Editorial

The Special Issue on *Advancement in Engineering and Computer Science (2019)* in the *Advances in Science, Technology and Engineering Systems Journal (ASTES Journal)* presents a comprehensive and contemporary collection of research that underscores the deepening synergy between engineering disciplines and computer science. The year 2019 marked a period of accelerated integration, where computational intelligence, data-driven methodologies, and software-centric approaches became central to innovation across engineering domains. This special issue captures these developments by bringing together contributions that reflect both the theoretical foundations and practical implementations shaping the future of engineering and computing.

A defining theme of this issue is the pervasive role of computational technologies in transforming engineering practice. Advances in artificial intelligence, machine learning, and data analytics have enabled engineers to design systems that are more adaptive, efficient, and capable of handling complex, real-time challenges. The research presented explores applications of these technologies in areas such as predictive modeling, system optimization, image and signal processing, and intelligent control systems. These approaches have significantly enhanced the ability to analyze large datasets, automate decision-making processes, and improve overall system performance.

The issue also highlights the rapid evolution of software engineering and its critical role in supporting modern technological systems. Contributions examine innovative software architectures, algorithmic developments, and programming frameworks that facilitate the development of scalable, secure, and high-performance applications. From cloud computing and distributed systems to cybersecurity and software reliability, the studies demonstrate how advancements in computer science are enabling more robust and flexible engineering solutions.

Another important aspect addressed in this special issue is the integration of hardware and software systems. The convergence of embedded systems, Internet of Things (IoT) technologies, and cyber-physical systems has led to the development of intelligent environments where physical processes are seamlessly connected with computational platforms. The research showcases how such integration enables real-time monitoring, control, and optimization in applications ranging from smart infrastructure and industrial automation to healthcare and environmental monitoring.

Innovation in computational modeling and simulation is also prominently featured. The use of advanced numerical methods, simulation tools, and virtual prototyping techniques has become essential for analyzing complex engineering systems and reducing development time and cost. The contributions illustrate how these tools are being applied to improve design accuracy, enhance system reliability, and support informed decision-making across various engineering fields.

The editorial team expresses its sincere gratitude to the authors, reviewers, and contributors for their valuable efforts in making this special issue possible. Their dedication has ensured the publication of high-quality research that advances both engineering and computer science. The works presented in this issue reflect a continuing shift toward intelligent, interconnected, and software-driven systems, offering meaningful insights and inspiration for future research and technological advancement.

Data analysis

ABSTRACT

With the development of big data, artificial intelligence and deep learning, various social information networks are becoming exponentially intelligent. Of all the various social networks, YouTube is so popular that it is called the YouTube era. Not only video viewers, but also actual video producers, influencer youtubers, are increasing, allowing individuals as well as operators to use and market contents on various topics. As the number of users and contents increases, the choice of information increases, but it is more difficult for individual and business owners to select information that meets their needs. Therefore, this study aims to analyze the channel of the subject that the user needs from various angles and provide the ranking of the channel to individuals and businesses. We crawl the channels and measure the average awareness and influencer youtuber of channels and channel videos by analyzing the qualitative data of quantitative data and comments which are statistical information. As a final case study, we recommend the English learning channel to individual users based on numerical data statistics and emotional analysis results to show the maximum of flipped learning effect regardless of time and space. Plus, we prove the maximum of the effectiveness of marketing by influencer channel which is influential to operators in the medium and long term.

1 Introduction

There are about 3.4 billion people using social media (SNS) among 7.6 billion people worldwide. Compared with the year 2018, about 280 million people started the SNS within a year. Especially with the development of big data, artificial intelligence and deep learning, various social information networks are becoming exponentially intelligent. One of them, YouTube is the most famous social platform for satisfying various objects such as users as well as businesses on top of the recommender system. However, as the development of technology and the emergence of big data have caused the exponential growth of YouTube channels, users are having difficulties in selecting personalized videos. In other words, users have difficulty in selecting a channel on top of the basic recommendation of YouTube, and they spend additional time searching for a good channel or comparing contents directly [1]–[4]. In aspects of the business operator, the new influencer marketing on top of YouTube data analysis is also emerging as a new and successful marketing strategy. Influencers are influential individuals, which can include the general public as well as entertainers and SNS stars. Using the recommedation on top of the influencer aware YouTube data analysis, the general public can easily consume the contents and at the same time be satisfied with the content.

As the application case studies based on influencer aware YouTube data analysis, in this paper we introduce the possibility of the flipped learning maximization of user education as well as business marketing satisfaction.

Regardless of age, interest in lifelong education has increased in various fields such as English and Chinese, and various contents based on smartphone such as internet lecture, radio, and learning application are attracting attention. As the number of smartphone users increases, demand for online content is growing more than offline. However, since the above-mentioned online service requires the motivation of the user to voluntarily learn, the more the time passes, the less motivated and the less interested in learning.

The popularity of the YouTube-based beyond time and space learning is increasing due to the characteristics of these

[*]Corresponding Author: Hayoung Oh, Address, Contact No & hyoh79@gmail.com

online learners. Internet lectures are similar to flipping learning in pedagogy, which is not an existing concept of 'off-line class', but can be learned anytime and anywhere by transcending time and space. In particular, Youtube provides big data that can be analyzed statistically of videos that are composed by influencer Youtuber in a free environment and have lots of choices in social network, so it can maximize the effect of flipped learning education. In other words, influencer aware YouTube video ranking based education does not require as much concentration as text-oriented education, and users can use it for free time very effectively. In particular, influencer aware YouTube video ranking based online education can maximize the effectiveness of education because it shows the candid reviews of ordinary users and the cases that are natural but helpful in real life on top of big data analysis quantitatively and qualitatively. Similar to the general online education methodologies, the influencer YouTube aware flipped learning education can solve the physical limitations and anyone can be educated in real time or streaming (pre-recorded streaming).

In aspects of the business operators, influencer aware YouTube data analysis based the marketing has become a new and solid strategy. As of February 2017, people spent 25.7 billion minutes on YouTube, a video platform. This shows that YouTube spending time has more than tripled in the past two years compared to 2015. In other words, research in video and photo-based YouTube influencers analysis techniques is critical in aspects of users and businesses, as it indicates that people are more interested in video content than text content over time. Specifically, if the business operators recommend the personalized video to the users by referring the features of influencer YouTuber with high quantitative and qualitative data analysis, the satisfactions of the users as well as businesses can be maximized. Different from the previous related schemes of YouTube big data anlysis, we consider velocity, veracity(Truth), value as well as volume and variety among five characteristics of big data.

As a result, in this paper, we propose an influencer aware YouTube ranking scheme for the channel recommendation technique to maximize the satisfaction of users as well as the businesses. As mentioned before, we show the flipped learning effect through explicit and implicit analysis of various data of the influencer provided by YouTube centering on the YouTube English learning channel. Based on numerical data such as the number of views and likes of channels collected by using Google and R's tuber package for four channels with the same ranking of the social channel. The primary statistic is given and those of positive and negative are calculated through emotional analysis of the comment. Finally, based on the numerical data statistics and emotional analysis results, the English learning channel is recommended to the user to maximize the flipped learning effect and the business satisfaction regardless of time and space. In future, the proposed method can be used for flipped learning of various contents because it can be used for analysis of big data of influencer aware YouTube channel in various fields as well as language field.

2 Related Work

Recently, in an environment where big data has grown exponentially, personalized recommendations are a great way to efficiently search for information and discover content with high satisfaction.

2.1 Recommender system

Based on how designing recommender systems, the recommendation systems are usually classified into the following categories [5]–[8]: Collaborative recommendation systems; Content-based recommendation systems; and Hybrid recommendation systems.

Collaborative filtering is currently the most wise and popular approach because of focusing more on rating-based recommendations. The collaborative methods predict the utility, preference or taste of items per a particular user using the items previously rated by other users as shown in figure 1.

On the other hand, content-based approaches are generally based on classical information retrieval such as keywords as content descriptors. Therefore, the content-based methods are very popular for recommending documents, news articles or web pages. Lastly, the hybrid systems [9, 10] is to combine two or more different approaches to maximize desirable properties.

	$Item_1$	$Item_2$	$Item_3$	...	$Item_n$
$User_1$	0	3	4	...	5
$User_2$	1	1	2	...	?
:	:	:	:	...	:
$User_m$	4	?	5	...	4

Figure 1: Collaborative recommendation systems

2.2 Social Network aware Recommender system

Youtube, which efficiently provides dynamic data such as video among various contents, is gaining popularity around the world. Although a basic recommendation system on the YouTube platform is installed to recommend high-profile videos, personal satisfaction is not high. Three factors can be used to determine ranking of recommendation systems. These are each of video quality, user specificity and diversity. The quality of the video includes quantitative information such as views, comments, favorites, upload time, and so on. User specificity is related to individual taste and preference. The way to check this is to consider the number of views or watch time of the watch record. Thereafter, in order to maintain the diversity of the video, there is a method of limiting the number of videos of the same channel [11]. In [12], the authors designed the recommendation system in consideration of the factors. In [13]–[16], different studies have attempted to verify the significance of influencer decision through R-based data analysis rather than heuristic

judgment. In this case, the data commonly used are nine characteristics (i.e., features) such as total number of views of the channel, number of videos of the channel, average number of videos views of the channel, number of channel subscribers, likes and dislikes of each video. In [13], the authors tried to normalize covariance of each variable and analyzed the correlation between each variable with views of the subordination variable. Plus, they proved that the average number of views on the channel and the number of subscribers on the channel had a positive relationship with the number of views. However, the degree of correlation was insufficient, and the statistical data alone have limitations in producing significant results, such as the determination of video recognition, etc. In [14], the authors first focused on the influencer YouTube data analysis with accompanying the 50 channels made using the blind date app 'swipe'. With the data, the release date of the video, likes , dislikes, the number, video length, hash tag count, total number of views of channels, number of videos of channels, average number of video views of channels, number of channel subscribers were analyzed as variables, and Principal Component Analysis and Multiple Regression Analysis were performed as well as R-based data analysis. The cumulative contribution rate of PCA1 and PCA2 was more than 80% of the total to compared these two factors to determine the importance of each variable. For the first component, the average number of views on the channel, comments on swipe videos, views on swipe videos, and likes of videos were -1.25, -2.6, -2.49, and -2.83, respectively, showing a strong negative value, while the video length of swipe video and the hashtags of swipe video were 3.31 and 1.95, respectively, showing a strong positive value. The second component showed a negative value with the number of views and video subscribers, and a weak positive value with the length of the video and tag count. In addition, author concluded that the number of videos of the channel is most influential on the influencer attribute decision model among the variables when the two components are judged synthetically. In Multiple Regression Analysis, only the number of videos reveals significance. However, the limitation of the Principal Component Analysis was that the differences among the variables were large, and for Multiple Regression Analysis, there is a mismatch with the Principal Component Analysis results, therefore the study also has a limit. In [15], the authors analyzed the comment of each video with time to demonstrate the continuing influence of YouTube Influencer. The group is classified as "Large group" and "Small group" based on the total number of comments. In the case of "Large group", the number of comments per an hour is similar and the decreasing width is constant over time. In the case of "small group" is assumed that the number of comments per an hour is irregular, and that the decreasing width is not constant over time. Accordingly, the paper selected the "Big3" of the group and used the decreasing width and consistency obtained through the existing "Large group" and "Small group" as an evaluation indicator. In the case of decreasing width, the smallest percentage was 3% and the largest percentage 2%. For consistency, the standard deviation was used, and the results were derived that the standard deviation of the "Large group" was relatively small compared to the standard deviation of the "Small group." This has proven that "Large group"'s influencer continues to receive people's attention in a stable manner. However, the limitations still exist because of the lack of connectivity with the recommendation system of YouTube through high-profile video analysis.

In [16], the authors proposed the importance of the analysis of the comments quantified through the questionnaire and suggested the link between the analysis of the comments and the generation of profits. According to the survey, 12 percent of users post their opinions on a regular basis, which means about 96 million people are actively writing their opinions, considering the size of the YouTube community is estimated at 800 million. Also, 34 % of the respondent of investigation read comments frequently and read comments 2-3 times after watching 53 % of the video. In the case of comments, those received a lot of likes if those were reasonable, practical and content-customized, and eventually showed that it could be used to increase the popularity of the videos and make profits. However, the existing study also has limitations due to the lack of connectivity with the recommendation system of YouTube through high-profile video analysis, and there is a limit to analyzing human contradictory behavior. In [17] the authors used YouTube comment analysis, TF-IDF (term frequency inverse document frequency) and Association Rule Analysis to select influencers. Comment analysis used the B-rated YouTube channel when searching for "English study", "English education" and "English learn" on the social blades that provide the YouTube ranking system. The comparison of TF (Terminal Frequency) and TF-IDF analysis then demonstrated that the TF-IDF analysis elicited more significant words. For example, when word analysis was conducted with the frequency of words (TF), common words related to learning such as "learn" and "lesson" or words that had nothing to do with the video content such as "love," "video" and "channel" were heavily weighted. In contrast, for TF-IDF analysis, words related to video content such as "resort," "plan," "proposal," "vegan," and "vegetarian" are expected to be talking about travel first and vegetarian second. Compared to TF analysis, TF-IDF extracts features of each video content and shows them well. Finally, the association among words was analyzed through the Association Rule Analysis. As a result of the Association Rule Analysis, the authors can see that words with high TF are generally generated as rules. In case of using TF-IDF, there is a limit to judge the association among words heuristically. In the case of Association Rule Analysis, the rules are generated based on the frequency of words in general, so that only meaningless words are repeated in the YouTube environment. However, the paper is considered to provide a cornerstone of the proposed technique because it found that the two methods can be only applied to select the influencers. Recommender systems of [18] collects information about users and businesses and how they are related. The recommender systems let users share their reviews about products, places, establishments or services. If a product receives more votes or reviews, it

becomes more popular among customers.

It is expected that higher number of positive reviews is beneficial for marketing's success of the product. Interactions based on user's followers are usually allowed by recommender systems. A user is considered a fan of another user when there's no personal relationship between them but still the former wants to see the latter's posts in his or her own main page. This type of social link is based on interests and affinities with celebrities, special products, places or common interests. When a review is posted, it is seen by the submitter's friends and followers, increasing its chances of readings about the reviewed product or place. The more social links a user has, the more persons will likely read the review. This social component has become an interesting aspect of recommender systems because it allows an increase of popularity of a product or place. In the case of the recommendation system mentioned in the thesis, the user-to-user social network is formed through the follow, and is also distinguished by the user-user fan through the interaction relationship. In general, reviews by users with many social networks (users with many fans) are more likely to be accessed by more users. These characteristics are an interesting part of the recommendation system, and many businesses approach these users for satisfaction. This proves that the existing research direction of recommending to companies for profit generation is reasonable. The current model excludes text analysis, but acknowledges that the analysis of comments exerts an influence on Influencer's numerical data.

