method. The identification of the critical zone of the system can determine the best location of the hybrid device. Then, the performance of the proper placement is compared to different selected locations in the system for justification purpose. It was found that UPFC incorporated through line 9-14 in the critical zone, helps in improving voltage magnitude, reducing active power losses as well as increasing maximum loading capacity of the system. However, the integration of the controller in the transmission system gave rapid and well- damped oscillations. Thereby, the optimal placement of the UPFC is highly dependent on the objective of the integration.

Direct chosen-ciphertext security
Twin Diffie-Hellman

ABSTRACT

Chosen-ciphertext attacks (CCA) are typical threat on public-key encryption schemes. We show direct chosen-ciphertext security modification in the case of attribute-based encryption (ABE), where an ABE scheme secure against chosen-plaintext attacks (CPA) is converted into an ABE scheme secure against CCA by individual techniques. Our modification works in the setting that the Diffie-Hellman tuple to be verified in decryption is in the target group of a bilinear map. The employed techniques result in expansion of the secret-key length and the decryption cost by a factor of four, while the public-key and the ciphertext lengths and the encryption cost remain almost the same.

1 Introduction

Access control is one of the fundamental processes and requirements in cybersecurity. Attribute-based encryption (ABE) invented by Sahai and Waters [1], where attributes mean authorized credentials, enables to realize access control which is functionally close to role-based access control (RBAC), but *by encryption*. In key-policy ABE (KP-ABE) introduced by the subsequent work of Goyal, Pandey, Sahai and Waters [2], a secret key is associated with an access policy over attributes, while a ciphertext is associated with a set of attributes. In a dual manner, in ciphertext-policy ABE (CP-ABE) [2, 3, 4], a ciphertext is associated with an access policy over attributes, while a secret key is associated with a set of attributes. In a KP-ABE or CP-ABE scheme, a secret key works to decrypt a ciphertext if and only if the associated set of attributes satisfies the associated access policy. The remarkable feature of ABE is attribute privacy; that is, in decryption, no information about the access policy and the identity of the secret key owner in the case of KP-ABE (or, the attributes and the identity of the secret key owner in the case of CP-ABE) leaks except the fact that the set of attributes satisfies the access policy. Since the proposals, it has been studied to attain certain properties such as indistinguishability against chosen-plaintext attacks (IND-CPA) in the standard model [4] and adaptive security against adversary's choice of a target access policy [5].

In this paper[1], we work through resolving a problem of constructing a shorter ABE scheme that attains indistinguishability against chosen-ciphertext attacks (IND-CCA) in the standard model. Here CCA means that an adversary can collects decryption results of ciphertexts of its choice through adversaries' attacking. Note that "provable security" of a cryptographic primitive is now a must requirement when we employ the primitive in a system, where it means that an appropriately defined security is polynomially reduced to the hardness of a computational problem. Moreover, the CCA security of an encryption scheme is preferable to attain because the CCA security is one of the theoretically highest securities and hence the scheme can be used widely.

To capture the idea of our approach, let us recall the case of identity-based encryption (IBE). The CHK transformation of Canetti, Halevi and Katz [7] is a generic tool for obtaining IND-CCA secure IBE scheme. It transforms any hierarchical IBE (HIBE) scheme that is selective-ID IND-CPA secure [8] into an IBE scheme that is adaptive-ID IND-CCA secure [8]. A point of the CHK transformation is that it introduces a dummy identity vk that is a verification key of a one-time signature. Then a ciphertext is attached with vk and a signature σ, which is generated each time one executes encryption. In contrast, the direct chosen-ciphertext security technique for IBE of

[*]Hiroaki Anada, 1–1–1, Manabino, Nagayo-cho, Nishisonogi-gun, Nagasaki, +81-95-813-5113 & anada@sun.ac.jp

[1]This paper is an extension of the work originally presented in SMARTCOMP 2017 [6]. The schemes of KP-ABKEM and KP-ABE have been newly proposed.

https://dx.doi.org/10.25046/aj030132

Boyen, Mei and Waters [9] is individual modification for obtaining an IND-CCA secure IBE scheme. It converts a HIBE scheme that is adaptive-ID IND-CPA secure into an IBE scheme that is adaptive-ID IND-CCA secure. Though the technique needs to treat each scheme individually, the obtained scheme attains better performance than that obtained by the generic tool (the CHK transformation). Let us transfer into the case of ABE. The transformation in [10] is a generic tool for obtaining IND-CCA secure ABE scheme. It transforms any ABE scheme (with the delegatability or the verifiability [10]) that is IND-CPA secure into an ABE scheme that is IND-CCA secure. A point of their transformation is, similar to the case of IBE, that it introduces a dummy attribute vk that is a verification key of a one-time signature. Then a ciphertext is attached with vk and a signature σ. Notice here that discussing direct chosen-ciphertext security modification for ABE (in the standard model) is a missing piece. One of the reasons seems that there is an obstacle that a Diffie Hellman tuple to be verified is in the target group of a bilinear map. In that situation, the bilinear map looks of no use.

1.1 Our Contribution

A contribution is that we fill in the missing piece; we demonstrate direct chosen-ciphertext security modification in the case of the Waters CP-ABE scheme [4] and the KP-ABE scheme of Ostrovsky, Sahai and Waters [11] To overcome the above obstacle, we employ the technique of the Twin Diffie-Hellman Trapdoor Test of Cash, Kiltz and Shoup [12]. In addition, we also utilize the algebraic trick of Boneh and Boyen [13] and Kiltz [14] to reply for adversary's decryption queries.

1.2 Related Works

Waters [4] pointed out that IND-CCA security would be attained by the CHK transformation. Gorantla, Boyd and Nieto [15] constructed a IND-CCA secure CP-ABKEM in the random oracle model. In [10] the authors proposed a generic transformation of a IND-CPA secure ABE scheme into a IND-CCA secure ABE scheme. Their transformation is considered to be an ABE-version of the CHK transformation, and it is versatile. Especially, it can be applied to non-pairing-based scheme.

The Waters CP-ABE [4] can be captured as a CP-ABKEM: the blinding factor can be considered as a random one-time key. This Waters CP-ABKEM is IND-CPA secure because the Waters CP-ABE is proved to be IND-CPA secure. For theoretical simplicity, we demonstrate an individual conversion of the Waters CP-ABKEM into a CP-ABKEM which is IND-CCA secure. Then we provide a CP-ABE scheme which is IND-CCA secure. As for KP-ABE, we demonstrate an individual conversion of KP-ABKEM of Ostrovsky, Sahai and Waters [11], which is IND-CPA secure, into a KP-ABKEM which is IND-CCA secure. Then we provide a KP-ABE scheme which is IND-CCA secure.

Finally, we note that there is a remarkable work of CP-ABE schemes and KP-ABE schemes with *constant-size* ciphertexts [16, 17]. Our direct chosen-ciphertext security modification is not constant-size ciphertexts but a different approach for easier implementation in engineering.

1.3 Organization of the Paper

In Section 2, we survey concepts, definitions and techniques needed. In Section 3, we revisit the concept, the algorithm and the security of the twin Diffie-Hellman technique. In Section 4, we construct a CCA-secure CP-ABKEM from the Waters CPA-secure CP-ABKEM [4], and provide a security proof. Also, we describe the encryption version, a CCA-secure CP-ABE. In Section 5, we construct a CCA-secure KP-ABKEM from the Ostrovsky-Sahai-Waters CPA-secure KP-ABKEM [11], and provide a security proof. Also, we describe the encryption version, a CCA-secure KP-ABE. In Section 6, we compare efficiency of our CP-ABE and KP-ABE schemes with the original schemes, and also, with the schemes obtained by applying the generic transformation [10] to the original schemes. In Section 7, we conclude our work.

2 Preliminaries

The security parameter is denoted λ. A prime of bit length λ is denoted p. A multiplicative cyclic group of order p is denoted $\mathbb{G}$. The ring of exponent domain of $\mathbb{G}$, which consists of integers from 0 to $p-1$ with modulo p operation, is denoted $\mathbb{Z}_p$.

2.1 Bilinear Map

We remark first that our description in the subsequent sections is in the setting of a symmetric bilinear map for simplicity, but we can employ an asymmetric bilinear map instead for better efficiency as is noted in Section 6. Let $\mathbb{G}$ and $\mathbb{G}_T$ be two multiplicative cyclic groups of prime order p. Let g be a generator of $\mathbb{G}$ and e be a bilinear map, $e : \mathbb{G} \times \mathbb{G} \to \mathbb{G}_T$. The bilinear map e has the following properties:
1. Bilinearity: for all $u, v \in \mathbb{G}$ and $a, b \in \mathbb{Z}_p$, we have $e(u^a, v^b) = e(u, v)^{ab}$.
2. Non-degeneracy: $e(g, g) \neq \mathrm{id}_{\mathbb{G}_T}$ (: the identity element of the group $\mathbb{G}_T$).

Parameters of a bilinear map are generated by a probabilistic polynomial time (PPT) algorithm $\mathtt{Grp}$ on input λ: $(p, \mathbb{G}, \mathbb{G}_T, g, e) \leftarrow \mathtt{Grp}(\lambda)$.

Hereafter we assume that the group operation in $\mathbb{G}$ and $\mathbb{G}_T$ and the bilinear map $e : \mathbb{G} \times \mathbb{G} \to \mathbb{G}_T$ are computable in PT in λ.

2.2 Access Structure

Let $\mathcal{U} = \{\chi_1, \ldots, \chi_u\}$ be a set of attributes, or simply set $\mathcal{U} = \{1, \ldots, u\}$ by numbering. An *access structure*, which corresponds to an access policy, is defined as a collection $\mathbb{A}$ of non-empty subsets of $\mathcal{U}$; that is, $\mathbb{A} \subset 2^{\mathcal{U}} \setminus \{\phi\}$. An access structure $\mathbb{A}$ is called *monotone* if for any $B \in \mathbb{A}$ and $B \subset C$, $C \in \mathbb{A}$ holds. The sets in $\mathbb{A}$ are called authorized sets, and the sets not in $\mathbb{A}$ are called unauthorized sets. We will consider in this paper only monotone access structures.

2.3 Linear Secret-Sharing Scheme

We only describe a linear secret-sharing scheme (LSSS) in our context of attribute-based schemes. A secret-sharing scheme Π over the attribute universe $\mathcal{U}$ is called linear over $\mathbb{Z}_p$ if:
1. The shares for each attribute form a vector over $\mathbb{Z}_p$,
2. There exists a matrix M of size $l \times n$ called the share-generating matrix for Π and a function ρ which maps each row index i of M to an attribute in $\mathcal{U} = \{1, \ldots, u\}$: $\rho : \{1, ..., l\} \to \mathcal{U}$.

To make shares, we first choose a random vector $\vec{v} = (s, y_2, \ldots, y_n) \in \mathbb{Z}_p^n$: s is a secret to be shared. For $i = 1$ to l, we calculate each share $\lambda_i = \vec{v} \cdot M_i$, where M_i denotes the i-th row vector of M and $\cdot$ denotes the formal inner product. LSSS $\Pi = (M, \rho)$ defines an access structure $\mathbb{A}$ through ρ.

Suppose that an attribute set S satisfies $\mathbb{A}$ ($S \in \mathbb{A}$) and let $I_S = \rho^{-1}(S) \subset \{1, \ldots, l\}$. Then, let $\{\omega_i \in \mathbb{Z}_p; i \in I_S\}$ be a set of constants (*linear reconstruction constants*) such that if $\{\lambda_i \in \mathbb{Z}_p; i \in I_S\}$ are valid shares of a secret s according to M, then $\sum_{i \in I_S} \omega_i \lambda_i = s$. It is known that these constants $\{\omega_i\}_{i \in I_S}$ can be found in time polynomial in l: the row size of the share-generating matrix M. If S does not satisfy $\mathbb{A}$ ($S \notin \mathbb{A}$), then no such constants $\{\omega_i\}_{i \in I_S}$ exist.

2.4 Attribute-Based Key Encapsulation Mechanism

Ciphertext-policy attribute-based key encapsulation mechanism (CP-ABKEM). A CP-ABKEM consists of four PPT algorithms (Setup, Encap, KeyGen, Decap)[2].

Setup$(\lambda, \mathcal{U})$**.** A setup algorithm Setup takes as input the security parameter λ and the attribute universe $\mathcal{U} = \{1, \ldots, u\}$. It returns a public key PK and a master secret key MSK.

Encap$(\mathbf{PK}, \mathbb{A})$**.** An encapsulation algorithm Encap takes as input the public key PK and an access structure $\mathbb{A}$. It returns a random string κ and its encapsulation ψ. Note that $\mathbb{A}$ is contained in ψ.

KeyGen$(\mathbf{PK}, \mathbf{MSK}, S)$**.** A key generation algorithm KeyGen takes as input the public key PK, the master secret key MSK and an attribute set S. It returns a secret key SK_S corresponding to S. Note that S is contained in SK_S.

Decap$(\mathbf{PK}, \mathbf{SK}_S, \psi)$**.** A decapsulation algorithm Decap takes as input the public key PK, an encapsulation (we also call it a ciphertext according to context) ψ and a secret key SK_S. It first checks whether $S \in \mathbb{A}$, where S and $\mathbb{A}$ are contained in SK_S and ψ, respectively. If the check result is False, it puts $\hat{\kappa} = \perp$. It returns a decapsulation result $\hat{\kappa}$.

Chosen-Ciphertext Attack on CP-ABKEM. According to previous works (for example, see [15]), the chosen-ciphertext attack on a CP-ABKEM is formally defined as the indistinguishability game (IND-CCA game). In this paper, we consider the *selective game on a target access structure* (IND-sel-CCA game); that is, the adversary $\mathcal{A}$ declares a target access structure $\mathbb{A}^*$ *before* $\mathcal{A}$ receives a public key PK, which is defined as the following experiment.

$\mathbf{Experiment}^{\text{ind-sel-cca}}_{\mathcal{A},\mathtt{CP\text{-}ABKEM}}(\lambda, \mathcal{U})$
$\mathbb{A}^* \leftarrow \mathcal{A}(\lambda, \mathcal{U}), (\mathrm{PK}, \mathrm{MSK}) \leftarrow \mathbf{Setup}(\lambda, \mathcal{U})$
$\epsilon \leftarrow \mathcal{A}^{\mathbf{KeyGen}(\mathrm{PK},\mathrm{MSK},\cdot),\mathbf{Decap}(\mathrm{PK},\mathrm{SK}_\cdot,\cdot)}(\mathrm{PK})$
$(\kappa^*, \psi^*) \leftarrow \mathbf{Encap}(\mathrm{PK}, \mathbb{A}^*), \kappa \leftarrow KeySp(\lambda), b \leftarrow \{0, 1\}$
If $b = 1$ then $\tilde{\kappa} = \kappa^*$ else $\tilde{\kappa} = \kappa$
$b' \leftarrow \mathcal{A}^{\mathbf{KeyGen}(\mathrm{PK},\mathrm{MSK},\cdot),\mathbf{Decap}(\mathrm{PK},\mathrm{SK}_\cdot,\cdot)}(\tilde{\kappa}, \psi^*)$
If $b' = b$ then return Win else return Lose.

In the above experiment, two kinds of queries are issued by $\mathcal{A}$. One is key-extraction queries. Indicating an attribute set S_i, $\mathcal{A}$ queries its key-extraction oracle $\mathrm{KeyGen}(\mathrm{PK}, \mathrm{MSK}, \cdot)$ for the secret key SK_{S_i}. Here we do not require any input attribute sets S_{i_1} and S_{i_2} to be distinct. Another is decapsulation queries. Indicating a pair (S_j, ψ_j) of an attribute set and an encapsulation, $\mathcal{A}$ queries its decapsulation oracle $\mathrm{Decap}(\mathrm{PK}, \mathrm{SK}_\cdot, \cdot)$ for the decapsulation result $\hat{\kappa}_j$. Here an access structure $\mathbb{A}_j$, which is used to generate an encapsulation ψ_j, is implicitly included in ψ_j. In the case that $S \notin \mathbb{A}$, $\hat{\kappa}_j = \perp$ is replied to $\mathcal{A}$. Both kinds of queries are at most q_k and q_d times in total, respectively, which are polynomial in λ.

The access structure $\mathbb{A}^*$ declared by $\mathcal{A}$ is called a *target access structure*. Two restrictions are imposed on $\mathcal{A}$ concerning $\mathbb{A}^*$. In key-extraction queries, each attribute set S_i must satisfy $S_i \notin \mathbb{A}^*$. In decapsulation queries, each pair (S_j, ψ_j) must satisfy $S_j \notin \mathbb{A}^* \vee \psi_j \neq \psi^*$.

The *advantage* of the adversary $\mathcal{A}$ over CP-ABKEM in the IND-CCA game is defined as the following probability:

$$\mathbf{Adv}^{\text{ind-sel-cca}}_{\mathcal{A},\mathtt{CP\text{-}ABKEM}}(\lambda, \mathcal{U}) \stackrel{\text{def}}{=} \Pr[\mathbf{Experiment}^{\text{ind-sel-cca}}_{\mathcal{A},\mathtt{CP\text{-}ABKEM}}(\lambda, \mathcal{U}) \text{ returns Win}].$$

CP-ABKEM is called *selectively secure against chosen-ciphertext attacks* if, for any PPT adversary $\mathcal{A}$ and for any attribute universe $\mathcal{U}$, $\mathbf{Adv}^{\text{ind-sel-cca}}_{\mathcal{A},\mathtt{CP\text{-}ABKEM}}(\lambda, \mathcal{U})$ is negligible in λ. Here we must distinguish the two cases; the case that $\mathcal{U}$ is small (i.e. $|\mathcal{U}| = u$ is bounded by a polynomial of λ) and the case that $\mathcal{U}$ is large (i.e. u

[2] In Gorantla, Boyd and Nieto [15], they say *encapsulation-policy* attribute-based-KEM (EP-AB-KEM) instead of saying ciphertext-policy attribute-based KEM here.

is not necessarily bounded by a polynomial of λ). We assume the *small case* in this paper.

In the indistinguishability game against *chosen-plaintext attack* (IND-CPA game), the adversary $\mathcal{A}$ issues no decapsulation query (that is, $q_{\mathrm{d}} = 0$).

Ciphertext-Policy Attribute-Based Encryption Scheme (CP-ABE). In the case of the encryption version (i.e. CP-ABE), Encap(PK, $\mathbb{A}$) and Decap(PK, SK_S, ψ) are replaced by PPT algorithms Encrypt(PK, $\mathbb{A}$, m) and Decrypt(PK, SK_S, CT), respectively, where m and CT mean a message and a ciphertext, respectively.

The IND-CCA game for CP-ABE is defined in the same way as for CP-ABKEM above, except the following difference. In Challenge phase, the adversary $\mathcal{A}$ submits two equal length messages (plaintexts) m_0 and m_1. Then the challenger flips a coin $b \in \{0,1\}$ and gives an encryption result CT of m_b to $\mathcal{A}$. In Guess phase, the adversary $\mathcal{A}$ returns $b' \in \{0,1\}$. If $b' = b$, then $\mathcal{A}$ wins in the IND-CCA game. Otherwise, $\mathcal{A}$ loses.

Key-Policy Attribute-Based Key Encapsulation Mechanism (KP-ABKEM) and Encryption Scheme (KP-ABE). The *key-policy* case is analogously defined as the case of the ciphertext-policy case. We state only the syntax and the security experiment of the key-policy ABKEM.

Setup($\lambda, \mathcal{U}$)**.** A setup algorithm Setup takes as input the security parameter λ and the attribute universe $\mathcal{U} = \{1, \ldots, u\}$. It returns a public key PK and a master secret key MSK.

Encap(**PK**, S)**.** An encapsulation algorithm Encap takes as input the public key PK and an attribute set S. It returns a random string κ and its encapsulation ψ. Note that S is contained in ψ.

KeyGen(**PK**, **MSK**, $\mathbb{A}$)**.** A key generation algorithm KeyGen takes as input the public key PK, the master secret key MSK and an access structure $\mathbb{A}$. It returns a secret key $\mathrm{SK}_{\mathbb{A}}$ corresponding to S. Note that $\mathbb{A}$ is contained in $\mathrm{SK}_{\mathbb{A}}$.

Decap(**PK**, **SK**$_{\mathbb{A}}$, ψ)**.** A decapsulation algorithm Decap takes as input the public key PK, an encapsulation (we also call it a ciphertext according to context) ψ and a secret key $\mathrm{SK}_{\mathbb{A}}$. It first checks whether $S \in \mathbb{A}$. If the check result is False, it puts $\hat{\kappa} = \perp$. It returns a decapsulation result $\hat{\kappa}$.

Chosen-Ciphertext Attack on KP-ABKEM. The *selective game on a target attribute set* (IND-sel-CCA game) is defined by the following experiment.

$\mathbf{Experiment}^{\text{ind-sel-cca}}_{\mathcal{A},\mathsf{KP-ABKEM}}(\lambda, \mathcal{U})$
$S^* \leftarrow \mathcal{A}(\lambda, \mathcal{U}), (\mathrm{PK}, \mathrm{MSK}) \leftarrow \mathbf{Setup}(\lambda, \mathcal{U})$
$\epsilon \leftarrow \mathcal{A}^{\mathbf{KeyGen}(\mathrm{PK},\mathrm{MSK},\cdot),\mathbf{Decap}(\mathrm{PK},\mathrm{SK}_{\cdot},\cdot)}(\mathrm{PK})$
$(\kappa^*, \psi^*) \leftarrow \mathbf{Encap}(\mathrm{PK}, S^*), \kappa \leftarrow \mathit{KeySp}(\lambda), b \leftarrow \{0,1\}$
If $b = 1$ then $\tilde{\kappa} = \kappa^*$ else $\tilde{\kappa} = \kappa$
$b' \leftarrow \mathcal{A}^{\mathbf{KeyGen}(\mathrm{PK},\mathrm{MSK},\cdot),\mathbf{Decap}(\mathrm{PK},\mathrm{SK}_{\cdot},\cdot)}(\tilde{\kappa}, \psi^*)$
If $b' = b$ then return Win else return Lose.

2.5 Target Collision Resistant Hash Functions

Target collision resistant (TCR) hash functions [18] are treated as a family. Let us denote a function family as $\mathit{Hfam}(\lambda) = \{H_\mu\}_{\mu \in \mathit{HKey}(\lambda)}$. Here $\mathit{HKey}(\lambda)$ is a hash key space, $\mu \in \mathit{HKey}(\lambda)$ is a hash key and H_μ is a function from $\{0,1\}^*$ to $\{0,1\}^\lambda$. We may assume that H_μ is from $\{0,1\}^*$ to $\mathbb{Z}_p$, where p is a prime of length λ.

Given a PPT algorithm $\mathcal{CF}$, a collision finder, we consider the following experiment (the target collision resistance game).

$\mathbf{Experiment}^{\mathrm{tcr}}_{\mathcal{CF},\mathit{Hfam}}(\lambda)$
$m^* \leftarrow \mathcal{CF}(\lambda), \mu \leftarrow \mathit{HKey}(\lambda), m \leftarrow \mathcal{CF}(\mu)$
If $m^* \neq m \wedge H_\mu(m^*) = H_\mu(m)$
then return Win else return Lose.

Then we define *$\mathcal{CF}$'s advantage over Hfam in the game of target collision resistance* as follows.

$$\mathbf{Adv}^{\mathrm{tcr}}_{\mathcal{CF},\mathit{Hfam}}(\lambda) \stackrel{\mathrm{def}}{=} \Pr[\mathbf{Experiment}^{\mathrm{tcr}}_{\mathcal{CF},\mathit{Hfam}}(\lambda) \text{ returns Win}].$$

We say that *Hfam* is *a TCR function family* if, for any PPT algorithm $\mathcal{CF}$, $\mathbf{Adv}^{\mathrm{tcr}}_{\mathcal{CF},\mathit{Hfam}}(\lambda)$ is negligible in λ.

TCR hash function families can be constructed based on the existence of a one-way function [18].

3 The Twin Diffie-Hellman Technique Revisited

A 6-tuple $(g, X_1, X_2, Y, Z_1, Z_2) \in \mathbb{G}^6$ is called a *twin Diffie-Hellman tuple* if the tuple is written as $(g, g^{x_1}, g^{x_2}, g^y, g^{x_1 y}, g^{x_2 y})$ for some elements x_1, x_2, y in $\mathbb{Z}_p$. In other words, a 6-tuple $(g, X_1, X_2, Y, Z_1, Z_2)$ is a twin Diffie-Hellman tuple (twin DH tuple, for short) if $Y = g^y$ and $Z_1 = X_1^y$ and $Z_2 = X_2^y$.

The following lemma of Cash, Kiltz and Shoup will be used in the security proof to decide whether a tuple is a twin DH tuple or not.

Lemma 1 ("Trapdoor Test"[12]) *Let X_1, r, s be mutually independent random variables, where X_1 takes values in $\mathbb{G}$, and each of r, s is uniformly distributed over $\mathbb{Z}_p$. Define the random variable $X_2 = X_1^{-r} g^s$. Suppose that $\hat{Y}, \hat{Z}_1, \hat{Z}_2$ are random variables taking values in $\mathbb{G}$, each of which is defined independently of r. Then the probability that the truth value of $\hat{Z}_1{}^r \hat{Z}_2 = \hat{Y}^s$ does not agree with the truth value of $(g, X_1, X_2, \hat{Y}, \hat{Z}_1, \hat{Z}_2)$ being a twin DH tuple is at most $1/p$. Moreover, if $(g, X_1, X_2, \hat{Y}, \hat{Z}_1, \hat{Z}_2)$ is a twin DH tuple, then $\hat{Z}_1{}^r \hat{Z}_2 = \hat{Y}^s$ certainly holds.*

Note that Lemma 1 is a statistical property. Especially, Lemma 1 holds without any number theoretic assumption. To be precise, we consider the following experiment of an algorithm *Cheat* with *unbounded computational power (not limited to PPT)*, where *Cheat*, given a triple (g, X_1, X_2), tries to complete a 6-tuple $(g, X_1, X_2, \hat{Y}, \hat{Z}_1, \hat{Z}_2)$ which passes the "Trapdoor Test" but which is *not* a twin DH tuple.

$$\begin{aligned}&\textbf{Experiment}^{\text{twinDH-test}}_{Cheat,\mathbb{G}}(\lambda)\\&(g,X_1)\leftarrow\mathbb{G}^2,(r,s)\leftarrow\mathbb{Z}_p^2,X_2=X_1^{-r}g^s\\&\mathbb{G}^3\ni(\hat{Y},\hat{Z}_1,\hat{Z}_2)\leftarrow Cheat(g,X_1,X_2)\\&\text{If }\hat{Z}_1{}^r\hat{Z}_2=\hat{Y}^s\wedge(g,X_1,X_2,\hat{Y},\hat{Z}_1,\hat{Z}_2)\\&\qquad\text{is NOT a twin DH tuple,}\\&\qquad\text{then return Win else return Lose}\end{aligned}$$

Let us define the advantage of *Cheat* over $\mathbb{G}$ as follows.

$$\begin{aligned}&\textbf{Adv}^{\text{twinDH-test}}_{Cheat,\mathbb{G}}(\lambda)\\&\stackrel{\text{def}}{=}\Pr[\textbf{Experiment}^{\text{twinDH-test}}_{Cheat,\mathbb{G}}(\lambda)\text{ returns Win}].\end{aligned}$$

Now we are ready to complement Lemma 1.

Lemma 2 (Complement for "Trapdoor Test" [12]) *For any algorithm* Cheat *with unbounded computational power,* $\textbf{Adv}^{twinDH\text{-}test}_{\text{Cheat},\mathbb{G}}(\lambda)$ *is at most* $1/p$.

For a proof of Lemma 2, see Appendix A.

4 Securing the Waters CP-ABKEM against Chosen-Ciphertext Attacks

In this section, we describe our direct chosen-ciphertext security technique by applying it to the Waters CP-ABE [4].

Overview of Our Modification The Waters CP-ABE is proved to be secure in the IND-sel-CPA game [4]. We convert it into a scheme that is secure in the IND-sel-CCA game by employing the Twin Diffie-Hellman technique of Cash, Kiltz and Shoup [12] and the algebraic trick of Boneh and Boyen [13] and Kiltz [14].

In encryption, a ciphertext becomes to contain additional two elements (d_1,d_2), which function in decryption as a "check sum" to verify that a tuple is certainly a twin DH tuple.

In security proof, the Twin Diffie-Hellman Trapdoor Test does the function instead. It is noteworthy that we are unable to use the bilinear map instead because the tuple to be verified is in the target group. In addition, the algebraic trick enables to answer for adversary's decryption queries. Note also that the both technique become compatible by introducing random variables.

Key Encapsulation and Encryption. The Waters CP-ABE can be captured as a CP-ABKEM: the blinding factor of the form $e(g,g)^{\alpha s}$ in the Waters CP-ABE can be considered as a random one-time key. So we call it the Waters CP-ABKEM hereafter and denote it as $\texttt{CP-ABKEM}_{\text{cpa}}$. Likewise, we distinguish parameters and algorithms of $\texttt{CP-ABKEM}_{\text{cpa}}$ by the index $_{\text{cpa}}$. For theoretical simplicity, we first develop a KEM CP-ABKEM.

4.1 Our Construction

Our CP-ABKEM consists of the following four PPT algorithms (Setup, Encap, KeyGen, Decap). Roughly speaking, the Waters original scheme $\texttt{CP-ABKEM}_{\text{cpa}}$ (the first scheme in [4]) corresponds to the case $k=1$ below excluding the "check sum" (d_1,d_2).

Setup$(\lambda,\mathcal{U})$**.** Setup takes as input the security parameter λ and the attribute universe $\mathcal{U}=\{1,\ldots,u\}$. It runs $\texttt{Grp}(\lambda)$ to get $(p,\mathbb{G},\mathbb{G}_T,g,e)$, where $\mathbb{G}$ and $\mathbb{G}_T$ are cyclic groups of order p, $e:\mathbb{G}\times\mathbb{G}\to\mathbb{G}_T$ is a bilinear map and g is a generator of $\mathbb{G}$. These become public parameters. Then Setup chooses u random group elements $h_1,\ldots,h_u\in\mathbb{G}$ that are associated with the u attributes. In addition, it chooses random exponents $\alpha_k\in\mathbb{Z}_p,k=1,\ldots,4,a\in\mathbb{Z}_p$ and a hash key $\eta\in HKey(\lambda)$. The public key is published as $\text{PK}=(g,g^a,h_1,\ldots,h_u,e(g,g)^{\alpha_1},\ldots,e(g,g)^{\alpha_4},\eta)$. The authority sets $\text{MSK}=(g^{\alpha_1},\ldots,g^{\alpha_4})$ as the master secret key.

Encap$(\textbf{PK},\mathbb{A})$**.** The encapsulation algorithm Encap takes as input the public key PK and an LSSS access structure $\mathbb{A}=(M,\rho)$, where M is an $l\times n$ matrix and ρ is the function which maps each row index i of M to an attribute in $\mathcal{U}=\{1,\ldots,u\}$. Encap first chooses a random value $s\in\mathbb{Z}_p$ that is the encryption randomness, and chooses random values $y_2,\ldots,y_n\in\mathbb{Z}_p$. Then Encap forms a vector $\vec{v}=(s,y_2,\ldots,y_n)$. For $i=1$ to l, it calculates $\lambda_i=\vec{v}\cdot M_i$, where M_i denotes the i-th row vector of M. In addition, Encap chooses random values $r_1,\ldots,r_l\in\mathbb{Z}_p$. Then, a pair of a random one-time key and its encapsulation (κ,ψ) is computed as follows.

$$\begin{aligned}&\text{Put }C'=g^s;\text{For }i=1\text{ to }l:C_i=g^{a\lambda_i}h_{\rho(i)}^{-r_i},D_i=g^{r_i};\\&\psi_{\text{cpa}}=(\mathbb{A},C',((C_i,D_i);i=1,\ldots,l)),\tau\leftarrow H_\eta(\psi_{\text{cpa}});\\&\text{For }k=1\text{ to }4:\kappa_k=e(g,g)^{\alpha_k s};d_1=\kappa_1^\tau\kappa_3,d_2=\kappa_2^\tau\kappa_4;\\&(\kappa,\psi)=(\kappa_1,(\psi_{\text{cpa}},d_1,d_2)).\end{aligned}$$

KeyGen$(\textbf{MSK},\textbf{PK},S)$**.** The key generation algorithm KeyGen takes as input the master secret key MSK, the public key PK and a set S of attributes. KeyGen first chooses a random $t_k\in\mathbb{Z}_p,k=1,\ldots,4$. It generates the secret key SK_S as follows.

$$\begin{aligned}&\text{For }k=1\text{ to }4:K_k=g^{\alpha_k}g^{at_k},L_k=g^{t_k}\\&\quad\text{For }x\in S:K_{k,x}=h_x^{t_k};\\&\text{SK}_S=((K_k,L_k,(K_{k,x};x\in S));k=1,\ldots,4).\end{aligned}$$

Decap$(\textbf{PK},\psi,\textbf{SK}_S)$**.** The decapsulation algorithm Decap takes as input the public key PK, an encapsulation ψ for an access structure $\mathbb{A}=(M,\rho)$ and a private key SK_S for an attribute set S. It first checks whether $S\in\mathbb{A}$. If the result is False, put $\hat{\kappa}=\perp$. Otherwise, let $I_S=\rho^{-1}(S)\subset\{1,\ldots,l\}$ and let $\{\omega_i\in\mathbb{Z}_p;i\in I_S\}$ be a set of linear reconstruction constants. Then, the decapsu-

lation $\hat{\kappa}$ is computed as follows.

Parse ψ into $(\psi_{\mathrm{cpa}} = (\mathbb{A}, C', ((C_i, D_i); i = 1, \ldots, l)), d_1, d_2)$;
$\tau \leftarrow H_\eta(\psi_{\mathrm{cpa}})$;
For $k = 1$ to 4 :

$$\hat{\kappa_k} = e(C', K_k) / \prod_{i \in I_S} (e(L_k, C_i) e(D_i, K_{k,\rho(i)}))^{\omega_i} = e(g,g)^{\alpha_k s}$$

If ${\hat{\kappa_1}}^{\tau} \hat{\kappa_3} \neq d_1 \vee {\hat{\kappa_2}}^{\tau} \hat{\kappa_4} \neq d_2$,
then put $\hat{\kappa} = \perp$, else put $\hat{\kappa} = \hat{\kappa_1}$.

4.2 Security and Proof

Theorem 1 *If the Waters CP-ABKEM$_{cpa}$ [4] is selectively secure against chosen-plaintext attacks and an employed hash function family Hfam has target collision resistance, then our CP-ABKEM is selectively secure against chosen-ciphertext attacks. More precisely, for any given PPT adversary $\mathcal{A}$ that attacks CP-ABKEM in the IND-sel-CCA game where decapsulation queries are at most q_d times, and for any small attribute universe $\mathcal{U}$, there exist a PPT adversary $\mathcal{B}$ that attacks CP-ABKEM$_{cpa}$ in the IND-sel-CPA game and a PPT target collision finder $\mathcal{CF}$ on Hfam that satisfy the following tight reduction.*

$$\begin{aligned} &\mathbf{Adv}^{ind\text{-}sel\text{-}cca}_{\mathcal{A},CP\text{-}ABKEM}(\lambda, \mathcal{U}) \\ \leq &\mathbf{Adv}^{ind\text{-}sel\text{-}cpa}_{\mathcal{B},CP\text{-}ABKEM_{cpa}}(\lambda, \mathcal{U}) + \mathbf{Adv}^{tcr}_{\mathcal{CF},Hfam}(\lambda) + \frac{q_d}{p}. \end{aligned}$$

Proof. Given any adversary $\mathcal{A}$ that attacks our scheme CP-ABKEM in the IND-sel-CCA game, we construct an adversary $\mathcal{B}$ that attacks the Waters scheme CP-ABKEM$_{\mathrm{cpa}}$ in the IND-sel-CPA game as follows.

Commit to a Target Access Structure. $\mathcal{B}$ is given $(\lambda, \mathcal{U})$ as inputs, where λ is the security parameter and $\mathcal{U} = \{1, \ldots, u\}$ is the attribute universe. $\mathcal{B}$ invokes $\mathcal{A}$ on input $(\lambda, \mathcal{U})$ and gets a target access structure $\mathbb{A}^* = (M^*, \rho^*)$ from $\mathcal{A}$, where M^* is of size $l^* \times n^*$. $\mathcal{B}$ uses $\mathbb{A}^*$ as the target access structure of itself and outputs $\mathbb{A}^*$.

Set up. In return to outputting $\mathbb{A}^*$, $\mathcal{B}$ receives the public key $\mathrm{PK}_{\mathrm{cpa}}$ for CP-ABKEM$_{\mathrm{cpa}}$, which consists of the following components.

$$\mathrm{PK}_{\mathrm{cpa}} = (g, g^a, h_1, \ldots, h_u, e(g,g)^\alpha).$$

To set up a public key PK for CP-ABKEM, $\mathcal{B}$ *herein* needs a challenge instance: $\mathcal{B}$ queries its challenger and gets a challenge instance $(\tilde{\kappa}, \psi^*_{\mathrm{cpa}})$. It consists of the following components.

$\tilde{\kappa} = e(g,g)^{\alpha s^*}$ OR a random one-time key $\kappa \in \mathit{KeySp}(\lambda)$,
$\psi^*_{\mathrm{cpa}} = (\mathbb{A}^*, C'^* = g^{s^*}, ((C_i^*, D_i^*); i = 1, \ldots, l^*))$.

Then $\mathcal{B}$ makes the rest of parameters of PK as follows.

Choose $\eta \leftarrow \mathit{HKey}(\lambda)$ and take $\tau^* \leftarrow H_\eta(\psi^*_{\mathrm{cpa}})$;
Put $e(g,g)^{\alpha_1} = e(g,g)^\alpha$;
Choose $\gamma_1, \gamma_2 \leftarrow \mathbb{Z}_p$, put $e(g,g)^{\alpha_2} = e(g,g)^{\gamma_2} / e(g,g)^{\alpha_1 \gamma_1}$;
Choose $\mu_1, \mu_2 \leftarrow \mathbb{Z}_p$, put $e(g,g)^{\alpha_3} = e(g,g)^{\mu_1} / e(g,g)^{\alpha_1 \tau^*}$,

$$e(g,g)^{\alpha_4} = e(g,g)^{\mu_2} / e(g,g)^{\alpha_2 \tau^*}.$$

Note we have implicitly set relations in the exponent domain:

$$\begin{aligned} &\alpha_2 = \gamma_2 - \alpha_1 \gamma_1, \quad \alpha_3 = \mu_1 - \alpha_1 \tau^*, \\ &\alpha_4 = \mu_2 - \alpha_2 \tau^* = \mu_2 - (\gamma_2 - \alpha_1 \gamma_1) \tau^*. \end{aligned} \tag{1}$$

A public key PK for CP-ABKEM become:

$$\mathrm{PK} = (\mathrm{PK}_{\mathrm{cpa}}, e(g,g)^{\alpha_2}, e(g,g)^{\alpha_3}, e(g,g)^{\alpha_4}, \eta).$$

Then $\mathcal{B}$ inputs PK into $\mathcal{A}$. Note that PK determines the corresponding MSK uniquely.

Phase 1. $\mathcal{B}$ answers for two types of $\mathcal{A}$'s queries as follows.

(1) Key-Extraction Queries. In the case that $\mathcal{A}$ issues a key-extraction query for an attribute set $S \subset \mathcal{U}$, $\mathcal{B}$ has to simulate $\mathcal{A}$'s challenger. To do so, $\mathcal{B}$ issues key-extraction queries to $\mathcal{B}$'s challenger for S *repeatedly up to four times*. As replies, $\mathcal{B}$ gets four secret keys of the Waters CP-ABKEM$_{\mathrm{cpa}}$ for a single attribute set S:

$$\mathrm{SK}_{\mathrm{cpa},S,k} = (K_{\mathrm{cpa},k}, L_{\mathrm{cpa},k}, (K_{\mathrm{cpa},k,x}; x \in \mathcal{S})), k = 1, \ldots, 4.$$

We remark that, according to the randomness in the key-generation algorithm of the Waters CP-ABKEM$_{\mathrm{cpa}}$, all four secret keys $\mathrm{SK}_{\mathrm{cpa},S,1}, \ldots, \mathrm{SK}_{\mathrm{cpa},S,4}$ are random and mutually independent. To reply a secret key SK_S of our CP-ABKEM to $\mathcal{A}$, $\mathcal{B}$ converts the four secret keys as follows.

$$\begin{aligned} &K_1 = K_{\mathrm{cpa},1}, && L_1 = L_{\mathrm{cpa},1},\ K_{1,x} = K_{\mathrm{cpa},1,x}, x \in S; \\ &K_2 = g^{\gamma_2} K_{\mathrm{cpa},2}^{-\gamma_1}, && L_2 = L_{\mathrm{cpa},2}^{-\gamma_1},\ K_{2,x} = K_{\mathrm{cpa},2,x}^{-\gamma_1},\ x \in S; \\ &K_3 = g^{\mu_1} K_{\mathrm{cpa},3}^{-\tau^*}, && L_3 = L_{\mathrm{cpa},3}^{-\tau^*},\ K_{3,x} = K_{\mathrm{cpa},3,x}^{\tau^*},\ x \in S; \\ &K_4 = g^{\mu_2 - \gamma_2 \tau^*} K_{\mathrm{cpa},4}^{\gamma_1 \tau^*}, && L_4 = L_{\mathrm{cpa},4}^{\gamma_1 \tau^*},\ K_{4,x} = K_{\mathrm{cpa},4,x}^{\gamma_1 \tau^*},\ x \in S. \end{aligned}$$

Then $\mathcal{B}$ replies $\mathrm{SK}_S = ((K_k, L_k, (K_{k,x}; x \in S)); k = 1, \ldots, 4)$ to $\mathcal{A}$.

(2) Decapsulation Queries. In the case that $\mathcal{A}$ issues a decapsulation query for (S, ψ), where $S \subset \mathcal{U}$ is an attribute set and $\psi = (\psi_{\mathrm{cpa}}, d_1, d_2)$ is an encapsulation concerning $\mathbb{A}$, $\mathcal{B}$ has to simulate $\mathcal{A}$'s challenger. To do so, $\mathcal{B}$ computes the decapsulation result $\hat{\kappa}$ as follows.

If $S \notin \mathbb{A}$ then put $\hat{\kappa} = \perp$,
else
  $\tau \leftarrow H_\eta(\psi_{\mathrm{cpa}})$;
  $\hat{Y} = e(C', g)^{\tau - \tau^*}, \hat{Z}_1 = d_1 / e(C', g)^{\mu_1}, \hat{Z}_2 = d_2 / e(C', g)^{\mu_2}$;
  If ${\hat{Z}_1}^{\gamma_1} \hat{Z}_2 \neq \hat{Y}^{\gamma_2}$ (: call this checking TwinDH-Test)
    then put $\hat{\kappa} = \hat{\kappa_1} = \perp$
  else
    If $\tau = \tau^*$ then abort (: call this case Abort)
    else $\hat{\kappa} = \hat{\kappa_1} = {\hat{Z}_1}^{1/(\tau - \tau^*)}$.

Challenge. In the case that $\mathcal{A}$ queries its challenger for a challenge instance, $\mathcal{B}$ makes a challenge instance as follows.

$$\begin{aligned} &\text{Put } d_1^* = e(C'^*, g)^{\mu_1}, d_2^* = e(C'^*, g)^{\mu_2}; \\ &\text{Put } \psi^* = (\psi^*_{\mathrm{cpa}}, d_1^*, d_2^*). \end{aligned}$$

Then $\mathcal{B}$ feeds $(\tilde{\kappa}, \psi^*)$ to $\mathcal{A}$ as a challenge instance.
Phase 2. The same as in Phase 1.
Guess. In the case that $\mathcal{A}$ returns $\mathcal{A}$'s guess $\tilde{b}$, $\mathcal{B}$ returns $\tilde{b}$ itself as $\mathcal{B}$'s guess.

In the above construction of $\mathcal{B}$, $\mathcal{B}$ can perfectly simulate the real view of $\mathcal{A}$ until the case Abort happens, except for a negligible case, and hence the algorithm $\mathcal{A}$ works as designed. To see the perfect simulation with a negligible exceptional case, we are enough to prove the following seven claims.

Claim 1 *The reply $SK_S = ((K_k, L_k, (K_{k,x}; x \in S)); k = 1, \ldots, 4)$ for a key-extraction query of $\mathcal{A}$ is a perfect simulation.*

Proof. We must consider the implicit relations (1). For the index 2, we have implicitly set the randomness $t_2 = t_{\mathrm{cpa},2}(-\gamma_1)$ and we get:

$$\begin{aligned}
K_2 &= g^{\gamma_2} K_{\mathrm{cpa},2}^{-\gamma_1} = g^{\gamma_2} (g^{\alpha_1} g^{a t_{\mathrm{cpa},2}})^{-\gamma_1} \\
&= g^{\gamma_2} (g^{\alpha_1} g^{a t_2/(-\gamma_1)})^{-\gamma_1} = g^{\gamma_2 - \alpha_1 \gamma_1} g^{a t_2} = g^{\alpha_2} g^{a t_2}, \\
L_2 &= L_{\mathrm{cpa},2}^{-\gamma_1} = (g^{t_{\mathrm{cpa},2}})^{-\gamma_1} = g^{t_2}, \\
K_{2,x} &= K_{\mathrm{cpa},2,x}^{-\gamma_1} = (h_x^{t_{\mathrm{cpa},2}})^{-\gamma_1} = h_x^{t_2}, x \in S.
\end{aligned}$$

For the index 3 and 4, see Appendix B.

Claim 2 *$(e(g,g),\ e(g,g)^{\alpha_1},\ e(g,g)^{\alpha_2},\ \hat{Y},\ \hat{Z}_1,\ \hat{Z}_2)$ is a twin Diffie-Hellman tuple if and only if $(e(g,g),\ e(g,g)^{\alpha_1 \tau} e(g,g)^{\alpha_3},\ e(g,g)^{\alpha_2 \tau} e(g,g)^{\alpha_4},\ e(C', g),\ d_1,\ d_2)$ is a twin Diffie-Hellman tuple.*

Proof. This claim can be proved by a short calculation. See Appendix C. □

Claim 3 *If $(e(g,g), e(g,g)^{\alpha_1}, e(g,g)^{\alpha_2}, \hat{Y}, \hat{Z}_1, \hat{Z}_2)$ is a twin Diffie-Hellman tuple, then $(\hat{Y}, \hat{Z}_1, \hat{Z}_2)$ certainly passes the* TwinDH-Test*: $\hat{Z}_1^{\gamma_1} \hat{Z}_2 = \hat{Y}^{\gamma_2}$.*

Proof. This claim is a direct consequence of Lemma 1. □

Claim 4 *Consider the following event which we name as* Overlook$_i$*:*

In the i-th TwinDH-Test*, the following condition holds:*

$$\begin{cases} \hat{Z}_1^{\gamma_1} \hat{Z}_2 = \hat{Y}^{\gamma_2} \text{ holds and} \\ (e(g,g), e(g,g)^{\alpha_1}, e(g,g)^{\alpha_2}, \hat{Y}, \hat{Z}_1, \hat{Z}_2) \\ \quad \text{is NOT a twin DH tuple.} \end{cases}$$

Then, for at most q_d times decapsulation queries of $\mathcal{A}$, the probability that at least one Overlook$_i$ *occurs is negligible in λ. More precisely, the following inequality holds:*

$$\Pr[\bigvee_{i=1}^{q_d} \textsc{Overlook}_i] \leq q_d/p. \tag{2}$$

Proof. To apply Lemma 2, we construct an algorithm $Cheat_{\lambda,\mathcal{U}}$ with unbounded computational power, which takes as input $(e(g,g), e(g,g)^{\alpha_1}, e(g,g)^{\alpha_2})$ and returns $(\hat{Y}, \hat{Z}_1, \hat{Z}_2)$ employing the adversary $\mathcal{A}$ as a subroutine. Fig. 1 shows the construction.

First, note that the view of $\mathcal{A}$ in $Cheat_{\lambda,\mathcal{U}}$ is the same as the real view of $\mathcal{A}$ and hence the algorithm $\mathcal{A}$ works as designed.

Second, note that the return $(\hat{Y}, \hat{Z}_1, \hat{Z}_2)$ of $Cheat_{\lambda,\mathcal{U}}$ is randomized in TABLE. Hence:

$$\begin{aligned}
&\sum_{i=1}^{q_\mathrm{d}} \frac{1}{q_\mathrm{d}} \Pr[\textsc{Overlook}_i] = \frac{1}{q_\mathrm{d}} \sum_{i=1}^{q_\mathrm{d}} \Pr[\textsc{Overlook}_i] \\
&= \mathbf{Adv}^{\text{twinDH-test}}_{Cheat_{\lambda,\mathcal{U}},\mathbb{G}}(\lambda).
\end{aligned} \tag{3}$$

Third, applying Lemma 2 to $Cheat_{\lambda,\mathcal{U}}$, we get:

$$\mathbf{Adv}^{\text{twinDH-test}}_{Cheat_{\lambda,\mathcal{U}},\mathbb{G}}(\lambda) \leq 1/p. \tag{4}$$

Combining (3) and (4), we have:

$$\begin{aligned}
&\Pr[\bigvee_{i=1}^{q_\mathrm{d}} \textsc{Overlook}_i] \leq \sum_{i=1}^{q_\mathrm{d}} \Pr[\textsc{Overlook}_i] \\
&\leq q_\mathrm{d} \mathbf{Adv}^{\text{twinDH-test}}_{Cheat_{\lambda,\mathcal{U}},\mathbb{G}}(\lambda) \leq \frac{q_\mathrm{d}}{p}.
\end{aligned}$$

Claim 5 *The probability that* Overlook$_i$ *never occurs in* TwinDH-Test *for every i and* Abort *occurs is negligible in λ. More precisely, the following inequality holds:* □

$$\Pr[\Big(\bigwedge_{i=1}^{q_d} \neg \textsc{Overlook}_i\Big) \wedge \textsc{Abort}] \leq \mathbf{Adv}^{tcr}_{\mathcal{CF},Hfam}(\lambda). \tag{5}$$

Proof. This claim is proved by constructing a collision finder $\mathcal{CF}$ on *Hfam*. See Appendix D. □

Claim 6 *The reply $\hat{\kappa}$ to $\mathcal{A}$ as an answer for a decapsulation query is correct.*

Claim 7 *The challenge instance $\psi^* = (\psi^*_{cpa}, d_1^*, d_2^*)$ is correctly distributed.*

Proof. These two claims are proved by a direct calculation. See Appendices E and F, respectively. □

Evaluation of the Advantage of $\mathcal{B}$. Now we are ready to evaluate the advantage of $\mathcal{B}$ in the IND-sel-CPA game. That $\mathcal{A}$ wins in the IND-sel-CCA game means that $(\tilde{\kappa}, \psi^* = (\psi^*_{\mathrm{cpa}}, d_1^*, d_2^*))$ is correctly guessed. This is equivalent to that $(\tilde{\kappa}, \psi^*_{\mathrm{cpa}})$ is correctly guessed because ψ^*_{cpa} determines the consistent blinding factor $\kappa^* = e(g,g)^{\alpha s^*}$ uniquely. This means that $\mathcal{B}$ wins in the IND-sel-CPA game.

Therefore, the probability that $\mathcal{B}$ wins is equal to the probability that $\mathcal{A}$ wins, Overlook$_i$ never holds in TwinDH-Testfor each i and Abort never occurs. So

Given $(e(g,g), e(g,g)^{\alpha_1}, e(g,g)^{\alpha_2})$ as input :
Set up
Initialize the inner state, put TABLE = ϕ;
Get a target access structure $\mathbb{A}^* \leftarrow \mathcal{A}(\lambda, \mathcal{U})$;
Compute the base $g \in \mathbb{G}$ from $(e(g,g), e)$;
Choose $a \in \mathbb{Z}_p$ and $h_1, \ldots, h_u \in \mathbb{G}$;
Put $\mathrm{PK}_{\mathrm{cpa}} = (g, g^a, h_1, \ldots, h_u, e(g,g)^{\alpha_1})$;
Get $(\kappa^*, \psi^*_{\mathrm{cpa}}) \leftarrow \mathbf{Encap}_{\mathrm{cpa}}(\mathrm{PK}_{\mathrm{cpa}}, \mathbb{A}^*)$;
Choose $\eta \leftarrow \mathit{HKey}(\lambda)$ and compute $\tau^* \leftarrow H_\eta(\psi^*_{\mathrm{cpa}})$;
Compute discrete logarithms $\alpha_1, \alpha_2 \in \mathbb{Z}_p$ of $e(g,g)^{\alpha_1}, e(g,g)^{\alpha_2}$ to the base $e(g,g)$;
Choose $\mu_1, \mu_2 \leftarrow \mathbb{Z}_p$, put $\alpha_3 = \mu_1 - \alpha_1\tau^*, \alpha_4 = \mu_2 - \alpha_2\tau^*$;
Put $\mathrm{PK} = (\mathrm{PK}_{\mathrm{cpa}}, e(g,g)^{\alpha_2}, e(g,g)^{\alpha_3}, e(g,g)^{\alpha_4}, \eta), \mathrm{MSK} = (g^{\alpha_1}, g^{\alpha_2}, g^{\alpha_3}, g^{\alpha_4})$;
Give PK to $\mathcal{A}$;
Phase 1
In the case that $\mathcal{A}$ makes a key-extraction query for $S \subset \mathcal{U}$;
Reply SK_S to $\mathcal{A}$ in the same way as **KeyGen** does using MSK;
In the case that $\mathcal{A}$ makes a decapsulation query for $(\mathbb{A}, \psi = (\psi_{\mathrm{cpa}}, d_1, d_2), S)$;
Reply $\hat{\kappa}$ to $\mathcal{A}$ in the same way as **Decap** does using MSK;
Compute $\hat{Y} = e(C', g)^{\tau - \tau^*}, \hat{Z}_1 = d_1 / e(C', g)^{\mu_1}, \hat{Z}_2 = d_2 / e(C', g)^{\mu_2}$;
Update TABLE = TABLE $\cup (\hat{Y}, \hat{Z}_1, \hat{Z}_2)$;
Challenge
In the case that $\mathcal{A}$ makes a challenge instance query;
Put $d^*_1 = e(C'^*, g)^{\mu_1}, d^*_2 = e(C'^*, g)^{\mu_2}, \psi^* = (\psi^*_{\mathrm{cpa}}, d^*_1, d^*_2)$;
Choose $\kappa \leftarrow \mathit{KeySp}(\lambda), b \leftarrow \{0,1\}$;
If $b = 1$ then put $\tilde{\kappa} = \kappa^*$ else put $\tilde{\kappa} = \kappa$;
Reply $(\tilde{\kappa}, \psi^*)$ to $\mathcal{A}$;
Phase 2
The same as in Phase 1;
Return
In the case that $\mathcal{A}$ returns its guess b^*;
Choose one triple $(\hat{Y}, \hat{Z}_1, \hat{Z}_2)$ from TABLE at random;
Return $(\hat{Y}, \hat{Z}_1, \hat{Z}_2)$.

Figure 1: An Algorithm $\mathit{Cheat}_{\lambda,\mathcal{U}}$ with Unbounded Computational Power for a Proof of Claim 4.

we have:

$$
\begin{aligned}
&\Pr[\mathcal{B} \text{ wins}] \\
&= \Pr[(\mathcal{A} \text{ wins}) \wedge \Big(\bigwedge_{i=1}^{q_{\mathrm{d}}} \neg\textsc{Overlook}_i\Big) \wedge (\neg\textsc{Abort})] \\
&= \Pr[\mathcal{A} \text{ wins}] \\
&\quad - \Pr[(\mathcal{A} \text{ wins}) \wedge \neg\Big(\Big(\bigwedge_{i=1}^{q_{\mathrm{d}}} \neg\textsc{Overlook}_i\Big) \wedge (\neg\textsc{Abort})\Big)] \\
&\geq \Pr[\mathcal{A} \text{ wins}] - \Pr[\neg\Big(\Big(\bigwedge_{i=1}^{q_{\mathrm{d}}} \neg\textsc{Overlook}_i\Big) \wedge (\neg\textsc{Abort})\Big)] \\
&= \Pr[\mathcal{A} \text{ wins}] \\
&\quad - (\Pr[\bigvee_{i=1}^{q_{\mathrm{d}}} \textsc{Overlook}_i] + \Pr[\Big(\bigwedge_{i=1}^{q_{\mathrm{d}}} \neg\textsc{Overlook}_i\Big) \wedge \textsc{Abort}]).
\end{aligned}
$$

Substituting (2), (5) and advantages into the above, we have:

$$
\begin{aligned}
&\mathbf{Adv}^{\text{ind-sel-cpa}}_{\mathcal{B},\mathtt{CP\text{-}ABKEM}_{\mathrm{cpa}}}(\lambda, \mathcal{U}) \\
&\geq \mathbf{Adv}^{\text{ind-sel-cca}}_{\mathcal{A},\mathtt{CP\text{-}ABKEM}}(\lambda, \mathcal{U}) - \frac{q_{\mathrm{d}}}{p} - \mathbf{Adv}^{\mathrm{tcr}}_{\mathcal{CF},\mathit{Hfam}}(\lambda).
\end{aligned}
$$

This is what we should prove in Theorem 1. □

4.3 Encryption Scheme from KEM

It is straightforward to construct our encryption scheme CP-ABE from CP-ABKEM. The IND-sel-CCA security of CP-ABE is proved based on IND-sel-CPA security of the Waters *KEM* $\mathtt{CP\text{-}ABKEM}_{\mathrm{cpa}}$.

Setup$(\lambda, \mathcal{U})$. The same as Setup of CP-ABKEM.

Encrypt$(\mathrm{PK}, \mathbb{A}, m)$. The same as Encap of CP-ABKEM except that Encrypt multiplies m by the blinding factor κ in the group $\mathbb{G}_T$. Encrypt returns $\mathrm{CT} = (C = m\kappa, \psi = (\psi_{\mathrm{cpa}}, d_1, d_2))$.

KeyGen$(\mathrm{MSK}, \mathrm{PK}, S)$. The same as KeyGen of CP-ABKEM.

Decrypt$(\mathrm{PK}, \mathrm{CT}, \mathrm{SK}_S)$. The same as Decap of CP-ABKEM except that Decrypt divides out C by the decapsulated blinding factor $\hat{\kappa}$. Decrypt returns the result $\hat{m}$.

4.4 Security and Proof

Theorem 2 *If the Waters* $\mathtt{CP\text{-}ABKEM}_{cpa}$ *[4] is selectively secure against chosen-plaintext attacks and an employed hash function family* Hfam *has target collision resistance, then our* CP-ABE *is selectively secure against chosen-ciphertext attacks. More precisely, for any given PPT ad-*

versary $\mathcal{A}$ that attacks CP-ABE in the IND-sel-CCA game where decryption queries are at most q_d times, and for any small attribute universe $\mathcal{U}$, there exist a PPT adversary $\mathcal{B}$ that attacks CP-ABKEM$_{cpa}$ in the IND-sel-CPA game and a PPT target collision finder $\mathcal{CF}$ on Hfam that satisfy the following inequality.

$$\begin{aligned}&\mathbf{Adv}^{ind\text{-}sel\text{-}cca}_{\mathcal{A},CP\text{-}ABE}(\lambda,\mathcal{U})\\ \leq& 2\Big(\mathbf{Adv}^{ind\text{-}sel\text{-}cpa}_{\mathcal{B},CP\text{-}ABKEM_{cpa}}(\lambda,\mathcal{U})+\mathbf{Adv}^{tcr}_{\mathcal{CF},Hfam}(\lambda)+\frac{q_d}{p}\Big).\end{aligned}$$

Proof. Given any adversary $\mathcal{A}$ that attacks our scheme CP-ABE in the IND-sel-CCA game, we construct an adversary $\mathcal{B}$ that attacks the Waters KEM CP-ABKEM$_{\mathrm{cpa}}$ in the IND-sel-CPA game as follows.

Commit to a Target Access Structure. The same as that of CP-ABKEM.

Set up. In return to outputting $\mathbb{A}^*$, $\mathcal{B}$ receives the public key PK$_{\mathrm{cpa}}$ for CP-ABKEM$_{\mathrm{cpa}}$. To set up a public key PK for CP-ABE, $\mathcal{B}$ *herein* needs a challenge instance: $\mathcal{B}$ queries its challenger and gets a challenge instance $(\tilde{\kappa},\psi^*_{\mathrm{cpa}})$. The rest of procedure is the same as that of CP-ABKEM, and $\mathcal{B}$ inputs PK into $\mathcal{A}$.

Phase 1. The same as that of CP-ABKEM except that $\mathcal{B}$ replies a decrypted message $\hat{m}$ to $\mathcal{A}$ for a decryption query.

Challenge. In the case that $\mathcal{A}$ submits two plaintexts (m^*_0,m^*_1) of equal length, $\mathcal{B}$ makes a challenge ciphertext CT* as follows and feeds CT* to $\mathcal{A}$.

$$\begin{aligned}&\text{Choose } b'\leftarrow\{0,1\},\text{ put } \tilde{C}^*=m^*_{b'},\tilde{\kappa};\\ &\text{Put } d^*_1=e(C'^*,g)^{\mu_1},d^*_2=e(C'^*,g)^{\mu_2};\\ &\text{Put CT}^*=(\tilde{C}^*,\psi^*=(\psi^*_{\mathrm{cpa}},d^*_1,d^*_2)).\end{aligned}$$

Phase 2. The same as in Phase 1.

Guess. In the case that $\mathcal{A}$ returns $\mathcal{A}$'s guess $\tilde{b}$, $\mathcal{B}$ returns $\tilde{b}$ as $\mathcal{B}$'s guess.

Evaluation of the Advantage of $\mathcal{B}$. A standard argument deduces a loss of tightness by a factor of 1/2. That is;

$$\begin{aligned}&\mathbf{Adv}^{\text{ind-sel-cpa}}_{\mathcal{B},\text{CP-ABKEM}_{\text{cpa}}}(\lambda,\mathcal{U})\\ \geq&\frac{1}{2}\mathbf{Adv}^{\text{ind-sel-cca}}_{\mathcal{A},\text{CP-ABE}}(\lambda,\mathcal{U})-\frac{q_{\mathrm{d}}}{p}-\mathbf{Adv}^{\mathrm{tcr}}_{\mathcal{CF},Hfam}(\lambda).\square\end{aligned}$$

5 Securing the Ostrovsky-Sahai-Waters KP-ABKEM against Chosen-Ciphertext Attacks

In this section, we describe our direct chosen-ciphertext security modification by applying it to the Ostrovsky-Sahai-Waters KP-ABE [11].

Overview of Our Modification The Ostrovsky-Sahai-Waters KP-ABE is proved to be secure in the IND-sel-CPA game [11]. We convert it into a scheme that is secure in the IND-sel-CCA game by employing the Twin Diffie-Hellman technique of Cash, Kiltz and Shoup [12] and the algebraic trick of Boneh and Boyen [13] and Kiltz [14].

In encryption, a ciphertext becomes to contain additional two elements (d_1,d_2), which function in decryption as a "check sum" to verify that a tuple is certainly a twin DH tuple.

In security proof, the Twin Diffie-Hellman Trapdoor Test does the function instead. It is noteworthy that we are unable to use the bilinear map instead because the tuple to be verified is in the target group. In addition, the algebraic trick enables to answer for adversary's decryption queries. Note also that the both technique become compatible by introducing random variables.

Key Encapsulation and Encryption. The Ostrovsky-Sahai-Waters KP-ABE can be captured as a KP-ABKEM: the blinding factor of the form $e(g,g)^{a\alpha s}$ in the Ostrovsky-Sahai-Waters KP-ABE can be considered as a random one-time key. So we call it the Ostrovsky-Sahai-Waters KP-ABKEM hereafter and denote it as KP-ABKEM$_{\mathrm{cpa}}$. Likewise, we distinguish parameters and algorithms of KP-ABKEM$_{\mathrm{cpa}}$ by the index $_{\mathrm{cpa}}$. For theoretical simplicity, we first develop a KEM KP-ABKEM.

5.1 Our Construction

Our KP-ABKEM consists of the following four PPT algorithms (Setup, Encap, KeyGen, Decap). Roughly speaking, the Ostrovsky-Sahai-Waters original scheme KP-ABKEM$_{\mathrm{cpa}}$ (the first scheme in [11]) corresponds to the case $k=1$ below excluding the "check sum" (d_1,d_2).

Setup$(\lambda,\mathcal{U})$**.** Setup takes as input the security parameter λ and the attribute universe $\mathcal{U}=\{1,\ldots,u\}$. It runs $\mathsf{Grp}(\lambda)$ to get $(p,\mathbb{G},\mathbb{G}_T,g,e)$, where $\mathbb{G}$ and $\mathbb{G}_T$ are cyclic groups of order p, $e:\mathbb{G}\to\mathbb{G}_T$ is a bilinear map and g is a generator of $\mathbb{G}$. These become public parameters. Then Setup chooses u random group elements $h_1,\ldots,h_u\in\mathbb{G}$ that are associated with the u attributes. In addition, it chooses random exponents $\alpha_k\in\mathbb{Z}_p,k=1,\ldots,4,a\in\mathbb{Z}_p$ and a hash key $\eta\in HKey(\lambda)$. The public key is published as PK $=(g,g^a,h_1,\ldots,h_u,e(g,g)^{a\alpha_1},\ldots,e(g,g)^{a\alpha_4},\eta)$. The authority sets MSK $=(\alpha_1,\ldots,\alpha_4)$ as the master secret key.

Encap$(\mathbf{PK},S)$**.** The encapsulation algorithm Encap takes as input the public key PK and a set S of attributes. Encap first chooses a random value $s\in\mathbb{Z}_p$ that is the encryption randomness. Then, a pair of a random one-time key and its encapsulation (κ,ψ) is computed as follows.

$$\begin{aligned}&\text{Put } C'=g^s;\text{For } x\in S: C_x=h^s_x\\ &\psi_{\mathrm{cpa}}=(S,C',(C_x;x\in S)),\tau\leftarrow H_\eta(\psi_{\mathrm{cpa}});\\ &\text{For } k=1\text{ to }4:\kappa_k=e(g,g)^{a\alpha_k s};d_1=\kappa_1^\tau\kappa_3,d_2=\kappa_2^\tau\kappa_4;\\ &(\kappa,\psi)=(\kappa_1,(\psi_{\mathrm{cpa}},d_1,d_2)).\end{aligned}$$

KeyGen$(\mathbf{MSK},\mathbf{PK},\mathbb{A})$**.** The key generation algorithm KeyGen takes as input the master secret key MSK, the public key PK and an LSSS access structure $\mathbb{A}=(M,\rho)$, where M is an $l\times n$ matrix and ρ is the function which maps each row index i of M to an attribute in $\mathcal{U}=\{1,\ldots,u\}$. For $k=1$ to 4, KeyGen first chooses

random values $y_{k,2},\ldots,y_{k,n} \in \mathbb{Z}_p$ and forms a vector $\vec{v_k} = (\alpha_k, y_{k,2},\ldots,y_{k,n})$. Then, for $i = 1$ to l, it calculates $\lambda_{k,i} = \vec{v_k} \cdot M_i$, where M_i denotes the i-th row vector of M, and it chooses random values $r_{k,i} \in \mathbb{Z}_p$. KeyGen generates the secret key $\mathrm{SK}_{\mathbb{A}}$ as follows.

$$\begin{aligned}&\text{For } k = 1 \text{ to } 4 : \text{For } l = 1 \text{ to } l :\\ &\quad K_{k,i} = g^{a\lambda_{k,i}} h_{\rho(i)}^{r_{k,i}}, L_{k,i} = g^{r_{k,i}}\\ &\mathrm{SK}_{\mathbb{A}} = (((K_{k,i}, L_{k,i}); i = 1,\ldots,l)k = 1,\ldots,4).\end{aligned}$$

Decap$(\mathbf{PK}, \psi, \mathbf{SK}_{\mathbb{A}})$**.** The decapsulation algorithm Decap takes as input the public key PK, an encapsulation ψ for an attribute set S and a private key $\mathrm{SK}_{\mathbb{A}}$ for an access structure $\mathbb{A} = (M, \rho)$. It first checks whether $S \in \mathbb{A}$. If the result is False, put $\hat{\kappa} = \perp$. Otherwise, let $I_S = \rho^{-1}(S) \subset \{1,\ldots,l\}$ and let $\{\omega_i \in \mathbb{Z}_p; i \in I_S\}$ be a set of linear reconstruction constants. Then, the decapsulation $\hat{\kappa}$ is computed as follows.

$$\begin{aligned}&\text{Parse } \psi \text{ into } (\psi_{\mathrm{cpa}} = (S, C', (C_x; x \in S)), d_1, d_2);\\ &\tau \leftarrow H_\eta(\psi_{\mathrm{cpa}});\\ &\text{For } k = 1 \text{ to } 4 :\\ &\quad \hat{\kappa_k} = \prod_{i \in I_S} (e(C', K_{k,i})/e(L_{k,i}, C_{\rho(i)}))^{\omega_i} = e(g,g)^{a\alpha_k s}\\ &\text{If } \hat{\kappa_1}^{\tau}\hat{\kappa_3} \neq d_1 \vee \hat{\kappa_2}^{\tau}\hat{\kappa_4} \neq d_2,\\ &\quad \text{then put } \hat{\kappa} = \perp, \text{else put } \hat{\kappa} = \hat{\kappa_1}.\end{aligned}$$

5.2 Security and Proof

Theorem 3 *If the Ostrovsky-Sahai-Waters* KP-ABKEM$_{cpa}$ *[11] is selectively secure against chosen-plaintext attacks and an employed hash function family* Hfam *has target collision resistance, then our* KP-ABKEM *is selectively secure against chosen-ciphertext attacks. More precisely, for any given PPT adversary* $\mathcal{A}$ *that attacks* KP-ABKEM *in the IND-sel-CCA game where decapsulation queries are at most* q_d *times, and for any small attribute universe* $\mathcal{U}$*, there exist a PPT adversary* $\mathcal{B}$ *that attacks* KP-ABKEM$_{cpa}$ *in the IND-sel-CPA game and a PPT target collision finder* $\mathcal{CF}$ *on* Hfam *that satisfy the following tight reduction.*

$$\begin{aligned}&\mathbf{Adv}^{ind\text{-}sel\text{-}cca}_{\mathcal{A},KP\text{-}ABKEM}(\lambda,\mathcal{U})\\ \leq &\mathbf{Adv}^{ind\text{-}sel\text{-}cpa}_{\mathcal{B},KP\text{-}ABKEM_{cpa}}(\lambda,\mathcal{U}) + \mathbf{Adv}^{tcr}_{\mathcal{CF},Hfam}(\lambda) + \frac{q_d}{p}.\end{aligned}$$

Proof. We will omit the description of the proof because the proof goes analogously to the case of CP-ABKEM in Section 4.2. □

5.3 Encryption Scheme from KEM

It is straightforward to construct our encryption scheme KP-ABE from KP-ABKEM. The IND-sel-CCA security of KP-ABE is proved based on IND-sel-CPA security of the Waters *KEM* KP-ABKEM$_{\mathrm{cpa}}$.

Setup$(\lambda, \mathcal{U})$**.** The same as Setup of KP-ABKEM.

Encrypt$(\mathbf{PK}, \mathbb{A}, m)$**.** The same as Encap of KP-ABKEM except that Encrypt multiplies m by the blinding factor κ in the group $\mathbb{G}_T$. Encrypt returns $\mathrm{CT} = (C = m\kappa, \psi = (\psi_{\mathrm{cpa}}, d_1, d_2))$.

KeyGen$(\mathbf{MSK}, \mathbf{PK}, S)$**.** The same as KeyGen of KP-ABKEM.

Decrypt$(\mathbf{PK}, \mathbf{CT}, \mathbf{SK}_S)$**.** The same as Decap of KP-ABKEM except that Decrypt divides out C by the decapsulated blinding factor $\hat{\kappa}$. Decrypt returns the result $\hat{m}$.

5.4 Security and Proof

Theorem 4 *If the Ostrovsky-Sahai-Waters* KP-ABKEM$_{cpa}$ *[11] is selectively secure against chosen-plaintext attacks and an employed hash function family* Hfam *has target collision resistance, then our* KP-ABE *is selectively secure against chosen-ciphertext attacks. More precisely, for any given PPT adversary* $\mathcal{A}$ *that attacks* KP-ABE *in the IND-sel-CCA game where decryption queries are at most* q_d *times, and for any small attribute universe* $\mathcal{U}$*, there exist a PPT adversary* $\mathcal{B}$ *that attacks* KP-ABKEM$_{cpa}$ *in the IND-sel-CPA game and a PPT target collision finder* $\mathcal{CF}$ *on* Hfam *that satisfy the following inequality.*

$$\begin{aligned}&\mathbf{Adv}^{ind\text{-}sel\text{-}cca}_{\mathcal{A},KP\text{-}ABE}(\lambda,\mathcal{U})\\ \leq &2\Big(\mathbf{Adv}^{ind\text{-}sel\text{-}cpa}_{\mathcal{B},KP\text{-}ABKEM_{cpa}}(\lambda,\mathcal{U}) + \mathbf{Adv}^{tcr}_{\mathcal{CF},Hfam}(\lambda) + \frac{q_d}{p}\Big).\end{aligned}$$

Proof. We will omit the description of the proof because the proof goes in the same way as the case of CP-ABE in Section 4.4. □

6 Efficiency Discussion

First of all, we remark that our individual modification to attain CCA security is applicable when a Diffie-Hellman tuple to be verified is in the target group of a bilinear map $e : \mathbb{G} \times \mathbb{G} \to \mathbb{G}_T$. Especially, it is applicable even when an original CPA secure scheme is based on asymmetric pairing [19], $e : \mathbb{G}_1 \times \mathbb{G}_2 \to \mathbb{G}_T$. For example, the Type 3 version [19] of the Waters CP-ABE scheme [4] can be found in [20]. Detailed discussions and results on real implementations are found for the case of CPA-secure ABE schemes [21, 20]. We note here that the efficiency comparison below enables to guess the implementation results of CCA-secure ABE schemes via our modification.

We compare the efficiency of our CP-ABE with the original Waters CP-ABE$_{\mathrm{cpa}}$, and our KP-ABE with the original Ostrovsky-Sahai-Waters KP-ABE$_{\mathrm{cpa}}$. We also compare the efficiency of our schemes with the CCA-secure CP-ABE and KP-ABE schemes obtained by the generic transformation in [10]. Here the generic transformation [10] is considered in the case of a small attribute universe, the delegation type [10] and the Lamport one-time signature [22]. Table 1 shows these comparison. Note that a hash function is applied to generate a message digest of bit-length λ before signing by a secret key of the one-time signature. Note also, for simplicity, we evaluate the lengths and the amounts of computation below in the case that an access structure $\mathbb{A}$ is "all-AND" and an attribute map ρ is injective (i.e "single-use" that is opposed to "multi-use").

Table 1: Efficiency comparison of IND-sel-CCA secure ABEs ([10] and ours) with the original IND-sel-CPA secure ABEs [4, 11].

Scheme	L(PK)	L(SK$_S$)	L(CT)	C(Enc)	C(Dec)
Generic transform [10], CP-ABE	$+4\lambda^2(\mathbb{G})$	$+4\lambda^2(\mathbb{G})$	$+3\lambda^2$(bit)	$+2\lambda^2$exp.($\mathbb{G}$)	$+2\lambda^2$pair.(e)
Our individual modification (CP-ABE)	$+3(\mathbb{G}_T)$	$\times 4$	$+2(\mathbb{G}_T)$	$+4$exp.($\mathbb{G}_T$)	$\times 4$
Generic transform [10], KP-ABE	$+4\lambda^2(\mathbb{G})$	$+0$	$+3\lambda^2$(bit)	$+2\lambda^2$exp.($\mathbb{G}$)	$+2\lambda^2$pair.(e)
Our individual modification (KP-ABE)	$+3(\mathbb{G}_T)$	$\times 4$	$+2(\mathbb{G}_T)$	$+4$exp.($\mathbb{G}_T$)	$\times 4$

1) λ is the security parameter. (For instance, $\lambda = 224$ or 256.)
2) L(data) denotes the length of the data. C(algorithm) denotes the computational amount of the algorithm.
3) + and $\times$ mean the increment and the multiplier to the length or to the computational amount of the Waters CP-ABKEM$_{\mathrm{cpa}}$ and the Ostrovsky-Sahai-Waters KP-ABE$_{\mathrm{cpa}}$.
4) ($\mathbb{G}$), ($\mathbb{G}_T$) and (bit) mean that the lengths are evaluated in the number of elements in $\mathbb{G}$, elements in $\mathbb{G}_T$ and bits, respectively.
5) exp.($\mathbb{G}$) and pair.(e) mean the computational amount of one exponentiation in $\mathbb{G}$ and one pairing computation by the map e, respectively.

Our individual modification results in expansion of the length of a secret-key and the amount of decryption computation by a factor of four, while the length of a public-key, the length of a ciphertext and the amount of encryption computation are almost the same as those of the original CPA-secure schemes. In the case that the size of an attribute set is up to ($\frac{2}{3}$ of) the square of the security parameter λ, the amount of decryption computation of our CP-ABE and KP-ABE are smaller than those of the CP-ABE and KP-ABE obtained by the generic transformation [10], respectively.

7 Conclusion

We demonstrated direct chosen-ciphertext security modification for ABE in the standard model in the case of the Waters scheme (CP-ABKEM$_{\mathrm{cpa}}$, CP-ABE$_{\mathrm{cpa}}$) and the Ostrovsky-Sahai-Waters scheme (KP-ABKEM$_{\mathrm{cpa}}$, KP-ABE$_{\mathrm{cpa}}$). We utilized the Twin Diffie-Hellman Trapdoor Test of Cash, Kiltz and Shoup and the algebraic trick of Boneh and Boyen [13] and Kiltz [14]. Our modification worked for the setting that the Diffie-Hellman tuple to be verified in decryption was in the target group of the bilinear map. We compared the efficiency of our CCA-secure ABE schemes with the original CPA-secure ABE schemes and with the CCA-secure ABE schemes obtained by the versatile generic transformation.

Appendix

A Proof of Lemma 2

The only one point to be complemented to the original proof (in [12]) is that even for any algorithm $\mathcal{A}$ with unbounded computational power, the statement holds. This is because, conditioning on the input fixed values (g, X_1, X_2), $\mathcal{A}$ only reduces the two-dimensional freedom $(r,s) \in \mathbb{Z}_p^2$ into the one-dimensional freedom $r \in \mathbb{Z}_p$ even if $\mathcal{A}$ correctly guesses the relation $s = rx_1 + x_2$. □

B Proof of Claim 1

For the index 3, we have implicitly set $t_3 = t_{\mathrm{cpa},3}(-\tau^*)$ and we get:

$$K_3 = g^{\mu_1} K_{\mathrm{cpa},3}^{-\tau^*} = g^{\mu_1}(g^{\alpha_1} g^{at_{\mathrm{cpa},3}})^{-\tau^*} = g^{\mu_1-\alpha_1\tau^*} g^{at_3} = g^{\alpha_3} g^{at_3},$$

$$L_3 = L_{\mathrm{cpa},3}^{-\tau^*} = (g^{t_{\mathrm{cpa},3}})^{-\tau^*} = g^{t_3},$$

$$K_{3,x} = K_{\mathrm{cpa},3,x}^{-\tau^*} = (h_x^{t_{\mathrm{cpa},3}})^{-\tau^*} = h_x^{t_3}, x \in S.$$

For the index 4, we have implicitly set $t_4 = t_{\mathrm{cpa},4}(\gamma_1\tau^*)$ and we get:

$$K_4 = g^{\mu_2-\gamma_2\tau^*} K_{\mathrm{cpa},4}^{\gamma_1\tau^*} = g^{\mu_2-\gamma_2\tau^*}(g^{\alpha_1} g^{at_{\mathrm{cpa},4}})^{\gamma_1\tau^*}$$

$$= g^{\mu_2-\gamma_2\tau^*} g^{\alpha_1\gamma_1\tau^*} g^{at_4} = g^{\mu_2-(\gamma_2-\alpha_1\gamma_1)\tau^*} g^{at_4} = g^{\mu_2-\alpha_2\tau^*} g^{at_4}$$

$$= g^{\alpha_4} g^{at_4},$$

$$L_4 = L_{\mathrm{cpa},4}^{\gamma_1\tau^*} = (g^{t_{\mathrm{cpa},4}})^{\gamma_1\tau^*} = g^{t_4},$$

$$K_{4,x} = K_{\mathrm{cpa},4,x}^{\gamma_1\tau^*} = (h_x^{t_{\mathrm{cpa},4}})^{\gamma_1\tau^*} = h_x^{t_4}, x \in S.$$

□

C Proof of Claim 2

Suppose that we are given a twin DH tuple $(e(g,g), e(g,g)^{\alpha_1}, e(g,g)^{\alpha_2}, \hat{Y}, \hat{Z}_1, \hat{Z}_2)$. Then, $d_i/e(C',g)^{\mu_i} = (e(g,g)^{\alpha_i})^{s(\tau-\tau^*)}, i = 1,2$. So, using the implicit relations (1), we have:

$$d_i = e(g,g)^{\alpha_i s(\tau-\tau^*)} e(g^s, g)^{\mu_i} = (e(g,g)^{\alpha_i(\tau-\tau^*)} e(g,g)^{\mu_i})^s$$

$$= (e(g,g)^{\alpha_i(\tau-\tau^*)} e(g,g)^{\alpha_i\tau^*+\alpha_{(i+2)}})^s = (e(g,g)^{\alpha_i\tau} e(g,g)^{\alpha_{(i+2)}})^s, i = 1,2.$$

This means that $(e(g,g),\ e(g,g)^{\alpha_1\tau} e(g,g)^{\alpha_3},\ e(g,g)^{\alpha_2\tau} e(g,g)^{\alpha_4}, e(C',g), d_1, d_2)$ is a twin Diffie-Hellman tuple.

The converse is also verified by the reverse calculation. □

D Proof of Claim 5

To reduce to the target collision resistance of an employed hash function family *Hfam*, we construct a PPT target collision finder $\mathcal{CF}$ that attacks *Hfam* using $\mathcal{A}$ as a subroutine. The construction is shown in Fig.2. (Note that the case Collision is defined in Fig.2.)

Note that the view of $\mathcal{A}$ in $\mathcal{CF}$ is the same as the real view of $\mathcal{A}$ until the case Collision occurs and hence the algorithm $\mathcal{A}$ works as designed.

To evaluate the probability in Claim 5, we consider the following two cases.

Case 1: the case that Abort ($\tau = \tau^*$) occurs in $\mathcal{B}$ in Phase 1. In this case, the target τ^* has not been given to $\mathcal{A}$. So $\mathcal{A}$ needs to guess τ^* to cause a collision $\tau = \tau^*$. Hence:

$$\Pr[\text{Phase 1} \wedge \Big(\bigwedge_{i=1}^{q_\mathrm{d}} \neg\textsc{Overlook}_i\Big) \wedge \textsc{Abort}] \leq \Pr[\text{Phase 1} \wedge \textsc{Collision}]. \tag{6}$$

Case 2: the case that Abort ($\tau = \tau^*$) occurs in $\mathcal{B}$ in Phase 2. In this case, if, in addition to $\tau = \tau^*$, it occurred that $\psi_{\mathrm{cpa}} = \psi^*_{\mathrm{cpa}}$ (and hence $C' = C'^*$), then it would occur that $\psi = \psi^*$. This is because the following two tuples are equal twin DH tuples by the fact that $\textsc{Overlook}_i$ never occurs:

$$(e(g,g), e(g,g)^{\alpha_1\tau} e(g,g)^{\alpha_3}, e(g,g)^{\alpha_2\tau} e(g,g)^{\alpha_4}, e(C',g), d_1, d_2),$$

$$(e(g,g), e(g,g)^{\alpha_1\tau^*} e(g,g)^{\alpha_3}, e(g,g)^{\alpha_2\tau^*} e(g,g)^{\alpha_4}, e(C'^*,g), d_1^*, d_2^*).$$

Hence both $S \in \mathbb{A}$ and $\psi = \psi^*$ would occur. This is ruled out in decapsulation query; a contradiction. So we have $\psi_{\mathrm{cpa}} \neq \psi^*_{\mathrm{cpa}}$; that is, a collision:

$$\psi_{\mathrm{cpa}} \neq \psi^*_{\mathrm{cpa}} \wedge H_\eta(\psi_{\mathrm{cpa}}) = \tau = \tau^* = H_\eta(\psi^*_{\mathrm{cpa}}).$$

Therefore, if $\textsc{Overlook}_i$ never occurs for each i, then only decapsulation queries for which $(e(g,g), e(g,g)^{\alpha_1}, e(g,g)^{\alpha_2}, \hat{Y}, \hat{Z}_1, \hat{Z}_2)$ are certainly twin DH tuples have the chance to cause a collision $\tau = \tau^*$, as is the case in $\mathcal{CF}$. Hence we have:

$$\Pr[\text{Phase 2} \wedge \Big(\bigwedge_{i=1}^{q_\mathrm{d}} \neg\textsc{Overlook}_i\Big) \wedge \textsc{Abort}] \leq \Pr[\text{Phase 2} \wedge \textsc{Collision}]. \tag{7}$$

Given λ as input :
Set up
Initialize inner state;
Choose a polynomial size attribute universe $\mathcal{U}$ at random;
Get a target access structure $\mathbb{A}^* \leftarrow \mathcal{A}(\lambda, \mathcal{U})$;
Run $\mathbf{Setup}_{\mathrm{cpa}}(\lambda, \mathcal{U})$ to get $(p, \mathbb{G}, \mathbb{G}_T, g, e), \mathrm{PK}_{\mathrm{cpa}}, \mathrm{MSK}_{\mathrm{cpa}}$;
Get $(\kappa^*, \psi^*_{\mathrm{cpa}}) \leftarrow \mathbf{Encap}_{\mathrm{cpa}}(\mathrm{PK}_{\mathrm{cpa}}, \mathbb{A}^*)$;
Output ψ^*_{cpa};
Receive, in return, $\eta \leftarrow HKey(\lambda)$ and compute $\tau^* \leftarrow H_\eta(\psi^*_{\mathrm{cpa}})$;
Choose $\alpha_2, \alpha_3, \alpha_4 \leftarrow \mathbb{Z}_p$;
Put $\mathrm{PK} = (\mathrm{PK}_{\mathrm{cpa}}, e(g,g)^{\alpha_2}, e(g,g)^{\alpha_3}, e(g,g)^{\alpha_4}, \eta), \mathrm{MSK} = (g^{\alpha_1}, g^{\alpha_2}, g^{\alpha_3}, g^{\alpha_4})$;
Give PK to $\mathcal{A}$;
Phase 1
In the case that $\mathcal{A}$ makes a key-extraction query for $S \subset \mathcal{U}$;
Reply SK_S to $\mathcal{A}$ in the same way as **KeyGen** does using MSK;
In the case that $\mathcal{A}$ makes a decapsulation query for $(S, \psi = (\psi_{\mathrm{cpa}}, d_1, d_2))$;
Reply $\hat{\kappa}$ to $\mathcal{A}$ in the same way as **Decap** does using MSK;
If $\hat{\kappa} \neq \perp$ and $\tau = \tau^*$ (: call this case Collision)
then return ψ_{cpa} and stop;
Challenge
In the case that $\mathcal{A}$ makes a challenge instance query;
Using MSK, put $d_1^* = e(g^{\alpha_1}, C'^*)^{\tau^*} e(g^{\alpha_3}, C'^*), d_2^* = e(g^{\alpha_2}, C'^*)^{\tau^*} e(g^{\alpha_4}, C'^*)$,
$\psi^* = (\psi^*_{\mathrm{cpa}}, d_1^*, d_2^*)$;
Choose $\kappa \leftarrow KeySp(\lambda), b \leftarrow \{0,1\}$;
If $b = 1$ then put $\tilde{\kappa} = \kappa^*$ else put $\tilde{\kappa} = \kappa$;
Reply $(\tilde{\kappa}, \psi^*)$ to $\mathcal{A}$;
Phase 2
The same as in Phase 1;
Return
In the case that $\mathcal{A}$ returns its guess b^*;
Stop.

Figure 2: A PPT Collision Finder $\mathcal{CF}$ that attacks *Hfam* for the proof of Claim 5.

Taking a sum of both sides of (6) and (7), we get:

$$\Pr[\Big(\bigwedge_{i=1}^{q_{\mathrm{d}}} \neg \textsc{Overlook}_i\Big) \wedge \textsc{Abort}] \leq \Pr[\textsc{Collision}] = \mathbf{Adv}^{\mathrm{tcr}}_{\mathcal{CF}, Hfam}(\lambda).$$

□

E Proof of Claim 6

It is enough to prove that

When $(e(g,g), e(g,g)^{\alpha_1}, e(g,g)^{\alpha_2}, \hat{Y}, \hat{Z}_1, \hat{Z}_2)$ is a twin DH tuple,
$\hat{\kappa} = \hat{Z_1}^{1/(\tau - \tau^*)} = e(g,g)^{\alpha_1 s}$ holds.

This is deduced as follows:

$$\hat{\kappa} = (d_1 / e(C', g)^{\mu_1})^{1/(\tau - \tau^*)} = ((e(g,g)^{\alpha_1})^{s(\tau - \tau^*)})^{1/(\tau - \tau^*)} = e(g,g)^{\alpha_1 s}.$$

□

F Proof of Claim 7

A direct calculation with equalities (1) shows:

$$d_i^* = e(C'^*, g)^{\mu_i} = e(g,g)^{s^*(\alpha_i \tau^* + \alpha_{(i+2)})} = e(g,g)^{\alpha_i s^* \tau^*} e(g,g)^{\alpha_{(i+2)} s^*},$$
$i = 1, 2.$

Hence $\psi^* = (\psi^*_{\mathrm{cpa}}, d_1^*, d_2^*)$ is legitimate and correctly distributed. □

ABSTRACT

This article is devoted to the problem of blocking the propagation of sound in a gas stream. This can be useful in the problems of pipeline acoustics and the design of automotive silencers, when it is necessary to ensure the opacity of the boundary (cross section of the pipe) for sound simultaneously with the free (ideally) flow through this boundary. The tool for solving this problem is the rapid periodic overlapping of waveguide (gas-conducting) channels in a system of parallel waveguides. The design of the proposed device assumes the following technological requirements: high mechanical rigidity of the elements, high accuracy of their manufacture and high rotor speed. Fulfillment of these conditions allows creating an effective device for blocking sound in the gas flow. Such a device may have small wave dimensions (with respect to the wavelength of sound) and a small expenditure of mechanical power to push gas through it very wide frequency range of silencing.

1. Introduction

In practice, sometimes it is necessary to place a filter in the path of the gas flow (with velocity v) in the pipe (and simultaneously sound with speed c in the tube as an acoustic waveguide). This filter must pass the flow of gas and block sound waves on its output. Such situations are encountered in problems of the acoustics of pipelines and also in the problem of designing exhaust silencers for cars with internal combustion engines. Next we will call such a device a silencer. The area of the inlet and outlet cross-section of the silencer is assumed equal S_0 , the average velocity of the flow at the inlet and outlet of the silencer is V_0 (see Figure 1). The time-average gas pressures at Q the outlet and inlet of the silencer are, respectively, p_0 and $p_0 + \Delta p$, where $\Delta p > 0$. The quality of the silencers is characterized by the following parameters:

(a) the degree

$$Q_1 = P_{out} / P_{in} \tag{1}$$

of sound pressure suppression (of course preferably $Q_1 << 1$);

(b) the frequency range

$$\omega_{\min} \le \omega \le \omega_{\max} \tag{2}$$

of sound suppression, preferably when

$$Q_2 = \omega_{\min} /(\omega_{\max} - \omega_{\min}) << 1 \tag{3}$$

(c) the wave dimensions

$$Q_3 = \ell \omega_{\min} / c \tag{4}$$

of the device (where ℓ is the geometric size of the silencer, c - is a sound speed, preferably when $Q_3 << 1$);

$$Q_4 \approx 2\Delta p / \rho V_0^2 << 1 \tag{5}$$

(d) the relative loss of power to propel the gas through the silencer (ρ - gas mass density, preferably when $Q_4 << 1$). For a silencer, this condition is necessary

$$Q_1 = P_{out} / P_{in} \tag{6}$$

Always this combination is desirable (in addition to (1))

$$Q_2 << 1,\ Q_3 << 1,\ Q_4 << 1. \tag{7}$$

Violation of the conditions (7) (or one of these conditions) is usually (for systems with parameters that are constant in time) a payment for the fulfillment of the condition (6). Widely known are the following three approaches [1] in the design of such devices: when narrow-band ($Q_2 > 1$) absorption is permissible

*Vladimir Arabadzhi: Institute of Applied Physics (RAS), 603950, Nizhny Novgorod, Ulianov st. 46, Russia, v.v.arabadzhi@appl.sci-nnov.ru

and one can be satisfied with resonant absorption of active suppression of sound; when large silencer dimensions are permissible ($Q_3 \geq 1$) and one can be satisfied by a Helmholtz resonator with a resonant frequency below the minimum sound frequency $\omega_{\min}$ in the flow at low energy costs to propel the gas; when the high energy expenditure for pushing the gas through a classical rigid plate, perforated with small holes ($Q_4 \sim 1$).

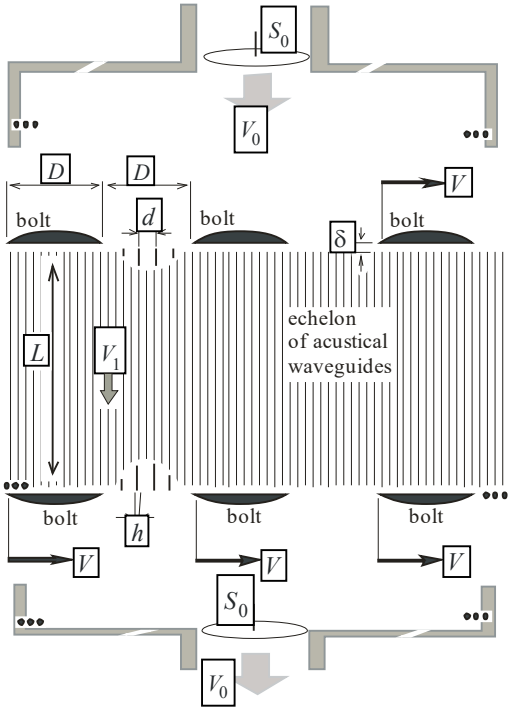

Figure 1. Two-dimensional version of cyclical wave bolt

2. Cyclical Wave Bolt

The above solutions [1] for blocking sound in a stream (with or without sound absorption) were based on systems with time-constant parameters. We now consider a system with parameters modulated in time [2]. We consider the infinite echelon (see Figure 1) of waveguides with rigid vertical plane walls, located at a characteristic distance

$$d >> h \tag{8}$$

from each other, where h is characteristic thickness of walls. Two horizontal systems of rigid thin bands (wave bolts) of the width D, separated from each other by the distance

$$D >> d \tag{9}$$

move horizontally (to the right) with the velocity V near the upper and lower edges of the echelon of above mentioned waveguides of length L. A sound wave is incident on top of this system and an excessive pressure Δp is applied to push the gas flow through this system. The gap between bolts and ends of waveguides is limited by condition $\delta < d$. We call such a parametric structure a cyclical wave bolt (CWB). From above, a sound wave falls on the echelon of waveguides, periodically blocked by wave bolts. If the conditions

$$L / c = D / V \tag{10}$$

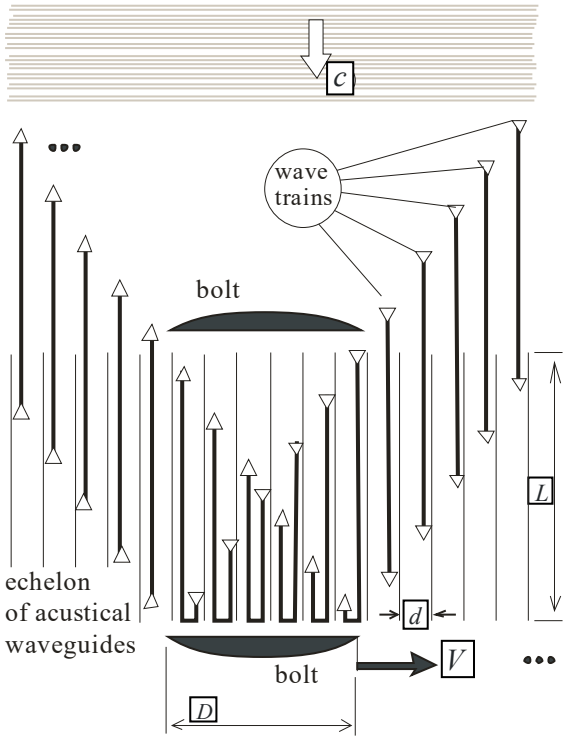

Figure 2. Space diagram of seven incoming wave trains, moving inside the echelon of waveguide channels

of synchronism are satisfied, the incident wave either reflects upward from the upper running bolts, or from the lower ones (Figure 2). Due to condition (10), each waveguide is open at both ends for a certain period of time D / V and is closed by wave bolts at both ends during a subsequent time interval of the same duration D / V. During the first interval (with open bolts), the sound wave fills this waveguide, during the subsequent interval (with closed bolts), the wave turns completely to reverse motion (due to full reflection from closed wave bolts). Thus, any perturbation propagating in a gas at a speed c cannot overcome CWB. On the other hand, for a gas flow this system is transparent. The only limitation of its transparency for the flow is the friction of the gas against the walls of the waveguides, which leads to additional energy loss. Waves, reflected not from the bolts, but from the open ends of the waveguides, do not leave the CWB. In principle, the operation of the system will be the same if the bolts are made stationary, and the train vertical walls is made to move at speed V.

3. Three-Dimensional Version of Cyclical Wave Bolt

Figure 3 shows a three dimensional cylindrical analogue (axially symmetric device) of the infinite two dimensional system described above.

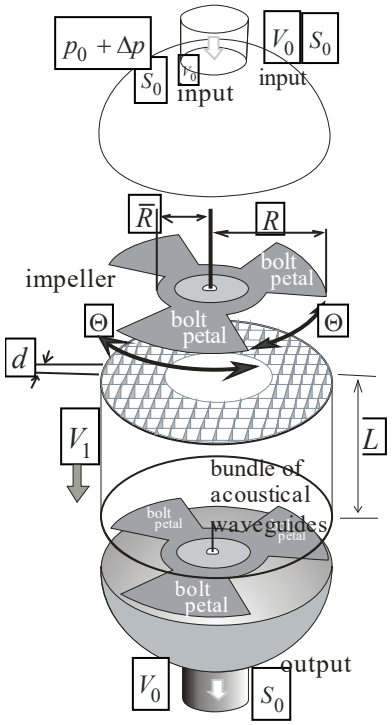

Figure 3. Three-dimensional version of silencer.

An infinite spatially periodic two dimensional bolt system is replaced by rotating (with angular frequency Ω) acoustically rigid (for sound in gas) impeller or rotary switch with N petals (bolts) with angular sectors $\Theta = \pi / N$ of the petals and the same angular sector between adjacent petals. Both ends of each waveguide of length L with a characteristic transverse dimension d (with rigid walls of thickness $h << d$) are open during time intervals $\tilde{t} + 2Tn \le t \le \tilde{t} + T + 2Tn$ and are closed at intervals $\tilde{t} + T + 2Tn \le t \le \tilde{t} + 2T + 2Tn$ of time by bolts (or petals of rotating impeller), where $\tilde{t}$ is a certain initial moment, determined by the point of placement of this waveguide and the phase of rotation of the impeller, where

$$T = \Theta / \Omega = L / c . \qquad (11)$$

The relation (11) is analog of synchronism condition (10). A bundle of tubes (waveguides) is located between the radii $\bar{R}$ and R. Any wave train that gets into the waveguide of length L in time $T = L / c$ has time to fully rotate to exit this waveguide. The maximum rigidity of structural elements and the maximum rotor speed are determined by modern state of technology level. We note that the gas velocity $V_1 = \chi V_0$ inside the waveguide tubes must ensure that the Mach number is small, i.e. $V_1 / c << 1$. By decreasing the value $\chi = S_0 / \pi(\bar{R}^2 - R^2) < 1$ we simultaneously reduce the Mach number inside the waveguides and the relative power loss Q_4. The rotor of the impeller is driven by an electric motor with a stabilized rotational frequency Ω. The frequency of incident waves in the flow is bounded from above only by the condition of one dimensionality of sound propagation in the rigid tube, i.e. its characteristic transverse scale d, i.e. $\omega_{\max} << c / 2\pi d$. Minimum cross-sectional dimension d of the tubes is limited below by the condition of a fairly low energy expenses to push gas trough the waveguides. The maximum cross-sectional dimension of the tubes is bounded above by the condition $d / V << L / c$. That the switching time of one tube is small compared with the propagation time of sound along the tube. Minimal length $L = c\Theta / \Omega$ of the tubes-waveguides is limited from below by the maximum achievable frequency Ω of the rotation of impeller. The minimum gap δ between the impeller (wave bolts, petals) and the ends of the tubes is limited from below by the manufacturing accuracy and stiffness.

Conclusions

Silencer considered can provide a low level of sound at the output, less engine power loss, a wider bands of sound suppression at smaller wave dimensions or, in other words, joint fulfillment of conditions (6), (7). The loss of power to push gas through acoustic waveguides can be reduced by shortening L and by increasing the rotational speed Ω of the impeller (until too much power is required to rotate it). The input and output of device can be interchanged, it acts symmetrically: it does not pass through itself the perturbation propagating in gas at the speed of sound.

Arabic Natural Language Processing

ABSTRACT

With the abundance of Internet and electronic devices bullying has moved its place from schools and backyards into cyberspace; to be now known as Cyberbullying. Cyberbullying is affecting a lot of children around the world, especially Arab countries. Thus, concerns from cyberbullying are rising. A lot of research is ongoing with the purpose of diminishing cyberbullying. The current research efforts are focused around detection and mitigation of cyberbullying. Previously, researches dealt with the psychological effects of cyberbullying on the victim and the predator. A lot of research work proposed solutions for detecting cyberbullying in English language and a few more languages, but none till now covered cyberbullying in Arabic language. Several techniques contribute in cyberbullying detection, mainly Machine Learning (ML) and Natural Language Processing (NLP). This journal extends on a previous paper to elaborate on a solution for detecting and stopping cyberbullying. It first presents a thorough survey for the previous work done in cyberbullying detection. Then a solution that focuses on detecting cyberbullying in Arabic content is displayed and assessed.

1. Introduction

As stated in the Abstract, this work is an extension to the author's previous work [1] which was published in the EMS2016 conference.

Children and teens were exposed to physical bullying before the abundance of internet, computers and handheld devices. Nowadays, bullying is performed using cyber technology. Around 50% of the youth of America are suffering from cyberbullying [2]. As for the Arab world: 20.9% of middle-school adolescents report bullying in UAE, 31.9% in Morocco, 33.6% in Lebanon, 39.1% in Oman and 44.2% in Jordan [3].

Awareness of cyberbullying is rising in the Arab world. Arab News [4] declares that they heard of numerous cyberbullying incidents in Saudi Arabia. One of the rare reports [5] on cyberbullying states that 60% of Gulf Countries' youth openly admit the presence of cyberbullying amongst their peers. This study also states that only quarter the predators online do bully their victims offline. Which means that internet have encouraged three quarters of the predators to bully others, while they wouldn't have considered bullying face to face.

Most of the previous research dealing with cyberbullying focused on the effects of cyberbullying. It was concerned with helping the victims after cyberbullying attacks, mainly from the psychological aspect. Less work was directed towards implementing technical methods to detect and stop an ongoing cyberbullying attack, or even to prevent cyberbullying attacks while or before they happen [6]

After the Introduction, this paper furnishes a background that covers the technologies underlying cyberbullying detection in Section 2. Then in section 3 presents a survey of all existing literature in both cyberbullying detection and multilingual techniques. It concludes at the end of section 3 that there is no work done on detecting cyberbullying attacks in Arabic language. Therefore, in section 4 a system for cyberbullying detection in Arabic content is proposed. This system is designed for preventing cyberbullying attacks, by detecting and stopping them. It uses Natural Language Processing (NLP) to identify and process Arabic words. Then Machine Learning (ML) techniques are used to classify bullying content. In section 5 the results obtained from the system are displayed and analyzed. Conclusions and future works are finally stated in section 6.

2. Background

2.1. Cyberbullying

Cyberbullying is defined as the use of Internet, cell phones, video game systems, or other technologies to send or post text or

* Batoul Haidar: batoul.haidar@net.usj.edu.lb

images intended to hurt or embarrass another person or group of people [7]. Some examples of cyberbullying include sending mean or threatening messages, tricking someone into revealing personal or embarrassing information and sending it to others, sending or forwarding private messages to others, sharing explicit pictures with others without consent, starting rumors via text message or online or creating fake online profiles on websites such as Facebook, Myspace, Twitter, etc. to make fun of people [7]. There are several categories of cyberbullying as stated by [8] and [9] :

- Flaming: starting a form of online fight.
- Masquerade: where there is a bully pretending to be someone else, in order to perform malicious intents.
- Denigration: sending or posting gossip to ruin someone's reputation.
- Impersonation: Pretending to be someone else and sending or posting material to get that person in trouble or danger or to damage that person's reputation or friendships.
- Harassment: Repeatedly sending profane and cruel messages.
- Outing: Publishing someone's embarrassing information, images or secrets.
- Trickery: Talking someone into revealing secrets or embarrassing information for the sake of sharing it online.
- Exclusion: Intentionally and cruelly excluding someone from an online group.
- Cyberstalking: Repeated, intense harassment and denigration that includes threats or creates significant fear.

Bullying and cyberbullying leave mental and physical effects on both the bully (predator) and the victim. Cyberbullying is more severe than physical bullying due to the fact that it is wider, public, and the victim has nowhere to escape. Victims of cyberbullying reported emotional, concentration, and behavioral issues, as well as trouble getting along with their peers. These victims were more likely to report frequent headaches, recurrent stomach pain, and difficulty sleeping. One out of four students revealed that they felt unsafe at school. They were also more likely to be hyperactive, have conduct problems, abuse alcohol, and smoke cigarettes [10].

As stated previously, cyberbullying detection systems mainly use Machine Learning and Natural Language Processing techniques in the course of detection. Thus before dwelling in the previous literature in the area of cyberbullying detection, a thorough background for ML, NLP and other techniques collaborating in the process of cyberbullying detection is displayed.

2.2. Machine Learning

Machine Learning (ML) is defined as the ability of a computer to teach itself how to take a decision using available data and experiences [11]. Available Data is known as *Training Data*. Decisions to be taken in ML might be a classification or prediction for new objects or data. The computer classifies a new piece of data by depending on learning algorithms. When the training data is labeled, i.e. classified by human experts, the algorithms depending on these labeled data are called Supervised Learning algorithms [12].

In cyberbullying detection, there could be a corpus of data manually labeled (or classified) by people as either containing harm or not, as described in Section 3. When the training data is unlabeled, the algorithms depending on these non-labeled data are called Unsupervised Learning algorithms [12]. They teach themselves how to classify the data based on similarities and differences between data. When both supervised and unsupervised learnings are combined together by using labeled and unlabeled data, to get the most out of both ways, the algorithm is known as Semi-supervised Learning algorithm [12].

When ML is used to classify a certain object as belonging or not belonging to a certain category, the machine learner is called *Binary Classifier* [13]; for example in spam email filtering, ML algorithms are used to take decisions against incoming emails and label them as either spam or not spam. A second type is when the task given to the classifier, is to match a certain object against several classes or categories, then it is called *Multi-Class Classifier*. A third type might be predicting a value for an object and is called *Regression*, i.e. predicting a priority level for an incoming email.

There are several ML algorithms available, from which the most frequently used in relevance to the scope of research of this paper will be mentioned.

- Naive Bayes: A probabilistic supervised learning method [14] that mainly calculates the probability of an item belonging to a certain class, depending on metrics obtained from training data. Naïve Bayes algorithm was used in some cyberbullying detection research, such as in [15] and [14]. It was used for sexual predation detection.
- Nearest Neighbor Estimators: A simple estimator [16] that uses distance between data instances, in order to map a certain instance to its closest distance neighbor, thus estimating the class of this instance, this algorithm was used in [17] and [18].
- Support Vector Machine (SVM): Also a supervised algorithm. SVM is a binary classifier that assumes a clear distinction between data samples. It tries to find an optimal hyper plane that maximizes the margin between the classes [12]. SVM was used in many cyberbullying detection systems [19] , [20].
- Decision Tree: Decision tree learners use a set of labeled data, thus they are supervised learners. Decision trees classify data using a command and conquer approach. The Trees compose of leaves and arcs. Each leaf of the tree represents a classification class and each arc represents a feature inspected from training data [21]. The C4.5 algorithm is an implementation of decision trees. It was employed in cyberbullying detection by [22] and [17].

ML algorithms are widely incorporated in cyberbullying detection systems as seen in Section III, due to the huge amount of

data incorporated in social networking platforms, which makes it hard to be processed by human power, thus comes the need for a machine learner.

2.3. Natural Language Processing

Natural Language Processing (NLP) is the collection of techniques employed to make computers capable of understanding the natural unprocessed language spoken between humans by extracting grammatical structure and meaning from input [23].

NLP is a common branch of all of Linguistics, Artificial Intelligence and Computer Science [24]. NLP research started with Machine Translation in the late 1940s [25]. Then it spread to other areas of application, such as information retrieval, text summarization, question answering, information extraction, topic modeling, opinion mining [26], optical character recognition, finding words boundary, word sense disambiguation, and speech recognition [24].

According to Chandhana [27], NLP can be divided into three areas; Acoustic – Phonetic: where acoustic knowledge studies rhythm and intonation of language; i.e. how to form phonemes, the smallest unit of sounds. Phonemes and phones are aggregated into word sounds. Phonetic knowledge relates sounds to the words we recognize. Morphological – Syntactic: Morphology is lexical knowledge which studies sub words (morphemes) that would form a word. Syntactic knowledge studies the structural roles of words or collection of words to form correct sentences. Semantic - Pragmatic: Semantic knowledge deals with the meaning of words and sentences, while pragmatic knowledge deals with deriving sentence meanings from the outside world or outside the content of the document [28].

2.4. Sentiment Analysis

Sentiment analysis is a textual analysis technique. Sentiment analysis is used to define the polarity, subjectivity or features of a certain text. By polarity we mean defining whether a certain content is positive, negative or neutral [29]. Both Machine Learning and Natural Language Processing techniques are incorporated in Sentiment Analysis.

Sentiment analysis is currently used in detecting the opinions of social media users. Opinions are studied in several areas such as marketing and politics

2.5. Common Sense Reasoning/Sentic Computing

Common sense is the knowledge (usually acquired in early stages of life) concerning social, political, economic and environmental aspects of the society we live in. Common sense usually varies among different cultures and is built from layers of learning experiments we acquire throughout life [30].

Computers do not have common sense reasoning by nature, but there is a research field, known by Sentic Computing [31], that aims towards transforming computers into machines that could feel. This field of research is a multidisciplinary approach to opinion mining and sentiment analysis, which uses common sense reasoning and web semantics in order to inspect the emotions, not just the opinions from certain text. The term 'Sentic' derives from the Latin 'Sentire', the root of words like sentiment and sensations.

2.6. Performance Measures

Some evaluation metrics were adapted in Information Retrieval (IR) and then extended to other fields of computer science such as ML. These evaluation metrics are used as measures for the performance of IR and ML systems. The most widely used metrics are Recall, Precision, Area under the ROC and F-Measure.

- Recall is the proportion of returned documents (or values) which are relevant (or correct) $Rl \cap Rt$ [32] out of all relevant documents returned and not returned [33]. The metric is also known as Sensitivity of a system.

$$R=(Rl\cap Rt)/Rl \quad (1)$$

- Precision is the proportion of returned documents (or values) which are relevant (or correct) Rl∩Rt [32]. The metric is also known as Accuracy of a system.

$$P = (Rl \cap Rt)/Rt \quad (2)$$

- F-Measure, proposed by van Rijsbergen in 1979, is a weighted harmonic mean of precision and recall. It is a combination between Recall and Precision metrics, which was introduced to overcome the negative correlation between Precision and Recall [34].

$$F\beta=(1+\beta^2)PR/(\beta^2P+R) \quad (3)$$

- F1 is a special case of F- measure with β =1. β Is a parameter to control the balance between Recall and Precision where $0\leq \beta \leq \infty$. When β is set to 0, it implies giving no importance to recall, when β tends to ∞ then no importance is given to precision, and when $\beta = 1$ then Recall and Precision will be given equal importance [35].

$$F1= 2PR/(P+R) \quad (4)$$

P: Precision
R: Recall
Rt: Returned documents
Rl: Relevant documents

- ROC (Receiver Operating Characteristics) graph [36] –or area- is an analysis technique which had been used originally in medical diagnosis, to be later adopted in Machine Learning evaluation. ROC depicts the tradeoff between True Positive and False Negative rates. ROC areas are categorized roughly according to the values:

0.9-1 = excellent (A)
0.8-0.9 = good (B)
0.7-0.8 = fair (C)
0.6-0.7 = poor (D)
0.5-0.6 = fail (F)

3. Previous Work

As stated previously, the research efforts in cyberbullying covered several areas, including the detection of online bullying when it occurs; reporting it to law enforcement agencies, Internet service providers and others for the purpose of prevention and awareness;

and identifying predators with their victims. No effort was directed towards detecting cyberbullying in Arabic language. This section focuses on the previous work done in the areas of cyberbullying detection, ML, feature extraction and cross language transliteration and translation since those are the main techniques used in the implementation of cyberbullying detection systems.

3.1 Cyberbullying Detection

Most of the research done in detecting cyberbullying constituted of either a filtration software or ML techniques. A filtration software has to be employed by social networking platforms, in order to automatically delete or shade profane words [37] [38] [39]; but the filtration method is first limited by its inability for detecting subtle language harassment and second it has to be manually installed [40].

Most work other than filtration methods employs ML techniques, where old corpora of comments or conversations is crawled, whether from Facebook, Twitter, Formspring (a platform similar to Facebook, popular between teens) or even real conversations of sexual attackers [41]. These corpora are used to feed ML algorithms responsible for detecting cyberbullying attacks by building a classification rule from the training set. The obtained classification rule classifies the testing set comments. Such work was done in [22] where the authors crawled data from Formspring and used the Amazons Mechanical Turk [42] for labelling comments. Then they used the learning methods from the Waikato Environment for Knowledge Analysis (WEKA) toolkit [43] to teach and test the model for classifying comments.

The problem of detecting subtle language cyberbullying attacks was tackled by Dinakar et al [6]. They depended on commonsense reasoning in the detection of cyberbullying content. As an example of the commonsense they used: they considered comments of wearing makeup when subjected on Males might indicate the presence of harassment. They built their datasets from both YouTube and Formspring for both training and testing. They used NB, JRip, J48 and SVM for text classifications. For feature sets they used general features, such as a list of unigrams or profane words, tf-idf weighting scheme, Ortony Lexicon for negative affect, Part-of-speech tags for commonly occurring bigrams, and Label Specific Features including frequently used forms of verbal abuse.

The weighting scheme tf-idf is the product of term frequency and the inverse document frequency in the dataset. It involves multiplying term frequency (tf), that represents the number of times a term occurs in a document, by inverse document frequency (idf), which varies inversely with the number of documents to which a word is assigned [44].

Nahar, Li and Pang [40] employed the tf-idf weighting scheme for building features. In addition they built a network composing of bullies and their victims. The network was used to rank the most active predator and its target. In [45] Dinakar et al. stated that detecting profane language cyberbullying is easier than detecting sarcasm and subtle language attacks. Chayan and Shylaja of [46] enhanced the performance of the cyberbullying detection model by 4%, through looking for comments directed towards peers by using Supervised ML and Logical Regression models. However they didn't detect sarcasm comments. Dadvar et al. [47] state that incorporating user context such as the user's history as a feature for training the cyberbullying detection model increases accuracy of classification; however they didn't include sarcasm detection in their system.

SVM was also used by Yin et al. [48] for classifying posts as containing harassment or not. They used documents from CAW 2 dataset, which included posts from Kongregate, Slashdot and Myspace. For feature selection they incorporated several features;

- *Local features,* they used tf-idf.
- S*entiment features,* such as 1- grams, 2- grams and 3- grams, and they also captured second pronouns.
- *Contextual features* in which they studied both the similarity of a post to other neighboring posts and the cluster of posts neighboring around a certain harassment post.

Capturing sentiment features only didn't perform well so they compared the performance of their system by mixing features. Tf-idf performed better than n-grams and foul words, however, combining tf-idf with contextual and sentiment features achieved an additional enhancement in results in Precision, Recall and F1-measure. A similar work was done by Dadvar et al. [47], who built their feature space from Content-based, User based and Context based features. They also proved that incorporating contextual features such as gender information from the user's profile enhances cyberbullying detection.

Other research efforts were focused around social network profiles, such as [17]. They presented a methodology to detect and associate fake profiles on Twitter social networks to real users. This system had been capable of linking the owners of a fake account on Twitter to a real account for one or more students in a school class; this was a case of a real cyberbullying incident. The system was devised by collecting features from tweets then analyzing the features using various supervised ML techniques included in WEKA. Afterwards the performance among these techniques was compared on True Positive Ratio (TPR), False Positive Ratio (FPR) and Area Under ROC Curve (AUC). Bayzick, Kontostathis and Edwards [49] proposed the BULLYTRACER software which detects cyberbullying in chat rooms 58.63% of the time.

Chen et al. [50] proposed a new model for detection which they named as the Lexical Syntactic Feature-based (LSF) model; it achieved a precision of 98.24% and recall of 94.34%. Their model calculated both a post and a user's offensiveness depending on the ratio of offense appearing in a user's posts. This model detects "strong profanity" in online posts by using lexical analysis methods such as Bag of Words; and subtle language harassment to which the authors referred as "weak profanity". Then the model uses semantic analysis and NLP techniques to analyze the context of sentences by studying the grammatical relations among words. This research was an extension to the work presented in [51] for cyberbullying posts filtration.

Most of the research in cyberbullying did not give importance for the distinction between cyberbullying and cyberagression, but

for Hosseinmardi et al. [52]. They proposed a definition for cyberbullying which is the ***repetition*** of harmful actions using electronic devices over a certain period of time. They stated that most of the work previously done in detecting cyberbullying was actually focusing on detecting cyberagression. They define cyberagression as a single instance of harmful action that if repeated over time would be considered as cyberbullying. They also demonstrated that a Linear SVM classifier can significantly improve the accuracy of identifying cyberbullying to 87%. In addition they incorporated using features other than text such as images for better detection of cyberbullying.

Another study on cyber aggression was done by Nakano et al [53]. They analyzed anonymous and non-anonymous questions and answers from ask.fm. Their study shows that anonymous questions tend to be more aggressive than non-anonymous ones. They also showed that replies to anonymous questions tend to be less aggressive than replies to questions from known profiles.

Potha and Maragoudakis [54] stressed on a window of time in order to study the textual patterns of previous conversations in order of predicting the upcoming actions of a predator. They incorporated time series modelling in their research in addition to SVM for features selection. SVD (Singular Value Decomposition) [55] was used for feature reduction and DTW (Dynamic Time Warping) [56] for matching time series collections.

Fuzzy Logic and Genetic algorithms were also used in cyberbullying detection [57], where a new system was proposed using those two methods. This system's performance was compared across precision, recall and F1 measures. The system achieved better in Accuracy, F1-measure and Recall than previous fuzzy classification methods with 0.87, 0.91 and 0.98 respectively.

3.2 Arabic Language

Work related to Arabic language is scarce due to the complex morphological nature of Arabic. Arabic language is used by around 300 million Arabs around the world, mainly Muslims. It is a script language which is read and written from right to left and it constitutes of an alphabet of 28 letters. Vowels in Arabic are represented by special punctuation marks called Diacritics [58]. There are three variations for Arabic languages going on together. The Classical Arabic which is the language of the Islamic manuscripts -such as the Quran and prayers- and Arab people until Mid-20th century. The Modern Standard Arabic (MSA) which is the formal language used nowadays in schools and news, and it is known by all Arabs. Finally comes the dialects, which are accents for the Arabic language, usually used informally between people. There are around 10 dialects, one for every country - or group of countries [59], [60]. Arabic dialects imply a difference in meanings of words between different countries. We might find some words that are considered profane in one country, while good or ordinary in others, for example the word "Yetqalash" in Yemen is a compliment while in Morocco it is an offensive word [61].

Arabic language is a challenging and complex language due to its nature, where Arabic words do not include capitalization [60]. The morphologic nature of Arabic inflicts a lot of ambiguity, and the Arabic corpus is very scarce. Arabic language is ranked the 7th around the world, and its use over internet is growing vastly [59], thus arose the research interest in Arabic language fields.

An extensive search was performed on available articles and publications and no previous work for cyberbullying detection in Arabic language texts and comments was found. But some papers in the fields of ML and NLP were found. The previous work done in Arabic deals with text preprocessing or text classification.

Ghaleb Ali and Omar [62], proposed a key phrase extraction method that combines several key phrase extraction methods with ML algorithms. The output from the key phrase extraction methods is used as features to the ML algorithms. The ML algorithm in turn classifies the feature as either a key phrase or not. They compared their results by using three ML algorithms: Linear Logistic Regression [63], SVM and Linear Discriminant Analysis [64]. They have proved that SVM gives the best results in key phrases extraction among the three algorithms.

Some work had been done in Arabic named entity extraction, such as Named Entity Recognition for Arabic (NERA) [65] to identify proper names in Arabic documents. NERA used a white-list of named entities and corpora compiled from various sources; its performance was measured across recall, precision and F1. The results were satisfactory; 86.3% 89.2% 87.7% respectively for person named entities.

Filtering for spam emails written in Arabic and English was done by El-Halees [66] on pure English, pure Arabic and mixed collections of emails. Several ML techniques were used, including SVM, NB, k-Nearest Neighbor (k-NN) [67] and Neural Networks. The performance of the system was measured across all three variations and SVM was proved to be best in pure English environment. The system performed less on pure Arabic emails, due to the inflictive nature of Arabic Language. The authors also proved that stemming Arabic words enhances the performance of the classifiers, where NB performed best with 96.78% Recall and 92.42% F1-measure.

Other than emails there are also attempts for detecting spam in social networks, such as Twitter. Such work was done by El-Mawass and Alaboodi in [68]. They elaborated a system to detect spam in Arabic tweets. Their system achieved significant accuracy, precision and recall measures.

Sentiment analysis is one of the text classification categories. Sentiment analysis classifies a certain text as positive, negative or neutral [69]. Sentiment analysis was done by Hamouda [70] on Facebook comments written in Arabic. They built a corpora from 6000 comments sampled from Facebook, preprocessed this corpora, and then applied classifications to determine the sentiment behind the comment. Three classifiers were used: SVM, NB and Decision trees. The best performance was achieved by SVM with 73.4% accuracy. Another attempt for sentiment analysis was done in [71] for Arabic Tweets, their special contribution was in handling Arabizi and dialects. They incorporated NB, SVM and k-NN for classification and the best accuracy was approached by NB.

In [72], Duwairi detected sentiments from dialectical Arabic texts. Two methods were applied for detection. First, by translating dialectical words into MSA, then detecting according to MSA

lexicon. Second method was by detecting dialectical lexicon. NB and SVM classifiers were used to detect both negative and positive polarities. The results obtained showed improvement in Precision, Recall and F-measure upon translating into MSA.

Sentiment analysis was applied on Arabizi also by Duwairi et al [69]. In their system they first converted Arabizi text into Arabic by using their own rule based method. They labeled their data using their crowdsourcing tool [71] and then applied SVM and NB for classification. A comparison between SVM and NB showed that SVM outperformed NB. However better results were achieved when they first eliminated neutral entries from the dataset.

Arabic tweets in Saudi Arabia were analyzed by Alhumoud, Albuhairi and Altuwaijri [73]. They analyzed the tweets using a hybrid approach. Their hybrid approach composed of building a classifier and training it using a one-word dictionary. They compared the results obtained from both their hybrid approach and the supervised learning approach. Two classifiers were used from WEKA, NB and SVM. Their results showed the outperformance of the hybrid approach.

A significant research effort was done on stemming for Arabic language. Stemming is a text preprocessing technique. In stemming words are truncated to obtain their roots [74]. Several stemmers for Arabic are available, including rule-based stemmers such as Khoja's [75] and light stemmers. Light stemmers blindly remove letters from words –affixes and suffices – without prior knowledge of roots [76]. Stemmers are either monolingual or multilingual. Gadri and Moussaoui [77] elaborated a multilingual stemmer. Their stemmer is Language independent and it used the n-gram technique. This stemmer segments words into bigrams, then statistical measures are used to reach the best root. This stemmer was tested against English, French and Arabic. The best success rate (94%) was achieved in small Arabic Datasets. In large datasets, the best results were for English (86, 50%) and the worst for Arabic (67, 66%).

4. Proposed System

As stated previously, one of the purposes of this journal is presenting a solution for the problem of cyberbullying in both English and Arabic languages. As seen in the previous section, there is some work done for detection in English, but none in Arabic Language. Proving the hypothesis that Arabic cyberbullying can be detected was a challenge. Thus in the first stage of the system the focus was on detecting cyberbullying in Arabic language.

Since the proposed system employs ML, a dataset had to be prepared to be used for training and testing the system. Two toolkits were tested for ML, Dataiku DSS and WEKA. The decision was to use WEKA toolkit because it supports Arabic language.

4.1 Data Preparation

In order to train and test the system, a huge amount of data had to be obtained. Thus, the choice was to scrap data from both Facebook and Twitter. This choice was inflicted by the fact that those two social media portals are the most widely used by the Arab nation, especially Arab youth.

For the data acquirement phase two custom tools were built. Those tools were implemented to scrap data from social networks, one for Facebook and the latter for Twitter. Twitter Scrapper was written using PHP while Facebook scrapper incorporated python. Both scrappers connected to a mongo dB server, where all downloaded tweets and messages were stored.

In the process of getting the data from Twitter, the Twitter Scrapper searches for Tweets according to a given location and perimeter. A huge database was accumulated using this tool. In order to get the tweets from the Arab countries we focused on the center of the Middle East Region as a location, and selected an area of 10,000 kilometers radius in each run. Thus the tweets were collected from Lebanon, Syria, Gulf Area and Egypt mainly. The size of the tweets database summed up to 4.93 GB.

Collecting Facebook data was harder, due to the restrictions imposed by Facebook security and privacy measures. In Facebook the data source had to be specified beforehand. It is specified by page IDs. The aim was for pages of public figures and news agency, since those pages include more discussions and interactions between Facebook users. The tool had to be run many times to get data. Each run required that the Facebook Page ID is specified to collect the data from it. Many requests were blocked due to privacy measures on the targeted pages. The Facebook database reached 0.98GB of size, thus the decision was to keep Facebook data for validating the system in a later stage and use the tweets dB for training and testing the system at the current stage.

4.2 Data Labelling and Preprocessing

Before the system training phase, the obtained data had to be cleaned and preprocessed. WEKA was used for this purpose as mentioned above. For the system in hand, version 3.9.1 of WEKA was used since it contains specific packages that will be mentioned later.

The only features included in the first stage were text (the content of the tweet) and language. Several languages were observed in the database, mostly Arabic, English and Turkish. All the tweets of languages other than English and Arabic were discarded. The remaining tweets were separated into two datasets, one having only tweets in Arabic language and the latter English. The dataset with only Arabic language was denoted by ArabicTweets. This Dataset contained 35273 unique tweets after removing all duplicates. While the English Dataset contained 91431 tweets.

Due to the sensitivity of Arabic language and to ensure the correct labelling of sarcastic cyberbullying content, Arabic tweets were labelled manually by adding an extra attribute to the dataset, which is the "bullying". This attribute was assigned to be the class attribute, where labelling will take place and it will be used by WEKA to evaluate the performance of the system. The values of bullying instances are either "yes" or "no". "Yes" is when the tweet contains cyberbullying and "no" otherwise. The server used to preprocess the datasets was a 3.5 GHz CPU and 32GB RAM's windows 10 virtual machine.

4.3 System Training and Testing

Training and classification procedures were done several times for the purpose of reaching the best results. Two models were chosen in the first stage, Naïve Bayes and SVM. Those two models were chosen based on analysis of the previous work done in the field of ML. Researchers reached a conclusion that those are the best two algorithms for text classifications – as mention in section 2 [54, 57, 59, and 61]. In the first model the system was trained using Naïve Bayes and promising results were achieved. The precision was 90.8514 % for the overall system. However this precision is somehow tricky. The dataset contained only 2196 bullying content out of the total 35273. Thus even if in the worst case the system classifies all the tweets as not bullying then it will be still achieving a high precision. Hence the analysis of the performance was shifted towards the actual cyberbullying content which was detected (or in other words classified as "yes"). The system in the first run was capable of detecting 801 out of 2196 actual bullying instances (or tweets) which is a good result and it proves the aim of the paper: Cyberbullying in Arabic is detectable!

In training the second model; the AffectiveTweets package was used [78] and specifically the TweetToSentiStrengthFeatureVector filter. This filter depends on the SentiStrength mechanism developed by Thelwall et al [79]. SentiStrength originally works with English, but it is capable of supporting other languages. SentiStrength works on weights of tweets: positive weights (2 to 5) are given to words denoting positive feelings and negative weights for negative feelings (-2 to -5). 1 and -1 are considered neutral. Then a list of Arabic profane words was collected and weighted manually. The weight given for profane words was (-5) which is the extreme negativity in SentiStrength. Afterwards the English lexicon files used by SentiStrength were replaced with custom built Arabic files including the weighted profane words.

In the process of customizing the SentiStrength files, the phrases added contained the profanity from several Arabic countries. This gave a chance for handling dialectical difference between Arabic countries implicitly. With more effort in including more dialectical varieties of phrases all the dialects in Arabic countries would be covered.

The dataset prepared had to be preprocessed before building the training model. Preprocessing was performed using WEKA. The set of techniques used for preprocessing included applying the TweetToSentiStrengthFeatureVector filter, converting strings to word vectors and normalizing. After that the system was trained using SVM. Training and testing the model is a time-consuming process (it took around 8 hours). As a preliminary stage, the system achieved results somehow close to the results achieved by Naïve Bayes in the first model. The model was capable of detecting 710 bullying instances. Those results are promising and they show that SentiStrength can be customized to be used in cyberbullying detection. The results achieved by the system are summarized in the next section.

5. Results Obtained

Table 1 shows the division of the classified instances. How many instances were classified correctly and how many wrong in each model and class. As seen, in Naïve Bayes model 31245 non-bullying instances were classified correctly. There are also 1832 non-bullying instances classified as containing bullying. As for the bullying instances, it is seen that 801 were classified correctly while 1395 were classified as not containing bullying.

Table 1: Classification Results

	Correctly Classified		Miss Classified	
Class	***no***	***yes***	***no***	***yes***
Naïve Bayes	31245	801	1832	1395
SVM	32479	710	1923	161

Table 2: Summary OF Rates

	Class	Precision %	Recall %	TP %	FP %	F-Measure %
Naïve Bayes	***no***	94.5	95.7	95.7	69.6	95.1
	yes	36.5	30.4	30.4	4.3	33.2
	Overall	90.1	90.9	90.9	64.7	90.5
SVM	***no***	94.4	99.5	99.5	73	96.9
	yes	81.5	27	27	0.5	40.5
	Overall	93.4	94.1	94.1	67.6	92.7

Table 2 displays the results obtained by WEKA after training and testing the model. Precision, Recall, True Positive Rate, False Positive Rate and F-Measure are displayed for both models, Naïve Bayes and SVM. In each model the measures mentioned are displayed for the two classes of the "bullying" attribute which are "yes" and "no". In the third row of every model there is the weighted measure from both classes.

There is a difference between the "yes" precisions of the two models noted in Table 2. SVM achieved a much higher precision for the "yes" class -0.815 for SVM and 0.365 for NB. This difference is due to the lower number of wrong classified instances by SVM as seen in Table 2.

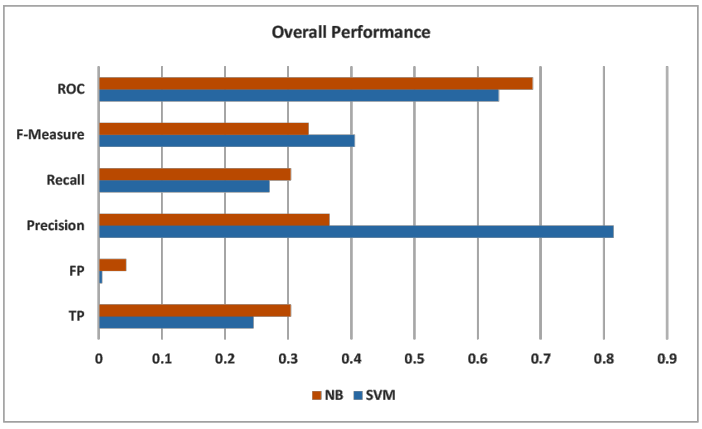

Figure 1: Difference in performance between NB and SVM

Figure 1 displays graphically the difference in performance between NB and SVM for the weighted class, or the overall per-

formance. As seen the precision achieved by SVM was much better than NB, while the other measures were somehow close, such as ROC, TP, FP, etc.

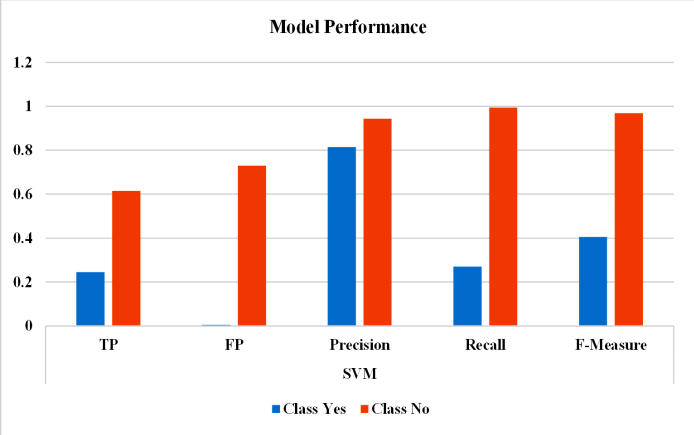

Figure 2: Comparison between the measures achieved by SVM model

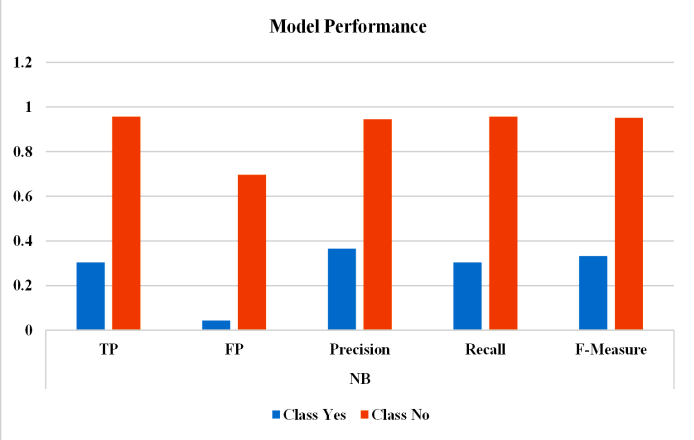

Figure 3: Results of NB Model

Figure 2 compares graphically between the measures achieved in both classes by SVM model, while Figure 3 displays the results of NB. As shown previously Table 1 and Table 2, the low number of False Positives, high precision and recall are significant.

The results obtained by this system are not perfect if compared with previous work done in English cyberbullying detection systems. But the aim of the paper was to prove that Arabic cyberbullying is detectable. Thus, the results displayed in the Tables and Figures above cannot be compared with previous work done for Arabic Language due to the negligibility of such work. Table 2 shows a recall of 30.4 for the "yes" class instances in the NB model, which means at least one third of the bullying in Arabic is detectable by the system.

The overall measures for both models give reasonable results. Although the focus was on the analysis of the "yes" class since it contains the bullying instances which are less than the "no" count. But the high precisions approached by the system denote that the model is not classifying a high number of non-bullying instances as bullying ones. Which is also an important point to consider.

6. Conclusion

The work done in this paper proves that detecting Arabic cyberbullying is possible. However, some effort is yet needed to enhance the performance of the system presented. Therefore, some future plans still need to be completed in later stages.

The first step is to enhance the performance measures achieved by the system through using hybrid training models, such as combinations of Distance Functions, NB and SVM. Treatment of Arabizi content is also in the future plans. This is a crucial point, since a lot of Arabic youth use the chat language on social networks for communication among each other. Thus the proposed system will be upgraded to handle cyberbullying when written in Arabizi.

Further plans incur training the system using deep learning methods instead of machine learning and then comparing the differences of the outcomes from the two schemes.

Water Quality Assessment and Prediction

ABSTRACT

Water quality assessment and prediction is a more and more important issue. Traditional ways either take lots of time or they can only do assessments. In this research, by applying machine learning algorithm to a long period time of water attributes' data; we can generate a decision tree so that it can predict the future day's water quality in an easy and efficient way. The idea is to combine the traditional ways and the computer algorithms together. Using machine learning algorithms, the assessment of water quality will be far more efficient, and by generating the decision tree, the prediction will be quite accurate. The drawback of the machine learning modeling is that the execution takes quite long time, especially when we employ a better accuracy but more time-consuming algorithm in clustering. Therefore, we applied the high performance computing (HPC) System to deal with this problem. Up to now, the pilot experiments have achieved very promising preliminary results. The visualized water quality assessment and prediction obtained from this project would be published in an interactive website so that the public and the environmental managers could use the information for their decision making.

1. Introduction

This paper is an extension of work of "Applying Parallel Programming and High Performance Computing to Speed up Data Mining Processing", originally presented in the 16th IEEE international Conference on Computer and Information Science, 2017 [1]. Water quality is an important issue. Not only can the drinking water directly influence our body as about 70% of the human body is made up of water, the natural water is also an important part as people like to have some entertainment activities near lakes or rivers. Nowadays the prediction of river or lake water qualities is more and more important. The traditional way to assess water quality is analyzing the water attributes' value. If the value is in a certain range, the quality of water can be classified. This is an easy and fast way, but it can only be used for assessment. To predict water quality, scientists need to use the chart to show the changes of an attribute in a period of time. This is a statistic way and can predict water quality in a relatively accurate way. The problem is it takes lots of time to analyze the water attributes and it can only predict a long period of time's water quality. As the results are analyzed by people, increasing water attributes for analyzing will greatly increase the workload [2, 3, 4, 5, 6, 7].

In this research, we use machine learning algorithm on water quality prediction. By applying machine learning algorithms, the increasing water attributes and cases are no longer a big problem. Compared with the traditional way, using machine learning can deal with a great number of data in a short time. It can also slightly reduce the human error on the analysis phase. The idea of implementation is not very complex. First, we use the K-MEANS algorithm to classify the data. The K-MEANS algorithm is a very basic, easy and important clustering algorithm. In this research, we specify K is 5, which means we want to classify the water data into five clusters to represent five water qualities from good, relatively good, medium, relatively bad, and bad. By analyzing each cluster's center; we will know which cluster represents what water quality. After that, we use the C5.0 algorithm to generate a decision tree [8]. In this research, we use five or seven water attributes for classification.

2. Significance

As water quality is more and more important, not only scientists but also the general publics are interested in the future natural water quality. Thus, the request to predict natural water quality like weather forecast is getting stronger. Unlike weather forecast which can use satellites to get, we can't use several satellites to cover a large area to collect water data. The data needs to be collected by observations in different places. It also takes far more time to analyze the data so that people can make a water quality prediction. The United States is a country with many rivers and lakes. The government has already established many water observations to monitor the water system of the country [9]. Collecting data is not so difficult. Making predictions in an efficient way is the key problem.

For this research, the most significant part is it completely uses the data from currently operational observations. This means the hardware cost of prediction is greatly reduced. As long as an observation station can provide enough data, this method can be used to predict water quality. By using machine learning technology, we can deal with a great amount of data in a short time, which can make water quality analyze very quickly. Although these kinds of water quality analysis may not be as accurate as biology analysis, it is accurate enough for water quality forecast to the generate public [10]. Compared with the traditional way for water quality research, the human factors in this research is relatively low. This can slightly reduce the possibility of human error.

