
$e_2 = x_3 - x_{3d};\ x_{1d} = x_d; x_{3d} = \alpha_d, \alpha_d = 0.$

According to the sliding control principle, we determine the general sliding surface for systems A and B:

$s_{1b} = \dot{e}_1 + \lambda_1 e_1 = \dot{x}_1 - \dot{x}_{1d} + \lambda_1 (x_1 - x_{1d}) = x_2 + \lambda_1 x_1 - (\dot{x}_{1d} - \lambda_1 x_{1d}$ (7)

$s_{2b} = \dot{e}_2 + \lambda_2 e_2 = \dot{x}_3 - \dot{x}_{3d} + \lambda_2 (x_3 - x_{3d}) = x_4 + \lambda_2 x_3 - (\dot{x}_{3d} - \lambda_2 x_{3d}$ (8)

where: λ_1, λ_2 are positive constants.

To ensure the control target for bridge crane (5) and (6), we define the sliding surface s_1 for system A to ensure precise control of trolley position and sliding surface s_2 for system B to ensure the general control target for bridge crane, that is: controlling the trajectory of the trolley, quenching the payload oscillation of the payload, the anti-disturbance. Therefore, we need to use the intermediate variable z to link the signal between the sliding surface s_1 and the sliding surface s_2. On that basis, the author defines the sliding surface s_1, s_2 as follows:

$s_1 = s_{1b} = \dot{e}_1 + \lambda_1 e_1 = \dot{x}_1 - \dot{x}_{1d} + \lambda_1 (x_1 - x_{1d}) = x_2 + \lambda_1 x_1 - (\dot{x}_{1d} - \lambda_1 x_{1d}$ (9)

$s_2 = \dot{e}_2 + \lambda_2 (e_2 - z) = \dot{x}_3 - \dot{x}_{3d} + \lambda_2 (x_3 - x_{3d} - z) = x_4 + \lambda_2 (x_3 - z) - (\dot{x}_{3d} - \lambda_2 x_{3d}$ (10)

Intermediate variable z are defined as follows:

$$z = \bar{z}.sat(s_1/\Phi_z) \quad (11)$$

where: $|z| \le \bar{z};\ 0 < \bar{z} < 1,\ \bar{z}$ is the upper limit of |z|, Φ_z is the boundary limit s_1.

$$sat(s_1/\Phi_z) = \begin{cases} sign(s_1/\Phi_z) & if \quad |s_1/\Phi_z| \ge 1 \\ s_1/\Phi_z & if \quad |s_1/\Phi_z| < 1 \end{cases}$$

Because of $\bar{z} < 1$ it can be effective in reducing. When s_1 reduced z is also decreases. When $s_1 \to 0,\ z \to 0,\ e_2 \to 0$ then $s_2 \to 0$ and achieves the control target for crane (5) and (6). Therefore, by adding intermediate variables z now s_1 and s_2 at the same time tends to 0.

According to the sliding control principle, when $\dot{s}_2 = 0$ we get the sliding control law for bridge crane, it looks like this:

$$u_{eq} = \frac{-\lambda_2 x_4 + \lambda_2 \dot{z} - f_2 + \ddot{x}_{3d} + \lambda_2 \dot{x}_{3d}}{g_2} \quad (12)$$

Control law (12) for bridge crane is a complex nonlinear function, for which $\dot{z}$ is not defined. Therefore, in this article, the author proposes adaptive fuzzy-sliding mode control law to imitate the sliding control law (12) based on fuzzy logic control and Lyapunov function.

3.2. Fuzzy controller based on sliding mode control principle

Define fuzzy controller with input s_2 and output u_f with fuzzy control rules *i-th as below*:

Rule i: IF s_2 is F_i THEN u_f is θ_i, i=1,2..n (13)

where: F_i is the input fuzzy set with the membership function $\mu_{Fi}(.)$ and θ_i are the changing singleton output values.

Defuzzification with centroid method, we obtain:

$$u_f(s_2, \theta) = \frac{\sum_{i=0}^{n} \xi_i.\theta_i}{\sum_{i=0}^{n} \xi_i} = \theta^T \xi \quad (14)$$

where: $\xi_i = \mu_{Fi}(s_2)$ is the reliability of the *i-th* fuzzy control rule.

$$\theta = [\theta_1, \theta_2, ..., \theta_n]^T;$$

$$\xi = [\xi_1 / \sum_{i=1}^{n} \xi_i, \xi_2 / \sum_{i=1}^{n} \xi_i, ..., \xi_n / \sum_{i=1}^{n} \xi_i]^T \quad (15)$$

According to the fuzzy approximation theory, there is an optimal fuzzy controller u_f^* of the form:

$$u_f^* = (\theta^*)^T \xi \quad (16)$$

where: θ^* is the optimal parameter set as follows:

$$\theta^* = \arg\min_{|\theta| \le M_\theta} \left\{ \sup_{|s_2| \le M_{s2}} |u_f - u_{eq}| \right\},\ \forall t \quad (17)$$

where: M_θ, M_{s2} are the appropriate values when designing.

The control signal (16) is closest to (12), in other words, the deviation *d(t)* is the smallest:

$$d(t) = u_f^* - u_{eq} \text{ với } 0 \le d(t) \le D \quad (18)$$

Here the limit *D* is a positive number, but it is uncertain in practice. Called $\hat{D}$ the estimated value of the limit D. Then the estimate of the limit *D* is $\tilde{D}$ is defined as follows: $\tilde{D} = D - \hat{D}$

Therefore, based on (12), the author proposed a new control law for bridge cranes (5) and (6) with the following form:

$$u = u(s_2, \theta, \hat{D}) = u_f(s_2, \theta) + u_c(s_2, \hat{D}) \quad (19)$$

Here $u_f(s_2, \theta)$ the fuzzy controller (14) has the closest value to (12); and $u_c(s_2, \hat{D})$ is the compensated controller to compensate for the deviation (if any) between control laws (14) and (12). The compensation controller $u_c(s_2, \hat{D})$ is determined based on the Lyapunov stability theory, ensuring the stable asymptotic bridge crane control system.

3.3. Adaptive laws based on Lyapunov function

Next, the author summarizes the compensation controller $u_c(s_2,\hat{D})$ and determines the adaptive law to update the parameters θ, $\hat{D}$ so that (19) optimal operation is closest to (12), which means $\theta(t)\to\theta^*$ and $\hat{D}(t)\to D$. Set $\tilde{\theta}=\theta^*-\theta$ and select Lyapynov function with the following form:

$$V(s_2,\tilde{\theta},\tilde{D})=\frac{1}{2}s_2^2+\frac{1}{2\eta_1}\tilde{\theta}\tilde{\theta}+\frac{1}{2\eta_2}\tilde{D}^2 \quad (20)$$

According to (10) sliding surface derivative s_2 and from (19) combined with (12), (15), (18), we obtain:

$$\begin{aligned}\dot{s}_2&=\dot{x}_4+\lambda_2(\dot{x}_3-\dot{x}_{3d})-\ddot{x}_{3d}-\lambda_2\dot{x}_{3d}\\&=\lambda_2x_4-\lambda_2\dot{x}_{3d}+f_2+g_2u-\ddot{x}_{3d}-\lambda_2\dot{x}_{3d}\\&=\lambda_2x_4-\lambda_2\dot{x}_{3d}+f_2+g_2(u_c+u_f-u_f^*+u_f^*)-\ddot{x}_{3d}-\lambda_2\dot{x}_{3d}\\&=g_2(u_f-u_f^*+u_c+d)\end{aligned} \quad (21)$$

The derivative (20) over time, combined with (14), (18), (21) we have:

$$\begin{aligned}\dot{V}(s_2,\tilde{\theta},\tilde{D})&=s_2\dot{s}_2+\frac{1}{\eta_1}\tilde{\theta}\dot{\tilde{\theta}}+\frac{1}{\eta_2}\tilde{D}\dot{\tilde{D}}\\&=s_2g_2(u_f-u_f^*+u_c+d)+\frac{1}{\eta_1}\tilde{\theta}\dot{\tilde{\theta}}+\frac{1}{\eta_2}(D-\hat{D})(-\dot{\hat{D}})\\&=s_2g_2(-\tilde{\theta}\xi+u_c+d)+\frac{1}{\eta_1}\tilde{\theta}\dot{\tilde{\theta}}-\frac{1}{\eta_2}\dot{\hat{D}}(D-\hat{D})\\&=\frac{1}{\eta_1}\tilde{\theta}(\dot{\tilde{\theta}}-\eta_1g_2s_2\xi)+s_2g_2u_c+\frac{1}{\eta_2}\hat{D}\dot{\hat{D}}+s_2g_2d-\frac{1}{\eta_2}D\dot{\hat{D}}\end{aligned} \quad (22)$$

According to Lyapunov stability theory, the bridge crane control system is stable, the necessary condition is $\dot{V}\le 0$. From there according to (22), we determine the compensation controller $u_c(s_2,\hat{D})$ according to (23) and the parameter $\hat{D}$ update law according to (24), the parameter θ update law as follows (25).

$$u_c=-\hat{D}sign(s_2g_2) \quad (23)$$

$$\dot{\hat{D}}=-\dot{\tilde{D}}=\eta_2|s_2g_2| \quad (24)$$

$$\dot{\tilde{\theta}}=-\dot{\theta}=\eta_1g_2s_2\xi \quad (25)$$

3.4. Prove asymptotic stability of bridge crane control system

Replacing (23,24,25) into (22) we obtain:

$$\dot{V}(s_2,\tilde{\theta},\tilde{D})=s_2g_2d-|s_2g_2|D\le 0 \quad (24)$$

According to (24), Lyapunov (20) function, $\dot{V}\le 0$, which ensures that $s_2,\hat{\theta},\hat{D}$ is limited. Thus, when time reaches infinity function *V* goes to 0:

$$\lim_{t\to\infty}V=0 \quad (25)$$

This also ensures that when $t\to\infty$ then $s_1\to 0, s_2\to 0$, $\theta\to\theta^*,\hat{D}\to D$, i.e. the crane control systems (5) and (6) are asymptotically stable, the output is tracked to the input reference.

Thus, the crane control system described by (5) and (6) uses the new control law proposed in the article, determined by (19), (14), (23), (24), (25) based on combination of sliding mode control, fuzzy logic and adaptive law based on Lyapunov function, ensuring precise control of the trolley position according to the set reference with eliminated payload oscillation, anti-disturbance.

The block diagram of adaptive fuzzy-sliding control system for 2D crane is shown as Figure 3, including: sliding surface block, fuzzy control block and compensation control block, parameters adaptive update block.

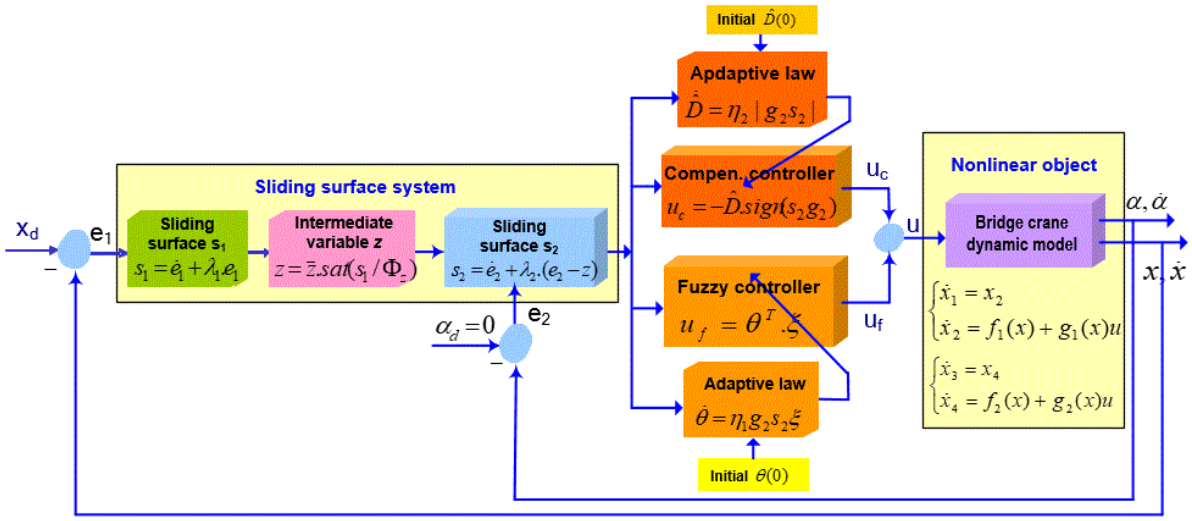

Figure 3. The block diagram of adaptive fuzzy-sliding control system for 2D crane

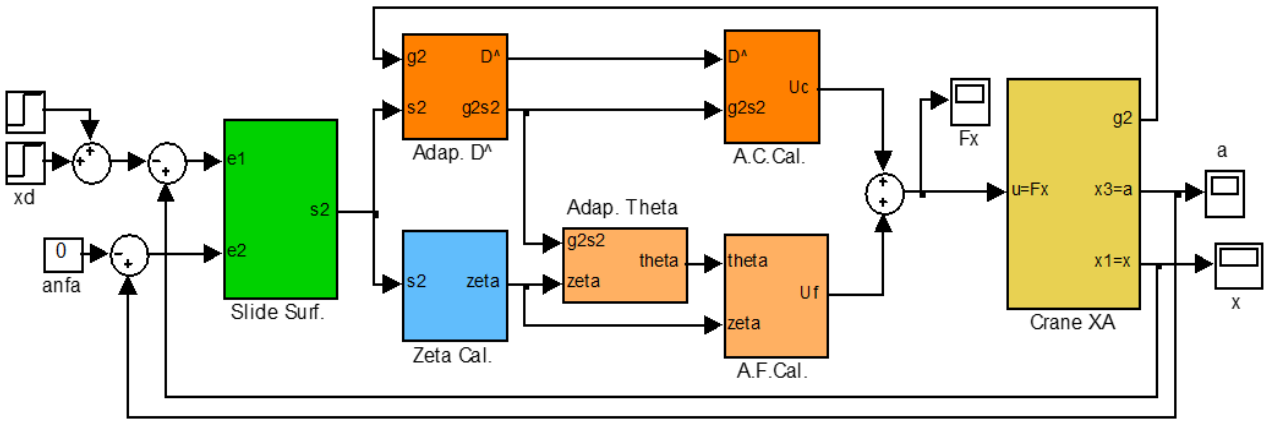

Figure 4. Simulation diagram of the bridge crane adaptive fuzzy-sliding mode control system

4. Simulation results

Simulation parameters of the crane are selected based on physical crane model at UTC laboratory [1].

According to the principle of sliding mode control [12] and crane parameters [1], we choose the sliding surface parameters as follows:

$$\lambda_1 = 0.6, \lambda_2 = 100, \eta_1 = 50, \eta_2 = 0.001, \bar{z} = 0.99, \Phi_z = 5.$$

Building a 2D crane control system on Matlab, using the adaptive fuzzy-sliding control law (AFS) proposed in the paper, we obtained the simulated system diagram as shown in Figure 4, including function blocks: Slide Surf block: calculate the sliding surface of the system; ZetaCal block: calculate ξ; Adap D^ block: calculate the update value $\hat{D}$ for the offset compensation controller; Adap. Theta block: calculate updated value θ for fuzzy controller; AF Cal. block: output of fuzzy controller; AC Cal. block: the output of the controller compensates for deviation; Crane XA block for bridge crane dynamic model.

Based on experience in crane operation and fuzzy control principle, with the above crane parameter [5], the author performs fuzzy input s_2 of the controller (14) by {NB, NM, NS, ZE, PS, PM, PB} having triangular integrated functions with domain $s_2 \in$[-20; +20] and fuzzy output u_f with {UN, UM, US, UZ, FS, FM, FB} having singleton functions with the physical value domain $u_f \in$[0;100].

Simulation scenario of the bridge crane adaptive fuzzy-sliding control system includes the following cases:

+ Case 1: Let the trolley run to position 0.5m and then the trolley runs to position 1.0m and changes coefficients λ_1, λ_2;

+ Case 2: Let the trolley run to position 0.5m and then the trolley runs to position 1.0m and changes coefficients η_1, η_2;

+ Case 3: Let the trolley run to position 0.5m and then the trolley runs to position 1.0m and changes coefficients $\bar{z}, \Phi_z$;

+ Case 4: The input reference is a slope;

+ Case 5: There is impact disturbance;

+ Case 6: Use AFS controller and PID controller [1].

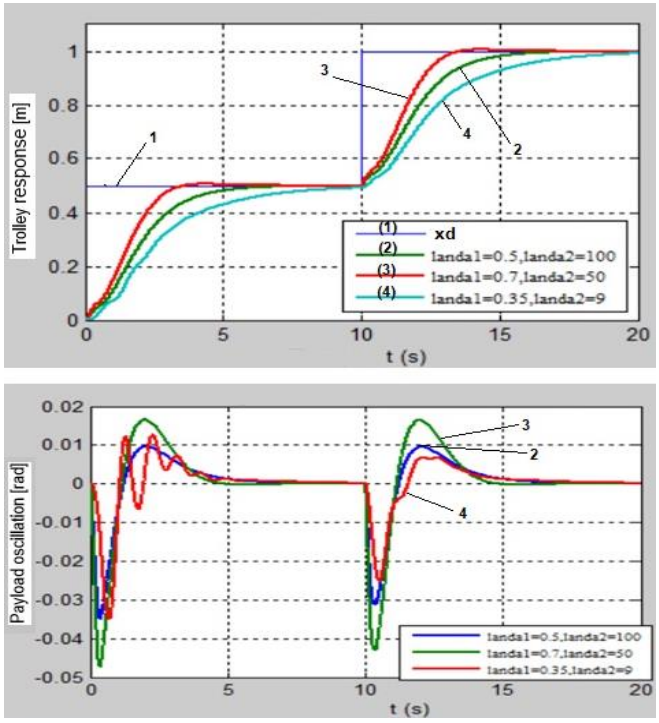

Figure 5. Crane response with different λ_1, λ_2

Table 1. The proposed controllers' performance

Index \ Controller	PID	AFS
Rise time	Small, ~2.5s	Small, ~2.5s
Over shoot	Large, 20.5%	Not
Steady time	Large, ~7s	Small, ~5s
Steady error	<5%, but large with disturbance	~0, or very small
Anti-swing payload	<10°, but large with disturbance	~0, or very small
Anti-disturbance	<10°, but large with loud disturbance	~0, or very small

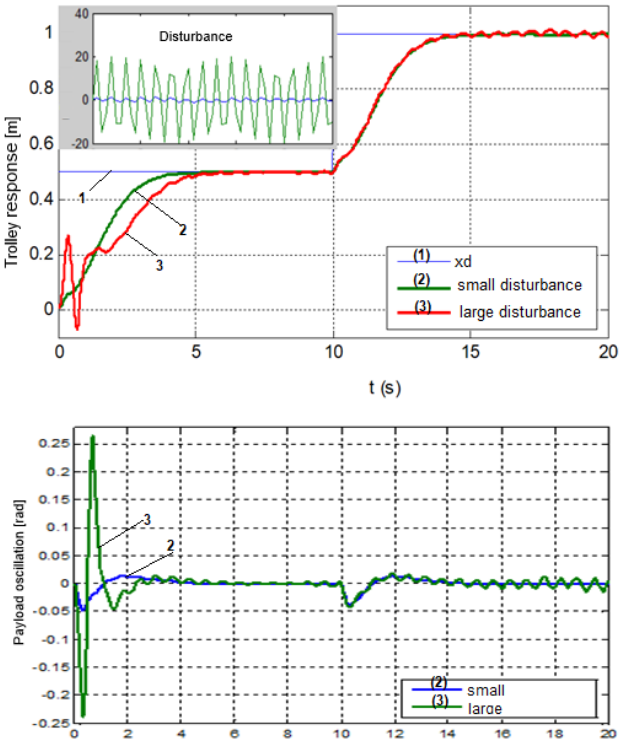

Figure 6. Crane response as affected by disturbance

Simulation results show that the quality of the bridge crane control system as using AFS controller is better than as using PID controller. The application of the AFS controller to the crane obtained the following results: quick trolley's position response, short settling time, eliminating steady error, anti-swing (or very small) payload, anti-disturbances (or very small).

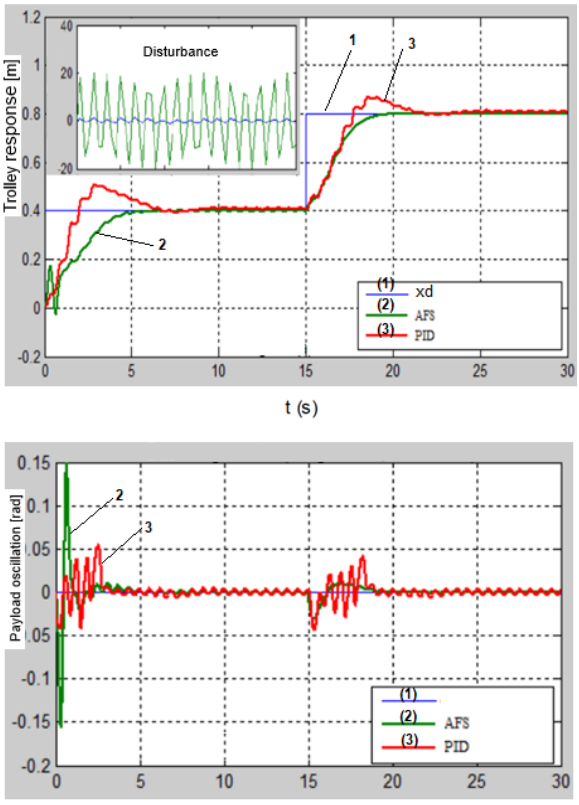

Figure 7. Crane response with AFS and PID controller

The simulation results also show that the selection of the coefficient of the sliding surface affects the quality of the adaptive control system of fuzzy-sliding crane, specifically as follows: when increasing λ_1, the trolley position response is better but greater is the payload oscillation; when decreasing λ_2 or increasing it too large, the payload swings strongly; when η_1 is too small or when η_2 is too large, the trolley position response has vibration and greater payload oscillation; when Φ_z decreases or $\overline{z}$ decreases too small, the trolley position response has vibration and the payload Will swing larger.

5. Conclusion

The article has proposed a new adaptive fuzzy-sliding mode controller (AFS) for 2D bridge crane based on combining sliding mode control with fuzzy logic and Lyapunov function. The AFS controller ensures the objective of controlling the position of the trolley tracking according to the reference trajectory, eliminating the payload oscillation and anti-disturbance (small amplitude). The quality of the bridge crane AFS control system is better than PID controller when crane is affected by large disturbance. The adaptive fuzzy-sliding mode control algorithm allows simple installation on hardware control devices with a normal amount of calculation. The AFS controller allows the crane to operate safely and reliably in harsh environments, such as the harbor.

The success of the AFS controller for 2D bridge crane will continuously study to be applied for the object in real time and for 3D crane with the random disturbances.

Conflict of interest

The authors declare no conflict of interest.

ABSTRACT

The definition of equipment and components of physical plants is a necessary step towards the development of simulation, control, and supervisory applications for the petrochemical industry. Often it happens that the same plant/equipment is (re)modeled on each application, causing a waste-of-time on repetitive (re)design, besides introducing potential inconsistencies between the models. Moreover, even though each software platform normally offers a different view of the same plant, it is desirable to have some kind of interoperability between them. This paper presents a solution for such issues named M4PIA, which consists in a Model-Driven Engineering (MDE) tool support developed mainly for petrochemical industry automation. M4PIA allows representing industrial plants by means of different and interchangeable object-oriented models, providing means to perform automatic code generation from a plant specification for different software platforms. Currently, our work involves using M4PIA in high-level automation manouvers and plant simulations. Evaluations studies performed with M4PIA shows that it covers most features expected from a MDE tool suite. Besides, the use of M4PIA is expected to result in less development time and costs, while it increases efficiency, maintainability, and reliability of the developed applications.

1 Introduction

There is no doubt that todays industrial environments are highly automated, at least in the first two layers of the ISA95 automation pyramid. The most basic layer, named *Field Level*, includes devices, actuators, and sensors. The *Control level* is immediate above, and accounts with PLCs and PIDs to control such devices. Programming PLCs and PIDs is typically done by means of integrated development environments (IDEs) that comply with international standards IEC 61131-3 [1] and IEC 61499 [2]. Rarely this kind of system does not make use of SCADA (supervisory control and data acquisition) in a third *Supervisory* layer.

The IEC 61131-3 standard [1] addresses PLC programming, including four programming languages and sequential function charts (SFC). It helps migrating software developed for one PLC type to PLCs of other vendors. Targeting distributed systems, the IEC 61499 standard [2] replaces the cyclic execution model of IEC 61131 by an event-driven execution model, which allows an explicit specification of the execution order of function blocks (FB). Both standards do not address equipment specification semantics.

To cope with procedures for automating continuous process operations there is the ISA 106 standard [3], which is typically deployed at the *Supervisory level*. Examples of commercial tools therefore are *Exapilot* from Yokogawa and *GenSym G2* from Ignite Technologies. The present work stands at this layer, and makes use of a proprietary tool with similar goals named MPA [4].

Another common need in automation systems, specially when advanced control techniques come to play, is performing simulations. Examples of tools for such purposes are Labview, Matlab/Simulink, and Modelica-based (like Dymola and OpenModelica). These tools provide powerful simulation cores, and also provide a vast library of components that allow designers to build virtually every system or system element they want to. It happens, however, that there is no specific semantics for equipment specification.

Considering an automation plant, the lack of semantics for equipment specification brings difficulties for representing this same automation plant in the different software de-

[*]Thaise Poerschke Damo, DAS/CTC/UFSC, +554837217606 & thaisedamo@gmail.com

velopment tools used in all automation levels. Such repeated representation is something quite common, for instance, to implement different perspectives in the automation domain: processes operation, monitoring, simulation, and control.

The work presented in this paper targets the integration of different perspectives in petrochemical industry automation through a tool support built on the Model-Driven Engineering (MDE) paradigm [5]. MDE is built on widespread techniques in Systems and Software Engineering, presenting the following main characteristics: (1) uses models in all the phases of software development to improve understanding; (2) raises the abstraction level of software system specifications, hiding platform-specific details; (3) develops Domain-Specific Languages (DSLs) [6] and frameworks to suit a domain; and (4) applies transformations to automate repetitive activities and improve product quality derived from Software Engineering (e.g., source code, libraries, processes, etc.) [7]. In other words, MDE proposes representation of diverse artifacts through modeling and tool support.

This paper presents M4PIA (Model-Driven Engineering for Petrochemical Industry Automation), which consists of an infrastructure and tool support to help the design of advanced control applications for the Petrochemical Industry. An evaluation of the proposal is also presented. Therefore, the remainder parts of this paper are organized as follows: Section 2 presents background information that motivates this research, highlighting the application domain and related works. Section 3 details the proposed M4PIA infrastructure and tool support. Section 4 shows the evaluation method employed for assessment. Section 5 details M4PIA assessment and presented obtained results. Section 6 highlights our conclusions and future works perspective.

2 Background

2.1 Advanced Control in the Petrochemical Industry

This work targets the design of advanced control strategies for the Petrochemical Industry. The advanced control does not intend to control the automation plant devices (valves, motors, etc) located in the *Field Level* of the automation plant. This low-level control should be done by the regulatory control in the upper, *Control level*, that executes on the PLCs. The advanced control stands at the *Supervisory level*.

For example, let us analyze the design cycle of an advanced control system for oil extraction platforms. Initially, designers should create a software-in-the-loop (SIL) environment, where the phenomena to be controlled (e.g. gas compression) is "executed" within a simulation tool (Labview, Simulink, Modelica) that communicates with the control software executing in the same hardware platform that will be used in the final system. Here, the automation plant elements are represented twice: (1) in the simulation model and (2) in the control software.

Before deploying the control system under design in the operational environment (the oil extraction platform), tests are typically performed in a hardware-in-the-loop (HIL) environment. At this point, instead of communicating the control system directly with the simulation tool, it must interact with the same hardware (PLCs) and software (drivers) that are used in the operational environment - here the PLCs communicate with the simulator. The communication between control software and PLCs is typically done by means of some kind of bridge, for instance OPC drivers. Using this kind of structure brings the need of creating a third plant representation, which stands for the supervisory software. A fourth plant representation could be used if an specific simulator is adopted in the HIL environment, which is something common in the oil industry. In theory, if the HIL implementation passes all tests, the control system is ready to be implemented in the operational environment.

Given such scenario, the problem under consideration in our work concerns providing a solution to optimize the long time needed to model the equipment in different software development tools (and languages). It also should reduce possible inconsistencies generated when moving from one model to the other. It is important to provide interoperability among such plant representations.

The development starting point of the proposed infrastructure was the analysis of a system called MPA (acronym for Automated Procedures Module). MPA software platform is widely used by the development team of Petrobras in the operation and control of several oil platforms and refineries. It can be used for simulation purposes and also to control the operation of real systems. In order to maximize the gains from using a MDE approach, it was also analyzed the system called EMSO (Environment for Modeling, Simulation and Optimization), a platform used for modeling and simulating chemical processes.

2.1.1 MPA Operation and Control Software

MPA [4] software was developed for oil platforms automation in order to support the development and execution of industrial control and automation applications. This software was developed by Tecgraf/PUC-Rio Institute under request of Petrobras S.A.

Automation is performed through operation maneuvers of plant equipment. Basically, MPA consists of an execution server and a configuration and management application. In the latter, industrial plants are modeled using object-orientation and diagrams are used to define the maneuvers in the respective plant. The server is responsible for executing the configured operation maneuvers in the diagrams and handles the equipment interacting with the supervisory system through OPC (OLE for Process Control) communication bridges.

Currently, processes equipment are modeled directly in LUA programming language as classes in the application's pre-configuration phase. In this phase, attributes and methods of each class are defined, i.e., of each type of equipment. One equipment can be used to compose another, being modeled as its attribute. Equipment classes are described in a pre-configuration file and loaded at the MPA configuration stage. The developer uses such info to define the plant equipment instantiation and to model the execution diagrams, in flow language, which describes the operating maneuvers of plant equipment, i.e., the sequence of equipment functions execution. Plant and flow files are saved separately in other file formats.

The infrastructure proposed in this paper is able to simplify the pre-configuration phase by generating code automatically, reducing the time spent in conceptual modeling for new plants or even guiding the development of similar supervision and control applications, reusing existing models by including, extending, or modifying them.

2.1.2 EMSO Simulation Software

EMSO [8] is a tool for modeling and simulating dynamic processes based on equations. It is part of a project maintained by a consortium of Brazilian universities and national petrochemical companies.

The EMSO platform is composed by a graphical interface and its own object-oriented modeling/programming language. Such language was created from the combination of the best modeling characteristics found in existing languages, resulting in a simpler language with a better code reusability.

EMSO modeling language is composed of three major entities: models, devices, and flowsheets. Model is the mathematical description of a device. Device is an instance of the model and represents a real process equipment. Flowsheet represents the process to be analyzed, which is composed of a set of devices. A model development in EMSO consists of defining a class of a real equipment or a part of a process. Model can be composed of parameters, variables, equations, initial conditions, and sub-models and can be based on a pre-existing one, only adding new functionalities.

The graphical user interface allows developers to create models, build flowcharts, check project consistency, execute simulations and visualize the results. The software has several consistency analysis of the model and the whole process to be simulated, including: initial conditions consistency, measurement units, and system of equations solvability. The platform is multithread, which allows real-time simulations to run more than one simulation at the same time.

The proposed solution aims to support equipment models by generating automatic codes and to maintain a correct correspondence between plants to be controlled by other applications and their simulated processes in EMSO for tuning tests and validation of control proposals.

2.2 Challenges Related with MDE Usage

Using MDE in the present work comes from the fact that it is a software development methodology with emphasis on the domain specification models, allowing to improve productivity, system understanding, and its maintenance and evolution. MDE paradigm proposes applications described through models at different levels of abstraction using standards such as the UML (Unified Modeling Language). More than just conceptual design, the produced models can be interpreted by automation tools that can generate schemas, code skeletons, and tests for multiple platforms. Definitions of more abstract layers provide formal basis for structuring lower-layer models. Thus, it is possible to facilitate design decisions and to build artifacts automatically from models, reducing development times and costs.

Additionally, MDE has been used to support software systems development in both academia [9]–[11] and industry [12]–[19]. Among the benefits credited to MDE, Mohagheghi et al. [20] highlight the following: shortened development time and increased productivity; improved software quality; automation through generation of code and other artifacts; provision of a common framework for software development across the company and lifecycle phases; maintenance and evolution; improved communication and information sharing among stakeholders. MDE is especially interesting for scenarios involving systems that should be made available on multiple platforms [21].

However, developing software systems with MDE is not trivial. Besides the development of domain specific languages, it requires an automated process, including transformation scripts that connects MDE resources, such as refinement tools and model-based operations [22]. In special, these works need specific assessment for their pieces, such as for DSLs, as well as for their integration promoted by model transformations. In this sense, Mohagheghi et al. [14] go beyond and also expose the criteria that led companies to adopt MDE. Such criteria involve the abstraction level that hides details, communicating with non-technical staff, as well as model-based simulation, execution, and test. In other words, a feature analysis is required.

2.3 Related Works

The idea to use object-orientation towards developing industrial automation systems is not new. For instance, in [23], the authors presented an environment that allowed to make object-oriented modeling of plant equipment ir order to further make automatic code generation. Even though the proposal was conceptually very interesting, it did not make use of standard modeling languages (at that time UML was emerging), so that it could not be adapted to current standards. More up-to-date standards were used by Thramboulidis in [24], but the foccus of that work was not on the static-structure of the plants but on their their dinamic behavior, specially targeting implementation on PLCs. In fact that was an anticipation of the recent IEC-61131-3 standard [1], which covers the use of object-oriented programming on PLCs.

Other related works only covered partially the issues presented in this paper. In chemical engineering domain, for instance, Becker [25] presented an UML-based framework for building integration tools that help developers in change propagation for maintaining inter-document consistency, focusing on relationships between flow sheets, that describe chemical processes and its simulation models. MindCSP solution [26] focuses on specifying the autonomic behavior of cyber-physical systems by its sensor-actuator networks and the autonomic control loops (monitor/analyze/plan/execute). Another example of approach that supports development of industrial control applications is the AUKOTON process [27], based on the UML Automation Profile, uses profile's concepts to represent the requirements, functionality and structure of the control applications, including requirements of stakeholders, alarm events, and control algorithms such PID, fuzzy and MPC. Other relevant applications of MDE are referenced in a state-of-the-art review of software engineering in industrial automation [28]. However, so far there is no other related work on MDE application with focus

on the generic definition of industrial plants equipment for sharing between different software: control, operation, and simulation platforms. This gap is fulfilled by the proposal presented in this paper.

3 Proposed M4PIA Infrastructure

The proposed M4PIA infrastructure is composed by: 1) domain specific languages, which intents to abstract three levels that hides details from implementation; 2) two sets of model transformations supporting automated model integration between these three DSLs; and 3) two sets of code generators. Everything is developed under the same Eclipse ecosystem, including the Eclipse Modelling Framework (EMF) [29], the Acceleo model transformation engine for code generator [30], and QVTo as a mean to make transformations between different metamodels [31].

A model in MDE represents part of a function, structure, or behavior of a system. The domain knowledge necessary to design M4PIA was acquired by the analysis of a significant set of applications designed on different software platforms from the petrochemical industry, seeking to identify typical requirements and behaviors of these systems. Understanding different applications provide the ability to differentiate general structures, the invariant domain aspects, from the specific structures, the variable aspects. Successive analysis and synthesis steps converged to the generic domain design model that was created.

In a model-driven engineering method, a high level of abstraction is typically used in the application development. The system development process in MDE starts with the highest abstraction model and decreases through properly defined transformations (model refinement). There are two MDE abstraction levels used in the present work: a platform independent viewpoint, the Platform Independent Model (PIM) and specific platform viewpoints, the Platform Specific Model (PSM). The latter contains details and characteristics of specific implementations platforms.

In a new application development its PIM model is created according to the provided metamodel (constructed based on domain conceptual analysis), then the PSM model is automatically generated by a Model-to-Model transformation (M2M), based on the PIM model and according to the PSM metamodel. Lastly, the platform-specific source code is generated from the PSM through an automatic Model-to-Text transformation (M2T). This process is illustrated in Figure 1.

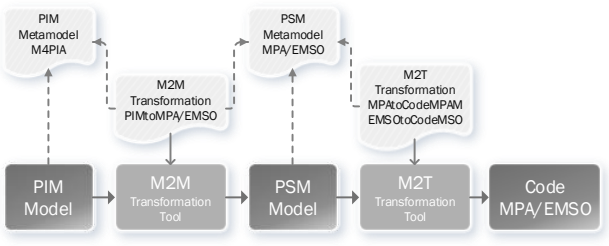

Figure 1: Development cycle using M4PIA

M4PIA infrastructure is built as support for the MDE of equipment class definition, so that applications for operation, control, and simulation platforms for the petrochemical industry can be created. The proposed solution was implemented in the EMF (*Eclipse Modeling Framework*) tool [29], in *Eclipse Oxygen* environment. The first and fundamental element built is the M4PIA metamodel, a PIM metamodel that represents the entire domain of the desired applications to be created, independently of its implementation platform. Then the PSM metamodels were constructed, defining the specificities of each supported platform. Based on metamodels, it was defined the M2M transformations from PIM model to PSM models and, at last, the M2T transformations for the automatic source code generation from each PSM model.

3.1 M4PIA Metamodel

The identification and analysis of petrochemical industry applications allowed the definition of a set of generic elements, capable of being shared by a wide range of industrial automation systems. This set of elements are materialized by means of a metamodel named *M4PIA*. Our aim is that M4PIA metamodel can contribute substantially for the implementation of new systems from such application domain, targeting reusability and facilitating automatic code generation.

The developed M4PIA metamodel is presented here through a class diagram designed using the *Eclipse Modeling Framework* and its *Ecore* metamodel, similar to UML. The proposed class diagram is shown in Figure 2. The representation shows a set of classes, interfaces, and collaborations, with their respective relationships, expressing results of the structure and requirements analysis of the problem domain and its components. Model constraints were specified using OCL (Object Constraint Language). The main metamodel elements are detailed next.

An entity is defined as the most elementary unit of the proposed model. The `Entity` class is considered abstract and only provides a basic structure for the more specialized classes in the hierarchy. A `Project` is instantiated and can be composed of several `Files`. These can be imported as libraries, `ImportedFile`, or be an entity group to have their source code generated by the infrastructure, `GeneratedFile`.

An `Equipment` is a type of entity that can contain attributes and methods, defined as specific classes to reflect physical characteristics and functions performed by the equipment in a plant.

The abstract class `Variable` represents a logical variable and can be `NonTyped` or `Typed`. Typed variables can be `EquipmentType` or `BasicType`, more specifically `Real`, `Integer`, `Boolean`, or `String`.

The `Method` class is a `Function` specialization and has exclusive connection to an `Equipment`. The `Function` class represents a logical entity that can either represent a high-level operation (in the physical domain of the plant) or a low-level (in the application domain). A function can have multiple `Variable` instances associated, acting as parameters or results, as well as may have a language and an associated code, which textually describes the instruction desired for the interpreter.

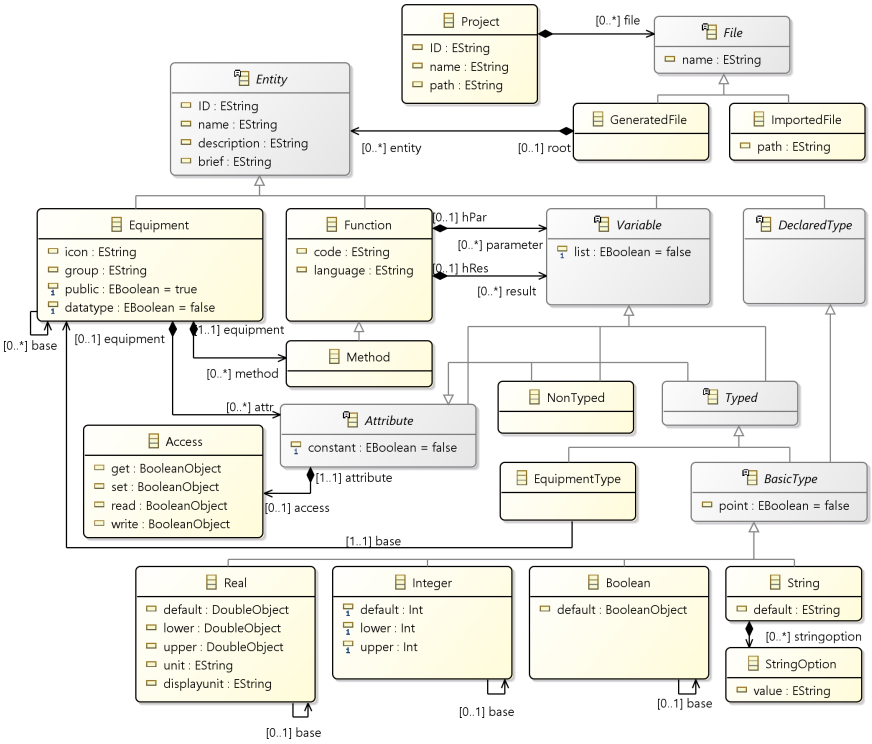

Figure 2: Elements of the proposed M4PIA metamodel

An equipment `Attribute` is a specific case of Variable which is allowed, through the relationships hierarchy, to assume a type that can be another `Equipment`. This aspect guarantees to the metamodel the ability to reproduce scenarios where there are natural recursions in relationships between equipment, i.e., an equipment or a machine that has other equipment as an attribute. For example, a specific type *Compressor* can be used as one of the attributes of a *Compression System*, both devices being instantiated by the `Equipment` class.

Furthermore in the `Attribute` context, there is a permission management for read or write operations, as highlighted in the `Access` class. New data types can be defined through the `DeclaredType` entity, based on basic types, and can be used as the basis for variables and attributes as well. For example, it is possible to declare a new type *Positive Real* and set a real type attribute *Position* of an equipment *Valve* based on the *Positive Real* type.

3.2 MPA and EMSO Metamodels

Given that the generic M4PIA metamodel was obtained through the analysis of the specific software platforms, the specific metamodels for each software are similar to the generic one and the main differences between them are further highlighted.

The PSM for MPA, or simply MPA metamodel, is depicted in Figure 3. The `Component` element corresponds to `Entities` in M4PIA. In addition to `Equipment`, the `Class` component can also be specified as `PointClass`, considered on the platform as a data type. `Variable` and `Attribute` classes are not abstract and must have an associated `Type`. Possible types are `BasicType`, point classes, and equipment. MPA basic types instances are imported automatically at the beginning of each project, they are: *Real*, *Integer*, *Logical*, and *Textual*. Four instances of native MPA point classes are also imported: *Real Point*, *Integer Point*, *Logical Point*, and *Textual Point*, each with its attributes.

In the MPA platform, codes are not exclusive related with functions, classes and files can also be composed by `Codes`. File codes are used to import components of the `DLL`, declaring the available `DLLFunctions` and their `DLLParameters`.

The second PSM developed is the EMSO metamodel, which is presented in Figure 4. Since EMSO is a simulation platform, mathematical models of the equipment, or `Devices`, are instantiated through the `Model` class. Functions are always related to a model as `Equations`. In this specific domain, `Variable` is an `Attribute` specialization and represents the variable attributes of the models and `Parameter` the constant ones. Variables cannot assume a textual type, but textual parameters can be instantiated through a `Switcher`. `Flowsheet` entities with their `Devices` and `Connections`, parameter `Estimation` and process `Optimization` were not considered primordial for the equipment description domain and are not specified at this stage of the project.

3.3 M2M and M2T Transformations

For each PSM supported by M4PIA infrastructure it is necessary to define the respective transformations. Transformations can be either model-to-model (M2M) or model-to-text (M2T). In M2M transformations the elements specified in the PIM model are mapped to elements from a specific PSM. M2M are implemented in our work using the *Eclipse QVTo* tool, an implementation of the standard

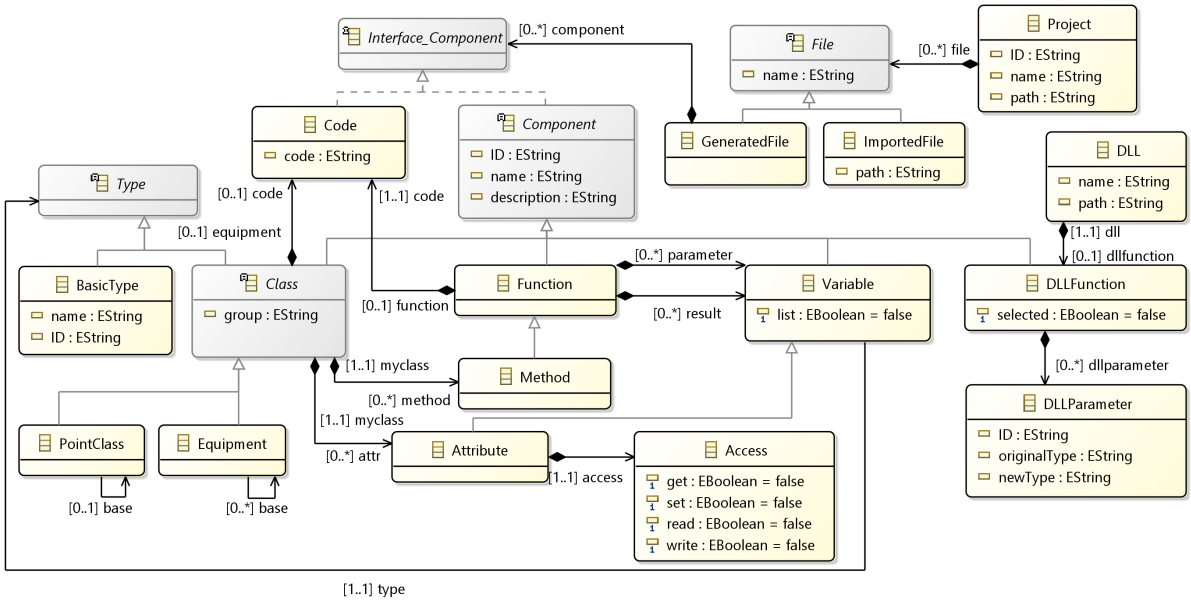

Figure 3: Elements of MPA metamodel

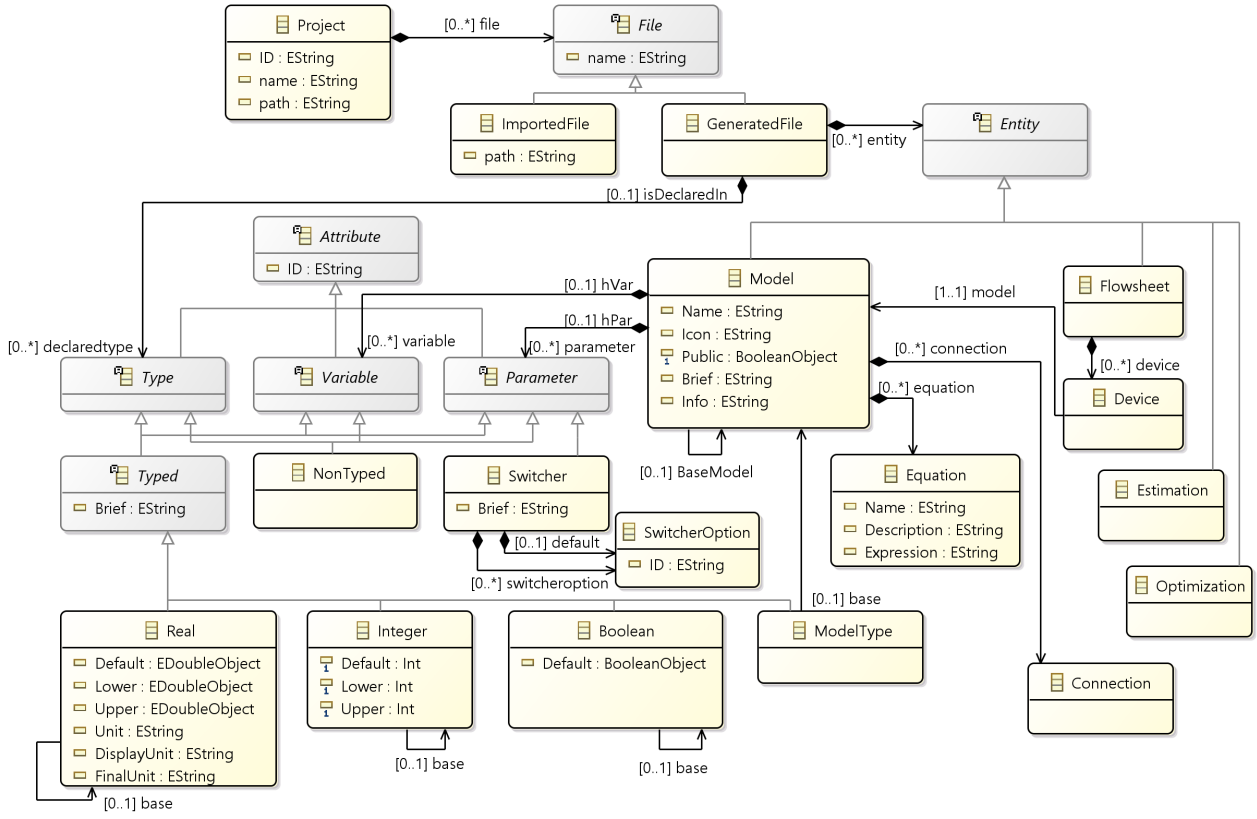

Figure 4: Elements of EMSO metamodel

OMG model transformation language QVTo (Operational Query/View/Transformation). The M2T transformations are developed specifically for each target platform. They are target in this work by using the *Eclipse Acceleo* tool for templates definitions and have as output the application source code ready to be used.

The explanation regarding each PSM metamodel provided in the previous section provide readers a good overview about the adopted M2M transformation rules, i.e., how the elements of the M4PIA metamodel (Fig. 2) map to the MPA metamodel (Fig. 3) and to the EMSO metamodel (Fig. 4). The M2T transformations are target in this work by using the *Eclipse Acceleo* tool for templates definitions and have as output the application source code ready to be used.

4 Evaluation Method

This section describes the evaluation method used to allow analyzing the completeness and applicability of the proposed infrastructure. Our goal is to capture the perception of M4PIA users in performing a characterization of the features associated with this MDE-based approach. By achieving this goal, it would allow us to understand whether the concepts introduced in M4PIA infrastructure really have potential in terms of technology, thus providing evidence of quality attributes associated with all the developed tools.

This evaluation, therefore, attempts an empirical study of type "feature analysis-experiment" [32], in a quantitative and qualitative experiment format. It allows providing evidences of suitability, very common for assessing tool support in computer science.

4.1 Context Selection

The context of this study is the academy, a first trial of in-vitro approach, with half of participants working in industry. The experiment captures the perceptions of individuals to measure the value of a technology in a real problem. It is applied with nine master students and two undergrad students from the Federal University of Pampa (Unipampa), all them with good knowledge on tool selection and software acquisition. This context configures a good sample, since students were introduced in the MDE theme, with desirable features from these tools. Therefore, it characterizes a good scenario to evaluate two main quality attributes for suitability that could be associated with the proposed tool support: completeness and applicability.

4.2 Experiment Design

No randomization and balancing: The subjects are not randomly placed into groups (not a randomized block design), so that only one design approach is performed by the same number of subjects. Thus, the goal is not to compare DSLs or code generators.

Blocking: The selected subjects for this quasi-experiment had different backgrounds in modeling systems, but no background in modeling petrochemical systems. Thus, to minimize the effect of eventual differences in experiences, the subjects received the same training. We also defined whether a subject is inexperienced or experienced, applying a survey, prior to the experiment, to qualify the subject background on the problem domain.

Instrumentation: It was provided a configured version of the Eclipse IDE with M4PIA plugins. The subjects installed this version in their notebooks in Windows or Linux. Then, we provided video tutorials in mp4 format, composed by: 1) A long duration video (75 minutes) depicting the proposed infrastructure, the needs and the proposed solution; 2) A second video (15 minutes) demonstrating how to use the Eclipse IDE, and 3) A third Video (25 minutes) demonstrating how to design a model using the proposed approach. Six other video-tutorials complement the other quantitative part of this experiment, focusing in evaluating specific design and codification tasks. However, they are irrelevant for the present evaluation, which focuses in presenting the feature analysis experiment.

4.3 Variables

Two sets of **independent variables** are used: (1) EMSO, MPA, and M4PIA; (2) Academic Experience and Industrial Experience. Besides, two **dependent variables** are used: Completeness and Applicability.

4.4 Data Analysis

Applicability: a survey to measure the quality attributes from the experience along design and transformation tasks. **Completeness**: a coverage analysis of the main features considered important in MDE including the following.

4.4.1 Desirable Features from MDE Tools

Feature 1: Platform independence: Also known as PIM support [33], it evaluates the capacity to model the PIM application at a high abstract level.

Feature 2: Multiview representation: Also known as PSM support [33], it evaluates the capacity to automatically generate a PSM model for a chosen target platform.

Feature 3: Platform adherence: Also defined in [33], it states whether multiple target platforms are supported.

Feature 4: Evolution: Also known as Application evolution (Changeability) [33] [34], observes if model changes should be done in PIM level and implies new execution of transformations.

Feature 5: Interoperability: Relates to model import/export (tool interoperability) [33], observes the support for exporting models in XMI format.

Feature 6: Flexibility: From [33], accounts for the flexibility to change the transformation process and model refinements.

Feature 7: Correctness: From [33], accounts for model validation in order to check consistency with its metamodel.

Feature 8: Expressiveness: Also called completeness [33] [35], observe if all domain concepts are needed.

Feature 9: Traceability: From [33], accounts for models traceability.

Feature 10: Reverse engineering: From [33], accounts for Code-to-model and PSM-to-PIM transformations.

Feature 11: Built on standards: From [33], accounts for the use of standarized technologies.

Feature 12: Well defined concepts: Adopted from [34], observes if there are no contradictions between concepts of the models.

Feature 13: Code generation: Feature from [35], accounts for how complete is the generated application code.

4.4.2 Metrics

Metrics for estimating the completeness of the features:

$$CFx = 1 - ((44 - Cov)/44)$$

Where CFx is the completeness for a feature x, 44 is the maximum value rank for each feature, and Cov is the computed by:

$$Cov = (TD + PD + NA + PA + TA)$$

Where Cov is the coverage for a feature, as the sum of the following values posted by each respondent: **TD** is 0 (zero) and replaces the survey value for "Totally disagree"; **PD** is 1 (one) and replaces the survey value for "Partially disagree"; **NA** is 2 (two) and replaces the survey value for "Not agree or disagree"; **PA** is 3 (three) and replaces the survey value for "Partially agree", and; **TA** is 4 (four) and replaces the survey value for "Totally agree";

Thus, at the end of the quasi-experiment, a questionnaire was filled out in a Google Forms, were the participants should rate different criteria, where those for feature analysis are built on a five point Likert scale (0=worst, 4=best) for the analysis of the proposed infrastructure.

5 M4PIA Assessment

In order to evaluate the applicability of the proposed solution, this section presents the impressions noticed by the 11 users previously mentioned. Such impressions were collected after the users modeled a simplified *Gas Compression System* (GCS). The model was further used to generate the control software in the MPA tool and the simulation software in the EMSO tool. All related development, including the PIM model design and the transformation executions, was done within the Eclipse environment.

The simplified GCS consists of one *surge tank* (a *knock-out drum* with a *flaring valve*), one *output header*, and two *one-stage compressors*. A *stage of a compressor* has one *heat exchanger*, one *suction drum*, one *compression element*, and one *recycle valve*. The *output header* has one *exportation valve* and two *gas-lift output valves*. Such system is illustrated in Figure 5. The present case study has 11 equipment, with a total of 36 attributes and 2 methods.

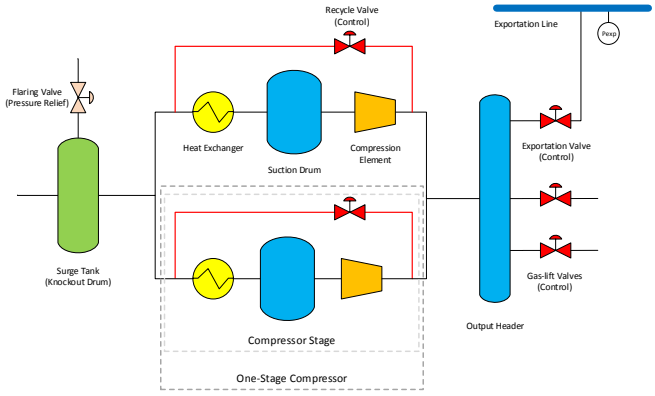

Figure 5: Simplified Gas Compression System

The work in the Eclipse tool can be summarized as follows. After creating a new project, the designer must create a PIM using the Eclipse tree structure. To illustrate how the designer interacts with Eclipse, Figure 6 shows the instantiation of three equipments from the GCS: `Compression Element`, `Compressor`, and `Compression System`. The former contains the following attributes: `Flow`, `Suction/Discharge Pressures`, and `Suction/Discharge Temperatures`. The latter has as attributes: `Power`, `Surge Tank`, `Output Header`, and a `List of Compressors`. It also has the method `Calculate Power of the Compression System`.

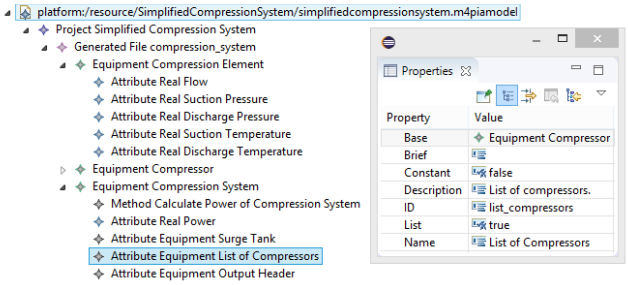

Figure 6: Illustration of the EMF tree structure

To model an equipment on both MPA and EMSO software platforms, the developers should seek out for generalization. For example, a *compression system* may have one or more *compressors* and a *compressor* may have one or more *stages*. Hierarchy is also highly desired, for example, a *valve* can be specialized in *pressure relief* or *control valve*, just as a *tank* can be specialized in *surge tank* or just a *knockout drum*. Given that in EMF the PIM is developed using a tree structure, as shown in Figure 6, the UML class diagram from Figure 7 was created to better illustrate the designed PIM.

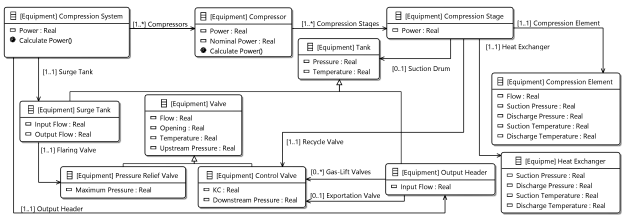

Figure 7: Class Diagram of the Simplified Gas Compression System PIM Model

After the PIM model development, the M2M transformations for MPA and EMSO platforms were performed. The PSM models were refined according to the specificity of each platform and it was possible to automatically generate the necessary source code to implement the compression system on the target platforms by applying the M2T transformations. In total, 245 effective lines of code were automatically generated for MPA and 117 for EMSO. One should recall that effective LOC means that comments and blank lines are not counted.

5.1 Preliminary Analysis

The system developed on this study can be considered small if compared to other existing applications, which can be five times bigger. In order to better illustrate the impact that the use of M4PIA can have on the development of the applications of this domain it is shown some data from a native MPA application example, which aims the detection and treatment of hydrate plug formation in gas pipelines of a floating production storage and offloading (FPSO). The numbers presented in Table 1 allow us to observe that an application with 50% more equipment classes (right on the table) can have twice the total amount of attributes and more than 12 times the number of methods. Observing the numbers regarding LOCs, the FPSO application is above 1K LOC. So it is not difficult to conclude that generating such code automatically – like M4PIA infrastructure does – can potentially save many working hours.

Table 1: Comparison of Domain Applications

	GCS	FPSO
Class of Equipment	11	17
Total Amount of Attributes	36	74
Total Amount of Methods	2	25
Effective Lines of Code (*LOC*) - MPA	245	1297
Instantiated Equipment	19	621
Instantiated Control Points	73	2428

5.2 Feature Analysis

In the following it is present data collected through a feature analysis, which allowed us to understand participants perceptions about the overall M4PIA infrastructure. The goal is to understand initial expectations of the overall approach introduced in the first video, so that their perception could help on the execution of the controlled experiment.

Figure 8 provides the answers to the analysis of Feature 1 - The approach allows to: model the application at platform independent level (PIM), at a high level of abstraction of the target problem used in the implementation (simulation, supervision, operation and control of industrial plants of the petrochemical industry. In this sense, nine from eleven students agree that this is an important feature provided in M4PIA infrastructure.

Figure 9 provides the answers to the analysis of Feature 2 - The approach allows: automatic generation of the platform-specific model (PSM) for the chosen target problem (simulation, supervision, operation and control of industrial plants in the petrochemical industry). Thus, nine from eleven students agree that this is an important feature provided by the infrastructure.

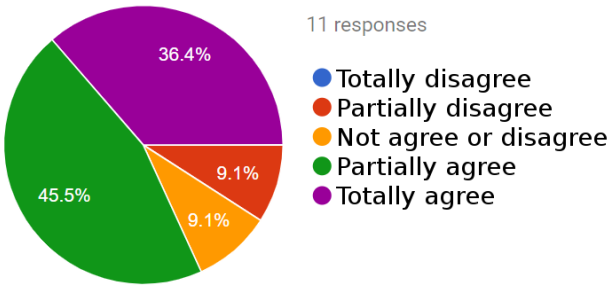

Figure 8: Analysis of Feature 1: Platform independence

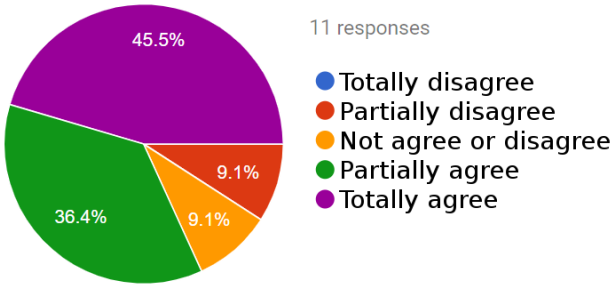

Figure 9: Analysis of Feature 2: Multiview representation

Figure 10 provides the answers to the analysis of Feature 3 - The approach allows: automatic generation of code for multiple target platforms. Seven participants agree that this is an important feature provided by the infrastructure, where five of them only partially agree. Thus, feature 3 should be planned for improvement.

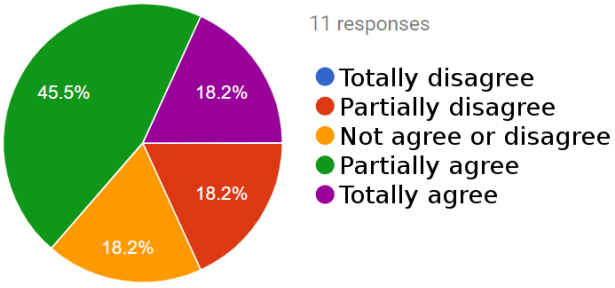

Figure 10: Analysis of Feature 3: Platform adherence

Figure 11 provides the answers to the analysis of Feature 4 - The approach supports the evolution of applications through model to model and model to code transformations. In this sense, nine from eleven students agree that this is an important feature provided by the M4PIA infrastructure. In fact, evolution is one of the greatest benefits promoted by MDE approaches for automated integration [14], and M4PIA is on a solid ground to allow this feature for their future users.

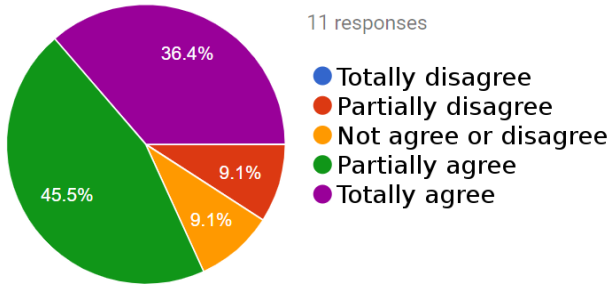

Figure 11: Analysis of Feature 4: Evolution

Figure 12 provides the answers to the analysis of Feature 5 - The approach supports model interoperability. That is, it is evaluated whether these are exported and imported in a standard way, such as those provided by OMG. Seven agree that this is an important feature provided by the infrastructure, where five of them only partially agree. Three answers were uncertain, and this is because OMG supports lots of other standards not handled in M4PIA.

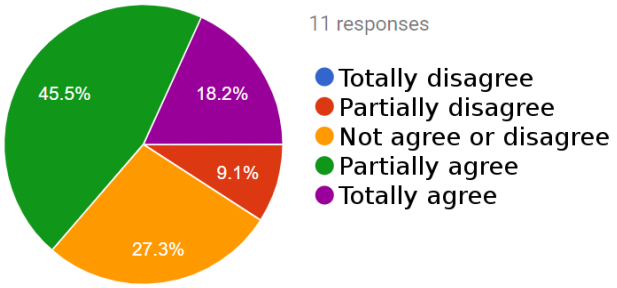

Figure 12: Analysis of Feature 5: Interoperability

Figure 13 provides the answers to the analysis of Feature 6 - The approach supports flexibility to change the transformation process and model refinements. Eight respondents agree that this is an important feature that should be provided by the infrastructure. Three answers were also uncertain, and this is because they did not scaled the problem through the demonstration.

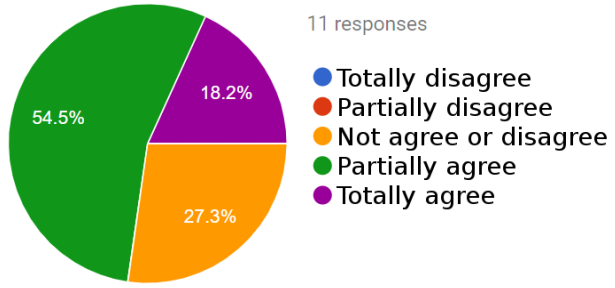

Figure 13: Analysis of Feature 6: Flexibility

Figure 14 provides the answers to the analysis of Feature 7 - The approach supports the validation of the models to verify consistency with their respective metamodels. Eight respondents agree with that statement, concluding that M4PIA provides this as an important feature for designers. Consistency in design is an essential feature in a MDE-based process that needs the correct code generation. It can only be ensured with a rich set of OCL rules [36].

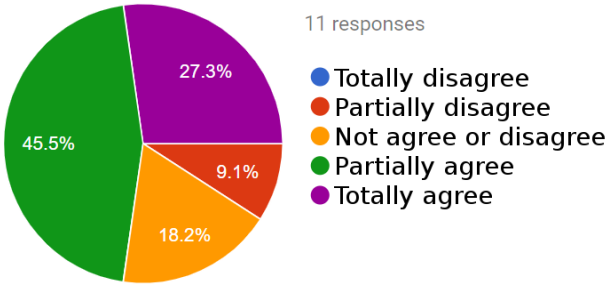

Figure 14: Analysis of Feature 7: Correctness

Figure 15 provides the answers to the analysis of Feature 8 - The approach is expressive and allows to express all the concepts of the represented problem domain. Nine from eleven respondents agree that this is a design feature associated with M4PIA. Thus, since the ability of express domain concepts is a requirement for DSL development, we conclude that the provided metamodels satisfy the modeling needs of the presented context.

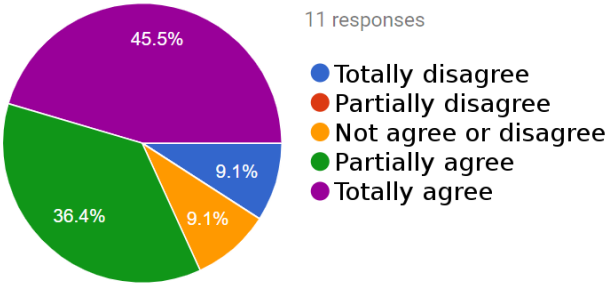

Figure 15: Analysis of Feature 8: Expressiveness

Figure 16 provides the answers to the analysis of Feature 9 - The approach supports the traceability of models. Nine from eleven respondents agree that this is a design feature associated with M4PIA. Trace is promoted through model-to-model transformations and are used for configuration management issues [37].

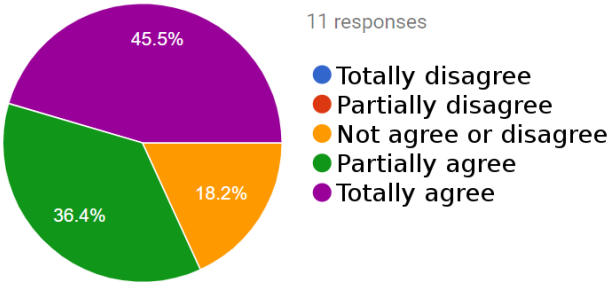

Figure 16: Analysis of Feature 9: Traceability

Figure 17 provides the answers to the analysis of Feature 10 - The approach supports reverse engineering from code to model. This statement was detected as an issue from the current version of M4PIA. first experimental trial. This feature is only implemented as a preliminary version of the infrastructure developed in ANTLr parser, not include in the provided Eclipse experimental package. In order to configure a reverse engineering into the Eclipse package, we are starting the development of reverse engineering using

MODISCO. So the answers for this feature analysis were also confused.

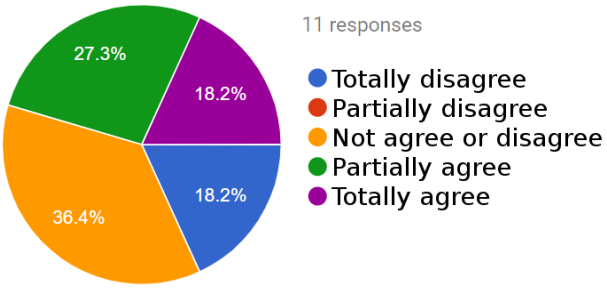

Figure 17: Analysis of Feature 10: Reverse engineering support.

Figure 18 provides the answers to the analysis of Feature 11 - The approach is heavily based on standards for building DSLs and model transformations. Nine from eleven respondents agree that this is an important feature associated with M4PIA. One of the answers reasoned that the adopted technologies is not a benefit.

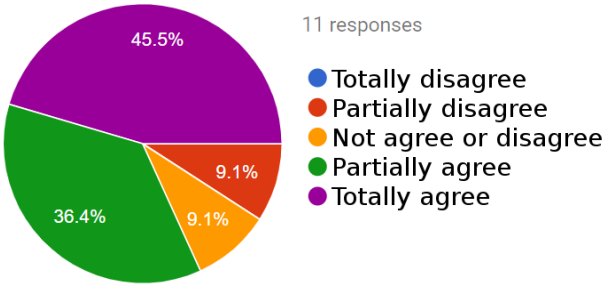

Figure 18: Analysis of Feature 11: Built on standards

Figure 19 provides the answers to the analysis of Feature 12 - There are no contradictions between the concepts of models in the M4PIA infrastructure. Here only five agree that the metamodels are well characterized, while five are still confused and suggested that they would have a stronger position with a better characterization of the context from the Petrochemical industry.

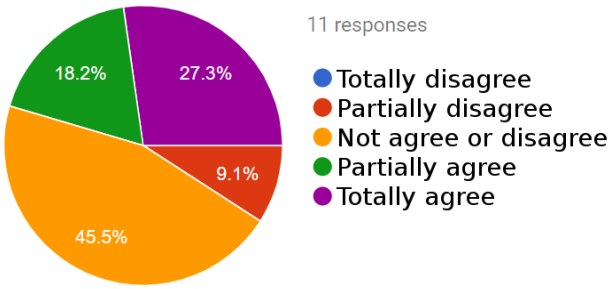

Figure 19: Analysis of Feature 12: Focused domain specific entities

Figure 20 provides the answers to the analysis of Feature 13 - The complete application code can be generated. six from eleven respondents agree that this is an important feature associated with M4PIA. Almost half the respondents or disagree or did not have sufficient information to conclude about that.

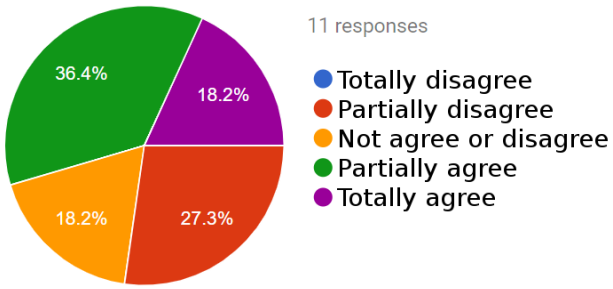

Figure 20: Analysis of Feature 13: Code generation

5.3 Final Remarks

Figure 21 presents the coverage analysis of the features after applying the metric. The highest possible score for each feature is 44. Figure 23 shows the dispersion bloxplot graph. Therefore, these graph demonstrates that M4PIA infrastructure is considered relevant for the stated problem.

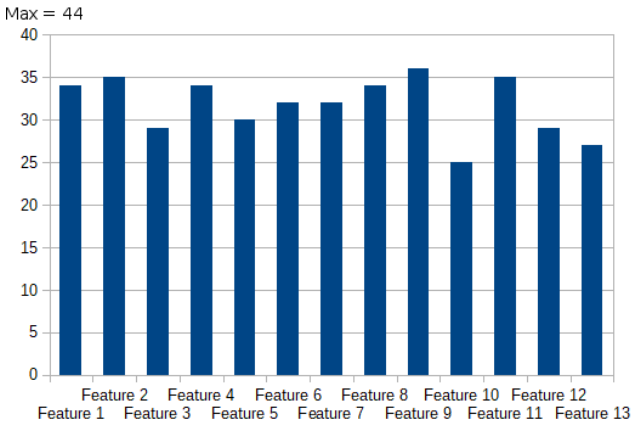

Figure 21: Coverage analysis of all the features

Finally, Table 2 presents the analysis of completeness of each analyzed feature. This data is also shown in Figure 22. The average of results from coverage is 72.73%, a good index suggesting the relevance to the MDE context. Thus, this suggests that we are on the way to achieve benefits reported by other MDE studies as well [14].

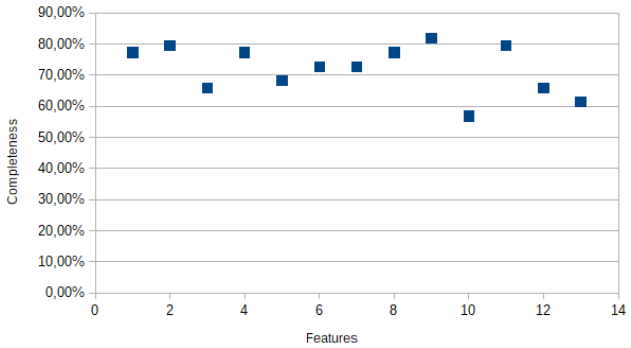

Figure 22: Completeness analysis of all the features.

5.4 Threats to Validity

As discussed by [32], studies of applicability using feature analysis experiment are usually target of the following

Table 2: Analysis of completeness after the feature analysis

	Feat 1	Feat 2	Feat 3	Feat 4	Feat 5	Feat 6	Feat 7	Feat 8	Feat 9	Feat 10	Feat 11	Feat 12	Feat 13
Uncovered	22.73%	20.45%	34.09%	22.73%	31.82%	27.27%	27.27%	22.73%	18.18%	43.18%	20.45%	34.09%	38.64%
Covered	77.27%	79.55%	65.91%	77.27%	68.18%	72.73%	72.73%	77.27%	81.82%	56.82%	79.55%	65.91%	61.36%
Total	100%	100%	100%	100%	100%	100%	100%	100%	100%	100%	100%	100%	100%

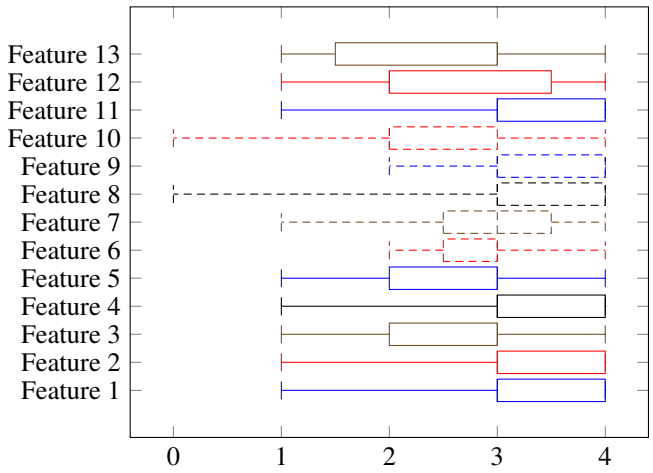

Figure 23: Boxplot of the analyzed features

threats to validity: 1) Benefits are difficult to quantify, 2) Benefits directly observable from the task output, 3) Relatively small learning time, and 4) Tool/method user population very varied. In the following, we present other threats conforming to [38].

5.4.1 Construct Validity

Feature analysis presents social threats to construct validity. In order to mitigate the Hypothesis guessing, before executing the experiment we: 1) presented the context of the problem; 2) presented the context of MDE tools; and 3) presented our goals, where we would evaluate their intuitiveness in using the M4PIA approach for each planned task along three different phases. These experimental tools were also important to mitigate the other two threats: Evaluation apprehension and Experimenter expectations. In order to mitigate the apprehension threat, an external executor for this quasi-experiment was used (the third author). This makes the study less biased, avoiding the interest in positive results, which could occur when the study is executed by the tool creators. The experiment executor also ensured the selection of subjects without any expectation about the evaluated tool, making clear their responsibility in feature analysis to rank M4PIA accordingly to the thirteen best MDE practices.

5.4.2 Internal Validity

This study was planned as a controlled experiment to be executed in three distinct phases: 1) the first one is to test the applicability of M4PIA; 2) the second one is the manual execution of the overall process, scoping design and codification tasks, performed without M4PIA; and 3) the last is the execution of the process with M4PIA. Along the execution of the first phase in the first trial, we observed that the internal validity threat called “mortality” would happen for the next phases due to the scarce available time from subjects. In order to mitigate this threat, and thus ensuring we would not loose subjects, we decided that participants could execute the experiment at home along three weeks. In this sense, they followed the video tutorials for execution of each requested task in a quasi-experiment rather than a fully controlled experiment, as initially planned. Therefore, in order to ensure the internal validity, the independent variable “time to accomplish each task” was not used.

5.4.3 External Validity

The results observed for feature analysis of M4PIA infrastructure are not generalized yet. For a such, we would need to repeat this study with, at least, three other subject profiles: 1) experts in physical plants presented on the development of simulation, control, and supervisory applications for the petrochemical industry; 2) experts both in physical plants and MDE; and 3) experts both in physical plants, MDE and software acquisition. Likewise, the threat “interaction of selection and treatment” was not mitigated, and will not gonna be while this experiment is not repeated with different subject profiles. Since our subjects are not experts in the problem domain, i.e. they are trainees in physical plants adopted by petrochemical industry, but they are experts in Software Engineering tool selection and software acquisition discipline, this study is also target of the threat “interaction of setting and treatment”. We mitigated this threat through nine video-tutorials, shared in the experimental package, which by the way are considered of high instructive quality.

5.4.4 Conclusion Validity

This study presents an associated threat, which is its low statistical power, as the evaluation presented was applied to only eleven participants. It happens that, for a feature analysis, the random heterogeneity of the subjects compensates the low statistical power, as it provides different perspectives

when evaluating the tool. Likewise, the subjects present two distinct evaluators profiles: half working on companies as professional software engineers and half characterized as students, where two of them are finishing the undergraduate school in Software Engineering. Thus, our conclusions are moderated and drawn accordingly to the statistical power provided.

6 Conclusions and Future Works

The current paper presented M4PIA, an MDE solution that facilitates the design and development of equipment classes for simulation, control, and operation of applications devoted for the petrochemical industry. It contains three metamodels, which is a rich material in respect to formalizing the representation of the elements that constitute petrochemical plants and the related control structure. These metamodels, together with the developed model transformation engines, serve to provide automatic code generation.

The conducted evaluation showed that the majority of the 13 features considered important in the scope of MDE are properly covered by the proposed M4PIA. Solutions to improve those features that were not highly ranked, like reverse engineering, are already under development. Moreover, as future work it is possible to state that M4PIA should evolve towards allowing even non-programmers (like plant engineers/designers) to describe plant structures and thereby providing additional help to develop the required applications. Therefore, a graphical modeling language might be adopted.

Conflict of Interest The authors declare no conflict of interest.

Acknowledgment Firstly we thank Cenpes/ Petrobras for the finance support that made this work possible. Thanks are also given to: (i) Tecgraf/PUC-Rio Institute team for the outstanding support in respect to MPA-related issues; (ii) Prof. Rafael de Pelegrini Soares (UFRGS) for his support in respect to the EMSO platform; (iii) the students from UNIPAMPA/Alegrete that did not measured efforts to perform the proposed evaluation protocol.

ABSTRACT

This study is the extension of the previous study about "Traffic Service Quantitative Analysis Method under Developing Country" in 2018 International Conference on Advances in Computing, Communications and Informatics (ICACCI). In the previous study, it is introduced how to make quantitative calculation for traffic congestion by traffic parameters and its characteristics curve such as traffic volume (q) to inverse of vehicle average speed (=1/v). In order to identify the traffic congestion condition, it is focused on vehicle speed ratio which is average speed (v_{ave}) to its free speed (v_f). And the threshold level is 2/3 (=v_{ave}/v_f). This 2/3 value comes from Viscous fluids model between parallel flat plates by using similarity of the viscous fluids flow and the traffic flow in India which is introduced at the CODATU XVII and UMI Conference 2017. This threshold value definition needs more traffic theory back up because its similarity between viscous fluids flow and traffic flow comes from the basis of traffic flow measurement results. In this extension study, it focuses on the occupancy of one of typical traffic parameter for traffic congestion. When it is compared between the traffic occupancy measurement data and Speed Ratio, the Speed Ratio 2/3 is the level of the occupancy 30%, which is used as traffic congestion condition. According to daily based traffic volume and average vehicle speed, the congestion condition is occurred by not only those traffic parameter, it is also considered about time zone traffic condition and its actual traffic condition. One of measurement point is always congested in the early evening even if its traffic volume is smaller than the morning traffic congestion. Therefore it is important to analyze traffic condition by time zone. As the result, it clarifies the relationship between Speed Ratio and occupancy. As the result, there are two types of traffic congestion in Ahmedabad city traffic.

1. Introduction

This study focuses on traffic flow and congestion analysis especially in the under developing country (India). In the previous study, it is proposed the traffic service quantitative traffic congestion analysis method in the International Conference on Advances in Computing, Communications and Informatics (ICACCI) [1]. From the actual measurement traffic data study during more than one month in Ahmedabad city of Gujarat State in India, the major traffic parameters are extracted from the traffic fundamental diagram such as traffic density (k) to vehicle average speed (v) and traffic density (k) to traffic volume (q), which introduced at the International conference CODATU 2017 [2].

As for obtaining the traffic parameters and analysis, the detail is explained in the next section. The previous study of CODATU introduces the unique traffic characteristics which is useful for using Envelopment Observation method because there is clear boundary in those characteristic and it is appropriate way to define the traffic parameters from their unique measurement data. The another phenomenon from the measurement data is vehicle speed ratio which is the ratio of average vehicle speed (v_{ave}) to free speed (v_f). The value of this speed ratio (SR) is valid for understanding congestion level of each road. When S.R. becomes lower than 0.65, the condition of road becomes congested. Author found similarity of this phenomena between the Indian traffic flow model and viscous fluids model between parallel flat plates.

In this extension of the research, more detail analysis is added between SR and occupancy of traffic parameter which is used as traffic congestion level judgement from traffic engineering. In addition, the relationship between parameter occupancy and traffic density is described in order to understand traffic congestion condition. As for the traffic congestion analysis, it also describes

* Tsutomu Tsuboi, 29-1 Mentoku Shinoda Ama, Aichi, +81-902738-3496, t_tsuboi@nagoya-denki.co.jp.

the time zone base analysis in this paper. From this time zone base analysis, we found there are two patterns for Ahmedabad traffic congestion condition. One is heavy traffic density congestion which follows the traffic flow theory and the other is unheavy traffic density congestion which is unique in India. Therefore it is important for considering what is the traffic congestion definition. when the traffic information is provided from the traffic information sign board so called VMS or Various Message Sign on the road.

2. Related Studies

2.1. Traffic Flow Theory and Measurement Analysis of Ahmedabad city

In the previous study for Ahmedabad traffic flow analysis at CODATU conference, the traffic fundamental diagram is introduced such as *k-v* curve (traffic density (*k*) to average vehicle speed (*v*)), *k-q* curve (traffic density (*k*) to traffic volume (*q*)), and *q-v* curve (traffic volume (*q*) to vehicle speed (*v*)). This analysis has been continued since Ahmedabad ITS or Intelligent Transport Systems business project from October 2014. The project is providing Ahmedabad city to provide its traffic condition for the drivers through VMS. The ITS system consist of four VMSs and 14 traffic monitoring cameras. The traffic flow condition is captured by the traffic monitoring cameras and its result of analysis is shown at the VMS for considering change route or using other transportation choice. The Ahmedabad ITS system configuration is shown Figure 1.

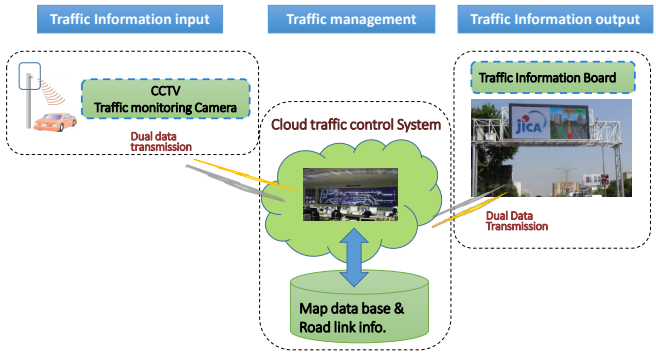

Figure 1: Ahmedabad ITS system configuration

In the CODAU study, authors found the unique characteristics of Ahmedabad traffic flow measurement data. There is clear boundary in each traffic fundamental diagram. The *k-v* curve and *k-q* curve at Camera#1 are shown in Figure 2.

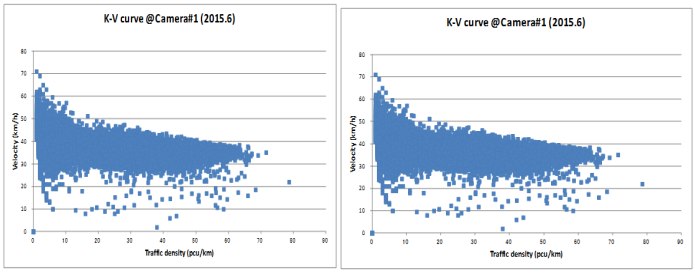

Figure 2: Traffic Flow Characteristics at Camera#1

From Figure 2, there is clear boundary in each characteristics curve by envelop observation. The other characteristics at other location are similar results which are omitted in this paper. When these boundary are taken as traffic flow characterizes, it is able to adjust traffic flow characteristics curve from traffic flow equation to the envelop line. The Figure 3 shows the example of adjustment result between traffic flow theoretical curve from its equation and the measurement data at Camera#1.

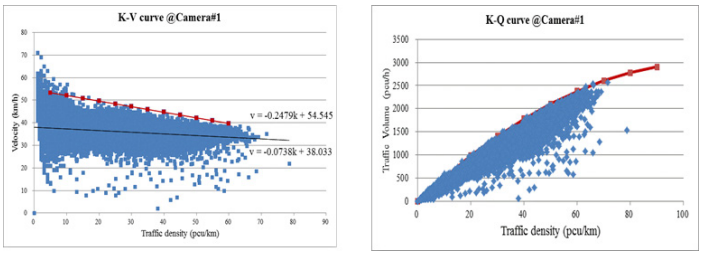

Figure 3: Traffic Flow Characteristics at Camera#1

In terms of traffic equation form the theory, traffic density (*k*) to traffic speed (*v*) equation is given by (1) and traffic density (*k*) to traffic volume (*q*) equation is given by (2). The equation (1) is so called Greenshields [3] curve.

$$v = v_f\left(1 - \frac{k}{k_j}\right) \tag{1}$$

v_f: free speed

k_j: jam traffic density

$$q = -\frac{v_f}{k_j}\left(k - \frac{k_j}{2}\right)^2 + \frac{v_f k_j}{4} \tag{2}$$

The theoretical curve illustration is shown in Figure 4.

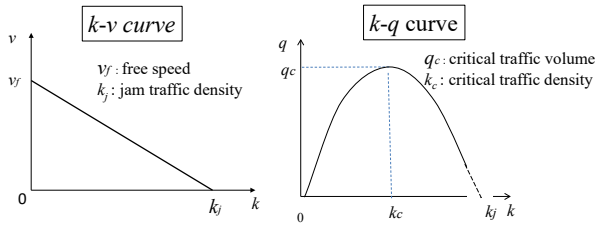

Figure 4: Theoretical Traffic Flow Curve

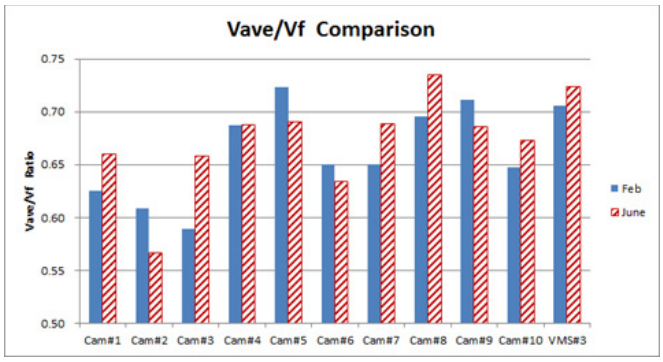
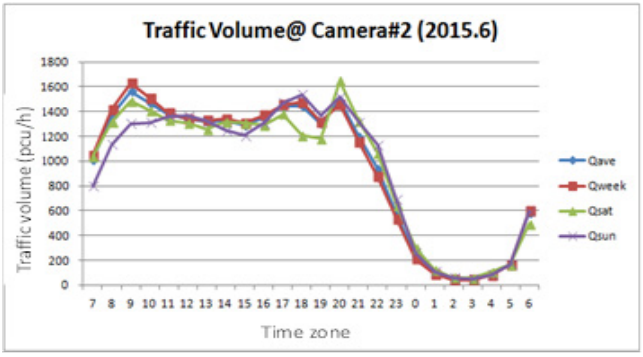
In the advanced country traffic flow, the actual measurement plots including Japan [4] are aligned with theoretical curve and or near boundary in Figure 4. Therefore the traffic characteristics curve from measurement in Ahmedabad is quite different from those of the advanced countries (refer to Figure 2).

2.2. Quantitative Traffic Congestion Study in Ahmedabad

The traffic congestion problem in developing countries become more serious situation these days, especially in India. Therefore it is crucial to establish for analysis method about the traffic congestion quantitatively. In the International Conference on Advances in Computing, Communications and Informatics or ICACCI, T.Tsuboi proposes quantitative traffic congestion analysis based on the actual traffic measurement in Ahmedabad. In this paper, it is introduced the traffic congestion by vehicle speed ratio (SR) which is the ratio of the average vehicle speed (v_{ave}) to the free speed (v_f). In ICACCI paper, it is defined that the

threshold level of traffic congestion is 0.65. The comparison SR at each traffic camera location is shown in Figure 5. According to Figure 5, the Camera#2 is most small value. And the actual daily traffic flow (traffic volume and average vehicle speed) at Camera#2 in June 2015 is shown in Figure 6 (a) and (b). From Figure 6(b), the average vehicle speed is lower than 20km/h, which shows the traffic congestion occurred [5].





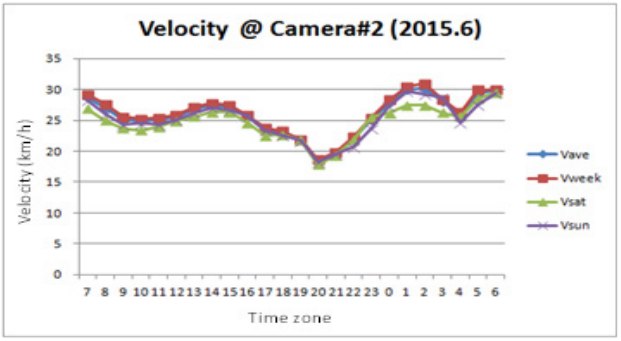


Figure 5: Traffic Speed Ratio Comparison in Ahmedabad

(a) Traffic Volume Time Zone condition at Camera#2

(b) Traffic Speed Time Zone condition at Camera#2

Figure 6: Daily Traffic Flow condition at Camera#2

From Figure 6 (b), it is a clear difference that Camera #2 vehicle velocity ratio is lower than other locations. According to traffic flow theory, most of measurement data of q–k curve is located at shadow area in Figure 7. And free traffic flow area is bottom part of q – k curve; jam traffic flow area is top of q – k curve. But our measurement data of q – k curve in Camera # 2 is located inside q – k curve (refer to Figure 7). The speed ratio of inside curve area is lower than 0.65 which means that its traffic condition becomes congested.

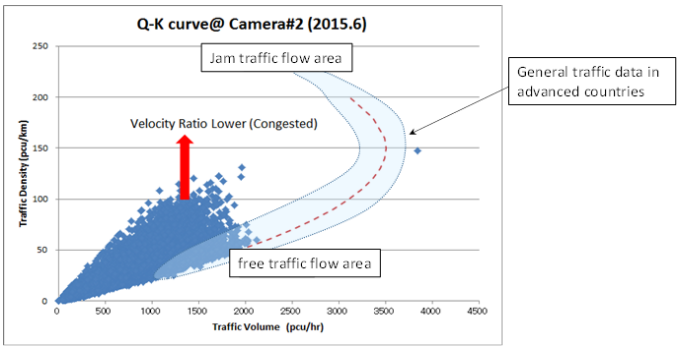

Figure 7: q – k Curve at Camera#2

In order to identify that inside curve area is under congested condition, we divide between two areas. One area has speed ratio equal and less than 065 and the other area has speed ratio more than 0.65. Figure 8 shows those two areas. According to Figure 8, the speed ratio equal and lower than 0.65 (≈ 2/3) is inside envelope line area. According to the previous traffic flow analysis, the threshold between free flow and congested flow occurs at the average vehicle velocity (v_{ave}) ≤ 2(v_f) /3 [2]. Therefore the traffic flow capacity is able to obtain by our envelope data analysis and it is able to be described by the traffic flow equation. This is the first time to show emerging countries traffic analysis and brings basic traffic flow parameters by boundary traffic analysis. And vehicle velocity ratio of average speed by free speed is good reference of explaining traffic jam condition; the critical value of speed ratio is 0.65 in this paper.

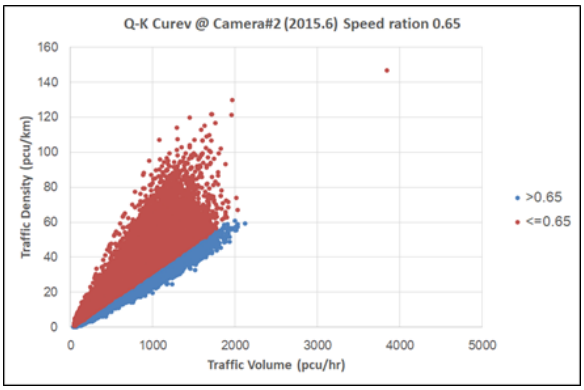

Figure 8: q – k measurement data by vehicle Speed Ratio at Camera#2

In terms of traffic congestion analysis, the congestion social loss analysis theory [6] is used. From the traffic flow theory, traffic volume (q) is mathematical product by vehicle velocity (v) multiplying to traffic density (k) shown in (3).

$$q = v \times k \tag{3}$$

Since the vehicle velocity (v) is inverse of travel time (t), then the vehicle velocity is described as $v = 1/t$. Therefore traffic volume (q) is a function of travel time (t). Assuming that the traffic user's opportunity n per unit time is constant, travel time (t) is proportional to the cost of traffic congestion. In another word, the relationship between traffic volume (q) and travel time (t) means the traffic supply curve of the relationship between traffic

service supply and cost. In order to analyze traffic volume (q), differentiating e (3) by (t) provides (4).

$$\frac{dq}{dt} = -\left(v\frac{dk}{dv} + k\right)\frac{1}{t^2} \tag{4}$$

When vehicle velocity (v) becomes large volume (travel time becomes small value), traffic density (k) becomes small value and then $dk/dv < 0$. Therefore he value in parenthesis of (4) is negative and then dq/dt becomes positive value. This relationship is illustrated in Fig.8. The supply curve line rises to the right from travel time ($1/v_f$) to ($1/v_c$), which means private cost curve for transportation. And when (v) becomes small value (travel time (t) becomes large value), the value in parenthesis of (4) becomes positive and the supply curve drops to the right, which corresponds to private cost curve drops to the right.

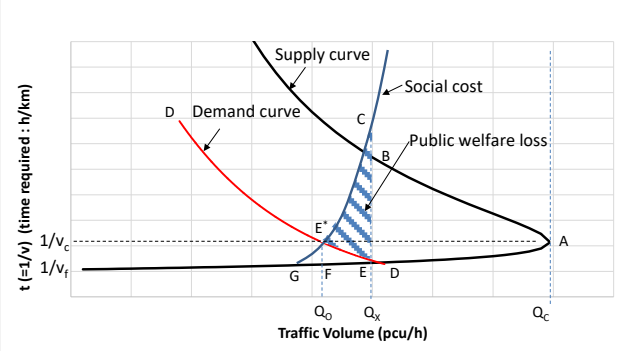

Figure 8: Road Traffic Service Market

In Figure 8, the point A is called hyper congestion condition at critical traffic volume (q_c) when traffic volume becomes larger beyond point A, travel time takes longer because of traffic congestion. There are two travel time (t) except point A. For instance, there are point E and point B at a certain traffic volume (Q_x). In case of point B, the travel time takes longer than that of at point E. If traffic demand curve D-D is given, the point E is cross point between demand curve D-D and supply curve which provides balance condition between traffic demand and supply. If social cost curve is given, the point E* becomes balance point between traffic demand and social cost. Then area CE*E provides traffic service cost loss caused by traffic congestion because infrastructure should cover at the level of traffic volume (Q_x) at the point E and social cost rises at the point C where its traffic volume (Q_x) is same as that of at the point E. Therefore area CE*E is defined as the public welfare loss which means traffic congestion social loss.

In order to calculate the public welfare loss from measurement data, it is necessary to define condition for each curve of Figure 8 from the actual measurement analyzed data. The condition of traffic congestion social loss is as follows:

- Supply curve is $q-v$ curve form envelopment observation.
- The critical speed (v_c) is used at SR=0.65 because this point is congestion threshold.
- Demand curve D-D is used from actual measurement traffic data.
- The social cost curve is unknown under this condition. Therefore BE* liner curve is taken.
- The congestion social loss is defined as area BE*E instead of area CE*E.

The Figure 9 shows the congestion social loss calculation example at Camera#2 with this quantitative social loss analysis. The result of Social loss analysis at all locations shows in Table 1. According Table 1, it is clear relationship between Speed Ratio (SR) and Social loss value.

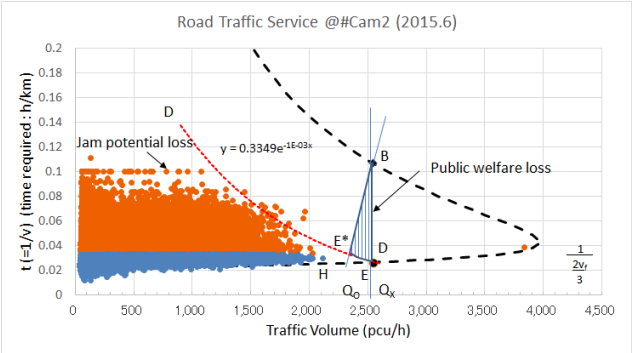

Figure 9: Road Traffic Service Market at Camera#2

Table 1: Social Loss and Speed Ratio

Location	SR(v_{ave}/v_f)	Social Loss
Camera#1	0.66	3.3
Camera#2	0.57	8.1
Camera#3	0.66	3.1
Camera#4	0.69	3.2
Camera#5	0.69	2.0
Camera#6	0.63	2.2
Camera#7	0.69	1.3
Camera#8	0.73	0.2
Camera#9	0.69	1.6
Camera#10	0.67	2.4
VMS#3	0.72	0.7

3. Traffic Congestion Analysis

In the previous section, the envelopment observation method is used for getting traffic flow equation from its measurement. Based on the each traffic flow equation, new quantitative social loss of traffic congestion analysis is introduced. In terms of traffic congestion judgement, the average vehicle speed is used. This average vehicle speed is different at each road and its condition. Therefore it is necessary to have some relative vehicle speed compared with normal driving speed which is taken as free speed in this paper. As for traffic congestion judgement, the average speed is not only parameter but also the traffic occupancy for example.

3.1. Traffic Occupancy

The traffic occupancy is used for one of parameters which shows the level of traffic congestion condition. There are two traffic occupancies in the theory, time occupancy and space occupancy. In real traffic management, time occupancy is often used for the freeway [7]. In this section, time occupancy is used.

The time occupancy is defined the percentage ratio between total measurement time (t) of the vehicles to a certain block of road section under certain time frame. The formula of time occupancy is provided by (5).

$$\mathrm{OC} = \frac{1}{T}\sum_{i} t_i \times 100\ (\%) \tag{5}$$

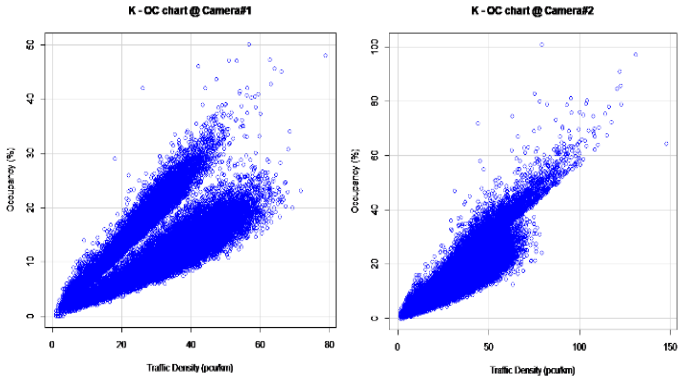
where T is time of measurement, (t_i) is detected time of vehicle (i)[8].

When number of existing vehicle a certain section is (N), average length of vehicle is ($\bar{l}$) in (6) is given.

$$OC = 100\frac{q}{v}\bar{l} = 100k\bar{l} \tag{6}$$

Therefore occupancy (OC) is proportional to traffic density (k) and traffic volume (q).

From the one month measurement data of Camera#1 and #2 in June 2015, traffic density (k) to occupancy (OC) relationship are shown in Figure 10. According to Figure 10, the relationship between (k) and (OC) is proportional.



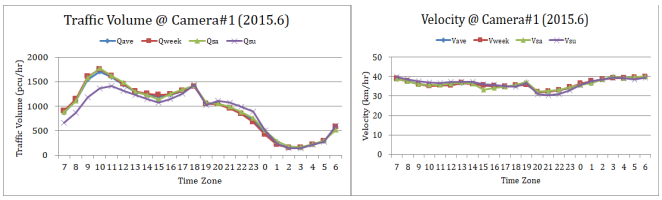


Figure 10: Example of k – q curve at Camera#1 and Camera#2

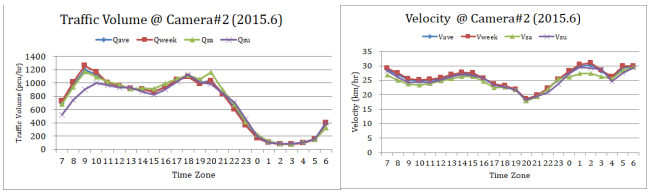

From Figure 10, it seems that the measurement data is plotted into two groups. In the section 3.3, time zone analysis is introduced because traffic congestion is dependent with time of a day (refer to Figure 6) [9].

3.2. Daily Traffic Condition

In this section, a daily traffic changes of traffic volume and velocity is described. In Figure 11, there are two cases of daily based traffic condition at Camera#1 and #2. The graph shows one month traffic volume changes from 7:00 am to next day 6:00 am and average vehicle velocity changes. There are two peaks of traffic volume in each case. One peak occurs between 7:00 am to 10:00 am and the second peak occurs between 18:00 to 20:00. When vehicle average speed is concerned, there is not so much changes of velocity in Camera#1 but different speed at Camera#2. In case of Camera#2, there is a drop during the second peak volume of traffic. And each graph shows classification by four cases—total one month average, weekday, Saturday, and Sunday. According to Figure 11, there is traffic jam in Camera#2 between 18:00 to 20:00 and the average vehicle speed goes down to less than 20 km/h which is confirmed the speed under heavy traffic congestion through the recorded traffic monitoring video data.

(a) Daily Traffic Condition at Camera #1

(b) Daily Traffic Condition at Camera#2

Figure 11: Daily Traffic Condition at Camera#1 and Camera #2

3.3. Occupancy and Traffic Density

As described in section 3.1, time zoning is adapted into Figure 10. In this section, six time zone is defined as shown in Table 2

Table 2: Social Loss and Speed Ratio

Zone Name	Time Zone
T1	7:00 — 10:59
T2	11:00 — 14:59
T3	15:00 — 18:59
T4	19:00 — 22:59
T5	23:00 — 2:59
T6	3:00 — 6:59

There are 6 time zones such as T1 is defined time frame from 7:00 am to 10:59 am which is most congested time frame as we see in Figure 11. And T4 is defined time frame from 19:00 to 22:59 which is the second congested time frame. In case of using this Time Zone classification for k - OC curve, Time Zone based k - OC curve is shown in Figure 12. In this paper, we focus on the characteristics at Camera#1 and #2.

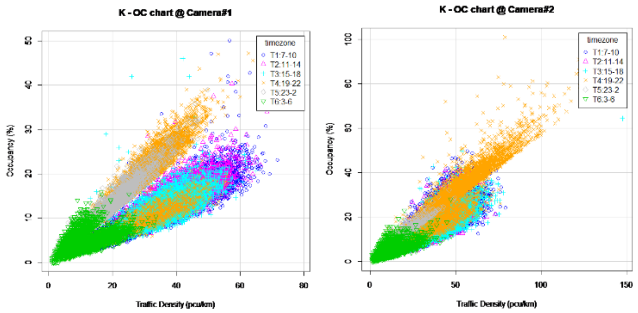

Figure 12: Time Zone based k – OC curve at Camera#1 and Camera#2

When the Time Zone based analysis, it is clear two groups data plot in Camera#1, where there is no traffic congestion condition compared with that of Camera#2. From the result of Camera#1 analysis, the upper group in k – OC curve comes from majority of

T4 (19:00-22:59). The lower group in k –OC curve comes from T1, T2, and T3. In another words, upper part of T4 is relative lower density compared with lower part of T4. This means there are two types of traffic congestion condition. Therefore one type of traffic congestion is defined as low density traffic congestion (herein after it is called as Low density Congestion) and the other one is higher traffic density congestion (herein after it is called as High density Congestion).

The next section describes traffic volume to occupancy and average vehicle speed to occupancy in order to understand the traffic congestion condition with other traffic parameters.

3.4. Occupancy and Traffic Volume and Speed

In Figure 11, it is shown about the daily traffic condition by traffic volume and average vehicle speed. In this section, it adapts Time Zone basis analysis for q-OC curve and v-OC curve in order to understand relationship between traffic volume to occupancy and average vehicle speed to occupancy.

The Traffic volume (q) to Occupancy (OC) Time Zone basis relationship at Camera#1 and #2is shown in Figure 13.

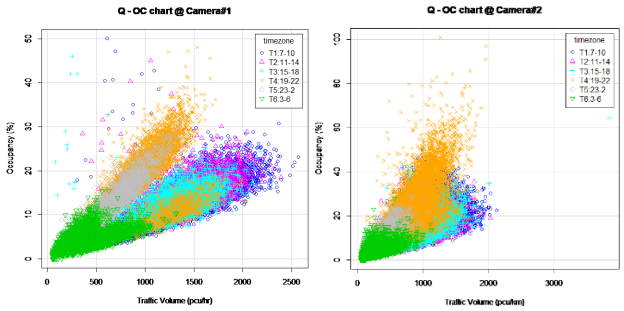

Figure 13: Time Zone based q – OC curve at Camera#1 and Camera#2

From the q – OC curve at Camera#1 in Figure 13, it shows more clear about difference between Low density congestion area and High density congestion area. The Low density congestion occurs in T4. It looks same trend of characteristics at Camera#2 but there is no clear two groups separation between Low density congestion and High density congestion.

The next Figure 14 shows average vehicle speed (v) to Occupancy (OC) relationship.

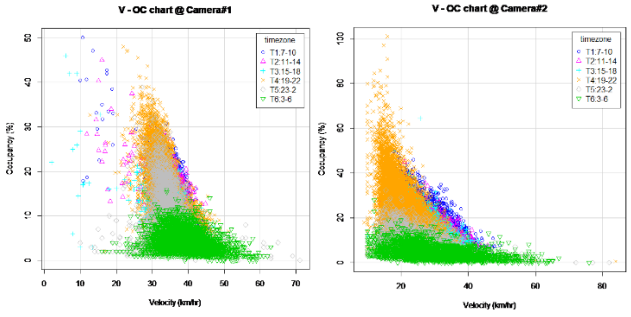

Figure 14: Time Zone based v – OC curve at Camera#1 and Camera#2

From Figure 14, it is clear that traffic congestion at lower than 30km/h occurs above 30% Occupancy condition.

Here is a question why Low density congestion occurs. It is considered at the next discussion section.

4. Discussion of Low density congestion

According to all traffic measurement location in Ahmedabad, the location Camera#2 is the most congested condition location (refer to Figure 5). And traffic condition during T4 time zone becomes most congested as described in previous section. The traffic volume at T4 of Camera#2 is the second peak of traffic volume in a daily condition as shown in Figure 6 (b) and Figure 11 (b). The highest peak of traffic volume occurs at T1 and T2. Therefore it is possible to define that High density congestion occurs at T1 and T2 and Low density congestion occurs at T4.

There is one more traffic parameter which is called Headway. The Headway is defined the distance between the front of driving vehicle group and the front of the second driving vehicle group (refer to Figure 15).

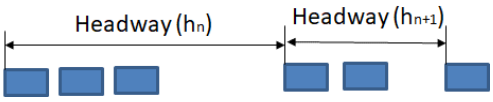

Figure 15: Headway definition

It is relative true the relationship between the small value of Headway and traffic congestion because its traffic density is large. The Headway ($\bar{h}$) and the traffic density relationship is described (7) from the theory.

$$\bar{h} = \frac{1}{k} = \frac{v}{q} \tag{7}$$

where $\bar{h}$ is average of headway. From (7) and (6), (8) is given.

$$\bar{h} = \frac{1}{k} = \frac{100\bar{l}}{OC} \tag{8}$$

From (8), the headway ($\bar{h}$) is inverse proportional to occupancy (OC) with the average of vehicle length ($\bar{l}$). The average of vehicle length is difficult to get from real measurement. Therefore the relationship between the average headway ($\bar{h}$) to occupancy (OC) is not exactly inverse relation. The Figure 16 shows $\bar{h}$ - OC curve at Camera#1 and #2. The vertical axis is legalism for clear display.

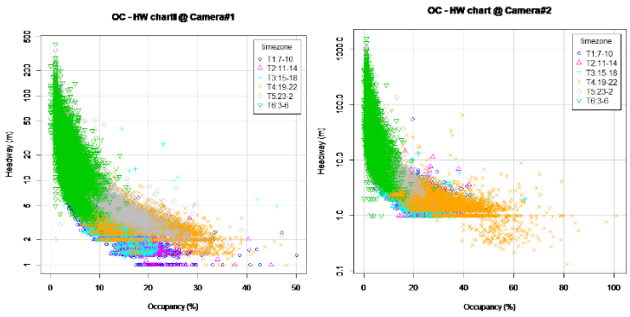

Figure 16: Time Zone based

From Figure 16, the traffic congestion occurs at T4 Time Zone and its Occupancy is above 30%. In this analysis, it is difficult to clarify between Low density congestion and High density congestion. The difference of Low density congestion and High density congestion becomes clear from traffic volume to occupancy or traffic density to occupancy relationship.

When it check the Time Zone of Low density, T4 and time period is from 18:00 to 22:59. After discussion with local traffic

police, they observe that the Low density congestion may be caused by limitation of parking space in the city. In the evening after work, the residents of Ahmedabad stop by restaurants and or shopping place and they make parking their vehicle at not permitted place such as along the street. Therefore this parking issues have potential for creating Low density congestion. If so, there is a solution for Low density congestion by preparing appropriate parking space for restaurant and shopping. The reason why the Low density congestion is detected by the traffic monitoring cameras is assumed that the collecting data is based on number of driving vehicles, not parking vehicles. For the traffic monitoring cameras, they take the vehicles as a part of side roads, which means parking vehicles make roads just narrow path and is unable to count the vehicles number as their traffic density. This situation tells that it is important to judge the traffic monitoring data by not only numerical data from the monitoring camera but also actual visual data.

In terms of quantitative social loss analysis method, the demand curve in Figure 9 is used from the measurement data, which is described as the condition of the quantitative social loss analysis method. When Figure 9 is mapped by time zone, it becomes Figure 17.

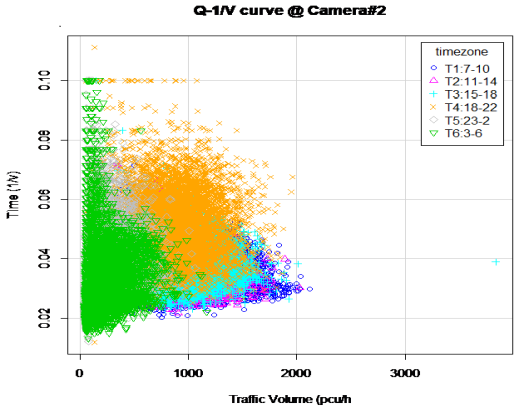

Figure 17: Time Zone based q-1/v curve at Camera#2

From Figure 17, Low density congestion area at T4 is located inside the demand curve. Therefore it is able to confirm proposed quantitative social loss analysis is valid.

5. Summary

In this study, there are three features for Indian traffic flow analysis.

- Feature 1: Introduce envelop observation method based on traffic flow data to provide traffic flow fundamental characteristics by traffic flow equation. It is able to get traffic flow parameters from this equation i.e. jam density (k_j), free speed (v_f).
- Feature 2: Propose quantitative social loss of traffic congestion method by only using traffic measurement data. As for critical speed (v_c), it is defined by Speed Ratio (SR)—average speed (v_{ave}) to free speed (v_f)—0.65 or 2/3 of (v_f), which is based on traffic flow analysis in India.
- Feature 3: There are two types traffic congestion condition in India, Low density congestion and High density congestion. It is presumed that Low density congestion mainly is caused by parking vehicle problem. Therefor Indian Traffic congestion occurs not only by large number of vehicles but also other infrastructure issues.

All this study analysis is based on one month of real traffic flow data in Ahmedabad city. It is necessary to have more different timing, location i.e. place, city, country. It is also important to have traffic video data in order to evaluate traffic congestion condition and understand congestion reason. The above all research items are future work.

Conflict of Interest

There is no conflict of interest in this study.

Efficiency

ABSTRACT

This research focussed on assessing the impact of using upgraded biogas from chicken waste on the performance of a gasoline generator. In the study, the characteristics of raw biogas were determined and a biogas upgrading device was developed before assessing the generator performance on upgraded biogas. A Geotech GA 2000 plus gas analyser was used for biogas characterization and a slightly modified Elemax SH 2900 gasoline generator (5 HP) was used. The findings revealed that biogas from chicken waste comprised of 57% CH_4 and 41% CO_2 with small amounts of H_2S, O_2 and NH_4. During biogas upgrading, the highest solvent to biogas flow rate used was 0.80. NaOH excelled with 93.0% CO_2 reduction followed by KOH at 82.5% and lastly water at 63.0%. Using upgraded biogas improved the generator's brake thermal efficiency from 14.2% for raw biogas to 17.6% for upgraded biogas. A locally fabricated scrubbing device significantly upgraded the biogas quality.

1. Introduction

Biogas is a renewable energy gaseous fuel produced from anaerobic digestion of biological wastes such as cattle dung, vegetable waste, sheep, poultry droppings, municipal solid waste, industrial waste water, land fill, etc. in the absence of oxygen and the presence of anaerobic microorganisms [1]. The process is achieved at elevated temperature range of 30 to 60°C. The produced biogas comprises of mainly methane (CH_4) and carbon dioxide (CO_2) with smaller amounts of hydrogen sulphide (H_2S) and ammonia (NH_4). Biogas is an excellent fuel for a large number of applications including production of heat and steam, electricity production, vehicle fuel and production of chemicals. In Uganda, the most common applications for biogas are cooking and lighting. Conventional gas burners and gas lamps can be modified to suit biogas by changing the air to gas ratio.

In this study, Okweru Poultry Farm was used as a case study. Apparently, biogas from chicken droppings was being used for lighting the chicken houses, heating the brooder and cooking by the farm workers. The researchers explored alternative uses for the biogas produced with focus on electricity generation using a gasoline generator.

Although biogas can be used as a fuel, it has an extremely low energy density on volume basis. This is because of the presence of CO_2 at higher quantities that reduce its calorific value, flame velocity and flammability range compared with other fuels [2]. The high CO_2 levels in biogas can be lowered through biogas upgrading. Global upgrading technologies include: absorption, membrane, absorption and cryogenic technology. Applying these techniques to small scale biogas plants presents complexity and high costs of investment. This leads to utilization of biogas without upgrading for basic applications in developing countries.

The utilization of biogas in stationary engines is a typical case where contaminants have to be removed for better performance. In dual fuel operation, increasing the ratio of biogas increases the brake specific fuel consumption while decreasing brake thermal efficiency and the brake engine power of a Compression Ignition (CI) engine [3]. It was reported in [4] that an improved thermal efficiency from 26.2% to 30.4%, when there is 21% reduction of CO_2 in biogas used in a Spark Ignition (SI) operation while a 15% CO_2 decrease in the biogas increased the thermal efficiency to 22% for dual fuel operations. However, there are other factors that influence the performance of a gas engine.

Various factors responsible for the low thermal efficiency of engines run on biogas were reported in [2]. These include; the long pilot ignition delay and high self-ignition temperature of biogas. These factors delay the fuel combustion process while the low burning velocity due to presence CO_2 leads to incomplete combustion. This increases the brake specific energy consumption and exhaust gas temperature of dual fuel modes.

This research aimed at ascertaining the performance improvement of a generator when upgraded biogas was used. This was carried out by analysing the characteristics of raw biogas and later developed a biogas upgrading unit. The performance of a generator was done using Model Elemax SH 2900 gasoline generator. Biogas upgrading reduces the levels of CO_2 which improves the burning velocity and calorific value of the gas among others. Through several experiments, the generator brake power output, brake specific fuel consumption and brake thermal efficiency were tested at different load profiles.

2. Materials and Methods

The experimental research included the determination of the biogas characteristics, biogas upgrading device design, fabrication and testing. Also experiments to assess generator performance were carried out for both raw and upgraded biogas. This yielded the primary data utilized in the analysis.

2.1. Characteristics of Raw Biogas

In line with biogas characterisation, a Geotech GA 2000 plus Gas Analyser was used to measure the percentage composition of the biogas constituents. The biogas pressure was measured in kPa using a pressure gauge while a thermocouple was employed for temperature measurement in degrees Celsius. The gas flow rate was measured in litres/minute using an Omega HHF11A Air flow meter.

2.2 Designing the Biogas Upgrading Device

The factors that influence the upgrading process include the dimension of the scrubbing tower, gas pressure, raw biogas composition, water flow rate and purity of the water in use. According to [5], it is possible to produce high quality CH_4 enriched gas from biogas by chemical absorption, where a packed bed column and bubble column are used to provide liquid to gas contact.

Therefore, a low-cost upgrading system was designed to receive raw biogas from the bottom and force it through packed marbles to reduce its CO_2 content. According to [6], for purification, the height to diameter ratio should be in the range 10:1 to 130:1. For experimental purposes, a device of height to diameter ratio of 10:1 was made and utilized in this study. Based on recommendations by [7], the column was divided into three parts. The top part is half the height of the bottom part while the middle part contains the packing. Marbles were used as packaging material and they occupied 70% of the column height. Based on the data above, the upgrading device was designed with dimensions as shown in Figure 1 while Figure 2 shows the assembly of the device.

2.3 Generator Performance

In internal combustion engines, the combustion of a fuel occurs with an oxidizer (usually air) in a combustion chamber that is an integral part of the working fluid flow circuit [2]. Petrol engines can run fully on biogas whereas diesel engines require combination of biogas and diesel. In the diesel engine, the primary gaseous fuel is inducted with air into the engine cylinder and a small amount of diesel, called pilot fuel is injected for promoting combustion [8].

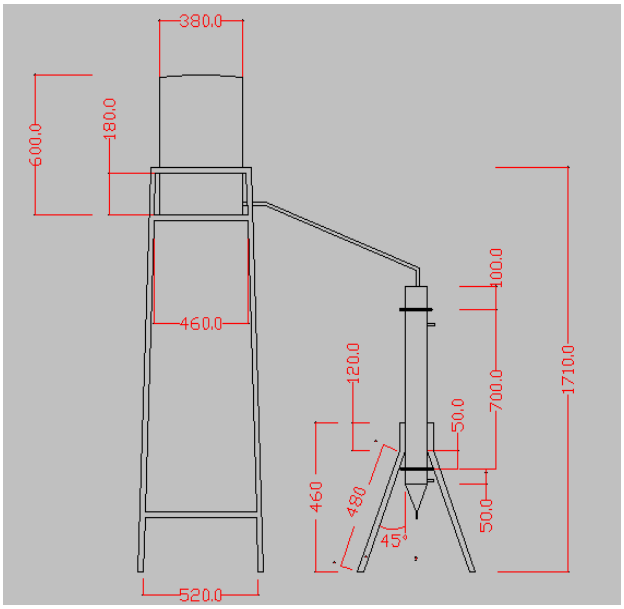

Figure 1: Design of the upgrading device (units in mm)

Figure 2: Assembly of the biogas purification device

To assess the generator performance, an Elemax SH 2900 gasoline generator was used. Elemax SH 2900 generator was used because it has a spark ignition engine which can easily ignite the biogas using the spark plug unlike compression ignition engines. Therefore, biogas could be used as a fuel without blending it as it is with compression ignition engines. Table 1 gives the generator specifications.

The gasoline generator was slightly modified to enable it run on biogas. This was done by inserting a wooden piece holding a 10mm metal duct in between the generator engine and carburettor. This duct was to direct biogas to the generator engine without necessarily changing its entire make-up. Therefore, as the generator run, the fuel could be swiftly changed from gasoline to biogas.

Table 1: Elemax SH 2900 Generator Specifications

S/N	Parameter	Specification
1	Model	Honda GX160 SH 2900 Generator
2	Engine type	4-stroke OHV
3	Rated power	3.6 kW @ 3600rpm
4	Cooling system	Air cooled
5	Ignition system	Transistorized magnets
6	Generator AC output	2400VA @ 220V, 50Hz

During experiments, biogas was collected in a polythene bag of capacity 1m^3. The generator was manually started on petrol and later biogas introduced. The supply of petrol was deliberately and steadily reduced as biogas was steadily introduced while regulating the air intake. Eventually, petrol was completely cut off and the generator ran on biogas. The experimental setup is shown in Figure 3.

The experiments were conducted under different loading conditions. Compact fluorescent lamps were used as the test loads. These test loads were grouped in percentage of the total load which was made of 16 lamps connected in series and parallel. Test load one comprised of 25% of the total load, load two was made of 50% while loads three and four were made of 75% and 100% of the total load respectively.

For each test load, various measurements were taken after stabilization. These include; current, voltage and fuel consumption. An ammeter connected in series was used for current measurement while a voltmeter connected in parallel with the test load was used for voltage measurement. Current was measured in amps while voltage was measured in volts. An air flow meter was used to measure the biogas flow for a given period of time. The results were used to determine the biogas fuel consumed by the generator for each test load given the period it was run. A ball valve connected to the pipe on the biogas bag was used to control the flow rate. The results obtained for each test load were used in calculation of Brake Power, Brake Specific Fuel Consumption (BSFC) and Brake Thermal Efficiency (BTE), using the formulae obtained from [2].

Engine brake power output (Pb):

$$\text{Voltage developed (V) x Current produced (I)} \quad (1)$$

Brake specific fuel consumption (BSFC):

$$\frac{\text{Fuel Consumption (FC)}}{\text{Engine brake power output (pb)}} \quad (2)$$

Brake thermal efficiency (BTE):

$$\frac{3600 \text{ x pb}}{\text{FC x LHV}} x\,100\% \quad (3)$$

Where LHV: Lower Heating Value of the gas.

Table 2 below shows the thermal content of biogas that was considered when calculating the Brake Thermal Efficiency. Since CH_4 is the only combustible gas in biogas, it was used when considering the lower heating value of the gas. From the biogas characterization done and the results obtained from the upgrading process, the heating values of biogas were obtained from Table 2 below based on their CH_4 content.

Table 2: Methane Yield from Animal Waste [9]

Animal	Typical experimental yield/kg manure	CH_4%	CO_2%	Thermal content MJ/m^3
Cattle	200 – 350 L	57.5%	46.5%	23
Poultry	550 – 650 L	70.0%	30.0%	28
Pig	400 – 500 L	65.0%	35.0%	26

Figure 3: Experimental Setup for the Generator Running *on Biogas*

3. Results and Discussions

3.1 Characterization of Biogas from the Digester

Biogas from chicken droppings was got from a 30m^3 Fixed Dome Digester. It comprised of 57.3% CH_4, 41.6% CO_2, 0.2% O_2, 332 ppm of H_2S and a balance of 0.4%. These were read at a digester temperature of 28.1^{o}C, pressure of 16kPa and maximum flow rate of 15litres/minute. Biogas from poultry wastes can comprise 70% CH_4 (Abdul Kareem, 2005). However, the variations exhibited can be attributed to numerous factors including the operating temperature of the digester, level of substrate mixing, the pH, carbon to nitrogen ratio (C:N) and toxins in the feedstock which may be as a result of the vaccines administered to the chicken. Biogas production can be increased by operating the digester at thermophilic temperature ranges. The said digester was run at mesophilic temperature ranges expected to be between 25-35^{o}C. Factors such as, optimum substrate mixing, neutral pH and optimum C: N ratios can affect the biogas yield quantities and component distribution.

3.2 Experimental Results obtained from the designed Biogas Upgrading Device

To establish the performance of the fabricated apparatus, different experiments were carried out to determine the device efficiency. This was done using three solvents including; H_2O, NaOH and KOH. At solvent to biogas flow rates of 0.20, 0.40, 0.60 and 0.80, the data captured was relating to biogas composition, CH_4 enrichment and CO_2 reduction. The comparative data obtained for analysis of the three solvents using average values is given in Table 3. The findings in table 3 indicate that at the same ratio of solvent to biogas flow rate, the CO_2 reduction was lowest for water, followed by KOH and highest for NaOH. On the other hand, the same ratios of the flow rate for the solvent to biogas, highest CH_4 enrichment was generated in NaOH, followed by KOH and lowest for H_2O. This is because solutions of NaOH and KOH have enhanced scrubbing capabilities for CO_2 removal. Figure 4 illustrates the percentage CH_4 enrichment using the various solvents at varying flow rate ratios.

Graphically, for the three solvents, best performance was exhibited at a ratio of NaOH to biogas flow rate of 0.80 where CO_2 reduction clocked 93% and the CH_4 enrichment level was 60.6%. The device thus performed better at higher flow rate ratios of 0.80 than at low flow rate ratios of 0.20 for all solvents. This is because there is more CO_2 absorption when the volume of solvent interacting with a given biogas volume is relatively high. Although better results are obtained at high flow rates, further increasing flow rate led to flooding of the device. Higher columns can properly cater for higher flow rates hence delaying flooding. The height of the column can be technically increased by packing. Packaging materials greatly increase the surface area of the column and hence interaction time of the gas and solvent thereby delaying flooding. Packaging further allows for efficient contact between the water (solvent) and gas phases in a counter current absorption process [7]. It is recommended that almost 70% of the column height should be filled with packaging material for good results [10]. However, the kind of packaging material defines the impact on the performance of the column. This is because packaging material affects the uniform distribution of the solvent and biogas as they flow across the column cross section.

3.3 Characteristic Generator Performance

Having developed and tested the performance of the biogas upgrading unit, control experiments were conducted to establish the performance of biogas in electricity generation. This was done by replacing the generator fuel from gasoline with biogas. Both raw and upgraded biogas was used and varying results were obtained.

3.3.1. Experimental Results of the Generator Performance on Raw Biogas

In this experiment, raw biogas was used in the generator. Ammeter, voltmeter and flow meter readings were recorded and used in Formulae 1 to 3, used to come up with data in Table 4. From the biogas characterization done, the CH_4 content was recorded at 57.3%. Therefore, the heating value of the raw gas was assumed to be 23MJ/m^3 or 20MJ/kg as earlier noted in Table 2.

3.3.2 Experimental Results of the Generator Performance on Upgraded Biogas

In this set of experiments, biogas was upgraded before it was used in the generator. After the biogas upgrading process, the CH_4 content was enriched to 78% using plain water as the solvent at water to gas flow rate ratio of 0.80. Therefore, the heating value of the upgraded biogas was assumed to be 28MJ/m^3 or 24.3MJ/kg since it had a higher CH_4 content than that quoted for poultry wastes with 70% CH_4 in Table 2. Ammeter, voltmeter and flow meter readings were recorded and used in Formulae1 to 3, and used to come up with data in Table 5. From Figure 5, the highest brake power is achieved at 100% loading of the generator with upgraded biogas recorded at 0.239 kW while the lowest brake power was attained at 25% electric load with raw biogas recoded at 0.060 kW. The current consumed increases with increase in the connected load. Therefore, the more loads connected, the higher the current consumed and hence an increase in brake power. This is in line with [2] where it is stated that increase in loading increases the combustion quality of the fuel and hence the power output of the generator. This is because the generator output depends on its fuel burning efficiency. From Figure 6, Brake Specific Fuel Consumption (BSFC) decreased with percentage electric load. This was because BSFC decreases with increase in electric load as it depends on fuel consumption directly and brake power inversely which increases with increase in brake load [2]. BSFC is higher for raw biogas at 2.07 kg/kWh as compared to that of upgraded biogas at 1.45 kg/kWh. This is because a larger volume of biogas was required for the same load for raw biogas than for upgraded biogas.

Upgraded biogas had a higher calorific value of 24.3 MJ/kg due to the high CH_4 content of 78% and hence the less volume of biogas required for the same load. It is well known that the calorific value of the fuel has an impact on the amount of fuel required for running the engine. On the other hand, Brake Thermal Efficiency (BTE) of upgraded biogas is higher than that from raw biogas. This is because a drop of CO_2 in biogas for dual fuelling increases the thermal efficiency. The highest value of upgraded biogas BTE was 17.6% compared to 14.2% of raw biogas and the lowest value for upgraded biogas was 10.2% as compared to 8.7% of raw biogas. BTE increases with increase in brake power. It can be noticed from Figure 6 that BTE increased with increased load. This is the same pattern demonstrated by brake power in Figure 5 since it's directly proportional with the percentage load. BTE further depends on brake power, fuel consumption rate and calorific value of biogas. Since upgraded biogas had a higher calorific value of 24.3MJ/kg compared to raw biogas' 20 MJ/kg and lower fuel consumption, it greatly contributed to the higher efficiency of upgraded biogas.

Table 3: Comparison of the Three Solvents on CH_4 Enrichment and CO_2 Reduction

Flow Rate Ratio	H_2O		KOH		NaOH	
	CH_4 enrichment	CO_2 reduction	CH_4 enrichment	CO_2 reduction	CH_4 enrichment	CO_2 reduction
0.2	18.3	42.8	26.4	54.8	43.5	76.4
0.4	23.2	48.6	34.0	65.4	51.1	84.9

Table 5: Generator Performance on Upgraded Biogas

S/N	ELECTRIC LOAD	25%	50%	75%	100%
1.	Voltage (V)	225.9	232.7	235	227.6
2.	Current (A)	0.27	0.52	0.80	1.05
3.	Pb (kW)	0.061	0.121	0.188	0.239
4.	Fuel consumption (kg/h)	88.6	140.0	183.2	201.2
5.	BSFC (kg/kWh)	1.45	1.16	0.97	0.84
6.	BTE (%)	10.2	12.8	15.2	17.6

During the start of experiments, the generator was run on petrol to heat up and later biogas introduced. This was because it was hard burning biogas at the generator start due to the high heating temperatures required. However, this wasn't the case when the generator had been running because the generator would have heated up already. This further highlighted the impact of biogas' low heating value. BTE increases with increased load due to increase in combustion zone temperature. Increase in load increases the combustion zone pressure and heat release rate. This improves the fuel combustion quality hence increasing the power output of the generator. Therefore, the higher the generator power output, the better the BTE.

4. Conclusion

The performance of the biogas upgrading device not only depends on the biogas flow rate but also depends on the dimensions of the scrubbing tower, biogas pressure, packaging material and purity of the water (solvent) used in the process. Upgraded biogas had a higher calorific value of 24.3 MJ/kg due to the high CH_4 content of 78% and hence the less volume of biogas required for the same load. Increase in load increases the combustion zone pressure and heat release rate. This improves the fuel combustion quality hence increasing the power output of the generator. Therefore, the higher the generator power output, the better the BTE. Using upgraded biogas improved the generator's brake thermal efficiency from 14.2% for raw biogas to 17.6% for upgraded biogas.

ABSTRACT

The authors propose a well balanced multi-value sequence (including a binary sequence). All the sequence coefficients (except the zero) appear almost the same in number, thus, the proposed sequence is so called the well balanced sequence. This paper experimentally describes some prominent features regarding a sequence, for instance, its period, autocorrelation, and cross-correlation. The value of the autocorrelation and cross-correlation can be explicitly given by the authors formulated theorems. In addition, to ensure the usability of the proposed multi-value sequence, the authors introduce its flexibility by making it a binary sequence. Furthermore, this paper also introduces a comparison in terms of the linear complexity and distribution of bit patterns properties with their previous works. According to the comparison results, the proposed sequence holds better properties compared to our previous sequence.

1 Introduction

Pseudo random sequences of having random numbers are crucial components of many cryptographic applications, for instance, key generation, session keys, masking protocol, navigation, radar ranging, and so on [1, 2, 3]. The security of these cryptographic systems deliberately depends on the randomness and unpredictability regarding the sequence. By using the non-linearity features of some mathematical functions, a pseudo random sequence of having excellent randomness characteristics can be generated. The major substances for randomness are independency of values (or lack of correlation), unpredictability (or lack of predictability), and uniform distribution (or lack of bias) [4]. Therefore, a prominent pseudo random number generator is essential to generate pseudo random sequence having good randomness property.

Most renowned pseudo random number generators are the Mersenne Twister (MT) [5], Blum-Blum-Shub (BBS) [6], Legendre sequence [7], and M-sequence [8]. Among those, the former two pseudo random number generators (MT and BBS) are well known considering their applications in cryptography rather than the theoretical aspect. On the other hand, the M-sequence and Legendre sequence are prominent geometric sequences regarding the theoretical aspect. As a result, the authors attracted in the pseudo random sequence generation research area by observing the theoretical prospect on the M-sequence and Legendre sequences.

A well balanced pseudo random signed binary sequence proposed in our previous work [9]. It is generated by utilizing a primitive polynomial, trace function, and Legendre symbol. The period and autocorrelation properties of the well balanced signed binary sequence were explained based on some experimental results. This work is actually an extension of previous works on the signed binary sequence by introducing additional two parameters k and non-zero scalar A (where k and A are responsible for generating multi-value sequence and extending the sequence period to its maximum value, respectively). It should be noted that the k-th power residue symbol is actually an extension of the Legendre symbol, therefore, this power residue symbol includes the case of the well balanced signed binary sequence. Furthermore,

this work is also an extension of our previous work on multi-value sequence [10] by considering additional two properties (linear complexity and distribution of bit patterns) and introducing its flexibility by making it binary sequence, whereas, previous multi-value sequence introduced along with its autocorrelation and cross-correlation properties (based on experimental observations only).

In this paper, the authors propose a well balanced multi-value sequence (including a binary sequence). Let $f(x)$ be a primitive polynomial of degree m and $\omega \in \mathbb{F}_q$ be its zero. Then, the sequence

$$\mathcal{S} = \{s_i\} \mid s_i = \mathrm{Tr}\left(\omega^i\right), i = 0, 1, 2, \ldots, q-2, \ldots$$

becomes a maximum length sequence whose period is $q-2$. Here, $\mathrm{Tr}(\cdot)$ is a trace function which maps an element of the extension field $\mathbb{F}_q$ to an element of the prime field $\mathbb{F}_p$. In brief, the proposed well balanced multi-value sequence generation procedure is as follows: in the beginning, a primitive polynomial generates maximum length sequence of vectors, then the $\mathrm{Tr}(\cdot)$ maps vectors to scalars, next a non-zero prime field scalar $A \in \{1, 2, \ldots, p-1\}$ added to the scalars, and finally k-th power residue symbol maps the scalars to a well balanced multi-value ($k+1$ values) sequence.

From the viewpoint of auto and cross-correlation, there are a lot of considerations to use multi-value sequence in communications [11, 12]. However, there are few papers regarding the usage of pseudo random binary sequence with a long period, high linear complexity, and good distribution of bit patterns in security applications. To make attention to the usability of the proposed sequence, the authors introduce the flexibility of their proposed well balanced multi-value sequence to make it more worthy. To do so, the authors explain how to transform their proposed sequence into a binary sequence (along with its linear complexity and distribution of bit patterns properties) due to the extensive usage of binary sequence in numerous applications (especially in cryptography).

All our previous works on sequence generation (both binary and multi-value) utilizes a mapping function during the sequence generation procedure. As a result, there exists a big difference between the appearance of sequence coefficients, which leads the distribution of bit patterns ununiform. On the other hand, the proposed sequence is a $k+1$ values well balanced multi-value sequence without applying any kind of mapping function. Therefore, all the sequence coefficients (except the 0) appear almost the same in number, thus, it is called a well balanced multi-value sequence. This balanced characteristic in the sequence coefficients contributes to low correlation (both autocorrelation and cross-correlation), high linear complexity, and almost uniform distribution of bit patterns, whereas, a suitable pseudo random sequence for cryptographic applications asks for such kinds of features.

This paper experimentally explains some prominent features regarding a sequence, for instance, its period, autocorrelation, and cross-correlation. The authors formulate theorems by which the value of the autocorrelation and cross-correlation can be explicitly given. This is one of the major contributions of this paper. Furthermore, to emphasize the usability of the proposed sequence, the authors introduce its flexibility by making it a binary sequence. In addition, a comparison result regarding the linear complexity and distribution of bit patterns properties are also included in this paper. According to the comparison results, the proposed sequence in this paper holds better properties compared to our previous sequence.

Notations

In this paper, the notation p denotes an odd characteristic prime, m be a extension degree, and q denotes the power of p, for instance, $q = p^m$. In addition, k is a prime number as well as a factors of $p-1$, such as $k \mid (p-1)$. $\mathbb{F}_q^* = \mathbb{F}_q - \{0\}$ stands for multiplicative group of $\mathbb{F}_q$ excluding the zero.

2 Preliminaries

This section briefly introduces a few mathematical fundamentals which are related to this research work such as primitive polynomial, trace function, and k-th power residue symbol. In addition, the multi-value sequence also introduced along with its properties.

2.1 Primitive Polynomial

A polynomial $f(x)$ of degree m over the prime field $\mathbb{F}_p$ is said to be irreducible if it cannot be factorized into smaller degree polynomials (including the scalar factor), then $f(x)$ is said to be an irreducible polynomial. Let e be an smallest positive integer and $f(x) \mid (x^e - 1)$. If $x = p^m - 1$, then the polynomial $f(x)$ is said to be a primitive polynomial.

Let ω be an arbitrary element in the extension field $\mathbb{F}_q$. If $f(\omega) = 0$, then ω is said to be the root of the primitive polynomial. In addition, ω becomes a primitive element in $\mathbb{F}_q$ and all the non-zero elements can be generated by the power of ω^i such as

$$\omega^0, \omega^1, \omega^2, \ldots, \omega^{q-2}.$$

The primitive element ω has a multiplicative order of $q-1$. An extension field $\mathbb{F}_q$ and its base field $\mathbb{F}_p$ holds the following property [13].

Property 1 Let ω be a generator of $\mathbb{F}_q^*$, $\omega^{(q-1)/(p-1)}$ becomes a non-zero element in prime field $\mathbb{F}_p$ and is also a generator of $\mathbb{F}_p^*$. □

2.2 Trace Function

A trace function is defined to find the sum of conjugates. Let $\mathbb{F}_q$ be an extension field and X be one of the elements (vector) of $\mathbb{F}_q$. On the other hand, let x be a prime field $\mathbb{F}_p$ element (scalar). The trace of X over $\mathbb{F}_q$ is the sum of conjugates of X with respect to $\mathbb{F}_q$. It is defined as follows:

$$x = \mathrm{Tr}(X) = \sum_{i=0}^{m-1} X^{p^i}. \tag{1}$$

Aforementioned the trace function $\mathrm{Tr}(\cdot)$ sums the conjugates in the extension field $\mathbb{F}_q$ and maps them as the prime

field $\mathbb{F}_p$ elements. As a result, it has a linearity property, which shown in the following equation.

$$\mathrm{Tr}\left(\alpha X + \beta Y\right) = \alpha \mathrm{Tr}\left(X\right) + \beta \mathrm{Tr}\left(Y\right), \tag{2}$$

where α, β are prime field $\mathbb{F}_p$ elements and X, Y are extension field $\mathbb{F}_q$ elements.

Property 2 Let $i = 0, 1, 2, \ldots, p-1 \in \mathbb{F}_p$. Then for each i the number of elements in the extension field $\mathbb{F}_q$ whose trace with regard to the prime field $\mathbb{F}_p$ becomes i be given by $q/p = p^{m-1}$. □

2.3 *k*-th Power Residue Symbol

The k-th power residue symbol with $(k > 2)$ is a generalization of the Legendre symbol to k-th powers [14]. Let a be an arbitrary element in the prime field $\mathbb{F}_p$, then the k-th power residue symbol $\left(a/p\right)_k$ can be defined as follows [15]:

$$\begin{aligned}\left(\frac{a}{p}\right)_k &= a^{(p-1)/k} \bmod p \\ &= \begin{cases} 0 & \text{if } a = 0, \\ 1 = \epsilon_k^0 & \text{else if } a \text{ is a } k\text{-th PR in } \mathbb{F}_p^*, \\ \epsilon_k^i & \text{otherwise } a \text{ is a } k\text{-th PNR in } \mathbb{F}_p^*. \end{cases}\end{aligned} \tag{3}$$

Throughout this paper, k is a prime number as well as a factor of $p-1$, such as $k \mid (p-1)$. According to the definition of the k-th power residue symbol $\left(a/p\right)_k$, a is called as the k-th Power Residue, when it has a k-th root in the base field $\mathbb{F}_p$. On the other hand, a is called as k-th Power Non-Residue. In addition, here ϵ_k is a primitive k-th root of unity belongs to $\mathbb{F}_p$ and it holds the relation $0 \le i < k$.

In Eq. (3), the value of the exponent i will be within the range of $0 \sim k-1$, since $\epsilon_k^k = \epsilon_k^0 = 1$. The k-th power residue symbol translates the scalars generated by the trace function $\mathrm{Tr}\left(\cdot\right)$ to a multi-value sequence. Thus, the sequence coefficients will be $\{0, \epsilon_k^i\}$, where $i \in \{0, \ldots, k-1\}$. In this paper, an alternate representation of the exponent i in Eq. (3) is as follows:

$$i = \log_{\epsilon_k}\left(\left(a/p\right)_k\right) = \log_{\epsilon_k}\left(a^{(p-1)/k} \bmod p\right). \tag{4}$$

Furthermore, the k-th power residue symbol holds the following property.

Property 3 For each i from 0 to $k-1$, the number of non-zero elements in $\mathbb{F}_p$ such that

$$\left(\frac{a}{p}\right)_k = \epsilon_k^i \tag{5}$$

is given by $(p-1)/k$. □

2.4 Multi-value Sequence and Its Properties

In this section, the proposed multi-value sequence introduced along with its period, autocorrelation, cross-correlation, linear complexity and distribution of bit patterns properties.

2.4.1 Notation

Throughout this paper, the proposed multi-value (more specifically, $k+1$ values) sequence $\mathcal{S}$ will be denoted as follows:

$$\mathcal{S} = \{s_i\}, i = 0, 1, 2, \ldots, n-1, \ldots, \tag{6}$$

where n denotes the period of the proposed sequence $\mathcal{S}$. In addition, here $s_i = s_{n+i}$.

2.4.2 Autocorrelation and Cross-correlation

The autocorrelation of a sequence is a measure for how much a sequence differs from its each shift value. In addition, the period and other patterns regarding a sequence can be obtained by evaluating the autocorrelation property [16]. Let $\mathcal{S} = \{s_i\}$ be a sequence and x be the shift value, then the autocorrelation $\mathrm{R}_{\mathcal{S}}(x)$ of $\mathcal{S}$ can be calculated by using the following equation as,

$$\mathrm{R}_{\mathcal{S}}(x) = \sum_{i=0}^{n-1} \tilde{\epsilon}_k^{s_{i+x} \times s_i}, \tag{7}$$

where $\tilde{\epsilon}_k$ is a primitive k-th root of unity over the complex number $\mathbb{C}$ [17] and it follows that

$$\mathrm{R}_{\mathcal{S}}(0) = \sum_{i=0}^{n-1} \tilde{\epsilon}_k^0 = n. \tag{8}$$

Furthermore, the cross-correlation property is as important as the autocorrelation property. It defines the similarities between two completely different sequences. If multiple sequences are used in an application (more specifically in any security application), then it is important to analyze their cross-correlation property to evaluate how much similar these sequences to each other. Considering this point, the cross-correlation value is preferred to be low [18, 19]. Let $\hat{\mathcal{S}} = \{\hat{s}_i\}$ and $\mathcal{S} = \{s_i\}$ be two sequences and x be the shift value, then the cross-correlation $\mathrm{R}_{\mathcal{S}}(x)$ between $\hat{\mathcal{S}}$ and $\mathcal{S}$ can be calculated by using the following equation as,

$$\mathrm{R}_{\hat{\mathcal{S}},\mathcal{S}}(x) = \sum_{i=0}^{n-1} \tilde{\epsilon}_k^{\hat{s}_{i+x} \times s_i}, \tag{9}$$

where $\tilde{\epsilon}_k$ is a primitive k-th root of unity over the complex number $\mathbb{C}$ [20, 21].

2.4.3 Linear Complexity

The linear complexity regarding a sequence is a measure of unpredictability by the length of the shortest Linear Feedback Shift Register (LFSR). In the literature, this length of the LFSR is referred to as the linear complexity [22]. The Berlekamp-Massey algorithm is an efficient method of determining the linear complexity of a sequence [23]. The forward unpredictability can be confirmed by the linear complexity property.

To calculate the linear complexity of a sequence $\mathcal{S} = \{s_0, s_1, \ldots, s_{n-1}\}$, at first, the sequence $\mathcal{S}$ needed to be represented by the polynomial expression $\mathcal{S}(x)$ as follows:

$$\mathcal{S}(x) = \sum_{i=0}^{n-1} s_i \cdot x^i, \tag{10}$$

where n denotes the period of the sequence $\mathcal{S}$. If we consider a binary sequence, then the sequence coefficients $s_i \in \{0, 1\}$, in other words, s_i belongs to $\mathbb{F}_2$. On the other hand, in case of multi-value sequence (k-values sequence), $s_i \in \{0, 1, 2, \ldots, k-1\}$, furthermore, $s_i \in \mathbb{F}_k$. After translating the sequence into polynomial, the linear complexity is evaluated by utilizing the equation in below (over $\mathbb{F}_2$ or $\mathbb{F}_k$).

$$\mathrm{LC}(\mathcal{S}) = n - \deg(\gcd(x^n - 1, \mathcal{S}(x))). \tag{11}$$

In the above equation, $\deg(f(x))$ denotes the degree of the primitive polynomial $f(x)$.

2.4.4 Distribution of Bit Patterns

The distribution of bit patterns is an important measure to judge the randomness of a sequence. As a reference, an M-sequence is well known for its uniform distribution of bit patterns. A uniform distribution of bit patterns means all the bit patterns (1-bit pattern, 2-bit patterns, 3-bit patterns, and so on) appear the same in number. Assume an M-sequence of having a period of 15 as follows and its bit distribution is shown in Table 1.

$$\mathcal{S}_{15} = \{1, 0, 0, 0, 1, 1, 1, 1, 0, 1, 0, 1, 1, 0, 0\}.$$

Table 1: Uniform distribution of bit distribution of an M-sequence [1].

n	$\mathrm{H_w}\left(b^{(n)}\right)$	$Z\left(b^{(n)}\right)$	$D_{S_{15}}\left(b^{(n)}\right)$
1	0	1	7
	1	0	8
2	0	2	3
	1	1	4
	2	0	4
3	0	3	1
	1	2	2
	2	1	2
	3	0	2

In an M-sequence, except 0 all the bit patterns appear same in number, therefore, the distribution of bit patterns of M-sequence is known as uniform.

It should be noted that the randomness and bit patterns hold a strong relationship with each other. In other words, the more uniform distribution of bits in a sequence, the sequence is more random.

3 Proposed Multi-value Sequence

The authors propose a well balanced multi-value sequence $\mathcal{S}$ by combining the features of the trace function and k-th power residue symbol. Assume that in the extension field $\mathbb{F}_q$, ω be a primitive element. Furthermore, A is a non-zero scalar which belongs to the prime field $\mathbb{F}_p$. Then, the proposed sequence $\mathcal{S}$ is defined as follows:

$$\mathcal{S} = \{s_i\},\ s_i = \left(\mathrm{Tr}\left(\omega^i\right) + A \middle/ p\right)_k, \tag{12}$$

here k is a factor of $p-1$, such as $k \mid (p-1)$. The sequence coefficients s_i in Eq. (12) can be described as the exponent of ϵ_k, such as ϵ_k^e. For instance, let $p = 7$ and $k = 3$, then the sequence coefficients in this example becomes $s_i \in \{0, 1, 2, 4\}$ and the 3-rd primitive root in $\mathbb{F}_7$ is equal to 2 or 4. In addition, let us fix 2 as a 3-rd primitive root. Then all of the non-zero sequence coefficients can be represented as an exponent of primitive root 2, this relation is developed as,

$$\epsilon_3\{1, 2, 4\} = \{2^0, 2^1, 2^2\} = \{\epsilon_3^0, \epsilon_3^1, \epsilon_3^2\}.$$

At first, the authors will focus on the autocorrelation and cross-correlation properties regarding the proposed sequence. It should be noted that the autocorrelation and cross-correlation are very close to each other. The main difference between them is the cross-correlation is calculated between two different sequences and the autocorrelation is focused in a single sequence. Thus, in the beginning, let us focus on the cross-correlation property. As mentioned earlier, using two different sequences of having the same period the cross-correlation is calculated. Let, $\mathcal{S}$ and $\hat{\mathcal{S}}$ be two different sequences which are defined as follows:

$$\mathcal{S} = \left\{ s_i \mid s_i = \left(\mathrm{Tr}\left(\omega^i\right) + A \middle/ p\right)_k \right\}, \tag{13a}$$

$$\hat{\mathcal{S}} = \left\{ \hat{s}_i \mid \hat{s}_i = \left(\mathrm{Tr}\left(\omega^i\right) + \hat{A} \middle/ p\right)_k \right\}. \tag{13b}$$

Here, A and $\hat{A}$ are non-zero elements in $\mathbb{F}_p$ can be represented by a generator $g \in \mathbb{F}_p$ such as

$$\hat{A} = g^h A, \tag{14}$$

here h satisfies the relation $0 \le h \le p-2$ and g needs to be given by $\omega^{(p^m-1)/(p-1)}$. When the value of $h = 0$, that is $\hat{A} = A$ which means $\hat{\mathcal{S}}$ and $\mathcal{S}$ becomes the same sequence. Thus, the cross-correlation becomes the autocorrelation of $\mathcal{S}$. After inspecting several experimental results, it was found that the value of the cross-correlation explicitly given by the following theorem.

Theorem 1 The cross-correlation between the two sequences $\hat{\mathcal{S}}$ and $\mathcal{S}$ is defined by the Eq. (13) is as follows:

$$\mathrm{R}_{\hat{\mathcal{S}},\mathcal{S}}(x) = \begin{cases} \left(p^m - 1 - p^{m-1}\right)\tilde{\epsilon}_k^{f_k(g^h)}, & \text{if } x = h\bar{n}, \\ -p^{m-1}\left(\tilde{\epsilon}_k^{f_k(g^j)}\right) - \tilde{\epsilon}_k^{f_k(g^h)}, & \text{else if } x = j\bar{n}, \\ -\tilde{\epsilon}_k^{f_k(g^h)}, & \text{otherwise,} \end{cases} \tag{15}$$

where $\bar{n} = n/(p-1) = (p^m - 1)/(p-1)$, h satisfies the condition in Eq. (14), and $0 \le j \ne h \le p-2$. □

If the value of $h = 0$, then $\hat{\mathcal{S}} = \mathcal{S}$ which actually means they becomes the same sequence. In this case, the cross-correlation in Eq. (15) becomes the autocorrelation after replacing the value $h = 0$.

[1] The notations $n, \mathrm{H_w}\left(b^{(n)}\right), Z\left(b^{(n)}\right)$, and, $D_S\left(b^{(n)}\right)$ means length of a bit pattern $b^{(n)}$, Hamming weight of the bit pattern $b^{(n)}$, number of zeros in $b^{(n)}$, and appearance of $b^{(n)}$ in numbers in a sequence period, respectively.

Theorem 2 The autocorrelation of a sequence $\mathcal{S}$ is given as follows:

$$\mathrm{R}_{\mathcal{S}}(x) = \begin{cases} p^m - 1 - p^{m-1}, & \text{if } x = h\bar{n}, \\ -p^{m-1}\left(\tilde{\epsilon}_k^{f_k(g^j)}\right) - 1, & \text{else if } x = j\bar{n}, \\ -1, & \text{otherwise}, \end{cases} \tag{16}$$

Corresponding to the above autocorrelation equation, the period of the proposed well balanced multi-value sequence undeniably given by $p^m - 1$. □

In the next section, the authors will introduce experimental observation regarding the period, autocorrelation and cross-correlation properties.

4 Example and Discussion

This section experimentally observes the proposed multi-value sequence properties such as its period, autocorrelation, and cross-correlation along with some examples. In this section, the notation $\mathcal{S}_2$ denotes the proposed sequence with the parameter $A = 2$. The proposed sequence in this paper is a multi-value sequence, thus its correlation is calculated over the complex number $\mathbb{C}$. To represent the absolute value of a complex number x, this section uses the notation $|x|$.

4.1 $p = 7, m = 2, k = 3$, and $A = 2, 3$

Assume, $x^2 + 4x + 5$ be a primitive polynomial over $\mathbb{F}_7$. Then, the generated sequence $\mathcal{S}_2$ having a period of 48 ($p^m - 1 = 7^2 - 1 = 48$) is shown as follows:

$$\begin{aligned} \mathcal{S}_2 = \{&2,4,1,4,4,1,1,4,4,2,2,2,4,2,1,2,2,0,4,0,4,4,2,0, \\ &0,1,2,1,4,2,4,1,1,1,0,1,4,0,2,1,1,2,1,2,4,1,0,2\}. \end{aligned} \tag{17}$$

The autocorrelation of this generated sequence $\mathcal{S}_2$ is calculated by the Eq. (7) and autocorrelation graph of $\mathcal{S}_2$ is shown in Figure 1.

$$|\mathrm{R}_{\mathcal{S}_2}(x)| = \begin{cases} 41 & \text{if } x = 0 \\ 6 & \text{else if } x = 8, 16, 32, 40 \\ 8 & \text{else if } x = 24 \\ 1 & \text{otherwise} \end{cases}.$$

To confirm the well balanced property in the proposed multi-value sequence, the authors introduce sequence coefficients appearance in the following Table 2. According to the table, it was found that in every case all of the sequence coefficients (except the 0) appears almost the same in number. This is one of the positive properties of the proposed sequence, thus, it is called as a well balanced sequence.

Table 2: Appearance of the sequence coefficients.

sequence coefficient	number of appearance
0	7
1	14
2	14
4	13

On the other hand, $\mathcal{S}_3$ is given as follows. It should be noted that the sequence $\mathcal{S}_3$ is different from the sequence $\mathcal{S}_2$, but both of them having the same period.

$$\begin{aligned} \mathcal{S}_3 = \{&4,1,4,1,2,4,0,1,1,2,4,2,2,4,4,2,2,1,1,1,2,1,4,1, \\ &1,0,2,0,2,2,1,0,0,4,1,4,2,1,2,4,4,4,0,4,2,0,1,4\}. \end{aligned} \tag{18}$$

The autocorrelation of this generated sequence $\mathcal{S}_3$ is calculated by the Eq. (7) and autocorrelation graph of $\mathcal{S}_2$ is shown in Figure 2.

$$|\mathrm{R}_{\mathcal{S}_3}(x)| = \begin{cases} 41 & \text{if } x = 0 \\ 6 & \text{else if } x = 8, 16, 32, 40 \\ 8 & \text{else if } x = 24 \\ 1 & \text{otherwise} \end{cases}.$$

The cross-correlation of $\mathcal{S}_2$ and $\mathcal{S}_3$ becomes as follows and the cross-correlation graph shows in Figure 3.

$$|\mathrm{R}_{\mathcal{S}_2,\mathcal{S}_3}(x)| = \begin{cases} 6 & \text{if } x = 0, 8, 24, 32 \\ 8 & \text{else if } x = 16 \\ 41 & \text{else if } x = 40 \\ 1 & \text{otherwise} \end{cases}.$$

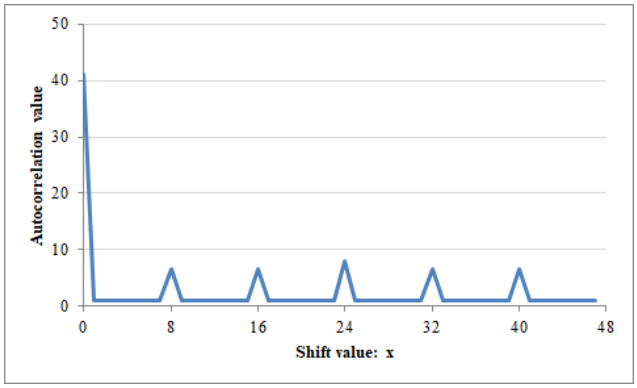

Figure 1: $|\mathrm{R}_{\mathcal{S}_2}(x)|$ with $p = 7, m = 2, k = 3$, and $A = 2$.

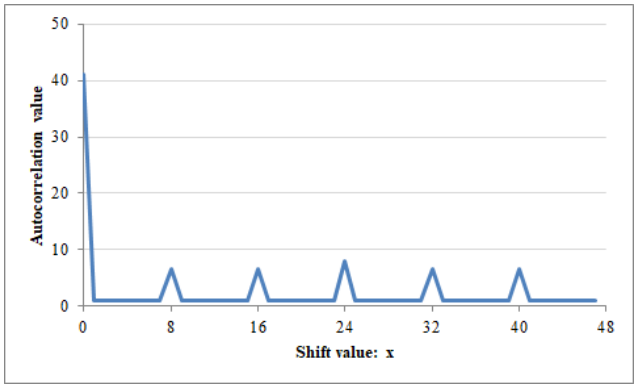

Figure 2: $|\mathrm{R}_{\mathcal{S}_3}(x)|$ with $p = 7, m = 2, k = 3$, and $A = 3$.

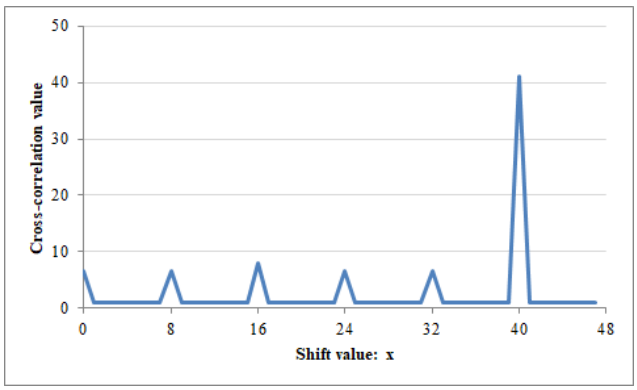

Figure 3: $|R_{S_2,S_3}(x)|$ with $p = 7, m = 2$, and $A = 2, 3$.

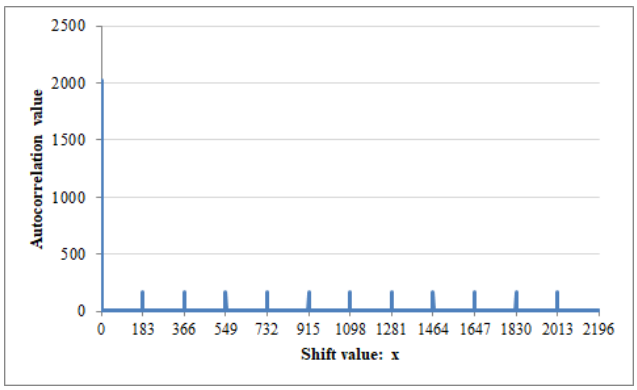

Figure 5: $|R_{S_7}(x)|$ with $p = 13, m = 3, k = 3$, and $A = 7$.

4.2 $p = 13, m = 3, k = 3$, and $A = 6, 7$

Assume, $x^3 + 6x^2 + 3x + 7$ be a primitive polynomial over $\mathbb{F}_{13}$. Then, the period of this generated sequence becomes 2196. Here, Figure 4 and Figure 5 respectively represents the autocorrelation graph of $\mathcal{S}_6$ and $\mathcal{S}_7$. Their cross-correlation graph is shown in Figure 6.

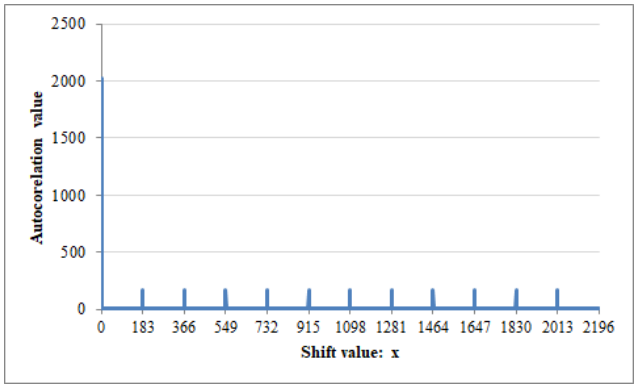

Figure 4: $|R_{S_6}(x)|$ with $p = 13, m = 3, k = 3$, and $A = 6$.

After observing the cross-correlation graphs, it was found that in each graph the number of peaks exactly is given by $p - 1$. Only a single peak has the maximum value, as an example, in Figure 3 the maximum peak value is 41 that corresponds to the first case ($x = h\bar{n}$) of Eq. (15). Remaining $p - 2$ smaller peaks conforms to the second case ($x = j\bar{n}$). Except all of these peak values, the remaining parts of the cross-correlation graph consistently having a constant value of 1, which confirms the final case of Eq. (15). It should be noted that only changing the value of non-zero scalar parameter $A \in \mathbb{F}_p$, different sequences can be generated. It is also observed that by changing all the other parameters such as primitive polynomial $f(x)$, extension degree m, non-zero scalar A, and prime factor k does not have any impact in the correlation (both autocorrelation and cross-correlation) evaluation.

Alike the cross-correlation, autocorrelation also have a $p-1$ number of peaks. Among them, only one peak hold the maximum value, while other peaks have small values and remaining parts holds a constant value of 1 and all of these values explicitly given by the Eq. (16).

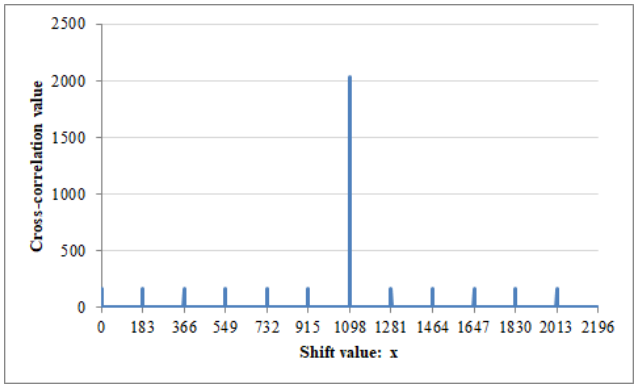

Figure 6: $|R_{S_6,S_7}(x)|$ with $p = 13, m = 3$, and $A = 6, 7$.

5 Flexibility of the Proposed Sequence and Its Application

Although nowadays multi-value sequence does not have enough application except the binary sequence especially in security applications. Therefore, the authors emphasize the flexibility of their proposed sequence to make it more worthy. To do so, the authors in this section, explains how to transform their proposed sequence into a binary sequence. In addition, this section also describes a comparison with our previous work [24] in terms of the linear complexity and distribution of bit patterns like crucial properties from the experimental viewpoint.

5.1 Proposed Binary Sequence

Binary sequences are extensively used in numerous applications (especially in cryptography). Although the authors proposed sequence is a multi-value sequence, it can be easily mapped into a binary sequence by setting the parameter value $k = 2$ and using the mapping function $M_2(\cdot)$. As mentioned previously, the proposed multi-value sequence is a well balanced sequence, in other words, all of the sequence coefficients (except the 0) appears same in number. To maintain the same property, the authors utilized the following algorithm (Algorithm 1) to make a uniform binary sequence from the well balanced multi-value sequence.

To make it binary sequence, a mapping function (intro-

duced in the following algorithm) is defined as,

$$M_2(s) = \begin{cases} 0 & \text{if } s = 0 \text{ or QR}, \\ 1 & \text{otherwise}, \end{cases} \tag{19}$$

By utilizing the parameters $p = 7$, $k = 2$, $f(x) = x^2 + 5x + 5$, and $A = 2$ the multi-value sequence becomes as,

$$\begin{aligned} \mathcal{S}_2 = \{&2,2,4,4,0,1,1,2,2,2,2,1,1,2,1,4,4,2,4,4,4,4,2,1,0,1,4, \\ &1,1,0,4,1,2,4,1,4,4,4,2,1,1,2,0,4,4,0,0,2,4,1,4,2,0\}. \end{aligned} \tag{20}$$

Algorithm 1 Generating procedure of the proposed uniform binary sequence

1: generate primitive element $\omega \in \mathbb{F}_{p^m}$
2: initialize flag $f \leftarrow 0$
3: **for** $i = 0$ to $p^m - 2$ **do**
4: compute ω^i
5: $a \leftarrow \left(\mathrm{Tr}\left(\omega^i\right) + A/p\right)$
6: **if** $a = 0$ and $f = 0$ **then**
7: $a \leftarrow 1$, $f \leftarrow 1$
8: **else**
9: $a \leftarrow p - 1$, $f \leftarrow 0$
10: **end if**
11: $s_i = M_2(a)$
12: **end for**

After using the above algorithm, the well balanced multi-value sequence in Eq. (20) can be transformed into a binary sequence as follows.

$$\begin{aligned} \mathcal{S}_2 = \{&0010000101110011111110001 \\ &1001001111000101001101 00\}. \end{aligned} \tag{21}$$

5.2 Comparison with Our Previous Work

Before applying any sequence in some security application, a lot of sequence properties needs to be well studied such as its period, autocorrelation, cross-correlation, linear complexity, distribution of bit patterns, and so on. The authors already discussed the former three properties. Additionally, this paper also includes a comparison with our previous work [24] regarding the linear complexity and distribution of bit patterns like crucial properties from the experimental viewpoint. It should be noted that from here on the authors previous sequence proposed in [24] will be called as NTU (Nogami-Tada-Uehara) sequence.

Linear Complexity

The linear complexity is an important measure to judge the unpredictability of a sequence. Thus, before recommending a sequence for any security application, its linear complexity needs to be well-studied. The linear complexity of the proposed sequence (binary case) and NTU sequence (previous sequence) having a period of 2400 are shown in Figure 7 and Figure 8, respectively. According to the comparison result, it is found that in both cases the linear complexity reaches to their maximum value. Since the M-sequence has the minimum linear complexity [25], on the other hand, the Legendre sequence has the maximum linear complexity [8]. It should be noted that the proposed sequence for being a well balanced sequence, its linear complexity reaches to its maximum value.

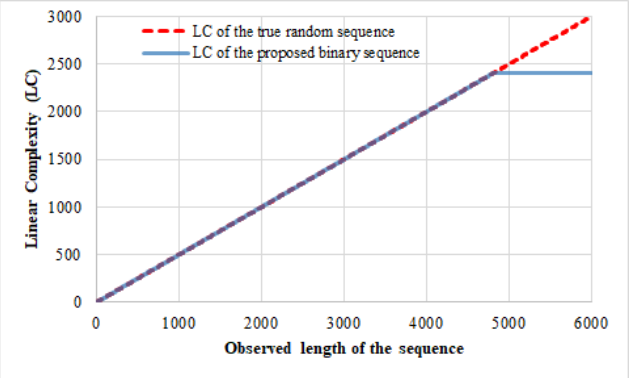

Figure 7: Linear complexity of the proposed sequence (binary case).

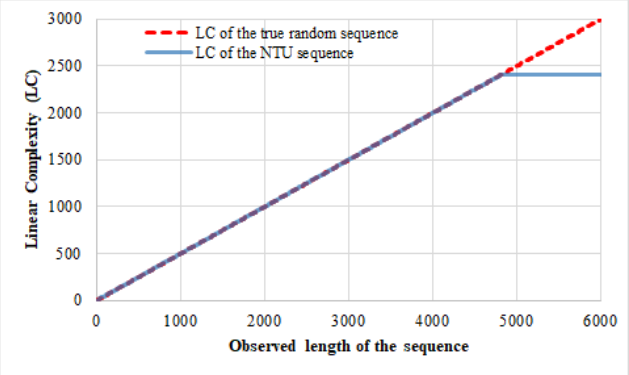

Figure 8: Linear complexity of the NTU sequence.

Distribution of Bit Patterns

The randomness of a sequence can be evaluated by observing the distribution of bit patterns of it. The bit pattern of the proposed sequence (binary case) and NTU sequence (previous sequence) having a period of 117648 are shown in Table 3. In the following table, the notations $n, b^{(n)}, Z\left(b^{(n)}\right)$, and $D_S\left(b^{(n)}\right)$ means length of a bit pattern, specific bit pattern, number of zeros in $b^{(n)}$, and appearance of $b^{(n)}$ in numbers in a sequence period, respectively. According to the comparison result, it is found that the distribution of bit pattern of the proposed binary sequence is almost uniform compared to NTU sequence.

The authors applied $k = 2$ and $M_2(\cdot)$ mapping function to make a uniform binary sequence from the well balanced multi-value sequence. It should be noted that after applying such a mapping function and uniformization algorithm, the sequence properties remains almost the same. For instance, only a small amount of change in the peak values regarding the autocorrelation, linear complexity remains the maximum, and distribution of bit patterns becomes almost uniform. In other words, they exhibit almost the same properties. It means the authors proposed sequence possesses a great flexibility.

Table 3: A comparison of distribution of 4-bit patterns between the proposed sequence (binary case) and NTU sequence.

As far the authors know, there are a lot of considerations to use multi-value sequence in communications from the viewpoint of correlation [11, 12]; however there are few papers regarding the usage of pseudo random sequence with a long period, high linear complexity, and good distribution of bit patterns in security applications. The most typical security application of the pseudo random binary sequence will be the XOR-based stream cipher. First of all, in such an application, the same key is used for both encryption and decryption. Thus, each user should have a different key. In this case, these keys should have a minimum cross-correlation property compared to each other. Under this circumstance, it is important to discuss the cross-correlation property between several sequences along with linear complexity and distribution of bit patterns properties. The authors briefly introduced a use case in the following section of their proposed well balanced sequence in this paper, to emphasis on its usability.

5.3 Application

One of the most common applications of the pseudo random sequence (binary case) is in a stream cipher. Basically, a stream cipher is divided into two classes: block cipher and stream cipher. Among these a block cipher uses the same key for both encryption and decryption of each block (≤ 64 bits) of data. On the other hand, in case of a stream cipher, encryption and decryption are performed by the bit wise $\oplus$ (XOR) operation with a key stream. Here, the authors restrict the discussion of their proposed pseudo random binary sequence in a stream cipher. An image of the stream cipher is shown in Figure 9. Few important considerations during the design of a stream cipher are the key (which used for both encryption and decryption) should have a long period, good randomness, and unpredictability properties due to the usage of the same key in both encryption and decryption. Here, the encryption is carried out by applying a bit-wise $\oplus$ (XOR) operation between the plain-text of byte stream M and encryption key K. Then, the cipher-text C is transmitted through a network. On the other hand, during the decryption, after the bit-wise $\oplus$ operation between the cipher-text C and the same key K, we will get the original plain-text M. In a stream cipher, a lot of sequences are assigned to several users, respectively. If these sequences have some correlation, then it will make some security vulnerabilities. Under this circumstance, it is important to observe the cross-correlation property between several sequences. Additionally, its linear complexity and distribution of bit patterns needs to be high and uniform, respectively to confirm its randomness. Although the authors proposed sequence is a well balanced sequence, it can be easily mapped into a binary sequence with a long period, typical auto and cross-correlation, high linear complexity, and almost uniformly distributed bit patterns features. After observing the experimental and comparison results, it can be concluded that the authors proposed well-balanced sequence (binary case) can be a prominent candidate for a stream cipher like applications.

6 Conclusion

The authors have proposed a multi-value sequence (including a binary sequence) which defined over the odd characteristic field. The k-th power residue symbol utilized in this paper which is an extension of the Legendre symbol. Additionally, the proposed sequence also includes the case of the signed binary sequence. Prominent features regarding a sequence for instance, its period, autocorrelation and cross-correlation of the proposed sequence discussed based on experimental results along with a theorem (by which the value of the correlation can be explicitly given). In addition, the authors also introduced the flexibility of their proposed sequence by making a binary sequence from a well balanced multi-value sequence. Furthermore, a comparison result regarding the linear complexity and distribution of bit patterns properties are also included in this paper. According to the comparison results, the authors proposed well balanced sequence holds better properties compared to our previous sequence.

As a future work, the more efficient calculation will be introduced for instance power residue symbol needs exponentiation calculation.

ABSTRACT

Photoluminescence (PL) of inhomogeneous porous silicon (PS) of p-type is investigated in this contribution. We measured the PL signal at equidistant positions separated by 0.05 mm in area localized between original crystalline Si (c-Si) wafer surface and electrochemically prepared PS layer. Two PL peaks localized at energies 1.8 and 1.9 eV were identified and their parameters were determined. The changes of PL maxima energy ("blue shift") in dependence on position were observed.

1. Introduction

Researching porous silicon (PS) structures is time-intensive. Extensive collection of results is presented e.g. in [1], but the interpretation of the origin of photoluminescence (PL) signals is still a problem.

Structural characteristics and luminescence of PS prepared by chemical etching were studied by Korsunskaya et al. in [2]. The luminescence spectrum of this type of PS was the result of superposition of two PL bands. The first band represents excitonic recombination in amorphous Si nanocluster smaller than 3 nm. The second band, which prevails at room temperature, is generated by the recombination of charge carriers mediated by the defects in silicon oxide.

Silicon nanocrystallines (NCs) are included in the PS in the form of nanowires on monocrystalline silicon surface composed of different phases of crystalline and amorphous Si. They are covered with oxides (SiO_y) and hydrides (SiH_x) (Tynyshtykbaev [3]). Authors concluded that the light emission originates in hydride coverages of nanocrystallines. In order to explain the character of PL centers, various models have been elaborated (see e.g. Lenshin [4], experimental analysis of aging effects). The model, in which the maximum of PL localized at 640 nm is related to defective levels os SiH_x and SiO_y components, is greatly accepted. The presence of groups SiO_xH_y, observed using FTIR spectroscopy in IR region, was reported in the work [5]. Only small influence of PL on surface morphology was found.

The homogeneity of effective PL from PS was studied by Kayahan [6]. Imaging spectroscopy technique was used by author in order to examine both the effect of atmospheric aging and light illumination applied during anodization process on spatial distribution of PL intensity. He concluded that chemical structure of PS surface plays role in PL and that quantum confinement effect related to surface states can be understood to be a source of luminescence.

Chan [7] observed dependence of energy of PL spectrum on size of pores in PS. Their size was controlled by concentration of HNO_3 in etching liquid. Observed "blue shift" of peaks was attributed to quantum confinement effect.

In this work are presented results of our PL experiments on PS. For evaluation of PL signal we used the decomposition procedure based on the fitting of the spectrum by the set of Gaussian peaks. The proper number of the peaks was estimated from the residuum of the fit (Brunner [8]).

2. Experimental Part

The contribution topic is to investigate the PL signal recorded on an inhomogeneous PS sample. The p-type boron doped Si wafers (100) with resistivity of 8 – 10 Ωcm and thickness 600 –

* Róbert Brunner, Email: robert.brunner@savba.sk

650 nm were used in the experiment. Standard PS was prepared by electrochemical etching process in the solution of HF and MeOH without illumination. Used apparatus is schematically depicted in the Figure 1. Electrical voltage 6V – 11V was applied through mask (Fig. 1) between the exposed area of the Si sample (positive potential) and Pt negative electrode. A constant current of 30 $mAcm^{-2}$ was maintained during the few minutes of the etching process. The PS was rinsed in ethanol and annealed in nitrogen at 250°C for 30 minutes.

Optical and electrical parameters of PS layer depend on the type and size of the formed crystallites that are controlled by etching process parameters. The mask affects current density in vicinity of their boundary. This shielding effect leads to generation of transient area between exposed and non-exposed part of surface of silicon wafer.

Measurements were performed in this transient area in 17 points separated by 0.05 mm starting from initial crystalline surface (after polishing and cleaning procedures) to prepared PS layer as shown in the Figure 2.

The PL of the sample was measured at ambient temperature. PL spectra were decomposed into Gaussian peaks (this process is explained in more details in [8, 9, 10]). Usage of Gaussian peaks is suitable for sufficiently homogeneous structures composed of domains (layers). Photon emission is considered as an event which is independent of other emission acts. This independence makes possible to use the central limit theorem, leading directly to the Gaussian profile of the PL peak. The presence of light emitting centers of different types in the sample gives the spectrum composed of a set of Gaussians.

The observed spectra were fitted in order to find parameters of the set of Gaussian functions (energy, intensity and width given as FWHM) and to calculate constant bias. This bias represents both noise and signal offset contribution. Root-mean-square (RMS) value was used in the role of the object function in the fitting process.

The calculated parameters of PL peaks (without bias) were statistically tested using bootstrap method (e.g. [11]) based on measured data set resampling. Confidence intervals of peak parameters were estimated using BCa percentile method ("bias-corrected and accelerated"). This version reduces the requirements on number of the used bootstrap data set. In our calculations we used 500 resampling procedures for each sample. Standard 5% confidence limit was used for confidence intervals.

3. Results and Discussion

Estimation of optimal number of PL peaks during fitting process was based on size of residuum. Figure 3 shows how residuum depends on the number of used peeks. Well visible "knee" indicates the optimal model. This approach is explained in more detail in [8] (but briefly speaking, usage of too small number of peaks omits relevant parts of the PL signal, whereas redundant peaks fit mainly the noise). In this case, two relevant PL peaks were found: ~1.8 eV and ~1.9 eV.

Figures 4 – 6 show dependence of parameters of PL peaks (in successive steps energy, intensity and FWHM). Signal was measured at ambient temperature. The visible dependence of parameters of peaks on the position of the measurement point is attributed to the lateral non-homogeneity of the PS layer in the transition region (Fig. 2). Calculated confidence intervals are slightly non-symmetrical. Possibility to evaluate such data sets is the main advance of the bootstrap method, because the approach based on the normal error distribution would be less effective.

Several trends were observed:

Increase of the PL peak energy in dependence on position of measurement point is visible in Figure 4. We suppose that this may be the consequence of the size effect caused by the etching of nanostructural elements. Namely it is related to the SiO_xH_y compounds covering the structure's surface. The presence of the SiO_xH_y has been confirmed in the works [5, 12] using FTIR spectrometry of the samples of this type in wavenumber range 790-1250 cm^{-1} (0.098 - 0.155 eV).

A noticeablw changes of power of PL signal in dependence on position of measured point can be seen in Figure 5. This is mainly the consequence of increased thickness of light-emitting PS layer in combination with interference of exciting light during PL experiment, but the size effect (controlling light conversion effectivity) can take place in this process also.

Observed changes of FWHM of peaks 1 and 2 on Figure 6 are close to zero and may be non-significant in comparison with the width of confidence interval. Otherwise the increase of FWHM may indicate the inhomogeneity of the sample.

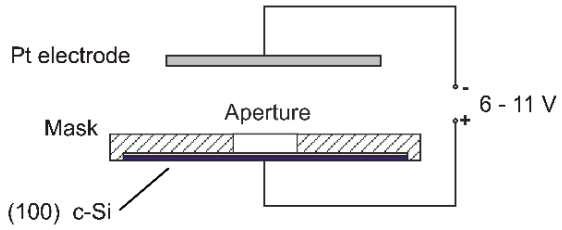

Figure 1: Experimental setup

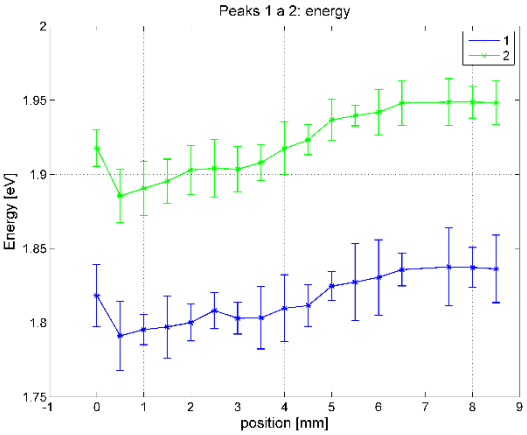

Figure 4: Dependence of energy on the position. Confidence intervals at confidence level α=0.05 are given

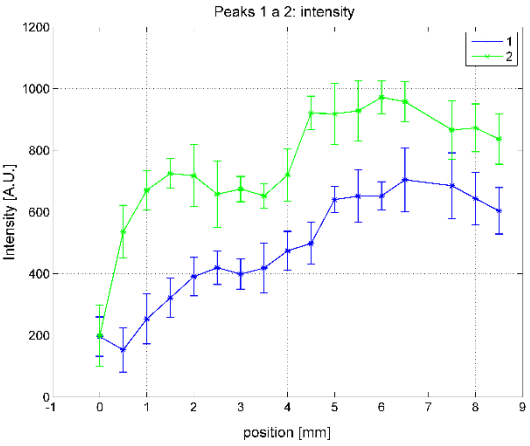

Figure 5: Dependence of intensity on the position. Confidence intervals at confidence level α=0.05 are given

4. Conclusion

Visible increased "blue shift" of both PL maxima (1: at 1.9 eV, 2: at 1.8 eV) occurred in all records in dependence of location of measuring point has been observed. We suppose that this effect is mainly related to the SiO_xH_y compounds that cover the PS structure's surface. This structure was modified during preparation of the sample by the non-homogeneous density of the current in transient region (in the vicinity of the mask boundary, see Fig. 1).

The corresponding FWHM of the peak marked as 1 is decreasing, whereas the value of the peak 2 is increasing in dependence on the position of measuring point. These effects are weak, however, the increase of the FWHM parameter may indicate the degradation of the sample homogeneity.

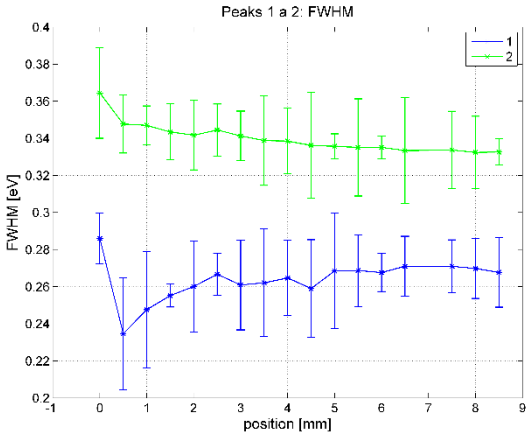

Figure 6: Dependence of width on the position. Confidence intervals at confidence level α=0.05 are given

ABSTRACT

Data mining is recognized as an effective technique for extracting and retrieving valuable information or decision from the vast available data. Because of the nature of the functionality of medical centers and hospitals, their data centers contain a collection of valuable information about their patients. By properly processing these data, different applications can be developed to utilize them. These applications could participate in predicting and diagnosing particular diseases. Two prime diseases realized to impact the overall health of society are heart diseases and diabetes. The presented work intends to develop and test a software application that helps doctors and practitioners predict the emergence of noncommunicable diseases (NCDs) such as diabetes and heart diseases. The application applies the predictive data mining model to the medical records which are collected from the Bahrain Defense Force Hospital (BDFH). The BDFH doctors evaluated the application and executed it on actual patients. The results obtained are accurately matching the expectation of doctors in BDFH. All kinds of risks are categorized appropriately according to the defined categories. As a conclusion, this application can help doctors in making proper decisions toward patient health risks. In addition, data mining is more supportive for the health sector and is essential for exploring the knowledge to be used in the health care sector.

1. Introduction

The term data mining refers to the process of knowledge discovery discipline in databases (KDD). It is associated with various computing fields; such as databases, artificial intelligence, as well as software engineering. It can also be used to overcome various problems that emerge where a large volume of data is involved.

The World Health Organization (WHO) is the world body that monitors international health. It showed that 68% of all mortality around the globe is due to noncommunicable diseases (NCDs), and the major killer NCDs are cardiovascular diseases (CVDs), diabetes, lung diseases, and cancer [1-2]. It added that heart diseases cause 12 million deaths globally. CVD comprises of various heart-related disease and its functioning problems that contribute significantly to the adult mortality in some countries.

The (popular) disease or new-generation disease is diabetes. It has emerged as a consequence of inactivity, fewer movements, sedentary lifestyle, and unhealthy eating habits. Given the low activities and other lifestyle reasons, the pancreas produces insufficient insulin to control blood sugar, resulting in diabetes. In a small country in the population such as Bahrain, these two NCDs present a multifaceted problem that must be addressed [3]. Hospitals and health centers accumulate a massive amount of patient's data. This data can be entered or fed to a data mining engine to help in predicting and diagnosing various types of diseases.

The accurate and efficient prediction is a consequence of medical diagnosis. Therefore, it is an important task at that stage. Unfortunately, not all doctors hold expertise for various specialization. In addition, the number of specialized practitioners is also found to be insufficient in many health centers, especially when it is related to heart diseases. Hence, there is a great need to develop a system that assists in predicting and forecasting the patient's diagnosis. It would certainly bring plenty of relief and help doctors.

This research is designed to assess the data of the patient concerning his health which is necessary to forecast NCDs using inferential data mining and KDD to assists the healthcare professionals in evaluating, as well as predicting, the recurrence or occurrence of NCDs. As a result, this research offers a platform for doing such a system to be able to develop all sets of rules and make them available to medical doctors and other practitioners to anticipate with a degree of correctness the prospect of NCDs among patients. To be able to detect the prime elements which are vital for NCD prediction, the development of an application takes place to compile the massive volumes of patient data for forecasting the potential future trends by employing data mining. Afterward, its testing occurs, which allows the physicians and experts to use the information pertaining to NCDs for improving its diagnosis and reducing the diseases. This project utilizes huge amounts of data obtainable from the BDFH to anticipate NCDs by employing data mining technique.

The contribution that the study adds is that it develops a software which predicts the diagnosis and is tested by BDFH actual practitioners. Using the software, the practitioners were gratified with the study results.

1.1. Purpose of the Study

The purpose of the study is to apply KDD and execute the inferential data mining technique to examine health data, which is essential for predicting NCD. This assists doctors in analyzing or even predicting the recurrence or occurrence of NCDs in patients. Currently, BDFH has no tools or techniques to undertake this task. Hence, a Predicting NCD Application (PNCDA) software will be developed by applying the inferential data mining technique on the compiled huge volumes of available vital data. This application will be available for doctors to be able to predict future trends with accuracy, for the NCD potential among the BDFH patients. Following it, the application will be assessed for demonstrating the model which enables the clinicians and other stakeholders to have access to this facility and use it during their diagnosis process to improve patients' health and to reduce such diseases.

Because of the sensitivity of this project as it deals with confidential patient data, two types of data will be utilized: secondary and primary data. Secondary data will be extracted from the records of the BDFH, while primary data are gathered in person where the related data are organized as per the software requirements. The approach of the interview will be used for collecting primary data, which will recruit about 30 percent to 40 percent of doctors, nurses, as well as BDFH paramedics.

1.2. Study Significance

The objective of this project is to experiment as well as assess different algorithms of data mining, which will assist in NCDs prediction, comparison, and contrast of the effective ways of predicting the disease. The experiment is assumed to serve as an instrumental tool for the doctors for predicting in complex medical cases related to NCDs and advice their parents as per the predictions generated through accurate algorithms, that will have a huge advantage for the field of medical science. This research would provide evidence that the technique of data mining is effective for physicians for predicting and forecasting risky medical cases as practiced across developed nations. This research is set to act as a predecessor for accumulating data for patients in the Kingdom of Bahrain in the future.

1.3 Study Limitations

The study has certain limitations such as it includes patients recorded in BDFH only in Kingdom of Bahrain. Once completed, the findings of the research would be communicated and discussed with the healthcare authorities in the kingdom, where additional comprehensive research can be conducted for covering the whole Bahrain population.

This whole research is categorized into five sections; where section two presents a comprehensive review of the data mining methods and its implementation in the medical discipline. Following it, section 3 provides an explanation of the process for data mining, which is used for the prediction system for NCD. It also provides a description of the prediction software, which is developed. The developed software for prediction and its results are reflected and analyzed in section four. Lastly, section five briefly summarize the overall findings of the research and provides a direction to the future researches for expanding the research horizon.

2. Theoretical Background and Literature Review

In the present times, an increased acceptance of the data mining on the international forums is being recognized, across different medicine and life spheres. Considering the dynamics scope of data mining related to its efficacy for enhancing the healthcare outcomes, this section intends to highlight the theoretical basis which assists in NCD determination as well as the application of the data mining in forecasting.

2.1. Non-communicable Disease

At present, the unbridled growth of NCDs is recognized as the primary cause of mortality across the world. It is reasoned that the increase in sedentary lifestyle and lack of exercise has added to its increase. As it is well-recognized that an active lifestyle is vital for proper maintenance and functioning of the human body. According to 2016 WHO statistics, more than 15 million deaths occurred as a result of NCD such as diabetes and cardiovascular disease [1]. The most surprising and alarming finding of this statistics was that almost half of the deaths were of individuals who were less than 70 years of age.

A. Diabetes

The statistical evaluation of World Health Organization (WHO) findings, and its comparison with the outcomes of 2014, it is found that diabetes had an increasing percentage of about 409 percent for 34 years, ranging from 1980 to 2014. The main contributor to the increasing percentage is the changing world dynamics where the living status of the majority of the countries has changed for both developing and underdeveloped countries [1]

As per the healthcare professionals, the disease of diabetes occurs when the gland of the body (pancreases) is able to release an adequate amount of insulin. It affects the human body function as insulin is responsible for carrying sugar from the bloodstream to numerous cells in order to be used as energy. The deficiency of insulin in the body makes its natural functioning difficult. As a

consequence, the body releases high levels of glucose in the urine. Its prevalence for a long-term can cause an organ to fail, cause CVD, and affect the other functions of the body. The deteriorative effects which emerge as a consequence of diabetes are the reason it is ranked as the fourth primary NCD by WHO [2]. It can also lead to the complication of CVDs. The WHO organization [2] documented that diabetes and CVDs were the reasons for more than 11 million fatalities that occurred before the age of 70, as shown in Figure 1.

The primary factor which contributes to the occurrence of diabetes includes the uncontrolled level of blood glucose. Using data mining techniques, the healthcare professionals across the world would be able to forecast illness in an effective manner and will be able to integrate better management technique for patients at high risk. This adds to the significance and needs for the disease analysis and predictions for overcoming it and providing relief to the majority of the patients.

Similar to other regions, Bahrain also lists diabetes as a major health concern. The prevalence of diabetes is found across different ages and populations comprising of different characteristics. The report by WHO for Bahrain documented that diabetes account to 13 percent of the deaths in the region. It also indicates the increasing detrimental outcomes of diabetes, which continue to grow at an increasing speed [3].

Generally, diabetes is categorized into two types; namely, type 1 and type 2. In type 1, the diabetic patient is required to be infused with artificial insulin using medicines and injections. Whereas, in type 2, the body gland (pancreas) produces insulin but is inadequate for the body. Majorly, type 2 diabetes is more prevalent among patients across the world. The population that is generally found to be affected by it comprise of adults, particularly people, in the middle-aged group, however, with the changing lifestyle and dynamics, its prevalence is found in children also.

The low prevalence of Type 1 diabetes is due to its interconnectivity with the external environment, which affects the body insulin-releasing cells. Though, the change in the lifestyle such as regular exercise and maintenance of adequate body weight can help prevent diabetes of type 2.

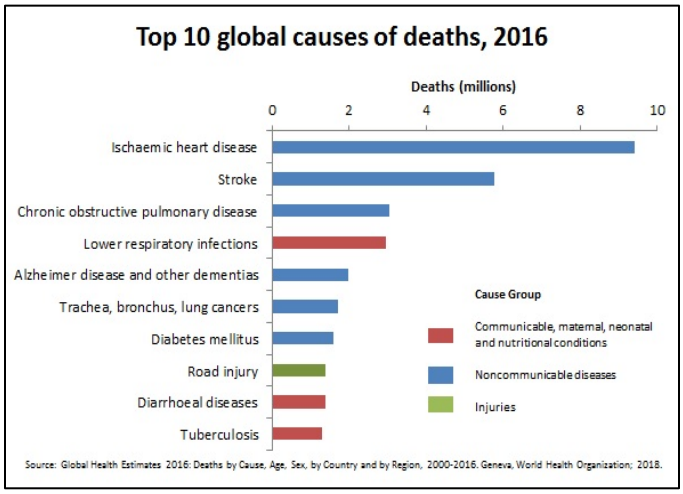

Figure 1: Primary Ten Causes of Death as Reported by WHO [1]

International Diabetes Federation has listed down following practices for preventing against diabetes:

1. It recommends that individuals must start a regime for losing some weight to overcome the effects of diabetes by enhancing insulin resistance and mitigating the prospects of hypertension. So, the people who are overweight are encouraged to sustain adequate body weight.
2. The consistency of physical exercise is integral for sustaining weight loss. It is because the indulgence in the physical activity overcomes arrhythmia, hypertension, and insulin sensitivity; improving the composition of the body; and developing psychological health.
3. Sustaining a healthy diet also overcomes the CVD related risk factors.
4. Smoking, depression, stress, and inadequate sleep can also be considered risky behaviors; therefore, it is preferable to avoid them.

B. Cardiovascular Diseases

Cardiovascular diseases comprise a number of disorders that are related to the heart and blood vessels for example;

Coronary heart disease which is caused by the clogging and narrowing or blockage of the blood vessels which supply the blood to heart muscles.

Cerebrovascular disease is caused by the issues in the arteries, which can affect the supply of blood to the brain. Example of the cerebrovascular disease is a stroke.

The peripheral arterial disease occurs due to plaque (calcium, fats, and other substances) that build up in the arteries supplying the blood to the head, limbs, and the other organs.

Rheumatic heart disease is caused because of the streptococcal bacteria, which attacks the tissues of the body, particularly of the brain and the heart.

Congenital heart disease is caused because of the anomalies of structure and the malformations at the time of birth.

Deep vein thrombosis and pulmonary embolism are caused due to the clotting of blood in the veins of the leg, which might be transferred to the organs like the lungs.

Myocardial infarction (MI) is the term which is used in the medicine for the NCDs in common, which also known as the heart attack. Cerebrovascular accident, which is also known as stroke, is also a kind of NCD and is a serious one. These illnesses or disease occur due to the defects and the faults of the heart and the arteries. The arteries are the vessels for the pumping of the pure blood from the heart into the body. Lack of exercise, bad eating habits, and fat accumulation in the body lead the fat cells to get deposited in the arteries' inner walls. Misuse of alcohol, the use of irregular tobacco, habits of eating, hypertension, and a host of circumstances and conditions lead to the CVA or MI.

Building up of fat inside the blood vessels and the arteries leading to the gradual vessel clogging. Without any treatment, medical care, or the changes in habits of eating or the lifestyles, it can lead to complete blocking of the blood flow. The unmanaged glucose levels in the blood, physical inactivity, and obesity are very common in the population nowadays. Formerly, people had a walking habit, they used to work in the farms, and the field were heavily involved in labor physically, which is rapidly reducing nowadays. Man, in search of comfort and the material gains, has

invented a lot of devices and machines, which has reduced the physical activity of humans. The emergence of the fast-food culture is also a danger to health and body, which most of us fail to understand.

If once diabetes, hypertension or the cholesterol imbalance is diagnosed, it is the high time to make sure that the person has the information regarding the upcoming dangers which might lead to the NCDs. These intermediate-risk factors defined by WHO must be highlighted by the primary health center and the clinics.

It is a general knowledge for the people who are having awareness that to stop or to reduce the dependency on the tobacco or the alcohol, to limit the oily and the greasy food that contains high fat and reducing sugar and the salt intake can help them in reducing the chances and the risks which are linked with the NCDs and the CVDs specifically. When a possible danger is detected, the patient should seek medical help immediately and make his lifestyles better. Further, people must use the proper medication for the control or restrict the damage that the factors can cause.

In most of the cases, there are no clear and visible indications for the MI and the stroke as well. It happens all of a sudden, and are not aware of it. Most of the MIs occur when people are sleeping. When the people feel the discomfort, and the pain in the chest or an extreme pain shoots up in the area of the right shoulder or jaws or the elbow, it can be considered as a warning that it can lead to developing of MI or CVA. The only option in this scenario is immediate medical attention.

The common symptoms which are linked with the CVAs are the insensitivity or the numbness in legs, arms, or face as well and it can be on one complete side of the body. There can be disorientation of speech, and even the difficulty in the vision as well. Severe dizziness or hallucinations or the headaches can happen, and in the intense cases, the patients got fainted too.

The third world is mostly affected by the NCDs; it is populated by middle and the low-income groups. The records of WHO speaks for themselves only. There is the accessibility to the medical care for the rich people while the people with the low or middle-income groups, if we look at the profiles of the country, have no or little access to the primary health care. In the countries across Southern America, Asia, and Africa, to approach the medical center is costly, which causes the late detection of NCD for the poor people.

According to the fact sheet of WHO [1], 26% of deaths in Bahrain are caused due to the CVDs. These statistics highlight the possibility of 13% deaths between the ages of 30 to 70 years and is caused by four NCDs. The physicians should record the factors of risks for the CVDs in order to reduce the strokes or the heart attacks by getting the right system for the storage of medical record and the analysis of the data.

C. Diabetes and cardiovascular disease: double jeopardy

Diabetes mainly contributes to the CVDs as proved by the clinical trials and the situation of the people who have suffered from CVDs. Due to the defects of crucial organs like kidneys and the liver, it becomes more difficult to pump the blood for the heart. The defects or the failure of kidney, liver, and the pancreas cause the threatening amount of toxins to sustain in the bloodstream.

The world of medicine has the challenge to handle this double-edged sword. This is the crucial time for the health centers and the governments to look at these two killers; CVDs and diabetes. To aid in reducing the deaths which are caused due to CVDs, data mining methods must be applied to predict the accurate occurrence or the reoccurrence of the CVDs and diabetes.

2.2. Evolution

Organizations nowadays produce a substantial amount of data specific to the institute. For improving the practicability concerning the use of data, researches have introduced algorithms which allow micro-focus on the data and position it as per the super-specific requirements. This advanced the efforts for the development and creation of the machine language algorithms which are useful in the analysis of the different analysis types and formation of decision without or little human supervision. Thus, the evolution of data mining is based on human needs, which assists in the identification of the relationship patterns and forecasting based on the presented layout of the program rules as well as stipulations.

The data mining is described by the researchers and practitioners using various terms. The concept of discovering knowledge from databases has been evolved from data mining. Earlier research of Fayyad et al.[4] has defined data mining as a procedure in which the data sets are implicitly and which reveal previously unidentified but significant information for effective decision-making. This whole procedure is termed as knowledge discovery in database (KDD).

This procedure can be applied in health care to predict the trends of many kinds of diseases and illnesses. Hence, instead of relying on the knowledge and experience, the data mining technique can be used by the doctors, more precisely for KDD to predict trends that would lead to better diagnoses.

KDD increases the efficiency and effectiveness of doctors by allowing them to treat a large number of patients at a given period. Moreover, such a system increases the opportunity for doctors of the same specialization across multiple firms, locations, as well as countries to e-share medical reports for devising best possible diagnoses in a time-effective manner.

The significance and usefulness of the data are evident from different perspectives. The logical alignment of the irrelevant data can be emphasized on the concealed or undiscovered correlations as well as patterns. This can provide valuable data which is critical for examining the individual as well as health being. The main notion is to briefly summarize the voluminous data and conclude its useful findings and information [5].

Data mining is regarded as a statistical interface, which is inclusive of other interference such as statistics, technology database, pattern recognition, data in machine-readable form as well as intelligent expert system [6].

Several definitions are set for data mining, which are raised according to the area of implication.

According to Krishnaiah et al. [7], the facility of data mining enables the use of data for identifying and using the data set trends. The primary findings of this database are to identify the

mechanical or automatic patterns, which require less input as well as efforts from the user.

Recently, the spectrum of data mining has enhanced, which is inclusive of artificial intelligence concepts which help in effective and fast-paced management and visualization of the data [8]. The other definition of data mining is provided by Han et al. [9], which states that it helps in the effective extraction of useful data.

Generally, the actual task of data mining is linked with the mechanical analysis of the voluminous amount of data, that is used to attain information which is not yet discovered. It assists in the identification of the data patterns, its categorization using the cluster analysis, odd records identification which require anomalies detection as well as its associated mining rule or dependencies.

Different statisticians' information system communities, as well as data analysts, use the data mining term. The procedure of KDD is recognized as complete, which requires the attainment of the data or discovery of new information. KDD core concept is of data mining; hence, it can be defined as an application which uses specific algorithms required for the analysis and extraction of the data patterns. It is also recognized as the KDD focal hub. It is inclusive of the intellectual approaches required for the data patterns extraction. From a healthcare perspective, the traditional methods are considered to integrate into statistical procedures for the process control comprising of numerous functions pertaining to the fundamental probability distribution which can be executed successfully for controlling the infection rate in hospitals [10].

Previously, in the 1960s, data mining was perceived to be an looked down by mathematicians as well as to statisticians alike. It was regarded as an unhealthy practice which improved its recognition using the term data fishing and data dredging, based on the hypothetical analysis of the data.

The terms database mining emerged in 1980 by HNC, a San Diego–based company, for describing the Database Mining Workstation [11]. With increasing years such as 1990, the term data mining was appeared to have been accepted as a legitimate phrase for describing the harvesting methods employed at the available data for forecasting the happenings in the future. Actually, different words were used for data mining, such as information harvesting, data archeology, knowledge extraction, information discovery, and so on [12].

The term "knowledge discovery in databases or KDD" was first initiated by Gregory Piatetsky-Shapiro and Parker [13]. Though, the relevance of data mining attained relevance as well as acceptance from the communities concerning artificial intelligence and machine learning. Furthermore, this term was also recognized within the business domain for the fourth estate communities. At present, both the terms, such as "data mining" and "knowledge discovery" are used interchangeably. Later in 2011, data mining was defined as data science.

2.3. Knowledge Discovery in Databases (KDD) Process

Knowledge discovery in databases (KDD) serves as a useful process that is used to extract important information from the expanded data. The information is gathered and filtered to extract only the required information. Information that has been collected is employed in the data set, which is further interpreted to attain a useful understanding regarding the given outcomes.

According to Maimon and Rokach [14], the target goals serve as important factors to successfully employ the KDD process. The process begins through fir, considering over the objectives, however, the final product is achieved in the form of newly developed information. This marks an end to the loop. Next involves data mining segments, where final output is achieved in the form of changes involved in the application domain. The results of the process are evaluated by employing fresh data sources while putting an end to the given loop. The finalizing of the process restarts the KDD process. Han et al. [9] elaborated the overall process through the given figure below:

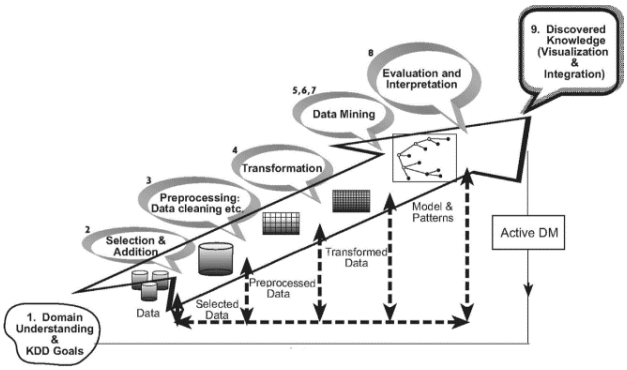

Figure 2. KDD process (Maimon & Rokach 2011)

Step 1. Develop a clear understanding of the application domains

The understanding related to the requirements of the healthcare professionals, and end-users, is of foremost value. This helps in providing a clear-cut vision to data miner in meeting the expectations while illustrating important knowledge regarding things that need explanation. It is further important to provide important knowledge regarding things that may help in achieving the desired objective. However, these requirements could be modified after the first round as the end-user might want to add additional functionalities. After identifying important knowledge, it is important for people contributing to the KDD process to function in accordance with the below-given steps. The steps are important for indicating preprocessing measures in the KDD process.

Step 2. Select data sets.

Selection of data sets is important to elaborate on the idea of the target goal. It further helps in providing important details regarding the type and the amount of data that is needed to achieve the target goal. The stage is of greater importance, since any wrong selection of data may lead to several complexities in preparing data. In such cases, the process may result in providing unimportant inferences that may weaken the overall effectiveness of the process.

Step 3. Perform preprocessing and cleansing.

Before processing the selected set of data, it must be filtered and cleaned. The idea is to improve and augment the reliability of the chosen set of data. The factor is important in providing maximum reliability to the selected data set. The cleansing

process includes removing noise or barriers that may impede processing; hence, eradicating the given barriers are crucial here. This might serve as a time-consuming process; still, it is effective in indicating maximum surety in terms of validity and reliability of data. In certain cases, insufficient data sets are achieved. However, situations, where ineffective data set, is intervened with accurate predictions, conscious efforts are required to attain expected outcomes. Consider an example; where irrelevant data of patient may act as a barrier in the overall process. Therefore, it is important to remove any such data at this stage

Step 4. Complete data transformation.

The next step is to make the data project-specific. This step ensures the provision of accurate data in a format that produces the required outcomes or results that will be utilized by the doctors to provide accurate predictions. The step is of significant value to provide valuable outcomes in any KDD project. However, important provisions in this regard may help in restoring the KDD process. Two significant methods, including; attribute transformation and dimension reduction are suggested by authors. KDD process serves as a useful tool in providing useful transformations. This helps in indicating maximum validity and efficacy to the formulated results.

Step 5. Choose the adequate data mining task.

Following the above procedure, the next task is to select the data mining type as per the nature of the project. This selection is based on the expected outcomes. Moreover, the selection between regression, and classifications or clustering is based on the desired outcome. Normally, the data mining outcome can be either forecasted, where data mining is done under controls of supervision, or description, where data mining occurs under visualization.

Step 6. Choosing the right algorithm for data mining.

This stage is reflected as the one which discusses the tactics to be used for obtaining the strategic objectives. Is it sufficient to use neural networks? Or is it better to use decisions? In fact, the selection is based on the searching pattern type which is found consistent to the given project and the desired end result. Does it relate to the results precision or decipherability or understandability that forms the project objective? The preference is more towards the neural networks when the precision of the results is required, while the appropriateness of the decision tree is found when gaining an understanding of the patterns and trends is required.

Step 7. Employ the algorithm of data mining.

In this step, the algorithm of data mining is implemented. It could be applied several times for obtaining the best result. For instance, the algorithm could be iterated using different controlling parameters, i.e., the low number of occurrences in a certain leaf or probably executed until the desired accuracy is obtained.

Step 8. Evaluate the mined data.

The mined data evaluation is the core of this KDD stage. This is primarily related to the reasonable interpretation and findings with respect to the discussed and defined goals of the project. This evaluation may promote the need to either add or remove a certain feature from the transformational stage of the data. This stage helps in achieving the usefulness of the data and its comprehension by the end user. Upon finalization, the found information is documented. When the found knowledge is being finalized by the KDD team, the whole data mining procedure is documented and assessed against the predetermined outcomes.

Step 9. Use of the discovered knowledge.

At this stage, the developed KDD process is evaluated for its effectiveness and efficiency by the end user, where refinement occurs in case the fine tuning of the data is required. Also, the created knowledge is being assessed for pilot-testing by practitioners and doctors for ascertaining the production of the desired outcomes. When a new product is being tested in a real environment, some conditions might variate from that at the laboratory. Therefore, these must comprise of the built-in ability to change, adapt, modify the derived knowledge in order to satisfy the end user.

2.4. Data Mining Techniques

Currently, an increased inclination of the researchers is concentrated on data mining. Generally, there are two types of data mining; namely, predictive model and the descriptive model. The two models are as follows;

A. Predictive Model

Prediction, as the name indicates constitutes of the correct envision of the future trend be logical computation of the data. The predictive model uses the previously available information for predicting future outcomes. This model is employed by various firms such as organizations who attempt to data mine the worth of an individual.

The predictive model data mining applies several techniques encompassing regression, classification, time series analysis, and prediction. This model is used for identifying the model that effectively matches the identified ideas or data sets. It is also helpful for class prediction of the objects when there is no availability of the class objects. The achieved model is primarily focused on the assessment of the identification classes set. To assess the numerical values and forecast, the statistical model of regression is used.

B. Descriptive model

This data mining model is employed to identify the data patterns to understand the relationship between the data attributes. The fundamental feature of the data is represented and summarized using the descriptive model. For instance, the customer database and identification of different sets can be useful to the marketers. The identified method can be employed for devising effective marketing programs for targeting audience.

The descriptive model applies several techniques such as clustering, summarization, association rules, and sequence discovery. In the clustering method, the analysis of the data object occurs without reference to the detected class label. Whereas, in the summarization, different properties and specialties of data values are to be considered as noise or outliers.

For the association rules, the same recreated rules are used for assessing the patterns and association among the different obtained characteristics. These are used for analyzing the data patterns for determining or forecasting their classification. Other systematic order identification is through sequence discovery which occurs for identifying the events in a timely manner rules and regulations. Figure 3 demonstrates the classifications of data mining.

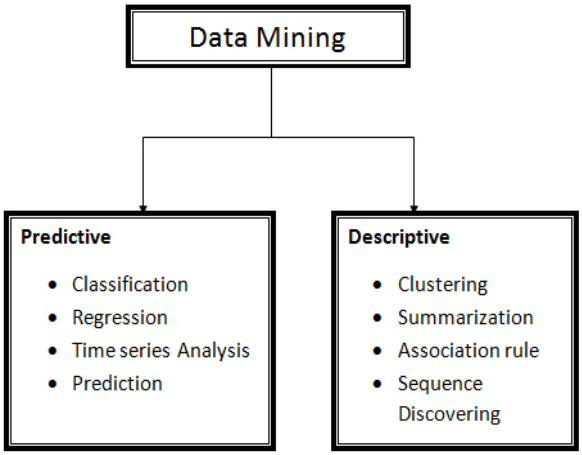

Figure 3. Tasks of Data mining

Among all the models presented in figure 3, the focus of the present study is on one named prediction-mining method.

2.5. Medical Applications Data Mining, Forecasting

Data mining has been widely used in medical applications to solve varies aspects. In this section we highlight some of them.

A. Health care informatics

Medical informatics is termed as dynamic because of the increasingly developing and shifting nature of both medical science and technology. According to Hersh and Hoyt [15], the discipline of health care informatics is related to the resources, materials, tools, and formal ways that are utilized for optimizing the storage, its management and retrieval of the needed biomedical information for effective decision-making, and problem-solving. Likewise, Athina and Konstantinos [16] highlighted that health care informatics employ modern communication, computer applications, as well as IT and computer system in medicine fields in the form of care provided, the delivered education, and research undertaken. Bronzino [17] stated that health care informatics uses different type of tool for using diverse which assists in utilizing and sharing information for improving the delivery of health care. Another term used is medical informatics whereas, it is also sometime referred by practitioners as clinical informatics or bioinformatics. Though, bioinformatics regard it as biological information analysis of the databases that are based on computer and statistical analysis of biological information in a speedy and improved manner. Clinical informatics concerns with maintaining data structure, data organization, and data search to make decisions using relevant data to conduct significant research in the medical discipline.

B. Data mining in medical discipline

Over the years, there is an increase in the computation analysis for deriving computer-based analysis and interference for improving the medical outcomes. The use of software and highly complex computation tools have increased. Previously, healthcare professionals majorly relied on their knowledge, skills, intuition and experience. However, at present, various channels have been developed across firms, regions, as well as states using both formal and informal sharing means for clinical experience which can be employed by the rest of the world. Data mining has provided great benefit to the medical field such as to forecast NCD and major other diseases.

This proliferation of the data mining has increased its efficiency in the medical discipline, where the use of data mining has become a norm where healthcare firms and facilities are being encouraged for meeting the need to predict the trends in disease and their occurrence. The significance of data mining, particularly for information management, is well established. Acharya and Yu [18] the developers of various computer-aided algorithms, have made the health facility more effective and have tremendously improved health care outcomes. Such as, it has aided in informatics, monitoring systems, as well as epidemiology. The difference between the pathological and normal data has facilitated improvement in the diagnosis and decision making.

Recent data mining techniques, as well as the essential statistical tools, can be used to assist doctors in diagnosing diabetes and CVDs. With the use of the statistical analysis, various CVDs encompassing stroke (cerebrovascular disease), cardiac arrests (coronary heart disease), congenital heart diseases, hypertension, peripheral artery disorder, arrhythmia, and heart failure with diabetes can be predicted. An overview of such systems is listed below.

Khaing [19] proposed an efficient approach for assessing and predicting the risk of heart disease. The primary stage is the execution of the k-means clustering algorithm with K=2 for extracting relevant data through clustering the heart disease database. By using k-parameter the number of fragments is mastered. Consequently, the extracted data of heart disease mine the frequent patterns with the use of maximal frequent itemset algorithm (MAFIA). Afterward, the execution of ID3 training algorithm occurs to produce the heart attack level following the decision tree. Although the accuracy of the findings obtained was 74% using k-mean–based MAFIA, there is a need to further increase this accuracy.

Many real-world medical data sets suffer from overlapping information. Overlapping k-means (OKM) is extended from the conventionally used k-means algorithm, and it is recognized as one of the most real-world medical data sets that inherent overlapping information. This clustering method enables one sample to be related to one or more than one cluster. Though, the issue of sensitivity in OKM is prevalent to the initial cluster centroids. Khanmohammadi et al. [20] proposed a hybrid method which assimilates the k-harmonic means and overlapping k-means algorithms (KHM-OKM). In this approach, the initialization of the cluster centers of OKM are obtained from the output of KHM. The performance of KHM-OKM is evaluated in

terms of completeness, homogeneity, and cluster size-quantity tradeoff, and it is found that it outperforms the OKM algorithm.

Feature selection is one of the integral steps in data mining. When selected properly, it improves prediction accuracy. Orthogonal Feature Extraction (OFE) is proposed by Jiang et al. [21], which uses the feature ranking techniques. The technique proposed is applied to improve cancer prediction accuracy. To make sure that the attributes of the selected features are accurate, they developed an algorithm that selects the linearly independent vectors iteratively that belong to top-ranked attributes. The results are compared with the analysis of principal component, neighborhood component, and linear discriminant. These three methods are outperformed by OFE in terms of computational complexity and performance.

Another heart disease prediction system is developed by Suvarna et al. [22]. This system combines optimization techniques and data mining. The optimization technique used is particle swarm optimization, which is modified by applying a constriction factor. In this inherently distributed algorithm, the solution is obtained through the interaction among several simple individuals called particles. The authors used *de facto* standard data sets for the reliability ranking of heart disease prediction. The three techniques used for comparing the result are: ID3, multilayer perceptron with backpropagation training and classification, and regression trees. The proposed approach outperforms these three techniques, producing accuracy of classification equal to 53.1%. But the accuracy is much lower than what is expected from actual practitioners.

Rairikar et al. [23] applied the backpropagation technique in genetic algorithm to develop a system that predicts. This prediction system uses 13 attributes obtained from cardiovascular disease information. The results are compared in terms of time complexity with two well-known classification of data mining techniques, which are KNN and Naive Bayes. The results showed that KNN is much better in its performance. However, this method is lagging measuring the accuracy of heart disease prediction.

Tomczak and Zieba [24] applied classification data mining in machine learning to solve two issues that appear when applying machine learning to medical diagnosis. One issue deal with the implementation of interpretable models such as decision tree and classification rules. The other issue deals with the imbalance between classes with high number of examples such as healthy patients and a class with low number of examples such as ill patients. The proposed model is a probabilistic combination of *soft rules*. These rules are constructed by introducing a new random variable called *conjunctive feature*. In addition, a new estimator is introduced to incorporate the knowledge about imbalanced data. This approach is tested using oncology data set. The results show that soft rules can perform well on data sets with small number of examples. In addition, the outcome is comparable with expert oncologists. Meanwhile, this work needs to be examined against large data sets.

Zhu and Fang [25] noticed that the current existing classification trees might not be able to properly provide classification for the provided predictor variables set, which may be categorized using a high error rate. To solve this, they proposed an algorithm that combines the logistic regression model and the trichotomous classification tree. This tree is used to split and establish the tree recursively until it meets the stopping rule of the tree splitting. The algorithm is tested on two real data sets: Pima Indian data set and Wisconsin Breast Cancer data set. The findings showed that the proposed algorithm is more accurate in predicting some diseases than the classification and regression tree. However, this technique suffers several limitations, including using binary response variable, the cost of variables used in classifications ignores the actual cost and thirdly, the variance-covariance between 2 categories use limited simulated normal distributions.

Several algorithms and methods such as regression, clustering, classification, neural networks, artificial intelligence, genetic algorithm, association rules, nearest neighbor, and decision tree have been executed by researchers to assist healthcare practitioners in the effective diagnosis of heart diseases or diabetes to prevent further diseases.

The above-mentioned research studies provide evidence for the effectiveness of the data mining concerning the field of NCDs prediction and correction. The objective of this research is to devise a practical model which can be executed by the healthcare practitioners in the main hospital of Bahrain, or where individuals belonging to particular demographics which adds to its generalizability across the worldwide health care centers.

What features the developed PNCDA is that it allows realistic and timely mean to forecast the general NCD forms, particularly CVDs and diabetes. Rather than using pre-defined datasets, this approach uses real data obtained form BDFH. Further, the developed PNCDA has been tested by actual practitioners from the mentioned hospital and the results met their expectation obtained from the conducted questioner as will be explained later.

3. Research Methodology

As the major outcome of this research is the prediction software system that aids the doctors and practitioners of the BDFH to effectively predict the NCDs of their patients, the first stage of this project is to identify the most effective factors and classify them. These factors must provide good input data (parameter) using an adequate model for data mining. These factors can be identified by the users of the proposed system. Three main factors are included in this research, such as, prediction methods for data mining, patient database, and software application implementation, which are used to characterize and devise a model to predict the cardiac arrest diagnosis as well as diabetes risk among the patients that are listed in the obtained BDFH data set. This research will use both forms of data (primary and secondary). It will integrate in data mining, its significance in healthcare, and medical field application for developing a software system that will be assessed in real situations for evaluating its performance.

3.1 Data Types

In this research, two types of data are used; secondary data and primary data.

A. Secondary data

Secondary data refers to the data that has already been assessed, used and collected by certain firms. In this research, the record of 23000 patients is obtained from BDFH, which are used for designing the required NCD prediction application.

B. Primary data

The data that is collected for the first time as per the defined objectives of the research are termed as primary data. The primary data for the study is collected using a questionnaire which is distributed across 30 specialized healthcare professionals in the hospital. Since all the questionnaire were completed and received; therefore, the response rate is termed as 100 percent. The objective of the questionnaire is to gather the necessary requirement, NCD diagnosis for medical characteristics, which include CVD and diabetes, which are the commonly found forms of NCD.

3.2 Data Collection Procedure

A survey was conducted using the questionnaire as a primary form of data collection. While, for the secondary form of data collection, the health center record was used following the development of the software application.

A. Primary data collection

The questionnaire-based survey was conducted among the doctors to clearly understand the expectations they hold as well as ideas about the current situation concerning NCDs from one side and to examine the awareness and the level of utilization of having a new software application that will help them in predicting NCDs from the other side. To evaluate the current situation concerning NCDs prediction, the BDFH doctors who are either endocrinologists or cardiologists were requested to fill in a questionnaire survey. It was done to gain an understanding pertaining to their perceptions and opinions about the expected software application.

B. Study Population and Sampling

In BDFH, 13 cardiologists and 17 endocrinologists are present. The sample of the study is the entire population given the relative ease to work around. Therefore, the sample would constitute of all the related doctors. The structured questionnaires were administered by the researcher to assess their perception and opinion.

4. Survey Data Analysis and Findings

This section provides information concerning the questionnaire model, which was used in the survey. The survey aimed to establish the importance of predicting model concerning NCD trends among the end-user, and doctors. The direct interviews were held with the doctors to explain to them the significance of developing the software.

The conducted questionnaire was aimed to examine the present scenario concerning the use of NCDs forecasting tools in the BDFH. The sample is formed by the total endocrinologists and cardiologists' populations who are presently on the rolls of the BDFH. As the interviews are conducted on a one-to-one basis; therefore, no interview was missed. The following results were achieved by the questionnaire;

The answers to the first question show that 70% of patients treated by these 30 doctors suffer CVDs and diabetes. This provides evidence that NCDs, more particularly, diabetes and cardiovascular disease are majorly found. The generic and common disease such as influenza cold, allergies, and sprain make a total of about 30 percent. The BDFH does not provide treatment for critical diseases such as cancer.

The second question examines the primary NCDs causes, where the doctors mentioned unhealthy eating habits, smoking, no exercise, and consumption of high-fat food as the major NCDs reasons.

Following third and fourth questions in the questionnaire are related to each other and are also analyzed together. Though 80 percent of the doctors are aware of the prevalence of some form of NCD prediction mechanism across the globe, they firmly say (i.e., 100%) that BDFH lacks any such system, mechanism or facility.

In the fifth and sixth questions, 24 among the 30 doctors (i.e., 80%) showed agreement that presence of computer-based application would assist in predicting such NCDs, which aids the BDFH in notifying patients on a continuous basis. In addition, 90 percent of them welcomed the idea of offering an application that can "correctly predict" the NCDs occurrence, which is essential.

5. Proposed Application System

The software system developed comprises of two main components; the prediction engine and the software application. The system functions as an intermediator (practitioner) between the prediction system and the user. The explanation of each component is presented in which first describes the data that is applied in the proposed prediction system.

5.1 Data Mining Engine

The application purpose is to assess the data of the patients to predict if the patient is at an NCD risk or not. The following tools are used for application programming;

1. VS.Net: Tool for writing the application.
2. VB.Net: Tool for coding the application.
3. Oracle DB: The database which is used for data storage and manipulation.
4. Toad Oracle: Tool for gathering the code and retrieving the data from the database.

Among various techniques for data mining, the research adopted the mining class comparison. This is used to mine a description which compares or distinguishes one class from another related class. It is used for meeting the project purpose based on stages which are followed for the process of mining comparison [9]. The stages are as follows;

1. *Data collection*. It comprises a set of relevant and useful data that is collected by the use of query processing. The segregation of the data occurs in the target class along with contracted classes set.

2. *Dimension relevance analysis*. This is executed only where there are several dimensions and only a few relevant dimensions are to be selected for analysis.
3. *Synchronous generalization*. This is applicable on the target class concerning the degree of control exercised by the user. The contrasting classes concept is to generalize the same level as those in the main target relation, to form the prime contrasting classes' relation.
4. *Presentation of the derived comparison*. The achieved class comparison can be represented in the form of tables, graph, and rules.

5.2 Patient Data Set

The researches, which tackle data mining for medical application use the available data sets such as heart-Statlog Medical data set [26], liver disorder, Indian liver patients, heart disease (Statlog), heart disease (original), hepatitis Parkinson's, Parkinson's, breast cancer Wisconsin (diagnostic), dermatology, and lung cancer [20].

This work is featured using the actual data set obtained from the BDFH, which contains the details and vitals of 23,000 patients.

Using the developed data set, that was extracted with the use of the discussed algorithm of data mining, the recognized pattern assists to predict the risk of getting heart disease and diabetes.

The data of all the patients were processed through the elimination of the repetitive records and completion of the missing details. The dummy values were used for filling the personal details (name and ID number, etc.). Moreover, the recurring patterns are mined with the use of proposed process of data mining. The attributes of the patients gathered from the database are; sex, age, chest pain (CP), FBS (fasting blood sugar), test BPS, rest ECG (electronic cardiographic), smoking, diet, as well as alcohol. Following it, these are used for classifying the patients, which are modified from the study conducted by Khaing [19] as some of them are unavailable in the data set, we have. Afterward, they are adjusted as per the survey conducted with the actual practitioners in the BDFH.

5.3 Application Process Description

The overall exercise was conducted with doctors who will be the main user of the developed software. This is to ascertain that all the unnecessary data is removed so that the prediction of NCDs is barrier-free. The data of the patients is derived from the three tables by executing the second step of KDD. Figure 4 presents the diagram for the entity relationship (ER). The information record of the patients is presented in the first table, second patients' vitals, such as, diet, blood pressure, chest pain type, smoking, and heart rate. The blood test collected from the lab is collected in table 3, where cholesterol and fasting blood sugar are its attributes.

Reflecting that the target class are the lab results and vitals, the "if condition" is used for the constructing class, along with attributes such as sex, age, chest pain (CP), FBS (fasting blood sugar), test BPS, rest ECG (electronic cardio graphic), smoking, diet, as well as alcohol (Table 1). The data mining query language (DMQL) can be used for the data mining task, as follows;

1. Used Patient_DB
2. Mine comparison as "Patient_NCD_Risk_Level."
3. In relevant to sex, age, CP, chol, FBS, test BPS, rest ECG, smoking, diet, alcohol
4. For "Vitals_View" and "Lab_Results"
5. Versus "if_condition_rule"
6. Evaluate sum
7. Show as "risk level."

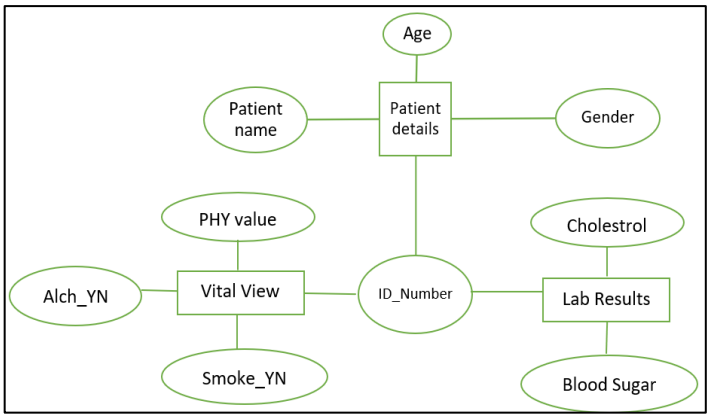

Figure 4. ER diagram of the proposed application

Initially, the change in the query occurs in two forms such as in the two interrelated queries where the two sets of relevant data tasks are accumulating; such as, one is obtained from Vital View table target class and Lab Results table, whereas the other is derived from the contrasting class, i.e., "if condition rule" which is written in the code classes.

Secondly, the two tables, i.e., Vitals View and Lab Results, are analyzed for their dimension relevancy. Furthermore, the weakly relevant dimension are removed, i.e., the removal of the patient information from the found test classes.

Thirdly, the synchronous generalization is applied from the target class to the controlling class level in order to produce the prime relation for the target class. With the use of "if condition" rule, the categorization of the attributes in the form of group is held. Initially, the ages are evaluated. In case, the age is less than 40, it is grouped as young age, whereas, if it lied between 40 to 60, it is grouped as medium age while for 60 or greater than 60, it is regarded as older age. Following it, smokers or alcohol drinkers are categorized. In case the patient is a smoker, he is characterized as group 1, and in group 2 if the situation is vice versa. Similarly, if the patient is an alcohol drinker then he is characterized in group 1, and in group 2 if he does not.

If the blood pressure (BP) of the patient is less than 80, then he is grouped into group 0, and group 1 if it is equal to or more than 80 and group 2 when the blood pressure is higher than 90. Likewise, for the classification of heart rate, if the heart rate is below or equal to 100, it is categorized in group 0 while if it is more than 100 and less then 150, it is categorized as 1. Similarly, in case the heart rate is greater or equal to 150, the patients are categorized in group 2.

Table 1. Attributes and values used in the proposed application

No.	Attributes	Description	Cut-off Value	Type
1	Age	Age of the	Age <=40 Age <=60 and >40	Young age Middle age Old age

		patients in years	Age >60	
2	Gender	Gender	1 0	Male Female
3	CP	Type of Chest Pain	Value 1 Value 2 Value 3 Value 4	Stable Angina Unstable Angina Nonangina Pain Asymptomatic
4	Test BPS	Resting blood pressure (in mmHg)	BP <80 BP <90 BP >90	Normal Normal to high High
5	Chol	Serum Cholesterol (mmg/dl)	Chol <5.2 Chol <5.2 and >6.2 Chol >=6.2	Normal High Severe
6	FBS	Fasting blood sugar	1 0	True False
7	Rest ECG	Resting electro cardiographic results	Val=0 Val=1 Val-2	Normal Abnormal Probable
8	Diet	On a healthy diet	0 1	True False
9	Smoking	Smoker patient	0 1	True False
10	Alcohol	Alcohol drinker	0 1	True False

```
If txtAge.Text.Trim() <= "40" Then
    strAge = "0"
    'MessageBox.Show("Young Age")
ElseIf txtAge.Text.Trim()> "40" And txtAge.Text.Trim() <= "60" Then
    strAge = "1"
    'MessageBox.Show("Middle Age")
ElseIf txtAge.Text.Trim() > "60" Then
    'MessageBox.Show("Old Age")
     strAge = "2"
End If
```

Figure 5. Comparison of condition for the age

Lastly, Table 1 presents a comparison of the resulting classes in the rules form. Such as, in case the classes are equal to 0 when there is no risk for patients. While patients are at high risk when the classes are equal to 2. Likewise, the patient is at lower risk, when the classes are equal to one, where the other classes combination occurs based on the recommendation of the actual practitioners.

Following the preprocessing, the previously mentioned attributes in Table 1 are utilized for the code application for using the IF condition. The classification of these values done in the form of cut-off value, following its comparison.

```
If Trim("" & sqlds.Tables(0).Rows(0).Item("SMOKE_YN")) = "Y" Then
       cmbSmoking.SelectedIndex = 1
ElseIf Trim("" & sqlds.Tables(0).Rows(0).Item("SMOKE_YN")) = "N" Then
       cmbSmoking.SelectedIndex = 2
End If

If Trim("" & sqlds.Tables(0).Rows(0).Item("ALCO_YN")) = "Y" Then
       cmbAlco.SelectedIndex = 1
ElseIf Trim("" & sqlds.Tables(0).Rows(0).Item("ALCO_YN")) = "N" Then
       cmbAlco.SelectedIndex = 2
End If
```

Figure 6. Grouping smoke and alcohol

The process of grouping the attributes are described by explaining the Figures 6–10 as follows:

Figure 6 shows the comparison if patients smoke or drink alcohol. In case the patient is a smoker, he is characterized as group 1, and in group 2 if the situation is vice versa. The same situation is followed if the patients is an alcohol drinker than he is characterized in group 1, and in group 2 if he does not.

Figure 7 presents the BP, for which if the patient BP is less than 80, then he is grouped into group 0, and group 1 if it is equal to or more than 80 and group 2 when the blood pressure is higher than 90.

```
If txtBP.Text.Trim().Substring(4, 2) < "80" Then
       strBp = "0"

ElseIf txtBP.Text.Trim().Substring(4, 2)>= "80"
      And txtBP.Text.Trim().Substring(4, 2) <= "90" Then
       strBp = "1"

ElseIf txtBP.Text.Trim().Substring(4, 2) > "90" Then
       strBp = "2"
End If
```

Figure 7. Grouping blood pressure (BP)

Figure 8 demonstrates the grouping of heart rate. If the heart rate is below or equal to 100, it is categorized in group 0 while if it is more than 100 or less then 150, it is categorized as 1. Similarly, in case the heart rate is greater or equal to 150, the patients are categorized in group 2.

Figure 9 displays the patients grouping as per his cholesterol level. The patient is grouped in 0, when the level of cholesterol is below 5.2, and in group 1 if the value of cholesterol is more or equal to 5.2. Similarly, these are grouped 2, when it is more than or equal to 6.2.

Figure 10 provides a list of conditions for chest pain. As per the program, if the grouping of the chest pain is done as 1, the patient experience chest pain, and 2 in case a risk of cardiac arrest prevails. It is grouped as 3 if a patient is experiencing coronary artery disease. Whereas for being grouped as 4, the patient is at high risk of chest pain.

Lastly, the class comparison results are presented in rules forms (Table 2) and process flow of the system is depicted in Figure 11.

5.4 Testing Results of the Application and its Predictive Performance

As explained above, the resulting conditions provide a comparison of the prime target classes and the executed "if condition rule" (Table 2), where risk results are the outcome of applying the aforementioned rules.

```
If txtHeartRate.Text <= "100" Then
       strHR = "0"

ElseIf txtHeartRate.Text > "100" And txtHeartRate.Text < "150" Then
       strHR = "1"

ElseIf txtHeartRate.Text >= "150" Then
       strHR = "2"

End If
```

Figure 8. Grouping heart rate

```
If txtCholesterol.Text < "5.2" Then
       strTotCh = "0"

ElseIf txtCholesterol.Text >= "5.2" And txtCholesterol.Text < "6.2" Then
       strTotCh = "1"

ElseIf txtCholesterol.Text >= "6.2" Then
       strTotCh = "2"

End If
```

Figure 9. Grouping cholesterol

```
If cmbChestPain.SelectedIndex > 0 Then

   If cmbChestPain.SelectedIndex = 1 Then
       strChPain = "1" 'Predictable Chest Pain

   ElseIf cmbChestPain.SelectedIndex = 2 Then
       strChPain = "2" 'Chest Pain Signal to Heart Attack

   ElseIf cmbChestPain.SelectedIndex = 3 Then
       strChPain = "3" 'Have Coronary Artery Disease

   ElseIf cmbChestPain.SelectedIndex = 4 Then
       strChPain = "4" 'Predictable Chest Pain

   End If

End If
```

Figure 10. Grouping chest pain

The software application is implemented using VB, and the samples of the screenshots are depicted in Figures 12 to 15. These screenshots serve as evidence for the program utility concerning the NCDs prediction for the tested patients. These samples of NCD predictions are shown for different risk levels: no risk, low risk, medium risk, and high risk.

5.5 Findings

The results are examined on the basis of the response gathered through a questionnaire survey, which was held among the doctors and the results achieved from the use of the developed application.

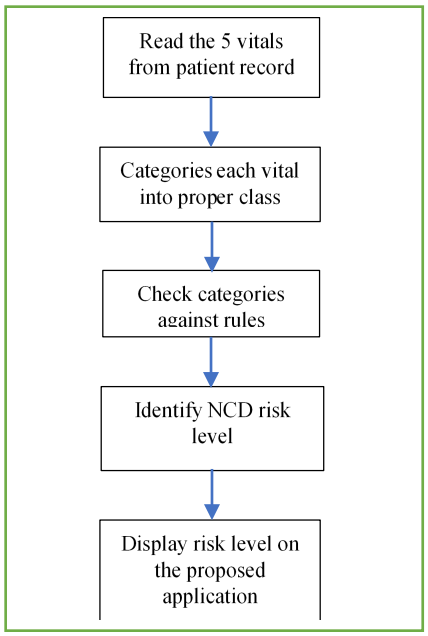

Figure 11. Flow diagram of the proposed application

Table 2. Classes and Risk Results Comparison

BP	Heart Rate	Cholesterol	Chest Pain	Age	Risk Result
0	0	0	0	0	No risk
0	1	0	1	0	No risk
0	2	0	1	0	No risk
1	1	1	1	1	Low risk
1	2	0	1	0	No risk
1	2	0	1	1	No risk
1	2	0	1	2	Low risk
1	2	0	2	2	Medium risk
1	2	1	1	1	Low risk
1	2	1	2	1	Medium risk
2	2	1	1	1	Low risk
2	2	1	1	2	Medium risk
2	2	1	2 or 3	2	High risk
2	2	2	1	1	Medium risk
2	2	2	2 or 3	2	High risk

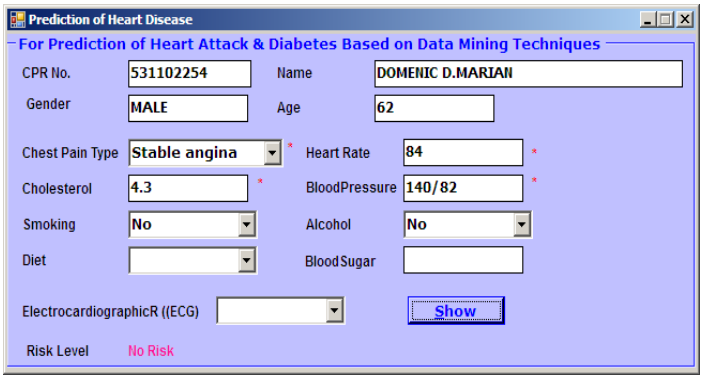

Figure 12. Sample of NCD prediction level: no risk

A. Survey Based Questionnaire Inferences

The questionnaire survey provides evidence that at present, there are no tools or the mechanism available in the BDFH, which is having almost 23,000 registered patients, for NCD forecasting

and prediction. The patient's record provides a massive volume data, yet there is no examination or the analysis of such essential data for the purpose of forecasting. The survey highlighted that most of the doctors are aware regarding the tools which are being used somewhere else and they will like to have applications that can help them better in the prediction of a patient's possibility for the occurrence or the recurrence of NCDs.

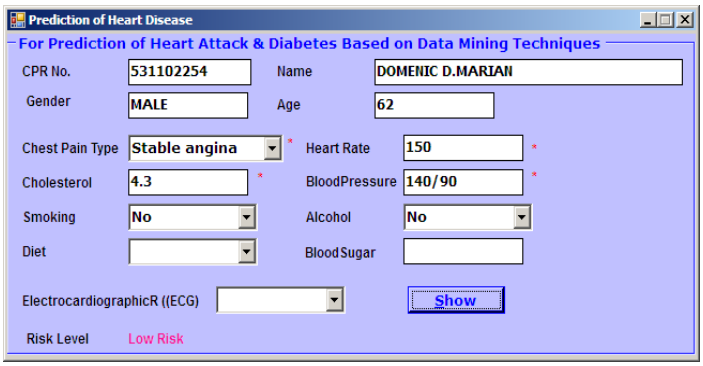

Figure 13. NCD prediction level (sample): low risk

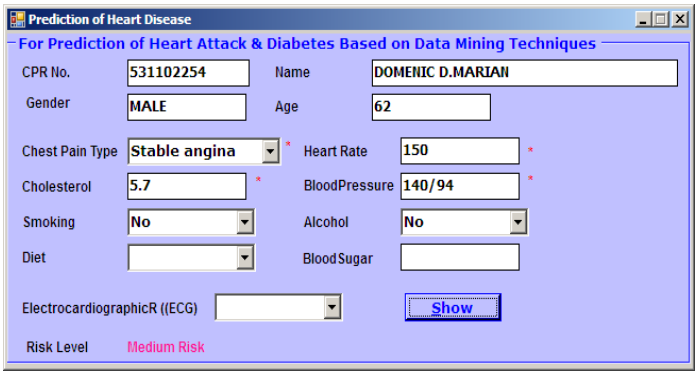

Figure 14. NCD prediction level (sample): medium risk

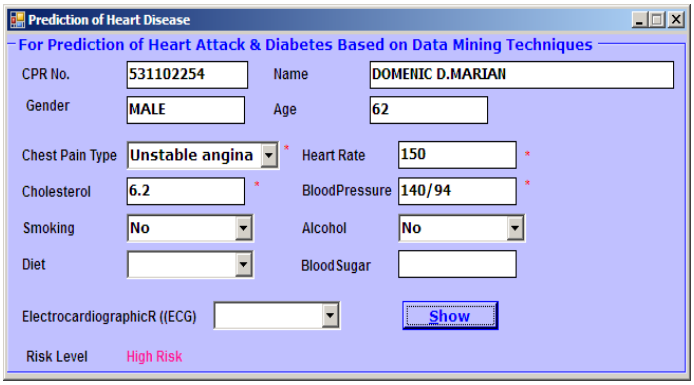

Figure 15. NCD prediction level (sample): high risk

B. Analysis of the developed software Inferences

The results obtained were discussed with the doctors and are considered as the levels of risks. The doctors were highly contented with the results as they accurately matched their expectations regarding the levels of risk. All kinds of risks are categorized appropriately according to the formerly mentioned categories. Additionally, they indicated high interests in the implementation of such applications live in their clinics. The application of the software has a proof for the accuracy and the efficacy of the suggested technique of the data mining for the forecasting of the NCDs for the patients of BDFH. However, the NCDs can lead to the possible mortality among the patients, the doctors who had a trial of the software feel excitement for its application as it can help them in the detection. As a matter of fact, they want to use it as soon as possible because they highly noticed that it supports quickly and gives better forecasting along with the briefing of the patient's record. On the other hand, the statistical analysis is not applicable to this study as the results are evaluated manually by the consulted practitioners.

Using the application, more savings in medical expenditure can occur avoiding loss of the duty timings and maximizing the utilization of the crucial medical facilities. This application will give the one-stop-shop to all the patients to get the accurate and the calculated information regarding their health. This application is considered to be an asset for the doctors so that they make sure that their detection or inferences are professional as well as correct. Further, such information can be utilized globally, for the patients having the health problems and have to travel abroad, the medical history and the forecasting for the NCD can be made online available or can be shared via emails.

6. Conclusions and Future Work

An application which uses the data mining algorithm for the class comparison has been invented to forecast the level of risk of occurrence or recurrence of NCDs such as diabetes and the heart diseases. Additionally, the outcomes of the application highlighted that the forecasting system could forecast NCDs efficiently, instantly, and effectively. This application helps the doctors to make the decisions regarding the health risks of a patient. It also creates the results, which make it closer to the situations of real life. Data mining, therefore, is more supportive for the health sector and is essential for exploring the knowledge to be used in the health care sector.

This research confirms that the health centers should have a software application or the system which can forecast the NCDs. To have raw data in a large volume is a must for the proper categorization rules which lead to the proper forecasting of NCDs. The forecasting is helpful for not only the physicians but for the patients too for their constant health check-ups. The application developed must be trialed on a constant basis, and the coding must be accurate in order to adopt the application across the various health centers and the clinics. Further, in the future, it can also be considered for the development of the mobile application for the patients where they can input their vitals and get the results instantly.

The developed application and the software can be extended for assisting in forecasting the level of risks for the other NCDs, for example, cancer, Alzheimer, chronic lung disease, stroke, and the osteoporosis. This can be achieved more by highlighting the associated vitals and their analysis to set the appropriate rules by the consultation linked with the expert practitioners. Finally, the obtained results can be further analyzed once the approach is applied on predefined data set with previously known level of risk of each NCD disease.

ABSTRACT

Dysphoria is a state faced when one experienced disappointment. If it is not handled properly, dysphoria may trigger acute stress, anxiety and depression. Typically, the individual who experienced dysphoria are in-denial because dysphoria is always being associated with negative connotations such as incompetency to handle pressure, weak personality and lack of will power. To date, there is no accurate instrument to measure dysphoria except using questionnaire by psychologists, such as: Depression, Anxiety and Stress Scale (DASS) and Nepean Dysphoria Scale (NDS-24). Participants may suppress or exaggerate their answers resulting in misdiagnosis. In this work, a theoretical Dysphoria Model of Affect (DMoA) is developed for dysphoria detection. Based on the hypothesis that dysphoria is related to negative emotion, the input from brain signal is captured using electroencephalogram (EEG) device to detect negative emotions. The results from analyzing the EEG signals were compared with DASS and NDS questionnaires for correlation analysis. It is observed that the proposed DMoA approach can identify negative emotions ranging from 55% to 77% accuracy. In addition, the NDS questionnaire seems to provide better distinction for dysphoria as compared to DASS and is similar to the result yielded by DMoA in detecting dysphoria. Thus, DMoA approach can be used as an alternative for early dysphoria detection to assist early intervention in identifying the patients' mental states. Subsequently, DMoA approach can be implemented as another possible solution for early detection of dysphoria thus providing an enhancement to the present NDS instruments providing psychologists and psychiatrists with a quantitative tool for better analysis of the patients' state.

1. Introduction

Stress is a condition experienced when an individual face a pressure or strain from adverse or demanding circumstances [1]. The individual life satisfaction is undermined when difficulties and challenges happen; ranging from the daily annoyances of the consequences of overstretched, time-pressured lifestyle such as traffic jams, lateness and work incompetency to the unexpected events faced in workplace, family lives, interpersonal relationship or even interaction with environment, such as road accident, bankruptcy, demise of a loved ones, loss of a pet or even handling natural disasters like flood or drought.

*Corresponding Author: Norhaslinda Kamaruddin, Advanced Analytics Engineering Centre, Universiti Teknologi MARA, Shah Alam, Selangor, Malaysia, norhaslinda@tmsk.uitm.edu.my, +603-55211163

Stress can cause positive reinforcement as it can be the source of motivation. For instance, healthy competition in workplace can boost morale of a worker to work harder and produced better results. However, if stress is not handled correctly, it can lead to other medical issues, such as; headaches, upset stomachs, anxiety, depression and other undesirable circumstances. [2]. Moreover, long term stress can contribute to other productivity issues, for example; high rate of absenteeism, high labour turnover, inefficient workforce and even high rate of accidents [3]. Hence, it is important to detect stress before it can be worse.

Generally, the number of individuals in every generation experienced stress level are increasing. This finding has been reported in a comprehensive study by American Psychological Association (APA) [4] with 23% and 37% are recorded for

millennials and older adults respectively from 2014 to 2017. The study segregated participants into four groups based on age, as follows; Millennials (18–38 years), Gen X-ers (39–52 years), Baby Boomers (53–71 years) and Older Adult (72 years and above). The survey was conducted online within the United States with participation of 3361 of adults. Figure 1(a)-(d) illustrate the American stress level by generations from 2014 till 2017.

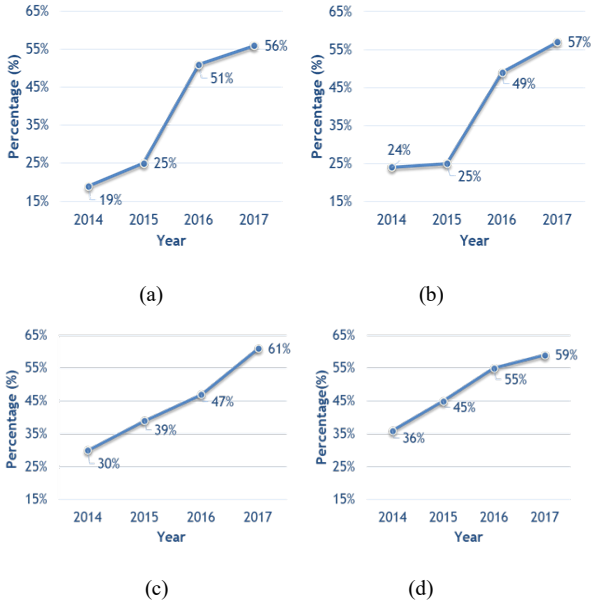

Figure 1: Graph of Stress Level Based on Generation. (a) Older Generation (b) Baby Boomers (c) Gen X-ers and (d) Millennials [4]

The survey results in Figure 1 show that higher number of younger generation experienced stress compared to Older Adult. Older Adults had the least stress levels as presented in Figure 1(a). Such trend is observed to be consistent from 2014 till 2017. This scenario may be linked to work stress as Older Adults typically have retired and are not formally working therefore their stress level is lower than younger generation who are still in employment. However, the highest change is observed in the year of 2015 to 2016 for Older Adults with 26% spike followed by 24% spike for Baby Boomers in the same duration as shown by Figure 1(b). This situation may be related to the United States Presidential Election that happened in 2016. The Baby Boomers and the Older Adults groups are highly affected as they are more in tune with the US political scenario as compared to the younger generations. Additionally, the survey revealed that a critical increment in the number of Americans who had encountered at least one symptom of stress in the previous month is observed from 71% in 2016 to 75% in 2017. Hence, the trend of stress experienced by individual is on the rise.

The finding by American Psychological Association [4] is consistent with the National Health and Morbidity Survey (NHMS) [5, 6] discovery that the trend of stress is rising, and it is reflected in the high leap of patients who suffer from mental illness as presented in Figure 2. In 2011, a total of 24,498 respondents were successfully interviewed and 6.3% reported to have mental health problem in Malaysia [5]. However, the NHMS V (2015-2018) survey [6] reported that 29.2% Malaysian adults aged 16 years and above in Malaysia experienced mental health problem. Such pattern shows a large increase over the last 4 years with almost four folds increment with factors such as younger Bumiputras female adult from low-income family is predicted to be at higher risk to experience mental health problem [5]. The report also mentioned that early recognition/detection and early treatment of depression must be enhanced.

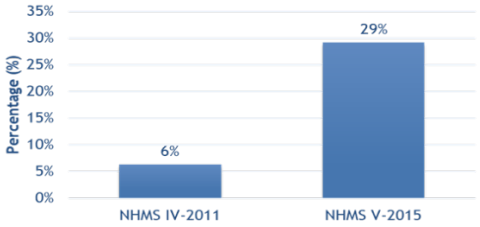

Figure 2: Mental Health Among Adult in Malaysia

Before an individual experienced stress, a state called dysphoria will be endured. Dysphoria can be defined as an emotional state with high degree of complexity and have a close relation to negative mood and in some cases can lead to frustration and dissatisfaction [7]. Dysphoria is usually connotated to anxiety, depression and stress, and can be experienced by any individuals at any time. Typically, dysphoria is viewed as everyday response once an individual face disappointment in his/her life. Figure 3 illustrates the simplified stages of mental cycle in handling disappointment [8]. Dysphoria is viewed as a starting point of either positive or negative adaptation states starting with normal condition to the circumstances when an individual faces a disappointment. When the individual cannot adapt to the dissatisfaction or disappointment, it can lead to dysphoria where the state of frustration is intense thus can lead to clinical depression or stress. On the other hand, the individual who is able to adjust and adapt to the disappointment may be able to carry out his life normally through adaptation. Since emotion indicates the mental state of an individual and is closely related to dysphoria emotion measurement methods is adopted [9]. Hence, the negative emotion that one experienced after disappointment can be empirically measured.

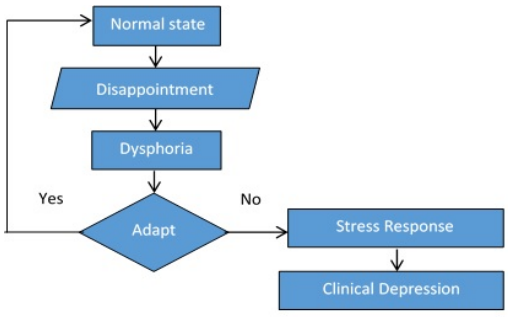

Figure 3: Mental cycle of handling disappointment

In this work, a Dysphoria Model of Affect approach is proposed to measure dysphoria from the brain signals captured using electroencephalogram (EEG) device. Such model can provide a datum for better comparative analysis with the standard psychological instruments to understand dysphoria such as DASS-21 and NDS-24 questionnaires. This is to eliminate the need to

validate the patient's answer by directly using neurophysiological input of the individual because patient have tendency to exaggerate or suppress the answers. Because dysphoria is very much related to negative emotion, emotion recognition methodology is adopted. For simplification, the working definition of dysphoria in this work is the state after disappointment of event that is prior to stress and it is always be associated with negative emotions [8].

This paper is organized in the following manner. Section literature review provides a summary of researchers concentrated efforts to recognize dysphoria and the fundamental concepts of dysphoria study are discussed. The methodology of the proposed approach of Dysphoria Model of Affect (DMoA) is presented in Section 3. The data collection, experimental result and discussion are given in Section 4. Subsequently, this paper concludes with conclusion and future work in Section 5. This paper is an extension of work originally presented in 2018 12th International Symposium on Medical Information and Communication Technology (ISMICT) [8].

2. Literature Review

2.1. Dysphoria and Psychological Instruments

Commonly, dysphoria is associated with depression, stress and anxiety [7,10,11,12]. Dysphoria is associated with depression because it shares the same features of depressive syndrome and dysphoric mood, such as sadness, despondence, despair, and others as suggested by [10]. Such notion is supported by Berner, Musalek & Walter [11] that the term dysphoria should be restricted to a condition of a morose, tense and irritated mood. It can also be recognized from stable and unstable mixed state. Moreover, anxiety may also refer to dysphoria because both have tension and the underlying hyperarousal in common. Dysphoria and anxiety can be experienced at the same time because dysphoria may happen due to long-standing stress. It is not uncommon for anxiety to arise on the background of dysphoric mood. In a certain personality disorder, dysphoria also can be incorporated such as affective instability, irritability, intense anger, and profound unhappiness [12]. These characteristics are shared or overlap with features of dysphoria. Furthermore, Starcevic et al. [7] stated that dysphoria is also associated with depression, interpersonal sensitivity, hostility and stress, reflecting broad but also complex and relatively non-specific relationship.

Dysphoria is assessed using several psychologists' instruments such as the Nepean Dysphoria Scale (NDS) [13], the Depression, Anxiety, Stress Scales (DASS) [14], the Beck Depression Inventory II (BDI II) [15], Perceived Stress Scale (PSS) [16], and the Anxiety Sensitivity Index (ASI) [17]. Typically, the participants are forced to select one answer from the fixed choice response format [18]. The participants need to respond to a series of standard measurement for attitude questions about a pre-determined topic that allow the degree of opinion rather than a simple yes and no answer. Such data enables better quantitative data analysis. The questionnaires can be provided to participants of either online or off-line dissemination method depending on the geographical availability of the participants. In summary, the PSS questionnaire is focusing on measuring the level of stress [16], the BDI-II can measure the level of depression [15] and the level of anxiety of an individual can be measured using the ASI instrument[17]. Based on the dysphoria descriptions that are being discussed earlier, dysphoria is very related to depression, anxiety and stress. All these factors can be measured using DASS [14] and NDS [13] questionnaire. It is expected to observe strong positive correlations between scores on the NDS and scores on the DASS-21. Hence, for the purpose of this work, both questionnaires are used to investigate dysphoria. The summary of the questionnaire and its focus is presented in Table 1.

Table 1: Summary of Questionnaire and Its Focus Study.

	DASS	PSS	BDI-II	ASI	NDS
Depression	√		√		√
Anxiety	√			√	√
Stress	√	√			√

The DASS-21 test is the psychological instrument to measure depression, anxiety and stress of an individual. It consists of 21 questionnaires and is able to measure the degree of depressions, anxiety and stress of the participant taking the test [14]. The participants are needed to specify indication of a symptom over the previous week based on a 4-point Likert scale. Each answer is recorded from 0 (did not apply to me at all over the last week) to 3 ('applied to me very much' or 'most of the time over the past week'). Calculation on the degree of depression (D), anxiety (A) and stress (S) is indicated is provided where every item of the questionnaire is related to either D, A or S score. The cumulative score of the D, A and S are used to indicate the level of severity, namely; normal, mild, moderate, severe and extremely severe. A trained psychologist or psychiatrist is needed to interpret the results and thus providing a more meaningful diagnostic for the patient.

The Nepean Dysphoria Scale (NDS) is a set of questionnaires to measure the severity of dysphoria [13] and expects participants to give evaluation of the frequency on a scale from 0 to 3 ranging from 'not at all', 'always', 'every day' to 'most of the time'. In this questionnaire, there are 4 factors that are being observed, namely; irritability, discontent, surrender and interpersonal resentment. Based on the summation of the score gathered from the itemized questions, the correlation matrix factor of NDS are calculated. The specified weightages are then used to get the maximum and average value of the scale. The value yielded are then compared to get the severity category of either normal, mild, moderate and severe.

2.2. Dysphoria and Negative Emotion

Dysphoria has recently been conceptualized as a complex emotional state that consists of discontent and/or unhappiness and a predominantly externalizing mode of coping with these feelings [7]. Many researchers relate dysphoria to negative emotions [10,11]. Dysphoria is also used as synonym for sadness or depression which describe a mixture of negative and unpleasant emotions [19].

A study by Caseras, Garner, Bradley and Mogg [20] examined the eye movement of the participants on negative images. The participants are grouped into dysphoric and nondysphoric group. In the experimental results, it was observed that dysphoric group have the tendency to look at the negative images longer than the control images as compared to the time taken by the nondysphoric

group. This result is in line with another work by McMakin, Santiago and Shirk [21] that observed the experiential reactivity to emotion in dynamic moment. Experimental results revealed that individual with dysphoric tendency and those who have not are equally responsive to both negative and positive film clips regardless of their dysphoric level. However, dysphoric group shows a lower ability to maintain positive emotion when they are looking at the positive film clips. Hence, it can be said that dysphoria is always associates with negative emotions.

The negative emotions are located in the negative valence axis region of Affective Space Model (ASM) [22]. The ASM consists of three main emotion primitives; namely: valance, arousal and dominance. The emotion primitives are actually the descriptive generic attributes of an emotion. These attributes function as constituents that act as a fully complementary description of the emotion. The affective space model can be divided into quadrants where each quadrant represents positive or negative value of the emotion primitives. The horizontal axis represents the valance value that indicates whether the emotion is perceived as positive or negative whereas the vertical axis representing the arousal which indicates the level of activation from passive to active. In this work, the focus is given on valence since valence is the effect of the emotion to an individual of either positive effect or otherwise. Figure 4 shows the Schlosberg's Model of Affect where dysphoria is labelled in pink rectangle in quadrant 2 and 3. Dysphoria happens at negative valance values regardless of its arousal of either active or passive.

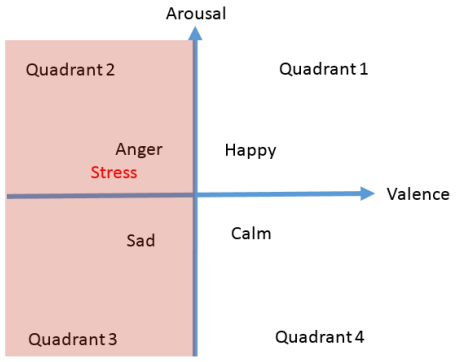

Figure 4: Model of Affect [22]

2.3. Dysphoria and Electroencephalogram (EEG)

Further reading shows that some researchers using EEG in dysphoria understanding. Siegle, Condray, Thase, Keshavan and Steinhauer [23] investigated the Gamma band in EEG signal in relating to emotional states for healthy, depressed and schizophrenia adults. The emotion condition assessment is using 3 methods; which are, never-depressed healthy controls, *Diagnostic and Statistical Manual of Mental Disorders* (DSM-IV) unipolar major depressive disorder and DSM-IV schizophrenia. During the assessment, the patients need to judge their own emotion of either positive, negative or neutral based on the words appearing on the screen of laptop. It is observed that depressed individual displayed both sustained and increased gamma-band EEG signals activity throughout the task while adults with schizophrenia displayed decreased gamma-band EEG signals activity. It is also observed that schizophrenia subjects displayed more affinity responses to negative word compared to neutral words and not significantly faster to positive than neutral words. Based on this study, it can be summarized that there are different responses towards negative words depending on either the patients suffer from schizophrenia or otherwise. Such responses can be monitored using the EEG signals produced by the depressed and schizophrenia groups.