3 System Model

The data used for the proposed scheme was based on 54 channels of influence, which produced promotional videos on the "Enligh Education" related channel. The videos are easy to use influencer attribute analysis because general public influencer can directly produce video and observe other users' reactions in various formats such as numerical information and comments on YouTube. YouTube's visible numerical data shows the date of creation of each video, likes, dislikes, length of the videos, number of hash tags, total number of views on the channel, the number of videos on channel, average number of views on the channel's video, and number of channel subscribers. The primary analysis of suggested techniques is to look at their correlation using various numerical data provided on YouTube quantitatively. At this time, the set hypothesis is that "if the correlation of each numerical data is high, can it be judged unconditionally that the recognition of the corresponding video is high?" In general, it is easy for general users to judge the quality of channel and video by trusting only the numerical data based ranking system of YouTube. However, since the average number of views of a channel is increased with only single click of a YouTube video, the actual playback time is unknown, such as whether the user actually viewed the videos, which parts of the videos were particularly popular, or whether they stayed for a certain period of time, rather than simply clicking them. In addition, YouTube does not provide access to statistics and visualization information (e.g., demographics information) of the audience, such as age, gender, etc., which videos are usually viewed highly by which user class. Therefore, we simultaneously analyze influencer YouTube data quantitatively and qualitatively as shown in figure 2

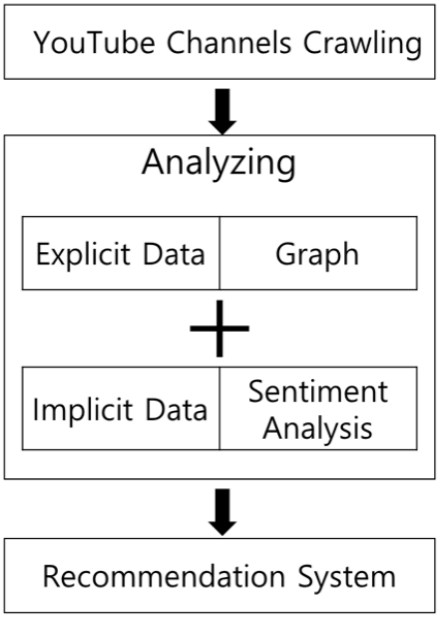

Figure 2: Recommendation System analysis flowchart

In detail, the English learning channels corresponding to B level, which is the self-rating of the social blade, were filtered based on the influencer criteria of the social network data. Those are the number of subscribers, English learning channels, which have a much higher number of views and likes, generally have a higher level awareness of videos as well as the number of videos with the long days of channel opening. We chose channels that were opened between 2016 and 2018 to allow for the latest videos of channel. The YouTube channel has its own concept, and English learning channels are largely divided into lecture type and talker type. One of the reasons that users prefer YouTube over Internet lectures is because they can learn English through content that is not formal and has a free atmosphere. Therefore, focusing on the talker-type channel except for the lecture type, we conducted research on ETK English, Interactive English, JForrest English and Real English With Real Teachers.

The study method used the statistical analysis software R tuber package. There are research [10] that used the chrome extension tool SelectorGadget. However, due to the limitations of the crawlable area due to the manual selection of the user and lack of real time property, considering the characteristics of R in which various packages exist, a tuber package for YouTube is used. We crawled the data on YouTube and explicitly extracted a statistical graph for the primary numerical social network data. Afterwards, we crawled the comment big data for each video on each channel through the package

for YouTube data access only and the Google open API, and performed the YouTube data qualitative analysis.

The overall research process is shown in figure 2

After crawling YouTube channel data in the Tuber package, we set up different research methods for each data type quantitatively and qualitatively. The social numeric data such as the number of likes and subscribers extracts the graph based on the mutual relationship and applies the qualitative approach through the emotional analysis to the comment data in which the opinions of actual users are reflected on the channel.

4 Proposed scheme

4.1 Research technique

YouTube provides statistics on channel and channel video. In this study, channel information and channel video information are distinguished from each other because channel and channel video are different. We use the number of subscribers to measure channel itself awareness. The recognition of channel videos is based on qualitative data analysis using comment data analysis as well as quantitative data such as number of views, likes, and comments. Therefore, the recognition of one channel, that is, the number of subscribers, is not popular and highly rated. After analyzing the quantitative and qualitative data of the channel and the channel video, the channels are ranked by synthesizing them.

4.1.1 Crawling

After selecting the influencer channels to be ranked, call the channel ID from the YouTube url address as follows and use the R tuber package to crawl the statistical information like followings. https://www.youtube.com/channel/ (Channel ID). When we enter the YouTube channel main screen, the above url address is generated, and the last part is the channel ID. The channel information is coded by entering the channel ID into the get_channel_stats function of the tuber package. The yt_search function calls up the video list of the channel, and the video statistics information is also retrieved using the ID of each video in the same manner as above. In order to organize the crawled statistical information by video and channel, the title and channel name are added to the same row and stored as a data frame. Each channel is refined in the same manner as described above, and then organized into one data frame. Then, column names such as "Title", "Likes", "Views", "Subscriptions", "Channel" The video title defines character type, number of likes, number of views, number of subscribers as integer type, and channel name as factor type.

The comment data corresponding to the qualitative data also uses the tuber package. A comment on the video is called up to generate a comment data frame for each channel, which consists of a comment and an video ID in one row. This identifies channel names as well as quantitative data.

4.1.2 Quantitative Data Analysis

The results of quantitative data analysis are graphically displayed for visualization. Quantitative data is a measure of channel awareness and channel video awareness, and uses statistics provided by YouTube. The awareness of the channel is the number of subscribers, and the video recognition per channel is confirmed by the number of views, likes, and comments. Since the number of subscribers and the number of comments are fixed, they can be displayed as a bar graph. The reason why the number of comments in a video is classified as a fixed value is because the comment does not need to consider the deviation for each video fairly. Since the number of comments is a measure of how much viewers are interested in the channel, we consider only fixed values equally. On the other hand, the number of views and likes are taken into account for distribution and the deviation is taken into account by video.

4.1.3 Qualitative data analysis

In this study, the comment data is analyzed at the same time as the statistical data provided by YouTube. Likes, in addition to the number of subscribers, we can rate those channels and videos with the feedback from people who actually watched the video. It is difficult to judge that the number of views is high because it can be climbed even if the user clicks the video once even if the viewer does not watch the video to the end. On the contrary, it is possible to determine whether the video is good or not by checking whether the user has stayed in the video for a longer time, that is, whether the video has been watched until the end. Comments on video, except spam, are mainly left after watching video, mainly video related content. The higher the ratio of the result, the comment and the video content match, the more the commenter will see the video. Therefore, the comment analysis can be used to determine whether the video is suitable for ranking highly. To understand the correlation between video and comment, we invoke video script and comment file and refine data. Sort videos and comment data classified by corpus by frequency. Then, the comment data is compared with the video data, and the matching word is denoted by 1, and the non-matching word is denoted by 0. Scoring function is used to score differently for each frequency, divided by the total number of corpus and expressed as a ratio.

That is, the proposed scheme used Term Frequency (TF) to measure the frequency of each video based on script and comments. If the comment data matches the script, a list of the words is generated. The more words and duplicates in scripts and comments, the more the subject and content match. As the number of words in the list increases, it means that the viewer has a high degree of understanding and understanding of the video. Therefore, the video is recommendable to other users with the increasing recommendation reliability by weighting the degree of correspondence between video and comment. The response of the viewer, that is, the content of the comment, becomes the criteria.

The proposed scheme also consider Inverse Document Frequency (IDF) for TF-IDF (Term Frequency-Inverse Document Frequency). The TF-IDF (Term Frequency-Inverse Document Frequency) is often used for keyword extraction and similarity between documents. The higher the value of the TF indicating the appearance frequency of a word, the higher the importance of the word is, but it is not an absolute measurement method. It is more likely that the word is often used in other documents, and the frequency and importance are inversely proportional. Thus, in many document clusters, we multiply the frequency of occurrence of the word IDF with TF to assign weights to the only frequently appearing words in a particular document. Therefore, we also considered TF-IDF per each channel video for the proposed scheme.

4.1.4 *Normalization*

Since quantitative data and qualitative data analysis can not be accessed from the same point of view, we use a normalization function. As shown in figure 3, we use the normalization function to integrate the quantitative and qualitative data analysis of each channel to provide the final channel ranking. As shown in figure 3, the reasons for putting the weight on the 20th word list are as follows. As a result of checking the list of words based on the experimental data, word matching ratios up to 20th were distributed on average regardless of the total number of words, and other words showed the same or subtle differences. Therefore, based on the TF-IDF, weights are assigned to the words from the first to the 20th.

Function 1 Scoring

```
1: if Words in MatchingList >=20
2:   for (i in 1:3)
3:     MatchingList[i] = 1.8
4:   for (i in 4:10)
5:     MatchingList[i] = 1.5
6:   for (i in 11:20)
7:     MatchingList[i] = 1.2
8: else
9:    for (i in 1:3)
10:     MatchingList[i] = 1.8
```

Figure 3: Normalization scoring function to integrate the quantitative and qualitative data analysis of each channel

The detailed rules for weighting criteria are as follows. The numbers 1 and 0 are assigned to the words that match each other. Since we place weight on words with a high percentage of match between video and comment content, they should be basically higher than the number 1 already granted. Therefore, based on various experiments as shown in figure 4, we have weighed the combinations of various numbers from 1.1 to 2 and confirmed the number that best matches the existing match ratio.

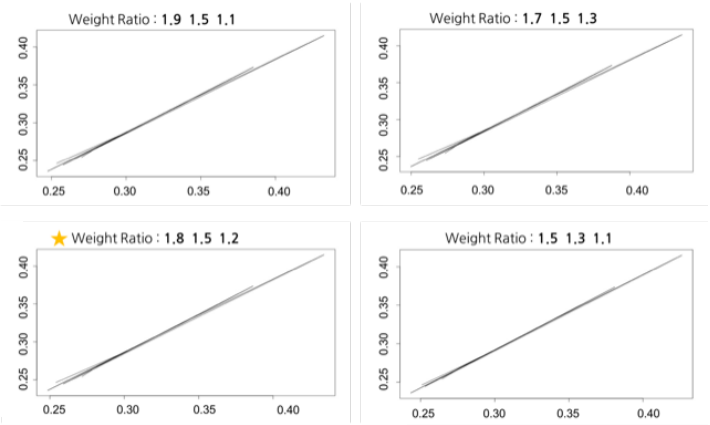

Figure 4: Weight ratio

4.2 *Experiment Data*

All the performance evaluation codes were written in the R environment suitable for data analysis, and the influencer channels with the subject of English learning were selected as the experimental subject. Four English language channels (English Coach, Interactive English, JForrest English, and Real English with Real Teachers) were selected based on the ratings of social blades that provide social rankings. In order to experiment with the channels that can be compared, we chose channels that can be compared with each other considering the channel information such as the total number of views, the number of subscribers, etc., except for the old channel. Quantitative data and qualitative data were analyzed for each channel. First, quantitative data analysis results are shown in figures figure 5–8.

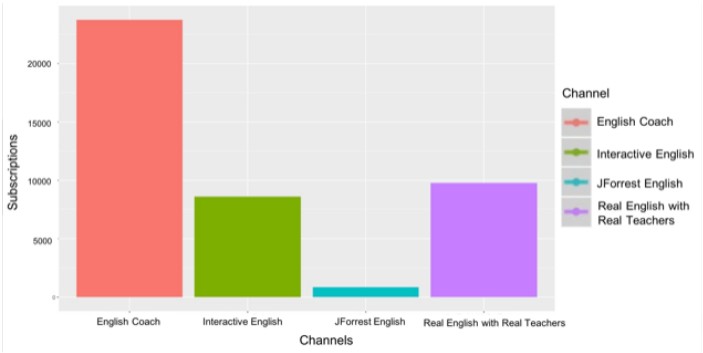

Figure 5: # of subscriber per channel

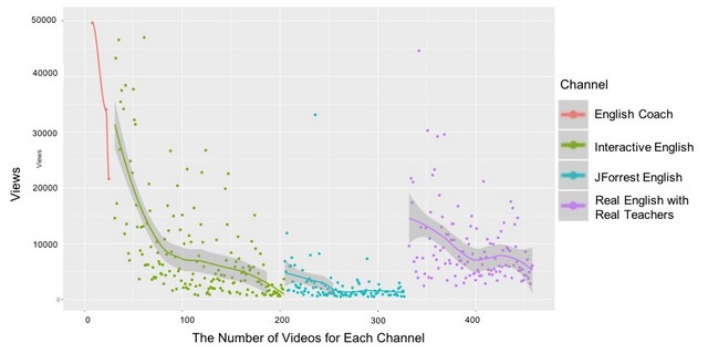

Figure 6: # of video views per channel

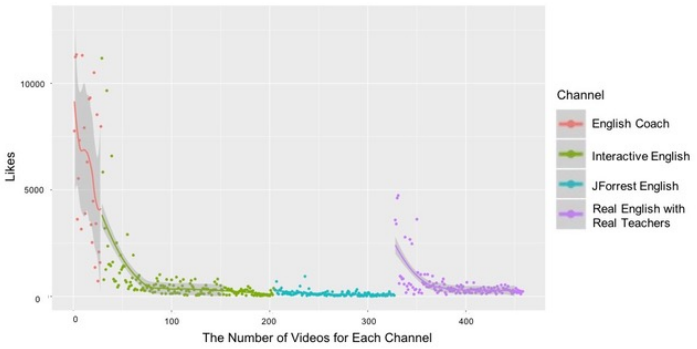

Figure 7: # of video likes per channel

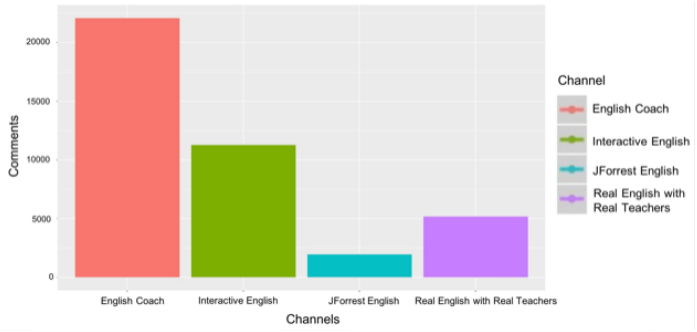

Figure 8: # of video comments per channel

Figure 9 and 10 show additional result graphs when considering different video data sets on the same channel.