3. Design and Implementation

There are four steps in this research: data selection, data preprocessing, classification, and assessment and prediction. The first two steps are preparing a suitable data for classifying. Step three is to make the classifications. It will be implemented by the K-MEANS algorithm. Step four will generate different decision trees for assessment and predicting by using the C5.0 algorithm.

Data selection is very important. This step is the root of this research. As this is a machine learning research, a "good" data definitely can greatly affect the results. The "good" here means it needs to have enough cases, enough attributes, and less missing data. Enough cases can ensure the number of training data. The accuracy of classifications is based on the number of training data. The more cases we have, the better the classifications will be.

The data we used was from the USGS website. USGS keeps the daily water data from 10472 observation sites all over the United States. Many of the sites keep about four attributes of the water. After checking all the sites keeping at least seven attributes, we finally choose the site numbered 08070200. This site is in San Jacinto River in Texas and the data is still updating till now. It keeps 7 attributes of the water, and has few missing values. In this research, we choose the data between 11/22/2005 and 09/08/2012 which has 2483 records [9].

The second step is data preprocessing. We made the data more meaningful for use. It included resetting the extreme data, and normalizing the data. To deal with the extreme data, we put the entire data of one attribute on a scatter chart and find the extreme value. Fig. 1 is an example of original "discharge" value shown in a chart. The x-axis represents different cases and the y-axis is value. It is very clear that the maximum value of discharge is about 8000. If we use these values directly and normalize them, the problem is most normalized value will be 0. This is definitely not good for classification as it cannot reflect the data distribution. To solve this problem, the idea is set all values greater than an "extreme value" to be equal to this "extreme value". In Fig. 2, we use the same data in Fig. 1 but set all values greater than 700 to be equal to 700.

Fig. 2 looks better than Fig. 1. It now can reflect the changes and distribution of the discharge. A problem here is how to set the "extreme value". In Fig. 2, we can see that there is not too much difference if we set the extreme value to 600 compared with 700, as most value are under 200. The key point is we do not want to change too much value as changing data is a kind of human factor. Making the charts have better data distribution with the least changes is the role of the extreme value. In this attribute, totally 136 values have been affected by setting the extreme value to 700, which is about 5% of the total 2483 values.

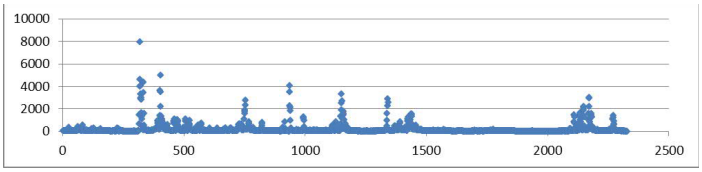

Figure 1, the original scatter chart of the discharge in this research. All values are either the original values or calculated values.

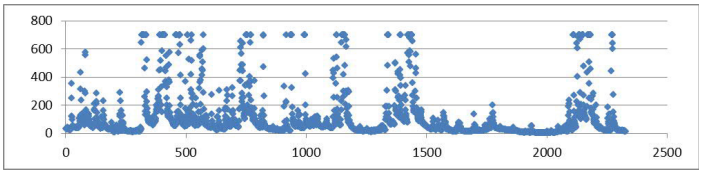

Figure 2, the new discharge chart which set all values greater than 700 to be equal to 700.

The third step of this research is classification. We want to classify the data into five clusters (classifications). Each cluster represents a certain water quality range from very bad, bad, medium, good, to very good. The method for classification is to implement the K-MEANS algorithm. The K-MEANS algorithm is a very basic but important algorithm for classification. It treats every node in an N-dimensional space. Each dimension represents an attribute. In this research, we used seven attributes, so each record was a node in 7-dimension spaces. We first gave five initial centers. Then based on the distance of each node and each center, we assigned every node a group. After that, we recalculated the distance of every node inside one group to move the center. So we repeated the iteration of assigning groups and moving centers until the distance between the new center and the previous center was smaller than a "quit distance" or the new center moved to a previous center node.

The last step of this research was assessment and prediction. Before we could make the assessment and prediction, the very first thing was to analyze which group represents what kind of water quality. This can be done by analyzing the center node's attributes. We needed to look up some references and some criteria of water. This was not easy but also not hard. The results of classification actually were the results for water quality assessment. We already classified the data into five groups. We could make a water quality assessment by generate a decision tree.

The main topic was how to make prediction. Before we could make the decision tree, we needed the training data. The format of the training data we used to generate the decision tree was "attributes" plus "classification results". If the training data was "day 1's attributes" plus "day 1's classification result", it was used to generate a decision tree for assessment. So, we "shifted" the classification results by 1day. The training data would be like "day 1's attributes" plus "day 2's classification result". This data can generate a decision tree for prediction. Fig. 3 shows how to "shift" the data. In this way, we lose one day's case as the last day only has attributes. This is a basic way for prediction. It uses previous 1day's attributes for prediction. An improved way is using more than 1 day's attributes. We first created an additional attribute which made the first line look like "day 1's attributes" plus "day 1's attributes" plus "day 2's classification result". Then we shifted it to "day 1's attributes" plus "day 2's attributes" plus "day 3's classification result". This was using previous 2 days' attributes to predict the third day's water quality. In our research, we used up to previous 8 day's attributes to predict the ninth day's water quality to see if the results have any improvements. This does not mean the more the better. In fact, adding more day's attributes is the same with adding water attributes. It can increase the data interference, which will increase the difficulty to generate the decision tree and reduce the accuracy of prediction.

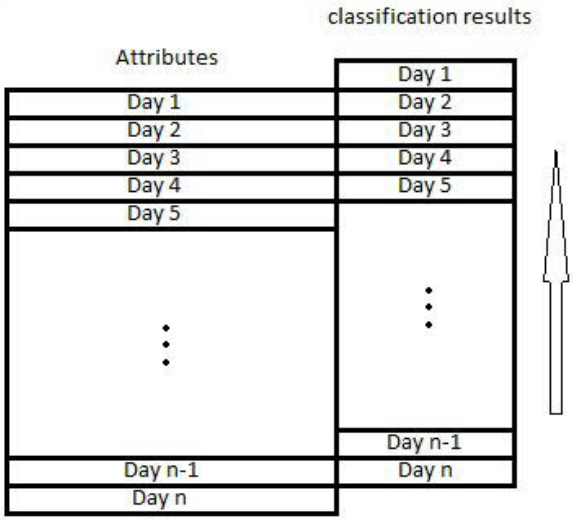

Figure 3, the idea of how to "shift" the classification result.

After preparing the training data, we used See5.0 to generate a decision tree. See5.0 is a software tool which implements the C5.0 algorithm. It can deal with a great amount of data in a short time and generate the decision trees by the classic method, the winnow method, and the boost method. It generates a decision tree and gives the importance of every attribute. Most times all attributes are used. If one attribute has not been used by the C5.0 algorithm, very often this attribute may have a linear relationship with some other attributes [9].

4. Result and Analysis

The results analysis of this research is based on the prediction accuracy. Among the 2483 records, the even records are used as training data to generate decision tree, the odd records are used as testing data. We tested the decision tree by testing data to get the prediction error rate.

The accuracy for assessment was quite good. Using the winnow method, the prediction accuracy was 93.5% by using seven attributes and 93.6% by using five attributes. Dissolved oxygen, turbidity and PH were mainly used attributes for assessment. The usage of temperature was relatively low, which shows the way we normalized the temperature reasonable. Using boost method, the prediction accuracy was 96.1% by using 7 attributes and 95% by using five attributes. The results of boost method show increasing attributes can increase the prediction accuracy.

The prediction has 32 results into 2 groups. One group used five attributes to predict, another group used seven attributes to predict. In this way, we can know if increasing attributes can improve the prediction accuracy. Both the winnow and the boost methods are used for test. One group have 8 tests differed by using different number of day's attributes.

Table 1 is the result for group 1. It shows the error rate for prediction the next day's water quality by using five attributes to classify the data into five classifications. Table 2 is the result for group 2. It shows the error rate for prediction the next day's water quality by using seven attributes to classify the data into five classifications. All the results above are the test error rate assigned by See5.0. Based on these results, we can change the data from error rate to prediction accuracy as an alternative.

Table 1, the error rate of predict the next day's water quality by using 5 attributes and 5 classifications. W stand for winnow method and B stand for Boost method.

Predict 2nd Day		Predict 3rd Day		Predict 4th Day		Predict 5th Day

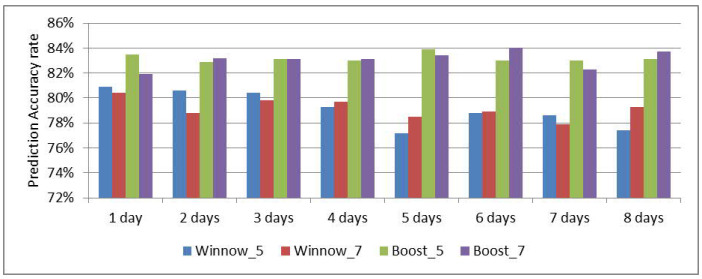

Figure 4, Prediction accuracy of two different methods and using different number of attributes on predict the next day's water quality to 5 classifications.

Figure. 4 shows the prediction accuracy for each method using different attributes. It proves the great performance of boost method. We can see using seven attributes has better performance. The winnow method seems to have no great difference. The boost method, however, shows the advantage of using seven attributes. Out of eight tests, five tests show using seven attributes can reach a better performance than using five attributes. Also using the boost method reaches the highest prediction accuracy, which is 84% by using previous six day's attributes to predict the next day's water quality.

This figure also shows some interesting results. As we mentioned before, increasing more day's attributes may not improve the prediction accuracy. Actually, these eight tests are all used to predict the next day's water quality. With the increase number of attributes, the prediction accuracy of the winnow method, generally speaking, is reducing. This is because data interference. No matter we increase the number of single day's attributes or we increase the number of days we use for prediction; they have same effect for the winnow method. When the attributes' number is greatly increased, the difficulty to generate the decision tree also increasing tremendously. The boost method, however, doesn't take too much effect from data interference. As each decision tree make a slightly improvement based on the previous decision tree's error, the "vote" mechanism can greatly reduce the data interference and has a better performance.

5. High Performance Computing Speed up the Processing

In this project, we were running machine learning program on Purdue University's High Performance Cluster – *Falcon*, which has 8 nodes, each with 4 CPUs, and/or *Miner*, which has 512 nodes, each with 4 CPUs. This high performance computing (HPC) system is supported by the Northwest Indiana Computational Grid (NWICG) program funded by the U.S. Department of Energy grant ($4.9 million). Taking advantage of the NWICG's HPC system, it is practical for us to use complexity to exchange the water quality prediction accuracy. HPC dramatically decreases the running time of the enumeration based algorithm, which is time consuming but more accurate.

Facilitated perfectly by the current existing Northwest Indiana Computational Grid, the project has applied the HPC system which dramatically decreases the running time of the enumeration based algorithm, so that makes this very time-consuming algorithm for water quality prediction becoming practical.

Up to now, the experiments of this innovative approach obtained very promising results. The sixteen-processor HPC system achieved more accurate water quality prediction and reduced the execution time by more than ten times. The experiment results showed applying machine learning models on HPC system is a very encourage direction for Northwest Indiana's water quality assessment and prediction.

In light of almost 3000 cases, the optimal enumerative algorithm is very time-consuming (running in days) when executing on a single machine. In order to improve the performance, we applied parallel programming on the enumerative algorithm. The program run on multi-processors in parallelism. The parallel computing assigned one process as the master process and others as slave process. The master process read in the data, broadcasted the data and other information to the slave processes. The parallel programming split the clustering calculation into threads for slaves. Each slave process worked on calculations for clustering. Finally, the master processor received the results from each slave process and chose the global optimized clustering [11, 12, 13].

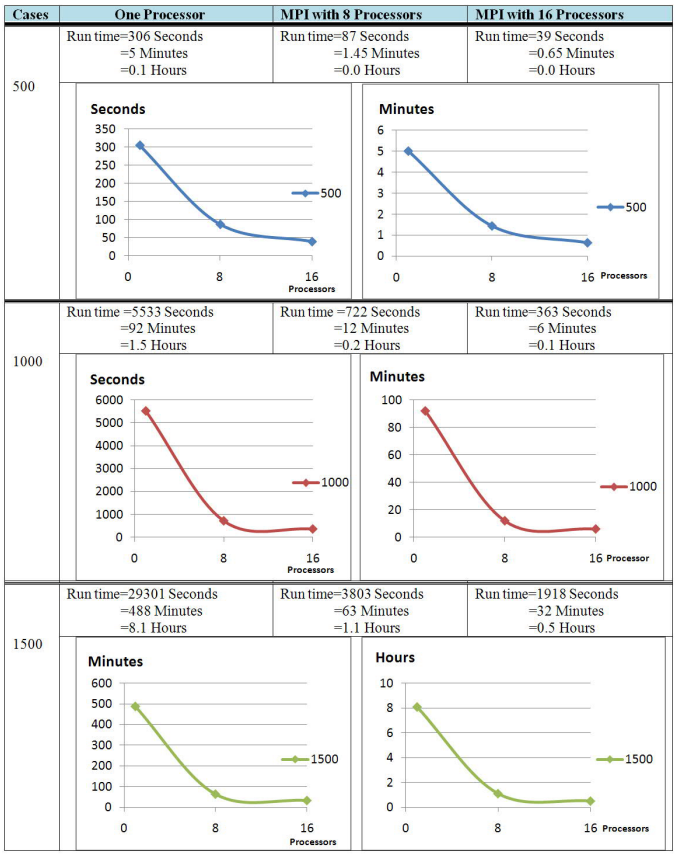

Figure 5, Experiment results with MPI on the HPC

Our experiments compared the running time of the enumerative algorithm using a single processor with that using HPC with 8 processors and 16 processors. The number of the cases was 500, 1000, 1500, 2000, 2500, and 2700 respectively. Figure 5 and Figure 6 below show the execution time of our preliminary experiments. It exposed the critical role of HPC for the time consuming enumerative algorithm to process large amount of data. For example, for 1500 cases, running on a single processor, it took more than eight hours to finish the clustering; whereas running on HPC with 16 processors, it only took about 32 minutes. This improvement of execution time is critical, because it is important to have a reasonable amount of indicative and representative data samples (cases) in order to discover patterns in data samples using machine learning technologies. It is not unusual to have a data set of 1500 cases by this approach.

The results of these experiments produced a solid fundamental for future developments in our water quality assessment and prediction project. We created decision tree employed C5.0 for the water quality assessment and prediction. Using the produced decision trees to predict unseen cases, the prediction accuracies reach 82 percent, two percent better than applying k-means algorithm and about the same improvement than applying the

mechanistic simulation models. It is anticipated that if we use more attributes of the water quality in the future, the accuracy rate could be further improved.

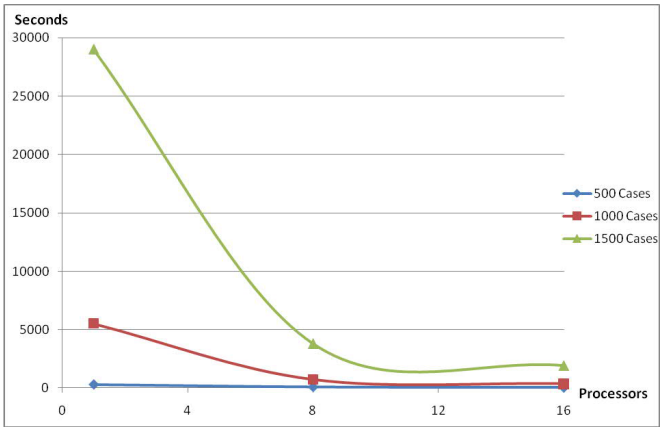

Figure 6, Execution time in seconds for comparison of various processors in HPC

6. Summary and Conclusion

In this research, by applying machine learning algorithm to a long period time of water attributes' data; we can generate a decision tree so that it can predict the future day's water quality in an easy and efficient way. The idea is to combine the traditional ways and the computer algorithms together. Using machine learning algorithms, the assessment of water quality will be far more efficient, and by generating the decision tree, the prediction will be quite accurate. The drawback of the machine learning modeling is that the execution takes quite long time, especially when we employ a better accuracy but more time-consuming algorithm in clustering. Therefore, we applied the HPC System to deal with this problem. Up to now, the pilot experiments have achieved very promising preliminary results. The visualized water quality assessment and prediction obtained from this project would be published in an interactive website so that the public and the environmental managers could use the information for their decision making.

ABSTRACT

The goal of this study was to use underwater robots instead of a diver's observations to monitor and record the condition of an obstructed seabed in a shallow area. It is difficult to investigate marine resources that exist in deep water shaded by rock due to large and/or small rocks on the seabed. To solve these problems, we newly constructed a flexible lengthening-shortening arm with a small camera unit for an underwater robot to assist in the management of fishery resources. In this paper, we describe the concept and configuration of the newly developed arm mechanism using a sliding screw mechanism to overcome obstacles by changing arm posture in a two-dimensional plane, and we demonstrate the experimental results of a path-tracing controller for the rear links. The results were that the maximum deviations between the target path and the tracing path were less than 4.0% of the total width of the arm mechanism. These results suggest that the newly developed path-tracing algorithm is effective for our flexible lengthening-shortening arm mechanism.

1. Introduction

This report is an extension of work that was originally presented at the 2017 IEEE International Conference on Mechatronics and Automation (ICMA) [1]. Extended points are as follows; (a) the geometric configurations and control parameters for an unique slider-screw mechanism of our system in Section 2.2.3, (b) waterproof design for the slider-screw mechanism in Section 2.2.4, (c) an operational test on land to clarify the validity of the flexible lengthening-shortening arm mechanism in Section 3.1, (d) an explanation of the details of the path-tracing algorithm in Section 4.2.3 and Appendix, and (e) improvements of the movement error occurred in previous work [1].

Underwater robots, such as autonomous underwater vehicles (AUVs) and remotely operated vehicles (ROVs), were developed to reduce the big burden on fishermen in managing fishery resources and/or the cost of submarine operations and risk to human life (e.g.; AUV for work in shallow waters and coastal areas [2], reduce the burden on divers [3], achieving the core sampling at shallow seabed [4], and achieving the video transect method instead of divers [5]). Generally, underwater robots are equipped with cameras to monitor and record the condition of the seabed rather than relying on a diver's observations. In the case of shallow sea areas, such as surf zones, there are many rocks and marine algae. Although these areas are useful as growth environments of fishery resources, it is assumed that the view of the camera is hindered and/or the robots cannot approach the target objects closely. In addition, it is difficult to investigate rock shadows, which cannot be penetrated by underwater robots, and the shellfish living deep within them.

There is a possibility that a survey could not be achieved using current robot arms (e.g.; dual arm operation [6] and tele-operated manipulators installed to ROV [7]). Instead of using robot arms, developing snake-type robots is one solution. Snake robots can search for and investigate targets, avoiding multiple obstacles by their serpentine motion in narrow environments where humans cannot intrude. Previously, many researchers had been developing

*Corresponding Author: Tasuku Miyoshi, Department of Mechanical Engineering, Iwate University, Morioka-city, Iwate 020-8551, Japan, Email: tmiyoshi@iwate-u.ac.jp

snake-type robots for investigating unknown environments and searching for disaster sites (e.g.; review of snake-type robots [8], tutorial of snake-type robot [9], and carrying out the inspection work [10]). Also, an amphibious snake-type robot, which moves in a serpentine motion for generating the forward propulsion in water, has been studied [11]. With this unique motion, however, it is necessary for the robot to keep thrusting in order to stay in place in shallow areas where wave disturbances occur from all directions. Without any propulsion force for forward movement by a serpentine motion, a mobile robot equipped snake-type arm mechanisms had been studied (e.g.; surveying robot equipped with snake-type arm on wheel robot [12], assembling an aircraft using a snake-type arm mounted on a traditional industrial robot arm [13], and linear motion mechanism mounted on base of snake-type arm [14]). When entering the camera at the tip of the arm into the narrow space, the snake-type arm changes its attitude so as to avoid obstacles and the intrusion operation (forward approach action) is in charge of the base unit. In order to investigate a narrow area in the shallow sea using AUV or ROV equipped an arm with snake-type mechanism, it is necessary to take forward motion while maintaining posture and position against the tidal current near the seabed. Therefore, we assumed that a snake-type arm, which had a forward movement mechanism and installed to AUV and/or ROV, is effective for investigating narrow areas in shallow sea. Hence, the purposes of this study were: 1) to construct a new robot arm that utilizes the features of a snake-type robot's obstacle avoidance, and 2) to evaluate the autonomous path-tracing algorithm to achieve obstacle avoidance at the part of the rear-link mechanism. In this paper, Section 2 outlines our newly developed arm mechanism and the results of the operation test. In Section 3, we propose a path-tracing algorithm of the rear-link mechanism required for obstacle avoidance and show the effectiveness of this algorithm experimentally.

2. Flexible lengthening-shortening arm mechanism (FLSAM)

2.1. Design specifications

We selected the following design specifications for the newly developed flexible lengthening-shortening arm mechanism (FLSAM):

1. The FLSAM can avoid obstacles,

2. The FLSAM can reach into rock shadows and penetralia,

3. The FLSAM can approach target objects closely, and

4. The FLSAM can obtain photos and movies for further analysis.

To satisfy the required specifications of the rotational and translational degrees of freedom, the FLSAM's design considers the following points:

A1. To avoid obstacles, the FLSAM should be equipped with rotational degrees of freedom,

A2. To reach into rock shadows and go near the target, the FLSAM should be able to expand its arm length by translational degrees of freedom, and

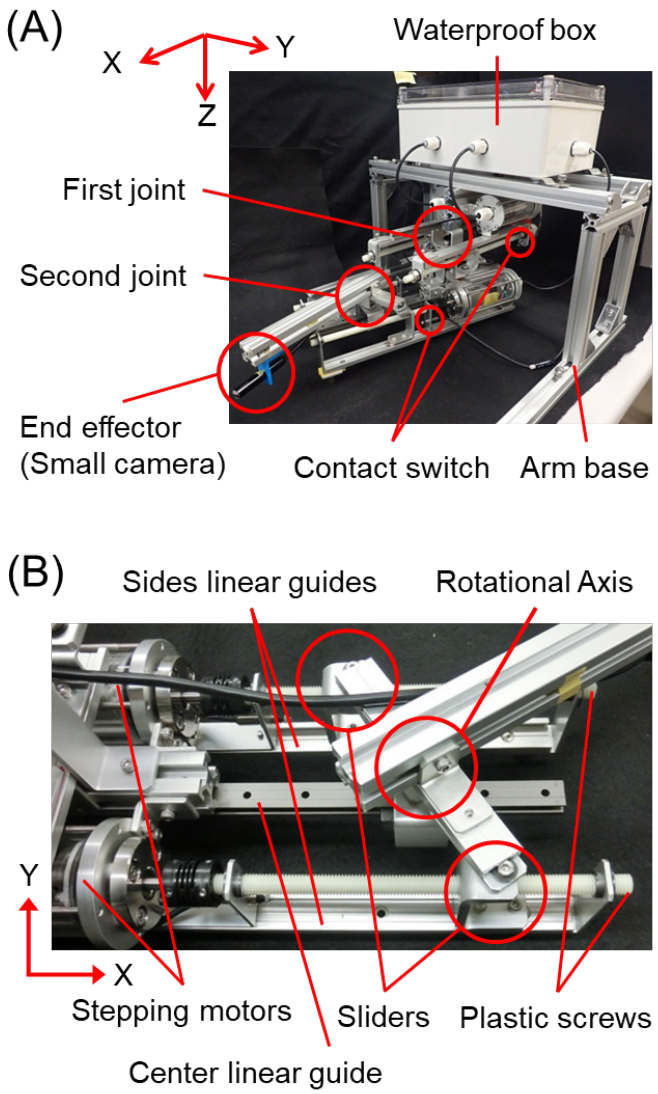

Figure 1: (A) Overview of the newly developed flexible lengthening-shortening arm mechanism, "FLSAM"; (B) mechanical details around the second joint of the FLSAM

A3. To obtain photos and movies, a small video camera should be installed on the FLSAM.

2.2. Configuration of the FLSAM

2.2.1. Overview of the FLSAM

Figure 1A shows an overview of the FLSAM, and the specifications are denoted in Table 1. Each joint consists of two stepping motors (PKP213D05A, ORIENTAL MOTOR Co., Ltd.), two plastic screws (MB-RENY-M8-300, MISUMI Corporation), and three linear guides (for both sides: NK-02-17-1-220-LLYZ, igus k.k.; for the center: TK-04-12-1-250, MISUMI Corporation). Each linear guide was in parallel, and sliders were installed on both sides of the linear guides. To achieve rotational degrees of freedom, the rotational axis was set at the center linear guide. As to the detailed structure of the joint, the appearance of the second joint is shown in Figure 1B. Contact switches (PTP5M3CB-L, MISUMI Corporation) were installed to detect the origin of the

sliders and to prevent an overrun. A small waterproof camera (WPMISC7M, THANKO Co., Ltd.) was equipped to record photos and movies from the end effector. Electric circuits with an AVR microcomputer (Arduino Uno R3, Arduino AG) were placed in a waterproof box (SPCM13-18-10-T, MISUMI Corporation).

2.2.2. *Sliding screw mechanism to achieve rotational and translational degrees of freedom of the FLSAM*

When constructing an arm with the simultaneous motion of the translational and rotational degrees of freedom, it is natural to couple the translational and rotational mechanisms. However, the arm mechanism increases in size due to the increased number of joints when the translational and rotational joints are arranged separately. Therefore, we adopted a sliding screw mechanism to achieve the translational and rotational degrees of freedom in one joint. The sliding screw mechanism could be expected to reduce the size and number of joints. Moreover, it could be said of this mechanism that (1) power consumption is low because it is not necessary to maintain the posture, and (2) it can operate in water without a lubricant [15].

Figure 2A–C shows the schematic of the sliding screw mechanism installed in the FLSAM. We arranged two sliding screws for one joint, and the slider part moves forward and backward with respect to the rotational volume of the first and second actuators. The FLSAM installed two sliding screw mechanisms; in total, four degrees of freedom were achieved. The changes in the stroke length of each sliding screw mechanism were defined by the number P_k [pulse] and frequency A_k [pulse/s] of pulses' input to the stepping motor, as

$$\begin{bmatrix} P_k \\ A_k \end{bmatrix} = \frac{R}{L_e} \begin{bmatrix} X_k \\ V_k \end{bmatrix} \quad (1),$$

where, k is the number of the slider (1 and 2 for the first joint, 3 and 4 for the second joint), X_k [mm] is the stroke length of each slider, V_k [mm/s] is the moving velocity of each slider, L_e [mm] is the lead of the screw, and R [pulse] is the number of pulses per

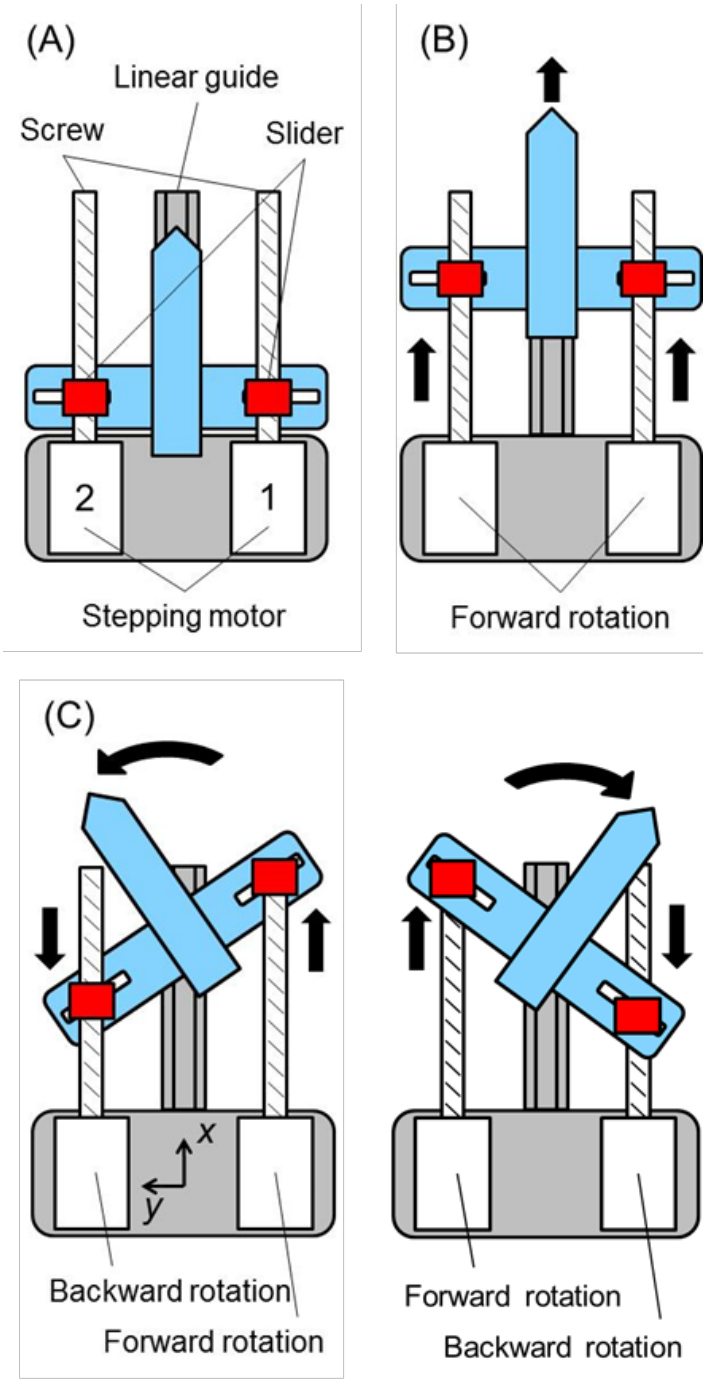

Figure 2: Schematic figure of the sliding screw mechanism installed in the FLSAM; (A) initial condition, (B) lengthened condition, (C) flexible condition

revolution of the stepping motor. In the FLSAM, the L_e is set at 1.25, and the R is 200.

2.2.3. *Geometric configuration of the sliding screw mechanism*

Figure 3 is the schematic of the geometric constraints and the definition of the control parameters by the sliding screw mechanism for the FLSAM. The $O_{i-1}X_{i-1}Y_{i-1}$ joint coordinate system was set at the base of the sliding screw mechanism. The

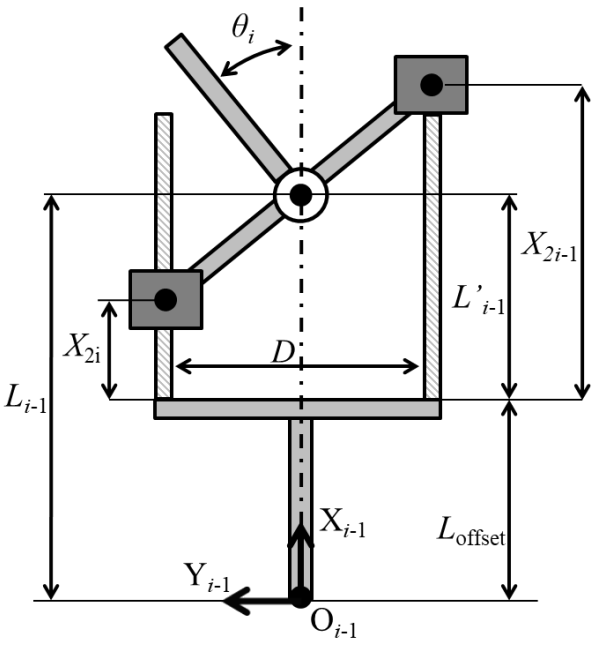

Figure 3: Schematic figure for the parameters of the sliding screw mechanism

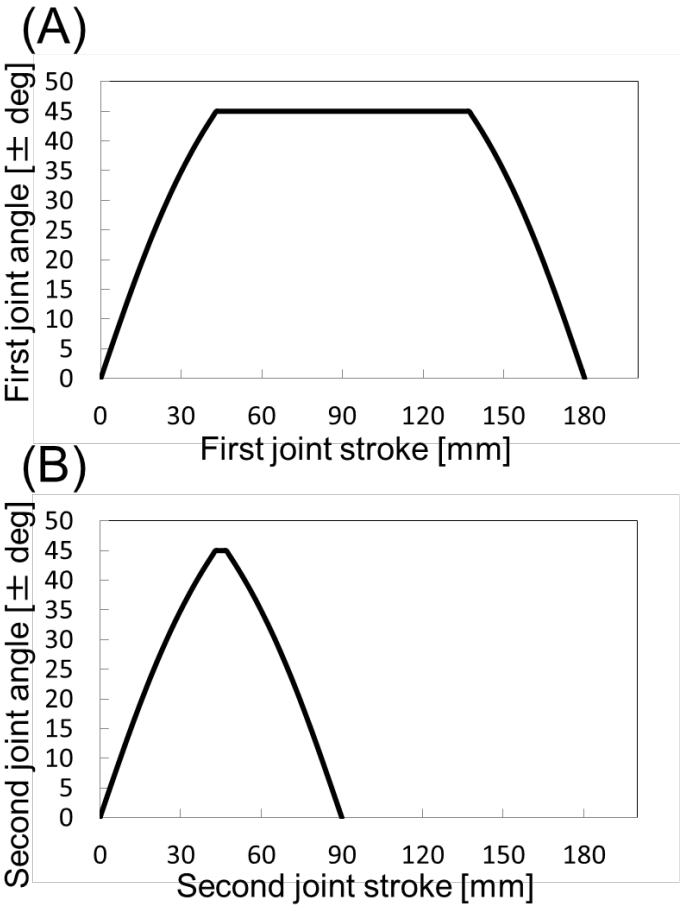

Figure 4: Geometric relationships between the joint range of motion and the joint stroke length; (A) first joint, (B) second joint

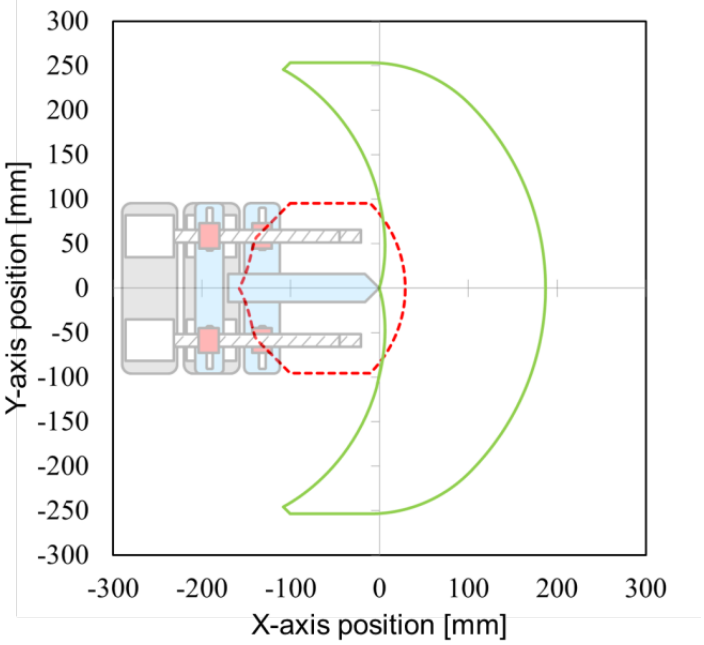

Figure 5: Schematic figure of the range of motion of the FLSAM; red broken line denotes the range of motion for maintaining the maximum flexibility, green line denotes the maximum range of motion

link length, L_{i-1}, and the joint angle, θ_i, were controlled by right- and left-moving sliders. The L'_{i-1}, L_{i-1}, and θ_i were calculated as

$$L'_{i-1} = \left(X_{2i-1} + X_{2i}\right)/2 \quad (2),$$

$$L_{i-1} = \left(X_{2i-1} + X_{2i}\right)/2 + L_{\text{offset}} \quad (3),$$

$$\theta_i = \tan^{-1}\left(\left(X_{2i} - X_{2i-1}\right)/D\right) \quad (4),$$

where L'_{i-1} (i=1, 2) is the link length while lengthening, shortening, and/or rotating. X_{2i-1} is the slider position at the side of the positive in the y-axis, X_{2i} is the slider position at the side of the negative in the y-axis, and D is the length between the two sliders. The position of the end effector of the FLSAM was operated by combinations of the L_{i-1} and θ_i. The movement speed of both sides of the slider is determined so that the operation time is the same according to the L_{i-1} and θ_i, since only the slider on one side works as a singular point.

The sliding screw mechanism has a unique characteristic, in which the maximum range of motion of a joint angle varies with the changes in the link length, as shown in Figure 4. Both maximum joint ranges of motion were set at plus/minus 45 degrees; however, the maximum joint range of motion is 0 degrees when the left and right sliders are at the minimum and/or the maximum position of the link length simultaneously. In addition, these maximum joint ranges of motion were independent parameters, so that it is possible to take the most flexible posture from 43 mm to 47 mm in the first joint and from 43 mm to 137 mm in the second joint. Figure 5 shows a range of motion of FLSAM. In this study, the range of motion was set at the inside area depicted by red line, which maintain the maximum flexibility of FLSAM (joint ranges of motion was at ± 45 deg). When

operating beyond this range, the maximum joint ranges of motion become small and the flexibility of the FLSAM decreases.

2.2.4. *Waterproof structure of the sliding screw mechanism*

The main parts of the FLSAM (sliding screws, sliders, guide rails, and a small camera) are highly water resistant. Cable entry and exit of the waterproof box equipped with an electrical system were waterproofed by cable grounding. Four stepping motors were waterproofed using custom-designed cylindrical housings, as shown in Figure 6. Basically, the housing is made watertight by careful fitting of the acrylic tube, aluminum lid, and O ring. The rotary shaft was waterproofed by combining stainless steel bushes, resin bushes, and a sealing material.

2.2.5. *System configuration of the FLSAM*

Figure 7 shows the system configuration of the FLSAM. The FLSAM's control program was constructed using commercialized software, LabVIEW 12.0.1 (National Instruments Japan Corp.). All control signals from the controller were communicated to Arduino via a serial port, and Arduino then calculated the control signals for the motor drivers (SFE-ROB-12779, SWITCH SCIENCE). Contact switch signals are the only feedback signals to determine the initial and/or the maximum lengthened condition of the FLSAM.

3. Operational tests of the FLSAM

3.1. *Operational test on land*

In order to check whether lengthening-shortening and flexion motions by a sliding screw mechanism of design requirement for image acquisition by a small camera are possible, a ground motion test was carried out. As targets for image acquisition, models of aquatic organisms (turtle, shark, dolphin, and seahorse) and an obstacle were placed randomly. The seahorse model was placed in the shadow of an obstacle that would be a blind spot from the initial posture of the FLSAM. One of the objects of this investigation is abalone, and the catch size is defined as more than 90 mm. For this reason, an imaging target model in this operational test was also the same size of abalone. Each mode size is shown in Table 2. Hence, the FLSAM avoided obstacles due to the lengthening-shortening and flexion motion of the arm and eventually was able to discover the seahorse model. The amount of the stroke length and velocity of each slider of the FLSAM was given as a numerical input from a PC, and the operator checked the posture of the FLSAM and the camera image visually. Figure 8 shows a typical image acquisition and a birds-eye view of the FLSAM operation. In the process of finally photographing seahorses, images were acquired, in order, of the turtle, shark, dolphin, and then the seahorse in this arrangement. When the base unit is stable, FLSAM is not affected by posture change due to disturbance in water because of the characteristics of the sliding screw mechanism. Therefore, when the FLSAM achieves the ideal motion on land, the FLSAM can perform the same operation even in water as on land. It was confirmed that the FLSAM can achieve lengthening-shortening and flexion motions as demanded of the design. Also, image acquisition with a small camera was achieved.

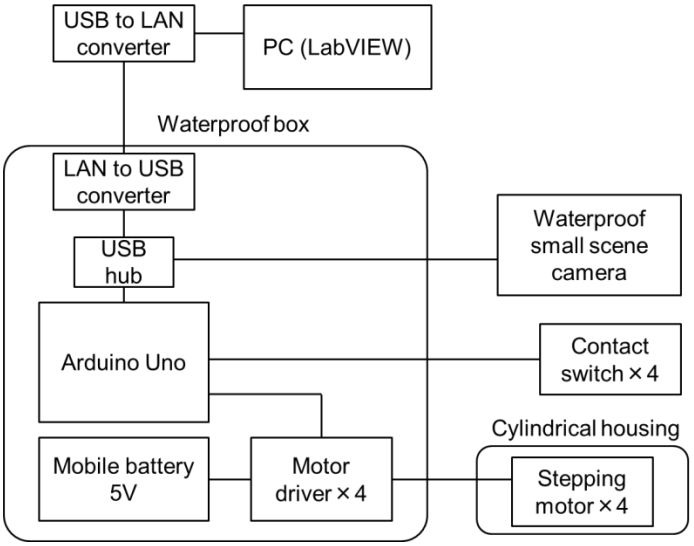

Figure 7: System configuration of the FLSAM

Table 2: Each mode size

Models of aquatic organisms	High [mm]	Length [mm]	Width [mm]
Turtle	40	90	70
Shark	60	170	90
Dolphin	50	110	40
Seahorse	60	40	30

3.2. Operational tests in water

Although it was confirmed that FLSAM could operate without any problems during the ground test, FLSAM was developed to be used in water. Therefore, it was necessary to conduct verification tests to confirm whether it can function properly underwater. Hence, this experiment was planned (1) to check the underwater

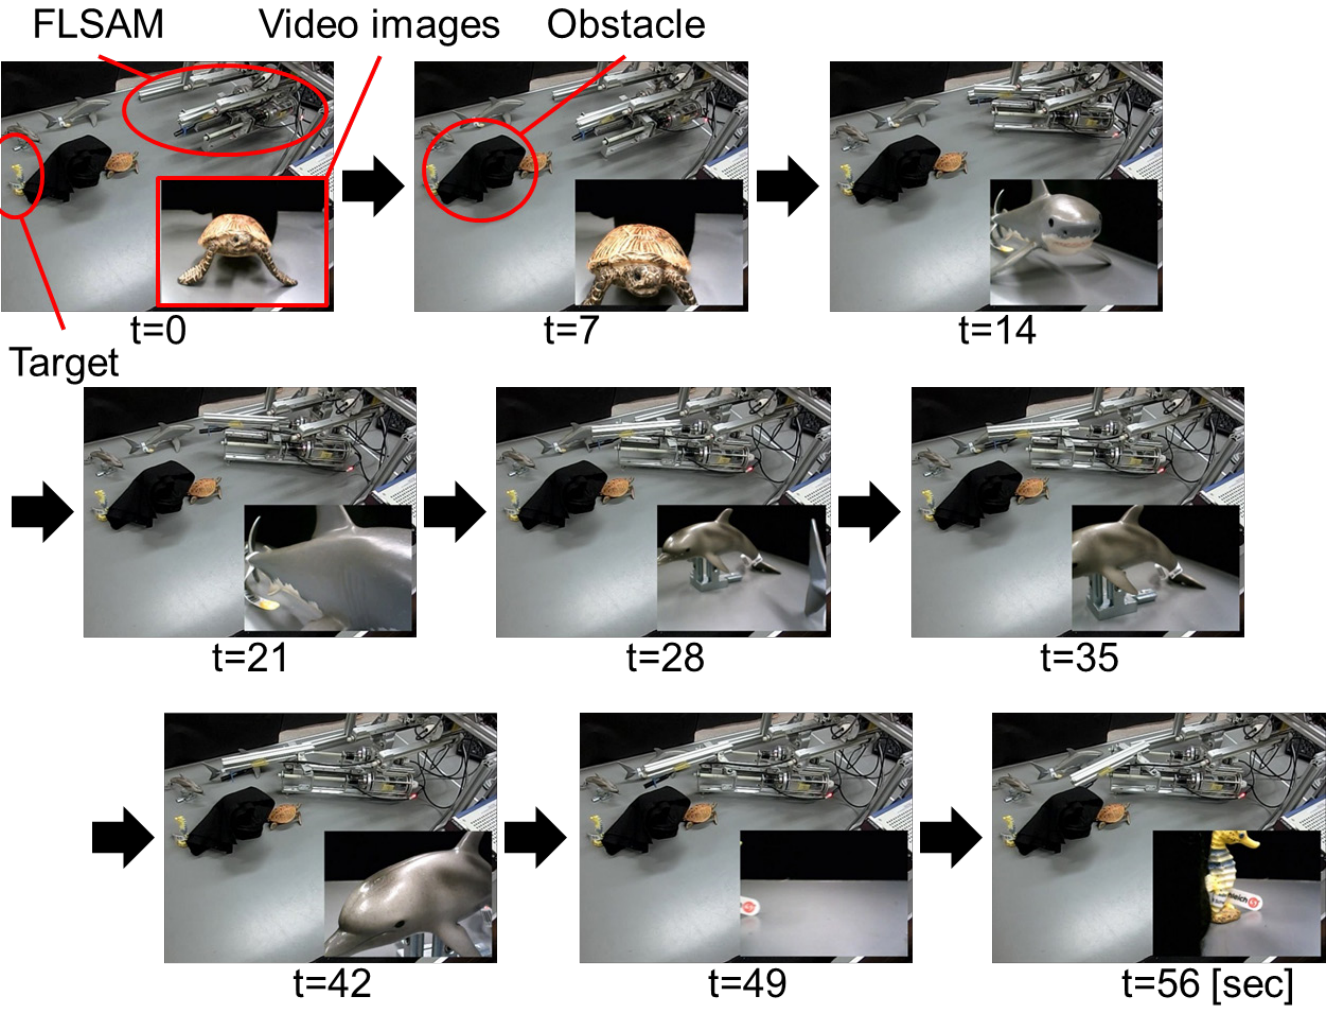

Figure 8: Time series of the state of the operational test conducted on land

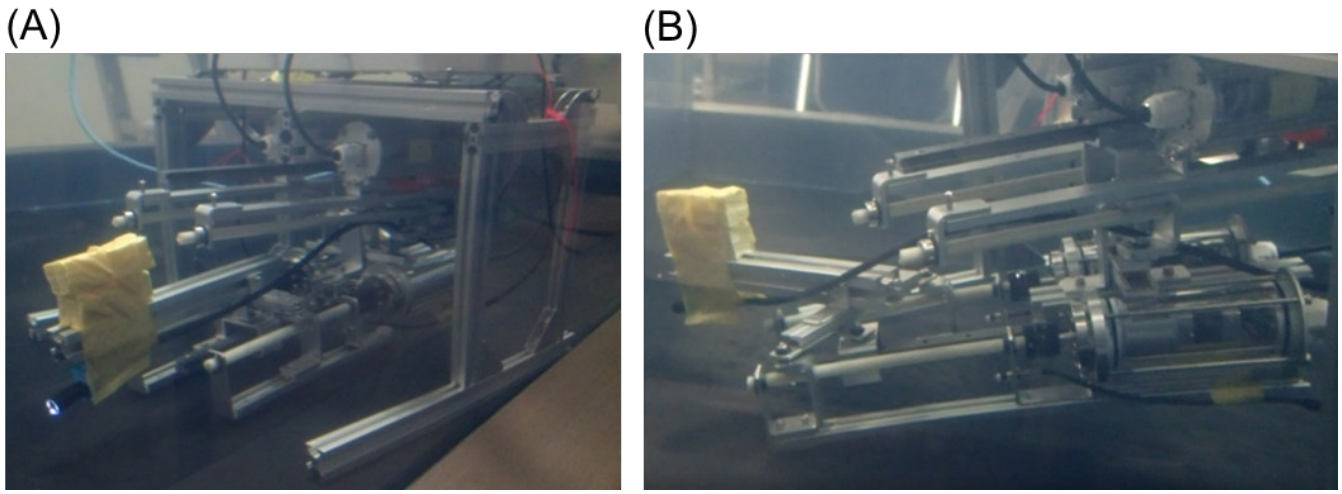

Figure 9: Typical states of the operational test in water; (A) the initial condition, (B) left-side flexed condition

motion, (2) to obtain camera images, and (3) to check the waterproof performance of the FLSAM.

The experiment was carried out in static water conditions (the water tank was 1.57 m deep × 1.2 m wide × 1.27 m high). The FLSAM was placed on the floor of the water tank in its initial condition, and then any arbitrary lengthening/shortening and/or flexion motion was operated manually. To make sure that the sliding screw mechanism of the FLSAM functions properly in water, lengthening-shortening and flexion motions were tested multiple times with reciprocated motions. Further, in order to ascertain whether there is a possibility of water leak into the motor housing due to vibration of the motor and/or the rotation of the shaft, the operation speed is changed while the underwater test continues. Also, video images were checked on the PC simultaneously to determine whether it is possible to acquire images via the small underwater camera installed. The operation of FLSAM was confirmed from the outside of the water tank.

From outside the water tank, it was confirmed that, for 30 minutes, the FLSAM performed every operation on the floor of the water tank. In addition, no water leaked into the housing. Figure 9 shows the typical condition during the operation tests of the FLSAM in water: (A) is the initial condition, and (B) is in the left-side flexed condition. In water, the FLSAM achieved the desired behavior commanded by the operator. However, as the arm lengthened, the FLSAM unexpectedly became tilted, and the small camera at the tip of the arm contacted the floor. This was due to the movement of the center of gravity that occurred when the arm was lengthened. Therefore, it is suggested that attitude control by the support base is required to acquire a stable image using the FLSAM.

4. Autonomous path-tracing experiment for rear-link mechanisms

4.1. Purpose of the path-tracing experiment

Path planning and tracing are key issues for investigating the shadows of rocks. In the case of the FLSAM, path planning and its tracing algorithm should also be installed to achieve obstacle avoidance and to reach into the depths of rock shadows to enable surveying. Methods of controlling a flexible robot arm with a retractable mechanism have been studied (e.g.; series studies of path-tracking control of a moray-type robot arm by same group [16–19], expands and/or contracts arm mechanism [20], and path tracking control of underwater snake-type robot [21]); however, it is impossible to plan a path in environments where the camera cannot obtain data due to blind sports and/or deep rock shadows.

Previous studies have developed methods of manipulating the tip of the arm using a camera image to intrude into an unknown environment (e.g.; surveying robot to avoid obstacles based on screw principle [22], double headed snake-type robot [23], and remotely operated snake-type robot [24]). The FLSAM that can enter unknown environments, such as rock shadows in water, is considered to be effective. Therefore, we adapted to control the FLSAM manually using only the video data obtained from the small installed camera. Figure 10 shows the schematic figure entering the rock shadows by changing the posture of the FLSAM. The operator decides the traveling direction of the tip of the arm using the obtained video data and then manipulates the traveling direction forward/backward and left/right so that only

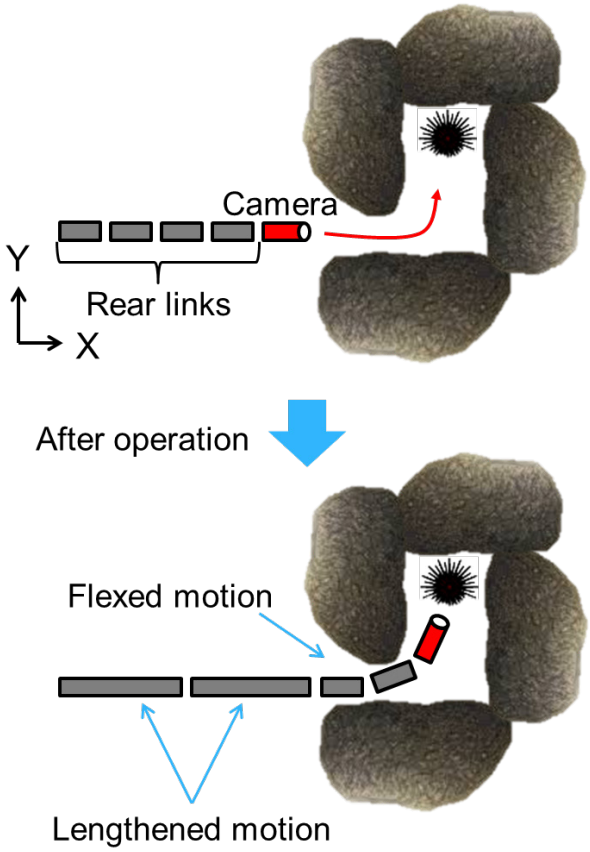

Figure 10: Schematic figure of entering the rock shadow by changing the posture of the FLSAM

the tip of the arm should be controlled manually. This means that the rear links would autonomously follow the movement path of the arm tip. Hence, the purpose of this experiment was to evaluate the accuracy of path tracing of the rear links using the FLSAM's control path-tracing algorithm.

4.2. Path tracing in the rear-link parts of the FLSAM

4.2.1. Definition of the rear-link in FLSAM

FLSAM has two sliding screw mechanism joints. That means that if the second link of the FLSAM equipped with the small camera is defined as the arm tip, the rear link is only the first link. However, it is difficult to evaluate the validity of the path-tracing algorithm by measuring the movement of one link. Hence, as shown in Figure 11AB, the virtual arm tip is defined as existing at the tip of the second link of the FLSAM, and the first link and the second link of the FLSAM are set as the rear links.

4.2.2. Target path defined by the Spline interpolation curve

The first and second rear links of the FLSAM autonomously trace the tip's moving path. In this research, we prepared the target path under the assumption that the tip's moving path is generated

by the movement of the virtual tip, and the first and second links of FLSAM trace this virtual path. For the target path, a cubic Spline interpolation curve capable of creating a two-dimensional curve in space was used. The details are described in Appendix-1; however, the first derivatives of the start point of the Spline curve are set to 0 in the boundary condition (A5). With respect to this definition, the slope of the Spline curve at the start point becomes 0. Therefore, the Spline curves of the target path and the X axis are continuous at the origin of the global coordinate system, and discontinuity of the arm joint angle can be avoided.

4.2.3. *Development of a path-tracing algorithm in the rear-links of the FLSAM*

Figure 11C shows a schematic of path tracing in a rear link of the FLSAM. In this study, the rear links of the FLSAM trace the Spline curve created as the target path to evaluate the validity of the path-tracing algorithm. In order to trace the target path, it is necessary to calculate each joint angle as output with the target path and each link length as input. Thus, as shown in Figure 11C, links L_0 and L_1 should lengthen and/or shorten to control the joint angles for tracing the target path.

At first, we defined each joint coordinate and link length as follows: the origin of the arm base as $J_0=[(x_0, y_0) = (0, 0)]$, the position of the first joint as $J_1=[(x_1, y_1) = (x_0 + L_0, 0)]$, the position of the later joints as $J_{j+1} = [x_{j+1}, y_{j+1}]$ (j = 1 to n); n is the number of total joints, the position of the arm tip is Jc (= J_{n+1}) = $[x_{n+1}, y_{n+1}]$, and the link lengths are L_j. J_0 and J_1 are determined by the initial arrangement and the link length of L_0. The outline of the procedure for deriving each joint position from each link length is as follows:

(1) let J_{j+1} be the point of intersection with the circle C_j of radius L_j centered on J_j and the Spline curve,

(2) let J_{j+2} be the point of intersection with the circle C_{j+1} of radius L_{j+1} centered on J_{j+1} derived in procedure (1) and the Spline curve,

(3) then repeat procedure (2) until Jc.

Here, we will describe procedures (1) and (2) in greater details. Where the C_j intersects with the interpolation interval, $S_i(x)$ is determined by the following conditional expression, since the Spline curve has a number of ith interpolation intervals:

$$(x_i - x_j)^2 + (y_i - y_j)^2 < L_j^2 < (x_{i+1} - x_j)^2 + (y_{i+1} - y_j)^2 \quad (5).$$

Then, solve the following simultaneous equations to find x_{j+1}:

$$C_j : (x_{j+1} - x_j)^2 + (y_{j+1} - y_j)^2 = L_j^2 \quad (6),$$

$$S_i(x_{j+1}) = a_i x_{j+1}^3 + b_i x_{j+1}^2 + c_i x_{j+1} + d_i (= y_{j+1}) \quad (7),$$

where x_{j+1} satisfies $x_i < x_{j+1} < x_{i+1}$. By repeating these procedures, each joint position is derived. Finally, each joint angle is derived by the following formula:

$$\theta_j = \tan^{-1} \frac{y_{j+1} - y_j}{x_{j+1} - x_j} - \theta_{j-1} \quad (8).$$

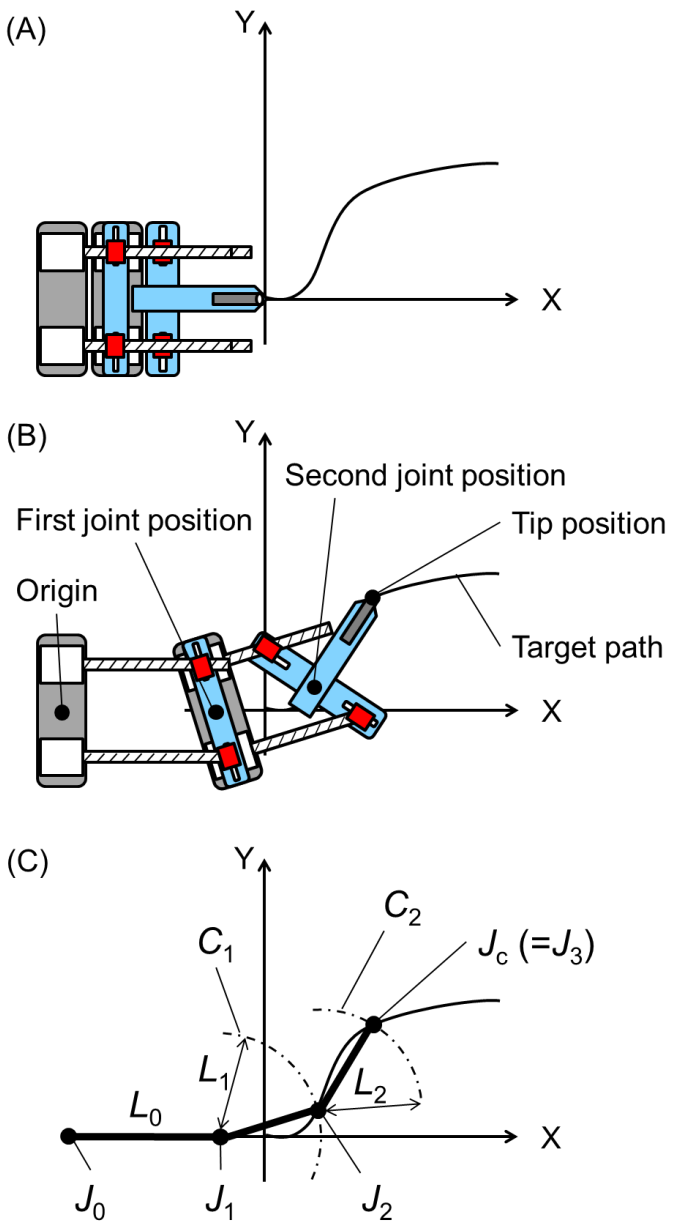

Figure 11: Schematic figure of the definition of the rear links in the FLSAM; (A) state of the arm tip on the ordinate of the global coordinate system, (B) definition of the rear links in FLSAM, (C) definition of each joint coordinate and link length

In this study, using each link length, L_j, and joint angle, θ_j, as input values, the path-tracing algorithm for the rear links calculates the output value as the number of pulses input to each stepping motor of the sliding screw mechanism. Thus, in the case of the FLSAM, $J_0=[(x_0, y_0) = (0, 0)]$ is the base position, the position of the first joint is $J_1=[(x_1, y_1) = (x_0 + L_0, 0)]$, the position of the second joint is $J_2 = [x_2, y_2]$, and the position of the arm tip is Jc (= J_3) = $[x_3, y_3]$, since the number of joints is two.

4.2.4. *Simulation of a path-tracing algorithm in the rear links of the FLSAM*

Computational simulation was performed to evaluate whether the proposed rear-link path-tracing algorithm works precisely enough to trace the target path (an arbitrary Spline curve). This simulation was done with a custom-designed graphical user

interface using LabVIEW 12.0.1. Figure 12 shows the simulation results of the trajectories of the tip and the second joint calculated by using each link length and joint angle output from the path-tracing algorithm. Thus, we confirmed that each joint is moving on the Spline curve completely, and that the path-tracing algorithm of the rear link of the FLSAM is correct.

4.3. Methods

The accuracy of the FLSAM motion was measured using a real-time three-dimensional motion capture system (VENUS3D, Nobby Tech., Ltd.). The conceptual motion pattern for path tracing in the FLSAM is shown in Figure 12, which shows that the initial posture was determined, in which the origin of the global coordinate system of the FLSAM was harmonized with the position of the arm tip. The tip of the end effector traced a predetermined target path, and then the rear links followed the tip motion, as shown in Figure 11B. For each slider of the FLSAM, the maximum moving speed was set to 5 mm/s. In addition, the L_{i-1} (i=1, 2) was lengthened by a step of 2 mm. Three target paths (a figure "S" pattern, an exponential figure pattern, and a sigmoid curve figure pattern) and three mirrored target paths were defined before the experiment and were started from the origin of the global coordinate system. Each pattern was followed in ten trials. The motion trajectory of the arm tip and the second joint were measured to compare the accuracy of the target paths and the motion of the FLSAM. All experiments were conducted on land.

4.4. Results and Discussion

Figure 13 shows the results of all ten trials of tracing (A) the figure "S" and its mirrored patterns, (B) the exponential figure and its mirrored patterns, and (C) the sigmoid curve figure and its mirrored patterns. Time series of the position of the tip in X and Y axis are shown in Fig. 14. It was observed that all ten path trials are highly reproducible, the tip of the FLSAM traced the target paths, and the tracking results and errors were also symmetrical in mirrored paths. These results confirm the validity of the path-tracing algorithm. The maximum and the root mean square of the deviations were (2.25 mm, 1.7 mm) for pattern (A), (1.86 mm, 0.66 mm) for pattern (B), and (4.7 mm, 1.48 mm) for pattern (C), respectively. All of these deviations were under 4.0% (2.8 mm) of the total width of the FLSAM (140 mm). Although the same tendencies had found in the previous studies (e.g.; series studies of path tracing of a snake-type robot using screw driving theorem by same group [25-26]) that the deviations are approximately 4.0%, it is suggested that the path-tracing algorithm for the FLSAM while path tracing is effective, and minimizing the deviations is a task for future studies. In addition, the movement error of 4% (2.8 mm) is below 4% or less of the survey target size of 90 mm or more. In this respect, the validity of the path-tracing algorithm of the rear links of the FLSAM proposed in this paper was confirmed.

We would like to construct an algorithm to achieve three-dimensional motion by changing the arrangement and the number of sliding screw mechanisms of the FLSAM. Further studies should be needed at least the following points; (1) to improve the accuracy of path tracing, since the tracing deviations would accumulate if the FLSAM would be expanded to increase the number of joints, making it possible for a large error to occur at the tip position and (2) to generate a following path of rear links from the movement path of the tip instead of the Spline curve used in this study.

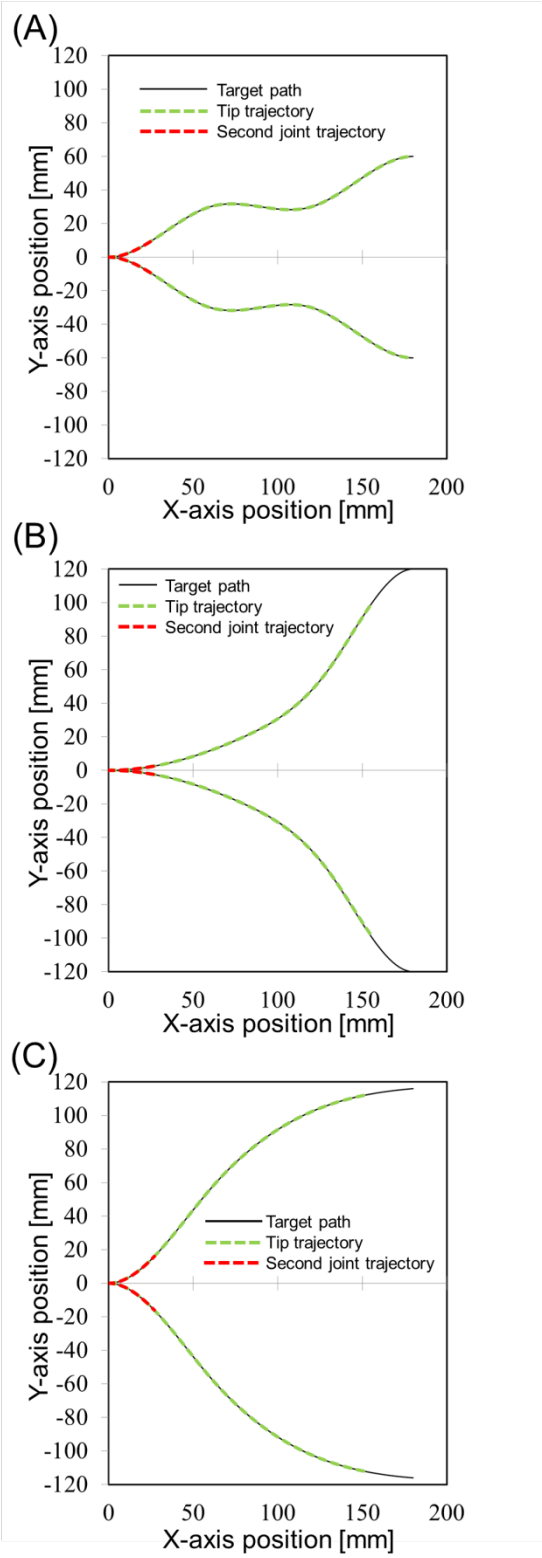

Figure 12: Simulation results of the path tracing algorithm; (A) figure "S" and its mirrored pattern, (B) the exponential figure and its mirrored patterns, and (C) the sigmoid curve figure and its mirrored patterns. Black lines are the target paths, green lines are the tip trajectories, and red lines are the trajectories of the second joint position.

5. Conclusion

In order to realize a flexible underwater robot arm, we adopted a sliding screw mechanism and developed a prototype device, a "FLSAM." Path tracing in the rear-link mechanisms and underwater operation tests were executed, and the results suggested that the sliding screw mechanism is sufficient for construction of a flexible underwater robot arm. However, to obtain stable video data, further modification, such as using an autonomous postural control base, is necessary. Further study is also needed to improve the path-tracing control performance using kinematic and dynamic analysis of the FLSAM.

Appendix-1: Calculation of the cubic Spline interpolation curve

For the target path, a cubic Spline interpolation curve capable of creating a two-dimensional curve in space is used. The *n*th Spline interpolation is continuous to the (*n*-1)th derivative function, and oscillations between the representative points hardly occur. In addition, it is effective for generating a target path simulating an obstacle-avoidance route, since it is possible to produce a complicated shape in accordance with the given interpolation points. In this study, a cubic Spline curve was calculated by setting the first interpolation point as the origin of the global coordinate system and sequentially setting the next interpolation point at an arbitrary position in two-dimensional space.

When (*n*+1) points are given, there are *n* interpolation divisions, and the polynomials exist in each division as follows:

$$S_i(x) = a_i x^3 + b_i x^2 + c_i x + d_i \qquad \text{(A1)} ,$$

where $S_i(x)$ is the cubic Spline curve function in the *i*th division; a_i, b_i, c_i, and d_i are the coefficients in *i*th division; and *i* (*i*=1 to *N*) equals the number of deviations. The coefficients of the polynomial (a_i, b_i, c_i, and d_i) are derived using the continuous condition (A2–4) at the interpolation point and the two boundary conditions (A5–6), as follows:

$$S_i(x_{i+1}) = S_{i+1}(x_{i+1}) \qquad \text{(A2)} ,$$

$$S_i'(x_{i+1}) = S_{i+1}'(x_{i+1}) \qquad \text{(A3)} ,$$

$$S_i''(x_{i+1}) = S_{i+1}''(x_{i+1}) \qquad \text{(A4)} ,$$

$$S_1'(x_1) = 0 \qquad \text{(A5)} ,$$

$$S_N'(x_{N+1}) = const \qquad \text{(A6)} ,$$

where the ith interpolation point coordinate is taken as (x_i, y_i), and $S_N'(x_{N+1}) = 0$ in this study. In the boundary condition (A5), the first derivatives of the start point of the Spline curve are set to 0, so that the Spline curves of the target path the and X axis are continuous at the origin of the global coordinate system.

Conflict of Interest

The authors declare no conflict of interest.

Fault Diagnosis

ABSTRACT

The world's pollution rates have been increasing exponentially due to the many reckless lifestyle practices of human beings as well as their choices of contaminating power sources. Eventually, this lead to a worldwide awareness on the risks of those power sources, and in turn, a movement towards the exploration and deployment of several green technologies emerged.

Proton Exchange Membrane Fuel cells (PEMFCs) are one of those green technologies. However, in order to be able to successfully and efficiently deploy PEMFC systems, a solid fault diagnosis scheme is needed. The development of accurate model based fault diagnosis schemes has been imposing a lot of challenge and difficulty on researchers due to the high complexity of the PEMFC system. Furthermore, confidentiality issues with the manufacturer can also impose further constraints on the model development of a commercial PEMFC system. In this work, an approach to develop an accurate PEMFC system model despite the lack of crucial system information is presented through the use of Siemens LMS AMESim software. The developed model is then used to develop a fault diagnosis scheme that is able to detect and isolate five system faults.

1. Introduction

Proton Exchange Membrane Fuel Cells are complex multi-physics systems (chemical, electrical, fluidic, thermal, and mechanical phenomena are inter-acting with one another). This makes the modeling and fault diagnosis of PEMFC systems a very difficult task. Furthermore, when the modeling is based on experimental testing and experimental data, some limitations are usually faced. For example, many physical system data may be absent or difficult to obtain with the system's supplied data acquisition. Furthermore, due to warranty issues, the addition of sensors might be difficult since only limited access to the systems is allowed. Likewise, other specific parameters might be unobtainable due to manufacturer confidentiality issues.

This paper is an extension of work originally presented in the 7th International Conference on Modeling, Simulation, and Applied Optimization (ICMSAO) [1]. It presents a novel approach, in which the Siemens software, LMS AMESim 14, is used as an alternative modeling tool to model a PEMFC system when such limitations are faced. The LMS AMESim software can serve as an excellent and attractive simulation and modeling platform for different complex physical systems such as automobile and aviation systems as well as power generation systems and transmission lines. Moreover, it has outstanding simulation capabilities that makes it an excellent platform for fault simulation, and fault diagnosis studies. The graphical user interface comprehensive library it contains makes it very easy to compile a complete system model from different system components. Instead of writing all the modeling equations which could be time consuming and is prone to modeling errors, a user

[*]Reem I. Salim, Electrical Engineering Dept., UAEU, 15551 Al Ain, UAE, Tel: +971507649740, Email: reemsalim@gmail.com

can use a ready accurate model better and focus on the parameter identification step in order to find the model that matches the pursued system performance measures. Furthermore, a researcher can easily change the scripts of the components used to better suit their system's design, as well as create new libraries with more specific components.

The ElectraGen™ 3 kW PEMFC system shown in Figure 1, is an actual commercial system used in practice in many sectors, especially in telecommunication companies. It uses hydrogen gas supplied from pressurized hydrogen cylinders as the anode fuel, and atmospheric air supplied by a compressor and humidified through a built-in humidity exchanger as the cathode fuel. The ElectraGen™ system is an outdoor air cooled system, and it is only operable at ambient temperatures ranging from –40°C to 50°C. It contains a total of 38 cells and can produce up to 3 kW of unregulated DC output power and has a rated voltage of 48V.

Figure 1: The ElectraGen™ PEMFC system and the 3 kW Load.

The module contains the ElectraGen™ 3 kW Fuel Cell stack with integrated microprocessor controller and safety features, a hydrogen pressure gauge which gives an indication of fuel level and the 3kW load which consists of 30 lamps, 100W each (see Figure 1). The system is connected through data acquisition to a GUI based on LabVIEW to monitor and log the different system variables (stack current, stack voltage, external voltage, individual cell voltages, cabinet temperature, cathode air temperature, coolant temperature, exhaust temperature, and hydrogen pressure). The ElectraGen™ system is installed outdoor and the experimental data sets collected from the system were taken at extreme environmental conditions in the summer at noon with the ambient temperature ranging from 48°C to 52°C. However, due to warranty issues, limited access to the systems was allowed and limited data was obtainable from the data acquisitions. Moreover, due to confidentiality issues with the manufacturer, several physical parameters were unobtainable such as active cell area, membrane length, volumes of cathode and anode chambers, mass of stack, etc. This made it very difficult to model the system and develop an accurate fault diagnosis scheme. Therefore LMS AMESim was used as an alternative modeling platform since all the common PEMFC modeling equations available in literature [2, 3] are already embedded in its library components.

Furthermore, it is convenient to mention here that the simulated model will not be an exact match for the ElectraGen™ system since not enough system readings were available to match the model to. However, it is the aim of this work to develop an AMESim model that is as realistic as possible by matching all the known features of the actual physical system (the ElectraGen™ system) to their equivalents in the AMESim model as best as possible. This model can then be used in the fault diagnosis study.

Section 2 presents the ElectraGen™ modeling and validation results using the Siemens LMS AMESim Software. In section 3, the simulation of five different system faults is presented, and in section 4 two residual generation techniques are evaluated and then outperforming technique is used to develop a fault diagnosis scheme in AMESim for the ElectraGen™ system. The fault diagnosis scheme is then evaluated and concluding remarks are finally given in section 5.

2. AMESim Modeling of the ElectraGen™ 3 kW System

The LMS AMESim software contains several embedded parameter identification tools including Genetic Algorithms (GA). However, in order to be able to use such tools efficiently, several software licenses are needed. To further explain this, GA is a population based mechanism that is known to be successful because it performs parallel evaluations, and when only one AMESim license is available, using GA becomes impractical. As an example, if the GA has 20 individuals in its population, and with a preset maximum number of generations of 500, this is equivalent to 10,000 runs of the software. With one system license, the software will be unable to perform parallel evaluations. Thus, if a single run of the software takes 1 minute, then the parameter identification process using GA and one system license will take 10,000 minutes (almost seven days).

As a result, matching the parameters of the AMESim model to the actual system performance of the ElectraGen™ system was done through trial and error. The LMS AMESim model developed for the ElectraGen™ PEMFC system is presented in Figure 2.

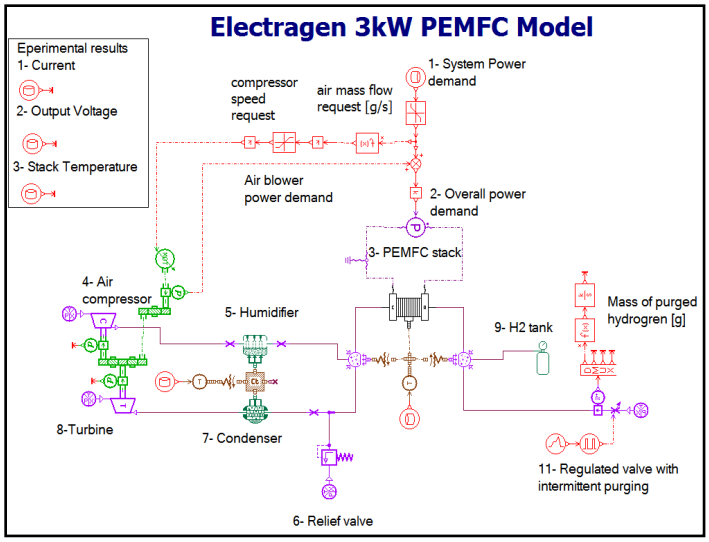

Figure 2: ElectraGen™ 3 kW system's model in AMESim.

2.1. AMESim Model Parameter Identification

The actual power demand data collected experimentally from the ElectraGen™ system was used as the input to the system in

Figure 2. After several trial and error attempts to match the stack voltage, stack current, and stack temperature values as best as possible to the actual experimental data collected from the system; the best obtained match is depicted in the following figures: Figure 3 gives the power demand input of the modeling data set, and Figures 4, 5 and 6 presents a comparison between the actual experimental current, stack voltage and stack temperature respectively to those resulting from the AMESim simulation model.

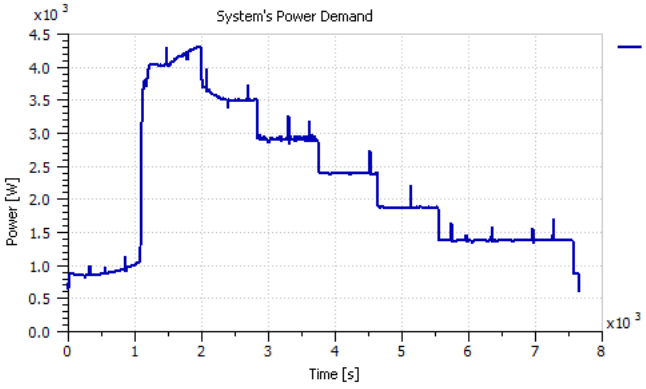

Figure 3: Power demand of the AMESim modeling data set.

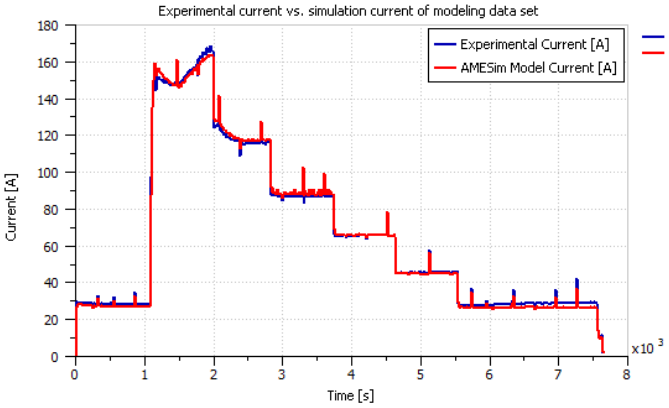

Figure 4: Experimental versus AMESim model's resulting current of the modeling data set.

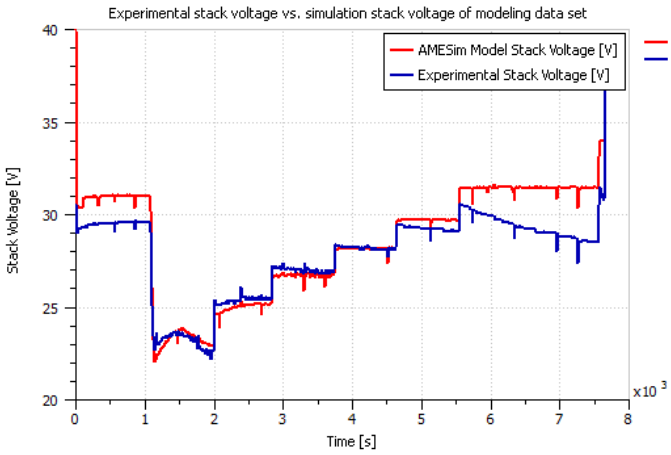

Figure 5: Experimental versus AMESim model's resulting stack voltage of the modeling data set.

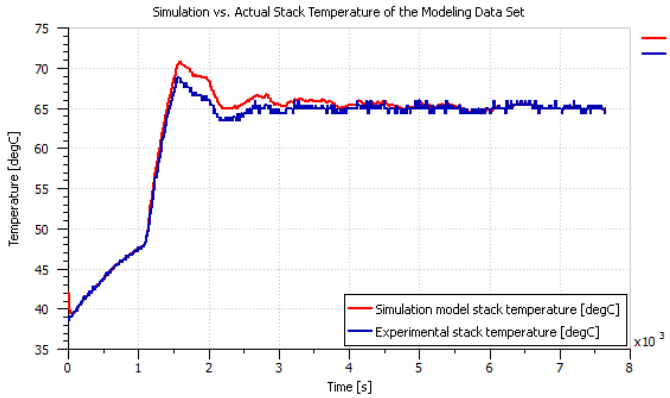

Figure 6: Experimental versus AMESim model's resulting stack temperature of the modeling data set.

2.2. AMESim Model Validation

Two other ElectraGen™ experimental data sets were used to validate the obtained AMESim model of Figure 2. Figure 7 presents the power demand of the first validation example and Figures 8 and 9 compare the actual experimental current and stack voltage to those obtained from the LMS AMESim model respectively. Similarly, the power demand of the second validation example is given in Figure 10, and a comparison between the actual and simulation current is presented in Figure 11, whereas a comparison between the actual and simulation stack voltage is presented in Figure 12.

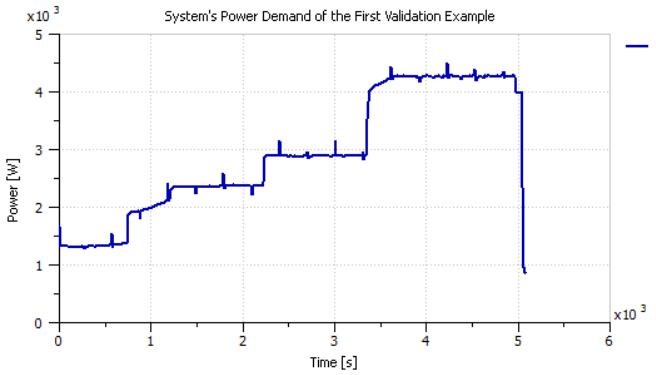

Figure 7: Power demand of the first validation example.

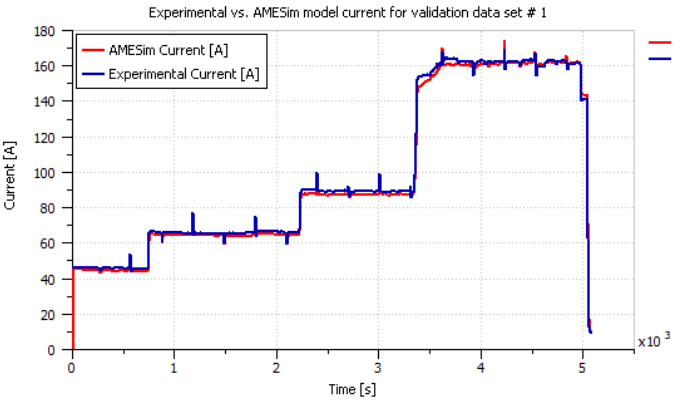

Figure 8: Actual versus simulation current of the first validation example.

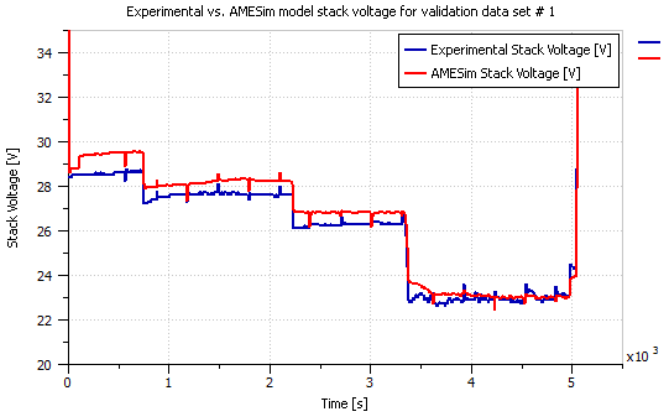

Figure 9: Actual versus simulation stack voltage of the first validation example.

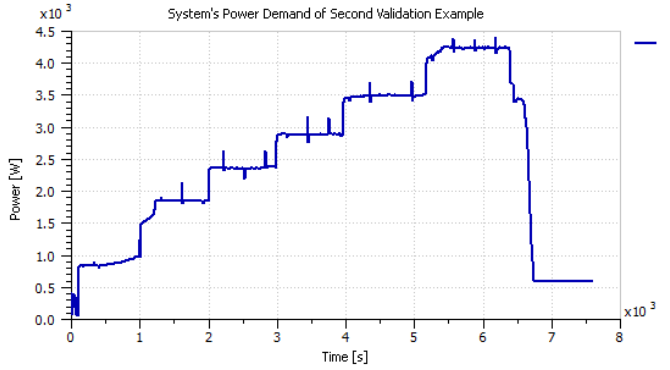

Figure 10: Power demand of the second validation example.

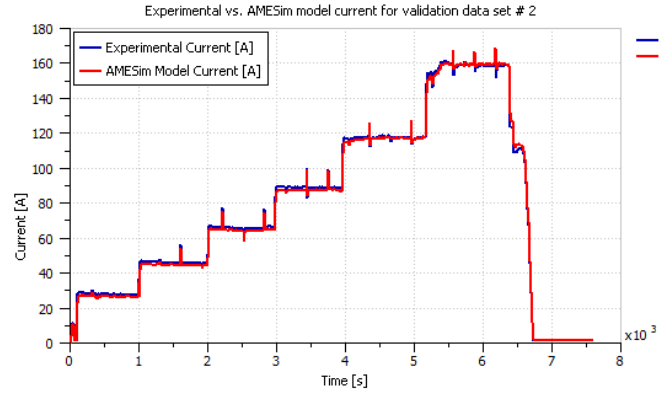

Figure 11: Actual versus simulation current of the second validation example.

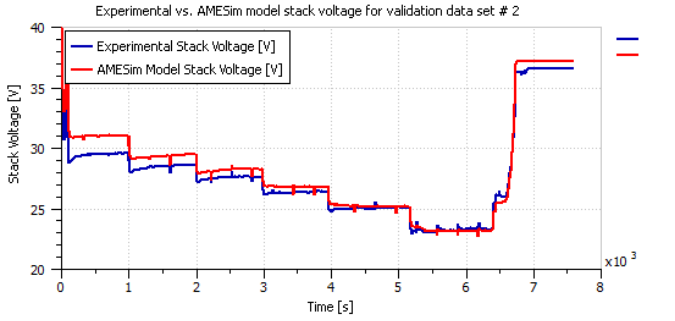

Figure 12: Actual versus simulation stack voltage of the second validation example.

Obviously, a perfect representation of the ElectraGen™ system is unobtainable through trial and error alone. Nevertheless, after validation, the AMESim obtained model proved to give a proper representation of the system's performance and was therefore used in the following fault diagnosis study.

Moreover, if resources (multiple licenses of the software) were available, a much more accurate representation of the system would have been achievable through the use of Genetic Algorithms in the parameter identification approach in AMESim, which would have in turn lead to a better fault diagnosis study.

3. Fault Simulation Using AMESim Model

Several faults were induced in the AMESim model and the system's performance measures towards those faults were recorded. The induced faults are:

1. Drying
2. Flooding
3. Air leakage
4. Hydrogen Leakage
5. Cooling System Failure

The above faults were simulated using different techniques.

3.1. Drying

Zawodzinski et al. were the first to describe the water content in the membrane by (λ) in [4] in order to estimate its state of humidity. As presented in (1), λ represents the ratio between the number of water molecules in the membrane to the number of ($SO_3^- H^+$) charge sites in the Nafion layer of the membrane [5].

$$\lambda = \frac{H_2O}{SO_3^- H^+} \quad (1)$$

The AMESim PEMFC stack module automatically calculates the water content λ in the membrane. Therefore, when simulating drying or flooding, λ would give an indication towards the membrane's state of health.

However, λ cannot be used in the fault diagnosis study because this parameter is not readily available in commercial fuel cells. Furthermore, the PEMFC undergoes drying condition when the water content in the membrane λ drops below 4 [6].

Therefore in order to simulate drying, the humidity level of the input air was set to be 0% and the target humidity level of the humidifier was dropped to 10% only. The water content in a healthy stack and that of a drying stack are compared in Figure 13. The water content of the stack that is undergoing drying is obviously well below 4. Figure 14 on the other hand depicts the difference between the polarization curve of a healthy stack and a drying stack. It is noticed that drying results in a significant voltage.

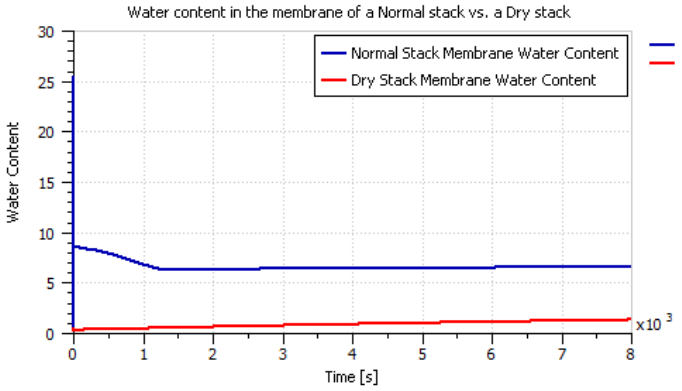

Figure 13: The water content in the membrane (λ) of a normal stack versus a dry stack.

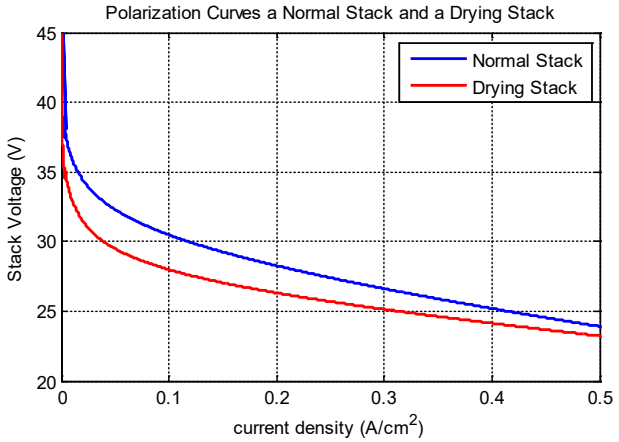

Figure 14: Normal stack's polarization curve in comparison to a dry stack's polarization curve.

3.2. Flooding

Flooding was simulated by dropping the stack temperature to 25°C while increasing the humidifier's target humidity level to 100%. Flooding affected both the voltage and current profiles of the stack as depicted in the polarization curve comparison given in Figure 15. Furthermore, Figure 16 shows the water content λ of the simulated flooded stack.

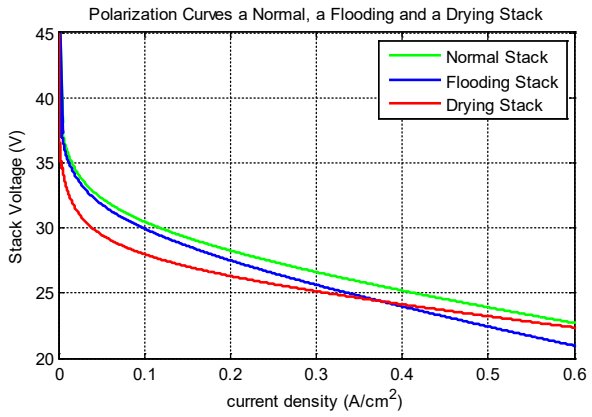

Figure 15: Comparison of pressure drop in a normal stack, a flooding stack and a drying stack.

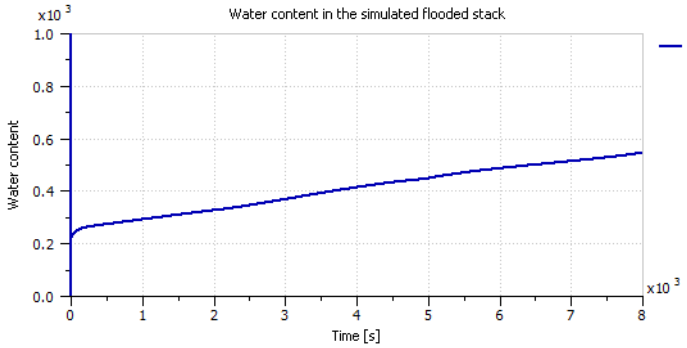

Figure 16: The water content in the membrane (λ) of the simulated flooding stack

Note that both flooding and drying result in similar effects to the stack's polarization curve. However, flooding seemed to also cause a distinctive effect on the cathode pressure drop. As the stack gets flooded with water, the pressure drop across the cathode increases. Nonetheless, in order to clearly see this effect on cathode pressure, the stack had to be fed with a step power demand profile such as that of Figure 17. The cathode pressure of both the healthy and flooded stacks with respect to the power demand input of Figure 16 are compared in Figure 17. The flooded stack showed a steeper drop in pressure when compared to the healthy stack.

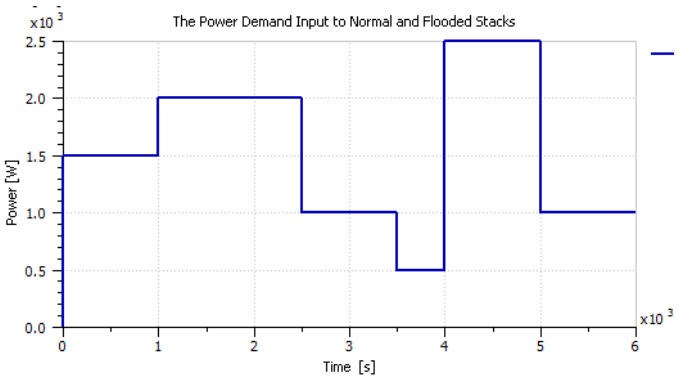

Figure 17: Power demand input to normal stack and flooding stacks.

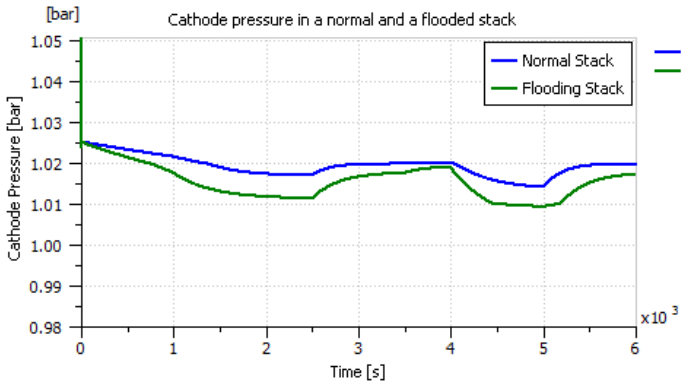

Figure 18: Comparison of pressure drop in a normal stack and a flooding stack.

3.3. Air leakage

In order to simulate air leakage, a relief valve was added right after the humidifier as depicted in Figure 19, and was set to leak air at a rate of around 10 g/s. Figure 20 shows the amount of leakage introduced in g/s. Furthermore, Figure 21 compares the input air flow rate to the PEMFC stack with and without air leakage.

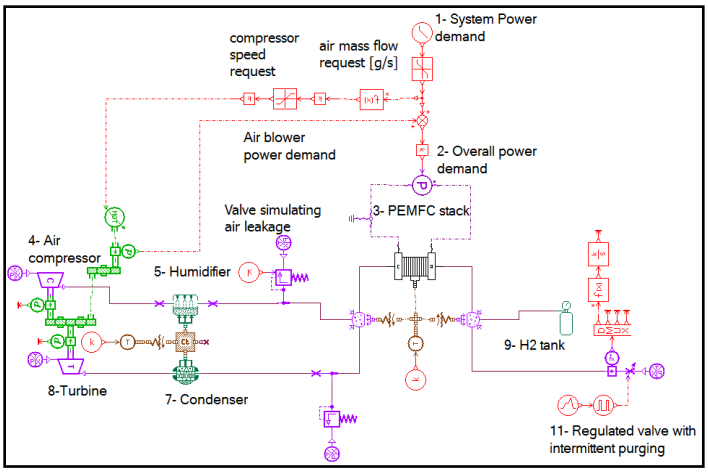

Figure 19: The relief valve added to the AMESim model to simulate air leakage.

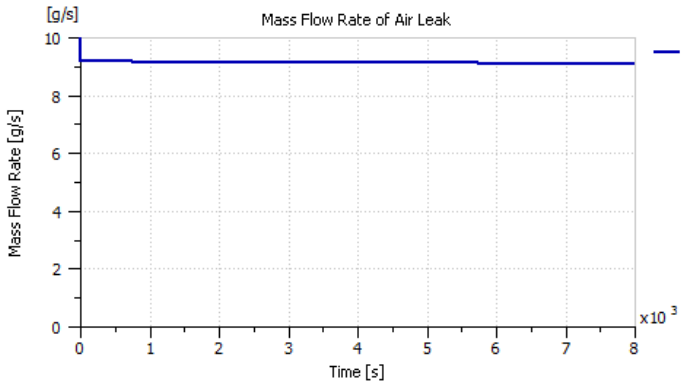

Figure 20: The flow rate of the air leakage induced to the PEMFC system.

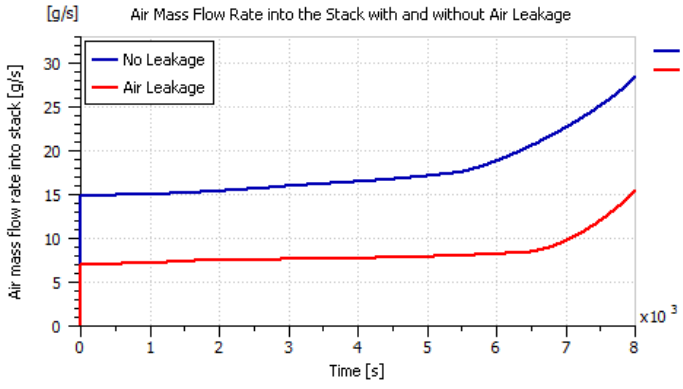

Figure 21: Input air flow rate to the stack with and without air leakage.

It can be deduced from the polarization curve comparison depicted in Figure 22 that the air leakage had no noticeable effect on the stack's current or voltage. However, it was noticed to impose a significant effect on the cathode pressure. To better see this effect, both the healthy and air leaking stacks were fed with the step power demand of Figure 17. Figure 23 shows the air leakage effect on the cathode pressure drop when compared to a non-leaking stack.

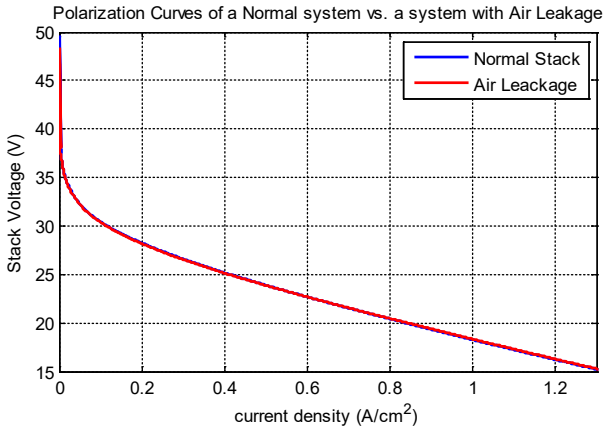

Figure 22: Polarization curves of a normal system vs. a system undergoing air leakage.

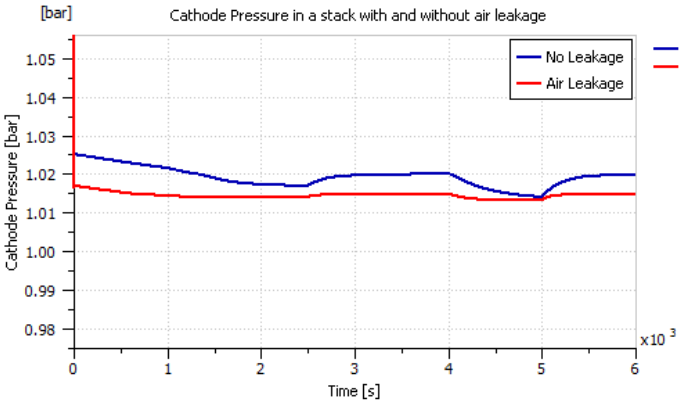

Figure 23: Pressure drop in the cathode of a normal system vs. a system undergoing air leakage.

3.4. Hydrogen leakage

Similar to air leakage, hydrogen leakage was also simulated through the addition of a relief valve right after the hydrogen canister as depicted in Figure 24 in order to leak hydrogen at a rate of 10 g/s. Figure 25 shows the amount of hydrogen leakage introduced in g/s.

Hydrogen leakage was found to result in a slight effect on stack's polarization curve as shown in the comparison of Figure 26. Furthermore, hydrogen leakage was also found to affect the anode pressure as shown in Figure 27, but had no significant effect on the cathode pressure as seen in Figure 28.

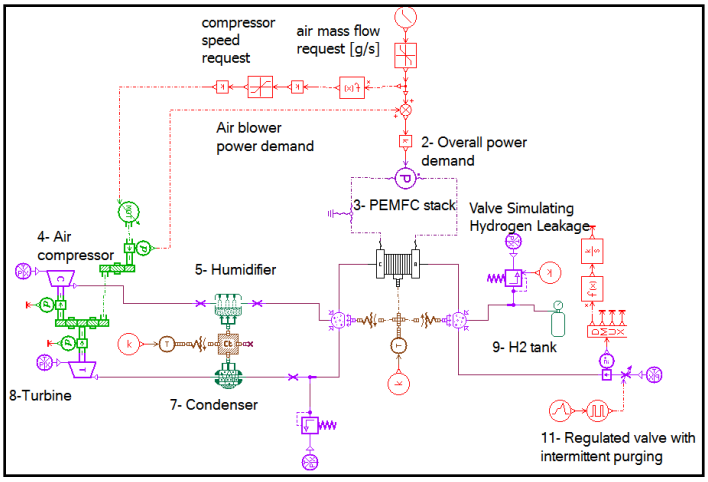

Figure 24: The relief valve added to the AMESim model to simulate Hydrogen leakage.

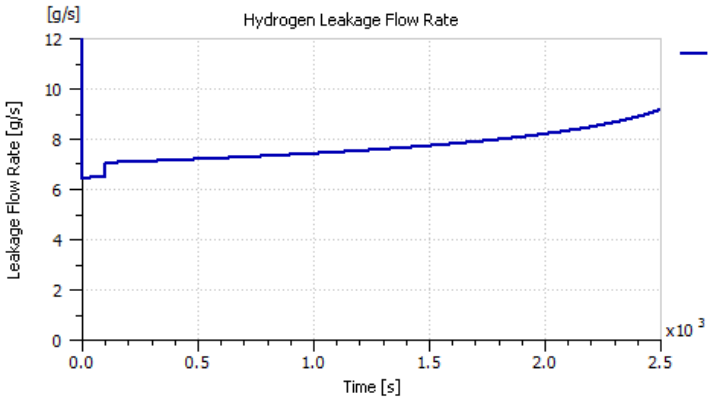

Figure 25: The flow rate of the Hydrogen leakage induced to the PEMFC system.

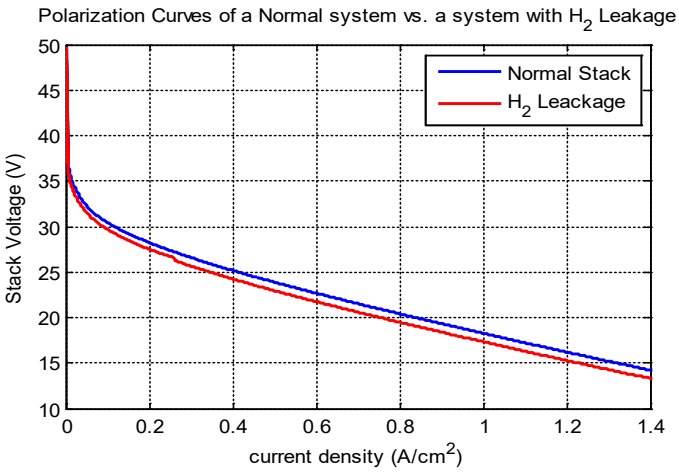

Figure 26: Polarization curves of a normal system vs. a system undergoing Hydrogen leakage.

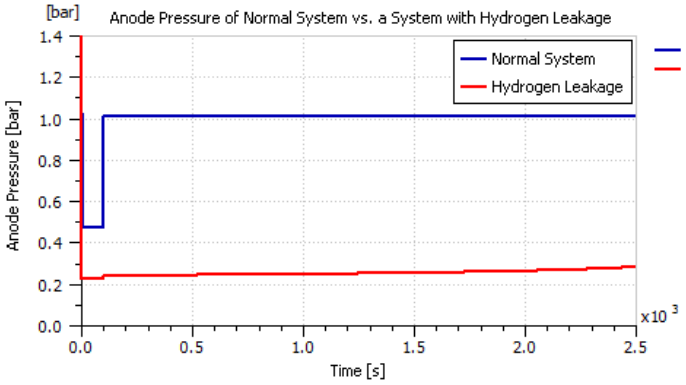

Figure 27: Anode pressure of a normal system vs. a system undergoing Hydrogen leakage.

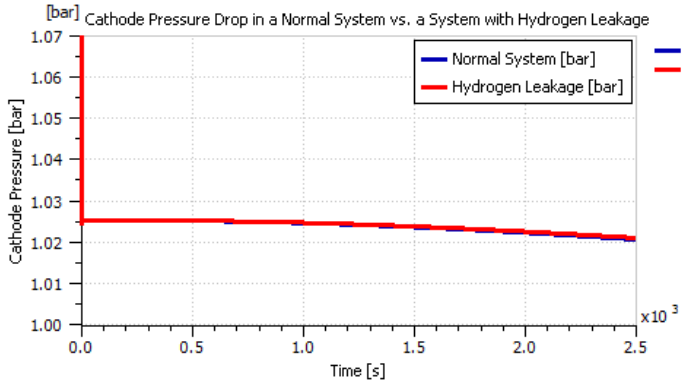

Figure 28: Pressure drop in the cathode of a normal system vs. a system undergoing Hydrogen leakage.

3.5. Cooling Failure

The stack temperature of the ElectraGen™ system should be maintained at a temperature value between 60°C to 65°C for maximum efficiency through air cooling. However, it is also convenient to mention that the stack temperature should never reach any value above 75°C in order to avoid damage of the membrane. Thus, it is important to flag a cooling system failure as soon as the stack temperature reaches 75°C or higher. Hence, the stack's temperature was increased to 75°C in order to simulate cooling failure. The polarization curve was found to undergo a significant effect with the increase in stack temperature as shown in Figure 29.

Note that the 75°C stack temperature results in a slight improvement in the system's polarization curve because the resistive components in the activation and ohmic voltage drop will decrease with the increase in stack temperature. However, at such an elevated temperature, drying of the stack will be inevitable. Furthermore, comprehensive literature review [7] revealed that operating the PEMFC at higher stack temperatures is a common stressor for almost all health degradation mechanisms. Thus, this slight improvement in the polarization curve is worthless since it will significantly shorten the PEMFCs lifespan.

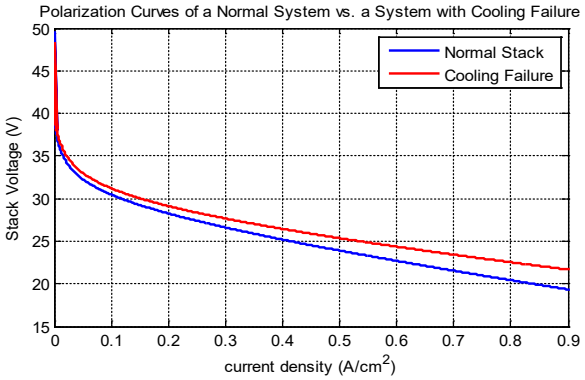

Figure 29: Polarization curve of a normal system vs. a system undergoing cooling failure.

Nonetheless, the stack temperature should be the main parameter used to detect the presence of cooling failure regardless of the effects on the voltage and current profiles. As soon the stack's temperature reading reaches 75°C is a cooling system failure fault should be flagged.

Note from Figure 29 that there is an improvement in the voltage performance of the fuel cell with the increase of stack temperature. This is expected since the rate of chemical reactions increase with the temperature causing this increase in voltage. However, it should also be noted that at this temperature value of 75°C, drying of the membrane is inevitable. Furthermore, high stack temperature is a well-known stressor for PEMFCs [8 – 11]. Thus, operating the system at such elevated stack temperatures will significantly reduce its lifespan, which makes this small voltage improvement at high stack temperature values worthless.

4. Fault Diagnosis

In this work, the model based fault diagnosis approach is based on the real-time comparison between the actual system performance and the performance predicted by the developed AMESim model. Any predicted discrepancies will be analyzed to determine the type of system fault occurring at the moment.

4.1. Residual generation

It can be concluded from the previous section that in order to detect discrepancies between the actual system and its developed model that can help in the fault detection and isolation process, five residuals (see Figure 30) should be generated based on the following five system variables: stack voltage (V_{stack}), current (I), stack temperature (T_{stack}), cathode pressure ($P_{Cathode}$) and anode pressure (P_{anode}).

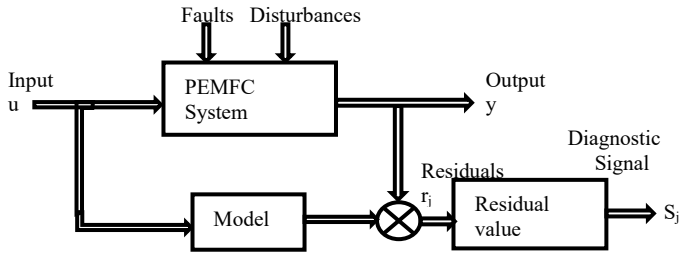

Figure 30: Residual generation diagram [12].

Several forms exist in literature for the calculation of residuals. In the simplest form given in (2), the absolute value of the residual (r_j) is compared to a relative threshold value (τ_j). The diagnostic signal (S_j) is then set to be "0" if the absolute residual is less than or equal to the threshold to indicate that no discrepancy is detected, and "1" if the absolute residual is greater than the set threshold which indicates that a discrepancy is detected [12]

$$S_j = \begin{cases} 0 & if \quad |r_j| \le \tau_j \\ 1 & if \quad |r_j| > \tau_j \end{cases} \tag{2}$$

Note that basing the fault diagnosis approach on the residuals calculated in (2) makes the approach prone to diagnosis errors. This is because the residuals of (2) are highly sensitive to instantaneous changes in the system such as the electromagnetic disturbance pulses which act on the system's measured signals as well as the occurrence of actual system faults.

Therefore, the calculation of those residuals can be slightly altered to decrease their sensitivity to disturbances. Thus, instead of calculating instantaneous residuals, they can be calculated over a moving window of time and judging the average of all residuals in that window as explained by (3), where N_r represents the number of residuals in the window [13]:

$$S_j = \begin{cases} 0 & if \quad \tilde{r}_j(N_r) = \frac{1}{N_r}\left|\sum_{n=0}^{N_r-1} r_{j,k-n}\right| \le \tau_j \\ 1 & if \quad \tilde{r}_j(N_r) = \frac{1}{N_r}\left|\sum_{n=0}^{N_r-1} r_{j,k-n}\right| > \tau_j \end{cases} \tag{3}$$

The threshold value for each residual is given in Table 1, and it was set based on the accuracy of the actual system sensors installed in the ElectraGen™ PEMFC system.

Table 1: Accuracy of actual sensors used to measure system variables

System variable	Sensor accuracy
Stack Voltage (V_{stack})	± 0.5 V
Current (I)	± 1 A
Stack Temperature (T_{stack})	± 3 °C
Cathode Pressure ($P_{cathode}$)	± 1 mbar
Anode Pressure (P_{anode})	± 1 mbar

4.2. Sensitivity assessment

Both the residual calculation techniques of (2) and (3) were implemented in LMS AMESim to study and assess their effectiveness and test their sensitivity towards electromagnetic disturbance pulses. Thus, a noisy step power demand signal with disturbance pulses was generated to help with the assessment. The system estimator however was fed with a clean power demand signal to test the diagnostic signals sensitivity toward those disturbance pulses.

The residuals that were calculated by the system are: r_1 which is based on the stack temperature (T_{stack}), r_2 which is based on the stack voltage (V_{stack}), r_3 which is based on the current (I), r_4 which is based on the anode pressure (P_{anode}) and r_5 which is based on the

cathode pressure ($P_{cathode}$). On the other hand, S_i is the respective diagnostic signal r_i.

The faults being detected by the proposed fault diagnosis approach are: (f_1 = Drying, f_2 = Flooding, f_3 = Air Leakage, f_4 = Hydrogen Leakage, and f_5 = Cooling Failure). The results of section III are summarized in Table 2 to help in the fault discrimination process, where 0 indicates that no discrepancies are detected between the predicted value and the actual measured value, and 1 indicates the positive detection of discrepancies whereas X indicates the fault exists whether the diagnostic signal detects discrepancies in the system variable or not. Note that the cooling failure that f_5, is set to be flagged as soon as the stack temperature reaches a value of 75°C (i.e. based on S_1) regardless of the effects on the stack voltage and current (i.e. S_2 and S_3).

Table 2: The effect of faults on diagnostic signals

fault	S_1	S_2	S_3	S_4	S_5
f_1	0	1	1	0	0
f_2	0	1	1	0	1
f_3	0	0	0	0	1
f_4	0	1	1	1	0
f_5	1	X	X	0	0

Figure 31 shows the fault diagnosis system built based on the instantaneous diagnostic signals calculation of (2). Figure 32 shows the noisy power demand signal fed to the actual system being diagnosed and the clean power demand signal fed to the system estimator. The diagnostic signals calculated based on the instantaneous residuals of (2) are shown in Figure 33.

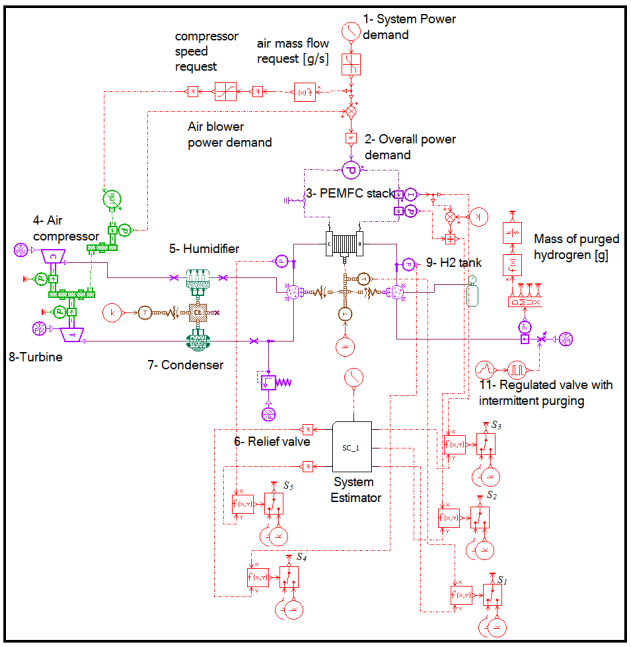

Figure 31: Fault diagnosis system based on instantaneous diagnostic signals.

It is obvious from Figure 33 that the diagnosis approach based on the instantaneous residuals in (2) is impractical and highly sensitive to electromagnetic disturbance pulses, which can therefore result in the detection of a faults when no fault actually exists. For instance, at around 150 s, both S_2 and S_3 diagnostic signals were triggered, which from Table 2 , will indicate the presence of the first fault f_1 (Drying).

Afterwards, the diagnostic signal of (3) was also implemented in LMS AMESim in order to be assessed based on three different moving windows of time (5 s, 10 s and 15 s). The same power signals of Figure 32 were used in the assessment to evaluate its sensitivity towards electromagnetic disturbance pulses. The fault diagnosis system built based on the diagnostic signals calculation of (3) is presented in Figure 34.

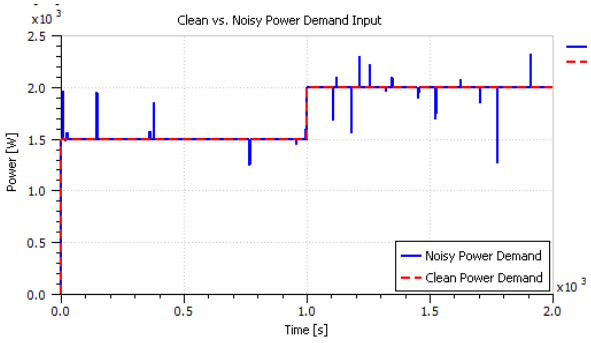

Figure 32: Clean and noisy power demand signals.

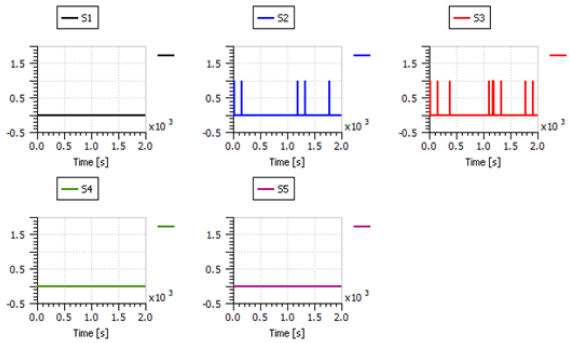

Figure 33: The effect of the pulsating noise on the five diagnostic signals.

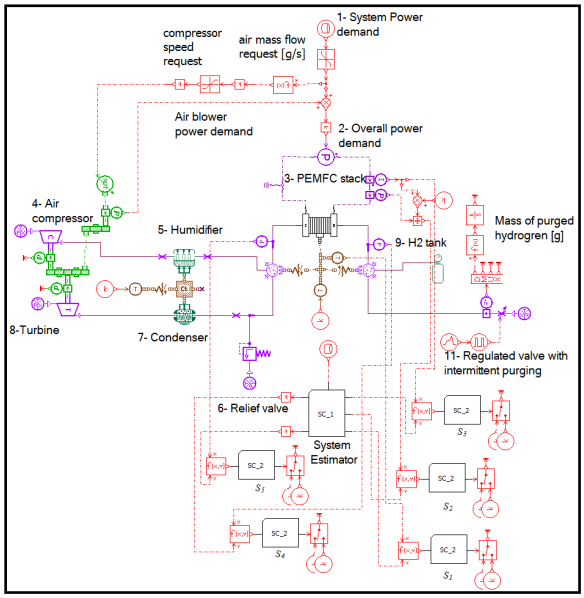

Figure 34: Fault diagnosis system based on diagnostic signals calculated over a window of time.

Note that a super-component was added to this model to help calculate the diagnostic signal over three different windows of time equal to 5 s, 10 s and 15 s. The contents of this super-component for the 5 s moving window of time is presented in Figure 35, whereas the super-component for the 10 s moving window of time is presented in Figure 36, and finally the super-component for the 15 s moving window of time is presented in Figure 37.

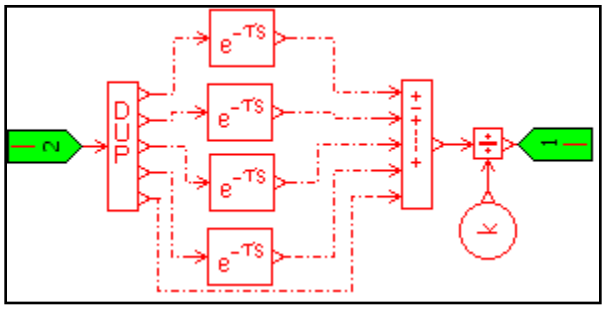

Figure 35: Super-component calculating diagnostic signal over a 5 *s* time window

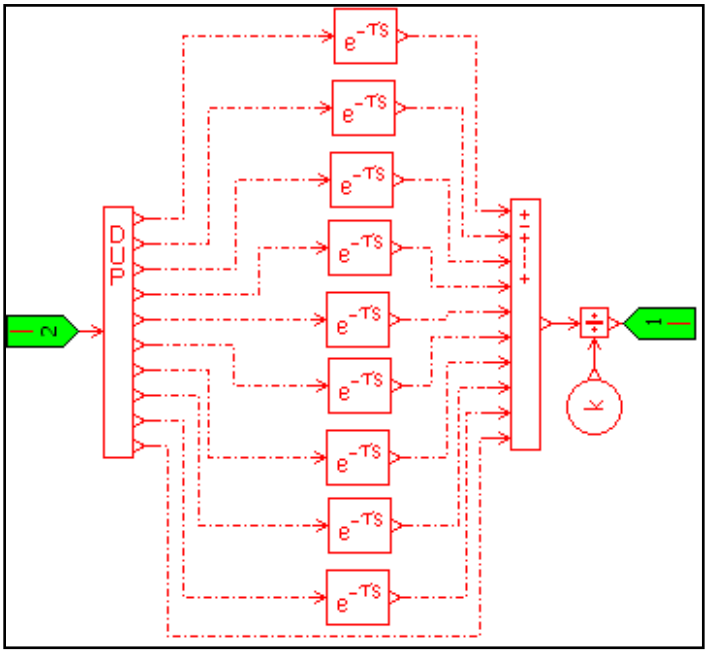

Figure 36: Super-component calculating diagnostic signal over a 10 *s* time window

Furthermore, the effect of the electromagnetic disturbance pulses on the calculation of the five diagnostic signals evaluated using a 5 s moving window of time is presented in Figure 38. Moreover, the effect of the disturbance pulses on the diagnostic signals utilizing a 10 s moving window is presented in Figure 39, and the effect of the disturbance pulses on the diagnostic signals utilizing a 15 s moving window is presented in Figure 40.

Figures 38, 39 and 40 prove that this diagnostic approach of (3) outperforms that of (2). However, it is convenient to mention here that most commercial PEMFC systems commonly have a minimum sampling time of 1 s. Therefore, basing the diagnostic signal on a 5 s window of time can prove to be impractical as seen in Figure 38. Furthermore, the diagnostic signals calculated based on both the 10 s and the 15 s moving windows of time proved to be effective and insensitive to electromagnetic disturbance pulses as seen from Figures 39 and 40. Nevertheless, using a 10 s moving window of time is preferred over the 15 s moving window of time in order to avoid delays in detecting faults as well as saving memory.

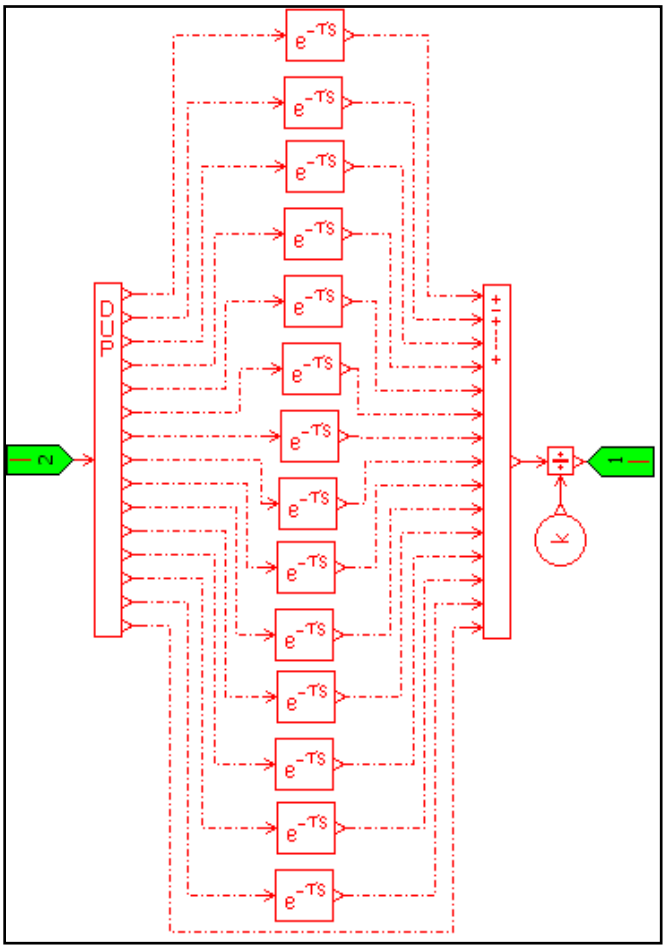

Figure 37: Super-component calculating diagnostic signal over a 15 *s* time window

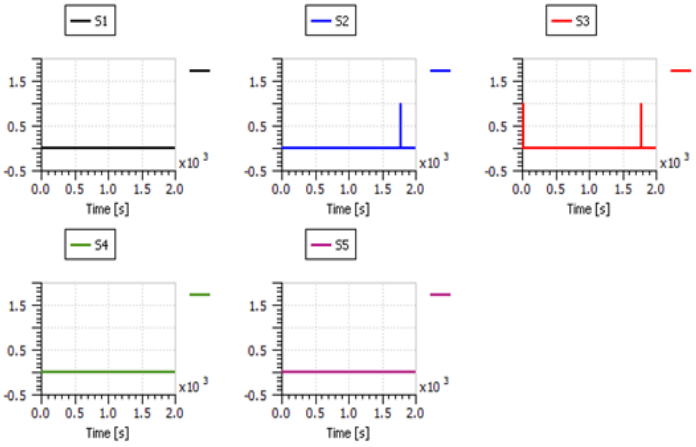

Figure 38: The effect of the disturbance pulses on the five diagnostic signals calculated using a 5 s moving window.

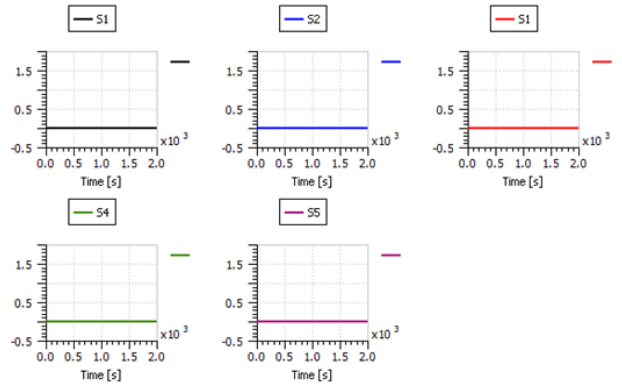

Figure 39: The effect of the disturbance pulses on the five diagnostic signals calculated using a 10 s moving window.

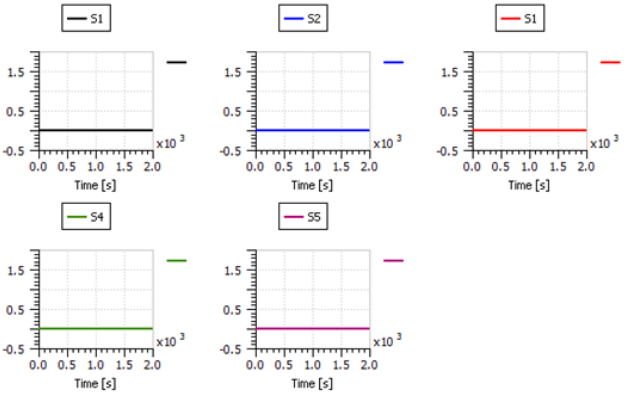

Figure 40: The effect of the disturbance pulses on the five diagnostic signals calculated using a 15 s moving window.

4.3. Fault diagnosis results

To test the proposed fault diagnosis scheme designed using diagnostic signals calculated over a 10 s moving window of time; the five system faults were induced at different times to evaluate the system's ability to detect and isolate the five system faults.

The first fault to be simulated was membrane drying. Thus, the relative humidity target of the humidifier was dropped to 10% and the effect of this action was immediately captured by the diagnostic signals S_2 and S_3 as seen in Figure 41, which – from Table 2 – clearly indicates the presence fault f_1 (drying of the membrane).

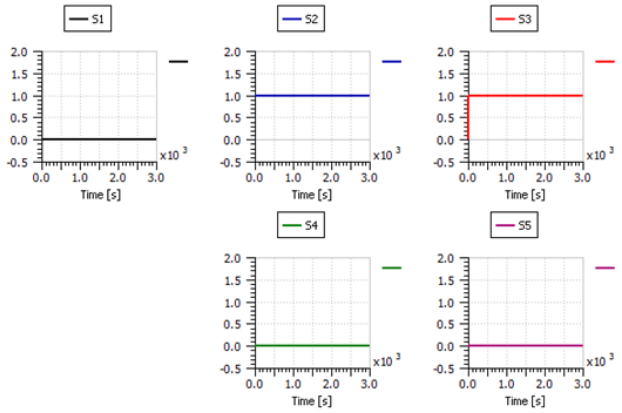

Figure 41: The diagnostic signals successfully detecting drying fault.

The second fault to be tested was membrane flooding. Therefore, the relative humidity target of the humidifier was raised to 100% while reducing the stack temperature to 25°C. Again, this action was clearly reflected on the diagnostic signals as seen from Figure 42, and the three diagnostic Signals S_2, S_3 and S_5 were triggered. However, it was noticed that the effect on the diagnostic signal S_5 was not as fast as that on diagnostic signals S_2 and S_3. This is expected since the increase in pressure drop needs some time to take effect. From Table 2, triggering S_2, S_3 and S_5 at the same time indicates the presence fault f_2 (flooding of the membrane).

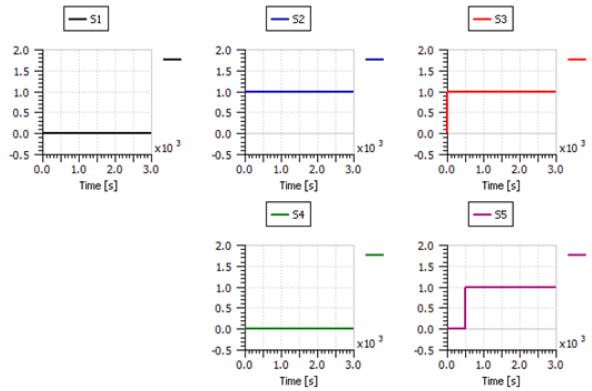

Figure 42: The diagnostic signals successfully detecting flooding fault.

The third fault to be tested was the air leakage in the supply manifold, which was simulated through the addition of a relief valve after the humidifier as shown in Figure 43. This relief valve was set to open with a flow rate of 9 g/s after 500 s of operation. Only one diagnostic signal was affected by this action at around 500 s as depicted in Figure 44. From Table 2, it can be deduced that triggering only S_5 indicates the occurrence of fault f_3 (air leakage).

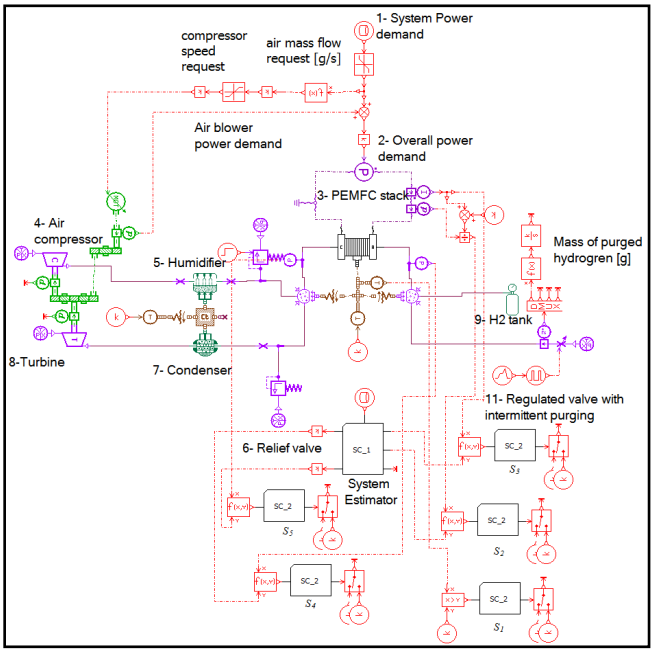

Figure 43: The modified diagnosis model with a relief valve to simulate air leakage.

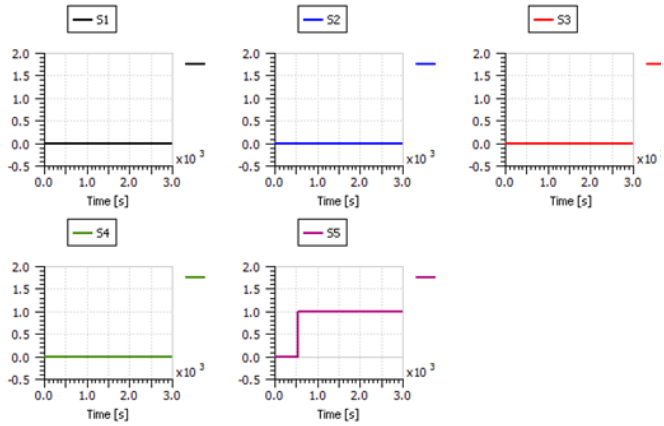

Figure 44: The diagnostic signals successfully detecting air leakage fault.

The next fault to be simulated was hydrogen leakage. As shown in Figure 45, the leakage was simulated through the addition of a relief valve right after the hydrogen supply canister. This valve was set to open with a flow rate of 8 g/s after 500 seconds of operation. The amount of hydrogen leakage can be seen in Figure 46.

From Figure 47, it is noticed that three diagnostic signals were triggered at around 500 s, which are S_2, S_3 and S_4. This clearly indicates the occurrence of fault f_4 (hydrogen leakage) as it can be deduced from Table 2.

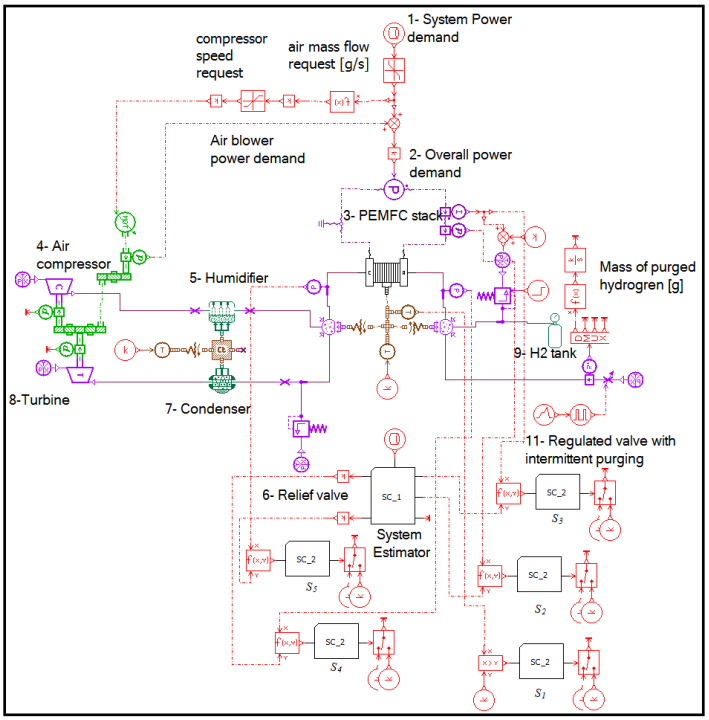

Figure 45: The modified diagnosis model with a relief valve to simulate hydrogen leakage.

Finally, the cooling system failure was tested by forcing the stack temperature to rise to 75°C after 1500 s of operation. The three diagnostic signals S_1, S_2 and S_3 were triggered by this action at around 1500 s of operation as shown in Figure 48. As it can be deduced from Table 2, and as previously explained in section III, S_1 alone is enough to flag fault f_5 (cooling failure) regardless of the effects on other diagnostic signals.

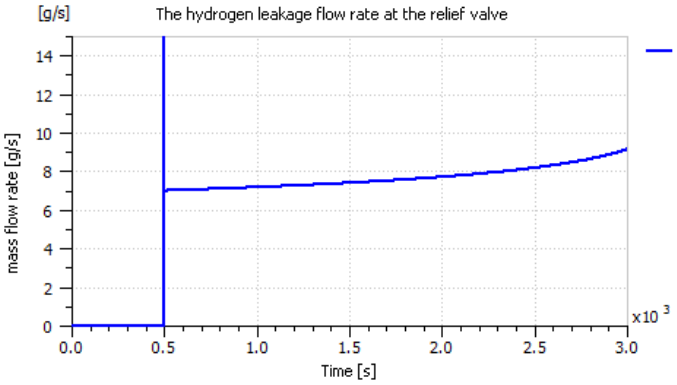

Figure 46: The hydrogen leakage flow rate at the relief valve.

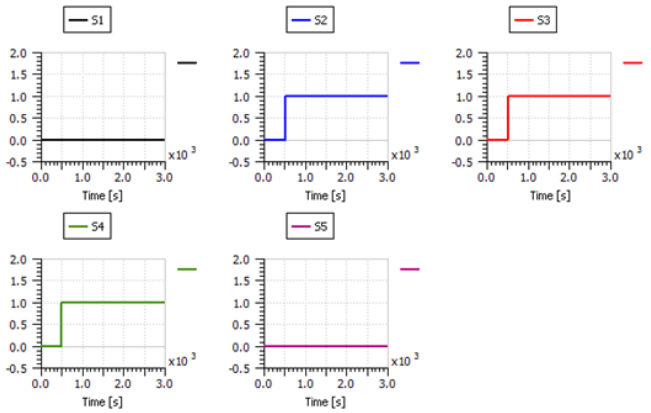

Figure 47: The diagnostic signals successfully detecting hydrogen leakage fault

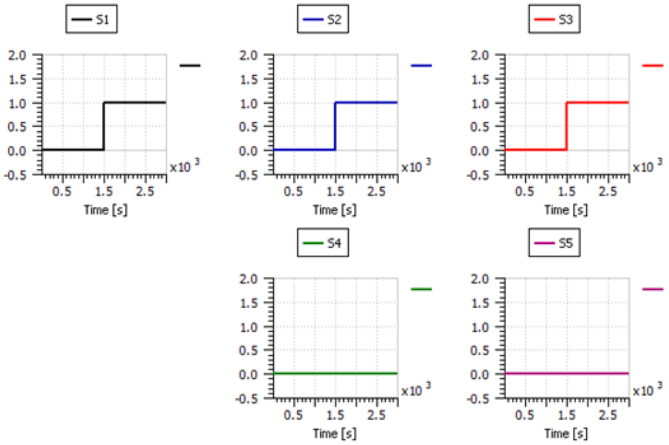

Figure 48: The diagnostic signals successfully detecting cooling system failure fault.

5. Conclusion

Fuel cells are extremely attractive clean power generation systems with the capability of someday replacing fossil fuels in the areas of power generation and transportation, while helping clean the environment by significantly lowering the world's pollution rates. However, to turn this green technology dream into reality, an accurate model that can effectively predict the fuel cell's performance in different conditions is desired. Such model can

then be used to study, simulate, and monitor the behavior of PEMFCs to detect any potential faults that can affect their performance.

Moreover, the complexity of the PEMFC model makes it very difficult and mathematically demanding to try and identify the modeling parameters. Furthermore, other limitations such as the absence of some parameters and confidentiality issues with the manufacturer can also limit the researchers' ability to develop an accurate fault diagnosis oriented model for a commercial PEMFC system. The Siemens software LMS AMESim 14.2 was used in this work as a solution to overcome such limitations.

A diagnosis oriented model of the ElectraGen™ PEMFC system was developed in LMS AMESim and five system faults (drying of the membrane, flooding of the membrane, air leakage, hydrogen leakage in the supply manifold, and cooling failure) were simulated to analyze their effect on different system parameters.

Diagnostic signals based on two different residual generation techniques were also assessed in this work, and the outperforming technique was implemented in the proposed diagnosis scheme. This diagnosis scheme was then tested in LMS AMESim against the five system faults under study and it was found to be very successful in both fault detection and discrimination.

Conflict of Interest

The authors declare no conflict of interest.

ABSTRACT

Due to the increasing bandwidth requirement of modern wireless communication systems, developing antenna having wider bandwidth have been receiving significant attention in the recent years. In this paper, a comparative analysis of the contacting feed (micro strip line and coaxial probe) and non-contacting feed mechanism (both Aperture Coupling and Proximity Coupling) in micro strip patch antenna has been done. In case of contacting feed, RF power is fed directly to the radiating patch using a connecting element such as a micro strip line whereas in case of non-contacting feeds, electromagnetic field coupling is done to transfer power between the micro strip line and the radiating patch. As per the latest research, ultra wide band technology is used in the frequency range from 3 GHz to 10 GHz. We have analyzed and compared the return loss and corresponding bandwidth of these four types of antenna at 5.853GHz so that this antenna may be used in medical as well as wireless applications.

1. Introduction

Micro strip patch antennas are considered as an indispensable tool in today's research oriented activities. The design and manufacturing cost of micro strip antenna is very cheap because of its 2D geometrical structure [1]. The patch antenna is a popular resonant antenna used for microwave wireless communications that require semispherical coverage. Some patch antennas avoid using a dielectric substrate and suspend a metal patch in the air above a ground plane using dielectric spacers; the resulting structure provides increased bandwidth. With an increase in frequency, the input impedance moves to the clockwise direction on the Smith chart [2]. Wireless and Medical applications requires small, low-cost, low profile antennas which has Omni directional radiation pattern in horizontal planes. Micro Strip patch antenna meets all requirements. Figure 1 shows a typical structure of a rectangular micro strip antenna.