From previous studies [7,8] it is noted that dysphoria is very much affiliated to negative emotions, thus it is proposed to use the electroencephalogram (EEG) in measuring the negative emotion of the individual and relate it the dysphoria. Lin et. al [24] applied machine learning algorithms to categorize EEG signals on emotional states during music listening. The main purpose of the research is to search emotion-specific features of the EEG signals and test the efficacy of different classifiers. The Valance-Arousal model is used as comparator of emotion. 26 subjects were instructed to keep their eyes closed and remain seated while listening to the sixteen excerpts from Oscar's film soundtracks and the EEG signals were recorded. Features are extracted using the Differential Asymmetry of 12 Electrode (DASM12), Rational Asymmetry of 12 Electrode (RASM12), Power Spectrum Density of 24 electrode (PSD24) and Power Spectrum Density of 30 electrode (PSD30) while Multi-Layer Perceptron (MLP) and Support Vector Machine (SVM) are used as classifier. As a result, SVM obtained an improvement classification performance from 81.52% ± 3.71% to 82.29% ± 3.06% compared to MLP classifier. The best result recorded were using DASMI12 using SVM as classifier. This study also concluded that the sensitivity metric for characterizing brain dynamic in response to emotional state (joy, angry, sadness and pleasure) are depending on the spectral power asymmetry across multiple frequency bands using DASM12.

Moreover, Sourina and Liu extended the work to recognize emotion from Fractal Dimension (FD) based algorithm using EEG signals [25]. The FD values are calculated from the EEG signal recorded from the corresponding brain lobes and mapped on the 2D emotion model. The International Affective Digitized Sounds (IADS) and music pieces labelled by other subjects with emotions using a questioner are used as stimuli to generate emotion to the subjects during the assessment. As a result, the FD were able to detect emotion with only using 3 electrodes and the data can be mapped into 2D Arousal–Valance model. The accuracy of 72% to 100% are recorded for arousal and valance level.

Based on the study of other researchers, we combine the understanding yielded from EEG emotion recognition and insights gathered from the DASS and NDS questionnaire to understand dysphoria. Figure 5 summarises the correlation between EEG, questionnaire and dysphoria.

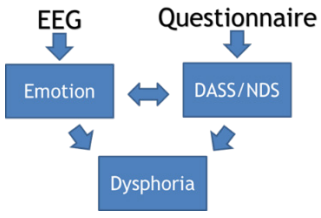

Figure 5: Overview of Correlations between DASS-21/NDS-24, Emotion and Dysphoria

3. Methodology

A theoretical framework of Dysphoria Model of Affect is presented in Figure 6. It consists of five phases, namely; data collection, pre-processing, feature extraction, classification and correlation analysis. Detailed description of each phase is presented in the next sub-sections.

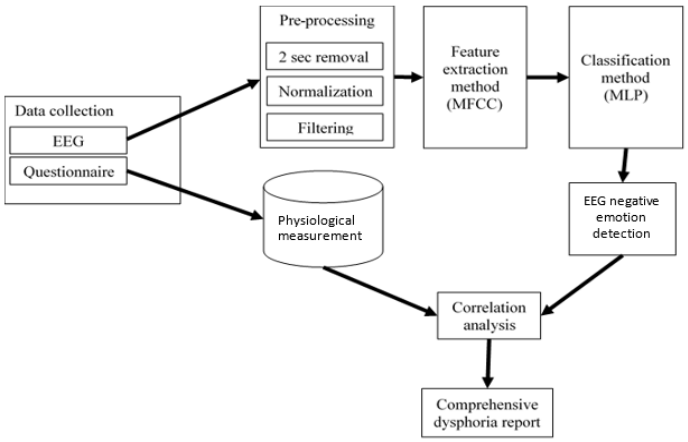

Figure 6: Theoretical Framework of Dysphoria Model of Affect (DMoA)

3.1. Data collection

In this preliminary work only four participants data were collected based on two type of inputs from the psychological instruments (DASS-21) and from the brainwave patterns using the captured EEG signals. The participants are healthy male with no medical record of experiencing acute depression, anxiety and stress with age mean of 27.5 years and variance of ±2.19 years. The participants also indicated that they are under the influence of medicine, drug or alcohol and voluntarily signed the consent form to adhere the IIUM ethic committee procedure.

Prior to taking the brainwave signal using the EEG device, all participants need to fill up two questionnaires namely; the personal information and also the DASS-21 questionnaires. This is to ensure that all four participants do not have any history of acute depression, stress or anxiety. Participants were first briefed about the experiments and were required to sign a consent form as needed by the IIUM ethics committee. To ensure consistency and to relate the study of psychological instruments to the brainwave patterns each individual was required to do the DASS-21 and the NDS-24 questionnaires prior to taking the individual brainwave pattern using the EEG device.

The DASS and NDS questionnaires results are gathered from each of all 4 subjects. The participants are asked to answer the questionnaire truthfully and to take their time to select the most appropriate answer for the questions. The participants can ask the meaning of the word in the questionnaire if they are unsure. This is to minimize misunderstanding that can lead to wrongly selected answer. The DASS questionnaire consists of 21 questions and the NDS questionnaire consists of 24 questions. The participants must answer all questions by selecting their choice in the questionnaire sheet. Once the participants finish answering the task, the questionnaire sheets are collected. Further analysis will be conducted based on the answers given by the participants.

In order to investigate the brainwave patterns signals recorded from the EEG device, the resting state of the participants need to be captured as a measurement basis. It consists of one minute of eyes close and eyes open. Then, it is followed with the reference emotion test based on the International Affective Pictures Systems (IAPS) [26] to analyse the responses of the different parts of the brain to four basic emotions of happiness, sadness, calmness and fear in one minute each respectively. In addition, sadness and fear video stimuli were presented to examine the negative emotion responses of each participant [8]. A final resting state data were collected based on a one minute each of eyes-open and eyes close after the video stimuli. The overall time taken for data collection in this work is 10 minutes without considering the pre-EEG experiment and post-EEG experiment tasks. Also note that all the EEG signals were captured and stored as numeric values to ensure compatibility of data using CSV file format. Table 2 shows the protocol that has been set for the data collection that consists of several condition which is resting state, emotional test and video stimuli.

Table 2: Protocol for EEG Experiment

Resting state (before)		Emotional test				Video stimuli		Resting state (after)	
Eye open 1minute	Eye close 1minute	Happy 1minute	Sad 1minute	Calm 1minute	Fear 1minute	Fear video 1minute	Sad video 1minute	Eye open 1minute	Eye close 1minute
2 minutes		4 minutes				2 minutes		2 minutes	

In the EEG data collection, the raw 19 channels EEG signals are captured using EEG device from BrainMarker. The device allows 19 channels EEG to be captured. However, in this work, only 6 channels are considered; namely, F3, F4, F7, F8, FP1 and FP2 to measure the negative emotion. These six channels are selected because signals from frontal brain are relevant to emotion processing according researchers [27, 28, 29] hence contains a lot of emotion information.

3.2. Pre-processing

Artifact and noise cancellation consist of three steps, namely; removing the first 2 seconds of the EEG signals, normalization and filtering. The pre-processing phase is important to ensure the analyzed data are in the region of interest and not biased or distorted by the effect of artifact and noise. Otherwise the data is regarded as inaccurate and misleading. The first 2 second of the 1-minute data of each protocol typically consists of 500 instances depending on the size of selected window size. The removal of this data is because it may not contain any useful information as the participant just starts to focus their attention to discriminate the emotion based on the presented stimuli. Then, the time vs frequency domain signals are then mapped into 19 channels to be extracted (19 channels x 14,500 instances). For the purpose of this study, only 6 channels data are considered to focus on the data of the brain frontal region.

The data from the 6 channels are normalized to [0,1] and filtered using the elliptical filter. The elliptical filters are employed to ensure to get the cut off frequency/clean signals before going

through feature extraction process. The EEG signals that are higher than 50Hz are also eliminated on the grounds that such data are usually artefacts gathered from various hand, eye and muscle movements.

3.3. Feature Extraction

Once the noise and artefacts are removed, relevant features are extracted for classification purposes. In this work, Mel Frequency Cepstral Coefficient (MFCC) feature extraction method is employed. In MFCC, window size and framing are two main components to observed. Windowing is a technique to cut the large signal into a manageable size for processing and analysis. Windowing is done for minimizing the disruptions at the starting and at the end of the frame, the frame and window function is being multiplied. If the window size selected is too large, the difference maybe too minimal for analysis whereas if the selected window size is too small, the information may not be enough for analysis. Frame is the process of dividing the signal in window into small frames to have reliable information. In the framing process, the raw EEG signals are blocked into small frames of N samples, with next frames separated by M samples (M<N) with this the adjacent frames are overlapped by N-M samples. This procedure of segregating up the signals into frames will proceed until the whole raw EEG signal is separated into small frames. Segregation of frame will make the computation more effective in term of time and processing. In this work, window type used is Hamming window with number of coefficients of 12 resulting to 12 features are extracted for each channel making it 72 features in total.

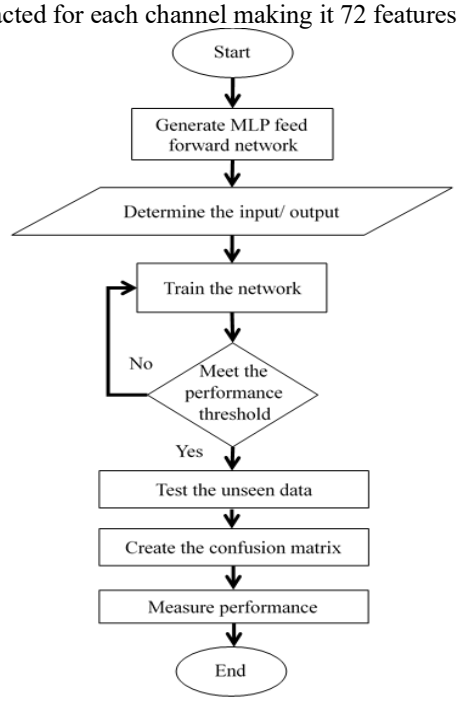

Figure 7: Flow Chart for Emotion Classification

3.4. Classification

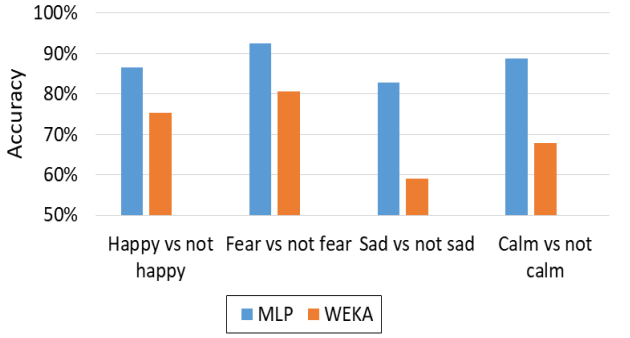
Data are arranged according to the experimental set up needs after the relevant features are extracted. In this work, k-fold validation technique is adopted. The data are randomly partitioned into 5 groups where each approximately have an equal size. One group is used for testing while the other four groups are used for prior training. The process is iterated until all fold are used for testing.

In this work, Multi-Layer Perceptron classifier is adopted based on prior work findings [8,29]. The steps of using the MLP are simplified in the flowchart in Figure 7. Input are feed to the 72-neurons input layer before they are passed to the 10-neurons hidden layer. Then, the summation process is conducted in the output layer. The weights of the learning function of each node are iteratively improved until the performance threshold is met.

4. Result and Discussion

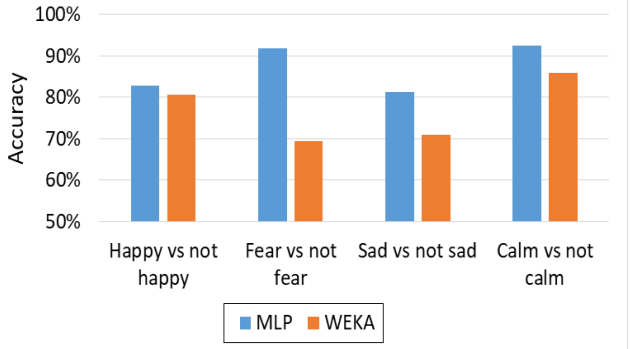
There are two types of experiment conducted in this work, namely; emotion recognition and emotion identification. For emotion recognition task, specific emotion is checked whether it is available or not. It is a 2-class classification task. Subsequently, the emotion identification task segregates the emotion individually and compare the intended emotion to the data pool.

4.1. Emotion Detection



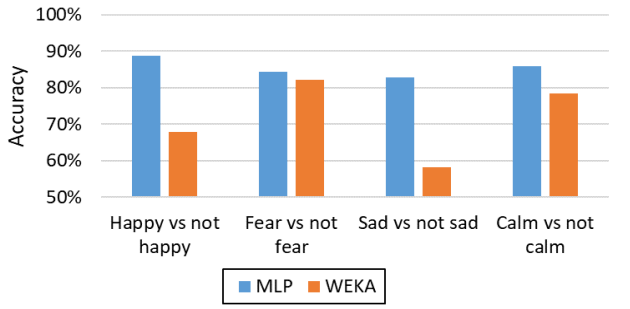
The emotion detection experiment is conducted to discern the existence of specific emotion in a pool of instances. The data are arranged for two-class classification task, for instance; happy versus not happy, fear versus not fear, sad versus not sad and calm versus not calm. The emotion data consists of 67 instances and the data that opposed of the specific emotion are the combination of 1/3 of each other emotions. The total number of instances for the experiment is 134 instances. Features extracted are 72 instances gathered from 12 MFCC coefficients from the six EEG channels of F3, F4, F7, F8, FP1 and FP2. The average of the ten iterations of the experiments are presented in Figure 8(a)-(d). As a comparison, the results gathered from WEKA are also presented. Results from WEKA are used as the base result because the WEKA results are consistent. From the experimental results, it is observed that the result obtained from MLP from Matlab (denoted as MLP) gives higher accuracy as compared to WEKA with increment of 10% to 16% accuracy. The best performance was recorded by MLP for Happy vs Not Happy experiment from Subject4 with performance of 95.5%. The worst performance was recorded by Calm vs Not Calm for Subject3 with performance of 58.2%.

4.1. Emotion Identification



The emotion identification experiment is conducted to observe the ability of the classifier to predict the specific emotion given a pool of different emotion data. The data are arranged in such a way that all emotion has a similar number of instances (67 instances each) gathered from the frontal EEG signals of F3, F4, F7, F8, FP1 and FP2 for all participant. Table 3 shows the detailed MLP experimental result accuracy for emotion identification. Each experiment is repeated 10 times because the MLP performance in Matlab may have difference of ±10%.

From the result in Table 3, it is distinguished that the highest emotion identified is happy by Subject4 which achieved 97.01% accuracy. On the contrary, the lowest emotion identified is fear by Subject3 which yielded 11.94% accuracy. The result then is summarized as in Table 4. Subject4 managed to record the highest average performance for emotion identification whereas the worst



performance is yielded by Subject2 with accuracy of 64.51%. It is also observed that MLP managed to achieve accuracy ranging from 64.51% to 76.72% as compared to WEKA with accuracy ranging from 55.97% to 63.81% that show slight superiority of MLP as compared to WEKA.

	Exp#1	Exp#2	Exp#3	Exp#4	Exp#5	Exp#6	Exp#7	Exp#8	Exp#9	Exp#10
Subject1	57.09	65.30	77.99	72.76	69.03	73.13	70.90	70.90	60.82	69.03
Subject2	52.99	77.61	83.58	69.40	82.84	84.33	72.01	79.10	85.45	79.85
Subject3	72.76	83.21	63.43	78.36	22.76	67.16	79.85	82.46	76.49	18.66
Subject4	86.94	61.19	72.76	70.15	73.13	54.10	70.90	68.66	74.63	68.28

Table 4: Summary of Emotion Identification Results

Participant	MLP Accuracy (%)	WEKA Accuracy (%)
Subject 1	68.69	55.97
Subject 2	76.72	63.06
Subject 3	64.51	60.45
Subject 4	70.07	63.81

4.2. Emotion Identification for Video Stimuli

Further analyses are conducted to see the difference in performance of using different media of stimuli, namely; static images and videos. For video stimuli, two videos of sad and fear videos are selected. Figure 9 and Figure 10 show the emotion identification experimental results for fear and sad videos respectively.

Figure 9 shows the bar chart of the experimental result yielded when using fear video. Based on the result, fear is consistently detected for Subject2, Subject3 and Subject4 with accuracy ranging from 33.1% to 37.1%. Subject1 recorded Calm as the highest emotion with difference of 3.5% lower than Fear. However, for the emotion experimental result Figure 10 shows the bar chart result for sad video using emotion identification network. Based on the bar chart, the highest emotion detected is fear in Subject4. Only Subject2 shows the highest sad emotion detected. This result shows inconsistency during video stimuli. This may due to the surrounding when eye open, the information enters through the eye in form of light. This information will react to the brain for visual perception.

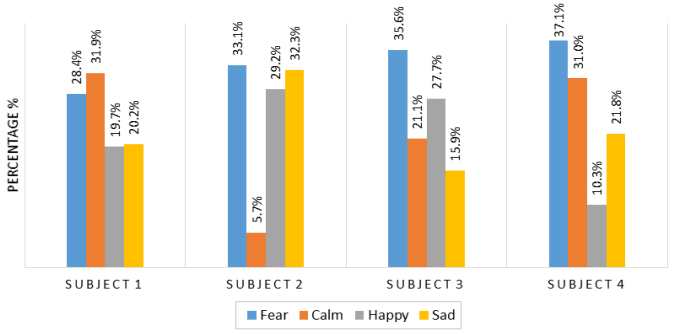

Figure 9: Emotion Identification Result using Fear Video

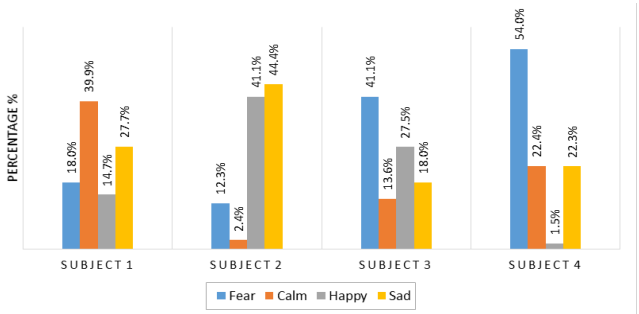
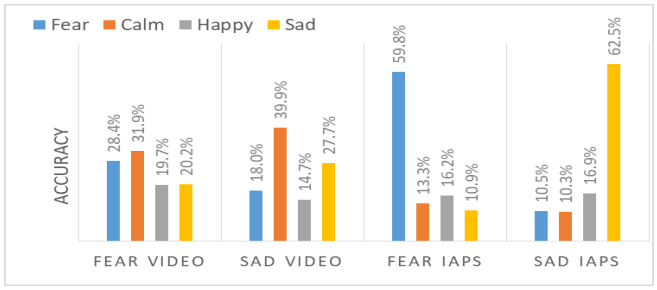
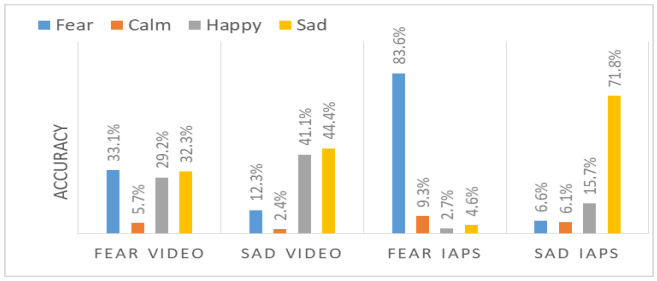
Extension of the comparison between the effect of emotion elicitation using dynamic emotional contents (video) and static images emotional contents (IAPS) are conducted. Figure 11(a)-(d) show the comparative accuracy of emotion recognition experiments between static images and videos for each subject.







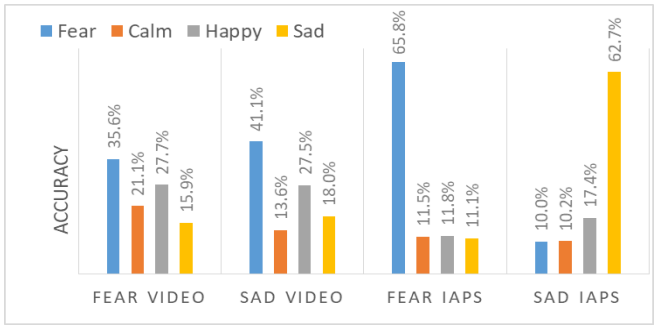


Figure 10: Emotion Identification Result using Sad Video

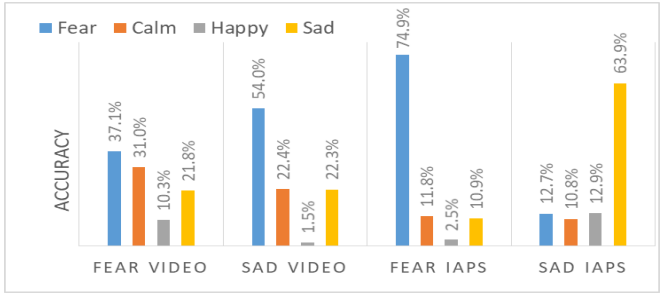

(a)

(b)

(c)

(d)

Figure 11: Result Comparison for Emotion Identification Result using Static Images and Videos for (a) Subject1 (b) Subject2 (c) Subject3 and (d) Subject4.

From the experimental results in Figure 11, the emotion identification result using static emotional contents outperformed the dynamic emotional content in all experiments. The highest accuracy achieved is fear IAPS with 83.6% for Subject2. Meanwhile the lowest accuracy is sad video for Subject4 with 1.5%. This is because the brain needs to process more information when video stimuli is exhibited instead of static images displayed in IAPS stimuli. Hence, lower performance is recorded.

4.3. Questionnaire result: DASS-21 & NDS-24

Table 5 and 6 shows the summary result of the DASS-21 and NDS-24 results respectively for all subjects. According to the depression, anxiety and stress score scale, all participants are in a normal condition. None any of them shows any negative result. However, in Table 6, Subject1 and Subject2 results indicated that they are in mild state as compared to Subject4 that recorded moderate and severe for Subject3 respectively. This result gives better insight as compared to the DASS-21 results that only indicate the participants are normal. Hence, the NDS is able to give more information about the participants' state as compared to the DASS-21 questionnaire and the DASS-21 questionnaire cannot be directly used to determine whether the subject is having dysphoria or otherwise.

Subject	DASS-21 score			Result
	Depression	Anxiety	Stress	
1	2	6	6	Normal
2	2	2	10	Normal
3	2	4	8	Normal
4	2	6	8	Normal

	Total factor Subject1	Total factor Subject2	Total factor Subject 3	Total factor Subject4
Irritability	10.8	8.68	23.2	15.2
Discontent	6.91	5.41	18.3	12.34
Surrender	5.98	5.07	12.9	8.284
Interpersonal resentment	3.41	2.14	7.39	4.55
Result	**Mild**	**Mild**	**Severe**	**Moderate**

4.4. Correlation between DASS-21, NDS-24 & EEG emotion identification

From the emotion identification experiments as in Table 7, fear is highly detected during the eye close which is in line with NDS-24 result that is severe for Subject3. There seems to be correlation between EEG emotion identification and NDS-24. However, it is not highly observable on Subject 1, 2 and 4 because NDS-24 result for each subject is only mild and moderate.

Table 7: Eye Close and Eye Open Before Experiment Training with Emotion Identification MLP Architecture

	Emotion	Before stimuli		After stimuli	
		Eye close	Eye open	Eye close	Eye open
Subject 1	fear	37.5%	43.0%	22.4%	43.0%
	calm	35.1%	25.1%	34.6%	25.1%
	happy	15.7%	24.8%	17.8%	24.8%
	sad	11.8%	7.2%	25.2%	7.2%
Subject 2	fear	41.5%	17.9%	1.2%	17.9%
	calm	10.9%	11.0%	5.4%	11.0%
	happy	31.4%	33.9%	52.0%	33.9%
	sad	16.3%	37.2%	41.5%	37.2%
Subject 3	fear	70.9%	12.2%	75.7%	12.2%
	calm	20.0%	16.4%	9.7%	16.4%
	happy	4.0%	45.7%	5.4%	45.7%
	sad	5.1%	25.7%	9.3%	25.7%
Subject 4	fear	26.4%	49.4%	1.0%	49.4%
	calm	19.6%	18.1%	16.9%	18.1%
	happy	46.3%	27.9%	76.9%	27.9%
	sad	7.8%	4.6%	5.2%	4.6%

5. Conclusion

The Dysphoria Model of Affect (DmoA) uses the neurophysiological data from the EEG devices and by extracting the emotional information from the brainwave patterns different emotions can be detected during the initial state of eyes closed. Such information are very useful in analyzing the mental state of an individual. In this preliminary study, the implementation of DmoA seems to be able to differentiate different classes of emotion fairly well thus resulting in a better tool for early detection of dysphoria as depicted by the NDS-24 results for Subject3. It is also observed that the DASS-21 questionnaire result could not differentiate dysphoria for all the subjects in this work. There are other psychological instruments that can be studied for detail analysis of dyphoria but would be expensive and require experts to interpret score. The proposed DMoA approach provides a new avenue for psychologist and psychiatrist to venture using EEG devices as tools for analyzing dysphoria, depression, anxiety and stress and can also be used in understanding personality traits or behaviour [29].

Bi-LSTM

ABSTRACT

This paper presents a solution for question answering system for Vietnamese language by integrating diacritics restoration and question classification via deep learning approach. It could be said that this will be the first research integrating two phases into Vietnamese question answering system. Question classification has a critical role in the question answering system. However if the question has too many missing diacritics, this will make the classification extremely more difficult. In this paper, both automatic insertion of diacritics and question classification tasks are built to rely on deep learning approach. For diacritics restoration task, we apply the Encoder-Decoder LSTM model. The result of the first step will be the input of question classification. We use pre-train word embeddings in the Bidirectional LSTM model for Vietnamese question classification. The deep learning approach for both tasks is powerful and highly accurate model. By integrating diacritics restoration and question classification into Vietnamese question answering system – ICTbot of Binh Duong Department of Information and Communications Support System – it has produced remarkably positive results; thus proves the practicability of this proposed system.

1. Introduction

Internet allows the researchers to save data and make them available to the public. However, it also makes the search of information in such big data environment more complicated and expensive. Question Answering systems have been developed as a new advanced research tools for this issue.

An automated question answering system has several key steps to follow such as:

- The user inputs the question through query interface. The question is analyzed, pre-processed and phrased into words.
- Question classification identifies the type of the question. This step is rather critical to achieve the most appropriate answering type.
- Finally, based on the result of Question classification, the system will choose the appropriate answer from the answer sets.

In the first step, if there are too many missing diacritics in questions, it will make it challenging for the second step - Question classification. A diacritic is a mark written either above or below a letter to alter its original phonetic or orthographic value. Diacritics are used in several languages' orthography. Nevertheless, in daily conversation, as a matter of convenience, diacritics are usually ignored in many languages. The absence of diacritics in question text makes it extremely challenging for both Question Classification and Question Answering system.

The Vietnamese alphabet uses Latin script with diacritical signs. However, Vietnamese has seven modified letters including ă, â, đ, ê, ô, ơ, and ư and also six tone marks including unmarked tone (ngang), acute (sắc), grave (huyền), hook above (hỏi), tilde (ngã), and underdot (nặng). Due to its diacritical complexity, when typing on phones or computers, most of Vietnamese people prefer to type non-diacritic characters as a matter of convenience. As a consequence, it sometimes causes the confusion or mis-interpretation for the recipients or readers. With that being said, integrating diacritics restoration into question classification is a critical task for Vietnamese question answering system.

We propose the Vietnamese Question Answering model with two phases in this paper. The first phase is automatically recovering the missing diacritics. And the second phase is integrating diacritics restoration into Vietnamese question

*Bui Thanh Hung, Engineering - Technology Faculty, Thu Dau Mot University, hungbt.cntt@tdmu.edu.vn

answering system. We use the Encoder-Decoder LSTM model for automatically recovering the missing diacritics and the Bidirectional LSTM model for Vietnamese question classification. We integrate diacritics restoration into Question classification of Vietnamese question answering system.

This paper consists of five sections. The related works are reviewed in Section 2. Our method is presented in Section 3. Section 4 mentions the procedure of constructing dataset, the experiment settings and discusses the outcomes of the experiments. Our work and possible future research are concluded in Section 5.

2. Related Words

Firstly, diacritics restoration – as the first step – could be run following two typical approaches: character-based [1-2] and word-based [3-5]. For Vietnamese language, many researches propose their methods to restore accents such as [6-9]. In this research we choose the Encoder-Decoder LSTM model that proposed recently by Bui [6] because of the advanced approach, and high accuracy for Vietnamese diacritics restoration.

For question classification, there are three main approaches: Rule-based, Machine Learning and Hybrid ones [10]. Using a few manually handcrafted rules to match the question is the rule-based approach. One of key challenges here is to define too many rules. Machine-learning approach is to train a classifier and use the trained classifier to predict the class label. Combining the two above - the rule-based and machine learning - is the hybrid approach. In terms of question classification, the most successful approaches are Machine Learning and hybrid methods. Nguyen et al. [11] proposed a SVM based method for the same task. Firstly, the question was parsed and tokenized, parts-of-speech were tagged, data removed stop-words and was stemmed. Next they extracted a lot of features and selected features before passing the data into a support vector machine for training. For test questions they used the same pre-processing. Deep Learning approaches have proved that it is significantly beneficial for text classification, summarization, machine translation, etc. as well as for question classification [12-15]. Andreas et al. [12] proposed compose neural networks for question answering. Kim et al. [16] employed Convolutional Neural Networks (CNNs) and treated questions as general sentences to achieve remarkably strong performance in the TREC question classification task.

With regards to our research, what differentiates it from the others is the Vietnamese question answering system. This is the first research integrating two phases - diacritics restoration and question classification into Vietnamese question answering system. The diacritics restoration is the Encoder-Decoder LSTM model and Question classification uses the Bi-LSTM model. The result of the first step will be the input of question classification.

3. Methodology

Our model includes two steps: Diacritics Restoration and Question Classification. In the first step, we use Encoder-Decoder LSTM model proposed by Bui [6] and in the second step, pre-train word embeddings are used in the Bidirectional LSTM model for Vietnamese question classification. We integrate the result of the first step into question classification. An overview of our architecture is illustrated in Figure 1. We will describe more details of each layer in our model as follows:

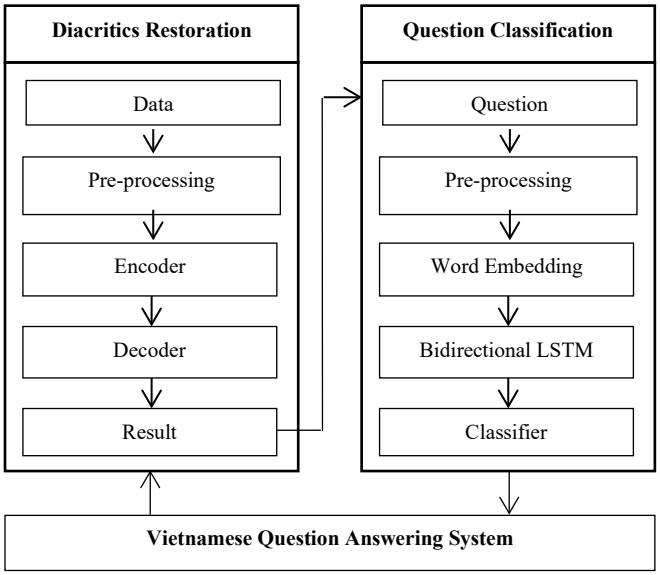

Figure 1: The proposed model

3.1. Word Embeddings

Indeed, it has been discussed for quite a long time to use vector representation for words. And recently there has been more and more interest in word embeddings - a technique which maps the words to vectors. Tomas Mikolov's Word2vec algorithm [17] is one driver for this which takes a big volume of text to create high-dimensional representations of words. By this way, it could identify the relationships between words which are not supported by external annotations. Thus, it proves to succeed in getting lots of linguistic regularities with such representation.

In this research, we use word embeddings - Continuous Bag of Words (CBOW) [17]. In the CBOW model, a variety of words illustrate the context for a defined target word which stands for a modification of neural network architecture. For example, with "trèo" (climbed) as the target word, let's use "mèo" (cat) and "trên" (on) as the words to describe the context. Figure 2 describes this model as below:

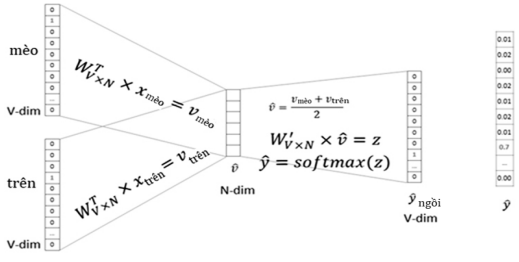

Figure 2: Continuous Bag of Words (CBOW)

3.2. LSTM

Long short-term memory (LSTM) [18] is a modification of the Recurrent neural networks (RNN). Thanks to the feedback loop in its architecture, this model has the ability to store the records of previous outputs.

Figure 3 represents a diagram of a simple LSTM cell. As befits the term deep neural networks, all single cells are combined altogether to shape a huge network. The cell unit represents the memory with five main elements: an input gate *i*, an output gate *o*, a forget gate *f*, hidden state output *h* and a recurring cell state *c*. Given a sequence of vectors (x_1 ,x_2, ..., x_n), σ is the logistic sigmoid function, the hidden state h_t of LSTM at time t is calculated as follows:

$$h_t = o_t * tanh(c_t) \quad (1)$$

$$o_t = tanh(Wx_0x_t + Wh_0h_{t-1} + Wc_0c_t + b_o) \quad (2)$$

$$c_t = f_t * c_{t-1} + i_t * tanh(Wx_cx_t + Wh_ch_{t-1} + b_c) \quad (3)$$

$$f_t = \sigma(Wx_fx_t + Wh_fh_{t-1} + Wc_fc_{t-1} + b_f) \quad (4)$$

$$i_t = \sigma(Wx_ix_t + Wh_ih_{t-1} + Wc_ic_{t-1} + b_i) \quad (5)$$

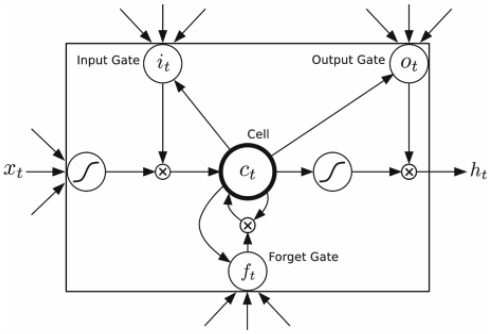

Figure 3: The Long Short Term Memory cell (Source: [19])

3.3. Bidirectional LSTM

Bidirectional LSTM [20] could be seen as a suitable model in many tasks of natural language processing. This model is modified version of LSTM by combining forward and backward LSTMs. The Bi-LSTM model is shown in Figure 4.

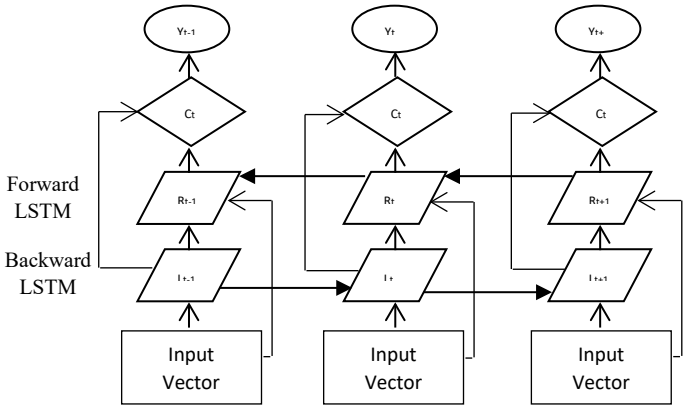

Figure 4: Bidirectional LSTM

Assuming that above equations are abbreviated to

$$h_t = \text{LSTM}(x_t\ h_{t-1}). \quad (6)$$

The forward $\overrightarrow{ht}$ and $\overleftarrow{h}$t the backward LSTM are defined as follows:

$$\overrightarrow{h_t} = \text{LSTM}(x_t, \overrightarrow{h_{t-1}}) \quad (7)$$

$$\overleftarrow{h_t} = \text{LSTM}(x_t, \overleftarrow{h_{t-1}}) \quad (8)$$

Where → denotes the forward and ← denotes backward. By taking the forward and backward LSTM as input, the Bidirectional LSTM $\overleftrightarrow{ht}$ at time *t* leads to further classification procedure:

$$\overleftrightarrow{h_t} = [\overrightarrow{h_t}, \overleftarrow{h_t}] \quad (9)$$

3.4. Diacritics Restoration

We used the Encoder-Decoder LSTM model proposed by Bui [6] for Vietnamese diacritics restoration. The Encoder-Decoder model was introduced by Kyunghyun Cho et al. [14]. This model learns to encode a variable-length sequence into a fixed-length vector representation and to decode a given fixed-length vector representation back into a variable-length sequence. This model is presented in Figure 5.

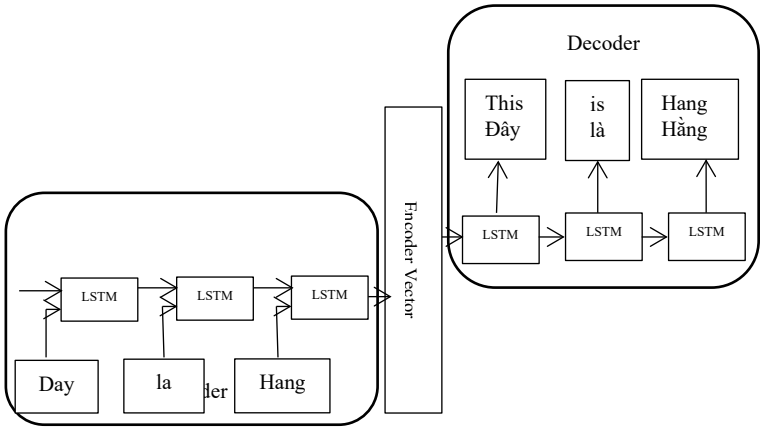

Figure 5: Encoder-Decoder LSTM model

In Figure 5, the input sequence is displayed to the network one encoded character at once. The output produced from this model is a fixed-size vector that shows the internal representation of the input sequence.

3.5. Question Classifier

The output layer is defined as follows based on the text vector studied from the Bidirectional LSTM model:

$$y = (W_d x_t + b_d) \quad (10)$$

where x_t: the text vector studied from the Bidirectional LSTM model; y: the degree of question class of the target text; W_d, b_d: the weight and bias associated with the Bidirectional LSTM model.

The Bidirectional LSTM model is trained by minimizing the mean squared error between the predictive question class and true question class. The loss function is identified as follows:

$$L(X, y) = \frac{1}{2n}\sum_{k=1}^{n}\binom{n}{k}\left\|h(x^i) - y^i\right\|^2 \quad (11)$$

$\mathbf{X} = \{x^1, x^1, x^2, \ldots, x^m\}$: a training set of text matrix

$\mathbf{y} = \{y^1, y^2, \ldots, y^m\}$: a question class ratings set of training sets

4. Experiments

We used dataset in [6] for the first step. This dataset was crawled from the official newspapers website from various categories like sports, world, business and entertainment. The size of dataset is 150 MB. The training dataset is 1500000 sentences and testing dataset is 5000 sentences. We removed all diacritical marks following the rule presented in [6].

To enable a LSTM network to process and remember more effectively, we are going to break dataset down to a lot of n-grams. Also, Vietnamese tone marks for a word can be determined from the small surrounding words in most of the cases; therefore something like a 5-gram or 7-gram model will rather fit for our purpose to some extent. So we have 11 million 5-gram with length varied mostly from 15-25 characters. In addition, as mentioned above, the easiest way to gather a lot of training data to add diacritical marks to Vietnamese text is to get a diacritical text then remove the diacritical marks.

As a machine learning framework, Keras with Tensorflow as a backend has been used. We used same parameters of [6] with 3 LSTM layers, each layer has 256 neurons. We optimized by Adam Optimizer with learning rate 0.002. We used Accuracy score - Accuracy of Diacritics Restoration (ADR) to evaluate the first step as below equation:

$$ADR = \frac{Number\ of\ corrected\ words}{Number\ of\ words} \quad (12)$$

We did experiements with the range of epochs, after about 300 more epochs, or 16 hours we got 97% accuracy and reduced loss to 0.07. Figure 6 shows the Loss of Diacritics Restoration over epochs and Accuracy of Diacritics Restoration per epochs are shown in Figure 7.

Since the used data was extracted from the newspaper websites, it might consist of unpopular words and a couple of errors. Therefore, the diacritic restoration in those cases usually will not achieve highly accurate results.

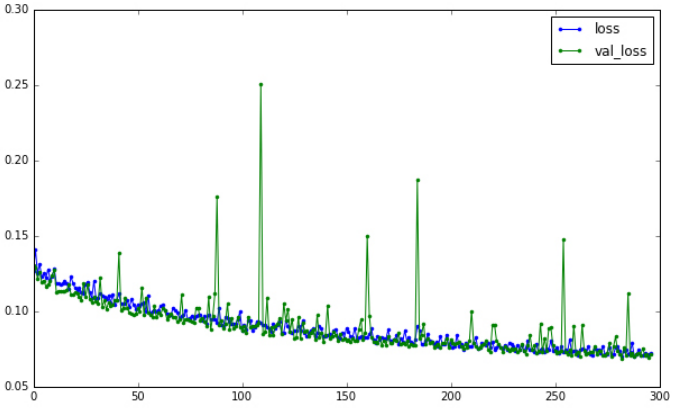

Figure 6: The loss of Diacritics Restoration over epochs

For the second task, we collected question classification dataset from Binh Duong Department of Information and Communications. This data includes 4 areas with 42 types of provincial administrative procedures [21]. The dataset has 560 questions labelled as five primary categories and 270 sub-categories. The main categories and their corresponding number of subcategories are listed in the Table 1. Table 2 shows the details our dataset for training and testing in Question Classification with ratio 8:2.

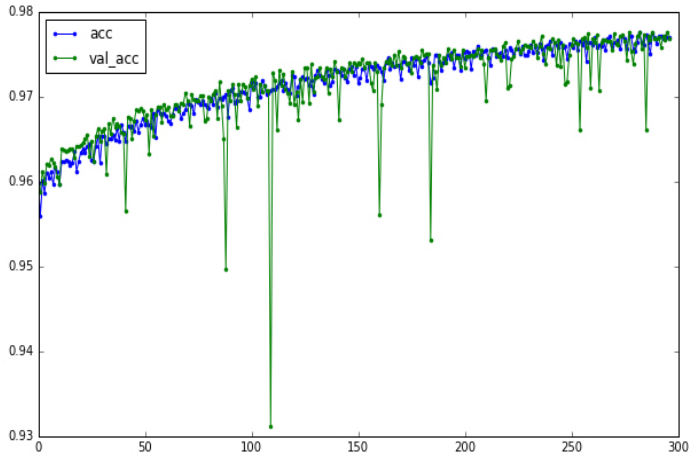

Figure 7: Accuracy of Diacritics Restoration task per epochs

Table 1: Describe of dataset of Question Classification

Categories	Number of Sub-Categories
Journalism	35
Postal	42
Broadcasting	84
Publishing	98
General Information	11

Table 2: Dataset of Question Classification

Name of Dataset	Number of Sentence
The set of questions	570
Sub- Categories	270
Train	456
Test	114

For pre-processing dataset, we used Pyvi (0.0.0.9 - Tran Viet Trung 2016) to tokenize Vietnamese, pre-train Vietnamese word embeddings by streetcodevn (Hung Le 2018). For our training models, we used Tensorflow and Keras libraries. The parameters of our question classification Bi-LSTM model are: Batch size: 500, number of hidden nodes: 128, Drop out: 0.2, epochs: 300, Sigmoid Activate function, Adam Optimization function and Binary cross entropy function. We evaluated performance of question classification by Accuracy of Question Classification (AQC) following below equation:

$$AQC = \frac{\#of\ correct\ predict\ questions}{\#of\ predict\ questions} \quad (13)$$

To evaluate our proposed model, we compared our results with the result of LSTM model separately as illustrated in Table 3. This

result reveals that our proposed model – the Bi-LSTM deep learning approach get the best results. From the result is shown in Table 3, it is obvious that the Bi-LSTM beats the LSTM model; therefore it could be said that the Bi-LSTM is the best-performing score comparing with the LSTM.

Table 3: The results of question classification

Model	AQC
LSTM	92%
Bi-LSTM	**95%**

We made an application by integrating the automated question answering systems into Binh Duong Department of Information and Communications Support System. The name of this application is ICTbot. The ICTbot is used to support Binh Duong Department of Information and Communications in General Information and four management categories: Journalism, Postal, Broadcasting and Publishing. The ICTbot allows users to input new questions and the result is the answers that have the highest accuracy of question classification. Figure 8 shows the ICTbot application.

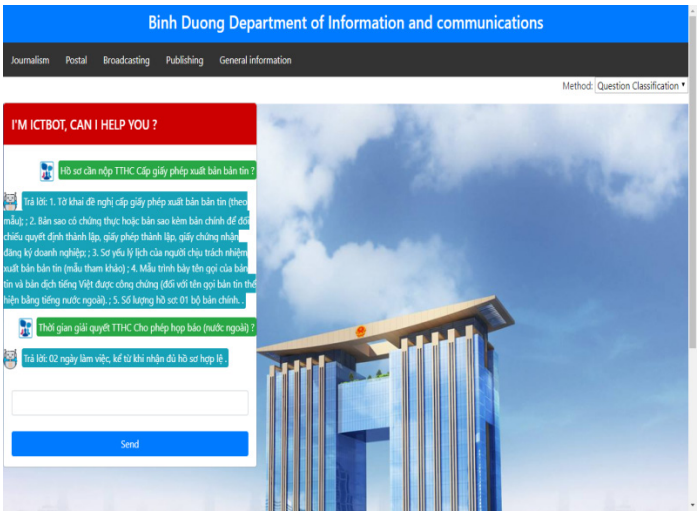

Figure 8: The ICTbot of Binh Duong Department of Information and Communications Support System.

Table 4: The results of question classification in different percentage of Accuracy of Diacritics Restoration

Percentage of Accuracy of Diacritics Restoration	AQC
>= 90%	95%
<= 75 and <90%	70% - 94%
<= 50 and <75%	48% - 69%
<= 25 and <50%	20% -47%
<25%	0-19%

To evaluate the differences in integrating diacritics restoration into question classification, we applied diacritics restoration by percentage into question classification. We counted the number of restoration words in test question dataset and integrated diacritics restoration in test question dataset by percentage of Accuracy of Diacritics Restoration. When percentage of diacritics restoration is equal or larger than 75%, question classification worked well, however when the percentage was so small question classification didn't work well or made a false label of the predict question. The result also depends on the length of question test. Table 4 reveals the result in different percentage of Accuracy of Diacritics Restoration. As a result, it could be seen that integrating diacritics restoration into question classification improves the accuracy of the system.

5. Conclusion

In this paper, we experimented our model by integrating diacritics restoration and question classification into Vietnamese question answering system. The result of the first step will be the input of question classification. It could be said that this is the first research integrating two phases into Vietnamese question answering system. We used the Encoder-Decoder LSTM model for Vietnamese diacritics restoration and the Bidirectional LSTM model for Vietnamese question classification. Our experiments proved that integrating diacritics restoration improves question classification. We also built a useful application based on Question classification – ICTbot and integrated in Binh Duong Department of Information and Communications Support System. In the future, we are looking to apply other deep learning approach and explore more features to improve the results.

ABSTRACT

Pursuit Evasion Game (PEG) is an abstract model of various significant problems that appear in both civil and military applications. Bio- Inspired strategies are found to be very useful in studying the PEG. While optimal response to the pursuit strategies are available using geometric control theory, it is shown in this paper that application of linear feedback control laws can further improve the time and tracking response of these strategies in capturing the evader by the pursuer. Empirical results based on computer simulation are used to illustrate the findings. Further, considering the case of sudden turn of the evader, moving at a lower speed, it is shown that both in theory and simulation that the evader can delay the capture by pursuer and in some cases even escape from being captured. These findings are in line with what is found in nature.

1. Introduction

Pursuit evasion game (PEG) is widely prevalent in nature. It is a game that is considered to be between the pursuer and an evader. PEG can be observed among animals when they chase a victim or when they battle for territory and even when they mate. In the context of engineering, PEG finds application in missile guidance and avoidance, aircraft pursuit and evasion, maritime asset protection etc.[1].

Initial study of PEG was mainly from the point of view of game theory [2]. PEG was further studied from the point of view of geometric control theory in [3]. Pursuit manifold is defined in terms of certain criteria involving relative distance and relative velocity between the pursuer and the evader. Using a control law which enables the pursuer to reach the pursuit manifold in an optimum way and keeping the pursuit invariant on the manifold, [3] studied three strategies found in nature, viz., motion camouflage (CM), constant bearing (CB) and classical pursuit (CP). The objective of the work reported in [3] is to find a justification for the prevalent use of CM in PEG in nature. It turned out that, keeping the speed of the pursuer and the evader constant and ensuring that the pursuer moves faster than the evader, [3] has been able to show through evolutionary games that CB and CP strategies always converge to CM strategy under certain fixed assumptions on evader motion thus supporting what is seen in nature.

However, Pais [4] has argued that if the evader control law is reactive (i.e. it is in some way dependent on the baseline vector joining the pursuer and evader locations and its rate of change), then the conclusions in [3] might not hold good. Wei [5] has dropped the constant speed assumption of both the pursuer and evader and allowed the pursuer to change its acceleration as required. Wei also introduced the case of victim turning suddenly left or right when the pursuer comes too close to the evader. A related problem to PEG of confinement and escape is addressed in [6].

Our aim in this paper is this. Considering PEG of a robotic pursuit of an enemy agent, can we consider the problem as a feedback control problem introducing proportional (P),proportional plus integral (PI) and proportional plus integral plus derivative (PID) laws to improve the performance of the pursuer? The performance can be studied under different bio-inspired pursuit strategies, such as CM, CB and CP. The evader may be allowed to follow reactive and non- reactive control laws. A simpler version of this study for the CM case only has been reported earlier in [7]. Further, in view of the increased agility of the evader (i.e. ability to turn at a lower speed compared to the pursuer), we ask what is the outcome of the PEG given the chance

*Corresponding Author: Lairenjam Obiroy Singh, obi3925@gmail.com

that evader makes a sudden 90 degree turn left or right? This paper is a much expanded version of [8] especially in regard to the sudden turn strategy of the evader.

Bopardikar [9] has shown the Bio- inspired co-operative strategies of pursuer for successful confinement of evader. [9] gives the required number of pursuers and speed ratio for guaranteed confinement strategy. X Liang and Y Xiao [10] show the coalition formation of robots for intrusion detection by using the game theory approach. The paper is based on the nature's coalition formation such as predator trying to catch the prey. An analytical method is used to study the tradeoff of coalition or collaboration between the robots.

Initial study of camouflage strategies [11,12] are considered when either pursuer or evader is stationary. Srinivasan [13] analyzed and investigated the motion camouflage and highlighted many ways for future extension. The authors of [14] study the unmanned surface vehicles (USVs) for performing patrolling operations and detecting intruders for harbor protection with a view to reducing the number of humans exposed to threat. An intelligent swarm management unit (SMU) is used for the supervision of all the USVs in operation. A real time motion planner for the USVs in the presence of multiple obstacles is also presented.

[15] addresses the problem associated with the classical pursuit evasion games and mentions that their study is more difficult than the classical one. The author of [15] also explored the geometry of the problem by obtaining sufficient conditions for both pursuer and evader to win. A max- min problem is formulated, from the pursuers point of view, which is solved using outer approximation method. The solution of the max- min formulation is used to synthesize a feedback solution governing the pursuer's behavior in the form of receding horizon control. [16] discusses a harbor defense situation and the author highlights the important features where the problem is different from the classical PEG.

The main contribution of the paper can be summarized as follows: (i) PI and PID feedback laws are shown to enable the pursuer to capture the evader in a shorter time compared to P alone for different conditions of the evader following non-reactive and reactive control laws. (ii) The PI, PID feedback laws followed by the pursuer enable him to capture the evader and not allow him to escape contrary to the the case of P alone. This is termed tracking performance of the pursuer (iii) In the case the evader uses his agility to turn 90 degree left or right suddenly with respect to the baseline, it is shown that the time to capture the evader can be delayed when the pursuer follows any of the CM, CB and CP strategies. (iv) It is also shown that in certain cases of CB followed by pursuer, with the evader following the sudden turn strategy, the evader is able to totally escape from the pursuer inspite of the speed advantage enjoyed by the pursuer.

The rest of the paper is organized as follows: The following section gives the required background on modeling of PEG and the pursuit manifolds under different strategies. Section 3 presents the feedback control system configuration considered together with the derivation of expressions for PI and PID for the three strategies. Also provided in section 3 is an analysis of the effect of sudden turn of the evader in respect of the CM, CB and CP strategies of the pursuer. Section 4 gives the simulation results together with the discussion on the comparative performance of the different control strategies as well as different control modes of the evader. Section 5 concludes the paper.

2. Background

Wei and Krishnaprasad [17], [18] model the interaction in pursuit in terms of gyroscopically interacting particles. We follow a similar approach.

$$\dot{r}_p = x_p\,,\ \dot{x}_p = y_p u_{pr}\,,\ \dot{y}_p = -x_p u_{pr} \qquad (1)$$

where $r_p \in \mathbb{R}^2$is the position of the pursuer, x_p its velocity and y_p is the acceleration of the pursuer. The steering control of the pursuer is given by the scalar u_{pr}. The motion of the evader (with speed υ) is given by

$$\dot{r}_e = \upsilon x_e\,,\ \dot{x}_e = \upsilon y_e u_e\,,\ \dot{y}_e = -\upsilon x_e u_e \qquad (2)$$

where $r_e \in \mathbb{R}^2$ is the position, x_e is the velocity and y_e is the acceleration of the evader. The steering control of the evader, u_e, is a scalar. We also define

$$r = r_p - r_e \qquad (3)$$

which is referred to as the 'baseline' between the pursuer and the evader.

2.1. Pursuit manifolds and cost functions

Two particle pursuer evader system is described in the Euclidean plane of two dimensions. We define the cost functions F on the pursuit manifold $G \in \mathbb{R}^2$ as $F: G \times G \to \mathbb{R}$ associated with different pursuit strategies as in [4] as follows where $(\cdot)$ represents the dot product between two unit vectors and $|\cdot|$ stands for the Euclidean norm.

$$\Gamma = \left(\frac{r}{|r|}.\frac{\dot{r}}{|\dot{r}|}\right) = \frac{\frac{d|r|}{dt}}{\left|\frac{dr}{dt}\right|} \text{ (motion camouflage)} \qquad (4)$$

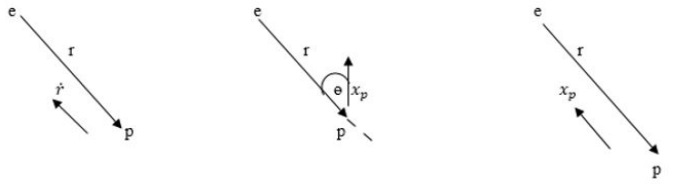
and

$$\Lambda = \left(\frac{r}{|r|}\ .\ R\ x_p\right) \text{(constant bearing)} \qquad (5)$$

where

$$R = \begin{bmatrix} cos\theta & -sin\theta \\ sin\theta & cos\theta \end{bmatrix}, \qquad (6)$$

for $\theta \in (-\pi/2, \pi/2)$.



For $R = I_2$ the identity matrix of order 2, we define

$$\Lambda_0 = \left(\frac{r}{|r|}\ .\ x_p\right) \qquad (7)$$

to be the cost function associated with classical pursuit.

All three cost functions Γ, Λ and Λ_0 are well defined and that they take values in the interval [-1,1]. The cost functions Γ, Λ and

Λ_0 define the respective pursuit manifolds. Γ is seen to correspond to the cosine of the angle between r and $\dot{r}$. Camouflage pursuit manifold is defined by the condition $\Gamma = -1$, which corresponds to the case of the angle between r and $\dot{r}$ being π. (see Figure 1(a)).

(a) (b) (c)

Figure. 1 Geometric representation of pursuit manifolds: (a) motion camouflage (CM) pursuit, (b) constant bearing (CB) pursuit and (c) classical pursuit (CP).

The constant bearing pursuit manifold is represented by the condition $\Lambda = -1$. This condition is satisfied when the heading of the pursuer makes an angle θ with the baseline vector (as shown in Figure 1(b)). Similarly, the classical pursuit manifold is defined by the condition $\Lambda_0 = -1$. This condition is satisfied when the heading of the pursuer is aligned (in opposite direction) with the baseline (see Figure 1 (c)).

3. System Modelling

3.1. Pursuit-Evasion system

Representing

$$r_p = [r_{px}\ r_{py}]^t$$

$$r_e = [r_{ex}\ r_{ey}]^t$$

we write (1) and (2) in terms of state equations as follows:

$$\left.\begin{array}{ll} x_1 = r_{px}; & x_7 = r_{ex}; \\ x_2 = r_{py}; & x_8 = r_{ey}; \\ x_3 = x_{px}; & x_9 = x_{ex}; \\ x_4 = x_{py}; & x_{10} = x_{ey}; \\ x_5 = y_{px}; & x_{11} = y_{ex}; \\ x_6 = y_{py}; & x_{12} = y_{ey}; \end{array}\right\} \quad (8)$$

$$\left.\begin{array}{c} \dot{x}_1 = \dot{r}_{px} = x_{px} = x_3 \\ \dot{x}_2 = \dot{r}_{py} = x_{py} = x_4 \\ \dot{x}_3 = \dot{x}_{px} = y_{px}u_{pr} = x_5u_{pr} \\ \dot{x}_4 = \dot{x}_{py} = y_{py}u_{pr} = x_6u_{pr} \\ \dot{x}_5 = -\dot{y}_{px} = -x_{px}u_{pr} = -x_3u_{pr} \\ \dot{x}_6 = -\dot{y}_{py} = -x_{py}u_{pr} = -x_4u_{pr} \\ \dot{x}_7 = \upsilon\dot{r}_{ex} = \upsilon x_{ex} = \upsilon x_9 \\ \dot{x}_8 = \upsilon\dot{r}_{ey} = \upsilon x_{ey} = \upsilon x_{10} \\ \dot{x}_9 = \upsilon\dot{x}_{ex} = \upsilon y_{ex}u_e = \upsilon x_{11}u_e \\ \dot{x}_{10} = \upsilon\dot{x}_{ey} = \upsilon y_{ey}u_e = \upsilon x_{12}u_e \\ \dot{x}_{11} = -\upsilon\dot{y}_{ex} = -\upsilon x_{ex}u_e = -\upsilon x_9u_e \\ \dot{x}_{12} = -\upsilon\dot{y}_{ey} = -\upsilon x_{ey}u_e = -\upsilon x_{10}u_e \end{array}\right\} \quad (9)$$

$$r = r_p - r_e = \begin{bmatrix} x_1 \\ x_2 \end{bmatrix} - \begin{bmatrix} x_7 \\ x_8 \end{bmatrix} = \begin{bmatrix} x_1 - x_7 \\ x_2 - x_8 \end{bmatrix} \quad (10)$$

$$\dot{r} = \dot{r}_p - \dot{r}_e = \begin{bmatrix} \dot{x}_1 \\ \dot{x}_2 \end{bmatrix} - \begin{bmatrix} \dot{x}_7 \\ \dot{x}_8 \end{bmatrix} = \begin{bmatrix} x_3 \\ x_4 \end{bmatrix} - \upsilon \begin{bmatrix} x_9 \\ x_{10} \end{bmatrix} \quad (11)$$

3.2. Feedback Laws.

In this sub-section, we formulate the pursuit strategies in terms of feedback control laws. The maintenance of the cost function Γ, Λ and Λ_0 associated with a strategy at the reference value of -1 on the respective manifold is represented in the form of a feedback control system as shown in figure 2. u_{pr} will take expresson for proportional control as u_p, for proportional integral control as u_{pi} and for proportional, integral and derivative control as u_{pid}.

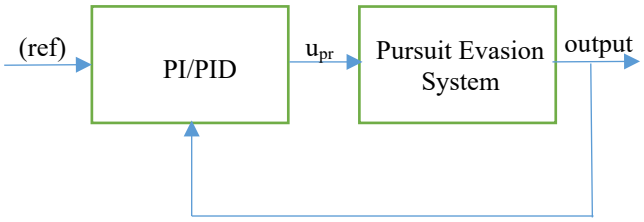


Figure. 2 Manifold Control

3.2.1. Feedback Laws for CM.

Using the results of [4] the feedback control law is defined as

$$u_p = -\mu_1 \langle \frac{r}{|r|} . \dot{r}^{\perp} \rangle \quad (12)$$

where $\langle\cdot\rangle$ represents the dot product of two vectors and $x^{\perp}$ is defined as the vector x rotated counter- clockwise in the plane by an angle $\frac{\pi}{2}$. In terms of the system model, (12) can be put as

$$u_p = -\mu_1 \langle \left[\frac{(x_1 - x_7, x_2 - x_8)}{\sqrt{(x_1 - x_7)^2 + (x_2 - x_8)^2}} \right] . [(\upsilon x_{10} - x_4), (x_3 - \upsilon x_9)] \rangle \quad (13)$$

where μ_1 is the proportional (P) setting of the controller.

Proposition 1:

Using (13) under CM, PI and PID control laws can be derived as

$$u_{pi} = -\mu_1 \langle \frac{r}{|r|} . \dot{r}^{\perp} \rangle - \mu_2 \int \langle \frac{r}{|r|} . \dot{r}^{\perp} \rangle \, dt$$

$$= -\mu_1 \langle \left[\frac{(x_1 - x_7, x_2 - x_8)}{\sqrt{(x_1 - x_7)^2 + (x_2 - x_8)^2}} \right] . [(\upsilon x_{10} - x_4), (x_3 - \upsilon x_9)] \rangle - \mu_2 \int \langle \left[\frac{(x_1 - x_7, x_2 - x_8)}{\sqrt{(x_1 - x_7)^2 + (x_2 - x_8)^2}} \right] . [(\upsilon x_{10} - x_4), (x_3 - \upsilon x_9)] \rangle \, dt \quad (14)$$

where μ_2 is the Integral (I) setting of the controller.

$$u_{pid} = -\mu_1 \langle \frac{r}{|r|} . \dot{r}^{\perp} \rangle - \mu_2 \int \langle \frac{r}{|r|} . \dot{r}^{\perp} \rangle \, dt - \mu_3 \frac{d}{dt} \langle \frac{r}{|r|} . \dot{r}^{\perp} \rangle$$

$$= -\mu_1 \langle \left[\frac{(x_1 - x_7, x_2 - x_8)}{\sqrt{(x_1 - x_7)^2 + (x_2 - x_8)^2}} \right] . [(\upsilon x_{10} - x_4), (x_3 - \upsilon x_9)] \rangle - \mu_2 \int \langle \left[\frac{(x_1 - x_7, x_2 - x_8)}{\sqrt{(x_1 - x_7)^2 + (x_2 - x_8)^2}} \right] . [(\upsilon x_{10} - x_4), (x_3 - \upsilon x_9)] \rangle \, dt$$

$$- \mu_3 \langle \left[\frac{(x_1 - x_7, x_2 - x_8)}{\sqrt{(x_1 - x_7)^2 + (x_2 - x_8)^2}} \right] . [(\upsilon^2 x_{12}\, u_e, -\upsilon^2 x_{11} u_e)] \rangle \quad (15)$$

where μ_3 is the derivative (D) setting of the controller.

Proof: - see Appendix 1

3.2.2. Feedback Laws for CB.

Considering CB, the expressions for the control law is given as follows.

$$u_p = -\mu_1 \left[\eta \langle \frac{r}{|r|}.Ry_p\rangle + \frac{1}{|r|}\langle \frac{r}{|r|}.\dot{r}^{\perp}\rangle\right] \quad (16)$$

In terms of system model, (16) can be put as

$$u_p = -\mu_1(\eta \langle \frac{(x_1-x_7, x_2-x_8)}{\sqrt{(x_1-x_7)^2+(x_2-x_8)^2}}.R(x_5,x_6)^t\rangle + \frac{1}{\sqrt{(x_1-x_7)^2+(x_2-x_8)^2}}\langle \frac{(x_1-x_7, x_2-x_8)}{\sqrt{(x_1-x_7)^2+(x_2-x_8)^2}}.(\upsilon x_{10} - x_4), (x_3 - \upsilon x_9)\rangle) \quad (17)$$

Proposition 2:

For CB the control laws for PI and PID can be expressed as follows.

$$u_{pi} = -\mu_1\left[\eta \langle \frac{r}{|r|}.Ry_p\rangle + \frac{1}{|r|}\langle \frac{r}{|r|}.\dot{r}^{\perp}\rangle\right] - \mu_2 \int \left[\eta \langle \frac{r}{|r|}.Ry_p\rangle + \frac{1}{|r|}\langle \frac{r}{|r|}.\dot{r}^{\perp}\rangle\right] dt$$

$$= -\mu_1(\eta \langle \frac{(x_1-x_7, x_2-x_8)}{\sqrt{(x_1-x_7)^2+(x_2-x_8)^2}}.R(x_5,x_6)^t\rangle + \frac{1}{\sqrt{(x_1-x_7)^2+(x_2-x_8)^2}}\langle \frac{(x_1-x_7, x_2-x_8)}{\sqrt{(x_1-x_7)^2+(x_2-x_8)^2}}.(\upsilon x_{10} - x_4), (x_3 - \upsilon x_9)\rangle) - \mu_2 \int (\eta \langle \frac{(x_1-x_7, x_2-x_8)}{\sqrt{(x_1-x_7)^2+(x_2-x_8)^2}}.R(x_5,x_6)^t\rangle + \frac{1}{\sqrt{(x_1-x_7)^2+(x_2-x_8)^2}}\langle \frac{(x_1-x_7, x_2-x_8)}{\sqrt{(x_1-x_7)^2+(x_2-x_8)^2}}.(\upsilon x_{10} - x_4), (x_3 - \upsilon x_9)\rangle)dt \quad (18)$$

$$u_{pid} = -\mu_1\left[\eta \langle \frac{r}{|r|}.Ry_p\rangle + \frac{1}{|r|}\langle \frac{r}{|r|}.\dot{r}^{\perp}\rangle\right] - \mu_2 \int \left[\eta \langle \frac{r}{|r|}.Ry_p\rangle + \frac{1}{|r|}\langle \frac{r}{|r|}.\dot{r}^{\perp}\rangle\right] dt - \mu_3 \frac{d}{dt}\left(\left[\eta \langle \frac{r}{|r|}.Ry_p\rangle + \frac{1}{|r|}\langle \frac{r}{|r|}.\dot{r}^{\perp}\rangle\right]\right)$$

$$= -\mu_1(\eta \langle \frac{(x_1-x_7, x_2-x_8)}{\sqrt{(x_1-x_7)^2+(x_2-x_8)^2}}.R(x_5,x_6)^t\rangle + \frac{1}{\sqrt{(x_1-x_7)^2+(x_2-x_8)^2}}\langle \frac{(x_1-x_7, x_2-x_8)}{\sqrt{(x_1-x_7)^2+(x_2-x_8)^2}}.(\upsilon x_{10} - x_4), (x_3 - \upsilon x_9)\rangle) - \mu_2 \int (\eta \langle \frac{(x_1-x_7, x_2-x_8)}{\sqrt{(x_1-x_7)^2+(x_2-x_8)^2}}.R(x_5,x_6)^t\rangle + \frac{1}{\sqrt{(x_1-x_7)^2+(x_2-x_8)^2}}\langle \frac{(x_1-x_7, x_2-x_8)}{\sqrt{(x_1-x_7)^2+(x_2-x_8)^2}}.(\upsilon x_{10} - x_4), (x_3 - \upsilon x_9)\rangle)dt - \mu_3\{(((x_3 - \upsilon x_9)\frac{1}{\sqrt{(x_1-x_7)^2+(x_2-x_8)^2}} - (x_1 - x_7)\frac{1}{\left(\sqrt{(x_1-x_7)^2+(x_2-x_8)^2}\right)^3}((x_1-x_7)(x_3-\upsilon x_9) + (x_2-x_8)(x_4 - \upsilon x_{10})), ((x_4 - \upsilon x_{10})\frac{1}{\sqrt{(x_1-x_7)^2+(x_2-x_8)^2}} - (x_2 - x_8)\frac{1}{\left(\sqrt{(x_1-x_7)^2+(x_2-x_8)^2}\right)^3}((x_1-x_7)(x_3-\upsilon x_9) + (x_2-x_8)(x_4 - \upsilon x_{10})).R(x_5,x_6)^t\rangle) + \frac{1}{\sqrt{(x_1-x_7)^2+(x_2-x_8)^2}}\langle \frac{(x_1-x_7, x_2-x_8)}{\sqrt{(x_1-x_7)^2+(x_2-x_8)^2}}, (\upsilon^2 x_{12}u_e, -\upsilon^2 x_{11}u_e)\rangle + \left\{-((x_1-x_7)^2+(x_2-x_8)^2)^{\frac{-3}{2}}((x_1-x_7)(x_3-\upsilon x_9) + (x_2-x_8)(x_4-\upsilon x_{10}))\right\}.\langle \frac{(x_1-x_7, x_2-x_8)}{\sqrt{(x_1-x_7)^2+(x_2-x_8)^2}}.(\upsilon x_{10} - x_4, x_3 - \upsilon x_9)\rangle \quad (19)$$

Proof: - See Appendix 2

3.2.3 Feedback Laws for CP.

Considering CP, the expressions for PI and PID control laws derived under proposition 2 are valid with $R = I_2$.

3.3 Control law for the Evader.

For the evader the steering control common to (CM, CB and CP of pursuer) can be as follows.

$$u_e = \cos t \quad \text{(prescribed)} \quad (20)$$

$$u_e = \langle \frac{r}{|r|}.\dot{r}_e^{\perp}\rangle \quad \text{(reactive)}$$
$$= \langle \left[\frac{(x_1-x_7, x_2-x_8)}{\sqrt{(x_1-x_7)^2+(x_2-x_8)^2}}\right].[(-x_{10}, x_9)]\rangle \quad (21)$$

$$u_e = \langle r.\dot{r}_e\rangle \quad \text{(sudden turn)}$$
$$= \langle \left[\frac{(x_1-x_7, x_2-x_8)}{\sqrt{(x_1-x_7)^2+(x_2-x_8)^2}}\right].[x_3 - \vartheta x_9, x_4 - \vartheta x_{10}]\rangle \quad (22)$$

3.3.1 Sudden Turn of evader

Sudden turn is followed by the evader when the baseline length is shorter than a threshold. The sharp turn is again prevalent in nature where the reduced speed of the evader (victim) compared to that of the predator gives the evader the advantage of agility which enables him to turn sharply trying to escape from the pursuer. The choice of abandoning the other steering laws in favour of the sudden 90-degree turn is taken once the baseline length between the pursuer and evader is perceived to be below a certain threshold. We show below the property that once the evader takes a sudden 90 degree turn with respect to the baseline, he continues to do so in all subsequent moves since the baseline distance between the pursuer and the evader continues to be below the threshold. The property is stated and proved next for the three cases of pursuer strategy, viz, CM, CB and CP.

3.3.1.1 CM

Proposition 3:

Referring the initial baseline between the pursuer and evader as r and after a tangential move for a time dt, the baseline is denoted as r'. Assuming that the pursuer follows the CM strategy it follows that $|r'| \leq |r|$.

Proof: - See Appendix 3.

Table. 1 Time to reach $|r| = 0$ and $\Gamma = -1$ for different combinations of $P(\mu_1), I(\mu_2), D(\mu_3)$ for different initial values of r_p and x_p for CM.

3.3.1.2 CB

Proposition 4:

For the case of CB, considering the instantaneous case of sudden turn of 90 degrees left or right by the evader, with the pursuer following the CB law under two cases.

where *r* and *r'* are the baseline vectors initially and after the lapse of an infinitesimal time respectively.

and (ii) $\emptyset < \frac{\pi}{2}$, it follows that

$$|r| = |r'|$$

if

$$\left(\frac{\vartheta}{p} + \sin\emptyset\right)^2 + (\cos\emptyset)^2 = \frac{2|r|\cos\emptyset}{p\,dt}$$

where dt is the instantaneous period of the step considered. ϑ and p are the velocities of the evader and the pursuer respectively.

Proof: - See Appendix 4.

Remark 1: To illustrate the use of result of proposition 4(ii)

Assume, $k = \frac{|r|}{p\,dt}$.

When $\vartheta = 0.6, p = 1, |r| = 1, p\,dt = 0.1$,

$k = 10$. Then as per the result of proposition 4 (ii),

$$(0.6 + \sin\emptyset)^2 + (\cos\emptyset)^2 = 20\cos\emptyset$$

$$\emptyset \approx 82.65 \text{ degrees}$$

3.3.1.3 CP

Proposition 5:

Assume *r* and *r'* defined as in Proposition 3. When the evader takes a sudden turn left or right 90 degree, with pursuer following CP law case, it can be shown that

$$|r'| \leq |r|$$

Proof: - See Appendix 5.

4. Simulation Results.

4.1. Time response

4.1.1 Non-reactive case

In this section, we provide the results of simulation of the dynamic equations given in section 3 and discuss the same. We assume u_e given by (20) corresponds to the non-reactive case of the evader. Tables 1-3 provide results obtained through computer, simulation of the pursuit evasion game for CM, CB and CP strategies respectively under P, PI and PID control. The first columns of Tables 1-3 provide the P, I and D gains used corresponding to μ_1, μ_2, μ_3 respectively. The next six columns correspond to different initial starting coordinates for r_p and x_p, r_e and x_e are assumed to be $(0,0)^t$ and $(1,0)^t$ respectively. The two sub- columns in Tables 1-3 correspond to time (t_r) to reach zero for the magnitude of r and the time (t_{mf}) to reach manifold characterized by $\Gamma = -1$, $\Lambda = -1$ and $\Lambda_0 = -1$ corresponding to CM, CB and CP strategies respectively for the first time. In Table 3, the blank cells correspond to the case of no significant results being obtained in the simulation.

It is seen in Table 1, corresponding to CM, that PI and PID laws tend to improve the performance of the pursuer compared to using P alone, which is the existing method. For example, comparing the rows corresponding to (1, 3, 0) and (1, 3, 3) against (1, 0, 0) in the first column, it is seen that t_r and t_{mf} are reduced in the case of PI and PID settings compared to P alone. This holds for all possible starting points considered. Similarly, it is seen in Table 2, corresponding to CB that PI and PID laws tend to improve on the performance of the pursuer compared to using P alone, which can be considered as the existing method. That is, t_r and t_{mf} are much reduced in the case of PI and PID settings compared to P alone. This holds for all possible starting points considered. Similarly, it is seen in Table 3, corresponding to CP, that PI and PID laws tend to improve the performance of the pursuer compared to using P alone, which is the existing method. That is, t_r and t_{mf} are much reduced in the case of PI and PID settings compared to P alone. This holds for all possible starting points considered.

Comparing the performance of CM, CB and CP under feedback laws, the initial condition column (1, 3, 5, 6) in Tables 1-3, show that the CM outperforms followed by CP and CB in terms of shorter t_r. In column 2 in Tables 1-3 the CP outperforms followed by CM and CB in terms of shorter t_r, and in column 4 in Tables 1-3 the CP outperforms followed by CM and CB in terms of shorter t_r. Similarly, in terms of shorter t_{mf} columns (1-4) in Tables 1-3, CM outperforms followed by CB and CP. For column 5 in Tables 1-3, CB outperforms followed by CM and CP in terms of shorter t_{mf}. For column 6 in Tables 1-3, CB outperforms followed by CP and CB in terms of shorter t_{mf}.

4.1.2 Reactive case

Simulation results of the dynamic equations given in section 3 by using u_e corresponding to (21) are given below.

It is shown in Tables 4-6, that PI/PID control (proposed) laws correspond to much shorter t_r and t_{mf} compared to P alone for the three strategies CM, CB and CP.

Comparison of the different strategies, under feedback laws, shows that in the column (1, 3, 6) in Tables 4-6 CM outperforms followed by CP and CB. In column (2, 4, 5) of Tables 4-6 CP outperforms followed by CM and CB in terms of shorter t_r. Similarly, in terms of shorter t_{mf} column (1, 4) in Tables 4-6 shows that CB outperforms followed by CM and CP. For column (2, 3) in Tables 4-6, CB outperforms followed by CP and CM in terms of t_r and t_{mf}. For column (5, 6) in Tables 4-6, CM outperforms followed by CB and CP in terms of t_r and t_{mf}. The controller setting of D is not included in Table 6 since no significant improvement is seen through simulation using derivative control.

4.1.3 Sudden Turn

Simulation results of the dynamic equations given in section 3 by using u_e corresponding to (22) are given below.

Tables 7-9 give the data of t_r and t_{mf} of CM, CB and CP strategies under sudden turn evader steering control laws. The empty cells in these tables mean insignificant value within the considered time frame. In CM strategies, we can see from Table 4 and Table 7 that by using sudden turn evader control laws, t_r and t_{mf} are much delayed (compare the first rows of Table 4 and

Table. 6 Time to reach $|r| = 0$ and $\Lambda_0 = -1$ for different combination of $P(\mu_1), I(\mu_2), D(\mu_3)$ for different initial values of r_p and x_p for CP.

Table 7) from using reactive or non-reactive evader control law for different initial conditions. In case of CB strategy, we can see from Table 5 and Table 8 that by using sudden turn evader control laws, evader escapes from the pursuer for all different initial conditions (compare the first rows of Table 5 and Table 8). This is a very significant result for the evader. For CP strategies, from Table 6 and Table 9, we can see that by using sudden turn evader control laws, capturing of evader is delayed for all initial conditions compared to the case when evader used reactive control law (compare the first rows of Table 6 and Table 9).

(b)

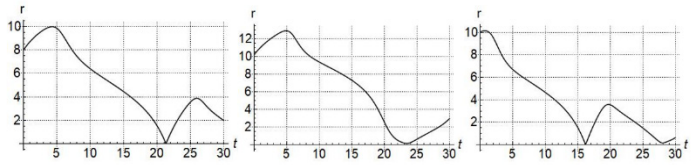
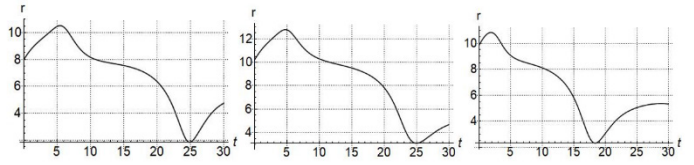
Figure. 4 r vs t plot for CB using (a) P and (b) PID.



(a)

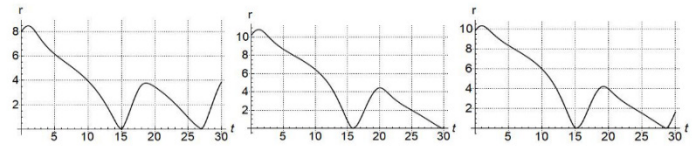
(b)

Figure. 5 r *vs* t plot for CP using (a) P and (b) PI.



4.2. Tracking response

Figures 3-4 show the response of the baseline magnitude $|r|(t)$ as function of time for different initial settings. When |r| becomes zero, it means the distance between pursuer and evader is zero, and hence the evader is captured. Figure 3(a) and Figure 4(a) correspond to P control while Figure 3(b) and Figure 4(b) corresponds to PID control. Similarly, for Figure 5(a) and Figure 5(b) correspond to P and PI respectively for different initial conditions. It is clearly seen from Figures 3-5 that tracking response of the zero line of the baseline magnitude (i.e. the zero line of the distance between the pursuer and evader) is clearly superior for PID/ PI control, compared to P alone (top rows in Figures 3-5). In fact, P alone is not able to track the zero-baseline magnitude at all. Note that the magnitude of baseline vector going to zero corresponds to evader being captured.

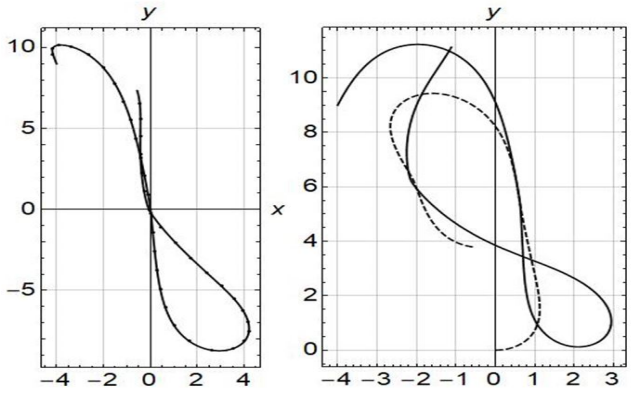


(a) (b) (c)

Figure. 6 r *vs* t plot for CM using sudden turn evader steering law.

(a) (b) (c)

Figure. 7 r *vs* t plot for CB using sudden turn evader steering law.

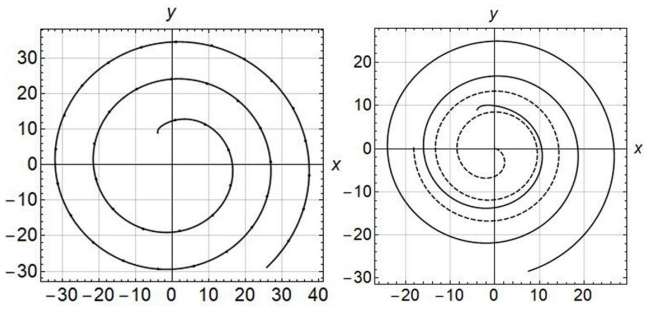


(a) (b) (c)

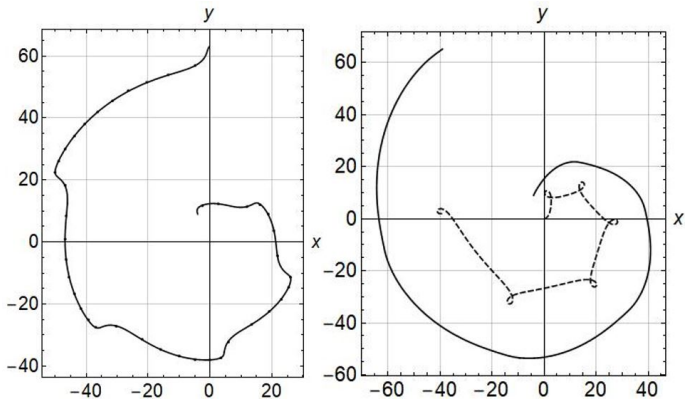
Figure. 8 r *vs* t plot for CP using sudden turn evader steering law.

Figures 6-8 show the response of the baseline magnitude $|r|(t)$ as function of time for different initial settings for CM, CB and CP strategies respectively. In Figure 6(a) represents the initial starting position of pursuer given as (0, 8) in x- y co-ordinate. 6(b) and 6(c) correspond to starting positions of (-2, 10) and (-4, 9) respectively. For the sake of comparison, (a), (b) and (c) in Figures 7 and 8 also correspond to the same respective starting positions. It is clearly seen from Figures 6-8 that the time to capture the evader by the pursuer is much delayed by using the sudden turn strategy compared to the case when evader used the reactive and non-reactive steering control laws. This can be seen by comparing Figure 3(a) with Figure 6, Figure 4(a) with Figure 7 and Figure 5(a) with Figure 8. In fact in Figure 4, $|r|(t)$ never reaches zero meaning that the evader is never captured in that case.

4.3. Trajectories of pursuer and evader.



We consider in this section, the actual trajectories followed by evader and pursuer.



(a) (b)

Figure. 9 For normal pursuer capture evader, (a) magnitude of r, (b) trajectories of pursuer (solid line) and evader (dashed line).

Figure 9 shows evader being captured in a certain time by the pursuer. Figure 9(a) shows the magnitude of r. Figure 9(b) shows the trajectories of pursuer and evader for a 30 sec timeline. The starting point of evader is (0, 0) in x-y coordinate and the starting point for the pursuer is (-4, 9). Figure 10 shows the case when the evader escapes from the pursuer. This happens only in the case of

(a) (b)

Figure. 11 For $\emptyset = 82.65°$, (a) magnitude of r, (b) trajectories of pursuer (solid line) and evader (dashed line).

CB strategies when evader suddenly turn 90 degree left or right as discussed in Proposition 4 case (i). So, in Figure 10 (a) the value of r keeps on increasing. Figure 10 (b) shows the trajectories of pursuer and evader in 30 sec timeline. Figure 11 is for the case when $\emptyset = 82.65°$ and the baseline distance between the pursuer and the evader tend to reach a constant value.

5. Conclusions

Pursuit evasion game (PEG) has been studied in the literatiure using geometric control theory. Control laws for the pursuer have been derived so as to make the pursuer follow a certain manifold according to the different bio-inspired strategies used. The performance of the pursuer control laws is specified in terms of time to capture the evader and tarcking of pursuer path on the manifold given certain fixed evader escape strategies Though the existing pursuer control laws are optimal, it is shown in the paper, through simulations, that adding integral and derivative actions to the pursuer control laws tends to improve the performance of the pursuer further independent of the strategy used. Towards that, the pursuer path tracking on the manifold is specified in terms of a feedback loop with the reference being the cost function of the manifold used. The proportional (P), proportional- integral (PI) and proportional- integral- derivative (PID) control laws are studied on the loop with the existing control law being considered as proportional law. Due to the noninear nature of control laws in a vector setting the derivation of PI and PID control laws are non-trivial.To mimic the nature further, a sudden turn strategy is assumed to be employed by the evader in view of evader's agility advantage while moving at a lower speed compared to the pusuer. The dynamics of the PEG with the sudden turn strategy of the evader has been studied through a theoretical analysis supported by simulation. It is shown that the sudden turn strategy can help the evader delay the capture by the pursuer and in a certain case the evader can even totally excape from the pursuer. As a future work, one could consider the case when the evader moves at a varying speed (instead of the constant speed assumed in the paper) as in commonly seen in nature.

Appendix 1:

Proof of Proposition 1

P and PI control:

u_p *and* u_{pi} are the control output of P and PI controller derived as given in the proposition in a straightforward way.

PID Control output u_{pid} can be derived as follows.

$$u_{pid} = -\mu_1 \langle \frac{r}{|r|} . \dot{r}^{\perp} \rangle - \mu_2 \int \langle \frac{r}{|r|} . \dot{r}^{\perp} \rangle \, dt - \mu_3 \frac{d}{dt} \langle \frac{r}{|r|} . \dot{r}^{\perp} \rangle$$

$$= -\mu_1 \langle \left[\frac{(x_1 - x_7, x_2 - x_8)}{\sqrt{(x_1 - x_7)^2 + (x_2 - x_8)^2}} \right] . [(\upsilon x_{10} - x_4), (x_3 - \upsilon x_9)] \rangle -$$

$$\mu_2 \int \langle \left[\frac{(x_1 - x_7, x_2 - x_8)}{\sqrt{(x_1 - x_7)^2 + (x_2 - x_8)^2}} \right] . [(\upsilon x_{10} - x_4), (x_3 - \upsilon x_9)] \rangle \, dt$$

$$-\mu_3 \frac{d}{dt} \langle \left[\frac{(x_1 - x_7, x_2 - x_8)}{\sqrt{(x_1 - x_7)^2 + (x_2 - x_8)^2}} \right] . [(\upsilon x_{10} - x_4), (x_3 - \upsilon x_9)] \rangle$$

Using the identity

$$\frac{d}{dt} \langle \alpha, \beta \rangle = \langle \dot{\alpha}, \beta \rangle + \langle \alpha, \dot{\beta} \rangle \tag{A.1}$$

put

$$\alpha = \frac{r}{|r|} \text{ and } \beta = \dot{r}^{\perp}$$

that is,

$$\alpha = \left[\frac{(x_1 - x_7, x_2 - x_8)}{\sqrt{(x_1 - x_7)^2 + (x_2 - x_8)^2}} \right] \text{ and } \beta = [(\upsilon x_{10} - x_4), (x_3 - \upsilon x_9)]$$

Considering equation (A.1), since

$\dot{\alpha} = \frac{\dot{r}}{|\dot{r}|}$ is orthogonal to $\beta = \dot{r}^{\perp}$

the first term of R.H.S of equation (A.1) is zero.

Now

$$\beta = [(\upsilon x_{10} - x_4), (x_3 - \upsilon x_9)]$$

from which

$$\dot{\beta} = [(\upsilon \dot{x}_{10} - \dot{x}_4), (\dot{x}_3 - \upsilon \dot{x}_9)]$$

that is,

$$\dot{\beta} = \left[\left(\upsilon^2 x_{12} u_e - x_6 u_p \right), \left(x_5 u_p - \upsilon^2 x_{11} u_e \right) \right]$$

using (9).

Approximating the term $\dot{\beta}$ as $\hat{\dot{\beta}}$ by neglecting the term associated with u_p,

$$\hat{\dot{\beta}} = [\upsilon^2 x_{12} u_e, -\upsilon^2 x_{11} u_e]$$

Therefore, equation (A.1) becomes

$$\frac{d}{dt} \langle \alpha, \beta \rangle = \langle \alpha, \hat{\dot{\beta}} \rangle$$

$$\frac{d}{dt} \langle \frac{r}{|r|} . \dot{r}^{\perp} \rangle = \langle \left[\frac{(x_1 - x_7, x_2 - x_8)}{\sqrt{(x_1 - x_7)^2 + (x_2 - x_8)^2}} \right] . [(\upsilon^2 x_{12} u_e, -\upsilon^2 x_{11} u_e)] \rangle$$

Therefore

$$u_{pid} = -\mu_1 \langle \frac{r}{|r|} . \dot{r}^{\perp} \rangle - \mu_2 \int \langle \frac{r}{|r|} . \dot{r}^{\perp} \rangle \, dt - \mu_3 \frac{d}{dt} \langle \frac{r}{|r|} . \dot{r}^{\perp} \rangle$$

$$= -\mu_1 \langle \left[\frac{(x_1 - x_7, x_2 - x_8)}{\sqrt{(x_1 - x_7)^2 + (x_2 - x_8)^2}} \right] . [(\upsilon x_{10} - x_4), (x_3 - \upsilon x_9)] \rangle -$$

$$\mu_2 \int \langle \left[\frac{(x_1 - x_7, x_2 - x_8)}{\sqrt{(x_1 - x_7)^2 + (x_2 - x_8)^2}} \right] . [(\upsilon x_{10} - x_4), (x_3 - \upsilon x_9)] \rangle \, dt$$

$$-\mu_3 \langle \left[\frac{(x_1 - x_7, x_2 - x_8)}{\sqrt{(x_1 - x_7)^2 + (x_2 - x_8)^2}} \right] . [(\upsilon^2 x_{12} u_e, -\upsilon^2 x_{11} u_e)] \rangle$$

Hence the result.

Appendix 2:

Proof of Proposition 2:

P and PI control:

u_p *and* u_{pi} are easily derived as given in the proposition.

PID control:

$$u_{pid} = -\mu_1 \left[\eta \langle \frac{r}{|r|} . Ry_p \rangle + \frac{1}{|r|} \langle \frac{r}{|r|} . \dot{r}^{\perp} \rangle \right] - \mu_2 \int \left[\eta \langle \frac{r}{|r|} . Ry_p \rangle + \frac{1}{|r|} \langle \frac{r}{|r|} . \dot{r}^{\perp} \rangle \right] dt - \mu_3 \frac{d}{dt} \left(\left[\eta \langle \frac{r}{|r|} . Ry_p \rangle + \frac{1}{|r|} \langle \frac{r}{|r|} . \dot{r}^{\perp} \rangle \right] \right) \tag{A.2}$$

Using the identity

$$\frac{d}{dt} \langle \rho, \omega \rangle = \langle \dot{\rho}, \omega \rangle + \langle \rho, \dot{\omega} \rangle \tag{A.3}$$

$$\frac{d}{dt} (\gamma \sigma) = (\dot{\gamma} \sigma) + (\gamma \dot{\sigma}) \tag{A.4}$$

put

$$\rho = \frac{r}{|r|}, \omega = Ry_p, \gamma = \frac{1}{|r|} \text{ and } \sigma = \langle \frac{r}{|r|} . \dot{r}^{\perp} \rangle \tag{A.5}$$

Now

$$\dot{\rho} = \frac{d}{dt} \frac{r}{|r|} = \begin{bmatrix} \frac{d}{dt} \frac{r_x}{|r|} \\ \frac{d}{dt} \frac{r_y}{|r|} \end{bmatrix} = \begin{bmatrix} \frac{|r| \dot{r}_x - r_x \frac{d}{dt} |r|}{|r|^2} \\ \frac{|r| \dot{r}_y - r_y \frac{d}{dt} |r|}{|r|^2} \end{bmatrix}$$

$$\dot{\rho} = \begin{bmatrix} \frac{\dot{r}_x}{|r|} - \frac{r_x \frac{d}{dt} \sqrt{r_x^2 + r_y^2}}{|r|^2} \\ \frac{\dot{r}_y}{|r|} - \frac{r_y \frac{d}{dt} \sqrt{r_x^2 + r_y^2}}{|r|^2} \end{bmatrix} = \begin{bmatrix} \frac{\dot{r}_x}{|r|} - \frac{r_x (r_x \dot{r}_x + r_y \dot{r}_y)}{|r|^3} \\ \frac{\dot{r}_y}{|r|} - \frac{r_y (r_x \dot{r}_x + r_y \dot{r}_y)}{|r|^3} \end{bmatrix} \tag{A.6}$$

$$\dot{\omega} = \frac{d}{dt} Ry_p = R \begin{bmatrix} \frac{d}{dt} y_{px} \\ \frac{d}{dt} y_{py} \end{bmatrix} = R \begin{bmatrix} x_{px} u_p \\ x_{py} u_p \end{bmatrix} \tag{A.7}$$

$\dot{\omega}$ is neglected since it is associated with the term u_p.

Therefore,

$$\frac{d}{dt} \langle \rho, \omega \rangle = \langle \dot{\rho}, \omega \rangle$$

$$= \langle \begin{bmatrix} \frac{\dot{r}_x}{|r|} - \frac{r_x(r_x\dot{r}_x + r_y\dot{r}_y)}{|r|^3} \\ \frac{\dot{r}_y}{|r|} - \frac{r_y(r_x\dot{r}_x + r_y\dot{r}_y)}{|r|^3} \end{bmatrix}, R \begin{bmatrix} y_{px} \\ y_{py} \end{bmatrix} \rangle$$

$$= \langle \left(\frac{x_3 - \upsilon x_9}{\sqrt{(x_1 - x_7)^2 + (x_2 - x_8)^2}} - \frac{(x_1 - x_7)\big((x_1 - x_7)(x_3 - \upsilon x_9) + (x_2 - x_8)(x_4 - \upsilon x_{10})\big)}{\sqrt{(x_1 - x_7)^2 + (x_2 - x_8)^2}^3} \right), R(x_5, x_6) \rangle$$

using equations (10) and (11).

$$\dot{\gamma} = \frac{d}{dt}\frac{1}{|r|} = \frac{d}{dt}\left(\sqrt{r_x{}^2 + r_y{}^2}\right)^{-\frac{1}{2}}$$

$$= -\left(\sqrt{r_x{}^2 + r_y{}^2}\right)^{-3}\left(r_x\dot{r}_x + r_y\dot{r}_y\right) \qquad \text{(A.8)}$$

$$\dot{\sigma} = \frac{d}{dt}\langle\frac{r}{|r|}.\dot{r}^{\perp}\rangle = \langle\frac{\dot{r}}{|\dot{r}|}.\dot{r}^{\perp}\rangle + \langle\frac{r}{|r|}.\ddot{r}^{\perp}\rangle \qquad \text{(A.9)}$$

$\langle\frac{\dot{r}}{|\dot{r}|}.\dot{r}^{\perp}\rangle = 0$, since $\frac{\dot{r}}{|\dot{r}|}$ is orthogonal to $\dot{r}^{\perp}$

So,

$$\dot{\sigma} = \frac{d}{dt}\langle\frac{r}{|r|}.\dot{r}^{\perp}\rangle = \langle\frac{r}{|r|}.\ddot{r}^{\perp}\rangle$$

Now,

$$\ddot{r}^{\perp} = \frac{d}{dt}\dot{r}^{\perp} = \frac{d}{dt}[\upsilon x_{10} - x_4, x_3 - \upsilon x_9]$$

$$= [\upsilon\dot{x}_{10} - \dot{x}_4, \dot{x}_3 - \upsilon\dot{x}_9] = \left[\upsilon^2 x_{12}u_e - x_6 u_p, x_5 u_p - \upsilon^2 x_{11}u_e\right]$$

using (9).

Neglecting the term associated with u_p,

$$\ddot{r}^{\perp} = [\upsilon^2 x_{12}u_e, -\upsilon^2 x_{11}u_e] \qquad \text{(A.10)}$$

Therefore,

$$\dot{\sigma} = \langle\frac{r}{|r|}.(\upsilon^2 x_{12}u_e, -\upsilon^2 x_{11}u_e)\rangle \qquad \text{(A.11)}$$

Thus,

$$\frac{d}{dt}(\gamma\sigma) = (\dot{\gamma}\sigma) + (\gamma\dot{\sigma})$$

$$= \left\{-\left(\sqrt{r_x{}^2 + r_y{}^2}\right)^{-3}\left(r_x\dot{r}_x + r_y\dot{r}_y\right).\left(\frac{\dot{r}}{|\dot{r}|}.\dot{r}^{\perp}\right)\right\} + \frac{1}{|r|}.\langle\frac{r}{|r|}.(\upsilon^2 x_{12}u_e, -\upsilon^2 x_{11}u_e)\rangle$$

$$= \frac{1}{\sqrt{(x_1 - x_7)^2 + (x_2 - x_8)^2}} \langle\frac{(x_1 - x_7, x_2 - x_8)}{\sqrt{(x_1 - x_7)^2 + (x_2 - x_8)^2}}, (\upsilon^2 x_{12}u_e, -\upsilon^2 x_{11}u_e)\rangle$$

$$+ \left\{-((x_1 - x_7)^2 + (x_2 - x_8)^2)^{\frac{-3}{2}}\big((x_1 - x_7)(x_3 - \upsilon x_9) + (x_2 - x_8)(x_4 - \upsilon x_{10})\big)\right\}.\langle\frac{(x_1 - x_7, x_2 - x_8)}{\sqrt{(x_1 - x_7)^2 + (x_2 - x_8)^2}}.(\upsilon x_{10} - x_4, x_3 - \upsilon x_9)\rangle$$

Hence it follows that

$$u_{pid} = -\mu_1(\eta\,\langle\frac{(x_1 - x_7, x_2 - x_8)}{\sqrt{(x_1 - x_7)^2 + (x_2 - x_8)^2}}.R(x_5, x_6)^t\rangle + \frac{1}{\sqrt{(x_1 - x_7)^2 + (x_2 - x_8)^2}}\langle\frac{(x_1 - x_7, x_2 - x_8)}{\sqrt{(x_1 - x_7)^2 + (x_2 - x_8)^2}}.(\upsilon x_{10} - x_4), (x_3 - \upsilon x_9)\rangle) - \mu_2\int(\eta\,\langle\frac{(x_1 - x_7, x_2 - x_8)}{\sqrt{(x_1 - x_7)^2 + (x_2 - x_8)^2}}.R(x_5, x_6)^t\rangle + \frac{1}{\sqrt{(x_1 - x_7)^2 + (x_2 - x_8)^2}}\langle\frac{(x_1 - x_7, x_2 - x_8)}{\sqrt{(x_1 - x_7)^2 + (x_2 - x_8)^2}}.(\upsilon x_{10} - x_4), (x_3 - \upsilon x_9)\rangle)dt$$

$$-\mu_3\{(((x_3 - \upsilon x_9)\frac{1}{\sqrt{(x_1 - x_7)^2 + (x_2 - x_8)^2}} - (x_1 - x_7)\frac{1}{\left(\sqrt{(x_1 - x_7)^2 + (x_2 - x_8)^2}\right)^3}((x_1 - x_7)(x_3 - \upsilon x_9) + (x_2 - x_8)(x_4 - \upsilon x_{10}), ((x_4 - \upsilon x_{10})\frac{1}{\sqrt{(x_1 - x_7)^2 + (x_2 - x_8)^2}} - (x_2 - x_8)\frac{1}{\left(\sqrt{(x_1 - x_7)^2 + (x_2 - x_8)^2}\right)^3}\big((x_1 - x_7)(x_3 - \upsilon x_9) + (x_2 - x_8)(x_4 - \upsilon x_{10})\big).R(x_5, x_6)^t\rangle) + \frac{1}{\sqrt{(x_1 - x_7)^2 + (x_2 - x_8)^2}}\langle\frac{(x_1 - x_7, x_2 - x_8)}{\sqrt{(x_1 - x_7)^2 + (x_2 - x_8)^2}}, (\upsilon^2 x_{12}u_e, -\upsilon^2 x_{11}u_e)\rangle + \left\{-((x_1 - x_7)^2 + (x_2 - x_8)^2)^{\frac{-3}{2}}\big((x_1 - x_7)(x_3 - \upsilon x_9) + (x_2 - x_8)(x_4 - \upsilon x_{10})\big)\right\}.\langle\frac{(x_1 - x_7, x_2 - x_8)}{\sqrt{(x_1 - x_7)^2 + (x_2 - x_8)^2}}.(\upsilon x_{10} - x_4, x_3 - \upsilon x_9)\rangle$$

Hence the result.

Appendix 3:

Proof of proposition 3:

Referring to Figure 12, *r* is the initial baseline while *r'* is the baseline in the next step after a lapse of time dt. p and ϑ are the velocities of the pursuer and the evader respectively. The sudden turn with respect to the baseline at every move result in a motion by the evader in a tangential direction resulting in describing the arc 'ab' in Figure 12 by the evader for arbitrarily small dt. We then have

$$|r| = |r'| + p\,dt$$

with $p > 0$, $dt > 0$ and with $dt \to 0$, It follows that $|r'| \leq |r|$. Hence the result.

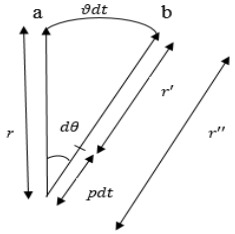

Figure. 12 Case of CM with sudden turn.

Appendix 4

Case (i):

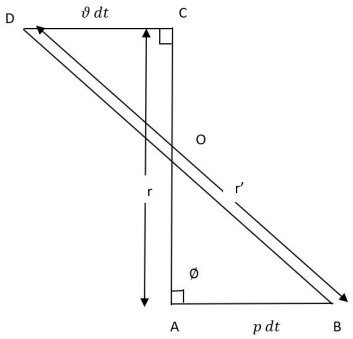

Figure. 13 Case of CB $\emptyset = \frac{\pi}{2}$ with sudden turn.

Figure 13 shows the initial baseline vector r between the pursuer (A) and evader (C). After an infinitesimally small time, with the evader taking the sudden turn of 90 degrees, let the position of evader and the pursuer be D and B respectively.

In right angle triangle AOB

$$OB > OA$$

Similarly, in right angle triangle COD

$$OD > OC$$

So,

$$OB + OD > OA + OC$$

$$|r'| > |r|$$

Case (ii):

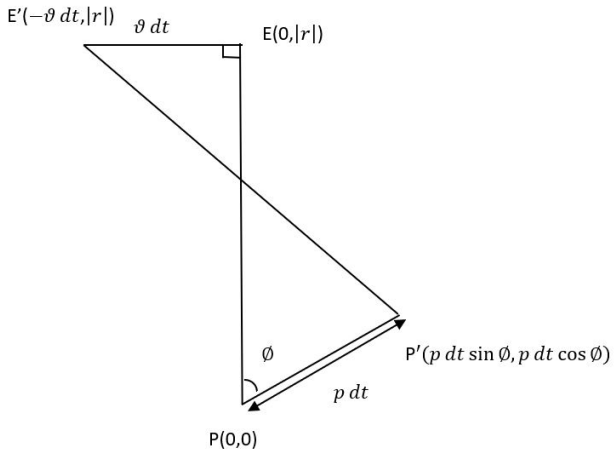

Figure. 14 Case of CB $\emptyset < \frac{\pi}{2}$ with sudden turn.

Figure 14 is redrawn from Figure 13 with $\emptyset < \frac{\pi}{2}$. Considering pursuer (P) as the origin, the coordinates of other points are easily derived. Point E denotes the evader. P' and E' are the positions of pursuer and the evader after a time dt. The baseline after time dt is given by vector

$$r' = (-\vartheta\, dt, |r|) - (pdt \sin \emptyset\,, pdt \cos \emptyset)$$

Now, to impose the condition that $|r'| = |r|$.

$$(-\vartheta\, dt - pdt \sin \emptyset)^2 + (|r| - pdt \cos \emptyset)^2 = |r|^2$$

$$\Rightarrow (\vartheta\, dt)^2 + (p\, dt)^2 (\sin \emptyset)^2 + 2\vartheta\, dt\, p\, dt \sin \emptyset + (p\, dt)^2 (\cos \emptyset)^2 - 2p\, |r| dt \cos \emptyset = 0$$

$$\Rightarrow \vartheta^2 + p^2 (\sin \emptyset)^2 + 2\vartheta p \sin \emptyset + p^2 (\cos \emptyset)^2 - \frac{2|r| p \cos \emptyset}{dt} = 0$$

$$\Rightarrow (\vartheta + p \sin \emptyset)^2 + p^2 (\cos \emptyset)^2 = \frac{2|r| p \cos \emptyset}{dt}$$

$$\Rightarrow \left(\frac{\vartheta}{p} + \sin \emptyset\right)^2 + (\cos \emptyset)^2 = \frac{2|r| \cos \emptyset}{p\, dt}$$

Hence the result.

Appendix 5:

Proof of Proposition 5:

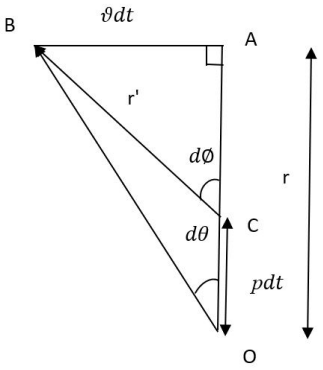

Figure. 15 Case of CP with sudden turn.

Figure 15 is similar to Figures 13 and 14 except that $\emptyset = 0$

Considering Figure 15,

$$\frac{\sin d\theta}{\sin d\emptyset} = \frac{CB}{OB} = \frac{|r'|}{\sqrt{|\vartheta\, dt|^2 + |r|^2}} \leq 1$$

$$\sqrt{|\vartheta\, dt|^2 + |r|^2} \geq |r'| \quad \forall\, dt$$

when $dt \to 0$

$$|r'| \leq |r|$$

Hence the result.

ABSTRACT

This paper presents the setup of eye tracking calibration methodology and the preliminary test results of the training model from the eye tracking data. Eye tracking requires good accuracy from the calibration process of the human eyes feature extraction from facial region. Viola-Jones algorithm is applied for this purpose by using Haar Basic feature filters based on Adaboost algorithm which extract the facial region from an image. From the extracted region, the eyes feature is selected to find the center coordinate of the iris and be mapped with the calibration point coordinates to create the training model of the eye calibration process. Thus, this paper shows the performance and efficiency of three training functions in Neural Network algorithm to get the best training model with fewer error for more efficient eye tracking calibration process.

1. Introduction

Human features which are once a very selective parameter has been widely applied as the main input for various research of vision. Detection and tracking of human features can improve the performance of system specifically such as security, safety and also human monitory. For eye tracking system, accurate detection of eyes feature extraction is important as it is the first information eye data and calibration process have to be done. Calibration is the process of measuring the eye gaze point calculation which recording the user's gaze before an eye tracking recording is started. For the calibration procedure to be achieve in good accuracy, good eye tracking method has to be applied. There are several types of the eye tracking such as electrography, scleral coil and the most popular method of video tracking. This paper is an extension of work originally presented in 2018 International Symposium on Agent, Multi-Agent Systems and Robotics (ISAMSR) conference [1].

Electrography is a method that uses electric potentials measured with electrodes placed around the eyes. N. Steinhausen, R. Prance, and H. Prance [2] applied three sensors of electrodes, P. Aqueveque and E. J. Pino [3] aims on developed a low cost electrography system while H. Manabe, M. Fukumoto, and T. Yagi [4] went into automatic drift calibration for electrography. This method requires only very low computational power but relatively poor gaze direction accuracy to locate where a subject is looking compared to a video tracking even though the time of eye movements can be determined.

For video-based eye tracking, calibration has been created by different approaches and presentations. There is an approach of calibration procedure where the user's gaze is being calculated and also an approach of calibration-free where the aims are towards removing the calibration process for a fully automatic system.

D. Model and M. Eizenman [5] proposed general method by extending the tracking range for the remote eye gaze tracking system. By using a stereo pair of cameras, the overlapping field of view is used to estimate the user eye parameters. While, J. Chen and Q. Ji [6] proposed general method by gaze estimation without personal calibration which is the 3D gaze estimation. There is also other research such as [7-9] that also applying the same concept of calibration-free and needed more added inputs while adjusting certain parameters. These research shows that calibration-free system is achievable but the need of calibration for measuring accuracy of user's gaze is still considered as the most important process that cannot be remove in eye tracking.

This paper aims to implement calibration process in order to achieve good accuracy and performance. In order to achieve these objectives, regression technique with good training function is needed. A research from K. Harezlak, P. Kasprowski, and M. Stasch [10] have focus on the process of calibration and analyses the possible steps with ways to simplify this process. The authors compared three regression methods of Classic Polynomial, Artificial Neural Networks (ANN) and Support Vector Regression

*Farah Nadia Ibrahim, Putrajaya, Malaysia, +6014-8271947 & fnadiaibrahim@gmail.com

(SVR) to build the calibration models with presents different sets of calibration points.

Another approach used detection of the user attention by moving calibration target. This technique is presented by K. Pfeuffer, M. Vidal, J. Turner,A. Bulling and H.Gellersen [11] where the work is focused on smooth pursuit eye movement. This system collects sample of gaze points by displaying a smooth moving target to the user. Three realistic applications have been designed with different abilities in each such as Automated Teller Machine (ATM), stargazing and lastly is the waiting screen application. However, this study showed that too slow and too quick effects the accuracy of the system.

Facial region is divided into several features such as eyes including pupil, iris, eye corners, eyelid, nose and mouth. There is a method using template matching in facial image presents by Bhoi, N, & Mohanty, M. N. [12] which use the correlation of the eye template as the eye region and P. Viola and M. Jones [13] that used integral images from Haar Basic filters with Adaboost algorithm to create the region of interest around the area of face features.

After taking consideration of eye tracking types and regression method, this paper adapts the same methodology of [10] in building the calibration models with displaying set of calibration points by using video-based tracking and applied Neural Networks algorithm as the regression method with implementation of Viola-Jones algorithm as the eye feature extraction technique. The extracted eye feature information from Viola-Jones become the input data for training the calibration model. To achieve best training model, three training functions are compared for its performance and processing time.

2. Proposed Method

2.1. Displaying the calibration point as a dot

At the beginning of calibration process, stimuli of calibration point must be display to the user. Thus, we have set up two different calibration points, 4 points and 9 points calibration dots each locate at different position. This process is projected to the computer screen in front of the user to generate the raw data of eye detection. The size of the computer screen is 1920x1080 in pixels. The displayed stimuli are divided evenly on the screen as in Figure 1 and 2.

Figure 1: Screen display of 4 calibration points

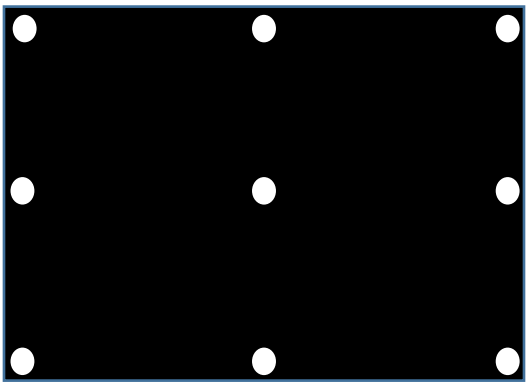

Figure 2: Screen display of 9 calibration points

From Figure 1 and Figure 2, the calibration points are being displayed to the user, one by one point. This process is being conducted by using a Logitech HD Pro Webcam C920 which is a full 1080p high definition. This webcam is equipped with the application of video, and photo capture, face tracking, and motion detection with the size of 640x480 in pixels. The setup of tracking the user's eye features and coordinates are as shown in Figure 3.

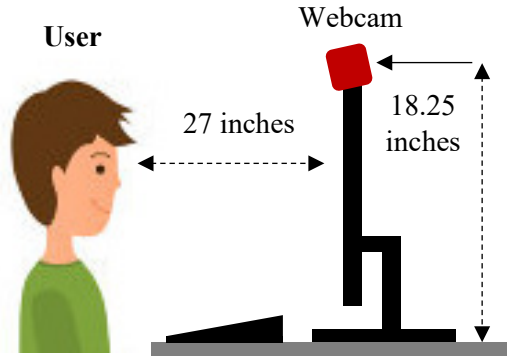

Figure 3: Setup of eye tracking

As seen in the figure above, the user's eye position is being recorded by the web camera. User looked at each point displayed for every 3 seconds at different locations of the calibration point that has been setup. The recorded process is saved in a video format. Thus, the images of user's interaction must be extracted frame-by-frame before the face and eye features detection being carried out. Figure 4 below shown the image of the user looking towards the displayed stimuli of calibration points of 4 points and 9 points on the computer screen.

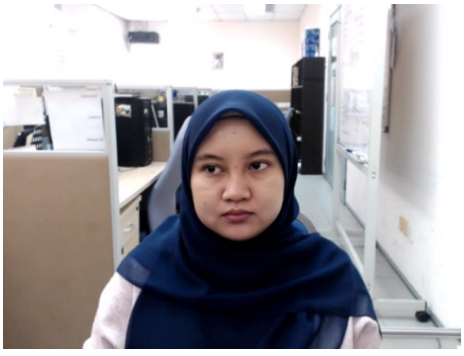

Figure 4: Image of user looking towards computer screen

2.2. Face and eye features detection

A video recording is the first step on capturing the user's eye images for the extraction of the eye center coordinates. As the next step of this research, the face and eye features detection are carried out by using a technique proposed by P. Viola and M. Jones [13], Viola-Jones algorithm. The input data for this algorithm is the image of the user as in Figure 4, that has been extracted frame-by-frame previously. Viola-Jones algorithm is widely known for its ability and performance in detecting the face feature.

P. Viola and M. Jones [13] proposed this method together by using the three main key attributions of integral images, AdaBoost classifier with more complex classifier in a cascade that has been proven to lessen the computational time with high level of detection accuracy. As per mentioned, this research has applied this algorithm which used the Haar-based features that involved the sums of image pixels within the face region in the rectangular areas as shown in Figure 5 and 6.

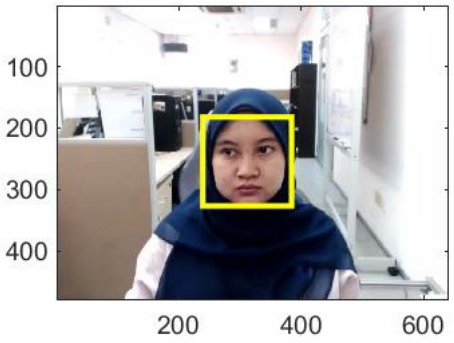

Figure 5: Face feature detection by Haar-like feature

From Figure 6, it shows the rectangular subset of the detection window that will determines whether it looks like a face. Two-rectangle features are shown in (A) and (B) while three-rectangle feature in (C) and (D) a four-rectangle feature. Two-rectangular feature is the different between the sum of pixels within two rectangular regions and both have the same size and shape with horizontally or vertically adjacent. As for three-rectangular feature is the different of the sum within two outside rectangles subtracted from the sum in a center rectangle. While the four-rectangle feature is the difference between the diagonal pairs of rectangles.

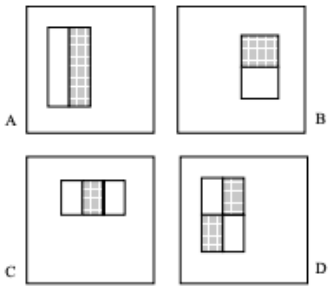

Figure 6: Example rectangle features shown relative to the enclosing detection window

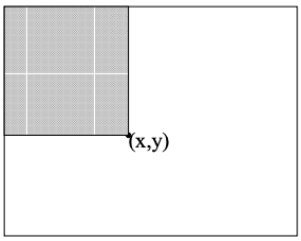

Figure 7: The value of integral image at point (x, y) is the sum of all the pixels above and to the left

Integral image is defined as the summation of all pixels in the image at point (x, y) above and to the left.

$$ii(x,y) = \sum_{x' \le x, y' \le y} i(x', y'),$$

where ii (x, y) is the integral image and i (x, y) is the original image (Figure 7). By using pair of recurrences:

$$s(x,y) = s(x,y-1) + i(x,y) \quad (2)$$

$$ii(x,y) = ii(x-1,y) + s(x,y) \quad (3)$$

where s (x, y) is the cumulative row sum, s (x, -1) = 0, and ii (-1, y) = 0, the integral image can be computed in one pass over the original image. By using integral image, any rectangular sum can be calculated in four array references as in Figure 8.

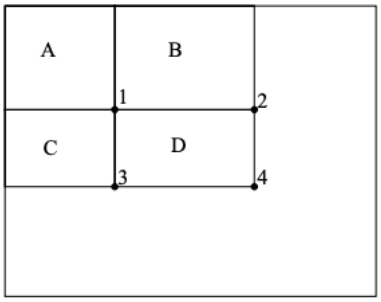

Figure 8: The sum of pixels within rectangle D can be calculate with four array references. The value of integral image at location 1 is the sum of pixels in rectangle A. The value at location 2 is $A + B$, at location 3 is $A + C$, and at location 4 is $A + B + C + D$. The sum within D can be computed as $4 + 1 - (2 + 3)$

Haar feature used the image integral area to compute the value of a feature and its classifier multiply the weight of each rectangle by its area and the results are added together. Since the detection moved across the image of integral, face recognition filter is applied and when the filter gives a positive answer, it will return feedback as face detected in the current rectangle window.

Each face recognition filter contains a set of cascade-connected classifiers that looks at a rectangular subset of the detection window and determines if it looks like a face feature. The classifier will move to the next classifier until all classifiers and filter give a positive answer, the face feature is considered recognized. The Adaboost algorithm is applied to the training of the cascade classifier to minimize the computational time.

The process of feature extraction is continued by filter out the eye pair feature. After the eye pair is detected, the algorithm extracted only half of the eye pair from the user's face feature image. The image of the eye feature is shown in Figure 9 below.

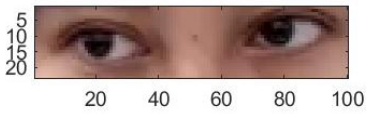

Figure 9: Eye pair feature

From the half of the eye pair feature, a circle detection algorithm is applied to extract the eye center coordinates. This circle detection is a feature extraction technique for detecting circles called Circle Hough Transform (CHT) where the parameters are containing the center of the circle and the radius. A circle can be described by:

$$(x-a)^2 + (y-b)^2 = r^2 \quad (4)$$

where (a, b) is the center of the circle, and r is the radius.

The coordinates will be used as the input data for training the calibration model. When the circle feature has been detected only then the eye center coordinates can be extracted and stored as the raw eye data. Figure 10 shown a circle that are being highlighted in the eye feature image.

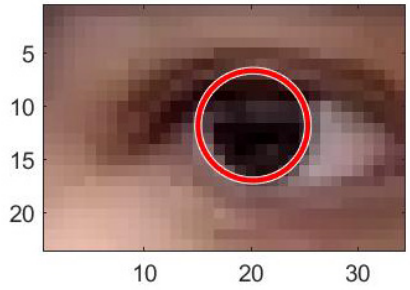

Figure 10: Circle detection on eye feature

2.3. Training the calibration model

After all processes of feature extraction has been done, the raw of eye center coordinates have been produced. These data must be normalized before training the data since the size of the user's eye feature images extracted from the video and the computer screen are different in value.

The normalized eye center coordinates data is stored and be used by Neural Network algorithm for training the model. Neural network can learn and identify images that have been manually trained or labeled for the system to process. A few researches have been conducted using the neural network like [14,15] where they both used neural network for training and identify the parameters of calibration, and input images. Thus, this paper used the approach of neural network to train the calibration model by using the normalized eye center coordinates data from previous process.

There are two sets of calibration points which are 4 points and 9 points that have been distributed at each specific location on the display screen. Thus, two neural networks are been trained for this paper. The type of neural network used is feed-forward back propagation algorithm.

Feed-forward is known for its simplicity of single layer perceptron network which consist of single layer of output nodes where the inputs are fed directly to the outputs via a series of weights. Back propagation is applied with the feed-forward neural network as it is a renowned representative from all iterative gradient descent algorithms that used for supervised learning. This method helps to calculate the gradient descent to looks for the minimum value of the error function in weight space as in Figure 11.

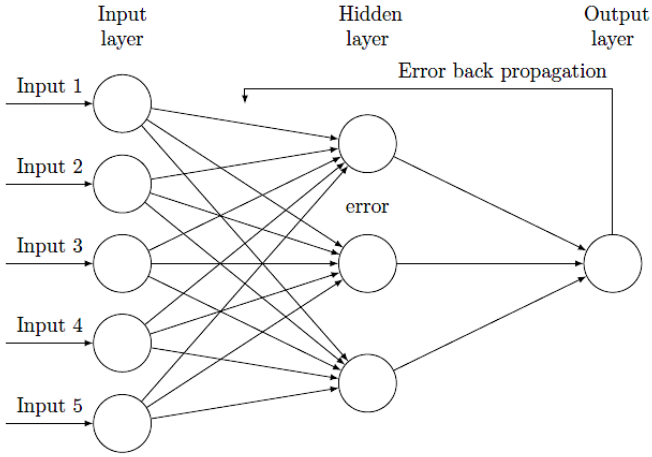

Figure 11: Neural Network architecture with back propagation

As shown in Figure 11, the input given is modeled by using real weights that are usually randomly selected. The output is computed for every neuron from the input layer, to the hidden layer, and to the outer layer. Error is then computed in the output by calculated the differences of the actual output with the desired output. This value will travel back from the output layer to the hidden layer to adjust the weights such that the error is decreased. This process is repeated until the desired output is achieved.

As for the training function, this paper compared the performance and computational time between 3 types of function which are Levenberg-Marquardt known for its fastest, Bayesian Regularization for its efficiency in difficult, small, or noisy datasets, and Scale Conjugate Gradient that requires less memory.

Levenberg-Marquardt (LM) is widely used optimization algorithm for it is outperform simple gradient descent and other conjugate methods. This algorithm provides the nonlinear least squares minimization. Basically, it consists in solving the equation:

$$(J^t J + \lambda I)\, \delta = J^t E \quad (5)$$

where J is the Jacobian matrix for the system, λ is the Levenberg's damping factor, δ is the weight update vector that we want to find, and E is the error vector contained the output errors for each input vector used for training the network. The Levenberg-Marquardt is very sensitive to the initial network weights and does not consider outliers in the data that can lead to overfitting noise. For this situation, we will compare the performance with another technique known as Bayesian Regularization.

Bayesian Regularization can overcome the problem in interpolating noisy data which allows it to estimate the effective number of parameters that actually used by the model such as the number of network weights. It expands the cost function to search for minimal error while using the minimal weights. This function works by introducing two Bayesian hyperparameters, *alpha* and *beta,* to tell which way the learning process must seek. The cost function is as follows:

$$C(k) = \beta^* E_d + \alpha^* E_w, \quad (6)$$

where E_d is the sum of squared error, and E_w is the sum of squared weights. By using Bayesian Regularization, cross validation can be avoided and can reduce the need for testing different number of hidden neurons. However, this technique may be failed to produce robust iterates if there is not much of a training data.

As for Scale Conjugate Gradient, developed by Moller [16], was designed to avoid time-consuming line search. The basic of this algorithm is to combine the model-trust region approach used in Levenberg-Marquardt with the conjugate gradient approach. It requires the network response to all training inputs to be compute several times for each search.

For achieving fast and efficient training model for calibration process, the best training function has to be selected. Thus, the three training functions consists of Levenberg-Marquardt, Bayesian Regularization, and Scale Conjugate Gradient are computed and analyzed the total iterations it takes for achieved minimal error, the processing time and the performance of the algorithm.

The training of 4 points calibration is being carried out first with the total number of neurons for hidden layer of 10, the input data of 200 and the output layer is 150. For each point of the input data, 50 values have been selected. The comparison of those 3 functions are as Table 1 below.

Table 1: Comparison of three training function for 4 points

Training Function	Iterations	Time	Performance
Levenberg-Marquardt	20 Epochs	1m 47sec	1.88e-09 mse
Bayesian Regularization	37 Epochs	5m 29sec	5.39e-08 mse
Scale Conjugate Gradient	76 Epochs	0sec	6.69e-07 mse

From Table 1, Levenberg-Marquardt achieved the minimal training with only 20 epochs of iterations, following with Bayesian Regularization of 37 epochs and lastly with the highest number of iterations of 76 epochs, Scale Conjugate Gradient. For the fastest function, Scale Conjugate Gradient achieved the best computational time with 0 seconds following with Levenberg-Marquardt and Bayesian Regularization. As for the best performance, Levenberg-Marquardt achieved it with only 1.88e-09 mean squared error that is nearest to zero values.

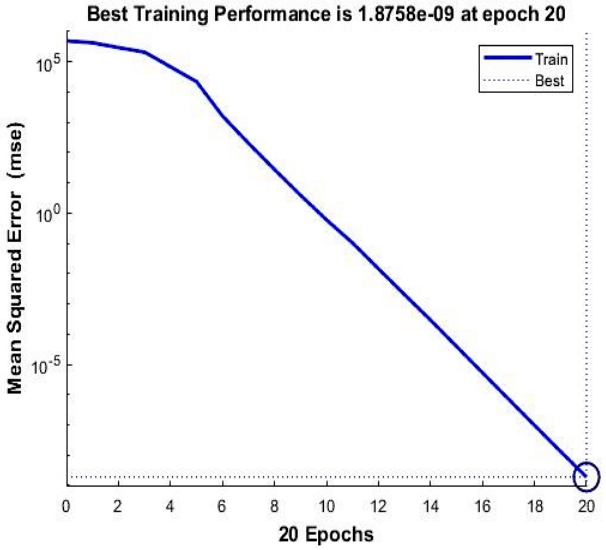

Figure 12: Performance of Levenberg-Marquardt for 4 points calibration model

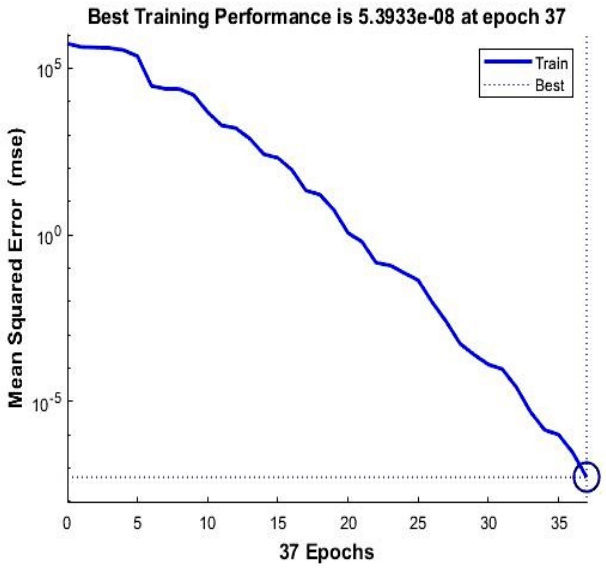

Figure 13: Performance of Bayesian Regularization for 4 points calibration model

From Figure 12,13 and 14, it is shown that the best training performance are from the training function of Levenberg-Marquardt, followed by Bayesian Regularization and Scale Conjugate Gradient. As for the regression values which measure the correlation between outputs and targets data, all three training functions achieved a close relationship with R value of 1 as shown in Figure 15.

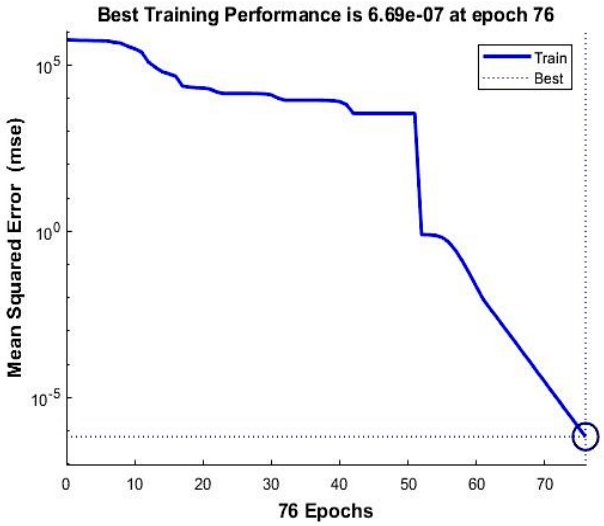

Figure 14: Performance of Scale Conjugate Gradient for 4 points calibration model

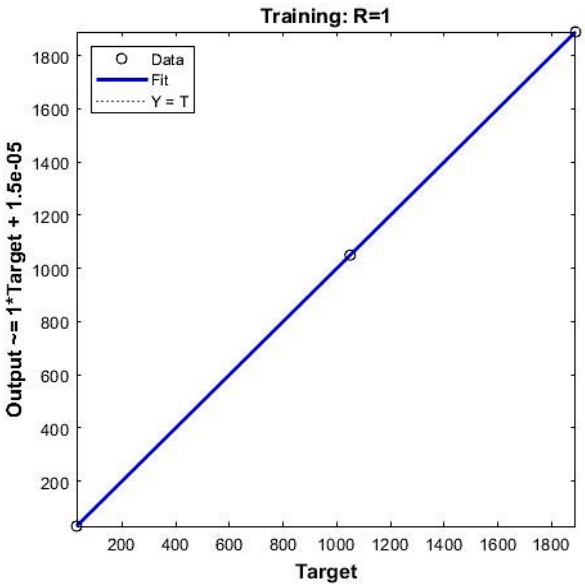

Figure 15: Regression values of all three-training function for 4 points calibration

For the training of 9 points calibration, the total number of neurons for hidden layer is 10, the input data of 455 and the output layer is 404. The total number of input data for each point are also 50 values which make the input data for neural network of 9 points calibration is 455. Table 2 shown the comparison of the three-training function for 9 points calibration.

Table 2: Comparison of three training function for 9 points

Training Function	Iterations	Time	Performance
Levenberg-Marquardt	20 Epochs	24m 55sec	1.97e-09 mse
Bayesian Regularization	43 Epochs	1h 25m 44sec	3.56e-08 mse
Scale Conjugate Gradient	446 Epochs	2sec	8.41e-07 mse

From Table 2, Levenberg-Marquardt achieved the minimum iterations of 20 compared to Scale Conjugate Gradient which achieved the highest iteration of 446 epochs. Even though Levenberg-Marquardt achieved the minimum iterations, it cannot be compared with Scale Conjugate Gradient for its computational time. This function required only 2 seconds to finish compared with the other two functions of Levenberg-Marquardt and Bayesian Regularization each takes around 24 minutes and 1 hour 25 minutes.

Since this modeling is from 9 points calibration which contains 455 inputs data, it's proven that Scale Conjugate Gradient are the fastest training function even by given many datasets. For the best performance of the training model, Levenberg-Marquardt outdone the other two functions by achieved mean squared error of 1.97e-09 as shown in Figure 16 below.

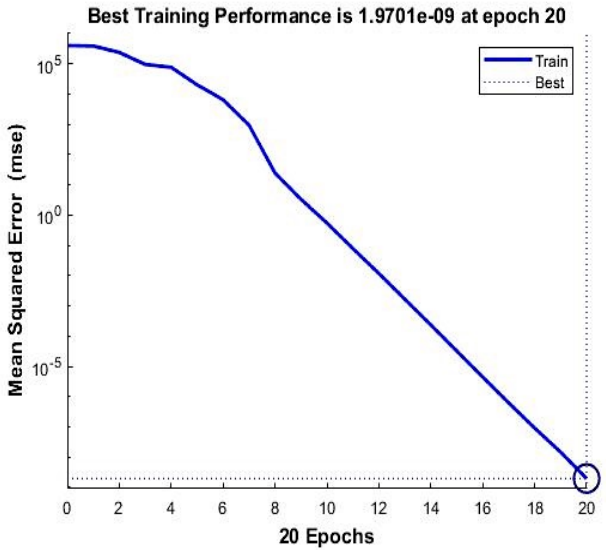

Figure 16: Performance of Levenberg-Marquardt for 9 points calibration model

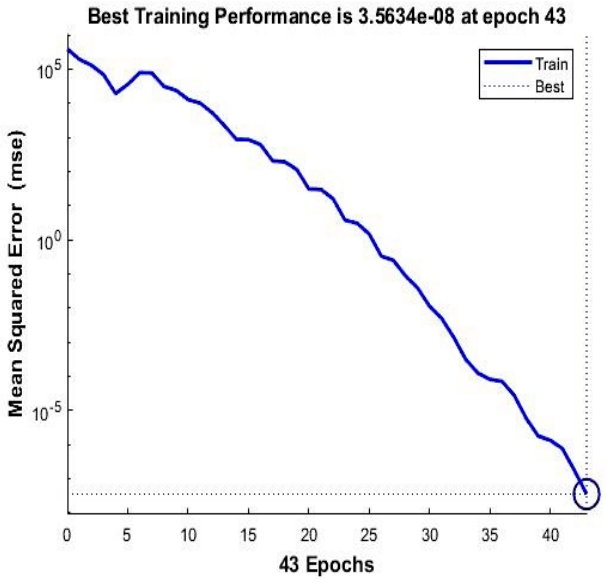

Figure 17: Performance of Bayesian Regularization for 9 points calibration model

Figure 17 and 18 are the performance achieved by Bayesian Regularization and Scale Conjugate Gradient for the 9 points calibration model. Bayesian Regularization achieved its best performance of 3.568-08 mse at the iterations of 43 while Scale Conjugate Gradient achieved its performance at 8.41e-07 mse at the iterations of 446.

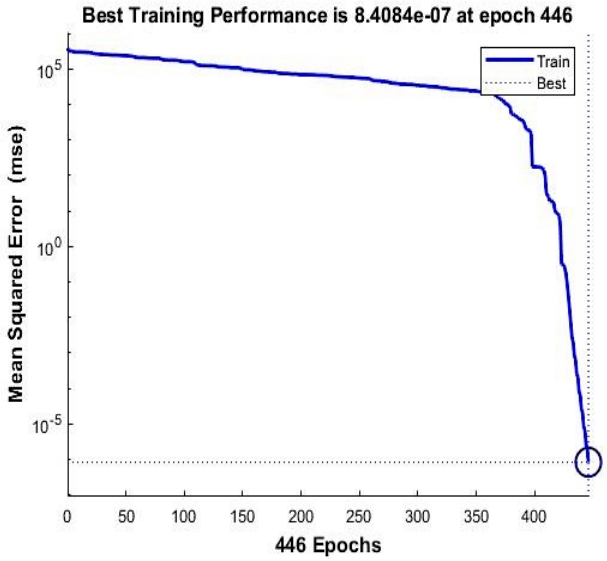

Figure 18: Performance of Scale Conjugate Gradient for 9 points calibration model

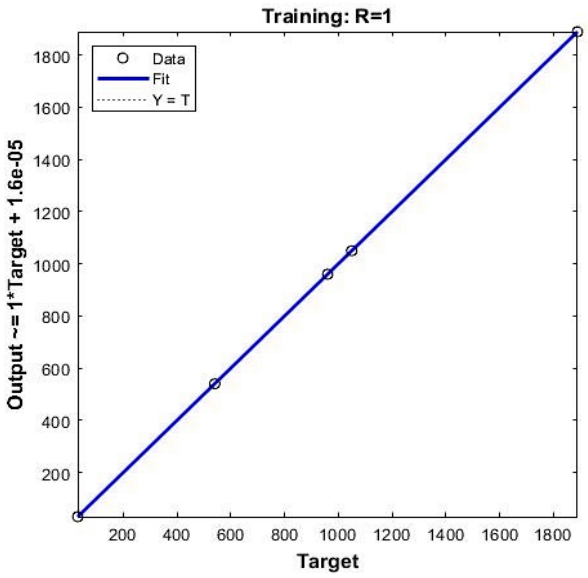

Figure 19: Regression values of all three-training function for 9 points calibration

As for the regression values, all the training functions have gained close relationship with R value of 1 as shown in Figure 19.

3. Discussion

The raw eye center coordinates data required normalization which are crucial process that can affect the performance of the data itself. Thus, this normalization can be improved or automated directly in the algorithm so that the process of the training data can be simplified. As for training models, back propagation is proven to be fast, simple and does not need any special mention of the features of the function to be learned but can be quite sensitive to noisy data and the actual performance dependent on the input data given. From the training functions that we have used, taken from the results of their performance, the best training function is Levenberg-Marquardt that is proven the best for its efficiency and good performance while gaining minimum iterations of error with fast computational time even though Scale Conjugate Gradient is a lot faster, the iterations of the error is too high.

4. Conclusions

In this paper, the eye feature extraction and calibration model were conducted by applying Viola-Jones and Neural Network algorithms. Viola-Jones approach using the Haar-like features that involve sums of pixels with integral image by minimizing computational time with Adaboost algorithm and detected the feature of face. As for the Neural Network, the feed-forward back propagation algorithm is applied together and compared the performance and efficiency of three training functions; Levenberg-Marquardt, Bayesian Regularization, and Scale Conjugate Gradient. The overall result shown that these algorithms can be applied and improve the performance and lessen the computational time for eye data training for calibration model.

Conflict of Interest

The authors declare no conflict of interest.

A B S T R A C T

Software architecture and design is an important component in the software engineering field. This aspect of software engineering covers the functional and non-functional requirements of any system being proposed to be developed, while software architecture deals with non-functional requirements, software design entails the functional requirements.

The objective of this paper is to critically analyze current topics in Software architecture and design. The method of analysis involved the use of inclusion and exclusion criteria of papers published in journals and conferences. These papers were accessed from digital libraries like ScienceDirect, and IEEE explore*, with a quantitative approach of analysis been imbibed. From the analysis, the result showed that, of 35 papers used in analysis, 34.3% discussed stakeholders' involvement and decisions in software design. 17.1% for design quality, 20% examined software reuse while 11.4% discussed software evaluation and 8.6% of papers reviewed discussed software management, evolution and software development life cycle each which should be more focused as it is the fundamentals of software design and architecture. From the analysis derived, stakeholder's involvement and decision in software design is an integral part in software building for effective use. Thereby making researchers dwell more on the topic. The least discussed topics was due to the expectations of researchers. Expecting readers to have a fore knowledge of the fundamentals of design which includes software management, evolution and software development life cycle.*

1. Introduction

Software Architecture gives the high-level description of a software and the discipline of creating the structures and systems [1]. It gives blueprint for the system, laying out tasks to be executed in a logical manner through the design [2]. It is the fundamental structural choices made vis a vis the business needs of the organization which may be costly to change once implemented [3]. Although there are no standard procedures to follow in software architecture that can address all issues of concern in general software development, certain factors should be of utmost non-negotiable fundamentals in software development, to ensure standardization thereby avoiding incessant collapse of systems witnessed in the early years of software developments [4]. Among the factors that will be enumerated briefly is the factor of proper documentation. This facilitates communication among stakeholders, captures decisions about the structures of the task and the design options – focusing on the decisions that must be right from the onset, otherwise, the imminent collapse of such system will be devastating– [5]. Since software architecture is largely driven by the required or expected functionalities, the current insight to software architecture is that required functionalities should reflect or incorporate all the quality attributes which include fault-tolerance, reliability, backward compatibility, extensibility, availability, maintainability, usability, security amongst others. Stakeholders concerns should reflect these quality attributes at both non-functional and functional stages without recourse to extra cost.

Software design envisions and defines software solutions to problem sets. It involves a sequence of steps that describe all aspects of the software in development [6]. Here, solutions to the problem the software is to solve are expressed in a logical sequence with details of their relationships. It begins with describing the total components to be built, then refine them to every detail. It is

*Isaac Odun-Ayo, Covenant University, +2348028829456
isaac.odunayo@covenantuniversity.edu.ng

the physical expression of all the processes that create solutions according to stakeholders' expectations. The designs are taken within the confines of fundamental principles which ensure designs are traceable to requirement analysis, uniformity, integration, structured for change etc. This ensures standardization while addressing the business objectives and stakeholders' needs [7]. In general, software development is dependent on time and cost and the design option should reflect these critical factors.

Software Design addresses all the expected required functionalities of the business objectives. This includes specifications of services, components, integration, data models and algorithms. Meanwhile, Software Architecture addresses design standard ensuring that it aligns with stated strategy as it pertains to business and technology of an organization. This includes considerations such as compliance, technology standards and operational efficiency. An architecture designed is intended to prevent repetitive mistakes in design or inconsistency with other aspects of the organization. It could be said that architecture is global optimization of software and design is local optimization [8]. In general, software architecture provides standardization upon which software designs are tailored.

Software architecture and software design are extremely important for a software project. So, here are brief points highlighting benefits of software architecture & design; solid foundation for software project, scalability of platform, increase performance, identification of area of cost savings, vision implementation, increase quality, better code maintainability, prioritization of goals, higher adaptability, faster platform, risk management and enable quicker changes among many others [9].

This study is aimed at helping researchers to have an in-depth knowledge of the fundamental as well as critical topics involved in software architecture and design of proposed and existing systems. It would also help in uncovering the critical gaps in which many researchers were not able to explore thereby improving knowledge as regards software architecture and design. The objective of this paper is to conduct a critical analysis on current topics in Software architecture and design. Published papers and articles on the topics discussed in the paper were reviewed with the percentages of each topic in relation to others were calculated.

Other parts of the paper are organized as follows: Section 2 gives review of some related work done, Section 3 gives a highlight on software architectural styles, Section 4 discusses Software Oriented Architecture, Section 5 is a discussion on Design Patterns; section 6 presents the results and discussion of the major topics selected for analysis from literatures. Section 7 gives a conclusion of the paper with recommendations for future work.

2. Related Work

In [10], the importance of software architecture as a vital aspect of software development was examined. The paper explored two important components, software evolution and re-usability. These are very critical component that helps curb the huge expenses involved in the development of software. Software architecture that can be evolved and reused should be in high demand, as software evolution and reuse are more likely to receive higher pay-off. [11] considers the fact that researchers cannot overlook the year's technology as well as the fact that software architecture employs fully detailed explorations of notations, techniques, analysis, tools and creation methods. There exist an intersection and interrelationship of software architecture with the study of software design, domain-specific design, program analysis, software families, specific classes of components and component-based reuse. The comparative analysis of software evolution methods in [12] explains the systematic comparison between architecture models and evolution methods centering its base on the scenario-based approach of software architecture.

The review on the successes and failure for software architecture in [13], gives insight into software architecture development and management process. It assesses previous literature and experiences to identify the factors that cause success and failure for software architecture and classifying these factors into subgroups as indicated by practitioners. [14] proposed a different methodology as a guide for practitioners supporting software architecture and design in an agile environment. Highlights of phases in software design process were covered, tools and techniques were proposed to implement those phases. Architectural design decisions and knowledge in [15], examine the essence of reusable architectural knowledge and the importance of documenting quality attributes along with the decisions captured during architectural design.

In [16], the concept of sustainability was introduced for software design. It was essential in integrating it into the existing catalog of design quality attributes. This was because design is a key factor in software development and this has been noted by many researchers. The information produced during software design tends to evaporate progressively due to certain conditions like software evolution. [17] considered all developed software need to meet required and specified quality standards as requested by users or stakeholders, quality being a major issue in software systems today. To achieve the quality requirements, different analysis approach was explored and a critical evaluation of the software system was carried out. This was to analyze the architecture, thereby verifying that quality requirements have been duly addressed in the design.

From an in-depth review of System Development Methodologies (SDMs) conducted by [18], a list of the important features in each methodology was made. Despite several SDMs, most of them share similar activities which include well known and practiced requirements-analysis, design, codification-test and implementation, all put together in project management. Four stages in the evolution of SDMs were reported which include pre-methodologies, rigor-oriented methodologies, agile-oriented methodologies and emergent service-oriented methodologies. Well-recognized SDMs in software engineering include Rational Unified Process, Microsoft Solutions Framework and Model-based (system) architecting and software engineering.

The software architecture chosen in the development of a software product is dependent on the software requirements and constraints. A Design Association Theory (DAT) to show the causal relationship of why a design should exist was proposed by [19] for associating design concerns, design problems and design solutions. DAT proposes a five-step association-based design

review process, which includes the extraction of requirements, extraction of design, construction of causal relationship between design elements and design solutions, discovery of potential design issues and verification and confirmation of design issues with architects. In documenting design decisions and design reasoning for objective evaluation, architects also utilize DAT. The DAT model helps designers and reviewers in associating architectural knowledge.

3. Software Architectural Styles

Architectural Styles are principles which shapes an application. It is more of an abstract framework of a system in the area of its organization. There are six major types of architectural styles. Namely:

3.1 Dataflow Architecture

In this, all software systems are categorized as lists of shifts on chronological set of input data, where data and operations are independent of each other. When data enters this system, it flows through the modules one at a time until they are assigned to some final destination [20]. Its aim is to achieve the qualities of reuse and immovability and is suitable for applications involving series of independent data computations on orderly defined input and output. There are three execution sequences between modules that the data flow architecture uses; Batch sequential, Pipe and filter or non-sequential pipeline mode and the Process control [20].

3.2 Data-centered Architecture

Data is centralized in this form of architecture and accessed frequently by other components that modify data. Its main purpose is achieving integrality of data. It contains different components that communicate using shared data repositories. The components access a shared data structure and are independent, meaning, they interact only through the data store. The flow of control sums the types of Data-centered architecture into two types; The repository and the blackboard architecture style. This form of architecture is mostly used in information system [20].

3.3 Hierarchical architecture

This views the whole system as a hierarchy structure whereby software systems are decomposed into subsystems at different levels in the hierarchy. It is mostly used in designing system software such as network protocols and operating systems. [20].

3.4 Interaction oriented architecture

The main aim of the interaction-oriented architecture is to separate users' interaction from data abstraction and business data processing. It divides the system into three major partitions: Data module (which provides the data abstraction and all business logic.), Control module (Which identifies the flow of control and system configuration actions) and the View presentation module (This is responsible for the visual or audio presentation of data output. It has two major styles: Model-View-Controller (MVC) and The Presentation-Abstraction-Control (PAC) [20].

3.5 Component based architecture

It is an architecture that decomposes software designs into functional components with their own methods, events and properties. These components become loosely coupled and reusable to provide modular programs that can be tailored to fit any need. [21]

3.6 Distributed architecture

This is a form of architecture that sits in the middle of a system and manages or supports the different components of that distributed system. Its aim is transparency, reliability, and availability. It hides the way in which resources are accessed and the differences in data platform, the resource location, different technologies from users, failures and resource recovery and a host of others. [20]. It is the most widely used form of architecture as it aligns with the technological advancement of the 21st century. Software development has improved greatly with the introduction of the internet. Software is now been distributed, components been reused, as well as introduction of concurrency and simultaneous change in the modification of data. These are the major advantages of the distributed architecture which has made it a common form of architecture in time past. [20]. There are different types of Distributed Architecture;

3.6.1 Broker Architecture: Mostly used to coordinate and enable the communication between registered servers and clients more like a software bus [20].

3.6.2 Client-server Architecture: Is commonly used by search engines, web servers, mail servers, it is mostly based on the functionality of the clients that is, requesting services of other components. The Service Oriented Architecture is a major sub-division of this. It supports business-driven Information Technology (IT) approach in which an application consists of software services and software service consumers. It has the ability to develop new functions rapidly which makes it mostly used along with its basic features which would be explained in the next section. [22]

Service Oriented Architecture would be further discussed due to its relevance in the current IT revolution. It is a known fact that cloud computing has come to stay and due to the integration ability of Service Oriented Architecture it has become a yardstick in the cloud computing revolution as their technologies have become more like bridges to the cloud.

4. Service Oriented Architecture (SOA)

SOA is a software architecture and design styles that entails the use of services as its main building component [23]. A service (as a software component), is a technique that allows access to several capabilities. SOA is now a mainstream software development mechanism. Despite the introduction of new architectural variants like cloud computing or micro-services [24], SOA is still widely used. This is due to its support for fast building applications using assembling of Internet-accessible services, allowing software organizations to hasten the development of distributed applications as well as a result time-to-market. After all this, a service is simply a distinct unit of performance that specifies a business function. This simply means it relies on Web Services for its implementation [24].

SOA carries out two core functions. Which are creating broad architectural models that explain application goals, including the approaches that help meet the goals. The second function is it defines the implementation specifications, which is mostly

integrated to the Web Services Description Language (WSDL) and the Simple Object Access Protocol (SOAP) specifications [25].

4.1 Major Principles of SOA

The major principles of SOA are [26]:

i. Regulate Service Contract - In this, there must be a form of description that explains what the service is about. This makes it easier for the client applications to understand what the service is meant to do.

ii. Loose Coupling –It entails components having little or no dependency on each other. This is a major characteristic of web services that emphasizes that there should be less dependency between web services and the client initiating this web service. Therefore, if any service functionality changes at any point in time, it should not hinder the client application from working.

iii. Service Abstraction - In this, service is ought to encapsulate its procedures and not expose how it executes its functionality. Explaining to the client application what it does and not how it does it for security purposes.

iv. Service Re-usability - Logic is separated into services with the aim of increasing reuse capability. In any technology, re-usability is a major issue as no one would want to spend time and effort writing the same codes again for multiple applications that require them.

v. Service Autonomy -The service knows everything about the application or system and what functionality it offers so it has complete control over the source code it encompasses.

vi. Service Statelessness - Superlatively, services ought to be stateless. Meaning they should not withhold any form of information from one state to the other.

vii. Service Discoverability - Services can be identified in a service registry. A service registry is a resource that allows controlled access to data for the controlling of SOA.

viii. Service Composability - It splits big issues into little ones. It is to be noted that not all functions should be embedded in an application and moved into one single service. Instead the service should be split into modules each having separate business functionalities.

ix. Service Interoperability - Services should accept and make use of various standards allowing different subscribers to use their various service.

For the implementation of SOA to be a success, you would need a productive SOA method that explains the plans, discoveries, procedures and the selected goals [26].

The integration platform for SOA plays a crucial role in the merging of existing application to cloud services. With SOA, components were split into services that became re-usable and easy to use among several systems. This is similar to the system means used in the automotive industry, where different layouts/systems share the same components e.g. engines. Cloud computing is re-vamping the IT world as we know it. The IT systems are utilized by users and companies. In the automotive industry, owners do not need to buy their own vehicles but can use car-sharing services. These service providers show the cars to several drivers. Comparably, in IT, a cloud service provider acts as a middle man and merges several clouds. Existing IT systems that require combination with new cloud-based solutions or inter-mediated are resolved using cloud service providers [37].

Cloud computing is re-modelling the IT industry and how its services are utilized, just like how petrol is soon going extinct in the automotive industry. Electric cars are now in use even as we use petroleum-based cars. As IT companies continue to make use of more cloud technologies the SOA technologies will continue to serve as bridges to the cloud.

Micro-service-based software architecture is the re-industrialized application of the SOA model. The components are developed as services using Application Programming Interfaces (API), just like the SOA would require. An API broker serves as a mediator to access components, ensuring SOA security and governance practices are followed.

SOA principles have taken us to the cloud and aides the most improved version of cloud software development techniques in use today. [27]

4.2 Advantages of SOA [28]

- Services can be reused in multiple applications independent of their interactions with other services.
- Due to service in-dependency, services can be easily updated or maintained without having to worry about other services.
- SOA-based applications are more reliable since they are small independent services that are easier to test and debug.
- Multiple instances of a single service can run on different servers at the same time.
- It improves Software Quality.

4.3 Disadvantages of SOA [28]

- Every time a service interacts with another service, complete validation of every input parameter takes place. This increases the response time and machine load, and thereby reduces the overall performance.
- There would be high investment cost as implementation of SOA requires a large upfront investment by means of technology, development, and human resource.

5. Design Patterns

Software design could be considered the most important aspect of software development as well as the most difficult process in a software development life cycle. Over the years, based on experience, programmers have embodied and recommended demonstrated results to fulfill the persistent issues that arise during design. Accordingly, the experience-based clarifications are composed and acknowledged as a consistent model for designs patterns [29]. Various design patterns have been presented and classified either as a sanctioned or a variation key to take care of design issues. The current programmed systems for design pattern(s) options help fledgling programmers to choose the more

proper pattern(s) from the rundown of relevant examples, to tackle an issue during the design period of software that is been developed. [29]

In software engineering, a design pattern is a general repeatable result for an ordinarily happening issue in programming structure [30]. Design patterns are used to ensure reuse of software design solutions in the early phases of software development, especially in the requirements engineering phase. Patterns do not provide visible solutions, but they present the concepts from which solutions are derived [31]. Design patterns have been introduced for defining good practices in software design [33]. Design patterns can be used in requirements engineering as patterns exist for core activities of a process. Design patterns are not pure inventions like a light bulb or a car. They are derived patterns that software engineers and architects found, that could be standardized to be used to solve similar problems categorized across three major areas; creational, structural and behavioral. When we determine the proper structure design for a task or issue, it helps us avoid changes that would require budgetary expenses, untenable, multiple and inefficient codes as the system scales up [32].

5.1 Classification and Selection of Design Patterns

The intrigue and involvement of programmers are utilized to present recent arrangement plans for the association of design patterns of specific concerns like object-oriented development and real-time applications [30]. The outline of current efforts describes the number of important categories of design patterns which relies upon the sort and multifaceted nature of target issues. For instance, [33] introduced three important classifications namely behavioral, creational, and structural in the setting of object-oriented advancement to solve recurring issues. In a specific circumstance of working applications, [30] introduced a catalog of thirty-four patterns, which are divided into five categories based on their relevance. In this paper, we would consider the object-oriented advancement categories.

A. Creational Design Patterns

Creational design patterns manage object creation systems attempting to make questions in a way that suits the circumstance. The essential type of object creation could result in design issues or added intricacy to the design. Creational design patterns take care of this issue by controlling this object creation [30]. These patterns can be further divided into class-creation patterns and object-creation patterns. Class-creation patterns use legacy viably in the instantiating of procedures while object-creation designs use assignment adequately to take care of business [35]. Creational design patterns are singleton, abstract factory, prototype, factory method, builder and object pool [31].

B. Structural patterns

Structural Design Patterns are used to ease a design by recognizing a straightforward method to acknowledge relationships [30]. These design patterns are tied in with sorting out various classes and object to frame bigger structures and give new usefulness [35].

C. Behavioral patterns

Behavioral design patterns are design patterns that identify basic correspondence designs among object and understands the patterns. By doing so, these patterns increment adaptability in doing this correspondence [30]. Behavioral patterns are about identifying basic correspondence designs among object and understanding the patterns that exist among them [35].

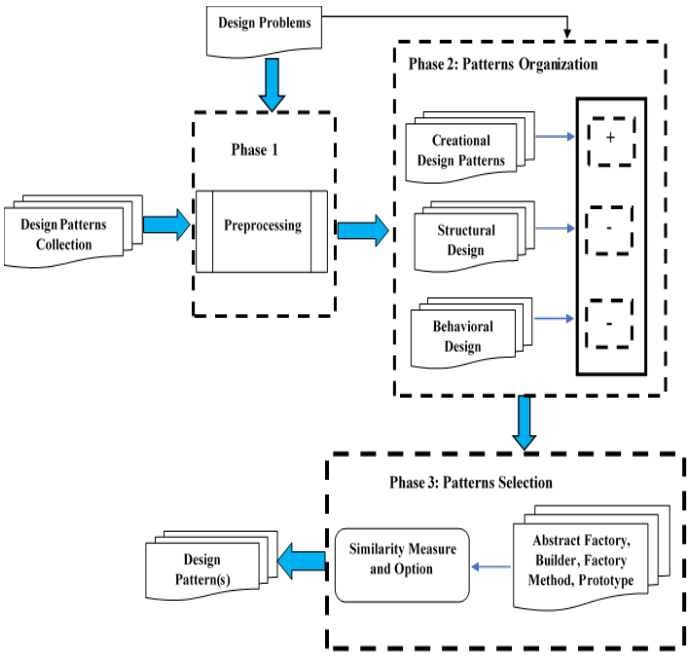

Figure 1: Diagrammatic Representation of Design Patterns Classification and Selection [34].

5.2 Design Pattern Topics

Six research design pattern topics concluded by [36] includes; pattern usage, quality evaluation, pattern mining, pattern specification, pattern development and miscellaneous issues.

i. Pattern development: This involves any advancements in design pattern research such as:
   a. Proposing a new model or new model language
   b. Reviewing model variants, composing models or elaborating a specific model, model evolution.
   c. Arranging current design patterns into distinct areas.
ii. Pattern usage: this relates to the commitment of utilizing patterns in the software development process. They are characterized into two primary groups:
   a. Pattern utilization
   b. Pattern application
iii. Pattern mining: this includes discovering examples of the pattern in the code or design of a system. It can be characterized into two major classes:
   a. Introduction
   b. Evaluation
iv. Quality Evaluation: the quality and effect of a design pattern on a system after applying it, is one important concern developers have. This can be characterized into two major classes:
   a. Pattern evaluation
   b. Application evaluation
v. Pattern specification: it includes utilizing distinctive strategies and notation of representing the patterns. The two main groups are:

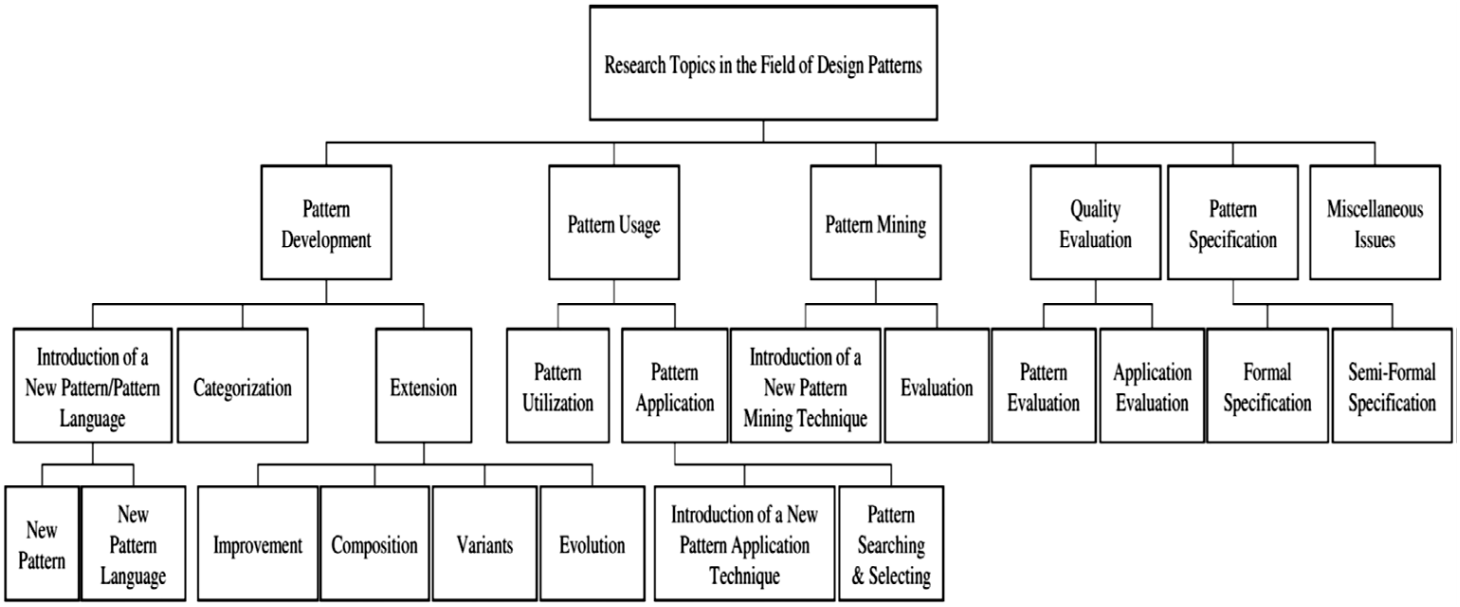

Figure 2: Design Pattern Research Tree [36]

a. Formal specification schemes
b. Semi-formal specification schemes

vi. Miscellaneous issues: this includes other issues that cannot fit into any of the previous classifications' issues such as re-factoring, code smells and anti-patterns. A major challenge of design patterns as discussed in [34,38, 39] is the searching and selection of design patterns before employing a right pattern into the system.

5.3 Pros and Cons of Design Patterns

It is worthy of note that there are very many design patterns available and a lack of understanding of these patterns pose problems for designers in software development especially for the novice [37]. Some of the pros and cons of the design patterns include:

Pros: [40]

- Easy to adapt and very flexible to predictable changes in business needs.
- Easy to test unit and validate individual components.
- Can provide organization and structure when business requirements become very complicated.

Cons: [40]

- Beginner engineers may not understand them, and these can cause a huge delay in development.
- Oftentimes used improperly without a realistic understanding of how the software is likely to change.
- It can add memory and processing overhead, sometimes it is not appropriate for applications such as low-level systems programming or certain embedded systems.

Design pattern, in general, enhances the nature of a product framework by giving a demonstrated solution for repeating design issues [41]. Also, the application of patterns brings about increment in quality and profitability of the software development process [31].

6. Results and Discussion

Table 1 shows several topics in software architecture and design alongside relevant work from several authors. Only one facet was used in this analysis, which are topics that relate to the subject (software architecture and design) discussed by these important authors. These topics were selected using inclusion and exclusion criteria. The essence of the selection criteria was to locate and add all papers that are necessary for the analysis. The inclusion and exclusion criteria were used to eliminate publications that were not significant to the study. It was observed that these topics were the most discussed and they also cut across academics and industry practice. The papers used for this review were access online from digital libraries like ScienceDirect, and IEEE explore. The authors and title of publications are listed in no particular order.

6.1. Software Evolution

Software evolution is the process of developing a software product, employing software engineering principles and methods. It follows the initial development of software and required maintenance. Updates are done till the desired software product is developed, thereby satisfying the (user) expected requirements [42]. This process implements changes to the original software, until the desired software is accomplished. Of the 35 papers used in this analysis, 8.6% of them reported on software evolution. From table 1, the findings show that software evolution though an integral part of software development was not substantially discussed by majority of the literature reviewed during the course of this study. This implies that there may be a decrease in research of software evolution.

6.2. Software Reuse

Software reuse involves creating new software systems from existing software frameworks rather than building software systems from beginning. This simple yet powerful methodology of software development was introduced in 1968 and now widely

adopted all over the world [43]. Only 20% of the papers reviewed, showed software reuse as a major aspect of modern software development**.** More literatures reviewed discussed this subject as indicated in table 1 above, this implies that research still goes on in this area with respect to software architecture and design, as well as in the aspect of software development.

6.3. Software Management

Software management refers to the art and science of leading and planning software projects. From the analysis carried out, software management covers 8.6% of the relationship between software architecture and design and other parameters considered. Like software evolution, the aspect of software management was not widely discussed in literatures reviewed. Substantial research is therefore made in software architecture and design in this area.

6.4. Software Development Life cycle

Software Development Life Cycle (SDLC) gives a description of the development process of a system from the initial study until the time it is updated or replaced. There are six steps that make up the SDLC [44]. The major function of the SDLC is to neatly lay out the process of system development. Despite being a popular and well-discussed topic in practice and theory. 8.6% of the reviewed papers discussed the topic. Unlike other topics, this is a major aspect of software, from the reviewed literature there was no substantial amount of discussion made in this aspect**.**

6.5. Software Evaluation

Comprehensively, non-systematic checklists can be applied to a program in the software evaluation process [45]. In recent times, software assessment using theory-based approaches which incorporates relevant criteria derived from psychological, linguistic and pedagogical models of language learning and teaching has been proposed. 11.4% of the 35 articles reviewed, discussed the importance of software evaluation in developed systems. There has been current research going on in the aspect of software evaluation, hence making it one of the major discussed topics from table 1 above.

6.6. Stakeholder Involvement/ Decision Making

The nature of the design problem also determines the form of decision that will be made. As reported in [46], a structured design problem makes the decision-making process better and easier. In this analysis, 34.3% of the articles reviewed, considered stakeholder involvement and in some cases, decision-making as a factor in software architecture and design, making it the most emphasized topic. This had the highest number of literatures discussing the topic, this implies that currently, more researchers are gearing towards this aspect during the course of their research to emphasize the need of stakeholders' involvement during software development.

6.7. Design Quality

If the quality of a design is not considered properly, it could lead to a negative impact on the product being developed [47]. The quality of any software is dependent on how well it conforms with the design plan of that product, it determines if the product would deliver the requirements desired properly and efficiently. 17.1% of the papers used for analysis discussed this topic, either directly or by evaluation of some design quality factors like quality attributes or design decisions. Also, this was among the topics discussed substantially in the selected literatures, which makes design quality a high recommended aspect of software architecture and design both in terms of academics as regards research and also in the industry.

From the results, the most discussed topics gotten from the analysis of selected literatures were stakeholder involvement and design, software reuse, design quality and software evaluation while the least discussed topics include software management, software evolution and software development life cycle.

7. Conclusion

Software architecture and design is an important component in the software engineering field. For success in the software engineering field both the architecture and design of software must be considered. Hence, various fundamental topics as regards software architecture and design have been analyzed.

The objective of this paper was to critically analyze current topics in software architecture and design. The method of analysis

adopted was the collection of published papers and articles on the topics discussed in the paper and the percentages of each fundamental topic was calculated. From the analysis, the result showed that, of 35 papers used in analysis, 34.3% discussed stakeholders' involvement and decisions, 17.1% for design quality, 20% examined software reuse while 11.4% discussed software evaluation and 8.6% of papers reviewed discussed software management, evolution and software development life cycle each.

From the analysis, it can confidently be concluded that aspects of software architecture and design such as software evolution, management, re-usability and building software which are fault tolerant, reliable, backward compatible, maintainable and secured are under-discussed. Several authors addressed various aspects of software architecture and design, but there are no standard procedures to follow that addresses all issues of concern in general software developments. As earlier stated, some factors should be non-negotiable in software development to ensure standardization thereby reducing incessant collapse of systems witnessed in the early years of software developments. This research stressed the significance and rigorous work involved in the development of software and outlined major factors that should be considered.

Therefore, it is important to note that a critical and rigorous analysis of software architecture and design is required to overcome the overall failure or crash of software in software development process and to also identify relevant gaps in the architecture and design styles or methods. Software architecture and design as an ever-growing field of software engineering, calls for further analysis to test and validate principles as they evolve. This study would help other researchers in the quest of knowing more about software development and the need to research further on the least discussed topics which are software management, software evolution and software development life cycle (SDLC).

Conflict of Interest

The authors declare no conflict of interest.

ABSTRACT

This work deals with the issue of understanding a user's behaviour as this is expressed via a gamified application. The notion of ontologies and the association of concepts in relevance to decisions that have to be made is used. The current work introduces a new process-based approach, based on collected large log files and associations of underlying decisions based on them. Both of them deal with work in extracting information for intelligent use, the main difference being that the first discovers but stops on a concept relation basis, while the other based on processes, as knowledge transactions, further to the associations on a 1:1 level maybe applied on a multi associative model. The objective of the current work is to introduce the methodology into gamified environments (such as but not limited to) games, for semi-automated understanding of user behaviour and furthermore, prediction and in instances, guidance via optimal paths of decision making activities, that are useful in gamified applications in various areas like the education. Both the initial ontology based, and the extension work on it, are based on mining association rules, in one instance treated as knowledge nodes (concepts) and in the second as underlying knowledge processes, based on big log files. This may be applicable to online games, that generate big log files of user selections, that are available for study and examination for extracting user behavioural patterns. As a result, maximum length of sequential patterns and items in them, are discovered in an algorithmic based methodological approach, providing in this way a set of guidelines for designing gamified applications.

1. Introduction

The work in this paper is based on the work presented in the 9th International Conference on Information, Intelligence, Systems and Applications (IISA 2018) under the title "On Ontologies and Knowledge Associations in Gamified Environments" [1]. Its contribution is bifold (a) it extends on a more generalized manner the work so far in the above and (b) it is getting additional research by providing an additional mechanism for knowledge associations. More specifically, the case (a) above is mainly based on single concepts relations – associations and its application in mobile devices in the tourist domain, while in the part (b) contribution of additional research the notion of knowledge transaction is introduces as a set of serially associated concepts – nodes, with the presentation of its application in a gamified environment (on line game). For clarity purposes and the distinction of concepts within the domain of gamification vs. the concepts in the game domain a brief introduction is provided below.

2. Gamification – Modeling User Behaviour

Gamification is the process of applying game techniques (e.g. dynamics, feedback, badges, leveling, etc.) to non-gaming contexts [2]. It is a new methodology that flourished just after 2008 [3] and refers to understanding a user's behaviours on making decisions, made in a context of gaming and hence drive them to expected outcomes. As a process, gamification is under study within the scope of computer science, mathematics, artificial intelligence as well as psychology disciplines in the context of persuasive technology [4]. It is important to be noted here the difference between gamification and gaming itself [5]. The evolving processes in gamification are used today in various domains like education, training, marketing, health human

resources in enterprises, e-commerce and so on [6]. Understanding thus the above and applying them on involved processes on the above sectors, is of great importance. In the current work we will go through the gamification-based implications in the context of the designing educational content for computer-based learning and applications.

Designing and implementing gamification applications is an iterative process which consists of six main steps: 1) define learning objectives, 2) delineate target behaviours, 3) describe the players (either students and/or teachers), 4) device activity cycles, 5) implement fun and involve psychological factors that affect learning in it and finally, 6) deploy the appropriate tools. This process is performed so far by experience, by playtesting the designed gamification schemas, examine the corresponding KPIs, check what is working or not and in case that failures of the design and implementation are identified, return to the design phase and start the process all over [7].

Here, we attempt to formally introduce, as gamification is an emergent technology, the design of gamification applications, by analysing game player's actions stored in log files, to the domain of education as a process-based methodology. We try in other words, to study the user engagement into the knowledge acquisition cycle, in a domain agnostic way, based on a semi-formal approach, where, beneath it, underlies the concept of positive and negative reinforcement via the semantics, the mechanics and dynamics that the gamification-based applications are characterized of.

Education and gaming have many in common. Some of them are learning on achieving objectives, introduction and use as much as possible of engagement (interactivity in learning process) concept, motivation in achieving the previous, game elements, like positive and negative reinforcements, awarding and/or discouraging in specific cases and so on.

The above provided, our research was driven by the interest in studying what is a very important issue in the above context, i.e., what are the implications and the impact of the possible social and psychological factors that are being introduced by the gamification methodology to the achieving of the learning objectives. There are certain questions that have to examined. For example, is the educational content being acquired and understood better if the subject is working in such an application alone, or in an antagonistic environment (one to one or one to computer), or finally in a cooperative team-based mode? Based on this, how social media and collaboration-based environment (electronic) assist this process? Should the subject "discover" the knowledge himself, in a role-based game manner, or should be driven/directed to it? If yes, in a "strict" or a more "flexible" way?

To study the above we introduce the concept of underlying processes in the gamification application that supports the learning process. We are going to examine the model of an educational application that underneath it exists a mechanism that discovers patterns in learning and at the same time tries to understand the individual's behavioural patterns and foresee future behaviour (knowledge extraction). This mechanism gets its input from a set of log files of collected raw data, that is generated from playing a respective game.

Log files in most cases, contain structured raw data that are coming and are registered as text files, coming directly from systems' interaction activities. This either comes from the user's or from other systems' components themselves activity or both them. In most cases, this raw data, comes in a structured and in a predefined format, while in other cases, due mainly to some external reasons and abnormalities, comes as incomplete data, introducing thus "noise" to the system. Out of these log files, the important aspect and the objective of the current work is to mine hidden knowledge, that can be characterized as knowledge produced during the game play (knowledge in action, while learning), in terms of underlying processes and patterns. Such concept of getting an advanced level of knowledge out of raw data, is also currently under both research and application, known as Big Data Analysis. To have such a repository of real time produced raw data in terms of log files that registers user behaviour in a game is in this step our objective and part of presenting our design methodology, in terms of underlying techniques.

More specifically, for experimentation purposes, we have selected and dealt with log files, that are being continuously generated out of the context of a game, played worldwide on the WEB 24/7/365, by thousands of players, in real time. Therefore, the generated log files are updated, using a generalized structured data model, that in many cases has the ability to expand or to reduce itself, in a dynamic way, as it will be presented in the following sections. Due to these idiomatic data type characteristics, initial and advanced parsing techniques had to be developed for two major reasons (a) to generate clear, coherent and consistent data sets and (b) to transform them, so to be persistent and hence to be stored and aggregated in a database for further exploration and processing. What we will concentrate on also here, is the discovery of interesting and meaningful patterns that signify the underlying existence of processes, towards a predictable and modifiable behaviour, a major research topic in the field of artificial intelligence [8].

3. Ontology Based Knowledge Discovery - The ONARM+ Methodology

In the previous presented work [1], we have introduced both the theoretical as well as the technical background of the ONARM+ methodology. Based on this, we have also presented in detail an application, in the domain of tourism. For this, we have considered the case of independed users that by potentially using our platform would exchange parts of their personal concepts, based on a centralized tourism [9] concept ontology, in a semi-automated and intelligent way. The scenario to be implemented based on our methodology, required 2 major components: (a) a client component named Concept-Net, that could be able to run either on mobile and/or desktop environments and (b) the Concept-Net Back End set of modules. Both of them and their subcomponents have been implemented as the following conceptual diagrams represent them (Figure 1):

Our work dealt on the concept relevance aspects with to the transformation of raw data obtained, via user selections and decision-making actions, in a specific domain (being domain agnostic), its comparisons with others on a concept basis, represented as an ontology of a specific domain.

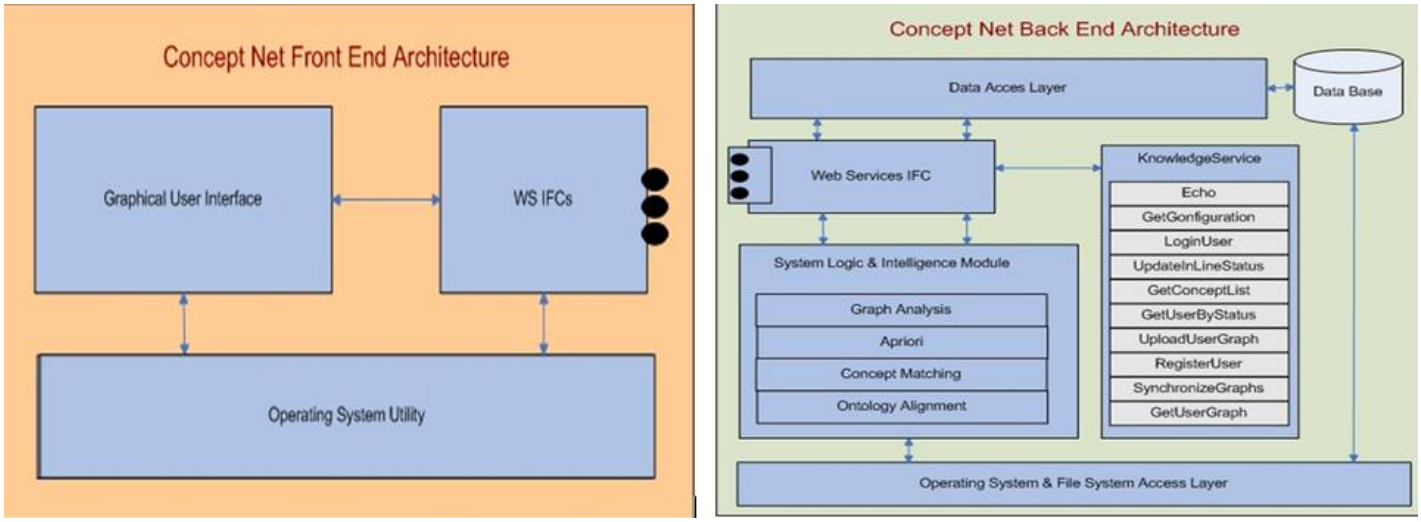

Figure 1: Left: (a) Client logical diagram, on the right (b) server-side components of the Concept-Net application

In short, during the process of knowledge extraction between the 2 users, firstly the discovery of concepts that are of common interest has to take place and then, the comparison via measures while on the final step, the merging of the parts of the specific ontology parts of each user to specific place of the ontology (aligning of them [10], [11]) takes place.

The methodology works under the assumption of existence of at least 2 user profiles, in terms of ontologies of interest. These represent the user's preferences and interests in a specific area and the categorization in a conceptual way that is depicted in a graphical way via the Protégé tool (The Protégé Ontology Editor, http://protege.stanford.edu /, last accessed on June 2, 2018). Also, there exists a central ontology that holds all concepts in the specific domain. As described in the work [1], the methodology is based on the Apriori algorithm [12], to identify. In general, the three major phases of the ONARM+ methodology are: (a) knowledge acquisition, (b) knowledge representation and (c) knowledge exchange.

While the association of concepts in terms of independent knowledge nodes, is of major significance in the discovery and exchanging knowledge processes, when we strive for understanding decision making in terms of a series of choices, then the above provide only partial information. To add value to the previous and essentially to introduce similarities and therefore predict more accurate user choices, we have introduced as an extension to this, the methodology below, which identifies similarities among processes for decision-making, in terms of generalized knowledge transaction processes. This is particularly useful, when not only we need to extract such information so to find similarities among users' profiles, but also equally significantly, to predict such patterns and in a second step, to be able to guide them, so that to trigger dynamic choices for desired user behaviour driving into.

4. Process based Knowledge Transactions Pattern Discovery

4.1. General

In this part, we go through our methodology and we provide an example for supporting the process of designing and development of educational applications based on gamification by using it. For this, we use knowledge extraction methodologies for extracting users' behavioural sequential patterns from large on-line game log files and propose to learners an optimal path or set of actions in a specific order, towards knowledge acquisition. Large game log files stored on line, are collected, processed, stored in an event data base and then transformed to appropriately format, for applying Apriori algorithm sequential pattern mining technique. Extracted patterns then are translated to set of proposed actions. The future path of user preferences in terms of decisions, can be (a) reinforced and (b) predicted by our methodology, while step by step educational/game objectives are achieved. Therefore, designers of educational gamification applications are provided with a set of means to select appropriate type of game mechanics/dynamics and offer selected action types in a user-cantered approach tailored to any individual's requirements. Following advancements in games based on electronic media and the advanced level of new generation familiarization with such environments, in conjunction with the fact that gamification has a wide application in education domain, as it is a useful mean for maintaining student participation and enhance engagement in the educational process, we focus on frequent sequential patterns extraction from game log files and transform them to powerful tools for implementing gamified educational applications.

4.2. Background

Knowledge is the ultimate resource in every enterprise's routine operations and signifies the holy grail to their success. Knowledge in human beings is better understood but not equally explained. Recent developments and technological advancement in all fields of IT technologies (hardware and software) generate on a continuous manner, on real time basis to all kind of unrelated at a first glance data, coming from simple to very complex applications and transactions. The rising need is therefore to discover underlying processes and provide meaning to them as upper level knowledge.

On the other hand, following this trend of advancements, games based on electronic media have evolved from simple applications in the very beginning, to very complex environments, many of them simulating real life experiences and scenaria. In the

domain of education, gamification has a wide application since it has been proved to be a useful mean for maintaining student participation and enhance their engagement in the educational process. Gamification is a mean that is widely used in the marketing domain targeting to foster both brand loyalty and awareness as well as to enhance customer engagement. As mentioned previously, these three key marketing concepts are relevant in the gamification context: engagement – "high relevance of brands to consumers and the development of an emotional connection between consumers and brands", brand loyalty – "the relationship between relative attitude and repeat patronage" and brand awareness, "the rudimentary level of brand knowledge involving, at the least, recognition of the brand name" [13]. Transforming these to learning processes in education, we have the students that are the consumers and the emotional connection to branding in our case the sources of educational context (humans, books, eBooks, web, Internet in general, etc). Therefore, the students can be seen as "highly engaged, emotionally driven players", in this gamified learning approach, where strategic decisions have to be made by them (intermediate learning objectives' achievements, towards the final overall knowledge acquisition, within the provided domain).

These complex gamified applications, therefore, require the track of players' actions and the estimation – calculation of potential responses to their decisions in an intelligent way. In recent years, the tracking and logging of this information and monitoring of the way that game engines and applications perform – has become widespread in the digital entertainment industry, providing sometimes very detailed and specific information on the performance of popular commercial titles with millions of players and installations in digital devices [14],[15]. It has been widely accepted in the academic and business fields that the so-called game telemetry can be a very powerful tool not only for game development but also to assist a variety of stakeholders via user modeling, behavior analysis, matchmaking and playtesting, [16] under the condition that it is processed in the right way. As a consequence, large amounts of game telemetry data are tracked, logged and stored, but not always is being correctly analyzed and used for drawing results and decisions useful to other applications. The challenge quickly became to deal with working with large-scale data, in a process based meaningful way, for extracting behavioral decisions [17]. Quickly, new methods have emerged [15] to assist analysts and decision makers to obtain the information they need to make better decisions. These included: automatic summarization of data, the extraction of the essence of the stored information, and the discovery of patterns in raw data. When datasets became very large (any dataset that does not fit into the memory of a high-end PC as large-scale, i.e. several GB and beyond) and complicated, the breakdown method to smaller sets of data was introduced. Applying on these raw data knowledge discovery processes will help identify and uncover patterns of behavior in it, whether user-derived or learning based-derived, and these, in turn, can be highly valuable.

In this work, we use sequential pattern mining to analyse game player's actions and behaviours, stored in log files.

The objective of the sequential pattern matching process is to discover patterns that take place in sequence(s), so to be used in prediction of future events that generate similar data. It has a great application domain, where human behaviour analysis plays a key role in making strategic role, that varies from students' behaviour and its impact in achieving learning objectives, customer analysis behaviour (and therefore prediction) up to security and alarm analysis, manufacturing engineering, WEB pages' prefetching and so on. In the sequential pattern matching a sequential database of records, expressed as patterns of events is provided to be analysed. The input must be sorted in absolute lexicographical order for the algorithm. The output is a subset of patterns that frequent occur within it, provided that a minimum support (at least), is entered as an expected indicator of the least desired frequency of occurrences of the patterns to be discovered within the total records of the database.

Historically, AprioriAll is the first sequential pattern mining algorithm. The authors of AprioriAll then proposed an improved version called GSP. The AprioriAll and GSP algorithms are inspired by the Apriori algorithm for frequent itemset mining [16].

4.3. Methodology Definitions and Assumptions

There are prerequisites that log files have to support to be useful for the pattern mining extraction. A non-exhaustive list of them is the "case-id", the "supporting activity", "event timestamping", "connectivity with other events, triggering or triggered by", information on resources, such the "user name", "system cost on event" and so on. These, so called event attributes, will allow the extraction of underlying processes, by associating such events and using a generalized model of event logs, consisting of cases, that in turn consist of events, consisting in turn of attributes. That introduces [18]:

1. A set of case(s) based process(es)
2. A set of events associated with processes via respective cases
3. An ordered set (tuple) of such events on a per case basis
4. A set of attributes per event (empty set allowed

As a final point to be noted, is the difficulty and the rareness of availability of user data in terms of raw data (and not in aggregated form), from the game providers, that generate and own these big data files.

At this point, the current work proposes a new methodology for discovering these meaningful patterns, using minimal human intervention (in terms of pre-processing, association and conclusions' analysis). In this section, the main steps of it are going to be presented below:

1. Data Source (Game) Selection. That was a very important step, so the proper game to be selected that conforms with the above requirements and restrictions. At the same time, the game had to offer in an open and continuous way the data being produced, in terms of log files.

2. Data Collection. Based on the fact that the previous criterion would have been met, to develop a method, that in an automatic way would be in a position to collect on a timely basis the generated data.

3. Data Maintenance. Provided the following were met, to further elaborate and develop an automatic way of synchronizing the data collection, so to avoid repeated and unnecessary steps, that

would lead in duplication of data collection. This in turn, most probably, would lead the game data provider to ban the data collection process and stop further experimentation. Unnecessary hits therefore for data collection purposes, had not only to be completely avoided, but at the same time to be carefully scheduled when to occur, avoiding Denial of Service as previously mentioned.

4. Data Transformation. This step was necessary so to introduce unique event game ids, that could be easily backwards traversed, in a meaningful way, reflecting all their attributes, that would lead to processes.

5. Data Persistence. Log files as previously explained are continuously updated in real time, as a stream of data. Out of this, chunks are not useful and have to be thrown away from mining, yet though to be identifiable in case of suspect of usefulness of it. Space and storage limitations had to be considered in the next step, being the storage in a local database.

6. Data Association. In sequence, the asynchronously generated data, has been through data cleansing and in this step, is provided in an automatic way as input to algorithms for association of it. In this step, any type of associative – rule-based algorithm could be used. It is important to be noted that since data can be easily transformed during input process to any given and expected requirement of the algorithm to be used can be applied to any type of these. For the purposes of this work the Apriori algorithm has been used [18].

7. Process Extraction via association rules. For this, the Apriori based algorithm GSP is used, with the objective to speed up the generation of interesting association rules, that will in turn lead to the mining of interesting process as proposed by [8]. The input of GSP is a sequence database and a user-specified threshold named minimum support (minsup, a value in [0,1] representing a percentage).

4.4. Technical Framework and Architecture

Based on the previous criteria, the selected game was the Alter Aeon. According to Wikipedia (https://en.wikipedia.org/wiki/Alter_Aeon), Alter Aeon was built on 1995, continuously and free provided since to thousands of people worldwide. It generates everyday thousands of lines of players' transactions, that are publicly available as streamed log files from the game developers. More details on the game and rules of playing can be found on its web site http://www.alteraeon.com.

For the specific log files, in short, the process was to download the HTML files and write them in local log files. The HTML page was created by the provider to provide the information and had to be parsed until at every entry in formation of value to be found regarding transactions. Then, the files were broken in different ways, so to match the mysqlite data base schema that was adapted. After that, the sequential files were generated and fed into the Apriori algorithm for sequential process associations.

The overall procedure from scheduled data collection from the WEB Data Source, storage of unstructured log files, transformation to structured local log files, database storage, Sequential data sets generation, Apriori as described in (Figure 2) have been implemented using Python 2.7 programming language and were tested in a distributed manner of 2 machines, connected via cloud. The first was used (a) for connection and data collection from game web site (server) of relevant data, (b) the storage of it as raw unstructured data to log files and (c) the transformation of it to local structured log files. These were implemented as a daemon set of processes, on an Ubuntu Linux server-based machine. The second part of the task was performed on a Mac Book Pro OsX with 16 GB RAM and 1 TB solid state HD.

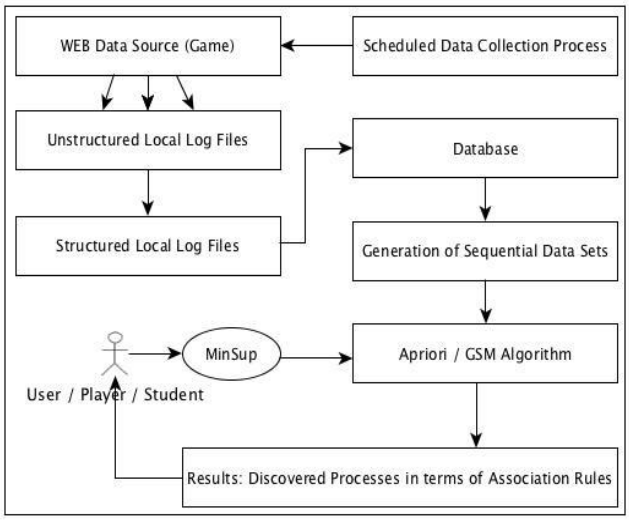

Figure 2: Overall Methodology Architecture

The separation of the overall task into two different sub tasks, in independent hardware platforms (machines), was a critical issue, since the generation of the sequential databases, as the log files were increased in size, was an intense and resources demanded issue. Additionally, the first machine has been configured to update its log files on an hourly basis (dynamically reconfigured). After this repetitive process (as many times as proper data required, here the system was collecting data for 3 consecutive months), the Apriori algorithm was applied, implemented in a Java application environment.

4.5. Results

4.5.1. Initial Results Presentation

In the diagram below (Figure 3), is shortly depicted the process for running the cleared and synthesized log files through the GSP Algorithm.

On the left-hand side of the above image, is a snapshot of the unstructured game log files, collected for a day transactional activity, from the game Web page and on the right is presented a sample of GSP process discovery outputs.

It is worth mentioned that such files were also aggregated to monthly basis and can be further aggregated to any time interval, depending on what time would like to be examined for process extraction. Initially the date / time has been registered and then event type has been recorded. Finally, on the last column, the detailed event description can be found, in a syntactically dynamic format, according the circumstances that the specific event took place.

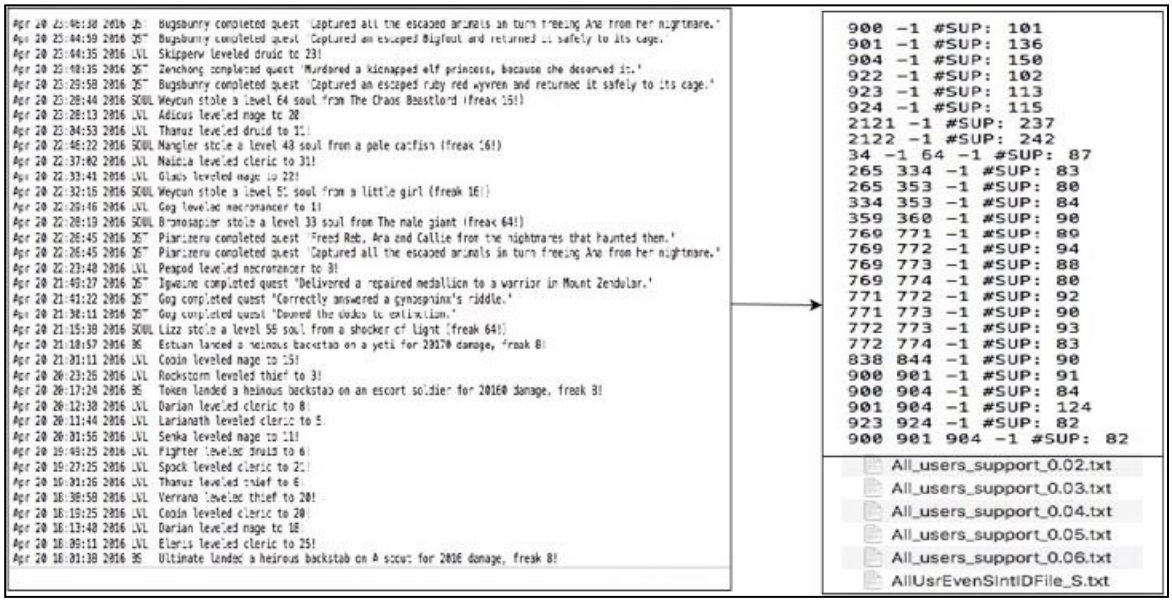

Figure 3: Initial Results Discovered by GSP algorithm.

On the right-hand side, there is (a) a sample of the process discovery after the GSP application; (b) on the lower right-hand side, the format of the filenames of the produced log files are presented, that contain the interesting associations, for processes found. It can be noted at the end of each filename, the respective minsup measure, as previously introduced, under which the process associations took place. (c) finally, on the right top, a sample of the output is presented. The (-1) stands as a separator of the frequently associated process id, that in previous steps has been uniquely composed for a player and player's activity in general to be able to be reversed tracked. As it can be seen in the sample output, there are interesting associations of frequency of 1-member, 2-member and 3-member activities. At the end, the number represents the measure of interestingness, as a measure of frequency of associated processes.

The application of the GSP Apriori implementation algorithm, provides all possible associations that could be found [12], by applying the specific minsup measure. Any sequential pattern mining algorithm could be used instead, as the VMSP [19], that works in a similar way taking the same data format as input and producing a similar file format as output, being different on the fact that provides the maximal model for the associations discovered by the sequential data files.

4.5.2. Processing of Initial Results – Extracting Behavioural Process Patterns

Sequential pattern mining is a research field studied for more than two decades, focusing now in two main areas a) Applications in the aspect of utilizing sequential pattern mining either in new applications or in new ways for existing applications and b) Algorithms either for designing more efficient algorithms or designing algorithm for handling more complex data or for finding more complex and meaningful patterns [20].

The present work contributes to the first area providing results that can be used in the design and development of new gamified applications and in the improvement of existing ones in any domain. The work performed during the experimental phase lead to the following main results:

1. The maximum length of sequential patterns varies inversely with the support value used. The finding was in line with the results stated by R. Agrawal and R. Srikant [8]

2. Sequential patterns discovered only for the events of the type "QUEST". This can be seen as the "repeated" choice of users at different "levels" to perform tasks in the game play in order to achieve certain objectives from simple to more complicated ones.

3. Sequential patterns mined were of maximum length three events for 0.02 support, of two events for support 0.03 when for support 0.04, 0.05 and 0.06 only single items were discovered, which lead to the conclusion that users for various reasons either internal (interest, resources etc.) or external (time availability etc.) are more familiar with this type of pattern.

4. Item members of two or three component sequential patterns were not present as single items in the higher support level sequential patterns mined. This fact may be interpreted and used to the design phase of the potential application(s), as a valuable hint, that helps designers combine "QUEST" elements, being at present not very popular, but of high interest, especially when associated with interaction with other facts / achievements, thus providing added value to them.

5. Single items discovered for support 0.04, 0.05 and 0.06, where not part of the maximum sequential patterns discovered with either two or three event sequence lengths, which can be seen as a cross checking point for implementing gamification strategy, where the importance is the relevance of the "QUEST" with the desired task to be performed.

The above findings are of great significance for designing gamification-based applications for behavioural prediction of users. This is because "QUEST"s can be seen as user behavioural

transactions that include events of high importance, for achieving the maximum objectives set in such applications, in any type of environments supporting well defined processes like, e.g. market(s), sales, e-learning regardless the type of gamification type applied (intrinsic or extrinsic) and so on. The current methodology overcomes the obstacle of the manual observation, association, extraction and in the end generalization, in a (semi-) manual way, based on intuitive approaches. On the contrary, the current work provides an automated algorithmic based methodological approach, for provision of a set of guidelines, to be used in the design process during the application development phase, which so far is based only on empirical findings. In the specific application selected in the current game, this is focused on using "QUEST"s, in the content of gamified applications, with the objective to drive the game user to maximal results, [6] in terms of "QUEST" usage, in a way that is familiar and transparent to him/her. Therefore, based on the fact that the maximum sequence length is 3, provides designers of gamification strategies, for the specific domain, means to select each time the appropriate "QUESTS" for achieving specific goals and drive via behavioural changes in terms of decision making in presented challenges, to the desired performance for selecting either desired actions, or products or services or education-based objectives available in a respective gamified application. On the other hand, the findings that single items gain added value when associated among other, is of great importance and can be used as guide for decision making vis-a-vis to the way that "QUESTS" are presented to the users of these specific gamified application(s).

Getting back to our case in the game selected for experimentation, as mentioned, a sample of 36.000 approximately user interactions have been collected into a respective SQLite database, categorized under 10 relevant tables of specific events types supported by the game. This data was collected on a periodic per hour and per day basis and then aggregated to a monthly based per user model. Running then the specific Apriori sequence algorithm, our methodology provided as an outcome, the conclusion that there was an interesting path of predefined processes expressed in terms of game terminology as "QUEST"s that was followed by the user as a sequence towards the game objectives. These (as all game events), have been coded as follows (processID, questID, questName):

900: q678 -> "Searched the fetid Caves of Pestilence and destroyed the weather machine"

901: q679 -> "Ruined the plans of Malkon the Plague Vampire and saved Archais from his evil machinations"

904: q682 -> "Breached the Fetid Caves of Pestilence to rescue a dwarven child"

It is important to be mentioned here, that the associations of the type (900 -> 901 -> 904) were discovered under the support measure of 0,02 and with frequency of 82 times among all possible processes interactions discovered. The number of the three (3) associated processes, is directly relevant to the sample data collected from the large log files produced by the gamified applications and they are also language/term agnostic. Finally, in the tuples discovered, the order is of significance, providing the sequence of these processes.

What this means, is that there is a significance in users' interestingness, when they use the gamified application, in getting, in a sequential way, from process 900 to 901 and to 904 by achieving their respective objectives. In other words, from the point of view of the behavioural analysis, the future path of potential user preferences getting from a point A to a point B, in terms of decisions, that can be achieved through multiple ways, can be (a) reinforced and (b) predicted by our methodology, while step by step game objectives are achieved.

This is a very important analysis and conclusion for applications that deal and are composed by decision making, based on a process-oriented approach.

5. Comparisons and Advancements – Generalizations & Potentials

The above findings, if applied in the education domain, will be of great significance and will provide initial guidance for developing gamified applications for the educational industry (eProducts, eServices and so on). Such applications need to be compliant and respect the overall model of "Input, Process and Output" (Heis, 2008) in the education domain, where input are the educational objectives that by the appropriate learning process are transformed to learning outputs that in turn are evaluated against the initial objectives (Figure 4).

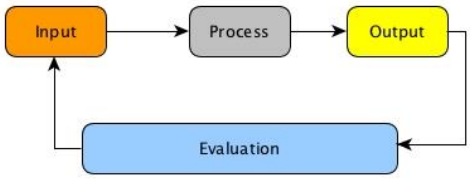

Figure 4: Input Process Output Model (Heis 2008, [220])

As a consequence, for drawing and implementing interesting, effective and challenging input for an educational application, being aware of the patterns that users are familiar with, through the "Evaluation" of their behaviour in such applications, would allow to provide to them more tailored to their needs "Input" for the educational "Process" that will allow the maximum "Output".

In terms of gamification resources, our methodology will enrich the decision process for creating and applying more personalised experience to end users and suitable quests, challenges, rewards etc. for being also compliant with the fact that designing user experience for educational applications that incorporate gamification strategies needs to facilitate the "ABCD" model educators use for writing and using learning objectives, whereas "A" means audience, "B" behaviour, "C" conditions under which the objectives have to be completed and "D" is the degree that learners have to achieve [21].

It is known that the type of proper motivation varies depending on the audience characteristics therefore for succeeding in adopting the above-mentioned model, given that learners are willing to participate in educational processes if they are subjects to appropriate education methods and resources, informed on the foreseen behavioural change and triggered enough for completing the set of achievements they are obliged to.

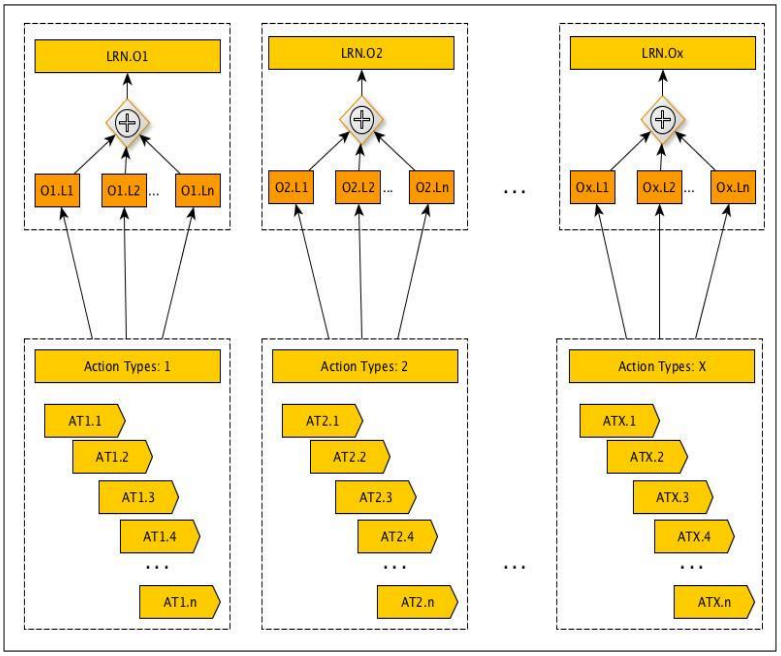

Figure 5: Design of an Educational Gamified Application

Even in Fogg's Behavior Model [22] is clearly stated that providing sufficient motivation, adequate ability and efficient activation to learners, results to the desired from the educator point of view "behaviour" achievement. As gamification contributes towards the provision of both motivation and activation of learners, it is important to employ suitable type and "portion" of them for resulting to successful applications and learning outcomes.

We select to present the potential application of our methodology to the education domain. For this purpose, we consider the education related processes, such that to be related in an input-process-output schema of relations, composing thus a system-oriented view point to it (education).

Our methodology will allow gamification applications in the above-mentioned education model, to use the "right" pattern each time, for supporting the desired behaviour for the learners, overcoming the theoretical obstacle that "the use of challenges in Information Systems though, may be limited because of a high number of monotone and standard tasks" [23]. Such strategy, hence, based on optimal path reinforcement of educational processes, will lead both teachers and students, to be informed and getting up to their educational objectives with a high degree of performance, understanding and productivity in the area.

Based on the above findings of our methodology, we attempt to design a gamified application. We consider again the educational domain for the target group of the application, that is independent of the subject that has to be introduced – taught.

The main course objectives are for the paradigm below (Figure 5), introduced as LRN.O1, LRN.O2, ..., LRNOX. It shows how action types will be connected to Learning Objectives for the design of an Educational Gamified Application. These are the necessary objectives to be achieved so that the course to be successful for the learner (or the learner group).

Every such Learning Objective Ox, in turn, can be achieved in the gamified application to be designed, by the achievement of respective objective game levels (Ox.Ln, meaning for the objective LRN.Ox, the Level n and so on). We assume that the number of levels per learning objective may vary, (but at least may have a value of 2).

On the other side, in our game design methodology we offer, the ability to the developer but at the same time to the player – learner, to design a variety of action types for the achievement of such levels, as described above and play freely by navigating and making actions – decisions through the game scenario. Such action types that are introduced by the game designer and implemented by the game developer, may be represented as a virtual library of actions, containing – being categorized further in sub-action types. For example, somebody may select to achieve the respective level, to read material, then to play a local educational game and then take a quiz to collect points towards next level. On the other hand, somebody else, may select to study much more material in sequence, so that immediately as soon as will take the quiz, to be sure that will also be awarded the next level. This model introduces the independent process in sequence selection towards one, the same objective achievement, allowing edutainment weight to be balanced by the user, on real time basis, i.e. how much game, how much, in app study, out app (text – notes) study, cooperative action types, info from social networks and so on will on demand use.

Collecting this information in large log files, as our application will run, will in turn produce frequent patterns of selected actions, where players achieved the objective much faster, as a function of selected action types. Our methodology then, when enough knowledge and processes will be collected, will propose to next player i, a proposed optimal path towards knowledge acquisition of the respective level, i.e., a set of Action Types, in a specific order, so the player – learner will be more productive. Of course,

this will be only a suggestion and the player will be always free to reject it and hence select his own path, towards the level achievement.

6. Conclusions and Future Work

As an extension to the ONARM+ previously presented work, we developed a formal methodology to support the design of gamified applications. It is based on analyzing game player's actions stored in log files to extract frequent patterns of actions. The extracted patterns are processed and classified according to the expected outcomes which can be supported in a gamification application.

This knowledge base for gamification of frequent sequential patterns of actions, along with the outcomes, they are considered as knowledge process-based transactions. Thus, given a specific domain and the expected outcomes for a gamification application, the designer could build it by selecting the proper patterns of the knowledge base above, so to drive via optimal decision making paths user behaviour changing, which is the basis for a variety of diverse domains, like marketing, learning, consumer/branding loyalty and so on. Apart from patterns, the knowledge base above. Based on this, we plan to extend our work so that the knowledge base above, to contain also meta-rules for controlling game techniques (e.g. dynamics, feedback, badges, levelling, etc.) and their relative association on a per user profile basis.

Finally, we have presented an educational game design concept, based on our proposed methodology, where the proposed application, introduces to new players – learners, accumulated optimal knowledge experience, towards game level achievements and their knowledge – learning objectives. In this game we tried to examine, using our methodology associations in user decisions and choices, as a set of concept-based processes, so based on an algorithmic approach to predict and drive choices of similar user profiles, on the same domain. While availability by developers of such real time on line games have been proven a task difficult to be achieved, future work will be focused in collecting more than an additional year's supplementary data to verify our findings vis-à-vis user behaviour.

Overall, initial interesting results of such associations were found, for specific players. Further work will concentrate also in five main directions (a) application of the maximal VMSP mining algorithm and comparison of results generate; (b) generalization of results found to a broader set of players; (c) application of the proposed methodology to other gamified domains, for mining underlying processes; (d) analysis of more other computer games (types) to extract more patterns and (e) the generalization of our work for groups of users instead of focusing to specific ones.

Conflict of Interest

The authors declare no conflict of interest.

ABSTRACT

Manufacturing System (MS) sizing is a crucial task to complete in order to obtain the desired MS performance and efficiency. It involves selecting the required number of resources from each used type in a given planning horizon. In fact, different approaches coupling simulation/optimization tools have been developed to solve this issue and evaluate the MS performance. One of these approaches is the Simulation Expert System Approach (SESA). Unfortunately, the application domain of this approach is limited in sizing only the production resources (machines and labor) but neglects the material handling system (MHS) components. Moreover, omitting the transferring problem is not viable in the real world due to its importance in each shop floor. Thus, the aim of this paper is to describe the evolution of SESA, then, to check if the simulation optimization tools used in SESA are still relevant. This paper also investigates the importance of incorporating MHS in this approach and finally proposes some improvement opportunities for SESA including the tackling of the MHS fleet sizing problem. In fact, the wide literature review performed in this research indicates that SESA is still a pertinent approach but it must be improved. Therefore, it is expected that SESA improvement opportunities proposed in this work will greatly assist industrialists in enhancing the overall MS performance, providing a significant productivity increase and a minimization of the total production costs.

1. Introduction

This paper is an extension of a work presented in the 6th IEEE International Conference on Advanced Logistics and Transport (ICALT) [1].

Due to intense competitivity in the industrial sector and to demand fluctuation, companies need to ensure better performance of their Manufacturing Systems (MS). An appropriately selected number of resources can improve the overall system performance. On the other hand, too much chosen resources means needless investment, whereas an insufficient number of chosen resources can make the system unable to produce the required quantities in the desired due date, which constitutes a financial loss (ie. penalties, loss of customers, etc.). Therefore, MS sizing is an important issue that must be considered to obtain the desired system performance. In fact, this issue has attracted the attention of several researchers. Hence, many types of approaches have been used to solve machines, labor and MHS fleet sizing problems. The Simulation/Expert System Approach (SESA), is one of these approaches used to solve MS sizing. It was proposed by [2] and enhanced by other researchers either by considering other resources or by altering the used tools. However, SESA still needs improvements to be applicable in real cases. However, one of its shortcomings is the lack of consideration for the material handling system (MHS). In fact, appropriate MHS choice and sizing is crucial for the MS design task [3]. Its main role is transferring parts between the various components of a MS in the most economical way, to ensure an efficient material flow. The interest of configuring and sizing the MHS is continually increasing in

*Corresponding Author Imen Lajmi, Sfax 3062, Tunisia, +21652486285, Email: lajmi.mezghani.imen@gmail.com

manufacturing facilities. Therefore, this research proposes some opportunities to improve SESA framework considering the MHS fleet sizing problem to make this approach more pertinent and applicable in real-world cases.

The remainder of this paper is as follows: Section 2 presents a brief literature review on the MS sizing problems. The originality of SESA and its evolution are presented in Section 3. Section 4 presents a survey of recent research studies to show the promising potential of SESA tools. Before concluding, section 5 suggests an improvement proposal for SESA.

2. MS Sizing problem

MS sizing problem is defined as the selection of the required number of resources from each type to be used in a manufacturing process for a given horizon.

2.1 Resources studied in literature

Several research studies dealt with the MS sizing problem, more precisely with the main manufacturing resources used in MS, such as (1) machines, (2) labor and (3) material handling system (MHS).

2.2 Machine selection problem

Machines represent a fundamental industrial equipment that allocates a part, for a period, to generate changes by performing certain tasks (generating the Added Value). Finding the required number of machines is an important task in the MS to achieve the target performances. Among the first research studies discussing the machine selection problem, we can cite [4] who developed neural networks to minimize the number of machines in each work center in a flexible manufacturing system. In addition, [5] proposed a mathematical formulation and a heuristic algorithm to find out the required number of types of machines in a group technology system that reduce the manufacturing cost. More recently, [6] developed a new modelling approach combining simulation/optimization methods to find the minimum number of machines required in each MS type. Besides,[7] used an artificial neural network approach coupled with a simulation tool to estimate the minimum number and the best scheduling of machines that enhance the mean tardiness and the mean flow time. In fact, [8] used two analytical methods to firstly, determine the optimal number of machines and the quantities produced in each period and secondly, determine the production plan and the periodic preventive maintenance scheduling to reduce the failures and minimize the total costs. Moreover, [9] used Discrete-Event Simulation (DES) and OptQuest to find out the optimal machine number. Two objective functions were used: maximizing the machine utilization rate and minimizing the waiting time in the queue.

The continuous dealing with the machine selection problem proves the importance of this issue in the MS improvement.

2.3 Labor selection problem

The human factor plays a crucial role in the creation, the responsiveness, the flexibility and the performance of industrial processes. The determination of the optimal number and quality of labor to be allocated is necessary in each MS. In fact, this issue has been the object of numerous research studies. For instance, [10] used Fuzzy AHP, TOPSIS and Simulation tools to determine the optimal number and assignment of labor in the system. Many performance measures have been used to achieve some objectives such as the average lead-time, the average labor utilization and the average waiting time. [11] used simulation and genetic algorithm to determine the optimum number and allocation of labor and the measure of the efficiency of their operation in an assembly shop. His aim is to maximize the throughput system. Similarly, [12]developed a simulation /optimization approach based on the genetic algorithm (NSGAII) to determine the required number of labor. [13] used CPLEX optimization software and DES (ARENA software) to determine the required number of operators in automobile chassis manufacturer while considering the labor fatigue in their attempt to satisfy the customer demand.

2.4 MHS fleet sizing

MHSs are used to transport goods and materials between workstations of a manufacturing system. Therefore, the number of vehicles greatly influences the performance of the MS. MHS are usually expensive, thus determining the appropriate number of vehicles is very a very important task. Hence, due to the importance of this problem, many recent research works dealt with this problem using different approaches. For instance, [3] developed an analytical model to estimate the minimum number of automated vehicles required by a flexible MS. The results of the regression analysis were compared with simulation results to show that the regression technique is a promising approach to resolve the fleet sizing problem. [14] used a simulation tool to determine the optimal vehicle number and material flow rate in a semiconductor manufacturing systems. [15] applied a queuing model to determine the required number of automated vehicles in a flexible MS containing multiple pickup and delivery points. The objective was to minimize the waiting times. As for, [16] applied the queuing theory to specify the required number of MHSs in a MS in order to maximize their utilization rate and minimize the investment costs. Besides, [17] used the bees algorithm to estimate the optimal number of MHS operated at the MS to maximize the profit. This algorithm is inspired by the foraging behavior of honeybees. On the other hand, [18] used multi-class Closed Queuing Networks (CQN) based on a linear programming to model the movement of MHS in a MS and determine the minimum MHS number. More recently, [19] has developed two analytical methods to determine the AGV fleet size in different layouts of flexible MS. In fact, different factors, such as the processing time, job sequence, job mix, loading/unloading stations and the number of work centers, are included in the model.

2.5 Synthesis

Table 1 presents a literature survey on the MS sizing problem the detailed analysis of which shows that the number of studies about the production resources selection area has grown considerably in recent years. In fact, the growing interest in this

subject shows the importance of the resolution of the resource selection problem in improving MS performance. However, one of the gaps in these studies is the absence of a correlation between the three types problems related to the selection of machines, of labor (operators) and of MHS components, which affect one another.

Table 1. Literature review on MS sizing

Types of resources	Research studies
Machine	[4-9]
Employees	[10-13]
MHS	[14-19]
Machine and employees	[20, 21]

Recently, some studies have combined machine and labor selection problems but without considering the MHS fleet sizing problem. For example, [20] used a simulation tool to size an effective automobile manufacturing process. The aim is to enhance the system throughput by determining the required number of repair stations, labor, machines and the best plan configuration. More recently, [21] has sized a functional MS to determine the required number of machines and employees that enhance the overall system performances for the purpose of respecting the Due Date (DD).

2.6 Used methods

Due to the variety of resources used in the production systems and the influence of one over the other, the search for the optimal size becomes more and more difficult. To overcome this difficulty, many methods are employed in the literature to tackle the sizing issue, which are classified into two main categories:

- Analytical methods;
- Simulation-based methods.

The first category can be classified into two main types: exact and approximate methods.

In fact, the exact methods like Branch-and-Bound, linear programming and others provide an optimal solution, which is suitable only for small sized problems. Therefore, the major weaknesses of these methods are their static and deterministic character, their mis-consideration of the dynamic and stochastic aspects of the system and their inconsistency with the MS sizing problem. Since the number of feasible solutions rises exponentially when changing the total number of resources, it is impossible to use complete enumeration for large-sized problems. As a consequence, heuristic and meta-heuristic methods are widely approved by the researchers to efficiency deal with the MS sizing problems.

Approximate methods, which are heuristic and artificial intelligence methods, as the expert system, artificial neural networks, genetic algorithm, Tabu search, particle swarm optimization, simulated annealing and others do not always guarantee the optimal solution.

On the other hand, the simulation-based methods, which fall into the second category, are widely used to solve MS sizing problems. In fact, simulation can provide a detailed analysis of the system performance and help managers to take the right decision.

Moreover, some studies developed approaches combining simulation and analytical methods to find out satisfying results (not optimal ones). Due to the effectiveness of this combination, [21] used an expert system simulation approach called “SESA” to look for the optimal number of two types of resources simultaneously: machines and labor. In fact, this work considers the stochastic and dynamic aspects. However, the major gap in this work is the neglect of transfer problem when sizing MS.

In the next section, the evolution of SESA and its originality are presented.

3. SESA Evolution

3.1. Originality of SESA

SESA is a prescriptive simulated approach developed by [2] to solve the MS sizing problem and more precisely, to identify the optimal number of machines in a simple static and deterministic MS. The framework of SESA is presented in Figure 1. The two principal tools used in SESA method are the simulation and the expert system, which work in a closed loop and exchange data and results.

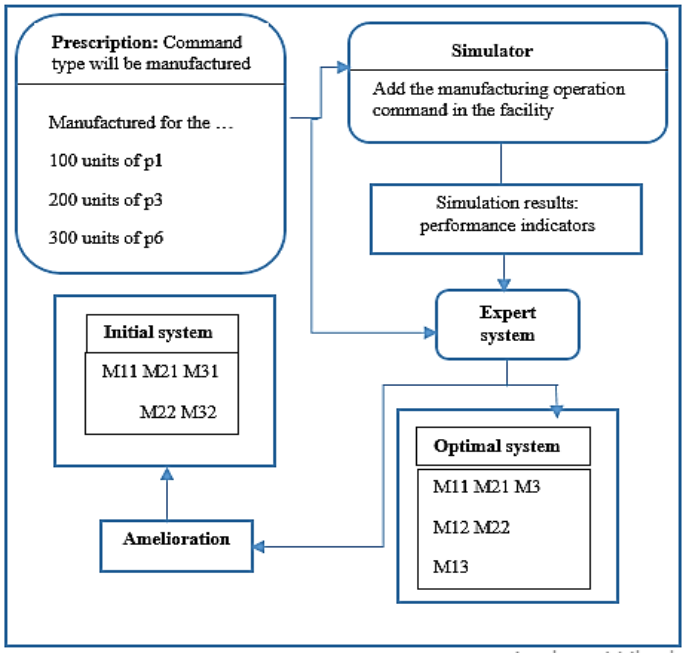

Figure 1. The framework of SESA [2]

The data of the studied MS and the typical order to be manufactured are the required inputs for the simulation step in order to establish the simulation procedure according to which the command type will be executed. This first step provides performance indicators such as the total operation time. For each scenario, the simulation model is run and the system performance measures are recorded. Then, the second step, it involves the expert system, which has as inputs the performance measures (provided

by simulation) and the performance limits. The main role of this step is to analyze the results provided by the simulator and establish one of these two cases:

- The system performance, which is optimized according to the actual context, or;
- The system performance, which needs to be improved according to the actual context. In fact, the expert system offers a problem diagnosis, according to the MS resources, in order to check if there is a lack or an excess of resources. Then, the ES provides a set of recommendations to adjust the resource number, which improves the system performance.

The simulator used in this original version is a deterministic tool named "SICOP". It is a simple program developed by "C language", which provides statistical results (performance measures). The expert system is "SEORAM", which is intended to minimize the Mean Flow Time (MFT). The results of this study indicate that combining the simulation and optimization tool is quite competitive, in terms of precision, when compared to the simulation itself. This approach helps to avoid the "try-error" aspect. Enhancement of the system performance proves the efficiency of this approach. Accordingly, other researches were encouraged to extend the application of this approach to be more applicable in real MS.
The weaknesses of this study are as follows:

- Misconsideration of the stochastic and dynamic aspects;
- Used tools and the total indices of performance chosen in this initiated approach are not used any more in research since they do not reflect any more the current tendencies of the industrialists;
- Misconsideration of the labor and MHS selection problems.

3.2. SESA improvement

Improvement of the Expert System used tool "ESMRS"

In the follow-up research work, [22] developed an improved version of SESA and applied it for Job Shop machine selection problem. The studied MS grouped the same machine type on departments and supposed that the requirement of labor and material handling system are neglected. The main focus was on the development of a new ES prototype named expert system for manufacturing resource sizing (ESMRS developed by Kappa. PC) (see Figure 2). A set of generic diagnosis production rules is developed. The main objectives were to improve the structure of research mechanism, recommend resource modification according to performance indicators provided by the simulation and overcome the "try-error" aspect. The results provide significant insights into the effective application of the enhanced ES.

Improvement of the simulation used tool

After that, [23]enhanced the framework of SESA, previously described, by using the simulation software "ARENA". This tool considered the stochastic and dynamic aspects, governs Manufacturing Orders launching (MO) as well as machine operating parameters. Thus, all entities of the same product type enter the MS according to a stochastic inter-arrival time (random distribution). Then, the entities stay on the machine queue until the machine becomes available. After that, the entity will be treated in a randomly chosen processing time (see Figure 3). The same optimization loop presented previously is used in [23] but the differences are:

- Use of a stochastic simulator tool;
- Use of more relevant performance indicators and;
- Considering the stochastic and dynamic aspect.

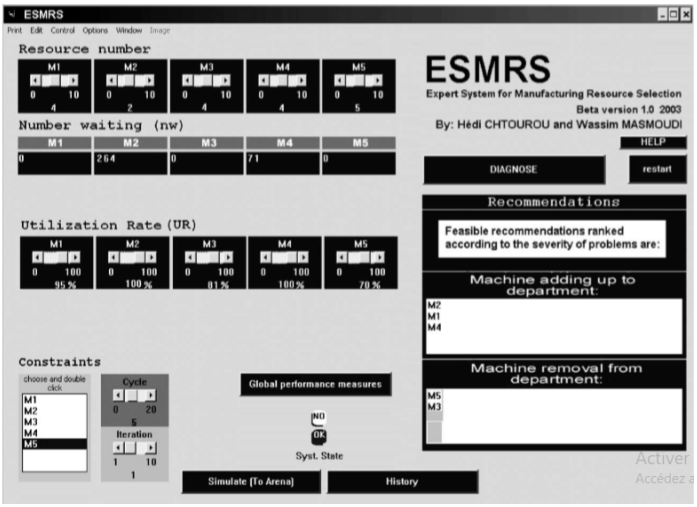

Figure 2. Enhanced ES interface [22]

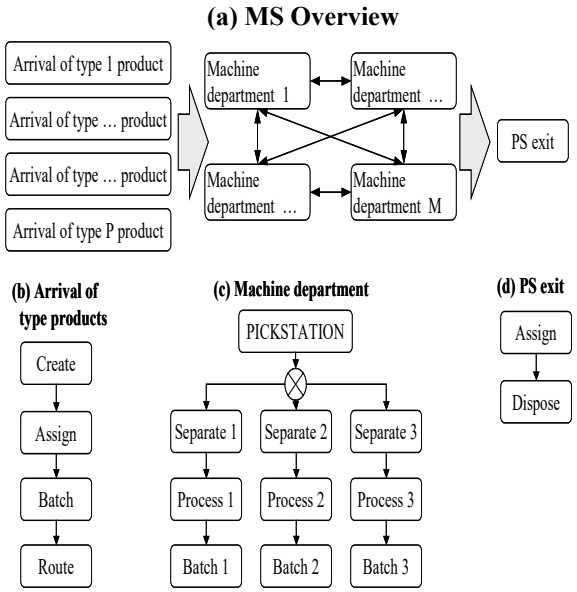

Figure 3. MS "ARENA" simulation model[23]

Despite improvements provided by [22, 23] to enhance the efficiency of SESA tools, this approach still limited in its application domain. It resolve only the machine selection problem.

3.3. Enlargement of SESA application domain

In an earlier work, [21] extended the application domain of SESA to select the optimal number of both machines and labor in a functional manufacturing system. This extension has already involved changes both in simulation model (see Figure 4) and ES interface (see Figure 5).

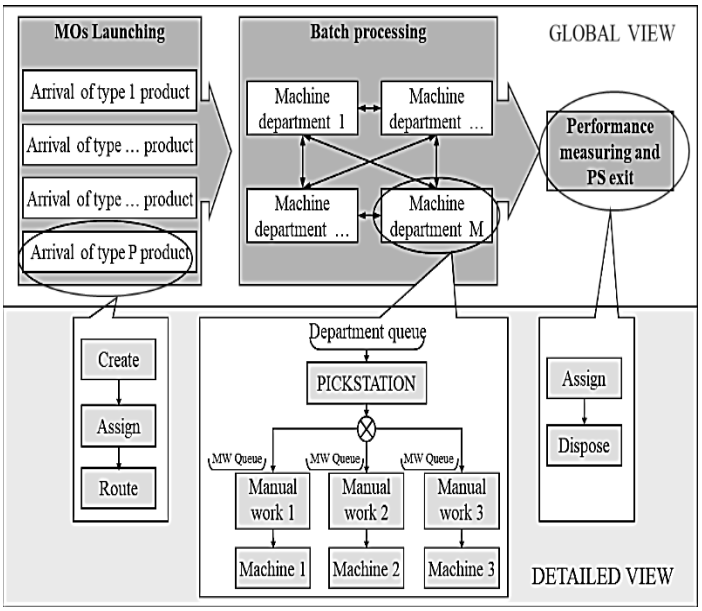

Figure 4. MS "ARENA" simulation model [21]

To build the simulation model, two inputs are required:
The MS data which represents the number of work center, Processing Time (PT) and Setup Time (ST) and;
The demand patterns, which represent the inter-arrival times, product type, load size and sequence.

Different performance indicators have been used to enhance the applicability of SESA. These indicators are: the rate of resource utilization, the average waiting time and waiting number of batches in resource queues, throughput, mean tardiness and mean earliness.

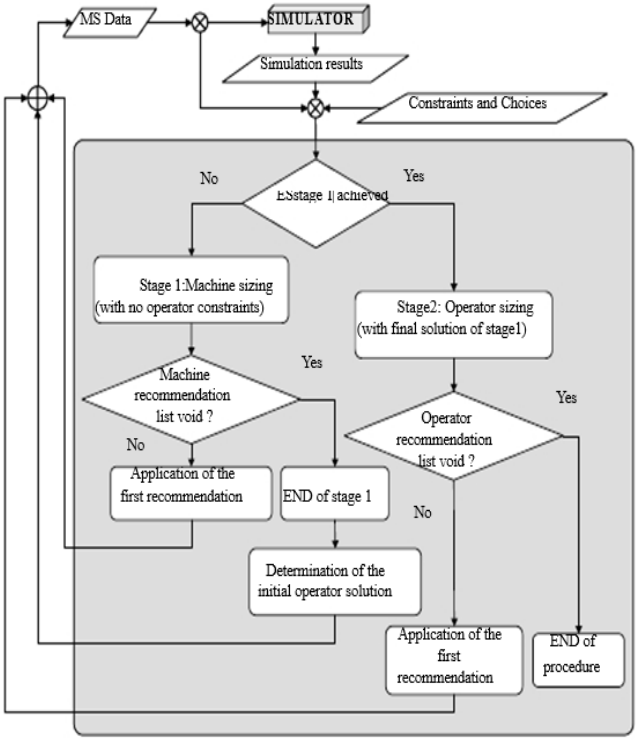

Figure 5. Enhanced ES interface [21]

The main target is to respect the DD in order to minimize the delay penalties and the storage costs. The DD indicator is more adequate for functional manufacturing context than MFT. The first objective is to minimize the Mean Tardiness (MT) and then minimize the Mean Earliness (ME), which is considered as the second objective. Besides, in order to avoid superfluous investment costs, all the resources should be fully utilized. The experiments with different levels of DD closeness indicate the important benefits of the approach improvements through the new performance measures and the enhanced ES interface.

The enhanced ES interface is divided into two main stages. The first stage is the machine selection problem without labor constraints and the second is the labor selection problem.

In the first stage, the ES starts with the study of the MS machine situation (without labor constraints). Thus, this stage supposes that the number of employees is equal to that of machines (assigning a worker to each machine). If the simulated system performance needs to be improved, the ES will recommend modifications regarding machine number. These changes overcome the problem and enhance the system performance. Thus, a new cycle is run with the modified machine number until the ES can not suggest other modifications. This situation presents the end of this stage. In the second stage, the ES resolves the labor selection problem with a machine balanced MS (according to the first stage results). The same optimization cycles will be run until they reach a non-improvable MS.

The confines of SESA developed by [21] is the neglect of the transfer network and MHS constraints when sizing MS component resources. In fact, MHS is significant in MS that has an effect on the system performance [24]. It can account for 30 –75% of the total cost, and efficient material handling can be primarily responsible for reducing a plant operating cost by 15–30% [25]. Therefore, MHS is very important in reducing the total manufacturing costs and increasing profits. Consequently, it is necessary to extend the application domain of SESA by incorporating material handling system constraints when sizing production resources. However, it is necessary to demonstrate the relevance of SESA tools. Therefore, the next section will provide a detailed survey of recent research studies using simulation and/or expert system for solving resource selection problem.

4. Is SESA a promising approach?

4.1. Is simulation always promising?

Simulation has been developing for a long time to became an essential tool for many disciplines. Its application fields may go from industry [26] healthcare [27, 28], urban design [29] military [30], among others. It has been widely proven by the scientific community and practitioners as a flexible technique by allowing modelling, testing and analyzing complex dynamic systems, namely for models where structure and behavior change over time. The simulation model is a representation of the real system. It may reduce the risks related to the implementation of new system design, production cost, production time, etc. It is used to analyze

and process huge quantities of data. As shown in Figure 6, simulation is a solid approach with many years of application and is a rapidly evolving research field [31].

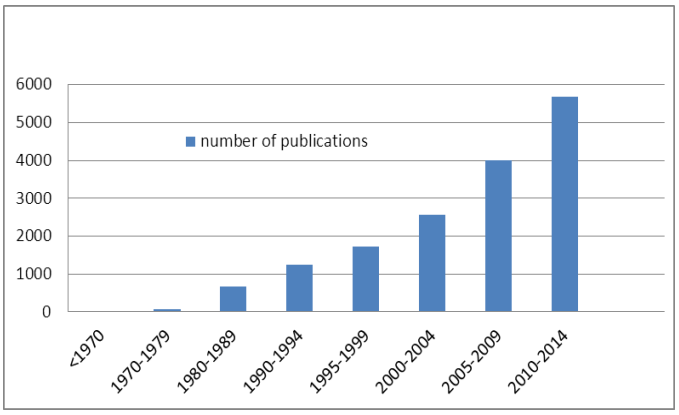

Figure 6. Evolution of simulation application

Discrete-event-simulation (DES) is mostly used to solve MS problems. Numerous benefits to use DES defined by [32]include: simulate a real system in a short time, study the interaction between different components, reduce cost and risk, monitor and control the system and others.

This approach has tackled different problems. A brief summary of DES applications to solve manufacturing systems is presented in Table 2. [33] revealed abundant references in more details about the simulation utilisation on other MS problems.

Table 2. Publications related to simulation approach

Authors	Years	Simulation application
[34]	2008	System and facility design
[35, 36]	2015, 2017	Planning and scheduling
[37]	2016	Production planning and control
[38]	2019	Supply chain design
[39]	2016	Inventory management
[40, 41]	2019, 2018	Maintenance
[42]	2016	Controlling and analyzing energy and power consumption
[43]	2018	Resource allocation

In all the above discussed studies, DES models have been proven as powerful decision support tools, which enables practitioners to accurately test, model, analyze and plan complex systems. Moreover, it is an efficient tool to search for optimal solution and evaluate the obtained results. Different DES tools have been used in literature.in this context, [44] compared these tools to identify the most popular and used ones. In fact, the ARENA commercial software has been the most popular and used tool for modeling and analyzing various complex MSs.

Nevertheless, the simulation tool may not be the first preferred in solving real-life system due to the "trial-and-error" nature of the development process and its lengthy computational requirements. This issue is particularly remarked when the solution space is mostly large and the time available to make decision and analysis is too limited. Thus, it is necessary to add an analytical method to the simulation tool to do an optimal decision-making. Therefore, the simulation tool has been coupled with an expert system approach.

4.2. Is the Expert system still promising?

The ES is an Artificial intelligence (AI) software application that attempts to simulate the knowledge and experience of human experts in a specific domain and make such expertise accessible on demand to the program user. This application was introduced by [45]for the first time in the 1980s. A growing interest in the use of ES has been seen for solving optimization problems in many domains such as Healthcare [46, 47], supply chain [48],transport [49], risk management [50] and others.

According to [51], the expert system includes three principal parts (Figure 7):

- User's interface that enables the user to ask questions and provide advice corresponding to it;
- Knowledge base that consists of facts and rules, which are created from information which are provided to it;
- Inference engine that helps to match the user's query with knowledge base and provides the result.

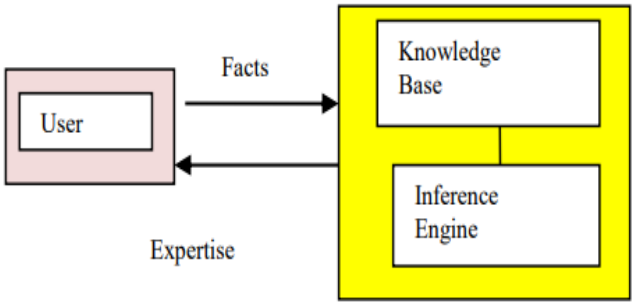

Figure 7. An Expert system environment

Table 3. Recent research studies used ES

Authors	Years	ES applications
[52]	2016	Evaluation of the performance of sustainable manufacturing
[53]	2016	Material handling equipment selection
[54]	2019	
[55]	2019	Layout designs
[56]	2018	Optimization of Design and Manufacturing Process
[57]	2019	Shift work
[58]	2015	Machine tool selection
[59]	2015	Material Selection
[53]	2016	
[60]	2017	
[61]	2018	Risk management

The main advantages of ES consist in reducing human error, always available, providing expertise at a minimum cost, which is used in any risky environment to solve complex decision problems

in different specific fields, obtain flexible and practical solutions, and respond at great speed, etc.

The capability of ESs to acquire performance similar to the human ones makes current researchers used it to solve various types of problem in MS (see Table 3).

4.3. Is coupling Simulation/Expert System promising?

Simulator systems generate large and a high variety of data that make decision making so difficult. Therefore, novel approaches combined simulation and optimization have been developed in literature to eliminate this gap. In fact, simulation based optimization approaches have received considerable attention from many recent researchers to solve MS problems. [62] proposed an improvement framework using genetic algorithm and DES to investigate the buffer size and job sequencing optimization problems. [63] combined the DES models and artificial neural network models of the production system. This combination was realized through an ES in order to evaluate the stability of a production system and implement production plans. [64] developed a practical approach using bee colony to improve throughput while minimizing waste energy and environmental impact. [65] proposed a novel methodology using ant colony and DES to select better facility allocations that minimize fixed and transportation costs.

Recent research studies applied the DES with ES in different application including industrial systems [66], food process [67], supply chain management [68], healthcare systems [69], risk management [70]and others.

The main advantage of this combination is that the DES can integrate compound system dynamics and uncertainties. Then, ES helps in efficiently getting optimal parameter values. The methodology is that the ES accesses the output of a simulation cycle and, depending on the user's objective, selects and retrieves the pertinent data and provides a mechanism for exception reporting. A greater degree of integration would be for the ES to explain the recommendations. Thus, the incorporation of DES with ES improves the decision-making process.

The research studies, cited in the previous three sub-sections, have been conducted to assess the trends of SESA approach and its capability to solve highly complex systems with stochastic variables. We can conclude that SESA is still promising but can be improved.

4.4. Limits of SESA

The application domain of SESA is limited in finding the optimal number of machines and employees without taking into account the MHS, despite its importance. A MHS can be defined as a vehicle that moves work-parts at short distances and usually inside the building. [71] affirms that the MHS represents a major portion of the total manufactured product cost. An efficient MHS can have a main impact on the operating cost, which reduces and increases the total throughput and department utilization. Moreover, a well selection of the required number of MHS is very important to significantly improve the efficiency of the MS. In fact, if the chosen number of MHS is less than the required number, the work-parts will saturate the storage areas between departments and their waiting time increases. Moreover, if the chosen number is higher than the required one, the MHS waiting time increases. This will cause an accumulation of vehicles, a saturation of the traffic lines and a system blockage. Besides, the MHS purchase cost is very high, so an accurate determination of their optimum number is required.

Consequently, considering MHS when selecting machines and labor, it is very important to significantly improve the efficiency of MS.

5. SESA improvement proposal

From previous sections, it is clear that SESA is always promising seen simulation and ES benefits. Nevertheless, it is a priority to take into consideration the MHS. Our contribution in this section is to highlight the opportunities of SESA improvements.

5.1. Proposal to enlarge the application domain

To enlarge the application domain of SESA, we will propose some improvement opportunities and develop a new strategy of SESA by considering the MHS fleet sizing problem (see Figure 8).

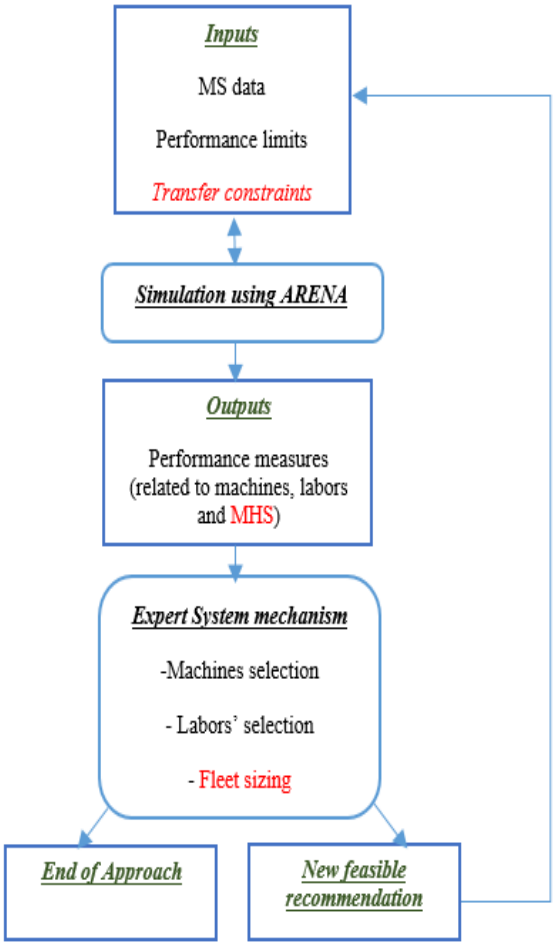

Figure 8. The new SESA framework

In the beginning, different characteristics related to the MHS will be integrated in simulation inputs. Then, new performance indicators related to the MHS will be considered to analyze system performance (see section 5.4). Finally, a new stage related to the MHS fleet sizing will be added to extend the expert system mechanism.

5.2. Improvement proposal of simulation model

To improve the simulation model developed by [21] and make the first investigation of taking into account the MHS when sizing MS, it is necessary to add different data related to the MHS within the MS data, which represent the simulation input. A representation of the improved model is presented in Figure 9.

The MHS data requirements can be:

- Type of material handling;
- Direction of movement (orientation);
- Transport distance;
- Load size;
- Loading and unloading time;
- Speed of material handling;
- Dispatching rule.

The components of this proposed model are as follows:

- Materials warehouse;
- Five departments (each one group the machinery with the same process capability) ;
- Parking (group the MHS);
- Finished Pieces (FP) warehouse.

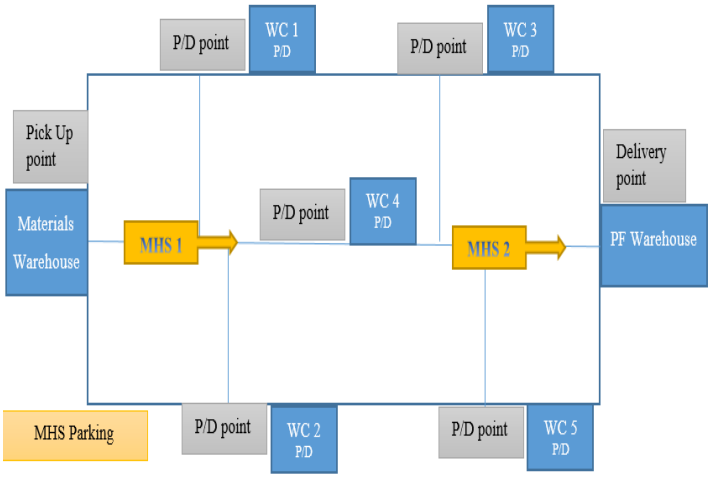

Figure 9. MS model including MHS

The MHS process, in this system, consist of four main steps:

- The unloaded MHS starts from the parking and moves to the pickup point to pick the load and goes to its destination (P/D point) related to the work center;
- The MHS stops to deliver the parts, picks up the new load if it exists;
- The loaded MHS moves to the next point whatever its storage area or work center, then the same operations will be repeated until the end of the procedure;
- MH returns to the parking.

The traveling time depends on: (1) the type of transporter (speed, loading time, unloading time, etc.); (2) the transfer network constraints like dispatching rule, orientation, distance between the departments etc.

5.3. Use of better Performance indicators

The performance indicators used by [21] are divided in two types:

- The main performance indicators are used to evaluate the global MS performance, in terms of tardiness, earliness and DD;
- Diagnostic performance indicators: they are used to resolve resource lack/surplus problems in each work center, which are represented as follows (Table 4):

Table 4.Indicators used by [21]

Indicators	Definition	Objective
Machine utilization rate (RUm)	Machine availability within a period of time	Maximize machine utilization
Labor utilization rate (RUop)	Labor availability within a period of time	Maximize labor utilization
Number of units in queue (WIP)	Total number of parts in queue and under process	Minimize WIP Parts in queue and parts in machine
Waiting time of units in queue	Total waiting time of parts in queue and under process	Minimize the waiting time of Parts in queue and parts in machines
Tardiness (Tr)	Time at which the task is completed after its date.	Minimize tardiness
Earliness (Er)	Time at which the task is completed before its date.	Minimize earliness

We can say that the performance indicators used by[21] are relevant but not sufficient to evaluate the performance of a MS including the MHS. The major shortcoming consists in neglecting the performance measure related to the MHS.

On the other hand, to improve SESA, it is necessary to measure the efficiency of the MHS, which can be characterized by several performance indicators.
In fact, previous research studies, in the field of fleet size, used different performance measures to analyze and evaluate the system performance. [18, 72-77].

Most of the indicators, related to MHS performance are:

- Vehicle utilization rate;
- Throughput rate;
- Vehicle waiting time;
- Vehicle blockage time;
- Empty vehicle traveling time;
- Total number of delivered loads;
- Number of units waiting to be transported;
- Waiting time of units to be transported;
- Availability/ unavailability of MHS.

5.4. Improvement proposal of the ES reasoning mechanism

The ES reasoning mechanism used by SESA is divided into two stages. The first stage aims at resolving machine selection problem without labor constraints (with a number of workers equal to the number of machines in each department). Then, the labor requirement problem resolution starts with a machine balanced MS.

According to our literature review, there has not been yet any expert system developed to select machines, labor and MHS simultaneously. In this work, we try to improve further ES reasoning mechanism in order to select not only the production resources (machines and labor), but also the material handling resources (trucks, pallets, etc.).To attain this objective, it is important to add another stage, in SESA, to resolve MHS fleet sizing problem (see Figure 10).

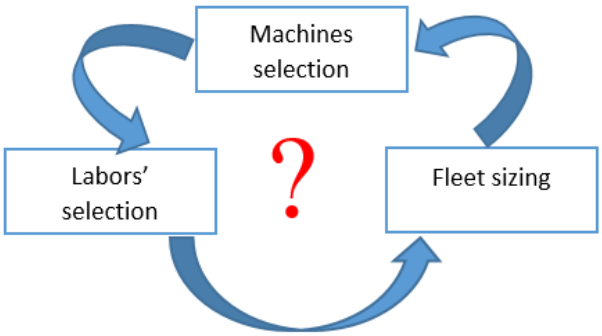

Figure 10. ES reasoning mechanism

The resolution of MHS fleet sizing problem requires new knowledge based rules related to the MHS in order to make the right decision of adding or deleting a MHS. The new stage must be in coherence with the other stages. We can take the example of the Lack and surplus of MHS resources. In fact, If the MHS utilization rate (ur) is less than the lower performance limits (supposed urmin=40%) there is a surplus of vehicles (the number of units waiting to be transported decreases but the MHS cost increases). In addition, If the MHS utilization rate (ur) is more than the higher performance limits (urmax=90%) there is lack of vehicles (the number of units waiting to be transported increases).

Example of the generic diagnosis production rule related to the lack of resources (ur>urmax):

MSS: Manufacturing system state.

If [GlobalPerformance: MSS= = OK] AND [D: ur>= D: urmax] Then D: problem=lack

The ES is a promising tool, as proved in previous section. It can be useful to various types of resource sizing problems. However, integrating an additional stage and finding an optimal order of three stages in the strategy structure is not an easy task. The feasible way to enhance SESA is to start with one problem, by giving a fixed number of resources for the others, then, using the solution of the first stage by solving the next problem, then, using the new information obtained from the second for solving the third problem. Each stage may have several iterations until satisfying results are obtained. In fact, it is necessary to identify the right ordering of selection problems because different ordering can provide different solutions. Unfortunately, the chained stages can address the complexity of the problem when dealing with a high-size problem. This approach becomes challenging to be applied.

Note that it is possible to combine other useful optimization approaches with simulation, such as the Artificial Neural Networks (ANN) Tabu algorithm, Genetic Algorithm, Data Envelopment Analysis (DEA), Regression Metamodeling etc. to identify the required number of resources.

6. Conclusion and Future Work

This paper discusses the originality and the evolution of SESA for sizing MS. The original version was created using static and deterministic tools to solve only the machine selection problems. Later research studies enhanced it by developing new stochastic and dynamic tools and enlarging its application domain by incorporating the labor selection problem. However, SESA is still limited, it neglects the MHS fleet sizing problem despite its influence on the machines and labor quantities. The provided literature survey indicates firstly that the MS sizing problem is continuously relevant due to its importance in ensuring the desired system performance. Secondly, the survey indicates that SESA is a promising approach for the MS sizing problem. The purpose of this study was to extend the application domain of SESA by integrating the MHS fleet sizing problem in the overall MS sizing task. The new SESA framework is thoroughly explained and its application and validation on actual case are proposed as future research.

Conflict of Interest

The authors declare no conflict of interest.

ABSTRACT

This work presents the development of an original idea for a walking robot with a minimum number of motors, simple construction and a control system based on the brain bioelectrical activities. Described are geometric and kinematic dependencies related to the robot movement, as well as brain-inspired IoT control method. Various aspects are discussed for improving the robot's qualities, concerning the shape of the robot's feet and base in order to overcome various obstacles and maintain the static mechanical equilibrium. Improvements in the mechanical design are provided to improve reliability and enhance the scope of robot's applications. A new IoT framework for creating Human-robot interaction applications based on Node-RED "wiring" of Emotiv Brain Computer Interface (BCI) and Arduino based robot is designed, developed and tested. An educational application how to train the joint attention of children by a mind control method based on neurofeedback from beta oscillation in the right temporoparietal region is illustrated in a Node-RED flow. The neurofeedback is exposed on the walking robot.

1. Introduction

Applications of walking robots include rescue operations, work and inspection in harmful and dangerous environments, military purposes, etc. Typically, they move in an environment with obstacles whose positions and dimensions are not known in advance. Their mechanical and control systems are designed to be able to avoid or overcome obstacles. In some cases, the obstacles can dynamically change in time. This leads to more complicated designs of the walking robots compared to robots on wheels or tracks. They have more degrees of freedom and are slower. A common problem is the task of climbing and descending stairs [1-5]. Experimental robots are developed with a small number of degrees of freedom and a special shape of their feet that overcome obstacles while maintaining static stability. [7]. For these reasons, alternative solutions are investigated [5], [6] and [7]. In [7], the author presented a low-budget two-legged robot which is able to maintain static equilibrium. Other simple solutions are also investigated, such as: passive-dynamic two-legged walking [7] and different variants inspired by nature [1], [2] and [8].

Walking robots are also used for educational purposes. The results in the scientific literature show positive reactions and improvement in the attentional and positive emotional state of children with special educational needs (SEN) [9]. Nonhumanoid walking robot Big-Foot is successfully implemented to support the education of such children in two day-care centers for children with SEN in Bulgaria [10]. Some ideas have been challenged with the special educators - how the walking robot to become more intelligent and personal, in order to act as a mediator for learning and socializing because these children show deficits in early social communication skills such as Joint Attention (JA), social requesting and referencing. Joint attention is the shared focus of two individuals on an object and gaze shifting and behavioral response are the most used measures to assess the establishment of JA [11]. However, children with ASD avoid eye contact or lose focus on humans quickly. In this context, our hypothesis is that the robot has the potential to establish JA better because these children trust robots more than humans [10] and we can use this as a pure social consequence of sharing an experience. Furthermore, the JA can be made visible on a robot by exploiting a neuro physiological approach instead of gaze tracking as an indicator for a shared focus of two individuals on a same object. By integrating walking robot with a brain-aware device we propose an innovative concept for establishing and assessing JA in more objective way. For example, the Big-Foot will climb stairs only if the active brain-patterns correlated to attention system of the human brain are observed and evaluated.

*Anna Lekova, +359887435648, alekova.iser@gmail.com

The proposed nontraditional brain-inspired Robotics intervention should run anytime and anywhere with a remote supervision of the special educator over the WiFi in order to aid children not only in schools but in family environment. Therefore, the proposed framework should comply to the concept for human-robot personal communication by augmenting intelligence to robot, however not digitally by pushing a button, clicking, dragging or speaking, but biologically and continuously through emotions, mental intentions or even via chemically released by neurons rewards [12].

All this imposes technical challenges concerning robot design, proper neuroscience computing and ubiquitousness. Movement of walking robots is accomplished in two ways: motion with maintaining static stability or use of dynamic gaits. When the number of legs is small, less than 4, maintaining static stability is not an easy task as it is necessary to change the center of gravity, which requires additional degrees of freedom. Overcoming obstacles with few supports is even harder. This article discusses a robot design that has only three supports. In this case the problem of maintaining static stability is overcome by increasing the area of these supports and using suitable shapes and materials.

The technical challenges concerning ubiquitous computing are how to merge people, processes, devices and technologies with sensors and actuators. We exploited the idea behind the Internet of Things (IoT) and the innovative" Cloud Computing" infrastructure [13]. Thus, all sensing, computation, and memory can be integrated into a single standalone Socially-assistive Robotics system. Node-RED [14] is an open source development tool built by IBM, which allows to wire up IoT as nodes in flows. Node-RED is built on Node.js and can run anywhere if the applications are capable of hosting node.js, such as small single board computers like the Raspberry Pi, personal laptops or in cloud environments, such as the IBM Cloud. The Node-RED connectivity allows nodes to collect and exchange data ubiquitously and its flow-based programming is an ideal solution to wire up the biological brain intelligence to robots anytime and anywhere. Based on the idea behind IoT, that uniquely addressable "things" communicate with each other and transfer data over the existing network protocols, we propose how the information channel between the human brain and external devices to be applied for IoT brain-to-robot control. By analogy to Visual servoing [15] and Tactile servoing [16], we defined a term "Brain servoing" (or brain-based robot control) that uses EEG feedback information extracted from the brain EEG sensor to control the motion of a robot. The control tasks intend to translate a specific brain activity interaction patterns in robot commands ubiquitously. The control instructions are transferred from continuously decoded JA performance metric into robot commands and are sent to the robot actuators via a Node-RED set-up Emotiv Brain-Computer Interface (BCI) to Arduino.

In this study we illustrate a non-traditional control method where the brain electrical activity is captured by EMOTIV brain-listening headset [17] and specific spatial and temporal brain frequencies correlated to JA are translated into commands to control the walking robot Big-Foot. Because the robot Big-Foot has a simple and innovative design, children with specific needs find it attractive, and it does not create feelings of anxiety and discomfort when interacting with it. This helps the robot function as a mediator between the children and the therapist. The 3D model of the robot is cheap and easy to be controlled by children. It is extremely maneuverable and can climb stairs. These features allow it to be used in educational games for children. To the best of our knowledge we first propose an IoT framework for creating Human Robot Interaction (HRI) applications based on Node-RED "wiring" of Emotiv BCI [18] and Arduino based robot.

2. Mechanical design and improvement of the robot

Fig. 1 presents the design of the robot and Table 1 lists its main components. Two engines are mounted in the body 5. The rotor of motor 2 is connected to and rotates the circular base 1. This allows the robot to change its orientation and turn when the feet 4 are raised above the ground. The motor 3, via a connecting shaft, drives the arms 7. At the end of the arms 7, the feet 4 are mounted. The feet maintain a constant orientation with respect to the base 1 and the body 5 by means of two gear mechanisms 6 with a gear ratio of $i=1$. This design allows the robot to rotate more than 360 degrees around axis $R1$. There is also no limitation of the rotation around axis $R2$. The two rotations are reversible, making the robot extremely maneuverable.

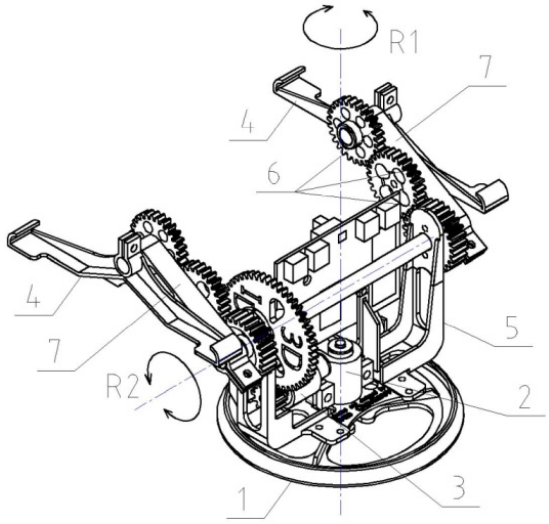

Figure 1: 3D model of the robot Big-Foot

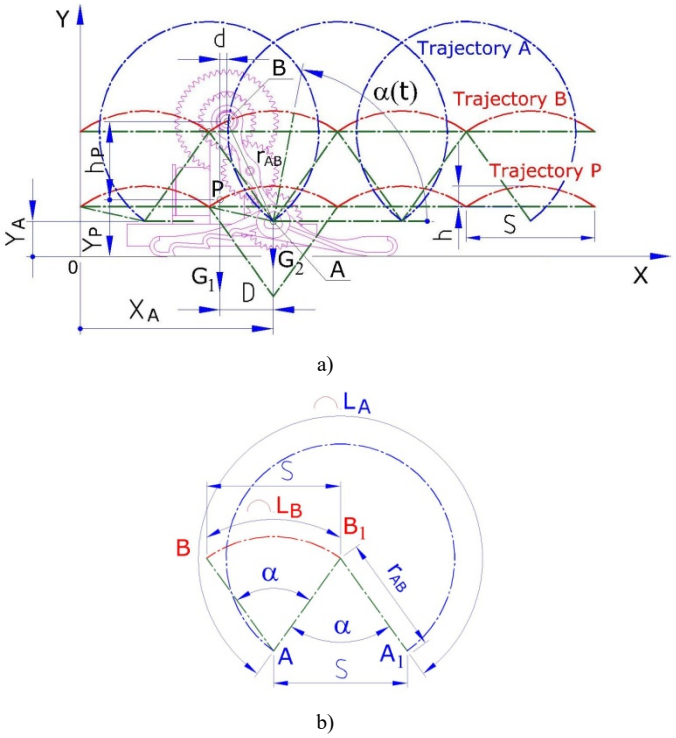
Table 1. Part list of the main components

Position	Part description
1	Circular base
2	DC motor for rotating the base
3	DC motor for rotation of the arms
4	Feet
5	Body of the robot
6	Gear transmission mechanisms
7	Rotating arms

When the robot moves on a flat terrain it passes through two main phases. During the first phase, the feet 4 are stationary on the ground. The arms 7 move, and the body 5, together with the base 1, is moved at a distance of one step S (Fig. 2a). All points on the robot's body move along trajectories that represent arcs of circles, for example, the trajectories of points B and P on Fig. 2. The radius r_{AB} is determined by the length AB of the arms 7. During this phase, the arms 7 are rotated at an angle α

Similarly, to the first phase, the trajectories of the points of the feet are also moving along arcs of a circle with radius r_{AB}. In this case, the angle of rotation of the arms 7 is $(2\pi - \alpha)$ (Fig. 2b). During this phase, the robot does not move forward but can rotate around axis *R1* (Fig. 1). The second phase ends when the feet touch the ground. The movements during the two phases are cyclically repetitive.



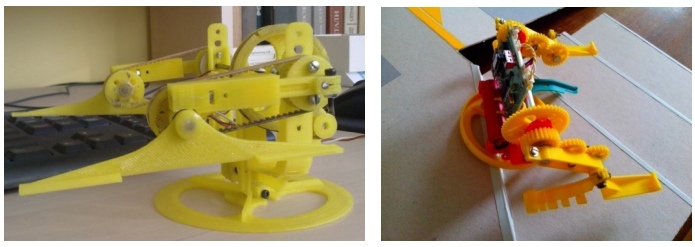


Figure 2: Trajectories of different points of the robot during the two phases of motion - a) and b) step S and angles of rotation of arm AB.

During the second phase, the robot's feet rise to a relatively high height, which helps to overcome high obstacles. The behavior of the robot has been verified through computer simulation and experiments with 3D printed prototypes.

More detailed descriptions of the kinematics and behavior of the robot in the various phases of its movement are described in [8], [19] and [20].

In the original idea described in patent [19], maintaining of parallelism between the feet and the base is achieved by a belt mechanism. The 3D printed prototype (Fig. 3a) showed that the belt drive is not suitable due to the need for considerable tensioning. The drawbacks of this model, described in more details in [20], have led to the need of improvement of the mechanical design.

a) b)

Figure 3: a) First 3D printed model, b) model with improved design climbing stairs.

Improvements have been made to the mechanical structure for a more reliable torque transmission. A new type of joint between the shaft and the feet is used (Fig. 4, position 8), which significantly reduces the stress concentration. This joint is realized by a smooth transition from a polygon to a circle, and the 3D printing technology allows its physical implementation and application in our model [20], [29].

Changing the shape of the feet and the round base makes it possible to overcome higher obstacles (Fig. 4, positions 9 and 10).

Another approach is used to improve the capabilities of the robot, namely to add additional elements. Two tails have been added (Fig. 5, position 11), which prevent the robot from rolling over when overcoming high obstacles.

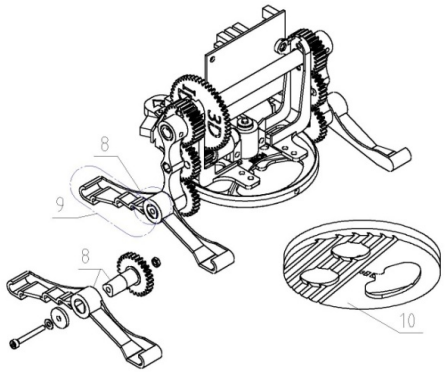

Figure 4: Improvements in the design of the Big-Foot robot

The addition a platform (Fig. 5, position 12) is used for applications of the robot for developing games for children with specific needs.

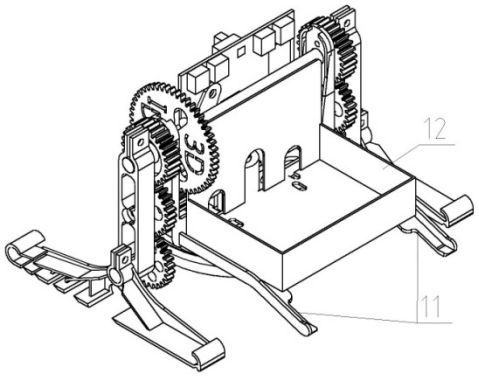

Figure 5: Walking robot with tails and a paltform.

3. Human mind control method of robot with Node-RED EmotiveBCI-to-Arduino interface

The most common way to control a robot is the joystick or mobile device. However, for some people the joystick or mobile control is difficult or impossible for many reasons and other (non-traditional) control methods have being developed based on the recent innovative sensors and technologies, such as motion sensing devices, etc. In this section, we present a non-traditional control method that rely on "Brain servoing" which uses feedback information extracted from a brain sensor (EEG feedback) to control the walking robot.

A traditional bi-directional DC control of two motors (operating at a voltage of 2.7-10.8V) is used. The current is about 1.2A per motor and the load on motor is up to 2A for few seconds. The H-bridge DC motor control is used in order to rotate motors in both directions. Four transistors in the circuit are controlled in pairs and play a role of switches to control the motor to rotate in both directions. Fig. 6 presents the connecting scheme and Fig. 7 the code uploaded on the ARDUINO MICRO. The end-user interfaces via dialog box for laptop or from mobile device are presented in Fig. 8.

Figure 7: The code for ARDUINO MICRO

The nontraditional control method intends to translate in robot commands a specific brain activity interaction patterns within a framework of IoT. Fig. 9 illustrates in general this framework for Brain-robot interaction and its deployment using a Node-RED tool. An application of EmotivBCI-to-Arduino Node-RED flow is explained in Section V. The commercial EEG devices, Emotiv EPOC or Emotiv Insight [17] could be used. The placement of electrodes are shown in Fig.10. In this study EEG data are acquired and recorded with the 14-channel neuroheadset EPOC+ and the EEG signals were sampled at the rate of 256 Hz. The data are wirelessly transmitted to a host computer through Bluetooth and further processed with EmotivBCI Node-RED Toolbox [18].