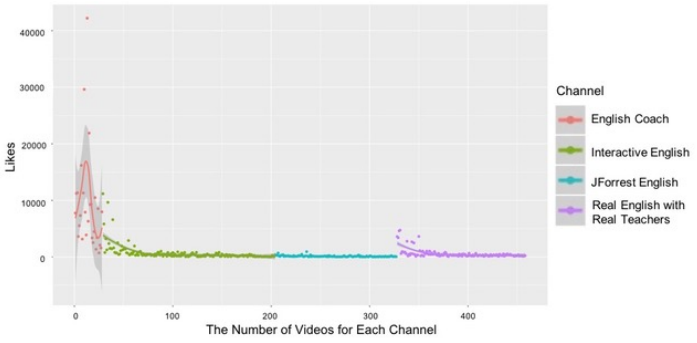

Figure 9: # of video likes per channel

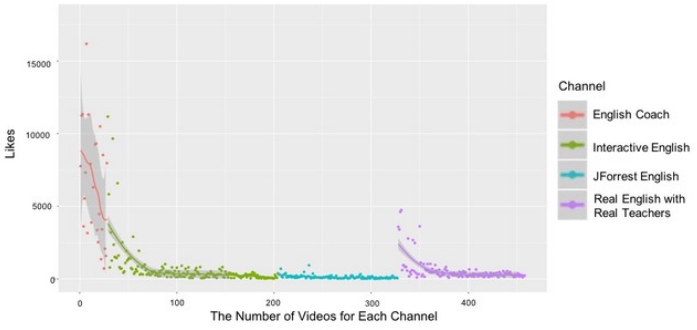

Figure 10: # of video likes per channel

Qualitative data analysis is shown in figure 11. The correlation between videos and comments is compared and scores are given.

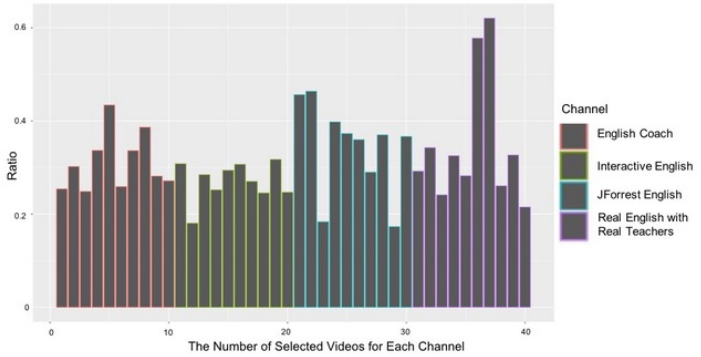

Figure 11: Correlation between video and comments per channel (i.e., Graph Analysis)

The above analyzes are different from each other of x coordinates because the fixed value graph and the distribution graph are mixed. To compare each graph, the analysis standard should be unified. As a result, all analysis results were adjusted through the normalization formula to integrate quantitative and qualitative data.

Figures 12, 13, 14 and 15 show cases where the quantitative data is normalized and re-expressed. Finally, considering both quantitative and qualitative information, it can be expressed as shown in figure 16. As the graph of quantitative and qualitative integrated normalization can be seen, satisfaction with other users can be increased at recommendation (ranking) when video is recommended considering qualitative data at the same time than when considering only quantitative data. Since the user actually watches the video for a long time and has a high probability of making a comment based on the contents of the video. In other words, the proposed scheme is more meaningful than the previous studies, the explicit analysis using the social network data alone, because it does not know the recognition of the video implicitly.

In addition, we found that the recommended videos of the proposed scheme were tracked for a certain period of time based on the same criteria. As a result, the amount of quantitative information such as the number of likes, comments, likes, and subscribers were increases and the quality correlation between video contents and comments was much higher, the performance was better than the existing methods.

In aspects of the business operators, their marketing strategies based on influencer YouTube data analysis were more successful than traditional approaches. Since the number of users and consistency degree between the contents and comments on top of big data analysis quantitatively and qualitatively were more higher with the trace analysis regardless of the time and space.

5 Conclusion

With the development of social networks and wired and wireless networks, global users are constantly using YouTube, a huge platform from multiple angles. Although it provides a basic personalized ranking system in YouTube, it is based on simple statistical information. Therefore, it does not support sophisticated ranking and recommendation system by utilizing hidden secret information qualitatively at the same time. In this study, we utilize two factors at the same time, and in particular, we prove that not only highly visible channels but videos are visible. This study is very meaningful because it can recommend the personalized recommendation system and the customized learning channel to the user in the future, and it can lay the cornerstone to lead to the application field that maximizes the flipped learning effect regardless of time and space as well as novel marketing strategy to the business operator.

A B S T R A C T

The purpose of this paper is to improve the thermographic method for detection the places of heat energy losses on the urban underground thermal pipelines using the computer system. This goal was achieved by building a heat map of the surveyed heating main with data layering directly on a computer map of the area, which can be accessed from a mobile device by authorization via the Internet (profile on the social network Google, Facebook, Twitter, etc.). An analytical model was proposed for converting the temperature values measured over the underground heating main by a non-contact digital pyrometer to an image of the RGB color model using the parameters of the HSV color model. The implementation of the integrated Google technologies complex (Google Firebase, Firebase Authentication, and Google Maps) in the technological process of urban housing and public services was realized. The information-measuring computer system (IMCS) was developed. The proposed improvements in the thermographic method provided independently from each other work of different service teams due to the exchange of data between structural units through the cloud data storage. The results of the practical research allowed detecting the place of the underground breakthrough of the heat pipe quickly, to position the repair equipment over the accident section precisely using the GPS module on the mobile device. Thus, the size of the dug road section was minimized, material resources were saved. The experimental studies carried out confirmed the correctness of the theoretical assumptions.

1. Introduction

The urgency of the searching problem and the reduction of heat loss via the construction elements is due to the need for a rigorous energy saving. This problem is exacerbated by the work of heat power engineering in many countries because of limited natural fuel resources. Therefore, significant attention is paid to reducing operating costs, and timely detection and elimination of emergencies on the heat mains. The detection of heat energy losses on underground thermal pipelines is the most problematic.

In the conditions of the modern urban economy, losses on heating lines are enormous. Increased heat losses along the pipelines and massive coolant leaks, in addition to economic damages, cause excessive thermal pollution.

In order to comply with environmental requirements, it is necessary to implement a set of measures to eliminate the causes of heat leaks on heating mains. It is necessary to improve the methods allowing receiving thermal energy on the main highways.

2.1. Overview of methods for determining losses in heat pipes

Methods for detecting and eliminating defects in main pipelines have been described by many researchers and scientists. [1, 2]. All over the world, common attention is paid to non-destructive techniques and technologies like acoustic leak detection, thermal imaging, tracer gas, radiotracers, etc. [1–4].

Scientifically based methods for non-destructive testing of leakages in pipelines are methods based on analysis of transient processes in pipes, in particular, the impedance method [5]. However, these methods have substantial limitations in the representation of system characteristics such as pipeline length (no more than 90 m) and location of leakage.

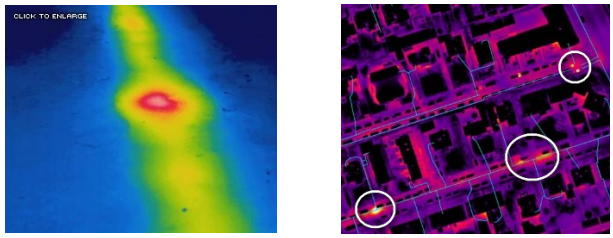
The detection and recovery time of the carrying capacity of pipeline sections with local damage can be significantly reduced through the measuring and statistical analytical procedures with using of the information-measuring computer system (IMCS).

The method of the negative pressure wave (NPW) is one of the most modern. Using this method, it is possible to track the appearance of a leak on the heating main without leaving the pipeline zone, while remaining at the central control station [6, 7]. At the time of occurrence of leakage of fluid in the pipeline, dilution waves appear. The pressure wave reaches the measuring points on either side of the leak and is recorded at the central dispatch post. The computing system processes the results of the incoming information and promptly calculates the leak location (within 1 minute). However, the accuracy of this method does not exceed ± 200 m.

Currently, sophisticated methods that combine acoustic and correlation principles of leak detection with remote registration on servers over the air are used on heating mains. However, the authors themselves have determined that such practices are ineffective when the heating main is located deeper than 2.5 m [8]. Also, the instruments used in the implementation of these methods do not work in the presence of increased noise (for example, moving vehicles). Considering that the majority of urban heating pipelines are laid under highways, these factors have a negative impact on the research results. The harmful properties of these methods also include the fact that to obtain the measurement results it is necessary to insert the peak of the sensor a good swift kick in the road ground (thus, destroying the highway). Also, there is a danger of the sensor damage by a stone, metal object, the ice, etc. on its way.

2.2. *The advantages and features of using the thermographic method*

From the analysis of the above methods, we can conclude that the thermographic method is the most promising. Infrared is a proven noninvasive technology, which locates leaks in the systems of heat pipes without any destruction owing to the digging of highways, under which heating mains in cities are usually laid.



Thermal infrared cameras can see leaking heating pipes, water/steam leaks, etc. If used properly, infrared technology is one of the most highly useful diagnostic tools available today.

It's available to detect places of the local heat leak on the underground thermal pipelines using the IMCS. Such a system should use infrared thermographic devices which can transmit data through wireless ports. This solution helps to determine thermal energy loss location to eliminate unnecessary digging, destruction and expense.

Figure 1, a shows how infrared technology is used to detect a heat loss from steam pipes located under the streets of New York and attributed as a breakdown [9]. These thermal mains demand immediate repair.

Infrared technology in combination with automatic analysis of aerial thermal images allows localizing leaks on district heating pipes immediately in several neighborhoods as shown in Figure 1, b.

In this case, it is essential that the diagnostic equipment moves strictly within the spatial corridor (street) along the heating main [10]. For example, such methods as remote sensing or airborne thermography are widely used in Sweden and Norway [11].

a. b.

Figure 1. Infrared detection the local (a) and large-scale (b) places of heat loss following an accident

Figure 2 shows the location of a non-leaking, but un-insulated unions on the heat pipelines (Mykolaiv, Ukraine). Thanks to the thermal imager, it is determined that this is a non-emergency situation and, in this case, a planned repair is needed. In addition, the thermal imaging method has helped not to unearth the entire section of the roadway over the heating main, but to carry out repairs through point pits.

Figure 2. Detection of the places technological heat energy losses through un-insulated unions

Results of heat pipeline leak detection have statistically analyzed using the methods of variance analysis and the pairwise comparison methods. The researches have shown that a higher going speed of IR camera would reduce the effect of noise on the collected thermal contrast and, therefore, would give better results of prediction the leak location [12].

2.3. *On lineaments and permits for the use of UAVs for moving thermographic equipment*

Usually, the leak imaging system is placed on rotor-wing and fixed-wing UAVs [13, 14]. One of the best modern hardware solutions for studying energy losses on the thermal line is the thermal imaging cameras mounted on a quadrocopter. By applying a UAV, it is possible to specify its operation area accurately [15]. But this solution is relatively expensive and costs about USD 20,000.

Moreover, most often such systems don't determine accurate GPS coordinates of the accident and are therefore useless for the repair team. At present, the leak detection team should wait for repairers at the identified accident section or create written and photo records.

It is positive that modern leak detection methods locate heat leak accurately to 1 sq. m, so any excavation reduces to a minimum when the pipes are repaired. However, such systems also don't have an accurate reference to the location by GPS coordinates. After detection, the place of thermal energy leaks, the written report with photos of thermogram locations and recommendations are made [3, 16, 17].

Due to the lack of the identification of technological objects in these methods, a manual inspection with accordance to the route was visualized on the map is done, after which a heat map is created [18].

In the Czech Republic, the system Workswell WIRIS has been developed, which can be fitted with a GPS sensor for storing location information on the position of the drone when producing a record about the detection of hot water leaks [14]. This system is designed to be mounted on a drone (UAV) too.

But there are two problems for the implementation of this method of study of energy losses. First, the above means of the thermal measurements are too expensive. Second, on June 11, 2018, the State Aviation Service of Ukraine banned flights of remotely manned aircraft (drones or UAVs) over roads of state importance, streets of cities and villages, etc. [19]. Similar prohibitions on the use of drones on the territory of settlements exist in other countries – Italy, Austria, Czech Republic, Great Britain, etc. [20, 21]. In USA the FAA rule will not allow operation of a small unmanned aircraft over a moving vehicle because impact of a small unmanned aircraft may distract the driver of a moving vehicle and result in an accident [22].

Thus, the problem under consideration is relevant not only for Ukraine but also for the majority of countries of the world using underground heat mains.

3. Problem Formulation

The purpose of the work is to improve the thermographic method for detection the places of heat energy losses on the urban underground thermal pipelines using the IMCS.

The object of the work is the data receiving and handling process for detection heat loss using a combination of terrain maps and results of heat measurements.

The subject of the work is a system for creating heat maps of energy leak on thermal pipelines according to the data of pyrometric non-contact measurements over the surface of underground heat mains.

The purpose of the work is achieved by solving the following research tasks:

- Analysis of existing algorithms and methods implementing heat map construction on the basis of collected data.
- Analysis of the existing base of devices for research and analysis the current temperature of objects.
- Development of an analytical model for forming a heat map and calculating its statistical indicators.
- Development of a software application for detection of heat energy leaks on thermal pipelines and visualizing the results of measurements on heat maps of the area.

In this article, it is proposed to collect thermal data using an on-duty car equipped the IMCS based on tablet and manual pyrometer with wireless transmission of measured temperatures to achieve the goal.

Unlike the above examples, this measuring device (that costs about $100 USD) has several advantages such as:

- Measuring the temperature of the object with the help of non-contact infrared beam.
- The ability to transmit data through Bluetooth port 4.0 to the computer equipment.
- Laser sight in the form of a circle with a point in the middle, that well visible at a sufficiently large distance (from the on-duty car).
- It is compact, convenient and not harmful for the operator health, unlike the equipment described in [5–9].

The practical value of the work is:

- Detection and localization of the breakthroughs of the heating main for the planning of repairing works, maintenance, etc.
- The possibility of identifying objects which emit heat.

4. Methods and techniques used for the solution of the problem

4.1. Development of the information-measuring computer system for detecting heat leaks

Thus, due to the inability to use drones for the inspection of heating mains in urban areas, it is proposed to analyze the thermal pipe state using a non-contact pyrometer. For example, the Testo 805i model can be used. The pyrometer and the tablet are the part of the IMCS on board the on-duty machine moving the diagnostic team.

Bluetooth infrared thermometer Testo 805i allows transmitting the measurement data to the mobile device (smartphone, tablet, etc.) via Bluetooth port 4.0 at a distance of 15–20 m. It requires iOS 8.3 (or later) / Android 4.3 (or later).

Unfortunately, the Testo 805i doesn't measure automatically, so, to receive data, it is necessary to press the button on the device each time. Doing every 10 seconds, the temperature will be measured every 100 m at a speed of 40 km/h (10 m/s).

The measured temperature is recorded into the database of the mobile device and uploaded to the cloud storage.

The structure of such a database should include separate fields for displaying different types of data in the processed request (dates, ambient temperature, temperature above the surface of the heating main, geolocation data of the break section, etc.) [23].

Then measured data can be plotted on the terrain map as values or as a heat map.

The structural scheme of the improved thermographic method of detecting leak places on heat pipes is shown in Figure 3.

Black color indicates the main blocks, hardware and software components and the primary connections between them, used in currently applied thermographic methods for detecting the breakthroughs of the heating main. The first proposed improvements to existing methods are highlighted in red.