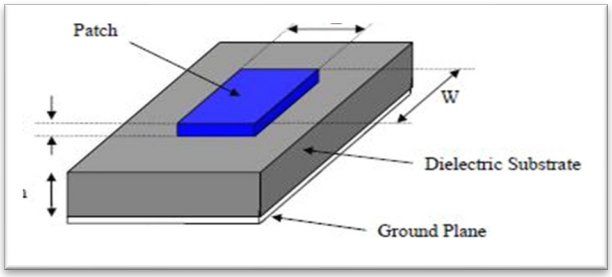

Fig 1: Micro Strip Patch Antenna

2. Feeding Mechanism

Suitable feeding technique plays an important role for antenna efficiency and better impedance matching. The feeding techniques used in the micro strip antenna are given below:

*Dr. Anjan Kumar Kundu, Institute of Radio Physics & Electronics,92, A.P.C Road, Kolkata-700009, +91-9874191584 (M), anjankumarkundu@gmail.com

2.1. Contacting Feed:

In this method, contacting element such as micro strip line or coaxial line is used to help the patch so that it can be fed directly to RF power. The most commonly used contacting feed methods are [3]:

1. Line Feed
2. Co-axial probe Feed

- **Micro Strip Line Feed:**

Micro strip line feed is one of the easier methods to fabricate as it is just a conducting strip connecting to the patch and therefore can be considered as extension of patch.[3-4] It is simple to model and easy to match by controlling the inset position. However the disadvantage of this method is that as substrate thickness increases, surface wave and spurious feed radiation increases which limit the bandwidth.

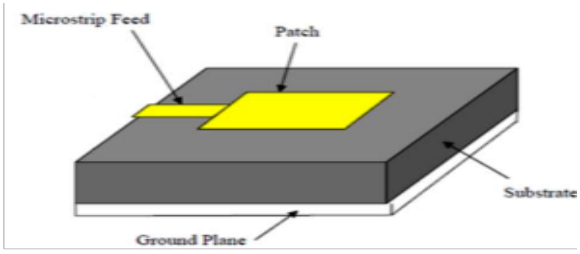

Fig 2: Micro strip Line feeding

- **Coaxial Probe Feed:**

Coaxial feeding is feeding method in which that the inner conductor of the coaxial is attached to the radiation patch of the antenna while the outer conductor is connected to the ground plane.

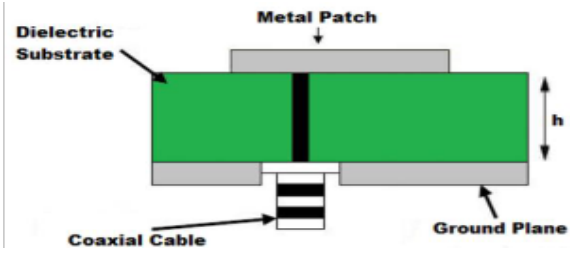

Fig 3: Coaxial Probe feeding

2.2. Non-Contacting Feed:

In this method, the RF power is transferred to the path from the feed line through electromagnetic coupling instead of feeding directly. The commonly used non-contacting feed methods are:

1. Aperture Coupled feed
2. Proximity Coupled feed

- **Aperture Coupling Feed:**

In the aperture coupled feed technique, the radiating patch and the micro strip feed line are separated by the ground plane. Coupling between the patch and the feed line is made through a slot or an aperture in the ground plane.

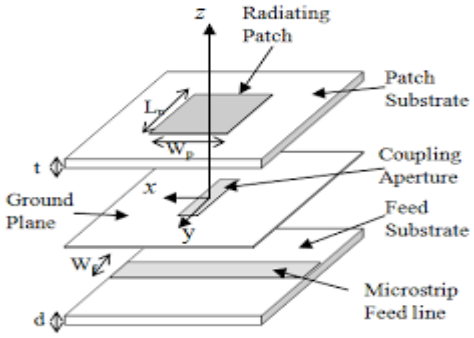

Fig 4: Aperture Coupled feeding

- **Proximity Coupling Feed:**

In this method, two dielectric substrates are placed such that the feed line lies in between the two substrates and the radiating patch is placed at the top of the upper substrate.

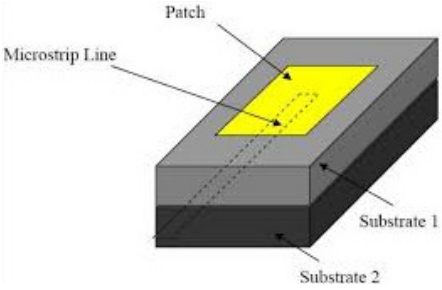

Fig 5: Proximity Coupled feeding

The two dielectric substrates can be selected independently to optimize both micro strip guided waves and patch radiating waves. The ranges of operating thickness of the substrate have a big effect on the resonant frequency and bandwidth of the antenna. Bandwidth of the micro strip antenna will increase with increasing substrate thickness. However, certain limits must not be exceeded, and otherwise the antenna will stop resonating. Therefore, [4], the measures for selecting a substrate may include the following:

(a) Surface-wave excitation.

(b) Dispersion of the dielectric constant and loss tangent of the substrate.

(c) Anisotropy in the substrate.

(d) Cost Effective

3. Study of Antenna Designing Parameters

There are three essential parameters for design of a rectangular micro strip Patch Antenna. Firstly, the resonant frequency (f_0) of the antenna must be selected appropriately. The frequency range for ultra wide band applications is from 3.1GHz to 10.6 GHz and the design antenna must be able to operate within this frequency range.

The second important parameter of good antenna design is dielectric substrate ($\in_r$). A thick dielectric substrate having low dielectric constant is desirable. This provides better efficiency, larger bandwidth and better radiation. FR-4 Epoxy which has a dielectric constant of 4.4 for lower substrate and RT –Duroid for upper substrate having dielectric constant of 2.2 and loss tangent equal to 0.009 can be used for new antenna design [5-6]. The other antenna parameters to be considered for design are length of the patch L, width W, height of dielectric substrate h and Loss Tangent. The patch length is considered around $L_g/2$ (L_g - Length of the ground plane) to initiate the radiation. The antenna is typically fed at the diverging edge on the dimension W because it offers sensible Polarization. The antenna parameters can be calculated by the transmission line method as exemplified below [7]:

3.1 Width of the Patch (mm):

Having specified the height of the patch antenna, the first step in the design procedure is to determine the width of the patch. This can be calculated using the following equation:

$$W = \frac{c}{2f_0\sqrt{\in r + 1}/2} \quad (1)$$

Where,

c = Speed of light in free-space (3×10^8 m/s)

f_0= Resonating frequency

3.2 Calculation of Effective Dielectric Constant (ϵ_{reff}):

This is calculated using the following equation:

$$\epsilon_{reff} = (\in r + 1)/2 + (\in r - 1)/2\left[1 + 12\ \frac{h}{w}\right]^{-0.5} \quad (2)$$

Where, h= height of the patch (mm)

W= width of the patch (mm)

3.3 Calculation of Effective Length (L_{eff}):

This is calculated using the following equation:

$$L_{eff} = \frac{c}{2f_0\sqrt{\in reff}} \quad (3)$$

3.4 Calculation of Length Extension (Δ_L):

The length extension is calculated using the following equation;

$$\Delta L = \frac{0.412h\ (\in reff + 0.3)(w/h + 0.264)}{(\in reff - 0.258)(w/h + 0.8)} \quad (4)$$

Where,

L= Patch length extension (mm)

h = height (mm)

W = width of the patch (mm)

3.5 Calculation of Actual Length:

The actual length of the patch antenna is calculated using the following equation;

$$L = Leff - 2\Delta L \quad (5)$$

4. Design and Simulation of Micro Strip Patch Antenna for Different Feeding Methods

4.1. Micro Strip Line Feed:

The antenna is designed at resonating frequency 5.853 GHz of WLAN. It is designed using transmission line model [8]. This section describes the design of rectangular patch antenna satisfying the given specifications:

Table 1: Design specification of Aperture Coupled Patch

Frequency	5.853 GHz
Antenna Dimension	29mm x 41mm
Dielectric Constant (RT Duroid)	2.2

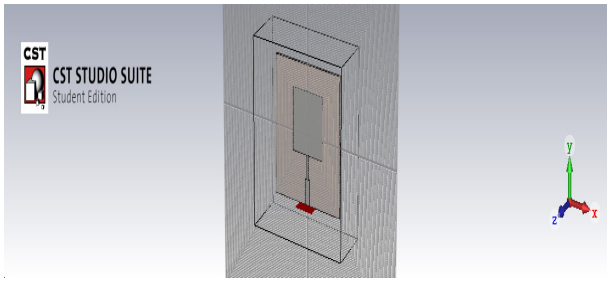

Fig 6: Designed Structures on CST Studio

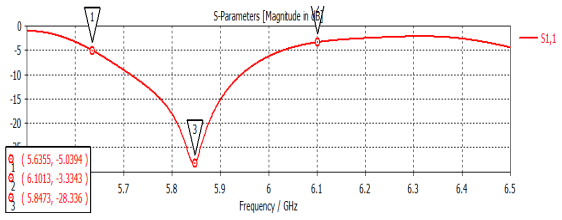

Fig 7: Return Loss S_{11} of simulated antenna at 5.853 GHz

Return Loss:

Fig 7 shows the S11 parameters (Return Loss = - 28dB) for the proposed antenna. The designed antenna resonates at 5.853 GHz.

Smith Chart:

The Smith Chart plot (Fig. 8) represents that how the antenna impedance varies with frequency and gives impedance of 50.4 ohms. For proper matching, the locus must be large so that it connects with the center point of the smith chart.

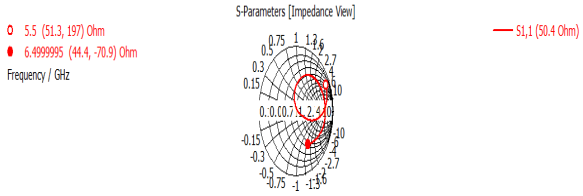

Fig 8: Smith Chart of simulated antenna at 5.853 GHz

Calculation of VSWR:

Fig. 9 shows the VSWR plot against frequency that numerically describes how well the antenna matches with the transmission line it is connected to.

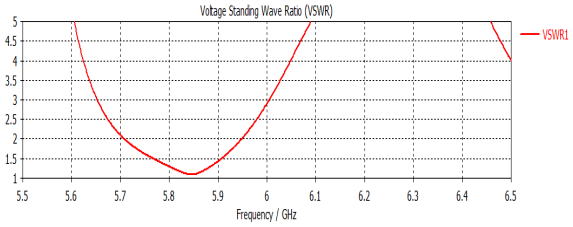

Fig 9: VSWR of simulated antenna at 5.853 GHz

4.2. Coaxial Probe Feeding:

The antenna is designed at resonating frequency 5.853 GHz of WLAN. It is designed using transmission line model. This section describes the design of rectangular patch antenna satisfying the given specifications:

Return Loss:

Fig 11 shows the S_{11} parameters (Return Loss = -37dB) for the proposed antenna. The designed antenna resonates at 5.853 GHz.

Table 2: Design specification of Proximity Coupled Patch

Frequency	5.853 GHz
Antenna Dimension	29mm x 41mm
Dielectric Constant (RT Duroid)	2.2

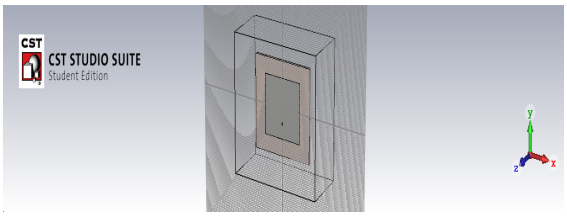

Fig 10: Designed Structure on CST Studio

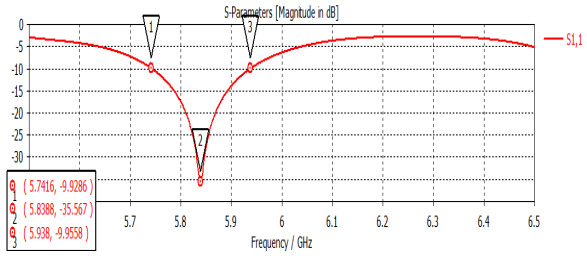

Fig 11: Return Loss S_{11} of simulated antenna at 5.853 GHz

Smith Chart:

The Smith Chart plot (Fig. 12) represents that how the antenna impedance varies with frequency and gives impedance of 50.21 ohms. For proper matching, the locus must be large enough that it passes through the center of the smith chart.

As it can be seen from Fig. 12, the circle cuts the resistive part at 0.5021, thus matching at 50.21 ohm.

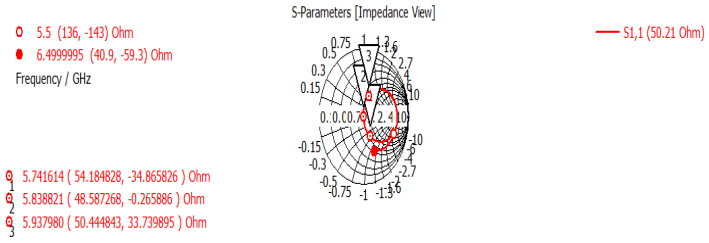

Fig 12: Smith Chart of simulated antenna at 5.853 GHz

Calculation of VSWR:

Fig. 13 shows the VSWR plot against frequency that numerically describes how well the antenna matches with the transmission line it is connected to.

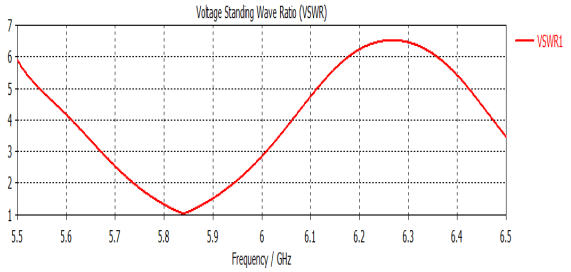

Fig 13: VSWR of simulated antenna at 5.853 GHz

4.3. Aperture Coupled Feeding:

The antenna is designed at resonating frequency 5.853 GHz of WLAN. It is designed using transmission line model. This section describes the design of rectangular patch antenna satisfying the given specifications:

Table 3: Design specification of Aperture Coupled Patch

Frequency	5.853 GHz
Antenna Dimension	29mm x 41mm
Lower Dielectric Constant (FR4)	4.4
Upper Dielectric Constant (RT Duroid)	2.2

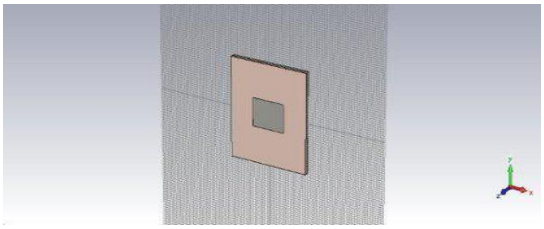

Fig 14: Designed Structures on CST Studio

Return Loss:

Fig 15 shows the S_{11} parameters (Return Loss = - 33dB) for the proposed antenna. The designed antenna resonates at 5.853 GHz.

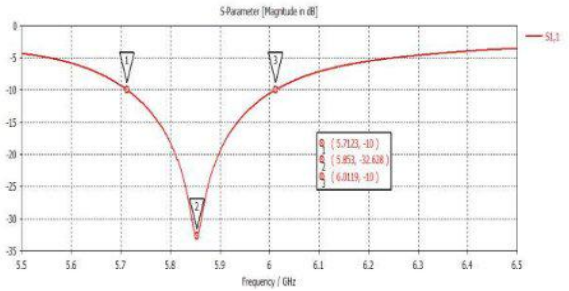

Fig 15: Return Loss S_{11} of simulated antenna at 5.853 GHz

Smith Chart:

The Smith Chart plot (Fig. 16) represents that how the antenna impedance varies with frequency and gives impedance of 49.93 ohms. For proper matching, the locus must be large so that it connects with the center point of the smith chart.

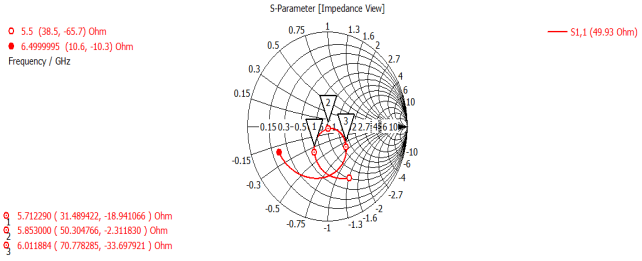

Fig 16: Smith Chart of simulated antenna at 5.853 GHz

Calculation of VSWR:

Fig. 17 shows the VSWR plot against frequency that numerically describes how well the antenna matches with the transmission line it is connected to.

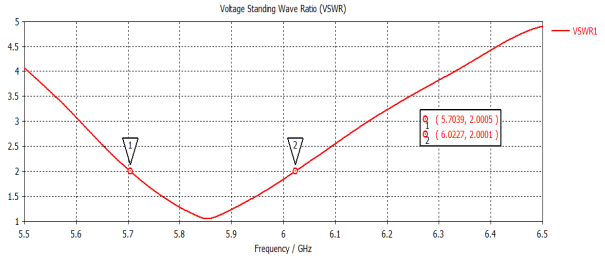

Fig 17: VSWR of simulated antenna at 5.853 GHz

4.4. Proximity Coupled feeding:

The antenna is designed at resonating frequency 5.853 GHz of WLAN. It is designed using transmission line model. This section describes the design of rectangular patch antenna satisfying the given specifications:

Table 4: Design specification of Proximity Coupled Patch

Frequency	5.853 GHz
Antenna Dimension	29mm x 41mm
Lower Dielectric Constant (FR4)	4.4
Upper Dielectric Constant (RT Duroid)	2.2

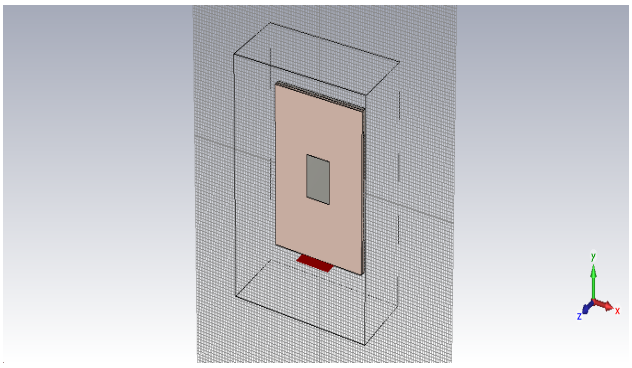

Fig 18: Designed Structure on CST Studio

Return Loss:

Fig 19 shows the S_{11} parameters (Return Loss = -47dB) for the proposed antenna. The designed antenna resonates at 5.853 GHz. More negative the return loss, higher the directivity and gain of the proposed antenna in particular direction.

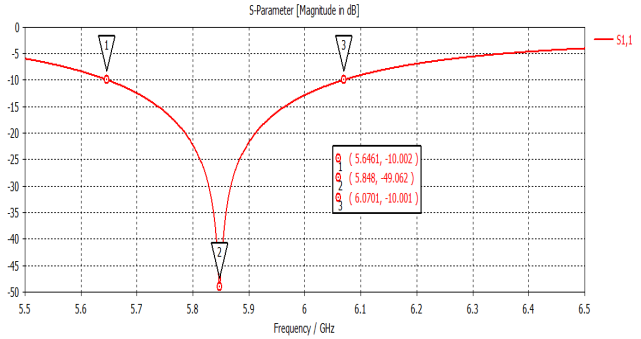

Fig 19: Return Loss S_{11} of simulated antenna at 5.853 GHz

1) Smith Chart:

The Smith Chart plot (Fig. 19) represents that how the antenna impedance varies with frequency and gives impedance of 49.97 ohms. For proper matching, the locus must be large enough that it passes through the center of the smith chart.

As it can be seen from Fig. 19, the circle cuts the resistive part at 0.4997, thus matching at 49.97 ohm.

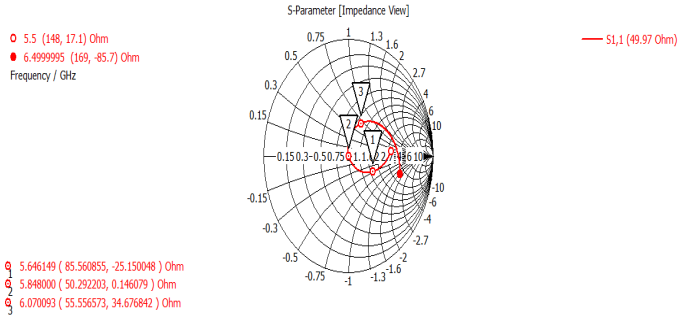

Fig 6.3: Smith Chart of simulated antenna at 5.853 GHz

3) Calculation of VSWR:

Fig. 20 shows the VSWR plot against frequency that numerically describes how well the antenna matches with the transmission line it is connected to.

5. Comparative Study of Important Parameters

Characteristics	Line	Coaxial	Aperture	Proximity
Return Loss (S_{11}) (dB)	-28	-37	-33	-47
Bandwidth (MHz)	250	210	320	475
VSWR	1.08	1.13	1.04	1.16
Impedance (ohm)	50.4	50.21	49.93	49.97

Table E : Comparison of Different Feeding Techniques

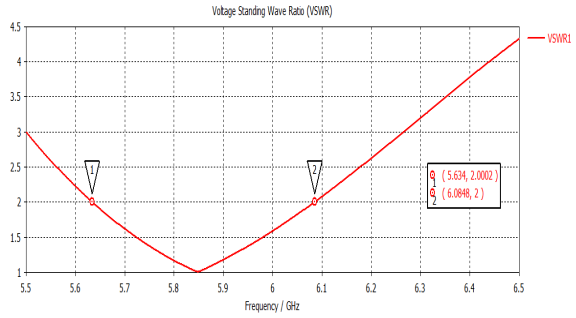

Fig 20: VSWR of simulated antenna at 5.853 GHz

Conclusion

Finally, the optimum result of all four feeding techniques of rectangular patch antenna on FR4 and RT-duroid substrate for Wi-max applications has been investigated. A comparison is made between feeding techniques [9-10] in terms of bandwidth, return loss, VSWR and impedance matching. So, we can see that selection of the feeding technique for a micro strip patch antenna is an important decision because it affects the bandwidth and other parameters also. A micro strip patch antenna excited by different excitation techniques gives different bandwidth, different gain, different efficiency etc. The maximum bandwidth can be achieved by proximity coupling. Proximity coupling gives the best impedance matching and radiation efficiency. Coaxial feeding technique gives the least bandwidth. We can also conclude that by changing the feed point where matching is perfect, the high return loss can be achieved at the resonant frequency. Various micro strip patch antennas with each different feeding technique are presented. The various parameters like return loss, smith chart, and VSWR are plotted for each antenna.

Conflict of Interest

The authors declare no conflict of interest.

Future Scope of Work

The designed patch antenna is intended for wireless applications. This paper mainly deals with the simulation of its characteristics for different feeding techniques which must have to be verified with the fabricated one. The size of this antenna ultimately restricts its usage mainly in biotelemetry in the field of medical applications. So, to extend its usage as an implantable one, its reduced size with similar characteristics has to be investigated. Using bio-compatible ceramic resins instead of conventional one to reduce its size has a great future scope of this work. Also, this design has to be compared with other miniaturized antenna techniques to ensure proper selection of implantable body antenna.

Acknowledgment

The authors of this paper would like to thank University Grant Commission (UGC) for giving the opportunity to work in

Modern Biology Group B: “Image and Imaging” under UPE-II. We also acknowledge all the contribution of corresponding IEEE authors and most importantly the publishers of related books and journals which gave immense support and inspiration in preparing this manuscript. Above all, the extreme mental support and source of inspiration from all the family members and friends are widely acknowledged.

ABSTRACT

This paper, presents the design of a temperature sensor based on RO (Ring Oscillator) in order to make a thermal study for the detection and localization of thermal peaks in a complex system. In this work, a simulation and FPGA implementation of a fully digital temperature sensor features a number of exact inverters that can be dynamically inserted. Before the transition to the implementation in FPGA board, the use of VHDL code is necessary to describe the exact number of inverters that form a single ring oscillator, in order to verify and validate the results obtained. This paper offers a solution to thermally induced stress and local overheating in complex system design which has been a major concern for the designers during the design of integrated circuit. In this paper a DE1 FPGA board cyclone V family 5CSEMA5F31C6 is used for the implementation.

1. Introduction

Decreasing feature sizes and increasing power and package contact densities are making thermal issues extremely important in complex system design. The main purpose of using a temperature sensor is to provide thermal monitoring for predicting local overheating or thermally induced stress. In this article, an intelligent sensor is used for thermal monitoring which is almost an ideal sensor due to its low power consumption. The main idea of this work is to simulate and implement a fully digital temperature sensor that can be dynamically inserted, operated and eliminated from the circuit once the test is done.

The intelligent sensor used in the design is actually based on ring oscillator. One of the important questions in the field of thermal issues of VLSI systems and micro-systems is how to perform the thermal monitoring, in order to indicate the overheating situations, without complicated control circuits.

Traditional approach consists of placement of many sensors everywhere on the chip, and then their output can be read simultaneously and compared with the reference voltage recognized as the overheating level. These techniques, though helpful to reduce the overall power consumption, may cause significant on-chip thermal gradients and local hot spots due to different clock/power gating activities and varying voltage scaling. It has been reported in [1] that temperature variations of 30 °C can occur in a high-performance microprocessor design.

The magnitude of thermal gradients and associated thermo-mechanical stress is expected to increase further as VLSI complex designs move into nanometer processes and multi-GHz frequencies. After the actual temperature is read, the value will be returned through the configuration ports of the FPGA. Then, the sensor will be removed from the chip. This type of oscillator used here is based on the switching time of an inverter. By connecting an odd number of inverters, a naturally oscillating signal is obtained at the output of each inverter of the chain. The oscillation frequency is directly related to the number of inverters. The more inverters there are, the lower the frequency is. To control the oscillation, an inverter can be replaced by a NAND gate, in order to stop or activate the oscillating system. Reference [2], [3], [4], [5] and [6] presents various techniques for varying the frequency of oscillation of the structure. These suggestions based on the voltage control of the delay generated by each cell, on the current control of the rise and falling time of each cell or on the controlled variation of the number of cells.

The advantage of this structure lies in the fact that it can be implemented both with an even number and an odd number of cells. This offers a greater tolerance on the constellation in phase of the signals available at output, but in the case of an implementation with an odd number of cells gives a sinusoidal signal in the output which makes the ring oscillator the perfect solution used ever to

*Corresponding Author: Aziz Oukaira; Email: ouka02@uqo.ca

give more information during the thermal monitoring. In fact, a ring oscillator consists of a feedback loop that includes a necessary odd number of inverters to produce the displacement of the phase which maintains the oscillation the total period is twice the sum of the delays of all the elements that make up the loop. Reversals can be made using the LUT (look-up table) of the configurable logic blocks (CLBs) or the programmable inverters included in the FPGA blocks. In any case, it is useful to insert an external signal to open the loop, as well as an output register to prevent variations in the frequency due to different loads. Thus, the sensor can give instantaneous temperatures.

The future of detectors based on the ring oscillator method is to help designers of more complex integrated circuits to optimize the management of thermal dynamics on the chip [7], [8] and [9]. In this paper in particular, the sensor used allows the detection of thermal peaks. The interests of a sensor based on this method are multiple [10] and [11]. Among the interests of the use of this sensor based on ring oscillator method, is that it can be easily integrated on a chip and can be dynamically inserted or removed from the design at any time due to its small size.

The rest of our work is organized as follows. Section 2, gives a description of the methodology used. Section 3, shows the implementation of the ring oscillator on the FPGA board to verify and validate the results.

2. Description of the methodology used

The new methodology adopted is to validate the control temperature of complex microsystems on a chip based of five inverters forming a ring oscillator [12]. This methodology has given very encouraging results for thermal monitoring in more complex integrated circuits. These simulations and FPGA implementation will then be generalized in high density microsystems, for the development of an integrated thermo mechanical stress control unit using our proposal described in this paper. The proposed ring oscillator depends on the temperature and its frequency changes accordingly. At a given temperature, the oscillator will exhibit a fixed frequency of oscillation.

2.1. Material and geometry of the complex design in COMSOL

We have made the simulation in COMSOL tool appointment with different materials and hardware layers and well on their ranking on the semiconductor. In this figure, we clearly see the reconciliation of our complex circuit layers. The complex model contains 36 Radial Board (RB) in which each RB contains 12 adapter board detector module (ABDM) and each ABDM contains 2 ASICs. Power of 0.6 W is dissipated in a complex circuit of the ASIC (4.68 mm x 5.97 mm) [13]. This amount of power is applied for 9 seconds to visualize the evolution and distribution of heat around the ASIC. Figure 1 shows the ASIC and its support modeled in COMSOL, the ASIC transmits event data through low voltage differential signaling links. To solve the thermal diffusion equations, the Dirichlet boundary conditions (DBC) at 298.15 °K are applied around the daughter board.

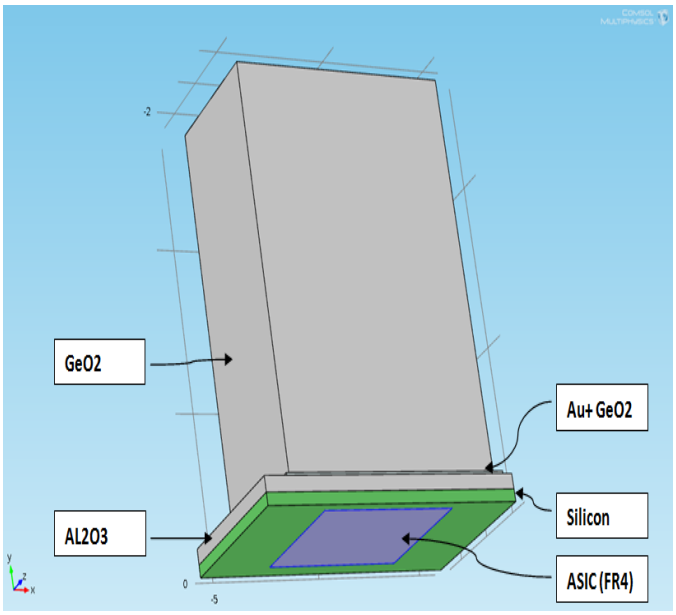

Figure 1 The ASIC modeled by the COMSOL tool.

This structure thus represents a continuous domain, by the method of finite elements consists first of a geometric discretization. The structure is subdivided into sub domains of the simple geometric form called finite element and defined not on the whole of the structure, but for each of its elements.

2.2. Thermal distribution of the complex design in COMSOL

It is very interesting to have a simulation environment that includes the ability to add different physical phenomena to the model studied. In this part, we will present the simulation results from heat sources represented the ASIC complex module in COMSOL tool. As you can see in Figure 2 shows the thermal behavior of our model complex design.

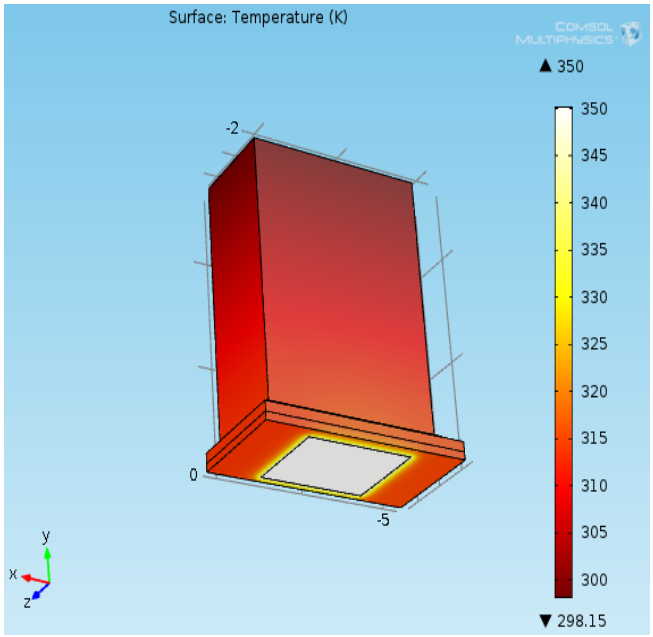

Figure 2 Thermal distribution of the ASIC in COMSOL tool.

This simulation of the ASIC complex module in COMSOL gives a good idea of the behavior and the thermal diffusion of heat sources in our complex system and shows the temperature up to 350 °K. The use of COMSOL tool gives us an idea about the thermal diffusion around the ASIC. According to another study done by [14] and the following Figure 3 presents the values of the temperature as a function of the frequencies of a ring oscillator.

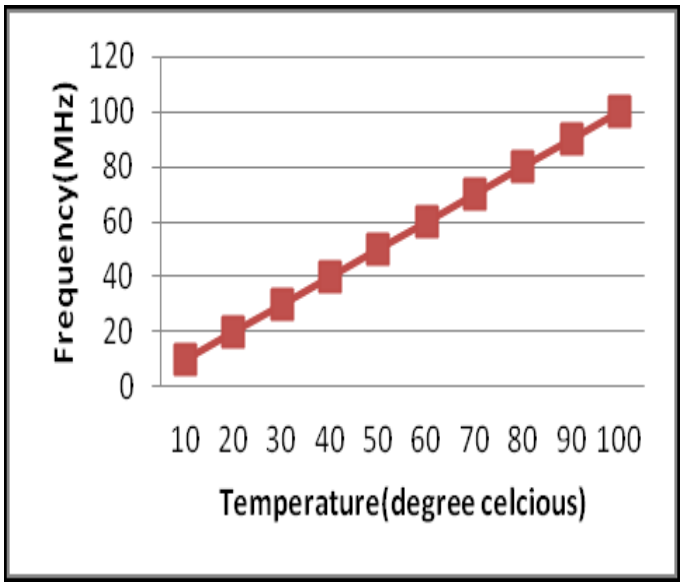

Figure 3 Température of (RO) ring oscillator showing frequency of oscillation linear to temperature.

this research which is done by [14] and the presentation of the results in ghraph form of integrated thermal sensors to monitor the temperature between 10 C to 100 C, according to our simulation under the tool COMSOL Fig. 3 and the study which is done by [12], we can deduce that temperature 77 ° C has our complex module corresponds to approximately 78 MHz (see Fig. 3). This perfectly corresponds to our simulation which is made for the ring oscillator with 5 inverters.

Now we need to validate these theoretical findings find by implementing a 5-inverter based sensor on an FPGA board that allows for different simulations, in [2] explains that more information can be found on the location of the thermal peak at the same frequency and the same temperature of the ring oscillators knowing that this type of ring oscillator sensor can only determine the necessary information if it receives sinusoidal signals, therefore a sinusoidal signal as an input.

3. Experimental implementation and results

The main purpose of this section is the implementation and validation of a single ring oscillator composed of five inverters. VHDL code is used to describe the RO module to facilitate the development of its architecture for its implementation in complex system design. This architecture is modeled in high-level language and simulated to assess its performance and finally implemented on FPGA. The simulation results are validated by using the software Modelsim under Quartus Prime, which allows simulating the behavior of the system in time. Our design flow will be divided into three main parts: simulation, synthesis, and implementation of the VHDL code on FPGA. A description of each part will be presented in the next paragraphs.

3.1. Creation and simulation of the VHDL code

This part, presents the description of the single ring oscillator based of five inverters using a VHDL code editor. The code editor used is Modelsim. Figure 4 shows the top-level module of a single ring oscillator.

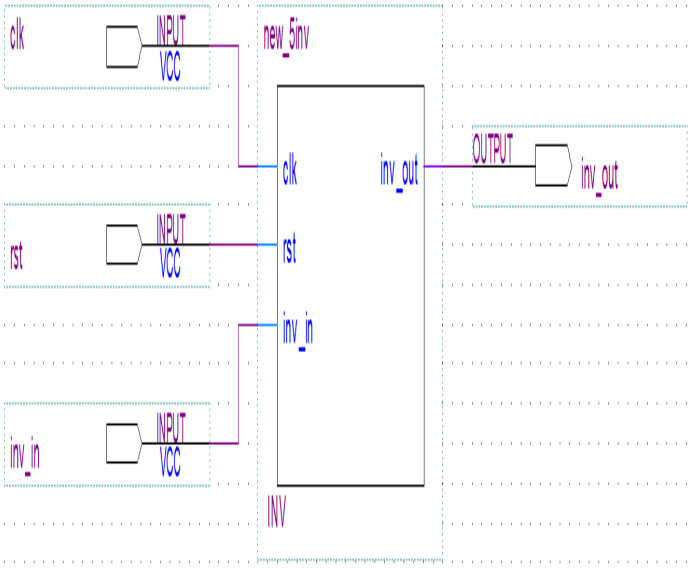

Figure 4 Top level of the ring oscillator composed of five inverters.

This structure in Figure 4 shows the top level of the ring oscillator composed of five inverters, this facilitates the simulation of the logic circuits thereafter. After having followed it, the modelization of a logic scheme of a ring oscillator based on five inverters with Quartus Prime and comes as the next step then the simulation step using ModelSim.

After generating the two .vhd files (the primary file system and the "Test Bench" file) with the "System Generator" the role of the Quartus Prime Navigator comes in order to synthesize the design and generate the RTL files as shown in Figure 5.

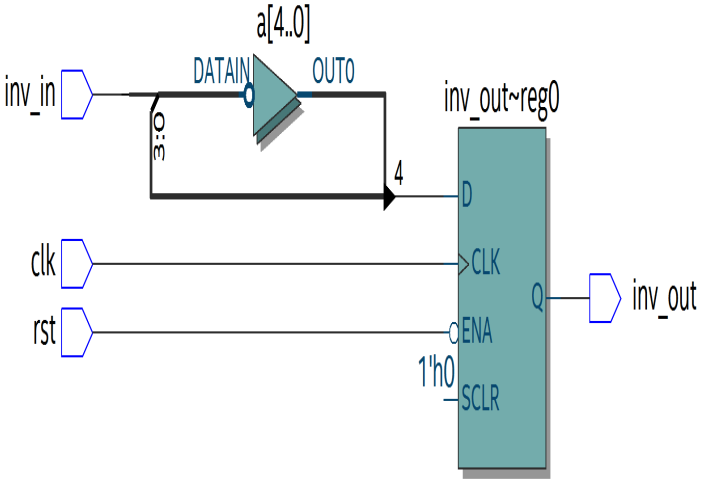

Figure 5 Structure of ring oscillator based five inverters in Quartus Prime tool.

The structure of the single ring oscillator based of five inverters, after synthesis with Quartus Prime from Altera is shown in (Figure

5). The VHDL code implemented was validated. In this part the simulation will be run with the same conditions used in [11], [12] and [14], to validate the experimental results. This Figure 6 shows the results found by the simulation using the Modelsim tool.

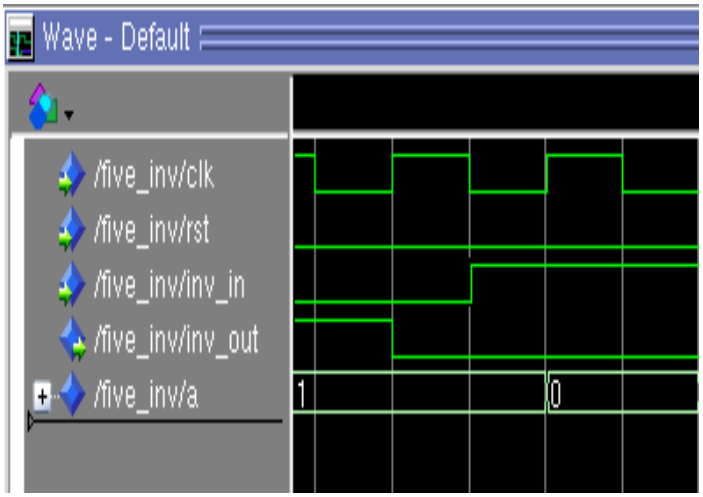

Figure 6 Display résulte of simulation the VHDL code.

As you can see in Figure 6, the signals of simulations are explaining the role of inverters for example for the logical value zero the output is the logical value 1 and the same thing for the second case. The results found validate the VHDL code since it is the correct operation of a single ring oscillator based on five inverters. In this paper, the GDS (gradient Direction Sensor) method for thermal peak detection is used, simulated and verified with a VHDL code and a 'test bench' at the laboratory LIMA the results found meet the initial specifications.

3.2. Implementation and downloading of the VHDL code

Once compiled after the assignment of the pins, the program is ready to be downloaded on the card DE1 cyclone V family and 5CSEMA5F31C6 as a device. This Figure 7 shows that the VHDL code is downloaded successfully on the card.

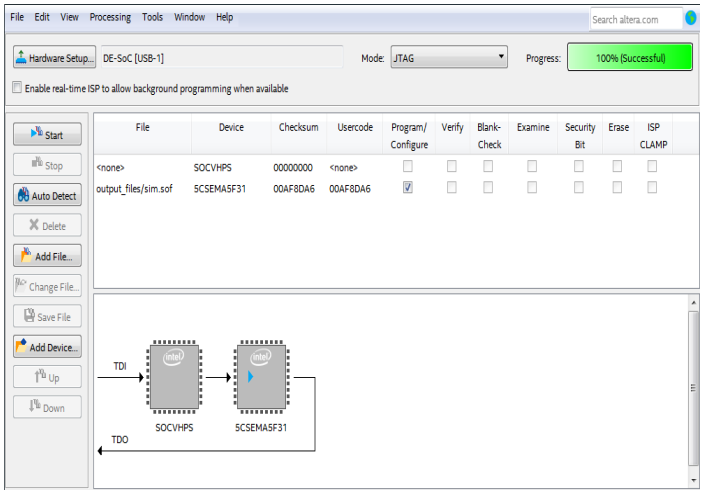

Figure 7 Downloading the code of DE1 Altera cyclone V.

After the download, the program was running and then the outputs were shown on the display of the card. The clock is at 50 MHz, so the outputs should change with a frequency of 50 MHz and the following Figure 8 shows the two values (1 and 0) after implementation on the LCD.

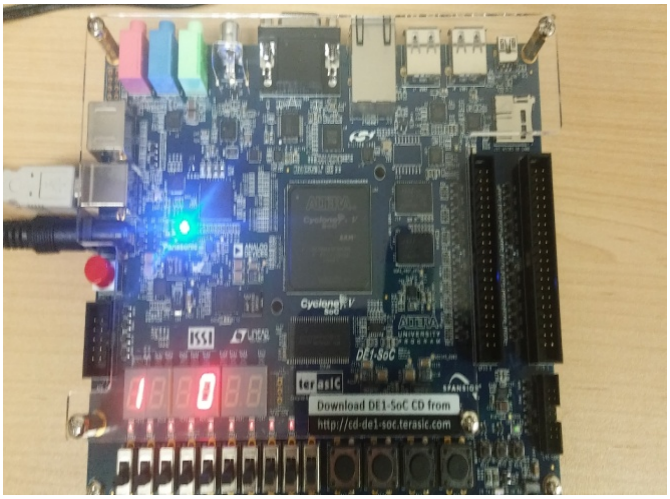

Figure 8 Validation of simulation results on the LCD after the implementation of DE1 Altera cyclone V.

This validation of the simulation results in Figure 8 shows that the value displayed on the LCD matches the results found before. The simulation and implementation on FPGA board DE1 can be applied in any kind of environment to get improved performance to control temperature of complex system design on a chip based of five inverters that will form a single ring oscillator with respect to the conventional schematic; it is also able to keep the temperature constant at the desired value regardless of changes in the load or environment. Thus, the overshooting problem can be solved up to great extent. One of the important issues in the field of electronics is overheating problems especially when it comes to integrated and complex systems and microsystems, but the mean question is how to perform thermal monitoring, to indicate overheating situations, without control.

This type of sensors all over the chip, and then their output can be shown simultaneously and be compared to the reference voltage recognized as the level of overheating. The idea of the proposed method is to validate the results predict the local temperature and gradient along the given distance in some places only on the monitored surface and evaluates obtained several real-time information in a short area in order to predict the temperature of the heat source. These peaks found are essential when monitoring the thermal matrix to avoid a critical induced thermo-mechanical stress. In addition, in most cases, overheating occurs in only one location.

4. Conclusion

The main objective of this paper is to simulate and implement a temperature sensor based on ring oscillator to make a thermal study at the junction. For this paper, we presented an experimental study for the implementation of a fully digital temperature to be dynamically inserted, operated and removed from the circuit after the test. Thus, the main advantage of this type of sensor is the analysis of the temperature during operation of the different blocks of a complex circuit implemented on FPGA. This will be useful for the integrated circuit designer because it offers a solution to thermally induced stress and local overheating in complex system

design which has been a major concern for the designers during the design of integrated circuits.

ABSTRACT

This article proposes a new MAC scheme for Vehicle-to-Infrastructure (V2I) communications that dynamically reallocates unused TDMA slots. By maintaining a balanced waiting time, the proposed TDMA based scheduling scheme allocates TDMA slots in a rational way to minimize merging and one-hop neighboring collision. The proposed scheme ensures dynamic reallocation of unused slots by using "time slot reassignment" mechanism. The scheme has been simulated in VEINS framework of OMNET++ network simulator and its performance has been compared with other conventional protocols. Experimental results show that our scheme performs better than existing schemes in terms of successfully transmitted data packets.

1. Introduction

In recent years, Vehicular Ad-hoc Networks (VANETs) technology has drawn interest of many researchers as a common platform for inter vehicle communication on highways or in urban environments [1-5]. As a special type of Mobile Ad-hoc Network (MANET), VANET provides communications among vehicles and between vehicle, and infrastructure via Road Side Units (RSUs). The relevance of VANET has been confirmed by the development of a specific IEEE standard, 802.11p, to support VANETs [2].

Different from other ad-hoc networks, VANET has unique characteristics of high node mobility, dynamic topology changes and strict delay constraints. The applications devised for VANETs can be divided into the following three services: safety services, traffic management and user-oriented services. Among these services, safety services usually require bounded transmission delays as well as low access delays. As the IEEE 802.11p standard does not provide a reliable broadcast mechanism with bounded communication delay [2, 6], it is not sufficient for VANET applications which are primarily envisioned to improve road safety.

As opposed to IEEE 802.11p, Time Division Multiple Access (TDMA) is inherently a collision free scheme with bounded access delay. Several protocols have been proposed in VANETs using TDMA to provide fairness and to reduce interference among vehicles. By concatenating or rescheduling time slots based on access priority, TDMA based schemes can also assign bandwidth resources to different vehicles on-demand. However, for TDMA based Medium Access Control (MAC) protocol, an efficient slot management is very crucial to ensure fairness as well as reusability of unused slots. VANETs, which have very dynamic topology, are very much prone to allocating a time slot in overlapping areas. In this case, two types of collision may occur: access collision between vehicles trying to access the same available time slots, and merging collisions between vehicles using the same time slots. Some researchers worked on collision issues and some worked on fairness; however, a comprehensive protocol to ensure fairness and reallocation of unused slots is still missing.

In this work, we propose a new TDMA based MAC scheme, Dynamic Reallocation based Window Access MAC (DRWA-MAC), to achieve fair slot allocation as well as reallocation of unused slots dynamically. Our scheme allocates time slots to the registered vehicles evenly; then it monitors the usage of the assigned slots to ensure the dynamic reallocation of unused slots in a fair way. Simulation results in OMNET++ show that our proposed scheme outperforms several existing schemes. This work

is an extension of our previous work originally presented and published in ECCE conference [1].

2. Related Work

VeMAC [7, 8] is a TDMA based scheme proposed for inter-vehicle communication in which vehicles in opposite directions (Left, Right) and roadside units (RSUs) are assigned with time slots in the same TDMA time frame by using logical segmentation. Though VeMAC can make use of the seven DSRC channels and decrease the rates of merging, and access collisions, it is burdened with the overhead of the size of the transmission control frame and cannot ensure reusability of an unused slot.

In ACFM [9], each RSU maintains a dynamic slot assignment cycle for vehicles in its coverage adaptively. Under the scenario of light traffic, ACFM controls the excessive increase of unassigned slots by shrinking slots assignment cycle frame by frame. When there is a mass of vehicles on roads, ACFM provides more available slots by expanding cycle. However, to avoid interference between adjacent segments, ACFM requires two orthogonal frequencies to ensure that the same frequency is not used for a distance of two hops.

TC-MAC [6] is a TDMA Cluster-based MAC protocol for VANET. It subdivides slots of control channel (CCH) into mini-slots to broadcast beacons or safety messages. Here, in each frame, each vehicle gets allocation on a time slot in service channel (SCH) and competes for a mini-slot on the CCH. A vehicle uses its mini-slot to inform the other vehicles of its transmission during time slot on the SCH. Cluster members can use their time slots on the service channels to exchange non-safety data in unicast or multicast communication mode. TC-MAC protocol was designed for simple highway traffic in which all the vehicles are moving in the same direction and it has high collision in bidirectional traffic and in urban scenarios due to the merging collision problem. TC-MAC also suffers from inter-cluster interference problem when two or more clusters are in close proximity.

PTMAC [10] is a prediction-based TDMA MAC protocol that predicts encounter collisions and effectively reduces the number of collisions while maintaining high slot utilization. Here, immediate vehicles within a two-hop neighborhood detects a potential collision if two vehicles occupies the same slot and the protocol removes the collision by asking one of them to change its current slot. As PTMAC makes TDMA slot assignment on a contention based approach, it is unable to ensure fairness.

FAWAC-MAC [1] is a TDMA based scheme that uses capture effect to send extra data in free or unused slots. Here, all vehicles, which are not the owner of the current slot, check whether its own slot is within a predefined window size. If not, they transmit their packets in low power while the original owner of the slot transmits packets in high power. Using capture effect, the RSU can distinguish the power levels. In the presence of a high power packet, all low power packets get discarded; while in the absence, low power transmission succeeds. When vehicle density is very high, FAWAC-MAC has a chance of low power packet collision in free slots and if the coverage area is large, then it may also be suffered by near-far effect.

FAWAT-MAC [1] uses time slot reassignment mechanism to transmit data in unused slots. Here, if an RSU detects no ongoing transmission within one fourth of the beginning time of a slot, it selects the slot as unused and invites another vehicle to transmit data in that slot. Upon reception of the invitation packet, the specific vehicle transmits data for the remaining time of the slot in a collision free manner. The slot allocation process of FAWAT-MAC can cause merging and one-hop neighboring collision for boundary vehicles. In this protocol, the waiting time for some of the high speed boundary vehicles can be so high that by the time they got their assigned slot, they may have left the corresponding RSU.

3. Proposed System

In this work, we propose Dynamic Reallocation based Window Access MAC (DRWA-MAC), an extension of the FAWAT-MAC protocol [1]. Our proposed protocol operates as a TDMA based MAC protocol in a centralized topology where RSUs control distribution and reallocation of slots.

3.1. Assumptions

We made the following assumptions regarding VANET's context in which DRWA-MAC operates:

- Each vehicle and RSU has a unique ID.
- Vehicles and RSUs are equipped with GPS and are perfectly time synchronized.
- At the beginning of each frame, the RSU transmits registration beacon and then, each vehicle, which receives that message, broadcasts a registration response message with its own ID, location and data size. For a certain amount of time, the whole registration response system is a contention based process.
- Each newly joined vehicle that does not have a slot and wants to get a new slot shall listen to the channel for one frame. Then, after receiving the registration beacon, they can register to the RSU.

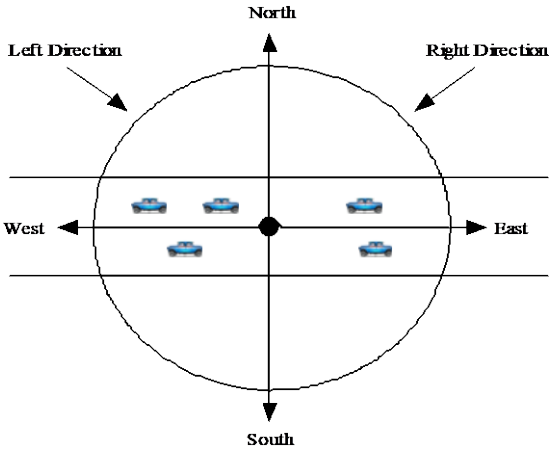

Figure 1: Right and left direction of vehicle movement as defined in the protocol

3.2. System Design

In our proposed DRWA-MAC protocol, we consider RSU based centralized VANET with a set of vehicles moving in lanes consisting of two-way traffic. In a two-way traffic system, we

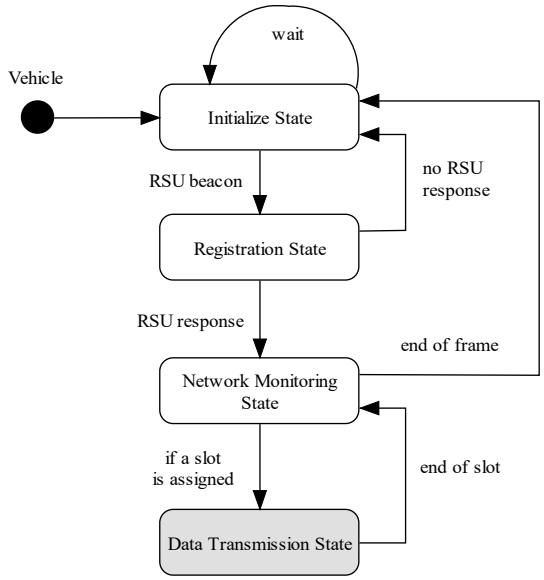

Figure 2: Vehicle state diagram in our scheme where a vehicle can be in one of the four states: initialize, registration, network monitoring, and data transmission

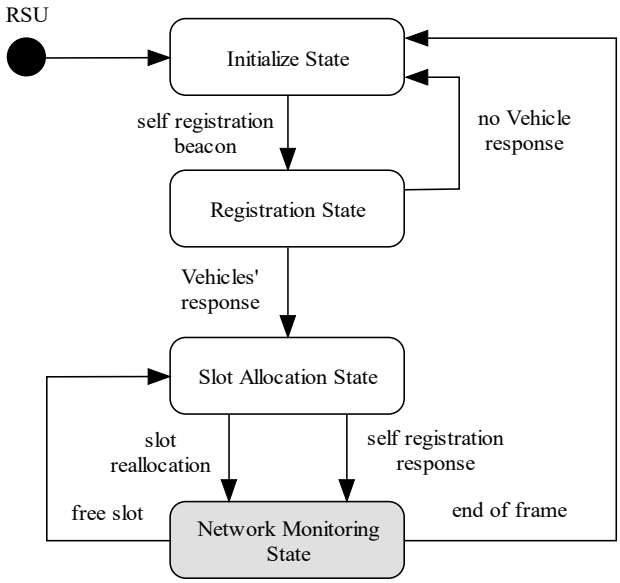

Figure 3: RSU state diagram in our scheme where the RSU can be in one of the four states: initialize, registration, slot allocation, and network monitoring

define a vehicle as positioned in left direction of a RSU's broadcasting area if it is placed in the west half and right direction, if it is placed in the east half, as shown in Figure 1.

Our scheme consists of three processes: (i) a contention based registration process, (ii) a fair slot distribution process and finally, (iii) a network monitoring process for reallocating unused slots. Considering the effect of these processes, the states of a vehicle and RSU in our proposed scheme is depicted in Figure 2 and Figure 3 respectively.

As shown in Figure 2, upon reception of RSU's registration beacon, a vehicle moves into the *registration state* from its *initialize state* and sends back a registration response. Then, after receiving RSU's response, the vehicle moves into the *network monitoring state*; once a slot is assigned, the vehicle moves to the *data transmission state* where it transmits data in the slot assigned to it. At the end of the slot, the vehicle moves back to the *network monitoring state* and waits for additional slots from the RSU. When data transmission is complete, the vehicle moves back to the *initialize state*.

As shown in Figure 3, after transmitting registration beacon, an RSU enters into the *registration state* where it receives response from vehicles for a short amount of time. After receiving registration response(s) from the vehicles, the RSU enters into the *slot allocation state* where it allocates available slot to the vehicles; then, it transmits a registration response message and moves to the *network monitoring state* where the RSU monitors network for free slots. If any free slot is detected, the RSU moves back to the *slot allocation* state; otherwise, it moves to the *initialize* state at the end of the TDMA frame.

4. Details of the DRWA-MAC Protocol

DRWA-MAC consists of three processes: (i) a contention based registration process, (ii) a fair slot distribution process, and (iii) a network monitoring process. In this section, we discuss the details of these processes and also, present our slot distribution algorithm.

4.1. Registration Process

At the beginning of the TDMA frame, RSU transmits a registration beacon for all the vehicles in its broadcasting area. Upon reception of the registration beacon, each vehicle sends back a registration response message to the RSU using a contention based approach. To accommodate the vehicles response, this contention based procedure continues for a certain predefined amount of time. Within registration response message, vehicles send back their ID, location and data size.

4.2. Slot Distribution Process

After registration process, RSU's usually have N number of participating vehicles that need to be assigned with S number of slots. As the registration response from each vehicle consists of location information, RSU can differentiate the L number of vehicles on its left and the remaining (N-L) number of vehicles on its right direction in a road with two-way traffic. Our protocol divides the available S slots into $S/2$ ODD, and S/2 EVEN sets. Then, the $S/2$ ODD slots are distributed among the L left directional vehicles and S/2 EVEN slots to (N-L) right directional vehicles. Our protocol uses a repeated round robin approach for channel assignment. In case the number of vehicles is less than the number of slots, i.e., S>N, one or more vehicle may get multiple slots in the same frame. An example is shown in Figure 4 where there are 8 slots in a frame with two left direction vehicles (*V[1]*, *V[3]*), and two right direction vehicle (*V[2]*, *V[4]*); a repeated round robin distribution will allocate slot 1, and 5 to *V[1]*, slot 2, and 6 to *V[2]*, slot 3, and 7 to *V[3]* and slot 4, and 8 to *V[4]*. On the other hand, if $L < S/2$ and $(N–L) > S/2$, one or more left directional vehicles will get multiple slots but $(N–L–S/2)$ right

Slot Numbers

1	2	3	4	5	6	7	8
V[1]	*V[2]*	*V[3]*	*V[4]*	*V[1]*	*V[2]*	*V[3]*	*V[4]*

Figure 4: Example of slot allocation in our proposed scheme using repeated round robin distribution where the index represents vehicle ID. In this example, there are 4 vehicles where each vehicle received 2 slots each

directional vehicles will not get any slot allocation. Our slot distribution algorithm is shown in Algorithm 1.

Algorithm 1: TDMA Slot Distribution

```
1:  foreach available slot s in frame f
2:      calculate even slot es and odd slot os
3:  foreach registered vehicle v
4:      If vehicle v is right directional and es>0
5:          assign an  even slot es to vehicle v
6:          es = es - 1;
7:      else if os>0
8:          assign an odd slot os to vehicle v
9:          os = os – 1;
10: s = s – v;
```

4.3. Transmission Monitoring Process

After slot assignment, vehicles usually begin transmission in their assigned slots. Even though all the vehicles register for TDMA slot, some of them may not use all of their assigned slot(s); this could be due to early completion of data transmission, passing over RSU's broadcasting area, detection of the safety message that is already broadcasted, etc. To avoid wastage, for each slot, our protocol employs a monitoring process at the RSU end to check whether an existing transmission is going on or not; if not, then it ensures reallocation. Here, an RSU detects transmission status by monitoring the first one fourth of the beginning time of a slot; if no data is transmitted during this period, the RSU mask the slot as a free and broadcasts a very light NULL packet similar to a becon signal. Inside the NULL packet, RSU sends the ID of the vehicle having maximum data size; this is possible because at the beginning of the frame, each vehicle registers with its data size. Upon reception of the NULL packet, the specific vehicle transmits data for the remaining time of the slot and hence, reallocation of unused slots is achieved in a collision free manner.

Figure 5 shows operation of the proposed DRWA-MAC in detail. Here, *V[1]*, and *V[3]* are left directional vehicles and *V[2]*, *V[4]* are right directional vehicles. *V[1]*, *V[2], V[3], and V[4]* have 24MB, 22MB, 4MB, and 4MB of data to transmit respectively. These vehicles V[1], V[2], V[3], V[4] are assigned with slots (*1*,*5*), (*3*,*7*) and (*2*,*6*), (*4*,*8*) respectively by our slot allocation algorithm. Considering max data size of each slot as *4* MB, at slot *7*, RSU will detect that there is no ongoing transmission in channel as *V[3]* has no data left to send and therefore, will select

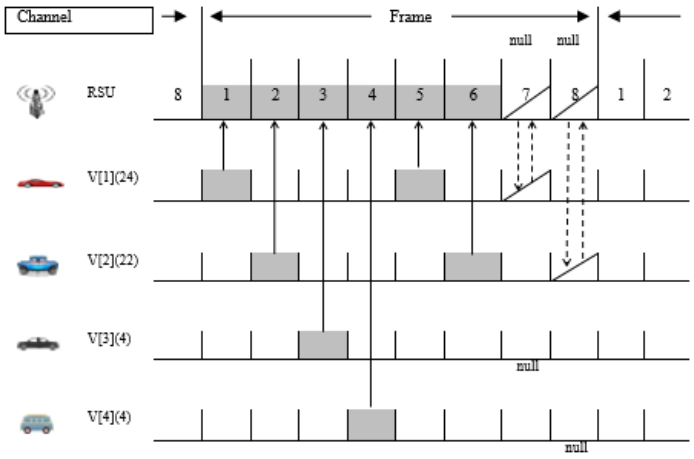

Figure 5: Operation of proposed DRWA-MAC with four vehicles and 8 slots in each frame where 4MB of data can be transmitted in each slot. Initial slot assignment is as shown in Figure 4

V[1] as it has *16* MB data remaining for transmission (out of 24 MB, V[1] has transmitted 8 MB in slot 1 and 5). So, *V[1]* will be able to send 3 MB of data in the remaining 3/4 of the slot and will have 13 MB data left for transmission. At slot *8,* RSU again will detect that there is no ongoing transmission in the channel as *V[4]* has no data left to transmit and will select *V[2]* as it has 14 MB data remaining while *V[1]* has 13 MB of data remaining to transmit.

5. Effectiveness

In our protocol, the use of "time slot reassignment" technique makes use of most of the wasted slots and hence, increases overall throughput of the TDMA network. As our protocol works in RSU based centralized topology, it is free of access collision. Since the proposed protocol uses RSU's guidance based "time slot reassignment" technique where a single vehicle is selected by RSU to send message in free slots, it is also free from hidden node collision.

Instead of straight forward segmentation like VeMAC, our protocol divides and allocates slots in ODD-EVEN basis and it balances waiting time of the partitioned vehicles. This distribution process also avoids or minimizes merging collision and one-hop neighboring collision. To support our argument, an example scenario is depicted in Figure 6. In this scenario, there are 2 RSUs, RSU[0], and RSU[1]. We show that vehicle *V[4]*, *V[6]* of *RSU[0]* and *V[5]*, *V[7]* of *RSU[1]* are one hop neighboring collision free as *RSU[0]* assigns EVEN slots to *V[4]*, and *V[6]* and on the other hand, *RSU[1]* assigns ODD slots to the vehicles *v[5],* and *v[7]*. Additionally, if we consider the position of vehicle *V[5]* of *RSU[1]* and *V[1]* of *RSU[0],* we can claim that our protocol also minimizes merging collision because both *V[5]* and *V[1]* are placed in left/west half of their respective RSU and each is assigned with ODD slots. By the time *V[5]* enters into the coverage area of *RSU[0]*, *V[1]* may leave and the slot freed by *V[1]* can be reassigned to *V[5]* so that *V[5]* can transmit data in the running frame.

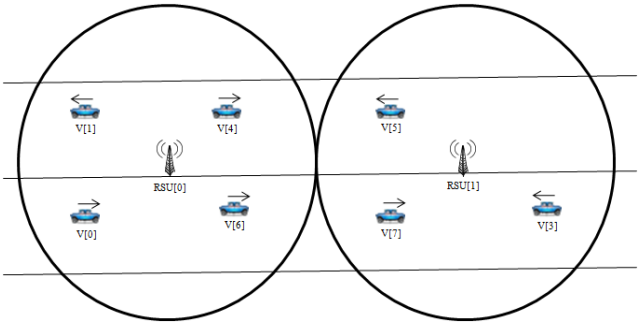

Figure 6: Example scenario of proposed DRWA-MAC protocol which depicts that the protocol is free from one-hop neighboring collision and merging collision

6. Simulation Results and Analysis

In our simulation experiments, we have compared the performance of our proposed DRWA-MAC protocol with ACFM, VeMAC, PTMAC, FAWAC-MAC and FAWAT-MAC in terms of number of successfully transmitted data packet, average delay, and data loss ratio on overall road traffic network.

6.1. Simulation Environment

We have implemented DRWA-MAC protocol on the VEINS [11] framework of OMNET++ [12] network simulator. The vehicle movement and related realistic road traffic scenario is generated using SUMO [13] urban mobility traffic generator.

In our scenarios, we considered a 2000m×1000m rectangular two way road traffic network with ten junctions as shown in Figure7, where each junction contains three lanes. We have covered our road network segment with three non-overlapping RSUs as shown in Figure 8.

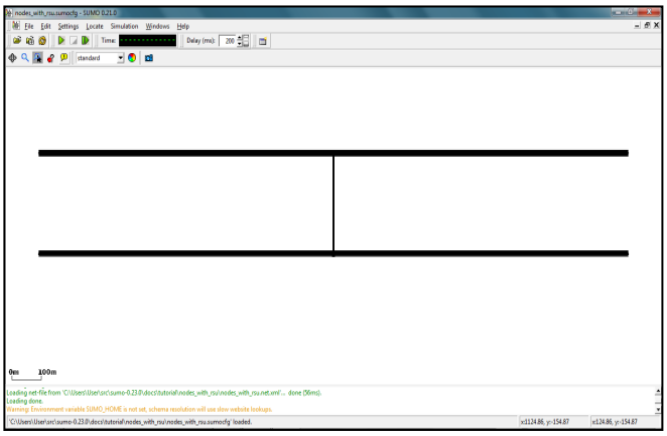

Figure 7: 2000m×1000m rectangular traffic network with ten junctions and 3×3 lane road in SUMO

Figure8: OMNET++ view of the road network with RSUs

Table 1: Simulation Parameters

Parameter	Value
Number of lanes	3+3
Number of scenario	5
Number of vehicles	22, 41, 61, 83 and 102
TxPower	20mW
TxDatasize	10Mbps
Number of slots per frame	256
Slot time	50ms
Registration time	2s
Simulation time	2 frames, on 258s to 288s

For comparison, we have devised five scenarios with 22, 41, 61, 83, and 102 vehicles and measured the performance of the mentioned protocols in cases where 10%, 15% and 20% of the registered vehicles were not using their assigned slots. Configuration of the simulation is listed in Table 1.

6.2. Simulation Result

In this section, we show performance comparison of DRWA-MAC with the aforementioned protocols.

Figure 9 shows performance comparison in terms of successfully transmitted data packets when 10% of the vehicles are not using their assigned slots. As shown in Figure 9, initially at light traffic, only FAWAC-MAC performed better than DRWA-MAC. However, the performance of FAWAC-MAC gradually decreased with the increase of traffic. In high traffic scenarios, the performance of VeMAC, ACFM, PTMAC and FAWAT-MAC degraded noticeably. This is because these protocols suffer from merging collision and one-hop neighboring collision. On the other hand, DRWA-MAC minimized these collisions and outperformed all the other schemes when network density is higher.

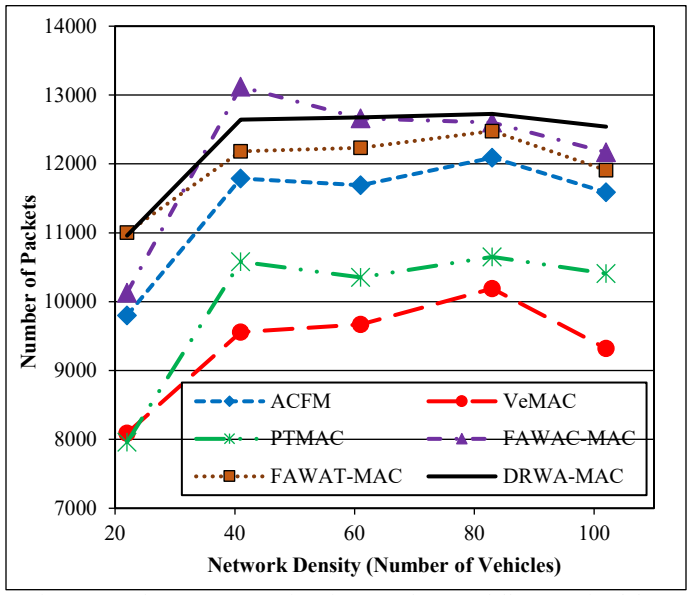

Figure 9: Performance comparison in term of successfully transmitted data packets when 10% of the vehicles are not using their assigned slots

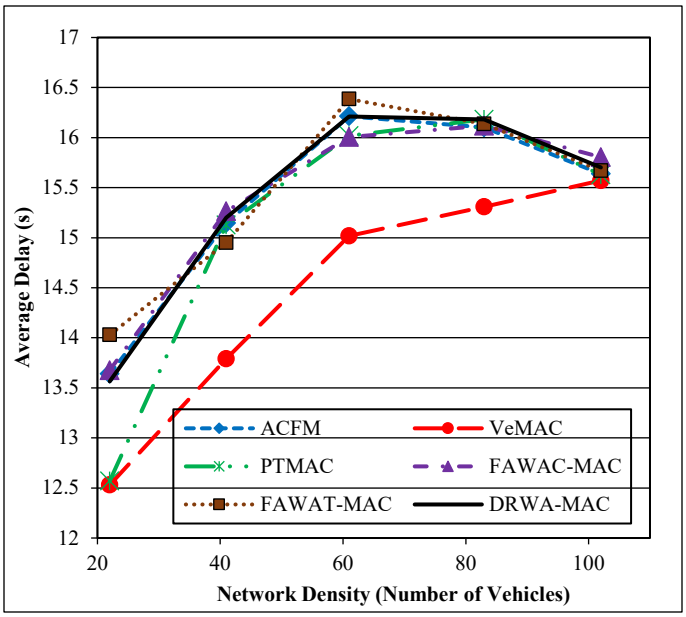

Figure10: Performance comparison in terms of average delay when 10% of the vehicles are not using their assigned slots

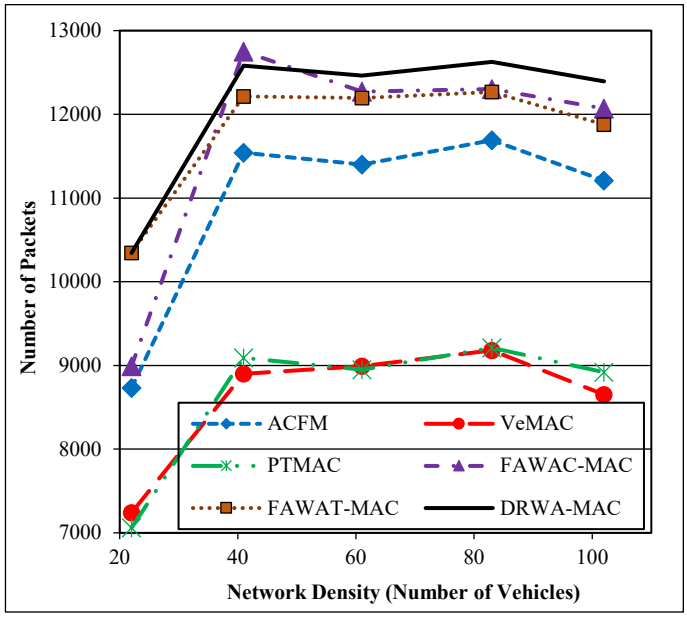

Figure 12: Performance comparison in terms of successfully transmitted data packets when 15% of the vehicles are not using their assigned slots

Figure 10 shows performance comparison in terms of average delay when 10% of the vehicles are not using their assigned slots. Though for a single channel, the overall throughput of VeMAC is not optimum, it has the most favorable average delay. On the other hand, our proposed DRWA-MAC performed better by maintaining almost the same average delay as ACFM, PTMAC, FAWAC-MAC and FAWAT-MAC.

Figure 11 shows performance comparison in terms of data loss ratio where 10% of the registered vehicles are not transmitting data in the assigned slots. Because of inherent huge low power transmission, as shown in Figure 11, FAWAC-MAC is having high data loss, though those low power packets were bearing opportunistic data. VeMAC has the lowest data loss ratio while DRWA-MAC has similar data loss ratio compared to other protocols.

In Figure 12 and 13, we show performance comparisons in terms of successfully transmitted data packets for cases where 15% and 20% of the registered vehicles are not transmitting data in their assigned slots respectively. With the increase of free slots, the performance of VeMAC, ACFM and PTMAC decreased as these protocols do not have any process to ensure reusability of slots. However, as FAWAC-MAC, FAWAT-MAC and DRWA-MAC

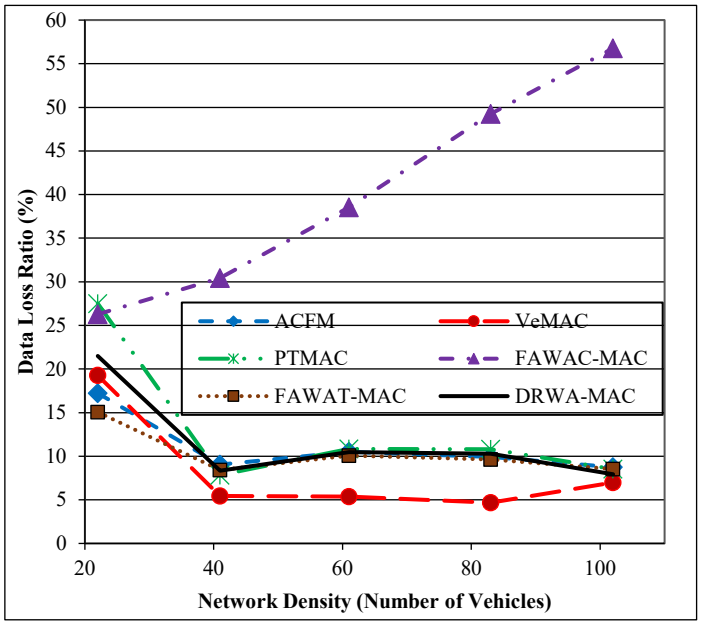

Figure11: Performance comparison in terms of data loss ratio when 10% of the vehicles are not using the slots assigned to them

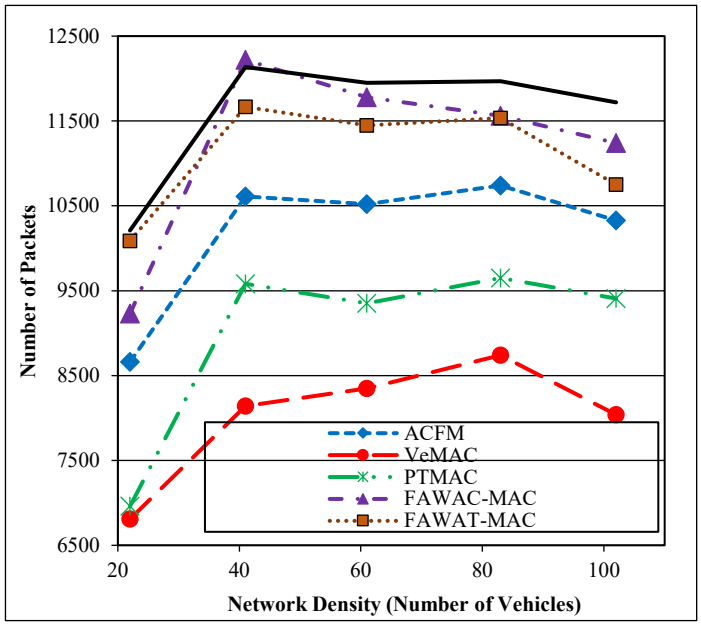

Figure 13: Performance comparison in terms of successfully transmitted data packets when 20% of the vehicles are not using their assigned slots

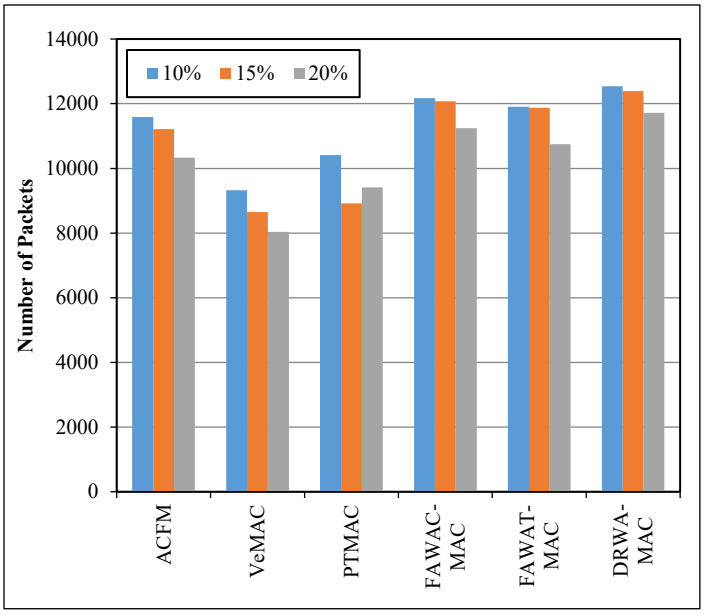

Figure 14: Bar diagram of successfully transmitted data packets by grouping scenarios where 10%, 15% and 20% of the vehicles are not using their assigned slots

can unsure reusability of free slots, their performance were not affected significantly. From Figure 9, 12 and 13, we can conclude that though FAWAT-MAC and DRWA-MAC improves the amount of successful data transmission by ensuring reallocation of free slots even though one fourth of the data capacity of those free slots degraded due to the detection delay of the RSU.

Figure 14 shows a bar diagram of successfully transmitted data packets for 102 cars in the network by grouping scenarios where 10%, 15% and 20% of the vehicles are not using their assigned slots. This diagram is also shows that with the increase of free slots, the performance of VeMAC, ACFM and PTMAC decreased, but the performance of FAWAC-MAC, FAWAT-MAC and DRWA-MAC were not affected significantly. As shown in the figure, DRWA-MAC outperforms all other schemes in terms of successfully transmitted data packet in all the experimental scenarios.

7. Conclusion

This article proposes a dynamic reallocation based window access scheme, DRWA-MAC, for centralized TDMA based VANETs. The proposed scheme maintains a balanced waiting time for vehicles by dividing TDMA slots into ODD slots and EVEN slots and then, by evenly distributing all TDMA slots among the registered vehicles in a rational way. Our slot allocation algorithm ensures fairness in slot allocation among the vehicles as well as reduces merging collision and one-hop neighboring collision. By dynamically monitoring and reallocating unused slots using “time slot reassignment” mechanism, the proposed DRWA-MAC achieved significantly higher throughput compared to other conventional TDMA based centralized protocols. Simulation results show the effectiveness of the proposed protocol in terms of successfully transmitted data packets, average delay and data loss ratio on overall road traffic network in different scenarios.

ABSTRACT

In the current industrial development, an increasing number of sensors is applied for monitoring of any kind of appliances and machines. A predictive mathematical model allows for realistic assessment of the health state of the appliance, indication of service requirements, as well as control of the appliance, serving as so-called digital twin on a control device.

Completely analogous modeling can be used for virtual testing, i.e. a (partial) substitution of physical experiments. The software-in-the-loop model provides realistic feedback to the physical specimen on the test rig and helps to increase the representativeness of the experiment and to reduce costs.

In a joint research project partially sponsored by the German Federal Ministry of Economics and Energy, the authors developed an approach for meta-modeling of dynamic systems. While the modeling process is fed by results from sophisticated simulations, or even test results as input data, the resulting model can be used for fast stochastic analyses as well as software-in-the-loop in dynamic real-time experiments. The approach was verified on tests of an aircraft high lift system.

1 Motivation and Objective

The prediction of test results is especially important for very expensive tests like in aerospace industrial applications, e.g. testing of high lift systems. As a matter of costs and manageability, the test specimen usually represents only a partial system. A realistic feedback of reactions from the remaining system by software driven actuators increases the representativeness of test results. Sophisticated procedures for realistic modeling of physical systems, e.g. algorithms for multi-body dynamics simulation, are available, but they require significant computation time and lack the ability of real-time performance. Therefore, there is a need to reduce computational cost maintaining high fidelity modeling.

Purely mathematical models can be established which are fast to compute, yet maintain accurate results. The authors' approach, which has been presented initially in [1], yields meta-models that approximate the dynamic response of the tested object. Models are built on the basis of physical simulations that represent the test results accurately, but require a computation time that would be prohibitive as for the applications indicated above. The results of real experiments can be used as input data as well. The proposed meta-models, having short response times, enable fast robustness analysis to assess the influences of uncertain parameters such as damping or friction and can be used as software-in-the-loop even in real-time dynamic experiments [2, 3], where often fast but simplified physics-based models are applied [4]. The requirements for development of the methodology, which will be presented in the following sections, are summarized as: speed in performance, flexibility to change of parameters, versatility and accuracy.

The combination of physical testing and virtual testing serves several purposes: evaluation of the test rig without risk of damage; substitution of parts of the tested system —or augmentation of the existing test—; more realistic and more complex tests and reduction of costs.

[*]Veit Bayer; Dynardo, Steubenstr. 25, D-99423 Weimar, Germany; Ph. +493643900847; E-mail veit.bayer@dynardo.de

https://dx.doi.org/10.25046/aj030141

Other applications of this approach can be thought of: fast meta-models can be implemented as digital twin on data acquisition and control devices for online monitoring of a system; in the development of a product, fast but accurate models are important for stochastic analyses such as predictive reliability assessment.

2 Methodology

Basis of the methodology proposed here is Dynardo's algorithm *Metamodel of Optimal Prognosis* (MOP). The procedure fits the best available model to given data points and avoids so-called over-fitting. It first starts a filtering of parameters by statistical criteria. Input parameters with negligible influence on the observed results are canceled from the data set, thus the dimension of the problem can be reduced effectively. Several model approaches, such as polynomials, moving least squares, kriging, are built up and tested by cross validation. The resulting *Coefficient of Prognosis* (CoP) is the complimentary value to the sum of squared residuals over the variation of result data. The CoP gives information, what amount of data variation is explainable by the meta-model, based on independent test data. The MOP result is the chosen model out of the set of available models with the largest CoP. The MOP is also used for sensitivity analysis [5, 6]. Conditional variances are computed by holding systematically one parameter at fixed values, indicating the relative contribution of this parameter to the total variation of the response.

The MOP deals with scalar response quantities only. For the intended application, results are time series, e.g. from a multi-body dynamics simulation. Hence a representation of the time series by scalar values has to be found, while avoiding to adopt the total set of discrete time steps. The approach makes use of a specific topic in probability theory, namely the random fields methodology [7, 8]. A random field is a quantity defined on a spatial domain, where the value at any point of observation is a random variable. Here, the domain is time instead of space. The training data for the model are produced by first sampling input values, either by design of experiments or quasi-random sampling, then computing the results for each input data set. The time-dependent results are then interpreted as random process or 1-D random field.

The key to a parametrization of the random process is the eigenvalue decomposition of the covariance matrix $\mathbf{C}_{XX}$ of the discretized time series $\mathbf{X}$,

$$\mathbf{\Psi}^T \mathbf{C}_{XX} \mathbf{\Psi} = \mathrm{diag}\{\lambda_i\}, \tag{1}$$

wherein $\mathbf{\Psi}$ is the matrix of eigenvectors, and $\mathrm{diag}\{\lambda_i\}$ holds the eigenvalues of the covariance matrix. From this, the so-called *spectral representation* of the random field can be derived [9]. Assuming that X are normal distributed with zero mean values (which can be subtracted for the analysis and added later again for synthesis of time series), new random variables Y are defined as

$$\mathbf{Y} = \mathbf{\Psi}^T \mathbf{X}, \tag{2}$$

which are normal distributed, independent, zero-mean and with a standard deviation given by

$$\sigma_{Y_i} = \sqrt{\lambda_i}. \tag{3}$$

For synthesis of the original time series $\mathbf{X}$, one makes use of the Karhunen–Loève series expansion

$$\mathbf{X} = \mathbf{\Psi} \mathbf{Y}. \tag{4}$$

A typical property of eigenvalue solvers is, that eigenvalues are stored in descending order. Since the eigenvalue of order i defines the amount of variation contributed by parameter Y_i to the total variation of the data, this gives a criterion for truncation of the series expansion and therefore a drastic reduction of the dimension [10, 11].

Summarizing, for generation of a time series $\mathbf{X}$ one needs the modal base $\mathbf{\Psi}$ of the covariance matrix, which we may call the set of "shape functions" in the following, and the respective "amplitudes" Y_i. Figure 1 shall illustrate the series expansion of (4) with an added mean value signal.

The shape functions are an unchangeable property of the data. Properties of the parameters Y_i have to be determined such that, the series expansion optimally represents the physical time series $\mathbf{X}$. For this purpose, MOP is applied to a training data set, from which the corresponding sample of amplitudes is calculated. This leads to the *Field-Metamodel of Optimal Prognosis* (F-MOP). Figure 2 shows the flow of analysis. Using these dynamic meta-models, we obtain a simplified and reduced parametric of the dynamic signal based on a statistical meta-model. The user does not need to find a parametrization himself.

In analogy to the sensitivity analysis of scalar data [5, 6], the Coefficient of Prognosis of the F-MOP can be plotted against the time axis, called F-CoP here. Moreover, sensitivity measures over time can be computed, such that it is possible to assess the model quality and the relative influence of input parameters on the response, locally within the entire observed time range. The procedure is realized by connecting the functionalities of the programs offered by Dynardo, optiSLang and Statistics on Structures (SoS).

3 Application Example: Aircraft High Lift System

The methodology which is described in the previous section is validated by the example of an aircraft high lift system. Instead of real experiments, virtual tests using a detailed model serve for generating the training data. The simulation model in MSC Adams/Flex comprises the inboard flap, outboard flap, transmission and actuators as well as the test rig. With that, model wing position, flap positions, loadings as well as

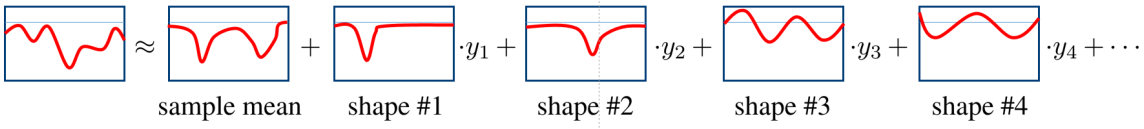

Figure 1: Illustration of Karhunen–Loève series expansion of a signal.

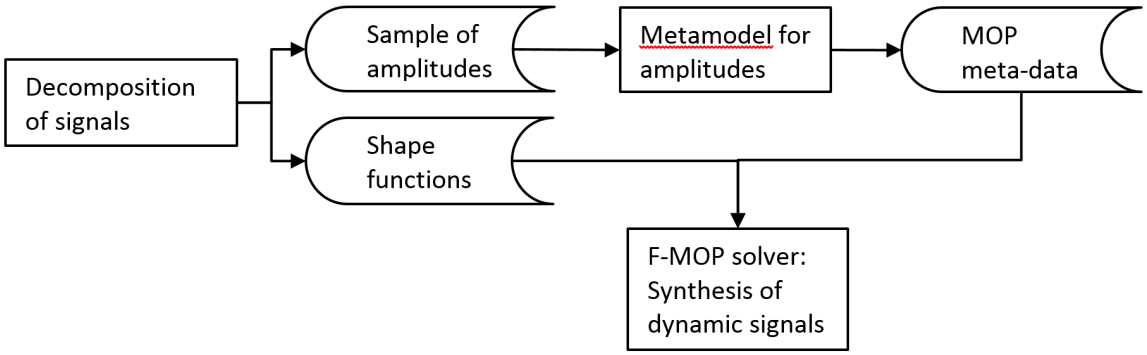

Figure 2: Overview of the approach of decomposing signals and generating meta-models for dynamic signals.

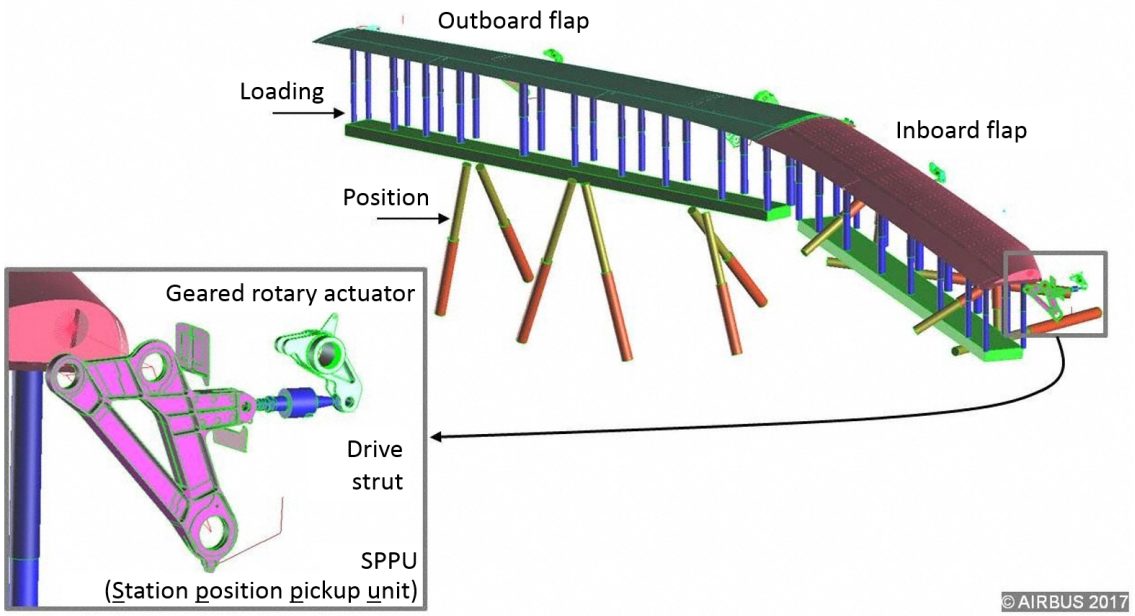

Figure 3: Adams/Flex model of the high lift system on a test rig.

actuator action and backlash can be simulated. Since friction is taken into account in the simulation, the model is actually non-linear. Figure 3 visualizes the tested system.

For the virtual test, wing and flap positions and loadings are given. The test case is a simulated rupture of two actuators simultaneously, one at the inboard flap, one outboard. As uncertain parameters, the stiffness of all actuators, backlash of all actuators, damping and friction parameters are sampled as input to the meta-modeling procedure. 200 parameter sets are simulated using MSC Adams/Flex, yielding signals over time of the dynamic responses. The responses observed are all actuator moments, drive strut forces and angles at the station position pickup units (SPPU). For these responses, dynamic meta-models shall be built.

4 Discussion of Results

Figure 4 –top– shows 4 typical signals picked out of the whole sample, here of the moment at actuator #2. Below, the prediction capability expressed as F-CoP is plotted. It can be observed that, the Coefficient of Prognosis of the model F-CoP [Total] is able to reach nearly 100% at the peaks of the signal, while its value drops where the oscillation passes the stationary value. At such points, scatter in data is rather numerical noise than information and cannot be explained by the meta-model. The relative influences of input parameters can be observed, too (largest: F-CoP[DV_Fric_Mue_PP_dyn] for Coulomb friction parameter).

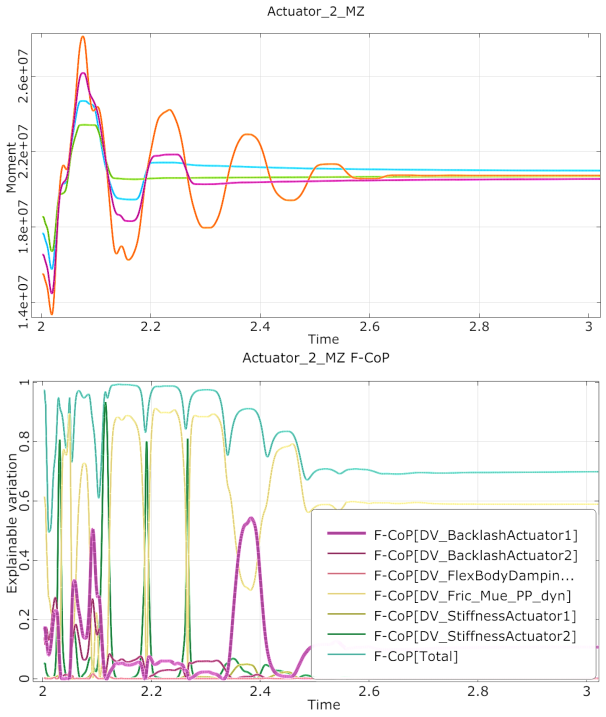

Figure 4: Top—Sample time series of moments at actuator #2. Bottom—Prediction capability of the model for the time dependent signal (F-CoP [Total]) and the impact of each input parameter on the total variation of the signal.

Another signal, the angle at SPPU #2, is examined in the same way, results are displayed in Figure 5. There is a constant shift for each sample. The F-CoP[Total] values are near 100% throughout the entire time range. The model quality is considered excellent by means of the statistical F-CoP criterion.

Finally, the original simulated time series and the series synthesized with help of the field meta-model shall be compared. Again, a few time series are arbitrarily picked from the whole sample. In Figure 6, the signals of the moment at actuator #2 are compared, and Figure 7 shows the comparison for the angles at the station position pickup unit #2. The left plots in both figures are the original simulation results obtained by MSC Adams/Flex, which serve as reference. The right plots are the signals which were synthesized by the field meta-models using the same input parameters as for the original simulations. The coincidence of original signals and meta-model results is excellent, particularly in the peaks. When the signals tend to be damped out, some artificial oscillations in the field meta-model results can be observed. These will vanish if the series expansion (refeq:KLseries) is truncated at a later position, thus more shape functions will be taken into account.

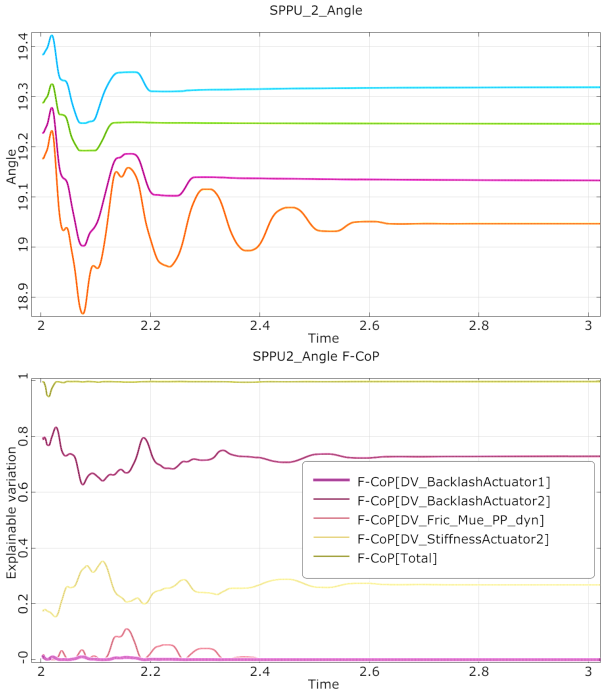

Figure 5: Top—Sample time series of angles at SPPU #2. Bottom—Prediction capability of the model for the time dependent signal (F-CoP [Total]) and the impact of each input parameter on the total variation of the signal.

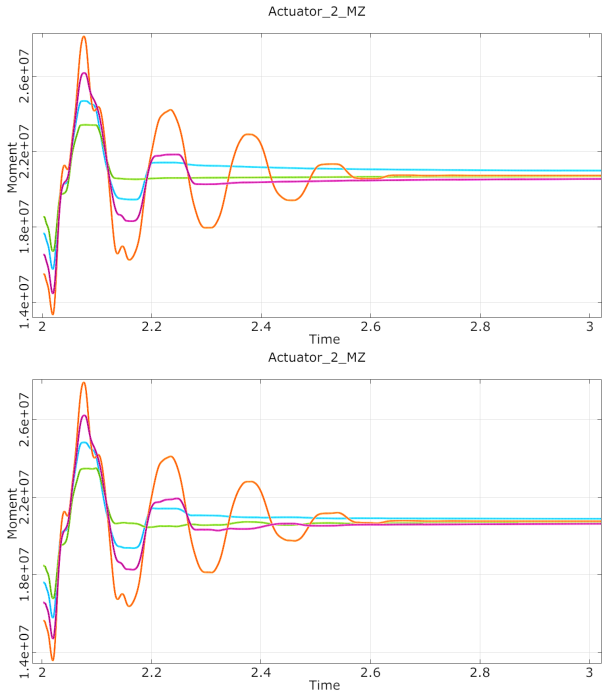

Figure 6: Sample time series of moments at actuator #2. Top—original results obtained from Adams/Flex. Bottom—synthesized signals by F-MOP.

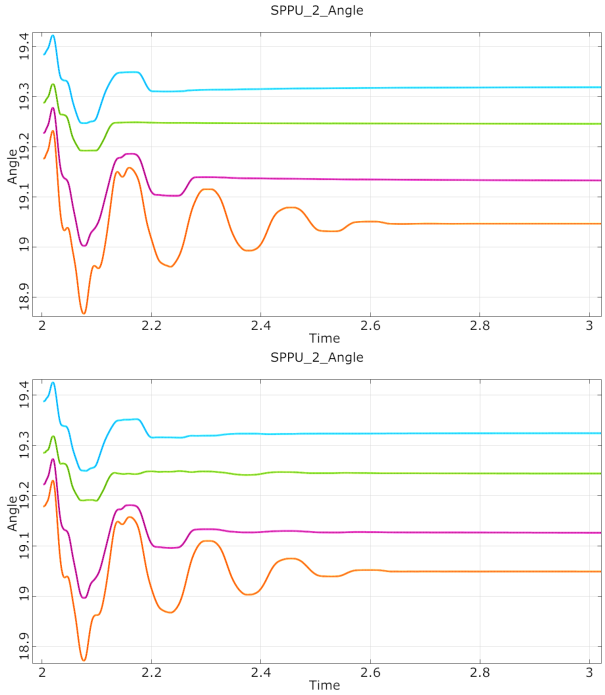

Figure 7: Sample time series of angles at SPPU #2. Top—original results obtained from Adams/Flex. Bottom—synthesized signals by F-MOP.

The proposed procedure has been applied also to other applications, e.g. for the parameter identification of non-linear material models in finite element analysis. The "signal" here is the load–displacement curve of a test specimen. In previous approaches [12], the signal was discretized into few equidistant steps, then meta-models were established by MOP for the single values on the curve. The squared residuals at these discrete points were used as criteria in a fast optimization procedure using MOP. For longer signals this approach is infeasible, moreover, it requires manual interference to identify characteristic points or relevant ranges. With the proposed approach, this is not necessary anymore. The field meta-model is valid for all points according to the raster of the original data, and one easily sees in which regions the parameters have what amount of influence.

5 Summary and Outlook

A new procedure is proposed in this article for meta-modeling of dynamic (time series) signals. It is based on the decomposition of a sample set of signals into a series consisting of shape functions scaled by amplitudes for each summand. The algorithm Metamodel of Optimal Prognosis is then applied to find the best fitting model for each amplitude. The Coefficient of Prognosis, which does an assessment of models with the statistical method of cross validation, is used as the selection criterion. It is possible to assess the model prediction capability even locally along the time axis. Moreover, sensitivity measures reveal the relative influence of parameters (as input to the dynamic analysis or experiment), also locally along the time axis.

The procedure has been applied to an aircraft high lift system. The training data were generated by virtual experiments, i.e. multi-body dynamics simulations. The surrogate models proved to be very accurate, by the CoP criterion as well as by direct comparison of the reference to the model time series. Unlike the high-fidelity simulation, the meta-models are very fast to compute, allowing e.g. for fast stochastic analyses in the scope of predictive reliability analysis. The models were also successfully implemented as software-in-the-loop into an experimental environment for real-time dynamic tests at the Airbus site.

Further developments are planned which will focus on more detailed model assessment and model improvement, locally in the time and parameter space. The range of application for this procedure is not limited to the above mentioned. Signals can be any xy-data, so fast surrogate models can be obtained, e.g., also for spectral analyses both in the low and high frequency domains, stress-strain curves of a material law etc. The field meta-models can also serve as digital twins which, fed by sensor data, monitor or control electronic appliances or machines.

ABSTRACT

This work describes computerized data acquisition system for current-voltage (I-V) characteristics of diodes. The proposed system consist of a personal computer pre-installed with LabVIEW, two units of power supply, an interface board, current and voltage sensors. Two devices under test (DUTs) are selected namely 1N4007 silicon and 1N34 germanium diodes. The current flow through the circuit and voltage across the diode is measured and I-V characteristic is successfully plotted. When data acquisition interrupted by the user, real time I-V curve with least-square fitting is plotted. The LabVIEW was employed primarily to display data from sensors and storing collected data for further post-measurement processing. Estimated forward voltage drop from plotted I-V curve was then compared with the published value from manufacturer's datasheet. Comparison revealed that developed system has been successfully characterized both DUTs base on the forward voltage drop obtained from the plotted I-V curve. Furthermore, proposed system architecture offers extra flexibility where stored data can be manipulated with minimum programming efforts. The application of the proposed system can also be extended for in-situ device characterization in various circuits.

1. Introduction

Rapid advancement in computerized measurement system around the world has seen the introduction of fast, simple, user-friendly and reliable solutions found in various applications. In recent years, rapid progress of the virtual instrument platform such as LabVIEW graphical programming language has simplified programming effort and produce simple yet highly-productive real-time computerized measurement system.

This paper is an extension of work originally presented in 2016 6th IEEE International Conference on Control System, Computing and Engineering (ICCSCE) [1]. In this report, we discussed in detail a system to determine I-V characteristics curve of germanium diode.

Proposed computerized I-V characterization system employed LabVIEW as the acquisition tool to obtain the data, analyze and display the result. Ease of use is one of our priority in this project. However, the complete functionality of LabVIEW is a plus factor that also satisfied the requirement of this project [2]. Virtual Instruments (VIs) in LabVIEW is utilized to construct a Graphical User Interface (GUI) as the time saving is the fair trade-off for the full low level control of other conventional programming languages such as C/C++, Visual Basic, and Matlab. Its graphical nature makes it ideal for measurement and data acquisition [3,4].

Simplifying data acquisition process and decreasing test time without scarifying the accuracy are primary goals in this project. Semiconductor diode is used in all sorts of electrical and electronic system. The electrical characterization of diode has been an important subject for more than half a century [5]. Semiconductor diode is an important device that exhibit non-linear relationship of I-V characteristics. In order to visualize the relationship, it is common to plot current versus voltage on graph. However, it is much more convenient to display the complete curve in an automated computer-based acquisition system.

2. System Description

This paper describes a LabVEW-based measurement method to plot I-V characteristics of semiconductor diodes. Figure 1 shows a block diagram of the main components of the measurement system that comprised mainly a personal computer with LabVIEW software, voltage and current sensors, interface board to be used between the sensors and computer, power supplies, and electronic circuit. In this research, LabVIEW 2012 was used in Windows 7 operating system. More precise sensors were used to measure voltage and current. The current sensor used

*Nor Shaida Mohd Saufi, Email: norshaidasaufi@gmail.com

was the Phidget CE-IZ02-32MS2-0.5 DC Current Sensor 0-1A powered by an external 12V power supply. The voltage sensor is Phidget Precision voltage sensor 1135 which measure differential voltage between input terminal and its output terminal. The current and voltage sensor was interfaced to personal computer through Phidget interface board 8/8/8 through Universal Serial Bus (USB) cable. Basically, the main components of the system and circuit used in this project is similar as described in [1] but we have used more sophisticated and better performance voltage and current sensors in terms of its measuring range and accuracy.

3. LabVIEW software

3.1. Block diagram

There are two windows for user to works on which are block diagram and front panel. LabVIEW is a programming environment which in block diagram, blocks representing functions, icons representing variables and lines representing data flows pass between different functional nodes [4]. LabVIEW is compatible with most of other hardware such as Phidget devices therefore they have their own blocks representing function. The communication between Phidget devices and LabVIEW software has been simplified using robust Application Program Interface (API) library which is accessible online for free. Figure 1 shows the block diagram of formula node in LabVIEW that was used to convert analog sensor value of voltage and current sensors to its corresponding value in volts and miliAmperes.

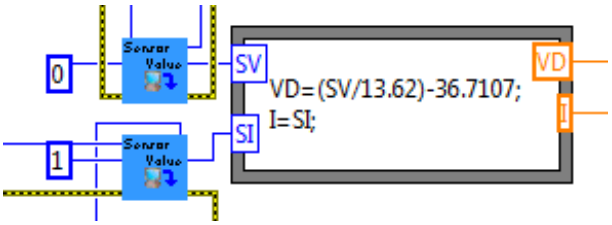

Figure 1. Formula node to write formula used to convert analog sensor value to voltage and current values

Particularly, Lev-Mar least square fitting method is expounded in the system which fit best the non-linear relation of diode. Figure 2(a) shows block diagram in LabVIEW for diode when user switch Curve fitting slide to Non-Linear and in Figure 2(b) is the block diagram when user switch slide to Linear. The saved data file in .csv can be accessed and plotted in Compare Graph when user clicked 'file path' and choose file location. The block diagram of the flow pass is shown in Figure 3.

Figure 3 shows block diagram that its function to read data from spreadsheet or .csv data file to be plot and compare in graph. The functional block can read and display multiple plot of germanium and silicon diode.

3.2. Graphical User Interface (GUI)

Front panel window is used as Graphical User Interface (GUI) of the system for user to interact with the program. Controls such as push button START, STOP, SAVE, PLOT and etc. as shown in Figure 4 are for user action to make the data displayed in indicator fields such as voltage, current value and also graphs. Before start the acquisition, user must make sure to check what is the electronic device to be tested. As we performed the measurement for I-V characteristics of diode, the Curve Fitting slide must be set to Non Linear. Next, when user clicked RUN button to start performing the acquisition, the LED of RATIOMETRIC STATE button is appeared green when the interface board is properly connected to computer and appeared red when it is not connected.

The voltage and current value appeared automatically and plotted on the I-V Characteristic graph. The fitting of I-V plot is plotted in real time until user push the STOP button to abort the execution. The graph provided a cursor for user to hover over the plotted line to find forward voltage drop of the diode as shown in Figure 4. The GUI gave user option in Curve fitting slide button to choose between linear and non-linear regression depends on what the characteristics of device the user testing.

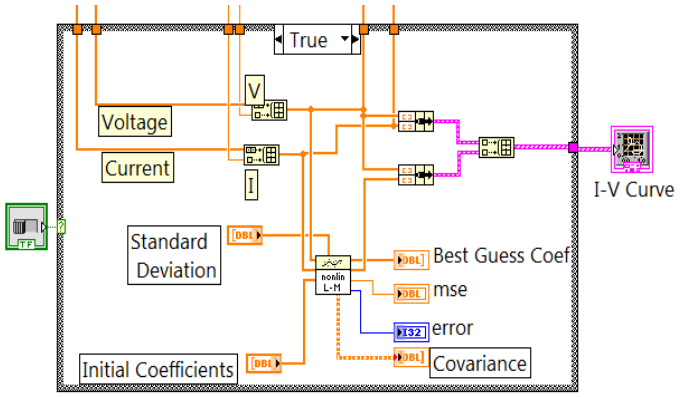

Figure 2(a). Block diagram of linear curve fitting

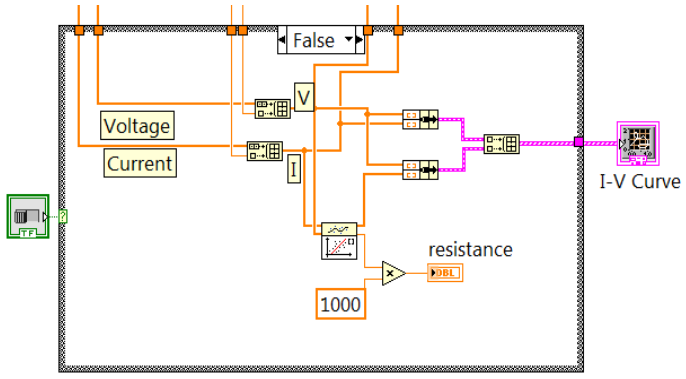

Figure 2(b). Block diagram of non-linear curve fitting

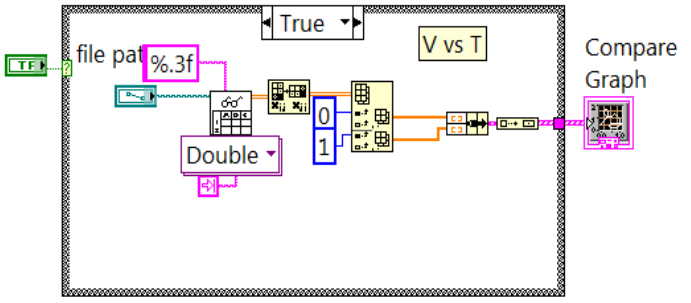

Figure 3. Functional block to read and plot graph from data file

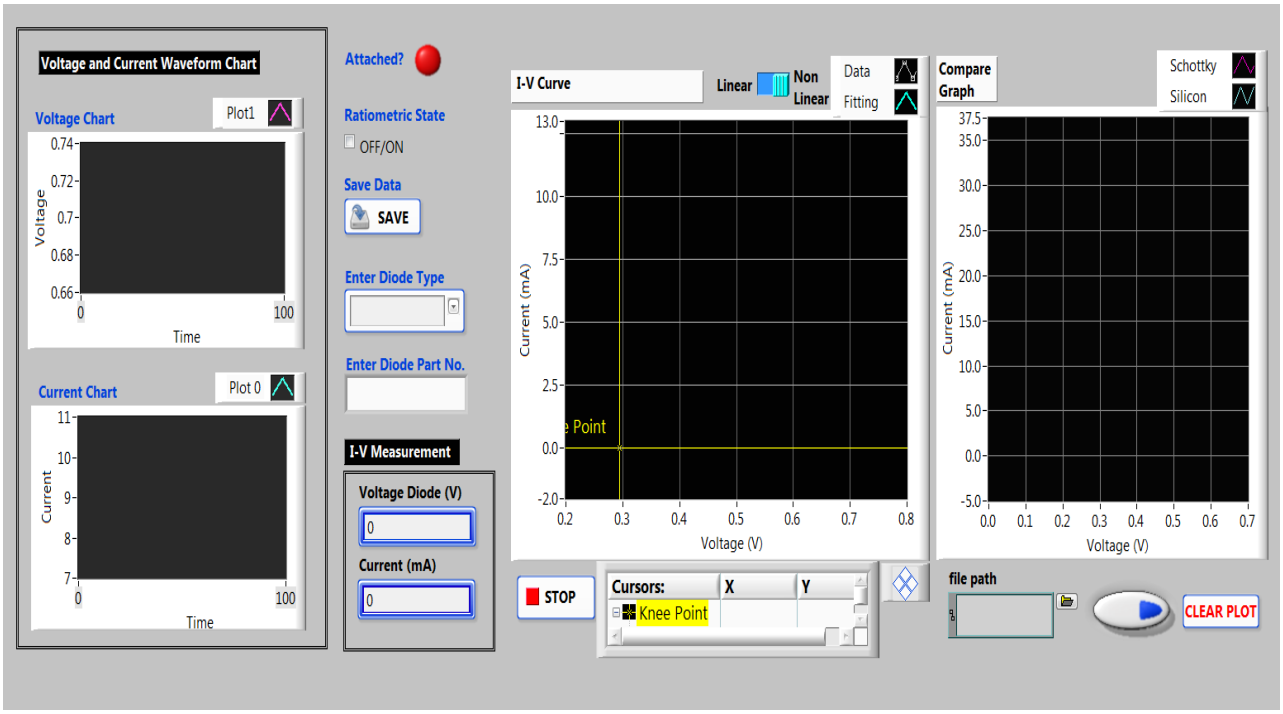

Figure 4. Graphical User Interface (GUI) developed in LabVIEW software

4. Analysis & Discussion

Recently in [1], silicon and Schottky diode has been studied which the system has shown the non-linear relationship of I-V characteristics. Upon studying the I-V graph, forward voltage drop of both diodes has been clarified which 0.7 volts for silicon and 0.4 volts for Schottky diode.

In this paper, the system has been tested on same silicon diode and characteristic of germanium diode is explored. The I-V characteristics graph plotted in Figure 5 can be seen that after the forward voltage drop, the current increases very rapidly where the device starts to conduct for both DUT. Below this voltage, current is less than 1% of maximum rated value of diode current [6]. Rated peak forward current for 1N34 and 1N4007 diode for most brand are 150mA and 30A [6,7]. Voltage increase slightly due to small internal dynamic resistance as the current change after the forward voltage drop is larger than the voltage change. The 1N34 germanium diode has much less defined result. The forward voltage drop is 0.4V which it is still shown low forward voltage drop. This germanium type of diode have low forward voltage drop which is fast switching speed and found uses in television and crystal radio application.

The silicon diode always expected to have value of forward voltage drop which is approximately 0.7 volts. The forward voltage drop was measured as 0.7 volts which this has support the theory behind its design. A germanium diode such as 1N34 have typically 0.3 volts forward voltage drop or low forward voltage drop means they are much more efficient compared to silicon diode. However, silicon diodes are resistant to heat, and better in terms of processing and stability. The results of this experiment appear to satisfy the theory behind diodes.

5. Conclusion

In this paper, a system for determination of current-voltage characteristics of diode has been developed and implemented. Based on LabVIEW software platform, this system measure current flow through the circuit and voltage across the diode to plot I-V characteristics of diode tested. From I-V plotted, forward voltage drop of silicon and germanium diode has been successfully determined. The possible research direction may include determination of voltage-current characteristics of any other two terminal components such as resistor or transistor. The ideality factor of diode can also be estimated by taking the natural log of current versus voltage plot.

Conflict of Interest

The authors declare no conflict of interest.

ABSTRACT

In this study, we use a new proposed framework to develop the Hamiltonian circuit learning games for college students. The framework is for enhancing learners' activities with learning reflexiveness. The design of these games is based on this framework to achieve the targeted learning outcomes. In recent years, the game-based learning is a very popular research topic. The Hamiltonian circuit is an important concepts for learning many computer science and electric engineering topics, such as IC design routing algorithm. The developed games use guiding rules to enable students to learn the Hamiltonian circuit in complicate graph problem. After the game, the learners are given a reviewing test which using the animation film for explaining the knowledge. This design concept is different from the previous studies. Through this new design, the outcome gets the better learning results under the effect of reflection. The students will have a deeper impression on the subject, and through self-learning and active thinking, in the game will have a deeper experience.

1. Introduction

The study of the paper is the research of the game-based learning technology. The game-based learning is an emerging research topics of the learning technology. Developing a video game as a learning tool might include many different tasks and considerations. Basically, how the game can be effective for learning is the main concern problem. This problem can arouse many challenging research problems such as the learning model of the game, the foci of the game, the players' attitude of the game and the game development. Many studies focused on the game developments such as the development of a new gaming technology, the usefulness of the gaming tool proposed by the game company and the development process of the learning game. Other studies might focus on the effectiveness of the game such as the learning process, the learners' attitudes. Moreover, some complicate topics of the game industry such as the immersive experience of the players brought research interests. Traditionally, the game for learning the specific subject is regarded as the serious game. Many different serious games have developed for different purpose of training and learning. Although the serious games have been used as the tool for education, most studies of the serious games remained on development of the functions of the game. Then how these games are effective and helpful for learning? This could be another challenging research topic. Our research goal is to find how to develop the effective learning method for game-based learning.

In this paper, a new framework for developing the learning game is proposed. Using advanced information technology, the design of digital games is booming in many applicable developments. Because of the unique interactive interesting and attractive features in digital games, it can arouse the students ' interest in learning, and improve the willingness to learn a specific knowledge. However, students are less likely to think about the contents after the game, but keep playing down. Usually, it is until the final online evaluation begins to help the students to recall the contents of the previous. The process of the final review is important for the design. This will not only can immediately check whether the students have learned the knowledge, but also can let students have the chance through self-initiative to get the targeted knowledge. Based on the above consideration, this study proposes a new method for developing the game for learning by using the Role-Playing Game (RPG), chapters of textbooks and story development.

*Meng-Chien Yang, Department of Computer Sciences and Communication Engineering, Providence University. Email: mcyang2@pu.edu.tw

In the beginning, we design the guiding rules to lead students to play the game. Suppose that there is a specific topic prepared for learning. The students are told to play the game linked to this topic. After the game, the learners are given a review test for enhancing the learning results. Meanwhile, we using a set of animation films to assist the learners. These films can be traced back to the pre-test which is given before the students play the game. Then, after the review test students will watch the related film with the content of the learning topic. This will strengthen the concept of knowledge link with the students in this topic.

In this paper, we use the above framework to design the game for learning an important subject: Hamiltonian circuit of the graph theory in discrete mathematics. The Hamiltonian circuit problem is to find an existing loop to visiting each vertex once on the graph. The Hamiltonian circuit problem is an important problem and can be applied to many different technological applications. To develop a game for learning the Hamiltonian circuit problem is an important problem both in computer science education and mathematical education.

In recent years, developing math games have become the popular research topic. The importance of mathematical games in mathematics education cannot be ignored. A practical approach of using the game for teaching math in the country junior high school was reported [1]. In addition, the author pointed out that the mathematical game teaching method has the following advantages and functions:

(1) to stimulate students' interest and motivation to learn mathematics [2];

(2) to help students from the specific experience to establish basic mathematical concepts and skills;

(3) to cultivate students to solve the problem of flexible and deep reasoning thinking ability

In another paper [3], the experimental results and infield tests showed that the existence of mathematical games have considerable potential. Our paper follows these previous studies and will continue to explore the learning changes brought by this new design approach. Based on the hypothesis of the above research project, we hope our study of developing the game of the Hamiltonian circuit problem can help the students learning this problem. In our study, we had invited students who taking the course of the graph theory to play the game. The testing results showed our proposed framework can develop the effectiveness game to help student learning.

The remaining of this paper is organized as the follows. Section 2 discuss related studies of the game-based learning. Section 3 describe the design of our proposed framework. Section 4 is the description of the game development and system modules of the proposed game for the Hamiltonian circuit problem. Section 5 is the report of experimental results and discussion. The conclusions are put in Section 6.

2. Studies of Serious Game and Game-Based Learning

The research projects related to our study are the studies of the serious game. Based on the definition of the famous game design textbook, the serious games are those games for education and study, simulation, health and growth [4]. Serious game gives the players fun experiences and other explorations. Serious game design is built in the "fun" under the premise of the players in the process of the game, while achieving a sense of accomplishment, knowledge and training, and further use of the nature of media and entertainment to convey the effect of information and education [5][6]. A famous study argued that the practice of the serious game has the meaning of learning and is a systematic learning, so that students can learn from the experience of the game [7].

There are new studies that "video games" will be a very influential tool for learning [8][9].Game-based learning is not a regular learning style but a revolution for education. It can increase the learner's motivation to learn and help learners to learn effectively to improve learning motivation and effectiveness. Learners playing the game, easily immerse into the game and the learning scenarios because of game challenges, level design or script story into the immersive state. Therefore, game learning can follow the experience of "heart flow" [10], a process to obtain the knowledge, so that learners immersed in the game. The theory of flow suggests that when learners are integrated into the task, they produce a state of mind that is isolated from the outside world. If students are in such a state of mind, students will have the highest motivation to learn.

The study of the serious game development could have many different aspects. Recently a reviewing paper [11] described some essential features of the serious games for education. In this paper, the authors stated that two major focus of the serious game are learners' attitude and game core mechanics. Another important study about how to use the serious game for collegiate computer science students is to use the game with course materials [12]. The development of the serious game might need the guidelines for design the game. A recent study [6] proposed the guidelines and stated the key factors of the serious game development. Based on the above studies, several factor could influence the design and implementation of the learning game. First, the connection between the learning materials and the learning game should be tight. Second, the development of the game should follow a guideline that can make the game to become a useful learning materials. Then, the third, the learning outcome should be evaluated with different and various considerations and assumptions. Based on these assumptions, our study focus on designing a new framework for developing the learning game. In this framework, we developed a new learning outcome called learning reflexiveness which can help the learners to enhance the learners' attitudes in the game-based learning process. The framework can help designer to develop the serious learning games.

3. Methodology and Framework of the Game Design

The design of our framework was initiated with the concepts of the flow simulation proposed by Csikszentmihalyi [10], [13]. When human are involve the activities with flow based on the theory proposed by Csikszentmihalyi, people can concentrate on these activities and have the immediate feedback. The flow simulation had been used the development of the playground and video games. The activities with flow can bring self-consciousness of awarding the related information and context. Based on this theoretical finding, we attempt developing the learning process with the game. We describe our design by the question what is a

good educational learning game? This will provide scaffolding for our proposed framework.

A good educational game can motivate the learners through the design of the presumptive learning situations. The presumptive learning situations are a set of conditional factors for identifying the initial condition of each learning level. The learning situation and RPG game scenarios are the main settings of the game. Meanwhile, in the domain of the game, the story narration is a factor that attracts the learners from being immersed in it. We create stories and game rules for the game. The learners follow the guideline proposed by [14] in the symbol of the code, through the code to show the navigation keys to read the story. The strategy of game design for each level should be in a gradually better mode that can help the learner to immerse into the story of the game. Following previous study, the game prepares easy, moderate and difficulty challenges to enhance the learners' self-esteem [15]. The design is to design a learning situation during learning low-challenge tasks to learning high-challenge tasks. We developed the setting of the game by adopting the concept of flow in different working environments.

We had study the game development for several years. We analyzed and found the following three motivational factors that help learners to play the games [16].

1. Challenge

Each game level can be design with a particularly challenge. The challenge will entice learners to continue the game. The design of challenges is to describe a clear game goal, then an uncertain outcome, and a related feedback. The different challenges can be design with different learning materials.

2. Curiosity

The interface on the screen and sound control can cause learners interest. The setting of the game world can be designed as an environment that the players can explore new items.

3. Fantasy

Fantasy environment is an important factor. It stimulates the intrinsic motivation of learners in two ways, one is to satisfy the learner's inner emotion, and the second is to meet the learners' cognitive needs, and to promote the learners to grasp the relationships in the game.

With these three factors, we add a new factor into the game development. The new factor is the reflexiveness of the learner. Once the learner is playing the game, the outcome and the challenges can help the learner to have the learning attitude to adjust the learning paths toward the meaningful goal. The reflexiveness for learning had been mentioned in the studies of mathematics education.

3.1. The Importance of Reflexiveness for Mathematics Learning

Reflexiveness mathematics learning refers to the fact that it is an effective way to learn mathematics through the reflection of the process of math learning activities. It is not only a general review or repetition of mathematics, but a deep understanding of mathematics activities involved in the knowledge, methods, ideas, and strategies and so on. The general operational mathematics is based on "learning knowledge" as the main purpose, concerned about the current academic performance; reflexiveness mathematics is based on "learning to learn" for the purpose of focusing on the current academic performance and students' future development [17].

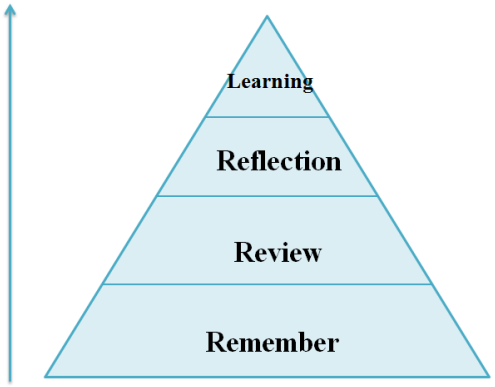

Figure 1: Reflectiveness of four learning levels

3.2. The reflexiveness in the proposed learning

Based on above discussions of the reflexiveness in mathematics learning, the reflexiveness can be applied to the other learning subject. The reflexiveness in the game-based learning can be illustrated as four different levels shown on Figure 1. The bottom level is the learning for remembering. This can be the basic of reflexiveness and are used as the fundamentals for accumulating knowledge. The second level is the learning with the reviewing content. The function of the second level is to enhance the effectiveness of the learning. The third is reflection which are the main level of our design. This level is to find the correct ways of learning the targeted subjects or courses. The final level is the effective learning process that the learners can successfully learn this subject.

We used the proposed framework to develop a game for learning the Hamiltonian circuit problem. The Hamiltonian circuit is an important graph in the graphic theory. The Hamiltonian circuit problem can be taught in the collegiate courses such as discrete mathematics, graph theory, combinatorial mathematics. The Hamiltonian circuit problem is an important concept in many computer science applications like logic design, routing problem. In next section, we describe our game that following the proposed framework.

4. Game Design and Game Play

In this section, the system design of the game is illustrated. At the beginning, the whole structure the game is to design with an RPG game structure combined with the fairy tale. Figure 2 shows the main menu of the game. The game is described as several chapters with different concepts of the Hamilton circuit. At the beginning of each chapter the learners will receive guidance rules. The guiding rules are put in a short RPG game and with a short introduction video clip. When the learner plays the RPG game, he can get the game rules. Using these rules, the learners can play and find the Hamilton circuit in a given graph (Figure 3). If the learner can successfully find the Hamilton circuit in the graph, the learner

can be guided to complete the chapter with more similar graphs. When the learners finish the chapter of the game, there is a chapter reviewing quiz which helps the learners to recall the process of gameplay. The learners can get an immediate feedback here and understand the correct answers which are the key terms of this chapter.

Figure 2 Main menu of the game

The reflexiveness setting in the whole scenario of the gameplay is a cyclic framework shown in Figure 4. In this framework, the learner can find the learning content in four different styles. The guide rules and the RPG game are used to attract the learner’ s attention. The game process is the main challenge and help the learner to understand the Hamilton circuit. The review test can help the learner to enhance the learning results. The teaching video can keep the learner’s interest and go to next chapter which is more difficult Hamiltonian graph.

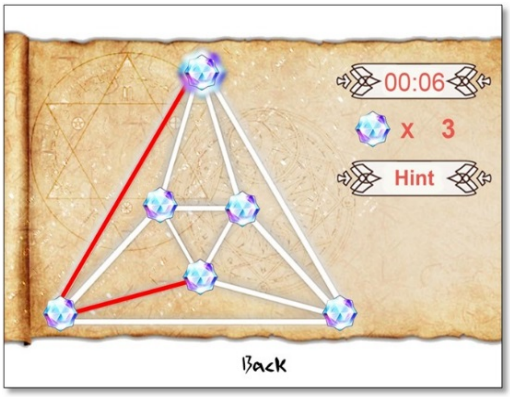

Figure 3: Gameplay for finding the Hamiltonian circuit

In addition, the reflective learning will affect the learners in two factors of each cycle. First, in the review of the test (Figure 5), learners need to recall the game experiences for answering these questions correctly. Second, the animated films with chapter concept guide, learners can link the game experience and answer process. An interesting design here is that the outcome of the story will vary depending on the score of the learner's game, which gives the learner the motivation to repeat the game.

Reflective learning should help the learners to get attention to the guidance and encouragement in the learning process. When the learners get the guide rules after the game, and in the review of the test to reflect on the game process and guide the rules of the tips, organize the answer to answer questions. When learners watch the teaching film for the second time of reflective activities, the learners will have reflective experience based on the pasting activities.

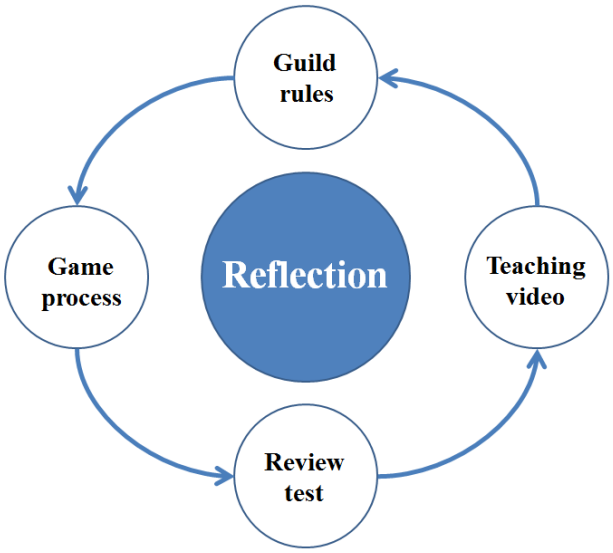

Figure 4: Game cycle that includes reflective learning.

The game is implemented with this system design. In the game, six cycles for the easy to complicate knowledge of the Hamilton circuit are implemented. After the review test, the learners can watch an animated film as the enhancement for learning reflection.

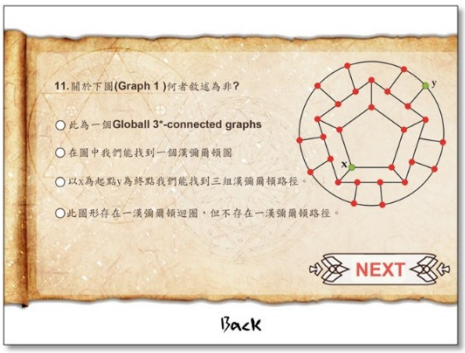

Figure 5: Screen shot of the online reviewing test

5. Implementation and Evaluation

The learning game was implemented and evaluated by a user–based evaluation and an expert-based working through evaluation. The approach was similar to a previous study of the educational serious game development [12]. A group of computer science major college students who taking the graph theory course were invited to participate the user-based evaluation. Our game was installed in a tablet computer and each participant was given 10 minutes to play the first three chapters of the game and then answered the quiz after the game. If the student could finish these three chapters successfully, the student would be given a big reviewing test and were asked to finish the remaining three chapters of the game.

The total number of students participating this experiment were 34. When the students finished the first three chapters of the

game, they were given a writing test for evaluating the basic concepts of the Hamiltonian circuit. When they finish the final chapter, the sixth chapter, the students were given a writing test with the complex knowledge of Hamiltonian circuits.

The experimental results showed 19 students had finished the first three chapters of the game and passed the basic test. Then, 15 students had finished the whole six chapters of the game and passed the advance test. Based on the evaluating, the developed game can be useful as a tool for teaching Hamiltonian circuit.

The second evaluation process is the expert walk-through test. We invited 8 computer major graduate students who had already understood the Hamiltonian circuit. When these students played the game, they were asked to find the shortcoming of the usability of the interface and evaluating the gameplay. Most students agreed that the game can help the beginner to learn the Hamiltonian circuit. Several mentioned the advanced part, the last three chapter should be improved with more illustration figures to help the learners play the games. Based on the suggestions, we are certain that the proposed framework can foster a comprehensive and effective learning.

6. Conclusion

In this paper, a framework for developing the learning games for advance computer science concept is proposed. In this framework, the learning process is arranged as a cycle with playing game, answering the review questions, watching the animation clips and being given the guiding rules. The framework is developed based on the concept of the flow and the fundamentals of the game theory. In addition, the reflexive review of the mathematical education is put in the framework and we coin a new learning attitude, reflexiveness. The reflexiveness design in the learning game can help the learners achieve the learning goal via playing.

We used this framework for developing the game for learning the comprehensive knowledge of Hamiltonian circuit. The results of evaluation showed that the game can help these participants to learn the Hamiltonian circuit. The game can be a useful teaching tool for courses related to graph theory and computer science. The game can be used for other purpose such that training course for novices to learn this concept at the IC design company.

The project has two successful results. First, we have develop a framework that can be useful as a guideline for other research studies who focus on developing the serious games for certain subject. Second, the game for teaching the Hamiltonian circuit can be useful as the teaching tool. In the next studies, we will explore and find more evidences that proposed framework is effective for the developing the serious learning game.

Conflict of Interest

The authors declare no conflict of interest.

ABSTRACT

Solving the Unit Commitment problem (UCP) optimizes the combination of production units operations and determines the appropriate operational scheduling of each production units to satisfy the expected consumption which varies from one day to one month. Besides, each production unit is conducted to constraints that render this problem complex, combinatorial and nonlinear. In this paper, we proposed a new strategy based on the combination three optimization methods: Tabu search, Particle swarm optimization and Lagrangian relaxation methods in order to develop a proper unit commitment scheduling of the production units while reducing the production cost during a definite period. The proposed strategy has been implemented on a the IEEE 9 bus test system containing 3 production unit and the results were promising compared to strategies based on meta-heuristic and deterministic methods.

1. Introduction

The main role of energy management is to ensure the production of active power in order to respond to the demand growth among a very little fuel cost [1,2]. Solving the Unit Commitment Problem (UCP) is very essential in electrical network planning. It can both optimize the daily operational planning of networks and reduce the total production cost among the improvement of the operating state of each unit leading to obtain the best unit commitment scheduling helping to respond to the power demand. Operations scheduling production units or Unit Commitment (UC) improve operational planning of the electrical grid while ensuring continuity of service [1-6]. The main purpose of solving the Unit Commitment problem is to schedule production units to respond to the consumed power with the minimization of the total production cost. The optimal planning [7-9] involves ensuring a better use of available generators subject to various constraints and guaranteeing the transfer of electrical energy from generating stations to the load. UC must satisfy the load demand, storage capability, minimum downtime startup and safety limits for each production unit.

The production scheduling comprises determining startup and each generation level for each unit in a given planning period [10-13]. Therefore, a study of literature [14,15] on methods which focus on unit commitment (UC) problem resolution shows that various optimization methods have examined this subject. Furthermore, Sasaki et al. demonstrated the possibility to use artificial neural network (ANN) to solve the UCP in which a large number of inequality constraints is processed. They have used the ANN to schedule generators and the dynamic programming to solve the load flow problem. The adopted strategy was compared to Lagrangian Relaxation (LR) and dynamic programming (DP) methods and the results offered a faster and cheaper solution compared to the LR and DP but it suffers from digital convergence because of the learning process. Certain works [16, 17] proposed a strategy based on tabu search method. They introduced new rules to generate an initial solution feasible to solve the Unit Commitment problem. This strategy consists on dividing the problem into two problems: the first combinatorial optimization problem is solved using tabu search algorithm and the second is a problem of nonlinear programming solved through the quadratic

programming routine. The structure resolution through Tabu search method is similar to that used by simulated annealing [18] even though TS is provided with a simplified configuration, so it is easy to pass from one optimization to the other. Indeed, the main advantage of the adopted strategy is to extend the search space provided for the best optimal solutions which are stored in the tabu list. This method has provided a lower production cost solution, but it's slower compared to the Lagrangian relaxation. However, T. Logenthiran et al. [19] have proposed a new approach based on particle swarm optimization (PSO) algorithm for solving the unit commitment problem. They presented three versions of particle swarm: binary particle swarm optimization (BPSO), improved binary particle swarm optimization (IBPSO) and combined use of particle swarm optimization and Lagrangian relaxation programming (LR-PSO) .The numerical results show that LR-PSO method has provided a lower production cost solution compared to LR, BPSO and IBPSO especially when the number of units important. Whereas, if the number of units is small, BPSO is taken as the best method since it has the lowest production cost compared to other algorithms. Other works, [20, 21] presented new approaches based on artificial intelligence to solve the UCP. The adopted approach combines two methods: tabu search and neural networks (ANN-TS) in order to get an optimal unit commitment scheduling allowing a minimal production cost in accordance to the constraints of the studied system. Artificial Neural networks provide a fast convergence to optimal solutions but it takes a lot of memory space because of the great number of constraints.

Cheng et al. [22] proposed a hybrid method based on the integration of the genetic algorithm in Lagrangian Relaxation Programming (LR-GA) to solve the problem of the planning of the operations of the production units. This integration consists in improving the Lagrange multipliers using the operators of the genetic algorithm to find a fast and an effective cost solution respecting all the constraints of the system. The implementation of this method requires two steps ; the first is to look for the minimum constraints of the Lagrange function under the multipliers constraint through dynamic programming. The second step consists on maximizing Lagrange's function while respecting the multiplier adjusted by the genetic algorithms. The experimental result of this method provides a faster and cheaper solution compared to the Lagrangian relaxation method (LR) and the tabu search method (TS). However, C. Christober et al. [23] presented a hybrid method combining the evolutionary programming the tabu search methods (EP-TS). The first has the advantage of a good convergence property, a significant acceleration based on the principle of traditional genetic algorithm and a high quality of solutions, but its major disadvantage is related to the dimensioning of the Unit Commitment problem. Tabu search method improves the status by avoiding imprisonment in the local minimum. The best solution is chosen by evolutionary strategy. Thus, the effort has been made to combine these two methods whose purpose is to meet the requirements of the generators commitment problem. The numerical results demonstrate that this method is efficient and accurate in terms of calculation time and minimization of the total production cost compared to the following methods: simulated annealing, taboo search, dynamic programming, evolutionary programming, Lagrange programming and LR- GA. By contrast, Kumar et al. [24] presented a hybrid method combining dynamic programming with Hopfield Neural Networks (DP-HNN). The proposed process consists on two steps: use of Hopfield neural networks from direct computation to generate the economic distribution (ED) and use of dynamic programming (DP) to plan generators. This approach provides a poor final solution in total of production cost over other methods, but is faster than LR, DP, GA, LR-GA and AS-GA. In addition, C. Asir et al. [25] presented a new approach based on artificial intelligence to solve the problem of allocation of units. This combines two methods: tabu research and Artificial Neural Networks (ANN-TS) and this in order to have an optimal solution that solves the problem of planning power with a minimum of total production cost with respecting all the constraints of the specified system. Neural networks provide a fast convergence solution but the programming of the algorithm takes up a lot of memory space because of the constraints of the problem. The tabu search is characterized by the flexibility of its memory and it is able to find good solutions. This algorithm gave a faster and cheaper result compared to tabu search, dynamic programming, Artificial neural networks, Lagrange programming, LR-GA, TS-GA and EP-TS methods. In addition, C. Asir [26] has developed another strategy which consists in integrating the tabu search with the genetic algorithm. The purpose of this technique is to find the planning of the production. This strategy depends on the exploitation of the total cost which can be minimized when it is subjected to a set of constraints. Tabu search can find good solutions using the tabu list while genetic algorithm is used to generate new solutions using its operators. The results demonstrate that this technique provides a low cost but slow solutions compared to ANN-TS. Alma et al. [27] proposed a hybrid approach combining fuzzy logic and the genetic algorithm (FL-AG) to solve the Unit Commitment problem. Genetic algorithm uses the actual coded chromosomes in contradiction with the most commonly used scheme which is binary coding. This method uses a strict priority order list in the genetic algorithm that generates different solutions. This list serves to reduce the size of the search space of the problem, while fuzzy optimization guides the entire search process in an uncertain environment (varying from load demand, renewable energy sources etc ...).The results of this technique offer a good final solution compared to dynamic programming and to the genetic algorithm.

According to our study, we thought to validate an approach to apprehend the whole unit commitment problem. To achieve this objective, our strategy for solving the Unit Commitment Problem is based on the combination of three stochastic optimization methods that are the Particle Swarm Optimization (PSO), the Tabu Search (TS) and Lagrangian Relaxation (LR) method in order to develop a proper unit commitment scheduling of the production units to minimize the production cost.

2. Notation

The notation used throughout the paper is stated below.

a_i, b_i, c_i : Coefficients of the production cost,

P_{ih} : Active power generated by the i^{th} unit h^{th} hour, $i = 1,2,3,....,N_g$ and $h = 1,2,3,....,H$

U_{ih} : On/Off status of the i^{th} production unit at the h^{th} hour, $U_{ih} = 0$ for the off state of one generating unit and $U_{ih} = 1$ for the operating status of one generating unit,

HSC_i : Hot start-up cost of the i^{th} unit,

CSC_i : Cold start-up cost of the i^{th} unit,

P_{rh} : System spinning reserve at the h^{th} hour,

P_{dh} : Amount of the consumed power at the h^{th} hour,

P_{Lh} : Total active losses at the h^{th} hour,

P_i^{min} : Minimum and maximum power produced by one generator,

P_i^{max} : Maximum power produced by one generator,

MUT_i : Continuously on-time of unit i .

MDT_i : Continuously down-time of unit i .

τ_i^{OFF} : Continuously off-time of unit i ,

SC_i : Cold start time of unit i .

N_g : Number of generating units,

H : Time horizon for UC (h).