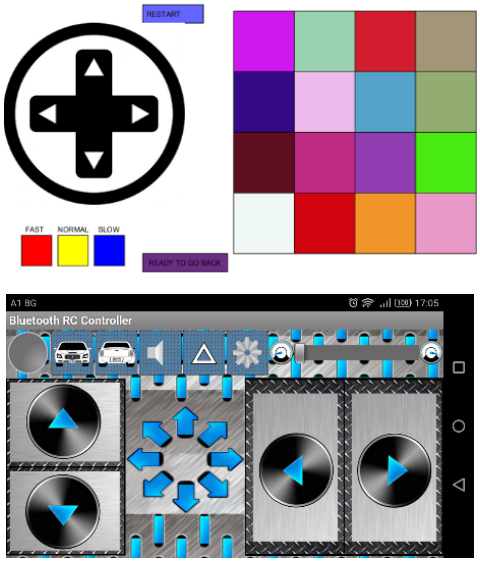

Figure 8: Traditional control methods of walking robot BigFoot

Figure 9: IoT framework for Brain-robot interaction - Node-RED EmotivBCI-to-Arduino Interface.

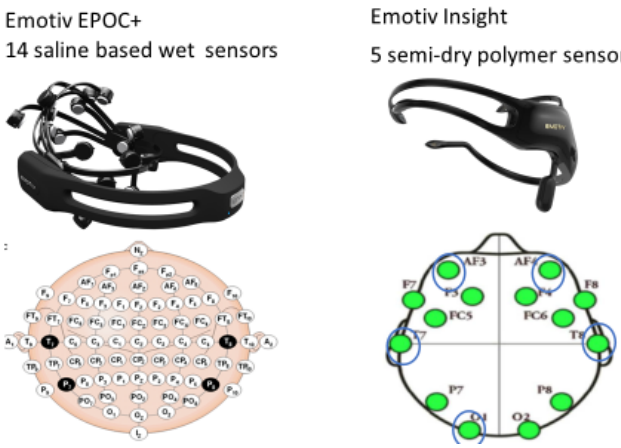

Figure 10: EMOTIV EEG headsets for EEG-based BCI - listen, record and transmit in real time the electrical activity of the brain

Node-RED uses a visual programming approach for 'wiring together' of code blocks and make up 'flows' to carry out tasks. It connects nodes as a combination of input nodes, processing nodes and output nodes in a browser-based flow editor using a wide range of nodes in the palette. The EmotivBCI Node-RED Toolbox is a custom library of input nodes for Node-RED which allow interfacing the EMOTIV technology with other Node-RED nodes and thus to create a wide variety of BCI integrations. Installation, node descriptions and use are presented in [18]. EmotivBCI Node-RED gets data from Emotiv Cortex (Cortex is built on JSON) and WebSockets for creating BCI applications and integrates data streams from the human headset with third party software or hardware. In a browser-based flow in a Web page, a user is

allowing to control the BigFoot rotation and direction of both motors using one of the following brain activity correlated patterns: in the frequency domain, correlated with human cognitive, facial and emotional states or directly by preliminary trained mental commands. EMOTIV offers the opportunity for the user to create and execute a number of Mental Commands [21], such as: push, pull, lift, drop, left, right, rotate left, rotate right, rotate forwards, rotate backwards, rotate clockwise, rotate anticlockwise, and disappear. The detected facial expressions are blink, left wink, right wink, raised eyebrows (surprise), furrowed brows (frown), smile and clenched teeth. The Emotiv technology currently offers five performance metrics detections: Engagement/Boredom, Frustration, Meditation, Instantaneous Excitement, and Long-Term Excitement, that are based on universal in nature brainwave characteristics and don't require an explicit training of the user [22].

All these correlated frequency patterns or detections are interpreted in the Node-RED function blocks and map to commands in order to control the walking robot by sending dynamically information to the serial port where the Arduino is connected. There are several ways to interact with an Arduino using Node-RED. As the Arduino appears as a Serial device, the Serial in/out nodes can be used to communicate with it after adjusting the serial port speed (baud rate) to be the same at both ends. We wired the EmotivBCI nodes to serial port and Arduino Software (IDE). We program the Arduino with the IDE, and then send and receive input over the serial port to interact with BigFoot. Two browser-based flows in a Web page, as well as Node-RED Graphical User Interface (GUI) are designed to allow the user to control the BigFoot motors dynamically by its own brain activity patterns in the frequency domain corresponding to the joint attention. Every 1 or 2 s a string for one of the following commands - 'S' for stop, 'F' for forward, 'B' for backward, 'L' for left rotation and 'R' for right rotation is sent. Except the neurofeedback exposed on the BigFoot, the GUI shows the rotation and direction as a feedback in the web page.

4. Application of the IoT framework for brain- robot control method

The walking robot is used in the development of educational play-like activities of children with SEN. Trough playing with the robot, the children improve their special orientation abilities, they learn easily and with fun by controlling the robot [11]. The interaction of children with the walking robot engages them to communicate with each other and develop their joint attention (JA). By using the non-traditional mind control methods, a neurofeedback rehabilitation is possible and will be effective for training the attention or emotion self-regulation of the brain function. We place the child's neurofeedback in the play-with-robot interventions and expose it on the walking robot.

Joint attention precedes the development of children mentalization skills [23]. Mentalization is the ability to understand the mental state, of oneself or others, that underlies evident behavior. Brain activity patterns in time and frequency domains correlated with JA are discussed in many papers [23], [24] and [25]. According to studies [25] and [26] the oscillatory brain activity in the alpha and beta ranges in the right temporoparietal region correlates with the anticipation and prediction of another person's responses and preferences. Authors in [23] have tested whether neuronal activity preceding JA correlates with mentalization in typically developing (TD) children and whether this activity is impaired in children with autistic spectrum disorder (ASD) who evidence deficits in JA and mentalization skills. TD children shown beta rhythm (15-25 Hz) in the temporoparietal region preceding the JA behavior, while ASD children did not show an increase in beta activity. In the study [23] statically significant difference in increasing the beta band power in the right parietal group of channels is found and again the data analysis suggested that the right temporoparietal region and the middle/superior frontal gyrus are the main brain regions contributing to the beta power differences between the two groups. Based on these neuroimaging findings we designed a play where a child can move the BigFoot to climb the stairs through a neurofeedback from the oscillatory brain activity in the alpha and beta ranges in the right temporoparietal region. Thus, we try to teach and train children joint attention by learning to modulate their rhythm power in the beta frequency band [15-25 Hz] in order to move the walking robot. The power spectrum of right temporoparietal lobe intensity is obtained by EmotivBCI tool and the changes in JA are calculated based on functional brain imaging in terms of event-related desynchronization (ERD) or event-related synchronization (ERS) [26].

According to Pfurtscheller [26] sensory and cognitive processing results in changes of the ongoing EEG in form of ERD/ERS that are highly frequency-band specific. For example, oscillations with 10 Hz comprise more synchronized neurons than oscillations with 40 Hz. The ERD is interpreted as a correlate of an activated cortical area with increased excitability and the ERS in the alpha and lower beta bands can be interpreted as a correlate of a deactivated cortical area [26]. Furthermore, the frequency of brain oscillations depends on the percentage of a population of neurons synchronized. With an increasing number of synchronized neurons, the average frequency becomes slower and if only 10% are synchronized, the amplitude is 10-fold the activity of the 90% of not-synchronized neurons.

In terms of information theory, a desynchronized system represents a state of maximal readiness and a maximum of information capacity [27]. The neuroscience explanation is the ERD, i.e. in the underlying neural network small areas of neurons involved in a particular neural computation (neural ensemble), work in a relative independent or desynchronized manner.

We use (8) to obtain the percentual decease (ERD) or increase (ERS) in the band power during a test (activation) interval compared with a baseline (reference) interval. The ERD/ERS index foe alpha and beta bands are the respond to different levels of JA:

$$ERD/ERS\% = (A-R) / R*100 \quad (8)$$

where A is the power within the frequency band of interest in the activity period and R is the preceding baseline or reference period. Positive numbers are obtained for ERS% and negative - for ERD% that reflect synchronization and a state of band power decrease. We tested our research hypothesis in pilot experiments with five students (right handed male and female in average age about 18 years old) by measuring whether the amount of alpha ERD increase and the amount of beta ERS increase with higher level of

JA and mentalization skills. The mean threshold of 5% for ERS in the beta rhythm was defined experimentally. We plan to perform the experiment explained in [23] with children with ASD in order to compare the establishment and assessment of JA based on the intervention and observations of the gaze shifting and behavioral response from practitioners versus establishment and assessment of JA by the brain-inspired robot control and a neurofeedback response.

The control commands are transferred from continuously decoded JA performance metric into robot commands and are sent to the robot actuators via Node-RED EmotivBCI-to-Arduino Interface. For this application, only the right temporal T8 and right parietal P8 electrodes are used for right-handed participants and their beta and alpha power are analyzed during the neutral or joint attention states. The power spectrum density for beta band is received continually from the EMOTIV Node-RED EEG streaming data. The command 'S' is sending to COM4 by default. In a function node, the ERS and ERD are calculated for each electrode and when alpha ERD significantly decrease and beta ERS increase (thresholds in %, specific for the participant), the corresponding command 'F' or 'B' is sent to COM4. The results showed that robot could be successfully navigated by the positive values of 5% for ERS in the beta rhythm, which is a correlate with joint attention on walking robot in order to complete a navigation task to climb stairs by human intention. In the future we will assign the percentual increase into fuzzy sets in order to define levels of difficulty for climbing stairs.

The Node-red flow for brain-robot interaction based on EmotivBCI toolbox is shown in Fig.11. After streaming the row data from the Emotiv node in the first Node-RED flow, the power of frequency bands of interest are stored in global variables. They are accessed in the second flow (Fig.12) to set-up the baseline settings in the frequency band of interest for 1 or 2 min. How the robot commands are mapped and sent to serial port can be seen in the first Node-RED flow.

We intend to test the proposed framework with a neurofeedback from the frontal theta for training and remembering the orientation in space and implicitly to expose it by the walking robot. The increase in theta power during successful encoding of new information is discussed from neurological point of view in [28] with the relationship with hippocampal theta induced in the cortex.

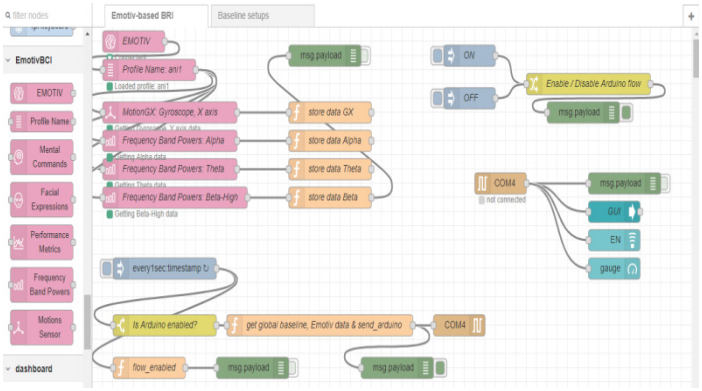

Figure 11: Node-red flow for EmotivBCI-Arduino interaction

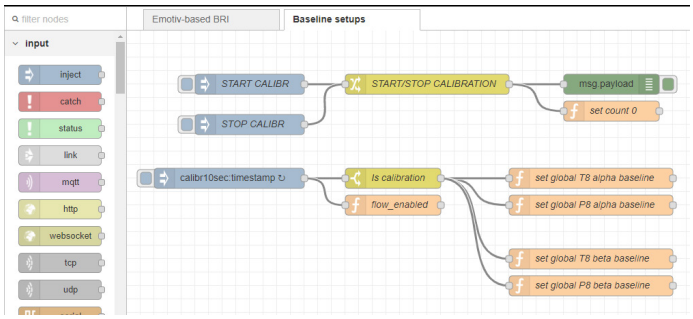

Figure 12: Node-red flow for baseline setting in the frequency band of interest

5. Conclusion

Although the proposed walking robot has a minimum number of mechanical components, it is extremely maneuverable. It has only two motors that makes it simple to control and suitable for educational or rehabilitation purposes. The robot is not expensive and easy to manufacture with a 3D printer. Several control methods are proposed, one of them is "Brain servoing" that uses EEG feedback and brain activity patterns for mind-based robot control. The proposed IoT framework for creating Human Robot Interaction (HRI) applications based on Node-RED "wiring" of Emotiv BCI and Arduino based robot has been applied for neurofeedback training. The results showed that robot could be successfully navigated by the level of human attention to complete a navigation task for climbing stairs.

In the future, the robot's design and control system will be enhanced by collecting and recording information from more sensors. Since, the proposed framework for mind-robot control is enough general, it will be easily applied for other areas of neurons involved in a particular neural computation, as well as other brain sensors and different humanoid or nonhumanoid robots in the IoT.

Conflict of Interest

The authors declare no conflict of interest.

Acknowledgment

This research is supported by the National Scientific Research Fund, Project N DH17/10. We thank to all high school students from the "National Professional High School for Computer Technologies and Systems", Pravets, Bulgaria, who participated in the experiments and implementation of the Arduino hardware.

ABSTRACT

Braille system is purposely made for visually impaired people, to support their literal communication in order to share their knowledge. Louis Braille introduced the braille system consists of series dots which are embossed to read by touching. Early days Braille papers are made manually, but at current days braille documents are made using machines. Due to lack of perceiving on braille symbols and characters, it was highly needed fact to develop Braille system to different languages. In the Sri Lankan context, we found that the mostly inconvenience are happening inside of Sri Lankan education system. Such as in Special Education centers, Colleges, and universities. Written Braille scripts are evolution by a limited number of people who are specialized in the Sinhala braille system. Also, the process of marking braille documents are not effective and efficient. The focus of this research is to address the issue of literal communication gaps between society and the blind people in Sri Lanka. Average quality single-sided composed Braille dot characters are identified with maximum accuracy by using several novel methodologies. Obtained results denote the proposed methodologies are with the highest accuracy and system performance are more efficient as promised. The research presents executable software prototype, includes proposed methods which align with optical braille recognition in order to transpose the recognize braille characters. Introduce of new binaries cell transcription method of Braille character from a Braille document and decoding them into Sinhala characters. The proposed cost-effective system can display decoded braille characters by normalizing to Sinhala text which is in a human-understandable form.

1. Introduction

1.1. Background

Society consists of different people who have various capabilities. Among them, there are some people who are less capable of doing some daily activities due to various reasons. Visual illness is one of the causes. Blindness is a visual illness, occur due to various physical or neurological factors. It can be occurred at birth, due to an accident or due to other disabilities or diseases. Most of the time these conditions make a serious effect on their lives and change the whole lifestyle. According to WHO (World Health Organization), around 314 million people worldwide are living with serious vision impairments. Among them, 37 million people are suffering from blind and 124 million people are having low vision. Moreover, 90% of those blind people are living in low economic countries.

*Shanmuganathan Vasanthapriyan, & email: priyan@appsc.sab.ac.lk

When we consider Sri Lanka, we are having a population of 21 million. Among the population, around 150,000 people are having eye blindness and around four hundred thousand (400,000) people are having a low vision. According to the report of "*National Survey of Blindness, Visual Impairment, Ocular Morbidity and Disability in Sri Lanka*" [1], the prevalence of blindness among those aged 40+ years is 1.7% and 15.4% for moderate visual impairment.

As we all know, we all are gifted with inborn talents. It's the same for visually impaired or low sighted people. Most of the time they are searching for their capabilities. In addition rest of the people are expecting them to play an integral role in the society by using their inherited talents [2]. But in most of the cases, the blindness inhibits those talents and search other's help. Blind people need to put an extra effort than the rest in order to live normal life [3]. As they all are part of humans, we have a responsibility to make their lives easier. We have to facilitate them to socialize with the world. The key for it is communication. In

addition, we have to help them to reach universal knowledge. We should share their wiseness within the world and help them to come after in their lives.

To keep flow their lives with an ordinal pattern of the society, they need to have a clear knowledge of with other ordinal lifestyles. When they come to get to know these facts, they face the major problem in communication, knowledge sharing, and knowledge gathering. Instead of achieving everyday needs, there ought to be a few techniques to make emerged their abilities and keep up them on with their gifts by giving them information and let them impart their insight into society.

It's critical to keep data in the written format since it assumes obviously job with regards to knowledge storing and sharing. For that composed learning from easygoing note to training, recorded data to encoded figure content we need images to trade that learning and data. As ordinary individuals, we have our very own written mechanism as indicated by our languages, just as outwardly visually impaired individuals likewise need some sort of images and method for the game plan of images so as to express their emotions, contemplations, information and so forth [4]. To come up with these challenges the world has come up with several mechanisms like braille system to make it happen [5].

This issue is especially clear in the schooling framework and University frameworks, where these days' blind students are educated in standard classes. A significant number of these blind students perform the evaluation, tests, and schoolwork composing utilizing the Braille medium. Notwithstanding, most educators of these understudies are not Braille proficient [6]. One strategy by and by used to beat this trouble is that the blind students work is first sent to trained Braille transcribes, where the Braille is translated to literary text and afterward sent back to the educator before it is marked. This makes pointless postponements and cost for the blind students, educator, and government. Issues additionally exist in the working environment where any data composed by a Braille client that will be deciphered by other Braille uneducated people, should be first interpreted by the Braille client themselves [7].

Also, blind people feel helpless when it comes to situations like filling application forms. Even we don't realize, application forms play a major role in human's life from birth to death. Instances such as have a birth certificate, Death certificate, enroll to a school, to enter an university, to get an occupation, to go abroad, to have visa likewise most of the important events are linked with application forms and filling an application means we are providing our personal and confidential details to another party in order to get an opportunity or a service [8].

Even they know Sinhala, English, Tamil or other languages, they don't know how to read or write in normal characters. Also, normal people don't how to read or write in Braille characters. So there is a huge gap between normal and blind people and society make feel those people as really disable and less confident.

When it's come to knowledge gathering and knowledge sharing, literally communication is a major medium in knowledge dissemination. In order to do communication, visually impaired people have many systems to accomplish this intention. The Braille system is the reliable and most famous system for this purpose. Braille system is a communication system which is literal. It enables blind and partially sighted people to read and write through using touch stimuli. They use this braille system for calculations, menus, signs, elevator, and books [3].

Louis Braille, a French teacher invented Braille in 1825. He formulated this concept by using the military secret codes. These secret military codes are known to be night writing. This technique is used by military soldiers at dark times to communicate with each other. These secret codes have twelve dot cell six dot height and two dots wide [9]. The only problem is Louis Braille was faced on when making the Braille system that visually impaired people cannot feel all the dots at one touch. Also, the finger doesn't have that much sensitivity for recognizing dots at on time. He made it to practical by making this cell 2 dots wide and 3 dots in height. In order to make it use as character set, made up of different combinations of raised dots (tiny palpable bumps) as above mentioned. In order to represent different characters or sequences of characters, the 3-by-2 (3 rows and 2 columns) arrangement was used [10, 11].

Sinhala is known as the official native language of Sinhalese. According to the Sri Lankan context, there have been new to the braille system by comparing to other languages. The Sinhala language is often considered as two alphabets or an alphabet within an alphabet. It is because of the presence of two sets of letters. The core set, known as the "*Suddha Sinhala*" (pure Sinhalese) or "*Eḷu Hoḍiya*" (Eḷu alphabet) can represent all native phonemes [12]. In order to deliver Sanskrit and Pali words, the Misra Sinhala (mixed Sinhala), an extended set was introduced by ancient scholars. Current Sinhala alphabet uses 60 letters in the alphabet. There are 18 vowels and 42 constants contain in today's standard Sinhala alphabet. However, there are 57 characters are used in present [12].

1.2. Sinhala language braille writing style

Sinhala braille and English braille are two different alphabets. They can't be combined. We can write only single alphabets letters only at once. Numbers are recognized from a pre identification character. The numbers are identified by the braille character "⠼". If "⠼" appears before any of the braille character the following character series until space appears is considered as numeric characters

Sinhala braille system has a different way of writing comparing to the normal Sinhala writing system. As previously mentioned with the combination of 2 by 3 arrangement of the braille dots we have 64 of different combinations use when braille writing. Braille diacritics are use made up with combining constant letters along with the vowels.

In Sri Lanka, most of the blind people are not going through any kind of education mechanism. There are fewer education centers which having knowledge of Braille system in Sri Lanka. People who have knowledge of the braille system only can read the braille documents and understand what visually impaired people have written, what they try to express. Most of the normal people don't have any knowledge on how to read braille documents and as a society, we fail to understand what they express in the literal way of their feelings and knowledge. There are some people write their own braille books and exposed to the world. In Sri Lanka, most of the visually impaired people stay at home, and the parents don't have knowledge of how to read or write Braille. Even if visually impaired people have to write braille, people who are at home cannot understand the braille documents. There is a clear gap between literal communication between sighted people and visually impaired people when it's come to share their knowledge.

This identified gap is addressed through this research using the software prototype.

There is a research conducted by Perera et. al, [13] that identify Sinhala Braille characters in single-sided Braille document and translates to the Sinhala language. This system was also capable of identifying Grade1 English Braille characters, numbers, capital letters and some words in Grade 2 English Braille system.

The main objective is to make a platform to understand braille fonts and convert it to Sinhala fonts in order to formalize communication between visually impaired people and the rest of other normal people. If there is a system which can translate written braille to Sinhala, It will be an excellent communication tool for sighted people (who do not know Braille) with blind writing. And it will reduce the time and money which needed to translate such documents; also, it will secure blind people's privacy in situations like filling application forms. In order to overcome above-mentioned problems research have to follow various researches and have found there are fewer studies have done come over to address these problems. By using latest Sinhala braille alphabet [14], documents are converted with high accurate and efficiency.

2. Methodology

The overall methodological framework is shown in the following figure 1.

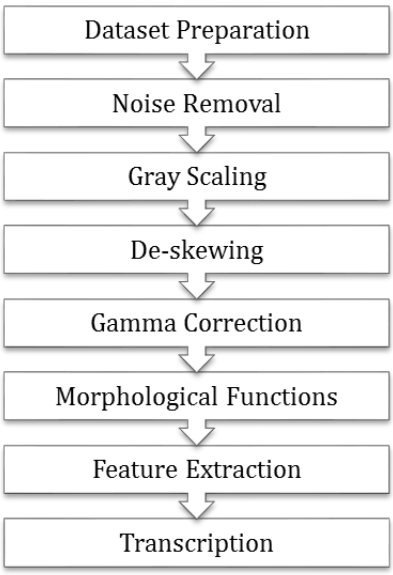

Figure 1: Methodological framework

2.1. Dataset preparation

As the first step in the research, the braille documents were collected. Both handwritten documents and typed documents were collected. The braille slate was used to write the handwritten document and braille typewriter was used for the typed documents. The size of the handwritten document was 9x12 inches and type documents were 8.5x11.8 inches and 9.5x12.5 inches.

After Braille documents have been collected, scanning was performed. In Optical Braille Recognition (OBR) scanning braille documents enable us to perform digitization which produces a digital image of the scanned Braille document. A flatbed scanner has been used for the digitization process. This is because it has been found as a cheap alternative to scan Braille images [8]. Figure 2 and Figure 3 shows the difference in light source distribution when grayscale.

Horizontal resolution and vertical resolution of 300 dpi and of 200dpi have been used for the scanning process. Most of the researches have been conducted in this area used 100 to 200 dpi resolution when scanning their documents so it is recommended to get quality images and the images are stored in JPEG format. Using this configuration Braille documents that are collected from different sources are scanned and prepared for subsequent processes.

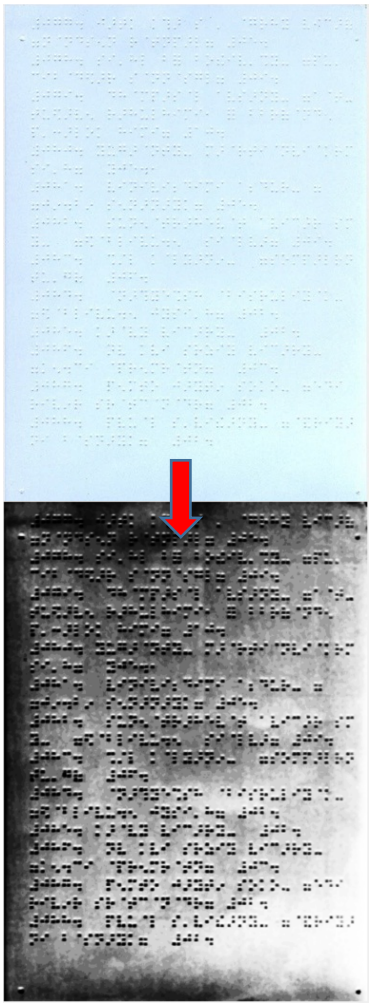

Figure 2: Braille Accusation Using Camera and After Grayscale

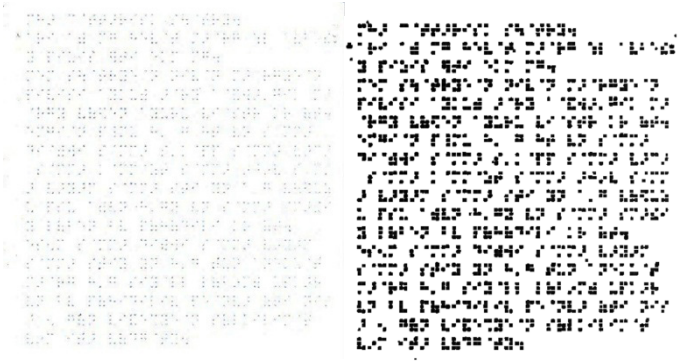

Figure 3: Braille Accusation Using Scanner and After Grayscale

Braille document property description

- Braille sheets: 12
- Resolution: 200 dpi, 300 dpi
- Digital format: Colour
- Image sizes: 9 X 12 inches, 8.5x11.8 inches, 9.5x12.5 inches
- Braille type: Single-sided
- Image format: JPEG

2.2. Pre-processing

Noise removal

Before starts to do any compilation on the scanned digital image, it's recommended to do pre-process part on the image. Before that, it's necessary to compare some technical aspects before coming to a conclusion which needs to select. There are several techniques on noise removal such as mean filtering, Median filtering, and Gaussian blur are some of it. In here research got selected the Gaussian blur for noise removal and later here it discussed why select Gaussian algorithm [15].

If the window size is small the effect of filters will reduce because it is not capable remove noise much effectively. If the window size is got increased it will remove the noise, but as well it will blur the braille bots and also the edges of the documents. Which lead to reduce the detail of the image where do not contain noise also.

There can be several ways of getting the braille document noisy. When considering the handwritten documents, according to the way of writer use the paper may lead to noise. Sometimes the environment may lead to noises. Another way of getting noise is paper may itself having some patches or print issues. However here below Figure 4 give a clear idea on how handwritten braille document have exposed for noise. Type documents are can be exposed to noise when they read by the visually impaired people because of the dust and other unnecessary things having on the fingers at the time of reading braille image [16]. Finally, in the end, there may be noise when getting through the scanner.

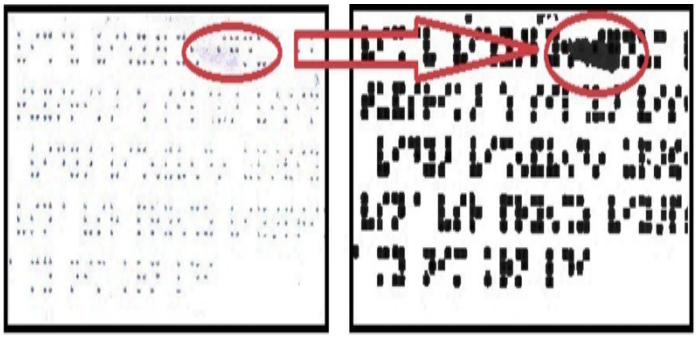

Figure 4: Noise on Handwritten Image after Pre-Processing

But in here its need to focus on both side at this stage. When using powerful noise removal algorithm to removing the noise it may affect to respective needed details on the documents which are not affected by the noise at high scale. With the above facts no need to use powerful noise removing algorithms because they may get the effect to somewhat on context [4].

Mean filter

Mean filtering is done using read pixel by pixel of the image and assign the mean value of values for its pre-defined kernel's structure center pixel. When the kernel is large, the center pixel may have a high effect through other pixel values. Even a pixel which does not contain noise also gets affected. Also, it should not affect the braille cell segmentation and features extraction. But this will lead to unnecessary complexity on future steps.

Median filter

This mechanism is a little bit ahead than the mean filter because the median filter is replacing a middle pixel with the median value of the kernel's center pixel. Which leads to damage the edges of the characters and edges of the fields [17].

Gaussian blur

Gaussian blur was used to remove the noise. Instead of utilizing other low pass filtering algorithms, Gaussian blur channel does not lessen braille dot details. However, it makes decrease noise in an incredible way. Figure 5 denotes how the Gaussian blur work on noise removing. As indicated by the Gaussian blur work it weighs more on closest pixels of the utilized kernel canter. Figure 6 shows how weight is distributed around the center pixel. Equation 1 shows Gaussian blur for one dimension.

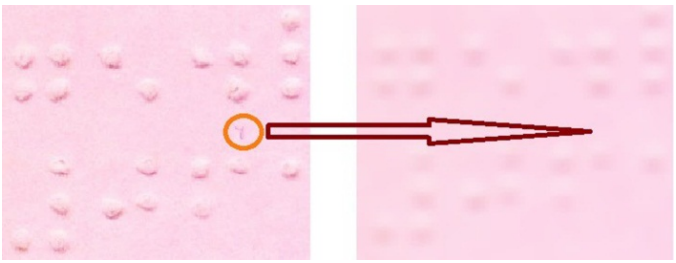

Figure 5: Gaussian Blur Apply On Noised Document

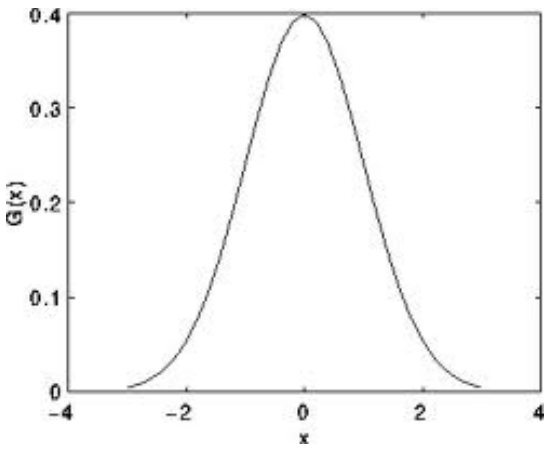

Figure 6: Pixel Weighting According To Kernel Center

$$G(x) = \frac{1}{\sqrt{2\pi\sigma^2}} e^{\frac{-x^2}{2\sigma^2}} \quad (1)$$

A filter using EmguCV was applied to the input in order to perform the smoothing function [18]. Equation 2 shows how EmguCV has done for the above mathematical operation (equation 1). Equation output pixel's value g (i, j) is determined as a weighted sum of input pixel values.

$$g(i,j) = \sum_{k,l} f(i+k, j+l)h(k,l) \quad (2)$$

The coefficients of the filter are the kernel which is represented by h (k, l). It helps to visualize a channel as a window of coefficients sliding over the image. Weighing of the pixel was done through f (i+k, j+l). Even though it is not the fasted filter it is good to filter for working with images. Gaussian filtering was done by convolving each point in the input array with a Gaussian kernel and then summing them all to produce the output array [18]. Table 1 describes the above mention details as a summary.

Table 1. Reasons Summary of Gray Scale, Mean Filter, and Gaussian Blur

Median Filter	Mean Filter	Gaussian Blur
Low Computational Cost	High Computational Cost	High Computational Cost
Preserve Image Details	Very Low Capabilities to Preserve Image Details	High Capabilities to Preserve Image Details
Low Memory Consumption	High Memory Consumption	Low Memory Consumption
Simple Implementation	Simple Implementation	Simple Implementation
Analytical Process Becomes Simpler	Analytical Process Becomes Relatively Complex	Analytical Process Becomes Relatively simple

2.3. Grayscale

The expectation of using gray scaling technology is not only for reducing noise but also several other results are expected. Since the resolution and quality of the image will higher according to the dpi of the input image. The time which takes for the process relatively large when quality is high, which is negatively affected for systems performance. But when do gray scaling it is an extremely small amount of time takes for the entire process.

On the other hand to conduct analyzing processes such as edge detection, segmentation, and feature extraction and classification techniques effectively it is necessary to reduce the intensity of the image since inputs to the system are color images. Since gray scaling contains only 0-255 values on pixels it is useful to use gray scaling such that it is easy to conduct analytical processes [19]. As the second step, convert the color image into a grayscale image. Figure 7 shows the result when the input image goes through gray scaling.

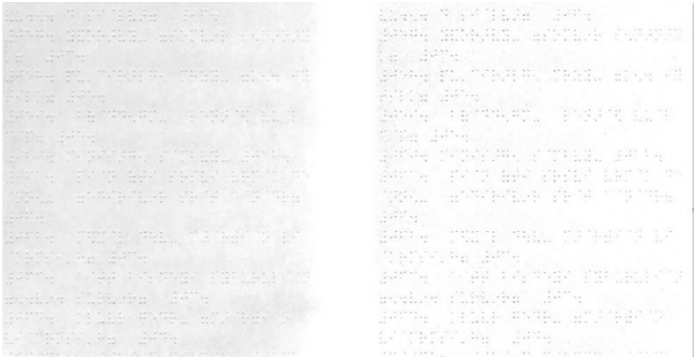

Figure 7: Gray Scale of Input Image

2.4. De-skewing

Rotation is used to de-skew braille documents in place of horizontal and vertical projection profiles.. In some cases the document may not have skewing errors but in general when braille documents are composed there is a possibility for skewing errors to occur. Instead of squandering increasingly computational capacity to de-skew documents, the work utilizes moderately fixed positions to de-skew the documents using rotation angle. Figure 8 demonstrates De-skewed image Utilizing Rotation.

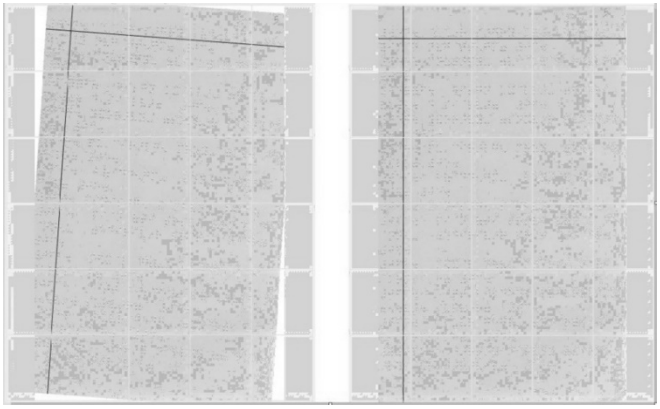

Figure 8: De-Skewed Image Using Rotation

2.5. Gamma correction

Gamma correction was done on the gray image to enhance subtleties of the braille spots. Gamma correction can be utilized in non-direct connections and in encoding or interpreting the luminance in images. Equation 3 and 4 demonstrate the calculation.

$$V_{out} = V_{in}^{\gamma} \tag{3}$$

$$\gamma = \frac{d \log (V_{out})}{d \log (V_{in})} \tag{4}$$

As this connection is nonlinear, the impact won't be equal for each pixel and will rely upon their original value. Whenever $\gamma<1$, the first original dark regions will be brighter and the histogram will be moved to one side and vice versa with $\gamma>1$. Here work utilizes the gamma= 4.0 and Figure 9 depicts the eventual outcomes on a grayscale image.

Figure 9: Gamma Correct on Gray Scale Image

2.6. Morphological erosion

Morphologic capacity disintegration is utilized to sharpen the edges of the braille spots. Unlike other methods, their morphologic capacities disregard the flaws which happen to the surface and state of the picture. Furthermore, administrators such as segregation and

joining of individual pixels and different pixels help locate the decorated braille dot. Disintegration impact as per the organizing component was utilized. In contrast to paired disintegration, grayscale disintegration improves the dot subtleties [9]. Indicating a picture by *f(x)* and the grayscale organizing component by *b(x)*, where B is the space that *b(x)* is characterized, the grayscale disintegration of *f* by *b* is given as in the equation (5). Image after Morphological Erosion is shown in Figure 10.

$$(f\theta b)(x) = \inf_{y \in B}[f(x+y) - b(y)] \quad (5)$$

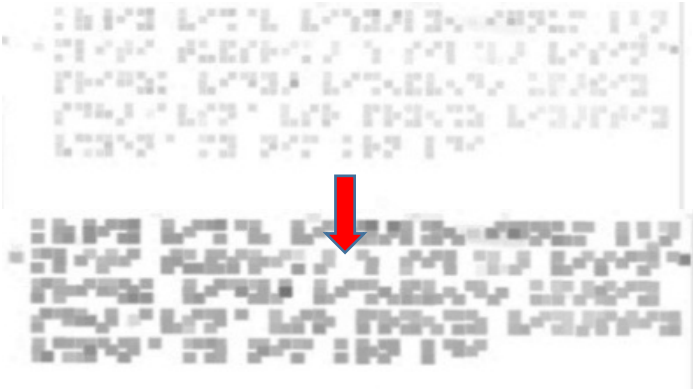

Figure 10: Image after Morphological Erosion

2.7. Feature extraction

Feature extraction is an illustrative system of the Braille image. The principle function of this procedure is to extract the Braille dots from the binaries image. The image capturing, pre-handling and division stages cause the image to be appropriate for various element extraction calculations. Some component extraction calculations are only concerned with the forms of the image while a few calculations ascertain each pixel of the image. Conversely, the underlying image might be noise influenced or obscured by different reasons..[7].

Simultaneously, the nature and the yield of the image pre-processing and division steps are determined by the picture feature and the extraction strategy. Feature extraction phase can be considered as the most important part of braille character translation because the accuracy of the translated character heavily depends on the extracted features of the cells.

Thresholding

Before the segment, the braille cell into six equal compartments, need perfect detection of braille dots. For this work have experimented on various thresholding techniques. First attempt was using straightforward thresholding strategies like Binary, To Zero thresholding and Binary inverse thresholding etc. The most intricate task was to recognize limit esteem in light of the fact that the reports have various hues and when checking, pixel luminance may change. To overcome the issue, in this research versatile thresholding Otsu strategy was utilized. Since the attempt was to make binomial pictures along the way of preparing part and it is the greatest contribution to Otsu thresholding, Otsu thresholding calculation located the bimodal qualities and attempted to discover the boundary that limits the weighted intra-class change. Bimodal picture is a picture whose histogram has two pinnacles. From the calculation, it takes the center of those histogram crests and computes the intra-class fluctuation.. Figure 11 shows the result of Otsu thresholding.

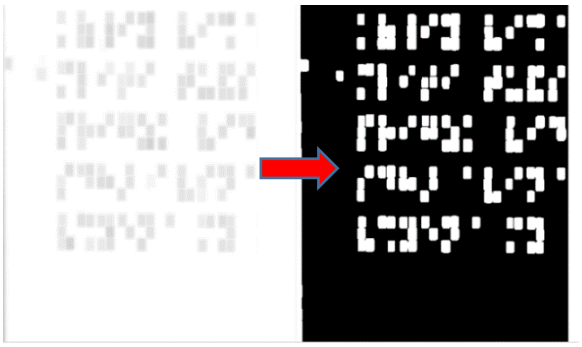

Figure 11: Image after Otsu thresholding

It actually finds a value of t which lies in between two peaks such that variances to both classes are minimum. After making thresholding, cell segmentation done using the standard braille dimensions.

The vertical as well as horizontal (however not corner to corner) separation between two focuses of neighboring dots in a specific cell is 2.5 mm. The separation between focus to focal point of relating spots in vertically contiguous cells is 5.0 mm, in the interim it is 3.75 mm for the horizontal neighboring cells.

2.8. Transcription

As presented in Figure 12 braille cells are sectioned and checked for the normal white pixels over 60%. On the off chance that the normal of white pixels is over 60%, it's perceived as substantial braille dot and marked as 1. If it's not, it is considered as there is no braille spot, which means the rate ascribed is 0.

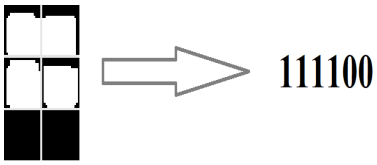

Figure 12: Cell transcription to binary values

Here below algorithm written for the binaries cell.

```
Inputs: erodeimg1, erodeimg2,
projection_x, projection_y; img,
resolutiondpi_x
For counter = projection_x to
projection and counter less than
height of erodeimg1 then
For counter = projection_x to
projection x + resolutiondpi_x and
less than width of erodeimg1 then
For counter = 0 and less than height
of img1 then
For counter =0 and less than width
of img1 then
do calculation:
Check row 1, column 1;
Check row 1, column 2;
Check row 2, column 2;
Check row 3, column 1;
Check row 3, column 2;
End for
End for
End for
End for
```

When binaries string array is extracted from the above way, the mapping to Sinhala Unicode is done using SQL Server. All the particular related string array contain it's Unicode in the database. The database connects to the system via Entity Framework in C#.

As a summary, for an example, Sinhala quote "ෟ ෟ ෟ

3.1. Threats to validity

With several approaches have done related to the work there is many limitations have found. Image acquisitions using different types of equipment would have an effect on results receiving. While the acquired image is not with the minimum dpi will affect results. With the lightning disturbances without equally spread on documents make the threat to results which observed. Cropping document with the desired way of the human pattern will lead to making half braille characters and direct effect on results we obtain.

4. Conclusion and Future Works

The Braille framework is a tactile technique broadly utilized by visually impaired individuals to read and write or peruse and compose. Braille documents contain lines of characters, where each character has six spots masterminded in three lines and two segments (three rows and two columns) and each dot can either be raised or be level as indicated by the corresponding character. Braille is reasonably understandable by visually impaired individuals; notwithstanding, sighted individuals need not have the option to comprehend these codes. Braille recognition system can connect the correspondence communication gap between visually impaired and sighted individuals. A ton of exertion has been made worldwide by specialists to connect this gap. In this investigation,

an endeavor has been made on the element extraction and characterization modules of Sinhala Braille acknowledgment as indicated by the Sri Lankan context.

This proposed programming model is fit for extracting Braille characters from a Braille document pursued by decoding them into Sinhala characters and after that standardization of the decoded Sinhala characters into readable Sinhala content. The transformation from Braille documents into Sinhala content is another zone where much research has not been completed.

An algorithm to distinguish dots in a picture of embossed Braille material obtained by an optical scanner was proposed. Despite the fact that the Braille dots have a similar shading as the foundation, they cast delicate shadows when checked with a standard flatbed scanner. These shadows are utilized to find the dots on the page.

In general, the methodology indicates achievability as a practical, cost-effective, quick and simple strategy to identify dots in Braille records. It doesn't require costly or complicated equipment. It utilizes a flatbed scanner which can be shared with different applications. Robustness to adapt to low-quality scans and imperfect reports are worked in at various levels. The outcomes got were promising during trials performed on single-sided embossed records, with over 95% accuracy.

The recognition rate for character recognition has the opportunity to get better. One approach to improve it is to actualize a Sinhala spell check algorithm. Any misrecognized image can be recognized since the word and sentence that the character has a place which would never again make sense.

It is important that every one of the examples in the investigations are sensibly all well-formed. A conceivable future upgrade in this undertaking is utilizing various allegations with numerous gadgets like cell phones. This may incorporate adding a few algorithms to progressively change different edges for various pieces of the framework, to represent fluctuation, for example, the shade of the paper. On account of slanted pictures, a few components to deal with the revolution will be automated. Indeed, even there are severe principles about the size of the spots utilized just as the dispersing between them, size of the braille specks in the wake of filtering is vary from record to report as indicated by its shading. If the feature extraction algorithm automatically adopted according to its color of the document there will be a much better extraction of features for classification.

ABSTRACT

Cloud computing recently emerged as an interesting model that enables computing and other related internet activities to take place anywhere, anytime. Cloud service providers centralize all servers, networks, and applications to allow their users' access at any time and from any location. Cloud computing uses already existing resources like server, CPU and storage memory but runs on a new technology known as virtualization. The core idea of virtualization is to create several virtual versions of one single computing device or resource. This enables many user operating systems to work on such a single underlying piece of device. Network bandwidth is one of the critical resources in a cloud environment. Bandwidth management involves the use of techniques, technologies, tools, and policies to help avoid network congestion and ensure optimal use of the subscribed bandwidth resources while also being a bedrock of any subscription-based access network. Bandwidth management is being utilized by organizations to allow them to efficiently utilize their subscribed bandwidth resources. Bandwidth management deals with the measurement and control of packets or traffic on a network link in order to refrain from overburdening or overloading the link which can lead to poor performance and network congestion. In this paper, the highest development with respect to virtualization in cloud computing is presented. This study review papers available on cloud computing and relevant published literature in multiple areas like conferences, journals etc. This paper examined present mechanisms that enable cloud service providers to distribute bandwidth more effectively. This paper is therefore a study of virtualization in cloud computing, and the identification of bandwidth management mechanisms in the cloud environment. This will benefit forthcoming cloud providers and even cloud users..

1. Introduction

This paper expands upon the findings of the research carried out in the 2017 international conference on next-generation computing and information systems [1]. It expands on cloud bandwidth management, its mechanisms, and challenges. Cloud computing means "almost anything can be accessed" [2]. This allows for ubiquitous, convenient, on-demand network access to customizable computing resources e.g. storage, networks, servers, services, applications etc. that service providers could quickly render with minimal intervention. Cloud computing is powerfully changing the manner in which organizations and enterprises perform IT-related activities. Cloud computing features like elasticity, scalability, multi-tenancy, resource pooling, lower initial investment, easy management, faster deployment, location independent, device independent, reliability, and security make it attractive to business owners and IT users [3],[4]. Cloud computing model permits outsourcing of computational resources in a way that is more effective. The huge computing power and storage size of cloud resources permit day-to-day internet users to perform their tasks on pay-as-you-go terms. Cloud data centers will keep expanding, as their client base becomes larger.

In general, the Cloud massive network is built using an approach known as virtualization which permits the installation of different applications and operating systems unto physical hardware. It creates a different layer for the operating system (OS) to seat on, thereby separating the OS from the physical hardware and the core OS. Virtualization is done on the physical hardware by installing a hypervisor. A Hypervisor is a common technique used for the implementation of Virtualization. It permits for different operating systems to be installed on the same hardware. Though the operating systems coexist on the same physical hardware, they behave as each OS have its dedicated resources. Some of the types of Hypervisors include VMware ESX, KVM, Xen, and Hyper-V. Another emerging approach for implementing

isaac.odunayo@covenantuniversity.edu.ng

virtualization is containerization commonly known as Container-based virtualization or operating system virtualization [5].

Cloud data centers normally have mechanisms for planning how their resources like computing space, memory, and bandwidth are released to the users. Bandwidth is required to distribute resources across different cloud networkS. It is very important to maintain cloud bandwidth to meet up with the increasing request from cloud resources across data centers. On a cloud network, the bandwidth size requested by a customer is usually not assured [2].

For a satisfactory performance and fair usage of the network, bandwidth management is used to achieve this with the implementation and creation of network policies which ensures that the sufficient amount of bandwidth being required is readily available for those time-sensitive and mission-critical applications. It also avoids opposition between lower priority traffic and the critical applications for the limited network. With cloud tenants making greater use of cloud networking infrastructure in a shared manner, there is an increased desire and a growing concern on how to arrange, reserve and monitor the bandwidth in the cloud computing environment [6], [7].

Generally, bandwidth management involves the use of techniques, technologies, tools, and policies put together by an organization in order to ensure optimal utilization of the available bandwidth [8]. The reason for a network bandwidth management is to ensure the accurate bandwidth size is available and assigned to the accurate users and application at the right location and time [9]. Generally, without an active plan for ensuring bandwidth management, the available bandwidth regardless of its size can never be sufficient for the ever-increasing request of the users [10]. Also, Malicious Cloud Bandwidth Consumption (MCBC) which attack is a new type of attack that aims to consume the bandwidth maliciously causing the financial burden to the cloud service host can be mitigated or avoided when utilizing bandwidth management [11].

Different operating systems (Oss) are running simultaneously on a physical server is a process known as Virtualization and is carried out utilizing a hypervisor or virtual machine manager (VMM). The physical network resources require sufficient bandwidth to assign to the virtual machines (VMs) and optimal bandwidth allocation to VMs is very critical especially in today's cloud data centers with massive networked VMs. Bandwidth management poses a significant tension especially within a cloud-computing environment that permits the idea of VMs to have specific aims like load balancing and failure tolerance. High latency and a sharp drop in network speed are expected if there is no sufficient bandwidth after VM-migration. Every initiated data transfer that must take place over the internet requires bandwidth. For example, server to VMs data transmission over the internet requires bandwidth; this is one reason why network administrators must ensure accurate bandwidth management.

The objective of this study is to analyze bandwidth management in a cloud-based computing and virtualization environment. Various area of virtualization and cloud computing will be discussed. This research will impart to the knowledge of cloud-based bandwidth allocation approaches and management. The remaining section of the research is as follows. Section 2 examines related work. Section 3 discusses virtualization in a cloud environment and bandwidth management mechanisms. Section 4 concludes the paper and suggests future work.

2. Related work

In [12] the author suggested a solution in Bandwidth Management on Cloud Computing Network, to distribute available bandwidth according to user priorities and actual demand of data transfer to-from the cloud is proposed. Three key metrics: throughput, response time and utilization for monitoring and analyzing the network performance were presented. In [13], the authors proposed an approach that will only permit the guaranteed bandwidth size when providing the requested service. It also discussed how Linux kernel module called Linux TC can be used to manage the allocation of network bandwidth. In [14], the authors proposed having a formal definition for cloud-based applications that are free and open to all. The authors built a Cloud Resources Allocation Model named CRAM4FOSS for these free and opened applications. According to the authors, the proposed solution is to accurately certify the stability of allocating Cloud resources. In [15], the authors discussed the idea of an open source virtualization. Several other virtualization ideas are addressed and afterward, analysis of two open sources IaaS systems was presented. [16] discussed the idea of skewness to strengthen the manipulation of servers. [17] proposed an approach to introduce separation of VMM concept instead of kernels separation concept since it will enable suitable separation of cloud VMs. In [18], the authors concentrated on the idea of VM migration for cloud providers and reviewed VM placements in data centers alongside its limitations and advantages were conducted. 1n [19], the authors focused on virtualization and its application in radiology. In [20], the authors highlighted how virtualization affects information security. In [21], the authors proposed a modular kind of the bandwidth manager that could rapidly adapt to unexpected changes that can be induced by the rates of dirty inactive applications or due to network congestion. The authors' goal is to optimize bandwidth consumption and latency during live VM migration. [22] proposed a combined algorithm for optimal allocation which enables network bandwidth and VMs to minimize the cost affiliated with the users. A decision is made by the algorithm to restrain network bandwidth and VMs from some specified cloud providers. [23] Argued on the importance of stability and fair bandwidth allocation. The authors proposed a method to prevent interference between the underlying hardware and VMs. In [24], the authors proposed an algorithm for dynamic bandwidth shaping while still maintaining the limitations on network resources. In [25], "Towards a Tenant Demand-aware bandwidth allocation strategy in the cloud data center" is discussed. The authors propose a strategy to handle the issue of over bandwidth subscription cloud datacenter. The main functions of the proposed system involve bandwidth prediction, bandwidth pre-allocation, and bandwidth gathering. In [26], the authors developed SpongeNet; which is a bandwidth allocation proposal that's made up of three determinants. Component one is to provide an accurate, flexible and simple way for users' requirements definition. Component two is an algorithm for merging policies to handle multiple goals. Component three is to guarantee fairness between dedicated and non-dedicated bandwidth users. In [27], the authors proposed a framework for predicting resource management to overcome the drawbacks of the reactive cloud resource management approach. In [28], the authors discussed the current trend and development in cloud computing and open source software. The authors found out that Open Source Software (OSS) like OpenStack provides the most comprehensive infrastructure in cloud computing and open source software.

3. Virtualization in Cloud Environment and Bandwidth Management

3.1. Virtual Machines and Containers Technology

A. Concept of Virtual Machines

The infrastructure layer is the host of the virtual machines (VMs) within the cloud network. It is a component within cloud computing. The core concept of virtualization is to separate OS from the underlying hardware, it divides a physical hardware machine such as a server into multiple virtual machines. This makes it possible to run all types of operating like Linux, Unix, Mac OS, and Windows on a host or physical machine, that is the coexistence of different operating systems on the same physical machine. Bandwidth size that closely matches the actual task and needs of each VM can be assigned. It allows for maximum utilization of the host machine. Hypervisors also knew as Virtual Machine Managers (VMSs) are used to create and control VMs. The virtual machine is then tied to the hypervisors and not directly to the physical hardware. There are two types of hypervisors. Type-1 hypervisors remove an extra layer between the underlying host hardware and the virtual machines because it executes directly on physical hardware without a base OS and acts as the operating system on the hardware. Here, physical hardware without a base OS can be known as a bare-metal. Type-2 hypervisors are hosted hypervisors since the installation is done on top of the existing OS on the physical hardware. These hypervisors execute as applications and the host machine won't need to be set up separately for setting up the virtual machines. Figure 2 depicts the Type-1 hypervisor and Figure 3 depict the Type-2 hypervisor [29].

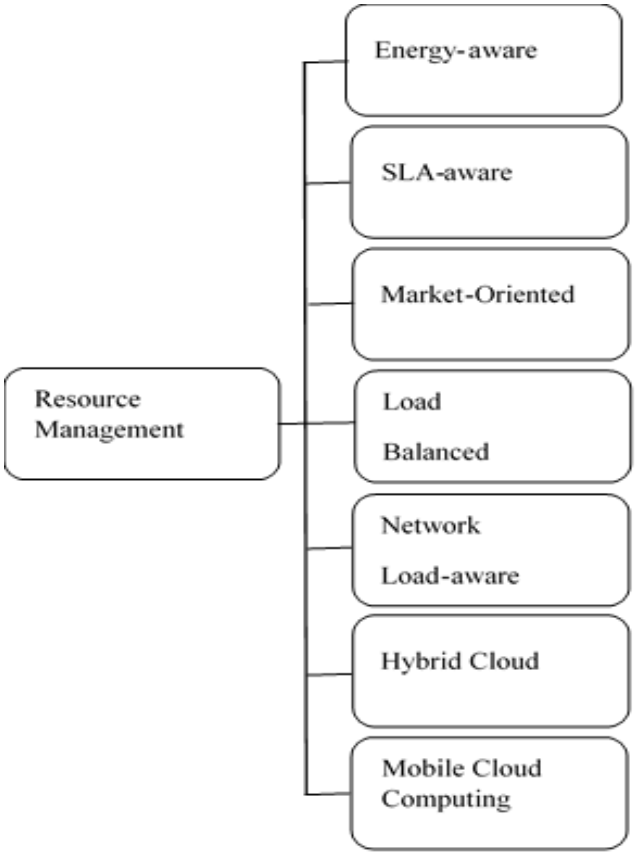

Figure 1: Classification of Resource Management Techniques [32]

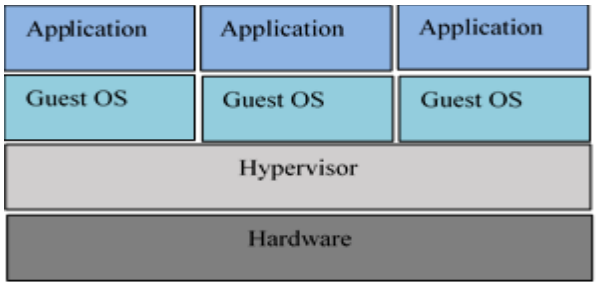

Figure 2: Type-1 Hypervisor [29]

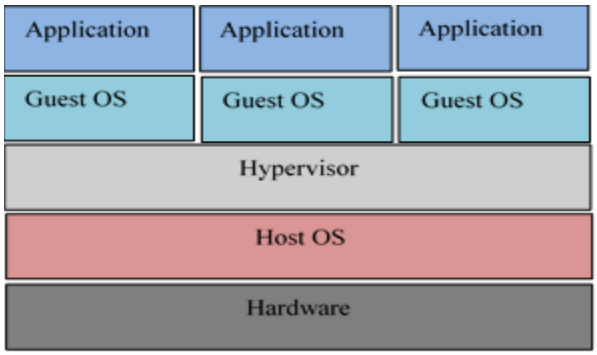

Figure 3: Type-2 Hypervisor [29]

B. Concept of Containers

Containerization is known as a virtualization technique which occurs within the OS level instead of the hardware level. Containers allow for easy migration between platforms and hosts compared to virtual machines and share a single OS kernel within an isolated environment [30]. This creates isolation confines within the application area instead of the server area which makes sure that if an error occurs within the single container, it won't affect the whole server or VM but only that individual container. Container technology is continuously evolving and guarantees an easy to deploy, streamlined and secure means of enacting certain infrastructure requirements while offering offer an alternative to VMs and mitigates the compatibility issues between applications which exists within the same OS [31].

Cloud containers are trending within the IT world and are modeled to virtualize just one application. Linux is the only server OS that supports cloud containers presently and Hyper-V containers are to be integrated to Microsoft Azure after being introduced by Microsoft [1].

C. Characteristics, Application, Benefits of Virtualization

In [1] it is highlighted the following characteristics of virtualization and its application areas as follows:

- Partitioning: This is a key feature in virtualization, used to logically divide a physical hardware resource for the installation of different/several operating systems.
- Isolation: Virtual machines coexist on the same physical hardware but each virtual machine exists separately from the core physical hardware and other virtual machines. With this feature, if there is a breakdown/downtime on one VM, the other active VMs will not be affected. Also, there is no data-sharing between VMs.

- Encapsulation: The encapsulated process maybe a business service and VMs can be stored and labeled as a file for identifying its service type. This averts the issue of hindrance amongst the applications. Storage, memory, networks, application, operating systems, and hardware are some of the application areas of virtualization. Here, to separate a software implies placing that software in a separate virtual machine space or in a container so that it does not coexist with other operating systems.

Virtualization of hosts or physical machines provides the following benefits [1]:

- Functional Execution Isolation: The hypervisor is assigned the responsibility of maintaining protection between the VMs and applications deployed on multiple VMs. Privileges may be given to users in their VM without violating the host integrity or isolation.
- Enhance Reliability: Hypervisors provides greater reliability of hosted virtualized applications due to their live migration capabilities enabling them to be independent and reliable.
- Customized Environment: Virtualization permits for the creation of customized space for a dedicated user, upon request for a customized and dedicated environment can be created and provided to handle a specific need.
- Testing and Debugging Parallel applications: Testing parallel applications can leverage virtualized environments, as a fully distributed system could be emulated inside a single physical host.
- Easier Management: Custom-made run-time environment can be migrated, started-up, shut down in a considerably variable way which depends upon the requirements of the person that is responsible for the essential hardware.
- Ability to coexist with legacy applications.
- VMs help to preserve binary compatibility in the run-time environment for legacy applications.

3.2. Resource Management Techniques

Cloud Resource management involves the procurement and release of cloud resources like physical hardware, storage space, virtual memory, and network bandwidth. Cloud resources can be physical or virtual components of limited availability. Resource management in virtualization environment and cloud computing is very critical. [32] used SLA-awareness, load balancing, energy efficiency etc. in the classification of resource management techniques, also depicted in figure 1.

- Energy-aware RM techniques: This involves minimizing the energy consumption by merging workload on a few numbers of physical servers. Virtual machines (VMs) on physical hardware with less load are migrated to other hardware that can accommodate more workload. This less loaded and idle hardware is then switched off to reduce the power expenses incurred by service providers and decreases Carbon dioxide (CO2) emission. [33] Presented a centralized control system for the allocation and management of all the concerned cloud resources. Resource Management (RM) choices are done hourly in order to reduce the subsequent effects. The choices can be based on the shutdown of the server, VM migration between multiple servers and powering up of the server.
- Load-balanced RM techniques: This is an important feature of the system in any computing environment. It is made use of in order to explain the idea of distributing the workload or traffic request between many resources and can maximize the performance of available bandwidth. Operations are moved amongst the physical machines after the load balancing algorithm have been applied and the system efficiently balances the load amongst the cloud resources while the usage by each server is examined. Once there is an overload of server resources, it migrates some of these workloads to an underutilized server but in a situation whereby both are underutilized, one server gets all the workload transferred to itself while the other server will be left unutilized or on standby. If hypothetically speaking that the workload migration failed, the server itself can be scaled down or up accordingly.
- SLA-aware RM techniques: Cloud-based Service Providers (CSPs) must strongly discourage the issue of violations, maintaining regular check during service provisioning to users. A service level agreement (SLA) is signed between the CSPs and customers which includes information such as the price, penalty clause that is enforced in an event of agreement violation and required a level of service(s). Authors in [34] proposed algorithms for capacity allocation in the hope of guaranteed SLA and handle fluctuating workloads which interfaces with the resource controllers that are geographically distributed while redirecting the network traffic load whenever congestion is observed. An application can also execute on different workloads and VMs equally allocated on the VMs if necessary. A workload analyst is utilized in order to predict future workload necessities throughout the workloads fluctuation and the capacity is altered on the premise of resultant predictions. Additionally, SLA violations can be mitigated by making sure that the response time is low when inter-VM communications are ongoing but if there is a higher response time, the VM is carried/moved to another physical machine.
- Market-oriented RM techniques: This involves solutions that are beneficial to cloud service providers and market-oriented. [35] Presented an RM technique where a SaaS service provider employs an IaaS service provider to serve its clients. Clients pay to the SaaS service provider for the services received and depending on the satisfaction level shown by the clients, a one-of-a-kind optimal function is utilized to calculate the amount that the user has to pay. According to [36], each cloud server has a dynamic voltage/frequency scaling (DVFS) module and it is assumed that a server cannot be switched on or off, also there is a common cost of VM migration

- Network load aware RM: This technique reduces high network traffic that can degrade the overall network performance. It allows service providers to choose a data center that could fulfill the interests of the clients. A user sends a request to the service provider and resources are assigned using an adaptive resource allocation algorithm. These algorithms achieve this by selecting a data center either based on the distance between the user or based on the distance between the data center. After the data center is chosen, the work is allocated to one of the servers thanks to the VM.
- RM techniques for the hybrid/federated cloud: In this technique, private cloud users are offered the benefit of utilizing the resources in a public cloud environment whenever there are insufficient resources to handle the needs of it, in-house users. To address the issue of decision-making on when to use public cloud resource, the authors in [37] presented a solution that is rule-based for hybrid clouds. Users' requests are divided into two which are the critical data/tasks request that is granted higher precedence and secondary data/tasks request that are granted lower priority. The critical data/tasks are hosted on the private clouds for security while the task with low priority can utilize the resources of both private and public cloud. When the resources of the private cloud are exhausted, the public cloud resources would be utilized.
- RM techniques for mobile clouds: Here, an energy efficient solution is presented to solve the problem of energy which is a major challenge in mobile systems. The authors in [38] proposed a technique to reduce the total power consumption. All the mobile devices primary job is to move the workload to one of the available servers in order to reduce the overall energy consumption.

3.3. Cloud Bandwidth Allocation Mechanisms

According to [2], bandwidth mechanisms used by Cloud providers in allocating bandwidth resource and ensuring load balancing include:

- Fair-Share Bandwidth allocation: In this approach, the specific time interval is set for the flow of the defined data size between the host machine and virtual machines. The Throughput and Network weight are used to ensure fairness during the data flows. When the calculated fair share values reach the random acceptable values, the packets are transferred otherwise they are dropped.
- Transmission Control Protocol (TCP): Here, packets are divided into segments and assigned a sequence number each to specify the order of the data. Transmission takes place at a specific time interval. An acknowledgment is received for every successful transmission otherwise, retransmission takes place. This approach is connection oriented and for end-to-end congestion controls.
- Bandwidth Capping: in this approach, a specific bandwidth limit is set for the VM when transmission of data is happening simultaneously.
- Secondnet: This approach guarantees the assignment of network bandwidth amongst every VM pair and the communication patterns between multiple pair of the VM can vary due to the time as well as the data received/transferred amongst them.
- Netshare: Utilized in big data centers and function as a central system for allocating bandwidth in a virtual cloud network. It lessens the tasks in data centers. Each Cloud customer is connected to various cloud network resources. Division of the network into slices is done and each of the slices is assigned bandwidth via the link connecting it to the cloud network.
- Approximate Fairness- Quantized Congestion Notification (AF-QCN): This is a congestion control approach for data centers, delivered via a switch. The network bandwidth is shared among the transmitter's connection to the VM.

3.4. Bandwidth Management Benefits

In [39] the author highlighted the following benefits using the Zscaler Bandwidth Control solution:

- Prioritization of business applications: It limits the possible impact of bandwidth-intensive applications like streaming media, file sharing, and social media business applications. Bandwidth constraints and policies are checked and reconfigured to meet user requirement
- Deliver a better user experience: features like segmentation of network traffic and retransmission provide a faster Internet connection and avoid loss of packet after a successful data transmission.
- Reduce costs and simplify IT: Eliminate the need to install and manage additional hardware in-house and prevent bottlenecks due to the enforced cloud policies.

In [26] the author highlighted the following benefits:

- Work-conservation
- Guarantees bandwidth
- Practical enforcement
- Fairness between tenants
- Applicability to different contexts
- Easy deployment
- Precise and flexible requirement expression
- Efficient bandwidth saving

In [25] the author presented the following benefits:

- Provides dynamic network management
- Improves network efficiency
- Easy integration.

3.5. Cloud Bandwidth Management Challenges

According to [40], as VMs scale bigger, utilizing more memory, higher bandwidth, the need to maintain optimal performance and health management tools become difficult for the existing management software. These tools require multiple

information about the different features of each VM, the underlying host storage infrastructure, machine, and networking. Supporting these tools and coordinating the activities of a large number of simultaneous users with management privileges require a secure connection in real-time with a high level of consistency and must be backward compatible. Scaling the bandwidth of the ever-increasing hundreds of VMs means improving the existing code for optimal performance. Since users are getting used to virtualization and migrating every one of their in-house server workloads/applications to virtual environments, the need to scale bandwidth capacity will continuously get bigger for the predictable future. The management software needed to scale bandwidth to reach the level of the users' needs is highly challenging. [9] Presented the following challenges in the utilization of bandwidth and can become a problem for the existing management tools:

- The absence of administrative support
- Uncontrolled users' downloads
- Virus attacks
- Higher demand compared to available bandwidth
- Unreliable Internet service provider
- Technical breakdowns
- Different user bandwidth requirements
- Too many network users

4. Conclusion

Cloud computing enables many organizations store, compute and retrieve/access their application from any location over the internet. This has shifts management core concern of maintaining in-house hardware resources and reduced the cost incurred. The concept of VMs-migration in cloud computing requires that the right bandwidth size must be made available on the host or physical machine. For example, when a VM is unable to serve its users request due to a technical failure on the host machine, the VM is moved to another physical machine to provide the needed services. VMs-migrated enables better management and optimization of the data centers and host machines. This paper focused on Cloud bandwidth management. An analysis of the concept of VM-migration and bandwidth management approaches was done. In conclusion, with the increasing number of cloud users and data centers, further research work for enhancing the bandwidth allocation approaches and management is required. This will further enhance the resource-sharing feature of the VMs.

Conflict of Interest

The authors declare no conflict of interest.

ABSTRACT

Research is dedicated to fuzzy reconstructions in the diachronic associative linguistics, and encompasses several simulation practices. The principles of an associative memory model and fuzzy computing with words are adopted in the working methodology. The evolved mathematical model reanimates the older patterns of Scottish associative map by means of fuzzy logic. The compiled fuzzy associative fields are connected by epidigmatic relations represented by fuzzy associative word structures in a fuzzy associative map constituting the grounds of the proposed thesaurus. The simulation of the historical associative thesaurus enables extended associative scrutiny: tracing associative antipodes, reconstructing an associative experiment for any map associate, finding words' similarities and distances, as well as associative differentiating and stratifying the Older Scottish lexis. The special interest represents the fuzzy associative differential, an electronic tool for estimating the lexis through its stable syntagmatic associates. All the simulation processes are fuzzy initiated and quantified. The proposed practice in its final configuration has no precedents, representing the novelty of theoretical interpretation and empirical application. The proposed terminology is mainly introduced by the researchers.

1. Introduction

Ethnoconsciousness of older speakers is the matter of research in the represented work. Associative maps of the modern ethnoses are mainly grounded on an associative experiment, which allows ascertaining the lingual associations through collecting the reactions of respondents to stimuli, the practice that is absolutely impossible for literal realization at the older language-states. Logically, to reconstruct the map and subsequently to simulate an associative experiment in the diachronic psycholinguistics seems real under the study of lexical relations present in the synchronic associative map. Such relations could be artificially reconstructed, quantified and canonically combined to reanimate the mental lexicon and all the related issues for the periods more or less remote in time.

In our research, the capability of fragmental reconstructing and activating the mental lexicon of Older Scots is realized with fuzzy modelling. The first turning point of the research is compilation of the diachronic synonymic sets of Older Scottish adjectives. The source of compilation is the Dictionary of Older Scottish Tongue (DOST) [1], an explanatory dictionary, providing the English description to Older Scottish lexis. The incentive is a synonymic set of English adjectives, any of which becomes an explaining semantic feature for the extricated Older Scottish synonyms. All those synonyms are gathered into a set, and ordered chronologically. Such sets are characterized by the connotative, stylistic and ethnic variability. The second decisive moment is the concluding of associativity nature of the compiled sets. The fuzzification of the sets is enabled by Zipf's regularity allowing to treat the diachronic measure, calculated for any set synonym, as that of associativity. In our research the compiled fuzzy sets are called the fuzzy associative fields (FAFs). The revealed fuzzy associative word structures (FAWSs) connect FAFs into the network, called an associative map or associative lexicon of Older Scots. Another associative relationship – antonymy – is brought into the structure, joining any FAF with its antonymic one. Thus a two-wing associative map is evolved at the stage. The fuzzy marking of the associative map allows us to

[*]Olena Basalkevych, 12 Zelena str., Lviv, 79005, +380955365348, olena.basalkevych@gmail.com

run the evolved network, realizing multitask simulation of the mental Older Scottish lexicon. Thus the first type of the run enables finding the associative chains through positive and negative wings of the map, called associative antipodes.

The following iconic associative relationship – syntagmatic one – attaches the available in the dictionary collocates to any adjective-knot of the network. Then the associative experiment in its nominal format is ready to be reproduced, bringing to any adjective of the map the words from its fuzzy associative structure; all existing till the moment associates within the major field; time antonym with its dominant and, finally, an available collocate. All the entries are collected in one fuzzy set, called a stimulated fuzzy associative field (SFAF). The simplest fuzzy metrics of similarity and distance could be found only within the same FAF, since they are not context- and turn-sensitive. The junction of the two antagonist-fields is regarded as a fuzzy differential, which enables the differentiation of the available Older Scottish lexis throughout the network. It gathers for any word the fuzzy subset of all its syntagmatic collocates available within the associative fragment. The new recommended method introduces into a traditional Osgood's semantic differential the expected denotative meanings. The electronic tool, created for the purpose, we call a fuzzy associative differential. The fuzzy stratification of Older Scottish lexis is another issue of the same approach. The electronic resource realizing all the facilities for the activated part of the associative map is called a fuzzy historical associative thesaurus (FHATh). All the techniques are grounded on the classical principles, notified in the following chapter, but represent an independent system, compiled in the series of previous author's works [2-4], mentioned throughout the paper. The absolute novelty of the practice lies in its possibility to imitate the older mental lexicon patterns on the basis of the proposed row of reconstructions, which was not applied in the diachronic linguistics before. The created electronic resource completely corresponds to the principle of computing with words: the user is pressing a word in the map and software returns the estimating phrase (supported with illustrating numbers) in response [5].

The classical sources whose concepts make the background of the developed mathematical model are analyzed in the following Chapter 2; and the comparison with the resonant works is realized afterwards (Chapter 3). The stages of development of the mathematical model are described in Chapter 4. The realization of the model resulted in different research techniques is explained in Chapter 5. The software packet and its principles of computing with words are described at the very end of the chapter. Finally, the received results are discussed (Chapter 6), and general conclusions are drawn (Chapter 7).

2. Report on Scientific Sources

2.1. Associative thesaurus of J.Kiss

One of the cotemporary and highly professional patterns of an associative map, reflecting the associative structure of words, was developed in 1972 under the aegis of British Medical Research Council by J.R. Kiss in his "An associative thesaurus of English", which is defined as a word association network represented by an oriented linear graph with labelled arcs, where the nodes are words and labels on the arcs give estimates of stimulus-response probabilities. As to its organization: "Two different approaches to the semantic structuring of the thesaurus data can now be distinguished. One is aimed at the discovery of semantic components for a word (covering all its word senses). The other is aimed at the discovery of groups of words which are relevant to each other because the concepts they label go together (although may not be similar to each other)" [6]. The concept becomes the first foundation of the proposed work. Our oriented graph of a network configuration called a fuzzy associative network (FAN) is organized following both processing approaches, the latter is well represented by FAFs gathering Scottish words whose main semantic components "go together" in synonymic sets of English adjectives, and the former completely corresponds to FAWSs.

2.2. Age-Frequency Regularity of G. Zipf

The second foundation is the regularity of G.K. Zipf stating the relationship between frequency and age of a word: "Hence, in sum, we have found not only a direct relationship between relative age and relative frequency, but also an inverse relationship between relative age and relative size in words of the same frequency" [7]. His conclusion on the English lexis time-age correlation states that the rank of the most frequent modern English words contains mostly the words originated from Old English [7]. In our research, Zipf's statement allows us to treat a diachronic measure as a frequency measure and therefore as an associativity one.

2.3. Fuzzy Logic

The state of affairs actualizes the third foundation of the work that is fuzzy logic, which shares the mathematical apparatus ready to fix the partial state of truth of a statement in our mind or speech. The honoured founder of the theory Lotfi Zadeh was working with the human language when fuzzy logic emerged, the logic implying the numerousness of partial truths on the way from nonsense to absolute. Lotfi Zadeh argued that probability lacks sufficient "expressiveness" to deal with uncertainty in the natural language. According to [8], in his "Computing with Words" Zadeh writes: "Humans have many remarkable capabilities. Among them there are two that stand out in importance. First, the capability to converse, communicate, reason and make rational decisions in an environment of imprecision, uncertainty, incompleteness of information and partiality of truth. And second, the capability to perform a wide variety of physical and mental tasks without any measurements and any computations. In large measure, Computing with Words is inspired by these remarkable capabilities."

A linguistic variable refers to the set of values more or less representing the emerged truth. The degrees of such a representation, or the measures of truth partiality, are caught by *membership functions*, normally, real numbers lying in the interval from 0 to 1 inclusively. The set is called a *fuzzy set*.

The formal definition: Let E be a countable or uncountable set and x be an element from E. Then *a fuzzy subset A of the set E* is characterized as a set of the ordered pairs $\{(x, \mu_A(x))\}, \forall x \in E$; where $\mu_A(x)$ is a characteristic fuzzy function (or a membership function) that takes its values in totally ordered set M or within [0;1], and indicates the level, or degree, of the element x belonging to the subset A. A linguistic variable alters in names, taking them from the set of verbal (word) characteristics,

representing all the sorts of it. Normally, such a set is called *a term set* [9, 10].

The fuzzification of our structure starts from the associativity measure that corresponds to a membership function, reflecting the degree of associativity of field members with a dominant. In short terms, Zipf's regularity enables fuzzy simulation of the diachronic associative thesaurus.

The fuzzy metrics of distance and similarity borrowed from the same theory [9] are available for all the elements of the represented associative map fragment.

Granularity in fuzzy logic implies dealing with data points within a granule as a whole rather than individually [11]. In our work it is used in consolidation phase while differentiating Older Scottish words. Available word-characteristics with their fuzzy estimates are grouped into six concept sets or granules with deriving the general probability and fuzzy measures for any granule. Fuzzy stratification is another way to address to the point data through the stratum which contains them [12]. The approach seems to be very profitable in the pay of the historical lexicography, naturally laying its verbal wealth layer over layer.

Thus the mathematical model of the represented work is extendedly grounded on fuzzy logic.

2.4. Osgood's Semantic Differential

The constructive element of FHATh is a junction of two antonymic FAFs which is constructed and recommended by our research to be used as a fuzzy associative differential (FAD). A FAD could be treated as a fuzzy diachronic modification of Ch. Osgood's semantic differential. FAD represents a lot of direct associates to different qualities, while the scales of the original Osgood's differential contain the intensity markers of these qualities. Preferably, literary meanings, since all of them are taken from the dictionary, are used in the scales of FAD, bearing classical denotative meanings with different connotative shades. Therefore, Osgood's conflict of 'connotative emotions' versus 'denotative precision' and the symbolic character of his differential scale-intervals [13] are moderated in our development. Meanwhile, the impartiality of Osgood's intensity markers whose applicability span could not be overestimated lacks in FAD. The most popular scales of Osgood's differential are Good-Bad, Strong-Weak and Active-Passive, representing so-called cross-cultural universals of Evaluation, Potency and Activity of the considered words. Our research adopts the universals for its measuring purposes.

2.5. Associative Network Memory Model

The principle of the network performance is comparable with "spreading activation" of an associative network memory model: when the concepts of interest are activated, "excitation" penetrates through the links to the associated concepts. More frequent in the past associations are stronger and easier to be excited. If the emitted excitation is potent enough to activate some of those associations and surpass the threshold, "activation is spread" and new concepts are brought to mind. The associative memory structure is highly metaphorical but still the only manner of simulating the physiology of the brain [14]. Normally, the network is evoked episodically in response to the stimulus, visualizing the associative map fragments which combine logogens as images of words, containing the information on the word valency, including stable associations. In the present work, the map is also activated episodically. Information on an associativity level of the map words as well as the smart orientation ability is hidden in the fuzziness of the network patterns.

3. Comparison Analysis

3.1. Fuzzy Hindi WordNet

In line with the proposed research, the fuzzy interpretation of Hindi WordNet [15] is realized with a fuzzy graph, and represents an ideal comparison pattern with similar underlain principles and inner graph morphology but a different fuzzification method. Our original work [2], which appeared earlier than the regarded comparison source, concentrated more on the paradigmatic and epidigmatic associativity of the proposed map. The most salient and fundamental difference of Fuzzy Hindi WordNet lies in treating the fuzzy graph vertices, synonymic sets, so-called synsets of nouns, verbs, adjectives, and adverbs as the sets of open-class words where the strength of every node is always 1 [15]. In our study the associative fields of adjectives are represented by fuzzy sets, employing the inherited vagueness of linguistic variable values that are normally represented by adjectives as degree-measurers [16]. Evidently, two works differ much by the calculus of membership functions: the classical expert opinions used in Fuzzy Hindi WordNet [15] seem to be hardly reachable for older languages, therefore we reasonably adapt a diachronic measure for the purpose. The weighed in the mentioned manner semantic and lexical connections in [15] are organized among synonymic sets and words, respectively, through association, hypernymy, hyponymy, meronymy, holonymy, antonymy, entailment, troponymy, gradation, and causative ties, whilst in [2] the epidigmatic relations are combining the different associative fields through the entries of the same words. As to the antonymic relation, in our case it immediately connects diachronic antonyms and the whole antonymic fields, containing them. The junction is realised through the antonymy of their dominants, following the proved associativity of antonyms [17]. The goals of fuzzy upgrade also diverge, since we represent a fuzzy reconstruction device whilst [15] is more about fuzzy metrics allowing to extricate the context word values in the modern Hindi discourse and text. As to the research sway, our work is rather an illustrated recommendation to a new type of historical thesaurus while Fuzzy Hindi WordNet represents an accomplished modern lexicography development.

3.2. Fuzzy Neural Networks

In the work, the morphology of the mentioned network is sophisticated in stipulation but simple in performance, and probably with much higher structural accuracy could be realized by means of a fuzzy neural network. It is equipped with fuzzy-valued connection weights and morphological neurons good at logical operations of conjunction and disjunction or dilation and erosion in terms of [18] among the others. All the more argument is that a neural network seems to be the most appropriate for simulating the associative reasoning [19]. Nevertheless, at the current stage of the research the proposed in the article fuzzy

model suffices completely the purposes of the set lexicological research.

4. Mathematical Model

The exposed interdisciplinary correlation of facts and dogmas flows out into the model serving the diachronic associative linguistics with fuzzy logic. The principles were originally conceived in the work [2], and developed in the following works, including [3, 4]. There could be discerned several stages in the evolution of the model.

4.1. Compilation of the Diachronic Synonymic Sets of Older Scottish Adjectives

The technique starts from the English synonymic adjectival sets taken from a dictionary of synonyms of Oxford Learner's Thesaurus (Oxford Thesaurus 2008) [20] or WordNet (WordNet 2006) [21]. They become the search stimuli in the DOST: the resulting Scottish adjectives contain them as defining semantic features. The reactions to all the English set adjectives are compiled into the set of Older Scottish synonyms. Their frame registers the first citations they were mentioned in, or so-called diachronic text prototypes [22], the year of the citations, or so-called advent time, their source, encyclopedic meanings and etymological notes. Synonyms are ordered in a chronological order, and any of them is attributed with a diachronic measure, calculated due to the formula:

$$W_i^{(y)} = \frac{y_i - y_{\min}}{y_{\max} - y_{\min}} \left(\frac{1}{n+1} - 1 \right) + 1, \qquad (1)$$

where ($y_{\max} - y_{\min}$) is a diachronic range of a set, ($y_i - y_{\min}$) is a distance to the appearance of the concrete word in a set, and n – the number of words in a set [23]. The organization and type of the sets imitate the Historical Thesaurus of the Oxford English Dictionary [24]. Primarily, the sets are called diachronic synonymic sets, and there are 100 of them in our database. They result in very heterogeneous collections of words affiliated by the same or comparable semantic features but reflecting the notable wideness of connotative, stylistic and ethnic coloration, which evidently leads them out of ordinary synonymy.

4.2. Associativity Nature of the Constructed Diachronic Synonymic Sets

The Dictionary of Older Scottish Tongue (DOST) is a resource most readily associated with Older Scots knowledge in people's mind, according to the dictionary definition given by Budanitsky [13]. The historically forged layers of lexis are stored there, keeping the primary syntagmatic associations reflected in numerous collocations and sentences, which contribute to the secondary paradigmatic associations [25]. Since all the words are dated, and represented with diachronic text prototypes, the historical dictionary like the DOST is expected to be the people's memory enfolded. The organization of memory is hypothetically comparable with an associative map as is mentioned in Chapter 2.5.

Therefore, the set goal of the research is to unfold fragmentally the associative map of Older Scots from the DOST. The paradigmatic collections within the received diachronic synonymic sets reflect the associative relationship, since *the process of their compilation is regarded as a discrete associative experiment with historical reaction* (the traditional associative experiment counting numerous reactions to a stimulus is called a discrete associative experiment with prolonged reaction [14]). The English synonyms, the DOST search items, play the role of stimuli. Thus at the stage, we rename the diachronic synonymic sets into synonymic associative fields.

4.3. Synchronization of the Associative Structures

The projection of the diachronic synonymic sets into the synchronic plane is realized by the mentioned in Chapter 2.2. Zipf's *age-frequency* correlating regularity, which states that the oldest words of the lexicon are the most frequent ones. On the other hand, the first words given during an associative experiment are the characteristics most frequent in mind, according to [14, 26]. Both facts directly influence the nature of the diachronic measure (1): it is converted into a frequency measure, and then in an associativity one. The hypothetical syllogism leads to the treatment of diachronic coefficients (1) as values of associativity of the field members with their dominant.

4.4. Fuzzification

Following the tenets of Chapter 2.3., E is a huge countable set of all the Scottish words (or adjectives only). From E, we could discern the fuzzy subsets A_j of words rendering specific semantic features or dominants, represented by English adjectives, which give the names to A_j. Membership functions or the degrees of reflecting these semantic features are completely expressed by associativity measures (1). Consequently, a Dominant is a linguistic variable and takes the values from its term set: *Dominant={Good, Bad, Strong, Weak, Active, Passive, Flexible, Inflexible, Brave, Cowardly, Intelligent, Stupid, Large, Small, Lucky, Unlucky,…}*. Altogether it contains 100 name-values (j=1:100). In our research, fuzzy subsets A_j are called *fuzzy associative fields* [2-4] or FAFs hence. For example, FAF *Active*= (douchty/1, fere/1, deliver/1, strenthy/1, licht/1, forthirwarde/0.99, unswere/0.87, agile/0.87, fery/0.87, active/0.78, wirkand/0.7, operative/0.66, lifly/0.63, tait/0.63, ȝape/0.63, restles/0.63, frak/0.63, trig/0.63, laborious/0.59, nocturnall/0.59, slepry/0.53, liver/0.52, throuche/0.49, gangand/0.46, actual/0.43, feat/0.42, ferdie/0.36, ȝauld/0.32, suddan/0.3, spritly/0.12, vigent/0.03).

From the totality of FAFs, we can extricate an associative word structure [2-4], epidigmatic relationship, stating the level of word associativity with different Dominants. We call it a *fuzzy associative word structure* [2-4] or FAWS hence. The example of FAWSs: Douchty=(Active/1, Vigorous/1), Agile=(Active/0.87, Vigorous/0.87), Unswere=(Active/0.87, Vigorous/0.86, Helpful/0.83).

Commenting the given instances, the variability of belonging for words Douchty, Agile and Unswere is not large, we observe the same Dominants with high associativity degrees in all the three cases, which states the intension nature of the mentioned semantic features.

4.5. Fuzzy Association Map

The unfolding of the associative map hidden in the historic dictionary starts from the connection of the evolved fuzzy

associative relations into the structure corresponding to the requirements of an associative thesaurus of English by J.Kiss [6]. The structuring approaches are well described in Chapter 2.1. and are completely sufficed by the combination of the developed FAFs and FAWSs into a map. One more strong associative relation proved by an associative experiment is an antonymic one [17, 27]. In our visualization, technically saying, we connect three positive FAFs Good, Strong, and Active with their antonymic ones Bad, Weak, and Passive, creating two wings of the *fuzzy associative map* or FAM [3, 4]. Any map wing contains a lot of between-field connections, combining the same words located in different fields. Some of the words and connections are distinctly represented in Figure1. The between-field connections themselves introduce into the map the epidigmatic relationship and are given by FAWS.

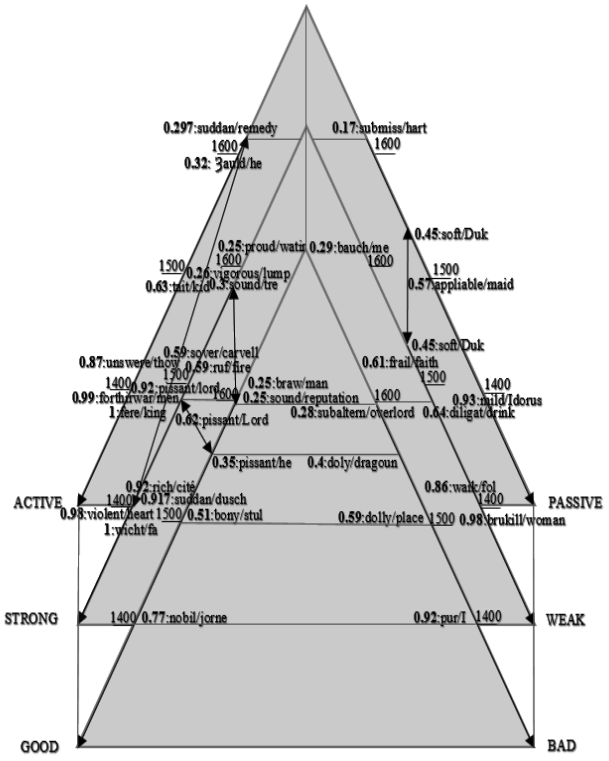

Figure 1: Fragment of FHATh.

The given fragment of a fuzzy associative map of Older Scottish adjectives covers the scales of the cross-cultural universal involved in the associative techniques of lexis Potency (Good-Bad), Activity (Active-Passive) and Evaluation (Good-Bad) ascertaining. Far not all the associates are visualized there: technically complete scales are represented by software forms.

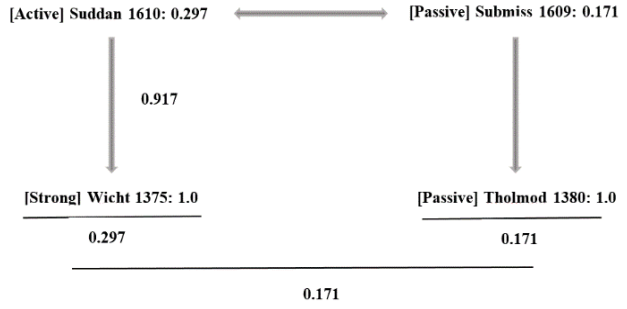
5. Simulating Techniques

The compiled map constitutes the ground for FHATh. In a final condition it is lined up with syntagmatic associations: any adjective of the set is paired with noun or pronoun taken from the diachronic text prototypes, represented by the DOST. The diachronic text prototype is the oldest quotation registered in the literature, containing the considered word. Following Zipf's regularity, we proved that the oldest word is the most frequent one and therefore contains the greater associativity strength. The same concerns the gained by the word syntagmatic relations, documented in the diachronic text prototype, which are the most prototypical and thus the most associatively stable. (Find the collocations in Figure 1.) Their fuzzy strength due to propagation acquires the fuzziness of the adjective.

The associativity of synonymic, antonymic and syntagmatic relations is supported by Deese in his «The structure of associations in Language and Thought», described in [17]. So the complete associative map is justified and thus ready to run. The activation of the associative map corresponds to the "spreading activation", caused by the "fired" stimulus, and is well-directed, since the map is represented by an oriented graph of a network configuration. The fuzziness plays its selective function in the process of network navigation. An associative map activated in the manner is called by our research a *fuzzy associative network* or FAN, and the process of its target activation is hence named the simulation of a target.

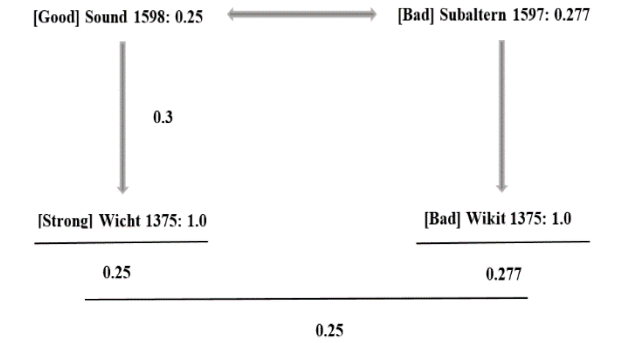
5.1. Associative Antipodes

The first target is an associative environment. Simulation of the associative environment ends up finding two associative chains through positive and negative map wings, called associative antipodes. To find the associative environment to the chosen on the map word, algorithm traces this word FAWS, detecting the word-place with the maximum membership function, after falls to the dominant of the found word as one with the maximum associative measure or membership function, and repeats the same scenario for this dominant till no more connections could be revealed, finding the n-association chain to a word-stimulus at the 2n-th step. The fuzziness of a chain acquires the minimum membership function of the passed places, according to conjunction in fuzzy logic:



$$\mu(\mathrm{x}_1 \cap x_2) = \min[\mu(x_1), \mu(x_2)]. \quad (2)$$

Then the same figurant is connected with its time-antonym, and the run is repeated within the opposite map wing till at the 2m-th step it reaches the m-association chain with the minimum membership function. Both chains constitute the n/m associative environment for the chosen word, or associative antipodes. The activated in the manner map we call *2 run fuzzy associative network* (2RFAN) [4]. In Figure 1, two pairs of antipodes are traced according to the algorithm. They are graphically derived in Figure 2.



The program realization of any thesaurus function, including the tracing of an associative environment, meets the principle of computing with words: a user is pressing a word in the associative map (Figure 3) and receives the evaluating phrase about the word's relations. The phrase is constructed on the basis of fuzzy values involved in estimating the associativity level or degree of belief of the received results (Figure 4).

The console (Figure 4) states that the positive associative environment for the word Suddan from the field Active is supposed to be Wicht from the field Strong with Low degree of belief (0.3). Its negative associative environment is supposed to be Submiss from the field Passive and the dominant Tholmond

from the same field, this time with Very low degree of belief (0.17). In its turn, the positive environment for Sound from Good is also Wicht from Strong but with lower degree of belief (0.25), and the negative antipode here is Subaltern from Bad and Wikit from Bad with Low degree of belief (0.28). The data support the graphics in Figure 2.

(a)

(b)

Figure 2: Associative antipodes: (a) [Suddan/Wicht]-[Submiss/Tholmod]; (b) [Sound/Wicht]-[Subaltern/Wikit]

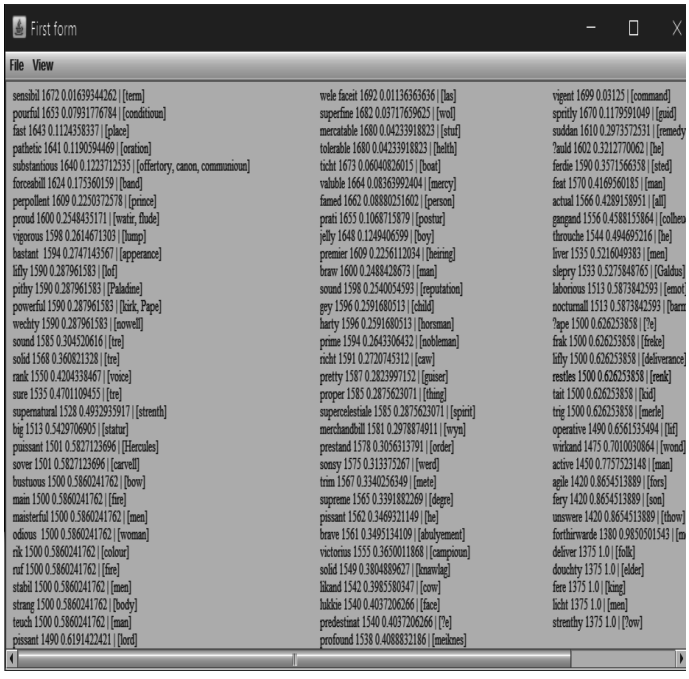


Figure 3: Map for selecting the words and realizing the simulation techniques.

In both cases we observe one semantic shift through positive map wing and no one but falling to the dominant in the negative wing. The same links could be singled out in Figure 1.

The found associative ramifications reveal the deepness of the associative map. On the limited fragment it shows quite a good coherence tendency.

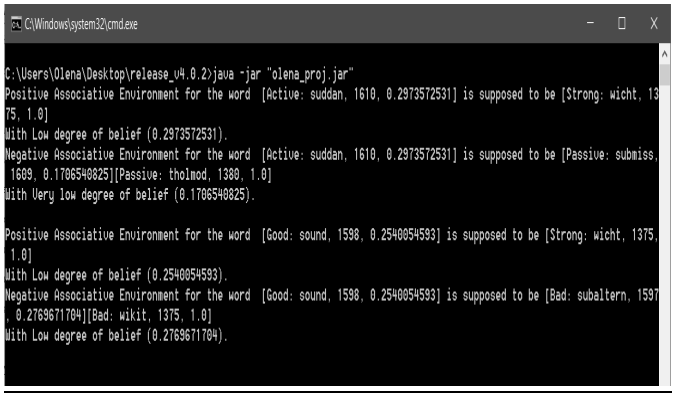

Figure 4: Console with results of tracing an associative environment for the word Suddan from the field Active, and Sound from the field Good.

5.2. Associative Experiment

According to the revealed regularities of the real associative experiment [14, 17, 25, 26], its schematic reproducing includes associative structure of the word (epidigmatic components), and from the field where its associativity is maximal: older synonyms of the word (paradigmatic components), collocates (syntagmatic components), time antonym and the dominant of a time antonym (paradigmatic components). All the entries are grouped into one fuzzy set or a *stimulated fuzzy associative field* or SFAF. Herewith, the dominant of the most associative field is entering the set with its proper fuzzy value 1 for subjective reasons of immersing in its mental plan. The membership function of a collocation is suggested by the adjective fuzziness. In such a case, an experiment could be treated as independent. The context-dependent experiment extracts the infield associations from the FAF of word localization. For instance, on pressing Pissant at the scale Good, within the framework of the independent associative experiment the algorithm traces all dominants Pissant belongs to [wicht/0.62, quhite/0.35]. The strongest association is observed in the FAF Strong, so an algorithm flexibly changes the field and extracts all the older synonyms, collocate Lord and time antonym Diligat with its dominant Tendir from FAF Weak, adds to the whole "community" the remaining dominant Quhite from the "calling" FAF Good, and orders the received fuzzy set. The program release of an associative experiment simulation for the stimulus Pissant is in Figure 5:

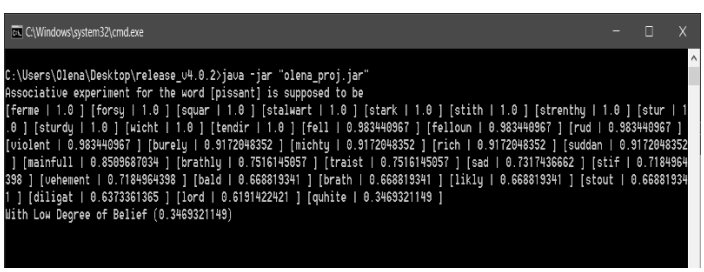

Figure 5: Console with the results of simulating an associative experiment for the stimulus Pissant.

The stability of the given SFAF or the associative reaction to the stimulus is read from the minimum membership function of its entries, normally that of the last element of the ordered SFAF. In our case, it is 0.35: with Low degree of belief the Older Scot would react to the stimulus Pissant in the proposed manner. If one needs more trustful result, the set should be cut at the required fuzziness level, expelling the newest and thus the rarest words.

5.3. Distance and Similarity

So far the infield trivial fuzzy metrics have been employed by FHATh to quantify the similarity and distance between associates. Thus the distance between associate x_i and associate x_j is

$$D = |\mu(x_i) - \mu(x_j)|, \quad (3)$$

where $\mu(x_i)$ and $\mu(x_j)$ are their membership functions or associativity measures, respectively, and their similarity is

$$S=1-D. \quad (4)$$

The classical fuzzy metrics' formulas are employed, and since they are not semantic-shift sensitive, we apply them only within a field. The between-field associativity metrics seem to be more complicated, and already regarded associative antipodes bring the maximum information on the direction and value of existing associativity among different fields. The program release for Distance and Similarity calculus for word-associates Valuble and Victorius from FAF Good is given in Figure 6:

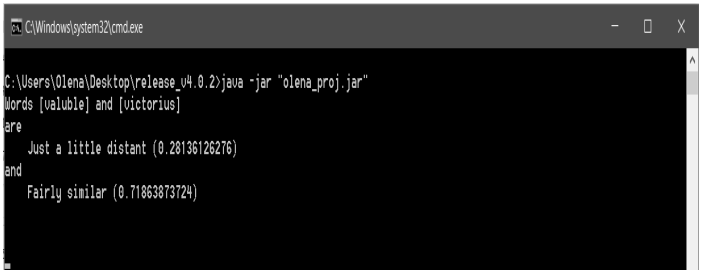

Figure 6: Release of fuzzy distance and similarity calculation for associates Valuble and Victorius from the FAF Good.

The Distance between Valuble and Victorius is rather small 0.28, that is why the software concludes that they are just a little distant. Therefore, the Similarity is quite high 0.72, with the conclusion that they are fairly similar.

5.4. Fuzzy Associative Differential

The function of the proposed by authors FAD is to provide as many associations to the considered quality as possible to describe it naturally and softly. The junction of antonymic FAFs serves the best for the purpose [3, 4]. All possible subtleties are gathered there and measured with associativity degrees. Three universals of Evaluation, Potency and Activity are depicted in Figure1: the space allows us to provide just sectional semantic values, the completeness of them is visible in the program forms (one of them is given in Figure 3). The scales are ready to serve any lexical request, and the tiniest shades of the quality could be communicated by them to the regarded word. In the case of the older language patterns, the service reflects the stable language collocations, provided by the diachronic text prototypes, and therefore treated as the most strengthened in time. So we gather all the possible characteristics for the collocate, regarded in the map, throughout all the six differential's scales and consolidate them into six fuzzy sets, or six granules in terms of fuzzy logic, mentioning the proper membership function $\mu_{Granule}$ and probability $P_{Granule}$ for any granule:

$$Word=\{Potency:[(Strong, \mu_{Strong}): P_{Strong}] \ OR/AND \ [(Weak, \mu_{Weak}): P_{Weak}]; \ Evaluation:[(Good, \mu_{Good}): P_{Good}] \ OR/AND \ [(Bad, \mu_{Bad}): P_{Bad}]; \ Activity:[(Active, \mu_{Active}): P_{Active}] \ OR/AND \ [(Passive, \mu_{Passive}): P_{Passive}]\} \quad (5)$$

Where, two antonymic granules, positive and negative, correspond to any criterion. Altogether, there are three universal criteria: Potency, Evaluation, and Activity.

For any of them:

$$P_{Granule}+P_{AntGranule}=1 \quad (6)$$

Positive and negative antonymic granules constitute a sample space: the probability of being strong is opposite to the probability of being weak.

The probability of any granule is equal to the sum of probabilities of its term-units:

$$P_{Granule}= = P_{Granule}(x_1)+ P_{Granule}(x_2)+...+P_{Granule}(x_k) \quad (7)$$

$$P_{AntGranule}= =P_{AntGranule}(x_1)+ P_{AntGranule}(x_2)+ ...+P_{AntGranule}(x_l) \quad (8)$$

Where, the number of term-units in both antonymic granules makes n: $n=k+l$, (9)

with k as the number of term-units in the positive granule, and l as that in negative one.

Then for any term-unit x_i either from positive or negative granule, the probability is:

$$P_{Granule}(x_i)=P_{AntGranule}(x_i)= 1/n \quad (10)$$

The membership function of the positive granule, following the disjunction in fuzzy logic, constitutes:

$$\mu_{Granule} = =max(\mu_{Granule}(x_1), \mu_{Granule}(x_2), ... \mu_{Granule}(x_k)) \quad (11)$$

Where, $\mu_{Granule}(x_1), \mu_{Granule}(x_2), ... \mu_{Granule}(x_k)$ are the membership functions of linguistic term-units of the positive granule.

The same for the negative granule:

$$\mu_{AntGranule}= = max(\mu_{AntGranule}(x_1), \mu_{AntGranule}(x_2), ... \mu_{AntGranule}(x_l)) \quad (12)$$

Where, $\mu_{AntGranule}(x_1), \mu_{AntGranule}(x_2), ... \mu_{AntGranule}(x_l)$ are the membership functions of linguistic term-units of the negative granule.

Thus we can create six differentiating granules for any collocate of the map, narrowing its evaluation to traditional

Osgood's coordinates, but implicitly contributing to them both denotative and connotative estimates of the criteria, to balance the situation when: "Osgood's semantic differential was an attempt to represent words as entities in an n-dimensional space, where measuring the distance between them could naturally follow from our knowledge of Euclidean geometry. Unfortunately, after extensive experimentation, Osgood found his system to rely on "connotative emotions" attached to a word rather than its "denotative meaning", and discontinued further research." [13] Our evaluation absorbs the extended psycholinguistic analysis, since according to J. Deese, associations reveal the latent mental lexicon, the hidden word's value [14, 17].

The example of fuzzy granule-differentiation for some Scottish lexis (He, Kid, and Thow) is notified in Figure 7.

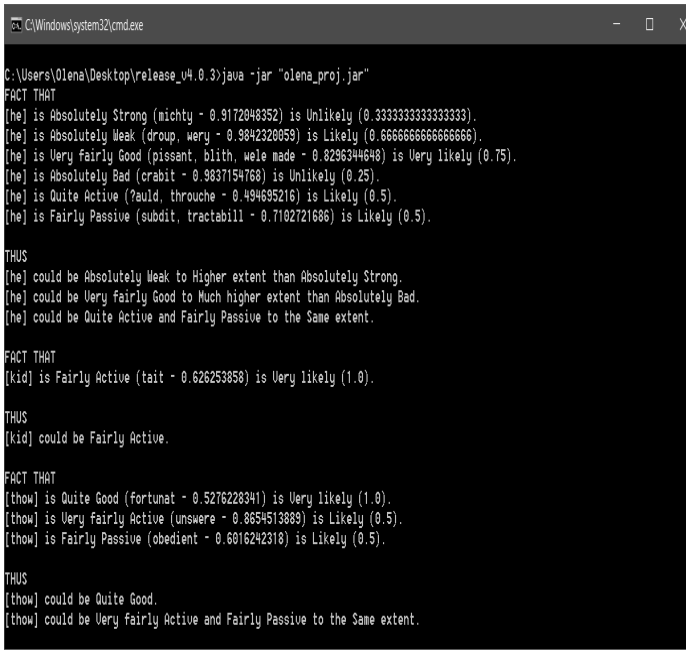

Figure 7: Console with the Older Scottish mental representations for He, Kid, and Thow.

The software reveals how Strong, Weak, Active, Passive, Good, and Bad He, Kid and Thow (in English 'thaw') are on the given map fragment:

Fact that

He is Absolutely Strong (michty - 0.92) is Unlikely (0.33)

He is Absolutely Weak (droup, wery - 0.98) is Likely (0.66)

He is Very Fairly Good (pissant, blith, wele made - 0.83) is Very Likely (0.75)

He is Absolutely Bad (crabit - 0.98) is Unlikely (0.25)

He is Quite Active (ʒauld, throuche 0.49) is Likely (0.5)

He is Fairly Passive (subdit, tractabill - 0.71) is Likely (0.5)

Thus, the software summarizes:

He could be Absolutely Weak to Higher Extent than Absolutely Strong

He could be Very Fairly Good to Much Higher Extent than Absolutely Bad

He could be Quite Active and Fairly Passive to the Same Extent

Thus the richest piece of the mental portrait on early and medieval *Him* has been represented by our fuzzy associative differential.

Kid and Thow are not so amply characterized on the fragment but still well-determined. According to the differential, "The fact, that *kid* is fairly active is very likely". As to *thaw*, the differential says that "Thow could be quite good" and "Thow could be very fairly active and fairly passive to the same extent."

The proposed by us electronic tool, called a fuzzy associative differential, seems to be very beneficial in the (re-)constructing of mental representations, and is highly recommended to the attention of cognitivists.

5.5. Fuzzy Lexis Stratification

On the other hand, the vertical cuts of the associative map in Figure 1 represent stratification figures of Older Scottish lexis [3, 4]. According to the late concept of Lotfi Zadeh, the special way of fuzzy classification was proposed as the way of organizing dictionary, encyclopedias and notebooks. It reveals the special relevance for the historical time-oriented thesaurus like ours.

The fuzzy stratification could open possibilities of ascertaining the lexis stratum gravity poles, time antonymy and significance status of the strata, all enabled by the manipulation with border membership functions [3, 4].

Any stratum in Figure 1 counts 100 years, and there are four of them within our figures for time-structuring of historical vocabulary of Potency, Evaluation, and Activity themes. The proposed by us fuzzy variable:

$$Gravity = \\ = (PositiveConcept/\ \mu(x_i);\ NegativeConcept/\ \mu(x_j)) \quad (13)$$

is introduced in any stratum, where $\mu(x_i)$ and $\mu(x_j)$ are the membership functions of the border (between-strata) antonymic terms x_i and x_j, respectively. The adopted error (the difference in advent time of the border words) makes 50 years.

The stratification for Potency was represented by authors in [3, 4].

Strong-Weak:
1400, (Burely/0.92) – 1420, (Smal/0.86);
1500, (Rik/0.59) – 1500, (Frail/0.61);
1600, (Proud/0.25) – 1600, (Bauch/0.29).
1300-1400 stratum: Gravity = (strong/0.92; weak/0.86);
1400-1500 stratum: Gravity = (strong/0.59; weak/0.61);
1500-1600 stratum: Gravity = (strong/0.26; weak/0.29).

In the same manner we characterize the sectional time antonyms, gravity or concept predominance within the remaining two structures:

Good-Bad:
1400, (Nobil/0.77) – 1400, (Pur/0.92);
1500, (Bony/0.51) – 1500, (Dolly/0.59);
1600, (Braw/0.25) – 1597, (Subaltern/0.28).

1300-1400 stratum: Gravity = (good/0.77; bad/0.92);
1400-1500 stratum: Gravity = (good/0.51; bad/0.59);
1500-1600 stratum: Gravity = (good/0.25; bad/0.28).

Active-Passive:

1420, (Unswere/0.87) – 1400, (Mild/0.93);
1500, (Lifly/0.63) – 1500, (Appliable/0.57);
1602, (Ʒauld/0.32) – 1609, (Submiss/0.17).
1300-1400 stratum: Gravity = (active/0.87; passive/0.93);
1400-1500 stratum: Gravity = (active/0.63; passive/0.57);
1500-1600 stratum: Gravity = (active/0.32; passive/0.17).

The balancing of values or the small predominance of negative concepts (the negative concepts being more alarming are traditionally more developed in equal development conditions) is observed in all the cases, except the latest stratum, which reveals the considerable gravity to the Active flank, pointing out to the notable development of the concept Active throughout the 16-th century. Linguists could speculate on historical reasons, for example, influence of Renaissance ideas in the case. According to Sapir, the language changes remain behind the cultural ones evoking them [28]. Therefore, approximately in the 14-15 centuries, at the time of High Renaissance, the concept Active became comparably more demanded.

5.6. Software Description

The architecture is the same as in [4] and based on MVP design template (*Model-View-Presenter*), delivering the visual reflection and event-procession behaviour into different classes, namely *View* and *Presenter*. In the case of 2RFAN, two XML files of the model DOM are chosen, for positive and negative runs of the 2RFAN.

The software performs altogether 5 main actions. They can be executed by the following button combinations realized in the given map (Figure 3):

- Left Click: Associative antipodes tracing.
- Left Click + Alt: Fuzzy Associative Word Structure evolving.
- Left Click + Shift: Word Differentiation through six scales of the FAD with final evaluative granularity.
- Left Click + Ctrl: Associative Experiment simulation for a chosen stimulus.
- Right click on two words of the same row: Distance and Similarity calculation for any two associates of the same field.

The provided interface is very sensitive and maximally friendly, making its evaluation in words. The correspondence between verbal estimators and membership functions (MFs) is given in Table 1.

The intervals are adopted from [8]. The proposed by us terms differ depending on words they modify: the first column modifies the degree of belief (modifiers for nouns); the second – all the six criteria as well as words Distant and Similar (modifiers for adjectives). In the proposed practice, the conclusion depends on the closeness of MFs to the centric characteristics, in favour of a more intensive modifier if MFs are equidistant from the two centers.

Table1: Correspondence between numeric and lexical evaluation.

Modifying terms for degrees of belief	Modifying terms for good, bad, active, passive, strong, weak; distant and similar	Range	Center
No	Not at All	0.17	0
Very Low	Just a Very Little	0.00 – 0.33	0.17
Low	Just a Little	0.17 – 0.50	0.33
Medium	Quite	0.33 – 0.67	0.50
High	Fairly	0.50 – 0.83	0.67
Very High	Very Fairly	0.67 – 1.00	0.83
Perfect	Absolutely	0.83	1

The terms for granule-probabilities depend on the probability distribution across two antonymic scales. There are four general terms and they are ranged by us in Table 2.

Table 2: Correspondence between granule-probabilities and terms.

Terms for Granule-Probabilities	Range
Very Unlikely	0.00 – 0.24
Unlikely	0.25– 0.49
Likely	0.5 – 0.74
Very Likely	0.75 – 1

The typical granule-estimating Zadeh's phrases [11] are adopted in our fuzzy associative differential (Chapter 5.4 and Figure 7).

The comparative terms for final conclusions on lexis differentiation depend on the number of shifts between the given above four probability ranges for the compared granules, and are given in Table 3.

Table 3: Comparative estimators for final conclusions on lexis differentiation.

Number of Shifts	Comparative Terms
0	the Same Extent
1	Higher Extent
2	Much Higher Extent
3	the Highest Extent

Thus the lexis and syntax of the phrases in Figures 4-7 are clarified by the aforesaid. The principle of computing with words seems to be utterly justified and profitable in linguistic conclusions like these.

6. Discussion

The electronic resource of the type recommends the method of associative modeling for the older languages, and thus extracts the linguistic knowledge of the remote times. The unfolded fragment of the associative map becomes the canvas for speculations on the Older Scottish consciousness. Many-sided conclusions on lexis development could be drawn from the realized on the map simulations. Associative antipodes' extraction reveals the reachability, coherence and deepness of the

map and, on the other hand, between-field associative communication. The chains count the semantic shifts of associations, notifying the reachability potency by the number of between-field transitions. The stability of the found positive and negative associative environment is characterized by the determined fuzziness values. The simulated associative experiment provides the most complete associative answer to the stimulus, meanwhile being sensitive to the forced turnovers in favour of the higher associativity relations. The constructed associative map makes it possible to derive an associative experiment for any map element, equipping it with paradigmatic (synonymic and antonymic), syntagmatic and epidigmatic associations. The fuzzy metrics' identification gives precise figures on similarity and distance between associates inside the field. The lexis differentiation practice provides the complete assessment analysis of nouns and pronouns of the map. The software groups the found characteristics for the regarded lexis into the fuzzy sets that correspond to the six scales Good, Bad, Active, Passive, Strong and Weak, constituting cross-cultural universals of Osgood's differential. The fuzzy sets are supported with joined probability-values and make the fuzzy granules, introducing the partial meanings of both connotative and denotative nature to the criteria of the scales, and breaking the limits of Osgood's differential. The special significance in this respect is referred to our fuzzy associative differential, designed for the purpose. The fuzzy stratification structures help us to draw the historical and lexical conclusions concerning the strata development. The fuzzy facilities are numerous and make the efficient research device, called an electronic FHATh, organized after the principle of computing with words, providing verbalized characteristics to the requested relations.

7. Conclusions

The fragment of a fuzzy model of associative memory provides complete and well-quantified associative relationship, episodically reflecting the world lingual picture of the older speakers, their communicational habits, lingual preferences, inbuilt attitudes and dispositions. The deepness of associative correlation and coherence of the area constitute the subject for the research conclusion. The prospect is observed in multiplication of the simulated network patterns ready to serve different stereotypes. The final combination of them in the larger network would enrich artificial intelligence with cognitive, behavioristic and evolutional linguistic data and mechanisms of their mining, which should broaden its historical prognostication abilities.

Patch Antenna

ABSTRACT

This article investigates different versions of a new multi-band micro-strip antenna design. NASA inspired the antenna design from "Hand of God" galaxy discovery. A multi-band operation between 0.15 and 8 [GHz] is obtained and captures up to 10 frequency bands. The antenna has a small area of 4 x 5 cm^2 and is printed on 1.6 mm epoxy-FR4 substrate. Adding slots and changing the feed position, led to different designs and increase in multi-band operation. Moreover, varactors are mounted on antenna surface, which resulted in frequencies as low as 50 MHz and as high as 8 GHz when. S11 simulations results were successfully compared with measured ones. Applications include different mobile generations, TV and different IoT systems.

1. Introduction

Multi-band antennas capture various segments of the frequency spectrum simultaneously. Yet, a challenging aspect of maintaing the required gain appears [1-6]. Of course, an antenna should have high efficiency to be able to capture many frequencies. Moreover, new technology requires smaller front end devices, and hence antenna size follows. Moreoever, selected frequencies are targetted, to cope with licenced frequency bands. Hence, research is still developing in this area.

Multiple frequency operation has become recently desired to engage IoT applications in same device. It allows performing technologies that require and or scan wide range of frequencies. For example, it is desirable to work with two mobile generations simultaneously [7]. Adapting to wearable technologies, [8], presented a relatively large antenna operating for different applications with up to six frequency bands. Alternatively, different bands related to same generation can be combined in same antenna [9]. Moreover, switches were mounted to achieve multiple resonances, while changing the switching scenario changes operation band being the L or S band [10,11]. Metamaterials were also exploited in [12] for multi-band operation.

The need to minimize space occupied by modern devices such as phones or sensors renders multi-band antennas more attractive since they replace many antennas [10], while still consistently frequencies in MHz range are mainly emitted by large antennas that are quarter wavelength, i.e. more than 12 cm in length and width [4,11,13,14]. This creates a challenge if high frequency ratio is targeted within same antenna. supporting different active parts of wireless spectrum. Low

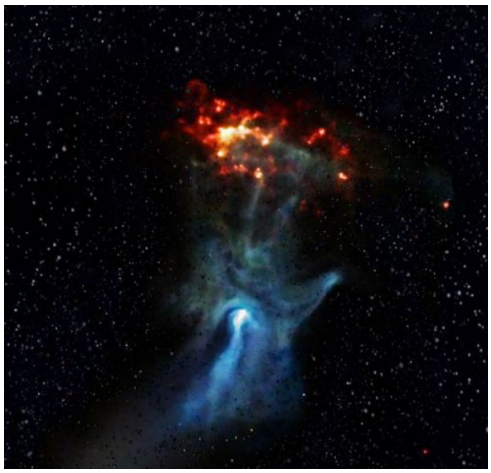

Figure 1: Galaxy named 'Hand of God' by NASA

This paper suggests a novel design that covers multiple low and high communications frequency bands, serves IoT applications, and maintains a compact size. The design is inspired by a photo of a galaxy captured recently by NASA, entitled 'Hand of God' [15]. Hence, this antenna duplicates a cosmic shape using

* Mervat Akram Madi, mm102@aub.edu.lb

electromagnetic radiation modelling, in an articulate way. Ultimately, the antenna presented here, resonates at frequencies near 0.1 [GHz] up to 8 [GHz], knowing that different techniques are used to enhance these aspects.

First, as power input position is varied, operating frequencies shifted. Hence, position of feed is an important parameter that is thoroughly investigated in the paper. Second, slots were easily incorporated in the design and enhanced increase of frequency operation in addition to bandwidth ratio. Third, varactors are added across slots to study their effect on frequency reconfigurability. As a result, frequency is tuned in the MHz range and resonance at 100 MHz is achieved, in spite of the very small physical length of the antenna.

The design of multiple extensions given by a hand shape is elaborated in this paper, since naturally each frequency is linked to a radiating element. Yet, the operation bands obtained outnumber the dipole, finger like extensions.

The antenna has compact volume of 4 x 5 x 0.16 cm^3, a new design that succeeds in combining more than six bands and captures ten bands in one specific scenario, with high frequency ratio of 53 starting at 0.15 [GHz], if no diodes are used. Frequencies above 8 [GHz] were not included in this research. 3G, 4G and IoT frequency applications are still main concern in antenna design. Authors present the 'Hand of God' for the first time, novelty is achieved in design, size and range of application [16]. In following sections, the antenna design significance is shown FEM modeling in HFSS. Third section shows the simulations results for feed through one chosen position. Section Four details all interesting scenarios in feeding positions and displays a comparison in S11 (return loss) results between measurements and simulations for the various fabricated prototypes. In section five, the effect of mounting varactors while DC voltage control is applied is shown. Sections six and seven show the current density and the corresponding radiation patterns for the resonant frequencies relative to the first discussed prototype.

2. Antenna Design Methodology

Due the importance of monopole, L and U shaped antennas in microstrip antenna design, the hand design holds importance in relation of design and shape. As the first draft of the patch design had shown multiple band characteristic, parametric sweeps that modify the shape for better resonance were done in FEM software tool HFSS. In fact, there is a conjecture that physical shapes in nature cope well with a certain frequency, and these shapes manifest certain cosmic frequencies, which is literally a direct link between shape and frequency. In fact, both ends of physics and metaphysics meet at the antenna design platform.

Moreover, the effective relation between having multiple extensions from a basic feed to a multiple frequency operation has immediately inspired me to recreate the hand shape on the patch after seeing the NASA photographs of a far galaxy. Yet, the use of FEM calculation tool for antenna design has facilitated turning the antenna conceptual design into an operating one. Here, experience in antenna design and persistence in using the HFSS software to explore all parametric influences on their own or in relation to other parameters has led to good results and even unexpectedly 9 resonant bands when slots were used.

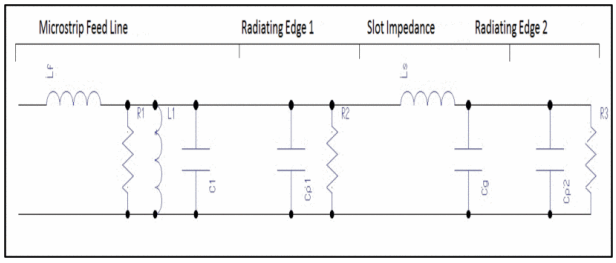

Figure 2: Equivalent circuit of slot loaded antenna

The 'Hand of God' [15], is source of inspiration of this design due to the photo captured by NASA telescope. The finger shapes and hand is a renovated form of dipole antenna array, with main 'palm' space acting as a relatively large capacitance that stabilizes antenna radiation operation at large frequencies in GHz range. This is no the first time a cosmic/natural shape is successfully exploited in electromagnetics, examples include the spiral shape (inspired from a galaxy [17]) and many others showing the beauty of science in relation to nature.

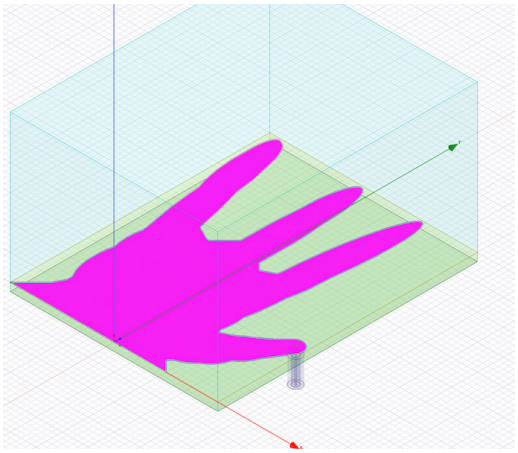

Figure 3: Simulated feed at 1st fingertip

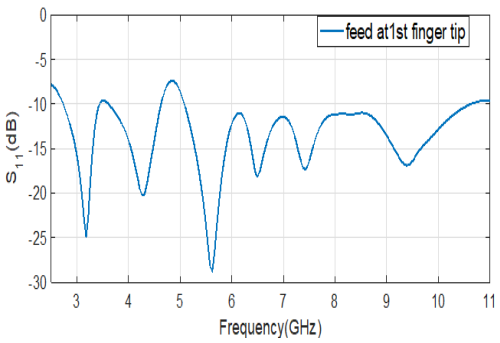

Figure 4: S11 simulated results of feed at 1st fingertip in Figure 3.

The antenna with four fingers combines inductive and capacitive effect of each extension. Yet, it forms a new way of

combining four dipole antenna extensions in a compact design. These were responsible for multiple frequency operation. In particular, each element has different length and shape, and spaces between elements play crucial role in minimizing destructive interference, since targeted frequencies have wavelengths comparable to antenna size. After performing many simulations on common area in the patch and length of the extensions, final design was achieved as shown in Figure 3. Initial setting of the model was even varied in total area and substrate material, but a double-sided FR4 substrate was most successful. Finally, small area of 4 x 5 cm ^{2} accommodated the multiple 'finger like' extensions to achieve the targeted multi-band operation.

Figure 5: First feed scenario prototype at 4th fingertip.

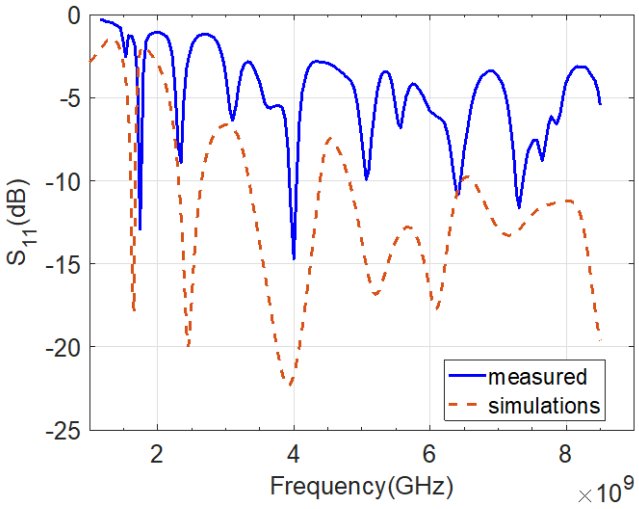

Figure 6: Comparison of S11 obtained in measurements and simulations results for 4th prototype (Figure 5).

Slots are used to increase bandwidth. Loading the radiating patch with slots or stub elements can extend bandwidth of the patch antenna. Additionally, varying the dimension of cutting slots on different locations and adjusting the shape of the slots like rectangular, circular, octagonal, fractal, and modified/partial ground plane, can help to obtain the desired bandwidth at estimated resonant frequency [18]. Slots are also used in size miniaturization of antenna [19] and increasing number of resonant frequencies [20].

Slot impedance is considered as series inductance and parallel capacitance, which adds to the total inductance and capacitance as shown in Figure 2, [21]. In fact, slots helped increase the number of resonant frequency bands over [0.1-8] GHz to nine with tunability over frequency range [0.2-0.8] GHz, and total area = 4 x 5 cm ^{2}. In a similar approach, [22] has used 3 slots to achieve three resonant bands tunable at 3 frequencies over [0.6-2.7] GHz, and an area = 5 x 10 cm^2. Slots with modes controlling method were used in [23]. Starting with a monopole at 0.25 λ then adding an open slot at 0.25 λ then a tuning pad, resulted in 2 bands [0.8-1.02] GHz and [1.69-2.73] GHz, knowing that the area = 10 x 6 cm^2. Multiple slits on a rectangular patch were also used in [20], to achieve 4 bands over [5.8-7.87] GHz and antenna area of 2.6 x 7.75 cm^2. Other methods can be listed here with corresponding characteristics, for example using multiport and theory of characteristic modes (TCM) to isolate frequency bands, resulting in 3 bands over [0.8-2.2] GHz [24]. In comparison, [25] mounted a 3D loop folded antenna (volume 60×5×5 mm^3) on 100×60×0.8 mm^3 FR4 substrate with full ground plane, for a mobile handset, to design a 3 bands tunable antenna over [0.8-2.5] GHz. Consequently, the present method is better improved over other methods due to carving the slots on the antenna patch along the extended finger shapes, which enhanced the resonant characteristic modes by doubling the mode effect being a result of splitting into two arms in a U shape.

3. Simulations basic design and effect of feed position

The antenna is a microstrip patch, with full ground, an area of 4 x 5 cm ^{2} and 1.6 mm thick epoxy FR4 substrate. The dimensions of finger shapes (see Figure 5) are 25.8 mm x 6 mm for 4th finger, 19.6 x 6 mm for 3rd finger , 21.5 mm x 6 mm for 2nd finger , 14 mm x 9.5 mm for 1st finger. The antenna feed is a coaxial cable as shown in Figure 3, where axes x, y, and z are in red, green, and blue respectively for later reference. In fabrication, an SMA connects the cable to the antenna at the variable positions to be discussed, where 50-Ω matching is considered.

Figure 7: Antenna prototype with the feed at the 2nd fingertip.

The design is modeled in FEM software, HFSS. In order to preserve the universal shape, and improve results and easily accommodate the shape in small area for better performance, simulations were the main guide to refine the design, where there

is no imperial formula to apply in this case. The underlying design

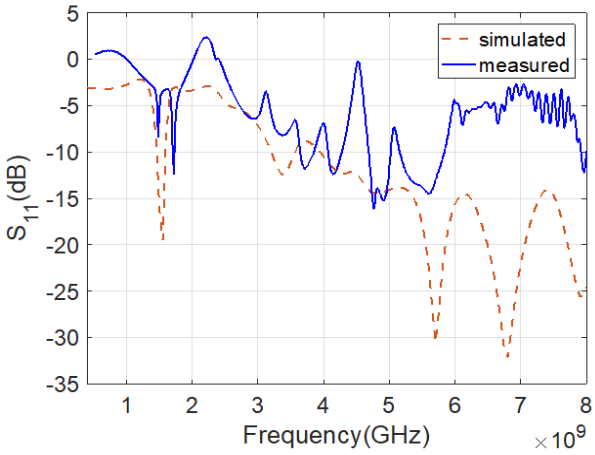

Figure 8: Comparison of S11 obtained in measurements and simulations results for 2nd prototype (Figure 7).

is an overlap of geometrical shapes like polygons, ellipses, circles, and lines in coherence with basics of drawing depicted from human anatomy. The area being restricted to 4x5 cm^2 has less extension of the wrist, which has shown no effect on multi-band aspect.

Feeding has been tested over 10's of potential positions. Yet, resonance was easily achieved when the coaxial feed is placed the fingers tips. For example, an ultra-wide band (121% bandwidth) between 2.7 and 11 [GHz] is obtained when the feed is at the tip of the first finger as shown in Figure 4. The results at the remaining fingertips are shown in comparison with measurements.

Figure 9: Antenna prototype with slots with the feed at the 1st fingertip.

4. Comparison between measurements and simulations results

A. First prototype, no slots and the power input at the fourth fingertip (Figure 5) :

The first prototype of feeding position at 4th fingertip is shown in Figure 5. It is fabricated as first test of the antenna simulations results. The reflection coefficient S11 is measure using a network analyzer that spams up to 8.5 [GHz].

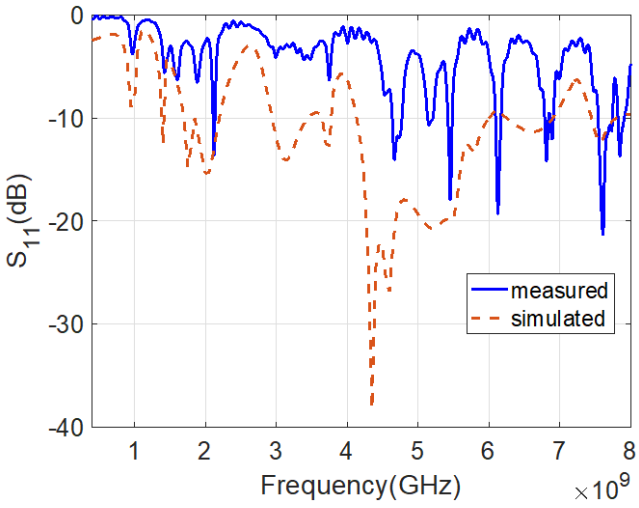

Figure 10: Comparison of S11 obtained in measurements and simulations results for prototype in Figure 9.

S11 results recorded in measurements coincide very well with simulated ones as shown in Figure 6. When comparing the resonance frequencies for the simulated and fabricated cases, small drift was obtained; i.e., (1,66, 1.74), (2.43, 2.34), (3.95, 4), (5.2, 5.06), (6.15, 6.42), and (7.2, 7.4) [GHz]. 0.27 [GHz] is the maximum difference between measured and simulated results due to many reasons, which include:

1) Modeling at a center frequency, while multiple frequencies are targeted and being discovered. As a result, slight differences

Figure 11: Antenna prototype with slots with the feed at the 2nd fingertip.

appear due targeting different frequencies while setting far field in the simulations at fixed wavelength.
2) Fabrication errors, resistive mismatch in the SMA connector, soldering and losses in measurement wires.
3) Since losses increase with frequency, discrepancy increases at

higher frequency to maximum of 0.27 [GHz].

B. Second prototype, no slots with feed at the second fingertip (Figure 7) :

For feeding position at second fingertip, comparing the S11 results as displayed in Figure 8 shows discrepancy at 6.85 GHz being a resonant frequency that did not appear in measurements unlike simulations. However, almost good matching is obtained for measured frequencies at 1.85, 3.85, 4.2, [4.8-5], 5.7 and 7.98 [GHz]. Largest differene between measurements and simulations in listed values is at 3.47 GHz obtained in simulations versus 3.78 GHz in simulations. Such discrepancies results are descirbed in paragarph A of section 4.

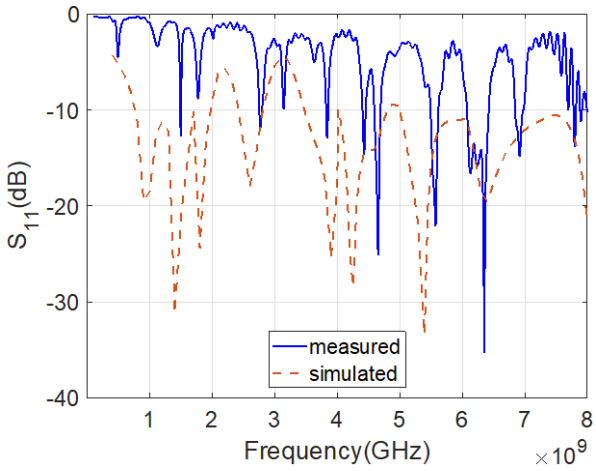

Figure 12: Comparison of S11 obtained in measurements and simulations results for prototype in Figure 11.

C. Third prototype, with slots and feed at the first fingertip (Figure 9) :

Adding slots along all fingers has created multi band operation for feed at all fingertips due to elongating the current path. Here the feed is at the first fingertip as shown simulated results show more like ultra wide band operation below 4 GHz. Common nature of multi-band operation is seen in both results with peaks almost coinciding or falling within matching region i.e for S11 belwo -10 dB. in Figure 9. Comaprision between measured and simulated results is shown in Figure 10. Measured results resonance is obtained at 2.15, 4.5, 5, 5.5, 6.05, 6.8 and 7.7 [GHz], while simulated results show more ultra wide band operation above 4 GHz in addition to several multi-band rsonances belwo 4 GHz. Multiple bands are seen in both results,

Figure 13: Antenna prototype with slots with the feed at the 3rd fingertip.

with peaks almost coinciding or falling within matching region i.e for S11 below -10 dB.

D. Fourth prototype, with slots and feed at the second fingertip (Figure 11) :

Adding slots with the coaxial feed position at the second fingertip is shown in Figure 11. The S11 measurements show good matching with simulation results (Figure 12) at the following resonant frequencies : 1.4, 1.83, 2.72, 3.9, 4.2, 4.78, 5.38, 6.32,6.97,8 [GHz] being the simulated obtained values with maximum difference of 0.25 [GHz]. Resonance at 1 [GHz] did not appear strong enough in measurements, hence it is not considered.

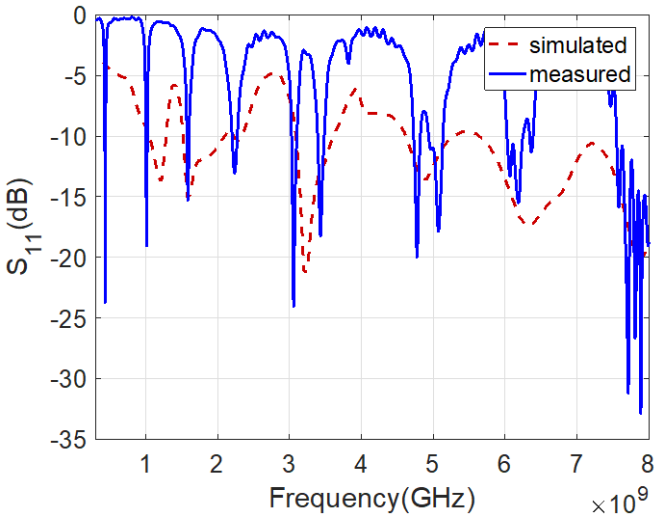

Figure 14: Comparison of S11 obtained in measurements and simulations results for prototype Figure 13.

E. Fourth prototype, with slots and feed at the third fingertip (Figure 13) :

Adding slots with the coaxial feed position at the third fingertip is shown in Figure 13. The S11 measurements show good matching with simulation results in Figure 14, at the

following resonant frequencies : 0.15, 1, 1.65, 2.25, 3, 3.4, 4.8, 5.08, 6.2, and [7.6-8] [GHz]. Resonance in measurements at 0.4 [GHz] could not be obtained in simulated results and hence it is not considered.

5. Dc biasing of mounted varactors

A simple experimental approach of adding varactors across slots was done as an arbitrary trial to check resonances and reconfigurabilty with DC biasing [26]. Simulations were not done to approve results as this experiment falls in further studies to explore the full frequency reconfigurability upon adding varactors. Moreover, experimental tools did not allow DC biasing to the full range of voltage, which is up to 60 V due to summing up the voltage across varactors, which take up to6 V each. As shown in Figure 15, varactors were added at the slots carved through second and third fingers. In order to DC bias the 13 varactors. Inductors were added across slots in 1st and 4th fingers as shown in Figure 15. Hence DC current was drawn through the inductors, which act as AC block at the same time [26]. S11 resonance at low frequencies is remarkable considering the size of the antenna. Frequency reconfigurability over [2.15-2.25] and [0.2-0.8] GHz is obtained upon DC biasing the antennas between [0-10] V as shown in Figure 16. Future studies are to be made by further increasing the DC voltage biasing range. Applications to such frequencies fall in DVB, TV broadcast, LTE, and many other telecommunications standards, which allow -6 dB S11 at maximum return loss [14]. Additional new frequency resonances are obtained at1, 1.6 and 2.15 [GHz] due to adding varactors as shown in Figure 16. The multi-band feature of the antenna at wide range of frequencies enables additional applications such as IOT [6] and energy harvesting [4,27].

Figure 15: Antenna prototype with slots with the feed between 1st and 2nd fingertip and using varactors along 2nd and 3rd fingers slots.

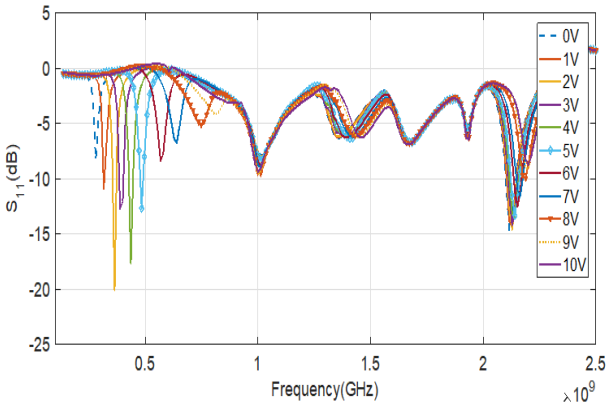

Figure 16: Comparison of S11 obtained in measurements and simulations of prototype in Figure 15 with frequency tunability upon varying the DC bias voltage.

6. Surface current density

Current flow at the antenna surface changes with frequency, consistently with the electric length required for frequency resonance [28]. Surface current density distribution is plotted from simulations for four frequencies as a demonstration. The first antenna prototype in Figure 6 is chosen as an example. Here the feed is at the 4th fingertip. Figure 17 shows the four current graphs corresponding to 1.66, 3.95, 5.2 and 7.2 [GHz] with same color scale with maximum at 6 [A.m^{-1}] and minimum at 0.012 [A.m^{-1}]. However, at 1.66 [GHz] the current density achieves highest value of 60 [A.m^{-1}]. Normally, lowest frequency corresponds to largest electric length and current density values. The current is first

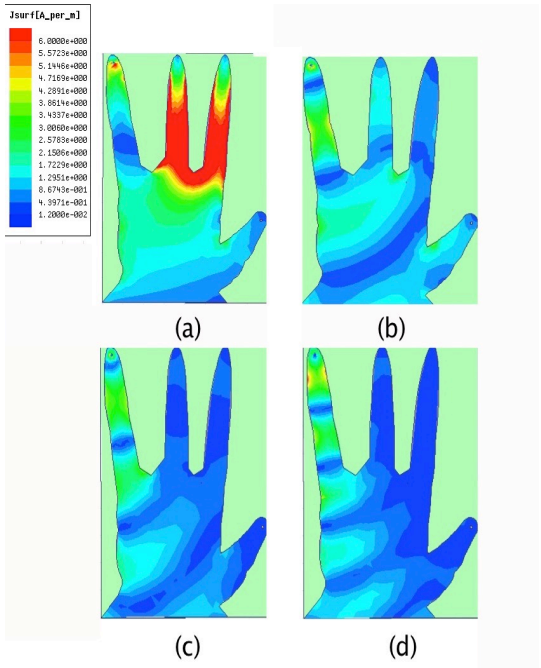

Figure 17: Simulated results for the current distribution for the 4 resonant cases corresponding to 1.66 GHz (Figure a), 3.95 GHz (Figure b), 5.2 GHz (Figure c), and 7.2 GHz (Figure d).

strong especially over the mid part of the hand 1.66 [GHz] in graph(a) of Figure 17; then the current surface area diminishes as

frequency increases as shown in graphs (b,c,d) of Figure 17. Of course, longest current path from input feed to furthest points in the patch assures the lowest frequency resonance. And obviously, the current is drawn to smallest area around the fourth fingertip where the feed is placed, at the highest frequency of 7.2 [GHz] as shown in graph (d) in Figure 17.

7. Radiation pattern

The current flow distribution in Figure 17 radiates the different patterns shown in Figure 18, [28]. The radiation pattern at the 2.43 GHz frequency is shown in Figure 18 (a). The common observed feature at low resonant frequencies is the symmetric current distribution with respect to the right diagonal resulting in a common radiation pattern at 1.66 and 2.43 [GHz]. Here, the axes are same as in Figure 5. Figure (b) has many peaks due to non-symmetric current density at 6.15 [GHz]. Figures 18 (a, b) show the main trend of radiation pattern at low (1.66 and 3.95 [GHz]) and high frequencies (above 5.2 [GHz]) respectively, as a

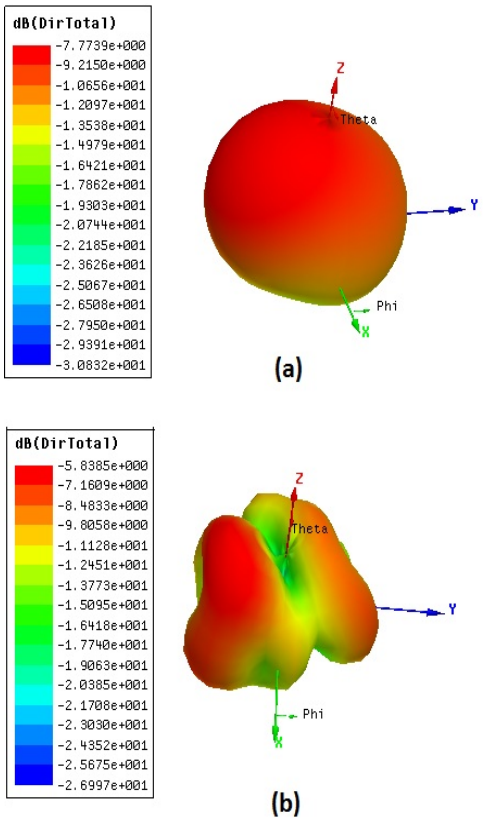

Figure 18: Radiation pattern at 2.43 and 6.15 [GHz] in (a) and (b) respectively.

consequence of change of current density symmetric distribution on the surface. A more description plot of the radiation pattern at 2.43 [GHz] is shown in Figure 19.

8. Conclusion

The 'Hand of God' motif has been successfully translated in antenna design modeling and served in achieving a multi-band operation. Slots are incorporated in the antenna showing an enhanced multi-band operation. In fact, 10 resonant frequencies were obtained over the interval [0.15-8] GHz for one prototype having slots and with the feed at third fingertip. Interesting increase in electrical length of the antenna results when varactors are added across slots. Consequently, resonance at low frequencies of 100 MHz is obtained. Moreover, frequency reconfigurability is observed at frequencies below 1 [GHz]. Finally, the shape, size, and wide range of antenna operation frequencies render it as multi-functional and suitable for different modern applications.

Service Level Agreements

ABSTRACT

Cloud computing is a technical "as-a-service" usage model utilizing virtualization. Virtual machines are the core of cloud computing that runs as independent machine grouped into different networks within the hypervisor. Practically done by deployment of clouds computing hosts enterprise servers in virtual machines on an array of high-end servers. Managing cloud resources has to do with controlling and limiting access to the pool of available resources. This brings about the conception of an agreement between the resource services cloud providers and the customers otherwise known as Service Level Agreement, in other to restrict access to provisioned resources. Resource provisioning is a flexible on-demand pay-as-you-go package that is negotiated; and signed based on SLAs between customers and cloud providers. SLAs enable cloud providers to evade costly SLA consequences payable when there are violations, optimizing the performance of customers' applications and professionally manage resources to reduce cost. These documents are the agreements called Service Level Agreements (SLAs). SLAs outline the expectations which are: terms, conditions, and services of the clients from their service providers regarding availability, redundancy, uptime, cost, and penalties in cases of violations. These ensure clients' confidence in the services offered. Managing resource is an on-going major issue in cloud computing. Considering the limitation of resources, it poses a challenge for cloud service providers to make provision for all resources as needed. This paper seeks a solution to problems that relates to the present trends and developments of what cloud Service Level Agreements are and it ensures so by reviewing current literature. Thus, this research is a study of cloud Service Level Agreements, cloud resource management and their challenges. This paper has made provision to act as guidance for future research and it is anticipated to be beneficiary to potential cloud end users and cloud service providers.

1. Introduction

This paper is an extension of work originally presented in 2018 International Conference on Next Generation Computing and Information Systems [1]. This expands on resource management on Cloud computing and its challenges. Cloud computing makes provision for services by cloud service providers to simplify computing, storage and applications development by an end user using the Internet. Cloud computing is a computing method that enables ubiquitous service which is accessible to a mutual group of computerised resources. . Cloud computing is not limited to networks, services, storage and applications which can be swiftly made provision for and made available with minimal supervision involved [2].

In a cloud environment, resource management is challenging because of the scalability of present data centers, the heterogeneity in types of resources, the interconnection amongst these resources, the inconsistency and irregularity of the load, and the variety of aim of varied end users [3]. Cloud computing and management of resource provisioning are actualized at:

a. Infrastructure-as-a-Service (IaaS) - resources not limited to physical machines, virtual machines, and storage devices are offered as a service to customers.

b. Platform-as-a-Service (PaaS) - offers pre-installed software to customers for application development and testing.

c. Software-as-a-Service (SaaS) - offers a service instance with customizable interfaces to many customers in a cost-efficient manner [2].

Cloud resources management and cloud services are made available based on established Service Level Agreement (SLA) indicated and contracted between Cloud service providers and their end users describing the relations of what is agreed, which

*Isaac Odun-Ayo, Covenant University, +2348028829456
isaac.odunayo@covenantuniversity.edu.ng

also does not exclude non-functional requests, such as quality of service (QoS). In [4], the authors discussed that cloud end users prefer to choose a cloud service appropriate for them from the major service providers that can offer services with adequate quality of service guaranteed.

Lock manager is an independent algorithm that runs on cloud for one manager per server. Algorithm is a set of steps used to solve computing problems such as consistency in maintaining distributed files in cloud computing. There are many client requests made to different servers, requesting for granting simultaneous access to the same file. These requests run independently of each other and pool resources with one another to maintain uniformity of the files in the cloud. This algorithm contributes solution to the major concerns for availability and scalability of file resources [5]. Making the provisioning of resource management flexible and reliable and SLAs are very important to Cloud providers and their clients. Flexible and dependable provision of resource management and SLA agreements in SaaS, PaaS and IaaS are important to the Cloud providers and their clients. This enables cloud providers to evade exorbitant SLA penalties billed for infringements, to professionally manage resources, and lessen charge while elevating the performance of clients' applications. To assure SLA of customer applications, cloud providers need refined resource and monitoring of SLA approaches to accomplish sufficient data for the management procedure [6].

Cloud computing makes use of the concept of virtualization and multi-tenancy to provide service for their end users. Enterprises can migrate some of their applications and utilize services based on appropriate agreements. Cloud computing is made up of four types of deployment: the public, private, community and hybrid clouds. Organizations own private cloud. The amenities can either be in-house or off and the management is by a third party. Private clouds are often perceived to be more secure. Service providers that offer their services with a cost to cloud users majorly own public clouds. Public cloud make use of big data centres most times across many geographical locations. They are perceived to be less secure. Community cloud are run by some firms that have shared mutual interest. The management could be a community or a third party. The combination of either private, community or public cloud is known to be Hybrid cloud. Hybrid computing is cloud utilizes on the benefits of the different cloud types.

Service Level Agreement (SLA) is an official agreement between service providers and clients to assure consumers the quality service expectancy can be realised [6], Service Level Agreement lifecycle involves six phases: ascertain the cloud service providers, outline the Service Level Agreement, institute an agreement, observe likely SLA violators, end SLA and implement consequences [6]. Service Level Agreements are used to officially define the services that offered, the Quality of Service anticipated from cloud provider, duties of both parties involve and possible fines [7]. According to [8], Service Level Agreements ought to comprise of five simple matters. They are: set of services that are made available by the cloud service providers; an explicit and imminent evidence terms of services offered; set of Quality of Service metrics for assessing service delivery points; a way of monitoring these metrics; and means of make a decision during disagreements that may arise as a result of failure in meeting the Service Level Agreement terms. It is imperative for cloud end users to delight in the resources and service assured by the cloud service provider, as the cloud service provider should gain optimally from the resources being provided [9].

The aim of this paper discusses cloud service computing, SLA and resource management. The paper discusses SLA in depth, looks at issues that relate to cloud computing and resource management from the industry perspective. The remaining paper is as follows. Section 2 studies related work. Section 3 converses Service Level Agreement in terms of resource management. Section 4 concludes the paper.

2. Related Works

Managing resources for cloud computing environments is an active field in research. We now present relevant work in Service Level Agreement, resource monitoring and management, framework, method, and model.

In [9], the authors presented dynamic data-centred virtual reality method that prevents Service Level Agreement defilements in combined cloud settings. This research offered an architecture that enables the release of end users resources without problems or violation of the Service Level Agreement. This achieved was through the use of several cloud service providers consumed by end users. SLA in Cloud Computing was offered in [10]; whereby the authors scrutinized SLAs between end users and cloud service providers. A Web Service Level Agreement structure was projected, applied, and confirmed. In [8], a structure for dialoguing SLA of Cloud-based Services was offered. The framework decides the best appropriate cloud service provider for cloud end users. These writers as well emphasised the significant characters of cloud dealers for optimal resource consumption by the cloud end user. The role of supremacy and other Service Level Agreement concerns in cloud environment were made known in [11]. The work untaken, includes main characteristics to be well thought-out when drafting up cloud service legal contracts in cloud computing. The problem of cloud domination was also evaluated with an understanding to determine right ways of handling information with least consequences. In [12], the writers proposed a method that concurrently provided for Quality of Service observing and resource optimal usage in cloud data centres. These authors offered a methodology which gathered user workloads into groups and used these groups to avert Service Level Agreement violation and at the time make better resource consumption, thus profiting both the cloud consumers and cloud providers.

In [2][13], the authors presented a resource monitoring framework which is push-pull technique for Cloud computing environments. This method is established in addition to dominant push and pull methodology monitoring method in Grids to Cloud computing with the aim to create a capable monitoring framework to be able to share resources in Clouds. In [14], the authors defined cloud federalism as being able to bring together services from different cloud vendors to provide a solution; an example is Cloud Burst. According to [15], on resource management, performing live migration is a recent feature concept within Cloud systems for active fault tolerance by flawless movement of Virtual Machines from waning hardware to unwavering hardware with the consumer not being aware of any change in a virtualized environment. Resource consolidation and management can be performed though the use of virtualization technologies. With the use of hypervisors contained by a cluster environment, it enables the consolidation of some standalone physical machines into a virtualized environment, therefore needing fewer physical resources when compared to a system without virtualization capabilities. Nonetheless, this

improvement is still inadequate. Big Cloud deployments have need of physical machines in thousands and megawatts of power.

Data-driven models can be used to manage resource cloud complex systems. The author in [16] discussed his dissertation and argued the advancements in machine learning for the management and optimization of today's resource systems through arising insights from the performance and utilization data these systems create. In other to bring to reality the vision of model-based resource management, there is need for the key challenges data-driven models raise to be dealt with such as uncertainty in predictions, cost of training, generalizability from benchmark datasets to real-world systems datasets, and interpretability of the models. Challenges of data-driven models includes:

a. Robust modelling procedures being able to work with noisy data, and to develop methods for model uncertainty estimates [17].

b. Data-driven model has to incorporate domain knowledge into the modelling process in order to increase the model accuracy and trust in the modelling results [17].

c. Transforming or migrating data from a relational schema to schema-less is difficult to accomplish due to data modeling challenges [18].

In [2], the authors designed a run-time monitoring framework name LoM2HiS to perform monitoring fixated towards increasing the scalability and practice in distributed and parallel environments. The run-time system observer target is to observe the services established on the negotiated and contracted Service Level Agreements by mapping rules; Cloud Service Provider's (CSP) clients request the provision of a contracted service; and the run-time monitor loads the service Service Level Agreement from the decided Service Level Agreement depository. Infrastructure resources are based on the service provisioning that represents hosts and network resources in a data center that host Cloud computing services. The design of this run-time monitor framework is aimed at being highly scalable.

There is a practice of dynamically allocating and de-allocating resources on physical machines in the public cloud environments [16]. As all kind businesses move to cloud, this leads to increase in varied workloads running in the Cloud; and each has diverse performance requirements and financial trade-offs [19]. According to [16], there are varied collection of Virtual Machine (VM) cloud providers, and the main problem of accurately and economically selecting the best VM for a specified workload resources is addressed. Considering the speed of growth in Cloud computing, some VM management platform solutions including OpenStack [13] has come into play.

Apache VCL in [20] is an open-source system for flexible resource providing and reserving of computation resources for different applications in a data center by the use of simplified web interface. In [16], the author discussed about Manjrasoft Aneka a service platform to build and deploy distributed applications on Clouds that makes provision for many applications for the transparency, exploiting distributed resources; and Service Level Agreement focused on allocating resource that distinguishes requested services based on their available resources and hence provides for consumers' needs.

3. Cloud Computing SLA and Resource Management

3.1. Service Level Agreement Concepts

1) National Institute of Standards and Technology (NIST)

The NIST describes cloud computing synopsis and recommendations in its publication [21], viewed from a viewpoint of cloud service provider. Based on this report, a usual profit-making cloud service level agreement has to consist of:

a. These agreements which should clearly include an agreement addressed to the consumer regarding constant availability of service, resolution of dispute steps, preservation of data, and legal protection of consumers' private information.
b. Cloud service provider has limitation of service offered due to effects of natural disasters that are beyond the control of cloud providers', outages in service, and updates. Cloud service providers are nonetheless obligated to provide realistic warning to their end users.
c. The anticipations from cloud consumers, which consist of receiving of terms and conditions including a fee for used services.

This NIST's point of view to Service Level Agreement is quite inflexible and baised in support of the Cloud providers. For a case in point, it does not take into contemplation choice for consumers to converse on the amendment to service level agreements with service cloud providers if the default SLA terms do not address all of the consumers' needs. The report also appeals consumers to know that Service Level Agreements may change at the providers' choice with practical reasons ahead of time notification. In order to be ready to transfer workloads to alternate cloud service providers in case of changes that might be undesirable. This though is not an easy activity, because of vendor lock-in and lack of standardization that could enable interoperability between cloud providers is still an on-going issue in cloud computing.

3.2. Service Level Agreement Levels

Some of the important levels related with cloud Service Level Agreements discussed:

a. Facility Level: The cloud service provider delivers on Service Level Agreement that covers the data centre services needed to conserve the client generated data and/or applications. These consist of things including electrical power, onsite generator, and refrigerating device. Service Level Agreements do assure high availability, fault tolerance, and data replication services.
b. Platform Level: There is need for physical servers, virtualization infrastructure, and network associated hardware possessed by the cloud provider and consumed by the cloud clients. Service Level Agreement at this level would contain information regarding physical security for the rejection of illegal accessibility to the building, facility, and computing resource. Checking background and analysing the character of staff should be carried out before employment by cloud service providers. [22] Every end user has control over his or her applications and some resources, while the CSP has complete control over the platform.
c. Operating System Level: A cloud service provider typically would convey certain volume of services managed to their clients. This additional service authorizes

the cloud provider to assure that the Operating System is properly continuous in operation so that it is reliably available. Service Level Agreements would enclose information regarding updates on security, system patches, confidentiality, or encryption, user authorization, and audit trails log files.

d. Application Level: This level provides safety against problems that associated with application level data. At this point, the cloud provider ensures the readiness, stability, and performance of their cloud user software which they are hosting. This is sometimes difficult to assure specifically in Infrastructure-as-a-Service and Platforma-as-a-Service whereby the end-user is only responsible for the application they put on the cloud.

3.3. Cloud Provider Service Level Agreement

The usual Service Level Agreement of cloud service providers include:

a. Service Assurance: This metric states the service level which a provider is obligated to over a contracted time frame.
b. Service Assurance Time Period: This explains the period of a service assurance ought to take place. The duration can be billed per month, or as contracted upon by mutual parties.
c. Service Assurance Granularity: This outlines the measure of resources for cloud providers to specify services assurance. For instance, the granularity can be as per service, per data centre, per instance, or per transaction basis. In relation to time of the assured service it can be fixed if granularity of service assurance is fine–grained. Service guarantee granularity can also be set up as accumulative of the considered resources such as contacts.
d. Service Guarantee: Oversights are occurrences which are not included in the service guarantee metric calculations. The oversight usually will contain mismanagement of the system by a consumer or an interruption connected with the programmed care.
e. Service Recognition: Is the account attributed to the customer or geared in the direction of forthcoming expenses if the service guarantee does not get realised. The total can be an inclusive or regulated acknowledgement of the consumer reimbursement for an overestimated service.
f. The Service Violation Measurement and Reporting: This explains how and who processes and informs of the violation of service assured respectively. The users typically do this but cloud service provider could also perform this role. In certain instances, a regulating service-monitoring third party could be assigned this.

3.4. Service Level Agreement Benefits and Challenges

2) **Service Level Agreement Benefits**

It is important to have comprehensive contract between the client and cloud provider to guarantee trust and confidence on both sides. The following are a number of the benefits of having a cloud Service Level Agreement [11]:

a. SLA supports solid understanding of cloud service and responsibilities of all stakeholders involved.
b. SLA assists the consumer to realise their understanding.
c. SLA emboldens clarity, accountability, and trustworthiness.
d. Make available information on team performance, capabilities, and staffing judgment.
e. SLA sees to the establishment of reassuring and communal functioning.

3) **Service Level Agreement Challenges**

All single agreement has certain challenges that requires both parties to deal with. These challenges include:

a. Service Level Agreements are difficult to achieve in cloud computing for the reason that some infrastructure and circumstances such as network and force majeure are beyond the control of both the cloud service provider and consumer, therefore challenging to draft a Service Level Agreement.
b. In circumstances where multi-tenancy is in use, Service Level Agreements relating to service separation and high obtainability may be challenging to for the cloud service provider for assurance.
c. Regarding cloud Software-as-a-Service model, Service Level Agreements are challenging to achieve due to the fact that it is almost impossible for the cloud service provider to assess all potential user software/application with diverse system configuration ahead of time.
d. It is challenging to come to an agreement on a cloud Service Level Agreement that is covering security. Distributed Denial of Service (DDoS), keystroke timing and side-channel attacks have been identified as some of the greatest common attacks in cloud environment [15] and continue to be a continuous challenge. As a result of the dynamic and always changing nature of these attacks, a cloud service provider can only at best give a general security-based Service Level Agreement and may not be capable of guaranteeing it.
e. In distributed and multi-cloud application deployment, Service Level Agreements are challenging to agree on as the several providers apply various standards. These standards are often proprietary and unable to interoperate therefore single Service Level Agreement for all parties concerned may be difficult to realise.

3.5. Resource Management and Challenges

4) **Resource Management Models**

Cloud provides a working tool towards achieving high efficiency in resource management and low cost service provisioning [2]. Sophisticated monitoring techniques are needed to cope with resources and the enforcement of SLAs by Cloud providers. Presently, most Cloud providers offer multi-tenant software as a service where provisioning of an application instance is made available to many customers. This has presented problems to monitor especially on the problem of how to ensure Service Level Agreements for diverse customers. The implementation of any application may affect the presentation of the others when Cloud providers make use of sharing resource for provisioning customer applications as a result of different economic reasons. Monitoring a Cloud environment can move to large number of nodes in a data center or distributed within geographical locations which is not a minor undertaking considering that the Cloud provider makes sure the monitoring processes does not make weak the performance of the applications being provisioned. In [23] [24] the authors discussed about ant colony algorithm, a job

programmed algorithm of cloud computing. Considering the cloud computing architecture and the that of ant colony algorithm analysis, managing cloud computing resources is intended to have varied rights management for its users, be it admins. It involves inspecting and the application status of host VM, monitor the task application and task performance scheduling, and the submission of computed tasks.

Sharing resources in cloud computing technology is established on virtualization of physical machines in order to attain most importantly security and performance separation. Virtual machines do share resources of physical machines when they are operational. These virtual machines provide individual customer services, and are shared among customers. It is quite challenging to effectively handle shared resources in order to decrease cost and achieve high utilization. According to [25], Autonomic resource management makes sure that Cloud providers serves huge number of demands without breaking terms of the SLA. With dynamism it manages the resources though the use of VM migration and consolidation. The upcoming computing paradigm is projected to be *utility computing;* that is, making computing services available when users require them, that is making computing services to become commodity utilities, just as internet, electric power, fuel, and telephone.

In [16], the authors pointed out that workload resource requirements are impervious, and during various points at production, it is tough finding out the resources critical for utmost performance. It has been difficult for hosted computing services like AWS Lambda for the load handled as black box functionality. It is understood that the performance detected may be due to primary environmental implementation, the allocation policies, issues performance isolation, or non-linear dependency of performance on resources accessibility. Monitoring resources expended while running task might aid in ascertaining resources for the utilization for that run, but will not indicate performance impacts in controlled set ups, or changed hardware or software.

The author Singh in [24], presented resource allocation model that evaluates users' request centered on resource requirements and resources that are available in order to get least run time. Information on resource represent if resources are available and configured. The resource allocation proposed algorithm assigns resource to negotiate the requirements for minimal run time. Client needs varies and heterogeneous therefore it is considerable to allocate using optimal solution. Availability of resource decides the allocation decision and performance, which brings about pool of various resources. Workload linked with the computing power available of the central processing unit is considered as below demand and present consumption of resources. In uncertain cloud environment, manage resources efficiently; allocation issue executed with swarm optimization tactic made better, the likelihood to look for best appropriate resource for task with least run time possible. Swarm practice is built on nature motivated and artificial intelligence system which involves of self-sufficient agent with combined activities with the use of decentralized system[24] [26].

These authors in [27] presented Ant Colony Optimization (ACO) based energy aware solution to address the problem of allocating resource. This proposed Energy Aware Resource Allocation EARA methodology aims to optimize the allocating of resources so as to make energy efficiency better in the cloud infrastructure while meeting up to the QoS requirements of the end users. The allocation of resources to jobs is based on their QoS requirements. EARA uses ACO at two levels which are: the level where ACO allocates virtual machines resources to jobs, and the level where ACO allocates physical machines resources to Virtual Machines. EARA is handled from the cloud service provider's and end users' point of view. This reduces: the overall energy consumption for the benefit of cloud service provider, and the overall execution cost and entire time of execution for the clients' satisfaction. Benefits of ant colony algorithm includes [28]:

a. Making use of decentralized approach to provide good solution to its single point of failure
b. Collecting information faster
c. Reduces load on networks.

Challenges of ant colony algorithm includes [28]:

a. Dispatching a lot of ants which result to network overloads.
b. Some operating parameters are not taken into consideration which might result to poor performance.
c. Points of initiating ants and the number of ants are not established.

In [29], the authors Zhang and Li proposed a user utility oriented queuing model to handle task scheduling in cloud environment. These authors modelled task scheduling as an M/M/1 queuing system, classified the utility into time utility and cost utility, and built a linear programming model to maximize total utility for time utility and cost utility. They also proposed a utility oriented algorithm to make the most of the total utility. They described the randomness of tasks with the $M/M/1$ model of queuing theory. This utility model involves one server, some schedulers, and some computing resources. When users' tasks are submitted, the server analyzes and schedules the tasks to different schedulers, and adds them to local task queue of the corresponding scheduler. This model can reschedule remaining tasks dynamically to get the maximised utility. Finally, every scheduler schedules its local tasks to obtainable computing resources. The main aim of utility computing is to make provision for the computing resources, which includes: computational power, storage capacity and services to its users while charging them for their usage [30]. In [31], the authors stated that utility computing makes provision for services and computing resources to customers, such as storage, applications, and computing power. This utility computing model services is the foundation of the shift to on demand computing, software as a service and cloud computing models. Benefits of utility computing:

a. The end user have no need to buy all the hardware, software and licenses needed in order to conduct business with cloud service provides.
b. Companies have the option to subscribe to a single service and use the same suite of software throughout the whole client organization.
c. It provides compatibility of all the computers in large companies.
d. It offers unlimited storage capacity

Disadvantages of utility computing:

a. Reliability issue. This means the service could be halted from the utility computing organization for any reason such as a financial trouble or equipment problems.
b. There are many servers across various administrative domains

Some utility computing driving factors [30]:

a. Virtualization enables the abstraction of computing resources so that a physical machine can function as a set of multiple logical virtual machines.
b. Resource pricing in other to develop a pricing standard that can gainfully support economy based utility computing paradigm.
c. Standardization and commoditization are important use of utility services. Standardized information technology services facilitate transparent use of services and make services ideal candidate for utility computing. The commoditization of hardware and software applications such as office suites is increasing with the acceptance of the open standards.
d. Resource allocation and scheduling handle user requests to satisfy user quality of service and maximize profit. A scheduler determines the resources based on what is required of a job which is a user request, performs the resource allocation, and then maps the resources to that job.
e. Service Level Agreement defines service constraints required by the end users. Cloud service providers know how users value their service requests, hence it provides feedback mechanisms to encourage and discourage a service request.

In [32], the author Kim proposed a resource management model that CloudStack supports. CloudStack is an effective resource model that enables scalability, multi-tenant, and it is a cloud computing software that manages the creation and deployment of cloud infrastructure. The system manager is unable to monitor VMs computing resources, but increases visibility into resource allocation and can look up the status of Virtual Machines such as if it is on or off at the console of cloud management. Comprehensive information regarding the status of the Virtual Machine chosen by the system manager can be monitored; examples are the central processing unit use rate, disk, and network activities. The main aim of this management model for resource is to evaluate unprocessed data, then report the statistical information about the Virtual Machine usage volume for the computing resources contained by the resources constraint. What this resource management model specifically does is that:

a. It enables system manager to look into the statistical analysis and the status from the log analysis framework from communication among VMs.
b. It aids system manager in generation of rules for the present constraint of obtainable computing resources gotten from the log analysis framework. An instance is when users make request and create Virtual Machines using a quad core central processing unit, the system manager has the choice of scaling down from a quad core to a dual core for the sum of central processing units constructed on the statistical report from the log analysis framework.
c. Based on firewall policy, it provides the chance to enable the system manager to script enabling the cloud management console to automatically, measure the virtual machines upward or downward.
d. Enables the system manager to produce policies during emergencies for service stability of the virtual machines.

5) **Resource Management Challenges**

Traditional resource management methods are not enough for cloud computing because they are on virtualization technology with distributed nature [33]. Considering the growth in Cloud computing, it has challenges for managing resource because of heterogeneity in hardware capabilities, per request service model, pay-as-you-use model and assurance to satisfy quality of service. Managing resources dynamically will reduce the resource controversy, scarcity of resources, fragmentation of resource, and overflow / underflow problems. To circumvent these difficulties resources should be adjusted with dynamism to manage resources efficiently in the cloud architecture [34].

There are challenges in the capacity to monitor resource and to manage SLAs in cloud computing, they include [2]:

a. Distributed Application Execution – NetLogger is a distributed system that monitors in order to observe and collect information of computer networks. In [2], the authors discussed ChaosMon, an application that monitors and displays performance information for parallel and distributed systems. This monitoring system is aimed to support application developers to enable them specify performance metrics and to also observe them visually in order to identify, evaluate, and comprehend performance logjams. This system is a distributed monitoring that has a centralized control.
b. Enforcement of the Agreed SLA – Enforcing SLAs is challenging and it involves complex processes whereby both parties might have to keep going back and forth until a mutual agreement is achieved. Implementation of different technologies poses challenges to evaluate Service Level Agreement documents, multifaceted deployment procedures, and scalability concerns. Ensuring uninterrupted monitoring and dynamic resource provision can be employed to put into effect agreed SLA.
c. Energy Management - Managing the consumption of energy is becoming challenging. Statistics and report show unchecked energy consumption might be a key problem in few years' time. According to [14], Stanford University made known that there is an annual increase of 56% in the consumption of electricity in data centers between 2005 and 2010.
d. Multi-Tenancy Application – This provision is becoming standard amongst Cloud providers to cost efficiently provide their sole instant application to numerous consumers. The technology approach is still challenging in its realization. In [2], the authors discussed proposed SLAs that is multi-tenant oriented in monitoring performance, in detection, and to schedule architecture with their clients. The writers aimed towards separating and guaranteeing optimized performance of each client in the Cloud space. This is complex and challenging to manage such resource because the cloud provider is making provision for every tenant with the same

application instance whereby the Service Level Agreements for the applications are contacted on per tenant basis. In situations like this, the workload of some tenants' applications will affect the unusual resource consumptions by other tenants considering the Cloud hardware, and all tenants share software resources. To solve this issue, a dynamic SLA mechanism architecture is designed, which monitors application grades, discerns what is not normal, and dynamically schedules shared resources to make sure of tenants' SLAs and optimize system performance.

e. High Availability - This is the server's availability for use for its intended purpose. High availability main objective is to ensure a system continues to function regardless of the failure of any components. This can be achieved through redundancy and elimination of single point of failure [14].

f. The Scalability of the Monitoring Mechanism - Key factors of cloud computing includes scalability of resource and application provisioning on-demand in a pay-as-you-go method. Cloud environments measure thousands of computing devices in large-scale environments; hence, the need for scalable monitoring tools. In [35], the authors proposed some methods to handle the challenges in setting up virtualized datacenter management systems that are scalable. The plan is to strategise a high performance and strong management tool that will be able to scale from some hosts to a large-scale Cloud datacenter. These authors indicated how they came about a scalability management tool by noting these challenges:
    a. Performance / Fairness;
    b. Security;
    c. Robustness;
    d. Availability; and
    e. Backward compatibility.

3.6. Trending Practices in Cloud Resource Management

Daily growing attributes and advancements in cloud computing are promising the future and luring organizations and stakeholders towards the use of cloud computing. This fast growth of cloud computing is in need of stricter security and large quantity of resources like memory, process and storage to meet the Service Level Agreement standards. The trending practices include:

a. Live Migration – The use of live migration of virtual machines is an indispensable attribute of virtualization, enabling a seamlessly and transparent migrating of virtual machines from a source host to another destination host, even though the VM is still running without interrupting VMs [36]. Cloud live migration is on the increase in cloud computing with the aim to gain the cloud benefits from non-cloud situated applications. Live migration is a recent concept within cloud computing that is utilized during practical fault tolerance for instance by faultlessly moving Virtual Machines away from faulty hardware to stable hardware without the consumer noting any adjustment in a virtualized space. This is so because in the use of live migration, the end user is unaware there is only a delay of 60 mini seconds to 300 mini seconds [15]. Virtual Machine live migration can be performed via static migration or Dynamic migration. In order to fulfill Service Level Agreement, static Virtual Machine migration is used as required resources gets carefully chosen as per requirement in SLA, but in dynamic Virtual Machine provisioning, the resources change dynamically to handle unforeseen workload changes [37]. Major benefit for live VM migration includes [36]:
    a. Load balancing, the moving of over-loaded servers to light-loaded servers in order to release congested hosts.
    c. Proactive fault tolerance and online maintenance

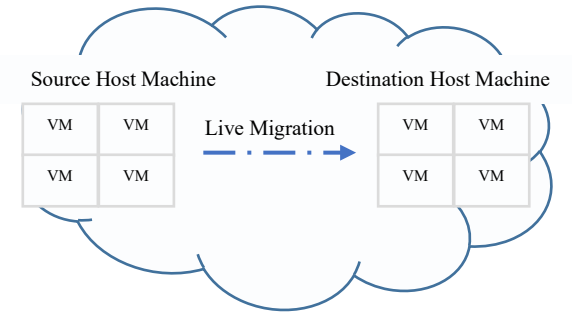

Figure 1: Live Migration [27]

b. Power Saving in Green Computing - the authors in [38] discussed a proposed resource-utilization- aware energy saving server consolidation algorithm for the provision of improved utilization of resources as it reduces the total number of virtual machines during live migrations. Experimental results demonstrated its ability to reduce the consumption of energy and violations in Service Level Agreement in cloud data center. In [39], the authors describes green data center as a depository of a competent management of the system with a reduced amount of power consumed environment. The power consumption by an average data center can be so enormous that it can serve as a power source for approximately 25,000 private homes. In [40], Jena presented an optimization algorithm that arrange job with the aim of achieving an optimized energy usage and overall computation time using Clonal Selection Algorithm (CSA). Dynamic Voltage Frequency Scaling (DVFS) technique designed to reduce the usage of cloud resources by managing the power voltage as well as the regularity of the processor without ruining the performance. In [41], the authors presented an optimization framework of two modules that run concurrently: the Datacenter Energy Controller that reduces the use of datacenter energy without degrading the Quality-of-Service (QoS) and; the Green Energy Controller that brings about renewable sources. This Green Energy Controller computes the anticipated energy budget for the datacenter by the use of the lithium-ion battery as an added energy reserve or the grid of both banks in which the Hybrid Electric Systems can drain. For cloud providers to make their services become green computing, they have to spend in renewable energy sources to generate power from renewable sources of energy, like wind, solar, or hydroelectricity [42]. Merging

resources can advance utilization and make provision for increase in space, power and cooling capacity within the same facility environment. Energy preserving approaches includes [43]:

a. Nano Data Center is a distributed computing platform that makes provision for computing and storage services and adopts a managed peer-to-peer model to form a distributed data center infrastructure.
b. Reduction of Central Processing Unit Power Dissipation adapts free cooling so that power dissipation reduces.
c. Server Consolidation is the migration of server roles from various underutilized physical servers to VMs for the reduction of hardware and energy consumption.
d. Energy Saving Strategy of System Software is a dynamic energy usage, so the operating system can dynamically manipulate the system unit for obtaining the minimal power consumption without degrading already assigned the task or any job in performance.
e. Live Migration of Virtual Machine is about the movement of a running Virtual Machine from one host to another.

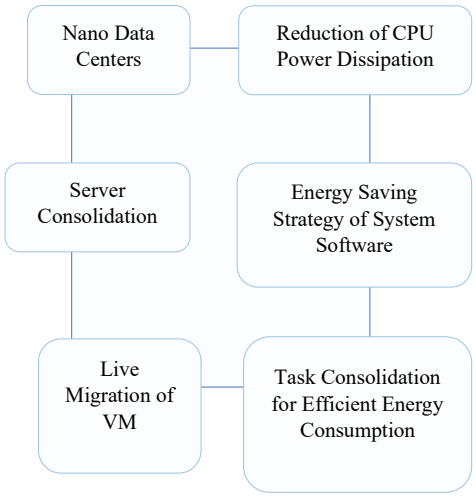

Figure 2: Energy Preserving Approaches [34]

3.7. Resource Grid Architecture Management

In [34], the authors proposed a Resource Grid Architecture for Multi Cloud Environment (RGA) for allocation and management of the resources with dynamism in virtual manner. Resource Management in Single Cloud Architecture is an ongoing area in research and RGA for Multi Cloud Environment is a current practice that has high scalability to manage resource at single cloud environments. This architecture presents a resource layer with logical resource grid and the usages of the VMs to project the resources in contrast to physical systems of a cloud. Experimentations have showed that their Resource Grid Architecture can efficiently manage the resources against numerous clouds and support the green computing. Logically, RGA is grouped into four layers to manage resource efficiently:

a. Cloud Layer - This layer investigates the assigned resources to cloud application in order to keep log of record for resource usage and directs the information to cloud Resource Prediction Unit for hot spot detection and cold spot detection. Local Resource Manager is a component that verifies the resource allocation and utilization only at cloud level and is a proxy of Global Resource Manager.
b. Network Layer - This layer supports high-speed commutation among cloud and is the backbone for the experimented architecture for the reason that intra cloud communication is very much in demand in the implementation for resource sharing and process sharing.
c. Virtual Machine Layer - This layer is a separate group of virtual machine for sole cloud architecture to accomplish the operational feasibility. Each group of virtual machine is a set of virtual machines for physical system representation and are constantly accessible to resource grid layer monitoring and resource mapping.
d. Resource Grid Layer – This layer is an assembly of management modules of this architecture such as Global Resource Manager; these modules are interwoven for the monitoring, analyzing, allocating and tracking of resource information of multiple clouds at a centralized virtual location.

4. Conclusion

Cloud computing makes provision for scalable, on demand, elastic, multi-tenant and virtualization of services to customers on the Internet through cloud service providers. The types of service are the SaaS which provides applications with customizable interfaces, PaaS provides platform for application development and testing, and IaaS which makes provision of storages and computing infrastructure to users and extends to physical machines, virtual machines. These services provided are based on the service level agreements between the cloud service providers and the client. The service level agreement stipulates the terms of the services makes provision for mutually beneficial transaction between the parties. This paper presented a survey of recent developmental trends and issues in resource management in cloud computing. Cloud computing is aimed at providing the best resource to its users. Many researchers are focused on request allocation and resource management for Cloud Computing. All-encompassing use of learning empowers systems to be dynamic in handling workloads and execution environments. This paper documented techniques for creating scheduling and resource allocation choices for cloud computing and the datacenters. This paper concluded with a review of resource management on Cloud computing and cloud SLAs.

ABSTRACT

In this work of technological development and research is presented the work done in the ITSAO to contribute to the use of clean energy such as photovoltaics and the implementation of activities to reduce electricity consumption by the technological community, the monitoring of electricity consumption is made on a monthly basis and an annual report is prepared in which the consumption monitoring and the reduction percentage thereof are shown by tables and graphs. The students of electronic Engineering carry out activities of optoelectronics and sustainable development where they intervene with the design and installation of photovoltaic systems that are part of their academic formation. It has a photovoltaic system that produces 2.16 kW-h / d and another will be installed to have photovoltaic energy in the tables of the ITSAO planters; these actions are part of the operational control related to the energy of the Integral Management System (SGI).

1. Introduction.

This paper is an extension of work originally presented in 2018 XXXI International Summer Meeting on Power and Industrial Applications (RVP-AI) [1] off the IEEE Sección México; in the Instituto Tecnológico Superior de Acatlán de Osorio, Puebla, México; work continues with the development of projects related to the saving of electrical energy with renewable energy applications and the replacement of fluorescent tube lamps by LED's lamps; this is how the Academy of Electronic Engineering has intervened in the installation and replacement of LED's tube lamps.

In [2] it presents a work aimed at reducing the consumption of electrical energy delivered by the conventional electricity network, through the use of photovoltaic solar energy. It is proposed the design of an electronic transfer system that facilitates the use of DC electric power from the solar panel, thus eliminating the use of the voltage inverter, commonly used in this type of applications and which increases the cost of the use of solar energy.

Alternative energies have always been present in the daily life of humanity, although their existence has often been unknown because of the need to put the economic over the environmental benefit. In addition to being free, they are clean and protective of the environment [2]. It is necessary to implement an adequate ecological culture in the present generations so that it contributes to the care of the global environment and in this way the new generations are already developed in an environmental system from which it will no longer be necessary to learn to adapt to the environment.

Currently as an example of the application of energy efficiency is in a house at least there is a device that requires the use of electrical energy for its operation, so in some cases there is a high demand and even waste of energy, when there is a considerable amount of these consumer elements, it affects the areas of the rural sector and certain cases of a greater proportion of electricity consumption, because although they have subsidized rates, they suffer increases in costs, thus paying the demand for generated consumption by other sectors, without worrying about the high value in the payment of the energy service. [2].

The study of renewable energies is currently presented as a very useful tool, due to the scarcity of conventional energy sources that have been exploited for several years, without thinking that this would lead humanity to a point where those resources would be exhausted [2]. This allows the development of research for the generation of electricity from clean energy sources in small, medium and large-scale production.

* Jeremias Bravo Tapia., Email: jrmsbt@hotmail.com

Energy efficiency is a primary consideration when designing off-grid renewable energy systems including portable micro-grids. This study focuses on characterizing the potential benefits associated with using energy-efficient exterior area lighting commonly associated with remote installations. Light-Emitting Diode (LED) luminaires are becoming more commercially available, and this study compares two LED products designed for exterior lighting to traditional metal halide lamps. The energy efficiency benefit of the LED luminaires is offset by their lower illuminance. However, a comparison of lighting standards for specific purposes such as security lighting indicates that LEDs may be appropriate for applications where a metal halide system would provide significantly more illumination than required at a much higher energy cost [3].

Measures to improve energy efficiency in small and medium enterprises do not apply due to financial reasons, lack of information and limited internal skills. Suggested information measures, audits, capacity building. As potentially effective measures to support the implementation of energy efficiency measures. Companies in Austria, Bulgaria, Cyprus, Italy, Romania, Slovakia and Spain have identified and implemented a wide range of energy efficiency measures, which in part consist of no-cost options, but are also partly innovative technical solutions [4]. This must be implemented throughout the world starting from our home to be able to impact the environment around us.

Energy efficiency has a vital part to play in all future energy scenarios. Improved energy efficiency limits energy demand growth to one-third by 2040 even though the global economy grows by 150%. Energy policy has traditionally been almost entirely concerned with energy supply and most often focused on the electricity system. The close link between electrification and modernization has given the electricity supply industry in all countries a strong political voice. Energy efficiency, energy conservation or “energy savings” has tended only to be given a high priority in times of crisis, when energy prices are particularly high or when economies face electricity shortages. This was most notable during the “oil crises” of the 1970s. Until recently, energy efficiency policy has always had a lower priority in energy policy development compared to energy supply [5].

All the energy used is ultimately to meet human needs. Natural gas is not burned to heat the room in which one lives by simply heating, but it is done to feel comfortable in that room. Energy is used to produce the materials that are needed to make consumer goods, for example, steel is produced to make cars, paper for printing books and fertilizers to grow more food so as not to be hungry. Energy is not a necessity in itself, it is one of the goods used to meet human needs that can be realized through the use of energy called energy services. [6].

Energy consumption in homes and buildings is large and, in the future, it tends to be unsustainable for our planet, both due to the depletion of natural resources and the irreversible damage it causes to the ecosystem. To help the sustainable development of Humanity it is essential to create an energy education that allows, without waste, continue using fossil fuels for the development of new energy technologies more efficient and in harmony with the environment. The option of renewable energies offers an alternative to achieve a social development that tends to the ecological and that in the future an economic benefit is obtained as well. The energy obtained from photovoltaic panels, specifically the Sun Irradiance, is proposed as an aid to minimize energy consumption in both houses and buildings. Currently, photovoltaic energy is still not profitable, but it seems to be the most viable option until now to solve the great problem of generating electricity without using fossil fuels [7].

The photovoltaic parks have taken great importance as renewable energy generation systems in individual buildings integrating from the design of the building involving the architecture and installers of photovoltaic systems; thus, the photovoltaic industry is a technology that is already included in the architectural design process [8], [9] & [10].

In ITSAO, a photovoltaic system will also be implemented in the gardens of the esplanade so that the technological community has the possibility of connecting their electronic equipment such as laptops and mobile devices outdoors on the rest tables.

2. Determination of solar radiation.

For the development of the photovoltaic part there is location data of the ITSAO in Google Maps [11]. Data provided by NASA corresponding to the solar radiation received by the solar panels, the hours of solar radiation were used to calculate the design of the battery bank and the temperature to see the performance of the solar panels [12].

The coordinates of the location of the ITSAO at a latitude of 18.226883 and a longitude of -98.040143 are shown in Figure 1 a). Figure 1 b) shows the location coordinates on the NASA platform in Prediction of Worldwide Energy Resource Prepare.

Next, Figure 2 shows the data that must be identified for the calculation and design of the photovoltaic system as the minimum radiation for solar panels inclined towards Ecuador, the days without sun in a month to determine the size of the battery bank and the maximum and minimum temperature at two meters high.

Figure 3 a) shows the behavior of the monthly days without solar radiation to add the days of autonomy in the design of the size of the battery bank, in Figure 3 b) the maximum temperature is shown and in Figure 3 c) the minimum temperature is shown at two meters high. this to determine the efficiency behavior of solar panels that depend on the temperature.

One of the very important parameters for the sizing of photovoltaic systems is the solar radiation that is received in the place of the installation of the solar panels, for this data is taken provided by NASA that as mentioned above are reliable data to work sizing, performance, days of autonomy and storage capacity.

Figure 4 shows parameters the solar radiation values in the ITSAO; days without sun, maximum temperature, minimum temperature; in blue are the radiation data for different inclinations are monthly data and an annual average.

Figure 5 shows the optimal peak solar radiation hours (HSP) to calculate the size of the sizing of the photovoltaic system on a monthly and annual basis; The annual average is 5.87 HSP with this the daily production that a solar panel will have is calculated according to its power provided by the manufacturer.

[12].

It is possible to determine that there is an annual average of 5.87 hours of minimum solar radiation equivalent to 5.87 kWh/m^2/day. For the photovoltaic calculations applying the rounding, 6 hours of solar radiation are considered.

3. A photovoltaic system installed with LED lamps.

It has a photovoltaic system installed with three 120 W solar panels giving 360 W-h between the three with a daily output of 2.16 kWh/d taking into account 6 hrs of solar radiation for this region. Figure 6 shows the module installed with the three solar panels.

Figure 6: Photovoltaic module installed in the ITSAO.

Figure 7: Battery bank.

Figure 8: Charge controller, batteries and inverter.

The LED lamp has a consumption of 30 W with a reflector installed at an approximate height of 10 m; By having 2.16 kWh/d of production, up to 7 lamps can be connected to work all night, considering a continuous operation of 10 hrs per day with the consumption of 300 W per night of each lamp. Figure 9 shows the installed lamp.

Figure 9: 30 W lamp with reflector installed.

The operational control of energy has the purpose of establishing guidelines and activities for the control of electrical energy in the ITSAO facilities applicable to all activities, processes, products and services that consume electricity.

To reduce electricity consumption to date, we have worked with the acquisition of LED lamp tubes to replace the fluorescent tubes that consume the most electrical energy; in all areas of the ITSAO the lamps have been replaced with the participation of the technological community. Figure 10 shows the LED lamps corresponding to the interior lighting of the ITSAO buildings.

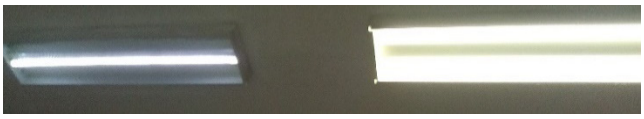

Figure 10: Lamps of LED tubes in operation.

Monthly monitoring of electricity consumption is made by comparing quantitatively the monthly consumption of the current year with the previous one so that the energy savings obtained through an annual report to the representative of the general management can be identified and analyzed annually.

Table 1 shows the monitoring of electricity consumption, in this case, corresponds to the annual report of consumption monitoring in 2016, Table 2 shows the monitoring of electricity consumption for 2017, Table 3 shows the monitoring of electricity consumption for the year 2018 and Table 4 shows the monitoring of electricity consumption for the year 2019.

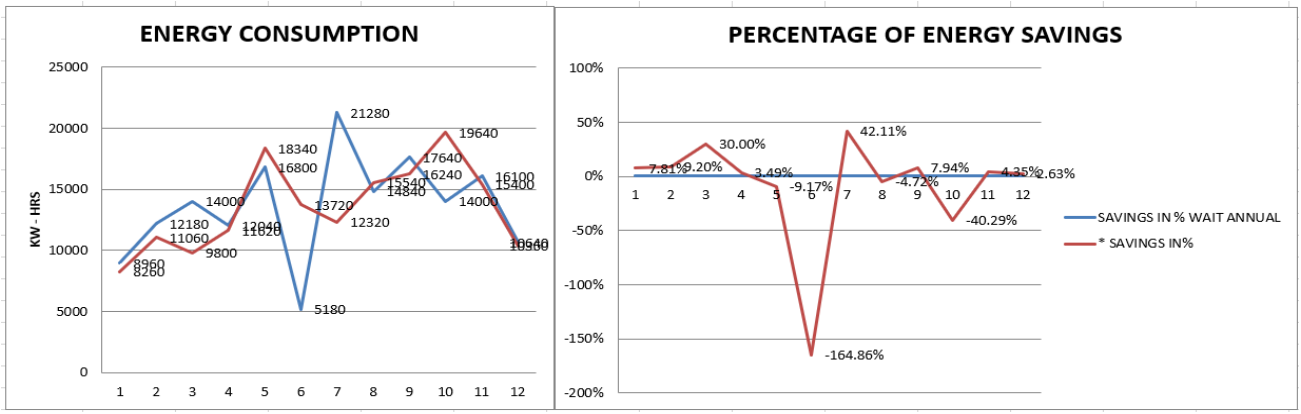

Figure 12: Graph of consumption in 2016 compared to 2015 and Graph of the reduction percentual for electricity consumption in 2016 compared to 2015.

One of the activities to be implemented is a photovoltaic system with the purpose of supplying electricity to the tables located in the planters of the esplanade; the conversion of solar energy to electricity will be applied so that the technology community can use it to power their electronic devices such as laptops and mobile devices while they rest or gather in the flower beds. Figure 11 shows an infographic that describes the operation and location of the photovoltaic elements and electrical power outlets

5. Results of the electric follow-up corresponding to the reports of 2016, 2017, 2018 and the current follow-up in 2019.

Figure 12 shows the comparison charts of electricity consumption and shows the relative comparison of electricity consumption reduction for 2016 compared to 2015.

Figure 13 shows the comparison charts of electricity consumption and shows the relative comparison of electricity consumption reduction for 2017 compared to 2016. In this case, electricity consumption increased due to the installation of air conditioning equipment in salons that did not have this electrical equipment.

Figure 14 shows the comparison charts of electricity consumption and shows the relative comparison of electricity consumption reduction for 2018 compared to 2017. In this case, electricity consumption increased due to the use of air conditioning equipment in salons that did not have this electrical equipment.

Figure 15 shows the comparison charts of electricity consumption and shows the relative comparison of electricity consumption reduction for 2019 compared to 2018. In this case, to date only monitoring is carried out until July the follow-up is in process.

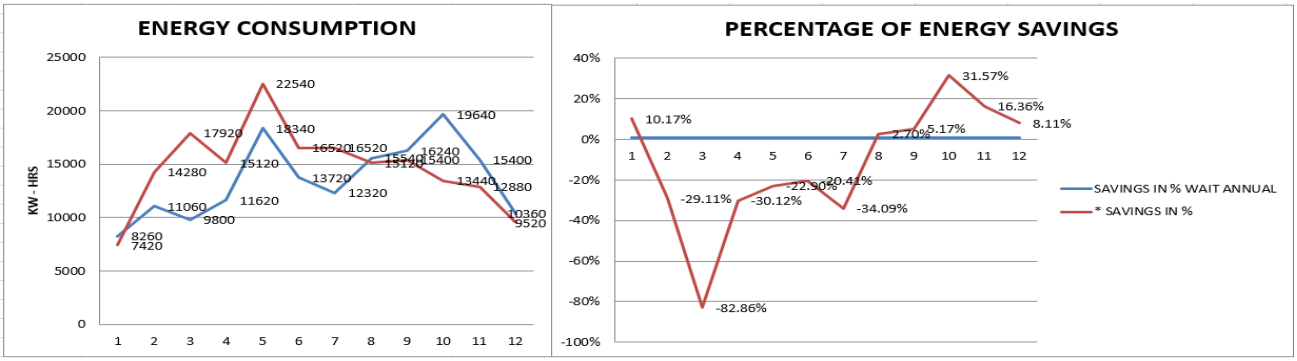

Figure 13: Graph of consumption in 2017 compared to 2016 and Graph of the reduction percentual for electricity consumption in 2017 compared to 2016.

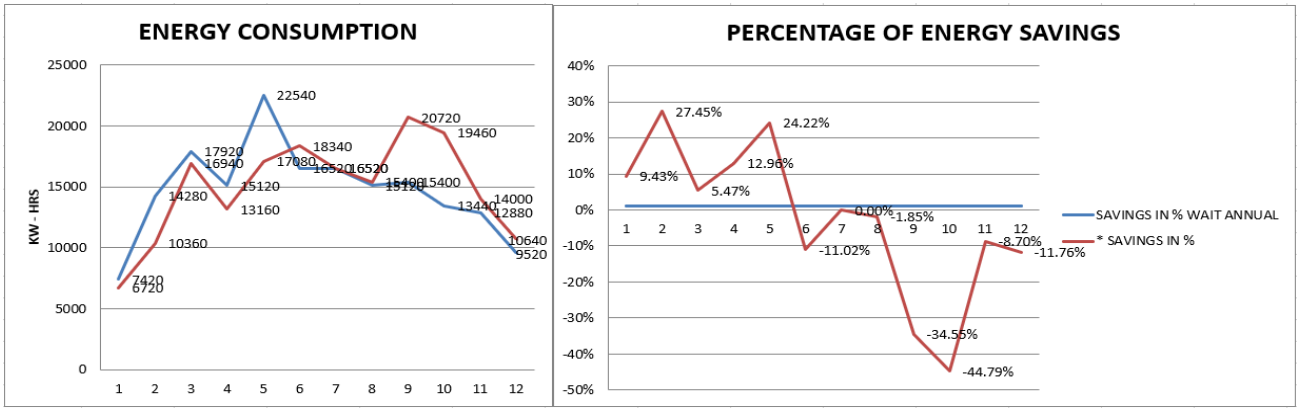

Figure 14: Graph of consumption in 2018 compared to 2017 and Graph of the reduction percentual for electricity consumption in 2018 compared to 2017.

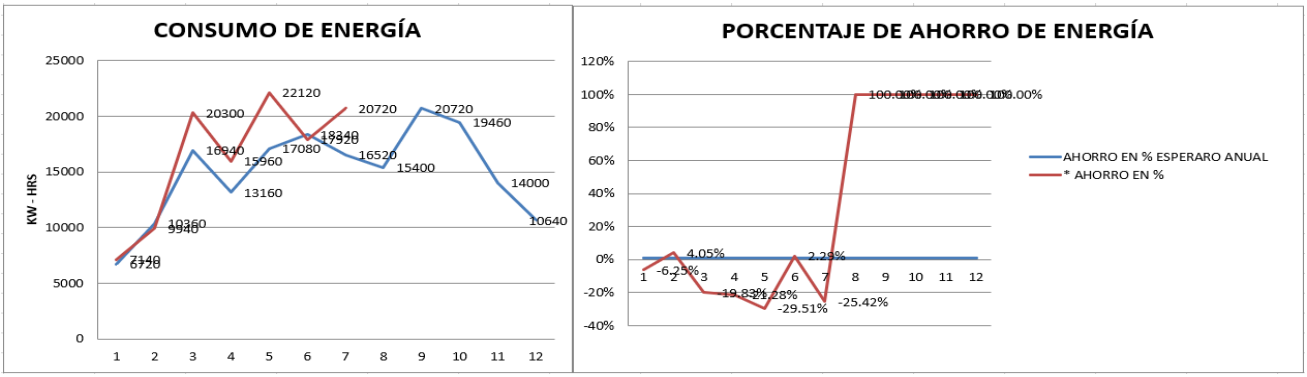

Figure 15: Graph of consumption in 2019 compared to 2018 and Graph of the reduction percentual for electricity consumption in 2019 compared to 2018.

The activities implemented are not only part of the Integrated Management System of the ITSAO, but they are also part of the academic and professional training of the students and the intervention of the Electronic Engineering Academy. They are also part of the research area corresponding to the research line "Renewable Energy and Energy Efficiency".

6. Conclusions.

With the execution of the activities carried out, the emphasis is mainly on the use of clean energies such as solar as an alternative means to obtain electricity for the external lighting of the ITSAO facilities, with the implementation of LED lamps it is possible to reduce the electricity consumption with sustainable approach; the entire technological community will be given the opportunity to use photovoltaic energy for their outdoor electronic devices. The students manage to carry out sustainable development practices, research foundations, research workshops and optoelectronics to strengthen their academic training. The activities implemented to reflect a good result by observing the graphs in the reduction of electricity consumption.

Conflict of Interest.

The authors declare no conflict of interest.

Acknowledgement.

The research was carried out with the support of the Electronic Engineering area and the ITSAO technological community within the framework of the implementation of the Environmental Management System and the research area.

ABSTRACT

The point of this study is to explore and elucidating the performance of the four-point Half-Sweep EGSOR (4HSEGSOR) iterative method to solve fractional two-point boundary value problems by using Caputo's fractional operator and family of finite differences (FD) schemes. To apply the iterative methods, linear system needs to be constructed via the discretization process with fractional order to get the approximation equation of the linear fractional two point boundary value problem by using the Caputo's derivative operator. Then the generated linear system has been solved using the proposed 4HSEGSOR iterative method. In the addition, the formulation and application of the 4HSEGSOR method to solve the problems are also presented. Three numerical examples and comparison are used to illustrate with tested FSSOR and HSSOR methods. The numerical results reveals the effectiveness of 4HSEGSOR method compared with tested iterative methods.

1. Introduction

This paper inspired from numerous researchers in science and engineering where there have been discuss the steady-state problems which refer to Fractional Boundary Value problems (FBVPs) since this problem become more attractive in the recent years in many applications such as mathematics, engineering, economy, and other fields [1,2]. Since the rapid growth of computer technology, the numerical techniques are used to solve the large size problem. Following that, there are many researcher have been proposed numerical methods to solve the FBVPs such as Fix et al [3] applied the Least Squares Finite-element methods, Li et al [4] applied the Reproducing Kernel method, Odibat et al [5] applied the Modified Homotopy Perturbation method, and Diethelm et al [6] applied the Extrapolation method. For instance, Sunarto et al [7] started the study on the finite different method to solve the unsteady-state problems using application of the SOR method. In addition, Sunarto et al [8] extended the study with the application of the full-sweep AOR iteration concept to the same problem. Furthermore, this study extend the study to steady-state problems and focus to two-point Fractional BVPs. The problem will be solved numerically and represented as follows [9]:

$$d(x)\frac{\partial^{\beta}v(x)}{\partial x^{\beta}}+a(x)\frac{\partial^{2}v(x)}{\partial x^{2}}+b(x)\frac{\partial v(x)}{\partial x}+c(x)v(x)=F(x),\ x\in[\gamma,\mu] \qquad (1)$$

with the Dirichlet boundary conditions,

$$u(\gamma)=\gamma_0, \qquad u(\mu)=\mu_1.$$

where $a(x)$, $b(x)$, $c(x)$ and $d(x)$ are known functions or constants respectively. Then the derivative term of fractional order is $\frac{\partial^{\beta}v(x)}{\partial x^{\beta}}$ and the parameter β represent fractional order with the range in this study consider as $1\le\beta\le 2$. To get the approximate solution of two-point FBVPs must be discretized to form an approximation equations. Based on the family of FD schemes and Caputo's fractional derivative operator, the approximation equations use to construct a linear system at each point.

For solving the linear systems which have large and sparse, there are several concept iterative methods from previous researchers have been discussed [10,11]. Other than that, Rahman et al. [12] studied the numerical solution of two-point FBVPs based on the iterative method where SOR method has been used

*Corresponding Author: Rostang Rahman, Mathematics with Economics Programme, Faculty of Science and Natural Resources, Universiti Malaysia Sabah, 88400 Kota Kinabalu, Sabah, Malaysia, Contact No:+60 14 654 1569, rostang054@gmail.com

and AGE method in studied Rahman et al. [13]. From the studied, this paper focus to expand the iterative method to the half-sweep scheme. The idea come from Abdullah (1991) who initiated of Half-sweep iteration which is ones of the common utilized use iterative techniques to solve any linear systems. Following that, in this paper proposed 4HSEGSOR iterative method as linear solver to increase the iteration convergence rate so as to solve the two-point FBVPs on the Caputo's FD approximation equation. To demonstrate the capability of the 4HSEGSOR method, the implementation of the Half-Sweep SOR (HSSOR) iterative method also considered as comparison method in this study and Full-Sweep SOR (FSSOR) iterative methods react as a control method.

After that, the approximation equation will be construct for the problem (1) based on the HS second-order Caputo's fractional operator via fractional derivative theory. Therefore, let discuss some definitions that can be applied to construct the approximation equation towards problem (1) by using the Caputo's fractional derivative operator.

Definition 1 [14]. The definition of fractional integral operator for Riemann-Liouville, ${}^{*}J^{\beta}$ of order $-\beta$ given by:

$$ {}^{*}J^{\beta}F(x)=\frac{1}{\Gamma(\beta)}\int_{0}^{x}(x-t)^{\beta-1}F(t)dt,\quad \beta>0,\quad x>0 \tag{2}$$

Definition 2 [14]. The definition of Caputo's fractional derivative operator, D^{β} of order $-\beta$ given by:

$$ D^{\beta}F(x)=\frac{1}{\Gamma(m-\beta)}\int_{0}^{x}\frac{F^{(m)}(t)}{(x-t)^{b-m+1}}dt,\quad \beta>0 \tag{3}$$

Where parameter β refer to $m-1<\beta\le m,\ m\in N,$ and $x>0.$

Definition 3 [15]. The function of Gamma denoted by $\Gamma(\beta)$ is a generalization of factorial function for complex argument with positive real part it is defined as:

$$ \Gamma(\beta)=\int_{0}^{\infty}x^{t-1}e^{-x}dx \tag{4}$$

To solve the problem (1) as mentioned in early section, we get numerical approximations by using fd scheme via the Caputo's derivative definition with Dirichlet boundary conditions and fractional derivative operator. In addition to that, the existence and uniqueness of the solution for the problem (1) can be referred and discussed by Diethelm in 2002 in the study Analysis of Fractional Differential Equations [16].

Theorem 4 (existence) [16]. Assume that $D:=\left[0,x^{*}\right]\times\left[x_0^{(0)}-\eta,\ x_0^{(0)}+\gamma\right]$ with some $x^{*}>0$ and let the function $F:D\to\mathbb{R}$ be continuous. Furthermore, define $x:=\min\left\{x^{*},\left(h\Gamma(\beta+1)/\|f\|_{\infty}\right)^{1/\beta}\right\}.$ Then there exists a function $v:[0,x]\to\mathbb{R}$ solving the initial value problem (1).

Theorem 5 (uniqueness) [16]. Assume that $D:=\left[0,x^{*}\right]\times\left[x_0^{(0)}-h,\ x_0^{(0)}+h\right]$ with the $x^{*}>0$. Besides that, let the function $F:D\to\mathbb{R}$ be bounded on D and fulfill a Lipschitz condition the second variable.

Before solving the problem (1), the solution domain of the problem has been confined to the finite domain $a\gamma\le x\le\mu$, with $1\le\beta\le 2$ whereas the parameter β refers to the fractional order derivative. In order to solve the problem (1), let consider the Caputo's fractional derivative of order β as:

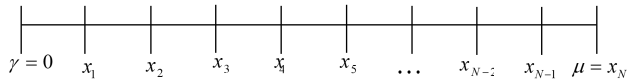
$$ \frac{d^{\beta}v(x_i)}{dx^{\beta}}=\frac{1}{\Gamma(2-\beta)}\int_{0}^{x_n}\frac{dv^{2}(s)}{dx^{2}}\left(x_n-s\right)^{1-\beta}ds \tag{5}$$

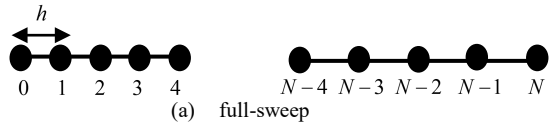
2. Half-sweep Approximation Equation

Before discretizing problem (1), let the solution domain of the problem be partitioned consistently to facilitate in discretizing process. In order to discretize, we consider some positive integers N which is the number of subintervals $[\gamma,\mu]$ and then the length of grid size are defined as.

$$ h=\Delta x=\frac{\gamma-\eta}{N} \tag{6}$$

and





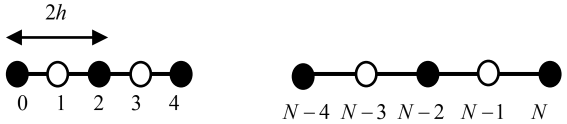


Figure 1: The distribution of interior node points over the finite grid network.

From the Figure 1, we develop the consistently grid network of the solution domain where the polar grid of the solution domain will be shown as $x_i=\gamma+ih,\ i=0,1,2,\ldots,N$ and the values of function $v(x)$ at point x_i are given as $v(x_i)=v_i$. As mentioned in Section 1, the half-sweep concept is imposed to improve the convergence rate. Here the different values of h from the current point to next point between full-sweep and half-sweep is shown in Figures 2 which is Figure 2(a) shows the implementation of the full-sweep iteration which all interior nodes are considered one by one point in which its distance for each point is h. However, for half-sweep iteration with its distance $2h$ can be seen in Figure 2(b).

(a) full-sweep

(b) half-sweep

Figure 2: The distribution of uniform grid network

After that, to obtain the approximation equation of problem (1), now the equation (5) will be consider to derive based on the

formulation of Caputo's fractional derivative operator which can be gotten by a straightforward quadrature formula as follows.

$$\begin{aligned}\frac{d^{\beta}v(x_i)}{dx^{\beta}} &= \frac{1}{\Gamma(2-\beta)}\int_0^{x_n}\frac{dv^2(s)}{dx^2}\left(x_n-s\right)^{1-\beta}ds \\ &= \frac{1}{\Gamma(2-\beta)}\sum_{j=0}^{i-1}\int_{jh}^{(j+1)h}\left(\frac{v_{i-j+1}-2v_{i-j}+v_{i-j-1}}{h^2}\right)\left(x_nh-s\right)^{1-\beta}\partial s \\ &= \frac{1}{\Gamma(2-\alpha)}\sum_{j=0}^{i-1}\left(\frac{v_{i-j+1}-2v_{i-j}+v_{i-j-1}}{h^2}\right)x\int_{jh}^{(j+1)h}\left(x_nh-s\right)^{1-\beta}ds \\ &= \frac{h^{-\beta}}{\Gamma(3-\beta)}\sum_{j=0}^{i-1}\left(v_{i-j+1}-2v_{i-j}+v_{i-j-1}\right)\left((j+1)^{2-\beta}-j^{2-\beta}\right)\end{aligned} \tag{6}$$

Then the discrete approximation of equation (6) can be given as

$$\frac{d^{\beta}v(x_i)}{dx^{\beta}} = \sigma_{\beta,h}\sum_{j=0}^{i-1}g_j^{\beta}\left(v_{i-j+1}-2v_{i-j}+v_{i-j-1}\right)+O(h) \tag{7a}$$

Where can be define by

$$\sigma_{\beta,h} = \frac{h^{-\beta}}{\Gamma(3-\beta)} \tag{7b}$$

and

$$g_j^{\beta} = \left(i+1\right)^{1-\beta}-i^{1-\beta}. \tag{7c}$$

However, this study don't use the operator (7) which is shown as the full-sweep Caputo's fractional derivative since this study focus to the half-sweep concept. Refer to the study of Sonarto et al [17] over the problem, we have propose the half-sweep concept to the Caputo's fractional derivative operator based on the operator (7) as follows:

$$\frac{\partial^{\beta}v(x)}{\partial x^{\beta}} \cong \sigma_{\beta,k}\sum_{j=0}^{N}g_j^{\beta}(v_{i-j+2}-2v_{i-j}+v_{i-j-2}) \tag{8a}$$

where we have the following expressions

$$\sigma_{\beta,h} = \frac{2h^{-\beta}}{\Gamma(3-\beta)} \tag{8b}$$

and

$$g_j^{\beta} = \left(\frac{i}{2}+1\right)^{2-\beta}-\frac{i}{2}^{2-\beta}. \tag{8c}$$

As mentioned in Section 1, using the second-order and first-order half-sweep central difference discretization scheme and half-sweep Caputo's fractional derivative operator (8), the second-order Half-Sweep Caputo's fd approximation equation for problem (1) given as:

$$\begin{aligned}d_i\sigma_{\beta,h}\sum_{j=0}^{j-2}g_{\beta}^{j}(v_{i-j+2}-2v_{i-j}+v_{i-j-2})+a_i(\frac{v_{i+2}-2v_i+v_{i-2}}{4h^2}) \\ +b_i(\frac{v_{i+2}-v_{i-2}}{4h})+c_i(v_i)=F_i\end{aligned} \tag{9}$$

Now, the approximation (9) is known as the half-sweep FD approximation equation it means that the value for each point considers at $i=2,\ 4,\ 6,\ \ldots,\ N-2$ refer to the figure 2(b) which show the distribution of grid network. By simplifying (9), the approximation equation can be written as:

$$a_i^{*}v_{i-2}+b_i^{*}v_i+c_i^{*}v_{i+2}-R_i=F_i, \qquad i=2,4,6 \tag{10}$$

Let us define

$$\left.\begin{aligned}&\lambda_i=\mathrm{d}_i\sigma_{\beta,h}, \quad a_i^{*}=\alpha_i-\mu_i-\lambda_i, \quad b_i^{*}=c_i-2\alpha_i+2\lambda_i, \\ &c_i^{*}=\alpha_i+\mu_i-\lambda_i, \quad R_i=\lambda_i\sum_{j=1}^{j-2}g_j^{\beta}(u_{i-j+2}-2u_{i-j}+u_{i-j-2})\end{aligned}\right\} \tag{11}$$

Again, besides the values of $i=2,4$, and 6 , the simplify of approximation equation (9) should be appeared for $i=8,10,12,\ldots,N-2$. To simplify the approximation equation, the second-order Half-Sweep Caputo's FD approximation equation can be expressed as follows:

$$R_i^{*}+p_iv_{i-6}+q_iv_{i-4}+r_iv_{i-2}+s_iv_i+z_iv_{i+2}=F_i, \quad i=8,10,12,\ldots,N-2 \tag{12}$$

where

$$\left.\begin{aligned}&q=\lambda_ig_2^{\beta}-2\lambda_ig_4^{\beta}, \quad p=\lambda_ig_4^{\beta}, \quad r=a_i^{*}-2\lambda_ig_2^{\beta}+\lambda_ig_4^{\beta}, \\ &s=b_i^{*}+\lambda_ig_2^{\beta}, \quad R_i^{*}=\lambda_i\sum_{j=6}^{j-2}g_j^{\beta}(u_{i-j+2}-2u_{i-j}+u_{i-j-2}), \quad z=c_i^{*}.\end{aligned}\right\} \tag{13}$$

According to equations (10) and (12), the linear system can be constructed in matrix form to facilitate in solving system of second-order half-sweep Caputo's approximation equations. As a result, the system of linear equations in the form can be given as:

$$A\underline{v}=\underline{f} \tag{14}$$

where can be define,

$$A=\begin{bmatrix}s_2 & z_2 & 0 & 0 & 0 & 0 & 0\\ r_4 & s_4 & z_4 & 0 & 0 & 0 & 0\\ q_6 & r_6 & s_6 & z_6 & 0 & 0 & 0\\ p_8 & q_8 & r_8 & s_8 & z_8 & 0 & 0\\ 0 & \ddots & \ddots & \ddots & \ddots & \ddots & 0\\ 0 & 0 & p_{N-4} & q_{N-4} & r_{N-4} & s_{N-4} & z_{N-4}\\ 0 & 0 & 0 & p_{N-2} & q_{N-2} & r_{N-2} & s_{N-2}\end{bmatrix}_{\left(\frac{N}{2}-1\right)\times\left(\frac{N}{2}-1\right)} \tag{15}$$

and

$$\underline{v}=\begin{bmatrix}v_2 & v_4 & v_6 & \cdots & v_{N-4} & v_{N-2}\end{bmatrix}^T \tag{16}$$

and

$$\underline{F}=\begin{bmatrix}F_2+p_2v_2\\ F_4+q_4v_4\\ F_6+r_6v_6\\ F_8+R_i\\ \vdots\\ F_{N-4}+R_{N-4}\\ F_{N-2}+R_{N-2}-z_{N-2}v_N\end{bmatrix} \tag{17}$$

3. Iterative Method

From previous discussion in Section 2 and refer to the linear system equation (14), the formulation of 4HSEGSOR iterative method will be discussed in this section to test the examples than record the numerical results of linear system. Based on the characteristics of the coefficient matrix A, it's showed the matrix have parse and large-scale. Following to the characteristics, the iterative methods are suitable option to solve the linear system [10]. Besides to improve the consequence rate of iterative method

for solving the linear system numerically, there are iterative methods have been proposed from previous researchers such as Jacobi, GS, and SOR methods. However, this study considers the application of 4HSEGSOR method as linear solver as mentioned in early this section.

Particularly, the 4HSEGSOR method is essentially the extension to half-sweep concept for the Four-point Explicit Group SOR (4EGSOR) iterative method which is combination between EG method developed by Evans [18] and SOR method developed by Young [10]. From previous study, Saudi and Sulaiman [19] have been discuss the explicit group to apply into the robot path planning and elucidated the EGSOR iterative method using Nine-Point Laplacian [20] in order to improve the consequence rate of iterative method in the study.

The aim of EGSOR method is to reduce the computational time of the convergence rate by uses small constant size groups strategy based on mesh point and weighted parameter "ω" with its range value given as $\omega \in [1,2)$. However, the main propose of the half-sweep iteration concept in this study is to reduce the computational complexities during iteration process. Following to that, the linear system was divided into several completed small group of four points ($p=4$) start with $i=8,16,24,\ldots,N-8$. However, for the first three points $i=2,4,$ and 6 can be treated as ungroup case [21]. Since this paper deals with application 4HSEGSOR iterative method for solving the linear system (14), it can be stated as:

$$\begin{bmatrix} v_i \\ v_{i+2} \\ v_{i+4} \\ v_{i+6} \end{bmatrix} = (1-\omega)\begin{bmatrix} v_i \\ v_{i+2} \\ v_{i+4} \\ v_{i+6} \end{bmatrix} + \omega \begin{bmatrix} s_i & z_i & 0 & 0 \\ r_{i+2} & s_{i+2} & z_{i+2} & 0 \\ q_{i+4} & r_{i+4} & s_{i+4} & z_{i+4} \\ p_{i+6} & q_{i+6} & r_{i+6} & s_{i+6} \end{bmatrix}^{-1} \begin{bmatrix} S_2 \\ S_4 \\ S_6 \\ S_8 \end{bmatrix}, \qquad (18)$$

for $i=8,16,24,\ldots,N-8$. To show the illustration, implementation of the 4HSEGSOR iterative method can be shown in Figure 3. Again the first three points, $i=2,4,$ and 6 can be stated as ungroup case in which these point can be used to construct the 3-point HSEGSOR method.

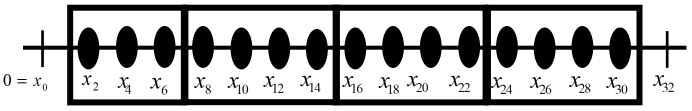

Figure 3: Implementation of the half-sweep 4EGSOR iterative method at solution domain m=32.

Based on Figure 3, Algorithm 1 is the implementation of 4HSEGSOR method that be summarized where the optimum values for the parameters, "ω" depends on the minimum number of iterations from several executions. The tolerance error set as $\varepsilon = 10^{-10}$.

Algorithm 1: 4HSEGSOR iteration

i. Set the value of parameters, $\underline{v}^{(0)} \leftarrow 0, \varepsilon \leftarrow 10^{-10}$
ii. Calculate the coefficient matrix, A.
iii. Calculate the vector, $\underline{F}$.
iv. Calculate the value of $\underline{v}^{(k+1)}$
    a) For $i=2$ calculate an ungroup cases.
    b) For $i=8,\ 16,\ 24,\ \ldots,\ N-8,$ calculate again equation (10).
v. Perform the convergence test, $\left|\underline{v}^{(k+1)} - \underline{v}^{(k)}\right| \le \varepsilon = 10^{-10}$. If yes, move to step (vi). Otherwise repeat the step (iv).
vi. Display approximate solution.

4. Numerical Experiment

This paper demonstrates three examples of numerical experiments for the comparison of two-point FBVPs where the exact solution for each example already given at $\beta = 1.50$. Besides that, this paper considers others two different values to analyse the performance of Caputo's Fractional operator in which $\beta = 1.25$ and $\beta = 1.75$ refer to Section 1 the range parameter "β" is $1 \le \beta \le 2$. Other than that, three different iterative methods will be implemented such as FSSOR, HSSOR and 4HSEGSOR methods. Beyond that point, considered such as number of iterations (K), computational time measured in second (s) and maximum absolute error (error) as measurement parameters in the numerical experiments need to be recorded while the convergence test considered the tolerance error which is fixed as $\varepsilon = 10^{-10}$. The following are three examples of numerical experiments for problem (1).

Example 1

By considering the fractional two point BVP below [22]

$$\frac{\partial^{\beta} v(x)}{\partial x^{\beta}} + \frac{\partial^2 v(x)}{\partial x^2} + v(x) = x^2 + x + \frac{4}{\sqrt{\pi}}\sqrt{x} + 3, \qquad 0 \le x \le 1 \qquad (19)$$

With the subject boundary condition as $v(0)=1,$ and $v(1)=3$, and the exact solution for the problem given by $v(x) = x^2 + x + 1$ when the value of $\beta = 1.50$.

Example 2

By considering the fractional two-point BVP below [23]

$$\frac{\partial^2 v(x)}{\partial x^2} + \frac{\partial^{\beta} v(x)}{\partial x^{\beta}} + v(x) = \frac{15}{4}x^{0.5} + \frac{15}{8}\sqrt{\pi}x + x^{2.5} + 1, \qquad 0 \le x \le 1 \qquad (20)$$

With the subject boundary condition as $v(0)=1,$ and $v(1)=2$, and the exact solution for the problem given by $v(x) = x^{2.5} + 1$ when the value of $\beta = 1.50$.

Example 3

By considering the fractional two-point BVP below [23]

$$a\frac{\partial^{\beta} v(x)}{\partial x^{\beta}} + b\frac{\partial^2 v(x)}{\partial x^2} + cv(x) = 4\sqrt{\frac{x}{\pi}} + x^2 + 2, \qquad 0 \le x \le 1 \qquad (21)$$

With the subject boundary condition as $v(0)=0,$ and $v(1)=1$, and the exact solution for the problem given by $v(x) = x^2$ when the value of $\beta = 1.50$.

The implementation for the numerical experiments consider the C programing language as a tools. Following to that, all the

results of numerical experiments have been recorded based on the iterative methods which are FSSOR, HSSOR and 4HSEGSOR methods in Tables 1, 2, and 3 with three different values of β as mentioned in early section. For the grid sizes have used at five different values where the values of m = 128, 256, 512, 1024, and 2048.

5. Discussions of result

Through numerical experiments results from Tables 1, 2, and 3 by imposing the comparison between HSSOR and 4HSEGSOR iterative methods with FSSOR method react as control method as discuss in Section 1 with three different values of parameter $\beta = 1.25$, 1.50, and 1.75 , it is conspicuously that number of iterations at Table 1 for HSSOR and 4HSEGSOR iterative method have declined. The result showed the number of iterations when the parameter set to $\beta = 1.50$, at size 128 declined from 769 for FSOR to 320 for HSSOR. Again, the number of iterations declined from 320 to 114 for 4HSEGSOR. It's the same situation for another size the number of iteration has declined. To show more clearly, the percentage of number iterations declined approximately by 82.20% –83.31%, 85.18% – 92.24%, and 83.77% – 95.58% which corresponds to the HSSOR iterative method. For execution time, the result showed 4HSEGSOR method reduce the computational complexity. The execution time when the

	HSSOR	5489	9.40	2.1230e-02	13970	23.85	1.3863e-05	34573	59.15	1.7054e-02
	HS4EGSOR	1892	5.28	2.1230e-02	2643	7.28	1.3931e-05	4729	13.02	1.7054e-02

parameter set to $\beta = 1.50$, a size 128 declined from 0.13 seconds for FSOR to 0.01 seconds for HSSOR. But, the number of iterations remain same from 0.01 seconds to 0.01 for 4HSEGSOR. It's the same situation for another size the execution time has reduce. To show more clearly, the percentage of execution time reduced about 90.00% – 97.67%, 92.31% – 98.71%, and 91.67% –98.75% corresponds to the HSSOR method. From the elucidating result for Table 1, the effectiveness 4HSEGSOR can be conform better compare to HSSOR.

In fact, Table 2 show that the numerical experiments for number of iterations HSSOR and 4HSEGSOR iterative method have declined. However, the result showed the number of iterations 4HSEGSOR drastically declined compare with HSSOR. It can be show when the parameter set to $\beta = 1.50$, the number of iteration declined from 5478 for FSOR to 541 for 4HSEGSOR meanwhile for HSSOR just to 2039 from 5478. It's the same situation for another size the number of iteration has drastically declined. To show more clearly, the percentage of number iterations declined approximately by 82.73%–83.00%, 85.44–92.24% and 88.74%–95.60% respectively as compared with the HSSOR method. Also for execution time, the result showed 4HSEGSOR method reduce the computational complexity. The execution time at size 2048 declined from 77.53 seconds for FSOR to 15.14 seconds for HSSOR. Again, the execution time declined from 15.14 seconds to 5.30 seconds for 4HSEGSOR. It's the same situation for another size the execution time has reduce. To show more clearly, the percentage of execution time reduced about 50.00%–93.16%, 75.00%–96.93%, and 66.67%–98.25% respectively than the HSSOR method. From the elucidating result for Table 2, the effectiveness 4HSEGSOR can be conform more better compare to HSSOR.

Lastly, from the numerical results in Table 3 show that the number of iterations for the 4HSEGSOR iterative method have declined. The result showed the number of iterations at size 512 declined from 2789 for FSOR to 1397 for HSSOR. Again, the number of iterations declined from 1937 to 473 for 4HSEGSOR. It's the same situation for another size the number of iteration has declined. To show more clearly, the percentage of number iterations declined approximately by 82.30%–83.42%, 86.07%–92.92% and 88.85%–95.74% respectively as compared with the HSSOR method. Also, implementations of computational time for the result showed 4HSEGSOR method reduce the computational complexity. The execution time at size 512 declined from 2.44 seconds for FSOR to 0.17 seconds for HSSOR. Again, the number of iterations declined from 0.17 seconds to 0.10 for 4HSEGSOR. It's the same situation for another size the execution time has reduce. To show more clearly, the percentage of execution time reduced about 93.75% - 100.00%, 96.08%–100.00% and 97.22%–100.00% respectively than the HSSOR method.

6. Conclusion

For the conclusion, this study success the numerical experiments of the application 4HSEGSOR iteration to solve the linear system generated by the steady-state problems which is two-point FBVPs. The family FD scheme and Caputo's fractional derivative operator was applied to construct the linear system. From the linear system, the iterative methods success to applied to get the approximation solution. From the numerical results recorded in Tables 1, 2, and 3 by imposing the comparison between HSSOR and HS4EGSOR iterative methods with FSSOR method react as control method, clearly the results promising two improvements in the number of iterations (K) and execution time (s). According to the numerical results are recorded, it can be showed that the HS4EGSOR method is superior and it has required a much lesser number of iterations and computational time to solve the problems.

ABSTRACT

This paper describes an architectural approach to the development of dynamic service-oriented systems for e-Health using the service orchestration mechanism and semantic technologies. The main idea is the dynamic synthesis of the complex functionality required by user or by software agent. This idea should help to build and easily extend the applied loose-coupled systems without strict dependencies on concrete web services and their invocation details. A sample scenario of such dynamic orchestration is covered and analyzed, possible ways of further improvement of this approach are given.

1. Introduction

This paper is an extension of work originally presented at the 2018 IEEE First International Conference on System Analysis & Intelligent Computing (SAIC) [1]. Since then the original research has been continued in the direction of development of service-oriented e-Health application. This paper covers more details of dynamic service orchestration and how it can be applied to the e-Health software design.

2. Problem Overview

Modern network applications widely use web service interaction to retrieve or update data. There may be a lot of interconnected services of different types (like SOAP or REST) interacting with each other and external third-party services, thus forming so called "service ecosystem". The interaction of these services may be implemented in different ways (see Figure 1):

- "Hard-coded" interaction: direct invocation of the service at specific URL is fixed in source code with all the invocation details. In this case even simple relocation of services to another URLs requires changing (and consequent recompiling, redeployment, retesting) of all dependent software modules (other web services, for instance).
- Services could use service discovery mechanism by means of some registry (in its simplest case by using some "name server" to translate service name to concrete URL. UDDI registry is an advanced example). This makes it easier to modify and scale the service ecosystem, but services are still tightly coupled by data formats and interaction patterns.
- Service choreography approach (e.g. "publisher-subscriber" model) could be implemented by means of some message broker. This event-driven service architecture consists of loosely coupled services that can be dynamically connected to each other through a subscription to different message types.
- Service orchestration approach: all interactions are controlled by external orchestration software. In such system services could be truly agnostic to their environment while publishing only their interface description.

It must be noted that in many real-life systems composed of hundreds of services all of these approaches may be implemented within a single service ecosystem (forming "heterogeneous" service ecosystem).

In any case it is only skilled developer who is capable to organize the inter-service communication to bring some functionality to the system. It is almost never possible for the end users to create new functionality without skills and knowledge in programming. This problem is partly solved by so called "workflow management systems" (like scientific workflow systems [2] or engineering ones [3]). Most of service-oriented workflow systems typically rely on the orchestration approach.

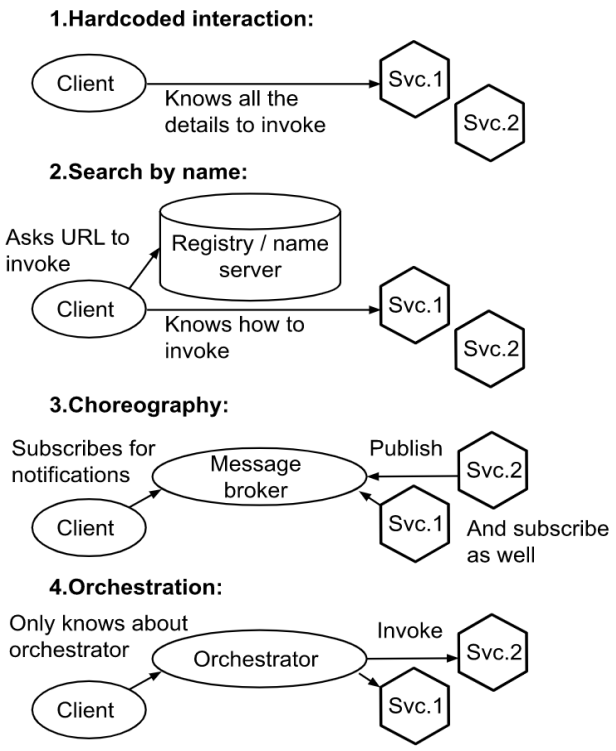

Figure 1: Some existing service interaction patterns (client could be implemented as another service as well)

2.1. Problem Definition

This paper focuses on a slightly different issue: how to make it possible for *both users and program agents* to request and execute the desired functionality *without any service-level knowledge* (existence of specific services and their interfaces' details)? In other words, dependencies between the clients and web services are forcing developers to update clients when service ecosystem changes. This costs time and extra QA efforts. We propose an approach that helps to avoid the update of the clients in case of changes in service ecosystem and thus makes it easier to maintain and improve the overall system.

Instead of making calls to specific services, or even "constructing workflows of services", software clients can issue "functionality requests" to some broker. While these requests can be fulfilled, the clients need no updates. The fulfilment of these requests could be organized using the orchestration approach, if there is no single service capable to provide the requested functionality. This is what we call here a "*dynamic semantic-based orchestration*": the automatic synthesis of a service workflows to provide the requested functionality (including some goal and output data). One of the main benefits of the dynamic orchestration is that service clients and services themselves are not coupled in any way except the functionality semantics. There is no need to keep track of web service interface changes on each client, it's only a knowledge base about services (which binds functionality semantics with service invocation details) that should be kept updated instead.

3. Possible Application Scenarios

There are a lot of application fields for dynamic semantic-based orchestration. Some of them are listed below.

Scientific and engineering workflows

There are a lot of existing 'Scientific workflow systems' and many of them support invocation of the remote services (Taverna workflows [4], Apache Airavata [5] etc.). The main problem there is a high complexity of constructing the service workflows for non-IT-domain specialists and scientists, because the workflow elements are bound to concrete services, their operations, and data formats. With the dynamic semantic-based orchestration the end users could just set the goals of the orchestration and receive the automatically built workflow. No need to deal with service-level details for the end users.

Performance monitoring dashboards

This feature can be implemented in medical (see further), scientific, engineering, industry production, financial and other domains. Given the ecosystem of services to fetch different parameters of the objects to monitor (patients' health data, the status of lab equipment or industrial equipment etc.). User needs a tool that can be used to easily construct and customize the KPIs. Possible solution: a user describes the functionality he needs in terms of some knowledge base, and new dashboard indicator will get its values from the dynamically orchestrated services providing the functionality requested.

Business analytics and data mining

Same as previous kind of scenario but it also involves the services for mining new knowledge from existing data helping to improve existing business processes. These workflows are more complex, compute intensive and provide valuable information (insights). It is a service-oriented analytics solution for business enterprises of different scale. In [6] a workflow management system for 'big data' mining is described. But its workflows are still composed manually by the end user.

Smart house and IoT

The dynamic semantic-based service orchestration can be used in controlling IoT devices, e.g. as a part of smart house. For example, anyone in the smart house environment can easily add new automation scenario, e.g. to control lighting, climate or heating or water supply in a smart way, just by describing the desired functionality. In a similar way this approach can be applied, say, to control production processes on factories or for stock management. The PROtEUS++ [7] is a promising example of a specialized workflow engine for IoT tasks, and by the way it supports dynamic service discovery using the semantic service description.

Workflows for e-Health

Workflows for patient's diagnostics and treatment (DTWf) could also be implemented with the help of automatic semantic-based service orchestration. The DTWf typically can contain invocation of basic services for diagnostics (like service to check blood pressure, controlling blood pressure data received from devices or manually entered by the patient), services of patient's health status prediction (based on the data provided by other services) and so on [8]. This application field will be mainly referred further as it is studied by authors in scope of implementation of the project of the mobile e-Health platform development.

4. Implementation

The main idea of the proposed solution is to hide as much low-level service interface specifics as possible from the client (functionality consumer), allowing the client to operate only with its goals and data. It is similar to how declarative programming languages (like SQL or SPARQL) differ from imperative ones: when working in a declarative style you need to specify what goal to reach but not how it should be reached. You actually don't worry about implementation details. Ideally the client just declares the new computational goal (e.g. "to get specific output results from specific input data" etc.) without referencing particular services. He only operates with terms and facts from the knowledge base that can help him to express his goal. The rest process is automated by means of automatic service discovery and automated orchestration.

The solution proposed is based on the following three main components (also implemented as services), as shown on Figure 2:

- *Service for execution* (SE) of functionality requests, which serves as a kind of broker and the single point of access for clients. It does not only find some concrete web services able to fulfil the client's request, but also is responsible for execution of any service operations and results provision. In other words, clients don't ask SE to find some services, they ask to do some actions, provide input data and wait for output. In order to fulfill client's request SE communicates with other two components.
- *Service registry* (SR). This service searches for available services that could provide the requested functionality (according to registered service's semantic annotations). In fact, it is an interface to the knowledge base containing facts about services and their functions. The second mission of SR is to find the possible service orchestration scenario if no single service matches the requested functionality. Then this scenario is passed to the Service orchestrator.
- *Service orchestrator* (SO). This service is responsible for execution of service workflows, created by SR. Workflows actually can consist either of a single service, or describe the orchestration scenario involving multiple services. This service complies with a SaaS model: new workflows can be deployed in a cloud infrastructure and can be interacted via the REST interface (invoked, queried about status and results, canceled, disposed etc.). It should be noted that today there are a lot of orchestration tools available. The orchestrator engine is a core part of SO and it can be implemented on top of many of existing tools, for example: BPEL engine, Taverna Workflows, Netflix Conductor (a microservices orchestration engine).

4.1. Service Registry and Knowledge Base

The SR has an extended functionality compared to UDDI registries. Instead of binding to standard fields and database schema, it is based on flexible knowledge base. Administrator-level users can add new facts or modify existing facts about services registered and extend the ontology with new classes. The SR can be queried about services in a similar way like Triple stores are queried with SPARQL queries. But the functionality of SR is not limited by simple querying the triple store. It includes the matchmaking logic helping to construct the complex service workflow according to the goals set and inputs provided. To do this the SR should contain the formalized knowledge on web service interaction details (protocols, procedures, interfaces), and the knowledge on basic data formats used and how to extract and transform the data from them (xml, JSON, CSV etc.). That's why the knowledge base should consist of domain ontology (to set goals, to describe services functionality and operations, inputs and outputs), service ontology (to allow automatic invocation, see Figure 3), and data formats ontology (to allow automatic data flow building).

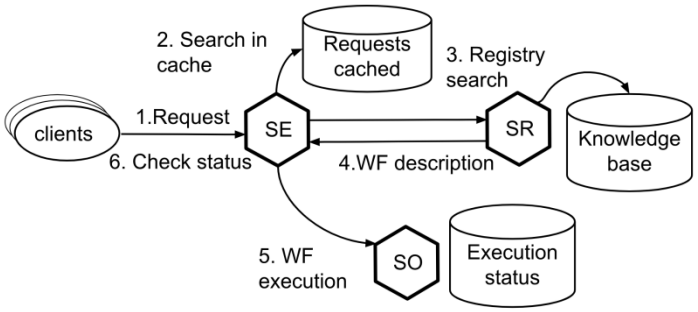

Figure 2: Main components of the proposed solution

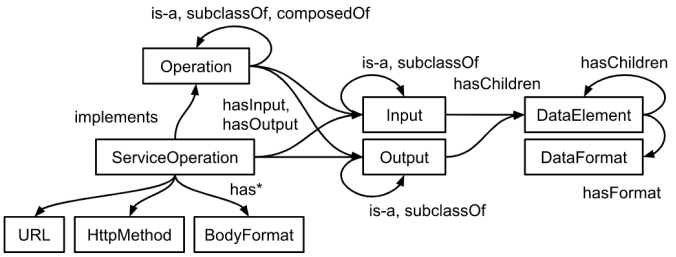

Figure 3: Service ontology (fragment)

4.2. Service Matchmaking

Existing standard solutions in service registration like UDDI are not enough for advanced semantic search. Instead it is proposed to rely on service ontologies, similar to OWL-S ontology [9], which will give more relevant results. Service matching can be done using the semantic proximity of the service ontology elements (from registry knowledge base and those from the "request for functionality" query) [10]. In order to compare these ontology elements, the following elementary proximity estimations are needed to be computed: proximity of classes, proximity of classes and instances, proximity of instances, proximity of predicates. Some service A can be called 'relevant' to some search query R only in case the proximity estimate is higher than some threshold value M_T (see further).

Another aspect is to choose what information should be included into comparison. It is proposed to use the following information categories: C (context), IOPE (inputs, outputs, preconditions, effects) and QoS.

The context C form search query can be formally defined as any information that could implicitly and explicitly impact the query generation by user (it can be profile-oriented, history-oriented, process-oriented, other context). An explicit context is

directly provided by user, while implicit one is that being gathered by any automated tool.

The service functionality can be matched by use of IOPE attributes. The *hasInput*, *hasOutput*, *hasPrecondition* and *hasEffects* query attributes (R) are matched against the corresponding ones from each service's description (A). Matching can be estimated as a one of following outcomes: "exact match", "plug-in" match when R is a subclass of A, "subsume" when R and A have common partial match, "failure" is A and R have nothing common.

QoS attributes include service price, performance, reliability, stability, scalability, security etc. The total match level estimation combines those estimations mentioned above:

$$M(R, A) = K_C M_C + K_I M_I + K_O M_O + K_P M_P + K_E M_E + \\ + K_{QoS} M_{QoS} > M_T$$

If we group IOPE and C requirements as functional requirements (FR) and QoS we refer to as non-functional requirements (NFR), and if we use mismatch-level (or level of matching error) as an indicator of matching failure (for practical reasons: to be able to use mismatch penalties instead of proximity estimations), then we'll have the following general matching error function:

$$E(R, A) = K_{FR} E_{FR} + K_{NFR} E_{NFR} < E_T$$

Both measures M and E could be used combined. First, we look for the single service with the highest M(R,A). If $M(R,A) > M_T$ then we accept it as a service providing requested functionality. If $M(R,A) < M_T$ then we need to compose a workflow of services with less possible $E(R,A) < E_T$. In order to estimate E for a workflow of services {A} we can use this general approach:

$$E(R, \{A\}) = K_{FR} E_{FR}^* + K_{NFR} E_{NFR}^*,$$

where * marks summary values for a workflow, for instance, internal inputs and outputs that are connecting services are excluded from error estimation.

During the practical implementation of a e-Health product with less than hundreds of service operations and without third-party services we found it sufficient to consider only IOE requirements (E for effects in form of functionality requested), without NFR. So, we used the following brief construct for the functionality request:

$$R = (F, \{I\}, \{O\}),$$

where F (function) – action to perform, I (input) – available inputs specification, O (output) – requested outputs specification. In a practical implementation we used JSON format, flexible enough to express complex I and O descriptions (see Figure 4). Here is a simple example of request to SE to get user name by ID:

```
{
  "operation":"get",
  "input":[
    {
      "name":"user",
      "properties":[
        {
          "name":"id",
          "value":"user001"
        }
      ]
    }
  ],
  "output":[
    {
      "name":"user",
      "properties":[
        {
          "name":"firstname"
        },
        {
          "name":"lastname"
        }
      ]
    }
  ]
}
```

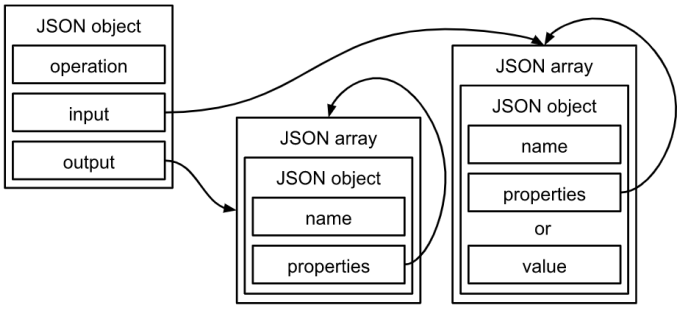

Figure 4: Inputs and outputs specification format

4.3. e-Health Application

The are many research papers studying the use of service-oriented architecture for medical software [11,12], and some of them mention service orchestration as a part of medical software, but this paper focuses on slightly different things, related to orchestration mechanism itself.

Workflow composition or, in other words, automatic semantic-based orchestration scenario synthesis, makes is easier to extend existing functionality of the system. It could be possible to get this new functionality even without development of new services: when the new functionality request could be satisfied with an orchestration scenario involving existing services. Before describing an example of such scenario, let us briefly describe the e-Health application that uses the proposed approach.

The e-Health application we develop is a system providing a virtual office for doctors and patients as an online point of their communication. It is useful in conditions when the nearest medical center is far from patient's home. In this situation the initial diagnostics can start online, and in many cases, it could be enough to help patient without real-life visit to the hospital. Also, the virtual doctor's office remembers all the patient treatment history and can provide some intelligent tool helpful for doctors and patients, like prediction of the crisis state of patients' health based on ordinary indicators like blood pressure, glucose level or complains about pain. This is an example of extended functionality that can be built by re-using the existing functions. The general

architecture blocks of this e-Heath application are presented on Figure 5.

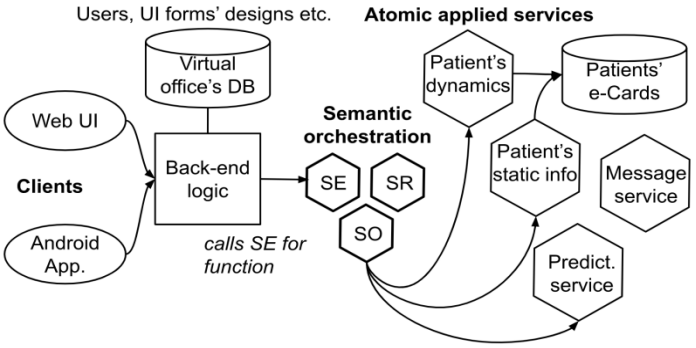

Figure 5: Virtual doctor's office using the dynamic semantic-based orchestration

Most of the office's functionality is not implemented just by back-end logic querying the database. There is a separate layer called "applied services" which is actually an API to do everything on patient's record. Conversations with doctors, diagnoses, treatment prescriptions, health indicators, reports – all of this is implemented with atomic REST services (we can call them microservices). The back-end logic's responsibility is to serve front-ends' requests and gather all necessary data for displaying to the user. Any call to operate patient's data is made as a "functionality request" with function, inputs and outputs provided to SE. This way we can truly separate back-end development and microservice API development, and only need to reflect important changes in a knowledge base of SR.

4.4. Service Workflow Composition Example

One of the examples where the dynamic orchestration takes place is the prediction of diabetes, heart problems and so on based on the last entered health indicators. This prediction is just a hint for the doctor and should only attract his attention to some possible problems (by displaying a warning), so there was no need to achieve very high accuracy of prediction. To develop such "intelligent" hint test datasets were analyzed, prepared and used for neural network training. This ended up as a separate service with one single output (binary warning flag) and a number of inputs (like weight, insulin and glucose level and much more) developed by separate team with machine learning background. In order to get the diabetes warning flag, the back-end developers just made a simple request: "given patient's ID and current date, run diabetes prediction and return warning flag". At the same time the SR's knowledge base contains information about inputs and outputs of all services, including the diabetes predictor.

Let's take a look at the process of execution of that request mentioned above. After JSON describing this request is accepted and parsed by SR, the SR itself starts to search for single service capable to satisfy the request. It founds the service operation with function briefly described like "Diabetes prediction". But this service operation has a lot of inputs, despite it has the output and function matching the request. So, no single service is found, and SR tries to build the workflow. It finds a lot of combinations of atomic services, but the best one (according to matching error penalties) is presented on Figure 6. It is executed, and the result is returned to the back-end caller (the client).

The Figures 7 and 8 shows two screens of a mobile client developed using the described diabetes prediction workflow to display a warning icon (the application's language is Ukrainian). The first screen is a menu screen for a doctor with a following action on a selected patient: indicators, chat, log, complains, diagnosis, treatment. The second screen shows some sample conversation between a doctor and his patient in a chat mode.

When a doctor selects someone of his patients, the diabetes prediction workflow is called, and the client displays or hides the warning icon (a circle with Ukrainian letter "D" inside) at the top of the screen related to that patient (seen on both screens on Figures 7 and 8). In a similar way any other predictor (e.g. for heart problems) is called via the dynamic semantic-based orchestration.

4.5. Evaluation of Results

The performance penalties for this sophisticated process of services invocation (compared with direct REST services calls) could be estimated through the workflow execution time T_{exec} :

$$T_{exec} = T_M + T_V + T_{WF} + T_S$$

where T_M is a matchmaking time, T_{WF} is a workflow execution related overhead (depends on workflow execution engine speed), T_S is a total time for the execution of the longest sequence of service invocations in a flow (web services execution time). There is also T_V which is a validation time of the composed workflow. Currently we don't use any validation technique, and fully rely on the consistency of the knowledge base during the automated workflow synthesis ($T_V = 0$). But there is a risk of the incorrect behavior of the composed workflows (like infinite loops) even if they were constructed without any inconsistency with the knowledge base, so we need formal modeling techniques. Petri nets [13] and process calculus [14] could be successfully used to model web service workflows and related tools will be further integrated to the system to improve its reliability.

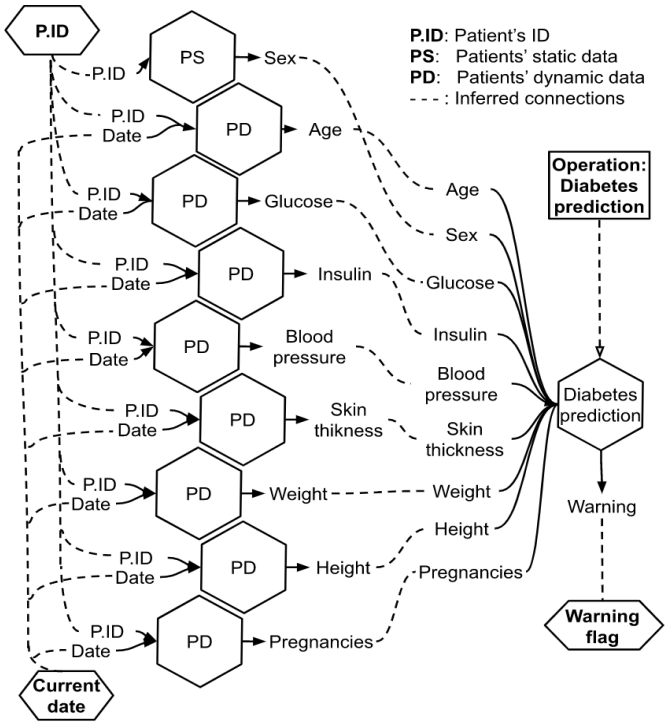

Figure 6: Diabetes prediction workflow (inputs and output are marked bold)

When comparing hard-coded scenario execution ($T_{exec}' = T_S$) with dynamic orchestration T_{exec}, the dynamic and flexible approach lasts longer by $T_{exec} - T_{exec}' = T_M + T_{WF}$, which was 3 to 5 seconds in case of small service registry (about 30 service operations) we used for diabetes prediction scenario. It should be noted that this time is seriously affected by the knowledge base facts quantity and quality (seriously impacts T_M).

In order to avoid same process of workflow synthesis each time a doctor needs a hint, the resulting workflow is cached in SR's knowledge base. The overhead is minimal and almost equal to ($T_{WF} + T_S$) because in this case $T_{exec}'' = T_C + T_{WF} + T_S$, where T_C is a cache search time and $T_C << T_M$). But in case of any changes in the knowledge base the cache should be cleared. This is a trade-off we get instead of updating the clients: the knowledge base update leads to reasoning on the updated facts and repeating the service matchmaking again from scratch. But found these knowledge base related activities less time-consuming then updating, redeploying and QA of all client applications.

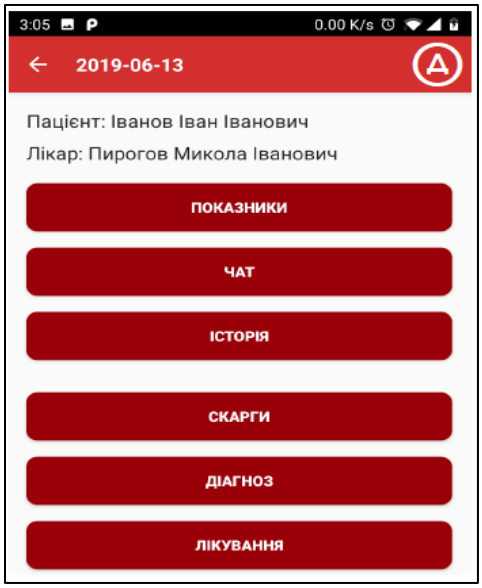

Figure 7: A 'patient menu' sample screen of the mobile e-Health application with diabetes warning icon at the top.

Figure 8: Chat screen of the mobile e-Health application, with diabetes warning icon at the top.

5. Conclusions and Future Work

This paper presented a description of a software architectural approach that aims to bring more flexibility to service-oriented systems and make service dependencies weaker. The main idea is to provide additional "abstract request layer" to the well-known service orchestration mechanism. The abstract request for functionality is being matched with the knowledge base of available web services to perform actual calculations.

The approach described has been successfully applied to the e-Health system, and it gives promising results for this application field, since e-Health applications typically have a lot of functions and data sources that could be accesses with the web service interfaces.

In our opinion this approach has the following benefits not only for e-Health domain but for other application fields as well:

- Service clients and web services are fully separated and could be developed independently by the teams of different development tools and background. The only dependency is the knowledge base (and service registry that uses it). Service ecosystem can be easily updated without changes to its clients. Only the knowledge base needs to be updated.
- It is possible to develop the UI for users to allow them easily construct the functionality requests and thus extend the functionality without help from software developers. This is one direction for our future work. It includes the development of workbench where users can test their requests and development of UI editor to control the displaying of requested results.
- In case of small service registries, the matchmaking process and workflow synthesis will not harm performance. This is true in case of avoiding usage of some existing heavyweight tools for orchestration like BPEL engines as the core for service orchestrator. The problem is that these tools like BPEL engines were basically designed for static workflows, not dynamic ones.

Of course, this vision has its drawbacks:

- The e-Health software must be very robust. But it has to be noted that the absence of hard-coded reference to concrete services there is a non-zero probability that SR will find wrong services or does not find anything thus producing wrong results returned by SE. From this point of view the only way in assuring the correct behavior is continuous testing of functions used by clients. When client gets updated with new functionality request call, this call should be added to the test plan. The improvements in QA of the solution presented are planned for our further work. At the same time formal models like Petri nets or process calculus can help to test the behavior of the dynamically generated workflows automatically.
- Another option to make sure correct services are matched to a request is to make only strict logical assertions by SR. No partial matching possible, service or workflow is either matching the request or not. In this case the clients will

need to use only strict request constructs and only correct ontology terms it their requests, thus making the new programming language to express the functionality requests. This will make it harder to add the new requests and make them work by end users and even programmers.

- In case of large registries of services, the matchmaking process could be time-consuming, since a lot of services could be "paired" according to their inputs and outputs and their functionality. So this solution will not work as expected in a system with hundreds of service operations and third-party services. And there will be problems if there are too many fine-grained microservices in the ecosystem even if it does not include external third-party services. In this case the matchmaking process should be restricted of simplified since e-Health software should operate without lags.
- Another problematic issue is the correct management of the knowledge base. Each time a new service is developed and should be registered in the system, there are a lot of work to do in the knowledge base. In fact, the knowledge base is the most important component of such system and requires very accurate updates, permanent logging of changes and intensive QA. Together with service registry it forms the fragile bottleneck of the system.
- Such complex interaction patterns could bring additional problems in security and data privacy. This is very important for e-Health applications working with personal medical data. But this aspect is out of scope of this paper.

Other possible directions for the future work are: research on the specifics of orchestrating services that control IoT devices and moving orchestrator service to the cloud infrastructure.

Acknowledgment

This paper describes partial results of the ongoing fulfillment of the project "The development of the modern service systems by the example of mobile medical system for a front-line settlements in the military conflict zone" by the National Technical University of Ukraine "Igor Sikorsky Kyiv Polytechnic Institute".

The Terms Of Trade

ABSTRACT

In this study, we develop the author's approach, based on the principles of modeling of the International Flows Equilibrium Exchange Rate (IFEER). As a result, a new model is built, depending on the main macroeconomic factors in the medium term. The model presents a wide system of basic factors, but many of the intermediate factors in the modeling were eliminated. The results are discussed in the context of the previously known results of economic theory.

1. Introduction

This paper is an extension of work originally presented in Eleventh International Conference "Management of large-scale system development" (MLSD 2018, IEEE Russian section) [1] .

In the scientific literature the nominal and real exchange rate models are widely represented in conditions of the dynamic general equilibrium (DSGE-models), the founders of which is the model Obstfeld-Rogoff [2] of monopolistic competition of two open economies. At the same time, the previous approaches to fundamental factors modeling were developed by Mussa [3] and Dornbush [4] in conditions of both the monetarist and Keynesian approaches.

Many authors emphasizes the effectiveness of fundamental factors models of nominal and real exchange rates (e.g., [5]).

Conditions for the existence of the equilibrium rates were allocated in 1945 by R. Nurkse [6], which paid considerable attention to the balance of payments equilibrium, the lack of restrictions on export-import operations and capital flows and internal stability of the economy.

However, from the standpoint of structural modeling, the known models of economic theory cannot provide adequate results for assessing of the equilibrium real or nominal rates level. In a significant majority the exchange rates are not expressed in terms of the equilibrium of the financial market, but in terms of the theory of purchasing power parity (PPP). Structurally, the exchange rate analysis is limited by the current balance. Herewith, it should be emphasized the role of the exchange rates in the process of regulating the external balances and the role of the indicator of competitive advantages in foreign trade flows.

To solve these problems, we propose to use the author's approach, based on the principles of the international flows equilibrium exchange rate (IFEER) modeling [1, 7].

2. Conceptual Bases of Modeling

It should be noted, that in this article we develop the IFEER-approach and the new equilibrium exchange rate model will be presented as a result.

Initially, we suppose that the world consists of two equal rights open economies and international trade flows take into account the trading competitive position of these countries. In this context, international trading bilateral competitive position is determined by the real exchange rate. It should be noted here, that approach "small open economy - the rest of the world" under IFEER-concept was used by the author in modeling of the Russian ruble exchange rate (e.g., [7]).

We consider all real market transactions at nominal exchange rates $e_i, i \in (1, L)$ on the domestic currency market that occurred in a certain period of time.

*Anton Kuzmin, Moscow, Russian Federation, a_kuzmin@rambler.ru

Then e_i, D_i, R_i in *i-th* transaction are: the bilateral nominal exchange rate, the amount in the determined foreign currency and the amount in the national currency respectively.

In this context, these variables are linked by ratios:

$$e_i D_i = R_i, \text{ and therefore, } e_i = R_i / D_i .$$

So, we define the synthetic value of the bilateral nominal exchange rate in conditions of varying degrees of free floating for the certain period as the sum of exchange rates, weighted by amounts in determined foreign currencies:

$$e \equiv \sum_{i=1}^{L} \frac{D_i}{\sum_{j=1}^{L} D_j} \times e_i , \quad (1)$$

Using the definition of the exchange rate in *i-th* transaction, we get from (1):

$$e = \sum_{i=1}^{L} \frac{D_i}{\sum_{j=1}^{L} D_j} \times \frac{R_i}{D_i} = \sum_{i=1}^{L} R_i \Big/ \sum_{j=1}^{L} D_j . \quad (2)$$

Next, on a conceptual level, we can disaggregate balance of payments flows:

$$e_t = 1 \Big/ e_t^* = (I_t + K_t^-) \Big/ (E_t + K_t^+) = \\ = (E_t^* + K_t^{*+}) \Big/ (I_t^* + K_t^{*-}), \quad (3)$$

where I_t - the demand in the national currency on imports,

E_t - the supply in the foreign currency from exports,

K_t^+ - the capital inflows in the foreign currency,

K_t^- - capital outflows in the national currency.

This formula takes into account such important components as export revenue, demand for imports, demand for foreign assets and so on.

Therefore,we are developing two-period model in the dynamics in times *t* and *t-1*.

Herewith, at time *t* value of the functions of export-import operations and capital flows will be directly determined by the international competitive position represented by the real exchange rate at the time *t-1*:

$$e_{t-1}^R = e_{t-1} P_{t-1}^* \Big/ P_{t-1} , \quad (4)$$

where P_{t-1}^* - the exernal prices index,

P_t - the internal prices index.

For the model verification the price indices can be represented by consumer prices index (CPI), GDP-deflator and so on.

In the analysis of exchange rates, many authors (e.g., M. Bahmani-Oskoee and G. Goswami [8]) determine the terms of trade, reflecting the effectiveness of export-import operations in world trade, as one of the determining factors of the dynamics.

For example, F. Caramazza [9] explored the expectations of investors of German mark against French franc dynamics – one of the main cross-rates in the world at that time. He explained the change in parity by largely fundamental macro-variables, including terms of trade and relative inflation differential. L. Bartolini [10] similarly revealed the relationship between market expectations of devaluation and CPI-indicator of trading international advantages.

In the author's model of the ruble exchange rate [11], the use of trade terms by micro-agents as the main determinant of foreign trade operations is proved and justified on the statistical series of import and export of Russia. However, they are expressed in adjusted nominal exchange rates at price levels, including actual export prices.

3. Exchange Rate Modeling: Medium-Term Equilibrium Dynamics

In the domestic foreign exchange market at time *t* export earnings as part k_E of the average real gross domestic output $(Q_t^{\frac{1}{x+1}} Q_{t-1}^{\frac{x}{x+1}})^{\delta}$ in foreign prices P_t^* depend on the decision of producers-exporters and the state of international trade conditions e_{t-1}^R at time *t-1*:

$$E_t = P_t^* k_E (Q_t^{\frac{1}{x+1}} Q_{t-1}^{\frac{x}{x+1}})^{\delta} (e_{t-1}^R)^z , \quad (5)$$

where $k_E = const$,

Q_t - real gross domestic output.

In a function (5) $k_E (Q_t^{\frac{1}{x+1}} Q_{t-1}^{\frac{x}{x+1}})^{\delta}$ says, that the produced exports are part of averaged real gross domestic output (e.g., real GDP).

Due to the stability Q_t, the averaging method does not give a significant contribution to the fluctuations of the functional dependence (5).

The parameter *z* is the response to change in international trading position and the index *x* is associated with indexes *z* and *y* in the functions (5) and (6): *x=(z-y).*

In a functional dependence (5) the parameter δ reflects the fact that the growth rate of export exceeds the growth of gross domestic product because of a limitation of domestic demand: $\delta \geq 1$.

In the framework of the simulation because of equal rights and symmetry of flows the export of a country is an import of counterparty.

By analogy with a functional dependence (5):

$$E_t^* = P_t^* k_I (Q_t^{*\frac{1}{x+1}} Q_{t-1}^{*\frac{x}{x+1}})^{\lambda} (e^{*R}_{t-1})^{-y} , \quad (6)$$

where $k_I = const$.

The parameter y also is the response to change in real international trading position.

So, using the formula (4) and $e_t = 1/e_t^*$, functional dependency (6) can be rewritten

$$E_t^* = I_t = P_t\, k_I (Q_t^{*\frac{1}{x+1}} Q_{t-1}^{*\frac{x}{x+1}})^{\lambda} (e_{t-1}^R)^y .$$

As can be seen from formula (3), capital flows and export-import operations directly affect the exchange rate dynamics.

It should be noted that many well-known models of economic theory have serious difficulties with formalizing of the impact of capital flows on the exchange rates. However, within the framework of the proposed IFEER-concept, we can directly determine these functional dependencies.

At the same time, the mechanism of formation of functional dependencies of capital flows is very similar to the mechanisms of formation of export-import operations regarding the chosen factor system. More details can be found in the author's work [1]. For example, at time t we suppose that non-residents buy part of the real averaged domestic product $k_{K^+}(Q_t^{\frac{1}{x+1}} Q_{t-1}^{\frac{x}{x+1}})^{\theta}$ in their prices:

$$K_t^{+} = P_t^* k_{K^+} (Q_t^{\frac{1}{x+1}} Q_{t-1}^{\frac{x}{x+1}})^{\theta} (e_{t-1}^R)^z , \qquad (7)$$

where $k_{K^+} = const$, $\theta \geq 0$.

Capital inflows are capital outflows of its counterparty:

$$K_t^{*+} = P_t\, k_{K^-} (Q_t^{*\frac{1}{x+1}} Q_{t-1}^{*\frac{x}{x+1}})^{\rho} (e^{*R}_{t-1})^{-y} , \qquad (8)$$

where $k_{K^-} = const$.