It should be noted that thanks to the proposed modifications, the repair team can operate autonomously, regardless of the diagnostic team, and receives information about the place of the

necessary repairs directly from the cloud storage. Also, the presence of the geo-coordinates of the accident section allows you to accurately position the repair equipment over the place of the heating main breakthrough. Replacing equipment from thermal imaging to pyrometric not only significantly reduces the cost of the solution, but also allows you to obtain digitized data associated with GPS coordinates.

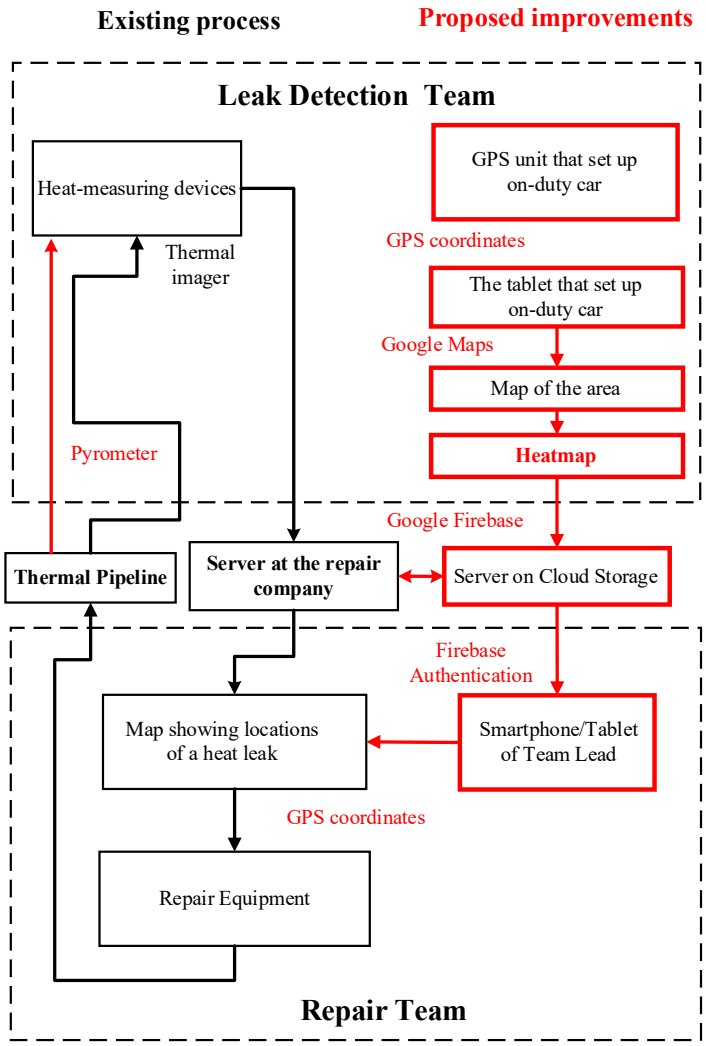


Figure 3. Structural scheme of the improved method for detecting leak places on heat pipes

Figure 4 shows a flowchart of the heat map formation.

Initially, temperature data is measured with a pyrometer, and if these data have been measured, they are recorded in the database, if not – the heat map will not be built, further measurements are crucial.

Further, when the temperature data have been received to the phone (or tablet), there is a process of tracking the coordinates, namely latitude, and longitude, using a GPS module of mobile phone or tablet. If the data is received – it is also entered in the database, and in the case of its absence – the heat map will not be built. The on-duty car equipped with IMCS moves further, to a point with new geolocation, where subsequent measurements would be made.

The final stage is the very construction of a heat map. To do this, you need to add GPS coordinates with measured temperature values into Google Maps [24]. To do this, it is necessary to use the library *com.google.maps.android:android-maps-utils.*

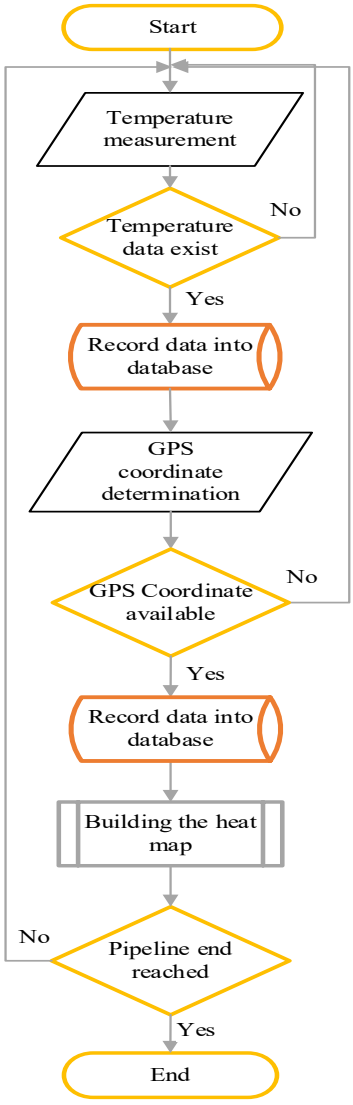

Figure 4. Flowchart of the heatmap building algorithm

The distinctive feature of the proposed method is the application of cloud technologies when obtained data (temperature and GPS coordinates) is uploaded to Google Firebase [25]. In this case, we propose an extended technological process shown in Figure 3.

4.2. Results of measurements and input data for research

During the practical research, measurements of the temperature over the heating main were carried out in preparation for the heating season (in October) on the segment of the thermal pipeline limited by the geocoordinates given in Table 1, along one street.

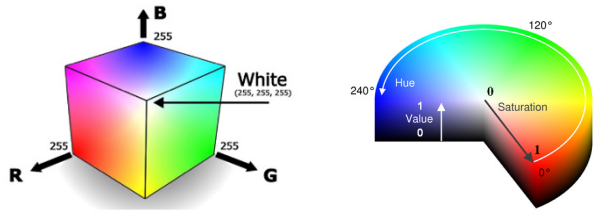
As a result of the temperature measurements, a breakthrough of the heat pipe was detected. The temperature over the heat main that differs significantly from others evidenced that.

Table 1. Temperature measurements on the thermal pipe in preparation for the heating season (in October)

Temperature (°C)	East longitude (degree)	North latitude (degree)	Conclusion on the state of the thermal pipe
+13.8	32.011009	46.970312	holistic
+14.2	32.012510	46.967368	holistic
+14.1	32.013154	46.965597	holistic
+22.6	32.013060	46.962030	breakthrough
+25.2	32.012781	46.961381	breakthrough
+7.2	32.012688	46.958510	holistic
+7.0	32.011994	46.953942	holistic
+7.1	32.012019	46.949474	holistic

Table 2. Temperature measurements on the thermal pipe during the heating season (in January)

Temperature (°C)	East longitude (degree)	North latitude (degree)	Conclusion on the state of the thermal pipe
+3.6	32.011009	46.970312	holistic
+4.1	32.012510	46.967368	holistic
+4.4	32.013154	46.965597	holistic
+5.2	32.013060	46.962030	holistic
+5.2	32.012781	46.961381	holistic
+3.4	32.012688	46.958510	holistic
+3.0	32.011994	46.953942	holistic
+4.1	32.012019	46.949474	holistic



After carrying out repairs, another temperature measurement of the heating main was made at the same points. Measurements were made during the heating season (in January), then the environment temperature was lower (Table 2). Therefore, the average temperature over the surface of the thermal pipelines has decreased compared to the previous measurements made in October.

However, as it can be seen, the temperature along the heating main does not differ significantly from one another, which is why we conclude that the breakthrough of the heating main in this place has been eliminated.

4.3. An analytical model for the formation of a heat map

It should be noted that tabular data is very inconvenient for perception and rapid analysis. Therefore, it was decided to build the heat map with visualizing of found heating main emergency sections on the area map on the basis of the measurements. For this purpose, an analytical model for the formation of a heat map was developed.

Two color models, RGB and HSV, are selected for conversions [26]. The RGB model describes the color space based on Red, Green and Blue colors (Figure 5, a). The HSV model operates with parameters Hue, Saturation and Value (Figure 5, b).

a. b.

Figure 5. RGB (a) and HSV (b) color models

However, if the colors are supposed to be interpreted using the human visual system, it is advisable to integrate the RGB space and the HSV space [27]. Besides, diagnostic and repair work on heating mains can be carried out at different times of the day, and the HSV color space is more resistant to changes in lighting. Therefore, it is advisable to formulate the mathematical equivalent of the projection of the HSV model vectors in the RGB color space.

In contrary to the studies about the usage of color models mentioned above [26–27], in this article, we propose using parameters Hue and Value of the HSV color model to construct the color gradient in the RGB color model. In this case, parameter Saturation equals a constant value. This approach reduces the computing power requirements concerning an IMCS set in an on-duty car. Thanks to that building a heat map for the thermal mains and combining it with a terrain map can be performed even on a tablet instead of a laptop with higher performance, but also more cumbersome and inconvenient to use in a moving car.

The pyrometer readings, corresponding to the seasonal temperature value of the section of the pipeline, are successively added to the array of temperatures $\{t_{i,j}\}$, where $i = \overline{0,N}$ is the number of all N rows of temperature values for each from N seasons, $j = \overline{0,25}$ – the number of columns of each temperature value in the matrix of the input file data to build a heat map.

To recount the parameters of the HSV color model in the value of each spectrum of the RGB color model, the temperature coefficient k of the HSV model should be calculated according to (1). This will allow scaling the temperature values to the color of a certain tone. To switch to the parameters of the color model, it is also necessary to calculate the basic statistical parameters, namely the maximum and minimum values of the temperature (2) – (3) from the set of temperatures (4):

$$k = \frac{(sp_{max} - sp_{min})}{(t_{max} - t_{min})}, \quad (1)$$

$$t_{max} = max\{t_{i,j}\}, \quad (2)$$

$$t_{min} = min\{t_{i,j}\}, \quad (3)$$

$$i = \overline{0,N}; j = \overline{0,25}, \quad (4)$$

where $sp_{max} = 360°$ – selected the maximum value of the color tone (Hue) of the HSV model, which corresponds to the red color; $sp_{min} = 120°$ – selected the minimum value of Hue of the HSV model, which corresponds to the green color. On the basis of the set minimum (green) and maximum (red) Hue values, a range is formed in the middle of which the value of 240° corresponds to the blue color, which in turn is the spectrum of the RGB color model.

Then the color tone parameter $H_{i,j}$ for each heat map segment using the temperature coefficient for the conversion the temperature values to the color values are calculated on the basis of the formula (5):

$$H_{i,j} = sp_{min} + (t_{i,j} - t_{min})\cdot k. \quad (5)$$

In a heat map, to draw a small segment of a certain color of the RGB palette, you need to convert the temperature values using the HSV color parameters. In the proposed analytical model (6) – (9) the saturation "S" is taken as a constant ($S = 1$). This parameter does not appear in further calculations to reduce the computing costs of a mobile device with limited computing capabilities, which is used in the described IMCS for thermal pipelines inspection. $V_{min} = 0.1$ – the minimal digit of the parameter "Value".

Therefore, the next step in forming a thermal image in the proposed analytical model is the conversion of temperature data into a color RGB model based on the rated values of HSV model parameters.

The values of the red, green, and blue components of the RGB spectrum are labeled $R_{i,j}$, $G_{i,j}$, and $B_{i,j}$, respectively and calculated as follows:

$$R_{i,j} = \begin{cases} V_{min}, H_{i,j} = 0 \; or \; H_{i,j} = 1; \\ |V_{min} - ad_{i,j}|, H_{i,j} = 2; \\ V, H_{i,j} = 3; \\ |V_{min} + ad_{i,j}|, H_{i,j} = 4. \end{cases} \quad (6)$$

$$G_{i,j} = \begin{cases} V_{min}, H_{i,j} = 0 \; or \; H_{i,j} = 1; \\ |V_{min} - ad_{i,j}|, H_{i,j} = 2; \\ V, H_{i,j} = 3; \\ |V_{min} + ad_{i,j}|, H_{i,j} = 4. \end{cases} \quad (7)$$

$$B_{i,j} = \begin{cases} V_{min}, H_{i,j} = 0 \; or \; H_{i,j} = 1; \\ |V_{min} - ad_{di,j}|, H_{i,j} = 2; \\ V, H_{i,j} = 3; \\ |V_{min} + ad_{i,j}|, H_{i,j} = 4, \end{cases} \quad (8)$$

$$ad_{i,j} = (V - V_{min})\cdot(H_{i,j}). \quad (9)$$

In this case, the higher the temperature the more the color is close to the red, and vice versa – the colder the temperature the more the color is closer to the blue. As shown in Figure 6, a, in the described model, the temperature scale is implemented in the temperature range from 0 to +25°C, which corresponds to the season when the heat pipelines in the region under consideration are prepared for the heating season.

Figure 6. Temperature scale for the season

It should be noted that thermal measurements can be carried out in different seasons when the temperature of the environment varies considerably over the seasons. When researching at another time of year, the visual temperature scale should be replaced by another scale reflecting temperature values that coincide with the seasonal ones.

When constructing temperature scales, it should be noted that the operating temperature range for the pyrometer is from minus 10°C to +50°C. But with negative values of the ambient temperature, the measurement error is significantly increased. Therefore, further temperature scales were built only for ranges in which the pyrometer measurement error did not exceed 1.5 %.

4.4. The software development

The software was developed in Android Studio 3.3.1, an application created for the Android platform with JDK ver. 11.0.

Let's consider the life cycle of the application. On the initial phase of the application, the task should be sent to diagnostic teams for inspection of the area.

Using the Firebase Cloud Messaging (FCM), the system server sends messages to clients about current tasks. There is an ability to send notifications (up to 2K bytes) and data messages (up to 4K bytes).

Upon receiving the assignment, the diagnostic teams on a duty car are headed to places of information gathering. After their arrival, the system reads its GPS coordinates and sends a message to the server about the diagnostic team location.

The diagnostic team of specialists measures the temperature values using pyrometers. Data via Bluetooth 4.0 technology are transmitted to a tablet/notebook storing a local database in SQLite. When the tablet is connected to the Internet, information is sent to the cloud database.

After completing the inspections by the diagnostic team, other services (mobile clients) will receive a message through the FCM for further works on the territory.

Using the web version of the application helps to create reports based on the data collected. The *JasperReports* library is used to generate reports on the server.

The UML Class Diagram of the developed application is given in "the help file" in the code repository. The shared code that would be good for further researching by other scientists is also placed there.

The following classes were developed:

CurrentApplication – the class responsible for the life cycle of the application. It performs one or another action depending on the state of the application.

PointModel is the class responsible for representing the single point information that is displayed on the map.

PointPackModel – a class serving as a container for the PointModel list.

BaseActivity is the base class (parent) for all Activity entity. This class is responsible for the elements with visual content.

BaseMapActivity is a class with the basic functionality of Google Map.

SplashActivity is the class responsible for displaying the application loading screen.

MainActivity is the class responsible for displaying a map with functional points.