3. Problem Formulation

Many works have been based on an analytical statement of the unit commitment problem [2,3,11, 18, 22]. We present in this paper a mathematical model of the unit commitment problem with limited security. This model is a mixed linear and constrained which has been adapted in several works [3, 9, 13, 15].

$$Min \left[F_T(P_{ih},U_{ih}) = \sum_{i=1}^{N_g} \sum_{h=1}^{H} [a_i P_{ih}^2 + b_i P_{ih} + c_i + ST_i(1-U_{i(h-1)})]U_{ih} \right] \quad (1)$$

Where;

ST_i: The starting cost of the i^{th} unit defined by:

$$ST_i = \begin{cases} HSC_i \ \ if \ \ MDT_i \le \tau_i^{OFF} \le MDT_i + SC_i \\ CSC_i \ \ if \ \ \tau_i^{OFF} \succ MDT_i + SC_i \end{cases} \quad (2)$$

The minimisation of the objective function is provided with the following constraints:

- System Constraints
  - Power balance constraints

$$\sum_{i=1}^{N_g} P_{ih} U_{ih} = P_{dh} \quad (3)$$

  - Spinning reserve constraints

$$P_{dh} + P_{rh} - \sum_{i=1}^{N_g} U_{ih} P_{ih} \le 0 \quad (4)$$

- Unit Constraints
  - Genration limits

$$P_i^{min}.U_i \le P_{ih}.U_i \le P_i^{max}.U_i \quad (5)$$

  - Minimum up-time constraint

$$U_{ih} = 1 \quad for \sum_{t=h-up_i}^{h-1} U_{ih} \le MUT_i \quad (6)$$

  - Minimum down-time constraint

$$U_{ih} = 0 \quad for \sum_{t=h-down_i}^{h-1} U_{ih} \le MDT_i \quad (7)$$

4. Methodology of resolution

In this paper, four optimization methods are available to solve the unit commitment problem; the first one uses the Particle Swarm Optimization (PSO). This strategy takes into account the advantage of PSO method for solving complex and nonlinear problems. The second method relies on the use of the Tabu Search approach (TS). The use of the TS approach is depicted to the flexibility of storage great memory of optimal solutions offered by this method. The third strategy shows the advantage of the Lagrangian relaxation providing the best convergence speed. Our strategy for solving the Unit Commitment Problem is based on the combination of three optimization methods that are the Particle Swarm Optimization (PSO), the Tabu Search (TS) and Lagrangian Relaxation (LR) method to find a good On / Off states scheduling of each production unit over a period of time leading to obtain a good production cost.

4.1. Particle Swarm Optimization

Particle swarm optimization provides a population based search procedure in which individuals called particles change their positions with time. This method is able to generate high quality of solutions within shorter calculation time and stable convergence characteristic than other stochastic optimization methods. The PSO model consists of a swarm of particles moving, figure 1, in a definite dimensional real-valued space of possible problem solutions [9,28,29].

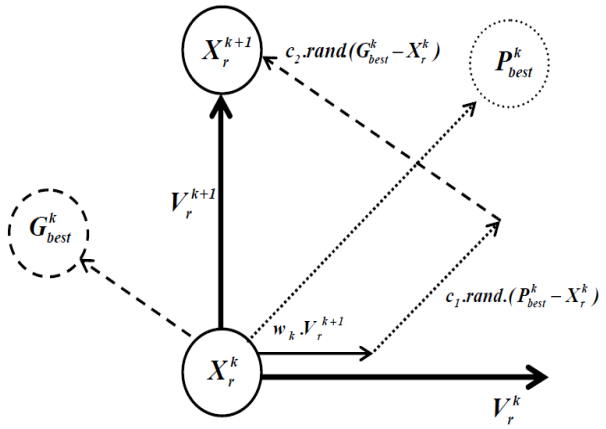

Figure 1. PSO research process

Every particle has a position $X_i = (x_i^1, x_i^2, ..., x_i^l)$ and a flight velocity $V_i = (v_i^1, v_i^2, ..., v_i^l)$. Indeed, each particle has its own best positions $P_{ibest} = (P_{ibest}^1, P_{ibest}^2, ..., P_{ibest}^l)$ and a global best position $G_{best} = (G_{best}^1, G_{best}^2, ..., G_{best}^l)$. Each time step is characterized by the update of the velocity and the particle is moved to a new position which is the sum of the previous position and the new velocity as shown in the following expression:

$$X_r^{k+1} = X_r^k + V_r^{k+1} \quad (8)$$

The update of the velocity from one particle to another is given by:

$$V_r^{k+1} = w_k.V_r^{k+1} + c_1.rand.(P_{best}^k - X_r^k) + c_2.rand.(G_{best}^k - X_r^k) \quad (9)$$

Where, c_1 et c_2 are acceleration constant, *rand* is a uniform random value between $[0,1]$, X_r^k and V_r^k are respectively the position and the velocity of one particle i at iteration k. w_k is the inertia weight factor defined by the following equation:

$$w_k = w_{max} - \frac{w_{max} - w_{min}}{k_{max}}.k \quad (10)$$

Where, w_{max} and w_{min} are the maximum and the minimum inertia weight factors respectively and k_{max} is the maximum number of iterations.

4.2. Tabu search

Tabu search uses a local or neighborhood search procedure to iteratively move from a solution X to a solution X' in the neighborhood of X, until some stopping criterion has been satisfied. To explore regions of the search space that would be left unexplored by the local search procedure, TS modifies the neighborhood structure of each solution as the search progresses [16,17]. The search for the optimal solution corresponding to minimal production cost consists on repeating an iterative process until reaching a stop criterion so as to find one solution neighbor to the optimal one as shown to the following equation:

$$P_{ibest} = P_{best} + \left[(b_i + 2.c_i.P_{best}).\left(\frac{P_i^{max} - P_i^{min}}{2} \right) \right] \quad (11)$$

The new neighborhood solutions $N^*(X)$ are determined through the use of memory structures. The search then progresses by iteratively moving from a solution X to a solution X' in $N^*(X)$. To determine the solutions admitted to $N^*(X)$, a tabu list (TL) memory is used, which is a short-term memory containing the solutions that have been visited in the recent past as less than the maximum number of iterations.

4.3. Lagrangian Relaxation

The Lagrangian relaxation solves the Unit commitment problem by relaxing or temporarily ignoring the constraints, power balance and spinning reserve requirements [13,15,30]. Therefore, to transform the complex nonlinear constrained problem into a linear unconstrained problem, we have considered the following Lagrangian function:

$$L(P_{ih}, U_i, \lambda_i) = \sum_{i=1}^{N_g}\sum_{h=1}^{H}[a_i P_{ih}^2 + b_i P_{ih} + c_i + ST_i(1 - U_{i(h-1)})]U_{ih} + \lambda_i.(P_d - \sum_{i=1}^{N_g} P_i U_{ih}) \quad (12)$$

Where, λ_i is the Lagrangian coefficient.

To establish our strategy, we have considered the partial derivatives of the Lagrangian function (12) with respect to each of the controllable variables equal to zero.

$$\frac{\partial L}{\partial P_{ih}} = \frac{\partial\left[[a_i P_{ih}^2 + b_i P_{ih} + c_i + ST_i(1 - U_{i(h-1)})]U_{ih}\right]}{\partial P_{ih}} - \lambda_i\left(\frac{\partial P_{dh}}{\partial P_{ih}} - U_{ih}\right) = 0 \quad (13)$$

$$\frac{\partial L}{\partial \lambda_i} = P_{dh} - \sum_{i=1}^{N_g} P_i U_{ih} = 0 \quad (14)$$

Equations (13) and (14) represent the optimality conditions necessary to solve equation systems (1) and (3) without using inequality constraints (equations (4) and (5)). Equation (13) can be written as follows:

$$\lambda_i = \frac{\frac{\partial\left[a_i P_{ih}^2 + b_i P_{ih} + c_i + ST_i(1 - U_{i(h-1)})]U_{ih}\right]}{\partial P_{ih}}}{\frac{\partial P_{dh}}{\partial P_{ih}} - U_{ih}} \quad ; i = 1,\ldots,N_G; h = 1,\ldots,H \quad (15)$$

4.4. Proposed Strategy

The process of the Unit Commitment problem resolution by the combined use of Tabu search, Particle swarm optimization and Lagrangian Relaxation (TS-PSO-LR) methods is carried out according to the flowchart in Figure 2.

The proposed strategy not only helps to reach the optimal solution as quickly as possible using the speed of the Lagrangian relaxation but also to proceed through PSO method to search effective solutions corresponding to a minimum production cost and this is obtained through a specific determination of the new velocity and then the next best position corresponding to the best amount of generated power produced by each unit when it's in the ON state.

In the proposed method, it's notable that P_{ibest} representing the best information of each particle and the history of each generated power P_{gi} of each production unit is preserved in the list $P_{best}List$. Herein, in spite of the possibility of the PSO method with the solution better than G_{best}^k around P_{best}^k, there is the possibility not to be searched enough that's why we have thought to use the history of P_{ibest}^l in $P_{best}List$.

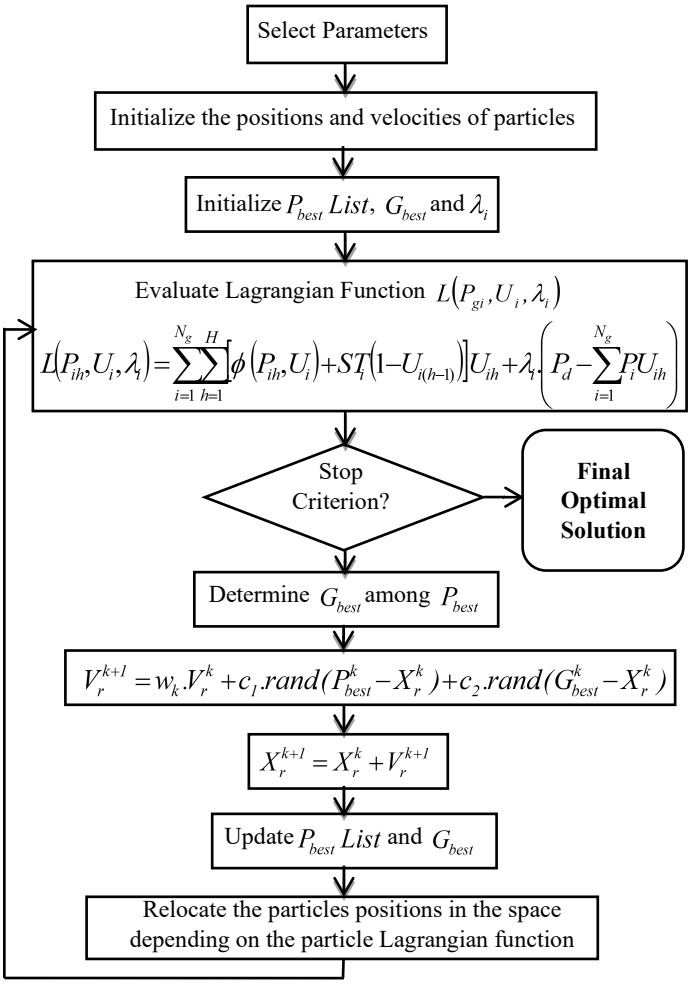

Figure 2. Flowchart of solving the unit commitment problem via Tabu Search, Particle Swarm Optimization and Lagrangian Relaxation

Whenever the particles lose the searching ability when the velocity V_r^k of one particle is very small, the TS-PSO-LR algorithm adapts the other $(P_{ibest}^2,...,P_{ibest}^l)$ instead of P_{ibest}^1 to update equation of velocity. This action increases the searching ability and helps to find more optimal solutions enabling a minimal production cost while considering a best unit commitment scheduling.

The proposed TS-PSO-LR strategy differs from other evolutionary computing techniques in providing an acceptable solution within a relatively short time and is likely to lead the search towards the most promising solution area. A step-by-step TS-PSO-LR for the optimization of the UC problem is outlined as follows:

Step 1: Initialization data for each unit production

Step 2: Create tabu lists $P_{best}List$

Step 3: Generate the position and the velocity (X_r^k, V_r^k) of each particle according to equations (8) and (9).

Step 4: Evaluation of each particle at an initial power value selected from the limit margins.

Step 5: Calculate the production cost function of each particle for each production unit,

Step 6: Calculate the Lagrangian coefficient λ according to the expression (15),

Step 7: Calculate the objective function of each particle according to equation (1),

Step 8: Save the best results in the tabu list $P_{best}List$

Step 9: If the stop criterion is satisfactory, the found values are those which corresponds to the desired optimal solution otherwise we return to step 3.

5. Simulation And Results

In order to test the performance of the optimization proposed method; the strategy has been applied to an IEEE electrical network 9 buses [13,15,31], having 3 generators, over a period of 48 hours. The characteristics of the different production units are given in Table 1.

Table 1: Characteristics of production units

U	P_{gimax} (MW)	P_{gimin} (MW)	a	b	c	MUT	MDT	HSC_i ($)	CSC_i ($)
1	582	110	0.0756	30.36	582	8	8	4500	9000
2	330	74	0.00031	17.26	970	8	8	5000	10000
3	115	25	0.00211	16.5	680	5	5	560	1120

In this paper, we have considered 48 successive periods in order to establish the temporal evolution of the power demand (Table 2).

Simulation results shown in Table 3 have proved that the adopted optimization methods have helped to establish an appropriate On/Off scheduling operating states of the production units while respecting the time constraints.

Nevertheless, through these methods we have arrived to reach an optimal production cost. Based on Table IV, the production cost found by the hybrid method based on the combination between Tabu search, Particle Swarm Optimization and Lagrangian Relaxation methods (TS-PSO-LR) method among 48 hours is about 1.5800e+06 $ lower compared to that obtained through Tabu search (PC = 2.2350e+06 $) and through PSO (PC= 1.7813e+06 $) or through Lagrangian Relaxation (PC= 1.6405e+08$). This result shows the best performances of the adopted strategy in minimizing the production cost and proves that we can get promising results through hybridization.

Table 4: Production Cost and Time required to converge for each optimized method

	TS	PSO	LR	TS-PSO-LR
Production Cost ($)	2.2350e+06	1.7813e+06	1.6405e+08	1.5800e+06
Time (s)	1.536 s	2.432s	4539s	127.082 s

Furthermore, concerning the resolution time, TS and PSO methods has presented the best time of convergence to an optimal solution compared to our strategy which requires 127.082 s to reach the global optimum. Besides, through Lagrangian Relaxation method, the unit commitment problem requires a lot of time to converge and this is explained by the complexity of the problem.

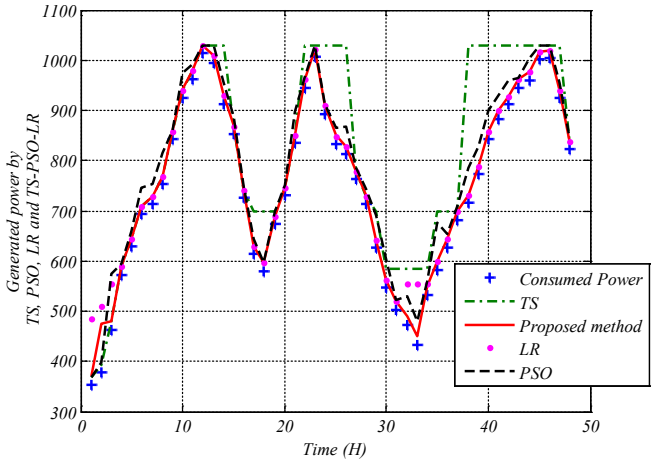

Figure 3. Generated power by TS, PSO, LR and TS-PSO-LR methods

It is interesting to note that the generated powers follow the optimum power quantities provided by the proposed optimization algorithm and the other optimization method. This demonstrates the high performance of the control algorithms adopted for the supervision of the system studied and proves the efficiency of the regulation loops for the different production units. In addition, the strategy adopts a permit to obtain sufficient and rapid planning in terms of convergence. Indeed, with the particular attention we offer you the considerable choice of input variables to particle swarm optimization method, we have managed via the proposed strategy to optimize the optimal solutions able to reduce the total cost of production.

Based on the results set out in Table 4, we find that our strategy has solved the Unit Commitment problem while addressing a planning of on-off states of production units. Planning that has complied with the constraints of each unit (minimum start-up MUT_i and shut-down times MDT_i). Moreover, we note that the power produced by the most powerful machine (615 MVA) remains unchanged throughout the 48 hours while the other production units vary to produce the amount of power demanded by the network.

Thanks to the simulation results, we can note that the Unit Commitment scheduling found by the hybrid approach has helped to obtain the minimum production cost compared to the other monotonous methods. This proves the main feature of the hybridization technique [32] that allows the combination of the advantages of various methods. Indeed, the tabu search, as table 4 shows, is found the most efficient regarding the convergence time but it has the highest total production cost. As for the Lagrangian relaxation, has allowed to have a very high production cost and requires a considerable time to converge. Whereas, the particle swarm optimization is conducted in a good convergence time but the cost is high compared to our TS-PSO-LR strategy. This comparison reflects the performance of the hybrid strategy, both in production cost and in convergence time.

Therefore, based on Figure 3, we can notice that the total amount of generated power by the production units is very similar to that consumed with a very limited amount of spinning reserve power compared to PSO, TS and LR methods where the generated powers are much higher than the amount requested. This proves the effectiveness of tracking of the consumed power per each hour and shows the performance of the algorithms enabling to get a minimal production cost. Besides, this minimal production cost has been established thanks to a good On/Off statements scheduling set for each production units (Figures 4 and 5). The organization is made through an estimation of the amount of load desired by the electric network, while taking into account of the allowable constraints.

We note that the optimal unit commitment scheduling found by our PSO-TS-LR strategy is characterized by the On status of the powerful unit (615 MVA) [3,6,8,9,13] throughout 48 hours and this is due to the minimum up and the minimum down-time constraints and to the power demand governed for each hour. We note that the unit commitment scheduling of the second production unit (370 MVA) is respecting the during minimum up/down time equal to 8 hours which proves the effectiveness of the control

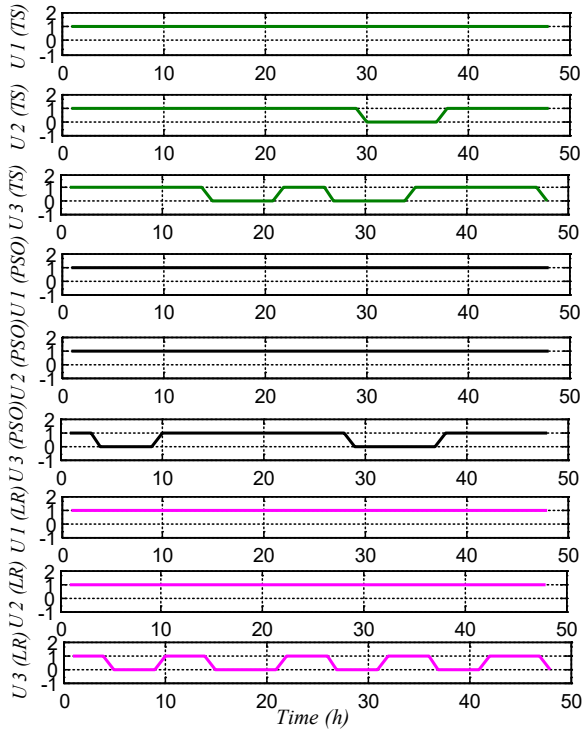

Figure 4. Optimal binary combination of units operation through TS method, PSO method and LR method

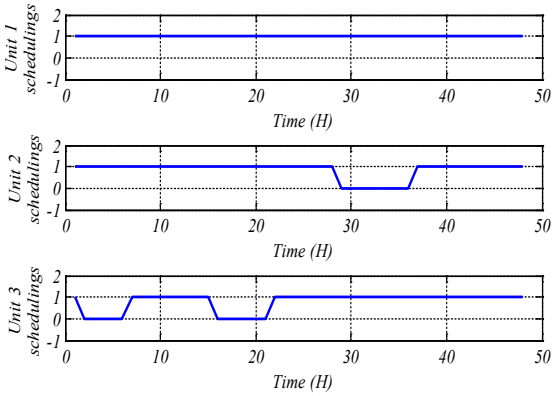

Figure 5. Optimal binary combination of units operation through hybrid TS-PSO-LR method

strategy. The third production unit undergoes Off status according to the production requirement and according to the power demand.

Furthermore, we confirm that our approach has allowed to select precisely the production units that should be available to respond to the load demand of the electrical network over a future period.

In addition, the adopted approach was promising both in terms of convergence to get the best optimal solutions to minimize the production cost and for an efficient unit commitment scheduling for the different production units, figure 6. Our strategy differs from other evolutionary computing techniques in providing an acceptable solution within a relatively short time and is likely to lead the search towards the most promising solution area.

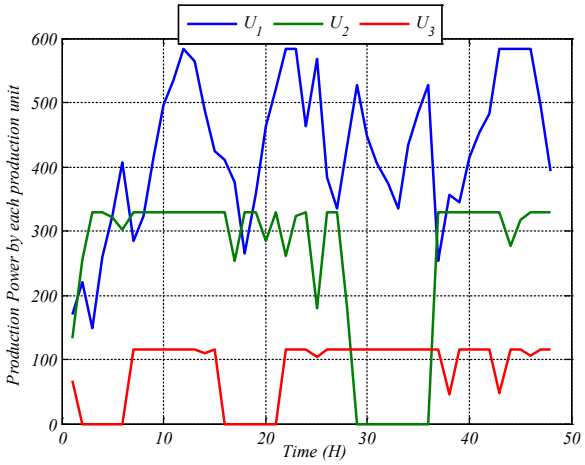

Figure 6. Generated Power by each production unit during 48 hours

6. Conclusion

This work shows the implementation of a new hybrid strategy which combines between Tabu Search, Particle Swarm Optimization and Lagrangian Relaxation. Herein, we have benefited from the rapidity of Lagrangian relaxation method, the storage solution with the memory of Tabu Search method and the flexibility to find optimal solution given by the Particle Swarm Optimization method. The proposed strategy TS-PSO-LR has presented high performances in optimizing the production cost and a capability of convergence to a global optimum as quick as possible compared to meta-heuristic (PSO, TS) and deterministic (LR) methods. In addition, the proposed strategy has ensured a proper unit commitment scheduling leading to get a minimal production cost. The right choice of the initial population suggests the possibility to obtain improvements in execution time. In addition, our strategy provides a fast enough time to converge to the optimal solution; which demonstrates the effectiveness of the adopted strategy compared to that obtained by Lagrangian Relaxation method and Particle swarm optimization methods.

ABSTRACT

To avoid biopsies, doctors use non invasive medical techniques such as the computed tomography. Even that, the detection of the liver remains a big challenge because of the gray level and shape variations which depend on patients and acquisition modalites. In this work, we propose to create a 3D liver model in the training phase of 3D active shape model algorithm. This training model will be deformed according to any given 3D data for liver segmentation. The contribution of our work is the use of the Non-rigid registration with a B-spline registration on the training phase. We tested our method on an open access database ("3D-IRCADb") and on our database obtained from the radiology department of the National Oncology Institute of Tunis. Both data-sets showed the reliability of the method with an accuracy equal to 69.98% and 71.18% respectively for our database and "3D-IRCADb".

1 Introduction

Computed Tomography (CT) is a non invasive technique with a large field of view. It helps doctors to detect some hepatic disease. First, they identify the liver from the abdominal CT slice using two phases of enhancement: portal and arterial. In each time of enhancement, the gray level of the liver changes. In this work, we propose a 3D method to extract the liver from the CT slice according to its shape. We use different 3D CT exam with different phases of enhancement containing normal and pathological cases. The aim of our work is to use an advanced technique of segmentation to extract liver from images of any type of modality. For that reason, we propose to use the Active Shape Model (ASM). The ASM have been recognized as robust solution for a supervised technique of segmentation. Our contribution is to improve the performance of the 3D ASM algorithm with a pre-processing phase using a non rigid registration based on B-Spline transformation. The following paper is an extension of work originally presented in the 7th International Conference on Sciences of Electronics, Technologies of Information Telecommunication" [1]. In this work, we improve the evaluation of results using the ROC-Curve analysis and we ensure the reliability of our method using our database in addition to the "3D-IRCADb". Also, we compare the results not only with the Isosurfaces also with the Marching Cubes 3D reconstruction. The paper is organized as follow: Section 2 presents some literature related works. In section 3, we explain the 3D-ASM method and its different steps for 3D-model construction. the proposed method is applied on the open access database "3D-IRCADb" and our database. In section 4, we use the ROC-Curve analysis to evaluate the 3D liver modeling. First, we compare our 3D model with the Isosurfaces 3D reconstruction, then, with the Marching Cubes technique. Finally, we resume our proposed method and the obtained results on the conclusion.

2 Related works

The major point of interest of the Computed-aided diagnostic system is to solve difficulties of the medical field. The segmentation technique is the most important step in those system. It allows the physicians to extract the region of interest and to analyze it for more helpful medical information. In this con-

https://dx.doi.org/10.25046/aj030145

text, many techniques of segmentation have been developed such as morphological operations exposed on the work of Pham The Bao et al.[2]to extract the liver from the volumetric CT images. In [3], they improved morphological operator algorithm by using the watershed technique to segment the micro-tomographic trabecular bone. The watershed algorithm is widely used to identify the region of interest. In [4],P. Rodrigues et al. used it with an open software "Mevislab" to extract the liver from the CT exam with a 87% of accuracy. In [5], the author used the Fisher algorithm to improve the watershed algorithm for the radar images segmentation. Moreover, there are some intensity based techniques which detect the object according to the intensity repartition. In [6], the author constructed a model of the intensity distribution for the surface of the liver, cysts and lesions. Then, they calculated the probability of pixel belonging to each classification of different regions. In [7], Alom et al. used the "SGM growing slice method", an algorithm for 3D segmentation of the liver. Also, we note that algorithms of classification are used to segment the liver. For example, in the work [8], authors made a new texture feature extraction to improve liver classification using K-mean algorithm. While, in [9], the author used the "Support Vector Machine" algorithm and the surface distance maps for 3D-liver segmentation from CT-scans. Previously exposed works are based on the intensity of the liver and its gray level. In order to improve the segmentation technique, we propose a 3D-supervised-method for liver segmentation to overcome problems of gray level variation.

3 Methods and materials

In this section, we will explain the use of the shape context based on non-rigid surface registration with a B-Spline transformation in order to adapt the Active Shape Model for 3D CT liver segmentation. We start by a global description of the proposed method. Then, we detail each step. Figure 1 describes the different steps of our work to segment 3D CT liver. First, we note that the cases of the two databases are acquired with different parameters. So each exam has different number of slices, resolution and voxel size. To create the 3D model of the liver using the 3D ASM, we must uniform the volumetric data in the pre-processing phase. Several works combine different registration algorithm with a 3D segmentation method to extract a volumetric data such as to segment the left ventricle in [10] and the mandibular canal in [11]. In our work we propose to use a non-rigid registration with a B-Spline transformation. After the pre-processing phase, the 3D CT-scan has the same size of the matrix of vertices and the matrix of faces. Those two matrix will be used on the training phase of the 3D-ASM. Finally, we create the 3D liver model in the testing phase of the 3D-ASM.

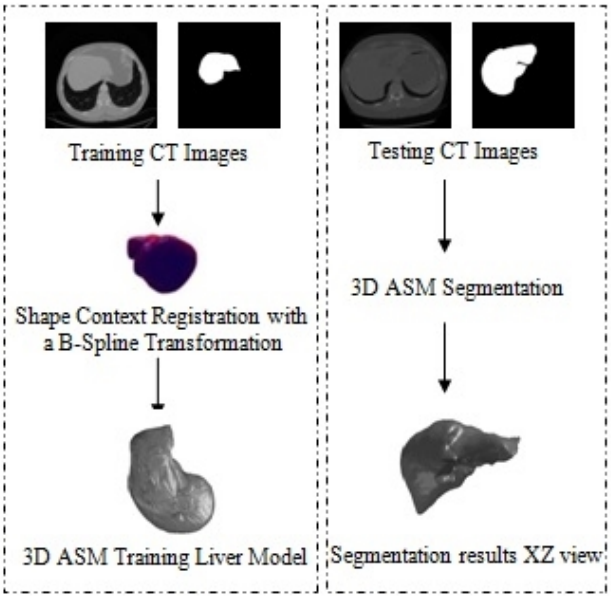

Figure 1: Diagram of the main work for 3D-ASM Liver segmentation

3.1 3D pre-processing CT-data

The CT-Scan measure the attenuation of the X-ray crossing the organ. These measurements are taken from different angles to produce a cross-sectional image called also slice separate with a thickness value. The total number of slices makes a volume information of the explored organ. However, doing the CT-Scan exam allows doctor to see details of the scanned organ in multi-planes (Coronal, axial and transverse). The obtained CT image is a matrix composed in pixels. Considering the the thickness between slices, each pixel represents a small volume element called also voxel. Its size depends on the matrix size, the thickness and the field of view. The CT images will be next stored as a numeric image. We note that the CT-images are coded according to thee Hounsfield units (UH) expressed by equation 1:

$$HU = \frac{\mu_{tissu} - \mu_{watter}}{\mu_{watter}} \quad (1)$$

In our work,we first change the UH to a gray level scaling using the DICOM header. We can define the gray value of a pixel as follow in equation (2):

$$Graylevel = \frac{UH \pm RescaleIntercept}{RescaleSlope} \quad (2)$$

where: The rescale intercept is equal to 0 for the IRCADb database and −1024 for our database; The rescale slope is equal to 1 for the both databases.
After changing the UH to the gray level scale, we uniform the slice number of the training data so all the training exams will have the same number of slices. We add a black slice at the end of the CT exam to reach the desired number. Then, we start the pre-processing step to achieve the same matrix size of

faces and vertices to all the training 3D data using the Shape Context Correspondence Point Model algorithm. It is based on a registration method. We can classify the registration into two classes: rigid and non-rigid transformation [12–14]. In our work, we employ a diffeomorphic B-Spline cubic transformation for no-rigid registration. We note : "C_1" a contour of an object 1 and "p_i" the number of points selected to define the contour; "C_2" a contour of an object 2 and "q_j" the number of points selected to define this contour. Then, we measure the cost function "C"between the two objects. It is defined in (3) as follow:

$$C(p_i, q_j) = \frac{1}{2} \sum_{k=1}^{k} \frac{[h_i(k) - h_j(k)]^2}{[h_i(k) + h_j(k)]} \quad (3)$$

With: h_i and h_j respectively histograms of the two shapes. After calculating the cost function, we minimize it to increase the degree of the similarity and the matching between the two shapes. To minimize the cost function, we choose a type of transformation in the registration phase. The type of transformation depends on the feature to be extracted from the object [15, 16], such as the match point algorithm[17], the 3D coordinate[18]and the intensity transformation using an iterative closet point algorithm [19, 20]. Figure 2 shows the different steps of the pre-processing phase. The first step of the registration phase using the Shape Context algorithm is to define the type of the transformation. In this work, we use the B-Spline cubic transformation. Then, we choose the mastery data which have the biggest number of slice and a floating data. This transformation is based on the surface matching with a spatial alignment of the two volumetric CT data. As an output of this phase, the CT exam will have the same size of vertices and faces matrix in order to be used on the next stage which is the 3D-ASM.

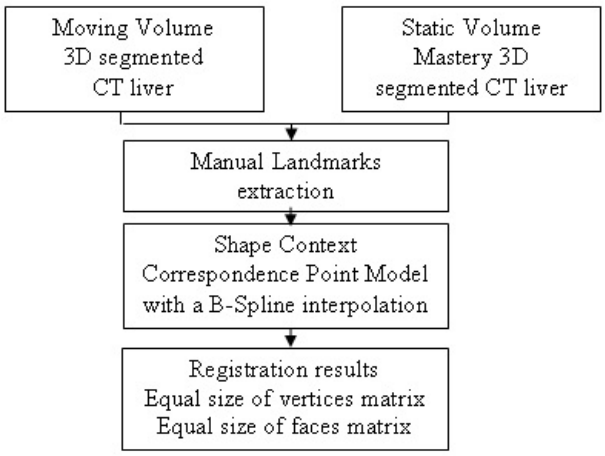

Figure 2: Pre-processing phase using Shape Correspondence Point Model

3.2 3D Active Shape Model

The 3D-ASM is an iterative supervised segmentation algorithm firstly proposed in [21] in 2002. It contains two phases: training and testing. Thanks to this algorithm based on the distribution point model (PDM) [22], we train our system to learn different liver shape variations. The input data in the training phase are 3D surface matrix containing the faces, the vertices of the 3D mesh and the binary volume of the extracted liver from the CT slice. At the beginning, we define for an object "O" a set of target point called landmark "n". The "n" points reform a vector of shape noted $X = (x, x_2, ..., x_n, y_1, y_2, ..., y_n, z_1, z_2, ..., z_n)^T$. After the identification of vector shape, we calculate from the 3D input data the covariance matrix. Then, we use the principal analyze components (PCA)[23]to identify the eigen-vectors"'x_i and their eigen-values. The PCA allows us to calculate the mean shape and its variations. Finally, we apply the PDM algorithm to create our training shape model noted $\tilde{X}$ in (4).

$$\tilde{X} = \bar{X} + \phi_s b_s \quad (4)$$

With: $\bar{X}$: aligned training shape; b_s:shape parameter vector of the shape. It is equal to $b_s = \pm m \sqrt{\lambda_i}$; $m \leq 3$; ϕ_s: eigenvectors corresponding to the eigenvalue of the covariance matrix. The next step in the 3D-ASM algorithm is to update the training model using the Mahalanobis distance[24]. Then, we apply the training deformed model to create our 3D liver model according to a given CT-data without doing a registration step.

4 Results and discussion

In this section, we start by a description of the databases used in this work and we present the obtained results. In order to evaluate the accuracy of our 3D liver modeling, we use the ROC-Curve analysis.

4.1 Description of databases

The proposed method was tested on two databases: our database (15 CT-exams) and the "3D-IRCADb" one (20 CT-exams). In [25], twenty radiologists expert describe the different parameters of the 3D IRCADb database. We found that the voxel size is various from one case to another from $0.57cm^3$ to $1.6cm^3$. Also in our database acquired at the radiology department of National oncology Institute "Salah AZAIEZ" of Tunis, the voxel size varies from 1.25cm*1.25cm*1.25cm to 1.4cm*1.4cm*1.4cm. For more efficiency, we use for the training phase, the 3D CT-scans with the same voxel size. In this work,for each database, we use the 80% of the CT-scan data having the same slice thickness for the training phase and 20% of 3D CT-scan for the testing phase.

4.2 Experiments

This study presents the use of the 3D-ASM for CT liver segmentation. For the beginning, we make a registration phase to recover some parameters such as rotation, scaling and translation in order to minimize the dissimilarity between two 3D CT-data. Figure 3 shows 3D mesh of the diffeomorphic B-Spline cubic registration. After the Shape Context registration, the output of this stage is used as input of the training phase of 3D-ASM algorithm. Different results of the 3D training shape are exposed in Figure 4.

Figure 3: 3D liver mesh of the B-Spline registration

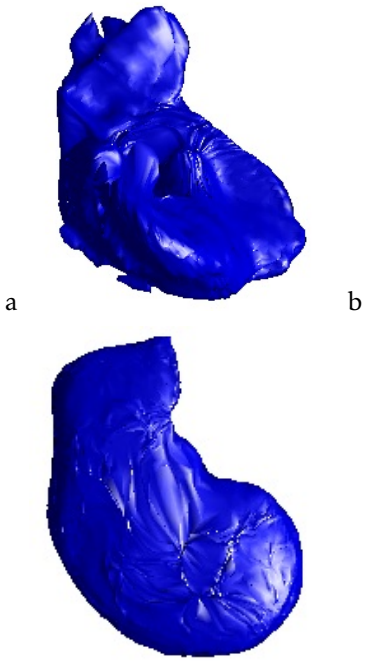

Figure 4: Training 3D model:a.Case from our database; b.Case from 3D-IRCADb database

To establish the proposed work, we use for the training phase of the 3D-ASM the cases which have the same thickness between slices and total number of slice. Then, we handle the corresponding Shape Context Points Model with a B-Spline transformation to create the same size of a 3D Liver grid. After the preprocessing step, we apply the 3D-ASM algorithm. To evaluate, in this work, the obtained results, we make a 3D reconstruction of the liver using the Isosurfaces and the Marching Cubes method.Then we compare them with the 3D-ASM of the liver. Figure 5 and figure 6 show different views of the 3D liver shape obtained from our database and the "3D-IRCADb" open access database.

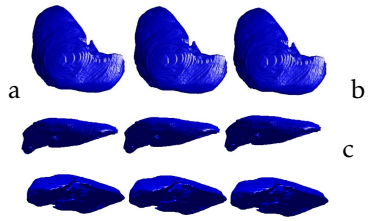

Figure 5: 3D liver segmentation of cases from "3D-IRCADb" database using respectively from the left to the right: the Isosurfaces, the Marching Cubes and the proposed method: a.XY view; b.XZ view; c.YZ view

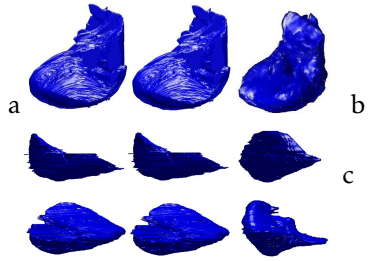

Figure 6: 3D liver segmentation of cases from our database using respectively from the left to the right: the isosurfaces, the Marching Cubes and the proposed method: a.XY view; b.XZ view; c.YZ view

After visual comparison, we use five parameters essentially used on ROC-curves analysis widely used in evaluation on the medical field [26]. These parameters are: sensitivity (SN), specificity (SP), accuracy (ACC), positive predicted value (PPV), negative predicted value (NPV) and area under the curve (AUC). We note the V_s is the segmented volume and V_{GT} the ground truth one. We define the True Positive(TP) as the degree of matching between the 3D mesh of V_s and the V_{GT} expressed in(5).

$$TP = V_s \cap V_{GT} \tag{5}$$

Its complement called False Negative (FN) is defined in (6).

$$FN = V_{GT} - TP \tag{6}$$

Moreover, we define the True Negative (TN) when we found a similarity on the false information. It is given in (7).

$$TN = 1 - (V_s \cup V_{GT}) \tag{7}$$

The False Positive (FP) is when our system detect a falsse mesh similiarity when there is no resemblance. It is given in (8).

$$FP = V_s - TP \tag{8}$$

According to those parameters, we calculate the sensitivity given in (9), the specificity given in (10) and the accuracy given in (11).

$$Sensitivity = \frac{TP}{TP+FN} \tag{9}$$

$$Specificity = \frac{TN}{TN+FP} \tag{10}$$

$$Accuraccy = \frac{TN+TP}{TN+TP+FN+FP} \tag{11}$$

We expose in tables 1 and 2 the different obtained values of the previously defined parameters. In this work, for each database, the liver was segmented by experts. So, we make a 3D reconstruction of these segmented volume using Isosurfaces and Marching Cubes techniques. Then, we apply the ROC-Curve independently. In the first hand, we apply it between our 3D results and 3D isosurfaces. On the second hand, we extract the different measure of the ROC-Curve between our 3D results and the Marching Cubes reconstruction.

	Our database	3D-IRCADb
Sensitivity (%)	68.38	63.8
Specificity (%)	71.57	59.36
PPV(%)	69.88	60.23
NPV (%)	70.85	59.52
Accuracy (%)	69.98	59.51
AUC	0.74	0.63

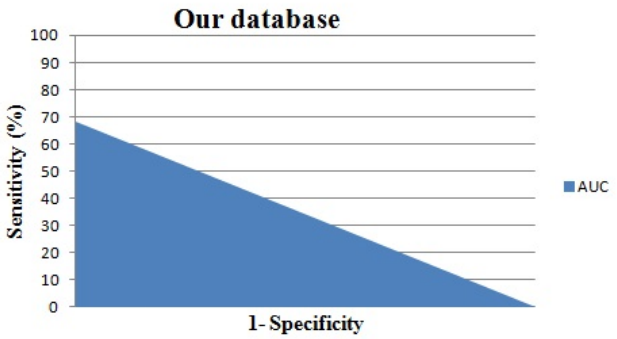

Table 1: Performances of the 3D-ASM with a B-spline registration versus the Isosurfaces reconstruction

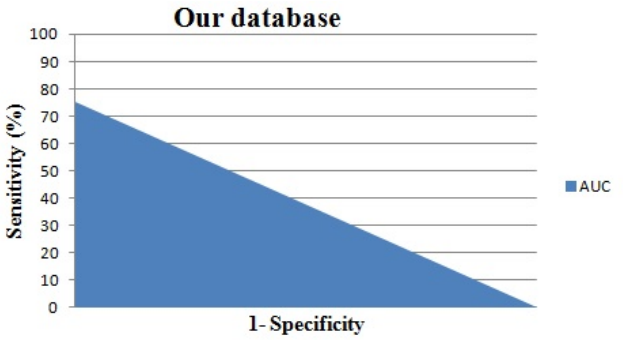
	Our database	3D-IRCADb
Sensitivity (%)	75.16	50.06
Specificity (%)	65.93	49.94
PPV(%)	69.16	50.07
NPV (%)	72.33	50.76
Accuracy (%)	70.44	50.07
AUC	0.74	0.49

Table 2: Performances of the 3D-ASM with a B-spline registration versus the Marching Cubes reconstruction

Comparaing to the Isosurfaces and Marching Cubes methods, the 3D-ASM based on the Shape Context registration with a B-Spline registration achieve about 70% of accuracy and 71,57% of specificity. Those promising results, ensure the efficiency of the proposed method based on a non-rigid registration for the pre-processing phase. We found that we achieve better results with our database.

(a)

(b)



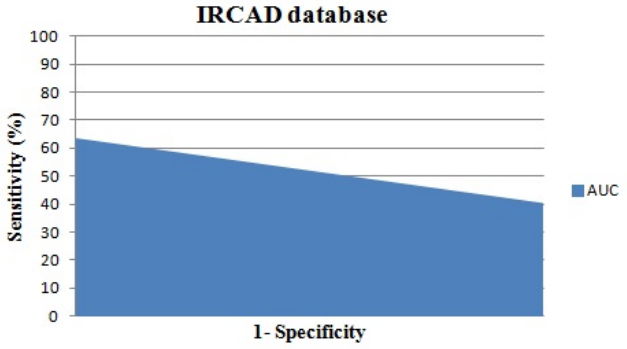


Figure 7: The area under the curve for cases from our database: a.versus Isosurfaces; b.versus Marching Cubes

(a)

(b)

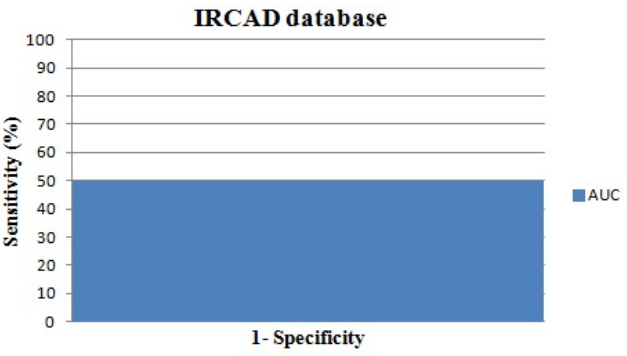

Figure 8: The area under the curve for cases from "3D-IRCADb"database: a.versus Isosurfaces; b.versus Marching Cubes

Our database contains pathological and normal cases. We used the normal cases for the training phase and we test the proposed method on pathological and normal cases. In fact, the 3D Active Shape Model is an advanced technique of 3D segmentation based on the shape. In this study, we prefer to use normals case with shape variation in order to create an efficient 3D learning model which will be deformed according to a given 3D CT-Scan exam. The inconvenient of the use of the pathological cases in the training phase is the no accurate liver shape since we can found one or several parts of the liver have been removed. The "3D-IRCADb" contains pathological cases without ablation which can be convincing for our study. To evaluate the efficiency of our proposed method using the "3D-IRCADb" database, we compare the 3D liver mesh obtained using our proposed method , the Isosurfaces and the Marching Cubes 3D reconstruction with the VTK files. The different results are exposed in the table 3. We found almost the same measure off the Area under the curve, presented in figure 9, but we achieve a slight improvement in terms of accuracy using the 3D Active Shape Model with a B-spline registration comparing to the Isosurfaces (Iso) and the Marching Cubes (MC).

	MC	Iso	Proposed Method
Sensitivity (%)	65.782	65.758	65.765
Specificity (%)	75.392	75.492	75.494
Accuracy (%)	70.629	70.648	71.182
PPV (%)	72.973	73.052	73.053
NPV (%)	68.775	68.744	68.736
AUC	0.757	0.756	0.751

5 Conclusion

In this work, we used the Active shape Modeling for 3D CT-liver segmentation. In order to well create our model, we used in the pre-processing phase the Shape Context Corresponding Point Model with a B-Spline cubic interpolation. Evaluation of the proposed method has been performed by using 20 CT-exams from the "3D IRCADb"'database and 15 CT-exams from our database. We acheive a good results for 3D liver segmentation with a 70% of accuracy. Results obtained using our database are better than those obtained with the open access database "3D-IRCADb". This is due to the fact that the "3D-IRCADb" database is composed only by pathological cases contrariwise to our database which is composed by normal and pathological cases. As a conclusion, it would be better to use only normal cases or a much bigger number of normal cases than pathological cases to build a good training model. The proposed method brings to the doctors and the researchers, an approximate 3D model for normal liver cases. As a perspective, we attend to extract some feature from this 3D model for normal liver i order to detect liver pathologies according to the liver 3D mesh.

Conflict of Interest The authors declare no conflict of interest.

Bilinear system

ABSTRACT

This paper deals with the design of adaptive observer for a class of nonlinear systems with time delays. Within this work, we develop an adaptive observer for a bilinear time delay system, then we extend those results in the presence of Lipschitz nonlinear functions in the system's dynamics. In the stability analysis of the estimation errors, we combine a Linear Parameter Varying (LPV) approach in the presence of time delays with a polytopic approach. The obtained stability conditions are given in terms of the solvability of Linear Matrix Inequalities (LMIs) on the vertices of a convex polytope. Numerical examples are finally given to show the effectiveness and feasibility of our results.

1 Introduction

This paper is an extension of work originally presented at the 6th International Conference on Systems and Control and entitled *"Full order adaptive observer design for time delay bilinear system"* [1]

During the last decades, several theoretical results with interesting applications were focused on the design of observers for nonlinear systems [2], [3], [4], [5], [6], [7] [8], [9] (and references there in). Due to the difficulty of setting the nonlinear behaviour in a system's dynamics and the non availability of all the state vector component, the design of observer is a challenging and open problem.

Indeed, since the presence of time delay is often encountered in the industrial processes, it is necessary to integrate it in the system model for a best modelization of these systems. The presence of time delay should not be neglected, because it can affect the systems performances and may lead, in certain cases, to its instability [10]. For these reasons, this class of systems has been intensively studied in the literature [11], [12], [13], [14] and will be considered also in the present work.

Apart the presence of time delays in a nonlinear model, another difficulty may appear: the presence of some unknown parameters, which should be taken into account in order to make the model more accurate. Hence, we propose in this work to design an adaptive observer, which does not only estimate the state vector of a nonlinear time delay system, but also the unknown parameters which affect its dynamics. Thanks to its ability to handle some challenging applications such as in robust and fault tolerant control, the adaptive observer allows to cope with the lack of knowledge on the system's unknown parameters. Classically, an adaptive observer may provide a suitable estimation of the states and the unknown parameters under some appropriate excitation conditions [3]. There are two major approaches to design adaptive observer. The first approach is based on the elaboration of an adaptation law derived from the stability analysis of a state observer. The convergence of the unknown parameters can be ensured under some persistent excitation [15], [16], [17]. The second approach consists in designing a state observer for an augmented system, where the state dynamics model is augmented with the dynamics of its unknown pa-

rameters. [18], [19], [20], [21].

In this paper, we consider an adaptive observer design for a class of nonlinear time delay systems where the dynamics are nonlinear in the states and in the unknown parameters and contains some bilinear terms. The nonlinearities considered satisfied a Lipschitz condition. Here, the convergence of the adaptive observers is treated in a more tractable way and does not require to satisfy the persistent excitation condition as in [22], [23], [24] and contrary to many previous contributions. In a first time, an adaptive observer will be proposed in the absence of some nonlinearities. The considered system represents a time delay bilinear system affected by unknown parameters. The bilinear systems do appropriately model some physical processes than linear or nonlinear ones. Nevertheless, the fact of considering a bilinear model does not suffice, due to the presence of nonlinear behaviour which ought to be integrated. For that reason, we consider in a second time the presence of some additional Lipchitz nonlinear functions. It is necessary to study those results separately because the design of adaptive observer in the first case does not derive from the second one due to the presence of some unmeasured state variables in the nonlinear functions, which make the problem more conservative.

This paper is structured so that the statement of the problem and some useful formulas are presented in the section 2. Section 3 is devoted to the design of adaptive observer for a bilinear time delay system. This result is extended in section 4, by the addition of nonlinear Lipschitz functions in the delayed bilinear system dynamics. In section 5, a discussion of the obtained results is made by comparison with some previous ones. Finally, in section 6, the obtained results will be applied to numerical examples to show their effectiveness.

Notations. Throughout this paper, $\mathbb{R}^n$ denotes an n-dimentional Euclidean space, and $\|\cdot\|$ the associated Euclidean norm [25], where

$$\|x\| = \sqrt{x^T x}, \quad \forall x \in \mathbb{R}^n \tag{1}$$

and using expression (1), the following induced matrix norm given by

$$\|A\| = \max_{\|x\|\neq 0} \frac{\|Ax\|}{\|x\|} \tag{2}$$

is used in this paper where $A \in \mathbb{R}^{n\times m}$.
$(*)$ will denotes the transpose of the off-diagonal parts of a matrix.

2 Problem statement

In this work, a class of nonlinear time delay systems is investigated where the state space model is given by the following equation

$$\dot{x}(t) = A_0 x(t) + \sum_{i=1}^{m} A_i u_i x(t) + \ell(x,u) + A_{d_0} x(t-\tau_0) + \sum_{i=1}^{m} A_{d_i} u_i(t) x(t-\tau_i) + Bu(t) + Gg(x,u)\theta \tag{3a}$$

$$\dot{\theta} = 0 \tag{3b}$$

$$y = Cx(t) \tag{3c}$$

where $x \in \mathbb{R}^n$, $u \in \mathbb{R}^m$, $\theta \in \mathbb{R}^q$, $y \in \mathbb{R}^p$ are the states vector, the input control, the unknown parameters vector and the output vector, respectively. τ_i for $i = 0,\dots,m$ are known constants delays. The matrices: $A_i \in \mathbb{R}^{n\times n}$, $A_{d_i} \in \mathbb{R}^{n\times n}$, for $i = 0,\dots,m$, $B \in \mathbb{R}^{n\times m}$, $G \in \mathbb{R}^{n\times r}$ and $C \in \mathbb{R}^{p\times n}$ are known with constant values.
The following assumptions are given and will be used in the sequel

Assumption 1. *The input $u(t)$ is bounded such that $u(t) \in \mathcal{U} \subset \mathbb{R}^m$, where*

$$\mathcal{U} = \{u : t \to \mathbb{R}^m / \forall t \in \mathbb{R}^+, u_{i,min} \leq u_i(t) \leq u_{i,max}, \mu_{i,min} \leq \dot{u}_i(t) \leq \mu_{i,max}\} \tag{4}$$

Assumption 2. *The function $\ell(x,u) : \mathbb{R}^n \times \mathbb{R}^m \to \mathbb{R}^n$ is Lipschitz in x, $\forall u \in \mathcal{U}$, i.e there exists a positive scalar b_1 such that*

$$\|\ell(x,u) - \ell(x^*,u)\| \leq b_1 \|x - x^*\| \tag{5}$$

The function $g(x,u) : \mathbb{R}^n \times \mathbb{R}^m \to \mathbb{R}^{r\times q}$ is bounded $\forall x \in \mathbb{R}^n$ and $\forall u \in \mathcal{U}$, that is there exists a scalar b_g such that

$$\|g(x,u)\| \leq b_g$$

and is Lipschitz in x, $\forall u \in \mathcal{U}$, i.e there exists a positive scalar b_2 where

$$\|g(x,u) - g(x^*,u)\| \leq b_2 \|x - x^*\| \tag{6}$$

Assumption 3. *The unknown parameters are supposed to be bounded such that there exists a scalar $b_3 > 0$ verifying*

$$\|\theta\| \leq b_3$$

Since assumption 1 holds, we have put the inputs $u_i(t)$, for $i = 1,\dots,m$, and their derivatives in the same vector

$$\delta = \begin{bmatrix} \delta_1 \\ \vdots \\ \delta_m \\ \delta_{m+1} \\ \vdots \\ \delta_{2m}^T \end{bmatrix} = \begin{bmatrix} u_1 \\ \vdots \\ u_m \\ \dot{u}_1 \\ \vdots \\ \dot{u}_m \end{bmatrix} \tag{7}$$

one can see that the vector δ belongs to a convex polytope, described by

$$\mathcal{P} = [u_{1,\min}, u_{1,\max}] \times \dots \times [u_{m,\min}, u_{m,\max}] \times [\mu_{1,\min}, \mu_{1,\max}] \times \dots \times [\mu_{1,\min}, \mu_{1,\max}] \tag{8}$$

Let us note Φ the set of vertices of the convex polytope $\mathcal{P}$, where its cardinality is equal to 2^{2m}, and described by

$$\Phi = \{\sigma = [\phi_1,\dots,\phi_{2m}]^T \in \mathbb{R}^{2m} / \forall i \in [0,m], \phi_i \in \{u_{i,\min}, u_{i,\max}\} \text{ and } \forall i \in [m+1,2m], \phi_i \in \{\mu_{i,\min}, \mu_{i,\max}\}\} \tag{9}$$

In what follows, we point out the problem of the design of adaptive observer, which allows a simultaneous estimation of the states and the unknown parameters. As these observers are usually designed to be applied in robust and fault tolerant control, the add of the term $Gg(x,u)\theta$ in the system dynamics allows to model uncertainties affecting the system in the case of robust control, or may be used to model faults in the case of fault detection and isolation [18], [26], this term is more general than only the term $G\theta$ as considered in [1] and in the section 3 of the present work.

In a first time, we propose an adaptive observer for system (3) without considering the presence of the nonlinear Lipschitz functions, i.e $\ell(x,u) = 0$ and $g(x,u) = 1$. In a second time, a more general adaptive observer is proposed for the considered class of nonlinear time delay systems (3). The obtained results do not lead to the results of the section before (see the discussion in section 5), which justify the structure of this work.

Before starting the observer design, let us give some useful relations used in this paper. For $x \in \mathbb{R}^n$ and $y \in \mathbb{R}^n$, the following well known inequalities hold

$$2\|x\|\,\|y\| \leq \beta x x^T + \frac{1}{\beta} y y^T, \quad \forall \beta > 0 \tag{10}$$

$$xz^T + zx^T \leq cxx^T + \frac{1}{c} zz^T, \quad \forall c > 0 \tag{11}$$

3 Observer Design without Lipschitz nonlinearities

In this section, we consider system (3) without Lipschitz nonlinear functions, i.e. $\ell(x,u) = 0$ and $g(x,u) = 1$. Thus, an adaptive observer is proposed under the following form

$$\dot{\hat{x}}(t) = A_0\hat{x}(t) + \sum_{i=1}^{m} A_i u_i \hat{x}(t) + Bu(t) + A_{d_0}\hat{x}(t-\tau_0) + \sum_{i=1}^{m} A_{d_i} u_i(t)\hat{x}(t-\tau_i) + G\hat{\theta}(t) + L_x(y(t) - C\hat{x}(t)) \tag{12a}$$

$$\dot{\hat{\theta}}(t) = L_\theta(y(t) - C\hat{x}(t)) \tag{12b}$$

where $\hat{x}(t) \in \mathbb{R}^n$ and $\hat{\theta} \in \mathbb{R}^q$ are the estimated states vector and the estimated unknown parameters vector, respectively. $L_x \in \mathbb{R}^{n\times p}$ and $L_\theta \in \mathbb{R}^{q\times p}$ are the observer's gains to be determined.

As a full order observer, we propose this structure of the observer, since it is the most commonly used in the literature, and had shown performance results. Within this observer, only two observer gains have to be determined, contrary to the full order observer structure as proposed in [23], which may be cumbersome to compute, due to the number of matrices to be computed.

The estimation error has the following dynamics

$$\dot{e}(t) = H(u)e(t) + \sum_{i=0}^{m} H_{d_i} e(t-\tau_i) \tag{13}$$

where

$$e(t) = \begin{bmatrix} e_x(t) \\ e_\theta(t) \end{bmatrix} = \begin{bmatrix} x(t) - \hat{x}(t) \\ \theta(t) - \hat{\theta}(t) \end{bmatrix}$$

$$H(u) = \begin{bmatrix} \sum_{i=1}^{m} A_i u_i - L_x C & G \\ -L_\theta C & 0 \end{bmatrix} \tag{14}$$

$$H_{d_i}(u) = \begin{bmatrix} A_{d_i} u_i & 0 \\ 0 & 0 \end{bmatrix} \tag{15}$$

Notice that we considered $u_0(t) = 1$ for reasons of simplification. Then, system (12) is an adaptive observer for the delayed considered system described by (3) with $\ell(x,u) = 0$ and $g(x,u) = 1$, if and only if the estimation error system described by (13) is asymptotically stable. The stability of the estimation error $e(t)$ and the computation of the observer's gains L_x and L_θ are ensured via the following theorem.

Theorem 1. *Assume that assumption 1 holds. System* (12) *represents an adaptive observer to system* (3) *(with* $\ell(x,u) = 0$ *and* $g(x,u) = 1$*), and the estimation errors system* (13) *is quadratically stable for* $\sigma^j \in \Phi$, $j = 1,\ldots,2^{2m}$, *if there exist matrices*

- $P(\sigma^j) \in \mathbb{R}^{(n+q)\times(n+q)}$ *where*

$$P(\sigma^j) = P^T(\sigma^j) = \sum_{i=0}^{m} \sigma_i^j \begin{bmatrix} P_{i1} & P_{i2} \\ P_{i2}^T & P_{i3} \end{bmatrix} > 0 \tag{16}$$

  $P_{i1} \in \mathbb{R}^{n\times n}$, $P_{i2} \in \mathbb{R}^{n\times q}$ *and* $P_{i2} \in \mathbb{R}^{q\times q}$, *for* $i = 0,\ldots,m$,

- $M \in \mathbb{R}^{(n+p)\times(n+p)}$, *given by*

$$M = \begin{bmatrix} M_{11} & S_2 M_{22} \\ S_1 M_{11} & M_{22} \end{bmatrix} \tag{17}$$

  where $M_{11} \in \mathbb{R}^{n\times n}$ *and* $M_{22} \in \mathbb{R}^{q\times q}$ *are nonsingular matrices.* $S_1 \in \mathbb{R}^{q\times n}$ *and* $S_2 \in \mathbb{R}^{n\times q}$ *are some tuning matrices.*

- $Y_1 \in \mathbb{R}^{n\times p}$ *and* $Y_2 \in \mathbb{R}^{q\times p}$

and a positive scalar γ, *such that the following LMIs holds*

$$\begin{bmatrix} \alpha^j_{(1,1)} & \alpha^j_{(1,2)} & \alpha^j_{(1,3)} & \alpha^j_{(1,4)} & \alpha^j_{(1,5)} \\ * & \alpha^j_{(2,2)} & \alpha^j_{(2,3)} & \alpha^j_{(2,4)} & \alpha^j_{(2,5)} \\ * & * & \alpha_{(3,3)} & \alpha_{(3,4)} & \alpha^j_{(1,5)} \\ * & * & * & \alpha_{(4,4)} & \alpha^j_{(2,5)} \\ * & * & * & * & \frac{-1}{\gamma} I_k \end{bmatrix} < 0 \tag{18}$$

where

$$\alpha^j_{(1,1)} = \sum_{i=1}^{m} \sigma^j_{m+i} P_{i1} + \sum_{i=0}^{m} M_{11} A_i \sigma_i^j + \sum_{i=0}^{m} A_i^T M_{11}^T \sigma_i^j - Y_1 C - C^T Y_1^T - S_2 Y_2 C - C^T Y_2^T S_2^T + \sum_{i=0}^{m} M_{11} A_{d_i} \sigma_i^j + \sum_{i=0}^{m} A_{d_i}^T M_{11}^T \sigma_i^j \tag{19a}$$

$$\alpha^j_{(1,2)} = \sum_{i=1}^{m} \sigma^j_{m+i} P_{i2} + M_{11}G + \sum_{i=0}^{m} A_i^T \sigma_i^j M_{11}^T S_1^T + \sum_{i=0}^{m} A_{d_i}^T M_{11}^T S_1^T \sigma_i^j - C^T Y_2^T - C^T Y_1^T S_1^T \quad (19b)$$

$$\alpha^j_{(2,2)} = \sum_{i=1}^{m} \sigma^j_{m+i} P_{i3} + S_1 M_{11} G + G^T M_{11}^T S_1^T \quad (19c)$$

$$\alpha^j_{(1,3)} = \sum_{i=0}^{m} \sigma_i^j P_{i1} + \sum_{i=0}^{m} A_i^T M_{11}^T \sigma_i^j + \sum_{i=0}^{m} A_{d_i}^T M_{11}^T \sigma_i^j - M_{11} - C^T Y_1^T - C^T Y_2^T S_2^T \quad (19d)$$

$$\alpha^j_{(1,4)} = \sum_{i=0}^{m} \sigma_i^j P_{i2} - M_{12} + \sum_{i=0}^{m} A_i^T M_{11}^T S_1^T \sigma_i^j - C^T Y_1^T S_1^T - C^T Y_2^T + \sum_{i=1}^{m} A_{d_i}^T M_{11}^T S_1^T \sigma_i^j \quad (19e)$$

$$\alpha^j_{(2,3)} = \sum_{i=0}^{m} \sigma_i^j P_{i2}^T - S_1 M_{11} + G^T M_{11}^T \quad (19f)$$

$$\alpha^j_{(2,4)} = \sum_{i=0}^{m} \sigma_i^j P_{i3} - M_{22} + G^T M_{11}^T S_1^T \quad (19g)$$

$$\alpha_{(3,3)} = -M_{11} - M_{11}^T \quad (19h)$$

$$\alpha_{(4,4)} = -M_{22} - M_{22}^T \quad (19i)$$

$$\alpha_{(3,4)} = -S_2 M_{22} - M_{11}^T S_1^T \quad (19j)$$

$$\alpha^j_{(1,5)} = [M_{11}A_{d_0}\sigma_0^j, 0, M_{11}A_{d_1}\sigma_1^j, 0, \ldots, M_{11}A_{d_m}\sigma_m^j, 0] \quad (19k)$$

$$\alpha^j_{(2,5)} = [S_1 M_{11} A_{d_0}\sigma_0^j, 0, S_1 M_{11} A_{d_1}\sigma_1^j, 0, \ldots, S_1 M_{11} A_{d_m}\sigma_m^j, 0] \quad (19l)$$

The observer gains are expressed by

$$L_x = M_{11}^{-1} Y_1 \quad (20a)$$

$$L_\theta = M_{22}^{-1} Y_2 \quad (20b)$$

Proof. The proof of the theorem 1 will be developed into two steps:

- In a first step, we give the stability conditions using a Lyapunov Krasovskii approach for LPV time delay systems, which leads to the resolution of an inequality.
- In a second step, we compute the observers matrices and we transform the obtained inequality into LMIs, using a Polytopic approach.

First Step. Let us consider a Lyapunov Krasovskii function candidate with this form

$$V(e) = \begin{bmatrix} e \\ \dot{e} \end{bmatrix}^T F(u) E \begin{bmatrix} e \\ \dot{e} \end{bmatrix} + \frac{1}{\gamma} \sum_{i=0}^{m} \int_{-\tau_i}^{0} \int_{t}^{t+\beta} \dot{e}^T(s)\dot{e}(s) ds d\beta \quad (21)$$

where $F(u) = \begin{bmatrix} P(u) & M \\ 0 & M \end{bmatrix}$, with $P(u) \in \mathbb{R}^{(n+p)\times(n+p)}$, $P(u) = P(u)^T > 0$ and M is a matrix with a structure described by (17). $E = \begin{bmatrix} I_{(n+q)} & 0 \\ 0 & 0 \end{bmatrix}$ and γ is a positive scalar.

Let us note $\varepsilon(t) = \dot{e}(t)$, and we rewrite system (13) under a descriptor form as follows

$$\begin{bmatrix} I_{(n+q)} & 0 \\ 0 & 0 \end{bmatrix} \begin{bmatrix} \dot{e}(t) \\ \dot{\varepsilon}(t) \end{bmatrix} = \begin{bmatrix} 0 & I \\ H(u) + \sum_{i=0}^{m} H_{d_i} & -I \end{bmatrix} \begin{bmatrix} e(t) \\ \varepsilon(t) \end{bmatrix} + \sum_{i=0}^{m} \begin{bmatrix} 0 \\ H_{d_i} \end{bmatrix} \int_{t}^{t-\tau_i} \varepsilon(\kappa) d\kappa$$

Then, using the latter equation, we differentiate the Lyapunov function in t, which leads to

$$\dot{V}(t) = \begin{bmatrix} e(t) \\ \varepsilon(t) \end{bmatrix}^T \mathbb{H} \begin{bmatrix} e(t) \\ \varepsilon(t) \end{bmatrix} + \sum_{i=0}^{m} \beta_i(t) - \frac{1}{\gamma} \sum_{i=0}^{m} \int_{t}^{t-\tau_i} \dot{e}^T(s)\dot{e}(s) ds \quad (22)$$

where

$$\mathbb{H} = \begin{bmatrix} h_{(1,1)} & h_{(1,2)} \\ * & h_{(2,2)} \end{bmatrix} \quad (23)$$

with

$$h_{(1,1)} = \dot{P}(u) + MH(u) + H^T(u)M^T + \sum_{i=0}^{m} MH_{d_i} + \sum_{i=0}^{m} H_{d_i}^T M^T$$

$$h_{(1,2)} = P(u) - M + H^T(u)M^T + H_{d_i}^T M^T$$

$$h_{(2,2)} = -M - M^T$$

and

$$\beta_i(t) = \begin{bmatrix} e^T(t) & \dot{e}^T(t) \end{bmatrix} F(u) \begin{bmatrix} 0 \\ H_{d_i} \end{bmatrix} \int_{t}^{t-\tau_i} \dot{e}(s) ds + \int_{t}^{t-\tau_i} \dot{e}^T(s) ds \begin{bmatrix} 0 & H_{d_i}^T \end{bmatrix} F^T(u) \begin{bmatrix} e(t) \\ \dot{e}(t) \end{bmatrix} \quad (24)$$

Using inequality (11), we majorate β_i as follows

$$\beta_i(t) \le \gamma \begin{bmatrix} e^T(t) & \dot{e}^T(t) \end{bmatrix} F(u) \begin{bmatrix} 0 \\ H_{d_i}(u) \end{bmatrix} \begin{bmatrix} 0 \\ H_{d_i}(u) \end{bmatrix}^T F^T(u) \times \begin{bmatrix} e(t) \\ \dot{e}(t) \end{bmatrix} + \frac{1}{\gamma} \int_{t}^{t-\tau_i} \dot{e}^T(s)\dot{e}(s) ds \quad (25)$$

Replacing inequality (25) in the expression of the derivative of the Lyapunov function $V(e)$ described by (22), implies

$$\dot{V}(e) \le \begin{bmatrix} e(t) \\ \dot{e}(t) \end{bmatrix}^T \begin{bmatrix} \overline{h}_{(1,1)} & \overline{h}_{(1,2)} \\ * & \overline{h}_{(2,2)} \end{bmatrix} \begin{bmatrix} e(t) \\ \dot{e}(t) \end{bmatrix}$$

where

$$\overline{h}_{(1,1)} = \dot{P}(u) + MH(u) + H^T(u)M^T + \sum_{i=0}^{m} MH_{d_i} + \sum_{i=0}^{m} H_{d_i}^T M^T + \gamma \sum_{i=0}^{m} MH_{d_i} H_{d_i}^T M^T$$

$$\overline{h}_{(1,2)} = P(u) - M + H^T(u)M^T + H_{d_i}^T M^T + \gamma \sum_{i=0}^{m} MH_{d_i}H_{d_i}^T M^T$$

$$\overline{h}_{(2,2)} = -M - M^T + \gamma \sum_{i=0}^{m} MH_{d_i}H_{d_i}^T M^T$$

The negativity of the derivative of the Lyapunov-Krasovskii function is equivalent to the following inequality:

$$\begin{bmatrix} \overline{h}_{(1,1)} & \overline{h}_{(1,2)} \\ * & \overline{h}_{(2,2)} \end{bmatrix} < 0$$

Applying the Schur complement on the latter inequality allows to get the following inequality,

$$\begin{bmatrix} a_{(1,1)} & a_{(1,2)} & a_{(1,4)} \\ * & a_{(1,3)} & a_{(1,4)} \\ * & * & \frac{-1}{\gamma} I_k \end{bmatrix} < 0 \tag{26}$$

where

$$a_{(1,1)} = \dot{P}(u) + MH(u) + H^T(u)M^T + \sum_{i=0}^{m} MH_{d_i}(u) + \sum_{i=0}^{m} H_{d_i}^T(u)M^T$$

$$a_{(1,2)} = P(u) - M + H^T(u)M^T + \sum_{i=0}^{m} H_{d_i}^T M^T$$

$$a_{(1,3)} = -M - M^T$$

$$a_{(1,4)} = [MH_{d_0}(u), \ldots, MH_{d_m}(u)]$$

with $k = (m+1)(n+q)$.

Second step. Now, using the polytopic approach, we consider that assumption 1 holds and that the inputs and their derivatives belong to the convex polytope $\mathcal{P}$ defined by (8). Then, using the vector δ given by (7), we rewrite the system's matrices, the Lyapunov matrix and its derivative as follows

$$P(u) = P(\delta) = P_0 + \sum_{i=1}^{m} \delta_i P_i, \tag{27a}$$

$$\dot{P}(u) = \overline{P}(\delta) = \sum_{i=1}^{m} \delta_{m+i} P_i \tag{27b}$$

$$H(\delta) = \begin{bmatrix} \sum_{i=0}^{m} A_i \delta_i - L_x C & G \\ -L_\theta C & 0 \end{bmatrix} \tag{27c}$$

$$H_{d_i}(\delta) = \begin{bmatrix} A_{d_i}\delta_i & 0 \\ 0 & 0 \end{bmatrix} \tag{27d}$$

Then, we compute inequality (26) in the whole set of the vertices of the polytope Φ. By taking the matrices $P^j(\sigma_i)$ and M with the form (16) and (17) respectively, we obtain the results given in the proof, where the observer's gains are given by (20). □

Now, as discussed in the introductory section, we consider in the next section a more general class of systems with Lipschitz nonlinearities.

4 Observer Design with Lipschitz nonlinearities

In this section, the objective is to design an adaptive observer for system (3) with the following general structure in order to estimate simultaneously the states vector x and the unknown parameters θ. For that reason, the following adaptive observer is considered

$$\dot{\hat{x}}(t) = \left(A_0 + \sum_{i=1}^{m} A_i u_i\right)\hat{x}(t) + Bu(t) + \ell(\hat{x},u) + A_{d_0}\hat{x}(t-\tau_0) + \sum_{i=1}^{m} A_{d_i}u_i(t)\hat{x}(t-\tau_i) + Gg(\hat{x},u)\hat{\theta}(t) + L_x(y - C\hat{x})$$

$$\dot{\hat{\theta}} = L_\theta(y - C\hat{x}) \tag{28}$$

where $\hat{x} \in \mathbb{R}^n$ and $\hat{\theta} \in \mathbb{R}^q$ are the estimates of the states x and the unknown parameters θ respectively. $L_x \in \mathbb{R}^{n\times p}$ and $L_\theta \in \mathbb{R}^{q\times p}$ are the observer's gains.

The convergence analysis made in this section is different from the section above, due to the presence of the Lipschitz nonlinear functions $\ell(x,u)$ and $g(x,u)$.

In order to ensure the convergence of the proposed adaptive observer, we had to choose the gains L_x and L_θ which guarantee that the errors $e_x(t) = x(t) - \hat{x}(t)$ and $e_\theta = \theta - \hat{\theta}$, converge to zero, in other words, the estimated vectors $\hat{x}$ and $\hat{\theta}$ converge to their actual values. Thus, this section is devoted to obtain the stability conditions in term of LMI.

Let us give the dynamics of the estimation errors $e_x(t)$ and $e_\theta(t)$ as follows

$$\dot{e}_x(t) = \left(A_0 + \sum_{i=1}^{m} A_i u_i - L_x C\right)e_x(t) + (\ell(x,u) - \ell(\hat{x},u)) + A_{d_0}e_x(t-\tau_0) + \sum_{i=1}^{m} A_{d_i}u_i e_x(t-\tau_i) + G\left(g(x,u)\theta - g(\hat{x},u)\hat{\theta}\right) \tag{29a}$$

$$\dot{e}_\theta(t) = -L_\theta C e_x(t) \tag{29b}$$

After adding and subtracting the term $\rho G e_\theta(t)$ to equation (29a), where ρ is a positive scalar, we obtain the following augmented error system

$$\dot{e}(t) = H(u)e(t) + \sum_{i=0}^{m} H_{d_i}(u)e(t-\tau_i) + H_\ell + \overline{G}\,\overline{H}_g \tag{30}$$

where H_{d_i} is defined by (15) and

$$H(u) = \begin{bmatrix} \sum_{i=1}^{m} A_i u_i - L_x C & \rho G \\ -L_\theta C & 0 \end{bmatrix}$$

$$H_\ell = \begin{bmatrix} \ell(x,u) - \ell(\hat{x},u) \\ 0 \end{bmatrix}$$

$$\overline{H}_g = H_g - \begin{bmatrix} \rho e_\theta(t) \\ 0 \end{bmatrix}$$

$$H_g = \begin{bmatrix} g(x,u)\theta - g(\hat{x},u)\hat{\theta} \\ 0 \end{bmatrix}$$

$$\overline{G} = \begin{bmatrix} G & 0 \\ 0 & 0 \end{bmatrix}$$

with $u_0(t) = 1$.

The quadratic stability of the estimation error system is ensured via the following theorem

Theorem 2. *Assuming that assumptions 1, 2 and 3 hold. System* (28) *is an adaptive observer for system* (3)*, and the estimation error is quadratically stable for $\sigma^j \in \Phi$, if there exist matrices*

- $P(\sigma^j) \in \mathbb{R}^{(n+q)\times(n+q)}$ *where*

$$P(\sigma^j) = \sum_{i=0}^{m} \sigma_i^j \begin{bmatrix} P_{i1} & P_{i2} \\ P_{i2}^T & P_{i3} \end{bmatrix} > 0 \tag{31}$$

  $P_{i1} \in \mathbb{R}^{n\times n}$, $P_{i2} \in \mathbb{R}^{n\times q}$ *and* $P_{i2} \in \mathbb{R}^{q\times q}$, *for* $i = 0,\dots,m$,

- $M \in \mathbb{R}^{(n+p)\times(n+p)}$, *such that*

$$M = \begin{bmatrix} M_{11} & S_2 M_{22} \\ S_1 M_{11} & M_{22} \end{bmatrix} \tag{32}$$

  where $M_{11} \in \mathbb{R}^{n\times n}$ *and* $M_{22} \in \mathbb{R}^{q\times q}$. $S_1 \in \mathbb{R}^{q\times n}$ *and* $S_2 \in \mathbb{R}^{n\times q}$ *are some tuning matrices.*

- $Y_1 \in \mathbb{R}^{n\times p}$ *and* $Y_2 \in \mathbb{R}^{q\times p}$

and scalars $\rho > 0$, $c_1 > 0$, $c_2 > 0$ *and* $\gamma > 0$, *such that the LMIs* (33) *hold (see next page), for* $j = 1,\dots,2^{2m}$, *where the blocks* $\alpha^j_{(1,3)}$, $\alpha^j_{(1,4)}$, $\alpha^j_{(1,5)}$, $\alpha^j_{(2,5)}$, $\alpha_{(3,3)}$, $\alpha_{(3,4)}$ *and* $\alpha_{(4,4)}$ *are given by* (19d), (19e), (19k), (19l), (19h), (19j) *and* (19i), *respectively. The blocks* $\omega^j_{(1,1)}$, $\omega^j_{(1,2)}$, $\omega^j_{(2,2)}$, $\omega^j_{(2,3)}$, $\omega^j_{(2,4)}$, $\omega^j_{(1,5)}$, $\omega^j_{(1,6)}$, $\omega^j_{(2,5)}$ *and* $\omega^j_{(2,6)}$ *are as follows*

$$\begin{aligned}
\omega^j_{(1,1)} &= \sum_{i=1}^{m} \sigma_{m+i} P_{i1} + \sum_{i=0}^{m} M_{11} A_i \sigma_i + \sum_{i=0}^{m} A_i^T M_{11}^T \sigma_i \\
&\quad - Y_1 C - C^T Y_1^T - S_2 Y_2 C - C^T Y_2^T S_2^T \\
&\quad + \sum_{i=0}^{m} M_{11} A_{d_i} \sigma_i + \sum_{i=0}^{m} A_{d_i}^T M_{11}^T \sigma_i \\
&\quad + \frac{b_1^2}{c_1} I_n + 2\frac{b_2^2 b_3^2 + b_2 b_3 b_g}{c_2} I_n \\
\omega^j_{(1,2)} &= \sum_{i=1}^{m} \sigma^j_{m+i} P_{i2} + \rho M_{11} G + \sum_{i=0}^{m} A_i^T \sigma_i^j M_{11}^T S_1^T \\
&\quad + \sum_{i=0}^{m} A_{d_i}^T M_{11}^T S_1^T \sigma_i^j - C^T Y_2^T - C^T Y_1^T S_1^T \\
\omega^j_{(2,2)} &= \sum_{i=1}^{m} \sigma_{m+i} P_{i3} + \rho S_1 M_{11} G + G^T M_{11}^T S_1^T \\
&\quad + 2\frac{b_g^2 + b_2 b_3 b_g + \rho^2}{c_2} I_q \\
\omega^j_{(2,3)} &= \sum_{i=0}^{m} \sigma_i^j P_{i2}^T - S_1 M_{11} + \rho G^T M_{11}^T \\
\omega^j_{(2,4)} &= \sum_{i=0}^{m} \sigma_i^j P_{i3} - M_{22} + \rho G^T M_{11}^T S_1^T
\end{aligned}$$

$$\begin{bmatrix} \omega^j_{(1,5)} & \omega^j_{(1,6)} \\ \omega^j_{(2,5)} & \omega^j_{(2,6)} \end{bmatrix} = P(\sigma^j)$$

The observer gains are expressed by

$$L_x = M_{11}^{-1} Y_1 \tag{34a}$$

$$L_\theta = M_{22}^{-1} Y_2 \tag{34b}$$

Proof. We rewrite the error system described by (30) in a descriptor form as follows

$$\begin{aligned}
\begin{bmatrix} I & 0 \\ 0 & 0 \end{bmatrix} \begin{bmatrix} \dot{e}(t) \\ \dot{\varepsilon}(t) \end{bmatrix} &= \begin{bmatrix} 0 & I \\ H(u) + \sum_{i=0}^{m} H_{d_i} & -I \end{bmatrix} \begin{bmatrix} e(t) \\ \varepsilon(t) \end{bmatrix} \\
&\quad + \sum_{i=0}^{m} \begin{bmatrix} 0 \\ H_{d_i} \end{bmatrix} \int_t^{t-\tau_i} \varepsilon(k)dk + \begin{bmatrix} 0 \\ H_\ell \end{bmatrix} + \begin{bmatrix} 0 \\ \overline{G}\overline{H}_g \end{bmatrix}
\end{aligned} \tag{35}$$

in order to put it in the Lyapunov function candidate $V(e)$, which will be chosen as in the first part, under the form (21). A computation of the derivative of the Lyapunov function $V(e)$ yields to

$$\begin{aligned}
\dot{V}(e) &= \begin{bmatrix} e(t) \\ \varepsilon(t) \end{bmatrix}^T \begin{bmatrix} \overline{W}_{(1,1)} & W_{(1,2)} \\ * & -M - M^T \end{bmatrix} \begin{bmatrix} e(t) \\ \varepsilon(t) \end{bmatrix} + \sum_{i=0}^{m} \beta_i(t) \\
&\quad + \alpha_1(e) + \alpha_2(e) - \frac{1}{\gamma} \sum_{i=0}^{m} \int_t^{t-\tau_i} \dot{e}^T(s)\dot{e}(s)ds
\end{aligned}$$

where $\beta_i(t)$ is defined by (24) and

$$\begin{aligned}
\overline{W}_{(1,1)} &= \dot{P}(u) + MH(u) + \sum_{i=0}^{m} MH_{d_i}(u) + H^T(u)M^T \\
&\quad + \sum_{i=0}^{m} H_{d_i}^T(u) M^T
\end{aligned} \tag{36a}$$

$$W_{(1,2)} = P(u) - M + H^T(u)M^T + \sum_{i=0}^{m} H_{d_i}^T M^T \tag{36b}$$

$$\alpha_1(e) = \begin{bmatrix} e \\ \varepsilon \end{bmatrix}^T F(u) \begin{bmatrix} 0 \\ H_\ell \end{bmatrix} + \begin{bmatrix} 0 \\ H_\ell \end{bmatrix}^T F^T(u) \begin{bmatrix} e \\ \varepsilon \end{bmatrix} \tag{36c}$$

$$\alpha_2(e) = \begin{bmatrix} e \\ \varepsilon \end{bmatrix}^T F(u) \begin{bmatrix} 0 \\ \overline{G}\overline{H}_g \end{bmatrix} + \begin{bmatrix} 0 \\ (\overline{G}\overline{H}_g) \end{bmatrix}^T F^T(u) \begin{bmatrix} e \\ \varepsilon \end{bmatrix} \tag{36d}$$

However, to give an upper bound to the derivative of the Lyapounov function, we had to give an upper bound to some terms. For the term $\beta_i(t)$, an upper bound was given by the inequality (25). So, we proceed, in the sequel, by giving an upper bound to the terms $\alpha_1(e)$ and $\alpha_2(e)$.

Using inequality (11), $\alpha_1(e)$ can be upper bounded as follows

$$\begin{aligned}
\alpha_1(e) &\le \frac{1}{c_1} \begin{bmatrix} 0 \\ H_\ell \end{bmatrix}^T \begin{bmatrix} 0 \\ H_\ell \end{bmatrix} + c_1 \begin{bmatrix} e \\ \varepsilon \end{bmatrix}^T F(u)F^T(u) \begin{bmatrix} e \\ \varepsilon \end{bmatrix} \\
&= \frac{1}{c_1} H_\ell^T H_\ell + c_1 \begin{bmatrix} e \\ \varepsilon \end{bmatrix}^T F(u)F^T(u) \begin{bmatrix} e \\ \varepsilon \end{bmatrix}
\end{aligned}$$

However the product $H_\ell^T H_\ell$ can be majorated by the following expression using (1) and (5)

$$\begin{aligned}
H_\ell^T H_\ell &= [\ell(x,u) - \ell(\hat{x},u)]^T [\ell(x,u) - \ell(\hat{x},u)] \\
&\le b_1^2 e_x^T(t) e_x(t)
\end{aligned}$$

$$\begin{bmatrix}
\omega^j_{(1,1)} & \omega^j_{(1,2)} & \alpha^j_{(1,3)} & \alpha^j_{(1,4)} & \omega^j_{(1,5)} & \omega^j_{(1,6)} & M_{11} & S_2M_{22} & 0 & M_{11}G & 0 & \alpha^j_{(1,5)} \\
* & \omega^j_{(2,2)} & \omega^j_{(2,3)} & \omega^j_{(2,4)} & \omega^j_{(2,5)} & \omega^j_{(2,6)} & S_1M_{11} & M_{22} & 0 & S_1M_{11}G & 0 & \alpha^j_{(2,5)} \\
* & * & \alpha_{(3,3)} & \alpha_{(3,4)} & 0 & 0 & M_{11} & S_2M_{22} & 0 & M_{11}G & 0 & \alpha^j_{(1,5)} \\
* & * & * & \alpha_{(4,4)} & 0 & 0 & S_1M_{11} & M_{22} & 0 & S_1M_{11}G & 0 & \alpha^j_{(2,5)} \\
* & * & * & * & \frac{-1}{c_1}I_n & 0 & \dots & & \dots & & \dots & 0 \\
* & * & * & * & * & \frac{-1}{c_1}I_q & 0 & \dots & & & \dots & 0 \\
* & * & * & * & * & * & \frac{-1}{c_1}I_n & 0 & \dots & & \dots & 0 \\
* & * & * & * & * & * & * & \frac{-1}{c_1}I_q & 0 & \dots & \dots & 0 \\
* & * & * & * & * & * & * & * & \frac{-1}{c_2}I_{n+q} & 0 & \dots & 0 \\
* & * & * & * & * & * & * & * & * & \frac{-1}{c_2}I_n & 0 & 0 \\
* & * & * & * & * & * & * & * & * & * & \frac{-1}{c_2}I_q & 0 \\
* & * & * & * & * & * & * & * & * & * & * & \frac{-1}{\gamma}I_k
\end{bmatrix} < 0 \quad (33)$$

then,

$$\alpha_1(e) \le e^T(t)\mathbb{N}_1 e(t) + c_1 \begin{bmatrix} e \\ \varepsilon \end{bmatrix}^T F(u)F^T(u) \begin{bmatrix} e \\ \varepsilon \end{bmatrix} \quad (37)$$

where

$$\mathbb{N}_1 = \begin{bmatrix} \frac{b_1^2}{c_1}I_n & 0 \\ 0 & 0_{q\times q} \end{bmatrix} \quad (38)$$

We note $\overline{\overline{G}} = \begin{bmatrix} 0 & 0 \\ 0 & \overline{G} \end{bmatrix}$, and we give an upper bound to α_2 as follows:

$$\begin{aligned}
\alpha_2(e) &\le \frac{1}{c_2}\begin{bmatrix} 0 \\ \overline{H}_g \end{bmatrix}^T \begin{bmatrix} 0 \\ \overline{H}_g \end{bmatrix} + c_2 \begin{bmatrix} e \\ \varepsilon \end{bmatrix}^T F(u)\overline{\overline{G}}\,\overline{\overline{G}}^T F^T(u) \begin{bmatrix} e \\ \varepsilon \end{bmatrix} \\
&= \frac{1}{c_2}\overline{H}_g^T\overline{H}_g + c_2 \begin{bmatrix} e \\ \varepsilon \end{bmatrix}^T F(u)\overline{\overline{G}}\,\overline{\overline{G}}^T F^T(u) \begin{bmatrix} e \\ \varepsilon \end{bmatrix}
\end{aligned}$$

where

$$\overline{H}_g^T\overline{H}_g = \|\overline{H}_g\|^2 \le 2\left(\|H_g\|^2 + \rho^2 e_\theta^T(t)e_\theta(t)\right)$$

with

$$\begin{aligned}
H_g^T H_g &= \left(g(x,u)\theta - g(\hat{x},u)\hat{\theta}\right)^T \left(g(x,u)\theta - g(\hat{x},u)\hat{\theta}\right) \\
&\le \left((g(x,u)\theta - g(\hat{x},u)\theta) + \left(g(\hat{x},u)\theta - g(\hat{x},u)\hat{\theta}\right)\right)^T \\
&\times \left((g(x,u)\theta - g(\hat{x},u)\theta) + \left(g(\hat{x},u)\theta - g(\hat{x},u)\hat{\theta}\right)\right) \\
&\le b_2^2 b_3^2 e_x^T(t)e_x(t) + b_g^2 e_\theta^T(t)e_\theta \\
&+ b_2 b_3 b_g\left(\|e_x^T(t)\|\,\|e_\theta(t)\| + \|e_\theta^T(t)\|\,\|e_x(t)\|\right) \\
&\le b_2^2 b_3^2 e_x^T(t)e_x(t) + b_g^2 e_\theta^T(t)e_\theta \\
&+ b_2 b_3 b_g(e_x^T(t)e_x(t) + e_\theta^T(t)e_\theta)
\end{aligned}$$

The latter inequalities lead to

$$\alpha_2(e) \le 2e^T(t)\mathbb{N}_2 e(t) + c_2 \begin{bmatrix} e \\ \varepsilon \end{bmatrix}^T F(u)\overline{\overline{G}}\,\overline{\overline{G}}^T F^T(u) \begin{bmatrix} e \\ \varepsilon \end{bmatrix} \quad (39)$$

where

$$\mathbb{N}_2 = \begin{bmatrix} \frac{b_2^2 b_3^2 + b_2 b_3 b_g}{c_2}I_n & 0 \\ 0 & \frac{b_g^2 + b_2 b_3 b_g + \rho^2}{c_2}I_q \end{bmatrix} \quad (40)$$

Hence,

$$\begin{aligned}
\dot{V}(e) \le \begin{bmatrix} e \\ \varepsilon \end{bmatrix}^T \Bigg(&\begin{bmatrix} \overline{W}_{(1,1)} + \mathbb{N}_1 + 2\mathbb{N}_2 & W_{(1,2)} \\ * & -M - M^T \end{bmatrix} \\
&+ c_1 F(u)F^T(u) + c_2 F(u)\overline{\overline{G}}\,\overline{\overline{G}}^T F^T(u) \\
&+ \gamma \sum_{i=0}^{m} F(u) \begin{bmatrix} 0 \\ H_{d_i}(u) \end{bmatrix} \begin{bmatrix} 0 \\ H_{d_i}(u) \end{bmatrix}^T F^T(u) \Bigg) \begin{bmatrix} e \\ \varepsilon \end{bmatrix}
\end{aligned}$$

Applying the Schur complement on the latter inequality, leads to inequality (41) (see next page), where the block $W_{(1,1)}$ is described by

$$\begin{aligned}
W_{(1,1)} = \dot{P}(u) + MH(u) + H^T(u)M^T + \sum_{i=0}^{m} MH_{d_i}(u) \\
+ \sum_{i=0}^{m} H_{d_i}^T(u)M^T + \mathbb{N}_1 + 2\mathbb{N}_2
\end{aligned}$$

$W_{(1,2)}$, $\mathbb{N}_1$ and $\mathbb{N}_2$ are given by (36b), (38) and (40), respectively.

Finally, using notations (27) and the information on the inputs and their derivatives, we compute inequality (41), to extract the observer gains via LMIs, which completes the proof. □

5 Discussion

1. In the literature, two major approaches have been developed to tackle the design of adaptive observer. These approaches are essentially based on:

   (a) the elaboration of a parameter adaptation law. Here, the unknown parameter vector is deduced from the stability analysis of a state observer and the convergence property of the parameter error is obtained by a persistence of excitation type constraint. Many contributions deal with this approach as in [5], [15], [17], etc.

$$\begin{bmatrix} W_{(1,1)} & W_{(1,2)} & P(u) & M & 0 & M\overline{G} & MH_{d_0} & MH_{d_1} & \dots & MH_{d_m} \\ * & -M-M^T & 0 & M & 0 & M\overline{G} & MH_{d_0} & MH_{d_1} & \dots & MH_{d_m} \\ * & * & -c_1^{-1}I_{n+q} & 0 & 0 & 0 & 0 & 0 & \dots & 0 \\ * & * & * & -c_1^{-1}I_{n+q} & 0 & 0 & 0 & 0 & \dots & 0 \\ * & * & * & * & -(c_2)^{-1}I_{n+q} & 0 & 0 & 0 & \dots & 0 \\ * & * & * & * & * & -(c_2)^{-1}I_{n+q} & 0 & 0 & \dots & 0 \\ * & * & * & * & * & * & -\gamma^{-1}I_{n+q} & 0 & \dots & 0 \\ * & * & * & * & * & * & * & -\gamma^{-1}I_{n+q} & \ddots & \vdots \\ * & * & * & * & * & * & * & * & \ddots & 0 \\ * & * & * & * & * & * & * & * & * & -\gamma^{-1}I_{n+q} \end{bmatrix} < 0 \tag{41}$$

(b) an augmented system for which the adaptive observer design is elaborated. In this case, the system dynamics are augmented with the dynamics of its unknown parameters as in [20], [26], [27], [21].

In our work, the design of our adaptive observers are based on the approach described in item (b). However, those results are established by assuming a Lyapunov function where the derivative depends of both the state and parameters errors. So, the assumption of persistent excitation is not required in our work since the matrix appearing in the derivative of the Lyapunov function is not block diagonal, unlike in [15] where the boundedness of this derivative depends only of the state error terms.

2. The use of a descriptor approach and augmenting the estimation error system as done in the present work give more additional degrees of freedom to the problem resolution and allow to overcome the problem of the product between the Lyapunov matrix $P(u)$ and the system's dynamic matrix $H(u)$ (see [28]).

3. First, due to the form of the block diagonal terms $\alpha_{(3,3)}$ and $\alpha_{(4,4)}$ appearing in both LMIs (18) and LMIs (33), the matrices M_{11} and M_{22} should be nonsingular matrices to satisfy the LMIs constraints. Notice that adding and subtracting the term $\rho G e_\theta(t)$ from equation (29a) allow to have the matrix M_{11} in the term $\omega_{(2,2)}$ in the LMI (33) given in theorem 2.

   Second, the matrix M is chosen with the form given by (17) for the following reasons:

   (a) If the matrix M is chosen under the following form

   $$M = \begin{bmatrix} M_{11} & M_{12} \\ M_{21} & M_{22} \end{bmatrix}$$

   where $M_{11} \in \mathbb{R}^{n\times n}$ and $M_{22} \in \mathbb{R}^{q\times q}$, $M_{12} \in \mathbb{R}^{n\times q}$ and $M_{21} \in \mathbb{R}^{q\times n}$, we will come across the following problem

   $$\begin{bmatrix} Y_{11} \\ Y_{21} \end{bmatrix} = \begin{bmatrix} M_{11} \\ M_{21} \end{bmatrix} L_x$$

   $$\begin{bmatrix} Y_{12} \\ Y_{22} \end{bmatrix} = \begin{bmatrix} M_{12} \\ M_{22} \end{bmatrix} L_\theta$$

   Then, the existence of the observer's gains depends on the following rank conditions

   $$\operatorname{rank}\begin{bmatrix} M_{11} \\ M_{21} \end{bmatrix} = \operatorname{rank}\begin{bmatrix} M_{11} & Y_{11} \\ M_{21} & Y_{21} \end{bmatrix}$$
   $$\operatorname{rank}\begin{bmatrix} M_{12} \\ M_{22} \end{bmatrix} = \operatorname{rank}\begin{bmatrix} M_{12} & Y_{12} \\ M_{22} & Y_{22} \end{bmatrix}$$

   which add some non-convex constraints to satisfy in theorem 1 and 2.

   (b) Putting the matrix M with a diagonal form, i.e. $M_{12} = 0$ and $M_{21} = 0$, implies that the blocks $\alpha_{(2,2)}$ and $\omega_{(2,2)}$ in LMIs (18) and (33) respectively, will be written as follow

   $$\alpha^j_{(2,2)} = \sum_{i=1}^{m} \sigma^j_{m+i} P_{i3}$$
   $$\omega^j_{(2,2)} = \sum_{i=1}^{m} \sigma_{m+i} P_{i3} + \frac{b_g^2 + b_2 b_3 b_g + \rho^2}{c_2} I_q$$

   and one can see that the LMIs (18) and (33) can not be satisfied.

   So, to avoid the above rank constraints, we set $M_{21} = S_1 M_{11}$ and $M_{12} = S_2 M_{22}$ where matrices S_1 and S_2 are a priori chosen tuning parameters. This leads to $Y_{21} = S_1 Y_{11}$ and $Y_{12} = S_2 Y_{22}$.

   However, one can see that, unlike matrix S_1, matrix S_2 does not appear in the diagonal blocks $\alpha_{(2,2)}$ and $\omega_{(2,2)}$ of LMIs (18) and (33), respectively. By the way, we can set $S_2 = 0$. Whereas, we need the condition $S_1 \neq 0$.

4. The obtained results in theorem 2 may appear as an extension of theorem 1. However, it is not the case. For the observer design in section 3, the nonlinear Lipschitz functions are taken as

   $$\ell(x,u) = 0 \ \text{ and } \ g(x,u) = 1$$

   which imply that assumption 2 will be as follows

$$b_1 = 0, \quad b_2 = 0 \text{ and } b_g = 1$$

Applying this assumption on the results of theorem 2, do not lead to the results obtained in theorem 1, due to the fact that this assumption does not cancel some terms in the block $\omega^{j}_{(2,2)}$ of the LMIs (33). In addition, the bound b_3 of the unknown parameters θ is not required in the design of adaptive observer in section 3.

6 Numerical examples

To illustrate the efficiency and the feasibility of our results, we give in the sequel some numerical examples. Let us consider a bilinear time delay system, with

$$A_0 = \begin{bmatrix} -4 & 2 \\ -1 & -1.52 \end{bmatrix} \quad A_1 = \begin{bmatrix} -0.4 & 0.8 \\ 0.27 & -0.4 \end{bmatrix}$$
$$A_{d_0} = \begin{bmatrix} -0.1 & 0.01 \\ -0.11 & -0.68 \end{bmatrix} \quad A_{d_1} = \begin{bmatrix} -0.8 & 0.08 \\ -0.2 & -0.04 \end{bmatrix}$$

We assume that the system is controlled by one bounded input control $u(t) = u_1(t)$

$$-0.2 < u(t) = u_1(t) = 0.2\sin(0.1t) < 0.2$$

with

$$B = \begin{bmatrix} 0.8 \\ 0.01 \end{bmatrix}$$

One can see, that the derivative is also bounded, such that

$$-0.02 < \dot{u}(t) < 0.02$$

Then, we assume that the system is affected by one constant unknown parameters θ, where

$$G = \begin{bmatrix} -0.09 \\ 0.9 \end{bmatrix}$$

The time delays are constant and known such that

$$\tau_0 = 0.9, \text{ and } \tau_1 = 0.4$$

The available measurement vector is given by

$$y(t) = x_1(t)$$

The Lipschitz nonlinear function $g(x,u)$ is bounded and chosen as follows

$$-0.2 \leq g(x,u) = 0.2\sin(u(t) - x_1(t)) \leq 0.2$$

and the function $\ell(x,u)$ is given by

$$\ell(x,u) = \begin{bmatrix} \sin(x_1(t)e^{-0.2u(t)}) \\ \sin(x_2(t)e^{-0.2u(t)}) \end{bmatrix}$$

The unknown parameters θ will be assumed to be bounded by $b_3 = 0.5$ only for the simulation in section 6.2.

6.1 Numerical results related to the first observer design without Lipschitz nonlinearities

By computing the LMIs (18), given in theorem 1, in the set of the vertices of the convex polytope $\mathcal{P}$, using the toolbox "Lmilab", we obtain the following matrices

$$P_0 = \begin{bmatrix} 8.1168 & -1.8823 & -1.7727 \\ -1.8823 & 7.9346 & -3.7539 \\ -1.7727 & -3.7539 & 8.8302 \end{bmatrix}$$
$$P_1 = \begin{bmatrix} 1.1724 & -1.0393 & -0.37411 \\ -1.0393 & 1.1054 & 0.36291 \\ -0.37411 & 0.36291 & 0.081736 \end{bmatrix}$$
$$M_{11} = \begin{bmatrix} 2.3048 & 0.15176 \\ 0.15176 & 2.4665 \end{bmatrix}$$
$$M_{22} = 7.1197$$
$$S_1 = \begin{bmatrix} -0.9 & -1.12 \end{bmatrix}$$
$$S_2 = \begin{bmatrix} -0.003 \\ 0.02 \end{bmatrix}$$
$$Y_1 = \begin{bmatrix} -2.8248 \\ -3.067 \end{bmatrix}$$
$$Y_2 = 5.6283$$
$$\gamma = 0.1$$

which yield to the following observer's gains

$$L_x = M_{11}^{-1} Y_1 = \begin{bmatrix} -1.1484 \\ -1.1728 \end{bmatrix}$$
$$L_\theta = M_{22}^{-1} Y_2 = 0.79053$$

Figures 1, 2 and 3 show that the observer gives a suitable estimation of the states x_1 and x_2 and the unknown parameters θ. They prove also that even if the values of the unknown parameters change, but still constant, the estimation of the states and the unknown parameter converge to their real values.

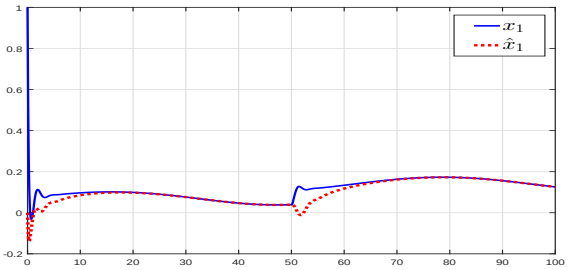

Figure 1: Variation of the state x_1 (—) and its estimation $\hat{x}_1$ ($\cdots$).

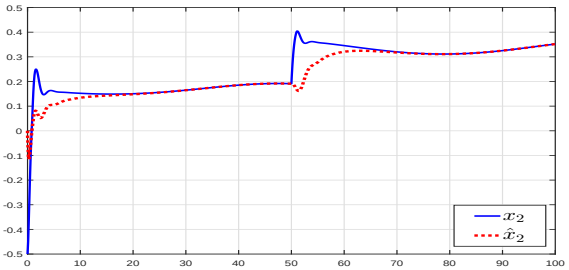

Figure 2: Variation of the state x_2 (—) and its estimation $\hat{x}_2$ ($\cdots$).

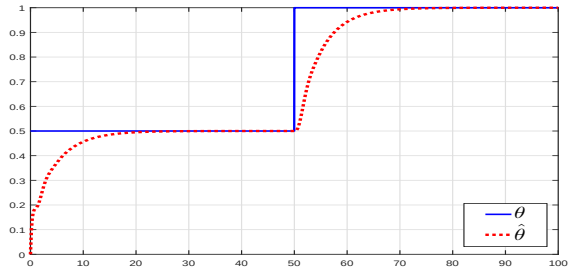

Figure 3: Variation of the unknown parameter θ (—) and its estimation $\hat{\theta}$ ($\cdots$).

6.2 Numerical results related to the second observer design with Lipschitz nonlinearities

By setting the tuning matrices S_1 and S_2 as follows

$$S_1 = \begin{bmatrix} -0.21963 & -0.36278 \end{bmatrix}$$

$$S_2 = \begin{bmatrix} 0.11754 \\ 0.049037 \end{bmatrix}$$

and fixing $b_1 = 0.2$, $b_2 = 0.2$ and $\rho = 0.1$, the resolution of the LMIs (33) given in theorem 2 using the toolbox "sdpt3" of Matlab, leads to the following observers gains

$$L_x = M_{11}^{-1} Y_1 = \begin{bmatrix} 0.41697 \\ -1.0876 \end{bmatrix}$$

$$L_\theta = M_{22}^{-1} Y_2 = 1.0292$$

with

$$P_0 = \begin{bmatrix} 1.1844 & -0.28959 & -0.032828 \\ -0.28959 & 0.61048 & 0.015679 \\ -0.032828 & 0.015679 & 0.084515 \end{bmatrix}$$

$$P_1 = \begin{bmatrix} 0.22818 & -0.07406 & -0.024134 \\ -0.07406 & 0.10067 & -0.0056328 \\ -0.024134 & -0.0056328 & -0.00030159 \end{bmatrix}$$

$$M_{11} = \begin{bmatrix} 0.31247 & 0.030714 \\ 0.030714 & 0.4203 \end{bmatrix}$$

$$M_{22} = 0.19653$$

$$Y_1 = \begin{bmatrix} 0.096884 \\ -0.44431 \end{bmatrix}$$

$$Y_2 = 0.20227$$

$$c_1 = 1.12, \quad c_2 = 0.58, \quad \gamma = 0.054$$

Using the obtained gains into the observer yields to a suitable estimation of the states $x(t)$ and the unknown parameter θ. The following figures show the effectiveness of our design.

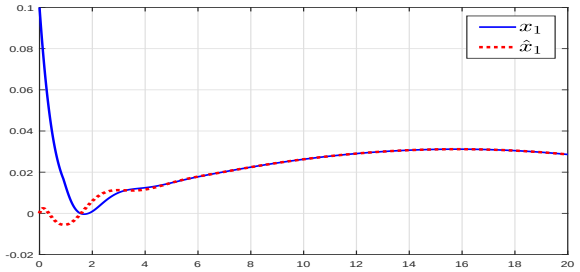

Figure 4: Variation of the state x_1 (—) and its estimation $\hat{x}_1$ ($\cdots$).

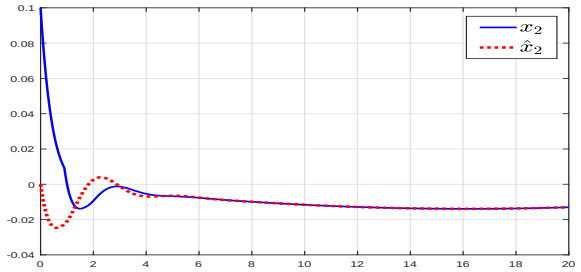

Figure 5: Variation of the state x_2 (—) and its estimation $\hat{x}_2$ ($\cdots$).

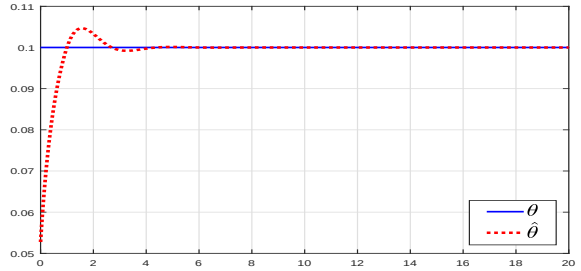

Figure 6: Variation of the unknown parameter θ (—) and its estimation $\hat{\theta}$ ($\cdots$).

7 Conclusion

The proposed adaptive observer for a class of nonlinear time delay system developed in this paper allows a suitable estimation of the state and the unknown parameter vectors, simultaneously. In a first time, a bilinear system with time delays is considered, which was extended by the addition of some nonlinear Lipshitz functions. The observer gains are obtained by solving LMIs in the vertices of a convex polytope. The simulation results show the performances and feasibility of the proposed approach. An extension of our adaptive observer design was presented in a second time, when a nonlinear Lipschitz functions interfere in the dynamics of a bilinear time delay system.

ABSTRACT

One of the prominent challenges of the automotive-transportation system is represented by the integration of security and safety properties within protocols, applications and connectivity mechanisms. A joint safety/security design can sometimes expose to trade-offs, since their requirements may not match perfectly or even be incompatible. This paper analyses an example of security and safety design, by combining integrity with encryption considering the constraints of a typical CAN protocol and real-time traffic. The analysis is presented modelling differently attackers, packet fragmentation issues and the residual probability of error of the combined scheme.

1 Introduction

The common thought about cars is that they are mechanical devices employed by passenger to move from a place to another. This is not true any more, or at least is not completely true since cars, or in general vehicles, in the last lustrum evolved to offer several services and connections that turn them into Cyber-Physical Systems (CPS) by the combination of sensing/actuation, processing, storing, and networking capabilities, as described by Fortino et al. [1]. Applications, sensors, park and driving assistants are integrated into commercial vehicles and they are considered standard features present in entry-level model of cars. Features, such as Internet connectivity, enlarge the attack surface of vehicles and, in particular, traditional communication protocols developed to work on isolated environments could not maintain the same level of robustness when new variables are taken into account. This is especially true if one considers that connectivity itself can be provided in multiple heterogeneous ways, which are not always predictable by the manufacturer anymore. For example, in [2], the author proposed a connectivity solution based on smartphones. On the other hand, practically all Electronic Control Units (ECUs) on a car are connected to one or more CAN busses, which is the traditional interface for intra-vehicle communications. The CAN bus use messages whose payload is at maximum 64bits length, and depending on the payload set, it can enable specific functionality of the vehicle, for instance enabling the accelerator of a car. The CAN bus protocol was not designed to embed security properties such as: *Authentication*, *Integrity* and *Confidentiality*, and the security aspects are left to higher layers of the protocols-stack, for instance the application level. An example of attack on the CAN bus protocol is that performed on a Jeep Cherokee by Valasek and Miller in 2015 [3], where the authors showed how to hack and remotely control a Jeep Cherokee. This attack exploit a security flaw in the *In-vehicle Infotainment* (IVI) system of the car to access the CAN bus network of the car. To fix this flaw, the Fiat Chrysler was forced to push a software update [4].

Security issues are a major challenge for connected vehicles, as reported in [5], and this is recognised also to have a relevant impact on vehicle's safety [6]; it is clear that *security* and *safety* are fundamental in the design of an intelligent transportation system, especially regarding the communication protocols and message protection schemes. It is important to note that the combination of safety and security issues is not exclusive of vehicular systems, but it affects the whole IoT world, especially systems which functionality is considered critical (e.g. medical devices).

In this work, we propose a solution to turn the CAN bus protocol as a *Security by Design* protocol by integrating authentication, integrity and confidential-

https://dx.doi.org/10.25046/aj030147

ity properties. Our solution proposes the adoption of a Message Authentication Code (MAC), targeted for CAN bus messages, that is then encrypted with an additional key. The message created guarantees authentication and integrity through the MAC, and confidentiality with the additional encryption. Our defence strategy is studied to be applied against a model of attacker that runs both a Honest-But-Curious (HBC) or Fully Malicious attack strategy. Furthermore, our solution is evaluated from a safety point of view, in particular regarding the residual probability of error (P_{re}). This is necessary since the outcome of the security MAC i.e. accept or reject a particular message is a form of error detection which could reveal also transmission errors (e.g. caused by noise), and the message containing the MAC could bring safety-critical information. For example, this scheme could be applied to SAE J1939 Torque/Speed Control 1 message, which embeds a 4-bit checksum within the 8-byte CAN payload. The residual probability of error is first evaluated using an ideal block cipher model, then simulation results are presented for a specific implementation choice. We show that averaging over the secret keys and over the possible messages, the value of P_{re} depends only on the length of the integrity tag used to decide whether the message is valid or not, and this is *independent* from how the integrity tag is generated. On the other hand, we show how the worst case combination of key and message reduces massively the ability of this scheme to detect transmission errors, assuming a simplified channel model. The worst-case P_{re} is then simulated, with considerations on the difficulty of finding the worst-case combination of key and message.

The main contributions of this paper is to analyse a message protection protocol from both a security and safety point of view, and highlight the trade-offs that result from the analysis. This paper is an extension of work originally presented in *IEEE MT-ITS* [7] and our contributions are summarized as follows:

- We improved the description of the analytical model for residual error probability by providing more details on the error model, new explanation on the computation of P_{re} and analytical results;
- We expanded the security analysis and we better modelled the attacker;
- We improved the safety analysis giving more details on the fragmentation and retransmission issues;
- We added more results and better described the analytical model depending on the statistical distribution of errors in the simple case of binary symmetric channel;
- We redraw the plots with the simulation results, using colours, to be easier to understand.

This paper is structured as follows: section 2 reviews the state of the art with regard to MAC algorithms and best practices, as well as error detection mechanisms; section 3 presents the message protection scheme discussed in this paper, discussing some design choices. In section 4, we introduce the attacker model and we make a security consideration on the MAC size. Section 5 exposes two aspects usually relevant for the safety of the system, that are packet fragmentation and the probability of residual error P_{re}. Section 6 discusses other message protection schemes and their security and safety properties, compared to the scheme proposed here. Finally, section 7 concludes the paper with some motivation for future research directions.

2 Related Works

The following works refers to lightweight Message Authentication Code solutions for devices that have limited computational resources, like processors and memory. Chowdhury and Dasbit in [8] introduce *LMAC*, a Lightweight Message Authentication Code (MAC) of 64bits dimension for Wireless Sensor Network that uses hash based symmetric key MAC. The authors show that LMAC is secure against passive and active attacks and it has a low overhead compared with other similar solutions. Another 64bits MAC, called *Chaskey* is presented by the authors of [9]. Chaskey uses 128bits key to generate a MAC which length is of 64bits or more. The authors say that Chaskey generates MAC that are suitable for 32bit Microcontroller and that it does not suffer of MAC truncation [10]. In [11] the authors show two versions of lightweight MAC of 64 and 128bits called *TuLP-64* and *TuLP-128* that are resources efficient and are though for body sensor networks. Then, in [12] the authors presented a lightweight MAC suitable for Smart Grid communications in which two devices reach mutual authentication by sharing a session key exchanged using Diffie-Hellman and a hash-based authentication code technique.

Regarding safety properties, such as the residual probability of error, Schiller and Mattes have analysed different ways of using nested CRC codes, for example in [13]. However, when it comes to cryptographic algorithms the kind of errors treated are related to security properties and possible vulnerabilities, see for example the survey in [14]. To the best of our knowledge, an explicit model for the residual probability of error of a system using cryptographic algorithms has not been developed, although the statistical properties of symmetric ciphers are sometimes studied in-depth, but always in the context of security, see for example [15].

3 Message protection scheme

The main scheme analysed in this paper is based on encryption, and is represented in Figure 1. In general, a message μ with length μ_{size} bits is combined with an integrity tag $\tau = H(k_2, \mu)$ of length τ_{size} , where k_2

is the *authentication key*. The combined $\mu\|\tau$ is then encrypted to obtain the ciphertext $c = ENC(k_1, \mu\|\tau)$, where k_1 is the *encryption key*; the ciphertext is then transmitted on the CAN bus. The receiver receives c', decrypts it and checks if $\tau' = H(k_2, \mu')$, with $\mu'\|\tau' = DEC(k_1, c')$, to decide if the message is valid.

There can be some variations in this scheme; for example the integrity code can be appended to μ to form the plaintext (also known as MAC-then-encrypt approach) with $c = ENC(k_1, \mu\|\tau)$, or it can be excluded from encryption (encrypt-then-MAC approach) with $c = ENC(k_1, \mu)\|\tau$. In both cases the MAC has to be computed using the original message μ. Sometimes the MAC-then-encrypt approach is considered less secure, for example see [16], but in this paper the scheme has no padding and a fixed length of the message, so these considerations do not apply. Considering the CAN bus, the first approach is more practical since there exist encryption algorithms with 64-bit block size, equal to the maximum payload of a CAN message; in this case there is no need for additional data to perform the encryption, and the ciphertext is computed as $c = ENC(k_1, \mu\|\tau)$. On the other hand, if the plaintext is different from the block size (like in the encrypt-then-MAC approach), the cipher must be used in counter mode, or a stream cipher can be used. Either way, there needs to be additional information shared between the sender and the receiver, e.g. a nonce, to perform the encryption; in this case the ciphertext is computed as $c = ENC(k_1, I, \mu)\|\tau$ with I being the shared information.

Another variant is to avoid the use of two different shared keys and define the integrity code as $\tau = H(\mu)$, where $H(\cdot)$ is a hash function like SHA1 or an error-detection code of the CRC family.

In this paper we consider only different possibilities for the integrity tag $\tau = H(\mu)$, which can be a proper Message Authentication Code, a hash function or a CRC; we do not consider then the encrypt-then-MAC approach, so we can define the plaintext $m = \mu\|\tau$.

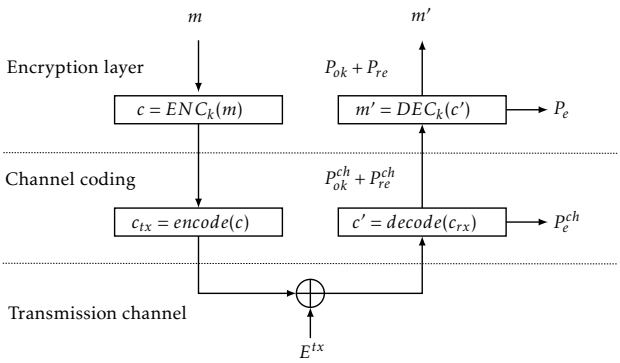

Figure 1: Message protection scheme.

4 Security considerations

When cars were not connected to the Internet, the attack surface was limited to local entry points that could make cars vulnerable to security attacks. Since connectivity has been embedded as feature inside cars, the attack surface is increased and it is not limited to local attacks, but also remote ones make a vehicle more vulnerable. This provides a higher impact to the security and safety of cars' passengers, and in addition, gives to attackers more and more kinds of attacks that they are able to exploit.

When, we talk about to local attacks, we refer to physical inputs to the vehicle that can be represented, for instance, by the auxiliary jack of the CD-Rom, USB ports, and the ODB2 connector. All these physical connectors require that an attacker has the opportunity to access the car and manipulate or alter the input to perform its attack. This, however, is possible but the impact is limited and less transparent to passenger. On the other side, remote attacks made on the wireless inputs enlarge the attack surface and may make attacks more relevant. Wireless inputs can be: the Bluetooth, Wi-Fi and cellular connections. In particular, exploiting the cellular connection, it would be possible to remotely access the In-vehicle infotainment (IVI) system of a car, and from that reading and writing into the CAN bus [3]. In fact, the IVI system are consoles that often run an operating system such as Windows CE, Linux, and may even run Android. So, attackers may exploit known vulnerabilities of unpatched version of those operating systems to perform their attacks. On this scenario, the Key Reinstallation Attacks (KRACKs) [17] has demonstrated that a vulnerability in the WPA2 protocol could allow *"attackers to use this novel attack technique to read information that was previously assumed to be safely encrypted. This can be abused to steal sensitive information such as credit card numbers, passwords, chat messages, emails, photos, and so on*[1]*."*. Thus, using KRACKs and exploiting an unpatched version of the Wi-FI provided by the IVI, an attacker could jump in the car's network getting sensitive information, and using that access as gateway to force and get in the CAN bus network of the vehicle.

4.1 Attacker Model

In this paper, we analyse the CAN protocol from the security and safety point of views. In particular, this section aims at modelling attackers, defining which are the attacks that they may exploit.

In the modelling phase, we consider that attackers may have local or remote access to the vehicle to compromise the CAN bus by forging or altering messages that may be considered valid by recipients. For instance, attackers may be able to exploit a weakness of the authentication module to remotely access the CAN bus network using a classic IP connection, and

once inside the vehicle, they forge valid message or even altering their contents.

To minimize the power of attackers, our defence strategy foresees that more attackers are not able to forge valid messages, keeping enabled confidentiality of proper messages generated. Also, we aim at identifying messages that were altered, i.e., *losing of integrity*. Thus, our defence strategy is based on three security properties that are:

Authentication: A recipient should be able to verify whether a message is sent by a legitimate sender;

Integrity: A recipient should be able to verify whether a message has been altered during its transmission;

Confidentiality: it guarantees that the content of a message is not revealed to an illegitimate entity, as it can happen with the Man-in-the-Middle (MITM) attack;

We apply our defence strategy against attackers who can play the following roles:

Honest-but-Curious (HBC): Also known as *Passive Attack*; an attacker may exploit the information legitimately gleaned by capturing messages exchanged over the CAN bus network, but he/she will not perform any malicious activity to harvest it.

Fully Malicious (FM): Also known as *Active Attack*; an attacker is able to forge or alter messages that are considered valid, after a verification step, by the recipient. So, the attacker strategy is to succeed in at least one of the following attacks:

- *Impersonation* attack: the attacker is able to assume the identity of one of the legitimate parties;
- *Guessing* attack: the attacker is able to forge a valid MAC after a number of trials.
- *Replay* attack: the attacker is able to re-use valid messages with a malicious or fraudulent aim;
- *Sniffing* attack: the attacker is able to read the content of any messages exchanged through the CAN bus network:

In Table 1, we combine the defence strategy to each attack presented above aiming at blocking or mitigating the corresponding attack.

4.2 Security considerations on encrypted MAC and MAC size

We introduced the Message Authentication Code in the CAN-message payloads to provide *by-design authentication* and *integrity* properties. At the same time, by encrypting $\mu||\tau$, we added the *confidentiality* property in messages to avoid that an attacker sniffs content messages exchanged among ECUs. However, even not considering encryption on messages, but even only the first two properties, an attacker is capable to sniff messages, but she will not easily forge valid messages due to the MAC. With encryption, the attacker's knowledge is still minor, and the probability to forge a valid message is linked to the *guessing attack* plus the encryption of $\mu||\tau$.

Dworkin in [18] points out the importance of choosing a robust MAC to be resistant against the guessing attack. In particular, Dworkin explains that a sound MAC is provided with a size greater than 64bits, i.e., $\tau_{size} \geq$ 64-bits. However, due to the standard CAN bus payload restriction, i.e., 64bit in total, it is very hard to keep that inequality true and we need a workaround to guarantee the security properties with a specific level of risk. Thus, the workaround can be implemented through two different strategies: i) concatenating a MAC which size is at least 64-bit, or ii) limiting the number of repeated trials of an attacker before considering invalid the key that generates the MAC. The first solution may cause the fragmentation issue that we detail better in §5.1. Instead, the second solution can be the best candidate for our workaround on τ_{size}. To this purpose, in [18], Dworkin illustrates how to calculate the right τ_{size} depending on the following two bounds:

MaxInvalids: as the limit on the number of trials that an attacker can perform before the key is retired;

Risk: the highest acceptable probability for an inauthentic message to be accepted as valid;

Then, due the above parameters, the τ_{size} should satisfy the following inequality:

$$\tau_{size} \geq lg(\frac{MaxInvalids}{Risk}). \quad (1)$$

Our goal is to satisfy the inequality 1 with a value of τ_{size} that is greater than or equal to 16. From inequality 1, the system can tolerate up to 30 (2^5) messages before considering the key invalid, and the system can accept 2^{-11}, i.e., $Risk = 2048$, chance of inauthentic messages. So, considering that the payload-size of a CAN-message is generically 48bits (μ_{size}) and the maximum bandwidth of the communication channel is 64bit ($bandwidth_{max}$), we obtain that $\mu_{size} + \tau_{size} \leq bandwidth_{max}$. The inequality 1 defines that the lowest condition to have a $\mu||\tau$ message for the CAN bus protocol is to have $MaxInvalids = 2^5$ and $Risk = 2048$.

5 Safety considerations

5.1 Fragmentation

It is well known that a standard CAN message is too short for the proper implementation of many security properties, since the maximum allowed payload length is 8 bytes. However there are use cases where using a second CAN message (e.g. for authentication

Attack	*Description*	**Defence**
Impersonation	Generating messages being identified as legitimate party	Authentication
Guessing	Forging or altering messages that are valid by the recipient	Confidentiality, Authentication, Integrity
Replay	Re-use messages that are considered valid by the recipient	Authentication
Sniffing	Read content of messages	Confidentiality

Table 1: Summary of attack and defence strategies.

purposes) is not acceptable since it introduce unnecessary latency in the complete reception of a message; this is mainly due to the low speed of CAN bus, which is typically 250 kB/s on vehicular networks, and can reach the maximum of 1 MB/s. Another reason is the increase of residual error rate in the communication (see for example the appendix D.5.2 of ISO 15998 [19]); however, this increase could be tolerated more easily since, to a first approximation, the P_{re} of a two-message scheme is roughly the double of the P_{re} of a single message. With these limitations, common application requirements allow for a rather limited security level achievable without changing the network communication protocol stack, and is fundamentally due, for a point-to-point communications, to the limited payload length of a single CAN 2.0 bus message. The use of CAN-FD could relax these limitations, but even in this case the maximum payload length is 64 bytes.

5.2 Retransmissions

In order to tolerate packet loss, communication protocols usually employ some form of re-transmission handling. Basically this means that if an error is detected on the packet, or if a timeout for packet reception expires, the transmitter sends again the same packet. Different variants of ARQ schemes (Automatic Repeat reQuest) exist, but the essential principle is that a data packet is sent more than one time without modifications. While this feature is usually handled transparently at link or transport layer, it is a potential security vulnerability, since an attacker could either inject errors or transmit duplicated packets to perform a replay attack (§4.1). Similar attacks are not hypothetical but have been demonstrated in reality, one of the most recent examples being the key reinstallation attack against WPA2 [17]. It is then desirable to handle retransmissions at the application level, if any, so sensitive security information like nonces, which must be used exactly one time, are handled properly. It is also worth considering that fragmentation makes retransmissions more complicated to handle efficiently, since here a small portion of a packet can be lost.

5.3 Probability of Residual Error

The analysis of the probability of residual error P_{re} in a communication protocol is usually a difficult task. In order to simplify the model, it is assumed that the channel coding is independent from the encryption scheme and it is possible to obtain a measure of P_{re} for channel coding, which correspond to P_{re}^{ch} with reference to Figure 1. In this way, it is possible to focus only on the performance of the message protection scheme discussed in this paper. Here P_{re} is obtained assuming Shannon's ideal cipher model, which has been used in other works like [20], and the results are compared with simulations where real algorithms are used for encryption and integrity.

5.3.1 Error model

According to Shannon's model, an ideal cipher is a random family of permutations, chosen independently for each possible key. More precisely, suppose $\mathcal{K}$ is the set of all keys and $\mathcal{M}$ is the set of all messages. An ideal block cipher is a map $ENC : \mathcal{K} \times \mathcal{M} \to \mathcal{M}$ where, for each key $k \in \mathcal{K}$, the encryption function $ENC_k(\cdot) = ENC(k, \cdot)$ is a random permutation on the message set $\mathcal{M}$ (independent of any other permutation). The same considerations apply to the decryption function $DEC_k(\cdot) = DEC(k, \cdot)$, which being the inverse of a random permutation is itself a random permutation.

In this context, it is more useful to fix a specific pair (k, m) of key and message, and consider the cipher text message set as:

$$\mathcal{C}' = \{c' : c' = c + e', e' \in \mathcal{E}'\} \tag{2}$$

while the plain text message set is:

$$\mathcal{M}' = \{m' : m' = m + e, e \in \mathcal{E}\} \tag{3}$$

where the set $\mathcal{E}'$ is the set of all possible undetected error vectors after channel decoding and before decryption, and $\mathcal{E}$ is the set of all error vectors after decryption. The addition here correspond to a bitwise XOR. While the elements of $\mathcal{E}'$ correspond basically to undetected transmission errors, the elements of $\mathcal{E}$ can be seen as undetected transmission errors transformed by the decryption function. For this reason, the distribution of the values in $\mathcal{E}$ depends on the distribution of $\mathcal{E}'$, in a different way for each different pair (k, m), since the function $E(k, \cdot)$ will correspond to a different and independent permutation. The relation between $\mathcal{E}'$ and $\mathcal{E}$ is then of the form $ENC : \mathcal{K} \times \mathcal{M} \times \mathcal{E}' \to \mathcal{E}$ which can be rewritten as the map $ENC_{(k,m)} : \mathcal{E}' \to \mathcal{E}$ identified by a specific pair of values (k, m). The explicit form can be derived from Figure 1 as

$$\begin{aligned} e = ENC_{(k,m)}(e') &= DEC(k, c') && (4)\\ &= DEC(k, c + e') && (5)\\ &= DEC(k, ENC(k, m) + e') + m && (6) \end{aligned}$$

Being $ENC(k,\cdot)$ and $DEC(k,\cdot)$ random permutations, equation 6 represent a random map from $\mathcal{E}'$ to $\mathcal{E}$. Each pair (k,m) correspond then to a different map $ENC_{(k,m)}$, independent from other maps. This means that each error vector e' on the transmission channel correspond to a random error vector e after decryption. Assuming that the pair (k,m) is chosen uniformly from the set $\mathcal{K}\times\mathcal{M}$, the random error vector e is itself uniformly distributed. In practice, the relation between e and e' is highly non-linear, since it strongly depends on the ENC and DEC functions, which in real block ciphers are usually highly non-linear functions themselves. This means that the approximation of uniform distribution of e, for any given e' and varying (k,m), is accurate as long as these conditions apply:

1. the real block cipher approximates a random permutation;
2. the messages in $\mathcal{M}$ are uniformly distributed;
3. the keys in $\mathcal{K}$ are uniformly distributed.

Condition 1 is itself an important security property, as shown for example in [21]. Condition 2 can be false depending on the context; for example, in a closed industrial control network the message set is usually limited; furthermore, messages in $\mathcal{M}$ can include integrity checks (as in the scheme discussed here) which alter the distribution of the plaintext. Condition 3 is another important security property, although some block ciphers have *weak keys* (e.g. DES and Blowfish). These conditions can be relaxed to having either the messages or the key uniformly distributed, provided that condition 1 still apply.

5.3.2 Computation of P_{re}

In this section, we assume these conditions are satisfied. Given that, as shown in section 3, the original message is $m = \mu\|\tau$, and the received message is $m' = \mu'\|\tau'$, the probability of residual error can be defined as the joint probability

$$P_{re} = P(\mu \neq \mu', \tau' = H(\mu')) \tag{7}$$

which correspond to the probability of having a correct integrity tag ($\tau' = H(\mu')$) but the decoded message is different from the original ($\mu \neq \mu'$) due to transmission errors. Considering that $ENC_{(k,m)}$ is a random map, each element of $\mathcal{C}'$ can correspond to all the possible values of $\mathcal{M}'$. If the elements of $\mathcal{C}'$ are uniformly distributed (such as when considering a random message attack) the probability that $\tau' = H(\mu')$, averaged over all the possible (k,m), can be computed by counting as

$$P^{avg}(\tau' = H(\mu')) = \frac{2^{\mu_{size}}}{2^{\mu_{size}+\tau_{size}}} = \frac{1}{2^{\tau_{size}}} \tag{8}$$

which is the probability of guessing a valid message. On the other hand, when transmission errors are considered, only one of the elements of $\mathcal{C}'$ correspond to the correct message, while all other elements have cumulative probability P_{re}^{ch}. The residual probability of error in this case can be computed as

$$P_{re}^{avg} = P_{re}^{ch}\frac{2^{\mu_{size}}-1}{2^{\mu_{size}+\tau_{size}}-1} \approx \frac{P_{re}^{ch}}{2^{\tau_{size}}}. \tag{9}$$

Both equations 8 and 9 are valid without making any assumption on the actual algorithm H used for computing τ.

This measure of P_{re} is, however, a measure for the average case, while from the safety point of view it is necessary to consider the worst case, that is:

$$P_{re}^{wc} = \max_{\substack{k\in\mathcal{K}\\ m\in\mathcal{M}}} P_{re} \tag{10}$$

This again can be computed by counting, but this time the actual distribution of $\mathcal{E}$, given by transmission errors, must be considered, specifically the one which maximise equation 10, which correspond to the worst-case pair (k^{wc}, m^{wc}). Using the ideal cipher model, the distribution in $\mathcal{E}$ can be obtained from a permutation of the distribution in $\mathcal{E}'$, so a simpler way to compute P_{re}^{wc} is to take the $2^{\mu_{size}}-1$ error vectors of $\mathcal{E}'$ with higher probability $P_{e'}$ and sum their probability. Clearly, the upper bound for the various $\mathcal{E}$ is

$$P_{re}^{wc} \leq P_{re}^{ch} \tag{11}$$

where equality would mean that the encryption procedure, even with an integrity check, is not effective at all in detecting transmission errors when (k^{wc}, m^{wc}) are used, because the relevant transmission errors e cause the plaintext to have an non-correctable error. More specifically, this correspond to the case where the $2^{\mu_{size}}-1$ most probable error vectors in $\mathcal{E}$ cover practically the whole amount of P_{re}^{ch}. The fact that this is independent from the particular algorithm H is because of the random map; in other words it is impossible to design an efficient integrity algorithm for this scheme as the distribution of e can not be known a priori.

This consideration exposes the trade-off between safety (as related to protection against random errors) and security (as related to protection against a malicious adversary). In the first case the statistical distribution of transmission errors is usually concentrated on a restricted set of values, and error detection codes are designed to detect the most probable errors, achieving a very high detection rate. On the other hand, if a malicious adversary is considered, all error patterns must be distributed ideally uniformly, otherwise an attacker may exploit its statistical characteristics.

5.3.3 Analytical results

To illustrate this problem, we consider a simplified model with a binomial distribution $\mathcal{E}' \sim B(n,k,p)$ (which would correspond in Figure 1 to the case with no channel coding and a Binary Symmetric Channel with probability of bit error p). The worst case P_{re}^{wc} can then be obtained by first listing the probability P_l

of each error vector e'_l with l bit set (note that must be $l > 0$); this list is then sorted incrementally and then the first values are taken, one error vector at a time, until exactly $2^{\mu_{size}} - 1$ error vectors are chosen. As shown in figure 2, where the worst-case residual probability of error is computed with the algorithm exposed above for different values of p in a binomial distribution, the value of P_{re} rapidly increases as the distribution of errors is more concentrated. Here τ_{size} is fixed to 64 bytes; similar results are obtained for different values. In figure 3 instead, μ_{size} is fixed to 256 bits and the worst-case P_{re} is plotted, and here the effect of the concentration of error distribution is also visible with effects similar to figure 2. This algorithm can be extended to the case where channel coding allows approximating the residual error distribution, for example if a CRC with a known minimum hamming distance H_{CRC} is used (some examples are available from the work of Koopman, see [22], for different payload lengths). In this case, the error vectors e_l with $l < H_{CRC}$ are not considered since they are detected by channel coding. However if channel coding include other information in the CRC (such as the length of the data payload) this approximation must be further refined.

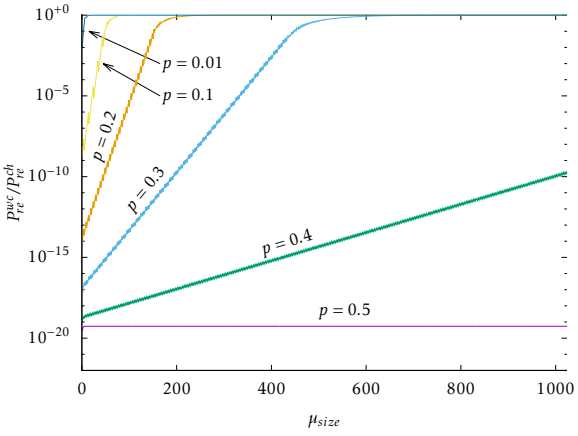

Figure 2: Normalised worst-case P_{re} obtained through computation, for different values of p. τ_{size} is fixed to 64 bytes.

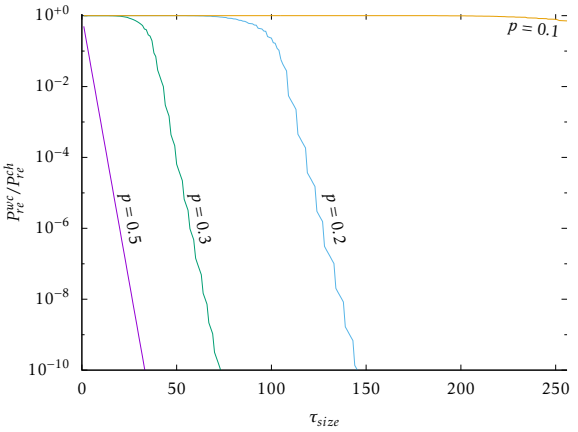

Figure 3: Normalised worst-case P_{re} obtained through computation, for different values of p. μ_{size} is fixed to 256 bytes.

5.3.4 Simulation results

The simulations have been performed applying the encryption scheme to randomly selected (k, m) and using different error vectors to obtain an approximation of P_{re}. For the ENC cipher, DES and AES have been used, while for H we used CRC, a truncated SHA1 hash function and a truncated HMAC scheme based on SHA1. The simulation have been implemented as a C++ program using the Nettle v2.7.1 cryptographic library. The simulations were run on a Intel i7 8-core laptop with 8 GB RAM; for each pair (k, m) a number of error patterns e' are generated, with the respective probability, and the normalised output P_{re} is computed as the ratio between the erroneous messages that resulted in $\tau = H(\mu)$ and the total number of erroneous messages. The plotted results represent a normalised $\frac{P_{re}}{P_{re}^{ch}}$, where the value of 1 represent equality in equation 11. The value of τ_{size} varies from 0 to 16; greater values, which in theory correspond to a lower P_{re}, have not been simulated since they would have taken too much time to yield a result with reasonable precision; however the results are still meaningful with respect to the theoretical model. The complexity of the simulation has three factors: k, m and e'. For example, using 1000 different keys, 1000 different messages and 10000 error patterns the total number of iterations is $1000 \cdot 1000 \cdot 10000 = 10^{10}$. However each value of P_{re} is evaluated using 10000 samples, so lower values close to 10^{-4} will have a lower accuracy. This explains the convenience to simulate with low τ_{size}.

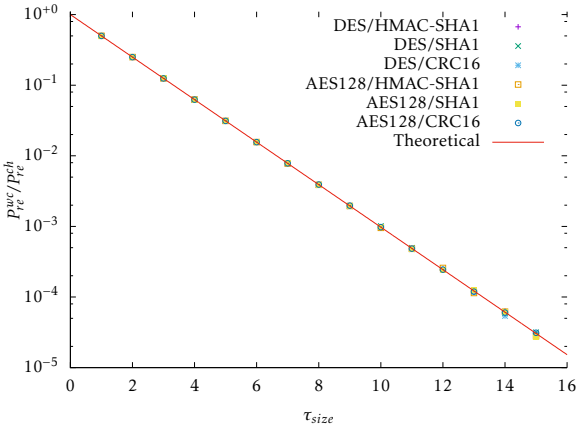

Figure 4: Normalised average P_{re} obtained through simulation and from equation 9, for different values of τ_{size}.

In Figure 4 the normalised P_{re}^{avg} is plotted, both resulting from equation 9 and from simulations. The correspondence between the theoretical model and the simulation results is very good, and the results are independent either from the H algorithm used to compute τ and the encryption algorithm ENC. Only a small glitch is visible for $\tau_{size} = 14$, presumably due to the relatively small number of iterations. The simulations results are accurate because all the P_{re} are av-

eraged over the pairs (k,m).

In Figure 5 and 6 the normalised P_{re}^{wc} is plotted with varying τ_{size}. The numerical values, displayed with a continuous line, are evaluated with the algorithm described in section 5.3.2, while the simulation results are taken as the highest value of P_{re} among all tested (k,m). In this case the simulations do not match the theoretical model; the reason is that while the theoretical model assumes that (k^{wc},m^{wc}) is known, in practice this is not true, although for some ciphers it could be feasible to calculate it. In this case a great number of (k,m) combinations are randomly chosen and the worst case is considered. However, being unable to scan all the (k,m) space, it is unlikely to find the worst case but only a "bad" pair (k,m) is found, for which P_{re} differ significantly from the average case.

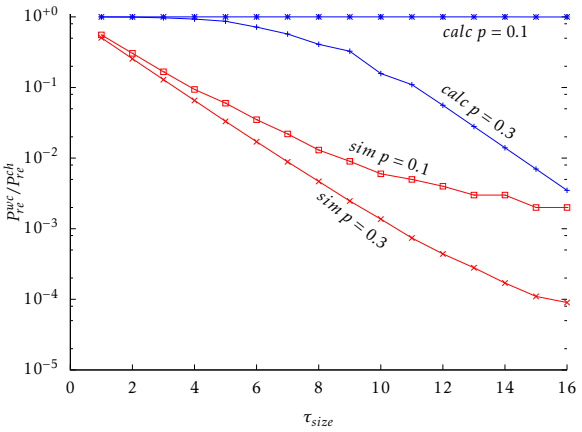

Figure 5: Normalised worst-case P_{re} obtained with $\mathcal{E}' \sim B(n,k,p)$ through calculation and simulation using a DES/SHA1 scheme, with $\mu_{size} + \tau_{size} = 64$, for different values of τ_{size}.

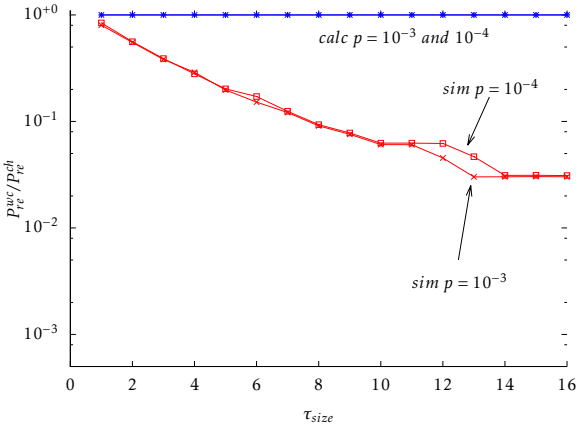

Figure 6: Normalised worst-case P_{re} obtained with $\mathcal{E}' \sim B(n,k,p)$ through calculation and simulation using a DES/SHA1 scheme, with $\mu_{size} + \tau_{size} = 64$, for different values of τ_{size}.