We can rewrite a functional dependence (8):

$$K_t^{*+} = K_t^{-} = P_t\, k_{K^-} (Q_t^{*\frac{1}{x+1}} Q_{t-1}^{*\frac{x}{x+1}})^{\rho} (e_{t-1}^R)^y .$$

Let's substitute dependences (5) - (8) in (3):

$$e_t = \Big[P_t k_I (Q_t^{*\frac{1}{x+1}} Q_{t-1}^{*\frac{x}{x+1}})^{\lambda} (e_{t-1}^R)^y + \\ + P_t k_{K^-} (Q_t^{*\frac{1}{x+1}} Q_{t-1}^{*\frac{x}{x+1}})^{\rho} (e_{t-1}^R)^y \Big] \times \\ \Big[P_t^* k_E (Q_t^{\frac{1}{x+1}} Q_{t-1}^{\frac{x}{x+1}})^{\delta} (e_{t-1}^R)^z + \\ + P_t^* k_{K^+} (Q_t^{\frac{1}{x+1}} Q_{t-1}^{\frac{x}{x+1}})^{\theta} (e_{t-1}^R)^z \Big]^{-1} =$$

$$= \Big[P_t (Q_t^{*\frac{1}{x+1}} Q_{t-1}^{*\frac{x}{x+1}})^{\rho} (e_{t-1}^R)^y \times \\ \times (k_I (Q_t^{*\frac{1}{x+1}} Q_{t-1}^{*\frac{x}{x+1}})^{\lambda-\rho} + k_{K^-}) \Big] \times \\ \times \Big[P_t^* k_E (Q_t^{\frac{1}{x+1}} Q_{t-1}^{\frac{x}{x+1}})^{\theta} (e_{t-1}^R)^z \times \\ \times (k_E (Q_t^{\frac{1}{x+1}} Q_{t-1}^{\frac{x}{x+1}})^{\delta-\theta} + k_{K^+}) \Big]^{-1}$$

Due to the significant stability of the members $(Q_{t-1}^{\delta/\delta+} Q_t^{1/\delta+1})$ and $(Q_t^{*\frac{1}{x+1}} Q_{t-1}^{*\frac{x}{x+1}})$, compared to price indicators P_{t-1}^* and P_t, we can consider as a constant the construct:

$$\frac{(k_I (Q_t^{*\frac{1}{x+1}} Q_{t-1}^{*\frac{x}{x+1}})^{\lambda-\rho} + k_{K^-})}{(k_E (Q_t^{\frac{1}{x+1}} Q_{t-1}^{\frac{x}{x+1}})^{\delta-\theta} + k_{K^+})} = k^{x+1} = const . \qquad (9)$$

Further, it can be rewritten as:

$$e_t = k^{x+1} \frac{P_t (Q_t^{*\frac{1}{x+1}} Q_{t-1}^{*\frac{x}{x+1}})^{\rho}}{P_t^* (Q_t^{\frac{1}{x+1}} Q_{t-1}^{\frac{x}{x+1}})^{\theta} (e_{t-1}^R)^{\delta}} =$$

$$= k^{x+1} \frac{P_t (Q_t^{*\frac{1}{x+1}} Q_{t-1}^{*\frac{x}{x+1}})^{\rho}}{P_t^* (Q_t^{\frac{1}{x+1}} Q_{t-1}^{\frac{x}{x+1}})^{\theta} (e_{t-1} P_{t-1}^* / P_{t-1})^{\delta}} = .$$

$$= k^{x+1} \frac{P_t (Q_t^{*\frac{1}{x+1}} Q_{t-1}^{*\frac{x}{x+1}})^{\rho}}{P_t^* (Q_t^{\frac{1}{x+1}} Q_{t-1}^{\frac{x}{x+1}})^{\theta} (e_{t-1})^{\delta}} \left(P_{t-1} / P_{t-1}^* \right)^x$$

So after regrouping we get:

$$e_t (e_{t-1})^x = \left(k \frac{P_t}{P_t^*} Q_t^{*\rho/x+1} Q_t^{-\theta/x+1} \right) \times \\ \times \left(k \frac{P_{t-1}}{P_{t-1}^*} Q_{t-1}^{*\rho/x+1} Q_{t-1}^{-\theta/x+1} \right)^x . \qquad (10)$$

After intertemporary separation of the fundamental economic variables in formula (10):

$$e_t = k \frac{P_t}{P_t^*} Q_t^{*\rho/x+1} Q_t^{-\theta/x+1} .$$

And after the designation $\theta' = \theta/x+1$ and $\rho' = \theta/x+1$ for convenience, we get:

$$e_t(P(t),Q(t),P^*(t),Q^*(t)) = k\frac{P_t}{P_t^*}Q_t^{*\rho'}Q_t^{-\theta'}. \quad (11)$$

4. Setting the Model Parameters and Verification

The starting point of the study of the medium-term exchange rate dynamics should be characterized by stability, both internal and external economic situation. More details can be found in the author's work [1].

We suggest that setting of the parameters ρ' and θ' can use the least squares method with a normalized differences of the nominal theoretical $e_t(\theta,\rho)$ and nominal market exchange rates under constraints $\rho' \geq 0$ and $\theta' \geq 0$:

$$ND(e)_t = \frac{e_t(\theta,\rho) - e_t(\text{nominal})}{e_t(\text{nominal})}. \quad (12)$$

At the starting point of the selected period it must be put: *P(start)=1, Q(start)=1, P*(start)=1, Q*(start)=1*. Coefficient k must be equal to the nominal market exchange rate at the starting point.

Next, the sum of normalized squared deviations (12) minimizes:

$$\begin{cases} \min\limits_{\theta',\rho'} \sum\limits_t \left(ND(e)_t\right)^2 \\ \theta' \geq 0 \\ \rho' \geq 0 \end{cases}. \quad (13)$$

In order to verify the model, it is advisable to consider the results in the context of the known results of economic theory of determination of the exchange rates.

For these intentions, let us rewrite formula (11) in logarithms:

$$\log e_t = \log k + (\pi_t - \pi_t^*) + \rho'\log Q_t^* - \theta'\log Q_t = \\ = \log k + (\pi_t - \pi_t^*) + \rho' q_t^* - \theta' q_t \quad . \quad (14)$$

Using the I.Fischer equation $PQ=MV$, where M is the money supply, V is the velocity of money, we present this in logarithms:

$$\pi = m + v - q\,.$$

Assuming in the medium term the rate of the velocity of money is constant and substituting (14) symmetrically for both countries, we obtain (with $a = \log k = const$)

$$\log e_t = \log k + (m_t + v - q_t - \\ -(m_t^* + v^* - q_t^*)) + \rho' q_t^* - \theta' q_t = \quad (15) \\ = a + (m_t - m_t^*) + (\rho'+1)q_t^* - (\theta'+1)q_t = \\ = a + (m_t - m_t^*) + \rho'' q_t^* - \theta'' q_t\,.$$

Verification of dependencies of a similar type (15), having the same system of fundamental macroeconomic factors, has been successful within the framework of verification of the monetary model. Of the works on this topic it should be noted econometric studies of models of fundamental determinants of B. R. Clarida et al. [12], J. Cheung, M. Chinn, and A. Pascual [13], I. Chowdhury [14].

It is also interesting to consider predictive abilities of dependencies of a similar type. One of the most famous is the study of J. Chen and N. Mark [15]. The forecasts for the formula of type (15) at $\rho'' = \theta''$ on different time horizons gave a significantly better result than in accordance with a random walk. And it was in the medium and long term.

5. Results and Conclusion

Exogenous variables are the total products Q and Q^* and the levels of external and internal prices P^*, P in the countries of the bilateral exchange rate in this model. Other basic intermediate determinants, such as export-import operations, capital flows, the terms of trade in the modelling process have been eliminated.

It should be noted here, that author's IFEER-concept of Equilibrium Exchange Rate (EER) correlates with the widely known economical concepts: behavioural EER (BEER) [16, 17] and fundamental EER (FEER) [18].

Using national consumer price and real domestic product indices and oil prices, the main research formula (11) was applied by the author to the study of the dynamics of the Russian ruble against the US dollar in the period 2013-2015. The results of econometric verification showed a very high quality of the model.

Thus, we can state the high practicality of models of fundamental determinants in relation to different currency pairs, based on both "real" (Russian ruble, US dollar, Canadian dollar, etc.) and "past" (German mark, French franc) currencies.

Conflict of Interest

The author declares no conflict of interest.

Blockchain Technology

ABSTRACT

With the advancement in the field of Internet-of-Things (IoT), event monitoring applications have rapidly evolved from a simple event data acquisition towards predictive event analytics involving multi-sensory data aggregation in a distributed environment. Existing event monitoring schemes are mainly relying on inefficient centralized processing mechanism, which may lead to the common single-point of failure for the entire system. In addition, there is no proper method for verifying the event data generated by the monitoring system. In this paper, we present a distributed event monitoring scheme using a Hierarchical Graph Neuron (HGN) distributed pattern recognition algorithm. HGN is a single-cycle learning graph-based recognition scheme that is modelled for in-network deployment. In this work, event data retrieved from multi-sensory IoT devices within a distributed event monitoring network is converted into pattern. To address the event data verification problem, we integrate our proposed scheme with blockchain technology. Combining this IoT event monitoring capabilities with blockchain-based data storage and verification could leads towards a scalable event detection and monitoring model for large-scale network. The results obtained from our simulation shows that the proposed scheme offers high event detection accuracy and capable of minimizing the event storage requirements on blockchain network.

1 Introduction

Since a decade ago, Internet-of-Things (IoT) has been extensively explored as a common platform for event monitoring. In industrial manufacturing applications, IoT plays an important role in monitoring and controlling processes. The monitoring systems designed for such applications require seamless interoperability between heterogeneous distributed IoT sensor devices and processing nodes, as well as an ability to analyze different types of sensor data.

The importance of such systematic interoperability may be conceptualized through an industrial scenario, wherein the plant maintenance is automatically scheduled by coordinating and synchronizing different sub-systems including distributed engineering, control, and maintenance sub-systems. Once a maintenance event is detected, the system can directly generate suitable downstream process controls, computed according to the applications requirements as to generate a correct response within the entire system.

A conventional way of performing event detection and monitoring usually involves a set of interconnected sensor devices that are linked to a centralized processing node (sink). These sensor devices made up the IoT infrastructure, enabling data acquisition process. With this method of implementation, common issues are related to communication and processing latency. Edge computing [1] is a form of computing model that enables data acquisition and processing to be performed within the close proximity of IoT devices.

Event monitoring involving critical applications such as environmental and disaster monitoring usually requires spatio-temporal data analysis for detecting unusual events or incidents. Machine learning and neural network algorithms are commonly being applied for such use cases. Nevertheless, these approaches involve complex computational procedures to be performed on resource-abundant processing nodes. In the context of large-scale and highly distributed IoT network, these approaches may not be suitable due to the resource-constrained specification of most IoT devices. Furthermore, massive data transmission may occur between the

[*]Anang Hudaya Muhamad Amin, Higher Colleges of Technology, P.O.Box 15825, Dubai, United Arab Emirates, +9712-2064772 & aamin@hct.ac.ae

sensor nodes and the processing node, due to large volume of data to be processed continuously.

A number of approaches have been carried out to enable complex machine learning and neural network algorithms to perform in a fully-distributed manner. However, most of the existing schemes suffer from the tightly-coupled processing mechanism in detecting and classifying event/non-event. Distributed algorithms that implement a graph-based approach show a promising way towards achieving purely-distributed processing mechanism.

Graph Neuron (GN) [2] is a distributed pattern recognition algorithm that follows the principles of graph theory with (vertex, edge) representation. GN algorithm has been implemented in several different case studies, including event recognition in wireless sensor networks (WSNs). GN performs a single-cycle in-network processing in its learning mechanism. As such, this improves its scalability against other graph-based pattern recognition schemes.

This paper is an extension of work originally presented in ICIAS 2018 [3]. In this paper, we extend our proposed idea on integrating a distributed pattern recognition algorithm and blockchain technology for event monitoring in IoT network. GN-based algorithm known as Hierarchical Graph Neuron (HGN) [4] is chosen as the distributed pattern recognition algorithm to be incorporated in the proposed IoT-blockchain infrastructure, enabling event detection and monitoring to be performed in a distributed manner, close to the event data acquisition point. Integrating blockchain network and IoT infrastructure allows the event signal or data from IoT devices to be stored and verified by blockchain nodes in the form of transaction using the distributed ledger mechanism. This approach provides a way to collect and preserve significant series of events that were captured and monitored by the IoT devices. Within this infrastructure, distributed pattern recognition could be implemented by identifying patterns of multiple sensor activation on IoT devices, and thus allowing complete transactions of event data to be recorded within the blockchain network.

The outline of this paper is as follows: Section 2 provides an overview on the current approaches towards distributed event monitoring. Section 3 focuses on the Graph Neuron (GN) based approach for event detection in a distributed environment. The model for integrated IoT-Blockchain platform for event monitoring is presented in Section 4. The proposed IoT-blockchain scheme with distributed pattern recognition for event monitoring is presented in Section 5. This section also includes description of the simulation works that have been performed. Finally, Section 6 concludes the paper.

2 Distributed Event Monitoring

A typical setup for distributed event monitoring network is shown in Figure 1. In this model, each IoT device act as an observer, which observe a stream of events. These observations would then be used for analysis involving either a simple function as collecting the number of observations or other complex computations such as identifying anomalies in the input distributions. Such computations usually being carried out by the coordinator node, who is overseeing the entire observations within the network.

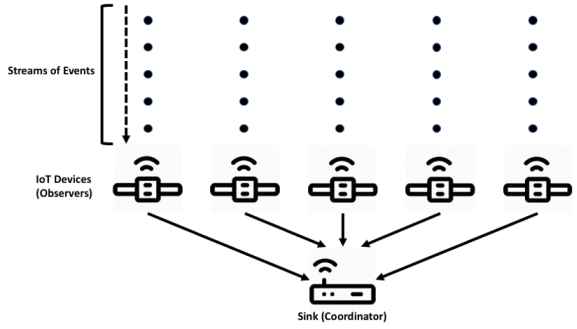

Figure 1: Distributed event monitoring setup with series of IoT devices as observers and processing node as coordinator.

There are a number of related works that demonstrate the distributed event monitoring activities carried out in different kinds of applications. These include the work by Wu et al. [5] and Ahmad Jan et al. [6].

In the survey conducted by Cormode [7], there are two approaches in deriving useful computations for the observations obtained from the sensor/IoT network. The first approach involves all the observers to simply send all the observations to a single and centralized coordinator. A drawback of such approach is such that it burdens the communication network between the coordinator and the observers. A second approach implements a periodic polling, in which at a particular time interval, the coordinator polls each observer for information on the observations and collates this information to get a snapshot of the current status since the last poll. A limitation of this approach is that it does not fit well, when considering event analysis using a non-linear computational model as in the continuous event monitoring applications.

The current centralized event monitoring systems that implement such coordinator-observer model can be seen in the works recorded by Ahmad Jan et al. [6] usually suffer from several limitations. Firstly, centralized event data processing can lead towards single-point of failure whereby failure of centralized node basically fails the entire event monitoring activity. Secondly, magnitude of data transmission to a central repository would be significantly increased as a result of massive number of IoT devices connected. This phenomena creates a connection gridlock from IoT devices to the centralized server.

Apart from the coordinator-observer model, other scheme such as presented by Basirat and Khan [8] utilizes the in-network processing capabilities that enable each IoT device to perform computation on observations within the body of the network, without relying on a centralized data processing node. With the in-network processing model, each IoT node is responsible for collecting the observations, as well as performing data aggregation. Analysis is carried out within the collaborative effort by each node, in exchanging critical information obtained from the observations.

Event monitoring with pattern recognition approach is widely applied in different application fields such as health informatics, manufacturing automation, and structural monitoring. Distributed pattern recognition algorithms such as Graph Neuron (GN) [9] and Vector Symbolic Architecture (VSA) [10] offer better schemes towards improved event

monitoring capability that runs on a distributed processing environment.

The proposed Graph Neuron (GN) based approach for event monitoring utilizes the in-network processing model that enables event identification to be conducted within the body of the network, rather than complex analysis and computations being performed at the processing node (coordinator). Discussion on how GN implements such processing model will be discussed in the next section.

3 GN-Based Approach for Event Monitoring

Graph Neuron (GN) is a single-cycle learning distributed pattern recognition algorithm that utilizes the in-network processing model [11]. The main characteristic of any distributed pattern recognition is such that it requires recognition of patterns to be implemented in a decentralized manner. Graph Neuron with similar feature, has been designed for fully-decentralized event detection scheme.

GN algorithm utilizes the graph-like pattern representation with each element of the pattern is represented with a *(value, position)* format. A variation of GN algorithm with hierarchical structure, known as Hierarchical Graph Neuron (HGN) was later developed by Nasution and Khan [4] that eliminates the crosstalk issue in GN implementation. In this paper, we present our proposed approach of utilizing HGN algorithm for distributed event monitoring on multi-sensor IoT devices.

3.1 Hierarchical Graph Neuron (HGN)

Hierarchical Graph Neuron (HGN) algorithm extends the functionality of Graph Neuron (GN) algorithm by increasing the pattern matching accuracy for highly-distorted patterns. HGN has been proven to eliminate the crosstalk issue found in GN implementation. The neuron firing in GN relies on the comparative function between stored and input elements on each neuron, which is called bias entry. These entries composed of *(value, position)* pairs that represent pattern elements. The approach is completely different from conventional neural network schemes whereby firing of neuron is based upon weight adjustment and calibration. Figure 2 shows a typical HGN network composition.

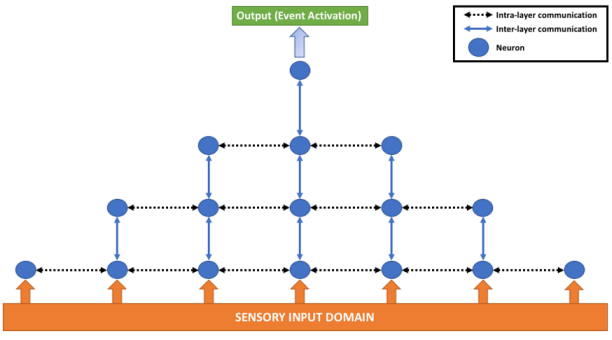

Figure 2: HGN network composition in a pyramid-like formation. Each neuron at the base layer corresponds to each input element within the sensory domain.

As shown in the figure, neurons composition in HGN network are arranged in a pyramid-like structure with base layer neurons act as input neurons to the network.

3.2 HGN Learning Mechanism

The neurons composition in each HGN network, n_{hgn} is represented by the following equation:

$$n_{hgn} = \left(\frac{p+1}{2}\right)^2 \tag{1}$$

Where p represents the number of input elements within the sensory input domain.

Following the graph-based structure, each neuron in HGN network composition forms a vertex that contains pattern element information (value or identification (ID)) while the adjacent inter-neuron communication is represented by the edge of a graph.

The HGN learning mechanism involves finding matched indices between input and stored patterns. In performing this comparison, each neuron compares its input pattern with the inputs obtained from its adjacent neurons. Adjacency information for each neuron is represented using the *(left, right)* formation. This adjacency information is known as bias entry and each neuron maintains an array of such entries. Each neurons bias array only stores the unique adjacency information derived from the input patterns. The pattern storage process involving N bias array sizes is represented in the following equation:

$$E^B = (\langle x, y \rangle; x \in N, y \in N) \tag{2}$$

Where E^B, comprises the sets of two-element ordered pair respectively, while x and y are the inputs within each entry. E^B can also be formed as one- or three-element ordered pair, depending upon the neuron location within the HGN hierarchical structure.

In retrieving matched bias entry, a linear search method is used on the adjacency information obtained for a given input pattern within each neuron through the bias array composition. The bias array entry is unique. Thus, the following equation shows a function to estimate the required number of comparisons for each input entry C_i, given n_{bEnt} number of bias entries in the array and r number of occurrences for each entry:

$$C_i = \frac{n_{bEnt} + 1}{r + 1} \tag{3}$$

In principle, HGN implements a single-cycle learning for recognizing patterns, through implementation of a graph-matching scheme on its pattern representation. Within HGN network composition, each neuron performs a forward propagation of index values obtained from the matching process as shown in Figure 3, from the base layer neurons towards the top neuron. The top layer neuron will decide on the event/non-event status based on the entire pattern recall search on the bias array composition. The procedures only involved a one-pass cycle for each input pattern, without any iterations involving value alteration as to obtain a recognition output.

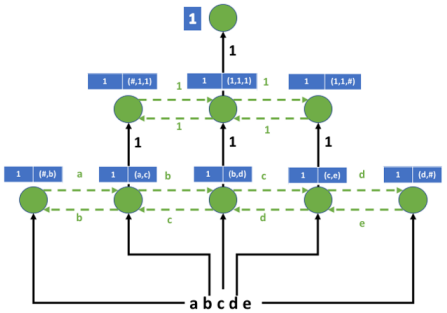

Figure 3: Neuron firing mechanism within the HGN network composition. Neuron activation is achieved through value comparison between adjacent neurons.

3.3 HGN for Event Monitoring

With distributed and lightweight features of HGN, an event detection scheme for IoT network can be carried out at the IoT device level. It could act as a front-end middleware that could be deployed within each IoT nodes in the network, forming a network of event detectors. Hence, the processing scheme minimizes the processing load at the sink and provides near real-time detection capability. Preliminary work on distributed HGN integration for distributed networks such as wireless sensor network (WSN) has been conducted by Muhamad Amin and Khan [12].

In integrating HGN within event monitoring, we have considered mapping each HGN processing cluster into each IoT node, with the assumption that each node is having more than one sensor inputs. Our proposed scheme is composed of a collection of IoT nodes and a sink. We consider a deployment of IoT network in two dimensional plane with M sensors, represented by a set $M = (m_1, m_2, ..., m_n)$, where m_i is the ith sensor. The placement for each of these sensors is uniformly located in a grid-like area, $A = (x \times y)$, where x represents the x-axis coordinate of the grid area and y represents the y-axis coordinate of the grid area. Each IoT node is assigned to a specific area of the grid as shown in Figure 4. The location of each sensor node is represented by the coordinates of its grid area (x_i, y_i).

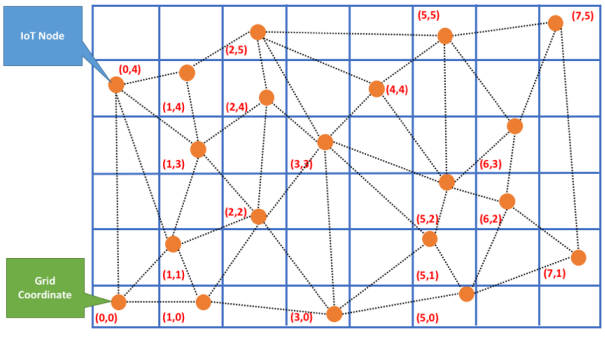

Figure 4: Cartesian grid layout used to identify location of IoT nodes in a two-dimensional space.

For communication model, HGN uses a single-hop mechanism for data transmission from IoT node to the sink. The use of *autosend* approach has been selected following the work by Saha and Bajcsy [13], to minimize error due to the loss of packets during data transmission. HGN event processing scheme involves minimal transmission of event data from IoT nodes to the sink, due to the ability for the front-end processing.

4 Integrating Blockchain in Distributed Event Monitoring

In this section, we present an overview of blockchain and its integration with the distributed event monitoring framework on IoT network.

4.1 Blockchain Technology

Blockchain provides a capability for verification of credentials and transactions using a distributed ledger mechanism. Such capability is of interest, especially when considering its integration with event monitoring system in IoT network.

Implementation of blockchain is not strictly limited to cryptocurrencies. In fact, there are many differences between cryptocurrency implementation and blockchain for industrial applications [14], including immutability and provenance. Blockchain has also been a point of interest in the field of shared economy applications (e.g. Uber, AirBnB) [15]. Nevertheless, past implementations of blockchain come with several limitations, including slow block generation period as mentioned in the Ethereum White Paper [16] and lack of loop implementation (Turing incomplete) [17]. Blockchain enables a decentralized mechanism for verification that allow participating nodes in the network to validate unique transactions through a distributed ledger (block). Figure 5 shows the decentralization approach in blockchain, in comparison with existing centralized approach.

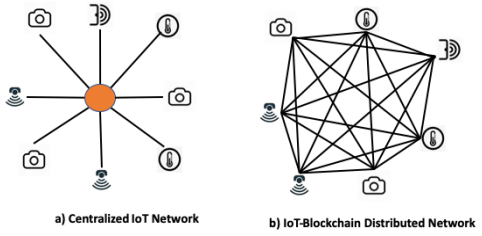

Figure 5: A comparison between conventional IoT network with IoT-Blockchain distributed network.

One of the important requirements for IoT integration on blockchain network is such that it requires fast validation and verification to be performed on blockchain network. Existing blockchain network such as Ethereum [18] has made this possible. Ethereum offers a smart contract deployment, as shown in Figure 6. It captures details of transactions including the value and its corresponding state. Developers can write a program that runs on top of Ethereum. With Ethereum as a blockchain platform, we can configure IoT devices to connect to this main network. This infrastructure would allow authentication of IoT devices through public key

infrastructure. IoT devices can utilize Ethereum platform for updating their action and behavior.

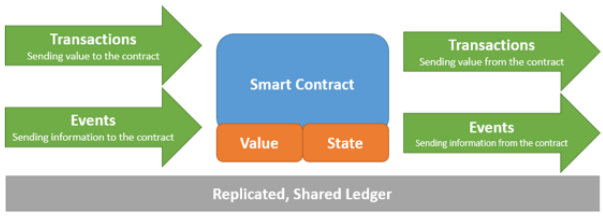

Figure 6: Smart contract deployment on Ethereum platform that captures details about transactions and events.

4.2 Device Synchronization

One of the important issues to be addressed in IoT network implementation within the IoT-Blockchain environment is device synchronization. As the number of devices increased, the need for proper synchronization mechanism is important. A work presented by Huh et al [19], demonstrated the synchronization of IoT devices on Ethereum blockchain network can be obtained using smart contract feature, which specify certain action and behavior of IoT devices. The smart contract can be used to place a code to indicate the detection of event by the IoT device.

In this paper, we demonstrate the use of blockchain network for the purpose of event data monitoring and verification. Blockchain offers immutability to the event data being captured from IoT network. Within the proposed model, sensor data are converted into activation patterns as shown in Figure 7.

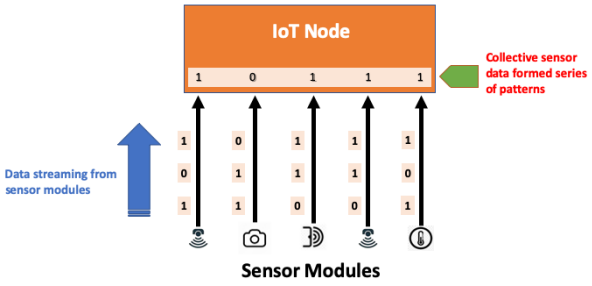

Figure 7: Inputs from sensor modules are treated as a pattern, to be processed by the IoT node.

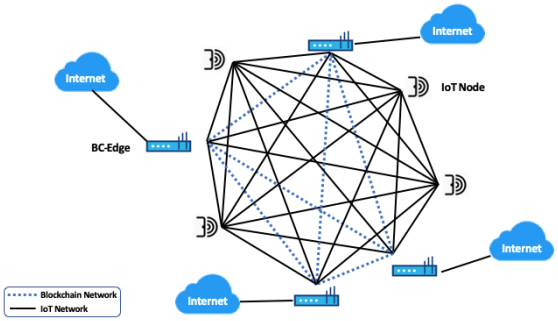
From the temporal perspective, this sensor data patterns vary across time. Our aim is to capture unique event data to be stored and verified on blockchain network. HGN distributed pattern recognition scheme is used to detect unique event, prior to storage and verification on blockchain network. In this work, similar data patterns would be treated as non-event and will be discarded. The hypothesis for this work is such that the block generation could be minimized accordingly.

5 Proposed Infrastructure

In this section, we present our proposed IoT-blockchain with distributed pattern recognition framework for event detection and monitoring. In addition, this section will also include details on the simulation works and corresponding results involving forest fire detection using HGN distributed pattern recognition scheme.

5.1 System Model

The proposed event monitoring infrastructure incorporates a distributed pattern recognition on IoT- blockchain network. Hierarchical Graph Neuron (HGN) has been selected as the distributed pattern recognition algorithm to be used in our model. In this implementation, assumption is made as such that each IoT node is capable of performing event data collection. Each IoT node is linked to a blockchain-edge (BC-Edge) node that hold a distributed ledger, as part of the blockchain network. Figure 8 shows the proposed infrastructure for HGN deployment in IoT-blockchain network.



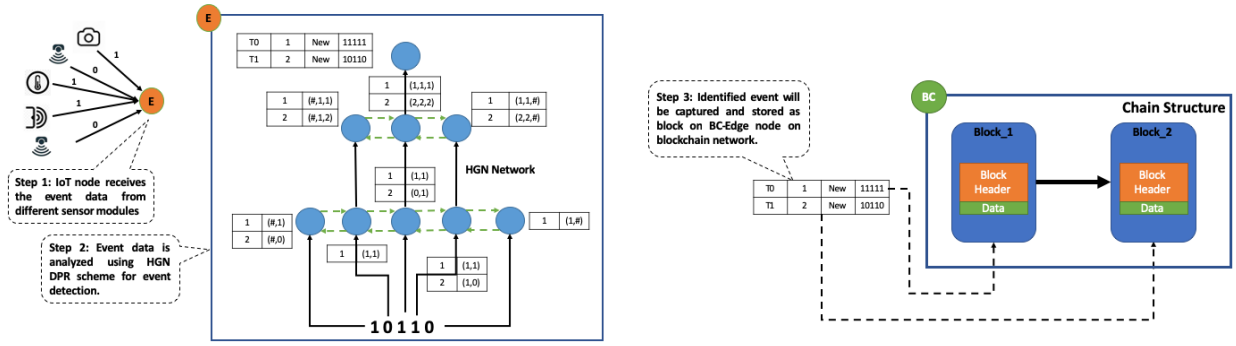


Figure 8: IoT-Blockchain network infrastructure for distributed event monitoring.

Note that the proposed scheme considered the use of multi-sensory IoT devices. Event monitoring is basically carried out at the device level, in which each device is capable of performing event detection using the HGN distributed pattern recognition algorithm. Figure 9 shows the detail event detection and verification procedures on IoT-blockchain network.

The network configuration used in this work is based upon the premise that all the nodes acquired communication capability with low latency in a full-mesh network structure.

In the proposed design, an IoT node N will establish its identity, and broadcast it to the BC-Edge nodes, B. For a given specific time interval T, the IoT nodes will communicate the event data (result from event activation using HGN scheme). This will then be processed by the BC-Edge node as event data for T. The analysis produces an output in the form of combined pattern index, event status, and event pattern as shown in the examples in Table 1. The event status contains information on the event, whether it is classified as new or recalled. Using this approach, only newly-recorded event will be stored and verified in the blockchain network.

As shown in Table 1, at T_2, event detected by IoT node *X02* is recalled and will be discarded. Similarly, at T_3, event

(a) Event data monitoring and detection.

(b) Unique event storage and verification on blockchain network.

Figure 9: Event monitoring with HGN distributed pattern recognition on integrated IoT-blockchain network.

Table 1: Outputs recorded by BC-Edge node, retrieved from the IoT nodes. Note that only unique event pattern will be stored in the blockchain network

Timestamp	IoT Node ID	Event Pattern	Index	Status
T_1	X01	10101	1	new
T_1	X02	11111	1	new
T_2	X01	10111	2	new
T_2	X02	11111	1	recall
T_3	X01	10111	2	recall
T_3	X02	11110	2	new

recorded by *X01* is recalled. Only unique event pattern will be captured and stored in the distributed ledger.

5.2 Event Monitoring Simulation

To demonstrate our proposed distributed event monitoring scheme, we designed a simulation work on event data analysis using the HGN algorithm. The analysis was conducted on the data related to forest fire, which contains 517 records as reported by Cortez and Morais [20]. Each event pattern detected was stored and verified using the SHA-256 secure hash algorithm on blockchain network.

We extracted five important features that contribute towards possibility of fire ignition, namely the ISI index, temperature, relative humidity (RH), wind and rain. For the purpose of simulation, the dataset is transformed into a binary representation using an interactive binning method. The range of values for each bin was specified according to the potential event (binary value 1) and non-event (binary value 0) as shown in the Table 2.

Table 2: Data values in different range used to identify each parameter as event.

Parameter	Data Range 1	Data Range 2
ISI	$x \geq 42.075$	$x \leq 14.025$
Temperature	$x \geq 23.325$	$x \leq 7.775$
Relative Humidity (RH)	$x \geq 63.75$	$x \leq 21.25$
Wind	$x \geq 6.75$	$x \leq 2.25$
Rain	$x \geq 4.8$	$x \leq 1.6$

Our assumption is such that the event data is continuous and recorded in a timely manner from T_0 till T_{516}, respectively.

5.3 Results and Discussion

In this section, we present the results of our simulation on event pattern recognition using the Hierarchical Graph Neuron (HGN) approach. The proposed scheme capable of detecting 19 unique events from the total of 517 event records. Consequently, the number of data blocks generated is reduced by 97%. This was made possible by identifying unique event patterns from the dataset. Figure 10 shows the event count distribution based on the 19 unique events detected using the proposed HGN distributed pattern recognition scheme.

Table 3 shows samples of event data for each corresponding unique event detected using our proposed HGN recognition scheme.

Apart from implementing the event data classification using HGN approach, we extended our analysis to examine the accuracy of our proposed recognition scheme on the simulated dataset. Based on the observation made, there were 40 event data that were misclassified as false positive (duplication of indices). As a result, the recognition accuracy for HGN in this simulation is at the rate of 92.3% with error rate of 7.7%. Further details on the misclassification can be seen in [21].

The simulation work that has been carried out demonstrate a high recall accuracy for HGN distributed pattern recognition implementation. The error rate for the event classification obtained is considerably low, as it only indicates value around 7.7%.In addition, the results prove that the number of unique events detected is significantly reduced. This is critical for ensuring efficient data block generation

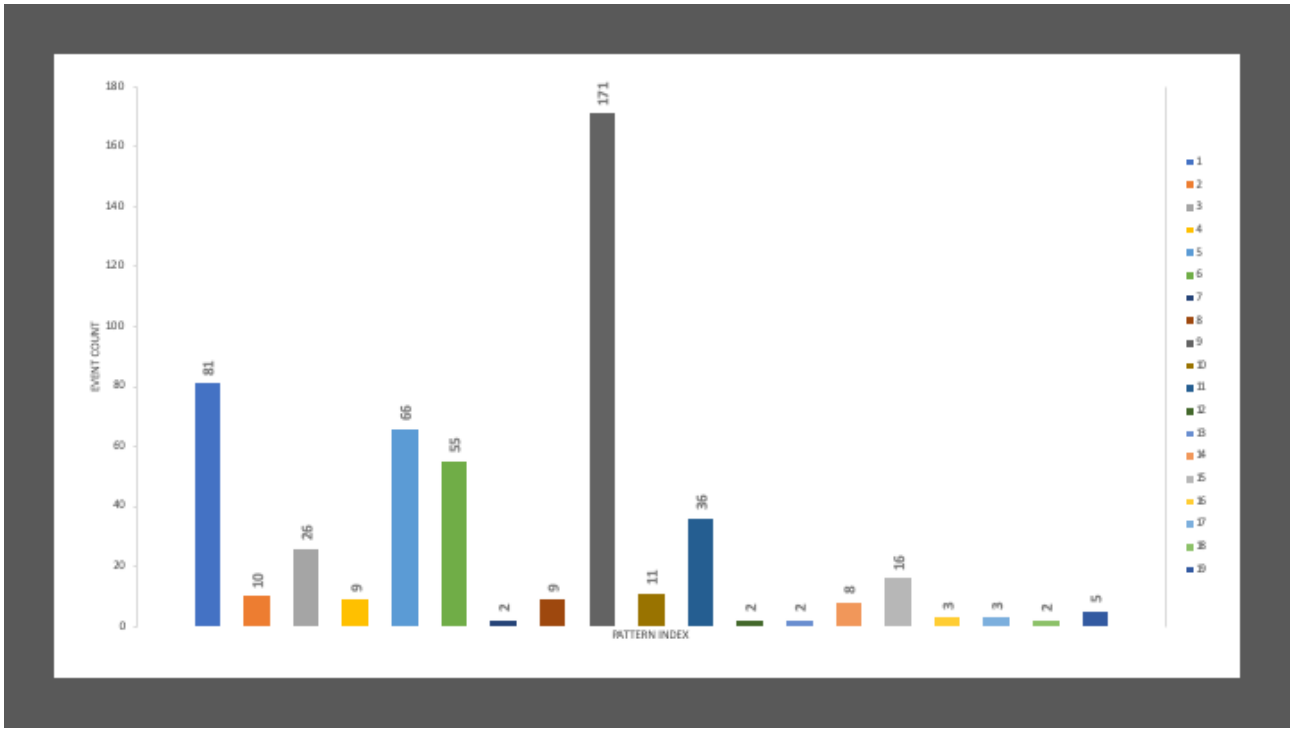

Figure 10: Unique event patterns detected using HGN distributed pattern recognition algorithm from the total of 517 event data recorded.

Table 3: Samples of forest fire event data that has been classified as unique event using HGN distributed pattern recognition algorithm.

Event ID	ISI Index	Temperature (°C)	Rel. Humidity (RH) (%)	Wind (km per hour)	Rain (mm per m^2)

within the blockchain network.

5.4 Future Work

Based on the simulation work that has been carried out, it was clearly indicated that the HGN distributed pattern recognition scheme is able to provide accurate classification of unique events. Our future work is basically to fully integrate the event classification module with blockchain network for event data storage and verification. The use of open-source hyperledger fabric platform [22] under the Linux Foundation Projects will be considered.

We intend to expand our research into effective scheme for data storage on blockchain. As the amount of data arises from events monitored on IoT network, the need for efficient data storage mechanism is important. At a preliminary stage, we propose a two-type storage mechanism, comprising event digest and event data. Event digest will be permanently stored in the blockchain network in the form of recorded blocks (on-chain), while the event data will be stored in conventional databases (off-chain). In implementing this scheme, it is expected that the storage requirement for event data could be further reduced.

In addition to the storage optimization, we would also aim to study on different consensus mechanisms for data verification on blockchain network. These include the proof-of-work (PoW) and proof-of-stake (PoS). The consensus mechanism enables peers and users within the network to verify the authenticity of the data that is stored on the blockchain network. Results of the study would assist us in implementing more efficient IoT-blockchain infrastructure for event monitoring on ioT network.

6 Conclusions

In this paper, we presented our on-going work on distributed event monitoring using a distributed pattern recognition algorithm on integrated IoT-Blockchain network. The proposed scheme implements a HGN recognition algorithm that performs a distributed event detection. Accuracy of HGN pattern recognition may improves the efficiency of distributed ledger storage mechanism in blockchain network. This enables unique event data to be stored and verified in a distributed environment. The simulation work being carried out shows that HGN algorithm exerts high recall accuracy with one-cycle learning. Furthermore, the algorithm is highly-suitable for in-network deployment.

HGN recognition approach also minimizes the needs for storing large amount of continuous event data on blockchain network. The detection mechanism in the proposed scheme also consider the entire state of the IoT network, rather than examining individual sensor input values.

For our future development, we intend to look into several aspects of IoT-blockchain integration, including the efficiency and effectiveness of the proposed scheme, through the scalability factor of the system in implementing multi-heterogeneous IoT-blockchain network. Apart from this, different consensus mechanisms in blockchain technology will be reviewed to analyze their effectiveness in the proposed IoT-blockchain scheme.

ABSTRACT

Popularity and affordability of smart phones and other data hungry devices add exponentially to the traffic demand of existing cellular networks. Cell densification and small cell deployment over existing macrocell has been identified as an effective solution to high traffic demand predicted for future wireless networks like 5G. Small cells are deployed over existing macrocells in a Heterogeneous network to offload traffic, ensure balanced load and good quality of service in the network. To achieve the purpose of HetNet, small cells are deployed in locations of high user concentration. Operators are required to be able to identify these locations for optimum small cell deployment. Presently, this decision is based on long term traffic data which create latency in small cell deployment especially in areas of unexpected hotspots. The work presented in this paper is a new strategy that can practically help operators to promptly identify locations for small cell deployment based on user cluster. This strategy involves a monitoring system that can be easily incorporated in a mobile cellular network base transceiver station (BTS) to monitor the coverage area and periodically identify positions for prompt and optimum small-cell deployment in HetNets. The monitoring system is a two element array system that uses RSS data to resolve DoA, range, user cluster and identify positions for small cell deployment. At any point in time, the network operator can visualize cluster locations relative to the base station and is able to identify hotspots. When small cells like micro-, pico-, or femto-cells are promptly deployed in areas of higher user concentration, high data rates and good quality of service in the network are maintained at all times. The network coverage area is divided into a series of azimuthal and range sectors, and users are located into the sectors where they belong. The strategy was simulated in MATLAB environment for WiFi networks with thirty users and results indicate 100% *accurate DoA estimation and MAE in range estimation of* 6*m for a known environment. Optimum positions for small cell deployment based on user clusters were correctly determined. Simulation was validated with experiment and result indicate close relationship between experiment and simulation with MAE difference in range estimation of* 1*m.*

1 Introduction

The exponential growth in data traffic demand on cellular networks and the promising solution offered by heterogeneous network and small cell deployment has triggered a lot of research interest in this area. It is obvious that homogeneous networks involving macro- only cells are insufficient in solving the capacity requirement of the present and future networks like 5G. This is due to high cost of macrocell BTS and the unavailability of cell sites especially in city centers. Small cells like micro-, pico- and femtocells are therefore deployed within the existing macrocell and integrated as a heterogeneous network. These small cells are cheaper to implement and site acquisition is also easier to get since even an existing electric pole or building roof is a potential site. Deploying small cells within existing macrocell gives rise to a big umbrella cell with a number of small cells, each positioned to serve a smaller coverage area within the big

cell as shown in Figure 1.

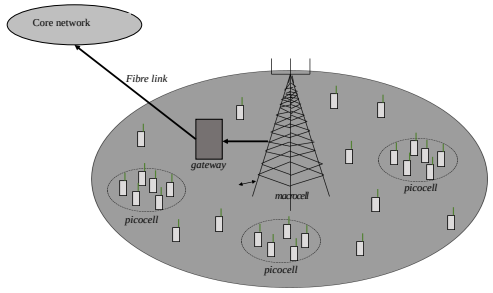

Figure 1: Heterogeneous network showing an umbrella macrocell with deployed picocells forming a 2-tier HetNet

Three main aim of heterogeneous network are (1) To offload traffic from macrocell, (2) Ensure balanced load in the network and (3) Ensure good quality of service to users. To achieve these objectives, small cells are deployed in a well targeted manager in most cases within locations of high user concentration (HUC). This therefore requires the network operators to be able to identify locations of HUC. Presently, these locations are determined using collected traffic data over a period of time and locations with high traffic demand is taken as HUC and position for small cell deployment. This approach does not give opportunity for prompt traffic offload, balanced load and good QoS using small cells especially in unexpected hotspot cases. This paper is an extension of the work originally presented in International Workshop on Computer Aided Modeling and Design of Communication Links and Networks (CAMAD) [1] which introduced the system based on simulation only. The work presented in this paper presents the application of the previous work as a strategy for prompt identification of optimum position for small cell deployment. Both simulation and experimental validation are presented to demonstrate the applicability of proposed strategy.

Strategies for small cell deployment can broadly be classified as Random Deployment Strategy (RDS) and Deterministic Deployment Strategy (DDS). RDS in most In RDS, small cells are randomly deployed within the macrocell while in DDS, the position for small cell deployment is determined based on some standing factors. Network performance for DDS and RDS was compared in [2] and their result indicate that DDS is a better option. Well targeted small cells has been shown to enhance QoS, offload traffic from macro-cell [3], ensure balance network load [4], improve energy saving capability and generally optimize performance [5] of the network. DDS can further be classified into uniformly distributed strategy (UDS), Cell edge strategy (CES) and user aware strategy (UAS). In UDS, a predetermined pattern of small cell deployment is followed for all macrocells owned my the network operator [6]. For CES approach, Small cells are arranged around the macrocell edge [7]. In UAS, locations of users are considered for small cell deployment based on usage or population. Normally, these data are obtained from long term traffic information [8] which does not provide prompt response to capacity requirement of hotspots especially when they are unexpected. Hotspots are locations of high demand characterized by high user concentration. A mobile small cell deployment strategy for unexpected hotspots which will ensure prompt response to traffic was proposed in [9] but with the assumption that network operators are able to promptly identify hotspot locations. To the best of our knowledge, there is no existing small cell deployment strategy with hotspot identification which is the contribution of this paper.

2 Problem Statement and Proposed Strategy

Considering a macrocell of a cellular network with 360° coverage. Looking at only 180 degrees coverage of this network as illustrated in Figure2 with base station (BS) located as indicated with red dot. Assuming there are so many users causing traffic overload on the existing macrocell and low quality of service (QoS) resulting to customer dissatisfaction. Some locations in this network are characterized with obvious clusters of users within the cell causing an overload on the macrocell base transciever station servicing this area. The strategy proposes a monitoring system to be deployed on the BS tower to monitor the coverage area so that it divides the area into azimuthal and range sectors as shown in Figure 2. By locating users into the individual azimuth-range classes, positions with HUC can be identified for small cell deployment. With blind or random placement of small cells in this network, the uncertainty of achieving the objective of HetNet will be high but with a monitoring system, it is almost certain that optimal placement of small cell based on user concentration will be achieved.

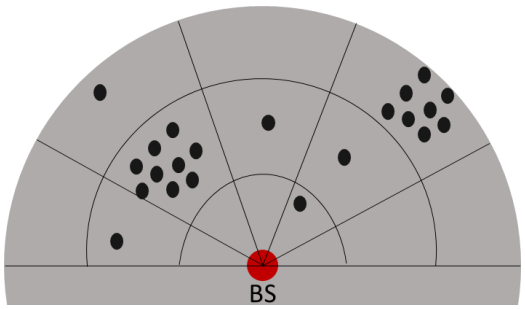

Figure 2: The proposed strategy for prompt small cell deployment

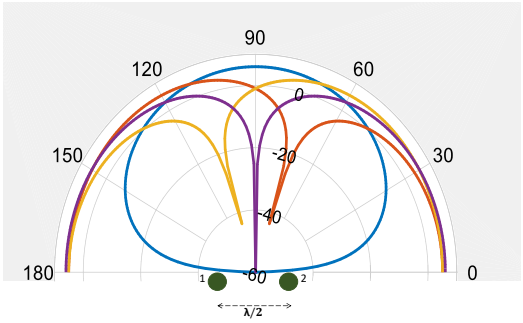

Figure 3: The proposed strategy for prompt small cell deployment

Assuming a two element array system is used for monitoring so that a directional main beam is produced on az-

imuth and steered to other azimuth locations as shown in Figure 3. This creates azimuth locations differentiated by main beam positions for angle of arrival localization of network users. By sharing the network coverage into range classes relative to the BS and estimating user range, users are located into different azimuth-range classes and users clusters can be identified.

3 User Cluster Localization and Optimum Position for Small Cell Deployment

To localize users by cluster, the system first estimates the DoA of each user. This is based on the azimuth position from where the maximum RSS was calculated when compared with measured RSS from other beam steered azimuth positions. It should be noted that the estimated DoA is not a precise estimate but considering the application, only a sector estimate is required. Second the system estimates range of each user using a range estimation model that is based on RSS-distance relationship. By fitting a curve in least square sense, a mathematical model that is applied for user range estimation is obtained. Combining estimated DoA and range, users are classified into created azimuth-range classes of the network.

3.1 Simulation

To test the proposed strategy, thirty users were randomly distributed within a simulated network coverage area as shown in Figure 4. The aim is to determine locations of user cluster and optimum positions for small cell deployment based on number of users in each cluster.

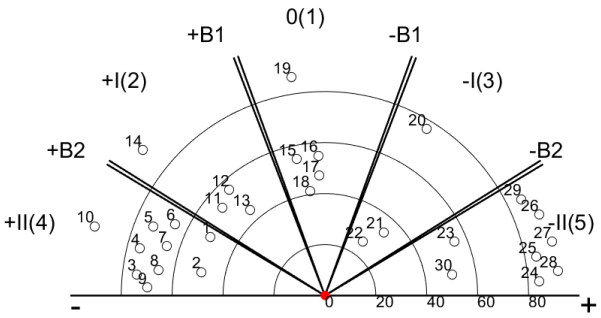

Figure 4: Actual location of users before localization

Assuming the network channel to be FSPL environment, the system acquires data for localization by calculating user RSS from all four main azimuth positions. Figure 5 is a plot of calculated RSS from all four main beam positions. From the calculated RSS data, it can be seen that different RSS values are measured from each azimuth position with a unique maximum value for each user. Using the calculated RSS, user DoA is calculated based on the azimuth position with highest calculated RSS for each user. Estimated DoA result of each user is shown in Figure 6.

Comparing the result of Figure 6 with the actual user locations of Figure 4, it can be seen that all users were correctly located to the azimuth position where they belong. Considering the accuracy of DoA estimation as the ability to locate users into each of the created azimuth sectors, this result gives 100% DoA estimation accuracy.

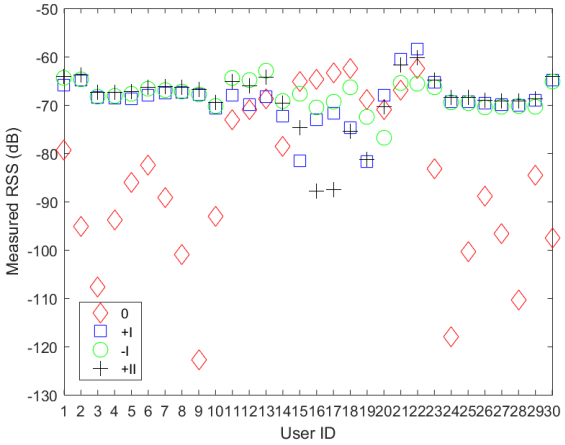

Figure 5: System simulated RSS from user devices in four main azimuth positions showing possibility of classifying DoA based on maximum RSS

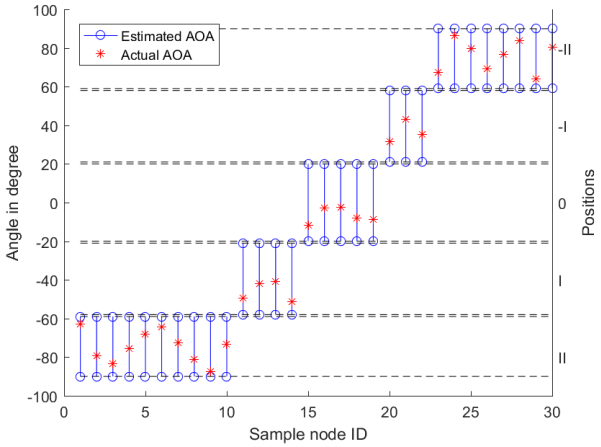

Figure 6: Estimated user DoA showing correct azimuth position localization of all users in the Network

To test the range estimation, four different environments, FSPL, HATA, ITU and WINNER defined by their empirical pathloss models of Equations 1, 2, 3 and 4 respectively were considered.

$$PL_{FSPL} = -27.5 + 20\log(f) + 20log(d) \quad (1)$$

$$PL_{HATA} = -35.4 + 20\log(f) + 26log(d) \quad (2)$$

$$PL_{ITU} = -28 + 20\log(f) + 20log(d) \quad (3)$$

$$PL_{WINNER} = -29.8 + 20\log(f) + 21.5\log(d) \quad (4)$$

where f is radio wave frequency in MHz, d is distance between BTS and user in meters. These environments were modeled and range estimation model developed for each environment. Using the measured RSS from FSPL environment, the four range estimation models for FSPL, HATA, ITU and WINNER were applied to estimate user range. Figure 7 shows the actual user range with the result of estimated range using these range models. To determine which of

the network location area is the optimum position for small cell deployment, users are classified into each of the sectors based on the estimated DoA and range. By counting the number of users in each class, user population per class is determined. Based on a preset threshold of number of users for small cell deployment depending on the type of small cell for the network, the optimum position for small cell deployment is determined. Assuming a micro-picocell network where a picocell is deployed in positions with atleast six users, optimum positions for small cell deployment in the simulated network are obtained as shown in Figure 8.

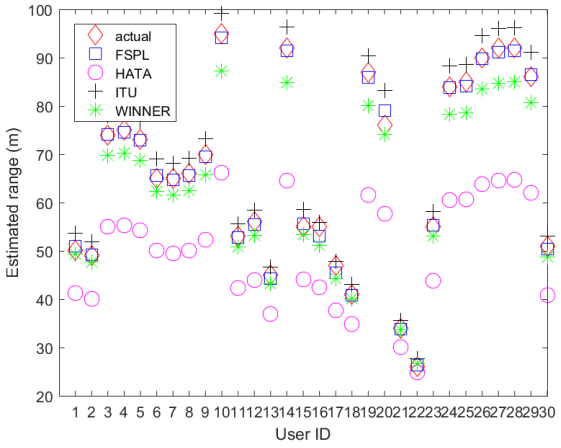

Figure 7: Estimated range of users using all four environment range estimation models for calculated RSS in FSPL environment

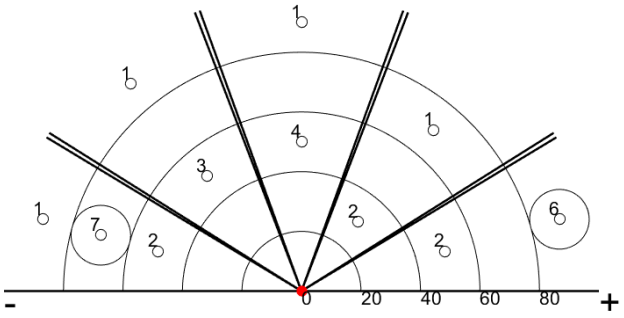

Figure 8: User cluster localization and optimum small cell deployment position identification

The range estimation result of Figure 7 gives a mean absolute error (MAE) of approximately 6m, 16m, 10m and 7m using FSPL, HATA, ITU and WINNER range models respectively. FSPL environment has given the least error in estimation because RSS was calculated in FSPL environment. This means that if the environment is known, the system is able to determine range estimation up to an accuracy of 6m but if the environment is unknown, the error in range estimation can increase up to 16m. By visually observing the result of Figure 7 and considering range estimated using FSPL range estimation model, it can be seen that users with ID numbers 1 to 10 and 23 to 30 located at azimuth positions +II and -II respectively were located with error in range estimation lying between 0 and 1m. Users with ID 11 to 14 and 20 to 22 located at azimuth positions +I and -I respectively were located with range estimation error between 1m and 37m. This is an indication that in a switched beam based localization systems, range estimation is azimuth position dependent. This will further be investigated in future work. Result of Figure 8 shows that user cluster and positions for small cell deployment can be determined.

3.2 Experimental Validation

Experiment was performed outdoor in the open field space of Ponderosa park in Sheffield, UK using a network of WiFi nodes as users. Figure 9 is a picture of the experimental setup. Figure 10 shows a model of the experimental environment with deployed users in their actual positions.

Figure 9: Outdoor experimental setup showing some of the distributed users on red and deployed observer system on yellow

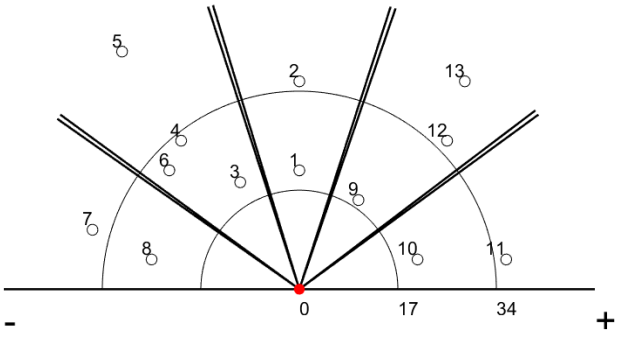

Figure 10: A model of the actual user position before localization

Ten RSS of these users were measured from a reference point where the monitoring system was positioned. Mean of the experimental measured RSS for each user from four main azimuth positions were obtained and plotted as shown in Figure 11. Using the measured RSS, DoA of users were estimated and result shown in Figure 12. Using the same measured RSS, user range were estimated using four range models representing four different environment scenarios. Result of Figure 13 shows actual, ITU simulated and experimental estimated range of users using all environment models. Next is to locate user clusters and identify locations for small cell deployment based on set threshold. Since only few (thirteen) users were used in this experiment, it was assumed that locations with up to two users are qualified for small cell deployment. Due to the small experimental area, coverage area was shared into three range sectors. Combining the estimated DoA and range, users are classified into

clusters by counting the number of users in each azimuth-range sectors of the coverage area. Figure 14 is result of experimental localized user clusters.

4 Result Analysis and Discussion

Comparing the actual user azimuth positions and the DoA estimation result of Figure 12, it can be seen that all users were correctly localized to their azimuth positions. Result has shown 100% accuracy for the used sample of users which validates the simulation DoA estimation result.

Result of range estimation shown in Figure 13 gives a mean absolute error (MAE) between actual and experiment of 2.51m, 3.56m, 2.19m and 2.54m for FSPL, HATA, ITU and WINNER open space range models respectively. This shows that the environment of RSS measurement is closely related to ITU model than other used range models. Comparing simulation and experiment, MAE in range estimation between experiment and simulation in ITU environment is 1.36m. This means that the mean deviation of experiment from simulation is approximately 1m and 2m from actual range. This shows that range estimation is achievable with manageable error levels. Apart from HATA which has a model that is well deviated from others, all other models are on the average, about 2.5m close to actual range. Deviation of experiment from simulation is just approximately 1m which means that this strategy is applicable and would work as modeled in simulation with a mean difference of $\leq$ 1.5m of range estimation in most known environments.

Comparing result of Figures 14 with the actual user positions, four small cell deployment locations were identified instead of two. This is due to over estimation of two of the users as a result of noise in measurement. This error may have been caused by the drizzling weather condition during this experiment. Also with few users and small number of users for small cell deployment as used here, this is expected but with a practical higher number of users required for small cell deployment in a real cellular network, this discrepancies will be reduced. The possibility of user cluster and small cell deployment position identification is promising with the results obtained from this experiment.

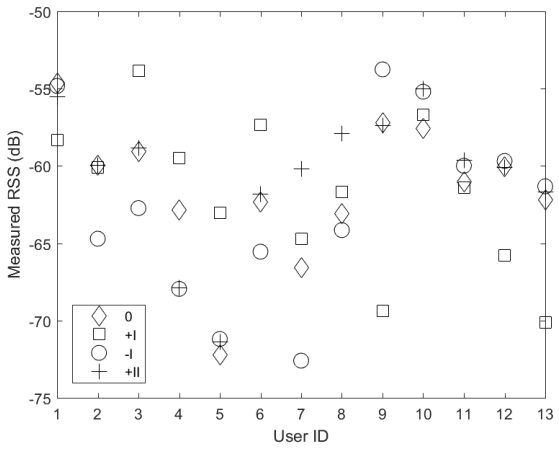

Figure 11: Measured RSS from user devices at all azimuth positions

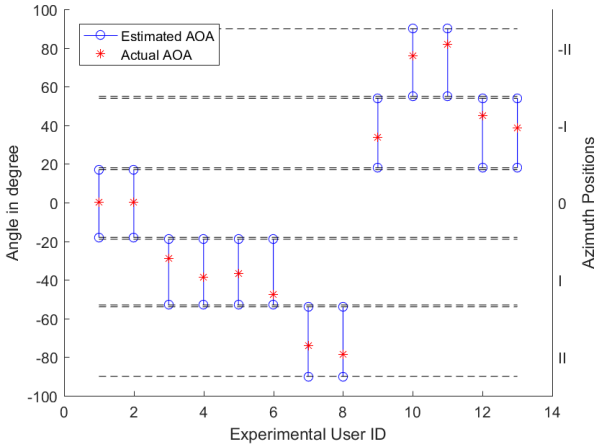

Figure 12: Experimental estimated DoA of users

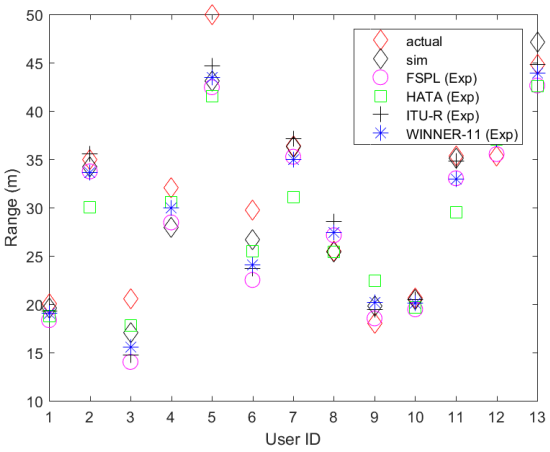

Figure 13: Experimental range estimation showing actual, simulated and experimental estimate

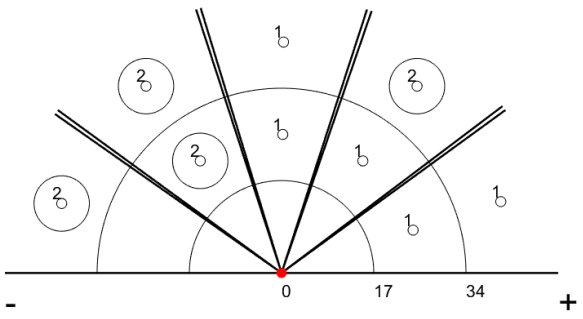

Figure 14: Experimental user cluster localization and optimum small cell deployment position identification

5 Conclusion

The work presented in this paper describes a novel and practical strategy for prompt small cell deployment in a heterogeneous network. This strategy involves using a monitoring system to periodically monitor the network coverage area of a wireless network and identify locations for small cell deployment based on user cluster localization. The entire

network coverage area is shared into azimuth and range locations for user cluster localization. By applying DoA and range estimation, user relative position is estimated. Number of users in each class is determined to identify optimum positions for small cell deployment. Both simulation and experimental results have shown that this strategy is applicable and user clusters can be correctly identified with minimal error.

Conflict of Interest The authors declare that there is no conflict of interest.

ABSTRACT

Water distribution networks are infrastructural systems designed for providing potable water to consumers. In these last decades, the importance of assessing and identifying emerging leakages has become a primary issue, because of the high level of water loss characterizing such systems worldwide. In this paper, a new approach aimed at the prompt localization of leakages occurring in water distribution systems is introduced. The methodology relies on the analysis of real-time pressure measurements and on Complex Networks Theory. Starting from a collection of nodes representing the locations of pressure sensors, links of a virtual, complex network are created on the basis of the values assumed by correlation coefficients between pressure measurements: if such values are above a given threshold, relevant nodes are considered to be connected to each other. In this way, information about the structure and topology of the complex network is easily derived. In particular, the degree centrality of the nodes is a key parameter allowing to identify the position of a leakage. The paper first analyzes a well-known literature example, and then proves the high reliability of the methodology for a real water distribution system.

1. Introduction

Water distribution systems (WDSs) are strategic infrastructures for the transport and the delivery of potable water to various types of customers [1]. However, the deterioration of ageing components (especially pipes and pumps), the rapid growth of urbanization and the statutory and contractual quality standards that have to be guaranteed to customers are playing a fundamental role in the decision-making process, especially for the increasing costs due to the operational management. In particular, water loss is a widespread problem in all the countries of the world: for a well-managed and controlled WDS, the level of water leakage can be less than 10% [2], but percentages of 40-50% are not uncommon even in developed countries [3,4].

Water utilities have to continuously monitor and control the functioning of the system: besides financial aspects and issues related to the interruption of service, energetic costs and environmental impacts are a major concern, making water loss identification and reduction one of the most challenging tasks [5].

[*]Matteo Nicolini, via del Cotonificio, 114, +39 0432 558742;
Email: matteo.nicolini@uniud.it

In this paper, a new approach for the early identification of emerging leakages in a WDS is presented. The novelty of the methodology resides in the analysis of pressure measurements through Complex Networks Theory [6]. The reliability of the method increases with the number of installed pressure gages, up to the ideal situation of having one sensor at every node of the WDS.

In this work, the assumption that pressure data are available at every junction of the system is made (a simulation model has actually been used in order to calculate them). In a real situation, such signals arrive from pressure gages properly installed in the field, and correlations between them should provide the information about the emergence of leakages to be detected. The aim of the study is to show the capability of the methodology of localizing a leakage since its first formation, provided the above hypotheses are satisfied. However, the methodology is still valuable even in real cases, characterized by a limited amount of measure points: in such situations, the zone with the most likely presence of a leakage can be identified.

Anyway, the proposed approach does not intend to solve the problem of precisely localizing a leakage in a real WDS. Instead,

the methodology represents a valuable alternative to other prelocalization techniques, or a useful tool to be adopted in conjunction with other approaches.

The rest of the paper is organized as follows: section 2 contains a literature review, section 3 describes the methodology, which is applied to a literature system in section 4; section 5 shows the results obtained from the application to a real WDS, and section 6 draws some concluding remarks.

2. Literature Review

Leakages in WDSs are usually classified into two main categories [7]: bursts, which are characterized by sudden activation and high flows, and background leakages, which do not surface and are low, background flows that can persist for years without being detected.

Since bursts can be identified by instrumentation (sometimes they are visible on the ground), they are repaired in a short period of time, leading to a small amount of water lost. In this context, several technologies are available: step-tests, noise correlators, gas-injections, acoustic sensing through conduit pigging, and others: see [8] for a review.

Instead, background leakages can determine huge volumes of water lost, unless some dedicated leakage identification and repairing activities are performed. In these last years, many water utilities have implemented pressure management, an approach consisting in the introduction and regulation of some pressure reducing valves (PRVs) with the aim to control the piezometric surface. The selective reduction of pressure in a WDS (typically during the nighttime) may result in considerable water and energy savings [9,10].

Other approaches rely on proactive identification of water leakages, in order to keep the level of water loss always under control. To this end, District Metered Areas (DMAs) are created, consisting in the subdivision of a WDS in continuously monitored portions [11]. The installed instruments (flow and pressure gages) allow to provide a nearly real-time estimation of water loss on a 24-hour basis, by analyzing the minimum night flow (MNF) occurring in the lowest consumption interval, that is, between 2:00 a.m and 4:00 a.m.. Such minimum demand conditions determine the maximum values of pressure in the system, and hence the highest values of leakage.

A totally different approach relies on transient methods, consisting in high-frequency analysis of pressures transients in a WDS after some surge has been created [12]. Others rely on a transient network simulation model, usually very difficult to calibrate [13].

In these last years, the rapid improvement in sensor technology and in data transfer and communication systems has greatly enhanced the activity of real-time control of water losses, although many problems remain unsolved: first of all, the possibility of identifying a leakage since its first formation [14].

Several researchers have been focused on the comparison between actual field measurements and the results obtained by a calibrated numerical model [15–17]. In such cases, the key-point is the level of accuracy of the simulation model, which can hardly be optimal, since it should also contain information on the leakages to be discovered. In particular [18] have introduced a methodology for leak-detection and localization coupled with demand calibration.

More recently, Complex Networks Theory (CNT) has received increasing attention for the comprehension of a wide spectrum of real systems, ranging from physical infrastructures to social communities [19,20]. Successful examples include functional (correlation) network approaches [21], to infer hidden statistical inter-relationships between macroscopic regions of the human brain [22] or the Earth's climate system [23], difficult to uncover with traditional non-linear time series analysis techniques [24].

The application of CNT to the design and operation of WDSs has attracted a growing number of researchers, because its inherent capability of unveiling hidden properties, not grasped by traditional analyses or modelling approaches [25]. CNT has been adopted for evaluating the topological characteristics and the resilience of a system [26], or for expansion strategies [27]. Several authors investigated vulnerability-related issues, like node vulnerability under cascading failures [28–30], spectral methods to establish vulnerability areas [31,32], or for evaluating robustness under random or intentional attacks [33]. Other studies focused on the analysis of the formation of isolated communities [34], on the segmentation of WDSs for the identification of District Metered Areas (DMAs) using general metrics and modularity [35,36]. The optimal sampling design has also been addressed with the modularity concept [37] and through a combination of classical optimization and CNT [38]. More recently, Complex Networks Theory has been adopted for a systematic classification of WDSs [39], and for their optimal design through a tradeoff between network cost and reliability, measured in terms of flow entropy [40].

All such studies have been mainly focused on the topological aspects of WDSs, deriving their main characteristics from the analysis of the real system. Actually, many hidden properties may be uncovered looking at functional or correlation ties between nodes, especially when simulation or field data are available.

3. Methodological Approach

Starting from a given WDS whose topological, geometrical and hydraulic characteristics are known, the simulation model of the system can be built. In this work, the software Epanet has been adopted, being an open-source and a standard toolkit for such kind of numerical analyses [41].

The two sets of equations the software solves at the generic time t_k are the continuity equation for each junction i:

$$\sum_j Q_{ij}(t_k) - D_i(t_k) = 0 \qquad (1)$$

and the flow-headloss relationship in every pipe connecting junctions i and j:

$$H_i(t_k) - H_j(t_k) = h_{ij}(t_k) = rQ_{ij}^n(t_k) + mQ_{ij}^2(t_k) \qquad (2)$$

where Q_{ij} is the flow in pipe ij, D_i is the demand at node i, H_i and H_j are nodal heads at junctions i and j, h_{ij} is the headloss between nodes i and j; r, n and m are, respectively, the resistance coefficient, the flow exponent and the minor loss coefficient. For each time t_k,

starting from known heads at the fixed grade junctions (typically, reservoirs or tanks), the software uses the gradient method [42] in order to solve the set of equations (1) and (2) for determining all the heads and flows. Once the head is known at each junction, the pressure is directly calculated as the difference between head and the elevation of that junction (the velocity head at each junction is neglected).

The simulation model allows to determine the variability of pressure, provided a user demand pattern is defined. A pressure 'signal', $p_i(t)$, may be associated at each junction i, and the correlation coefficient c_{ij} between every pair of pressures signals at junctions i and j can be calculated. In this paper, the Pearson correlation coefficient has been adopted; it is given by the following expression:

$$c_{ij} = \frac{\sum_{k=1}^{T}(p_i(t_k)-\bar{p}_i)(p_j(t_k)-\bar{p}_j)}{\sqrt{\sum_{k=1}^{T}(p_i(t_k)-\bar{p}_i)^2 \cdot \sum_{k=1}^{T}(p_j(t_k)-\bar{p}_j)^2}} \qquad (3)$$

in which t_k represents the discretized time of the numerical module, T is the number of time steps of the simulated time horizon, and $\bar{p}_i$ is the average pressure at the i-th junction.

The temporal variability of pressure depends mainly on the fluctuation of the customers' demand: the higher the request of water, the lower is the pressure. Usually, distribution systems supplying water to residential areas are subjected to an almost spatially-uniform user demand. In this way, the temporal variability of pressure is very similar at all junctions, and the correlation coefficient c_{ij} is very close to the value of one. In other words, there is a strong linear relationship between pressure at junctions, properly described by the (linear) Pearson correlation coefficient.

However, the presence of many tanks or control devices, such as pressure regulating valves, inverter of pumps and other facilities, may introduce non-linearities in the relationships between pressures, and the correlation coefficient may not represent an appropriate measure. The more general case, which will be evaluated in future research, can be analyzed through non-linear correlation parameters or, more simply, looking for subsets of the considered time horizon for which linear correlations exist between pressure signals.

The methodology starts by creating a similarity matrix in which every element c_{ij} is the Pearson correlation coefficient between real-time measurements of pressure sensors (or pressures calculated by the simulation model) at i and j.

From the similarity matrix, an adjacency matrix representing a virtual, undirected complex network may be built (Figure 1). In this network, the nodes are the points of measurement and the links are created if the correlation coefficient between pressure signals is high enough. In other words, if c_{ij} is above a chosen threshold, θ, the related element a_{ij} of the adjacency matrix is 1, and zero otherwise (elements in the diagonal are set to zero).

In an ideal system with no leakages and characterized by a spatial uniform demand pattern, that is, the same typology of customers' consumption, there is a strong correlation between pressure signals, and the related complex network is heavily connected (it is a complete graph). As an example, Figure 1 (left) shows the situation in which four sensors are installed at junctions 3, 9, 28 and 31. In the case of no leakage, the similarity matrix presents very high values of correlation coefficients, and the adjacency matrix is that typical of a complete graph (Figure 1, top right).

The formation of a leakage starts to 'break' correlations among the node nearest to the leakage and the others, inducing a progressive link removal, depending on the amount of water loss. This is due to the fact that only the time-varying flow out of the leakage is a function of pressure, with different dynamics from customer's demand.

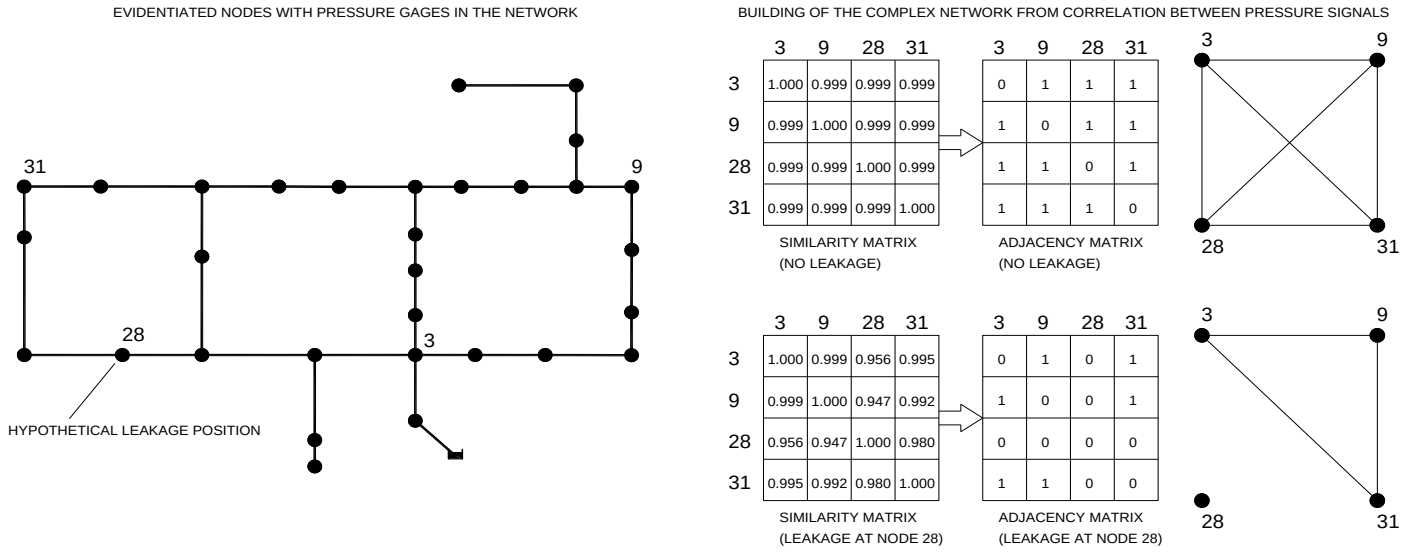

Figure 1: Difference between similarity matrix, made by Pearson correlation coefficients, c_{ij}, and adjacency matrix, in which the value of 0 or 1 assumed by each element depends on the threshold chosen for c_{ij} (in the example θ = 0.990). In this case, the size of matrices is less than the number of junctions of the water distribution system, being equal to the number of installed pressure gages (indicated on the left of the figure). The hypothetical position of a leakage is also shown, together with its impact on the matrices and the resulting virtual network.

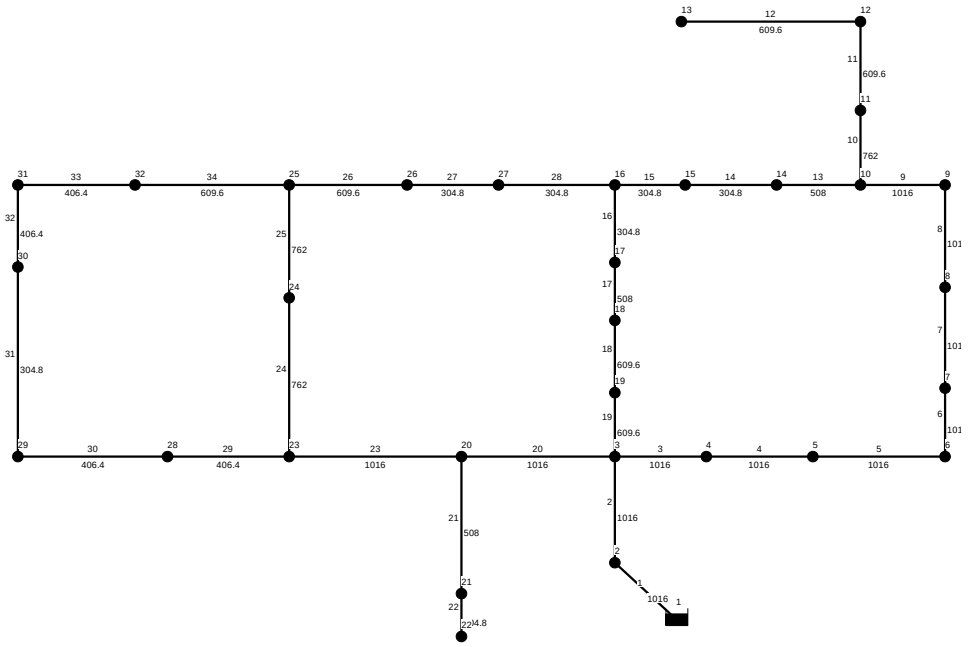

Figure 2: *Hanoi WDS adopted for the analyses. Link number and diameter (in mm) are indicated along the pipes*.

If a leakage is formed at the *i*-th junction of a WDS, the total discharge $Q_i(t_k)$ outflowing at time t_k equals the nodal demand, and can be expressed as the sum of consumer's request and pressure-dependent water loss:

$$D_i(t_k) = Q_i(t_k) = \alpha(t_k) q_i + c[p_i(t_k)]^u \qquad (4)$$

in which q_i is the average demand at node i, $\alpha(t_k)$ is the multiplier coefficient characterizing the demand pattern at time t_k (Figure 3), $p_i(t_k)$ is the pressure at node i, and c and u are the leakage coefficient and the leakage exponent: they determine, respectively, the leakage entity and its dependence on the pressure (for an ideal leakage of circular shape on a steel pipe, $u = 0.5$).

Figure 1 (bottom right) shows the example of a leakage present at junction 28: it is easily seen that the values of the correlation coefficient in the similarity matrix decrease when the position with the leakage is involved in the calculation, giving rise to a less connected network.

The parameter adopted for the identification of the junction in which a leakage is forming is the degree centrality: the degree of a node represents the number of its nearest neighbors (in other words, the number of its connections). For an undirected network (as in this case) the column vector of node degrees' **k** is given by (the symbol **1** represents an all-one column vector):

$$\mathbf{k} = (\mathbf{1}^T \mathbf{A})^T = \mathbf{A}\,\mathbf{1} \qquad (5)$$

in which **A** is the adjacency matrix [17]. Thus, the junction in which the leak is emerging is the one characterized by the lowest correlation with respect to all the others, and the related node in the complex network has the lowest degree centrality.

4. Application to a Literature System

The methodology has been applied to the Hanoi WDS (Vietnam), since it represents a well-known literature example (Figure 2): it was introduced for the first time by [43] and then analyzed by many authors [44]. The model of the main system consists of 32 junctions and 34 pipes, organized in three loops (see [43] for the data). The numerical simulation model has been used to artificially create pressure signals at every junction of the main system, where a pressure sensor is considered to be available.

Figure 3 shows the pattern assumed for customers' demand: its variability is typical of residential consumption, with two peaks during the day, respectively in the morning and in the evening, and a minimum during the nighttime. The time resolution adopted is 5 minutes.

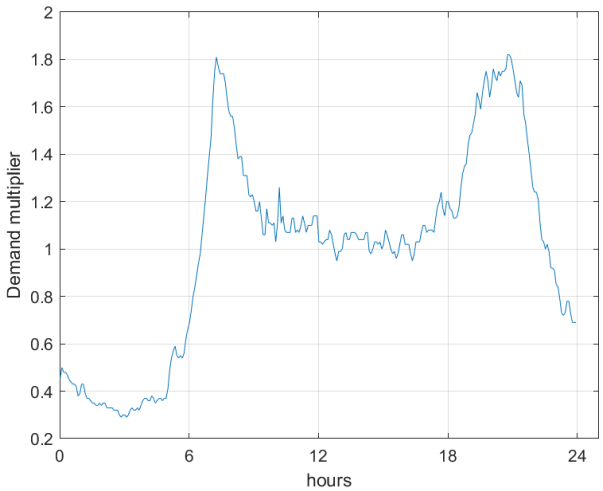

Figure 3: Temporal variability of demand multiplier $\alpha(t_k)$ in (4), describing customers' demand.

In Figure 3, the typical oscillations due to the stochastic nature of demand are evident. In the present paper, the simple case of uniform spatial distribution of demand pattern has been assumed. Due to the importance of correctly simulating users' demand variability, future research will focus on such issue: to this end, the

approach adopted by [45,46] appears the most suitable for real-time analyses. The time variability of pressure in the case of no leakage in the system is shown in Figure 4.

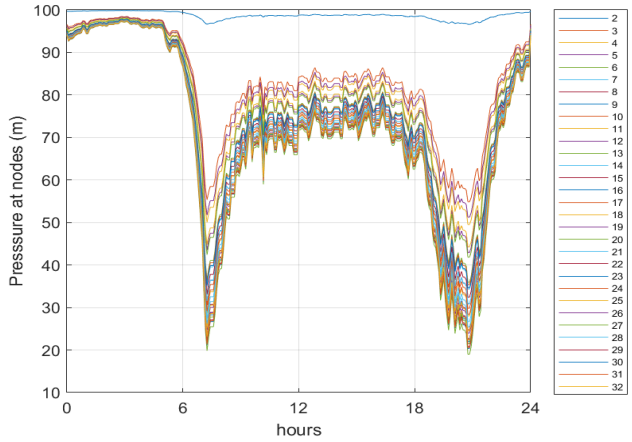

Figure 4: Pressure variability over 24 hours for the junctions of Hanoi WDS.

The results have been obtained by simulations performed with Epanet software [39], with a hydraulic time step of 5 minutes and a Hazen-Williams roughness coefficient of 130 for all pipes.

The correlation between signals is evident, and may be confirmed by the plot of Figure 5, where the relationship between pairs of nodes keeping junction 2 in abscissa are shown. Similar results may be plotted for other pairs of junctions. Such behavior confirms the validity of linearity assumption between pressures

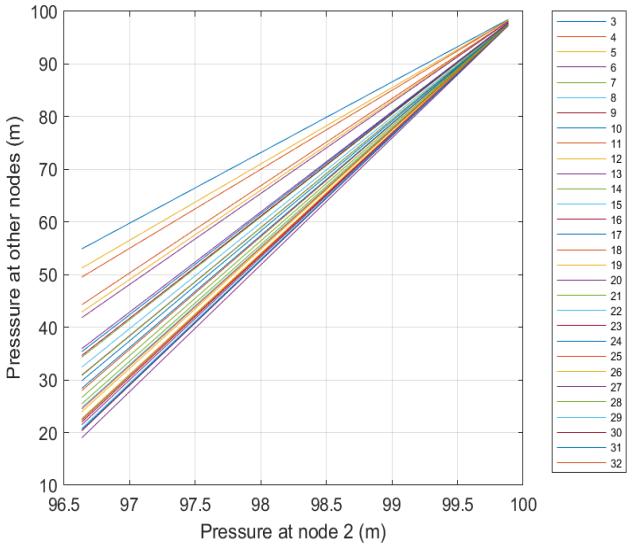

Figure 5: Correlation plot for pairs of pressures between junction 2 and others

Figure 6 is a heatmap plot of the global results obtained with reference to one leakage in all possible positions, and characterized by an average outflow of 5 l/s, which may appear to be large, but actually is a relatively small value if compared to the user demand at junctions (100 l/s on average). For each column, representing an assumed position of a leakage, the figure shows the degree centrality of the nodes on a blue-tone basis, i.e., the darkest the color, the bigger is the degree of a node.

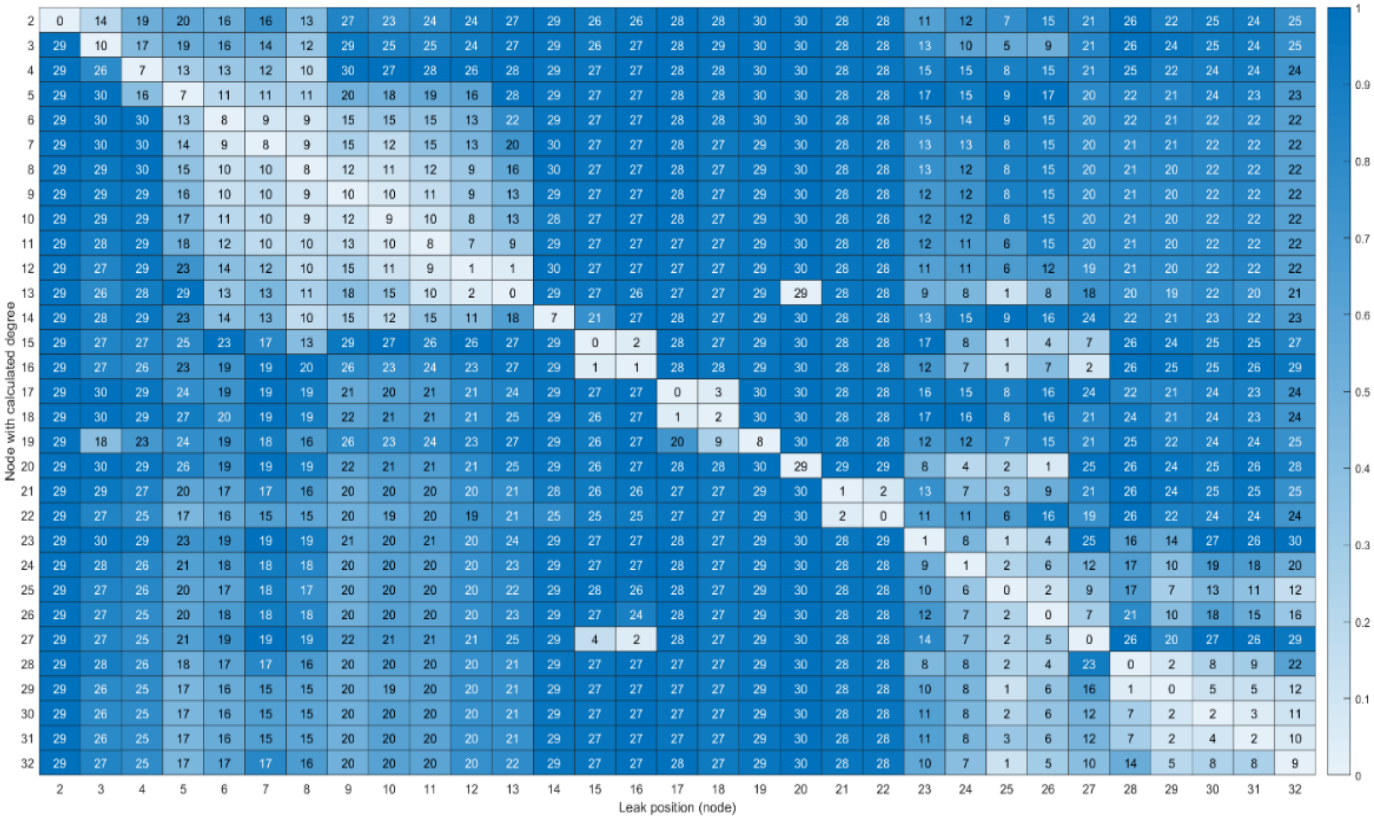

Figure 6: Heatmap representation of degree centralities when varying the position of one leakage of 5 l/s in Hanoi WDS. Number in columns are the node degrees for a fixed leakage position

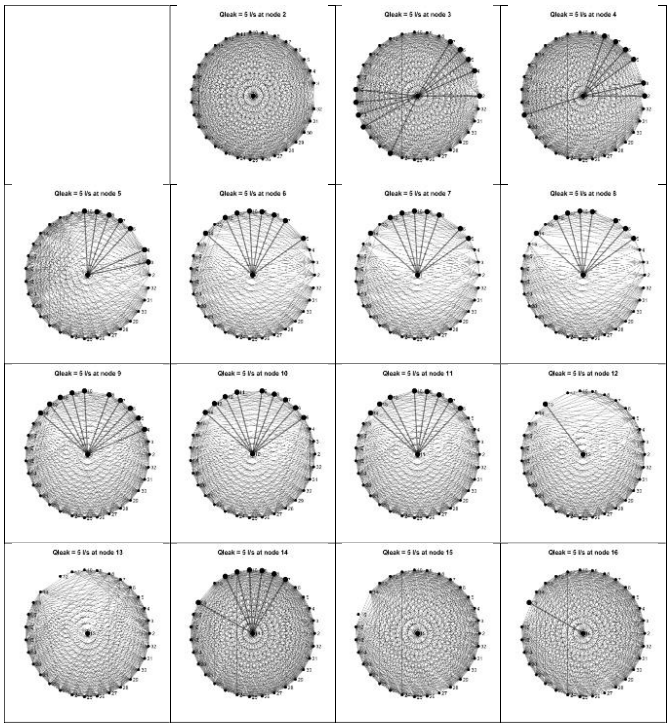

Figure 7: Round plots of virtual correlation networks obtained when varying leakage position (nodes 2 to 16). The junction where the leakage is activated is drawn at the center of each plot. Thick lines are the links connecting the central node to others, while other connections are indicated with thin lines.

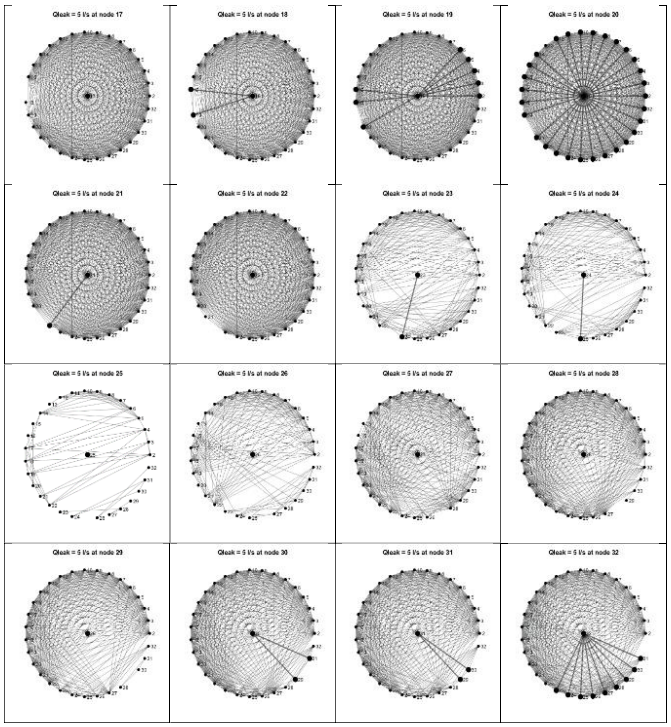

Figure 8: Round plots of virtual correlation networks obtained when varying leakage position (nodes 17 to 32). The junction where the leakage is activated is drawn at the center of each plot. Thick lines are the links connecting the central node to others, while other connections are indicated with thin lines.

In this way, the lightest cell represents (for each column) the node with the least degree centrality, that is, that affected by the leakage. This is confirmed by the number indicated in each cell, giving the degree centrality. Only simulations with one leakage at a time have been considered.It is evident that, in all the cases analyzed, the node with the smallest degree is that one in which the leakage is present.

Figure 7 and Figure 8 show round plots of the virtual networks in which the node where the leakage is activated is drawn at the center. Thick lines represent the connections the central node has with others, while thin lines indicate those between other nodes.

For each plot, the number of thick lines is the degree centrality of the node with the leakage. Such figures provide a pictorial representation of the absence of connections for the central node due to the presence of a leakage. In other words, such node is the most 'isolated'

5. Application to a real system

In order to test the reliability of the methodology, it has been applied to the western district of Tobruk city, Libya (Figure 9, left).

Figure 9: Left: layout of the city of Tobruk (Libya), and of the western district WDS (right), where the junctions characterized by the highest frequency values reported in Figure 10 are also indicated.

It covers a surface of 8 km^2 and serves a population of 54600 inhabitants. The average flow supplied is 240 l/s. The model of the system includes all the details of the network, and is made of 1139 junctions and 1621 pipes (Figure 9, right).

In this case, the performance of the methodology has been evaluated as the percentage of success in identifying the junction affected by the leakage (or its neighbors, according to a predefined tolerance of 200 m, representing the average length of the pipes), varying several parameters like threshold, θ, leakage coefficient, *c*, and leakage exponent, *u* (4).

Table 1 reports the results obtained for a tolerance distance of 200 m (in other words, it is considered a good result whenever the junction with the smallest degree centrality falls within 200 meters from that in which the leakage is activated). It can be observed that, independently of the parameters assumed, the rate of success of the methodology is around 90%. This is due to the fact that there are some junctions having the minimum value of degree centrality when leakages are activated at their surroundings.

To this end, the results in terms of frequency of occurrence of the nodes have been analyzed: Figure 10 shows several cases obtained with two values of the leakage exponent (u = 0.5; 1.0) and five values for the leakage coefficient (c = 0.1,…0.5), which are typically encountered in real situations.

Table 1: Performance indicator (PI) giving the percentage of success of the methodology when applied to Tobruk WDS, with varying threshold, θ, leakage coefficient, *c*, and exponent, *u*. (The threshold number, θ, indicated as 1-10^{-4} means 0.9999.)

θ	*c*	*u*	PI (%)
1-10^{-4}	0.5	0.5	90.34
1-10^{-6}	0.5	0.5	75.94
1-10^{-7}	0.1	0.5	86.65
1-10^{-6}	0.1	0.5	90.61
1-10^{-6}	0.1	1.0	90.61
1-10^{-5}	0.1	0.5	88.85
1-10^{-5}	0.2	0.5	90.17
1-10^{-5}	0.3	0.5	90.87
1-10^{-5}	0.4	0.5	91.83
1-10^{-5}	0.5	0.5	92.01
1-10^{-5}	0.1	1.0	88.85
1-10^{-5}	0.2	1.0	90.17
1-10^{-5}	0.3	1.0	90.87
1-10^{-5}	0.4	1.0	91.83
1-10^{-5}	0.5	1.0	92.01

In an ideal situation, all nodes should be characterized by a frequency of one, and the frequency plots would be uniform. However, from Figure 10 it can be observed that some of them exhibit very high frequency values, indicating that their minimum degree centrality occurs not only when a leakage is present there, but also when it is activated at several other surrounding junctions. When analyzing in more detail the nodes characterized by the highest values of frequency, it can be noted that they represent particular situations of 'bottlenecks' of the WDS (Figure 9, right). In these cases, their minimum degree centrality hinders some other non-linear property not captured by the linear Pearson correlation coefficient, which is still under investigation.

6. Discussion and Concluding Remarks

The paper has presented the results of a new methodology introduced for the localization of leakages emerging in water distribution systems. The main advantage of the approach is that it relies only on the measurements of pressure and on cross-correlations between signals, thus avoiding the need of comparing such data with a 'reference' (and not well defined) scenario given by a simulation model, whose optimal calibration is generally very difficult to attain. In this paper, the simulation model has been adopted with the only purpose of generating the pressure signals.

The novelty of the research resides in the fact that it analyzes pressure measurements through Complex Networks Theory, its reliability increasing with the number of installed pressure sensors. However, the proposed approach does not represent a final solution to the problem of leakage identification, but it has to be considered a further support in the process of leakage prelocalization, that is, a fast method to assess the integrity of a WDS and, eventually, to identify areas where prompt interventions should be planned.

Two test cases have been considered: the first, representing a well-known literature system, proved the best performance of the methodology in precisely localizing the node where the leakage is emerging (which is characterized by the least degree centrality with respect to all the others); the second, a real-world network, showed a high rate of success (around 90%). The difference between the results obtained can be ascribed to the fact that, in the first case, only the main transport pipes are included in the model (in other words, the model simulates the principal 'skeleton' of the water distribution system). In the second case, given by a real WDS, all the pipes have been modeled, and hence the flows in the links may arrange in such a way that the conditions of minimum degree centrality do not always occur at the junction where the leakage is present, but rather in some other surrounding nodes. Actually, this is not a problem in real situations, since water managers are interested in quickly identifying the area where the leakage is forming.

Other issues still under investigations are represented by the influence on the spatial distribution of demand pattern and the presence of several reservoirs and tanks, which actually limit the performance of the methodology. In any case, the current trend in WDS management is to divide such systems in DMA (District Metered Areas), for a better control of water leakages: thus, each DMA (which is often supplied by at most one reservoir, or may be modeled in such a way through appropriate boundary conditions) can be considered as a single system and the proposed methodology applied accordingly.

The requirement of linear correlation between pressure variability is fundamental for the success of the methodology. However it is only a necessary condition, as proved by the second test case, for which the linearity in correlation is not sufficient to always guarantee the minimum degree centrality at the node with the leakage, hindering some other non-linear property not captured by the linear Pearson correlation coefficient. Also this issue is currently under investigation.

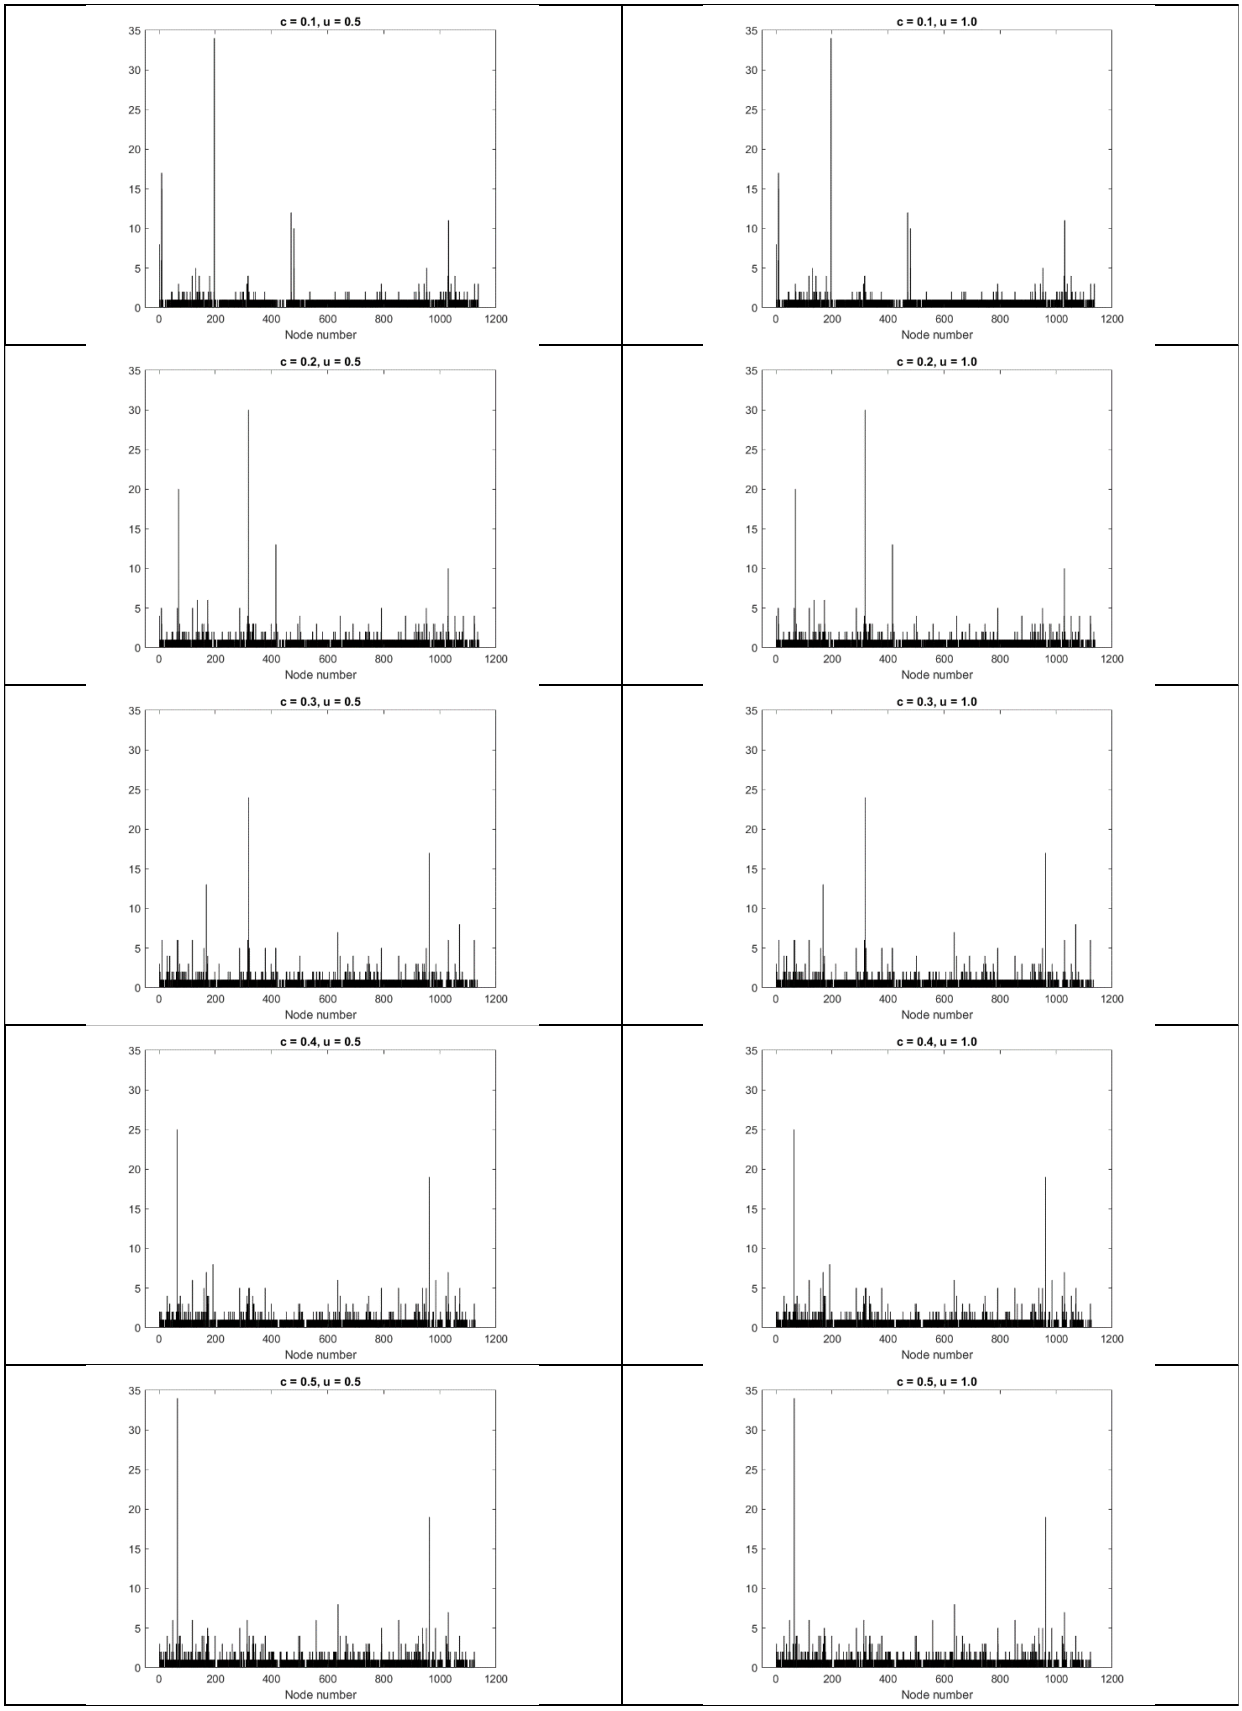

Figure 10: Frequency plots of junction occurrences in minimum degree centrality when varying leakage position and for different values of leakage coefficient, *c*, and exponent, *u*. Correlation threshold of $1\text{-}10^{-5}$ has been assumed.

Acknowledgment

ABSTRACT

The Malaysian government has recently announced to increase the share of renewable energy generation from 2% to 20% of the total electricity consumption by year 2030. However, integrating a significant level of renewable energy sources on the distribution network without proper coordination will cause adverse effects that leads to unnecessary operation costs to the stakeholders. Various solutions including energy storage system are proven to be an effective way to overcome the issues caused by the integration of renewable energy sources. However, energy storage system using batteries have limitations such as limited life cycle and environmental hazards. As such, alternative source such as fuel cell which is well known for its zero pollutant can be considered. In this paper, a distributed static synchronous compensator integrated with a hydrogen system (DSTATCOM-Fuel cell) is proposed. The hydrogen system consists of fuel cell and electrolyzer to perform power exchange within the grid for regulating the voltage magnitude at 1 p.u. Various case studies have been conducted to validate the efficacy of this proposed combination and the results have shown that the DSTATCOM-Fuel cell can effectively mitigates the voltage rise up to 12.3% while maintaining high penetration of the photovoltaic systems.

1. Introduction

This paper is an extension of work originally presented in the International Conference on Smart Grid and Clean Energy 2018 [1]. Malaysia is expected to receive significant growth of the grid-connected renewable energy sources as the government has recently set a new target to commit on increasing the renewable energy generation from the current 2% to 20% of the total electricity consumption by year 2030 [2]. However, the growth of renewable energy sources on the electrical networks without proper coordination can create technical challenges that lead to the malfunction of power electronic devices, reduction of network efficiency, and improper operation of power protection system which gives high operating cost impact to the stakeholders. Curtailing and limits the amounts of grid-connected renewable energy have always been applied in order to avoid the deterioration of electrical power quality [3] despite these measures can greatly reduce the generation of clean energy and affect the commitment to increase the share of renewable energy generation [4]. Many solutions have been research, and realized that integrating large-scaled energy storage system by manipulating the real and reactive power exchange within the system can be used to regulate the network voltage [5–9]. Besides, energy storage system integrated with STATCOM are used to enhance the transient stability [10–14], improve voltage sags [15], smoothen wind farm power output and terminal voltage by incorporates real and reactive power control ability [16–18]. Although these combinations have proven useful, however, batteries have few disadvantages such as limited life cycle, voltage and current limitation and environmental hazards [19–21]. Therefore, more exploration on new alternative solutions and their corresponding control strategies become obligatory. Unlike the other batteries, fuel cells is an environmental friendly and well known for its zero pollutant, high efficiency, modularity, high power and reliable [22] which has the capability of high charge and discharge cycles. In this paper, a distributed static synchronous compensator integrated with a hydrogen system (DSTATCOM-Fuel cell) is proposed for active and reactive power compensation. In this combination, the DSTATCOM regulates reactive power output to maintain the voltage at 1 p.u. with the hydrogen system operates through the discharging and charging of the fuel cell and electrolyzer respectively to regulate active power based on the PV power output and voltage magnitude. Various case studies are conducted

*Jianhui Wong, Universiti Tunku Abdul Rahman, wongjh@utar.edu.my

to validate the performance of the proposed solution to mitigate the voltage rise issues while allowing high penetration from grid-connected PV systems.

2. Typical Malaysian Low-voltage Distribution Network in Radial Topology

The paper begins with a preliminary study to investigate the impact on system voltage with the integration of grid-connected PV systems on the radial distribution network. It is followed by an efficacy analysis using MATLAB Simulink to validate the performance of the proposed DSTATCOM-Fuel cell system to regulate the system voltage at 1 p.u while maximize the capacity of the grid-connected PV systems on the distribution network.

2.1. Modeling Electrical Network

A typical Malaysian low-voltage distribution network for small sub-urban area as shown in Figure 1. This network can be categorized into three sections according to its voltage level; (i) 132 kV incoming supply, (ii) 33 kV distribution substations, (iii) 11 kV distribution substations. The 132 kV incoming supply is the sub-transmission network of the national grid, the voltage is then stepped down to 33 kV by the 132/33 kV power transformers installed in the 33 kV distribution substations. The 33 kV is further stepped down to 11 kV using the 33/11 kV power transformer to a suitable voltage level for utilization. In this network, feeder 4 being the longest feeder will be modelled and the proposed DSTATCOM-Fuel cell system is integrated on feeder 4 to validate the efficacy.

There are 11 distribution substations across the radial feeder 4 with each of them are rated at 11/0.4 kV. The distance between each substation is indicated in Figure 1. The primary sides of the 11/0.4 kV transformers are labelled as 1, 2, 3 … and 11, while the secondary sides of the 11/0.4 kV transformers are labelled as 1a, 2a, 3a … and 11a. Table 1 and Table 2 show the technical specifications of the power transformer and conductor respectively. The locations of the distribution substations, the typical load characteristics and photovoltaic system power output were collected from the utility company.

A three-phase PV system is placed at the terminals 1a, 2a, and 3a in case 1 and 9a, 10a, and 11a in case 2 to investigate the impact of PV systems towards voltage rise on the network. Equation 1 shows sizing of the PV system is based on the penetration levels as follows:

$$PL = \frac{E_{PV}}{E_{load}} \times 100\% \quad (1)$$

where,

PL is the penetration level of the PV system (%)
E_{PV} is the total PV energy yield for the day (kWh)
E_{load} is the daily energy consumption at the load (kWh)

Based on the PV power output profile and load profile used in this study, it is determined that for 100% PV penetration level, the PV system should be sized at 500 kW. Thus, the PV system capacity for 60%, 70%, 80%, and 90% PV penetration are 300 kW, 350 kW, 400 kW, and 450 kW respectively.

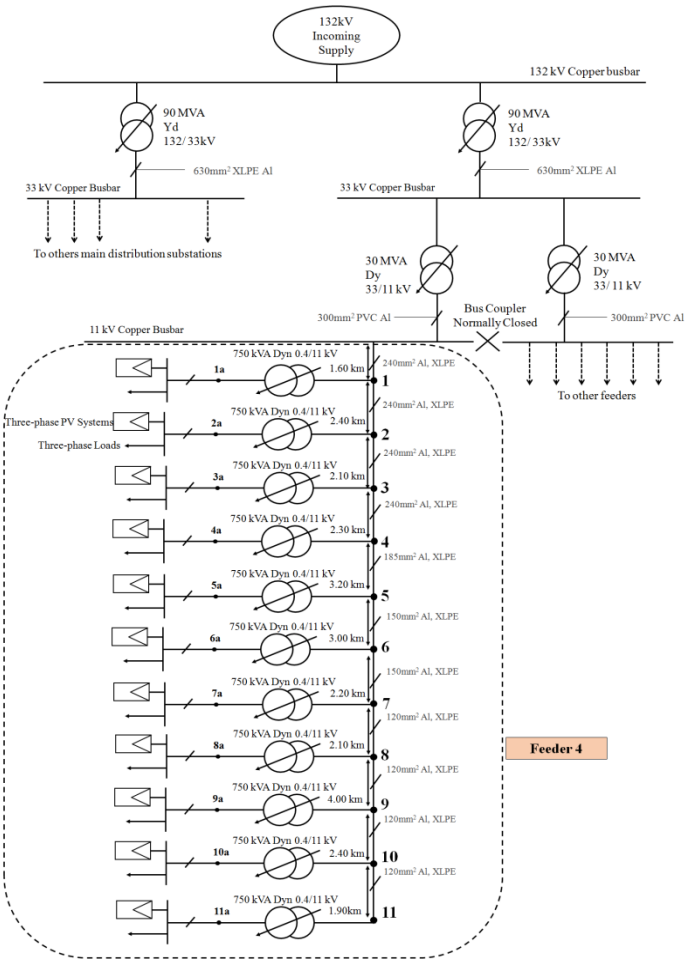

Figure 1: Typical Malaysian low-voltage distribution network in a sub-urban area.

Table 1: Technical Specification of the oil-immersed power transformers

Descriptions	Voltage Level (kV)	Rated Power (MVA)	Vector Group	Percent Reactance (%X)
Three-phase power transformers	132/33	90.00	Yd11	13.50%
	33/ 11	30.00	Dyn11	10.00%
	11/ 0.4	0.75	DYn11	4.75%

Table 2: Technical Specification of the conductors

Voltage Level (kV)	Cross-sectional Area (mm2)	Material	Insulator	R (Ω/km)	X_L (Ω/km)
0.4	300	Al	PVC	0.1300	0.0720
11.0	120	Al	XLPE	0.2990	0.0873
	150	Al	XLPE	0.2645	0.1603
	185	Cu	PILC	0.1950	0.0829
	240	Al	XLPE	0.1610	0.1524
33.0	630	Al	XLPE	0.0627	0.1070

2.2. Modeling DSTATCOM-Fuel Cell System

The proposed DSTATCOM-Fuel cell system is shown in Figure 2. The system consists of a DSTATCOM with an integrated hydrogen system. The hydrogen system consists of a fuel cell, an

electrolyzer, and a hydrogen storage tank. The hydrogen system is connected to the DC capacitor of the DSTATCOM through a boost converter which regulates the DC voltage from the hydrogen system to the desired level. The DSTATCOM consists of a DC capacitor, a three-phase pulse-width-modulated voltage source converter (VSC), and a coupling transformer. The coupling transformer connects the VSC to the network and functions to provide galvanic isolation and voltage regulation at the point of common coupling (PCC). The DSTATCOM, fuel cell, and electrolyzer are rated at 500 kVAr, 500 kW, and 500 kW respectively to match the PV system capacity at 100% PV penetration.

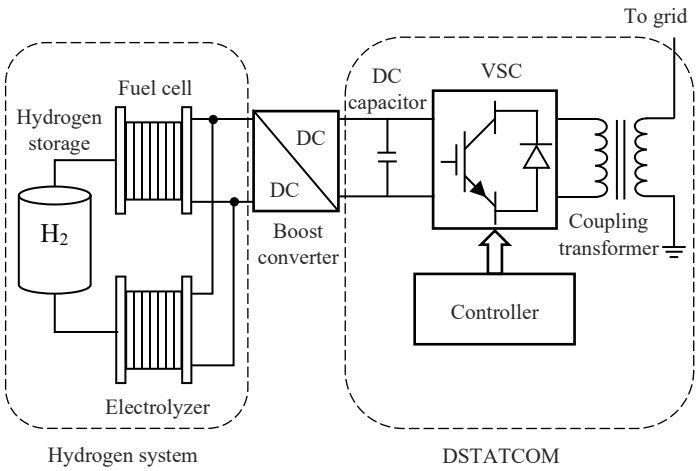

Figure 2: Schematic diagram of DSTATCOM-Fuel cell

The proton membrane exchange fuel cell (PEMFC) is used for the hydrogen system as it has a low operating temperature of 60-80°C, a high electrical efficiency range of 40-50%, a fast start up time, and high power density which makes it suitable for use in distribution networks [23,24]. A 500 kW PEMFC is modelled based on the NedStack PS6 datasheet. The parameters of the 500 kW PEMFC stack is shown in Table 3. The voltage-current (V-I) and power-current (P-I) curve of the fuel cell stack is shown in Figure 3.

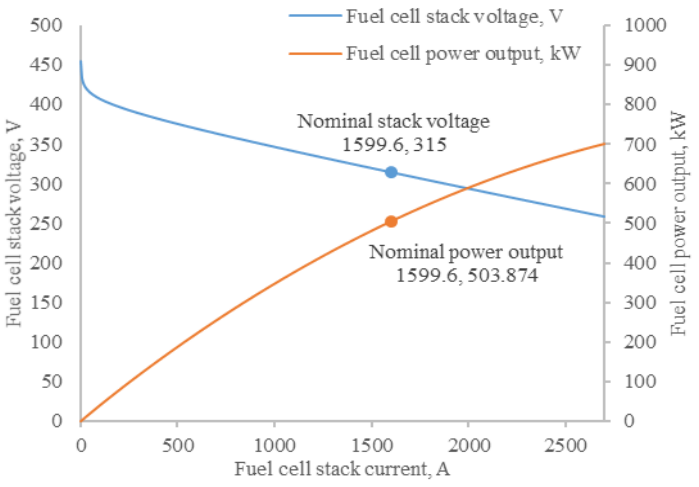

Figure 3: V-I curve and P-I curve of the fuel cell stack.

Table 3: Technical specification of the PEMFC stack

Rated capacity	504 kW
Nominal voltage	315 V
Nominal current	1333 A
Number of cells connected in series	455
Number of strings connected in parallel	12
Total number of cells in the fuel cell stack	5460

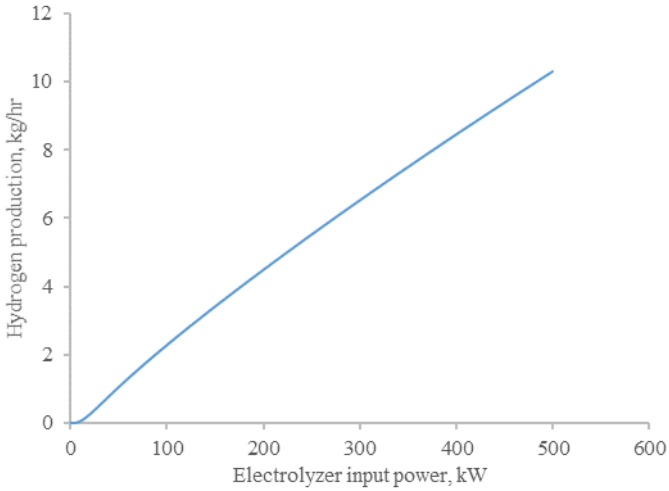

Figure 4: Hydrogen production of electrolyzer stack.

An alkaline electrolyzer stack is modelled based on the Photovoltaik, Elecktrolyse, Brennstoffzelle Und Systemtechnik (PHOEBUS) plant installed at Julich, Germany as reported in [25]. In order to create a 500 kW electrolyzer system, 19 electrolyzer stacks each rated at 26 kW are modelled and connected in parallel. The voltage-current relationship and hydrogen production of the electrolyzer system are modelled as described in [26,27]. The hydrogen produced by the electrolyzer is stored into a hydrogen storage tank without compression. The hydrogen storage tank capacity is 30 kg of hydrogen. The hydrogen production of the electrolyzer model is shown in Figure 4.

2.3. Control Strategies for Voltage Regulation

Figure 5 shows the control scheme for the DSTATCOM-Fuel cell. The objective of the controller is to mitigate voltage rise issue on the network by active and reactive power compensation. The voltage at the PCC, V_{PCC}, is measured and DSTATCOM performs reactive power compensation to regulate the voltage at 1 p.u. The voltage rise on the network occurs mainly due to high PV penetration. Hence, controller will initiate the hydrogen system charging operation when the PV power output, P_{PV}, is higher than the load consumption, P_{load} and the hydrogen tank level is less than 100%. If P_{PV} is less than P_{load}, the control will check if V_{PCC} is below the statutory limit of 1.1 p.u. If yes, the control will initiate the hydrogen system discharging operation if the hydrogen tank level is more than 20%. A minimum threshold of 20% for the hydrogen tank level is set to ensure a safe operation of the fuel cell.

If V_{PCC} exceeds the 1.1 p.u. limit, the control will stop the charging and discharging of the hydrogen system and only reactive power compensation will be used to regulate the voltage.

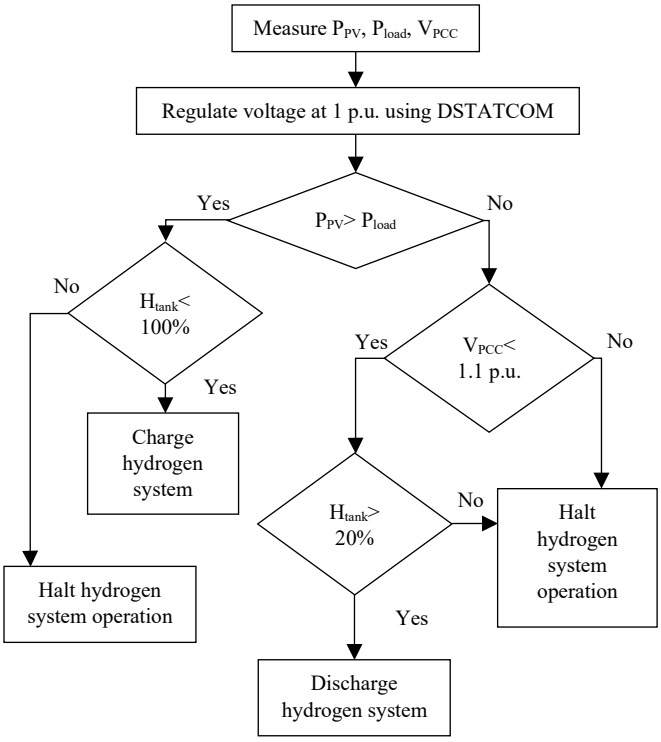

Figure 5: Flow chart of the DSTATCOM-Fuel cell controller.

3. Simulation Results

3.1. Impact of PV system allocation on voltage rise severity:

In this case study, the impact of PV system allocation on the system voltage is studied. Two cases are considered; i) Case 1 where a PV system is connected at terminals 1a, 2a, and 3a respectively, ii) Case 2 where a PV system is connected at terminals 9a, 10a, and 11a respectively. The PV power output profile used in this case study is the average hourly PV power output measured at Selangor, Malaysia during the month of April, 2018. The network is simulated for a period of 24 hours to determine the maximum voltage rise that occur within one full day.

Figure 6 shows the voltage magnitude of the load terminals 1a, 2a, and 3a for case 1. Figure 7 shows the voltage magnitude of the load terminals 9a, 10a, and 11a for case 2. In both cases, the maximum voltage is measured when there is 0%, 60%, 70%, 80%, 90%, and 100% PV. The voltage magnitudes shown in these two figures are the maximum voltage measured within the 24-hour period.

In case 1, the maximum voltage at terminal 1a, 2a, and 3a violates the 1.1 p.u. statutory limit when PV penetration exceeds 70%, 80% and 90% respectively. The maximum voltages at 1a, 2a, and 3a when PV penetration is 100% are 1.12 p.u., 1,12 p.u. and 1.11 p.u. respectively. It is noticed that in this case, the voltage rise severity reduces at terminals further away from the 11 kV main substation.

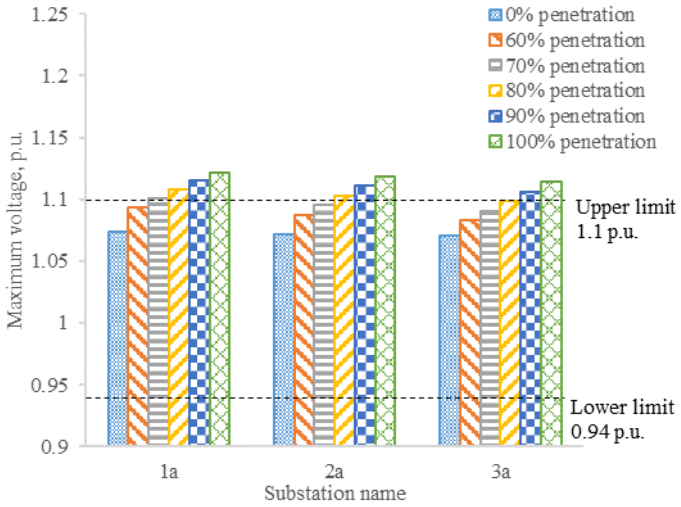

Figure 6: Maximum voltage magnitude of the load terminals when the PV system is connected at the terminals 1a, 2a, and 3a.

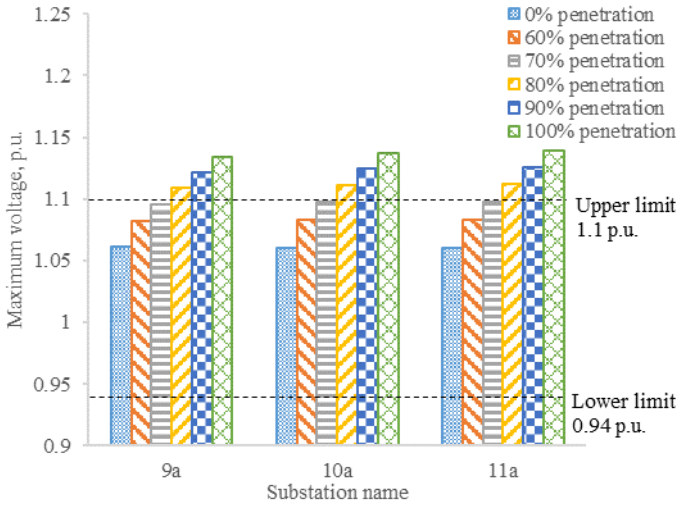

Figure 7: Maximum voltage magnitude of the load terminals when the PV system is connected at the terminals 9a, 10a, and 11a.

In case 2, the maximum voltage at terminal 9a, 10a, and 11a violates the 1.1 p.u. statutory limit when PV penetration exceeds 80%. The maximum voltages at 9a, 10a, and 11a when PV penetration is 100% are 1.13 p.u., 1.14 p.u., and 1.14 p.u. respectively. It is noticed that in this case, the voltage rise severity increases at terminals further away from the 11 kV main substation.

Comparing case 1 and case 2, it is noticed that when several PV systems are placed near the 11 kV substation, the voltage rise impact is greatest at the terminal located nearest to the main substation. Conversely, when multiple PV systems are placed at the end of the load terminals, the voltage rise is most severe at the terminal located furthest from the main substation.

Overall, it is observed that the voltage rise is more severe when multiple PV systems are placed at terminals furthest to the 11 kV main substation. The voltage increase as PV penetration increases is also more significant when the PV system is connected to the last three terminals compared to the first three terminals.

3.2. Efficacy Analysis for DSTATCOM-Fuel Cell System:

In order to determine the effectiveness of the proposed system for mitigating voltage rise caused by PV systems, a DSTATCOM-Fuel cell system is connected to terminals 1a, 2a, and 3a in case 1 and to terminals 9a, 10a, and 11a in case 2.

Figure 8 and Figure 9 show the comparison of the voltage rise for both cases when the PV system penetration level is 100%. It is observed that in both cases, the maximum voltage is maintained at 1 p.u when DSTATCOM-Fuel cell is connected. The regulation of voltage at the terminals with a connected PV system also affects the voltage at the other terminals. This effect is more significant in case 2 where the voltage at the neighboring terminals is reduced by as much as 2%. Overall, by using DSTATCOM-Fuel cell voltage rise can be reduced by as much as 10.7% in case 1 and 12.3% in case 2.

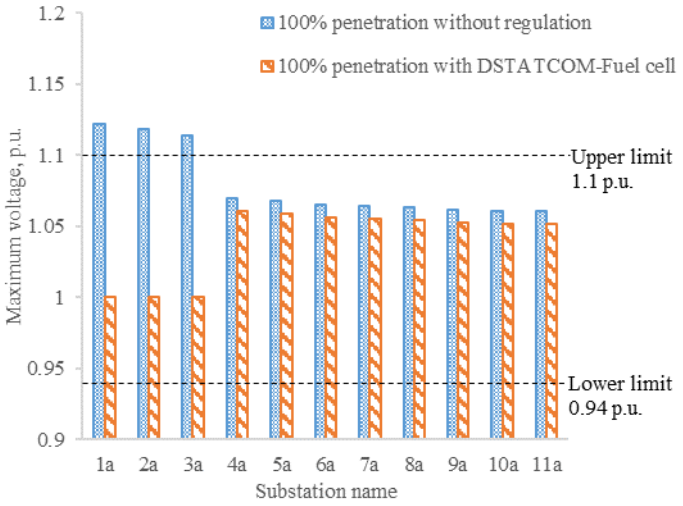

Figure 8: Comparison of voltage rise at 100% with and without regulation by DSTATCOM-Fuel cell in case 1.

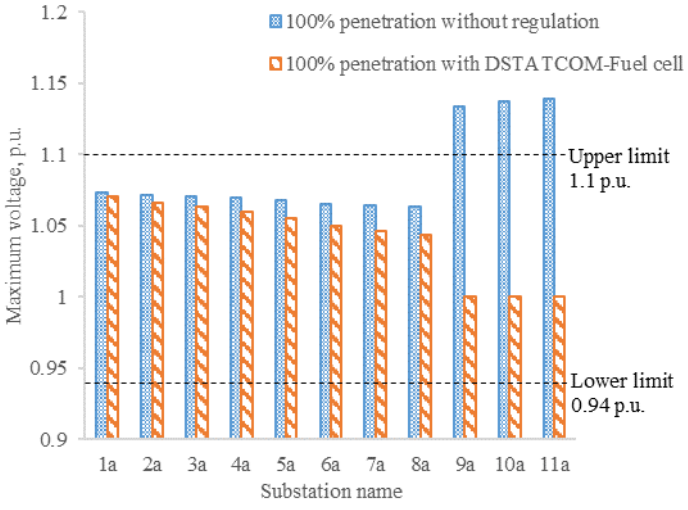

Figure 9: Comparison of voltage rise at 100% with and without regulation by DSTATCOM-Fuel cell in case 2.

Figure 10 shows the regulated power output at terminal 11a in case 3 after active power compensation by the DSTATCOM-Fuel cell system relative to the PV power output and load consumption. In order to mitigate voltage rise issues caused by reverse power flow, a combination of active and reactive power compensation is used depending on the PV power output and hydrogen tank level. When the PV power output is less than the load consumption, the hydrogen system in the DSTATCOM-Fuel cell will supply active power to the network to match the load consumption if the voltage does not exceed the statutory limit of 1.1 p.u. and the hydrogen tank level is not less than 20%. When the PV power output exceeds the load consumption, the hydrogen system charging operation is initiated if the hydrogen tank level is not full and the excess power is absorbed by the hydrogen system and converted to hydrogen.

It is observed that from 3:45:00 to 7:15:00 and 21:30:00 to 0:00:00, the regulated power is 0 kW. This is due to the hydrogen tank level being below 20%. Hence, the hydrogen system does not carry out the discharging operation during this period.

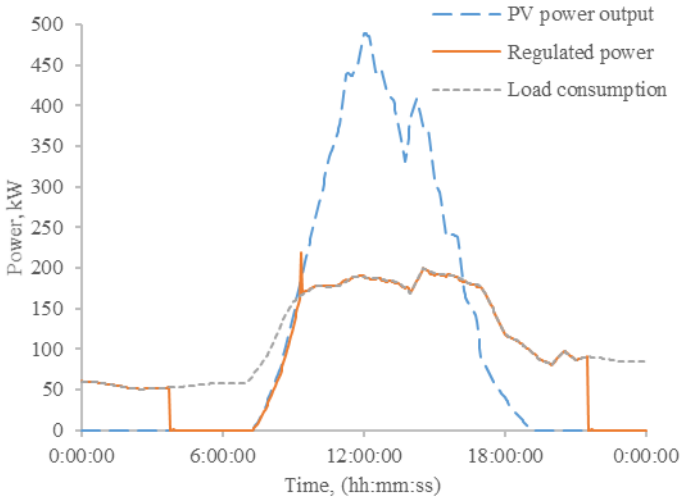

Figure 10: Regulated power output relative to PV power output and load consumption at terminal 11a in case 2.

Figure 11 shows the voltage levels throughout the day at terminal 11a in case 3. It is observed that there is significant voltage rise up to 1.14 p.u. which coincides with the peak output of the PV system. When the DSTATCOM-Fuel cell system is connected, the voltage is regulated at 1 p.u. throughout the day.

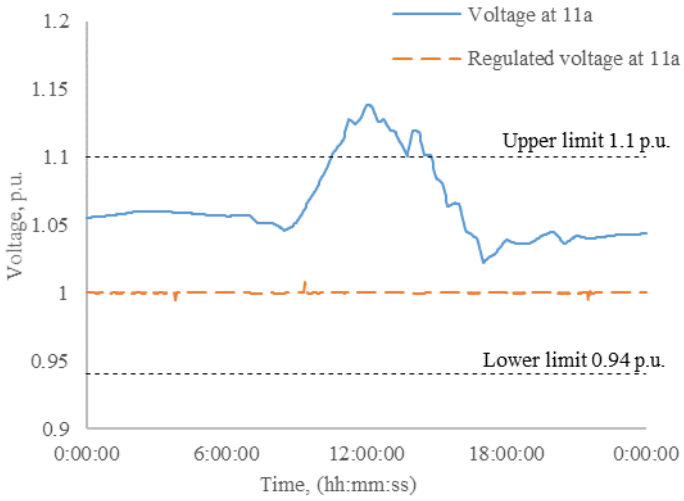

Figure 11: Regulated and unregulated voltage using DSTATCOM-Fuel cell at terminal 11a when a photovoltaic system generates 100% of the total consumed power.

Figure 12 shows the active power compensation by the fuel cell and electrolyzer and the reactive power compensation of the DSTATCOM. It is noticed that the DSTATCOM is constantly absorbing reactive power to reduce voltage level and regulated the voltage at 1 p.u. The hydrogen system charging and discharging operation depends on the PV power output. When the PV power output is high and exceeds the load consumption, the electrolyzer absorbs active power and converts it to hydrogen. When the PV power output is low and is less than the load consumption, the fuel cell supplies active power if the voltage magnitude is within the statutory limit of 1.1 p.u. It is noticed that from 3:45:00 to 7:15:00 and 21:30:00 to 0:00:00, the fuel cell does not supply any active power due to low hydrogen tank levels.

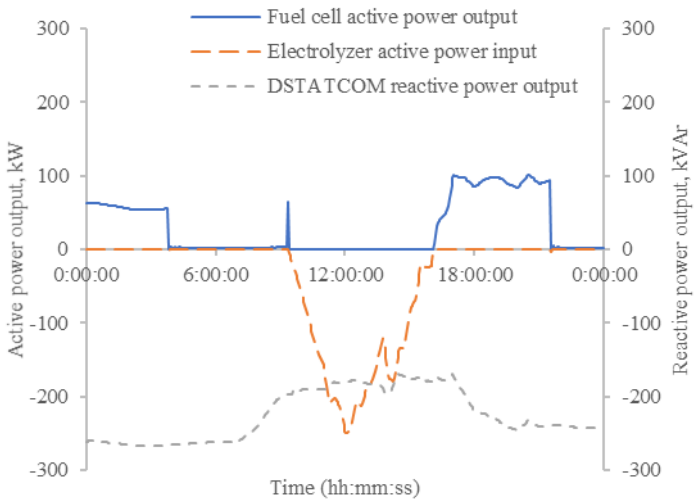

Figure 12: DSTATCOM-Fuel cell active and reactive power output at terminal 11a.

Figure 13 shows the hydrogen tank levels throughout the day. For this study, a starting level of 50%, which is 15 kg of hydrogen, has been assumed in this simulation. It is noticed that when the hydrogen tank level reaches 20%, the discharging operation of the system is turned off. Hence, only a minimal amount of hydrogen is consumed by the fuel cell to maintain the DC voltage in the DSTATCOM.

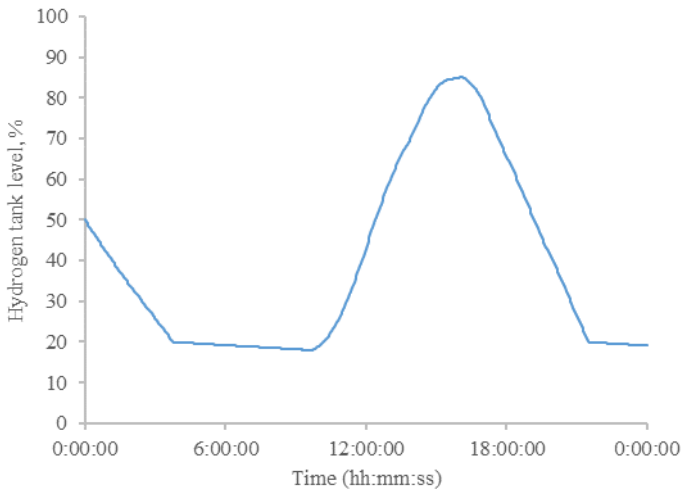

Figure 13: Hydrogen tank levels throughout the day.

4. Conclusion

Integrating large amount of renewable energy sources without suppressing the power quality always has been a challenge to the utility company. The voltage rise issues become severe when large amount of PV systems are installed across the end of a long feeder in a radial distribution network. This paper presented a DSTATCOM-Fuel cell system to perform power exchange within the grid for mitigating the voltage rise issues without curtailing the high penetration of PV systems. Excess power generated from the PV system will be converted into hydrogen and store in a hydrogen tank via an electrolyzer. In the event of high load consumption during low renewable energy generation, fuel cell will generate electricity using the hydrogen stored in the tank. Various case studies are conducted in this paper to validate the efficacy of the proposed DSTATCOM-Fuel cell system and the results have shown that this combination can mitigate the voltage rise issues up to 12.3%, maintaining the voltage at 1 p.u. while allowing high penetration of PV systems presence in the network.

ABSTRACT

A 3D image adds realism in viewing experience and can assist in simplifying the graphical displays. A Third dimension supplement to the input can improve pattern recognition, and can be used for 3D scene reconstruction and robot navigation. Recently popularity of 3D hardware is also increased which makes it a hot topic. The production of content as 3D is not matching with its need so there is scope of improvement of these 3D contents. Monocular cues give profundity data when seeing a scene with one eye. When a spectator moves, the evident relative movement of a few stationary articles against a foundation gives indicates about their relative separation. Depth estimation from monocular cues is a difficult task because single image lacks prior information like depth information, motion information etc. In Depth using scene features depth is estimated by exploring the features like shape, edges, color, texture and as well as an analysis of the environment of the scene that are of interest with respect to the target. Different objects have different hue and value and hence color is useful for depth estimation. Shape and texture provides disparity which is used to estimate depth. The main problem in converting a 2 dimensional to 3 dimensional images using single image is that it lacks information required for reconstruction in 3D data. While doing conversion by taking different cues or combination of multiple cues from scene conversion has been done e.g. structure form shape, motion, defocus etc. But such methods work for restricted scenarios not for global scenes. For instance, outdoor algorithms worked poor for indoor algorithms. Here we have implemented automatic conversion of 2 dimensional to 3 dimensional images using monocular image which can convert global images in visually comfortable 3D image.

1. Introduction

In this era 3D supporting hardware's are increasing, but the demand of content in 3D and its availability does not go hand in hand. Still 3D contents are surpassed by the 2D contents. So there is a requirement of 3D data and obvious many researchers are already working on this to close this gap in the future. One solution of direct taking 3D using multi-view method is available but it is costly and already there is large amount of 2D data is available; it will be costly to create newly 3D contents. To work on this problem, there should be the technique which convert large amount of 2D available data into 3D. The converted data should have comfortable visual quality and should not time consuming.

The available 2D data is a monocular data, which is taken from using only single view. The main problem in conversion of 2 dimension to 3 dimension using single image is that it lacks information required for reconstruction in 3D data. As discussed earlier in 2 dimension to 3 dimension conversion two approaches are available i.e. automatic and semi-automatic. Semiautomatic method gives good results but this method is time consuming and costly. Real time implementation of automatic method is preferable as semi-automatic method requires human intervention and is also known as a most trustable tool in extracting the depth from a particular scene. Disparity-pixels extracting algorithm and the camera quality determines the accuracy of the results.

2D image depth estimation is usually done in steps. A monochromatic-picture is oulined by depth where a distant separation from a camera is demonstrated by a low intensity and neaby separation is shown by a high power. i.e. it deals with luminance intensity [1]. Thus depth map, as afunction of the image co-ordinates, presents the depth in corresspondence to the camera position of a point in the visualscene. Estimating depth from a single picture or video quite exciting. As depth is an

*Priya Arokia,VIIT Research scholar,9923240728,Email: prinnu@yahoo.com

important cue of a scene which is lost in image acquisition. Because of this reason and several application needs this information, hence various methods are proposed to extract depth.

Depth Image Based Rendering (DIBR) needs a flow of mono-scopic images and a subsequent flow of depth map images that gives details of per pixel depth. Knowing the depth of each point in an input picture, rendering of any close-by perspective into a sample picture can be done by anticipating the pixels of the first picture to their appropriate 3-D areas and re-anticipating them onto the world-picture-plane. In this manner, DIBR grants the formation of novel pictures, utilizing data from the depth maps, as though they were caught with a camera from various perspectives. A favorable position of the DIBR approach is the higher capability with which coding of the depth maps can be done, than two scenes of common pictures, consequently lessening the transfer speed required for transmission. Rendering an image /video has been well realized and there are also very many algorithms available for producing quality and standard images.

In the left image the closer objects to the camera are located in the right while in the right image they are located in the left. The objects farther away from the camera appears in the same place in both the images. The object displacement in the two images is the disparity. The higher depth is indicated by a smaller disparity and a lower depth by a higher disparity. This is why pixel matching between the two images is essential. Output classification into dense and sparse is done on the stereo correspondence algorithms. An optimum mix of speed and accuracy is obtained by applying method of segments & edges.

Real time applications like robotics require dense output. Since our focus was oriented towards algorithms for real time application, the focus was on ‘dense stereo correspondense’. According to [2] dense matching algorithms are divided as local and global matching. The local one is either area based or feature based. Since the disparity is determined chiefly by the intensity values of a particular window, area-based local method applies variable windows. The window size, depending on the output can be changed such that a dense output is obtained to suit most of the real time applications. The feature extraction on which the feature based methods rely on provides a sparse output. However, they are quite fast. The accurate global methods, also called the energy based methods are rather very slow and computanionally expensive.

The object/features mapped in both right and left images is assumed to have the same intensity and the algorithms would be implemented. The illumination effects on the objects, with different view points of the cameras, may at times create a diffrence in the intensity values and invalidate these assumptions. Although the two cameras under consideration are completely tuned and both the images are simltaneously captured, stereo vision normally fails in non-ideal lighting. The reason is that the orientation or the pose of the cameras with respect to the light source may result in the variation of the light intensity of the captured images from the respective view points.

Pixel matching is then the whole idea. For this matching the pixels in the left images are to be looked for in the right images. The search becomes difficult if by chance the variations are both in the x and the Y co-ordinates, since the images are captured by to cameras from two different view points.. Image rectification, nothing but the process of horizontally aligning the epipolar lines of the two cameras is deployed to avoid this. Unidirectional alignment is done by means of linear transformations like rotate, skew and translate.

Authors have proposed an automatic 2D to 3D conversion algorithm rooted on multiple depth indications. Three distintive methods were considered for depth generation and consequently 2-D scene one depth generation method was carriedout [3]. The limitation of this method is latency. A few researchers have presented automatic pathway of learning the 3-D scene structure. In this pathway, an easier algorithm is recommended that learns the scene depth from a huge store of image + depth pairs. The produced anaglyph images provides a decent 3-D perception. However, they are notabsolutely devoid of distortions.

As image or video is having its attributes at a pixel level that are learned by a point transformation, it is applied to a monocular image.. The limitation of this system is cannot apply same transformation to images with potentially different global 3D scene structure.The same authors have also presented method to automatically convert a monoscopic video into stereo for 3D visualization. They are taking plausible automatically extracted depth maps at every frame and presented a framework using temporal information for improved and time-coherent depth when multiple frames are available. They have mixed indoor and outdoor images; hence indoor images work poor for outdoor images and vice-versa. This system is complex.

Guttmann proposed semi-automatic user defined strokes corresponding to a rough estimate of the depth values are defined for the image of interest in the scene[4]. This particular system finds the depth values for the rest of the image, and produces a depth map in order to create stereoscopic 3D image pairs. This can be further extended to automatic method.

This paper proposes the use of image rectification after the calibration of the camera.

The remainder of this brief is arranged as follows. Section II provides the process block diagram and its explanation. Section III presents the simulation results, Section IV subjective analysis and Section V draws the conclusion.

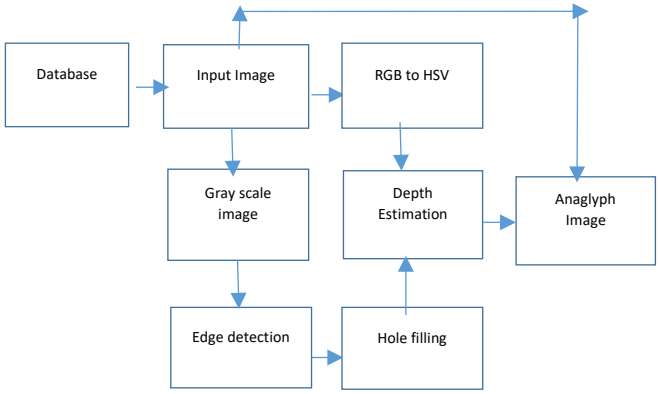

Figure 1.Block diagram of process

2. Process Block Diagram

2.1. Process flow

In 2D-to-3D conversion, input is a RGB monocular color image. Bit depth gives number of bits per pixel and here bit depth should be 24 as the input expected is a RGB image. As an input one can give image of file formats JPEG, BMP and PNG. Figure 1 is the block diagram of the whole process.

The input image is taken from database. Four datasets are used i.e. Make3D dataset [5], NYU dataset [6], Middlebury dataset [7] and our own dataset. Make3D dataset is of outdoor images. It consists of 534 images, each is having 1704X272 dimensions.

The NYU-depth v2 dataset is involved video grouping from assortment scenes taken indoor captured by both RGB and Depth cameras of Microsoft Kinect. This dataset consists of indoor scenes like basements, bedrooms, bathrooms, bookstores, cafe, classroom, dining rooms, kitchens, living rooms, offices etc. Middlebury dataset is one of the well-known dataset, which comprised of stereo images of various scenes along with its ground truth. We also have created indoor dataset of 22 images each image is of 4608X3456 using Sony Device [8]. Input image is given from one of this dataset. For computational efficiency original input images are re-sized.

2.2. RGB to HSV Conversion

The Papilio one is an expandable development board having a "Xilinx Spartan 3E FPGA chip", which is powerful and is in open-source. The whole conversion process happens in Papilio one.

The conversion process of RGB to HSV is shown in Figure 2. 2D query image is given from PC through MATLAB to Papilio one and the development board is used for conversion.From HSV value (V) attribute is considered here to estimate depth and hence a color model from RGB to HSV conversion is done.

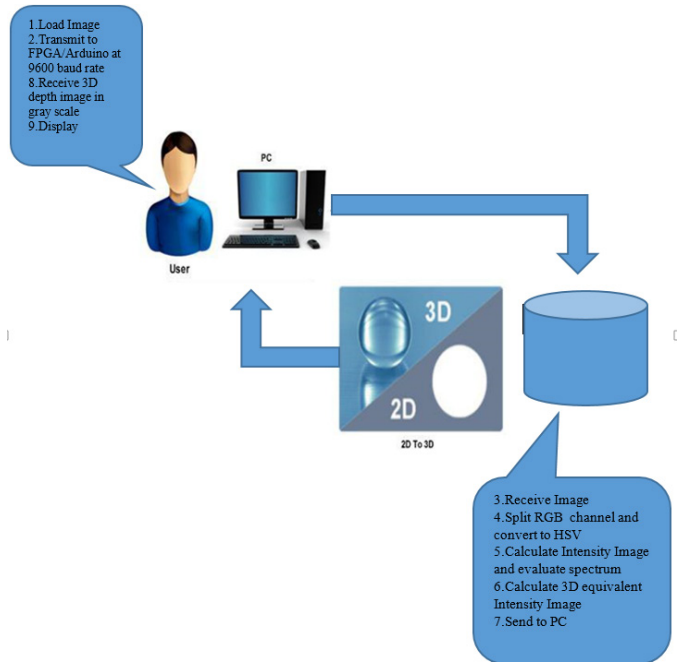

Figure 2. Block diagram of process

Since Papilio One is used for conversion and it has memory constraint ,instead of whole image being sent at a time to the kit, serially pixels are sent to Papilio One for computation one row after another. HSV image is then generated in MATLAB from these processed pixels.

2.3. Edge detection

As per Figure 1 the next step is to detect the edge. Here the input images are converted to gray scale for proper edge detection. Edge detection is the technique of identifying those points in the digitized image which causes a drastic change in the splendor of the image or that causes discontinuities. The edges are identified by rapid change in frequency. The objective is to capture these much needed rapid variations in the properties of the world. Edge detection is done by applying masks on the input which transforms the image into output image highlighting the sharp edges in the object. There are several masks available like Canny, Prewitt, Sobel, Roberts etc. which extracts the sharpness in the images.

The Canny detection is a popular edge detection method. It basically locates the maxima of gradient-I in the neighborhood. Gaussian channel derivative is used to compute the gradient. All the four steps [9] are used to detect the edges of the image. The strategy utilizes two edges, to distinguish solid and frail edges, and incorporates the powerless edges in the yield just on the off chance that they are associated with solid edges. Gaussian channel is connected to evacuate any clamor show in a picture, and more inclined to identify genuine powerless edges [10].

Object should be detected properly, because if it is not then the next operation of hole filling will not be performed properly. Morphological dilation operation is added before the hole-filling to improve the object detection. Pixels are added to the object boundaries during dilation and the number of pixels added is a function of the shape & size of the structuring elements deployed for processing the image.

2.4. Hole filling and depth estimation

The images under go morphological operations viz., dilation and after dilation operation, the detected objects are filled using MATLAB imfill function. For this filling operation first labeling is done using `bwlabel' function which generates a matrix same size as that of the input matrix containing labels for all connected objects in the input matrix.

The input "n" can either be a four connected or eight connected objects with a default value of eight. The pixels with 0 labelling coressponds to the background and the labelling from 1 through 8 coressponds to each of the coneected objects. The ouput gives the number of the connected objects in the iput image. Along with bwlabel function n is used to return vectors of indices for the pixels that make up a specific object. Then that specific object is cropped for filling new depth values using `imcrop' function. This function creates an interactive crop image. From that cropped object maximum and minimum values are calculated. For the same coordinates, values of V (intensity) retrieved from FPGA are stored in array. From the array maximum and minimum values of V are searched to calculate the range. 255/range = multiValue. So for the same coordinates the

new value which gives depth is calculated using following equation:

$$val=((imgHSV(yy,xx,3))-minVal)*multiVal \quad (1)$$

where, val is new depth value of depth, (imgHSV(yy,xx,3) gives values of V for that particular pixel, minVal is minimum value from array and multivalue .

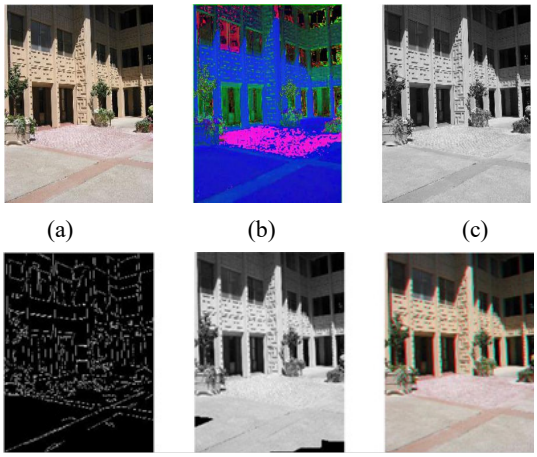
2.5. Anaglyph Image Generation

So far depth map image is estimated, now using this depth map and 2D input image anaglyph image is generated. The anaglyph image is generated by using the difference value of each pixel from the depth map. Each pixel is shifted by the corresponding difference value in an input image. The parallax is given by

$$parallax(x,y)=C[1-depth(x,y)]/128 \quad (2)$$

where C is the maximum parallax. Anaglyph image is got by shifting each pixel to the right by parallax(x,y)/2.

Algorithm:



- Load input 2D image from database.
- Send input images pixel serially to FPGA to perform RGB to HSV conversion.
- Display HSV image on PC.
- Convert input image to grayscale image.
- Perform Canny edge detection on grayscale image.
- Display edge detection output.
- Perform dilation operation on edge detection output.
- Perform hole filling operation.
- Label images for object detection.
- Crop the detected objects.
- From the HSV image get the values of V for the same coordinates of the object.
- Assign depth value to new pixel using equation 1 and display.
- Generate anaglyph images and display.

3. Simulation Results

The algorithms we used work only for restricted scenario since cues are not considered. Proposed algorithm is tested for indoor image database, outdoor images database and database created by our own. Figure 3 is the output of various stages of proposed block diagram.

Input is from Make3D dataset of 500X 500 resolution. The first dataset used is a Make3D dataset made up of out-door images which has the depth fields that are acquired by a laser finder. For computational efficiency, the images are resized and the resolutions of the Make3D images are 1704 x 2272. All the stages of the block diagram are given as the output. Figure 3 (f) gives the 3d output which has to be viewed by the 3d glasses.

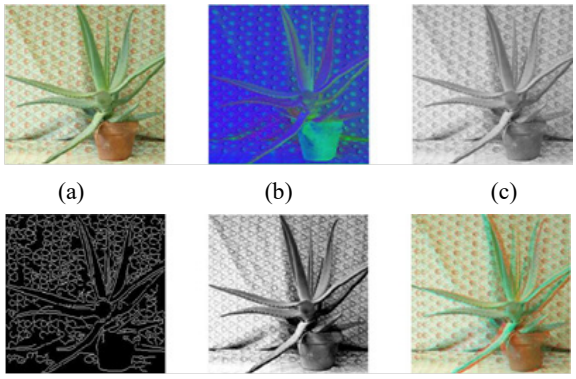


Figure 4 is the output of various stages and Input is from Middlebury dataset of 300X 259 resolution an in-door image, for computational efficiency, the images are re-sized. Figure 4 (f) gives the 3d output which has to be viewed by the 3d glasses.

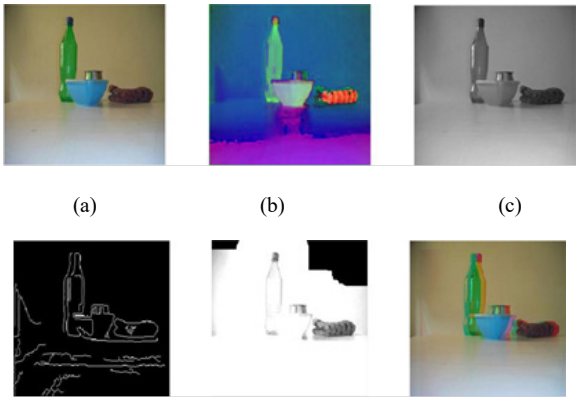
(a) (b) (c)

(d) (e) (f)

Figure 3: (a) Query (b) HSV (c) Grayscale (d) Edge Detected (e) Depth (f) Anaglyph .



(a) (b) (c)

(d) (e) (f)

Figure 4: (a) Query (b) HSV (c) Grayscale (d) Edge Detected (e) Depth (f) Anaglyph.

We continued the experiment with our own database with dataset of 300 X 225 resolution, indoor images. The quality of the output was good as that of the Middlebury.

(a) (b) (c)

(d) (e) (f)

Figure 5: (a) Query (b) HSV (c) Grayscale (d) Edge Detected (e) Depth (f) Anaglyph

Following is the analysis of the images in terms of computing time efficiency of Make 3D dataset. The algorithm was executed in MATLAB and in FPGA and the table shows the time taken of the images for execution.

Table 1: Analysis of Images from Make3D Dataset

Size of input image	Execution time	
	MATLAB	FPGA
100*100	1.08ms	15min 26s
200*200	1.76ms	1hr 00min
300*300	9.05ms	2hr 26min
400*400	37.41ms	4hr 06min
500*500	122.65ms	-
600*600	274.75ms	-
700*700	505.38ms	-
800*800	888.00ms	-
900*900	1451.07ms	-
1000*1000	2196.97ms	-

The time taken by MATLAB to execute the complete process using a single core processor is in milliseconds and for FPGA the time taken is exponentially increasing with increase in the size of the input image. For any real time processing MATLAB would give a time efficient output and the future scope is to extend this algorithm work for multi-core processors.

4. Subjective analysis

Various objective quality metrics like MSE and PSNR are available. This can be used for objective analysis of 2D but not suitable for the 2-D to 3-D contents [11]. The generated depth-map is a pseudo-depth map and is not a real depth-map. So to evaluate the visual quality of output of proposed algorithm it is compared with other algorithms [12]. Figure 6 shows the form shared with people to mark the quality of the images shared with them to analyze. It shows the credit score in percentage depending on the visual perception of the viewer.

Figure 7 shows the subjective analysis of people. For subjective analysis survey from 50 people with normal or correct-to-normal visual acuity and stereo acuity for visual comfort of output. We have shown them output of our algorithm and for the same images output of other two methods. Images are taken from standard dataset.

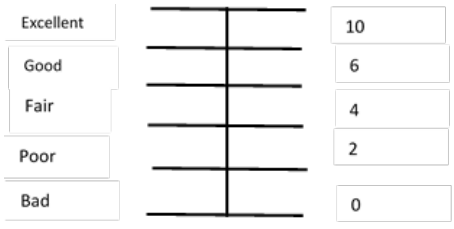


Figure 6: Rating scales used for assessment

Table 2 shows subjective evaluation, where M1 is our method, M2 is global method and M3 is Make3d algorithm. People has given good scale to our algorithm while excellent scale to other to algorithms. The scale on which people has given rating is shown in Figure 6. From the survey its found that they felt proposed methods output good, while of other two method's excellent. The subjective analysis also shows that proposed algorithm provides comfortable viewing experience.

Table 2: Sample Analysis of Images from Make3D Dataset

5. Conclusion

In current scenario, 2D-to-3D conversion is a very active research area as it gives more lifelike viewing experience and hence its popularity is increasing. As there are many hardware available which support 3D and hence there is an urgent need of 3D contents. Though there are distinct methods introduced by researchers but these method works for restricted scenes.

In this paper 2D-to-3D image conversion was implemented which can take global image as an input. The work comes under automatic approach of conversion, in which algorithm itself does the whole conversion. Using RGB to HSV conversion along with simple MATLAB operations 2D image is converted into 3D. The method was tested on three distinct standard databases and on our own database. For output analysis subjective evaluation was done on 10 people for visual comfort of implemented systems output with the output of other two methods. People rated output as good from scaling range as visual comfort.

The work can be further extended by working on video. Here conversion from RGB to HSV step is implemented on starter kit of FPGA; it may be possible to implement whole system on a computational efficient FPGA.

Conflict of Interest

The authors declare no conflict of interest.

Acknowledgment

The authors hereby express their gratitude to Dr. D Y. Patil Institute of Engineering, Research and Management, Akurdi for facilitating this research. We are highly privileged to have got the much needed support and assistance from almost each and every people of the institution for the successful outcome of this work. Special thanks, to all the teaching staffs of the institution, for their constant encouragement and guidance which has helped us in successfully completing this work. .

Improving the hand motor skills in post-stroke patients through rehabilitation based on movement intention derived signals from the brain in conjunction with robot-assistive technologies are explored. The experimental work is conducted using Electroencephalogram based Brain-Computer Interface (EEG-BCI) system and the AMADEO hand rehabilitation robotic device. Two protocols using visual-cues and then using a 2-Dimensional (2D) interactive game is presented on a computer screen to healthy subjects as well as post-stroke patients performing the hand movements. The movement intention signals during hand movement are detected through the Support Vector Machine (SVM) classifier. The intent signals produced at six distinct electrodes are investigated to determine electrodes contributing most to the SVM classifier's performance. Overall, the game protocol shows better classification results for both healthy and stroke patients compared to the visual-cues protocol. FC3 is found to be the most consistent electrode site for the detection of the motor intention of the hand for both protocols. In the experimental work, average classification accuracy for the visual-cues protocol of 67.56% for healthy subjects and 56.24% for stroke patients were obtained. For the game protocol, the classifier accuracy produced for healthy participants was 79.7% and for the post-stroke patients was 66.64%. The results confirm that the intention signal is more pronounced during more engaging activities, such as playing games, for both healthy and stroke subjects. Therefore, the effectiveness of rehabilitation therapy for post-stroke patients could be significantly enhanced using interactive and engaging exercise protocols.

1. Introduction

This paper is an extension of work presented in 18th IEEE International Conference on Bioinformatics and Bioengineering (BIBE) [1]. Stroke is the main cause of prolonged disability among adults [2]. The most common impairment occurs when a stroke victim has a motor loss of limb(s) on one side of the body causing difficulty with walking and ability to perform activities of daily living. There are many types of rehabilitation therapies currently being practiced, and others being investigated. One of the therapies types being investigated and coming into clinical practice is Robot-Assisted therapy. Advancement in robotic technology over the last decade has led to increasing interest in this type of therapy. For example, Ang et al. [3] used the MIT-Manus robot for a randomized control study with 26 stroke patients to restore their arm movement. Similarly, a haptic knob robot is being used for arm rehabilitation of stroke survivors with positive outcomes [4]. A state-of-the-art robotic device called AMADEO, designed for fine finger motor skill improvement was tested on eight cortical stroke patients and resulted in a 35% increase in their hand movement after multi-session training [5]. All these strategies of post-stroke rehabilitation depend on some neurological adaption that occurs in the patient's brain to restore the impaired function of the limb. The brain's ability to adapt to new neural changes, even in adulthood, is called the neuroplasticity or brain plasticity [6].

Brain-Computer Interface (BCI) has an ability to utilize neuroplasticity mechanisms to improve motor function of post-stroke patients during their rehabilitation process [7]. Enhanced motor intention improves motor execution which in turn is fed back to the rehabilitation process. The mechanism of neuroplasticity reinforces the neural pathways which control the movement, leading to functional and motor recovery of the

*Corresponding Author: Maryam Butt, mb077@uowmail.edu.au

patients [8]. Brain signals that have been used in BCI systems include Electroencephalogram (EEG), Magnetoencephalography (MEG), ElectroCorticoGraphy (ECoG), as well as functional Near-InfraRed Spectroscopy (fNIRS). Amongst these modalities, EEG is the most common modality employed to drive various BCI systems [9]. It is popular because it is not an invasive approach to record the brain's electrical activities, and because EEG signals have the highest resolution in time-domain [10].

Many studies demonstrate applications of EEG-BCI systems to detect movement intention for various upper-limbs, such as movements of the arm [11-15], elbow [16], [17] and wrist [18] and hand [19-23] for post-stroke rehabilitation.

A self-paced reaching arm movement with the help of a haptic device has been studied in [11] and [12]. In a single-trial EEG protocol, the intention of reaching movement was detected about 500 ms before the actual limb movement [11]. In the follow-up study, the movement directions were decoded up to 76% accuracy for healthy subjects and up to 47% accuracy for stroke patients performed with their impaired arm [12]. Ibanez et al. [13] recruited six healthy subjects and six stroke patients to detect the movement onset of voluntary arm reaching action. The results showed that the True Positive Rate (TPR) of the classifier for healthy participants was 74.5±13.8% while for stroke patients, TPR was 82.2±10.4%. In another study, four chronic post-stroke patients participated in eight training sessions based on arm reaching actions [14]. The intention for the movement was decoded using an EEG-BCI system which then triggered Functional Electrical Stimulation (FES) for further assistance to perform the task. The authors stated that their protocol correctly classified about 66% of movements with an average detection latency of 112±278 ms. Moreover, clinical tests and kinematics results proved the feasibility of the designed intervention for post-stroke recovery.

Among many classifiers, Support Vector Machine (SVM) classifier is commonly used in intent detection of limb movement. For example, Frisoli et al. [15] proposed a gaze-based robot-assisted arm movement protocol in which the real-time movement of a robotic device was controlled by the intended signal of subjects. A Motor Imagery (MI) based EEG-BCI system was used to detect the intention signal through SVM. The authors reported a classification accuracy rate of 89.4±5% for robot-based movement mode. Similarly, Hortal et al. [16] measured the classification performance of SVM by designing a hybrid EEG-BCI system composed of an exoskeleton device and FES for elbow movement. The hybrid BCI system was tested using two training protocols which were MI-based training protocol and a training protocol based on motor intention detection. In the first training protocol, the authors achieved a classification accuracy of about 83% for healthy subjects and 65.3% for stroke patients, while in the second training protocol, the accuracy achieved was approximately 77% and 71.6% for healthy and patient groups, respectively.

Asynchronous EEG-BCI systems are also being deployed for motor intent detection of upper limbs. The triggering of a robotic device through intention signal was studied by Bhagat et al. [17] for elbow joint movement using an asynchronous EEG-BCI robot-assisted system. The motor intent signal of four chronic stroke patients was detected which then triggered an exoskeleton device called MAHI-EXO-II to encourage and guide the active participation of subjects. The intention signal was detected on average −367±328 ms before the actual motor execution. Bai et al. [18] also developed an asynchronous BCI protocol for real-time and online prediction of the self-paced movement of the wrist. Seven healthy subjects were recruited in the study to perform an extension of their wrist whenever they wanted. The authors successfully predicted the voluntary movement at approximately 0.6 s before the real execution of the movement.

The latest applications of EEG-BCI systems have been in detecting intention for movement of the hand, which has a greater complexity of movement than other upper limbs. The hand occupies the largest cortical representation in the motor cortex of the brain [24] as well as playing the most vital role in our daily life activities. Muralidharan et al. [19] distinguished resting state from the extension of fingers by using an open-loop EEG-BCI system. They detected attempted finger extension by post-stroke patients at about 200 to 600 ms before the actual movement onset. Only one EEG channel has been used by Jochumsen et al. [20] to detect motor intent signal during palmar grasp action using handgrip dynamometer. The signal was then decoded into speed and force. They showed that approximately 75% of the movements were detected 100 ms before movement onset, and approximately 60% of task-related movements were accurately decoded into the force and speed levels according to the performed task movements. In a separate study, Jochumsen et al. [21] also distinguish between the intention for three types of grasp tasks (palmar, pinch and lateral) achieving accuracy of 79%, 76%, and 63% respectively during 1-class, 2-class and 3-class classification problems. Ofner et al. [22] classified several arm movements which include hand-opening, hand-closing, forearm supination, forearm pronation, elbow extension as well as elbow flexion. The authors state that one movement can be classified from another with 55% classification accuracy. This research group achieved the classification accuracy of 93% while classifying grasping actions of hand from its rest state compared to the classification results stated by Jochumsen et al. in [21] [23].

In this study, we combine detection of motor intention signals using EEG-BCI system with robot assistive technologies to improve the effectiveness of the hand motor skills in post-stroke patients. Our first stage of research based on an EEG-BCI system and the AMADEO finger-hand rehabilitation robotic device (Tyromotion GmbH, Graz, Austria) is reported. The experimental setup is designed for classification of movement intention of hand-closing versus rest state. It consists of two distinct protocols, which we refer to as protocol A and protocol B. Protocol A, termed as visual-cues protocol, consists of hand-opening and hand-closing pictures which are presented to subjects. In protocol B subjects played an AMADEO game called Shoot-out. We utilize SVM, which is the most common supervised learning algorithm used for these classification problems. Intention signal produced at different single electrodes' positions during hand movement is analyzed to determine the electrode that is most consistent for the accuracy of SVM classifier.

The rest of the paper is organized as follows. In section 2, the experimental platform and experimental set up are introduced. In section 3, the pre-processing of the signals produced in the experimental work and the classifications method, the classification performance metrics are described. In section 4, the

results of the validation of the approach on stroke patients and benchmarking against the healthy subjects are presented. Some conclusions are finally drawn in section 5.

2. Experimental Design and Platform

2.1. Participants

The participants in the experimental work consisted of healthy subjects and post-stroke patients. The healthy subjects consist of four male participants with a mean age of 28 years and no history of any neurological disorder. Two post-stroke patients both right hand dominant were initially assessed through two commonly used clinical tests, namely the Motor Assessment Scale (MAS) and Fugl-Meyer Assessment (FMA) scale. Table I shows each patient's demographic details as well as their clinical tests scores. The Ethics committee at the University of Wollongong approved all methods and procedures performed in this experiment (Ethics application number: 2014/400). All participants provided written informed consent before this study commenced.

2.2. AMADEO Finger-Hand Rehabilitation Device

The AMADEO finger-hand rehabilitation device is an end-effector robot-assistive system specifically developed for hand movement recovery of post-stroke patients as shown in Figure 1 [25]. It has five Degrees-of-Freedom (DoF) allowing both passive and active movements of fingers as well as the thumb. The robot can generate various patterns of fingers and thumb movements as well as subjects can interact with the robotic device through 2D games.

(A) (B)

Figure 1: (A) AMADEO Finger-Hand Rehabilitation Unit (B) Hand-Arm Adjustment Support

2.3. Acquisition of EEG Signal

The EEG signals were acquired by deploying a 32 electrodes Ag/AgCl Quick-Cap (Compumedics-Neuroscan) in accordance to the 10-20 system for positioning electrodes. The electrode positioning diagram of the Quick-Cap is given in Figure 2. The Grael 4K EEG amplifier was employed in this study which has been set to 2048 Hz of sampling frequency. Of the 32 channels, the FPz electrode was used as the ground electrode and the CPz was set as the reference electrode. Thirty remaining electrodes were used for the acquisition of brain signal. In addition, the two electrodes were placed below the left eye and on the supraorbital ridge to record vertical eye movements and eye-blinks. Moreover, two other electrodes placed over the outer canthus of both eyes were used to monitor horizontal movements of eyes.

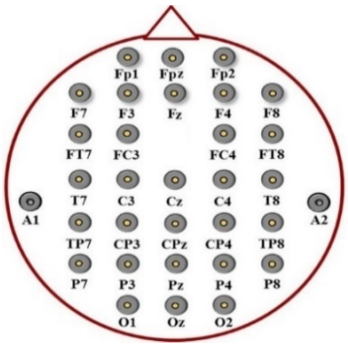

Figure 2: Quick-Cap Electrodes Positions

2.4. Experimental Setup

Participants were seated upright on a comfortable chair with their right arms attached to the AMADEO hand-arm adjustment support unit. During protocol A, each participant was trained to focus on visual-cues displayed on a computer screen. Visual-cues displaying hand-opening and hand-closing pictures to alert subjects to perform these specific hand movements. The hand-closing pictures were displayed every 5 s, followed by the hand-opening pictures 1 s later with a 4 s waiting period. This resulted in 5 s gap between any two hand-closing visual-cues. Each set comprised 23 trials of hand movements during this protocol.

Of the games available on the AMADEO system, the 'Shoot-out' was chosen for use in protocol B. The playing screen of Shoot-out game is shown in Figure 3. In this game, the subject closes their hand to shoot the drum coming out at equal time intervals. Subjects have up to 23 trials of the hand movements in each block.

Figure 3: AMADEO Shoot-out Game

Table 1: Stroke Patients' Details and Clinical Test Scores

Gender	Age	Stroke type	Time since stroke (months)	Lesion location	Paretic Hand	MAS Hand Score (0-6)	FMA Hand Score (0-14)
Female	64	Ischemic	7	Left pons	Right	2	9
Male	60	Ischemic	4	Left pons & left frontal regions	Right	2	8

All participants performed 6 blocks consisting of 23 trials (6 x 23 = 138) for both protocols. At each hand-closing event, manual event markers were sent to the CURRY 8 (Compumedics, Neuroscan) software which was used for EEG acquisition. Protocol B was the Shoot-out game of AMADEO, which was more interesting and interactive compared to protocol A. We explored the hypothesis in this study that whether a stronger motor intention signal can be produced and detected through SVM during protocol B than protocol A.

3. Signal Processing for Motor Intention Detection

The intention signal during hand-closing movements was detected by offline analysis of the data for both healthy and stroke subjects. The movement intention of a limb produces special EEG patterns in specific parts of the brain and such slow event-related potential is called Movement Related Cortical Potential (MRCP). It appears in the delta frequency band of EEG signal as a direct-current shifts up to 2 s prior to cue-based as well as self-initiated movements [26]. When the person performs the required motor action, the MRCP disappears. The continuous EEG signal at the selected electrodes is divided into two types of epochs. The first, containing MRCP signal is called Move epoch and the second, which does not have an MRCP signal, is named as No-Move epoch. Different time-domain features of MRCP signal are extracted from both these epochs. SVM algorithm is then employed to classify Move and No-Move epochs and, therefore, detecting intention signal of the hand movement.

3.1. Pre-processing

The first step in pre-processing is to filter the EEG signal for the frequency range between 0.1-1 Hz [17] as this narrow range of delta band best captures the anticipatory based MRCP [27]. This band-pass filtering was applied in three steps: first, a high-pass filter with cut-off frequency (f_c) of 0.1 Hz was applied; second, for re-referencing of signals, a Common Average Reference (CAR) filter was applied to all signals; and third, a low-pass filter with f_c of 1 Hz was applied. Both low-pass and high-pass filters were 4th order Butterworth causal filters. After filtering, the signals were down-sampled from 2048 Hz to 20 Hz to increase computational efficiency [17]. The CURRY 8 (Compumedics-Neuroscan) software was used to perform all the aforementioned pre-processing steps.

3.2. Epoch Extraction & Channel Selection

For further processing, the data were imported into a MATLAB toolbox known as 'EEGLAB'. Generally, MRCP signal does not exist 2 s before the onset of movement, all Move epochs were extracted from continuous EEG data between -2 s to 0 s with 0 s indicating the instance of actual motor execution. Between 0.5 s to 2.5 s, No-Move epochs were extracted when subjects opened or relaxed their hands. Therefore, epoch length was fixed at 2 s for both epochs. All Move epochs were inspected visually for artifacts, for instances eye-blinks, head movement, and other movement-related artifacts, and then these were removed from the data.

The EEG electrodes located over the left hemisphere of the brain were only chosen because the right-hand movement was considered in this experiment. The electrodes selected were C3, FC3, CP3, Cz, T7 and a Short Laplacian (SL) channel calculated using the C3-(FC3+Cz+CP3+T7)/4 formula [28]. In literature, the C3 channel is most commonly used for right-hand motor intention detection using the MRCP signal. The four neighboring electrodes of the C3 channel and their linear combination were also investigated to determine the best electrode choice for each protocol. It is possible that the negative peak of the MRCP exists before -1.5 s is due to artifact presence. Therefore, every Move epoch was again visually inspected and such Move epochs and their counter-part No-Move epochs were deleted to get the final processed data which was then used to extract features of MRCP signal.

3.3. Feature Extraction & Classification

The two time-domain features from both the Move and No-Move epochs were extracted. These features were the negative peak and the slope of the MRCP signal. The Move epochs have prominent negative peak and slope of MRCP signal compared to No-Move epochs. Based on these time-domain features, the SVM classifier differentiates between both epochs. These were plotted and outliers were removed (along with their counter-class features) before applying the SVM. This prevented biasing the results of SVM due to outliers. In each protocol, an average of 10±2 epochs was rejected per subject. The Move class was marked with a label of '1' and the No-Move class was marked with a label of '0'. Depending on these input features, the SVM classified between class 1 and 0. Three-fourths of the dataset was utilized for training data while one-fourth was used as test data for classification.

3.4. Evaluation of SVM Classifier Performance

The SVM classifier's performance was determined based on classification accuracy percentage, True Positive Rate (TPR)–also known as sensitivity and True Negative Rate (TNR)–also called specificity. They were calculated using the relationships given in (1), (2) and (3) where True Positive, False Positive, True Negative and False Negative were abbreviated as TP, FP, TN, and FN respectively.

$$\text{Accuracy}=(TP+TN)/(TP+TN+FP+FN) \quad (1)$$

$$TPR=TP/(TP+FN) \quad (2)$$

$$TNR=TN/(TN+FP) \quad (3)$$

Receiver Operating Characteristics (ROC) curve was analyzed to determine the classifier's performance during protocol A and B. Moreover, Area Under the Curve (AUC) for the ROC curve was calculated for both protocols. In the end, all these performance metrics were compared to find out which protocol helps better to maintain stronger motor intention level in both healthy subjects and stroke patients and therefore, obtaining better classification results. In addition, these results also could show which electrode was the best choice for intent detection during protocol A and protocol B.

4. Results & Discussion

The experimental work demonstrated the utility of the AMADEO device for rehabilitation of post-stroke patients, while also performing the motor intention detection using the described SVM algorithm.

Six electrodes which include C3, FC3, CP3, Cz, T7, and SL were chosen to determine the importance of electrode selection in intent detection during each protocol. Performance metrics were calculated after the SVM application on test data, including classification accuracy, TPR, TNR and AUC for ROC.

4.1. Intent Detection of Stroke Patients

The performance of the SVM algorithm for detection of hand motor intention signal produced by the stroke patients is studied in this sub-section. Table II presents the accuracy of the SVM classifier at all six selected electrodes for protocols A and B. For protocol A, the FC3 electrode shows the maximum accuracy of the SVM classifier of about 72%. Whereas, the same electrode shows classification accuracy of 89% for intent detection when stroke patients perform the hand movement during protocol B. This supports our hypothesis that during protocol B, subjects are more involved in performing hand movement and are likely to have greater classification accuracy as compared to protocol A. The same trend is demonstrated by the results of C3, CP3, T7, and SL electrodes. However, for electrode Cz, protocol B is showing lower classifier's accuracy than that for protocol A. The list of electrodes based on the classification accuracies from high-to-low for protocol A is FC3, Cz, SL, C3, T7, and CP3. A similar list for the protocol B is FC3, SL, C3, CP3, T7, and Cz. It is clear from the classifier accuracy results that for both protocols, FC3 shows the maximum classifier performance. However, for protocol B the classifier's accuracy is higher than that for protocol A at all electrode sites except Cz.

4.2. Intent Detection of Healthy Subjects

The results of the classifier accuracy for healthy subjects for protocols A and B are presented in Table III. The analysis of data for healthy subjects shows that protocol B has better accuracy of SVM classifier than protocol A, except for the channels Cz and T7. With respect to the results acquired for FC3, protocol B has an accuracy of SVM classifier of 98% while the classification accuracy of protocol A is 86%. From Table III, it is clear that the classifier's accuracy varies in accordance with the selected electrode. For protocol A, the electrodes can be listed as FC3, Cz, C3, T7, SL, CP3 electrodes can be ranked in order of their effectiveness in determining the intent signal. Similarly, for protocol B, the ranking is FC3, C3, SL, CP3, Cz, T7.

Table 2: Accuracy of SVM Classifier for Post-Stroke Patients

Channel	SVM Classifier's Accuracy (%)	
	Protocol A	Protocol B
C3	52.88	81.01
CP3	26.25	60.16
FC3	72.22	88.89
Cz	70.45	34.56
T7	49.29	51.43
SL	66.33	83.78

Table 3: Accuracy of SVM Classifier for Healthy Subjects

Channel	SVM Classifier's Accuracy (%)	
	Protocol A	Protocol B
C3	64.58	92.86
CP3	57.7	76.3
FC3	86.25	98.0
Cz	73.81	70.0
T7	63	57.69
SL	60.0	83.33

When the Cz electrode from stroke patients' data as well as the Cz and T7 electrodes from healthy subjects' data were chosen, protocol A had slightly better classification accuracy than protocol B. There could be many possible reasons for this apparent contradiction. The artifact removal is performed using visual inspection method so it might be possible that the data at Cz and T7 electrodes still contain some artifacts in the test data used for protocol B that made the classifier accuracy for protocol B less than protocol A. Moreover, the outlier values removal form Cz and T7 electrodes might cause loss of large data points for protocol B and due to fewer test data values, the performance of protocol B has deteriorated.

4.3. Other Performance Metrics of the SVM Classifier

The accuracy alone cannot justify the performance of the classifier, therefore, sensitivity (TPR) and specificity (TNR) parameters should be also considered. The TPR and TNR values show whether the extracted features in Move and No-Move classes are distinct enough to be classified accurately by SVM. Figure 4 shows bar graph representations of TPR and TNR using stroke patients' data from protocol A at all six electrodes. Similarly, Figure 5 shows TPR and TNR values at all selected electrodes for protocol B. For protocol A, Figure 4 shows that

TNR for CP3, FC3, Cz, and SL is significantly lower than its corresponding TPR. On the other hand, in the case of T7, TNR is slightly higher and slightly lower for C3. However, for protocol B, TNR is higher than TPR for each choice of electrode except for CP3 and T7 as shown in Figure 5.

Similarly, TPR and TNR values using data of healthy subjects for both protocols is shown in Figure 6 and Figure 7. In the case of protocol A, Figure 6 demonstrates that TPR obtained for C3, Cz and FC3 is higher than its corresponding TNR, whereas, for CP3, T7, and SL, the reverse is the case. Figure 7 shows that TPR, for all six electrodes, is higher than its corresponding TNR for protocol B indicating that the Move class contains the adequate features to correctly detect motor intention signal.

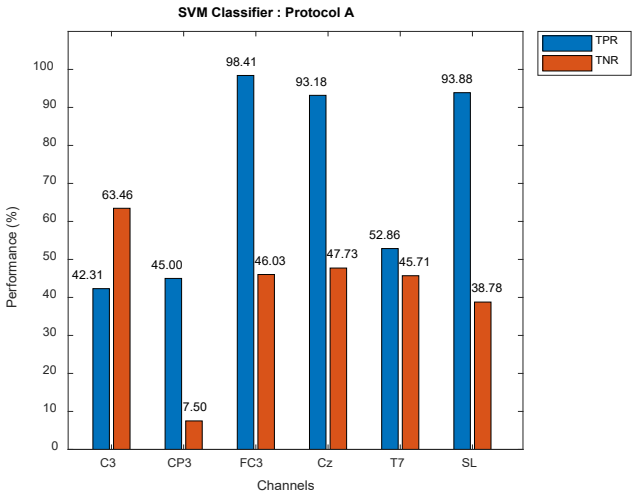

Figure 4: Protocol A Stroke Patients Data

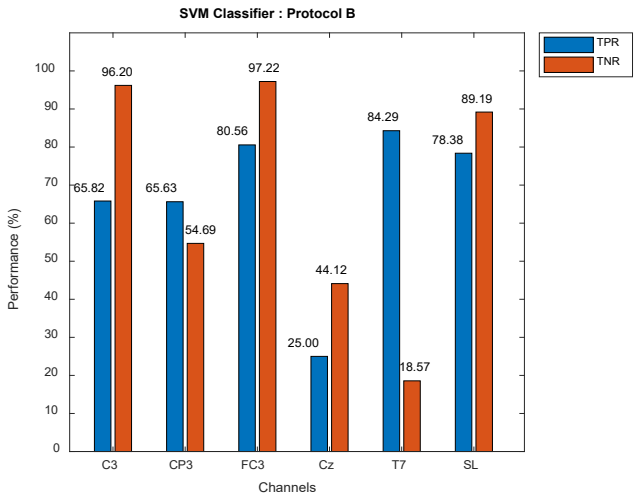

Figure 5: Protocol B Stroke Patients Data

ROC curve is another way of comparing the performance of the SVM classifier for protocols A and B. Figure 8 shows the ROC curve for the FC3 channel, the most appropriate channel for intent detection of hand movement for this experiment, for healthy participants which shows that protocol B has superior performance.

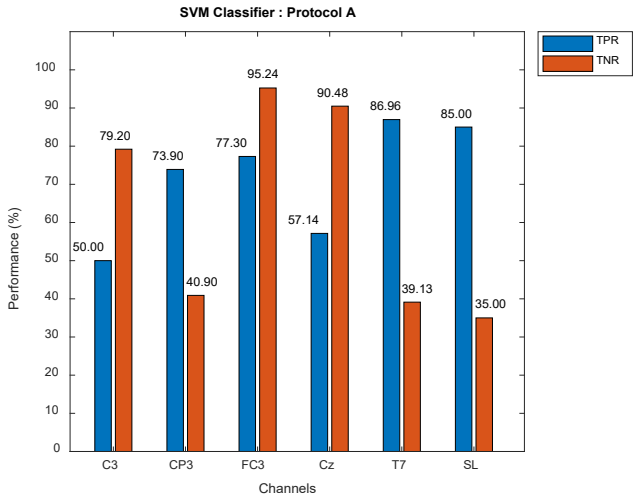

Figure 6: Protocol A Healthy Subject Data

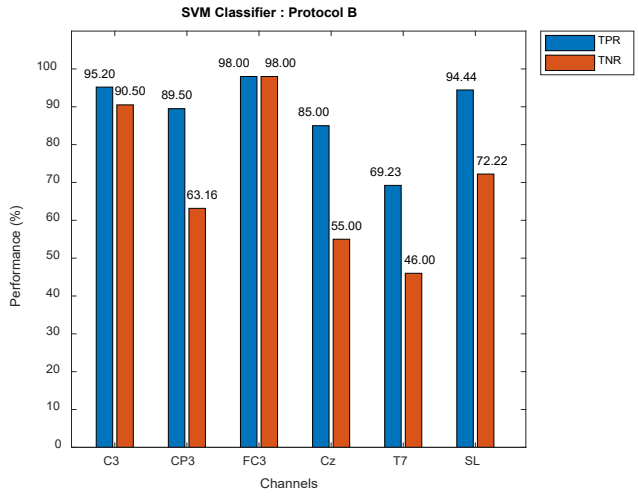

Figure 7: Protocol B Healthy Subject Data

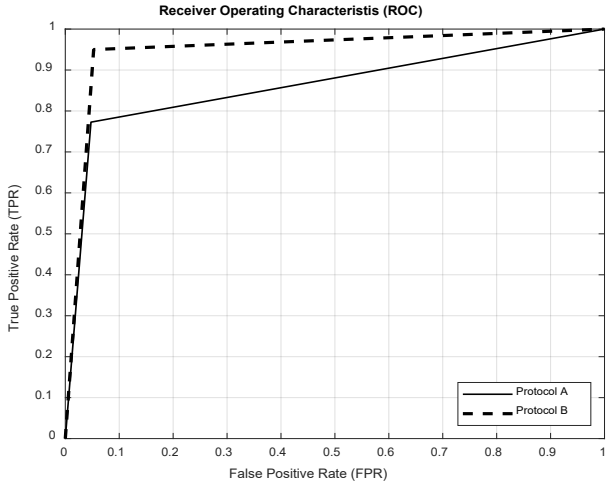

Figure 8: ROC Curve Using FC3 Channel

The Area Under the Curve (AUC) for ROC is also an important factor in assessing the classifier performance. The excellent classifier has an AUC value of 1 whereas 0.5 value

shows its random guessing behavior. The AUC values for FC3 channel for both healthy subjects and stroke patients are listed in Table IV. It is found that AUC for protocol B is greater than protocol A for both healthy subjects and stroke patients which was the expected outcome. Moreover, AUC value for protocol B in the healthy group is ~0.95 which is approximately equal to ideal AUC value for the classifier.

Table 4: Area Under the ROC Curve for FC3 Channel

Group	AUC for FC3 Channel	
	Protocol A	Protocol B
Stroke	0.7222	0.8889
Healthy	0.8626	0.9487

5. Conclusion

The utilization of EEG-BCI system together with AMADEO robotic rehabilitation system for the functional recovery of the hand of the post-stroke patients was reported as the first stage of our work. The movement intention for both healthy participants as well as post-stroke patients was detected using SVM classifier. Two protocols that were based on simple visual-cues and the AMADEO 2D game were used to detect the hand-closing movement intention vs the resting state. This was followed by an evaluation of the SVM classifier performance by selecting different single electrodes. The average classifier accuracy of 67.56% for the visual-cue protocol and 79.7% for the gaming protocol was achieved for healthy subjects. Similarly, for stroke patients, the classifier accuracy obtained was 56.24% and 66.64% for the visual-cue and the game protocols respectively. The results demonstrated that the 2D games, for example, AMADEO Shoot-out were better activities in retaining concentration compared to static pictures using visual-cues. We conclude that gaming scenarios are preferable for robot-based rehabilitation exercises to promote the active participation of the patients. The FC3 electrode was found to be the best single electrode for the designed experiment with both protocols. Both TPR and TNR were important in determining the performance of the classifier, as these parameters could indicate whether good results of the classifier were obtained either by detecting positive class or negative class accurately. In addition to TPR and TNR, it was shown that the ROC plot and AUC parameters of the classifier could also be used as the performance metric evaluators for the classifier.

Conflict of Interest

There is no conflict of interest among authors.

Acoustic Power

ABSTRACT

Thermo-acoustic technology is very potential to be applied to convert heat into another energy source. The complete thermoacoustic engine construction requires a resonator connected to a core where there is a heat exchanger. The thermoacoustic core has a function as an acoustic power generator while the resonator functions as a storage of acoustic power which will shift the amplitude or phase of oscillating pressure or volume flow rate. Experimental testing was carried out to obtain the performance of a quarter wave length of standing wave thermoacoustic engine (SWTE). The resonator is made of a 2 inch Sch 40 stainless steel pipe with a length of 390 mm. The results of this experiment showed that the measured pressure amplitude was 4800 kPa with a working frequency of 138 HZ and produced an acoustic power of 22.85 watts. The parameters of this experimental test are used for the simulation program. The acoustic power generated from the simulation is 20.13 watts, 18.67 watts and 17.82 watts respectively for the length of the resonator 390 mm, 780 mm and 1170 mm.

1. Introduction

Thermoacoustic is a technology related to heat transfer to pressure oscillation, so the use of the term "Thermo" comes from the heat transfer process while "acoustic" comes from pressure oscillating in the working fluid. This term was first introduced by [1] who was credited with laying a theoretical foundation for the field of thermoacoustic research. Thermoacoustic technology is more interesting to develop because of its superiority compared to traditional energy conversion system technologies [2]. The advantage lies in thermoacoustic devices that have immovable components and simple construction (basically pipelines), making such systems very reliable and requires low construction and maintenance costs.

Thermoacoustic devices classified into thermoacoustic engine (TAE) and thermoacoustic refrigerators (TAR) depending on the practical application of the thermoacoustic effects. TAE turns thermal energy into acoustic energy. The thermal energy comes from a significant temperature difference derived from a heat exchanger that applied to two ends of porous material. TAR converts acoustic energy into temperature differences utilizing acoustic waves imposed along with porous material. This process causes temperature differences that occur in the two heat exchangers [3].

The main components of a TAE or TAR are a resonator tube, a porous material (stack) and two heat exchangers. A standing wave type produces a half wavelength or a quarter wavelength which generate in the resonator. The thermoacoustic phenomenon takes place in porous material when the temperature gradient that is worn along the porous material interacts with the oscillation of sound waves. The heat exchanger is responsible for transferring heat in and out of the thermoacoustic device at the desired temperature, thereby maintaining the temperature gradient applied to the porous material [4].

Swift [5] built and tested this SWTE using a 5-inch diameter stainless steel pipe with electric heating. The working fluid used is Helium at an average pressure of 13.8 bar. The result is an acoustic power that can be generated at 630 W with an efficiency of heat conversion to acoustic power of 9% and a Carnot efficiency of 13%. Thermoacoustic prime mover (TAPM) which has a resonator length of 128 cm, uses a stack of stainless-steel mesh numbered 14, two heat exchangers and water at atmospheric pressure as gas acting inside the resonator. Successfully designed, built, and evaluated by [6].

There are two types of acoustic waves generated by the thermoacoustic engine, standing waves, and traveling waves. Both of these wave types depend on the type of resonator used. Thermoacoustic engines require high-temperature gradients to produce sound. The temperature gradient itself occurs in part often called the stack (for a traveling wave thermoacoustic engine called a regenerator), placed between the hot and cold sides of the thermoacoustic engine. Thermoacoustic engine research mostly is done on the standing wave type due to its ease of configuration, which only consists of a resonator pipe and the thermoacoustic core which is directly connected to the resonator and placed near the other end. This thermoacoustic core is a heat exchanger (HHX), stack, and cold heat exchanger (CHX).

The influence of the length of the resonator pipe on frequency is carried out by [7] who investigate the performance of prime mover thermoacoustic traveling waves at a small onset temperature difference, which is obtained by mounting the stack in the right position on the horizontal resonator pipe.

The resonator tube is one of the critical components of a thermoacoustic engine. Many studies have been conducted on the effect of resonance tube on thermoacoustic performance, most of them focused their research on resonance tube length which is considered the dominant factor that determines the frequency of the system

The effect of the resonance tube on a standing wave thermoacoustic engine is researched by simulating a linear thermoacoustic. In this simulation, the SWTE is connected to a pulse tube refrigeration to obtain the temperature gradient on the core side. The results of this simulation calculation show that the prolongation of the resonance tube can cause a decrease in the working frequency [8].

Hariharan et al. [9] conducted a study with variations in stack geometry and resonator length to determine the SWTE performance. In this study, variations in the length of the resonator carried out with lengths of 200, 300, 400, and 500 mm. Variation of the length of the resonator influences the pressure amplitude, wave frequency, and acoustic power so that it will also affect its efficiency.

The TAE model whose resonator length can be regulated was examined by [10] which consisted of 103 mm ceramic honeycomb stack, volume buffers, and shell-tube type heat exchangers. The TAE performance was evaluated using six different types of stack. The length of the resonators used were 50 mm, 100 mm, and 150 mm placed in three different places. The length of the resonator that can be set in this study aims to choose the best working frequency so that the TAE can work optimally and produce the highest acoustic power.

The influences of the tube diameter of traveling wave thermoacoustic are not sensitive; hence, the resonance frequency of the radial dimension is always ignored. Therefore, the way to adjust the working frequency is to vary the length of the resonator tube. However, for a small thermoacoustic system, the influence of the radial dimension cannot be neglected [11].

The resonator is one of the key components of a thermoacoustic engine because it's save acoustic power. Resonator supply the instances and compliances that the working frequency is related to it. The unwanted eddying or non-linear pressure variations should be avoided by using a straight tubular resonator pipe without step, misalignment, and sudden transition. However, A straight, uniform-diameter resonator is seldom the best design [12].

This paper is an extension of work originally presented in the 2018 4th International Conference on Science and Technology (ICST), by changing some variations but still focusing on simulations as a way to analyze the performance of this SWTE. The author has conducted research on the effects of resonator diameter on SWTE performance by simulations using DeltaEC. The results show that the simulations with resonator diameter variations from the close-open SWTE have no significant effect [13].

Experiment testing was conducted beforehand to get the results of the parameters used. The results of this experiment will be used to validate the results of the simulation. The parameters of the simulation results that have been confirmed with settings in the SWTE experiment are then used as SWTE simulation parameters in variation length of the resonator. Simulation of an SWTE is easy to do using DeltaEC . This program was made by Dr. Bill Ward and Dr. Gregori Swift from Los Alamos National Laboratories (LANL) [14].

2. Theoritical basis

The quarter wave length resonator is a tube closed at one end and open at the other. This resonator can be explained in a lumped element model consisting of compliance in series with inertance [15].

The working frequency is related to the inertance (L) and compliance C) of the component in the thermoacoustic engine, and they can be described by the equation [12]:

$$L = \frac{\rho_m l}{A} \tag{1}$$

$$C = \frac{V}{\gamma P_m} \tag{2}$$

Where A and l are the sectional area and length of the resonator tube, respectively. ρ_m is average density and P_m is the pressure of the gas. V and γ are the volume compliance and the specific heat, respectively.

The acoustic intensity I for the measured sound wave was calculated using the modified two sensor method [16]:

$$I = \frac{1}{8\omega\rho_m}\left\{\mathrm{Im}[H]\left(|P_A|^2 - |P_B|^2\right) + 2\,\mathrm{Re}[H]\,|P_A||P_B|\sin\theta\right\} \tag{3}$$

H is defined by:

$$H = \frac{kF}{\cos\left(k\frac{\Delta x}{2}\right)\sin\left(k\frac{\Delta x}{2}\right)} \tag{4}$$

Where *Re* [ ] is the real component and *Im* [ ] is the imaginary components. P_A and P_B are acoustic pressure waves measured by pressure sensors mounted close together along the resonator, and $\theta = \arg [P_A/P_B]$ represents phase lead of pressure wave P_A relative to P_B, k is complex wave number and Δx is the difference in distance between the two pressure sensors.

F is a complex factor calculated by:

$$F = 1 - \frac{2J_1\left(i^{3/2}\sqrt{2}r_0/\delta\right)}{\left(i^{3/2}\sqrt{2}r_0/\delta\right)J_0\left(i^{3/2}\sqrt{2}r_0/\delta\right)} \quad (5)$$

And

$$k = -ik_0\sqrt{\frac{J_0\left(i^{3/2}\sqrt{2}r_0/\delta\right)}{J_2\left(i^{3/2}\sqrt{2}r_0/\delta\right)}}\sqrt{\gamma + (\gamma-1)\frac{J_2\left(i^{3/2}\sqrt{2\sigma}r_0/\delta\right)}{J_0\left(i^{3/2}\sqrt{2\sigma}r_0/\delta\right)}} \quad (6)$$

Where γ and σ is notation of the specific heat ratio and Prandtl number, respectively. J_n represent the n^{th} order complex of Bessel function, k_0 is the wave number, and r_0 is the radius of duct.

The results of the acoustic intensity calculation (I) are then used to calculate the acoustic power $(\dot{E})$ in the following equation:

$$\dot{E} = \dot{I}A \quad (7)$$

3. Methodology

This research uses an SWTE that is open at the end of the resonator but closed at the end adjacent to the thermoacoustic core as seen in Figure 1. Resonators are made of 2-inch Sch. 40 stainless steel pipes with a length of 390 mm. Two heat exchanger devices used are made of copper both for hot heat exchangers (HHX) and cold heat exchangers (CHX). Both of these heat exchangers flank the stack made of stainless-steel wire mesh, with a porosity of 88.26%. The heat source for heating the HHX comes from 6 pcs glow plug from an 11 VDC diesel engine, and CHX is cooled using water.

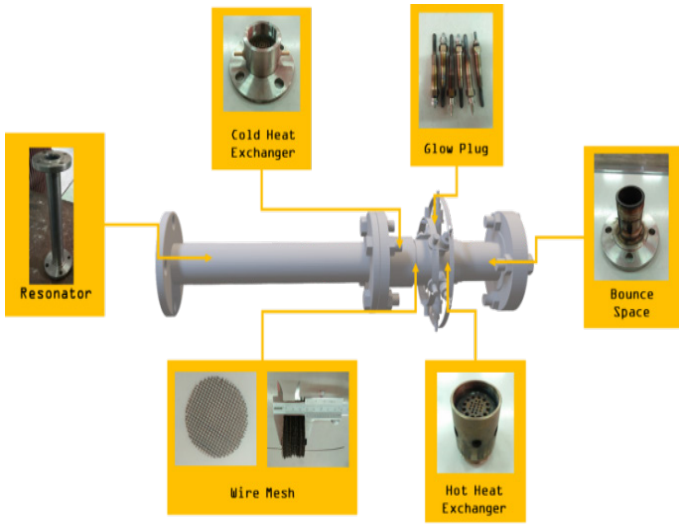

Figure 1: The main components of a close-open thermoacoustic engine

The first step is experimental testing to find out the acoustic intensity of SWTE with a resonator length of 390 mm. In this experimental test, temperatures were measured using two type-K thermocouples placed in HHX (hot side) and CHX (cold side) connect to National Instrument 9234 module. Two M102A05 PCB pressure sensors are mounted on the resonator with a distance between them of 50 mm, used to measure acoustic pressure with readings using the National Instrument module 9234 as well. As a heat source, 6 glow plugs from diesel engines are used which are connected to the transformer battery charger. The set-up of this experimental test is shown in Figure 2.

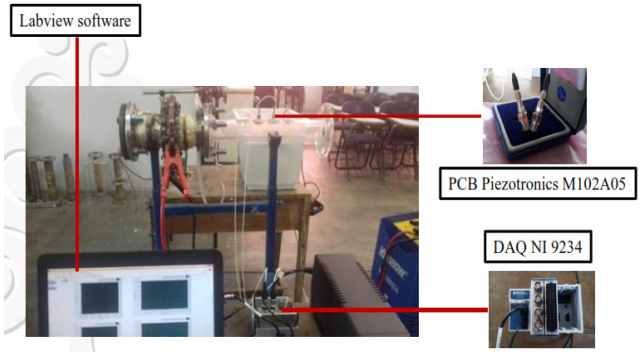

Figure 2: SWTE experiment set-up

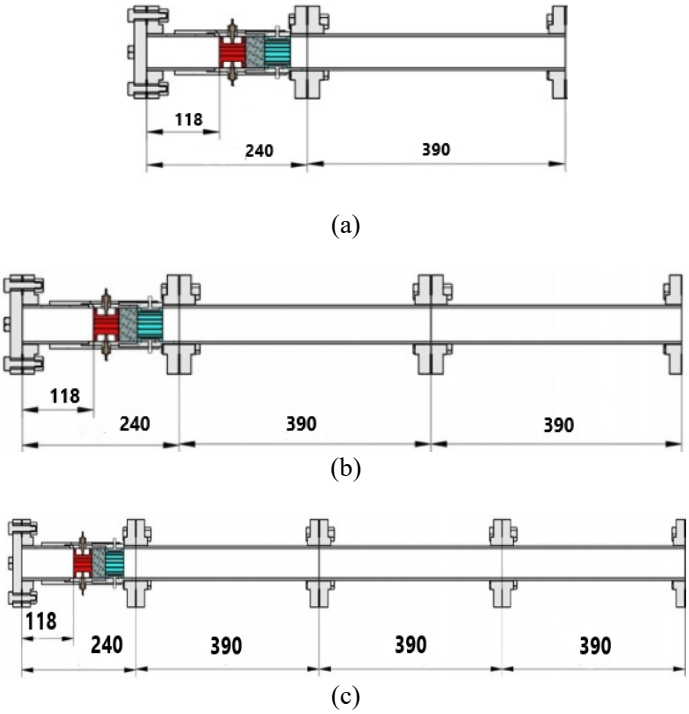

Figure 3: SWTE simulation set-up with a variation of resonator length; a. 390 mm , b. 780 mm , c. 1170 mm length of resonator tube.

The second step is simulation with DeltaEC software to find out the performance of SWTE. The first simulation uses experimental test parameters at a 390 mm resonator length. The experimental data in the first step of the study were used to validate the simulation results in the second step. After the two results between the experiment and the simulation are validated, a simulation program is further developed to predict the performance of the SWTE at variations in the length of 780 mm and 1170 mm as seen in Figure 3.

The display of measurement results using NI 9234 data logger as a simulation parameter that was read by Labview is shown in Figure 4. at point 1 and around 3600 Pa, 138 Hz at point 2. The measurement data from these two pressure sensors are then processed to get the acoustic intensity and acoustic power using equations 3 and 7. The final result for this experiment is the acoustic power of 22,853 watts.

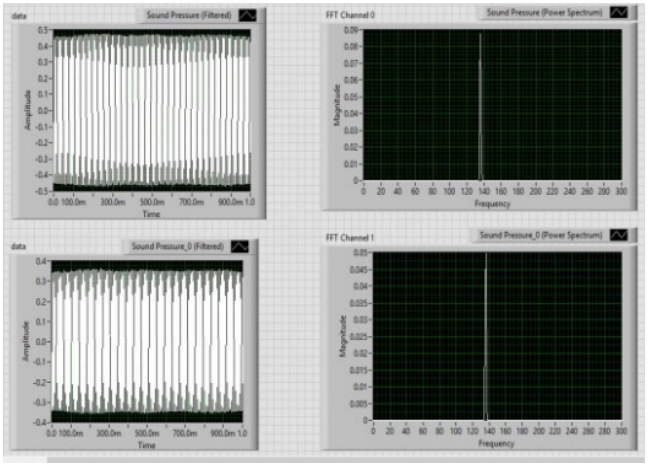

Figure 4: Pressure Amplitude and frequency of SWTE ekperiment result.

4. Result and Analysis

The result of program execution is a schematic SWTE construction diagram with segments of the components used, as presented in Figure 5. It is in a closed on one side state expressed by the SURFACE segment. The other components are Excess pipe, which is stated by DUCT segment, HHX and CHX components are expressed by HX segment, STKSCREEN segments express wire mesh stack, and resonator tube is expressed in DUCT segment.

The DeltaEC program shown in Figure 6 begins by entering the initial parameters as used in the experiment testing, followed by settings for each segment used. In Segment 6 which is the Duct segment for the resonator, a variation of the resonator length of 390 mm is included so that the total power and the acoustic power generated by the SWTE system. The simulation program that has been successfully executed to obtain the performance of SWTE is then used to simulate the performance of SWTE at the length of other resonators. This simulation is done by changing the program simulation parameter at segment DUCT.

The acoustic power that was successfully generated from the simulation for a 390 mm resonator length was 20,13 watts. The difference in acoustic power between experimental results and simulation results is 3%, so this difference is still acceptable because the value of the deviation is even smaller than 10% [12].

The distribution of acoustic power from the system can be seen from the graph in Figure 7 as a result of program execution. The red line shows the total energy on the device while the blue line is the acoustic power. In the segments 1 and 2, which are bounce space areas, there is no power generation. Acoustic power starts to be generated in the core area of SWTE, and the highest is in the field of stack wire mesh which is almost 30 watts. Momentary out of CHX this power goes down and will tend to be constant along the resonator tube which is around 20 watts. The total power of this system is 680 watts, so the efficiency of SWTE with a resonator length of 390 m is 2.94%.

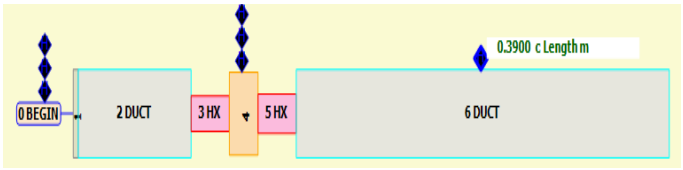

Figure 5: Schematic diagram result of simulation for 390 mm resonator length.

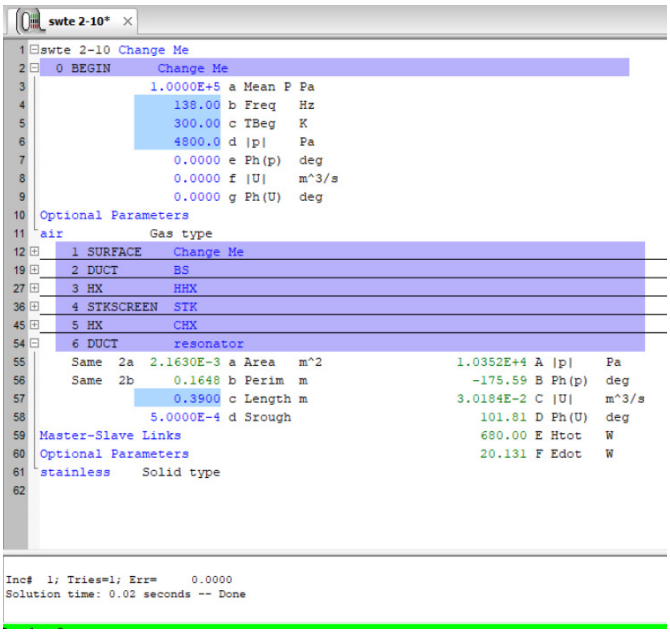

Figure 6: Result simulation of power at 390 mm of resonator length

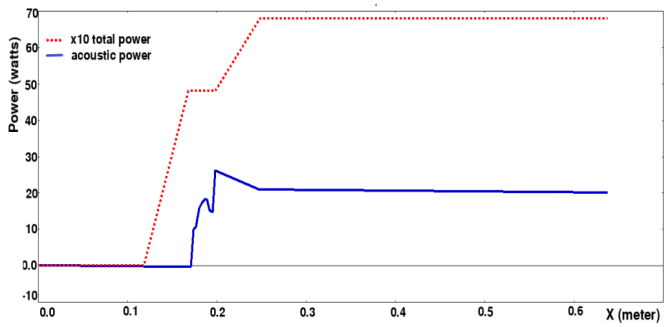

Figure 7: Power distribution of SWTE use 390 mm of resonator length.

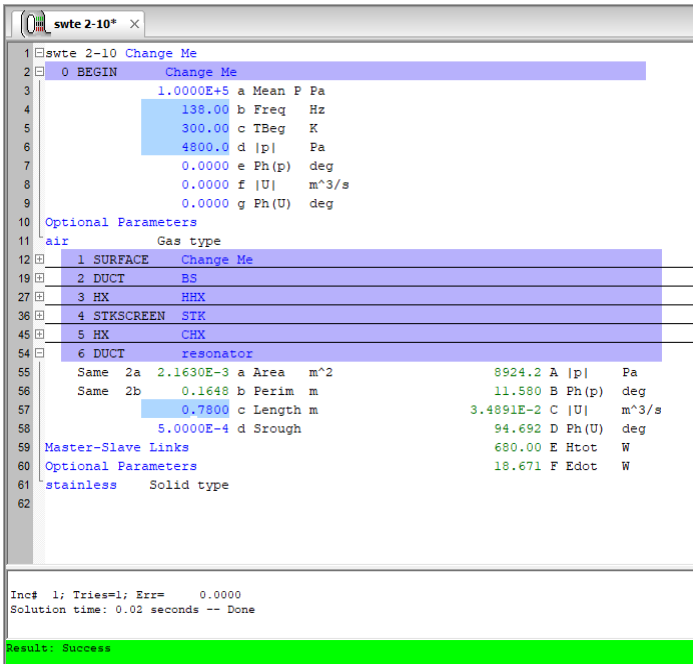

Figure 8: Result simulation of power output at 780 mm of resonator length

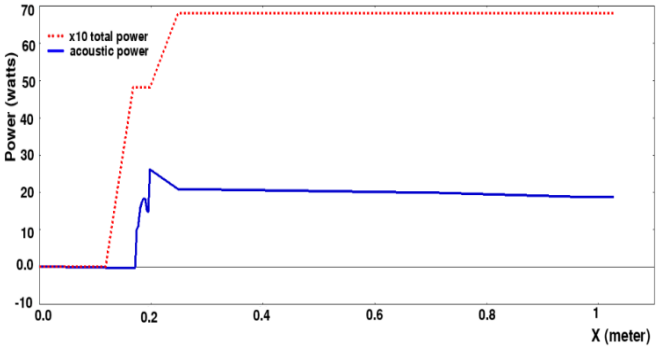

Figure 9: Power distribution of SWTE use 780 mm of resonator length.

Figure 8 to 11 presents acoustic power generated for a resonator length of 780 mm and 1170 mm, respectively. The simulation with a 780 mm resonator length is done by changing the segment 6 in the program by liquefying the other parameters in a fixed condition, as shown in Figure 8. The output power for this condition is 18.67 watts for acoustic power and 680 watts for total power. There was no change in total power due to variations in this second simulation; no other parameters were changed. The efficiency gained from this conditioning system is 2.7%.

As shown in Figure 9, for the length of resonator tube 780 mm at a position of 0 to 0.18 m there is no power generation because a bounce space occupies this position as an air reservoir. At intervals of $0.18 \leqslant x \leqslant 0.2$ m, which is the position of the HHX and stack, the acoustic power starts to rise and reaches the highest value shortly after leaving the stack, which is 26.12 watts. CHX occupies the area at $0.2 \leqslant x \leqslant 0.4$ m intervals, resulting in acoustic power of 20.96 watts. This value is lower than when the stack exits due to water cooling on the CHX side. This value will tend to be constant when passing through the resonator at a distance of $0.4 \leqslant x \leqslant 1.2$ m, which is equal to 18.67 watts.

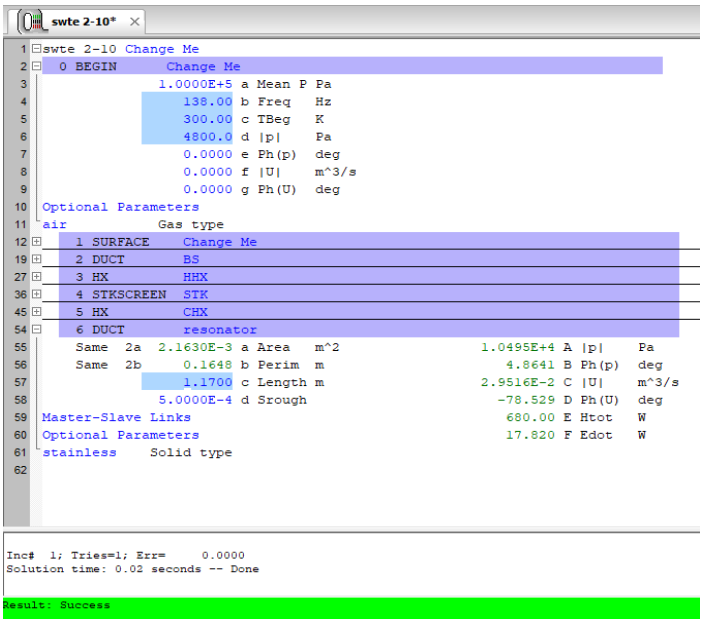

Figure 10: Result simulation of power output at 1170 mm of resonator length

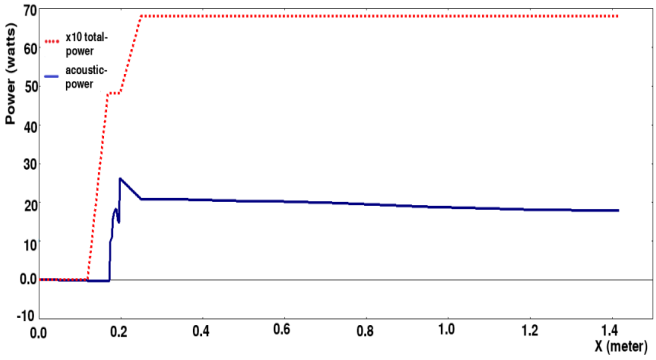

Figure 11: Power distribution of SWTE use 1170 mm of resonator length

The simulation results for the variation of the resonator length of 1170 mm are presented in Figure 10. Like the two previous simulations, segment 6 of the resonator length is changed to obtain information on the amount of output power generated by this system. The results can be seen that the total power produced is still constant at 680 watts because there is no change in the thermoacoustic core parameters. The acoustic power generated is smaller by 17.82 watts so that the efficiency of the system as a result of this third simulation is 2.62%.

The acoustic power distribution as presented in Figure 11 has the same trend with the simulation results for the variation of the resonator lengths of 390 mm and 780 m, where on the bounce space side the end is closed, there is no power generated, the core has the highest value and the resonator will tend to go down until the side open end on this system.

Based on the simulation results for SWTE with variations in the length of the resonator, the results show that the longer the resonator tube, the output power of the system will decrease. The prediction from this simulation is following the research conducted by [9] and [10], namely that the length of the resonator will affect the acoustic power so that it will also affect its efficiency.

The way to increase the standing type of performance can be done by changing to the co-axial type without changing the length of the resonator. Takeyama [17] has tested it by inserting an inner tube into the resonator to the bounce space area. The inner tube used is smaller than the diameter of the resonator tube, as seen in Figure 12. Estimation of co-axial performance can be done by simulations using DeltaEC, such as research by [18] which conducted this simulation to optimize co-axial traveling-wave thermoacoustic cooler powered by the standing-wave thermoacoustic engine.

The simulation results of the co-axial type of thermoacoustic engine which the inner tube diameter of 25 mm and 580 mm length presented in Figure 13. The acoustic power is 30 watts. There was an increase of about 10 watts compared to the SWTE type result in both simulation and experimental. The total energy that can be achieved by co-axial is about 100 watts, so the efficiency of this system is around 3%, slightly higher than the SWTE.

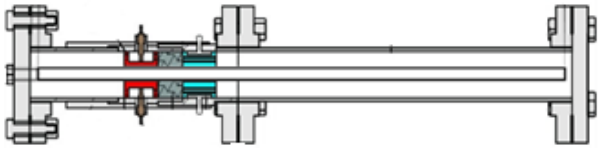

Figure 12: Co-axial thermoacoustic engine contruction.

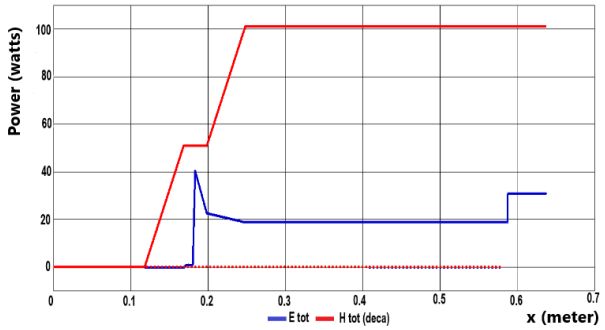

Figure 13: Power distribution of co-axial use 25 mm inner tube diameter

A summary of the comparison of research results in this paper is presented in Table 1

Table 1: Comparison of test results with variations in resonator length

Methods	Length of Resonator (mm)	Acoustic Power (watts)
Experiment	390	22.85
Simulation	390	20.13
Simulation	780	18.67
Simulation	1170	17.82
Simulation (co-axial)	390	30.00

5. Conclusion

Simulations to predict the performance of SWTE open-close have been carried out. Its application for a 390 mm resonator length successfully made, and the results match the experimental data. Execution of other resonator lengths, namely 780 mm and 1170 mm, states that a prolonged resonator reduces the acoustic power produced by this device. Another method for increasing engine performance without changing the length of the resonator is by making the device co-axial type.

Conflict of Interest

The authors declare no conflict of interest.

ABSTRACT

Noise control is essential when applying speech recognition in noisy environments such as factories. In this study, a signal processing for noise cancellation is proposed by using a noise-insensitive bone-conducted speech signal together with an air-conducted speech signal. The speech signal is generally expressed by a nonlinear model. The extended Kalman filter is very famous as a state estimation method for nonlinear systems. However, this filter needs a linearized approximation model for the nonlinear systems. By using the sample point called Sigma point, the unscented Kalman filter (UKF) can be applied to the nonlinear system model without linear approximation. In this study, new type method is proposed based on the UKF. Although UKF considers Gaussian noise, an extended UKF considering non-Gaussian noise is proposed. A noise cancellation method is derived by use of air- and bone-conducted speech signals. The validity of this method is investigated by using both conducted speech signals measured in a noisy real environment.

1 Introduction

Recently, speech recognition systems are used in car navigation systems and smart speakers etc.. However, speech recognition can not be performed effectively in circumstances with heavy noises. Therefore, some countermeasures against surrounding noise are indispensable in such situations.

Kalman filter has been applied to many noisy circumstances as a noise cancellation method for speech signal [1],[2],[3]. This filter assumes a linear model subject to white and Gaussian noise as the system equation and the observation equation [4],[5]. Though, the extended Kalman filter (EKF) [6] can be applied to nonlinear systems, linear approximation models of nonlinear systems are required. Therefore, many improvements are necessary for the noise cancellation method to apply it to actual speech signal processing. From the above viewpoint, in our preciously reported study, a noise cancellation method was proposed by using air- and bone-conducted speech signals in the situation contaminated by non-Gaussian and non-white noises [7].

However, since the calculation of the expansion coefficients in the previous algorithm was very complicated, a simplified method is required.

On the other hand, the unscented Kalman filter (UKF) by use of unscented transformation (UT) method can be applied to nonlinear system[9]. The UT method is a technique for calculating the statistics of a random variable that has been nonlinearly transformed. The set of samples on so-called sigma points(σ-points) are chosen so that they capture the specific properties of the underlying distribution. Therefore, this method can be applied to arbitrary nonlinear systems. In our previous study, a noise cancellation method based on only air conducted speech signal has been proposed by applying the UT method [8].

In this study, a new noise cancellation algorithm based on air- and bone-conducted speech signals is proposed by considering the UT method. The relationship between air-conducted speech signal and backgrand noise is expressed as an additive model based on the additive property of sound pressure. However, propagation mechanism of bone-conducted speech signal is complicated and has to be considered as an unknown system in general. Therefore, a system model including unknown parameters is introduced in this study. More specifically, the sample points obtained by using the UT method are introduced. The noise cancellation algorithm is derived by use of an expansion expression of Bayes' theorem. This method can be considered non-Gaussian properties of noises and nonlinear correlation information between the speech signal and observation. Furthermore, the validity of the proposed method is experimentally confirmed by applying it to real speech signal with noises.

2 Theory

2.1 Modeling of Air- and Bone-Conducted Speech Signals

We consider the original speech signal x_k, observed air-conducted speech signal y_k and bone-conducted speech signal z_k at discrete time k. The observation y_k is contaminated by a surrounding noise v_k. According to the additive property of sound pressure, the following relationship can be established.

$$y_k = x_k + v_k, \tag{1}$$

where the mean and variance of v_k are known. In order to derive the propagation model of the bone-conducted speech signal, the correlation information between x_k and z_k is required.However, it is difficult to obtain prior information on the unknown speech signal x_k. In this study, a new adaptive algorithm for noise cancellation is proposed by introducing a propagation model with unknown parameters between x_k and z_k as the bone-conducted speech signal model for z_k:

$$z_k = a_k x_k + b_k w_k, \tag{2}$$

where w_k is a random noise ($mean : 0, variance 1$) and a_k and b_k are unknown parameters.

2.2 Estimation Method Combined Bayes' Theorem with UT Method

The conditional joint probability distribution of the specific signal x_k and the unknown parameters a_k and b_k is expressed by using expansion expression of Bayes' theorem[10]. To simplify the derivation process of the estimation algorithm, σ-points and the weighting coefficients are introduced in expansion coefficients.

The conditional probability distribution of x_k, a_k and b_k is expressed as

$$\begin{aligned}
&P(x_k, a_k, b_k | Y_k, Z_k) \\
&= P_0(x_k | Y_{k-1}, Z_{k-1}) P_0(a_k | Y_{k-1}, Z_{k-1}) P_0(b_k | Y_{k-1}, Z_{k-1}) \\
&\quad \sum_{l=0}^{\infty} \sum_{m=0}^{\infty} \sum_{n=0}^{\infty} \sum_{s=0}^{\infty} \sum_{t=0}^{\infty} A_{lmnst} \\
&\quad \varphi_l^{(1)}(x_k) \varphi_m^{(2)}(a_k) \varphi_n^{(3)}(b_k) \varphi_s^{(4)}(y_k) \varphi_t^{(5)}(z_k) \\
&\quad / \sum_{s=0}^{\infty} \sum_{t=0}^{\infty} A_{000st} \varphi_s^{(4)}(y_k) \varphi_t^{(5)}(z_k),
\end{aligned} \tag{3}$$

with

$$A_{lmnst} \equiv \left\langle \varphi_l^{(1)}(x_k) \varphi_m^{(2)}(a_k) \varphi_n^{(3)}(b_k) \varphi_s^{(4)}(y_k) \varphi_t^{(5)}(z_k) | Y_{k-1}, Z_{k-1} \right\rangle, \tag{4}$$

where $Y_k (= \{y_1, y_2, ..., y_k\})$ and $Z_k (= \{z_1, z_2, ..., z_k\})$ are sets of air- and bone-conducted speech signal data up to time k. The above five functions $\varphi_l^{(1)}(x_k)$, $\varphi_m^{(2)}(a_k)$, $\varphi_n^{(3)}(b_k)$, $\varphi_s^{(4)}(y_k)$ and $\varphi_t^{(5)}(z_K)$ are orthonormal polynomials of degrees l, m, n, s and t with weighting functions $P_0(x_k \mid Y_{k-1}, Z_{k-1})$, $P_0(a_k \mid Y_{k-1}, Z_{k-1})$, $P_0(b_k \mid Y_{k-1}, Z_{k-1})$, $P_0(y_k \mid Y_{k-1}, Z_{k-1})$, $P_0(z_k \mid Y_{k-1}, Z_{k-1})$, which can be chosen as the probability functions describing the dominant part of the fluctuation. As the examples of standard probability functions, Gaussian distribution is adopted:

$$\begin{cases}
P_0(x_k \mid Y_{k-1}, Z_{k-1}) = N(x_k; x_k^*, \Gamma_{x_k}), \\
P_0(a_k \mid Y_{k-1}, Z_{k-1}) = N(a_k; a_k^*, \Gamma_{a_k}), \\
P_0(b_k \mid Y_{k-1}, Z_{k-1}) = N(b_k; b_k^*, \Gamma_{b_k}). \\
P_0(y_k \mid Y_{k-1}, Z_{k-1}) = N(y_k; y_k^*, \Omega_k), \\
P_0(z_k \mid Y_{k-1}, Z_{k-1}) = N(z_k; z_k^*, \Phi_k),
\end{cases} \tag{5}$$

with

$$N(x; \mu, \Gamma) = \frac{1}{\sqrt{2\pi\Gamma}} e^{\left\{ -\frac{(x-\mu)^2}{2\Gamma} \right\}},$$

$$\begin{aligned}
&x_k^* \equiv \langle x_k \mid Y_{k-1}, Z_{k-1} \rangle, \\
&\Gamma_{x_k} \equiv \left\langle (x_k - x_k^*)^2 \mid Y_{k-1}, Z_{k-1} \right\rangle, \\
&a_k^* \equiv \langle a_k \mid Y_{k-1}, Z_{k-1} \rangle, \\
&\Gamma_{a_k} \equiv \left\langle (a_k - a_k^*)^2 \mid Y_{k-1}, Z_{k-1} \right\rangle, \\
&b_k^* \equiv \langle b_k \mid Y_{k-1}, Z_{k-1} \rangle, \\
&\Gamma_{b_k} \equiv \left\langle (b_k - b_k^*)^2 \mid Y_{k-1}, Z_{k-1} \right\rangle, \\
&y_k^* \equiv \langle y_k \mid Y_{k-1}, Z_{k-1} \rangle, \\
&\Omega_k \equiv \left\langle (y_k - y_k^*)^2 \mid Y_{k-1}, Z_{k-1} \right\rangle, \\
&z_k^* \equiv \langle z_k \mid Y_{k-1}, Z_{k-1} \rangle, \\
&\Phi_k \equiv \left\langle (z_k - z_k^*)^2 \mid Y_{k-1}, Z_{k-1} \right\rangle.
\end{aligned} \tag{6}$$

The orthonormal polynomials[11] with five weighting probability distributions in Eq. (5) are then specified as

$$\varphi_l^{(1)}(x_k) = \frac{1}{\sqrt{l!}} H_l\left(\frac{x_k - x_k^*}{\sqrt{\Gamma_{x_k}}} \right), \tag{7}$$

$$\varphi_m^{(2)}(a_k) = \frac{1}{\sqrt{m!}} H_m\left(\frac{a_k - a_k^*}{\sqrt{\Gamma_{a_k}}} \right), \tag{8}$$

$$\varphi_n^{(3)}(b_k) = \frac{1}{\sqrt{n!}} H_n\left(\frac{b_k - b_k^*}{\sqrt{\Gamma_{\beta_k}}} \right), \tag{9}$$

$$\varphi_s^{(4)}(y_k) = \frac{1}{\sqrt{s!}} H_s\left(\frac{y_k - y_k^*}{\sqrt{\Omega_k}} \right), \tag{10}$$

$$\varphi_t^{(5)}(z_k) = \frac{1}{\sqrt{t!}} H_t\left(\frac{z_k - z_k^*}{\sqrt{\Phi_k}} \right). \tag{11}$$

The estimates for mean and variance (i.e., conditional mean and variance) of x_k, a_k, b_k, which are the first and second order statistics, can be expressed as follows:

$$\begin{aligned}
&\hat{x}_k \equiv \langle x_k \mid Y_k, Z_k \rangle \\
&= \frac{\sum_{l=0}^{1} \sum_{s=0}^{\infty} \sum_{t=0}^{\infty} A_{l00st} c_{1l} \varphi_s^{(4)}(y_k) \varphi_t^{(5)}(z_k)}{\sum_{s=0}^{\infty} \sum_{t=0}^{\infty} A_{000st} \varphi_s^{(4)}(y_k) \varphi_t^{(5)}(z_k)},
\end{aligned} \tag{12}$$

$$\begin{aligned}
&\hat{a}_k \equiv \langle a_k \mid Y_k, Z_k \rangle \\
&= \frac{\sum_{m=0}^{1} \sum_{s=0}^{\infty} \sum_{t=0}^{\infty} A_{0m0st} d_{1m} \varphi_s^{(4)}(y_k) \varphi_t^{(5)}(z_k)}{\sum_{s=0}^{\infty} \sum_{t=0}^{\infty} A_{000st} \varphi_s^{(4)}(y_k) \varphi_t^{(5)}(z_k)},
\end{aligned} \tag{13}$$

$$\hat{b}_k \equiv \langle b_k \mid Y_k, Z_k \rangle = \frac{\sum_{n=0}^{1}\sum_{s=0}^{\infty}\sum_{t=0}^{\infty} A_{00nst} e_{1n} \varphi_s^{(4)}(y_k)\varphi_t^{(5)}(z_k)}{\sum_{s=0}^{\infty}\sum_{t=0}^{\infty} A_{000st}\varphi_s^{(4)}(y_k)\varphi_t^{(5)}(z_k)}, \quad (14)$$

$$P_{x_k} \equiv \left\langle (x_k - \hat{x}_k)^2 \mid Y_k, Z_k \right\rangle = \frac{\sum_{l=0}^{2}\sum_{s=0}^{\infty}\sum_{t=0}^{\infty} A_{l00st} c_{2l} \varphi_s^{(4)}(y_k)\varphi_t^{(5)}(z_k)}{\sum_{s=0}^{\infty}\sum_{t=0}^{\infty} A_{000st}\varphi_s^{(4)}(y_k)\varphi_t^{(5)}(z_k)}, \quad (15)$$

$$P_{a_k} \equiv \left\langle (a_k - \hat{a}_k)^2 \mid Y_k, Z_k \right\rangle = \frac{\sum_{m=0}^{2}\sum_{s=0}^{\infty}\sum_{t=0}^{\infty} A_{0m0st} d_{2m} \varphi_s^{(4)}(y_k)\varphi_t^{(5)}(z_k)}{\sum_{s=0}^{\infty}\sum_{t=0}^{\infty} A_{000st}\varphi_s^{(4)}(y_k)\varphi_t^{(5)}(z_k)}, \quad (16)$$

$$P_{b_k} \equiv \left\langle (b_k - \hat{b}_k)^2 \mid Y_k, Z_k \right\rangle = \frac{\sum_{n=0}^{2}\sum_{s=0}^{\infty}\sum_{t=0}^{\infty} A_{00nst} e_{2n} \varphi_s^{(4)}(y_k)\varphi_t^{(5)}(z_k)}{\sum_{s=0}^{\infty}\sum_{t=0}^{\infty} A_{000st}\varphi_s^{(4)}(y_k)\varphi_t^{(5)}(z_k)}. \quad (17)$$

Where coefficients are appropriate constant satisfying the following equality:

$$\begin{aligned} x_k &= \textstyle\sum_{l=0}^{1} c_{1l}\varphi_l^{(1)}(x_k), (x_k - \hat{x}_k)^2 = \sum_{l=0}^{2} c_{2l}\varphi_l^{(1)}(x_k), \\ a_k &= \textstyle\sum_{m=0}^{1} d_{1m}\varphi_m^{(2)}(a_k), (a_k - \hat{a}_k)^2 = \sum_{m=0}^{2} d_{2m}\varphi_m^{(2)}(a_k), \\ b_k &= \textstyle\sum_{n=0}^{1} e_{1n}\varphi_n^{(2)}(b_k), (b_k - \hat{b}_k)^2 = \sum_{n=0}^{2} e_{2n}\varphi_n^{(3)}(b_k). \end{aligned} \quad (18)$$

By using the UT method, the expansion coefficients defined by (4) can be realized for arbitrary nonlinear systems. When the UT method is applied to approximate the means and variances of x_k, a_k, b_k, y_k and z_k, the σ-points $x_k^{*(i)}$, $a_k^{*(i)}$, $b_k^{*(i)}$, $y_k^{*(i)}$ and $z_k^{*(i)}$ are obtained as sample points, as follows:

$$\begin{aligned} x_k^{*(0)} &= x_k^*, \\ x_k^{*(1)} &= x_k^* + \sqrt{(1+\lambda)\Gamma_{x_k}}, x_k^{*(2)} = x_k^* - \sqrt{(1+\lambda)\Gamma_{x_k}}, \\ a_k^{*(0)} &= a_k^*, \\ a_k^{*(1)} &= a_k^* + \sqrt{(1+\lambda)\Gamma_{a_k}}, a_k^{*(2)} = a_k^* - \sqrt{(1+\lambda)\Gamma_{a_k}}, \\ b_k^{*(0)} &= b_k^*, \\ b_k^{*(1)} &= b_k^* + \sqrt{(1+\lambda)\Gamma_{b_k}}, b_k^{*(2)} = b_k^* - \sqrt{(1+\lambda)\Gamma_{b_k}}, \\ y_k^{*(0)} &= y_k^*, \\ y_k^{*(1)} &= y_k^* + \sqrt{(1+\lambda)\Omega_k}, y_k^{*(2)} = y_k^* - \sqrt{(1+\lambda)\Omega_k}, \\ z_k^{*(0)} &= z_k^*, \\ z_k^{*(1)} &= z_k^* + \sqrt{(1+\lambda)\Phi_k}, z_k^{*(2)} = z_k^* - \sqrt{(1+\lambda)\Phi_k}, \end{aligned} \quad (19)$$

The σ-points are decided so as to obtain the approximately same mean and variance as original variables. Where λ is a regulation parameter. The weights to be used are obtained as follows:

$$\begin{aligned} W^{(0)} &= \frac{\lambda}{(1+\lambda)}, \\ W^{(1)} &= \frac{1}{2(1+\lambda)}, \\ W^{(2)} &= \frac{1}{2(1+\lambda)}. \end{aligned} \quad (20)$$

Here, the weighing coefficients $W^{(i)}$ have to satisfy the normalization constraint.

$$\textstyle\sum_{i=0}^{2} W^{(i)} = 1. \quad (21)$$

Each expansion coefficient A_{lmnst} defined by (4) is obtained specifically by substituting σ-points $x_k^{*(i)}$, $a_k^{*(i)}$, $b_k^{*(i)}$, $y_k^{*(i)}$ and $z_k^{*(i)}$ into the conditional expectation of x_k, y_k and z_k.

$$\begin{aligned} A_{10010} &= \tfrac{1}{\sqrt{\Gamma_{x_k}}\sqrt{\Omega_k}} \textstyle\sum_{i=0}^{2} W^{(i)}(x_k^{*(i)} - x_k^*)(y_k^{*(i)} - y_k^*), \\ A_{10020} &= \tfrac{1}{\sqrt{2}\sqrt{\Gamma_{x_k}\Omega_k}} \textstyle\sum_{i=0}^{2} W^{(i)}(x_k^{*(i)} - x_k^*)\left\{(y_k^{*(i)} - y_k^*)^2 - \Omega_k\right\}, \\ A_{20010} &= \tfrac{1}{\sqrt{2\Gamma_{x_k}}\sqrt{\Omega_k}} \textstyle\sum_{i=0}^{2} W^{(i)}\left\{(x_k^{*(i)} - x_k^*)^2 - \Gamma_{x_k}\right\}(y_k^{*(i)} - y_k^*), \\ A_{20020} &= \tfrac{1}{2\Gamma_{x_k}\Omega_k} \textstyle\sum_{i=0}^{2} W^{(i)}\left\{(x_k^{*(i)} - x_k^*)^2 - \Gamma_{x_k}\right\} \cdot\left\{(y_k^{*(i)} - y_k^*)^2 - \Omega_k\right\}, \\ A_{10001} &= \tfrac{1}{\sqrt{\Gamma_{x_k}}\sqrt{\Phi_k}} \textstyle\sum_{i=0}^{2} W^{(i)}(x_k^{*(i)} - x_k^*)(z_k^{*(i)} - z_k^*), \\ A_{10002} &= \tfrac{1}{\sqrt{2}\sqrt{\Gamma_{x_k}\Phi_k}} \textstyle\sum_{i=0}^{2} W^{(i)}(x_k^{*(i)} - x_k^*)\left\{(z_k^{*(i)} - z_k^*)^2 - \Phi_k\right\}, \\ A_{20001} &= \tfrac{1}{\sqrt{2\Gamma_{x_k}}\sqrt{\Phi_k}} \textstyle\sum_{i=0}^{2} W^{(i)}\left\{(x_k^{*(i)} - x_k^*)^2 - \Gamma_{x_k}\right\}(z_k^{*(i)} - z_k^*), \\ A_{20002} &= \tfrac{1}{2\Gamma_{x_k}\Phi_k} \textstyle\sum_{i=0}^{2} W^{(i)}\left\{(x_k^{*(i)} - x_k^*)^2 - \Gamma_{x_k}\right\}\left\{(z_k^{*(i)} - z_k^*)^2 - \Phi_k\right\}, \\ A_{10011} &= \tfrac{1}{\sqrt{\Gamma_{x_k}}\sqrt{\Omega_k}\sqrt{\Phi_k}} \textstyle\sum_{i=0}^{2} W^{(i)}(x_k^{*(i)} - x_k^*)(y_k^{*(i)} - y_k^*)(z_k^{*(i)} - z_k^*), \\ A_{20011} &= \tfrac{1}{\sqrt{2\Gamma_{x_k}}\sqrt{\Omega_k}\sqrt{\Phi_k}} \textstyle\sum_{i=0}^{2} W^{(i)}\left\{(x_k^{*(i)} - x_k^*)^2 - \Gamma_{x_k}\right\} \cdot(y_k^{*(i)} - y_k^*)(z_k^{*(i)} - z_k^*), \\ A_{10021} &= \tfrac{1}{\sqrt{2}\sqrt{\Gamma_{x_k}\Omega_k}\sqrt{\Phi_k}} \textstyle\sum_{i=0}^{2} W^{(i)}(x_k^{*(i)} - x_k^*) \cdot\left\{(y_k^{*(i)} - y_k^*)^2 - \Omega_k\right\}(z_k^{*(i)} - z_k^*), \\ A_{10012} &= \tfrac{1}{\sqrt{2}\sqrt{\Gamma_{x_k}}\sqrt{\Omega_k\Phi_k}} \textstyle\sum_{i=0}^{2} W^{(i)}(x_k^{*(i)} - x_k^*) \cdot(y_k^{*(i)} - y_k^*)\left\{(z_k^{*(i)} - z_k^*)^2 - \Phi_k\right\}, \\ A_{20012} &= \tfrac{1}{2\Gamma_{x_k}\sqrt{\Omega_k\Phi_k}} \textstyle\sum_{i=0}^{2} W^{(i)}\left\{(x_k^{*(i)} - x_k^*)^2 - \Gamma_{x_k}\right\} \cdot(y_k^{*(i)} - y_k^*)\left\{(z_k^{*(i)} - z_k^*)^2 - \Phi_k\right\}, \\ A_{10022} &= \tfrac{1}{2\sqrt{\Gamma_{x_k}}\Omega_k\Phi_k} \textstyle\sum_{i=0}^{2} W^{(i)}(x_k^{*(i)} - x_k^*) \cdot\left\{(y_k^{*(i)} - y_k^*)^2 - \Omega_k\right\}\left\{(z_k^{*(i)} - z_k^*)^2 - \Phi_k\right\}, \\ A_{20021} &= \tfrac{1}{2\Gamma_{x_k}\Omega_k\sqrt{\Phi_k}} \textstyle\sum_{i=0}^{2} W^{(i)}\left\{(x_k^{*(i)} - x_k^*)^2 - \Gamma_{x_k}\right\} \cdot\left\{(y_k^{*(i)} - y_k^*)^2 - \Omega_k\right\}(z_k^{*(i)} - z_k^*), \\ A_{20022} &= \tfrac{1}{2\sqrt{2}\Gamma_{x_k}\Omega_k\Phi_k} \textstyle\sum_{i=0}^{2} W^{(i)}\left\{(x_k^{*(i)} - x_k^*)^2 - \Gamma_{x_k}\right\} \cdot\left\{(y_k^{*(i)} - y_k^*)^2 - \Omega_k\right\}\left\{(z_k^{*(i)} - z_k^*)^2 - \Phi_k\right\}, \end{aligned} \quad (22)$$

with

$A_{00000} = 1, A_{10000} = A_{00010} = A_{00001} = A_{20000} = A_{00020} = A_{00002} = 0.$

Furthermore, expansion coefficients of a_k, y_k and z_k are

expressed as follows:

$$
\begin{aligned}
A_{01010} &= \frac{1}{\sqrt{\Gamma_{a_k}}\sqrt{\Omega_k}} \sum_{i=0}^{2} w^{(i)}(a_k^{*(i)} - a_k^*)(y_k^{*(i)} - y_k^*),\\
A_{01020} &= \frac{1}{\sqrt{2}\sqrt{\Gamma_{a_k}\Omega_k}} \sum_{i=0}^{2} w^{(i)}(a_k^{*(i)} - a_k^*)\left\{(y_k^{*(i)} - y_k^*)^2 - \Omega_k\right\},\\
A_{02010} &= \frac{1}{\sqrt{2}\Gamma_{a_k}\sqrt{\Omega_k}} \sum_{i=0}^{2} w^{(i)}\left\{(a_k^{*(i)} - a_k^*)^2 - \Gamma_{a_k}\right\}(y_k^{*(i)} - y_k^*),\\
A_{02020} &= \frac{1}{2\Gamma_{a_k}\Omega_k} \sum_{i=0}^{2} w^{(i)}\left\{(a_k^{*(i)} - a_k^*)^2 - \Gamma_{a_k}\right\}\\
&\qquad \cdot\left\{(y_k^{*(i)} - y_k^*)^2 - \Omega_k\right\},\\
A_{01001} &= \frac{1}{\sqrt{\Gamma_{a_k}}\sqrt{\Phi_k}} \sum_{i=0}^{2} w^{(i)}(a_k^{*(i)} - a_k^*)(z_k^{*(i)} - z_k^*),\\
A_{01002} &= \frac{1}{\sqrt{2}\sqrt{\Gamma_{a_k}\Phi_k}} \sum_{i=0}^{2} w^{(i)}(a_k^{*(i)} - a_k^*)\left\{(z_k^{*(i)} - z_k^*)^2 - \Phi_k\right\},\\
A_{02001} &= \frac{1}{\sqrt{2}\Gamma_{a_k}\sqrt{\Phi_k}} \sum_{i=0}^{2} w^{(i)}\left\{(a_k^{*(i)} - a_k^*)^2 - \Gamma_{a_k}\right\}(z_k^{*(i)} - z_k^*),\\
A_{02002} &= \frac{1}{2\Gamma_{a_k}\Phi_k} \sum_{i=0}^{2} w^{(i)}\left\{(a_k^{*(i)} - a_k^*)^2 - \Gamma_{a_k}\right\}\\
&\qquad \cdot\left\{(z_k^{*(i)} - z_k^*)^2 - \Phi_k\right\},\\
A_{01011} &= \frac{1}{\sqrt{\Gamma_{a_k}}\sqrt{\Omega_k}\sqrt{\Phi_k}} \sum_{i=0}^{2} w^{(i)}(a_k^{*(i)} - a_k^*)(y_k^{*(i)} - y_k^*)(z_k^{*(i)} - z_k^*),\\
A_{02011} &= \frac{1}{\sqrt{2}\Gamma_{a_k}\sqrt{\Omega_k}\sqrt{\Phi_k}} \sum_{i=0}^{2} w^{(i)}\left\{(a_k^{*(i)} - a_k^*)^2 - \Gamma_{a_k}\right\}\\
&\qquad \cdot(y_k^{*(i)} - y_k^*)(z_k^{*(i)} - z_k^*),\\
A_{01021} &= \frac{1}{\sqrt{2}\sqrt{\Gamma_{a_k}\Omega_k}\sqrt{\Phi_k}} \sum_{i=0}^{2} w^{(i)}(a_k^{*(i)} - a_k^*)\\
&\qquad \cdot\left\{(y_k^{*(i)} - y_k^*)^2 - \Omega_k\right\}(z_k^{*(i)} - z_k^*),\\
A_{01012} &= \frac{1}{\sqrt{2}\sqrt{\Gamma_{a_k}}\sqrt{\Omega_k\Phi_k}} \sum_{i=0}^{2} w^{(i)}(a_k^{*(i)} - a_k^*)(y_k^{*(i)} - y_k^*)\\
&\qquad \cdot\left\{(z_k^{*(i)} - z_k^*)^2 - \Phi_k\right\},\\
A_{02012} &= \frac{1}{2\Gamma_{a_k}\sqrt{\Omega_k\Phi_k}} \sum_{i=0}^{2} w^{(i)}\left\{(a_k^{*(i)} - a_k^*)^2 - \Gamma_{a_k}\right\}\\
&\qquad \cdot(y_k^{*(i)} - y_k^*)\left\{(z_k^{*(i)} - z_k^*)^2 - \Phi_k\right\},\\
A_{01022} &= \frac{1}{2\sqrt{\Gamma_{a_k}\Omega_k\Phi_k}} \sum_{i=0}^{2} w^{(i)}(a_k^{*(i)} - a_k^*)\\
&\qquad \cdot\left\{(y_k^{*(i)} - y_k^*)^2 - \Omega_k\right\}\left\{(z_k^{*(i)} - z_k^*)^2 - \Phi_k\right\},\\
A_{02021} &= \frac{1}{2\Gamma_{a_k}\Omega_k\sqrt{\Phi_k}} \sum_{i=0}^{2} w^{(i)}\left\{(a_k^{*(i)} - a_k^*)^2 - \Gamma_{a_k}\right\}\\
&\qquad \cdot\left\{(y_k^{*(i)} - y_k^*)^2 - \Omega_k\right\}(z_k^{*(i)} - z_k^*),\\
A_{02022} &= \frac{1}{2\sqrt{2}\Gamma_{a_k}\Omega_k\Phi_k} \sum_{i=0}^{2} w^{(i)}\left\{(a_k^{*(i)} - a_k^*)^2 - \Gamma_{a_k}\right\}\\
&\qquad \cdot\left\{(y_k^{*(i)} - y_k^*)^2 - \Omega_k\right\}\left\{(z_k^{*(i)} - z_k^*)^2 - \Phi_k\right\}.
\end{aligned}
\tag{23}
$$

The expansion coefficients of b_k, y_k and z_k ($A_{00110}, A_{00120}, A_{00210}$, A_{00220}, $A_{00101}, A_{00102}, A_{00201}$, A_{00202}, $A_{00111}, A_{00211}, A_{00121}$, A_{00112}, $A_{00212}, A_{00122}, A_{00221}$, A_{00222}) are calculated through the same manners.

After substituting (1) (2) into the definition of four parameters y_k^*, Ω_k, z_k^* and Φ_k in (6), the following expressions can be derived.

$$y_k^* = x_k^* + \langle v_k \rangle, \tag{24}$$

$$\Omega_k = \Gamma_{x_k} + \left\langle (v_k - \langle v_k \rangle)^2 \right\rangle, \tag{25}$$

$$z_k^* = a_k^* x_k^*, \tag{26}$$

$$\Phi_k = (\Gamma_{a_k} + a_k^{*2})(\Gamma_{x_k} + x_k^{*2}) + (\Gamma_{b_k} + b_k^{*2})\left\langle w_k^2 \right\rangle - a_k^{*2} x_k^{*2}. \tag{27}$$

In order to derive the predicted values of the speech signal x_k and the unknown parameters a_k, b_k, the time transition of the speech signal x_k is expressed as follows.

$$x_{k+1} = F x_k + G u_k, \tag{28}$$

where, u_k is a random input with mean 0 and variance 1. Parameters F and G are calculated from time correlation information of x_k and x_{k+1}:

$$F = \frac{\langle x_{k+1} x_k \rangle}{\langle x_k \rangle^2}, \quad G = \sqrt{(1 - F^2)\left\langle x_k^2 \right\rangle}. \tag{29}$$

Therefore, x_{k+1}^* and $\Gamma_{x_{k+1}}$ can be expressed as follows:

$$x_{k+1}^* = F\hat{x}_k + G\langle u_k \rangle, \tag{30}$$

$$\Gamma_{x_{k+1}} = F^2 P_{x_k} + G^2\left\langle (u_k - \langle u_k \rangle)^2 \right\rangle, \tag{31}$$

Since the parameters a_k and b_k are constants, time transition models are introduced for the recursive estimation.

$$a_{k+1} = a_k, b_{k+1} = b_k. \tag{32}$$

By using these relationships, the predictions are given as follows,

$$a_{k+1}^* = \hat{a}_k, \ \Gamma_{a_{k+1}} = P_{a_k}, \tag{33}$$

$$b_{k+1}^* = \hat{b}_k, \ \Gamma_{b_{k+1}} = P_{b_k}. \tag{34}$$

The state estimation algorithm with expansion coefficient A_{lmnst} reflecting linear and nonlinear correlation information among variables and statistics of non-Gaussian noise is completed.

3 Experiment

In order to confirm the validity of the proposed noise cancellation algorithm, we compared it with the method using only the air-conducted speech signal. The compared method was derived by considering the following conditional probability distribution.

$$
\begin{aligned}
&P(x_k, a_k, b_k \,|\, Y_k)\\
&= P_0(x_k \,|\, Y_{k-1}) P_0(a_k \,|\, Y_{k-1}) P_0(b_k \,|\, Y_{k-1})\\
&\quad \sum_{l=0}^{\infty}\sum_{m=0}^{\infty}\sum_{n=0}^{\infty}\sum_{s=0}^{\infty} A_{lmns}\\
&\quad \varphi_l^{(1)}(x_k)\varphi_m^{(2)}(a_k)\varphi_n^{(3)}(b_k)\varphi_s^{(4)}(y_k)\\
&\quad / \sum_{s=0}^{\infty}\sum_{t=0}^{\infty} A_{000s}\varphi_s^{(4)}(y_k).
\end{aligned}
\tag{35}
$$

Based on (35), the estimates of mean and variance of x_k are derived as follow:

$$
\begin{aligned}
\hat{x}_k &\equiv \langle x_k \mid Y_k \rangle\\
&= \frac{\sum_{l=0}^{1}\sum_{s=0}^{\infty} A_{l00s} c_{1l} \varphi_s^{(4)}(y_k)}{\sum_{s=0}^{\infty} A_{000s}\varphi_s^{(4)}(y_k)},
\end{aligned}
\tag{36}
$$

$$
\begin{aligned}
P_{x_k} &\equiv \left\langle (x_k - \hat{x}_k)^2 \mid Y_k \right\rangle\\
&= \frac{\sum_{l=0}^{2}\sum_{s=0}^{\infty} A_{l00s} c_{2l} \varphi_s^{(4)}(y_k)}{\sum_{s=0}^{\infty} A_{000s}\varphi_s^{(4)}(y_k)}.
\end{aligned}
\tag{37}
$$

Male and female speech signals were used in the experiment. The speech signal data were measured in the anechoic

chamber in the acoustic laboratory. The observed speech signal are contaminated with the white noise, the pink noise and the machine noise respectively. The spectra of these noises are shown in Figures 1-3. Furthermore, the observation data of air-conduced speech signal were created by mixing noises with speech signal on a computer.

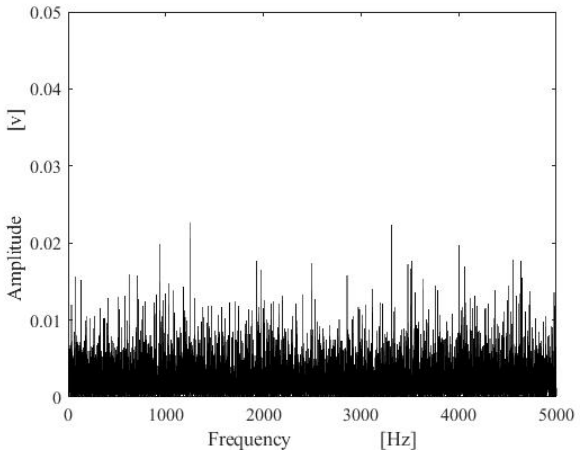

Figure 1: Spectrum of white noise.

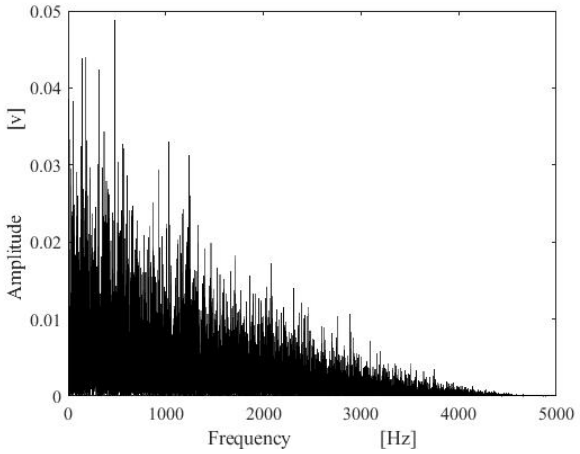

Figure 2: Spectrum of pink noise.

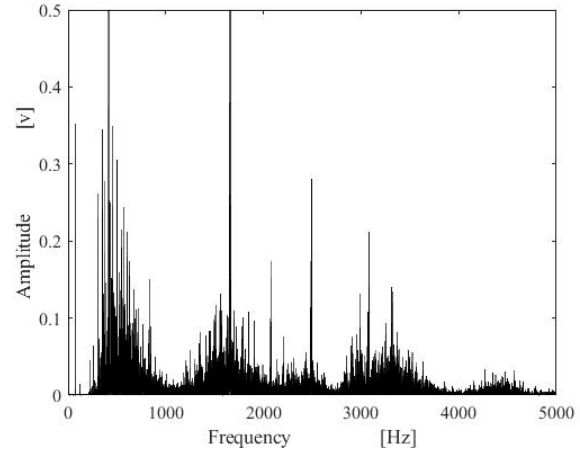

Figure 3: Spectrum of machine noise.

Table 1 shows the specifications of the personal computer for signal processing in the experiment. The signal processing time for speech signal of about 3.5 seconds in length was from 0.5 to 0.8 seconds.

Table 1: The specifications of the personal computer.

	Specification
PC	Dell Vostro 3650
CPU	Intel Core i7-6700 @ 3.40GHz
MEMORY	8.00G
OS	Win 10 Pro 64bit

As an evaluation method of estimation result, the Root Mean Square Error (RMSE) and Performance Evaluation Index (PEI) are adopted.

$$RMSE = \sqrt{\frac{\Sigma(x_k - \hat{x}_k)^2}{N}}, \tag{38}$$

$$PEI = 10\log_{10}\frac{\Sigma x_k^2}{\Sigma(x_k - \hat{x}_k)^2} \quad [dB]. \tag{39}$$

As the RMS Error is smaller value, the better estimation result is obtained. On the other hand, the larger the PEI is, the better the estimation is. Table 2 and Table 3 show the results for the male speech signal and a female speech signal respectively. In the cases of lower noises, almost the same estimation results are obtained in the proposed method and the compared method. On the other hand, in the case of higher noises, the proposed method obtains better results than the compared method. Furthermore, in comparison with our previous method [7] with complicated algorithm, almost the same accurate estimation results are obtained as the proposed method. Therefore, the superiority of the proposed method adopting the simplified algorithm could be confirmed.

Table 2: Comparisons of RMSE and PEI for a male speech signal.

(a) white noise

	Proposed method		Compared method

4 Conclusion

In this paper, a new method to suppress noise for speech signal has been proposed, which is applicable to actual en-

vironment with non-Gaussian and non-white noises. The aim of the proposed method is to improve the accuracy of estimation by using air- and bone-conducted speech signals.

The proposed method considered σ-points of not only x_k but also unknown parameter a_k, b_k and observation values y_k, z_k. Moreover, this study has proposed a method including the higher order correlation information between σ-points. Our algorithm has been realized by utilizing the Bayes' theorem as the fundamental principle of estimation and UT method using σ-points. Application of our algorithm has been made to real speech signal contaminated by noises. It has been revealed by experiments that better estimation results could be obtained by the proposed algorithm as compared with the method without using bone-conducted speech signal. However, we have not tried to apply the proposed algorithm to real speech recognition by use of a voice recognition software. Therefore, by applying the algorithm to speech recognition system, the effectiveness of the theory has to be confirmed experimentally.

The proposed approach is quite different from those traditional standard techniques. However, we are still in an early stage of development, and a number of practical problems are yet to be investigated in the future. These include: (i) Introduction of a realistic nonlinear model expressing the actual propagation characteristics of bone-conducted speech signal instead of the simple model in (2). (ii) Consideration of higher order expansion coefficients A_{lmnst} $(l, m, n, s, t \geqq 3)$, in the estimation algorithm. (iii) Selection of an optimal point to put the sensor to measure the bone-conducted speech signal.

ABSTRACT

This study reviewed articles on information technology governance (ITG) in the Malaysian context and categorized the issues found in ITG implementation according to organizational-related and human-related issues. It further analysed the impact and role of information technology (IT) human capability in ITG implementation in developing countries like Malaysia, which is still in the infancy stage of ITG. This study found that most organizations in Malaysia are not only facing organizational-related issues but also human-related issues as well. However, there are insufficient studies on how implementation issues between organization and humans are interrelated. The roles of IT human capability in ITG implementation has been heavily underrated as most studies focused on ITG mechanisms and the impact of ITG on firm performance. Issues highlighted in past studies were summarized and used to explain the roles of IT human capability in ITG implementation. The findings revealed that the number of issues reported in the human-related category was slightly more than organizational-related issues. This study explains the role of IT human capability in ITG and reduces the ambiguity of IT human capability in ITG for future research activities.

1. Introduction

Since the beginning of the 21st century, organizations worldwide have been focusing on integrating Information Technology (IT) into organizational business processes. IT has emerged as one of the most important tools for organizations to retain and improve their competitive advantage. Rapid development in IT has enabled organizations to streamline their operations by improving organizational agility and information flow throughout the entire organization. Strategic alignment between business & IT strategies has become one of the main focuses of organizations in order to ensure that IT tools can be fully utilized to support business decisions. However, organizations have encountered more IT investment failures than expected. According to Aziz *et al*., [1], the number of IT failures has been growing since the last decade. Despite all the attention given, the implementation of IT governance (ITG) has not been easy, especially for developing country.

2. Problem Statement

The ITG concept has become increasingly well-known to worldwide organizations due to the importance of good IT governance that is constantly developing at a rapid pace in support of business decisions. The ITG concept has garnered increased attention from scholars and practitioners around the globe but the concept is still relatively new to Malaysia. There are numerous ITG frameworks that are readily available for adoption, such as Control Objectives for Information and Related Technologies (COBIT 5.0) and Information Technology Infrastructure Library (ITIL v3). The ITG concept has been constantly evolving as the COBIT and ITIL frameworks have already seen multiple updated versions up till now. Organizations have been trying to adopt various practices and frameworks for governance purposes. However, the implementation of ITG is a difficult process especially for organizations in developing country like Malaysia as there are various barriers to the adoption of ITG practices [2]. In addition, the number of studies on factors that inhibit the positive implementation of ITG has been less than ideal, and even

worse for developing countries. ITG awareness and practices are severely lacking in the Asian region [3]. For a developing country like Malaysia, where ITG implementation is still at the infancy stage, more studies should be conducted to increase the understanding of ITG. Lacks of ITG awareness, guidelines and practices have also been reported concerning the public sector in Tanzania [4]. Therefore, this study attempted to examine and categorize ITG issues that are consistently faced by Malaysian organizations. This study also explained why most issues are interrelated and emphasized on how IT human capability can mitigate ITG implementation issues.

3. Research Context

3.1. Information Technology Governance (ITG)

Due to the massive amount of attention given to the field of ITG, researchers and experts have given various definitions and expectations of ITG. One of the most accepted definition of ITG is "the distribution of decision rights and accountability in order to induce positive behaviour or patterns in managing and using IT resources" [5]. ITG is also defined as the "utilization of organizational capacity by the board, executives and IT management team to formulate and implement IT strategy as well as achieve strategic alignment between business and IT" [6]. ITGI defined ITG as an integral part of corporate governance aided by adequate leadership, structures and processes to ensure IT sustainability and act as an extension of an organization's strategies and objectives [7].

3.2. Information Technology Capability

Although IT capability has seen various definitions in previous studies, the definitions have been centred on "the ability to manipulate IT resources and costs" [8]. The definition was extended by stating that IT resources have been combined to support business-related decisions [9]. Both definitions referred to the ability to utilize and manipulate IT-related resources and other complementary resources to support businesses in value-added ways [10]. Aside from controlling IT resources, IT capability is specifically referred to as the ability to affect organizational goals through the control of IT-related costs [11].

IT capability is placed in between technical capabilities and IT-related organizational capabilities. However, most of the classifications included three of the following, namely IT infrastructure capabilities, IT human capabilities, and IT-enabled intangibles [8, 10-13]. IT infrastructure capabilities is defined as the ability to provide sustainable infrastructure services to support business-related processes or IT-related tangible assets that include IT systems, gadgets, and various tools and applications that form the very base of IT infrastructure and shared throughout the firm [8,12,14]. IT human capabilities refer to the combination of technical and managerial skills of IT professionals in solving and attending various organizational needs [8,12]. IT-enabled intangibles are referred to as intangibles made available due to the utilization of IT resources. These intangibles include knowledge assets, synergy, relationship assets, responsiveness and others [8,10]

3.3. ITG Issues in Malaysia

Since the sources of information for ITG implementation issues were found to be lacking in the review process, data collected for this study included those from studies concerning various sectors, such as public, financial and higher education sectors. Most organizations in Malaysia are still in the infancy stage of ITG implementation, as reported by [2]; hence, the factor of sector diversity is expected to have minimal effect on the barriers to initially accept the basic implementation of ITG. This study has classified issues faced by organizations that implement ITG into two main categories. The first category is organizational-related, and the second category is human-related. Further details on the categorization and issues found will be discussed in the section on findings.

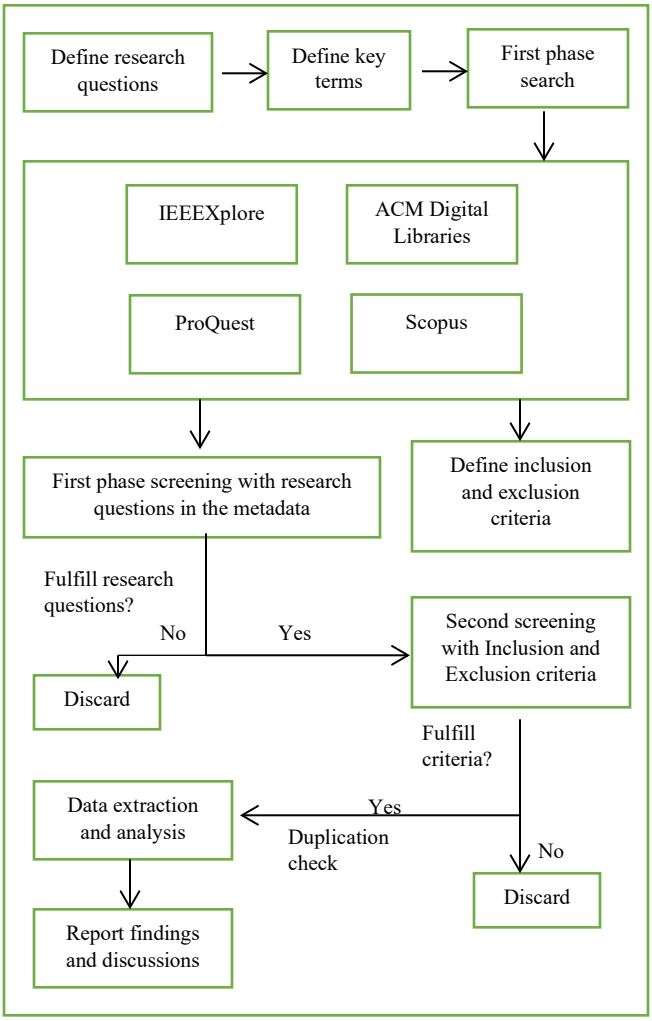

Figure 1: Systematic Literature Review Process

4. Systematic Literature Review

The methodology used in this study was the systematic literature review method. The guidelines for a systematic literature review were provided by Kitchenham [15]. This type of review is mostly used when the study intends to identify any research gap or interpret any area of interest in a span of time. This methodology helps the researcher to be better positioned for future research activities according to the research gaps found in the review process. The steps undertaken for systematic literature review in this study are as follows: i) Define the research questions; ii) Define key terms for searching the database; iii) First phase literature search and selection process; iv) Define

inclusion and exclusion criteria for the second phase selection process; v) Data extraction and analysis; and vi) Report findings and discussions. Figure 1 illustrates the systematic literature review process undertaken in this study.