5. Experimental Results and Analysis

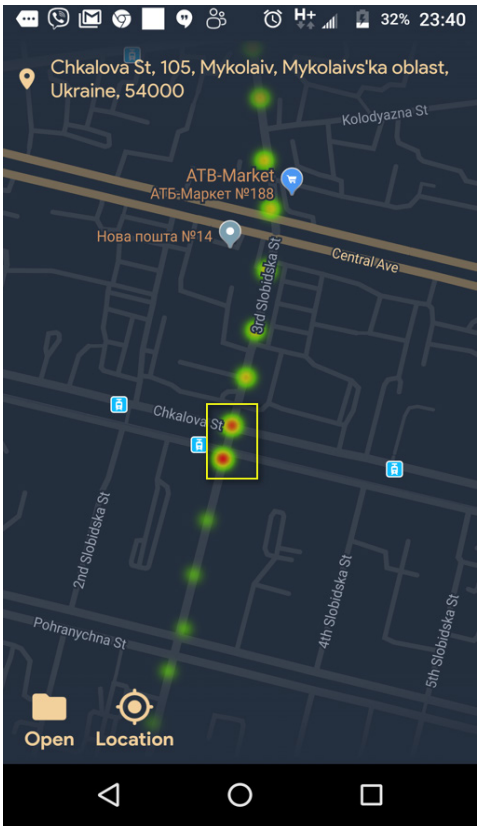


Figure 7 shows screenshots of the interface of the developed Android application.

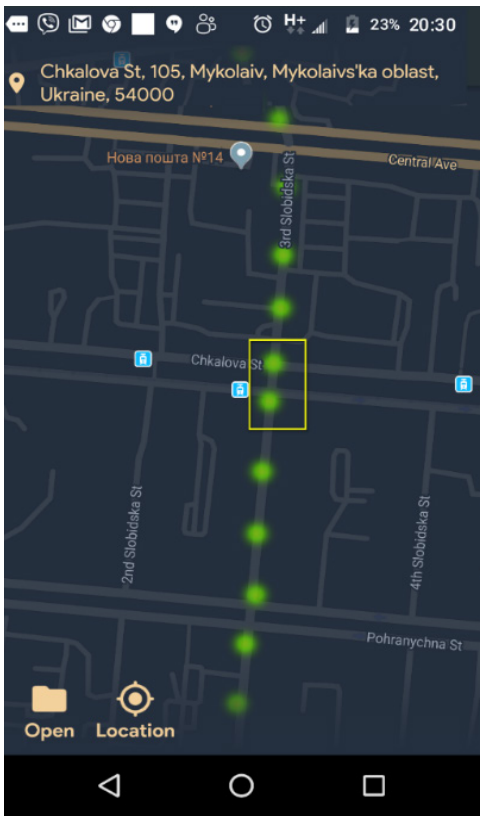
In Figure 7 you can see the map and two buttons. The button "Location" is responsible for the current location of your mobile device (or tablet). The button "Open" is responsible for opening a file from the database needed to build a heat map.



The file was filled via a Bluetooth-port with results of temperature measurements made a pyrometer Testo 805i.

From the analysis of the heat map in Figure 7, the place of heat energy leak from the underground pipeline can be seen (in the area highlighted by a yellow square). It is possible to speak about the presence of heat leaks based on the temperature gradient constructed on the scale in fig. 6. The red color inside the selected two spots (in the color spots above on the map there is no such color at all, or it is represented in an insignificant proportion to the area of the whole spot) indicates the presence of heat leaks in these places of the heating main. In the developed system, accurate geo-coordinates (latitude and longitude) of the section of the break of the underground heating main are registered and available to the repair team (see Table 1). These coordinates can be refined by more frequent pyrometric measurements at a previously diagnosed area and marked on a Google map of a larger scale. Then it will be possible, with higher sampling, to perform image segmentation of the spot of the color scale for sensors of the automated system of technological control [28]. The maximum spot area, indicated in the red inside, will show a more accurate accident section. This will allow the positioning of repair equipment directly above the area of the heating main break. The accuracy of diagnosis is limited only by the measurement interval of the device (3 seconds) and the speed of movement of the operator of the diagnostic team.

Automated fixation of the geo-coordinates of the accident site with their plotting on the terrain map is performed in none of the methods described in the literature.

a.

b.

Figure 7. The heatmap showing the breakdown (a) on the thermal pipeline and its eliminated (b)

With the data of the developed IMCS, it is also possible to conclude that after the detected leakage point along the pipe main, the temperature over the surface of the underground heating pipe has been reduced to the ambient temperature on the date of measurement (green labels in Fig. 7, but without a color gradient according to the developed temperature scale for the studied season).

After the computer diagnostics were carried out, the received data was transferred to the corresponding repair company. The unearthing of the heating pipeline by the found coordinates of the breakthrough has confirmed the fact of the accident precisely in the detected place of the heating main. It was discovered as a result of temperature measurements and reflected in Figure 7, a. The red color in the center of the spot corresponds to the raised temperature. And Figure 7, b shows the same place, but already with the eliminated breakthrough (see the yellow rectangle).

The advantages of the proposed method are that the repair team can operate independently of the work schedule and the location of the diagnostic team specialists. When the repair team arrives at the place of heat energy leakage, the brigadier is authorized on Firebase by any mobile device (smartphone, tablet, etc.). In this case, his profile in any social network can be used – Google, Facebook, Twitter, etc.

When the access to the heat map of the thermal pipeline has given, brigadier of the repair team can compare the own GPS coordinates with the coordinates received from the cloud service. Then it is able to combine the repair equipment accurately (excavator, pump, etc.) with detected places of the heat energy leak from the heat map.

6. Conclusion

Based on the analysis of the methods the detection of the thermal energy leak places on thermal pipelines, the relevance and necessity of developing new analytical models and software for the search and mapping leaks on heating mains with the help of heat maps have been established.

An analytical model for forming a heat map and calculating its statistical parameters was proposed. The convert of the temperature values of a non-contact digital pyrometer from an underground heating main to the image of the RGB color model using the parameters of the HSV color model was substantiated.

A software application for building heat maps based on measured temperature data for the Android platform with JDK 11.0 version was developed. Introduced Firebase Authentication, integrated with popular social services. Due to the heat map layered on Google Maps, the repair team got the opportunity access to detected places of the heat energy leak regardless of the work schedule and the location of the diagnostic team.

Experimental researches with the developed IMCS for the needs of urban housing and communal services for detection places of heat energy leak in the city underground thermal mains due to pipe accident have been carried out. The conducted studies confirmed the sufficient accuracy of the results for the optimal location of repair equipment on detected places of the pipe breakthrough.

The perspective of further development of the thermographic method to detect the places of heat energy loss using the IMCS and cloud services has shown.

As a development of the method, it can be supplemented, besides the technology of processing surface temperatures, also with information technologies of visual information processing on purpose more accurate geo position of heat leaks [29].

In the future, the proposed method for the diagnosis of thermal outflows can be used for both technical and biological objects. For each of the goals, it will be necessary to build separate temperature scales in the appropriate temperature range based on the proposed analytical model. Also, the pyrometric equipment should also be selected with the accuracy of measurement and the price of dividing the scale corresponding to the constructed temperature scale.

The developed system has a lower cost (up to 50 times) compared with similar thermographic systems based on thermal imagers. Also, the proposed system is safe for the operator compared to diagnostic systems based on ultrasound, radiation and electromagnetic non-invasive methods for monitoring heat leaks described in the analyzed literature.

Conflict of Interest

The authors declare no conflict of interest.

Acknowledgment

The research was carried out with the support of the Ministry of Education and Science of Ukraine within the framework of the state-funded scientific research works at the Petro Mohyla Black Sea National University.

ABSTRACT

The importance of programming skills has increased with advances in information and communication technology (ICT). However, the difficulty of learning programming is a major problem for novices. Therefore, we propose a logic error detection algorithm based on structure patterns, which are an index of similarity based on abstract syntax trees, and error degree, which is a measure of appropriateness for feedback. We define structure patterns and error degree and present the proposed algorithm. In addition, we develop a Logic Error Detector (LED) Application Programming Interface (API) based on the proposed algorithm. An implementation of the proposed algorithm is used in experiments using actual data from an e-learning system. The results show that the proposed algorithm can accurately detect logic errors in many programs solving problems in the Introduction to Programming set.

1 Introduction

The Fourth Industrial Revolution has increased the demand for engineers [1] [2] [3]. Until recently, computer science was learned by university students, often in engineering fields. Because of a shortage of engineers in many countries, attempts have been undertaken to introduce computer science into secondary school education.

A study suggested that the high school ICT curriculum should focus on computer science [4]. A report by the Royal Society of the United Kingdom emphasized the importance of computer science skills in primary education [5]. The report pointed out problems in ICT education, such as those in class content and the loss of opportunities for students. In addition, it proposed to redefine ICT into three areas, namely computer science, information technology, and digital literacy, among which computer science is a particularly important area. The movement to implement programming education is accelerating globally.

For introducing programming in school education, many problems have been identified and various teaching methods have been proposed [6] [7]. A report summarizing three years of compulsory programming education in the UK published in 2014 found that it was patchy and fragile [8]. The report briefly discussed the difficulty of programming education.

A student's inherent interest in computer programming affects learning. Learners with an interest in programming can effectively learn in large groups with a single teacher, as is done in the university. Such learners can solve problems by investigating them or asking questions. However, traditional teaching methods may be unsuitable for novices and learners who are not interested in programming. One of the most effective ways for novices to learn is one-on-one learning with a teacher. This is especially true for programming because programs that accomplish a given task can be written in various ways. Teachers must thus strictly evaluate the program written by a learner.

Programming includes complex language constructs and requires logical thinking, similar to that used in mathematics. Programmers must consider algorithms, memory space, execution time, and code size. However, exhaustive and quantitative evaluation of programs by a human teacher is difficult. In addition, programs may not work as expecting due to various bugs. It is difficult even for experienced teachers to deal with every bug.

To improve this situation, it is necessary to assign a knowledgeable teacher to several novice programmers. However, this is not possible in classes that introduce programming due to a lack of human resources. To solve this problem, methods for estimating the difficulty of programming problems using cluster analysis and problem recommendation algorithms have been proposed [9] [10]. In addition, attempts have been made to identify early crisis situations experienced by novice programmers using clustering [11]. However, many studies considered only optimizing human resources and

*Corresponding Author: Yuto Yoshizawa, The University of Aizu, Computer Science and Engineering, Fukushima 965-8580, Japan

presenting a course to users. The quality of teaching still depends on the actual teacher. To solve this problem comprehensively, an intellectual tutoring system is required.

Online judge systems are environments in which programming can be learned independently [12]. An online judge is an online execution environment that executes and verifies source code submitted by users. Users can improve their programming skills by solving problems in various categories (e.g., syntax, semantics, algorithms, data structures). In addition to automatic verification, an online judge provides a quantitative performance evaluation (execution time, memory usage, etc.) of the program. Although online judges satisfy certain requirements of an autonomous learning environment, it is extremely difficult for novice programmers to continue learning using online judges because they do not provide concrete feedback. Originally, online judges were created for programming contests, in which a solution is either accepted or rejected. Thus, programmers can only recognize that their program has an error, not which type of error (e.g., logic error, compile error, run-time error). For such a program, which is "executable for any input", but "does not satisfy the specifications of the problem", the judgment does not provide useful support for the user. Therefore, novice programmers tend to give up if their logic errors cannot be debugged.

There are various approaches to programming education, including methods that use program execution traces and program dependence graphs. Here, we propose a logic error detection algorithm based on structure patterns, error degree, and abstract syntax trees. A structure pattern is a list generated from the corresponding abstract syntax tree and is an index of similarity at the structure level. An error degree is a value generated from a result of the detection algorithm and is an index of similarity at the characteristic level. The goal of the proposed algorithm is to provide optimal and personalized feedback to individuals. The proposed algorithm provides personalized feedback based on filtering using structure patterns, error degree, and the characteristics of abstract syntax trees.

In this paper, an algorithm for detecting logic errors and the corresponding API, which can be used to construct intelligent coding editors, are presented. The results of quantitative and qualitative experiments are shown. The quantitative experiments are used to verify the detection range of logic errors. The results show that the proposed algorithm can detect logic errors in many cases. The qualitative experiments are used to determine the detection accuracy and evaluate the appropriateness of feedback based on the detection results. The proposed algorithm is shown to detect logic errors and provide appropriate feedback in many cases. In some cases, generated feedback was inappropriate for learning support. This paper is an extension of the work originally presented in "2018 9th International Conference on Awareness Science and Technology (iCAST)" titled "Logic Error Detection Algorithm for Novice Programmers based on Structure Pattern and Error Degree" [13].

The remainder of this paper is organized as follows. Section 2 presents related research. Section 3 describes the logic error detection algorithm. Section 4 describes the LED API. Section 5 presents experiments that use data from an online judge system. Section 6 shows and discusses the experimental results and suggests possible improvements. Finally, Section 7 summarizes the main conclusions.

2 Related Research

The goal of the present study is to construct an autonomous learning environment for novice programmers. However, autonomous learning of programming has not been clearly defined.

Learner autonomy has been mainly considered in the field of foreign language education by researchers such as Holec [14] [15]. Dickinson proposed the concept of autonomous learning, where learners do not rely on teachers, but are themselves responsible for the results, and make all decisions related to learning [16]. Therefore, autonomous learning can be broadly defined as self-learning controlled by the learner.

This definition of autonomous learning assumes that the learning environment is appropriate. However, there is a shortage of teachers in programming education. In the present study, autonomous learning of programming is defined as autonomous learning in an environment without an actual teacher.

Thus far, a number of approaches to support novice programmers have been proposed. In this paper, we present methods that have different targets and structures, and require different educational resources.

Wu et al. designed practice teaching and assessment methods around an online judge system and proposed resolution methods for existing problems in hybrid learning [17]. Semi-automatic evaluation methods that focus on reducing the burden on teachers have also been proposed [18]. In this approach, students are grouped according to the structure of their source code submitted to the online judge, and guidance is provided for each group. Using a network of online judge users, a hybrid method that allows other users to be asked for guidance has been proposed [19]. This approach uses a clustering result based on the similarity of source code. In addition, a method that uses solutions and a language model based on long short-term memory (LSTM) networks for bug detection has been proposed [20].

Fault localization with program execution traces is a well-known technique for detecting logic errors. Using this concept, Su et al. constructed a Moodle-based online learning environment to provide feedback for logic errors [21]. In a study related to this technique, the accuracy of logic error detection using only 20% of the source code and the effectiveness of feedback using a lightweight spectrum-based algorithm were verified [22].

There are approaches that target specific logic errors to support novices. These approaches focus primarily on conditional branches and detect common logic errors, such as careless mistakes in conditional expressions, priority violations, and infinite loops [23] [24].

Targeted at advanced novice programmers, FrenchPress [25] is an eclipse plugin that focuses on programming style and supports programmers who have not yet assimilated the object-oriented paradigm.

In the present study, logic errors are detected by comparing a source code that may include logic errors with correct source codes stored in an online judge system. A comparison of source code is generally performed to detect code clones (i.e., similar or identical fragments of code) [26] [27] [28]. The following four types of method are commonly used to detect code clones.