In Figure 7 and 8 the normalised P_{re}^{wc} is plotted with varying p. For low values of p, the value of P_{re}^{wc} does not change a lot, since the most probable error patterns are always the ones with 1 bit error. On the other hand, with higher p the value of P_{re}^{wc} approaches P_{re}^{avg}, which is reached with $p = 0.5$, corresponding to a uniform distribution. The issue of finding the worst case (k,m) is then different depending on the bit error probability of $B(n,k,p)$. For low p, approximately under 0.1, it is easier to find a pair (k,m) with high P_{re} since the most probable error patterns are the ones with only 1 bit error and are exactly $\mu_{size} + \tau_{size}$. On the other hand, for higher p, the most probable error patterns are a much great number, because it is easier to find more than one bit error. This explains the difficulty of finding the pair (k^{wc},m^{wc}) to simulate P_{re}^{wc} accurately.

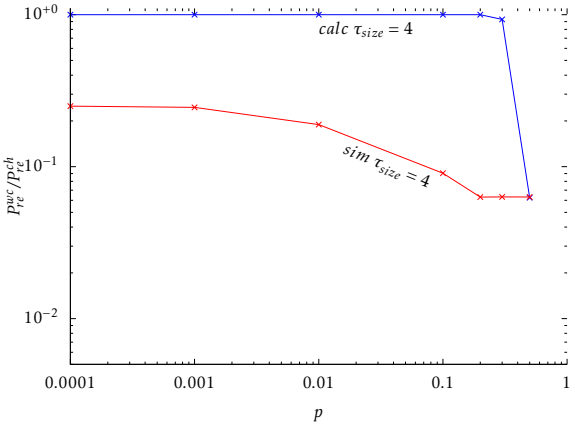

Figure 7: Normalised worst-case P_{re} obtained with $\mathcal{E}' \sim B(n,k,p)$ through calculation and simulation using a DES/SHA1 scheme, with $\mu_{size} + \tau_{size} = 64$, for different values of p.

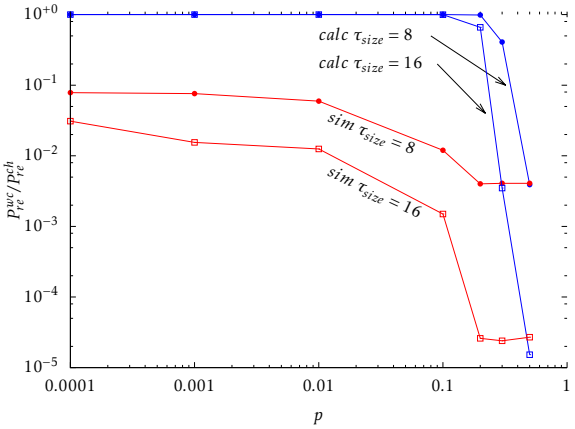

Figure 8: Normalised worst-case P_{re} obtained with $\mathcal{E}' \sim B(n,k,p)$ through calculation and simulation using a DES/SHA1 scheme, with $\mu_{size} + \tau_{size} = 64$, for different values of p.

6 Discussion

In Table 2 different message protection schemes are compared and ordered with decreasing security properties. The message protection schemes addressed

Scheme	Resists to	Security properties	Leaking out	Safety properties
ENC + MAC	Fully Malicious with chosen plaintext	Confidentiality Authentication Integrity	-	Strongly depends on (k, m)
ENC + CRC	Fully Malicious with chosen plaintext	Confidentiality Integrity	-	Strongly depends on (k, m)
plain + MAC	Fully Malicious	Authentication Integrity	Plaintext to FM and HBC attackers	Depends on $H()$
plain + CRC	Honest-But-Curious	-	Plaintext to FM and HBC attackers	Good under common channel assumption [13]
plain	-	-	Plaintext to FM and HBC attackers	-

Table 2: Summary of message protection schemes.

in this paper correspond to the ENC+MAC and ENC+CRC schemes, depending on the choice of $H()$, to resist a fully malicious attacker with chosen plaintext. The main alternative scheme, which does not consider the Confidentiality property, is evaluated for reference, based on literature work. Here the trade-off appears clear comparing the ENC+CRC and plain+CRC scheme; while the first has better security properties, the latter has better safety properties under common channel models, because CRC codes are designed specifically for correcting transmission errors.

7 Conclusion

In this paper, we have presented an analysis showing that a security property, like encryption, directly influences the probability of residual error, which is a safety property. On the other hand, the restricted size of the CAN bus payload forces the length of a MAC code to respect the fragmentation constraints which can be imposed by real-time requirements. With respect to similar schemes without encryption, by using a second CRC in addition to that one at the physical layer, the combination *ENC+CRC* performs worse; this is due to the intrinsic properties of block ciphers, which transform the distribution of errors to uniform on average. Other message protection schemes could have a less drastic impact on the worst-case error detection capability, or even this error detection capability could be embedded into the encryption algorithm itself, but then the risk is to offer the possibility for a side-channel attack.

Future works include the design and study of different message protection schemes, to offer a better trade-off between safety and security, for example improving the performance of the integrity tag τ with respect to transmission errors. Additionally, an experimental testbed on a real CAN bus would be useful to assess the performance of the protocol.

Conflict of Interest The authors declare no conflict of interest.

ABSTRACT

In this paper, we investigate the decentralized control problem for large-scale interconnected systems. The synthesis of the decentralized controller consists in determining gains which ensure the stability of the global system. To calculate these gains, three approaches are presented. Our main contribution is to develop a new decentralized stabilization approach which the decentralized local gains are calculated and formulated via the resolution of linear matrix inequalities (LMIs) problem. A numerical simulation comparison of the three methods is performed on an interconnected double-parallel inverted pendulum.

1 Introduction

This paper is an extension of the work originally we presented in the International Conference on Advanced Systems and Electric Technologies, 2017 [1]. This work treats three approaches dealing with the decentralized control of interconnected systems.

In fact, large-scale interconnected systems have received considerable attention in recent years due to its presence in several fields such as power electronics, robotics, communication, aerospace, transportation networks, manufacturing processes, biochemical applications and others. Designing a centralized control for these systems may not be efficient due to the modular nature of the system that can prevent the sharing of information between the various subsystems. Thus it is important to decompose the large-scale system into several subsystems. This decomposition which can be physical or mathematical, can make structures easier to control. This includes the implementation of decentralized control law.

In this way, it is necessary to decompose the global system into a number of interconnected subsystems for which, instead of a single centralized controller, a set of independent decentralized controllers is built. Thanks to its structure, the decentralized control has several advantages, mainly: the minimization of the information rate processed by the control units, the simplicity of the developed control laws compared to the centralized case and the improvement of the reliability of data transfer using only local information.

Many works in literature have been devoted to the decentralized control problems for interconnected systems. The decentralized adaptive control has been studied in [2–6]. The robust decentralized control is presented in [7–9]. The decentralized control using sliding mode approach is developed in [10–13].

Decentralized stabilization problem is the subject of our work. This problem is extensively studied in the literature and different design approaches were proposed accordingly [14–18]. To ensure the stability of the interconnected system formed by n subsystems, it is necessary to verify the local stability at each subsystem as well as the overall stability taking into account their interconnection.

The main contribution of this paper consists in developing some conditions allowing the synthesis of decentralized control laws that will ensure the stability of the overall interconnected system. In this way, we propose in this work a new decentralized stabilizing control approach for the interconnected systems. Indeed, the outcomes of this development are formulated in terms of linear matrix inequalities (LMIs).

The presented methods in our paper are applied to the physical system of two inverted pendulums interconnected by a spring. For the design of the decentralized control scheme, each pendulum should be seen as a subsystem. Many works used the typical system easily isolated into two subsystems to approve the validity of their proposed decentralized control approaches [19–22].

The rest of the manuscript is structured according to the following outline : The second section is reserved to formulate the problem and present the

https://dx.doi.org/10.25046/aj030148

studied interconnected system formed by two parallel inverted pendulums coupled by a spring. In section 3, decentralized control approaches for the interconnected systems are presented, which are the decentralized quadratic optimal control and the decentralized pole-placement control. The last part of this section focuses on the development of a new decentralized stabilization control approach by using the Linear Matrix Inequalities Formulation. Section 4 is devoted to the implementation of the decentralized control approaches presented and developed in the previous section on the studied system. A comparative study between the three control approaches is presented to prove the validity of the new proposed approach. Finally, conclusions and some perspectives are given in the fifth section.

2 Problem Formulation and Description of the Studied Dynamic System

2.1 Problem Formulation

Large-scale interconnected systems are represented as follows:

$$\dot{x}_i = A_i x_i + B_i u_i + \sum_{\substack{j=1 \\ j\neq i}}^{n} H_{ij} x_j, i = 1, 2, .., n \qquad (1)$$

where $x_i \in \mathbb{R}^{n_i}$ and $u_i \in \mathbb{R}^{n_i}$ denote the state vector and the control vector of i^{th} subsystem, respectively.
$A_i \in \mathbb{R}^{n_i \times n_i}$ is the state matrix and $B_i \in \mathbb{R}^{n_i \times m_i}$ is the control matrix of each subsystem.
H_{ij} represents the term of interconnection between the i^{th} subsystem and the other subsystems.

The global interconnected system composed of N subsystems can be rewritten in a compact form as follows:

$$\dot{x} = Ax + Bu + Hx \qquad (2)$$

where:

- $x^T = [x_1^T, x_2^T, .., x_n^T]$ is the state vector of the global system ;
- $u^T = [u_1^T, u_2^T, .., u_n^T]$ is the control vector of the global system ;
- $A = diag[A_i], B = diag[B_i]$;
- H is the matrix formed by the terms of interconnection having the following form

$$H = \begin{bmatrix} 0 & H_{12} & \cdots & H_{1n} \\ H_{21} & 0 & & H_{2n} \\ \vdots & \vdots & \ddots & \\ H_{n1} & \cdots & \cdots & 0 \end{bmatrix}$$

2.2 Description of the Studied System : Double Inverted Pendulums Coupled by a Spring

We present in this section the description of the studied system formed by two interconnected inverted pendulum and its dynamic modeling.
In this system, two identical inverted pendulums of mass m directly mounted on the motor shafts in parallel where τ_1 and τ_2 are the input torques of each motor. These pendulums are connected to each other by an elastic spring of constant k which is mounted at the height a.
θ_1 and θ_2 are the angular displacements and of the pendulums from vertical.
New particular movements appear compared to the single movement of the individual pendulum. The interconnected inverted pendulums system is shown in figure 1 [23].

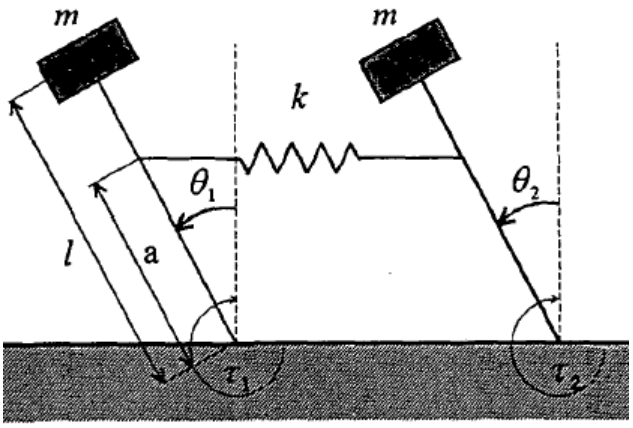

Figure 1: Modeling of the parallel inverted pendulum

The Lagrangian is defined as the difference between the kinetic energies and the potential energies of the system.

The kinetic energy for each pendulum is described by the following form:

$$T_i = \frac{1}{2} J_i \dot{\theta}_i^2 \qquad (3)$$

where J_i is the moment of inertia of the i^{th} pendulum and $\dot{\theta}_i$ is the angular velocity of i^{th} pendulum.

The total kinetic energy of the global system is then:

$$T = \frac{1}{2} J_1 \dot{\theta}_1^2 - \frac{1}{2} J_2 \dot{\theta}_2^2 = -\frac{1}{2} ml^2 \dot{\theta}_1^2 - \frac{1}{2} ml^2 \dot{\theta}_2^2 \qquad (4)$$

The potential energy for each mass is represented as follows:

$$V_i = mgl(1 - cos\theta_i) \qquad (5)$$

The potential energy of the spring is calculated using Hooke's law:

$$V_{spring} = \frac{1}{2}kx^2 = \frac{1}{2}k(-a\,sin\theta_1 + a\,sin\theta_2)^2 \quad (6)$$

The total potential energy of the system is given by:

$$\begin{aligned} V &= mgl(1-cos\theta_1) + mgl(1-cos\theta_2) \\ &+\tfrac{1}{2}k(-a\,sin\theta_1 + a\,sin\theta_2)^2 \end{aligned} \quad (7)$$

The Lagrangian of the interconnected studied system is written as follow:

$$\begin{aligned} L &= T - V \\ &= -\tfrac{1}{2}ml^2\dot{\theta}_1^2 - \tfrac{1}{2}ml^2\dot{\theta}_2^2 - mgl(1-cos\theta_1) \\ &-mgl(1-cos\theta_2) + \tfrac{1}{2}k(a\,sin\theta_1 - a\,sin\theta_2)^2 \end{aligned} \quad (8)$$

The Euler-Lagrange equations are given by:

$$\begin{cases} \frac{d}{dt}[\frac{\partial L}{\partial \dot{\theta}_1}] - \frac{\partial L}{\partial \theta_1} = \tau_1 \\ \\ \frac{d}{dt}[\frac{\partial L}{\partial \dot{\theta}_2}] - \frac{\partial L}{\partial \theta_2} = \tau_2 \end{cases} \quad (9)$$

Using Lagrange equations (9), we can easily show that the nonlinear equations of motion of the parallel inverted pendulum system are:

$$\begin{cases} -ml^2\ddot{\theta}_1 + mgl\,sin\theta_1 - ka^2[cos\theta_1(sin\theta_1 - sin\theta_2] = \tau_1 \\ -ml^2\ddot{\theta}_2 + mgl\,sin\theta_2 - ka^2[cos\theta_1(sin\theta_2 - sin\theta_1] = \tau_2 \end{cases} \quad (10)$$

Assuming a small angular displacement, the nonlinear equations of motion (10) can be replaced by the following linear model around the equilibrium point $\theta_1 = \theta_2 = 0$:

$$\begin{cases} -ml^2\ddot{\theta}_1 + mgl\,\theta_1 - ka^2(\theta_1 - \theta_2) = \tau_1 \\ -ml^2\ddot{\theta}_2 + mgl\,\theta_2 - ka^2(\theta_2 - \theta_1) = \tau_2 \end{cases} \quad (11)$$

So, the dynamics of the studied system composed of the two interconnected inverted pendulums are described by the following equations:

$$\begin{cases} -ml^2\ddot{\theta}_1 = mgl\theta_1 - ka^2(\theta_1 - \theta_2) - \tau_1 \\ -ml^2\ddot{\theta}_2 = mgl\theta_2 - ka^2(\theta_2 - \theta_1) - \tau_2 \end{cases} \quad (12)$$

For the design of the decentralized control scheme, each pendulum should be seen as a subsystem. Equations (12) can be writen into state equations with a standard choice of state variable for the i^{th} pendulum:

$$x_i(t) = \begin{bmatrix} \theta_i(t) \\ \dot{\theta}_i(t) \end{bmatrix}$$

The system consisted of two interconnected inverted pendulums is then described by the following state equations:

$$\begin{cases} \dot{x}_1 = A_1x_1 + B_1u_1 + H_1x_2 \\ \dot{x}_2 = A_2x_2 + B_2u_2 + H_2x_1 \end{cases} \quad (13)$$

with

- x_1, x_2 the state vectors of the subsystems ;
- u_1, u_2 the control vectors of the subsystem such as the input torque of each motor ;

The matrices and interconnection terms of the i^{th} subsystem are given by:

$$A_i = \begin{bmatrix} 0 & 1 \\ \frac{g}{l} - \frac{ka^2}{ml^2} & 0 \end{bmatrix}, B_i = \begin{bmatrix} 0 \\ \frac{-1}{ml^2} \end{bmatrix}$$
$$H_i = \begin{bmatrix} 0 & 0 \\ \frac{ka^2}{ml^2} & 0 \end{bmatrix}, i = 1, 2$$

The global system formed by two identical inverted pendulums coupled by a spring can be expressed by the following global state representation:

$$\dot{x} = Ax + Bu + Hx \quad (14)$$

where

- $x^T = [x_1^T, x_2^T]$ is the state vector,
- $u^T = [u_1^T, u_2^T]$ is the control vector.
- $A = diag(A_1, A_2)$ is the characteristic matrix:

$$A = \begin{bmatrix} 0 & 1 & 0 & 0 \\ \frac{g}{l} - \frac{ka^2}{ml^2} & 0 & 0 & 0 \\ 0 & 0 & 0 & 1 \\ 0 & 0 & \frac{g}{l} - \frac{ka^2}{ml^2} & 0 \end{bmatrix}$$

- $B = diag(B_1, B_2)$ is the control matrix:

$$B = \begin{bmatrix} 0 & 0 \\ \frac{-1}{ml^2} & 0 \\ 0 & 0 \\ 0 & \frac{-1}{ml^2} \end{bmatrix}$$

- H is the term of interconnection:

$$H = \begin{bmatrix} 0 & 0 & 0 & 0 \\ 0 & 0 & \frac{ka^2}{ml^2} & 0 \\ 0 & 0 & 0 & 0 \\ \frac{ka^2}{ml^2} & 0 & 0 & 0 \end{bmatrix}$$

with

m The mass of each pendulum, in Kg
l The rod length, in m
a The connecting position of the spring, in m
k The stiffness of spring, in N/m
g The acceleration of gravity, in $m.s^{-2}$
θ_i The angular displacement of the i^{th} pendulum, in Rad
τ_i The input torque of i^{th} motor, in $N.m$

3 Decentralized Control Approaches of Interconnected Systems

Possible control strategies for large-scale interconnected systems are generally based on a decentralized solution. A decentralized control structure applied to a process of n interconnected subsystems is shown in Fig 2.
The decentralized control partitions the measurement information and elaborates a local and independent control law for each subsystem.
It is necessary to check the stability of the interconnected system by examining two main aspects:
- Local stability: at each subsystem.
- Overall stability: taking into account the interconnections.

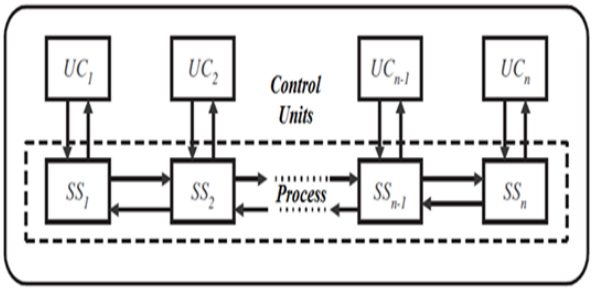

Figure 2: Decentralized control structure

The synthesis of the decentralized controller consists in determining the local gains K_i which ensure the stability of the overall closed-loop system.
To respect the decentralized information structure constraint, each subsystem is controlled by the local control law:

$$u_i(x) = -K_i x_i \quad i = 1,..,n \tag{15}$$

which leads to the following global control law of the overall system (2):

$$u(x) = -Kx \tag{16}$$

where $K = diag(K_1, K_2, .., K_n)$ is the block diagonal control gain matrix. Using global state-feedbacks, we get the closed loop system dynamics as following:

$$\dot{x} = A_f x \tag{17}$$

where:

$$A_f = \begin{bmatrix} A_1 - B_1K_1 & H_{12} & \cdots & H_{1n} \\ H_{21} & A_2 - B_2K_2 & & \vdots \\ \vdots & \vdots & \ddots & \vdots \\ H_{n1} & \cdots & \cdots & A_n - B_nK_n \end{bmatrix}$$

To calculate the gains K_i, different approaches can be considered.

3.1 Decentralized Quadratic Optimal Control

The decentralized control synthesis consists in considering the decoupled subsystems defined by the following state equations:

$$\dot{x}_i = A_i x_i + B_i u_i \tag{18}$$

and minimizing the modified quadratic criteria [24]:

$$J_i = \frac{1}{2}\int_0^\infty e^{2\alpha t}(x_i^T Q_i x_i + u_i^T R_i u_i)dt \tag{19}$$

Let $Q_i(n_i \times n_i), i = 1,..,n$ semi positive definite matrices, $R_i(m_i \times m_i), i = 1,..,n$ positive definite matrices and α a positive real.
The decentralized optimal control laws for each isolated subsystem can be expressed as a linear state feedback:

$$u_i = -K_i x_i, \quad i = 1, 2, .., n \tag{20}$$

where

$$K_i = R_i^{-1} B_i^T P_i \tag{21}$$

and P_i is the symmetric positive definite matrix solution of the following algebraic Riccati equation:

$$A_i^T P_i + P_i A_i - P_i(B_i R_i^{-1} B_i^T)P_i + 2\alpha P_i + Q_i = 0 \tag{22}$$

These decentralized state feedbacks applied to the interconnected system lead to the following global state representation:

$$\dot{x} = (A - BR^{-1}B^T P)x + Hx \tag{23}$$

where $R^{-1} = diag[R_i^{-1}]$ and $P = diag[P_i]$.
A sufficient condition to guarantee the stability of the overall system taking into account the interconnections, is given by the following theorem which proof is detailed in Appendix A.

Theorem 1 [24]:
The decentralized control law (16) is globally and asymptotically stabilizable for system (17) if the matrix F, given by(24), is positive definite.

$$\begin{aligned} F &= 2\alpha P + W - (PH + H^T P) \\ W &= Q + PBR^{-1}B^T P, \quad Q = diag[Q_i] \end{aligned} \tag{24}$$

3.2 Decentralized Pole-Placement Control

Pole-placement technique is a controller design method in which we determine the places of the closed loop system poles on the complex plane by setting a controller gain.
In this work we will apply this method for interconnected systems composed of n different subsystems that can be easily isolated. Firstly, it is necessary to verify the local stability.

For each subsystem, Ackermann's formula is used to find the control gain matrices.

Theorem 2: Ackermann's formula [25]
The controllability matrix C can be formed from:

$$C = [B\ AB...A^{n-1}B]$$

The feedback matrix K can be found as:

$$K = [0\ 0...1]C^{-1}P_d(A)$$

where P_d is the desired characteristic polynomial.

Using the local gain matrices obtained by Akermann's formula for each subsystem, the matrix in closed loop A_f of the global system taking into account the interconnection is given by:

$$A_f = \begin{bmatrix} A_1 - B_1K_1 & H_{12} & \cdots & H_{1n} \\ H_{21} & A_2 - B_2K_2 & & \vdots \\ \vdots & \vdots & \ddots & \vdots \\ H_{n1} & \cdots & \cdots & A_n - B_nK_n \end{bmatrix}$$

Stability condition:
In order to be stable, the eigenvalues of the system $\dot{x} = A_f x$ must all lie strictly in the left half of the complex s-plane. That means, the eigenvalues must all have strictly negative real parts.

3.3 Synthesis of a Decentralized Stabilization Control

This section deals with the global asymptotic stabilization of linear interconnected systems within the framework of Linear Matrix Inequalities (LMIs). We present the development of a new decentralized control approach.
To compute the gain matrix K, so that the closed loop system (17) is asymptotically stable, let consider the quadratic Lyapunov function represented by the following form:

$$V(x) = x^T Px \tag{25}$$

where P is a positive definite symmetric matrix of the following form:

$$A = \begin{bmatrix} P_1 & 0 & \cdots & 0 \\ 0 & P_2 & \cdots & 0 \\ \vdots & 0 & \ddots & \vdots \\ 0 & 0 & \cdots & P_n \end{bmatrix}$$

The time derivative of $V(x)$ is developped as :

$$\begin{aligned} \dot{V}(x) &= \dot{x}^T Px + x^T P\dot{x} \\ &= x^T A_f^T Px + x^T PA_f x \\ &= x^T (A_f^T P + PA_f)x \end{aligned} \tag{26}$$

The global asymptotic stability of system (17)provided with the decentralized control law (16) is ensured when the time derivative $\dot{V}(x)$ is negative definite which is equivalent to:

$$A_f^T P + PA_f < 0 \tag{27}$$

We note this expression by $\breve{A} = A_f^T P + PA_f$ with

$$A_f = \begin{bmatrix} A_1 - B_1K_1 & H_{12} & \cdots & H_{1n} \\ H_{21} & A_2 - B_2K_2 & & \vdots \\ \vdots & \vdots & \ddots & \vdots \\ H_{n1} & \cdots & \cdots & A_n - B_nK_n \end{bmatrix}$$

$\breve{A}$ can be written as:

$$\breve{A} = \begin{bmatrix} (A_1 - B_1K_1)^T & H_{12}^T & \cdots & H_{1n}^T \\ H_{21}^T & (A_2 - B_2K_2)^T & & \vdots \\ \vdots & \vdots & \ddots & \vdots \\ H_{n1}^T & \cdots & \cdots & (A_n - B_nK_n)^T \end{bmatrix}$$

$$\begin{bmatrix} P_1 & 0 & \cdots & 0 \\ 0 & P_2 & \cdots & 0 \\ \vdots & 0 & \ddots & \vdots \\ 0 & 0 & \cdots & P_n \end{bmatrix} + \begin{bmatrix} P_1 & 0 & \cdots & 0 \\ 0 & P_2 & \cdots & 0 \\ \vdots & 0 & \ddots & \vdots \\ 0 & 0 & \cdots & P_n \end{bmatrix}$$

$$\begin{bmatrix} A_1 - B_1K_1 & H_{12} & \cdots & H_{1n} \\ H_{21} & A_2 - B_2K_2 & & \vdots \\ \vdots & \vdots & \ddots & \vdots \\ H_{n1} & \cdots & \cdots & A_n - B_nK_n \end{bmatrix}$$

So,

$$\breve{A} = \begin{bmatrix} A_1^T P_1 + P_1 A_1 - K_1^T B_1^T P_1 - P_1 B_1 K_1 & P_1 H_{12} + H_{21}^T P_2 \\ P_2 H_{21} + H_{12}^T P_1 & \ddots \\ \vdots & \vdots \\ P_n H_{n1} + H_{1n}^T P_1 & P_n H_{n2} + H_{2n}^T P_2 \end{bmatrix}$$

$$\begin{bmatrix} \cdots & P_1 H_{1n} + H_{n1}^T P_n \\ \ddots & \vdots \\ \ddots & \vdots \\ \cdots & A_n^T P_n + P_n A_n - K_n^T B_n^T P_n - P_n B_n K_n \end{bmatrix}$$

$$< 0 \tag{28}$$

Multiplying (28) on the right and then on the left by P^{-1} where P^{-1} is also symmetric positive definite matrix, inequality (28) becomes:

$$\begin{bmatrix} P_1^{-1}A_1^T + A_1P_1^{-1} - P_1^{-1}K_1^T B_1^T - B_1K_1P_1^{-1} & H_{12}P_2^{-1} + P_1^{-1}H_{21}^T \\ H_{21}P_1^{-1} + P_2^{-1}H_{12}^T & \ddots \\ \vdots & \vdots \\ H_{n1}P_1^{-1} + P_n^{-1}H_{1n}^T & \cdots \end{bmatrix}$$

$$\begin{bmatrix} \cdots & H_{1n}P_n^{-1} + P_n^{-1}H_{n1}^T \\ \ddots & \vdots \\ \ddots & \vdots \\ \cdots & P_n^{-1}A_n^T + A_nP_n^{-1} - P_n^{-1}K_n^T B_n^T - B_nK_nP_n^{-1} \end{bmatrix}$$

$$< 0 \tag{29}$$

It should be noted that the inequality matrix (29) has nonlinearities that are difficult to solve. We then use the changes of variables (30) and (31).

$$S_i = P_i^{-1} \tag{30}$$

$$L_i = K_iP_i^{-1} \tag{31}$$

Thus, the problem (29) can be rewritten to the form of linear matrix inequalities :

$$\begin{bmatrix} \breve{a}_{11} & \breve{a}_{12} & \cdots & \breve{a}_{1n} \\ \breve{a}_{21} & \breve{a}_{22} & & \vdots \\ \vdots & \vdots & \ddots & \vdots \\ \breve{a}_{n1} & \breve{a}_{n2} & \cdots & \breve{a}_{nn} \end{bmatrix} < 0 \tag{32}$$

where:
$\breve{a}_{11} = S_1 A_1^T + A_1 S_1 - B_1 L_1 - L_1^T B_1^T$
$\breve{a}_{12} = H_{12} S_2 + S_1 H_{21}^T$
$\breve{a}_{1n} = H_{1n} S_n + S_1 H_{n1}^T$
$\breve{a}_{21} = H_{21} S_1 + S_2 H_{12}^T$
$\breve{a}_{22} = S_2 A_2^T + A_2 S_2 - B_2 L_2 - L_2^T B_2^T$
$\breve{a}_{n1} = H_{n1} S_1 + S_n H_{1n}^T$
$\breve{a}_{n2} = H_{n2} S_2 + S_n H_{2n}^T$
$\breve{a}_{nn} = S_n A_n^T + A_n S_n - B_n L_n - L_n^T B_n^T$

In order to find the gain matrices K of the decentralized control law, we have to solve the following LMI problem:

$$\begin{cases} S_i > 0 \quad i = 1, .., n \\ (32) \end{cases} \tag{33}$$

The following result is proved::
The interconnected system (17) provided with the decentralized control law (16) is asymptotically stable if LMI problem (33) is feasible.

4 Simulation results

This section is devoted to the implementation of the three decentralized control approaches exposed and developed in the previous section.
It consists in studying the stability by decentralized quadratic optimal control, decentralized pole-placement control and decentralized stabilization control based on LMI applied to the interconnected inverted pendulums system (Figure1), presented in Section2. The parameters of the studied system are summarized in Table 1.
In last party of this section, we carry out a comparative study between these three studied decentralized approaches to confirm the validity and the efficiency of the proposed approach.

Parameter	Value	Unit
m	0.4489	Kg
l	0.325	m
a	0.21	m
k	340.22	N/m

Table 1: The studied system parameters

Using the numerical parameters, model (14) of interconnected system composed of two parallel inverted pendulums is given by:

$$\dot{x} = \begin{bmatrix} 0 & 1 & 0 & 0 \\ -286.2486 & 0 & 316.4332 & 0 \\ 0 & 0 & 0 & 1 \\ 316.4332 & 0 & -286.2486 & 0 \end{bmatrix} x + \begin{bmatrix} 0 & 0 \\ -21.0903 & 0 \\ 0 & 0 \\ 0 & -21.0903 \end{bmatrix} u \tag{34}$$

To improve the performance of the studied system, we will apply the different studied approaches to guarantee an adequate stabilization.

4.1 Application of the decentralized optimal control approach

For this decentralized control, we focus on minimizing the modified quadratic criteria (19) for each separate pendulum.
The weighting factors are selected as follows:

$$\alpha = 0.2,$$
$$R_1 = R_2 = 0.0043$$
$$Q_1 = Q_2 = \begin{bmatrix} 1 & 0 \\ 0 & 0 \end{bmatrix}$$

The positive definite solution P_i of the Ricatti equation for each inverted pendulum is obtained by solving the equations (22):

$$P_1 = \begin{bmatrix} 0.0724 & 0.0014 \\ 0.0014 & 0.0002 \end{bmatrix}$$
$$P_2 = \begin{bmatrix} 0.0725 & 0.0014 \\ 0.0014 & 0.0002 \end{bmatrix} \tag{35}$$

Using (20) and (21) we obtain the decentralized control gain matrices:

$$K1 = [-7.0068 \ -0.8247]$$
$$K2 = [-7.0068 \ -0.8247]$$

To guarante the stability of the overall interconnected double-inverted pendulum, we should verify the theorem(24) when calculating the matrix F:

$$F = \begin{bmatrix} 0.3360 & -0.0278 & 0 & 0 \\ -0.0278 & 0.0030 & 0 & 0 \\ 0 & 0 & 0.3360 & -0.0278 \\ 0 & 0 & -0.0278 & 0.0030 \end{bmatrix}$$

The eigenvalues of the matrix F are given by:

$$\begin{bmatrix} 0.3383 \\ 0.0007 \\ 0.3388 \\ 0.0007 \end{bmatrix}$$

We can easily verify that matrix F is positive definite, so the decentralized control law stabilizes asymptotically the overall interconnected system (17).

The performances of the controlled system are shown in Figure3. The curves present the evolution of

the system state variables with decentralized optimal control, when some perturbations occur on θ_1 and θ_2. From the simulation results shown in these curves, it can be seen that the decentralized optimal control is able to enhance stability of the studied system in approximately 0.6 seconds.

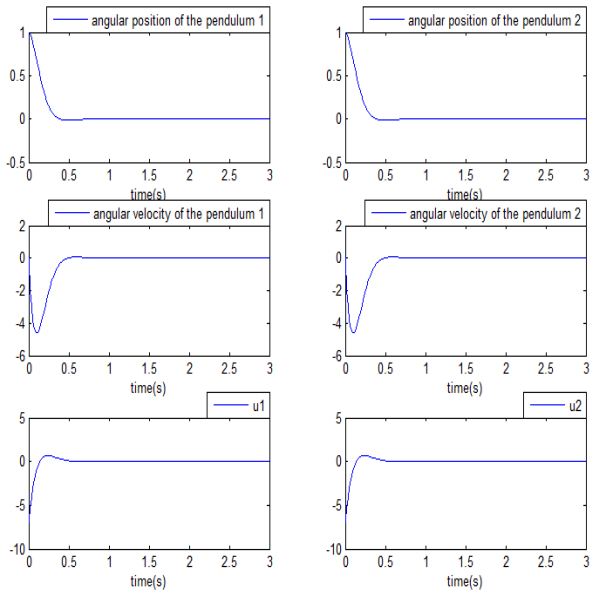

Figure 3: Evolution of the system state variables and corresponding decentralized optimal control signals

4.2 Application of the decentralized pole-placement control approach

In order to apply the decentralized pole-placement for the studied interconnected system, we shall firstly decompose the system into two decoupled inverted pendulums.
Thus, the dynamical model of the isolated subsystems is given by:

$$\dot{x}_1 = \begin{bmatrix} 0 & 1 \\ -286.24 & 0 \end{bmatrix} x_1 + \begin{bmatrix} 0 \\ -21.09 \end{bmatrix} u_1 \qquad (36)$$

$$\dot{x}_2 = \begin{bmatrix} 0 & 1 \\ -286.24 & 0 \end{bmatrix} x_2 + \begin{bmatrix} 0 \\ -21.09 \end{bmatrix} u_2 \qquad (37)$$

Since both (A_1, B_1) and (A_2, B_2) are controllable, we can move their poles to any desired locations, we choose the following desired eigenvalues:

$$\lambda_1^1 = -24; \lambda_2^1 = -18; \lambda_1^2 = -24; \lambda_2^2 = -12$$

In this case we calculate the local gains using the Ackermann's formula [25] :

$$K1 = [-6.9108 \ \ -1.9914]$$

$$K2 = [-0.0830 \ \ -1.7096]$$

Figures 4 and 5 present the evolution of the state variables and their corresponding pole-placement control signals for each isolated pendulum. From the simulation results shown in these curves, we can verify the local stability at each decoupled pendulum.

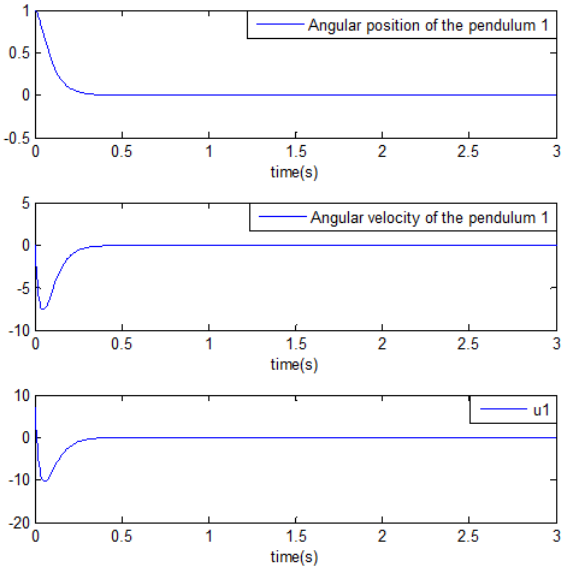

Figure 4: Evolution of the state variables and corresponding pole-placement control signals for the first decoupled pendulum

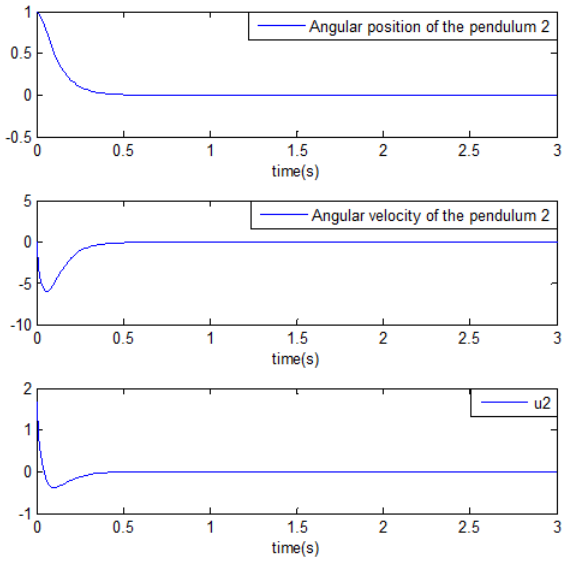

Figure 5: Evolution of the state variables and corresponding pole-placement control signals for the second isolated pendulum

After having applied the formula of Ackermann for each isolated decoupled pendulum, we obtain the closed loop matrix A_f of the overall interconnected system.

$$\dot{x} = A_f x = \begin{bmatrix} 0 & 1 & 0 & 0 \\ -432 & -42 & 316.4332 & 0 \\ 0 & 0 & 0 & 1 \\ 316.4332 & 0 & -288 & -36 \end{bmatrix} x \qquad (38)$$

The eigenvalues of the system (38) have strictly negative real parts:

$$\lambda_1 = -0.9487$$
$$\lambda_{2,3} = -19.5639 \pm 17.0966i$$
$$\lambda_4 = -37.9236$$

Thus, the overall interconnected system provided with such a decentralized control law is asymptotically stable.
The curves in Figure6 illustrate the evolution of the system state variables and the corresponding decentralized pole placement control signals of the double inverted pendulum coupled by a spring, subjected to the same perturbations on the variable θ_1 and θ_2.
From the simulation results shown in these curves, it can be seen that the decentralized control is able to enhance stability of studied system in approximately 4 seconds.

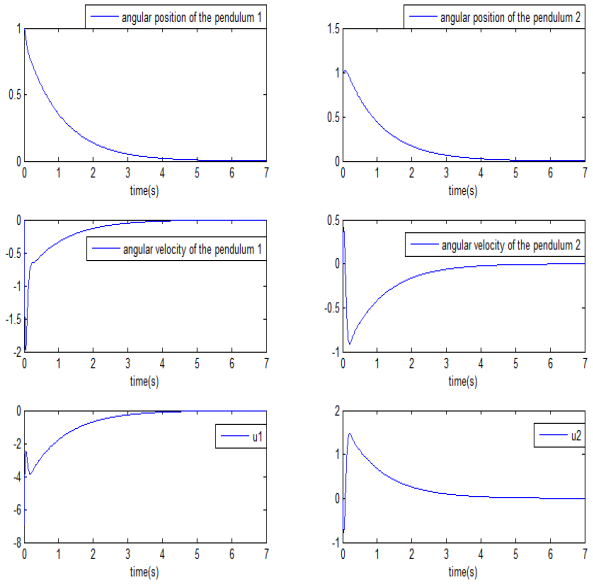

Figure 6: Evolution of the system state variables and corresponding decentralized pole-placement control signals

4.3 Application of the decentralized stabilization control approach

We consider the application of the proposed decentralized stabilizing control developed in section 3.3. on the studied system formed by two inverted pendulums coupled by a spring.
In this part, we solve the proposed LMI formulation in order to find the decentralized gains of the double inverted pendulum.
So we obtain:

$$\begin{cases} S_1 > 0 \\ S_2 > 0 \\ \begin{bmatrix} \breve{a}_{11} & \breve{a}_{12} \\ \breve{a}_{21} & \breve{a}_{22} \end{bmatrix} < 0 \end{cases} \quad (39)$$

where :
$\breve{a}_{11} = S_1 A_1^T + A_1 S_1 - B_1 L_1 - L_1^T B_1^T$
$\breve{a}_{12} = H_{12} S_2 + S_1 H_{21}^T$
$\breve{a}_{21} = H_{21} S_1 + S_2 H_{12}^T$
$\breve{a}_{22} = S_2 A_2^T + A_2 S_2 - B_2 L_2 - L_2^T B_2^T$

By solving problem LMI (39) we obtain the decentralized control gain matrices:

$$K1 = [-8.4386 \ \ -1.0841]$$

$$K2 = [-31.6377 \ \ -2.4752]$$

The evolution of the state variables of the dynamic system composed of two interconnected inverted pendulums with decentralized control by LMI is depicted in Figure 7.
It is clearly seen, from these curves, that the proposed decentralized stabilization control approach is efficient, it allows the best stabilization of the studied system despite the strong disturbances affecting the interconnection between its subsystems.

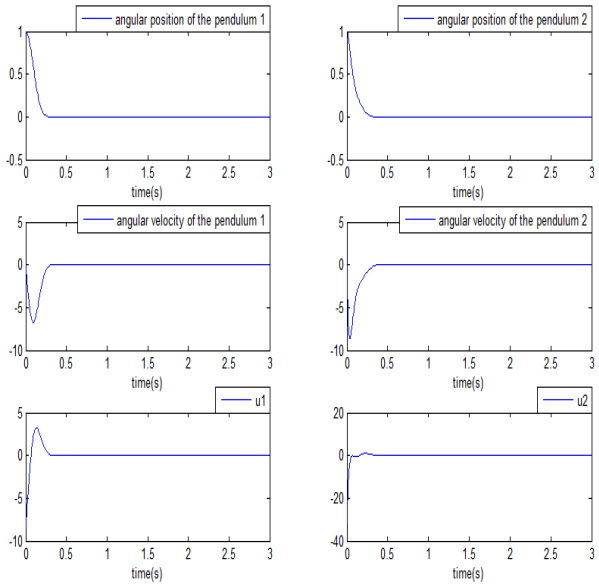

Figure 7: Evolution of the system state variables and corresponding decentralized stabilizing control signals

4.4 Comparative study of the three approaches

We present in this section a comparative study between the three decentralized control approaches studied in section 3.
The visualization of the curves in figure 3, 6 and 7 presenting the evolution of the system state variables and the corresponding control signals, submitted to the same perturbations, shows that the three studied decentralized control approaches can improve the stability of the interconnected system with double inverted pendulums coupled by a spring.

However, we find some disadvantages when applying the decentralized quadratic optimal and decentralized pole-placement on interconnected system. We were obliged to decompose the overall system into

a number of isolated subsystems and then to determine gain matrices that verify local stability for each subsystem. Then we present some sufficient conditions on the obtained gains to guarantee the global stability of the overall system taking into account the interconncetion terms. Indeed, we note an advantage for the proposed new stabilization decentralized approach using LMI problem which calculation of the local gains takes account of the interconnections terms.
On the other hand, when we compare the stabilization times of the three presented approaches, we note that our proposed approach is able to stabilize the system more quickly than other approaches.

5 Conclusion

This extended paper is devoted to the decentralized control techniques of large-scale interconnected systems. In this context, we have presented and studied some decentralized control approaches which objective is to synthesize the gains matrices in order to guarantee the stability of the global system. Our contribution focuses on the development of a new decentralized stabilization control approach based on linear matrix inequalities LMI.

The different approaches studied and formulated in this paper have been applied and validated on a double-parallel inverted pendulum coupled by a spring.
The simulation results have shown that it is possible to ensure the stability and improve the performance of the studied system controlled by each of the decentralized control laws relating to the proposed methods when some sufficient conditions are verified.
Comparative study presented in the fourth section has confirmed the validity and the efficiency of the proposed approach based on LMI which succeeded to ensure quickly the stability of the system and calculated the local gains taking account of the interconnections terms.

Many interesting directions for future research remain. One of the possible perspectives is to develop decentralized control nonlinear approaches for multi-robot cooperative system manipulating a common object.

Appendix A

The proof of the ***Theorem 1*** is based on Lyapunov direct method. Let V be the Lyapunov function defined by the following quadratic form:

$$V(x) = x^T P x \tag{40}$$

Using (23), The time derivative of V (x) is developped as :

$$\begin{aligned} \dot{V} &= x^T(A^T P - PBR^{-1}B^T P)x + x^T H^T P x \\ &\quad + x^T(PA - PBR^{-1}B^T)x + x^T PHx \end{aligned} \tag{41}$$

So (41) becomes

$$\begin{aligned} \dot{V} &= x^T(A^T P + PA - 2PBR^{-1}B^T P)x \\ &\quad + x^T H^T P x + x^T PHx \end{aligned} \tag{42}$$

Then, using the expression (22) in (42), we obtain:

$$\dot{V} = -x^T[2\alpha P + W - (PH + H^T P)]x \tag{43}$$

To ensure the asymptotic stability of system (23) , $\dot{V}$ should be negative definite, then which is equivalent to the matrix F:

$$\begin{aligned} &F = 2\alpha P + W - (PH + H^T P) \\ &W = Q + PBR^{-1}B^T P, \;\; Q = diag[Q_i] \end{aligned} \tag{44}$$

should be positive definite.

Newton Raphson power flow method
UPFC

ABSTRACT

The occurrence of many failures in the power system can lead to power instability and affects the system parameters to go beyond its operating limits. It may lead to obstructing the secure operations and reliability of power systems. Ensuring power system security needs proper actions to be taken for the undesirable contingency. Thus, security analysis is important tasks in modern energy management systems. This paper proposes an approach based on the Newton Raphson power flow method for power system security analysis. Firstly, the contingencies will be specified to assess their impact on the transient stability. Secondly, the selected contingencies will be classified in the order of severity. In addition, the integration of the Unified Power Flow Controller (UPFC) to enhance the transient stability of the power system is considered. The proposed method is implemented on the IEEE-14 bus system. We performed this case study using the well-known software EUROSTAG.

1. Introduction

Security analysis of a power system plays a significant role in the growth and development of modern societies. Given that the power system is a large-dimension complex system, it might be the site of various disturbances, making its chaotic behavior and difficult to control [1]. Thus, ensuring the security of the electric network becomes an essential task for operators and researchers.

Following a violent disturbance enormous damage may occur in the power system and impacts directly its normal operation. We can note that the concept of network security is broader than the stability of networks [2]. It is defined as the ability of power system to maintain its stable operation after each disturbance or unfavorable change of the system [3]. However, the level of security is deemed satisfactory if, firstly, it is able to ensure the production-consumption balance within certain acceptable limits related to line's power flows, voltage in each node and operating points of generation units and if, on the other hand, it is able to persist in a more or less violent disturbance.

Therefore, the system operator must ensure that the power system operates at a secure operating point where all equipment is within their safe limits. If the failure is not controlled suitably, this could lead to a disastrous event such as major blackouts and impact then the economic and environmental requirements [4].

The advent of FACTS devices has been a boon to the power industry. These devices provide fast and effective control of the various parameters of the power system to improve their stability and preventing other related cascade accidents [5-9]. The UPFC is one of the most versatile FACTS devices, providing independent control of the voltage, real and reactive power of the transmission under its supervision. This device enhances the power system security.

N. Hashim *et al*. [10] have presented an analysis of transient stability of IEEE 14 bus test system. They studied the effect of the fault location on system stability; and they analyzed the characteristics of the machine states including speed, rotor angle, output electrical power and the terminal voltage of the machine after a three-phase short-circuit which occurs at different points of the system. The IEEE-14 bus system has been also studied in [11], wherein both authors have studied the effect of fault location and critical clearing time on the system stability. In order to achieve this, they analyzed the behavior of the synchronous machine, in particular, the angular position of the rotor. They proposed to rapidly isolate the faulted part to increase stability margin.

A. Zerigui [12] provided a solution to the problem of transient stability. To test a constrained optimal power flow, and estimate critical clearing time she developed a new analytical function. She applied her strategy to test large networks up to 145 buses. While in [13] the authors just used nine-bus IEEE system to confirm their proposed method. They presented a global approach to transient stability constraint optimal power flow based on SIME model.

www.astesj.com
https://dx.doi.org/10.25046/aj030149

Likewise, authors in [14] analyzed the transient stability for IEEE-9 bus test system. Then, they proposed a simple control method based on the equal area criterion for calculating critical clearing time. To improve the stability margin, the temporal evolution of the frequency and voltage, with and without load shedding, is performed.

For three decades, J-C Chow et al [15] have formulated the contingency classification problem into a pattern recognition problem and then design a Hopfield model to detect a prescribed set of patterns. This optimization method, which uses the linear programming technique, considers only the steady-state security assessment problem.

In order to explain the contribution in deepening understanding of the power system security problem, the authors in [16], proposed an efficient steady-state contingency classification methodology based on Rough Set Theory. Through this analysis, they could classify the system operating in four different states.

Abdulrazzaq, A. [17] used the Newton Raphson load flow method for the power system contingency ranking only for the line outage.

In most cases, the researchers deal with the security analysis in the steady case, considering the execution time of computational simulations performed. The main purposes of security analysis are the fast identification of critical contingencies and their evaluation related to the severity level [18-20].

This paper is an extension of work originally published in the Proceedings of the International Conference on Sciences of Electronics, Technologies of Information and Telecommunications [21].

This paper focuses on the contingency analysis that comprises three steps. Firstly, we create the contingencies list containing all sets of possible contingencies that may occur in a power system. Secondly, the classification of severe contingencies from the list that may lead to the supply and security constraints violations is achieved. Lastly, the evaluation of contingencies is necessary. In addition, a curative action using UPFC devices to avoid the effects of most severe contingencies is proposed. To verify our proposed approach, we perform simulations on an IEEE 14-bus power system.

2. Analysis of Electrical Networks security

The security analysis of an electrical network is related to its dynamic state or steady state following the disturbance. In dynamic security analysis, the transition from the existing operating condition for the new operating conditions and the fact that during the transient state should not be cascading outages are considerations of interest. The dynamic security analysis is normally done in a deterministic approach using analytical tools such as load flow calculation, dynamic simulation, etc. Indeed, these tools use a detailed model of the electrical system to determine the system dynamic response with respect to each of the analyzed contingencies. Analysis methods of the dynamic security of electrical networks are classified into four groups: methods based on numerical simulation, pattern recognition methods, direct methods and hybrid methods [22-25]. In this paper, we propose heuristic method because it is easier to set up and it gives quick and good solutions to difficult problems.

2.1. Operating States of a Power System

In security analysis, power system may operate in different states, namely normal, emergency, alert, extreme state and restorative [26, 27]. A system is said to be in normal operating state when it satisfies equality and inequality sets of constraints. This is equivalent to the fact that there is no overloaded equipment and all the variables of the system are within the normal operating limits [28, 29]. Following every single contingency the system must be able to operate in a secure way while respecting all the constraints. However, if the contingency is highly dangerous or the system generation drops below the required amount, the system operation may be insecure indicating an alert state. In this case, the equality and inequality constraints are still satisfied nevertheless; preventive action is needed to restore the normal state. In case of preventive control failure, the system security level may be under the permissible limit. Therefore, the inequality constraints are no longer maintained and the system enters in an emergency state. It is to be mentioned that in case of a sufficiently serious contingency, the system transits directly to the extremis state.

To overcome the emergency state, control measures should be initiated immediately. If these actions are not efficient or are not taken at the adequate time, the state of the system is said in extremis. This state is characterized by violated equality and inequality constraints which may cause the loss of some parts of the system or a total system blackout. Otherwise, the rapid and efficient application of control actions brings the system to the restorative state. In that instance, the implementation of other control measures may lead the system either to the normal state or the alert state.

2.2. UPFC device

UPFC (Unified Power Flow Controller) is the most powerful and versatile device. It can control three parameters either individually or in appropriate combinations at its series connected output while maintaining reactive power support at its shunt connected input device. Therefore, the aim of UPFC is to enhance the usable transmission capacity of lines and control the power flow [30-35].

The model of UPFC implemented in a transmission line is shown in Figure 1. A series converter connects with the line through an insertion transformer. A shunt converter connects with the line through a second transformer. The DC terminals of the two converters are linked together, and their common DC voltage is supported by a capacitor bank. A mathematical model of the UPFC is well-detailed in Reference [36].

3. Mathematical Model of power system

In order to analyze, simulate, design and control the electric power system operation, steady-state and dynamic system performances properly are explained.

3.1. Description of system

In general, a power system can be modeled by the following set of nonlinear differential-algebraic equations:

$$\dot{x} = F(x, y, \lambda)$$
$$0 = G(x, y, \lambda) \quad (1)$$

Where x is a vector of state variables, y is a vector of network variables, and λ represent the control and parameter variable which may be used to control or tune power system performance.

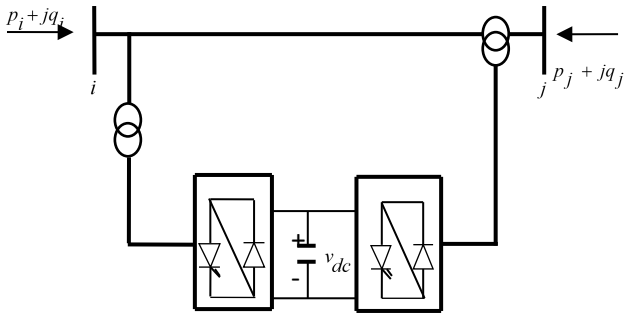

Figure 1. UPFC model.

The differential equation F represents governing dynamics of power systems, which is associated with generators, excitation systems, and speed governor. The differential variables x consist of the states of dynamic components such as rotor angles and rotor speed.

$$x = [\delta, \omega]^T \quad (2)$$

The algebraic equation g represents the network power balance of power systems. The algebraic states y includes bus voltages and bus phase angles. It is also known as control variables.

$$y = [V, \alpha]^T \quad (3)$$

The active and reactive powers injected at any bus are given by Equation (4). Therefore, it is a function of voltage magnitudes and angles for all the buses, as well as the admittance, magnitude, and angle, for the transmission network.

$$\begin{cases} P_i = V_i . \sum_{i=1}^{n} Y_{ij} . V_j . \cos(\alpha_i - \alpha_j - \theta_{ij}) \\ Q_i = V_i . \sum_{i=1}^{n} Y_{ij} . V_j . \sin(\alpha_i - \alpha_j - \theta_{ij}) \end{cases} \quad (4)$$

Where Y_{ij},θ_{ij} are, respectively, the admittance magnitude and angle for the transmission line i-j, V_i, V_j are the voltages at bus i and j, α_i, α_j are the voltages angles, and n is the number of studied network buses.

The active and reactive power functions are evaluated by this load flow equations:

$$\begin{cases} P_{Gi} - P_{ci} - P_i = 0 \\ Q_{Gi} - Q_{ci} - Q_i = 0 \end{cases} \quad (5)$$

P_{ci}, Q_{ci}, P_{Gi} and Q_{Gi} are respectively active and reactive power consumed and produced for bus i.

Equations (6) give the output active and reactive power. These equations show that P and Q are functions of the bus voltages and rotor angle. X_T and E_q represent respectively transfer reactance between buses and internal voltage of the generator.

$$\begin{cases} P = \frac{E_q . V_i}{X_T} . \sin\delta \\ Q = \frac{V_i^2}{X_T} - \frac{E_q . V_i}{X_T} . \cos\delta \end{cases} \quad (6)$$

3.2. Model of Machine

The generator model is represented by the four-order model as follows:

$$\begin{cases} \frac{d\delta}{dt} = \omega - 1 \\ M . \frac{d^2\delta}{d^2 t} + \frac{d\delta}{dt} . D = P_m - P_e \\ \frac{dE'_q}{dt} = \frac{1}{T'_d} . (E_{fd} - E'_q + (X_d - X'_d) . i_d) \\ \frac{dE'_d}{dt} = \frac{1}{T'_q} . (-E'_d + (X_q - X'_q) . i_q) \end{cases} \quad (7)$$

δ is the rotor angle of the machine, ω is the rotor speed, M is an inertia coefficient of machine, D represents the damping coefficient of machine, Pm, Pe are the mechanical and electrical power of the machine, E'_d, E'_q are the voltage behind the direct and quadrature axis transient reactance X_d', X_q' respectively, T'_{d0} is the d-axis open circuit transient time constant, T'_{q0} is the q-axis open circuit transient time constant, and E_{fd} represents a field voltage.

3.3. Security Contraints

The security constraints are based on the operating limits which have to be satisfied for normal operation of the power system. In order to operate the system within an acceptable security domain, the basic security constraints are as follows:

$$V_{min} \le V \le V_{max} \quad (8)$$

$$P_{gmin} \le P_g \le P_{gmax} \quad (9)$$

$$Q_{gmin} \le Q_g \le Q_{gmax} \quad (10)$$

$$\delta_{min} \le \delta \le \delta_{max} \quad (11)$$

4. Proposed Method

Considering the fact that the electrical network operates under two main types of constraints; constrained supply (C1) of energy (C2) which imposes that all consumers must be supplied and operations constraints require that the system variables should be within specified operating limits.

During a normal operating state, all constraints are satisfied. It is characterized by a sufficient level of stability margins so that the system can withstand a single contingency. When the system satisfies all the supply and security constraints without reserve power generation, it passes in an alert state. This means that in the event of a contingency, at least one inequality constraint will be violated. Therefore, preventive actions have to be taken to bring the system to a secure state. The power system enters an emergency state from an alert state when a contingency occurs. In this case, all the equality constraints are satisfied and at least one inequality constraint is violated. Consequently, the system requires an immediate implementation of corrective actions to prevent the damage of equipment. However, once the severity of the disturbance is very high, both equality and inequality constraints are violated. Thus, the system passes in an extreme state.

In this paper, we consider the time taken by the system to transit from a secure state into another one where is not secure as an index for ranking serious contingencies. Therefore, the contingency is deemed severe when both constraints of the network are not satisfied and, it is potentially harmful if only the constraints of system operation are not satisfied. In the case of both constraints are respected, the contingency is recognized as being harmless.

To achieve this aim, a fast strategy is proposed to identify power system dynamic behavior using the time domain simulation method. A corrective control to restore power system operating equilibrium after disturbances has been also proposed. This strategy is based on a deterministic approach using analytical tools such as load flow calculation and dynamic simulation. Newton-Raphson method is used to solve load flow problem. In this method, optimal solution can be obtained using iterative method. It usually converges faster than other methods. Then, the identification of properties by the best solutions and introduce them as boundaries of the problem are mainly fulfilled. Firstly, the assessment of different operating state according to a set of selected contingencies is required. Then, security assessment is based primarily on steady-state load flow analysis and transient analysis of the power system. The based approach gives priority to the most severe cases for thorough analysis, and the stable cases are previously eliminated from the list.

Figure 2 depicts the flowchart of the proposed method.

5. Simulation

5.1 Case Study

Figure 3 shows the single line diagram of IEEE 14-bus system. It consists of five synchronous machines. There are eleven loads in the system. Three step-up transformers, one of which is three winding transformer. The generators are modeled as an ideal voltage source behind the synchronous reactance of the machines. The model of transmission lines considers the resistance and the reactance. The loads are modeled as constant impedance. The all data for simulation were selected from [37]. We performed all simulations using software package EUROSTAG [38]. This software is a powerful tool dedicated to dynamic simulations. Its major advantage is the high rapidity of its algorithm.

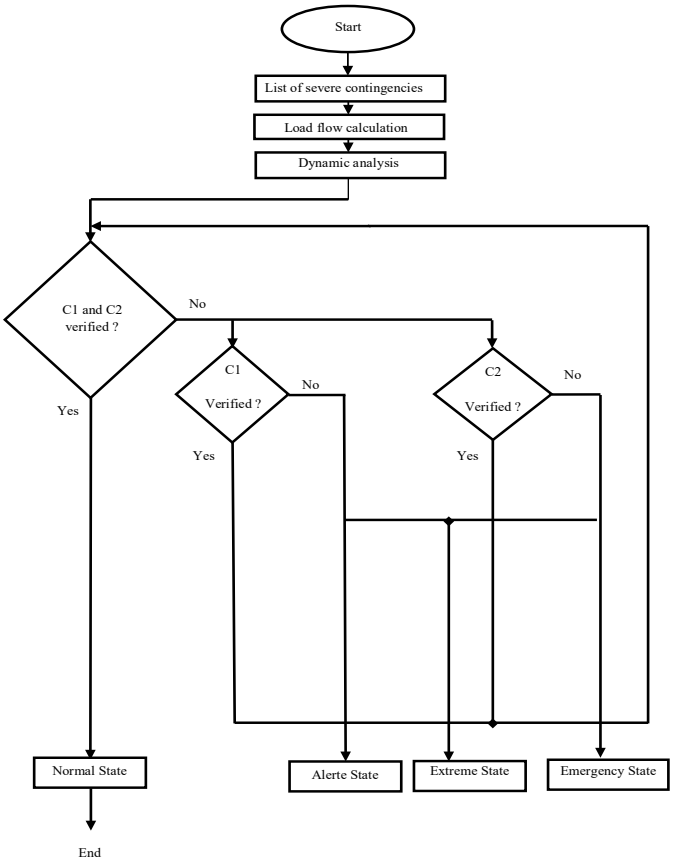

Figure 2. Flow chart of proposed method.

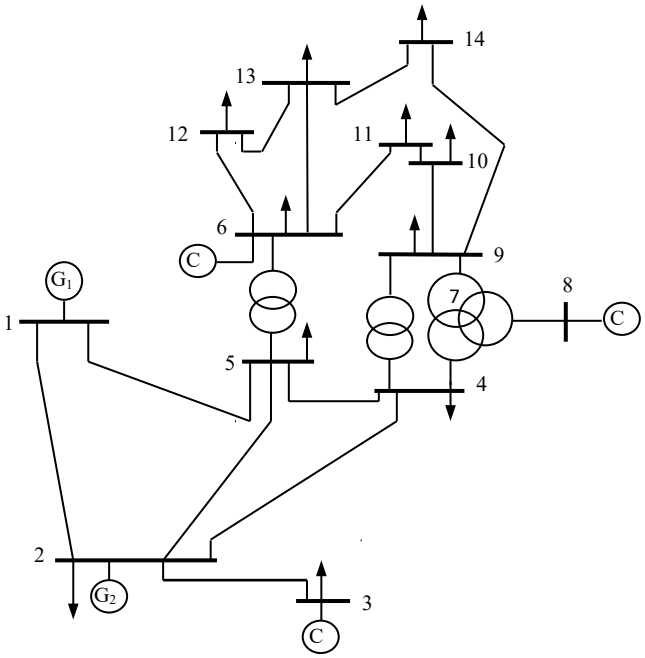

Figure 3. Single line diagram of IEEE 14-bus system.

5.2 Contingency Classification Method

Contingency analysis should be performed for the unexpected and severe events that may occur in power system. Table 1 presents the contingencies list containing the contingencies that may occur in a power system. For the contingencies classification, we considered two criteria; maintaining the network characteristics in their acceptable ranges, and ensuring a balance between production and consumption. A contingency is deemed very dangerous when both constraints of the network are not satisfied, which corresponds to an extreme state. It is potentially dangerous if only the constraints of system operation are not satisfied; the network is in an emergency state. Whenever the system goes to alert state under severe contingency; is that the constraint of energy supply is not fully respected. If both constraints are respected the contingency is recognized as being harmless; as a result, the network is stable. Thus, this contingency is ineffective on the loss of system and it can be rejected.

Table 1. Contingency Index.

Contingency	Index
Bolted fault	I
Impedant fault	II
Increase of load by 10%	III
loss of generator G1	IV
loss of generator G2	V
Opening of line 8-7	VI
Opening of line 2-3	VII

5.3 Simulations Results

At time 250s, we simulated different types of fault and we followed the temporal transition of the system. Table 2 defines the emergency state, alert and the extreme state of network study. We can notice that the range of stability is different for each type of fault. Loss of generator G1 remains the scariest of all faults on network stability. In order to have reasonable accuracy in the classification of contingencies, the detailed assessment of the contingencies is necessary. The aim is to detect the worst case for the transient stability of the test system. Thus, we tested the impact of line opening, loss of power generator, and the severity of three-phase short-circuits.

5.3.1 Line opening scenario

We should first look at how the line opening affects the transient stability of the system. To achieve that, we propose the tripping of lines one by one. All system parameters (frequency, voltages at different buses, rotor angle of the two machines) must be within the allowable range to predict the security of the system.

Therefore, all security practice is followed. For the opening of line 1-5, the behavior of the two machines is different; G1 accelerates while the machine G2 decelerates. Both machines accelerate, in case VII and oscillations are much less than line 1-5. In the case of opening the line 9-14, a voltage drop at bus 14 passes from 0.971pu to 0.928pu, oscillations amplitude of the rotor angle is important. With the opening of line 8-7, we note a separation of the network in two sub-networks; the first sub-network includes the machines G1, G2, G3, and G6. The second involves only the machine G8. Following this fault, a drop in voltage appears at the terminals of all the consumer nodes and an increase of 2.5% of the voltage at bus 8 with a slight oscillation of voltages.

Table 2. Operating modes of the test system

State	Alert State	Emergency state	Extreme State
I	[250.1 250.4]	] 250.4 250.413]	]250.413 250.414]
II	[251.5 252]	] 252 253]	] 253 255]
III	-	-	-
IV	] 250.07 250.114]	] 250.114 250.13]	] 250.13 250.15]
V	] 250.9 251.5]	] 251.5 257]	] 257 260]
VI	-	-	-
VII	-	-	-

We note that the variation in the speed and power of the two generators have a damped oscillatory regime. Then we can say that the system is stable under these conditions because generator speed and hence rotor angle regain their stability after few highly damped oscillations. In conclusion, the opening of a single line does not disrupt the stability of the network; this contingency may be classified as non-dangerous.

5.3.2 Loss of machine scenario

In order to study which of two machines is critical, we simulated separately, the case of the loss of machine G1 and G2 and followed the transient behavior of the system. As shown in Table 3, in the first case, the two machines are unstable, and the system exhibits a total voltage collapse. While in the second case, only machine G2 becomes unstable, and we note the oscillations of the rotor angle and acceptable electrical power. There are thus among the two machines disturbed during the fault, a machine that is more stable than the other after the elimination of fault. This is confirmed by the necessary critical clearing time that leads to instability. The critical clearing time must be equal to 0.114s for that the machine G2 becomes unstable, while the machine G1 maintains its stability during the definitive loss of G2. The machine G1 does undergo smaller oscillations than the machine G2 in the post-fault configuration. Due to its high nominal power, and that it is chosen as the reference generator. We confirm that machine G1 is critical.

5.3.3 Impact of location of the short-circuit

We will now proceed to study the impact of location of the fault on security margin of the network. A bolted three-phase fault was applied respectively to the nodes 2, 6, 5 and 14 at time t = 250s. The time duration of this fault is 100ms. The choice of nodes is relevant, bus 2 is producer node, a compensator is connected to bus 6, and bus 5 is a consumer node that is linked to two producer nodes and bus 14 is a weak node. Table 4 summarizes all the results of simulations. We noticed that during a fault at bus 2, the system

puts only 0.413s to pass in an extreme state, bus 6 take 5.3s, the bus 5 puts 1.05s and bus 14 passes to an extreme state after 1s.

Let us note that transient system behavior is associated with large oscillations of both machines outputs. Therefore, a short circuit applied at bus 2 and bus 14 impacts greatly the stability of the network. These fault types are therefore classified as a dangerous contingency.

Table 3. State of both machine G1 and G2

Parameters	Loss of G1	State of G2	Loss of G2	State of G1
f(Hz)	40	unstable	49.84	Stable
δ1 (deg)	diverge		15.94	
δ2 (deg)	50		diverge	

Table 4. Variation of Fault Location

Bus	Alert state	Emergency State	Extreme State
2	] 250.1 250.4]	] 250.4 250.413]	] 250.413 250.414]
6	] 250.1 253.7]	] 253.7 255. 3]	] 255.3 260]
5	] 250.1 250.8]	] 250.8 251.05]	] 251.05 251.1]
14	] 250.1 250.8]	] 250.8 251]	] 251 251.3]

5.3.4 *Load increase*

Similarly, we have performed simulations of load variation from 5% to 100%. Table 5 illustrates the stability intervals for three states of the system. We notice that the system satisfies both constraints energy supply and operating for 40% load increase on the system. On the other hand, from 70% the system loses the balance between production and consumption. For a 100% increase in load, the system is subject to voltage collapse. This is explained by the fact that the machine G1, during normal operation, generates only 233MVA (47%) while its nominal capacity is 615MVA. Thus, we note that the machine G1 has reserves to provide the required active power, but obviously, can only satisfy a large load variation.

It is noteworthy that in a multi-machine network, stability for the frequency range is ± 0.4Hz, the critical load of the system is thus 40%. Then, we can indicate that the system is highly vulnerable to voltage collapse in the event of heavy load increase. Furthermore, if we bear in mind that when transition time is small in an emergency or extreme state, this contingency is more severe and requires the treatment.

Numbered contingencies III, V, and VII pose no risk because the network remains stable. As against the others should be analyzed as they can cause loss of synchronism of system. Potentially dangerous contingencies are maintained in a waiting list because some of them can be harmful. Whereas the dangerous contingencies, I, II and IV must be treated. Figure 4 shows the impact of an increase of load on frequency value and rotor angle of the two machines.

Table 5. Stability Margin Depending on Load Increasing

State	Alert State	Emergency state	Extreme State
Stability margin	] 5 40]	] 40 70]	] 70 100]

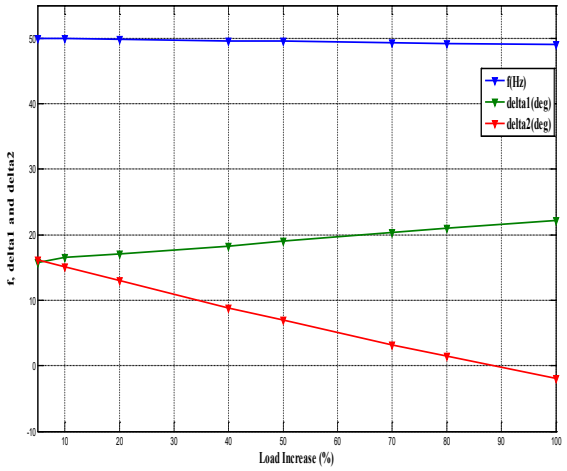

Figure 4. Impact of an increase of load on frequency value and rotor angle of the two machines.

5.4 *Contribution of UPFC on the voltage stability*

The enhancement of voltage stability of the test system using the UPFC is studied. We connect UPFC to the system at different locations. Power dimension of UPFC is ± 200 MVAR. Two scenarios are performed. At first, we consider a total load increase of 40%. Then, a three-phase fault is applied at bus 14. The fault duration is 100ms.

The UPFC was integrated in the middle of line 2-3. Then, it is connected in the middle of line 1-2. Lastly, the UPFC is integrated in the middle of line 9-14.

Table 6 shows the voltage level of all bus under load increase of 40%. Regardless of its location, the UPFC improve almost the voltage level of all bus.

Figure 5 shows the effect of the UPFC on the behavior of voltage at bus 9 and bus 2 with and without the UPFC. The addition of the UPFC has remarkably improved the behavior of voltage.

Here, we consider a bolted three-phase fault at bus 14. The fault duration is 100ms.

Figure 6 and Figure 7 respectively illustrate the temporal evolution of voltages at bus 2 and bus 9 with and without the UPFC.

It should be noted that a short circuit at bus 14 causes a voltage drop which reaches its minimum beyond a certain threshold value and regains its initial value after highly damped oscillations in the presence of the UPFC. Therefore, the UPFC provides the best control of voltage and a good damping of oscillations.

Table 6. Load Increase of 40%

	Sans FACTS	UPFC in line 2-3	UPFC in line 1-2	UPFC in line 9-14
BUS1	1.060	1.060	1.060	1.060

6. Conclusions

This paper presented a classification of contingencies as well as curative action against faults affecting the voltage stability of the system. Extensive studies of the behavior of IEEE 14-bus system for different contingency cases revealed that is subject to instabilities under well-defined fault conditions. We have demonstrated through this paper that power system suffered from severe contingencies leading to their instability. Thus, we investigated effective methods to improve the stability of power network. A comprehensive analysis of the network security testing has allowed us to classify contingencies in an increasing order of

severity. Some of these contingencies may cause serious instability on the network, and others may not be critical. As a result, it is necessary to focus attention on a limited number of contingencies and seek remedial action through UPFC device, which has a role to reduce the possibility of voltage collapse and limit damage of fault, as overloads and short -circuit. Therefore, the UPFC was most effective in improving voltage stability and reducing the harmful effects of dangerous contingencies.

ABSTRACT

Examples of analytical calculations of the system characteristics of the hardware and time complexity of the correlation system based on a certain number of microphones and the corresponding number of interrelations are presented. The structural solutions of the hardware special processor implementation of such class of multichannel devices for recognition and identification of types and the spatial location of sources of acoustic signals are developed. The structural model of the spatial identification of sources of acoustic signals in Cartesian coordinates of a two-dimensional Hamming space with the priority placement of microphones as receivers of acoustic signals is proposed.

1. Introduction

This paper is an extension of work originally reported in 14th International Conference the Experience of Designing and Application of CAD Systems in Microelectronics (CADSM) [1].

Development of theoretical foundations of information technology and software - hardware correlation signal processing is actual scientific - applied problem is to be solved in many industries. Identification of sources of acoustic signals (SAS) relative spatial placement of microphones - receivers of acoustic signals (RAS) is also included. The given problem is a primary-industry-technical task of the special technique [2–4].

Analysis of the known research results. In [5–8] the authors created successful but far from optimal solution of such problem is working out localization accumulated information systems. The determination of spatial parameters (θ) azimuth and distance to the SAS (φ) the use of a certain number of (q) correlates for a given number of those (m) microphones is taken as the base of the system.

The example of the structure of Acoustic Localization by Accumulated Correlation (ALAC) system [5] is shown in Figure 1.

It should be noted that the number of required correlators for a given number of chaotic space placed microphones RAS is determined by the condition of symmetry correlation matrix (1).

$$\begin{array}{ccccc} MK & 1 & 2 & 3 & 4 \\ 1 & 1 & R_{12} & R_{13} & R_{14} \\ 2 & R_{21} & 1 & R_{23} & R_{24} \\ 3 & R_{31} & R_{32} & 1 & R_{34} \\ 4 & R_{41} & R_{42} & R_{43} & 1 \end{array}, \quad (1)$$

where $R_{ii} = 1$, are placed along the diagonal;

$R_{ij} = R_{ji}$ – are identical, according to the symmetry of the matrix (1).

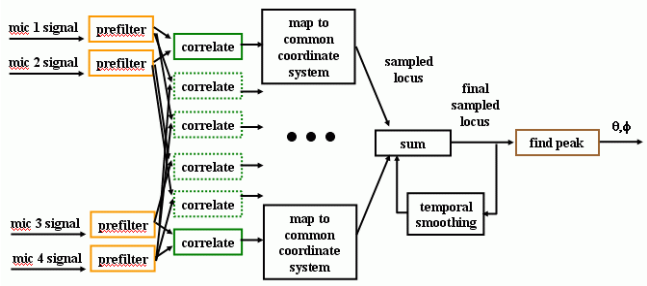

Figure 1. Structure of the ALAC

So, according to the information technology of the correlation processing of the SAS signals in ALAC system, the required amount of (q) correlates for a given number of the (m) microphones is determined by the expression:

$$q = (m^2 - m)/2. \quad (2)$$

The graph of dependency (2) with different numbers of microphones is shown in Figure 2.

For implementation of each correlator in ALAC system the integrated assessment multiplicative correlation function is used by the expression:

$$L(q) = G(\int_{\tau(i,q)-\frac{w}{2}}^{\tau(i,q)+\frac{w}{2}} x_i(t) \times x_j(t-\tau_{i,q}+\tau_{j,q})dt) + \quad (3)$$

$$+ \alpha V_E,$$

where: q – the identifier of the SAS; G – the integrated cross-correlation function; $x_i(t)$ and $x_j(t-\tau_{i,q})$ – current and delayed on the time interval $\pm\tau_{i,q}$ acoustic signals (AS) accordingly; αV_E – damping energy coefficient of the cross-correlation function on the interval $\tau_{i,q}$.

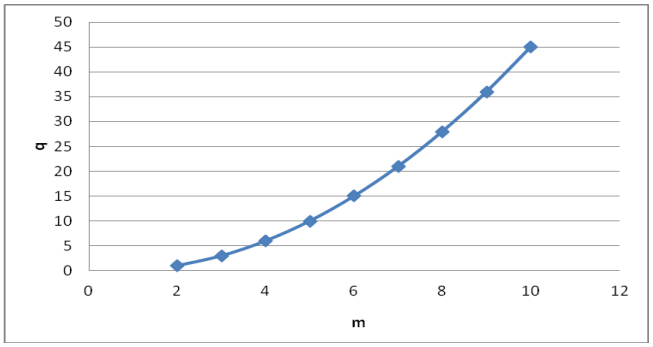

Figure 2. The dependence of the required number of correlators on the number of microphones in the system

The analysis of the analytic expression (3) allows to determine that the implementation of R_{xx} correlates in ALAC system is based on a time delay, $x_i(t)$ multiplying and $x_j(t-\tau)$ integrating analog signals, essentially limiting its functionality, simplifying and increasing the speed and accuracy also prevents it implementation based on digital microelectronics crystals and programmable integrated-circuit logic (FPGA).

The purpose of the work is to develop and explore systemic and structural characteristics of digital special processor computing centered multiplicative correlation function.

2. Formulation of the problem

The purpose of the work is to develop a digital correlator to determine the location of the acoustic signal source.

In order to study the principles of improving and optimizing system features of digital correlators as the basic components of the discovering system, analysis of system features of special processor and computing digital multiplicative correlation estimates by the expression is carried out [9]:

$$R_{xx}(j) = \frac{1}{n}\sum_{i=}^{n} \overset{\circ}{x} \times \overset{\circ}{x}_{i-j}; \quad j \in \overline{0,m}, \quad (4)$$

where: $R_{xx}(j)$ – is centered autocorrelation function; $\overset{\circ}{x}_i$ and $\overset{\circ}{x}_{i-j}$ – are centered digital value and analog signals $x_i(t)$ and $x_j(t-\tau)$; n – is the volume of the sample data set $\left\{\overset{\circ}{x}_i\right\}$; m – is the number of points of correlation function $R_{xx}(j)$; j – is discrete digital delay unit point x_{i-j} in time.

The example of the interaction in time of the digital signals $\overset{\circ}{x}_i$ and $\overset{\circ}{x}_{i-j}$, where C – constant threshold and corresponding asymptotic of the correlation function $R_{xx}(j)$ is shown in Figure 3.

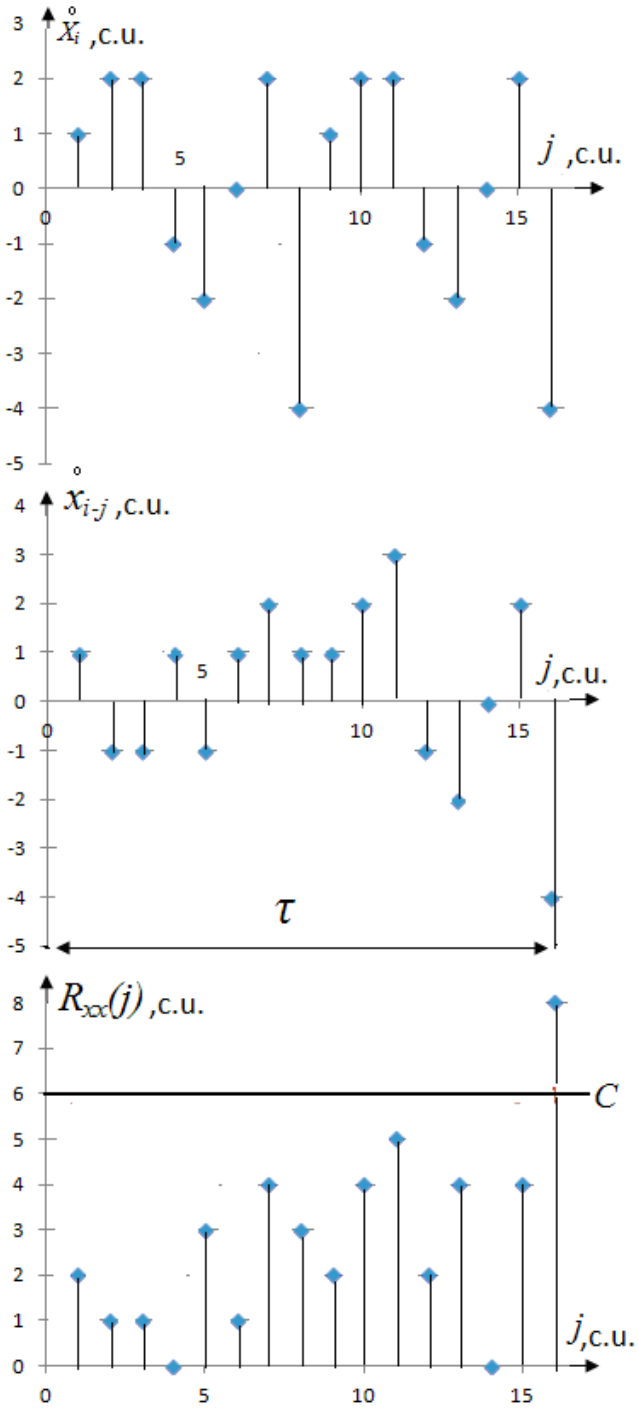

Figure 3. Example of temporal interaction sampled in time and amplitude quantized digital signals and corresponding digital asymptotic estimates multiplicative correlation function in conventional units (c.u.)

Figure 3 shows that at the time of coincidence the current τ digital streams until the moment $\overset{\circ}{x}_i$ of the reception of acoustic signal $x_i(t)$ by a remote microphone SAS level of correlation between the previously obtained a SAS close to the microphone signal $x_j(t-\tau)$ to digital value j – s correlator outputs do not exceed the threshold level constant C and at the time of singing falling at the time fixed main lobe function $R_{xx}(j)$ and accordingly j a numeric value that corresponds to the duration Δt used for direction finding SAS. Obviously, depending on the structure of the stream of digital samples $\overset{\circ}{x}_i$ that reflect the analog signal generated $x(t)$ by a remote SAS in the vicinity of the main lobe $R_{xx}(j)$ functions will emerge sufficiently large lateral lobes, which require separate examination for specific researched objects that have SAS.

In [10] the authors showed that in general for calculation the correlation function $R_{xx}(j)$ according to expression (4) based on a processing arrays of digital data x_i which representing the converted analog-to-digital converter (ADC) input analog signals $x(t)$ you should do the following:

1) define the digital evaluation expectation:

$$M_x = \frac{1}{n}\sum_{i=1}^{n} x_i; \quad (5)$$

2) calculate the array centered values:

$$\overset{\circ}{x}_i = x_i - M_x;\ i \in 1,n; \quad (6)$$

3) calculate the variance:

$$D_x = \frac{1}{n}\sum_{i=1}^{n}(x_i - M_x)^2 = \frac{1}{n}\sum_{i=1}^{n}\overset{\circ}{x}_i^2; \quad (7)$$

4) calculate the correlation function $R_{xx}(j)$ centered on the expression (4);

5) calculate the normalized correlation function:

$$\rho_{xx}(j) = \frac{R_{xx}(j)}{D_x};\ i \in \overline{1,m}; \quad (8)$$

6) perform the comparison of the digital value $\rho_{xx}(j)$ which changes in boundaries $-1 \le \rho_{xx}(j) \le +1$, with boundary constant $0 < C \le 1$:

$$\rho_{xx}(j) > C_0;\ \rho_{xx}(\neq j) < C_0; \quad (9)$$

7) register a digital value j which corresponds to the time delay Δt of the acoustic signal $x(t)$ between two microphones placed at different distance from SAS.

This correlation algorithm of digital processing acoustic signals on a base of multiplicative function (4) is greatly simplified if before the analog-to-digital converter (ADC) pre-differentiation analog $x(t)$ signal is performed and it is passed through a device of automatic gain control.

Such pre-processing of the analog signals $x_i(t)$ and $x_j(t-\tau)$, which are formed on the outputs of the microphones allows to remove from algorithm of calculating operations (5–8) and immediately calculate correlation digital integrated assessment (4) and compare it values at all points j of the constant threshold $R_{xx}(j) > C$.

As it will be shown later, the numerical value of this constant is selected due to the given parameters of digital correlator, which implements the calculation of the multiplicative function $R_{xx}(j)$. Such parameters are:

1) the number of quantization levels of analog signals

$$A = 2^k;\ -\frac{A}{2} \le \overset{\circ}{x}_i \le +\frac{A}{2};$$

2) binary output bit ADC k

$$k = 4,8,10,12;$$

3) the sample size of the database $\left\{\overset{\circ}{x}_i\right\}$

$$n = 2^r;\ r = 4,5,6,7,8,...;$$

4) the number of points correlation function

$$m = 2^l;\ l = 8,10,12....$$

The basic structure of the investigated correlation processing of acoustic signals special processor designed for their processing is shown in Figure 4.

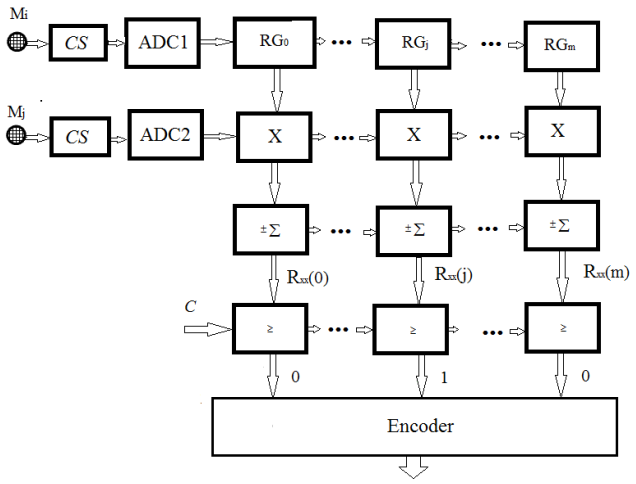

Figure 4. The basic structure of the digital special processor for correlation processing of acoustic signals

The following notions are used in Figure 4: M_i; M_j – RAS microphones; *CS* – conditioners signals; *ADC* – analog-to-digital converter; $RG_0 ... RG_m$ – multi bit shift register source $\pm\overset{\circ}{x}_i$; X – digital binary multiplier; $\pm\sum$ – reversing saving up adder; $\ge$ – module comparing numerical values of the correlation function $R_{xx}(j)$ threshold constant C; encoder – encoder codes Haar – Rademacher.

The work of the digital correlator is as follows. Acoustic signals which are taken by microphone M_i and with a certain time M_j lag are converted to electrical signals which passing

through conditioners signals (CS) are filtered, normalized on power and enter the inputs of the first ADC1 and second (ADC2) alternating analog - digital converters parallel type.

Output k – bit binaries ADC1 come to k – bit input of the multibit shift register (MSR) where RG_j are stored in memory registers, the outputs are fed to the first $j-x$ digital multipliers inputs (X). Binary k – bit codes that are generated at the output ADC2 with a certain time delay corresponding to the time delay of acoustic signals M_j, which are simultaneously fed to all second input ($j-x$) k – bit binary multipliers (X), the outputs of which received $2k$ – bit binaries enter the relevant inputs $(2k+\log_2 n)$ – bit reversible accumulating adder ($\pm\sum$), where codes are received digital values point correlation function $R_{xx}(j)$.

Simplification of operations of division by sample size data set (n) in formula (4) is achieved throughout its multiplicity of 2 degrees, allowing to get the average value of digital codes point correlation function by discarding four junior level in the original binary code accumulating $\pm\sum$. Obtained codes $R_{xx}(j)$ with the bit $2k$, or with less precision $2k–r$, where r = 2,4,6, ... are compared to the corresponding ($j-x$) module compare ($\geq$), the output of which is formed m – bit position code Haar type (00 ... 10 ... 0) , the position "1" of which corresponds to the numerical values of the time delay of acoustic signals received Δt by spatially located microphones M_i and M_j.

For example, when the number of points of the correlation function m = 4096 binary code Δt has 12 bits, that corresponds to Δt = 0.0025 measurement accuracy and uncertainty, and at m = 1024, corresponds to 10-bit binary code and the accuracy does not exceed Δt = 0.001.

The structural scheme shown in Figure 4 can be used for measuring the distance to the SAS by gradient method in case when the source and signal receivers are located anyone line. The example of gradient method is demonstrated in Figure 5.

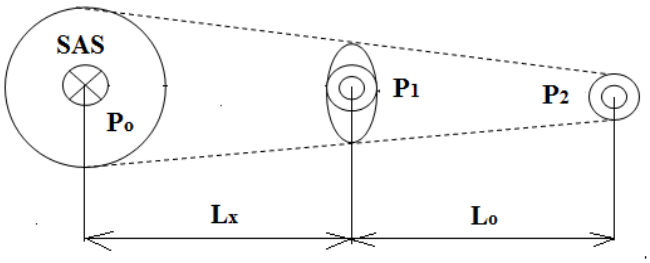

Figure 5. Spatial diagram of SAS capacity changes

The distance to the source is defined by formula

$$L_x = L_0 + \frac{\ln \Delta P}{\alpha},$$

where: α – is the coefficient of acoustic sound energy attenuation in the atmosphere; $\Delta P = P_1 - P_2$ - capacity difference of the signals received from the first and second microphones.

3. Structure of the proposed correlator

The analysis of the expression (4) and the structure of the corresponding digital special processor shows that the presence of the centering operation and the multiplication of alternating digital codes $\pm\overset{\circ}{x}_i \times \pm\overset{\circ}{x}_{i-j}$ complicates the implementation of such a special processor and significantly reduces its performance compared to its functionally equivalent implementation based on the Hamming distance estimation according to the expression

$$G_{xx}(j) = \frac{1}{n}\sum_{i=1}^{n} | x_i - x_{i+j} |, \qquad (10)$$

where centering and multiplication operations are not applied. The application of the Hamming distance estimation based on the calculation of the modular correlation function allows to realize the operation of determining the modular difference between the two digital values $|x_i - x_{i-j}|$ in the microelectronic performance proposed in [9] according.

The purpose of improving the ALAC correlation system is:

1) implementation of the digital representation and correlation acoustic signals processing;
2) reduction of the number of digital correlations of the system;
3) reduction of algorithmic and hardware complexity and increase of speed of digital correlators;
4) implementation of the tabular method for the identification of the spatial location of sources of acoustic signals based on time delay of acoustic signals between microphones;
5) adaptation of the digital correlator to the form of an acoustic signal generated by different sources of sound.

To meet these objective, a method of correlation processing of the acoustic signal with priority placement of microphones [11,12] is proposed on the basis of the multiplicative function (4) converted to the normalized form (8).

Despite successful problem solution for determining time delay of acoustic signals between microphones Δt, such structure of a special processor does not allow to determine independently the spatial coordinates of the source of acoustic signal since it requires more than one base. That is, the number of hardware equipment of such a system increases almost twice. In addition, the use of multiplicative correlation functions $R_{xx}(j)$ and $\rho_{xx}(j)$ requires the implementation of modules for the multiplication and accumulation of reversible interchangeable digital data which considerably complicates the algorithm for processing digital data and the hardware implementation of such a system.

In order to optimize the characteristics of the investigated correlation system the authors propose to implement it on the basis of three microphones, with the priority of spatial placement of one of the microphones at the testbed, and the application of a modular correlation function Gij which allows to identify time delays between acoustic signals Δt_1, Δt_2 and Δt_3 based on the estimation of the Euclidean distance in the Hamming space.

Implementation of the principle of digital processing of acoustic signals allows to reduce significantly the hardware complexity of a single two-channel correlator. The structure of the system is shown on Figure 6.

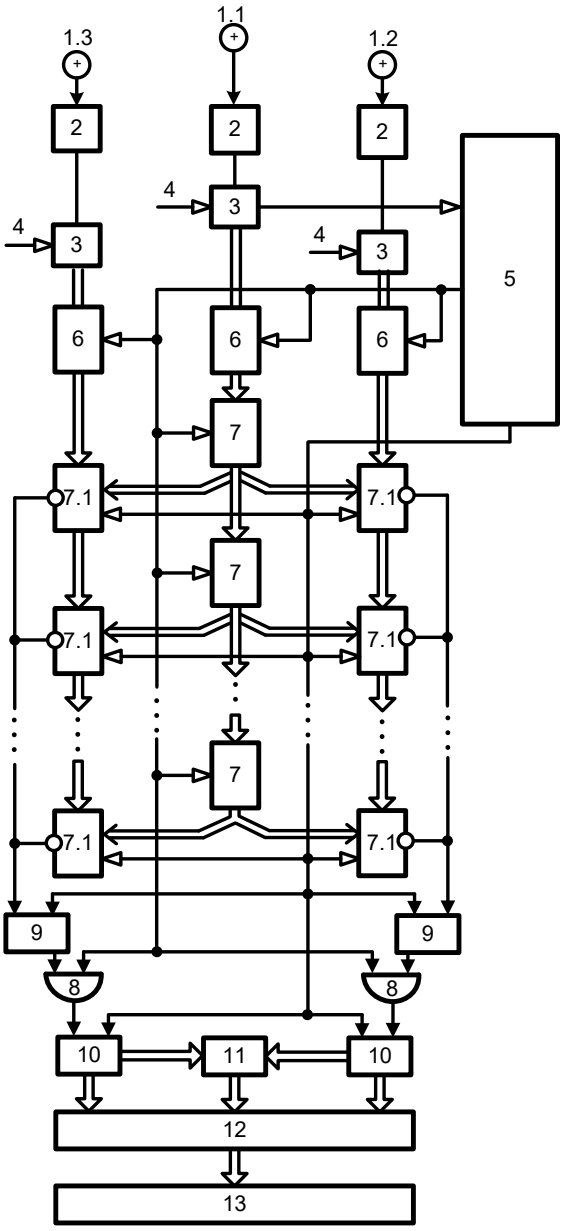

Figure 6. Flowchart of multichannel device for the calculation of modular correlation function

Multi-channel device for calculation of modular correlation function consists of: 1.1, 1.2, 1.3 - respectively: the first priority, second and third receivers of acoustic signals; 2 - amplification automatic adjustment; 3. matched filter of acoustic signals; 4 - reference acoustic signal input; 5 - synchronizer; 6 - parallel-type ADC with output source codes in the binary numeral system of the Rademacher theoretic-numerical basis; 7 - multichannel shift register; ; 7.1 - reverse-accumulation adder; 8 - logical elements AND; 9 - threshold storage of modular differences; 10- RS - triggers; 11 - binary counters; 12 - modular-difference adder; 13 coordinate system based on read-only memory (ROM).

At the beginning of the operating cycle of the device signal S_o of the first output synchronizer 5 generates initial pulse, which resets the memory registers of all cumulative adders of modular differences 9, trigger inputs 10, and binary counters 11 to the zero state.

Input analogue acoustic signals x (t), y (t), z (t), which are generated by a remote source of acoustic signals, enter the input of the acoustic signal receiver 1.1 which is spatially closer to the source of acoustic signals and with some delay in time Δt_1 and Δt_2. Correspondingly, they enter the inputs of related acoustic signal receivers 1.2 and 1.3. Being formed on the outputs of the acoustic signal receivers 1.1, 1.2 and 1.3, electrical signals come to the inputs of the corresponding devices of automatic amplification adjustment 2. Electric signals are produced at their output terminals and are normalized by amplitude and positive indicative potential. Generated, output signals of the automatic amplification adjustment devices 2 flow to the first inputs of matching filters 3. The second filter inputs are connected to the input terminals of reference acoustic signal input 4, and the outputs are connected with the first inputs of corresponding ADC 6.

During the operation cycle of the device the clock signals of the second output of the synchronizer 5 Sx synchronize the formation of source codes x_i, y_i and z_i on the outputs of the corresponding ADCs 6, the corresponding shifts of the digital codes x_{i-j} in the multichannel shift register 7, and pulses coming from the outputs of the corresponding logic elements AND 8 on the inputs of the corresponding counters 10. At the same time, corresponding threshold amounts $\sum_{i=1}^{n}\left|x_{i-j}-y_i\right| \bmod P;\ \sum_{i=1}^{n}\left|x_{i-j}-z_k\right| \bmod P$, s are formed in the accumulated aggregates of the modular differences 9 of the first and second groups, the excess of which causes the formation of a zero potential which converts the corresponding trigger 10 into a single state of the S-input in one of the channels of each group on the inverted outputs of adder accumulator of modular differences 9.

The accumulated amount of impulses in the first counter 11 Δt_1 and in the second counter 11 Δt_2 enters the first and second inputs of the coordinate system 12, and the resulting modular difference in the modular increment adder 12, enters the third input of the coordinate system 13, the output in the form of a code Δt_3. This is the output of the device. Figure 7 shows a timeline diagram of the formation and processing of acoustic signals with the registration of time delays between three microphones Δt_1, Δt_2 and Δt_3 and corresponding values of the source sound coordinates selected from ROM.

For example, at $\Delta L = 1$ м; $i \in \overline{1,256}$, $j \in \overline{1,256}$, which corresponds to the binary codes i and j with 8 bit capacity, the number of sound identified sources with coordinates C_{ij} equals 128^2=8192, and with $i \in \overline{1,64}$ and $j \in \overline{1,128}$ respectively $32 \times 64 = 2048$, and with $i \in \overline{1,16}$ and $j \in \overline{1,32}$ equals respectively $8 \times 16 = 128$. Hence, it corresponds to the spatial dimensions of the testbed targets 256×256; 64×128 and 8×16 m.

4. Research results

The application of multiple autonomous systems of parallel direction finding of acoustic signal sources with respectively

small number of nodes in the Hamming space allows to reduce significantly the accuracy requirements of the digital representation of values Δt_1, Δt_2 and Δt_3.

The required memory for tactical representation of coordinates of the acoustic signal source at $i \in \overline{1,256}$ and $j \in \overline{1,256}$ equals 256 Kbytes.

Generalized chart of acoustic signal processor operation in the Hamming distance based on the modular correlation function is shown on Figure 8.

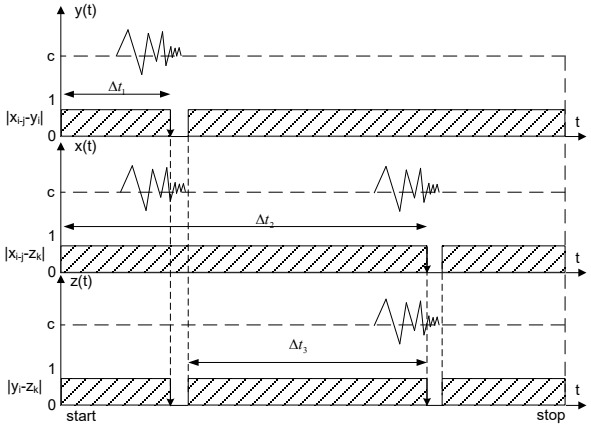

Figure 7. Timeline diagram of code correlation-modular formation of acoustic signal time delay.

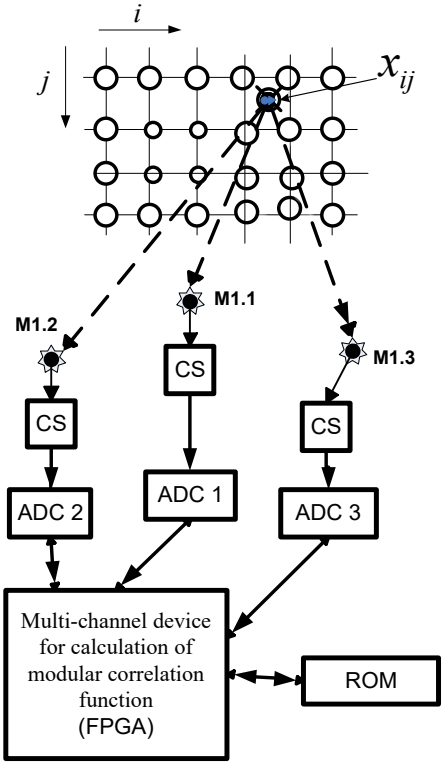

Figure 8. Basic structure of digital special processor for correlation processing of acoustic signals in the Hamming distance

The accuracy of the proposed digital correlator depends on:

- the resolution of a multichannel shift register (Figure 6, element 7);
- the size of square of a Hamming space x_{ij} (Figure 8), which is stored in ROM.

5. Conclusions

The purpose of the work was to develop a structure of a digital correlator to determine the location of the acoustic signal source.

Concept design of an automatic system to determine the location of the acoustic signal source has been proposed. It is based on open architecture and provides connection of multiple autonomous acoustic receivers to the system of correlation special processor using wireless communication channels. This allows automatic collection, processing and data transfer regarding operational conditions in the coverage area of acoustic receivers.

The proposed method of optimizing the structure of multi-channel digital correlates with priority spatial placement of a microphone and application module correlation function to process acoustic signals can significantly simplify the algorithm of calculations, reduce the hardware complexity correlates. This allows enhancing its performance, justifying feasibility and effectiveness of these solutions in the established system of monitoring sources of acoustic signals. The proposed chart allows reducing the number of correlators by 3 times.

Conflict of Interest

No conflict of interest in this paper has been identified.

ABSTRACT

Engineering schools must adopt or develop their own systems and processes for graduate attribute assessment. In this paper, we take a systems engineering approach to graduate attribute assessment and propose a system architecture and tool-supported continuous improvement process with key algorithms and mathematical analysis to process the data and provide performance management reporting. Over several iterations, we have introduced and evaluated improved systems support in a collection of tools called the Graduate Attribute Information Analysis system (GAIA). GAIA integrates course indicators as well as external indicators from a variety of sources. It provides a tool-supported continuous improvement process with templates and notifications for all deliverables. There are sound algorithms and tool support and built-in mathematical analysis for data collection and reporting that includes quantitative and qualitative data; weighted grading; historic trend analysis; improved visualization of results; and standardized reports at both the course level and the program level that can be used either for accreditation or to inform program improvement.

1. Introduction

The Canadian Engineering Accreditation Board (CEAB) requires engineering programs to collect data and assess 12 graduate attributes (GA) as part of a continuous improvement process to ensure the programs are adequately preparing students to be licensed as professional engineers in Canada [1]. The CEAB does not specify how graduate attributes should be measured or how the data should be managed. Engineering schools must adopt or develop their own systems and processes. Radloff, de la Harpe, Dalton, Thomas and Lawson report that for over a decade, academic faculty finds GA assessment challenging [2]. They see the need for faculty to develop a shared understanding of how to integrate GA assessment within the teaching of their courses.

This paper is continuation of the work originally presented in 2017 14th International Conference on Engineering of Modern Electric Systems (EMES) [3]. In this paper, we take a systems engineering approach to graduate attribute assessment and propose a system architecture and tool-supported continuous improvement process with key algorithms and mathematical analysis to process the data and provide performance management reporting. Our research methodology to validate our approach is an iterative combination of action and design science research methodology. We work with the faculty of software, computer and electrical engineering programs in the School of Electrical Engineering and Computer Science at the University of Ottawa to perform graduate attribute assessment, while at the same time identifying gaps, and prototyping improved tool support in our lab. Over several iterations, we have introduced and evaluated improved systems support in a collection of tools called the Graduate Attribute Information Analysis system (GAIA).

In our initial assessment of systems support for graduate assessment at uOttawa, we did not encounter the "academic resistance" discussed by Chanock in his article on developing GA assessment criteria [4]. However, we did identify that existing systems, tools and processes already in place at University of Ottawa School of Engineering tended to complicate rather than support the task. The key issues identified were cognitive overload, lack of clarity, and lack of defined systems and processes.

The first version of GAIA was introduced in 2015 and has progressed through three iterations or versions. The architecture integrates course indicators (such as tests, assignments, quizzes, exams or selected questions) from any learning management system (LMS) as well as external indicators from a variety of sources (such as student surveys, employer evaluation or different types of feedback forms). There is a systematic tool-supported

*Aneta George, SEECS, University of Ottawa, Ottawa ON K1N6N5, Canada

continuous improvement process with templates and notifications for all deliverables. There are sound algorithms and tool support and built-in mathematical analysis for data collection and reporting that includes quantitative and qualitative data; weighted grading; historic trend analysis; improved visualization of results; and standardized reports at both the course level and the program level that can be used either for accreditation or to inform program improvement.

2. Literature Review

We researched and compared solutions from two sources - engineering institutions from countries members of Washington accord; and engineering schools across Canada.

There have been several attempts by different universities to create their own tool that will inform student learning, serve accreditation, and inform program development. In 2004, Maxim describes an assessment plan for student performance in three undergraduate engineering programs - computer science, information systems, and software engineering at the University of Michigan at Dearborn,[5]. It lists course learning outcomes (LO), the measurement instruments used to assess them, student achievement on each particular outcome, and the average score [5]. It gained popularity because of its ability to serve simultaneously as a grade book and LO evaluation tool.

The University of West Georgia, US, created a custom-designed software tool to collect, analyze and report assessment data for program requirements and for accreditation purposes. The tool called COMPASS supported an existing open-source classroom management system by adding the ability to map course LO. It allows for review and analysis of collected assessment data, but lacks a direct reporting feature. The data needs to be retrieved and formatted in order to produce a course assessment report. This complicated the process of data analysis and its implementation for informing program improvement [6].

The Curtin University of Technology in Perth, Australia followed a similar approach in developing the Outcomes Database web-based tool in 2005. It mapped course LO, unit LO, generic graduate attributes and assessment rubrics. The reports it generated helped provide an outcomes focused assessment [7]. Although the paper does not specify any method of tool evaluation, it does show that the Outcomes Database was successfully implemented across courses that share common units in Information Technology, Computer Science and Software engineering.

In his thesis, Essa proposes a custom-developed ABET Course Assessment Tool (ACAT) at the University of Nevada Reno that further improves the Michigan approach [8]. The goal of ACAT is to streamline the course assessment process and standardize reporting. To validate the design and user interface of the tool, Computer Science and Engineering faculty members perform a usability study. Usability of the tool was tested, based on International Organization for Standards criteria [9] that measure effectiveness, efficiency and satisfaction in a specified context of use by specific users. The results showed that the tool created is an improvement over the existing manual process used to assess GA. This study is one of the earliest we have identified that attempts to theoretically compare technology adoption issues between three different tools – COMPASS, Outcomes Database and ACAT. A comparison of the features in two off-the-shelf systems, Compass and Outcomes Database, and the ABET Course Assessment Tool (ACAT), shows 100% compatibility for ACAT, 33.3% for Compass and 66.7% for Outcomes Database.

In 2015, the University of Notre Dame, Australia introduced an outcomes-based curriculum mapping system, Prudentia©. It allows for constructive alignment between different learning outcomes and informs assessment and instructional methodology [10]. The week point of the tool as described by the author is its dependence on the quality of the curriculum framework itself.

Deferent statistical ways to analyze and interpret assessment data was presented by the Office of Academic Planning and Assessment (OAPA) at the University of Massachusetts [11].

Integrating data by cohort using analytical methods and correlations, a method similar to the one used in GAIA, is the subject of collaborative research between Northern Arizona University, Christopher Newport University and James Madison University [12].

Weber addresses the major concern in data analysis – reliability of the results [13]. He explores the use of T-test, ANOVA and ANCOVA to compare different treatments of assessment data for reliability.

Approaches by Canadian universities involve adopting suitable vendor products, adapting tools and processes in place and evolving them into their own learning management system that suits the institutional needs.

A comparison of different GA assessment compatible software tools available on the market was provided in a series of papers by Kaupp, Frank and Watts [14, 15, 16]. Considering the ability of each tool to handle and process data, they classify several outcomes-based assessment support vendor products into five categories – Learning Management Systems (LMS), Learning Content Management Systems (L/CMS), Assessment Platforms (AP), Analytics Systems (AS) and Curriculum Mapping Tools (CMT). Their study concludes that none of the tools is able to manage the GA assessment data independently and they can only address a specific aspect of the GA process [17]. Being distinct from the actual assessment process was identified as a common general weakness for all vendor tools. Issues like duplication of grading, need for uploading/re-entering data by instructors, agreement with other tools or systems or data record forms and most of all incompatibility with diverse nature of student assessment turns them into an additional tool rather than major carrier of assessment analysis for program improvement. Furthermore, the authors compiled evaluation criteria for tool adoption identifying that popularity of the tool should not be used as measure for its functionality. The choice should rather be made based on the compatibility of the tool with institutional needs and systems.

Identifying the process of measuring GA performance as the most difficult step in meeting accreditation requirements. Saunders and Mydlarski from McGill University discuss adopting current institutional resources and evolving them into a software information system [18].

Queen's University, University of Calgary, University of Toronto, Concordia University, University of British Columbia, University of Manitoba and Dalhousie University outlined and

compared their institutional approaches to accreditation requirements in a joint publication [19]. In the research, Concordia University is identified as one of the first Canadian engineering schools to develop their own Learning Management System when enabled them to collect data and allow for sharing between users.

Developing our algorithms, we explored the different ways for administering assessment data presented by Carleton University [20], University of Alberta [21] and University of Calgary [22]. Carleton University and University of Alberta merged the twelve CEAB graduate attributes with respective indicators, measures and rubrics. University of Alberta adds an additional step to the process by involving sub-categories associated with learning objectives.

3. GAIA

Engineering programs in Canada need to demonstrate that their graduates possess twelve specific attributes [23]: engineering knowledge; problem analysis; investigation; design; use of engineering tools; individual and teamwork; communication skills; professionalism; impact of engineering on society and the environment; ethics and equity; economics and project management; life-long learning. An Accreditation Board (AB) Report indicates that accreditations completed in 2015 were the first ones, which included Graduate Attribute Assessment and Continual Improvement compliance [24].

In developing the architecture for GAIA we had the following objectives:

- find a way to use (when possible) and/or modify (when needed) assessment tools and rubrics already in place;
- integrate GAs, key performance indicators (KPI), assessment tools, measurement criteria, course information sheets, data collection and analysis into one information system;
- measure GA performance and allow data to inform a continuous improvement process for each program
- generate reports and perform mathematical analysis to inform program improvement;
- be user-friendly and time-efficient;
- minimize cognitive overload for any data collection or analysis task.

3.1. System Architecture

GAIA provides three types of performance management support – collecting data, processing data and generating reports. Figure 1 below shows the GAIA architecture. It includes an academic platform (faculty administrator, program coordinator, program professors, course professors and students) focused on in-class evaluation and a non-academic platform (employers, co-op office, alumni and students) focused on evaluation mechanisms external to the class room. Data collected through the Academic Platform (AP) is associated with program-related courses and traditional courses typically supported by a Learning Management System (LMS). The Non-Academic Platform (NAP) deals with all other sources of data using Registration Management System (RMS), university-run surveys and outside survey sources. GAIA's performance is managed by a system administrator to assure regular assessment data flow and support reporting of results in a timely manner.

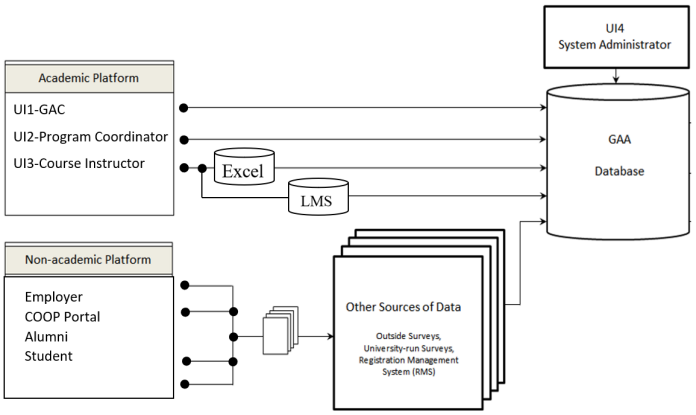

Figure 1: GAIA Architecture

Tool support needs to provide the GAA database (DB) with four types of user interfaces – Graduate Attribute Committee (GAC, UI1), program coordinator (UI2), course instructor (UI3) and system administrator (UI4). Furthermore, it needs to accommodate data fed by different machine interfaces for learning management systems (LMS) and tools already in place for the process of data recording and reporting, as well as qualitative data reported through the COOP portal.

Figure 2 shows the data processing performed by GAIA. It uses different algorithms to process graduate attribute assessment data and generate reports for accreditation agencies in addition to supporting a continuous improvement process for each engineering program. It applies different algorithms to process qualitative and quantitative data input by faculty directly, or imported from a variety of sources. We have identified four MI sources for GA assessment data – LMSs, COOP portal, employer evaluation reports and student surveys. GAIA's architecture pulls external data from these sources in three different ways:

- Using CSV files
- SQL server
- ODBC compliant sources

GAIA's architecture also supports Excel's External Data feature. Once data is initially placed at the location selected by the user, the Refresh button from the Excel Data tab allows for automated updates reflecting data changes at the source. This process is usually set up and performed by the system administrator. GAIA also allows the use of Open Database Connectivity (ODBC) as a programming interface to pull data from different database management systems (DBMS) such as Blackboard or D2L, both currently used at the University of Ottawa.

3.2. Tool Supported Continuous Improvement Process

GAIA supports a systematic continuous improvement process for each program. Creating and implementing improvement steps are initiated and overseen by the members of respective Program Curriculum committees. Success is reported and gaps identified based on consecutive cycles of data analysis performed supported by GAIA as shown in Figure 3 below.

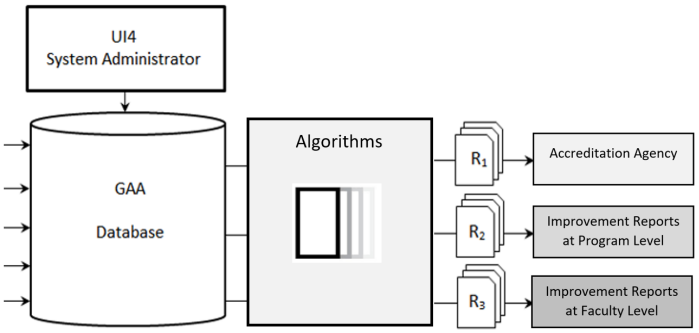

Figure 2: Data Processing for Reporting

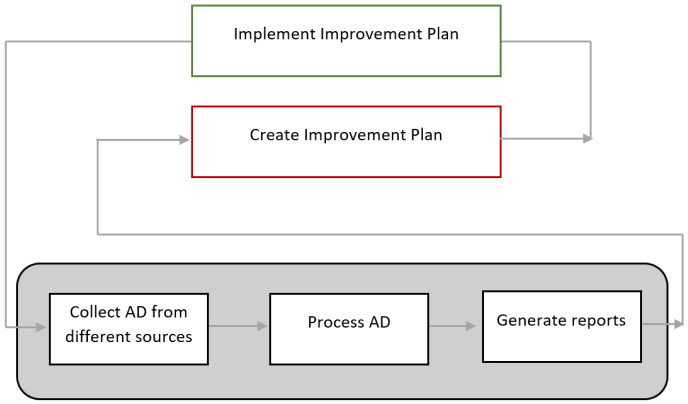

Figure 3: GAIA-supported Continuous Improvement Cycle

The top-down approach, illustrated in Figure 4, mandated by a common continuous improvement process (CIP) leads to a common set of indicators that can be shared across programs. There is a standardized program report that charts a common set of indicators across the 12 graduate attributes. The data for those indicators is obtained from measuring student achievement on the learning outcomes compiled into the common set of high-level indicators specified in the Program Reports. Initially, each program had its own set of performance indicators, which was problematic when trying to achieve consistent reporting at the faculty level that could support cross-program comparisons. Each program aggregated data is clustered into three levels:

- Level I (Course Level): Learning Outcomes presented at the bottom row in Figure 4;

- Level II (Program Level): Performance Indicators, indicated in Figure 4 in black ovals;

- Level III (Meeting Accreditation Requirements): Graduate Attributes analysis for accreditation and program improvement.

At level III we have the 12 graduate attributes specified by CEAB for graduate attribute assessment. Each program has its own set of measurement criteria used to report on achievement for a particular performance indicator (KPI). Selected KPIs are integrated to report on respective graduate attributes (GA). Those indicators are determined by the measurement of learning outcomes for particular courses. The compilation into indicators is mandated in a standardized fashion by the faculty to ensure that achievement is reported in a consistent fashion within a standardized process of continuous improvement.

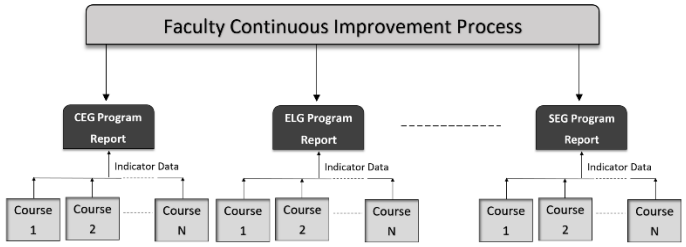

Figure 4. Faculty Continuous Improvement Process.

3.3. Tool-Supported Data Collection and Reports

GAIA provides data collection and reports at two different levels using Course Data Entry Form (CDEF) for individual courses and the Program Report Form (PRF) for an entire engineering program. Data for CDEF is provided by UI3 or input through CVS, SQL server or ODBC compliant sources. Data to Data for PRF is automatically processed and integrated from all the CDEFs for a program. CDEF provides reports and analysis for individual courses. PRF provides reports and analyses across the entire program.

As discussed in section 3.1, GAIA generates three major types of reports – reports for accreditation, improvement reports at program level and improvement reports at faculty level. They are presented in table and graph forms to improve visibility and usefulness. Different tool components, algorithms and data sources are involved in each.

A compiled data report is generated at course level and reflects GA achievement for courses which typically take two semesters to complete. Example for such course is a capstone project. Figure 5 and Figure 6 show a sample report generated for the purpose of this paper in table and graph form respectively.

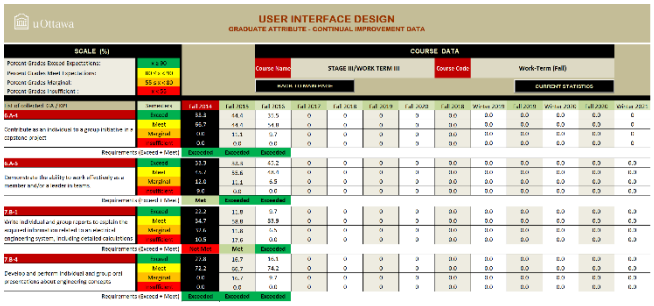

Figure 5. CDEF Table Report Form.

As illustrated in Figure 5 above the report uses color coding to better indicate the level of achievement for the course toward accreditation requirements. Using the CEAB meeting requirements scale with 60% - 80% boundaries. All courses that show achievement per GA below the lower bound did not meet expectations. Their status is shown in red. Above the upper bound of 80% indicates exceeding expectations (shown in dark green shading). The accepted level for meeting accreditation requirements is indicated in light green.

The current statistics graph illustrated in Figure 7, provides a graphical presentation of a historic trend of data collected for selected course. It allows for easy comparison of achievement for

an entire accreditation cycle and gives a better visualization of the overall graduate attribute assessment against meeting accreditation requirements. The Report button allows users to see a historic trend of data in table form.

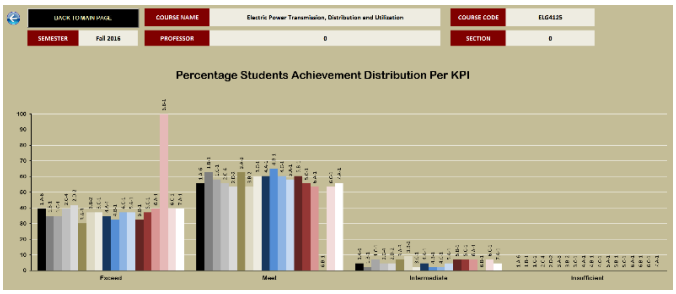

Figure 6. CDEF Graph Report Form.

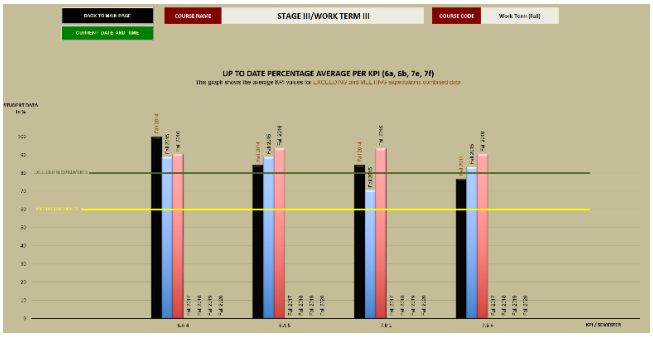

Figure 7. CDEF Current Statistics Report Form.

The Program Report Form (PRF) provides similar statistics which reflect achievement at program level. These reports are used by the curriculum committee members to inform program improvement. The PRF is a read-only workbook. It collates the assessment data provided by CEDF for all courses on a semester basis. This component of the tool measures and reports the cumulative impact individual courses have on overall program performance. It is generated in table and graph form per graduate attribute. A sample report is shown on Figure 8.

(a) (b)

Figure 8. PRF generated report (a) table form, (b) graph form.

A special report form is used to track COOP work-placement data. Data is fed into GAIA from the University of Ottawa COOP Portal using CVS, SQL server or ODBC compliant sources. The report is used to inform on students' ability to secure their first COOP position. A sample of such report form is simulated for the purpose of this paper and is shown on Figure 9.

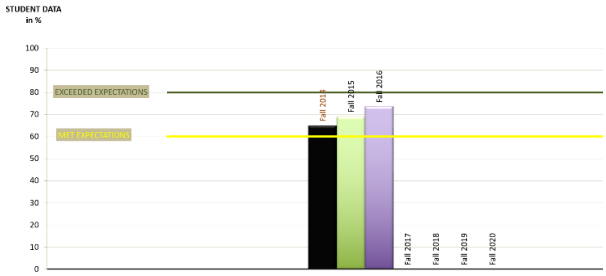

Figure 9. Work-Term Placement Data Report Form.

GAIA allows for comparison between cohorts by generating two reports: the Graduate Attribute Report per Cohort (GAR/C) and the Course Progression Report per Cohort (CPR/C). The former arranges averaged GA data per attribute, while the latter tracks students' achievement as student progress in their program. Data from both cohort reports are used for comparison to provide a historic data trend for further curriculum development. Furthermore, the COOP Progress Report per cohort (COOPR/C) adds reliability in analyzing students' employability and professional skills assessment provided by employers. Table 1, Table 2 and Table 3 below illustrate the datum of cohort reports. It is based on SEG course sequence selected by the program GA Committee to report on GA achievement. Color codes indicate the relative level of the course within the program as follows:

- blue shading is used for Year 5 courses
- green shading is used for Year 4 courses
- peach shading is used for Year 3 courses
- magenta shading is used for Year 2 courses
- no shading is used for Year 1 courses

Table 1. Graduate Attribute Report per Cohort (GAR/C)

	Graduate Attribute											
Courses	GA1	GA2	GA3	GA4	GA5	GA6	GA7	GA8	GA9	GA10	GA11	GA12
	SEG 3101	SEG 3101	SEG 3103	SEG 491 1	SEG 2105	SEG 2105	SEG 2911	SEG 491 1	SEG 2911	SEG 2911	SEG 4105	SEG 4911
		SEG 491 1			SEG 3101	SEG 4105	SEG 491 1	SEG 1911				SEG 1911
					SEG 3102	SEG 491 1						

Table 2. Course Progression Report per Cohort (CPR/C)

To illustrate the mechanism of data sorting behind the three cohort reports we generated random data that is being used for demonstration purposes in all tables and graphs. To follow the course progression within a cohort GAIA combines a historic trend data per respective courses according to the course sequence of the specific engineering program (i.e. software engineering in this sample). To generate GAR/C GAIA for cohort N, GAIA will use

Year (N) data for SEG4911 and SEG4105, Year (N-1) data for SEG3101, SEG3102 and SEG4145; Year (N-2) data for SEG2106 and SEG2911; Year (N-3) data for SEG2105, SEG3103, SEG3125; and Year (N-4) data for SEG1911. This is illustrated in Table 4 below.

Table 4. Use of historic trend data for generating cohort reports (GAR/C and CPR/C)

Cohort (Year)	Course	Graduate Attribute
GA Data (N)	SEG4911	2, 4, 6, 7, 8, 12
	SEG4105	6, 11
GA Data (N – 1)	SEG3101	1, 2, 5
	SEG3102	5
	SEG4145	11
GA Data (N – 2)	SEG2106	Xxx
	SEG2911	7, 9, 10
GA Data (N – 3)	SEG2105	5, 6
	SEG3103	3
	SEG3125	Xxx
GA Data (N – 4)	SEG1911	8, 12

The data-supported framework for cohort reports is illustrated in Figure 10. It represents a combination of methodologies described in Figure 1, Figure 2, Figure 4 and Table 4.

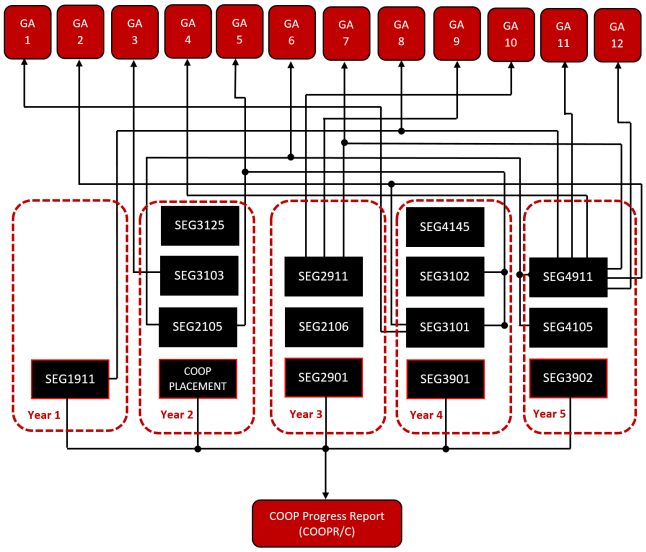

Figure 10. Data-Support Framework for Cohort Reports.

4. Results and discussion

GAIA's improvement and further development is based on ongoing research on latest developments in the area of data management and analytics and the input provided by its users. Mapping the goals stated in section 3 has enabled us to establish an ongoing user-centered tool evaluation. It addresses the different users (U1, U2, U3 and U4 as listed in Figure 1) targeting their specific context of use. Thus, GAIA needs to reflect specific user requirements and specific program requirements for each

university actor. The GAA DB needs to accommodate different types of input data, analyze qualitative and quantitative data, and produce reports has to meet the latest accreditation requirements and inform a continuous program improvement process. Input on the report efficiency and efficiency of the improvement process are being provided by the GA Committee members per program. The ongoing evaluation process as described above is illustrated in Figure 11.

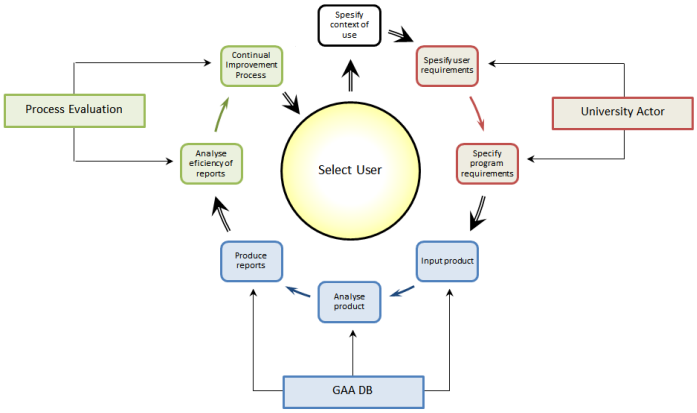

Figure 11. User-Centered Tool Evaluation Process

The following list of evaluation criteria are used for tool evaluation:

4.1. Perceived Ease of Use (PEOU)

This is a core variable, which measures the degree of belief that mastering the tool will not require any extra effort. In the TAM 2 model this construct is defined as a direct determinant of perceived usefulness [25]. Example for its use in academia is the study performed by Park in 2009 [26].

4.2. Perceived Usefulness of the Tool (PU)

Perceived Usefulness is the degree to which a user believes the tool will help successfully complete the task and excel at their job performance. This is a core variable, used to measure adoption in academia assessing learning performance, academic productivity and supporting learning process [26].

4.3. Attitude Toward Using the Tool

The attitude toward use measures the user's feeling about performing the task using the tool. It shows the user's desire to actually use the tool, their positive or negative evaluation of performing the behavior. It measures the ability to perform the task faster, improve user performance when using the tool, using the tool is related to increase of productivity and effectiveness. As a core variable, it is a part of almost every TAM construct set. Samples for its use in academia can be found in the studies by Kim, Park and Tsai [26, 27, 28].

4.4. Behavior Intention to Use the Tool (BI)

It measures the strength of the user's intention to use the tool or the degree of one's willingness to use the tool. It is one of the best indicators of the real usage of the tool. In other words, the actual use depends on the user's intentions to apply effort. It is a combined measure of the wish to finish the task and planning its use in the future.

4.5. Perceived Usage of the Tool

This is the amount of time interacting with the tool and the frequency of its use. Measuring this variable has highest

importance for Faculty Administrator (UI1) as manager interested in evaluating the impact of the tool as a whole.

4.6. Experience Using the Tool

Prior experience was identified as a determinant of behavior in 1980 by Ajzen and Fishbein long before Davis proposed the technology acceptance model [29]. Measuring the variable is mentioned in several studies [30, 31]. According to the studies, experienced users show strong correlation to perceived usefulness of the tool and the behavioral intention to use the tool. Being related to the number of years using the tool, this construct provides valuable information in terms of university users being ready to deal with measuring graduate attributes an ongoing process in a long term.

4.7. Complexity of the Tool

This variable measures the extent to which the user expects to use the tool without any additional effort. It has to do with the tool being difficult to understand and use. Complexity is measured in terms of time taken for the task and integration of tool usage results into existing tool. Complexity is inversely proportional to perceived usefulness (PU) and perceived usage as aspects of adoption. It is also measured by the extent to which the user realizes the possibility of computer crash or data loss.

4.8. Mandatory versus Voluntary Use of Tool

This variable is measured by the extent to which adoption is perceived as a mandatory or non-mandatory task. It is positively related to the behavioral intention to use the tool. In our particular case, the use of the tool is mandatory (requirements enforced by CAEB), so definitely imposed on Faculty Administrator (UI1) and Program Coordinator (UI2). Therefor this variable is not-applicable for them and should be noted as such in their respective evaluation criteria. Participation is mandatory for UI1 and UI2. It becomes mandatory for UI3 if their course is included. At the same time, UI3 cannot easily be coerced for tenured professors so UI3 adoption is critical. Similarly, indirect UI for students, employers etc. cannot be coerced so adoption into process is also critical. The point of this is how to weight the importance of various aspects of the tool. The reporting to CEAB is mandatory and critical so that UI adoption is both constrained and important, but adoption by administrator and coordinator will be coerced so not so critical.

4.9. Interoperability

This measure the tool compatibility with other systems or tools used simultaneously.

4.10. Handling Assessment Data

This measure reflects on tool's ability to serve as database and allow for historic trends of analysis and comparison. The ability to use quantitative and qualitative data is to be evaluated as well.

4.11. Reporting Ability

Tests the tool against its ability to produce reports on course and program levels. Quality of reports and their use to inform program improvement is part of this criteria.

4.12. Alignment with CEAB accreditation requirements

This construct provides direct information on the user's belief that the work performed will serve the need it was intended for. Analysis of the results will have a wide range of application – from indication for improving the tool, to explanation about the user's attitude and perceived intentions

5. Conclusions and Future Work

Creation of GAIA reflected the need for our engineering programs to respond to CEAB accreditation requirements. Ever since it follows the changes implemented to the criteria to provide best support for reporting graduate attributes. Flexibility of the tool and the fact that it is onside made allows for immediate modifications to take place. It is constantly improved following the requests and recommendations from instructors, program coordinators or faculty administrators as well.

In future work, a structural equation model showing the relation between major and external variables in terms of hypotheses will be added. Such a graphical representation of the research model will clearly show the relationships between constructs and specify hypotheses with respect to those relationships. The structural equation modeling (SEM) technique can be employed using the LISREL program. Then direct/indirect effect and t-values will have to be calculated to identify the state of each hypothesis as "Supported" or "Not-supported". Secondary future research will also include further improvement of the model and and more case studies to validate. The goal will be to achieve technology adoption results consistent with expectations. Such results will allow us to measure the tool satisfaction level and predict its usability in specifically constrained contexts.

Conflict of Interest

The authors declare no conflict of interest.

Acknowledgment

We would like to acknowledge funding from NSERC and the School of Electrical Engineering and Computer Science at the University of Ottawa which supported this research. We would especially like to thank Claude D'Amours, Emad Gad, Voicu Groza, Stéphane Somé and Marc-André Daoust for their partnership and support.

ABSTRACT

Fully Homomorphic Encryption (FHE) is considered as a key cryptographic tool in building a secure cloud computing environment since it allows computing arbitrary functions directly on encrypted data. However, existing FHE implementations remain impractical due to very high time and resource costs. These costs are essentially due to the computationally intensive modular polynomial multiplication. In this paper, we present a software/hardware co-designed modular polynomial multiplier in order to accelerate homomorphic schemes. The hardware part is implemented through a High-Level Synthesis (HLS) flow. Experimental results show competitive latencies when compared with hand-made designs, while maintaining large advantages on resources. Moreover, we show that our high-level description can be easily configured with different parameters and very large sizes in negligible time, generating new designs for numerous applications.

1. Introduction

This paper is an extension of the work originally presented in 2017 IEEE International Symposium on Design and Diagnostics of Electronic Circuits and Systems [1].

Homomorphic encryption is one of the most significant advances in cryptography in the last decade. It allows arbitrary computations on ciphertexts without compromising the content of the corresponding plaintexts. Thus, data can remain confidential while it is processed, enabling useful tasks to be accomplished with data being stored in untrusted environments. Considering the recent growth in the adoption of the cloud computing and the large deployment of the internet of things, homomorphic cryptography will have a major impact on preserving security and privacy in the coming years. Enterprise customers in the medical and financial sectors, for example, can potentially save money and streamline business processes by outsourcing not only the storage but also the computation of their data to public clouds.

Since the introduction of the first fully homomorphic encryption (FHE) scheme by Gentry [2] in 2009, we have noticed substantial research in the area, for the purpose of designing new homomorphic encryption algorithms, improving the schemes, their implementations, and their applications. Among them, the schemes that are based on Ring Learning With Errors (RLWE) [3] [4] [5] are among the most efficient homomorphic schemes because of their simpler structure, strong hardness assumptions, reduced key size, and reduced ciphertexts expansion with respect to previous schemes. Many of these RLWE-based schemes have been implemented in software [6] [7] [8] [9]. Results report very large latencies and resources consumption. So, in order to improve the performance of homomorphic encryption schemes, there has been research into the hardware acceleration of various homomorphic schemes and their building blocks. To date, there have been few hardware implementations for cryptosystems based on the RLWE problem. The corresponding architectures were mainly designed for fixed and small length operands and optimized for a restricted set of parameters [10], [11], [12], making them limited in terms of target applications and security requirements.

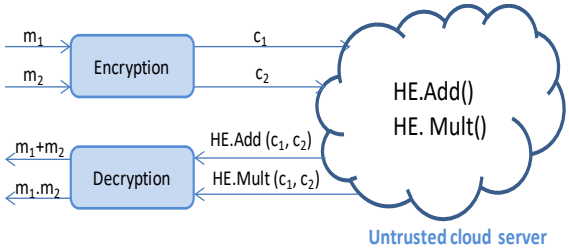
This paper presents a flexible and configurable accelerator implementing modular polynomial multiplication; the main performance bottleneck in RLWE-based homomorphic schemes. The work describes a software/hardware (SW/HW) co-designed architecture based on a High-Level Synthesis (HLS) approach. By combining HLS and SW/HW partitioning, we are able to easily configure our modular multiplier with large parameters (larger than those seen in the literature) suited for high security requirements. In addition, our modular polynomial reducer can be defined as any generic (cyclotomic) polynomial, allowing optimizations in the homomorphic context. We demonstrate the efficiency of the approach on many designs of full modular

*Asma Mkhinini, Univ. Grenoble Alpes, CNRS, Grenoble INP[**], TIMA, F-38000 Grenoble, France, asma.mkhinini@univ-grenoble-alpes.fr Institute of Engineering Univ. Grenoble Alpes

polynomial multipliers satisfying different area/latency trade-offs. So, our results can guide a designer in his choice of the appropriated configuration with respect to the targeted application.

The paper is organized as follows. In section 2, the background information is introduced. Section 3 presents the related works. Section 4 describes our proposed design. Implementation details are reported and discussed in section 5.

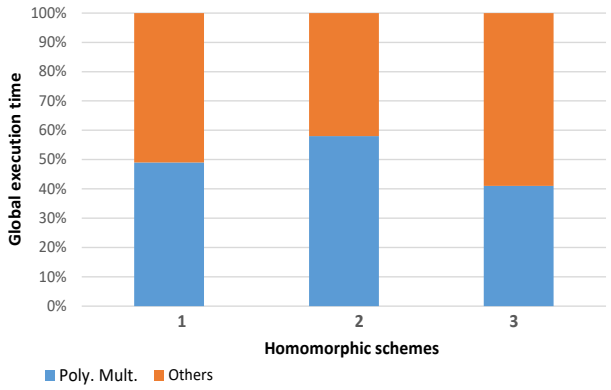
2. Theoretical background



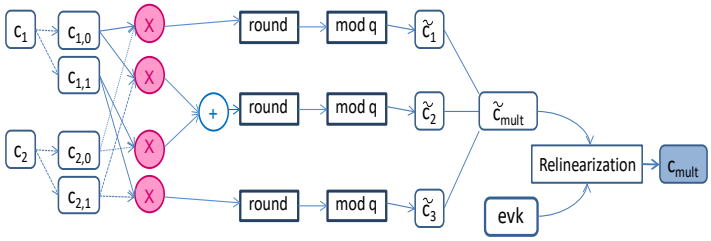
2.1. Homomorphic encryption

The purpose of homomorphic encryption is allowing computations on encrypted data. This means that if a user has a function called f and wants to get $f(m_1, m_2, \dots, m_t)$ for some plaintext messages $(m_1, m_2, \dots, m_t)$, it is possible to instead compute on the corresponding ciphertexts$(c_1, c_2, \dots, c_t)$obtaining a result which decrypts to $f(m_1, m_2, \dots, m_t)$.

Formally, if $\text{Encrypt}(m_i) = c_i (i = 1..t)$ then when evaluating a function f homomorphically on$(c_1, c_2, \dots, c_t)$, we get:



$$\text{Decrypt}\,[f(c_1, \dots, c_t)] = f(m_1, \dots, m_t)$$



Since every function f can be expressed as a series of additions and multiplications over some algebraic structure, a homomorphic encryption scheme can be defined as an augmented encryption scheme with two additional functions HE.Add() and HE.Mult() to add or multiply on ciphertexts, that result in a ciphertext encrypting respectively the sum or the product of the underlying plaintexts. Figure 1 shows an example of application of FHE in the context of cloud computing. When the number of successive additions HE.Add() and multiplications HE.Mult() can be unlimited during the evaluation step (i.e., computation of the function f), the scheme is known as a fully homomorphic encryption scheme. This generally requires to periodically refresh the ciphertext, otherwise it will be impossible to decrypt. This operation is performed in the encrypted domain and is called "bootstrapping".