The first step in the systematic literature review is to define the research questions for the literature screening process involving the metadata in the first phase. The research questions set for literature screening are as follows:

i) Is the article related to information technology governance?

ii) Are there any primary findings on the implementation of information technology governance?

iii) Did the study take place in developing countries or Malaysia?

The literature searches were conducted on 6 databases, which were IEEEXplore, ACM Digital Libraries, Scopus, Science Direct, Springer Link, and ProQuest. The initial search began in November 2018 and was updated in June 2019. Some of the terms used for literature searches only in the metadata are "information technology governance", "information and communication technology governance", "IT governance", and "ICT governance". Thus, if the initial search presented 500 or more hits, the term "Malaysia" is added to the search results, if available, or in the full text to limit the search results to the context of this study. Moreover, if the results yield less than 50 hits, the newly added term "Malaysia" is deleted, and the previous results are considered. As for the literature search in Science Direct, there were 1,297 hits after the term was added. The results were then filtered according to articles with open accessibility. The results of the literature searches are listed below:

i) IEEEXplore – 454

ii) ACM Digital Libraries – 158

iii) SCOPUS – 97

iv) ProQuest – 25

Next, initial screenings were carried out by referring to the research questions. After the initial screenings, the breakdown in the number of qualified articles were 16 articles from IEEEXplore, 7 from ACM Digital Libraries, 47 from SCOPUS, and 1 from the ProQuest database. The inclusion and exclusion criteria for the second phase of screening were then determined, as shown in Table 1 below.

Table 1: Inclusion and Exclusion Criteria

Inclusion Criteria	Exclusion Criteria
Paper written in English	Paper not written in English
Full accessibility	Partial/No accessibility
Findings related to organizations in Malaysia	Findings unrelated to organizations in Malaysia
Findings reveal IT governance implementation issues and causes	Findings did not reveal IT governance implementation issues
Primary study	Non primary study

In the second phase, the criteria were used in the literature selection process after reading the full text. Finally, 11 articles were selected, and after removing redundant articles, 10 articles had fulfilled the criteria, and 2 additional articles outside the database were found from previous studies and referred by related authors in the qualified articles. A total of 12 articles had qualified for this study. As the study focused only in the context of Malaysian organizations, the number of qualified articles was low. Figure 2 illustrates the number of articles published per year.

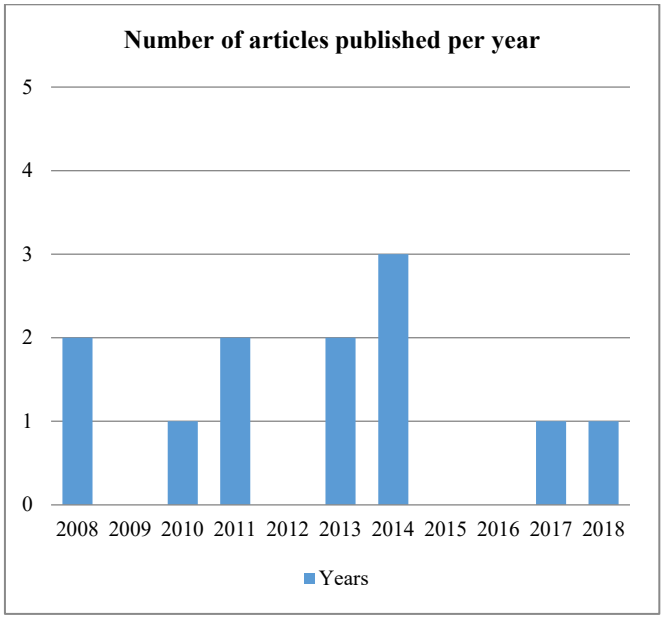

Figure 2: Number of articles published per year

As shown in Figure 2, the number of articles published per year is unusually low, especially after 2014. This might be because most studies on ITG had focused on the benefits and impact of ITG on firm performance instead of barriers to ITG implementation. As reported in [16], most organizations that participated in the study had a low ITG maturity level. Therefore, this study attempted to summarize issues that consistently inhibited the process of ITG implementations and adoption, as well as to propose potential solutions for future studies.

Table 2 reveals that most of the articles reviewed had both organizational and human-related issues in ITG implementation with the exception of 2 papers where one focused solely on IT practitioners and the other focused more on structural issues, such as the lack of defined roles and responsibilities. Human-related issues were mentioned 21 times and organizational-related issues were mentioned 18 times in all 12 articles. Table 3 shows the issues that were found in each category, while Table 4 shows the classifications of key issues found in articles after the reviewing process.

4.1. Organizational-related Issues

The issues in this category are regarded as issues faced during ITG implementation due to organizational decisions pertaining to the structure, guidelines and practices, as well as the support from top management. Organizational issues are related to top-down decision making where structures, responsibility and accountability, policy, guidelines and practices as well as

direction and goals are determined by the top management to be implemented by the entire organization. Hence, organizational-related issues are mostly related to the upper level of an organization. The subcategories proposed by this study pertaining to organizational-related issues are structure, guidelines and practices and top management.

4.1.1. Structure

Structure issues defined in this study refer to issues developed due to lack of assignation in accountability and responsibility in ITG. Structural issues are one of the most commonly found issues faced by newcomers to ITG implementations [4, 17-20]. As ITG is still a relatively new concept in Malaysia, organizations often struggle to develop appropriate structures or hierarchy of power in terms of ITG implementation. More often, a IT steering committee and IT strategy committee should be established by involving the Chief Information Officer (CIO). It was reported that structural issues were not functioning well as the CIO did not understand his/her role and responsibility in ITG [18]. Without an appropriate structure in place, there would be lack of transparency in the governance process and even difficulties in justifying IT-based decisions [19]. In addition, lack of structure can lead to communication issues [2]. Organizations will find it difficult to refer to the personnel in-charge as no one will assume the responsibility for related issues without a structure in place [18]. Similar issues were reported as there was a lack of a platform for management to discuss IT-related issues [21].

4.1.2. Guidelines and Practices

Guidelines and practices issues arise due to the lack of ITG guidelines and practices in the organization. Guidelines and practices are complementary factors to a reliable governance structure, which also contributes to the creation of transparency for justifying the ITG implementation processes [19]. The lack of strategic guidelines for IT funding in public universities was reported in [18]. It was revealed that IT projects that were initially approved or agreed by the IT committee were rejected eventually due to financial issues.

Miscommunication and improper guidelines led to a lack of coordination between departments and facilities regarding the utilization of IT resources. Guidelines and practices together with a reliable ITG structure prevent information disparity between the expectations of the CIO and implementation on the ground [21]. A study on Malaysia's public sector revealed that 76.19% of organizations had a low ITG maturity level. Findings also showed that IT managers expected at least an average level of ITG practice despite the lack of proper mechanisms and exposure to ITG practices [16].

4.1.3. Top Management

ITG should be driven and initiated from the organization's top level [19]. Top management support is classified as an organizational issue because top level executives are responsible for deciding organizational initiatives for moving forward in the right direction. Successful ITG implementation often depends on the top management's initiative to offer sufficient support. In addition, ITG implementation is also influenced by internal organizational cultures and politics. It is important for top management to recognize the needs for ITG and assign appropriate accountability according to initiatives, beginning from the top of the organization [3].

Lack of support and commitment from top management is one of the current issues faced by Malaysia organizations when implementing ITG [2, 22]. Similar situations where the top management was lackadaisical in supporting ITG was also reported [1], which then resulted in a lack of adequate resources to manage assigned controls as the top management willingness to incorporate ITG into the organization's future strategy is highly dependent on the recognition and knowledge about the importance of ITG.

No.	Key Findings/ Issues					
	Organizational-related			Human-related		
	①	②	③	④	⑤	⑥
1	Lack of steering committee	Lack of documented practices		IT skills at basic level	Lack of understanding	
2	Communication breakdown and lack of commitment	Lack of approach for funding strategy		Lack of skills and knowledge in CIO and staffs	Lack of CIO with adequate ITG understanding	Lack of CIO presence in ITG and lack of IT initiative
3		Lack of exposure in ITG practices	IT accountability for top management		Recognition and knowledge from top management required	
4			Lack of top management support	Lack of adequate human resource		
5	ITG affected by culture and politics	Communication issues	Lack of top management support	Lack of time, training, knowledge and skills	Lack of ITG awareness	
6				ITG requires continuous commitment	ITG requires special knowledge	
7	Weak structure and lack of clear roles and responsibilities					
8	Communication breakdown	Lack of coordination and alignment		Lack of capable human resources	ITG responsibilities placed on IT only	Lack of CIO presence and effort to create awareness
9	Lack of governance in collaboration	Lack of governance in collaboration			Lack of understanding towards the importance of ITG	
10	Lack of accountability and transparency	Lack of justification on expense and resources	ITG should be driven from top management			ITG requires leadership
11		Lack of exposure on proper guidelines and mechanisms		Insufficient proficient IT personnel	Lack of consistent understanding on ITG	Lack of official directive
12			Lack of top management support	Complexity in ITG practices		

Table 4: Classification of Key Issues

Key Findings/Issues					
Organizational-related			Human-related		
Structure	Guidelines and Practices	Top Management	Competencies	Awareness and Understanding	Leadership
• Lack of adequate structure and accountability	• Lack of documented practices and guidelines • Lack of guidelines for collaborations • Lack of exposure	• Lack of top management support • Lack of top management accountability	• Lack of adequate IT-related skills • Lack of adequate managerial skills • Lack of human resources	• Lack of awareness and understanding on ITG • Lack of recognition of ITG	• Lack of role in CIO • Lack of IT initiative

4.2. Human-related Issues

Human-related issues refer to issues originating from human resources caused by the lack of quality, competency, and understanding required for managing and completing tasks required by organizations. Specifically, human-related issues in this study refer to barriers to ITG implementation due to insufficient personnel with quality to manage and govern IT-related resources and issues. In human-related issues, the personnel included in this study were the CIO and other personnel involved in ITG from the middle to the top management level. Three subcategories in human-related issues are competencies, awareness and understanding as well as leadership quality.

4.2.1. Competencies

Competency issues are often overlooked by organizations since most of the attention is placed on ITG frameworks and practices. Competency in this study refers to the ability of ITG personnel to manage and complete assigned responsibilities and practices related to ITG. The terms competency and capability are often used interchangeably due to how closely their interpretations are. Competence is defined as having the ability to utilize skills, knowledge and the capacity to satisfy or achieve current needs. Capability is defined as qualities, abilities, and the potential to develop accordingly to meet future needs by adapting to changes in a dynamic environment while generating new knowledge for improving working performance [23]. Therefore, in order to fit in the context of this study, where current ITG issues can be safely regarded as current ITG needs, the term competency is used in this subcategory. Most senior management and CIOs lack knowledge and experience in ITG because ITG is a relatively new concept compared to working skills and experience [1,3,17-18]. In addition, it was reported that the complexity of ITG practices was the highest ranked barrier from the technical aspect [22]. The prerequisites for ITG personnel have been elevated as ITG committees are required to plan, manage, and monitor IT initiatives. ITG personnel also need to master non-technical skills such as business strategic planning, leadership, and communication [16]. Hence, due to the increased prerequisites for ITG personnel, organizations have been lacking human resources equipped with proficient skills in technical and non- technical aspects to resolve ITG issues and challenges.

4.2.2. Awareness and Understanding

As mentioned previously, top and senior management need to recognize the need for ITG to ensure smooth top-down implementation [3]. Such recognition requires adequate awareness and understanding about ITG. Awareness and understanding issues refer to issues that occur due to the lack of experience and understanding on the potential benefits of ITG in organizations. Awareness can elevate performance and allow accurate understanding of situations that can further lead to better decision making by leaders [3]. The authors had further revealed 3 level of ITG awareness in reference to Endsley's theory of awareness [24]. The first level of awareness includes gathering perceptual information from the surrounding and focusing on elements that are beneficial and relevant. One example of this is to understand the availability of resources, infrastructure, and skills required to achieve current tasks. The second level of awareness includes integrating perceptual information with experiences and knowledge to assess the significance of the context, which is the role of ITG in organizations [25]. The third level of awareness includes projecting future elements by anticipating the changes that can be brought to the operational environment. Examples of third level awareness are management of IT resources that meet organizational needs, lead the initiative in addressing IT issues, ensure continuous alignment between business and IT, and leverage IT potentials to enhance business growth. It was found that top management perceives that there is no need for ITG as there is a lack of awareness and knowledge [2]. There were no efforts by the top management to create awareness about ITG adoption [21]. Instead, all the issues were thought to be an IT-only responsibility, which further leads to a disoriented alignment between strategic business and IT planning. Business executives did not understand the strategic value of IT as it was thought to be insignificant [26]. Business executives failed to understand IT issues and there was a severe lack of collaboration between business and IT. IT managers assumed a high-level of maturity for ITG but in reality, 76.19% of the organizations were still in position of low ITG maturity [16]. This could be due to different levels of understanding regarding the definitions of ITG and ITG itself. Most implementations were highly dependent on instructions, and there was a lack of initiative to actively seek improvement. All the issues mentioned above indicate that most

organizations in Malaysia still lack ITG awareness and understanding.

4.2.3. Leadership

Leadership quality in this study refers to the ability of top and senior management to spearhead the IT initiative in ITG implementation. As most of the organizations are still at the infancy stage of ITG, lower levels of the organization hierarchy need to be guided by top management. This requires top management to lead using the IT initiative and provide direction from the highest level of the organization [19]. For top management to lead, adequate knowledge about ITG is required. Therefore, a lot of issues arise because even the top management has a low understanding of ITG itself [18]. There is a possibility of a lack of official directives concerning ITG, which causes the lack of collaboration between business and IT [16]. Top management should always initiate the active involvement of stakeholders in ITG, while providing sufficient guides and empowering key personnel with expectations and support. As most personnel lack ITG knowledge and experience, top management plays a major role in ensuring the continuity and sustainability of ITG. Presence of the CIO was insignificant because the responsibilities were not up to a respectable standard [21]. There was no effort to create awareness and liaison between business and IT. Hence, the IT department assumed all responsibility for issues identified. Leadership in ITG is especially vital for organizations at the infancy stage as the top management is responsible for setting the guidelines and directions for organizations to move forward. Newcomers to ITG need explicit guidance or they would just become simple rule followers instead of skilled personnel actively seeking continuous innovation and improvement.

5. Role of IT Human Capability

IT human capability mentioned in this study refers to technical capabilities, business capabilities and behavioural capabilities [12]. Technical capabilities refer to technical skills and knowledge in a specific area of expertise. Business capabilities refer to the IT personnel's ability to understand and manage overall business processes and environments. Behavioural capabilities refer to the IT personnel's interpersonal ability to interact effectively with others. The results show that both organizational-related and human-related issues are major factors that help organizations to implement ITG in Malaysia. It is undeniable that both issues need unwavering attention from organizations in order to implement ITG and move it in the right direction.

ITG is more than just following rules and guidelines. ITG requires continuous commitment from organizations to ensure sustainability, and having competent human resources is one of the prerequisites for future sustainability, whether in business or ITG [25]. It has been stated that organizations might be governing IT with less than adequate prerequisites in terms of IT capabilities [10]. Development of ICT personnel has been one of the focuses of the Malaysian Strategic IT Plan 2011 [26]. However, findings indicate that there is a lack of effort or mechanisms for developing IT personnel in the area of ITG. Although issues have been categorized into organizational-related and human-related categories, both issues are interrelated as one issue can cause the other to surface.

One of the primary issues in organizational-related issues is the lack of adequate structure and accountability in ITG. The lack of organizational structure is not directly related to IT human capability, but it should be taken into consideration when forming the ITG structure. When forming the ITG structure, organizations should assess whether there are qualified personnel available and accountable for ITG implementation. It is undeniable that collaboration issues [21,26] have consistently emerged during ITG implementation. In the selection of qualified personnel for ITG, there is no doubt that at least certain levels of business and behavioural capability should be considered as ITG often requires collaborative efforts for strategic alignment purposes. This requires personnel to possess some level of business acumen and the capability to work well with other units when needed. It raises further questions on whether business or IT executives should be held accountable, as most business executives possess business capabilities without IT skills, and most IT executives possess IT capabilities without business skills. It does not mean that business executives are required to possess IT capabilities but at least they should be aware of the importance of ITG since IT executives are now required to extend their understanding of business knowledge [27]. It was also revealed that business and IT, which act in collaboration, can lead to ITG effectiveness and strategic alignment as knowledge sharing between business and IT executives lead to a better understanding of each other's environment [28-29]. For example, it has been revealed that a web-based system developed in a university aligns the entire existing or new program with the Malaysian Qualification Framework (MQF) [30]. Similar web-based systems can be designed to monitor and align ITG prerequisites pertaining to certain personnel involved. Training should be given for those who do not meet the prerequisite capabilities for ITG.

Guidelines and practices are some of the most common issues faced when implementing ITG. Guidelines and practices are available through frameworks like COBIT 5.0 and ITIl.v3. However, despite the availability of frameworks in the market, not all practices and mechanisms are suitable for every organization. One main purpose of guidelines and practices is to help and give direction to organizations intending to implement ITG. It is also important to practice the relevant mechanisms that help develop positive IT behaviours throughout the entire organization. One of the common issues with the availability of frameworks is the lack of instructions on how to perform tasks with the right mind-set. ITG is more than just simply following rules and guidelines. Organizations must also implement various ITG mechanisms that help to develop individuals with adequate capabilities so that ITG efforts are sustainable in the future. It is important for organizations to develop enough ITG awareness among IT personnel through various practices and mechanisms. As reported, organizations with awareness imbue governance-related mind-sets into daily routines and practices [3]. Personnel with the ability to actively lead and think using IT initiatives are better than rule followers. Guidelines and practices provide the basis for incorporating ITG into daily routines, but it depends on the personnel's capability to understand and manage tasks effectively. In addition, only qualified IT personnel who are aware of the importance of ITG will actively think of the processes and

guidelines that need to be improved and adapted to the changing business process. Therefore, IT human capability is important for the continuous improvement of ITG implementation in an organization.

Gaining top management support has been an issue for organizations in Malaysia as top management lack the understanding of the importance of ITG. Moreover, lack of top management support directly affects the outcome of ITG implementation as resources are often procured with the approval of the top management. It is important to convince the top management about the implementation of ITG in order to gain their support. It has been proven that new IT deployment is easier with firm commitment from the top management [30]. However, it is not easy to convince the top management as ITG is a long-term project that requires various resources to succeed. Therefore, having capable human resources that are knowledgeable in ITG can ensure the continuity and success of ITG implementations, especially in the future. The CIO plays an important role in convincing top management as the CIO often acts as a liaison between business and IT executives. The CIO who is capable of recognizing, understanding, and relaying the importance of ITG to the top management ensures better allocation of resources for a smoother implementation process.

Unlike organizational-related issues, human-related issues are directly related to IT human capability. As mentioned before, competencies refer to the ability to satisfy current needs with skills and knowledge. Therefore, organizations need to develop current competencies into capabilities in order to adapt to future challenges. Currently, ITG is presented as a brand-new challenge that requires human resources with proficient skillsets and capabilities for organizations in Malaysia. Most Malaysian organizations lack competent human resources for implementing ITG. The lack of competency generally includes IT as well as managerial skills and knowledge, which are part of technical and business capabilities. The issues are especially troubling for the public sector as most public sectors have a more or less fixed number of staffs. Therefore, a recruitment of additional experts or capable personnel was less likely to occur unless external expertise is specifically consulted. Hence, organizations need to develop human resources that are proficient in ITG supplemented by the help of various practices and mechanisms. However, competency issues consistently emerge from organizations suggesting that organizations are more focused on setting rules and guidelines rather than developing capable human resources that are supposedly accountable for ITG tasks. This creates the culture of passive governance where actions are only taken based on rules and instructions. As mentioned earlier, personnel involved in ITG should be equipped with business knowledge and ITG awareness. This can be achieved with job rotations and cross training between business and IT units [27]. A web-based system can be developed to record all qualifications and skills of related personnel. All training and rotations should be provided based on specific skills that are lacking. Qualified personnel with cumulated experience in the task can improve the efficiency of the process and are more inclined to offer and seek improvements for ITG.

Another factor of passive governance comes from the lack of awareness and understanding of ITG. ITG requires leaders with enough understanding and knowledge about the ITG concept to lead with IT initiative and active thinking in order to create a good culture of governance. Results revealed that the importance of ITG was severely underestimated by organizations. Few cases reported that senior management did not recognize the importance of ITG and felt that ITG was unnecessary [3,26]. There was also a case where ITG was thought to be only as an IT responsibility [21]. Issues like this clearly show that the roles of ITG in organizations were ambiguous to entire organizations, or at least to the top management and business executives. For ITG implementation to be successful, ITG awareness must be spread throughout the organization so that strategic alignment between business and IT can be achieved. Organizations must reach consensus on the role of ITG, and how it can affect organizations moving forward. As mentioned previously, awareness allows organizations to imbue certain mindset into daily practices. For this case, ITG awareness prevents the culture of passive governance and allows personnel to be actively involved in the governance process moving forward. In this case, awareness and understanding must be included as part of IT human capability as both play a big role in adapting to new challenges.

In this study, leadership is listed under behaviour capability since leadership is an essential ability to lead and interact with others. From the leadership aspect, the CIO is expected to be in the midst of ITG implementation. However, previous articles reveal that CIOs in Malaysian organizations lacked leadership qualities, especially in terms of IT initiative [16, 18-19]. In ITG's infancy stage, leadership plays one of the most important roles in ITG implementation as beginners in the organization need more guidance than ever. The CIO is seen by practitioners as the main driver in ITG [27]. However, the CIO should not be the only one to be held responsible for leadership issues. Anyone in the organization who is aware of the importance of ITG should be leading-by-example in order to create more ITG exposure. As mentioned previously, ITG should be driven from the top management downwards. Therefore, the top management must take responsibility in leading the IT initiative by recognizing the importance of instilling a successful ITG.

Finally, as mentioned by [10], the use of IT capability has been ambiguous in the ITG literature. Therefore, this study attempted to clear the ambiguity by exploring and explaining the role of IT human capability in ITG implementation. This study can contribute to future studies on the relation between ITG and IT human capability.

6. Conclusion

In conclusion, this study explained the interrelated relations between organizational-related and human-related issues by justifying the role of IT human capability. This study also clarified the ambiguity concerning the use of IT capability on ITG literature. Through systematic literature review, it has become clear that structure and guidelines help ITG to consistently move in the right direction. However, without specific capabilities, such as business, technical, and behavioural capabilities possessed by related personnel, ITG cannot be implemented effectively since most ITG implementation and practice requires collaboration from both business and IT units for the sake of strategic alignment. Therefore, it can be concluded that both organizational and human

factors are important for the consistency, efficiency and effectiveness of ITG. Additionally, researchers are encouraged to commit further studies on IT human capability and ITG implementation in Malaysia in order to compensate the lack of proven ITG studies in the Malaysian context. This study also attempted to further highlight the importance and role of IT human capability in the midst of ITG implementation and mechanisms in order to garner more attention toward human-related issues since developing countries like Malaysia are affected by issues such as the lack of qualified human resources. Therefore, organizations should pay equal attention to both organizational and human-related issues in order to create a well-built structure, framework, and environment that are well-suited for ITG implementation at the infancy stage.

Conflict of Interest

The authors declare no conflict of interest.

Grading estimate

ABSTRACT

Predicting trainees' final academic results in the early stage of programming class is a significant mission in the field of learning analytics. Performing exercises in programming class is hard and it takes a lot of time for trainees. For this reason, careful support with trainees are offered in many classes through classroom assistants (CAs). Even with CAs' assistances, managing a programming class is difficult. Because each trainee's coding activity is different from another's, even when each of them is solving the same exercise. Classroom assistants with little teaching experience have difficulty for understanding the unique features of trainee's coding activity. We have employed data mining to analyze trainees' coding activities to distinguish those various features. The objective of this research is to present such behavioral features of trainees to CAs to enrich their assistance for the trainees. In order to investigate the timing of guidance, we conjectured the academic results from the chronicle record of coding activities.

1. Introduction

This paper is an extension of the work originally presented in 2017 International Conference on Computational Science and Computational Intelligence (CSCI) [1].

In programming exercises, Individual trainee's coding activity varies from person to person, even when each trainee is answering the common exercise. The aim of this research is to display many coding features of trainees to classroom assistants (CAs). We conjectured the academic results to indicate the timing of instruction to the CAs.

Through the analysis of the logs of trainees by using the data mining techniques, we can find the learning pattern of each trainee. This analysis helps instructors to identify "at-risk" trainees [2]. Programming exercises in higher education institutions allow trainees to solve individual tasks. Since the skill levels of trainees differ, each of them has to work on tasks in an individual way [3]. Some trainees solve exercises easily, while others take much time. Therefore, many schools employ CAs to provide assistances for the trainees. CAs are expected not only answer questions of trainees but also to provide comprehensive assistances for the trainees with large assignments [4]. For this reason, a CA needs to understand who needs assistance, what kind of assistance the trainee needs, and under what circumstances assistance the trainee confusing [5].

Predicting trainees' final academic results in the early stage of programming class is a *significant mission* in the field of learning analytics. For instance, one can perform regression analysis for this purpose [6]. In order to catch the timing when the instructors intervene to the trainees who need help, instructors need to conjecture the trainees' future scores of the programming exercises. In order to provide such estimations, the authors have developed and used a unique programming exercise support system [7]. The system is called PRESS, and through the analysis of the outputs of PRESS, we have succeeded to identify the coding activities.

Trainees' progresses differ from each other, because of the difference of individual skill levels [3]. We have found that this skill level difference can be observed in the coding mode. Trainees who show slow progress have poor coding modes. PRESS demonstrates that such situations are common. Such trainees often

*Toshiyasu Kato, Nippon Institute of Technology 4-1 Gakuendai, Miyashiro-machi Minami-saitama-gun Saitama, 345-8501, Japan, katoto@nit.ac.jp

stop programming and become disgusted [8]. Therefore, it is important for instructors to identify what kind of trainees have programming exercises at an early stage [4].

We have conjectured the trainee's academic results in order to get the timing when CAs start assistance for the problematic trainees. According to the instructor's opinion, trainees who take a lot of time for exercises tend to have low academic results. In this paper, we give details of the results of evaluation experiments on this estimation. As a result, CAs became to comprehend the trainee's coding activities without having prior programming support experience.

2. Related Work

Several researchers have reported that coding activities has improved trainee's skills by assisting in debugging and coding methods. Ryan has built a model that enables trainees to improve their skills by analyzing debug logs and execution results [9]. Our study analyzes coding history in addition to debug logs.

Alex proposed a tutor on a computer to support trainee programming [10]. The tutor checks whether the trainees are on the correct trajectory and advises trainees in a wrong track. For instance, an instructor may give trainees a hint on how to reconstruct their programs. Our research aim is to improve trainees' practical skills by supporting coding methods.

There are past researches targeted at study how to support trainees through their learning chronicle data. In such studies, scientists have analyzed teaching materials using techniques based on statistical methods on Support Vector Machines (SVM). For instance, Yamada et al. detected contents on the Web pages that were difficult for trainees to comprehend by logistic regression [11]. In that research, they have created models with seven explanatory parameters, namely latent time, gaze point distance moved, gazing point movement speed, mouse distance moved, mouse speed, the amount of mouse wheel rotation, and correct identification. Yamada's evaluation experiment have achieved the identification rate of 81% by using SVM and time series data to improve coding activities, such as compilation and execution frequency.

Researches on foreseeing trainee's performance by machine learning (ML) algorithm that takes advantages of trainee's learning chronicle data as teaching data are as follows.

Guo, Zhang, Xu, Shi, and Yang applied deep neural network (DNN) to the data from 12,000 trainees in Chinese elementary and junior high schools to predict five academic results in high school entrance exams [12]. They found that deep learning can predict academic results with highest accuracy rate (Accuracy) among many ML methods.

Belachew and Gobena employed three types of ML algorithms, namely neural networks, Naive Bayes and support vector machines to predict results of 993 trainees at Wolkite University in Ethiopia [13]. They found that, as a result of comparison, Naive Bayes had the highest accuracy rate.

Ahmad, Ismail, and Aziz used three ML algorithms, namely Naive Bayes, decision trees, and rule bases to predict the performance of about 500 trainees in Malaysian [14]. As a result, they reported that the rule base has the highest accuracy rate.

Amrieh, Hamtini, and Aljarah used three ML algorithms, namely neural nets, decision trees, and Naive Bayes, to predict performance with data from 480 trainees at Jordanian University [15]. They found that decision trees and neural networks obtained the highest accuracy rates.

In these preceding researches, variety of ML algorithms are applied to trainee data, and researchers who tackled this problem demonstrated how and what way each of the ML methods succeeds to predict the final scores. Unfortunately, the data used for the evaluation are largely different from each other, and the data used in many studies are not open to the public. It is difficult for a third party to pursue further study through conducting a comparative experiments with a follow-up test or alternative method. We can only use them as reference data.

3. Analysis of Coding Activities

In this research, we have set up data on the coding activities of trainees in 2014 and 2015 classes analyzed in previous study [16, 17]. Table 1 displays the explanatory parameters used for the analysis. We have measured all of the data and then analyzed the analysis targets using PRESS. We have examined the following two approaches to the data.

- Unsupervised classification.
- Estimation of exercise-solving time.

Table 1: Explanatory parameters

Type of characteristics		
Time	Frequency	Error
Problem-Solving	Compilation	Number of errors
Compilation interval	Execution	Number of similar errors
Execution interval		

3.1. Unsupervised classification

We have used Ward's method, which is a representative hierarchical clustering [18] [19]. Clustering is a process that groups objects into classes of similar objects [20]. We have formed from

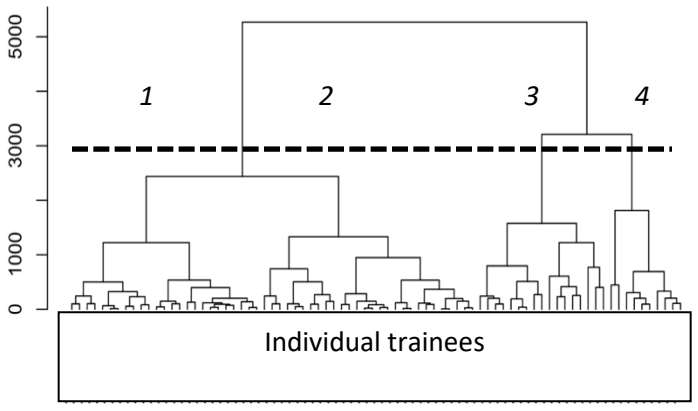

Figure 1: Clustering by Ward's method

Table 2: Explanatory parameters for each cluster

Cluster	Solving time [s]	Compilation interval [s]	Execution interval [s]	Compilation frequency	Execution frequency	Number of errors	Number of similar errors	Number of trainees
1	528	209	267	7	5	1	1	25
2	812	379	606	6	3	3	3	28
3	1405	590	1160	7	3	4	3	17
4	1506	228	337	18	13	5	4	10

the patterns (observations, data elements, or characteristic vectors) into clusters (groups or subsets) based on those localities and connectivity in the n-dimensional space as shown in Figure 1. Figure 1 demonstrates the cluster analysis of the seven explanatory parameters. Table 1 indicates the summary of explanatory parameters for each cluster in Figure 1.

We have perceived the following clusters:

- Cluster 1: A group solved the exercise in short time. In this group, trainees understand each problem they encounter while coding.
- Cluster 2: A group solved the exercise in short time. In this group, trainees are coding without understanding the details of their problems.
- Cluster 3: A group solved the exercise in long time. In this group, trainees are cursorily checking the error contents and cording without full comprehension of their problems.
- Cluster 4: A group solved the exercise in long time. In this group, trainees are cording without checking any error details.

3.2. Length estimation of time for solving exercises

The trainees in each cluster should receive cluster-specific instructions. Therefore, instructors and CAs need to identify the features of the trainees in the class and pay special attentions to those who take a long time to solve given exercises. The cluster analysis, however, cannot conjecture the duration for solving exercises in the future. For this reason, CAs cannot know which trainees need certain types of guidance at the beginning or before class. In order to ameliorate this hindrance, we used the 2014 class coding activities as training data and tried to predict the exercise-solving time in 2015 class activities. Table 3 displays the coding activity data for two years. The values of the explanatory parameters for each year are averaged values (excluding the number of trainees). These data are taken from two programming exercises of the same content each year.

We have used logistic regression to decide whether trainees' exercise-solving time would be long or short. Logistic regression is a typical statistical method that illustrates the relationship between two different series of data [21]. We can assume that one of the series of data as independent variables, and the other data are dependent variables. We assume that the output variable takes one value from a set of fixed values. This value corresponds to a class of the classification problem. The regression equation is displayed in Equation (1). p is the probability conjecture of the

$$p = \frac{1}{1+e^{-(\beta_0+\beta_1\chi_1+\beta_2\chi_2+\cdots+\beta_k\chi_k)}} \quad (1)$$

Table 3: Coding activities in 2014 and 2015

	2014	2015
Number of trainees	85	80
Solving time (Problem) [s]	815	936
Compilation interval (Average) [s]	295	352
Execution interval (Average) [s]	513	584
Compile frequency	10	8
Execution frequency	5	5
Number of errors until correct answers	7	3
Number of similar errors that are most frequent	4	3
Number of trainees late submission	32	35
Number of exercise resolutions	40	41

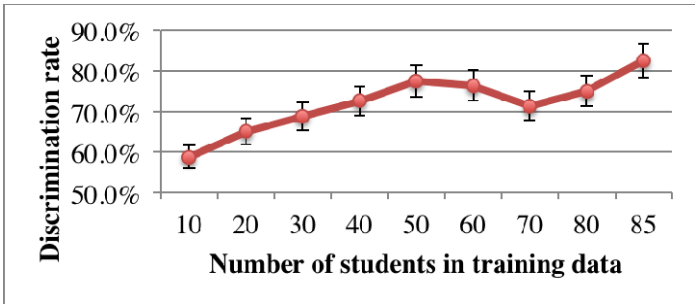

Figure 2: The number of trainees in the training data and discrimination rate

objective variable. In this research, we obtained the probability p of a long exercise-solving time. β_0 is a constant, β_1, β_2, ... β_k are regression coefficients, and $\chi_1, \chi_2, \ldots \chi_k$ are explanatory parameters.

We first applied training data to logistic regression to determine constant and regression coefficients. We used Tensor Flow for this calculation. Tensor Flow is a representative tool for DNN [22]. We used cross-entropy as a learning error function for the supervised classification problem and carried out optimization using the steepest descent method [23]. The objective variable for logistic regression must be represented in the 0/1 binary. We set the teaching data to 0 when it was longer than the mean exercise-solving time and to 1 if it was shorter than the mean exercise-solving time.

We created a model with the 2014 data, and then we applied the 2015 data to the model and conjectured the length of the exercise-solving time. The discrimination rate was 82.5%. The

parameters at this time were a learning rate of 0.015 and the number of learning iterations was 70,000. Figure 2 displays the number of trainees and the identification rate used in the training data for ML.

4. Estimating Academic results from Trainees' Activities

Now that we have the conjecture of the exercise-solving time, we next conjectured academic results to find the timing of instruction. In order to improve accuracy much further, we have used 2016 data in addition to the last two years (Table 3). Table 4 displays the coding activities for 2016 class and Table 5 displays the academic results by three years. The academic results are based on the final exam at the end of the semester.

The subjects (trainees) are sophomores in a Java programming class from our institute. Each year, the same instructors took the charge of the class, but the academic results are differed from year to year as a subjective evaluation of instructors has been added. For this reason, we have defined the estimation rate as follows along with the coincidence rate:

$$Estimation\ rate\ = \frac{Estimated\ academic\ results\ \pm 1}{Number\ of\ trainees}$$

Based on the data of these three years, we have conjectured the academic results through the following procedure.

1. Normalize the input data.
2. Decide the features.
3. Decide network configuration and parameters.
4. Conjecture the accuracy by creating a network model.
5. Check the estimation accuracy.
6. Repeat steps 3 to 5 to improve accuracy of the estimation.
7. Analyze by changing the hidden layer

Table 4: Coding activities in 2016

Number of trainees	107
Solving time (Exercise) [s]	639
Compile interval (Average) [s]	405
Execution interval (Average) [s]	139
Compile frequency	7
Execution frequency	2
Number of errors until correct answers	5
Number of similar errors that are most frequent	2
Number of trainees late submission	51
Number of exercise resolutions	38

Table 5: Academic results in programming exercises

Academic results	2014	2015	2016
1: Failing	17	1	5
2: Below pass	33	13	34
3: Pass	17	17	34
4: Very good	21	36	30
5: Excellent	2	15	7

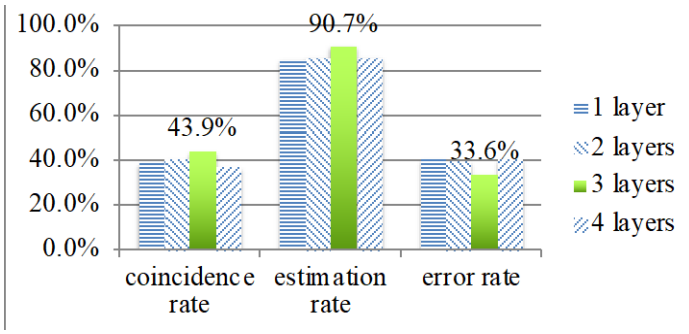

Figure 3: The coincidence rate, estimation rate, and error rate

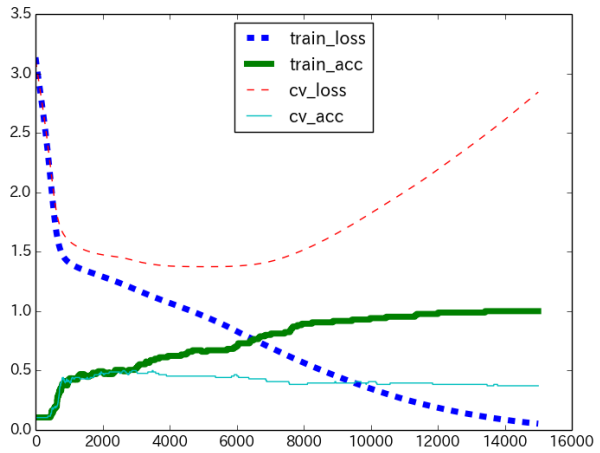

Figure 4: Loss and accuracy when the hidden layer is three layers

Figure 3 displays the coincidence rate, estimation rate, and error rate in the case of one, two, three and four hidden layers respectively. The error rate in Figure 3 is calculated by sum of the divergences between conjectured academic results and final academic results then divided by the number of trainees.

In addition to these parameters, we have chosen the following features to analyze the trainees' activities. They are duration for solving the exercises compile frequency, execution frequency, the number of similar errors that are most frequent, and the number of exercises they resolved. Through various machine-learning situations, we have found that the case of three hidden layers provides the most accurate estimation. Figure 4 displays the best case of our experiments; that has three hidden layers.

Table 6 displays the mean values of explanatory parameters. We have normalized them for each academic result. There was no trainee conjectured to earn the academic result of 5 (highest). In academic result, the number of exercises solved and the time for solving exercises are particularly related.

In addition to the experiments using DNN, we have performed performance prediction using three ML algorithms. The algorithms used in this experiment are Random Forest, SVM, and Naive Bayes. The objective of these experiments is to assess the performance of different ML algorithms.

With those ML algorithms, the purpose is also classification; the same as DNN. Also, we used the same data set for analysis as

Table 6: The mean values of feature quantities normalized for each academic result

Ac. result	Exercise-solving times	Compile times	Execution times	Similar Errors	Number of exercise resolutions
1	1.66	-0.40	-0.96	-0.78	-2.28
2	0.25	0.44	-0.44	0.47	-0.65
3	0.20	-0.77	-0.69	-0.68	-0.61
4	-0.96	-0.32	0.32	-0.30	1.01
5	-	-	-	-	-

Table 7: Estimation results

	Accuracy	Precision	Recall
DNN	0.70	0.41	0.46
Random Forest	0.62	0.34	0.37
SVM	0.58	0.32	0.42
Naive Bayesian	0.58	0.32	0.38

DNN. The reason for adopting these three types is that they were used for performance prediction in the previous researches [11] [13] [14] [15].

Table 7 displays the results of various data mining methods. The interpretation of precision and recall values here depends on each class and each academic result. This value is based on the average of all academic result classes. From these results, we can confirm that the academic results can be conjectured through analysis of coding activities by any MLs. DNN provides the most accurate predictions, but precision and recall values are low. From the perspective of accuracy, our method can find trainees who would fail from the class. However, since precision and recall are low, there is an exercise that the same method does not guarantee the same accuracy every year.

5. Discussion

We have conducted experiments of DNN with various combinations of explanatory parameters. We could not identify one single particular dominating explanatory parameter. We can conclude that all the explanatory parameters contribute almost equally to the accurate estimations. What we can state is that the DNN provides the highest values as displayed in Table 7.

For this data set, we can conclude that we can predict the performance of each trainee by any algorithms we select, even though the Deep Leaning provides the best results. However, precision and recall values are low even in DNN. The reason may be that the trainees are not the same every year and the final exam is different each year. The low value of precision and recall can be explained that the past trainee's patterns were not suitable for the target trainee's patterns. This can be expected to improve accuracy by increasing the number of trainee patterns each year.

Regarding the explanatory parameters, the most relevant activities to the academic results are the frequency of compilations and the number of similar errors. Trainees who display too frequent compilation and produce a number of similar errors are expected to receive low academic results. We can conclude that these trainees are doing programming without knowing what wrong they have done in the programming. However, there were some trainees with low academic results despite the small amount of compilations. There is a possibility that these trainees just copied their programs from other trainees. Instructor should intervene trainees those who compile too frequently in a short period of time. Also, we have observed that intervention is necessary for trainees who have not compiled for a long time. From these observation, we can conjecture that not only we can build a system that let instructors know which trainees need interventions but also we can construct a computerized automatic intervention system for trainees who need help.

We interpret the results in Table 6 and consider each group of trainees has the following features.

- Ac. result 1: A group solved the exercises in short period and produced a small number of executions. Some trainee in this group may be programming carefully, but in practice most of them are less motivated and not programming at all. This group of trainees may be waiting for their friends' solutions of the task.
- Ac. result 2: A group compiled the programs very frequently, causing the similar errors. This group of trainees may not investigate the cause of the error very well, and may just execute their program mindlessly. Because this type of trainees do not understand the cause of the error, the final exam scores also tend to be low.
- Ac. result 3: A group produced a small number of compilations and executions**.** In this group, trainees do not produce the same type of errors many times. Trainees are coding while they are investigating the cause of the error carefully. They are trying to understand every error they produced. Therefore, their final exam scores tend to be high.
- Ac. result 4: A group consumed very short period for solving the exercises. Trainees in this group solve many exercises. We observed trainees in this group can understand exercise sentences quickly and can program for solutions quickly. Therefore, their final exam scores tend to be very high.

The numbers of incorrect estimations are as follows. There were six cases where the conjectured academic result was 4 and the actual academic result was 2. Also, there were four cases where the conjectured academic result was 2 and the actual academic result was 4.

The reason why there were no trainees of academic result 5 in Table 6 may be that the number of exercises solved was small. Actually, we do not have enough training data with trainees with this highest academic result.

6. Conclusion

In this paper, we have analyzed the trainee's coding history to conjecture exercise-solving time and academic results. The objective of this estimation is to support CAs in order to assist trainees in programming exercises. We have carried out the analyses to classify trainees who perform programming exercises.

We have applied ML to construct a model that represents the coding activities of a programming class and then applied that model to the coding activities of trainees in the following year to conjecture the results from the data for the past two years. As the results, we have observed that the coincidence rate is 43.9%, and the plus or minus 1 estimation rate was 90.7%. In addition, in the analysis using four types of ML, we have found that DNN provides the most accurate estimation. However, since the values of precision and recall are low, it is necessary for us to investigate the coding history of the trainees of each year, and then improve our analysis.

As the data mining, we discovered that DNN, Random Forest, SVM and Naive Bayes can foresee the same results with sufficiently high accuracy by the same data. We clarified the results and found that we could conjecture the academic results even with a small amount of explanatory parameters.

As a future direction for research, we analyze each lesson more methodically so that we can conjecture the results at an early stage while maintaining the estimation rate high. We also plan to apply this method to other programming classes that use other programming languages than Java, such as Python.

ABSTRACT

Hadoop has certain issues that could be taken care to execute the job efficiently. These limitations are due to the locality of the data in the cluster, allocation of the jobs, scheduling of the tasks and resource allocations in Hadoop. Execution in the mapreduce remains a challenge in terms of efficiency. So, an improved Hadoop architecture that takes care of the computation time has been discussed. The improved architecture addresses the communication issues with the task trackers, inefficient clean up task, heartbeat function. Comparing with native Hadoop, the improved Hadoop reduces the total time taken for running the reducer tasks. The performance of the improved system using optimization serves better in the computation time.

1. Introduction

Big data has a huge volume, velocity and variety of information, which produces cost effective, new forms of information processing that helps in decision making, prediction and automation etc. Big data analytics is the process of analyzing large and varied data sets i.e., big data to discover hidden patterns, unknown correlations, trends, user preferences and other useful information that can help organizations to take better decisions in business. Parallel processing in data analytics has appeared as an interdisciplinary research area due to the nature and large size of data [1]. Pattern matching/mining or analysis need huge amount of complex data processing and computing [2].

Significant and reasonable allocation of resources are required to solve complicated problems [3]. It is very difficult to understand and process the data using traditional processing techniques. Big data parallel processing platforms has selected new possibilities to process the structured, semi-structured or unstructured data [4].

1.1 Problem Statement

Data localization and the resource allocation for the tasks are the challenges in the Hadoop. Effective and efficient resource allocation are the challenges in the map reduce framework. In order to implement an architecture with the data gathered from different sources of the systems as in the banking practice and various data processing supports as in the traditional global financial systems, an improvement in the computation time is required.

1.2 Motivation

Financial sectors and the banks are facing severe demands due to the growth of data processing. This happens not only from the improved regulatory requirements and an inconsistency in the data sources. The cost has to be reduced without compromising scalability and flexibility. In this scenario, the financial services industry shows tremendous interest in applying big data technologies to extract the significant value from the large amount of generated data. So, there is a requirement to improve the computation time of the process.

The proposed system addresses the issues in communicating with the task trackers, inefficient cleanup tasks, heartbeat function. Time taken for the reducers to complete the task has been reduced, which helps in better computation time.

The sections of the paper are divided as follows: Section 2 discussed some related works. In section 3, Hadoop map reduce

* Nachimuthu Maheswari, Email: maheswari.n@vit.ac.in

work flow and its performance is discussed. In section 4, the enhanced hadoop system is discussed. In section 5, the implementation phase is discussed. In section 6, the results are evaluated and discussed. In section 7, the conclusion is provided. Finally, in section 8, the future works are discussed.

2. Related Work

The improvement in Hadoop Mapreduce performance has suggested from different concerns or aspects. Many works have suggested in the improvement of the performance of mapreduce jobs and the hadoop, such as scheduling the jobs and computation time improvement. Scheduling the job and the execution time are considered as the important features of Hadoop [5] [6]. Various studies have given the information and have received the results using their ideas [7] [8]. Few people focus on the time of starting and ending process of map reduce job processing [9]. Issues in the system memory could be addressed to improve the performance of the overall system [10]. Apart from Hadoop, few studies utilize a distributed caching method to enhance the performance of Hadoop [11] [12]. Shm Streaming [13] proposes a streaming type of schema to give First In First Out queue as lock less which joins Hadoop and other programs. Hadoop spreads the redundant data into various nodes in various racks. This will be helpful in false tolerant issues. Various studies consider the improvements in data locality development for the betterment of hadoop [14]. Few, discuss on the data types for the betterment in the performance of Hadoop [15].

3. Hadoop Overview

Hadoop is an open source framework for distributed storage and processing. It gives solutions for big data processing and analysis. Hadoop has a file system that stores the data relevant to the applications. The interface is known as the Hadoop Distributed File System (HDFS). Hadoop Distributed File System shares the resources for data analysis. The major parts of Hadoop are map reduce and Hadoop Distributed File System. Other hand, moving the computing towards the data is less costlier than movement of data towards computing [16]. Hadoop allocates file system to store huge amount of data files across the nodes in the clusters.

In HDFS, the Hadoop cluster has two components, which are the masters- Name Node and the slaves- Data Nodes. In Hadoop cluster, name node is responsible for maintaining the file system. It helps in maintaining the data and sending the jobs to the corresponding data nodes responsible for the application data [17]. Job tracker works in the master node. Job Tracker takes care of the data related to the applications in the data nodes with the help of the task tracker for processing. Each task is running in the respective allotted slot in a data node, which has a fixed amount of map/reduce slots.

3.1 Mapreduce

Map reduce processes the job that splits the input data of the job into independent parts and stores the data in HDFS. During map reduce execution phase, multiple map tasks are processed in parallel. After the completion of the map tasks multiple reduce tasks are processed in parallel [18]. With respect to the applications the total number of allotted map tasks be different than that of reduce tasks. Data that are stored in HDFS and processed in map/reduce framework is the form of key and value pair. It has stored and used in the map/reduce tasks to determine the required results at the end of the job. The final results will be displayed in the key and value combination.

3.2 Mapreduce Work flow

HDFS stored the data required for the map reduce job and the data is distributed in to the blocks. Each mapper processed one block in the same time. Inside the mapper phase, the user can give the logic as per theproblem requirements. So that the map tasks runs on all the nodes in the cluster and computes the data parallelly that are stored in the blocks.

The mapper output is stored in the local disk as it is only the intermediate output. If it is written on HDFS, that will create unnecessary multiple copies as the HDFS always replicates the data. The mapper output is sorted/shuffled and submitted to the reducer. The shuffling/sorting has taken care by the internal process. Reducer phase is the next phase of processing and the user can specify his/her own statements. Input to the reducer is given by all the mappers. The final output is produced by the reducer and written on HDFS.

4. Improved Hadoop System

The focus is on transferring the relational data into HDFS using sqoop. The exported data is analysed using Hive by using Hive Query Language [19]. The data is partitioned and is fed into MapReduce for further processing. The MapReduce jobs are optimized due to the changes done in the configuration of Job in progress, Task in progress and Task tracker files of hadoop.

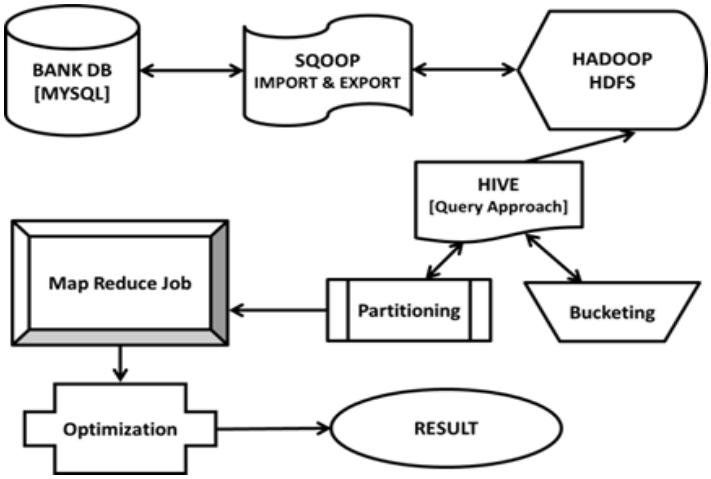

Figure.1 Diagrammatic representation of the proposed system

The bank MySql Database contains the required datasets. The data is exported to HDFS using Sqoop tool. Then Hive does the partition of the exported data, for which the results gets stored in HDFS. Then the Hive partitioned data is analysed and fetched from HDFS for MapReduce processing. The next step is Optimisation, which is like the heart of the work. Once the optimisation is over, the results are compared with that of the native hadoop to prove the working correctness of the work as

shown in Figure 1. The flow of the proposed system is explained below:

System Work flow

Step 1: Client requests for data sets. Bank data set is transferred from Mysql to HDFS using Sqoop.

Step 2: Hive extracts the data and partition the data set for map reduce programming.

Step 3: Changes performed in the Jobinprogress, Taskin progress, task tracker files.

Step 4: Name node initializes the job. Data fetched from the data node and performs the job.

Step 5: Performance of the results with respect to the computation time is compared with the native Hadoop.

4.1 Data Collection and Preprocessing

The Initial phase of the work is data collection. The article has a bank dataset that contains the account details, customer details and transaction details in MySql database.The transfer of the dataset into hadoop (HDFS), i.e, data migration is done using Sqoop tool. Sqoop supports for transferring data from relational databases to Hadoop.

Data from the three datasets (account,customer and transaction) are combined with its attributed and produced 21,215 records. The final combined dataset has the following attributes: account number, transaction type, amount, month and year.

In this phase, the dataset is fetched into hadoop (HDFS) using Sqoop Tool as in Figure 2. Using Sqoop, customized functionalities can be performed like fetching the particular column or fetching the dataset with specific condition and data can be stored in hadoop (HDFS).

Figure.2 Data preprocessing using sqoop

4.2 Data Analysis

In this phase, the dataset is analysed using HIVE tool which will be stored in hadoop (HDFS). For analyzing the dataset, HIVE uses HQL Language. Hive is chosen because it is a data warehouse by itself. Hive has the ability to work on top of an existing Hadoop cluster and provides SQL-like interface. The user can map the existing Sqoop tables to Hive and operate on them as shown in Figure3.

4.2.1 Partitioning

Hive arranges the tables into partitions. The records are partitioned based on the transaction type(with draw, transfer, deposit). Partitioning helps in dividing a table into related parts based on the values of partitioned columns as shown in Figure 4. Partitioning is useful in querying a portion of the data.

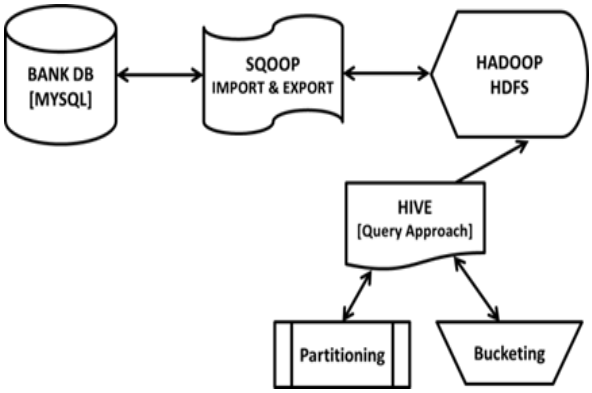

Figure.3 Data analysis using Hive

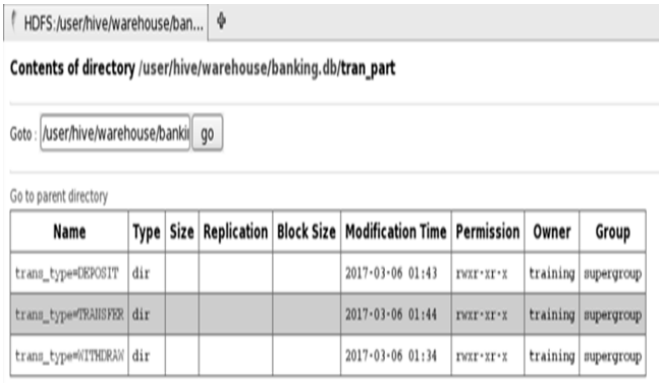

Figure.4 Partitioning the transaction data

The number of rows loaded and the time taken to load the partitioned data into HDFS is shown in Figure 5.

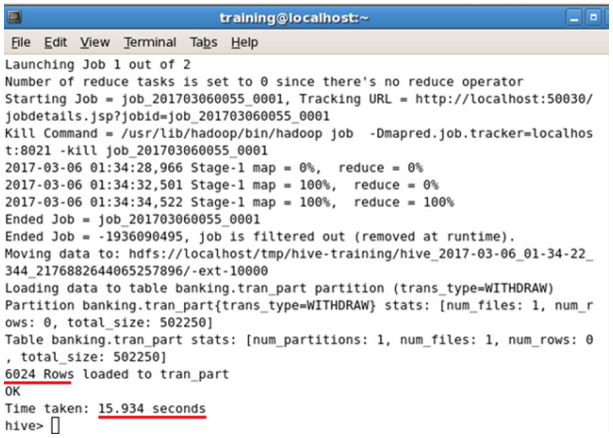

Figure.5 Loading partitioned data into HDFS

4.2.2 Bucketing

Bucketing decomposes data into manageable or equal parts as shown in Figure 6. The user can restrict the number of buckets to store the data. It provides faster query response. The number of required buckets can be given during the table creation. Loading of equal volume of data has to be done manually by programmers is a significant issue.

Choosing partitioned data over bucketed data

The size of the loaded partitioned data in the three partitions is less when compared to the size of the loaded bucketed data.

Bucketing works well when the field has high cardinality (number of possible values a field can have) and data is evenly distributed among buckets. Partitioning works best when the cardinality of the partitioning field is low.

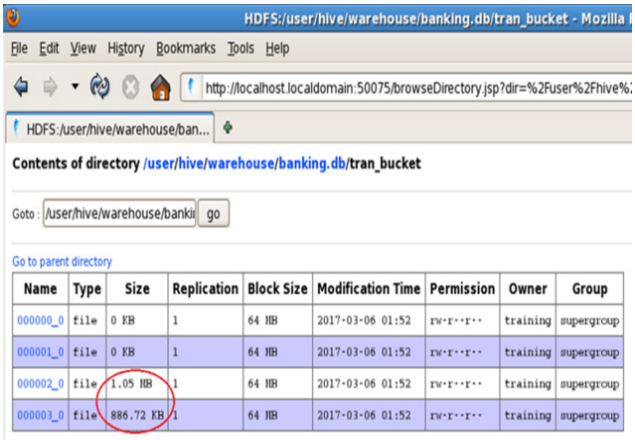

Figure.6 Bucketed data in HDFS

4.3 Data Processing

Data Processing is done using Hadoop Madpreduce. The partitioned data is fed into MapReduce for the processing. The main factor considered is the SLOTS_MILLIS_REDUCES[20]. It represents the total time taken for running the reduce tasks in milliseconds in the occupied slots. It also includes the tasks that where started speculatively as shown in Figure 7.

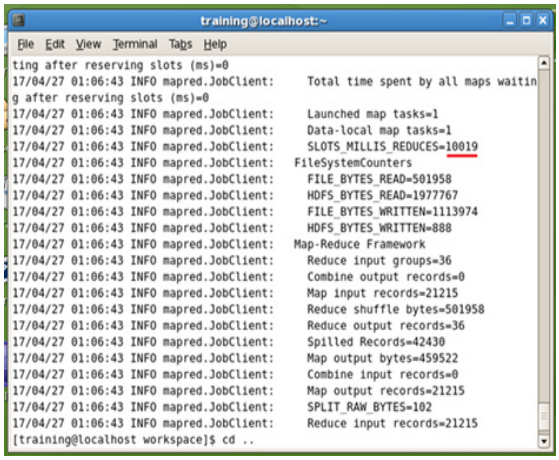

Figure.7 Running mapreduce job

4.4 Optimisation

Optimisation can be done to the native hadoop by changing the configuration factors of the system. There are three main files in hadoop[21], to which the changes are done to obtain an improved and an optimised version of hadoop. The files in hadoop to which the changes are made in order to obtain an improved version are

JobInProgress.java

JobInProgress maintains all the information in order to keep the job on the straight. It maintains its JobProfile and its updated JobStatus, along with a set of tables for doing bookkeeping of its tasks.

TaskInProgress.java

TaskInProgress (TIP) maintains all the information required for a task in the lifetime of its owning Job. A given task might be executed or re-executed, so level of indirection is needed above the running-id itself. A given TaskInProgress contains multiple taskids, zero or more of which might be executing at any one time, allowing speculative execution. A TIP allocates enough taskids to account for all the speculation and failures it will ever have to handle. TIP is dead when they are up.

TaskTracker.java

Task tracker is a process that initiates and monitors the map reduce tasks in the environment. It communicates the Job tracker for assigning the tasks and update the status.

4.4.1 JobInProgress

The changes made to the JobInProgress.java are as follows,

Contacting the tasktracker at once

In native hadoop, the task can contact the TT only after the whole task gets completed. So change is made so that, once the runJobSetupTask() works, the task can contact the TT then and there. It is beneficial as the TT is well informed of the on-going tasks and can also help to avoid speculations.

Launching Synchronised Cleanup

In native hadoop, Cleanup task is called once at the end of the task. The change made here is the introduction of Synchronised Cleanup task, which is launched before the cleanup task. It updates the last known cluster size then and there. It is highly beneficial in case of multiple tasks.

Later check of Cleanup

It checks whether the cleanup task is launched already or if the setup is not launched already. The later check is beneficial when the number of maps is zero.

4.4.2 TaskInProgress

The changes made to the TaskInProgress.java are as follows,

Skipping feature

Since completed reduces (for which the outputs go to hdfs) are not failed, this failure is noted only for completed maps, only if the particular tasked completes the particular map. However if the job is done, there is no need to manipulate completed maps. Reset the successful TaskId since no successful tasks can be concluded while running. There can be failures of tasks that are hosted on a machine that has not yet registered with restarted jobtracker. Therefore, the skipping feature recalculates the counts only if it is a genuine failure.

SetComplete function

When the TIP is complete, the other speculative subtasks will be closed when the owning tasktracker reports in and calls should close on the required object.

4.4.3 TaskTracker

The changes made to the TaskTracker.java are as follows,

Resetting heartbeat interval from the response

The name node and the data node communicate using Heartbeat messages. After a certain amount of time, if the Name Node does not receive any response from Data Node, then that particular Data Node is declared as dead. The normal heartbeat period is three seconds. If the name node is not receiving the heartbeat from a data node in ten minutes, then the name node decides the data node to be not in service and the data node's replicas are considered to be unavailable. The name node allocates the new replicas for the unavailable blocks in the other data nodes. The heartbeat message from the data node carries the information regarding the storage, amount of usage and transfer rate of data in the current state. Such details are helpful for the name nodes allocation of blocks and the decision making in load balancing.

By resetting heartbeat interval from the response, the TT knows the completed tasks. Once cleanup of the completed task is over, normal operation is resumed.

5. Implementation

5.1 Mapper Class

The map task is to process the input data. The input data is stored in the Hadoop Distributed File System (HDFS). The input file is passed to the map function and read line by line. The mapper processes the data and produces the intermediate data. The amount, transaction type, year and month are initialised according to the positions in the input data. The mapper class writes the year, month, transaction type and amount along with the sum into HDFS.

5.2 Reducer Class

This stage is the combination of the shuffle and the reduce stage. The Reducers job is to process the data that comes from the mapper. After processing, it produces a new collection of output, which will be stored in the HDFS.

5.3 Driver Class

The Driver class verifies the arguments from the command line. The input/output file details, job details are available in the command line. It assigns values for the job. The driver starts the execution from the main () method. In this method, a new configuration object and the Job are instantiated.

The job.waitForCompletion() helps to unveils the job perfectly. This driver code helps to wait for the job completion. The job status will be updated after the job completion. The true argument informs the framework to write verbose output to the controlling terminal of the job.

6. Results and Discussion

The work has done using bank data, which is analysed to identify the future trends in the sector. The improvement in the Hadoop performance is ensured by the factors such as computation time, time taken for running reduce tasks, contacting the task trackers at once, synchronised clean up, skipping feature, resetting the heartbeat interval.

6.1 Health of the file in HDFS after optimization

The fsck command in hadoop runs a HDFS file system checking utility. It is designed for reporting problems with various files. It checks health of hadoop file system. It produces a report that gives the complete health of the file system. HDFS is considered healthy if all the files have a minimum number of replicas as shown in Figure.8.

Table 1. Performance Analysis

Figure.8 Health status of the result

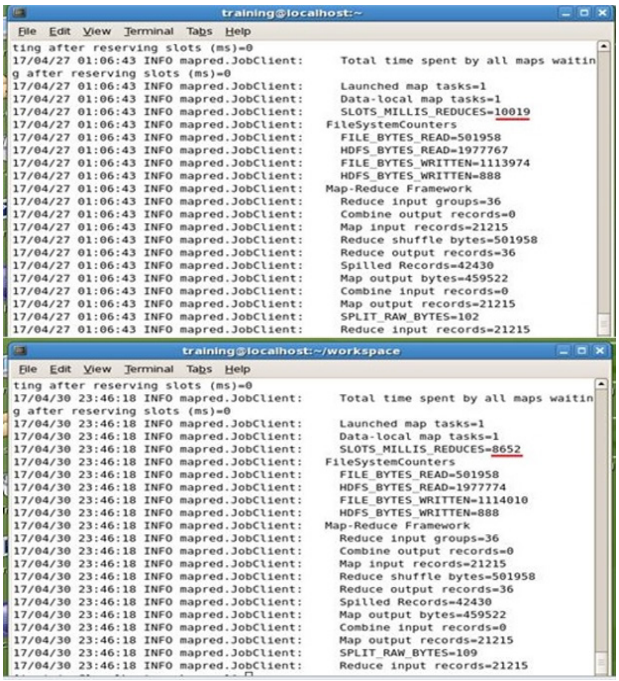

Figure.9 Performance - before and after optimization

SLOTS MILLIS REDUCES is the total time spent by all reduces in the occupied slots. Difference in the time taken for running reduces tasks before and after optimisation is noted to be 1367ms as shown in Figure 9. After optimization it takes less time.

6.2 Performance Analysis

The performance of the job for the same input is analysed before and after the optimisation is show in Table 1. Job duration, Map task time and Reduce task time are taken as the factors for the performance analysis. The time taken to complete the job is less after optimization is shown in Figure 10. The performance has evidently improved after the optimisation.

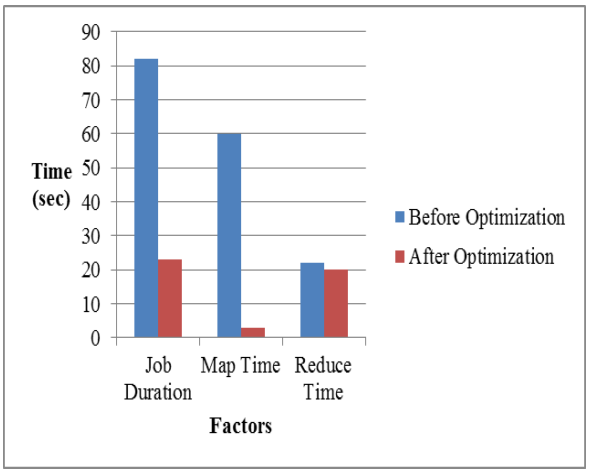

Figure.10 Performance Evaluation

7. Conclusion

In this article, an improved hadoop framework is presented. It includes analysing the internal working of the Hadoop MapReduce job, so that changes are done to the job in progress, task in progress and task tracker files. In H2Hadoop [19] the work was concentrated on the DNA dataset only and in the improved hadoop [22] they have considered the text data and the performance time was not reasonably improved. The changes performed to optimise the system in this article are in contact with the job tracker at once, launching synchronised cleanup function, cleanup later checkup, skipping feature, resetting the heartbeat interval from the response, avoiding speculative tasks resulted in an improved hadoop framework. The performance of the improved system using optimization is better in the computation time.

8. Future Work

Performance factors

The other performance factors of File System Counters, MapReduce Framework can be modified to obtain a more optimised hadoop system.

Tool for better performance

The result can be analysed using Spark to obtain a faster performance than Hadoop, as spark runs in-memory on the cluster, and it is not tied to Hadoop MapReduce paradigm. This makes repeated access to the same data much faster. Spark can run as a standalone or on top of Hadoop YARN, where it can read data directly from HDFS.

Security issues in Hadoop can be addressed at various levels, including but not limited to file system, networks, scheduling, load balancing, concurrency control, and databases.

ABSTRACT

The current industrial landscape is becoming increasingly aware of the need to optimize energy use and management for all domains, including telecommunications. Among others, RF Energy Harvesting is a promising technique for 5G systems as an alternative to traditional energy supply sources. This paper presents 5G landscape and ecosystem. It positions RF-Energy Harvesting in 5G context and reviews its techniques. It also considers constraints and research trends for different aspects needed to make RF energy harvesting ready for deployment along with 5G enabling technologies.

1 Introduction

This paper is an extension of the overview originally presented in 2017 about *RF Energy Harvesting For 5G* at the International Renewable and Sustainable Energy Conference (IRSEC) [1]. In fact, due to the rapid evolution of new technologies, the world faces new challenges concerning Energy Efficiency (EE). The transformation in users habits, driven by the installation of new services and the creation of new needs, especially in telecommunication, resulted in a significant rising in volume demand and requirements diversity. These transformations are leading the development of the fifth Generation (5G) of mobile systems, expected by 2020 [2], and research is being conducted to issue this new generation. In addition to the growing number of subscribers, new applications as for smart cities, smart grids, Internet of Things (IoT) and Machine-2-Machine (M2M) communications imply an increasing number of sensors, and thus the need of reviewing the system design. The sophisticated power hungry future handsets, the very large number of simpler sensors, and the dense network architecture necessary to respond to the growing needs are all factors to make energy management an urgent issue for future systems. EE appears thus as a major development key of 5G systems, as pointed in many 5G visions by telecommunication industry actors [3, 4, 5]. In order to enhance the energy consumption and management, techniques like Radio-Frequency Energy Harvesting (RF-EH), virtualized network functionalities, cloud technologies, etc. are proposed.

Energy aspects in 5G systems have attracted a lot of attention in the last years, and many studies, reviews and tutorials have considered these aspects. For example, in [6], authors provide a survey on energy-efficient wireless communications, with a discussion on the most relevant challenges at that time. General energy efficient technologies are discussed iwith no specific interest in EH solutions. Authors in [7] give an overview of EH techniques, in particular on EH power management policies optimizations, with specific stress on Wireless Sensor Networks (WSNs) and on ambient RF harvesting. In their survey [8], authors discuss 5G green network EE and promising technologies and architecture for its optimizations. Among these techniques, EH is discussed as well as other key enabling techniques, but specific EH integration is not detailed. The authors in [9] also consider EH from a circuit design point of view, particularly for embedded systems, and authors in [10] research RF-EH for IoT from an implementation perspective, including the design of antennas, rectifiers, and matching networks.

This paper aims to give a general review of EH in 5G systems, which includes both ambient and dedicated EH. In addition, considering the imminent commercial launching of 5G, and the ongoing standardization of 5G New Radio (5GNR) [11], an updated overview of RF-EH techniques is needed taking into account the standardization landscape. To this end, 5G requirements and use cases, as well as 5G ecosystem and some of the key 5G enabling technologies, are

presented in the first section. In addition, a special subsection is dedicated to IoT, as one of the most RF-EH appealing 5G enabled use cases. The second section discusses EE in 5G networks from both network and terminal sides, while RF-EH implementation challenges and candidate solutions are reviewed in the the third section. The fourth section presents RF-EH in 5G ecosystem, giving a literature review of combinations between RF-EH and some of the most important 5G key enabling technologies. A conclusion of the paper is then given.

2 5G general technological landscape

2.1 5G Requirements

Compared to current mobile generation, 5G mobile data rate volume per area is expected to be multiplied by 1000, and user data rate as well as the number of connected devices are expected to be multiplied by 10 to 100. Battery life should also be 10 times longer, and latency 5 times shorter. 5G requirements are summarized in Figure 1, and the International Telecommunication Union (ITU), which has established an R&D programme worldwide on International Mobile Telecommunications for 2020 and beyond values(IMT-2020), has established a 5G framework as illustrated in Table 1 [12].

Table 1: 5G requirements

Requirements	Desired Value
Data Rate	1 to 10 Gbps
Data Volume	9 GB/h (busy period) and 500GB/month/user
Latency	Less than 5 ms
Battery Life	One decade
Connected devices	300000 devices/AP
Reliability	99.999%

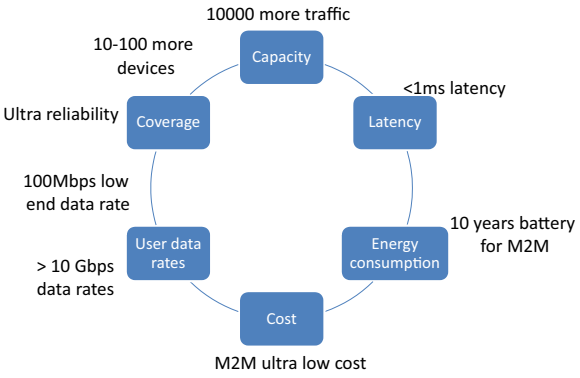

Figure 1: 5G key requirements summary (Source [13])

5G systems are meant to manage at the same time very low cost devices, such as sensors, and advanced ones, such as smartphones and tablets. For example, simple devices may choose not to use large bands. Thus, in the same system, and in some frequency bands, smart devices will use a band of 100 MHz while sensors only 10 MHz. Note that 5G will have to manage much denser networks than today, around 1 million connections/km^2, and the more predominant design parameter will thus be the cost/area.

2.2 5G use cases

Traditional as well as new use cases are addressed in 5G, and this implies new challenges. The corresponding requirements are specified by several organizations and research actions.

Each use case has its own requirements, such as throughput, delay, reliability, etc. and consequently uses different techniques. Hence, a wide range of devices, such as smartphone, wearable, MTC, etc., are being all expected to use 5G systems in a diverse heterogeneous environment. A categorization example of use cases has been developed by the Next Generation Mobile Networks (NGMN) Alliance through representative examples, which leads to 8 families of use cases [14], illustrated in Figure 2.

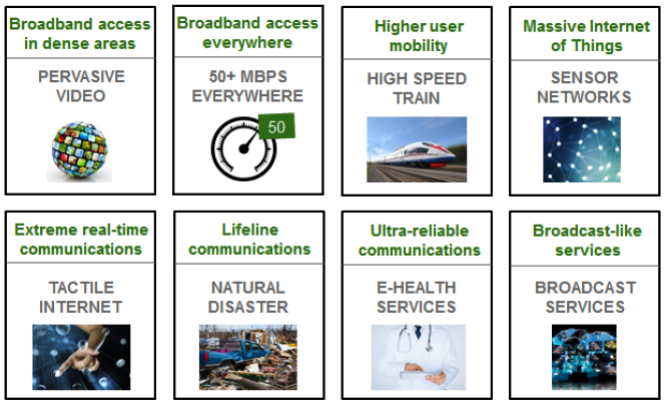

Figure 2: Families of use cases identified by NGMN (Source[14])

For example, smart cities applications including metering, city or building lights management, environment monitoring, and vehicle traffic control can be deployed as WSNs. These services, when aggregated, form a high density devices environment with heterogeneous technologies that need to be managed in a common communication and interworking framework, where very low cost devices with very long battery life may exist. 5G may provide platform for such deployments. Another example of 5G use cases is the mobile Video Surveillance, which is expected to be deployed almost everywhere. This means an automated analysis of the video footage with constraints, though relatively reduced for battery life, but high for reliability and security of the network as well as performance and interactivity with remote systems.

Note that the 3rd Generation Partnership Project (3GPP) issued and approved four Technical Reports on 2016, which outlined new Services and Markets Technology Enablers (SMARTER) [15], and contained more than 70 different use cases categorized into different groups :

- Massive Internet of Things, particularly relevant to the new vertical services, such as smart home and city, smart utilities, e-Health, and smart wearables.
- Critical Communications, for which there is more need for latency, reliability, and availability. Use case

examples are industrial control applications and tactile Internet.

- Enhanced Mobile Broadband, including use case families related to higher data rates, higher density, deployment and coverage, higher user mobility, devices with highly variable user data rates, fixed mobile convergence, and small-cell deployment.

- Network Operation, addressing functional system requirements, including for example flexible functions and capabilities, new value creation, migration and interworking, optimizations and enhancements, and security.

Example of projects exploring EE and EH in 5G systems is Sustainable Cellular Networks Harvesting Ambient Energy (SCAVENGE) [16], which is a project funded from the European Union's Horizon 2020. It defines among others an architecture framework for EH networks for Core Network (CN) and Radio Access Network (RAN).

2.3 5G ecosystem

5G systems cover a large span of use cases, with different data rates, latencies, reliabilities, densities, required powers, etc. This implies many tradeoffs, and a highly scalable architecture. As described in [17], the new 5G ecosystem is complex and involves many participants, including manufacturers for components, chipsets, network equipments and wireless devices, in addition to mobile networks operators, application developers and even users themselves, all overlaid by different standardization entities. As stated in [18], the first mover of 5G is the wireless part as it establishes foundations for the feasibility of final products and services. Many connectivity options are considered in 3GPP, which allows several deployment alternatives. However, as highlighted in [18] the focus for initial deployments is on non-standalone NR and standalone NR, as the deployment of several options may make the whole 5G ecosystem too complex. The simplification of 5G through reduction of deployment options is also adopted by other industry actors, such as Ericsson [19].

2.4 Examples of 5G key enabling technologies

5G systems require an important change in the cellular architecture as well as key wireless technologies. The requirement for massive network capacity along with the increased user experience suggest research in numerous dimensions. In particular, the RAN appears as one of the biggest challenges. For example, the increase in bandwidth demand implies the optimization of current systems spectrum use, unlicensed spectrum use and the allocation of new bands, starting with the move to millimeter wave (mmWave) bands. The optimization of spectrum use also means that, among others, new waveforms and advanced Multiple Input Multiple-Output (MIMO) will be used. Extreme densification and offloading are also key elements to enhance capacity, which implies an urgent need for virtualization and softwarization of the network. As presented in [4], the Figure 3 illustrates these needs in three distinct dimensions.

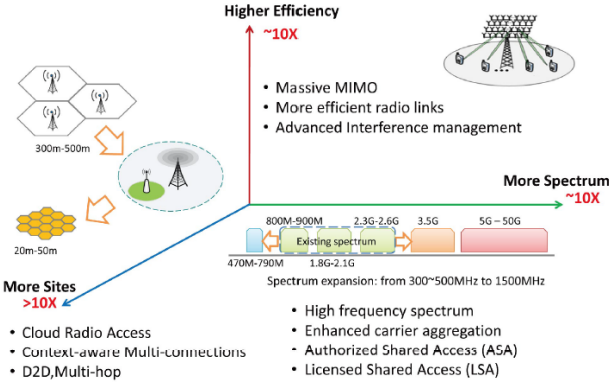

Figure 3: 5G technological research in three different dimensions (Source: [4])

Examples of key 5G enabling technologies are given in the remainder of this subsection.

2.4.1 Spectrum allocation

5G is a convergence of previous and new systems, and its spectrum is expected to be a combination of allocated and new bands. Some of the spectrum below 6GHz is thus being re-purposed for use with newer technologies; it is the primary 5G band, as decided in WRC 2015. Complementary 5G bands above 6GHz, are expected to be allocated in the 2019 World Radiocommunication Conference (WRC 2019) [20] (October). Illustration of these bands is given in Figure 4. On the The 3rd Generation Partnership Project (3GPP) Release-15, the New Radio-Unlicensed spectrum (NR-U) work item supports both the existing 5GHz unlicensed band and the new "greenfield" 6GHz unlicensed band. Other unlicensed and shared spectrum bands, including mmWave, can be expected in coming releases [11], even though it is not as mature as current frequency bands. In fact, mmWave has rather hostile propagation characteristics, as well as a current comparatively high equipment cost, which has limited its use so far. However, 5G mmWave mobile technology have been already demonstrated, as first by Samsung in May 2013 [21], and later by others, as for Huawei [22]. A more accomplished 5G pilot system was demonstrated in 2018 Winter Olympics [23].

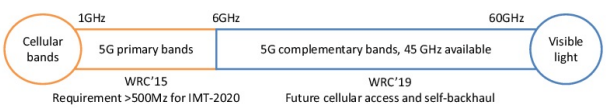

Figure 4: WRC-15 and WRC-19 5G spectrum allocation

Integration of many bands for the same transmission can be made through Cognitive Radio (CR), motivated by the underutilization of many frequency bands. In fact, CR allows dynamic allocation of underutilized resources, after their sensing, in an opportunistic way without altering the other users, and thus to expand the spectrum of a cellular networks on demand and at a relatively low cost [24, 25].

2.4.2 Carrier Aggregation (CA)

As 5G is a convergence of many systems, the 5G radio access uses simultaneously many technologies, with possibly different frequency bands. This may enable a more effective use of the crowded and fragmented spectrum, a simultaneous use of different Radio Access Technologies (RATs) and more flexibility of resource allocation. However, this implies also the need to aggregate different carriers. CA is already used in Long Term Evolution (LTE) since 3GPP Release 10 for inter and intra LTE-LTE contiguous carriers aggregation. Release 11 presented Intra-band non-contiguous CA, and Release 12 presented CA for Frequency Division Duplex (FDD) and Time Division Duplex (TDD). Release 13 presented CA for 5 GHz WiFi bands, called Licensed Assisted Access, and Release 14, which starts 5G standardization, defines more cases following the 5G adopted bands [26]. Some issues should be considered for Internet Protocol (IP) configuration, interference coordination and time synchronization. Moreover, resource scheduling over the aggregated bands should be optimized and may use advanced tools, such as game theory [27].

2.4.3 Massive MIMO

Many techniques used to enhance spectrum efficiency are surviving in 5G, while other new techniques are proposed. MIMO antennas techniques is already used for LTE and LTE-Advanced (LTE-A), and 5G proposes massive MIMO as one of its most important enabling techniques. In fact, thanks to multiple antennas at the Base Station (BS), the energy in downlink can be focused to form beams towards the User Equipment (UE). In 5G, a large number of antennas, i.e. massive MIMO, can enable the serving of many users in an accurate way. Moreover, when combined with other 5G techniques, like small cells and mmWave, it provides significant capacity, as required for 5G systems [28]. Note that massive MIMO can also be used for backhauling [29].

2.4.4 Channel modeling

In 5G systems, the expected bands to be used, especially above 6GHz, are not addressed by current models, and accurate models are needed to enable many of the physical layer techniques. Thus, research is already conducted for mmWave characterization in several environments [30]. As indicated in [31], the new channel model extends the existing 3GPP 3D channel model, and handles frequencies up to 100 GHz in several mobility scenarios. In this optic, 3GPP RAN Meeting for example was held in Busan Korea in June 2016 and approved the first standard for the mobile broadband 5G high-frequency ($6 - 100$ GHz) channel model.

2.4.5 Signal waveforms

Multicarrier modulation, particularly Orthogonal Frequency Division Multiplexing (OFDM), is adopted in LTE and enables good spectrum efficiency. However, it still presents some drawbacks, as it inserts a Cyclic Prefix (CP) that reduces the efficiency, in addition to its large sidelobes, and thus considerable Out-Of-Band (OOB) emission, resulting from the rectangular pulse shaping,as well as its high Peak to Average Power Ratio (PAPR). Most popular candidates waveform for 5G, in addition to OFDM, include :

- Filtered OFDM, which removes OOB emissions by filtering the signal [32].
- Filter Bank based MultiCarrier-Offest Quadrature Amplitude Modulation (FBMC-OQAM), which is a modified OFDM requiring no CP and thus enhancing spectrum efficiency [33]. Sub-carriers are filtered at both transmitter and receiver sides, and this reduces OOB and makes the signal more robust against Doppler effect, Inter-Symbol Interference (ISI), synchronization imperfections, spectrum fragmentation, etc. This also results in self-equalization, which can reduce the number of unused subcarriers, and blind channel tracking, reducing pilot contamination and thus enhancing massive MIMO functioning.
- Universal Filtered Multi Carrier (UFMC), which filters subbands rather than subcarriers [34]. This gives more flexibility to the design. The use of a prefix in this case depends on filters design.
- Generalized Frequency Division Multiplexing (GFDM), which also provides a flexible structure via adjustable pulse shaping and subcarrier filtering. In addition, data symbols are grouped both in time and frequency domains. However, filtering flexibility implies self-created interference, which is dealt with using iterative interference cancellation at the receiver [35].

2.4.6 Multiple access

The multiple access technique used in 4G is OFDMA, which may survive for 5G. However, massive MIMO in a dense network context, multi-user MIMO (MU-MIMO) can be enabled using Spatial Division Multiple Access (SDMA). For higher capacity, Non-Orthogonal Multiple Access (NOMA) schemes are also proposed for 5G, as it allows more than one user to share the same subband without coding or spreading redundancy [36, 37, 38]. For this scheme, users are superposed in time and frequency, and have different powers following their channel conditions. Differentiation of the users is then performed using Successive Interference Cancellation (SIC), which uses joint processing combined with subcarrier and power allocation algorithm [39, 40]. An illustration of NOMA mechanism is given in Figure. 5. So far, 3GPP NR has specified flexible technology framework that can be tuned to enable a wide range of 5G scenarios, and more specifications are expected for Release 16 [41].

2.4.7 Ultra Dense Network (UDN)

5G brings a substantial network architecture redesign, particularly through densification, in order to support the expected heavy traffic. Networks densification has been used since the second generation (2G) for capacity scaling, but the ultra densification for future networks can provide an extreme and user-centric reuse of system bandwidth on the spatial domain, and improve propagation conditions by reducing the distance between the end user and the BS. It implies

an increased spatial reuse of system resources, a large node density and irregular deployments. Challenging issues about UDN include among others interference management, heterogeneous multi-RAT optimization, the possibly high cost of a dense infrastructure, the cell-edge effect, and the backhauling.

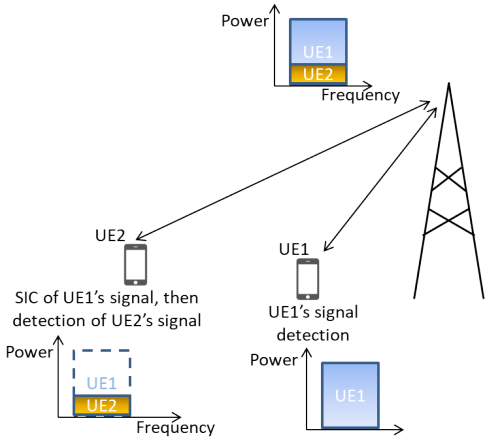

Figure 5: Downlink NOMA in a simple scenario with one BS and two UEs

2.4.8 Cloud-Based Radio Access Network (C-RAN)

As network densification is a key 5G networks enabler, it is expected that BSs will have to handle a heavy radio processing. A suggested solution in this case is the Cloud-based RAN (C-RAN). In fact C-RAN dissociates the Base-Band processing Unit (BBU) from the Remote Radio Heads (RRHs); For resource optimization, the BBU part is moved to a pool, or to the cloud, which is a virtualized cluster connected to the core network through the backhaul, and the transmission of the radio signal is performed by RRHs based on computed signals from the cloud. On the otehr hand, RRH is connected with the cloud BBU pool via a fronthaul.

RRHs are cheaper and simpler if cloud based computations are used. This allows thus more scalability and densification opportunities. It can also reduce the delay for inter-cell coordination and permits more joint optimization of processing, e.g. for cooperative interference management, scheduling, Coordinated Multi-Point, etc. [42].

C-RANs can also be self-organizing; intelligent smart cells are deployed in the area covered by a macro BS, and can enable advanced clustering and coordination schemes to enhance mobility and handovers. In addition, C-RAN in Heterogenous context lead to H-CRAN, where different types of nodes, including low power and high power nodes, use the same computing pools. The H-CRAN is illustrated in Fig. 6.

2.4.9 Network architecture

5G cellular networks are expected to be multi-RAT and multi-layer. Considering emerging 5G use cases, current network architecture is relatively incompetent to address 5G requirements. Thus, one of the central objectives in 5G architecture is network flexibility. Logical core and RAN have to be split to allow their evolution and to ease their deployment. To this end, the European Telecommunications Standards Institute (ETSI) adopted the separation of User Plane (UP) functions and Control Plane (CP) functions, and modularization of the function design, e.g. to enable flexible and efficient network slicing [44]. Similarly, a 5G architecture made of three layers and a management entity is presented by NGMN [45]. It is based on a central cloud and typically comprises multiple data centres which may be very distant, and connected to each other or to the central cloud or edge clouds. Figure 7 illustrates this topology as viewed by the project 5G NOvel Radio Multiservice Adaptative network architecture (5G NORMA), which is one of the 5G Public Private Partnership (5G PPP) projects under the Horizon 2020 framework [45].

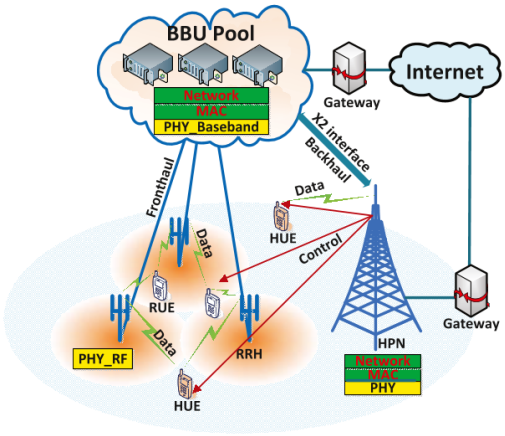

Figure 6: H-CRAN : Heterogeneous Cloud Radio Access Networks (Source [43])

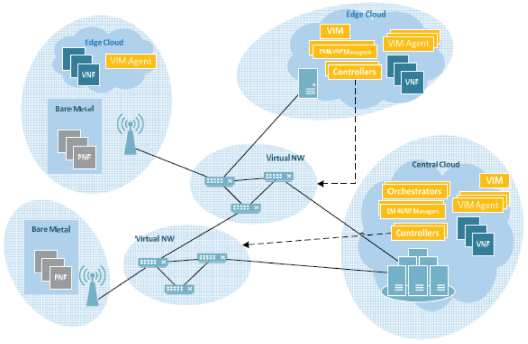

Figure 7: 5G NORMA topology view on architecture

As suggested in [46], in order to avoid redundancy, low layer functionalities are insured by radio logical network while a network cloud provides all higher layer functionalities. In addition, functions can be dynamically deployed in the network cloud through Software Defined Networks/Network Functions Virtualization (SDN/NFV).

In addition to layers, 5G uses network slicing to deliver services with different performance characteristics. It is a network technique, initially for the core network but extended to an End-to-End (E2E) concept including also RAN part. For example, massive IoT service, connecting fixed sensors that measure humidity, temperature, etc. to mobile networks, does not require advanced mobility features, critical in serving mobile phones. In contrary, a mission-critical IoT service, like autonomous driving or remote controlled

robots, requires a very low E2E latency. To avoid building a dedicated network for each service, multiple logical networks over a single physical network can be insured through network slicing. The physical network is sliced up into different virtual E2E slices, with specific network functions and RAT parameters, following the requirements of the use case or business model. Note that network slicing also limits error propagation between slices.

2.4.10 NFV/SDN

An important trend for 5G networks is virtualization, as it enables resource sharing. In addition, hardware and software have to be dissociated, and network functions to be moved towards software. Assuming separation between control and data, NFV is an important 5G architecture driver. It provides network adaptability and scalability [44], boosted by automated mechanisms; simple and fast operations will be needed to deploy new network features, and resources can be easily shared through the abstraction of physical resources to a number of virtual resources. An illustration of wireless network virtualization is given Figure 8.

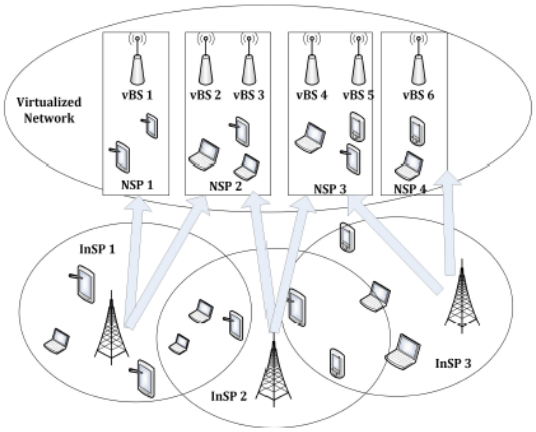

Figure 8: An example of wireless network virtualization (Source [47])

NFV uses a virtualized commercial server to set up network function software in virtual machines. RAN works thus as edge cloud while core works as core cloud. Connectivity among virtual machines located in edge and core clouds is insured by SDN. This makes thus the network architecture ultra-flexible; NFV processes network functions in the cloud, and SDN creates and exposes private virtual networks, linking thus the cloud back to the network. SDN enables the orchestration of the NFV physical and virtual infrastructure resources, through supporting provisioning and configuration of network connectivity and bandwidth.

2.4.11 Mobile Edge Computing

The diversity of 5G applications and the density of the network may lead to congestion, which may be solved by Mobile Edge Computing (MEC), mainly standardized by ETSI, 3GPP and ITU-T. MEC provides Information Technologies (IT) and cloud computing functions in the RAN, in close proximity to mobile subscribers. This enhances responsiveness to content, services and application requests, and enables thus ultra-low latency, high bandwidth radio network information.

MEC introduces new processing capabilities in the BS for new applications, with a new functions separation and a new interface between BBU and Remote Radio Unit (RRU). This is linked to C-RAN as C-RAN implements baseband processing capabilities in distributed locations. A demonstration for a 5G MEC proof-of-concept was conducted by Ericsson and Vodafone [48].

Note that MEC is currently deployed in LTE networks as an add-on to offer services in the edge. However, 5G system specifications provide new functionalities for edge computing [44].

2.4.12 Device to Device communications (D2D)

High-density expected for 5G networks can also be solved by D2D communication. In fact, unlike voice-centric systems, where no spatial proximity is assumed between communication parties, some data communication cases may imply collocated devices which try to wirelessly share content. In this case, it can be more efficient to use proximity-based D2D communication, which may also enhance capacity and coverage when devices act as transmission relays. Note that D2D is already used in 4G, and presents some challenges for 5G. Figure 9 presents typical downlink D2D scenario.

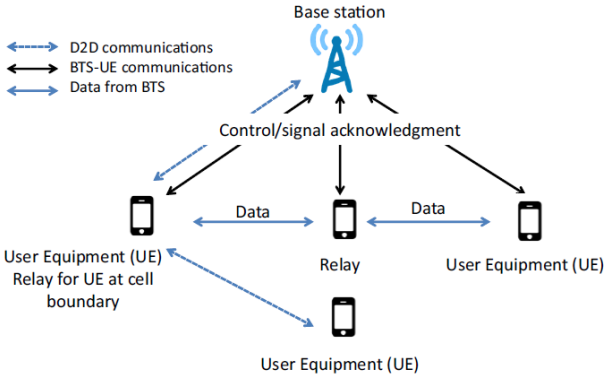

Figure 9: D2D typical scenario (Source [49])

2.5 IoT applications landscape

2.5.1 IoT characteristics

In IoT applications, a large variety of devices is implied, from small devices to big data centres. The devices can be self-empowered, battery-empowered or connected to the grid. For IoT specific applications, most devices, in number, are battery-empowered or self empowered, i.e. using EH.

IoT is distinct from WSN as it has specific characteristics. In particular, IoT energy sources have the following characteristics [50]:

- Scalability, as IoT often imply large deployments in possibly variable locations with different accessibilities. In this case, batteries are not ideal.
- Maintenance-free, as the deployments often imply a large number of devices. Wired empowering would be thus impossible and battery-based one would be costly.

- Mobility support, as for many applications, the devices are mobile.
- Long life-time, as in some applications, and because of difficult maintenance, devices are supposed to work autonomously up to several decades.
- Flexibility, as capacity and size of energy sources may vary following the IoT application.
- Low-cost, as IoT are usually deployed in a large scale, which means that a small difference in the unit cost may limit affordability of the application.
- Sustainability, as large scale deployments may imply significant power consumption, requiring thus sustainable power solutions.
- Environment-friendly, as IoT popularity may imply serious environmental impact, especialy if disposable batteries are used for devices powering.

Currently, solutions meeting these characteristics with very low power consumption are standardized, but having energy autonomy is even more attractive. EH-enabled nodes techniques, as well as batteries storing harvested energy and optimized low power circuits, have to be thus combined with power saving mechanisms and network resource management. Note that for traditional wireless networks, many factors are important in the design. For example, the acceptable latency of the transmission can lay from some milliseconds to some days. Transmission rate is also generally low, mostly some kilobytes per second. Similarly, the distance between nodes is critical, as it contributes in the definition of the transmission power. Depending on the application, the distance can range from centimeters to kilometers, and it can vary over time when mobility of the nodes is considered.

2.5.2 IoT standards and solutions

RF-EH globally provides little energy compared to other energy sources. Thus, it is more suitable for low power IoT applications. These are hence one of the most interesting motivations for RF-EH technologies development. It is also one of the vectors in international standardization bodies. Even though solutions exist since many years for low-power applications, including Wi-Fi, Bluetooth, and ZigBee, these are unsuitable for long-range cellular and M2M, which are essential for IoT. Low-Power Wireless Area Networks (LPWANs) aim to respond to such requirements. In fact, in order to achieve a low-power long-range communication, high receiver sensitivity is needed, as fine as to −130 dBm against −90 to −110 dBm in traditional technologies. This means that a higher energy per bit is needed, and thus that the modulation rate should be slower.

One of the major issues for M2M communications is the low-power long-range communication. LPWAN technologies, in order to achieve a long range capability, need to use high receiver sensitivities, up to −130 dBm compared with the −90 to −110 dBm in many traditional wireless technologies. This implies a higher energy per bit and thus a slower modulation rate. The two most popular solution for LPWAN are Sigfox and LoRaWAN. The first one is a global IoT network, aiming a low deployment cost of long-range, small-message device communication. It is a narrowband technology using extremely slow Binary Phase Shift Keying (BPSK) modulation. The second one is an LPWAN specification for long-range low-datarate wireless battery operated devices communication, promoted by LoRa Alliance, which coverage is comparable to a cellular network.

3GPP addressed categories and new standards for IoT requirements [51]. New users categories (cat1-6) are introduced starting from LTE Release 8. Release 10 defines 6-8 categories, and Release 12 defines LTE Cat-0. This category suits IoT applications and general M2M applications needs with low data rates in short bursts. This results in a reduced complexity and power. NarrowBand-IoT (NB-IoT) and LTE-M (or eMTC for enhanced Machine-Type Communications), are two complementary technoogies for IoT applications. NB-IoT is a direct candidate of Sigfox and LoRa, as it is less energy consuming and can address a large amount of connected devices. It can be deployed as a standalone solution or inside an LTE carrier, and will have more in-band deployment flexibility in 5G NR. LTE-M addresses another connected devices category which is more constrained in latency, mobility and density. Application examples are e-health, security, object tracking, etc. LTE-M however is more energy consuming. An illustration of LTE IoT evolution is given in Figure 10.

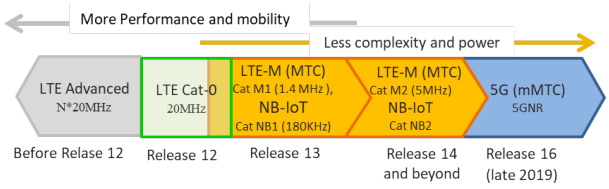

Figure 10: 3GPP IoT solutions standards

Note that many 5G technologies are specified to support IoT deployment, such as include D2D, SDN, NFV and MEC. For example, C-RAN reduces the cost of ultra-dense networks, expected especially with IoT deployments, through the simplification of BSs. This enables flexible and adaptable deployment.

3 5G Energy considerations

Today, energy is a major issue in all industries, including telecommunications. For example, the Mobile and wireless communications Enablers for Twenty-twenty Information Society (METIS) project considers EE as an important 5G topic [52]. The objectives of the project lead to technical goals with in particular a much denser network, containing low-power devices requiring higher battery life, up to 10 times longer than current batteries.

3.1 Energy efficiency on network side

5G will densify the network in order to increase the coverage and the capacity of the system. However, as power consumption is expected to increase at the same time, a challenging issue for 5G is the EE. For example, considering

data centres in the network, the author in [53] examines the variety of clusters and clouds that implies the need for power-saving control mechanisms. He presents network and cluster resources control algorithms, as well as an integrated and hierarchical control of the resources. Similarly, as treated by the project EARTH [54], improving EE at BS level need a variety of technologies. For example, it is proposed in [55] to use Cellular Partition Zooming (CPZ) to reduce energy consumption; following the present users in the area, the BS zooms in for coverage or out for sleep mode, which is energy saving.

Optimizations, categorized on green energy researches, aim BS energy use reduction [56]. In fact, the power consumption in the Operation Expenditure (OPEX) in today's mobile systems is dominated by networks, up to 90%, and only 10% is for mobile user. The network electricity supply is thus a critical issue in mobile industry, especially for regions with difficult grid power connection. Alternative energy sources, light, wind, vibrations, etc. are considered. However, alternative energies, especially renewable ones, present some challenges regarding availability and volumes. In particular, combining renewable energy sources at BS is critical. For example, the japanese operator NTT DoCoMo launched in July 2004 the *DoCoMo Eco Tower* [57], which is an experimental an self-powered 3G BS. Thid BS uses solar and wind power at once. Similarly, Alcatel proposed *Eco-sustainable Wireless Networks* to replace current generators [58]; Alcatel has an Alternative Energy Program combining alternative energy sources and energy-efficient equipments and networks.

Note that RF-EH appears as a candidate technology to further optimize energy management in 5G. In particular, EH from RF signals is actively studied and mathematical models are made in order to make it possible in the near future, as proposed in [59]. In the same scope, researches are interested in several scenarios, as cooperative multicast communication in [60]; EH relays harvest energy from the BS transmissions following two power splitting strategies at the relays for EH, and analytical expressions of outage probability are given for these strategies.

3.2 Energy efficiency on terminals side

Battery life is a major constraint for equipments' design. In fact, it can be lengthened through enhancement of its capacity, use and recharge process. The overall EE of the network would be consequently improved. 5GPPP establishes requirements for future 5G systems considering ultra-efficient 5G hardware, especially in terms of energy consumption, flexibility and compatibility with heterogeneous environments [61]. The interface between network and terminal can use massive MIMO technique to enhance EE, in addition to new waveforms and to network radio resources optimization. The air interface, procedures, and signaling can also be enhanced in terms of energy consumption through sleep modes, simplified procedures access schemes, and more efficient modulation, spreading and coding that allow low transmission powers. Energy consumption can be reduced using EH from environmental energy sources, such as light, heat and vibration [62]. However, as they vary along location, time, weather conditions, etc., it can be difficult to guarantee a given Quality of Service (QoS) that is required in some wireless applications. A possible solution for this problem is ambient radio signals harvesting, i.e. RF-powered energy-harvesting network (RF-EHN) [63, 64].

Note that circuit design has also to be coherent with EE optimization. Many technologies are discussed to prepare 5G-ready handsets, as in [65]. The research areas for that purpose include RF design, mobile cooperation, context awareness and seamless roaming among multiple technologies. New techniques for power amplification, antenna and filter design, and RF architecture are being studied for future handsets design. For example, M2M and D2D communications may use wireless power transfer technologies and optimization of sleep mode switching in order to have a battery-less sensor operation.

4 RF Energy harvesting implementation

4.1 Energy harvesting sources

EH has been already widely deployed using several energy sources. It consists on absorbing ambient energy in order to utilize it instantly or later. The most popular harvested energy sources are solar energy, wind energy, tidal waves energy, mechanical energy, electromagnetic energy, thermal energy, etc. EH sources and their corresponding sensors are illustrated in Figure. 11 [10].

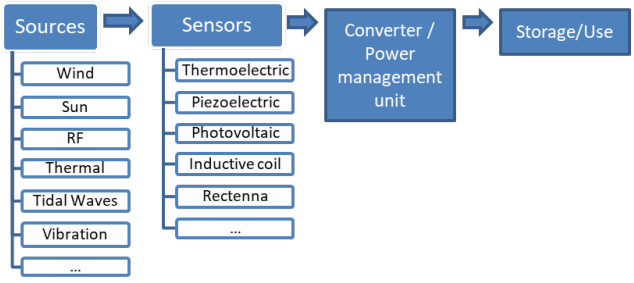

Figure 11: Energy harvesting sources and sensors

- RF sources have a power density ranging from 0.1 μW/cm^2 for ambient RF to 1000 μW/cm^2 for dedicated RF [10]. Electricity in that case is produced through magnetic inductive coupling: a loop with time varying current induces a receive loop with an open circuit voltage, and the resulting voltage can thus be directly used or stored in a battery for later use.
- Harvesting energy from heat is based on thermal energy generator, which uses the difference of temperatures to generate electricity. However, it has a low efficiency(5-10%) [50] and needs a temperature difference of 30°C. The power density in this case is about 135 mW/cm^2 at 10°C [66].
- Sun and light EH, i.e. solar and photovoltaic energy, is very popular nowadays due to its power density, efficiency, and flexibility. The light is collected by a semiconductor material, usually silicon, that produces DC power by the movement of electrons in the

semiconductor. The electricity is then stored in batteries or supercapacitors. The power density is about 100 mW/cm^3, but it requires direct exposure to light, which limits its use indoor [66].

- Mechanical energy is by the other hand harvested from vibration, pressure, etc. Among others, piezoelectric material, when exposed to a mechanical force, makes a polarization of ions in the crystal. This has a high energy density, which is about 50 μJ/N [66]. An example of piezoelectric EH for IoT applications can be found in [50].

4.2 Energy Harvesting constraints

EH presents an interesting solution to current energy consumption issues. However, it also presents some design constraints, as ambient RF waves figure among the most challenging energy sources. It suffers more particularly from :

- Causality, so that when harvested in the present, the energy is only available in the future, .
- Difficulty of concurrent EH and information transmission, at least for current designs.
- Efficiency loss when converting RF harvested signal to Direct Current (DC).
- Finite nature of energy storage.

For some applications, difficult environment access, connection cost and mobility makes it difficult to charge sensors or, at least, with a certain periodicity. In addition, if EH is used, for some EH sources, harvested energy depends on time and/or location and may not be enough for terminal's needs. Examples of time dependance are stillness time for vibration energy and night time for solar energy. Electromagnetic Radiation appears thus as an interesting stable and predictable energy source.

A cellular system can integrate EH using a standalone technique, hybrid technique or Simultaneous Wireless Information and Power Transfer (SWIPT) technique [67]. For the first technique, it allows to equip only some entities with EH. Hybrid EH empowers the system by both grid and EH, which may solve occasional unavailability of EH. SWIPT empowers the devices with harvested radio wave frequencies through which data is being received, as developed in 4.4.1.

Most of current mobile systems broadcast RF signals, carrying energy that presents a true opportunity as a source. At the same time, considering this possibility, the RF energy can supply devices. This implies the use of Wireless Power Transfer (WPT), and promising techniques are studied in order to implement such systems. The most significant examples are :

- Magnetic resonance coupling, which uses near-field signals and covers an extent ranging from some centimeters to some meters. This makes this technique adapted for charging mobile phones and hybrid electric vehicles, and its efficiency is 30% to 90% for a Tx-Rx distance ranging from 0.75m to 2.25m [68].
- Resonant inductive coupling, which exploits near-field signals and can also be used suitable for mobile phones charging, passive RF IDentification (RFID) cards and contactless cards. Frequency bands for this technique range from 10 KHz and 30 MHz and have an efficiency from 6% to 90% respectively [69].
- RF energy transfer, which uses far-field waves. Its coverage ranges from few meters to several kilometers and is suitable for wireless body and WSNs. Its efficiency is 0.4% to over 50% for −40 and −5 dBm input power, respectively [70]. This technique is being increasingly researched these last years and is gaining growing maturity, which promises new networks concepts, such as Wireless Powered Communication Networks (WPCN) [71].

The circuit suggested in [72] for ambient RF energy battery charge, as may be used in IoT-like applications, is made of a rectifier circuit and an impedance matching network. It converts RF waves to Direct Current (DC). Unlike EH circuit, information decoding uses down-conversion and sampling to process the baseband signal. For EH, a dedicated circuit directly connected to a receiving antenna, called a rectenna (rectifier antennas), captures energy which is converted then into functional DC voltage. This operation is called RF-to-DC conversion.

A rectenna has five main components: an antenna, the network matching the output impedance of the antenna to the rest of the circuit, a low pass filter that eliminates higher-order harmonics, the rectifier which is a diode, and DC filter load (peak detector). Such rectennas are designed in [73], operating at 27.5GHz, and achieve rectification with coupling between the input and output microstrip lines in the design. Note that EH-Oriented transceivers, especially rectennas, can be adopted in most cases for both indoor and outdoor applications and provide an efficient RF-to-DC conversion, reaching 80% in some configurations [74].

Figures 12 and 13 illustrate separately respectively energy and information receivers, which have to be combined for an EH scenario.

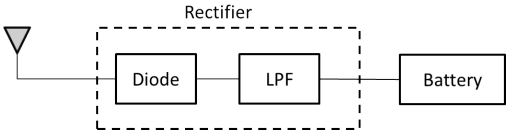

Figure 12: Simplified energy receiver scheme

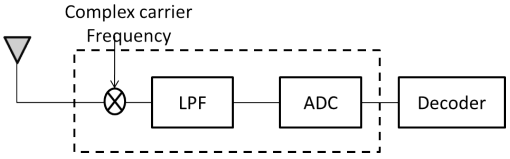

Figure 13: Simplified information receiver scheme

In the case of a receiver combining both EH and information decoding, the received power is split between the two either statically or dynamically. The splitting depends on the variations of RF energy and information, and also in the

needs of the receiver. The combined receiver can separate information and energy circuits [75], as illustrated in Figure 14, or it can integrate both in the same circuit, as illustrated in Figure 15.

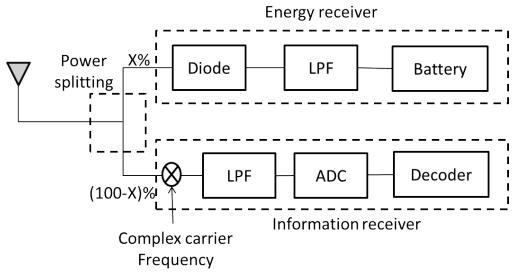

Figure 14: Separated information and energy receiver

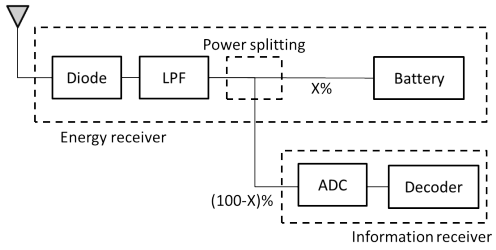

Figure 15: Integrated information and energy receiver

Authors in [75] show that there is a tradeoff exists between harvested energy and achievable rate, so that either integrated or separate receivers are selected depending on the harvested energy.

In teh remainder of this paper, RF-EH is considered. Note that RF energy by nature implies a relative time variability, as well as a sporadic aspect. On the other hand, this technology at mobile networks' scale is much younger than other energy sources harvesting, and accumulates thus less technology mastering and experience.

4.3 RF Energy Harvesting hardware

Several 5G use cases announce the need for self-sufficient and self-sustaining equipments. This energy chase covers the network as a whole including terminal devices, network elements and data centres, and EH can bring a solution for such requirements [72]. However, implementation of RF-EH presents many challenges, including, in some scenarios, the conception of rectennas to collect RF energy and the WPT [73]. Two categories can be cited for WPT: generation of electric power within few meters, i.e. near-field, and generation in an extent that can reach few kilometers, i.e. far-field. The efficiency of energy transfer in near-field case can reach up to 80% [76]. The WPT in far-field appears as RF or microwave signal and uses antennas for transmission and reception then converts it to power by rectifier circuits.

From a hardware point of view, antenna designs already exist for EH from interference signals issued from GSM, WLAN, UMTS and related applications, where antennas are designed with the potential to be used in EH systems. Several categories are also proposed in the literature for different frequency bands such as 900MHZ, 940MHz, 1.95GHz and 2.44GHz, 0,8 to 12GHz [77, 78, 79, 80, 81]. The designed antennas can be integrated in an antenna array to increase the gain and preserve a very high frequency bandwidth.

Though the harvested energy remains suitable for low power electronics, as it is rather low compared to other EH sources. However, a major challenge for RF-EH is still the low power sensitivity and legal restrictions of maximum authorized RF power radiation.

n the other hand, following [82], the global EH market is expected to reach 974.4 Million USD in 2022 when it was only 268.6 Million USD in 2015. This growth is driven by electronic sensors with ultra low-power and by embedded systems, which involve an energy issue. EH can be used to solve this issue, as suggested in [83], and EH relays can be considered, especially when the devices use WPT through RF signals. These signals carry both information and energy, and suggest for relays to charge themselves by extracting energy from the signals they overhear.

Note that RF-EH chips are already being developed as indicated in [84], where a startup has raised 30 million USD in funding to develop chips that can be powered by ambient radio frequencies. More generally, EH from other sources is also coming to reality, as the market for EH chips will approach 3.4 billion USD by 2022 according to the report in [85]. The mentioned report cites some companies that are in the race for EH chip market, and include for example Apple, National Instruments, Analog Devices, STMicroelectronics, Powercast, Renesas, Microchip Technology, Texas Instruments, Mentor Graphics, etc. An example of optimizations for RF Energy in a WSN using Powercast can be found in [86].

4.4 RF Energy harvesting approaches

In order to supply power to the nodes through WPT, it is possible to use either BSs already present in the network, or dedicated Power Beacons (PBs) specifically deployed, as illustrated in Figures 16 and 17. The latter has the advantage of being easy to deploy as it doesn't need backhauling. In both cases, energy beamforming can improve the EH efficiency, and distributed cooperative beamforming can be used to provide data rate fairness [87].

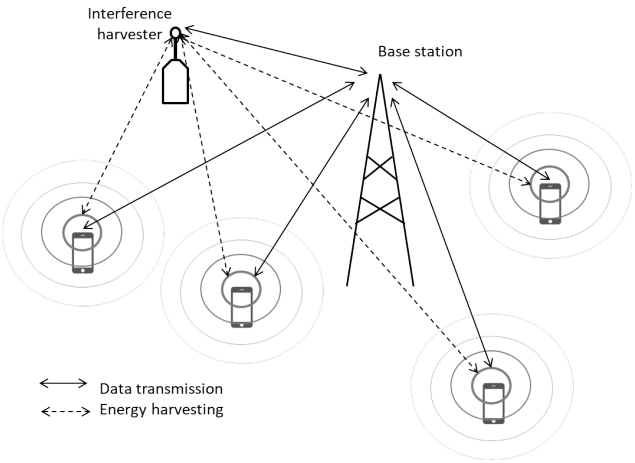

Figure 16: Illustration of the dedicated energy sources to supply RF energy

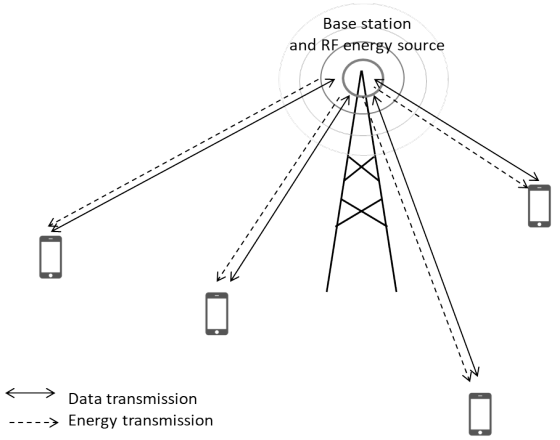

Figure 17: Illustration of the use of existing BSs to supply RF energy

4.4.1 Simultaneous Wireless Information and Power Transfer

Many suggestions for EH receiver architectures are inspired from the use of WPT in wireless networks. Actually, the same electromagnetic field can be used both for information and energy transfer to the end users and/or devices. This case is called Simultaneous Wireless Information and Power Transfer (SWIPT).

Two different tasks have to be completed by an EH receiver: decoding information and harvesting energy. The ideal case would integrate in the same receiver both functions with no power loss. However, realistic case dedicate a circuit for each task, so that EH and information decoding are performed separately. Authors in [75] suggest an intermediate solution that partially combines EH and information decoding circuits in a manner that the rectifier performs a part of the information decoding.

In a SWIPT configuration, a time slot, or a received signal power portion, are used for EH. The rest of time, or of power, are intended for decoding information. Nevertheless, time sharing scheme is more interesting as energy receivers and information receivers, which are usually distinct, have different power sensitivities. Note that there is a tradeoff between energy transfer rate and information transmission rate following the channel. For example, in an Additive White Gaussian Noise (AWGN) channel, maximum information rate target and maximum power transfer efficiency target are compatible.

There are technological issues that still need to be addressed in order to enable SWIPT use for wireless network deployment. For example, if we consider the nature of the transfers in SWIPT, the variation detection in RF signal by the receiver defines the information amount it can decode. The relationship between the two can be described by the Signal to Interference plus Noise Ratio (SINR), i.e. ratio between the power of the signal power and the disturbance power, including interference, noise and eventually any other disturbance affecting the decoding. In practice, even though a signal power can be low, its information rate could be very high. This is however not true for energy amount carried by an RF signal, which depends on its magnitude only. Hence, in a SWIPT, there is a trade-off between transferred energy amount and information rate, as it is not possible to maximize the "rate" of the two transfers simultaneously. Consequently, there is a need to adapt te network design for SWIPT implementation, leading to research issues on the design, analysis and optimization of SWIPT-based networks architectures and protocols. For example, in [88], the wireless powering of terminals in an UDN considers game theoretical approach of power allocation in a network of Full-Duplex (FD) BSs which serve an area highly dense of half-duplex (HF) user equipments. Considering EE and coverage optimization problem for such network as a mean field game gives an optimal strategy to adapt BSs for this type of network settings. SWIPT can also be considered in cooperative communication networks, as proposed in [89], where relays harvest powers to be able to amplify and forward data. An optimization, such as maximum ratio combining, can be then operated considering direct and relayed signals.

Note that there are many variants of SWIPT schemes following the integration in the model of other 5G techniques or the consideration of specific use case. An example is given in [87], where a cooperative communication network is considered with a distributed energy beamforming and simultaneous communication with several users. Moreover, when used with NOMA, efficient EH can be performed, and EE can be enhanced with the use of EH pilots for channel estimation.

4.4.2 Dedicated RF sources powering

Many tools are proposed in case of powering through dedicated RF energy source, as in [90] where optimal power allocation is suggested for frequency division multiplexing, meaning that data transmission and EH can be performed simultaneously, and time division multiplexing, meaning that data transmission and EH are implemented in different time slots but in the same frequency band. Optimal EH and information transmission strategy is then given and long-term throughput can be optimized. Note that authors in [91] considered the possible optimizations in the case of dedicated energy sources for WPT as in IoT applications. Authors showed that power control is critical for system achievable rate improvement in the case of a finite blocklength, and when the Tx power is asymptotically optimum, performance is nearly optimum.

PBs provided by the network, can be integrated in a relay network. For example, [92] suggests that relay nodes harvest transmitted power from the PB station to forward signals to destination. The information can be relayed but also power, following adequate protocols to optimize power splitting, especially in the presence of multi-antennas. Another example using dedicated RF charging in the case of smart wearables, where the energy consumption is very low, is discussed in [93]. This implies a mix of operator-deployed and user-deployed systems that will need to cooperate. Authors in fact highlight through system-level evaluation the preference for omnidirectional energy transmission in this case.

4.4.3 Interference harvesting

An increasing number of users are actively using mobile systems and demanding continuously improved quality of

experience. In addition to the diversity of end devices and of applications, each with its own constraint, 5G uses a heterogeneous UDN to respond to the current landscape, which already implies the coexistence of many RF signals on different bands. In fact, as illustrated in Figure 18, today's current deployments imply the presence of many signals, which can be harvested to power devices. In particular, GSM bands present a higher RF power density, while other sources may also be exploited for energy harvesting, such as Amplitude Modulation (AM) radio stations and Ultra High Frequency (UHF) RFID.

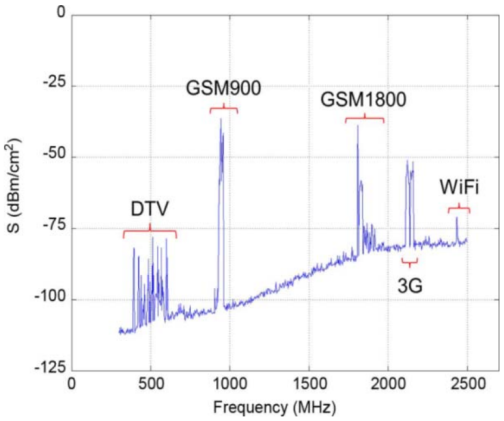

Figure 18: Example of measured RF power densities of main RF energy sources in an urban outdoor location (Source [94])

A given device using a given system is exposed to signals intended for other users in the same network, signal from other networks, or signals on other bands. These signals are usually seen as interference and many techniques and resources are used to mitigate it. It has to be carefully dealt with in an EH context for different types of channels, including broadcast channels, multicast channels, multiple access channels, and multi-user interference channels, as reviewed in [95]. However, they can also be seen as an energy source to harvest.

Figure 19 illustrates the case where signal from the user can be harvested by an interference harvester, which is a node capable of communicating itself with the BS. The harvesting and transmitting are usually sequential.

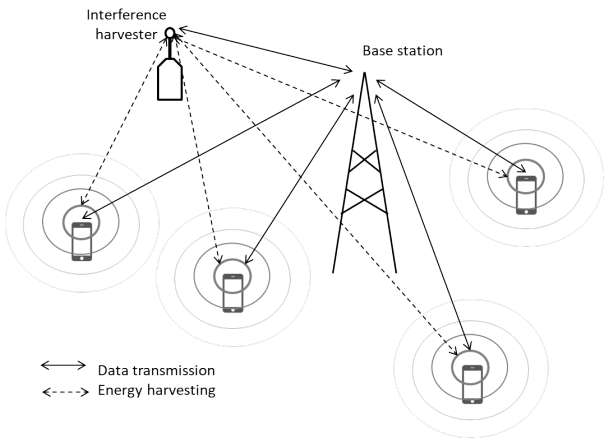

Figure 19: Example of an interference Harvesting scenario

The authors in [96] present opportunistic communication for devices that can reconfigure according to the the band they use, which makes them able to separate useful signal from possibly harvestable OOB interference. Nevertheless, interference harvesting from the same band requires additional processing, and strategies to realize this harvesting are currently being researched, and promising to be a key enabling factor for self-sustainable transmissions in 5G networks [97]. Similarly, authors in [98] present a cooperative wirelessly powered communication network protocol, where distant users overhear uplink signals of users and downlink access point broadcast signals, and time allocation for uplink and downlink are jointly optimized, which increases users rate and improves user fairness and transmission delay. Actually, the analysis of RF-EH performance has been considered in works such as [99], where the harvested energy mean, transmission outage probability and power outage probability are studied.

The energy can be also harvested from parts of the signal of the same user. An example with multicarrier modulations, as in [74], considers the fact that the Cyclic Prefix (CP) is used when still analog and thus, its energy can be harvested. The CP would remove inter-symbol interference, and at the same time contribute in SWIPT implementation, especially for WPT in downlink.

A backscatter communication architecture is suggested in [100], which combines ambient EH and reflection of this same energy modulated, with all its related signal processing aspects and multiple access techniques.

4.5 RF Energy harvesting scenarios

Globally, as enumerated in [95], three EH and transmission protocols can be identified:

- Harvest-Use (HU), for which the device is powered by EH directly, without using any buffer. Data transmission is thus possible only when harvested energy can cover the processing energy cost.

- Harvest-Store-Use (HSU), for which a storage device, typically a battery, is used to gather harvested energy. This energy is then available for use only in the next time slot. This case has to consider carefully possible storage inefficiency during the charging and leakage during the storage. For example, only about 70% of the energy is stored in Ni-MH rechargeable batteries while 95% can be reached with a supercapacitor. However, a battery implies less leakage than a supercapacitor.

- Harvest-Use-Store (HUS), which uses two energy storage devices : a supercapacitor storing the harvested energy for immediate use, and a buffer storing the remaining energy for later use.

The energy buffer is critical when using one of these protocols. Other schemes in a different optimization perspective can consider storage constraints, QoS requirements or capacity achieving targets. An example is the introduction of a sleep-and-awake mechanism to enhance the achievable rate [95].

4.6 RF Energy harvesting scheduling

In order to have an efficient EH system, and depending on the used EH protocol used, the energy consumption has to be adapted to the EH. This is to prevent energy outage or overflow. Thus, the design of energy use scheduling is critical. It can be offline or online, following the case where channel state information is available at the beginning of the transmission or only on the fly.

Energy scheduling depends on many parameters, such as data throughput, transmission competition time, mean delay, outage probability, quality of coverage, message importance, grid power consumption when there is a hybrid power supply, etc. For instance, the scheduling of RF harvested energy optimizes the time duration of information processing and EH. A tradeoff between the minimum information outage probability and the maximum average harvested energy defines the optimal mode switching between the two functions at the receiver. A review of scheduling techniques can be found in [95].

The signaling in wirelessly empowered communication networks has also to be carefully designed. In fact, if wireless powered communication networks control is centralized, signaling overhead, as well as optimizations in case of large number of devices can be prohibitively complex. Thus, a distributed EH random access protocol can be adopted, as in [101], where a slotted ALOHA is used a harvest-until-access protocol. The proposed algorithm optimizes the average channel throughput without knowledge of full channel state information, especially when the number of devices is large, which reduces the complexity and overhead of a centralized management.

Integrated spectrum and energy control mechanisms are presented for a typical heterogeneous 5G network in [102]. In this work, the authors consider the network where the devices have different EH capabilities and perform a cooperative resource sensing for CR implementation. In this case, both energy and spectrum are *"harvested"*. This leads to an architecture and model with specific spectrum and energy control mechanisms in many 5G scenarios, and consequently a Medium Access Control (MAC) protocol for this context. Another energy and spectrum efficiency optimized MAC protocol for 5G EH can be found in [103], where SWIPT is considered for cooperative and non-cooperative schemes with EH capabilities in a CR aided 5G networks.

5 RF Energy harvesting in 5G ecosystem

5G ecosystem integrates a wide range of use cases, using established and new technologies. EH is researched to be integrated with key 5G enablers, and examples of these researches are given in the remainder of this section.

5.1 UDN RF-EH-enabled

UDN are among main 5G enablers for many use cases, including IoT. Considering ambient RF-EH in dense networks, many implementation and operation challenges arise including energy availability, EH mode selection, cooperation between BSs and devices. In particular, there are tradeoffs between EE, SINR and outage probability, as highlighted in [104], where it is found that co-channel interference EH can bring efficiency improvement, especially if combined with an optimization of BSs parameters.

When the capacity is limited, the H2020 project SCAVENGE [105] suggests that cells can be split so that some are master Access Nodes (AN) while the others are EH AN. In case of heavy traffic, all ANs would be enabled to provide required capacity, while for light traffic, a part of EH AN can be switched off. This can be possible as UDN have high probability of Line-of-Signt, making the access easier for devices without the need of EH ANs. Backhauling the cells, if using wireless connection, makes the deployment cheaper and more flexible. In particular, EH ANs backhauling can use mmWave or be self-backhauling. In the second case, the access and the backhauling use the same link, shared in time and/or frequency. In the first case, mmWave can provide EH capabilities for rapid AN installation. In particular, for some deployment scenarios, micro cells with low power can be used, for which an EH powering and a wireless backhaul are suitable. The use of EH in this case, as indicated in [105], can be cost-effective. It can also provide an easy coverage and deployment in rural areas, easy cell planning, reduced environmental impact and cost saving in long-term.

Note that WPT can be used between BSs in addition to terminals. This will imply a new cell planning based for example on energy balancing connection and QoS-aware BS planning.

5.2 RF-EH in C-RAN

C-RAN and H-CRAN aim to provide a high data rate, energy efficient network. However, because of its heterogeneous nature, H-CRAN is more energy consuming as it has a larger number of RRHs than C-RAN. When the network is dense, the energy requirements become critical and several adaptations and optimizations have to be made. EH can bring thus a solution as in [106], where BSs are suggested to be powered with EH, and can also power devices. A throughput optimization in that case can be performed under receiver charged energy constraint. The grid energy consumption in the case H-CRAN downlink with one grid-powered BS and many RRHs EH-powered is studied in [67] and a model and optimization of user association, power allocation and EH constraints are given. In this scenario, the EE optimization is modeled as a fractional mixed integer nonlinear programming problem, which can be solved in few iterations. This improves the number of users, who are mostly associated to EH-RRHs, and thus decreasing the grid energy consumption.

In a UDN deployment, the implementation cost can be high due to infrastructure and small cells backhauling, and C-RAN can en be used to reduce this cost, especially for low data rate traffic as in IoT. The fronthauling then can use EH for an energy efficient deployment [105]. Similarly, the energy cost in an RF-EH combined with an energy management and scheduling in H-CRAN context is considered in [107]. RRHs in that case are EH-powered, and a hierarchical framework based on economical model and using energy sharing and energy trading between 5G actors, and more specifically internet service providers, can provide a

framework for the system design.

5.3 RF-EH enabled MEC

In MEC, computing resources are available at the edge of the mobile network, i.e. BSs, in order to ensure low latency and to reduce core network traffic. Globally, two main scenarios are considered for EH and MEC combination. Either EH capability is deployed at the MEC BS (or resource server) to prevent possible grid energy absence or unavailability in some scenarios, like natural disasters or remote areas, or it is implemented on device side, which is more suitable in case, for example, of IoT. Study of the state of the art for these two scenarios can be found in [108]. For the first scenario, energy forecast and EH enabled BSs load balancing have to be controlled. An example considers BSs equipped with EH capabilities and may reduce thus by the same occasion energy consumption. The authors in [109] suggest to optimize the BSs and virtual MEC resources use following traffic load and forecasted harvested energy parameters. The heuristic optimization employs sleep mode for BS and soft-scaling for Virtual machines. The authors announce up to 69% energy saving in single BS case, that can be enhanced by up to 16% in BSs cluster. Similarly, an illustration of the second scenario can be found in [110] and present a low-complexity dynamic computing offloading strategy for MEC with EH. This strategy decides computation offloading power and device transmit power, without the need of distributed information, and is easily implementable, besides being asymptotically optimum.

5.4 D2D with EH

D2D communication suffers from a major constraint, which is energy. EH can be thus integrated to devices in order to solve this issue, and many studies consider this case and provide theoretical performance derivation for different scenario. For example, in [111], the authors consider the scenario where UEs in a traditional cellular network assisted with relays use decode-and-forward cognitive D2D communication and EH. They provide analytical expression for main performance parameters, which helps to optimize link robustness. Another scenario can consider D2D in large-scale cognitive cellular networks as by authors in [112], where D2D transmitters harvest energy from dedicated multi-antenna PBs. A power transfer model with three possible power transfer policies can be proposed, in addition to an information signal model with two considered receiver selection cases. In addition to outage probability, secrecy is also considered in the analysis conducted by the authors and complete the framework for secure D2D communication.

5.5 RF-EH with key 5G RAN techniques

Spectral efficiency is critical in current mobile systems, particularly in RAN. Thus, spectrum optimizations have to be considered, in combination with RF-EH techniques. Reviewed techniques in the rest of this section include cooperative communications and cognitive radios, in addition to massive MIMO, NOMA and D2D. The combinations and optimizations usually consider many of these techniques at a time, in order to prepare its integration on practical systems.

5.5.1 Cooperative communications

In an EH network, nodes may have different channel and energy conditions, which may enhance performance using a cooperative approach. Transmission schemes for cooperative networks, multi-user networks, cognitive radio networks and cellular networks are thus to be considered.

Multi-user environment is an example of scenarios with EH, where interference management mechanisms have to be effective. Moreover, this environment presents spatial diversity gains that offer an opportunity to enhance system performances through collaboration between network nodes, which form a virtual MIMO system. Among studied aspects for cooperative networks, the power allocation is to be optimized under EH models, as well as throughput in delay constrained environment, and joint power allocation and time scheduling with EH.

Another example of EH integration issues is the joint optimizations of EE and frequency bands in the design of wireless-empowered transceivers, as presented in [74] where in-band interference harvesting is designed so to realize self-sustainable communication architecture.

5.5.2 NOMA

The adaptation of EH with 5G coming techniques, such as NOMA or CR networks, is an important issue to address for RF-EH deployment. In fact, there is a need for more comprehensive design for both new technologies, NOMA and RF-EH. Such combination may if established provide an efficient use of the energy and radio spectrum in energy efficient and sufficient networks, as in [113]. Other examples of issues are modeling and analysis of large scale EH networks and relay-based EH networks, as well as the design of energy cooperative strategies between harvesting devices. Note that in addition to energy and power transfers, it is fundamental to consider energy storage at end nodes, which ideally would consume harvested energy immediately within a transmission cycle.

Analysis tools for EH NOMA are intensively investigated, as in [114] where users outage probability under imperfect channel state information and imperfect SIC in a cooperative EH NOMA network is derived. Another example of mathematical modeling for user grouping, power and time allocation can be found in [115], which adopts a mesh adaptive direct search algorithm to optimize data rate and transmit power for each user with reasonable complexity. Similarly, outage probability is calculated for relay systems with NOMA and EH in [116], where the multiuser downlink is considered and BSs use multiple antennas to beamform information and energy.

NOMA use in specific wireless powered IoT relay systems with RF-EH capabilities can be found in [117], where RF-EH and information transmission system with time switching and power splitting relaying are considered. Due to the constrained nature of IoT nodes, the authors propose for IoT nodes to first harvest energy from the source node, either with time switching relaying or power splitting relaying

protocol. After that, the information of the source node is transmitted by the relay node as well as its own information using NOMA. The description of this system is mathematically derived by the authors, allowing several optimizations of system parameters.

5.5.3 Massive MIMO

Massive MIMO is a key 5G enabler, and its integration with EH schemes has been studied by many researchers. In [118], the authors explore the use of massive MIMO in heterogeneous networks. The deployment considers macrocells where users harvest energy to maximize their uplink power by minimizing uplink pathloss. It is found that user association should be optimized to maximize both harvested energy and information transfer. In this case, the downlink received power and the uplink received power should be both considered in the optimization. The stochastic model for the harvested energy and its link to uplink achievable performance demonstrates the added value of massive MIMO on that point, though the gain may deteriorate with network density. The proposed model enables however the study of massive MIMO and RF-EH integration with other technologies.

Another example of 5G techniques integration can be found in [119], where the downlink of a C-RAN enabled scenario with distributed large-scale MIMO is considered. Each RRH is powered EH and the grid in order to secure the RRHs from possible EH unavailability. The problem problem of BS energy consumption minimization under QoS constraints in this scenario can be solved using linear programming or an online energy management algorithm.

SWIPT in massive MIMO systems is studied in [120], where an analytical study of hybrid and full-dimensional processing is performed. It considers hybrid precoding and beamforming BS and derives expressions for harvested energy, achievable rates and energy-rate tradeoff for growing number of BS antennas and network nodes. A hybrid precoding and combining is proposed which optimizes harvested energy with little energy-rate tradeoff degradation.

5.5.4 mmWave

mmWave is attractive for EH as it is intended to be integrated for large antenna arrays and a dense network, presenting thus interesting harvesting opportunities. However, it propagation characteristics, i.e. poor penetration and diffraction, may limit its use to some scenarios. Many studies though consider RF-EH for mmWave communications. For example, authors in [121] consider a scenario where mmWave signal provides energy and/or information to low power devices and derive key information and EH performance parameters as well as overall coverage performance. This establishes an analytical framework to design network and device parameters, for example for antenna geometry optimization.

A study on combination of NOMA with massive MIMO using mmWave can be found in [122], where SWIPT is used to enhance EE. Hybrid precoding is used for mmWave massive MIMO, and information and energy can both be *"harvested"* by users thanks to a power splitting receiver. Algorithms are proposed to select a user per beam, and an analog precoding is then performed to all beams, then users grouping is performed and a digital precoding is applied. An iterative joint optimization of power allocation and power splitting reaches finally a maximized achievable sum-rate.

Note that antennas design for mmWave specific applications are also a challenge, as investigated in [123], where the authors consider ambient RF-EH antenna on textile for wearable in mmWave, and provides up to 40% on-body and 60% off-body radiation efficiency.

5.5.5 Cognitive Radio

Cognitive radio environment needs to be adapted with EH. As already mentionned, CR is often considered with other 5G enabling technologies. In fact, the spectrum usage is optimized as Secondary Users (SUs) use the spectrum of Primary users (PUs), following different priorities and cooperation strategies. These strategies may incorporate information transmission and spectrum sharing among nodes, but also EH strategies. In this case, both PU and SU get benefits as the PU improves his throughput through SU as relay node, and SU gets more spectrum usage opportunities from PU's spectrum. In addition, PU's bands access can be supported by SU's harvested energy. Conventional cognitive radio networks, e.g., spectrum allocation and management, spectrum sensing and handover, spectrum sharing, are reconsidered to enhance the network reliability in an EH context where, in addition, harvesting, spending or conserving energy have to be optimized.

An example of transmission CR schemes in RF-EH network can be found in [124], where an analytical study characterizes dedicated PBs. Information transfer and EH operate asynchronously in different bands. Another example considers a two-way relay assisted CR NOMA network [125]. In this example, a joint optimization of power allocation, transmit power and power splitting ratio is proposed. Similar throughput maximizations under QoS constraints can be found in [126] for a CR context.

6 Conclusion

This paper is a reflection of the increasing interest on new techniques to make energy use more efficient in 5G systems. It aims to provide a comprehensive review on RF-EH-enabled 5G networks. To this end, 5G standardization, requirements, use cases, ecosystem and key enabling technologies were reviewed, and particularly their energy aspects. RF-EH was then highlighted as a promising technique to solve energy supply and/or optimization. Different aspects of EH were exposed, including implementation and network protocols. The paper then presents literature review of RF-EH integration with 5G enabling technologies, as well as some research trends and challenges following the integrated technologies.

Conflict of Interest The authors declare no conflict of interest.

Health Information Technology is playing a key role in healthcare. Specifically, the use of electronic health records has been found to bring about most significant improvements in healthcare quality, mainly as relates to patient management, healthcare delivery and research support. Health record systems adoption has been promoted in many countries to support efficient, high quality integrated healthcare. The objective of this work is the implementation of an Electronic Health Record system based on a relational database. The system architecture is modular and based on the concentration of specific pathology related parameters in one module, therefore the system can be easily applied to different pathologies. Several examples of its application are described. It is intended to extend the system integrating genomic data.

1. Introduction

This paper is an extension of work originally presented in IEEE 4th International Forum on Research and Technology for Society and Industry [1]

The collection of health information for patient data management including patient characteristics, treatments and outcomes has been over the years a most important aspect of health care [2, 3]. EHRs, which replace paper medical records to collect people's health information, integrate different and heterogeneous data and are one of the most widely used Health Information Technology (HIT) tools. HIT contributes to the improvement of quality of care, to patient's safety and to the reduction of health care costs by making available accurate documentation and rapid information retrieval and management. The adoption of EHRs has been promoted in many countries, both at government level an in the private sector, even though their adoption is still rather limited, mostly because of standardization, certification, security and privacy aspects and concerns. The adoption of standard based EHR systems has been found to be able to reduce spending for healthcare to a great extent [4]. EHRs can improve patient care and safe practice, however potential risks related to medical error, systems failure, and security and legal responsibility aspects should be considered, identifying barriers for EHRs adoption and ways to address them [5-9]. Moreover, organizational and human factors can promote or hamper the adoption of a EHR [10]. Further relevant aspects of EHRs are interfaces with other information systems, that should be based on standard formats, such as Health Level 7 Clinical Document Architecture (HL7 CDA), HL7 Version 3, openEHR and on controlled vocabularies such as Logical Observation Identifiers Names and Codes (LOINC), "International Classification of Diseases (ICD), Systematized Nomenclature of Medicine (SNOMED) and others [11]. The need for generic and interoperable EHRs has been recognized, specially as relates to interoperability, for the preservation of clinical information across heterogeneous systems [12]. Standards are needed to implement interoperability between systems.

An EHR system contains quantitative data (clinical data), qualitative data (text documents), and medication records. The related amount of data is rapidly expanding, and big data technology is going to play a key role in this respect, specially as relates to natural language processing, clinical decision support, integration of genomics and system biology with EHR data, knowledge dissemination and interaction with patients [13].

The set of requirements that must be met by EHR systems is defined by ISO 18308:2011. According to this standard the scope of the EHR is regarded as broader than documentation, prevention and treatment of illnesses. ISO 18308 relates to shared EHR information and to the EHR system aspects that may be used for the support and coordination of patient-centred continuity of care. An EHR system includes data repositories, directory services,

*Corresponding Author: Mauro Giacomini. Via all'Opera Pia, 13 – 16145 Genoa (Italy) email: mauro.giacomini@dibris.unige.it

knowledge services containing terminological system, care pathways and workflows, user applications and other modules and services. An EHR architecture can be classified according to a data approach, a concepts approach and a process/service approach. These approaches are present in existing systems and in specific domain languages and modelling languages [14]. A medical record system has been developed, adopting the three approaches above. The medical record system that has been developed is based on Health Level 7 (HL7) standard and can be easily tailored to the needs of different clinical wards. The use of this standard allows the system to support interoperability between the main components of the Hospital Information System (HIS), such as the Laboratory Information System (LIS) and the Pharmaceutical Information System (PIS), and can be easily extended for example to the radiology information system (RIS) and to the picture archiving and communication system (PACS). A Service Oriented Architecture (SOA) has been adopted, that can be defined as an open extensible, composable architecture based on autonomous, interoperable and reusable services, implemented as a Web services [15]. SOA has been employed in healthcare after adoption in other sectors, such as banking, transport and industrial automation [16]. SOA is widely used for real time implementation in large distributed systems, mostly because it supports the easy integration of new software within the existing one, reducing the impact on service users and cost [17-20]. Moreover, the SOA paradigm has been successfully implemented in the design of several distributed healthcare systems [21-23].

2. Materials and Methods

The system has been implemented taking into account the specific needs of different departments of the San Martino hospital in Genoa (Italy).

The workflow relating to a visit includes the identification of the patient through the information already present in the HIS obtained by a pseudo-anonym code according to the specifications of UE General Data Protection Regulation, (GDPR) [24]. The information on laboratory analyses is obtained by query of the hospital LIS and the information on therapies is obtained by query of the PIS of the hospital. The data are stored on different platforms which do not interact with each other, therefore its direct use is cumbersome and with possible misunderstandings. In order to address this problem, a system based on a relational database developed with Microsoft SQL Server 2017 has been set up, which has made it possible to create a consistent and logical representation of the information. It is worth noting that, in order to achieve GDPR compliance, the data in the database are stored by pseudo-anonymization techniques. A pseudo-anonymous code is used to query the database, in a secure fashion. The information relating to the identity of the patient is present only at the physician interface level, after authentication [23].

The database has been designed developing a conceptual model of the data, abstracting relevant aspects of the activities and processes relating to patient management. A conceptual model is a set of rules and conventions that allows to move from a reality of interest to a conceptual scheme of the data. The model has been divided into three levels that represent respectively the protagonists of the project (level 0), the clinical event (level 1), and the format of the parameters and results (level 2).

In level 0 the main actors and features of the project have been considered, defining the fundamental entities and the relationships among them. The Entity-Relation (E-R) diagram shows the general logistical aspects of the platform (Figure 1). Patients are followed up and subsequently entered into the database by the operators. Both patients and operators are linked to the centres involved in each clinical study. Each operator may be authorised to access more than one clinical study, and each patient can be involved in more than one study. Moreover, the clinical events relating to each patient may take place in different centres (the latter aspect being of fundamental importance, since different centres may use different units of measurement and ranges of normality). Each study may consider more than one clinical event, some of which may be common to those of other studies, while others may be specific to certain studies only.

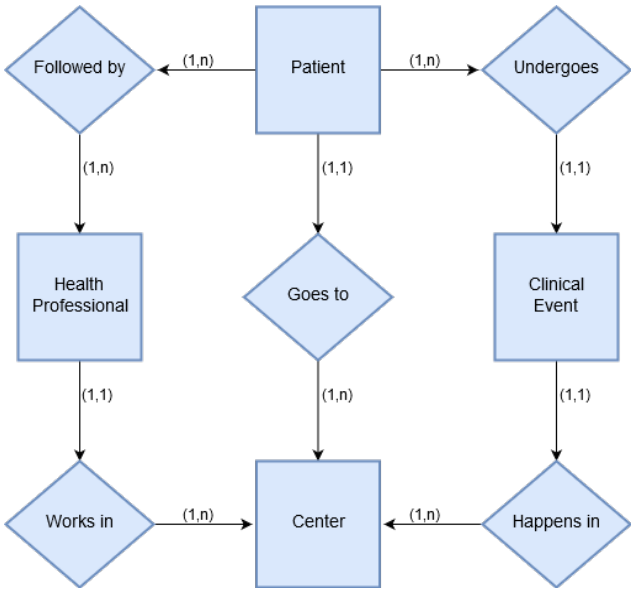

Figure 1. Entity relationship diagram for level 0

Level 1 of the E-R diagram (Figure 2) shows the meta-descriptive approach that has been adopted to manage clinical events and make the database structure as simple and general as possible. The main element is the definition of different Event Types. Within the conceptual definition of systems implemented with E-R diagrams [25], attributes are the elements that describe in detail the characteristics of entities and relationships. By transforming E-R diagrams with relational logic schemes, these attributes become columns of tables in databases. This approach, if applied to our case, binds the set of elements considered in a medical record (which happens in many third-party applications), blocking it in the data base (DB) construction.

When developing the system, it has been chosen to store the names of the elements that are regarded as rows of the table (called "parameters"). Another table (called "categories") has been categorized, and related with the clinical reality through the links in the table that derive from the relation shown in in figure 2 (diamond "considered aspect divided by"). This choice allows to use the same DB and the same software for several tables and to easily characterize the individual parameters in a strong semantic way (using international codes such as - LOINC - ICD - ...). This greatly helps interoperability.

The most important aspects have been divided into different "Categories". These are "containers" of parameters, homogeneous

from the conceptual point of view, but not necessarily homogeneous from a data format point of view (for example, a clinical event of the "Therapy" type has a "Therapy information" category, including parameters such as "Adherence" and "Therapy start date"). Each clinical event has Results, which are the values of the parameters of that particular event.

Events are grouped into types. Parameters are also grouped into types, which are translated and mapped in LOINC using standardized dictionaries, in order to support data reuse.

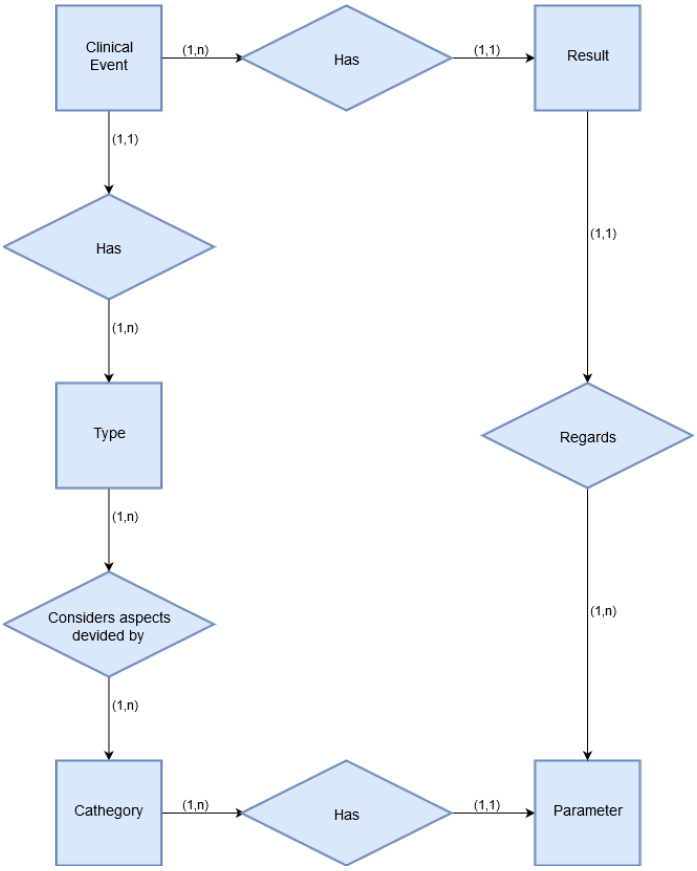

Figure 2. Entity relationship diagram for level 1

Level 2 shows the entities and relationships which are taken into account to manage the Parameters and Results of Clinical Events. Each Parameter has a specific format (typically real integer, string or Boolean), so the results (i.e. the records corresponding to the values of the parameters of an event) can have different formats. The E-R diagram (Figure 3) takes into account the fact that all parameters stored in the database have their own units of measurement and range of normality, but these units and ranges are different for each centre that may be involved in the network. This is of fundamental importance for the work carried out by the physician. In the transition from the conceptual scheme to the logical scheme, great attention has been paid to this aspect, in order to allow each user to work with the tools that are most familiar to him/her. Moreover, the differences between the units of measurement have been taken into account in the data extraction algorithm. All records relating to a single parameter are converted into a standard unit of measurement, defined by the users as the ones which are most widely used.

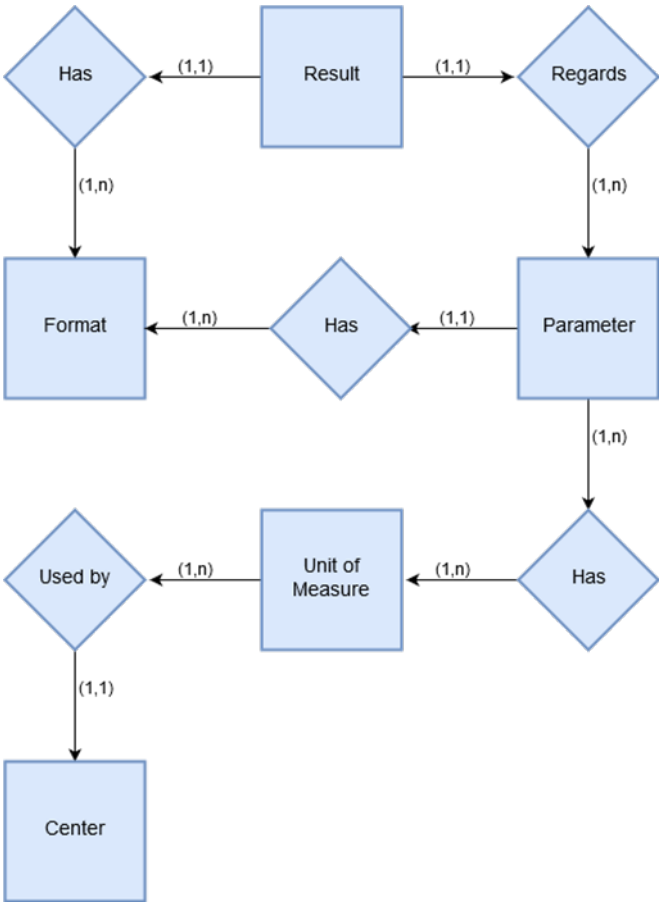

Figure 3. Entity relationship diagram for level 2

The implementation, including the creation of a web client and a web service, has been carried out in Visual Basic .NET using Microsoft Visual Studio 2015 software.

The system architecture has been designed with special reference to interoperability, according to HL7 in the HSSP (Healthcare Services Specification Project). The HSSP, started in 2005 by HL7, focuses on standard software services for healthcare, enabling the use of SOA, which has been recognised as extremely useful for interoperability, code reuse and new needs response [26]. Standards service interfaces for infrastructure reuse capability and specific health facility were considered providing a methodology for the implementation of relevant services [27].

Specifically, the HL7 Clinical Document Architecture (CDA) has been used for the encapsulation of clinical data that can be easily exchanged between applications, retaining their semantic significance [28].

Clinical parameters are associated differently with specific names and internal codes in different hospital and/or health centres. In order to allow the communication among different centres, the codes used by different hospitals/centres have been translated into LOINC language with regard to clinical trials [29], international Anatomical Therapeutic Chemical Classification System (ATC), national Marketing Authorisation (AIC) for drugs, International Classification of Diseases 9th version (ICD9) for diagnosis and ISO Country 3166-1 for the classification of the country of origin of patients.

Table 1. Clinical events for the Maculopathies, HIV, and Tuberculosis

Maculopathies	**HIV**	**Tuberculosis**
Personal data	Blood sample taken	First visit
Anamnestic	Admission history and physical note	Visit
Calendar	Medical history unknown	Microbiological examination
Eye examinations	Therapy	Laboratory examination
Maculopathies	Discharge summarization note	Resistance development
Laser Injection Therapies	Specialist visit	Instrumental examination
Primary Diagnosis	Submission questionnaire	Therapeutic treatment
Secondary Diagnosis	Non-Haart Therapy	Alcohol test
Clinical Folder	Adverse event	
Two Eyes	Qualitative therapy	
Pharmacovigilance Card	Repeated medical history	
Ozurdex Monitoring Card	Vaccination	
Visual Functioning Questionnaire	Microbiological culture	
Retina Plus - Personal data	Failure	
Retina Plus - Access	Instrumental examination	
Retina Plus - Questionnaire	Visit Control	
Telescreening	Pregnancy	
Laboratory Exams		
Plaquenil Protocol		
Certificates		
Allergies		

The “San Martino” hospital in Genoa is equipped with a network infrastructure made of two Local Area Networks (LANs) that are not connected to each other (the hospital LAN and the university LAN). Specifically, the parts of the HIS are placed in the hospital LAN, which is not accessible from external networks for security reasons, because of the hospital firewall. The access to data and to the required information is granted by a virtual private network (VPN), capable to securely connect the two LANs, allowing access for clients belonging to the university network.

The original data are sent through the VPN and, by tunnelling protocols and advanced encryption, are secured by a protective barrier before they are shipped over a potentially dangerous infrastructure such as the Internet. Tunnelling is a multi-protocol (IPsec) data encapsulation process within another IP packet that is shipped over the network. In order to transmit the data to authorized end recipients only, the data are packaged twice by a specific authentication system in which access levels depend on user role.

The strong modularity of the system allows to use the general structure described above for different diseases. The system has so far been used for the implementation of the EHR for the Ligurian HIV network [30-32], for ophthalmology [33, 34] and for infectious diseases [35]. For each of these cases, different clinical events, parameter categories and parameters have been implemented in order to provide a tool which is very suited to the specific needs of physicians and caregivers. Table 1 and table 2 show, respectively, the clinical events and the categories of parameters for the three scenarios.

3. Results

The system that has being developed is hosted in Genoa university network. The user interface of the system is divided into several parts, each concerning a specific section of the medical visit. The EHR system is managed through a web interface that, for security reason, can only be accessed within the Genoese hospital and university LANs. The system interaction with the physician or caregiver takes place as follows. When the user logs in he/she is redirected to the page relating to the specific patient selection and the examination starts. After obtaining access permission, the caregiver can either manually enter the data of a new patient or see the data for a patient who is already present in the data base.

For a new entry, the related information is retrieved from the hospital databases and, after translation into LOINC, is stored in the EHR system database. The clinical parameters are retrieved from the LIS and the information on the laboratory tests is stored by an array of CDA which is sent to the web service which stores it in the system database.

A section of the clinical diary allows physicians to inspect the exams that are available for each patient. The physician can see all specific visits, their dates and parameters. The information for each clinical event is retrieved and updated by algorithms that taking into account the ethical committee permissions.

The creation of the web pages for user interface is also guided by the structure of the DB, i.e. a page is formed for each event, within which all parameters related to that event are presented. The type of value for each parameter (integer, real, list or free text, date) automatically inserts the selection of the most suitable input tool for that type (textbox, dropdown list, calendar, ...). The measurement units for the numerical parameters and the normal ranges also (possibly linked to the patient's personal data, age, sex, height, weight) are also automatically inserted.

Table 2. Categories for Maculopathies, HIV, and Tuberculosis

Maculopathies	**HIV**	**Tuberculosis**
Personal data	Phenotype and viremia	Symptomatology
Anamnestic	Carbohydrate metabolism	Inflammation indices
Calendar	Cardiovascular profile	Diagnosis of tubercular infection
Visuals and symptoms	Liver functionalities	Sputum microbiological examination
Front and rear segment	Renal function	Microbiological examination of bronchoaspirate
Laser Injection Therapies	Oxidative stress	Microbiological examination of urine
Primary diagnosis	NK phenotype	Microbiological examination of faeces
Secondary diagnosis	Anamnestic	Microbiological examination of other material
Topical therapies in progress	Non-Haart Therapies	Resistance
Expert	Inflammation parameters	Instrumental examinations
Folder	Leukocyte formula hemochrome	Localization
Exclusion criteria	Monocyte populations	Inpatient
Prohibited treatments	Mocyte activation markers	Comorbidity
Interruption of treatment	Inflammation mediators	Treatment
Pharmacovigilance Card	Lymphocyte Proliferation	Side effects
Ozurdex Monitoring Card	Therapy information	First-line oral agents
Visual Functioning Questionnaire	Drugs therapy	B: Injectable agents II line
Appendix of Optional Additional Questions	Information about hospitalization	A: Fluoroquinolones
Retina Plus Personal data	Diagnosis of hospitalization	C: Other second line agents
Retina Plus Access	Diagnostic and therapeutic procedures	D1: Deputy agents
Retina Plus Questionnaire	Discharge information	Laboratory examination
Telescreening	Comorbidity	CBC
Grape harvesting	Discharge diagnosis	D2: Deputy agents
Laboratory Exams	Non-Haart Drugs	D3: Deputy agents
Instrumental examinations	Objective examination	
Microbiology tests	Chemistry	
Plaquenil start therapy	Specialist visit information	
Plaquenil	HIV information	
Blood pressure	HBV information	
Certified	HCV information	
Allergies	Hepatitis	
	T lymphocyte activation markers	
	Side effects therapy	
	Submission questionnaire	
	Non-Haart Drugs	
	Information on drugs therapy	
	Details of side effects therapy	
	T reg	
	Concomitant therapy	
	Adverse event therapy	
	HCV adverse event	
	Qualitative HCV therapy	
	Qualitative HIV Therapy	
	Vaccination	
	Microbiology	
	Non-hepatitis serologies	
	Instrumental examination information	
	Control visit information	
	Resistance	
	Pregnancy	
	Barthel ADL (Activities of Daily Living)

Table 3. Use of EHRs for pathologies

	Initial year	Patients	Parameters	Events	Values	Sessions
HIV	2013	4540	802	200424	6481673	9033
Maculopathies	2014	5554	801	52335	955753	2166
Tuberculosis	2016	324	125	6460	103691	2324

4. Discussion and Conclusions

An EHR system has been set up in order to meet the needs of medical and clinical personnel. The main aspects that have been considered relate to the management of visits and to the setting up of a clinical diary according to the standards currently in use.

The objectives of the study have been met as shown in table 3, in which the system's application to maculopathies, HIV, and tuberculosis are described. Specifically, for the three pathologies the table shows the initial year, the numbers of patients which have been recorded, the numbers of related parameters, the number of events and the number of values that have been stored. The last column, named "session", shows the number of days in which an operator queries an EHR.

The system aims to simplify physician's, nurses' and caregiver's work for administration and management of treatment and follow-up. Moreover, it aims to support multicentric tracking for patients who are treated in several hospital facilities and the conduction of clinical trials. The system was set up focusing on parameters and parameter types, grouping them in one specific module. This facilitates the use of the system for different pathologies, because the pathology related data are in one module per pathology. The use of one single section for the management of different pathologies allows for easy use by different departments of one hospital and by different hospitals. This design choice also facilitates data reuse.

The main problems and limitation that have been encountered relate to data availability, because of data anonymity requirements for security and privacy. In the first place, this problem has been circumvented requiring the hospital to make the data pseudo-anonym, while keeping the link between the pseudo anonym code and the patient identity separate from the data and managed by the hospital system only, on physically separated platform. Moreover, the data which are copied onto the EHR system platform are encrypted by up to date techniques which protect them from attacks. Therefore, even if the data were red this would not provide any useful information

It is intended to evaluate the system performance by questionnaires addressing usability by physician, nurses and care giver.

Further developments mostly relate to the integration of genomic data in the system [36, 37]. This aspect is becoming increasingly important and the parameter focused architecture of the system is suitable in this respect. The integration of genotype and phenotype information in the EHR and the insertion of genomic information in clinical workflows would facilitate the planning, administration and evaluation of genetically enabled care.

ABSTRACT

Enhancing underwater visualization using hybrid technique is generally employed into oceanic production. Through growing oceanic learning, undersea processing has drawn extra importance owing towards necessary task of picture towards attaining data. Although, suitable to reality of dust-like constituent and beam reduction, undersea descriptions continually experience small contrast and color alteration. In this paper, we estimate submerged beam transmission progression also intend an effectual means to defeat the backscatter trouble. Our scheme generally includes three steps; first, we reconstruct the picture using adaptive regularization. Second, we separate the reconstructed picture with weighted decomposition; third, we exploit color adjustment along with dehazed process via gradient guided filter towards holding dual mechanisms independently; at last, re-establish fine effect, we use hybrid technique for enhancing the picture. The tentative outcome illustrates that our proposed process extensively get better quality of unclear submerged descriptions. In common, our proposed method verified as well-performed and effectual than existing technique.

1. Introduction

In the modern years, scientists and researchers have exposed their main concern in capturing the aquatic life beneath the water. Although the statement that 70% of the globe encloses water includes enormous energy, abundant mineral assets and biological resources. The living beneath the water is still not as much look at. Conversely, challenges related by capturing descriptions beneath the water have been complex to defeat, owing to carry-over haze and color cast. The muddy nature of water suitable to process element such as mineral deposits, sand and plankton, showed a huge difficulty in undersea look at region. These elements set up lack of clarity in undersea descriptions which spoils the clearness and ocular analysis of the picture and in turn, inappropriate for any advance use. Researchers have finished that the spreading and absorption property of beam underneath are the chief basis for this deformation [1]. While water is roughly 800 times denser than air, so when beam penetrate from air to water, it come across reflection fact at the surface owing to which only unfair measure of beam go through water. Afterwards the beam undergoes spreading cause when it strikes and element and minerals suspend in water. Scattering diverges the beam in dissimilar directions which diminish the measure of beam falling on the object captured underneath. The end effect of spreading outcome is that the undersea captured descriptions are dim in look [2]. A further problem is causal to lack of clarity of picture that the water molecules take up certain measure of beam when beam hit on them. Because the mass of water is larger than air, it employs dissimilar absorption possessions for diverse beam wavelengths, so the color of undersea descriptions is typically deformed. Generally, red part vanishes first as of its highest wavelength, where blue beam, by small wavelength, convey the greatest path beneath water. Therefore, undersea descriptions are often dominated via blue color. In common, color cast and beam scattering reason deviate color along with contrast degradation into descriptions attained undersea as shown in Figure 1.

In contrast, our system uses dual phases specifically Adaptive Regularization for restoration and Hybrid technique intended for improving its quality. In this work we suggested for merging the thought mainly dictionary knowledge by structural cluster along with picture restoring functions.

Our advance establishes novel regularization to beat a superior stability among local and non-local strength. Generally, our algorithm interprets learning through local and non-local similarity give inference of each picture elements. The restored picture decomposes into dissimilar elements for signifying their

[*]Chrispin Jiji, 8951627124 & chrispinjij@gmail.com

basic depiction, later uses diverse development for every part individually along with hybrid technique introduced for rebuilding enhanced picture. The projected process is close towards or even slightly superior to the state-of-the-arts. Tentative results exposed that projected process extensively outperforms many important process in existing arts.

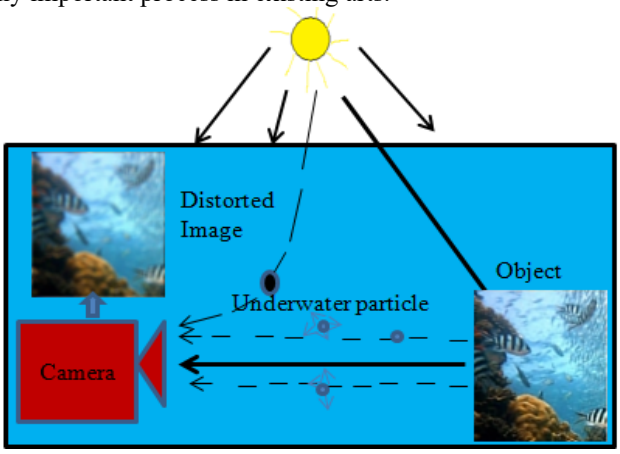

Figure 1: Underwater Imaging System

The summary of this work described as follow. Section 2 portray existing art. Section 3 projects hybrid technique using gradient guided filter for enhancing undersea descriptions. Section 4 illustrates numerical experiments. At last, Section 5 concludes this work.

2. Existing art

Enhancement system for undersea degradation typically explore the undersea optical form and balance bad possessions caused by water along with elements, or simply via undersea processing process for enhancing unclear imagery. State-of-arts are generally considered meant for single image enhancement, since multi-images may limit performance choice, slow down the processing speed. Instinctively, handling this concern well, undersea optical form must consider and investigated at first. Among different undersea imaging methods, the representation method [3], give a complete undersea optical form, within which beam transmission path, beam reduction relation of dissimilar color channel, vertical as well as horizontal deepness of undersea surroundings, non-natural beam possessions and etc are in use. This process is entirely with real form and meet outstanding for a few undersea problems, conversely, its evaluation procedure is difficult and time overwhelming, which is hard to meet, but it gives a full-scale study of undersea surroundings. Fusion-based method, which combines processing outcome by color correction system and histogram equalization method, it also makes a superior outcome for several submerged environments, though, it merely uses scheme of image processing as well as ignoring submarine features, hence ending results undergo more or less fog, data defeat as well as over-enhancement difficulty. To explain these problems well, both processes combined and projected a new method. Semi-inverse approach in [4] employed towards perceiving foggy region and then expected atmospheric rate in plain areas. At last, they meet enhanced picture using a simple weighted fusion.

For few picture, particularly scenes underneath, mist exposure using semi-inverse system will be unsuccessful suitable to the small dissimilarity among true and the inverse picture. This means if hazy region exposure not succeeds and obtains a bad performance. To solve this problem, a simple fusion-based dehazed method using a dissimilar descriptions also resultant from true picture [5], [6]. The primary picture estimate white balance process, and the next input picture through a simple linear change for enhancing contrast of hazy picture. At last, the pixel-fusion scheme uses three weight maps for combining that imagery for enhancing visibility of foggy picture also extended fusion-based scheme [7]. Fusion-based dehazed procedure is easy, speedy as well as meets alike result as the DCP scheme in [8] and [9]. But it is not succeeding when the picture includes inhomogeneous haze. The cause is that this process did not take into account the deepness data of a hazy picture. The dual descriptions attained by gamma correction by various scales for sandstorm enhancement [10]. The enhanced fusion-based approach using various descriptions uses single picture dehazed scheme in [11]. Fusion approach is new and efficient intended for single picture defogging. The primary picture is for enhancing dissimilarity; in addition, later picture mainly for compensating color deformation as well as decrease halo effect plus noise. While above techniques are fast as well as simple, they cannot make excellent picture. Amusingly, the multi-scale progression can be approximated with well-organized and visually satisfying single-scale process [12]. HR fusion in [13] has to be measured as a possible balance, useful to our process when high resolution is required.

The algorithm [14] are effective methods with low computational complexity also great performance, which stretch histograms of picture for improving the dynamic range compress the display area towards enhancing dissimilarity, but these methods often cause over-enhancement, amplify the noise and show poor effect on color correction. Owing towards the drawbacks of single image processing, some relatively complicated methods are proposed. Meanwhile, [15] proposes a retinex-based approach to deal with undersea issues, however, performance of this system is not distinct, color cast as well as contrast degradation still exist. The system may guess a uniform [16, 17] or an extra reasonable non-uniform [18] background-radiance. Enhancement technique eliminates the colour cast [19, 20] with overall white balancing.
This work is extensive to the effort primarily obtained through ICCIC [21]. Moreover, the projected work is for Enhancing Underwater Image in blurry conditions using hybrid technique. Revised outcome much improves lighting plus color cast trouble during submerged descriptions. Excellence process not essential to resolve substantial type of corrupted representation, other than fairly enhances dissimilarity also gets superior picture excellence as individual illustration view. Experimental results show good performance meant for underneath representation.

2.1. Motivation

Underwater distorted descriptions typically to explore optical model also compensating bad effects caused by underwater element uses processing scheme to restore performance of distorted images. The state-of-arts are mostly designed for single-image enhancement, since multi-images may limit performance range and slow down processing speed. Towards handling this problem well, initially we considered Image re-establishment process. The physical system of ocular imaging, reverse

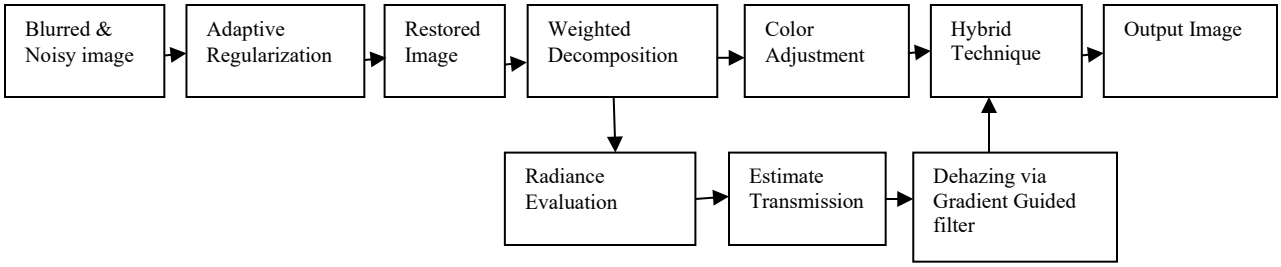

Figure 2: Block diagram of Proposed Method

degradation process and balance distortion to get clear imagery but it has small visibility and color cast problem. Image enhancement process do not get the source of picture degradation into account, but mainly use targeted version to get better dissimilarity, detail, and ocular possessions. It provides complete undersea ocular form, where the illuminated transmission path, beam reduction of dissimilar color path taken into concern totally based on physical model and achieves excellent for some underwater backscatter issues. However, its evaluation development is difficult and time-consuming, but it gives full-scale analysis of undersea situation. To enhance dissimilarity, visibility, color spread of restored imagery, fusion-based model which boost picture by fusing several input imageries have received much attention. The processing results by color constancy and dehazed algorithm, generates good results. However, it only uses technique of image processing and so its results suffer from more or less haze, information failure as well as over-enhancement problem.

In order to solve this issue well, we proposed a Hybrid Technique for Enhancing Underwater Image in blurry conditions by joining dehazed technique via gradient guided filter with color balance of the restored imagery.

3. Proposed Method

As depicted in Figure 2 our new scheme primarily to Enhance Undersea picture in blurry conditions using hybrid technique. Initially, we recreate the picture using adaptive regularization. Secondly, we split reconstructed picture using weighted decomposition. Thirdly, improve contrast and texture information using Dehazing via gradient guided filter. Here we estimate global radiance by obtaining average rate vector as brightest rate, transmission map evaluation mainly for enhancing texture feature. Fourth, a color adjustment towards enhancing color. At last, we used hybrid technique for obtaining better picture by computing the mechanisms of dual weights in addition to efficient.

3.1. Adaptive Regularization for Restoration

For an image $d \in P^{HXW}$, we believe patch based depiction $d_m = Pd \in P^N$, $m = 1,2,.....N$ where P indicates a parameter to extract patch d_m as of d . Suppose a known dictionary φ_m meant for d_m , we get $d_m = \varphi_m \alpha_m$ entails α_m as sparse depiction of d . In particular, restoration describes

$$D = \left(\sum_{i=1}^{N} P_i^T P_i \right)^{-1} \left(\sum_i P_i^T d_i \right) \tag{1}$$

The iterative shrinkage key towards l1-estimation is widely used in previous art. Since the evaluation of $\hat{d}$ get simplified by convergence, trained by a novel dictionary. At present let us include adaptive regularization term [22, 23]. For every patch d_m k-nearest-neighbors patch signify $d_m^{(1)},.....d_m^{(k)}$. The weighted guess is representing

$$\hat{d_i} = \sum_{t=1}^{k} w_{m,t} D_i^{(t)}, w_{m,t} = \exp\left(-\left\| D_m - D_m^{(t)} \right\| / h \right) \tag{2}$$

where h stands for constant to manage the window. Since (2) local form by picture roughly considered with

$$D_L(d) = \sum_{m=1}^{M} \left\| d_m - a_{k_m}^T \chi_m \right\|_2^2 \tag{3}$$

In matrix type (3) represents

$$D_L(d) = \sum_{m=1}^{M} \left\| (I - V) d_m \right\|_2^2 = \left\| (I - V) \varphi \alpha \right\|_2^2 \tag{4}$$

where I specify identity matrix and

$$V(m,n) = \begin{cases} a_i, if\ d_n \text{ is an element of } \chi_m, a_m \in a_{k_m} \\ 0, \text{ otherwise} \end{cases} \tag{5}$$

It follows from (2) that the nonlocal similarity in a picture roughly considered through

$$D_{NL}(d) = \sum_{m=1}^{M} \left\| d_m - \sum_{t=1}^{k} w_{m,t} d_m^{(t)} \right\|_2^2 \tag{6}$$

which can be written more efficiently in a matrix type as

$$D_{NL}(d) = \sum_{m=1}^{M} \left\| (I - W) d_m \right\|_2^2 = \left\| (I - W) \varphi \alpha \right\|_2^2 \tag{7}$$

Where I stands for the identity and

$$W(m,l) = \begin{cases} b_i^l, if\ d_m^l \text{ is an element of } \beta_m, b_m^l \in b_m \\ 0, \text{ otherwise} \end{cases} \tag{8}$$

Joining (4) and (7), we have the next novel regularization as

$$\hat{\alpha} = \arg\min \left\{ \left\| d - H\varphi\alpha \right\|_2^2 + \sum_{m=1}^{M} \sum_{n=1}^{N} \lambda_{mn} \left| \alpha_{m,n} \right| \right\} + \gamma \left\| (I - V) \varphi \alpha \right\|_2^2 + \eta \left\| (I - W) \varphi \alpha \right\|_2^2 \tag{9}$$

where a novel regularization factor η manage stability among local variation with nonlocal strength. The nonlocal regularization term not only imposes nonlocal similarity however as well not directly assist the evaluation of signal variance essential with λ_{mn} as $\lambda_{mn} = \frac{2\sqrt{2}\sigma_w^2}{\left|\hat{\sigma}_{m,n}\right| + \varepsilon}$ where $\sigma_{m,n}$ and σ_w signifies the variance of signal and noise correspondingly.

3.2. Weighted Decomposition

Weighted decomposition used to separate imagery into various parts and then perform several schemes according to their characteristics. Techniques like wavelet transform and weighted decomposition are most well-liked process. Former scheme is time consuming and cannot take out the characteristics. Later on initiate a weighted decomposition means, which divide true picture into dual part, one conveys the illuminant part as another states the reflectance part of picture as:

$$I_c(d) = I_c^R(d) + I_c^I(d) \tag{10}$$

where $c \in \{r,g,b\}$ signifies every color part of picture, $I_c^R(d)$ denotes reflectance part and $I_c^I(d)$ represents illumination part.

$$I_c^R(d) = \Upsilon . I_c(d) \tag{11}$$

$$I_c^I(d) = (1-\Upsilon) . I_c(d) \tag{12}$$

where Υ denotes weighted factor which improve the dissimilarity of reflectance part for removing backscatter as

$$\Upsilon = \xi . \frac{I_c(d)}{I_c^{\max}} \tag{13}$$

Where $I_c^{\max}$ denotes maximal pel rate of color, ξ signify a direct cause by resolving reflectance weight, $\xi \in (0,1)$, if $\xi = 0$, the entire picture treated as illuminate part, while $\xi = 1$, the entire picture is denoted by reflectance part.
The backscatter outcome simply exists with illuminate part, whereas reflectance part simply experiences as of color deformation.

3.3. Radiance Evaluation

To approximate background beam, a supreme approach is to select a picture element, while color deformation and dissimilarity degradation are distance dependent. Though, in this system, scenes are vivid than surrounding beams, may perhaps an unwanted collection outcome. To get precise outcome, we exploit a hierarchical searching means using quad-tree subdivision [24]. Initially, the picture broken up into four identical rectangular areas, after that used for all area by estimating mean rate subtracted from standard deviation as

$$Score_l = \frac{1}{3N} \sum_{c\in\{r,g,b\}} \sum_{d=1}^{N} I_l^c(d) - \frac{1}{3} \sum_{c\in\{r,g,b\}} \sqrt[2]{\frac{\sum_{d=1}^{N} \left(I_l^c(d) - \bar{I}_l^c \right)^2}{N}} \tag{14}$$

Where $l = 1,2,3,4$ stand for four image areas, N denotes the picture element number contained by the area, $I_l^c(d)$ signifies picture element of d rate c section in l area, $\bar{I}_l^c$ represents mean picture element rate of c part in l area. Later, we choose the area by least variance, as well as split into quadrant areas. This procedure continues until the size is smaller than threshold. The average rate attained as surrounding beam and considered as brightest rate with the complete representation.

3.4. Estimate Transmission

The transmission rate cannot be selected randomly; dissimilarity improvement with data defeat lessening must chose keen on concern. First, dissimilarity improvement cost task, E_c, with data loss cost task E_i reduce dual function concurrently, while dissimilarity improvement cost as negative summation of C_{MSE} of every color channels, furthermore data defeat cost as summation of square of reduced picture elements as

$$E_c = -\sum_{c\in\{r,g,b\}} \sum_{d=1}^{N} \frac{\left(J_c^T(d) - \bar{J}_c^T \right)^2}{N} = -\sum_{c\in\{r,g,b\}} \sum_{d=1}^{N} \frac{\left(I_c^T(d) - \bar{I}_c^T \right)^2}{N.t(d)^2} \tag{15}$$

$$E_i = -\sum_{c\in\{r,g,b\}} \sum_{d=1}^{N} \left\{ \left(\min\left\{0, J_c^T(d)\right\} \right)^2 + \left(\max\left\{0, J_c^T(d) - 255\right\} \right)^2 \right\} \tag{16}$$

At last, for every local region the best transmission rate $t(d)$ is approximated by reducing the later task as,

$$E = E_c + \gamma . E_i \tag{17}$$

where γ denotes weighted factor to organize the control of data loss cost.

3.5. Dehazing via Gradient Guided Filter

The Guided filter in [25] refine transmission map but cannot signify fine next to a few boundaries. While there might be a few halos in the descriptions. The halos decrease the visual excellence of the resultant descriptions. Hence Gradient guided filtering is an effectual and process transmission map, use input picture as guidance can have executed by linear system as

$$(L + \lambda . U) . t = \lambda . \tilde{t} \tag{18}$$

where L represents matting Laplacian matrix, U denotes identity matrix, and λ signify regularization factor. The Laplacian matrix represents

$$L_{ij} = |\omega|\left(\delta_{ij} - W_{ij}\right) \tag{19}$$

where $|\omega|$ stands for number of picture elements in a block, δ_{ij} denotes Kronecker delta, and W_{ij} represents gradient guided filter [26] kernel weight as:

$$W_{ij} = \frac{\left(\chi\left(D^{'}\right)+\varepsilon\right)}{mn}\sum_{p}^{m}\sum_{p}^{n}\frac{1}{\chi\left(D^{'}\right)+\varepsilon} \tag{20}$$

where $\chi\left(D^{'}\right) = \sigma_{G,1}\left(D^{'}\right)\sigma_{G,\xi_1}\left(D^{'}\right)$, ξ_1 denotes dimension of filter and D signify guidance picture.

To reach a precise transmission map as well as fine points, the advanced diffusion map split up into smooth and detailed part as

$$t = t_{smooth} + t_{\det ail} \tag{21}$$

where t_{smooth} signify smooth part of transmission map while $t_{\det ail}$ denotes detailed part. For smooth part, we obtain Gaussian low-pass filter as effective smoothing filter, and denoted as:

$$G\left(d,b\right) = \frac{1}{2\pi\sigma^2}.e^{\frac{\left(d^2+b^2\right)}{2\sigma^2}} \tag{22}$$

where σ denotes scale factor of Gaussian blur. Therefore, the smooth and detailed part can estimate as

$$t_{smooth} = t * G \tag{23}$$

$$t_{\det ail} = t - t_{smooth} \tag{24}$$

Following, the improved transmission map evaluated as:

$$t_{enhanced} = t_{smooth} + \alpha.t_{\det ail} \tag{25}$$

where α represents the enhancement factor to manage the improved measure of detailed part.

3.6. Color Adjustment

The reflectance part returns the texture and fine points of submerged picture, and only undergoes color deformation caused with energy absorption underneath. Simplest color adjustment [27] is an outstanding means for confirming vast stability among adjustment concert in addition to data loss. The energy absorption in undersea causes color distortion. To overcome this problem, simplest color balance scheme for only extend the picture element of color means whereas conserve data as much as probable with physically set dissimilar truncation relation of color channel, so their histograms are capable towards maximum range [0,255]. For quick stretch, apply an affine transform function on each color channel for mapping picture element from 0 to 255. Though, only some unusual pels previously map most and least standards, for improving color act with small picture element by peak and least rates prior to affine transform task. In fact, this procedure source extra or less white and black area may seem to be not natural. In general, this algorithm not focuses for proper color allotment, but give color adjustment with contrast to some degree.

3.7. Hybrid Technique

A hybrid technique mainly combines dual imagery to generate clear representation. The vital task is mainly for computing weight maps of descriptions furthermore joins them mutually by luminance, saliency along with exposedness weight map for deriving normalized weighted maps [28].

Luminance weight map [29] represents luminance factor of every picture part, created with computing STD among color channels along with luminant rate, where luminant rate l represents:

$$l = \alpha.r + \beta.g + \gamma.b \tag{26}$$

where $\alpha + \beta + \gamma = 1$, each denotes weight constraint of color part.

It is capable for exactly reflect luminant measure of picture and illustrate better improvement; it confirms negative possessions on contrast and colourfulness. Headed for avoiding these, introduces successive weight maps.

Saliency weight-map [30], reflects salient things and points, intends to highlight this discerning submerged sight. Main drawback is for overestimating important area, as a result exposedness weight-map exploits to assure precision as well as defend middle color in picture.

Exposedness weight-map [30], assess significance of exposed picture elements. It protects local dissimilarity be non-exaggerated or non-understated. In general, picture element rates close to average rate are likely to have superior look. Gaussian-modelled remoteness to average rate represents

$$W_E = e^{-\frac{\left(I(d)-\bar{I}\right)}{2\sigma^2}} \tag{27}$$

where σ denotes standard deviation, $I(d)$ signify pel rate set at location d and $\bar{I}$ represent mean rate. As a result, the entire weight maps proficient for generating fine look for output imagery. The normalized weight map is simply computes:

$$W_{norm} = \sum_{k=1}^{K} W_k \tag{28}$$

where W_k specify the kth weight map.

The last free backscatter and color deformation picture be derived as:

$$R_c = \sum_{n=1}^{N} W_{norm}^{n}.J_c^n \tag{29}$$

where R_c denotes color part of fused image, J_c^n signifies color part of nth input. To get enhanced output, we basically exploit a multi-scale pyramid decomposition system for achieving fusion technique. The joint development represents

$$R_c^l = \sum_{n=1}^{N} G^l\left\{W_{norm}^n\right\}.L^l\left\{J_c^n\right\} \tag{30}$$

where $L^l\left\{J_c^n\right\}$ denotes Laplacian pyramid of color part of n^{th} input representation, $G^l\left\{W_{norm}^n\right\}$ is n^{th} stabilized weight map and l represents pyramid stages. While this scheme achieves quite rapid with the enhanced output image can make excellent result.

4. Experimental Results and Analysis

The projected technique evaluates the state-of-art processes; by imagery composed as of representational undersea test imagery and dissimilar metrics utilized to compare enhancement performances of these processes.

4.1. Qualitative Evaluations

To verify the effectiveness adaptive regularizations, we primarily use reconstruction outcome taking place in picture *seer* with projected technique in Figure 2. Adaptive regularization shows improved results to remove ringing artifacts near boundaries. The projected technique in Figure 3 composed of adaptive regularization to reconstruct the imagery, weighted decomposition process to separate illuminant and reflecting part. The illuminant part is to improve contrast and texture details using dehazing via gradient guided filter. The reflecting part is to enhance color using color adjustment. Finally, Hybrid technique used to enhance the result. As of Figure 4 weights of dual mechanisms applies a proficient technique for attaining excellence picture. In order to represent different features, we used numerous weight map process to compute the descriptions of true imagery and then join to obtain normalized weight maps. Evaluation of a projected scheme with existing technique shown in Figure 5. The scheme in [21] better reconstructs the picture but fails to enhance its visibility. The scheme in [14] fails to correct and enhance visibility of degraded picture, amplify noise as well as show poor effect on color adjustment. The process in [15] over-enhance distorted picture, which causes severe, color distortion along with noise amplification, thus integral performance of enhanced picture is worse. The scheme [30] gets good result, not only correcting the color casting but also enhancing the contrast for removing haze. Though, dissimilarity is overstretched in [24], a few picture elements reduced using over-flow or under-flow. The over-enhancement problem in [25] for test images and some information loss exist as well as in boundary effect due to guided filter introduced. Our projected technique is close towards or even somewhat improved than state of the arts. The RGB color space of dissimilar patch dimension in Figure 6 attains fewer pel map result. Moreover, RGB color space in Figure 7 of original imagery with improved results that all the pels of original picture maps into RGB color space gather in left corner, where is large green rate and small blue and red rate, and other method make more or less stretch of the pixel mapping results. The mapping outcome of our scheme is most excellent and it maps the largest area in the RGB color space, which means it has the best integral dynamic compression range. However, many mapping pixels of our method mapped the boundary, i.e., dark region and brightest region, it indicates that there is information loss of our method.

4.2. Quantitative Evaluations

The submerged quality metrics for evaluating and analyzing excellence of underneath imagery, including gray mean, standard deviation, mean gradient etc. The gray mean rate of an image reflects integral intensity, and higher the gray mean is, higher the intensity is, while standard deviation of a picture reflects high frequency part of a picture, which relates picture contrast, higher the standard deviation is, higher the contrast is as well as greater color data. Meanwhile, [31] show that a picture shows good integral quality when gray mean among 100 and 200 and its standard deviation among 35 and 80 after they analyzed and statistic a large measure of imagery. Mean gradient reflects speed of the changes of minor details in picture; it can represent the features of texture transform and the degree of clearness well. Table 1 review metric outcome for reconstruction used for different patch dimension also patch by small dimension offer better result. Following, Table 2 achieves best results in [15], μ_{RG} and $\boldsymbol{\mu_{YB}}$ which are close to zero. The largest $\boldsymbol{\sigma_{RG}}$ in [25], largest $\boldsymbol{\sigma_{YB}}$ in original imagery. Overall, our method obtains the highest score after computing the PSNR, SSIM, UICM, UIConM and UIQM value, lowest score in SSIM. Consequently, projected system is better than existing system giving enhanced outcome.

$$Mean = \frac{1}{UV}\sum_{u=1}^{U}\sum_{v=1}^{V}E(u,v) \tag{31}$$

$$\sigma^2 = \frac{1}{UV}\sum_{u=1}^{U}\sum_{v=1}^{V}\left\{E(u,v)-Mean\right\}^2 \tag{32}$$

$$AG = \frac{1}{UV}\sum_{u=1}^{U}\sum_{v=1}^{V}\sqrt{\frac{\left[E(u,v)-E(u+1,v)\right]^2+\left[E(u,v)-E(u,v+1)\right]^2}{2}} \tag{33}$$

Where σ^2 denotes standard deviation, *Mean* represents mean picture element, *AG* represents mean gradient and *UV* signify amount of picture elements. Efficient metric UIQM composed of three independent measurements [32-34] as described below.

a) Undersea Image Colorfulness Measurement (UICM)

The performance of color correction used for evaluating performance of undersea picture improvement progression, with red-green (rg) along with yellow-blue (yb) color parts are used:

$$rg = r - g \tag{34}$$

$$yb = \frac{r+g}{2} - b \tag{35}$$

Considering that submerged picture often suffers heavy noise, the asymmetric alpha-trimmed statistical standards [35] used for measuring submerged picture colorfulness,

$$\mu_{rg} = \frac{1}{N - T_L - T_r}\sum_{x=T_L}^{N-T_r} Intensity_{rg}(x) \tag{36}$$

where N signify total number of pels in the rg part and all pels sorted as $x_1 < x_2 < ..... < x_N$, $T_L = \alpha_L N$ and $T_r = \alpha_r N$ are the amount of least and most picture element to be reduced as of

sorted order $x_1 < x_2 < ..... < x_N$. The average rate μ_{rg} corresponds to chrominance gray, and average rate close towards nil in rg-yb color part imply superior for balancing color. Further, the second-order statistic variance is defined by:

$$\sigma_{rg}^2 = \frac{1}{N}\sum_{x=1}^{N}\left(Intensity_{rg}(x) - \mu_{rg}\right)^2 \quad (37)$$

σ_{rg}^2 represents the pixel activity. The first and second order statistic information μ_{yb} and σ_{yb}^2 of the yellow-blue part be computing in similar way. The whole, colorfulness coefficient parameter is expressed as

$$UICM = -0.0268.\sqrt[2]{\mu_{rg}^2 + \mu_{yb}^2} + 0.1586.\sqrt[2]{\sigma_{rg}^2 + \sigma_{yb}^2} \quad (38)$$

b) Undersea Image Sharpness Measurement (UISM)
Sharpness reflects details and edges of an image, and fine captured images are likely to show better sharpness. For more efficient, enhancement measure estimation (EME) as

$$EME = \frac{2}{s.t}\sum_{K=1}^{s}\sum_{L=1}^{t}\log\left(\frac{I_{\max,K,L}}{I_{\min,K,L}}\right) \quad (39)$$

where picture divided by $s.t$ blocks, and obtain the maximal and minimal pel values in each block, $\frac{I_{\max,K.L}}{I_{\min,K,L}}$ indicates comparative dissimilarity relation in every block. Then the undersea image sharpness measure (UISM) can be written as:

$$UISM = \sum_{c=1}^{3}\lambda_c.EME\left(grayscale\ \text{edge}_c\right) \quad (40)$$

where λ_c stands for weight coefficient of each color part.

c) Undersea Image Contrast Measurement (UICM)
Intended for submerged descriptions, dissimilarity Distortion is usually happened with backscattering. The contrast performance be measured by:

$$\log AMEE = \frac{1}{s.t}\sum_{K=1}^{s}\sum_{L=1}^{t}\frac{I_{\max,K,L} - I_{\min,K,L}}{I_{\max,K,L} + I_{\min,K,L}}.\log\left(\frac{I_{\max,K,L} - I_{\min,K,L}}{I_{\max,K,L} + I_{\min,K,L}}\right) \quad (41)$$

and submerged picture contrast measure be written as:

$$UIConM = \log AMEE\left(\text{I}ntensity\right) \quad (42)$$

d) Undersea Image Quality Measurement (UIQM)
Undersea descriptions modelled as linear superposition of absorbed as well as spreaded part. Meanwhile, absorption and scattering by dusk-like particles causes color casting, sharpness attenuation with dissimilarity distortion. Consequently, logical use of linear form to create entire UIQM as:

$$UIQM = \alpha.UICM + \beta.UISM + \gamma.UIConM \quad (43)$$

where α , β , and γ signifies weight coefficients to organize each measure as well as balance their values.

5. Conclusion and Future Work

This work is mainly for Enhancing undersea representation in blurry conditions using Hybrid technique. Our scheme composed with Adaptive regularization for recreation, weighted decomposition procedure to separate recreated imagery into color change along with dehazed schemes separately, then multi-scale fusion technique towards enhancing picture. The strong with effective Hybrid technique which incorporate the description of all fused imagery into resultant outcome constitute backbone of projected scheme. In fact, the projected scheme generally beats other methods in terms of qualitative as well as quantitative evaluations. Our technique confirms excellent act for undersea imagery, but border effect cause data loss. Meantime, our technique does not outperform some of the state-of-art system and even direct over improvement for precise cases. The challenging work for future would be to find out a well-organized means to about vertical deepness and optimize the transmission deepness of undersea imagery more precise, at last build up absolute, effective and well-organized system.

Conflict of Interest

The authors declare no conflict of interest.

ABSTRACT

eSign is an online electronic signature service which is recently gaining more prominence in India. eSign is based on two online services from UIDAI, viz. a viz., Aadhaar based authentication and retrieval of resident's eKYC information after taking his/her consent. With increased adoption of Aadhaar based services, privacy of user data has become more and more important. Present method of taking boolean consent from resident through non-UIDAI entity may not be acceptable for two main reasons, first is that the consent does not include in itself a proof from resident that the consent is indeed taken from him/her and second is that the resident may wish to have better privacy and fine grained access control rules to access his/her eKYC data. Bakshi et.el have introduced a mechanism to improve amortized performance of eSign using a digital access token. In this work, the digital access token is enhanced to include Privacy Enhancing and Fine-Grained Access Control (PEaFGAC) Statements for facilitating Privacy Aware eSign. These tokens can be used by other entities to access eKYC data of the resident with better access controls enforced by the resident. This paper briefly describes the present model of eSign, the earlier proposed model of eSign followed by the proposed model of Privacy Aware eSign. The proposed model of Privacy Aware eSign is also analyzed using BAN logic assuming Dolev-Yao security environment.

1 Introduction

eSign is an online electronic signature service in India which is being promoted by Government of India as part of its Digital India Initiative. As opposed to traditional dongle based electronic signature, *eSign* provides benefits such as less cost, no manual authentication, no requirement of special hardware device and no requirement for the end user to keep any key secret. With the passage of *Information Technology Act (ITA-2000)*, an electronically signed digital document is considered equivalent to a handwritten signed paper document. In India, *eSign* is being regulated by *Controller of Certifying Authority (CCA)* and is being operated by certain designated empaneled agencies known as *eSign Service Providers (ESP)*. *ESP* provides its services to application specific agencies known as *Application Service Providers (ASP)*. *ASP* provides *eSign* service to the end users. *eSign* is governed by *Public Key Infrastructure (PKI)* which is further governed in legal matters by the national legislature of the country.

To avail *eSign* service, a resident needs to enroll with *Unique Identification Authority of India (UIDAI)* and receive a 12-digit identity number called *Aadhaar* [1] [2]. As part of the enrollment process, resident needs to provide information about his/her identity and address to *UIDAI* such as *Name*, *Date of Birth*, *Address*, *Phone number*, *Email-id*, *Biometric (fingerprint-scan, iris-scan)* etc. The process of obtaining this information from the end user is known as *Know Your Customer (KYC)* and is initially introduced by *Reserve Bank of India (RBI)* for financial banks [3]. Traditionally, this process involves submission of a self-attested physical form along with necessary physical documents, followed by verification and approval by receiving organization. eKYC is an online service which facilitates completion of KYC process electronically. eKYC has some significant benefits over traditional KYC, eKYC eliminates submission of physical documents by customer, is faster and is less error prone. *UIDAI*'s eKYC service facilitates a third entity to retrieve resident's identity, address and other details after taking explicit consent and authorization from the resident.

With increased adoption of *Aadhaar* based identification,

*Corresponding Author: Puneet Bakshi, IIT Guwahati, b.puneet@iitg.ac.in

many online services are now using *Aadhaar* based services and with its such wide adoption, privacy of user data has become even more important. Although *Aadhaar* based eKYC service provides access to eKYC data only after taking an explicit consent from the resident, this way of taking consent from resident has two shortcomings. First is that the consent is taken by *non-UIDAI* entity and does not encode in itself a proof from resident that the consent is indeed given by the resident. Second is that providing a boolean consent is too broad, either an unconditional access is given to the whole eKYC information or no access is given at all. A resident may wish to have a better privacy enhancing fine-grained access control to his/her eKYC data. Resident may wish to define a privacy and access control policy dictating the *scope* of information which can be provided, the *purpose* for which the information can be provided and *recipients* to whom the information can be provided. For example, a resident may wish to disclose only his/her name and address, only for electronic signature purpose and only to a specific *eSign* Service Provider.

In [4], the author explained two limitations of present *eSign* model. The first limitation is that the eKYC data access reflects a restrictive *self-only*, *full-resource* and *unlimited* access control. Author pointed out that a resident may wish to have a better access control mechanism which allows third entities to access part of a resource which is to be used for a specific purpose and for a limited time period. The second limitation is that for each *eSign* request, resident has to authenticate itself each time and to include the authentication proof in each such request. Author pointed out that if a resident needs to *eSign* multiple times, time taken by initial authentication phase will be a major bottleneck. The author proposed that amortized performance of eSign can be improved using *digital access token* which encodes in itself the authentication proof and other information such as how many *eSign* requests can be made using this token and the expiry time of the token.

This paper is an extension of [4] and the digital access token is enhanced to implement *Privacy Aware eSign*. Our main contribution in this paper is to introduce a method to implement *Privacy Aware eSign* using *Privacy Enhancing and Fine-Grained Access Control (PEaFGAC) Statements*. A resident can encode these statements in digital access token for better access to his/her eKYC data. This token can be provided to third entities so that they can present this token for claiming protected resource from *UIDAI*. This paper also presents security analysis of the proposed scheme using *Burrows-Abadi-Needham (BAN)* logic. The analysis shows that in the proposed scheme, even if the network is unreliable, the exchanged information is reliable and is secured against eavesdropping.

The remainder of this paper is organized as follows. Section 2 presents related work. Notations used in the paper are reported in figure 1. Section 3 presents Aadhaar based eKYC service. Section 4 presents *eSign* version 2.0 model. Section 5 presents *eSign* model proposed in [4] to improve amortized performance of *eSign*. Section 6 presents proposed *Privacy Aware eSign* model using privacy enhancing and fine-grained access controlled eKYC. Section 7 presents formal security analysis of the proposed model using *BAN logic* and finally section 8 concludes the paper.

$\{X\}_Y$	X is signed by key Y
SK_Y	Symmetric key of entity Y
SK_{Y_Z}	Symmetric key shared by entities Y and Z.
PR_Y	Private asymetric key of entity Y
PB_Y	Public asymetric key of entity Y
R_i	Resident
ASP_i	Application Service Provider
ESP_i	eSign Service Provider
$UIDAI$	Unique Identification Authority of India
ID_{R_i}, ID_{ASP_i} ID_{ESP_i}	Identities of R_i, ASP_i and ESP_i
TID_{ESP_i}, TID_{ASP_i}	Unique transaction identifiers generated by ESP_i and ASP_i
PW_{R_i}	Password of R_i for login to ASP_i portal
$AadhaarNo_{R_i}$	Aadhaar No of R_i
C_{R_i}	Cookie associated with R_i's logged-in session, assigned by ASP
PR_{B_i}, PR_{ASP_i} PR_{ESP_i}, PR_{UIDAI}	Private keys of R_i browser, ASP_i, ESP_i and $UIDAI$
PB_{B_i}, PB_{ASP_i} PB_{ESP_i}, PB_{UIDAI}	Public keys of R_i browser, ASP_i, ESP_i and $UIDAI$
$n*_!$	nonces such as $n1_{ASP_i}$, where $*$ is any integer and ! can be R_i, ASP_i, ESP_i or $UIDAI$
$DataR_i(DataA_i,$ $DataE_i, DataU_i)$	Intermediate data in plaintext to be send by R_i (ASP_i, ESP_i, $UIDAI$)
$SignR_i(SignA_i,$ $SignE_i, SignU_i)$	$\{H(DataR_i)\}_{PR_{Ri}}$
$consent_{use_ekyc}$	Consent from resident whether his/her eKYC can be used
$consent_{genuse_at}$	Consent from resident whether a digital access token can be generated for later use
$License_{ASP_i}$ $License_{ESP_i}$	License for ASP_i (ESP_i) to use services from ESP (UIDAI)
M_i	Message (in plaintext) to be eSign
DSC_{Ri_Mi}	Digital Signature Certificate generated for message M_i for resident R_i
$\{M\}_{eSign_R_i_ESP_i}$	eSigned message (by R_i) through ESP_i
$H()$	One way cryptographically secure hash fn
$\|\|$	Concatenation operator
$\oplus$	XOR operator

2 Related Work

Digital tokens are increasingly being used in many cryptography related applications to achieve varied objectives.

U-Prove [5] is an identity management solution based on blind signatures [6] which uses digital tokens to achieve objectives of privacy and anonymity. *U-Prove* consists of two protocols, viz., issuance protocol and presentation protocol. In issuance protocol, identity provider issues digital token to the subscriber which (s)he can later present to the verifier in presentation protocol so that the service provider can grant resource access to the subscriber. A *U-Prove* token consists of a unique token identifier, a public key of the token which aggregates information in the token, a token information field which encodes token specific information, a prover information field which is opaque to the issuer, issuer signature on all the other token contents and a boolean value which indicates whether the token is protected by a device. *U-Prove* uses digital tokens effectively by encoding necessary information in it in cryptographically secure way to achieve objectives such as privacy and anonymity.

OAuth2 [7] is an authorization framework which allows delegation of access to protected resources to a third party by using digital tokens referred to as access tokens. Access tokens are issued to Clients by *Authorization Server* after taking permission from *Resource Owner*. An access token can be of two types, viz., a bearer token and a MAC token. A bearer token is an opaque string which can be used to claim access to a resource by any entity who presents the

token. A MAC token is essentially a shared symmetric key which is used to sign a challenge by the client to prove its possession of the token to authorization server. *OAuth2* uses digital tokens effectively for access delegation and is used by many organizations for data sharing.

Bitcoin [8] is a decentralized digital currency which can be transacted over peer-to-peer bitcoin network. A bitcoin network is composed of cryptographically secure linear chains of blocks with each block containing a header and a collection of transactions. A transaction is essentially a digital token that changes ownership of bitcoins from one entity to another. Each transaction in bitcoin network is broadly composed of three parts, viz., input, output and amount. Input refers to the previous owner of the bitcoins, output refers to the new owner of the bitcoins and amount refers to the amount of bitcoin that is transacted. Bitcoins uses cryptographically secure digital information containers (similar to digital tokens) effectively for the realization of digital currency.

Although Attribute Based Encryption (ABE) is also evolved to protect privacy of user data, it is based on Identity Based Encryption (IBE). An agency may not shift from PKI to IBE framework for a number of reasons.

3 Aadhaar based e-KYC service (v2.1)

Aadhaar based eKYC service is available to general citizens only through certain empaneled agencies such as *eSign Service Provider (ESP)* and the infrastructure network is secured by certain designated agencies known as *Authentication Service Agency (ASA)* and *KYC User Agency (KUA)*. eKYC service is hosted as a stateless REST based web service over HTTPS and the details are sent as input data encoded in XML. Figure 2 depicts Aadhaar's eKYC webservice as specified in eKYC v2.1 specification [9]. The specification provides following information about element *rc* which represents the resident consent.

"rc – (mandatory) Represents resident's explicit consent for accessing the resident's identity and address data from Aadhaar system. Only valid value is "Y". Without explicit consent of the Aadhaar holder application should not call this API [9]."

As can be seen from the specification, *rc* is a boolean consent and assumes that it has been transferred from resident to *UIDAI* unaltered. Although intermediate communication channels between various entities from resident to *UIDAI* are well secured and access to eKYC data is provided only after receiving explicit consent from resident, this way of taking consent from resident has two shortcomings. First is that the consent is taken by a *non-UIDAI* entity and does not encode in itself a proof from resident that it is (s)he who provided the consent. This is because residents do not have any registered tamper proof crypto device which can be used to encrypt user consent using resident specific PIN or password. Second is that providing a boolean consent is too broad, either an unconditional access is given to the whole eKYC information or no access is given at all. A resident may wish to have a better privacy enhancing fine-grained access control to his/her eKYC data indicating details on *scope*, *purpose* and *recipient*.

Figure 2: Aadhaar's eKYC 2.1 API

4 Present model of eSign in India

In *eSign* version 2.0 [10], a resident first registers itself with a front end application specific agency viz. a viz., *Application Service Provider (ASP)*. A resident can use either OTP based authentication or biometric based authentication. In case of OTP based authentication, OTP generation request is forwarded to *UIDAI* via *ASP* and *ESP*. *UIDAI* generates an OTP and sends it to resident's registered mobile number. In case of biometric based authentication, resident gets his fingerprint/iris scanned through a registered device. After authentication phase, resident now initiates an eSign request through *ASP* by providing it the consent to use his/her eKYC, the document to be signed and his/her *Aadhaar* number. *ASP* calculates cryptographic hash of the document and sends it along with the resident's consent and resident's *Aadhaar* number to *ESP*. *ESP* takes authentication proof from resident, creates a random symmetric key SK_{ESP_UIDAI} and a

Personal Identity Data Object (*PID*). *PID* encodes in itself the resident's authentication proof and the cryptographic hash of the *PID* object ($SHA256(PID)$). *ESP* first encrypts *PID* with SK_{ESP_UIDAI}, second encrypts cryptographic hash of *PID* ($SHA256(PID)$) with SK_{ESP_UIDAI} and third encrypts SK_{ESP_UIDAI} with public key of *UIDAI* (PB_{UIDAI}). *ESP* now wraps them in a new object called "Auth" and sends it to *UIDAI* in eKYC request. *UIDAI* provides eKYC information to *ESP*. Using received eKYC information, *ESP* generates a Digital Signature Certificate (DSC) and provides it to *ASP*. *ASP* provides the digitally signed document to the resident.

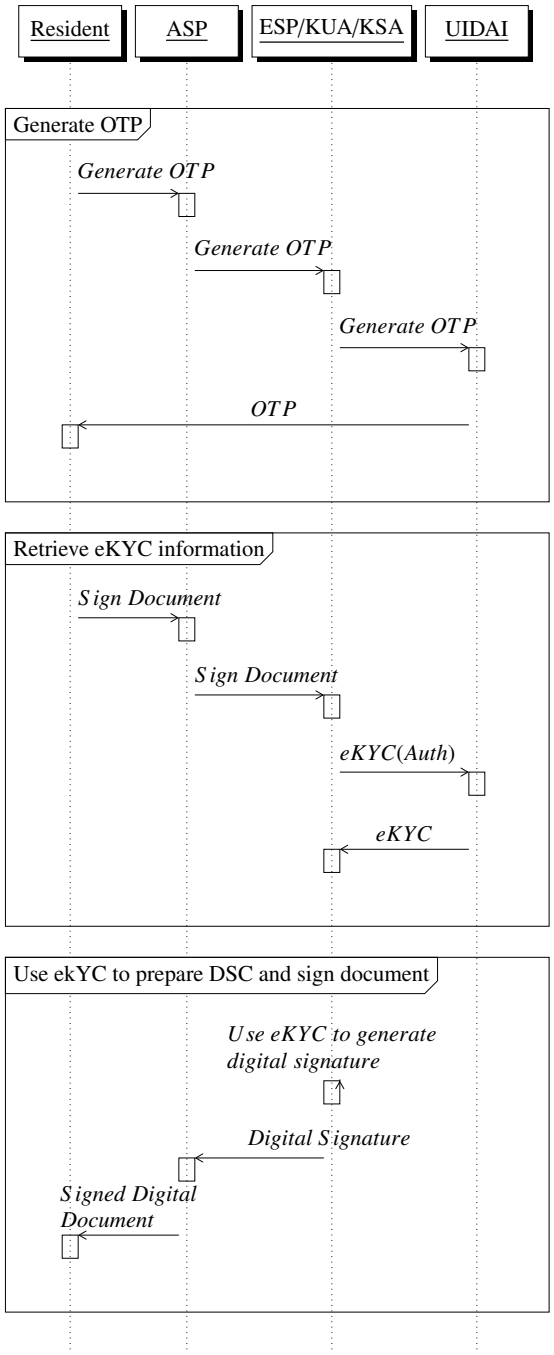

Figure 3: Sequence diagram of eSign 2.0

In practice, the initial authentication phase in *eSign* request is most time consuming since it involves either the manual text input (in case of OTP based authentication) or the physical scan of the fingerprint/iris (in case of biometric based authentication). Other than that, in some use cases such as *Create Birth Certificate*, *Create Death Certificate*, *Student Enrollment*, etc., the application is most heavily used during a certain time period (nearing the end of a deadline) which puts a sudden nationwide load on *UIDAI* services.

5 eSign model as proposed in [4]

In [4], author explained two limitations of present *eSign* model and proposed a mechanism to address the same. The first limitation is that in present model of *eSign*, eKYC data access reflects a restrictive *self-only*, *full-resource* and *unlimited* access control. Author pointed out that the resident may wish to have a better access control mechanism reflecting *third-entity-also*, *partial resource*, *use-limited* and *time-limited*.

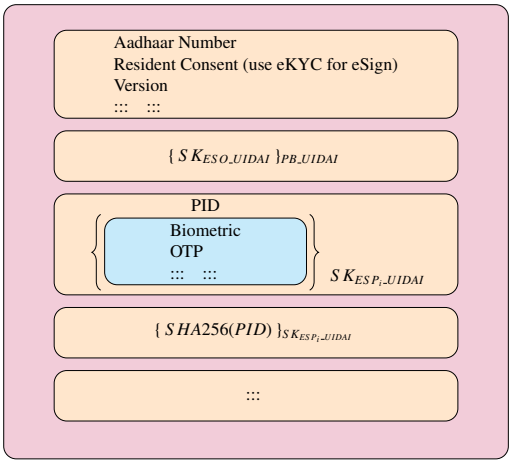

Figure 4: Auth Object (eSign 2.0)

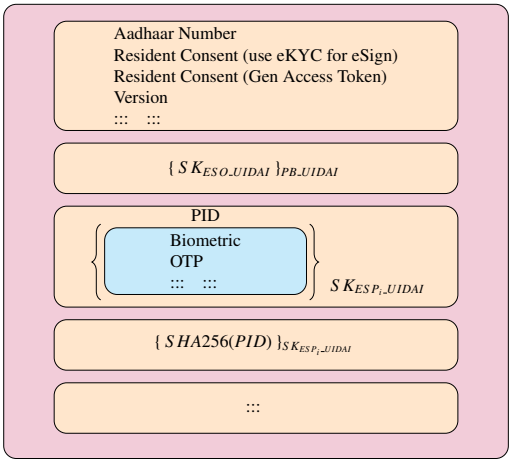

Figure 5: Auth Object as proposed in [4]

The second limitation is that a resident has to authenticate himself/herself for each *eSign* request and include the corresponding authentication proof in each *eSign* request.

If a resident wishes to *eSign* a large number of documents, the initial authentication phase will comprise most of the overall *eSign* time. After taking necessary consent from the resident, his/her authentication proof be stored with *ESP* in first request and is reused in rest of the requests.

A digital access token [figure 6] can be used to include claims from participating entities (*ESP* and *UIDAI*). A new service named *GenerateAccessToken* is proposed to be introduced by *UIDAI*.

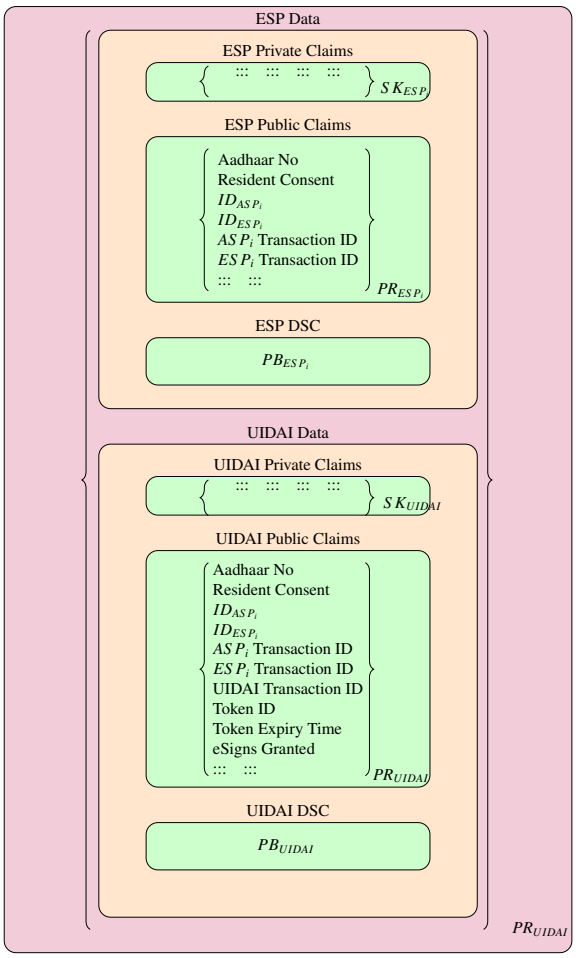

Figure 6: Access Token Structure as proposed in [4]

In this proposed model of eSign [figures 7, 8], resident first authenticates himself/herself using OTP or biometric based authentication and sends *eSign* request to *ASP*. *ASP* forwards this *eSign* request to *ESP*. *ESP* takes OTP and permission to generate access token from resident and creates an "Auth" object. This "Auth" object is created as before but additionally including *ESP* claims as well. *ESP* sends *GenerateAccessToken* request to *UIDAI* including "Auth" object. After receiving this request, *UIDAI* creates an access token including its own claims as well as claims received from *ESP*. *UIDAI* sends this access token back to the *ESP*. Now, *ESP* sends eKYC request to *UIDAI* including this access token instead of the "Auth" object. After receiving eKYC information from *UIDAI*, *ESP* generates *Digital Signature Certificate (DSC)* from it and provides the same to *ASP*. *ASP* embeds DSC in the document and sends the digitally signed document to the resident. For all rest of the *eSign* requests, *ESP* can reuse the same access token in eKYC requests and avoid the initial authentication phase.

The paper also presented two usability scenarios, based on whether the eKYC information can be cached by *ESP* or not. If *ESP* is permitted to reliably and securely store eKYC information of the resident, even the repeated eKYC requests from *ESP* to *UIDAI* can be avoided.

The paper also presented performance comparison analysis of proposed model with present model and found substantial improvement in amortized performance of *eSign*.

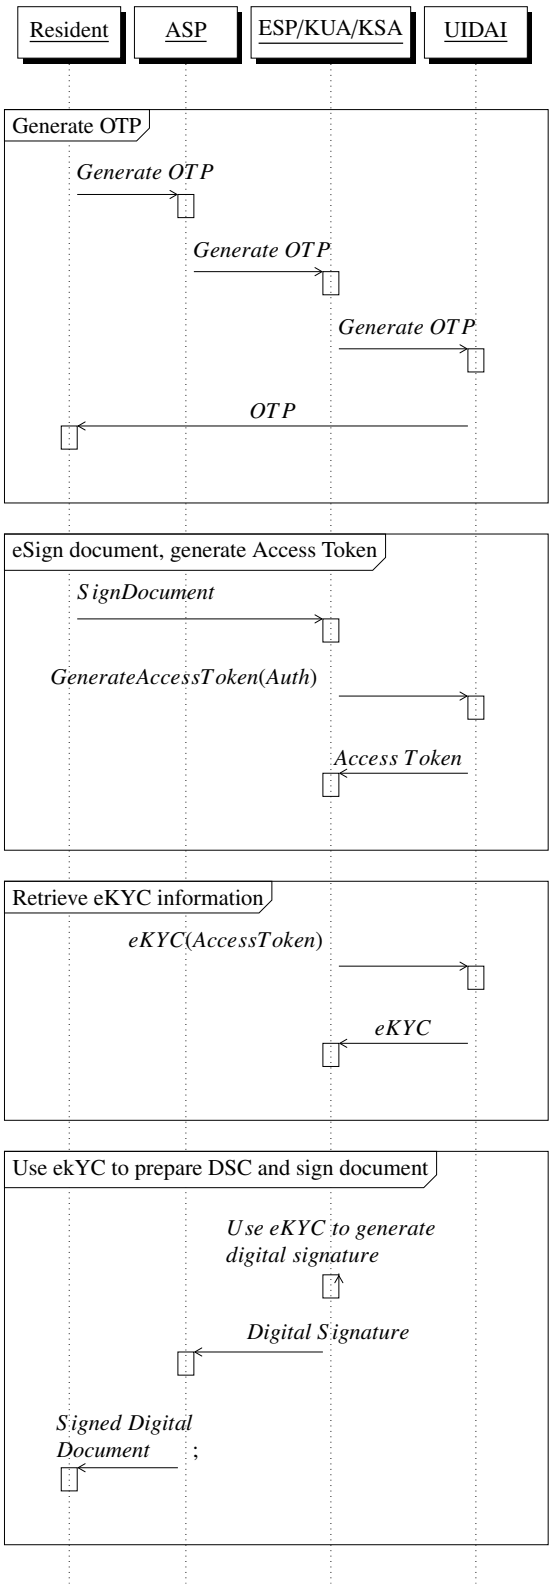

Figure 7: First call to eSign in eSign model proposed in [4]

6 Privacy Aware eSign model

In earlier proposed model [section 5] digital access token is used to increase amortized performance of *eSign* by storing necessary claims from *UIDAI* and *ESP*. The same token can be enhanced to include claims from resident as well. A resident can encode claims related to privacy and fine grained access control of his/her eKYC data. A stricter *PEaFGAC* statements may be enforced centrally at *UIDAI* level and an

overriding less strict rule can be supplied with each eKYC request to grant access to the requesting entity.

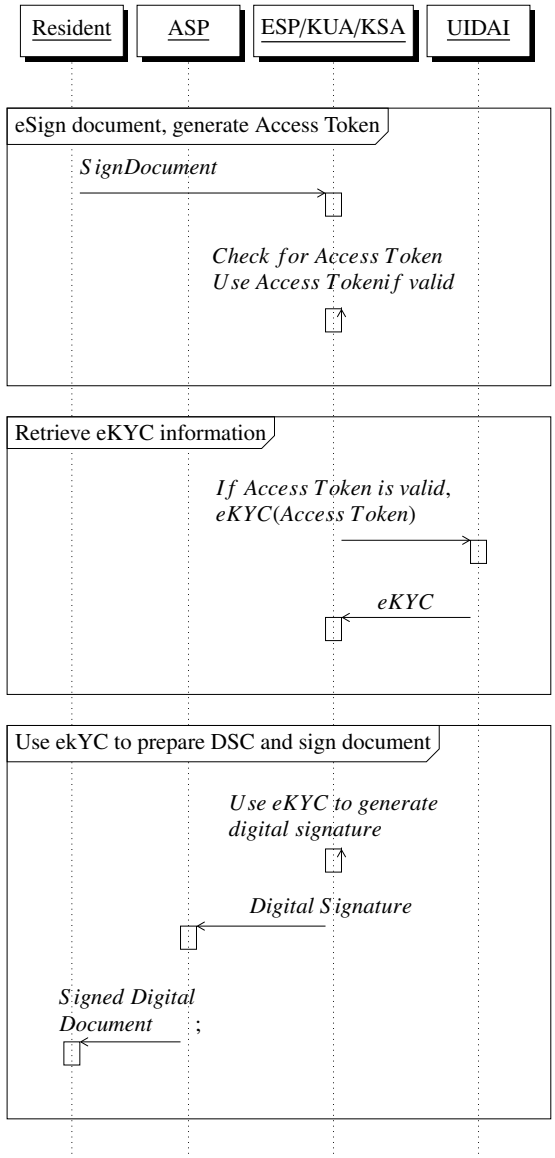

Figure 8: Second call to eSign in case eKYC needs to be fetched again

6.1 Privacy and Fine-Grained Access Control (PEaFGAC) Statements for eKYC data

A *PEaFGAC* statement encodes in itself the *scope* of information which can be provided, the *purpose* for which the information can be provided and attributes of *recipients* to whom the information can be provided. These statements are comprised of small sub-statements which are combined using relational operators. Each statement is identified by a numeric *id* and an alphanumeric *tag*.

An example of a *PEaFGAC* statement is presented in figure 10. This statement encodes in it that the purpose for seeking eKYC information should be *eSign*, seeking entity must either have the email in domain *finance.iitg.ac.in*, or must be working in *finance* department of *Indian Institute of Technology, Guwahati (IITG)*, or must have a designation of *director* or above. The statement is uniquely identified by a statement identifier (*ID*) and has a small alphanumeric representational string (*TAG*). Other than these, the staement also encodes in it the purpose for which eKYC can be accessed (*Purpose*), required (*eKYC*) attributes of information seeker (*AP*) and eKYC information which can be provided to the requester (*scope*). If required, a user can have multiple privacy statements for his/her eKYC data represented by different tags.

Figure 10: Example of a PEaFGAC statement

It is assumed that all entities which request eKYC data also have their eKYC information available with *UIDAI*. This include not just the users but the organizations such as *ESP*s as well. To better know an entity (both users and organizations), it is proposed that eKYC fields are expanded to include more details such as entity type (indicating whether the subject is a human or an organization), resident's organization, resident's department, resident's designation, etc. When an entity attempts to access eKYC data of a resident, entity's eKYC data and purpose for which the eKYC data is sought are verified against *PEaFGAC* statement protecting eKYC data to decide whether the requisite access can be granted or not. Only if the access can be granted, will the eKYC data be provided to the requesting entity. The eKYC data provided to the entity is limited in scope by *PEaFGAC* statement. For rest of this paper, eKYC data is assumed to consists of at least the information presented in figure 9.

6.2 PEaFGAC Token

The token structure introduced in [4] can be enhanced to include resident claims including *PEaFGAC* statement [fig-

ure 11]. Before sending an *eSign* request, resident creates a *PEaFGAC* token by sending a token generation request to *UIDAI* through *ASP* and *ESP*. During token generation process, resident is redirected to *UIDAI* web page where (s)he provides OTP value for authentication and *PEaFGAC* statement for privacy and fine-grained access to his/her eKYC data. Subsequently *UIDAI* verifies the OTP value and signs cryptographic hash of the statement with its private key and stores the signed hash in resident's private claims and stores the statement in plaintext in resident's public claims section of *PEaFGAC* digital access token.

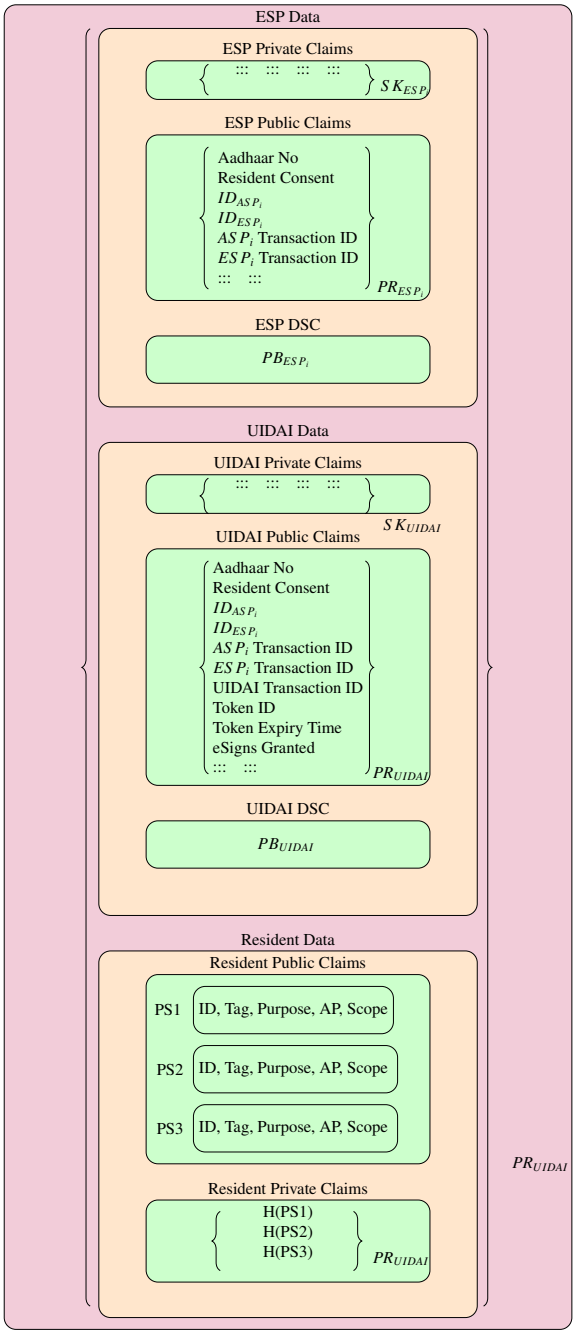

Figure 11: Proposed PEaFGAC Token Structure

Figure 12 depicts the sequence and details of communication messages among participating entities for generation of a token. First column indicates the message identifier, second column indicates the participating entities and the direction of communication and third column indicates what message is sent and how it is constructed.

Figure 12: Proposed PEaFGAC Token Generation protocol

6.3 Proposed Privacy Aware eSign model using PEaFGAC statement for eKYC data and PEaFGAC token

This section presents how *PEaFGC* statement for eKYC data and *PEaFGAC* token can be used to implement *Privacy Aware eSign*. It is assumed that *PEaFGAC* token has already been generated as explained in section 6.2. It is also assumed that the communication channel between resident and *ASP* is secured using SSL/TLS, between *ASP* and *ESP* is secured using SSL/TLS and between *ESP* and *UIDAI* is secured using dedicated secure leased lines.

Figure 13 depicts the sequence and details of communication messages transferred in *eSign* request in case eKYC needs to be fetched again.

Figure 13: Proposed Privacy Aware eSign model

7 Formal Security Analysis of the proposed model using BAN Logic

This section presents formal security analysis of the proposed scheme using *Burrows-Abadi-Needham (BAN) logic* [11]. Because of space limitation, it is assumed that PEaFGAC token has already been generated securely.Analysis of the token generation request can be done similarly.*BAN logic* is a well-known model used to find beliefs of participants in a cryptographic protocol.

Operator Usage	Description
$P \models X$	P believes statement X
$P \lhd X$	P sees statement X
$P \mapsto X$	P controls X
$\#(X)$	Message X is fresh
$P \overset{K}{\leftrightarrow} Q$	P and Q share key K
$\overset{K}{\mapsto} P$	P has K as its public key
$P \overset{X}{\rightleftharpoons} Q$	Formula X is a secret known only to P and Q
$\{X\}_K$	Formula X is encrypted using K
$\langle X \rangle_Y$	Formula X is combined with formula Y

Figure 14: Fundamental BAN operators

Operator Usage	Description
$M_{eSign_R_ESP_CCA}$	eSign of message M is done by Resident R through ESP approved by CCA $M_{eSign_R_ESP_CCA}$ $= M \| DSC_{R_M}$ $= M \| \{eKYC_R \| H(M)\}_{PR_R} \|$ $PB_R \| SignChain$ $= M \| \{eKYC_R \| H(M)\}_{PR_R} \|$ $PB_R \| \{PB_R\}_{PR_{ESP}} \|$ $\{PB_{ESP}\}_{PR_{CCA}}$
$P \models E_i \overset{secure}{\longrightarrow} E_j$	P believes that communication from entity E_i to E_j is secure
$P \models E_i \overset{secure}{\longleftarrow} E_j$	P believes that communication from entity E_j to E_i is secure
$P \models E_i \overset{secure}{\longleftrightarrow} E_j$	P believes that communication between entities E_i and E_j is secure in both directions
$P \models E_i \overset{ACTPerm}{\longleftrightarrow} E_j$	P believes that entity E_i has given permission for action ACT to entity E_j
$P \models C_R \rightsquigarrow E_i$	P believes that cookie C_R is associated with logged-in entity E_i
$E_R \models E_R \overset{C_{E_R} \rightarrow ID_{E_R}}{\longrightarrow} E_R$	E_R believes that it has securely communicated its identity ID_{E_R} to entity E_R through cookie C_{E_R}

Figure 15: Extended BAN operators

The security environment is assumed to be based on *Delev-Yao model* in which all messages are communicated over public channels and an attacker can see, modify, compose and replay messages but cannot break cryptographic principles. The security environment also assumes that an attacker can decipher messages if he has a valid decryption key. Some of the fundamental operators used in *BAN logic* are defined in figure 14. An extension to *BAN* logic, defined in figure 15 is required to analyse the proposed model.

Rules of Inference

[R1:] *Message meaning rules* concern the interpretation of messages. They all derive beliefs about the origin of messages.

For shared secrets, the inference rule is

$$\frac{P \models Q \overset{Y}{\rightleftharpoons} P,\ P \lhd \langle X \rangle_Y}{P \models Q \rhd X}$$

That is, if P believes that the secret Y is shared with Q and sees $\langle X \rangle_Y$, then P believes that Q once said X.

[R2:] The *nonce-verification* rule expresses the check that a message is recent, and hence, that the sender still believes in it:

$$\frac{P \models \#(X),\ P \models Q \rhd X}{P \models Q \models X}$$

That is, if P believes that X could have been uttered only recently and that Q once said X, then P believes that Q believes X.

[R3:] The *jurisdiction* rule states that if P believes that Q has jurisdiction over X, then P trusts Q on the truth of X:

$$\frac{P \models Q \Rightarrow X,\ P \models Q \models X}{P \models X}$$

[R4:] The *seeing* rule states that if a principal sees a formula, then he also sees its components, provided he knows the necessary keys:

$$\frac{P \lhd (X,Y)}{P \lhd X},\quad \frac{P \lhd \langle X \rangle_Y}{P \lhd X},\quad \frac{P \models Q \overset{K}{\leftrightarrow} P(.) P \lhd \{X\}_K}{P \lhd X},$$

$$\frac{P \models \overset{K}{\mapsto} P,\ P \lhd \{X\}_K}{P \lhd X},\quad \frac{P \models \overset{K}{\mapsto} P,\ P \lhd \{X\}_{K^{-1}}}{P \lhd X}.$$

Note that if P sees X and P sees Y it does NOT follow that P sees (X, Y) since that means that X and Y were uttered at the same time.

[R5:] The *fresh* rule states that if one part of the formula is fresh, then the entire formula must be fresh.

$$\frac{P \models \#(X)}{P \models \#(X, Y)}.$$

[R6:] The *belief* rule states that if P believes one part of the formula, then it also believe part of the formula.

$$\frac{P \models (X, Y)}{P \models (X)}.$$

Extended Rules of Inference

[R7:] If receiver entity E_R believes that C_R is a cookie associated with a unique session from resident R, PB_B is public key with browser used by resident R, PB_{E_R} is public key of receiver entity E_R, n_R is a fresh nonce generated by R, E_R receives message of the form $\{CommMsgReq(X||C_R||n_R, \{H(X||C_R||n_R)\}_{PR_{B_i}})\ \}_{PB_{E_R}}$, then E_R believes that X is sent by entity R and communication channel from R to E_R is secure and no message is observed, modified or replayed by an intruder.

$$\begin{array}{lll} E_R & \models & \overset{PB_{E_R}}{\longmapsto} E_R, \\ E_R & \models & C_R \rightsquigarrow S, \\ E_R & \models & \#n_R, \\ E_R & \models & \{\{Y\}_{PR_R}\}_{PB_R} = Y \\ E_R & \lhd & \{\ CommMsgReq\ (\\ & & \quad X||C_R||n_R, \\ & & \quad \{H(X||C_R||n_R)\}_{PR_{R_i}})\ \}_{PB_{E_R}} \\ \hline E_R & \models & R \xrightarrow{Secure} E_R, \\ E_R & \models & R \rhd X \end{array}$$

[R8:] If receiver entity E_R believes that PB_{E_R} is public key of receiver entity E_R, n_{E_R} is a fresh nonce generated by E_R, E_R receives message of the form $\{\ CommMsgReq\ (X||n_{E_R}, \{H(X||n_{E_R})\}_{PR_{E_R}})\ \}_{PB_{E_R}}$, then E_R believes that X is sent by entity E_R and communication channel from E_R to E_R is secure and no message is observed, modified or replayed by an intruder.

$$\begin{array}{lll} E_R & \models & \overset{PB_{E_R}}{\longmapsto} E_R, \\ E_R & \models & \{\{Y\}_{PR_{E_R}}\}_{PB_{E_R}} = Y, \\ E_R & \models & \#n_{E_R} \\ E_R & \lhd & \{\ CommMsgReq\ (\\ & & \quad X||n_{E_R}, \\ & & \quad \{H(X||n_{E_R})\}_{PR_{E_R}})\ \}_{PB_{E_R}} \\ \hline E_R & \models & E_R \xrightarrow{Secure} E_R \\ E_R & \models & E_R \rhd X \end{array}$$

[R9:] If receiver entity E_R believes that communication from all possible sender entities E_{R_i} to E_R $(\forall i = 1...n)$ is secure, then E_R believes that communication channel to E_R is secure and no message is observed, modified or replayed by an intruder.

[R10:] If resident R believes that C_R is a cookie associated with a unique session from resident R, PB_{E_R} is public key of entity E_R, n_R was a fresh nonce generated by R and used in a previous request call from R to E_R, R receives a message of the form $\{CommMsgRes(X||(n_R+1), \{H(X||(n_R+1)\}_{PR_{E_R}})\}_{PB_{E_R}}$, then E_R believes that X is sent by entity R and communication channel from R to E_R is secure and no message is observed, modified or replayed by an intruder.

[R11:] If sender entity E_R believes that PR_{E_R} is private key of sender entity E_R, PB_{E_R} is public key of receiver entity E_R, n_{E_R} was a fresh nonce generated by R and used in a previous request call from E_R to E_R, E_R receives message of the form $\{CommMsgRes\ (X||(n_{E_R}+1), \{H(X||(n_{E_R}+1)\}_{PR_{E_R}})\}_{PB_{E_R}}$, then E_R believes that X is sent by entity E_R and communication channel from E_R to E_R is secure and no message is observed, modified or replayed by an intruder.

[R12:] If sender entity E_R believes that communication from all possible receiver entities E_{R_i} $(\forall i = 1...n)$ is secure, then E_R believes that communication channel to E_R is secure and no message is observed, modified or replayed by an intruder.

[R13:] An electronic signature (M_{ieSign}) is a valid signature only when resident verifies that three main parts in signature, viz., $eKYC$, $H(M)$ and $SignChain$ are as expected.

Assumptions

The protocol makes several assumptions. The assumptions relevant for the discussion of this paper are listed below.

[A1:] It is assumed that all sessions from all residents R_i keeps their cookie C_{R_i} secret.

[A2-A6:] The scheme makes several assumptions about public keys. For example, R_i believes that PB_{ASP_i} is public key of ASP_i. Similar to this, other entities also make similar assumptions. These assumptions are listed below.

$$\begin{array}{llll} R_i & \models & \overset{PB_{ASP_i}}{\longmapsto} & ASP_i \quad ...(A2) \\ ESP_i & \models & \overset{PB_{ASP_i}}{\longmapsto} & ASP_i \quad ...(A3) \\ ASP_i & \models & \overset{PB_{ESP_i}}{\longmapsto} & ESP_i \quad ...(A4) \\ UIDAI & \models & \overset{PB_{ESP_i}}{\longmapsto} & ESP_i \quad ...(A5) \\ ESP_i & \models & \overset{PB_{UIDAI}}{\longmapsto} & UIDAI \quad ...(A6) \end{array}$$

[A7:] ASP_i assumes that all valid cookies C_{R_i} are associated with a valid ongoing session from a unique valid user R_i already logged in to ASP_i portal.

$$ASP_i \models C_{R_i} \rightsquigarrow ID_{R_i} \quad \forall i = 1..n$$

[A8-A15:] R_i and ASP_i assumes that all nonce $n*_{R_i}$ (where $*$ is any integer used in the scheme) are fresh. Similar to this, other entities also make similar assumptions. These assumptions are listed below.

$$\begin{array}{lll} R_i & \models & \#n*_{R_i} \quad ...(A8) \\ ASP_i & \models & \#n*_{R_i} \quad ...(A9) \\ ASP_i & \models & \#n*_{ASP_i} \quad ...(A10) \\ ESP_i & \models & \#n*_{ASP_i} \quad ...(A11) \\ ESP_i & \models & \#n*_{ESP_i} \quad ...(A12) \\ UIDAi & \models & \#n*_{ESP_i} \quad ...(A13) \\ UIDAI & \models & \#n*_{UIDAI} \quad ...(A14) \\ ESP_i & \models & \#n*_{UIDAI} \quad ...(A15) \end{array}$$

[A16:] It is assumed that when ASP_i receives message of the form $CommMsg(DataA_j, SignA_j)_{PB_{ASP_i}}$ from ESP_i, it has verified the validity of data, i.e., $\{SignA_j\}_{PB_{ESP_j}} = H(DataA_j)$. The same assumption is made for all entities receiving messages of this form.

Goals to be achieved.

Following are the goals which are envisaged to be achieved by the proposed model.

[G1-G6:] Sender entity must be sure that the data received by receiver entity is same as what was sent by it and is not modified, observed or replayed by an intruder after it was sent by the sender entity. Similarly, receiver entity must be sure that the data received by it is same as what was sent by sender entity and is not modified, observed or replayed by an intruder after it was sent by the sender entity.

$$\begin{array}{llll} ASP_i & \models & R_i & \overset{secure}{\longleftrightarrow} \quad ASP_i \\ R_i & \models & R_i & \overset{secure}{\longleftrightarrow} \quad ASP_i \\ ASP_i & \models & ASP_i & \overset{secure}{\longleftrightarrow} \quad ESP_i \\ ESP_i & \models & ASP_i & \overset{secure}{\longleftrightarrow} \quad ESP_i \\ ESP_i & \models & ESP_i & \overset{secure}{\longleftrightarrow} \quad UIDAI \\ UIDAI & \models & ESP_i & \overset{secure}{\longleftrightarrow} \quad UIDAI \end{array}$$

[G7:] Resident R_i must be sure that at the end what he receives is indeed a digital signature on message M_i, signed by resident's private key and generated by the genuine ESP_i. $R_i \models M_{ieSign} = M_{eSign_R_i_ESP_i_CCA}$

Idealization

BAN idealization of communication messages in communication phase is shown in table 1

Table 1: BAN Idealization of Proposed Protocol (Part I: M1-3) and (Part II: M4-8)

$M1$	ASP_i	$\lhd$	$\{login\ ($ $ID_{R_i} \| PW_{R_i} \| PB_{B_i} \| n1_{R_i}$ $\{H(ID_{R_i} \| PW_{R_i} \| PB_{B_i} \| n1_{R_i})\}_{PR_{B_i}}$ $)\}_{PB_{ASP_i}}$
$M2$	R_i	$\lhd$	$\{loginRes\ ($ $C_{R_i} \oplus (n1_{R_i}+1)$ $\{H(C_{R_i} \oplus (n1_{R_i}+1))\}_{PR_{ASP_i}}$ $)\}_{PB_{B_i}}$
$M3$	ASP_i	$\lhd$	$\{signdocASPReq\ ($ $M_i \| consent_{use_ekyc} \| consent_{genuse_at} \| C_{R_i} \| n2_{R_i})$, $\{H(M_i \| consent_{use_ekyc} \| consent_{genuse_at} \| C_{R_i} \| n2_{R_i})\}_{PR_{B_i}}$ $)\}_{PB_{ASP_i}}$
$M4$	ESP_i	$\lhd$	$\{signdocESPReq\ ($ $H(M_i) \| AadhaarNo_{R_i} \| ID_{ASP_i} \| License_{ASP_i} \| TID_{ASP_i} \| consent_{use_ekyc} \| consent_{genuse_at} \| n1_{ASP_i}$, $\{H(H(M_i) \| AadhaarNo_{R_i} \| ID_{ASP_i} \| License_{ASP_i} \| TID_{ASP_i} \| consent_{use_ekyc} \| consent_{genuse_at} \| n1_{ASP_i})\}_{PR_{ASP_i}}$ $)\}_{PB_{ESP_i}}$
$M5$	$UIDAI$	$\lhd$	$\{kycESPReq\ ($ $AT_{R_i} \| H(M_i) \| n1_{ESP_i}$, $\{H(AT_{R_i} \| H(M_i) \| n1_{ESP_i})\}_{PR_{ESP_i}}$ $)\}_{PB_{UIDAI}}$

$M6$	ESP_i	$\triangleleft$	$\{kycESPRes\ ($ $eKYC_{R_i} \| (n1_{ESP_i} + 1)$ $\{H(eKYC_{R_i} \|$ $(n1_{ESP_i} + 1))\}_{PR_{UIDAI}}$ $\}_{PB_{ESP_i}}$
$M7$	ASP_i	$\triangleleft$	$\{signdocESPRes\ ($ $\{eKYC_{R_i} \| H(M_i)\}_{PR_{R_i}} \|$ $PB_{R_i} \| \{PB_{R_i}\}_{PR_{ESP_i}} \|$ $\{PB_{ESP_i}\}_{PR_{CCA}} \|$ $TID_{ASP_i} \| (n1_{ASP_i} + 1),$ $\{H(eKYC_{R_i} \| H(M_i)\}_{PR_{R_i}} \|$ $PB_{R_i} \| \{PB_{R_i}\}_{PR_{ESP_i}} \|$ $\{PB_{ESP_i}\}_{PR_{CCA}} \|$ $TID_{ASP_i} \|$ $(n1_{ASP_i} + 1))\}_{PR_{ESP_i}}$ $)$ $\}_{PB_{ASP_i}}$
$M8$	R_i	$\triangleleft$	$\{signdocASPRes\ ($ $M_i \| \{eKYC_{R_i} \| H(M_i)\}_{PR_{R_i}}$ $\| PB_{R_i} \| \{PB_{R_i}\}_{PR_{ESP_i}} \|$ $\{PB_{ESP_i}\}_{PR_{CCA}} \| (n2_{R_i} + 1)$ $\{H(M_i \| \{eKYC_{R_i} \| H(M_i)\}_{PR_{R_i}}$ $\| PB_{R_i} \| \{PB_{R_i}\}_{PR_{ESP_i}} \|$ $\{PB_{ESP_i}\}_{PR_{CCA}} \|$ $(n2_{R_i} + 1))\}_{ASP_i}$ $)$ $\}_{PB_{B_i}}$

Analysis

[P1-P6:] Using messages M1, M3 and rule R7, it can be deduced that ASP_i believes that communication from R_i to ASP_i is secure. Using messages M2, M8 and rule R11, it can be deduced that ASP_i believes that communication from ASP_i to R_i is secure. From these two deductions, it can further be deduced that ASP_i believes that communication between R_i and ASP_i is secure in both directions.

Using M1, M3, R7, R8,
$ASP_i \models R_i \xrightarrow{secure} ASP_i$ ($I1$)

Using M2, M8, R11,
$ASP_i \models R_i \xleftarrow{secure} ASP_i$ ($I2$)

Using I1 and I2,
$ASP_i \models R_i \xleftrightarrow{secure} ASP_i$ ($G1$: *Proved*)

Using M1, M3, R10, R11
$ASP_i \models R_i \xrightarrow{secure} ASP_i$ ($I3$)

Using M2, M8, R8,
$ASP_i \models R_i \xleftarrow{secure} ASP_i$ ($I4$)

Using I3 and I4,
$ASP_i \models R_i \xleftrightarrow{secure} ASP_i$ ($G2$: *Proved*)

Using M4, R7,
$ESP_i \models ASP_i \xrightarrow{secure} ESP_i$ ($I5$)

Using M7, R11,
$ESP_i \models ASP_i \xleftarrow{secure} ESP_i$ ($I6$)

Using I5 and I6,
$ESP_i \models ASP_i \xleftrightarrow{secure} ESP_i$ ($G3$: *Proved*)

Using M4, R11,
$ASP_i \models ASP_i \xrightarrow{secure} ESP_i$ ($I7$)

Using M7, R8,
$ASP_i \models ASP_i \xleftarrow{secure} ESP_i$ ($I8$)

Using I5 and I6,
$ASP_i \models ASP_i \xleftrightarrow{secure} ESP_i$ ($G4$: *Proved*)

Using M5, R7,
$UIDAI \models ESP_i \xrightarrow{secure} UIDAI$ ($I7$)

Using M6, R11,
$UIDAI \models ESP_i \xleftarrow{secure} UIDAI$ ($I8$)

Using I7 and I8,
$UIDAI \models ESP_i \xleftrightarrow{secure} UIDAI$
($G5$: *Proved*)

Using M5, R11,
$ESP_i \models ESP_i \xrightarrow{secure} UIDAI$ ($I9$)

Using M6, R8,
$ESP_i \models ESP_i \xleftarrow{secure} UIDAI$ ($I0$)

Using I9 and I10,
$ESP_i \models ESP_i \xleftrightarrow{secure} UIDAI$ ($G6$: *Proved*)

[P7:] Using message M9 and rule R13, it can be deduced that R_i believes that $\{M_i\}_{eSign}$ is a valid electronic signature.

Using M9 and R13,
$R_i \models \{M_i\}_{eSign} = \{M_i\}_{eSign_R_i_ESP_i_CCA}$
($G7$: *Proved*)

8 Conclusion

This work is an extension of the work [4] on enhancing amortized performance of *eSign* by using digital access tokens including claims from *ESP* and *UIDAI*. In this work, the digital access token introduced in [4] is extended to include privacy and fine-grained access control statements for access to resident's eKYC data. This enhanced token can be used by third entities to access the protected eKYC data with better privacy and fine-grained access control rules enforced by the resident. A formal security analysis of the proposed model using *BAN logic* is also presented.

ABSTRACT

Location-based service has been widely used in modern life. It brings a lot of convenience to our lives. Improving the accuracy of location prediction can provide better location-based service. We propose a location prediction method based on the variable-order Markov model with time feature and user's spatio-temporal rule. First, the user's trajectory data needs to be abstracted, and then the useful stay points in the user's trajectory are extracted. The location prediction is performed by scoring each candidate area, and the score is composed of scores in time and space dimensions. Finally, for the possible zero frequency problem, it is solved by mining the spatio-temporal rule of the user. Experiments using the actual data set GeoLife show that the proposed method improves the prediction accuracy.

1. Introduction

With the popularity of mobile location devices, the acquisition of location information is becoming more and more easier. Location-based services have become common services in our lives. It is necessary for us to mine location data and use the acquired knowledge to extend location services or improve service quality. Location prediction is an important research point in the field of location data mining, which can provide us with better recommendation services, social networking services and so on.

This paper is an extension of work originally presented in conference name [1].

Markov chain is a set of discrete random variables with Markov and the probability of each event depends only on the previous event. The Markov process is named after the Russian mathematician Andrey Markov. In this process, the future state is only related to the current state and has nothing to do with the past. Markov chain is divided into continuous Markov chain and discrete Markov chain. In discrete state-space, discrete time random process is called discrete Markov chain, and continuous time random process is called continuous Markov chain. [2]

Markov chain is a common statistical model, which is widely used in various kinds of prediction. It has the advantages of simplicity and efficiency, and is a good representation of time series data. Therefore, it can also be used for location prediction.

In literature [3], a location prediction method based on adaptive higher-order Markov model was proposed, which significantly improves the accuracy of location prediction. The difference between a higher-order Markov model and a Markov model is that the future state depends on the current state of the model and the past k-1 state of the model, not just the current state. However, it does not solve the problem of not finding current state in the history data, which is called the zero frequency problem. Literature [4] used variable-order Markov model for location prediction. It is based on high-order Markov model and makes the best use of history data. The zero frequency problem is also solved by an approach called escaped rule. Moreover, we found that many people have a regular life activity. By analyzing these people' history data, certain rules can be mined in time and space. These rules can be used in location predication. In the literature [5], the author not only considered the influence of user space factors on location prediction, but also considered the time factor, which further improved the accuracy of location prediction. This lets us notice the importance of time factor in location predication. Literature [6] provided a method for location prediction by using space-time rules, which is not only simple, but also can obtain good prediction results. These studies gave us a lot of inspiration.

*Corresponding Author: Ying Xia, Email: xiaying@cqupt.edu.cn

With lots of studies, a location predication method based on variable-order Markov model with time feature and user's spatio-temporal rule was proposed. It included the preprocessing of data, the construction of variable-order Markov model with time feature and the analysis of the time and spatial rules of users. First, data preprocessing makes the location data more suitable for location prediction. Since time and spatial factors both have impact on location predication, a variable-order Markov model with time feature is constructed for location predication. Finally, for the case that the variable-order Markov model cannot be used to perform the prediction, the prediction is made by analyzing users' time and spatial rules.

2. Data preprocessing

Before predicting the location, location data needs to be preprocessed, which includes three steps, that is, data cleansing, location information abstraction and stay point extraction.

2.1. Data cleaning

The purpose of data cleansing is to make the data more real, regular, and easy to handle. First, you need to modify the irregular data to make it more regular. Second, data not in research range needs to be deleted. In this study, Beijing was chosen as the research object so the range of location data control is between east longitude 115.25 ˚ to 117.3 ˚ and north latitude 39.26˚ to 41.03˚. If not, it is regarded as data that is not in this range. Finally, incomplete or unreal data are cleaned up.

2.2. Location information abstraction

Location data is usually obtained by mobile device. And it is mainly composed of coordinate location data. The data are very detailed and it is difficult for us to analyze them. Location data needs to be abstracted into area data to perform conventional mining. The abstraction of location data also helps decrease computational complexity. In literature [7], the idea of building active grid was proposed. We use this method to abstract the location data:

- First, the user's activity range is set in a large rectangular area and the edge is parallel to the longitude and latitude lines.
- Then, the rectangular area is divided into a square grid. And the user's location point is mapped to the grid.
- Finally, active grid is connected based on time passage. This is user's active grid sequence.

The raw location data is composed of points. This is original trajectory data. $\{p_1,p_2...p_i...p_n\}$. P_i is the location point in the trajectory data. After the abstraction, the original user location sequence $\{p_1,p_2...p_n\}$ is converted to active grid sequence $\{z_1,z_2...z_i...z_n\}$. z_i is the grid in the abstract trajectory data.

2.3. Stay points extraction.

The stay points of moving objects are important points or areas such as shopping centers, workplaces, places of residence and so on. These points should be emphasized in location-based services. Therefore, the stay points in the trajectory need to be extracted. And there are many ways to extract stay points. The method of considering time and space factors is not only simple but also effective. It is based on the principle that a place is a stop point when you stay longer than the set time. The extraction method includes the following steps:

- Set the time value *t*, which is the standard of residence time.
- Search the area with residence time exceeding t in the trajectory data. The residence time is calculated by the difference between the maximum residence time and the minimum residence time.
- The stay points by time chronological order constitutes the new track.

The trajectory data composed of residence points are extracted by the above method. Algorithm 1 is the pseudocode used for the residence point extraction.

Algorithm 1 Stay points extraction

Input: User's historical data d_data and stay time threshold t

Output: User's stay points s_area

The maximum time value to stay in the area time_max

The Minimum time value to stay in the area time_min

Sort the data of d_data by time

for each area of d_data **do**

  stay time = time_max -time_min

  if stay time > t

    The area add to the stay area s_ area

end for

return s_ area

3. Location Prediction

The method of location prediction includes constructing variable-order Markov model with time feature and analysis of user's time and spatial rules. It's named location prediction based on variable-order Markov model with time feature and user's spatio-temporal rule (VMTST).

3.1. Variable-order Markov Model with Time Feature construction and prediction methods

Variable-order Markov model is an improved model based on high-order Markov model. It makes use of the excellent prediction ability of the high-order Markov model and further realizes the automatic selection of high-order Markov model order. Time feature are also important for location prediction. Thus, time feature and variable-order Markov model are combined, and the scoring method is used to achieve the location predication. The method is as follows:

- Extract the historical track data composed of user's stay points.

- Search history tracks based on the user's current track. If the matching historical trajectory information is found, the transition probability of the next grid in these trajectories is calculated. It is called *P*.
- If the matching track information is not searched, some active grids must be removed and then new current track is created. The earliest active grids need to be removed because the earlier an active grid arrives, the less impact it will have on its future location. This process requires multiple executions until matching trajectory data is found.

  For example, Figure 1 shows the user's historical trajectory. If the user's current trajectory (Z_2-Z_3), all historical trajectory data containing (Z_2-Z_3) are searched. Z_4 after calculation is the highest region with transition probability. Region Z_4 is the predicated result. But if the user's current trajectory is (Z_4-Z_5-Z_6). The current trajectory is not found in history data. Z_4 is the earliest region and has the least influence on location predication, so Z_4 region should be deleted and search it again from the historical track.

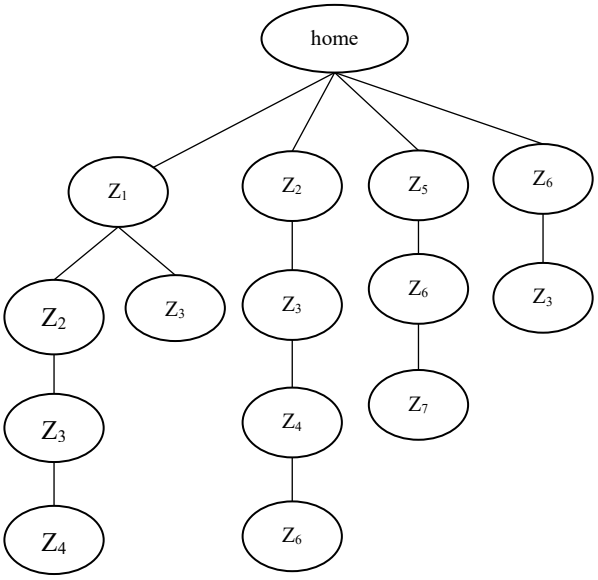

Figure 1: User's historical trajectory

- For each candidate region, their scores are composed of spatial accessibility scores and time feature scores. The scoring formula is as follows:

$$Score = W_1 * P + W_2 * S \quad (1)$$

  W_1 and W_2 are the weights which are possible to reach spatial scores and time characteristic scores in the total scores.

  Time information includes two parts: date and time. Therefore, the score of time feature *S* is composed of two parts: the periodic coefficient of the date and the similarity score of time.

$$S = C * Si \quad (2)$$

  Si is the similarity score of time. Clustering and normalization idea is used here. It is obtained by the following formula.

$$Si = 1 - t/12 \quad (3)$$

$$t = th - tn \quad (4)$$

  th is the hourly portion of historian data record.

  tn is the hour component of current status.

  C is the periodic coefficient of date. It is divided into workdays and holidays. It is calculated by the following rules:

  If record date and forecast date are workdays, it means the location data is regular. Thus, the value of *C* is greater than 1.

  If historical date and forecast date are holidays, it means the location data is irregular. Thus, the value of *C* is less than 1.

  In other cases, *C* is 1 .

- The zone with the highest score is used as the predicting outcomes.

The location prediction algorithm of variable-order Markov model with time feature is as follows:

Algorithm 2 Construction of the variable-order Markov model with time feature

Input: users historical data *h_data*,users current trajectary *c_try*

Output: users next area *n_zone*

The weight of the space in the total score W_1

The weight of the time in the total score W_2

while Search from historical data (*h_data*) with user's current trajectory(*c_try)* return false

c_try = remove the earliest zone from the user's current trajectory

if the number of areas in user's current trajectory ==1

break

Calculate the transition probability *P* of each next areas in the matched trajectory

for each area of next areas **do**

Calculate the time similarity score *Si* and date coefficient *C* for this area

Time feature score for this area *S* = *C*Si*

Score for this area *score* = W_1*P+W_2*S

end for

Search for the highest scored area *n_zone* in the next area of historical data

return *n_zone*

3.2. Analyze Spatio-temporal Rule of Moving Objects

When users have less historical data, it is difficult to search matching historical track information. Location predication is done by analyzing the user's time and spatial rules. Spatio-temporal rule mainly refers to the regularity of users' time and spatial positions at different times. The following methods are used to analyze the spatio-temporal rule of users:

- The time interval is set to *t*.
- In the user's historical data, count the number of occurrence of user in each interval and each active grid. The region with the maximum number is the hot spot region during this time period.
- Set the numbered ID for each time period in time order.
- The result of spatio-temporal rule is composed of ID, hot region.

During this period, the more time periods are divided, the better the prediction effect is, but the more time is needed for calculation. It is easy to understand that the more active grids are present, the more likely they are to become a mobile destination for users. Therefore, hot spot active grids with the maximum number of occurrences are the prediction area based on spatio-temporal rule. Algorithm 3 describes this process.

In the location prediction, the user's current activity time matches the ID in the spatio-temporal rule. Next ID hotspot region is searched in the spatio-temporal rule, which is considered a place where users may arrive in the future. This process is algorithm 4.

Algorithm 3 Analysis of user's spatio-temporal rule

Input: users historical data *h_data*, time period *t*
Output: users spatio-temporal rule result *s_t_result*
Dividing the time period according to the value of *t*
for each time period **do**
  Set a number for each time period *t_ID*
  Calculate the area with the most user arrivals during this time period *max_area*
  t_ID and *max_area* added to the spatio-temporal rule result *s_t_result*
end for
return *s_t_result*

Algorithm 4 Location prediction using user's spatio-temporal rule

Input:users spatio-temporal rule result *s_t_result*
recording time of the user's current trajectory *r_time*
Output:location prediction area obtained by users spatio-temporal rule *next_area*
Get the number of the *r_time* named *n_ID*
for each number in the time period **do**
  if *n_ID* = number in the time period
    get the hot area of the next time period *hot_area*
    next_area=hot_area
return *next_area*

Prediction accuracy and recall rate were used as evaluation indexes in the experiment. The formula is as follows:

4. Experiment

4.1. Experimental design

In order to verify the effectiveness of the proposed prediction method, experiments were performed using the GeoLife [8] trajectory data set. This data set includes trajectory data of 182 users over five years. It has about 18,670 tracks, including longitude, latitude, time and other information. And it records track data like users' work, entertainment and sports as well as other outdoor activities.

After data cleansing, extract the user's ID, longitude, latitude, date, time and other attributes. The experiment data set is shown in table 1. 10% data is randomly selected for test data and the rest are training data. Experimental research area is east longitude 115.25˚ to 117.3˚ and latitude 39.26˚ to 41.03˚. The size of grid unit is 100m*100m, the limit time of residence time point t is 10 min and the time interval selected for the analysis of users' spatio-temporal rule is 2 hours.

Contrast model:

MM: High order Markov location predication model.

VOMM: Location prediction model proposed in literature[4] uses variable-order Markov model for location prediction and escaped rules to solve the zero frequency problem.

VMSTPM: The location prediction model is proposed in literature [1]. This method uses the variable-order Markov model for location prediction and also uses spatio-temporal rule to solve the zero frequency problem.

4.2. Evaluation Factors

$$Precision = \frac{accurate}{accurate+wrong} \quad (5)$$

$$Recall = \frac{accurate+wrong}{total} \quad (6)$$

Table 2: The value of W_1 and W_2 in different situation

	case 1	case 2	case 3	case 4	case 5	case 6	case 7	case 8	case 9
W_1	0.1	0.2	0.3	0.4	0.5	0.6	0.7	0.8	0.9
W_2	0.9	0.8	0.7	0.6	0.5	0.4	0.3	0.2	0.1

Table 3: The value of C_1 and C_2 in different situations

	case 1	case 2	case 3	case 4	case 5	case 6	case 7	case 8	case 9
C1	1.1	1.2	1.3	1.4	1.5	1.6	1.7	1.8	1.9
C2	0.9	0.8	0.7	0.6	0.5	0.4	0.3	0.2	0.1

In the above equations, accurate indicate the number of correct predictions, wrong indicate the number of incorrect predictions total indicate the number of all testing trajectories.

4.3. Analysis of Experimental Results

First, the coefficients in the candidate region scoring formula were tested by experiments and prediction accuracy was used as the evaluation index. The experiment selected nine different values, as shown in table 2. From table 2, we can see that the prediction accuracy is the highest when W_1 and W_2 are 0.3 and 0.7. It proves the importance of time feature to location prediction. Thus, when the weight of time feature is great, the prediction accuracy is higher.