Text-based methods directly compare source code as text. This type of comparison includes a lot of unique information, such as

variable names. Token-based methods compare tokens obtained by a lexical analysis of source code. Since this type of comparison is not affected by unique information, such as variable names, it has relatively high accuracy. Tree-based methods compare code based on abstract syntax trees obtained by a syntax analyzer. Since parts unrelated to the meaning of the program are omitted from the syntax tree, the structural information of the source code is used for comparison. Semantic-based methods compare code using various information obtained from a parser. A program dependence graph is primarily used. It is possible to detect discontinuous code clones, which are difficult to find using other methods.

The results obtained from text or token comparison are not necessarily consistent with the structure of the source code. Therefore, it is difficult to generate accurate feedback when using text- and token-based methods for detecting logic errors. Since the program dependency graph used in semantic-based approaches has information on data dependency and control dependency, it is possible to perform a comparison based on semantics rather than the description of source code. However, in the isomorphism judgment of graphs, although the semantics of the programs are the same, it is considered difficult to detect logic errors that differ only in internal values. A comparison using abstract syntax trees is based on the structural information of source code and thus can be performed at the syntax level, considering for example *if* statements or *for* statements. Therefore, this method is considered to be suitable for detecting logic errors by a feedback algorithm.

3 Logic Error Detection Algorithm

In the present study, two kinds of source code, namely "wrong code" and "correct code", are used to demonstrate the proposed algorithm. The wrong code is code submitted to an online judge and judged as "Wrong Answer". It is the target for detecting logic errors by the proposed algorithm. The correct code is code judged as "Accepted" and stored in the online judge system. It is the comparison target for detecting logic errors by the proposed algorithm.

3.1 Logic Error

A logic error is a bug in a program that triggers erroneous behavior but does not cause abnormal termination. In other words, logic errors induce behavior not intended by the programmer. Programs that contain logic errors are valid programs that can be compiled and executed. To debug a logic error, the user must determine the cause of the error by tracing variable information during execution using a number of test cases. Table 1 shows some common examples of logic error.

3.2 General Approach of Proposed Algorithm

In the present study, we propose a logic error detection algorithm based on a comparison between wrong and correct code. The proposed algorithm uses a comparison method based on an abstract syntax tree, which is a data structure in which the grammatical structure of source code is represented by finite labeled oriented trees. An abstract syntax tree is recursively defined by a minimum unit, called a syntax, generated by a parser. For example, *if* and *for* statements are recursively defined by a number of constructs.

Table 1: Common examples of logic error

Type of logic error	Cause
Loop condition	Incorrect number of iterations of *for* statement
Conditional branch	Incorrect conditional expression in *if* statement
Output format	Incorrect rounding
Data type	Incorrect data type
Calculation	Incorrect operator in binary expression
Indexing	Wrong index accessed

In the present study, a construct that is recursively defined by other constructs is denoted as a nonterminal construct, and a construct that is not recursively defined by other constructs is denoted as a terminal construct. Examples of nonterminal constructs are *if* statements and conditional expressions, and examples of terminal constructs are character strings and numeric values. Specifically, the algorithm compares abstract syntax trees of the target source code by applying the following steps recursively.

1. If the information on terminal constructs of the same kind is not different, it is not judged as a logic error.
2. If the information on terminal constructs of the same kind is different, it is judged as a logic error.
3. If the constructs are the same kind of nonterminal construct, they are compared to each other.
4. In other cases, a logic error is judged to have occurred.

The algorithm detects constructs that are logic errors. Algorithm 1 shows the pseudocode of the logic error detection algorithm.

The proposed algorithm can compare compilable source code. However, because of the characteristics of abstract syntax trees, a comparison of source code with different tree shapes generates detection results that are unsuitable for detecting logic errors. In addition, even if the shapes of the trees are the same, a comparison of code with different node meanings will generate incorrect detection results. Therefore, the proposed algorithm has two phases.

In the first phase, an appropriate comparison target is selected. The proposed algorithm compares only two source codes and detects logic errors. However, the user may attempt to solve a problem using various approaches. For example, a loop can be implemented using a *for* statement or a *while* statement. If the detection algorithm is applied to the source code of programs that have quite different structures, incorrect results will be obtained. Figures 1 and 2 show examples of a comparison of source code that uses different algorithms. A suitable comparison target is required to detect logic errors.

Algorithm 1 Logic Error Detection

Require:
x = expression in wrong code, x_n = n-th expression of x
y = expression in correct code, y_n = n-th expression of y
Ensure:
E = an array of Logic Error : Array

```
1:  function DETECTION(x, y)
2:      E ⇐ empty array
3:      if x and y are terminal constructs of the same kind then
4:          if x and y are the same information then
5:              return E                                          ▷ Step 1
6:          else
7:              return E ⇐ x                                      ▷ Step 2
8:          end if
9:      else if x and y are nonterminal constructs of the same kind then
10:         if the number of expressions of x and y are the same then
11:             for i = 1 to the number of expressions in x do
12:                 Connect E and DETECTION(x_i, y_i) together    ▷ Step 3
13:             end for
14:             return E
15:         end if
16:     end if
17:     return E ⇐ x                                              ▷ Step 4
18: end function
```

Figure 1: Example of detection with a *for* statement approach

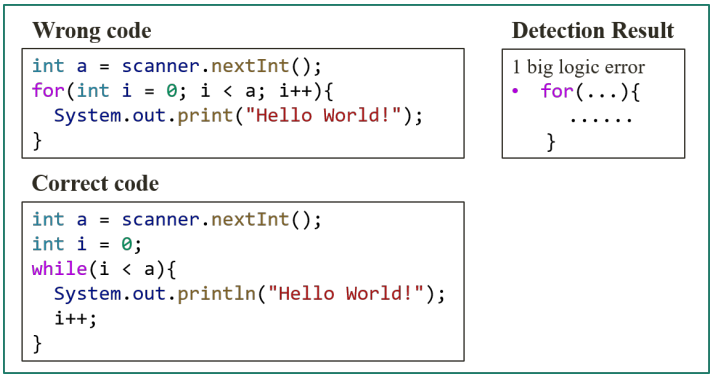

Figure 2: Example of detection with a *while* statement approach

In the second phase, the best detection result is selected. The proposed algorithm generates feedback for the user based on a comparison of the source code. However, the algorithm that the user employs to solve a problem is independent of the source code structure. For example, how conditional branches and libraries are used depends on the user's characteristics. If the detection algorithm is applied to the source code of programs with different algorithms, we may provide feedback while ignoring the characteristics of the corresponding user.

Figures 1 and 3 show examples of a comparison of source code that uses different loop constructions. Therefore, we need to give feedback based on correct codes that has the same characteristics as those of the target codes.

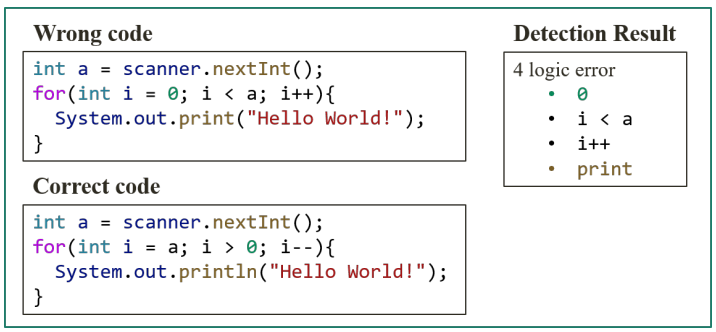

Figure 3: Example of detection with a decrement algorithm

3.3 Structure Pattern

In the present study, structure patterns are used in the first phase. A structure pattern is a list generated from the corresponding abstract syntax tree and is an index of similarity at the structure level. Moreover, it is core data obtained by a depth-first search of the abstract syntax tree and includes a list of expressions and block statements. The generated list contains expressions such as a variable declaration and assignment, and control structures such as *for* and *if* statements. Therefore, a structure pattern can be considered to express the general form of source code.

Figure 4 shows a sample source code. Figure 5 shows an example of an abstract syntax tree parsed from the sample source code. Table 2 shows an
example of a structure pattern generated from the sample source code.

```
int a = sc.nextInt();
int b = sc.nextInt();
if(a < b) {
  System.out.println("a < b");
}else if(a > b) {
  System.out.println("a > b");
}else {
  System.out.println("a == b");
}
```

Figure 4: Sample source code

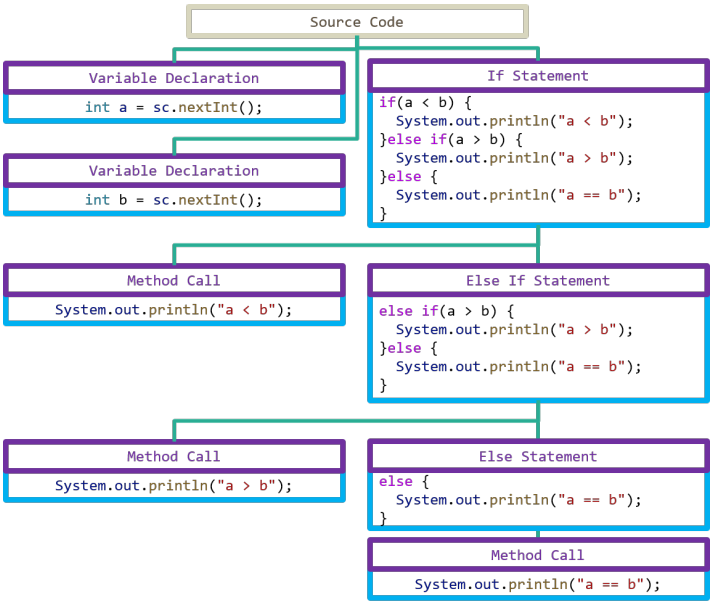

Figure 5: Abstract syntax tree for the source code in Figure 4

Programs with the same structure patterns have the same order and kind of constructs. Therefore, we can obtain appropriate comparison targets by filtering correct code using the structure pattern. For example, the structure patterns for the source code in Figures 1 and 2 are shown in Tables 3 and 4, respectively. As shown, appropriate correct codes for comparison can be obtained by filtering according to the structure pattern.

Table 2: Structure pattern for the source code in Figure 4

Index No.	Syntax
1	Variable Declaration
2	Variable Declaration
3	*If* Statement
4	Method Call
5	*Else* Statement
6	*If* Statement
7	Method Call
8	*Else* Statement
9	Method Call

Table 3: Structure pattern of wrong code and correct code shown in Figure 1

Index No.	Syntax
1	Variable Declaration
2	*For* Statement
3	Method Call

Table 4: Structure pattern of correct code shown in Figure 2

Index No.	Syntax
1	Variable Declaration
2	Variable Declaration
3	*While* Statement
4	Method Call
5	Binary Expression

3.4 Error Degree

In the present study, the error degree is used in the second phase. An error degree is a value generated from a result of the detection algorithm and is an index of similarity at the characteristic level. Moreover, it is a total value obtained by assigning a weight according to the type of detected logic error and can be expressed as (1).

x = the number of logic errors
w = weight of logic error
n = the number of logic error types

$$E_{rrordegree} = \sum_{i=1}^{n} x_i w_i \tag{1}$$

The error degree is zero when the wrong code is compared with itself. An increase in error degree indicates that the source code has characteristics different from those of the wrong code. Therefore, we can obtain optimal feedback by comparing the wrong code with all versions of correct code and by filtering the detection results using the error degree. Table 5 shows the weighting rules. The weight depends on the logic error type in the source code. For example, errors at the element level, such as terminal constructs

and operators, have lower weight, whereas errors at the syntax level, such as the type of syntax and its presence in the code, have higher weight. Errors related to the number of constructs are weighted in proportion to this number.

Table 5: Weighting rules for error degree

Error type	Weight
Terminal construct	1
Operators in expressions	3
Number of constructs	2*constructs
Existence of component	5
Construct that exists only on one side	10
Types of construct for comparison	10

The error degree compensates for the weaknesses of filtering by structure pattern. For example, Figures 6 and 7 show the results of logic error detection for the source code of programs with the same structure patterns presented in Figure 1 and Figure 3. As shown in these figures, more accurate feedback can be obtained by calculating the error degree from the detection result.

Detection Result

Logic Error	Error Type	Weight
print	Terminal construct	1

Error Degree = 1

Figure 6: Detailed detection results for source code in Figure 1

Detection Result

Logic Error	Error Type	Weight
0	Types of construct for comparison	10
i < a	Operators in expressions	3
i ++	Operators in expressions	3
print	Terminal construct	1

Error Degree = 17

Figure 7: Detailed detection result for source code in Figure 3

3.5 Extended Detection Algorithm

The purpose of the proposed algorithm is to support autonomous learning by detecting logic errors in a wrong code and providing the corresponding feedback. The detection algorithm provides feedback through the following steps.

1. Analyze the judged source code and generate a structure pattern.
2. From the data stored in the online judge system, extract correct codes with the same structure pattern.
3. Compare all of the extracted correct codes with the wrong code, and calculate the error degree based on the detection results.
4. Provide information obtained based on the detection result with the lowest error degree as feedback for the user.

Algorithm 2 shows the pseudocode of the extended logic error detection algorithm.

4 Implementation of Algorithm API

Section 3 described the proposed logic error detection algorithm for general online judge systems. In the present study, we also developed an LED web API for the proposed algorithm that is compatible with Aizu Online Judge (AOJ) [29].

4.1 Aizu Online Judge

AOJ is an online judge system developed and operated by the University of Aizu. An online judge system is a service that compiles and executes programs submitted by users and automatically evaluates their accuracy and performance using various test cases and verification machines. At present, AOJ contains source code from 60,000 users and 4 million judgments. AOJ contains various problems, such as those used in programming contests (e.g., ACM-ICPC) and those specific to a certain topic, including Introduction to Programming (ITP), “Algorithm and Data Structures”, and related libraries. For these problems, limit values are set for CPU time and memory usage, and the user can practice by solving the problem under these limitations.

The user obtains a verdict by submitting the answer code for each question to the judge system. The judge system instantly provides feedback (accepted/rejected) based on various test cases for the problem, together with the CPU time and memory usage. The type of failure (Time Limit Exceeded, Memory Limit Exceeded, Runtime Error, etc.) is also given in the feedback. Users can debug their code based on the feedback and resubmit code as many times as desired. In the present study, the aim is to detect logic errors, so we only cover programs corresponding to "Accepted" and "Wrong Answer".

AOJ has an API for accessing a part of its database. The API can be used for developing various tools. For example, there are submitted source code, submission history including log of trial and error.

4.2 Logic Error Detector API

In the present study, we developed an LED that uses source codes stored in AOJ. Furthermore, by implementing peripheral functions, we developed as a web API for the LED.