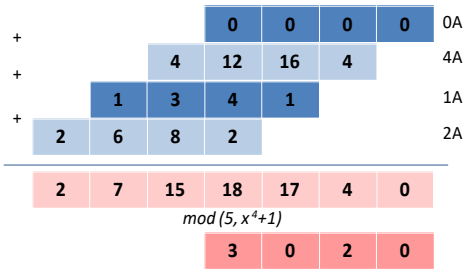
2.2. Analysis of software implementations of homomorphic schemes

In order to define the most frequent and time consuming functions during the execution of homomorphic encryption schemes, we profiled existing software implementations [6] [8] of three RLWE-based cryptosystems. Figure 2 shows the profiling results. The analysis reports that polynomial multiplication consumes 41% to 58% of the total execution time. The polynomial multiplication is needed in the encryption, decryption, and evaluation (homomorphic multiplication) steps, as well. For instance, we resume in Figure 3 the operation flow of homomorphic multiplication of two ciphertexts (c_1, c_2) in case of scheme 2 (see Figure 2). In practice, we need 4 polynomial multiplications in order to get c_{mult}. For this reason, a hardware acceleration of this function is of great interest. Hence, an optimized implementation of the modular polynomial multiplication is the target of this paper.

2.3. Modular polynomial multiplication in RLWE-based schemes

In RLWE-based cryptosystems, the primitives are defined over a modular polynomial ring of the form $R_q = \mathbb{Z}_q[x]/f(x)$ where f(x) is a specific irreducible polynomial (cyclotomic polynomial) of degree n and q is an integer modulus ($q > 0$). Parameters n and q define respectively the degree and the coefficient size of polynomials in R_q. Operating in R_q requires reductions modulo q and modulo f(x).

Let $A(x) = a_{n-1}x^{n-1} + \dots + a_0 \equiv (a_{n-1}, \dots, a_0)$ and $B(x) = b_{n-1}x^{n-1} + \dots + b_0 \equiv (b_{n-1}, \dots, b_0)$ be two polynomials of R_q. Computing $C(x) = A(x) \times B(x)$ in R_q needs to first compute the polynomial multiplication of A(x) and B(x) and then reduce the result modulo $(q, f(x))$.



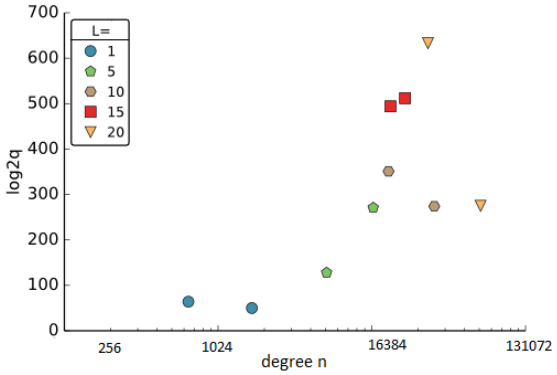
Here is a simple example where $n = 4$, $q = 5$ and $f(x) = x^4 + 1$. We choose:
$A(x) = x^3 + 3x^2 + 4x^1 + 1 \equiv (1,3,4,1)$ and
$B(x) = 2x^3 + 1x^2 + 4x^1 + 0 \equiv (2,1,4,0)$
As shown in figure 4, the result $C(x) = A(x) \times B(x)$ mod $(q, f(x))$ is equal to C_{inR} (3,0,2,0).

2.4. Parameters Derivation

The schemes based on the RLWE problem are governed by a number of inter-related parameters. The modulus q and the degree n are chosen in order to satisfy a given security level λ and a given multiplicative depth L (defined as the maximal number of multiplications that the scheme can handle before it becomes

necessary to apply the bootstrapping procedure). The derivation of these parameters is getting increasing attention lately, in order to provide easy-to-use guidelines for real world applications. In a nutshell, the methodology for parameters extraction aims at sizing these parameters in order to respond to the desired trade-off between security, efficiency, and correctness. Real use-cases of homomorphic cryptosystems define requirements for the multiplicative depth L and the security level λ, then one needs to choose the corresponding values of n and q. Figure 5 illustrates the wide space of practical parameters for RLWE-based schemes with different constraints on L. These configurations are extracted from [6] where the authors explain how to choose these parameters in order to guarantee correctness and security against lattice attacks. They use a lattice basis reduction algorithm based on the van de Pol and Smart approach. This algorithm determines an upper bound on the modulus in a given dimension and for targeted numbers of multiplicative depth L, to ensure a given security level.

For example, with L set to 1, polynomials with a degree around 1024 and coefficients on less than 100 bits can be sufficient. But another scheme requires at least a degree $n = 101853$ and a coefficients size $\log_2(q) = 278$ bits to achieve a security level $\lambda = 80$ bits and a multiplicative depth of 20. Consequently, if we want to target a large set of real applications, our design must be flexible and accept such variations of the parameters.



3. Related works

Two principal ways are employed in order to accelerate homomorphic cryptosystems: hardware implementation and GPU (Graphic Processing Unit) acceleration. Hardware accelerators focus mainly on accelerating the most complex functions of homomorphic encryption schemes. There has been some research already conducted into hardware implementations of RLWE-based schemes and their related building blocks. Almost all of them focus on the polynomial multiplication.

Many of these implementations have used the Number Theoretic Transform (NTT) or the Negative Wrapped Convolution (NWC) to perform polynomial multiplication in R_q efficiently. NTT and NWC are two special forms of the Fast Fourier Transform (FFT), known as the asymptotically fastest algorithm for computing polynomial multiplication.

In [10], Doröz et al. propose an implementation of the modular polynomial multiplication computed with the NTT algorithm and a Barrett reducer. A pre-computation based on the Chinese Remainder Theorem (CRT) is performed on input polynomials to reduce the size of coefficients. The overall architecture is based on an array of units, which gives some flexibility to process several residue polynomials in parallel. They evaluate their architecture on polynomials of fixed degree $n = 2^{15}$, and fixed coefficients size $log_2(q) = 32$ bits. Their accelerator was dedicated for a specific homomorphic scheme. In [11], Chen et al. present an optimized design of the modular polynomial multiplication.

All computations are carried out in the FFT domain on polynomials with degree n ∈ [256, 2048] and coefficients size ∈[20, 29]. They provide a selection method for the parameter set supporting efficient modular reduction, meeting at the same time the security requirements for RLWE and Somewhat Homomorphic Encryption (SHE) schemes. SHE means that the maximum number of successive operations in the encrypted domain is limited. Though efficient, this selection leads to many restrictions on the polynomials supported by the design: polynomial modular reduction is in fact computed with respect to the common choice $f(x) = x^n + 1$. When FFT multiplication using NWC is employed, they show that the modular reduction $(x^n + 1)$ is eliminated; this elimination comes at the expense of pre- and post-computation steps. A hardware architecture for the modular polynomial multiplication is described in [13]. They provide a fast unit for polynomial operations using CRT and NTT for multiplication combined with an optimized memory access scheme and a Barrett reduction method. The implemented unit can be used to instantiate a specific encryption scheme. Results are provided for $n = 32768$ and $log_2(q) = 1228$ bits. The authors of [14] use the Karatsuba algorithm to implement the modular polynomial multiplication in hardware. They demonstrate that for various degrees and coefficient sizes, Karatsuba can be a good alternative to FFT. Lastly, Jayet-Griffon et al. [12] consider the polynomial multiplication of 512-degree polynomials with 32-bit coefficients. They analyze and compare three algorithms (Karatsuba, FFT, and Schoolbook): the Schoolbook method is shown as the most efficient for a hardware implementation, due to its simple and regular structure. Modular reductions were not covered in their work.

All the aforementioned related works reported significant speed up factors when compared with software implementations. This speed up illustrates that further research into hardware implementations could greatly improve the performance of FHE schemes. However, they are almost all designed for fixed length operands and optimized for one specific type of multiplication algorithm (mainly FFT-based algorithms) which puts restrictions on the parameters selection. This makes them limited to some specific schemes and application domains. Besides, the operand

sizes are not very large, which has a direct impact on the security level of the cryptosystem. When modular polynomial reductions are performed, the simplest (and more limiting) choice is often selected.

Consequently, existing designs can be considered as proof-of-concept implementations only suitable for homomorphic encryption with small multiplicative depth circuits and low computation complexity. In the homomorphic context and because of its rapid growth evolution, new designs with a wide range of parameters are needed. These parameters are very large, consume large amounts of memory, and require many resources in order to perform efficient computations. Thus, memory storage and available resources in a target device should be taken into consideration, especially when manufacturing a specific circuit is not affordable and FPGA (Field Programmable Gate Array) platforms are therefore intended.

4. Software/Hardware design description

4.1. General presentation

We propose a hybrid and flexible SW/HW design based on a generic polynomial multiplier. This design is basically constructed from two parts: a dedicated hardware accelerator, and the software running on a general-purpose processor. Our solution aims at improving the overall performance and supporting much larger parameter sets than previous designs while optimizing resources for a given computation performance level. As in most previously published approaches, we will demonstrate our solution on FPGA-based implementations. However, the same approach may also be used with pre-characterized libraries to generate an application-specific integrated circuit (ASIC). The general-purpose processor can be implemented on-chip, or the hardware part of the accelerator can be connected to a computer. The interface between hardware and software can thus be performed, for example, through a high performance AXI (Advanced eXtensible Interface) bus, when software is running on an embedded processor, or a PCI (Peripheral Component Interconnect) express bus in the case of a computer processor. The choice should take into account the performance targeted for the global design, the communication and post-processing overheads, as well as the implementation constraints.

4.2. Design configurability

Our accelerator has been designed to support polynomials of any degree and any coefficients size. This goal has been met thanks to four hierarchy levels. As shown in Figure 6, level 1 and level 3 compute the product of two polynomials with large degree, while levels 2 and 4 deal with the product of coefficients with large sizes. This approach allows us to design efficient implementations for the lower (smaller) blocks, and configurable algorithms for the upper (larger) ones.

The designer starts by defining the input parameters (degree, coefficients size and irreducible polynomial used for the modular reduction).

In order to compute the multiplication of large input polynomials, we first represent the inputs as sets of polynomials of smaller fixed degree K. Then, we compute the pairwise products of each pair of sub-polynomials, using a hardware block for the multiplication of polynomials of fixed degree K based on the Schoolbook algorithm. This algorithm is not the fastest from a pure algorithmic point of view (asymptotic complexity), but it has three main advantages: it is more efficiently implemented on FPGA targets [12], it does not require pre- or post-processing and it does not impose any specific constraints thus allowing the possibility of optimizations such as batching (see section 5.3). An additional reason for choosing this algorithm is that the proposed decomposition limits the degree of the polynomials at level 3, so the degrees required to take full advantage of the asymptotic complexity of other algorithms is not reached.

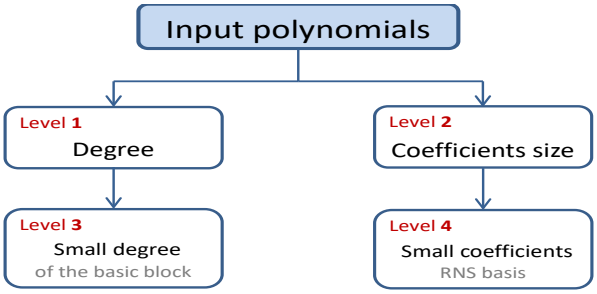


Figure 6. Multi-level design

The product of large coefficients is calculated through a RNS (Residue Number System) approach [15]. The advantage of RNS is that computations can be performed in parallel, that can result in a significant speed-up. We convert each large coefficient into a set of several values of smaller size by applying the RNS transformation. This technique can be easily made (almost) independent of the coefficient size: in order to support larger coefficients, it is sufficient to add a new element to the existing RNS basis without need to change the underlying architecture. A more detailed description of our approach is discussed in [16].

Let us mention that for small degrees and/or small coefficients sizes, level 1 and/or level 2 are optional (see Figure 6), as the algorithm can operate directly on full size operands.

4.3. SW/HW Partitioning

Our hybrid design implements part of the computations in software and part of them in hardware. The adopted partitioning is summarized in Figure 7. On the software-level, we consider simple and cheap computations such as input representations in subset polynomials, RNS basis generation, and polynomial additions; additionally, polynomial modular reduction is also computed on the main processor, in order to take advantage of the flexibility of a software implementation.

The hardware part implements the product of large coefficients in the RNS domain, and the Schoolbook multiplication algorithm at the polynomial level.

In order to reach our goals in terms of flexibility (size of parameters, but also implementation target), the hardware blocks are generated with a High Level Synthesis (HLS) tool.

4.4. High Level Synthesis

High Level Synthesis aims at transforming a generic input algorithm into a Register Transfer Level (RTL) architecture for a given target technology. This allows obtaining better productivity

when compared to classical implementation approaches using direct RTL design in languages such as VHDL or Verilog, as the designer can work on a higher level language which is much easier to maintain.

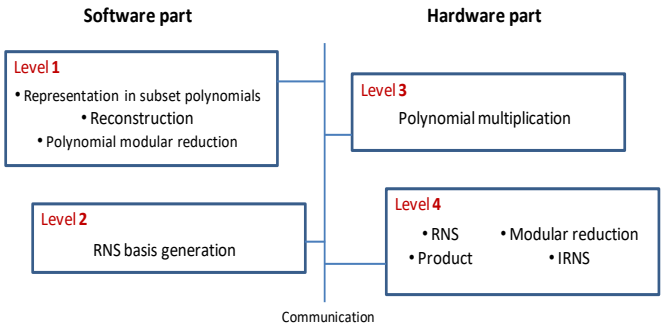

Figure 7. Modular polynomial multiplier: SW/HW partitioning overview

Several HLS tools exist; in this work, we use AUGH [17] since it is open, it may support different targets through the corresponding tool chain, and it can provide early estimations about the performance of the final result that can guide the designer in rapid refinement loops. AUGH is an autonomous HLS tool: it generates RTL descriptions quickly, under only global resource and frequency constraints [18]. This is achieved by performing incremental transformations of the input design description. The small complexity of the design space exploration (DSE) algorithm and the efficient use of all internal circuit structure constraints make this HLS tool very fast and able to generate pertinent solutions.

In this work, we will target two different FPGA technologies and a SoC (System on Chip) from Xilinx, but the methodology can be applied to other targets as well, provided that the corresponding flow is available. In our context, specifying new polynomials just implies to modify the input algorithms described in C language and let the HLS tool produce the RTL descriptions for every new specification (see Figure 8). Changing other parameters is fast and simple as well, as the designer can modify directly the high level description of the algorithm. Similar interventions on a RTL description of the design would take much more time and would be much more prone to errors due to a more complex description code.

AUGH provides different techniques for design optimizations, including unrolling and pipelining for the loops, wiring for the branch conditions and using maximum operator sharing [18]. Each RTL generation is analyzed by the user who can then command the HLS tool (with these directives) to converge towards a better solution in the next trial. DSE process detects possible transformations of the design that bring more parallelism, and applies these transformations until the user resource constraints are reached. Then, the RTL design description is generated.

5. Implementations, comparisons and discussions

5.1. Comparison with the state of the art

In order to provide a fair comparison of our results with the state of the art, we configure our design with parameters as close as possible to [10], [11] and [12] and perform the synthesis on similar targets.

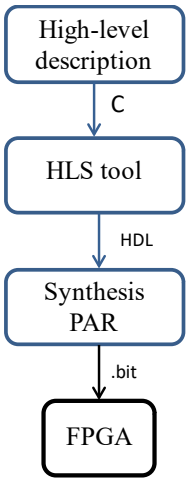

Figure 8. HLS based approach: tool chain

We set parameters for multiplication of polynomials of degree 512, 1024 and 32768 and with coefficients sizes of 26 and 32 bits. Under these configurations and for the smallest degrees, we do not divide inputs into smaller polynomials and we feed our basic block of level 3 directly with the corresponding polynomials.

Table 1 demonstrates that our approach, though about twice slower compared to manually optimized designs, consumes much fewer resources than the two designs reported in [11]. We obtain a reduction by a factor of 9 on average. This significant difference can be explained by the choice of the polynomial multiplication algorithm. For the FTT- and NTT-based algorithms (as in [11]), the pre- and post-computation steps are complex and require storing additional parameters. For the Schoolbook method, no pre- and post-computations are needed and we only have to store the input and output coefficients. Thus, FTT and NTT implementations have lower latency than our accelerator thanks to their lower complexity and their hand-crafted design but have several constraints and require a large amount of hardware resources.

For comparison with [12], where the authors implement the Schoolbook algorithm, we present two solutions in Table 2. In order to exploit parallelism and to achieve the minimal latency, we apply an optimization directive of AUGH not allowing operator sharing. Doing so, we instruct the HLS tool to use as many DSPs as possible: in this case only LUTs are used to store the coefficients and a maximum number of DSPs can be easily parallelized (first design in Table 2). In the other solution (second design in Table 2) BRAMs are used to store information, which limits the number of DSPs that can be used efficiently. It must be stressed, however, that our results are after placement and routing, while [12] only gives results after synthesis. Depending on the choice made with the HLS tool, the latency may be only slightly augmented (+28%) compared with the noticeable gain in resources (more than 35x). Resources can be further reduced up to a factor of 41 with the second solution, but leading to a loss of performance by a factor of 12.6.

For polynomials with degree 32768 used in [10], we divide the inputs into polynomials of degree 8192 and we apply our

approach first without any optimization. In this case (first design in Table 3), the hardware resources required by our design are nearly 28 times less than [10] on average; on the other hand, our design has a latency of 41 ms, while the authors of [10] report a latency of about 9.5 ms. Since our accelerator requires relatively few hardware resources, we can compute in parallel on 4 instances: with this optimization, the second design in Table 3 has a latency comparable to [10], while still maintaining a large advantage in resources.

Globally, these examples of results for our designs show that they consume fewer resources than the state of the art thanks to the proposed approach, while achieved performances can be close to hand-made designs. Using fewer resources also leads to possible parallelization of several instances while meeting the resource constraints of a given FPGA; in that case, even better performances can be reached. The approach offers at the same time a large degree of configurability, allowing the designer to change several important parameters on-the-fly. In addition, our approach is highly flexible, since the same generic high-level description can be used to produce a new circuit with different area/performance trade-offs i.e., we can generate a very cheap (but slow) polynomial multiplier, or a fast but more resource consuming one. Other possible optimizations can be applied, as it will be shown in the next sections.

5.1. Design space exploration

With our flexible design, we can instantiate our architecture with different coefficients size and different degrees, targeting several platforms. Larger parameters imply large values of n and q that grant high security levels and significant multiplicative depths.

When we handle large coefficients, our approach proposes to transform them into their respective RNS representation. The choice of the RNS basis (size and co-prime modulus) is primarily based on the coefficients size of the input polynomials and the available resources on the target device. The key idea is to take advantage of the parallelism offered by the RNS representation and speed up our computations. If we ever need to increase the supported size, it is sufficient to extend the RNS basis without need to change the underlying architecture.

The RNS basis size and modulus are kept as parameters as well as the degree K of the basic block performing the Schoolbook multiplication. Let us now fix for example the coefficients size at 64 bits and vary the degree from 8192 to 32768 to cover a new range of parameters. For each degree, we choose a different degree K of the basic block. When the resources of our target are sufficient, we perform computations in parallel on several instances.

Figure 9 shows that some configurations are more efficient than others. In fact, when computations are running on P instances in parallel, we roughly multiply the resources by P and divide the latency by P (illustrated by the cases of n=8192 and n=32768, figure 9). But, setting for example K=1024 to calculate the multiplication of polynomials with a degree 16384 is not an appropriate configuration. The performance loss is essentially due to 16^2 calls to the basic block *Polynomial_K*. When changing K and/or applying an optimization, the latency is also affected by the cost of the data transfers and therefore some configurations are not suitable.

Figure 9. Performance of our designs on polynomials with 64-bit coefficients and

different configurations (degree K, parallelization, degree P)

Several multipliers with different area/performance ratios can be generated by modifying the RNS basis and the degree K of the basic block, and also by the parallelization of the computations on many instances of the basic block. Thanks to the HLS design flow, rapid feedback on circuit characteristics is used to evaluate deep architectural changes in short time and pick up the more suitable parameter sets. Then, the designer can select the design satisfying his constraints among the set of generated circuits. The development timeline of a new solution is about 3 hours on average, which is a very short time in comparison with a hand-made design.

5.2. Our system performances

In this section, we evaluate the performance of our hybrid modular polynomial multiplier with respect to the communication times between hardware and software. We run computations on polynomials of degree 512 with 32-bit coefficients and we pick two choices for the modular polynomial:$f(x) = x^{512} + 1$, and a general cyclotomic polynomial of degree 512. This choice is motivated by the possibility, allowed by a generic polynomial, of applying the batching optimization [19].This technique can be used in order to pack multiple messages into one single ciphertext, therefore allowing parallel homomorphic evaluations. Hence, it permits great versatility in the computations and improves performance. This technique is based on the CRT theorem and requires that the polynomial f(x) is different from $x^n + 1$.

To transfer data, we consider an AXI interconnection between the hardware and software part. Our platform is the Zybo Zynq-7000. In our case, we send to the FPGA two input polynomials of 32*512 bits each and we receive one polynomial of 73*1024 bits. We use one high performance AXI bus to send the input coefficients and two high performance AXI buses to receive the output polynomials: this is due to the fact that the polynomial reduction is made in software, and the multiplication result is thus (almost) twice larger than the operands. With this solution, we can enhance the performance of our system and have the final result faster: a speed up factor of about 2.98 is obtained compared with a solution with only one bus, as the hardware acceleration is mitigated by the data transfers.

Our architecture reports a global latency, including transfers, of 0.75 ms when $f(x) = x^{512} + 1$ and of 1.89 ms when f(x) has a general form, which is still very fast compared to pure software implementations.

When compared with the state of the art, we have shown that our implementations consume few resources but report smaller speed-up factors. To counter this, we have proposed to run computations on many instances of the basic block in parallel. Figure 10 illustrates an optimized proposition when performing computations on 4 instances of blocks with degree 512 in parallel.

5.3. System evaluation on larger parameters

In this section, we evaluate our approach on designs with larger parameters. For each configuration, we choose two forms of the irreducible polynomial f(x). The first one corresponds to the popular choice $x^n + 1$. The second one has a general form and allows optimizations in the homomorphic context. Tables 4 and 5 provide implementation results and comparisons with software implementations we developed with Sage and run on a Intel Core i5-2450M (2.5 GHz). We decided to make such a comparison in order to get the same parameters configuration of parameters and because published works do not cover such parameters. Our reference embedded platform (the Zybo board) has processing power and memory that are not even comparable to desktop or server CPUs. Nonetheless, and withstanding the overhead of the data transfers through the AXI bus, the results obtained are quite interesting.

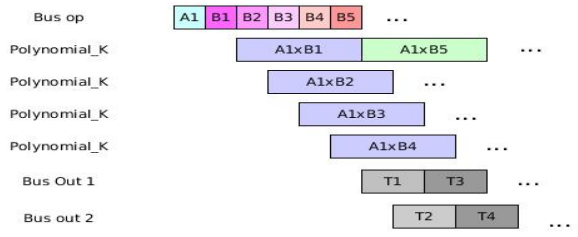

Figure 10. Parallelization of the computations on many instances of the basic block *Polynomial_K* [1].

Table 4. Implementation results (ms) when $f(x) = x^n + 1$

n	q	Software implementation	Our design
4096	32	32.6	2.1
8192	64	76.7	5.8
16384	128	162.8	11.7

Table 5. Implementation results (ms) when f(x) has a general form

n	q	Software implementation	Our design
4096	32	41.8	4.1
8192	64	88.5	12.7
16384	128	202.9	21.8

Results show that our approach reports significant speed-up factors when compared with pure software implementations, in spite of the large parameter values. The latencies when the

polynomial reduction is computed modulo $x^n + 1$ are better than the reduction modulo a polynomial with general form. This is due to the complex form of the polynomial in the second case (only 2 coefficients vs. (n+1) coefficients) and to the number of iterations required to get the final results. For a fair comparison, it must be stated that such a general form is not covered by most works in the literature, especially when hardware implementations are considered.

Several software implementations and libraries dedicated to homomorphic cryptography exist today [20], **Error! Reference source not found.**[21], which achieve very interesting performance when executing on high-end processors. These implementations are usually based on the NTT-based algorithm in order to speed up the modular multiplication on very large operands. This algorithm, however, has very large requirements in terms of memory usage, it constrains the choice of parameters, and it is usually optimized by exploiting the advanced instruction set available on modern processors, such as SSE and AVX. When targeting limited devices and/or current client-server frameworks, those implementations cannot be used directly because of the memory cost, or do not perform well enough due to missing advanced instructions. For this reason, a comparison with these works is difficult, since different application domains and platforms are targeted.

6. Conclusion and future works

We present a flexible and generic SW/HW co-design for the modular polynomial multiplication, the most computationally intensive operation in homomorphic cryptosystems based on the RLWE problem. Given the large parameters required in such schemes, we propose an RNS based algorithm and an efficient decomposition of the large input polynomials. Our design can be easily configured thanks to a HLS approach and sets no restrictions on the parameters that define the RLWE problem leading to high security levels and large multiplicative depths when necessary. Our approach can also optimize the accelerator for applications requiring small parameters. Our architecture can be instantiated to accelerate any RLWE-based scheme; additionally, even if the proposed methodology has been illustrated only on the polynomial multiplication, it can be used to implement and accelerate other primitives required by homomorphic schemes.

Future works include more complex communication schemes, such as using two AXI High Performance input ports and thus increase the number of instances performing in parallel. As the memory is one major bottleneck, we can reduce the amount of memory by controlling and scheduling the loading of sub-polynomials $A_i(x)$ and $B_j(x)$. It may also be interesting to evaluate the benefits of a hardware implementation of the polynomial reduction. Other primitives used in the FHE schemes may also be implemented in hardware using the same methodology. Finally, these accelerators will be integrated to evaluate a full homomorphic scheme on an FPGA/processor platform targeting embedded applications, and the performance will be compared to state-of-art software libraries ported to the same environment.

ABSTRACT

Drug abuse problem is not a new problem, but it is still serious in Hong Kong. The emergence of hidden drug abuse youth has brought more difficulties to them and their parents. The usual ways of providing anti-drug abuse assistance are not sufficient to these types of young people. Intelligent methods have been developed to assist anti-drug workers. In this paper, we present three mobile applications with a set of intelligent tools for parents and social workers to help our young people. The applications have an alerting tool to detect the possibility of drug abuse of a young student, and to alert corresponding parents and social workers for remedial actions. Another function is the nearby notification tool to help social workers in identifying people who may need assistance. For the alerting function, a number of data mining and text analysis techniques have been adopted for behavior analysis. A supporting instant messaging has been co-developed for communicating alerting messages.

1. Introduction

Drug abuse problem is not a new problem, but it is still a big problem in Hong Kong Society. Even there is a tendency of decreasing in drug abusing, the government report indicated that the age of first drug taking is decreasing. This shows that the problem is in serious with depth (age) but not the width(quantity). Besides, from the perspective of teenagers, they do not have much knowledge on how to get the treatment service from different organizations.

Furthermore, Hong Kong has another problem which is the hidden youths or "socially withdrawal". The term "hidden youths" is originated from Japanese word "Hikikomori" and it means that a person is scheduled at home by at least six months [1]. There is one more level under the "hidden youths" which is "Otaku" in terms of Japanese. There are different characteristics for "Otaku", but the commonly use is that "Otaku" always stay at home for activities and avoid social activities. A study found that these people are satisfied with their quality of life [2]. Also, it is difficult for other people to interact with them normally. And once they are drug abuser, they become the riskiest group of people as people cannot discover them easily and help them return to life. In Hong Kong, it has been reported that, since 2010, 80% young drug abusers take drugs at home.

*Vincent Ng, Department of Computing, The Hong Kong Polytechnic University, 852-2766-7242, Email: cstyng@comp.polyu.edu.hk

According to Narcotics Division, the median drug abuse history of newly reported abusers (i.e. the time for abusers to be reported to the CRDA by reporting agencies from their first drug abuse) remained between 1.7 and 2.1 years during 2007 to 2009. It then increased continuously to 5.9 years in 2015, and dropped to 4.6 years in 2016 [3]. One reason is because psychotropic substance abuse is more popular among young drug abusers [4]. Unlike traditional drugs such as heroin, psychotropic substance abuse is more "hidden" in nature. Young drug abusers tend to take psychotropic substance at home. It is hard for us to bring the young drug abusers to light.

Smartphones have become popular among young people. There are close to 5 million Hong Kong persons aged 10 and over had smartphones in 2014 and the smartphone penetration rate has exceeded 77.2% [5]. Developing anti-drug mobile applications can be an effective way to pass healthy information to young people as well as parents and social workers. Hence, in 2014, we submitted a proposal to the Beat Drugs Fund in HKSAR to develop a series of mobile applications for students, parents and social workers with a backend platform to support information sharing.

In our design, we aim to find out the hidden or potential drug abusers, and to warn their family and anti-drug workers about the problem. Another important function is to support the nearby function for social workers to access young people. For the rest of the paper, Section 2 provides the background review. Next, in Section 3 and 4, we describe our application design and

implementation approach. Section 5 concludes our present work in this paper.

2. Background Review

2.1. Anti-Drugs and Behavior Analysis Mobile Apps

Dealing with the drug abuse problem, different parties in Hong Kong society have developed different mobile applications to link with the youths. There are two mobile applications recently developed in HK and they are “Anti-Drug Information Center” and “毒癮無可忍” to deal with the drug abuse problem. The “Anti-drug Information Center” (禁毒資訊站) developed in Macau provides the drug information as shown in Figure 1 and can support parents as a simple drug abuse detection tool [6].

Figure 1. Home screen of the Anti-drug Information Center

This mobile application adopts an expert system approach which is based on the anti-drug resource kit designed by the T.W.G.Hs. CROSS Centre [7]. However, there were criticisms on the test because the behavior criteria could have different interpretations, not only for detecting drug abuse issues. For example, it simply identifies “emotionally unstable” and “performance mysterious contact with friends” as symptoms of drug abuse, but these symptoms can also be characterized adolescent.

For the ”毒癮無可忍” application, it was developed by a Christian organization. It also provides the drug related information and detection test. The information it provided are the real cases sharing, information of referral center and some encouragement message from the bible. The detection test is rule-based and has a number of questions as shown in Figure 2. That is, when your answer meets all criteria of detection, response will then show up. The responses are video formats so as to arise interest and attention of the young people.

Drugout is an iOS Apps aims to passing knowledge about anti-drug [8]. In the application, players will try to help a game avatar to fight with his drug abuse issues as shown in Figure 3. Score will be accumulated during the actions, and players can get bonus score if they invite others playing the application. Finally, there will be real prizes given to the high score players. Overall, it is an interesting game that can attract students to play and be able to deliver the anti-drug information to the players. The bonus scoring can encourage players to invite more people play the game and players can experience what a drug abuser will suffer from the drugs. Yet, it only provides information without any communication platform. Also, its use is for the youth and parent may not get help from this application.

Figure 2. Addiction testing

Figure 3. Dragout

Another similar mobile application is called Detoxification [9]. Besides anti-drug information, it also provides interesting game and situational questions which raise awareness of drug abuse as shown in Figure 4. Yet, the detoxification application has not been completed and it also lacks of resource links to support youths when they encounter a problem.

Another type of mobile applications is for behavioral analysis, such as the “Pro-sociality Behavior Test”. It contains a self-assessment to test pro-sociality behavior tendency. Its problem is having too many questions for an assessment and users often feel tired when doing it. There is a similar mobile application, “Depression Test”, for depression testing [10]. It provides a nice historical review and users can see the changes of their depression levels. The application provides no connection between users and social service organizations. Users cannot find an easy way to seek for help if they encounter a problem.

Although there are many mobile applications about behavior analysis in the app stores, most of them are not related to anti-drug.

This motivates us to develop a suitable solution with design objectives below:

- Provide an accurate prediction based on behavioral information provided by users.
- Able to detect potential drug abuse with a few guided questions with their answers.
- Able to provide connection and interaction channels between users and anti-drug social service organization.

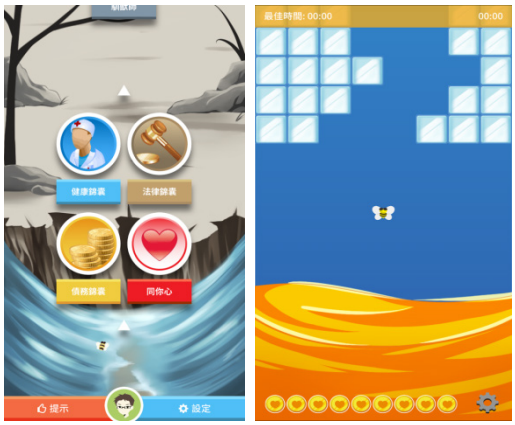

Figure 4. Detoxification

2.2. Alerting Systems

Alerting systems have been applied in different service domains. The Brigham Integrated Computing System (BICS) provided a clinical alerting system at Brigham and Women's Hospital (BWH) since June 1994 [11]. It used an event monitor to determine whether a new clinical data warrants an alert. The notification program would send an automated e-mail message messages to a duty physician, or through other means of communication. The physician could then log on any computer to review the alert and take immediate therapeutic action. The alerting system reduced the time it took for physicians to respond to critical laboratory results. Physicians thought that the communicated information was important and the service can help clinicians to be well informed of important abnormalities in the flood of data they have continually receiving.

Alerting system is also essential for providing the location and information about vehicles to passengers, owners or users [12]. Bus transportation system has been proposed to track a large number of buses simultaneously and detects the routes and directions automatically through GPS satellite [9]. It used a web-based, mobile communication and SMS platform for communicating bus arrival times and predicted the real-time inter-station speed.

Email alerting has been proposed with education, health care and other life applications. They can be used for two-way knowledge translation, which involves receiving case situation to professionals and then sending their evidence-based recommendations. In [13], it is reported that professionals were familiar with email communication. While many felt comfortable and liked using emails in their professional life, yet some others felt overwhelmed by the volume of emails they receive. The study also suggests that email alerting can contain valid and trustworthy information as an easy way to disseminate information to multiple recipients. This would give the reader an option to read emails immediately or later.

Instant messaging alerting is another frequent channel to support alerting messages. The major advantage of instant messaging alerting is real time or instantly delivered. When a receiver is online, the message will be received as soon as the user sends it. Also, instant messaging alerting tends to be confined to a single line and easy to read [14]. However, instant messaging systems are often of proprietary platforms and cross platform support is difficult. Communicating via instant messaging requires that both parties have accounts with the same instant messaging service.

With the above reviews, we have proposed to use multiple channels for sending our altering messages, both email and instant messaging. As social workers are familiar with both channels, this multi-channel platform can effectively work for their clients.

2.3. Location Sharing

Check-in provides location awareness support so that it can act as a channel to share, comment and rate any spots in different areas. It aims to establish a location-based social network (LBSN) for users. All users included students, parents, social workers can publicize their current locations to others. Through this check-in step, users can contact their friends nearby and chat with instant messaging. A special function for social workers is that they can be notified the youths' current locations if youths choose to open the information.

In Google Map, users can leave comments and rate places. The comments and ratings are public to everyone in the world. More than comments and rating, users can also upload and share photos about the spot. Sharing the location with user's friends through other applications like Facebook and Whatsapp, is available in Google Map [15]. A good example is an application developed by Apple Inc., FindMyFriends. It allows users to follow and track friends with their mobile device. Users can also choose to share their location with others. The app determines users' location using GPS in the device. If the user is requested by his friends to see their current location, users can contact their friends on the map immediately with the contacts in their device [16].

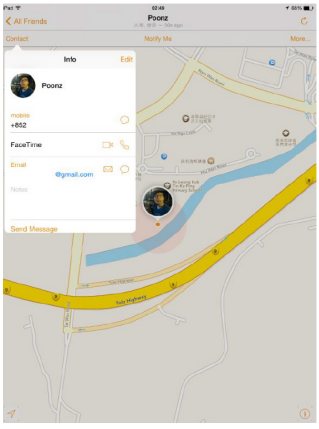

Figure 5. FindMyFriends

Another similar application is Swarm which is developed by Foursquare. It is a companion application of Foursquare. Users are allowed to share their locations within their social network. A check-in can be broadcasted to through other channels like Facebook or Twitter. User can easily see nearby friends, make future plans as well as checking in a location. Figure 6 shows a check-in page of Swarm.

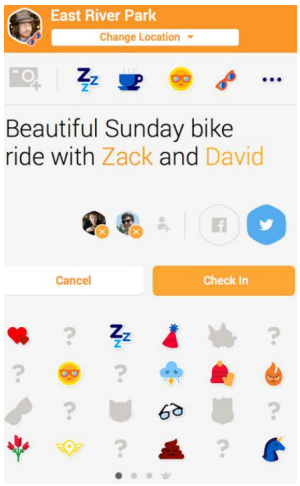

Figure 6. Swarm in Foursquare

Swarm has all the required functions for our objectives in the aspect of location sharing. From "check-in" and "check-out" to chat with friends. However, because our target users require a high level of confidentiality, only secured sharing platform is allowed.

3. Design Methodology

After the review the current problems in the previous sections, a set of mobile application is decided to develop to suit the needs from the different users. For parents, the mainly functions will help them on drug abuse detection of their kids and they can use the application to seek for professional help and build a community between other parents and social workers. For students, the application will try to collect their data that will be useful to the project team, also the application will help the youth have more connection with their parents, friends and social workers by instant messaging or share their location information. For social worker, they should able to use the application to upload the anti-drug information and give help to the youths and their parent. With the types of users, 3 different mobile applications have been designed and developed and they are called Aurora, Giai and Theoi, respectively.

In the rest of this section, the overall design and three functional components are presented. The first component is on the youth behavioral analysis for users to predict a potential drug abusing case. The second component is to support the alerting function when such case is detected. It can effectively work for their clients. The last is about the location sharing and near-by search support.

3.1. Overall Design

At the beginning of our work, teachers, principals, students, social workers and anti-drug experts have been consulted and surveyed on the suitable functions of the three applications. For the student mobile application, it includes the following functions:

a) Head News Center: An information receiving channels for youths to receive anti-drug information, such as events, activities. Some of the news can be in a form of alerting and pop-up such that youths would receive something interesting to consider. It is a way to encourage youths to get more positively involved in the community. An interest profile can be set by the young user for customized information.

b) Q&A Section: a resourceful function for youths to receive answers of common questions, such as where and how they can seek help.

c) Survey (game corner): it is useful to collect youth's current status from time to time. They can provide some of their own data on a voluntarily basis with a bonus point encouragement. The bonus point scheme can be supported by small souvenirs (produced by the project). The survey is in the form of a small game and its data collected can be made available to the social workers and the project team.

d) Searching: a searching function for allowing the youths to quickly identify the information from (a), (b) or (e).

e) Dashboard: a sharing space for users to post/upload their digital products (games, videos, art works, etc.) for sharing. After attending training workshops available from the project, these products can be shared and users can rate them. After uploading, other users can access these products.

f) Quick Contact: this function supports a user to contact a social worker for assistance quickly. The user can enter free text or answer a number of pre-set questions and a social worker would be alerted and try to arrange help.

g) Instant Messaging: with different groups (among youths, parents, and social workers) formed, members within each group can do online chat and share information.

h) Check-In/Location Information: the function is to support users in contacting people nearby and using it as a social media platform for attracting youths. It allows a user to release his/her current location information to other users. It is a powerful tool so that a user can know any other users in the same area. Users can provide comments of the check-in locations. It is a voluntary basis and the access of the location information is limited to the people that the user allows. Some initial designs have been done as show in the next page.

The second application, Giai which focuses on parental support, is developed for parents with the functions below. For similar functions in Aurora, the functional descriptions are skipped.

a) Head News Centre

b) Searching

c) Dashboard

d) Quick Contact

e) Instant Messaging

f) Friend List: a function which allows a user to add a friend or create a new user group (limited to some types of users).

g) InfoSeek: it is a searching function similar to the Location Information function in the Youth Apps

h) Family Center: this is the intelligent alerting tool. It enables parents to input their observations of their children on a regular basis. The input is semi-guided which can help parents to enter structured information with certain set of unusual behaviors. Once parents' observations are entered, the second function is to perform analysis with the knowledge base of an expert system available in the backend server. The expert system is designed and developed by the project team with the help of anti-drug experts and social workers. In case of parent users do not how to start, a series of prompts (similar to a quiz/survey) can be used to collect data. The analysis result would be in form of hints or advice to parents, suggesting where to seek help or acquire further information. This function can work with (f) above to ease the worries of parents.

i) Parental Corner: it is a special sharing space for parental groups and social workers to share information in addition to Dashboard and Head News Center. Parents/social workers can post articles or provide comments/advice of any articles. This corner can access special cases, emergency procedures and FAQs that are stored in a knowledge repository developed by antidrug experts and/or social workers. A searching feature similar to (b) is available also. This function is aimed to encourage parents to form mutual supporting groups for helping each other.

j) Referral Center: the function is acting a help-contact service which allows a parent to have an initial contact with a social worker. This is a resourceful function for youths to receive answers of common questions, such as where and how they can seek help.

The third application, Theoi, is developed for social workers with the functions below. For similar functions in the other applications, the functional descriptions are skipped.

a) Head News Center

b) Searching

c) Dashboard

d) Instant Messaging

e) Friend List

f) InfoSeek

g) P-Action+: Parents are able to request help from social workers with the altering tool, an email with test records will be generated automatically and sent through their own email accounts which they used in registration.

h) Y-Action+: It is similar to P-Action+ but the corresponding contacts are youths.

i) Enrich+: According to the feedbacks from social workers, a web base platform is developed for this function, instead of included in the apps. It allows social workers to post and share information, and update the FAQ database.

Figure 7 shows the software architecture of the system in which different modules are labeled with different border colors. Modules in the red rectangles mean these are shared by all 3 applications. Modules in blue, green and purple rectangle represent the functions only serve students, parents and social workers respectively.

3.2. Behavior Analysis

For the behavior analysis component, there are 4 core modules as the training, classifying, calculating and collecting. In training module, we have chosen 2 techniques, decision tree (see Figure 9) and logistic regression, to build a classifier with the given training data. The calculating module is to estimate an index for possible explanation of the recommendation. The collecting module will receive user's feedback and store them for the enhancement of our analysis (i.e. re-training with additional data). The 4 modules will work together to analyze behavior of youths as shown in Figure 7.

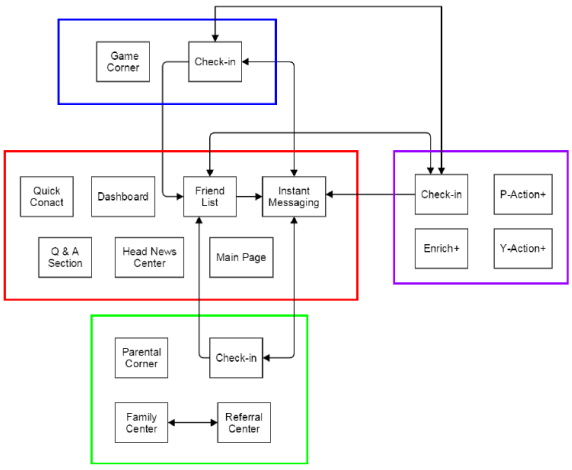

Figure 7. System modular design

The training module will run every time when the additional data is available. It will retrieve the training data and then apply a set of weight behavior criteria with the construction of a decision tree and the execution of logistic regression algorithm independently. The training results will pass to the classifying module and the calculating module afterwards. As the current available is small, the overhead of re-constructing the prediction model is acceptable. Yet, when the dataset size becomes larger, an incremental technique should be considered.

The classifying module is going to utilize the decision tree. A user is required to complete a set of guided questions which represent the behaviors of a potential drug abuser. Then the survey answers will be input to the decision tree. If it is classified as a non-drug abuser, it will bypass the calculating module and return the index as 0. Otherwise, it will go on the calculating module.

The calculating module is going to use the results of logistic regression. It is used for selecting a explanation description by estimating an index, which refers to the probability of drug abuse.

The determined class and index will return to the user. The collecting module is an optional module. A user can return expected status of the predicted drug abuse case to the server. This user feedback and the results of the previous survey will be added to the training data for later prediction improvement.

Input :
X = Training set,
A = each behavioral criteria scale for each training data set from database (training data)
Y = class for each training data set from database (training data)
B = each behaviora criterial scale from a user (according to survey)

Output: Decision tree

// Stage 1 – Training function (construct tree)
Create a new tree T with a single root node.
if stoppingCriterion(X) then
    Mark T as a leaf with the most common value in X as a label.
else
    Find a that obtain the best splittingCriterion(ai,X; y).
    Label n with a.
    for each outcome vi of a do
        Set subtree ti = treeGrowing(a=viX; A; y).
        Connect the root node of nt to the subtree ti with an edge that is labelled as vi.
    return T

Formula for spliting:

$$Q_{left}(\theta) = (x, y)|x_j <= t_m$$
$$Q_{right}(\theta) = Q \setminus Q_{left}(\theta)$$
$$G(Q, \theta) = \frac{n_{left}}{N_m} H(Q_{left}(\theta)) + \frac{n_{right}}{N_m} H(Q_{right}(\theta))$$
$$\theta^* = \operatorname{argmin}_\theta G(Q, \theta)$$

// Stage 2 – Classifying function
    SearchTree(B, T)

Figure 8. Decision Algorithm

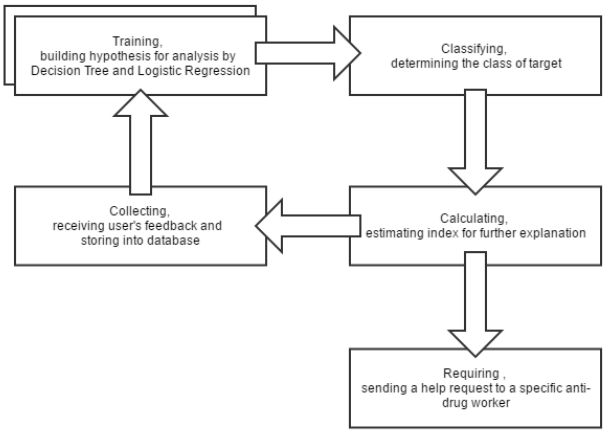

Figure 9. Behavior Analysis Framework

3.3. Altering

For the alerting component, there are 3 modules as confirmation, generation, and sending (as shown in Figure 10). In the confirmation module, we collect the information on the results of behavior analysis, user's demographic data, and the social worker whom users have chosen. Information would then be passed to the generation module. The generation module is used for generating email and instant message. They are generated by two servers in parallel. After that, the sending module will send the messages out.

3.1. Location Sharing and NearBy Support

Check-in support is a major component of our applications. Through the establishment of a healthy location-based social network (LBSN), it does not only share location-embedded information to an existing social network, but also create a new social structure by connecting individuals. With the location information, a person-to-person communication function can be enable, which is called the Friends Nearby Notification in our applications.

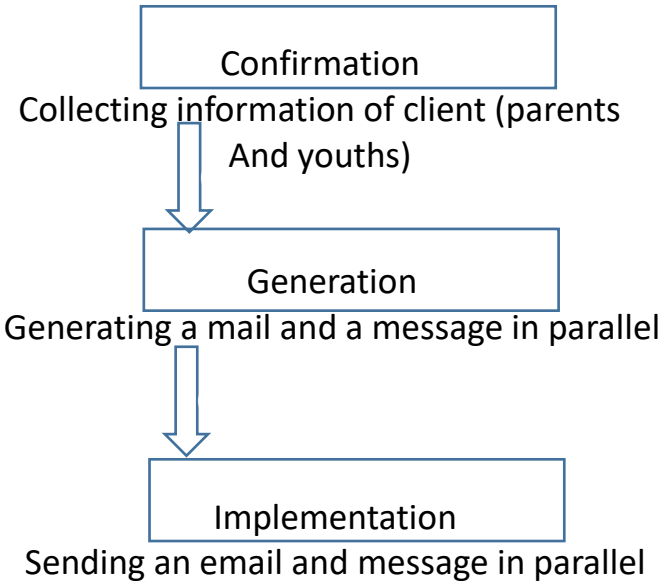

Figure 10. Alerting component

When a user would like to view others' comments to his current location, he can get them from a safe and secured database. Users can chat with their friends or other user after reading their comments. They can be redirected to Instant Messaging engine. In order to find their friends for having a face-to-face talk, the find route function is provided. The default origin will be the user's current location, and after user selecting a destination, data will be sent to the server. A string in JSON format will be returned and transformed into a polyline shown on the map which represents the route between two places. In our design, the Friends Nearby helps users to identify all nearby friends and accessibilities with the following features:

- Notify users when friends are in proximity
- Check nearby friends or accessibilities in regular time intervals
- Provide setting to turn off notification to support privacy
- Provide setting to hide from a particular friend.
- Show the nearby friends and accessibilities details, such as distance away from it, and contact info.

- Call or send short messages to nearby friends.

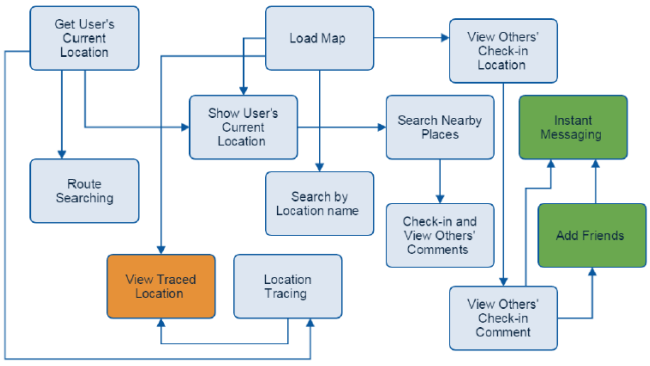

Figure 11. Check-in function

Figure 11 shows how the check-in function is designed and the starting module is the top left box in the figure, 'Get User Current Location.' The boxes in green are the functions that linked with other parts of the platform while the orange box is the function only available for social workers to trace locations of young people, provided with their permission. The locations of these young people will be uploaded to a central database for every 10 minutes. Social workers can view the students' location on the map by retrieving location information from the database.

4. Implementation

The mobile applications and its backend support are designed as a 3-tier client server model as shown in Figure 12. When a user uses a smartphone to access the system, requests will be sent to middle tier, i.e. web server, through HTTP request first. Then, the web server will translate the request into SQL queries and sent it to a database server to retrieve data. The return data will be transformed into JSON response and sent to the client device. All functions are based on different modules as shown in Figure 12.

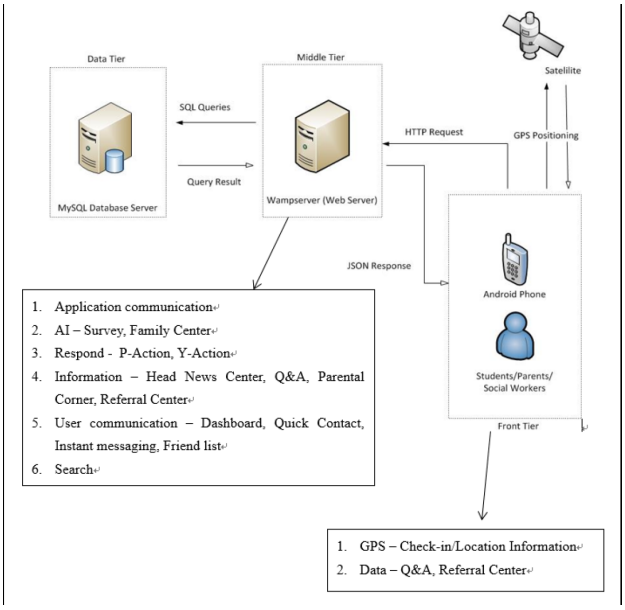

Figure12. Three tier implementation

In the current design, check-in requires only 2 relational tables. The first one stores basic user information, latitude and longitude, which are automatically uploaded by the application. The later one stores all check-in records. We do not archive all user location information since the amount of data is too large to be stored locally. For finding out a user's location, there are two common methods GPS and A-GPS. After balancing the advantages and disadvantages, we are using GPS to locate a user if it is available. If not, A-GPS will be applied. Figure 13 shows a location detection of a user.

Without GPS assistance, a user can check-in manually by entering his nearby location. Google Places API Web Service is used here since it can save device's resources. Several parameters including location, radius and API Access Key are required to retrieve the nearby locations. Location information in the format of latitude and longitude of user's current location can be gotten automatically by the system. Radius means the distance in meters within the returned place results. Check-in sets it as 100 meters since the known maximum error of A-GPS is 100 meters. After preparing these parameters properly, an HTTP request will be sent to Google. Maximum 20 locations will be returned by Google in JSON format. The returned results will contain sort of information about the location. Only place name will be shown to users in a list as shown in Figure 14.

Figure13. Location detection – Check in

Check-in provides location awareness support so that it can act as a channel to share, comment and rate any spots in different areas. Users can share their current location with others. Only 4 data values are required to "check-in", i.e. username, check-in's location, comment and rating. Username will automatically be gotten by the system. Check-in location is stored after user finds the nearby locations. A user can also enter comments and ratings about the location in Check-in page as shown in Figure 15. An error will be shown if the length of a comment is more than 160 English characters and 80 Chinese characters. A limit is set with the same idea from the famous social network like Twitter and Weibo. They have a special feature that the post length is limited. According to [17], 160 characters provide plenty of space to express most of their thoughts with friends. Chinese messages can usually present more information or feelings with fewer words.

Thus, 80 characters should be a proper length constrain in a check-in comment.

Figure14. A list of NearBy locations is returned

Figure15. Comments for a checked location

The behavior analysis module is implemented with Python 2.7 at the server end. We have selected the scikit-learn toolkit to support the decision tree and regression analysis [18]. The CART (Classification and Regression Trees) is used for building a model to determine if a person is a potential drug abuser. The same toolkit contains the logistic regression function in its 'liblinear' library and it is adopted.

The Drug Abuse Screening Test (DAST-10) is a 10-item brief screening tool formed the basis of the data being used in the behaviors modules [19]. Other data attributes, such as sleeping patterns, school academic performance, washroom visiting frequency and periods being alone, are included. During of the development of the module, the project team could not acquire the live data because of privacy issues. Instead, a pseudo dataset of 250 records (cases) is generated randomly with 20 attributes per case. Anti-drug experts were then invited to label the cases with different level of drug abuse (where 0 means nil and 5 means high potential). The first 200 records have been used for the decision tree and regression analysis in the scikit-learn toolkit. Cross-validation was then used to verify the accuracy and the results were in the range of 70-80%. The last 50 records were used as additional data for the continuous training. Yet, the results have not been improved.

The email alerting method is mainly based on PHPMailer. It is an open source class with methods to support HTML-based email and attachments. The messaging alerting method is mainly based on Messaging Queuing Telemetry Transport (MQTT) [20, 21]. MQTT is standardized by OASIS as standards to transport data. In MQTT, there is no message formats specialized in it and standard used is depending on developers. But it has advantages over using HTTP and XMPP, which it is low-weight in transmission as lower size in overhead and more energy saving [22, 23].

With the above set up environment, three mobile applications have been developed. The mobile apps for parents contain the alerting tool. It has a main page which displays Drug Abuse Prediction and or Result Feedback (see Figure 16).

In the behavior analysis, the parents act as observers to record their children's behaviors. When the parent starts the drug abuse prediction test, a series of questions on youths' behavior has to be answered in order to get the prediction results. The estimated probability of drug abuse is returned to the screen of the mobile device as shown in Figure 16. When a warning or alerting message is received, parents can seek help from social workers who have joined the platform according to their regions. In seeking the help, parents can provide more specific information about themselves and their children so that suitable social workers in the district can be located faster. They can also describe the situation in order to shorten the remedial time. When a help request is sent, the selected social workers will receive a notification from our platform as a reminder and email message describing parent's situation.

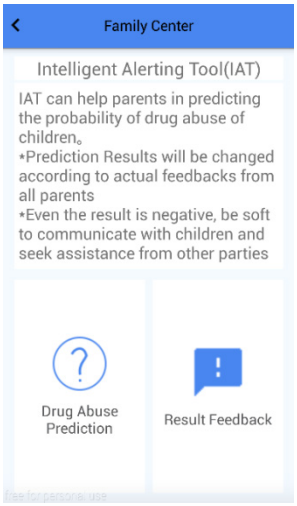

Figure 16a Main Page of behavior analysis

Figure 16b Result of probability of drug abuse

For result feedback, parents are required to answer "positive result" or "negative result" to confirm the drug abuse problem of their children (see Figure 17b). And the feedback is limited to previous detection, which any new prediction will overwrite the old predictions for feedback.

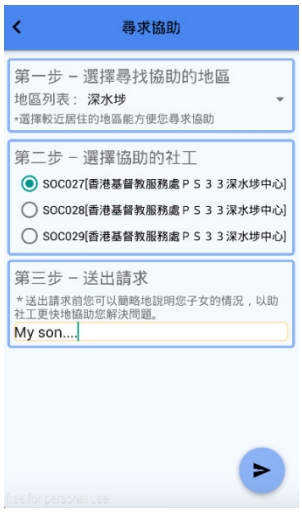

Figure 17a Seek help from social worker in different district

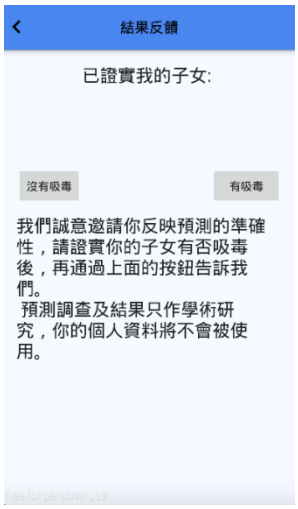

Figure 17b Result feedback

5. Conclusions

In this paper, we have presented three mobile applications with a set of intelligent tools for parents and social workers to help our young people as shown in Figure 18. The application for parents has a tool to analyze drug abuser behavior and send alert to them. The applications have been placed in GoogleStore for download availability.

The work is funded by the Beat Drugs Fund of HKSAR. We have invited a number of secondary schools, community centers, anti-drug experts and social workers to try the applications. All data is collected with a centralized server with confidentiality protection and agreement from users. Users can have options to select if any personal data can be used. Towards the end of the project, positive feedbacks from different user groups have been received. Many parents are interested in the alerting tool while expecting more rules and advice can be embedded.

Figure18. Three mobile applications for anti-drug abuse

Conflict of Interest

The authors declare no conflict of interest.

A B S T R A C T

This paper is an extension of work originally presented in conference name. The goal is to propose new fault detection and fault isolation techniques for a polytypic linear parameter-varying system (LPV). In this work, an adaptive observer design is formulated for a given polyquadratic Lyapunov function. Subsequently, new sufficient conditions are given in terms of Linear Matrix Inequalities (LMIs).
To show the effectiveness of the proposed algorithm, an illustrative example is included.

1. Introduction

Research on fault detection, from a theoretical and experimental point of view, has been intensively developed during the last decades. All physical systems must operate normally and without anomaly. However, some conditions cause one or more faults in the process and interrupt this operation. So fault detection is an essential task to avoid degradation of system performance or even its damage [1].

The synthesis of observers for uncertain systems is based on the asymptotic stability of the error estimation equations or on the eliminating influence of uncertain perturbations and measurement of error on errors estimation. Linear Parameter varying system (also known as LPV system) is a special class of system that includes parameters-varying equations and parameters-varying state-space equations. These uncertain systems can be considered as a linearization of state-space nonlinear systems.

The polytopic LPV form is a special class of LPV systems. Indeed, it is a description of the system as a convex combination of sub-models defined by the vertices of a convex polytope [2] [3]. Subsequently, these sub-models are combined by convex weighting functions which give a global model. Similarly, [4] proposes a linear piecewise interpolation model of a diesel engine. The nonlinear model of the machine was transformed into an LPV model.

The synthesis of LPV observers is a direct extension of the LTI control methodologies [5]. The LPV theory has allowed to extend linear methods to nonlinear domains [6]. LPV modeling is used to study nonlinear systems, multiple models or switched models [7].

In this paper, the main contribution is a generalization of the obtained results for actuator fault reconstruction in [1] for LTI systems to continuous-time LPV systems. It was proved that linear methods could be extended to nonlinear domains [8] [9]. In this direction, the actuator fault reconstruction problem is articulated as an LMI feasibility problem. The existence of polyquadratic Lyapunov function could insure the stability of the error estimation [10].

Due to the varying parameter, the polyquadratic approach considers that the Lyapunov function depends on the parameters associated with the description of the polytope.

The paper is organized as follows: In section 2 a model of linear polytopic time-varying (LPV) system is presented. An adaptive observer for fault detection is described in section 3. In section 4, we introduce the polyquadratic adaptive observer for the polytopic LPV system which leads to less conservative conditions on terms of LMI. The simulation result illustrates the effectiveness of our contribution.

Notation. For conciseness the following notations are used: $sym\ (A) = A + A^T$, $\begin{bmatrix} A & B \\ \bullet & C \end{bmatrix} =, \begin{bmatrix} A & B \\ B^T & C \end{bmatrix}$

2. Problem Statements and Preliminaries

A continuous-time LPV system in presence of fault can be described by the state-space equations in the following form:

$$\begin{cases} \dot{x}(t) = A(\theta(t))x(t) + B(\theta(t))u(t) + E(\theta(t))f(t) \\ y(t) = Cx(t) \end{cases} \quad (1)$$

Where $x \in \mathbb{R}^n$, $u \in \mathbb{R}^m$ and $y \in \mathbb{R}^p$ are, respectively, the state space, the input and the output vectors of the system. Variable $f(t)$ represents actuator fault.

The scheduling θ is a set of varying parameters evaluated in hypercube domain Θ such as:

$$\Theta = \left\{ \theta(t) \in \mathbb{R}^p \mid \theta_1 \in \left[\theta_1^{\min}, \theta_1^{\max}\right], ..., \theta_p \in \left[\theta_p^{\min}, \theta_p^{\max}\right] \right\} \quad (2)$$

Where $\theta_i^{\min}$ and $\theta_i^{\max}$, $i = 1,...,p$ are the lower and upper bounds of the parameter.

The parameter dependent Lyapunov function is assumed to be measurable [11] :

$$\theta(t) = \left[\theta_1(t) \quad \theta_2(t) \quad \cdots \quad \theta_r(t)\right]^T \in \mathbb{R}^r \quad (3)$$

Furthermore, LPV system (1) can be defined via barycentric combination of a matrix polytope described by N vertices [12].

$$\begin{aligned} A(\theta(t)) &= \sum_{i=0}^{N} \rho_i(\theta(t)) A_i \\ B(\theta(t)) &= \sum_{i=0}^{N} \rho_i(\theta(t)) B_i, \\ E(\theta(t)) &= \sum_{i=0}^{N} \rho_i(\theta(t)) E_i \end{aligned} \quad (4a)$$

$$\begin{aligned} &\sum_{i=0}^{N} \rho_i(\theta(t)) = 1 \\ &\rho_i \geq 0 \end{aligned} \quad (4b)$$

Where $A_i \in \mathbb{R}^{n \times n}$, $B_i \in \mathbb{R}^{n \times m}$, $E_i \in \mathbb{R}^{n \times r}$ are time invariant matrices defined for the i^{th} ertex of the hypercube and $\rho_i\left((\theta(t))\right) = \rho(\theta_i^{min}, \theta_i^{max}, \theta, t)$. The weighting function $\rho_i\left((\theta(t))\right)$ define the relative contribution of each vertices (A_i, B_i, E_i) to build the system described by $(A(\theta), B(\theta), E(\theta))$.

2.1. Assumption 1 [11]:

The state-space matrices $\left(A\left(\rho(\theta(t))\right), B\left(\rho(\theta(t))\right)\right)$ are continuous and bounded functions and depend on $\rho(\theta(t))$.

2.2. Assumption 2 [11]:

The real parameters $\rho(\theta(t))$ that can be known by on-line measurement values exist in LPV system and vary in a polytope Θ as:

$$\begin{aligned} &\rho(t) \in \Theta \\ &\Theta = \left\{ \sum_{i=1}^{N} \alpha_i(t) w_i : \alpha_i(t) \geq 0, \sum_{i=1}^{N} \alpha_i(t) = 1, N = 2^r \right\} \end{aligned} \quad (5)$$

And the rate of variation $\dot{\rho}(\theta(t))$ are well defined at all times and vary in a polytope $\Theta_v$as:

$$\dot{\rho}(t) \in \Theta_v \quad (6)$$

With

$$\Theta_v = \left\{ \sum_{k=1}^{N} \beta_k(t) v_k : \beta_k(t) \geq 0, \sum_{k=1}^{N} \beta_k(t) = 1, N = 2^r \right\} \quad (7)$$

The following assumption is made:

2.3. Assumption 3:

Without loss of generality matrix C is considered full row rank.

2.4. Assumption 4:

$$rank(CE_i) = rank(E_i) = p \qquad \forall i = [1,...,N] \quad (8)$$

2.5. Assumption 5:

The triple matrix (A_i, E_i, C) is observable.

For simplicity, the time variable t of $\theta(t)$ will be omitted if no confusion is caused.

3. Adaptive Observer Design

For polytopic LPV system (1), an adaptive observer is described by the following state representation:

$$\begin{cases} \dot{\hat{x}}(t) = A(\theta(t))\hat{x}(t) + B(\theta(t))u(t) \\ \qquad + E(\theta(t))\hat{f}(t) - L(\theta(t))(y(t) - \hat{y}(t)) \\ \hat{y}(t) = C\hat{x}(t) \end{cases} \quad (9)$$

Where $\hat{x}(t)$, $\hat{y}(t)$ are the state and outputs estimated vectors and $\hat{f}(t)$is the fault estimation.

In this case the gain matrix is given by the following polytopic form:

$$L(\theta) = \sum_{i=0}^{N} \rho_i(\theta) L_i \quad (10)$$

Where L_i represents the gain of i^{th}vertex.

Remark 1: Since it has been assumed that the pair (A_i, C) is observable, the gain matrices L_i can be selected such that $(A_i - L_i C)$ is stable.

Denote $e_x(t)$, $e_y(t)$, $e_f(t)$ are respectively state ,output and fault estimations errors :

$$\begin{aligned} e_x(t) &= \hat{x}(t) - x(t) \\ e_y(t) &= \hat{y}(t) - y(t) \\ e_f(t) &= \hat{f}(t) - f(t) \end{aligned} \quad (11)$$

Then, the error dynamics are expressed as follows:

$$\dot{e}_x(t) = \sum_{i=1}^{N} \rho_i(\theta(t))\left((A_i - L_i C)e_x(t) + E_i e_f(t)\right) \quad (12)$$

$$\dot{e}_y(t) = C\dot{e}_x(t) \quad (13)$$

The default $f(t)$ is constant, hence $\dot{f}(t) = 0$ [13], consequently the derivate of $e_f(t)$ with respect to time can be written as:

$$\dot{e}_f(t) = \dot{\hat{f}}(t) \tag{14}$$

The state observer (9) is combined with the law for the fault estimation updating of the form [1]

$$\dot{\hat{f}}(t) = -\Gamma F e_y(t) \tag{15}$$

Where $F \in \mathbb{R}^{r\times p}$ and $\Gamma \in \mathbb{R}^{r\times r}$ is the learning rate.

It has been to note a modification of (13) is presented in [1], [6] for time varying $f(t)$ in the form:

$$\dot{\hat{f}}(t) = -\Gamma F(\theta)\left(\dot{e}_y(t) + \sigma e_y(t)\right) \tag{14}$$

Where $\sigma \in \mathbb{R}$ is a positive scalar and can guaranty $\lim_{t\to\infty} e_x(t) = 0$ and $\lim_{t\to\infty} e_f(t) = 0$.

4. Main Result

Consider the LPV system described by (1) with an additive fault. The choice of the parameter-dependent Lyapunov functions for polytopic systems is a dilemma in the literature. The rate of change of the scheduling parameter could be represented in diverse methods. [14] proposed a rate of change that cannot be physically justified. Furthermore, in the expression given by [13], the derivative of the uncertain parameter does not impose special conditions.

In this section, we develop a new adaptive observer for LPV polytopic system. Before, we introduce some instrumental tools which will be used in the proof of characterization of this observer.

4.1. Lemma 1 [1]:

Given scalar $\mu > 0$ and symmetric positive definite matrix $P\left(\rho(\theta(t))\right)$, the following inequality holds:

$$2x^T y \le \frac{1}{\mu} x^T P(\theta) x + \mu y^T P(\theta)^{-1} y \qquad x, y \in \mathbb{R}^n \tag{17}$$

4.2. Lemma 2 *[15]:*

Given a symmetric matrix $\psi \in \mathbb{R}^{n\times n}$, and two matrices P, Q of column dimensions n, there exists X such that the following LMI holds:

$$\psi + sym(P^T X^T Q) < 0 \tag{18}$$

If and only if the projection inequalities with respect to X are satisfied:

$$\mathcal{N}_P \psi \mathcal{N}_P^T < 0, \quad \mathcal{N}_Q^T \psi \mathcal{N}_Q < 0 \tag{19}$$

Where $\mathcal{N}_p$ and $\mathcal{N}_Q$ denote arbitrary bases of the null spaces of P and Q respectively.

Proof. See [15]. ■

4.3. Lemma 3:

Let Φ a symmetric matrix and N, J matrices of appropriate dimensions. The following statements are equivalent:

- $\Phi < 0$ and $\Phi + NJ^T + JN^T < 0$.
- There exists a matrix X such that:

$$\begin{bmatrix} \Phi & J + NX \\ J^T + X^T N^T & -X - X^T \end{bmatrix} < 0 \tag{20}$$

Proof: The proof is obtained remarking that (19) can be developed as follows:

$$\begin{bmatrix} \Phi & J + NX \\ J^T + X^T N^T & -X - X^T \end{bmatrix} = \begin{bmatrix} \Phi & J \\ J^T & 0 \end{bmatrix} + sym\left\{ \begin{bmatrix} 0 \\ I \end{bmatrix} X^T \begin{bmatrix} N^T & -I \end{bmatrix} \right\} < 0 \tag{21}$$

and by applying Lemma 2 . ■

In this part, we consider the case such as the fault is time-varying, which implies $\dot{f}(t) \neq 0$, and the derivate of $e_f(t)$ with respect to time is:

$$\dot{e}_f(t) = \dot{\hat{f}}(t) - \dot{f}(t) \tag{22}$$

The objective of this section is to propose an approach to design a new adaptive observer for polytopic LPV system (1). So, we propose the following Theorem 2.

Theorem 2. Under the assumptions 1, 2 and 3, the system (9) is an adaptive observer for the system (1) if, for a given scalars $\sigma > 0$, $\mu > 0$, $\alpha > 0$ and $\nu > 0$, there exists, for each vertex, asymmetric positive definite matrix $P_i \in \mathbb{R}^{n\times n}$, $L_i \in \mathbb{R}^{n\times r}$, $G_i \in \mathbb{R}^{r\times r}$ and $X_1 \in \mathbb{R}^{n\times n}$ such that the following conditions hold:

$$\begin{bmatrix} \nu P_i - 2P_i + sym(P_i A_j) & -\frac{2}{\sigma} A_j^T P_i E_k & P_i + X_1 & P_i - \alpha C^T L_i^T \\ \bullet & -\frac{2}{\sigma} E_k^T P_i E_j + \frac{1}{2\mu\sigma} G_i & 0 & -\frac{2}{\sigma} E_j^T P_i \\ \bullet & \bullet & -X_1 - X_1^T & 0 \\ \bullet & \bullet & \bullet & -2\alpha I \end{bmatrix} < 0 \tag{23}$$

Under constraint:

$$E_j^T P_i = F_i C \tag{24}$$

The gain observer matrix of the system (1) is given by the following polytopic form:

$$L(\theta) = \sum_{i=0}^{N} \rho_i(\theta) L_i \tag{25}$$

Remark 3: The principle of the polytopic formulation is based on the fact that the system and stability conditions (here in a LMI form) have affine dependence on the parameters. If, for some reason, the affine dependence is lost, the stability of the system is not equivalent (or even implied only) to the feasibility of the LMI at each vertex [16], [17], [18].

Proof: With respecting to the system parameter, it is clear that $e_x(t)$ is linear. Thereby, consider the Lyapunov polytopic function defined by:

$$V\left(e_x(t),\right) e_f(t)) = e_x^T(t) P(\theta) e_x(t) + e_f^T(t) \Gamma^{-1} e_f(t) \tag{26}$$

Where $P\left(\rho(\theta(t))\right) > 0$ is a symmetric positive defined matrix.

Then, the derivative of (26) with respect to t is:

$$\dot{V}\left(e_x(t), e_f(t)\right) = \dot{V}_1\left(e_x(t), e_f(t)\right) + \dot{V}_2\left(e_x(t), e_f(t)\right) < 0 \quad (27)$$

Where :

$$\begin{aligned}\dot{V}_1\left(e_x(t), e_f(t)\right) &= \dot{e}_x^T(t)P(\theta)e_x(t) \\ &+ e_x^T(t)\dot{P}(\theta)e_x(t) + e_x^T(t)P(\theta)\dot{e}_x(t) \\ &= e_x^T(t)\Big[\dot{P}(\theta) + \left(A(\theta) - L(\theta)C\right)^T P(\theta) \\ &+ P(\theta)\left(A(\theta) - L(\theta)C\right)\Big]e_x(t) \\ &+ e_f^T(t)E^T(\theta)P(\theta)e_x(t) \\ &+ e_x^T(t)P(\theta)E(\theta)e_f(t)\end{aligned} \quad (28)$$

And

$$\begin{aligned}\dot{V}_2\left(e_x(t), e_f(t)\right) &= \frac{1}{\sigma}\dot{e}_f^T(t)\Gamma^{-1}e_f(t) + \frac{1}{\sigma}e_f^T(t)\Gamma^{-1}\dot{e}_f(t) \\ &= \frac{1}{\sigma}\left(\dot{\hat{f}}(t) - \dot{f}(t)\right)^T \Gamma^{-1}e_f(t) \\ &+ \frac{1}{\sigma}e_f^T(t)\Gamma^{-1}\left(\dot{\hat{f}}(t) - \dot{f}(t)\right)\end{aligned} \quad (29)$$

Substituting (16) into (28) leads to :

$$\begin{aligned}\dot{V}_2\left(e_x(t), e_f(t)\right) &= -\frac{2}{\sigma}e_f^T(t)\Gamma^{-1}\dot{f}(t) \\ &- \frac{2}{\sigma}e_f^T(t)\Gamma^{-1}\Gamma\Big[F(\theta)\left(\dot{e}_y(t) + \sigma e_y(t)\right)\Big] \\ &= -\frac{2}{\sigma}e_f^T(t)\Gamma^{-1}\dot{f}(t) - \frac{2}{\sigma}e_f^T(t)F(\theta)C\dot{e}_x(t) \\ &- e_f^T(t)F(\theta)Ce_x(t) - e_x^T(t)C^T F^T(\theta)e_f(t)\end{aligned} \quad (30)$$

Then, substituting (12) and (13) into (30), the following inequality is hold:

$$\begin{aligned}\dot{V}\left(e_x(t), e_f(t)\right) &= e_x^T(t)\Big[\dot{P}(\theta) + \left(A(\theta) - L(\theta)C\right)^T P(\theta) \\ &+ P(\theta)\left(A(\theta) - L(\theta)C\right)\Big]e_x(t) \\ &+ e_f^T(t)E^T(\theta)P(\theta)e_x(t) \\ &+ e_x^T(t)P(\theta)E(\theta)e_f(t) \\ &- e_f^T(t)F(\theta)Ce_x(t) \\ &- e_x^T(t)C^T F^T(\theta)e_f(t) \\ &- \frac{2}{\sigma}e_f^T(t)\Gamma^{-1}\dot{f}(t) - \frac{2}{\sigma}e_f^T(t)F(\theta)C\dot{e}_x(t)\end{aligned} \quad (31)$$

If the following condition is introduced:

$$\begin{aligned}&e_f^T(t)\Big[E^T(\theta)P(\theta) - F(\theta)C\Big]e_x(t) \\ &+ e_x^T(t)\Big[P(\theta)E(\theta) - C^T F^T(\theta)\Big]e_f(t) = 0\end{aligned} \quad (32)$$

This implies that:

$$E^T(\theta)P(\theta) = F(\theta)C \quad (33)$$

The inequality (31) becomes by using (33) and :

$$\begin{aligned}\dot{V}\left(e_x(t), e_f(t)\right) &= e_x^T(t)\Big[\dot{P}(\theta) + \left(A(\theta) - L(\theta)C\right)^T P(\theta) \\ &+ P(\theta)\left(A(\theta) - L(\theta)C\right)\Big]e_x(t) \\ &- \frac{2}{\sigma}e_f^T(t)E^T(\theta)P(\theta)\left(A(\theta) - L(\theta)C\right)e_x(t) \\ &- \frac{2}{\sigma}e_f^T(t)E^T(\theta)P(\theta)E(\theta)e_f(t) \\ &- \frac{2}{\sigma}e_f^T(t)\Gamma^{-1}\dot{f}(t)\end{aligned} \quad (34)$$

From Lemme 1, we can suppose that:

$$\begin{aligned}&2\left(-\frac{1}{2\sigma}e_f(t)\right)^T\left(\Gamma^{-1}\dot{f}(t)\right) \\ &\le \frac{1}{2\mu\sigma}e_f^T(t)Ge_f(t) + \frac{\mu}{2\sigma}f_1^2\lambda_{\max}\left(\Gamma^{-1}G^{-1}\Gamma^{-1}\right)\end{aligned} \quad (35)$$

Then, subsisting (35) in (34), the following inequality is done:

$$\begin{bmatrix} a_{11} & * \\ a_{21} & a_{22}\end{bmatrix} < 0 \quad (36)$$

With:

$$a_{11} = \dot{P}(\theta) + sym\left(\left(A(\theta) - L(\theta)C\right)^T P(\rho)\right)$$

$$a_{21} = -\frac{2}{\sigma}E^T(\theta)P(\theta)\left(A(\theta) - L(\theta)C\right)$$

$$a_{22} = -\frac{2}{\sigma}E^T(\theta)P(\theta)E(\theta) + \frac{1}{2\mu\sigma}G(\theta)$$

The derivate of the Lyapunov function is defined as follows:

$$dP(\theta)/dt = \sum_{k=1}^{N}\beta_k(t)Pt(v_k) = \sum_{k=1}^{N}\beta_k(t)\left(P(v_k) - \hat{P}_0\right) \quad (37)$$

$$\dot{P}(\theta) = \sum_{i=1}^{N}\dot{\rho}_i(\theta)P_i \quad (38)$$

$$\sum_{i=1}^{N}\dot{\rho}_i = 0 \quad (39)$$

The rate $\dot{\rho}(t)$ can be represented in several ways. In fact most of the time, it is difficult to give adequate modeling of it. For LPV system, the derived parameter does not vanish as in the LTI case.

In our case, we suppose that [14]:

$$\dot{\rho}(t) < \upsilon\rho(t) \quad (40)$$

$$\dot{P}(\theta) < \upsilon P(\theta) \quad (41)$$

Unfortunately, (41) is not convex in P and L, and cannot be solved by the LMI tools.

We can introduce some transformations to simplify the product term $(P(\theta)L(\theta)C)$ of the inequality (41). In fact, in this solution

we introduce an additive variable in order to allow the decoupling between the Lyapunov matrix and the observer gain in one side and to preserve a general structure to the Lyapunov matrix in the other side.

We suppose that:

$$\Phi=\begin{bmatrix} \upsilon P(\theta)-2P(\theta)+sym\left(P(\theta)A(\theta)\right) & \\ -\frac{2}{\sigma}E^T(\theta)P(\theta)A(\theta) & \\ * & \\ -\frac{2}{\sigma}E^T(\theta)P(\theta)E(\theta)+\frac{1}{2\mu\sigma}G(\theta) \end{bmatrix} \quad (42)$$

$$N^T=\begin{bmatrix} I & 0 \\ -L(\theta)C & 0 \end{bmatrix} \quad (43)$$

$$J=\begin{bmatrix} P(\theta) & P(\theta) \\ 0 & -\frac{2}{\sigma}E^T(\theta)P(\theta) \end{bmatrix} \quad (44)$$

By lemma 2 with (42), (43) and (44), there exists a matrix X of appropriate dimensions such that inequality (45) is satisfied.

$$\begin{bmatrix} M_1 & M_2 & M_3 & M_4 \\ * & M_5 & 0 & M_6 \\ * & * & -X_1-X_1^T & 0 \\ * & * & 0 & -2\alpha I \end{bmatrix}<0 \quad (45)$$

Where

$$\mathrm{X}=\begin{bmatrix} X_1 & 0 \\ 0 & \alpha I \end{bmatrix} \quad (46)$$

$$M_1=\upsilon P(\theta)-2P(\theta)+sym(P(\theta)A(\theta))$$

$$M_2=-\frac{2}{\sigma}A(\theta)P(\theta)E(\theta)$$

$$M_3=P(\theta)+X_1$$

$$M_4=P(\theta)-\alpha C^T L^T(\theta)$$

$$M_5=-\frac{2}{\sigma}E^T(\theta)P(\theta)E(\theta)+\frac{1}{2\mu\sigma}G(\theta)$$

$$M_6=-\frac{2}{\sigma}E^T(\theta)P(\theta)$$

Remark 4: The main advantage of problem (45) will appear when dealing with poly-quadratic observer. In that case, we will see that it theoretically improves the obtained results.

5. Numerical example

The above-described algorithm was applied to reconstruct the fault applied to the following LPV system described in [5] as:

$$A(\theta)=\begin{bmatrix} -1.75+\theta_2 & 1 & 0 & 0 \\ 1 & -1+\theta_1 & 0 & 0 \\ -1.8 & -1 & -0.75+\theta_1 & 0 \\ -1 & 0 & 0 & -1-\theta_2 \end{bmatrix}$$

$$B(\theta)=\begin{bmatrix} 1+\theta_1 & 1 \\ 1 & 0.5+\theta_2 \\ 1 & 0 \\ \theta_2 & 0 \end{bmatrix},\ C=\begin{bmatrix} 1 & 0 & 1 & 0 \\ 0 & 1 & 0 & 1 \\ 0 & 0 & 1 & 1 \end{bmatrix}$$

$$E(\theta)=\begin{bmatrix} 0 \\ 0.6+\theta_1 \\ 0 \\ 1 \end{bmatrix}$$

$$\sum_{i=1}^{N}\sum_{j=1}^{N}\sum_{k=1}^{N}\rho_i(\theta)\rho_j(\theta)\rho_k(\theta)\begin{bmatrix} vP_i-2P_i+sym(P_iA_k) & \cdots & -\frac{2}{\sigma}A_jP_iE_k & \cdots \\ * & \cdots & -\frac{2}{\sigma}E_k^TP_iE_j+\frac{1}{2\mu\sigma}G_i & \cdots \\ * & \cdots & * & \cdots \\ * & \cdots & * & \cdots \end{bmatrix}$$

$$\begin{bmatrix} P_i+X_1 & P_i-\alpha C^TL_i^T \\ 0 & -\frac{2}{\sigma}E_j^TP_i \\ -X_1-X_1^T & 0 \\ 0 & -2\alpha I \end{bmatrix}<0 \quad (47)$$

The gain scheduling vector is defined as:

$$\theta=\begin{bmatrix} \theta_1 & \theta_2 \end{bmatrix}^T \quad (48)$$

Where

$$\theta_1\in\begin{bmatrix} -0.05 & 0.05 \end{bmatrix} \quad (49)$$

$$\theta_2\in\begin{bmatrix} -0.1 & 0.1 \end{bmatrix} \quad (50)$$

The system has four vertices and evolves in a hypercube. The weighting functions, which verified (4b), are computed as follows:

$$\begin{aligned} \rho_1(\theta)&=\frac{\theta_1-\underline{\theta_1}}{\overline{\theta_1}-\underline{\theta_1}}\frac{\theta_2-\underline{\theta_2}}{\overline{\theta_2}-\underline{\theta_2}}=\frac{(\theta_1+0.05)(\theta_2+0.1)}{0.02} \\ \rho_2(\theta)&=\frac{\theta_1-\underline{\theta_1}}{\overline{\theta_1}-\underline{\theta_1}}\frac{\overline{\theta_2}-\theta_2}{\overline{\theta_2}-\underline{\theta_2}}=\frac{(\theta_1+0.05)(0.1-\theta_2)}{0.02} \\ \rho_3(\theta)&=\frac{\overline{\theta_1}-\theta_1}{\overline{\theta_1}-\underline{\theta_1}}\frac{\theta_2-\underline{\theta_2}}{\overline{\theta_2}-\underline{\theta_2}}=\frac{(0.05-\theta_1)(\theta_2+0.1)}{0.02} \\ \rho_4(\theta)&=\frac{\overline{\theta_1}-\theta_1}{\overline{\theta_1}-\underline{\theta_1}}\frac{\overline{\theta_2}-\theta_2}{\overline{\theta_2}-\underline{\theta_2}}=\frac{(0.05-\theta_1)(0.1-\theta_2)}{0.2} \end{aligned} \quad (51)$$

The four local models represented the LPV system are calculated as the following:

$$A_1=\begin{bmatrix} -1.85 & 1 & 0 & 0 \\ -1 & -1.05 & 0 & 0 \\ -1.8 & -1 & -0.8 & 0 \\ -1 & 0 & 0 & -1.1 \end{bmatrix} \quad (52)$$

$$A_2 = \begin{bmatrix} -1.65 & 1 & 0 & 0 \\ -1 & -1.05 & 0 & 0 \\ -1.8 & -1 & -0.8 & 0 \\ -1 & 0 & 0 & -0.9 \end{bmatrix} \quad (53)$$

$$A_3 = \begin{bmatrix} -1.85 & 1 & 0 & 0 \\ -1 & -0.95 & 0 & 0 \\ -1.8 & -1 & -0.7 & 0 \\ -1 & 0 & 0 & -1.1 \end{bmatrix} \quad (54)$$

$$A_4 = \begin{bmatrix} -1.65 & 1 & 0 & 0 \\ -1 & -0.95 & 0 & 0 \\ -1.8 & -1 & -0.7 & 0 \\ -1 & 0 & 0 & -0.9 \end{bmatrix} \quad (55)$$

$$B_1 = \begin{bmatrix} 0.95 & 1 \\ 1 & 0.4 \\ 1 & 0 \\ -0.1 & 0 \end{bmatrix}, \quad B_2 = \begin{bmatrix} 0.95 & 1 \\ 1 & 0.6 \\ 1 & 0 \\ 0.1 & 0 \end{bmatrix}, \quad (56)$$

$$B_3 = \begin{bmatrix} 1.05 & 1 \\ 1 & 0.4 \\ 1 & 0 \\ -0.1 & 0 \end{bmatrix}, \quad B_4 = \begin{bmatrix} 1.05 & 1 \\ 1 & 0.6 \\ 1 & 0 \\ 0.1 & 0 \end{bmatrix} \quad (57)$$

$$E_1 = E_2 = \begin{bmatrix} 0 \\ 0.55 \\ 0 \\ 1 \end{bmatrix}, \quad E_3 = E_4 = \begin{bmatrix} 0 \\ 0.65 \\ 0 \\ 1 \end{bmatrix} \quad (58)$$

By applying algorithm (9), gains matrices are as the following:

$$L_1 = 10^{-7} \times \begin{bmatrix} 0.8103 & 0.1578 & -0.489 \\ 0.1433 & 0.0788 & -0.0832 \\ 0.3573 & 0.0560 & -0.1950 \\ -0.3956 & 0.0074 & 0.2464 \end{bmatrix}$$

$$L_2 = 10^{-7} \times \begin{bmatrix} 0.9953 & 0.2005 & -0.6049 \\ 0.1606 & 0.0981 & -0.0962 \\ 0.4209 & 0.0641 & -0.2329 \\ -0.4902 & 0.0192 & 0.3089 \end{bmatrix}$$

$$L_3 = 10^{-7} \times \begin{bmatrix} 0.7851 & 0.1489 & -0.4744 \\ 0.1376 & 0.0795 & -0.0798 \\ 0.3467 & 0.0535 & -0.1886 \\ -0.3845 & 0.0104 & 0.2398 \end{bmatrix}$$

$$L_4 = 10^{-7} \times \begin{bmatrix} 0.8443 & 0.1676 & -0.5104 \\ 0.1469 & 0.0780 & -0.0860 \\ 0.3687 & 0.0576 & -0.2022 \\ -0.4115 & 0.0053 & 0.2563 \end{bmatrix}$$

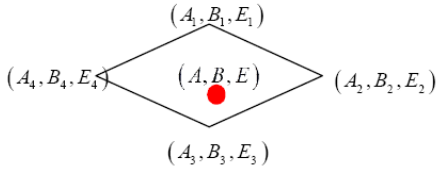
$$P_1 = 10^{-7} \times \begin{bmatrix} 0.1529 & 0.0034 & 0.0439 & -0.0329 \\ 0.0034 & 0.0098 & 0.0042 & -0.0004 \\ 0.0439 & 0.0042 & 0.0175 & -0.0138 \\ -0.0329 & -0.0004 & -0.0138 & 0.0254 \end{bmatrix}$$

$$P_2 = 10^{-7} \times \begin{bmatrix} 0.1877 & 0.0023 & 0.0523 & -0.0407 \\ 0.0023 & 0.0126 & 0.0044 & 0.0002 \\ 0.0523 & 0.0044 & 0.0203 & -0.0169 \\ -0.0407 & 0.0002 & -0.0169 & 0.0328 \end{bmatrix}$$

$$P_3 = 10^{-7} \times \begin{bmatrix} 0.1500 & 0.0032 & 0.0429 & -0.0319 \\ 0.0032 & 0.0097 & 0.0040 & -0.0000 \\ 0.0429 & 0.0040 & 0.0172 & -0.0134 \\ -0.0319 & -0.0000 & -0.0134 & 0.0250 \end{bmatrix}$$

$$P_4 = 10^{-7} \times \begin{bmatrix} 0.1562 & 0.0033 & 0.0448 & -0.0343 \\ 0.0033 & 0.0099 & 0.0043 & -0.0008 \\ 0.0448 & 0.0043 & 0.0179 & -0.0144 \\ -0.0343 & -0.0008 & -0.0144 & 0.0261 \end{bmatrix}$$

The synthesis of the LPV observer gains L_i for each vertex is achieved with LMI Toolbox of Matlab. The observer gain L of the system described by (58) is determined offline using (9) in the different simulation case bellow. The parameters of simulation are fixed as $\sigma = 10^{10}, \Gamma = 120 \, and \, \mu = 0.2$.



To illustrate the effectiveness of our algorithm, we choose a particular system matrix (A, B) computed using (4) for arbitraries values of $\theta_1 = 0.03$ and $\theta_2 = 0$:

$$A = \begin{bmatrix} -1.756 & 1 & 0 & 0 \\ 1 & -1 & 0 & 0 \\ -1.8 & -1 & -0.75 & 0 \\ -1 & 0 & 0 & -1.006 \end{bmatrix} \quad (59)$$

$$B = \begin{bmatrix} 1 & 1 \\ 1 & 0.494 \\ 1 & 0 \\ -0.006 & 0 \end{bmatrix} \quad (60)$$

$$E = \begin{bmatrix} 0 \\ 0.6 \\ 0 \\ 1 \end{bmatrix} \quad (61)$$

The given LPV system is defined in the vertex as shown in the figure above:

A. Case of constant fault signal

In the first case, consider the constant fault described by the following equation:

$$f(t)=\begin{cases}0 & t>0\\ 2 & 51\le t\le 20s\\ 0 & 101\le t\le 150\\ 2 & other\end{cases} \quad (62)$$

Figure 1 and Figure 2 show the estimation of the fault applied to the system described by matrix (59), (60) and (61).

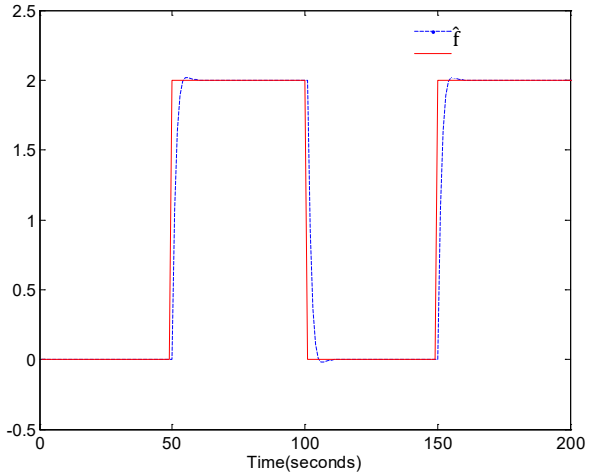


Fig. 1. f and its estimation $\hat{f}$.

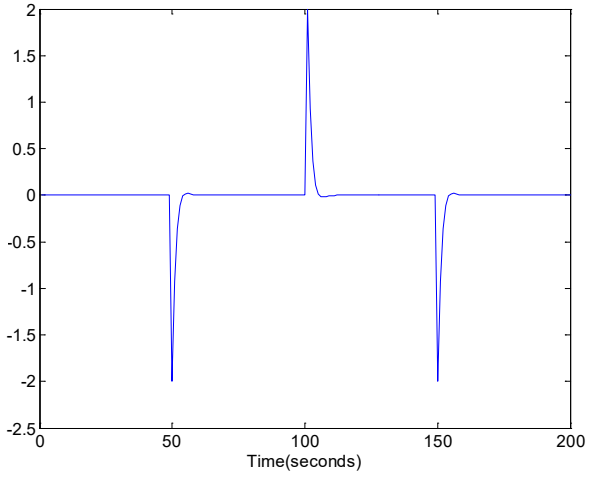

Fig. 2. The error $e_f(t)$ of the fault estimation

B. Case of variable fault signal

The actuator fault is described by:

$$f_{a2}(t)=\begin{cases}0.1\sin 5t+0.04\cos 3t\\ \quad +0.06\sin t+0.05\\ 0 \quad other\end{cases} \quad 7s\le t\le 12s \quad (63)$$

For the arbitrary values of $\rho(\theta)$, the simulation results are as the following:

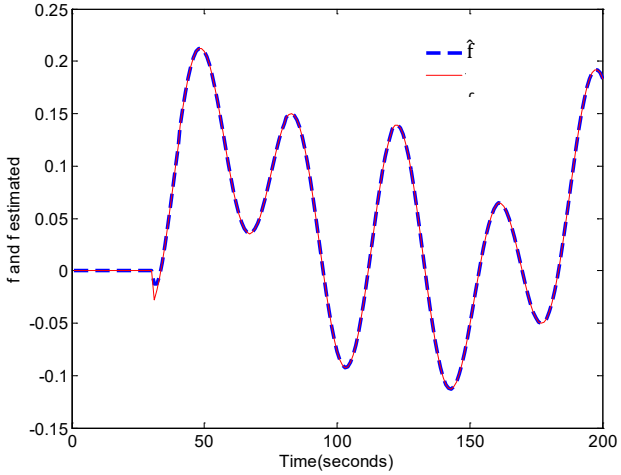

Fig. 3. f and its estimation $\hat{f}$.

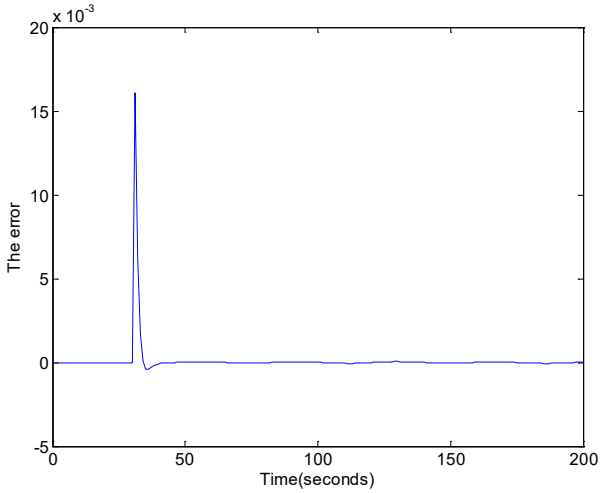

Fig. 4. The error $e_f(t)$ of the fault estimation

For the different types of fault signals considered above, Figure 2 and Figure 4 show the evolution of the error estimation. As can be observed, the error estimation converges asymptotic to zero even in the presence of disturbances. The real and the estimated constant and variable faults are displayed in Figure 1 and Figure 3 respectively. Summarizing, this approach can estimate the states and the fault functions with good performance and small error.

6. Conclusion

In this paper, an adaptive LPV observer using LPV approach has been presented for a polytopic system. A constant fault and a variable fault were considered. A polyquadratic Lyapunov function was used to perform the stability analysis. The problem was formulated in terms of linear matrix inequalities to develop the observer. The simulation results show the performances of the proposed observer. The main advantage of this representation is that it doesn't depend directly on the varying parameter. Moreover, this representation is defined as a difference between two parameters that evolve in two known and defined polytopes.

ABSTRACT

In recent years, a number of studies have been conducted exploring the potential of digital tour guides, that is, multimedia components (e.g., 2D graphic, 3D models, and sound effects) that can be integrated into digital storytelling with location-based services. This study uses component-based software engineering to develop the content of game-based tourism information services. The results of this study are combined with 3D VR/AR technology to implement the digital 2D/3D interactive tour guide and show all the attractions' information on a service platform for the gamification of cultural tourism. Nine kinds of game templates have been built in the component module. Five locations have completed indoor or external 3D VR real scenes and provide online visitors with a virtual tour of the indoor or outdoor attractions. The AR interactive work has three logos. The interactive digital guide includes animated tour guides, interactive guided tours, directions and interactive guides. Based on the usage analysis of the component databases built by this study, VR game types are suited to object-oriented game templates, such as the puzzle game template and the treasure hunt game template. Background music is the database component required for each game. The icons and cue tones are the most commonly used components in 2D graphics and sound effects, but the icons are gathered in different directions to approximate the shape of the component to be consistent. This study built a vivid story of a scene tour for online visitors to enhance the interactive digital guide. However, the developer can rapidly build new digital guides by rearranging the components of the modules to shorten the development time by taking advantage of the usage frequency of various databases that have been built by this study to effectively continue to build and expand the database components. Therefore, more game-based digital tour guides can be created to make better defined high-quality heritage attractions understood.

1. Introduction

In the United States, museums and historical sites generated 15 billion U.S. dollars in revenue in 2017 [1]. With the rapid development in information technology, the diversification and popularization of mobile carriers have made for rich digital content development. The Taiwan Tourism Bureau survey analysis also shows that cultural tourism has become an important tourism trend. The integration of multi-material, cross-platform and cross-industry values has become another focus of the content industry. Digital guides and online tourism maps of museums and historical sites' interactive tourist information services have gradually changed reading habits in recent years, replacing the hard copy of tourism guide maps. Since the development of the global digital economy, the output of digital content industries in Taiwan [2, 3] has reached over a 10% annual growth rate in recent years and a value of about 32 billion U.S. dollars in 2015. Based on the advantage of many excellent manufactories of information and communication technology in Taiwan, virtual reality technology has been regarded as an important driver of the digital economy. Applications such as commercial games, knowledge learning, and museum guides have increasingly introduced virtual reality, augmented reality, and mixed reality in Taiwan. For example, HTC and Foxconn Technology Group announced the first

*Corresponding Author: Wei-Hsin Huang, Tatung University, Taipei, Taiwan, R.O.C., Email: wshuang@ttu.edu.tw

VIVELAND™, which includes many virtual reality games, in Taiwan [4]. The Institute of Transportation adopted an interactive mixed reality platform [5] to develop a tool to assist teachers to teach children to walk safely around their schools [6]. The Shihsanhang Museum of Archaeology invites visitors to use a virtual reality tool to explore an important Taiwanese underwater cultural asset, the British steamship SS Bokhara, which sank near Taiwan in 1982 [7].

1.1. Digital Tour Guiding

Brown in [8] examined earlier applications that demonstrated location‐aware guiding by mobile devices, such as Cyberguide, which enabled a visitor to locate nearby bars, and GUIDE, which provided visitors with a means of personalizing information to suit their own interests and the environmental parameters. To increase the interactive elements, Bellotti in [9] built VeGame to operate on a cellular phone-mediated wireless connection between a pocket PC and the server, which communicated with the pocket PC via Bluetooth. VeGame was designed to enhance tourists' experience of art and history through a pleasant and challenging interaction with the heritage and people of Venice. When mobile devices became more widely used, Ballagas in [10] designed REXplorer, a device consisting of a Nokia mobile phone, a global positioning system (GPS) receiver, a camera, and a stretchable textile overlay with a zipper on the back that transformed a standard phone keypad into an 8-key game interface. Tourists could use REXplorer with gestures to interact with the significant buildings in Regensburg, Germany. Regarding indoor tour guiding, in addition to radio frequency identification (RFID) technology for positioning [11], Tsai in [12] proposed a position estimation method to design a location-aware tour guide system to be used with a personal digital assistant (PDA) by visitors to the National Palace Museum of Taiwan. As the user moved closer to items in the collection, the size of the materials became larger on the screen. Steiniger and Edwardes [13] indicated that location-based services (LBS) combined with GPS, geographic information systems (GIS), quick response (QR) codes, mobile facilities and scene-point tour databases are an important future direction of such technology. Currently, advances in mobile technology make it feasible to use virtual and augmented reality technology for learning [14]. Doong in [15] investigated the chocolate-related knowledge learning effect of a game-based learning system developed with a cross-platform of LBS and mixed reality technologies. The virtual treasure-hunt game world was the real location of a chocolate factory that the participants had to find on Google Maps.

1.2. Agile Development and Component-Based Software Engineering (CBSE)

Developing game-based digital content is an expensive and risky activity. Using CBSE methods allows one to design digital content quickly by reusing existing functions and models to produce a system [16]. Folmer and Mehm's overview of developing games with components presents a reference architecture that outlines the relevant areas of reuse and signifies some of the problems with developing components unique to the domain of gaming [17, 18]. Elements characteristic of games (good competition, character development, improvement, inspiring and creative challenges, and activity) can easily be adapted to the needs arising from cultural settings. The results would be an increase in motivation and the development of positive relations with the cultural subject. Based on the spirit of the agile development method, Wu Junyue (2013) devised a set of development processes for mobile customer service that are best for the mobile service application [19]. Wu Junyue's development process f reduces the output of unnecessary documents and uses repetitive development processes to shorten the development schedule. For these reasons, a challenge for the scientific community is to find new ways to visualize and disclose 3D digital contents to achieve better access to and communication of cultural heritage information [20]. Therefore, the purpose of this study is to determine how to develop digital guides rapidly and make them suitable for more kinds of handheld equipment.

1.3. 3D Virtual Game-based Environment

Effective learning is situated, active, and problem-based and requires immediate feedback [21]. Gaming elements provide an instructional environment with stimulation and learning motivation [22, 23]. A well-designed virtual educational game provides complex holistic problem-based environments, making it possible to develop situated understanding [24] and thus supporting effective learning. Virtual game-based environment designs follow the rules of game design. Nevertheless, the purpose is not only to entertain [25] but also to use the characteristics of video and computer games to create attractive and immersive learning experiences to achieve specific learning objectives [26]. In addition to the four important features (gameplay, feedback, interface, and challenge) of a good game [25], the design of a game-based learning system must further consider the realism of the game, the opportunities to explore and obtain new information, and the meaning of learning controls [26]

1.4. Agile Development and Digital Content Development

The effectiveness of the selection of the game template components and the game design is also the most thought-out part of the process of implementation. For example, Teng Feng Fishball Museum (TFFM) at Tamsui is a food tourism location where the TFFM combines the history and cultural characteristics of the Tamsui. The TFFM is focused on individuals or family members and is supported by a rich history and cultural knowledge. The TFFM can present more profound educational material and understanding with 3D VR game types. However, this kind of innovative food museum can also present a variety of innovative food products by focusing on entertaining 2D game templates. Both digital guides focus on increasing the pleasure of the user experience, allowing the user to learn more about tourist attractions, or increasing tourists' pleasure in traveling on their own. Digital guides also meet educational needs and draw visitors into visiting the museum.

2. Methods

2.1. The Game-based Tourism Information Service System (GTISS)

The Game-based Tourism Information Service System (GTISS) was developed for the purpose of breaking geographical and temporal restrictions. 3D virtual and game-based tourist attractions were created using Unity software. Three major elements are including in the GTISS: itinerary planner, games and

virtual reality design, and cultural tourism features. The concept of CBSE was adopted in the development of the GTISS by agile methods.

The GTISS is designed to break geographical and temporal restrictions by creating 3D virtual and game-based tourist attractions using Unity software. There are three major elements in the GTISS, including an itinerary planner, virtual game-based design, and cultural tourism features. The concept of CBSE was adopted in the development of the GTISS by agile methods. Employing CBSE in the design of a tourism information platform expedites the process, that is, multimedia components (e.g., game plans, 2D icons and pictures, music, sound effects, 3D models, and programs) in a previously created database can be used and reused for various projects, which lowers the threshold for developing a tourism information platform and adds value to existing tourism materials. Cultural tourism is often full of story-like elements; thus, to enhance the attractiveness of a cultural tourism information platform, it is necessary to improve its storytelling ability and incorporate the LBS and game elements into the platform [27]. Web3D, GIS, GPS, and Unity3D VR software were used in the present study. The goal of CBSE is to establish a digital content development platform consisting of reusable components; this platform can shorten the time for developing a project. Drawing on the concept of CBSE, the multimedia component database allows developers who do not have enough game development background to design the content of the platform easily. Finally, all the components in the database were created to be compatible with the Unity 3D engine.

To develop the GTISS, first, information content about tourist attractions was collected. Then, based on the features and characteristics of each tourist attraction and the corresponding game plans, appropriate components in the multimedia component database were searched to design a game that presents the information about each tourist attraction. LBS integrated the QR code to enhance the contextualized interaction. Tiered with levels of difficulty, it features requirements, such as time limits and penalties, that add excitement and competition to the game. The accomplishment of finding a destination involves answering questions or solving problems in some well-known scenic spots. Moreover, for users, the platform provides travel guides to the tourist attractions by showing available public transport through dynamic maps and consecutive pictures of real street views. In addition, by using Google Maps application program interfaces (APIs), the platform shows the GPS locations of the tourist attractions on Google Maps, which is familiar to many users.

2.2. Agile Development and Digital Content Development

A number of tourist attractions that the government actively promotes were selected for information collection. Each digital guide for the tourist attractions provides public transport information integrated into the digital map to promote a Low Carbon Tour. Applying the appropriate game plan for an attraction's information confirms that the characteristics of the attraction's content are sufficient for the resources required for the game plan. For example, if there is not enough information about the attraction, then the use of the real tour will lead to digital guide content that is not attractive. Finally, we applied the modular component and game design principles of the plan to archive the digital guides. With the Unity 3D engine, the completed digital guide can be built into different carrier formats (such as html, apk, and exe). The process of component-based agile game and digital content development used by this study is shown in Figure 1.

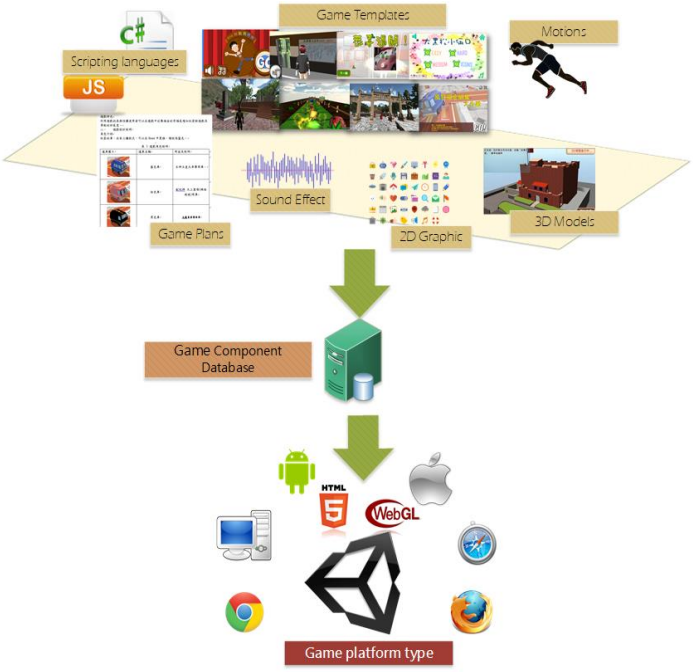

Figure 1 The process of use agile design method to make digital content

The effectiveness of the selection of the game template components and the game design is also the most thought-out part of the process of implementation. For example, Teng Feng Fishball Museum (TFFM) at Tamsui is a food tourism location where the TFFM combines the history and cultural characteristics of the Tamsui. The TFFM is focused on individuals or family members and is supported by a rich history and cultural knowledge. The TFFM can present more profound educational material and understanding with 3D VR game types. However, this kind of innovative food museum can also present a variety of innovative food products by focusing on entertaining 2D game templates. Both digital guides focus on increasing the pleasure of the user experience, allowing the user to learn more about tourist attractions, or increasing tourists' pleasure in traveling on their own. Digital guides also meet educational needs and draw visitors into visiting the museum.

To rapidly develop a game-based digital guide, component-based templates were used to develop a digital guide of tourist attractions. The construction of the modular component database replaced the homemade or commercially available development resource modularization database. Seven component databases were established and used to develop a game-based digital guide that can be viewed on webpages or handheld devices. The component databases are shown in Table 1. A motion database and a game template database were recently completed. After developing several games, the humanoid character can be used in a cross-game motion template. We expanded our motion database

by using x-box to scan simple motions that the game needed and binding the motion to the characters.

Table 1: Component-Database of this study

Database Name	Content
3D Model	The 3D model library contains models such as character, buildings, and objects that built from a variety of modeling software, such as 3D Max, Maya, and SketchUp. All models are finally imported in the development engine with .fbx format
2D Graphic	This database contains illustrations for animations and interface designs such as picture or icon. The 2D material in database licensed under creative commons. Some of these art files may contain .jpg, .png, and so on in different file formats.
Scripting language	This study aimed at scripting and sorting all kinds of shareable functions in game templates. For example, the function of these feet for the game interface to return and explain the function, the game time count/pause/stop, props configuration, character action control. All scripts has been documentation for re-use by non-game developers.
Game Plan	The game template of this study will be self-development and collect from web resource database. We write planning documents for each free or paid game template for non-game developer to use.
Sound Effect	Collect, organize and use the sound studio or online recording software produced by the various sound effects database. All content licensed under creative commons, and contains include .mp3 or .wmv and other file formats of sound.
Motion	In addition to collecting free motion files available on the network, find out how to organize the motion files from ready-made game templates into other game templates. This study also used X-Box for Motion capture to record the movements of real people and mapping the movements onto the CG character.
Game Template	By implement the game plan into real game, there are eight game template had been build. There are nine game template in our database.

In addition to the integration of models, animations and sound effects in the game development process, the development of game script language is also very important. However, the number of script resources that can be used directly in the game is less than the number of models or sound effects. As shown in Figure 2, if building a script language database can be organized, then the time that programmer used to rewrite the code can be saved. The developer simply confirms the required functionality, finds the appropriate script resource in the database, and imports it into the Unity game engine. Fine-tuning allows game developers to quickly develop game features and add new script into the script database.

2.3. 360-Degree Virtual Tour Guide

To increase the sense of participation, an attempt was made to imitate the indoor and outdoor feeling of the attractions that visitors would experience. Some of the attractions are not well defined by their location or are connected to a factory, and the user cannot find the entry.

This study uses Google Street View's screenshots to build a 360-degree VR scene. The application of this 360-degree scene setting in this platform mainly provides an indication of the user's arrival status at the attraction. Using the 360-degree circular guide at the entrance increases the user's understanding of the geographical location of the scenery. The design of this scene can be applied to the design of future AR scenes. The scene of this study is based on the use of Google Street View and real indoor photos made during field trips to build outdoor and indoor scenes. In the future, the user may use the camera lens of the mobile device as a source, and the digital guide instructs the user to provide information or tips based on all the current locations.

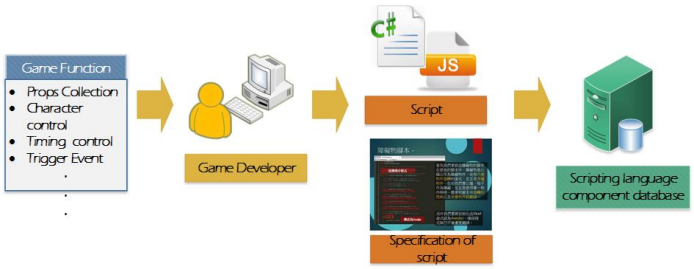

Figure 2 The process of build Scripting language component database

3. Results

3.1. Game-based Component Database

This study built seven component databases, as described in Table 1. Figure 3, Figure 4 and Table 2 are the samples of the 3D models, different motions and sound effects collected in this study in the present component databases. Regarding the 3D character models, for example, there are currently ten 3D character models in the database. As shown in Figure 3, the same character can be used in different games quickly with various motions. The movement of running includes running forward, turning left, and turning right. The motions of touching the head and waiting are bound to form the other motion. Some motion files for men and female are different. In the different games shown in Figure 3, it is possible not only to reuse the 3D character model in the game template but also to use 3D models of terrain and trees. User interface (UI) templates in the 2D graphic database can be created for different attractions easily, quickly and repeatedly. As shown in Figure 4(a), the same UI template was used in the National Dr. Sun Yat-sen Memorial Hall and the Vigor Kobo Dream Museum. Through a color change, the same UI component can quickly adapt to each game template. Similarly, by using consistent icons, the user can understand the meaning of the graphic on the screen. As shown in Figure 4 (b), the icons on the screen are the indispensable elements that guide the user to operate the icon related functions. During the preliminary stage of design, it took about a month to accomplish the construction of a scenic spot whereas only five working days were needed in the later stage for the creation and modification of an attraction, which is the most time-consuming of the entire project.

3.2. The Tourism Digital Guiding Platform (TDGP)

In the present study, the GTISS was designed and shown as in Figure 5. All attraction locations were labeled in Google Maps and categorized into six types: food, shopping, heritage, transportation, education, and entertainment. User-friendly interfaces enable visitors to find interesting locations easily. Fifteen cultural locations were chosen and designed in the TDGP. Figure 6 shows the template for planning the route to the destination (e.g., from Taipei Main Station to the Taiwan Socks Museum). Users can choose to board at the mass rapid transport (MRT) station. Then, according to the routing algorithm, the user can achieve the minimum number of transfers or the shortest distance calculated from the number of stops. Both the interactive display technology of the LBS geographic location and the 3D VR/AR are important trends in the digital content industry.

The interactive traffic information guideline was provided by the destination websites. Combined with the street/attractions and

outdoor/indoor navigation technology of an attraction's features, users can have an in-depth understanding of the tourist information and be impressed by the digital tour guides.

The completion of each level involves answering questions and solving problems. Answers to the questions can only be found by asking locals questions, exploring the surroundings, or using certain services specific to a location. At the outset, the QR code of a zone must be photographed, and when all the questions in that zone are answered or when the problems are solved, the user can then advance to the next level of his/her choice.

Figure 6 shows useful travel guides included in the tourist attractions with available public transport route information through dynamic maps. By using the 360-degree circular guide, consecutive pictures of real street views can be provided to increase the visualization and understanding of those locations (shown in Figure 7). The platform shows the GPS locations of the tourist attractions on Google Maps, and more LBS information can be added to the system.

The 2D/3D game-based learning content of fifteen attractions are shown in Figure 8. These are famous attractions in Taiwan and are promoted by the Taiwan Tourism Bureau. The development of a digital tour guide is mainly based on 3D game types. However, the architecture is the main part of building the 3D models of the attractions, and it requires more time and work to adjust during the development process. To attain the purpose of the agile development of the new digital guide, this study also built some interesting 2D game templates for our database to save time and reduce the needed process in developing digital tour guides, as shown in Figure 8.

3.3. 3D AR / VR Game-based Tourism Service

Seven databases were used in designing the 15 attractions for the effective and efficient development of the game. Table 3 shows the number of 2D graphics with the game templates applied in the 15 attractions. Figure 9 shows several 2D graphics used in the game templates. Most reusable images are icon-type graphics, which can change color, size, and text. In addition, each game has background music, which was chosen from the background music (BGM) database based on rhythm and types. Table 4 shows all the music applied in the game templates for the study.

To create a 3D VR game template, a goal-oriented puzzle or treasure hunt was created by interacting with the object in the scene (Table 5). The Unity3D game engine was used to build indoor and outside VR panoramas of attractions in this tourism platform. Google street view was used for outdoor scenes, and 3D models with real indoor photos of the museums were created in the present study. Through the implementation of an online VR tour, users can have pleasure and further understand the details of the attractions.

There are nine kinds of game templates built in the component modules. By using these component modules, a digital guide with 3D VR real scenes were provided to visitors for touring both the indoor and outdoor attractions (as is shown in Figure 10). This study organized the game-based component templates and created vivid scenarios of scene tours for visitors to enhance the interaction with the digital guide. Nine kinds of game templates with three game types are shown in Table 5.

During the 2D game development period, a navigation e-book was also built to be merged with the 3D model. The design of the navigation e-book has been improved from the original 2D material to the 3D model library by adding a UI interface for a more interesting and clear introduction. To upgrade the function of the navigation e-book content, we incorporated 2D text descriptions and dynamic 3D guidance to enhance the entire navigation e-book'tals readability. This navigation e-book is released on a Unity platform. There is a PC version, a web format, and an .apk format for other handheld devices.

Animations and interactive elements were added to this navigation e-book to increase the interactivity between the digital content and the users. Using Lan Yang Museum's 3D navigation e-book as an example, on the floor map page, by clicking on the 3D text on the left and the red indicator on the right side of the page, it will move to the floor on the map (Figure 11(a)). In the traffic guide page, the 3D models of moving trains and buses, as shown in Figure 11(b), were also added to improve the appeal of the e-book as well as the enjoyment of the visitors.

To further expand our VR games into AR games. Three museums' logo images were chosen as the AR image-based

identification, which can generate four identifications supported by the Unity software: single picture identification, cuboid identification, cylinder identification and 3D object identification. When the AR glass lens captures the correct image object, other instructions from the weblink or hyperlink to the museum website are triggered (as shown in Figure 12).

It is important to design and develop game-based digital tour guides using agile development and component databases in the future. Game-based digital guide learning easily increases not only the entertainment effect but also the understanding and recollection of the cultural attractions. However, to accomplish this complex work (drawing the 3D model, writing the coding, producing the music, etc.) requires a long development process. Developers with experience in game design need at least a month to finish a game project without using a component database. Using the game-based component database, intern students with no experience in game development were trained to complete the first digital game guide within two weeks. After completing the first project, four intern students found new attractions and used game templates to develop new game-based digital guides on their own. The intern students can not only develop independently but also shorten the design period to within a week. In the future, non-game professional tour staff can complete their own interesting digital tour guides easily and quickly.

After the platform is established, the attention of younger users can be captured by measuring the accuracy of the questions that users answer before and after using the platform. If the digital tour guide of this platform is sufficient to attract users to browse, read and memorize the content, the accuracy of the answers in post-test results should be improved. There were 477 student participants. Their ages ranged from 18 to 22 years old, and the number of female students (338 or 70.9%) was higher than the number of male students (139 or 29.1%). This study used a pre-test and post-test on knowledge content design issues for the platform attractions. The pre-and post test aimed to examine whether students enhanced their understanding of the attractions and the online travel planning. The items include an itinerary planner, games and virtual reality design, cultural features of the attractions, and Tourism English. Students did the pre-test before the experiment and the post test after it. The experiment lasted for one hour. The purpose of the system design was explained and the operational functions were demonstrated before the experiment. Pre- and post-tests were created based on the content of the system to examine student learning on the platform. As shown in Figure 13 (a), both males and females increased their correct answer rate after using the platform. Figure 13 (b) shows the pre- and post-test correct answer rates for question 3-1 in the questionnaire. The post-test correct answer rates for both males and females were 10% or higher than the pre-test. These results are sufficient to initially demonstrate the validity of the digital tourism content on the platform established by this study. The game-based digital tour guides with locality-specific information and culture in mind can make not only real hands-on experiences but also experiences that are memorable and worth sharing.

ABSTRACT

This paper describes the design and analysis of a regenerative braking system for a permanent magnet synchronous motor (PMSM) drive for electric vehicle (EV) applications. First studied is the principle for electric braking control of a PMSM motor under field-oriented control (FOC). Next, the maximum braking torque in the regeneration mode as well as the braking torque for the maximum regeneration power, respectively, are deduced. Additionally, an optimum switching scheme for the inverter is developed with the objective of maximizing energy recovery during regenerative braking to the DC-bus capacitor. The integration of an ultracapacitor module with the battery allows for the efficient and high power transfer under regenerative braking. It was important to manage the power flow to the DC-bus as this is a key issue that affects the efficiency of the overall system. Finally, the amounts of braking energy that can be recovered, and the efficiency with which it can be returned to the battery/ultracapacitor, is analyzed for a PMSM coupled with a DC motor as the load. The results of the analysis are validated through experimentation.

1. Introduction

Interest in regenerative braking is growing drastically nowadays; as the market is slowly transitioning to electric vehicles (EV) instead of the traditional vehicles that run on fossil fuels. Regenerative braking (RB) utilizes the kinetic energy generated by the motor during the deceleration, or braking, process. Therefore, recovering the braking energy is an effective approach for improving the driving range of an EV [1]-[4]. Usually, within traditional vehicles, all of the braking energy is lost in the form of heat due to friction losses. In RB, the motor acts as a generator and the kinetic energy is harvested by applying the proper switching schemes to the power converter switches. This harvested energy can be used to charge the vehicle's battery, or stored in an ultracapacitor bank [5]-[8]. A hybrid energy storage system can be used to alternate power generation and storage between an ultracapacitor and a battery, depending on the required power. Knowing the parameters of the system is essential to building a clear idea regarding the amount of energy harvested as opposed to that being generated.

The permanent-magnet synchronous motor (PMSM) is widely adopted as the traction motor in electric vehicles (EV) due to its high efficiency and high torque density. Vector control, also called field-oriented control (FOC), is a popular and powerful method in electrical drive applications. This control strategy is used to effectively control the PMSM motor torque and flux in order to force the motor to accurately track the command trajectory regardless of machine and load parameter variations, or any other external disturbances [9]. Electric braking control of the PMSM based on FOC is realized by requesting a negative q-axis current according to the braking torque demanded. The maximum amount of current produced while braking is calculated depending on many variables, including the motor speed and input voltage [10].

This paper is an extension of work originally presented in ICMSAO'17, where regenerative braking was analyzed for a DC motor with battery/supercapacitor energy storage [11]. The maximum amount of current produced by the DC motor while braking was calculated depending on the system variables such as motor speed, armature resistance, and input voltage. The theoretical analysis was next validated by experimental results. The effect of varying the duty cycle of the braking signal was also studied to find the optimal duty cycle that gives the best efficiency in regenerative energy harvesting.

In this paper, electric braking is first analyzed for the PMSM under Field Oriented Control (FOC). Next, a dedicated maximum Energy Recovery Switching Scheme (MERSS) is developed to control the inverter switches during regenerative braking to maximize energy recovery. Regenerative braking energy calculations are confirmed by experimental results on a prototype

*Corresponding Author: Andrew Adib, Email: b00062741@aus.edu

PMSM motor drive system. The harvested energy is stored into the DC-bus capacitor. The efficiency with which energy can be returned to the ultracapacitor is analyzed for the FOC scheme and the MERSS. The analysis, benefits, limitations and experimental results of each control strategy are provided.

This paper is divided into 5 sections; section 2 presents the concept of regenerative braking under FOC and provides some theoretical analysis of the required motor current during this mode of operation. Section 3 presents the maximum energy recovery switching scheme. Section 4 presents the experimental results and discussion when braking the PMSM under FOC and MERSS. Finally, the conclusion is presented in Section 5.

2. Regenerative Braking of the PMSM Under FOC

In conventional passive dynamic braking the kinetic energy of electric machines is dissipated through the armature coils and the additional braking resistors. The principle of the regenerative braking with the voltage-source inverter is similar to that of the conventional dynamic braking, however; the additional resistors are eliminated and no additional power switches are used.

According to the driving conditions, the braking process can be classified as either constant speed braking or variable speed braking. The constant speed braking is usually required during the downhill road driving, while the variable speed braking often occurs during the general deceleration process.

2.1. System Setup

Figure 1 shows the general topology used in electric vehicle applications with hybrid energy storage, where the mechanical load is typically coupled to a Permanent-Magnet Synchronous Machine supplied by a battery source through an inverter. An ultracapacitor module is used as an auxiliary power source connected through a bi-directional DC-DC converter to the DC-link, thus making it possible to obtain an optimized charge/discharge operation mode.

2.2. Regenerative Braking principle of the PMSM

The FOC scheme for the PMSM is shown in Fig. 2. In FOC, the stator phase currents are measured and converted into a complex vector. This current vector is then transformed to a coordinate system rotating with the rotor of the machine.

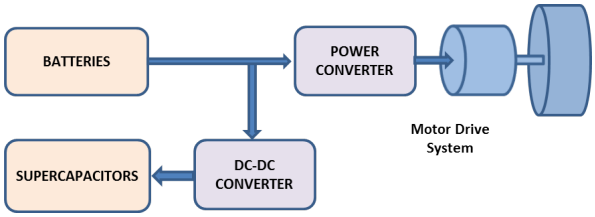

Figure 1: Topology of the Battery-Ultracapacitor Energy Storage System

The real x-axis component of the stator current vector i_d, in this rotor flux-oriented coordinate system, is used to control the rotor flux linkage. The imaginary y-axis component i_q is used to control the motor torque. For the PMSM, maximum torque–current control can be achieved by holding the d-axis current at zero ($i_d = 0$).

Electric braking control, based on FOC, is realized by requesting a negative q-axis current according to the braking torque demanded, or by controlling the speed to follow a ramp reference and gradually approach zero [6].

The input power and the electromagnetic power can be expressed as

$$P_{in} = V_d i_d + V_q i_q, \quad (1)$$

$$P_{em} = T_{em}\omega\,, \quad (2)$$

$$T_{em} = \frac{3}{2}\frac{p}{2}\lambda_{PM} i_q\,. \quad (3)$$

where, i_d and i_q are the d-axis and q-axis current components, V_d and V_q are the d-axis and q-axis voltage components, ω is the motor speed, T_{em} is the electromagnetic torque, λ_{PM} is the permanent magnet flux, and p is the number of poles.

The electric machine power losses are given as

$$P_{loss} = i_d^2 R + i_q^2 R. \quad (4)$$

where, R is the per-phase stator resistance. By balancing the input and output power

$$P_{in} = P_{em} + P_{loss}, \quad (5)$$

$$P_{in} = \frac{3}{2}\frac{p}{2}\lambda_{PM} i_q \omega + R(i_d^2 + i_q^2). \quad (6)$$

To find the regions of regenerative braking, P_{in} is set to 0. This means that no power is being drawn from the DC source.

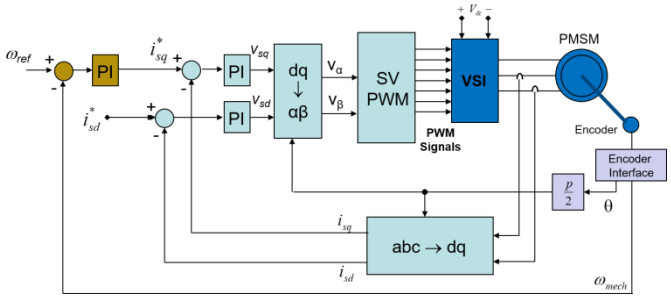
Next, an expression for i_q in terms of i_d can be found

$$i_q = \frac{-\frac{3p}{22}\lambda_{PM}\omega \pm \sqrt{\left(\frac{3p}{22}\lambda_{PM}\omega\right)^2 - 4R^2 i_d^2}}{2R}. \quad (7)$$

The equivalent electromagnetic torque is given as

$$T_{em} = \frac{3}{2}\frac{p}{2}\lambda_{PM}\left(\frac{-\frac{3p}{22}\lambda_{PM}\omega \pm \sqrt{\left(\frac{3p}{22}\lambda_{PM}\omega\right)^2 - 4R^2 i_d^2}}{2R}\right). \quad (8)$$

This equation describes the electromagnetic torque inside the regenerative braking region. To find the boundaries of this region, the above equation is solved for the maximum and minimum braking torque.



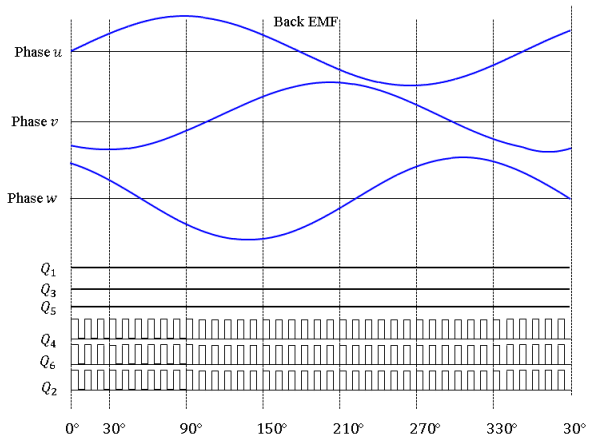


Figure 2: Field Oriented Control Scheme of the PMSM

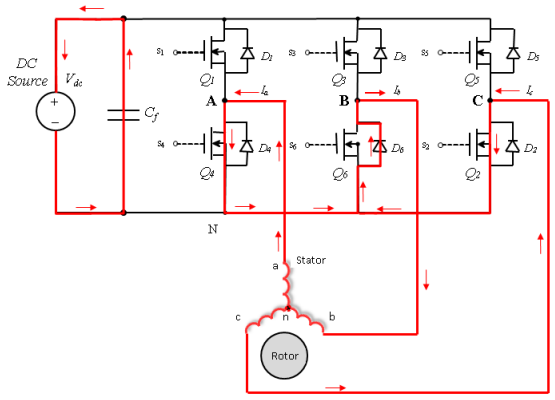
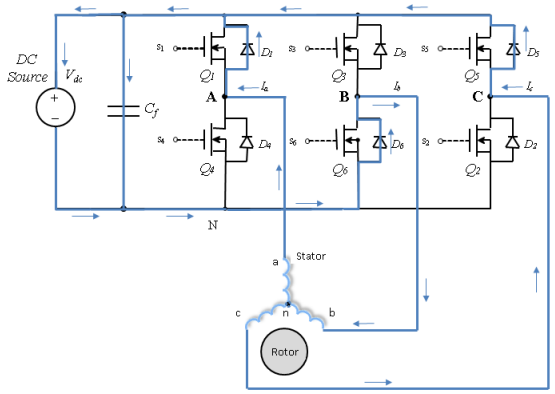
$$\frac{dT_{em}}{di_d} = 0. \quad (9)$$



Therefore,

$$i_d = 0. \quad (10)$$



Substituting this result in equation (7) gives

(a)

(b)

(c)

Figure 3: Regenerative braking scheme. (a) Emf and PWM switching signals, (b) Current flow during ON-Time and 0-30° period. (c) Current flow during OFF-Time and 0-30° period

$$i_q = -\frac{3P\lambda_{pm}}{4R}\omega. \tag{11}$$

The equivalent electromagnetic torque is then given by

$$T_{em} = -\frac{\left(\frac{3}{4}p\lambda_{pm}\right)^2}{R}\omega. \tag{12}$$

This equation defines the minimum electromagnetic torque needed by the PMSM to operate the machine in the regenerative braking region.

Next, to find the maximum regenerative braking current absorbed, the input power is minimized.

$$\nabla P_{in} = \begin{bmatrix} \frac{\partial P_{in}}{\partial i_d} \\ \frac{\partial P_{in}}{\partial i_q} \end{bmatrix} = \begin{bmatrix} 2Ri_d \\ \frac{3}{2}\frac{p}{2}\lambda_{pm}\omega + 2Ri_q \end{bmatrix}. \tag{13}$$

The minimum power is obtained by setting this gradient to zero and solving for both variables, i_d and i_q.

$$i_d = 0, \tag{14}$$

$$i_q = -\frac{3p\lambda_{pm}}{8R}\omega. \tag{15}$$

The equivalent electromagnet torque generated by these current commands is given by

$$T_{em} = -\frac{9p^2\lambda_{pm}^2}{32R}\omega. \tag{16}$$

This torque guarantees maximum absorbed current by the DC source during regenerative braking.

3. Regenerative Braking with the Maximum Energy Recovery Switching Scheme (MERSS)

The switching scheme of the inverter is developed with the objective of maximizing energy recovery during regenerative braking. The idea is to utilize the motor phase inductors along with the inverter switches, functioning as a boost converter and allowing the phase currents to reverse their direction to flow back to the DC-bus capacitor [12], [14]. Regenerative braking is achieved by controlling only the lower switches (Q_2, Q_4, Q_6) through PWM and switching OFF all of the upper switches (Q_1, Q_3, Q_5) as shown in Fig. 3. In this mode of operation, the three lower switches are controlled with the same PWM command signal. During the ON-time, a path is provided for the phase current to flow in the negative direction through the closed switch, or in the positive direction through the free-wheeling diode depending on the polarity of the back emf.

Figure 3a shows the phase relationship between the back EMF, armature current, and the switching signals. Figure 3b and Figure 3c both show the closed loop path of the 3-phase currents during the 0-30s time interval of each cycle. During the OFF-time, the phase currents must maintain their direction and are therefore forced to flow through an alternate path created by the upper free-wheeling diodes, $D_1 - D_3$ and then back to the DC-bus capacitor. In this time period, regenerative braking is achieved and the capacitor is charged by the recovered electrical energy.

4. Experimental Testing and Discussions

In this section, experimental results of the regenerative braking process are analyzed to confirm the theoretical analysis. The energy recovered by the DC-bus capacitor is compared to the motor's mechanical energy to evaluate the efficiency of the

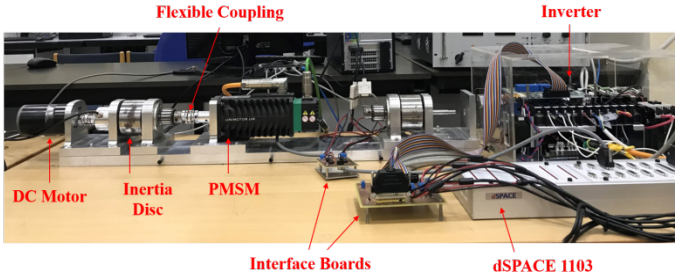
regenerative braking process. Figure 4 shows the topology of the PMSM experimental setup. The system consists of a PMSM, which is controlled using a MYWAY MWINV-9R144 inverter. The inverter switches are controlled using the dSPACE 1103 board. The PMSM is coupled with a Bühler DC Motor through flexible couplings and additional disc inertia mounted on the same shaft. The DC motor acts as a mechanical load and is controlled using a DC-DC converter, which in turn is controlled using a dSPACE 1104 board. Two encoders are used: the first is an incremental encoder directly connected to the DC motor side, and the second is a sine/cosine encoder connected to the PMSM side. The system parameters are listed in Table 1.

In the following sections, regenerative braking is implemented on the PMSM machine controlled with FOC. Two methods are implemented to realize regenerative braking. The first method is based on speed control and uses a ramp speed reference with negative slope to brake the motor. This linear deceleration simulates the braking of an EV, where the speed decreases gradually until it reaches 0. The braking time is adjusted by controlling the slope of the reference speed.

The second method operates the PMSM in torque control mode. The speed control loop is disconnected from the vector control scheme and the current commands, i_d^* and i_q^*, are generated directly. The i_q^* command will generate a negative torque that brings the motor to a stop. As discussed in section II-B, generating this torque guarantees maximum current absorption by the DC source, allowing for the returned current to achieve a higher amplitude and therefore the recovered energy is maximized.

Table 1: Motor drive system parameters

Parameter	*Value*
Resistance (R_{p-p})	6.8 Ω
Total inertia (J)	0.00315 Kg.m^2/s^2
Back EMF constant (K_b)	98 $V/krpm$
Torque constant (K_t)	1.6 Nm/A
Rated Torque	3.9 Nm
Stall Current	2.7 A
Inductance (L_{p-p})	24.3 mH
Damping coefficient (B)	4.741x10^{-4} Nm/(rad/s)
Coulomb friction (τ_c)	0.1343 Nm



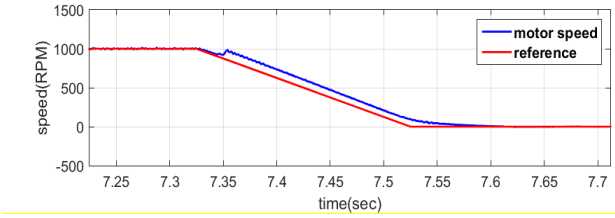


Figure 4: PMSM drive system

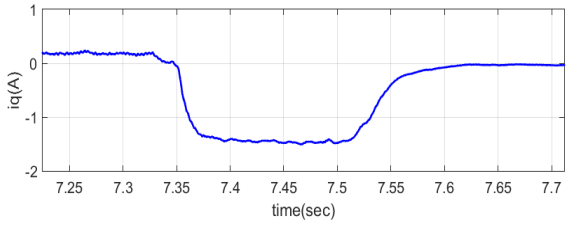

In order to observe the voltage increase during regenerative braking, the three-phase line is disconnected from the inverter and the DC-link voltage is maintained only by the DC-bus capacitor. As a result, the voltage begins decreasing. In this period of time, the motor is operating under constant speed. Once the DC-link voltage reaches 300V, the regenerative braking command signal is triggered and the motor operates under braking mode.

4.1. Regenerative braking using speed control mode

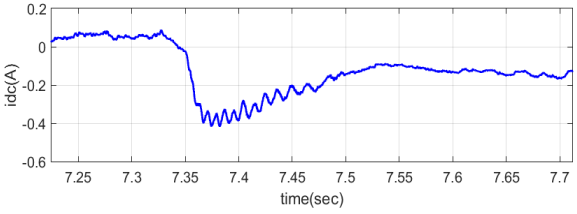

Figure 5a shows the reference speed and actual speed of the PMSM before and after regenerative braking is activated. The motor decelerates gradually to zero with a breaking time set to 0.2s. During the regenerative braking period, a negative q-axis current, i_q^*, is generated by the FOC controller as shown in Figure 5b. The motor mechanical energy is supplied back to the capacitor. Figure 5c shows a negative DC-link current indicating that energy is flowing from the motor to the capacitor. Figure 5d shows that the capacitor voltage is being charged during this period.

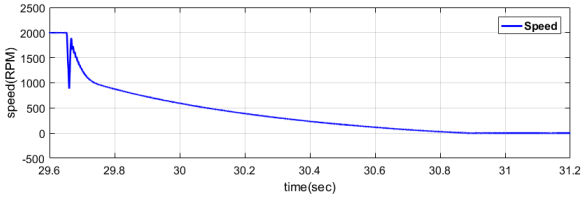
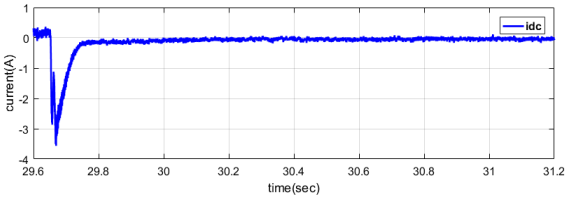
(d) DC-bus voltage

Figure 6: PMSM transient response during regenerative braking under the torque control mode of operation



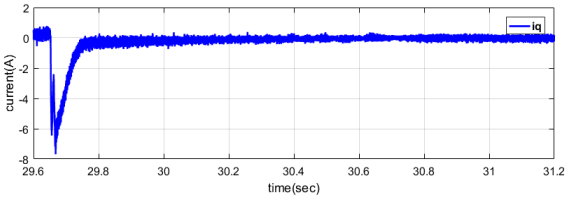
4.2. Regenerative braking using torque control

Figure 6 shows the motor variables during the torque mode of operation. Initially, the motor speed is regulated by FOC to the desired reference value. Once regenerative braking is initiated, the speed controller is disabled and the motor torque is controlled through the q-axis current. Figure 6a shows the reference current, i_q^*, and the generated q-axis current, i_q.

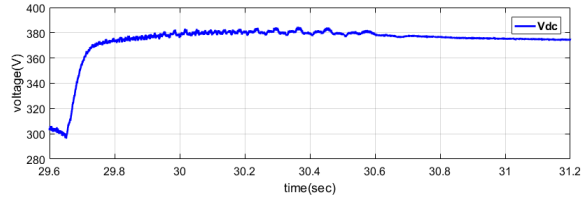


The braking time must be tuned in order for the speed to reach zero at the end of the breaking time. Table 3 summarizes the regenerative braking event results under the torque control mode of operation. The results indicate that greater amounts of energy are harvested with the torque control operational mode in comparison to the case of the speed controlled braking.