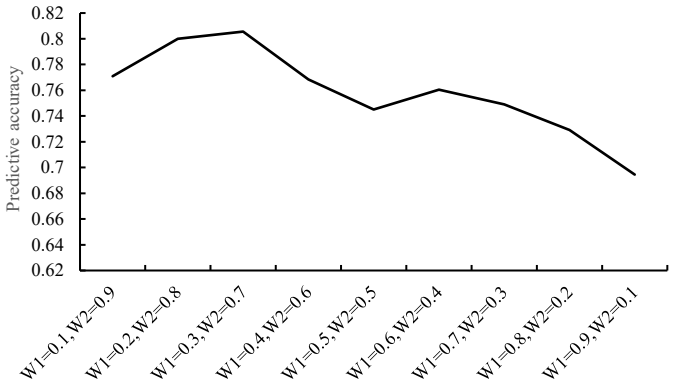

Figure 2: Prediction precision of W_1 and W_2 in different situations

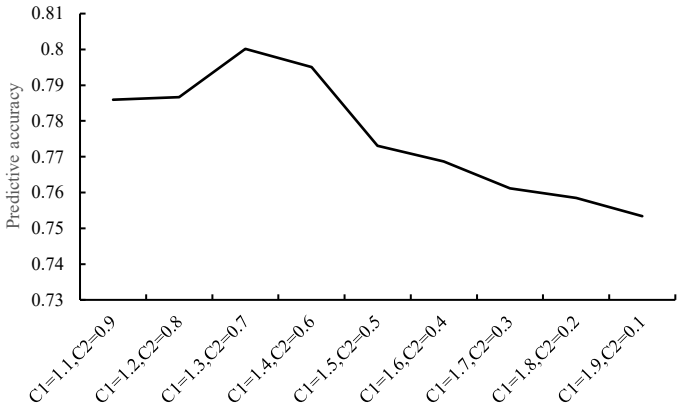

Figure 3: Prediction precision of C_1 and C_2 in different situations

Besides, the period coefficient value of the date obtained the best value by experiments. The value of C is C_1 when record date and prediction date are both workdays. And the value of C is C_2 when both historical date and prediction date are holidays. C_1 and C_2 take the values in table 3. It can be seen from figure 3 that the prediction outcome is best when C_1 is 1.3 and C_2 is 0.7. Therefore, other experiments were performed with these values.

Then, lots of prediction experiments were performed to verify the prediction outcome of the model. The prediction outcome is shown in figure 4. And VMTST at different orders showed more accurate prediction result. The best prediction result is obtained in the second order, which is about 30% higher than the original high-order Markov model and about 20% higher than the VOMM model. In figure 5, we can see that VMTST model is more stable in higher-order predictions. Therefore, it is better to use the current state and a history state for location prediction. This will get the optimum result. These results show that VMTST model has good predictive performance.

Figure 4: Prediction precision with different orders

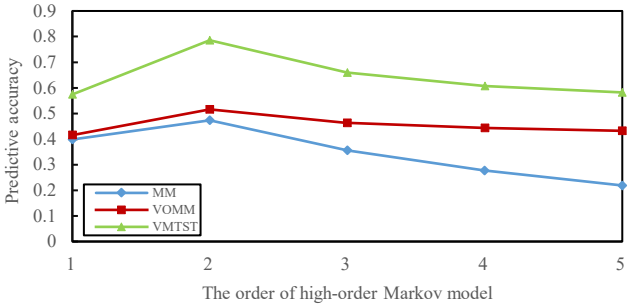

Figure 5: Prediction precision with different models

Experiments were conducted to verify the importance of time in prediction. The prediction accuracy is still used as the evaluation index in the experiment. And the results are shown in figure 6. It can be seen that the prediction accuracy of VMTST is higher than that of VMSTPM with different orders, which proves that time feature is a very important factor in location prediction.

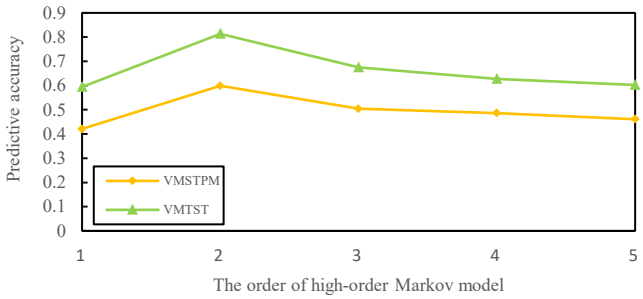

Figure 6: Prediction precision of VMSTPM and VMTST

The figure 7 is the comparison of recall rates of three models. As you can see, the recall rate of VMTST is 1.0, which is higher than high order Markov model. This means that it is effective to solve the zero frequency problem by using the user's spatio-temporal rule. However, the recall rate of VOMM model is also 1.0, which means VOMM model also solves the zero frequency problem. More experiments are required to verify the performance of VMTST.

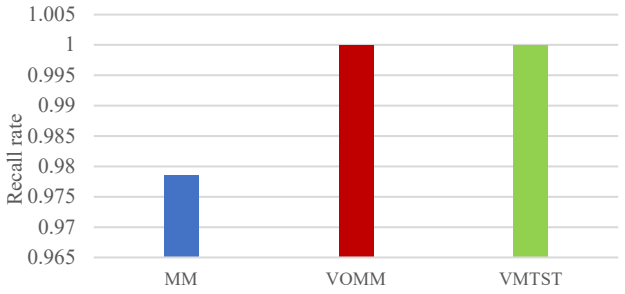

Figure 7: Recall rate of different models

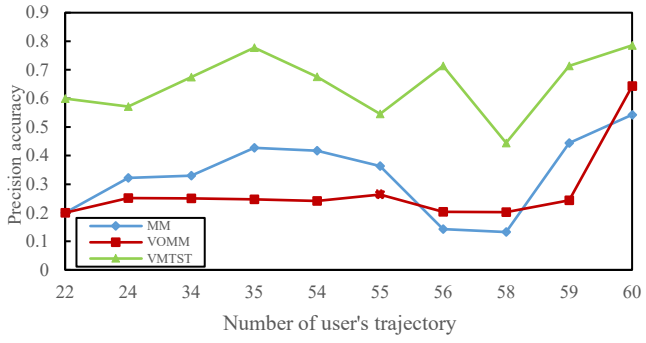

Figure 8: Prediction precision of users with fewer trajectory

The above experiments show that the spatio-temporal rule can solve the zero frequency problem. But, it is necessary to verify the performance of spatial and temporal laws in predicting accuracy through experiments. The experiment selected 10 users with less historical data. Therefore, it is easier to generate zero frequency problem. And it can be seen from the experimental results in figure 8 that when the trajectory quantity is small, the prediction accuracy of VMTST model is still higher than other models. Therefore, the spatio-temporal rule of users is more suitable to solve the problem of zero frequency.

5. Conclusion

A location prediction method was proposed in this paper, including preprocessing of location data, construction of variable-order Markov model with time feature and analysis of user's spatio-temporal rule. The preprocessing of position data makes the research scope fixed and the track data easier to analyze and process. Variable-order Markov model is an improved model of high-order Markov and it has higher location prediction accuracy. The time features are added to the variable-order Markov model to further increase the prediction accuracy. The problem of zero frequency can be solved by analyzing the spatio-temporal rule of users. Finally, lots of experiments were carried out using the actual trajectory data set.

By summing up the experiments, we can conclude that VMTST model improves the prediction accuracy. Time features are very important for location prediction. And the spatio-temporal rule can solve the problem of zero frequency, and be also more suitable.

In the future, we will look for new methods to mine the spatio-temporal rule of users so as to get the higher prediction accuracy. Also we will study the application of location prediction method in practice.

ABSTRACT

We examine design principles from more than 20 years of experience in the implementation and protection of mission critical flight systems used by the Mission Design and Navigation Section at NASA's Jet Propulsion Laboratory. Spacecraft navigation has rigorous requirements for completeness and accuracy, often under critical and uncompromising time pressure. Fault tolerant and robust design in the ground data system is crucial for the numerous space missions we support, from the Cassini *orbital tour of Saturn to the Mars rover* Curiosity. *This begins with the examination of principles learned from fault tolerant design to protect against random failures, and continues to the consideration of computer security engineering as a derivative effort to protect against the promotion of malicious failures. Examples for best practice of reliable system design from aviation and computer industries are considered and security fault tolerance principles are derived from such efforts. Computer security design approaches are examined, both as abstract postulates (starting from cornerstone principles with the concepts of Confidentiality, Integrity, and Availability) and from implementation. Strategic design principles including* defense in depth, defense in breadth, least privilege, *and* vulnerability removal *are target points for the design. Additionally, we consider trust in the system over time from its sterile implementation, viewed against the backdrop of Time Based Security. The system design is assessed from external access data flows, through internal host security mechanisms, and finally to user access controls. Throughout this process we evaluate a* complementary intersection *– a balance between protecting the system and its ease of use by engineers. Finally, future improvements to secure system architecture are considered.*

1. Introduction

This paper examines approaches used in the process of securing the computer systems employed by the Navigation Ground Data System. This text is meant to serve as a discussion about best practices in computer security engineering. It is based on twenty years of the author's practical, "in the trenches", field experience on systems involved in this effort. These systems comprise a multi-mission network that encompasses the navigation elements of more than forty current and previous interplanetary flight missions here at the Jet Propulsion Laboratory. This paper does not seek to be a prescriptive document (do this one thing, buy this product, etc.), but instead seeks to examine a process of how secure systems are designed – i.e., what general security principles we have found valuable [1].

Few systems require as much resiliency or have as much risk of causing negative (and final) outcomes as the computer systems used in support of Flight Operations. Scant resources are often available for the maintenance of complex hardware and software architectures, and these high-availability/high-reliability systems are often expected to function without (and moreover cannot *tolerate*) the regular sorts of software updates expected in other computational environments.

As an example, one of these missions, Cassini, from its launch in October of 1997, would spend seven years crossing the solar system, arriving at and entering into Saturn orbit in June, 2004. It would then orbit Saturn nearly three hundred times over thirteen years, conducting hundreds of targeted flybys of Saturn's largest moons during its mission lifespan, finally coming to a fiery end in Saturn's atmosphere in September of 2017. This operational effort would be conducted on a network of computer systems having a requirement for no more than two minutes of unplanned downtime

*Robert M. Beswick, 4800 Oak Grove Dr., Pasadena, CA 91109 USA, 1-818-393-0539, Robert.M.Beswick@jpl.nasa.gov

a year (99.9995% availability) [2]. For a network that could not be upgraded (except in minor incremental steps) during the length of the entire 13-year Saturn orbital tour, maintaining and keeping such a computer network secure, as well as supporting backwards compatibility (and obsolescent hardware) would be a challenging problem. In fact, the systems used over the launch and interplanetary voyage across the Solar System contained less processing power, storage, and *total* memory than the author's current iPhone – and these systems would have to be kept functional and secure in case there was a need for backwards comparison.

While some organizations may have little need for a computational environment larger than a client-server configuration of a few systems, others may require a more complex environment. The Ground Data System for Navigation is constructed in the manner of a classic Development and Operations model with development and production networks of several hundred servers and workstations. This network is used by teams of engineers working, often under critical time pressures, with rigorous requirements for accuracy [2].

For this environment, it should be clear that a particular cryptographic protocol, a set of software, or even an appliance will not solve these security challenges. This is not an application problem but instead a systems problem. As in other engineering disciplines, in such an environment the design must be based on good *principles*, because, like with the pouring of a foundation of a building, you only get one such opportunity.

Part of the effort in this discussion stems from the author's own struggles to find a good systemic set of definitions and guidance while endeavoring to build a more secure network. What you see here is a reflection on the insights I was trying to find for my own efforts. Furthermore, many current efforts in computer security research are based not on building a secure system but tearing a system down. Indeed, a great deal of present investigation in computer security is based around the twin ideas of "if it ain't broke, don't fix it", and "try and see if can be broken". Accordingly, extensive research across the spectrum of computer security is being conducted in the field of penetration testing, where the primary methodology is to break into an existing setup and then fix the discovered problems. While this can be helpful in discovering specific flaws, it does not provide much help in trying to understand a more general architecture model of security.

An example of this is perhaps best exemplified by the software tool known as "Chaos Monkey" – part of an open source suite of tools called "The Simian Army" that was originally designed for the cloud infrastructure of the streaming media service Netflix [3]. This software set comprises a series of tools that help the design of resiliency in a set of virtual machine instances. It does so by randomly shutting down members of the set of virtual machines. By forcing developers and systems engineers to prepare for unexpected failure, a more fault tolerant network design will emerge (it is hoped). This has been further expanded and generalized to even more powerful tools that comprise "Chaos Gorilla", which randomly simulates the shutdown of an entire Amazon Availability Zone, or the even more devastating "Chaos Kong", which simulates the shutdown of an entire Amazon Region [4]. This design is an example of "survival of the fittest", incorporating a genetic algorithm-like approach to the design of secure systems.

Critical questions that should be raised in conjunction with this software are, "How does a developer or systems engineer build a more stable and secure system? What principles should be used? What methods should be avoided?"

Continuing with the metaphors given above, consider an analogy to the above (genetic) algorithm: a team of stone-age architects trying to build a bridge across a river, first by using a captive monkey, then a captive gorilla, and then a giant mythical beast to try throwing stones and batter a pile of rocks into a working bridge. While such a method will produce some results (albeit very slowly), what about other engineering approaches to design? What of the arch and the use of suspension? What about the consideration of tension and compression and the use of different materials in the construction of a bridge?

Clearly other engineering principles can be useful here in order to produce an initial design and improve upon it before bringing someone to attempt to tear it down. In like manner, this paper is a study on security architecture design, and hopes to add to such efforts by discussing principles on "how to build a (better) bridge".

A word about the expected audience of this paper: the design principles discussed in Sections 2 and 3 are aimed at top level design of secure systems, and may be of greatest use for project management and systems engineers (it could also be titled "how to avoid buying crap"), while Section 4 covers an example implementation targeted more for computer systems architects and systems administrators. The paradigms covered in Section 2 and 3 are observed derivations from fault tolerance and have wide applicability in systems engineering, while Section 4 applies this methodology to securing a specific computer system.

2. System design approaches: Fault Tolerance and Security

Fault Tolerance

2.1. Fault Tolerance

There are several valuable definitions for the concept of fault tolerance. Fault Tolerance, according to Carl Carson, comprises "...a design that enables a system to continue its intended operation, possibly at a reduced level, rather than failing completely, when some part of the system fails" [5, p. 167].

This has been categorized by Barry Johnson in the approaches taken for fault tolerance in microprocessor design as [6]:

- Minimize the number of points where a single fault will cause the whole system to fail.
- Graceful degradation – known also as "Fail-Gently", a system's ability to continue operating in the event of a failure, having a decrease in operating capacity no worse than necessary for the severity of the failure.
- Redundancy in components – both in space, having multiple parts that can be utilized, and in time, with the repeatability of an operation.

Jim Gray and Daniel Siewiorek help characterize such steps to provide high availability in computer systems by examining single points of failure to promote [7]:

- Independent failure – where each module functions so that if it fails, it does not impact other modules in the system.
- Design diversity – using hardware and software from differing organizations to promote independent failure modes (e.g. differing *types* of failure).

There are abundant examples of fault tolerant design. This is a well understood area of systems engineering. From the 135-year old Brooklyn Bridge in New York [8], to the current Eastern Interconnection power grid of the United States [9], approaches such as these are needed where one must trust the behavior of a system to work, and to work in predictable ways.

As an aspirational example, consider one such computer design further at the highest end of the reliability spectrum. The primary flight control system of the Boeing 777 achieves ultra-high reliability metrics. It is a highly redundant, highly available system comprising the fly-by-wire avionics controls and is a rare example of a true Triple Modular Redundant (TMR) system (with little exception the highest level of redundant design, having three redundant components for each single point of failure), in both computer nodes, software, and hardware. It has service metrics requiring a maximum rate of failure of the flight computers of 1.0×10^{-11} failure/hours (i.e. a failure of the flight computers less than 1 in 100 billion flight hours) [10]. This is an example of what can be done with sufficient effort and due diligence – a computer system millions of passengers a year put their trust in.

2.2. Security Fault Tolerance

In like manner, this paper considers computational systems that one can trust – as is done with the physical systems described above. From fault tolerance, we can derive similar approaches to deal with the actions of intelligent actors[1] rather than random chance or stress failure modes. Such an approach was described affectionately by Ross Anderson and Roger Needham as "Programming Satan's Computer" [11]. While the application of these principles we apply here to the flight computer and network security of our systems, the principles are applicable across the board to security design. Such design promotes:

- Secure systems should be resilient from random chance and predicted stress modes of failure.
- Secure systems should also be resistant to direct action.
- Simplicity of design, known as the popularized KISS principle, is a golden virtue in secure systems [12].

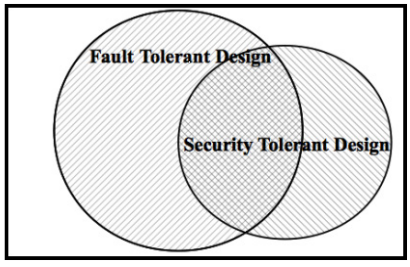

Figure 1: Relation of Fault Tolerant and Security Tolerant Design

These principles can be considered in four approaches:

2.2.1. For the most critical systems, use a machine that has only one function.

This approach has the benefit that in the event of a failure, you have lost only that one function. There are numerous examples in security design. Indeed, "appliance" IT systems, such as web servers, email servers, firewalls, and similar systems use this approach. As a good analogy: in (most) kitchens, refrigerators and ovens are not a part of the same appliance – even though they have the same task of changing and maintaining food temperature.

2.2.2. For redundancy in a security context ideally differing configurations should be used.

This technique considers that the systems in a given setup should not all have the same potential vulnerability (and therefore not truly redundant against a threat). It is an example of the previously discussed design diversity. Examples of this include the use of multiple arrays of web servers – running different OS/web server software, or application servers that use differing configurations and password sets, or multiple (different) backup systems – e.g. tape, disk, and cloud service providers. As an analogy, consider the commute from a major urban center: it is better to have several differing options for transport, be it freeway, commuter train, bus, or even surface streets. In the event one method is impacted, other options are available to return home.

2.2.3. Single points of failure of a system should be few, and truly independent.

As observed above, in a security context, systems that are single points of failure should be truly *independent* of other points of failure. Such single points of failure should be examined closely to ensure that they are actually single, independent, points of failure.

This goes hand in hand with the first point about single use. One example of this can be seen in network file server "appliances" that perform the function of serving files – other application sets such as virus checkers and configuration management tools may be run on the files themselves, but they are seldom loaded on the file servers. This design approach is often misunderstood in poor implementations, especially where security may be seen as a software package or an add on feature. As an analogy consider tires that serve as critical single points of failure for a modern car – in a similar manner, it would be absurd if a failure of the GPS system caused the tires to fail!

2.2.4. Systems should Fail-Safe and/or Fail-Gently.

In case of failure, a security system should degrade safely (known as Fail-Safe), and/or compromise only a limited part of the overall system or otherwise take an "acceptable" amount of time to fail ("Fail-Gently"). Examples of this abound, many of them utilizing cryptography, such as disk and file encryption, password login for most computer systems, firewalls, network segmentation, and network Intrusion Prevention Systems (IPS). An analogy can be found in the mechanical realm in that high grade safes are rated

[1] To be clear: this term is meant here to describe human attackers, not intelligent software agents. They may also be described as malicious actors, or threat actors depending on context. The colloquial and overlapping terms of hackers, crackers, or security hackers are also used in the general news media.

for time against tools, cutting/welding torches, and explosives. Some safes may have mechanisms that break or cause the safe to be unopenable if drilled or otherwise tampered with.

3. Computer Security Design

3.1. Abstract Principles

This computer security design incorporates the above techniques through increasing grades of refinement. Abstract concepts of Confidentiality, Integrity, and Availability (the traditional trinity of security) help to determine the "who, what, when, and where" of the security needs for navigation computation. These principles provide definition for the key concerns for securing a system, not in terms of technique, or subsystem protected, but rather in terms of what features in the computational environment must be protected.

3.1.1. Confidentiality

Confidentiality is referred to as "the concealment of information or resources" [13, p. 4]. This can be of high priority for some financial systems, where customer data is not only a crucial part of business operations, but also where strong legal regulations may come into play for control of customer information. It may be critical in military computer systems (for some cases it may be more desirable to destroy the system than allow the unauthorized release of information). This is significantly less crucial in the field of navigation computation. Such information for navigation comprises mechanisms used to authenticate access to the systems, network and system configuration information (possibly of use to subvert security), and restricted navigation software. An example of a baseline concern for Confidentiality can be seen even in the naming of individual systems, as such host names may reveal a great deal of information about the underlying network design [14]. Consider a hypothetical, badly named example from JPL: the host name "cas-web-serv3", which immediately gives information the system in question is running a web server daemon, for the Cassini project, and that most likely there are (at the minimum), two similar servers.

3.1.2. Integrity

Integrity is "the trustworthiness of data or resources ... usually phrased in terms of preventing improper or unauthorized change" [13, p. 5]. Integrity is particularly critical for navigation computation, as improper or unauthorized modification of the environment could cause very serious problems. Corrupted data sets, results or software could cause terminal errors in spacecraft control. With regard to the accuracy required for navigation of spacecraft missions, the sensitivity placed on the accuracy and integrity of the data, software, and corresponding results cannot be overstated. One such example of the critical nature of Integrity is seen in the previous case of the Cassini project. Integrity was critical on such a mission, which consisted of one of the largest teams of navigation engineers ever assembled, flying on the navigation computer system one of the most complex orbital and interplanetary trajectories ever designed [15].

3.1.3. Availability

Availability is "the ability to use information or resources" [13, p. 6]. Conceptually, it is the most direct derivation of principles coming from fault tolerant design. Availability in the context of navigation computation, has an additional concern that someone could deliberately try to deny access to a system service or data sets. The 24-hour-a-day, 365-day-a-year activity calendar of spacecraft navigation indeed makes this a crucial concern [15]. An event which causes the system to be unavailable, which in other industries might be cause for concern, could lead to the premature end of a multimillion dollar space mission.

3.2. Implementation

From these abstract principles, there are a number of paradigms that are employed for the implementation of better protection. Accordingly, strategic archetypes are used in the work toward good security design.

3.2.1. Defense in Depth

Defense in depth is a military security term with a long historical pedigree. Instead of a single defensive stronghold or chokepoint, this strategic principle is based around a series of overlapping defenses, forming a type of fault tolerant redundancy [16, pp. 40-44] in that a failure of one part of the system does not lead to the failure of the whole system. Considering a networked computer system, this can be seen on a variety of levels in overlapping defenses: starting at the network perimeter firewall, the network segmentation rules used on the network switches, the host based firewall, the protections applied to the processes that connect to the network, and then the internal host security measures that must be bypassed by a potential attacker. This is analogous to a defensive perimeter made up of a series of overlapping walls and fortifications, much like that seen in that of a medieval castle, or World War I trench warfare, presenting so many obstacles to entry that an adversary, having a choice, will pick a less well defended target [17, p. 259].

3.2.2. Defense in Breadth

Defense in breadth is a term serving as the converse for *defense in depth*. It involves the concept that a secure system design must consider the whole system in its implementation, or an attacker will simply ignore a well fortified part of the system and instead chose an easier route into the system. All of the previous paradigms of overlapping defenses, minimization, elimination, and security over the system life, must be considered for *every* part of the system. This is a difficult task and it does lay bare the challenge of the security engineering process. By definition this is an effort to examine the totality of all of the possible attacks against the system. Indeed, this defensive principle is referred to by Sami Saydjari as *Ensure Attack-Space Coverage*. He acknowledges that achieving this comprehensive coverage is a large and challenging problem, and one that is usually not well understood, but he underlines its necessity as a security engineering principle when he remarks "Depth without breadth is useless; breadth without depth weak. " [18, pp. 133-135] Consider an analogy from a failure of this principle: putting a well-locked door with a security system on a Hollywood film set facade; while it is possible to break through the front door, it is much easier to simply walk around the side or back of such a facade because most such sets do not even have a back wall. History is rife with excellent examples of the failure to consider the whole scope of ways an adversary could carry out an

attack. One such example can be seen in the WWII failure of the Maginot line on the French-German border. [2]

3.2.3. Least Privilege

The principle of *least privilege* is that subjects (processes and users by extrapolation) should be given only the rights and accesses for the tasks the subjects need to perform, and no more [13, p. 457]. This avoids many possibilities for the manipulation of a process (or manipulation by a user) to get them to do things they were not intended to do. There are many similarities to ideas in finance and accounting where financial mismanagement and corruption in corporations are prevented by not allowing any one person to take charge of all the corporate finances – also known as the "two man" rule. As an example, consider a hypothetical printing utility that can write to a central spooling directory as a privileged user. It is discovered that by manipulating the input files sent to the printer, it is possible to write to other directories on the system. With some effort and cleverness it may become possible to overwrite critical system files or even get remote access to the system. By changing the permissions of the spooling directory and removing the ability to run as a privileged user, the printing utility can continue to function, without enhanced access, thereby removing its capability to be misused. A similar analogy is a classic safe deposit box repository in a bank, where two people (each with a different key) are required for access to a given safe deposit box.

3.2.4. Vulnerability Removal

When we remove potential vulnerabilities, we can elude the many problems that come with those vulnerabilities, and sometimes avoid other issues as well. Matt Bishop refers to this as *The Principle of Economy of Mechanism* [13, pp. 459-460]. An example of *vulnerability removal*: a self-replicating worm that attacks email server processes can do little damage if you do not have an email server on your system. Likewise, if you do not have a web server running on your system, there is no need to monitor for such and keep up with attendant patches. Making sure that (along with the software and its own attendant maintenance) possible vulnerabilities in buggy software are not installed, can save tremendous resources and time over the system lifetime. As an analogy, this is akin to not just locking a side door into a building, but instead never constructing the door into the building in the first place.

3.2.5. Sterility and Absolute Security

We now consider the idea of *sterility.* This is a point along a spectrum of levels of trust in a given system. Understanding how much one can trust such a system may help determine how it should be used and where it should be placed on the network. A few (very rare) systems we consider to be sterile and have *absolute security*, the top of this spectrum, or "security beyond any reasonable doubt". [3] To be clear: this is a theoretical initial state, a starting point for definition, and *no* connected or exposed system can be said to be sterile and in this state. This is a valuable concept, especially as we consider the next paradigm. It is comparable to a definition of an initial starting point (a *t0*) that is useful when considering how that system might evolve over time.

Let us further consider, that a system implemented on a closed network, built from a secure image is secure, or *sterile* to the limits of confidence one has in the hardware (and the hardware vendors), network, and the software media (DVD or secure image and/or patch servers, etc.) used to construct the system. On such a spectrum of trust this system would be seen as approaching *absolute security* considering these limits of confidence. This useful idea can be seen as extrapolated (as systems in miniature) from credentials, passwords, or certificates that also have not been exposed. We can liken this to issues seen in medical care, or food preparation and handling, where much effort for hand washing, cleanliness, or cooking is undertaken to produce sterile areas, or clean food for consumption.

3.2.6. Security over time or robustness

The previous paradigms examine the implementation of a static system. Considering the evolution of a system state over time, one should also consider how the system is secure during its implementation and over its whole lifecycle. How robust is this system? How much can it be trusted and how does that trust change over time? This is similar to principles of Communications Security (COMSEC) and Operations Security (OPSEC). These are military security terms that examine the communications and background operations processes of military organizations, working to prevent compromise of communications, and the processes of such organizations. As in a military organization, our trust in a system will change over time. This is strongly dependent on the environment and networks that connect to this system. It is very important to examine these connections and method of contact to characterize the *security over time* of a system.

This concept is akin to what Winn Schwartau called "Time Based Security" [18, p. 34]. In Time Based Security, a system would be considered "secure" if the time to break through the system protection (Pt) was greater than the time required to detect (Dt) and to respond (Rt) to the intrusion. This can be expressed as:

$$Pt > Dt + Rt \quad (1)$$

Time Based Security suffers in the great difficulty of quantifying these values in (1), for the system protection, detection, and reaction time. Nonetheless Time Based Security does help illustrate well that security over time is a derivation from the fault tolerant concept of Fail-Gently, as discussed above.

Coming from the previous point about sterility, trust in a sterile system must change when it is attached to outside networks. Our confidence in such a system is then based on the security configuration of the external network, internal host, and user

[2] The Maginot line was designed to protect France from a German incursion in the event of a second world war. It was an excellent example of the principles discussed here, providing significant fault tolerant, defense in depth, with carefully considered access and both perimeter and internal security. A marvel of military engineering, its primary construction protected the French-German border. Most elements of the line were operational and fully prepared to continue fighting *after* the fall of France, and had to be ordered to surrender with the French capitulation. The designers famously did not consider (mostly due to the staggering costs to expand the fortification) an assault across the French-Belgian border.

[3] This is a functional term that in our model is akin to, but not the same as, the mathematical term *perfect security* – such as the unbreakable one-time pad [36].

controls of the system. Log mechanisms can help give indications of change to the system. If this trust is misplaced, the system could be compromised, and the system could become untrustworthy and itself a source of security concerns. As in the previous section we consider that this is akin to handling a compromised password or certificate, and in most cases the system must be rebuilt.

There is considerable kinship between these ideas and the study of infection and food-borne illness. The frequent admonition about hand washing before meals comes to mind. What things did one touch or pick up? Do you have a thermometer to see if the food is cooked? A brisket set out too long at a picnic may "go bad" and become a host to viruses, worms and other sources of contagion. It may be possible to sterilize it, or at least to clean the dish containing the item. Much care is required to safely clean dishes under food handling regulations, but having gone bad, food, no matter how savory, almost all of the time must be thrown out.[4]

4. System Evaluation

Keeping these principles of secure system design in mind, we consider an example case: a single computational node and the techniques and mechanisms put to use to create a secure system. Our model system is a server running Red Hat Enterprise Linux 7. Particular care is taken in its construction as it serves as a fundamental "building block" in our system plan. This security design takes on several design principles found in architecture in that the strength of a system can often be improved, not by what one adds, but by what one takes away. Also, this serves as an effective approach in considering the overall security of our environment. Moreover, many systems are actually allocated in a "one engineer, one workstation" ratio. Similar efforts can just as easily be a network segment, implemented in a network group.

It is useful to reiterate here: this is *example*. These security architecture guidelines can be applied in many other approaches and types of system setups. This is an outline that other system architects and system engineers can follow to create their own secure systems. It is hoped that this demonstration will help to make these key concepts and their application in design more clear. This system-design model is a simple one. It is to serve as a means to explain principles and their use in an architecture. As we extrapolate to a network, or a network-of-networks we get a clearer understanding of these principles and their use in a model. Complexity may be introduced in efforts to move towards a particular architecture model.

For example, one such effort called Zero Trust computing, moves towards a very atomic model of trust, that of so called "de-perimeterisation" where the outer defenses of a network system are assumed to be ineffective. Zero Trust uses the same design goals, but with an aggressive application of the principle of *least privilege* applied to every element of a network [20, pp. 2-3, 12-18]. It involves the hardening of every computational node, and every network connection and data access, and moves away from the traditional specialization of gateways, firewalls, and trusted subnets or zones. The model we discuss is agnostic to such efforts, as approaches we take here are equally valid for such designs. A more "classic" network security model is, simpler to explain.

Our fundamental design goal is to create a system that can be trusted and relied upon to perform the difficult task of spacecraft navigation. This design effort sought to find an optimal tradeoff between usability and security, the point of both maximal utility (for the users) and security: a point where users could work without being fettered by obtrusive security measures, while confident that their work is safe. Indeed, it is a mistaken, albeit popular, notion that security must interfere with usability, and that secure systems must necessarily be hard to use. Much of the time this misconception is due to a poor implementation of a secure feature, or a security control that was added on as an afterthought to a software system. Failing to consider these requirements and needs of the users also can lead to the perceived adversarial role of security in an organization. The idea of examining the security controls in consideration with the user environment is referred to by Matt Bishop as the *Principle of Psychological Acceptability* [13, pp. 464-466]. The strategy we consider here strives to find a complementary intersection between usability and security, an optimal point where these two groups of competing requirements reach their maximum effectiveness [21]. This is similar to the concept known as the Center of Percussion (known also as the so-called "sweet spot") as found in weapons, aircraft, sound engineering, and sports equipment design – where multiple factors combine into an optimum response from a given amount of effort [22]. Analogously, these competing needs are similar to the economic concept of the law of supply and demand.

Finding this complementary intersection requires the evaluation of both security and user requirements. For an example of this optimal intersection, consider the often maligned password change requirements of most institutions.[5] Usually eight or more alpha-numeric, and special characters are required, often with other "randomness" requirements. These passwords often have to be changed every 180 to 90 days (or less). As a matter of cryptographic security, the longer the encrypted password hash, the more difficult it becomes to conduct a brute force attack to obtain the unencrypted password. Hand in hand with this, changing the password more frequently helps ensure that even if the password is broken or obtained by some other means, the window of exposure is short before a new password is created. Evaluating these security requirements, without user input, leads to more "random" and longer passwords, approaching something looking akin to line noise, with changes occurring in shorter and shorter time intervals. Taken alone, this might be considered to be a positive trend.

However, it has been widely known for some time that the user response to such policies tends to decrease the security of the system [23]. Users, unable to remember their ever-changing passwords, proceed to create easily guessable password combinations, or worse still, write passwords down in easy-to-find locations such as next to computer monitors or under keyboards. Evaluating both security and user utility requirements can instead lead to an optimal solution for these concerns. This could include

[4] There are limitations to this analogy. One of my associates who is a professional chef cited several counter examples – however he was quick to note that this holds true for 99% of food handling concerns.

[5] A memorable and humorous example of this can be found at http://xkcd.com/936/

a longer password rotation with a longer password, or possibly a smart card and a password (for two- or three-factor authentication).

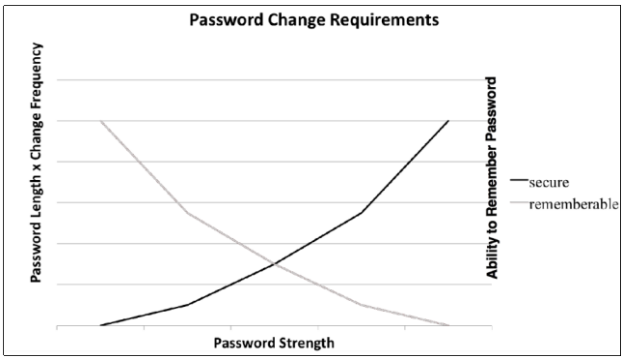

Figure 2: Complementary intersection of password controls.

But how can this optimal intersection point of security and usability for this system be determined? For this system design an initial setup is undertaken stemming from security design requirements and user needs. Numerous manuals for securing systems can be used *a priori* to determine a baseline configuration. We have used recommendations from the National Institutes for Standards and Technology (NIST) [24], the Information Assurance Directorate (previously named the System and Network Attack Center) of the National Security Agency (NSA) [25], or the Center for Internet Security (CIS) [26]. Using the security principles we discuss, these (and other) security approaches are evaluated, determining what user needs are crucial while seeking as secure a configuration as practicable. Areas of conflict (and overlap) are considered and from this iterative changes can be made.

Changes are then evaluated on the privilege, area and criticality of the alteration. Iteration towards an optimal state is a manual process of testing, examination, and consultation with users. For our model, there are three areas of concern: external network access, internal host security, and user level access controls. These areas have differing complementary intersections: the optimum trade-space differs between these areas of concern. Once this optimal state is determined, we then consider the evolution of this security state over time.

4.1. External Network Access

Under the greatest amount of scrutiny, the area of greatest care for the system design is the configuration of external network access. This is an exercise in optimization and extreme minimization. While users will be surveyed for input on desired services, security needs predominate in this area over almost all user concerns. Every access point (open network port or service) is of the highest concern as network access control is the first and best line of defense against intrusion. As we note above this approach can be generalized: this principle applies to both individual computer nodes, as well as networks of computer systems. For an analogy, if the network is compared to a street, an IP address would be the street address of the building and the ports would be the doors of that building. A firewall could be a wall surrounding that building (having its own doors/gates), or around several buildings in a compound. This analogy can be further extended much like that of a design of a military base (or a medieval fortress) with layered defenses. Again, this system design model is a simple one, and other design choices may factor into such an extension. In the area of external network access, the interplay between security controls and user needs will be very heavily tilted toward security because this represents the first, best chance to block an attacker (at the gate).

As mentioned previously this security design could be used in other system approaches. When we examine network access points to the model system, we should also consider other access points, such as physical connections to the system like the ubiquitous USB or Thunderbolt connectors. One can also consider similar methods by extrapolation to evaluate a database system, or a file storage system, by examining the controls on the data, and the access points to that data.

The approach utilized involves cutting down to the absolute minimum the number of open network ports, and then over those ports minimizing the content and amount of data transferred. Among the network testing tools we use, two include the Nmap port scanner (providing a comprehensive scan of all open ports on a machine) [27], and Nessus, a widely available network security scanner that helps probe for security vulnerabilities on the remaining open ports [28]. Indeed, although the user community may with regularity request the installation of numerous software applications that will have their own unique web server on an additional open port, such services will usually be disallowed. This is necessarily an iterative process. Sometimes if taken too far and too many ports are closed off and services shut down, the machine will not be able to communicate over the network. There may be times as well when certain user applications really do need to have a port opened for them. These should be examined most carefully. Those few services that are still available will be expected to be extremely secure against external subversion, such as the SSH remote login/file transfer/port forwarding service. In this approach:

- First test the system absent the host based firewall. This is to ensure the underlying system is secure without it. The firewall should not be the only point where outside connections are minimized and controlled. *Almost all network services can be shut down on a secure system with no real difficulties to the underlying function of the operating system!*
- Next test the system with the host based firewall engaged. In many cases stateful packet filtering can be used to trace (and allow) replies to network calls, which will eliminate the necessity for most holes in the firewall.

Table 1 depicts the results of this process for our example. From more than twenty open network ports on our initial image (which is a great improvement over previous Red Hat Linux versions) we reduced the number of open network services to a bare minimum of essential network services:

Table 1: Number of open network services with and without Firewall – Final Minimum Services

Firewall State	**TCP**	**UDP**	**ICMP**
No Firewall	3	6	2
Firewall	2	3	2

This is an excellent example of the point made earlier that the strength of a system can many times be improved by what is taken away from it. Contrasting these results with the hundreds or thousands of network services on a general home Mac or Windows computer can be enlightening as to the current default state of computer security.

4.2. Internal Host Security

A highly secure system that is impossible to use for its primary duties is not very *useful*. In evaluating our system's internal host security, the interplay between security controls and user requirements must be nearly equal due to the competing concerns to both keep it working as efficiently, and as secure, as possible for the users of the system.

By analogy, inside the building, the use of the building by its inhabitants is an important design consideration. Is it a home? A bank? A police station? Safe construction approaches are dictated for all buildings by fire codes, but how a building is used will determine much of a building's interior design.

For our own computation environment, this process of system hardening considered functions and services the user community required:

- The completion of operational duties such as supplying critical data sets to mission partners and utilization of mission critical flight software.
- The supply of required capability for a task or job role (e.g. visualization and formatting tools, viewers, editors, functional compilers, and third party software).
- The provision of *useful* utility functions and software (e.g. BR/DVD/CD archiving, external export of interesting graphical output, the capacity to safely load removable file systems, and network printing).

From these characterizations, a definition evolved of what behaviors were expected of a user and conduct they should *never* be expected to engage in. With such a set of definitions we removed from the system those privileges and programs a user was never expected to use, and added further constraints so users would have difficulty in performing anomalous activities.

Similar to the approaches used to secure the external network access of the machine, a software tool was used to evaluate the internal security settings of the machine and produce benchmarks for enhancement. Created by the Center for Internet Security (CIS), the CISscan package was used to evaluate the internal host security for the system [26]. It provides a set of metrics for assessing security configurations for a number of package distributions, as well as operating system platforms, allowing comparisons between variant software sets, alternate configurations, and operating systems. Representing an effort to create a "best practices" industry standard guideline to system security, the CISscan package is based around a set of consistent standards, that can be used to evaluate a given system against such metrics. With this tool, it was possible to create a security baseline, make sure that configuration changes and patching continued to meet that baseline, and iterate to a desired system configuration.

Categorical changes to the internal security settings included:

- Removal of extraneous executable permissions. The ability to change users in a program is an especially serious concern. SetGID and SetUID executables have the ability to change the group and user of the process that runs them. With this ability such programs present an extreme security risk. Some programs however, such as the ones that are required for users to log into the system need such a capability. Like our evaluation of open network services, almost all operating systems have a needlessly high amount of these types of programs by default. Even the latest versions of Red Hat Enterprise 7 contain numerous examples of programs with too many privileges. In our system, with effort we reduced the number of these very sensitive programs from 45 SetUID executables in the initial install to a total of 15 in the final secured configuration (see Table 2 for full discussion).
- Limit the installation of new software. Every new software installer has the potential to open up new vulnerabilities. It is far better to avoid such problems by not installing the software at all. As noted, this may minimize many maintenance issues as well, including keeping the software secure and patched. A related question for discussion is, "does your software really *need* its own web server?"
- Limit or otherwise shut down all unnecessary system services. For some minimal operating system configurations, the number of system services running on startup can be counted on one hand. This is a far cry from the average computer, which can have more than a hundred processes running at any given moment before anyone has logged in. Such extraneous processes can represent significant vulnerabilities on a system, especially if they have a network port open.
- Modify key network and kernel data structures. By changing the settings of key network and kernel configuration values, it is possible to significantly increase the protection of the system against denial of service attacks and other security failures with the occasional cost of small increases in memory use. Indeed, lowering user limits (number of users) and per-process (number of processes) on the system, significantly lower the odds an application can harm system function, blocking a denial of service attack by preventing such software from consuming system resources. Fortunately this area is one of the least likely to result in negative feedback and consequent user pushback.
- Restrict file system permissions on untrusted and/or critical file systems, secure application sets, and use caution for removable file systems. Crucial file systems are mounted read-only on most machines in our environment (especially the ones containing critical software). Also, file systems that are removable cannot execute programs with SetGID or SetUID privilege as it is trivial to create such programs that can give the user elevated privileges (thus bypass system security) on a different system and load them from a removable device.

These categorical changes are summarized both from the metrics of the CISscan tool and with direct metrics (where possible). Results of these efforts are shown in Table 2 and Table 3, taken from our model system image at four different revision times.

Table 2 examines direct metrics that can be compared across several differing system images. This includes the total number of SetGID and SetUID programs in the image, the number of "classic" System V and "new" Systemd services, as well as kernel settings (variables) changed for hardening the internal system and network from attack. For the first four rows of metrics, lower is better, for the last two rows, higher is better:

Table 2: Navigation OS Direct Metrics

Metric	Initial Install [6]	June 2016	April 2017	May 2018 [7]
(Lower numbers are better)				
Total SetUIDs	45	15	15	15
Total SetGIDs	23	18	19	19
Systemd Services	136	55	58	58
Sys V Services	5	2	2	2
(Higher numbers are better)				
Kernel variable changes	3	11	14	14
Network changes	2	4	4	4

Table 3: Navigation Red Hat Enterprise 7 Security Metrics (Center for Internet Security Benchmarks)

CIS category	May 2015	June 2016	April 2017	May 2018 [6]
Updates, Add. Security	38%	45%	45%	47%
OS	12%	11%	11%	11% (est.)
Special Services	67%	67%	67%	79%
Net Configuration	91%	92%	92%	91%
Log & Audit	50%	55%	55%	57%
System Access	45%	41%	41%	39%
User Account	14%	14%	29%	43%
Tests passed/failed	71/66	87/79	88/78	110/79 [8]

Table 3 tracks more general changes in *types* of configurations, and in order to track such changes over time, the CISscan tool is used. Breaking the OS into areas of concern, these metrics measure how secure such categories are compared to a reference model. For some cases, with the addition of software sets or new features requested by users, these scores went down. While the results are broad and vary by software sets and installed feature, they give the ability to check the aggregate state of security and compare changes over time. This may be invaluable when a software installer decides to reset a host of security settings. Such changes are very apparent in these results, and this tool also proves itself useful in providing aspirational (and safe) examples for academic papers. Relevant CIS categories along with numeric percentages for several system images are given. For these values a higher percentage is better, but it can be nearly impossible, and (mentioned previously) less than useful to reach a 100% score.

4.3. User Access Controls

The controls directly placed on user action in this security model is an area where considerable compromise is necessary in the interplay between system security and user needs. The domain is one where (for the Navigation systems) the need for usability is a greater priority than security. By analogy, consider the use of badge controlled rooms in a building. While such security may be appropriate for certain high security buildings where this type of security is required, it may not be as suitable for a supermarket or a home. Two such systems are in general available for most OS platforms.

4.3.1. Discretionary Access Control

In Linux this user control is based on standard process and file permissions, allowing for access control of critical system files and granting users the ability to manage access to data sets and user files. This mechanism allows for a separation of users and data, with these management controls based on Discretionary Access Control (DAC) mechanisms, such as traditional Unix process and file management. Such controls have been standard on almost all operating systems for some time. Care should be taken to avoid overly restrictive user settings. Unlike the previous areas, it is hard to come up with a general standard for these controls. There might be significant difference in file system and data permissions even for different teams on the same system. Indeed, all that we can recommend here is due diligence in the application of these protections.

4.3.2. Mandatory Access Control

Mandatory Access Control (MAC) is an alternate security mechanism that is available under Linux, referred to as SELinux [29]. Part of a series of research projects out of the United States' National Security Agency, this series of software modules seeks to bring aspects of highly secure operating system designs to the Open Source community [30]. These features, which allow for a second, very granular control over user actions, previously were available only on highly secure and expensive computer designs. These modules are included with the Red Hat Enterprise Linux distribution and are a part of our model image. User access can be granted or revoked to a specific file or process, categorized by role. For example, on a system without SELinux, the critical system password file (/etc/shadow), cannot normally be read, however the time it was last modified and the size can be read by an unprivileged user of the system. Such information, such as when the file was last changed (i.e. the last time a password was modified) could be useful to an attacker. For a machine running SELinux with restrictive settings however that file cannot even be listed by an unprivileged user of such a system: no information about that file will be returned *at all*.

[6] The initial install was not suitable for general use and underwent significant change. It is close but not equivalent to the May 2015 release of Table 3.

[7] It should be noted in both Table 2 and Table 3 (below) that the system contained almost five times as many software packages in the May 2018 release as the initial install due to new feature requests and open source changes.

[8] CISscan was updated and several tests were added and expanded. This category had changed significantly in the new version and the value was derived from the previous test method.

However, as we note, how well the users can use the system is a crucial concern for this area. Unlike the specialized intelligence and military computer systems that utilized Mandatory Access Control initially, users of general purpose engineering machines, like those of the navigation computing environment, typically do not have the same expectations or same security concerns about how such machines should function. The use of such constraints could potentially make the user experience miserable, or simply untenable. Furthermore, familiar applications could fail in unexpected ways. Such controls are also quite difficult to configure in a correct manner to support the Navigation user community. There are few use cases where this level of security restriction for these *User Access Controls* area, has been found useful, in comparison with the application of greater restrictions on the *External Network Access* and *Internal Host Security* subsystems.

A trial run of the SELinux system was undertaken on a limited set of operations workstations to evaluate the utility of these controls. The proposed idea was to apply an iterative process to determine the areas of the system utilized normally by the user base. SELinux was run in permissive mode over the course of several weeks, and the SELinux system was examined to determine those areas where the users would be blocked by the SELinux policy. From these conflicts a model of user activity was built up over several months, which allowed for changes to be made to the SELinux policy rules, or changes to be made to user software and/or user behavior. Over time the sum of these changes helped define *expected* user actions. Areas of the system that users did not use and did not need, would be blocked off from user activity.

In principle this is a good approach. However a formal effort examining this method noted two major difficulties [31] and these difficulties have not changed significantly:

- System analysis and configuration: Getting the computer system and its processes working, and working with the correct permission sets was significantly more technically challenging than expected. Many errors were only solved by trial and error. A considerable amount of time was spent to get the system to a working and stable state.
- User analysis: This process (even on earlier versions of SELinux) was not unusually difficult. However downtime could be required during the analysis iterations, and these iterations could make it difficult to accommodate system and user activity changes (users do not like having to log out of their systems repeatedly). This may be an area that functions better for environments that are more static.

At this time methods of Mandatory Access Control such as SELinux are still being evaluated for use in Navigation. Although it offers much improved control mechanisms, and even allowing the automatic design of user access from user actions, our current examination of the intersection between system security and user utility in this area does not recommend its use at this time.

4.4. Evolution of system security over time

Unlike the previous parts of this section which deal with the issues of creating an initial, secure system state, here we consider the evolution of that state over time. As we observed in our discussion on *security over time* how this state changes is strongly subject to the environments and networks that connect to our system.

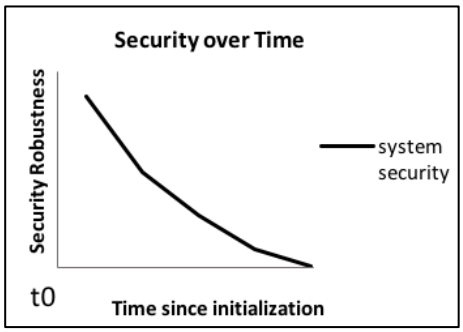

Figure 3: Security over time.

How this confidence in a system changes, and hence the *slope* of the security state in the figure above is very dependent on events in the local environment and the vulnerabilities that emerge over time. It may be nearly linear over time, or an exponential die-off due to newly discovered vulnerabilities. For example, a powered down system on a shelf (or offline storage for a VM) will not change at all. However once connected, many factors will strongly affect the slope of the curve, such as the age of the patching and software set, the security controls, and the environment to which it is connected. This is highly particular to the environmental factors acting on the system: even systems at the same site may have wide variance in this evolution. Understanding this, and remediating such changes is a large part of the maintenance lifecycle of a system. The only clear guidance that can be offered is that, as with a broken password, a system compromise will cause the curve to have a cliff (or stair-step) function in the trust of the system. This will require a system reset or reinstall to resolve.

5. Future Considerations and Conclusions

Considering the evolution of the cyber threat environment and trying to discern what new challenges will arise and how to meet these concerns is a subject of ongoing interest and research for this author. The navigation computational environment conducts critical activity on a 24/7/365 schedule, and cannot afford to be the victim of a security compromise. It is an important system that needs protection. While tips and techniques for security have dramatically changed since this author started as a system administrator, the underlying principles discussed here have changed little in two decades, or not at all. Such archetypes are examined in this paper, and while the particular technical points can change, the foundational ideas will likely remain the same.

One case in point, as noted “de-perimeterisation” approaches like Zero Trust computing may help our approach to computational and network security by encouraging rigorous security at every computational node and network connection. This is a refreshing model which brings to mind some of the most secure intelligence facilities and military fortifications of the last century. It is a vast improvement on the simple, single-defensive layer (sometimes called the hard exterior / soft interior) model which ends up being the most common approach taken in network security. Indeed, we advocate an approach in this paper of being hard on the exterior *and* hard on the interior!

While it is heartening to see such enthusiasm, and much good can come from this, it is important to remember that these efforts (still) need to consider both the complementary intersection of security and user design requirements, as well as the importance of the fault tolerant protection of *all* of the critical computational elements. As we mention above, solving the totality of this defense in breadth problem is a *hard* one. Indeed, not considering these two avenues of concern can lead to situations where the computational environment is perceived by the users as as more akin to something like a prison, or worse still, end up promoting a failure of protection akin to that seen in the previously mentioned Maginot line. Especially in the second case, aggressive efforts as Zero Trust are expensive and challenging to implement and can (from exhaustion of resources in time and effort) lead to the promotion of the failure they sought to prevent! If even a simple approach cannot be executed correctly, attempting to implement a more complex model (like Zero Trust) can be a dubious undertaking.

Another example showcasing this fundamental difference is the spate of attacks based in speculative execution on modern x86 processors (as well as methods to remediate them). These have been of tremendous concern and rapid development for the entire computer industry over the past 12 months [32]. However, the architecture problems at the source of these issues are fundamental design concerns that were identified in their implementation nearly twenty years ago [33].

In addition, a few observations may be derived from the principles espoused above. To the author's mind these should be regarded as obvious and self-evident. Unfortunately, that is often not be the case.

Of these, the most significant is *don't engineer in single points of failure*. For example, after considerable effort to construct a secure, fault tolerant network design, with a hardened firewall and a focused IDS, it is a contradictory effort to then layer a poorly secured Active Directory server for single sign-on for the network (or a poorly configured VPN to access such systems). Such a setup is self-defeating – at best. Fault tolerant and secure design should not be ignored for "just one service". In a similar manner the implementation of a poorly designed security tool designed to examine (or worse, modify) the entire enterprise environment can serve to help implement a large security hole for the entire enterprise. Indeed, as Sami Saydjari relates, there is particular concern with such enterprise security tools as such systems are the highest priority targets of attackers [19, p. 346]. Ease of management of an enterprise network is a nice goal. However, one of the questions that should come up is, "by *whom*?" Single points of failure must be closely, closely watched, as they can be doors that potentially open up the whole network to attack.

This goes with the concept that uniformity of design is not necessarily good. "Balkanization" or the promotion of multiple differing configurations (as long as each of those configurations are secure) promotes design diversity, as discussed in Section 2. While this may not be desirable from a management perspective, such diversity can lead to independent modes of failure, and hence increased security fault tolerance.

Similar to this is the desire to patch often, in the effort to be secure. These two concepts are not, as popularly believed, the same. While this may go against the grain of the currently popular DevOps and Agile software engineering paradigms, it is clear that, absent other testing schemes, it is wise to take the approach of "wait and see" when patching systems.[9] Such updates may introduce bugs, new vulnerabilities, or other unforeseen issues. This is especially true in times of stress after the announcement of major computer security bugs. Large companies can and do make mistakes, and a patch failure that in individual systems may cause pain and irritation could lead to a catastrophic failure or outage if on a critical system.[10]

Finally, one of the bigger trends in current computation lies in the increase in the use of virtual and cloud computing systems. Distributed systems such as these can offer significantly lower costs if (and this is still a big "if") their security and reliability metrics can meet the requirements of their customers. Architecture principles discussed here are (as much as they can be made to be) platform agnostic. One computer security researcher relates the major difference in cloud computing as, "Fundamentally, cloud security is a primary concern due to loss of control ... We've seen this before – [with] outsourcing..." [34, p. 24]. Does the cloud service provider follow fault tolerant and security fault tolerant design principles? Can such questions even be answered by such services?

This loss of control over the configuration for the security environment and for critical events, continues to be problematic for the Navigation use case for cloud computing, especially with concerns over Availability [34, p. 96]. With cloud computing, ownership of the systems and operational processes is by an outside organization. As a part of the operations of our computational environment, it has sometimes taken extraordinary effort to ensure the continuing functioning of our systems in times of stress. This has sometimes meant the difference between mission success and failure. In an emergency, wide latitude is given to operational staff to keep systems running and restore failed systems as fast as possible to meet the needs of flight operations. With an emergency in a remote cloud computing environment, can one even expect to get a responsible engineer on the phone? Without control over that environment, it is obvious we cannot, as Flight Director for NASA Chris Kraft said, ''...take any action necessary for mission success'' [35, p. 392].

It is hoped that the ideas in this paper will provide assistance to administrators and system engineers, and especially the astronautical community. Aspirational goals are presented here, in the hope of providing a guideline to follow for your own design

[9] A major point of defense in depth is that a single failure should not provide the opportunity for compromise on a wide scale. This should be one of the benefits of such an architecture focused approach. Many times a significant vulnerability in our systems crossed our desks with an organizational rallying cry of "patch now!", "patch now!" and we would discover that we had limited to no exposure from the vulnerability because of other defense in depth controls that were in place. Our goal is to be proactive rather than reactive. While we do have emergency patching mechanisms in place, we prefer not to use them unless truly necessary.

[10] It may be instructive to examine the release schedule (and following systems failure reports) for the firmware and software updates for the MELTDOWN/SPECTER vulnerability of 2018. Having a *running* server is in most cases preferable to one that is "currently patched", but "awaiting motherboard replacement."

efforts. These principles can be applied in Ground Data Systems design problems, as well as in other areas of systems engineering. This is particularly valuable in a community of austere budgetary realities where our bespoke systems engineering is based around missions with only a few, or (more often) only a single deliverable.

In an ideal world we would be able to trust our computer systems in the same way that when we drive a car, we trust its brakes. I believe that this optimistic idea is a badly needed one in the design of the increasingly complex and intertwined computer systems that comprise our world today. With the current state of computer security this can appear hopeless, however it is clear, as with the encouraging Boeing flight control system [10], there *are* computer systems that have been designed to be truly fault tolerant. A hard problem is not necessarily an impossible problem. There is no reason we can not also do this in computer security.

Conflict of Interest

ABSTRACT

Recently, augmented reality (AR) technology has been applied to the interaction technology between human and virtual objects. In AR interaction technology, it is necessary for users to be able to manipulate virtual objects intuitively. Thus, we focus on manipulating virtual objects directly with the user's bare hands in this study. On the other hand, in AR technology, since the 3-dimensional (3D) model is superimposed on the image of the real space afterwards, it is always displayed on the front side than the user's hand (occlusion problem). Thus, it becomes an unnatural scene in some cases. In this study, this system detects hand area of the user by extracting depth information, color information and using canny edge detection in the user's hand. Thus, this system performs hidden surface removal along the area of the user's hand by considering the object-context relations between the user's hand and the virtual object. In the evaluation experiment, it is confirmed that the hidden surface removal in this study make it possible to distinguish between finger boundaries and to clarify and process finger contours. This work is an extension of the paper entitled "Hidden Surface Processing for Interaction of Hand and Virtual Objects Using Leap Motion Controller" published in 2018 International Conference on Information and Communication Technology Robotics (ICT-ROBOT).

1 Introduction

Augmented reality (AR) is used in many fields including education, medicine and entertainment, and its applications became widespread [1, 2, 3]. Also, the interaction with the virtual objects is required in those papers. Therefore, we think that more precise virtual object manipulations in AR will be performed in the future.

On the other hand, since hands are our main means of interaction with objects in real life, AR interfaces should also be able to be for free hand interaction with virtual objects.

Furthermore, it is important to be able to adapt to more detailed tasks by hand in order to handle a wide range of fields such as medical care and education.

In the conventional study [4], by putting a marker, a special glove, etc. on a user, the user's position information was acquired and interaction with a virtual object was realized. However, these methods may give the user a sense of discomfort such as weight due to wearing. Therefore, bare hand interaction is required.

However, since the 3-dimensional (3D) model displayed by the AR is superimposed on the image of the real space afterwards, the 3D model is always displayed on the front side and user's hand is hidden by virtual objects. Thus, the scene may become an unnatural scene, and the user cannot see the object-context relations of the virtual object and his/her hand, and feels that it is difficult to manipulate the virtual objects.

In the existing study [5], the system used transparent 3D models and the 3D models followed each fingers of the user based on the depth information of the user's hand. In this way, they performed hidden surface removal and tackled the occlusion problem. However, since the 3D models which follow the user's fingers are larger than the finger, a wider range than the actual finger was displayed on the front (see Figure 1). In addition, no description has been given of a case where there is a multiple virtual objects in the existing study.

In other related study [6], using the Kinect sensor in order to obtain depth information of the user, hidden surface removal was realized when an arm was inserted between multiple virtual objects. Also, it was the same even when

*Corresponding Author: Makoto Sakamoto, 1-1, Gakuen-Kibanadai-Nishi, Miyazaki City, Miyazaki, 889-2192, Japan, sakamoto@cs.miyazaki-u.ac.jp

it came to deformable virtual object. However, the Kinect sensor is a sensor that roughly recognizes human motion and depth information, and the study didn't focus on the interaction between hands and virtual objects.

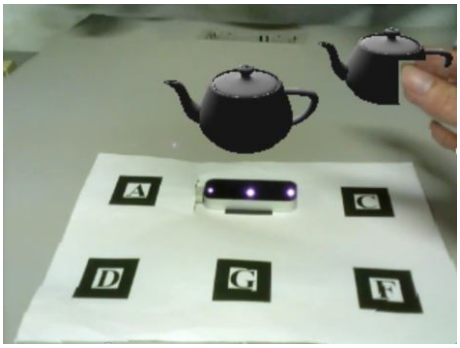

Figure 1: Hidden surface removal in existing study

In this study, we use Leap Motion Controller to acquire depth information of the user's hand. Additionally, this system acquires RGB (Red, Green and Blue) information from the web camera. Based on these pieces of information, the contour of the hand is extracted to realize hidden surface removal along the contour of the hand.

In this study, we aim to cope with more detailed virtual object manipulations by conducting hidden surface removal along the outline of the user's hand. Moreover, we conduct a manipulation of grasping a virtual object of primitive model by hand and confirm whether it works properly.

2 Proposal

In order to conduct hidden surface removal along the contour of the user's hand, this system detects hand area of the user by extracting depth information, color information and edge detection in the user's hand.

First, in order to extract hand area, we use the RGB image based on color information. Next, based on the depth information of the hand, a blue point group is created on the thumb, and a green point group is created on the other fingers. These point groups are displayed at their positions only when the hand is in front of the virtual object. In addition, the hidden surface removal along the fingers is realized by using the hand area extracted first and the result of edge detection. Also, in order to cope with multiple virtual objects and distinguish the object-context relations of the blue point group and the green point group, we use the Z-buffer method.

In this way, when the user's hand is near from camera than the virtual object, the user's hand is correctly displayed on the front side of the virtual object, and the user can grasp the anteroposterior relationship between the user's hand and the virtual object.

2.1 System Component

This system consists of a Web camera, the Leap Motion Controller, PC and AR marker. In this study, since this system needs accurate position information of user's fingers, we use the Leap Motion Controller that can acquire various data relating to user's hand with high accuracy.

The purpose of use of each of the devices shown above is as follows:

- Web camera: Acquisition of real image and recognition of marker.
- The Leap Motion Controller: Obtaining 3D coordinates of the user's fingers.
- Monitor: Video output.
- AR marker: Acquisition of position and tracking of virtual objects.

The Leap Motion Controller and the webcam both use camera features, which causes the camera features to interfere with each other. Therefore, this system addresses this problem by using network programming. This system acquires data of 3D coordinates of the user's fingers with the Leap Motion Controller on the server side. In addition, this system sends the data to the client side. On the other hand, this system acquires images with the Web camera, and conducts image processing and video output using the data which received from the server side on the client side.

This system controls the position and orientation of the virtual objects is by recognizing the AR marker. Therefore, the AR marker needs to be recognized by the web camera. However, when the user manipulates virtual objects, the AR marker may be covered by his/her own hand. Therefore, this system adopts a method of treating Marker A to Marker F as one marker (see Figure 2). Thus, even when a part of the marker is covered, the virtual objects can be displayed properly.

We place the Leap Motion Controller on the position of Marker B. This system displays the virtual objects on the position of Marker C and Marker G (see Figure 2).

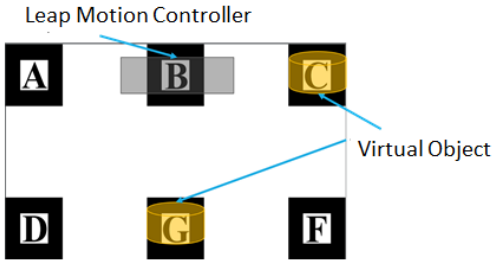

Figure 2: AR marker

2.2 Development Environment

We use ARToolKit for AR marker recognition and camera control. And, we develop this system using OpenGL for displaying virtual objects and OpenCV for various image processing. Here, the resolution of the camera is 320×240 pixels.

2.3 Flow of Image Processing

The processing flow comprises of several steps as shown in Figure 3. In Figure 3, the block of light red background indicates that it is generated image.

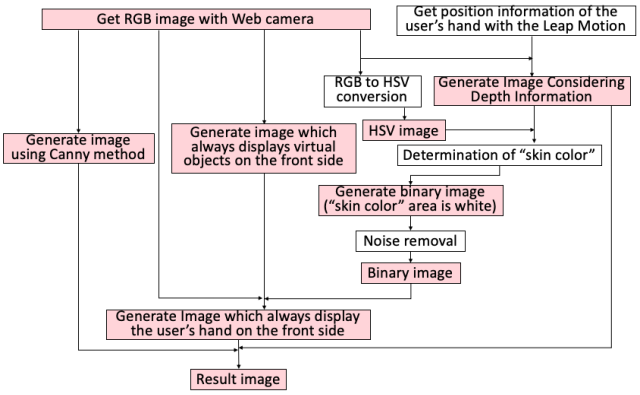

Figure 3: Flow of image processing in this system

2.4 Processing of Camera Image

This system gets RGB image with the web camera (see Figure 4). In this study, in order to use the HSV (Hue, Saturation and Value) color space often used in the processing of color images, this system converts RGB images to the HSV color space.

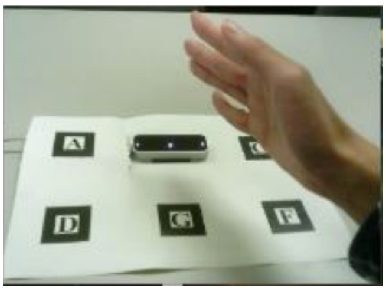

Figure 4: RGB Image

2.5 Generation of Binary Image

2.5.1 Determination of "skin color"

This system needs to extract the area of skin color for detection of the user's hand area. At first, this system puts red point on the finger which are the closest to the camera (see Figure 5). A certain range is given to the HSV value obtained from the pixel of that point, and it is defined as "skin color".

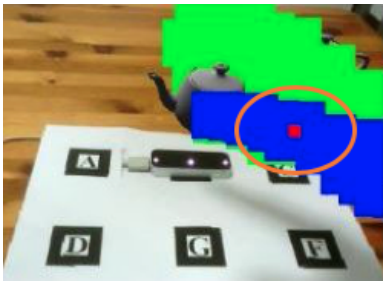

Figure 5: Red point

Next, this system detects the user's hand area as binary images.

The procedure is shown below.

1. Get the 3D coordinates of the proximal phalanx of the finger which are the closest to the camera with the Leap Motion Controller.
2. Generate images that red point is plotted around the acquired position.
3. Obtain the 2D coordinate value of pixel units in the red point.
4. In Figure 4, this system gets average values of HSV in the pixel values corresponding to the coordinates acquired in step 3.
5. Apply an appropriate range to each value of Hue, Saturation, Value and decide it as "skin color".

2.5.2 Noise removal

The binary image generated by this system contains salt and pepper noise at first. Therefore, this system conducts erosion and dilation twice in 8-neighbor in order to remove noise.

However, that alone cannot remove the noise sufficiently (see Figure 6). This is because, in this method, this system has to conduct erosion and dilation multiple times in order to remove loud noise. However, it needs complicated calculation.

Therefore, regarding to the loud noise, this system removes the noise in the area of the hand by conducting the following processing (see Figure 7).

1. Determine white area including red point (which is put on the finger which is closest to the camera) as hand area.
2. Fill the inside of the hand area with black and the outside of the hand area with white.
3. Invert white and black.

In this way, all noise in the hand area is removed (see Figure 8).

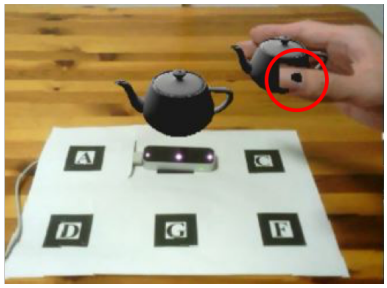

Figure 6: Result image including noise

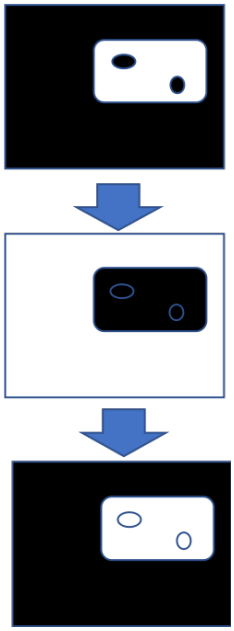

Figure 7: Noise removing process

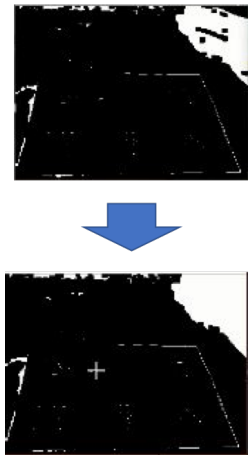

Figure 8: Noise removing

2.6 *Generate Image Considering Depth Information*

This system acquires 3D coordinates of the distal bone, middle phalanx, basal bone and metacarpal bone of the user's hand (see Figure 9) with Leap Motion Controller.

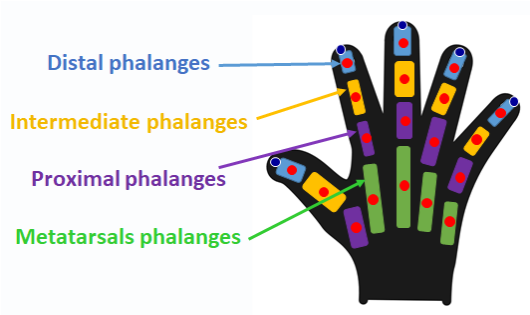

Figure 9: Hand joint

Based on the acquired position information of the fingers, this system generates images plotting blue point group (following the position of the thumb) and green point group (following the position of a finger other than the thumb).

Blue point group displays at the positions of each joint of the thumb when the user's thumb is front of the back object (see Figure 10).

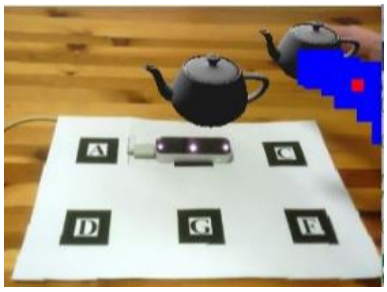

Figure 10: Blue point group following the thumb

In addition, green point group displays at the positions of each joint of the fingers except thumb when the user's fingers except thumb are front of the back object (see Figure 11).

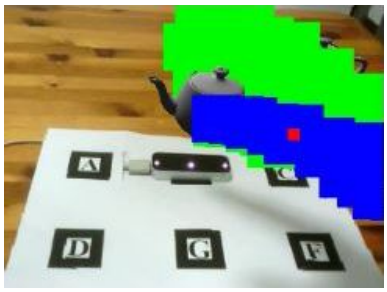

Figure 11: Blue point group and green point group following the whole hand

Furthermore, this system makes it possible to handle multiple virtual objects of different depths. The object-context relations between the back virtual object and the hand of the user is determined depending on whether or not blue point group and green point group are displayed. On the other hand, the object-context relations between the virtual object on the near side and the user's hand is determined by using the Z-buffer method. Using the Z-buffer method, when a finger is positioned behind the virtual object, blue point group and green point group following the position of the finger are hidden by the virtual object. In this way, this system can determine the object-context relations between the user's hand and the virtual objects even if there are multiple virtual objects.

2.7 *Generate Images which Always Display The Hand in Front of Virtual Objects*

This system synthesizes the original RGB image (see Figure 12-a) only in the white area in Figure 13 to the image in Figure 12-b. Thus, this system generates images that the user's hand is always displayed on the front of the virtual object (see Figure 12-c).

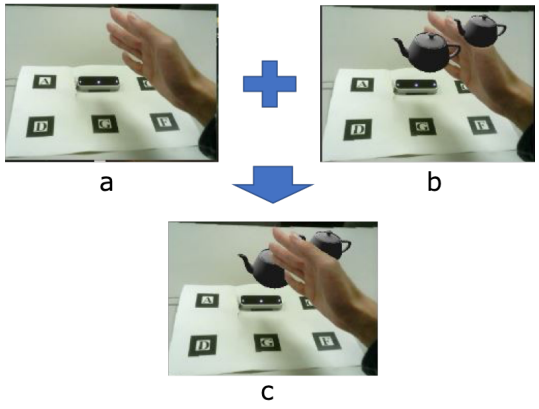

Figure 12: Generation of images which hand is displayed front

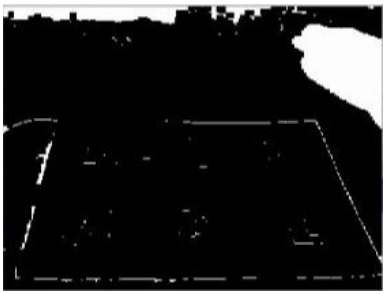

Figure 13: Binary image

2.8 Generate Result Images

The area in Figure 12-b corresponding the area of the blue point group, the green point group and the red point group (in the case where the position of the proximal phalanges of thumb is in front of the virtual object) of Figure 14-a are replaced with the image shown in Figure 14-b (Figure 12-c). Thus, based on the depth information, this system generates images that the hand is displayed in front of the virtual object (see Figure 14-c).

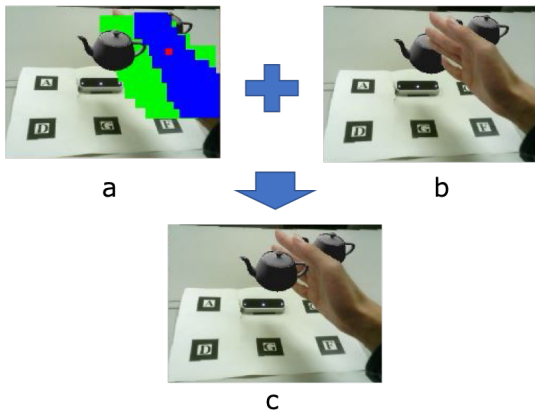

Figure 14: Generation of result images

2.9 Distinction between Fingers Using Canny Edge Detection

The white area in Figure 13 indicates the hand area. However, no distinction between fingers is made from this image. Therefore, if hidden surface removal is conducted based on this image, even if only the thumb should be subjected to hidden surface removal like Figure 15, other fingers are involved and processing is conducted.

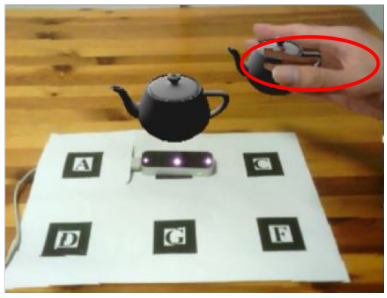

Figure 15: Involved other fingers

Therefore, we need edge detection of the user's thumb in order to solve this problem.

Edge detection is the name for a set of mathematical methods which aim at identifying points in a digital image at which the image brightness changes sharply or more formally, has discontinuities. The point at which image brightness changes sharply are typically organized into a set of curved line segments termed as edges.

We need to detect finger edge in order to distinguish between thumb and other fingers. Furthermore, at the time of the edge detection, the edge must be one clear line, since the area of the thumb extracted by edge detection is filled in the area surrounded by the edges in the later processing.

In this study, we use Canny edge detection algorithm [7] to find an edge of the user's thumb. Because it provides better results and efficiency than other available algorithm when we want to detect clear edges [8].

Canny edge detector uses two thresholds and if the intensity of that pixel is below that lower threshold than it is assigned "0" value that can be none edge and if the intensity of any pixel is above that the higher threshold than it is assigned "1" value and can be edge.

In this study, we distinguish the thumb from the other fingers. In order to detect the thumb, the thumb is surrounded by an ellipse, and the inner area surrounded by it and the boundary displayed by edge detection is extracted. The area is the thumb area (see Figure 16).

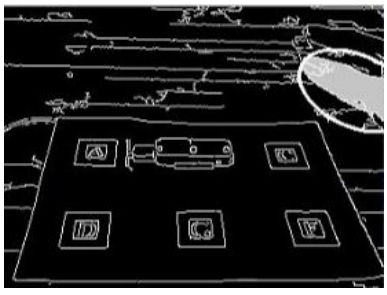

Figure 16: Extraction of the thumb area

The following process is conducted to detect the thumb.

1. Get two coordinates of upper left end and lower right end of blue point group (see Figure 17-a).

2. Make an ellipse based on a line connecting the two points (which are the coordinates acquired in step 1).

3. Overlap the ellipse surrounding the thumb on the image generated based on the Canny edge detection (see Figure 17-b).

4. Fill the area surrounded by the ellipse and the edge in Figure 17-b which corresponding to the position including the red point group in Figure 17-a with gray.

5. Regards this gray area as the thumb area.

In this way, this system generates result image (see Figure 17-c).

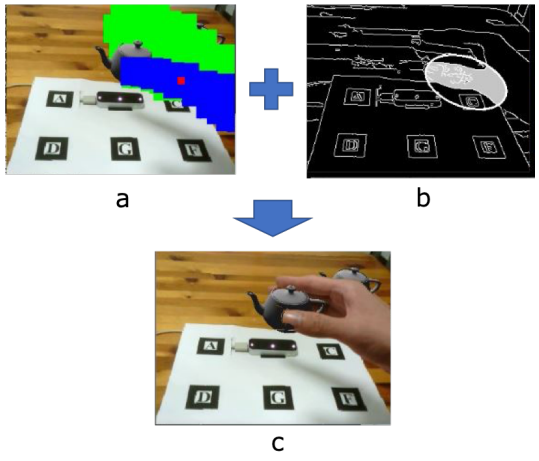

Figure 17: Distinction between the thumb and the other fingers

3 Experimental Results

We executed this system to confirmed whether hidden surface removal along the fingers is possible or not.

First, we checked whether this system can cope with multiple virtual objects. In this system, the object-context relations between the back virtual object and the hand of the user is determined depending on whether or not blue point group and green point group are displayed. In order to confirm whether this is properly processed, we placed the virtual object at position C in Figure 2 and performed manipulation that a user grabs the virtual object. On the other hand, the object-context relations between the virtual object on the near side and the user's hand is determined by using the Z-buffer method. In order to confirm whether this is properly processed, we placed the virtual object at position G in Figure 2 and performed manipulation that a user grabs the virtual object.

Furthermore, we performed grasping manipulations on virtual objects of 3D primitive figures from various directions in order to confirm whether this system is applicable to virtual objects of various shapes.

3.1 In the case of an object behind

Since only the thumb comes to front side than Marker C, the blue point group follows only the thumb (see Figure 10) and draw the thumb properly on the front of the virtual object (see Figure 18).

Figure 18: Result at the position of C in the AR marker

3.2 In the case of an object in front

This system conducted the hidden surface removal considering multiple virtual objects by the Z-buffer method. The blue point group follows only the thumb and the green point group follows the other fingers (see Figure 11). Besides, only the point group of the thumb was drawn on the front of the virtual object by the Z-buffer method. As a result, it was possible to draw only the thumb on the front (see Figure 19).

The blue point group and green point group in Figure 11 are based on the depth information of the user's fingers. Also, the anteroposterior relationship between the blue point group and the green point group is correctly displayed by the Z-buffer method. In this way, when the thumb is positioned behind the other fingers, the green point group is displayed on the front side of the blue point group.

Figure 19: Result at the position of G in the AR marker

3.3 Various trials

We tested three movement patterns for each 3D objects. Here, we use cube (see Figure 20), cone (see Figure 21) and torus (see Figure 22) as 3D primitive objects.

In this section, we display the virtual object at position B.

Each movement is as follows.

1. Grip the virtual object from the side.

2. Grip the virtual object from the top.

3. Grip the virtual object while the user's thumb is behind the other fingers.

The results are shown below. Here, "Grip the virtual object from the side", "Grip the virtual object from the side", and "Grip the virtual object from the side" in order from the left in Figure 20 - Figure 22.

Figure 20: Cube

Figure 21: Cone

Figure 22: Torus

4 Consideration

We confirmed that this system can perform correctly hidden surface removal even when a user manipulates multiple virtual objects by Z-buffer method from the experiment result. In addition, we also confirmed that this system is effective for virtual objects of various shapes.

The distinction between the virtual object and the user's hand was not clear when using the Z-buffer method when considering the depth between the virtual object and the user's hand. Therefore, if there is only one virtual object or if the depth coordinates of the virtual objects are all at the same position, it is better to have blue point group follow the thumb of the user only than to have blue point group and green point group follow the palm of the user's hand.

Regarding gripping the virtual object from the side (see Figure 20), it was confirmed that the hidden surface removal was accurately distinguished without involving a nearby finger.

Regarding gripping the virtual object from the top (see Figure 21), sometimes the hidden surface removal of the base of the thumb did not work well, and a virtual object was displayed superimposed on the thumb. This is because the area of the thumb extracted by the Canny method is smaller than the area of the real thumb.

Regarding gripping the virtual object while the user's thumb is behind the other fingers (see Figure 22), it was confirmed that the hidden surface removal was properly treated even when the fingers other than the thumb were on the near side. This is an effect of the present system because the determination of the skin color is conducted on the foremost finger. Also, at this time, since the blue point group is moved to the back from the green point group, processing such as the Canny method for the thumb is ignored.

5 Conclusion

The future of AR as interaction technology in users and virtual objects looks bright. In recent years, AR has been applied to a wide range of fields such as education, medicine, entertainment and a guide for various tasks. Among them, the user directly manipulates virtual objects with their bare hands. In the future, we expect further development of interaction manipulation, and more detailed virtual object manipulation will be required.

Thus, we proposed and implemented hidden surface removal along the fingers, aiming at being able to apply to more detailed works about interaction manipulation in AR. In this study, we paid attention to detection the contour of the hand to realize hidden surface removal along the user's fingers. In this system, processing based on hand depth information, color information and edge detection is conducted to detect hand contours.

As for edge detection, the Canny method was used to reduce noise and obtain a clear contour. By these processes, appropriate hidden surface removal was realized without involving other fingers.

In the evaluation experiment, it was shown that it can cope with multiple virtual objects. In addition, we tested various grip methods for virtual objects of various shapes, and showed that they manipulate normally.

As future works, since the generation of binary images is not stable at the time of skin color detection, it needs the solution. Moreover, since the contour of the thumb is interrupted at the time of the Canny edge detection, it needs to set more appropriate threshold in Canny edge detection.

Legendre symbol

ABSTRACT

The distribution of bit patterns is an important measure to check the randomness of a sequence. The authors of this paper observed this crucial property in a binary sequence which generated by using a primitive polynomial, trace function, and Legendre symbol defined over the sub extension field. The authors create a new dimension in the sequence generation research area by considering the sub extension field, whereas all our previous works are focused in the prime field. In terms of distribution of bit patterns property, this research work has notable outcomes more specifically the binary sequence (defined over the sub extension field) holds much better (close to uniform) bit distribution than the previous binary sequence (defined over the prime field). Furthermore, the authors theoretically proved the distribution of bit property in this paper.

1 Introduction

In this IoT era, we communicate with each other through the internet. Therefore, secure communication is the major matter of concern. We use symmetric cryptosystems (Advanced Encryption Standard (AES) [1]) and asymmetric cryptosystems (Rivest Shamir Adleman (RSA) [2], and Elliptic Curve Cryptography (ECC) [3]) to establish a secure communication. A pseudo-random number is one of the crucial parts of these cryptosystems. More specifically, in case of cryptography, to generate the keys (public key, private, session key, and so on) a pseudo-random number generator is used. A prominent pseudo-random number generator is essential to generate pseudo-random number having randomness property (along with other good statistical properties). Consequently, the security of these cryptosystems deliberately depends upon the randomness property regarding a sequence. Thus, it is mandatory to evaluate the randomness of a sequence before utilized them in any cryptosystems. Basically, two crucial properties namely the linear complexity [4] and the distribution of bit patterns regarding a sequence are nowadays well-known to check the randomness of a pseudo-random sequence. In this work, the authors restrict the discussion on the distribution of bit patterns property to evaluate the randomness of a sequence.

Most renowned pseudo-random number generators are the Mersenne Twister (MT) [5], Blum-Blum-Shub (BBS) [6], Legendre sequence [7, 8], and M-sequence [9]. Among those the former two pseudo-random number generators (MT and BBS) are well-known considering their applications in cryptography rather than the theoretical aspect. On the other hand, the M-sequence and Legendre sequence are prominent geometric sequences regarding the theoretical aspect. As a result, the authors attracted in the pseudo-random sequence generation research area by observing the theoretical prospect on the M-sequence and Legendre sequences.

The Legendre sequence [7, 8] is generated by applying the Legendre symbol over the odd characteristic field. It has a long period, high linear complexity, and the distribution of bit patterns of the Legendre se-

https://dx.doi.org/10.25046/aj040246

quence is known to be close to uniform [10, 11]. On the other hand, M-sequence is generated by a linear recurrence relation over the finite field. It has a maximum period but minimum linear complexity. In addition, M-sequence [9] is well-known for its uniform distribution of bit patterns [12]. Our previous work on geometric sequence [13] combines the features of the Legendre sequence and M-sequence. As mentioned previously, linear complexity and distribution of bit patterns are the important measures to evaluate the randomness of a sequence. So, regarding the linear complexity, our previous sequence [13] always possess high value. Unlike the linear complexity, the distribution of bit patterns in [13] doesn't reaches up to the mark alike the Legendre sequence and M-sequence. Hence, its a scope to improve the distribution of bit patterns in our previous sequence.

The trace calculation is an important step during our sequence generation procedure. Lets focus on the important aspect regarding this calculation. In case of prime field $\mathbb{F}_p$, the trace function maps an element of the extension field $\mathbb{F}_{q^M}$ to an element of the prime field $\mathbb{F}_p$. Therefore, the number of possible trace outputs will be in the range of $\{0 \sim p-1\}$. In other words, if we calculate the trace over the prime field, then it will output p kinds of values. On the other hand, in case of the sub extension field $\mathbb{F}_q$, the trace function maps an element of the extension field $\mathbb{F}_{q^M}$ to an element of the sub extension field $\mathbb{F}_q$ and the number of possible trace outputs will be in the range of $\{0 \sim q-1\}$ which means the trace outputs q kinds of values. It should be noted that here $M = m/m'$, $q = p^{m'}$, and m' be one of the factors of m. From the theoretical perspective, more variation in the trace values contribute to the better appearance of bits (0 and 1) in a sequence. This is one of the important aspects to consider the sub extension during the sequence generation procedure to improve the distribution of bit patterns in our previous sequence [13]. After utilizing the sub extension field, the detailed improvement in distribution of bit patterns is introduced in the result and discussion section in this paper.

Recently, the authors started to consider the sub extension field during the sequence generation procedure, which is a new dimension of our research work on generation of pseudo-random sequence (whereas our previous works on binary sequence [13] and multi-value sequence [14, 15] are considered in the prime field). As a result, our recent works on binary sequence [16] and multi-value sequence [17] experimentally observed the linear complexity, autocorrelation properties, respectively. As mentioned previously, the distribution of bit patterns is an important measure to evaluate the randomness of a sequence. Thus, the authors of this paper consider the distribution of bit patterns in a binary sequence which generated over the sub extension field.

The Legendre sequence and M-sequence are the base of the sequence research area. Their properties are already proven, therefore many researchers attracted by those sequences. As mentioned previously, our sequence also generated by the idea of the Legendre and M-sequences. Consequently, the authors thought that its properties can be theoretically proven and fortunately its proven (which shown in the later section of this paper). This is one of the contributions of the authors in this paper. Moreover, they also make a comparison between the binary sequence defined over the sub extension field with their previous work on binary sequence in terms of distribution of bit patterns property. According to the comparison result, binary sequence (defined over sub extension field) holds much better (close to uniform) distribution of bit patterns than the previous binary sequence [13]. Finding this improvement by considering the sub extension field is the major contribution of this paper.

The authors of this paper observed the distribution of bit patterns in a binary sequence which generated by a primitive polynomial, trace function, and Legendre symbol over the sub extension field. In brief, the sequence generation procedure is as follows: at first, it uses a primitive polynomial over the odd characteristic field $\mathbb{F}_p$ to generate maximum length vector sequence as elements in $\mathbb{F}_{q^M}$, then the trace function maps the extension field $\mathbb{F}_{q^M}$ elements to the sub extension field $\mathbb{F}_q$ elements, and finally the Legendre symbol binarizes the sub extension field $\mathbb{F}_q$ elements to a binary sequence. The authors already observed the period, autocorrelation, cross-correlation, and linear complexity properties of the binary sequence (which generated over the sub extension field) in their previous works [16, 17]. Thus, this paper focused on the distribution of bit patterns property. In brief, the authors count the number of appearances for each n-bit patterns (where $1 \leq n \leq (m/m')$). After observing many experimental results, the authors found that the number of appearances of each bit pattern is related to the number of zeros contained in each bit pattern. Furthermore, the authors theoretically proven the distribution of bit patterns equation. Moreover, they also make a comparison with their previous work [13].

Throughout this paper, p and q denote an odd prime number and its power $q = p^{m'}$, respectively, where m be a positive integer which mainly denotes extension degree and m' be one of the factors of m. In addition, $M = m/m'$ and $\mathbb{F}_q^*$ denotes the multiplicative group of $\mathbb{F}_q$, that is $\mathbb{F}_q^* = \mathbb{F}_q - \{0\}$.

2 Preliminaries

This section briefly explains some fundamental concepts of the finite field theory such as group, field, primitive polynomial, trace function, Legendre symbol, and dual bases. Then, binary sequence is introduced along with its period and distribution of bit patterns properties.

2.1 Group

A group is a non-empty set $\mathbb{G}$ with a binary operation $\circ$ on its elements denoted as $< \mathbb{G}, \circ >$, which satisfies

the following axioms.

- **Closure** For $\forall_{a,b} \in \mathbb{G}$, the result of $a \circ b$ also exists in $\mathbb{G}$ and it is uniquely given.
- **Associativity** Elements in group $\mathbb{G}$ should follow associativity. i.e. $(a \circ b) \circ c = a \circ (b \circ c)$, where $a, b, c \in \mathbb{G}$.
- **Identity element** There exists an element $e \in \mathbb{G}$ such that $\forall_a \in \mathbb{G}$, $a \circ e = e \circ a = a$.
- **Inverse element** For $\forall_a \in \mathbb{G}$, there exists an element $b \in \mathbb{G}$ such that $a \circ b = e = b \circ a$, where b is called inverse element of a.

Commutative group A group $\mathbb{G}$ will be commutative if $a \circ b = b \circ a$ for all $a, b \in \mathbb{G}$.

Group generator For a given group $\mathbb{G}$ if there is an element $g \in \mathbb{G}$ such that for any $a \in \mathbb{G}$ there exists an unique integer i with $a = g^i$ then g will be called as a generator of $\mathbb{G}$.

Order of a group The order of a group $\mathbb{G}$ often denoted as $\#\mathbb{G}$ is the number of elements in the group $\mathbb{G}$.

Cyclic group A group $\mathbb{G}$ will be cyclic if there exists at least one generator $g \in \mathbb{G}$ and it is denoted as $\mathbb{G} =< g >$. From the definition of cyclic group, it can be visualized that each element in a cyclic group can be generated with iterative operations of generator g which shown in the following Figure 1.

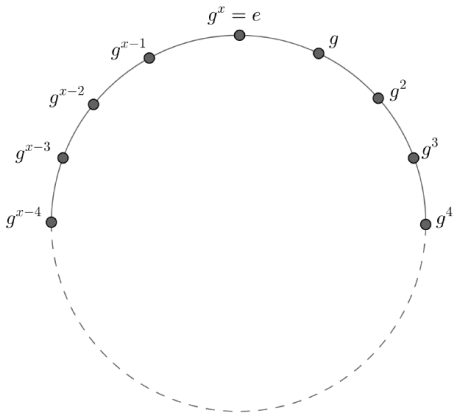

Figure 1: cyclic group.

Multiplicative group A cyclic group is called multiplicative if we tend to write its group operation in the same same way we do multiplication, that is

$$f = g \cdot x \text{ or } f = g^x.$$

2.2 Field

A field $< \mathbb{F}, +, \cdot >$ is a set that obeys two binary operations denoted by + and $\cdot$, such that

- $\mathbb{F}$ is a commutative group with respect to addition (+) having identity element 0.
- Let $\mathbb{F}^*$ is a subset of $\mathbb{F}$ having non-zero elements of $\mathbb{F}$ i.e. $\mathbb{F}^* = \mathbb{F} - \{0\}$. Then $\mathbb{F}^*$ will be called a commutative group with respect to multiplication $(\cdot)$, where every element should have multiplicative inverse in $\mathbb{F}^*$.
- For all $a, b, c \in \mathbb{F}$ the distributive law will be followed, i.e. $a \cdot (b+c) = a \cdot b + a \cdot c$ and $(b+c) \cdot a = b \cdot a + c \cdot a$.

Sub field Let $\mathbb{F}_1$ is a sub field of a field $\mathbb{F}$. Then $\mathbb{F}_1$ will be called a sub field if $\mathbb{F}_1$ obeys the laws of field with respect to the field operation inherited from $\mathbb{F}$. In addition, if $\mathbb{F}_1 \neq \mathbb{F}$, then $\mathbb{F}_1$ is a proper sub field of $\mathbb{F}$.

Prime field Let p be a prime. The ring of integers modulo p is a finite field of characteristic p having field order p denoted as $\mathbb{F}_p$ is called a prime field.

Extension field A subset $\mathbb{F}_0$ of a field $\mathbb{F}$ that is itself a field under the operations of $\mathbb{F}$ will be called a sub field of $\mathbb{F}$. In this case, $\mathbb{F}$ is called an extension field of $\mathbb{F}_0$. An extension field of a prime field $\mathbb{F}_p$ can be represented as m-dimensional vector space that has m elements in $\mathbb{F}_p$. Let the vector space be the m-th extension field be denoted as $\mathbb{F}_{q^M}$. The order of a extension field $\mathbb{F}_{q^M}$ is given as p^m (here $q = p^{m'}$ and $M = m/m'$).

In very brief, it can be said that a prime field ($\mathbb{F}_p$) is a subset of sub extension field ($\mathbb{F}_q$) and sub extension field $\mathbb{F}_q$ is also a sub set of extension field $\mathbb{F}_{q^M}$ which shown in Figure 2.

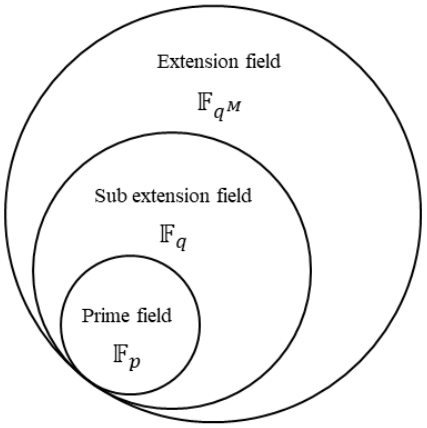

Figure 2: $\mathbb{F}_p \subset \mathbb{F}_q \subset \mathbb{F}_{q^M}$.

2.3 Primitive Polynomial

Consider a polynomial $f(x)$ of degree m over prime field $\mathbb{F}_p$. If it is not factorized into smaller degree polynomials over the prime field $\mathbb{F}_p$, it is called an irreducible polynomial. Consider the smallest number e such that $x^e - 1$ is divisible by $f(x)$ over $\mathbb{F}_p$, it is known that e becomes a factor of $q^M - 1$. Then $f(x)$ is especially called a primitive polynomial, when e is equal to $q^M - 1$. Its zero ω belongs to the extension field $\mathbb{F}_{q^M}$ and it becomes a primitive element in $\mathbb{F}_{q^M}$ that generates every non-zero element in $\mathbb{F}_{q^M}$ as its power ω^i (for $i = 0, 1, 2, \ldots, q^{M-2}$).

2.4 Trace Function

This work utilizes the trace function to map an element of the extension field $X \in \mathbb{F}_{q^M}$ to an element of the sub extension field $x \in \mathbb{F}_q$ as,

$$x = \mathrm{Tr}_{q^M|q}(X) = \sum_{i=0}^{\frac{m}{m'}-1} X^{p^{im'}}. \tag{1}$$

A crucial point, the above trace becomes an arbitrary element in $\mathbb{F}_q$ and the trace function has a linearity property over the sub extension field $\mathbb{F}_q$ as follows,

$$\mathrm{Tr}_{q^M|q}(aX + bY) = a\mathrm{Tr}_{q^M|q}(X) + b\mathrm{Tr}_{q^M|q}(Y), \tag{2}$$

where $a, b \in \mathbb{F}_q$ and $X, Y \in \mathbb{F}_{q^M}$.

2.5 Legendre Symbol

The Legendre symbol $\left(a/q\right)_2$ is used to check the quadratic residue for any arbitrary element a in $\mathbb{F}_q$. It is defined as,

$$\begin{aligned}\left(a/q\right)_2 &= a^{(q-1)/2} \\ &= \begin{cases} 0, & \text{if } a = 0, \\ 1, & \text{else if } a \text{ is a QR in } \mathbb{F}_q^*, \\ p-1, & \text{otherwise } a \text{ is a QNR in } \mathbb{F}_q^*. \end{cases}\end{aligned} \tag{3}$$

Here, QR and QNR stand for Quadratic Residue (QR) and Quadratic Non-Residue (QNR), respectively. Additionally, the non-zero element a is called the QR if it has a square root in $\mathbb{F}_q$, otherwise a is called the QNR. In this paper, the Legendre symbol is used for translating a vector sequence generated by the trace function over $\mathbb{F}_q$ to a binary sequence. Above mentioned QR and QNR in $\mathbb{F}_q$ holds the following important property.

Non-zero elements are the roots of $x^{q-1} - 1$ in $\mathbb{F}_q^*$ over $\mathbb{F}_q$ without any duplicates. Since it is factorized as follows:

$$x^{q-1} - 1 = \left(x^{(q-1)/2} - 1\right) - \left(x^{(q-1)/2} - 1\right). \tag{4}$$

It is thus found that the number of QR's and QNR's in $\mathbb{F}_q^*$ are the same and it is given by $(q-1)/2$. In addition, these numbers are important part in proving the theorem in the later section of this paper.

2.6 Dual Bases

The dual bases plays an important role in proving the theorem shown in this paper. It is defined as follows:

Let $\mathbb{F}_{q^M}$ be a finite field and $\mathbb{F}_q$ be a finite extension of $\mathbb{F}_{q^M}$. Then the two bases $\mathcal{A} = \{\alpha_0, \alpha_1, \ldots, \alpha_{m-1}\}$ and $\mathcal{B} = \{\beta_0, \beta_1, \ldots, \beta_{m-1}\}$ of $\mathbb{F}_q$ over $\mathbb{F}_{q^M}$ are said to be the dual (or complementary) bases if

$$\mathrm{Tr}_{q^M|q}\left(\alpha_i \beta_j\right) = \begin{cases} 1, & \text{if } i = j, \\ 0, & \text{otherwise}, \end{cases} \tag{5}$$

where $1 \le i, j \le m-1$.

2.7 Binary Sequence and Its Properties

This paper introduces a binary sequence along with its period and distribution of bit patterns properties as follows.

2.7.1 Generation Procedure and Period

Let ω be a primitive element in the extension field $\mathbb{F}_{q^M}$, where $M = m/m'$, m be a composite number which denotes the extension degree of the primitive polynomial, and m' be one of the factors of m. Then, by utilizing the trace function and Legendre symbol a binary sequence $\mathcal{S}$ is generated as follows:

$$\mathcal{S} = \{s_i\}, s_i = f_2\left(\left(\mathrm{Tr}_{q^M|q}\left(\omega^i\right)\Big/p\right)\right), \tag{6}$$

where $i = (0, 1, 2, \ldots, \lambda - 1, \ldots)$, $s_i \in 0, 1$ and $f_2(\cdot)$ be a mapping function, which translates the 0, 1, and $p-1$ values sequence generated by the Legendre symbol to a pseudo-random binary sequence. This mapping function is defined as follows:

$$f_2(s) = \begin{cases} 0, & \text{if } x = 0, 1 \bmod q, \\ 1, & \text{otherwise.} \end{cases} \tag{7}$$

After observing many experimental results, the authors derive the equation for the period λ of the binary sequence as,

$$\lambda = \frac{2(q^M - 1)}{q - 1}. \tag{8}$$

2.7.2 Distribution of Bit Patterns

From the viewpoint of security, the distribution of bit patterns is as important as the linear complexity. If a sequence holds the uniform distribution of bit patterns, then it becomes difficult to guess the next bit after observing the previous bit patterns. For example, let's assume a binary sequence having a period of 12 as $\mathcal{S}_{12} = \{1, 0, 1, 0, 1, 0, 1, 0, 1, 0, 1, 0\}$. If we observe the 1-bit pattern in this sequence, then we can find that it has a uniform distribution of 1 and 0. In other words, 1 and 0 appear same in number. However, when we check 2-bit patterns on $\mathcal{S}_{12}$, we find that it only has two types of patterns (10 and 01). In this case, we can easily predict the next bit patterns after observing the previous patterns. For example, let us make a sub-sequence of $\mathcal{S}_{12}$ as $\{1, 0, 1, 0, x_5, x_6\}$, we can easily guess x_5 and x_6 as $x_5 = 1$ and $x_6 = 0$. Therefore, it is also essential to evaluate the distribution of bit patterns of the sequence to confirm its randomness. In other words, the uniformity of the distribution contributes to the randomness from the viewpoint of unpredictability.

3 Distribution of Bit Patterns in Binary Sequence

In this section, we will introduce the bit distribution of binary sequence which generated over the sub extension field. In addition, bit distribution of M-sequence and Legendre sequence is also introduced here. Throughout this section $b^{(n)}$, $Z(b^{(n)})$ and $D_{\mathcal{S}_\lambda}(b^{(n)})$ denotes a bit pattern of length n, number of 0's in $b^{(n)}$, and number of appearance of $b^{(n)}$ in $\mathcal{S}_\lambda$, respectively. For example, in a binary sequence of period 15, a 3-bit pattern $b = 101$ appears 4 times. Then, these notations become $b^{(3)} = 101$, $Z(b^{(3)}) = 1$, and $D_{\mathcal{S}_{15}}(b^{(3)}) = 4$.

3.1 Bit Distribution of M-sequence

The M-sequence [9] is generated by a linear recurrence relation over the finite field. M-sequence has a maximum period and uniform distribution of bit pattern except for the case of $Z(b^{(n)}) = n$ but it has minimum linear complexity. Let, $f(x) = x^4 + x + 1$ be a primitive polynomial over $\mathbb{F}_2$, then using the linear recurrence relation a M-sequence of period 15 becomes as follows.

$$\mathcal{S}_{15} = \{1,0,0,0,1,1,1,1,0,1,0,1,1,0,0\}. \quad (9)$$

The distribution of n-bit pattern in (9) is shown in Table 1, here $1 \le n \le m$. In the case of M-sequence, except the all-zero pattern, every pattern appears same in number. For example, when $n = 3$ all patterns appear 2 times (except 000 pattern). In other words, they are uniformly distributed. Every M-sequence has such good distribution of bit pattern feature.

Table 1: Bit distribution of the M-sequence $\mathcal{S}_{15}$.

	100	2	2
	011	1	2
	101	1	2
	110	1	2
	111	0	2

3.2 Bit Distribution of LegendreSequence

Legendre sequence [7, 8] is generated by applying the Legendre symbol over the odd characteristic field. Legendre sequence has a long period, high linear complexity, and the distribution of bit pattern is close to uniform. Let, $p = 23$, then the Legendre sequence of period 23 becomes as follows.

$$\mathcal{S}_{23} = \{0,0,0,0,0,1,0,1,0,0,1,1,0,0,1,1,0,0,1,0,1,0,1,1,1\}. \quad (10)$$

The distribution of n-bit pattern in (10) is shown in Table 2. In case of Legendre symbol, bit patterns appearance is close to uniform.

Table 2: Bit distribution of the Legendre sequence $\mathcal{S}_{23}$.

	110	1	2
	111	0	2

3.3 Bit Distribution of the Proposed Binary Sequence

Let $\mathcal{S}_\lambda$ be a binary sequence of having a period of λ. Again, let $b^{(n)}$, $Z(b^{(n)})$, and $D_{\mathcal{S}_\lambda}(b^{(n)})$ denotes a bit pattern of length n, number of 0's in $b^{(n)}$, and number of appearance of $b^{(n)}$ in $\mathcal{S}_\lambda$, respectively. Then, the distribution of bit patterns in the binary sequence which defined over the sub extension field can be given by the following theorem.

$$D_{S_\lambda}\left(b^{(n)}\right) = \begin{cases} q^{M-(n\cdot m')} \cdot \left(\frac{q-1}{2}\right)^{n-Z\left(b^{(n)}\right)-1} \cdot \left(\frac{q+1}{2}\right)^{Z\left(b^{(n)}\right)} & \text{(11a)} \\ \qquad \text{when } 0 \le Z\left(b^{(n)}\right) < n, & \\ \lambda - \sum_{u=0}^{Z\left(b^{(n)}\right)} {}_nC_u \cdot D_{S_\lambda}\left(b^{(n)}\right) & \text{(11b)} \\ \qquad \text{when } Z\left(b^{(n)}\right) = n. & \end{cases}$$

Let ω be a primitive element in the extension field $\mathbb{F}_{q^M}$, where $M = m/m'$, m be a composite number which denotes the extension degree of the primitive polynomial, and m' be one of the factors of m. Then, utilizing the trace function and Legendre symbol one period of a binary sequence is generated as follows.

$$\mathcal{S}_\lambda = \{s_i\}, s_i = f_2\left(\left(\mathrm{Tr}_{q^M|q}\left(\omega^i\right)\Big/\!\!\Big/ p\right)\right), i = 0,1,2,\ldots,\lambda-1,\ldots, \quad (12)$$

Here λ be the period of the sequence and it is given by the following equation as,

$$\lambda = \frac{2(q^M - 1)}{q - 1}. \quad (13)$$

At first, a primitive polynomial is used, then the trace value is calculated, then the Legendre symbol outputs zero, QR or QNR in $\mathbb{F}_q$, and finally the sequence coefficients s_i is given by the mapping function $f_2(\cdot)$.

The authors of this paper observe the distribution of n-bit patterns in a binary sequence. It should be noted that here n satisfies $1 \leq n \leq (m/m')$ relation. The distribution of n-bit patterns evaluated by observing the consecutive sequence coefficients $(s_i, s_{i+1}, \ldots, s_{i+(n-1)})$. Particularly,

$$\begin{aligned} s_{i+0} &= f_2\left(\left(\mathrm{Tr}\left(\omega^i \cdot \omega^0\right)\right\rVert_p\right), \\ s_{i+1} &= f_2\left(\left(\mathrm{Tr}\left(\omega^i \cdot \omega^1\right)\right\rVert_p\right), \\ &\vdots \\ s_{i+(n-1)} &= f_2\left(\left(\mathrm{Tr}\left(\omega^i \cdot \omega^{n-1}\right)\right\rVert_p\right), \end{aligned}$$

where $0 \leq i \leq (q^M - 2)$. By observing the above sequence coefficients, the distribution of bit patterns $D_{\mathcal{S}_\lambda}$ is determined by the following trace values.

$$\mathrm{Tr}\left(\omega^i \cdot \omega^0\right), \mathrm{Tr}\left(\omega^i \cdot \omega^1\right), \ldots, \mathrm{Tr}\left(\omega^i \cdot \omega^{n-1}\right). \quad (14)$$

Let $\mathcal{A} = \{\alpha_0, \alpha_1, \ldots, \alpha_{m-1}\}$ be a basis, ω be a primitive element and with this basis ω^i is represented as,

$$\omega^i = \sum_{j=0}^{m-1} a_{i,j}\alpha_j, \text{where } a_{i,j} \in \mathbb{F}_q \text{ and } 0 \leq i \leq q^M - 2. \quad (15)$$

Again let $\mathcal{B} = \{\omega^0, \omega^1, \ldots, \omega^{n-1}, \beta_n, \ldots, \beta_{m-1}\}$ be a dual basis of $\mathcal{A}$ in $\mathbb{F}_q$ over $\mathbb{F}_{q^M}$. Then we also have

$$\omega^t = \omega^t + \sum_{j=0}^{\frac{m}{m'}-1} 0 \cdot \beta_j, \text{where } 0 \leq t < n. \quad (16)$$

Since $\mathcal{A}$ and $\mathcal{B}$ are dual bases to each other, then $\mathrm{Tr}\left(\omega^i \cdot \omega^t\right)$ be calculated as follows.

$$\begin{aligned} \mathrm{Tr}\left(\omega^i \cdot \omega^t\right) &= \mathrm{Tr}\left(\sum_{j=0}^{m-1} a_{i,j}\alpha_j \cdot \left(\omega^t + \sum_{j=0}^{\frac{m}{m'}-1} 0 \cdot \beta_j\right)\right) \\ &= a_{i,t}. \end{aligned}$$

Therefore, by using the dual basis, the distribution of bit patterns $D_{\mathcal{S}_\lambda}\left(b^{(n)}\right)$ determined by the trace values becomes as follows.

$$\begin{aligned} &\mathrm{Tr}\left(\omega^i \cdot \omega^0\right), \mathrm{Tr}\left(\omega^i \cdot \omega^1\right), \ldots, \mathrm{Tr}\left(\omega^i \cdot \omega^{n-1}\right) \\ &= (a_{i,0}, a_{i,1}, \ldots, a_{i,n-1}). \end{aligned}$$

Thus, instead of using sequence coefficients $(s_i, s_{i+1}, \ldots, s_{i+(n-1)})$, we can consider the dual basis representation of these coefficients as $\left(a_{i,0}, a_{i,1}, \ldots, a_{i,(n-1)}\right)$. Additionally, all the above trace values belong to the sub extension field $\mathbb{F}_q$.

Furthermore, $\omega^i\left(0 \leq i \leq q^M - 2\right)$ in (15) represents every non-zero vectors in the extension field $\mathbb{F}_{q^M}$ as,

$$\left\{\mathrm{Tr}\left(\omega^0\right), \mathrm{Tr}\left(\omega^1\right), \mathrm{Tr}\left(\omega^2\right), \mathrm{Tr}\left(\omega^3\right), \ldots, \mathrm{Tr}\left(\omega^{q^M-2}\right)\right\}. \quad (17)$$

According to the trace property, non-zero $\mathbb{F}_q$ elements appear $q^{M-m'}$ times and zero appears one less than the other elements i.e. $q^{M-m'} - 1$ times in the above equation.

3.3.1 Relation Between the Sequence Coefficients With the Trace Values and Legendre Symbol Calculation

Depending on the three different types of trace values (0, QR, and QNR), the Legendre symbol outputs three different values (0, 1, and $p-1$), and finally the mapping function outputs 0 and 1 as sequence coefficients s_i. This dependency between the trace and Legendre symbol is explained as follows.

Table 3: Relation between the sequence coefficients with trace and Legendre symbol calculation -I.

s_i	$\mathrm{Tr}\left(\omega^i\right)$
0	0 or QR in $\mathbb{F}_q^*$
1	QNR in $\mathbb{F}_q^*$

According to the above table, the sequence coefficient 0 comes from the two cases: one is for the $\mathrm{Tr}(0)$ case and another one is for the QR in $\mathbb{F}_q^*$ case. To deal with this two cases uniquely, let us denote **0** and 0 for the first and second cases, respectively. In addition, 1 comes for QNR in $\mathbb{F}_q^*$ case. Thus the above table can be further modified as follows.

Table 4: Relation between the sequence coefficients with trace and Legendre symbol calculation -II.

s_i	$\mathrm{Tr}\left(\omega^i\right)$
0	0
0	QR in $\mathbb{F}_q^*$
1	QNR in $\mathbb{F}_q^*$

To distinguish the appearance of 0, this paper uses the notation **0**, when zero comes from $\mathrm{Tr}(0)$ and 0 when zero comes from QR. Let the number of **0** be denoted by u and $T_{u,n}$ denotes the number of bit patterns including u times **0** and $Z(b^{(n)}) - u$ times 0. Thus, T_n can be considered as,

$$\sum_{u=0}^{Z\left(b^{(n)}\right)} T_{u,n}. \quad (18)$$

In the following section, the distribution of bit patterns in the binary sequence defined over the sub extension field theoretically proven.

3.3.2 Proof of (11a)

The period of the binary sequence is given by the following equation as,

$$\lambda = \frac{2(q^M-1)}{q-1}. \tag{19}$$

After rewriting the above equation we obtain,

$$q^M - 1 = \lambda \cdot \left(\frac{q-1}{2}\right). \tag{20}$$

To observe the distribution of bit patterns, the above relation becomes as follows.

$$D_{\mathcal{S}_{q^M-1}}\left(b^{(n)}\right) = D_{\mathcal{S}_\lambda}\left(b^{(n)}\right) \cdot \left(\frac{q-1}{2}\right). \tag{21}$$

Thus, we must consider two cases of the sequence length such as $\mathcal{S}_{q^M-1}$ and $\mathcal{S}_\lambda$. Hence, we will observe the distribution of bit patterns in $\mathcal{S}_{q^M-1}$ as $D_{\mathcal{S}_{q^M-1}}\left(b^{(n)}\right)$ and $\mathcal{S}_\lambda$ as $D_{\mathcal{S}_\lambda}\left(b^{(n)}\right)$.

In the previous section, we explained that n-bit patterns can be considered as $b^{(n)} = (a_{i,0}, a_{i,1}, \ldots, a_{i,n-1})$. On the other hand, the remaining $(m-(n\cdot m'))$-bit patterns are composed of $(a_{i,nm'}, a_{i,nm'+1}, \ldots, a_{i,m-1})$ coefficients of ω^i, which is given by the (16). In addition, the number of combinations of $(a_{i,nm'}, a_{i,nm'+1}, \ldots, a_{i,m-1})$ becomes $q^{M-nm'}$. It should be noted that here ω^i represents all of the non-zero coefficients in the extension field $\mathbb{F}_{q^M}$.

As mentioned previously, when the trace value is equal to 0 or QR, then the sequence coefficients becomes **0** and 0, respectively. In addition, if the trace value is equal to QNR, then the sequence coefficients becomes 1. Additionally, u denotes the number of **0** in $b^{(n)}$ $\left(\text{where } 0 \le u \le Z\left(b^{(n)}\right)\right)$ from $\mathrm{Tr}(0)$, then the other 0's comes from $Z\left(b^{(n)}\right) - u$ QR's, and finally 1's comes from $n - Z\left(b^{(n)}\right)$ QNR's. Therefore, by separating 0, $T_{u,n}$, and T_n the combination of n-bit patterns can be given as follows.

$$\begin{aligned} T_{u,n} = {}& {}_nC_u \cdot {}_{n-u}C_{Z\left(b^{(n)}\right)-u} \cdot \left(\frac{q-1}{2}\right)^{Z\left(b^{(n)}\right)} \\ & \times {}_{n-Z\left(b^{(n)}\right)}C_{n-Z\left(b^{(n)}\right)} \cdot \left(\frac{q-1}{2}\right)^{n-Z\left(b^{(n)}\right)} \end{aligned} \tag{22}$$

Furthermore, T_n can be derived as,

$$\begin{aligned} T_n &= \sum_{u=0}^{Z\left(b^{(n)}\right)} T_{u,n} \\ &= \sum_{u=0}^{Z\left(b^{(n)}\right)} {}_nC_u \cdot {}_{n-u}C_{Z\left(b^{(n)}\right)-u} \cdot \left(\frac{q-1}{2}\right)^{Z\left(b^{(n)}\right)} \\ &\quad \times \left(\frac{q-1}{2}\right)^{n-Z\left(b^{(n)}\right)} \end{aligned} \tag{23}$$

According to the above equation, T_n can be calculated by $Z\left(b^{(n)}\right)$. In addition, there are ${}_nC_{Z\left(b^{(n)}\right)}$ possible bit patterns that have the same $Z\left(b^{(n)}\right)$. To calculate the $D_{\mathcal{S}_{q^M-1}}\left(b^{(n)}\right)$ for each $b^{(n)}$, T_n needs to be divided by ${}_nC_{Z\left(b^{(n)}\right)}$.

$$\begin{aligned} D_{\mathcal{S}_{q^M-1}}\left(b^{(n)}\right) &= q^{M-(n\cdot m')} \cdot \frac{T_n}{{}_nC_{Z\left(b^{(n)}\right)}} \\ &= q^{M-(n\cdot m')} \sum_{u=0}^{Z\left(b^{(n)}\right)} \frac{{}_nC_u \cdot {}_{n-u}C_{Z\left(b^{(n)}\right)-u}}{{}_nC_{Z\left(b^{(n)}\right)}} \\ &\quad \times \left(\frac{q-1}{2}\right)^{Z\left(b^{(n)}\right)-u} \cdot \left(\frac{q-1}{2}\right)^{n-Z\left(b^{(n)}\right)} \end{aligned} \tag{24}$$

The above equation can be further modified as follows.

$$\begin{aligned} & \sum_{u=0}^{Z\left(b^{(n)}\right)} {}_nC_u \cdot {}_{n-u}C_{Z\left(b^{(n)}\right)-u} \\ &= \frac{n!}{\left(n-Z\left(b^{(n)}\right)\right)!} \cdot \sum_{u=0}^{Z\left(b^{(n)}\right)} \cdot \frac{1}{u!\left(Z\left(b^{(n)}\right)-u\right)!} \\ &= \frac{n!}{\left(n-Z\left(b^{(n)}\right)\right)!} \cdot \sum_{u=0}^{Z\left(b^{(n)}\right)} \cdot \frac{1}{u!\left(Z\left(b^{(n)}\right)-u\right)!} \\ &\qquad \times \frac{\left(Z\left(b^{(n)}\right)\right)!\left(n-Z\left(b^{(n)}\right)\right)!}{n!} \\ &= \sum_{u=0}^{Z\left(b^{(n)}\right)} \frac{(Z(b^{(n)}))!}{u!(Z(b^{(n)}))!} = {}_{Z\left(b^{(n)}\right)}C_{Z\left(b^{(n)}\right)-u}. \end{aligned} \tag{25}$$

Thus, (24) becomes as follows:

$$\begin{aligned} D_{\mathcal{S}_{q^M-1}}\left(b^{(n)}\right) &= q^{M-(n\cdot m')} \sum_{u=0}^{Z\left(b^{(n)}\right)} {}_{Z\left(b^{(n)}\right)}C_{Z\left(b^{(n)}\right)-u} \\ &\quad \times \left(\frac{q-1}{2}\right)^{Z\left(b^{(n)}\right)-u} \cdot \left(\frac{q-1}{2}\right)^{n-Z\left(b^{(n)}\right)} \end{aligned} \tag{26}$$

By using the bilinear theorem, the above equation can be rewritten as,

$$\begin{aligned} D_{\mathcal{S}_{q^M-1}}\left(b^{(n)}\right) &= q^{M-(n\cdot m')} \cdot \left(\frac{q-1}{2}\right)^{n-Z\left(b^{(n)}\right)} \\ &\quad \times \left(\frac{q-1}{2}+1\right)^{Z\left(b^{(n)}\right)} \\ &= q^{M-(n\cdot m')} \cdot \left(\frac{q-1}{2}\right)^{n-Z\left(b^{(n)}\right)} \cdot \left(\frac{q+1}{2}\right)^{Z\left(b^{(n)}\right)}. \end{aligned} \tag{27}$$

From the (21), $D_{\mathcal{S}_\lambda}\left(b^{(n)}\right)$ holds the following relation as follows,

$$D_{\mathcal{S}_\lambda}\left(b^{(n)}\right) = D_{\mathcal{S}_{q^M-1}}\left(b^{(n)}\right) \cdot \left(\frac{q-1}{2}\right)^{-1}. \tag{28}$$

Therefore, using the (27), $D_{\mathcal{S}_\lambda}\left(b^{(n)}\right)$ can be given by the following relation as,

$$\begin{aligned} D_{\mathcal{S}_\lambda}\left(b^{(n)}\right) &= q^{M-(n\cdot m')}\cdot\left(\frac{q-1}{2}\right)^{n-Z\left(b^{(n)}\right)} \\ &\quad\times\left(\frac{q+1}{2}\right)^{Z\left(b^{(n)}\right)}\cdot\left(\frac{q-1}{2}\right)^{-1} \\ &= q^{M-(n\cdot m')}\cdot\left(\frac{q-1}{2}\right)^{n-Z\left(b^{(n)}\right)-1}\cdot\left(\frac{q+1}{2}\right)^{Z\left(b^{(n)}\right)}. \end{aligned} \tag{29}$$

Thus, the first part of the (11a) is proven.

3.3.3 Proof of (11b)

Let us consider the case that $Z\left(b^{(n)}\right)=n$. Therefore, the combination of n-bit patterns except the all-zero patterns is given as follows:

$${}_nC_{Z\left(b^{(n)}\right)}. \tag{30}$$

Thus, the distribution of all-zero patterns becomes

$$D_{\mathcal{S}_\lambda}\left(b^{(n)}\right)=\lambda-\sum_{u=0}^{n-1}{}_nC_u\cdot D_{\mathcal{S}_\lambda}\left(b^{(n)}\right). \tag{31}$$

Thus, the second part of the (11b) is proven. In addition, the theorem in (11) is also proven.

4 Result and Discussion

This section explains the distribution of bit patterns in the binary sequence which generated over the sub extension field based on some experimental results. Then, a comparison between the binary sequence defined over the sub extension field and our previous geometric sequence [13] also introduces in terms of the distribution of bit patterns property. Here, H_{wt} denotes the hamming weight.

4.1 Experimental Results

Let us consider the distribution of bit patterns in the binary sequence, introduced in this paper which generated over the sub extension field in the following examples.

Example 1 *Let $p=5, m=4$, and $m'=2$, then the sequence having a period of* 52 *becomes as follows its distribution of n-bit patterns is shown in Table 5.*

$$\begin{aligned} \mathcal{S}_{52} = \{&0100110100000010101111001 1 \\ &1011001011111001010000110 0\}. \end{aligned} \tag{32}$$

Table 5: Bit distribution of the binary sequence $\mathcal{S}_{52}$ with $p=5, m=4$, and $m'=2$.

n	$H_{wt}(b^{(n)})$	$Z(b^{(n)})$	$D_{S_{52}}(b^{(n)})$
1	0	1	27
	1	0	25
2	0	2	14
	1	1	13
	2	0	12

Example 2 *Let $p=3, m=6$, and $m'=2$, then the sequence having a period of* 182 *becomes as follows its distribution of n-bit patterns is shown in Table 6.*

Table 6: Bit distribution of the binary sequence $\mathcal{S}_{182}$ with $p=3, m=6$, and $m'=2$.

n	$H_{wt}(b^{(n)})$	$Z(b^{(n)})$	$D_{S_{182}}(b^{(n)})$
1	0	1	101
	1	0	81
2	0	2	56
	1	1	45
	2	0	36
3	0	3	31
	1	2	25
	2	1	20
	3	0	16

Example 3 *Let $p=7, m=9$, and $m'=3$, then the sequence having a period of* 235986 *becomes as follows its distribution of n-bit patterns is shown in Table 7.*

Table 7: Bit distribution of the binary sequence $\mathcal{S}_{235986}$ with $p=7, m=9$, and $m'=3$.

n	$H_{wt}(b^{(n)})$	$Z(b^{(n)})$	$D_{S_{235986}}(b^{(n)})$
1	0	1	118337
	1	0	117649
2	0	2	59341
	1	1	58996
	2	0	58653
3	0	3	29757
	1	2	29584
	2	1	29412
	3	0	29241

4.1.1 Observation

It was found that the experimental results explicitly support the (11). In addition, the number of appearance of each bit pattern is related to the number of zeros contained in each bit pattern. Moreover, $D_{\mathcal{S}_\lambda}(b^{(n)})$

increases in proportion to $Z(b^{(n)})$. To confirm this, let us check the **Example** 2 with $n = 3$.

$Z(b^{(3)}) = 0$:

$$D_{S_{182}}(b^{(3)} = 111) = 3^{6-(3\times2)} \cdot 4^{3-0-1} \cdot 5^0 = 16.$$

$Z(b^{(3)}) = 1$:

$$D_{S_{182}}(b^{(3)} = 011) = 3^{6-(3\times2)} \cdot 4^{3-1-1} \cdot 5^1 = 20,$$
$$D_{S_{182}}(b^{(3)} = 101) = 3^{6-(3\times2)} \cdot 4^{3-1-1} \cdot 5^1 = 20,$$
$$D_{S_{182}}(b^{(3)} = 111) = 3^{6-(3\times2)} \cdot 4^{3-1-1} \cdot 5^1 = 20.$$

$Z(b^{(3)}) = 2$:

$$D_{S_{182}}(b^{(3)} = 001) = 3^{6-(3\times2)} \cdot 4^{3-2-1} \cdot 5^2 = 25,$$
$$D_{S_{182}}(b^{(3)} = 010) = 3^{6-(3\times2)} \cdot 4^{3-2-1} \cdot 5^2 = 25,$$
$$D_{S_{182}}(b^{(3)} = 100) = 3^{6-(3\times2)} \cdot 4^{3-2-1} \cdot 5^2 = 25.$$

$Z(b^{(3)}) = 3$:

$$D_{S_{182}}(b^{(3)} = 000) = 182 - (1 \times 16 + 3 \times 20 + 3 \times 25) = 31.$$

4.2 Comparison With Our Previous Work

By combining the features of the M-sequence and Legendre sequence our previous work [13] proposed a geometric sequence, namely NTU (Nogami-Tada-Uehara) sequence. According to our previous research work, NTU sequence always holds long period, low correlation, high linear complexity properties which are the important considerations to use any sequence in cryptographic applications. Another crucial consideration before utilizing them in any secure applications, is to judge the randomness of a sequence. To do so, we need to evaluate the distribution of bit patterns property in a sequence. After the experimental observation, it was found that in terms of distribution of bit patterns NTU sequence is not uniformly distributed. In other words, in case of binary NTU sequence, there is much difference in appearance between the 0 and 1. To improve this drawback, instead of prime field (which used in the NTU sequence generation procedure), we focused on the sub extension field during the sequence generation procedure in this research work. As a result, after utilizing the sub extension field, the distribution of bit patterns becomes close to uniform. This comparison is shown in the following tables (Table 8 and Table 9).

It should be noted that the NTU sequence is controlled by 2 parameters (p and m), on the other hand the sequence over the sub extension field is controlled by 3 parameters (p, m, and m'). Therefore, it is not possible to make the comparison between these two sequences in terms of the same length (in other words, the same period λ). The authors kept the difference as minimum as possible.

One of the most notable outcomes of this comparison result is the NTU sequence holds higher difference in terms of the appearance between the 'all zero' and 'all one' patterns. In other words, it also confirms the ununiform distribution of bit patterns. On the other hand, sequence defined over the sub extension field minimizes this difference to make it close to uniform. This comparison graphically shown in Figure 3.

Table 8: Comparison in bit distribution between the sub field binary sequence and NTU sequence -I.

n	$H_{wt}(b^{(n)})$	$D_{S_{182}}(b^{(n)})$	%	$D_{NTU_{242}}(b^{(n)})$	%

Recently, there are lots of considerations to use a long period pseudo-random sequence in cryptographic applications. The use of binary sequence in a stream cipher is one of the most common application. Before applying a sequence in such applications, the linear complexity and distribution of bit patterns are considered as the most important properties regarding a sequence to check its randomness. Among these two, the authors observed the linear complexity property in their previous work [16] and it always holds a maximum value of the linear complexity. As a continuation, the authors focused on the distribution of bit patterns in this paper. According to the comparison results, the binary sequence generated over the sub extension field holds much better (close to uniform) compared to our previous binary sequence in terms of distribution of bit patterns. Therefore, the binary sequence defined over the sub extension field can be a suitable candidate for some cryptographic applications.

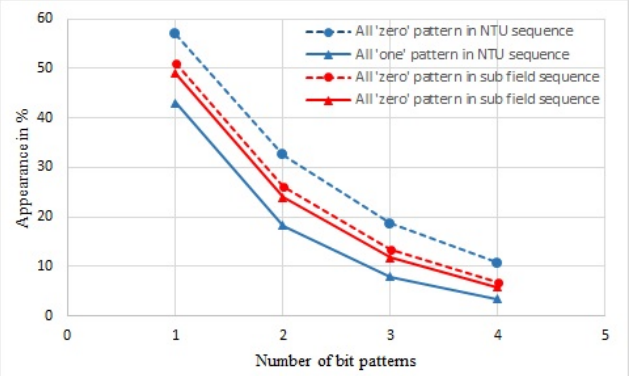

Figure 3: Appearance of 'all zero' and 'all one' bit patterns in the NTU and sub field sequence.

5 Conclusion

In this paper, the authors observed the distribution of bit patterns in a binary sequence which defined over the sub extension. The number of appearances is related to the number of zeros contained in each bit pattern. Furthermore, the authors theoretically prove the distribution of bit patterns property. In addition, they also made a comparison between the binary sequence defined over the sub extension field and our previous work on binary sequence based on distribution of bit patterns property. According to the comparison results, the binary sequence generated over the sub extension field holds much better (close to uniform) compared to our previous binary sequence. As a future work, we would like to consider an efficient implementation to enhance the usability of our proposed sequence a Cryptographically Secure Pseudo Random Number Generator (CSPRNG).

Conflict of Interest The authors declare no conflict of interest.

A B S T R A C T

Although social media is used by an ever-increasing number of businesses, its benefits have not yet been fully exploited. Social media analytics tools can prove helpful in this regard, since they comprise a unique information source for business intelligence. As the social media environment rapidly evolves, various social media analytics tools are emerging. This research examines the usefulness of social media analytics tools for assessing corporate websites and Facebook pages. Two social media analytics tools, Website Grader and LikeAlyzer, are selected to evaluate the wine industry in Greece and Germany. A comparative study of the two countries is subsequently presented. The paper suggests that researchers and practitioners can easily use these analytics tools to acquire valuable quantitative data for a fast, effective and efficient assessment of corporate websites and Facebook pages and thus improve their social media usage. The results show that the two countries present similarities, but there is great potential for improvement in their use of social media.

1. Introduction

Digital marketing is transforming the very nature of business through the implementation of digital technologies which serve the marketing goals of businesses. Digital marketing is classified into various categories, including search engine marketing (e.g. Bing, Google), influencer marketing, social media (SM) marketing, online display advertising, mobile marketing, affiliate marketing (e.g. Amazon), email marketing, and content marketing.

SM marketing provides an innovative way of communicating with the public, attracting new and maintaining old customers, improving customer relationships, creating brand awareness, increasing market share and return of investment, gaining business revenue from sales, and engaging more customers in charities, corporate social responsibility activities and other issues [1]. Nowadays, more firms are gradually adopting SM, for example, YouTube, Twitter, Pinterest, Google+, Facebook, Instagram, and Flicker, setting aside their initial doubts regarding their effectiveness [2].

As the digital environment evolves, SM hold a substantial position in the next generation business intelligence platform. Effective SM use can have a decisive impact on a digital marketing campaign [3]. Thus, more and more SM analytics tools are emerging. Understanding SM usage in the context of digital marketing through analytics tools is critical for both academic and business communities. These tools have become a unique information source for assessing a business's presence in the SM environment as they collect, monitor, analyze, summarize and visualize a vast amount of SM data [4]. However, businesses from various sectors, including the food and beverage industry, have not yet exploited the full potential of these tools.

Wine may be considered a social product, as it is included in the top eight product categories involved in discussions over the internet. Thus, the internet provides an ideal medium for wine promotion and sale. Surveys have shown that in comparison to many other consumer products, wine appears more often as a search engine keyword [5]. In the past wine consumers sought information from specialized magazines, books, and newsletters. Lately more and more consumers are consulting SM connoisseurs, sommeliers and the wine-loving audience in order to help them decide on a satisfactory wine purchase. On the other hand, businesses have a lot to gain from the feedback provided by customers through SM. Professionals in the wine industry are

*Corresponding Author: Constantina Costopoulou, tina@aua.gr, +302105294183

trying to understand consumer behavior and preferences through the opinions and criticism diffused through various SM [6].

Today competition in the wine market is at its highest level to date. Around the world the vineyard surface area covers 7.4 million hectares and the production of wine has reached 292.3 million hectoliters. The exact number of wine producers cannot be safely estimated since, in addition to professional winemakers, there are hobbyists, family micro-businesses and single producers. In 2018 Italy, France and Spain were the dominant global wine exporters. Specifically, in terms of volume Spain is the largest exporter and the three countries together represent half of the world market. In terms of value, France – maintaining a successful strategy for high quality products – is the leader; France and Italy together hold a share of the global market of approximately 30% [7].

However, this intense competition requires new strategies which go beyond the production of high quality wine, leading wineries to strive for differentiation [8]. Towards this end, SM have succeeded the geographic decoupling of wine customers and wineries affecting data collection and sharing, communication, and the overall wine purchasing experience.

Despite the significant impact of SM on wine customers and winery businesses [9, 10] digital marketing for wine is still complex [11]. Wineries are increasingly adopting SM [12] but at a slow pace, as most lack the knowledge to incorporate and exploit SM effectively in their marketing strategy [13-16]. A study of Italian wineries has shown that it is principally large wineries with a number of employees with SM knowledge and skills that are highly motivated for adopting SM [17].

The current study aims to shed light on the usefulness of SM analytics tools for helping businesses to evaluate SM usage, plan their SM efforts and revise them regularly. It focuses on the wine industry in Greece and Germany. Two freely available online tools are used to extract useful data for both countries. The German market holds the largest share of wine imports in Europe, becoming a target for wine exporting countries, such as Greece. In addition, Greek wine exporters are trying to become more active in the German market [18].

The article is structured as follows. We begin with a discussion of SM analytics tools. We then outline the methods and tools used for assessing German and Greek wineries' websites and Facebook pages. The SM analytics tools, Website Grader and LikeAlyzer, are selected as these offer an accurate/comprehensive and quick assessment. Next, we present the evaluation for the two countries – 105 Greek and 100 German wineries. Finally, we provide the survey results and draw some conclusions.

2. SM Marketing

SM regard communication means among people, allowing content to be created and shared in the digital networking environment [19]. SM can be described as an online platform for participation, discussion, and sharing; its use encourages the exchange and diffusion of opinion and information among users [20]. [21] argues that the revolutionary role of content publishers provided to SM users contributes to a democratization of information. Although SM comprise sources of information, they also provide social and emotional support, as within the SM context there is emphasis on the interaction rather than on the content itself [22, 23]. [24] distinguishes five main categories of SM: collaborative projects (e.g. Wikipedia); social networking sites (e.g. Facebook); content communities (e.g. YouTube, Pinterest, and Flickr); blogs (e.g. Blogger, Tumblr, and Twitter); and virtual worlds (e.g. Second Life). SM reflect daily life discussions, occurring at work or at home, at a restaurant or supermarket, which travel far away from the place they happen and are communicated to the public through the digital world [25]. According to the definition by [26], SM can be considered an interactive dialogue. This "dialogue is often triggered by consumers/businesses and/or products/services that circulate among them to set in motion a revealing communication on promotional information, so that it allows learning from one another's use and experiences, eventually benefitting all of the involved parties" [p. 290].

While for individuals SM serve as a means of communication for users with similar interests, businesses can leverage user conversations about their products, services and brand, and engage in discussions for using the relevant information to make better business decisions [27]. [28] designates SM marketing as an interdisciplinary and interoperable concept that uses SM to achieve business aims by adding value for the parties involved. [29] defines it as the use of SM technologies (e.g. Web 2.0, Web 3.0) and software for creation, communication, delivery and sharing of offers that have value for business owners.

SM marketing focuses on producing attractive content for customers and promoting the use and sharing of this content through the various social networks they follow. In this way "word-of-mouth" marketing is practiced, establishing a strong relationship between consumers and products, with a limited cost for businesses [5]. Although the general public uses SM primarily to develop social contacts rather than for shopping, the success of SM marketing is based on a more indirect approach. More specifically, instead of offering products for sale, the company encourages members of a community to discuss and disseminate the use and benefits of these products [30]. Several businesses try to exploit consumers' opinions expressed through SM by involving them in product design choices [31] using SM analytics tools. In light of this, a significant number of data services, platforms and tools have been developed [32]. Some of the most popular examples are: Buffer, Hootsuite, Google Analytics, Talkwalker, TapInfluence, Brand24, Klear, Keyhol, Quintly, IBM Watson Personality analytics, BuzzSumo, Funnel.io, nTuitive.social, Sprinklr, Website Grader, MeetEdgar, MavSocial, ZohoSocial, Lithium, Social report, SumAll, Social Mention, Cyfe, Sendible, Eclincher, SproutSocial, AgoraPulse, Bit.ly, Everypost, Socedo, Socialoomph, and Fanpage Karma. However, there are also analytics tools for specific SM, for example weepi, Followerwonk, Postchup, Twitonomy and Tweetdeck for Twitter; Komfo, Sociograph.io, LikeAlyzer and AdEspresso for Facebook; Owlmetrics, Storyheap and SocialDrift for Instagram; and ViralWoot and Tailwind for Pinterest. Table 1 presents a literature review of the use of SM analytics in various business sectors. The review was based on the Google Scholar search engine.

3. Methods and Tools

The approach used for the evaluation of the corporate wineries' websites and their Facebook pages can be analyzed in three phases:

Table 1. Social media analytics tools review

Social Media Analytics Tools	Paper	Sector
Facebook: Sociograph.io	[33]	Traded firms
	[34]	Radiology

- Determination of the sample of winery businesses.
- Selection of appropriate SM analytics tools for assessing websites and Facebook pages.
- Data collection and analysis.

The survey was conducted in 2019 and the sample for Greek and German wineries was identified through the Google search engine. For the Greek market the keywords used were: "winery", "retail sale winery", "Greek winery", "wine", "wine trade", "winemaking", "wine in Greece". For the German market the keywords used were: "Wein", "Weingut", "Deutscher Wein", "Wein Online-Shop", "German wineries", and "German wines". 105 Greek and 100 German wineries were identified, which have a corporate website and/or a Facebook page.

The selection of the appropriate SM analytics tools was based on the aforementioned literature review (Table 1) and free online availability of tools. Website Grader (website.grader.com) was selected for corporate websites and the LikeAlyzer (likealyzer.com) was selected for Facebook pages [35, 54, 64-67].

Website Grader is a comparative online tool, which evaluates a website based on a standard rating (from 0 to 100) in relation to other sites. The rating indicates whether the website works well for the company and helps to improve website quality. More specifically, the features that Website Grader evaluates are:

- *Performance:* evaluates the overall appearance of a website, the size of web pages and its speed. Performance is probably one of the most important features, as it is associated with the visitor's first impression and experience of the website. This can help increase the visibility and impact of the business. The value of this feature ranges from 0 to 30. The *performance* feature includes the following characteristics: page size, page requests, page speed, browser cashing, page redirects, compression, and render blocking.
- *Mobile readiness:* refers to the capacity to view the website on any mobile device, for example smart phones, in terms of response and viewer settings. As a large portion of the purchasing community visits pages and makes extensive use of the internet and SM from their mobile device, the flexibility of a website to work efficiently on these devices is important. Its value ranges from 0 to 30. Responsiveness and viewport are the characteristics included in this feature.
- *Search Engine Optimization (SEO):* relates to the ranking of the website by search engine users. The short title of a website, short descriptions and keywords can help improve the rankings. Its value ranges from 0 to 30. The *SEO* feature includes the following characteristics: page titles, sitemap, headings, and meta description.
- *Security:* checks the existence of a security certificate, such as a Secure Sockets Layer (SSL), for ensuring security and authentication of information submission. The value of this feature ranges from 0 to 10.

The LikeAlyzer tool was selected for the evaluation of wineries' Facebook pages. It is a popular analysis tool [66], which provides monitoring and feedback on an organization's Facebook presence and impact, allowing the comparison and exploration of Facebook potential. More specifically, it assesses any Facebook page, provides suggestions for improvement and compares it with other Facebook pages. The features that the LikeAlyzer evaluates are the following:

- *Frontpage:* refers to the visitor's first impression of the page. This includes information about the business, for example, about, username, profile picture and cover photo, and call to action.
- *About:* regards more detailed business information, such as milestones, contact information, location and products.
- *Activity:* concerns the activity of the page and how often it occurs. It evaluates the number of pages liked, native

Facebook videos, the number of posts per day, and the average post length.

- *Response:* refers to the response to visitors, either through comments on posts or through personal messages. It evaluates whether visitors can post.
- *Engagement:* evaluates visitors' activity on the page, and some features that can only be accessed by the page developer. The number of people who have interacted with the page and the total page likes are measured.

It is worth noting that LikeAlyzer does not provide an overall score, but each feature is graded from 0 to 100%.

4. Results

4.1. The Greek Case

Europe is a leader in global wine exports. In Greece the importance of the winemaking sector is reflected in its potential for promoting traditional products abroad [18]. As one of Greece's main export products, wine comprises more than 50% of the total export value of the Greek beverage industry. Fragmentation of domestic production and the large number of businesses that are exclusively active in winemaking, mainly small and medium sized companies, are the main characteristics of the sector [3]. There are also large wineries with extensive distribution networks throughout Greece, which are responsible for a significant proportion of wine production. Moreover, although the Greek economic crisis has resulted in a decrease in demand, recently it has generated an increased interest in non-bottled wines [68].

Of the 105 Greek wineries in the sample, 86% have a corporate website for promoting and advertising their products/services, 72% support a Facebook page, 37% use Instagram, 38% use Twitter, 17% use YouTube, and 10% use Pinterest. This leads to the conclusion that Greek wineries use and trust SM, and especially Facebook, Instagram and Twitter, for marketing activities [3]. It is evident that Greek wineries have turned to the digital environment for success in the market. The wine industry has been among the slowest to adopt SM [69]. As regards the year the winery established its internet presence, 24% established between 1999 and 2005, 22% between 2006 and 2011, while 54% between 2012 and 2018. Turning to the languages supported by corporate websites, 82% are both in Greek and English and 18% only in Greek, indicating that the majority are interested in export activities.

Greek winery websites were evaluated with Website Grader. The overall mean score was 66.42%. The overall mean score for each of the Website Grader features is: (a) *performance:* 19.45/30; (b) *mobile readiness:* 23.62/30; (c) *SEO:* 17.06/30 and (d) *security:* 6.12/10. Figure 1 shows the scores of *performance* characteristics of a Greek winery website.

Figure 2 shows the overall recommendations of the Website Grader tool for the improvement of the particular website. The recommendations refer only to *performance* and *SEO* features, which scored lower than satisfactory values.

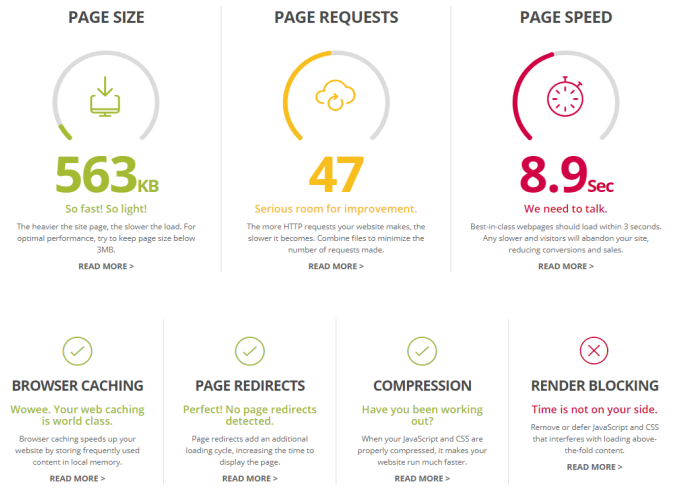

Figure 1. Website Grader Results for performance characteristics of a Greek winery website

Figure 2. Website Grader recommendations for performance and SEO characteristics of a Greek winery website

Next, the results from the LikeAlyzer evaluation are presented. The *Frontpage* feature mean score for the sample is 97% and is analyzed according to the following attributes:

• Profile picture and cover photo: 92.81% of the wineries use a profile picture/cover photo in their profile.

• Username: 93.75% use a shortened page address to promote their business more easily.

• About: 89.06% provide information about the page and what someone can expect when starting to follow the page.

• Call to Action: 100% use "Call to Action" buttons (e.g. "Message Now", "Call Now", "Sign Up Now", "Shop Now") to support interaction with users and promote the business' main objectives.

The *About* feature mean score is 72% and is analyzed according to the following attributes:

• Milestones: only 3.13% use milestones to tell the story of their business.

• Contact information: 64.06% of all contact information (telephone, email, website) is provided on the Facebook page. The percentage is quite low compared to the usefulness and convenience of this information for users. In addition, the lack of

such information has a negative impact on the reliability and safety of the page.

• Location: 70.31% provide the location of their headquarters.

• Products: 26.56% promote their products on their page.

The *Activity* feature mean score is 54% and is analyzed according to the following attributes:

• Posts per day: 0.24 are the daily posts made by businesses, which needs improvement to enhance user engagement.

• Average post length: 192.88 characters is the average length of the posts, which can be improved as it has been noted that posts with 40-100 characters generate more user engagement.

• Pages liked: 42.06 is the average number of "Likes" made by the businesses in the sample to other businesses. Increasing this average will positively affect the cross-sector dialogue and interest, as well as the overall engagement.

• Native Facebook videos: 1.56 is the average number of videos published. Given that video is considered the most engaging format on Facebook, this feature needs to be improved.

The *Engagement* feature mean score is 3% and is analyzed according to the following attributes:

• People talking about this: on average 163 users accessed the page or interacted with its content within the past week.

• Total page likes: 5,840 is the average number of "Likes" by users per business. A larger number of likes corresponds to the business' wider reach.

The *Response* feature mean score is 85% and is analyzed according to the following attribute:

• Users can post: 52.38% of businesses offer their users the option of posting on their page.

4.2. The German Case

German businesses have a long history in the wine sector. For the last forty years Germany has been a leader in global wine imports. Most of the Greek wine imports are made by Germany. Despite the maturity of the German wine sector, it is currently undergoing structural changes. In the near future it is expected that expenditure for marketing will increase, as consumer habits change and new marketing approaches and channels (e.g. blogs and electronic auctions) are required on the basis of a strategic path for sustainability [71,72]. The German Wine Institute, which comprises the country's wine industry marketing organization for the generic promotion of German wines domestically and abroad, already uses SM tools, including Twitter, Instagram, YouTube and Facebook [73].

In 2012 German wineries' SM usage was explored in two research studies [6, 74]. In [6], a sample of 321 German wineries was studied to identify winemakers' SM preference. Facebook was found in this study to be German winemakers' favorite platform. In [74] the SM usage of German wineries and its impact on a sample of Facebook and non-Facebook users was assessed. The turnover of purchases of Facebook users was higher than that of non-users as they are interested in sales offers from wineries they support through SM. 87% of the sample purchased wine from a specific winery and 15% purchased wine from this winery on a regular basis.

All 100 German wineries have a corporate website and 53% also have a Facebook page. Concerning the year the winery established its internet presence, 61% established between 1998 and 2005, 15% between 2006 and 2011, and 24% in 2018. As regards the languages supported by corporate websites, 29% are only in German, 71% are available both in German and English, and 7% support a third language.

Data collected from the German wineries indicate that they engage in SM marketing practices to a high degree. Regarding SM usage, 96% of wineries use Facebook, 28% use Instagram, 8% use Twitter, and 1% use YouTube and Pinterest.

German winery websites were evaluated with Website Grader, achieving an overall mean score of 70.58%. Specifically, the scores for each feature are presented as follows: (a) *performance:* scores reached an average of 23.61/30; (b) *mobile readiness*: 23.27/30; (c) *SEO*: 16.79/30; and (d) *security*: 7.65/10.

Next, the results from the LikeAlyzer evaluation are presented. The *Frontpage* feature mean score of the sample is 94.30% and is analyzed according to the following attributes:

• Profile picture and cover photo: 86.79% of the wineries use a profile picture/cover photo in their profile.

• Username: 94.34% use a shortened page address.

• About: 81.13% provide information about the page.

• Call to Action: 100% use "Call to Action" buttons.

The *About* feature mean score is 82.90% and is analyzed according to the following attributes:

• Milestones: only 9.43% use milestones.

• Contact information: 85% of all contact information is provided on the Facebook page. The percentage is not extremely high, offering scope for improvement for the German wineries.

• Location: 90.56% provide the location.

• Products: 9.43% promote their product, showing low exploitation of Facebook for promotion.

The *Activity* feature mean score is 42.50% and is analyzed according to the following attributes:

• Posts per day: 0.09 are the daily posts.

• Average post length: 186.74 characters is the average text size of the posts.

• Pages liked: 28.91 is the average number of "Likes".

• Native Facebook videos: 0.91 is the average number of videos published.

The *Engagement* feature mean score is 3% and is analyzed according to the following attributes:

• People talking about this: on average 70 people have interacted with a page.

• Total page likes: 4,515 is the average "Likes" made by users per business.

The *Response* feature mean score is 90.56% and is analyzed according to the following attribute:

• Users can post: 90.56% of businesses allow users to post on their page.

In the following figures an example of a German winery assessed with LikeAlyzer is presented. Figure 3 presents the overall impression of the Facebook page, and Figures 4 and 5 show the assessment of Frontpage and Activity features respectively.

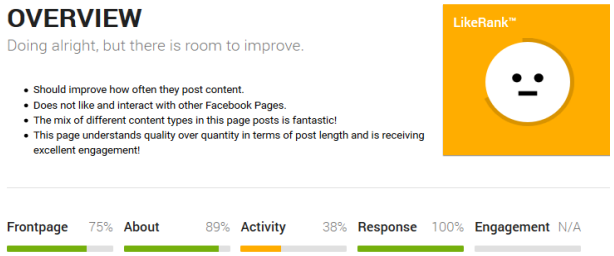

Figure 3. Overview of the Facebook page of a German winery assessed by LikeAlyzer

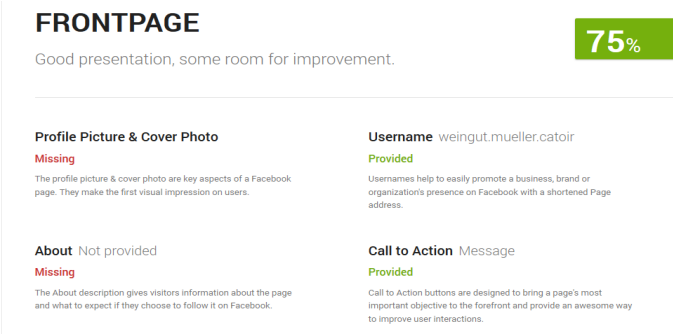

Figure 4. Frontpage feature assessment by LikeAlyzer

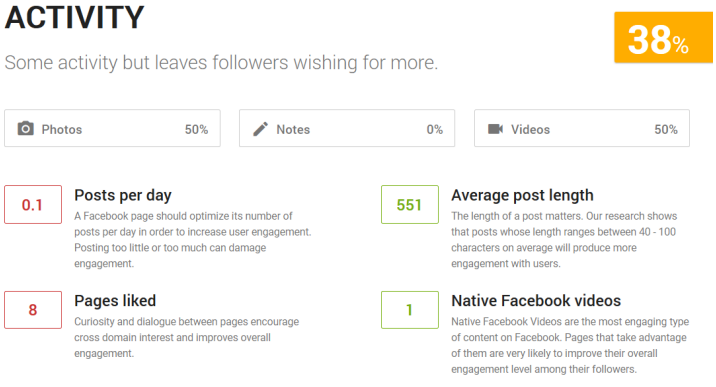

Figure 5. Activity feature assessment by LikeAlyzer

4.3. Discussion

The assessment results of the Greek and German wine industry using Website Grade and LikeAlyzer tools are presented in Table 2. According to the Website Grader evaluation, the *performance* rating for Greece is 19.45 out of 30, and for Germany 23.61. This slight difference in *performance* of German corporate websites shows that they create a better first impression and experience for users. However, Greek winery websites enrich their content with many images and videos in addition to a standard description of their products, which significantly reduces their speed. Regarding *mobile readiness*, Greek and German websites have similar scores, though flexibility and responsiveness for mobile devices have to be further improved. Moreover, according to [4], 60% of users are unlikely to return to a website with accessibility problems from a mobile device, while 40% of users choose to visit a competitor's site. It is therefore essential for winery websites to offer customers an optimized experience for their smart phones and tablets. SEO was 17.06 for Greek wineries and 16.79 for German. Greece seems to be ranked more highly when customers search through a search engine. As regards security, Greek websites scored 6.12, while German websites are ahead with a score of 7.65. Security seems to be moderate for both countries; Greek websites in particular need immediate improvement with the implementation of security protocols such as SSL.

Table 2. Greek and German winery assessment results from Website Grader and LikeAlyzer

Features	**Countries**	
	Greece	**Germany**
Website Grader		
Overall	66.42 %	70.58 %
Performance	19.45/30	23.61/30
Mobile readiness	23.62/30	23.27/30
SEO	17.06/30	16.79/30
Security	6.12/10	7.65/10
LikeAlyzer		
Frontpage	97.00	94.30
About	72.00	82.90
Activity	54.00	42.50
Engagement	3.00	3.00
Response	85.00	90.56

Well-designed corporate websites provoke customers' emotional reactions while browsing [76]. From the study of German and Greek wineries' corporate websites, there is an overall impression that the website design presents some differentiation. In particular, Greek wineries' homepages have rich, impressive and colorful photos with people celebrating food and wine, experiences from product use, and information on the winery's history, showing a better understanding of how to project customers' ideal experience. In contrast, the appearance of German wineries' websites is less meticulous, generating less positive or even negative comments/impressions among users [3]. A German study conducted in 2016 showed that websites with large-sized, high-quality photos of joyful people or inspired moments, such as a panoramic view of the vineyard, can potentially create an emotional impact on users/customers [75]. Customers' emotional influence and engagement can be taken forward when wineries try to tell their own business story, allowing customers to get to know the winemakers better and identifying similar values that connect them.

Our research also provides data on extroversion to foreign customers. Specifically, 83% of Greek wineries and 71% of German wineries provide their websites in at least two languages. This indicates that Greece constitutes a dynamic player in wine exports and endeavors to develop its export activities further, and highlights Germany's position as the largest importer of wine.

The LikeAlyzer evaluation shows that Greek and German winery Facebook pages are in general terms at similar levels. However, both countries have prospects for further improvement.

Regarding the *Frontpage* feature that shapes visitors' first impressions, Greece's score of 97% is higher than Germany's score of approximately 94%. Concerning the *About* feature, German pages provide a satisfactory amount of business information. However, it is worth mentioning that Greek wineries exploit Facebook more effectively than Germany by providing more product information. The *Activity* feature scores are low for both countries although Greek pages have more posts per day, pages liked and native videos. The *Engagement* feature has the same score (3%) for both countries since only Facebook page administrators have access to the specialized data. Finally, Germany scores more highly for *Response*, showing that German wineries allow more user interaction.

5. Conclusions

Enterprises recognize the value of SM analytics in innovation and product development, and customer service operations and strategy. Social media analytics are recently used by business managers and professionals.

SM analytics are easier to use than traditional media analysis and can provide a fast, effective and efficient assessment of corporate websites and Facebook pages. This is verified by the current research. Two freely available SM analytics tools were used to assess the corporate websites and Facebook pages of the winery industry in Greece and Germany. Few studies to date have focused on the implementation of SM analytics in the food and beverage industry. In this research the use of such tools has proved easy and effective, providing specialized data which can offer valuable insights into the wine industry in both countries. The websites of German wineries are of higher quality – from a technical perspective – than those of Greek wineries. However, the latter have a stronger Facebook presence. This can be explained by the overall attitude of Greek internet users and businesses towards SM usage. According to the Digital Economy and Society Index 2019 [77], the percentage of internet users that uses SM is 73%, 57% and 65% for Greece, Germany and the European Union respectively; the percentage of businesses that uses SM is 21%, 16% and 21% for Greece, Germany and European Union respectively.

The key contribution of this paper lies in the use of simple standard analytics to help winery managers and practitioners to plan their SM efforts and revise them regularly, using inexpensive open source tools. A limitation of this paper regards the exclusive focus on Facebook. Assessing the overall SM strategy of wineries requires the study of other SM, for example, Pinterest, Instagram, and Twitter. Such platforms can have additional potential for online visibility and direct sales by linking to corporate websites or electronic shops [75]. Future work will focus on the use of free SM analytics tools for Twitter and Instagram for retrieving data that can be used to build an overall assessment of the wine industry, as well as other food and beverage sectors. It is expected that this research will give researchers and practitioners an assessment of the wine industry and motivate them to use SM analytics tools to improve digital marketing strategies in the wine and other industries, for example, tourism, health and entertainment. This in turn can help to create a roadmap for exploitation of SM benefits.

Timetabling Process
Allen's Interval Logic

ABSTRACT

Time scheduling as seen in timetabling processes with few and/or competing resources has exposed complex interoperable time scheduling. Attempts to resolving these time scheduling processes has been undertaken, using several classical methods, with difficulty due to inherent complexities, constraints and conflicting issues. The use of ontology-based approaches to resolve time complexity is recently adopted due to its ease in interoperability and reuse of data. The probability weighted ontology provides the various types of complexity as a requirement for the complexity reduction. To determine the optimality of the resulting timetable required the evaluation of its criteria using the analytical hierarchy process. The need for a formal representation to explicate the intelligent behaviour of the ontology-based framework of the temporal scheduler arises. Hence, this work is aimed at providing that formal representation of the logical part of the ontology. The basic rules handling the constraints in the timetabling process are outlined with the corresponding formal representations of the interval-based logic using first-order logic. The semantic model of the temporal scheduler is further described following Guarino's formal ontology model. The unified modeling language (UML) design of a system framework prototype that adopts the formal model is also given. Through the formal ontology-based framework, all constraints that will give optimality are explicated and incorporated into the allocation reasoned, which results in an optimal formal ontology-based model. This will ensure reliability, ease of use and the likelihood of re-usability of the resulting timetable.

1. Introduction

This paper is an extension of work originally presented in a conference [1]. Scheduling is a constrained allocation of resources to objects in space and time, aimed at minimizing the total cost of a set of used resources [2]. This involves creating schedules by temporarily assigning activities to resources considering one or more objectives and some constraints. Project scheduling in [3] with emphasis on testing the dependencies of ordered activities using Pearson's Correlation Coefficient (PCC) is not centered on temporal scheduling which is the focus of this paper. Basically, PCC is used in [3] to obtain weights for activities and then classify them as dependent or independent so as to avoid frequent usage of same resources multiple times thereby reducing expenses and project duration. Temporal reasoning is a suitable methodology to synchronize operations, make allocations for resources, determine sequences of operations, and evaluate average earliness or tardiness of a schedule. Time, which is modeled by quantitative values and constraints, is used to represent every schedule [4, 5]. Formalizing time scheduling process is a complex task that involves different reasoning strategies, structures and elements from multiple languages. Several attempts of formalizing time schedules using classical techniques exist in the literature (simulated annealing [6], genetic algorithm [7], Tabu search [8, 9], case-based reasoning [10], and graph coloring approach [11, 12, 13, 14]. However, these approaches lack formalization and are not simple to implement needed semantics during problem solving. Moreso, their solutions, though functional, may be error prone when considering new sets of constraints. Ontology-based approaches are emerging to resolving such complexities due to their ease in interoperability and reuse of data. The identified time complexities in [1] can be resolved in the allocation reasoner

*Daniel Ekpenyong Asuquo: Department of Computer Science, University of Uyo, Nigeria; +2348035680549; danielasuquo@uniuyo.edu.ng

(AR) by implementing the represented formal notations that describe the embedded semantics in the given rules applicable for inference in the weighted ontology framework. In this work, the heuristics are formalized through ontology [15], by explicitly incorporating all constraints that will give valid answers to the competency questions in the AR and to enable their execution by ontology reasons.

The focus of this work is to construct the basic rules handling the constraints in the timetabling process with the corresponding formal representations of the interval-based logic [16, 17] using first-order logic. Furthermore, the semantic model of the temporal scheduler is further described following Guarino's formal ontology model.

The rest of the paper is organized as follows. Section 2 reviews related works and the use of ontology in scheduling problems including publishing meetings and event, resource allocation and timetabling while section 3 presents a formalization of the complexity reduction rules using first order logic and Allen's interval relations for optimal time scheduling process. Section 4 presents the semantic model of the formal time scheduling ontology with different components for obtaining optimality of time, with a mathematical description of the conceptual model. In section 5, unified modeling language (UML) diagrams are used for structural and behavioral description of the time scheduling ontology (TSONT) while section 6 concludes the paper.

2. Related works

Ontology is a model building tool for specifying the scope of an application domain as well as it entities with the attributes or desired system features. Formally, it represents knowledge as a hierarchy of concepts within a domain and uses shared vocabulary to denote the concepts' types, properties, functionalities and interrelationships. Ontology has been used as a structural tool to organize information and represent knowledge about the world in many areas, such as Artificial Intelligence (AI), Semantic Webs, Information Architecture, System Engineering, Library Science and so on. The formalization of rules enables the complexities found in the production of timetable to be managed and optimized. Ontology is capable of uniquely combining inherent techniques such as semantic search, ontology matching and ontology mapping to reduce the timescale and cost complexity in data and resolve conflicts that always occur. A typical complexity reduction case between two departmental ontologies is shown using the Anchor-PROMPT mapping technique [18]. The representation of the complexity types using the probability weighted ontology (PWO) [19] and the evaluation of its gold standard criteria using analytic hierarchy process (AHP) model [1] provide users with the window to reschedule any time based on the level of identified complexity to attain optimality. The various users' windows for rescheduling are formally represented in the following sections.

Anchor-PROMPT is a conventional ontology mapper that automatically finds semantically similar features (described by terms) between two ontologies, taking a set of pairs of related terms from the source ontologies as input. Commonalities in two different departmental ontologies are mapped together to expose the causes of conflict or clash and resolve them. Consider the mapping of two departmental ontologies shown in figure 1 with Computer Science department in Faculty of Science as an anchor department, owning a certain course, CSC211. This course, CSC 211, is also being offered by students of the departments of Mathematics, Statistics and Physics in the same faculty, Vocational Education in faculty of Education, and Geo-Informatics in faculty of Environmental Studies. Ontology mapping involves linking the interactions around the course in the anchor department with that of the departments it is providing services to. In case of any clash or conflict with other courses offered by the students of any cooperating departments, the Time Scheduler or Allocation Reasoner (AR) along with the interval-based reasoning formally represented in this paper will re-schedule either of the courses concerned to resolve the conflict.

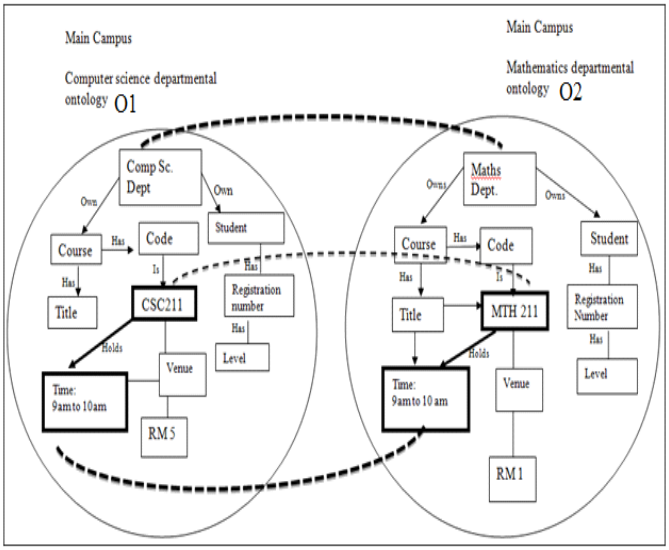

Figure 1. Mapping of two departmental ontologies

As shown in Figure 1, the mapping of ontology O_1 and ontology O_2 by Anchor- PROMPT involves accepting pairs of related terms called anchors, defined by the user or automatically identified by lexical and syntactic matching, as input, from the source graph (ontology); and traversing the path between the anchors in the corresponding ontology. The link between the classes (nodes) defined by the hierarchical relations forms a path. The Anchor-PROMPT then compares the terms along these paths to find similar terms frequently appearing in similar positions on similar paths. In a nutshell, once the sets of similar terms are generated, e.g. {CSC211, MTH211}, scheduled for the same time $\{t_1, t_1\}$ and in the same venue $\{v_1, v_1\}$ which is also scheduled, the AR will be notified, and with the help of the interval-based reasoning, the AR will automatically reschedule either CSC211 or MTH211 for another time and venue respectfully giving priority to CSC211 on account that the high number of cooperating departments produces more complexities, as identified in PWO [1].The identified time complexities as resolved in the AR are expressively represented using formal notations to describe the embedded semantics in the given rules applicable for inference in the weighted ontology framework [1].

2.1 Ontology in scheduling and timetabling

Ontology has been applied in several scheduling task. The ontological framework in [20] specifies a meta-model that provides a vocabulary for formulating application model in a problem domain as well as a set of constraints on what can be expressed. The authors proposed the use of ontology to structure and simplify the process of constructing domain-specific problem-solving tools. Their work focused specifically on the task of scheduling, which ultimately led to the development of OZONE - a toolkit for configuring constraint-based scheduling systems.

With OZONE, it was possible to define domains, constraints as well as reusable and extensible concepts for describing and representing scheduling problem. In [21], a brief review of ontology for scheduling and publishing meetings and events was presented with a framework having a single consistent representation with a hierarchical structure capable of capturing some uncertainty and complexity that occur in real world system. The work attempts to present a balance between logical complexity in the ontology and the content language.

In [22], a generic task ontology for scheduling problems was proposed, expressing that ontology is generic if it is both domain and application independent. The work clearly described the class of scheduling tasks, independently of various ways by which these tasks can be solved. The given ontological framework provided a fairly fine-grained structure needed to build the scheduling system. The given cost related axioms ensure that an optimal solution or result is constructed by subsuming the various preferences in a scheduling task specification. Also, resource availability axiom was used to tackle the conflict between various jobs for the use of same resources depending on their overlapped time range.

An ontology-driven system for solving resources-constrained scheduling problems, orders-oriented and lean mass customization-based manufacturing was presented in [23]. This aimed at getting an easily customizable scheduling system that could be richly exploited by different manufacturers. Within the project Model Based Java Software Development Technology, it assumed the commencement of system development from the ontological conceptualization of the domain, constructing the models of the problem and implementing the system through transformation of models into codes.

In [24], a generic library problem solving method for scheduling application, following the limited coverage provided by different attempts made in the past in developing the libraries of scheduling problem-solvers was proposed. They subscribed to the Task-Method-Domain-Application knowledge modeling framework which provides a structured organization for the different components of the library and approached the work at two different levels – the task level and the method level. At the task level, a generic scheduling task ontology was constructed to formalize the space of scheduling problem. At the method level, a generic problem solving model of scheduling that generalize from the variety of approaches to scheduling problem-solving was constructed. In their work, they subscribed to a top down approach of scheduling construction and analyzed the importance of scheduling research both from the theoretical and engineering perspectives.

The authors in [25] proposed a framework which brought a step toward a generic semi-automatic timetabling tool. They investigated different types of timetabling problems and developed a framework for timetabling application with a central domain ontology tagged “ontology for timetabling”. The work developed a local search component that can deal with the search space based on problem characteristics passed on by the semantic components and was simplified into steps in order to generate good quality timetables in a reasonable amount of time. The first step was towards solving general problem that consists of mapping their data representation onto the ontology. The next step was using the tools to assists in determining the constraints and object of the problem. Custer *et al*. [25] based their timetabling ontology on the general OZONE scheduling ontology in [20] and developed a generic algorithmic component to generate a solution for real world problems.

The formal relationship between different components in a particular universe of discourse is described using formal languages. These descriptions are the basis for any ontology. An explicit description of the domain of discourse is formally represented in the formal ontology model in Figure 2 [26]. This model is adapted in this work for the semantic model of the formal time scheduling ontology in section 4, as it gives an explicit description of the domain of discourse**.**

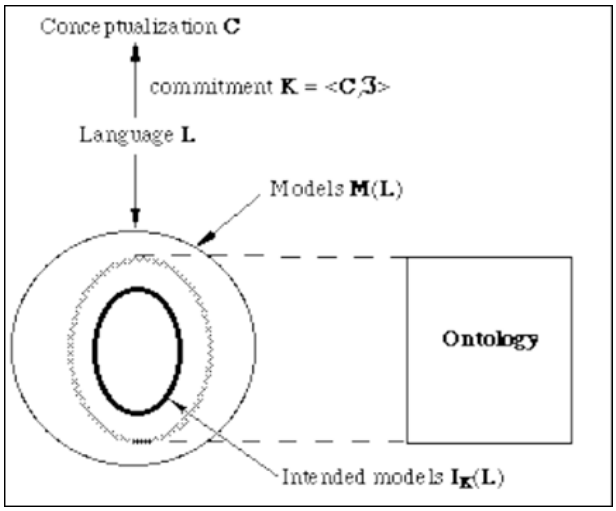

Figure 2. Formal ontology model [26]

3 Complexity reduction rules and axiomatization

The set of competency questions - which are constraints to be satisfied, introduces the time complexities under consideration. Some of the commonly applied competency questions include: Are students from other cooperating departments or faculty offering this course with students of the

host department? Is the said course scheduled for the same time with course(s) in the serviced or cooperating department? Is the said course scheduled to hold in the same venue with course(s) in the other department? Are there students in other levels in the cooperating departments who enroll for this course? Is a particular lecturer scheduled to teach more than one course at the same time? Is the venue for the lecture on different campuses from that of students offering the course? Is more than one course allotted a particular venue at the same time? The Rule set comprises rules that address the constraints /complexities and also proposes axioms for their resolutions through the application of Allen's interval relations. The assumption that a faculty has all its constituent (departments) within the same locality (campus) hold for this work: A sub-set of the rules is given as follows:

R1: IF student of $dept_1$ *offers* $course_1$ AND $dept_1$ NOT *owns* $course_1$ THEN $time_1$ for $course_1$ **NOT *overlaps*** $time_2$ for $course_2$ in $dept_2$.

R2: IF $course_1$ *holds* at $time_1$ and $course_2$ holds at $time_2$ AND $time_1$ ***equals*** $time_2$ AND students offer $course_1$ and $course_2$ THEN $time_1$ and $time_2$ ***overlaps***.

R3 IF $course_1$ *holds* at $time_1$ and $course_2$ holds at $time_2$ AND time1 is ***during*** $time_2$ AND students offer $course_1$ and $course_2$ THEN $time_1$ and $time_2$ ***overlaps***.

R4: IF $course_1$ *holds* at $time_1$ and $course_2$ holds at $time_2$ AND $time_1$ ***starts*** with $time_2$ AND students offer $course_1$ and $course_2$ THEN $time_1$ and time2 ***overlaps***.

R5: IF $course_1$ *holds* at $time_1$ and $course_2$ holds at $time_2$ AND $time_1$ ***finishes*** at $time_2$ AND students offer $course_1$ and $course_2$ THEN $time_1$ and $time_2$ ***overlaps***.

R6: IF $course_1$ and $course_2$ are of the same department, $dept_1$, THEN reschedule $course_2$ to a different time from $course_1$ (**NOT *overlaps***).

R7: IF $course_1$ and $course_2$ are in the same faculty but different departments ($dept_1$ and $dept_2$), THEN $time_1$ and $Time_2$ for $course_1$ and $course_2$ respectivelyshould **NOT *overlaps*** or $course_1$ **NOT *during*** $course_2$.

R8: IF $course_1$ and $course_2$ are not in the same faculty, THEN time for $course_1$ and time for $course_2$**NOT *overlaps*** and **NOT *meets***.

R9: IF $time_1$ for $course_1$ and $time_2$ for $course_2$ ***meet***, THEN $time_2$ for $course_2$ or $time_1$ for $course_1$ will be re-scheduled for next available time (**NOT *meets***)

R10: IF time for $course_1$ and $course_2$ are ***equal*** AND venue for $course_1$ is the same venue as venue for $course_2$, THEN $course_2$ should be re-scheduled for the next available time or $course_2$ re-scheduled for the next available venue

R11: IF time for $course_1$ and $course_2$ are ***equal*** or ***meet***, AND the lecturer teaching $course_1$ in $campus_1$ is also scheduled to teach $course_2$ in $campus_2$ within the space of a period, THEN $course_2$ should be res-scheduled for another time greater than a period.

R12: IF $course_1$ is fixed to hold at $time_1$ at $campus_1$ AND $course_2$ $time_2$ at $campus_2$ THEN $time_1$ **NOT *meets*** $time_2$.

R13: IF students who previously failed $course_1$ offer $course_1$ again, and are taking lectures at $time_1$ THEN $time_2$, for their current level course, **NOT *overlaps*** $time_1$.

R14: IF $course_1$ in $campus_1$ and $course_2$ in $campus_2$, THEN $time_1$ for $course_1$ and $time_2$ for $course_2$ **NOT *meets*** or **NOT *overlaps.***

R15: IF venue capacity is less than students' enrolment in $course_1$ THEN re-schedule $course_1$ another suitable venue.

Formalizing the complexity reduction rules in the previous section explicitly and expressively using First-Order Logic(FOL) yields the following AX1 to AX15 as axioms. The conventional approach of conceptualizing domain concepts; **lecturer, student, venue and time** with relations specific to the domain under consideration: *owns, has, offers, holds* and *teaches,* results in a non-optimal time scheduling. This therefore calls for the inclusion and utilization of the Allen's interval relations; ***overlaps, meets, equals, during*** and their negations. Axioms AX1 to AX15 are rule instances that form the basis for the AR based on ontology and produces an optimal time-scheduling process.

Let S,V,T,C, L represent students, venue, time, course and levels respectively. Let $S=\{s_1, s_2, \ldots s_n\}$ be the set of students, $V=\{v_1, v_2, \ldots v_n\}$ be the set of venues, $CS=\{cs_1, cs_2, \ldots cs_n\}$ be the set of courses, $T=\{t_1, t_2, \ldots t_n\}$ be the set of time slots , P = {p1, p2, …, p3} be the set of campuses and $L=\{L_1, L_2, \ldots L_n\}$ be the set of students level

AX1: *s, d1, cs1, t1, cs2, d2, t2,*

AX12: *cs1, t1, p1, cs2, t2, p2.*
holds(cs1,t1,p1) holds(cs2, t2, p2) equals (t1, t2) equals (p1, p2) meets (t1, t2)

AX13: *s, cs1, t1, d1, cs2, t2.*
offers(s,cs1,t1) offers(s, cs2, t2) owns(d1, c1)
equals(t1, t2) equals(l1, l2) overlaps(t1, t2).

AX14: *s, cs1, t1, d1, cs2, t2.*
offers(s,cs1,cs2)
holds(cs1, p1) holds(cs2, p2)
meets(t1,t2)overlaps(t1, t2).

AX15: *s, cs1,v1, t1, nos, v2, vcap.*
offers(s, cs1, v1) holds(cs1, v1, t1) (nos>vcap)
holds(cs1, v2)

As an interpretation, axiom *AX6* can be read thus*: 'For all students, courses and departments, there exist course cs2, such that cs2 is offered by student and department owns student and cs2 is not own by department. It therefore follows that time$_1$ for cs1 should not overlap with time$_2$ for cs2".*

This formalism utilizes *offers and owns as* domain-specific relations. It also explored a reverse relation to *owns* between students and departments. The power of Allen's interval relation, ***overlaps***, is also brought into consideration not forsaking the expressive tools in FOL. The use of the universal and the existential qualifiers gave life to the axiom. Putting all these together in Protégé ontology tool where the departmental timetable ontology has been developed and mapped together with reasoning to make the task of responding to the earlier proposed competency questions an easy one. A general and optimal lecture timetable with clear semantics as described in the formal representation is thus achieved.

4 Semantic modeling of the formal time scheduling ontology

Figure 3 represents the semantic model of the formal time scheduling ontology with different components which are related accordingly to show how an optimality of time can be obtained. The semantic model of the formal time scheduling ontology is adapted from the semantic model by Guarino [26], where, Time Scheduling Ontology (TSONT) is defined as the conceptualization of the domain concepts expressed mathematically in equation (1). Further description of the conceptual model is explicated in equations (2) to (4), where a set of conceptual relations, R is on a structure, S being the model of the language L with vocabulary V.

$$C_{TS} =< D_T, T_C, R > \quad (1)$$

$$<D_T, T_C> = DSR + AIR \quad (2)$$

The resulting model is given as < S, I > w*here,*

$$S = <D_T, R> \quad (3)$$

and the usual interpretation function, I is expressed as $I = V \rightarrow D_T R$. Fixing the intentional Time Schedule by means of a structure such as $< C_{TS}, P>$ where,

$C_{TS} = < D_T, T_C, R>$ and $P:V \rightarrow D_T R$ is an intentional interpretation, hence, $K = < C_{TS}, P >$ is an Ontological commitment for L. That is, L commits to C_{TS} by means of K and C_{TS} is the underlying conceptualization of K. With the commitment,

$$C_{TS} =< D_T, T_C, R, I > \quad (4)$$

where, C_{TS} is the time scheduling conceptualization, D_T is the timetabling domain, T_C *is the* interdepartmental allocation complexities, R is the relations, *DSR* is the Domain Specific Relation, *AIR* is the Allen Interval Relations, I is the Interpretation, P is the Intentional Interpretation, S is the Structure, and K is the Ontological Commitment. The mathematical model in equation (1) is used to give a semantic interpretation that will further explicate the logic behind ontology.

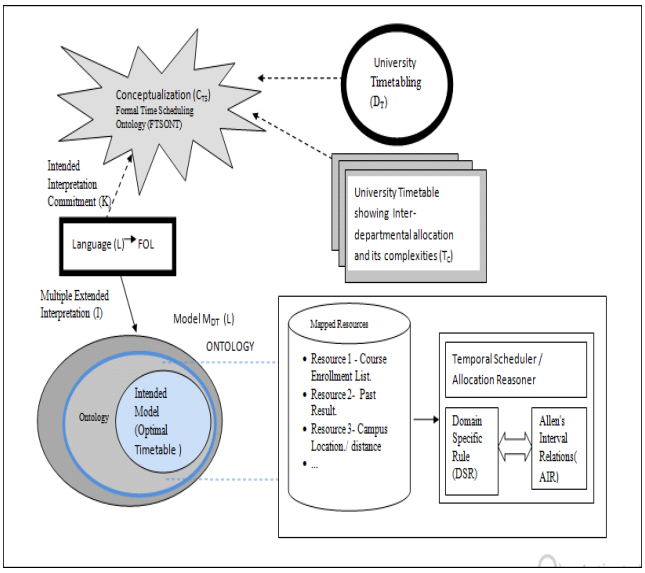

Figure 3. Semantic model of the formal time scheduling Ontology

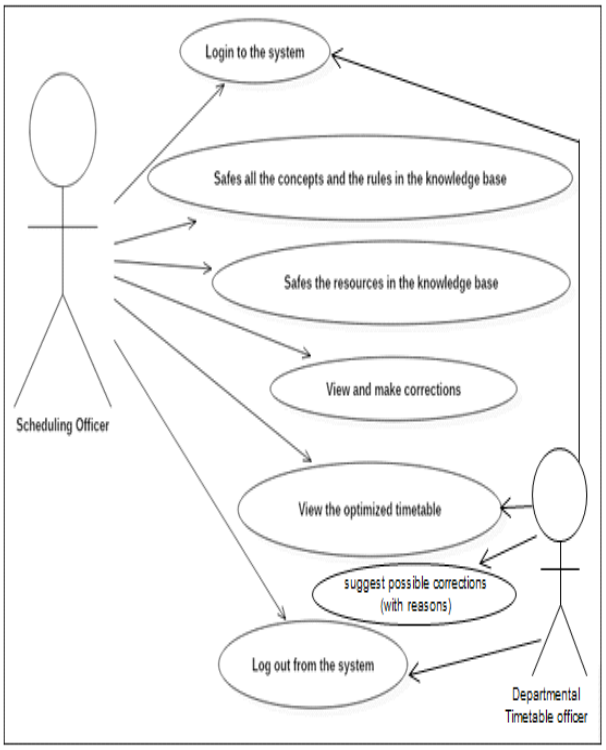

Figure 4. Use case diagram for the TSONT framework

5. System design for TSONT model

5.1 Use case description

The Use Case diagram in figure 4 gives a clear understanding of the developed time scheduling ontology (TSONT) system. The concepts and the resources of the timetable are saved into the knowledge base by the scheduling officer, after a successful log in. The scheduling officer then sends the resources to the allocation reasoner or time scheduler for proper allocation of time. Furthermore, the officer can view the system outcomes, make corrections where necessary, and then review for optimized timetable, and then logs out. The departmental timetable officers can in turn log in to view the optimized timetable, suggest possible corrections for consideration and effect by the scheduling officer, and logs out.

5.2 Class diagram for TSONT framework

Figure 5 represents the class diagram of the TSONT framework, which shows the interactions between classes that constitute the domain of discourse. The student offers courses and the courses are taught by the lecturers. Courses are held in venues, and each venue has an interval of time assigned for it. The venue also has its capacity which informs the number of students that can be allocated to the venue.

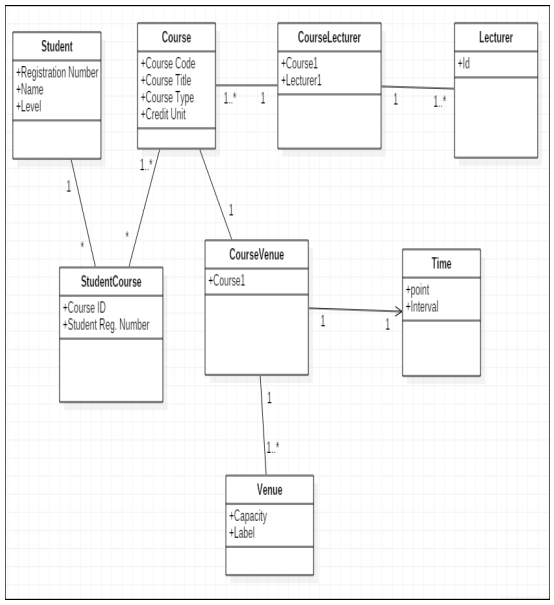

Figure 5. Class diagram for TSONT framework

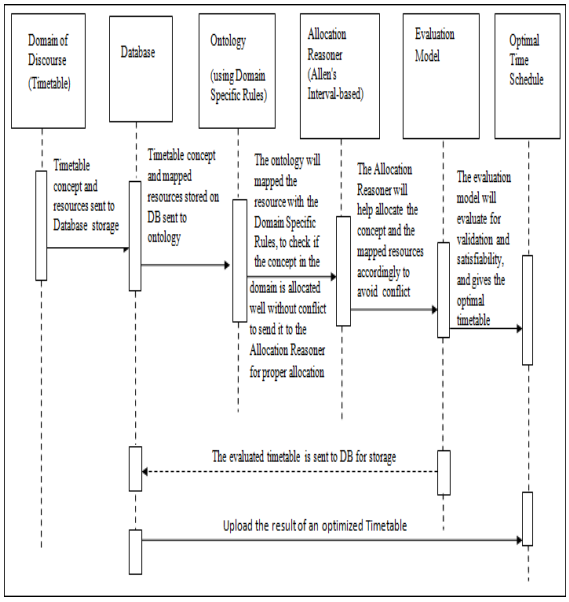

Figure 6. Sequence diagram for the TSONT framework

5.3 Sequence diagram

Figure 6 represents the sequence diagram of how the proposed TSONT system works. The resources used for time schedule and the concepts of the domain of discourse are sent to the database (DB) for storage. The ontology picks the concepts and resources needed for time schedule and sends them to the AR, which helps the rule-based and the interval-based relations, check and allocate the courses, lecturers, venue to the time-slots and to a particular set of students, considering the students who failed or dropped course at a lower level.

The AR sends the results to be evaluated by an ontology evaluation tool, for validation and satisfiability, after which the conclusion of a time complexity free time schedule is sent back to the DB for storage and future reuse. The DB uploads the optimized time schedule for printing and distribution.

6. Conclusion

The university timetabling, an instance of space-time related conflicts or complexities, requires the design of an interval-based temporal ontology to help in its resolution demands full understanding of how the ontology handles the constraints that will answer the stated competency questions. The formal axioms from the stated rules update the constraints in the ontology using the interval based relations. The implementation of the represented formal notations to describe the embedded semantics in the given rules is applicable for inference in the weighted ontology framework. It aims at formalizing the heuristics through ontology, by explicitly incorporating all constraints that will give valid answers to the competency questions in the AR and enabling their analysis and resolution by the ontology-based reasoners. The formal semantic model further explicates the ontology and shows how it is applicable for intelligent complexity reduction and resolution in time scheduling process. The time scheduling ontology based on this formal semantic model will provide an optimal time table schedule.

Path Switching Time

ABSTRACT

Recently, communication demands often change because of the various network services in companies and individuals. Software Defined Networking (SDN) has emerged as a viable control paradigm that allows flexible communication, using OpenFlow as its default standard and enabler. However, when changes happen frequently in SDN networks due to unforeseen reasons -such as a network failure or topology changes- it takes a long time to perform all the operations. For instance, to change a routing path, first new paths must be calculated, then the controller must transmit the commands to the network elements, which has to process those commands. This process can cause a delay, or even disruption, in the communication service. Therefore, this paper proposes a network control method to reduce the time to change a path using OpenFlow.

1. Introduction

1.1. Background and Overview

This paper is an extension of a previous work originally presented at the 5th International Conference on Information and Communication Technologies for Disaster Management (ICT-DM2018) [1]. Recently, the spread of cloud services has led to the diversification of communication [2], as well as the demand for frequent changes on the communication demand.. Thus, it is necessary to respond promptly to such demands, e.g., unexpected network failure. In particular, a technology that can control the network flexibly is needed.

Therefore, SDN [3,4] and OpenFlow [5,6] have recently attracted attention. SDN can control the network flexibly by software and OpenFlow is one of the most popular southbound implementation protocols of SDN. The OpenFlow architecture consists of an controller and OpenFlow-enabled switches which are centrally managed by the controller. In this OpenFlow network, when a failure or server configuration change occurs, all the paths of the traffic that is passing by through the involved switches from a source to a destination (also known as flow) must be changed.

To change the path of a flow, a new flow entry must be installed in all the switches' memory. A flow entry is represented by a condition part and an action part. The condition part includes specific values on fields within the flow header, such as MAC address or IP address. The action part includes how to route the flow when the values of its header match the values of the condition part.

However, it takes a long time to change various paths of the several flows.Specifically, it takes around 10 ms to change a single path due to the influence of the transmission time of a flow entry form the controller to the switch, and the processing time to add flow entry into the switch [7, 8, 9]. Therefore,in time-sensitive situations, such as disasters, in which several paths must be changes in a short period of time, not all the flow changes will be successful . For example, SONET (Synchronous Optical Network) needs to be recovered within 50 ms, but, it will be challenging to change more than six flows within that time [10]. This time constraint can lead to delays or even service outage. In this way, a technique to switch many flows in a short time is needed.

The main goal of this research is to reduce the delay or service outage in OpenFlow networks, with particular focus on the time needed to change the path of a flow. The proposal consists of a network control method that considers the time needed to change a path in each switch. In this method, the initial assumption is that

[*]Satoru Izumi, 2-1-1, Katahira, Aoba-ku, Sendai, 980-8577, +81-22-217-5453, izumi@ci.cc.tohoku.ac.jp

the network model consists of OpenFlow-enabled switches with different processing time, linked by connections with different bandwidth. Then, the paths with the shortest switching time and the least bandwidth requirements are selected. The basic design was described in [1], and the preliminary simulation experiments presented in [11]. In this paper, the authors evaluate the effectiveness of the proposed method using emulated environments. Based on the obtained results, we confirmed that the proposed method can reduce the switching time for all paths, so that it can realize the reduction of communication delay and network services outages.

1.2. Novelty and Contribution

In this work, a novel approach which chooses communication paths considering not only the processing time to add flow entry of the switch, but also the available bandwidth in the links. Existing approaches mainly focus on the reduction of the calculation time of the paths, or using a backup path in advance. However, they do no deal with the processing time of the switch.

By considering both the processing time and the bandwidth, it can shorten the path switching time and improve the amount of data transferred in a short period. Moreover, tt can also contribute to the reduction of the packet-loss due to the communication interruption during the network failure. This method is effective for services that require lowdelay communication. Furthermore, it is possible to improve the amount of data transfer between two sites in the situation where path change frequently, such as is the case in a disaster situation.

1.3. Paper Organization

In the following Section 2, we explain the related work on fast path switching and the target problem. In Section 3, we describe the proposed control method. The design of the algorithm is shown in Section 4. Then, Section 5 shows the evaluation of the proposed method and its effectiveness. Finally, we conclude this paper in Section 6.

2. Related Work

2.1. Related Work on Fast Path Switching

There are several authors that studied fast path switching in OpenFlow networks, which are mainly categorized in two approaches. The first approach, consists of switching to a backup path registered in advance in a proactive manner [13,14,15], while the second one reactively calculates a new path when a request occurs [10,16,17,18]. These authors select the paths considering a variety of single parameters, e.g., switching time, bandwidth of the link between the controller and the switch, and power consumption. However, all of them largely depend on the available amount of memory (TCAM) to hold the flow table. In this research, we deal with methods for calculating and switching the path reactively.

Cascone et al. [13] proposed a recovery mechanism based on fast reroute of paths in disaster situations. Mohan et al. [14] investigated algorithms to choose a backup path to decrease the number of flow entries. Stephens et al. [15] showed a mechanism to compress the flow table for fast recovery from link failure.

Astaneh et al. [10] proposed a path selection method to reduce the path switching time while considering the communication bandwidth. They reduced the cost of the path switching compared to the traditional approach of using Dijkstra's algorithm. Sharma et al. [16] proposed an in-band based path switching method for failure recovery. Paris et al. [17] showed a dynamic control scheme for network reconfiguration. Malik et al. [18] proposed a method to reduce the path calculation and switching time by partially reusing the route before the change of path. Therefore it can reduce the number of added flow entries.

2.2. Target Problem

The related work presented in the previous section did not take into account environments in which there are heterogeneous switches. Many organizations often build their network by combining switches with various specifications because of budget constraints and differences on the time of purchase [12]. Moreover, the processing time is also different in these switches, causing large delays when there is a heavy traffic on low-processing time switches. Therefore, it is necessary to create a network control method to cope with the difference in processing time when adding flow entries.

3. A Proposal of Control Method Considering Path Switching Time

3.1. Overview

In this section, to solve the problems mentioned above, the authors of this paper propose a network control method that considers the path switching time of each switch. In this method, the network model is designed with different processing time for each switch, and the proposed algorithm selects paths with the shortest time for all paths. Our proposed method considers both the processing time of the switch and the network bandwidth.

The proposed method chooses a path with enough bandwidth, and that goes through high-performance switches to add a flow entry, so that the overall path switching time is reduced when there are several flows. In addition, the proposed method also selects paths sequentially without considering the combination of paths, so that the computational time per path is reduced.

3.2. Path Selection Considering Path Switching Time

This section presents the basic concept of the path-selection mechanism that considers the path switching time as shown in the example depicted in Figure 1. In this example, there are four switches (S_1 to S_4) and the processing time to add a flow entry in each switch is different. Now, there is a communication flow from S_1 to S_4, and for some reason the path must be changed. In this case, there are two candidate paths; p_1 ($s_1 \rightarrow s_2 \rightarrow s_3$) and p_2 ($s_1 \rightarrow s_4 \rightarrow s_3$). The overall path switching time of the flow is the processing time for the switch on the path that has the maximum processing time. For instance, the path switching time of p_1 is 4.0 ms and that of p_2 is 6.0 ms. Thus, the proposed method chooses p_1 which has the shortest switching time.

3.3. Path Selection Considering Available Bandwidth

The path cost, which is used to choose the path with enough communication bandwidth, is calculated by the available bandwidth of the links on the path. Such that when the link with a larger communication bandwidth is used in the path, the path cost

is smaller. Conversely, when the link bandwidth of the path is smaller, the path cost is larger. In the example shown in Figure 2, the path cost of the upper path is smaller because the bandwidth of the links on that path are larger than the ones in the lower path, and therefore the former is selected.

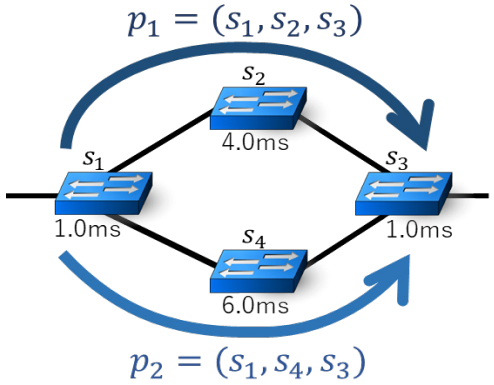

Figure 1: Example of Path Selection Considering Path Switching Time

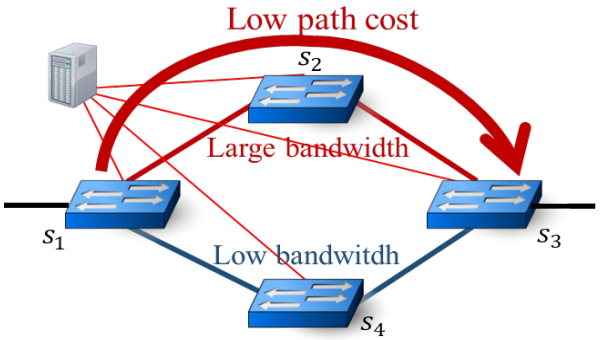

Figure 2: Example of Path Selection Considering Available Bandwidth

4. Design

4.1. Network Model

The network model is defined as below.

- $s_i \in S\ (i = 1, 2, ..)$: Switch
- t_i : Processing time for adding one flow entry into s_i
- $e_{i,j} \in E$: Link between s_i and s_j
- $B_{i,j}$: Available bandwidth of $e_{i,j}$
- p_k : Path (list of switches)
- $c_{i,j}$: Link cost of $e_{i,j}$ (= 1Gbps/$B_{i,j}$)

4.2. Definition of Path Switching Time

The path switching time is defined as:

"The time from the arrival of the first additional flow entry from the controller to the switch until the completion of the path switching on all switches"

Figure 3 shows an example. Suppose that tthere are three flows (flow 1, 2, and 3) assigned to the paths shown in Figure 3. In this case, t_1 is 1 ms, and s_1 needs to switch the three flows. Thus, the time to complete the processing of the additional flow entry is 1 ms * 3 = 3 ms. Then, t_2 is 4 ms and the s_2 needs to switch two flows (flow 1 and 2). Therefore, the time to complete the processing of the additional flow entries is 8 ms (4 ms * 2). For the other switches, the time is calculated in the same way. Finally, the path switching time in this example is 8 ms, which is the longest time to complete the process.

The path switching time $T(P_m)$ for a set of paths (P_m) is defined as in (1)

$$T(P_m) = \max_{\{i|s_i \in S\}} \{t_i \times \sum_{p_k \in P_m} z_i(p_k)\} \quad (1)$$

Here, $z_i(p_k)$ means whether the list of p_k includes s_i.

$$z_i(p_k) = \begin{cases} 1\ (s_i \in p_k) \\ 0\ (otherwise) \end{cases} \quad (2)$$

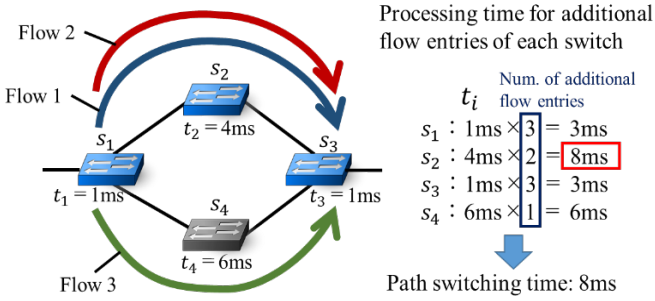

Figure 3: Example of Path Switching Time

4.3. Link Cost

The proposed method prioritizes the path switching time rather than the path cost, and chooses paths sequentially. The overview of the sequential path selection method is as follows:

- Choose a path for one flow at a time.
- Substract the required bandwidth of the flow from the link bandwidth on the path, and update the link cost every time the path is selected.
- Assign a flow to the path until there is no available bandwidth left for the flow.

Figure 4 shows an example of the link cost update. If the link bandwidth is 1 Gbps, the link cost is 1. Then, when a flow requires 300 Mbps of bandwidth, it is inserted into the link. The available bandwidth of the link becomes 700 Mbps, and the link cost increases to about 1.4.

Figure 4: Example of Link Cost Update

4.4. Flow of Path Selection

This section explains the process of path selection. In order to consider both the processing time of the switch and the path cost, the proposed method chooses paths as detailed below.

1. Compute the paths with the smallest increase in the path switching time.
2. Choose the path with the lowest path cost form the computed paths.
3. Repeat process 1 and 2 for the number of flows that needs to change.

5. Experimentation

5.1. Overview

The proposed method was evaluated in an emulated environment. The network used in the experiment is shown in Figure 5. Here, the available bandwidth $B_{i,j}$ of all links is set as 1 Gbps. Also, the processing time of the source switch, and destination switch was set to 1 ms; while remaining switches were randomly set from 1 to 10 ms.

Several flows with different required bandwidth were inserted, and randomly shutdown links. After the link is down the paths of the flows are switched. To compare the effectiveness of the proposal, the obtained throughput is obtained and compared with an existing method, which selects paths considering only path cost.

In this experiment, Mininet (ver. 2.2.2) [19] was used as a network emulator on a single computer, whose specification is as below:

- CPU: Intel (R) Xeon (R) CPU E5-2650 v4 @ 2.20 GHz) x 8 cores
- Memory: 16 GB

We also used OpenDaylight (0.3.3-Lithium-SR3) [20] as the OpenFlow controller, and OpenVSwitch (ver. 2.5.5) [21] as the OpenFlow switch.

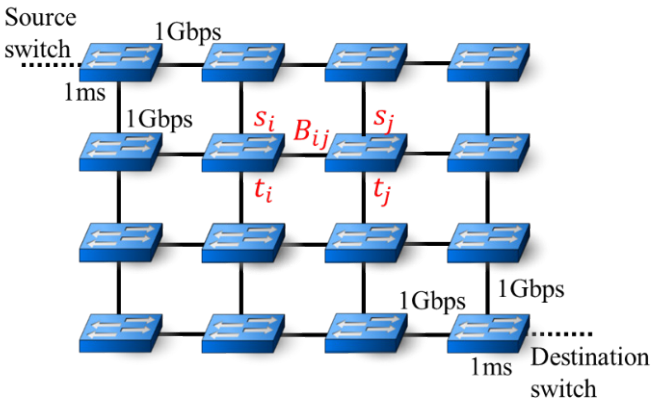

Figure 5: Network Topology Used in the Experiment

5.2. Results

The authors categorize the throughput comparing the proposed method with the existing method into the following three patterns:

- The proposed method always dominates (Win).
- The proposed method dominates until a certain time (Win[time]).
- The proposed method is equal to the existing method (Eq).

Examples of graphs of the three patterns are shown in Figures 6, 7, and 8. The comparison of the data transfer amount between the proposed method and the existing method is shown in Table 1. From the table, it is observed that when the total bandwidth of the flows is 1,800 Mbps or more, and the number of disconnected links is large, the data transfer amount of the proposed method is always better. However, when the total bandwidth of the flows is 1,800 Mbps or more, and the number of link disconnections is small, then the amount of transferred data of the proposed method is larger within 0.1 to 0.2 seconds.

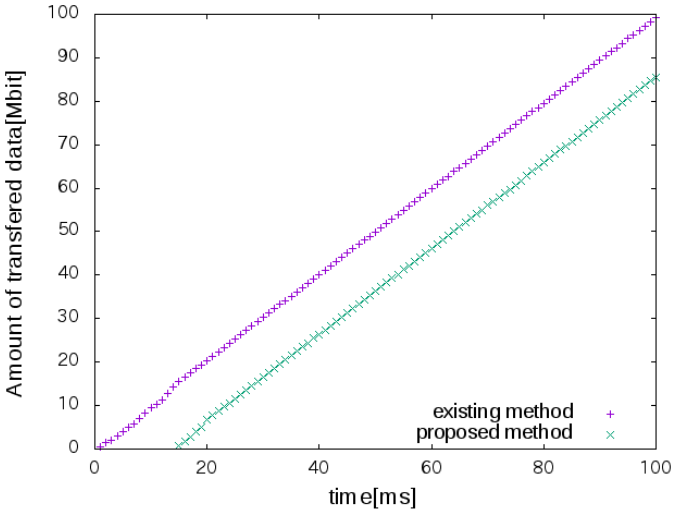

Figure 6: The Proposed Method Dominates Always (Win)

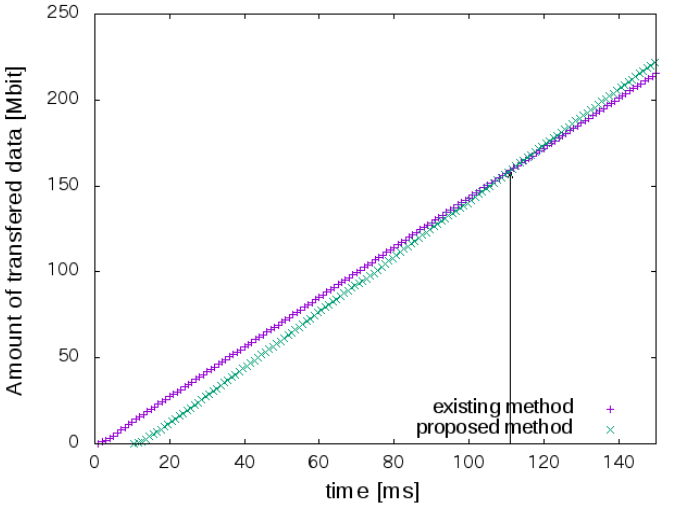

Figure 7: The Proposed Method Dominates Until A Certain Time (Win[112s])

Moreover, when the total bandwidth of flows is less than 1,400Mbps, and the amount of transferred data of the proposed method is larger is within 1.5 seconds, the proposed method is larger regardless of the number of disconnected links. Finally, when the total bandwidth of flows is less than 1,200 Mbps, the proposed method is always better.

Table 1: Comparison of the data transfer amount between the proposed method and the existing method

		Total bandwidth of the flows [Mbps]										
		1,000	1,200	1,400	1,600	1,800	2,000	2,200	2,400	2,600	2,800	3,000
Number of down links	0	Win	Win	Win [1.5ms]	Win [0.3ms]	Win [0.1ms]	Win [0.1ms]	Win [0.1ms]	Win [0.1ms]	Win [0.1ms]	Win [0.1ms]	Win [0.1ms]
	4	Win	Win	Win [1.5ms]	Win [0.3ms]	Win [0.2ms]	Win [0.2ms]	Win [0.2ms]	Win [0.1ms]	Win	Win	Win
	8	Win	Win	Win	Win [0.2ms]	Win [0.1ms]	Win	Win	Win [0.1ms]	Win	Win	Win
	12	Win	Win	Win	Win [0.1ms]	Win	Win	Win	Win	Win	Win	Win
	16	Win	Win	Win	Win	Win	Win	Win	Win	Win	Win	Eq
	18	Eq	Eq	Eq	Eq	Eq	Eq	Eq	Eq	Eq	Eq	Eq

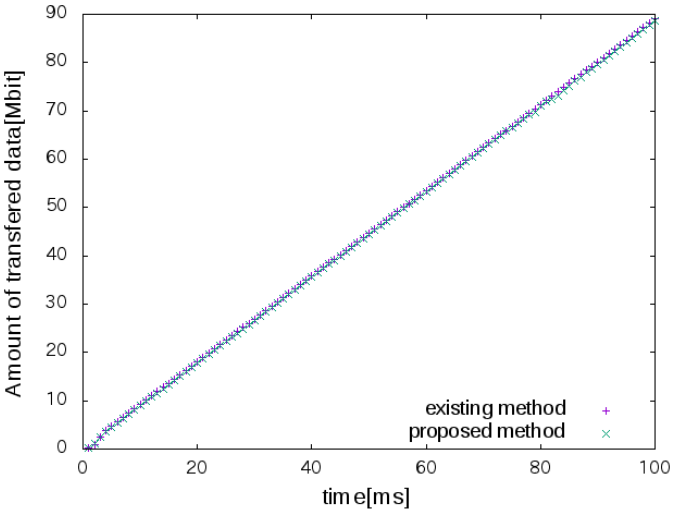

Figure 8: The Proposed Method Is Equal To The Existing Method (Eq)

5.3. Discussion

From the experimental results in the previous sections, the authors of this paper confirm that the proposed method is more effective than the existing method, since the amount of transferred data is equal or larger to the existing method while the path switching time is shortened. Morever, the path switching process is more effective than the existing method when these events occurs frequently and there is not enough bandwidth.

6. Conclusion

This paper presents a network control method considering the path switching time in SDN. We designed the path selection method and evaluated with an emulated experimentation. From the experimental results, it is confirmed that the proposed method is effective in situation where changes occurs frequently in a short time due to link disconnection and restoration (e.g., disasters).

As future work, we will extend the proposed method by introducing other parameters and experiment with real networks. Currently, we focused on the time from the arrival of the first additional flow entry from the controller to the switch until the completion of the path switching on all switches. Thus, we will evaluate the total time of changing paths from the moment some events occur until they complete changing the paths in comparison with related work.

Conflict of Interest

The authors declare no conflict of interest.

ABSTRACT

In the past decades, various ideas have proposed for reconductoring of overhead lines to enhance power transmission capacity considering growing energy demand. Conventional method of reconductoring is use to take couple of weeks but availability of shutdown for a prolong period is a major constraint in line uprating. Emergency restoration structure (ERS) is effective to deliver such challenging task within hardly 4-5 hours line shutdown only. This quick restoration and easiness is mobility features are making ERS versatile for restoration even after any natural disasters. In this article, a case study of 132 kV restorations is described as a conceptual proof of concepts. Successful execution of this project resolved a 400 kV transmission line hindrance between Atur and Indira Puram since March 2017 and was likely to remain idle due to a 132 kV single circuit transmission line crossing its route.

Nomenclature

A_e	effective surface area of structure
B	base width of ERS
b	arm length of ERS
C_a	amplification factor
C_f	overall force co-efficient
C_F	shape co-efficient
C_g	gust response factor
E_i	expenditures
F	wind force
H	structure height
H_G	wind gradient
i	years count
k_0	factor of conversion
k_1	probability factor of risk
k_2	factor of terrain roughness
k_3	factor of site topography
m	overturning moment
p	surface contact pressure
P_s	ultimate pull out force
P_t	anchor surrounding force
P_u	shearing stress
r	discounting rate
R_i	factor of probabilistic cost
S	conductor stringing load
S_T	total structural area
V_G	wind speed
V_h	wind speed at certain height
V_H	wind speed above ground level
V_b	regional basic wind speed
V_d	design wind speed
V_r	reference wind speed
w	failure zone effective soil weight
α	wind speed inequality co-efficient
φ	structural solidity ratio
ρ	air density
$1/\lambda$	increase in velocity exponent with height

ERS	emergency restoration structure
FoS	factor of safety
MDD	maximum dry density
MSPT	maximum bearing test of soil
NPV	yearly expenditures net present value
OMC	optimum moisture content of soil
RoW	right of way
R&D	research and development
SPT	standard penetration test
T&D	transmission and distribution
UTS	ultimate tensile strength

1. Introduction

1.1 General

In the era where power became basic necessity, it becomes essential for utilities to strengthen their infrastructure for accommodating the changes posed by deregulation and transfer reliable power to the consumers [1]. Pressure on the existing network to transfer more power has led to transmission line congestion. These issues could be addressed by uprating as it allows considerable increase in power transfer capability within the existing infrastructure. It's troublesome as shut down is required for reconductoring as these lines are invariably over loaded. The primary concern in emergency restoration is to revive the transmission network and get the line charged and back into operation within the stipulated time frame. These are the key objectives that compelled the development of an Emergency Restoration Structure (ERS).

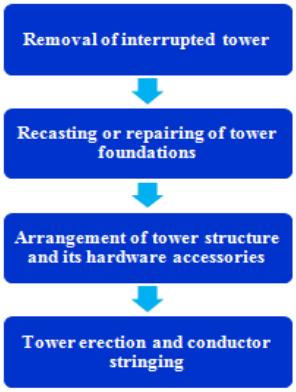

Figure 1: Flowchart of power restoration by conventional method

The Indian Power Grid has developed more complex after the resolution of "One Nation One Grid" by the Central Government. The T&D industries are enduring with R&D challenges like - reliability maintenance, useful life expansion, enhancement of transmission capacity by upgrading/uprating and public & employee safety [2-4]. The overhead transmission lines are covering miles of distance thus; it is exposed to several weather related calamities (*e.g.,* speedy wind, heavy rain, cyclone *etc*) throughout the wide area [5-7]. Unavailability of electricity due to any of these reasons or may be due to regular maintenance purpose may cause inconvenience to the consumers' along with financial loss to the service provider [8-16]. These issues could be resolved by improving grid resiliency using ERS bypass arrangement. The proposed ERS usage less time and RoW in compare conventional method of restoration considering following steps (as presented in Figure 1).

Now-a-days, most of the transmission lines are functioning inefficiently due to decay in the transmitting property. Rejuvenation of aging transmission infrastructure is required to boost its efficiency. The key challenges faced by any power transmission system are as below:

- *Transmission line congestion*
- *Fewer private players*
- *Lack in investments*
- *Strategic planning unavailability*

Transmission line utilities are always trying to reduce customer minutes lost and to avoid any concurrent financial losses [17]. They are always investing in quick restoration technology; even they are getting their manpower trained to counter devastation on emergency basis caused by natural disasters. Previously, such investment was required on a case specific critical components inventory. This led to a major chunk of financial reserves availability to handle such situations [18, 19]. The interchangeable modular ERS structure could be easily transported to even difficult locations and can be reused in future exigencies. The ERS could reduce the inventory of spare towers substantially by using it as temporary service. The installation of ERS was being optimized to overcome site challenges and reduce labour effort with rigorous installation and minutely observing the safety parameter as well enhancing the speed of the process. In this paper, a case study of 400 kV transmission line between Atur and Indira Puram, abandoned since March 2017 and was likely to remain idle due to a 132 kV Single Circuit Transmission line crossing its route.

1.2 Motivation behind the Present Study

Pressure on the existing network to transfer more power has led to transmission line congestion. These issues could be addressed by uprating as it allows considerable increase in power transfer capability within the existing infrastructure. It's troublesome as shut down is required for reconductoring as these lines are invariably over loaded. The primary concern in emergency restoration is to revive the transmission network and get the line charged and back into operation within the stipulated time frame. These are the key objectives that compelled the development of an ERS tower [20-22].

1.3 Paper Layout

In continuation of aforementioned discussions, remaining study has been presented in succeeding sections. Section 2 presents development of modular ERS structure; while Section 3 deals with reconductoring using ERS, Section 4 focused on overhead transmission line restoration; Section 5 presents observation of the Case Study and finally, the paper has been concluded in Section 6.

2. Development of ERS Module

A quick restoration of power using ERS tower could be made based on certain aspects [23-24], which are as under:

2.1 ERS Design Considerations

A case study has been done on an executed project for UPPTCL. In this paper, the guyed ERS towers were deployed for

reconductoring purpose under influence of varying wind speed in between the wind zone 30-55 m/s up to30 m height of tower as per IS:875-1987(Part III).The proposed structure sustained a major bending moment of lateral forces under influence of both tensile and compressive forces. There is optimal allocation of guy wires are required to gain stable workability of the structure. The project was successfully delivered on 5th June, 2017. The whole study could be co-related with following formulations:

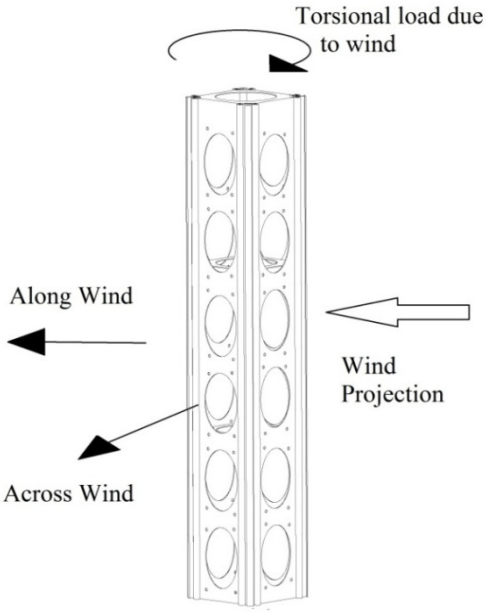

Figure 2: ERS structures' isometric view

According to metrological requirements of the site, the referred wind speed [25-28] could be given by (1),

$$V_r = \frac{V_b}{k_0} \tag{1}$$

Designed wind speed [25-31] of the ERS set up could be given in (2),

$$V_d = V_r k_1 k_2 k_3 \tag{2}$$

As per Devenport formulations for wind gradient is given by (3) [25-28]. Torsion wind load is shown in Figure 2,

$$V_H = V_G \left(\frac{H}{H_G} \right)^{\alpha} \tag{3}$$

The sectional view shows the side view of the single plane which has oval hollow section to optimize the weight and reduce effective wind pressure on the section. In order to prevent deformation of the structure several construction optimization was done. Significant features of ERS have been briefed as below:

- Erection is very quick due to modular and interchangeable section.
- Minimum numbers of component and identical fittings to reduce identification and segregation process.
- Quick installation with minimum power interruption and cost effective.
- No need of special foundation or tools.
- Erection is possible in any kind of soil and terrain.
- Compatible with 66 kV-765 kV stringing.

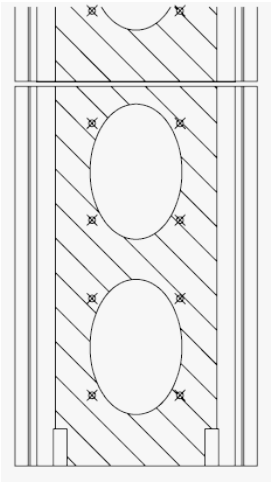

Figure 3: Sectional front view of the ERS module

Wind force [29] imposing on ERS module is given by (4),

$$F = C_f p A_e \tag{4}$$

Dynamic pressure [29], considering design variables is formulated by (5),

$$p = \frac{C_g C_F C_a \rho V_h^2}{2} \left(\frac{H}{h} \right)^{\frac{1}{\lambda}} \tag{5}$$

As per Ryle's formula, the ERS base width could be presented by equation (6) [29],

$$B = 0.013\sqrt{m} \tag{6}$$

For maintain FoS at $32^{o}\mathbf{C}$, the conductors' tension without any external load should not exceed 35% of the specified UTS. However, this percentage shrinks to 25% under loaded condition. Aspect ratio is 65.93 of the ERS modular tower as shown Figure 3 and it can be formulated as in (7) [29],

$$\varphi = \frac{S_T}{Hb} \tag{7}$$

Pull out forces to evaluate anchoring of ERS can be formulated by equation (8),

$$P_u = P_s + P_t + w \tag{8}$$

As per CIGRE, the costing NPV of the undertaken project could be formulated by (9) [30, 31],

$$NPV = \sum_{i=0}^{n} \frac{(E_i + R_i)}{(1+r)^i} \tag{9}$$

2.2 ERS towers' Hardware Integration

The ERS tower comprises of multiple components, each of these (as portrayed in Figure 4) are equally important and designed for meeting emergency requirements of the overhead

line. Each modular columns (height: 3 m) are identical and fabricated of high strength steel, so they can be easily mounted without following any particular sequence of the complete tower. Foundation plates are designed such it can allow distribution of weight to the ground with minimum load bearing capacity. There was one articulated gimbals joint, which allow linking between foundation plate and sections. The composite insulators were used to reduce RoW issues although at higher voltage levels.

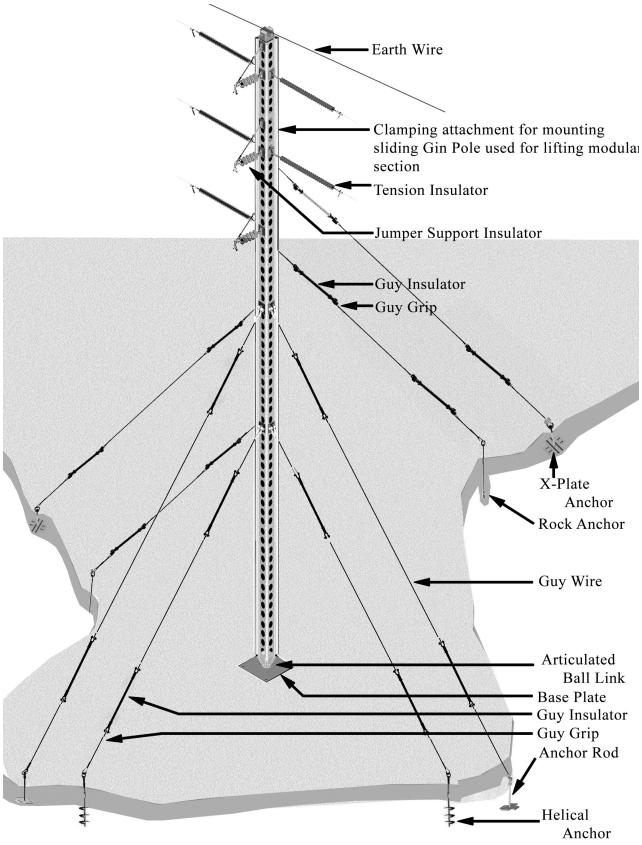

Figure 4: Generalized ERS Set Up.

3. Overhead Transmission Line Restoration

This paper briefly presents a case of electricity transmission from Loni to Mohan Nagar division (UP, India) under following subsections:

3.1 GIS Mapping of the Site

The ERS tower has been utilized at UPPTCL site to re-build 132 kV lines confronting flyover, water passage and street intersections, separately (depicted in Figure 5). However, 132 kV overhead lines was thwarting hanging of 400 kV transmission lines, as height of that line was 51 m from the top most earth wire.

Consequently, a restructuring was made to curtail height of 132 kV by de-amassing second tower (ref to Figure 5) such that, the 400 kV line can be set back on it. Total three ERS towers have been utilized to bypass. Usually, three weeks supply interruption could have been there with conventional method for restoration but application of ERS has delivered this project by 5 hours only. Before initiating execution work of this project, a extensive site survey and planning was done to accomplish this project.

Figure 5: Ghaziabad site restoration layout

3.2 Deployment of Restoration Works

In the current work, three ERSs (height: 30m) were deployed based on the requirements of the specific site UP state, in order to meet resilience and sustainability of bypass arrangement [28]. The analysis of stringing arrangement was performed using PLS CADD software tools. The complete solutions for line restoration or construction of any kind of bypass line by using ERS tower on rental or end to end services basis is being provided, as we have a dedicated team of execute the work. It involves several steps for the enactment of the ERS installation:

Step-1: The initial step involves site survey of the installation site. There are various factors that are taken into account before the installation. A dedicated team is at the first analyses and collects information regarding site. It includes the information such as accessibility to the site, existing tower to ERS tower clearance, RoW clearance, layout of the site, span length *etc*. Site accessibility also helps to pre-determine the anchor to be used for the type of soil as well kind of tools. After the examination process and collection of all the details, the project engineers proceed towards the next step. The load assessment is done by the design team as per the side condition and feasibility.

Step-2: The second step involves material transportation such as the modular sections and all the equipment that are required for the proper guying and installation of the tower.

Step-3: The third step includes the installation part. Most importantly the major advantage of our ERS towers is that civil foundation is not required. The tower is entirely supported using guy wires. Hence, it is essential that all the guy wires are properly anchored to the soil. Our team took this as a challenge and developed different kind of anchors that would support the structure for different soil conditions.

Step-4: After the installation of ERS base the gimbals joint is then attached to it and with the help of it modular section is installed. Gin poles are used for lifting the next modular sections one by one.

Step-5: For stabilizing the tower guy arrangement has been used. After that all the hardware are installed and conductor stringing is done. Some extra wires are removed to ease the congestion along the axis of the conductor since the

tensioned conductor support the tower followed by inspection and joint commissioning to charge the line.

The overhead transmission line has been circumventing from tower-1 to that of -2 by a new root as mapped in Figure 6(a) and erected line was shown in Figure 6(b).

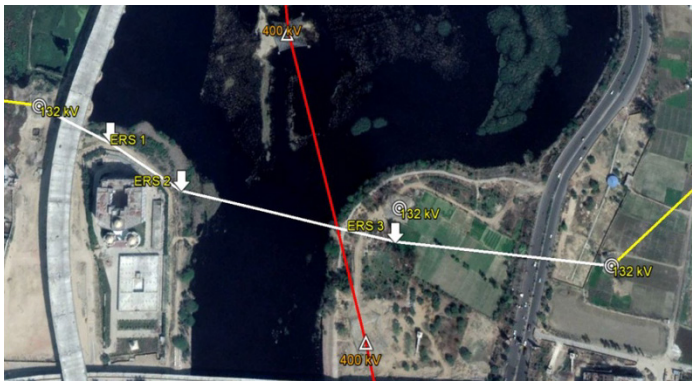

Figure 6(a): Bypass arrangement routing layout

Figure 6(b): Flyover and river crossing

The range existences between re-steered lines are customary cross section tower-1 to ERS-1: 111 m, ERS-1 to -2: 93 m, ERS-2 to -3: 229 m lastly ERS-3 to regular lattice tower-3: 250 m. In continuation with site overview, skilled team with their tools deployed to pursue the project.

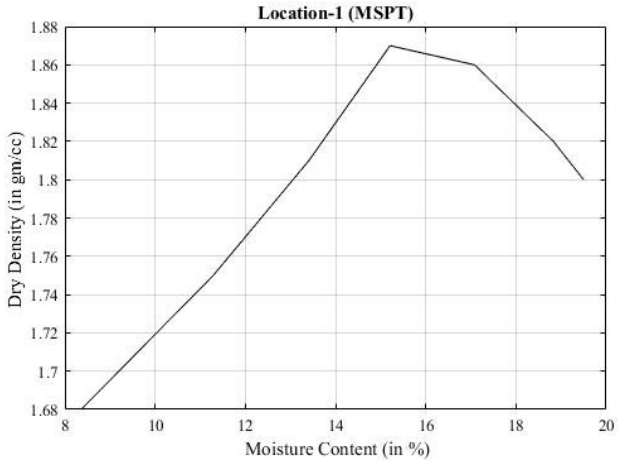

Figure 7: Characteristics of MSPT test for soil sample-1.

4. Observations from Case Study

The heavy compaction test has been tested for soil samples taken from location-1 and -2 while; light compaction test is found to be appropriate for location-3. These types of test were carried out to check MDD and OMC of soil as per IS: 2720 (Part VIII) 1983. The field dry density core cutter testing method complying IS:2720 (Part VII & XXIX) has been performed across the field at each location as shown in Table 1.

Table 1: Field test findings from core cutter method.

Parameters	Sample- 1	Sample- 2	Sample-3
Field BD (gm/cc)	1.93	1.91	1.92
Field MC (%)	4.79	6.16	4.82
Field DD (gm/cc)	1.84	1.80	1.83
DD (% of MDD)	98.39%	96.25%	97.86%

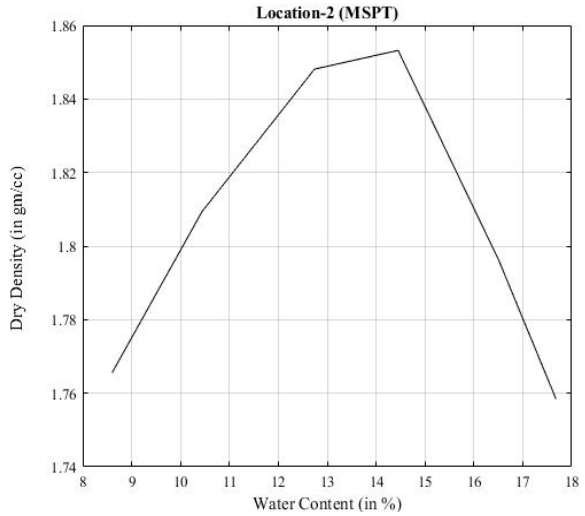

Figure 7: MSPT test characteristics of soil sample-2.

The recorded test findings of moisture content and dry density are provided in Table 2 and their graphs are plotted in Figure 7-9. The interesting outcomes (OMC & MDD) are highlighted by **boldfaced** in the subsequent column of Table 1. The compaction test observations exceeding 95% of the MDD; thus, the site was viable to erect the ERS tower.

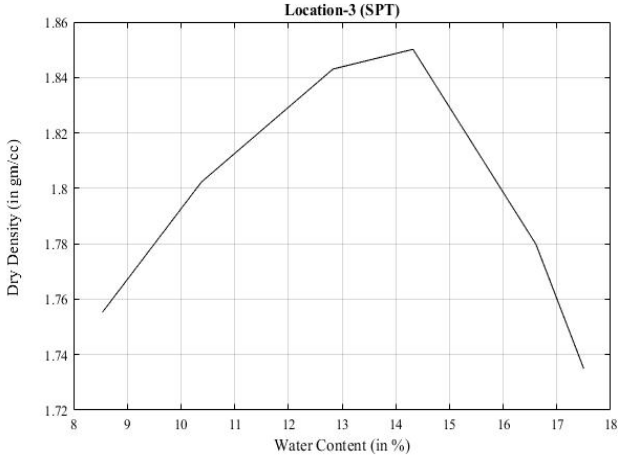

Figure 8: SPT test characteristics of soil sample-3

Table 2: Results obtained after compaction test

Locations	Testing methods	Parameters	
		Content of moisture (%)	Dry density (gm/cc)
1	MSPT	8.360	1.68
		11.29	1.75
		13.41	1.81
		15.21	**1.87**
		17.08	1.86
		18.83	1.82
		19.50	1.80
2	MSPT	8.600	1.766
		10.44	1.809
		12.74	1.848
		14.45	**1.853**
		16.51	1.796
		17.68	1.758
3	SPT	8.540	1.76
		10.38	1.80
		12.83	1.84
		14.32	**1.85**
		16.61	1.78
		17.50	1.73

Table 3: Site specific benefit comparison

S. No.	Particulars	Restoration using ERS	Conventional restoration
1	Structural footprint	<1 m^2	36-64 m^2
2	Foundations of structure	Not required.	Depth: 2-4 m
3	Angle of protection	65º	30º
4	Down time of supply	5 Hours	20 Days
5	Average value of power flow	5 MW	5 MW
6	Generation loss/day	120000 Units	120000 Units
7	Unit price	INR 2.5	INR 2.5

After execution of this project, a cost-benefit analysis was made (given in Table 3) to ascertain future scope of ERS in service customers.

5. Conclusion

Indeed, even in open vitality markets, electricity transmissions are normally considered as a usual monopoly and sometimes bring contests among investors. This starts leapfrogging of new ideas so as to get by in the aggressive power industry. Thusly, development of ERS gives an elective potential answer for detour the customary transmission tower for rebuilding just as line reconductoring. Line uprating proves to be a smart solution to cater the increased loads on existing transmission lines. However, this exercise is problematic as the shutdown required for reconductoring cannot be provided as those lines are already critical. This exercise helped in completing a project which would evacuate 580 MW lines where substantial investment was already made on 98% stretch of the line and associated substation would have remained idle for indefinite period. Project milestones and achievements are concluded as below:

- *Line Crossing:* Stringing was challenging as the line had a flyover, a river and a highway crossing
- *Delay in Shutdown:* Even after installing the ERS, re-tapping was frenetic due to shutdown required for 2 hours from UPPTCL was difficult.
- *No Heavy Machinery:* No heavy machinery or earth movers were introduced for execution of above, other than for transportation, which depicts the agility of the system.
- *Challenging Feat:* The bypass line across the highway was done without any disruption of highway traffic even for a minute.
- *Rough Weather:* There was stormy wind after erection but no damage was made to the ERS.

Conflict of Interest

Authors are declaring that there is no conflict of interest with any other individual or organization.

Acknowledgement

The project shown as a case study was done for UPPTCL, India. Authors are thankful to Mr. Arup Das (SCPL) and Mr. Prakash Reddy (SCPL) for their active co-operation.

ABSTRACT

The increase of elderly population creates the need to promote healthy aging, with autonomy and independence, for preserving the functional capacity and quality of life as much as possible. To achieve this goal the recommendations include walking a certain amount of steps daily, given that the exact amount of steps changes with age, lesions, and chronic health conditions that can affect health and well-being.
Understanding how much exercise is adequate for an individual requires specialized knowledge and training. It is important to avoid risks that include: (1) be too aggressive in exercising and increase injuries, create new ones, and later refrain in exercising more; or (2) be too conservative and in the long run have an activity level under each one's potential and below what is recommended.
In this article is proposed and discussed a framework that aims to support people having an adequate level of activity for its particular condition and to do it without disrupting daily routines. The framework is supported by a software system built for monitoring well-being and physical activity in the context of Smart Cities. The system is composed by: (1) smartphone applications that interact with the end-user for showing possible exercises and walk routes, and that collects some relevant data; (2) a back-office application that collects and presents data obtained from the smartphone applications. The back-office application is designed for health professionals to follow users' progression over time, to recommend new exercises or to correct less optimal situations.
The first tests with a system implementing this framework show that the solution is robust and able to be used in a large scale.

1 Introduction

This paper is an extension of work originally presented in 2018 2nd International Conference on Technology and Innovation in Sports, Health and Wellbeing (TISHW) [1].

Active and healthy aging is important as individuals should have the best life possible and this usually means a long and healthy life. It is important for individuals as well as for communities since a political concern is the mounting pressure on national health services of aging societies due to the ever larger proportion of elderly population. Therefore it is important to minimize costs associated to assistance to people and digital technologies can give an important contribution. As healthier aging benefits both individuals and societies, there is a growing awareness of the importance of promoting it, with autonomy and independence, and preserving each one's functional capacity.

The question is thus: how to help people aging with good health? Several studies suggest that monitoring people's level of activity has the potential to foster health and well-

[*]Mário Rodrigues, IEETA – Campus Universitário de Santiago, Aveiro, Portugal, Tel. +351 234 370 500 & mjfr@ua.pt

being by transforming it from an individual goal towards a collective and social goal [2, 3]. Some experiments have concluded that the use of information and communication technology (ICT) enabled devices to collect individual performance data, a communication network for sharing those data, can contribute to increase the activity levels and to promote community building. Other studies go further ahead and infer that connecting residents and municipal health professionals through digital applications can decrease ansiety levels thus increasing well-being and promoting a sense of comfort as for instance to reassure young parents that a nurse is as close as a click of a button [2]. Mobile health (mHealth) is a paradigm that refers to medical and health practice supported by mobile devices. Despite the rapid growth of mHealth, mainly due to the significant growth in mobile device penetration [4], there are still a number of challenges including the need of having a high degree of security, reliability, quality, and effectiveness. Technological advances (e.g. accelerometers) have allowed for the objective measurement and characterization of physical activity and sedentary behavior in terms of volume, duration, intensity and frequency. This helps to personalize strategies and interventions aiming to increase physical activity and decrease sedentary behavior as well as goal setting [5]. Most mobile applications (apps) related to health, well-being, and physical exercise are not properly validated or under the supervision of health professionals, even though some are quite popular and well rated by users [6]. Privacy concerns also arise when apps collect and store data. The importance and potential impact on people's life of health related advices and personal information makes it a quite sensitive topic to be explored without proper validation and supervision.

In this paper we discuss and present a framework for a monitoring system of wellbeing and physical activity in the context of Smart Cities. The framework is more than a single mHealth app as it is designed for health professionals take control and operate the system, having access to user specific information as well as to contextual information about users' environment.

Although the proposed framework is more than an app, as it will have health professionals operating the system and will take into consideration contextual and user specific information, the app is a key component as it will be the interface for end users. The back-office component is designed to work with a range of alternative apps however it is important to provide a default app that, at least, works as a showcase of good practices and helps to illustrate the framework potential.

The framework is designed for the global Smart City, in the sense that its technical solutions and its conceptual approach take advantage of sensor and city state information. The framework is deployed in a concrete Smart City: the Smart City of Águeda that is a member of the Open and Agile Smart Cities. Águeda was selected for two reasons: (1) it is recognized nationally and internationally as one of the most dynamic Smart Cities of Portugal; (2) it belongs to a region where the proportion of elder population is increasing, as in many other Portuguese and European areas. The Portuguese census of 2011 showed that 22,5% of the population of in this region was 65 years old or more.

From the city authorities perspective, collecting information where people usually practice outdoor exercise, or stroll, is valuable for planning public spaces. More and better infrastructures like fitness equipment, benches for people to seat and rest for a while, children's playgrounds, sports equipment as Basketball fields, among other, can be better located if city officials posses such information. Also, concerning mobility, is important to know here people concentrate when deciding the location of bicycle parking structures, electrical vehicle's chargers, bus stops, and so on and so forth [7].

After the introduction in this section, section II presents the relevant background and related work on smart city projects and on mHealth and related mobile applications. The third section explains the developed work, discussing the relevant implementation details and presenting the interface of the system. The following section, Section IV, discusses the main features of the proposed framework and explains how it helps to mitigate known shortcomings in current mHealth solutions. The paper ends with the conclusions in section V.

2 Background and Related Work

This section will first provide some background information on smart cities followed by recent relevant projects on this topic. Then, the section introduces background information on mHealth ending with a description of three of the most popular apps for mHealth.

2.1 Smart Cities

Smart City has become a key marketing term for researchers and politicians to justify technological investments in urban areas. Several cities and less dense urban areas in quite different stages of development claim to be smart, with no clear definition of what a Smart City is. One universally accepted aspect is that ICT are the smartness enabler. With this reality in mind, some researchers have identified a minimal set of features that must fulfilled for an urban area be able to claim its smartness [8]. It is widely accepted that to be considered smart an urban area must: (1) have an explicit agenda about the development of its smartness; (2) providing open data about itself; (3) provide software services or mobile applications that may be used widely; and (4) have some kind of digital infrastructure that allow data communication in its area of actuation.

As a measurement of the order of magnitude of smart city initiatives, a study from 2017 [8] found that "more than 300 cities of all types and sizes participate in approximately 40 coalitions, thinking tanks and forums or are being advised by organizations, in their attempts to co-define their innovative future, while most of them claim to be smart, and almost all cities want to engage in this era". Smart cities aim to improve the quality of life for residents and visitors. As such, most of the city's intelligence indicators are defined with respect to the potential impact on people's lives. The study conducted in [9] lead to the observation that "a Smart City is quintessentially enabled by the use of technologies (especially ICT) to improve competitiveness and ensure a more sustainable future by symbiotic linkage of networks of peo-

ple, businesses, technologies, infrastructures, consumption, energy and spaces".

The European Union (EU) adopted an indicator that measures the city's smartness according to six dimensions [9, 10]. This indicator is also adopted here because of its relevance and because the proposed framework will be implemented in an EU city, and the dimensions are:

1. Smart Governance - relates to the degree of citizen participation in public life, transparency of governance, and the quantity and quality of public and social services.
2. Smart Economy - how competitive is the economy measured by its innovative spirit, entrepreneurship, international insertion, among other.
3. Smart Mobility - addresses concerns such as the existence of transport infrastructure considering (inter-)national and local accessibility, availability of IT infrastructure, and sustainability of the transportation system.
4. Smart Environment - what is the concern level about natural resources, including environmental conditions, air quality, sustainable resource management and ecological awareness.
5. Smart People - is about human and social capital, including the level of qualification, the promotion of lifelong learning and ethnic plurality, and the openness of minds.
6. Smart Living - is relative to the quality of life, including cultural and educational facilities, health conditions, quality of housing and tourist attractiveness, among other.

Smart City initiatives can address any combination of these six dimensions, and can be quite distinct in terms of goals and technical solutions adopted. For example, innovation in Smart Living includes transformations in construction, urban planning and renovation of facilities whereas innovation in Smart Mobility may involve tracking systems, and in Smart Governance may just entail a change in official procedures without further material investment. Overall, solutions that drive initiatives may involve cyber-physical integration of sensors and other hardware, or be primarily a software engineering challenge to generate new applications and services, or be more closely related to data science and analysis of big data. Considering the six dimensions of the EU smart city indicator, the framework proposed is aligned with the Smart Living dimension. As such, here will be described works that contribute to Smart Living and that are ready to be deployed in a real context.

2.1.1 i-SCOPE

The i-SCOPE project – interoperable Smart City services through an Open Platform for urban Ecosystems [11] covers four dimensions of the Smart City indicator: Living, Environment, Mobility, and People. In the context of the project was developed an open platform that supports three services: (1) optimization of buildings energy consumption through the precise evaluation of the potential and loss of solar energy; (2) environmental monitoring through real-time noise mapping, leveraged by the involvement of citizens, as citizens and their mobile devices can act as sensors, thus being able to measure noise levels throughout the city in a distributed way; and (3) a service more related to this work, which aims to improve the inclusion and personal mobility of elderly citizens and mobility difficulties. In this context, the platform presents a detailed urban layout, with features and barriers, to allow a precise and personalized routing service that takes into account the characteristics of individuals and the city [11]. The i-SCOPE had pilots implemented in the cities of Wien (Austria), Newcastle (United Kingdom), Indjija (Serbia), Lázio Region (Italy), and Zadar County (Croatia).

2.1.2 Amsterdam Smart City Platform

The Amsterdam Smart City Platform [12, 13] is an initiative that includes several projects developed and implemented in Amsterdam (The Netherlands). Being a comprehensive initiative, it contributes to the various profiles of the Smart City indicator. From the set of projects that contribute to the profile of Living, two are related more related to the framework discussed in this work: VITAMINE [14] and PAUL - Active Urban Living based on playful data [15].

The VITAMINE project, dubbed the Dutch word for vitamin, was created to help the elderly who are looking for a suitable lifestyle [14]. The idea is to increase the frequency of training activities by providing and supporting an additional home workout program. The absence of an exercise supervisor or instructor is mitigated by the availability of online support. In addition, it also focuses on the diet of its users and the example given is to examine whether the use of extra protein has or does not effect on exercise.

The PAUL project aims to understand how the physical activity of city dwellers can be increased using custom apps [15]. It is observed that different apps to stimulate people to exercise exercise use different strategies [6]. The way to encourage more exercise, or at least maintain the same level of activity, varies and can be motivational messages, games, or peer comparison. The project assumes that the type of app that works best for a particular person is a highly individual choice. Thus, the project studies how to make the best match between the user and the app.

2.2 mHealth

Health Apps are a good option for the elderly especially because of its mobility and portability. However, some important issues need to be addressed since older people often find it difficult to use new technologies including smartphones and respective apps [16]. However, the Internet and the use of smartphones among the elderly population will increase in the near future, as the elderly in the future will be more likely to use the Internet to search information than the elderly today. In addition, they are concerned about health and are likely to use the Internet for health-related issues [17]. Thus, there seems to be a potential interest in older adults to use mHealth apps, which is essential for these systems to be adopted by that group.

The development of new ICT applications, especially those that need mobile devices or the Internet, should help reduce the digital divide. This suggests that, in order to have an application accessible to a large group of older adults, it is appropriate to opt for a human-centered design process whose key premises are the active involvement of users in the development process as well as in the evaluation of interactive systems [18]. In addition, a human-centered design choice also appears to be a valuable approach when developing a mobile health application for other stakeholders, such as health professionals.

Experiments exist with context-aware recommender system that offers personalized recommendations of exercise routes to people according to their medical condition, and real-time information from a smart city [19]. This recommender has predefined routes and selects the best route based on a memory-based method that employs neighborhood search (to determine groups of similar users) and on information such as air quality, ultraviolet radiation, wind speed, temperature, and precipitation. The user can then select the best course according to their profile (age, effort, distance) and can inform the system about unexpected situations that could affect other users. Users can also propose new routes [19].

There are dozens of fitness apps and discussing a representative set here would not bring further insights into discussion. Nevertheless, here will be described three popular and feature-full apps selected from dozens due to their higher ratings voted by hundreds of users, for better understanding of what is being made and the real potential of such applications. The first application was developed for iOS and Android, the second one just for iOS, and the third one just for Android.

2.2.1 Pacer Pedometer & Step Tracker

This app uses a set of parameters based on the smartphone sensors and usage patterns to classify the user's lifestyle from sedentary to highly active [20]. It contains a step counting algorithm, and allows to check the performance over a certain period of time, presenting results using graphics for easier reading. The historical data is recorded and can be used to check whether or not the user has progressed against their goal, in terms of number of steps per day as well as calorie and weight loss. A set of predefined objectives are defined to give users a sense of progression. The app encourages users to exercise in case of a long period of poor activity, and it has a social component in which users, besides being able to share the number of steps taken, can also encourage friends to exercise as well.

2.2.2 The Walk: Fitness Tracker Game

This app was created in conjunction with United Kingdom's National Health Service and essencially is a game to stimulate people to walk more often [21]. The apps monitors the activities of the user to verify if the user is walking, provides several stories and users are required to move for progressing in the story. So this app is masked in a game for encouraging people to reach the adequate number of steps per day thus improving their health. As such, it motivates users to follow the story and not so much to take into account the number of steps or distance traveled.

2.2.3 Pedometer - Step Counter

The main feature of this app is a step counter. As a secondary functionality, it computes several metrics acquired through specifically designed exercises [22]. The application records the evolution of the metrics over time. Users can have training plans focused on each part of the body with the purpose of achieving their own goals more efficiently, addressing more specifically the part of the body they intend to exercise. It includes several other tests possible using the smartphone sensors such as hearing test and color blindness test.

3 Developed Work

The objective of this framework is to explain how mHealth can be further improved by making sure that health professionals are at the core of the decisions, without hindering the vibrant existing mHealth app market. Having health professionals at the core of the decisions means that users are followed by health professionals, and not just by algorithms or predefined generic reference values, and that they are in control of the recommendations passed to users having the ability to take into account the individual health history or recent changes in its health conditions. Health professionals also have access to contextual information such as weather conditions, points of interest and sidewalk conditions, among others, to obtain an accurate perspective of the real environment where users will develop their walks. They are able to recommend (new) exercises and walk paths, or introduce the necessary changes to correct less optimal situations.

3.1 Framework Description

Figure 1 depicts the proposal overview. Distinct type of mHealth apps are able to interact with the back-office application. At the top of the figure is represented a health professional analyzing the users' data and assuring that they have the best possible walk program, at the bottom of the picture are represented some users doing their exercises, and between them is a system composed by the communication networks and by the back-office.

Two health professionals helped defining the requirements of the framework, of the back-office application, and helped to define personas to guide the user experience requirements. The requirements identified for the back-office application are discuss in detail in [1]. The back-office application is composed by five main modules:

1. Health professional interface - is a web based graphical user interface that integrates information from the other components, presenting it to health professionals in an intuitive and organized way. The interface is multi-user as distinct health professionals can follow distinct sets of end-users. Also there is the ability to share users to accommodate events such as vacations or planned leaves. It is considered particularly important providing an area where health professionals can

find all essential information to support their decision-making process, making it easier, faster and less prone to errors. The two interface panels presented as Figures 2 and 3 will be explained next.

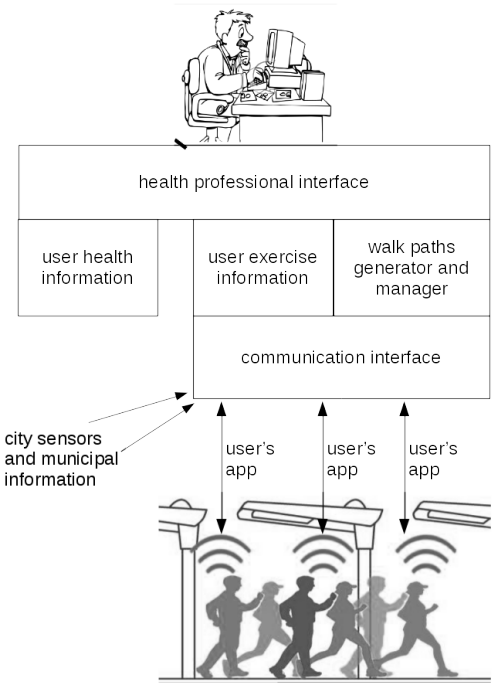

Figure 1: Depiction of the core actors of the system with details regarding the dataflow and the main system modules.

2. User health information module - manages health information that is private and sensitive. This information is never accessible to the mobile app or to any other module than the health professional interface. The informaton is stored in a specific and isolated database and it is inserted by the health professional when the user subscribes the service. This information is updated whenever the user meets with the health professional responsible for its follow up. Fig. 2 presents a screen-shot of the health professional interface relative to this module. The left panel contains generic information such as user's name, contacts, weight and height, and education. The right panel contains the user's medical record that includes heart rate, blood pressure, six minute walking test (6MWT), regular medication, and a medical record of some relevant conditions. No special concern about data security – other than stock data encryption - was taken care in the prototype development as, when deployed, these part of the system needs to comply to the specific norms of each instituion and/or can just be a reference to an already existing database.

3. Exercise information module - manages user exercise information that, being private information, is not as sensitive as the one managed by the user information module. Since this module interacts with the communication interface that, by its turn, interacts with the (third party) apps, there exists an increased factor of vulnerability. For that reason this module does not explicitly have information about the user. The user is referred by a code that does not encode personal information. This code is for the health professional interface query the user health information module about which user corresponds to a given code. When this happens the user health information module just replies if that health professional is authorize to view such data. Fig. 3 presents the health professional interface relative to the exercise information. In the left panel is visible the resume of the user, at the center a map showing the walk routes suggested to the user and, at the right panel, the amount of times the user walked those courses.

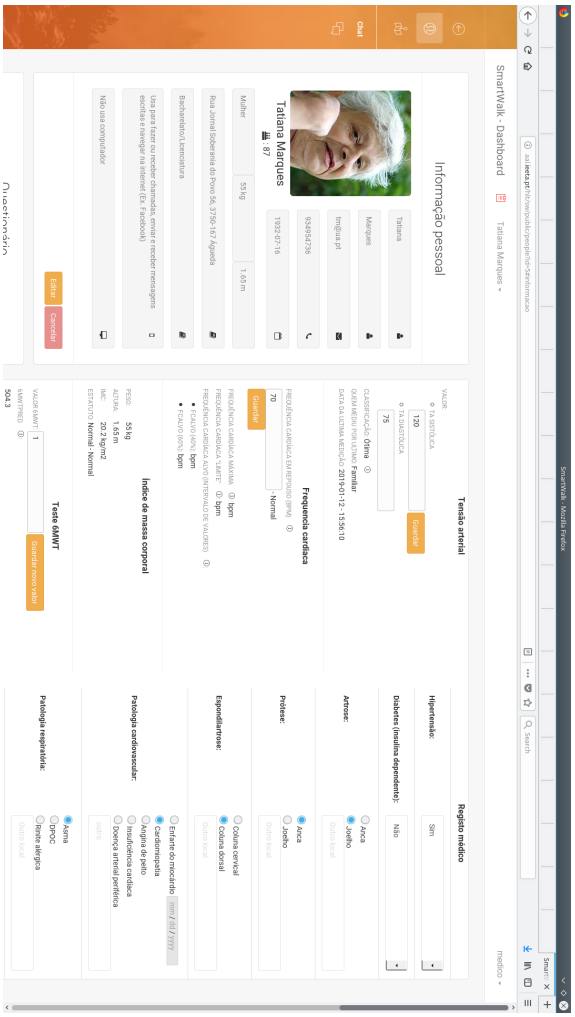

Figure 2: The back-office screen to insert and visualize health information of one user.

4. Walk paths generator and manager - this module allows to generate paths using multi-criteria [23]. It is possible ask for path of a given distance, to force paths to include given places - like rest areas or streets without cars - and also to exclude some areas such as more polluted areas or less safe. Then the algorithm optimizes the rest of the path by preferring streets with larger sidewalks, avoid the busiest roads, etc [23]. The interface of this module is a contextual menu that

pops up by right-clicking at the map of the exercise interface (see menu inside the map in Figure 3).

5. Communication interface - is handles all data received from or passed to the apps, receives data from the city sensors (temperature, wind, air quality,...) and from the municipality information systems (roads/streets under maintenance, social events,...). This interface is implemented as a RESTful Web Service and so it does not start a communication by its initiative. When the system has to pass information to someone, that information is stored and later sent when the mobile app initiates a communication with the system and ask for such information. If the health professional needs to contact the user the contact request goes by alternative ways such as short message service (SMS) or e-mail.

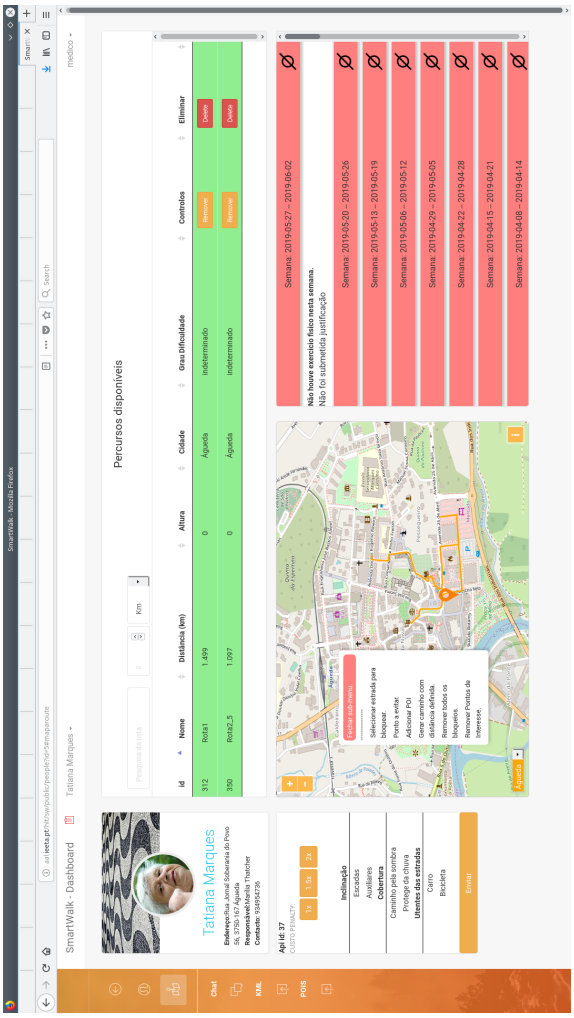

Figure 3: The back-office screen to define a walk plan for a given person, and to see how often that plan was executed.

3.2 Data Transport

The ability to allow distinct apps to interact with the back-office application implies a public definition of the data to be passed between the apps and back-office, besides the implementation of the communication interface.

The back-office sends to the app free text messages for users' information in JavaScript object notation (JSON). To send the walk paths, the back-office application generates a file in keyhole markup language (KML) format, places that file in an externally acessible universal resource location (URL), and sends that URL in the JSON message.

The data transport is made by JSON and a data package can contain one or more of the following sections: (1) user messages, (2) physical activity, (3) heart data, (4) inactivity justification.

All data packages include a code that represents the user. This code does not contain personal information as mentioned before, is used for the back-office associate the received data with the respective user. As such, in case of communication interception is not possible to identify the user just by looking to the data package.

All pieces of information have a timestamp representing when that information was generated. These timestamps are used for correctly build the events timeline at the back-office. As users can use apps without an active data link the time when the information arrives at the back-office can be quite distinct of when it was generated.

The section "User Messages" contains information written by users. It can have any free text message the user wants to share with the health professionals, namely questions regarding any concern he may have. This specific part of the package is bi-directional in the sense that the healt professional can use it to send messages (questions) to users. It also includes information about medications the user is taking. Table 1 presents an example of a message.

Table 1: Example of a "user messages" section.

```
"User Messages": [{
  "Message": {
    "Text": "Everything is OK",
    "Time Stamp": "2019-01-09  15:56:10"
  }},{
  "Medications": [{
      "Name": "Placebo 1",
      "Time Stamp": "2019-01-09  15:56:10",
      "Amount": 10,
      "Reason": "Arrhythmia"
    }, {
      "Name": "Placebo 2",
      "Time Stamp": "2019-01-09  15:56:10",
      "Amount": 4,
      "Reason": "Headache"}]}]
```

The section "Physical Activity" includes information of routes walked by users and how was the experience in terms of satisfaction, polution, etc. It includes information about how many stops the user has made during the course because it is an indicator of problems - it should be considered a stop if the user remains at the same place for a minute or more. It is also collected information about if any pain was felt and its location, the total duration of the walk, and a list of global positioning system (GPS) coordinates representing the actual path made. Table 2 presents an example of this data section.

Table 2: Example of a "physical activity" section representing that the route 305 was walked during 40 minutes with two stops, the first during 1 minute and the second for 10 minutes.

```
"Physical Activities": [{
  "Physical Activity": {
    "Active": {
      "Start": "2019-01-09 15:56:10",
      "Stop": "2019-01-09 16:36:10",
      "Route": {
        "Other": "No Comments",
        "Satisfaction": {
          "Pleasure of Course": 3,
          "Pollution Level": 2,
          "Luminosity": 8,
          "State of the tours": 6,
          "Population Density": 4
        },
        "Difficulty": 4,
        "RouteId": 305 },
      "StopDuringActivity":[{
          "Start": "2019-01-09 16:06:10",
          "Stop": "2019-01-09 16:07:10",
          "Coords": "40.575423,-8.446624"
        }, {
          "Start": "2019-01-09 16:09:10",
          "Stop": "2019-01-09 16:19:10",
          "Coords": "40.575612,-8.446191"
        }],
      "Pain Condition": {
        "Hands": 0,
        "Feet": 0,
        "Ribcage": 0,
        "Thigh": 4,
        "Head": 7,
        "Shoulders": 0,
        "Lumbar": 3,
        "Neck": 1,
        "Knee": 0,
        "Arms": 0,
        "Hip": 0 },
      "Duration": 40,
      "Path": ["40.575320,-8.446634",
               "40.575320,-8.446639",
               ...]}}}]
```

Two very important measures of effort, that have implications on the helth and well-being, are the heart rate and the blood pressure. This are reported in a "heart data" section illustrated in Table 3. These values are stored in the "exercise information" module and not in the "user health information" module since there is no guarantee that is was correctly obtained. These values are used just for monitoring and, if a consistent anomaly is verified, the next time the health professional meets the user he will try to understand the reason of the anomaly.

When some user is inactive for a long period of time, the back-office issues an alert for the health professional. If he finds appropriate it can question the user the reason of its inactivity. An example is presented in Table 4.

Table 3: Example of a "heart data" section representing that the values were obtain by a familiar. Other options could be a drug store or a health professional.

```
"User Heart Data": {
  "Blood Pressure": {
    "Diastolic": 70,
    "Systolic": 120
  },
  "Time Stamp": "2019-01-09  15:56:10",
  "Heart Rate": 68,
  "Who Measured": "Familiar" }
```

3.3 Mobile App

As mentioned before, the data transport of the framework is open and standardized for allowing third party apps to integrate the framework seamlessly. Nevertheless it was found important to provide a default app that, at least, helps to illustrate the potential of the framework.

Table 4: Example of a "inactivity" section. The main purpose is to allow helath professional understand if users were just busy and did have time to use the system or if it is a situation that need proper attention.

```
"Justification of inactivity": [{
  "Justification": {
    "Other": "None",
    "Time Stamp": "2019-01-09  15:56:10",
    "Absence": true,
    "Disease": false
  }
}, {
  "Justification": {
    "Other": "None also",
    "Time Stamp": "2019-01-09  15:56:10",
    "Absence": false,
    "Disease": true }}]
```

The devices that run the app are required to have wifi capabilities in order to send the data for the back-office and, to receive from it, the walk paths in KML format. They also need to have a GPS sensor for helping users complete the walk paths assigned to them, and acquiring information about the paths users actually did for subsequent analysis by health professionals.

The devices are not required but are strongly encouraged to have a heart beat sensor. This recommendation is due to the heart beat rate is strongly correlated with physical effort, and thus should be monitored by health professionals to assess if exercises are adequate to the given persons. It is not mandatory as heart beat rate and blood presure can be measured after the exercise by a health professional, or in a publicly available machine or at home, and then the values can be inserted manually. Even if the app is running on a device with a heart beat sensor, such as in the case of smartwatches, current technology is not accurate if a person is moving, thus the exercise should be finished before the value is measured.

3.4 Default App Implementation

Apps can run on devices such as smartphones and/or smartwatches. Apps running on smartphones have the advantage of benefiting from a bigger screen for the grphical user interface and longer energy autonomy, alongside these devices are well widespread troughtout population. Apps running on smartwatches have the advantage of benefitins from a heart beat sensor and being less intrusive as these devices are smaller. The default app runs combined on both types of devices: it runs on a smartwatch that acquires heart beat data and passes it by bluetooth low energy (BLE) to the smartphone, which combines that data with its own (GPS, user inputs, ...) and sends alltoghether to the back-office.

A default app was thus designed taking usability considerations adequate for older people [24, 25], and fully developed to show how each framework feature is accionable from the app. The user interface was designed with the support of three personas and two usage scenarios specifically developed to foster discussion and reflection [25]. Those three personas were characterized in terms of age, personality behaviour, and interests. One usage scenario was elaborated including one of the three personas while in the other scenario the other two personas interacted with which other.

The findings obtained from the personas and scenarios development lead the designed decisions of the app including: the way it was designed, how it works, and why it is easy to use for an elderly user who may not be used to the technology or has health impediments that make its use difficult [26]. The automatically app provides help if it is waiting for user's input and no activity is detected. Figure 4 presents a screen capture of such event in the home screen.

When the app does not detect an available heart beat sensor it will prompt users about the heart rate. Such form is presented in Figure 5. The fields DATE and HOUR will have as default values the current date and hour, respectivelly.

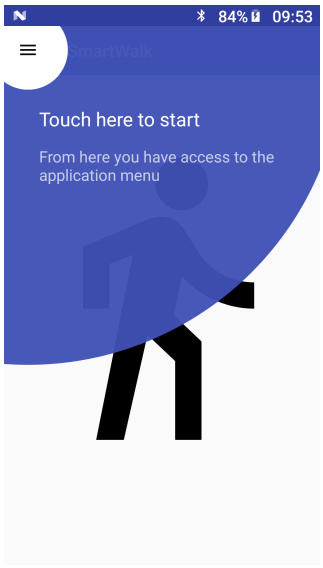

Figure 4: Screen capture of the default app home screen. The app provides contextual help when user action is required and no user activity is detected.

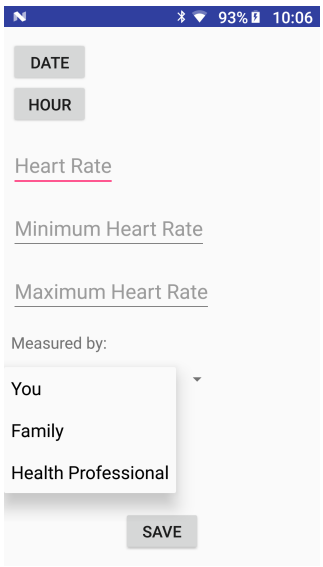

Figure 5: Screen capture of the default app. The app allows manual insertion of data if sensors are not available or if users prefer to measure themselves or ask someone else.

4 Discussion

Projects that conform to this framework can contribute to the challenges associated with the Smart Living profile. This profile is about lifestyles, behavior and consumption made through ICT, healthy and safe living in a culturally vibrant city with diverse cultural facilities, and good quality accommodation. Smart Living also promotes tourist attractiveness and high levels of social cohesion and social capital [9].

In particular, these types of systems described here can contribute to a healthy ICT-based lifestyle, as it aims to support people to maintain an adequate level of physical activity by advising them with a walk plan defined by a professional and transmitted using an ICT-based solution. In addition, health professionals, by knowing the places where people walk, can propose the most popular places to walk, thus being safer and more appealing. As it includes contextual information such as climatic conditions, points of interest, and temporary events among other, it has the potential to contribute to increase tourist attractiveness. One possibility that this type of system offers is also to propose joint walking plans, thus contributing to increase social cohesion.

Placing health professionals at the center of the decision allows individualized and quite different paths for individuals who, even if at first glance may seem to have the same profile, may have very different needs among themselves. [27] states that physical activity among the older population differs widely. According to studies that gathered information from ethnographic studies and interviews with health professionals, it is necessary to create different profiles of the elderly, with respect to physical activity and health conditions, and consequently create and adapt different routes to a specific profile. Adequate physical activity levels vary with health conditions and lifestyle [28]. Considering this, it is necessary to evaluate the health of users, namely the elderly. Thus it is of utmost importance to allow health professionals evaluate and define the profile of the user, and adapt the path of the walk to their state of health, physical activity level,

and personal preferences.

Regarding health conditions, the first thing to evaluate is whether the user needs to see a doctor before becoming more physically active. This can be reported using the Physical Activity Readiness Questionnaire - PAR-Q [29]. Then the 6-minute walk test - 6MWT [30] will be used to assess the user's level of physical activity. Other health information should be requested, such as an existing medical diagnosis, location and intensity of pain, usual medication, heart rate, and usual physical activity. With this package of health professional information can define the profile of the elderly.

A characteristic highlighted by one of the personas created was the need to make periodic evaluations face to face. For example, if a user as a health problem as breaking a leg, there is a need to make a new health assessment, or if the user leaves the city for a period of time and does not engage in any physical activity. Health information is needed to define the profile of the elderly and to customize the routes for the health conditions of the users, so it is necessary to have different routes. This also allows us to adapt the routes to personal information about the user, for example, a user who prefers routes integrated in a natural environment or if he prefers to pass in a local market. Finally, to induce and motivate the practice of physical activity, it is necessary to maintain face-to-face contact through periodic health assessment and to maintain the adaptability and personalization of the routes.