Algorithm 2 Extended Logic Error Detection

Require:
X = submitted code
Y = array of accepted programs, Y_n = n-th accepted program
Ensure:
F = Feedback
function EXTENDED DETECTION(X) ▷ Step 1
  R = empty array
  $p_{attern} \Leftarrow$ structure pattern of X ▷ Step 2
  $Y \Leftarrow$ all the correct codes submitted for a given problem as X
  $Y \Leftarrow Y$ that have the same structure pattern as p_{attern} ▷ Step 3
  for i = 1 to number of Y **do**
    add detection result based on ALGORITHM 1(X, Y_n) to R ▷ Step 4
  end for
  return $F \Leftarrow$ detection result with the lowest error degree in R ▷ Step 5
end function

From the viewpoint of data availability and practicality, source codes in Java language are analyzed and utilized for the LED API. There are three main reasons for selecting Java. Firstly, it is often adopted as an introduction to object-oriented programming languages for novice programmers. Secondly, it is the second most frequently used language in AOJ. The use of stored data makes it possible to detect logic errors more accurately, so there must be a sufficient number of comparison objects. Thirdly, an open-source library called JavaParser can be used to convert source code written in Java into an abstract syntax tree.

The LED API is implemented using docker containers that serve as a web server, an application server, and a database server. Figure 8 shows an architecture diagram of the LED API.

The web container, based on Nginx, is responsible for front-end processing and acts as a reverse proxy. At the front-end, we implemented tools for research and simple editors using Vue.js and trial of API is possible. The reverse proxy controls access to the application container. Only the web container is exposed to the outside world via the API to prevent attacks on the application and database containers.

The application container is responsible for the back-end processing by the LED, which is the application that implements the proposed algorithm. Since only the host can connect to the database container, it can be used together with the reverse proxy of the web container to prevent attacks on the database container.

LED is a Java application developed using Spring Boot based on Spring Framework. MySQL and Hibernate, as an object-relational mapper, are adopted. JavaParser is used for parsing source code written in Java.

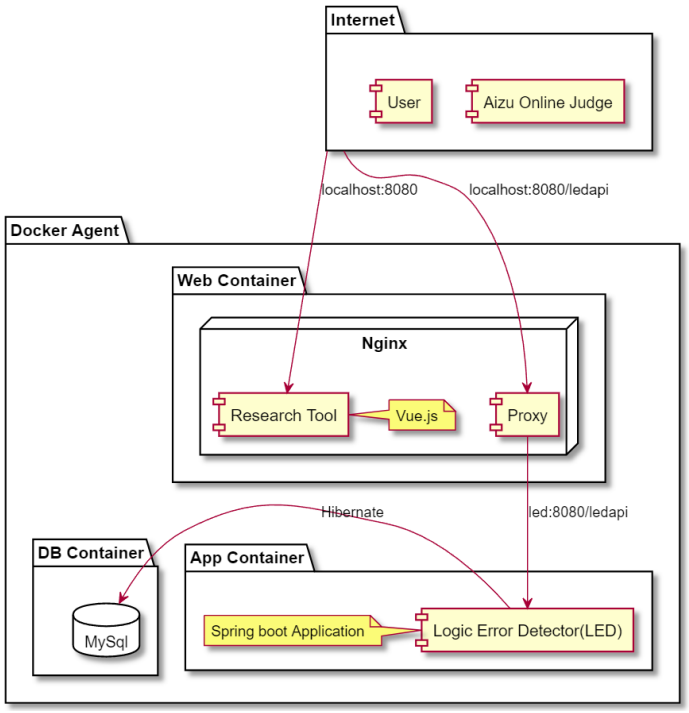

Figure 8: LED architecture diagram

4.3 Class Composition

Figure 9 shows a class diagram of LED. The SourceCode class is used to represent source codes submitted to and stored in AOJ. It has a many-one relation with the Problem, Status, and StructurePattern classes. It includes information on the ID of the user who submitted the code, the ID of the judge, and the submitted code.

The StructurePattern class represents the structure pattern of source code for each program. It has an one-to-many relationship with the SourceCode and PatternComponent classes.

The PatternComponent class is used to represent the type and order of syntax in the structure pattern. It has many-to-one and composition relationships with the StructurePattern class. This is because the structure pattern includes the type and order of syntax, and there are cases where the source code of multiple programs has the same structure patterns, but the pattern component completely depends on the structure pattern.

The ErrorReport class is used to represent the comparison result

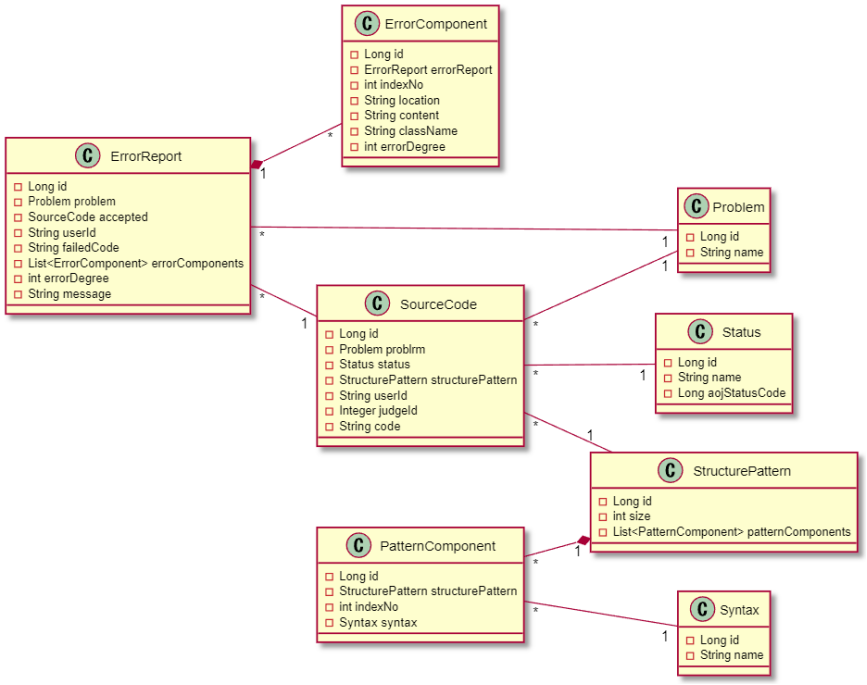

Figure 9: LED class diagram

of the logic error detection algorithm and is also a feedback class of the LED API. It has a many-to-one relationship with the SourceCode and Problem classes. It has many-to-one and composition relationships with the ErrorComponent class. It includes information on wrong codes in which logic errors were detected and correct codes used to generate the detection result selected by filtering using the error degree.

The ErrorComponent class is used to represent details of the detected logic error. It has the location, content, class of syntax, and error degree information of the logic error detected in the wrong code.

4.4 Behavior

Figure 10 shows the relationship between classes and objects. The flow of logic error detection using the LED API is as follows.

1. The user submits a source code that is judged as "Wrong Answer".
2. The wrong code is analyzed and its structure pattern is generated.
3. The structure pattern of the wrong code is searched for in the database.
4. Correct codes with the same structure pattern as that of the wrong code are searched for in the database and used as candidate codes for detection.
5. Using LED, all candidate codes are respectively compared to the wrong code and an error report is generated.
6. The error report with the lowest error degree is provided to the user as feedback.

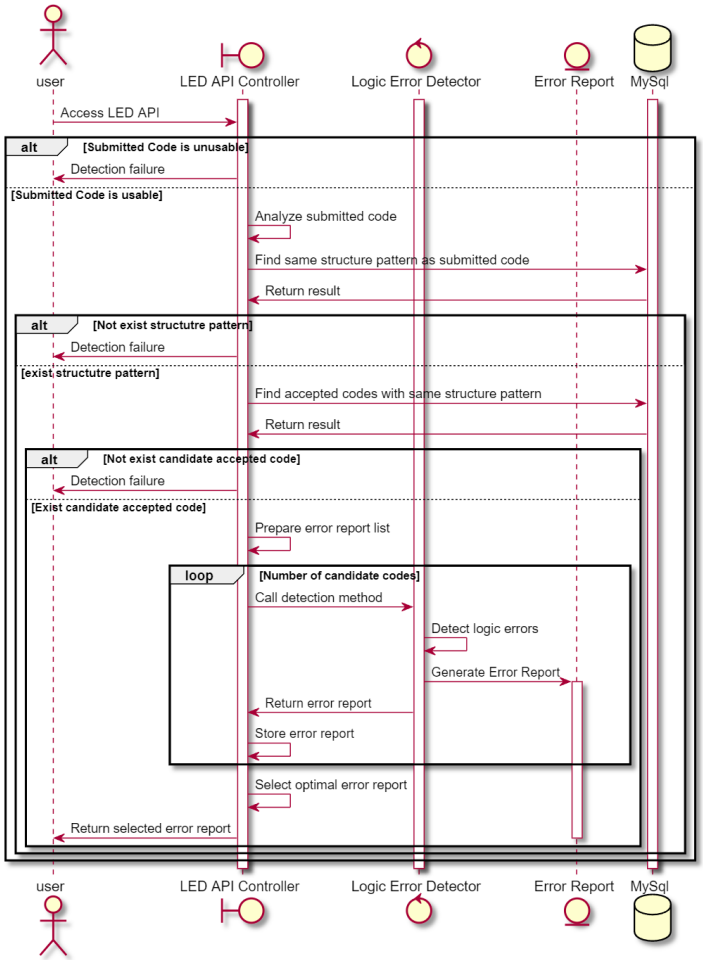

Figure 10: LED sequence diagram

5 Experiment

We conducted quantitative and qualitative experiments using the LED API and AOJ. The LED API is first used to detect logic errors in wrong code submitted by a user who has never solved the problem. Therefore, in this experiment, source codes judged to be "Wrong answer" in AOJ were used as wrong codes.

5.1 Basic Dataset from AOJ

AOJ has a problem set for novices called ITP. In this experiment, all problems in ITP were used. The dataset consists of source code that satisfies the following conditions.

- Submitted to solve the target problems.
- Judged as “Accepted” or “Wrong Answer”.
- Written in Java.
- Consists only of the main method.
- Considered not to be created by the same user.

Tables 6 and 7 show the details of the dataset. “Problem Id” is the problem id of the experimental target. “Usable Programs” is the number of available programs. “Structure Pattern” is the number of structure patterns. “Common Pattern Programs” is the number of programs with the most common structure pattern.

5.2 Experiment 1: Quantitative Method

This subsection describes experiments conducted using quantitative methods.

AOJ stores all the source codes submitted by users. Therefore, there are correct and incorrect answers to certain problems submitted by a given user. By comparing correct codes and the wrong code submitted by a given user, it is possible to obtain reliable feedback *F* necessary for debugging. From the inclusion relation of feedback *F* and feedback *F'* obtained using the LED API, we measure what portion of logic errors can be detected by the proposed algorithm.

In this experiment, we evaluated whether the following statements are true:

- The LED API can be used to detect all logic errors.
- The LED API can be used to detect some logic errors.

For evaluating the first statement, we measured whether *F'* completely includes *F*. The code debugged based on information provided by feedback *F* has already been accepted by AOJ. Therefore, when feedback *F'* completely includes feedback *F*, it can be regarded that all the logic errors were detected.

For evaluating the second statement, we measured whether *F'* contains some of *F*. During debugging, a user may modify not only the algorithm, but also variable names, the order of processing, etc. Therefore, when some of feedback *F* are included in feedback *F'*, it can be regarded that some logic errors were detected.

The following procedures were applied to each target problem.

1. Apply the proposed algorithm to correct code and wrong code submitted by a given user and obtain feedback *F*.
2. Generate feedback *F'* from the wrong code using the LED API.
3. Determine the inclusion relation of *F* and *F'*.

The dataset consists of source code that satisfies the following conditions.

- Correct code and wrong code that submitted by the same user.
- These two programs have the same structure patterns.

5.3 Experiment 2: Qualitative method

This subsection describes experiments conducted using qualitative methods.

In Experiment 1, the accuracy of logic error detection was investigated using a quantitative method. However, the experiment only measured the detection range, and it is not known whether the feedback is sufficient for debugging. Therefore, we manually debugged a code using feedback from the LED API and verified whether the wrong code was acceptable by AOJ. In this experiment, we evaluated whether the following statements are true:

- The LED API can be used to correctly detect logic errors.
- The provided feedback is appropriate for supporting learning.

The following procedures were applied to each target problem.

1. Randomly select a wrong code in AOJ.
2. Detect logic errors using the LED API.
3. Debug the wrong code manually using feedback and verify whether the debugged code is acceptable by AOJ.

Table 6: Problem Information

Problem ID	Topic	Summary of Problem
ITP1_1_A	Getting Started	Print "Hello World" to standard output.
ITP1_1_B		Calculate the cube of a given integer x
ITP1_1_C		Calculate the area and perimeter of a given rectangle.
ITP1_1_D		Read an integer S [second] and convert it to h:m:s.
ITP1_2_A	Branch on Condition	Print small/large/equal relation of given two integers a and b.
ITP1_2_B		Read three integers a, b and c, and print "Yes" if $a < b < c$, otherwise "No".
ITP1_2_C		Read integers and print them in ascending order.
ITP1_2_D		Read a rectangle and a circle, and determine whether the circle is arranged inside the rectangle.
ITP1_3_A	Repetitive Processing	Print "Hello World" 1000 times.
ITP1_3_B		Read an integer x and print it as is for multiple test cases.
ITP1_3_C		Read two integers x and y, and print them in ascending order for multiple test cases.
ITP1_3_D		Read three integers a, b, and c, and print the number of divisors of c in [a, b].
ITP1_4_A	Computation	Read two integers a and b, and calculate a / b in different data types.
ITP1_4_B		Calculate the area and circumference of a circle for given radius r.
ITP1_4_C		Read two integers, a and b, and an operator op, and then print the value of a op b.
ITP1_4_D		Read a sequence of n integers $a_i(i=1,2,...n)$, and print the minimum value, maximum value, and sum of the sequence.
ITP1_5_A	Structured Program I	Draw a rectangle whose height is H cm and width is W cm.
ITP1_5_B		Draw a frame whose height is H cm and width is W cm.
ITP1_5_C		Draw a chessboard whose height is H cm and width is W cm.
ITP1_5_D		Structured programming without *goto* statement.
ITP1_6_A	Array	Read a sequence and print it in reverse order.
ITP1_6_B		For given a deck of cards, find missing cards.
ITP1_6_C		Count the number of elements in a three-dimensional array.
ITP1_6_D		Read a n×m matrix A and a m×1 vector b, and print their product Ab.
ITP1_7_A	Structured Program II	Read a list of student scores and evaluate the grade for each student.
ITP1_7_B		Find the number of combinations of integers that satisfy 1) three distinct integers from 1 to n, and 2) sum of the integers is x.
ITP1_7_C		Read the number of rows r, columns c, and a table of r×c elements, and print a new table that includes the total sum for each row and column.
ITP1_7_D		Read a n×m matrix A and a m×l matrix B, and print their product.
ITP1_8_A	Character	Convert uppercase/lowercase letters to lowercase/uppercase.
ITP1_8_B		Read an integer and print the sum of its digits.
ITP1_8_C		Count the number of appearances for each letter (ignoring case).
ITP1_8_D		Find a pattern p in ring-shaped text s.
ITP1_9_A	String	Read a word W and text T, and print the number of times that word W appears in text T.
ITP1_9_B		Read a deck (a string) and shuffle it, and print the final state (a string).
ITP1_9_C		Read a sequence of Taro and Hanako cards and report the final scores of the game.
ITP1_9_D		Perform a sequence of commands including reverse and replace operations.
ITP1_10_A	Math Functions	Calculate the distance between two points $P1$($x1$, $y1$) and $P2$($x2$, $y2$).
ITP1_10_B		For the given two sides of a triangle a and b and the angle C between them, calculate the area, circumference, and height of the triangle.
ITP1_10_C		Calculate the standard deviation.
ITP1_10_D		Read two n-dimensional vectors x and y, and calculate Minkowski's distance, where $p=1,2,3$, ∞.
ITP1_11_A	Structure and Class	Simulate rolling a dice.
ITP1_11_B		Print the integer on the right side face of the rolled die.
ITP1_11_C		Read two dice and determine whether they are identical.
ITP1_11_D		Read n dice and determine whether they are all different.