4.3. Regenerative braking using the Maximum Energy Regeneration switching scheme (MERSS)



To evaluate the PMSM performance with MERSS, the motor is initially powered by the DC-bus capacitor to operate the drive system in driving mode. Next, a break command is activated to operate the system in regenerative braking mode.



(a) Motor speed

(b) q-axis current

(c) DC-link current

(d) DC-bus voltage

Figure 7: PMSM transient response during regenerative braking under MERSS mode of operation. ω_0=2000 rpm, d=0.7

As a result, the phase currents reverse their direction and provide energy back to the DC-bus capacitor. The DC-bus voltage increases allowing the DC-bus capacitor to be charged.

Figure 7 shows the transient response of motor speed, q-axis motor current, DC-bus current, and DC-bus voltage. The motor is initially running at constant speed and the DC-bus capacitor is supplying power. When the break command is received, the motor starts decelerating until it comes to rest. The regenerative braking region is a subset of this period where the kinetic energy of the

rotor is used to generate electrical energy, and the motor acts as a generator. Figure 8 shows the electric power and energy recovered by the DC-bus capacitor. Following the braking command, energy recovery is activated through the MERSS and the capacitor voltage increases as current is absorbed by the capacitor. Regenerative breaking stops when the motor current reaches the minimum level set by the speed, as given through equation (11).

This process was repeated for different motor speeds and different PWM duty cycles. Varying the duty cycle of the brake command will change the ON-OFF times of the lower inverter switches, as explained previously in Figure 3. Increasing the ON-time period will charge the motor's inductance for a longer time allowing for the storage of additional energy. This process is similar to the operation of a boost converter. However, if it the ON-period is heavily increased, energy will not be fully recovered due to a short OFF-time period, and will eventually be lost in the switching process. For this reason, the duty cycle must be carefully selected for optimum energy recovery. Figure 9 shows the regenerated power and energy as a function of duty cycle for different motor speeds.

The maximum regenerated energy is compared with the mechanical energy to evaluate the efficiency of the system under MERSS. The energy of the motor and the energy stored in the ultracapacitor during braking are given by:

$$\mathrm{E_{mech}} = \frac{1}{2}\mathrm{J}\omega_0^2, \tag{17}$$

$$E_{cap}(k) = E_{cap}(k-1) + \frac{T_s}{2}[P_{cap}(k) + P_{cap}(k-1)], \tag{18}$$

where, ω_0 is the initial speed of the motor when the braking process starts. Therefore, the efficiency of the braking process takes into consideration the power losses during switching.

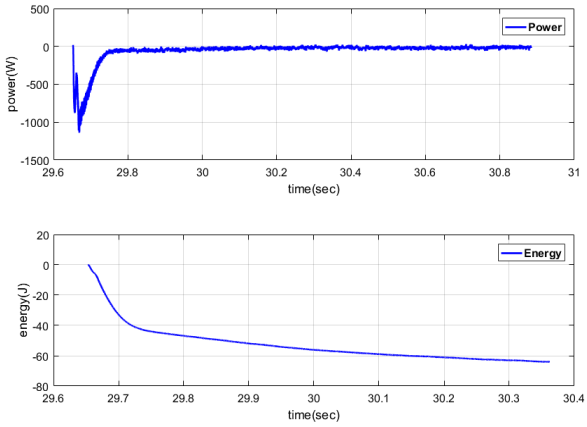


Figure 8: Electric power and energy recovered by the DC bus with MERSS. ω_0=2000 rpm, d=0.7

Table 4 summarizes the results from this experiment and displays the efficiency, as well as the energy harvested. It can be observed that the optimum duty cycle that yields maximum energy recovery is a function of the speed.

The performance of the MERSS is next compared to FOC by conducting the regenerative braking experiments with FOC under the same operating conditions. Table 5 shows a summary of the results. It can be observed that MERSS yields always a better efficiency than FOC.

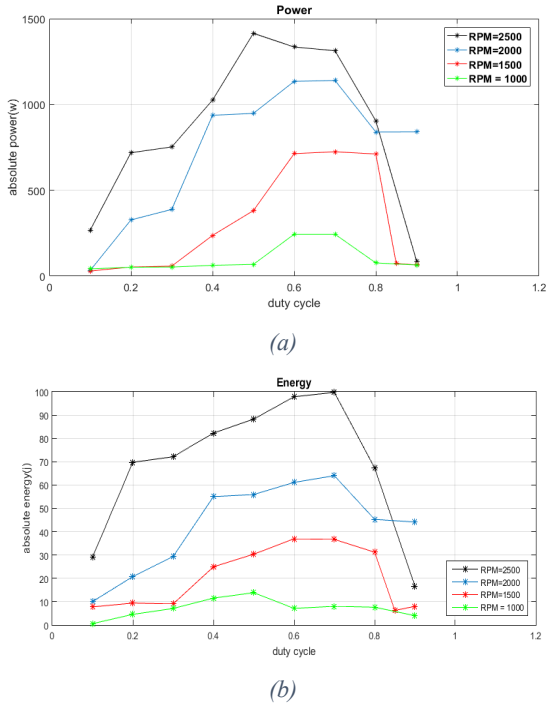

Figure 9: Electric power and energy recovered on the DC bus with MERSS

$$\eta = \frac{E_{cap}}{E_{mech}}. \tag{19}$$

Table 4: Maximum efficiency of braking at different motor speeds with MERSS.

ω_0 (rpm)	Duty Cycle	$E_{mech}(J)$	E_{cap} (J)	η (%)

	2000	-3.564	85.9	-7.683	69.09	64.00	92.64

5. Conclusion

This paper discusses regenerative braking in a PMSM drive system. A new maximum energy recovery switching scheme is developed and compared to FOC. Analysis is carried out on an experimental setup to confirm the effectiveness of regenerative braking under the new scheme. Experimental results show that the maximum current absorbed by the ultracapacitor does not exceed a set limit which is in turn dependent on the ultracapacitor's voltage, internal resistances of the system and the motor speed. The effect of varying the duty cycle is also studied to uncover the

highest efficiency duty cycle for optimum harvesting of regenerated energy.

ABSTRACT

Detect and tracking of moving weak targets is a complicated dynamic state estimation problem whose difficulty is increased in case of high clutter conditions or low signal to noise ratio (SNR). In this case, the track-before-detect filter (TBDF) that uses unthresholded measurements considers as an effective method for detecting and tracking a single target under low SNR conditions. In this paper, a particle filter based track-before-detect (PF-TBD) method is proposed to address the problem of detection and tracking with unthersholded data and a binary variable of the existence of the target for two motion models. Simulation results using image measurements based on TBD scenarios are also presented to demonstrate the capability of the proposed approach.

1. Introduction

The classical approach to target tracking is based on target measurements (position, range rate, and so forth) that are extracted by thresholding the output of a signal processing unit of a surveillance sensor [1].The primary role of thresholding is to reduce the data flow and thus simplify tracking. For a target of a certain signal-to-noise ratio (SNR), the choice of the detection threshold determines the probability of target detection and the density of false alarms. The false alarm rate, on the other hand, affects the complexity of the data association problem in the tracking system. In general, higher densities of false alarms require more sophisticated data association algorithms.

The undesirable effect of thresholding the sensor data, however, is that in restricting the data flow, it also throws away potentially useful information. For high SNR targets this loss of information is of little concern because one can achieve good probability of detection with a small false alarm rate. Recent developments of stealthy military aircraft and cruise missiles have emphasized the need to detect and track low SNR targets. For these dim (stealthy) targets, there is a considerable advantage in using the unthresholded data for simultaneous detection and track initiation [2], [3]. Depending on the type of sensor in use, the unthresholded data can be a sequence of range-Doppler maps, bearing-frequency distributions.

The concept of simultaneous detection and tracking using unthresholded data is known in literatures as track-before-detect (TBD) approach. Typically TBD is implemented as a batch algorithm using the Hough transform [4], dynamic programming [2] [3] or maximum likelihood estimation [5].

TBD algorithms based on the Hough transformation, dynamic programming or maximum likelihood methods are generally computationally intensive [6]. With recent advancement in Sequential Monte Carlo techniques, TBD algorithms implemented using PF are now computationally feasible [7] [8].

In this paper we also develop a recursive Bayesian TBD estimator; however, our formulation and implementation are based on the particle filter [7] [9]. The PF based TBD incorporates unthresholded data and a binary target existence variable into the target state estimation process. The presence and absence of target are explicitly modelled [10] [11]. This concept, allows us to calculate the probability of existence of the target directly from the filter.

The paper is organized as follows: section 2 the system dynamics and measurement model, are introduced for the TBD application. In section 3 formulates the TBD approach as a nonlinear filtering problem and describes the conceptual recursive Bayesian solution. The implementation of this solution using a particle filter is presented in section 4. In section 5 collects our simulations and results. Finally, we report our conclusions and direction for future research in section 6.

2. Formulation Problem

2.1. Dynamic Model

We assume that want to track a target moving in a 2-D plane with an unknown state vector s_k at time step k. We consider the state model given by:

$$s_{k+1} = Fs_k + v_k \quad (1)$$

Where F is the state transition matrix, assuming constant velocity motion and coordinate turn motion respectively, k is the discrete-time index, v_k is the process noise sequence, and s_k is the state vector defined as:

$$s_k = [x_k \quad \dot{x}_k \quad y_k \quad \dot{y}_k \quad I_k] \quad (2)$$

Here $(x_k, y_k), (\dot{x}_k, \dot{y}_k)$ and I_k denote the position, velocity, and the intensity of the target, respectively.

2.2. Transition Matrix

A target can be present or absent from the surveillance region at a discrete-time k. Target presence variable E_k is modelled by a two-state Markov chain, that is $E_k = \{0,1\}$. Here 0 denotes the event that a target is not present, while 1 denotes the opposite. Furthermore, we assume that transitional probabilities of target "birth" P_b and "death" P_d, defined as:

$$P_b \triangleq P\{E_k = 1 | E_{k-1} = 0\} \quad (3)$$

$$P_d \triangleq P\{E_k = 0 | E_{k-1} = 1\} \quad (4)$$

Are known, the other two transitional probabilities of this Markov chain, the probability of staying alive $1 - P_d$ and the probability of remaining absent $1 - P_b$ respectively, are given by:

$$1 - P_d \triangleq P\{E_k = 1 | E_{k-1} = 1\} \quad (5)$$

$$1 - P_b \triangleq P\{E_k = 0 | E_{k-1} = 0\} \quad (6)$$

The corresponding transition matrix for the Markov process is:

$$\Pi = \begin{bmatrix} 1 - P_b & P_b \\ P_d & 1 - P_d \end{bmatrix} \quad (7)$$

2.3. Sensor Model

The sensor provides a sequence of two-dimensional images (frames) of the surveillance region, each image consisting of $(n \times m)$ resolution cells (pixels). A resolution cell corresponds to a rectangular region of dimensions $\triangle_x \times \Delta_y$ so that the center of each cell (i, j) is defined to be at $(i\Delta_x \times j\Delta_y)$ for $i = 1, \dots n$ and $= 1, \dots m$.

At each resolution cell (i, j) the measured intensity is denoted as $z_k^{(i,j)}$ and modeled as:

$$z_k^{(i,j)} = \begin{cases} h_k^{(i,j)}(s_k) + \omega_k^{(i,j)} & if\ target\ present \\ \omega_k^{(i,j)} & if\ target\ absent \end{cases} \quad (8)$$

Where $h_k^{(i,j)}(s_k)$ is the target contribution to intensity level in the resolution cell (i, j) and $\omega_k^{(i,j)}$ is measurement noise in the resolution cell (i, j), assumed to be independent from pixel to pixel and from frame to frame. Thus for a point target of intensity I_k at position(x_k, y_k), the contribution to pixel(i, j) is approximated as:

$$h_k^{(i,j)}(s_k) \approx \frac{\Delta_x \Delta_y I_k}{2\pi\Sigma^2} \exp\left\{-\frac{(i\Delta_x - x_k)^2 + (j\Delta_y - y_k)^2}{2\Sigma^2}\right\} \quad (9)$$

Where Σ is the amount of blurring introduced by the sensor. The complete measurements recorded at time k a $n \times m$ matrix denoted as:

$$z_k = \left\{z_k^{(i,j)} : i = 1, \dots, n, j = 1, \dots, m\right\} \quad (10)$$

While the set of complete measurements collected up to time k is denoted as usual: $Z_k = \{z_i, i = 1, \dots k\}$.

3. Bayesian Solution to TBD Filtering

The formal recursive Bayesian solution can be presented as a two-step procedure, consisting of prediction and update.

3.1. Prediction

The predicted target state can be written in terms of the target state and existence at the previous time, giving

$$\begin{gathered} p(s_k, E_k = 1 | Z_{k-1}) = (1 - \\ P_d) \int p(s_k | s_{k-1}, E_k = 1, E_{k-1} = 1) \times \\ p(s_{k-1}, E_{k-1} = 1 | Z_{k-1}) ds_{k-1} + \\ P_b \int p_b(s_k) p(s_{k-1}, E_{k-1} = 0 | Z_{k-1}) ds_{k-1} \end{gathered} \quad (11)$$

The pdf $p_b(s_k)$ denotes the initial target density on its appearance.

3.2. Update

The update equation in the Bayesian framework is given by:

$$\begin{gathered} p(s_k, E_k = 1 | Z_k) = \\ \frac{p(z_k | s_k, E_k = 1) p(s_k, E_k = 1 | Z_{k-1})}{p(z_k | Z_{k-1})} \end{gathered} \quad (12)$$

Where prediction density $p(s_k, E_k = 1 | Z_{k-1})$ is given by (11) and $p(z_k | s_k, E_k)$ is the likelihood function given by:

$$\begin{gathered} p(z_k | s_k, E_k) = \\ \begin{cases} \prod_{i=1}^{n} \prod_{j=1}^{m} p_{S+N}\left(z_k^{(i,j)} \middle| s_k\right), & for \quad E_k = 1 \\ \prod_{i=1}^{n} \prod_{j=1}^{m} p_N\left(z_k^{(i,j)}\right), & for \quad E_k = 0 \end{cases} \end{gathered} \quad (13)$$

Here $p_N\left(z_k^{(i,j)}\right)$ is the probability density function of background noise in pixel (i, j), while $p_{S+N}\left(z_k^{(i,j)} \middle| s_k\right)$ is the likelihood of target signal plus noise in pixel (i, j),given that the target is in state s_k, This two probability density function can be further expressed as:

$$p_N\left(z_k^{(i,j)}\right) = \mathcal{N}\left(z_k^{(i,j)}, 0, \sigma^2\right) \quad (14)$$

$$p_{S+N}\left(z_k^{(i,j)}\middle|s_k\right)=\mathcal{N}\left(z_k^{(i,j)},h_k^{(i,j)},\sigma^2\right) \quad (15)$$

Since the target (if present) will affect only the pixels in the vicinity of its location (x_k,y_k), the expression for $p(z_k|s_k,E_k=1)$ can be approximated as follows:

$$p(z_k|s_k,E_k=1)\approx \prod_{i\in C_i(s_k)}\prod_{j\in C_j(s_k)} p_{S+N}\left(z_k^{(i,j)}\middle|s_k\right)\cdot \prod_{i\notin C_i(s_k)}\prod_{j\notin C_j(s_k)} p_N\left(z_k^{(i,j)}\right) \quad (16)$$

Where $C_i(s_k)$ and $C_j(s_k)$ are the sets of subscripts i and j, respectively, corresponding to pixels affected by the target.

4. A Particle Filter for Track Before Detect (PF-TBD)

The recursive Bayesian solution of the track problem described in the previous section can be implemented using a particle filter [7] [9] [12] [13]has some similarities to the MMPF [14]. In this case we introduce the augmented state vector to include the existence variable. $y_k=[\mathrm{s}_k^T \quad E_k]^T$. Let us denote a random measure that characterizes the posterior probability density function at $k-1$, namely $p(y_{k-1}|Z_{k-1})$, by $\{y_{k-1}^n,\omega_{k-1}^n\}_{n=1}^N$.As usual, N is the number of particles, while y_k^n consists of s_k^n and E_k^n.The pseudocode of a single cycle of the PF developed for the TBD problem is presented in Table 1. The next step is the prediction of particle target states; this is done, however, only for those particles that are characterized by $E_k^n=1$.For remaining particles (with $E_k^n=0$), the target state components are undefined. There are two possible cases here:

4.1. Newborne Particles

This group of predicted particles is characterized by the transition from $E_{k-1}^n=0$ to $E_k^n=1$.The target state particles are uniformly drawn at time step k based on some a priori information on the minimum and maximum possible values on the target state.

4.2. Existing Particles

This group of particles that continues to stay "alive", with $E_{k-1}^n=1$ to $E_k^n=1$.The state transition model in equation (1) is used to update the target state particles.

The importance weights are computed next. For this purpose we need to introduce the likelihood ratio in pixel (i,j) for a target in state s_k^n, defined as:

$$\ell\left(z_k^{(i,j)}\middle|s_k^n\right)\triangleq\frac{p_{S+N}\left(z_k^{(i,j)}\middle|\mathrm{s}_k^n\right)}{p_n\left(z_k^{(i,j)}\right)} \quad (17)$$

$$\ell\left(z_k^{(i,j)}\middle|s_k^n\right)=\exp\left\{-\frac{h_k^{(i,j)}\left(h_k^{(i,j)}-2z_k^{(i,j)}\right)}{2\sigma^2}\right\} \quad (18)$$

Where $h_k^{(i,j)}$ was defined in (9). Equation (18) follows from (14), (15), and (11). The importance weights (up normalizing constant) are now given by [7]:

$$\tilde{\omega}_k^n=\begin{cases}\prod_{i\in C_i(s_k^n)}\prod_{j\in C_j(s_k^n)}\ell\left(z_k^{(i,j)}\middle|\mathrm{s}_k^n\right) & if \quad E_k^n=1\\ 1 & if \quad E_k^n=0\end{cases} \quad (19)$$

$[\{y_k^n\}_{n=1}^N]$ =TBD-PF$\left[\{y_{k-1}^n\}_{i=1}^N,z_k\right]$

- Target existence transitions using the Regime Transition Algorithm given in [6]

$[\{E_k^n\}_{n=1}^N]$ =RT$[\{E_{k-1}^n\}_{n=1}^N,\Pi]$

- FOR $i=1:N$
  - IF a newborn particle ($E_{k-1}^n=0$ and $E_k^n=1$) Draw $s_k^n\sim q_b(s_k|z_k)$
  - IF an existing particle ($E_{k-1}^n=1$ and $E_k^n=1$) Draw $s_k^n\sim q(s_k|s_{k-1}^n,z_k)$
  - Evaluate importance weight using (13)
- END FOR
- Calculate total weight: t =SUM$[\{\tilde{\omega}_k^n\}_{n=1}^N]$
- FOR $n=1:N$
  - Normalize: $\omega_k^n=t^{-1}\tilde{\omega}_k^n$
- END FOR
- Resample using systematic resampling algorithm given in [6]

$[\{y_k^n,-,-\}_{n=1}^N]$ =RESAMPLE$[\{y_k^n,\omega_k^n\}_{n=1}^N]$

The PF for track-before-detect performs target detection using the estimate of the posterior probability of target existence. This estimate is computed as:

$$\hat{P}_k=\frac{\sum_{n=1}^N E_k^n}{N} \quad (20)$$

And satisfies $0<\hat{P}_k<1$. Target presence is declared if $\hat{P}_k$ is above a certain threshold value. This declaration can then trigger the initialization of a track based on the estimated target state

$$\hat{s}_{k/k}=\frac{\sum_{n=1}^N s_k^n\cdot E_k^n}{\sum_{n=1}^N E_k^n} \quad (21)$$

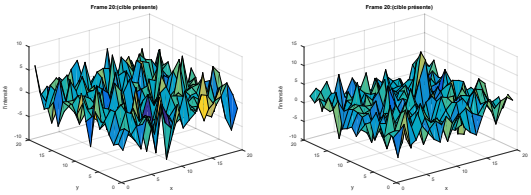
5. Simulation and Results

In the simulation we used two scenarios for target motion and random walk model is adopted for target intensity.

5.1. Scenario1

The first model is a nearly constant velocity model is used. The dynamic model [15] for the target can be described by (1).

Where $F=diag[F_1,F_1]$,$Q=diag[Q_1,Q_1,q_2T]$



and $F_1=\begin{bmatrix}1 & T\\ 0 & 1\end{bmatrix}$, $Q_1=q_1\cdot\begin{bmatrix}T^3/3 & T^2/2\\ T^2/2 & T\end{bmatrix}$

Where q_1 and q_2 denote the level of process noise in target motion and intensity, respectively. A sequence of 30 frames of data has been generated with the following parameters:

$\Delta_x=\Delta_y=1, n=m=20, T=1s, \sigma=3, \Sigma=0.7$. The target is absent from frame 1 to frame 5 to be introduced in frame 6 with the initial intensity I_0 .The initial state is $[4.2 \quad 0.45 \quad 7.2 \quad 0.25 \quad I_0]$ [6] [16] [17].

The simulations are conducted under an initial intensity $I_0 = 9, 13$ and 25, which corresponds to an SNR of 3.18,6.71, and 12 dB, respectively, according to the calculation equation $SNR = 10log\left[\frac{I\Delta_x\Delta_y/2\pi\Sigma^2}{\sigma}\right]^2$. The target exists until frame 24 and is again absent in frames 25, 26,…, 30.

Figure 1 (a) and (b) show the measurement frame at time step 20 for 6.71dB and 12 dB peak respectively.

(a) (b)

Fig. 1. Measurements Frame (20): (a) for 6.71 dB Peak SNR, (b) for 12 dB Peak SNR for CV model.

The particle filter parameters are selected as follows: transitional probabilities $P_b = P_d = 0.05$;initial existence probability $\mu_1 = 0.05; v_{\min} = -1\ unit/s$; $v_{\max} = 1\ unit/s$; initial intensity range from $I_{min} = I_0 - 5$ to $I_{max} = I_0 + 5$; $p = 2$ and number of particles $N = 2000$.

In figure (2) the probability of presence is shown for a SNR of 6.71 dB. Existence probability remains very stable and above 0.97 until frame 25.Then it drop sharply in frame 26, when the target is disappear.

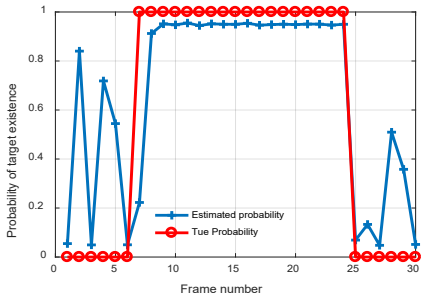


Fig. 2. True and Estimated Target Existence Probability for SNR=6.71 dB

Figure (3) displays the true target path against the track, produced by the filter. Note how the target trajectory deviates slightly from the straight line due to process noise. The PF-TBD tracks the target with a small positional error.

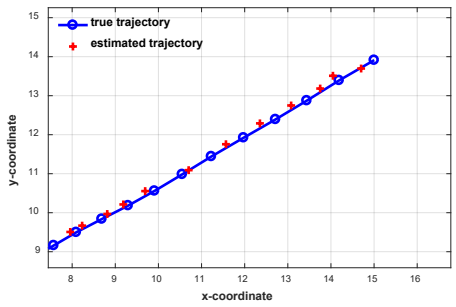

Fig. 3. True and Estimated Target Trajectory for SNR=6.71 dB

Figure (4) shows the position RMSE for three different peak SNR conditions (3.18 dB,6.71 dB, 12 dB). The position error is lower in 6.71 dB than 3.18 dB. As it can be seen, the PF-TBD was able to closely track the target even under low SNR.

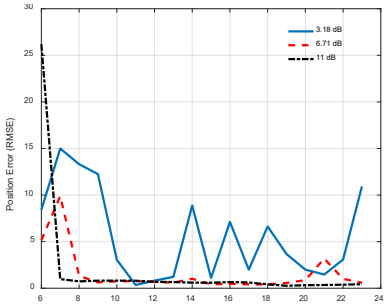

Fig. 4. Position RMSE for the PF-TBD for differnet peak SNR

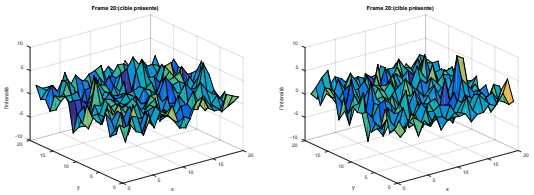
5.2. Scenario2



The second model is a Coordinate turn model is used [15]. The dynamic model for the target can be described by (1).

Where:

$$F = \begin{bmatrix} 1 & F_1 & 0 & F_2 & 0 \\ 0 & F_3 & 0 & -F_4 & 0 \\ 0 & -F_2 & 1 & F_1 & 0 \\ 0 & F_4 & 0 & F_3 & 0 \\ 0 & 0 & 0 & 0 & 1 \end{bmatrix}, Q = \begin{bmatrix} Q_1 & Q_2 & 0 & Q_3 & 0 \\ Q_2 & Q_4 & -Q_3 & 0 & 0 \\ 0 & -Q_3 & Q_1 & Q_2 & 0 \\ Q_3 & 0 & Q_2 & Q_4 & 0 \\ 0 & 0 & 0 & 0 & Q_5 \end{bmatrix}$$

And $F_1 = \frac{sin(\Psi T)}{\Psi}$, $F_2 = \frac{(-cos(\Psi T)+1)}{\Psi}$, $F_3 = \cos(\Psi T)$, $F_4 = \sin(\Psi T)$, $Q_1 = \frac{2(\Psi T - sin(\Psi T))q_1}{\Psi^3}$, $Q_2 = \frac{(1-cos(\Psi T)q_1)}{\Psi^2}$ $Q_3 = \frac{(\Psi T - sin(\Psi T)q_1)}{\Psi^2}$, $Q_4 = q_1 T$, $Q_5 = q_2 T$, $\Psi = 6$ is a constant angular rate.

Figure 5 (a) and (b) show the measurement frame at time step 20 for 6.71dB and 12 dB peak respectively.

(a) (b)

Fig. 5. Measurements Frame (20): (a) for 6.71dB Peak SNR, (b) for 12dB Peak SNR for CT model.

In figure (6) the probability of presence is shown for a SNR of 6.71 dB. Existence probability probability is still increase above frame 7 until frame 17 and still stable until frame 25. Therefore, it drops rapidly following the target disappears from the monitoring region after frame 25.

Figure (7) shows the true and estimated target trajectories for coordinate turn model, the estimated trajectory is very close to the true trajectory.

Figure (8) shows the position RMSE for three different peak SNR conditions (3.18 dB,6.71 dB, 12 dB). The position error is lower in 6.71 dB than 3.18 dB. As it can be seen, the PF-TBD was able to closely track the target even under low SNR.

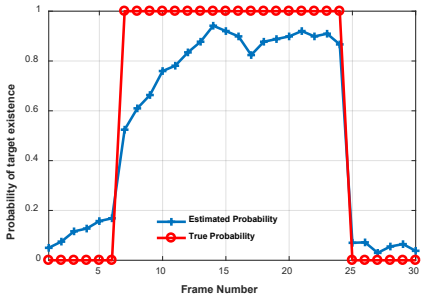


Fig. 6. True and Estimated Target Trajectory for SNR=6.71 dB

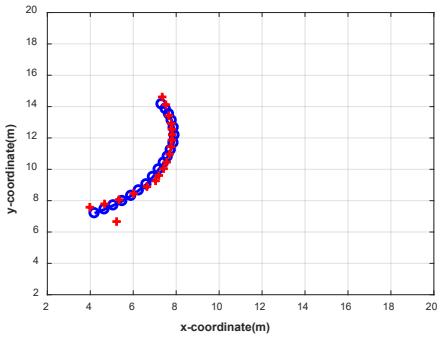

Fig. 7. True and Estimated Target CT Trajectory for SNR=6.71

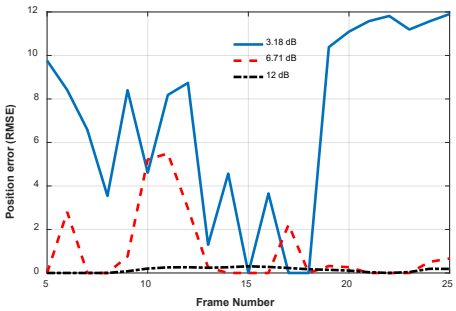

Fig. 8. Position RMSE for the PF-TBD for differnet peak SNR

6. Conclusion

In this paper, to manipulate moving weak targets, the PF-TBD algorithm is proposed for two dynamics models (CV and CT). The major advantage of the track-before-detect approach based on target existence variable and as a result, the developed particle filter can detect and track low SNR maneuvering target. The results from the simulation show that the PF-TBD algorithm has a successfully detection and tracking performance, both for constant velocity and coordinate turn models of moving targets, under severe conditions such as high noise or low SNR. Therefore, further work will mainly concentrate on how to detect and track multiple targets in high noise and high clutter.

ABSTRACT

In this work, a representative combinational circuit is visualized in various ways. It is abstracted (concretized) from transistor level to gate level and a structure-preserving transition is carried out into a signal flow graph. For creating a signal flow plan it is necessary to swap the nodes and the edges in the signal flow graph. After having executed this action the result is a signal flow plan. A value table exhibits the coding of the whole circuit. Then the so called module view is used to get the familiar compact and directed display and neighborhood relations are repeated once more, the resolution method is used. It is observed that undefined results can occur in digital circuits. But, these must be avoided in safety critical circuits. These events have to be secured in practice by costly and expensive verification and testing. In order to deal with the problem now, the structure-preserving modeling has to be understood, since this is the only way to achieve a one-purpose, qualitative and cost effective search for errors.

1 Introduction

This paper is an extension of work orginally presented at the 20th IEEE International Symposium on DDECS 2017, Dresden, Germany [1].

In order to ensure the functional safety of circuits or systems which are regarded as critical to safety, the mutual convert of models and functions is of great importance. The inconsistency problem is omnipresent; therefore, the essential claim for conformity with the formal derived function and the function derived from the real structure has a present role [2]. The directed mode of operation of a system should be represented by a circuit or switching table, also called a table of values, one-to-one in the sense that the encoding can be reproduced. In safety-critical circuits it is necessary not defined results, which often occur in complex circuits, to avoid or to monitor. The transferability of circuits into additional and other display possibilities is therefore a necessary property to ensure the functional safety of safety-critical circuits. In this work, a representative combinational circuit is visualized in various ways. In all these representations, however, it should be noted that the "structure-preserving modeling and transfer" is maintained. This means that the formally derived function must consistently match the function derived from the respective representation type. Both functions must in no case have inconsistencies, since only the fault-free function is included in the circuit. Functional safety can be guaranteed by the condition of the *structure-based modeling and transfer.*
To present the application we use an electrical circuit as a use case. And visualize it in various ways like Gate Level (GL), Signal Flow Graph (SFG), Signal Flow Plan (SFP), Module View (MV), Resolution Method (RM) and KV diagram. During creation of different display possibilities, we explain the rules of the structure-based modeling and transfer. In addition, the mathematical axioms, which are based on Propositional Logic (AA), are declared. The advantage of the method is that each type of representation (respectively presentation) has a depth of accuracy, clarity and compactness. The transferability of circuits into other possibilities of directed representation is a necessary property to ensure the functional safety of safety critical circuits.

Organization of the paper: First, the theoretical foundations are briefly explained in Chapter 2. They are regarded as basic knowledge in order to understand this work. Subsequently, the implementation is described in detail by an example in Chapter 3 and visualized by sketches and mod-

https://dx.doi.org/10.25046/aj030158

els. In the end, the results and the core outline of the work are summarized again and an outlook is given.

2 Theoretical Foundations

2.1 Category level (CL)

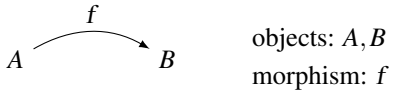

Figure 1: Morphism f from A to B

Morphisms are concretized on category level. A morphism is a directed association between two objects being associative and identitive. In Fig. 1, the morphism f acts on object A and is substituted (=) by object B.

2.2 Value table (VT)

The table of values, also known as truth table or switching sequence table, is a tabular list of the truth value course of a logical statement. In this table, the assignments of the inputs are linked together and the states at the outputs are shown binary. Value Tables (VT) are used for logic operations such as AND, OR, NAND and NOR gates, but also for flip-flops or complex circuits [3], [4]. A value table thus serves to represent the value of a composite statement as a function of the truth values of its partial statements. Tab. 1 shows a truth table for a NOT (left), AND2 (middle) and OR2 (right) function. The input for a NOT function is A and for AND2 and NOR2 the inputs are A and B.

A	NOT A	A	B	A AND B	A	B	A OR B
0	1	0	0	0	0	0	0
1	0	0	1	0	0	1	1
		1	0	0	1	0	1
		1	1	1	1	1	1

Table 1: Value table for NOT (left), AND2 (middle) and OR2 (right) function in (0,1)

2.3 Combinational circuits (CC)

A	B	A NOR B
0	0	1
0	1	0
1	0	0
1	1	0

Table 2: Value table for NOR2 circuit

Under a combinational circuit is a circuit that is realized with simple basic gates such as AND, OR and inverters to understand. It realizes a one-to-one mapping, a function. The outputs of this logic are dependent on the inputs, which means there is no feedback from the outputs to the inputs. The output variable is thus only a function of the input variables [4]. Tab. 2 shows the value table for NOR2 circuit. NOR2 represents a combinational circuit, because the circuit does not include feedback.

2.3.1 Abstraction of a circuit

Under an abstraction of a circuit is a kind of "simplified" representation to understand. A complex, combinational circuit is shown in a different way, in order to make it easier to understand. However, in the various representations, the core message of the output circuit must not be changed. So the function of the circuit must not be changed when transferring it to another representation. The circuit must deliver the same function, no matter in which visual presentation it is shown. For example, an abstraction of a circuit is the transfer of a circuit from the transistor level to the gate level. In addition, a circuit can be presented in its module view (MV) (see section 2.10), which is an isomorphism to the signal flow plan of the circuit. The aim of an abstraction of a circuit is the simplified or clearer visual design or presentation.

2.3.2 Structural changeover and modeling

In order to be able to carry out a structure-faithful modeling, it is to be known that two parallel connected transistors are combined in propositional logic as follows. Fig. 2 shows two transistors connected in parallel. V_{DD} is the operating voltage.
It is a complex gate with two inputs $(\bar{A}, \bar{B})$ and one output (C) between which the logical link "OR" exists. This OR2 outputs "1" at the output when one of the inputs are assigned a "0". This means that if one of the two inputs is assigned a "0", the output creates a "1". The two transistors are connected in parallel, they must be concatenated (addition in field algebra). Furthermore the operating voltage V_{DD} has to be considered. It runs in series with each of the two transistors, it muss be catenated (order, multiplication in field algebra) with two transistors.

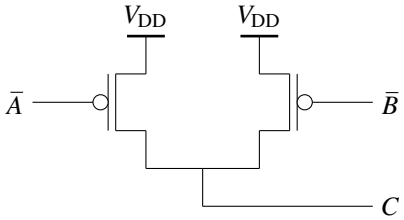

Figure 2: Example of parallel connected transistors

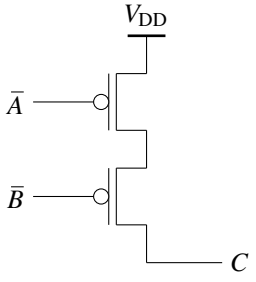

Figure 3: Example of serial connected transistors

If C in Fig. 2 is to be expressed as a function (contrary to logic, only true values can be processed in propositional logic (see section 2.9)), then this is:

$$C = V_{\mathrm{DD}} \cdot (\bar{A} + \bar{B}) \tag{1}$$

In Fig. 3 two transistors are connected in series. It is a complex gate with two inputs $(\bar{A}, \bar{B})$ and one output (C) between which the logical link "AND" exists. This AND2 outputs "1" at the output when both inputs are assigned a "0". This means that if both of the two inputs is assigned a "0", the output creates a "1". Furthermore the operating voltage V_{DD} has to be considered. It runs in series with each of the two transistors, it muss be catenated with two transistors. C can be expressed in propositional logic as follows:

$$C = V_{\mathrm{DD}} \cdot (\bar{A} \cdot \bar{B}) \tag{2}$$

Structure-faithful modeling unites function and structure one-by-one in the sense of a monomorphism injective - that is, the structure has at most one solution (this is the function) - and of a epimorphism surjective - that is, the function has at least one solution (that is the structure). Such a mapping enables a one-to-one (local-bijective) and understandable description of a generating system. During transferring into various presentation possibilities the structure-faithful modeling has a significant role. It is extraordinary important that the formally derived (modeled) function coincide with the function generated by the real structure. Consequently the function has to correspond to reality and shall not exhibit any inconsistencies. Only in this way the functionality of a circuit can be ensured. Structure-faithful therefore means that the relation to reality must never be lost during modeling. Shortly spoken, each pin of the model at gate level (GL) must show up in the real world at transistor level (TL). But, pins have to be correctly labelled in reality at transistor level (TL). This is mandatory.

During the transfer, it is also important that the function generated from the real structure consistently matches the function derived from the signal flow graph or any other type of presentation. Only in this way the functionality of the generating circuit can be ensured. In addition, there is a structure-based transfer only in the absence of inconsistencies. A transfer of the signal flow graph or of the circuit into a value table must also be structure-faithful. Thus the function derived from the evaluation table must correspond to the same function derived from the signal flow graph or the generated circuit. Shortly spoken, each undefined pin of a given reality or not proper assigned signal of a given model has to be shifted to undefined. We consistently use the symbol "$*$".

2.4 RS Buffer

In complex circuits, many structures exist that can create undefined results. These undefined results must not occur in safety-critical circuits, since otherwise the desired function of the circuit cannot be guaranteed. For this reason, the RS buffer structure is established [2]. It can intercept undefined cases in combination with a dual-rail approach. Thus, it is possible to stabilize a complex circuit in its function without glitch. These stabilized states do not produce unpredictable events and can therefore be processed by the circuit without causing errors. Fig. 4 shows the circuit symbol and Fig. 5 shows the circuitry of the RS buffer. The value at the node X in the circuit corresponds to the value at the pin $\bar{Y}$, because of the inverter. Thus, the X is neglected for the sake of clarity in the VT of Tab. 3. On closer examination of Tab. 3, it is noticeable that the RS buffer triggers a switching process only during assignments $(S, \bar{R}) = (1,0)$ and $(S, \bar{R}) = (0,1)$. The old state is retained for assignments $(S, \bar{R}) = (1,1)$ and $(S, \bar{R}) = (0,0)$. The function for the output Y is therefore $Y = R(S \vee Y) \vee S(R \vee Y) = YR \vee YS \vee SR$.

S	$\bar{R}$	Y
0	0	Y
0	1	0
1	0	1
1	1	Y

Table 3: Value table of the RS buffer [2]

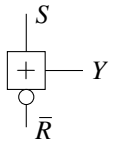

Figure 4: Circuit symbol of the RS buffer

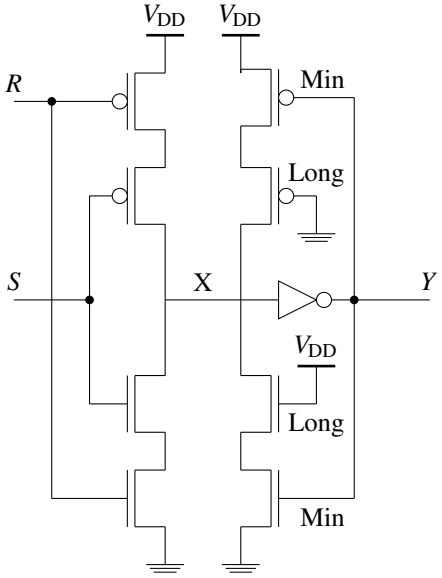

Figure 5: Circuit of the RS buffer [2]

2.5 Signal flow graph (SFG)

The signal flow graph (SFG) is a vividly method to present the internal structure of a system or the interaction of several systems. This presentation allows a better understanding of the function as well as the interrelations of one or more systems. In addition, the signal flow graph is the appropriate tool for abstracting functions or connections to one level above category level (associativity and not identity). The signal flow graph is a directed and weighted graph whose nodes represent objects (sets) and its edges morphisms (functions). The edges of this graph can be understood in a dual view (SFP) as small processing units which process incoming signals (edges) in a particular form and then send the result to all outgoing edges (signals). Signal

flow graphs are formally defined graphs [5]-[9].

2.6 Signal flow plan (SFP)

The signal flow plan (SFP) has a special significance in control engineering and, with the representation method, is based on a block diagram and adds to a further loan of the relationships within a system. A signal flow plan is used to identify the complexity of a system. This contains unidirectional blocks, also called nodes, which transmit incoming signals as small processing units into outgoing signals. In the signal flow graph these are represented by edges. From an SFP, the transfer function of a system can be derived. The signals are redirected to edges, unlike the signal flow graph. In the signal flow graph, they are represented by nodes. Edges in a signal flow plan are also directed connections between two nodes. They illustrate the effect of a signal by its weighting. Furthermore, it is possible to transfer a signal flow graph into a signal flow plan by transferring nodes into edges and edges into nodes [5], [7], [9]. Fig. 6 shows a simple example of a signal flow plan derived from a signal flow graph. The input signals x_0 and x_1 adds up to an output signal y.

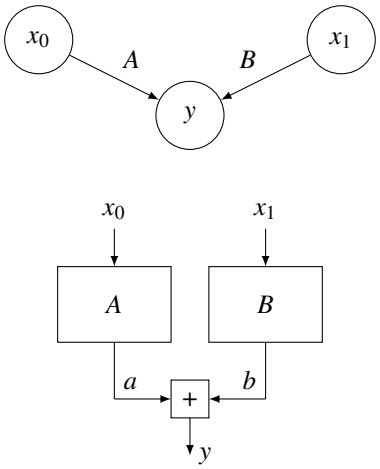

Figure 6: From a signal flow graph (above) to a signal flow plan (below)

2.7 Boolean algebra (BA)

The switching algebra (boolean algebra) is based on decisions and comparisons, so it can explain and visualize logical links very well. Successful results are represented by a "1", unsuccessful results by a "0". These two symbols are complementary to one another. At any time, each pin must be occupied, because only then the system can be a total system and can be calculated by the switching algebra. The switching algebra is not sufficient for a detailed representation of a circuit. However, it is suitable for the functional description without restrictions to the general [10].

2.8 Positive logic (PL)

In the positive logic the symbol "1" stands for a successful event. Unsuccessful events are called undefined. Positive logic is an event that occurs just as it is expected. This means that if a negative event is expected and it occurs, this event is considered successful. This also applies analogously to a positively expected event. If a positive event is expected and it occurs, then this event is also successful. In the positive logic, therefore, only the "1" exists as a value [11]. Here, we need a "0", too. Therefore, the "0" is also a "1" but only a part (child) of the "1".

2.9 Propositional logic (AA)

The propositional logic comes from the formal logic and can be continued into the switching algebra without restrictions to the general. This "Aussagenlogischer Ausdruck (AA)" describes the relationship between statements. Statements can be seen partially in the propositional logic. This means that there should be only one unary statement. The symbols are true (w) and not false ($\bar{\text{f}}$). The following example is intended to illustrate the propositional logic: The statement $Y = (A \wedge \bar{B}) \vee C$ contains two statements and is nevertheless unary, regardless whether is equal to a positive literal or a negative literal. The following statement contains only one statement and is also unary $\bar{Y} = (A \wedge B)$. Thus, in AA a statement is always true, only its complemented content can be interpreted as "false". The logical sign for a true statement is "w " or "$\bar{f}$" [11], [12].

2.10 Module view (MV)

Through a model representation, a real system can be displayed simpler and clearer. The natural section of reality can be simplified by model visualization, and the model representation can also serve as a reference model for further development of a system. In order to represent a real circuit with real electrical components as a model, the structure-faithful transfer is of great importance. In addition, it is necessary that in safety-critical circuits, the modeling is performed structurally, because only then the structure-related functional safety of the circuit is guaranteed. This means that the formally derived and modeled function with which the function created by the real structure must be absolutely identical. Fig. 7 shows a simple example of the asymmetric and irreflexive module view. Due to the directed representation as a module view, a clear visualization is achieved. You can see the input (input vector) X, the output F and the programming vectors Z and Y. By presenting it as a module view, the complexity of the representation can be completely directed.

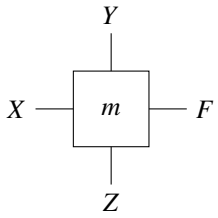

Figure 7: Example of a module view

Only the inputs, outputs and programming vectors are seen. The function, how exactly the interaction of these variables ever is, is not described and explained. The function (transitive closure) is represented by m (model) [5].

2.11 Resolution method (RM)

The resolution method (RM) is a method to check the truth value. It is primarily about being able to prove the satisfiability or unfulfillability. In order to provide this proof, a clause set is extended by new clauses, called resolvents, until an empty clause is generated. If this succeeds, the initial quantity is unsatisfiable. Here, the clauses are conjunctions. A set of clauses, therefore, is a disjunction. It follows that if an empty clause can generated, the initial set is tautological. Resolvent of clauses C_1 and C_2 (according to literal l) is given in [13]. An example of the resolution method is shown in Fig. 8. Here you can see that the clause set can be non-tautologically fulfilled, since in the end no empty clause can be generated. Will be a clause set with the resolvent resulting from their clauses, this results in a logically equivalent set of clauses. This can be reunited with its resolvents without affecting satisfiability, and so on. If finally the empty clause can be formed, a tautological set is proven. In the other case, for example if the last clause is not empty, this is the proof of the satisfiability of the disjunvtive clauses.

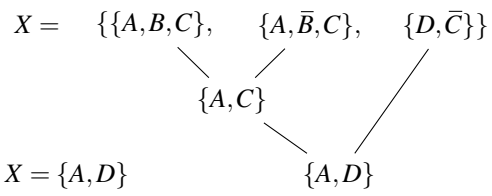

Figure 8: Example of a resolution

The resolution method obeys the following neighborhood relations:

- The resolver $\{y,z\}$ (largest common cover) can be generated from the clauses $\{x,y\}$ and $\{\bar{x},y,z\}$.
- The resolver $\{\}$ can be generated from the clauses $\{x\}$ and $\{\bar{x}\}$.

Definition: Let C_1 be a clause containing the literal l and let C_2 be a clause containing the literal $\bar{l}$. Then the clause is called:

$$C = (C_1 \backslash \{l\}) \cup (C_2 \backslash \{\bar{l}\}) \tag{3}$$

2.12 KV diagram

The Karnaugh-Veitch diagram (KV diagram) is used for the clear presentation and simplification of Boolean functions into a minimal expression. A KV diagram can be used to transform any disjunctive normal form (DNF) into a minimal disjunctive logical expression. The diagram is labeled with the variables at the edges. Each variable occurs in negated form (negative literal) and not negated form (positive literal). The assignment is arbitrary. However, it should be noted that horizontally and vertically adjacent fields may only differ in exactly one variable [4].

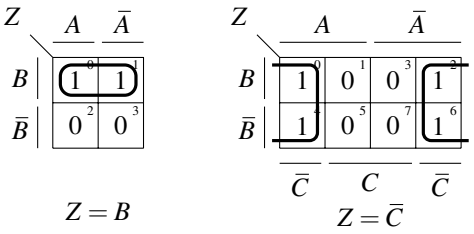

Figure 9: KV diagram examples

Minterm Method:

- Try to group as many horizontally and vertically adjacent fields as possible that contain a "1" (1, 2, 4, 8, 16, 32, ...).
- A block may continue over the right / left or bottom of the chart.
- From these identified blocks so many are to be selected that all "1" fields are covered (Fig. 9).
- Now the conjunct terms are formed.
- These conjunctive terms are linked with an OR and a DNF results.

Maxterm method: This method differs from the Minterm method in the following points:

- Instead of ones, zeros are combined into blocks.
- Subsequently, disjunction terms are formed.
- These disjunction terms are AND, resulting in a conjunctive normal form (CNF).

3 Implementation

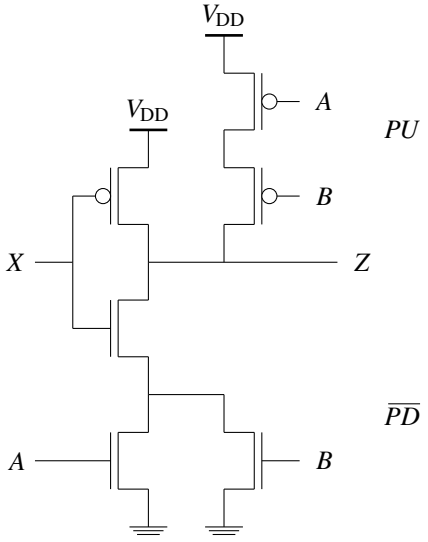

Figure 10: Simple electrical circuit at transistor level (TL)

In this Chapter, an electrical circuit is considered at the transistor level in Fig. 10. Afterwards, the circuit is transfered from the transistor level into the gate level in a structured manner. It should be noted that the analog circuit, that

is, the circuit at transistor level, is described at the gate level in propositional logic. Subsequently, the circuit is converted into a signal flow graph and signal flow plan at the gate level. Various possibilities for the representation of the output circuit, then such as the evaluation table, the module view or the resolves are presented. With all these possibilities of representation, it should be noted that the respective derived function must not have any inconsistencies that means, the formally derived function must agree with a function generated from a real structure (TL). Fig. 10 shows the circuit at the transistor level, this circuitry is a combinational circuit because there are no feedback lines, which is to be transferred to the gate level. It is a complex gate with three inputs and an output.

3.1 Concretization to gate level

The analysis of a circuit at the transistor level is more detailed and more complex than viewing at the gate level, since the representation in gates is only a "model" which allows a simplified and clear view of the circuitry. The transfer of a structure at the transistor level into a structure at the gate level is therefore a concretization (often called abstraction) and serves to increase the clarity and simplify the understanding of the structure. From propositional logic and category point of view, however, transistor level (parent) is the abstraction of the gate level (child). This is important to keep in mind.

In the first step is now the electrical circuit transferred to the gate level. First, the pull-up (PU) and the pull-down $(\overline{PD})$ are viewed separately from each other. When the transistors of the pull-up or pull-down are connected in parallel, they must be concatenated. On the other hand, when the transistors are connected in series, they must be catenated. Furthermore the operating voltage V_{DD} has to be considered in the pull-up. This runs in series with each of the two lines of the pull-up. And the mass potential runs serially to both line of the pull-down.
The transistors in the *PU* are switched with a "0" low-active input and the transistors in the $\overline{PD}$ are switched with a "1" high-active input. *PU* and $\overline{PD}$ are connected by a composition (concatenation). With the composition it is meant that different things are substituted but do preserve their directed manner (the morphisms are preserved). This composition ensures the RS buffer in Fig. 5. In Fig. 5 after the pull-down, a switch "¬" is installed in order to meet the propositional composition (we use switch to replace the two levels "0" and "1", we can switch from one level to another). The function of the RS buffer has already been explained in the basic chapter. The operating voltage is usually designated with V_{DD}, the reference point is the mass with the low-active input $\overline{\mathrm{GND}}$ (since the gate level has been in AA, the ground is written as $\overline{\mathrm{GND}}$). Please keep in mind that pins have to be coded correctly. You have to choose the correct literals, either positive literals or negative literals.

In the second step subcircuits are described as concrete mathematical functions in the propositional domain (in the AA domain). It should also be noted that each partial circuit is basically at least disjunct, in this case even complementary, this mean a pull-up (PU) and a pull-down $(\overline{PD})$. Pull-up means that the output is pulled up to the operating voltage V_{DD}. This part of the circuit is low-active since a logical "0" must be present at the primary input in order to trigger the switching process. The $\overline{PD}$ draws the output to the mass potential. It is referred to as high-active, since a logical "1" must be present at the primary input, so that a switching process is triggered. For example, Tab. 3 shows the functionality of the RS buffer. The operation is assumed to be already known. Thus, the circuit consisting of a *PU* and a $\overline{PD}$ has the following equation:

$$Y = PU + \neg\overline{PD} = S + \neg\bar{R} \tag{4}$$

Eq. 4 will play an important role in the later course of the work. After all steps, as explained above, have been carried out, a structure-preserving model at the gate level results. Important is, that during all steps inconsistencies must not occur. In Fig. 11, the electrical circuit is now displayed in propositional logic at gate level. As described above, the *PU* and $\overline{PD}$ are summarized using the composition. In addition, a switch is built between $\overline{PD}$ and the composition. Its task is also to highlight the low-active input of the RS buffer. It is important that the stars here in the continuation only serve as a "monitor" for checking. If the circuit is designed correctly, each star $(*)$ can only supply a "0".

In the third step, the node *Z* (pin *Z*) is expressed in a function: The *PU* and $\overline{PD}$ is connected to the composition "+". The operating voltage V_{DD} flows in series with the inputs in the *PU*. The mass runs serially to all inputs in the $\overline{PD}$. The switch between composition and pull-down switches the logic value of the last part to a negative literal - the substitute of its complement in Eq. 4. In summary, it should be emphasized that viewing at the gate level (in propositional logic) allows a directed and more simplified view, which makes the derivation of the function at node *Z* easier.
The node *X* is treated as another input. Thus, it must be noted that node *X* affects the *PU* and the $\overline{PD}$. Furthermore, the *PU* and the $\overline{PD}$ are linked by a composition. This composition works like an RS buffer. The inputs are then linked to the logical operators. Not to forget is the switch, which is between $\overline{PD}$ and the composition. This "switches" the part of the function belonging to the $\overline{PD}$. The operating voltage V_{DD} and the mass run serial to the inputs.
The stars $(*)$ also serve (Fig. 11) for to check the correctness of the circuit. For example, each individual star can only assume the value "0" in order to ensure that the circuit is correctness. Fig. 11 shows the structure-faithful modeling of the circuit at gate level (in AA). After the circuit is transferred to gate level, the node *Z* can be expressed as a mathematical function in Eq. 5.

$$Z = V_{\mathrm{DD}} \cdot (\overline{X} + \bar{A} \cdot \bar{B}) + \neg(\overline{\mathrm{GND}} \cdot (A + B) \cdot X) \tag{5}$$

The circuit at gate level in Fig. 11 shows the concreteness of the output circuit (Fig. 10). As described above, it was transferred from the transistor level to the gate level in a structure-preserving manner. The functions derived at the transistor level and the functions derived at the gate level must be identical with respect to their partial order (directed manner), this means the function of the circuit must

not be changed by the transfer. Only then is the transfer a structure-faithful one.

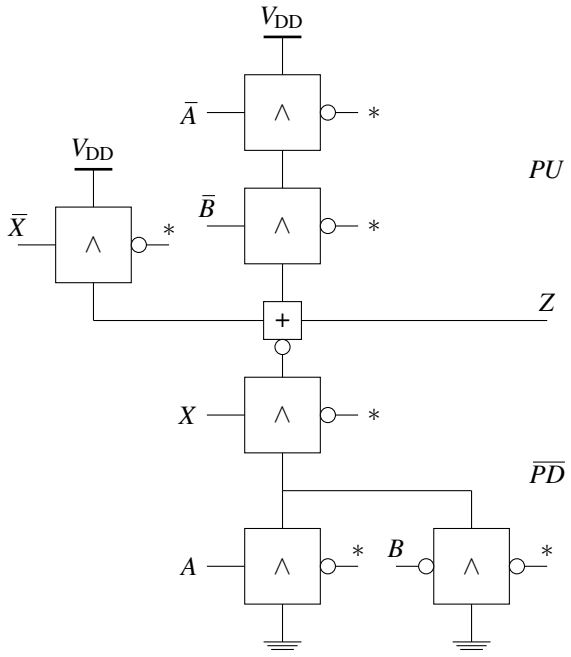

Figure 11: Simple electrical circuit at gate level (in AA)

The gate level can be viewed as a model view. It serves to increase clarity as well as contribute to an understanding of the circuit.

3.2 Transfer to a signal flow graph (SFG)

With the basic knowledge from Chapter 2, the function Z is now transferred step by step into an SFG at Fig. 12.

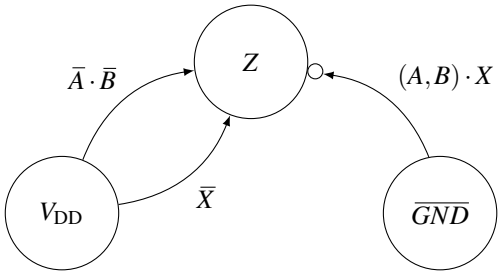

Figure 12: SFG of electrical circuit

For the creation of SFG, it is determined which signals are visualized in a node and which are represented by an edge. The operating voltage V_{DD} and the ground $\overline{GND}$ are visualized by a node, while the inputs, also the X, are used as edge weights for the processing of the signals. The operating voltage is catenated by the inputs $\overline{A}$, $\overline{B}$ and $\overline{X}$. Please remember that we are in propositional logic. The negative literal $\overline{A}$ is not the complement of A but can be substituted by the complement of A, $\overline{A} = \bar{A}$. BA is constituted by $\overline{A} = \neg A$. Thus, V_{DD} represents a node while the inputs with the switch reside on the edges. The third edge has as an edge weight the catenation of the X with the two inputs A and B. The mass is represented as a node. The switch (bubble at node Z) must be considered as shown in Fig. 12. These three edges end at to the node Z. The switch, which must be installed here, is not to be forgotten. These two edges concatenate to the node X. When looking at the Z function it is noticeable that the node X has a major influence on this function:

It is important that the function Z generated from the real structure is consistent (in the direction) with the functions derived at the gate level and the signal flow graph. The SFG allows a further comprehensible and simple visual consideration of the problem. The system is represented simply and visually by weighted, directed graphs. In dual sense (SFP), blocks are small processing units that process incoming signals (that are edges) in a certain form and send the result to all outgoing edges (that are signals). In Fig. 12, the comma "," means in parallel. We use the comma "," to write different things next to each other but preserving the directed manner. Since the directions have to be preserved in the structure faithful modeling and transfer, we announce two edges A and B next to each other. From Fig. 12 follows equation 6:

$$Z = V_{DD} \cdot (\overline{X} + \bar{A} \cdot \bar{B}) + \neg(\overline{GND} \cdot (A + B) \cdot X) \qquad (6)$$

3.3 Transfer to a signal flow plan (SFP)

As already explained, the node can be interpreted in the dual sense as a partition, a signal, and an edge over its weight as processing (operation) of the signal. Thus it generates (substitutes) a new signal. The states of the output circuit are to be found in the nodes. The edges are supplemented with their weights. If the electrical circuit is now considered more closely at gate level, the background knowledge of this work can be used to derive a signal flow plan. It is important to know that the function which is derived from the signal flow graph has to coincide with the function which is derived at the gate level. For only then the modeling has been done in a structured way and the relation to reality has not been lost. In order to be able to transmit a signal flow graph into a signal flow plan, the following must be carried out. By interchanging nodes and edges, a signal flow graph results in a signal flow plan and vice versa.

In order to set up a signal flow plan one has to determine which signals are visualized in a node and which are represented by an edge. The edge is a directed line, which connects two nodes and effects the processing of a signal via its weight. The mass as well as the operating voltage represent the nodes in the SFG. The primary inputs are shown as edges. The signal flow plan (action plan) is used to determine the complexity of a system. The nodes (blocks) in a signal flow plan are small processing units that transmit incoming signals on edges into outgoing signals on edges. Fig. 13 shows the signal flow plan derived from the signal flow graph of the electrical circuit. The signals, in this case the edges (nets) of the signal flow plan, are found on the nodes of the signal flow graph. The nodes (blocks) of the signal flow plan are found in the edges of the signal flow graph.

After the gate level of node Z has been transferred to a signal flow plan, the signal flow plan is displayed in a module view (Fig. 14).

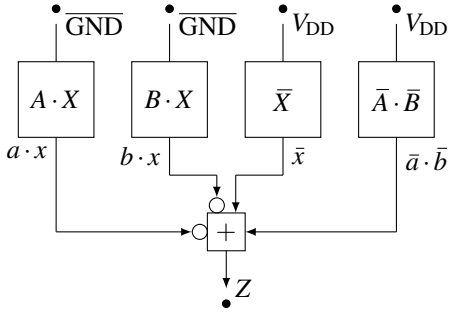

Figure 13: SFP of an electrical circuit

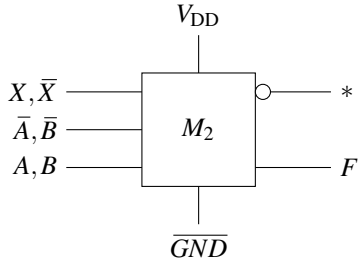

Figure 14: Module-view of an electrical circuit

This digital structural element serves for further simplified viewing of the real system. This further simplifies understanding of the structure. The module-view for node Z has:

- an input vector (inputs): A, B, $\overline{A}$, $\overline{B}$ and $X, \overline{X}$
- a programming vector (states): $\overline{\text{GND}}$ and V_{DD}
- an output vector (output): $Z =: F$

As the MV is using the transitive closure it preserves all pins (that occur in reality). Therefore, it is structure-faithful and a compact presentation of the circuit.
Within M_2, the function is outdated here. We can convert this function from MV to other display posibilities structure-faithful.
At the star $(*)$ we should only observe the "0".

3.4 Evaluation table of the circuit

In the next step the node Z (Eq. 7) of the output circuit (Fig. 11) is shown in the form of a total switching table (in positive logic (Tab. 4), followed by the partial switching table in positive logic (Tab. 5).

$$Z = V_{\text{DD}} \cdot (\overline{X} + \overline{A} \cdot \overline{B}) + \neg(\overline{\text{GND}} \cdot (A + B) \cdot X) \qquad (7)$$

The function in Eq. 7 can be expressed as follows:

$$\begin{aligned} Z &= (Z, \overline{Z}) \\ &= V_{\text{DD}} \cdot (\overline{X} + \overline{A} \cdot \overline{B}), \neg(\overline{\text{GND}} \cdot (A + B) \cdot X) \\ &= V_{\text{DD}} \cdot (\overline{X} + \overline{A} \cdot \overline{B}) + \neg(\overline{\text{GND}} \cdot (A + B) \cdot X) \\ &= PU + \neg\overline{PD} \end{aligned} \qquad (8)$$

In Eq. 7, the node Z is represented in different versions. $Z = (Z, \overline{Z})$ means that Z is a partition of two blocks provided by a positive and a negative literal. The last part of Eq. 7 means that Z consists of two parts, the pull up and the pull down. The relationship between PU and $\overline{PD}$ is the same as already shown in Eq. 4, not to forget the composition "+" between PU and $\overline{PD}$, the RS buffer.
Tab. 3 is also required in order to be able to set up the switching table. The operating voltage V_{DD} depends on the pull-up. It is important to know that if only the operating voltage supplies a "1", a reliable switching process can be present in the PU. The pull-down depends on the mass, $\overline{\text{GND}}$. A switching operation in the $\overline{PD}$ can only take place when the mass is at "0".
Tab. 4 shows the total switching table of node Z in positive logic (PL). On closer examination of the table it can be seen that this table is composed of three divisional tables. The result of the PU and the $\overline{PD}$ and the node Z represent a further table. The coding universe for the PU consists of the operating voltage V_{DD} and $(\overline{A}, \overline{B}, \overline{X})$. For the $\overline{PD}$, the coding universe consists of (A, B, X) and $\overline{\text{GND}}$. Thus the table for the PU and $\overline{PD}$ has a total of $2^4 = 16$ assignments. The output Z represents the respective state for the one-to-one coding of the table.
The lower part of the table (last eight lines) represents assignments which tend not to trigger any switching operations. The reason for this is that during the pull-up the operating voltage V_{DD} can only assume the value "1". The mass does not matter. For pull-down, $\overline{\text{GND}}$ must only have the value "0", so that a switching operation is triggered. The operating voltage does not matter.
The results of the pull-up and the pull-down are calculated by Eq. 7. In order to determine the resulting node Z, Tab. 3 is to be considered. It represents the relationship between PU and $\overline{PD}$.
In the next step, the total switching table Tab. 4 (in PL) is transferred to a partial switching table Tab. 5 (in PL). The correctness of the partial switching table is only given because a structure correct transformation and modeling has taken place. This ensures that the circuit has been designed without errors and thus a partial switching table can be applied without errors.
Tab. 5 shows the partial switching table of node Z. The operating voltage is unsignificant for the $\overline{PD}$, whereas in the PU it can trigger a switching operation only with a "1". The mass is meaningless for the PU, whereas only a "0" the mass in the $\overline{PD}$, triggers a switching process. Thus the last eight lines of the total switching table is lost. For the safety of a defect-free structure it can be firmly assumed that in these assignments, the output Z assumes the states in Tab. 5.
The symbol $*$ represents undefined.

3.5 Resolution method for the circuit

In the last step, the node Z (Eq. 9) of the output circuit (Fig. 11) is entered into a KV diagram.

$$Z = V_{\text{DD}} \cdot (\overline{X} + \overline{A} \cdot \overline{B}) + \neg(\overline{\text{GND}} \cdot (A + B) \cdot X) \qquad (9)$$

PU					$\overline{PD}$							
$\overline{\text{GND}}$	$\overline{X}$	$\overline{A}$	$\overline{B}$	V_{DD}	V_{DD}	X	A	B	$\overline{\text{GND}}$	PU	$\overline{PD}$	Z
$*$	0	0	0	1	$*$	0	0	0	0	1	$*$	1
$*$	0	0	1	1	$*$	0	0	1	0	1	$*$	1
$*$	0	1	0	1	$*$	0	1	0	0	1	$*$	1
$*$	0	1	1	1	$*$	0	1	1	0	1	$*$	1
$*$	1	0	0	1	$*$	1	0	0	0	1	$*$	1
$*$	1	0	1	1	$*$	1	0	1	0	$*$	1	0
$*$	1	1	0	1	$*$	1	1	0	0	$*$	1	0
$*$	1	1	1	1	$*$	1	1	1	0	$*$	1	0
$*$	0	0	0	0	$*$	0	0	0	1	$*$	$*$	$*$
$*$	0	0	1	0	$*$	0	0	1	1	$*$	$*$	$*$
$*$	0	1	0	0	$*$	0	1	0	1	$*$	$*$	$*$
$*$	0	1	1	0	$*$	0	1	1	1	$*$	$*$	$*$
$*$	1	0	0	0	$*$	1	0	0	1	$*$	$*$	$*$
$*$	1	0	1	0	$*$	1	0	1	1	$*$	$*$	$*$
$*$	1	1	0	0	$*$	1	1	0	1	$*$	$*$	$*$
$*$	1	1	1	0	$*$	1	1	1	1	$*$	$*$	$*$

Table 4: Total switching table (in PL): PU, $\overline{PD}$ and Z

$\overline{X}$ for PU X for $\overline{PD}$	$\overline{A}$ for PU A for $\overline{PD}$	$\overline{B}$ for PU B for $\overline{PD}$	V_{DD}	$\overline{\text{GND}}$	PU	$\overline{PD}$	Z
0	0	0	1	0	1	$*$	1
0	0	1	1	0	1	$*$	1
0	1	0	1	0	1	$*$	1
0	1	1	1	0	1	$*$	1
1	0	0	1	0	1	$*$	1
1	0	1	1	0	$*$	1	0
1	1	0	1	0	$*$	1	0
1	1	1	1	0	$*$	1	0

Table 5: Partial switching table (in PL): PU, $\overline{PD}$ and Z

For this purpose, Eq. 9 must be converted into a DNF system, as can be seen in the following.

$$Z = V_{\text{DD}} \cdot \overline{X} + V_{\text{DD}} \cdot \overline{A} \cdot \overline{B} + \neg(\overline{\text{GND}} \cdot A \cdot X) + \neg(\overline{\text{GND}} \cdot B \cdot X) \quad (10)$$

Due to the different terms of the Eq. 10, a better understanding of the KV diagram is to be developed in Fig. 15. It is noticeable that some fields overlap in the diagram. In particular, this fields are occupied by "1" and "¬1". The question is how this field actually looks in the KV diagram in AA. Now Eq. 10 is a concrete equation (Category Level). The KV diagram for this equation is to be represented in AA. In this case, the switch "¬" is substituted by complement since the KV diagram is in the Aussagenlogik (AA), the propositional logic, the logic of statements. The KV diagram now looks as Fig. 16. The blocks of the KV diagram (Fig. 16) are now determined from Eq. 10 as follows:

$$(\overline{A} \wedge \overline{B} \wedge V_{\text{DD}}) \vee (X \wedge A \wedge \overline{\text{GND}}) \vee (B \wedge X \wedge \overline{\text{GND}}) \vee (\overline{X} \wedge V_{\text{DD}}) \vee (V_{\text{DD}} \wedge \overline{\text{GND}}) \quad (11)$$

Therefore in Eq. 11, $V_{\text{DD}} \wedge \overline{\text{GND}}$ represents a redundant block, a redundant prime implicant. This case is visualized by dashed lines. This part of the equation is now used for resolving. Fig. 17 shows the resolution method for node Z. The clauses ($\{\overline{A}, \overline{B}, V_{DD}\}$, $\{X, A, \overline{GND}\}$, $\{X, B, \overline{GND}\}$, $\{\overline{X}, V_{DD}\}$) are derived from Eq. 10. In order to be able to determine the clauses, the equation was first transformed into a DNF system in order to connect the switch neglected. Only by neglecting the switch can a resolvent be formed. In order to determine the folowing clauses ($\{\overline{A}, \overline{B}, V_{DD}, \overline{GND}\}$, $\{\overline{A}, \overline{B}, V_{DD}, GND\}$, $\{X, A, GND, \overline{V}_{DD}\}$, $\{X, A, \overline{GND}, V_{DD}\}$, $\{X, B, \overline{GND}, \overline{V}_{DD}\}$, $\{X, B, \overline{GND}, V_{DD}\}$, $\{\overline{X}, V_{DD}, GND\}$, $\{\overline{X}, V_{DD}, \overline{GND}\}$), the ones in the KV diagram (Fig. 16) have to be viewed individually. $\{V_{DD}, \overline{GND}\}$ comes from prime implicant (dashed lines) of Fig. 16.

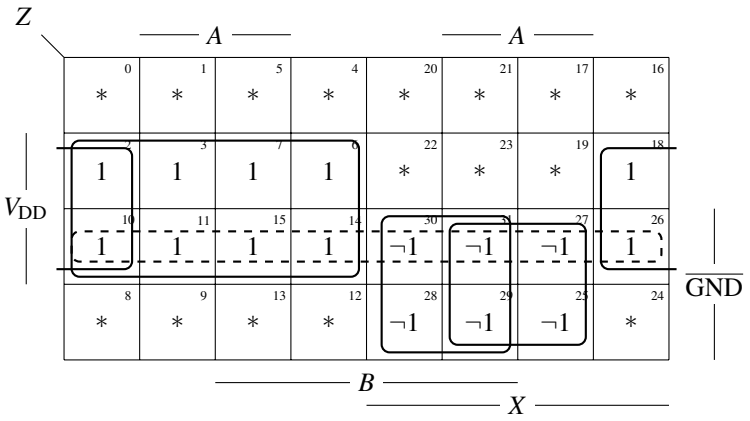

Figure 15: KV diagram for Z (electrical circuit in PL)

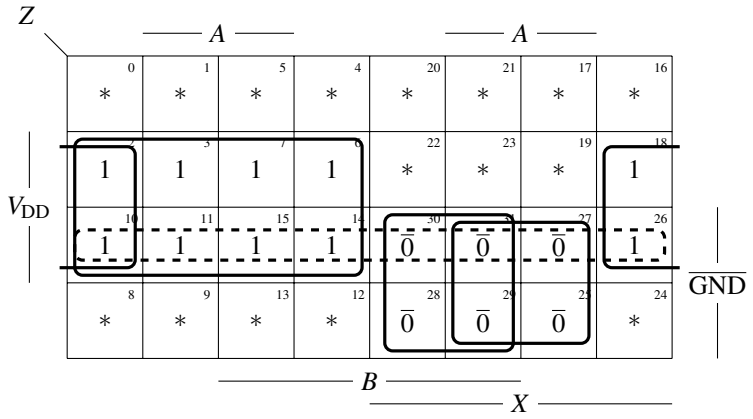

Figure 16: KV diagram for Z (electrical circuit in AA)

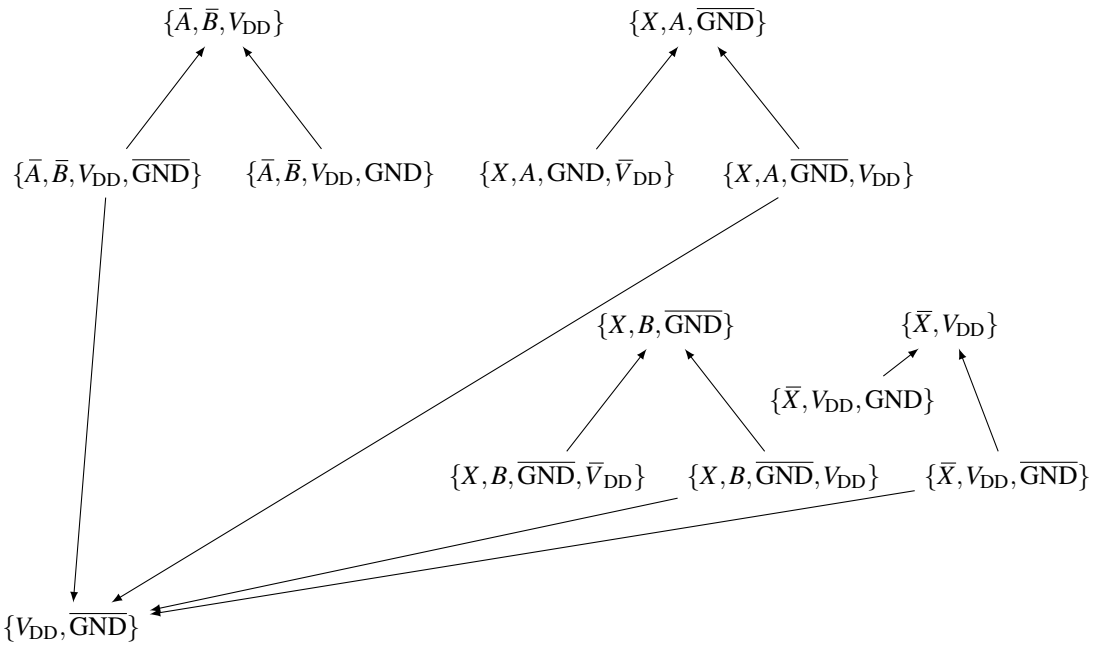

Figure 17: Resolution method for the electrical circuit in PL

So it is noticeable that the KV diagram shows additional information when looking at the ones. The ones that can be useful in resolving are selected. Resolves can be generated only from certain clauses. As already explained in Chapter 2, the following holds: The resolver $\{y,z\}$ can be generated from the clauses $\{x,y\}$ and $\{\bar{x},y,z\}$. The resolver $\{\}$ can be generated from the clauses $\{x\}$ and $\{\bar{x}\}$. The prime implicant (dashed) in the KV diagram is made up of this clause: V_{DD}, $\overline{\mathrm{GND}}$.
This clause resolves from three different clauses, as shown in Fig. 17.

4 Conclusion

The transferability of circuits into other possibilities of representation is a necessary property to ensure the functional safety of safety critical circuits. In this work an output circuit has been visualized in various display possibilities. Each type of presentation has its advantages and disadvantages. Moreover, each type of representation has a depth of accuracy, clarity and compactness. However, all of these representations are common in that their "structure-faithful modeling and transition" must be preserved. This means that a formally derived function has to match consistently with the function derived from the respective representation type. Both functions must in no case have inconsistencies, because only then the fault-free function of the circuit can be maintained. Shortly spoken, each pin of the model at gate level must show up in the real world at transistor level. But, pins have to be correctly labelled in reality. This is mandatory.

ABSTRACT

Cloud computing allows users and enterprises to process their data in high performance servers, thus reducing the need for advanced hardware at the client side. Although local processing is viable in many cases, collecting data from multiple clients and processing them in a server gives the best possible performance in terms of processing rate. In this work, the implementation of a high performance cloud computing engine for recognizing handwritten digits is presented. The engine exploits the benefits of cloud and uses a powerful hardware accelerator in order to classify the images received concurrently from multiple clients. The accelerator implements a number of neural networks, operating in parallel, resulting to a processing rate of more than 10 MImages/sec.

1 Introduction

We live in the era of 'Big Data', where a vast amount of structured, semi-structured and unstructured data are being generated at an ever-accelerating pace and can be mined to obtain valuable information. The most commonly used approach to process this kind of data is to aggregate raw data into large datasets, probably extend them with metadata, and then apply machine learning and/or artificial intelligence algorithms in order to identify repeatable patterns [1]. Artificial neural networks are a rapidly developing category of machine learning structures that give computers the capability to learn without being explicitly programmed to perform specific tasks. They consist of different layers for analyzing and learning data. Each layer consists of a large number of highly interconnected processing elements (neurons), working together to learn from previous data in order to solve specific problems by making proper decisions.

Boltzmann Machine (BM) is a typical example of a neural network structure. BMs are probabilistic Markov Random Field models that use a layer of hidden variables to model a distribution over input variables, called visible variables. In general, learning a Boltzmann machine is a computationally demanding process. However, the learning problem can be simplified by imposing restrictions on the network topology, which leads to Restricted Boltzmann Machines (RBMs)[2]. RBMs are structured as bipartite undirected graphs, which results to efficient inference implementation, and are particularly capable of learning complex features. The last few years, many applications based on RBMs have been developed to cover a large variety of learning problems, such as image classification, speech recognition, collaborative filtering and so on. One such example application is the recognition of handwritten digits. Learning an RBM corresponds to fitting its parameters, so that the distribution represented by the RBM models the distribution underlying the training data, handwritten digits in this case [3]. The storage resources and the time required not only to train an RBM but also to make real-time predictions on new coming data increases exponentially with the number of parameters. Thus the development of a handwritten digit recognition application on a single user machine is a non-trivial task.

Nowadays, cloud computing solutions provide new capabilities to users and enterprises for processing their data remotely in high performance servers. Users do not have to invest in information technology infrastructure, reducing the need for

https://dx.doi.org/10.25046/aj030159

advanced hardware at the user side. In addition, cloud providers specialized in a particular area, such as image processing, can bring advanced services to a single user, complex services that are not easily afforded by individual users. Another important benefit is the high processing rate that can be achieved when a high performance server is used for processing requests from multiple independent users.

In this work, which is an extension of the work originally presented in [4] and [5], we exploit the vast amount of resources provided by cloud computing along with the high computation capabilities offered by hardware accelerators in order to build a complete cloud-based engine that can be used in real-time handwritten digits recognition (HDR). The engine collects images from multiple sources over the cloud and processes them as fast as possible resulting in high processing rate. The high processing rate is achieved by using a powerful hardware accelerator that implements a number of neural networks operating in parallel. A major advantage of the proposed engine is that the training of the neural networks is not only performed once during initialization of the system, but it is also fed with new images periodically, thus improving the accuracy of the prediction results. The engine is presented in detail in the sections that follow.

Section 2 gives an overview of existing implementations, especially on handwritten digits recognition. Section 3 analyzes Restricted Boltzmann Machines and how they can be modified in order to be used to solve classification problems, such as image recognition. Section 4 presents the architecture and the functionality of the proposed cloud-based computing server. Section 5 highlights the communication interface between the server and the hardware accelerator. Section 6 describes in detail the implementation of the neural networks, with emphasis on the architecture of the dedicated hardware accelerator. A complete system prototype was developed, which is presented in Section 7. Experimental results that demonstrate the system performance in terms of processing rate for both implementations are also presented.

2 State of The Art

The scientific area of automatic handwriting recognition is of great interest for both academia and industry. Existing algorithms are so efficient in learning to recognize handwritten digits that they are used, for example, by post offices to sort letters and banks to read personal checks. MNIST is the most widely used dataset for studying handwritten digit recognition [6]. State-of-the-art models that present accuracy results in the range of 0.35% down to 0.23% error rates are based on large Convolutional Neural Networks (CNNs), either in the form of a deep single network optimized with various training techniques or as a committee of many smaller networks [7], [8], [9]. The best results so far, 0.21% error rate, have been claimed by an approach based on regularization of neural networks using DropConnect [10].There is a listing of the state-of-the-art results and links to the relevant papers on the MNIST and other datasets collected by Rodrigo Benenson [11].

The disadvantage of CNNs is that they are very resource-demanding and their training and inference procedures are extremely time-consuming. As the amount of data increases, machine learning moves to the cloud and big clusters of high-performance servers are used for providing real-time results. Most works mainly deal with implementing the training procedure by using distributed servers over the cloud ([12], [13]) or by using higly scalable FPGA implementations ([14], [15]). In this work, a high performance computing engine that accepts images from multiple clients over the cloud and classifies them with high accuracy is presented.

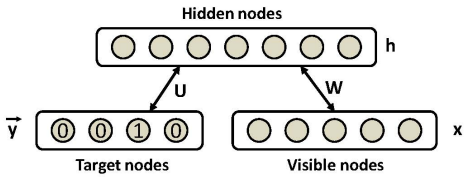

Figure 1: Discriminative RBM modeling the joint distribution of inputs and target classes.

3 Classification Restricted Boltzmann Machines

Restricted Boltzmann Machines are usually used as feature extractors for other learning algorithms or as initializers for deep feedforward neural network classifiers, not as standalone classifiers. However, authors in [16] have proposed a discriminative variant of RBMs that can be used autonomously in classification tasks offering good performance results. The bipartite undirected graph of such an RBM is illustrated in Figure 1. Given a training set $D_{train} = \{(x_1, y_1), ..., (x_i, y_i), ..., (x_D, y_D)\}$, where i denotes the i-th example of the set consisting of an input vector x_i and the corresponding target class $y_i \in \{1, ..., C\}$, we use the specific RBM to model the joint distribution between a layer of N hidden variables $\mathbf{h} = (h_1, ..., h_N)$, usually referred as features, and the observed variables $(\mathbf{x}, \mathbf{y})$. It is a parametric model where the parameters Θ = **(W,b,c,d,U)** represent the following:

- **W:** Weights matrix between **x** and **h**
- **U:** Weights matrix between $\mathbf{e}_y$ and **h**
- **b,c,d:** Respective biases of **x**, **h** and $\mathbf{e}_y$

and $\mathbf{e}_y = (1_{i=y})$ for $i \in \{1, ..., C\}$ the 'one out of C' vector representation of y.

We consider the binary version of the model where each node, hidden or visible, may be in one state, **ON** or **OFF**. A node adopts a new state as a probabilistic

function of the states of its neighboring nodes and the weights on its links to them. It stands:

$$p(h_j = 1|y,x) = sigm(c_j + u_{jy} + \sum_i w_{ji}x_i) \quad (1)$$

$$p(x_i = 1|h) = sigm(b_i + \sum_j w_{ji}h_j) \quad (2)$$

$$p(y|h) = \frac{\exp(d_y + \sum_j u_{jy}h_j)}{\sum_{\text{for all y}} \exp(d_y + \sum_j u_{jy}h_j)} \quad (3)$$

where $sigm(x) = 1/(1 + e^{-x})$ is the logistic sigmoid function.

After the model has been trained, the conditional probability $p(y|x)$ is used for classification. The conditional probability $p(y|x)$, can be computed using $p(y|x) = argmin(F(y,x))$:

$$F(y,h) = -d_y - \sum_j \log(1 + e^{(c_j + u_{jy} + \sum_i w_{ji}x_i)}) \quad (4)$$

where $F(y,h)$ is called *free energy*.

In order to train an RBM to solve a particular classification problem, an objective has to be defined that the learning procedure will try to minimize for all examples in the dataset D_{train}. It is possible to choose among various different objective functions, but generally the following three are used [17]:

- Generative Training Objective
- Discriminative Training Objective
- Hybrid Training Objective

3.1 Generative Training Objective

Given that the model defines a value for the joint probability $p(x,y)$, a natural choice for a training objective is the generative objective:

$$L_{gen}(D_{train}) = -\sum_{i=1}^{|D_{train}|} \log p(y_i, x_i) \quad (5)$$

Computing $\log p(y_i, x_i)$ and its gradient with respect to any RBM parameter Θ is intractable. Fortunately it has been shown that the gradient can be well approximated using the Contrastive Divergence estimator. The analytical computation is replaced by an estimate at a sample generated after a limited number of Gibbs sampling steps, with the sampler's initial state for the visible variables set at the training example (x_i, y_i). A single Gibbs sampling iteration is usually sufficient to learn a meaningful representation of the data [18]. Then, this gradient estimate can be used in a stochastic gradient descent procedure for training. A pseudocode of the procedure is given in Algorithm 1, where γ is the learning rate. Usually, the weights **(W,U)** are initialized using small random values, while the biases **(b,c,d)** are initially zero. Ideally, RBMs require parameter updating after each single example, but mini-batch updating can be also used. However, in order to ensure fast model convergence, the batch size should remain relatively small.

Algorithm 1 RBM Training over (x,y) using 1-step Contrastive Divergence

Input: w_{ij}

for all training samples (x,y) **do**

1. Calculate $p(h = 1|x,y)$ for all hidden nodes
   Sample the hidden distribution $< h_0 >$
2. Perform Gibbs sampling for k steps (k=1):
   Calculate $p(x|h_0)$ for all visible nodes and $p(y|h_0)$ for all target nodes
   Sample the visible distribution $< x_k >$ and the target distribution $< y_k >$
   Calculate $p(h = 1|x_k, y_k)$ for all hidden nodes
   Sample the hidden distribution $< h_k >$
3. Calculate gradients:
   $gW =< h_k > * < x_k > - < h_0 > *x$
   $gU =< h_k > * < y_k > - < h_0 > *y$
   $gb =< x_k > -x$
   $gc =< y_k > -y$
   $gd =< h_k > - < h_0 >$
4. Update weights and biases:
   $W' = W - \gamma * gW$
   $U' = U - \gamma * gU$
   $b' = b - \gamma * gb$
   $c' = c - \gamma * gc$
   $d' = d - \gamma * gd$

end for

3.2 Discriminative Training Objective

The generative training objective can be decomposed as follows:

$$L_{gen}(D_{train}) = -\sum_{i=1}^{|D_{train}|} \log p(y_i|x_i) - \sum_{i=1}^{|D_{train}|} \log p(x_i) \quad (6)$$

This means that the RBM classifier will dedicate some of its capacity at modeling the marginal distribution of the input only. Since classification is a supervised learning task and we are only interested in obtaining a good prediction of the target given the input, we can ignore the unsupervised part of the generative objective and focus on the supervised part. So, the discriminative training objective is defined as:

$$L_{disc}(D_{train}) = -\sum_{i=1}^{|D_{train}|} \log p(y_i|x_i) \quad (7)$$

The most important advantage using this training objective is that it is possible to compute exactly its

gradient with respect to the RBMs parameters for each example (x_i, y_i). For the various model parameters it stands:

- For Θ = **(c,W,U)**:

$$\frac{\vartheta \log p(y_i|x_i)}{\vartheta \Theta} = \sum_j sigm(O_{y_i j}(x_i)) \frac{\vartheta O_{y_i j}(x_i)}{\vartheta \Theta} - \sum_{j,forally} sigm(O_{yj}(x_i)) p(y|x_i) \frac{\vartheta O_{yj}(x_i)}{\vartheta \Theta} \quad (8)$$

where $O_{yj}(x) = c_j + u_{jy} + \sum_i w_{ji} x_i$ for hidden node j.

- For Θ = **(d)**:

$$\frac{\vartheta \log p(y_i|x_i)}{\vartheta d_y} = 1_{y=y_i} - p(y|x_i), \forall y \in \{1, ..., C\} \quad (9)$$

- For Θ = **(b)** the gradient is zero, since the input biases are not involved in the computation of $p(y|x)$.

3.3 Hybrid Training Objective

The effectiveness of both generative and discriminative approaches on various problems has been studied and it has been shown that they have quite different properties. For classification tasks, adding the generative training objective to the discriminative training objective is a way to regularize the second one. To adapt the amount of regularization, the Hybrid Training Objective can be used:

$$L_{hybrid}(D_{train}) = L_{disc}(D_{train}) - \alpha L_{gen}(D_{train}) \quad (10)$$

where the weight α of the generative part can be adjusted based on the performance of the model on a validation set.

3.4 Training using MNIST

In this work, RBMs were applied on a classic classification problem, handwritten digit recognition using the MNIST dataset [6]. MNIST is a large database of handwritten digits, commonly used for training various image processing systems. The database is also widely used for machine learning and pattern recognition methods. The original MNIST dataset is used here, which contains 60,000 training and 10,000 test examples with 28x28 grey-scale images corresponding to all 0-9 digits. This is a multiclass classification problem, where the number of target classes is 10. Before final integration, the best parameters for the RBM model should be selected. These parameters include the number of hidden nodes N, the learning rate γ, which training objective is minimized, the generative weight α, as well as the batch size bs. For that reason, a complete Matlab simulation model was developed and the effect of the different parameters was studied using a validation set. It should be noted that for the specific problem, Hybrid Training led to faster convergence.

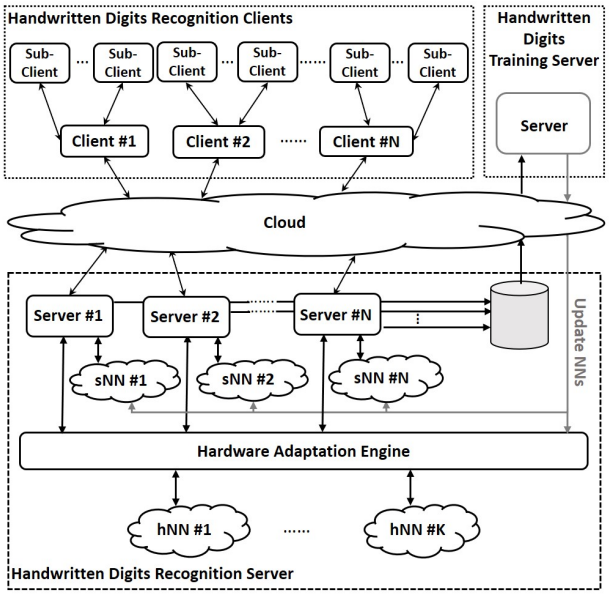

Figure 2: The HDR Computing Engine Architecture

4 HDR computing engine architecture

Based on Classification RBMs, a high performance computing engine able to serve a large amount of real-time requests for detecting the correct values of handwritten digits was implemented. This is a complete infrastructure with multiple entities specially designed either for training of already accumulated data or for real-time classification of multiple new images. Concerning the neural networks implementation, both software modules and dedicated hardware accelerators were developed.

The architecture of the proposed HDR computing engine is shown in Figure 2. This engine accepts requests from various clients from the cloud and processes them in real-time. The system is composed of three basic entities, which are a) Handwritten Digits Recognition clients, b) Handwritten Digits Recognition servers and c) Handwritten Digits (HD) training server. The HDR clients can either be individual clients or sets of sub-clients that are serviced by an HDR client that combines their requests in a single data stream. Each HDR client is associated with a dedicated HDR server. The number of HDR servers that are executed at any given time is variable and is determined by the number of HDR clients that are supported. The main advantage of the proposed architecture is that it does not use a set of predefined parameters but it uses the information of a large number of clients for continuously updating the weights and biases of the HDR algorithm, achieving

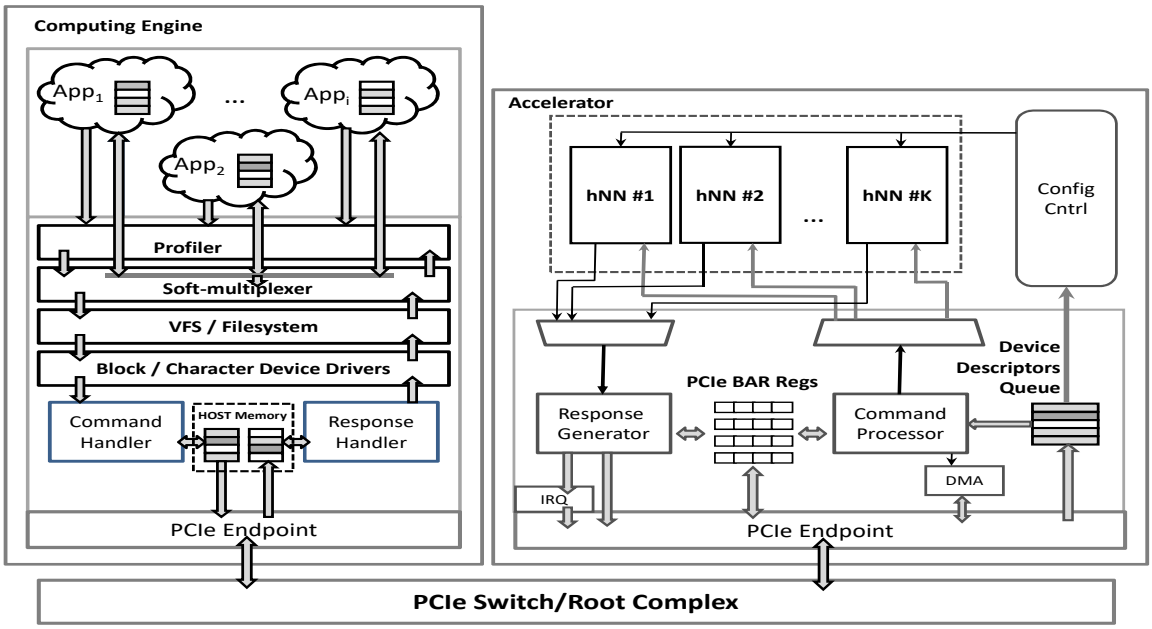

Figure 3: Hardware Adaption Engine - Interfacing with the HDR hardware accelerator

high accuracy for a given complexity. The HD training server is responsible for updating these parameters. More specifically:

HDR Clients: A two-way TCP/IP connection [19] between every HDR client and a dedicated HDR server is established. They exchange variable size data blocks, serviced either partially for better latency or as a whole block for better processing rate.

HDR Servers: When a request for a new connection arrives, a new HDR server thread is activated. Each thread receives bunches of images by its client and stores them temporarily to its local memory. Each HDR server may accept different types of requests from its client. The requests may differ at the number of images per block, the image size, i.e. 16x16 or 28x28 pixels, and pixel information coding (1 bit per pixel, 8 bits per pixel etc.). The server uses either its built-in processing capability to serve the requests, which means that the neural network is implemented in high-performance software, or forwards them to a dedicated hardware accelerator.

HD Training Server: The HD training server receives data and performs the training of the RBM neural networks. The data are forwarded to the HD training server either during initialization of the system or periodically during normal operation. In the latter case, the HDR servers send a random subset of images along with the information regarding the digit recognition. After training, the HD training server is responsible for sending the updated parameters, weights and offsets, back to all neural networks.

Concerning the neural network implementation there are three possible configurations.

(i) *Software-only Configuration:* a software NN (sNN) is initialized per HDR thread. Each NN accepts images by its corresponding thread, classifies them and returns the predicted digits.

(ii) *Hardware-only Configuration:* a small number of NNs implemented in hardware (hNN) is available to all server threads and is shared among them. The execution time is much smaller compared to the software implementation and that results to much higher processing rate. The hardware accelerator is based on a powerful FPGA board attached to the computing engine's CPU using a high-speed interface, either native PCIe Gen 3.0 with more than 1 GBps useful transfer rate [20] or the Coherent Accelerator Processor Interface (CAPI) [21]. An entity called Hardware Adaptation Engine (HAE) provides a seamless interface between the server threads and the accelerator. This entity is described analytically in the next section. Each HDR server does not use a specific hNN but whichever is available. The hardware accelerator may consist of multiple FPGA boards and/or GPUs. Although this architecture is significantly more efficient, in the case of a heavy workload, each hNN may have to process a huge bunch of images. In this case, a hybrid configuration is most preferable.

(iii) *Hybrid Configuration:* the images are still processed by the hardware accelerator (hNNs) but when the processing delay exceeds the software execution time, then the sNNs start receiving some of the images for classification.

5 Hardware Adaptation Engine

The HDR servers receive bunches of images from their clients and store them in a FIFO at the input

of HAE. Each HDR server has its own dedicated FIFO. HAE is responsible for forwarding these images for recognition to the hardware accelerator. HAE consists of multiple functional units that are shown in Figure 3. Initially, the Profiler decides the next block of images that has to be forwarded to the Soft-multiplexer. The number of images per block is selected so that the total system performance is maximized. The Soft-multiplexer interfaces with the hardware accelerator through Block/Character device drivers. The drivers and the accelerator communicate through shared host memory areas. When the images have been processed by the accelerator, a response with the digits values is fed back to the proper HDR server. A more detailed description of the HAE functional units follows.

5.1 Profiler

It is responsible for selecting the next block of images that has to be handled by the Soft-multiplexer. The Profiler decisions depend on the number of pending commands and the total response statistics (execution time etc.). The HDR servers inform the Profiler about their pending commands, while the Soft-multiplexer provides timing information regarding command execution. Initially, the Profiler selects the commands of the next block using either a round-robin or a static algorithm with fixed priorities. When enough statistics have been collected, dynamic allocation that takes into consideration the current load is feasible.

5.2 Soft-multiplexer

It makes the basic calls for interfacing with the Character/Block device drivers (e.g. open, close, pwrite, pread, ioctl etc). The Soft-multiplexer processes the selected block, extracts the commands and forwards them to the drivers. After receiving a notification for the completion of a command, the Soft-multiplexer forwards a response to the corresponding server thread. The soft-multiplexer also informs the Profiler about the execution time of each bunch of images.

5.3 Character/Block Device Driver

It is responsible for transferring the data from user space to kernel space and vice versa, for address translation and interrupt handling. The commands are associated with a data structure, in the form of a descriptor, which is the basic information provided to the hardware accelerator. The Device Driver activates the Command and Response Handler for forwarding commands and receiving the respective responses from the accelerator. The Command Handler accepts commands, creates the descriptors and stores them in a shared host memory area (Host Descriptors Queue). Each descriptor may contain one or more commands, associated with data from the same or different HDR servers. When a block of descriptors has been processed and their responses are ready, the accelerator sends an MSI-X Interrupt to notify the Response Handler that responses are stored in another shared host memory area (Responses Queue). The Response Handler decodes each response and forwards the corresponding results to the Soft-multiplexer.

At the accelerator's side, the Command Processor is responsible for accessing the descriptors at the host's main memory and transferring them into accelerator's local memory (Device Descriptors Queue). It decodes the descriptors, transfers the requested images using a DMA engine and feeds any available hNN. When the image processing has been completed the Response Generator prepares the responses that contain the classified digits, stores them in the Responses Queue and sends an interrupt to the Device Driver.

6 Neural Network Implementation

For better exploitation of the hardware resources, images of 16x16 pixels, with 1 bit/pixel, are used. This can be achieved by proper prefiltering and scaling, without affecting significantly the total system's accuracy. For this image size each hNN uses less hardware resources, thus enabling more hNNs to be integrated in the given accelerator resources, while the accuracy is only slightly reduced. These images are generated by the original ones after proper filtering and optimum threshold application. The pre-processing takes places at the client side before transmission. Before moving to the actual neural network implementation, a theoretical analysis of certain parameters regarding the prediction procedure is necessary.

6.1 Theoretical Analysis

As aforementioned, classification is based on the calculation of *free energy* [22], given by (4). For implementation purposes this equation is rearranged as follows:

$$S_m = \sum_{i=1}^{N_v} (v_i \cdot WV_{i,m}) + HB_m \tag{11}$$

$$LE_{k,m} = \log(1 + \exp(S_m + WT_{k,m})) \tag{12}$$

$$Fe_k = -(\sum_{m=1}^{N_h} LE_{k,m} + TB_k) \tag{13}$$

$$t_k = 1 : min(Fe_k) \tag{14}$$

where N_h is the number of hidden nodes, N_t the number of target nodes, $m \in [1, N_h]$, $k \in [1, N_t]$, v_i is visible node i, h_m is hidden node m and t_k is target node k. Fe_k is the *free energy* of target node k. Regarding the weights and biases, VB_i are the biases of visible nodes, TB_k are the biases of target

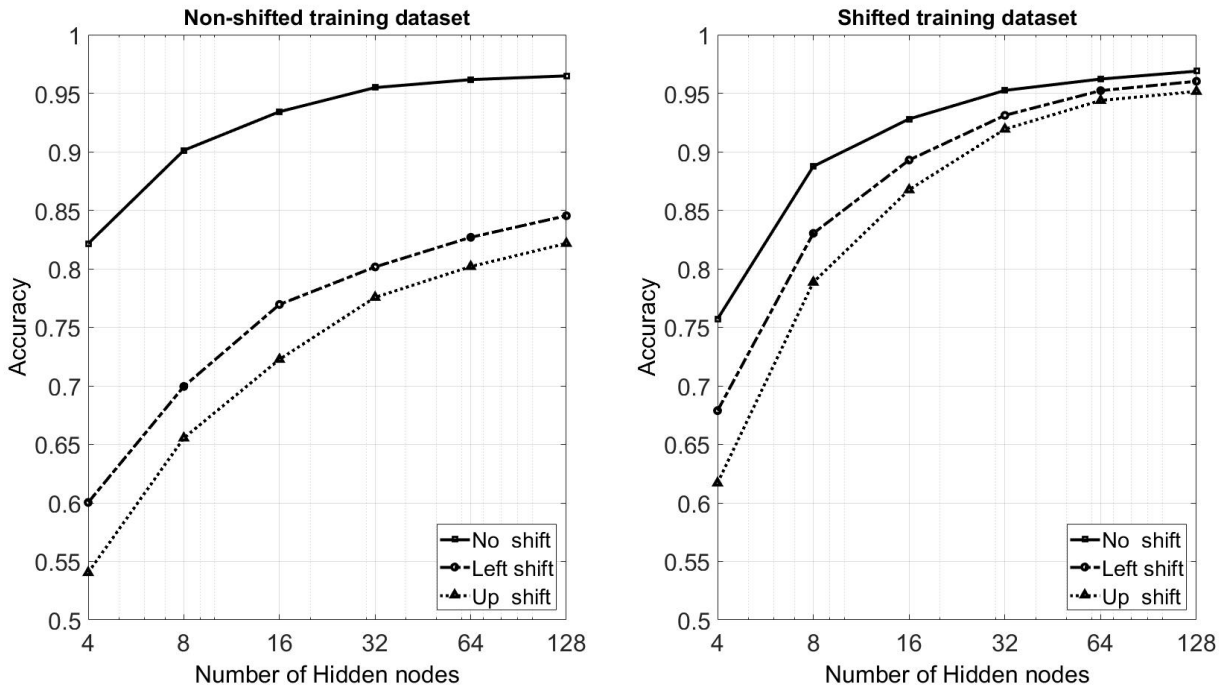

Figure 4: The influence of different training datasets on classification' s accuracy.

nodes, HB_m are the biases of hidden nodes, WV are the weights between visible and hidden nodes and WT are the weights between target and hidden nodes.

In order to study more thoroughly the accuracy of the proposed implementation and validate its effectiveness under a broader set of images, the initial dataset was extended with shifted versions of the original images. More specifically, four additional datasets were created, each one being a shifted copy of the initial one. The images were shifted to the left, right, up or down by a single pixel. In this way, the final dataset is a superset of the original one. Training was performed using both datasets, the original non-shifted one and, to keep the dimensions the same, a randomly selected collection of 60,000 images from the shifted dataset.

Figure 4 shows the effect of the training dataset on the classification accuracy of the model, when it is applied on three individual datasets, the original test dataset with the non-shifted images, the test dataset with the images that have been shifted left by one pixel and the test dataset with the images that have been shifted up by one pixel. As expected, the use of the shifted version for training leads to better overall accuracy, except in the case of the original dataset and for a small number of hidden nodes. This is explained by the fact that an RBM can model fewer dependencies when it includes a small number of hidden nodes, thus being subject to overfitting on the training dataset. Similar results can be taken for the datasets with the one-pixel right and down shifting.

Figure 4 also helps to specify the number of hidden nodes that will be used in both the software and hardware implementations of the neural network. It is obvious that the choice of 32 hidden nodes is a satisfactory trade-off between accuracy and complexity. By choosing 64 hidden nodes the accuracy improves only 2.2%, while the hardware complexity increases almost 8 times.

6.2 Software only Configuration

As described in Section 4, each HDR server receives requests from multiple clients. In software implementation each HDR server implements one RBM neural network. In order to have multiple sNNs operating in parallel, the server application is multithreaded, one thread per neural network. When a high performance CPU engine is used, multithreading results to better exploitation of the available cores. Software multithreading is mostly effective on multiprocessor or multicore systems, where actual parallel or distributed processing is feasible.

Each thread is responsible for classifying the incoming images, by calculating their *free energy* (4) with respect to each one of the ten possible classes. Therefore, vector and matrix operations dominate the computations. To achieve high performance, the threads use off-the-shelf highly-optimized libraries that exist for a variety of computer architectures.

6.3 Hardware only Configuration

Regarding the implementation of the hardware accelerator, a major consideration involves the arithmetic, fixed or floating-point, that will be

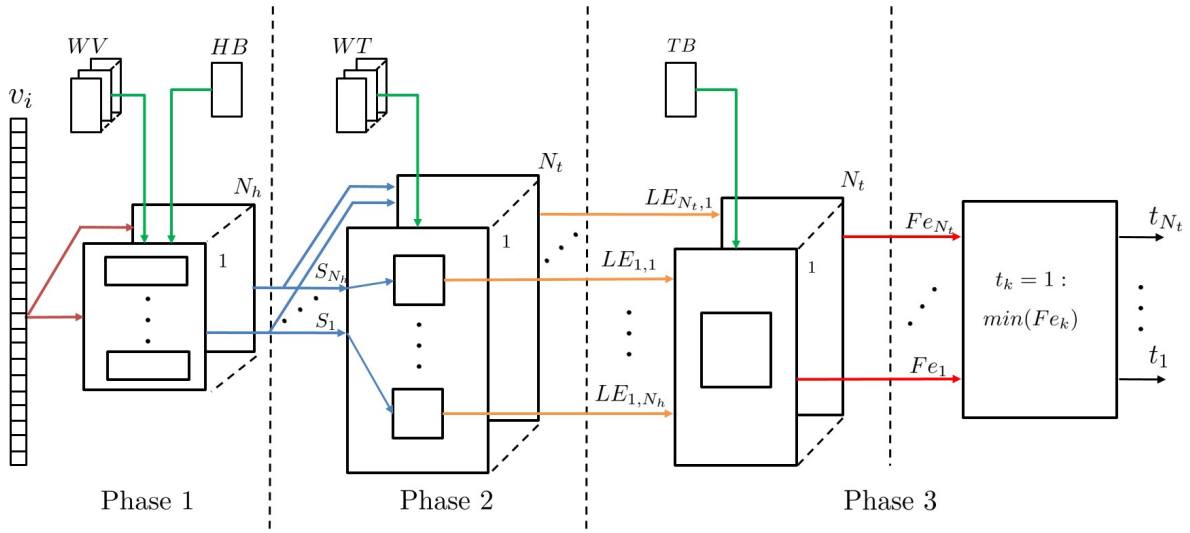

Figure 5: Accelerator Architecture

used for the calculations. The proposed design uses fixed-point arithmetic for all linear functions (*add*, *mul*, *cmp*) and single-precision floating-point for non-linear functions, like *log* and *exp* in (12). To specify the range of the fixed-point arithmetic, simulations were run and statistics were collected based on all available training and test data patterns.

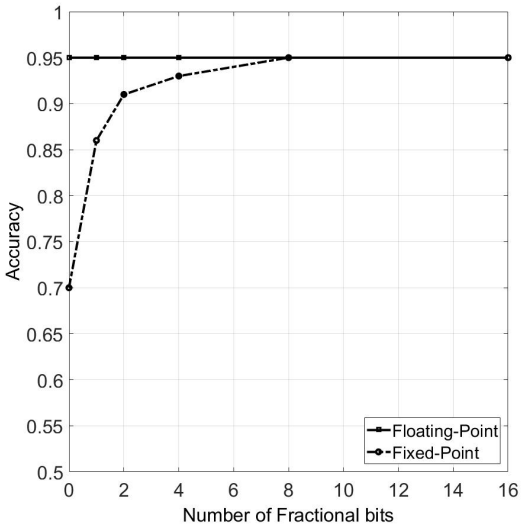

Figure 6: Accuracy vs Fractional bits ($N_h = 32$)

Figure 6 shows the accuracy results for various fixed-point number configurations. It can be seen that by using 16-bits fixed-point numbers, with the first 8 bits being used for the sign bit and the integer part and the remaining 8 bits for the fraction, a good classification accuracy of 95% can be achieved.

The proposed architecture is based on equations (11), (12) and (14) and is organized into three separate phases, shown in Figure 5. The time required to execute each phase determines the performance increase that can be achieved by proper pipeline. Whenever needed, the results of each phase are stored in shared memories and/or cascaded registers. The weights and biases are stored in dual-port RAMs and/or FIFOs, so that they are initialized/updated during system operation when new training data have been used.

A detailed description of the three phases comprising the accelerator architecture follows:

(i) *Phase 1:* Each image consists of a set of pixels, which are represented as binary values. This simplifies the multiplication part of (11), since instead of arithmetic multiplications, low complexity multiplexing functions can be used. The incoming image determines the weights that have to be used in the sum of products. Figure 7 shows a detailed scheduling of the operations implemented in this phase. Each *load* operation refers to reading WV values from memory. The *sel* of each multiplexer is connected to the corresponding pixel of the input image. This module needs 2 clocks to perform *load* and *mux* operations in order to feed the adder trees. After this point all additions are completed in 6 clocks. A total of 4 such modules is used.

Each of these modules includes 256 adders and is responsible for calculating 8 S_m results. Equation (11) determines that a total of 32 S_m results is needed. Every module operates in a pipeline manner. Although each S_m needs 8 clocks to be calculated, by using pipeline a total latency of 37 clocks is achieved.

(ii) *Phase 2:* Apart from the first addition, phase 2 is implemented using floating-point arithmetic. It was designed using the functionalities of Xilinx's Floating-point IP core [23]. The architecture of phase 2 and the respective timing diagram is given in Figure 8. Equation (12) is implemented in two similar and with same latency stages: $exp(a + b)$ and $ln(a + b)$.

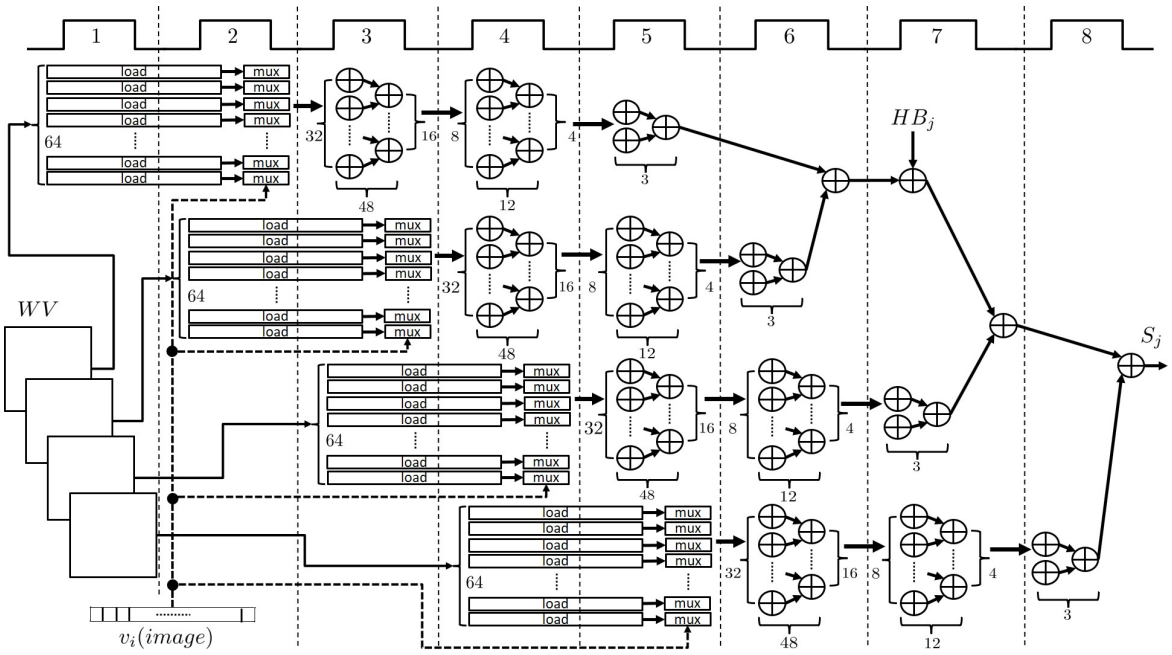

Figure 7: Phase 1 of Accelerator Architecture: Addition and Multiplexing Scheduling

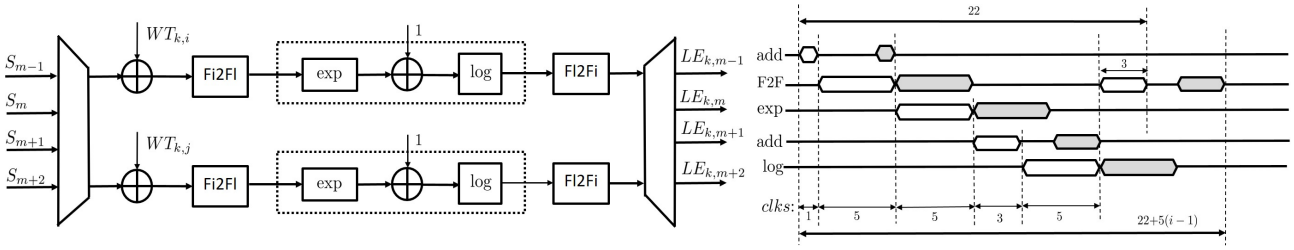

Figure 8: Phase 2 of Accelerator Architecture: Block Design (left) and Timing Diagram (right)

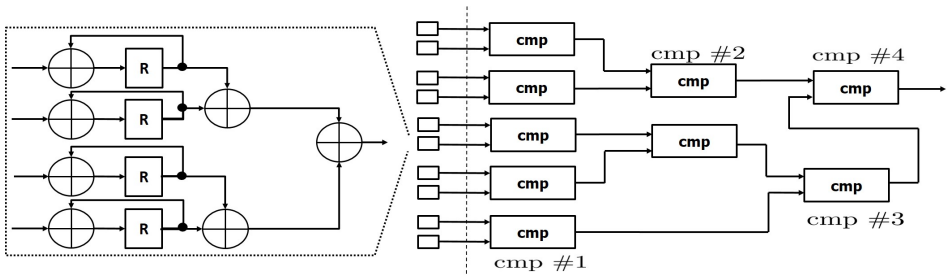

Figure 9: Phase 3 of Accelerator Architecture: Block Design

Therefore, two LE values can be calculated simultaneously using pipeline. For optimum performance, multiplexing of the incoming S_m values is performed, thus reducing the hardware complexity without decreasing the processing rate, and then fixed-to-floating point transformation is applied. Since the Fixed-point addition with the Fixed-to-Floating ($F2F$) operation lasts for less than the duration of each of the aforementioned processing stages, the same floating-point circuit (indicated with a dotted line) can be used for processing continuously a stream of S_m values. Since a total of $N_h x N_t$ LE values have to be calculated, the number of such circuits is determined by the multiplexing/demultiplexing used. $Fl2Fi$ in this figure corresponds to floating-to-fixed transformation. Phase 2 is the slowest phase of the whole accelerator. Reducing its latency would lead to improvement of the whole processing rate of the accelerator. To achieve this, sets of four LE values are calculated simultaneously. However, the required DSP resources are doubled.

(iii) *Phase 3:* The last phase is divided into two distinct sub-phases. The first accumulates the $LE_{k,j}$ inputs from Phase 2 to produce the Fe_k

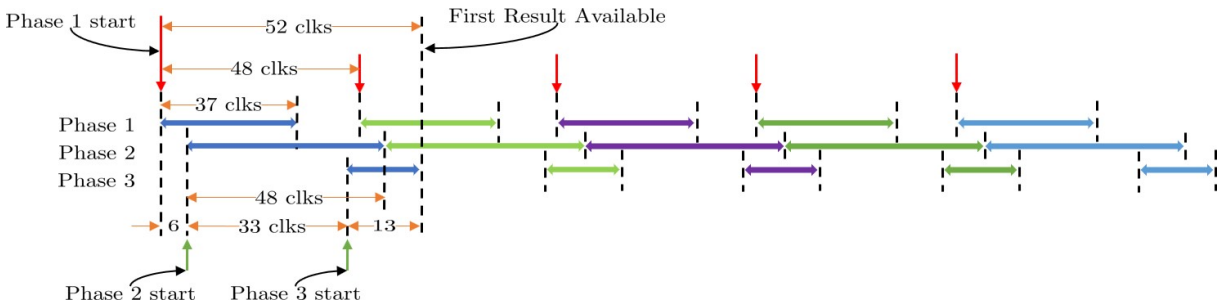

Figure 10: Pipeline strategy applied between processing phases

results (13). The second sub-phase uses the N_t computed Fe values in parallel and in a few clock cycles determines the digit (14) that corresponds to the class of the input image. Figure 9 presents the architecture of Phase 3.

Since all these phases have different processing times and do not require all the results of the previous phase to be available in order to proceed, pipeline can be used for increasing the whole system's processing rate. The latency of phase 1 is 37 clocks. In phase 2 the latency is 48 clocks and 10 such circuits are used in parallel. The combined latency for phase 3 is 10 clocks and 10 circuits implementing the accumulation process are used. Therefore the total latency per hNN without pipeline is 95 clock cycles. A pipeline of two is used and so the module is ready to receive new images every 48 clock cycles, with a latency of 52 clock cycles, as shown in Figure 10.

7 System Prototyping and Performance Results

The above described HDR Cloud Service has been implemented and tested in Xeon and Power8 servers (Table 1) while the hardware accelerator has been implemented in a Virtex-7 FPGA. For generating various workloads, an i7 server has been used, where various clients were implemented with user-defined workload patterns. The HDR clients send bunches of images over 1 Gbps ethernet link.

7.1 Software only Configuration

The applications of clients and servers were developed in C. Provided that HDR servers are multi-threaded, a very popular API is used for threading an application, known as POSIX Thread [24]. Also, CBLAS library is used for performing all the necessary vector and matrix operations. The OS of all platforms is Linux ubuntu 15.10.

In order to validate the efficiency of this configuration, the data rate achieved (in KImages/secs) for various computing servers (Table 1) and for various bunches of images (KImages/req) was measured. To preserve consistency with the hardware implementation, the number of hidden nodes used in sNNs is 32.

Table 1: Clients and Server Platforms

Platfrom	CPU		Memory		
	Cores	GHz	GB	Type	MHz
Xeon	6	1.60	16	DDR3	2133
Power8	4	3.00	64	DDR4	1600/1333
Power8	8	3.32	64	DDR4	1600/1333

When the number of images per request is small the total performance drops because the time between consecutive requests is much higher compared to the processing time of each request. On the other hand, the number of images per request does not affect the performance when it is more than a few hundreds since the overhead is absorbed. This can be seen in Tables 2 and 3.

Table 2: Processing rate [KImgs/sec] using software HDR implementation (N_t =32 and 1KImgs/req)

	Number of HDR Clients			
Servers	1	4	16	64
Intel Xeon	13.20	55.01	82.31	83.10
Power8	16.12	50.52	95.01	98.14
Power8	14.39	46.92	149.03	171.86

Table 3: Processing rate [KImgs/sec] using software HDR implementation (N_t =32 and 10KImgs/req)

	Number of HDR Clients			
Servers	1	4	16	64
Intel Xeon	13.31	55.36	82.11	82.77
Power8	16.20	59.82	98.13	100.09
Power8	14.48	54.88	155.33	171.20

Based on Tables 2 and 3, it is evident that the system performance has a linear relation with the number of HDR clients. For a small number of clients, the system is not fully utilized due to the communication overhead. Each client waits for the completion of a request before sending a new one. As the number of clients increases, this overhead is amortized and full system utilization is achieved. So, the performance increases with the increase in the number of clients. The performance reaches different maximum values, depending on the server platform

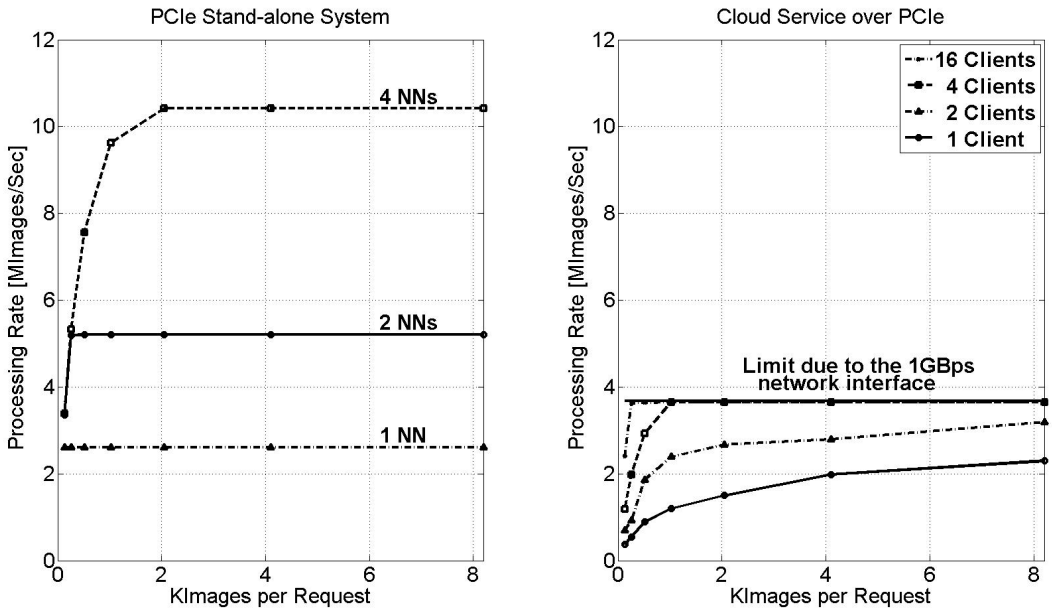

Figure 11: Processing rate using hardware HDR implementation over PCIe

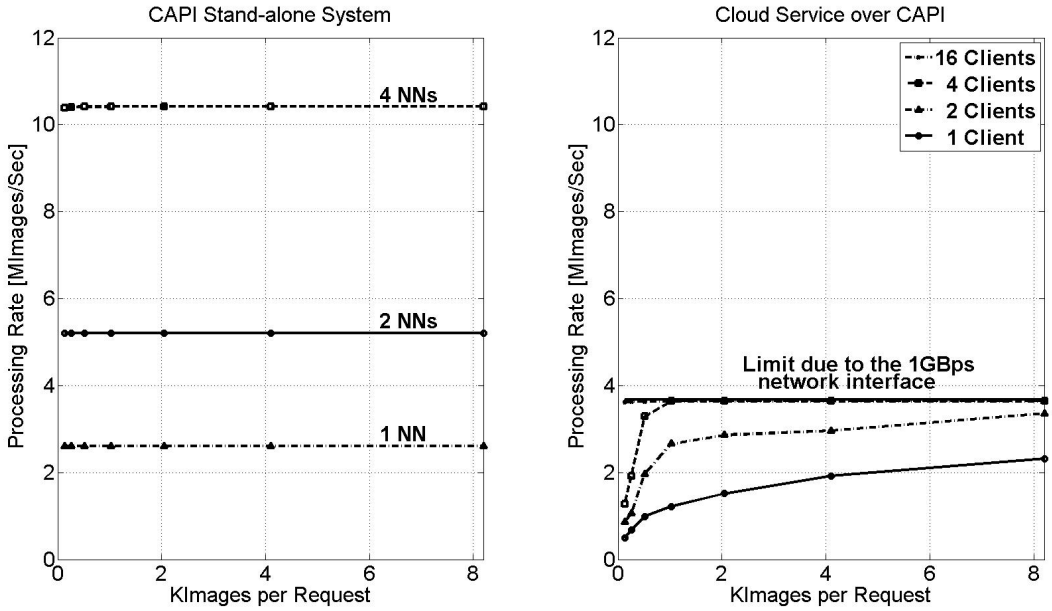

Figure 12: Processing rate using hardware HDR implementation over CAPI

used. This is mainly due to the fact that each server has different number of CPU cores (Table 1). As mentioned, when multiple threads are running, they are distributed to different cores and exploit better the capabilities of each CPU.

7.2 Hardware only Configuration

As far as the accelerator is concerned, based on the latency numbers provided above, a processing rate of 2.6 MImages/sec, at 125 MHz, is achieved by each hNN module. To maximize the total accelerator performance, four hNN modules operate in parallel. That results to a total processing rate of 10.4 MImages/sec, at 125 MHz. The limitation of four modules is introduced by the available resources of the specific Virtex-7 FPGA board (Table 4).

The accelerator supports two interfaces, PCIe Gen 3.0 with 8 lanes and Coherent Accelerator Processor Interface (CAPI). In both cases, a databus of 1024 bits is used that provides images up to four hNNs simultaneously.

The accelerator was attached to a Power8 server with 8 cores (Table 1). For each interface (PCIe, CAPI) two different sets of experiments were conducted in order to measure the performance of the hardware configuration. The results concerning the PCIe are shown in Figure 11. The left part illustrates the

accelerator's processing rate by varying the number of images per request as well as the number of hNNs implemented in the accelerator. In this case, the images are stored locally to the server and not received from multiple clients over the network. The number of images per request does not affect the performance when 1 or 2 hNNs are implemented in the accelerator. The rate is 2.6 MImages/sec and 5.2 MImages/sec correspondingly. When 4 hNNs are integrated, the maximum rate (10.4 MImages/sec) is achieved when each request contains at least 2K images.

Table 4: Implementation parameters of a neural network (N_t =32, XC7VX690T-2 Virtex-7 FPGA)

	Phase 1	Phase 2	Phases 3-4	Total
BRAMs	4 %	1 %	1 %	6 %
DSP	-	13 %	-	13 %
FFs	1 %	3 %	1 %	5 %
LUTs	7 %	8 %	1 %	16 %
Slices	-	-	-	18 %

The right part of Figure 11 illustrates the processing rate, when 4 hNNs operate in parallel, varying the number of connected clients over the network. It is obvious that the maximum rate of this set-up can be achieved even for a small number of active clients. Although in the case of 4 hNNs the maximum achievable rate is 10.4 MImages/sec it can be seen that the maximum processing rate of the whole set-up is less due to the used network interface (934.4 Mbps data rate over a 1 Gbps Ethernet link), since the communication interface becomes the systems bottleneck. Nevertheless, the system with 1 Gbps network interface and hardware acceleration is up to 21 times faster compared to the software implementation.

The achieved processing rates when CAPI is used are shown in Figure 12. The performance is slightly better when 4 hNNs are implemented in the accelerator as it can be seen in the left part of the figure. In this case, the accelerator reaches its maximum value even for a small number of images per request. So, the configuration with CAPI outperforms the configuration with native PCIe. Traditional I/O attachment protocols, like PCIe, introduce significant device driver and operating system latencies, since an application calls the device driver to access the accelerator and the device driver performs a memory mapping operation. With CAPI instead, the accelerator is attached as a coherent CPU peer over the I/O physical interface.

8 Conclusions

The design and implementation of a computing engine for handwritten digits recognition was presented. This engine can be used for cloud applications and achieves high performance, in terms of processing rate, when a hardware accelerator with multiple neural networks is used, as demonstrated by experimental results. Details of neural networks implementation on reprogrammable logic have also been described. The architecture can be parameterized in order to achieve the best compromise between hardware complexity and processing performance.

ABSTRACT

In this modern age, information technology (IT) plays a role in a number of different fields. And therefore, the role of security is very important to control and assist the flow of activities over the network. Intrusion detection (ID) is a kind of security management system for computers and networks. There are many approaches and methods used in ID. Each approach has merits and demerits. Therefore this paper highlights the similar distribution of attacks nature by using K-means and also the effective accuracy of Random Forest algorithm in detecting intrusions. This paper describes full pattern recognition and machine learning algorithm performance for the four attack categories, such as Denial-of-Service (DoS) attacks (deny legitimate request to a system), Probing attacks (information gathering attacks), user-to-root (U2R) attacks (unauthorized access to local super-user), and remote-to-local (R2L) attacks (unauthorized local access from a remote machine) shown in the KDD 99 Cup intrusion detection dataset.

1. Introduction

On the Internet, users share valuable information around the world. The internet has created various ways to threaten the stability and security of interrelated systems. Both of these mechanisms are static and dynamic. Static mechanisms like firewalls and software updates provide dynamic security and mechanisms such as intrusion detection systems. Today, security is the most serious problem for getting valuable information. Therefore, static mechanisms or dynamic mechanisms are needed to protect individual information despite the precautionary technology. The intrusion detection system detects not only successful aggression, but also helps monitor and prevent timely action.

The intrusion Detection System (IDS) is a standard component of a security infrastructure that allows network administrators to detect policy violations. Check all incoming and outgoing network activity and determine suspicious patterns that indicate network or system attacks from people trying to break or compromise the system.

A secure network must provide the following:

- Data confidentiality: Data transferred over the network must be accessible only to data that has been approved accordingly.
- Data integrity: Data must maintain integrity from when it is sent when it is received. No damage or loss of data from random events or malicious activities is accepted.
- Data availability: The network must be resistant to service attack denial.

IDS technology based on tracking process can be categorized into two approaches:

Abuse/Signature detection: This technology searches for signature attacks and known signatures in network traffic and are used as a reference to detect future attacks. Regularly updated databases are usually used to store signatures of known attacks. The way this technology controls intrusion detection is similar to antivirus software. The advantage of this type of detection is that it can accurately and efficiently detect known attacks. Anomaly detection: This technology is based on tracking traffic anomalies. The gap between traffic is monitored and regular profiles are measured. Different implementations of this technology have been reserved based on metrics used to measure the deviation of traffic profiles. The advantage of this detection type is that it is well suited to detect unknown attacks.

IDS are divided into two parts based on analysis and retention of audit data:

* Yi Yi Aung, Email: yiyiaungresearch@gmail.com

Host-based IDS (HIDS): HIDS is a home based tracking method that allows the system to collect data in the form of multiple host activity records, such as event logs and system logs. Since everything is in the host, there's no need to install additional hardware or software [1]. The advantages of hosted IDS are to check the success or failure of attacks, monitor system activity, and detect attacks that IDS networks cannot detect, close tracking and real-time responses, are not required.

Network-based IDS (NIDS): NIDS is a network approach that collects data directly from a network monitored as a packet instead of collecting data from a particular host / agent. Most NIDS are a free and easy-to-use operating system [2]. Network-based IDS offers advantages such as low cost of ownership, easier, placement, network attack detection, evidence preservation, real-time tracking and rapid response, and detection of failed attacks.

2. Literature Review

Most of intrusion detection system focused on four major attack categories such as denial of service, probe, user-to-root, and remote-to-local but this author specially emphasized on User-to-Root (U2R) attacks in NSL-KDD dataset by using Weka tool. This paper focused on a comparative study analysis of user-to-root attack, which the attacker tries to access normal user account and gains root access information of the system based on several machine learning techniques such as navie bayes, random forest, J48, etc [3].

This paper analyzed anomaly intrusions detection system by using Random Forest classifier with Principal Component Analysis. The author got experimental results by using simulation connection dataset of NSL-KDD. The performance of the system was measured by using Precision, Recall and F-Measure. And also this paper was specially focused on to detect various attacks present in Denial of Service (DoS) such as Neptune, Smurf, Pod, Teardrop, Land, Back, Apache2, Processtable, Mailbomb [4].

This paper used C4.5, CART (Classification and Regression Trees), Random Forest, and REP (Reduced Error Pruning) Tree to investigate the detection of intrusions contained in KDDCUP 1999 DARPA dataset. And compared the performance of the above algorithms based on the measures such as Accuracy, Learning Time (in seconds) and Size of the Tree. According to the experimental results, Random Forest was better as it correctly identifies more number of instances than other. And the accuracy of the REP Tree was very less than other algorithms but the learning time of REP Tress is very less than other [5].

They used Support Vector Machine with Principal Component Analysis (PCA) to choose the optimum feature subset that was useful in applying for intrusion detection system. To determine the effectiveness and feasibility of the proposed IDS system, they choosed NSL-KDD dataset for simulation their system. They found that PCA algorithm is good to select a best subset of features for classification of intrusions. It can help to speed up the training and testing process of intrusions detection which is important for high-speed network applications [6].

In this proposed paper, several classification techniques and machine learning algorithms have been considered to categorize the network traffic. Out of the classification techniques, they have found nine suitable classifiers like BayesNet, J48, PART, JRip, Random Tree, Random Forest and REPTree. The comparison of these algorithms has been performed using WEKA tool [7].

Security has become a crucial issue for computer systems. IDS can protect to our computer network. Different classification and clustering algorithms have been proposed in recent year for IDS. In this paper, multiple algorithms were analyzed to find the optimal algorithm. At last the optimal algorithms Random Forest and DB Scan were occurred for IDS [8].

The purpose of this survey paper was to describe the methods/ techniques which are being used for Intrusion Detection based on Data mining concepts and the designed frame works. This survey paper stated the methods and techniques of data mining to aid the process of Intrusion Detection and the frameworks [9]. The concept of intercepting these two different fields, gives more scope for the research community to work in this area. New approaches enhanced the existing interference detecting system and it was a stepping stone to build effective and efficient IDS to detect different types of attacks [10].

This paper proposed a novel hybrid model for intrusion detection. The proposed framework in this paper may be expected as another step towards advancement of IDS. The Hybrid framework led to effective, adaptive and intelligent intrusion detection [11].

This paper drew the conclusions on the basis of implementations performed using various data mining algorithms. Combining more than one data mining algorithms had be used to remove disadvantages of one another and lead to a better performance than any single classifier. Different classifiers had different knowledge regarding the problem [12].

3. Methodology

This section consists of the conversation of the two algorithms of data mining classification approaches. These are K-means and Random Forest.

3.1. K-means Clustering Algorithm

Clustering, based on distance measurements performed on objects, and classifying objects (invasions) into clusters. Unlike classification, classification because there is no information about the label of learning data is an unattended learning process. For anomalous detection, we can use welding and in-depth analysis to guide the ID model. Measurement of distance or similarity plays an important role in collecting observations into homogeneous groups. Jacquard affinity measurement, the longest common order scale (LCS), is important that the event is to awaken the size to determine if normal or abnormal. Euclidean distance is approximately two vectors X and Y in space Euclidean n-dimensions, the size of the distance widely used for vector space. Euclidean distance can be defined as the square root of the total difference of the same vector dimension. Finally, grouping and classification algorithms need to be channeled effectively, massively, it possible to handle dimension of network data and heterogeneity [13].

In this paper, we use K-means algorithm to cluster dataset connections. The K-means algorithm is one of the widely recognized clustering tools. K-means groups the data in accordance with their characteristic values into a user-specified number of K distinct clusters. Data categorized into the same cluster have identical feature values. K, the positive integer denoting the number of clusters, needs to be provided in advance. The steps involved in a K-means algorithm are given consequently: [14]

1. K points denoting the data to be clustered are placed into the space. These points denote the primary group centroids.
2. The data are assigned to the group that is adjacent to the centroid.
3. The positions of all the K centroids are recalculated as soon as all the data are assigned.
4. Repeat steps 2 and 3 until the centroid unchanged.

This results in the partition of data into groups. The preprocessed dataset partition is performed using the K-means algorithm with K value as 5. Because we have the dataset that contains normal and 4 attack categories such as DoS, Probe, U2R, R2L.

3.2. Random Forest Algorithm

One of the most popular methods or frameworks used by scientists in the science of data is Random Forest. It is a supervised classification algorithm. It can be seen from its name, which is to create a forest by some way and make it random. There is a direct relationship between the numbers of trees in the forest and the results it can get: the larger the number of trees, the more accurate the result. But one thing to note is that creating the forest is not the same as constructing the decision with information gain or gain index approach [15].

Random Forests grows many classification trees. Each tree is grown as follows:

1. If the number of cases in the training set is N, sample N cases at random – but with replacement, from the original data. This sample will be the training set for growing the tree.
2. If there are M input variables, a number mM is specified such that at each node, m variables are selected at random out of the M and the best split on this m is used to split the node. The value of m is held constant during the forest growing.
3. Each tree is grown to the largest extent possible. There is no pruning.

There are many of top benefits of Random Forest algorithm. Some of these benefits are as follows:

- Accuracy
- Runs efficiently on large data bases
- Handles thousands of input variables without variable deletion
- Provides effective methods for estimating missing data
- Maintains accuracy when a large proportion of the data are missing

4. KDDCup 99 Dataset

The evaluation of any intrusion detection algorithm on real network data is extremely difficult mainly due to the high cost of obtaining proper labeling of network connections. Due to the real sample cannot be gotten for intrusion detection, the KDDCup'99 dataset is used as the sample to verity the performance of the misuse detection model. The KDDCup'99 dataset, referred by Columbia University, was arranged from intrusions simulated in a military network environment at the DARPA in 1998. It contains network connections obtained from a sniffer that records all network traffic using the TCP dump format. The total simulated period is seven weeks. It was performed in the MIT Lincoln Labs, and then announced on the UCI KDD Cup 1999 Archive [16].

KDDCup'99 dataset have two variations of training dataset; one is a full training set having 5 million connections and the other is 10% of this training set having 494021 connections. Since the whole dataset is huge, the experiment has been performed on its smaller amount of dataset that is 10% of KDD. Additionally, the KDDCup'99 dataset includes many attack behaviors, classified into four groups: Probe, Denial of Service (DoS), User to Root (U2R), and Remote to Local (R2L) [17]. These can be seen in table I. Normal connections are created to profile that expected in a military network. The detailed information of the two variations of training dataset can be seen in table II.

Table I: Various Attacks and Categories

Categories	Attacks Subclass
DoS	back, land, Neptune, pod, smurf, teardrop
Probe	ipsweep, nmap, portsweep, satan
U2R	buffer_overflow, loadmodule, perl, rootkit
R2L	ftp_write, guess_passwd, imap, multihop, phf, spy, warezclient, warezmaster

Table II: Number of Instances in KDD and 10% KDD

Class	Whole KDD	10 % KDD
DoS	3883370	391458
Probe	41102	4107
U2R	52	52
R2L	1126	1126
Normal	972780	97278
Total	4898430	494021

The data set includes 41 features classifying the data records into normal or a type of attacks. The features consist of 34 types of numeric features and 7 types of symbolic features, according to different properties of attack. The nature of features can be divided into the following groups [18].

- Basic Features: Basic functions can be obtained from the packet header without checking the load.

- Content Features: Domain knowledge is used to assess the original TCP packet load. This includes features such as the number of unsuccessful login attempts.
- Time-based Traffic Features: This function is designed to capture properties in the 2-second window. Examples of such functions are the number of connections to the same host every two seconds.
- Host-based Traffic Features: Use the history window to estimate the number of connections (in the case 100) and not the time. Therefore, host-based functionality is designed to assess attacks that include two or more intervals.

4.1. Pre-Processing

KDDCUP 99 data set is pre-processed in order to make it suitable for the data mining learning algorithm. Pre-processing is performed for the following reasons.

Each record in the dataset consists of categorical as well as numeric features. Textual (plain) data is used for categorical features. K-means algorithm needs numeric data (either discrete or continuous). The first step in pre-processing is to covert this categorical feature attributes to numeric attributes. For converting symbols into numerical form, an integer code is assigned to each symbol. For instance, in the case of protocol type feature, 0 is assigned to tcp, 1 to udp, and 2 to the icmp symbol and so on. The dataset contains three categorical attributes while the rest of the thirty eight attributes are numeric. Every category of an attribute is assigned a specific number.

We have used K-means and Random Forest to define normal and attacks in the system. They need specific format so we have converted the dataset to K-means and Random Forest compatible format.

5. Experimental Results and Discussion

To facilitate the experiments, we used eclipse java and weka tool to implement the algorithms on a PC with 64-bit window 7 operating system, 4GB RAM and a CPU of Intel core i3-4010U CPU with 1.70GHz. Data come from MIT Lincoln laboratory of KDDCup99 data set. The table lists the number of instances available in the whole dataset, 10% of KDDCup'99 dataset.

The analysis is performed by using K-means and Random Forest algorithms. We use K-means algorithm to generate heterogeneous dataset to nearly homogeneous dataset. The clustering results of K-means algorithm are described from table III to table VIII.