A system conforming to the proposed framework was implemented and tested with simulated users. The simulated users asked for walking courses and sent information regarding their physical activities (see Table 2), and sometimes other data relative to the other parameters, using distinct combinations of the four information sections. Users also sent information sections that were not defined and that should be silently ignored. The system handled efectivelly the distinct combinations of information sections and the information sections not defined. These results show that this design should cope well with upgrades since one major difficulty for upgrading systems is when distinct versions with distinct features coexist in the same environment. Although just one instance (and thus one version) of the back-office is expected in one usage environment, regarding the mobile applications one should expect a variety of implementations and with different versions. The system was also tested for temporary loss of connectivity and didn't show problems in such cases. The option of having a back-office connectivity module implementing a RESTful web service proved quite robust to the loss of connectivity events.

To extend the system in the future is necessary to define the JSON format of the message to be passed between the back-office and the apps, and implement the respective code and extend the database if necessary. These are the miminum things to do in any case. There is no necessity to change the lower level communication mechanisms between the back-office and the apps as the extension is just in the semantic part of the content.

In this stage of the work there is no automation (e.g. no artificial intelligence methods involved). This work was about designing and validating a monitoring platform that could be used by mobile apps with the benefit of having health professionals supervising the exercises. Without this stage consolidated this framework would be like alternatives already available: fully automated solutions not necessarily validated by health professionals.

A possible future extension would be provide some statistics as the places most visited by users, for instance for city planning purposes. This can be readilly available and it was not addressed since since third parties didn't yet identified those needs.

5 Conclusion

This article presented a framework to help people to have a more adequate physical activity, using the infrastructure of smart cities when it exists. As people age, because of their individual health history, it is more difficult to know what the proper level of physical exercise is, and therefore they should have the support of a professional with specialized knowledge and training. If people are left alone by deciding their own level of activity, they may be too aggressive and aggravate their injuries, create new ones and refrain from exercising more, or be very conservative and, in the long run, have a level of activity under their potential.

For this, information about chronic conditions, previous surgeries and current injuries, among others, is needed, raising concerns about privacy, and people are often reluctant to share these details. As such, the framework is designed to be operated by people who already know this information, or who are already legally authorized to own it, health professionals and probably the local public health unit. Also, special care was taken to make sure that health sensitive information remains private.

The back-office application was designed for health professionals be able to make fast, error-free decisions and minimize the risk of overloading them with much more work. In addition, the end user application can be made by third parties. One default app was designed and developed considering that some people are able to easily operate the smarphone and some have difficulties in using ICT, some may have problems of vision, etc. The best guidelines for the interfaces of the elderly were considered.

The project is implemented in Águeda, a city of about fifty thousand inhabitants, and ready for large-scale testing. The municipality of Águeda is a stakeholder in the project and it is expected that the project will be implemented definitively after all the tests and eventual corrections. All the technology planned for use is available in the market, such as smarphones and wristband models. This is important because the project is being deployed locally, but it has been carefully designed to be deployed (easily) in any other city.

Conflict of Interest The authors declare no conflict of interest.

ABSTRACT

Neurological signals are generally very weak in amplitude and strongly noisy. As a result, one of the major challenges in neuroscience is to be able to eliminate noise and thus exploit the maximum amount of information contained in neurological signals (EEG...). In this paper, we aimed at studying the N400 wave of the Event-Related Potentials (ERPs) that may reflect the effects of vowelling and semantic priming in Arabic language. To improve the quality of the recorded ERP signals, we considered a nonlinear filtering method based on 10th order Daubechies discrete wavelet transform combined to principal component analysis (PCA). Among all tested wavelets, the Daubechies one showed high values of the used signal processing metrics. Thus, it allowed a significant enhancement of the signal to noise ratio while using only 10 ERP trials. In addition, we confirm its effectiveness while comparing the filtered outputs to those obtained using the averaging technique implemented in the conventional EEGLab toolbox. In a second step, the Mexican Hat function was used to achieve continuous wavelet analysis of the filtered signals. This time-scale analysis method permitted to get an alternative representation of the ERPs and to detect the N400 wave with significantly greater accuracy.

1. Introduction

The Event Related Potential (ERP) N400 wave is a negative deflection or component elicited by the brain as a reaction to semantically unexpected words in sentence contexts [1]. The N400 component has been found in many languages, such as English, French, Mandarin Chinese..., but to our knowledge, only a few studies have examined the occurrence of an N400 in the Arabic language [2].

The shallow or deep character (i.e vowelled or unvowelled words respectively) of written depends on how its phonology is reflected by the orthography of the language. Indeed, Arabic written words are composed from consonant and long vowels in addition to diacritics. These last reflect the vowellisation of the written word in order to enable inferring specific pronunciation. Also, Arabic is characterized by a non-concatenative morphology whereby every surface form is analyzable into a consonantal root, that conveys semantic meaning, and a word pattern (made up of vowels and of a subset of consonants) conveying morphosyntactic and phonological information.

In the present experiment, we recorded and analyzed ERP, in particular the N400 component, while participants performed a semantic judgment task with Arabic words. As many neural signals, ERPs are very weak signals and strongly corrupted by noise. Thus, previous studies aimed at improving the quality of ERP signals using statistical methods [3,4], linear and nonlinear adaptive filtering [5], neural network based techniques [6] and wavelets denoisng techniques [7,8].

In the present study, our aim was to go one step further to improve the quality of ERP signals. We used discrete wavelet combined with principal component analysis (PCA) as nonlinear filtering tools. This allowed us to enhance the signal to noise ratio and thereby to highlight the N400 component. In addition, we used

* El-Mehdi Hamzaoui, Email: hamzaouielmehdi@gmail.com

the Mexican hat function to achieve the time-scale analysis of the filtered ERPs in order to detect the N400 with more accuracy.

2. Material and methods

2.1. Experiment

In our experiment, which was approved by the Ethics Committee of the Mohammed V University, a total of 20 Master MSc and PhD students (10 women), aged between 20 and 34 years old, were tested after giving their written consent to participate in the experiment. They were all right-handed and without neurological disorders. They all use Arabic daily.

Each participant was comfortably seated in a Faradized room and was asked to silently read two words that were successively presented at the center of a computer screen. A total of 256 Arabic prime-target word pairs were used as stimuli with 128 pairs presented in the vowelled condition and 128 pairs presented in the unvowelled condition. For each condition, 64 pairs were semantically related and 64 pairs were semantically unrelated. For both vowelled and unvowelled pairs, two lists were constructed so that across lists, the same target word was paired once with a semantically related prime and once with a semantically unrelated prime [2]. The order of presentation of the two lists was balanced across participants.

EEG data was continuously recorded using 24 electrodes (impedance < 5kΩ) mounted on an elastic head cap according the 10/20 International EEG System [9]. The signals were amplified using SAI amplifiers (San Diego) and recorded at a sampling frequency of 250 Hz. The Electro-Occulogram (EOG) was recorded from an electrode placed under the right eye to detect eye blinks. Finally, two reference electrodes were placed on the left and right mastoids. The experiment was conducted in a Faraday's cage in order to reduce external interference [10].

The analyzed ERP signals correspond to the electrodes F3, F4, C3, C4, P3, P4, Fz, Cz and Pz. Previous results have shown that the N400 component is larger over centro-parietal regions of the right hemisphere than over frontal regions.

At the end of the experiment, three participants have been excluded because they present too many ocular and muscular artifacts contaminating the EEG signal.

2.2. Data analysis

Since the creation of wavelets, scientific and technical applications based on this mathematical tool have continued to be developed [11,12], exploiting their power and their efficiency for to perform multiresolution data analysis [13,14]. In the present work, we used a filtering technique developed by AminGhafari M. et al., [15] in order to denoise multivariate signals. This method combines both univariate wavelet decomposition of the signal and the principal component analysis (PCA) of the resulting wavelet coefficients in order to evaluate the correlation structure of the noise.

According to AminGhafari M. et al., [15], the algorithm performs the filtering task in four main steps. First, for a matrix X (nxp) of p observed signals, we achieve the wavelet decomposition at a defined level K. This results into two matrices D_k and A_k that contain respectively the details and approximation coefficients up to the level K of the p signals. Second, using the matrix Dj of finest details, a minimum covariance estimation is calculated and used for the diagonalization of a robust estimate of the noise covariance matrix. The obtained diagonal matrix is then used for changing the basis at each level 1<i<K. In the third step, the matrix D_k undergoes a classical one-dimensional soft thresholding. We then apply the PCA to both the detail and approximation coefficients matrices in order to choose the appropriate number of useful principal components. The best number is automatically defined using the Kaiser distance criterion which retains components associated with eigenvalues higher than the mean of all eigenvalues.

From the simplified matrices D and A, inverting the wavelet transform provides a new matrix containing the filtered signals. These lasts correspond to the main features of the original matrix X.

In our study, we tested 8 wavelet functions belonging to 5 wavelet families which are Daubechies of order 10 (db10) [16,17], Coiflets of order 5 (coif5) [18], Symlets of order 4 and 8 (sym4 and sym8 respectively) [19], Biorthogonal (bior1.1) [20] and Reverse Biorthogonal (rbio1.5) [18].

To evaluate the performance of the different wavelets, we computed the structural similarity index (SSIM), which is usually used to evaluate image quality on the basis of its luminance, contrast and structure characteristics. It is based on the comparison of an image I with a reference image [21,22]. It is known that the closer the SSIM value is to 1, the stronger the structural similarity between the evaluated image and the reference image is. By contrast, an SSIM value close to 0 indicates that there are no similarities between the 2 images [21]. To use this metric, we considered the matrix containing the wavelet based filter's output signals as an image (30 matrices of 9 analyzed electrodes x 2200 samples for each participant) and we compared it to the matrix that contained the averaged trials for each electrode.

In addition, we computed the signal-to-noise ratio (SNR) via a MATLAB® routine. This signal processing metric is commonly used to assess the performance of signal processing methods. It is often expressed in decibels as [23,24]:

$$SNR = 20.log_{10}(\frac{P_x}{\sigma^2}) \quad (1)$$

where P_x and σ^2 denote the power density of the original and the noise signals respectively.

In the case of closer SNR values, we also used the mean square error (MSE), given by the following equation 2, as second metric to evaluate the accuracy of the chosen wavelet. The value of the MSE, the closer the filtered signal is to the original one and thus the better filtering method is [6,10,21,23].

$$MSE = \frac{1}{N}\sum_{n=1}^{N}(x(n) - \hat{x}(n))^2 \quad (2)$$

where $x(n)$ and $\hat{x}(n)$ denote the original and the filtered signals respectively. N is the length of x(n).

In the second step, we used the continuous wavelet transform (CWT) as an alternative method to the classical signal time representation. This is based on the idea that wavelet analysis can provide accurate and specific time-frequency decomposition of

neurologic signals. This method has already been applied to EEG denoising [18,24,25], ERP component separation [26], spindle and spike detection [27,28,29], etc. It allowed an automatic processing of the signal and provided both qualitative and quantitative information.

The continuous wavelet transform converts a continuous signal into extremely redundant signal of dual continuous variables which are the translation and the scale. The resulting changed signal is easy to interpret and valuable for time-frequency or time-scale analysis [30]. In general, CWT of a signal s(t) is defined as:

$$S(\alpha,\beta) = \frac{1}{\sqrt{\alpha}}\int_{-\infty}^{+\infty} \psi\left(\frac{t-\beta}{\alpha}\right)^{*} . s(t)dt$$

where α and β represent the scaling and the dilation factors respectively, whereas ψ* is the complex conjugate of the mother wavelet function.

The scale α is associated to the wavelet's central frequency Fc and varies according to frequencies (in Hz) by:

$$\alpha = \frac{F_c}{f * \Delta T} \quad (3)$$

ΔT is the sampling period.

For time-scale analysis, we represented the modulus of the CWT coefficients, which corresponds to the energy density of the analyzed signal, according to $\log_2(\alpha)$ (ordinate axis) and time (abscissas axis) [12]. In this graphical representation, called scalogram, a color map is used to quantify the energy density of the transformed signal. The highest value of the energy corresponds to the white color whereas the lowest is represented by black color [31,32,33].

In our application, ψ is chosen to be the Mexican Hat (equation 4), which is the second-order derivative of the Gaussian function. This last is not a wavelet, but all its derivatives can be used as wavelets, particularly the first and the second derivatives [34,35]. In practice, the Mexican Hat is expressed by the real function of equation (5) and represented by the figure 1 below.

$$\psi(t) = \frac{2}{\frac{1}{\pi^4}\sqrt{3\delta}}\left(\frac{t^2}{\delta^2} - 1\right) exp\left(-\frac{t^2}{2\delta^2}\right) \quad (4)$$

where 0<δ<1 represents the wavelet width [35]

$$\psi(t) = (1-t)exp\left(-\frac{t^2}{2}\right) \quad (5)$$

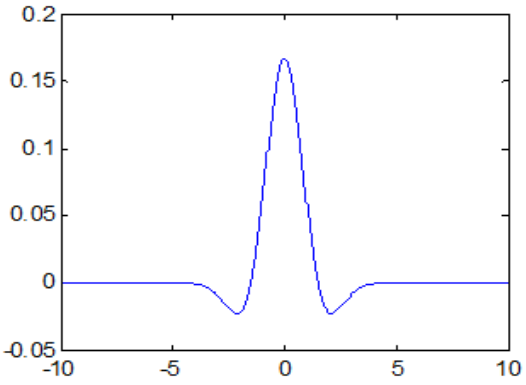

Figure 1. Plot of real function of the Mexican Hat function.

As illustrated by this figure, the Mexican Hat waveform looks like most of the waves that compose the ERPs (Figure 2). This was the reason to use it to perform the time-scale analysis of our data set. In addition, this function is easy to implement under the MATLAB environment.

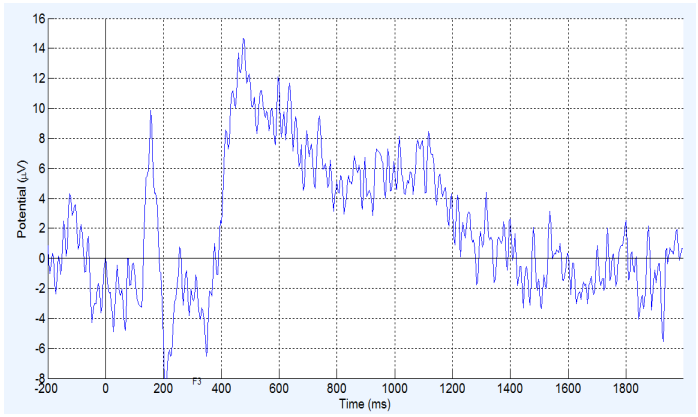

Figure 2. Example of recorded ERP.

3. Results and discussion

The averaged values of the performance metrics, SNR and MSE, corresponding to the application of the Aminghafari's algorithm with different DWT functions to our signals are presented in Table 1. As described in the Materials and Methods section, we recorded 30 ERP signals per electrode from each participant (9 electrodes and 20 participants). We processed 5, 10 and 15 trials to evaluate the efficiency of the filtering algorithm and thus to define the most accurate DWT function that allowed a good filtering of the ERPs. Results showed that the 10th-order Daubachies wavelet (db10) yielded the best results in terms of accuracy of de-noising ERP signals. In fact, this DWT function shows the highest SNR values and the lowest MSE values in all test conditions.

Importantly, and as presented in Table 2, db10 showed the highest values of the structural similarity index for all electrodes. In addition, and as illustrated on Figure 3, its application to filter the ERPs showed good improvement of the visual quality of waveforms' plots.

Visual comparison of these results to those obtained using the classical averaging method implemented in the EEGLab Toolbox showed that, for each electrode, the same visual quality of plots is obtained via our method and via EEGLab when averaging all recorded signals for SNR values of about 3.5. However, using our db10-PCA filtering method, only 5 to 10 ERP trials are sufficient to improve the SNR value and to highlight the occurrence of an N400 component. This can be explained by the fact that our filtering method is a nonlinear technique that takes into consideration some statistics of the signal and how the noise is affecting the signal. By contrast, the averaging method is a linear method that assumes that the noise is additive, white and Gaussian.

In order to still improve accuracy in N400 waveform detection, a time-scale representation of the ERP signals was performed on the basis of the Mexican hat CWT function. An example of results obtained for the 9 recorded electrodes is illustrated on Figure 4.

Table 1: Averaged values of metrics obtained using 5, 10 and 15 EEG trials.

Wavelet Name		5 ERP trials		10 EEG trials		15 EEG trials	
		MSE	SNR	MSE	SNR	MSE	SNR

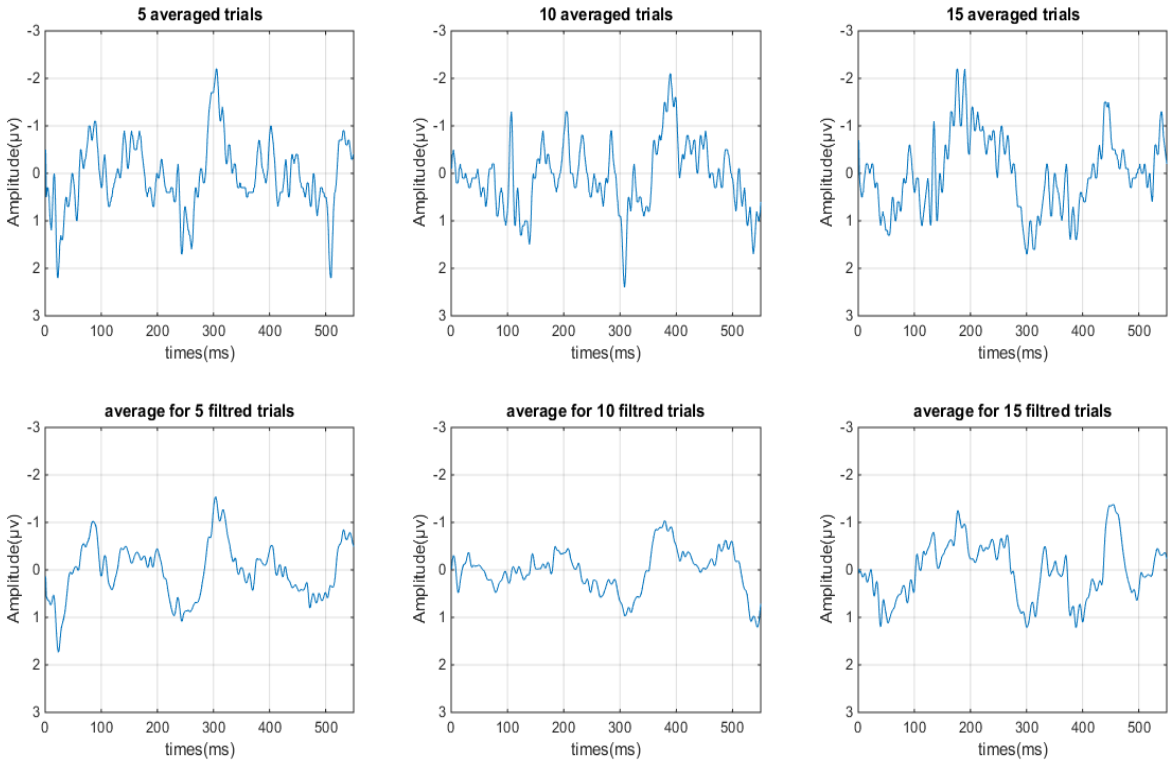

Figure 3. 5, 10 and 15 ERP trials filtered using both EEGLab Averaging technique (Up) and the developed db10-PCA filtering method (down).

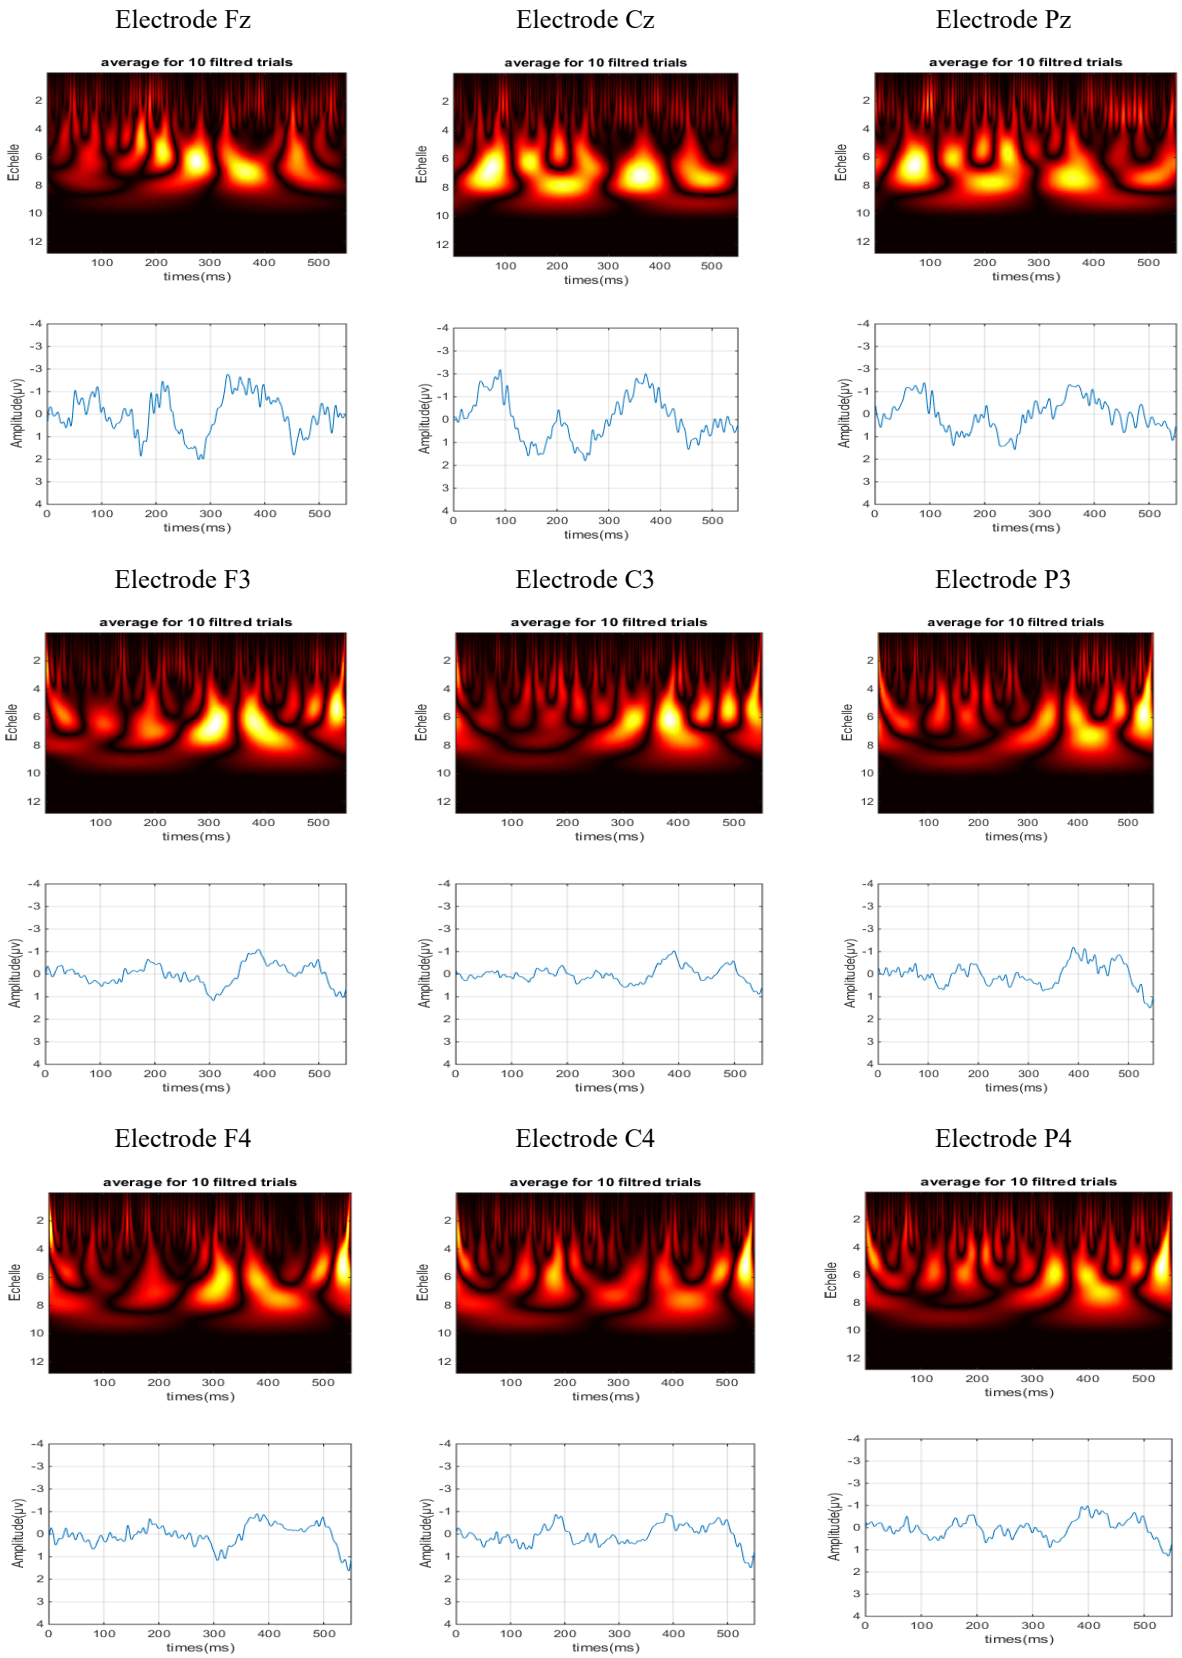

Figure 4. Scalograms of the average of 10 filtered ERP trials using db10-PCA.

Visual reading of these scalograms revealed the presence of light-colored vertical bands for medium and small scales, depicting smaller changes throughout the ERP signal. In particular, high-energy concentrations are observed in the time range of the N400 component [360; 470msec] and for scales between 3 and 8. Importantly, these regions correspond to a maximum energy around the position of the N400 component in the temporal representation of the ERP signal.

Based on these results and similar ones obtained by processing the entire set of data available for this study, the maximum energy localization in time and scale allowed us to define a qualitative criterion to detect the N400 occurrence and position. Moreover, we have demonstrated in our previous scientific works, that the primed Arabic words elicit smaller N400 components than unprimed Arabic words [2]. This result is confirmed by the use of the CWT technique. Indeed, for unprimed Arabic words, a high energy band is detected around 380 to 410 millisecond, that is, in a narrow range of about 30 milliseconds, whereas for primed words, this energy region is of very low intensity.

4. Conclusion

In this study we exploited the wavelets, as signal processing tools, to improve the quality of the ERP signals recorded during a semantic priming task in Arabic. We used the discrete wavelet transform to denoise the recorded signals. Moreover, the filtering procedure combined the DWT and the PCA methods to form a nonlinear filter that allowed us to improve the visual quality of ERP plots based on a few trials only. Importantly, using the SSIM, the SNR and MSE metrics, we demonstrated that 10th-order Daubachies wavelet of order 10, was the most efficient to improve the SNR and thus to reveal the occurrence of the N400 component. Finally, visual comparison with the results obtained using EEGLab tools, showed that our procedure allowed a clear improvement of the quality of the ERP plots.

In a second part, we used the continuous wavelet transform based on the Mexican Hat function to perform the time-scale analysis of the filtered ERPs. The resulting scalograms allowed us to define qualitative and quantitative criteria to detect the presence of the N400 component in the auditory and visual evoked signals. The qualitative criterion consists of visual reading of the energy density representation whereas the quantitative criterion is based on defining with acute precision the maximum of the N400 energy within time and scale positions. In this case, we found that, for unprimed Arabic words, a high energy band is detected between 3 and 8 on scale axis and in the time range [380; 410msec]. This last corresponds to the normal position of the N400 wave in the temporal representation of an ERP. In the case of primed Arabic words, a very low intensity energy region is present in the time range [360; 470msec].

Conflict of Interest

The authors declare no conflict of interest.

ABSTRACT

FM broadcast stations generate reverse intermodulation signals that cause communication problems between ATC controllers and pilots in the Air Traffic Control systems (ATC) in Thailand. In this paper proposes a balanced RF power amplifier using the improvement 3-dB quadrature hybrid couplers to reduce the reverse intermodulation of FM broadcasting systems. The mathematics analysis of the balanced RF power amplifier for two closely located FM stations shows that can reduce the reverse intermodulation products. A reverse signal from nearby FM stations travels into two amplifiers of a balanced amplifier that create intermodulation signals. The quadrature hybrid coupler in a balanced RF amplifier to provide intermodulation signals of two amplifiers have a 180˚ out-of-phase which cause reducing intermodulation signals. In this paper designs 3-dB quadrature hybrid couplers for a proposed RF balanced amplifier. The low-cost PCBs are used to make prototype couplers. The proposed couplers are provided experimental results of return losses that are lower than -15 dB. The directed port has a coupling coefficient -3.3 dB and the coupled port has a coupling coefficient -3.4 dB. The prototype couplers are applied to a balanced amplifier that obtains a maximum output power 210 watts with 17.20 dB gain. A proposed balanced RF amplifier is measured the reverse intermodulation products of with a situation of two closely located FM broadcast stations to compare with a single-stage class-C amplifier. The experimentation demonstrates of the transmitter using a balanced RF power amplifier that can reduce an intermodulation product 18.47 dBc.

1. Introduction

The RF power amplifiers are important components for wireless communication systems. The design techniques for RF amplifier can use classes A, B, C, and AB, etc. Each type of class-amplifiers has different features and performances. The class-C amplifiers are suitable for FM broadcasting systems because it has the output power and efficiency higher than other types. The disadvantage of class-C power amplifiers is non-linearity which creates harmonic and intermodulation signals. Harmonic signals are multiple of the fundamental frequency. It can be eliminated by using the Low Pass Filters. Intermodulation signals are unwanted signals of non-linear RF power amplifiers. When the power amplifier of FM station is injected by two frequencies which are generated intermodulation signal to fall into the other frequency ranges. The intermodulation products can be calculated from $2f_2$-f_1 and $3f_2$-$2f_1$ [1].

Although, the FM broadcast station uses an RF power amplifier with a single frequency. In practice, the signals from nearby FM broadcast stations can radiate to the own station. In Figure 1, two closely located FM broadcasting stations, the signal from a reverse transmitter radiates into a carrier transmitter via an antenna and transmission line in the reverse direction, called "Reverse Signal". The reverse signal travels until it present at the input of a carrier transmitter. So, the station own signal and the reverse signal create intermodulation signals, called "Reverse Intermodulation (RIM)".

The FM broadcast station uses a low pass filter in the final stage to block unwanted signals, such as harmonic and intermodulation signals. A low pass filter has a wide transition band, the frequency response to change from a pass-band to a stop-band. Which frequencies of intermodulation products are very close to a cut-off frequency point of the filter that cannot eliminate intermodulation products with a low pass filter. The FM broadcast station using the frequency band is 88-108 MHz that are close to the frequency band of Air Traffic Control (ATC) systems, using the frequencies between 108-137 MHz. Therefore, reverse intermodulation signals from FM station generates may be interferences communication between air traffic controllers and pilots, as shown in Figure 2. [2]

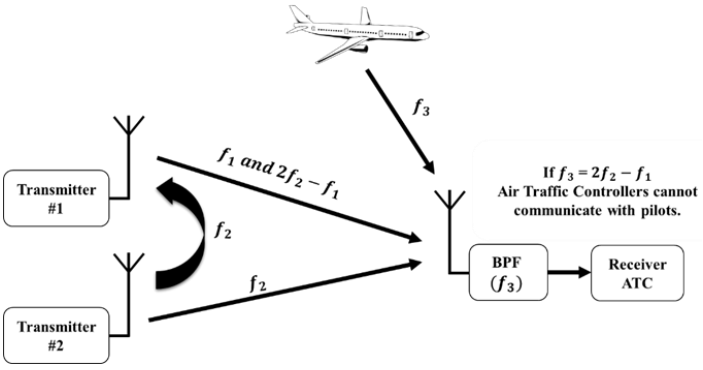

Figure 2: Intermodulation products interference to Air Traffic control systems

To overcome this problem, circulators or cavity bandpass filters are alternatives to reduce intermodulation products. It can block reverse signals from nearby stations and unwanted signals from the own station. Disadvantages of circulators and cavity bandpass filters are adding considerable cost, complexity and power loss to a system. As will be shown, none of the techniques available to reduce reverse intermodulation are particularly attractive.

This paper presents a balanced RF power amplifier using the improvement 3-dB quadrature hybrid couplers to reduce reverse intermodulation signals of FM broadcast station. The concept of balanced RF power amplifiers is structured from two identical quadrature couplers and two signal-stage amplifiers. The reverse signal from nearby FM stations radiates to the own station until it present at the input of two signal-stage amplifiers that generated intermodulation signals. The second quadrature hybrid coupler provides a 180˚ out-of-phase of two intermodulation signals from two amplifiers that can cancel intermodulation signals. The mathematics analysis of a balanced RF power amplifier for two closely located FM stations shows that can reduce the reverse intermodulation products, will be explained in section 3. In the previous work presents a design and implementation of the prototype 3-dB quadrature couplers [3]. In this work, prototype 3-dB quadrature couplers are included in a structure of a balanced RF power amplifier to reduce reverse intermodulation signals of FM broadcast station.

The quadrature hybrid couplers are an important component for a balanced RF power amplifier. Due to it can separate an input signal into two identical amplifiers and combines both output signals. The quadrature hybrid coupler has a very beneficial feature that can reduce a reverse intermodulation signal of FM broadcasting systems. The branch-line hybrid couplers are applied to traditional couplers for the balanced rf power amplifier. The branch-line is a simple type of quadrature couplers that are realized by using four transmission lines to construct a single-box coupler [4]-[5]. Each line in the single-box is a quarter-wavelength transmission line. The disadvantage of branch-line couplers is a large physical size because a quarter-wavelength transmission line determines the physical size of branch-line couplers. Especially, FM broadcasting systems use a low-frequency range that is a long transmission line that increases physical size. The large physical size is unsuitable to use for an RF power amplifier of the FM stations [6]-[10]. The quadrature hybrid couplers in this paper are structured by using the broadside-coupler stripline technique to reduce the size of couplers. Section 4 describes the design, implementation of quadrature hybrid couplers.

The prototype quadrature couplers are applied to a balanced RF power amplifier. The two identical single-stage amplifiers use a class-C RF amplifier with two MRF151 N-channel MOSFETs and operate at the frequency range of 88-108 MHz. Experimental results of the total output power, a frequency response of prototype balanced power amplifier will be presented in section 5. The situation of two closely located FM broadcast stations is used to create the reverse intermodulation signal. Two carrier transmitters that use a single-stage power amplifier and a balanced RF power amplifier have been measured. The FM broadcast station using a balanced power amplifier eliminates the intermodulation signals by using the phase-shifting property of the quadrature hybrid coupler. The reverse signals (f_R) from nearby FM stations and the intermodulation signals have a 180˚ out-of-phase which can be canceled the reverse signals and RIM signals without the cavity bandpass filters and circulators. Experimental results of the FM broadcast station using a balanced RF power amplifier comparing with single-stage RF power amplifier are presented in sections 6.

2. RF Power Amplifier for FM Broadcasting Systems

2.1. Class-C Power Amplifiers

The RF power amplifiers are an electronic circuit that transfers an input power to load such as the antenna by amplifying. FM broadcasting systems require high output power and efficiency. The Class-C amplifier offers the highest efficiency more than Class-A, Class-B, and Class-AB. The efficiency of Class-C amplifiers can be approximated about 70-80%. The disadvantage of Class-C amplifiers is non-linearity which has poor distortion qualities and generates harmonics [11]. When two signals are the input of an amplifier that creates intermodulation components (IM). The several techniques are presented reducing the intermodulation distortion by improved the RF power amplifiers, such as the feed-forward techniques [12], etc. They are

suitable to the multicarrier amplifiers which cannot eliminate the reverse signal from nearby FM broadcast stations.

2.2. Non-linear Distortion and Intermodulation Products

Non-linear distortions can be described in terms of a non-linear relationship between the input and output signals. The non-linearity creates several effects such as harmonic and intermodulation signals. Harmonic signals are unwanted signals which are included a number of integer multiples of an input frequency. Intermodulation signals occur when an input of non-linear systems are composed of two frequencies. FM broadcast stations use a Class-C amplifier that is a nonlinear system. Therefore, we can express by:

$$y(t) = \alpha_1 x(t)+\alpha_2 x(t)^2+\alpha_3 x(t)^3+\alpha_3 x(t)^4+\ldots \quad (1)$$

Where $y(t)$ represents the output, $x(t)$ represents the input and α_n represents the gain coefficient.

$$x(t) = A_1 \cos(2\pi f_1 t) + A_2 \cos(2\pi f_2 t) \quad (2)$$

If an input signal consists of two signals with different frequencies that are applied to a nonlinear system (1). The resultant of the output can be expressed as:

$$\begin{aligned} y(t) = {} & \left[\frac{\alpha_2 A_1^2}{2}+\frac{\alpha_2 A_2^2}{2}\right]+ \\ & \left[\alpha_1 A_1+\frac{3\alpha_3 A_1^3}{4}+\frac{3\alpha_3 A_1 A_2^2}{2}\right]\cos(2\pi f_1 t)+ \\ & \left[\alpha_1 A_2+\frac{3\alpha_3 A_2^3}{4}+\frac{3\alpha_3 A_1^2 A_2}{2}\right]\cos(2\pi f_2 t)+ \\ & \left[\frac{\alpha_2 A_1^2}{2}\right]\cos(2\pi 2f_1 t)+\left[\frac{\alpha_2 A_2^2}{2}\right]\cos(2\pi 2f_2 t)+ \\ & \left[\frac{3\alpha_3 A_1^2 A_2}{4}\right]\cos\left(2\pi t(2f_1+f_2)\right)+ \\ & \left[\frac{3\alpha_3 A_1 A_2^2}{4}\right]\cos\left(2\pi t(2f_2+f_1)\right)+ \\ & \left[\frac{3\alpha_3 A_1^2 A_2}{4}\right]\cos\left(2\pi t(2f_1-f_2)\right)+ \\ & \left[\frac{3\alpha_3 A_1 A_2^2}{4}\right]\cos\left(2\pi t(2f_2-f_1)\right)+\ldots \end{aligned} \quad (3)$$

From (3), the output that does not contain only the fundamental frequency. The nonlinearity gives other frequencies adding to output components. The second term of this expression shows the amplitude of the fundamental frequencies. The third term shows the second-order harmonics. The fourth and fifth terms show third-order intermodulation distortions. The terms of $2f_1$-f_2, $2f_2$-f_1 are third-order intermodulation products. The intermodulation signals are very close to fundamental frequencies which are cannot be easily filtered.

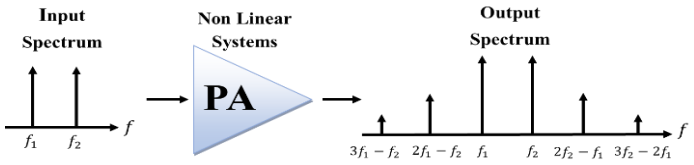

Figure 3: Intermodulation Products of nonlinear systems

3. Balanced RF Power Amplifier

The balance RF power architecture shows in Figure 4. Two identical signal-stage amplifiers are parallel connecting with two quadrature hybrid couplers. Both amplifiers share the same input signal ($x_{in}(t)$) which is fed through the quadrature hybrid coupler. The first quadrature hybrid coupler on the input is the splitter that divides an input signal (from port 1) into two equal amplitude outputs (port 2 and port 3) with a 90˚ phase difference. The input signal of the first amplifier (PA1) has been 90˚ phase-shifted and the signal of the second amplifier (PA2) has been 180˚ phase shifted. Two amplifiers have the same bias voltage that provides equal output power capability. The second quadrature hybrid coupler on the output is a combiner that is connected to the output stages of two amplifiers. which an output signal of PA1 connect to port 1 and an output signal of PA2 connect to port 4. Both output signals are in-phase on port 3 that means output signals from two amplifiers are combined. While output signals are out-of-phase at port 2 that mean the output signals from two amplifiers are canceled. A port 2 of a hybrid coupler is an isolation port that is terminated by match load 50Ω.

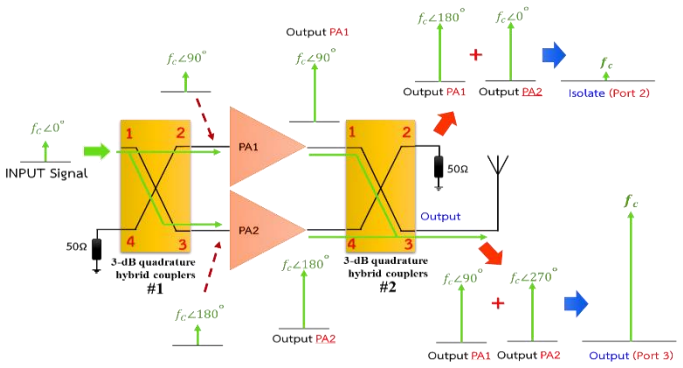

Figure 4: The balanced RF power amplifier structures

3.1. Analysis of the Balanced RF Power Amplifier to Reduce Reverse Intermodulation Products

This paper proposes the balanced RF power amplifier that reduces the reverse intermodulation products. From Figure 5, an input signal is $x_i(t)$ which represents the FM modulation signal. The input signal is fed through the first quadrature hybrid coupler which separates an input signal into two equally signals with a 90˚ phase difference, we can express by:

$$x_{i1}(t) = \frac{1}{2}\cos(2\pi f_C t+90^\circ) \quad (4)$$

$$x_{i2}(t) = \frac{1}{2}\cos(2\pi f_C t+180^\circ) \quad (5)$$

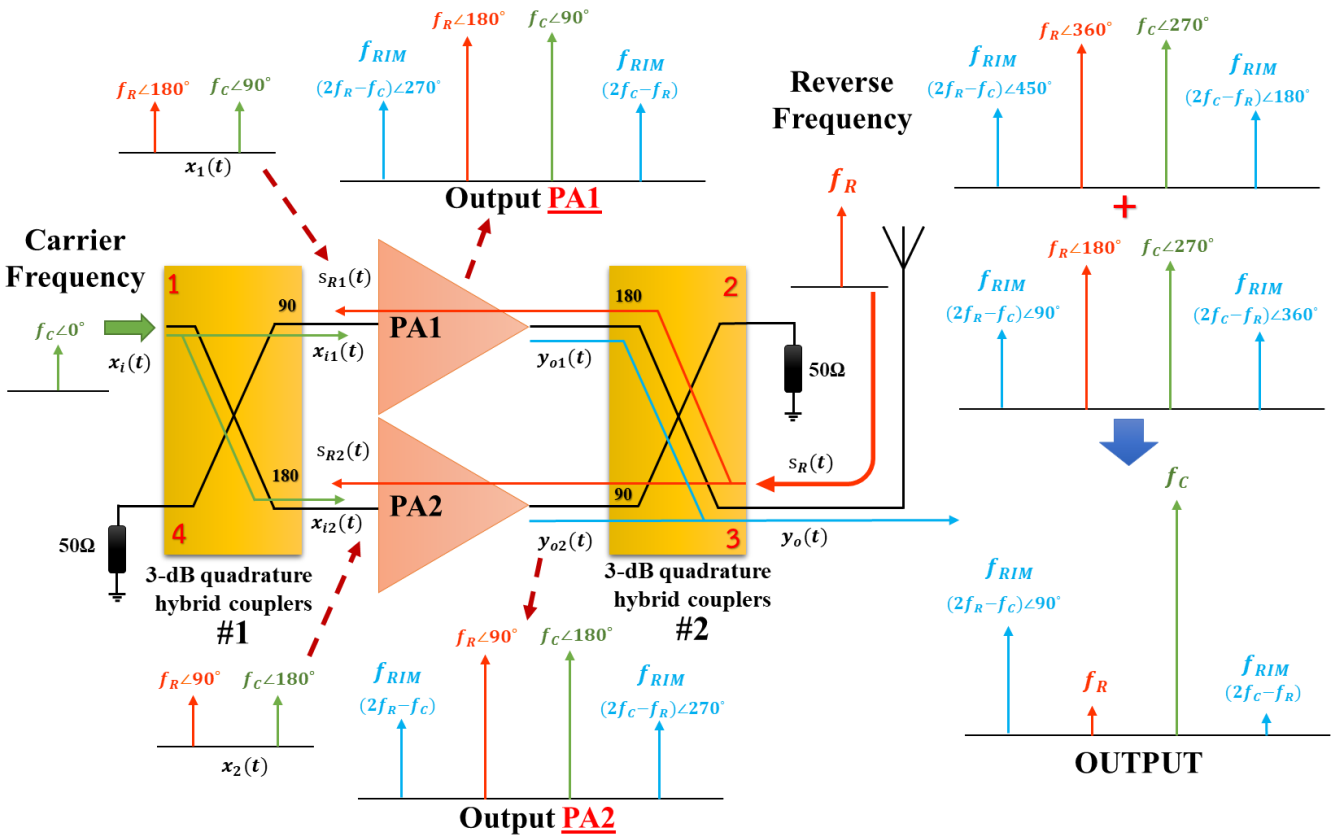

Figure 5: The analysis of a balanced RF power amplifier to reduce reverse intermodulation products

Where $x_{i1}(t)$ is an input signal for the first power amplifier and the $x_{i2}(t)$ is an input signal for the second power amplifier. The f_C represent a carrier frequency. When the reverse signal ($S_R(t)$) from nearby FM station travels in a reverse direction until it presents at the output stage, the port 3 of a second quadrature hybrid coupler. A similar expression for the output stage of a balanced amplifier, a second quadrature hybrid coupler is the symmetric 4-port microwave device that separates a reverse signal to two equally signals with a relative phase difference of 90˚. We can express both reverse signals by:

$$S_{R1}(t) = \frac{1}{2}\cos(2\pi f_R t + 180^\circ) \quad (6)$$

$$S_{R2}(t) = \frac{1}{2}\cos(2\pi f_R t + 90^\circ) \quad (7)$$

Where $S_{R1}(t)$ and $S_{R2}(t)$ are the respective reverse signals traveling into two power amplifiers and the f_R is a frequency of a reverse signal. Both reverse signals travel in the reverse direction through the coupler until they present at the input of each amplifier. Input signals ($x_i(t)$) together with the reverse signals ($S_{Ri}(t)$) present at an input of each power amplifiers, can be written as follows:

$$x_1(t) = x_{i1}(t) + S_{R1}(t) \quad (8)$$

$$x_2(t) = x_{i2}(t) + S_{R2}(t) \quad (9)$$

The $x_1(t)$ and $x_2(t)$ are the respective input signals of two power amplifiers. We use $x_1(t)$ and $x_2(t)$ to a nonlinearity equation of power amplifiers (1). Therefore, a resultant of the output can be expressed as:

$$\begin{aligned} y_{o1}(t) = {} & [\alpha_2] + \left[\alpha_1 + \frac{9\alpha_3}{4}\right]\cos(2\pi f_R t + 180^\circ) + \\ & \left[\alpha_1 + \frac{9\alpha_3}{4}\right]\cos(2\pi f_C t + 90^\circ) + \\ & \left[\frac{\alpha_2}{2}\right]\cos(2\pi 2f_R t + 180^\circ) + \\ & \left[\frac{\alpha_2}{2}\right]\cos(2\pi 2f_C t + 90^\circ) + \\ & \left[\frac{3\alpha_3}{4}\right]\cos(2\pi t(2f_R + f_C) + 90^\circ) + \\ & \left[\frac{3\alpha_3}{4}\right]\cos\left(2\pi t(2f_C + f_R)\right) + \\ & \left[\frac{3\alpha_3}{4}\right]\cos(2\pi t(2f_R - f_C) + 270^\circ) + \\ & \left[\frac{3\alpha_3}{4}\right]\cos\left(2\pi t(2f_C - f_R)\right) + \\ & \left[\frac{\alpha_3}{4}\right]\cos(2\pi 3f_R t + 180^\circ) + \\ & \left[\frac{\alpha_3}{4}\right]\cos(2\pi 3f_C t + 90^\circ) + \ldots \end{aligned} \quad (10)$$

$$y_{o2}(t) = [\alpha_2] + \left[\alpha_1 + \frac{9\alpha_3}{4}\right]\cos(2\pi f_R t + 90^\circ) + \quad (11)$$

$$\left[\alpha_1 + \frac{9\alpha_3}{4}\right]\cos(2\pi f_C t + 180^\circ) +$$

$$\left[\frac{\alpha_2}{2}\right]\cos(2\pi 2f_R t + 90^\circ) +$$

$$\left[\frac{\alpha_2}{2}\right]\cos(2\pi 2f_C t + 180^\circ) +$$

$$\left[\frac{3\alpha_3}{4}\right]\cos\left(2\pi t(2f_R + f_C)\right) +$$

$$\left[\frac{3\alpha_3}{4}\right]\cos(2\pi t(2f_C + f_R) + 90^\circ) +$$

$$\left[\frac{3\alpha_3}{4}\right]\cos\left(2\pi t(2f_R - f_C)\right) +$$

$$\left[\frac{3\alpha_3}{4}\right]\cos(2\pi t(2f_C - f_R) + 270^\circ) +$$

$$\left[\frac{\alpha_3}{4}\right]\cos(2\pi 3f_R t + 90^\circ) +$$

$$\left[\frac{\alpha_3}{4}\right]\cos(2\pi 3f_C t + 180^\circ) + \ldots$$

The $y_{o1}(t)$ and $y_{o2}(t)$ are respective output signals of two power amplifiers. Both output signals are several effects of a nonlinear distortion that contains the term of the carrier frequency, the reverse frequency, the harmonics, and the third-order intermodulation products. Both output signals are combined by a second quadrature coupler which is connected to an output signal $y_{o1}(t)$ at port 1 and an output signal $y_{o2}(t)$ at port 4. The term of a reverse frequency (f_R) and the term of intermodulation product ($2f_C$-f_R) are out-of-phase on port 3 of a second quadrature coupler. Thus, the reverse signal and the intermodulation signal are canceled. A similar expression, a term of a carrier frequency (f_C) is in-phase on port 3. So that the total output power can be increased and can be expressed as:

$$y_o(t) = 2\alpha_2 + 2\left[\alpha_1 + \frac{9\alpha_3}{4}\right]\cos(2\pi f_C t + 270^\circ) + \quad (12)$$

$$\alpha_2\cos(2\pi 2f_C t + 270^\circ) +$$

$$\left[\frac{6\alpha_3}{4}\right]\cos(2\pi t(2f_C + f_R) + 180^\circ) +$$

$$\left[\frac{6\alpha_3}{4}\right]\cos(2\pi t(2f_R - f_C) + 90^\circ) +$$

$$\left[\frac{\alpha_3}{4}\right]\cos(2\pi 3f_C t + 270^\circ) + \ldots$$

The math model of balanced RF power amplifiers with a carrier frequency (f_C) 100 MHz and a reverse frequency (f_R) 95 MHz is simulated. The line spectrums of simulation results show in Figure 6. The intermodulation signals in term of ($2f_C$-f_R) and a reverse signal are eliminated.

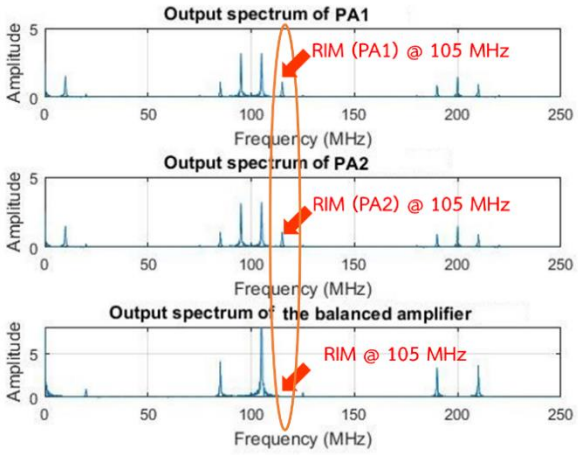

Figure 6: Simulation results of the math model based on a balanced RF power amplifier

3.2. Intermodulation Measurements

The third-order intermodulation distortion creates additional frequencies in terms of $2f_1 - f_2$ and $2f_2 - f_1$. The measurement is described by the power ratio between the power level of a fundamental frequency and intermodulation products, can be expressed as:

$$P_{IM3}(\text{dBc}) = P_C(\text{dBm}) - P_S(\text{dBm}) \quad (13)$$

Where the P_C is a power of a fundamental frequency and the P_s is the power of a third-order intermodulation product. The P_{IM3} is the intermodulation level (dBc) of an intermodulation product relative to a power level of the fundamental frequency.

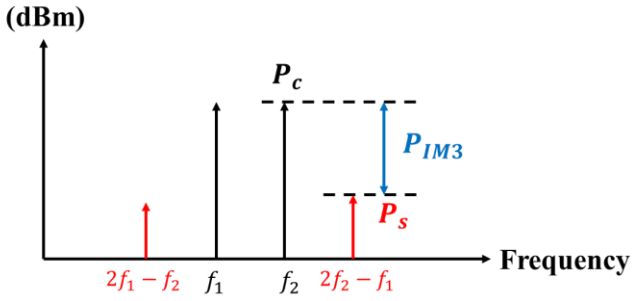

Figure 7: Intermodulation Distortion Measurement

4. Design and Implementation of 3-dB Quadrature Hybrid Couplers

The conventional couplers for balance power amplifiers use branch-line hybrid couplers because it is simple and easy to make. The size of the branch-line couplers is increased when using in an FM frequency range. The reducing of the physical size of branch-line couplers, many methods have been suggested. The slow-wave transmission line technique can make short-wavelength transmission lines by reducing phase velocity [13]-[17]. The increasing of inductances and capacitances with the same ratio causes reducing phase velocity while a characteristic impedance of the coupler is unchanged. Also, lumped-element hybrid couplers use for reducing the circuit size of branch-line hybrid couplers [18]-[19]. Lumped-element circuits are realized by using

LC-microstrip resonance circuits to replace the line sections of branch-line couplers. The lumped-element circuits have a characteristic impedance equivalent to the quarter-wavelength transmission line while the circuit size of lumped-element circuits is shorter than the branch-line couplers.

Lange couplers are two parallel microstrip lines with alternate lines on the same surface [20]- [21]. The alternate lines can reduce the occupied area of couplers. However, after the circuit of couplers have been processed, the circuit requires wire bonders for bonding the conductor spacing of coupler lines [22]. Wire bonders increase the manufacturing processes which are difficult to realize. Broadside-coupler striplines are the hybrid couplers without bonding wires [23]. The broadside-coupler structure comprises two parallel quarter-wavelength transmission lines on the opposite surface. A coupled line is a floating transmission line overlay on a signal line. The length of a coupled line determines the physical size of the hybrid couplers. It can be significantly reduced the occupied area of couplers by using symmetrical circuits of two parallel striplines with the opposite surface and using tightly stripline. The coupling coefficient of couplers is increased by using printed circuit broads with a small substrate thickness, e.g., 0.1mm substrate thickness, which has expensive cost and is difficult to find [24]-[29].

The broadside-coupled striplines in this paper consist of two parallel lines which are embedded in a dielectric between two ground planes [26]-[28], as shown in Fig. 8. The energy transfer from a signal line to a coupler line occurs at the through parallel striplines.

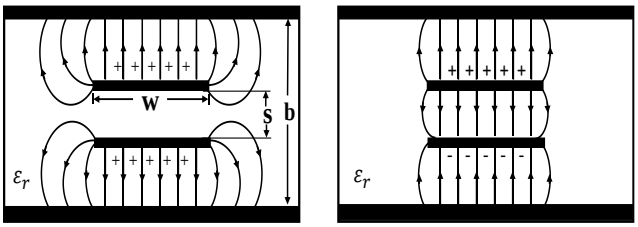

Figure 8: voltages and currents on two striplines.
(a) Even-mode field distribution.
(b) Odd-mode field distribution.

The configuration as shown in Fig. 8 is used to design a broadside coupler. The coupling coefficient can be calculated in terms of a characteristic impedance (Z_0). The voltage coupling coefficient (C) is calculated from the characteristic impedances of even-mode (Z_{0e}) and odd-mode (Z_{0o}) which can be expressed as [30]:

$$Z_{0e} = Z_0\sqrt{\frac{1+C}{1-C}} \tag{14}$$

$$Z_{0o} = Z_0\sqrt{\frac{1-C}{1+C}} \tag{15}$$

According to Cohn [31]-[33], the even-mode and odd-mode characteristic impedances with respect to ground planes can be calculated by:

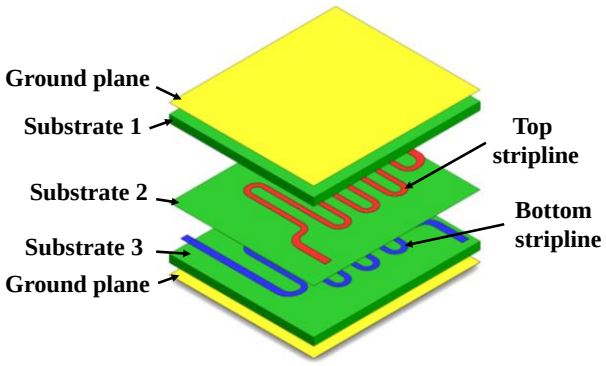
$$Z_{0e} = \frac{188.3}{\sqrt{\varepsilon_r}}\frac{K(k^{\square})}{K(k)} \tag{16}$$

$$Z_{0o} = \frac{296.1}{\sqrt{\varepsilon_r}\frac{b}{s}\,tan^{\square-1}(k)} \tag{17}$$

Where $K(k)$ and $K(k^{'})$ are complete elliptic integrals of the first kind and $k' = \sqrt{1-k^2}$. The ground plane spacing (b) and the spacing between two parallel striplines (s) are used to calculate the k parameter which can be calculated by:

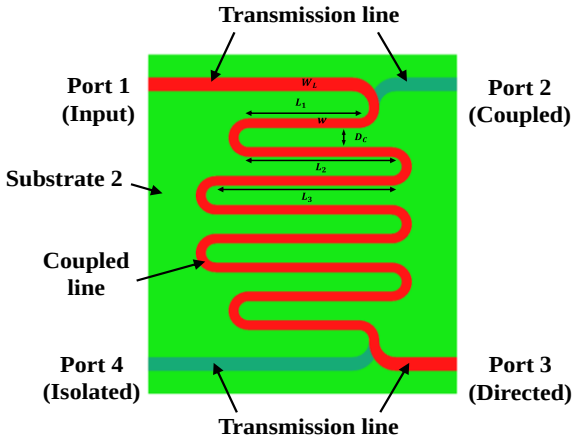
$$\frac{K(k')}{K(k)} \approx \frac{2}{\pi}\ln\left[\frac{4}{k}\right] \tag{18}$$

Thus, we can calculate the stripline width (w) from:



$$\frac{w}{b} = \frac{1}{\pi}\left[\ln\left(\frac{1+R}{1-R}\right) - \frac{s}{b}\ln\left(\frac{1+\frac{R}{k}}{1-\frac{R}{k}}\right)\right] \tag{19}$$

$$R = \sqrt{\left[\frac{\left(k\frac{b}{s}-1\right)}{\left(\frac{1}{k}\frac{b}{s}-1\right)}\right]} \tag{20}$$



The circuit design of a 3-dB quadrature hybrid coupler, as shown in Figure 9. The top stripline is embedded between the substrate 1 and the top ground plane. The bottom stripline is embedded between the substrate 3 and the bottom ground plane. The space between the top stripline and the bottom stripline is inserted by a substrate 2, as shown in Figure 9 (a). Assume, the input signal is injected into port 1, called "input port". The bottom stripline passes an input signal to port 3, called "directed port". Also, an input signal is coupled via the top stripline to port 2, called "coupled port". An input signal is divided by a 3-dB quadrature hybrid coupler into two equal amplitude outputs with a 90˚ relative phase difference. The input and coupled signals are canceled at the port 4 that has no signal going out from this port, called "isolated port".

The hybrid coupler is implemented at the frequency of 98 MHz, It is a center frequency of FM broadcast systems. The FR-4 printed circuit broads (PCB) are used to make prototype couplers. A dielectric constant (ε_r) of an FR-4 PCB is 4.6 and a substrate thickness (s) is 0.8 mm. Assuming the characteristic impedance (Z_0) is 50 Ω, coupling coefficients (C) is 0.707 The summarize calculated parameters from (14) – (20) are the stripline width (w) 2.54 mm. The ground plane spacing (b) is 10.4 mm. The length of a coupled line (L) is 385 mm. The circuit of a 3-dB quadrature hybrid coupler using tightly microstrip line, as shown in Figure 9(b). This circuit designed is simulated with the CST software to verify a proposed hybrid coupler.

Due to the general FR-4 PCBs have 1.6 mm and 0.8 mm substrate thickness while the dimension of ground plane spacing (b) of the proposed coupler is 10.4 mm. Thus, we choose an FR-4 PCB with 1.6 mm substrate thickness to make substrate 1 and substrate 3 which can be made by using PCBs piling up to three layers. The constructed of a prototype coupler is shown in Fig. 9. The overall physical dimension is 75×85 mm.

4.1. Measurement Results of the Quadrature Hybrid Couplers

In this section presents the experimental results of the prototype 3-dB hybrid coupler. The frequency range between 25 MHz to 150 MHz has return losses lower than -15dB, as shown in Figure 11. The center frequency of an FM broadcasting systems (98MHz) provides a maximum coupling coefficient, as shown in Figure 12. The coupling coefficient between a signal line and a coupler line is -3.4 dB (S21) and The transmitted coefficient between a signal line and a coupler line is -3.3 dB (S31). The relative phase difference between the two output ports is 90 ± 2˚, as shown in Figure 13. The measured isolations (S41) are lower than -17 dB. The input and coupled signals are canceled at the port 4.

5. Design and Implementation of Balanced RF Power Amplifiers

The balanced power amplifier was implemented by using two prototype 3-dB quadrature hybrid couplers. The first coupler divides an input signal into two identical single-stage amplifiers. The amplifier modules were designed for FM broadcasting systems, at 88-108 MHz frequency range, based on class-C push-pull amplifiers. The single-stage amplifier consists of 2 x MRF151 N-channel MOSFET. The bias configuration set a drain-source voltage (Vds) = 48V, drain-source current (Ids) = 0.3A and gate-source voltage (Vgs) = 2.9V. Maximum output power is 250-W with gain 14 dB. Two amplifiers have the

same bias voltage which provides an equal output power capability. The output signals from two amplifiers are combined by the second quadrature coupler. The total power is transmitted to the antenna systems.

The prototype of a balanced power amplifier shows in Figure 14. The port 1 of the first couplers is an input port and the port 3 of the second couplers is an output port. Isolated ports, port 4 of first couplers and port 2 of seconded couplers, are terminated by a dummy load 50 Ω. When the input and output impedance is poorly matched with the RF power amplifiers that are propagated signals reflected into a dummy load.

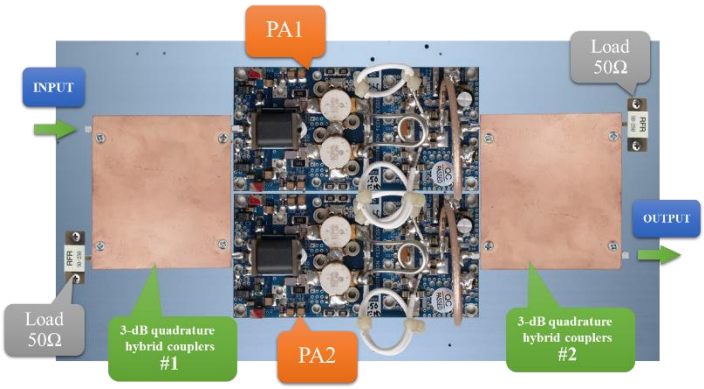

Figure 14: The configuration of a prototype balanced RF power amplifier

5.1. Measurement Results of the Balanced RF Power Amplifiers

The ROHED&SCHWARZ NRP2 Power meter is used to measure a balanced RF power amplifier. The Agilent E4421B signal generator creates an FM modulation signal and injects to the input port of a balanced amplifier. The first measurement focuses on the output power of each single-stage amplifier. The proposed balanced amplifier was tested at frequency 105 MHz that is a reverse frequency. Output powers of each amplifier module compared to the input power level displays in Figure 15. when the input power level is 4 watt that provides the output power of two amplifiers approximately 116.20 watts and 118.90 watts respectively. The line curves of two amplifiers have been overlapped. The result shows that two amplifiers are equal output power capability which can be combined.

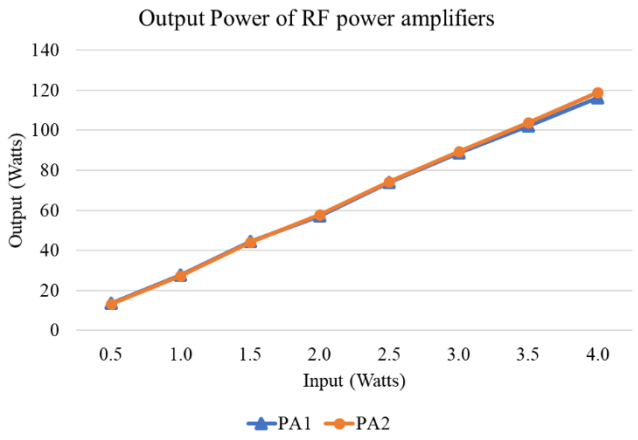

Figure 15: Measured results of the output power of each amplifier module

The second measurement focuses on the total output power of a balanced RF power amplifier. The total power is realized by the sum of two signals from two single-stage amplifiers that use the second quadrature hybrid coupler. The prototype balanced amplifier obtains an output power of 210 watts with a gain of 17.20 dB when the input power level is 4 watts. The output power has been dropped off 25.1 watts from sum signals of two amplifiers due to the insertion loss of the coupler at the output stage.

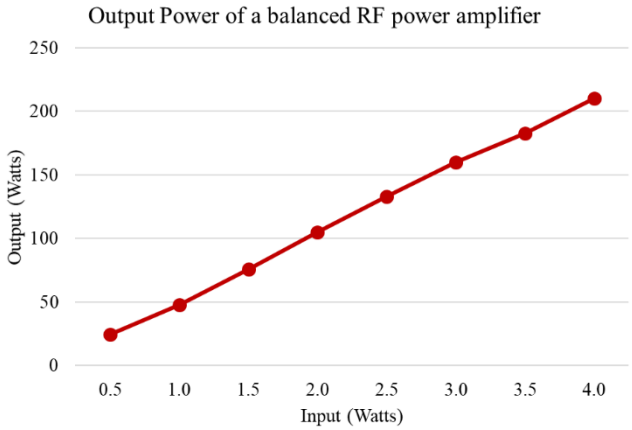

Figure 16: Measured results of the balanced RF power amplifier

6. Measurement Results of a Balanced RF Power Amplifier using to Reduce Reverse Intermodulation Products

6.1. Measurement Setup

This section presents experimental results of the FM broadcast station using a balanced RF power amplifier to reduce the reverse intermodulation. A practical setup, as shown in Figure 17, is used to demonstrate the situation of two closely located FM broadcast stations. The one FM transmitter generates a reverse frequency (f_R) that is transmitted 500 watts output power at 99.50 MHz. Another FM transmitter generates a carrier frequency (f_C) at 105.00 MHz. The two parallel antenna systems for a reverse frequency and a carrier frequency are installed in the same tower which has a height 60 meter. This configuration provides a maximum level of reverse intermodulation products. The reverse transmitter uses a cavity bandpass filter in the output stage which ensures to block unwanted signals from this transmitter.

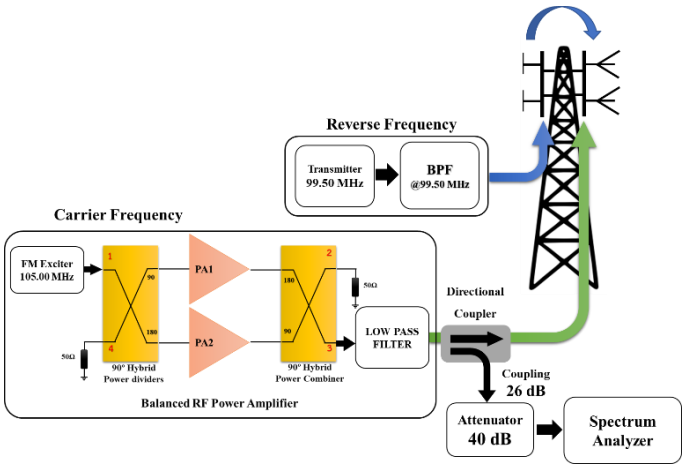

Figure 17: Measurement setup to demonstrate the situation of two closely located FM broadcast stations.

Two transmitters are measured in this research. The first transmitter uses a single-stage RF power amplifier, based on a class-C push-pull, and the second transmitter uses a prototype balanced amplifier in this research. Two transmitters are used to generate a carrier frequency (f_C) that is transmitted 200 watts output power at 105.00 MHz. Almost output signals from a transmitter is measured via a directional coupler with a coupling value of 26 dB and an attenuator of 40 dB. Intermodulation products are provided in terms of $2f_1 - f_2$ and $2f_2 - f_1$ that are a frequency of 94.00 MHz and 110.50 MHz respectively. Since the frequency of 110.50 MHz is out of an FM frequency band and falls into the frequency range of Air Traffic Control systems. Therefore, the measurement results consider the intermodulation product in terms of $2f_2 - f_1$ only.

6.2. Measurement Results of the FM transmitters using a single-stage power amplifier.

Measurement results of a carrier transmitter using a single-stage power amplifier present in Figure 18. The carrier transmitter transmits an FM modulation signal that is the frequency of 105.00 MHz without cavity bandpass filters. The signal strength of a reverse frequency, at the frequency of 99.50 MHz, is -42.35 dBm that is a signal traveling until it present at the output state of the carrier transmitter, port 3 of the second quadrature coupler. The output power of a carrier frequency at 105.00 MHz is -17.55 dBm and the intermodulation level at 110.50 MHz is 30.87 dBc.

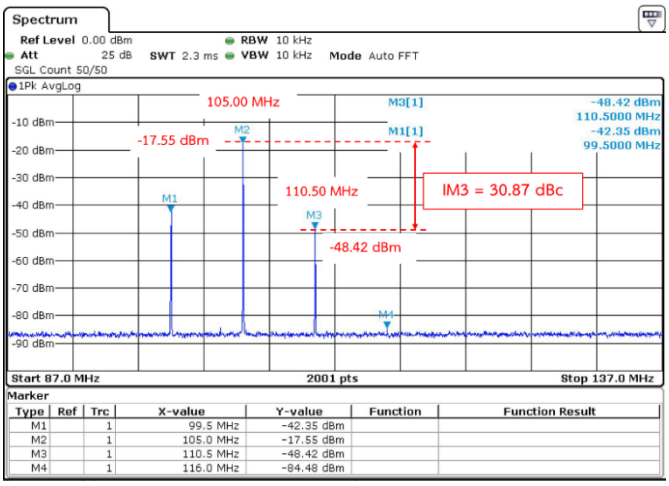

Figure 18: Intermodulation level of the FM transmitter using a single-stage RF power amplifier

6.3. Measurement Results of the FM transmitters using a Prototype Balanced RF Power Amplifier

The FM transmitter using a prototype of a balanced RF power amplifier is measured that is compared with a single-stage RF power amplifier. The output power of a balanced amplifier must be adjusted equal to a single-stage RF power amplifier. From Figure 17, the frequency spectrum shows that the signal strength of a reverse frequency at 99.50 MHz is -50.89 dBm which is decreased by 8.54 dBm. The output power of a carrier frequency at 105.00 MHz is -16.50 dBm and the intermodulation level is 49.34 dBc. Table 1 shows a comparison of the measurement results of two FM transmitters that use a single-stage RF power amplifier and a balanced RF power amplifier. It shows that both transmitters provide the same power level which is approximate -17 dBm. A power level of a reverse frequency is less than a single-stage RF power amplifier. The balanced RF power amplifier provides a good performance that improvements an intermodulation level from 30.84 dBc to 49.34 dBc. Measurement results are according to the analysis in section 3. The results show the mitigation of an intermodulation signal that is approximate 18.47 dBc without cavity bandpass filters. The mitigation intermodulation signal is difficult to obtain a maximum reduction due to the quadrature hybrid couplers have slightly different amplitudes and phases.

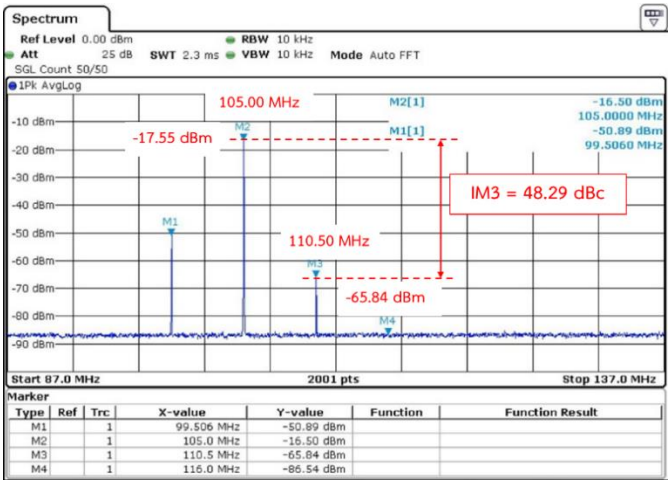

Figure 19: Intermodulation level of the FM transmitter using an FM transmitter using a Balanced RF Power Amplifier

Table 1: Measurement results of two FM transmitters.

	Signal Strength		
Frequency (MHz) / Amplifier types	99.50 (dBm)	105.00 (dBm)	110.50 (dBc)
The single-stage RF power amplifier	-42.35	-17.55	30.87
The balanced RF Power Amplifier	-50.89	-16.50	49.34
Δ	-8.54	1.05	18.47

7. Conclusions

This paper proposes a balanced RF power amplifier using the improvement 3-dB quadrature hybrid couplers to reduce the reverse intermodulation of FM broadcast stations. The balanced RF power amplifier was implemented by using the prototype 3-dB quadrature hybrid couplers. The FR-4 low-cost PCB with a broadside-coupled striplines technique is chosen to construct prototype couplers that can reduce the overall size of a hybrid coupler and suitable to use for balanced RF power amplifies. Experimental results of the prototype coupler, The return loss is lower than -15 dB. The coupled port has a coupling coefficient -3.4 dB and the directed port has a coupling coefficient -3.3 dB. The phase difference between a coupled and directed port is $90 \pm 2^{\circ}$. Isolation values are lower than -17 dB. The overall size of the prototype couplers is 75x 85 mm. We apply a prototype 3-dB quadrature hybrid couplers to a balanced power amplifier which are structured from two identical quadrature couplers and two signal-stage amplifiers. The two identical single-stage amplifiers use a class-C RF amplifier with the MRF151 N-channel MOSFET and operate at the frequency range of 88-108 MHz. A balanced

amplifier obtains an output power of 210 watts with a gain of 17.20 dB when the input power level is 4 watts.

The situation of two closely located FM broadcast stations is used to create the reverse intermodulation signal. The one transmitter generates a reverse signal (f_R) at 99.50 MHz that is transmitted 500 watts output power and another transmitter generate a carrier signal (f_C) at 105.00 MHz. The antenna systems for two frequency are installed in the same tower which has height 60 meters. Two carrier transmitters which use a balanced RF power amplifier and a single-stage RF power amplifier are measured. The carrier transmitter using a balanced RF power amplifier improvements an intermodulation level from 30.84 dBc to 49.34 dBc. The results show the mitigation of an intermodulation signal approximate 18.47 dBc without cavity bandpass filters. The mitigation intermodulation signal is difficult to obtain a maximum reduction due to the quadrature hybrid couplers have slightly different amplitudes and phases.

ABSTRACT

The entire electrical system is changing at an abrupt speed since its beginning. With the rapid advance of renewable energies (which are constantly subject to fluctuations), the electricity generation is distributed to countless locations. The traditional model of the unidirectional flow of electricity is leaning towards multidirectional flows. This situation needs significant changes in the transport infrastructure of the electrical power system and mode of operation. Technological advancements are making a smarter and more organized management system of electricity supply and demand. This development needs to incorporate modern communication, monitoring, and control capabilities, along with the intelligent transport, generation, and storage value chain. Digital substations integrate thousands of sensors by providing greater comfort, self-reliance, availability, and safety while at the same time reducing costs, risks, and environmental damage. Conventional power system lacks digital communication, remote monitoring & control, and consumer participation. Fiber-optic cabling in digital substations will attain not only real-time data transmission but also remote maintenance. The comparison between conventional and digital substations has also been presented in this work along with latest trends in smart protection. Electronic protection and control devices based on a microprocessor, communicating with cloud servers, will enhance the flexibility to control and monitor the digital substations. A significant amount of data generated by components in the electrical substations will allow greater sophistication of the monitoring, diagnostic, protection and optimization capabilities of the facilities. The goal for the review of said advancements is to have a smart electrical system with greater efficiency and better user experience.

1. Introduction

The existing grid infrastructure seems to meet part of the expectations (from traditional and renewable generation to transport and part of the distribution), but it must improve significantly from the end user and the functionalities expected from it. The forecasts indicate moderate growth in demand, a substantial increase in renewable energies and a need for firm and flexible power [1]. Consequently, a new concept of an electrical network, i.e., "intelligent network" emerges. The basic definition of "intelligent networks" may correspond to "Electric networks that intelligently integrate the behavior and actions of all the actors connected to them (those who generate electricity, those who consume it and who perform both actions) to provide a safe, economical and sustainable electricity supply"[2]. In such networks, very advanced integrated systems are used in the process of supplying electricity at all levels. The function of these integrated systems is to protect the components of the electrical system, control of the power flow and the monitoring of the process. For example, electrical system automation devices are integrated into communication networks to exchange information between various devices, as well as with supervisory systems. The technological trends of the integrated systems in the automation of electrical systems will be determined by three different technological trends such as electronic Integration, integration of switching equipment and data communication [3].

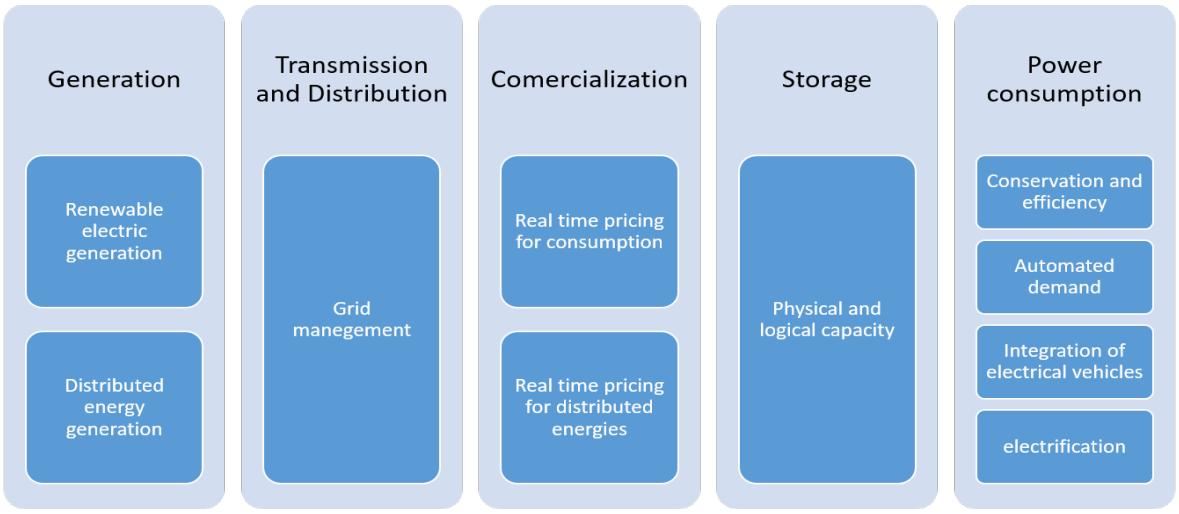

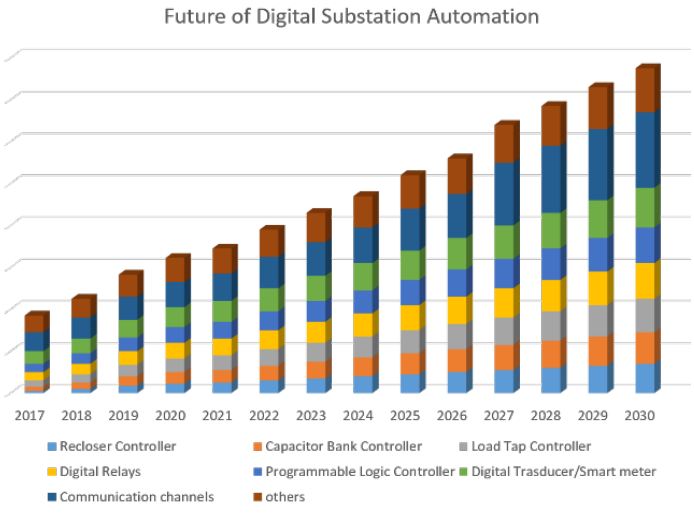

Figure 1. Challenges for current grid topology.

In the last years, an extensive research of energy production based on fossil energy sources has been performed. Fossil fuel sources have been exploited believing that there is an infinite availability of resources, but these sources cause huge damage to environment. The old energy model based on fossil fuel energy involved a chain of processes like generation, distribution, transportation, and consumption. However, to meet the consumer demand, it is necessary to upgrade the above energy model to distributed energy generation. This new energy model (Figure 1) will support variety of energy sources and an increase in the use of renewable energy and efficiency.

The main advantage of the recent energy model is distributed energy generation system. This system allows individuals to generate energy at micro-level and link to the national grid [4], which drastically reduces losses caused by the energy transport. This system facilitates the connections of all kinds of renewable energies to the system, which will ultimately improve the power system. This is possible by promoting the integration of non-manageable energies such as wind or solar power and by using energy storage devices that will be able to charge and discharge in the network. Keeping in mind the future growth and energy trends, the future projection of digital substations is provided in Figure 2.

To carry out all the actions mentioned previously, the grid topology must [5], [6] have following features.

- Allow self-management of incidents, to deal with the defects that have occurred in the system and guarantee the electric flow in all the points.
- Be equipped with strength against attacks and destabilizations.
- Increase the flow of consumer participation, promoting the local generation process and providing excess energy to the network during peak hours.
- Have the capacity to supply power of adequate quality to the digital era. The higher number of generation points will allow the delivery of different energy qualities for each type of application.
- Fix a variety of generation and storage modes, thanks to the micro-grids and the generation of the energy that is distributed.
- Facilitate the flowering of markets, due to the inclusion of new elements in the network such as the electric vehicle, a more sizeable number of renewable energies, etc.
- Perform a more competent optimization of your assets and operation; this is achieved by automating all the elements that are involved.

2. Composition of Smart Grids

The Smart Grid concept refers to intelligent management of electricity using computer and communication technologies. The smart grid concept encompasses many interconnections between the different elements of the generation, transmission and distribution of electricity. In addition, the concept is strongly linked to the inclusion of unconventional renewable energies (both large-scale with large generators and household level) in the electricity grid, thus changing the current paradigm of uniqueness in generation towards a distributed generation concept.

Smart grid is smart energy network that integrates all the parameters of generation, transmission, distribution and

consumption. It also provides advanced control processes to achieve an efficient and sustainable supply (Figure 3) [7]. The motivation behind creation of smart grid is: care for the environment, reliability and quality of supply and improvement in the operation of networks.

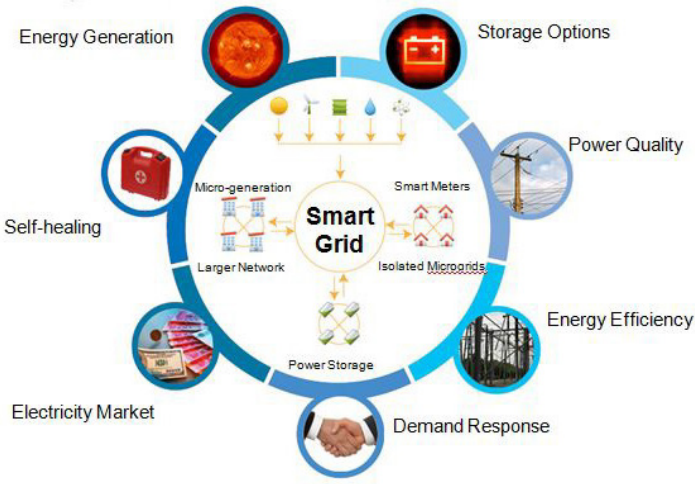

Figure 3. Different aspects that make up the smart grid

The following components must be developed to meet the above-mentioned objectives objective of smart grid:

2.1. Smart Metering:

The smart metering helps consumers to generate their own energy and inject surplus generated energy into the network at a certain price. This increases the dynamism of the system and decreases the prices of electricity [8].

2.2. Load Management:

The data delivered by the smart meters helps in effective management of load. The hourly consumption of energy as delivered by meters is the main deciding factor for the connection or disconnection management of generation sources and loads. This connection or disconnection can be automatic through intelligent controllers, which entails awareness and education of the population in general. Conclusively, this helps in developing a culture of low consumption and energy saving.

2.3. Inclusion of Renewable Energies and Electric Mobility

The smart grid also covers the issue of microgeneration in households. For that purpose, it is necessary to study the natural resources that can be used in the houses of different geographical sectors of the country and improve the technologies in their connection to the distribution lines.

2.4. Renewal of The Current Transmission Networks:

A fundamental point to achieve the above points requires the inclusion of an effective transmission network. The distributed generation and a strong increase in the amount of non-conventional renewable energies injected into the network require a transmission system that supports these bidirectional flows.

So, conclusively smart grid requires different technologies that can ensure a correct operation of this new network due to the complexity that is added to become intelligent [9].

3. Latest Developments in Smart Protection

Microgrid is normally operated parallel with utility grid and e.g. during faults in upstream network it can be separated quickly from utility grid and operated independently as an island grid. MMS will be responsible from the overall economic and energy effective operation of microgrid taking account the technical boundary conditions in both normal and island operation. In this paper only technical aspects related to LV microgrids are discussed. Technical choices made in the microgrid concept must be such that they can be justified by the needs of normal operation, but at the same time allowing and supporting the solutions needed

for implementation of island operation.

In overall the operation and control of LV microgrid is a very complex issue because there are number of things that will have influence to the behavior of microgrid in different ways. For example the dynamics of islanded microgrid, e.g. lack of inertia, is totally different when compared to the normal operation of the microgrid parallel with utility grid. Islanded microgrid is much more sensitive to disturbances and successful island operation requires fast, accurate and stable control.

In addition the protection of the future microgrid is a challenging issue and very strongly connected to the control and operation issues of a microgrid. The conventional protection in distribution networks is designed to operate for high fault current levels in radial networks, but during island operation of the microgrid high fault currents from the utility grid are not present. Also most of the DG units that will be connected to the LV microgrid in the future are converter interfaced and have limited fault current feeding capabilities. This means that the traditional fuse protection of LV network is no longer applicable and new protection methods must be developed. The developed protection scheme for microgrid must be supported by the technical choices made in the microgrid operation and control issues.

In the development of the new protection scheme for LV microgrids many things must be considered including amount of protection zones in LV microgrid, speed requirements for microgrid protection in different operation states and configurations and protection principles for parallel and island operation of the microgrid.

4. Technological Trends

Among the new technological trends of smart grids, substations are intelligent networks, which are designed to manage the consumption of each element connected to it in an "intelligent" way [10]. These networks will use innovative equipment and services, along with new communication, control, monitoring, and self-diagnosis technologies that will help to achieve the following objectives [11]:

- Reinforce and automate the network, achieving an improvement in the functionality of the system, having better quality values and less loss in the network.

- Optimize the connection between the areas that have renewable energy sources, improving the connection capacities and reducing connection costs.
- Study the decentralized generation architectures, making smaller installations (distributed generation) in balance with the system [12].
- Develop intermittent generation integration and new storage technologies
- To advance in the development of the electricity market, allowing new functionalities and services to the market.
- Allow consumers to manage their energy efficiency better through active demand management.
- Enable the penetration of the electric vehicle, accommodating these new mobiles and dispersed loads to the grid, minimizing the development of new infrastructure and enabling the energy storage features they possess [13].

4.1. Advanced Automated Distribution

Advanced distribution automation allows the electrical power distribution system to be completely controllable to increase efficiency, sustainability and reliability. Some applications for advanced automation of distribution are monitoring, data acquisition and control, voltage and reactive power control, fault localization, automatic reconfiguration, isolation and restoration service, user information, time management, asset management and remote control. The main reason for the advanced distribution automation is to guarantee the safety of the service, the quality of the energy and the efficiency of the energy system. The above is possible once the next three control processes of the distribution operation are automated [14]. These control processes are: (1) the data is arranged almost in real time, (2) the optimal decisions and (3) the coordination with the services of the different generation and distribution systems to control the distribution operations.

An automated system of advanced distribution will be able to perform data collection, along with the verification and correction of consistency of that data. Besides, the system should reconfigure the multilevel feeder. It should be pre-armed with the corrective action schemes and the organization of urgency actions in distribution. It should take care of the previous assembly of recovery schemes and coordination of corrective actions in the distribution, registration, and reports [15].

4.2. Distributed Energy Resources

Distributed energy source technologies consist of storage and power generation resources labeled as "behind the meter." These resources are installed at customer's end and are operated to supply partial or total energy consumed by the client [16]. These energy resources may also be able to inject energy into the distribution system and the transmission system or into a local network in parallel with the public network. Moreover, certain technologies such as combined heat and power (CHP) systems, photovoltaic solar energy (PV), microgrids, wind turbines, microturbines, standby generators and energy storage are included [17]. These resources represent immense importance because they can contribute to the reliability of the network. They may be able to produce energy to support the load of the host or the system. These technologies have evolved at a great pace in the years that have passed. However, the current challenges require unique planning, operation, and market management [18].

Moreover, the term that characterizes it as "behind the meter" means that it represents certain resources that are not directly connected to the commercial electric power system but are connected to the customer's access point. In this case, it is possible that the resources are acting to meet the customer's internal electrical loads, or the resources may be working to sell to the electric power system [19].

4.3. Information and Communication Technologies

Advancement in information and communication technologies (ICT) has been helping to maintain the distribution of electricity while limiting the environmental consequences. In addition to this, ICTs allow greater incorporation of renewable energy sources, allowing the transport of little carbon. ICT also includes electric vehicles and inducing changes in the structure with respect to excessive consumption of electricity [20]. Among its specific political implications, ICTs include convergent telecommunications services. These services can be the changes in connectivity requirements, changes in the roles of ICT companies as partners in the electricity sector and the development of new ability for personnel of the industry [21]. Smart electrical substations guarantee the interoperability between elements connected to the network. They ensure privacy to the critical infrastructures and commercial use of power-sharing applications.

The communication between different devices of the Transformation Center and the Control and Supervision Center has not yet had a standard that allows efficient data communication. This limitation makes it difficult to implement the SCADA systems in the transformation centers [22]. Moreover, the interface with the relays was in many cases non-existent. To resolve these problems, the International Electrotechnical Commission launched some standard protocols called as IEC 61850. This protocol defines the communication between different devices connected to a local area network. Intelligent Electronic Devices (IEDs) are replacing the old wired communication techniques.

IEDs can integrate communication elements for tele-control [23]. Out of the three main layers of smart grid technologies (energy layer, communication layer, and application layer), the communications layer enables the existence of the smart grid (Figure 4). Communication technologies act as a circulatory system to interconnect the different systems and devices. It links the energy layer with the application layer, to communicate both with the energy supply chain [24].

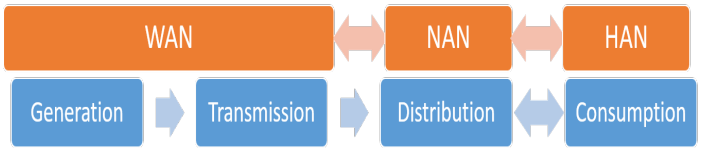

Figure 4. Smart grid topology for power flow in blue and information flow in orange

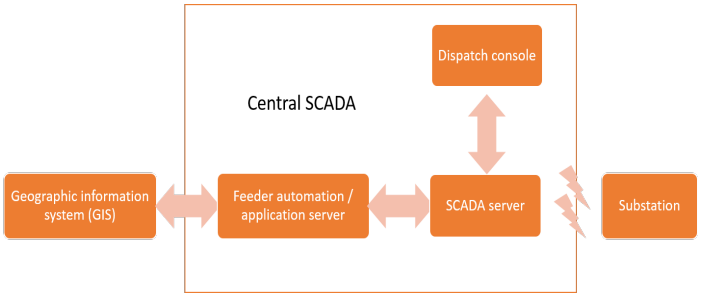
4.4. Supervisory System

The components of a supervisory system range from detection equipment, fault protection, communication, measurement, and data processing by the software. The software integrates all the intelligent devices (IED) that are part of the system [25]. However, the most relevant components of a supervisory system are the sensors of state and measurement. These sensors are installed in the field and are the base of the generation information for the supervising system. The status sensors have only two possible values zero or a logical one. These logical values reflect the states of the control elements of the system. For example, the status of a power switch can be estimated by the logical values of these sensors [26]. The protection relays that are currently manufactured are mainly IEDs. A typical IED (Intelligent Electronic Device) can contain around five to twelve protection functions and five to eight control functions. Control functions include separate devices control, an "auto-recloser" function, the self-monitoring function, and the communication functions etc. [27]. Currently, some IEDs work with the standard for the automation of IEC61850 electrical substations. This standard allows interoperability and good communications capacity (Figure 5) [28].



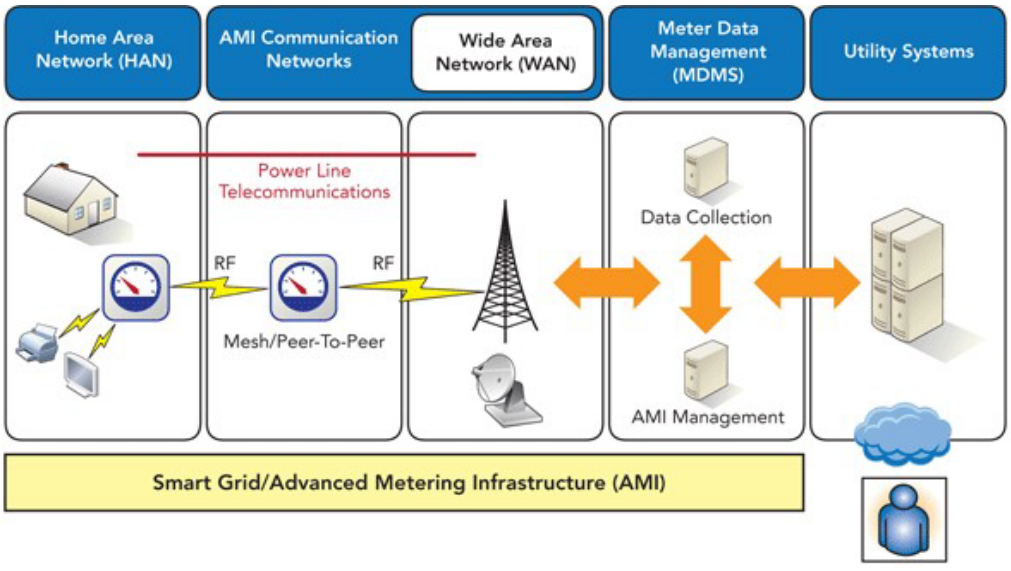


Figure 5. Feeder automation based on SCADA, current proposals in execution.

The communications network is the backbone of the entire supervisory system in real time. Its efficiency will depend on the speed and response time of the system to external events. The software is the last component that is required in the supervisory system; it is the way of representing the system [29].

4.5. Protection and Automation of the Network

The automation systems in substations for interconnecting a series of devices have existed for about 20 years, using proprietary protocols. These methods have been mainly responsible for the supervision of elements. Nowadays, this type of systems has evolved and continue to do so by following the protocols and actions declared in IEC 61850 [30]. This can be achieved by using peer-to-peer communications and enabling the exchange of data between systems at various levels and with various tools. This system also allows the supervision, control a series of devices or variables [31]. On the other hand, the increase in renewable energy generation and co-generation require the application of technologies in such a way that their management and protection is possible [32]. This impact on electrical networks is currently manifested, both in the transmission and distribution. The effect on substations, both in their protection and in their control, has been profound. This is due to the need of managing the intermittent electricity and several voltage levels [33].

The automation systems in substations for interconnecting a series of devices have existed for about 20 years, using proprietary protocols. These methods have been mainly responsible for the supervision of elements. Nowadays, this type of systems has evolved and continue to do so by following the protocols and actions declared in IEC 61850. This can be achieved by using peer-to-peer communications and enabling the exchange of data between systems at different levels and with various tools. This system also allows of supervisory control of devices or variables [34]. On the other hand, the increase in renewable energy generation and co-generation require the application of technologies in such a way that their management and protection is possible. The effect on substations, both in their protection and in their control, has been profound. This is due to the need of managing the intermittent electricity and several voltage levels. Therefore, for the development and supervision of the elements of the network, there are many emerging solutions for energy monitoring and parameters associated with it [35].

5. Digital Substations Control

To carry out and be able to develop all the functionalities that are expected from smart grids, this capacity (primarily redundant bi-directional data communications and the possibility of remote management) must be reproduced throughout the entire distribution network. It is already beginning to work in the section of the electrical consumption measurement infrastructure [36]. It must be implemented and improved in all sections of the power system.

The systems are based on bidirectional communications, technologies are associated with RF (radio frequency) wireless communications or power line carrier communications or broadband options (Figure 6) [37].

The desired functionality of smart meters could be the bidirectional communications with the electric company and with other devices (such as possible local energy managers). The other possible use of smart meter is alarms associated with quality of supply, personalization of the contract, planning, and possibility of bidding and purchase of electricity at the desired moments and control of loads, etc. [38]. This communication and monitoring capacity must be expanded to all measurement points and equipment in the electrical infrastructure. Also, it should be able to manage all distributed energy resources, considering not only the amount of energy flow but also the direction of it.

The technologies that affect smart grids are those that try to optimize and rationalize the management of electricity demand. As already mentioned, electrical energy cannot be stored (at least in enormous quantities), so it is necessary to generate it at the same time as it is needed. This situation means that at the very moment when a dedicated appliance is turned on, there must be a power plant (or any other type of electricity generator) that produces the necessary electricity [39].

5.1. Transport Network

To guarantee the electrical supply, in the absence of a line, the topology can be reconfigured to redirect the energy flows and thus avoid cutting off the supply. In this case, the systems of fault detection and reconfiguration of the network must act in small time spans for the control to be carried out in real time.

5.2. Distribution Network

The trend towards Smart Grids implies a replication or expansion of the existing capacities in the transport network to the distribution network. Considering that, unlike the conventional transport network, there are several owners and managers of the distribution networks. This situation will involve the definition of standard instruments and the creation of tools based on proven technology solutions. These tools will allow the integration of all types of generating plants, decentralized management of energy and automation of distribution and measurement services, supported by a system of communications that reaches the end user [40].

The electrical distribution companies can analyze and remotely control the electrical network by replacing meters with smart equipment. This equipment can take hourly measurements with Tele-management capacity [41]. In most cases, to guarantee interoperability, it is likely to install concentrators in the transformation centers with communication capabilities to control center of the corresponding distributor [42]. On the contrary, for the communication between the transformation center and the meters, the tendency in Europe is to use the power line carrier. The evolution of current electricity grids towards intelligent electricity networks implies the start of new intelligent equipment. This equipment will have local decision-making capacity and new communication technologies or the adaptation of existing ones. The current map of communication protocols used in the electrical system is very extensive and is regulated by the TC57 technical committee of the International Electrotechnical Commission (IEC). Thus, IECTC57 brings together several working groups to standardize the communications in the electrical system through the development of data models and generic interfaces. Each of these working groups has been responsible for defining and maintaining a communication standard based on the communication needs of each point of the electrical network [42].

Thus, it is worth highlighting:

- IEC60870-5 to communicate SCADA masters and electrical substations for the control and acquisition of data on serial lines or TPC / IP
- IEC60870-6, also known as TASE-2 for communications between powers centers over WAN networks.
- IEC61970 to interconnect energy management applications or EMSs in the environment of the control centers.
- EC61968 to communicate the control centers with the systems of the distribution network.
- IEC61334 for communications on PLC distribution lines.
- IEC62325 that defines a new interface between local utilities and the liberalized energy market.
- IEC62351 to determine security profiles to be used in all the previous ones at the TCP / MMS / 61850 level.
- IEC61850 (see fig 5) for automation in the environment of electrical substations (station and process buses) and communication between their IEDs (Intelligent Electronic Devices).

With the reference IEC61850 (see Figure 7 [43])), other similar regulations have been developed in other areas of application [44] such as:

- IEC61400-25 inherits a subset of communications services defined in IEC61850. It provides a new mapping of communications to Web Services and extends the data model modeling the functionalities, data, and attributes present in a wind turbine.
- IEC61850-7-420, which extends the data model by modeling the features, data, and attributes present in distributed generation systems such as photovoltaic systems, storage systems, diesel generators and heat exchange systems.
- IEC61850-7-410 is identical to IEC61850-7-420 for hydroelectric power plants.

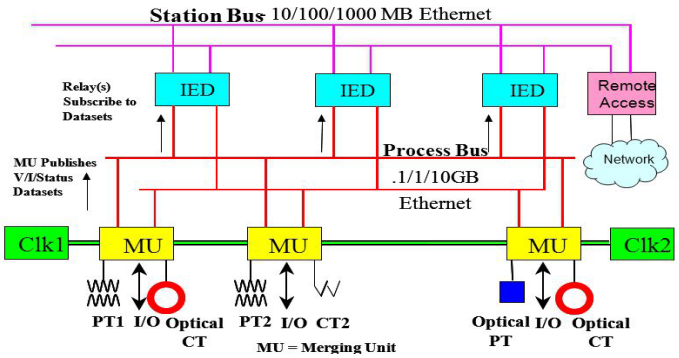

Figure 7. IEC61850 substation architecture.

6.1. Less Copper

Digital Substations utilize less copper by (1) replacing copper cables between switchyard and relay house by fiber optics, (2) replacing horizontal wiring between protection and control IEDs with IEC 61850, (3) reducing the number of connections between primary apparatus and redundant process interface modules and (4) reduction in cables for power supply and other connection for primary equipment.

6.2. Less Transport

In digital substation, more than 30 tons of material can be saved [45]. This helps in less transportation. The fiber optic installation reduces the cabling under 90% and by using optical instead of conventional CTs achieves an 80% weight reduction on CTs.

6.3. Space Reduction

IED installations require less space than conventional IOs. A space reduction around 30% to 60% for panels is possible. This results in higher integration of control and protection systems and reduction of switchyard footprint.

6.4. Less Installation and Outage Time

Digital substations cause faster installation of control systems due to reduction in number of panels for installation. There are fewer cables to be pulled, connected and tested. This causes reduction of feeder outage time by 40 to 50% during secondary system upgrades. This helps in full system test from process IO to protection, control and SCADA system offsite and Installation of new FO based system while the station is in service

6.5. Operational Cost Reduction

The Supervision of all exchanged data reduces the need for periodic maintenance testing and permanent supervision enables fast and precise actions in case of failures. IEC 61850 testing and simulation features enable fast and save isolation and testing of protection functions. Standard compliance enables efficient future retrofits of the secondary system (see Figure 5).

7. Conclusions and Recommendations

This work provides a review on digital substations importance and their working. This work emphasized on the importance of digital substations along with latest trends in modern smart grids. The provided comparison study proved the effectiveness of modern digital grids over conventional grids as well.

Apart of above-mentioned benefits, digital substations in Smart Grids provide a series of direct advantages to energy companies and end users that will help in the development of the energy market. The evolution of the electricity network provides the distribution companies with following benefits:

- Reduction of energy losses.
- Efficiency.
- Accomplish the optimization of the network infrastructure.
- Offering a better service to the client, with more commercial advantages (new rates, payment for use, etc.).

The users get the following benefits:

- Pay per use.
- Flexible rates.
- Remote management of the power supply.

Although at present, the home automation sector is in a complicated situation. It is promoting the instillation of control and automation systems in the home aimed at increasing energy efficiency, reducing energy losses, generated energy integration and accessibility to people with disabilities [46]. Currently, the number of agents involved in the electricity system has increased due to the liberalization of the energy market. The appearance of new participants is expected such as energy companies, system integrators, auditors, etc. It also predicts the development of renewable energies e.g., efficient solar cells, wind powered systems [47]-[48] and electric vehicles exponentially, in parallel with Smart Grids. So, it is necessary to keep these concepts in mind when carrying out any research or development related to the evolution of the electrical network.

R & D in the field of telecommunications for the development of new communication techniques and optimization of existing ones is still in progress. Technologies such as PLC, wireless connections or fiber optic, will provide a fundamental part of the Electrical Network of the future. Development in areas of power electronics, energy transport, electrical storage, energy efficiency, automated systems, new intelligent control techniques, etc. needs more investment and research [49]. Insofar, smart grids would play a great role in the development of smarter world having smart cities, smart homes, smart vehicles, etc. The ultimate requirement is to create systems of objects that are configured automatically and can operate autonomously [50]-[53].

Conflict of Interest

The authors declare no conflict of interest.

This paper proposes Halbach array PM linear generators for direct conversion of ocean or sea wave energy. This generator is proposed to be directly coupled to a reciprocating wave energy system which may be a valued alternative for pneumatic and hydraulic systems. In this research, air-cored permanent magnet PM linear generator has been optimally designed according to optimal cost and performance indices. The design depends on Halbach array PM arrangement. The design this linear generator is appropriate for direct extraction of energy from sea waves specially at small wave amplitude. The finite element method and the space harmonic analysis are used to develop the electromagnetic design of this topology. In this article, the concept of the extraction of maximum permissible power from sea waves is established according to the direct wave energy converters hydrodynamics model. The dynamic analysis of the Halbach array linear generator is investigated during the state of maximum power extraction.

1. Introduction

This paper is an extension of work originally presented in 2018 Twentieth International Middle East Power Systems Conference (MEPCON) under title (Optimal Design of Slotless PM Halbach Array Linear Generator for Wave Energy Converters at Maximum Power Transfer Condition) [1]. Nowadays, the energy sources have great importance allover the world. Because of the expected deterioration of fossil fuels accompanied with hazardous environmental impacts, it is indispensable to establish clean renewable sources of energy. Ocean and sea waves energies are considered promising alternative renewable energies resources. On the Earth, it is considered as the largest renewable energy source. The running cost of this type of energy is low. Moreover, it is clean energy source. However, is not competently employed up till now. Preliminary reviews show that marine power has the ability to significantly contribute in energy market all over the world. Experts expect that the economical visibility of ocean or sea energies is very effective. It is expected that if wave-capturing technologies become totally developed, the predicted developed wave energy may equal 750 Trillion kWh/year [2].

Recently, numerous technologies are established to extract electric energy from seas or oceans waves [3]. These technologies are called the wave energy converters (WECs). They can transfer the mechanical wave energy to electrical energy. Such types of converters utilize the concept of a water column changing or buoy body movement [4]. Some of developed converters are more and more commercially established. There are some WECs directly convert the oscillating wave motion to reciprocal vertical movement. The small reciprocating motion with a speed about 2m/s may be obtained by these devices in some seas such as Mitterrandian Sea. Some researchers suggest the usage of induction generators to produce electric energy from sea waves. Nevertheless, this technology requires a hydraulic transmission system to convert the small velocity of the vertical motion to high rotational speed[5]. The wave energy converters which depend on the direct conversion of wave energy have great advantage related to the simple construction free of mechanical transmission system. The linear permanent magnet synchronous generators LPMSG have been developed and implemented as WECs which depend on the principle of Archimedes wave swing [1, 6]. The main shortage of such linear synchronous generators is the high cogging force. On the other hand, the air-cored tubular permanent magnet linear generators are suggested to overcome such force [7]. Therefore, the elimination of cogging force reduces the stress on the machine parts so there is no need for additional structure support. These machines can be built without the usage of back-iron. Therefore, the elimination of back-iron from stator and forcer leads to the

[*]Electrical power and machines department, faculty of engineering, Tanta university, Tanta, Egypt, +201153026587, ahmed.elgebaly@f-eng.tanta.edu.eg

elimination of their corresponding core loss. Additionally, such generators have significant lightweight compared with the conventional linear synchronous generators. The improvement of flux distribution in the air-cored PM generators improve their performance from the point of view of the developed voltage and power [1]. Halbach array arrangement is applied to provide low space harmonics magnetic field, which leads to further sinusoidal waveform of induced voltage and more developed power with the same forcer current. The field uniformity leads to extracting of higher power over small time. Therefore, the Halbach arrangement is proposed to be implemented in these generators to gain its performance improvements [1, 2, 8].

The optimized design of the proposed PM Halbach array linear generators requires the fulfilment of some indices; such as cost minimization and the production of appropriate voltage and power level. The recent optimization techniques are applied to obtain the optimal design of generator which is suitable for wave energy extraction [9]. In this paper, the design details are taken into consideration to obtain the optimal design. The design variables include the generator topology, the appropriate PM arrangement, the coils design and the generator overall dimensions. Moreover, this research proposes the concept of maximum power tracking MPT to make use of the most delivered wave energy. Preliminary, the MPT concept is explained in this paper according to the hydrodynamic performance of the WEC. The application of MPT mode requires the implementation specific control technique and power electronics converter [10].

2. Modelling of hydrodynamics of direct WEC

Figure1 demonstrates the structure of air-cored tubular PM linear synchronous generator for WEC based Halbach array configuration. According to this design, the floating buoy is directly connected to the movable translator of the PM linear generator where its base is strongly fixed to the sea bottom. The generator base may be connected to the sea bottom via wires. The changing of the height of the wave is the base of the operation of the WEC. The hydrodynamic model of the direct buoy WEC has been developed previously in numerous researches [5, 11]. The difference forces act on the moving part of the translator have been modeled. Without reaction force control, the moving part are affected by three forces; the input force produced by the wave, the extracted output power and the inertia force. It is recommended to integrate a suitable mechanical spring in the WEC to develop reaction force counteracts the force of inertia developed by the movable parts. The maximum power transfer condition in the WEC systems happens when both the inertia and the spring forces are equal in value and opposite in direction [1, 2].

The buoy may take a cylindrical shape with radius r and its motion is limited to be along the vertical axis (z). The cylinder is partly immersed. When the wave acts on the buoy in x direction as illustrated in Figure (1), a force is applied on the buoy cylinder due its tendency for floating. In this study, the incident wave is considered to have sinusoidal wave for simplicity.

The buoy motion equation can be formulated as the following:

$$m\frac{d^2z}{dt^2} = F_{stf} + F_{gen} + F_{hyd} \quad (1)$$

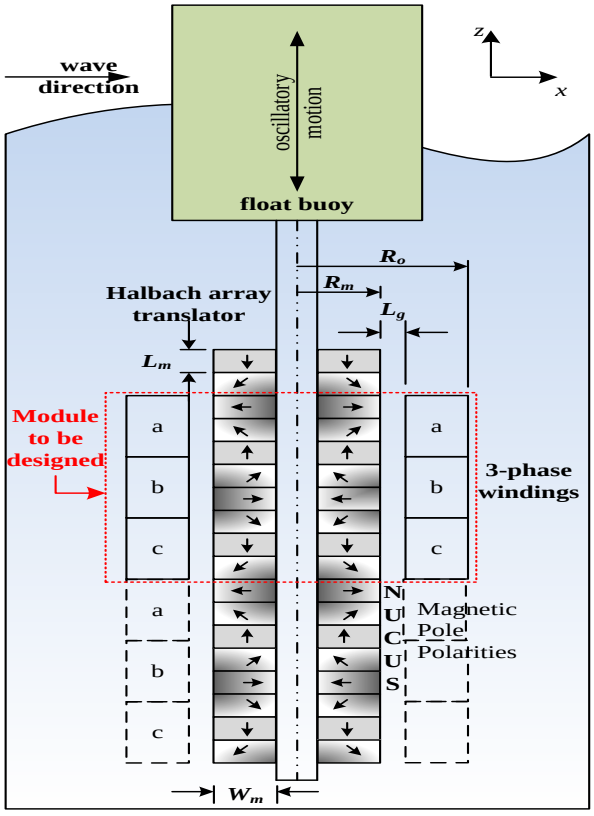

Figure 1: Proposed tubular Halbach array slotless linear generator for wave energy conversion

where m is movable parts mass i.e. buoy and Halbach array PMs. F_{stf} is the force produced by the spring, F_{gen} is the reacting generator force due to electrical power extraction, and F_{hyd} are hydrodynamic forces applied on the buoy exerted by the wave.

The stiffness or spring force is proportional to the translator displacement,

$$F_{stf} = -k_{st}\, z \quad (2)$$

where k_{st} is the constant of spring and z is the displacement on the vertical axis away from the balance point.

The force that causes the electrical power is modeled as a damping force where the produced force is proportional to the movable parts velocity. Therefore, the generated force is determined as:

$$F_{gen} = -B\frac{dz}{dt} \quad (3)$$

where B is the coefficient of damping which depends on the generated power. This coefficient should be continuously adjusted to enable the generator to extract the maximum allowable power from the wave.

The Archimedes' principle provides the equation that determine the hydrodynamic force correlated to the volume of water displaced:

$$F_{hyd} = -\rho g \pi r^2 z \quad (4)$$

To study the hydrodynamic model in steady state mode, all equation should be transfer to the frequency domain by applying Fourier transformation. At steady state, the cylinder is assumed to be exposed to sustained alternating force has a frequency ω. The output power from the generator can be maximized when the system is in the resonance where the stiffness force equals in magnitude the inertia force. Therefore, the natural frequency ω_r of the hydrodynamic system can be determined by [11]:

$$\omega_r = \sqrt{\frac{\rho g \pi r^2 + k_{st}}{m}} \quad (5)$$

The design of buoy cylinder relies on the hydrodynamic parameters which achieve the maximum power transfer condition. In this research, the proposed design is suitable for south shores of the Mediterranean Sea where the frequencies of the waves are within 3 radian per second [12]. The spring constant is determined depending on WEC rating and generator parameters [11]. Figure 2 illustrate the relation between the radius of buoy cylinder and the proper stiffness constant at different masses of movable parts. The required stiffness constant decreases with the increment of the radius. If the stiffness constant has negative values, the mass of the translator should be increased to achieve resonance condition [13]. So, the adjustment of spring constant is very vital to achieve the resonance condition; and therefore, to achieve the maximum power transfer condition. Nevertheless, the frequency of incident sea waves is continuously changed; so, the stiffness constant

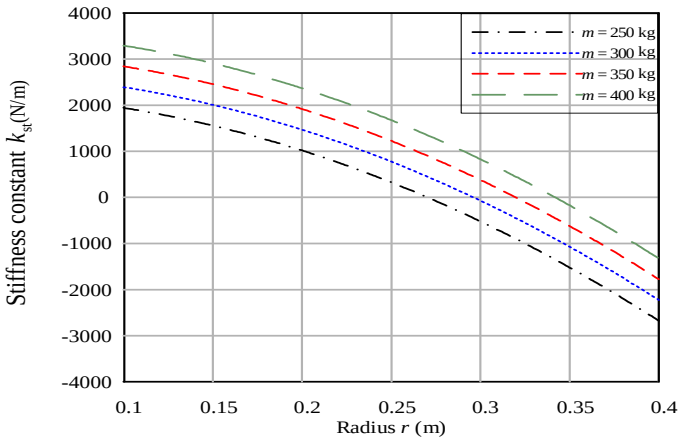

Figure 2: Variation of required stiffness constant with radius at different masses at ω_r = 3 rad/s

should be changed to change the natural frequency of the system to produce the maximum permissible power. The active adjustment of the stiffness constant is very complicated if it is mechanically implemented. Therefore, in this research, a adaptive electric spring is implemented to regulate the stiffness constant to run in resonance manner for different frequencies of the incident wave. The stiffness force or reaction force [10] can be created electrically due to certain current and voltage adjusted by power electronics converters. In this article, reaction force is applied during the operation of the generator to produce maximum power. Nevertheless, the movable parts mass should to be minimalized to reduce the reaction force and consequently, the produced generator current and its corresponding losses. Therefore, the mass of the generator movable parts is a vital index to obtain the optimized design.

3. Design of Halbach array WEC generator using FEM

Figure 1 illustrates that the proposed PM Halbach array linear generator has fixed coils surround a PM tubular Halbach array. The translator is composed of directed polarized permanent magnets for instance NdFeB. The magnets fluxes are directed with special sequence North (N) and South (S). But, the complete of the magnetic flux requires some magnets to be oriented in (C) direction. The PMs labeled (U) are oriented with 45 degrees or 135 degrees to produce smooth sinusoidal distributed flux. The resultant field tracks the translator motion, passing through the the concentrated coils. This paper studies the design of one module and the other modules have the same design parameters.

Low velocities WECs requires large reactive forces, therefore large dimension generators. In such iron-cored generators, the robust magnetic field leads to a noteworthy attraction force between the movable part and stator [14]. The structure can be significantly saved in the case when the cogging force can be decreased or even cancelled. The slotless air-cored linear generator is considered as a solution. The Halbach array has a vital advantage over the traditional air-cored related to the production of magnetic flux with less space harmonic content. The proposed generator module has the next ratings: 600 w rated power, 60 V rated phase voltage, the height of the wave about 1 m and the frequency of the wave about 3 rad/s. The ratings of the generator and wave is suitable to be applied on South Mediterranean Sea [12].

The proposed module may be repeated vertically to absorb larger amount of power from the incident wave. The overall length of generator depends on the depth of sea in the place of installation and on the stresses applied on the construction of the generator. In this research, the proposed generator has 3 kW; so, it consists of five modules. The following procedures explains the steps to obtain the optimal design of one module.

The investigation of the proposed model has been achieved by the application of finite element method by using FEMM package. Due to the slow motion of the translator in such type of generators, the analysis of the generator is considered magnetostatic problem. The problem of electromagnetic field is analyzed depending on FEM. The following equations is solved by FEM to analyze any electromagnetic problem. The vector of magnetic potential **A** is related to the vector of current density **J** by the following equation:

$$-\frac{1}{\mu}\nabla^2 \boldsymbol{A} = \boldsymbol{J} \quad (6)$$

where, (μ) is the permeability that depends the flux density for nonlinear materials. The advantage of solving FEM problem depending on the vector potential **A** is that all circumstances to be fulfilled are integrated within on equation. If **A** is determined for any geometry, the corresponding density of magnetic flux can be determined according:

$$\boldsymbol{B} = \nabla \times \boldsymbol{A} \quad (7)$$

The proposed designs of the generators are analyzed by FEM to achieve the required ratings. Figure 1 illustrates the various dimensions of the module; R_o the outer radius of the module, τ is the pole pitch, L_g is air gap length, L_m is PM segment height, W_m is PM thickness and R_m is the PMs cylinder outer diameter.

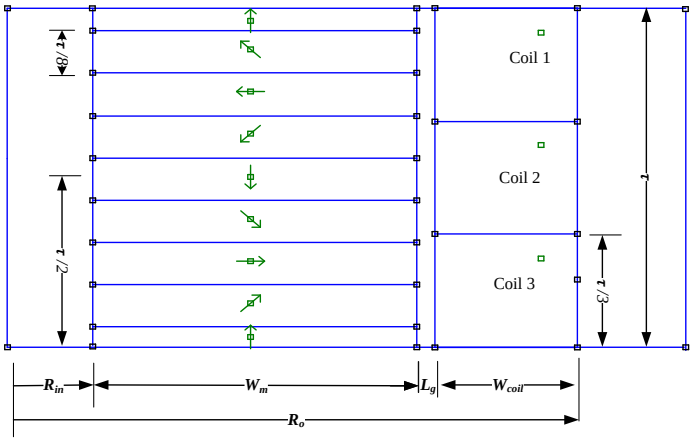

Figure 3: Full dimensions of one module of the proposed generator design

There are additional generator design parameters foi instance number of windings of each coil, the cross-section area of the copper conductors and the coil's filling factor. FEM analysis helps to determine the parameters of the design which achieve the suitable ratings. For any proposed dimensions and materials, FEM can calculate the different variables of the generator such as flux linkage, developed force overall weight. For each determined variable, the objective function is formulated to obtain the optimized design. Figure 3 illustrate the full dimensions applied in FEM for axisymmetric representation while R_{in} is the PMs cylinder inner radius, W_{coil} is the coil width and τ is the pole pitch. Along one pole pitch, the PM cylinder is divided into eight species. Along the full length of the translator, there are number of pole pitches equals N_{pit}. Over each pole pitch, the stator contains three coils where each coil presents one phase. The modularity of the proposed design allows to provide different generator ratings. Consequently, in case of 600 W module, generators of 1200, 1800 and 2400 W are developed. The control system applied for one module can be applied for the other modules without modifications.

Because of tubular shape of generator, the simulated model in FEMM is presented in axisymmetric dimensions. Several efforts have been achieved in [1], [2] and [5] which present a good guide to determine the probable ranges of design variables appropriate for the predetermined ratings demonstrated in Table.1.

The package FEMM is used to implement the finite element analysis of the proposed generator. The slow motion of the translator and the currents low frequencies which passes through coils lead to solving of the finite element problem as magnetostatic problem.

The optimization problem has some constrains; the first constrain is the filling factor of each coil should be less than 85 %; the second constrain is the losses which shouldn't exceed 50 % of the developed power. The dissipation of generator losses under water governs the description of constrains [2].

Some of post-process results of FEM present important terms which formulate the objective function. The obtained parametes are are as the following, the volume of PM segment Vol_{pm}, the volume of the coil Vol_{coil}, the produced loading force F_d, copper losses P_{cu}, and the maximum flux linkage at no-load λ_{max}. Some post-process results are essential to obtain some fitness function terms. The mass of both PMs and coils should be determined as the following:

$$M_{pm} = 8\ Vol_{pm}\ \rho_{pm} \tag{8}$$

$$M_{coil} = 3\ Vol_{coil}\ \rho_{cu}\ k_f \tag{9}$$

where M_{pm} is the mass PM cylinder for one module, ρ_{pm} is the PM material density, M_{coil} is the three-phase coils mass, ρ_{cu} is the density of copper and k_f is the filling factor. The maximum flux linkage per pole pitch λ_{max}/τ is an essential parameter should to be calculated to formulate the objective function.

The objective function is formulated to obtain the optimized design according to the next indices:

1- minimization of coils' mass
2- minimization of PM translator mass
3- achieving the rated power
4- achieving the rated voltage

Consequently, the objective function is formulated as the following:

$$O.F = k_1 M_{coil} + k_2 M_{pm} + k_3 \left| P_d - P_{dref} \right| + k_4 \left| \frac{\lambda_{\max}}{\tau} - \left(\frac{\lambda_{\max}}{\tau} \right)_{ref} \right| \tag{10}$$

and the fitness function to be maximized is:

$$fitness = -O.F \tag{11}$$

where P_d is the produced power by certain model, P_{dref} and $(\lambda_{\max}/\tau)_{ref}$ present the reference values and constants k_1 to k_4 are used as weighting factors to adjust the contribution of $O.F.$ terms.

Figure 3 illustrates the FEM presentation of one module located at the balance position where $z = 0$. With minimum number of calculations, this position has advantage related to the determination of required values of maximum flux linkage at no-load for coil 2 and developed force at loading if both coil 1 and coil 3 have maximum current. the proposed arrangement provides the benefit of obtaining the terms of objective function deprived of carrying out a complex dynamic modeling using FEM.

Table 1: the probable ranges of design variables appropriate for the proposed Halbach array generator

Variable	Symbol	Range	Unit
PM thickness	W_m	1: 9	Cm
Inner radius of PMs cylinder	R_{in}	0.5: 7	Cm
Air gap width	L_g	0.05: 0.5	Cm
Coil width	W_{coil}	2.5: 6	Cm
Pole pitch	τ	8: 15	Cm
Turns number of each phase	N	150: 300	Turn

In this research, the Genetic Algorithm (GA) is applied to obtain the optimized design with minimum weight and losses and provides voltage and power ratings.

Figure 4 demonstrates the flux produced by the Halbach array where the flux is directed out of the side area of the cylinder and partly deleted in the inner side of the cylinder. For the same generators volume, the characteristics related to providing higher power density of Halbach array linear generator is better than these of air-cored generator [2].

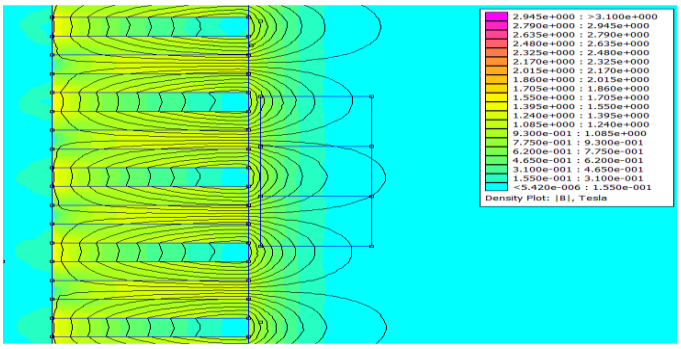

Figure 4: The Halbach array produced magnetic flux distribution and contour

To obtain the optimal values for the parameters, GA is applied to maximize the fitness function. In this study, the generation consists of 20 gene is applied. The six parameters are coded within one gene as binary string where these parameters are illustrated in Table.1. Therefore, the gene is composed of 120 bit. Then, the design parameters are passes to FEMM package to obtain their indices and design results. Then, the post-processing parameters are calculated. Therefore, the objective function and fitness value is determined for each gene. Then, GA applies its reproduction processes. The developed programs are carried out using programming language C++ and MFC library.

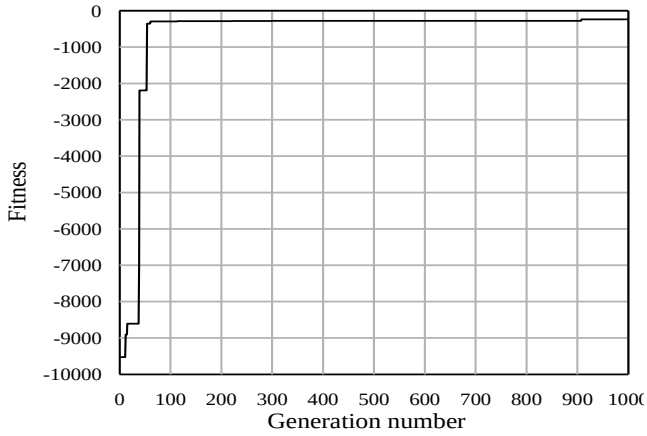

Figure 5: Fitness variation with GA generations for the optimization problem

The process of search is completed if the fitness value is stable at almost fixed value. Figure 5 demonstrates the changing of the fitness value versus the number of generation. After 1000 generation, the maximum fitness is stabilized at -270 as best vakue as shown in Figure 5. The stabilized fitness value is achieved approximately after 120 generations.

Table 2 illustrates the details of optimized design of the proposed generator topology for the specified ratings. The developed parameters of the optimized design are used in the dynamic analysis of the generator when it works in maximum power transfer state. The power density of the optimized design equals 41.6 W/kg which is more than the conventional air cored by 10% which equals 38 W/kg [15].

Table 2: The detailed parameters and dimensions of the optimized design

Dimensions		
Symbol	value	Unit
R_{in}	1.27	cm
W_m	4.37	cm

4. Performance assessment of Halbach array linear generator of WEC at maximum power transfer

According to the dimensions determined by the FEM, each coil of the there-phase has flux linkage over the displacement with one pole pitch illustrated in Figure 6. The flux linkage has sinusoidal waveform over τ.

Figure 7 demonstrations the equivalent circuit of the three-phase Halbach array linear generator. The there-phase equivalent

circuit model consists of three EMF supplies e_a, e_b and e_c. the phases assumed to be connected in star. Moreover, the model for each phase contains an internal winding resistance r_{in}, self-inductances L_a and the mutual induced voltage due to currents pass in the other phases is presented by two dependent sources. The load

$$\begin{bmatrix} e_a \\ e_b \\ e_c \end{bmatrix} = \frac{d}{dt}\begin{bmatrix} \lambda_a \\ \lambda_b \\ \lambda_c \end{bmatrix} = \frac{d}{dz}\begin{bmatrix} \lambda_a \\ \lambda_b \\ \lambda_c \end{bmatrix}.\frac{dz}{dt} = \frac{d}{dz}\begin{bmatrix} \lambda_a \\ \lambda_b \\ \lambda_c \end{bmatrix} v_z \quad (12)$$

$$\begin{bmatrix} v_a \\ v_b \\ v_c \end{bmatrix} = \begin{bmatrix} e_a \\ e_b \\ e_c \end{bmatrix} - \begin{bmatrix} r_{in} & 0 & 0 \\ 0 & r_{in} & 0 \\ 0 & 0 & r_{in} \end{bmatrix}\begin{bmatrix} i_a \\ i_b \\ i_c \end{bmatrix} - \begin{bmatrix} L_a & M_{ab} & M_{ca} \\ M_{ab} & L_b & M_{bc} \\ M_{ca} & M_{bc} & L_c \end{bmatrix}\frac{d}{dt}\begin{bmatrix} i_a \\ i_b \\ i_c \end{bmatrix} - \begin{bmatrix} i_n & r_n \\ i_n & r_n \\ i_n & r_n \end{bmatrix} \quad (13)$$

$$\text{where } i_n = i_a + i_b + i_c \quad (14)$$

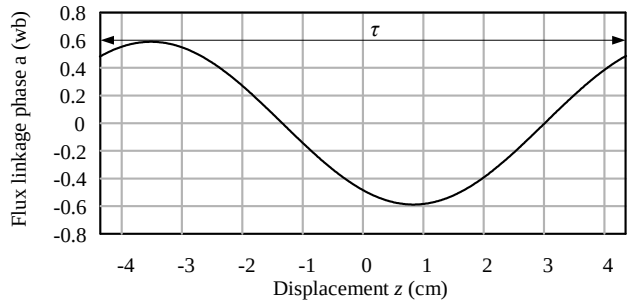

Figure 6: The changing of flux linkage with the vertical displacement over one pole pitch

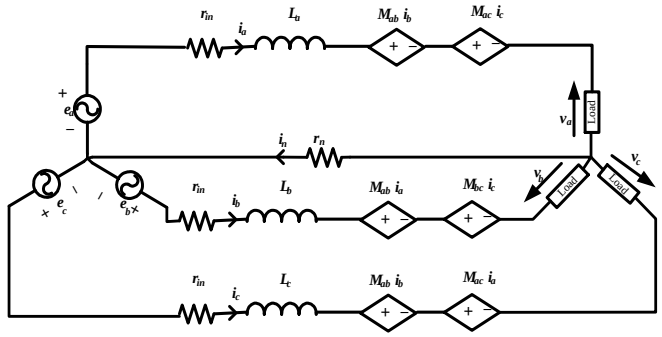

Figure 7: The equivalent circuit of the three-phase model of proposed Halbach array linear generator

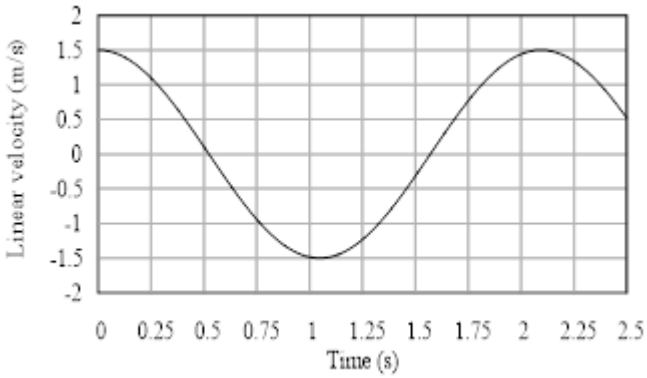
To apply the maximum transfer condition from the mechanical point of view, the inertia force should be eliminated by stiffness force produced by applying current i_q* has phase shift of 90° with the induced phase voltage envelop [1]. From electrical point of view, the maximum power transfer happens when the circuit current is in phase with applied voltage. So, there is another current i_d* is in phase with voltage and therefore with the velocity. In (12), the voltage mainly relies on flux linkage and the velocity of the PM cylinder regarding the three-phase coils. In this generator, the energy is extracted from both rising and falling motions.

Now, the proposed Halbach array generator module is tested under two cases; the first when the maximum wave velocity equals 1.5 m/s and the second when it equals 1 m/s. Figure 8(a) shows the velocity applied on the floating buoy of WEC where the maximum velocity equals 1.5 m/s. This velocity is supposed to have sinusoidal waveform while its positive value means that the direction is up towards and the negative value means the reverse direction. As shown in Figure 8(b), the span of displacement ranges from 50 to -50 cm. Figure 8(c) illustrates the changing of the coils flux linkage during translator movement. As shown in Figure 8(d), the three phase voltages have 120° phase shift between each other although the voltages amplitude changes. Correspondingly, the velocity of the generator is directly related to the frequency of the induced voltages. The frequency related to speed should be considered during the voltage control of the generator output. The way of power extraction related to the value of currents passes through coils. Thus, the MPT is achieved by current regulation technique. Therefore, the MPT is achieved by allowing current i_q to pass through coils to produce stiffness force cancels the inertia force. Figure 8(e) illustrates the current i_q where its envelop has 90° phase shift with the envelop of voltage. Therefore, current i_q envelop is in phase with the translator displacement according to equation (2). The production of active power is achieved by allowing current i_d to pass through generator phases. The envelop of current id is in phase with the envelop of induced voltage as in Figure 8(e). Therefore, the maximum power transfer is achieved by allowing total current i_{tot} to be pass through each phase; where



$$i_{tot} = i_d + i_q \quad (15)$$

These currents for phase a are illustrated in Figure 8(f). The total current with its two components can cancel mechanical inertia and electrical inductances. Figure 8(g) demonstrates both the stiffness and inertia powers which have the same amplitude and opposite sign. Figure 8(h) demonstrates the total output power P_{tot} produced by the generator at MPP and the output power P_{out}.

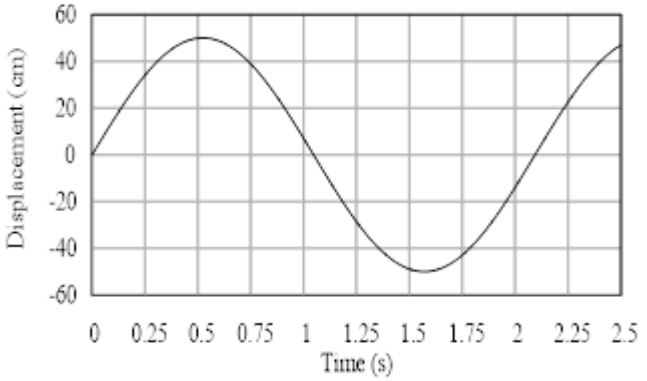


Figure 9 illustrates the generator performance at 1 m/s maximum velocity. It can be observed that the span of movement is reduced by 36 cm. Although the flux linkage, in this case, has the same amplitude, the induced phase voltages have less amplitude because they depend on the velocity. The currents are reduced due to the reduction of reaction forces and the total and output power. According to the results at different velocity, the concept of operation of MPT can applied to obtain the maximum power from the waves.

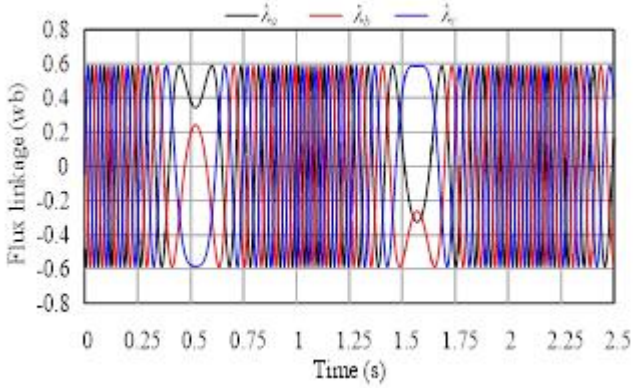
5. Conclusion



Slotless tubular Halbach array linear generator has been developed to be used within wave energy converter system at maximum power transfer condition. The simple hydrodynamic model of the WEC have been developed to describe the hydrodynamic circumstances to achieve MPT condition. The principle of operation of the proposed Halbach array linear generator has been introduced. Moreover, the parameters affects the design of the generator have been derived to formulate the proper objective function. The FEM has been used to get the design parameters for different dimensions of the generator. The GA in combined with FEM is used to get the optimal parameters of generator design achieves the maximum fitness value. The optimized design has been modeled and simulated to study its performance in the maximum power transfer condition. The WEC system has been simulated to work with low velocity sea waves as these in the Mediterranean Sea. The MPT has been successfully achieved by using the concept of current control to cancel all system inertias.

Recommender Systems (RSs) are termed as web-based applications that make use of filtering methods and several machine learning algorithms to suggest relevant user objects. It can be said that some techniques are usually adopted or trained to develop these systems that generate lists of suitable recommendations. Conventionally, RS uses a single rating approach to preference user recommendation over an item. Recently, multi-criteria technique has been identified as a new approach of recommending user items based on several attributes or features of user items. This new technique of item recommendation has been adopted to solve several recommendation problems compared to the single rating approach. Furthermore, the predictive performance of the multi-criteria technique when tested proves to be further efficient as compared to the traditional single ratings approach. This paper gives a comparative study between two models that are based on the features and architecture of fuzzy sets system and adaptive genetic algorithm. Genetic Algorithms (GAs) are robust and stochastic search techniques centered on natural selection and evaluation that are often applied when encountering optimization problems. Fuzzy logic (FL) on the other hand, is known for its wide application in diverse fields in science. This study aims to evaluate, analyze, and compare the predictive performance of both methods and present their results. The study has been accomplished using Yahoo! Movies dataset, and the results of the performance of each model have been presented in this paper. The results proved that both techniques have significantly enhanced the system's accuracy.

1. Introduction

The advancement of Internet of things together with the rapid growth of e-commerce websites has caused uneasiness for customers to choose appropriately from the overwhelming number of items offered by these websites [1]. This fast development of web-based tools and the steady accessibility of a variety of information on the web have also given rise to the problem of information overload. As such, this has led online customers to make poor choices while purchasing items online [2]. To overcome this persistent problem, there is a need to introduce an intelligent decision support system that has the potential to scan through the available items using some computational and machine learning techniques to find and recommend appropriate items to users. Hence the need for RSs. Currently, RS is a significant tool that solves problems of information overload. It solves this problem by suggesting only items that are suitable to users. Increasing the number of items sold in e-commerce sites and an increase in customers' satisfaction from buying items online is one of the key benefits of RSs [3].

RS is a web-based application that supplies users with recommendations of items that might be of interest to them. The recommendations of items to users may be personalized or non-personalized [4]. The personalized recommendations are typically presented as orderly lists of items offered to the system user. It takes into consideration users' previous history for rating and predicting items. On the other hand, non-personalized recommendation systems recommend what is popular and relevant to all the users, which can be a list of top-5 items for every new user. Consequently, RS studies the user behaviour first, which could be expressed explicitly by the user through the rating of items or implicitly by just clicking on items. After learning the user's behaviour, it suggests items that might be useful to the user based on what it has learned from the user. It further suggests an ordered list of items in a way the user will like or rate them [3].

*Mohamed Hamada, University of Aizu, Software Engineering Lab, Japan, +81 242 372617, Email: mhamada2000@gmail.com

Rating of items by the user is one of the main forms of data transaction that is collected by the RS and uses it to classify RS into traditional RS and multi-criteria RS.

Traditionally, the commonly used recommendation approach adopted is either a hybrid-based, content-based or collaborative filtering approach. These approaches, together with subdivisions of collaborative filtering approach are shown in Fig. 1 [4]. These methods obtained an overall rating of a specific user on an item. Ratings of the users over items are used by recommendation algorithms to evaluate and predict users' preferences on new items. Single criterion rating tends to be inadequate in most cases because they have been proven to offer recommendations that are not quite efficient in achieving user desires, since users are unable to define their opinions based on various attributes of the item.

Multi-criteria Recommender Systems makes use of several items attributes to define the appropriateness of user items [5]. As an example, in a Movie RS, part of the attributes sighted may be the direction, action, visual, story. Multi-criteria RSs improves the Single criterion RS by putting into consideration varied items attributes in which users may like. Unlike Single Criterion RSs, users are capable of providing individual preference ratings on various item attributes. In most cases, additional relevant information offered by multi-criteria recommender systems helps to enhance recommendation value accurately. This enhancement depicts different features that a user may like about the item. In most RSs research, accuracy has been the most extensively examined point of emphasis [3]. However, more research is mandated on the effectiveness of new methods to integrate the multi-criteria rating information into the recommendation process efficiently. Therefore, this work aims to analyze and investigate how to use genetic algorithms and fuzzy technique to improve the precision in a multi-criteria RS. The study also provides a comparative analysis of the efficiencies of the two techniques.

The current paper is separated into five distinct sections, together with section 1. Section 2 presents a summary of traditional and multi-criteria RSs. Section 3 presents the methodology and frameworks used to implement both systems. Section 4 presents the results and comparison of both methods. Finally, section 5 presents the conclusion and discusses future work

2. Concept of Collaborative Filtering (CF)

CF is among the very commonly used approaches in generating valuable recommendations due to its human nature centred approach. It mainly "use the wisdom of the crowd or what seems to be common amongst my cycle" to recommend items to me. This is centred on the connection between users of the system and the item itself. It performs well in complex object recommendations (for example movies and music), which are seen to be totally autonomous from any machine-readable prediction of the items recommended.

Various companies have used RSs by implementing numerous algorithms that cut across different area. An example of such implementation is the statistical interactive learning techniques implemented by CleverSet, and also, the classical CF implemented in Net Perceptions [6] and Amazon [7].

CF approaches are mostly categorised into Memory-based and Model-based filtering method. The latter method makes use of earlier activities of the user to acquire a predictive model. This is done either by making use of some statistical analysis or machine learning techniques in making relevant recommendations [1]. Memory-based filtering approach makes use of recommendations grounded on similarities that exist in comparing previous activities or users' stored data. According to literature, there exist two ways commonly used to achieve memory-based techniques (item-based or user-based techniques) [8]. Fig. 1 shows a summary of the recommendation techniques. Model-based techniques can be developed using algorithms, some of such algorithms include Bayesian classifiers [9], Support vector machine, Neural networks [10], Boltzmann machine, Fuzzy patterns [11], Latent features, Genetic algorithms [12] and Matrix factorizations [13].

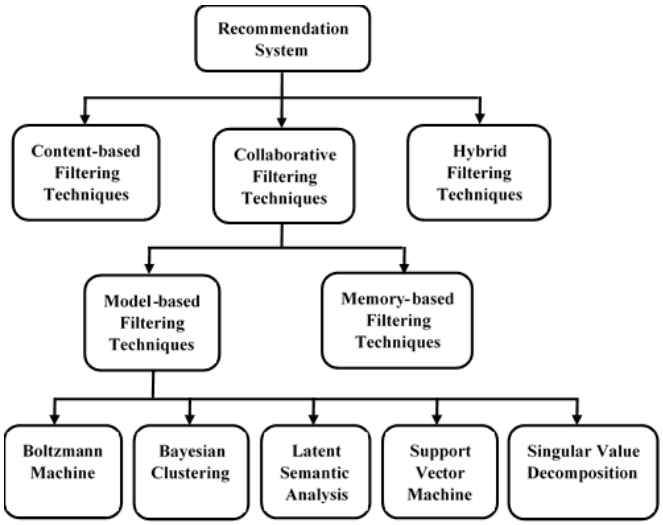

Figure. 1 Overview of existing recommendation methods

2.1. Asymmetric Singular Value Decomposition (ASVD)

ASVD is an extension of SVD. It relates to three vectors (c_i, d_i, $L_i \in \mathbb{R}^f$), also, users are signified by the objects they desire. User predictions to an item are represented in Eq. (1).

$$R'_{ui} = b_u + b_i + \mu + L_i^T(|R(u)|^{-0.5}\sum_{j\in R(u)}(R_{uj} - b_{uj})c_j + |N(u)|^{-0.5}\sum_{j\in N(u)} d_j) \quad (1)$$

by minimalizing the normalized squared error, we obtained Eq. (2).

$$\min_{b^*,L^*,c_i^*,d_i^*}\sum_{(u,i)\in K}(R_{ui} - \mu - b_u - b_i - L_i^T(|R(u)|^{-0.5}\sum_{j\in R(u)}(R_{uj} - b_{uj})c_j + |N(u)|^{-0.5}\sum_{j\in N(u)} d_j))^2 + \lambda(b_u^2 + b_i^2 + \| L_i\|^2 + \sum_{j\in R(u)}\|c_i\|^2 + \sum_{j\in R(u)}\|d_i\|^2) \quad (2)$$

where R_{ui} represent user ratings u to item i, μ represent the overall mean rating, b_u and b_i represent detected deviation of user u and observed deviation of item i correspondingly, $R(u)$ represent a set of the total items rated by the user u which are known ratings, $N(u)$ represent the set of all items which are rated by u, this can either be a known or an unknown rating and j represent an item.

The regularized squared error was minimised using stochastic gradient descent, and the boundaries λ and γ are

assigned positive real values of 0.002 and 0.005 respectively [14].

2.2. Multi-Criteria Recommender System (MCRS)

Majority of the RSs in use today are based on a single criterion rating which contains the overall user's satisfaction of an item [3]. Single criterion rating hides the users' choices and misleads the system when predicting items to the users [15]. It works in two-dimensional space of users and its utility function as expressed in Eq. (3)

$$R: Users \times Items \rightarrow R_0. \quad (3)$$

The utility function is gotten from the user inputs, e.g., transaction history or numeric ratings.

Single-criterion rating systems have shown successful recommendations in many areas. However, research in RS has identified the benefits of multi-criteria RS to enhance the prediction accuracy [16]. Multi-criteria RS does this by providing detailed information about the user ratings than a single-criterion RS and this enhances the recommendation process [5]. To determine the utility function of a user for a given item, we consider the overall rating R_0 and the user's ratings $R_1, \ldots, R_k$ for each criterion c (c = 1, 2, ..., k). Thus, the utility function R for multi-criteria RS is given as in Eq. (4)

$$R: Users \times Items \rightarrow R_0 \times R_1 \times R_2, \ldots, R_k. \quad (4)$$

2.3 Genetic Algorithm

Genetic Algorithms (GAs) are a robust and stochastic search technique centered on natural selection and evaluation that is frequently applied when encountering optimization problems. GA applications are frequently used when dealing with combinatorial optimization problems [17]. GA applies the same knowledge as any other evolutionary algorithm. It makes use of data collected from a set of individuals, represented as *G(i)*, where *G* represents the set (population), and *i* represents the number of the set (individuals). Each of the individuals is evaluated by assigning an appropriate fitness value, which is dependent on how respective individual is close to finding a solution to the problem. As its iteration continues, it finally approaches a local minima/maximum of the function.

A possible solution for a GA problem in GA is often called *chromosome or individuals*. Chromosomes are referred to as a set of genes; where each gene is represented by a distinct bit of nearby bit that encodes a part of the possible solution. Chromosomes are often scrambled as a sequence of bit string characterized abstractly in a genetic form. *Locus* is referred to as a location that has the encoding of some traits, while an *Allele* is a representation of each possible value of a locus (0 or 1) [18].

The *genotype* is referred to as a set of genes that exist in a genome, while the *Phenotype* is referred to as the physical representation of the genotype. After each encoding of the chromosome, the next step is to apply several reproduction procedures to the genotype. The genetic operators, such as the crossover, selection and mutation works on the genotype plot in other to return the value of the best chromosome.

Lastly, the stochastic nature of GA makes it challenging when trying to guarantee a solution that is optimal, and the algorithm may never stop running, which prompts for a termination condition. The algorithm is said to terminate only when the stopping criterion is met. The flowchart of a GA is shown in Fig. 2.

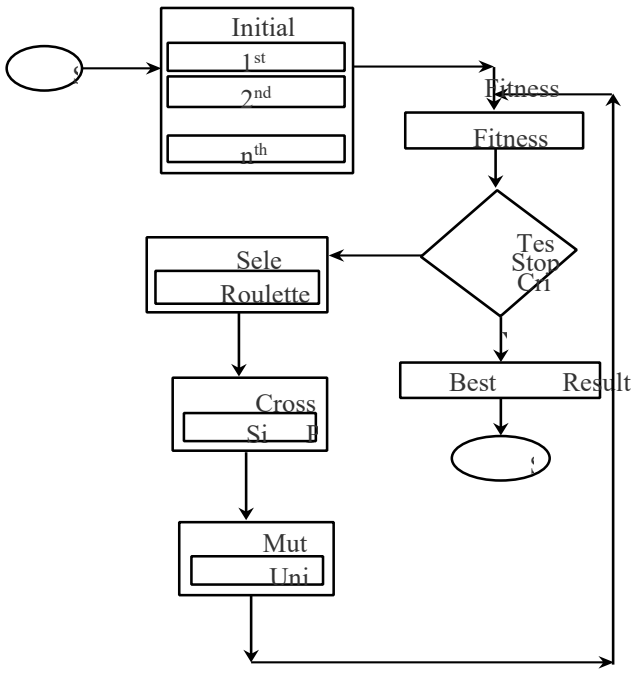

Figure 2 Flow chart of a standard genetic algorithm

2.3.1 Adaptive GA

Adaptive genetic algorithms are a subset of genetic algorithms. They provide substantial functionality improvements over the traditional GA implementations [19]. The configuration of genetic algorithms operators such as the probability of mutation and probability of crossover is a significant deterministic factor which affects the performance of a GA. The main function of GA is that, they help to modify the operators automatically, this is done by fine-tuning the operators centred on the algorithm's state [20]. These fine-tuning operations offered by GAs helps in maintaining convergence capacity and population diversity. The modification is centred on the values of the fitness solution which are, the best fitness value of the recent population and the best fitness value of the average population.

2.4 Fuzzy logic: An overview

Fuzzy Logic (FL) is a concept that is gotten from the fuzzy set theory which was developed by Lotfi Zadeh in 1975 [22]. It is a technique that can be used to mathematically express human reasoning or language by using a range of real numbers between 0 and 1. A membership function (MF) expressed as μA and defined as $\mu A: X \rightarrow [0, 1]$ is used to express the degree of membership of elements in a fuzzy set A.

2.4.1 Fuzzy logic architecture

Fuzzification

This step involves converting crispy set of inputs to a fuzzy set.

Linguistic variables

These are variables whose values are represented using ordinary language

Membership Function (MF)

It is used to represent graphically the amount of satisfaction a user got from an item.

Fuzzy Rule

It controls the output variable by applying some set of rules

Defuzzification

It is used to get a crispy value.

3. Methodology

This section presents the methods and frameworks used in the implementation of both systems.

3.1. Experimental dataset

Both systems were evaluated using Yahoo! Movie dataset collected from their website [5]. The dataset is a multi-criteria dataset that consists of user preferences ratings on movies based on four various movie features as follows: direction (c1), action (c2), story (c3), and visual (c4) effect of the movie. Each criterion ratings were considered on a 13-fold scale ranging from F through A^+ where F denotes the lowest preference, while A+ denotes the highest preference. An overall rating (c_0) denotes the total satisfaction derived by the user. The sample of the dataset is shown in Table 1.

Table 1: User Rating Obtained from *Yahoo*! Movies Rs

User ID	direction (c_1)	action (c_2)	Story (c_3)	visual (c_4)	Overall rating	Movie ID
1	10	10	10	8	9	100
	5	8	3	2	5	25
2	1	5	8	2	4	48
1	7	7	5	9	5	320
	10	13	4	13	10	360
3	7	8	10	10	9	224

For simplicity to model both systems, these categorical data were transformed to the numerical dataset as shown in Table 2.

The datasets were pre-processed to remove inconsistency that arose due to missing ratings. In the end, we achieved a total of 6078 users, 978 movies and 62,156 ratings with 0.0105 total sparsity estimate. The global median, global average, and standard deviation are 11.0000, 9.5221, and 3.5232, respectively. The summary of the records is shown in Table 3.

Table 2: User Rating Obtained from Yahoo Movies Rs (After Conversion)

Values	Frequency-rating	Percentage (%)	Cumulative-Percentage(%)
1	3395	5	5
2	1340	2	8
3	1522	2	10
4	1329	2	12
5	2051	3	16
6	2428	4	19
7	2489	4	23
8	3251	5	29
9	5586	9	38
10	7006	11	49
11	6702	11	60
12	12153	20	79
13	12904	21	100

Table 3: Rating Frequency of The $user \times item$ In Yahoo! Movie Datasets After Preprocessing.

User ID	direction (c_1)	action (c_2)	story (c_3)	visual (c_4)	Overall rating	Movie ID
1	B^+	B+	B+	B	B+	100
	D^-	B	D-	D	C	25
2	F	C	B	D	D+	48
1	C^+	C+	C	B-	C	320
	B^+	A+	D+	A+	B+	360
3	C^+	B	B+	B+	B-	224

3.2. Adaptive GA MCRS Methodology

The Adaptive GA method for rating approximation was divided into different stages:

1) Prediction of N multi-criteria Rating: This was done by decomposing the *k*-dimensional multi-criteria ratings into *k* single rating problem. To predict the unknown multi-criteria rating, an ASVD was used. For the next stage, the individual ratings were combined to provide an overall prediction of the ratings.

2) Acquiring the Function: This stage was aimed at approximating the connection between the original multi-criteria ratings and overall ratings of the items, such that $R_0=f(R_1,\ldots, R_k)$. An Adaptive GA was used to obtain the optimal weight of the individual benchmark for respective users over several criteria.

Feature weight is the priority a user gives to a feature, which may differ for each feature. In our method, Adaptive GA was applied to modify the weight to take user priorities for several features. User feature weight is denoted as a set, weight (u_a) = [w_i] (where i = 1, …, z, and z = number of features). Any feature with the weight zero is ignored for further calculation. Any double-valued vector strings are used to represent the genotype. The proposed adaptive GA parameters are reviewed below:

i. ***Initial Population*:** The original set of the population was created randomly with a size of 40 which consist of valid feature weights.

ii. ***Fitness Function*:** Fitness function is one of the most significant parts of GA. This function determines the success level of the individual chromosome after the population set is initialized. For a user who is active, a separate chromosome c is allocated a fitness function. The examined fitness function computes the accuracy of the predicted items using generated random weights. Eq. (5) represents the proposed fitness function.

$$fitness\ (c) = 1 - \left(\frac{\sum_{j=1}^{N_a} \left| R_{0j} - \left(\frac{w_1 R_{j1} + \cdots + w_z R_{jz}}{(w_1 + \cdots + w_z)} \right) \right|}{N_a} \right) \quad (5)$$

where N_a represent the aggregate number of times an individual chromosome c was tested, R_j represent the real ratings and R_{0j} represent the total ratings of u_a on an item, i_j.

iii. **Reproduction:** his step was solely dependent on the value of individual chromosome's fitness function. The fitness function defined for individual chromosome in the set of the population was computed and the chromosomes with the highest fitness rate were chosen as best chromosomes. The best chromosomes are reserved for the following generation.

iv. **Selection:** Roulette wheel selection technique was used, where parents are chosen according to their fitness value. Using the roulette wheel technique, each chromosome is allocated a slice of the wheel and the size of the slice is proportional to each chromosome's fitness. The wheel is then rotated and any chromosome the wheel lands each time was chosen.

v. **Crossover:** A single point crossover was selected to be implemented for the crossover. The selected crossover point was done randomly along the mated string length, then the next crossover point bits were swapped. The crossover probability was dependent on the fitness function, due to the fact that it's an adaptive GA.

vi. **Mutation:** Diversity was introduced by adopting uniform mutation. The value of the chosen gene was replaced with a uniform random value, selected between the specified upper and lower bounds for the gene by the mutation operator. The mutation probability was dependent on the fitness function, due to the fact that it's an adaptive GA.

vii. **Termination Condition:** Stopping criteria were centred on a well-defined number of initiations (100), and also on the convergence of best fit chromosomes.

3. Predicting Total rating: The calculation of the unknown total rating for test data was accomplished using the weighted sum of each predicted ratings. This was generated as depicted in Eq. (6).

$$R'_0 = \frac{\sum_{i=1}^{z} w'_i \times R'_{ji}}{\sum_{i=1}^{z} w'_1} \quad (6)$$

Where R'_j represent the predicted rating of u_a to i_j of the particular multi-criteria ratings. Developing Eq. (6) yields Eq. (7)

$$R'_0 = \frac{w'_1 R'_{j1} + \cdots + w'_z R'_{jz}}{(w'_1 + \cdots + w'_z)} \quad (7)$$

The aim of multi-criteria recommender systems is to generate a recommendation list for active users. The RS calculates the unknown total ratings by using feature weight function. Lastly, all unrated items and objects were sorted in non-increasing order with respect to the total ratings. Fig. 3 summarizes the working process of the Adaptive MCRS.

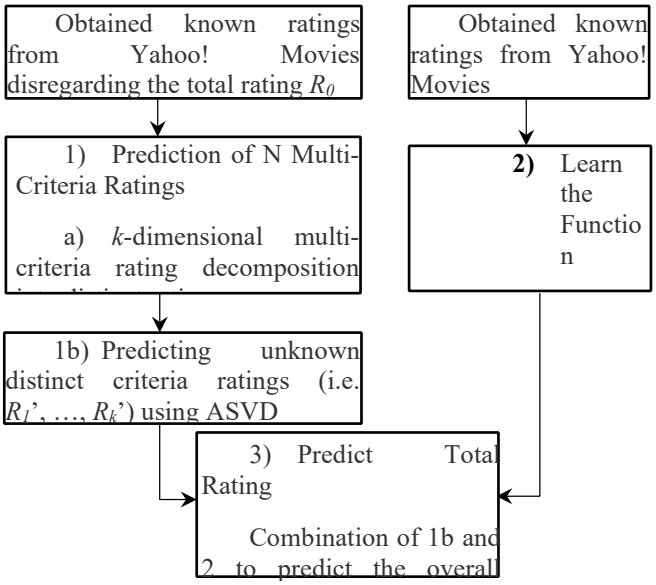

Figure 3 Structure of Adaptive Multi-Criteria Recommender System

3.3. Fuzzy-based MCRS Methodology

i. Predict N Multi-criteria rating

This step involves the decomposition of the n-dimensional multi-criteria rating space $R: Users \times Items \rightarrow Ro \times R_1 \times \ldots \times Rn$ where $(i = 1, \ldots, n)$ into n single-rating recommendation problems as $R: User \times Item \rightarrow R_c (c = 1, 2, \ldots n)$. The proposed model learns and predicts the user ratings for new items, however, we did not consider the overall rating at this stage.

$$(a, b, c) = \begin{cases} 0, & for\ x \leq a \\ \frac{x-a}{b-a} & for\ a \leq x \leq b \\ \frac{c-x}{c-b} & for\ b \leq x \leq x \\ 0 & for\ x > c \end{cases} \quad (8)$$

ii. Learn the Relationship f

This stage involves the computation of the relationship f relating to the overall rating r_0 and multi-criteria $r_1, \ldots, r_k$. Also, The aggregation function is considered as shown in the work of [21]. We integrated the FL technique to find the degree of satisfaction derived by a user from an item. Firstly, the user's ratings were represented using linguistic terms including (high, medium, low, etc.) and triangular membership function as shown

in TABLE 4. We considered a triangular membership function whose membership function is well-defined by the real numbers expressed as (a, b, c) as shown in Eq. (8).

We defined the membership function using 13 linguistic terms to represent interests of users and degrees to which each criterion was chosen. To compute the weight that determines the actual degree of membership of each criterion rating, this is calculated by dividing each user rating by n as shown in Eq. (9) below:

$$w_i = \frac{R_i}{n} \quad (9)$$

Where R_i represent user rating for each item and n represent the total number of fuzzy linguistic value.

We then derived the relationship f to learn how the user rates an item. Eq. (10) shows the aggregation function.

$$f(x_u^j) = \frac{\sum_{i=1}^{n} w_i\, c_i}{\sum_{i=1}^{n} c_i} \quad (10)$$

Where Ci is the users' criteria ratings and W_i is the weight associated with each criteria rating (for $i = 1, 2, \ldots, n$)

The relationship f for each user criteria rating for j items was computed, the function that resulted in the highest degree of membership for user u, for j ratings ($j = 1, 2, 3, \ldots n$) is chosen as the most preferred criterion for the user as shown in Eq. (11).

$$f(x_u) = max\{f(x_u^j)\}. \quad (11)$$

Table 4: Membership Function

User rating	TFN	Linguistic terms
1.0	(0,1,2)	V-V-V-V-low
2.0	(1,2,3)	V-V-V-low
3.0	(2,3,4)	V-V-low
4.0	(3,4,5)	V-low
5.0	(4,5,6)	Low
6.0	(5, 6,7)	Medium-low
7.0	(6,7,8)	Medium
8.0	(7,8,9)	Medium-high
9.0	(8,9,10)	High
10.0	(9,10,11)	V-high
11.0	(10,11,12)	V-V-high
12.0	(11,12,13)	V-V-V-high
13.0	(12,13,14)	V-V-V-V-high

i. Predict Overall rating

At this stage, the model predicts the overall rating $r'_0 = f(r'_1, r'_2, \ldots, r'_k)$ for an active user u_a. This is achieved through the integration of the trained fuzzy MCRS and the

single rating technique (Asymmetric SVD) so as to present the top-N recommendation to a user u_a. To calculate the overall rating for the user u_a, we use Eq. (12).

$$r'_0 = \frac{\sum_{i=1}^{n} w'_i \times P'_{ji}}{\sum_{i=1}^{n} w'_i} \quad (12)$$

Where

W_i represents the selected weight of the users to item i, and P_i represents the predicted rating of the users to the item i_j.

3.4. Implementation

Java programming language was used for implementing both systems. Java is a class-based, object-oriented programming language that is rich in FL and GA libraries that enhanced the process of both systems implementation,

3.4.1 Performance Metrics

To check the precision of both systems we explored the three categories of prediction precision measures [3]. As follows:

1. Rating predictions**:** Root Mean Squared Error (RMSE) and Mean Average Error (MAE) were used.

(a) RMSE: checks the precision of the predicted ratings as defined in Eq. (13) below:

$$RMSE = \sqrt{\frac{1}{|T_s|}\sum_{(u,i)}(\varepsilon T_s)\left(\widehat{P_{ui}} - r_{ui}\right)^2} \quad (13)$$

(b) MAE is defined in Eq. (14)

$$MAE = \frac{1}{T_s}\sum_{(u,i)}(\varepsilon T_s)\left|\widehat{P_{ui}} - \widehat{r_{ui}}\right| \quad (14)$$

Where: T_s = Test sets of user − item pairs (u, i) , $\widehat{P}_{ui}$ represent the predicted rating generated by the system and r_{ui} represent the actual rating of the user.

2. **Usage prediction**: This is used to measure the accuracy of the system based on how the system would predict the item a user would add to their content list. We considered Recall and Mean Average Precision (MAP) for the top-10 recommendation, which is defined in Eq. (15) and Eq. (17).

(a) $$recall = \frac{\#tp}{\#tn+\#fn} \quad (15)$$

Where tp is the number of positive useful items and fn is the number of useful predictions that are not in the top-n recommendation list.

(b) MAP: This calculates the value of Average Precision (AP) throughout the distinctive levels of recall. The value of MAP is expected to be less than or equal to 1 for a good algorithm and 0.5 for a bad algorithm. Eq. (16) and Eq. (17) was used to calculate these

$$AP = \frac{\sum_{i=1}^{N}(\text{precision(i)}\times\text{recall(i)})}{\text{number of relevant items}} \quad (16)$$

$$MAP = \frac{\sum_{u=1}^{M} AP_u}{M} \quad (17)$$

Where M represents the total number of items that are relevant in the catalogue of Top-N recommendation

3. **Ranking prediction**: This evaluates how accurate the

system would predict how a user would rank items according to their preference. Three approaches were considered, they are

(i) Area under the curve of Receiver Operating Characteristics (ROCAUC),
(ii) Fraction of Concordant Pairs (FCP),
(iii) Normalized Discounted Cumulative Gain (NDCG).

$$(a)\ ACU = \frac{1}{N}\left[\left(\sum_{i=1}^{\#tp_u} rank_{uj}^{+}\right)^{\#tp+1}_{2}\right] \quad (18)$$

where $rank_{uj}^{+}$ is the Position of the k^{th} relevant item on the top-N recommendation

$$(b)\ FCP = \frac{n_c}{n_c + n_d} \quad (19)$$

where n_c is the number of concordant pairs defined as:

$$n_c = \sum_u \varepsilon \cup |i,j| \left\{ \widehat{r_{ui}} > \widehat{r_{uj}} \Rightarrow \hat{r}_{ui} > \hat{r}_{uj} \right\} \quad (20a)$$

and n_d is the number of corresponding discordant defined as:

$$n_d = \sum_u \varepsilon \cup |(i,j)| \left\{ \hat{r}_{ui} > \hat{r}_{uj} \Rightarrow \hat{r}_{ui} \leq \hat{r}_{uj} \right\} \quad (20b)$$

4. Results and Discussion

This section discusses the results of the experiments done

4.1. Experiment

To verify the precision and efficiency of both systems, experiments were done using the Yahoo! movie dataset. An offline experiment was performed to simulate the actual system. Both systems were compared with their corresponding traditional collaborative filtering technique known as Asymmetric Singular Value Decomposition (AsySVD). We performed each test using a 10-fold cross-validation rule, which randomly divides the datasets into 10 separate subsets. The dataset was divided on a ratio of 90: 10 where 90% is used as training-sets and 10% as a test-set. The precision of both systems was checked by applying the metrics discussed in section 3.3.1. The results of evaluating the systems were compared with their corresponding traditional rating. TABLE 5 and TABLE 6 give the breakdown of the resulting performance evaluation of the system. We used Adaptive MCRS, Fuzzy-MCRS and AsySVD to represent Adaptive Genetic MCRS, Fuzzy logic model and Asymmetric SVD respectively.

Table 5: Performance Evaluation Results

Performance-measure	AsySVD	Adaptive-MCRS	%Accuracy Improvement
MAE	2.3980	1.5990	0.7990(49.9%)
RMSE	3.0900	2.1220	0.9680(45.6%)
MAP	0.0200	1.0290	1.0090(98.1%)
AUC of ROC	0.6880	0.9510	0.2630(27.7%)
FCP	0.7100	0.9460	0.236(24.9%)

It can be clearly seen from TABLE 5 above that the Adaptive MCRS outperforms the traditional AsySVD. The results proved that Adaptive MCRS achieved better predictive performance. The Adaptive MCRS approach achieved a decrease in prediction accuracy in terms of RMSE and MAE. RMSE and MAE had a value of 0.968 and 0.799 respectively, this decrease might seem minute, but it is able to generate a totally dissimilar answer and interpret into substantial enhancement on the accuracy and quality of recommendation. Adaptive MCRS achieved a MAP of 1.029, outperforming the traditional AsySVD by 50.5%. There is a necessity for recommendation algorithm to generate recommended ordering of objects or items that matches how users would have ranked the same item since users are frequently concerned of the items at the top-N recommendation list. The Adaptive MCRS achieved a more accurate and improved rank accuracy of 33.2% and 38.2% respectively for FCP and AUC when compared to the conventional AsySVD, which implies that Adaptive MCRS will provide a further precise top-N recommendation list to users. Fig. 4 is a line chart clearly demonstrating the high-performance result achieved by Adaptive MCRS as compared to AsySVD.

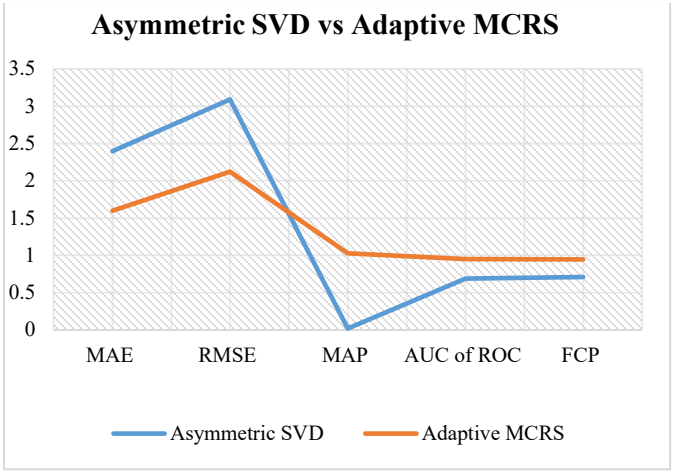

Figure. 4. The result of the evaluation of Adaptive MCRS

The result From Fig. 5 and TABLE 6, shows that Fuzzy-MCRS achieved a lower prediction error in RMSE and MAE, and similarly shows a higher-ranking accuracy in AUC and FCP. This indicates that modelling a multi-criteria RS using fuzzy logic would yield an efficient and more accurate system than the traditional AsySVD.

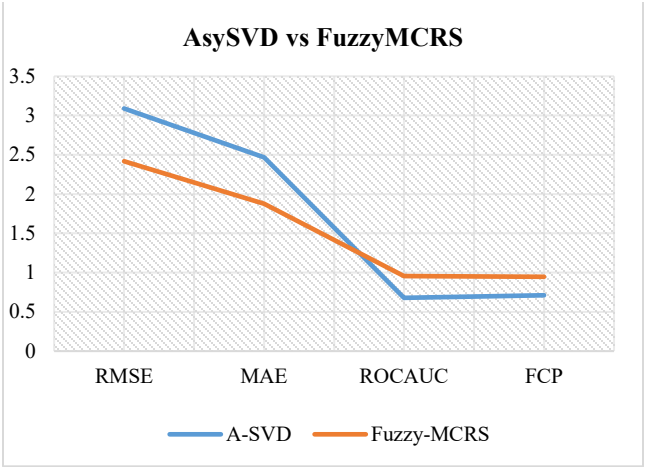

Figure 5. Comparing AsySVD and Fuzzy-MCRS

Table 6: Comparison of Result Of The Evaluation

Metrics	Fuzzy-MCRS	AsySVD	Accuracy Improvement
RMSE	2.4176	3.0895	0.6719(27.7%)
MAE	1.8753	2.4677	0.5924(31.5%)
ROCAUC	0.9558	0.6786	0.2572(26.9%)
FCP	0.9467	0.7118	0.2349(24.8%)

Table 7 and Fig. 6 clearly shows the comparison of the experimental result from both models. Adaptive MCRS resulted in lesser prediction inaccuracy in MAE and RMSE than the Fuzzy-MCRS, which implies that Adaptive MCRS yielded a better rating prediction than Fuzzy-MCRS. But both models seem to have equivalent usage accuracy, although Fuzzy-MCRS seem to have produced a higher usage accuracy level in ROCAUC and FCP than the Adaptive MCRS. This shows that Fuzzy-based model would be ideal for predicting the ranking behaviour of users for an item since it studies the exact degree to which a user will rank items to their content list and the order in which the items would be ranked. Similarly, Adaptive MCRS would be ideal to model a system that would be accurate in predicting and classifying the rate of satisfaction derived by a user from a purchased item.

Table 7: Comparison of Fuzzy-Mcrs and Adaptive-Mcrs

Metrics	Fuzzy-MCRS	Adaptive MCRS	Percentage Change
RMSE	2.4176	2.122	0.2956 (13.9%)
MAE	1.8753	1.599	0.2763 (17.3%)
ROCAUC	0.9558	0.951	0.0048 (0.5%)
FCP	0.9467	0.946	0.0007 (0.1%)

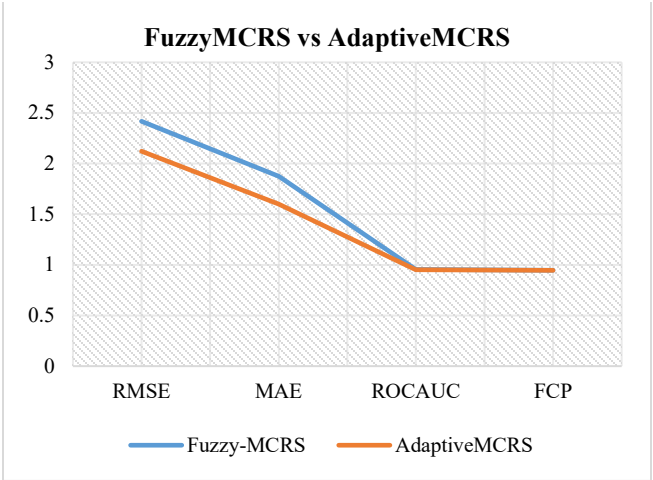

Figure. 6. Comparison of Fuzzy-MCRS and Adaptive MCRS

5. Conclusion

Providing efficient techniques for integrating the criteria ratings in multi-criteria RSs is of the utmost significance in predicting preferences of users based on several attributes of the items. Machine learning methods and other powerful techniques from the area of artificial intelligence should be the priorities, especially in product recommendations such as movies, song, and other items that could be purchased online. In this study, two important techniques (Adaptive genetic algorithm and fuzzy logic) have been proposed for developing recommendation models that could efficiently integrate the criteria ratings for making good recommendations. The experiments were conducted using a real-life dataset from Yahoo Movies, and the results have been analysed and compared. The study has shown that the two techniques realized the objectives of delivering better recommendation and predictive performance. This performance includes a reduction in error prediction and increased classification and rank accuracy. Lastly, the obtained experimental results from associating the predictive implementation of both multi-criteria recommender systems using the adaptive genetic algorithm and fuzzy logic, with existing conventional CF approach showed that the proposed system produced results that are better and also outperformed the conventional CF recommender system. Nonetheless, to achieve a better performance, it is recommended to design a hybrid model which could resolve some of the issues realized in the results of both systems.

Therefore, we propose to integrate both models to achieve higher performance. However, in the future, we plan to acquire a larger amount of data from a different domain to further certify the accuracy of the proposed system.

Marginal cost

ABSTRACT

To reduce its high last mile logistics cost, a company may explore different options such as a horizontal collaboration with another company that has a similar logistics requirement. Traditionally, the collaboration can be conducted through an outsource contract mechanism where the company may need to guarantee a certain number of logistics demands or usage for a fixed period of time. This may incur a fixed transportation and logistics cost for the company. For a company who has more fluctuated logistics demands, it would be difficult to guarantee a certain number of logistics demands or usage for an outsourcing mechanism. The company may end up paying more than it should. Alternatively, the company may want to explore horizontal collaboration with a more flexible contract mechanism such as the "4th party milk run" (4PMR). The 4PMR model leverages on the last mile excess capacity of one company to fulfill the last mile logistics demands for another company based on a pay-per-use arrangement. Using the 4PMR model, the fixed transportation and logistics cost would be translated into a marginal cost. This paper describes the 4PMR model, including the optimization model and its computation experiment on two last mile logistics scenarios. The first scenario is a hypothetical scenario based on our field study in Jakarta, Indonesia with a small number of deliveries, while the second scenario is an actual scenario with a large number of deliveries based on existing routes of a Logistics Service Provider (LSP) in Surabaya, Indonesia. The experiment results show that 4PMR is able to provide a significant reduction in last mile logistics cost. To complement the experiment results, industry perspectives for implementing the 4PMR model is also reviewed.

1. Introduction

This paper is an extension of the work originally presented in the 2017 6th IEEE International Conference on Advanced Logistics and Transport (ICALT) in [1]. Loss of logistics efficiency becomes the highest across the supply chain at the nearest point to the aggregated or single demand point [2, 3]. This last (or sometimes first) mile logistics face significant fulfillment constraints, making it the most expensive part of the overall supply chain. For a company that moves millions of tons of materials every year, reducing the last mile logistics cost by a few cents can save tremendous amounts of money. As such, the company looks for new strategies to reduce the last mile logistics cost. Several strategies such as a horizontal collaboration with other similar companies or partners in the same level of the supply chain are now attracting the interest of those companies [4, 5, 6].

In supply chain, collaborations between companies can be grouped into two, namely: vertical and horizontal collaboration [7]. The vertical collaboration includes collaboration between companies in different level of supply chain [7], such as Vendor Managed Consignment Inventory (VMCI) model [8] and Collaborative, Planning, Forecasting and Replenishment (CPFR) model [9]. While the horizontal collaboration includes two or more

* Corresponding author: Linda William, School of Informatics and IT, Temasek Polytechnic, 21 Tampines Ave 1, Singapore 529757, Telp: +65-6780-5274, email: lwilliam@tp.edu.sg

unrelated or competing companies at the same level of the supply chain [7]. In horizontal collaboration, a company can work closely with another company that has similar logistic requirements by sharing resources and taking advantage of potential distribution synergies [10]. The benefits of horizontal collaboration are increasing vehicle utilization on the main tracking routes and vehicle efficiency as well as better improving resource management and delivery service level to the customers. Although vertical collaboration has been deeply studied and implemented [11], horizontal collaboration is still in its infancy [12, 13].

As illustrated in Figure 1, horizontal collaboration can be done in several forms. A company may explore the option of engaging one or more companies (e.g. Logistics Service Provider (LSP)) in a form of fixed outsourcing contracts to fulfill its last mile logistics demands. The company may need to guarantee a certain number of logistics demands or usage for a fixed period of time (e.g. monthly, quarterly or yearly) to the outsourcing companies. Using outsourcing, the company is able to save a substantial amount of money because the company does not need to invest in costly logistics-related assets such as transportation vehicles. Generally, this kind of outsourcing would incur a certain amount of fixed transportation and logistics costs.

For a company who has more fluctuated logistics demands, it would be difficult to guarantee a certain number of logistics demands or usage for outsourcing mechanism. The company may need to pay the fixed cost even though it has minimum logistics demands. For this kind of company, a model with a flexible (and often less binding) agreement, such as "uberization" and "4th party milk run" (4PMR) would be beneficial. These models use the pay-per-use mechanism that allows the company to pay only based on its logistics demands. It would reduce the logistics cost by translating the fixed costs to marginal costs. For example, the company does not need to pay fixed cost of 90,000/month for having only 50 last mile logistics demands.

These models use sharing economy concept to reduce the transportation costs. Uberization mainly focuses on conducting the deliveries using crowdsourcing, while the 4PMR model focuses on collaborating with one company (B2B) that has existing delivery routes/networks along the last mile delivery locations.

This paper focuses on analyzing the 4PMR model for reducing last mile logistics cost. It extends the model in [1, 14]. The 4PMR model is developed as an optimization model and solved using two metaheuristics solvers/algorithms. To investigate the cost reduction, we test the model on two scenarios. The first scenario is a hypothetical scenario based on our field study in Jakarta, Indonesia. It consists of 40 random logistics demand samples. While the second scenario is an actual scenario based on 9,622 logistics demands from an LSP in Surabaya, Indonesia. Our experiment results show that the 4PMR model is able to reduce 4.16% and 24.84% of the logistics cost in the first and the second scenario respectively. This provides a promising indication that the 4PMR model would be able to reduce the last mile logistics cost. To complement the experiment results, we also gather industry perspectives for implementing the 4PMR model in its day-to-day logistics operations.

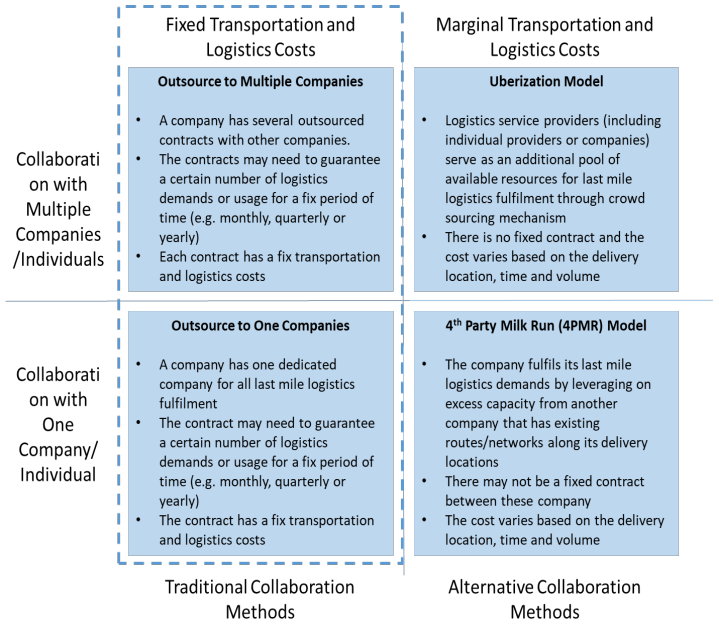

Figure 1. Horizontal Collaboration Strategies

The remainder of the paper is organized as follows. Section 2 presents the overview of 4PMR and its related works. Section 3 reviews the 4PMR optimization model. Section 4 describes the solvers/algorithms to solve the 4PMR and section 5 describes the computational experiments, including the scenarios and experiment results. Section 6 reviews the industry perspective on implementing 4PMR model. Lastly, section 7 presents the conclusions.

2. 4th Party Milk Run (4PMR) Model

2.1. Overview

The 4PMR model leverages on the excess capacities from one company that has existing designated routes along the last mile logistics demand locations of another company. The company with existing designated routes (henceforth as providing company) needs to serve those routes periodically regardless of the delivery volume. These routes may not be fully utilized and may have significant excess capacities. These unused capacities can be tapped and used by another company (henceforth as receiving company) to fulfill its last mile logistics demands.

In 4PMR model, the routing is based on the existing routes or networks from the providing company. It would stop at several locations to fulfill logistics demands from the receiving company.

2.2. Benefits of 4PMR model

The 4PMR model would bring benefits to the collaborating companies. These benefits can be categorized into three groups: costs and productivity, service and market position.

1. Cost and productivity benefits

One potential benefit of using the 4PMR model is to reduce logistics costs [15, 16]. Both collaborating companies, providing and receiving companies, would be able to achieve logistics cost reduction. By joining their delivery requirements, these companies can utilize and optimize their logistics-related assets. This can be

translated into a lower logistics cost and lower capital investment for logistics-related assets as it would need a lesser number of logistics-related assets.

One example of this cost reduction is on empty backhaul utilization. The providing company may have existing routes from area A to area B. If there is an imbalance of deliveries where all the loads come from area A to area B with no loads from area B to area A, the providing company must absorb the cost of the empty vehicle return (empty backhauls). However, if another company has last mile logistics demands in the opposite direction (from area B to area A), the company can make use of the empty backhauls. The providing company would be able to reduce its costs of absorbing empty backhaul while the receiving company would be able to negotiate a lower transportation cost.

2. Service benefits

For the receiving company, the 4PMR model would add the company capabilities to serve low demand areas. It allows the company to facilitate more frequent deliveries for wider geographic areas. The receiving company would be able to expand its area coverage by collaborating with the providing company that operates in different areas with minimum additional setup cost. It provides flexibility in providing more service and reaching more potential customers.

3. Market Position

For the providing company, the 4PMR model would enable the company to have "insinking" opportunities where the company would be able to replicate its 4PMR model to provide services to different companies and proactively select a group of companies with a strong synergy potential [10, 17]. It would create another business opportunity for the providing company. It would further increase vehicle utilization and reduce the last mile logistics cost.

2.3. Related Works

Two areas of works that is closely related to ours are the Vehicle Routing Problem (VRP) [18, 19] and Milk Run Logistics [20, 21]. VRP aims to provide optimal set of routes for a fleet of vehicles to fulfil logistics demands. It has many variants, including VRP with Time Windows [22, 23], Capacitated VRP [24, 25], green VRP [26, 27] and ride-sharing VRP [28, 29]. While Milk Run Logistics is essentially a logistics method that uses routing to consolidate the transportation of goods that has the following characteristics: small lot of transport, less than truckload, geographically sparse demands [20], as illustrated in Figure 2. As shown in Figure 2, milk run model reduces the excess capacity by consolidating the deliveries from different companies (i.e. Company X and Company Y).

3. Optimization Model

One potential concern with the 4PMR model is that the providing company may not have a direct route to fulfill the receiving company' logistics demands (direct from an origin location to a final destination location). It may need to go through several stops/hops/transit locations before it can finally deliver to the final delivery destination. There is a need to match the providing company existing routes with the receiving company logistics demand locations.

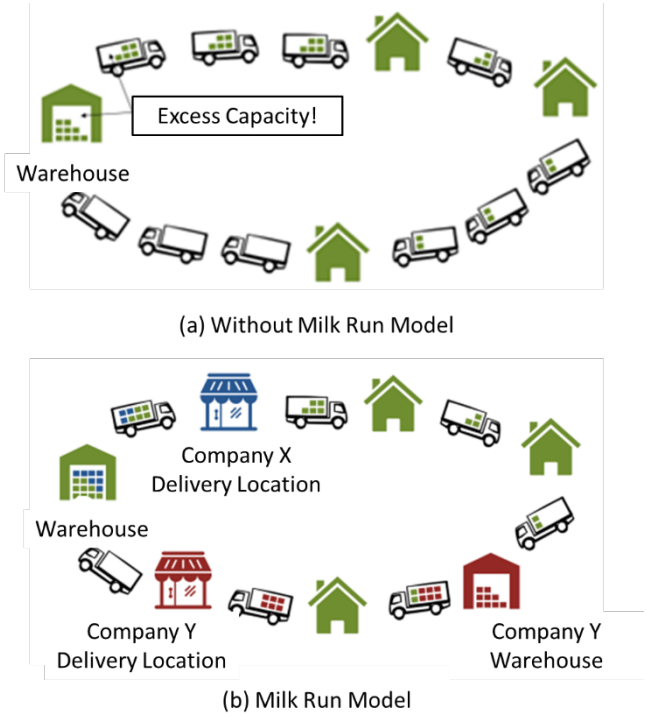

Figure 2. Milk Run Model Illustration

To match the logistics demands with the existing routes, an optimization model for the 4PMR is developed. The 4PMR model is defined as follows. Let $G = (v, e)$ be a directed graph representing the providing company existing routes. It consists of a set of locations, as vertexes or nodes (the term vertex and node are used synonymously throughout the paper), denoted by $V = \{v_1, v_2, \dots, v_n\}$, and a set of routes, as arcs E $\subseteq$ V x V, denoted by an ordered pair of nodes (u, v), where $u \in V$ and $v \in V$. e_{uv} represents a directed route from node u to node v. Each arc e_{uv} has an excess capacity Q_{uv} and time capacity T_{uv}. To simplify the problem, we consider each arc to have a fixed excess capacity Q_{uv}. For each arc e_{uv}, d_{uv}, t_{uv} and c_{uv} represent a non-negative travel distance, a non-negative travel time and a non-negative transportation cost for arc e_{uv}, respectively. A path is defined as a sequence of arc $p_{uv} = \{u = u_1, (u_1, u_2), (u_2, u_3), \dots, (u_{l-1}, u_l), u_l = v\}$.

Let $L = \{1, \dots, n\}$ be a set of logistics demands of the receiving company. Each delivery $l \in L$ has delivery load size q_l, origin node u and destination node v. $[w_u, z_u]$ denotes the time window in origin node u. While $[w_v, z_v]$ denotes the time window in destination node v. Each delivery service at origin node u and destination node v must take place between the time windows. For each logistics demand $l \in L$ from origin node u to destination node v fulfilled by 4PMR model, the delivery cost is defined as $c^l(p)$, where $c^l(p) = \sum_{(u,v)\in p} c^l_{uv}$. If the delivery fulfillment cannot be done using the 4PMR model (due to capacity or time constraints), it will use a direct delivery. The delivery cost for the direct delivery denotes as c^l_d, where in general $c^l(p) \ll c^l_d$.

There are a lot of constraints that can be included in the 4PMR model, such as capacity, transportation cost, overall cost, transportation distance, and time windows. These constraints depend on the nature of the collaboration between providing and

receiving companies and the nature of the products being delivered. In this paper, we only use one constraint, capacity. The capacity for logistics demands fulfilled by the 4PMR should not exceed the fixed weight capacity Q_{uv} for each arc. The model can be expended to include more constraints.

Using these notations, we define the 4PMR problem as:

$$Min\ Z = \sum_{l \epsilon L} \left(\min \left(\min \left(\sum_{(u,v) \epsilon E} c_{uv}^{l} \times x_{uv}^{l} \right), c_{d}^{l} \right) \right) \quad (1)$$

Subject to:

$$x_{uv}^{l} = \begin{cases} 1, if\ delivery\ request\ l\ can\ use\ arc\ (u,v) \\ 0, otherwise \end{cases} \quad (2)$$

$$\sum_{l \epsilon L} q_{l} \times x_{uv}^{l} \leq Q_{uv} \qquad \text{for every } (u,v) \in E \quad (3)$$

Constraint (2) and (3) ensures that the capacity for logistics demands fulfilled by the 4PMR model goes through a certain arc should not exceed the fixed weight capacity for that arc.

4. Solvers and Algorithms

The 4PMR optimization model is implemented in two solvers/algorithms. The first solver is designed for a small dataset with less than 50 logistics demands. It uses an evolutionary function in Microsoft Excel [30]. The function is based on genetic and evolutionary algorithm to seek "good" solutions for a limited dataset. This solver fits the purpose to provide a preliminary result for further study and exploration.

The second solver is used for large problem sizes. It is developed using a meta-heuristic algorithm that combines the Dijkstra algorithm with the Greedy algorithm [31]. The algorithm has two parts as illustrated in Figure 3. First, it uses the Dijkstra algorithm to produce all the shortest paths for each pair of delivery locations in the existing routes. It also calculates the logistics cost for each of the shortest path. Second, it runs the greedy algorithm to assign the logistics demands to the path with minimum cost. It will also re-configure the shortest paths and re-calculate the logistics cost, if necessary.

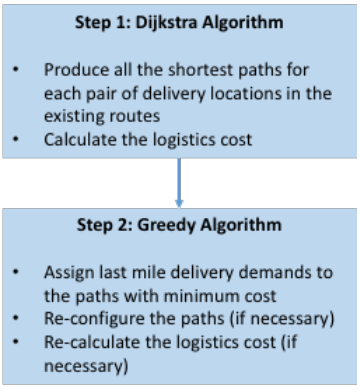

Figure 3. Meta-Heuristics Algorithm for Solving 4PMR

5. Computational Experiments

5.1. Small Problem Size

The 4PMR model was tested on a hypothetical scenario based on our field study in Jakarta, Indonesia in December 2016. The scenario comprises of a providing company with 5 existing routes. The routes connect 12 nodes. In each route, the delivery starts from and returns to the providing company' warehouse. The logistics demands are derived from a receiving company with 40 logistics demands in several locations along the providing company's routes. The receiving company produces goods and uses a hub-and-spoke model to deliver goods to all its customers within the same distribution network. The receiving company has a headquarter/main warehouse for its hub-and-spoke model. The providing company's warehouse and the receiving company's headquarter are located in different locations (represented by different nodes).

Given that the logistics demands originating from the receiving company, all the logistics demands share the same origin point – the receiving company's headquarter. For the hub and spoke distribution network, the utilization of the vehicles is 80% and that they return back to headquarter empty.

We run the first solver for this scenario. The experiment results are shown in Table 1. The results show that the 4PMR model is able to get a 4.16% reduction for the receiving company. For the no collaboration (own vehicle) model, the company will have additional costs to purchase the vehicles also (which is not included in the comparison). The detailed results for this experiment can be found in [1].

Table 1. Experiment Result of the 4PMR Model in Small Problem Size

Solution	Parameters		
	Total number of logistics demands	Number of logistics demands using 4PMR model	Logistics Cost
No collaboration (own vehicle)*	40	0	56.737
The 4PMR model	40	11	54.377

*: only logistics cost, without capital cost to purchase the vehicles

5.2. Experiment Result in Large Problem Size

To evaluate the performance of the 4PMR model in large problem size, we tested the model on scenario based on actual delivery routes from one Logistics Service Provider (LSP) in Surabaya, Indonesia. The LSP has an existing network comprising 27 nodes/locations with existing routes in Greater Surabaya, Indonesia. Each route has a certain excess capacity (around 20% of the overall capacity). The logistics demands were derived from real logistics demands from one FMCG company operated in Surabaya, Indonesia. We used 10 days of logistics demands in July

2015. It comprises of 9,622 logistics demands for different locations in Greater Surabaya.

Using the second solver, we run the 4PMR model for this scenario. In our experiment, we set the processing (i.e. execution) time to 10 second. To compare the 4PMR model with another horizontal collaboration, we also calculated the transportation cost for outsource mechanism. We assumed that the company needs to pay for 1 dollar for each delivery with minimum delivery of 1,000 deliveries/day.

The experiment results are shown in Table 2. The results show that the 4PMR model is able to get a 24.84% reduction from the no collaboration model and 29.54% reduction from the outsource model. For the no collaboration (own vehicle) model, the company will have additional costs to purchase the vehicles also (which is not included in the comparison).

6. Industry Perspective in Implementing 4PMR

While the benefits of the 4PMR model are clear, implementing it can be challenging. The challenges are varied depending on the company and also the industry. Based on our observation and close interaction with one e-commerce company in Singapore, we observe these two main challenges.

Table 2. Experiment Result of the 4PMR Model in Large Problem Size

Solution	Parameters		
	Total number of logistics demands	Number of logistics demands using 4PMR model	Logistics Cost
No collaboration (own vehicle)*	9,622	0	9,622.0
Horizontal collaboration with outsource	9,622	0	10,264
With 4PMR	9,622	2,656	7,231.6

*: only logistics cost, without capital cost to purchase the vehicles

Firstly, stakeholders of the 4PMR model (i.e. providing and receiving company) will require access to as much real-time data as possible. The providing company needs to provide information about its routes and excess capacities so that the receiving company can decide on whether to utilize those excess capacities or not. When excess capacities are eventually bought up, the providing company then has to update its information again to show the latest excess capacities and the routes to fulfill the receiving company's last mile logistics demands. Hence, software that leverages on secure and real-time data is needed. The Internet and the Internet of Things (IoT) can be used to facilitate information sharing (e.g. mobile applications to link providing and receiving companies).

For the providing company with existing the Transportation Management Software (TMS), another challenge will be to integrate the 4PMR solver/algorithm with its TMS. As TMS typically captures information about the vehicle, the cargo, the route and schedule, the logistics demands using the 4PMR model should be updated to the company's TMS.

Secondly, potential stakeholders of the 4PMR model (i.e. potential providing and receiving company) need to be convinced about the benefits of the 4PMR model. The potential providing company needs to evaluate whether the effort both in terms of IT infrastructure changes and manpower training to improve excess capacities worthwhile and whether there is an obvious return on investment. The potential receiving company needs to analyze its last mile logistics requirements and decides if the 4PMR model would be able to fulfill its business needs. For example, if a company requires trucking of large volumes (typically half to full truckload), it needs to understand that it risks its deliveries for not being fulfilled by the providing company because there are simply not enough excess capacities. Alternatively, if a company requires frequent trucking of easily forecasted volumes, it may need to evaluate the 4PMR model cost versus the traditional outsource model.

7. Summary and Key Take Away

This paper introduces the 4th Party Milk Run (4PMR) model for collaboration between similar companies in the same level of the supply chain. The 4PMR model leverages the excess capacities from one company (i.e. providing company) that has existing designated routes along the pick-up and delivery locations of another company (i.e. receiving company). The providing company needs to serve those routes periodically regardless of the delivery volume, and often these deliveries are not at full capacity. These unused capacities can be tapped and used by the receiving company to fulfill its last mile logistics needs. It would potentially bring benefits to the companies involved in terms of costs and productivity, service and market position.

Two solvers are designed to implement the 4PMR model. The solvers aim to match the providing company's existing routes with the receiving company's logistics demands. The first solver is used for small problem size scenario, while the second solver is used for large problem size scenario. We run these solvers for two scenarios – a small problem size scenario and a large problem size scenario. From the experimental result, it is also revealed that 4PMR is able to reduce logistics cost for up to 4.16% (in the small problem size scenario) and 24.84% (in the large problem size scenario).

Conflict of Interest

The authors declare no conflict of interest related to this paper.

ABSTRACT

While the Kalman filter, including its many variants, has been the staple of the tracking community, it also has been shown to have drawbacks, particularly when tracking through a maneuver. The most common issue is a lag in the position of the target track compared to the true target position as the target performs its maneuver. Another more problematic issue can occur where the filter covariance collapses, requiring the filter to be reinitialized. Techniques exist to compensate for maneuvers, but generating their response relies on detection of error between the estimated trajectory and the measured target position. In this effort, a maneuver detection routine is developed that can be used in conjunction with more standard maneuver compensation approaches. This routine is able to validate the existence of a maneuver more quickly than use of the inherent detection relied upon in the other methods. Maneuver detection is performed by an evidence accrual system that uses a fuzzy Kalman filter to incorporate new information and provide a level of evidence that maneuver is occurring. The input data uses behavior characteristics of the Kalman gain vector from the tracking algorithm.

1. Introduction

Feature objection extraction [1, 2] is an evidence accrual technique that can be applied to classification problems. An undirected tree [3] with various levels of information is used to connect evidence nodes. Each node has a level of evidence and an associated level of uncertainty similar to a state in a Kalman filter. Within the tree, nodes represent levels of evidence of what might be elementary information or a complex combination of information. This paper extends work originally presented in the 2018 Conference on Innovations in Intelligent Systems and Applications [1]. In theory, every node can be measured directly or indirectly. Unlike typical evidence accrual methods [4-6], the states are not probabilistic. When evidence points to more than one solution, multiple competing solutions can each have levels of evidence. Evidence can affect nodes at the same level, with the same evidence potentially increasing one or more than one node in levels of evidence, while others may have their levels decreased, and still other nodes at the same level may not be affected at all.

Feature objection extraction (FOX) propagates information within the tree using a variety of function or function-approximation relationships. The measured information is injected using a fuzzy Kalman filter [1, 7]. As will be described in detail, the FOX evidence accrual system decomposes high-level concepts into simpler concepts until it reaches root nodes which are comprised elementary information. Figure 1 describes a basic FOX tree with different connections and a variety of level of elementary information.

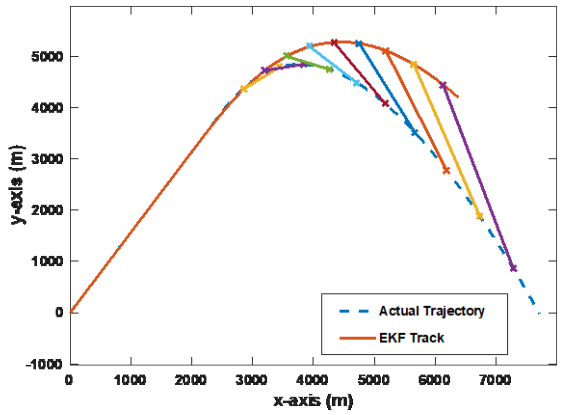

Figure 2: Ballistic target and standard tracker result in lagging of track through maneuver

FOX is incorporated into a tracking system to detect a target's maneuver and can use the computed values of the track to produce a measure of evidence that maneuver is occurring. Maneuver detection is important because, if the target dynamics are not modeled correctly for a maneuver, the tracking system can have an offset or a time-lag in its estimation of the target position and velocity. In Figure 2, an example of a maneuvering target trajectory is shown, alongside the target track from a Kalman-filter based tracking system, a more typical approach. The figure shows a track lagging the true target trajectory as the target proceeds through the maneuver. This comparative result illustrates the deleterious effects that can result when a maneuver occurs. Tracking problems also become more prevalent when the measurement lies in the unobservable space of the track kinematics, as seen in [8]. For example, if an angle-only tracker is used, the filter can become numerically unsound and require a reinitialization. In the tracking problem, losing a target or creating large target kinematic-errors can be life-or-death issue. If a maneuver can be detected, the tracking algorithm can be modified to improve performance and avoid catastrophic failures.

The Kalman filter, and its numerous variants, such as the extended Kalman filter (EKF) [9] and the unscented Kalman filter [10], have long provided the predominant core approaches for kinematic target-tracking systems [11]. To reduce the deleterious effects that maneuvers have on a tracking system, compensation approaches have been developed. The most widely used technique is the interacting multiple model (IMM) and its variants [12]. The IMM incorporates various maneuver models. The IMM system creates weighted combinations of models by comparing the residuals of each measurement to each model's prediction. The residual scores are used to interpolate between the models and create a weight for the state of each motion model to create a more accurate state estimate of the target position and velocity. Other techniques include adaptive Kalman filters such as a neural extended Kalman Filter (NEKF) [13] that also employ the Kalman filter residuals to adapt their maneuver parameters to more closely model that of the actual target dynamics.

All of these approaches rely on the residual measures to detect and make the adjustments. While the residual is an effective measure, variations in uncertainty can mask the maneuver until the residual value becomes significantly large. Fortunately, there exist other metrics as part of the Kalman filter that can detect a maneuver. Besides the residual, the behaviors of the Kalman gain can also indicate that the target is in a maneuver.

FOX can be employed to combine the disparate information and the associated uncertainty, providing for an effort at detection based upon more than one type of measure. In the problem demonstrated in this work, there is an injection of Kalman gain data provided by the aforementioned fuzzy Kalman filter, augmenting the residual measures, and the evidence is propagated using fuzzy, linear, and nonlinear relationships.

Four further sections provide an overview of the development of this approach and analyze its capability. Section 2 overviews the EKF, the most prominent variant of the Kalman filter used in tracking that provides the Kalman gains. Section 3 describes the Kalman gain behaviors that can provide information measures to indicate a target maneuver. Section 4 describes the FOX evidence accrual maneuver detection technique. In Section 5, examples of maneuvering targets are described and are used to exemplify the capabilities of FOX as a maneuver detection technique.

2. Target Tracking with the Extended Kalman Filter

For kinematic target tracking, the discrete-time dynamics of the are defined in (1).

$$\boldsymbol{x}_{k+1} = \boldsymbol{F}\boldsymbol{x}_k \tag{1}$$

The subscript k indicates discrete time, and $\mathbf{x}$ is the standard state-vector representation of the target behavior represents position and velocity. In (2), the state vector represents three dimensions

$$\boldsymbol{x}^T = [\boldsymbol{x} \quad \dot{\boldsymbol{x}} \quad \boldsymbol{y} \quad \dot{\boldsymbol{y}} \quad \boldsymbol{z} \quad \dot{\boldsymbol{z}}]. \tag{2}$$

The target dynamics $\mathbf{F}$ are often described with the straight-line motion model

$$\mathbf{F} = \begin{bmatrix} \boldsymbol{F}_{2x2} & \mathbf{0}_{2x2} & \mathbf{0}_{2x2} \\ \mathbf{0}_{2x2} & \boldsymbol{F}_{2x2} & \mathbf{0}_{2x2} \\ \mathbf{0}_{2x2} & \mathbf{0}_{2x2} & \boldsymbol{F}_{2x2} \end{bmatrix}, \tag{3a}$$

where

$$\mathbf{F}_{2x2} = \begin{bmatrix} \mathbf{1} & \boldsymbol{dt} \\ \mathbf{0} & \mathbf{1} \end{bmatrix}. \tag{3b}$$

The term dt is the time difference between the last sensor report on the target and the latest sensor report.

While the dynamics are linear, the measurements provided by sensors are often nonlinear. Using active sensors, such as radar, a complete measurement space for the three-dimensional target-track would be a report ***h(x)*** of range, bearing, and elevation, shown in (4)

$$\mathbf{h}(\mathbf{x}) = \begin{bmatrix} range \\ bearing \\ elevation \end{bmatrix} = \begin{bmatrix} \rho \\ \beta \\ \varepsilon \end{bmatrix}, \tag{4}$$

where

$$\rho = \sqrt{\left(x_{tgt} - x_{plt}\right)^2 + \left(y_{tgt} - y_{plt}\right)^2 + \left(z_{tgt} - z_{plt}\right)^2}$$

$$\beta = \arctan\left(\frac{x_{tgt} - x_{plt}}{y_{tgt} - y_{plt}}\right)$$

$$\varepsilon = \arctan\left(\frac{z_{tgt}-z_{plt}}{\sqrt{(x_{tgt}-x_{plt})^2+(y_{tgt}-y_{plt})^2}}\right),$$

and the subscript *tgt* denotes target component and the subscript *plt* denotes the platform.

Since these measurements are generated relative to the sensor platform, when they are reported to the tracking algorithm, they may be transformed to a universal coordinate system, such as earth-centered-earth-fixed (ECEF), be relative to the tracking system, or be relative to a localized flat earth [14]. To maintain the accuracy of the measurement, though, it is kept in a nonlinear-coordinate frame rather than being mapped into the track-coordinate frame which would linearize the tracking system. This is one reason the extended Kalman filter (EKF) is the most prevalent tracking algorithm [11].

These measurements are the driving inputs for the tracking algorithm. The EKF uses its estimate of the measurement and the residual between the estimated and reported measurements to correct its state-estimate of the target kinematics. The process of EKF to accomplish this is defined in (5a-e)

$$\mathbf{K}_k = \mathbf{P}_{k|k-1}\mathbf{H}_k^T\left(\mathbf{H}_k\mathbf{P}_{k|k-1}\mathbf{H}_k^T + \mathbf{R}_k\right)^{-1} \tag{5a}$$

$$\mathbf{x}_{k|k} = \mathbf{x}_{k|k-1} + \mathbf{K}_k\left(\mathbf{z}_k - \mathbf{h}\left(\mathbf{x}_{k|k-1}\right)\right) \tag{5b}$$

$$\mathbf{P}_{k|k} = \left(\mathbf{I} - \mathbf{K}_k\mathbf{H}_k\right)\mathbf{P}_{k|k-1} \tag{5c}$$

$$\mathbf{x}_{k+1|k} = \mathbf{f}\left(\mathbf{x}_{k|k}\right) \tag{5d}$$

$$\mathbf{P}_{k+1|k} = \mathbf{F}_k\mathbf{P}_{k|k}\mathbf{F}_k + \mathbf{Q}_k, \tag{5e}$$

where **H**, based on (4), provides the Jacobian of the output-coupling function:

$$\boldsymbol{H} = \begin{bmatrix} \frac{\delta\rho}{\delta x} & 0 & \frac{\delta\rho}{\delta y} & 0 & \frac{\delta\rho}{\delta z} & 0 \\ \frac{\delta\beta}{\delta x} & 0 & \frac{\delta\beta}{\delta y} & 0 & 0 & 0 \\ \frac{\delta\varepsilon}{\delta x} & 0 & \frac{\delta\varepsilon}{\delta y} & 0 & \frac{\delta\varepsilon}{\delta z} & 0 \end{bmatrix}. \tag{6}$$

The function **f** is the modeled target dynamics, and the matrix **F** in (5d-e) is the associated Jacobian. As stated previously, the target dynamics are usually defined as (3a). The subscript indicates discrete time, with $k|k$ is the estimate at the time k given all the information up to that time and $k+1|k$ is the estimate for time $k+1$, given all the information up through time k.

The process noise, **Q**, indicates the accuracy of the system dynamics, and is usually modeled as integrated white noise [15]:

$$\boldsymbol{Q} = q^2\begin{bmatrix} \boldsymbol{Q}_{2x2} & \boldsymbol{0}_{2x2} & \boldsymbol{0}_{2x2} \\ \boldsymbol{0}_{2x2} & \boldsymbol{Q}_{2x2} & \boldsymbol{0}_{2x2} \\ \boldsymbol{0}_{2x2} & \boldsymbol{0}_{2x2} & \boldsymbol{Q}_{2x2} \end{bmatrix} \tag{7a}$$

$$\boldsymbol{Q}_{2x2} = \begin{bmatrix} \frac{dt^3}{3} & \frac{dt^2}{2} \\ \frac{dt^2}{2} & dt \end{bmatrix}. \tag{7b}$$

As the process noise is increased, the dynamic model, **F**, in (5d-e) is weighted less. The measurement becomes more dominant in the processing, allowing more of the measurement noise to be passed thought the filter to the track solution. As the process noise is decreased, in contrast, the reaction of the tracking algorithm becomes less responsive to the measurement and more smoothing occurs.

While not explicit in the (5a) and often overlooked, the EKF's Kalman gain is affected by the process noise, the error covariance **P**, and the state estimate **x**. The state estimate is injected into the Kalman gain though the output-coupling Jacobian **H**. The gain is also affected by the measurement noise **R**. The measurement noise relates to the quality of the sensor. A standard radar will have its angle accuracies based on its beamwidth, for example while the range accuracy will be based on the resolution of the pulse signal. The accuracy indicates that the target can be anywhere within the beam and so-called range bin, as with airborne radar.

Since a Kalman filter is used, the accuracy is represented as a Gaussian distribution. (If the accuracy is not Gaussian, techniques such as Gaussian sums could be used to represent the measurement accuracy [16], but that is beyond the needs of these developments.) In Kalman filtering, the ratio of **Q** to **R** represents the relative belief of the target-motion model versus that of the sensor reports. If **Q** is smaller relative to **R**, the measurements will have a reduced of effect on the target track and the results from measurements over time will be smoothed, with the effects of noise less pronounced. If this ratio is reversed, the measures will dominate the track behavior, with the effects of individual measurements more pronounced in the target track. It is of note that, since the EKF is a measurement driven method, measurements will always ultimately have some effect on the target track. When the measurements noise is smaller, the measurement effects will have a faster impact on the track as sensors are viewed as more accurate.

3. Kalman Gain Monitoring

The extended Kalman filter (EKF) behaves differently than the Kalman filter for linear time-invariant systems. While the Kalman filter for such systems is predictable in nature, the EKF will vary over time. The variations in the error covariance **P** are affected by the nonlinear behavior of the system and the local estimate in both the update equation of (5c) and the prediction equation of (5e).

The behavior of the Kalman gain within the EKF, the vector **K**, often precedes the noticeable changes of the error covariance. This arises as the Kalman gain is affected both by the nonlinearities directly in (5a) and by the variations in the error covariance matrix. As the gains change over time, the filter can inherently detect changes in the actual system that vary from the estimation model. In [1], for a target tracking application of the extended Kalman filter, the Kalman gains demonstrated that over time there existed features in their behaviors that coincided with target maneuvers. The analysis of [1] looked at the individual gains, tracking both position and velocity of the targets in two-dimensional space using a range and bearing measurement. The resulting behaviors of the eight element Kalman-gain vector were used as features to identify when various maneuvers, including turns and simple linear accelerations, occurred. Another example is provided here.

The details of the scenario are shown in Figure 3. The target simulates the behavior of a submarine as it is being tracked by another vessel. The submarine maintains a straight-line trajectory with a constant speed. The trailing vessel also maintains a constant

speed and course. After some time, the target maneuvers. This represents a concept in a submarine-tracking problem where, being tracked, the target maneuvers to clear baffles to "see" the trailing ship and possibly cause a break-in-track of the enemy's tracking system. The platform ship then maneuvers, followed quickly by the submarine maneuvering again. These successive maneuvers can result in the filter becoming numerically unsound.

Figure 4 shows the behavior of the four Kalman gains related to the range over this whole scenario and is marked where the target and the sensor platform perform maneuvers. The Kalman gains show different behaviors, including a sharp transient, a significant change in the slope of the gain, and a zero-crossing.

The other four gains, which relate to the bearing measurements, are shown in Figure 5, and are larger in magnitude, but similar in relative behavior. Other test cases [1, 17], have also shown the gains to high frequency behaviors during maneuvers.

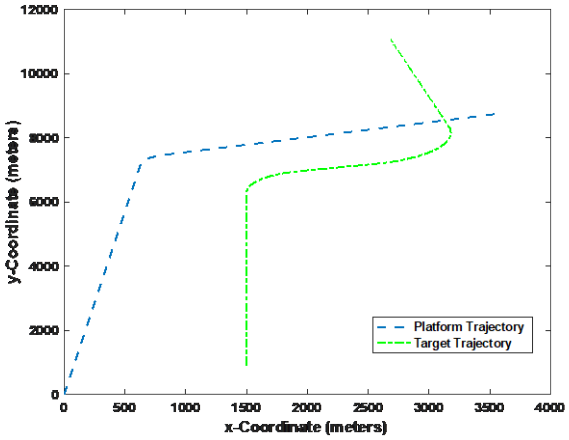

Figure 3: A manuevering target being tracked by a maneuvering sensor platform

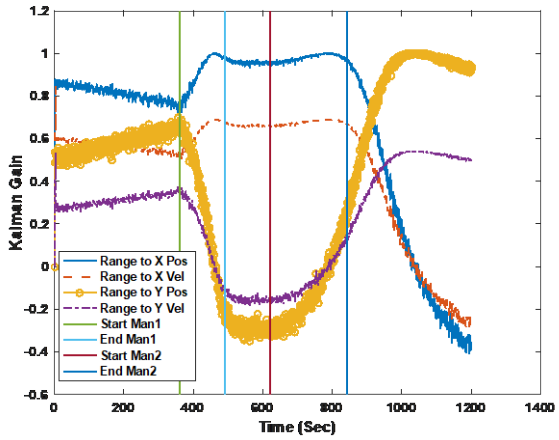

Figure 4: The behavior of the range-related Kalman gains over the course of the scenario with the target maneuvers marked

From these various test cases, the features of interest to detect a target maneuver have been determined to include monitoring the frequency behavior, the zero-crossings, the transient behavior, the slope performance, and the ownship (platform) maneuvers. It has also been determined that only a subset of the Kalman gains are necessary to observe. These include the gains related to the position states and range measurements K_{11} and K_{31} and all of the gains related to the bearing measurements K_{i2}, where those required vary by feature

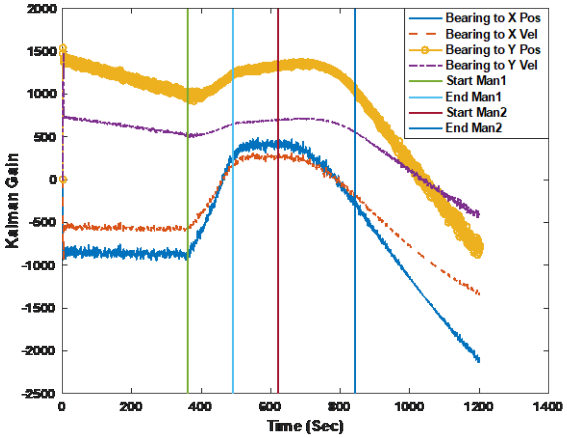

Figure 5: The behavior of the bearing-related Kalman gains over the course of the scenario with the target maneuvers marked

4. Evidence Accrual Using Feature Object Extraction

Many evidence accrual methods have been developed to combine information which, in this case, provide a level of evidence that a maneuver is occurring or has ceased to be. The primary evidence accrual techniques are the Dempster-Shafer method [5] and the Bayesian taxonomy approach [4], also referred to as the Pearl Tree. While these techniques have been utilized for decades, they have drawbacks, including that both represent the information as probabilities that update following Bayes rule. Also, uncertainty in the information that is the basis of the probabilities is not modeled easily, even with Dempster-Shafer.

FOX provides for distinct levels of evidence, such as of maneuver and for a non-maneuver separately. Since the measures of evidence are generated independently, the scores, unlike probabilities, are not related and an increasing evidence for one decision (i.e., a maneuver) need not decrease the other decision (i.e., no maneuver). Evidence can prove one or multiple decisions thus changing all or some of the decision.

FOX is also designed to provide a quality score with each level of evidence. The quality score is similar to a Kalman filter error covariance in that a high score indicates uncertainty while a low score indicates a high degree of certainty about the evidence score. The corroboration of evidence gathered from various behaviors can improve the certainty that an event occurred. Conversely, with multiple sources of evidence, maneuver events can be detected with one gain behavior being triggered while the others have not met the threshold.

For the maneuver detection problem, each of the elements of the Kalman gains' behaviors from the target tracking system can be used individually to indicate when a target maneuver is being initiated.

The FOX technique is designed to decompose a complex classification problem into a series of smaller and simpler problems. For the maneuver detection problem, a unidirectional tree is employed, as shown in Figure 6, illustrating use of FOX to accrue evidence based upon multiple behaviors of the Kalman

For maneuver detection, the top level is *Detected Maneuver.* The degree of evidence for this evidence node is limited to a range between 0 and 1. A corresponding tree for determining a level evidence for no maneuver occurring would be similar in concept with different linkages. The next level of this tree is comprised the individual-event detections of the tracking-system's Kalman gain vector: *Zero Crossing*, *Gain Frequency,* and *Slope Variation.* These three components are combined to create the *Detected Maneuver* scores. As the evidence levels in these states increase

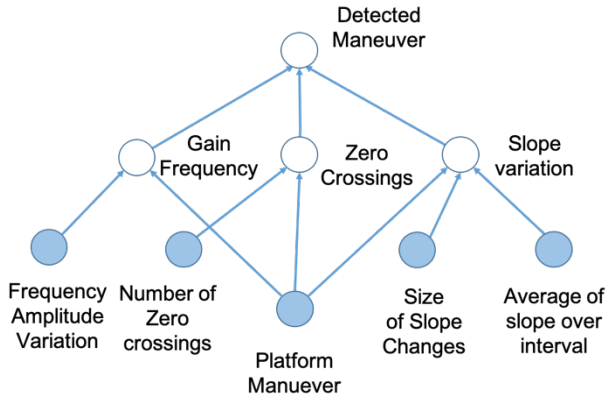

Figure 6: The proposed evidence accrual tree decomposition for Kalman gain maneuver detection approach of FOX

from 0 to 1, the overall detection-levels vary based not only on the lower-level scores but the quality level as well. Poor quality scores are weighted less than higher quality scores.

6, the shaded states indicate elementary-evidence input nodes. These represent the elemental measurements such as the measured frequencies or number of zero crossings. The unshaded nodes are referred to as states of interest. These are states of combined information.

approach is that, unlike the states of Markov chain [6], these states need not be disjoint nor do the states need be a complete representation of all the states of the system.

While the Kalman gain elements of the target tracking system provide evidence to the FOX evidence accrual system which employs a Kalman filter itself. To clarify, the Kalman filter of the FOX system in this case, actually a fuzzy Kalman filter, is different than that of the tracking system that is a source of evidence.

The level of evidence for a state of interest can be generated in two ways. The first is through direct observation, which implies a direct measurement is available, as shown with the shaded nodes. The evidence is then processed through a substate, depicted with a clear node. The tree of Figure 6 shows some substates have multiple injection nodes flowing into them. The FOX Kalman filter that injects the evidence into the tree nodes is a fuzzy Kalman filter (FKF). The FKF takes the multiple inputs and creates a single-output fuzzy measure. Substates that do not have direct evidence injection are generated using systems theory. The substates connect to state of interest through links that represent the functional relationship.

The FKF of the FOX system is based upon a development of Watkins [7] and modified in [2]. This approach was selected to allow a wide variety of measurement types and uncertainty models to be used with ease. The FKF implementation is a straightforward variant of the standard Kalman filter with a modification in the update equations. The FKF is defined in (8) with five equations, (8a) to (8e). Comparing the sets of equations, (5) and (8), two of these, the Kalman gain equation of (5a) and (8a), and the state update equation of (5b) and (8b), are the ones where counterparts differ. The fuzzy measures are incorporated by using the first moment, indicated as mom_1, of the consequent fuzzy membership function, referred to as m_{adj}, or the membership adjunct.

$$\mathbf{K} = \mathbf{P}_{k|k-1}\mathbf{H}^T(\mathbf{H}\mathbf{P}_{k|k-1}\mathbf{H}^T + mom_1(m_{adj}(\mathbf{R})))^{-1} \tag{8a}$$

$$\mathbf{x}_{k|k} = \mathbf{x}_{k|k-1} + \mathbf{K}(mom_1(m_{adj}) - \mathbf{H}\mathbf{x}_{k|k-1}) \tag{8b}$$

$$\mathbf{P}_{k|k} = (\mathbf{I} - \mathbf{K}\mathbf{H})\mathbf{P}_{k|k-1} \tag{8c}$$

$$\mathbf{x}_{k+1|k} = \mathbf{F}\mathbf{x}_{k|k}$$

$$\mathbf{P}_{k+1|k} = \mathbf{F}\mathbf{P}_{k|k}\mathbf{F}^T + \mathbf{Q}_k \tag{8e}$$

The use of fuzzy logic provides for simplified linguistic based conversion from the measurement coordinate systems to the evidence space, which has been defined as a value between 0 and 1. If the measurement and uncertainty values are crisp, the FKF devolves into the standard Kalman filter.

The nature of the measurement data determines whether the fuzzy measure or a crisp measure is used. A true measure such as the number of zero crossings or a known even as the knowledge of a platform maneuver would be a crisp value that would map into crisp groupings. The mapping of data into groupings, such as a determination based upon the frequency behavior or degree of slope change, would be fuzzy.

Once elementary evidence is injected into the tree, it can propagate another FKF process or through the use system theory process as follows. A state of interest and its direct-substates are represented in vector form as

$$\mathbf{x}_S = [x_{s1} \quad x_1 \quad x_2 \quad \cdots \quad x_n \quad x_n] \tag{9}$$

The state of interest or of the node value is the first element of the state vector.

Using first-order observer decomposition [18], the evidence dynamics are given as

$$\mathbf{x}_{k+1} = \begin{bmatrix} f(xa, x_{s1}, \ldots, x_{sn}) \\ \begin{bmatrix} 0 & f_1 & 0 & \cdots & 0 \\ 0 & 0 & \ddots & \ddots & \vdots \\ \vdots & \vdots & \ddots & \ddots & 0 \\ 0 & 0 & \cdots & 0 & f_n \end{bmatrix} \mathbf{x}_k \end{bmatrix}. \tag{10}$$

The state of interest is comprised of its substates and the previous value of the state of interest. The observer concept provides a forgetting factor. This forgetting factor and the observer updating equation are used to incorporate the quality factor of each sub-state. In (10), the uncertainty can be incorporated as a simple scaling in the state values or in the state-of-interest function, $f(\cdot)$.

The associated error covariance or uncertainty equation is propagated by (11).

$$P_k = f_a P_{a,k-1} f_a^T + f_1 P_{s1,k-1} f_1^T + \cdots + f_n P_{sn,k-1} f_n^T + q_x. \tag{11}$$

This decomposition of the problem into the individual substates reduces the complex model of the interactions of information into simplified operations. The decomposition also simplifies the incorporation of the uncertainty into the state vector.

4.1. Maneuver Detection Fuzzy Membership Functions

To generate the injection evidence, the following antecedent and consequent functions along with their associated inference engines were considered:

4.1.1. Frequency Amplitude Variation

When a maneuver occurs, some Kalman gain elements experience high frequency changes in amplitude. The high frequency behavior indicates that a maneuver could be occurring. As seen in [17], the high frequencies indicate potential issues with the Kalman filter that are a result of sharp maneuvers. The frequencies are mapped into a score using two input antecedent functions: *Max_frequency_value* and *Ratio_of_high_frequency_to_low_frequency_power.*

Figure 7 provides a four-element antecedent function that breaks the fast Fourier transform (FFT) spectrum of a time slice of the Kalman gain maps into the four trapezoidal-based functions. Figure 8 shows the five-element triangular antecedent membership functions that represents the ratio of the power of the highest-tenth of the spectrum to the lowest tenth of the spectrum. Table 1 provides the inference engine of the two sets of membership functions. These map to the consequence functions shown in Figure 9. These are defuzzified using the FKF.

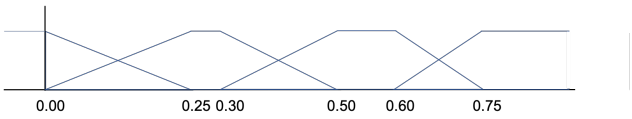

Figure 7: Kalman Gain Frequency amplitude variation FFT time slice antecedent function

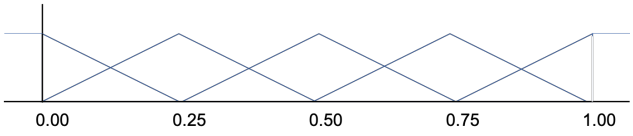

Figure 8: Kalman Gain Frequency amplitude power ratio membership function

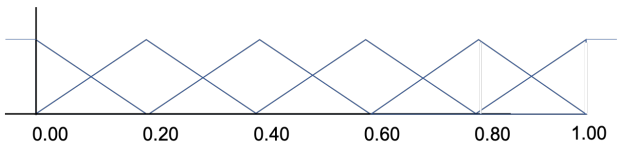

Figure 9: Kalman Gain Frequency Consquence Function

Table 1: Kalman Gain Frequency Inference Engine

	Frequency Maximum Membership Function			
Frequency Power Ratio Membership Function	1	2	3	4
1	1	2	3	4
2	1	2	4	4
3	2	3	4	5
4	2	4	5	5
5	3	4	5	5

4.1.2. Number of Zero Crossings

The number of zero crossings is a crisp value. The number of zero crossings num_{ZC} is mapped into a score ZC_{score}:

$$ZC_{score} = \begin{cases} 0 & num_{ZC} = 0 \\ 0.2 & num_{ZC} = 1 \; or \; 2 \\ 0.6 & num_{ZC} = 3, 4, or \; 5 \\ 1.0 & num_{ZC} > 5 \end{cases} \tag{12}$$

4.1.3. Slope Changes

The size of the slope changes in a given time interval is measured. The value is an absolute value of the difference between the initial slope and the ending slope compared to the maximum and minimum values. This crisp value is mapped similarly to the number of zero crossings but, are mapped evenly across four regions are mapped into the scores:

$$SC_{score} = \begin{cases} 0 & \frac{slope_{max}}{slope_{min}} \leq 0.5 \\ 0.33 & 0.5 < \frac{slope_{max}}{slope_{min}} \leq 2.5 \\ 0.67 & 2.5 < \frac{slope_{max}}{slope_{min}} \leq 4.0 \\ 1.00 & 4.0 < \frac{slope_{max}}{slope_{min}} \end{cases} \tag{13}$$

Unlike the other injection evidence mentioned here, the uncertainty is also fuzzy. The size in the slope changes creates the next score. Figures 10 depicts a five-element trapezoidal function that map the change in slopes. Table 2 provides the inference engine that maps into the consequence function represented by five triangular functions as seen in Figure 11. Again, the defuzzification is performed by the FKF.

Table 2: Kalman Gain Slope Inference Engine

	SC_{score}			
Slope Average Membership Function	0.0	0.33	0.67	1.0
1	1	1	2	3
2	1	2	3	3
3	3	3	4	4
4	5	5	5	5
5	5	5	5	5

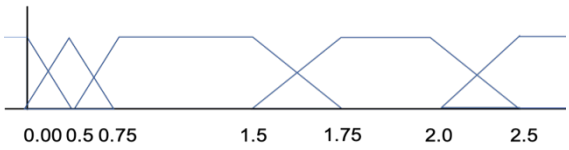

Figure 10: Changes in Kalman Gain Slope Membership Function

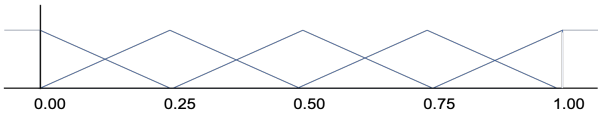

Figure 11: Changes in Kalman Gain Slope Consquence Function

Now that the direct evidence has been defined, the higher level nodes, depicted in Figure 4, can also be defined. The function relating the three sets of substate evidence to the *Detected Maneuver* state is defined with the limited linear combination in (14).

$$\boldsymbol{x_{MD}}(k) = \min\big(1, \mu(k)\big),$$

$$\mu(k) = [0.7 \quad 0.47 \quad 0.7]\, \boldsymbol{x_{MD}}(k),$$

with

$$\boldsymbol{x_{MD}} = \begin{bmatrix} x_{MDfreq} \\ x_{MDZC} \\ x_{MDslope} \end{bmatrix}, \tag{14}$$

where $\mathbf{x_{MD}}(k)$ is the estimated level of evidence at time k for detection of a maneuver state. The states that comprise $\mathbf{x_{MD}}$ are $\boldsymbol{x_{MDfreq}}$, the frequency behavior of the Kalman gain used to detect a maneuver, $\boldsymbol{x_{MDZC}}$, which is the incidence of zero-crossings for a Kalman gain value, and $\boldsymbol{x_{MDslope}}$, which is the change in slope of the Kalman gain value that indicates a manuever. For $\boldsymbol{x_{MD}}$, the score was not directly weighted by the measurement uncertainty and is solely based on the current values of the components.

The subnode x_{MDZC} is defined at time k as

$$x_{MDZC}(k) = [0.2 \quad 0.95] \cdot \begin{bmatrix} x_{MDNZC}(k-1) \\ \max\big(1, x_{lc}(k-1)\big) \cdot \big(1 - x_{pltmnv}(k-1)\big) \end{bmatrix}, \tag{15}$$

where $x_{pltmnv}(k)$ is either 1 or 0, with a 1 indicating the platform is, and a 0 indicating that it is not, in a maneuver at time k. x_{lc} is defined based upon whether the measurement is range-bearing in (16) or bearing only in (17), using elements of the Kalman gain. For range-bearing,

$$x_{lc}(k) = 0.4\, x_{K11}^{ZC}(k) + 0.4\, x_{K31}^{ZC}(k) + 0.4\, x_{K12}^{ZC}(k) + 0.4\, x_{K22}^{ZC}(k) + 0.4\, x_{K32}^{ZC}(k) + 0.4\, x_{K42}^{ZC}(k), \tag{16}$$

or, if the measurement is bearing-only

$$x_{lc}(k) = 0.67\, x_{K11}^{ZC}(k) + 0.67\, x_{K21}^{ZC}(k) + 0.67\, x_{K31}^{ZC}(k) + 0.67\, x_{K41}^{ZC}(k). \tag{17}$$

Here, the subscript *Kij* indicates the ith, jth element of the Kalman gain and $x_{Kij}^{ZC}(k)$ indicates the Kalman gain number of zero-crossings upto time *k*.

The subnode x_{MDfreq} is defined in (18) and (19) for the range-bearing measurement and in (20) and (21) for the bearing measurements.

For the range-bearing subnode $\boldsymbol{x_{MDfreq}}$,

$$x_{MDfreq}(k) = \Big[\min\Big(1, \mu_{freq}(k)\Big)\Big] \cdot \big(1 - x_{pltmnv}(k-1)\big), \tag{18}$$

where

$$\mu_{freq}(k) = [0.9 \quad 0.2 \quad 0.3 \quad 0.3 \quad 0.3 \quad 0.2]\, \mathbf{x}_{\mathrm{Krb}}^{freq}(k),$$

and

$$\mathbf{x}_{\mathrm{Krb}}^{freq}(k) = \begin{bmatrix} x_{MDfreq}(k-1) \\ x_{K11}^{freq}(k) \\ x_{K31}^{freq}(k) \\ x_{K22}^{freq}(k) \\ x_{K32}^{freq}(k) \\ x_{K42}^{freq}(k) \end{bmatrix}. \tag{19}$$

For the bearing-only measurement, the subnode x_{MDfreq} is defined similarly, but with different Kalman gains, as

$$x_{MDfreq}(k) = \Big[\min\Big(1, \mu_{freq}(k)\Big)\Big] \cdot \big(1 - x_{pltmnv}(k-1)\big), \tag{20}$$

where

$$\mu_{freq}(k) = [0.9 \quad 0.6 \quad 0.6 \quad 0.5]\, \mathbf{x}_{\mathrm{Kb}}^{freq}(k),$$

and

$$\mathbf{x}_{\mathrm{Kb}}^{freq}(k) = \begin{bmatrix} x_{MDfreq}(k-1) \\ x_{K21}^{freq}(k) \\ x_{K31}^{freq}(k) \\ x_{K41}^{freq}(k) \end{bmatrix}. \tag{21}$$

Finally, the subnode $x_{MDslope}$ is defined in (22) and (23) for range-bearing measurements and in (24) and (25) for bearing-only measurements. For range-bearing,

$$x_{MDslope}(k) = \Big[\min\Big(1, \mu_{slope}(k)\Big)\Big] \cdot \big(1 - x_{pltmnv}(k-1)\big), \tag{22}$$

where

$$\mu_{\mathrm{slope}}(k) = [0.7 \quad 0.4 \quad 0.4]\, \mathbf{x}_{\mathrm{Krb}}^{slope}(k),$$

and

$$\mathbf{x}_{\mathrm{Krb}}^{slope}(k) = \begin{bmatrix} x_{MDslope}(k-1) \\ x_{K12}^{freq}(k) \\ x_{K32}^{freq}(k) \end{bmatrix}. \tag{23}$$

For bearing only,

$$x_{MDslope}(k) = \left[min\left(1, \mu_{slope}(k)\right)\right] \cdot \left(1 - x_{pltmnv}(k-1)\right), \quad (24)$$

where

$$\mu_{slope}(k) = [0.7 \quad 0.4 \quad 0.4]\, \mathbf{x}_{\mathrm{Kb}}^{slope}(k),$$

and

$$\mathbf{x}_{\mathrm{Kb}}^{slope}(k) = \begin{bmatrix} x_{MDslope}(k-1) \\ x_{K11}^{freq}(k) \\ x_{K31}^{freq}(k) \end{bmatrix}. \quad (25)$$

5. Scenario, Example, and Analysis

In each of two examples, an EKF target tracking system is employed and the FOX system as previously described is applied. The scenario used to demonstrate the effectiveness of FOX technique as applied to the maneuver detection problem was summarized in Section 2 and is illustrated in Figure 3. The simulator was developed in MATLAB by the authors. The scenario lasts 1200 seconds. A platform is heading 5 degrees west of north for 480 seconds at 15 kts. Then, the platform changes heading and speed over 60 seconds to 65 degrees west of north and to 9 kts. The platform remains at this heading and speed for the rest of the scenario. The target heads due north for 360 seconds at 15 kts. Then the target changes course and speed over 130 seconds. The course is changed to 70 degrees west of north, and the speed is slowed to 10 kts. At 620 seconds into the scenario, the heading and speed is changed again. This time the acceleration of the target is changed over 224 seconds. The speed is changed to 15 kts while the heading is changed to 10 degrees east of north.

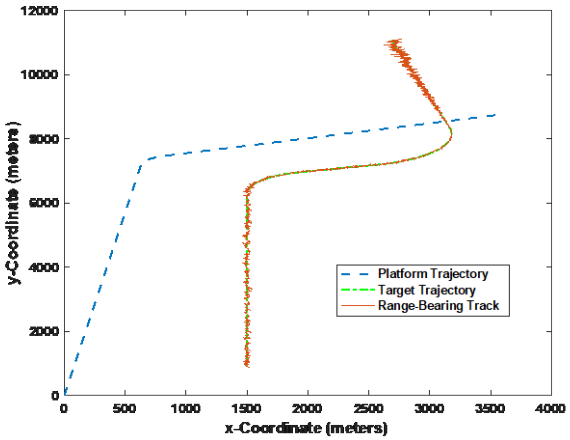

Figure 12: The test scenario with the tracked target using range and bearing meaasurements.

The platform sensor in the first example is a range-bearing sensor with a reporting time of 1 second. The range accuracy is 0.01 m while the bearing accuracy is 0.0003 radians. In the second example, the range sensor is turned off, while the bearing sensor has the same sample time and accuracy in the first example.

5.1. Example 1

The target track of the scenario when using the range-bearing measurement is shown in Figure 12. The associated Kalman filter gains associated to the range measurements are seen in Figure 4 and the gains associated to the bearing measurements were provided in Figure 5. The gains are windowed over a 20 second segment. The window continually slides until the end of the scenario. Figure 13 shows the resulting maneuver detection score.

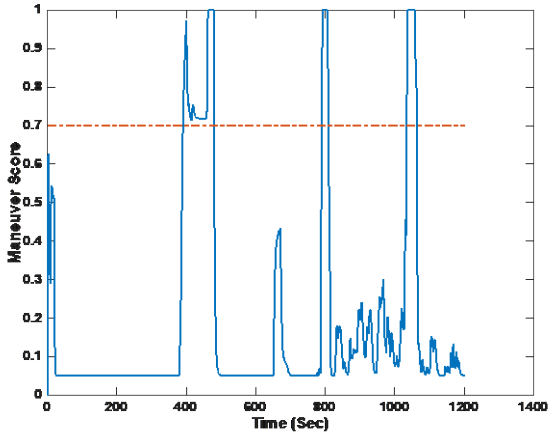

Figure 13: FOX maneuver-detection system results for the range-bearing example

The maneuver detection results indicate that the FOX maneuver detection does detect the target maneuvers when the measurements driving the tracking system contain both a range and a bearing. Using a detection threshold of 0.7, the first target maneuver is detected 31 seconds after it begins (near 400 seconds into scenario) and FOX continues to detect it until the platform begins its maneuver. The second maneuver is detected 170 seconds into its 224 second increase-in-speed and turn. When the target switches from east to west in absolute bearing, the event is detected as a maneuver for 30 seconds. The sharper maneuver (the first maneuver) is detected earlier and for a longer percentage of time of the maneuver. The maneuver has a significant effect on the range and bearing change and impacts the Kalman gain relatively more than a measurement that has little relative impact as with the second maneuver.

In the second maneuver, the effect on the Kalman gain vector values is smaller; the change in bearing and range is smaller at first, and then builds. This compares similarly to the results in [1, 17] in that the closer a target is to the platform and the sharper the maneuvers, the greater the Kalman gain behavior. When the target moves from east to west of the platform, the bearing changes from positive to negative. While the tracker handles the transition smoothly, the sign-changes affect the Jacobian of the measurement-coupling function **H**, as in Eq. (5a). This would be the same if the platform were to maneuver. The results indicate that using the Kalman gains are able to provide indication of maneuvers. The underlying scores indicate that slope behavior is important in target turns. The frequency behavior complements the zero-crossing in the last two detections.

5.2. Example 2

Figure 14 shows the target track overlaid the truth track for the scenario. The target track is, as expected, terribly inaccurate as bearing-only measurement makes the target location and velocity partially unobservable [19]. The target also maneuvers, and this exacerbates the issue [20]. The associated Kalman gains are shown in Figure 15. The Kalman gains are similar to the bearing gains of

range-bearing measurement of Example 1. The gains are windowed over a 20 second segment. The window continually slides until the end of the scenario. Figure 16 shows the maneuver detection score.

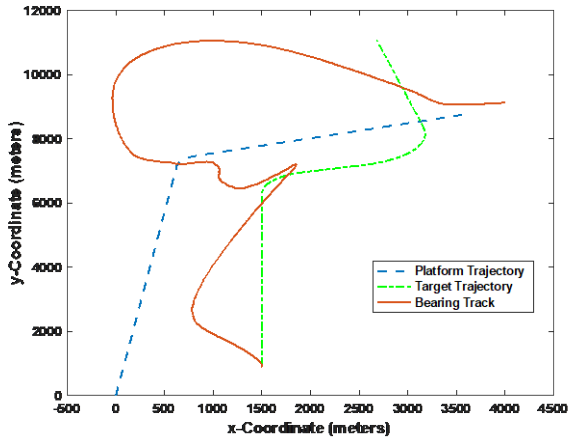

Figure 14. The test scenario with the tracked target using bearing-only measurements where the target position and velocity become unobservable

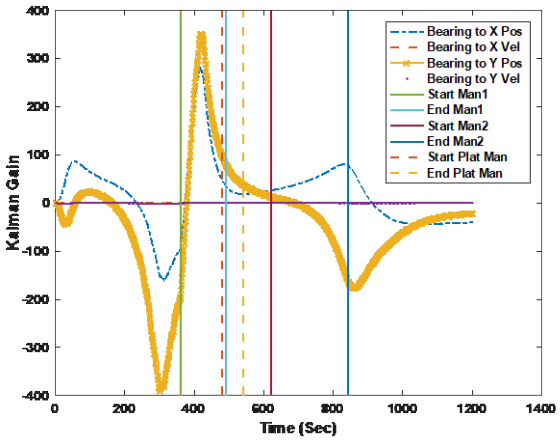

Figure 15: The bearing-only related Kalman gains as mapped over the entire scenario with target and platform maneuvers indicated

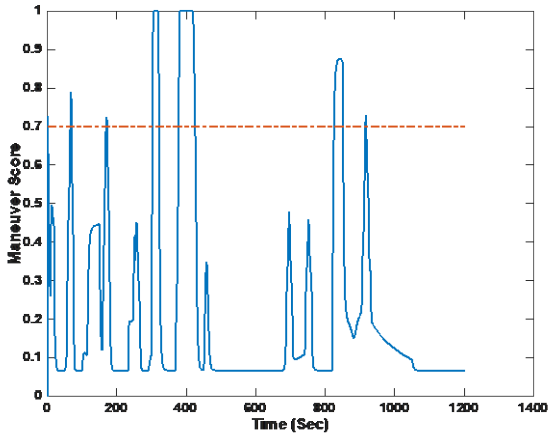

Figure 16: FOX maneuver-detection system results for the bearing-only tracker

The maneuver detection algorithm shows six detections of maneuvers. As discussed in [8], the estimations from a bearings-only track have significant observability issues. The fact that the target is moving originally parallel to the sensor platform results in the range information not being observable. This often collapses the range uncertainty covariance. Three times the target track is detected as a maneuver. In watching the tracker behavior, the Kalman gain is actually providing indications of the failure of the tracking system. When the target maneuvers, the algorithm detects this behavior as the EKF becomes more inaccurate. The platform maneuver provides a pseudo cross-fix which temporarily corrects the track but does not provide enough information to stabilize the filter. The second maneuver is detected later than the maneuver when the range-bearing tracking. For this unobservable measurement type, the FOX algorithm will detect issues with the tracker performance besides maneuvers.

5.3. Summary of Results

The two test scenarios indicate that the FOX maneuver-detection algorithm was able to provide triggers when the target is in or concluding a maneuver. The algorithm also detects other events, particularly the failure of the EKF. This would indicate that at times a reset in the tracker could be useful. It also indicates that behaviors, such as the change from east-to-west of the target, needs to be incorporated into the algorithm similar to the platform maneuver.

6. Conclusions

In this paper, the FOX evidence accrual technique was applied to the problem of detecting target maneuvers using measures from the Kalman gain behaviors from an EKF tracking routine. The algorithm was demonstrated to a variety of events most notably, when the trackign system begins to numerically collapse. Kalman gains of an EKF are important element in detecting tracking failures or changes. The results indicate that other highest-level nodes,i.e., target cross-overs and Kalman collapse, should be incorporated into the FOX system. Maneuver detection can be exploited to work with EKF tracking systems. Incorporation of the method into an interacting multiple-model (IMM) tracking system is planned to advance the applicability of the technique.

Conflict of Interest

The authors declare no conflict of interest.

ABSTRACT

Nowadays, the realization and follow-up of a team activity takes place in different execution environments (e.g. mobile phone, PC) through the use of computer applications. This implies context changes that generate interruptions in the activity. To improve the continuity of an activity with the reduction of interruptions during the development of this activity, would help to finish a task in a shorter time. An example of interruption occurs when a user initiates an activity on a device and decides to continue working on it on a different device, thus facing additional steps that must be performed to obtain the updated information on the desired device. The interruptions can be found in several domains as in the previous example that refers to the work developed through multi-devices or collaborative systems (CS). In this article we present a proposal for a model that incorporates the continuity attribute in the CS development process, to support its users to carry out Collaborative Activities (CA) through different devices with the least possible number of interruptions, so that that way the user does not require additional steps that extend the time of the task and negatively affect the process of transferring his CA to another device.

1. Introduction

This article is an extension of a previous work, in which a Conceptual model to improve the continuity of the workflow of collaborative activities in multi-devices is presented [1]. Collaborative activities can be developed within the Collaborative Systems (CS). CS allow a team of people to work on a common task, through a user interface in a shared environment, virtually [2]. Currently, due to the increase in the capabilities of mobile devices, these are used to perform different activities, gradually replacing the need for the use of a personal computer. This allows to conceptualize that the users of a CS can interact from any of their devices. An example of this scenario is a group of people which for different reasons of time and space decide to use a tool that supports distance collaboration, such as Google Drive®, with which it is possible to give continuity to an activity from a laptop, a tablet or a mobile phone.

The flow of continuity of an activity is limited due to the additional steps that are required to perform activities in multi-devices [3, 4]. These additional steps are considered interruptions, which are presented once the user wishes to continue performing an activity in a new device, such as: saving progress made in the source device, to later log in to the target device, open the application and position to the last state or download the advances in the new device; to name a few. It is important to mention the existence of tools that offer the user a flow of activity that involves fewer steps such as Apple AirPlay®, which in conjunction with Apple TV® wirelessly transmits movies, music and photos from any IOS® device; or Google Drive® offering the creation of content and editing flow, documents, photos and videos, allowing users to access them from any device.

Due to the problem described above, in this work we propose a model that offers continuity to the workflow of CA with support to multiple devices, seeking to reduce the number of interruptions that the user faces each time he wishes to resume a task in a different device. That is, for any user, the process of transferring the last state of information from one device to another is transparent.

* Mirian Janeth Avalos-Viveros, Email: zs17000719@estudiantes.uv.mx

The structure of this article is as follows: Section 2 addresses the aspects of Collaborative Systems, Collaborative Activities, Workflow and Continuity. Section 3 presents papers that support continuity in the workflow. Section 4 shows the challenges and opportunities identified from the analysis of the state of the art. Section 5 presents the proposal of a conceptual model that offers continuity in the CA workflow in multi-devices. Section 6 shows the proposal of a conceptual architecture for the construction of a CS under the concept of continuity. In section 7 a case study is presented to be implemented under the proposed model and architecture, as well as the design of the prototype. Finally, section 8 presents the conclusions and introduces future work.

2. Collaborative activities and Workflow

2.1. Collaborative systems

CS are computer systems that support collaborative work among groups of people who share common goals [2]. These CS are classified based on space, where collaborators can be found in the same place or in different geographical spaces; also, they are classified based on time, where people work at the same time (synchronous), or at different times (asynchronous) [5].

The CS offer functionalities for communication, coordination and collaboration, also known as the 3C's. The communication is through the sending and receiving of messages between team members, as well as the way in which these users observe what the rest of their team is doing. The coordination provides the way to organize the activities to be carried out. The collaboration considers functionalities necessary for users to achieve a collaborative activity [6, 7].

2.2. Collaborative activity

In [8] the activity theory (AT) is presented, representing it in a triangular figure with the elements that intervene in a collaborative activity and its relationship. The elements that make up the triangular system of activity correspond to: subjects, tools, community, division of labor, rules, objects and results; in [9] it is described as the relationship given by the link that exists between two elements of the system with another of the same. During the development of a CA, the people who are involved are immersed in a little-explored element so far: the workflow, by means of which one can know the interruptions that are generated during the life cycle of a task; for example, an interruption to the continuity of the workflow could occur when the user is writing a text on his cell phone and receives a phone call. At this moment, the flow is interrupted and the continuity suffers pauses due to the change of context.

2.3. Workflow

The workflow of an activity is a set of actions that need to be carried out to achieve a specific purpose. The [3] workflow considers two types of activities: individual activity flow and flow of sequenced activities. In the flow of individual activity, the user carries out only one activity, for example: watching a video, reading a book, editing a text, among others, making use of different devices, where each of them takes up the activity from the same point where the previous device left it. While in the stream of sequenced activities, the task flow is composed of different activities that must be performed by users to achieve the final goal; generally, each activity is carried out in a different device according to the needs of the activity, in different contexts of space and time [10]. The flow of activity suffers interruptions in its process due to changes in context, as previously mentioned; that is, there is no continuity in the process of completing a task.

2.4. Continuity

Continuity can be defined as the execution of steps without interruptions. The duration of an activity is an important factor that allows to determine the continuity within a task that is being carried out through a device. For that purpose, it [3] shows three ways in which the flow of continuity is carried out in accordance with the duration of the activity: multiple sessions, context changes and their tasks. With multiple sessions, when an activity is extensive, the user manages to complete it in multiple steps and different devices, depending on the context. While, in context changes of an activity, the user ends session and later takes it back, perhaps in a new device depending on the context where the user is. However, in the case of subtasks, when an activity is relatively extensive, it can be divided into subtasks; which can be different from each other and require a different place of context (time, location, among others.), therefore they can be made in different devices. Figure 1 shows the example of the user John who is in different context changes during the performance of a particular activity. He begins his work at his school using a desktop computer but changes the context to work using his laptop; this generates interruptions (represented by spikes, see Figure 1) that the user faces when he decides to transfer the information to a new device. Later, the user John decides to stop using the desktop computer to continue working from his tablet or cell phone, because he needs to be in motion (in this case he is experiencing interruptions to make possible the transfer of workflow). Finally, when he returns to his work area (school kitchen), he projects the content of the activity on a screen.

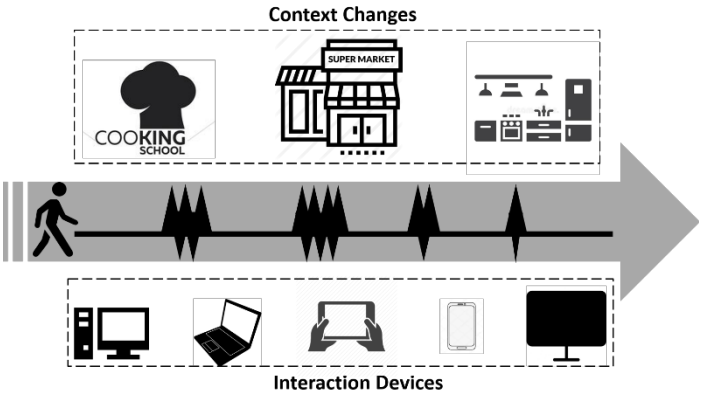

Figure 1: Continuity of a task with changes of context and devices.

3. Works on the continuity in the workflow

Currently, most people have multiple devices and interact with each other to perform their daily tasks [4, 10, 11], this because mobile devices (cell phones or tablets) have capabilities similar to those of a desktop computer or laptop, as people seek to try to keep their work at their disposal at all times. But this has brought unattractive events for users, for example: [12] discovered that when there was no storage in the cloud, people e-mailed the URLs of the websites they visited, to access them from a different device; in [11], a study finds that there are systems with an unintuitive design so that users have continuity in the interaction with multiple devices. In scenarios like this, where the user wants to work with

the devices, the transfer of the task between each device becomes a negative charge.

As a consequence of the lack of continuity in the process of carrying out the activity, there is a disconnection between the actions required of the user when he is using multiple devices [7].

As time passes, proposals have been sought to solve the lack of continuity with the aim of providing the user with the way to transfer information from one device to another without the intervention of unfavorable solutions such as: email, desktop software remote, USB drives, among others. Koren and others, in [13] propose an architecture for the mobility of the session of applications between different mobile devices, within the contributions include support for the discovery of nearby devices and the transfer of sessions with support for interactions based on the exchange of messages and files. However, they present problems in the transfer of the status of the activity.

Cabarcos and others, in [14] propose the design of an architecture for single session initiation in multi-devices (SuSSo) that includes the definition of storage formats of flow of operation session for the transfer of information in an abstract level, so that it can be easily implemented in any electronic device and guarantee interoperability of the cloud service in all devices; in this way sessions initiated from a device transfer their content to a second device without any problem.

Salminen and others, in [15], propose the implementation and evaluation of a middleware to migrate the user interface. The middleware is responsible for having control in the handling of events of the user interface and, in this way, the aforementioned component is transparent for the application. According to the tests carried out by the authors, the studies show that the preference for doing a task in a mobile device depends on the degree of familiarity that the user has with the keyboard of his cell phone, and they consider not having the need to incorporate a new method in order to finish their task before.

Cheng in [16]proposes a middleware capable of handling communication through different devices. The virtual browser facilitates operations between devices according to a predefined file. This research divides a DOM tree into multiple sub_DOM trees, to dynamically manage subviews on multiple devices and link them into a single virtual device. The author presents problems in the development of his proposal, for example: the difficulty to share events and the synchronization of elements and statuses.

Ghiani and others, in [17] present a process of migration for the permanence of status of the tasks that the user is doing in the device called source to the target device, that is, to which he wants to move the user interface to continue his interaction. The authors seek to provide: i) flexible support in several aspects taking into account the variety of possible devices that users may want to use, and ii) an accessible solution for the migration of any application developed with standard Web language, without using any specific complement. According to the tests carried out in this work, they obtained two variants as a result of user evaluations: ease of use and utility.

Pyla and others, in [18] designed a continuous user interface prototype that guarantees a seamless migration of tasks for users who try to perform a specification of requirements and collect tasks, using a tablet and a desktop computer. This system provides support for automatic migration of the task context (eg, applications that were in use) between two devices. In an evaluation carried out, the participants informed that the proposal helped to mitigate the effects associated with the disconnections of tasks, also informed that the automatic availability of the necessary data in the computers and modules contributed directly to a higher perceived reliability and lower error probability.

Currently, there are proprietary applications that offer continuity during the flow of activity, these are available for public use where some have cost and others are freely available, such as: Google Drive®, Netflix®, Office package ®, among others. In Google Drive®, the user has information availability from any device, as long as the device is linked to the same email account; the changes that are made are automatically saved by the tool. In the case of Netflix®, the user can access the exact minute in which he was watching a movie or series in his last session. In desktop systems such as the Office® parcel, if a document that has already been edited is opened, it asks the user if he wishes to continue working from the place where he was previously doing it. In [18] and [19], studies are presented to users where they interact with at least two devices to perform a task. Among the results obtained, an aspect that stands out from the others is the need to have a continuous interface design, for the process of information transfer with fewer steps towards a new device. Additionally, in [19], the authors consider that this aspect could improve the user´s experience when interacting with multi-devices in the development of tasks.

Table 1: Summary of related works

Work	Collaborative	Problems
Koren el at. (2013)	Yes	When the transfer of activity states is made to a new device, there is loss of information.
Cabarcos (2012)	No	The entire state of the task is not preserved.
Cheng (2012)	No	Conflict when several devices share information.
Ghiani et al. (2012)	Yes	Registration to the platform is required to obtain continuity in the devices.
Salmien et al. (2007)	No	Additional steps that users seek to avoid.
Pyla et al. (2009)	No	It does not allow working in parallel in a task with two devices.

In our review of the literature, limited efforts were found that seek to provide continuity in the workflow through multi-devices. Table I summarizes the problems of the papers presented in this section; it is also indicated that only two out of the six works have a collaborative approach as proposed in this research work.

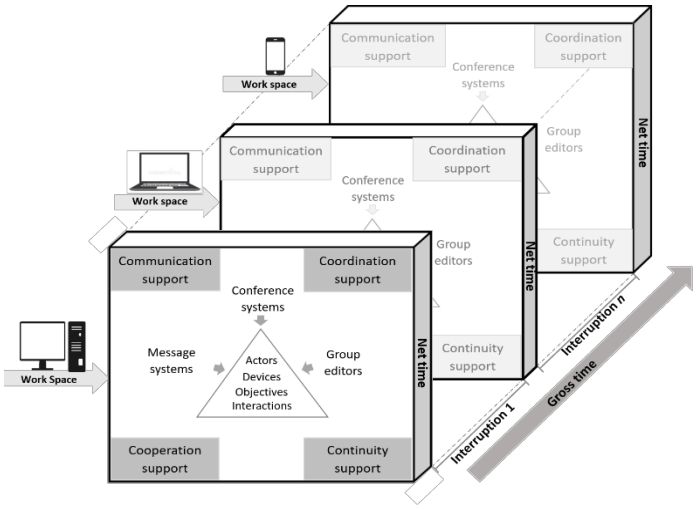
4. Challenges and opportunities to support the continuity of the workflow.

In an exploratory way, we conducted a preliminary study with two teams of five members, each of which held a Collaborative

Activity that included two tasks; the Google Drive® tool was used to perform the tasks. In the first task, they used their computer; once finished this, they had to change device. The second task was developed using their cell phone. After performing the activity by teams, the users were questioned about their experience when doing the activity in multi-devices.

As a result of the exploratory study, we observed that the majority of users usually do tasks through their different devices, but they express displeasure when they need to execute a series of steps to change the device, such as opening the application in the cell phone or downloading the advance in the new device; reason why some users requested to continue the activity from their computer, to avoid extending the time of completion of the task due to interruptions.

Therefore, within the identified challenges and opportunities, is to build a mechanism for the development of Collaborative Systems that transfers information between multi-devices with the least number of interruptions, achieving so that users can work on their tasks not only from their office, school or area where they normally do it, but from any context in which they find themselves and wish to continue working through the device that best adapts to the context. In this way, the user would be provided with a way to carry out Collaborative Activities from any of their devices whenever they wish, according to their needs and interaction preferences, and without being limited to working only in specific spaces.



5. Conceptual model for the continuity of the workflow

As a consequence of the analysis of the works related in this research, this article proposes the Model 4C's, as a frame of reference to provide the Collaborative Systems developers with the continuity element.

With the Model of the 4C's, the number of interruptions can be reduced through continuity support, to minimize additional steps when the user resumes work on a new device. Another contribution of the Model of the 4C's, is to allow users to carry out collaborative activities in multi-devices without affecting the workflow of the CAs by the operating system or the user's context change.

The Model of the 4C's is an instance of the Model 3C's, which arises from the models: 3C's [2] , [19] , Mars [20] and CAMCOS [21], taking components such as: communication, cooperation, coordination, workspaces, actors, interactions; which in turn are linked to the continuity element proposed in this work. The 4C's model is shown in Figure 2.

In a Collaborative Activity, groups of actors (users) participate in a group work space to carry out joint activities; These actors also have an individual work space, a space in which each user carries out their activities independently. Within both spaces, users perform different interactions that represent actions to complete a particular activity, which are executed within the three properties of the CS: communication, coordination and cooperation; but, in addition, continuity is required to offer the user the possibility of interacting through different devices during the performance of a task.

For this reason, it is necessary to include in the 3C's model of [4] the continuity element, which provides the user with permanence of the last status of the task when a context change is presented, that is, when the user for external reasons or preference of interaction is in the need of leaving the device with which he initiated the CA and requires to retake it in a different device. In order to provide continuity to the CA workflow through multi-devices, the 4C's model considers 8 elements: 1) Family of actors, 2) Actors, 3) Roles, 4) Objects, 5) Tasks, 6) Interactions, 7) Artifacts and 8) Work spaces; which are described in Table II. These elements are interrelated to propitiate an environment that minimizes interruptions in the sense that the statuses of each of them can be transferred to another device.

Table 2: Elements of the 4C′s model for collaborative applications.

Elements	Description
Family of actors	Set of names of actors where each actor has a different role.
Actors	People or software that carry out CA, through the interaction of different artifacts
Roles	Role that each user plays within the realization of an AC.
Objects	Everything that the actor can manipulate through interactions to achieve goals.
Actions	Actions that the user carries out to fulfill the collaborative activity.
Interactions	Realization of an action by a user through different artifacts within the system.
Mechanism	Hardware that the user uses to carry out his AC, within the SC, such as cell phone, tablet, laptop, desktop computer, among others.
Workspaces	Place where actors perform their actions in a group or individual way through an mechanism.

6. Conceptual architecture

Based on the 4C's conceptual model, we designed a conceptual architecture that supports the continuity of the CA workflow, through which the user can work in a collaborative activity from different mobile devices with a reduced number of interruptions in the process of information transfer and status of the task. The proposed architecture is shown in Fig. 3.

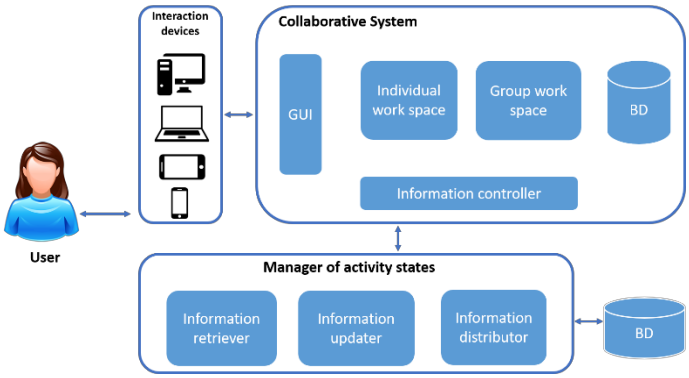


Figure 3: Conceptual architecture of the 4C's model

The continuity support starts once the user selects the device to start the CA. The interaction device is the means of communication between the application and the user. It is responsible for sending requests to the system in order to obtain updated information, and the system receives these requests through the activity's status manager.

Within the activity's status manager, three components are considered: an information retriever, an information updater and an information distributor. The information retriever obtains the last modifications of the users, in addition to the last workspace where they stopped.

The information updater is responsible for unifying the information of the individual and group workspace of the users and generates a new version of the progress of the team's work. When the user wants to resume the activity in a new device, the information distributor obtains the latest version of the work's progress and shows it to the user from the workspace in which he/she is working, supporting in this way the continuity of the workflow of the collaborative activity in multi-devices.