Table III: Detailed Information of Attack Categories in Cluster-1

Attacks	Total Records	Correctly Classify Records	Incorrectly Classify Records
DoS	107219	107217	2
Probe	1610	1605	5
U2R	0	0	0
R2L	6	3	3
Normal	10	3	7
Total	108845	108828	17

Table IV: Detailed Information of Attack Categories in Cluster-2

Attacks	Total Records	Correctly Classify Records	Incorrectly Classify Records
DoS	1067	1065	2
Probe	1221	1207	14
U2R	4	0	4
R2L	1	0	1
Normal	21235	21230	5
Total	23528	23502	26

Table V: Detailed Information of Attack Categories in Cluster-3

Attacks	Total Records	Correctly Classify Records	Incorrectly Classify Records
DoS	280782	280782	0
Probe	0	0	0
U2R	0	0	0
R2L	0	0	0
Normal	16	14	2
Total	280798	280796	2

Table VI: Detailed Information of Attack Categories in Cluster-4

Attacks	Total Records	Correctly Classify Records	Incorrectly Classify Records
DoS	2203	2202	1
Probe	12	1	11
U2R	46	29	17
R2L	1087	1068	19
Normal	75409	75398	11
Total	78757	78698	59

Table VII: Detailed Information of Attack Categories in Cluster-5

Attacks	Total Records	Correctly Classify Records	Incorrectly Classify Records
DoS	187	186	1
Probe	1264	1255	9
U2R	2	0	2
R2L	32	22	10
Normal	608	604	4
Total	2093	2067	26

Table VIII: Detailed Information of Attack Categories with Clustering

Attacks	Total Records	Correctly Classify Records	Incorrectly Classify Records
DoS	391458	391452	6
Probe	4107	4068	39
U2R	52	29	23
R2L	1126	1093	33
Normal	97278	97249	29
Total	494021	493891	130

By analyzing the clustering results, the characteristics of Denial of Service (DoS) attacks are mostly related to themselves in cluster-3. And then, it is closely similar to the nature of Probe attacks in cluster-1. Probe attacks are also mostly related to DoS attacks in cluster-1. And then, it is nearly same with the nature of

Normal by looking in cluster-5. Normal is mostly similar nature with User-to-Root attacks and Remote-to-Local attacks by studying in cluster-4. And then, Normal is related to Probe by studying cluster-2 and cluster-5. Normal is related to all attacks by looking in all 5 clusters because attacks mimic to normal behavior in intrusions.

Then we apply Random Forest algorithm to know the intrusions and normal traffic. The performance of attacks categories with Random Forest algorithm in 5 clusters of K-means can be seen from table IX to table XIV. The Precision and Recall of the normal and attacks detection are good and the false positive rate is nearly zero.

Table IX: Performance Analysis of Attack Categories in Cluster-1

Attacks	False Positive Rate	Precision	Recall
DoS	0.00738	0.999888	0.999981
Probe	0.000009	0.999377	0.996894
U2R	0	0	0
R2L	0.000018	0.6	0.5
Normal	0.000018	0.6	0.3

Table X: Performance Analysis of Attack Categories in Cluster-2

Attacks	False Positive Rate	Precision	Recall

6. Conclusion

This paper presents a comparative analysis hybrid machine learning technique to detect Denial of Service (DoS) attacks, Probing (Probe) attacks, User-to-Root (U2R) attacks and Remote-to-Local (R2L) attacks. We can know the similar nature of attack group by using K-means algorithm. And then we use Random Forest algorithm to classify normal and attack connections. The experiments show that, KDDCup 99 dataset can be applied as an effective benchmark dataset to help researchers compare different intrusion detection models. Future work includes analyzing with other data mining algorithms to classify attack categories and how it can detect on other real time environment dataset.

ABSTRACT

This paper is devoted to the analysis of aircraft dynamics in the cruise flight phase under windshear conditions. The study is conducted with reference to a point-mass aircraft model restricted to move in a vertical plane. We formulate the problem as a differential game against the wind disturbances: The first player, autopilot, manages, via additional smoothing filters, the aircraft's angle of attack and power setting. The second player, wind, produces disturbances that are transferred, also via smoothing filters, into most dangerous wind gusts. The state variables of the game are subject to state constraints representing aircraft safety conditions related, for example, to the altitude, path inclination and velocity. Viability theory is used to compute the so-called viability kernels, the maximal subsets of state constraints where an appropriate feedback strategy of the first player can keep aircraft trajectories arbitrary long for all admissible disturbances generated by the second player. A grid method is utilized, and challenging computations in seven dimensions are conducted on a supercomputer system.

1 Introduction

Atmospheric conditions such as windshear continue to be considered as a source of potentially severe consequences. They are dangerous for aircraft during landing or take-off, because the wind gusts can occur at relatively low altitudes. Nevertheless, windshear is also dangerous during the cruise flight phase because it can lead to violation of the prescribed flight level.

In view of threats related to wind disturbances, there is permanent interest in designing robust aircraft guidance and control schemes (possibly for use with autopilots). The related question consists in finding safety domains, i.e. sets of initial states from which the control problem can be solved in the case of worst wind disturbance whose components lie in a known range.

There exist a large number of works devoted to the problem of aircraft control in the presence of severe windshears. In particular, papers [1–6] address the problem of aircraft control during take-off in windshear conditions. In works [1] and [2], the wind velocity field is assumed to be known. It is shown that open loop controls obtained as solutions of appropriate optimization problems provide satisfactory results for rather severe wind disturbances. Nevertheless, it is clear that the spatial distribution of wind velocity cannot be measured with appropriate accuracy, and therefore feedback principles of control design are more realistic. Different types of feedback controls are proposed in papers [3–6]. In [3], the design of a feedback robust control is based on the construction of an appropriate Lyapunov function. Robust control theory is used in [4] to develop feedback controls stabilizing the relative path inclination and (in [5] and [6]) for the design of feedback controls stabilizing the climb rate.

An approach based on differential game theory (see e.g. [7]) is presented in paper [8] in connection with the problem of landing. A high dimensional nonlinear system of dynamic equations is linearized and reduced to a two-dimensional differential game using a transformation of variables. The resulting differential game is numerically solved, and optimal feedback controls are constructed and tested in the nonlinear model against a downburst.

https://dx.doi.org/10.25046/aj030161

Another method, also based on differential game theory, is used in papers [9] and [10] to find feedback controls that are effective against downbursts. This approach assumes the computation of the value function, which is a viscosity solution (see. e.g. [11] and [12]) of an appropriate Hamilton-Jacobi equation. The numerical implementation utilizes dynamic programming techniques described in [13] and [14]. The case of known wind velocity field as well as the case of unknown wind disturbances are considered.

Recent investigations [15] and [16] utilize a method (see [17]) for the fast computation of rough approximations of solvability sets in linear conflict control problems. Using techniques of sequential linearization, this method is applied to nonlinear aircraft dynamics to design an appropriate control for take-off in the presence of downbursts.

The current paper addresses the problem of retaining trajectories in an appropriate flight domain (AFD) corresponding to the cruise flight phase (cf. [18] and [19]). Viability theory (see e.g. [20]) provides numerical methods (see e.g. [21], [22], and the Appendix) for finding the viability kernel, i.e. the largest set of initial states lying in the AFD from which viable trajectories emanate. More precisely, it includes all initial states for which there exists a feedback control that generates trajectories remaining in the viability kernel for all possible admissible wind gusts. In the case where the initial state does not belong to the viability kernel, there exists a method of designing a wind disturbance such that all trajectories violate the AFD for all possible controls.

As for wind conditions, it is assumed that only bounds on the wind velocity components are imposed. The dynamics of the aircraft will be considered as a differential game (cf. [9] and [10]) where the first player chooses control inputs, whereas the second player forms the worst wind disturbance. It is assumed that the first player is able to measure the current state vector, whereas the second player can measure both the current state vector and the current control ("future" values are not available) of the first player. Therefore, the second player may use the so-called feedback counter strategies (see [7]).

The current paper has common features with the open-access publication [23] concerning the model description and solution method. It should be noted that the publication [23] is mainly focused on theoretical fundamentals of the differential game approach. Regarding computational results, paper [23] formulates a problem of constructing the viability kernel in seven dimensions and performs several steps of the algorithm to show its feasibility. In contrast, the current paper addresses aspects of implementation on large scale grid computers and completely solves the above mentioned seven-dimensional problem including simulation of optimal trajectories.

The paper is structured as follows:

Section 2 outlines a point-mass aircraft model describing the vertical motion of a generic modern regional jet transport aircraft. The model is closely related to the one described in paper [23]. The difference consists in a more clear method of deriving the dynamics equations.

In Section 3, state constraints related to the cruise flight phase are formulated, and the corresponding computed viability kernels are demonstrated through their three-dimensional sections. Additionally, trajectories yielded by an optimal feedback strategy, working against an optimal control of the disturbance, are shown. It should be noted that an optimal control of the disturbance can be constructed either as counter or pure feedback strategy because the so called saddle point condition holds for the differential game under consideration.

Section 4 outlines some aspects of parallel implementation of the computational method on a supercomputer system. The parallelization principles and data flow inside and between compute nodes are sketched. The novelty of our approach and comparison with existing software tools are discussed.

Section 6 (Appendix) briefly outlines the concept of differential games and viability kernels. Grid schemes for the computation of them are sketched. The details can be found in [23].

2 Model equations

In this section, a point-mass model representing the vertical motion of a generic modern regional jet transport aircraft is considered. Table 1 introduces euclidean coordinate systems (COS) that are necessary to compute the forces exerted on the aircraft. The origins of COSs are located either at the aircraft gravity center (CG) or at a fixed reference point (O) on the earth surface.

Table 1: Aircraft coordinate systems

COS	**Index**	***x*-axis**	**Origin**
Local	N	Parallel to the Earth's surface (x_N) and upwards (z_N)	O
Kinematic	K	In direction of $\overrightarrow{V_K}$	CG
Aerodynam.	A	In direction of $\overrightarrow{V_A}$	CG
Thrust	P	In positive direction of the symmetry axis of the turbine (aft looking forward)	CG
Body Fixed	B	In direction of the nose and in the symmetry plane of the aircraft	CG

Here, $\vec{V}_K$ and $\vec{V}_A$ are kinematic and aerodynamic aircraft velocities, respectively. The angles defining the relationship between the coordinate systems are the following (see also Figure 1):

α_K the kinematic angle of attack,
α_A the aerodynamic angle of attack,
γ_K the kinematic path inclination angle,
σ the thrust inclination angle.

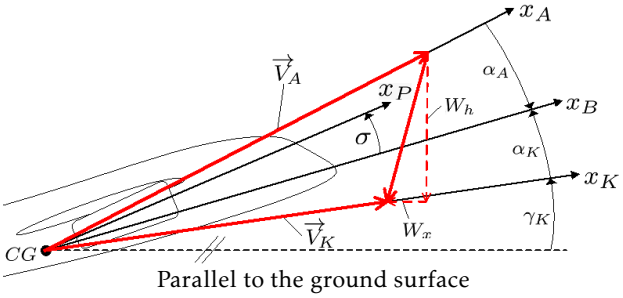

Figure 1: Aircraft coordinate systems and angles

Matrices for the transformations $K \to N$ (Kinematic to Local), $A \to B$ (Aerodynamic to Body), $B \to K$ (Body to Kinematic), and $P \to B$ (Thrust to Body) are defined as follows:

$$M_{NK} = \begin{bmatrix} \cos(\gamma_K) & -\sin(\gamma_K) \\ \sin(\gamma_K) & \cos(\gamma_K) \end{bmatrix},$$

$$M_{BA} = \begin{bmatrix} \cos(\alpha_A) & -\sin(\alpha_A) \\ \sin(\alpha_A) & \cos(\alpha_A) \end{bmatrix},$$

$$M_{KB} = \begin{bmatrix} \cos(\alpha_K) & -\sin(\alpha_K) \\ \sin(\alpha_K) & \cos(\alpha_K) \end{bmatrix},$$

$$M_{BP} = \begin{bmatrix} \cos(\sigma) & -\sin(\sigma) \\ \sin(\sigma) & \cos(\sigma) \end{bmatrix}.$$

The position propagation is given in the local coordinate system (N), whereas the translation dynamics are derived in the kinematic coordinate system (K). The model equations read as follows:

$$\dot{x}_N = V_K \cos(\gamma_K), \quad (1)$$
$$\dot{z}_N = V_K \sin(\gamma_K), \quad (2)$$
$$\dot{V}_K = \frac{X_T}{m}, \quad (3)$$
$$\dot{\gamma}_K = \frac{Z_T}{m V_K}. \quad (4)$$

Here, X_T and Z_T denote the components of the total force $\vec{F}_T$ represented in the kinematic coordinate system (K), and the notation m stands for the aircraft mass. As usually, $\vec{F}_T$ comprises aerodynamic, propulsion, and gravitation forces:

$$\vec{F}_T = \vec{F}_A + \vec{F}_P + \vec{F}_G.$$

Aerodynamic forces. They are defined as follows:

$$\vec{F}_A = M_{KB} M_{BA} \begin{bmatrix} C_D \\ C_L \end{bmatrix} \frac{1}{2} \rho V_A^2 S,$$

where C_D and C_L are the drag and lift coefficients, respectively, $\rho = \rho(h)$ is the air density (depends on the altitude), V_A the aerodynamic velocity, and S the wing reference area.

The lift and drag coefficients $C_D(\alpha_A, M)$ and $C_L(\alpha_A, M)$ are taken in the form:

$$C_D(\alpha_A, M) = c_1^D + c_2^D \alpha_A + c_3^D M + c_4^D \alpha_A^2 + c_5^D \alpha_A M + c_6^D M^2 + c_7^D \alpha_A^3 + c_8^D \alpha_A^2 M + c_9^D \alpha_A M^2, \quad (5)$$

$$C_L(\alpha_A, M) = c_1^L + c_2^L \alpha_A + c_3^L M + c_4^L \alpha_A^2 + c_5^L \alpha_A M + c_6^L M^2 + c_7^L \alpha_A^3 + c_8^L \alpha_A^2 M + c_9^L \alpha_A M^2, \quad (6)$$

where the coefficients c_i^D and c_i^L, $i = 1,...9$ are determined from least square fitting to experimental data.

The absolute value, V_A, of the aerodynamic velocity can be derived using its relation to the kinematic velocity $\vec{V}_K$ in the Local frame (N) and the wind velocities W_x and W_z in the x_N and z_N directions, respectively. Therefore,

$$V_A = \left\| (\vec{V}_K)^N - \begin{bmatrix} W_x \\ W_z \end{bmatrix} \right\|, \quad (7)$$

and finally, using the matrix M_{NK}, this implies the formula

$$V_A^2 = (V_K \cos\gamma_K - W_x)^2 + (V_K \sin\gamma_K - W_z)^2.$$

The aerodynamic angle of attack α_A is computed as follows:

$$\alpha_A = \arctan\left(\frac{w_A}{u_A}\right),$$

where u_A and w_A are x_B and z_B-components of the aerodynamic velocity, respectively.

The Mach number M is defined as follows:

$$M = \frac{V_A}{c}, \quad c = \sqrt{\kappa R T(h)},$$

where c is the speed of sound, κ the adiabatic index for air, R the gas constant for ideal gases, and $T(h)$ the temperature of air at the altitude h. See [23] for more details.

Propulsion Forces. Thrust forces are modeled considering a two-engine setup. Thus,

$$\vec{F}_P = 2 M_{KB} M_{BP} \vec{F}_{P\text{net}}, \quad \vec{F}_{P\text{net}} = \begin{bmatrix} f_V(\delta_T, M) \\ f_\gamma(\delta_T, M) \end{bmatrix},$$

where $\delta_T \in [0,1]$ is the thrust setting, and the functions f_V and f_γ are approximated similar to formulas (5) and (6), with δ_T instead of α_A. See [23] for more details.

Gravitation Force. For a simple gravitational model with constant acceleration g, the corresponding force is computed as:

$$F_G = M_{KN} \begin{bmatrix} 0 \\ -g \end{bmatrix},$$

where M_{KN} is the inverse (transpose) of M_{NK}.

The following two equations are added to the dynamics (1)-(4) to exclude jumps in the controls:

$$\dot{\alpha}_K = \widetilde{\alpha}_K, \quad \dot{\delta}_T = \widetilde{\delta}_T \tag{8}$$

Furthermore, the following equations produce smoothing of wind disturbances:

$$\dot{W}_x = -k_w(W_x - \widetilde{W}_x), \quad \dot{W}_z = -k_w(W_z - \widetilde{W}_z), \tag{9}$$

where the time constant, k_w, is chosen as $k_w = 1\,s^{-1}$.

3 Problem setting and simulation results

Problem. The model consists of equations (2), (3), (4), (8), and (9). Thus, the state vector has seven variables: z_N, V_K, γ_K, α_K, δ_T, W_x, and W_z. The controls are associated with the rate of the angle of attack, $\widetilde{\alpha}_K$, and the rate of the thrust setting, $\widetilde{\delta}_T$. Their instantaneous changes are permitted. The disturbances are now associated with the artificial variables $\widetilde{W}_x$ and $\widetilde{W}_z$ that are inputs of the filters (9). Thus, the physical wind components W_x and W_z do not exhibit instantaneous jumps.

The following constraints on the controls and disturbances are prescribed:

$$\begin{gathered}\widetilde{\alpha}_K \in [-5,5]\,\text{deg/s}, \;\; \widetilde{\delta}_T \in [-0.3,0.3]\,1/\text{s}, \\ |\widetilde{W}_x| \le 5\,\text{m/s}, \;\; |\widetilde{W}_z| \le 5\,\text{m/s},\end{gathered} \tag{10}$$

and the following state constraints are imposed:

$$\begin{aligned}&h_N := z_N - h_0 \in [-90,90]m, \\ &V_K \in [100,200]\,\text{m/s}, \;\; |\gamma_K| \le 10\,\text{deg}, \\ &\alpha_K \in [0,16]\,\text{deg}, \;\; \delta_T \in [0.3,1],\end{aligned} \tag{11}$$

where $h_0 = 10000\,\text{m}$ being the cruise flight altitude.

Additionally, the state constraints $|W_x| \le 5\,\text{m/s}$ and $|W_z| \le 5\,\text{m/s}$ hold automatically because of equations (9) and the constraints (10).

In the numerical construction, the box $[-100,100]\times[90,210]\times[-15,15]\times[-4,20]\times[0.2,1.2]\times[-6,6]\times[-6,6]$ of the space $(h_N, V_K, \gamma_K, \alpha_K, \delta_T, W_x, W_z)$ was divided in $200\times120\times30\times24\times14\times12\times12$ grid cells. The sequence of time steps, $\{\delta_\ell\}$, was chosen as $\delta_\ell \equiv 0.01$, and the computations were performed until $\left|\mathcal{V}^h_{\ell+1} - \mathcal{V}^h_\ell\right| \le 10^{-5}$ for all grid nodes. Totally, 4471 steps of the algorithm (19) were done. The computation has been done on the SuperMUC system at the Leibniz Supercomputing Centre of the Bavarian Academy of Sciences and Humanities. The computation was distributed over 100 compute nodes with 16 cores per node, which is regarded as "middle task" on the SuperMUC system. The runtime was about 40 h.

Figures 2-4 show different three-dimensional sections of the seven-dimensional viability kernel. Figures 5-7 respectively demonstrate the same three-dimensional sections and the corresponding projections of two optimal trajectories emanating from points lying in the viability kernel. The start point of trajectory 0 lies near to the boundary of the viability kernel, whereas trajectory 1 starts from a point lying deep inside of the viability kernel. The trajectories are computed when the control uses its optimal feedback strategy, and the disturbance utilizes its optimal counter feedback strategy (see the Appendix). The time step size used in the simulation of the trajectories was equal to 0.01. It is seen that the trajectories go to their attraction cycles and remain there. The simulation time interval is $[0, 15\,\text{min}]$. Figure 8 shows a three-dimensional section of a smaller viability kernel corresponding to the shrinkage of the state constraints (11) by the factor 0.7. The corresponding three-dimensional projection of two optimal trajectories are shown. It is seen that the disturbance can keep trajectory 0 outside the reduced viability kernel because the start point lies outside of it.

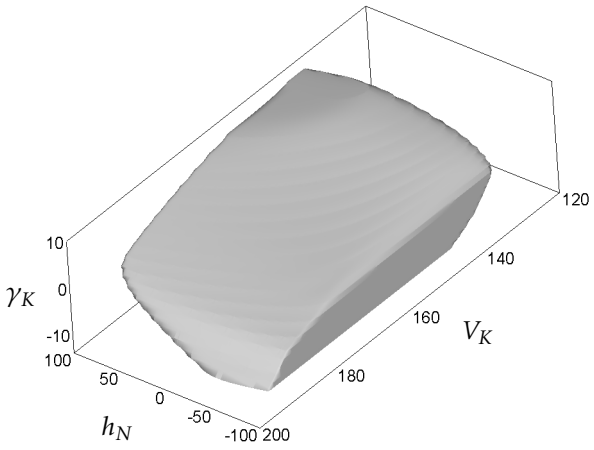

Figure 2: A three-dimensional section of the viability kernel: $\alpha_K = 8$, $\delta_T = 0.65$, $W_x = 0$, and $W_z = 0$.

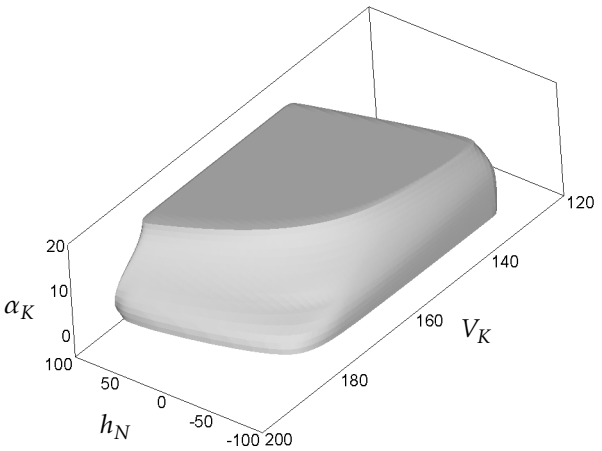

Figure 3: Another three-dimensional section of the viability kernel: $\gamma_K = 0$, $\delta_T = 0.65$, $W_x = 0$, and $W_z = 0$.

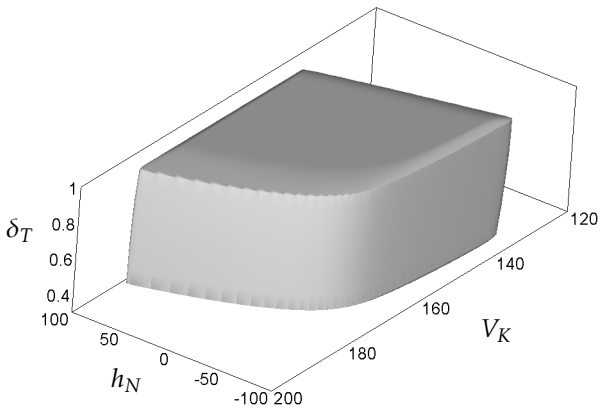

Figure 4: One more three-dimensional section of the viability kernel: $\gamma_K = 0$, $\alpha_K = 8$, $W_x = 0$, and $W_z = 0$.

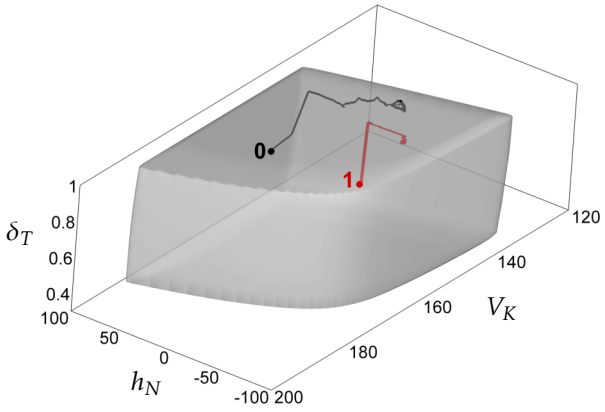

Figure 7: The same section as in Figure 4 and projections of the same two trajectories as in Figure 5.

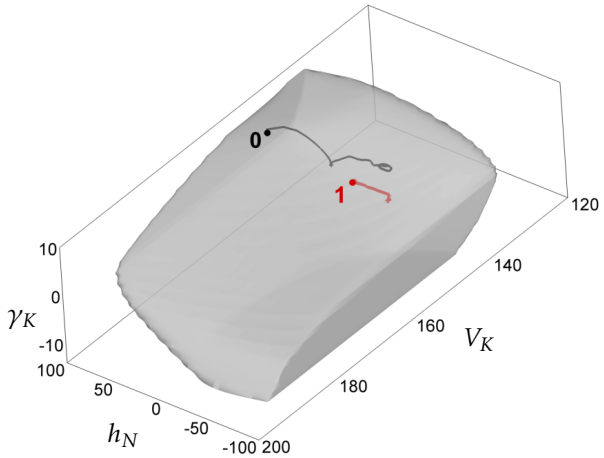

Figure 5: The section from Figure 2 and projections of two trajectories generated by an optimal feedback strategy of the control and an optimal counter feedback strategy of the disturbance. The start points are marked with bullets.

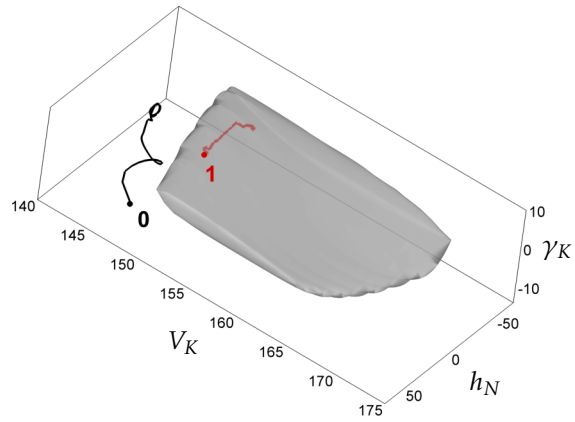

Figure 8: The section ($\alpha_K = 8$, $\delta_T = 0.65$, $W_x = 0$, and $W_z = 0$) of a smaller viability set corresponding to the shrinkage of the state constraints by the factor of 0.7. Projections of the same trajectories as in in Figure 5 are shown. Since the start point 0 does not belong to this viability set, the disturbance can keep the trajectory outside of it.

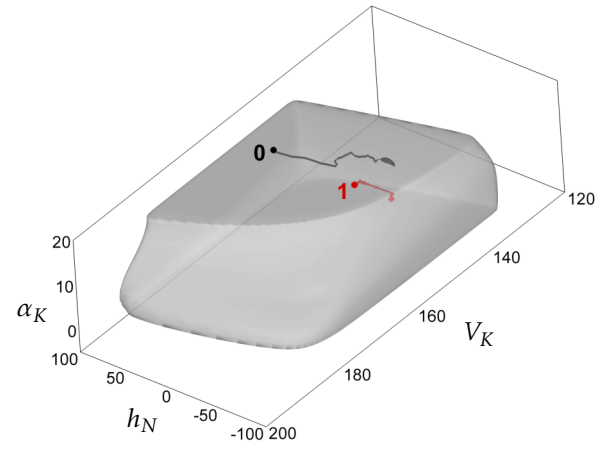

Figure 6: The same section as in Figure 3 and projections of the same two trajectories as in Figure 5.

4 Implementation Aspects

4.1 Grid Computing, Parallelization and Scaling

We use a self developed software code to implement the algorithms of the grid scheme outlined in Appendix 6.3. The code is parallelized using a mixed MPI/OpenMP technique. The first two dimensions of the grid are decomposed, whereas the other dimensions remain unmodified. A compute node cartesian topology (see Figure 9) is then created such that each compute node corresponds to a grid cylinder. Additionally, each grid cylinder is supplied with ghost nodes that allow us to compute divided differences (18) used e.g. in the algorithm (19). In Figure 9, the

lines connecting the compute nodes show the data flow supported by MPI. The parallelization inside of each compute node (i.e. inside a grid cylinder) is supported by OpenMP.

The problem considered in this paper deals with a seven-dimensional grid of 200×120×30×24×14×12×12 cells. Each of the first two dimensions was divided into 10 parts. Thus, there were 100 grid cylinders, each of size $20 \times 12 \times 30 \times 24 \times 14 \times 12 \times 12$, plus the necessary ghost grid nodes. Therefore, the required memory per compute node was equal to about 8 GB.

Our observations show a good scaling behavior (see Table 2). The results were obtained for the problem of computing the viability kernel in five dimensions on a $200 \times 120 \times 30 \times 24 \times 14$ grid. The relative speedup normalized to 32 cores and absolute timing of 30000 steps are shown.

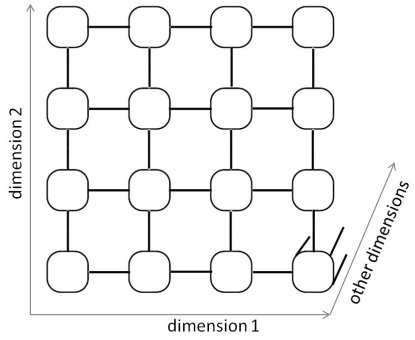

Figure 9: Compute node cartesian topology used in our applications.

Table 2: Scaling behavior of the code

# of cores	Linear prediction of scaling	Observed scaling	Wall time [h]	Performance/core [GFlop/s]
32	1	1	9.7	20
128	4	3.5	2.8	17.5
1600	50	38	0.25	15.2

4.2 Novelty of the method used

This paper utilizes a new method for computing viability kernels, which is based on the results of paper [21]. It is proven in [21] that the viability kernel is the Hausdorff limit of the sets $\{x : V(x,t) \le 0\}$ as $t \to -\infty$, where $V(x,t)$ is the value function (see [7]) of a state constrained differential game .

The numerical implementation of this method requires a theoretical basis and a stable numerical procedure for the treatment of transient Hamilton-Jacobi equations related to differential games with state constraints. Such a theoretical basis is given in paper [13] where the conventional conditions for viscosity solutions are modified to account for state constraints. This theoretical background is numerically implemented in [13] and [14], which results in monotone stable grid scheme (17) and (19). This enables us to perform a large number of time steps, usually several thousands.

Another new feature is that the corresponding software code is deeply parallelized using hybrid MPI/OpenMP techniques and adapted to run on a supercomputer system. Moreover, diverse modified variants of the code, based on sparse representations of grid functions, are tested.

4.3 Comparison with existing software

The well known software for solving Hamilton-Jacobi equations is the Level Set Method Toolbox (LSMT) described in [24]. This tool is really appropriate for solving rather general problems. However, it is not indicated in the manual whether the LSMT can compute viability kernels for differential games with *state constraints*. Moreover, according to the manual, the LSMT is not parallelized, whereas our software runs on a multi-node system.

5 Conclusion

This investigation shows that methods of differential games theory and viability theory can by applied to nonlinear aircraft models to investigate potential control abilities in the presence of wind disturbances. The new feature of our approach is the consideration of viability kernels for differential games. Feedback strategies of the players can be found from limiting grid "value functions" defining viability kernels (cf. Appendix). It is important that the amount of stored data is relatively small, which permits to implement the computed feedback strategies on a flight simulator. Further research will be focused on the treatment of models with more state variables, which will allow us to consider more realistic problems. Moreover, accounting for additional sources of uncertainty such as sensor errors or modeling uncertainties is planned.

6 Appendix

This section briefly summarizes a method presented in [23] for computing viability kernels. Such a summary should help to provide a self-contained presentation.

6.1 Differential game

Consider a conflict control system with the autonomous dynamics

$$\dot{x} = f(x,u,v),\ x \in R^n,\ u \in P \subset R^p,\ v \in Q \subset R^q. \quad (12)$$

Here; x stands for the state vector; u and v denote control inputs of the first and second players, respectively; and the compact sets P and Q describe constraints imposed on the control and disturbance variables, respectively. Further, it is assumed that all functions of x have global properties. For example, the right-hand side f is supposed to be bounded, continuous, and Lipschitzian in x on $R^n \times P \times Q$.

In the following, it is assumed that the Isaacs saddle point condition

$$\min_{u\in P}\max_{v\in Q}\langle s, f(x,u,v)\rangle = \max_{v\in Q}\min_{u\in P}\langle s, f(x,u,v)\rangle, \quad (13)$$

is true for all $s \in R^n$ and $x \in R^n$. Note that this condition holds for the problem under consideration because controls and disturbances are additively separated in the model equations.

6.2 Viability kernel

For any $v \in Q$, consider the differential inclusion

$$\dot{x} \in F_v(x) = \overline{\text{co}}\{f : f(x,u,v), u \in P\} \quad (14)$$

Let $G \subset R^n$ be a compact set such that $G = \overline{\text{int}\, G}$, this set will play the role of the state constraint. Let T be an arbitrary fixed time instant, and $N = (-\infty, T] \times G$. For any subset $W \subset N$ and any time instant $t \le T$, define the time section of W through the relation $W(t) := \{x \in R^n : (t,x) \in W\}$.

Definition 1 (u-stability property [7]) *A set $W \subset N$ is called u−stable on $(-\infty, T]$ if for any position $(t_*, x_*) \in W$, for any time instant $t^* \in [t_*, T]$, for any fixed $v \in Q$, there exists a solution $x(\cdot)$ of the differential inclusion (14) with the initial condition $x(t_*) = x_*$ such that $(t^*, x(t^*)) \in W$.*

The next proposition is taken as a basis of the definition of viability kernels.

Proposition 1 *[see [21] for the proof] Let W be a maximal u-stable subset of $N = (-\infty, T] \times G$. If $W(t) \neq \varnothing$ for any $t \le T$, then the set*

$$K = \bigcap\nolimits_{t\le T} W(t)$$

is nonempty, and $W(t) \to K$ in the Hausdorff metric as $t \to -\infty$. The set K is called the viability kernel of G and denoted by $Viab(G)$.

Proposition 2 *Let $\bar{t} > 0$ be an arbitrary time instant, and $x_* \in Viab(G)$. Then there exists a feedback strategy $\mathcal{A}(x)$ of the first player such that all trajectories yielded by $\mathcal{A}$ and started at $t = 0$ from x_* remain in the set $Viab(G)$ for all $t \in [0, \bar{t}]$ and any actions of the second player. If $x^* \notin Viab(G)$, then there exists a feedback strategy $\mathcal{B}(x)$ and a time instant t_f such that all trajectories yielded by $\mathcal{B}$ and started at $t = 0$ from x^* violate the state constraint G for $t > t_f$ and any actions of the first player.*

6.3 Grid method for computing viability kernels

For the implementation of numerical method, it is convenient to represent viability kernels as level sets of an appropriate function. Let G_λ be a family of state constraint sets defined by the relation

$$G_\lambda = \{x \in R^n, g(x) \le \lambda\}, \quad (15)$$

where a continuous function g is chosen in such a way that, e.g., G_0 being the desired state constraint. It is necessary to construct a function V representing the viability kernels as follows:

$$Viab(G_\lambda) = \{x \in R^n, V(x) \le \lambda\}. \quad (16)$$

Such a function can be computed as a limiting solution, as $t \to -\infty$, of an appropriate Hamilton-Jacobi equation arising from conflict control problems with state constraints (see [13]). A grid approximation of V is computed as described below (cf. [21], [22], and [23]).

Let $\delta > 0$ be a time step length, and the tuple $h := (h_1, ..., h_n)$ defines space step sizes. Set $|h| := \max\{h_1, ..., h_n\}$ and introduce the following upwind operator defined on grid functions related to the discretization h:

$$\Pi(\phi;\delta,h)(x) = \phi(x) + \delta \min_{u\in P}\max_{v\in Q}\sum_{i=1}^{n}(p_i^{\text{right}} f_i^{+} + p_i^{\text{left}} f_i^{-}), \quad (17)$$

with f_i being the components of $f(x,u,v)$, and

$$\begin{aligned} &a^+ = \max\{a, 0\}, \quad a^- = \min\{a, 0\}, \\ &p_i^{\text{right}} = [\phi(x_1, ..., x_i + h_i, ..., x_n) - \phi(x_1, ..., x_i, ..., x_n)]/h_i, \\ &p_i^{\text{left}} \ = [\phi(x_1, ..., x_i, ..., x_n) - \phi(x_1, ..., x_i - h_i, ..., x_n)]/h_i. \end{aligned} \quad (18)$$

Let $\{\delta_\ell\}$ be a sequence of positive reals such that $\delta_\ell \to 0$ and $\sum_{\ell=0}^{\infty}\delta_\ell = \infty$. Consider the following grid scheme:

$$\mathcal{V}^h_{\ell+1} = \max\left\{\Pi\left(\mathcal{V}^h_\ell; \delta_\ell, h\right), g^h\right\}, \ \mathcal{V}^h_0 = g^h, \quad \ell = 0, 1, \ldots, \quad (19)$$

where g^h is the restriction of g to the grid defined by h.

It can be proven that $\mathcal{V}^h_\ell$ monotonically converges point-wise to a grid function $\mathcal{V}^h$, and this function define approximations of the viability kernels according to formula (16), see [23] for more details.

Remark 1 *In (17), the operation $\min_{u\in P}\max_{v\in Q}$ can be changed for $\max_{v\in Q}\min_{u\in P}$ to obtain almost the same result. The difference tends to zero with $|h|$. The proof follows from the fact that the original operator (17) and the modified one satisfy the same consistency condition (see [13]) involving the following Hamiltonian H:*

$$H(x,p) := \max_{v\in Q}\min_{u\in P}\langle p, f(x,u,v)\rangle = \min_{u\in P}\max_{v\in Q}\langle p, f(x,u,v)\rangle.$$

Numerical computations confirm this observation.

6.4 Control design

This section outlines one of possible methods of control design. Consider the grid scheme (19) assuming that ℓ is large enough so that the required approximation is reached, i.e. $\left|\mathcal{V}^h_{\ell+1} - \mathcal{V}^h_{\ell}\right|_{L_\infty} \le \epsilon$.

The optimal control u and the worst disturbance $v(u)$ at the current state x of the game can be found as solutions of the following program:

$$u, v \to \min_{u\in P} \max_{v\in Q} \mathcal{L}^h\Big[\mathcal{V}^h_\ell\Big]\Big(x + \tau f(x,u,v)\Big). \qquad (20)$$

Here, $\mathcal{L}^h$ is an interpolation operator (see e.g. [14]) defined on the corresponding grid functions, and τ being a parameter which should be several times larger than the time step size of the simulation procedure to provide some stabilization. Note that the function $\mathcal{V}^h_\ell$ can be transferred to a sparse grid (see e.g. [25] and [26]), which may essentially reduce the storage space. The disadvantage of such a technique is a certain loss of accuracy and a slower performance.

Remark 2 *As it is described above, the second player uses the so-called feedback counter strategies, i.e. functions of x and u, where u being the current control action of the first player. Since the saddle point condition (13) holds, the theory of differential games says that the second player can achieve the same result using pure feedback strategies, i.e. functions of x. For example, a near optimal strategy of the second player can be obtained as a solution of the problem*

$$u, v \to \max_{v\in Q} \min_{u\in P} \mathcal{L}^h\Big[\mathcal{V}^h_\ell\Big]\Big(x + \delta f(x,u,v)\Big),$$

see also Remark 1. Thus, the both players achieve optimal results using pure feedback strategies.

Remark 3 *If u and v appear linearly in the right-hand side of (12), then* min *and* max *operations in (17) and (20) can be computed only over extreme points of the sets P and Q respectively. This can be proven using the same arguments as in Remark 1.*

Remark 4 *If x_0 being a start point of the game, then x_0 lies in the approximate viability kernel defined as:*

$$\{x \in R^n : \mathcal{V}^h_\ell(x) \le \mathcal{V}^h_\ell(x_0)\},$$

and all trajectories approximately remain in this set. However, if the second player works non-optimally for a while, then, most likely, $\mathcal{V}^h_\ell(x(\bar{t})) < \mathcal{V}^h_\ell(x_0)$ for some $\bar{t} > 0$, and therefore, the state vector $x(\bar{t})$ lies now in the smaller viability kernel

$$\{x \in R^n : \mathcal{V}^h_\ell(x) \le \mathcal{V}^h_\ell(x(\bar{t}))\}.$$

Thus, faults of the second player improve the result of the first one.

Conflict of Interest The authors declare no conflict of interest.

ABSTRACT

Mobile broadband has gained momentum with the growing demand of user data rates. Long Term Evolution (LTE) technology is the step in mobile communications evolution, developed to satisfy high data rate demand, and meet better spectral efficiency requirements. Effective radio resource management and inter cell interferences are the major challenges. Fractional Frequency Reuse (FFR) is one of the effective interference avoidance mechanisms applied to LTE networks to yield optimal throughput. In this extended paper, we propose a novel performance metric, weighted throughput on user satisfaction, and evaluate an existing adaptation process that dynamically adjusts to optimal network performance determined by FFR mechanism with mobile users. The performance of FFR mechanism with mobility model, adaptation process, and femtocell densification is evaluated and optimized for proposed metric and other metrics. Results optimized by proposed metric show comparatively higher average throughput and lower variance among user throughput.

1 Introduction

Orthogonal Frequency Multiple Access (OFDMA) offers great spectrum efficiency and flexible frequency allocation to users. However, in LTE OFDMA networks the system performance is severely hampered by the Inter-Cell Interference (ICI) due to the frequency reuse, where the cell edge users will experience high interferences from neighboring cells.

FFR is one of the interference management techniques which require minimal or no coordination among the adjacent cells. The basic mechanism of FFR is to partition the macrocell area into spatial regions and each sub-region is assigned different frequency sub-bands for users. In [1, 2], the user satisfaction metric introduced by the authors is evaluated for users' mobility and the performance is compared with other reuse schemes. The authors propose a dynamic mechanism that selects the optimal FFR scheme based on the user satisfaction metric. The proposed mechanism is evaluated through several simulation scenarios that incorporate users' mobility and its selected FFR scheme is compared with other frequency reuse schemes in order to highlight its performance. The research is further enhanced in [3] where cell edge reuse factor is set to 1.5 and results are generated to determine the optimal inner radius and frequency allocation. In [4, 5], a performance study is carried out, where FFR partitions each cell into two regions; inner region and outer region, and allocates different frequency band to each region based on reuse factor. In [6], a frequency reuse technique is proposed which aims at maximizing throughput via combinations of inner cell radius and frequency allocation to the macrocell. In this work, the authors study the interference mitigation techniques in femtocell/macrocell networks and proposed a FFR mechanism that leads to increased overall system performance. Work in [7] proposes a mechanism that selects the optimal FFR scheme based on the user throughput and user satisfaction. In [8, 9], authors present a FFR optimization scheme based on capacity density (bit/s/m^2), which show better performance compared to conventional Reuse-1 and Reuse-3 schemes. The authors formulate an optimization problem and solve it by simulation. Graph theory and similar optimization techniques are presented in [10], a graph-based framework for dynamic FFR in multi-cell OFDMA networks is proposed in this work. The proposed scheme enhances the conventional FFR by

https://dx.doi.org/10.25046/aj030162

enabling adaptive spectral sharing per cell load conditions. Such adaptation has significant benefits in a practical environment, where traffic load in different cells may be asymmetric and time-varying. Work in [11, 12] provides analysis of the inter cell interference coordination problem in multi-cell OFDMA systems. In order to reduce the interference without losing much frequency resources in each cell, cell users are partitioned into two classes, interior and exterior users. Results determine the optimal configuration of the interior and exterior regions' dimensions as well as the optimal frequency reuse factor.

Authors in [13] use two-stage heuristic approach to find optimal frequency partitioning. The authors intend to propose the FFR scheme by introducing the concept of normalized Spectral Efficiency (nSE). With the optimal Frequency Reuse Factor (FRF), the FFR scheme can maximize the system SE with throughput improvement of cell-edge users. To solve the problem, they divide it into two sub-problems. However, this scheme is asymptotically optimal with the assumption of the uniform distributions of signal and interference in sectors. The simulation results demonstrate the gain of the system SE is about 3% by proposed FFR scheme. The goal in work in [14] is to improve the cell edge throughput as well as the average cell throughput, compared to a network with frequency reuse factor 1. The cell capacity under those reuse schemes is estimated and compared. To attain both high spectral efficiency and good coverage within sectors/beams, a scheme based on coordinated scheduling between sectors of the same site, and the employment of frequency reuse factor above 1 only in outer parts of the sector, is proposed and evaluated. The resulting sector throughput increases with the number of active users. When terminals have one antenna and channels are Rayleigh fading, it results in a sector payload capacity between 1.2 (one user) and 2.1 bits/s/Hz/sector (for 30 users) in an interference-limited environment [15]. In [16], the authors review some of the recent advances in ICI research and discuss the assumptions, advantages, and limitations of the proposed mechanisms. They propose a scheduling algorithm to schedule users based on channel quality and quality of service (QoS) metrics.

Authors in [17] investigate an OFDMA radio resource control (RRC) scheme, where RRC control is exercised at both RNC and base stations. In [18], the authors present an analytical solution to carry out performance study of various frequency reuse schemes in an OFDMA based cellular network. Results of performance study show that results obtained through analytical method are in conformity with those obtained through simulations. In [19], the authors analyze the FFR scheme and propose a dynamic FFR mechanism that selects the optimal frequency allocation based on the cell total throughput and user satisfaction.

Extensive work is done to optimize network performance of FFR mechanism [20]. FFR and exploitation of the channel state information at the transmitter (CSIT) are effective approaches to improving the spectrum efficiency of the outer coverage region. When channels vary within a physical transmission frame, the above improvement is substantially suppressed. To remedy this, work in [21] develops new FFR patterns for OFDMA systems with frequency or time division duplexing (FDD/TDD) in time-varying channels. Simulation results show significant performance gains of the proposed schemes over the existing ones. A semi-centralized joint cell muting and user scheduling scheme for interference coordination in a multi-cell network is proposed under two different temporal fairness criteria. The authors in [22] propose a general pattern set construction algorithm in this paper. Numerical results are provided to validate the effectiveness of the proposed scheme for both criteria. The impact of choice of the cell muting pattern set is also studied through numerical examples for various cellular topologies. Densely deployed cellular wireless networks, which employ small cell technology, are being widely implemented. Authors in [23, 24] aim to maximize the system's throughput through the employment of FFR schemes. The authors derive the optimal configuration of the FFR scheme and evaluate the systems performance behavior under absolute and proportional fairness requirements. Table 1 shows comparison between previous published work and paper contributions.

Table 1: Comparison

Parameter	Previous Work	Current Paper
Throughput variance	High	Low
Femtocells adaptation	Minimal	High

This paper evaluates the performance of the sectorized FFR mechanism with five metrics; four existing and one proposed, which determine the values for inner region radius and frequency allocation for optimal results. For a specific mobility model, an adaptation process is applied to the FFR mechanism optimized for each of the five metrics and its performance is evaluated. Results are also generated and evaluated for non-adaptation process for the same network. Results prove that the proposed metric shows lower variance in user throughput compared to the other metrics from previous published work. The optimized FFR mechanism shows reacting to the adaptation process with user mobility even with the addition of femtocells.

2 FFR Mechanism

The topology of Figure 1 consists of 16 cells with four non-overlapping resource sets. Each cell of the topology is divided into two regions; inner and outer region. The total available bandwidth of the system is split

into four uneven spectrum, denoted by A (blue), B (green), C (red) and D (yellow). Spectrum A, B, and C have equal bandwidth and are allocated in outer regions with Frequency Reuse 3. On the other hand, spectrum D is allocated in all inner regions with Frequency Reuse 1. The frequency resources in all inner regions are universally used, since the inner region users are less exposed to ICI.

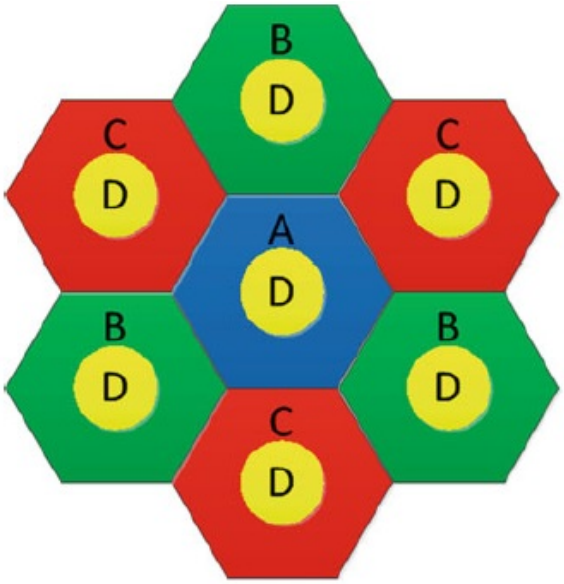

Figure 1: Strict FFR Deployment in LTE Macrocell Deployment [4]

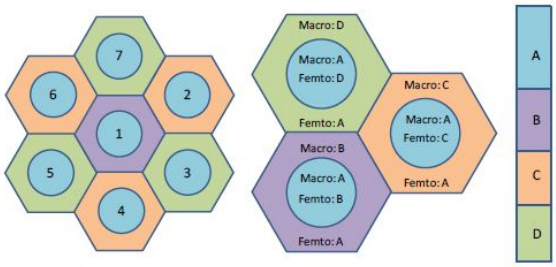

Figure 2: Strict FFR Deployment in LTE Macrocell-Femtocell Deployment [25]

From user's perspective, Integer Frequency Reuse (IFR) can be regarded as a special case of FFR. In IFR, all resource blocks (RBs) allocated to a cell can be used anywhere in the cell without any specification of user's location. For comparison, the FFR scheme that is selected by adaptive mechanism is compared with variations of IFR. The macrocell coverage area is partitioned into center-zone and edge-zone. The entire frequency band is divided into two parts, one part is solely assigned to the center-zone (e.g., sub-band A in Figure 1) and the other part is partitioned into three subbands (e.g., sub-bands B, C, and D) and assigned to the three edge-zones [26]. Figure 2 shows the Strict FFR network layout for integrated macrocell-femtocell deployment. Note that femtocell uses different frequency bands than the overlay macrocell to minimize or eliminate the inter-tier interference in the network.

3 System Model

A set of multicast users are uniformly distributed in the grid of 16 macrocells. In order to find the optimal inner region radius and frequency allocation in the deployment, the mechanism divides each cell into two regions and calculates the total throughput for the following 40 Frequency Allocations (FA), assuming Frequency Reuse 1 and x for inner and the outer regions respectively [26], where x is the frequency reuse factor of 3. Each FA corresponds to paired value of fraction of inner region resource blocks and inner region radius.

- FA1: All 25 resource blocks are allocated in inner region. No resource blocks are allocated to the outer region.
- FA2: 24 resource blocks are allocated in inner region. $1/x$ resource block allocated to the outer region.
  ⋮
- FA39: 1 resource block allocated in inner region. $24/x$ resource blocks allocated to the outer region.
- FA40: No resource blocks are allocated in inner region. $25/x$ resource blocks allocated to the outer region.

For each FA, the mechanism calculates the total throughput, user satisfaction, user fairness, and weighted throughput values based on new metrics. This procedure is repeated for successive inner cell radius (0 to R, where R is the cell radius). The mechanism selects the optimal FFR scheme that maximizes the cell total throughput. This procedure is repeated periodically in order to take into account users' mobility. Therefore, the per-user throughput, the cell total throughput, User Satisfaction (US), and other metrics are calculated in periodic time intervals (the exact time is beyond the scope of this manuscript) and at each time interval, the FFR scheme that maximizes the above parameters is selected. This periodic process is called adaptation [28]. The system model described above can be used for supported LTE bandwidths ranging from 1.4 MHz to 20 MHz.

The signal-to-interference-plus-noise (SINR) for downlink transmission to macro user x on a subcarrier n can be expressed as,

$$SINR_{x,n} = \frac{P_{M,n} G_{x,M,n}}{N_0 \Delta f + \sum_{M'} P_{M',n} G_{x,M',n}} \quad (1)$$

where, $P_{M,n}$ and $P_{M',n}$ is transmit power of serving macrocell M and neighboring macrocell M' on subcarrier n, respectively. $G_{i,M,n}$ is channel gain between macro user i and serving macrocell M on subcarrier n and $G_{i,M',n}$ corresponds to channel gain from neighboring macrocell M'. Finally, N_0 is white noise power spectral density and Δf is subcarrier spacing.

The channel gain G, given by the following equation is dominantly affected by path loss, which is assumed to be modeled based on urban path-loss PL is defined as,

$$G = 10^{-PL/10} \tag{2}$$

Additionally, for the throughput calculation, the capacity of a user i on a specific subcarrier n can be estimated via the $SINR$ from the following equation,

$$C_{i,n} = W \cdot \log_2(1 + \alpha \cdot SINR_{i,n}) \tag{3}$$

where, W denotes the available bandwidth for each subcarrier divided by the number of users that share the specific subcarrier and α is a constant for a target bit error rate (BER) defined by $\alpha = -1.5/ln(5 \cdot BER)$. Here, BER is set to 10^{-6}.

The expression of the total throughput of the serving macrocell M is given as follows,

$$T_i = \sum_n \beta_{i,n} C_{i,n} \tag{4}$$

where, $\beta_{i,n}$ represents the subcarrier assigned to user i. When $\beta_{i,n}$=1, the subcarrier is assigned to user i. Otherwise, $\beta_{i,n}$=0.

4 Mobility Model

This paper evaluates network performance in a scenario with mobile users in the highlighted cell of the topology presented in Figure 3. During the experiment that lasts for 217 seconds, 24 users of the examined cell are moving randomly inside the cell with speed 3 km/h, according to the Pedestrian A channel model [27]. It is assured that all of them remain into the cell's area, ensuring that their total number will remain constant. This corresponds to low mobility scenario with zero to minimal handover.

5 Performance Metrics

The paper evaluates the network performance for adaptive and non-adaptive FFR mechanisms with user mobility. For comparison, the adaptive FFR scheme that is selected by proposed mechanism is compared with three different cases. The first case, where the optimal inner radius and frequency allocation remain constant through the adaptation process, is referred to FFR non-adaptive. The second case, where the cell bandwidth equals the whole network bandwidth, is called IFR with frequency reuse 1 (IFR1). In the third case, the inner region radius is zero and each cell uses one third of the networks bandwidth. This case is called IFR with frequency reuse 3 (IFR3). The difference with the IFR1 case, lies in the fact that only co-channel base station are considered in interference calculation and as a consequence, the interference base station density is divided by 3.

5.1 Existing Metrics

This paper uses a metric US defined by authors in [28]. It is calculated as the sum of the users' throughput divided by the product of the maximum user's throughput and the number of users (X). US ranges between 0 and 1. When US approaches 1, all the users in the corresponding cell experience similar throughput. However, when US approaches 0, there are huge differences in throughput values across the users in the cell. This metric will be utilized in scenarios where fairness to the users is significant such as cell throughput and Jain fairness index.

$$US = \frac{\sum_{x=1}^{X} T_x}{max_user_throughput \cdot X} \tag{5}$$

With metric WT defined by the authors in [28], the aim is to not only generate low variance of the per-user throughput values but also obtain higher values of the cell total throughput.

$$WT = JI \cdot T \tag{6}$$

where T is the cell mean throughput.

To obtain a metric of fairness for performance evaluation, the Jain fairness metric introduced in [29] is used. Assuming the allocated throughput for user i is x_i, Jain fairness index for the cell is defined as,

$$JI = \frac{(\sum_{i=1}^{X} x_i)^2}{X \cdot \sum_{i=1}^{X} x_i^2} \tag{7}$$

This metric is interesting for the evaluation of the proposed method due to its properties. It is scale-independent, applicable for different number of users and it is bounded between [0, 1], where 0 means "total unfairness" and 1 means "total fairness" in terms of throughput division among the users.

5.2 Proposed Metric

This section introduces a new metric, weighted throughput based on user satisfaction WT_{US}, to add weights to the cell throughput corresponding to specific inner radius and inner bandwidth such that the resultant throughput is higher than the corresponding throughput optimized at user satisfaction alone and all the users in the corresponding cell experience similar throughput.

$$WT_{US} = US \cdot T \tag{8}$$

From (6), (8), it is clear that the metrics are cell-based.

6 Performance Evaluation

6.1 Mathematical Model

The product model is applied as mathematical model in the new metric definition and development. Previous metric, weighted throughput, adds the benefits

of the individual component metrics, throughput and fairness index. Similarly, the proposed metric defined by the product model of throughput and user satisfaction, is expected to perform better than the individual component metrics.

6.2 Simulation Parameters

Table 2 are parameters set for simulation.

Table 2: Simulation Parameters

Parameter	Value
System Bandwidth	5 MHz
Subcarriers	300
Subcarrier Bandwidth	180 KHz
Cell Radius	250 m
Inter eNodeB distance	500 m
Noise Power Spectral Density	-174 dBm/Hz
Subcarrier spacing	15 KHz
Channel Model	Typical Urban
Carrier Frequency	2000 MHz
Number of macrocells	16
Macrocell Transmit Power	46 dBm
Path Loss	Cost 231 Hata Model
Users' speed	3 km/h PedA

A sample uniform deployment considered in simulation is shown in Figure 3. Macrocells are located at cell centers. Active users are randomly distributed and are shown with white dots.

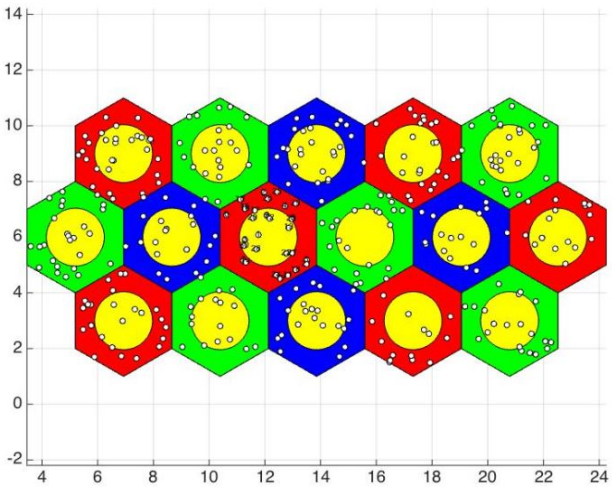

Figure 3: Strict FFR Uniform Deployment for Simulation

6.3 Simulation Guidelines

Note that the simulation is run assuming a stable downlink data traffic, since the simulation framework is analyzing data for downlink traffic. A network snapshot where user association to macrocell remains stable for the duration of the simulation run is considered as the users are associated to the base stations with maximum SINR. A frequent handover will occur in high mobility environment and that is not included in the scope of this paper. The simulation software for our research is based on [30].

6.4 Performance Analysis

6.4.1 Comparison of New Metric to Other Metrics

The new metric is introduced due to the following reasons, better performance in terms of average user throughput and effective user fairness in terms of variance in user throughput. Figure 4 proves the user throughput optimized with new metric shows better performance and low variance.

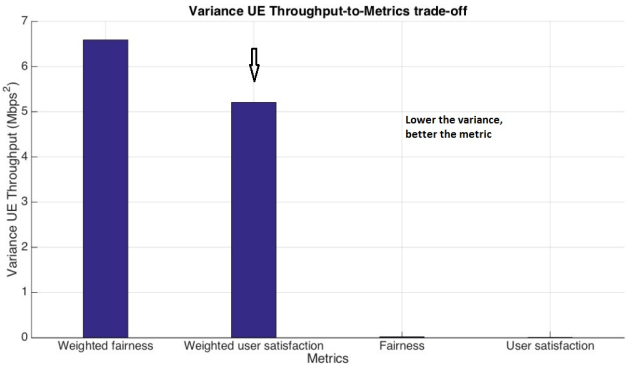

Figure 4: Comparison of Variance in User Throughput

6.4.2 Static Users - Metric Performance

Simulation is carried out by applying the metrics on users with static positions and performance is evaluated with respect to inner region subcarriers and inner region radius. Figures 5 - 8 show the metric performance with respect to inner region subcarriers. Figures 9 - 12 show the metric performance with respect to inner region radius.

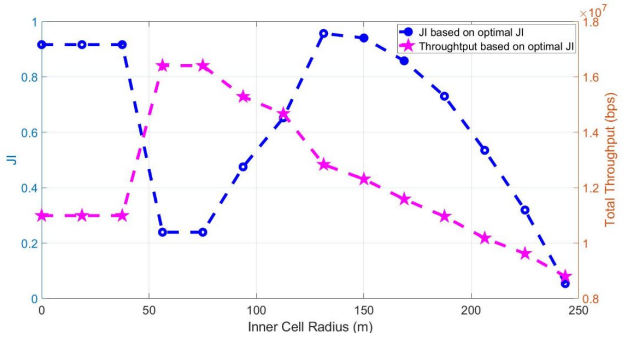

Figure 10: Fairness Index Metric Performance for Static Users to Inner Region Radius

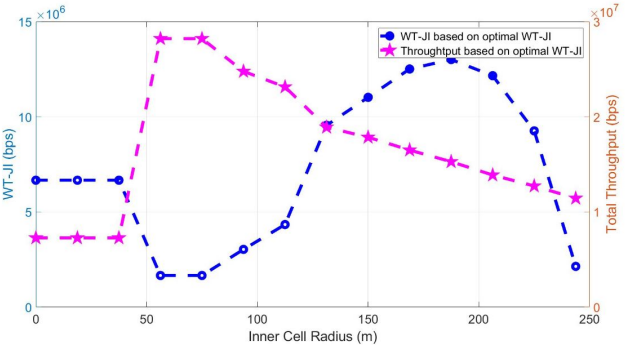

Figure 11: Weighted Fairness Metric Performance for Static Users to Inner Region Radius

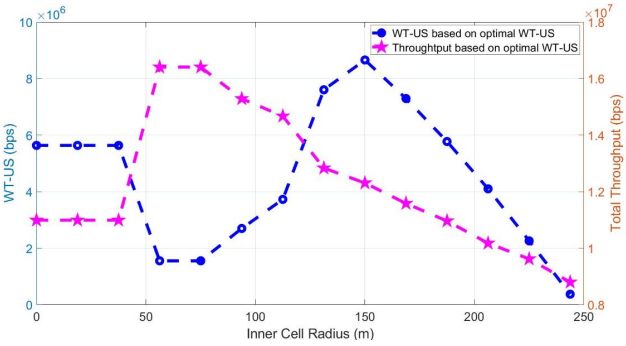

Figure 12: Weighted User Satisfaction Metric Performance for Static Users to Inner Region Radius

6.4.3 Adaptive versus Non-adaptive mechanisms - Metric Performance

As user mobility is introduced and new positions are determined, the simulation calculates metrics and optimal inner radius and subcarrier allocation for adaptive and non-adaptive variations for each FFR mechanism. For non-adaptive FFR mechanism, optimal inner radius and subcarrier allocation remain constant even after the user position changes and performance metrics are calculated. For adaptive FFR mechanism, new values of optimal inner radius and subcarrier allocation are determined based on the new user position and optimal FFR performance. Therefore, the adaptive FFR mechanism reacts to user mobility better than non-adaptive FFR mechanism. Figures 13 - 17 show

FFR performance for all metrics with adaptive and non-adaptive mechanisms applied. In all the adaptive versus non-adaptive mechanisms comparison results, the adaptive mechanism applied on the metrics perform better than non-adaptive mechanism. Particularly, the proposed metric performance Figure 17 shows higher throughput than other metrics and better performance versus non-adaptive and IFR variations. For both weighted user satisfaction (proposed metric) in Figure 17 and weighted fairness (existing metric) in Figure 16, the adaptation process is visible between 50 to 200 seconds. However, despite common benefit of better reaction to the adaptation process, weighted user satisfaction performs better with higher throughput compared to weighted fairness. There is a co-relation between adaptation trend and inner region radius as shown in Section 6.4.4.

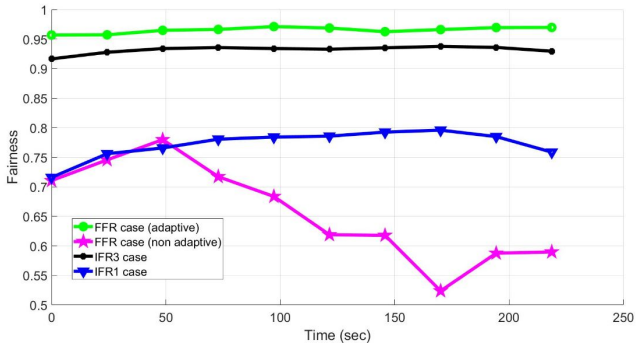

Figure 15: Comparison of adaptive versus non-adaptive mechanisms for Fairness Index

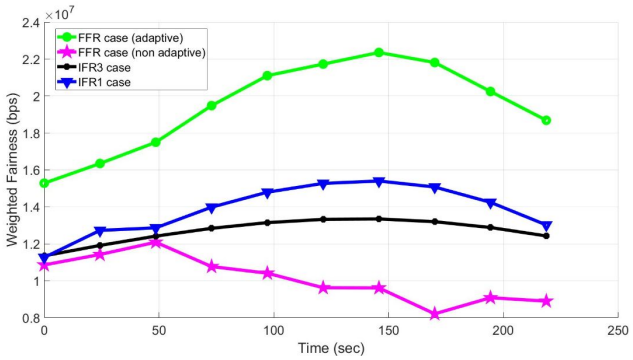

Figure 16: Comparison of adaptive versus non-adaptive mechanisms for Weighted Fairness

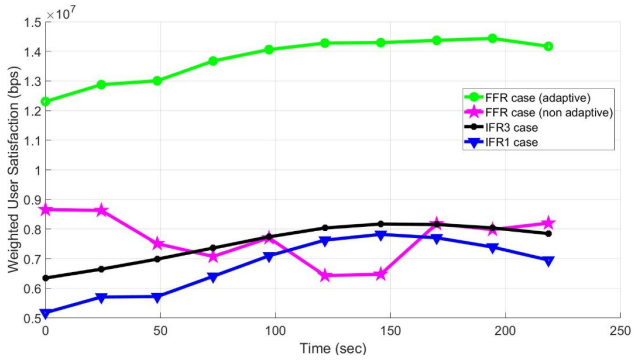

Figure 17: Comparison of adaptive versus non-adaptive mechanisms for Weighted User Satisfaction

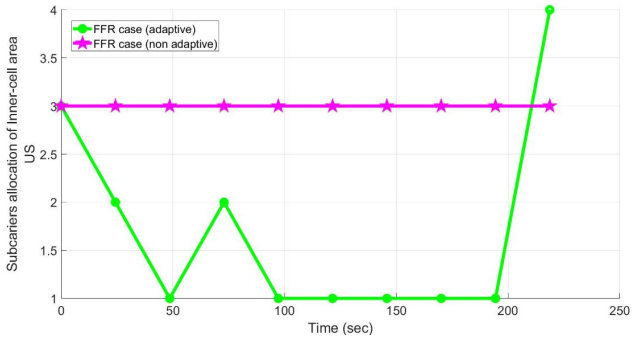

Figure 18: Comparison of Subcarrier Allocation for User Satisfaction

6.4.4 Adaptive versus Non-adaptive mechanisms - Subcarrier Allocation and Inner-Cell Radius

The throughput trend optimized for each metric can be explained with inner region subcarrier and inner region radius results. Figures 22 - 25 show effect of adaptation process on subcarrier allocation for all metrics. Figures 22 - 25 show effect of adaptation process on inner region radius for all metrics. Both subcarrier allocation and inner region radius show active response to the adaptation process applied to the network during the simulation time. For weighted user satisfaction, Figure 25 and weighted fairness Figure 24, the subcarrier allocation reacts positively to the adaptation process between 50 and 200 seconds. High throughput trend during this time interval can be explained due to allocation of all 25 subcarriers. Similarly, the range of

inner region radius changes with the adaptation process during the simulation time compared to its static trend in non-adaptive mechanism as shown in Figures 25, 24.

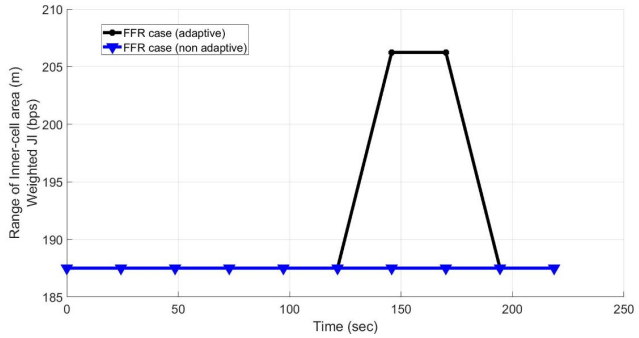

Figure 24: Comparison of Range of Inner-cell for Weighted Fairness

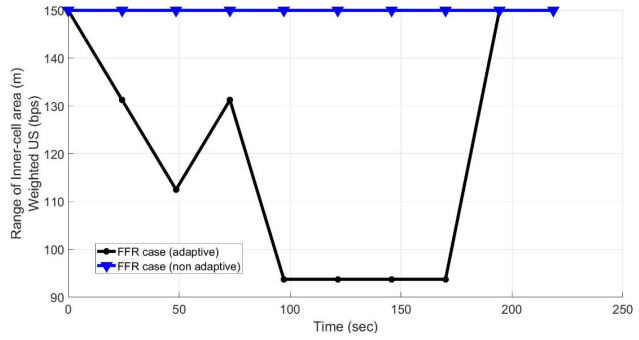

Figure 25: Comparison of Range of Inner-cell for Weighted User Satisfaction

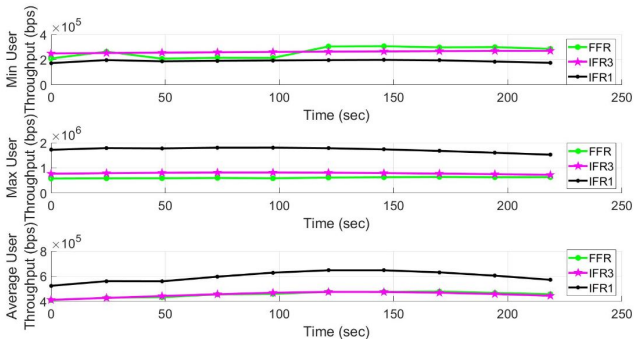

Figure 26: Comparison of Minimum, Maximum, Average for User Satisfaction

6.4.5 Adaptive versus Non-adaptive mechanisms - Minimum, Maximum, and Average Values

FFR mechanism simulation compares their minimum, maximum, and average results over time. Figures 26 - 29 show the metric performance. Maximum and average throughput shows lowest performance for FFR mechanism optimized for weighted user satisfaction metric. This is obvious result since the goal of the new metric is to reduce variance in user throughput and maintain relatively high overall throughput.

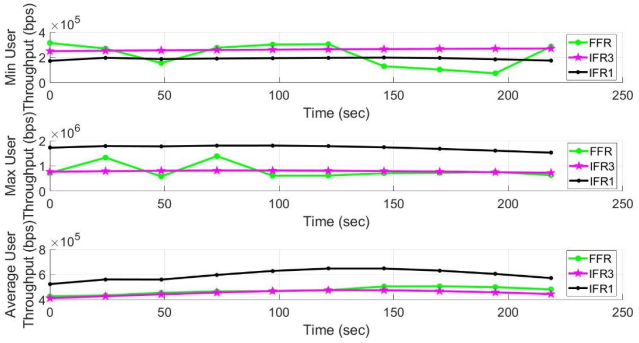

Figure 27: Comparison of Minimum, Maximum, Average for Fairness Index

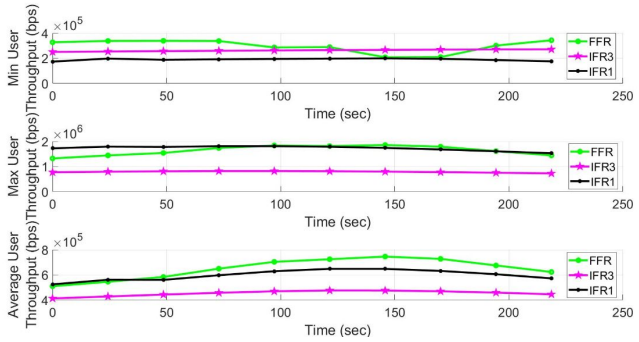

Figure 28: Comparison of Minimum, Maximum, Average for Weighted Fairness

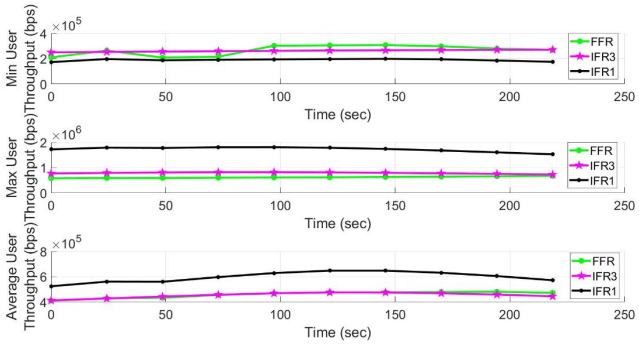

Figure 29: Comparison of Minimum, Maximum, Average for Weighted User Satisfaction

6.4.6 Adaptive versus Non-adaptive mechanisms - Femtocells

LTE femtocells have been developed to increase capacity and raise the throughput of cell-edge users. In this simulation, the LTE network is extended with randomly placed femtocells in each macrocell, assuming an uniform femtocell co-channel deployment. Despite the high throughput benefits, femtocell deployment experience relatively high level of interference from neighboring macrocells and femtocells. FFR frequency deployment is set as indicated in Figure 2. Simulation results in Figure 30 and 31 indicate higher throughput due to addition of femtocell radio resources. Adaptive trend is in line with the previous results without femtocells, where the network throughput adapts to the moving user locations. Network throughput optimized to weighted user satisfaction metric shows higher maximum and average throughput compared to IFR1 and IFR3 due to the presence of additional frequency resources.

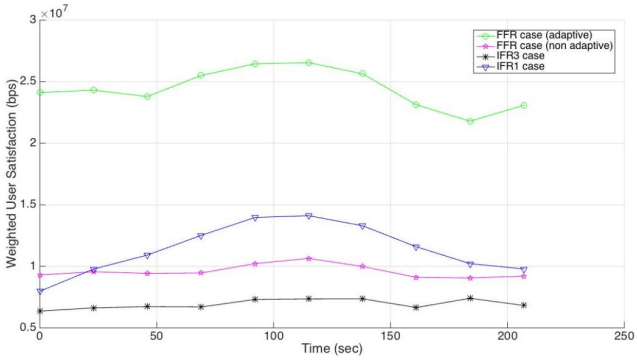

Figure 30: Comparison of adaptive versus non-adaptive mechanisms for Weighted User Satisfaction with Femtocells

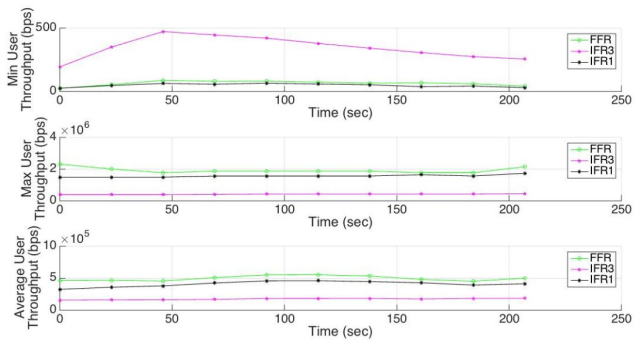

Figure 31: Comparison of Minimum, Maximum, Average for Weighted User Satisfaction with Femtocells

7 Conclusion

In conclusion, the paper evaluated the adaptation process in LTE FFR mechanism. The selected FFR mechanism based on the optimal inner region radius and frequency allocation performed better than other interference co-ordination mechanisms. The FFR mechanism optimized using weighted throughput user satisfaction made a positive trade-off between the existing metrics, as it maintained relatively high total throughput and reduced the variance of per-user throughput. The proposed metric reacted better to the adaptation process in mobility scenarios and generated higher throughput compared to the other metrics. With extreme densification in future mobility, the effect of femtocells on

the network throughput optimized for new metric on moving users was studied. A good research extension would be to review impact of femtocell densification and uniform grid placement on the adaptation process with the proposed metric.

ABSTRACT

Cloud computing has become a compelling paradigm built on compute and storage virtualization technologies. The current virtualization solution in the Cloud widely relies on hypervisor-based technologies. Given the recent booming of the container ecosystem, the container-based virtualization starts receiving more attention for being a promising alternative. Although the container technologies are generally considered to be lightweight, no virtualization solution is ideally resource-free, and the corresponding performance overheads will lead to negative impacts on the quality of Cloud services. To facilitate understanding container technologies from the performance engineering's perspective, we conducted two-stage performance investigations into Docker containers as a concrete example. At the first stage, we used a physical machine with "just-enough" resource as a baseline to investigate the performance overhead of a standalone Docker container against a standalone virtual machine (VM). With findings contrary to the related work, our evaluation results show that the virtualization's performance overhead could vary not only on a feature-by-feature basis but also on a job-to-job basis. Moreover, the hypervisor-based technology does not come with higher performance overhead in every case. For example, Docker containers particularly exhibit lower QoS in terms of storage transaction speed. At the ongoing second stage, we employed a physical machine with "fair-enough" resource to implement a container-based MapReduce application and try to optimize its performance. In fact, this machine failed in affording VM-based MapReduce clusters in the same scale. The performance tuning results show that the effects of different optimization strategies could largely be related to the data characteristics. For example, LZO compression can bring the most significant performance improvement when dealing with text data in our case.

1 Introduction

The container technologies have widely been accepted for building next-generation Cloud systems. This paper investigates the performance overhead of container-based virtualization and the performance optimization of a container-based MapReduce application, which is an extension of work originally presented in the 31st IEEE International Conference on Advanced Information Networking and Application (AINA 2017) [1].

The Cloud has been considered to be able to provide computing capacity as the next utility in our modern daily life. In particular, it is the virtualization technologies that enable Cloud computing to be a new paradigm of utility, by playing various vital roles in supporting Cloud services, ranging from resource iso-

https://dx.doi.org/10.25046/aj030163

lation to resource provisioning. The existing virtualization technologies can roughly be distinguished between the hypervisor-based and the container-based solutions. Considering their own resource consumption, both virtualization solutions inevitably introduce performance overheads to running Cloud services, and the performance overheads could then lead to negative impacts to the corresponding quality of service (QoS). Therefore, it would be crucial for both Cloud providers (e.g., for improving infrastructural efficiency) and consumers (e.g., for selecting services wisely) to understand to what extend a candidate virtualization solution incurs influence on the Cloud's QoS.

Recall that hypervisor-driven virtual machines (VMs) require guest operating systems (OS), while containers can share a host OS. Suppose physical machines, VMs and containers are three candidate resource types for a particular Cloud service, a natural hypothesis could be:

> *The physical machine-based service has the best quality among the three resource types, while the container-based service performs better than the hypervisor-based VM service.*

Unfortunately, to the best of our knowledge, there is little quantitative evidence to help test this hypothesis in an "apple-to-apple" manner, except for the similar qualitative discussions. Furthermore, the performance overhead of hypervisor-based and container-based virtualization technologies can even vary in practice depending on different service circumstance (e.g., uncertain workload densities and resource competitions). Therefore, we decided to conduct a twofold investigation into containers from the performance's perspective. Firstly, we used a physical machine with "just-enough" resource as a baseline to quantitatively investigate and compare the performance overheads between the container-based and hypervisor-based virtualizations. In particular, since Docker is currently the most popular container solution [2] and VMWare is one of the leaders in the hypervisor market [3], we chose Docker and VMWare Workstation 12 Pro to represent the two virtualization solutions respectively. Secondly, we implemented a container-based MapReduce cluster on a physical machine with "fair-enough" resource to investigate the performance optimization of our MapReduce application at least in this use case.

According to the clarifications in [4, 5], our qualitative investigations can be regulated by the discipline of experimental computer science (ECS). By employing ECS's recently available Domain Knowledge-driven Methodology (DoKnowMe) [6], we experimentally explored the performance overheads of different virtualization solutions on a feature-by-feature basis, i.e. the communication-, computation-, memory- and storage-related QoS aspects. As for the investigation into performance optimization, we were concerned with the task timeout, out-of-band heartbeat, buffer setting, stream merging, data compression and the cluster size of our container-based MapReduce application.

The experimental results and analyses of performance overhead investigation generally advocate the aforementioned hypothesis. However, the hypothesis is not true in all the cases. For example, we do not see computation performance difference between the three resource types for solving a combinatorially hard chess problem; and the container exhibits even higher storage performance overhead than the VM when reading/writing data byte by byte. Moreover, we find that the remarkable performance loss incurred by both virtualization solutions usually appears in the performance variability.

The performance optimization investigation reveals that various optimization strategies might take different effects due to different data characteristics of a container-based MapReduce application. For example, dealing with text data can significantly benefit from enabling data compression, whereas buffer settings have little effect for dealing with relatively small amount of data.

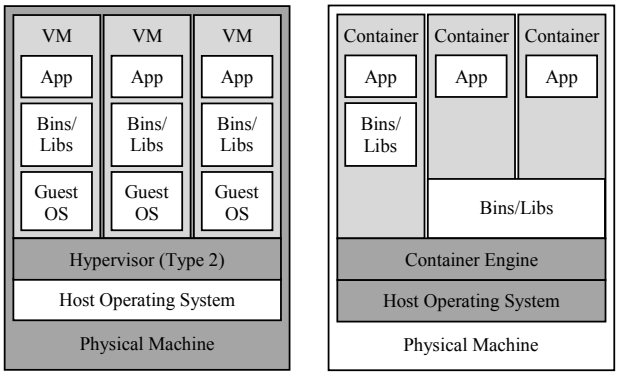
Overall, our work makes fourfold contributions to the container ecosystem, as specified below.

(1) Our experimental results and analyses can help both researchers and practitioners to better understand the fundamental performance of the present container-based and hypervisor-based virtualization technologies. In fact, the performance evaluation practices in ECS can roughly be distinguished between two stages: the first stage is to reveal the primary performance of specific (system) features, while the second stage is generally based on the first-stage evaluation to investigate real-world application cases. Thus, this work can be viewed as a foundation for more sophisticated evaluation studies in the future.

(2) Our method of calculating performance overhead can easily be applied or adapted to different evaluation scenarios by others. The literature shows that the "performance overhead" has normally been used in the context of qualitative discussions. By quantifying such an indicator, our study essentially provides a concrete lens into the case of performance comparisons.

(3) As a second-stage evaluation work, our case study on the performance optimization of a MapReduce application both demonstrates a practical use case and supplies an easy-to-replicate scenario for engineering performance of container-based applications. In other words, this work essentially proposed a characteristic-consistent data set (i.e. Amazon's spot price history that is open to the public) for future performance engineering studies.

(4) The whole evaluation logic and details reported in this paper can be viewed as a reusable template of evaluating Docker containers. Since the Docker project is still quickly growing [7], the evaluation results could be gradually out of date. Given this template, future evaluations



can be conveniently repeated or replicated even by different evaluators at different times and locations. More importantly, by emphasizing the backend logic and evaluation activities, the template-driven evaluation implementations (instead of results only) would be more traceable and comparable.

The remainder of this paper is organized as follows. Section 2 briefly summarizes the background knowledge of container-based and the hypervisor-based virtualization technologies. Section 3 introduces the fundamental performance evaluation of a single container. The detailed performance overhead investigation is divided into two reporting parts, namely pre-experimental activities and experimental results & analyses, and they are correspondingly described into Section 3.2 and 3.3 respectively. Section 4 explains our case study on the performance optimization of a container-based MapReduce application. Section 5 highlights the existing work related to container's performance evaluation. Conclusions and some future work are discussed in Section 6.

2 Hypervisor-based vs. Container-based Virtualization

When it comes to the Cloud virtualization, the de facto solution is to employ the hypervisor-based technologies, and the most representative Cloud service type is offering VMs [8]. In this virtualization solution, the hypervisor manages physical computing resources and makes isolated slices of hardware available for creating VMs [7]. We can further distinguish between two types of hypervisors, namely the bare-metal hypervisor that is installed directly onto the computing hardware, and the hosted hypervisor that requires a host OS. To make a better contrast between the hypervisor-related and container-related concepts, we particularly emphasize the second hypervisor type, as shown in Figure 1a. Since the hypervisor-based virtualization provides access to physical hardware only, each VM needs a complete implementation of a guest OS including the binaries and libraries necessary for applications [9]. As a result, the guest OS will inevitably incur resource competition against the applications running on the VM service, and essentially downgrade the QoS from the application's perspective. Moreover, the performance overhead of the hypervisor would also be passed on to the corresponding Cloud services and lead to negative impacts on the QoS.

To relieve the performance overhead of hypervisor-based virtualization, researchers and practitioners recently started promoting an alternative and lightweight solution, namely container-based virtualization. In fact, the foundation of the container technology can be traced back to the Unix `chroot` command in 1979 [9], while this technology is eventually evolved into virtualization mechanisms like Linux VServer, OpenVZ and Linux Containers (LXC) along with the booming of Linux [10]. Unlike the hardware-level solution of hypervisors, containers realize virtualization at the OS level and utilize isolated slices of the host OS to shield their contained applications [9]. In essence, a container is composed of one or more lightweight images, and each image is a prebaked and replaceable file system that includes necessary binaries, libraries or middlewares for running the application. In the case of multiple images, the read-only supporting file systems are stacked on top of each other to cater for the writable top-layer file system [2]. With this mechanism, as shown in Figure 1b, containers enable applications to share the same OS and even binaries/libraries when appropriate. As such, compared to VMs, containers would be more resource efficient by excluding the execution of hypervisor and guest OS, and more time efficient by avoiding booting (and shutting down) a whole OS [11, 7]. Nevertheless, it has been identified that the cascading layers of container images come with inherent complexity and performance penalty [12]. In other words, the container-based virtualization technology could also negatively impact the corresponding QoS due to its performance overhead.

(a) Hypervisor-based virtual service. (b) Container-based virtual service.

Figure 1: Different architectures of hypervisor-based and container-based virtual services.

3 Fundamental Performance Evaluation of a Single Container

3.1 Performance Evaluation Methodology

Since the comparison between the container's and the VM's performance overheads is essentially based on their performance evaluation, we define our work as a performance evaluation study that belongs to the field of experimental computer science [4, 5]. Considering that "evaluation methodology underpins all innovation in experimental computer science" [13], we employ the methodology DoKnowMe [6] to guide evaluation implementations in this study. DoKnowMe is an abstract evaluation methodology on the analogy of "class" in object-oriented programming. By integrating domain-specific knowledge artefacts, DoKnowMe can be customized into specific methodologies (by analogy

of "object") to facilitate evaluating different concrete computing systems. The skeleton of DoKnowMe is composed of ten generic evaluation steps, as listed below.

(1) Requirement recognition;
(2) Service feature identification;
(3) Metrics and benchmarks listing;
(4) Metrics and benchmarks selection;
(5) Experimental factors listing;
(6) Experimental factors selection;
(7) Experiment design;
(8) Experiment implementation;
(9) Experimental analysis;
(10) Conclusion and documentation.

Each evaluation step further comprises a set of activities together with the corresponding evaluation strategies. The elaboration on these evaluation steps is out of the scope of this paper. To better structure our report, we divide the evaluation implementation into pre-experimental activities and experimental results & analyses.

3.2 Pre-Experimental Activities

3.2.1 Requirement Recognition

Following DoKnowMe, the whole evaluation implementation is essentially driven by the recognized requirements. In general, the requirement recognition is to define a set of specific requirement questions both to facilitate understanding the real-world problem and to help achieve clear statements of the corresponding evaluation purpose. In this case, the basic requirement is to give a fundamental quantitative comparison between the hypervisor-based and container-based virtualization solutions. As mentioned previously, we concretize these two virtualization solutions into VMWare Workstation VMs and Docker containers respectively, in order to facilitate our evaluation implementation (i.e., using a physical machine as a baseline to investigate the performance overhead of a Docker container against a VM). Thus, such a requirement can further be specified into two questions:

RQ1: How much performance overhead does a standalone Docker container introduce over its base physical machine?

RQ2: How much performance overhead does a standalone VM introduce over its base physical machine?

Considering that virtualization technologies could lead to variation in performance of Cloud services [14], we are also concerned with the container's and VM's potential variability overhead besides their average performance overhead:

RQ3: How much performance variability overhead does a standalone Docker container introduce over its base physical machine during a particular period of time?

RQ4: How much performance variability overhead does a standalone VM introduce over its base physical machine during a particular period of time?

3.2.2 Service Feature Identification

Recall that we treat Docker containers as an alternative type of Cloud service to VMs. By using the taxonomy of Cloud services evaluation [15], we directly list the service feature candidates, as shown in Figure 2. Note that a service feature is defined as a combination of a physical property and its capacity, and we individually examine the four physical properties in this study:

- Communication
- Computation
- Memory
- Storage

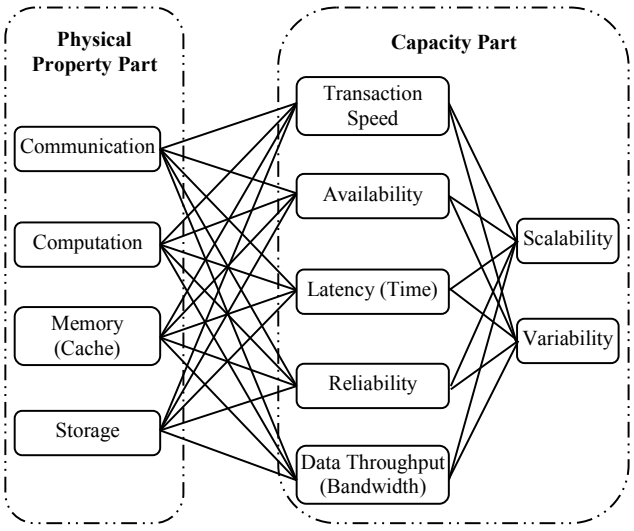


Figure 2: Candidate service features for evaluating Cloud service performance (cf. [15]).

3.2.3 Metrics/Benchmarks Listing and Selection

The selection of evaluation metrics usually depends on the availability of benchmarks. According to our previous experience of Cloud services evaluation, we choose relatively lightweight and popular benchmarks to try to minimize the benchmarking overhead, as listed in Table 1. For example, Iperf has been identified to be able to deliver more precise results by consuming less system resources. In fact, except for STREAM that is the de facto memory evaluation benchmark included in the HPC Challenge Benchmark (HPCC) suite, the other benchmarks are all Ubuntu's built-in utilities.

Physical Property	Capacity Metric	Benchmark	Version
Communication	Data Throughput	Iperf	2.0.5
Computation	(Latency) Score	HardInfo	0.5.1
Memory	Data Throughput	STREAM	5.10
Storage	Transaction Speed	Bonnie++	1.97.1
Storage	Data Throughput	Bonnie++	1.97.1

Table 1: Metrics and benchmarks for this evaluation study.

In particular, although Bonnie++ only measures the amount of data processed per second, the disk I/O transactions are on a byte-by-byte basis when accessing small size of data. Therefore, we consider to measure storage transaction speed when operating byte-size data and measure storage data throughput when operating block-size data. As for the property computation, considering the diversity in CPU jobs (e.g., integer and floating-point calculations), we employ HardInfo that includes six micro-benchmarks to generate performance scores, as briefly explained in Table 2. HardInfo is a tool package that can summarize the information about the host machine's hardware and operating system, as well as benchmarking the CPU. In this study, we employ HardInfo for CPU benchmarking only.

Benchmark	Brief Explanation
CPU Blowfish	Encrypting blocks of random data using the Blowfish algorithm.
CPU CryptoHash*	Checking the ability of the computer to find the hash of a specific test file.
CPU Fibonacci	Calculating the 42*nd* Fibonacci number.
CPU N-Queens	Solving the combinatorially hard chess problem of placing N queens on an $N \times N$ chessboard such that no queen can attack any other.
FPU FFT	Computing a fast Fourier transform.
FPU Raytracing	Generating an image by tracing the path of light through pixels in an image plane and simulating the effects of its encounters with virtual objects.

*The higher the better. (The lower the better for the others.)

Table 2: Micro-benchmarks included in HardInfo.

When it comes to the performance overhead, we use the business domain's *Overhead Ratio*[1] as an analogy to its measurement. In detail, we treat the performance loss compared to a baseline as the expense, while imagining the baseline performance to be the overall income, as defined in Equation (1).

$$O_p = \frac{|P_m - P_b|}{P_b} \times 100\% \quad (1)$$

where O_p refers to the performance overhead; P_m denotes the benchmarking result as a measurement of a service feature; P_b indicates the baseline performance of the service feature; and then $|P_m - P_b|$ represents the corresponding performance loss. Note that the physical machine's performance is used as the baseline in our study. Moreover, considering possible observational errors, we allow a margin of error for the confidence level as high as 99% with regarding to the benchmarking results. In other words, we will ignore the difference between the measured performance and its baseline if the calculated performance overhead is less than 1% (i.e. if $O_p < 1\%$, then $P_m = P_b$).

[1] http://www.investopedia.com/terms/o/overhead-ratio.asp

3.2.4 Experimental Factor Listing and Selection

The identification of experimental factors plays a prerequisite role in the following experimental design. More importantly, specifying the relevant factors would be necessary for improving the repeatability of experimental implementations. By referring to the experimental factor framework of Cloud services evaluation [16], we choose the resource- and workload-related factors as follows.

The resource-related factors:

- *Resource Type:* Given the evaluation requirement, we have essentially considered three types of resources to support the imaginary Cloud service, namely physical machine, container and VM.
- *Communication Scope:* We test the communication between our local machine and an Amazon EC2 t2.micro instance. The local machine is located in our broadband lab at Lund University, and the EC2 instance is from Amazon's available zone ap-southeast-1a within the region Asia Pacific (Singapore).
- *Communication Ethernet Index:* Our local side uses a Gigabit connection to the Internet, while the EC2 instance at remote side has the "Low to Moderate" networking performance defined by Amazon.
- *CPU Index:* The physical machine's CPU model is Intel Core™2 Duo Processor T7500. The processor has two cores with the 64-bit architecture, and its base frequency is 2.2 GHz. We allocate both CPU cores to the standalone VM upon the physical machine.
- *Memory Size:* The physical machine is equipped with a 3GB DDR2 SDRAM. When running the VMWare Workstation Pro without launching any VM, "`watch -n 5 free -m`" shows a memory usage of 817MB while leaving 2183MB free in the physical machine. Therefore, we set the memory size to 2GB for the VM to avoid (at least to minimize) the possible memory swapping.
- *Storage Size:* There are 120GB of hard disk in the physical machine. Considering the space usage by the host operating system, we allocate 100GB to the VM.
- *Operating System:* Since Docker requires a 64-bit installation and Linux kernels older than

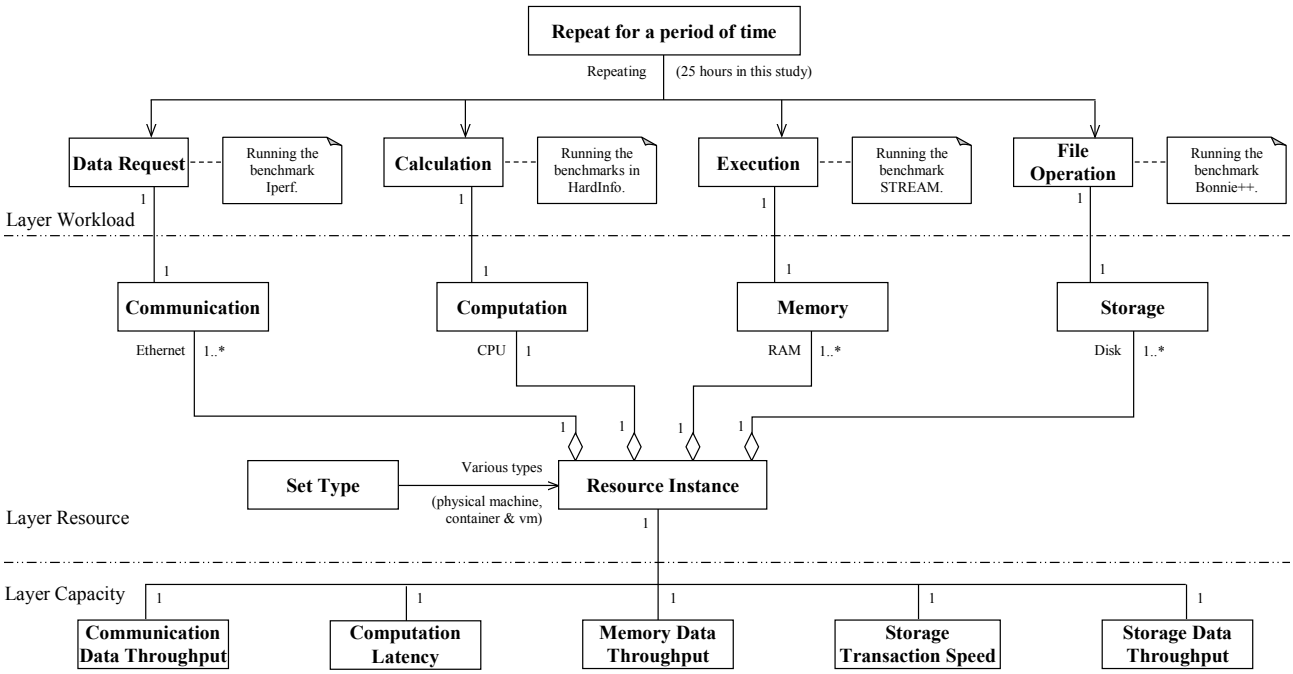

Figure 3: Experimental blueprint for evaluating three types of resources in this study.

3.10 do not support all the features for running Docker containers, we choose the latest 64-bit Ubuntu 15.10 as the operating system for both the physical machine and the VM. In addition, according to the discussions about base images in the Docker community [17, 18], we intentionally set an OS base image (by specifying `FROM ubuntu:15.10` in the Dockerfile) for all the Docker containers in our experiments. Note that a container's OS base image is only a file system representation, while not acting as a guest OS.

The workload-related factors:

- *Duration:* For each evaluation experiment, we decided to take a whole-day observation plus one-hour warming up (i.e. 25 hours).
- *Workload Size:* The experimental workloads are predefined by the selected benchmarks. For example, the micro-benchmark CPU Fibonacci generates workload by calculating the 42*nd* Fibonacci number (cf. Table 2). In particular, the benchmark Bonnie++ distinguishes between reading/writing byte-size and block-size data.

3.2.5 Experimental Design

It is clear that the identified factors are all with single value except for the *Resource Type*. Therefore, a straightforward design is to run the individual benchmarks on each of the three types of resources independently for a whole day plus one hour.

Furthermore, following the conceptual model of IaaS performance evaluation [19], we record the experimental design into a blueprint both to facilitate our experimental implementations and to help other evaluators replicate/repeat our study. In particular, the experimental elements are divided into three layers (namely Layer Workload, Layer Resource, and Layer Capacity), as shown in Figure 3. To avoid duplication, we do not elaborate the detailed elements in this blueprint.

3.3 Experimental Results and Analyses

3.3.1 Communication Evaluation Result and Analysis

Docker creates a virtual bridge `docker0` on the host machine to enable both the host-container and the container-container communications. In particular, it is the Network Address Translation (NAT) that forwards containers' traffic to external networks. For the purpose of "apple-to-apple" comparison, we also configure VM's network type as NAT that uses the `VMnet8` virtual switch created by VMware Workstation.

Using NAT, both Docker containers and VMs can establish outgoing connections by default, while they require port binding/forwarding to accept incoming connections. To reduce the possibility of configurational noise, we only test the outgoing communication performance, by setting the remote EC2 instance to Iperf server and using the local machine, container and VM all as Iperf clients.

The benchmarking results of repeating `iperf -c XXX.XXX.XXX.XXX -t 15` (with a one-minute interval between every two consecutive trials) are listed in Table 3. The `XXX.XXX.XXX.XXX` denotes the external IP address of the EC2 instance used in our experiments. Note that, unlike the other performance features, the communication data throughput delivers periodical and significant fluctuations, which might be a result from the network resource competition at both our local side and the EC2 side during working hours. There-

fore, we particularly focus on the longest period of relatively stable data out of the whole-day observation, and thus the results here are for rough reference only.

Resource Type	Average	Standard Deviation
Physical machine	29.066 Mbits/sec	1.282 Mbits/sec
Container	28.484 Mbits/sec	1.978 Mbits/sec
Virtual machine	12.843 Mbits/sec	2.979 Mbits/sec

Table 3: Communication benchmarking results using Iperf.

Given the extra cost of using the NAT network to send and receive packets, there would be unavoidable performance penalties for both the container and the VM. Using Equation (1), we calculate their communication performance overheads, as illustrated in Figure 4.

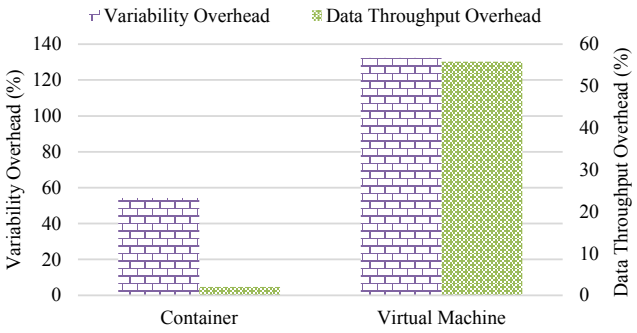

Figure 4: Communication data throughput and its variability overhead of a standalone Docker container vs. VM (using the benchmark Iperf).

A clear trend is that, compared to the VM, the container loses less communication performance, with only 2% data throughput overhead and around 54% variability overhead. However, it is surprising to see a more than 55% data throughput overhead for the VM. Although we have double checked the relevant configuration parameters and redone several rounds of experiments to confirm this phenomenon, we still doubt about the hypervisor-related reason behind such a big performance loss. We particularly highlight this observation to inspire further investigations.

3.3.2 Computation Evaluation Result and Analysis

Recall that HardInfo's six micro benchmarks deliver both "higher=better" and "lower=better" CPU scores (cf. Table 2). To facilitate experimental analysis, we use the two equations below to standardize the "higher=better" and "lower=better" benchmarking results respectively.

$$HB_i = \frac{Benchmarking_i}{\max(Benchmarking_{1,2,\ldots,n})} \quad (2)$$

$$LB_i = \frac{\frac{1}{Benchmarking_i}}{\max\left(\frac{1}{Benchmarking_{1,2,\ldots,n}}\right)} \quad (3)$$

where HB_i further scores the service resource type i by standardizing the "higher=better" benchmarking result $Benchmarking_i$; and similarly, LB_i represents the standardized "lower=better" CPU score of the service resource type i. Note that Equation (3) essentially offers the "lower=better" benchmarking results a "higher=better" representation through reciprocal standardization.

For the purpose of conciseness, here we only specify the standardized experimental results, as shown in Table 4. Exceptionally, the container and VM have slightly higher CPU N-Queens scores than the physical machine. Given the predefined observational margin of error (cf. Section 3.2.3), we are not concerned with this trivial difference, while treating their performance values as equal to each other in this case.

Benchmark	Physical machine	Container	VM
CPU Blowfish	1	0.986	0.942
CPU CryptoHash	1	0.992	0.943
CPU Fibonacci	1	0.999	0.976
CPU N-Queens	0.996	1	0.997
FPU FFT	1	0.966	0.924
FPU Raytracing	1	0.968	0.941

Table 4: Standardized computation benchmarking results using HardInfo.

We can further use a radar plot to help ignore the trivial number differences, and also help intuitively contrast the performance of the three resource types, as demonstrated in Figure 5. For example, the different polygon sizes clearly indicate that the container generally computes faster than the VM, although the performance differences are on a case-by-case basis with respect to different CPU job types.

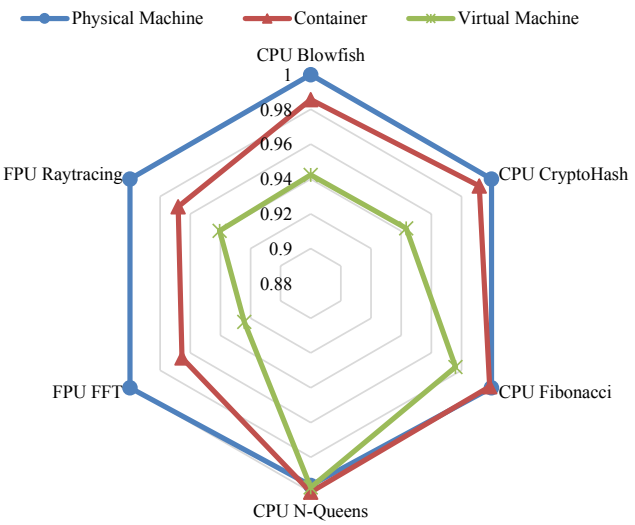

Figure 5: Computation benchmarking results by using HardInfo.

Nevertheless, our experimental results do not display any general trend in variability of those resources' computation scores. As can be seen from the calculated performance overheads (cf. Figure 6), the VM

does not even show worse variability than the physical machine when running CPU CryptoHash, CPU N-Queens and FPU Raytracing. On the contrary, there is an almost 2500% variability overhead for the VM when calculating the 42*nd* Fibonacci number. In particular, the virtualization technologies seem to be sensitive to the Fourier transform jobs (the benchmark FPU FFT), because the computation latency overhead and the variability overhead are relatively high for both the container and the VM.

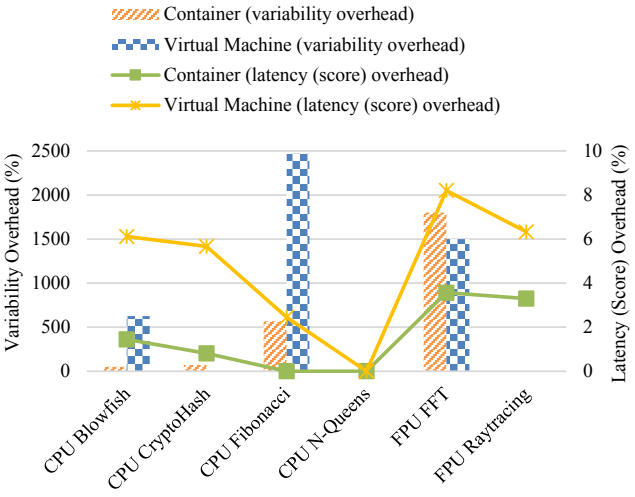

Figure 6: Computation latency (score) and its variability overhead of a standalone Docker container vs. VM (using the tool kit HardInfo).

3.3.3 Memory Evaluation Result and Analysis

STREAM measures sustainable memory data throughput by conducting four typical vector operations, namely Copy, Scale, Add and Triad. The memory benchmarking results are listed in Table 5. We further visualize the results into Figure 7 to facilitate our observation. As the first impression, it seems that the VM has a bit poorer memory data throughput, and there is little difference between the physical machine and the Docker container in the context of running STREAM.

Operation (MB/s)	Physical machine	Container	VM
Copy	2902.685	2914.023	2818.291
(Std. Dev.)	(4.951)	(12.579)	(57.633)
Scale	2916.247	2910.485	2765.737
(Std. Dev.)	(3.783)	(14.488)	(59.193)
Add	3335.634	3332.822	3159.188
(Std. Dev.)	(3.765)	(14.405)	(58.385)
Triad	3341.327	3340.416	3204.811
(Std. Dev.)	(3.976)	(26.361)	(59.004)

Table 5: Memory benchmarking results using STREAM.

By calculating the performance overhead in terms of memory data throughput and its variability, we are able to see the significant difference among these three types of resources, as illustrated in Figure 8. Take the operation Triad as an example, although the container performs as well as the physical machine on average, the variability overhead of the container is more than 500%; similarly, although the VM's Triad data throughput overhead is around 4% only, its variability overhead is almost 1400%. In other words, the memory performance loss incurred by both virtualization techniques is mainly embodied with the increase in the performance variability.

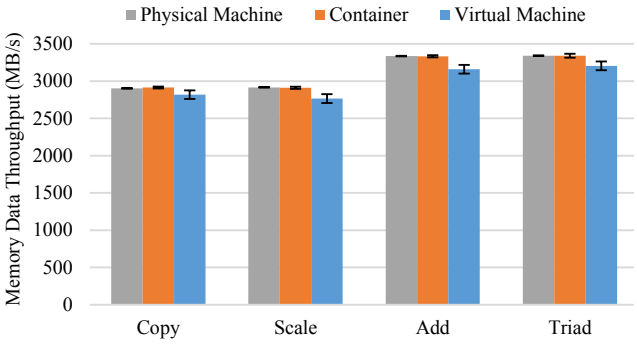

Figure 7: Memory benchmarking results by using STREAM. Error bars indicate the standard deviations of the corresponding memory data throughput.

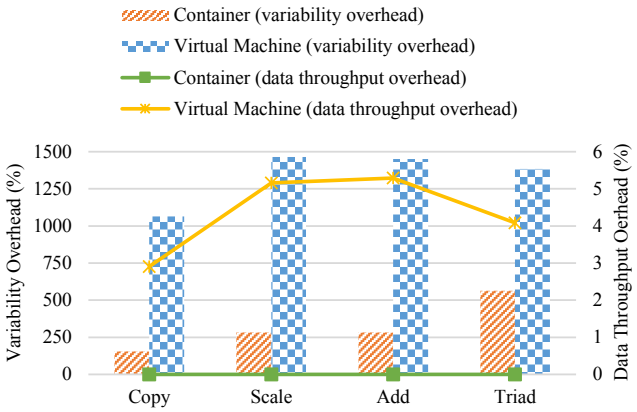

Figure 8: Memory data throughput and its variability overhead of a standalone Docker container vs. VM (using the benchmark STREAM).

In addition, it is also worth notable that the container's average Copy data throughput is even slightly higher than the physical machine (i.e. 2914.023MB/s vs. 2902.685MB/s) in our experiments. Recall that we have considered a 1% margin of error. Since those two values are close to each other within this error margin, here we ignore such an irregular phenomenon as an observational error.

3.3.4 Storage Evaluation Result and Analysis

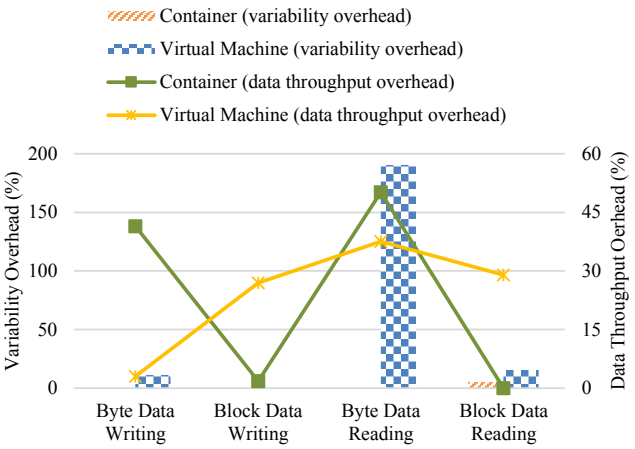
For the test of disk reading and writing, Bonnie++ creates a dataset twice the size of the involved RAM memory. Since the VM is allocated 2GB of RAM, we also restrict the memory usage to 2GB for Bonnie++

on both the physical machine and the container, by running "`sudo bonnie++ -r 2048 -n 128 -d / -u root`". Correspondingly, the benchmarking trials are conducted with 4GB of random data on the disk. When Bonnie++ is running, it carries out various storage operations ranging from data reading/writing to file creating/deleting. Here we only focus on the performance of reading/writing byte- and block-size data.

To help highlight several different observations, we plot the trajectory of the experimental results along the trial sequence during the whole day, as shown in Figure 9. The first surprising observation is that, all the three resource types have regular patterns of performance jitter in block writing, rewriting and reading. Due to the space limit, we do not report their block rewriting performance in this paper. By exploring the hardware information, we identified the hard disk drive (HDD) model to be ATA Hitachi HTS54161, and its specification describes "It stores 512 bytes per sector and uses four data heads to read the data from two platters, rotating at 5,400 revolutions per minute". As we know, the hard disk surface is divided into a set of concentrically circular tracks. Given the same rotational speed of an HDD, the outer tracks would have higher data throughput than the inner ones. As such, those regular patterns might indicate that the HDD heads sequentially shuttle between outer and inner tracks when consecutively writing/reading block data during the experiments.

The second surprising observation is that, unlike most cases in which the VM has the worst performance, the container seems significantly poor at accessing the byte size of data, although its performance variability is clearly the smallest. We further calculate the storage performance overhead to deliver more specific comparison between the container and the VM, and draw the results into Figure 10. Note that, in the case when the container's/VM's variability is smaller than the physical machine's, we directly set the corresponding variability overhead to zero rather than allowing any performance overhead to be negative. Then, the bars in the chart indicate that the storage variability overheads of both virtualization technologies are nearly negligible except for reading byte-size data on the VM (up to nearly 200%). The lines show that the container brings around 40% to 50% data throughput overhead when performing disk operations on a byte-by-byte basis. On the contrary, there is relatively trivial performance loss in VM's byte data writing. However, the VM has roughly 30% data throughput overhead in other disk I/O scenarios, whereas the container barely incurs overhead when reading/writing large size of data.

Our third observation is that, the storage performance overhead of different virtualization technologies can also be reflected through the total number of the iterative Bonnie++ trials. As pointed by the maximum x-axis scale in Figure 9, the physical machine, the container and the VM can respectively finish 150, 147 and 101 rounds of disk tests during 24 hours. Given this information, we estimate the container's and the VM's storage performance overhead to be 2% (= |147−150|/150) and 32.67% (= |101−150|/150) respectively.



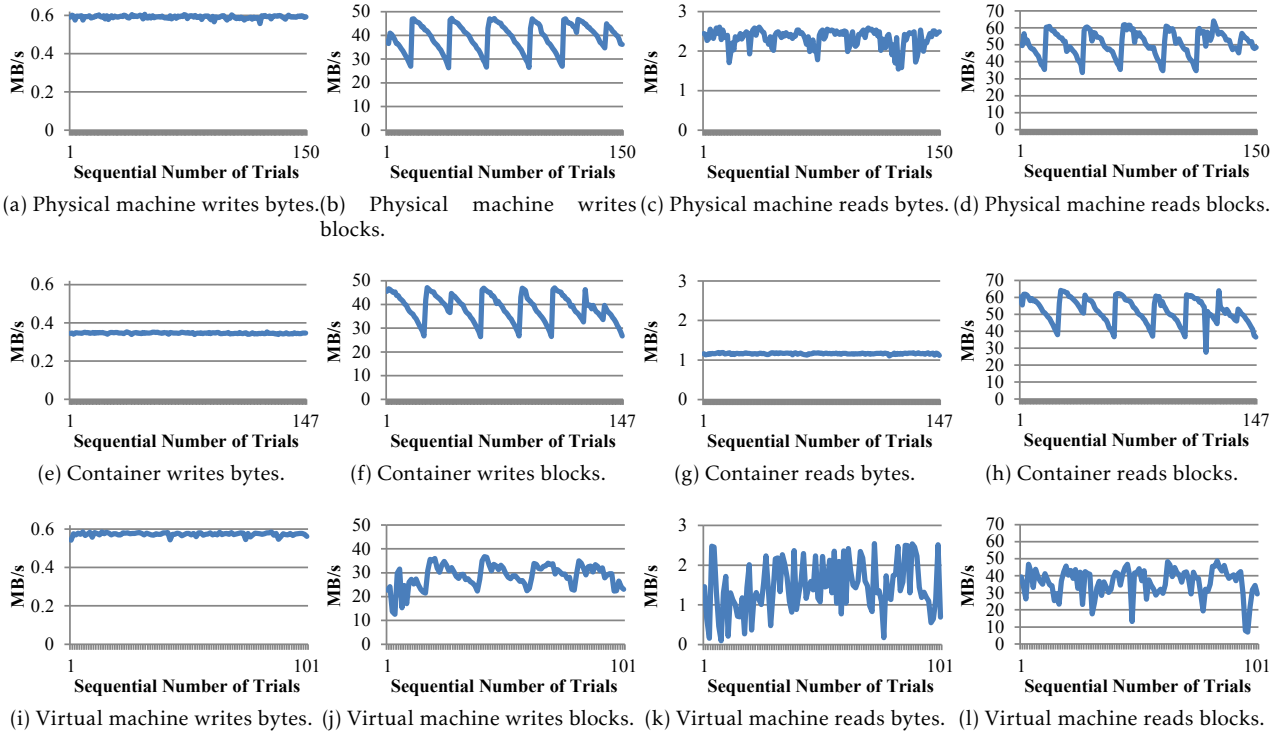


Figure 10: Storage data throughput and its variability overhead of a standalone Docker container vs. VM (using the benchmark Bonnie++).

3.4 Performance Evaluation Conclusion

Following the performance evaluation methodology DoKnowMe, we draw conclusions mainly by answering the predefined requirement questions. Driven by RQ1 and RQ2, our evaluation result largely confirms the aforementioned qualitative discussions: The container's average performance is generally better than the VM's and is even comparable to that of the physical machine with regarding to many features. Specifically, the container has less than 4% performance overhead in terms of communication data throughput, computation latency, memory data throughput and storage data throughput. Nevertheless, the container-based virtualization could hit a bottleneck of storage transaction speed, with the overhead up to 50%. Note that, as mentioned previously, we interpret the byte-size data throughput into storage transaction speed, because each byte essentially calls a disk transaction here. In contrast, although the VM delivers the worst performance in most cases, it could perform as well as the physical machine when solving the N-Queens problem or writing small-size data to the disk. By further comparing the storage filesystems of those two types of virtualization technologies, we believe that it is the copy-on-write mechanism that makes containers poor at storage transaction speed.

Driven by RQ3 and RQ4, we find that the performance loss resulting from virtualizations is more visible in the performance variability. For example, the container's variability overhead could reach as high as over 500% with respect to the Fibonacci calculation and the memory Triad operation. Similarly, although the container generally shows less performance variability than the VM, there are still exceptional cases: The container has the largest performance variation in the job of computing Fourier transform, whereas even the VM's performance variability is not worse than

(a) Physical machine writes bytes. (b) Physical machine writes blocks. (c) Physical machine reads bytes. (d) Physical machine reads blocks.

(e) Container writes bytes. (f) Container writes blocks. (g) Container reads bytes. (h) Container reads blocks.

(i) Virtual machine writes bytes. (j) Virtual machine writes blocks. (k) Virtual machine reads bytes. (l) Virtual machine reads blocks.

Figure 9: Storage benchmarking results by using Bonnie++ during 24 hours. The maximum x-axis scale indicates the iteration number of the Bonnie++ test (i.e. the physical machine, the container and the VM run 150, 147 and 101 tests respectively).

the physical machine's when running CryptoHash, N-Queens, and Raytracing jobs.

4 Container-based Application Case Study and Performance Optimization

4.1 Motive from a Background Project

Adequate pricing techniques play a key role in successful Cloud computing [20]. In the de facto Cloud market, there are generally three typical pricing schemes, namely on-demand pricing scheme, reserved pricing scheme, and spot pricing scheme. Although the fixed pricing schemes are dominant approaches to trading Cloud resources nowadays, spot pricing has been broadly agreed as a significant supplement for building a full-fledged market economy for the Cloud ecosystem [21]. Similar to the dynamic pricing in the electricity distribution industry, the spot pricing scheme here also employs a market-driven mechanism to provide spot service at a reduced and fluctuating price, in order to attract more demands and better utilize idle compute resources [22].

Unfortunately, the backend details behind changing spot prices are invisible for most of the Cloud market participants. In fact, unlike the static and straightforward pricing schemes of on-demand and reserved Cloud services, the market-driven mechanism for pricing Cloud spot service has been identified to be complicated both for providers to implement and for consumers to understand.

Therefore, it has become popular and valuable to take Amazon's spot service as a practical example to investigate Cloud spot pricing, so as to encourage and facilitate more players to enter the Cloud spot market. We are currently involved in a project on Cloud spot pricing analytics by using the whole-year price history of Amazon's 1053 types of spot service instances. Since Amazon only offers the most recent 60-day price trace to the public for review, we downloaded the price traces monthly in the past year to make sure the completeness of the whole-year price history.

In this way of downloading price traces, it is clear that around half of the overall raw data are duplicate. Moreover, the original price trace is sorted by the timestamp only, as shown in Table 6. To analyze spot service pricing on an instance-by-instance basis, however, the collected price data need not only to be sorted by timestamp but also to be distinguished by the other three attributes, i.e. Instance Type, Operating System and Zone. Thus, we decided to implement a preprocessing program to help clean the data, including removing the duplicate price records and categorizing price traces for individual service instances.

Tag	Price ($)	Timestamp	Instance Type	Operating System	Zone
SPOTINSTANCEPRICE	0.072700	2017-10-04T13:39:11+0000	m1.large	Windows	us-east-1a

Table 6: A small piece of Amazon's spot price trace.

4.2 WordCount-alike Solution

Given the aforementioned requirement of data cleaning, we propose a WordCount-alike solution by analogy. WordCount is a well-known application that calculates the numbers of occurrences of different words within a document or word set. In the domain of big data analytics, WordCount is now a classic application to demonstrate the MapReduce mechanism that has become a standard programming model since 2004 [23]. As shown in Figure 11, the key steps in a MapReduce workflow are:

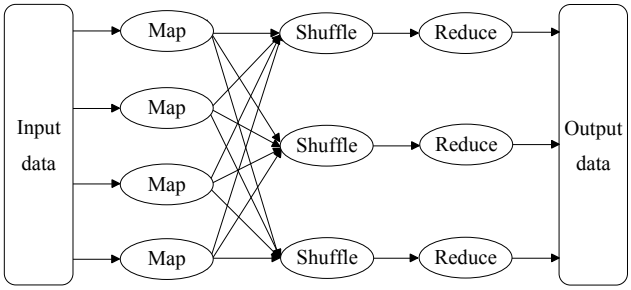

Figure 11: Workflow of the MapReduce process.

(1) The initial input source data are segmented into blocks according to the predefined split function and saved as a list of key-value pairs.

(2) The mapper executes the user-defined map function which generates intermediate key-value pairs.

(3) The intermediate key-value pairs generated by mapper nodes is sent to a specific reducer based on the key.

(4) Each reducer computes and reduces the data to one single key-value pair.

(5) All the reduced data are integrated into the final result of a MapReduce job.

Benefiting from MapReduce, applications like WordCount can deal with large amounts of data parallelly and distributedly. For the purpose of conciseness, we use a three-file scenario to demonstrate the process of MapReduce-based WordCount, as illustrated in Figure 12. In brief, the input files are broken into a set of <key, value> pairs for individual words, then the <key, value> pairs are shuffled alphabetically to facilitate summing up the values (i.e. the occurrence counts) for each unique key, and the reduced results are also a set of <key, value> pairs that directly act as the output in this case.

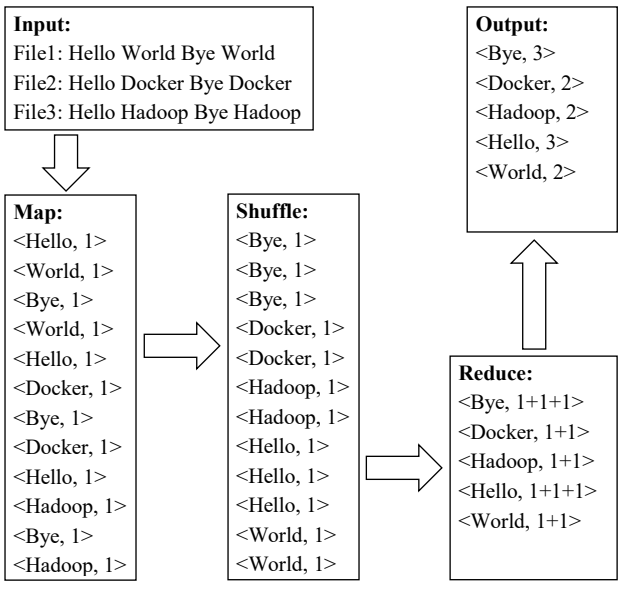

Figure 12: A Three-file Scenario of MapReduce-based WordCount.

Recall that the information of Amazon's spot price trace is composed of Tag, Price, Timestamp, Instance Type and Zone (cf. Table 6). By considering the value in each information field to be a letter, we treat every

single spot price record as an English word. For example, by random analogy, the spot price record "tag price1 time1 OS1 zone1" can be viewed as a six-letter word like "Hadoop", as highlighted in Figure 13.

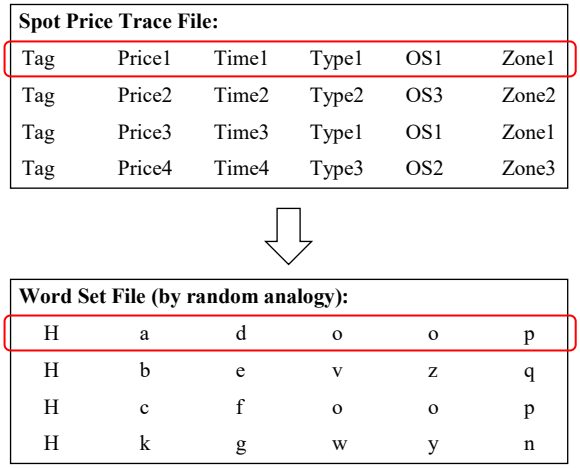

Figure 13: Treating spot price records as six-letter words.

As such, we are able to follow the logic of WordCount to fulfill the needs of cleaning our collected spot price history. In particular, instead of summing up the occurrences of the same price records, the duplicate records are simply ignored (removed). Moreover, the price records are sorted by the order of values of Instance Type, Operating System, Zone and Timestamp sequentially during the shuffling stage, while Tag and Price are not involved in data sorting. To avoid duplication, here we do not further elaborate the MapReduce-based data cleaning process.

4.3 Application Environment and Implementation

Unlike using "just-enough" environment for micro-level performance evaluation, here we employ "fair-enough" hardware resource to implement the MapReduce-based WordCount application, as listed in Table 7. In detail, the physical machine is Dell PowerEdge T110 II with the CPU model Intel Xeon E3-1200 series E3-1220 / 3.1 GHz. When preparing the MapReduce framework, we choose Apache Hadoop 2.7.0 [24] running in the operating system Ubuntu Server 16.04, and using Docker containers to construct a Hadoop cluster. In particular, Docker allows us to create an exclusive bridge network for the Hadoop cluster by using a specific name, e.g., `sudo docker network create --driver=bridge cluster`.

Environmental Item	Specification
Physical Machine	Dell PowerEdge T110 II
Operating System	Ubuntu Server 16.04
Java Environment	JDK 1.8.0
MapReduce Framework	Hadoop 2.7.0

Table 7: Summary of application environment.

In our initial implementation, we realized a three-node Hadoop cluster by packing Hadoop 2.7.0 into a Docker image and starting one master container and two slave ones. As illustrated in Figure 14, such a Hadoop cluster can logically be divided into a distributed processing layer (i.e. MapReduce workflow) and a distributed file-system layer (i.e. Hadoop Distributed File System (HDFS) in this case). When running a MapReduce application, the main interactions are:

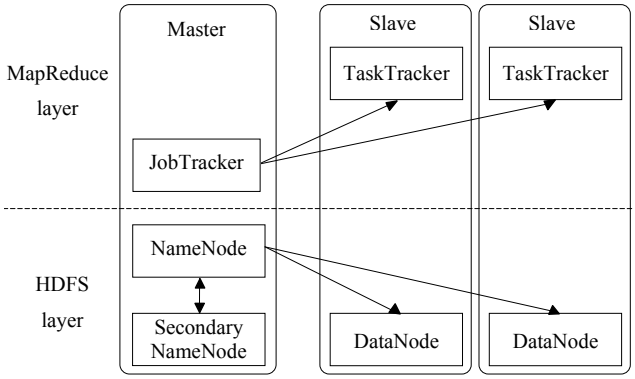

Figure 14: A three-node Hadoop cluster.

(1) A MapReduce job can run in a Hadoop cluster.

(2) The JobTracker in the cluster accepts a job from the MapReduce application, and locates relevant data through the NameNode.

(3) Suitable TaskTrackers are selected and then accept the tasks delivered by the JobTracker.

(4) The JobTracker communicates with the TaskTrackers and manages failures.

(5) When the collaboration among the TaskTrackers finish the job, the JobTracker updates its status and returns the result.

4.4 Performance Optimization Strategies

It is known that the performance of MapReduce applications can be tuned by adjusting the various parameters in the three configuration files of Hadoop. However, it is also clear that there is no one-size-fits-all approach to performance tuning. Therefore, we conducted a set of performance evaluation of our data cleaning application, in order to come up with a set of optimization strategies at least for this case.

- **Setting Timeout for Tasks.** A map or reduce task can be blocked or failed during runtime for various reasons, which would slow down the execution, and even result in the failure, of the whole MapReduce job. Therefore, by using TaskTracker to kill the blocked/failed tasks after a proper time span, those tasks will be able to be relaunched to save some waiting time. Given our relatively small size of data, we reduce the default timeout value from ten minutes to one minute, as shown below.

```
<!--Configuration in mapred-site.xml-->
<property>
  <name>mapred.task.timeout</name>
  <value>60000</value>
</property>
```

- **Turn on Out-of-Band Heartbeat.** Unlike regular heartbeats, the out-of-band heartbeat is triggered when a task is complete or failed. As such, JobTracker will be noticed the first time when there are free resources, so as to assign them to new tasks and eventually to save time. The configuration for turning on out-of-band heartbeat is specified as follows.

```
<!--Configuration in mapred-site.xml-->
<property>
  <name>mapreduce.tasktracker.
          outofband.heartbeat</name>
  <value>true</value>
</property>
```

- **Setting Buffer.** To begin with, we are concerned with a threshold percentage of buffer, and a background thread will be issued to spill buffer contents to hard disk when the threshold is reached. Inspired by the storage micro-benchmarking results (cf. Section 3.3.4), we decided to increase the threshold from 80% to 90% of buffer. As for the amount of memory to be buffer size, we double the default value (i.e. 100MB) for an intuitive test. These two parameters can be adjusted respectively as shown below.

```
<!--Configuration in mapred-site.xml-->
<property>
  <name>io.sort.spill.percent</name>
  <value>0.9</value>
</property>
<property>
  <name>io.sort.mb</name>
  <value>200</value>
</property>
```

- **Merging Spilled Streams.** As a continuation of spilling buffer contents to hard disk, the intermediate streams from multiple spill threads are merged into one single sorted file per partition which is to be fetched by reducers. Thus, we can control how many of spills will be merged into one file at a time. Since the smaller merge factor incurs more parallel merge activities and more disk IO for reducers, we decided to increase the merge value from 10 to 100, as shown below.

```
<!--Configuration in mapred-site.xml-->
<property>
  <name>io.sort.factor</name>
  <value>100</value>
</property>
```

- **LZO Compression.** Recall that the data we are dealing with are plain texts. The text data can generally be compressed significantly to reduce the usage of hard disk space and transmission bandwidth, and correspondingly to save the time taken for data copying/transferring. As a lossless algorithm with high decompression speed, Lempel-Ziv-Oberhumer (LZO) is one of the compression mechanisms supported by the Hadoop framework. In addition to various benefits and characteristics in common, LZO's block structure is particularly split-friendly for parallel processing in MapReduce jobs [25]. Therefore, we install and enable LZO for Hadoop by specifying the configurations below.

```
<!--Configuration in core-site.xml-->
<property>
  <name>io.compression.codecs</name>
  <value>org.apache.hadoop.io.compress.
          GzipCodec,org.apache.hadoop.
          io.compress.DefaultCodec,
       com.hadoop.compression.lzo.
          LzoCodec,com.hadoop.
          compression.lzo.LzopCodec,
       org.apache.hadoop.io.compress.
          BZip2Codec</value>
</property>
<property>
  <name>io.compression.codec.
                  lzo.class</name>
  <value>com.hadoop.compression.
              lzo.LzoCodec</value>
</property>

<!--Configuration in mapred-site.xml-->
<property>
  <name>mapreduce.map.output.
                  compress</name>
  <value>true</value>
</property>
<property>
  <name>mapreduce.map.output.
              compress.codec</name>
  <value>com.hadoop.compression.
               lzo.LzoCodec</value>
</property>
```

- **Doubling Slave Nodes.** In distributed computing, a common scenario is to employ more resources to deal with more workloads. Recall that map and reduce tasks of a MapReduce job are distributed to the slave nodes in a Hadoop cluster, and the physical machine used in this study has a Quad-Core processor. To obtain some quick clues at this current stage, we try to improve our application's performance by doubling the slave nodes, i.e. extending the original three-node cluster (with two slave nodes) into a five-node one (with four slave nodes). Note that, in this optimization strategy, we keep the other configurations settings by default.

4.5 Performance Evaluation Results

Due to the time limit, we follow "one factor at a time" to perform evaluation of the aforementioned optimization strategies. Furthermore, to confirm the effects of

these optimization strategies, we are concerned with 2GB+ and 5GB+ data respectively in the performance evaluation. Correspondingly, we draw the evaluation results in Figure 15 and 16 respectively.

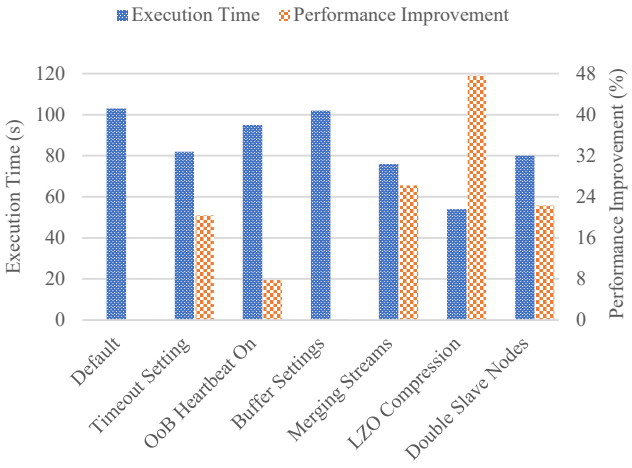

Figure 15: Performance optimization for 2GB+ data cleaning.

The results show three relatively different patterns of optimization effects. First, LZO compression acts as the most effective optimization strategy, and it can improve the performance nearly by 50% when dealing with 2GB+ data. Second, we can expect similar and moderate performance improvement by three individual strategies, such as merging more spilled streams, reducing the timeout value, and doubling the slave nodes. Third, out-of-band heartbeat and buffer settings seem not to be influential optimization strategies in this case.

These different optimization patterns could be closely related to the data characteristics of our application. On one hand, since text data can be compressed significantly [26], our application mostly benefits from the optimization strategy of LZO compression. On the other hand, since the current price traces used in this study are still far from "big data", the buffer setting could not take clear effects until the data size reaches TB levels.

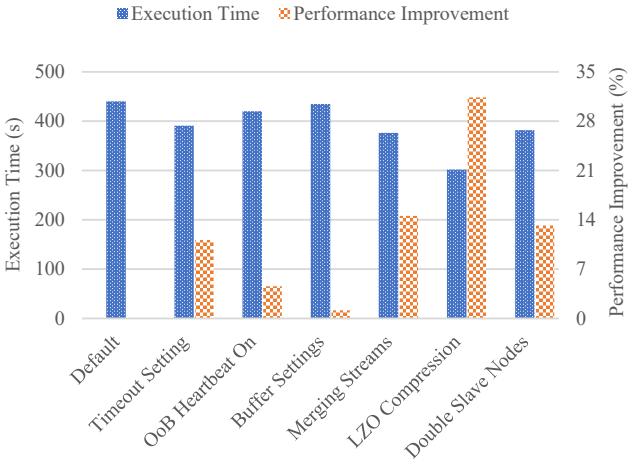

Figure 16: Performance optimization for 5GB+ data cleaning.

5 Related Work

Although the performance advantage of containers were investigated in several pioneer studies [3, 27, 10], the container-based virtualization solution did not gain significant popularity until the recent underlying improvements in the Linux kernel, and especially until the emergence of Docker [28, 29]. Starting from an open-source project in early 2013 [7], Docker quickly becomes the most popular container solution [2] by significantly facilitating the management of containers. Technically, through offering the unified tool set and API, Docker relieves the complexity of utilizing the relevant kernel-level techniques including the LXC, the cgroup and a copy-on-write filesystem. To examine the performance of Docker containers, a molecular modeling simulation software [30] and a postgreSQL database-based Joomla application [31] have been used to benchmark the Docker environment against the VM environment.

Considering the uncertainty of use cases (e.g., different workload densities and QoS requirements), at this current stage, a baseline-level investigation would be more useful and helpful for understanding the fundamental difference in performance overhead between those two virtualization solutions. A preliminary study has particularly focused on the CPU consumption by using the 100000! calculation within a Docker container and a KVM VM respectively [32]. Nevertheless, the concerns about other features/resources like memory and disk are missing. Similarly, the performance analysis between VM and container in study [33] is not feature-specific enough (even including security that is out of the scope of performance). On the contrary, by treating Docker containers as a particular type of Cloud service, our study considers the four physical properties of a Cloud service [15] and essentially gives a fundamental investigation into the Docker container's performance overhead on a feature-by-feature basis.

The closest work to ours is the IBM research report on the performance comparison of VM and Linux containers [34]. In fact, it is this incomplete report (e.g., the container's network evaluation is partially missing) that inspires our study. Surprisingly, our work denies the IBM report's finding "containers and VMs impose almost no overhead on CPU and memory usage" that was also claimed in [35], and we also doubt about "Docker equals or exceeds KVM performance in every case". In particular, we are more concerned with the overhead in performance variability.

Within the context of MapReduce clusters, Xavier et al. [10] conducted experimental comparisons among the three aforementioned types of container-based virtual environments, while a set of other studies particularly contrasted performance of OpenVZ with the hypervisor-based virtualization implementations including VMWare, Xen and KVM [3, 27]. The significant difference between these studies and ours is that we focus more on the performance optimization of a

container-based MapReduce cluster in a specific application scenario.

Note that, although there are also performance studies on deploying containers inside VMs (e.g., [36, 37]), such a redundant structure might not be suitable for an "apple-to-apple" comparison between Docker containers and VMs, and thus we do not include this virtualization scenario in our study.

6 Conclusions and Future Work

It has been identified that virtualization is one of the foundational elements of Cloud computing and helps realize the value of Cloud computing [38]. On the other hand, the technologies for virtualizing Cloud infrastructures are not resource-free, and their performance overheads would incur negative impacts on the QoS of the Cloud. Since hypervisors that currently dominate the Cloud virtualization market are a relatively heavyweight solution, there comes a rising trend of interest in its lightweight alternative [7], namely the container-based virtualization. Their mechanism difference is that, the former manages the host hardware resources, while the latter enables sharing the host OS. Although straightforward comparisons can be done from the existing qualitative discussions, we conducted a fundamental evaluation study to quantitatively understand the performance overheads of these two different virtualization solutions. In particular, we employed a standalone Docker container and a VMWare Workstation VM to represent the container-based and the hypervisor-based virtualization technologies respectively.

Recall that there are generally two stages of performance engineering in ECS, for revealing the primary performance of specific (system) features and investigating the overall performance of real-world applications respectively. In addition to the fundamental performance of a single container, we also studied performance optimization of a container-based MapReduce application in terms of cleaning Amazon's spot price history. At this current stage, we only focused on one factor at a time to evaluate the optimization strategies ranging from setting task timeout to doubling slave nodes.

Overall, our work reveals that the performance overheads of these two virtualization technologies could vary not only on a feature-by-feature basis but also on a job-to-job basis. Although the container-based solution is undoubtedly lightweight, the hypervisor-based technology does not come with higher performance overhead in every case. At the application level, the container technology is clearly more resource-friendly, as we failed in building VM-based MapReduce clusters on the same physical machine. When it comes to container-based MapReduce applications, it seems that the effects of performance optimization strategies are closely related to the data characteristics. For dealing with text data in our case study, LZO compression can bring the most significant performance improvement.

Due to the time and resource limit, our current investigation into the performance of container-based MapReduce applications is still an early study. Thus, our future work will be unfolded along two directions. Firstly, we will adopt sophisticated experimental design techniques (e.g., the full-factorial design) [39] to finalize the same case study on tuning the MapReduce performance of cleaning Amazon's price history. Secondly, we will gradually apply Docker containers to different real-world applications for dealing with different types of data. By employing "more-than-enough" computing resource, the application-oriented practices will also be replicated in the hypervisor-based virtual environment for further comparison case studies.