7. Case study

Based on the elements of the 4C's model and the conceptual architecture proposed above, a case study is being addressed through a scenario where, during the process of developing an CA, it is required to transfer the information to different mobile devices, in order to test whether the elements identified in the conceptual architecture are sufficient to provide the user with a continuous workflow, in the performance of collaborative activities in multi-devices.

The case study was modeled so that a team of actors worked on different activities for a common goal (to prepare a dish and generate a recipe). There are three types of actors: the administrator (teacher of the cooking school), the team representative and the members of the work team. Each actor plays a role within the collaborative activity; the administrator is the evaluator of the final product that each team elaborates, the team representative is the organizer of activities within the team and the member of the team is the buyer of ingredients. The actors interact with different artifacts during the collaborative work process such as: a desktop computer or a laptop to send the list of ingredients to the work team, as well as to make the recipe for the final product; a cell phone to perform tasks that require user mobility such as going to a supermarket to buy the ingredients of the dish; a tablet where users can count on a broader work space compared to the telephone, but also with mobility in the different workspaces where the actors must move to meet the objective of the activity.

The design of the Co-Kitchen system was made using the user-centered design methodology, an approach that allows iterations with the design throughout the life cycle of the product and in this way to redesign the system in order to meet the expectations and needs of end users [22]. Within the work framework for the design of human-centered interactive systems [23], the design process starts from the understanding of the context of use to specify the requirements of users, make a proposal of design solution and finally evaluate the design.

Phase one of the design process has been specified at the beginning of this section, where the modeled study case is detailed. Once analyzed and understood the context of use, we identified the requirements that the actors have in accordance with what they do within the system; in this way we knew the functionalities that the system should provide. In Table III, the functionalities of the system are described.

Table 3: Functions of the prototype Team Cooking

Function	Description
Create team	The administrator can create a work team.
Create list of ingredients	The administrator generates a list of the ingredients that the team must use to prepare a dish.
Assign tasks	The team representative is responsible for assigning tasks to each member of the team. Tasks such as buying ingredients, looking for kitchen utensils, lighting the oven, among others.
Create recipe	All the team at the end of the proposed dish, should generate a recipe for cooking it; for this each one must describe within the kitchen format the procedure for the realization of it, resulting in the recipe of the dish.

Once the requirements and functionalities that the system should provide the user in order to carry out his tasks were identified, the next step was to create the proposed design solution, which is shown and described below in Figures 4, 5, 6 and 7.

For the design of the proposal we use standard components such as: buttons, menus, text fields, etc., as well as: pointers, chat, and lists of connected users, according to [24] [25], who propose to simplify the development of groupware interfaces and to reduce the time of information search by grouping related elements in such a way that it is easy for the user to identify in which section is the element that he requires in order to perform a task.

In Figure 4, the start screen that the team representative actor displays when logging into the system is displayed. On the left side are the actions that can be executed within the system, in the center part of the screen you can see the work area and on the right

side there is the collaboration area where, through a list of connected users, the actor is kept informed of the presence of users who are collaborating during the realization of the CA and, at the top of that same side, we can also see the presence of each member, as well as the progress that each one of them has.

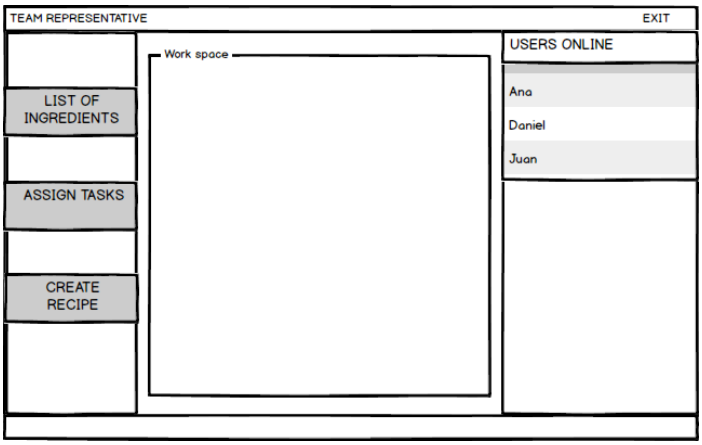

Figure 4: Team representative window.

Figure 5: Window to visualize list of ingredients.

In Figures 5, 6 and 7, what happens when the user clicks on one of the buttons on the left side is shown. When selecting "List of ingredients" (see Figure 5), in the work area the list of ingredients that was sent by the teacher of the cooking class is loaded. In case of selecting the option "Assign tasks" (see Figure 6), within the work area the team representative can enter the tasks assigned to each member of their team, which once assigned arrive as notification to the members to begin to work on them.

Finally, for the option to create a recipe (see Figure 7) within the work area, the actor works together with the rest of the team members in making the previously prepared recipe. Since it is a shared work area, each user has access to specific areas of the recipe according to the tasks previously assigned, which can be reported and described in the recipe.

The design of the solution proposal corresponds to a Web version loaded from a laptop or a tablet, but in the case of using a mobile device such as a cell phone, the design of the interface must be redesigned to fit a smaller screen, so that the work area is not affected and so the actor can work through it without complications.

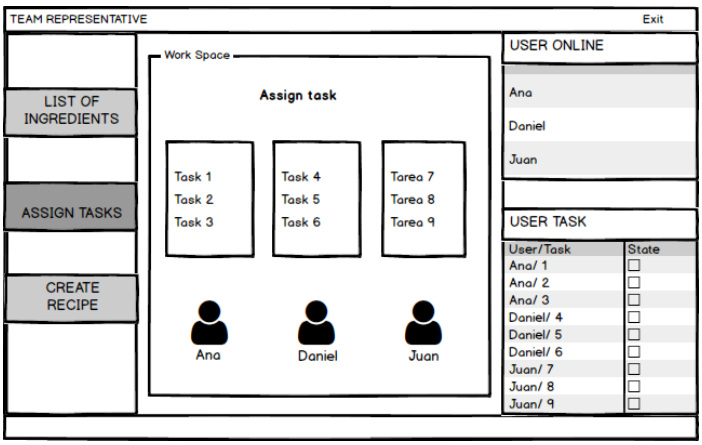

Figure 6: Window to assign tasks

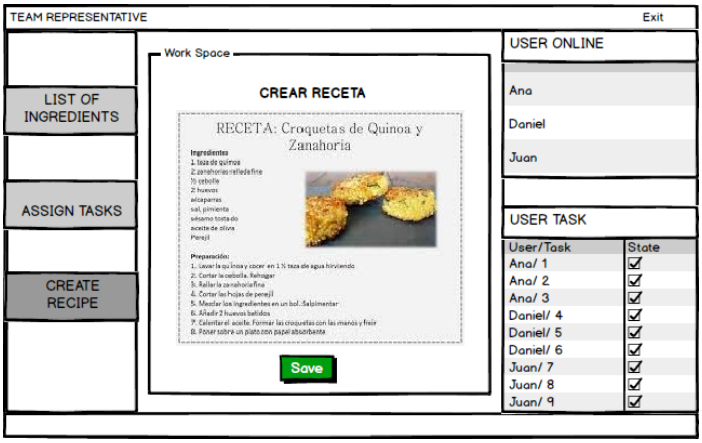

Figure 7: Window to create recipe.

8. Conclusions and future work

The advance of technology generates systems for collaboration between groups of people that interact with each other through the computer. Nowadays, it is possible to carry out an activity from different mobile devices such as: a cell phone, a tablet or a laptop, providing the user mobility to perform their activities. However, there is a gap in the conservation of the task status when moving to a new device. Therefore, this problem needs to be addressed in order to offer users systems that provide continuity to their workflow by requiring changes in the context of use during the performance of a task. That is why in this article we propose the model of the 4C's and the conceptual architecture to support users to carry out a collaborative activity in multiple devices in a shorter time. This proposal includes the continuity element of the model 3C's of [2], and the manager of states in the conceptual architecture, seeking to minimize the number of interruptions during the transfer of information from the collaborative activity through different mobile devices

As future work, we plan to continue with phase four of the framework for the design of interactive human-centered systems [23], corresponding to the evaluation of the design proposal

presented in this article, to subsequently work on a redesign under the observations and suggestions obtained from its evaluators.

Once the iterations of the design and evaluation process of the system design proposal have been finalized, we will give the appropriate follow-up to the construction of the Co-Kitchen system, to subsequently test the system and test whether our proposal effectively improves the continuity of the workflow of a collaborative activity when it is carried out through multi-devices, reducing the time in the interruptions that the user experiences when transferring and resuming the activity in a new device.

Visible/UV contrast ratio

ABSTRACT

High gain-bandwidth product and visible/UV contrast photodetectors are vital in Visible Light Communication (VLC) and Ultraviolet (UV) reflectance imaging applications respectively. We adopt material and structural optimization to perceive such photodetectors with back-illuminated Optical Field Effect Transistor (OPFET) wherein any potential difference in absorption coefficient of the semiconductor material between the visible and the UV range (higher in the UV region) can be explored at its full potential. The results have been analyzed using the photoconductive and the photovoltaic effects, the series resistance effects, scaling rules- induced effects, and channel length-variation effects. We consider the three most prominent and functional materials in the visible range (Si, GaAs, and InP) for material-based optimization. Structural optimization is performed employing a range of medium gate lengths. The gate electrodes utilized are Indium-Tin-Oxide (ITO) for Si and GaAs with high Schottky barrier heights of ~0.71 eV and ~0.98 eV respectively whereas the Schottky contact on InP is gold (Au) with a high barrier height of ~0.8 eV. The operating visible and UV wavelengths are 600 nm and 350 nm respectively. The results suggest that GaAs OPFET has wide bandwidth potential in the gigahertz range apart from its high sensitivity and visible/UV contrast features. The InP-based OPFET exhibits high sensitivity and sub-gigahertz frequency response; and can compete or surpass the GaAs OPFET in terms of the visible/UV contrast ratio. The Si OPFET shows bandwidth in the megahertz range along with high sensitivity but exhibits low contrast ratio. The structural parameters have a significant effect on the detector response. The results are in-line with the experiments. This paper reflects the performance of the investigated detectors towards the said applications through optimization and the associated analysis represents the dependence of the obtained response on the device material and structural parameters, thus, opening the door for further research.

1. Introduction

This paper is an extension of work originally presented in *The IEEE Conference on Emerging Devices and Smart Systems* (*ICEDSS'18*) [1].

Visible-Light Communication (VLC) is an emerging alternative to RF-based communication to suffice for the increasing demand for bandwidth. Its potential applications include Li-Fi (Light-Fidelity) Networks, vehicle to vehicle communication, robots in hospitals, underwater communication, and information displayed on sign boards [2]. The photodetectors contributing to VLC should feature high gain-bandwidth product apart from low dark current. Presently, the state-of-art photodetectors being employed in VLC include the p-i-n and the Avalanche photodiodes (APDs). p-i-n detectors provide high speed detection but without amplification whereas the APDs offer high gain but as the frequency increases, the gain reduces significantly. On the other hand, Ultraviolet (UV) reflectance imaging is a well-known application in biomedical engineering. It requires photodetectors with high visible/UV contrast ratios alongwith high visible sensitivity and low dark current. There is no much information available on the visible/UV contrast features of any photodetector. The contrast ratio should be high in order to appropriately control the ambient visible light in the presence of background UV radiation during imaging and enabling erroneous

operation. Low dark current improves the device performance. Both the applications have one thing in common: they need photodetectors operating in the visible range. Three most featured materials capable of operating in the visible region include Si, GaAs, and InP. These possess distinct electrical and optical properties which motivate one to conduct research using these materials. One potential candidate to cater to high gain-bandwidth product applications is a phototransistor or a photoFET. Optical Field Effect Transistor (OPFET) or optically controlled Metal-Semiconductor Field Effect Transistor (MESFET) has been a widely studied device over the past few decades for its applications as photodetectors, optically-controlled amplifiers, oscillators, and switches [3]-[13]. However, the research lacks the assessment or the impact of the OPFET device incorporating these materials from the optimization point of views i.e. material and structural optimization. Further, analysis of the attained results and the correlation of the detector responses with the material and the structural parameters can substantiate further research. Thus, in this paper, we call for material and structural optimization of the visible-range back-illuminated OPFET detector for communication and visible/UV contrast applications. The back-illuminated OPFET model (without substrate effect) is purposely chosen so that any significantly high difference in absorption coefficient at the visible and UV wavelengths is potentially used for contrast applications. The transparent gate materials considered for simulation are Indium-Tin-Oxide (ITO) for Si and GaAs whereas gold (Au) for InP. The corresponding barrier heights are ~0.71 eV, ~0.98 eV, and ~0.8 eV respectively. Possibly large barrier heights have been chosen since these can have considerable positive effect on the photovoltage and the photoconductive effect through the modulation of the depletion width.

A theoretical semi-analytical model accounting for photoconductive and photovoltaic effect is presented. The continuity equations have been solved analytically to yield the carrier densities whereas the charges are calculated numerically using the Trapezoidal method. The total drain-to-source current is estimated using the model given in [14]. The trap effects have been neglected in this work.

We begin with the theory followed by the results, discussion, and the relevant analysis. We conclude with a brief summary.

2. Theory

The back-illuminated device structure is schematically shown in Fig. 1. The gate is shorted to the source for a reduction in the number of power supplies. The channel is n-type uniformly moderately doped whereas the substrate is p-type semi-insulating. The illumination is guided by a fiber inserted from the rear side of the device through the substrate upto the active layer-substrate interface. The radiation is absorbed in the channel and the substrate regions creating electron-hole pairs. The holes contribute to photovoltage after crossing the Schottky junction which increases the drain-to-source current through a reduction in the depletion width (photovoltaic effect). On the other hand, the electrons are directed toward the channel which increases its conductivity upon the application of the drain-to-source voltage (photoconductive effect).

The device characteristics are depicted by the three regions of operation: the linear, the pinch-off, and the saturation regions. The drain-to-source saturation current depends upon the total charge, the gate width, and the saturation velocity and is limited by the voltage drop across the source series resistance. The drain-to-source conductance also depends upon the total charge (however, at zero drain-to-source voltage), the carrier mobility, and the gate width; is inversely proportional to the gate length, and is limited by the source and drain series resistances. The total drain-to-source current is given by [14]:

$$I_{ds} = I_{dss}(1+\lambda V_{DS})\tanh(\eta V_{DS})$$

where the symbols have the same meaning as stated in [14]. The parameter η is defined as the ratio of the drain-to-source conductance to the saturation current as the drain-to-source voltage tends to zero. Thus, on one hand, the drain-to-source current is directly proportional to the saturation current; on the other hand it is inversely proportional to the saturation current through the parameter η under the hyperbolic tangent expression. This shows that there is limitation on the total current that can be achieved. The parameter η also signifies that the total current is directly proportional to the conductance as V_{DS} tends to zero under the hyperbolic tangent expression. Hence, the conductance as V_{DS} tends to zero and the saturation current are the prominent factors determining the total drain-to-source current apart from the voltage, V_{DS}, and the total current is limited by the source and drain series resistances.

Under illumination, the total charge is boosted due to the photovoltaic and the photoconductive effects which enhances the saturation current and the drain-to-source conductance limited by the series resistances. In addition, with the increase in the optical power, the photovoltage increases reducing the series resistances and augmenting the current. The source and drain series resistances are calculated based on the method provided in [15]. The reader is advised to follow [1] for the modeling equations and the calculation of the carrier densities, photovoltage, and the total charge.

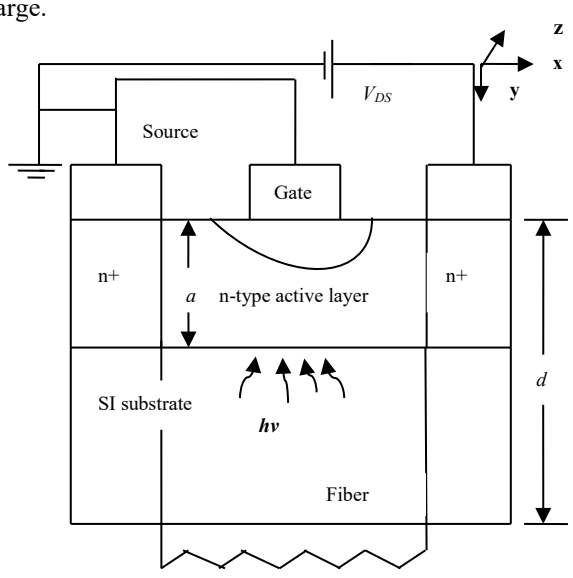

Figure 1. The schematic structure of the back-illuminated model of OPFET.

The detector parameters such as responsivity, dark current, and visible/UV contrast ratio are defined in [1]. Here we define the 3-

dB bandwidth and the unity-gain cut-off frequency (f_T) of the device. The bandwidth is the highest modulation frequency which the photodetector can detect without errors. Mathematically, it is given by the frequency at which the photocurrent response falls to 0.707 times its DC response. The unity-gain cut-off frequency is the operating frequency at which overall gain of the device falls to unity. The f_T is given by the ratio of the transconductance to 2π times the gate-to-source capacitance. The transconductance is the variation in the drain-to-source current with the variation in the gate-to-source voltage and is the amplification factor. The gate-to-source capacitance is the change in the space charge below the gate and its sidewalls with the change in the gate-to-source voltage and is a switching parameter. Thus, fT represents the amplification bandwidth of the device. The simultaneous detection-cum-amplification bandwidth is given by either of the two (3-dB bandwidth or the f_T value), whichever is smaller.

3. Results and Discussion

The simulations have been carried out in MATLAB with MEX coding feature. The results have been validated with experimental work published elsewhere [3] (Figure 2). The results have been compared with the commercially available software (Visual TCAD)-based simulations and have shown close resemblance (Figure 3) (Gate length of 4 μm, gate width of 4 μm, active layer thickness of 0.27 μm, and doping concentration of 4×10^{22} /m^3). The drain-to-source bias voltage is variable whereas the gate-to-source voltage is set to zero volts. The wavelengths used are 600 nm for the visible light and 350 nm for the UV radiation. The photon flux densities of 10^{16}, 10^{19}, and 10^{22} /m^2-s used in these simulations correspond to optical power densities of 0.33 μW/cm^2, 0.33 mW/cm^2, and 0.33 W/cm^2, respectively at 600 nm and 0.57 μW/cm^2, 0.57 mW/cm^2, and 0.57 W/cm^2 respectively at 350 nm. The structural optimization is performed over a wide range of medium gate lengths from 3 μm to 5 μm. However, only the four most relevant sets are provided here for comparison. The design variables are chosen based on the scaling rules stated in [16]. The materials being employed are Si, GaAs, and InP for the back-illuminated OPFET device with the gate electrodes being Indium-Tin-Oxide (ITO) for Si and GaAs, and gold (Au) for InP. The simulated optimization results are presented in Table I. The parameters used for calculation are given in Table II. The comparison with the state-of-art photodetectors and amplifiers is provided in Table III showing significantly enhanced response. Figure 4 depicts the drain-to-source current responses under dark and illumination for all the three devices at a gate length of 3 μm and an active layer thickness of 0.27 μm at an intensity of 10^{19} /m^2-s clearly showing the sensitivity to visible light. Figure 5 portrays the frequency responses of the three devices at a gate length of 3 μm and an active layer thickness of 0.27 μm at an intensity of 10^{19} /m^2-s demarcating that the GaAs, InP, and Si OPFET devices operate at high, moderate and low data frequency ranges respectively.

3.1 Series resistance and photovoltage analysis in Si, InP, and GaAs OPFETs

Beginning the discussion with the Si back-illuminated OPFET, this device exhibits the largest series resistances among all the material devices with similar dimensions in the visible range. With the smallest Schottky barrier height of ITO-Si junction (~0.71 eV), the series resistance ought to be the smallest due to the larger undepleted channel thickness in the spacing between the gate and the source, and the gate and the drain (depletion width is dependent upon the barrier height). This should have drawn larger current through the channel charge. However, due to the low electron mobility (~0.09 cm^2/(V.s)) and the said barrier height, upon which the current flowing in the spacing between the gate and the source, and the gate and the drain depends upon (barrier height directly affects the voltage drop across the channel), the current significantly falls. This raises the series resistance value to compensate for the fall with the increment in the depletion width through the voltage drop across the series resistance. Other materials, GaAs and InP exhibit lower and almost equal series resistances. This is attributed to the higher mobility of GaAs (~0.5 cm^2/(V.s)) and higher barrier height of ITO-GaAs junction (~0.98 eV) (through the voltage drop) which tend to increase the current in the spacing and lower the resistance. The same barrier height also tends to decrease the current (through the increment in the depletion width) and raise the resistance, however, the factors supporting the lowering of the resistance supersede those raising it, resulting in net reduction of resistance. For InP, the mobility is (~0.43 cm^2/(V.s)) and the barrier height of Au-InP junction is (~0.8 eV). In this case, the mobility is significantly high whereas the barrier height is moderate. With the moderate barrier height, the series resistance ought to be between that of Si and GaAs, but due to the high mobility the series resistance in InP features the same as that in GaAs. The series resistances play an important role in limiting the photocurrent. The series resistances decrease with illumination.

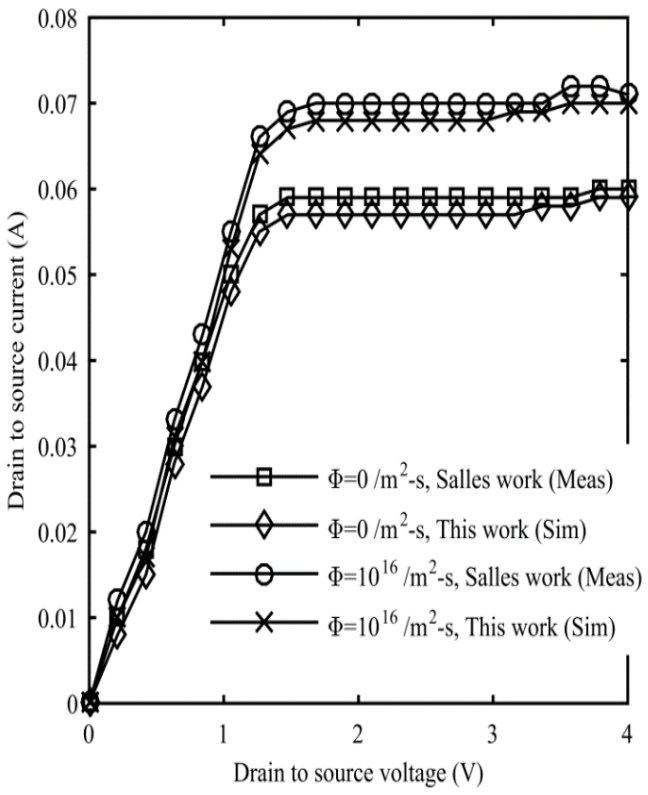

Figure 2 Comparison of the present model results with the experiments in [3].

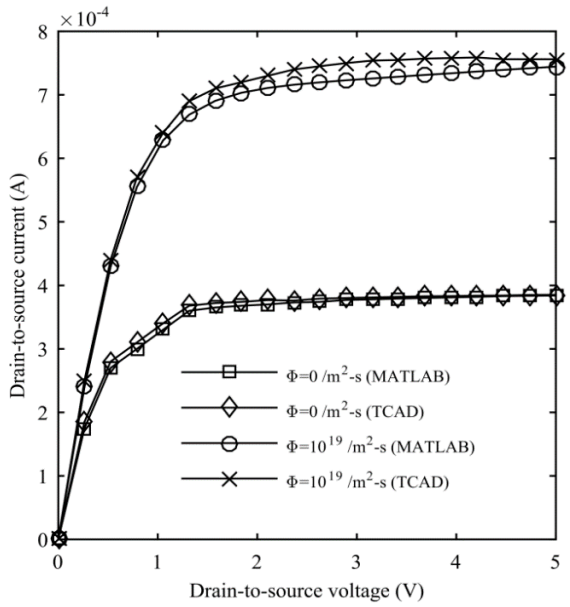

Figure 3 Comparison of the present model results with the simulations using Visual TCAD Software.

The photovoltage generated is almost the same in both Si and InP devices (~0.27 V, ~0.46 V, and 0.61 V) in the visible range considering most of the sets. This can be explained as follows: The photovoltage depends upon the photogenerated hole density crossing the Schottky junction which in turn, depends upon the absorption coefficient, the photon flux density, the hole lifetime, and the saturated hole velocity. The absorption coefficient of Si at 600 nm is 7.5×10^5 /m, the hole lifetime is 75 µs, and the saturated hole velocity is ($\sim6.3\times10^4$ m/s). On the other hand, the corresponding parameters for InP are 1×10^7 /m, 0.3 µs, and ($\sim5.6\times10^4$ m/s) respectively. The hole density is directly proportional to the absorption coefficient, the photon flux density, and the hole lifetime ($\alpha\Phi\tau_p$), whereas it is inversely related to the saturated hole velocity through ($1+\alpha v_y\tau_p$).The values suggest that the terms directly as well as inversely related to the hole density are almost the same in both the cases since any difference in individual parameters between the two material systems is cancelled out when their product is evaluated. One more parameter upon which the photovoltage is dependent upon is the reverse saturation current density through the Schottky barrier height. The photovoltage is inversely related to the saturation current density, and the saturation current density is inversely related to barrier height. Hence, the photovoltage is directly related to barrier height. Since, the barrier heights of ITO-Si andAu-InP junctions are (~0.71 eV) and (~0.8 eV) respectively, the photovoltage tends to be more in the InP device. However, since InP possesses a high absorption coefficient of 1×10^7 /m corresponding to an absorption depth of 0.1 µm, the hole density experiences an exponential decrease with distance and fewer holes cross the Schottky junction as compared to the Si device. The moderate absorption coefficient of 7.5×10^5 /m results in a large absorption depth thus, causing a lesser degradation of hole density with distance. As a result, the photovoltage developed is almost the same in both the cases. On the other hand, the photovoltage generated in GaAs OPFET is enhanced (~0.398 V, ~0.576 V, and ~0.755 V). This is due to the moderate absorption coefficient of GaAs in the visible region (4×10^6 /m), the higher saturated hole velocity ($\sim9\times10^4$ m/s), and the significantly higher Schottky barrier height of the ITO-GaAs junction (~0.98 eV) superseding the effect of lower hole lifetime (10^{-8} s). The saturated hole velocity positively affects the photovoltage through the photogenerated hole current density in the equation for photo voltage.

At the lowest gate length under consideration of 3 µm and the highest doping concentration of 5×10^{22} /m^3 (gate length-doping concentration product is constant from scaling rules [16]) with an active layer thickness of 0.15 µm, the OPFET devices exhibit the lowest dark and photocurrents among all the sets. This is ascribed to the very less active-layer thickness, as well as the low gate length and the gate width along with the reduced sensitivity at the higher doping concentrations. This proportionally decreases the current although the high doping concentration induces significant channel charge.

3.2 Analysis of Si OPFET at 3 µm gate length and 0.15 µm channel thickness

The drain-to-source currents obtained using Si OPFET are (0.36 mA, 0.9 mA, 1.7 mA, and 15.6 mA). The large series resistances owing to the small active layer thickness (0.15 µm) and significantly high barrier height (~0.71 eV) limit the said currents. At the flux density of 10^{16} /m^2-s, the photovoltaic effect is significant (0.28 V) whereas the photoconductive effect is negligible as compared to the photovoltaic effect (due to the lower power level) resulting in a current of 0.9 mA. The photoconductive effect will add to the response only when the photoconductive charge is comparable to the doping-induced charge. As the flux density is increased to 10^{19} /m^2-s, the photoconductive effect also contributes in addition to the photovoltaic effect (0.46 V) owing to the higher power level and the long electron lifetime (75 µs). Most of the photoconductive contribution emanates from the depletion region since the major portion of the channel is depleted owing to high barrier height, small channel thickness, and the large series resistance which incurs significant voltage drop across it. This results in a quite high current of 1.7 mA. At the flux density of 10^{22} /m^2-s, the current is significantly enhanced (15.6 mA) owing to the considerably high contribution from the photoconductive effect in the depletion region. There is no photovoltaic contribution; instead the device shows negative sensitivity i.e. increase in depletion width with illumination. This arises due to the substantially high current from the photoconductivity which incurs large voltage drop across the series resistance. Thus, the depletion width increments with illumination surpassing the effect of photovoltage-induced reduction of the depletion width. As such, the responsivities attained are (5.3×10^8 A/W, 1.32×10^6 A/W, and 1.49×10^4 A/W) which are significantly high owing to the above discussed phenomena and the low dark current. The 3-dB bandwidths exhibited by this device are (0.16 MHz, 0.136 MHz, and 0.57 MHz). These megahertz range bandwidths are due to the long electron and the hole lifetimes (75 µs) upon which the bandwidth is inversely related through the modulation of carrier lifetime with frequency. At the lowest flux density, the bandwidth is 0.16 MHz due to the contribution from the photovoltaic effect alone. At the higher flux density, the bandwidth falls to 0.136 MHz due to both photovoltaic and photoconductive effects adding to the response.

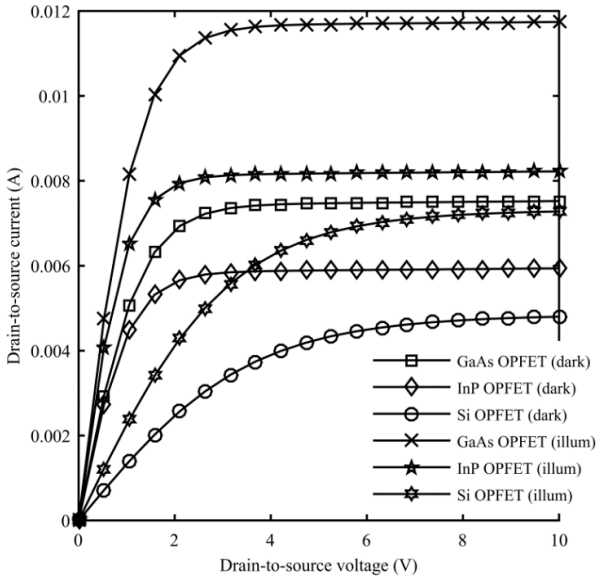

Figure 4 Comparison of the Si, InP, GaAs OPFET devices under dark and illumination.

This can be explained by the fact that when the identical frequency responses of two independent comparable effects are added, the net frequency response exhibits reduced bandwidth as compared to the individual ones. As the flux density is increased further, the bandwidth rises to 0.57 MHz. This is attributed to the sole and substantially high contribution from the photoconductive charge as compared to the previous responses. The transconductances obtained are the lowest among all the sets (1.4 mS, 2.4 mS, 3.9 mS, and 29.1 mS) due to the reduced dimensions at this gate length which decreases the overall current and the reduced sensitivity at high doping concentrations. Note that at constant photovoltage, the depletion width sensitivity is higher at lower doping concentrations. The transconductance increases with the increase in the optical power [6], [7], [9], [10] since at a constant doping concentration, the depletion width sensitivity is higher at larger photovoltages. However, at the highest flux density, this does not hold good where the device experiences negative sensitivity. In this case, it is the high photoconductive charge which results in high saturation current and is independent with the change in the gate-to-source voltage due to the complete depletion of the channel. The drain-to-source conductance evaluated at zero drain-to-source voltage also is high due to the induced charge and is sensitive to the variation in the gate-to-source voltage since the channel is undepleted (zero drain-to-source voltage). Further, the conductance is affected by the dependence of the series resistances on the gate-to-source voltage. The above reasons suffice for the observed high transconductance. The gate-to-source capacitances are also the lowest among all the sets (0.0546 pF, 0.084 pF, 0.105 pF, and 0.0076 pF) owing to the same reasons as applicable to the transconductances, however, here the gate region space charge replaces the drain-to-source current. The reasons hold good for the lower flux densities. However, at the higher flux density, the space charge is considerably reduced due to the photoconductive electrons in the depletion region de-ionizing the charged donor ions. Also, the gate-to-source capacitance is independent of the change in the photoconductive charge (which is a major contributor to the response) since it is a measure of the space charge variation with the gate-to-source voltage. These reasons explain the significant drop in the capacitance at the higher flux density. As such, the unity-gain cut-off frequency attained is (4.08 GHz, 4.53 GHz, 5.89 GHz, and 606.7 GHz). Under UV illumination of 350 nm, the photovoltage is slightly enhanced (0.31 V, 0.49 V, and 0.61 V) as compared to that under visible light since Si possesses a larger absorption coefficient of 1×10^7 /m at the UV wavelength. The smaller active layer thickness (0.15 μm) enables significant number of holes to cross the junction before the generated carriers experience degradation due to the dependence on the distance. The series resistances experienced by the device are almost the same due to the slight difference between the photovoltages. The drain-to-source current is almost the same at the lower intensity (1 mA) whereas there is a considerable boosting of the current at the higher intensities. This is attributed to the large absorption coefficient of Si under UV light which augments the photoconductive charge in the depletion region. At these intensities, the large currents develop large voltage drops across the series resistances thus inducing negative sensitivity and eliminating the photovoltaic contribution. The currents so obtained are 7.9 mA and 16.1 mA. The lesser enhancement of current at the flux density of 10^{22} /m^2-s is due to the limitation of the drain-to-source conductance (at zero drain-to-source voltage) by the series resistances and the large saturation current due to the induced charge also limiting the factor η as discussed earlier thus, restricting the total drain-to-source current. As such, the responsivities attained are (3.53×10^8 A/W, 4.33×10^6 A/W, and 9×10^3 A/W). The responsivities at the flux densities of 10^{16} and 10^{19} /m^2-s are slightly lower than the visible range responsivities. This is because the device uses more power to detect UV light than the visible light since the power is directly proportional to the photon energy. Hence the visible/UV rejection or the contrast ratios are very low (1.5, 0.3, and 1.65).

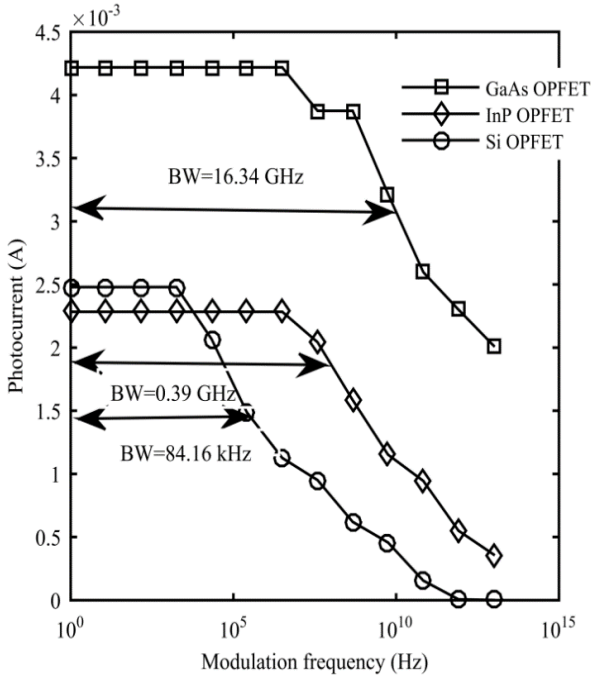

Figure 5 Frequency responses of the Si, InP, GaAs OPFET devices.

3.3 Analysis of InP OPFET at 3 μm gate length and 0.15 μm channel thickness

Discussing the InP OPFET with a gate length of 3 μm and an active layer thickness of 0.15 μm, the photovoltage is slightly enhanced (0.297 V, 0.476 V, and 0.65 V) as compared to the Si OPFET due to the small active layer thickness which eliminates the degradation of the generated carriers with distance as would occur in other cases. The series resistances are significantly lower than the Si OPFET but comparatively higher than that at higher gate length devices due to the reasons discussed earlier. The conducting photovoltaic charge is higher in the case of the InP OPFET in the presence of series resistances. This is because, the Si device possesses larger series resistances which incurs considerable voltage drop across these resistances thus, limiting the photovoltaic effect. Further, the photovoltage is slightly higher in the InP detector. This charge determines the saturation current. Hence, the saturation current is higher in the InP device. The conducting photovoltaic charge in the absence of series resistances i.e. at V_{DS}=0 V, is lower in the case of InP OPFET. The above emanates from the fact that at a fixed doping concentration and at a given gate-to-source voltage, the depletion width sensitivity to illumination is higher in both the lower barrier height and the lower dielectric constant device i.e. Si device. This charge determines the drain-to-source conductance at V_{DS}=0 which is higher in the Si OPFET however, is limited by the presence of series resistances which are larger in the case of Si detector. One more factor which differentiates the two devices is the electron mobility upon which the conductance depends upon and is substantially higher in the case of InP. The dark current is lower in the InP device due to the higher barrier height. The above factors result into slightly higher photovoltage-induced currents (1.3 mA, and 2.2 mA) in the InP OPFET than the Si OPFET. At the flux density of 10^{22} /m^2-s, the photoconductive charge from the depletion region alone contributes since the device exhibits negative sensitivity as mentioned earlier and the channel is totally depleted. The InP detector generates a current of 27.8 mA as opposed to 15.6 mA in the Si OPFET. This can be explained as follows: Since the absorption coefficient of Si is moderate (7.5×10^5 /m), there is almost uniform photogeneration throughout the fully depleted channel of 0.15 μm thickness. The absorption coefficient of InP is high (1×10^7 /m) due to which only a part of the depletion region carries significant number of carriers. Thus, the contributing charge is one order higher in the case of Si OPFET than the InP OPFET. This results in a large saturation current in the Si device. However, the conductance is lower in the Si device owing to lower electron mobility and larger series resistances. Since the saturation current appears in the numerator and as well as the denominator (through the hyperbolic tangent expression (see (1))), the large saturation current also limits the total drain-to-source current in the Si device. As a cumulative effect, the current is larger in the InP OPFET. These currents are the lowest among all the sets due to the reasons discussed earlier in the case of the Si OPFET. The 3-dB bandwidths achieved are (67.35 MHz, 0.26 GHz, and 3.84 MHz). These bandwidths are higher than that in Si OPFET owing to the shorter hole and electron lifetimes (0.3 μs) in InP as compared to 75 μs in Si. The boosting of the photovoltage as the intensity is increased from 10^{16} to 10^{19} /m^2-s also boosts the bandwidth from 67.35 MHz to 0.26 GHz. At the flux density is raised to 10^{22} /m^2-s, the bandwidth drops to 3.84 MHz due to the following: Under dc conditions or at lower frequencies, the photoconductive effect is significantly high and is the sole contributor. However, as the frequency is increased, the photoconductive contribution starts decreasing due to the dependence of the electron lifetime on frequency. This reduces the voltage drop across the series resistance thus, widening the effective channel width and increasing the photovoltaic contribution. Hence, at the juncture of the 3-dB point, both the effects effectively contribute causing the drop in the bandwidth. The responsivities attained are (9.97×10^8 A/W, 1.9×10^6 A/W, and 2.7×10^4 A/W) which are higher than that in the Si device due to larger photocurrents. The InP detector exhibits transconductances of (2.3 mS, 4.3 mS, 5.6 mS, and 6.7 mS). These values are higher than that for Si OPFET except at the flux density of 10^{22} /m^2-s. As explained earlier, the saturation currents, the drain-to-source conductances, and the mobility involved are higher in the InP device whereas the series resistances are lower in the InP device at the lower intensities. The depletion width sensitivity to the applied gate-to-source voltage with the other factors kept constant is higher in the lower barrier height and the lower dielectric constant device (Si OPFET). But, in practice, due to larger series resistances and the lower mobility of Si, the net effect is the larger sensitivity in the InP device. Further, the photovoltage is slightly larger in the InP device. Due to the above factors, the transconductances are higher in the InP OPFET at the lower flux densities. But at the intensity of 10^{22} /m^2-s, the channel is fully depleted. The depletion state does not affect the saturation current in terms of magnitude (it grows without bounds in spite of the presence of the series resistances). This is because, when the channel gets depleted (due to the large voltage drop across the series resistances), it is the photoconductivity in the depletion region which takes over role of the otherwise contributing photoconducting charge from the neutral channel region. Since the photoconductive charge in Si OPFET is very high and one order higher than that of the InP OPFET, the saturation current is considerably higher in the Si device. This current is insensitive to the applied gate-to-source voltage owing to the complete depletion of the channel. However, the drain-to-source conductance changes with the gate-to-source voltage since it is evaluated at V_{DS}=0 which means a finite undepleted channel width. This conductance is lower in magnitude as well as less sensitive to the change in the gate-to-source voltage in the Si detector due to the lower mobility and limiting effects of the series resistances. But, the effect of very large saturation current in the Si device supersedes the effect of lower conductance and its sensitivity to generate higher transconductance. The transconductance increases with the increase in the optical intensity due to the enhancement of the photovoltaic effect upto the flux density of 10^{19} /m^2-s and high contribution of photoconductive effect at the intensity of 10^{22} /m^2-s. On the whole, the transconductances obtained at this gate length are the lowest among all the sets due to the reasons stated earlier for the Si OPFET. The gate-to-source capacitances attained in the InP device are (0.034 pF, 0.0695 pF, 0.092 pF, and 0.016 pF). These values are lower than that of Si device. This is explained by the fact that at a constant or slightly varying photovoltage and a fixed doping concentration, the depletion width sensitivity to the applied gate-to-source voltage is larger for the lower barrier height (and dielectric constant) device i.e. Si OPFET. The capacitances increase with optical power and fall at the highest flux density and are lowest among all the sets due to the same reasons as described earlier in the case of Si device. The unity-gain cut-off frequencies

thus obtained are (10.76 GHz, 9.74 GHz, 9.65 GHz, and 65.4 GHz). Under UV illumination, the photovoltages developed are substantially lower (0.0943 V, 0.27 V, and 0.44 V) than that in the visible region owing to the very high absorption coefficient of InP in the UV region (7.6×10^7 /m).This generates significantly large number of carriers only upto a small distance from the absorption surface (i.e. the active layer-substrate interface). The generated carriers crossing the Schottky junction are considerably low due to the significant degradation of the carriers with distance (the active-layer thickness (0.15 μm) is much larger than the absorption depth (0.013 μm)). The drain-to-source currents obtained are (0.272 mA, 0.54 mA, 1.2 mA, and 30.1 mA). Due to the lesser photovoltages, the currents obtained are lower in the UV region upto the intensity of 10^{19} /m^2-s. At the flux density of 10^{22} /m^2-s, the current is higher (30.1 mA) owing to the substantially high contribution from the photoconductive effect in the depletion region emanating from the larger absorption coefficient of InP in the UV region. The photovoltaic effect plays no role at this intensity since the device exhibits negative sensitivity. The responsivities obtained are (1.53×10^8 A/W, 5.2×10^5 A/W, and 1.71×10^4 A/W) based on the above photocurrents and further assisted by the fact that the device uses more optical power in the UV region than the visible region. The visible/UV contrast ratios obtained are (6.516, 3.65, and 1.58).

3.4 Analysis of GaAs OPFET at 3 μm gate length and 0.15 μm channel thickness

Discussing the GaAs OPFET device possessing a gate length of 3 μm and an active-layer thickness of 0.15 μm, this device develops photovoltages of (0.41 V, 0.58 V, and 0.76 V) in accordance with [7] which are substantially higher than the Si and the InP devices. Under dark, the channel is totally depleted on account of a large Schottky barrier height of ITO-GaAs junction (0.98 eV). Thus, the current from the device channel ceases to exist but there is a small current flowing in the device due to the presence of the shunt resistance. The higher photovoltages ought to have produced larger photovoltaic charge responses as compared to the other detectors (InP OPFET). However, since the channel is deeply depleted (beyond the active-layer thickness), the developed photovoltages do not open the channel wide enough (of course, limited by the series resistances) as opposed to the InP device. The InP device is partially depleted under dark and the generated photovoltages (0.297 V, 0.476 V, and 0.65 V) are able to significantly reduce the depletion width thus yielding greater photovoltaic charges than the GaAs device. In spite of this, the drain-to-source currents (97.1 μA, 1.4 mA, 2.5 mA, and 54.9 mA) and the transconductances (0, 5.5 mS, 7.5 mS, and 67.2 mS) achieved in GaAs OPFET under illumination are higher than the InP device. This is attributed to the higher electron saturated velocity (1.2×10^5 m/s) of GaAs as compared to InP (7.6×10^4 m/s) which considerably increases the saturation current further assisted by slightly lower source series resistance in GaAs. Also, the slightly higher electron mobility of GaAs (0.5 m^2/(V.s)) as compared to InP (0.43m^2/(V.s)) and the lower source and drain series resistances in the GaAs device enhances its drain-to-source conductance even if the conductance in the absence of series resistances is almost the same in both the devices. As a result, the higher currents are attained. The larger transconductances emanate from the amplification of the charge due to the depletion width sensitivity to the applied gate-to-source voltage by the higher electron saturation velocity in GaAs producing larger change in the saturation current. Further, the amplification of the said charge under the absence of series resistance by the higher mobility of GaAs so also the lower series resistances results in larger variation in the drain-to-source conductance. This, on the whole, produces a larger change in the drain-to-source current with the applied gate-to-source voltage. Also, the photocurrents are slightly enhanced due to the lower dark current. At the flux density of 10^{22} /m^2-s, the photocurrent as well as the transconductance are considerably enhanced. This is owing to the boosting of the saturation current and the conductance due to the substantially high contribution from the photoconductive effect in the depletion region as a result of moderate absorption coefficient of GaAs and one order of magnitude higher lifetime (1 μs). The transconductance is much higher than the other two devices because of high saturation current and greater magnitude of the drain-to-source conductance as well as its higher sensitivity to the applied gate-to-source voltage. The gate-to-source capacitances under illumination (0.064 pF, 0.086 pF, and 0.018 pF), on the whole, are lower than the other devices due to the earlier stated fact that the sensitivity of depletion width to the change in the gate-to-source voltage is higher with devices bearing lower barrier height and lower dielectric constant when other factors are almost constant. The capacitance dependence upon the optical power is the same as analyzed with other devices. As such, the f_T values attained are (13.68 GHz, 13.79 GHz, and 596.5 GHz). The 3-dB bandwidths exhibited by the device are (1.5 GHz, 6.3 GHz, and 1.1 MHz) which are considerably higher than the other two detectors at the lower intensities owing to the significant photovoltaic effect and lower hole lifetime (10^{-8} s) with the photovoltage increasing with the optical power. However, at the higher intensity, the bandwidth falls due to the significant sole contribution from the photoconductive effect with a large electron lifetime of 1μs. The responsivities obtained are (1.24×10^9 A/W, 2.4×10^6 A/W, and 5.37×10^4 A/W) in line with [27] which are larger than the other two devices due to larger photocurrents. Under UV light, the response falls significantly (1.57×10^8 A/W, 6.4×10^5 A/W, and 2.56×10^4 A/W), due to the lower photovoltages (0.19 V, 0.37 V, and 0.55 V) owing to the larger absorption coefficient of GaAs (8×10^7 /m) which enables lesser hole density to traverse the Schottky junction. In this case, the significantly high generation takes place only at or near the absorption surface. Also, the larger photoconductive charge contribution at the high intensity of 10^{22} /m^2-s, emanating from more than one order of magnitude larger absorption coefficient of GaAs than that in the visible region produces large saturation current and large conductance wherein the large saturation current limits the total current. The currents obtained are as (97.1 μA, 0.37 mA, 1.2 mA, and 44.9 mA). The contrast ratios obtained are (7.9, 3.75, and 2.1).

3.5 Comparative Analysis of Si, InP, and GaAs OPFETs at 3 μm gate length and 0.27 μm channel thickness

As the active layer thickness is widened to 0.27 μm, keeping the gate length constant at 3 μm, the series resistances are significantly reduced owing to the wider thickness. However, they are still higher in the Si device as compared to the other two devices. The photovoltage remains almost the same in the Si and the GaAs OPFETs whereas it is slightly decreased in the InP OPFET explained by the possession of moderate absorption

Table 1: Comparative Studies of Si, InP, and GaAs OPFET detectors (1st set)

coefficient by Si and GaAs which enables significantly high hole density to cross the Schottky junction even if the channel thickness is increased.

On the other hand, the high absorption coefficient of InP results in lesser hole density to traverse the junction when the channel is widened. With the increase in active-layer thickness, the drain-to-source currents and the photocurrents are substantially enhanced due to the increment in the conducting charge as well as the reduction in the series resistances, however, with some exceptions at higher intensity of 10^{22} /m^2-s. At this flux density, in InP OPFET, due to the low series resistance, and the moderate Schottky barrier height, the increase in the channel thickness leads to the partial depletion of the channel. Hence, both the neutral channel and depletion regions contribute to the photoconductive effect significantly. However, owing to the large absorption

coefficient of InP, the contribution from the depletion region is lesser as compared to that at the lower active-layer thickness since the absorption depth is small and the most of the generated carriers in the far end of the depletion region are negligible as compared to that in the near end. But, it is still larger than the neutral channel contribution attributed to the factor in the denominator of the electron density equation in the depletion region which is absent in the equation for electron density in the neutral channel region. This results in one order higher density in the case of depletion region considering the same thicknesses for their contribution (by inspection of the two equations). At this intensity, the photovoltaic effect also contributes to the response, due to partial depletion of the channel and the device does not exhibit negative sensitivity. However, in overall, the response falls as compared to that at the lower channel thickness resulting in a lower current of 16.8 mA. In the other two detectors, these phenomena do not occur as the series resistance is sufficiently large in Si OPFET and the barrier height is considerably high in the GaAs OPFET thus maintaining complete depletion of the channel thickness at this flux density. Further, due to the moderate absorption coefficient of Si and GaAs (absorption depth is large), the photoconductive effect from the whole of the depletion region contributes significantly, thus, boosting the photocurrent. The devices exhibit negative sensitivity as usual at this intensity, thus, eliminating the photovoltaic response. The transconductances are boosted as the channel thickness is increased owing to the larger currents involved and the lesser limitation of the depletion width sensitivity due to the lower series resistances. This produces greater change in the saturation current and the drain-to-source conductance, however, again with some exceptions. In the Si OPFET, at the flux density of 10^{22} /m^2-s, the transconductance falls to 27.1 mS from 29.1 mS which is attributed to the larger photoconductive effect contribution from the depletion region induced by the greater depletion area leading to substantially high enhancement of the saturation current which is independent of the gate-to-source voltage. In this case, the channel is totally depleted sowing to the large voltage drop across the series resistance. The large saturation current limits the total current, and the only significant variation with the gate-to-source voltage is the considerable drain-to-source conductance (being evaluated at V_{DS}=0), on the whole, causing a fall in the transconductance. Similarly, in the GaAs OPFET, analogous phenomena occur, but in this case the saturation current involved is much lower than in the case of Si OPFET. This is due to the lesser contribution from photoconductivity in the depletion region since the electron lifetime in Si is more than one order of magnitude higher than that in GaAs. Also, the significant conductance variation with gate-to-source voltage is limited by the series resistances causing a substantial drop in the transconductance. These phenomena do not occur in InP OPFET, since the channel is partially depleted with a significant contribution from the photovoltaic effect, and the photoconductive effect from the depletion and the neutral channel regions with lower series resistances (as discussed earlier). However, this contribution is comparatively lower than the photoconductivity alone in the case of Si and GaAs OPFETs. This results in the rise in the transconductance from its previous value at the lower active layer thickness but exhibiting smaller values compared to that in Si and GaAs OPFETs. One anomalous behavior is observed at the flux density of 10^{19} /m^2-s in the InP OPFET, wherein the transconductance falls to 4.9 mS from its previous value of 5.6 mS at the lower active layer thickness and is also lower than its value (5.3 mS) at the flux density of 10^{16} /m^2-s. The reason behind this is still under our own investigation. The gate-to-source capacitance values increase with the increase in the channel thickness owing to the fact that at the lower channel thickness, with the applied drain-to-source voltage of 10 V, significant channel area is depleted as compared to that with the higher channel thickness. This is because the applied voltage drops itself across the channel in the form of the channel voltage which varies nearly linearly from zero at the source end to V_{DS} at the drain end. Thus, the change in the space charge with the change in the gate-to-source voltage is greater in the structure possessing larger channel thickness leading to the enhancement of the gate-to-source capacitance. As such, with the obtained tranconductance and capacitance values, the Si OPFET experiences an overall rise in f_T whereas the InP and the GaAs devices perceive a drop in the f_T with the widening of the channel thickness. With the enhanced photocurrents, on the whole, all the detectors show increased responsivities with the increment in the channel thickness. The 3-dB bandwidths obtained using Si device with the active layer thickness of 0.27 μm are as (0.66 MHz, 84.16 kHz, and 0.57 MHz) as compared to its previous values at the lower channel thickness (0.16 MHz, 0.136 MHz, and 0.57 MHz). The boosting of the bandwidth at the lower flux density is owing to the increase in the photovoltaic effect whereas the fall at the flux density of 10^{19} /m^2-s is due to the rise in the photovoltaic effect but simultaneous augmentation of the photoconductive effect due to widening of the channel thickness, thus, causing the drop. The reason for the constant bandwidth at the intensity of 10^{22} /m^2-s is still under our own study. The frequency responses of the InP device are (32.9 MHz, 0.39 GHz, and 4.156 MHz) at the higher active layer thickness as opposed to (67.35 MHz, 0.26 GHz, and 3.84 MHz) at the lower channel thickness. At the intensity of 10^{19} /m^2-s, the rise in the bandwidth is due to the increase in the photovoltaic effect. The slight increase in the bandwidth at the flux density of 10^{22} /m^2-s can be discussed as follows: At the lower channel thickness, at dc or lower frequencies, the photoconductive effect alone contributes but as stated earlier at the juncture of the 3-dB point, both the photovoltaic and the photoconductive effects are equally contributing. This results in a bandwidth of 3.84 MHz. On the contrary, at the higher channel thickness, under dc or lower frequencies, both the effects contribute significantly but the photoconductive charge is higher. But as the frequency increases, the photovoltaic charge starts incrementing whereas the photoconductive charge starts decreasing. Thus, at the juncture of the 3-dB point, the photovoltaic charge has rose to significantly high value but the photoconductive charge has decreased significantly. Hence, the non-equally contributing charges results in a wider bandwidth (4.156 MHz).The reason behind the drop in the bandwidth at the optical intensity of 10^{16} /m^2-s is still being investigated (shows anomalous behavior being contrary to the increase in the photovoltaic effect). On the other hand, the bandwidths attained using GaAs OPFET are (12.87 GHz, 16.34 GHz, and 0.72 MHz) as compared to that at the lower channel thickness (1.5 GHz, 6.3 GHz, and 1.1 MHz). At the lower flux densities, the enhancement of the photovoltaic effect results in the rise in the bandwidth whereas at the higher intensity, the device shows anomalous behavior being contrary to the increase in the photoconductive effect alone. The UV responses of the Si OPFET

device (4.8 mA, 5.9 mA, 9.9 mA, and 28.1 mA) are almost the same as that in the visible region except at the flux density of 10^{19} /m^2-s (higher in the UV region) owing to the two orders higher absorption coefficient of Si in the UV region. This significantly boosts the photoconductive effect in the depletion region at this flux density in addition to the contribution from the photovoltaic effect thus increasing the response. The photovoltages developed are almost the same as that in the visible region and slightly lower than that at the lower active layer thickness attributed to the larger absorption coefficient of Si in the UV region. This signifies that the generated carriers undergo significant degradation before these traverse the Schottky junction after travelling through the active layer thickness of 0.27 µm starting from the absorption surface. Due to the almost same photovoltages as that in the visible region, the series resistances almost remain unaltered. At the flux density of 10^{16} /m^2-s, the response remains unchanged due to similar photovoltaic effect. At the intensity of 10^{22} /m^2-s, the insensitive response to the wavelengths under consideration is because although the photoconductive effect in the depletion region is considerably enhanced in the UV region owing to the larger absorption coefficient, this leads to a larger saturation current and the conductance; the total current limited by the saturation current. As such, the responsivities attained are lower at the flux densities of 10^{16} and 10^{22} /m^2-s due to the insensitive response with the use of higher photon energy in the UV region. The slightly higher responsivity at the intensity of 10^{19} /m^2-s is due to the enhanced photocurrent. The contrast ratios obtained are (1.45, 0.826, and 1.73) which are very low signifying that the Si detector can function well in both the visible and UV regions. In the InP OPFET, there is significant degradation of photovoltage at the UV wavelength (0.105 mV, 42.1 mV, and 0.2107 V) owing to the very large absorption coefficient of InP (7.6×10^7 /m) and the higher channel thickness (0.27 µm). Due to the low photovoltages, the series resistances are higher. The photoconductive responses are negligible compared to the photovoltaic currents due to the small absorption depth and generation area. The currents involved are (5.9 mA, 5.9 mA, 6.1 mA, and 6.9 mA) leading to responsivities of (0.0764 A/W, 1.02×10^5 A/W, and 5.4×10^2 A/W). The contrast ratios thus obtained are (1.75×10^{10}, 22 and 19.7). This shows that the InP device with the structure under consideration can detect visible light with high responsivity under background UV radiation with rejection ratio of 1.75×10^{10}at the intensity of 10^{16} /m^2-s. At the higher intensities, the ratios are not high but can suffice in certain instances of applications. In the GaAs OPFET, similar situation occurs under UV illumination since the absorption coefficient of GaAs (8×10^7 /m) is identical to that of InP (7.6×10^7 /m) signifying small absorption depth. With this, the photovoltages produced are (2.6 mV, 0.12 V, and 0.3 V), the currents induced are (7.5 mA, 7.5 mA, 8.2 mA, and 9.5 mA) and the responsivities registered are (48.88 A/W, 4×10^5 A/W, and 1.15×10^3 A/W) rejecting UV wavelength with the factors of (5.21×10^7, 10.25, and 68.7).Thus, the rejection ratio is inferior to the InP OPFET at the lower intensities and vice versa at the higher intensity.

3.6 Comparative Analysis of Si, InP, and GaAs OPFETs at 4 µm gate length and 0.3 µm channel thickness

When the gate length is elongated to 4 µm from 3 µm with a proportionate increase in the active layer thickness to 0.3 µm from 0.27 µm and a corresponding increment in gate width from 100 µm to 150 µm, the doping concentration is reduced to 4×10^{22} /m^3 from 5×10^{22} /m^3 considering constant gate length-doping concentration product from scaling rules [16]. These changes in the structural parameters have a significant change in the device parameters and some of them can be correlated based upon certain basic facts and phenomena. At first, the series resistances are reduced due to the larger channel thickness. Secondly, the photovoltages remain almost unaltered owing to the materials' absorption depths which are sufficient enough to cause the hole density crossing the junction to experience very less carrier decay with distance. The drain-to-source currents proportionally increase with the gate length ascribed to the corresponding increase in the gate width, the active layer thickness, the electron saturated velocity (velocity decreases with the doping concentration) and the lower series resistance which raises the value of the saturation current although the lower doping concentration induces less conducting channel charge under dark. The increase in electron mobility (mobility also decreases with the doping concentration), the gate width to the gate length ratio, and the lower drain and source series resistances boosts the drain-to-source conductance in spite of the lower doping concentration under dark. The longitudinal increment of gate length induces more conducting charge along the gate length which increases the current under dark. Under illumination, the photocurrents introduced also increase with the gate length: Since the photovoltages are maintained at almost the same values, it's a fact that at a fixed photovoltage and a constant gate-to-source voltage, the depletion width sensitivity to the applied illumination is higher at the lower doping concentrations i.e. the structure possessing a higher gate length. However, the reduced doping concentration induces less conducting charge which supersedes the depletion width sensitivity to give lesser photovoltaic charge. Nevertheless, due to the parameters and the factors mentioned under the dark condition in addition to the above-mentioned facts, the photocurrents are enhanced as compared to their values at the lower gate length.

At the flux density of 10^{22} /m^2-s, at the most at the intensity of 10^{19} /m^2-s in Si OPFET (due to high electron lifetime), the photoconductive effect significantly contributes to the response owing to the larger channel thickness in addition to the above stated factors to produce very large response. The transconductances also rise with gate length due to the fact that at a fixed photovoltage, the depletion width sensitivity to the applied gate-to-source voltage is larger at the lower doping concentrations (higher gate length). This is assisted and limited by the other factors as mentioned earlier for the drain-to-source current and the photocurrent enhancement. The significant boost of transconductance at the intensity of 10^{22} /m^2-s is due to the significant photoconductive effect (in Si and InP OPFET) wherein the saturation current is sufficiently high but at its optimum to produce significant change in the drain-to-source current with the applied gate-to-source voltage through the drain-to-source conductance. In GaAs OPFET, there is a fall in the transconductance owing to the large saturation current limiting the conductance change with the gate-to-source voltage. The gate-to-source capacitances are also incremented with the gate length on account of the fact that at a given photovoltage, the depletion width sensitivity to applied gate-to-source voltage is higher at the lower doping concentrations.

This is further assisted by the greater gate width, gate length and active layer thickness, which offer larger transverse, longitudinal, and lateral space charges superseding the effect of lower doping concentration on the total charge. Owing to the enhancement of the transconductances and the gate-to-source capacitances, the unity-gain cut-off frequencies experience a rise with the gate length since the rate of transconductance increase is greater than that of the gate-to-source capacitance except in GaAs OPFET at the flux density of 10^{22} /m^2-s due to the fall in the transconductance. The responsivities decrease on the whole with gate length although the photocurrents are enhanced since the devices use greater optical power to produce a given photocurrent, optical power being directly proportional to the gate length and the gate width of the devices. However, in the case of Si and GaAs OPFETs, at the

intensity of 10^{22} /m^2-s the responsivity increases due to large photoconductive effects. The bandwidths exhibited by the devices are: In Si OPFET, with the elongation of the gate length, the bandwidths attained are (0.72 MHz, 44.5 kHz, and 0.41 MHz) as opposed to (0.66 MHz, 84.16 kHz, and 0.57 MHz) at the lower gate length. The slight rise in the bandwidth at the intensity of 10^{16} /m^2-s is attributed to the fact that the depletion width sensitivity increases at lower doping concentration (or higher gate length) which creates the roll-off slope of the photovoltaic charge or current frequency response curve to be gentler thus, broadening the response. The fall in the bandwidth at the flux density of 10^{19} /m^2-s in spite of the roll-off slope of the photovoltaic effect being gentler is owing to the increase in the photoconductive contribution due to larger channel thickness. The reason behind the drop in the bandwidth at the intensity of 10^{22} /m^2-s is still under study. On the other hand, in the InP OPFET, the bandwidths obtained are (92.6 MHz, 0.36 GHz, and 3.84 MHz) as compared to (32.9 MHz, 0.39 GHz, and 4.156 MHz) at the lower gate length. The same principles apply for the attained bandwidths at the flux densities of 10^{16} and 10^{19} /m^2-s, however, the slight fall in the bandwidth at the intensity of 10^{19}/m^2-s is due to the limitation by the series resistance. Whereas at the flux density of 10^{22} /m^2-s, there is slight drop in bandwidth owing to the fall in the photovoltaic charge response as compared to that at the lower gate length due to lower doping concentration but maintaining almost the same photoconductive contributions. This is owing to the contribution adjustment between the neutral channel and depletion regions signifying that at the juncture of the 3-dB point, both the effects contribute significantly resulting in the fall of bandwidth (3.84 MHz). The 3-dB bandwidths attained with the GaAs OPFET device are (4.57 GHz, 42.4 GHz, and 0.615 MHz) as compared to (12.87 GHz, 16.34 GHz, and 0.72 MHz) at the lower gate length. The reduction in the bandwidth at the lower intensity is contrary to the fact of gentler roll-off slope of photovoltaic charge frequency response (reason behind it is under study) whereas it is in line with the said fact at the intensity of 10^{19} /m^2-s. The slight drop in the bandwidth at the flux density of 10^{22}/m^2-s is contrary to the increment in photoconductive response with gate length and is under investigation. Under UV illumination, in the Si OPFET, the photovoltages are almost the same as that in the visible region since the increase in the absorption coefficient in the UV region by two orders of magnitude is neutralized by the lesser absorption depth maintaining the same values. The photocurrent is almost the same at the flux density of 10^{16} /m^2-s due to the same photovoltage. At the intensity of 10^{19} /m^2-s, the photocurrent is enhanced as compared to its value in the visible region owing to the substantial enhancement of the photoconductivity on account of the two orders of magnitude higher absorption coefficient in the UV region. At the flux density of 10^{22} /m^2-s, almost the same photocurrent is maintained although there is boost in the photoconductive effect due to the large saturation current which limits the total current. The responsivities obtained are (3.5×10^8 A/W, 2.34×10^6 A/W, and 2.4×10^4 A/W) with the visible/UV contrast ratios as (1.71, 0.8, and 1.74). This shows again that at this gate length, the Si device can detect both the visible and UV wavelengths with high sensitivities. The InP OPFET can reject very well the UV radiation and detect visible light with the rejection ratios as (Very High, Very High, and 28.556) at this gate length ascribed to the very high absorption coefficient of InP in the UV region which limits its absorption depth and the generation area. Also, due to the larger active layer thickness, the photovoltages generated are significantly degraded which produces zero response at the lower intensities whereas considerable response at the higher intensity due to somewhat moderate photovoltage owing to the higher optical power level. On the other hand, the GaAs OPFET exhibits rejection ratios of (Very High, 16.05, and 137.54). This can be explained as follows: Although the absorption coefficient of GaAs is almost the same as that of InP, the photovoltages generated in GaAs are slightly higher than that in InP owing to the larger barrier height. Hence, the GaAs device produces zero response (due to very low photovoltage) at the lower intensity whereas substantial responses (due to reasonable photovoltages) at the higher intensities which account for the obtained ratios.

3.7 Comparative Analysis of Si, InP, and GaAs OPFETs at 5 μm gate length and 0.4 μm channel thickness

As the gate is elongated to 5 μm from 4 μm, with a corresponding increase in the active layer thickness to 0.4 μm from 0.3 μm, and the gate width to 200 μm from 150 μm,thedoping concentration is reduced to 3.2×10^{22} /m^3. This tends to increase the depletion width sensitivity but is significantly limited by the voltage drop across the series resistances since the large channel thickness induces high conducting charge under dark which considerably raises the dark current. The series resistances are substantially lowered due to large active layer thickness. In the Si OPFET, the photovoltages remain almost unaltered due to the moderate absorption coefficient of Si. The currents induced in the Si OPFET are (11.9 mA, 13.8 mA, 17.5 mA, and 150.2 mA). The current increase with gate length is due to the reasons described earlier. It is the photovoltaic effect enhancement at the lower intensities whereas the photoconductive effect is boosted at the higher intensity due to larger channel thickness resulting in a larger current of 150.2 mA. The transconductances are considerably boosted (7 mS, 8.1 mS, 7.6 mS, and 100 mS) as compared to that at the lower gate length due to the principles stated earlier. The transconductance increases with illumination initially as usual, but falls at the flux density of 10^{19} /m^2-s due to the limitation by the voltage drop incurred across the series resistance owing to larger current involved (17.5 mA). At the intensity of 10^{22} /m^2-s, although the current is very large, it is due to the photoconductive effect which is insensitive to the voltage drop across the series resistance and can gain sensitivity through the change in the conductance with the applied gate-to-source voltage. The gate-to-source capacitance increases further with the gate length as usual due to the reasons explained earlier (0.18 pF, 0.216 pF, 0.23 pF, and 0.013 pF). These result in the f_T values of (6 GHz, 6 GHz, 5.2 GHz, and 1.42 THz). The Si detector shows bandwidths of (0.72 MHz, 30 kHz, and 0.41 MHz) at this gate length. The unchanged value at the lower flux density is owing to the limitation posed by the series resistance effect. The drop in the bandwidth at the intensity of 10^{19} /m^2-s is attributed to the fall in the photovoltaic charge response with gate length (due to the lower doping concentration) and the increase in photoconductivity from larger channel thickness. The reason behind the unaltered bandwidth of 0.41 MHz at the intensity of 10^{22} /m^2-s is still unknown. The responsivities attained at this gate length are (5.54×10^8 A/W, 1.63×10^6 A/W, and 4.07×10^4 A/W) which are lower than that at the previous gate length as the

device uses more illuminated area for achieving the said photoresponse. In the UV region, the Si OPFET device generates slightly lower photovoltages owing to the higher absorption coefficient which means a smaller absorption depth and due to the large channel thickness, slightly fewer holes make it to the Schottky junction. Due to slightly lower photovoltage, the drain-to-source current is slightly reduced as compared to that in the visible region (13.4 mA) at the flux density of 10^{16} /m^2-s. However, at the flux density of 10^{19} /m^2-s, the response is raised to 18.6 mA due to the significant photoconductive contribution from the depletion region emanating from larger absorption coefficient of Si. At the intensity of 10^{22} /m^2-s, the response falls to 143.7 mA since the photoconductivity is enhanced whereby a large saturation current limits the total current. The responsivities achieved are

(2.55×10^8 A/W, 1.14×10^6 A/W, and 2.26×10^4 A/W). As such, the contrast ratios obtained are (2.17, 1.43, and 1.8).

In the InP OPFET with a gate length of 5 μm, the currents are further enhanced at the lower intensities whereas at the higher intensity, the photocurrent drops owing to the limited sensitivity caused by the presence of large dark current. This, in addition to the photocurrent creates large voltage drop across the series resistance. Thus, with a finite channel width due to moderate barrier height of Au-InP junction and the high absorption coefficient of InP, the photoconductive effect contributes non-significantly as compared to the lower gate length. In this case, the contributions are divided between the neutral channel region and the depletion region, with depletion region still the major contributor. This induces lesser change in the photovoltaic charge as compared to that at the lower flux density. Hence, both the photovoltaic and photoconductive effects fall at this flux density at this gate length causing a drop in the photocurrent. The transconductance rises as opposed to its value at the lower gate length under dark explained by the reasons discussed earlier since the current is comparatively lower which does not significantly limit the sensitivity through the series resistance. However, as the flux density increases, significantly high drain-to-source currents are introduced which considerably limit the depletion width sensitivity due to the voltage drop across the series resistance. At the intensity of 10^{22} /m^2-s, the transconductance is nearly zero since the reduction in photovoltaic sensitivity as explained earlier is almost totally compensated by the rise in the photoconductive sensitivity with the applied gate-to-source voltage resulting in the zero transconductance. The capacitances as usual are raised above their values at the lower gate length. The limitation of the transconductance and the rise in the capacitance leads to the fall in the unity-gain cut-off frequencies (5.5 GHz, 5.6 GHz, 5.5 GHz, and 0.653 mHz). The bandwidths drop at the lower flux densities (62.2 MHz, and 0.33 GHz) owing to the series resistance limiting effects. At the higher flux density, the bandwidth is raised (6.2 MHz). This can be discussed as follows: At the lower gate length, at dc or lower frequencies, both the photoconductive and the photovoltaic effects contribute with significantly high contribution from the photoconductive effect in the depletion region (owing to the lower channel thickness). As the frequency is increased, the photovoltaic charge starts increasing since the otherwise limited sensitivity under large current is converted into non-limited sensitivity. In this case, the increment in frequency lessens the photoconductive charge in the depletion region due to the dependence of electron lifetime on frequency. This reduces the overall current and hence, the voltage drop across the series resistance. This signifies that at the juncture of the 3-dB point, both the photovoltaic and the photoconductive effects are equally contributing. Further, it is known that when two similar effects are contributing to the response with equal operating lifetimes, the net frequency response has a bandwidth which is lower than that of the individual ones. This results in a bandwidth of 3.84 MHz. On the contrary, at the gate length of 5 μm, under dc or lower frequencies, both the effects contribute significantly but here the photovoltaic effect contribution has increased and the photoconductive contribution has decreased (still photoconductive charge is higher). But as the frequency increases, as explained in the previous case, the photovoltaic charge starts incrementing whereas the photoconductive charge starts decreasing. Thus, at the juncture of the 3-dB point, the photovoltaic charge has rose to significantly high value but the photoconductive charge has decreased significantly. Hence, the non-equally contributing charges results in a wider bandwidth (6.2 MHz). The responsivities attained are (5.1×10^8 A/W, 9.3×10^5 A/W, and 3.5×10^3 A/W) which account for the generated photocurrents and the optical power used under visible light. Under UV illumination, the photovoltages are severely degraded and the photoconductive responses are negligible owing to the very large absorption coefficient of InP and the larger active layer thickness which produce zero responsivities. Thus, the visible/UV contrast ratios are very high. This shows that the InP OPFET with a gate length of 5 μm is a high sensitivity detector with a very high contrast between visible and UV wavelengths but at the expense of a larger dark current. Discussing the GaAs OPFET device with a gate length of 5 μm, this device exhibits the same photovoltages as that with other gate lengths owing to the moderate absorption coefficient of GaAs even if the channel thickness is increased to 0.4 μm. Due to the larger active layer thickness and the high photovoltages, the series resistances are substantially reduced. As usual with the elongation of the gate length, the drain-to-source currents and the photocurrents are significantly enhanced (17.5 mA, 21.5 mA, 24.2 mA, 275.4 mA), however, this time with the limitation by the series resistances owing to the larger currents involved. The transconductance drops under dark (7.9 mS) since the dark current is very high (17.5 mA) as compared to its value at the previous gate length (9.4 mA) thus, limiting the sensitivity. At the flux density of 10^{16} /m^2-s, the transconductance is enhanced (12.7 mS) due to significant photovoltaic effect. At the flux density of 10^{19} /m^2-s, the transconductance falls (10.6 mS) due to larger current involved (24.2 mA) thus inducing series resistance-limited effect. At the intensity of 10^{22} /m^2-s, the transconductance slightly rises (30 mS) due to the substantial photoconductive effect in the depletion region insensitive to the voltage drop across the series resistance, thus, inducing a large saturation current independent of the gate-to-source voltage also limiting the total current and the device gaining the sensitivity through the significant conductance change with the applied gate-to-source voltage. The capacitances are increased as usual (0.16 pF, 0.2 pF, 0.22 pF, and 0.036 pF). As such, the f_T values obtained are (7.6 GHz, 10.11 GHz, 7.65 GHz, and 133.1 GHz) which are lower than the values at the lower gate length. The 3-dB bandwidths attained are (19.15 GHz, 19.15 GHz, and 0.615 MHz). At the intensity of 10^{16} /m^2-s, the bandwidth enhancement is due to the larger sensitivity. At the flux density of 10^{19} /m^2-s, the drop in the bandwidth is due to the limitation by the series resistance. The unaltered bandwidth at the intensity of 10^{22} /m^2-s is owing to no significant change in the photoconductive charge. The responsivities achieved are (1.18×10^9 A/W, 2×10^6 A/W, and 7.59×10^4 A/W) which account for the generated photocurrents utilizing larger illuminated areas. Under UV light, the photovoltages are significantly degraded owing to the very large absorption coefficient of GaAs and wider channel thickness (0.4 μm). This produces zero photoresponses at the lower flux densities but at the higher flux density since the optical power level is high and on account of the very high absorption coefficient of GaAs, the photoconductive effect from the depletion region is large. This is because the photovoltage is very low and the high photoconductive current develops significant voltage drop across the series resistance thus, making the channel totally depleted and producing high response (4.42×10^4 A/W). Hence, the visible/UV

rejection ratios attained are (Very High, Very High, and 1.72). Thus, the GaAs OPFET is comparable to the InP OPFET at the lower intensities in terms of contrast ratio whereas it is inferior to the InP OPFET at the higher intensity.

Conclusion

We studied in detail the visible light and the UV photoresponses of the three efficient materials-based (Si, InP, and GaAs) back-illuminated OPFET photodetectors for VLC and UV reflectance imaging applications i.e. high gain-bandwidth product and high visible/UV contrast applications respectively. The results were analyzed based on the photoconductive and the photovoltaic effects, the series resistance effects, scaling rules- induced effects, and channel length-variation effects. The GaAs OPFET emerges

as a high-performance photodetector with higher responsivities, higher 3-dB bandwidth in the gigahertz range, and high visible/UV rejection ratios. On the other hand, the InP OPFET device can compete or even surpass the GaAs OPFET device in terms of contrast ratio with high photoresponse but inferior to the GaAs device and bandwidth in the sub-gigahertz range. Whereas the Si OPFET device exhibits high responsivities inferior to the InP device at the lower intensity and ranging between that of the InP and the GaAs devices at the higher intensities but the bandwidth is in the sub-megahertz range and the contrast ratios are very low. All the devices show significant unity-gain cut-off frequencies. On the whole, the drain-to-source currents, the photocurrents, the transconductances, and the gate-to-source capacitances increase with the elongation of the gate length and the widening of the active layer thickness. The responsivities decrease with the gate length. The photovoltages remain almost unaltered. The series resistances reduce with the gate length and the active layer thickness. Very High visible/UV rejection ratios are observed at the higher gate lengths in the case of the InP and the GaAs OPFETs. The 3-dB bandwidth under photovoltaic conditions in normal circumstances increase with the gate length but in some instances is limited by the series resistance effects. Also, with the enhancement of the photoconductive effect with gate length, the bandwidth increases. However, in other circumstances, wherein the bandwidth depends upon both the photoconductive and the photovoltaic effects, and their relative contributions, the bandwidth can either increase or decrease with gate length. The unity-gain cut-off frequency has an arbitrary dependence upon the gate length based upon the relative contributions of the transconductance and the gate-to-source capacitance. The GaAs OPFET detector exhibits the highest detection-cum-amplification bandwidth of around 11 GHz using a gate length of 3 μm and an active layer thickness of 0.27 μm at the flux densities of 10^{16} and 10^{19} /m^2-s whereas it shows a bandwidth of 11.5 GHz with a gate length of 4 μm at the intensity of 10^{19} /m^2-s, thus, showing its potential as detector-cum-amplifier in Opto-Electronic Integrated Circuits (OEICs)-based high bandwidth VLC applications such as Li-Fi (Light-Fidelity Networks). At 3 μm gate length, it exhibits the highest responsivities of 2.55×10^9 A/W and 4.1×10^6 A/W at the intensities of 10^{16} and 10^{19} /m^2-s respectively. Further, the corresponding visible/UV contrast ratios are 5.21×10^7 and 10.25. The InP OPFET attains a modest detection-cum-amplification bandwidths of 92 MHz, 0.36 GHz and 3.84 MHz at the 4 μm gate length and at the flux densities of 10^{16}, 10^{19}, and 10^{22}/m^2-s respectively with the corresponding high responsivities as 7.4×10^8 A/W, 1.47×10^6 A/W, and 7.97×10^3 A/W and contrast ratios as (Very High, Very High, and 28.5). These values suffice for moderate bandwidth VLC applications viz. hospitals and healthcare, under-water communication, defence, and security. The Si OPFET device can operate in low data rate VLC applications such as general positioning, vehicle and transportation, and smart lighting, due to its low detection-cum-amplification bandwidths of 0.66 MHz, 84.16 kHz, and 0.57 MHz at the gate length of 3 μm and an active layer thickness of 0.27 μm at the flux densities of 10^{16}, 10^{19} and 10^{22} /m^2-srespectively, with the corresponding responsivities of 9.35×10^8 A/W, 2.43×10^6 A/W, and 2.3×10^4 A/W. The Si OPFET is not suitable for visible/UV contrast applications. These devices show good prospects for communication and contrast applications. The comprehensive analyses presented here which relate the effect of the structural and the material parameters on the device parameters through physics-based discussion will aid in conducting further research.

Table 5: Parameters employed in calculation.

Parameters used in calculation (Si)			
Parameter	**Name**	**Value**	**Unit**
μ	Low field electron mobility	(~ 0.09)	(m^2/V.s
Φ_B	Schottky Barrier Height (ITO-Si)	(~ 0.71)	(eV)
v_{vn}	Saturated electron velocity	~9.4×10^4	(m/s)
v_{vp}	Saturated hole velocity	~6.3×10^4	(m/s)
τ_p	Lifetime of holes	75×10^{-6}	(s)
τ_n	Lifetime of electrons	75×10^{-6}	(s)
ε	Permittivity	1.04×10^{-10}	(F/m)
α	Absorption Coefficient @ 600 nm	7.5×10^5	(/m)
α	Absorption Coefficient @ 350 nm	1×10^7	(/m)
Parameters used in calculation (InP)			
μ	Low field electron mobility	(~ 0.43)	(m^2/V.s
Φ_B	Schottky Barrier Height (Au-InP)	(~ 0.8)	(eV)
v_{vn}	Saturated electron velocity	~7.6×10^4	(m/s)
v_{vp}	Saturated hole velocity	~5.6×10^4	(m/s)
τ_p	Lifetime of holes	0.3×10^{-6}	(s)
τ_n	Lifetime of electrons	0.3×10^{-6}	(s)
ε	Permittivity	1.11×10^{-10}	(F/m)
α	Absorption Coefficient @ 600 nm	1×10^7	(/m)
α	Absorption Coefficient @ 350 nm	7.6×10^7	(/m)
Parameters used in calculation (GaAs)			
μ	Low field electron mobility	(~ 0.5)	(m^2/V.s
Φ_B	Schottky Barrier Height (ITO-GaAs)	(~ 0.98)	(eV)
v_{vn}	Saturated electron velocity	~1.2×10^5	(m/s)
v_{vp}	Saturated hole velocity	~9×10^4	(m/s)
τ_p	Lifetime of holes	1×10^{-8}	(s)
τ_n	Lifetime of electrons	1×10^{-6}	(s)

ε	Permittivity	1.14×10^{-10}	(F/m)
α	Absorption Coefficient @ 600 nm	4×10^{6}	(/m)
α	Absorption Coefficient @ 350 nm	8×10^{7}	(/m)

Table 6: Performance comparison with state-of-art photodetectors and amplifiers.

Ref. No.	Year	Detector	Optical Power Density	Responsivity (A/W)	Bandwidth	Amplifier Type and f_T (Hz)
[17]	2004	PIN	NP (Not Provided)	0.36 A/W @ 660 nm	1.35 Hz	TIA (25 GHz)

ABSTRACT

The integrating model becomes one of key trends in engineering design. The more the product has functional specifications, the more the industrial consumer apply in many fields. In this paper, a fusion design of architecture platform for autonomous system is demonstrated. It is greater due to combining the specifications of various types in commercial market such as driving structure, multi-functional model or autonomous level. Therefore, plentiful advantages of systems are converged into one platform. From customer's requirements, the system parameters and specifications are offered to consult during the process of design. To compare with previous works, the enhancement of tractor-trailer, lifting-carrier and auto-feeder using differential driving mechanism is merged successfully. The detailed design of prototype involves the development of hardware components and infrastructure. Later, the modeling of autonomous system is simulated on computer to meet the employed conditions. The force analyzing scheme helps to predict the working ability to complete their mission. To verify the proposed design, an experimental version of this system is tested in different cases. In mode of lifting carrier, the vehicle and cargo that become a rigid body, follow the reference trajectory in practical map. In another circumstance, vehicle plays a role as leader which take along with cargo, as follower. From these results, it can be seen that the proposed design is feasible, effective and capable in real world. In future works, a fleet of autonomous vehicles mixing multi-modes in the same map should be considered.

1. Introduction

In the worldwide era, a large-scale system becomes more popular due to its huge advantages. Especially, in online shopping business, it needs a thousand of employers who work in distribution center or warehouse every day. Reducing the labor cost means that enormous profits are earnt. Therefore, the producer would always discover the methods to lessen the operating payment. One of common ideas is to use autonomous vehicle that carry goods to human operators [1, 2]. Various challenges had to be overcome in order to make this viable system, from design of robust autonomous vehicles, real-time communication, the coordination of vehicle and various control algorithms which permit the system to adapt and reconfigure itself leaning on the environment and working conditions. Generally speaking, grounded automated vehicle (GAV) is digested into several sub-categories. Authors in [3, 4] posed the lifting type of vehicle to elevate cargo in production site. The veridical product has three wheels including one driven wheel and two driving wheels. Two driving wheels of GAV have independent brush motors while the other is passive wheel. This model is very widespread nowadays since its movement is free and high loading capability.

The second one is forklift type with steering mechanism [5, 6]. This kind of vehicle often appears in port transportation, harbor storehouse or container yard. The main benefits are to provide heavy loading ability and powerful lifting mechanism. In most of its applications, it requires human to sit on. The diesel engine version is cheaper than one using electric engine. However, because its dimension is large, it needs more space to operate than others. In the other style of GAV, i.e. tractor-trailer transporter [7, 8], the long combination vehicle is gradually becoming more public in certain circumstances because of vantages related to decrease costs for material transportation and diminish fuel

* Thanh Phuong Nguyen, Email: nt.phuong@hutech.edu.vn

consumption. This research implements active trailer steering control to improve the maneuverability of long truck-trailer combinations. The problem of swept path width during cornering could be solved by nonlinear control strategies. The effectiveness of proposed approach is evidenced on experimental platform.

In reality, there is a need to integrate these above vehicles into a compact unit. The emerging trend helps to overcome the existing limitations such as particular control problems of model type, enhancing carrier, reducing shared workspace, improving low speed maneuverability and so on. Besides, the saving cost on buying an integrated platform is rather than separated ones. In this paper, we present a fusion design of automated vehicle in multi-applications. After the problem statement is given in Section II, the novel idea based on combining between lifting carrier and truck-trailer model is to provide many expandable developments. The study of proposed pattern that is demonstrated in Section III enables the modern mechatronics system design. Section IV performs the actualizing works in each type whenever vehicle adapts to different scenarios. Later, the verification of proposed design is proved through experimental tests of Section V. Finally, some conclusions about this approach are commented for further development in Section VI.

2. Problem Statement

GAV or autonomous robot which is energized by electric power, play the role as a potential means of transportation in future. Due to great rewards in logistics, e-commerce, factory automation, social service and in some situations, public carriage, it has attracted the attention of industry and academic. There are numerous forms of classifications in GAV, such as wheeled structure, driving mechanism or their purposes. Referring to four wheels and driving by front-side, authors [11] investigated the control scheme to realize the yaw moment in presence of unknown mismatched disturbances. An integral sliding mode control was embedded into differential drive assistance steering (DDAS) to guarantee the transient control performance. In the case of complete failure of active front-wheel steering system, a robust composite nonlinear feedback strategy [12] to achieve path following was studied in detail. Besides, by utilizing fault-tolerant control with DDAS, an innovative multiple-disturbances observer-based method was applied in considering the tire force saturations. With a variable speed integral PID controller and a coordinated control system based on adaptive weighting dependent vehicle speed [13], both the ideal steering wheel torque and expected yaw rate could be obtained. However, they are hard to employ in commercial market owing to unreachable real-time performance, especially in emergency stop case. Via driving mechanism in rear-side, some car prototypes have been commercialized effectively. The control problem seems to be more difficult since the leading angle is adjusted lately. Furthermore, the head of car is light weight. It tends to be unstable when running at high velocity. To be more flexible, four wheels of electric vehicle have been driven. In [14], the wheel driving torque on each motor could be modulated precisely and continuously to attain not only maneuverability but also energy-saving mode simultaneously. The distribution strategy of torque control using multi-objective optimization was categorized into high layer and low layer. Although the developed method was simulated, the effectiveness of this approach has not verified in experimental platform yet.

In the other configuration, the three wheels framework becomes one of key topics to develop. In [15], to decline the error dynamic stabilization problem, a nonlinear sliding mode control law is employed to surpass. The control organization is uniformly asymptotically stable if unknown disturbances and modeling uncertainties are bounded. It utilized the nonholonomic constraints and transitional trajectory to acquire feasible state trajectories. Though, in practical context, the mass changes incessantly and it is hard to measure inertial moment of whole system (vehicle and load) precisely. The most concern of two-wheeled configuration is balancing control algorithm. The reporters [16] analyzed a passive inverted pendulum model as an investigational device. The sampling effect of the digital control is simulated as a zero-order hold. The stabilization of the upright position is possible by choosing proper control parameters as function of the sampling period of the controller. There are many limitations such that nonlinear characteristics (friction, behavior of electro-mechanical) are not mentioned while they still occur in model. Also, the system coefficients are not prearranged exactly. Sometimes, the omni-directional mobile robot including four mecanum wheels was installed in manufacturing fields. The authors [17] introduced the design and development of omni-based robot orienting to intelligent factory. The upper sections are named as control level and application level while the lower one is chassis frame. Each modularized wheel was located on a vertical suspension mechanism to ensure the moving stability and keep the distances of four wheels invariable. In the unknown semi-structured indoor environment, the data from a Kinect visual sensor and four-wheel encoders were fused to localize the mobile robot using an extended Kalman filter with specific processing. The existing difficulties in the model are to eliminate the slipping phenomenon on mecanum wheel and restrict loading competence.

The other types of GAV are forklift truck and tractor-trailer vehicle. The prototype forklift is regularly applied in container yard, pallet-based storehouse or cold storage. The structure of forklift [18-20] entails of a single active rear wheel and two non-driven front wheels balanced in electric stacker. Around the automatic forklift, several sensing modules, for instance, positioning encoder, laser scanner or GPS-indoor are often attached to collect environmental information. The drawbacks of forklift robot are too dangerous to actuate in medium or small-scale area, high maintenance cost and inflexible motion. In the coordinated control approach [21, 22], a tractor-trailer vehicle could be ensured to track trajectory and maintain vehicle kinematics restriction and dynamics maneuvers simultaneously. In the level of kinematics, linear quadratic regulator and model predictive control were used to assess the posture controller separately. For dynamics analysis, sliding mode control and global terminal sliding mode control were inspected to design the dynamic controller for the tracking of the desired velocities generated online. Nevertheless, the viability and application of this method are still questioned.

As a result, the incorporated requirements become an inevitable trend in our era. The contributions in this paper are, (a) analyzing the fusing hardware of models between tractor-trailer form and lifting carrier form, (b) build up an experimental platform of GAV based on the analysis design positively and enforce it safely on working map.

3. Analysis of Fusing Model

Based on the new trend of fusion, multi-function should be merged various roles into one platform. For instance, the autonomous vehicle is able to elevate cargo in vertical direction and pull freight horizontally. The vertical lifting vehicle modeling is illustrated as Fig. 1. It is assumed that vehicle and freight become a rigid body which has total weight m_{vl} .

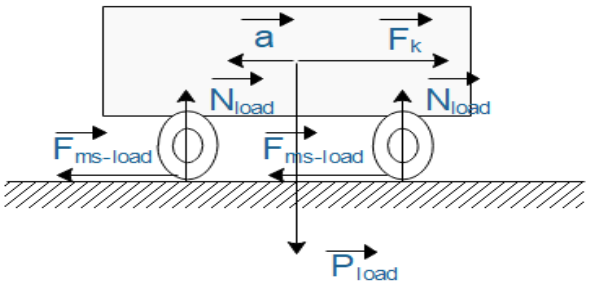

Figure 1: Forces act on lifting type model.

$\vec{a}$: acceleration of rigid body

$\vec{P}_{load}$: gravity force of rigid body

$\vec{N}_{load}$: reaction force on plane due to Newton's law

$\vec{F}_{ms-load}$: friction force between wheel and plane

$\vec{F}_k$: driving force from motors

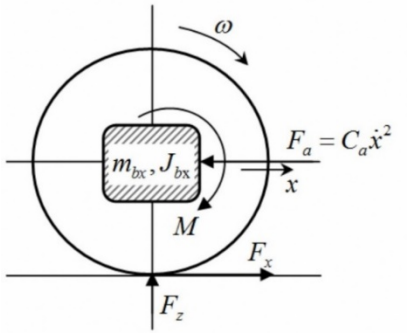

Figure 2: Analysis of driving wheel actuator.

According to second law of Newton, we have

$$\sum \vec{F} = m\vec{a} \Leftrightarrow m_{vl}\vec{a} = \vec{F}_k + \vec{F}_{ms-load} \quad (1)$$

$$F_k = m_{vl}a + F_{ms-load} \quad (2)$$

$$F_k = m_{vl}a + P_{load}\mu_{ms-load} \quad (3)$$

The force F_k is estimated as 17,405 N approximately. It is considered that vehicle moves on high stiffness plane as Fig. 2. If there is no slipping phenomenon, then, the constraints of design parameters to avoid this problem must be met below condition.

$$P_c \le P_k \le P_\varphi \quad (4)$$

where $P_c = F_k + P_f + P_i + P_\omega + P_j$

The force P_f helps maintaining driving wheel and plane in contact.

$$P_f = \mu' N = \mu' m_{vl} g \quad (5)$$

The inertial moment of driving wheel J_{wheel} is computed as.

$$J_{wheel} = \frac{1}{2} m_{wheel} 2r_{wheel}^2 \quad (6)$$

The symbol r_{wheel} is radius of driving wheel. Therefore,

$$P_j = \left(m_{vl} + \frac{J_{wheel}}{r_{wheel}^2} \right) a \quad (7)$$

Due to the movement on flat, the drag force P_i could be cancelled. The volume of vehicle is small, hence, the air resistance force P_ω is ignored.

By choosing adhesion coefficient $\varphi = 0.7$, the force P_φ is determined as.

$$P_\varphi = \varphi m_{vl} g \quad (8)$$

A relationship between driving force and moment of driving wheel is presented as.

$$P_k = \frac{M_1}{r_{wheel}} \quad (9)$$

As a result, the moment of driving motor M_1 , which is essential to control the system, should be complied with following constraint.

$$2,71 \le M_1 \le 24,89 \quad (10)$$

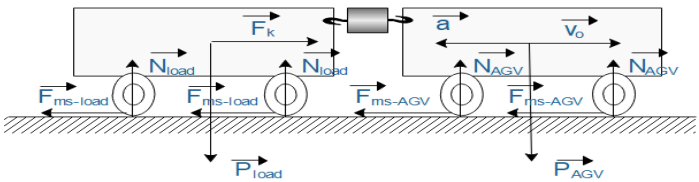

Figure 3: Forces act on tractor-trailer type model.

To certify the operation of truck-trailer type, an analysis of this modeling is shown as Fig. 3. The leader and follower are connected via a hook. The first vehicle is active drive while the other is passive one. In this case, we concern on interacting forces among them and angular driving wheels.

Theoretically speaking, the leader vehicle obligates to provide larger traction force to drive a chain of followers. This additional force is deliberated as $F_k^{'}$. Thus, the new force F_k^{new} that is necessary to drive whole system is denoted.

$$F_k^{new} = F_k + F_k^{'} \tag{11}$$

Consider that it pulls the followers not greater than its weight. Adding the safe ratio as our experiences, the new force F_k^{new} could be rewritten as.

$$F_k^{new} = 2,2F_k \tag{12}$$

Besides, the factors (material, structure or inside components) of driving wheel would affect on adhesion coefficient ϕ. The estimated moment of driving motor M_2 is renewed as.

$$4,32 \le M_2 \le 38,73 \tag{13}$$

4. Fusion Design in Proposed Hardware

In this section, the detailed design of proposed model is mentioned. Fig. 4 shows the inside frame of mechanical parts in vehicle. Generally speaking, the architecture of system is classified into three main layers (base, middle and lifting layer) and one intermediate layer. The base layer is the lowest one and stiff enough to bear the entire mass of whole system. The driving mechanism connoting DC motors with gears, drivers, soft couplings, battery, electric cylinder and so on, is located on base layer. Four rolling actuators that are hang on middle layer play a role as feeding actuator automatically. One electric cylinder is situated at center of the middle layer to upraise goods. Eventually, the lifting layer is at top. The electromagnetic lock, dwelling in this layer, is exploited to pull load horizontally. The intermediate one is a framework for holding and suspending among layers.

(b)

Figure 4: Vertical view (a) and horizontal view (b) of hardware structure design.

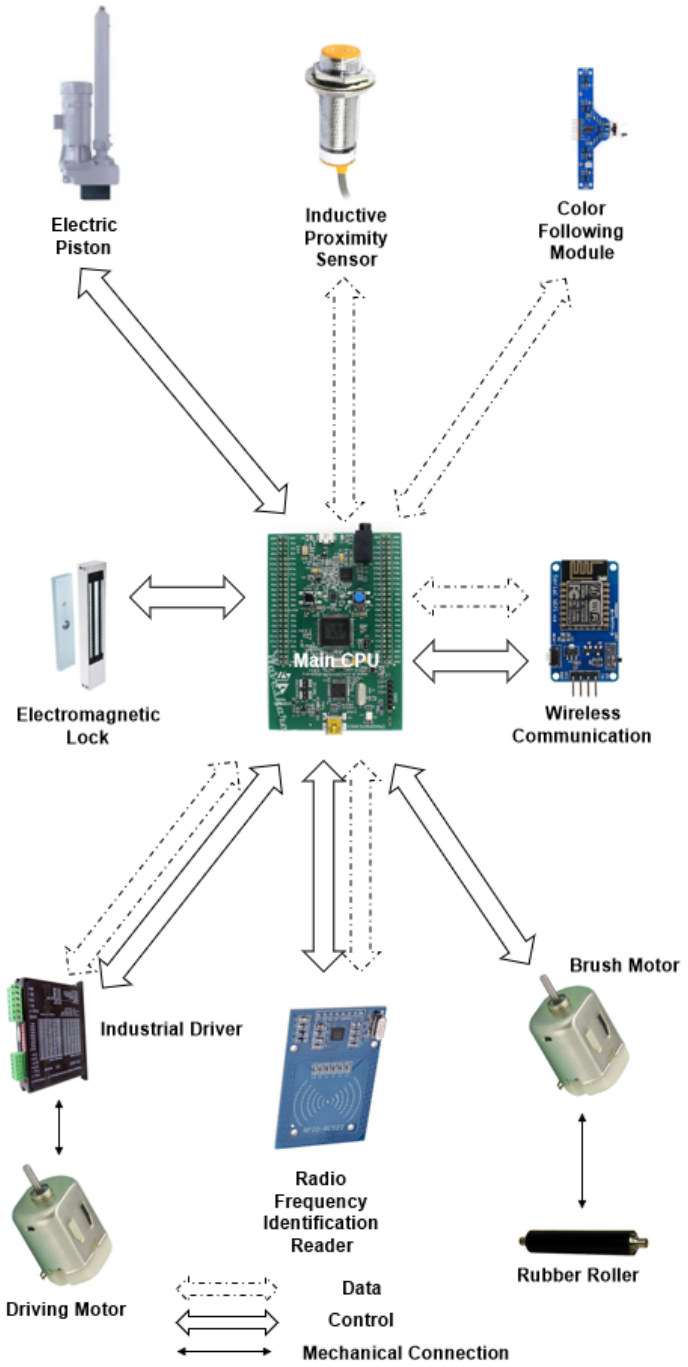

Figure 5: Diagram of data and control bus in proposed system.

Fig. 5 demonstrates the threads of data transmission and elements of control scheme in proposed system. It is powered by 32-bit MCU up to 168 MHz with floating point unit, 1 Mbyte flash memory, 192 Kbyte RAM, various I/Os, three channels of 12-bit ADC, two channels of DAC providing high performance and wide range of applications. For the internal signals, the data bus accommodates exchanging information (sensors or network protocol) whilst the control bus encompasses synchronizing interface (actuators, drivers). Due to centralized control method, the system is effective, reliable highly and simple to debug. However, to enlarge the real time performance, the coding needs to be optimized in firmware level.

The navigation problem of vehicle is also an attractive issue in control of system. The Radio Frequency Identification (RFID) technology is involved to lessen the burden data transmission. In each crossroad or corner, RFID card is occupied under the line guide. In the bottom side of vehicle, the card reader is stayed at central point to read and notify the unique code to host computer. The operator, who sits in center control room, could determine where the system locates in working map.

5. Research Results

It has been known that the combining approach must deal with various challenges and the gap between computational design and real world should be as small as possible. Henceforth, the system is validated experimentally in real scenario shown in Fig. 6. The architecture of control topology consists of local controllers and central one. The main microprocessor in local controller is powerful with high computing ability, fast processing and expandable peripherals. The host personal computer is with i7 core, high speed clock and visual monitoring capability. The supervisor would stay in control area to supervise the operation of system. The local controllers and central manager are contacted via wireless communication. The control messages are unceasingly transferred among them to prevent unfortunate incident.

Figure 6: Experimental model of proposed vehicle.

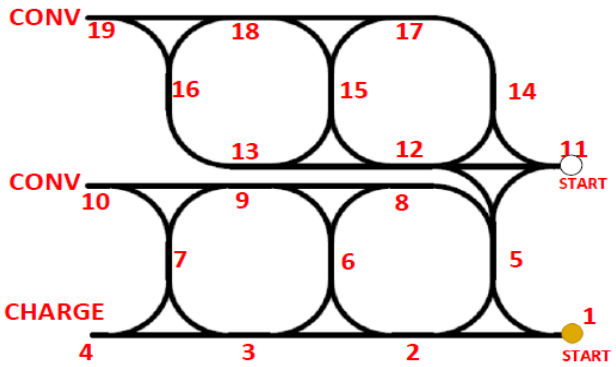

Figure 7: Overview of mapping area in workspace.

To imitate the practical situations in factory or distribution center, an overview of mapping working sector is drawn in Fig. 7. For multi-agent system, there are two reference regions are in parallel to enhance industrial productivity. The start points, charging section and conversing node are formed to offer various circumstances. At initial stage, vehicle moves to cargo's location

and bring to target position. In the case that the cargo must be out of storage, vehicle takes to conversing node. The battery management is gathered at charging station. Whenever level of energy is low, autonomous vehicle sends a notification to host server and move to charging node.

Figure 8: Experimental test scenario of tractor-trailer model.

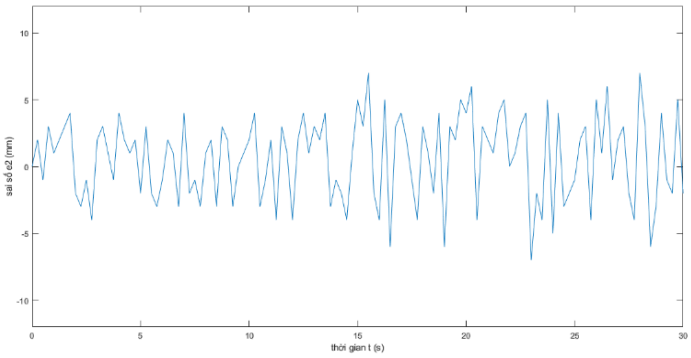

Figure 9: Experimental test scenario of lifting model.

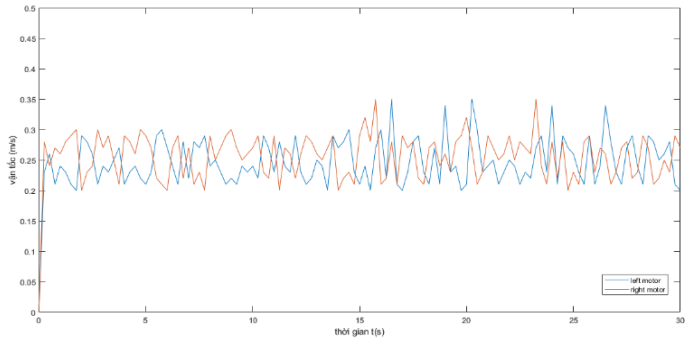
The shelf of cargo is made of steel and its height comply with industrial standard. There are only two floors, but its floors can be extendable. Four caster wheels are attached under the shelf to assist the free motion. The experimental validations include two-fold: first, vehicle begins at start point, it passes serial points to target position. Then, the lifting layer is gone up as height as the bottom floor of shelf. At that moment, the local controller activates electromagnetic lock to maintain force. It drives the shelf according to reference path as Fig. 8. The reverse process is actuated in target position: inactivate the electric lock, lift down and gradually move to next position.

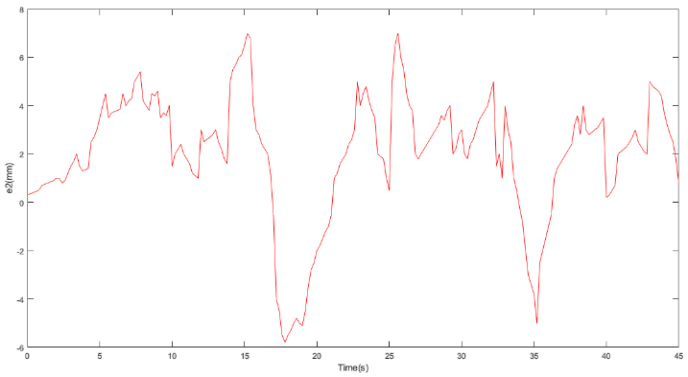


Sequently, the lifting mode is experimented as Fig. 9. In this case, the autonomous vehicle is compelled to accomplish the mission: brings the rack of payload from initial position to final location. Launching at start point, it comes to site of shelf by tracking linear and circular path. Later, vehicle orders lifting part to move up elevating the shelf. At this time, vehicle and cargo become a rigid body. Both of them are conveyed to final place and released there. The grounded robot could come back start point and ready for next task.

Table 1: Comparative Tracking Error Results in Experimental Tests

Test case	RMS	Average
Lifting model	0.157	0.268
Truck-trailer model	0.082	0.194

(a)



(b)

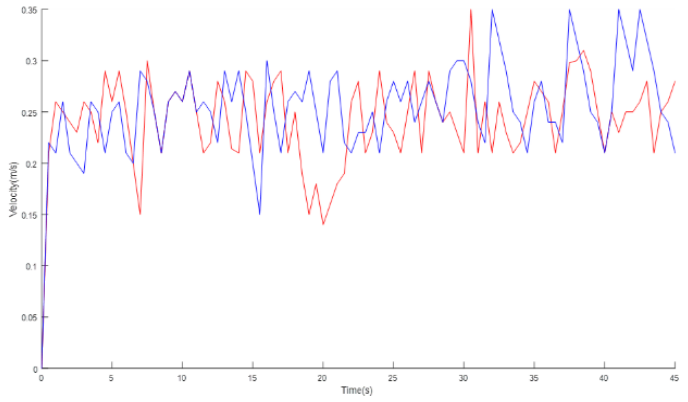


Figure 10: Experimental performance of truck-trailer model, (a) tracking error, (b) velocity of left wheel and right wheel.

The monitoring parameters in this study are tracking errors and control speeds. In differential drive, the variations in velocity of left and right wheels have an effect on directional movement. The tracking error governs the output performance in whole system. Fig. 10 and Fig. 11 show experimental results in two case studies respectively. In truck-trailer test, the leader must take a follower behind carefully. The motion of trailer affects on tracking error of front-runner. If leader moves so fast, it tends to deviate from reference path at corner. Otherwise, the force is too small to steer a follower or time-consuming motion costs too much.

In lifting test, the weight of whole system including total mass on shelf plus itself is heavier. Consequently, the motion seems to be more difficult. The value of tracking error, in this scene, is larger than others while the velocities of wheels are adjusted continuously. To visualize the differences in two cases, Table 1 reports the tracking error (Root-Mean-Square value and average value). From these results, it could be seen obviously that tracking error in lifting mode is larger than one in truck-trailer mode. The reason is that the control scheme drives harder when vehicle and cargo become a rigid body.

(a)

(b)

Figure 11: Experimental performance of lifting model, (a) tracking error, (b) velocity of left wheel and right wheel.

6. Conclusions

In this paper, a multi-purposes implementation for autonomous grounded vehicle is fused into an unique framework in practical factory. The proposed design is feasible, low cost and complies with industrial solicitations whilst it still conserves flexible motion. Furthermore, the integrating approach ensures that it is not only useful in various applications, but also it provides wide development trends, such as smaller, smarter or more convenient. From the successful results of research, it could be achievable in logistics, manufacturing industry, material transportation and training.

Conflict of Interest

The authors declare no conflict of interest.

ABSTRACT

The problem of recognizing traffic sign boards in a correct fashion is one of the major challenges since there is an alarming rate of increase in the number of road accidents happening because of incorrect interpretation of traffic sign boards in bad weather conditions. In this paper, a comparative analysis of various noise removal techniques based on calculating different parameters which decide the quality of input roadway symbol like Mean Squared Error (MSE), Peak Signal to Noise Ratio (PSNR) as well as Structural Similarity for measuring Image Quality (SSIM) is being performed and the best technique will be chosen among them which gives minimum Mean Squared Error (MSE) value and maximum Peak Signal to Noise Ratio (PSNR) and Structural Similarity for measuring the Image Quality (SSIM) values. This technique will be quite useful for de-noising a given image which is present in both the testing and the training image databases.

1. Introduction

There is a huge demand in the market as there is a rapid development in improving the existing system which ensures in giving security to the driver during the course of driving a vehicle. This leads to the development of a system that provides a helping hand thereby incorporating new techniques used for the purpose of detecting as well as recognizing the traffic signs. Nowadays, many automobile industries are extending in the market due to an increase in the demand for smart cars as a result of the rising competition among its fellow industries [1-5].

In the areas where there is a large amount of travelling, the regulation of the speed of the vehicles is done by the use of sign boards. They are used for limiting the current velocity of moving vehicles and are considered to be a part that comprises of some major categories of traffic signs [6-10].

A rise in the number of roadway accidents is observed because of ignoring the sign boards which try to limit the velocity of a moving vehicle for the persons who are driving a vehicle. Generally, it is observed that the persons who are not aware of the potential danger during the course of driving consequently meet a serious accident thereby even leading to their deaths [11-15]. There is an urgent need for development of a system which can be used to recognize the Speed Limit Signs (SLS) in an automatic fashion and may be used for alerting the driver [16-20]. There are two major steps which are involved in the processes of detecting and recognizing the Speed Limit Signs (SLS). The first step is to detect the potential candidates which are known as the Regions of Interest (ROI) usually comprising sign board images and the second step is to recognize the ROI in order to extract the correct category of sign board images [21-25].

During the course of driving a vehicle [26-35], the driver tends to ignore the speed limit sign boards that convey a message to restrict the velocity of a moving vehicle thereby suffering from a

collision which may ultimately lead to the death of the driver consequently becoming a reason for increasing number of roadway accidents [36-45]. The development of a system that is capable of recognizing the Speed Limit Signs (SLS) in an automatic fashion as well as alerting the driver at the same time is the need of the hour [46-50].

It is generally observed that various automobile industries are increasing in the market because of the demand of smart cars. This is the result of the rising competition among its fellow industries thereby facilitating the growth of systems. It would provide a helping hand thereby incorporating some new techniques used for the purpose of detecting as well as recognizing the traffic signs. In recent years, since there is a large requirement in the market because of rapid growth in the improvement of the existing system, a secure driving environment is provided [1-5]. The maximum speed limit sign boards are generally employed to restrict the velocity of a moving vehicle and are used for regulating the velocity of a vehicle in the case of areas where there is a large amount of travelling thereby comprising of a major category of traffic signs [6-10]. During the course of driving a vehicle, the driver tends to ignore the speed limit sign boards that convey a message to restrict the velocity of a moving vehicle thereby suffering from a collision which may ultimately lead to the death of the driver consequently becoming a reason for increasing number of roadway accidents. The development of a system that is capable of recognizing the Speed Limit Signs (SLS) in an automatic fashion as well as alerting the driver at the same time is the need of the hour [11-15]. The process of detecting as well as recognizing the SLS normally comprises of two major steps namely, detecting the potential candidates known as the Regions of Interest (ROI's) consisting of the sign board images and recognizing the ROI so that the category of sign board images can be extracted in a correct fashion [16-20]. The main objective of detecting a sign board image can be accomplished with the help of extracting the primary visual features like the color and the shape which are present inside a given input image [21-25] such as the color feature is employed for detecting the red SLS while the shape feature is employed for detecting circular or rectangular sign board images [26-30]. If we study the research work which is done in the past, we will come to know that the rectangular speed limit signs [31-35] are usually detected with the help of shape-based methods [36-40], for example, if we study the research work which is carried out by [41-45] we will find that the rate of detecting the sign board images was increased in the rough conditions, especially, during the night time [46-50].

The circular sign board images are detected by making use of the color-based and/or the shape-based methods, for example, if we consider the research work which is carried out by [1-5]. Next step which is involved in the process of recognizing the SLS comprises of two important techniques, namely, the processes of recognizing sign boards that are available in a broad range as well as recognizing each and every character on a given sign board. If we take an example of strategy that incorporates recognizing a given sign board which is made available in a wide range, one may find a complete candidate sign to be considered for recognizing process [6-10]. If we take the example of digit-based methods, the process of extracting multiple characters for recognizing numerical portrait of velocity which is exhibited by a moving vehicle rather than classifying a complete sign board image treating it as a single entity is performed [11-15]. The process of recognizing sign board images is treated as one of the important factors for driver assistance system because it plays an important part in controlling the road traffic thereby issuing a warning signal and giving proper guidance to the drivers [16-20]. It is observed that ignoring the sign boards because of distraction or being in a psychological state by the drivers is the main cause of roadway accidents which are occurring in last few years [21-25]. There is an urgent need for incorporating an automatic system for the purpose of recognizing the sign boards and is considered to be a main factor for building an autonomous navigation system [26-30]. In order to detect and recognize the sign boards [31-35] with a faster speed and higher efficiency, particularly, in a real time scenario, the proposed system [36-40] should have a higher precision so that the process identification of sign board images can be performed in a correct manner [41-45]. The detection and the recognition efficiencies can be affected if the system is busy in managing certain complicated issues [46-50].

The various problems that are associated with these systems include the variations in the illumination such as light levels, twilight, fog, rain and shadow, motion blur and sign occlusion [1-10]. The effectiveness can be considered to be one among the major factors because the complete navigation system is damaged by the improper classification and lack of detection of sign board images. But, later it was revealed that the systems that are currently present in the literature part are unable to provide 100% accuracy. The research scholars were motivated by the results which are given in the section above and there was an improvement in the performance of system that is capable of detecting as well as recognizing the sign board images even in the complicated situations and thus highlights the importance of our research work in building this method that is being presented in this review paper. A novel technique which is used for the process of detecting, tracking and classifying the sign boards at a faster speed from a moving vehicle even in the difficult conditions was proposed by [11-20]. In order to extract the candidate regions of the sign boards, a color-based segmentation technique was being proposed in the course of detecting the sign board images. The HOG features are applied in order to encode the sign board images which are detected and the feature vectors are also computed. The process of detecting and recognizing the sign board images in an automatic manner remains as one of the daunting task that comprises of a variety of areas of application, for example, if we consider reinforcements resulting from a rapid growth in the arena of providing a safe driving environment to a driver who is driving a vehicle, taking a survey of existing road conditions that are prevalent in our surroundings so that potential dangers can be judged and proper steps can be implemented in order to prevent them from happening [21-30].

1.1. Traffic signs interpretation

When we compare the research work which is done on automatically detecting and recognizing symbol-based traffic sign board images and recognizing the textual information which is present inside the sign board images, we will find that a small amount of research work is done on recognizing the textual information which is present within a sign board image in comparison with the former [31-40]. One of the main difficulties that are associated with this procedure such as presence of variation in lighting conditions as well as shadowing effect that is caused due to improper lighting conditions, the effect of causing a blur, causing an occluding effect due to improper and less amount of light as well as deteriorating of sign board images can be considered responsible for causing this scenario to a smaller extent [41-50]. During the course of driving, we cannot distinguish in between sign board images as well as images that belong to some another class other than sign boards merely on grounds that provides the information which is provided by their primary visual features like the color and the shape but some extra temporal or contextual information should also be provided supplementing this information, since the information that is given by color and the shape of traffic signs as well as non-traffic signs proves to be inadequate [1-10]. Based on this hypothesis, it is observed that there are large numbers of images that does not fall in the class of sign boards which are classified from images falling in a particular class of sign boards although detected successfully from the original images which is found most frequently within a sign board image that tends to appear in somewhat cluttering fashion, as we normally observe in the case of a road scene [11-20]. It is generally observed that when there is lack of some supplementary information such as the structural and temporal information, there are large numbers of false positives (FPs) that are detected by the system especially when we observe the top scene, thus facilitating the process of detecting the traffic signs which is present in both the images in a rather successful manner [21-30]. The possible solution to this problem was provided by the use of primary visual features like the color and shape of traffic sign board images that are employed in the process of detection of a large number of text-based traffic sign board images. One should also take proper care that no True Positives (TPs) are ignored thus reflecting the importance of the process of over segmentation [31-40]. In order to eliminate unlikely candidates, an enormous amount of candidate regions which are detected with the help of structure of the scene and the temporal information that is conveyed by them were diminished to a greater extent [41-50]. One of the main objectives of an intelligent transportation system is to provide a safe and secure driving environment thereby ensuring the safety of the surrounding traffic. We can devise a new technique ensuring the safety of the surrounding traffic by implementing an on-board camera-based driver alert system which helps in recognizing sign board images such as stop signs and speed limit signs [1-10]. Traffic Sign board images convey important information regarding the present condition about the roadway as well as tend to provide other information for the purpose of navigation. They can be thought of as planar rigid objects which are having different colors and shapes. The primary visual characteristics of an image constitute the color, shape and pictogram which help us to provide relevant information which is embedded in it. The area of Intelligent Transportation Systems is gaining popularity nowadays and many car manufacturing companies are focusing their eyes on the area of Advanced Driver Assistance Systems since it contains a broad spectrum available for carrying out research and development especially in the domain of Traffic Sign Recognition [11-20]. In the year 2008, Mobil eye entered into a joint venture ship with Continental AG and three additional new updates were installed in the BMW 7 series that comprised of lane departure warning, speed limit information based on the method of detecting sign board images and intelligent headlight control. One of the major challenging tasks which is confronted by modern car manufacturing companies is to recognize the sign boards correctly particularly in an uncontrolled environment [21-30].

There are three steps in a typical traffic sign board image recognition system that mainly consists of detecting a particular traffic sign from other signs by using some detection method followed immediately by the process of elimination of noise from it with the help of some pre-processing techniques and finally recognizing that traffic sign by using some pattern recognition and machine learning approaches. We can augment the existing system with the help of tracking algorithm so that the speed of recognition can be increased, so that we can focus on a tiny region of the object which is detected for the purpose of recognition. In this research paper, more emphasis is laid on the process of recognizing traffic sign board images; we can leave the remaining three methods, viz., detection, rectification and tracking. One can find the research work done on the problem of recognizing traffic signs dating from the last century, and the proof of this work is found in an ancient survey which was lastly updated in May 1999, given in [31-40]. Since, there are plenty of techniques available in the field of recognizing traffic sign boards over a past few decades, we do not try to give a comprehensive literature survey, and instead concentrate on several background work most relevant to the present research. Due to the growth of different intelligent methods pertaining to driver assistance systems (DAS), it is trying to prove its superiority over the currently existing approaches which are present in Intelligent Transportation Systems. In the DAS, the task of detecting and recognizing traffic signs can be considered as one of the major approaches for acquiring information regarding a safe driving environment and we can also take precautionary measures in order to overcome the potential hazards faced by driver particularly while driving a vehicle along the road. The process of recognizing the sign board images, that too in a real environment, proves to be a herculean task if we want the technique to be done with greater accuracy and within a stipulated time, since the visibility of sign boards can be affected due to some undesirable factors to a larger extent. So far, many algorithms have been proposed for traffic sign recognition [41-50]. In [1-10], an entirely different approach of the currently prevailing AdaBoost algorithm is utilized in order to detect a

traffic sign by deployment of batteries of classifier algorithms that are given proper training to split the classes in an error correcting output code framework. A robust sign similarity measure which is built by using the SimBoost or a fuzzy regression tree framework, a technique which is used for recognizing traffic signs is proposed in [11-20]. We all are familiar with the Support Vector Machine (SVM) algorithm which happens to be a good classifier that is very popular in the domain of computer vision. In order to facilitate the process of detecting and recognizing road signs in an automatic fashion, an entirely different method is presented in [21-30] in which a SVM is used for traffic sign detection while a Gaussian kernel SVM is adopted for traffic sign recognition [31-40]. In order to classify an unknown traffic sign, an Eigen-based traffic sign recognition system was proposed in [41-50] taking the help of Principal Component Analysis (PCA algorithm) by selecting the most effective components of traffic sign board images. Boosted by the successful applications on handwritten digits recognition, convolutional neural network (CNN) has also been employed on traffic sign classification [1-10]. In [11-20], instead of various features, a CNN is trained directly with the raw pixel values of traffic sign images. Moreover, a better result is obtained by integrating the results obtained by a CNN and a multilayer perceptron (MLP). Gradient orientation is one kind of useful information in various object recognition methods, including the traffic signs. Traffic scene analysis is a very important topic in computer vision and intelligent systems [21-30]. The traffic signs are manufactured in such a fashion that they convey important information regarding the present condition and other information of the road. They are rigid and simple shapes with eye catching colors and the information they carry is easy to understand. However, accidents may still occur when drivers do not pay attention to a traffic sign in time [31-40]. So, in order to overcome these difficulties, there is an urgent need for implementing an automatic real time traffic sign recognition system which is capable of detecting and recognizing traffic sign board images. The above factors make the problem of detecting and recognizing traffic sign boards very complicated and still remains a daunting task for most of the research scholars [41-50].

1.2. Signs interpretation methods

There has been a lot of improvement in the field of detecting and recognizing the textual information which is present inside an image [1-10]. The different techniques which has led to an improvement in this area can be classified into two major types, one is the Region-Based Methods and another one is the Connected Component (CC) based methods [11-20]. The local features for example, texture are used by the region based methods for the purpose of locating the regions which contain the textual information in an image and the connected component-based methods are used for the purpose of segmentation of the characters that are present in the textual information within a particular traffic sign board image on an individual basis with the help of information like the intensity, color distribution and the edges of an image [21-30]. The Connected Component based methods normally comprises of three stages, the first stage is used for the purpose of detecting CCs which are present inside an image followed by a second stage in which the CCs that are not very similar are eliminated based on their features which is subsequently followed by a final stage in which grouping of the remaining CCs is performed into words or lines [31-40]. It was revealed that the amount of research work which targeted specifically on the task of detecting the textual information which is present inside a particular traffic sign board image is restricted to a narrow spectrum because of the difficulty in performing the given task. The methods that are currently available in the literature consist of two steps, the first step is the process of detecting a given sign board image and the second step is the process of recognizing a particular image [41-50]. The research work which is carried by founding the candidate regions by combining the characteristics that are obtained by combination of Shi characteristics as well as Tomasi characteristics, the prototypes that are obtained through the mixing of characteristics that are derived from Gaussian functions as well as that which are obtained by the process of analyzing a given image on the basis of its geometrical properties. It was postulated on the basis of the textual information which is present inside a given sign board image that is visible if we take some plane surface that is oriented in the upward direction thereby giving due regards towards the movement as well as the axis of the camera that exhibits the photonic characteristics and properties. If we consider the real world, it may be possible that the sign boards which contain the textual information within it may tend to appear if one looks it from its own perspective to be somewhat in synchronism with the original image of the sign board [1-10]. So, there is an urgent need for incorporating a perspective transform which gives the OCR a better possibility of performing the task of recognizing the textual information that is contained inside a sign board image. The process of matching of the candidate regions with the help of consecutive frames was done and the process of interpretation was then performed with the help of an OCR system when their size was considered to be adequate. The detection rate was found to be 88.9% and the false detection rate was found to be 9.2%, which was based on database containing 22 video sequences with video sequence having a length of 30 seconds duration. The work which was done by [11-20] comprised of segmentation of the areas that are present inside an image and the extraction of these regions seem to attract the research scholar for the purpose of carrying out his own research which is propounded on the grounds of the information that is conveyed by the primary visual characteristics of an image thereby taking help of some limiting criterion that is applied to channels that contain the chromaticity as well as the luminosity components if we consider the most popular technique which is deployed for the purpose of segmentation of sign board images [21-30]. If we compare the tracing of outer boundaries that are present inside every single blob with the help of Fourier transformation by adopting an approach that increases the speed

of computation of the process thereby reducing the duration that is required for every single computation with those obtained by adopting the same method from an arbitrary uniform plane lamina which can be considered as an example for the purpose of implementing our technique was being employed in order to find the rectangular regions [31-40]. The quadruple corners which can be thought of as an area that resembles a rectangle were being searched by deploying the process by taking peaks of the area that is traced from an entire image with the help of transformation of complete image using Fourier method thereby increasing the speed for carrying out the process of computation thus reducing the duration required for every single computation and by taking help of aforementioned corners, thereby carrying out the task of rotation of corresponding areas that are chosen for the purpose of extraction from complete image trying for the process of alignment of the textual information consisting of mainly the characters that is present inside a given sign board image particularly in upward direction. If we consider the point of view of a vehicle, it is revealed that the above method is not sufficient if we try to consider the process of recovering above area that is present on the chassis of the vehicle if the point of view of the observer is taken for the process of consideration which consists of textual information inside a sign board image and the perspective correction which is given in [41-50] tries to provide a more robust solution to this problem. There was a lack of output that represents the content which is illustrated in a more sophisticated fashion thereby giving the amount of content which is extracted from a given sign board image which is contributed through the research work that is illustrated in the existing literature. If we consider some existing techniques that are given by [1-10], we will come to know that they exhibit some peculiar characteristics that mainly focuses on taking help from MSERs that mainly exerts a thrust on detecting both the images that represent the significant information related to existing road conditions as well as if we consider some characters that are present in the textual information which is contained within a given sign board image. If we try to combine the processes of segregating the original image as well as the characters that are present in an image if we try to see the image particularly in sunlight thereby constituting a container, we come to know of the interesting fact that the areas which are present on the chassis of a vehicle having a whitish as well as bluish appearance are subjected to the process of detecting each of the components that are present inside a given video sequence [11-20]. By taking help from both the mechanical systems that tend to classify the basis functions thereby supporting the conventional technique which can be deployed for the process of classifying a given image as well as the classification method that is presented by some research scholars, these regions were then again subjected to the process of classification. More emphasis was placed on the geo-localization of sign board images with the help of information which is supplied by a Global Positioning System, and the technique was then applied to single images, without the use of temporal information [21-30]. If we try to make an approximation about size of our complete world, we will come to know that height of textual content which is present inside an image was used along with the spacing in between our camera and images that carry some message about the prevalent road conditions. The rates that are required for the processes of detecting, recognizing as well as classifying the words, numerical characters as well as symbolic information that is represented by the alphabets present on a particular sign board image that are taken from shorter, longer as well as medium distances in between the observer and the sign board images were being given by the existing authors. If we consider the ranges for the process of detecting and recognizing the traffic sign board images, it was found that the range for detecting the sign boards was lying in between 13.09% and 90.18%, while the range for the process of recognizing the sign boards was found lying in between 8.51% and 87.50%. Our proposed method overcomes the numerous limitations which are faced by the method that were proposed by [31-40] in which postulates were propounded for the method of detecting traffic sign board images that comprised of textual information within it and are sufficient for providing a high recall rate. The additional FPs was eliminated by making use of structural and temporal information that is conveyed by a particular image by our technique which is being propounded in the above section. One can find the output of system which we derived in the course of performing experiments that get highlighted from our research work are sufficient enough for giving a proof to the proposed method which is described in the section above. The research work which was done by [41-50] used a rough OCR technique in detecting and recognizing the textual information contained in the sign boards was superceded by our proposed method that uses the concept of recovering original information contained in sign board images comprising point of view from an observer as well as techniques that involve the usage of merging two portions of any kind of objects that is present along lateral portions of an object. One may find manuscripts from earlier and past research works which reflect our propounded system performing with better outcomes alone is sufficient enough for giving a proof to our proposed method which is given the section above. If we consider the research work which was done [1-10] takes the help of temporal information used for detecting symbol-based traffic sign board images which is further contributed by the research work that is described in this review paper by embedding the structural information that is present in the scene. We can find a huge amount of research work that focuses on the problem of detecting the textual information which is present in sign board images by taking help from a mobile sensor and mainly depends on the devices that can be worn by the driver, for example, the techniques that are mentioned in [11-20] and the methods which are mainly applicable to mobile robotics can be found in the research work that is presented by [21-30]. We can find a number

of databases which are used for the purpose of validation of systems used for detecting and recognizing the sign board images which includes the famous dataset which is included in the research work that is done by [31-40] as well as the database that is included in the research work which is done by [41-50]. The above databases find no use in order to validate our proposed method which is entirely based upon detecting and recognizing the sign boards containing textual information within them and are more concentrated upon the process of detecting the symbol-based sign boards. A camera with knowledge of all the parameters used in the process of calibration was used for extracting the data [1-10]. One may consider the process of recognizing a particular sign board image amongst all other members, a Herculean task when it comes to recognizing sign board image from a group of other sign boards. It is found that a variety of techniques are available in the arena of classifying known sign board images ranging from ordinary methods like the matching of templates to sophisticated machine learning techniques. One of the very significant and most important algorithms which are employed to perform the task of classifying multiple sign board images can be attributed to well-known Support Vector Machine (SVM) algorithm. If the transcripts authored by [11-20] are considered, one can find the significance attached to automatically detecting and recognizing sign board images taking help of Support Vector Machines (SVMs) in combination with Gaussian kernels. However, the system was required to classify candidate blobs into a shape class before recognition. As a sequence, only the pixels that were part of the sign were used to construct the feature vector. In [21-30] different methods other than those which are currently available in the context of detecting and recognizing sign boards in an automatic fashion were brought to the notice of people. It can be very well understood from this study that a comparatively greater emphasis was laid in enhancing the accuracy of existing methodologies prevalent in detecting and recognizing sign boards in an automatic fashion thereby resulting in the reduction of number of support vectors which are required in due course of the complete process leading to a sudden fall in the necessity of memory and time for testing new samples [31-40]. An SVM segmentation approach for traffic sign recognition was given in [41-50] while in [1-10], an effective strategy helping in the process of recognizing slanted speed limit signs by extracting the rotation invariant features with the help of Fourier based wavelet descriptor was introduced. The different categories of sign board images were classified with the help of Support Vector Machines (SVMs) consisting of binary tree architecture. In [11-20], a shape-based classification was developed using an SVM. In order to represent the features, two types of features including a binary image and Zernike moments were used. The main objective behind carrying out this research work was recognizing seven categories of traffic sign shapes as well as five categories of speed limit signs. In addition to SVMs, AdaBoost is also a popular classification approach. A color insensitive Haar wavelets feature combined with the AdaBoost algorithm was introduced in to develop a country-independent recognition module [21-30]. By using the concept of a class similarity measure that is learnt from image pairs, realization was achieved with the help of a new newer version of the existing AdaBoost algorithm which is known as SimBoost algorithm [31-40]. The solution to the problem of classification between multiple classes can be obtained if we compare the similarities between an unknown example and prototype from each class, subjected to the condition that an estimate of the similarities between any two images is made available. The stop and give way signs in different and complex surroundings were successfully classified by taking help from an array of weak classifiers in a reliable fashion. [41-50] took the help of classifiers which are trained to refine the type of traffic sign like neural networks and AdaBoost classifiers was also being taken. With the help of AdaBoost feature selection procedure, suitable features were chosen from a very large pool of features consisting of Haar, moment, symmetry, frequency and other features. The results which were obtained from the various classifier algorithms were combined over time and merging of the signs that are quite similar on both the sides of the roadway was accomplished taking help of fusion module that incorporated combining a Bayesian network and a decision tree [1-10]. An Error Correcting Output Codes (ECOC) which takes help from a forest of optimal tree structures that are embedded in the ECOC matrix were also being formulated along with the existing methods. An entirely different approach that is suitable for classifying sign boards belonging to different classes by using the ECOC technique was introduced [11-20]. The ensemble of binary classifiers that were given training on categories of sign board images, having two partitions was taken and the ECOC was being implemented with the help of above scheme [21-30]. The decomposition of the original problem into a set of complementary problem having two classes that are encoded in ECOC matrix which tend to share the classifiers across the original classes was performed. In [31-40], a comparison was performed considering the class specific sets of discriminative local regions in between a discrete color image of the viewed sign with other images. By using the principal of one versus all dissimilarity maximization, they were learnt in offline mode from the standard templates of sign board images [41-50]. The comparison in between the robust discrete color image was initiated by using a color distance transform which served as a basis for defining this dissimilarity. It becomes a challenging task when it comes to the method of comparison of the actual performance since there is no such kind of ideal database or procedure for performance evaluation of several machine learning approaches that try to find a solution to the problem of recognizing traffic signs, even though they are present in the literature part [1-10]. There has been a rapid growth in research and development sector especially in the area of detecting and recognizing traffic sign board images over the last few decades.

Several novel ideas and effective methods have been proposed [11-20]. Usually, the detection part hunts [21-30] potential regions of traffic signs whereas the category to which a traffic sign belongs is determined by the recognition part [31-40]. The traditional methods which are used for the purpose of detecting sign boards can be grouped into three main classes, viz., color-based methods, shape-based methods and the sliding window-based methods [41-50].

1.3. Definitions of various Performance Metrics used for Image Quality Evaluation

The various performance metrics such as the Mean Squared Error (MSE), Peak Signal to Noise Ratio (PSNR) as well as the Structural Similarity for measuring the Image Quality (SSIM) which are used for evaluating the quality of a given traffic sign board image are defined as follows:

1.3.1. Mean Squared Error (MSE)

The Mean Squared Error (MSE) or the Mean Squared Deviation (MSD) of an estimator or of a procedure for estimating an unobserved quantity is defined as the average of the squares of the errors that is the average squared difference in between the estimated values and what is estimated. The mathematical equation which governs the Mean Squared Error (MSE) is given as below:

$$\text{Mean Squared Error (MSE)} = \frac{1}{n}\sum \qquad I = n + 1^{n+q}\,(Y_i - Y_i') \quad (1)$$

where n is the total number of predictions generated from a sample of n data points on all the variables, Y is the vector of observed values of the variable being predicted.

where M × N represents the size of an image.

1.3.2. Peak Signal to Noise Ratio (PSNR):

The Peak Signal to Noise Ratio (PSNR) is defined as the ratio in between the maximum possible power of a given signal and the power of corrupting noise that affects the fidelity of its representation. The mathematical equation which governs the Peak Signal to Noise Ratio (PSNR) is given as below:

$$\text{Peak Signal to Noise Ratio (PSNR)} = 20\log_{10}(MAX_I) - 10\log_{10}(\text{MSE}) \quad (2)$$

where MAX_I is the maximum possible pixel value of the image and MSE is the Mean Squared Error, I is the m × n noise free monochrome image and its noisy approximation is denoted by K.

1.3.3. Structural Similarity for measuring the Image Quality (SSIM)

The Structural Similarity for measuring the Image Quality (SSIM) is defined as the technique which is used for measuring the similarity in between two images and it is also employed to predict the perceived quality of digital television and cinematic pictures as well as other kinds of digital images and videos. The mathematical equation which governs the Structural Similarity for measuring Image Quality (SSIM) is given as below:

$$\text{Structural Similarity for measuring Image Quality (SSIM)} = (2\mu_x\mu_y + c_1)(2\sigma xy + c_2)/(\mu_x^2 + \mu_y^2 + c_1)(\sigma_x^2 + \sigma_y^2 + c_2) \quad (3)$$

where

μ_x is the average of x
μ_y is the average of y
σ_x^2 is the variance of x
σ_y^2 is the variance of y
σ_{xy} is the covariance of x and y

c_1 and c_2 are the two variables to stabilize the division with weak denominator.

2. Software Tool used

The MATLAB R2019a software is utilized in the synthesis of various roadway symbols from input test dataset during the course of performing experimental procedure.

3. Experimental Results and Discussion

A set of various roadway symbol images belonging to numerous categories is taken into consideration which comprising a total number of 679 roadway symbols constituting training dataset belonging to 18 different classes of roadway symbols and there are a total number of 48 roadway symbols incorporating testing dataset.

The training dataset comprises of symbols containing some printed details embedded on their outer surface and symbols that do not have any kind of printed details embedded on their outer surface. This manuscript depicts the numerous roadway symbols incorporated in dataset used for implementing this research project.

Some examples of traffic sign board images comprising of various colors and shapes which are present in the training image database as well as testing image database are depicted in the section of this manuscript (Figure 1 and Figure 2) shown as below:

Figure 1 Examples of various roadway symbols from the Training image database

A short summary of numerous methods incorporated during the course of investigation is given in section 3.1.

Figure 2 Examples of various roadway symbols from the Testing image database

3.1. Anisotropic Diffusion Filtering Type 1

The technique of Anisotropic Diffusion Filtering which is also popular by another name Perona Malik Diffusion is primarily used to reduce the unwanted disturbance present in roadway symbols. The technique of Anisotropic Diffusion Filtering Type 1 can be represented with the help of a mathematical equation which is given as follows:

$$c\,(\|\otimes I\|) = 1/1 + (\|\otimes\ I\|/K)^2 \qquad (4)$$

where the constant K controls the sensitivity to edges and is usually chosen experimentally or as a function of the noise in the image, □ denotes the Laplacian operator and it also denotes the gradient and c (x, y, t) is the diffusion coefficient and it controls the rate of diffusion and is usually chosen as a function of the image gradient so as to preserve the edges in the image, I (:, t) : Ω → R be a family of gray scale images.

The results which are obtained after carrying out the process of Anisotropic Diffusion Filtering Type 1 of the roadway symbols comprising input testing image database (Figure 3) are depicted as below:

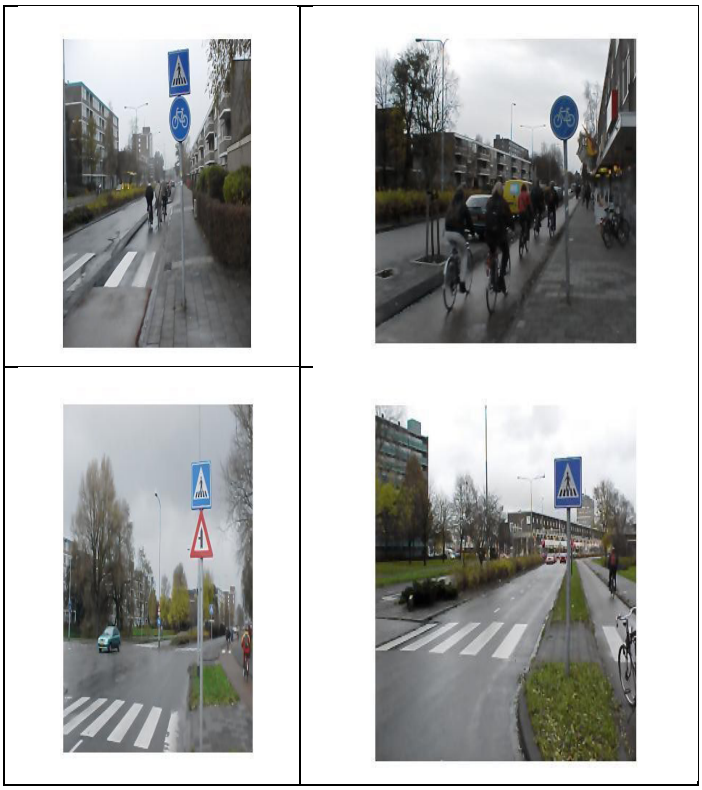

Figure 3 Testing image database Anisotropic Diffusion Filtering Type 1 Results

The results which are obtained after carrying out the process of Anisotropic Diffusion Filtering Type 1 of the roadway symbols comprising input training image database (Figure 4) are depicted as below:

Figure 4 Training image database Anisotropic Diffusion Filtering Type 1 Results

3.2. Non-Local Means Type 2

In this technique of Non-Local Means Filtering, a given color image is converted into the L*a*b color space thereby facilitating the Non-Local Means Filter to smooth the colors which are having similarity in visual perception. For the purpose of computing the numerical value of standard deviation and the Euclidean distance from the origin (e_{dist}), a homogenous L*a*b patch from the image is being extracted so that the standard deviation of e_{dist} is calculated in order to estimate the amount of noise contained in it. The mathematical equation which governs the process of Non-Local Means Type 2 is given as follows:

$$u(p) = 1/C(p) \int_{\Omega} v(q) f(p, q) dq \quad (5)$$

where u (p) is the filtered value of the image at the point p, v (q) is the unfiltered value of the image at the point q, f (p, q) is the weighting function and the integral is evaluated over $\forall q \in \Omega$ and the normalizing factor C (p) is given by the formula which is given as follows:

$$C(p) = \int_{\Omega} f(p, q) dq \quad (6)$$

The results which are obtained after carrying out the process of Non-Local Means Type 2 of the roadway symbols comprising input testing image database (Figure 5) are depicted as below:

Figure 5 Testing image database Non-Local Means Type 2 Results

The results which are obtained after carrying out the process of Non-Local Means Type 2 of the roadway symbols comprising input training image database (Figure 6) are depicted as below:

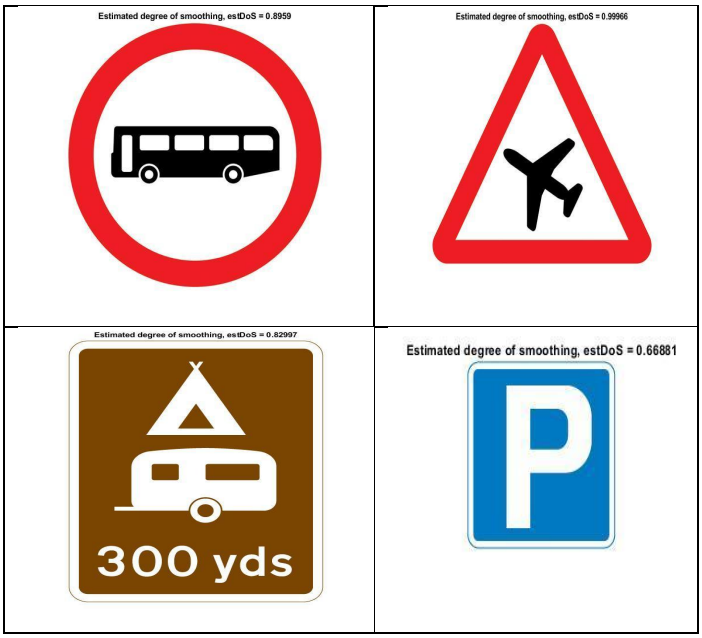

Figure 6 Training image database Non-Local Means Type 2 Results

3.3. Image Denoising using Deep Neural Network (DNN)

In this technique of denoising a given gray scale image by using a Deep Neural Network (DNN), the pretrained denoising convolutional neural network named as 'DnCNN' is being retrieved and the amount of noise which is present in the noisy version of the original gray scale image is subjected to the process of removal.

The results which are obtained after carrying out the process of Image Denoising using Deep Neural Network (DNN) of the roadway symbols comprising input testing image database (Figure 7) are depicted as below:

Figure 7 Testing image database Image Denoising using Deep Neural Network (DNN)

The results which are obtained after carrying out the process of Image Denoising using Deep Neural Network (DNN) of the roadway symbols comprising input training image database (Figure 8) are depicted as below:

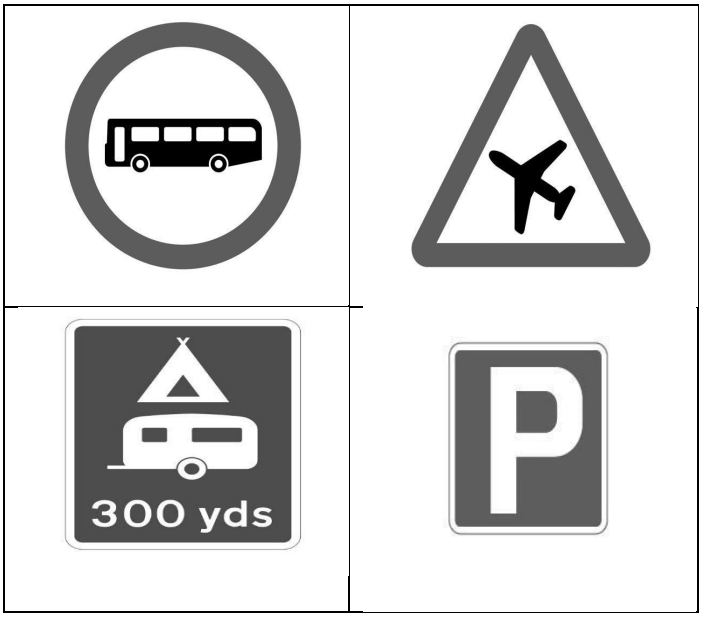

Figure 8 Training image database Image Denoising using Deep Neural Network (DNN) Results

The comparative analysis of various image denoising techniques based on various image quality metrics like Mean Squared Error (MSE), Peak Signal to Noise Ratio (PSNR) and the Structural Similarity for measuring the image quality (SSIM) from the past 2-3 years comprising input testing image database is given in the tabulated fashion which is shown (Table 1) as below:

Table 1: Comparative Analysis of Image Denoising Techniques based on various Image Quality Metrics like Mean Squared Error (MSE), Peak Signal to Noise Ratio (PSNR) and Structural Similarity for measuring the Image Quality (SSIM) for Testing image database from the past 2-3 years

3.4. Arithmetic Mean Filter

The Arithmetic Mean can be defined as being equal to the sum of the numerical values of each and every observation divided by the total number of observations. The arithmetic means of a given set of numbers each one is having a numerical value a_1, a_2, a_3, ……..., a_n can be calculated by using the formula which is given as below:

$$\text{Arithmetic Mean (A.M.)} = a_1 + a_2 + a_3 + \ldots\ldots\ldots + a_n/n \quad (7)$$

where a_1, a_2, a_3,……., a_n are n number of physical quantities, n is the total number of physical quantities and A.M. is the Arithmetic Mean of the n number of physical quantities which are taken into consideration.

The results which are obtained after carrying out experiments with the help of an Arithmetic Mean Filter (Figure 9) are presented as below:

Figure 9 Testing image database Arithmetic Mean Filtering Results

3.5. Circular Averaging Filter (Pillbox)

The technique of removing salt and pepper noise from an image can be accomplished with the help of smoothing filter which also helps in removing the sharp edges thereby refining the small contours as well as ridges from it. It is useful in removing minute information before the operation of extracting an object having greater size from the image resulting in the amalgamation of tiny regions in between the two portions that are present in lines or curves, thereby telling its significance about the reason for including in the pre-processing step. The results that are obtained after applying Averaging Filter to the roadway symbols that are present in our image dataset are presented in the below section of this manuscript (Figure 10) as follows:

Figure 10 Testing image database Circular Averaging Filter (Pillbox) Results

3.6. Harmonic Mean Filter

A Harmonic Mean Filter can be defined as the reciprocal of the arithmetic mean of the reciprocals of a given set of observations. The Harmonic Mean can be calculated by using the mathematical expression which is given as below:

$$\text{Harmonic Mean (H.M.)} = \frac{1}{x_1} + \frac{1}{x_2} + \frac{1}{x_3} + \ldots\ldots\ldots + \frac{1}{x_n} \quad (8)$$

The results which are obtained after carrying out experiments with the help of a Harmonic Mean Filter (Figure 11) are presented as below:

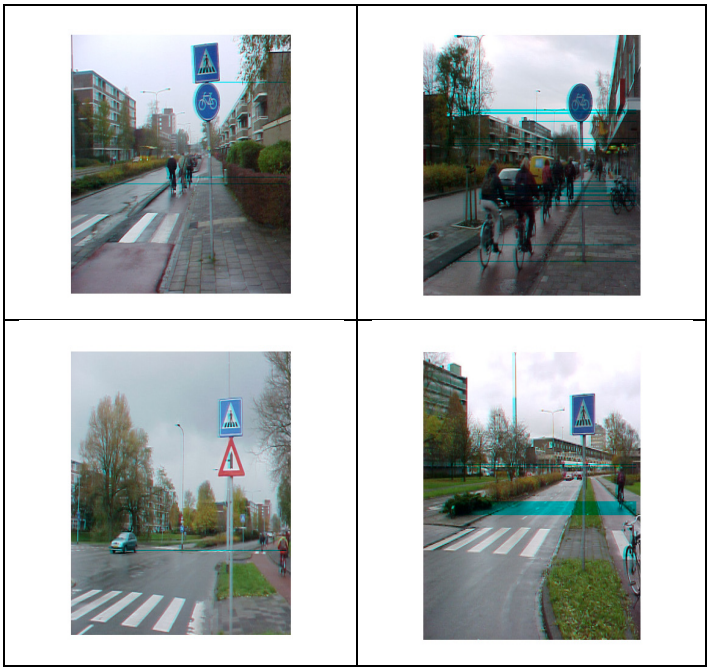

Figure 11 Testing image database Harmonic Filter Results

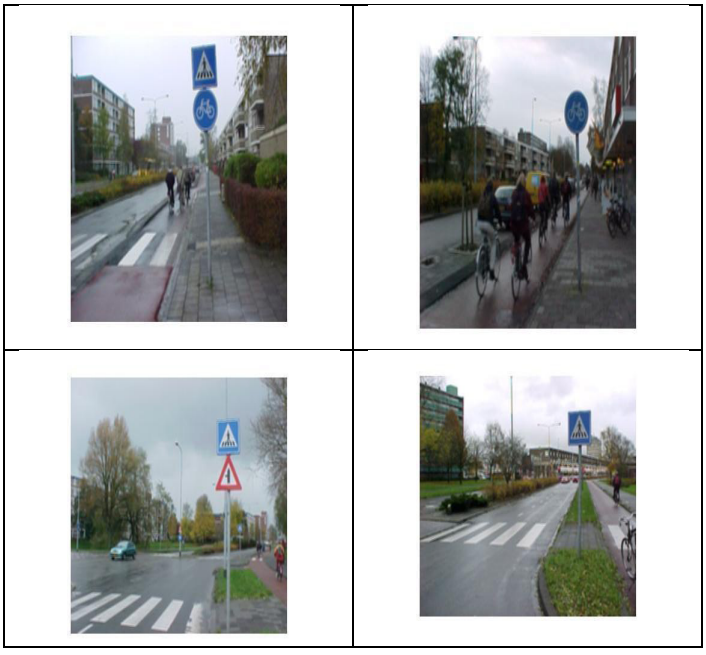

Figure 12 Testing image database Box Filter Results

3.7. Box Filter

The Box Blur or sometimes called as Box Linear filter can be defined as a spatial domain linear filter in which each pixel in the resulting image possess a value which is equal to the average value of its neighboring pixels present in the original input image. It is a type of low pass or a blurring filter.

The results obtained after carrying out experiments with the help of a Box Filter are presented in Figure 12.

3.8. Gaussian Filter

The Gaussian function is defined as follows:

$$g(x, y) = 1/2\pi\sigma^2 e^{-(x2 + y2)/2\sigma2} \quad (9)$$

where a, b and c are the arbitrary constants, x is the distance from the origin in the horizontal axis, y is the distance from the origin in the vertical axis and σ is the standard deviation of the Gaussian distribution. The Gaussian function is derived from the name of a well-known scientist named Carl Friedrich Gauss. The results which are obtained after carrying out experiments with the help of a Gaussian Filter (Figure 13) are presented as below:

Figure 13 Testing image database Gaussian Filter Results

The comparative analysis of various image denoising techniques based on various image quality metrics like Mean Squared Error (MSE), Peak Signal to Noise Ratio (PSNR) and the Structural Similarity for measuring the Image Quality (SSIM) comprising the input testing image database is given in a tabulated fashion which is shown (Table 3) as below:

Table 3 Comparative Analysis of various Image Denoising Techniques based on various Image Quality Metrics like Mean Squared Error (MSE), Peak Signal to Noise Ratio (PSNR) and Structural Similarity for measuring the Image Quality (SSIM) for Testing image database from the research paper presented in IEEE ESTCON-ICIAS-2018 International Conference held at UTP, Malaysia from 13th-15th August 2018

4. Novelty of the Proposed Research Work

The main objective of our proposed research work is to identify the best technique which helps in removing the noise which is naturally present in an image among various noise removal techniques based on different image quality metrics like Mean Squared Error (MSE), Peak Signal to Noise Ratio (PSNR) and the Structural Similarity for measuring Image Quality (SSIM).

The best technique is identified from its counterparts by assuming that it is having the least numerical value of Mean Squared Error (MSE) as well as it is also having the greatest numerical value of Peak Signal to Noise Ratio (PSNR) and Structural Similarity for measuring Image Quality (SSIM).

The Non-Local Means Type 2 and the Image Denoising using Deep Neural Network (DNN) techniques were combined and applied to the input traffic sign board images which are present in the testing image database and the results so obtained are shown in (Figure 14) as below:

After the process of calculating the numerical values of Mean Squared Error (MSE), Peak Signal to Noise Ratio (PSNR) and the Structural Similarity for measuring the Image Quality (SSIM) was completed, it was observed that the Mean Squared Error (MSE) value was found out to be 113.83027446809 and the Peak Signal to Noise Ratio (PSNR) and the Structural Similarity for measuring the Image Quality (SSIM) values were found out to be 31.578017021277 and 0.90815744680851 respectively.

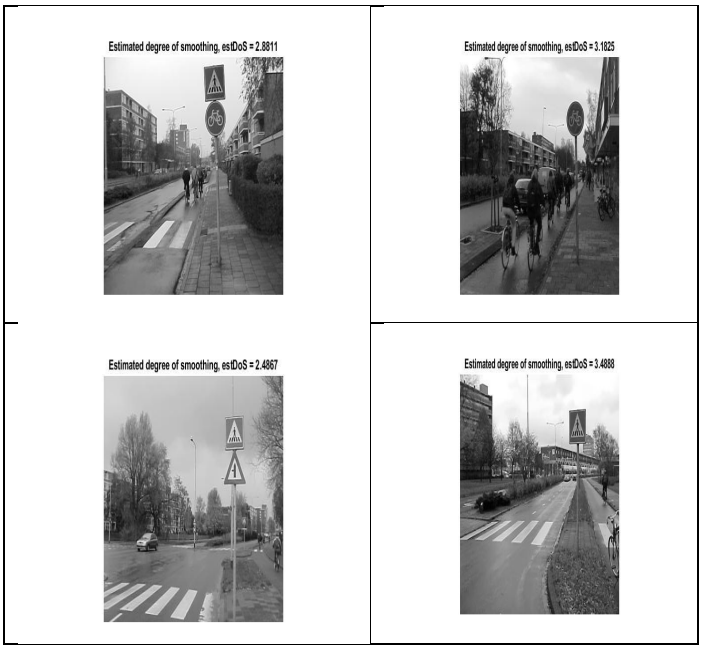

Figure 14 Testing image database Results obtained by combining the Non-Local Means Type 2 + Image Denoising using Deep Neural Network (DNN) Techniques

The technique of Anisotropic Diffusion Filtering Type 1 was combined with Non-Local Means Type 2 technique and applied to the input traffic sign board images which are present in the testing image database and the results so obtained are shown in (Figure 15) as below:

After the process of calculating the numerical values of Mean Squared Error (MSE), Peak Signal to Noise Ratio (PSNR) and the Structural Similarity for measuring the Image Quality (SSIM) was completed, it was observed that the Mean Squared Error (MSE) value was found out to be 1.5655462333826 and the Peak Signal to Noise Ratio (PSNR) and the Structural Similarity for measuring the Image Quality (SSIM) values were found out to be 47.416585376662 and 0.99865745937961 respectively.

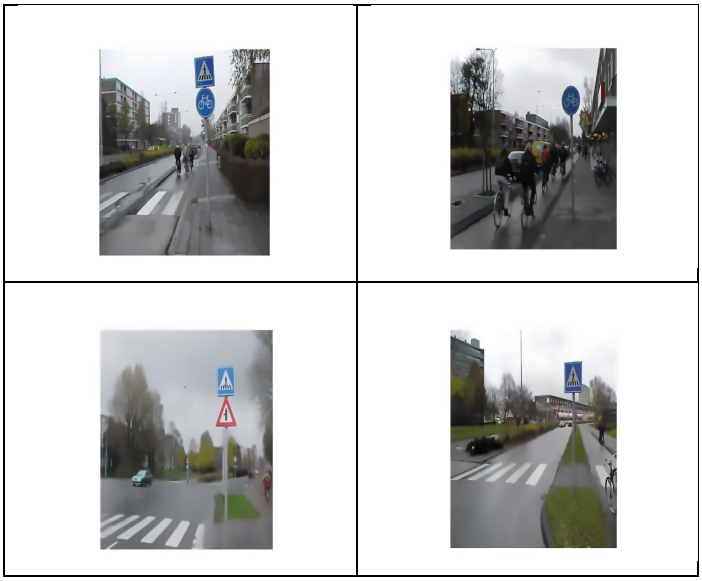

Figure 15 Testing image database Results obtained by combining the Anisotropic Diffusion Filtering Type 1 + Non-Local Means Type 2 Techniques

The techniques of Non-Local Means Type 2 and Anisotropic Diffusion Filtering Type 1 were combined and applied to the input traffic sign board images which are present in the training image database and the results were obtained after the execution of this experimental procedure which are shown in the figure that is given (Figure 16) as below and the numerical values of the Mean Squared Error (MSE), Peak Signal to Noise Ratio (PSNR) and the Structural Similarity for measuring the Image Quality (SSIM) were found out to be 255.94895760709, 24.440101624815 and 0.95028419497784 respectively.

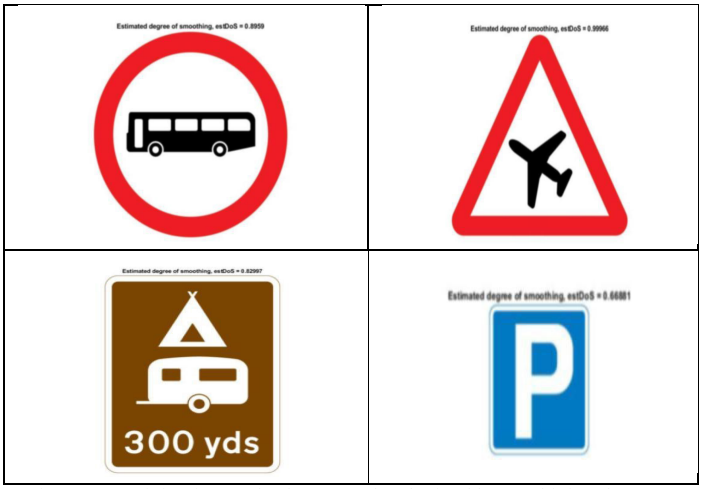

Figure 16 Training image database Results obtained by combining the Non-Local Means Type 2 + Anisotropic Diffusion Filtering Type 1 Techniques

The Non-Local Means Type 2, Anisotropic Diffusion Filtering Type 1 and Non-Local Means Type 2 techniques were combined and applied to the input traffic sign board images which are present in the training image database and the results which are obtained after the execution of the experimental procedure are shown in the figure which is given (Figure 17) as below and the numerical values of the Mean Squared Error (MSE), Peak Signal to Noise Ratio (PSNR) and Structural Similarity for measuring the Image Quality (SSIM) were found out to be 76.349860118168, 31.671063072378 and 0.97056218611521 respectively.

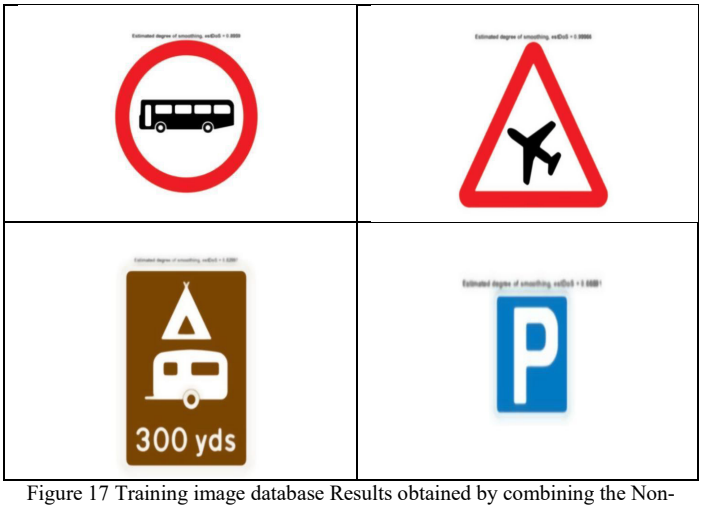

Figure 17 Training image database Results obtained by combining the Non-Local Means Type 2 + Anisotropic Diffusion Filtering Type 1 + Non-Local Means Type 2 Techniques

The techniques of Non-Local Means Type 2, Anisotropic Diffusion Filtering Type 1, Non-Local Means Type 2 and Image Denoising using Deep Neural Network (DNN) were combined and applied to the input traffic sign board images which are present in the training image database and the results which are obtained after carrying out the experimental procedure are shown in the figure which is given (Figure 18) as below and the numerical values of the Mean Squared Error (MSE), Peak Signal to Noise Ratio (PSNR) and Structural Similarity for measuring the Image Quality (SSIM) were found out to be 0.022547858197932, 66.103574150665 and 0.99989054652881 respectively.

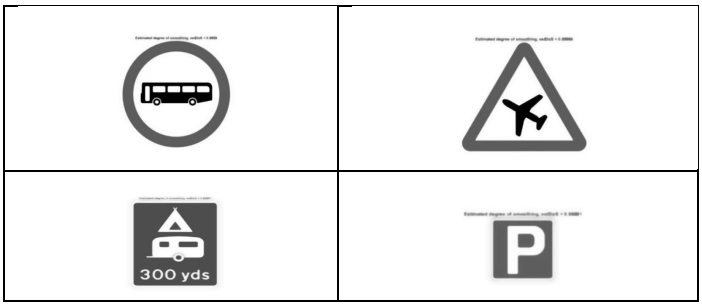

Figure 18 Training image database Results obtained by combining the Non-Local Means Type 2 + Anisotropic Diffusion Filtering Type 1 + Non-Local Means Type 2 + Image Denoising using Deep Neural Network (DNN) Techniques

The comparison of these image quality parameter numerical values for different combinations of Anisotropic Diffusion Filtering Type 1, Non-Local Means Type 2 and the Image Denoising using Deep Neural Network (DNN) techniques which are employed for removal of noise present in the testing image database is given in the tabulated fashion shown (Table 4) as below:

The comparison of these image quality parameter numerical values for different combinations of Anisotropic Diffusion Filtering Type 1, Non-Local Means Type 2 and the Image Denoising using Deep Neural Network (DNN) techniques which are employed for removal of noise present in the training image database is given in the tabulated fashion shown in Table 5:

Table 4 Comparative Analysis of various combinations of Image Denoising Techniques based on various Image Quality Metrics like Mean Squared Error (MSE), Peak Signal to Noise Ratio (PSNR) and Structural Similarity for measuring the Image Quality (SSIM) for Testing image database

S. No.	Year	Techniques used	Mean Squared Error (MSE) Values	Peak Signal to Noise Ratio (PSNR) Values	Structural Similarity for measuring Image Quality (SSIM) Values
1.	2018	Anisotropic Diffusion Filtering Type 1	40.282	32.121	0.892

Table 5 Comparative Analysis of various combinations of Image Denoising Techniques based on various Image Quality Metrics like Mean Squared Error (MSE), Peak Signal to Noise Ratio (PSNR) and Structural Similarity for measuring the Image Quality (SSIM) for Training image database

S. No.	Year	Techniques used	Mean Squared Error (MSE) Values	Peak Signal to Noise Ratio (PSNR) Values	Structural Similarity for measuring Image Quality (SSIM) Values
1.	2018	Anisotropic Diffusion Filtering Type 1	110.887	27.897	0.877
2.	2018	Non-Local Means Type 2	0.080	61.175	0.999
3.	2017	Image Denoising using Deep Neural Network (DNN)	0.970	51.267	0.998
4.	2018 + 2017	Non-Local Means Type 2 + Image Denoising using Deep Neural Network (DNN)	1.565	47.416	0.998
5.	2018 + 2018	Non-Local Means Type 2 + Anisotropic Diffusion Filtering Type 1	255.948	24.440	0.950
6.	2018 + 2018 + 2018	Non-Local Means Type 2 + Anisotropic Diffusion Filtering Type 1 + Non-Local Means Type 2	76.349	31.671	0.970
7.	**2018 + 2018 + 2018 + 2017**	**Non-Local Means Type 2 + Anisotropic Diffusion Filtering Type 1 + Non-Local Means Type 2 + Image Denoising using Deep Neural Network (DNN)**	**0.022**	**66.103**	**0.999**

If the testing image database is considered, it is observed that if the techniques of Anisotropic Diffusion Filtering Type 1, Non-Local Means Type 2 and Image Denoising using Deep Neural Network (DNN) are combined, the numerical values of different image quality metrics like the Mean Squared Error (MSE), Peak Signal to Noise Ratio (PSNR) and the Structural Similarity for measuring the Image Quality (SSIM) were found out to be 0.13772127659574, 61.466536170213 and 0.99981489361702 respectively. Therefore, it is clear that the above technique which is mentioned in this research paper proves to be the best technique which can be used for the purpose of noise removal from input traffic sign board images present in the testing image database since the numerical values of Mean Squared Error (MSE) is the least as compared with its other counterparts and the numerical values of the Peak Signal to Noise Ratio (PSNR) as well as the Structural Similarity for measuring the Image Quality (SSIM) are the greatest as compared with its other counterparts.

If the training image database is considered, it is observed that if the techniques of Non-Local Means Type 2, Anisotropic Diffusion Filtering Type 1, Non-Local Means Type 2 and Image Denoising using Deep Neural Network (DNN) are combined, the numerical values of different image quality metrics like the Mean Squared Error (MSE), Peak Signal to Noise Ratio (PSNR) and the Structural Similarity for measuring the Image Quality (SSIM) were found out to be 0.022547858197932, 66.103574150665 and 0.99989054652881 respectively. Therefore, it is clear that the above technique which is mentioned in this research paper proves to be the best technique which can be used for the purpose of noise removal from input traffic sign board images present in the training image database since the numerical values of different image quality metrics like the Mean Squared Error (MSE) is the least as compared with its other counterparts and the numerical values of the Peak Signal to Noise Ratio (PSNR) as well as the Structural Similarity for measuring the Image Quality (SSIM) are the greatest as compared with its other counterparts.

Conclusion and Future Scope

In this paper, a comparison of various image denoising techniques was done in order to choose the best technique among a set of three different techniques and their three different combinations which was being applied to the traffic sign board images present in the testing image database and four different techniques and their seven different combinations to the traffic sign board images present in the training image database based on calculating different parameters which decide the quality of input roadway symbols like Mean Squared Error (MSE), Peak Signal to Noise Ratio (PSNR) as well as Structural Similarity for measuring Image Quality (SSIM) and after a thorough comparison, it was concluded that the combination of Anisotropic Diffusion Filtering Type 1, Non-Local Means Type 2 and Image Denoising using Deep Neural Network (DNN) techniques which was being applied to the traffic sign board images present in the testing image database and the combination of Non-Local Means Type 2, Anisotropic Diffusion Filtering Type 1, Non-Local Means Type 2 and Image Denoising using Deep Neural Network (DNN) techniques which was being applied to the images which are present in the training image database has the maximum Peak Signal to Noise Ratio (PSNR) as well as Structural Similarity for measuring Image Quality (SSIM) values and a minimum Mean Squared Error (MSE) value as compared to other techniques. These techniques will be applied to the traffic sign board images which are present in both the testing as well as training image databases in future research work for the purpose of noise removal from input traffic sign board images.

Conflict of Interest

The authors mention and acknowledge the funding sources which were provided during the course of performing the research work and there are no significant conflicts of interest.

Acknowledgments

A sincere vote of thanksgiving must be extended to Vellore Institute of Technology, Vellore administration and every one among the stakeholders whose contribution towards the completion of this work in a successful fashion paved the way for implementing it on a broad level.

Hardware Support

ABSTRACT

Spatial and temporal isolation is a crucial issue in embedded systems executing multiple tasks with several levels of criticality. This is considerably significant in the context of multi-processor (or multi-core) embedded systems running multiple mixed-criticality applications in parallel. This work deals with the issue of isolation of different application classes on Network on Chip (NoC) architectures and proposes a lightweight hardware mechanism able to support mixed-criticality requirements and specifically designed to be introduced into existing network interfaces. This mechanism supports the execution of different and contemporary applications with several criticality levels by supervising the messages exchange among network nodes, with the introduction of limited hardware and software overhead on the monitored network. The proposed solution is described and evaluated by means of logical simulations and an implementation on reconfigurable logic, using a reference NoC architecture with mesh topology. Scalability of the proposed approach is also discussed and evaluated by means of network simulations. Results show an area occupation less than 1% in a 3x3 mesh NoC, and a good scalability of the proposed mechanism in an 8x8 mesh network, indicating it as a valid lightweight solution able to enforce isolation in NoCs.

1. Introduction

It is possible to define the criticality of the generic component of a system as the level of assurance needed for that element [1]. Embedded system is a clear example of mixed-criticality system if different software elements executing on the same hardware platform possess two or more levels of criticality. The fundamental problems in mixed-criticality system management are (i) the simultaneous satisfaction of discordant requirements regarding advantageous access to shared resources, in order to make the most of performance of the system, (ii) and a strict partitioning to avoid disorder between different elements.

Regarding single-processor embedded systems, it is essential to guarantee the isolation between tasks in terms of time, and several techniques able to ensure temporal determinism of running have been presented in scientific literature [2]. On the other hand, about multi-processor systems, different applications run in parallel on different processors. The applications must compete in accessing shared resources, taking advantage of the specific communication architectures of different hardware implementations. Recently, it was possible to observe a growing interest towards the usage of Network on Chip (NoC) architectures [3] as a platform for systems with high mixed criticality. Compared to traditional shared (hierarchical) bus solutions, NoCs can more efficiently support the implementation of multi and many core systems. Table 1 (inspired by the works presented in [4] and [5]) provides a qualitative comparison of the two approaches.

In this prospective, the present work shows a mechanism with lightweight hardware for the management of mixed criticality in a multi-processor embedded system conceived on a Network on Chip. In particular, the aim is to give a hardware-based support in order to control the flow of the messages through the NoC, with the goal of guaranteeing a reserved access to the NoC itself on the base of the criticality level of the different tasks running on the NoC nodes. In such a way, the proposed mechanism supports spatial and temporal isolation, since, in a given period, only a subset of the tasks can access the NoC and the connected resources. Indeed, temporal isolation ensures no interference in the time domain among tasks to access to a shared resource (i.e., mutual exclusive access), while spatial isolation protects a shared resource

*Luigi Pomante, Email: luigi.pomante@univaq.it

Table 1: Shared bus vs. NOC: a qualitative comparison

	Concurrent access to different resources	Throughput	Physical implementation Overhead	Scalability	Design complexity	Power dissipation	Area occupation	Max frequency
Shared Bus	-	-	=	-	+	-	-	-
NoC	+	+	=	+	-	+	+	+

so that tasks are able to freely perform access only to a part of it, or only a subset of existing tasks are able to access to that resource [6].

The main characteristics of the proposed mechanism are the following ones:

- limited effect on system performance, thanks to a hardware-based approach;
- no limit on the number of criticality levels in the system;
- supporting both spatial and temporal isolation.

In particularly, the innovation points of the proposed approach are the followings:

- independency from NoC topology, i.e., it can be adapted to each NoC scenario;
- portability among different networks.

It is worth noting that this paper extends the one presented in [7], by providing:

- detailed HW design, described in Hardware Description Language (HDL), together with logical simulation (sec. 4);
- extended scalability analysis by means of OMNET++ simulations (sec. 5 and 6).

The paper is outlined in this way. Section 2 describes the most important concepts related to the management of isolation in the context of mixed-criticality in multi-processor and NoC based systems; the section also briefly summarizes the current main existing strategies for the effective management of the different criticality levels. Section 3 shows the proposed mechanism and details its advantages. Section 4 illustrates the detailed HDL-based HW design and simulation issues. Section 5 and 6 show the analysis of a simulated platform that helps to test the effectiveness of the proposed mechanism for NoC with more nodes. Finally, Section 7 summarizes conclusions and discusses future works.

2. Isolation in Mixed-Criticality Systems

Spatial and temporal isolation is a fundamental issue for embedded systems. In particular, for those systems that perform multiple activities with different levels of criticality, or better to say, mixed critical embedded systems. The topic is particularly significant for areas such as aeronautics and automotive. Several standards have the specific purpose of finding a solution to this problem and two significant examples are the AUTOMOTIVE OPEN SYSTEM ARCHITECTURE (AUTOSAR, [8]), a software architecture in the automotive area, and the Aeronautical Radio INCorporated (ARINC, [9]), which gives the specifications for spatial and temporal sectioning in avionics applications critical for safety (ARINC 653).

In order to examine the issue of mixed criticality, different analytical models can be followed [1]. Usually, applications are modelled as a group of elements. Each one consists of a finite number of tasks. Each task is expected on a processing resource, that can be shared among different tasks. For the present analysis, each task executes a specific activity by performing a certain number of jobs and it is periodically scheduled on a shared processing resource.

Focusing on criticality, several schemes have been presented in literature defining of levels of criticality, from the easiest one, where only two levels are allowed (i.e., non-critical and critical), up to configurations where the number of allowed levels is potentially unlimited [10]. Focusing on isolation, the tasks belonging to components with a lower criticality level shall not be able to interfere with higher criticality ones.

In literature, different studies have analyzed the problem of the management of mixed criticality in single processor systems, from the isolation point of view [2]. A static allocation of memory during compilation phase is an appropriate strategy in order to reach spatial isolation. Contrarily, a Memory Management Unit and a Memory Protection Unit could support isolation for dynamic memory allocation. Another appropriate strategy in order to reach isolation between tasks with several criticality levels is virtualization. Anyway, full virtualization is generally not satisfactory for embedded systems (especially if exists real-time constraints), indeed the required overhead may be impactful on the temporal constraints of the application. The usage of Hypervisors [11] in these situations permits to run ate the same time several operating systems upon a platform in sharing with low overhead, but still maintaining the isolation of time and space [12].

It is fundamental in a multi-processor system with shared bus architecture, administer the access to shared communication elements. This could be done by partitioning the system in order to eliminate disturbances among applications executing on different cores, or on peripherals device with DMA. The issue of partitioning in multi-processor systems is already addressed by Pellizzoni et al. [13], with the definition of the Architectural Analysis and Design Language, which is a form of Architectural Description Language used for mixed-critical systems that supports by construction the monitoring and optimization of the communication and processing phase. The time-triggered model [14] is a different method of partitioning, where a high level of criticality is related to the time-triggered traffic, while traffic

Table 2: Routing arbitration policies for NoCs.

Arbitration Policy	Round Robin	Time Division Multiplexing	Fixed Priority
Description	Usually aimed at obtaining fairness on arbitration, but not used in real-time systems, given the problems in calculating the worst-case latencies for the various transactions.	The various data flows are statically allocated to separated time slots. This arbitration policy is largely adopted in real-time and mixed criticality implementations, but determining a reservation scheme for the various time slots is not trivial.	The various transactions are managed based on predefined priority levels.

triggered by events is generally the best effort. Time-Triggered Ethernet or TTP/C are kind of protocols that support this kind of communication mechanism called Time-Division Multiple Access (TDMA). If no isolation-oriented strategies are implemented, the management of shared resources is usually demanded to the specific bus arbitration.

Finally, in a multi-processor system based on NoC, router arbitration schemes are fundamental. Generally, NoCs are conceived on the arbitration policies shown in Table 2.

2.1. State of Art

Schoeberl [15] suggested a regular structured time-triggered NoC (TDMA-based) capable to support foreseeable communications both on-chip and off-chip. This architecture uses a pseudo-static communication schedule implemented in a Cyclone II EP2C35 *Field-Programmable Gate Array* (FPGA) on the Altera DE2 board. The underlying network topology is simple (e.g., ring structure) and optimized for easy routing (wire routing, not message routing). They implement a simple demo application (a voting triple modular redundancy sensor), but they evaluate the scheduling policy offline for each different scenario. An advanced tool to calculate and verify the schedule is important to render the proposed NoC useful.

Tobuschat [16] developed a NoC capable to support natively a mixed criticality. This system is conceived on a methodology (namely, back suction) capable to maximize the bandwidth allocated for low importance messages, guarantying that the most critical messages are delivered by satisfying the related deadlines. The authors said that sufficient independence is reached, and worst-case behavior can be predicted through the usage of virtualization, monitoring infrastructure, and control mechanisms. Programming of the monitors is only possible by the system controller, so its correct implementation becomes an essential point of this work, introducing additional load to the system. Furthermore, the knowledge of all possible interference enables timing predictable behavior of the whole system, but this assumption is not simple to verify with respect to real scenarios.

Burns [17] described the Wormhole Protocol for Mixed Criticality (WPMC). This protocol points out the dual-criticality, fixed priority NoCs. Furthermore, if an infraction in transaction deadlines is catched, it permits to limit the use of communication elements in favor of high criticality transactions. Successively, WPMC has been updated in order to advance the low criticality packets average latency and the latency of the worst-case of the high criticality ones [18]. The main limitations of this work are related to the maximum number of criticality levels considered (not more than two), the lack of a mode change protocol among several criticality levels, and the study of mixed-criticality end-to-end latency analysis (i.e., considering task execution as well as traffic-flows).

More in general, state of art solutions to provide isolation converge on two main areas: Time Division Multiplexing, that implies a conservative design with increased resource requirements [15], and Monitoring of the System, to react in case of unexpected situations.

The mechanism proposed in this paper falls in the second category, with the novelty that the monitoring mechanism is moved into the NoC itself, involving only NoC interconnection elements and not NoC nodes. This specific aspect will be analyzed, in more detail, in the following section. In this way, the introduced mechanism is independent from the NoC topology, as the control action can be applied independently from the specific NoC architecture. The mechanism is also easily portable, as it is simple to introduce custom communication control strategies into existing network interfaces. These are the two main advances respect to the state of art.

3. Proposed HW Support for Isolation

This paper proposes a mechanism able to consider the different criticality levels of tasks running on a NoC, and to regulate the network traffic basing on specific network parameters. The system model is firstly introduced, then the proposed mechanism is detailed and analyzed.

3.1. System Model

In the proposed approach, a NoC consists of, at least, two *Nodes* (N) and one or more *Routers* (R). Every node includes one or more processors/cores, memories, and other peripherals. Intra-node communications can entrust on several approaches (generally a hierarchical bus and shared-memory structure). These internal details are not a constraint for the proposed structure, so they will be considered abstracted from now on. Inter-node communications are conceived on message passing: this implies that every node possess a *Network Interface* (*NI*), exploited to send/receive messages, and linked to a single router port. Every single router can be linked, to other *NI* and/or to other routers, considering on the NoC topology. The routers transmit the messages to final nodes according to the used routing protocol.

In Figure 1, it is shown a schematic reference NoC, consisting of four nodes and routers connected in a mesh topology. Every node of the NoC run one or more tasks T_i. In our case a task could represent an OS process, thread or simply a generic abstraction of a piece of software that executes a specific function). Each task is characterized at least by a *task criticality level* (c_i), i.e., the level of insurance associated to the task itself. Each task has a default criticality statically assigned at design-time and can deliver a

message (M) over the NoC through the NI of the node on which it is running. Every message is then outlined by a *priority* equal to the sender task criticality.

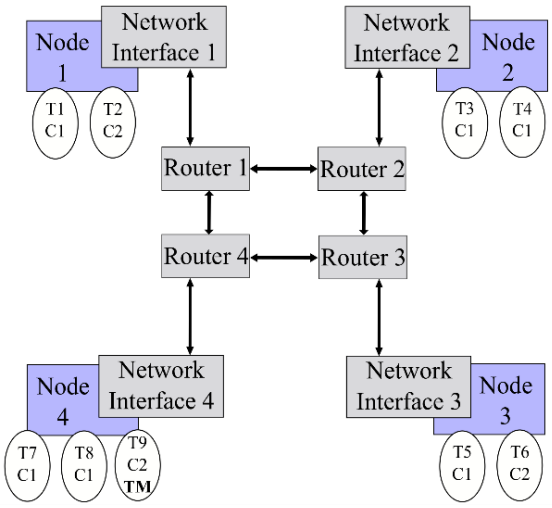

Figure 1: NoC with 4 nodes in a mesh topology.

3.2. Proposed HW mechanism

In order to define a mechanism supporting isolation, the network status is characterized by a global parameter named *Severity*. At certain time, the NoC will perform with a level of severity S in the range [1, Smax]. The isolation mechanism relies on the following two hypotheses:

- for a given temporal instant, only the messages sent by tasks with a criticality level $c \geq S$ can be transmitted by the NI and forwarded to the routers;
- the severity level can be modified, at run-time, by tasks that have specific privileges. These tasks (*Task Masters*, indicated as TM in Figure 1) are statically defined at design time.

At start-up, the system works in the least conservative mode, with a minimum severity level. If an anomaly condition is detected, and tasks with high criticality need to be executed, the system may switch to higher severity level, causing those tasks with higher criticality to access the network without competition with lower criticality ones. The following additional hypotheses are assumed:

- each NI can store the severity level of the network, to allow the transmission of new messages only if their criticality is greater or equal than S;
- the severity level of the network could be modified (raised or lowered) by a TM, by introducing inside the network a message which change the *severity*. This message is propagated to all network nodes and processed inside the NI. The reception of a message with a change in severity will activate an update of the severity level memorized inside the interface.

Being only the TM able to change the NoC Severity, the configuration of the system results to be protected: indeed, an untrustworthy entity is not able to change this configuration and possibly corrupt the system itself. The condition to prompt for a Severity change depends on the presence of anomalies: metrics able to indicate when an anomaly is verified can be defined, depending on the application executed on the NoC; then, by monitoring these metrics, it is possible to relate the TM transmission of a Severity change with the anomaly identification.

Observing Figure 1 and supposing that it is related to a scenario with two levels of criticality and two levels of severity, when the NoC possess a severity level equal to one, all the tasks can send and receive messages through the network. The routers could use a simple *First-in First-out* (FIFO) policy to manage the message forwarding toward the proper ports: when the FIFO is full, the message is rejected by the router, waiting for space in the queue. When a TM (T9 in the example of Figure 1) starts the procedure to change the level of severity of the NoC, all the NI shall be notified in order to update the corresponding value. When the severity level reaches the value of two, only T2, T6 and T9 are enabled to send messages while all the tasks will be able only to receive them. It is important noting that the designer owns the responsibility in order to eliminate, or to keep tolerable, conditions where a task cannot react to the message of a more critical one due to the NoC severity level possessed in that moment.

The reference HW design of the severity management mechanism, able to implement the isolation mechanism above described, is shown in Figure 2. It has an *Input Buffer* (called Message Buffer in the figure) to manage message traffic from the node: when a message from the node reaches the input of the buffer, the *Comparator* module checks if the criticality of the input message is greater or equal than the current network severity (stored in the *Severity Register*). If that is the case, the output of the comparator will be low, and the message will be stored into the *Message Buffer*. Otherwise, the output of the comparator will be high, and the message will be rejected: specifically, the loading of the message buffer will be inhibited, and a reject notification will be sent to the node. This functionality is described in the flowchart shown in Figure 3, where the methods *fillInputBuffer(), Analyze(), StoreMessageBuffer()* and *Reject()* implement, respectively, the reading from the node, the analysis of the received *Message*, the storage into the message buffer to transmit along the NoC and the rejection of the *Message*.

As above indicated, the aim of the proposed hardware mechanism is to assist the NoC design where, at a certain time, only the packets sent by a task with criticality greater or equal than the severity of the NoC are transmitted. The NI of nodes that executes the sending tasks blocks all other messages. It should be highlighted that this degradation is often tolerable in systems with mixed-criticality [17], as it eliminates any influence between lower and higher criticality flow. It can be noticed that the suggested solution does not reduce the number of criticality network levels. Also, it can be noticed that the proposed mechanism supports both spatial and temporal isolations: the former is ensured by the fact that only tasks with criticality greater than S can use the network resources to send messages. The latter is ensured by the fact that Severity can be changed over time, so giving the opportunity to all the tasks to access the network resource in specific temporal slots while still being able to assure that the most critical ones, when needed, can run without interferences due to less critical tasks.

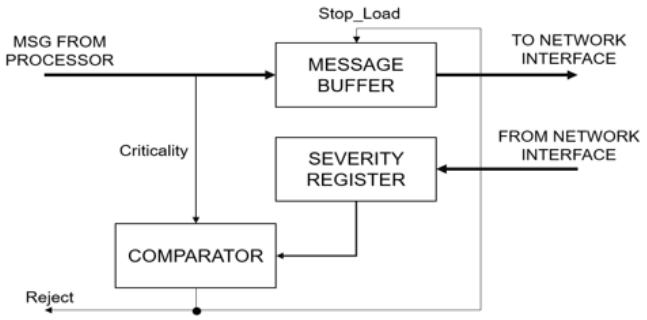

Figure 2: Implementation of the mechanism in a Network Interface (NI).

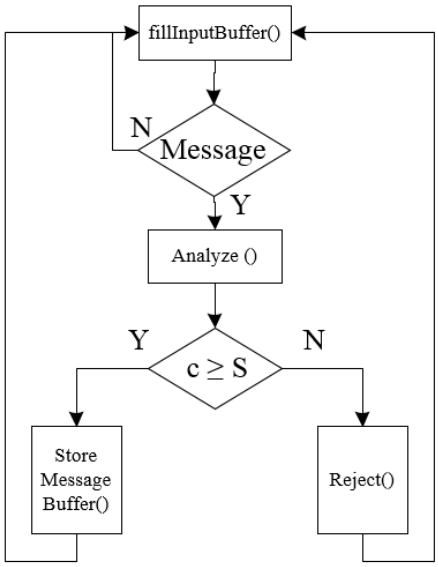

Figure 3: Functionality of the proposed HW mechanism.

4. HW Mechanism Design and Validation

This section presents the approach adopted to design and validate the proposed HW mechanism. The interests have been focused on three features: behavior validation, practicability check, and evaluation of the scalability. Regarding the first one, it allows to check if the developed mechanism behaves as expected. It is mainly based on HDL-based design and simulations. The second feature allows to check if this mechanism is possible to realize on real systems. It is based on a *Hardware-In-the-Loop (HIL)* approach applied to a simple NoC implementation on an FPGA platform. The final and third one (described in section 5) allows to check if it is possible to exploit the mechanism in real-size NoC. So, it is based on a *Network Simulation* approach to validate behavior and evaluate scalability, without the need to develop very complex NoCs. So, the following paragraphs, presents all the details needed to understand the performed HDL-based design and simulations activities.

4.1. Selected Reference NoC

A reference NoC has been considered for validation activities. It is an open-source NoC [19] described in HDL, that can be simulated and synthetized on FPGA. Such a NoC is of interest, since its design is very simple, allowing to reduce the number of required logic units for prototypal implementations. Moreover, it is provided with a MATLAB program to monitor the network traffic at run-time.

The reference NoC architecture consists of a network of nodes able to send and receive data, in order to complete their actions. Devices in nodes can be of different types, such as processors, memories and input/output devices. A network adapter is used to connect a device to a router, and a router connects the node to the rest of the network. Packet switching is used as a communication method across the network, with packets used as the communication medium.

Specifically, there are three types of packets in the network: *write*, *read_request* and *read_return*, as shown in Figure 4. All of them have a header, to indicate their type, and other fields depending on their goal.

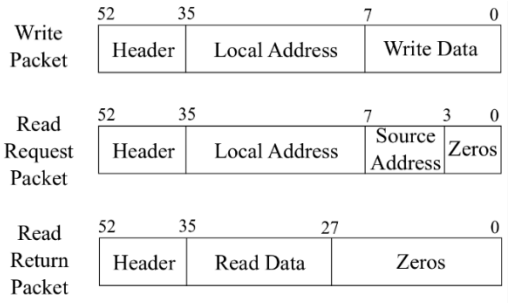

Figure 4: Packets of the reference NoC.

The *write* packet is sent by a master node to write data to a slave, while a *read_request* is sent by a master node to a slave one, and the latter replies with a *read_return* packet. *write* and *read_request* packets require a destination address: the reference NoC has a 32-bit address space, where the first 4 bits are used as the unique node IDs, while the remaining 28 bits are used for local addresses. The *read_request* packet also contains the source ID used by the receiver to send the *read_return*. *read_return* packets only contain the destination node ID of the source where they are replying to. A *write_packet* contains 8-bits of write data, while a *read_return* contains 8-bits of read data. The packets are sent over one clock cycle, rather than broken up over multiple clock cycles, to keep the hardware and logic simple.

Focusing on *network adapter* (NA), it represents interface between the node and the router, and its purpose is to convert signals from the local bus into a suitable packet format for the network, and back again. There are two types of network adapters and devices: *master* and *slave*. The *master network adapter* receives the following signals from the master device: *write_address*, *write_enable*, *write_data* and *read_request*. A master device can connect to the network adapter and the network should be totally transparent. The NA sends back *not_ready*, *read_return* and *read_*data. Any device wishing to connect to the network needs to handle a *not_ready* signal from the network adapter. Its output interface with a router is a *packet_data_out*. It can receive a busy signal from the router and a *read_return* packet.

Routers have five sets of channels connected to them, as shown in Figure 5. As the mesh organization is used in the network, four directions can be identified: *north*, *east*, *south*, *west*, and one additional channel going toward the *local* network adapter. The router is clocked with the global clock of the system. In order to

move the packets around the network from sources to destinations, routers look at a special field of the incoming packets, called *xy-counters* [19]: they give priority to *y-direction*, firstly check in what vertical direction they should forward the packet, and then checking for the horizontal one. If a router receives a packet in which both x and y counters are set to 0, then it indicates that the packet was destined for that router and that it has now reached its destination (and should be forwarded to the local network adapter).

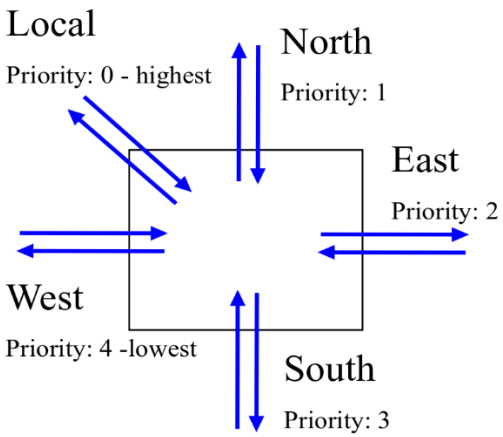

Figure 5: Router.

In order to support on debugging actions, a hardware monitoring system is offered together with the reference NoC [20] [21]. The monitoring system interfaces with an UART controller, allowing the communication with a host computer. A MATLAB program is also provided to be executed on host computer, providing a visual representation of the current traffic on the network, which is updated several times per second.

The proposed HW isolation mechanism has been integrated in an instance of the reference NoC discussed in the previous sub-section, composed of 16 nodes in a mesh topology, shown in Figure 6. Each device within a node is represented by a simple *finite state machine* that acts as a master or slave processor (in the following TP — *Test Processor*), executing some specific instructions.

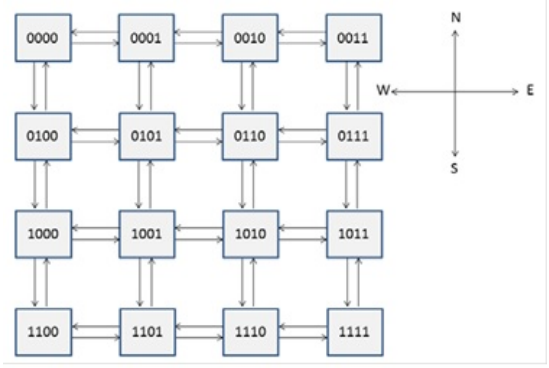

Figure 6: Reference 16 meshed nodes NoC.

In such a reference NoC, *Severity* and *Criticality* concepts have been introduced. If a TP tries to send a message with criticality less than current network severity, the message is blocked by NA. It is worth noting that messages are not blocked by routers, since, in this case, they are unaware of the isolation mechanisms. This improves portability but also means that, when a severity change occurs, all the packets already inside the networks are still able to freely circulate. In this case, they will be managed accordingly to their priority, as expected by the type of NoC. For validation purposes, *Criticality*, *Severity* and *Priority* have been set in the interval [0, 7]. In order to support the proposed approach, the NoC has been modified to introduce a fourth type of packet, called *severity_change,* shown in Figure 7. The goal of the packet is to allow a *master* task to trigger a severity change.

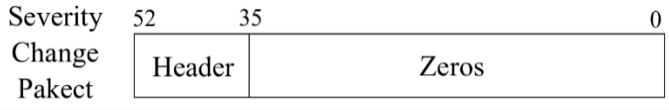

Figure 7: Packets managed by the reference NoC.

Together with the introduction of a new packet type, further assumptions have been done to reduce the management complexity of the network, focusing on the purpose of the tests:

- TM has been associated to the node in the upper-right corner of NoC shown in Figure 6. The corresponding TP is the only one able to change the severity of the network.
- Severity change requests are forwarded by following a snake-coil path, as shown in Figure 8. Routers forward such a packet only in one fixed direction

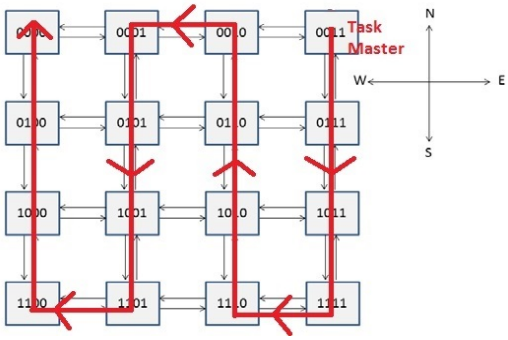

Figure 8: Snake-coil path.

Master and slave NA adopt a two-levels input buffer at both TP and Router side. By means of them and a proper busy signal, it is possible avoid losing input packets. If two packets are concurrently coming from TP and Router, they are managed at the same time, if possible, otherwise they are serialized giving priority to the one with greater criticality. As said before, the criticality/severity check is performed only in Master NA, specifically by checking the input buffer at TP side. This represents the major change with respect to the reference NoC. Another important one is that, if a message coming from TP is not accepted by NA, TP is notified by means of a proper *msg_rejected* signal. A detailed view on NA modifications is shown in Figure 9 and Figure 10.

The router is identical to the reference NoC one, apart from the need of improving the existing priority-based routing approach. In fact, in the case of concurrent packets forwarding, greater priority shall be given to criticality instead than to the port. It is worth noting that such a policy is simply priority-based, i.e., the router does not need to know about the criticality/severity mechanisms (in fact it is designed to work without knowing anything about the current severity level).

4.1. Validation by means of logical simulation

The above discussed NoC has been described in VHDL and simulated by means of Xilinx *ISim* [22]. In this way, it has been possible to verify the right forwarding of packets and the behavior of the proposed mechanism. In Figure 11, the simulated NoC is shown: it is composed of 16 nodes with different IDs (represented both in binary and hexadecimal base). Nodes 6, E and F are the master ones (i.e., they have a master NA and a master TP). In the considered test case, they perform some writings and readings by involving node 8 (*slave*). Written data (*write_data*) are composed of node ID and a progressive number (from 0 to 3, since, in the considered test case, each node performs 4 consecutive writing). In Figure 12, the main communication paths between the masters and slave node number 8 are shown.

Test 1 – Router packet forwarding

The first proposed test has the goal of verifying the correct packets forwarding done by routers. In Figure 13, it is shown the router close to master Node A managing input from ports N, E, and S, and forwarding them towards W (since all the write operations are related to node 8). The reported values represent the *write_data* field in hexadecimal base. In the presented test case, master NAs make use of their 3-bits ID LSB as criticality values for their sent messages; with this assumption, the following criticality values have been considered: criticality 6 for node 6 (110), criticality 6 for node E (110), criticality 7 for node F (111).

In Figure 13, it can be noticed that packets from nodes 6 and E reach the router with 1 clock cycle anticipation (since node F is far than the others). It is also possible to notice that the first two *write* packets (60 and e0), that requires the same output port, are correctly forwarded giving priority to the packet 60 (same criticality, but N port). Then, the newly arrived f0 is quickly forwarded, since it has greater criticality with respect to e0. The output is the sequence f0, f1, f2, f3. Since also the *read_request* packets form F have criticality 7, they are always forwarded in a single clock cycle (f0 is high for 4 clock cycles).

Test 2 – Isolation

In Figure 14, the isolation capability of the proposed mechanism is verified. Considering a severity level set to maximum value (i.e., 7) and stored by each NA, a TP tries to send a message with criticality less than the current severity. In particular, the TP tries to send 4 *write* and 4 *read_request* packets with criticality 6 (110); it receives the *msg_rejected* signal for 8 clock cycles. It is worth noting that, in this test, *msg_rejected* notifications are not managed in any way by the TP (e.g., no tentative resending).

Test 3 - Severity change

In Figure 15, a severity change in the NoC is shown. It is possible to notice the *severity_change* packet (highlighted in red) firstly sent by node 3 (the only allowed to do it, since it is supposed to be the only one to have a TM) to its NA. Then, such a command is forwarded to the whole NoC (following the path already shown in Figure 8), i.e., each NA updates its internal current severity value and setups a new message to forward the severity_change command to the next node.

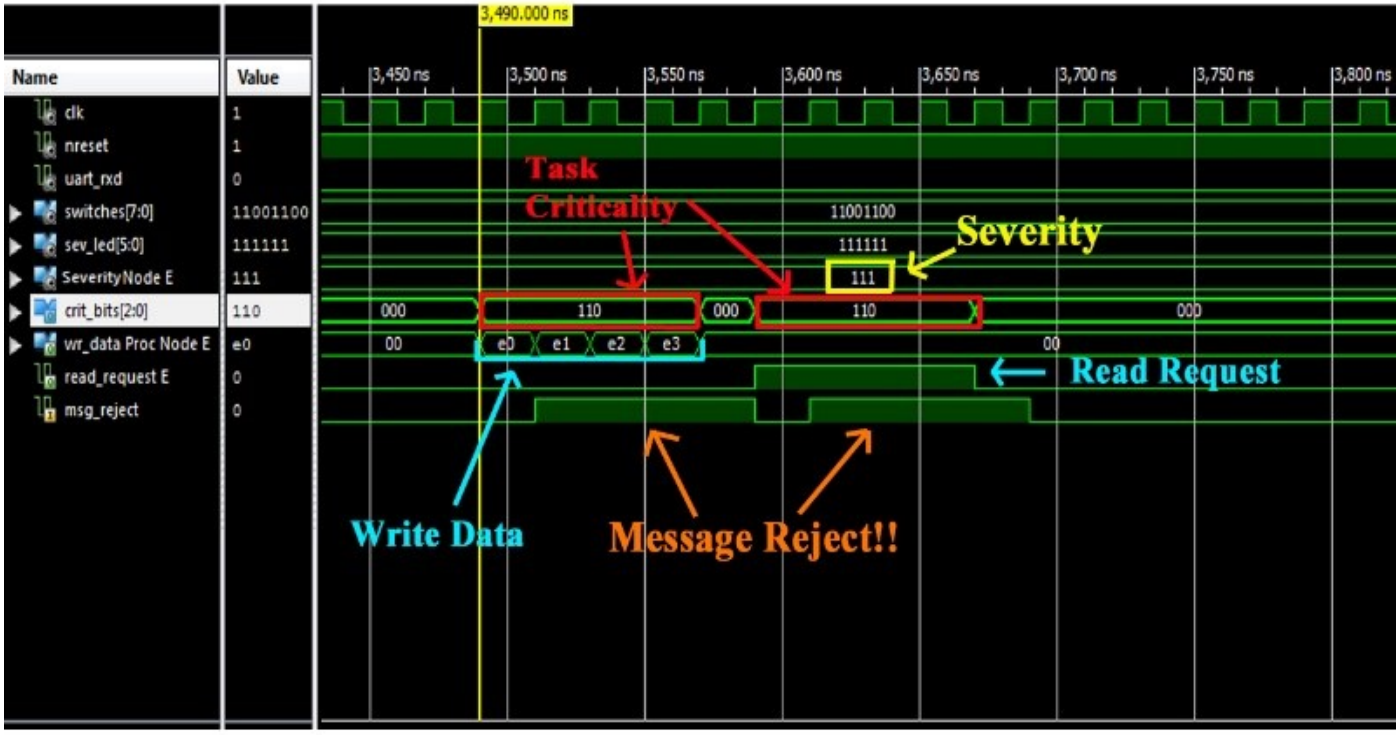

Figure 14: Criticality/Severity check.

4.2. HIL-based validation

In order to validate a prototypal implementation of the proposed mechanism, an instance of the reference NoC, enriched with that mechanism, has been implemented on a Xilinx Spartan-3 FPGA [23] using Xilinx *ISE Design Suite 14.7* [24]. The testbed is shown in Figure 16. The prototype consists in a NoC with a 3x3 mesh topology, where each node device is represented by a master or slave *Dummy Processor* (DP), namely a simple finite state machine that acts as a processor executing some specific instructions. Such a network implements an 8-level Severity and Criticality system. To keep low the complexity, while focusing on proposed mechanism features, the TM has been associated to the node in the upper-right corner so that the corresponding DP is the only one able to change the severity of the NoC (actually, the corresponding dummy processor has been designed so that the user can manually decide when to do severity changes and at what value, by using board switches). Aside from the node at the top right that holds the Task Master, all other nodes have been randomly distributed between the two master and slave types, and the associated Dummy Processors have been configured to create a decent amount of traffic packets at all criticality levels in the network. Severity change requests are forwarded to the other nodes by following a fixed snake-coil path, as shown in Figure 17.

All packets are forwarded by routers with a *Packet-Criticality* based priority policy [19]: the routers first check in which vertical direction they should forward the packet, and then check for the horizontal one. If a router receives a packet in which both x and y counters are set to 0, then it indicates that the packet was destined for that node and that it has now reached its destination. If, at a given time, two or more packets from the input ports are destined to the same output port, a conflict occurs, and priority is given to the packet with the highest criticality, whereas other packets are blocked before they can be sorted out later. In the case of equal criticality, priority is given according to the input port of the conflict packets, by following the descending order: Local, North, East, South and West. It is worth noting that such a policy is simply priority-based, i.e. the router does not need to know about the criticality/severity mechanism (indeed it is designed to work without knowing nothing about the current severity level).

Master and slave NA adopt a two-level input buffer at both DP and Router side. By means of them and a proper busy signal, it is possible avoiding losing input packets.

After the system implementation on Spartan 3 FPGA, the monitoring system and the MATLAB program have been used to check the NoC status. Red wires indicate connections that have a lot of traffic, yellow ones indicate a small amount of traffic while white ones indicate no traffic at all. Other than the traffic, it is also possible to check the amount of *busy* and *msg_rejected* events. In Figure 18, it is possible to notice that with a low severity level (000) traffic is quite high, since all the nodes are able to send messages

After the setting of a severity change to the highest severity level (111) (the changing of severity using the TM is shown in Figure 17), the traffic appears to be heavily reduced, as shown in Figure 19. The area occupations are reported in Table 3. The impact is very small, so the adjective “lightweight”.

Figure 15: Severity Change.

Table 3: Area occupation.

	FFs	LUTs	f_{MAX}
Complete NoC with the proposed mechanism	37 %	70 %	125 MHz
Proposed mechanism (area per each NI)	1 (<1%)	2 (<1%)	-
Proposed mechanism (area in 3x3 mesh)	9	18	-

5. Scalability evaluation

In this section, a model of the reference NoC has been developed using the Omnet++ simulator [25] with the aim to evaluate the scalability of the proposed mechanism. The model of the NoC supports *n*-levels Severity and Criticality. Multiple standard (unprivileged) tasks and Master tasks can be statically associated to each node of the network, and different traffic patterns can be associated with each task. The simulator includes a statistic unit able to investigate the traffic sequences, and the possibility to use a flexible time base module able to model synchronous and asynchronous NoC. In the case of synchronous NoC, the model of the network makes use of a module (named the Time-base synchronizer) able to generate clock messages, ensuring synchronous communication between the various nodes. Other model features are the following:

- in a fixed, predetermined device, a single TM executes on the platform
- each router uses the *xy* routing strategy shown previously and the broadcasting of the Severity Change Packet;
- the TM can determine the traffic status and eventually its congestion, by inserting a special broadcast packet called the Inquire Packet (IP);

The TM will modify the severity by sending a *Severity Change Packet* if the measured congestion status exceeds a predefined threshold, or if there is a timeout elapse. This severity administration policy needs an additional overhead for the development of the routers, as every router should be capable to follow the number of queued packets and deal with the IP. Furthermore, the suggested enquiry strategy needs the insertion of additional packets inside the network, possibly disturbing with device traffic.

In Figure 20, there is the result of a simulation of the modelled system in case of a synchronous 8x8 NoC. This figure shows the total number of packets inserted into the network over time, reported in generic time units (i.e., number of clock cycles) and two indices of the network status: the number of queued packets at a certain time and the current network severity. It should be observed that the value of the two network indices is multiplied by one hundred for a better clarity of the figure. It can be seen that the traffic regulation mechanism is adequately capable to limit the traffic of the network in case of congestion, allowing only the successful transactions of high criticality messages in a timely manner: this shows the feedback that the proposed mechanism can provide when unexpected behavior from the tasks are verified.

In Figure 21, it is reported the number of total sent messages (red line) and the number of dropped messages (blue line). The number of dropped messages is lower than the total messages that go through the network. In particular, the number of total messages in the tested time interval is $4.14 \cdot 10^6$, while the number of dropped messages is $3.00 \cdot 10^6$.

6. Further Analysis

Thanks to effort spent on creating a model, further analysis has been done by means of system simulations, introducing other aspects and evaluating a different broadcast strategy and a different management of the control traffic messages.

6.1. Different broadcast strategy

In this test, routers have the possibility of changing the broadcast of the Severity Change Packet. There are two possibilities:

- *snake-coil strategy*: the message, with TM in the node at the top right of the network, is broadcast one router at a time in a north-south direction, then moves one step to the left when the message reaches a router located at the northern or southern limit in the network itself and resume the journey in the north-south direction. The method is already described and used in the previous two sections.
- *star-broadcast strategy*: it takes its name from the design formed by the overall path travelled by the messages. The origin node of the messages can be in any position. The first router forwards the packet to all the connected ports in order to reach the maximum number of routers. Routers located along the north-south axis respect to the first router forward the message to the east, west and north, if they received the message from the south, or forward it to east, west and south, if they received it from the north. Finally, the routers that receive the packet from the east [or west] forward the broadcast packet along the west [or east] direction in order to make the broadcast packet continue along the east-west axis (see Figure 22).

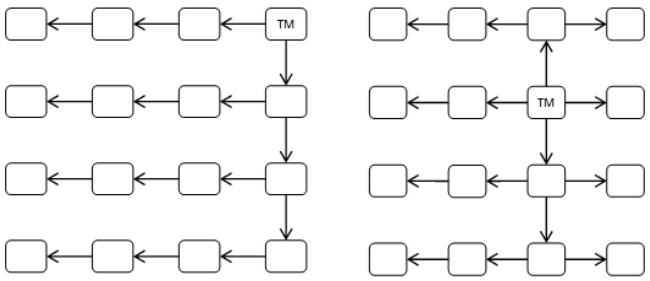

Figure 22: Star-broadcast strategy.

In Figure 23, it is shown the behavior of the system in case of a synchronous 8x8 NoC with the star-broadcast strategy instead of snake-coil one. As in previous section, the value of the two network indicators is scaled by a factor of one hundred for better clarity of the graph. Here, the TM periodically sends a control signal to which all routers respond by entering their own maximum queue value. In this period, the TM waits a maximum time equal to 10 clock cycles between one message and another before deciding to change the severity of the network. After this time, if the TM does not receive all the answers, then the network severity increases, trying to moderate the circulation of messages. Vice versa, when all the messages are received by the TM, the latter can decide to decrease the severity of the network. When all the messages are received, the TM in this test evaluates the average of the received answers.

The test shows that the proposed mechanism manages to control the flow of messages within the network, although the network itself is flooded with many control messages. The peak of messages reached within the network exceeds one thousand units, a situation in which the severity of the network is zero. In this case, there are several messages in the network and the TM fails to receive all the control messages, so the network severity is raised to one (one hundred in Figure 23).

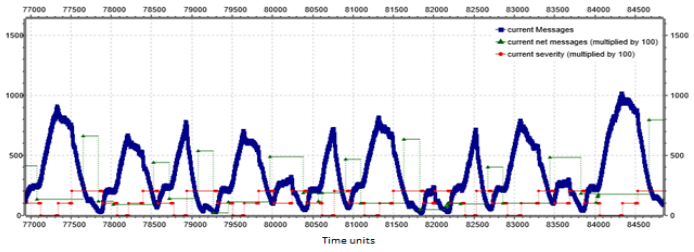

Figure 23: Simulation of a synchronous 8x8 mesh network without traffic control and with star-broadcast strategy

This leads to a decrease of messages in the network, but not enough so the TM causes another increase in severity. With severity two (two hundred in Figure 23), the severity does not decrease until the value answered by all nodes is less than a threshold value. The response received from all the nodes is averaged in order to obtain an indicative value of the network state. The value is considered only when the responses are received from all the routers. Subsequently, two tests are conducted on this type of broadcast strategy. The first one, shown in Figure 24, uses an exact average value obtained from all the responses received. In the second case, shown in Figure 25, the average is modified in correspondence of a minimum value in order to be higher.

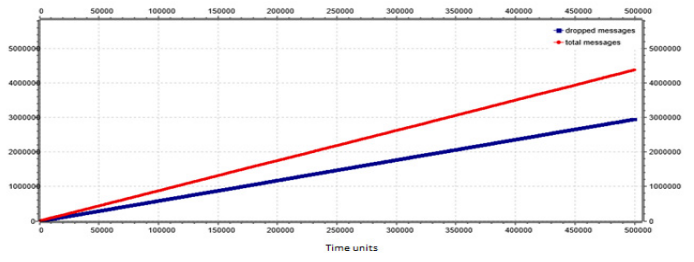

Figure 24: Number of total messages (red line) and number of dropped messages (blue line) for a synchronous 8x8 mesh network with star-broadcast strategy, exact average case.

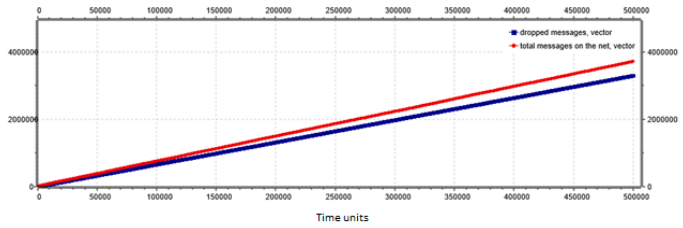

Figure 25: Number of total messages (red line) and number of dropped messages (blue line) for a synchronous 8x8 mesh network with star-broadcast strategy, modified average case.

Considering these two results, the network that performs best for message delivery time is the one that uses the modified average of traffic. However, this method results in a lower number of total messages sent over the network. Furthermore, with the use of the modified average, the maximum capacity of the routers results decreased in messages of a 20%.

6.2. Control traffic messages management

In this situation, devices and routers use two types of states to differentiate the type of messages processed, by extending the functionalities already present in the implemented NoC. Here, a single slot is dedicated to control traffic messages management. Two states have been identified:

- State zero indicates classic operation, i.e. read, write and reply messages are exchanged.
- State one only messages intended for traffic control are exchanged.

The traffic control messages in this type of network have a priority equal to that of the TM, in order to do not mix service messages with those of communication useful between the cores. Currently this functionality is supported only for a synchronous NoC. For a synchronous 8x8-node networks with control traffic messages management, the best behavior is obtained with the star-broadcast strategy (see Figure 26 and Figure 27). Here, there is a better delivery time for all messages.

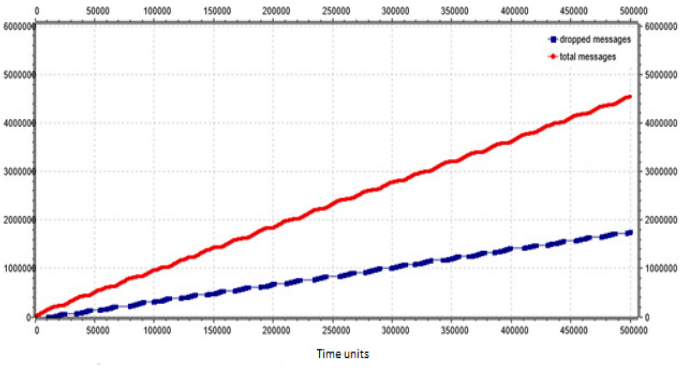

Figure 26: Number of total messages (red line) and number of dropped messages (blue line) for an 8x8 mesh network with control traffic messages management and snake coil strategy.

Analyzing all the experimental results for 64-node networks without control traffic messages management, the broadcast strategy that behaves best is the snake coil, unless the star-broadcast strategy modifies the average of the messages received. Therefore, if we consider the modified average, the star-broadcast improves and shortens the delivery time of the messages.

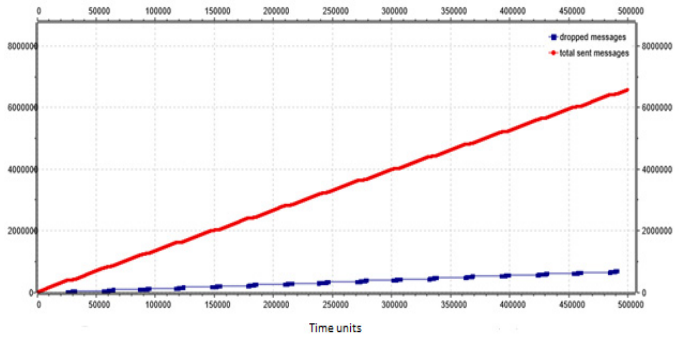

Figure 27: Number of total messages (red line) and number of dropped messages (blue line) for an 8x8 mesh network with control traffic messages management and star-broadcast strategy.

For the 64-node network with control traffic messages management, the best behavior is given by the star-broadcast. It must be remembered that, in the network with state, a fixed delay is introduced in the maximum time of delivery of the messages equal to the time of control necessary to probe the network. Despite this, the star-broadcast strategy keeps the average delivery time of messages low, even if it has a high delivery time.

7. Conclusions

Isolation is an important issue for embedded systems on which multiple tasks with different level of criticality are running. This paper has suggested a lightweight isolation mechanism to be introduced into existing Networks on Chip. This mechanism supports the execution of multiple applications with different criticality levels by supervising the packet exchange between network nodes. It does not reduce the criticality levels and it supports both spatial and temporal isolation. The system main innovation is its autonomy from the topology of the NoC and its easily flexibility among different NoCs. Small NoC implementations have been provided, showing the small impact in the area occupation, and motivating the adjective “lightweight”. Simulation on a network simulator has been proposed to evaluate the behavior of the mechanism on a NoC with more elements, and the feedback applied when there are unexpected situations is shown.

8. Future Works

Future works involve a further analysis to precisely characterize the overhead of proposed mechanism in a real existing NoC solution, and to investigate the best severity change policy. Moreover, given the outlined results, the possibility of adding a lightweight support for network status analysis will be explored as well.

Conflict of Interest

The authors declare no conflict of interest.

A B S T R A C T

In this paper, a *multiple-objective Metaheuristics study is discussed. Initially, three mono-objective metaheuristics will be explored in order to design and optimize Radio-Frequency integrated inductors. These metaheuristics are: An evolutionary algorithm called The Differential Evolution (DE), An algorithm supported on Newton's laws of gravity and motion called the Gravitational Search Algorithm (GSA) and, finally, A swarm intelligence algorithm called the Particle Swarm Optimization (PSO). The performances of these three mono-objective metaheuristics are evaluated and compared over three benchmark functions and one application to optimize the layout of a RF silicon-based planar spiral inductor, the double π-model is adopted. Secondly, three references multi-objective metaheuristics using Pareto front are used respectively the multi-objective PSO (MOPSO), the Pareto envelope-based selection algorithm-II (PESAII) and the multi-objective evolutionary algorithm based on decomposition (MOEA/D). The performances of these multi-objective optimization algorithms are evaluated and compared over two bi-objective benchmark functions and the same application used in the first section. Two conflicting performances were optimized, namely the quality factor 'Q' (to be maximized) and the device area 'dout' (to be minimized) for the RF inductor. It was concluded that the multiple-objective PSO are significantly more efficient and robust for difficult problems than the other metaheuristics.*

1. Introduction

Nowadays, the advances in the integration technology agree the conception and the realization of complex integrated electronic systems. Therefore, the decision-making must be broached in an optimal way. Decision making can be seen as a set of the following steps: "Formulation", "Modelling", "Optimization", and "Implementation" of the problem [1]. In order to increase the accuracy of the optimization model, or algorithm, up to an adequate solution is establish, the decision making process could be repeated. The block "Optimization of the problem" is a vital part of this process and can be found in many areas, like engineering among others, and particularly in the topic of Radio Frequency (RF) circuit design [2-4].

The mono-objective optimization algorithms are classified into two categories: the heuristics and the metaheuristics algorithms. In fact, the first category is developed to solve a specific problem [5]. The second category represent a group of optimization techniques where theses popularity are increased during the last two decades and being considered the most successful and promising optimization algorithms [6–8]. The most used ones in the literature are the Evolutionary Algorithms (EA) such as local search (LS), simulated annealing (SA), tabu search (TS), genetic algorithms (GA) [9-14] etc.

Recently, a new group of nature inspired metaheuristic algorithms were published in literature. These metaheuristics are part of Swarm Intelligence. These techniques are based on animal behaviour and insect conduct, aiming to mimic their skills solving daily problems. In the area of Radio Frequency (RF) circuit design, Swarm Intelligence (SI) techniques are broadly applied, and among such techniques the PSO "Particle Swarm Optimization" [15–17], and the ACO "Ant Colony Optimization" [18–21], are the most used.

In this paper a multiple-objective metaheuristics study is discussed. Firstly, we propose to evaluate and compare such references mono-objective metaheuristics optimizing such

houcine.marouani@gmail.com

benchmark functions and one Radio-Frequency application in terms of convergence, robustness and time computing. Three mono-objective algorithms are considered: An evolutionary algorithm entitled the Differential Evolution (DE), an algorithm based on Newton's laws of gravity and motion entitled the Gravitational Search Algorithm (GSA) [22, 23], and a swarm intelligence algorithm entitled the Particle Swarm Optimization (PSO). The drive issue for this comparative study is to give some sort of substantiation for the choice of the "best" metaheuristic among others [24]. Secondly, multi-objective problems are discussed. A study was conducted to the maximization of the quality factor Q and the minimization of the device area d_{out} for the Radio-Frequency (RF) integrated inductor circuit [25-30]. Three algorithms for multi-objective Pareto optimization [31-39] are used. An evaluation concerning the performances of the three abovementioned multi-objective metaheuristics: the convergence and the robustness analyses are offered [40-41].

The structure of this work is the following. Section 2 presents a summary of the mono-objective metaheuristics used. Results and analysis regarding the convergence and the robustness study of the three algorithms over three benchmarks functions are offered in Section 3. Section 4 reports the application of these mono-objective optimization applied to the layout of a RF silicon-based planar spiral inductor. Section 5 presents the uses of multi-objective algorithm to optimize both the maximum quality factor and to minimize the device area of the RF inductor with three multi-objective algorithms: the multi-objective particle swarm optimization (MOPSO), the Pareto Envelope-based Selection Algorithm II (PESAII) and the Multi-Objective Evolutionary Algorithm based on Decomposition (MOEA/D). A comparison of its performance's meters is concluded. Finally, Section 6 wrap up the final remarks, conclusion and future works.

2. An overview on the mono-objective metaheuristics

2.1. Differential Evolution algorithm

In 1997, Storn and Price developed the differential evolution (DE), which belongs to evolutionary algorithm category. It is an effective, robust and simple global optimization algorithm [13].

Differential evolution algorithm is similar to the genetic algorithm [25], uses similar genetic operators like crossover, mutation and selection operators. Comparing both algorithms, the best solutions achieve are dependent of the process, the genetic algorithm relies on crossover operators while the differential evolution algorithm on the mutation operation (differential strategy) [26]. DE generates new candidates (trial vectors) of its population according to target vector manipulation and difference vector. Afterwards, it compares the performance of the resulting candidate against the original members, and if it shows to have a better solution, it changes it; else, keep the original candidate. The differential evolution algorithm technique uses three operators: mutation, crossover and selection.

2.1.1. Mutation Operator

The *mutation* operator is defined as follows:

$$V_i^{k+1} = X_{r1}^k + F\ (X_{r2}^k - X_{r3}^k) \tag{1}$$

Where V^{k+1} is the i^{th} trial vector produced by the mutation strategy; k represents the generation to which the population belongs; $r1$, $r2$, and $r3$ are mutually exclusive integers arbitrarily generated from 1 to N (N is the population size) and F is a scaling factor with optimal value in the range of *0.5 to 1.0*.

2.1.2. Crossover Operator

One the *mutation* operation is done, the crossover operator is applied to maintain the miscellany of the population. The crossover operator generates the offspring individual U_i at the k^{th} generation by selecting the solution component values from X_i or V_i, using the following equation (2):

$$U_{ij}^{k+1} = \begin{cases} V_{ij}^{k+1}\ if\ \ rand \le CR \\ X_{ij}^k\ otherwise, \end{cases} \tag{2}$$

where CR: the crossover probability $\in [0, 1]$.

2.1.3. Selection Operator

The selection operator is adopted to compare the trial vector U_i^k with the target vector X_i^k if the fitness of the trial vector is more suitable than the target vector. Such operation, which occurs every k^{th} generation, is presented in equation (3):

$$X_i^{k+1} = \begin{cases} U_i^k\ if\ f(U_i^k) \le f(X_i^k) \\ X_i^k\ otherwise, \end{cases} \tag{3}$$

where f: the fitness function.

The flowchart of DE algorithm is given in Figure 1.

2.2. Gravitational Search Algorithm

In [22, 23], the authors proposed the gravitational search algorithm as a new swarm intelligence metaheuristic. This metaheuristic is based on Newton's laws of gravity and motion. In GSA, a cluster of agents (solutions) named masses are used to solve and find the optimal solution (best agent). Based on the gravitational force, where all objects are attracted among each other, and this force causes a global movement of such objects towards objects with heavier masses [23]. The weightier masses, representing the best solutions, are known for moving slowly compared to those less heavy. The GSA is represented by N agents, where the position of the i^{th} object is defined with (4):

$$X_i = (x_i^1, ..., x_i^d, ..., x_i^N) \text{ for } i = 1, 2, ..., N \tag{4}$$

where x_i^d is the position of ith object in the d^{th} dimension and N is dimension of the problem to be optimized.

The mass values of every objects are defined by (5):

$$M_i(t) = \frac{fit_i(t) - worst(t)}{\sum_{j=1}^{N} (fit_j(t) - worst(t))} \tag{5}$$

where $fit_i(t)$, $M_i(t)$ represents the fitness value and the mass value of the object *i* at *t*, and $worst(t)$ is evaluated by (6):

$$worst(t) = \max_{j\in\{1,\ldots,N\}} fit_j(t) \tag{6}$$

To estimate the total forces and the acceleration of an agent, it should be evaluated over gravity law, equation (7), then equation (8). Resulting, the new velocity is calculated by equation (9) and the new position is computed by equation (10).

$$F_i^d(t) = \sum_{j\in kbest, j\neq i} rand_j G(t)\frac{M_j(t)M_i(t)}{R_{ij}(t)+\varepsilon}(x_j^d(t)-x_i^d(t)) \tag{7}$$

$$a_i^d(t) = \frac{F_i^d(t)}{M_i(t)} = \\ = \sum_{j\in kbest, j\neq i} rand_j G(t)\frac{M_j(t)}{R_{ij}(t)+\varepsilon}(x_j^d(t)-x_i^d(t)) \tag{8}$$

$$v_i^d(t+1) = rand_i \times v_i^d(t) + a_i^d(t) \tag{9}$$

$$x_i^d(t+1) = x_i^d(t) + v_i^d(t+1) \tag{10}$$

where $R_{ij}(t)$ is the Euclidian distance between two agents, *i* and *j* defined as $R_{ij}(t) = \| X_i(t), X_j(t) \|_2$. k_{best} is the set of first *K* agents with the best fitness value and biggest mass. k_{best} is a function of time, which is initialized to k_0 at the beginning and is decreased with time. k_0 is adjusted to *N* and reduced linearly to 1. Moreover, *G* is reduced in a exponentially way from G_0 toward zero by time.

The flowchart of GSA algorithm is given in Figure 2.

2.3. Particle swarm optimization

The particle swarm optimization algorithm is a swarm-intelligent metaheuristic proposed by Kennedy and Eberhart [15]. PSO is an optimization algorithm that describes the social behavior of animals like birds and fish in search of food.

In PSO, each particle (solution) flies through the design/search space and moves randomly in the following three simple rules:

- Cohesion: the particles are attracted to the average position of the group or best position 'p_{best}';
- Alignment: the optimal value attained until here via every particle in the social neighbourhood 'l_{best}',
- Separation: to avoid collisions, particles keep a certain distance between them, the optimal particle position found in all the swarm 'g_{best}'.

Therefore, the new velocity and the particle position on the next iteration are performed through equations (11) and (12):

$$\vec{v}_{k+1}^{i} = \omega_k \vec{v}_k^{i} + c_1 r_1(\vec{p}_k^{i} - \vec{x}_k^{i}) + c_2 r_2(\vec{p}_k^{g} - \vec{x}_k^{i}) \tag{11}$$

$$\vec{x}_{k+1}^{i} = \vec{x}_k^{i} + \vec{v}_{k+1}^{i} \tag{12}$$

ω_k is an inertia weight, defined via a decreased inertia function by equation (13) in the training progress for objective the reduction of the influence of the past velocities.

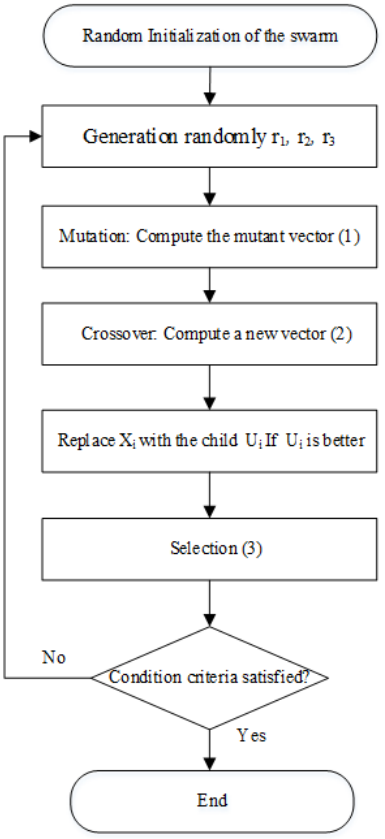

Figure 1: DE Flowchart

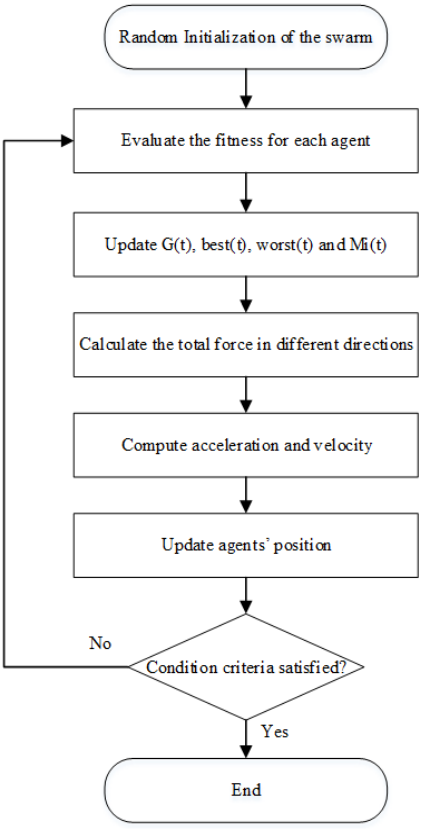

Figure 2: GSA Flowchart

Where

c_1 : the cognition learning rate,

c_2 : the social learning rate,

p_k^i : the best individual position,

p_k^g : the best global position,

$r_{1,2}$: two random parameters $\in [0,1]$.

$$\omega_k = \omega_k^{max} - \frac{\omega_k^{max} - \omega_k^{min}}{total_iter} iter \quad (13)$$

where

ω_k^{max} : the initial weight,

ω_k^{min} : the final weight,

total_iter: the number of the total iteration,
iter: the number of the current iteration.

The flowchart of PSO algorithm is given in Figure 3.

3. Application examples: the mono-objective problems

A. Benchmark function

Three mono-objective metaheuristics are used respectively the DE, GSA and PSO over three benchmark functions. A robustness study regarding the aforementioned metaheuristics is presented. The parameters used to characterize the three algorithms are shown in Tables 1, 2 and 3. For simulation and study proposes, the three metaheuristics were tested 100 times for each one of the benchmark functions.

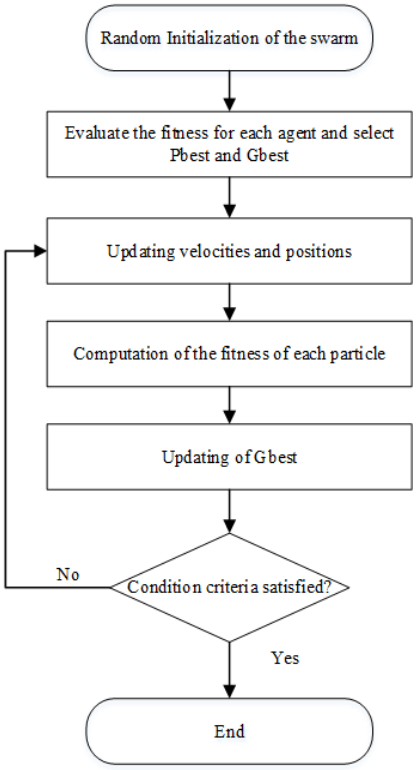

Figure 3: PSO Flowchart

Table 1: The DE parameters

Population size	*Number of Iterations.*	*beta_min*	*beta_max*	*CR*
100	1000	0.2	0.8	0.2

Table 2: The GSA parameters

Number of agents	*Number of Iterations.*	*Elitist Check*	*Rpower*	*min_flag*
100	1000	1.0	1.0	1.0

Table 3: The PSO parameters

Swarm size	*Number of Iterations.*	*w*	*c1*	*c2*
100	1000	1.0	1.5	2.0

3.1. Benchmark function application

In object to check performances of such mono-objective metaheuristics, a bunch of commonly used benchmark functions, considering this sort of problems/algorithms, were used [24]. These problems permit testing these mono-objective algorithms to confirm their convergence, concerning the approximation to the global solution [8, 18, 24]. The set of three benchmark functions are offered in Table 4.

Table 4: The benchmark functions

Item Function	*Objective functions to minimize*
Function #1	$F1 = \sum_{i=1}^{n} x_i^2$ Range: [-100; 100]; Dim n=2
Function #5	$F5 = \sum_{i=1}^{n-1} [100(x_{i+1} - x_i^2)^2 + (x_i - 1)^2]$ Range: [-30; 30]; Dim n=2
Function #7	$F7 = \sum_{i=1}^{n} [1:dim].*(x_i^4) + rand$ Range: [-1.28; 1.28]; Dim n=2

3.2. Optimization results

Function F1

The results of the benchmark function F1 are compared via the correspondent three optimization algorithms, as illustrated in Figure 4.

A Boxplots representation is used (due to probabilistic characteristic of these metaheuristics) to display the distribution of obtained measures [27]. In the following, 100 runs are considered for this function. The robustness analysis using the box-plot for the benchmark function F1 is presented in Figure 5.

Function F5

The results of the benchmark function F5, via the correspondent three optimization algorithms, are represented in Figure 6.

In the following, 100 runs are considered for function F5. The robustness analysis using the box-plot for the benchmark function is presented in Figure 7.

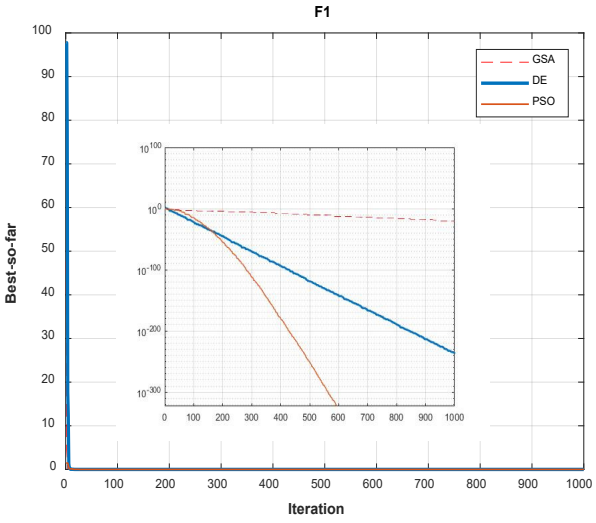

Figure 4: Convergence results of F1 with GSA, DE and PSO.

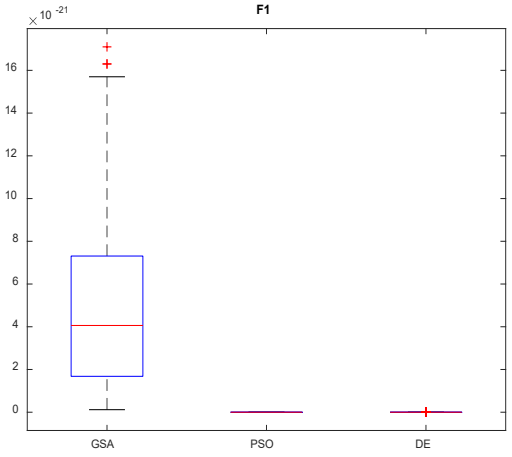

Figure 5: Robustness analysis of F1

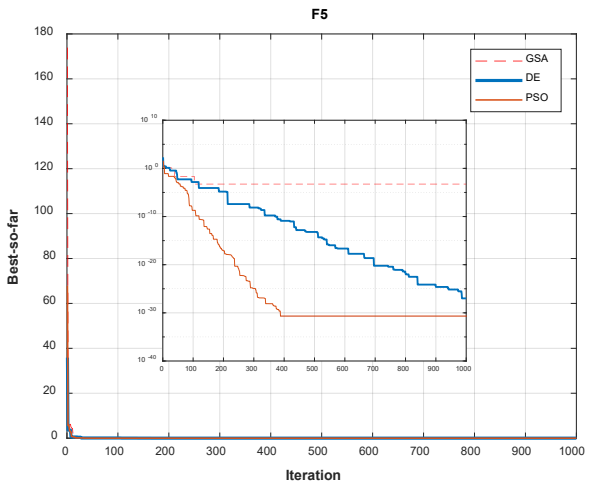

Figure 6: Convergence results of F5 with GSA, DE and PSO.

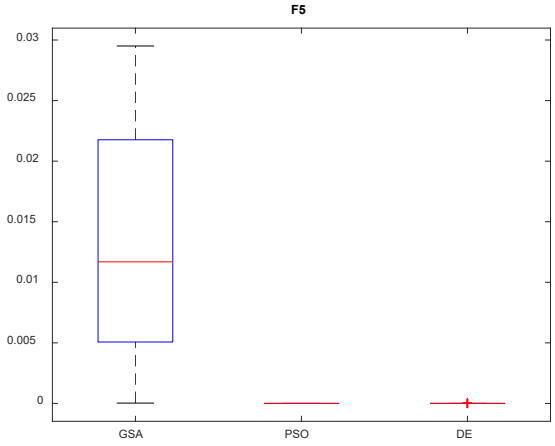

Figure 7: Robustness results of F5.

Function F7

The optimization results of the benchmark function F7, via the corresponding three algorithms, is illustrated in Figure 8. 100 runs are considered for function 7. The robustness analysis using the box-plot for the benchmark function F7 is presented in Figure 9.

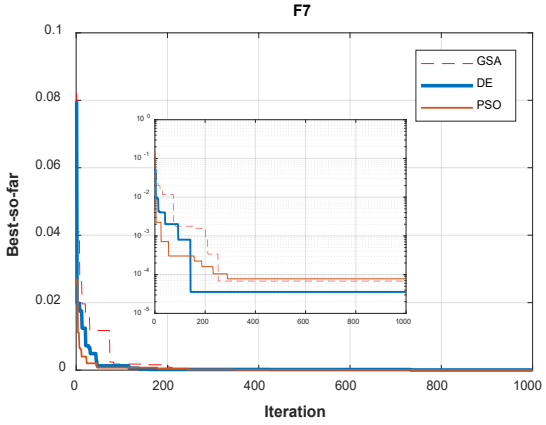

Figure 8: Convergence results of F7 with GSA, DE and PSO.

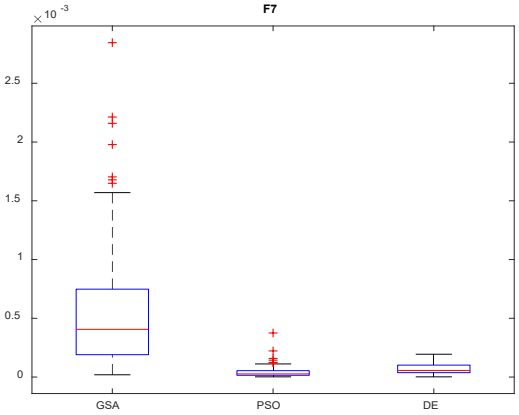

Figure 9: Robustness results of F7.

Figure 10 presents a Radio Chart representation of the average (AVG) execution times over 100 runs of three algorithm GSA, DE and PSO for the three benchmark functions.

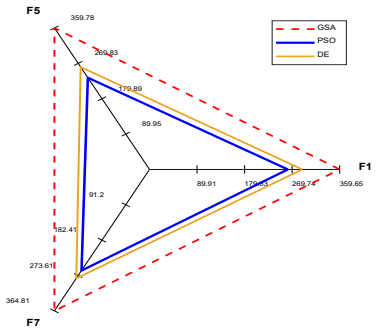

Figure 10: The average computing time of GSA, DE and PSO.

In accordance with the convergence of results regarding the three mono-objective metaheuristics according to the three benchmarks functions (Figures 4, 6 and 8) and the robustness results displayed in Figures 5, 7 and 9, we notice that DE and PSO have the better results compared to GSA.

The average executing time is illustrated in Figure 10. This figure shows that PSO is faster than DE and GSA.

Therefore, and according to the results achieved, the PSO algorithm is the most efficient algorithm, as it presents a best compromise among convergence, robustness and computational time.

B. Application example: RF spiral inductors

a. An overview on the integrated spiral inductors

CMOS technology is nowadays the only option able to fit the low-cost demand and to integrate digital, as well as analog radio-frequency (RF) modules on a single chip to realize the RF system on-chip (SoC). The efficiency and reliability of CMOS-RF blocks can be improved by means of on-chip passive devices (same substrate), such as voltage-controlled oscillators (VCO), low-noise amplifiers (LNA) and especially CMOS spiral inductor. Spiral inductor is broadly used and their applications in millimeter-wave circuit are investigated. High performance on-chip inductor has become increasingly important with their increasingly frequencies operation of the circuits.

Integrated spiral inductors models are based on the layout parameters, as displayed in Figure 11. These parameters are:

- w: the inductor width,
- s: the spacing between track,
- n: the number of turns,
- N_{side}: the inductor shape (square, hexagonal, octagonal),
- d_{in}: the internal diameter,
- d_{out}: the external diameter.

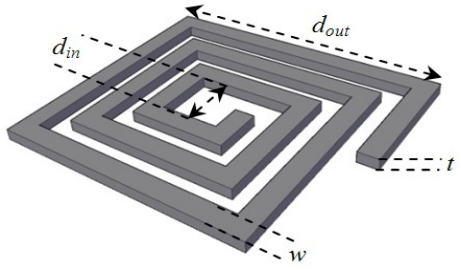

Figure 11: Layout characteristics for a square inductor.

For assessing the quality of the inductor design, different characteristics may be considered: the quality factor (Q), the operation frequency for the maximum Q, the self-resonant frequency f_{SR}, the inductance value L or the area. In this work, two parameters are selected: the quality factor Q and the device area d_{out}. Therefore, all the abovementioned characteristics are strongly dependent on the spiral inductor geometric parameters, technological constraints parameters and the application of this RF inductor.

At high frequencies, the simple but widely used single-π equivalent-circuit model can't accurately characterize the electrical performance of silicon-based planar spiral inductor. Many other equivalent-circuit inductor models have been reported in past decade [28]. In this paper, the double-π model is adopted and illustrated in Figure 12. This model lumped-element is evaluated with a wide range of equations and these values are specified in [29-30]. This model is represented by:

- DC parameters (Rs, Rp, Lo, Lp);
- Crossover capacitance, Cs: referred as the capacitance between the spiral and the underpass required to connect the outside to the inner turn of the planar inductor;
- Metal-to-metal capacitance, Cc: effect due to the proximity of inductor tracks;
- Metal-to-substrate capacitance, Cox;
- Rsub and Csub: the ohmic losses in the conductive silicon substrate;
- Rsc: the electric coupling between lines over the conductive substrate.

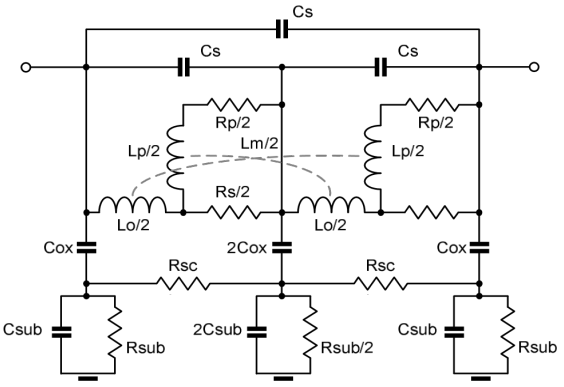

Figure 12: Inductor double π-model.

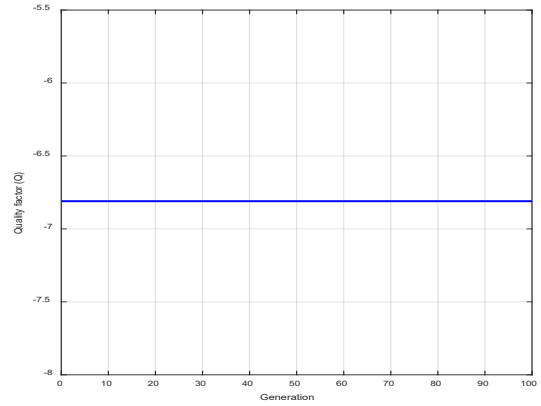
Table 5: Physical parameters

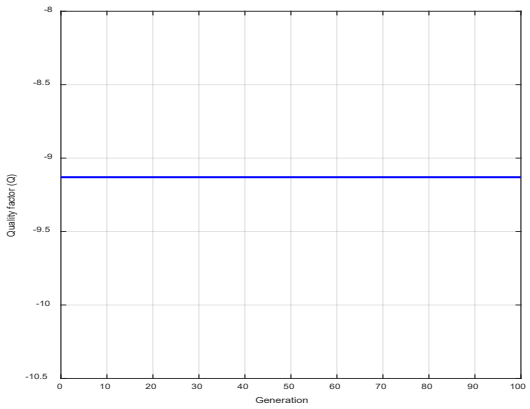
Parameters	Value
Metal Thickness (t)	2.8 µm
Space between turns (s)	2.5 µm
Sheet Resistance	10 mΩ/□
Oxide Thickness	5.42 µm
Oxide Thickness between spiral and underpass	0.26 µm
Oxide Permittivity (ε_r)	4
Substrate Thickness	700 µm
Substrate Permittivity (ε_r)	11.9
Substrate Resistivity	28 Ω cm

b. Optimization results



In this section, results highlight the ability of the PSO algorithm to perform the spiral inductor on Silicon technologies, the UMC130 technology is addressed. The conception for two inductors with 5.0 nH value, 6 nH value operating at 0.7 and 1 GHz, respectively, is considered. The technological and physical parameters are presented in Table 5, whereas the determination of the layout parameters is enabled with the uses of the constraint's parameters or technology constraints represented in Table 6. In addition, is considered a minimum space between tracks (s) of 2.5 µm and a maximum output diameter dout of 250 µm.

Table 6: Constraints parameters



Parameters	Min	Max
w (µm)	5.0	20.0
d_{in}(µm)	20.0	80.0
n	1.5	15.5

The inductor quality factor Q, desired to be higher as possible, is the objective function to be optimized.

Figures 13 displays the optimization results with PSO algorithm (13.a, 13.b) for two inductors: the first inductor of 5.0 nH value operating at 0.7 GHz and the second inductor of 6 nH value operating at 1 GHz. The maximization of the quality factor Q is addressed.

(a)

(b)

Figure 13: Optimization results with PSO (Quality factor Q vs. Generation): (a) 5 nH, frequency= 0.7 GHz, (b) 6 nH, frequency= 1 GHz.

Table 7 gives the optimization results values (inductor sizes) with PSO algorithm.

Table 7: Optimization and simulation results

L = 5nH, Frequency = 0.7 GHz					
Algorithm	w (µm)	d_{in} (µm)	n	$d_{out\text{-}Op}$ (µm)	Q_{Op}
PSO	10.88	60.40	5.67	206.91	6.81
L = 6nH, Frequency = 1.0 GHz					
Algorithm	w (µm)	d_{in} (µm)	n	$d_{out\text{-}Op}$ (µm)	Q_{Op}
PSO	9.00	61.90	6.08	196.90	9.13

4. Application examples: the multi-objective Optimization Algorithms

4.1. The multi-objective particle swarm optimization

Multi-Objective Particle Swarm Optimization (MOPSO) is proposed by Coello *et al*., [31]. The goal of the MOPSO and generally all the multi-objective algorithms is to provide a set of Pareto optimal solutions (with non-dominated solutions) of the aforementioned problem. All the non-dominated particles, this means all solutions, in the swarm are then collected into a sub-swarm named *repository*, and each particle selects its global best target. A group of MOPSO can be found in related literature, like:

- The non-dominated sorting PSO [32],
- The MOPSO using the Crowding Distance mechanism associated with a mutation operator which increasing the exploration ability of the particles and maintains the diversity of non-dominated solutions in the external archive by MOPSO-CD [33-35],
- The MOPSO using the Crowding Distance mechanism associated with a mutation operator and the Roulette Wheel selection technique to select social leader or global best to avoid an excessive number of non-dominated solutions in the external archive MOPSO-CDR [36].

The MOPSO version used in this paper use the Grid Making technique, instead of the crowing-distance computation which requires sorting the population consistent with each objective function value in ascending order of magnitude. This version uses the Grid Making technique with the mutation operator and the Roulette Wheel selection called MOPSO-GMR [37]. The flowchart of MOPSO algorithm is given in Figure 14.

4.2. Multi-Objective Evolutionary Algorithm based on Decomposition

The multi-Objective Evolutionary Algorithm supported on Decomposition (MOEA/D) is an evolutionary algorithm. The MOEA/D has adopted a technique that consists in decomposing the multi-objective optimization problems into several single-objective, called sub-problems. Each sub-problem has its own best solution ever found which is determined associating all of solutions found by algorithm. There are several methods to define the decomposed objective functions, for example: the weighted sum,

the distance or the norm of difference vector, the predefined ideal point in the objective space. The MOEA/D algorithm is developed by Zhang and Li [38]. The flowchart of MOEA/D algorithm is given in Figure 15.

4.3. Pareto Envelope-based Selection Algorithm II

The third multi-objective algorithm is an evolutionary algorithm: Pareto Envelope-based Selection Algorithm II (PESA-II). The PESA-II is based in the same genetic algorithm mechanism associated with the selection based on Pareto envelope. The PESA-II is configured with an external archive to save the approximate Pareto solutions. This means that the Parents and the mutants are selected based on the grids created as well as in the geographical distribution of archive members (external archive) [39].

The general process of the PESAII algorithm is as follows, with IP is the size of the internal population and EP is the size of the external populations(archive). The flowchart of PESAII algorithm is given in Figure 16.

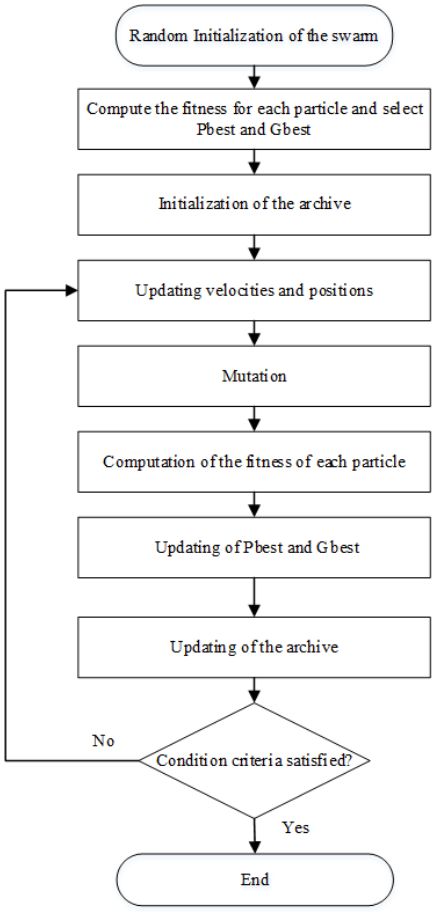


Figure 14: MOPSO Flowchart

4.4. Performances metrics: Hypervolume (HV)

The quality of the Pareto Fronts obtained by the multi-objectives algorithms can be evaluated through a few metrics. The most used performance metric was the *hypervolume* (HV) metric, also known as *S-metric* or *hyper-area*. The hypervolume indicator considers all three aspects: accuracy, diversity and cardinality.

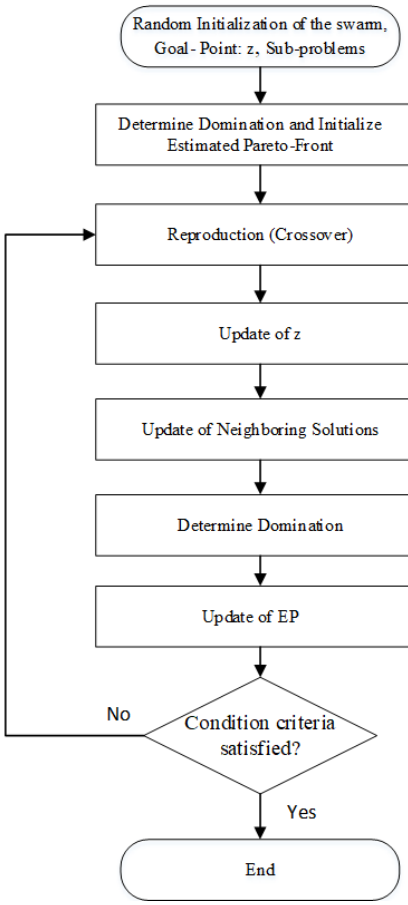

Figure 15: MOEA/D Flowchart

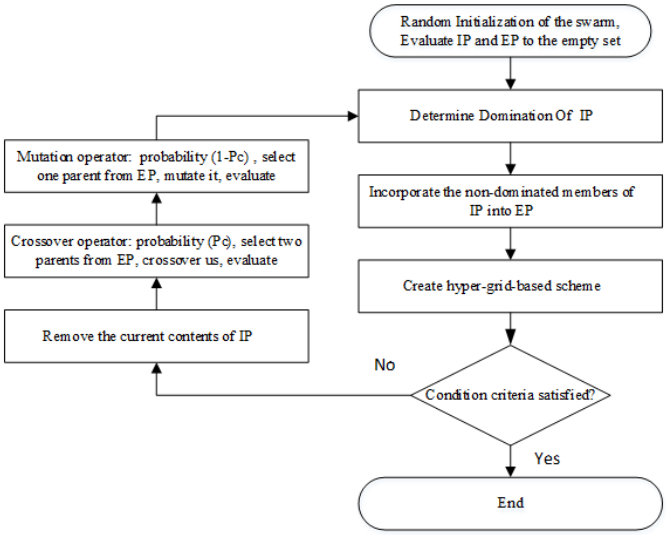

Figure 16: PESAII Flowchart

Thus, it is possible to measure the size of the objective space enclosed by an approximation set. To compute such enclosed space a reference point must be adopted. Figure 17 display a graphical representation of this performance indicator. Whenever one approximation set completely dominates another approximation set, the first HV will be superior than the second. Therefore, the HV is supposed to be *Pareto compliant* [40-41].

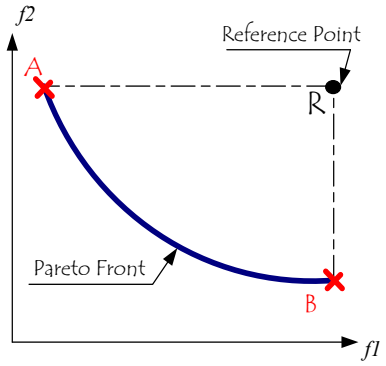

Figure 17: Example of the dominated Hypervolume in 2D.

4.5. Results of the test function and RF inductor applications

The aim consists of optimizing two conflicting performances: maximizing the Quality factor Q, and minimizing the device area, d_{out} by generating the trade-off surface (Pareto front). We give optimization results using the well-known PESAII and MOEA/D techniques for a RF inductor with value of 6 nH at 1 GHz. Also, two test function of ZDT family are used for benchmarking the performance of multi-objective Pareto optimization methods are illustrated in table 8.

Table 8: Multi-objective benchmark functions of Zitzler (ZDT)

Item Function	Objective functions to minimize
ZDT1 Objectives=2 Range: [0; 1]; Dim n=30	$f_1(x) = x_1$ $f_2(x) = g(x)\left[1-\sqrt{\frac{x_1}{g(x)}}\right]$ $with\ g(x) = 1+9\left[\frac{\sum_{i=2}^{n} x_i}{(n-1)}\right]$
ZDT6 Objectives=2 Range: [0; 1]; Dim n=10	$f_1(x) = 1-e^{(-4x_1)}\sin^6(6\pi x_1)$ $f_2(x) = g(x)\left[1-(\frac{f_1(x)}{g(x)})^2\right]$ $with\ g(x) = 1+9\left[\frac{\sum_{i=2}^{n} x_i}{(n-1)}\right]^{\frac{1}{4}}$

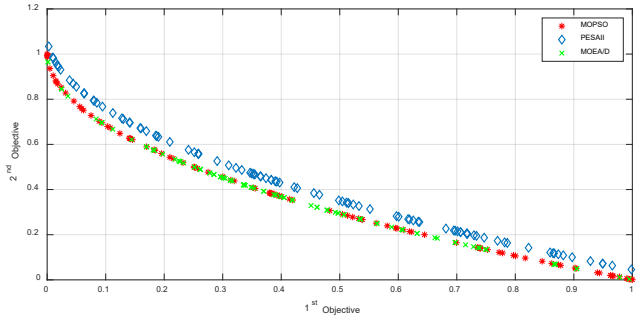

Figure 18: Pareto Front (MOPSO vs. PESAII vs MOEA/D) for ZDT1.

Figure 18, 19 and 20 represents the Pareto fronts obtained using MOPSO, PESAII and MOEA/D for ZDT1, ZDT6 and RF inductor application, respectively. Where it can be noticed that the better distribution given by MOPSO, when compared to PESAII and MOEA/D.

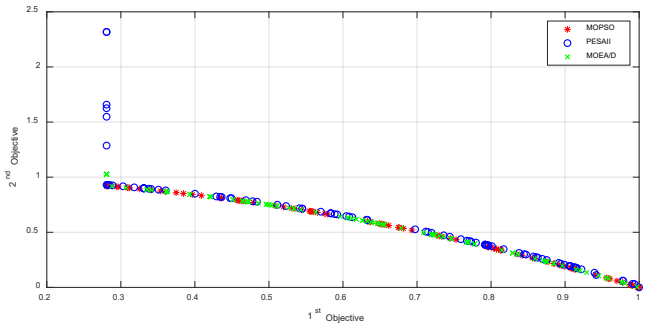

Figure 19: Pareto Front (MOPSO vs. PESAII vs MOEA/D) for ZDT6.

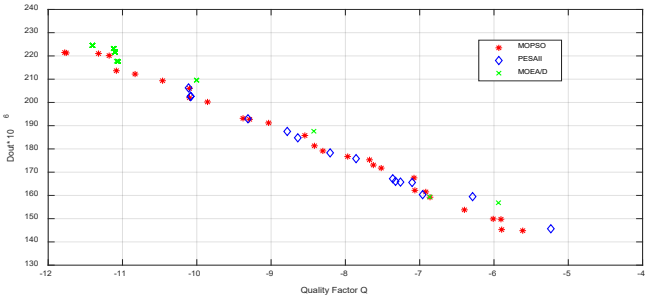

Figure 20: Pareto Front (MOPSO vs. PESAII vs MOEA/D) for RF inductor.

4.5.1. The hyper-volume indicator HV

Table 9 presents the average, maximum, minimum, and deviation values of the hypervolume indicator, over 20 runs of each algorithm, for two test function ZDT1, ZDT6 and the RF inductor application.

Table 9: Average, max, min, and standard deviations of the hypervolume indicator

		PESAII	MOEA/D	MOPSO
ZDT1	Avg	0.6918	0.7291	0.7587
	Max	0.7087	0.7563	0.7609
	Min	0.6643	0.6488	0.7558
	Std	0.0139	0.0346	0.0019
ZDT6	Avg	0.4782	0.4506	0.4869
	Max	0.4873	0.4843	0.4893
	Min	0.4675	0.3840	0.4849
	Std	0.0063	0.0577	0.0016
RF Inductor	Avg	0.5235	0.3272	0.5496
	Max	0.5260	0.4113	0.5508
	Min	0.5196	0.2663	0.5476
	Std	0.0025	0.0577	0.0017

Figure 21 represents the average value of the HV indicators for the 3 multi-objective problems. As a consequence, the MOPSO algorithm admits the highest average value of the HV indicator.

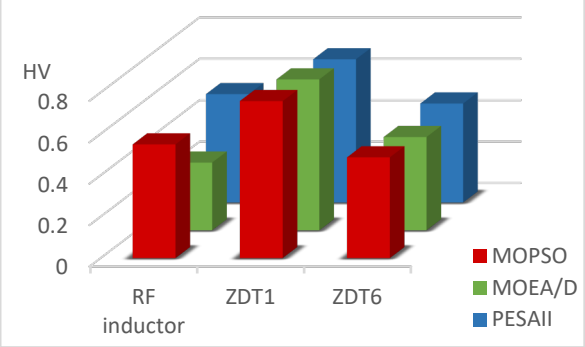

Figure 21: Average values of the HV indicators for the 3 multi-objective problems

4.5.2. *Computing time*

The maximum and the minimum execution times over 20 runs of each algorithm, is given in Table 10. Figure 16 displays the average value of the execution times.

Table 10: Average, Max and Min of the execution time

Time(S)		PESAII	MOEA/D	MOPSO
ZDT1	Avg	152.69	278.48	62.94
	Max	157.56	281.77	73.90
	Min	149.64	275.02	55.67
ZDT6	Avg	130.46	281.47	58.55
	Max	137.07	294.05	66.35
	Min	125.49	268.88	54.36
RF Inductor	Avg	105.91	166.25	54.71
	Max	106.53	221.28	58.07
	Min	105.28	141.38	51.58

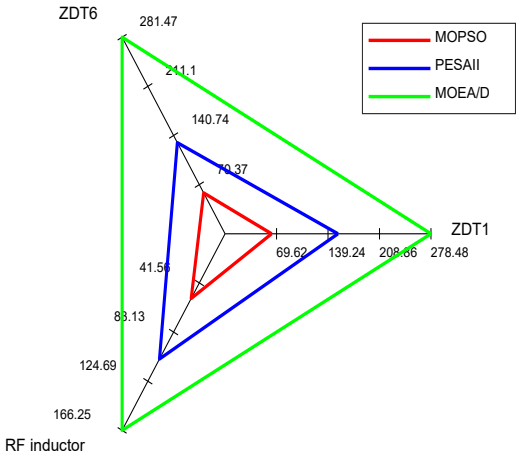

Figure 22: AVG execution time considering the three multi-objective problems

A comparison of the execution times is illustrated using the Radio Chart representation (figure 12) aiming to highlight the speediness of each algorithm. It can easily conclude that MOPSO is the faster when compared with other metaheuristics.

5. Conclusion

An objective comparison among the optimization results obtained via multiple-objective metaheuristics, dealing with performance optimization of RF circuits, is presented in this work. In first part, mono-objective metaheuristics are used. Among these metaheuristics the Swarm Intelligence metaheuristics like the Particle Swarm Optimization (PSO) and the Evolutionary Algorithms such us the Gravitational Search Algorithm (GSA) and the differential evolution algorithm (DE). These three algorithms were used to optimize three benchmark functions and the RF integrated inductors configured with the inductor double π-model. Results obtained shows that the use of swarm-based techniques in sizing and designing RF circuit offers a good argument, principally the PSO algorithm. In second part of this paper, we applied the multi-objective technique to solve two conflicting performances problem: the quality factor (Q) maximization as well as the minimization of the device area (dout) of the same RF application example using three multi-objective algorithms: firstly the multi-objective particle swarm optimization (MOPSO); secondly the multi-objective Evolutionary Algorithm based on decomposition (MOEA/D) and, a third one, the Pareto Envelope-based Selection Algorithm-II (PESA-II) by generating the trade-off surface (Pareto-front). The results obtained, which are supported by two performance metrics, a) the hypervolume indicator (HV) and b) the execution time, shows the following: MOPSO is better than other metaheuristics according to HV indicators, also MOPSO is the faster than other metaheuristics according to the CPU computing times.