6 Results and Discussion

In this section, we present and discuss the results of each experiment.

6.1 Results of Experiment 1

Table 8 shows the results of Experiment 1. "Problem Id" is the problem id of the experimental target. "All Users" is the number of users who submitted source code. "Usable Users" is the number

Table 7: Statistics of the Dataset Used in the Experiment

Problem ID	Number of Programs	Usable Programs	Structure Pattern	Common Pattern Programs

of users who submitted both correct and wrong code with the same structure patterns (and thus logic errors can be detected using the LED API). "Whole Success Users" is the number of users for whom all logic errors were detected using the LED API. In other words, this is the result of the first statement. "Partial Success Users" is the number of users for whom some logic errors were detected using the LED API. In other words, this is the result of the second statement. "Whole Success Ratio" is the ratio of Whole Success Users to Usable Users. "Partial Success Ratio" is the ratio of Partial Success Users to Usable Users. "Difference Success Ratio" is the difference between Whole Success Rate and Partial Success Rate.

The first item is the complete detection rate of logic errors. The results of the experiment show that all logic errors were detected for many problems. Overall, we succeeded in detecting logic errors in more than 70% of programs.

The second item is the partial detection rate of logic errors. The results of the experiments show that a higher detection ratio for partial logic errors was achieved for many problems. Overall, we succeeded in detecting logic errors in more than 80% of programs.

6.2 Results of Experiment 2

Table 9 shows the results of Experiment 2. The first item is the detection accuracy of logic errors. Considering the features of the evaluation method, it was considered that logic errors could not be correctly detected when the source code could be modified only by factors outside the feedback range. The results of the experiment show that we successfully detected logic errors in 100% of test cases. Therefore, the proposed detection algorithm has sufficient ability to detect logic errors in wrong code.

The second item is related to the appropriateness of feedback. The experimental results show that we succeeded in providing appropriate feedback in 80.4% of the test cases. This evaluation item is based on the qualitative method used to verify the appropriateness for supporting learning. Therefore, we should discuss the appropriateness of the judgment.

6.3 Discussion

In this subsection, we discuss the experimental results. Some ideas for improvement based on the experimental results are also given.

6.3.1 Discussion for Experiment 1

The results of Experiment 1 confirm that the proposed detection algorithm can support users who attempt to solve problems. We also confirmed that the detection algorithm can detect all the logic errors in a wrong code in many cases. However, results for statement 2 indicate that feedback may contain syntax that is unrelated to the algorithm. Therefore, it is necessary to improve detection accuracy by improving the detection algorithm.

6.3.2 Discussion for Experiment 2

The results of Experiment 2 confirm that logic errors can be detected by the proposed detection algorithm. In addition, we confirmed that the detection algorithm can provide appropriate feedback in many cases. Therefore, it is necessary to generalize some specific cases and to improve the algorithm.

6.3.3 Discussion for All Experiments

The results of the two experiments confirmed that the proposed algorithm can accurately detect logic errors and provide appropriate feedback. The proposed algorithm detects logic errors using source codes stored in the online judge system. To increase accuracy, we filter the codes using structure patterns and error degree. Therefore, detection accuracy depends on the diversity of source code stored in the online judge system. In the present study, although we only considered codes written in Java, the proposed algorithm can be applied to all context-free languages. There is more source code written in languages such as C and C ++, and thus logic errors can be detected with higher accuracy.

6.3.4 Improvements

In this subsubsection, we suggest some improvements based on the experimental results.

Based on the results of Experiment 1, we suggest the following two improvements. One improvement is the removal of elements not related to logic errors detected by the detection algorithm. For example, elements with the same meaning in different formats, such as variable names and logical expressions, can be removed because they are not related to logic errors. Another improvement is the use of a comparison method that is independent of the structure pattern (i.e., generalization of the algorithm). In Experiment 1, a rule regarding the structure pattern as a condition of the dataset was used. This rule was used because the LED API does not have a function for comparing
source codes with different structure patterns. Therefore, we suggest generalizing the algorithm by unifying the variable declaration part and determining the format of the calculation formula. This generalization would make it possible to compare source codes with different structure patterns without changing the meaning of the algorithm.

Based on the results of Experiment 2, we suggest the following three improvements. The first improvement is a comparison method of conditional branching. The conditional branching algorithm strongly depends on the logical expression that is employed by the user. In particular, filtering by structure pattern is not effective for problems that require multiple standard outputs using conditional branching. Therefore, we suggest a comparison based on a logical expression and feedback regarding the processing order. The second improvement is a comparison method of binary expressions. Because binary expressions are parsed using certain rules, a comparison between binary expressions from different structures are not effective. Therefore, we suggest making the error degree more accurate by implementing special logic to compare binary expressions. The third improvement is a review of the weighting when the type of syntax is the same but the elements are different. As an example, method call expressions can be very different, even using the same kind of syntax.

Table 8: Results of Experiment 1

	Users		Success Users		Success Rate		
Problem ID	All	Usable	Whole	Partial	Whole	Partial	Difference
ITP1_1_A	3502	358	335	358	93.58%	100.00%	+6.42%

ITP1_11_B	64	1	1	1	100.00%	100.00%	0%
ITP1_11_C	32	1	1	1	100.00%	100.00%	0%
ITP1_11_D	13	0	0	0	0.00%	0.00%	0%

Table 9: Results of Experiment 2

Feedback Type	Reason for Judgment	Cause of Logic Error	Rate	Total
Appropriate	Can be debugged	Literal	6.5%	80.43%
		Output format	19.6%	
		Binary expression	15.2%	
		Loop condition	8.7%	
		Type and output format	2.2%	
		Conditional branch	19.6%	
		Used type	4.3%	
		Used method	4.3%	
Inappropriate	Direct answer	Position of variables	17.4%	19.57%
	Ignored the algorithm	Non-optimal feedback	2.2%	
Wrong	Cannot be debugged		0.0%	0.0%

However, even with such a comparison, the error degree is a very small numerical value. In particular, standard output methods and various library methods are sometimes compared, so that optimal feedback cannot be generated in some cases. Therefore, we suggest measuring to what extent the syntax has the same meaning by using the namespace and arguments. We also suggest detecting the parent syntax itself as a logic error, such as when only variable names are detected as logic errors.

7 Conclusion

This study proposed a logic error detection algorithm based on structure patterns and error degree to support novice programmers. The proposed algorithm uses data in an online judge system to detect logic errors in wrong code and provides feedback for supporting problem solving. In addition, we developed the LED web API based on the proposed algorithm. The LED API is compatible with the online judge system, so it can promote autonomous learning with the corresponding environment.

Two experiments were conducted to verified the accuracy of the proposed algorithm. The experimental results show that the proposed algorithm can accurately detect logic errors and provide appropriate feedback. The proposed algorithm detected logic errors in programs for all the problems in the Introduction to Programming 1 set with high accuracy. In addition, the detection accuracy depends on the amount of data in the online judge system.

Although we constructed the autonomous learning environment and detection algorithm in Java, the proposed algorithm can be applied to various programming languages, such as C/C++, Python, and Ruby. Although the presented LED API is oriented to detec logic errors, the algorithm is capable of suggesting possible solutions. So, our future works include the extension of the API after conducting further experiments.

ABSTRACT

A new microstrip patch antenna for ultra-wideband applications is presented in this paper. The design and performance of the antenna component are discussed. The propounded antenna is mounted on a compact FR-4 substrate having dimensions 20 x 30 x 1.6 mm^3 with relative permittivity εr=4.3. The rectangular patch antenna is slotted with two types; rectangular and semi-circle slots so as to ensure a broad bandwidth. The results reveal that the antenna covers the frequency range of 3.1–7.5 GHz with a reflection coefficient reduced to -55 dB and a maximum gain of 5.9 dB. The details of the simulated and measured results for reflection coefficient are presented, showing a good agreement between them. To analyze the effect of the slots, the surface current distribution is investigated. The performances of good impedance matching are achieved within the operating band. Simulations are performed using CST Microwave Studio. The propounded antenna can be deployed for UWB applications and other radio communication services systems such as high-resolution radar, military communication, communications and sensors, position location and tracking.

1. Introduction

UWB technology has recently attracted significant attention in wireless communications thanks to its main features in particular high bandwidth and data rate, ensuring secure communication in military applications. The world of ultra-wideband (UWB) has changed in very recent history. In February 2002, the FCC (Federal communications commission) issued a ruling that UWB could be used for commercial applications on unlicensed basis as well as for radar and safety applications. The decision authorized very low power spectral density emission in a bandwidth ranging from 3.1 to 10.6 GHz [1-3]. UWB appears to be a technology very promising for wireless communications at very high levels data-rate, high-precision radar and imaging systems. UWB systems use short pulses (of the order of the picosecond), repeated at a certain rate that can be up to several giga-impulses per second, offering thus a very high bandwidth with a very low transmission power level. This offers UWB systems the possibility of coexisting with other systems.

To fulfill the demand in this type of communications, many research on UWB antenna design have been published. Most of them focused on patch antennas because of their simple structure, small size, low cost, low complexity, light weight, and high-speed data rate. They are considered as good candidates for UWB applications among many versions of UWB antennas. Nevertheless, micro-strip patch antenna has narrow bandwidth.

To resolve this problem and obtain the desired performances, many methods are used. The typical technique focus on cutting slots of several forms in the radiating element, the ground plane, and the feed line. Nowadays, many slot shapes are available and discussed by various researchers [4-6]. Slot antennas have proven to be useful in that context. However design and placement of these slots on the radiating element is challenging as compared to the other traditional techniques. The purpose of this project is to design a micro-strip patch antenna for UWB applications that covers the frequency range of 3.1–7.5 GHz.

2. Design and Configuration of the Antenna

The propounded antenna is a rectangular patch antenna which is fed by a micro-strip line and mounted on a dielectric substrate named FR4-lossy, with thickness h=1.6mm and relative

permittivity εr=4.3, having dimensions of 20 x 30 x 1.6 mm^3. These specifications for the substrate are a part of material parameters window on CST Microwave Studio. The material used in the patch and the ground is lossy copper with a thickness of Mt=0.035mm as given in Tab .1. The width of the line feeding is 3 mm and the length is 14.5 mm. The partial ground plane is also used with the propounded antenna geometry as shown in Figure 1. To investigate the impact of various antenna's characteristics (different slots), a meticulous parametric study was performed. The parametric values of the propounded antenna are shown in Tab.1. The antenna is excited by a 50-Ω micro-strip feed line. The parameters measurement of the patch are calculated using the following formulas [7]:

Width formula of rectangular:

$$W_p = \left(\frac{c}{2 f_r}\right)\left(\frac{\varepsilon_r + 1}{2}\right)^{-0.5}$$

Where c = 3×108 ms-1 and $\varepsilon_r = 4.3$

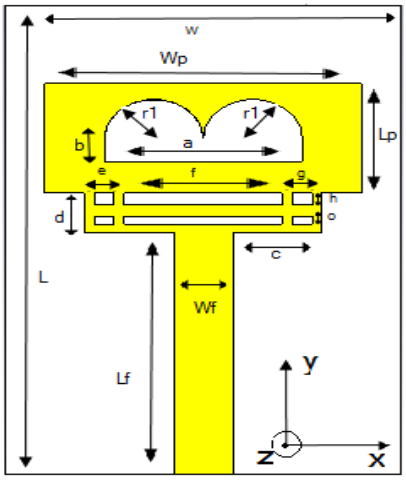
Formula of effective dielectric constant:

$$\varepsilon_{eff} = \left(\frac{\varepsilon_r + 1}{2}\right) + \left(\frac{\varepsilon_r - 1}{2}\right)\left(1 + \frac{12\ h}{W_p}\right)^{-0.5}$$

At h=1.6mm

Formula of length extension:

$$\Delta L = 0.412\ h\left(\frac{\varepsilon_{eff} + .3}{\varepsilon_{eff} - 0.258}\right)\left(\frac{\left(\frac{W_p}{h}\right) + 0.264}{\left(\frac{W_p}{h}\right) + 0.8}\right)$$



Length formula of rectangular:

$$L_p = \left(\frac{c}{2 f_r \sqrt{\varepsilon_{eff}}}\right) - 2\Delta L$$

To amplify the coupling between the feed line and the slots, multiple slots are introduced in order to broaden the operating bandwidth of the antenna. Having a quite large slot is logical transition to obtain wide bandwidth from an aperture-coupled patch. The first two slots are designed by combining rectangular and semi-circle slots placed in a juxtapose way [8-10]. In addition, different other rectangular slots are included in the radiating element. The structure of the antenna design is illustrated in Fig .1.

(a)

(b)

Figure 1 Design of the propounded UWB antenna (a) Top (b) Bottom

To improve the performance of micro-strip patch antenna, it is advisable to design a combination of two or more slots on the radiating element. This can be observed from the discussed literature survey that a micro-strip patch antenna with slots can be designed for wireless applications [11]. The technique employed in this paper retains the same elementary structure of the antenna with different slots included in the radiating element. In order to obtain a wide bandwidth, a rigorous investigation on different parameters in terms of feed width (Wf), feed length (Lf) and different slots width and length was performed. From the analysis we found the optimum dimensions of above parameters to be 3 mm, 14.5 mm respectively for the feed line, to meet the

requirement. The slots dimensions and other antenna's parameters are listed in Tab .1 on the basis of undertaken parametric analysis.

Figure 2 presents the simulated reflection coefficient of the antenna, the antenna without rectangular slots and the antenna without semi-circle slots. When different slots are included, a wide bandwidth is achieved from 3.1 to 7.5 GHz with three resonant frequencies at 3.9, 5.95 and 7.3 GHz. Effect of using different slots is shown. We notice that the propounded antenna is the best candidate to meet the requirements in terms of UWB bandwidth. The flow chart of the propounded antenna's design methodology is presented in figure 3.

3. Results and Discussions

The propounded UWB antenna is designed by opting for the optimal values of above parameters in order to cover the frequency range 3.1- 7.5 GHz. Both numerical and experimental tests have been achieved to assess the effectiveness of the propounded antenna and the results are presented in this section. Toward this end, the antenna was fabricated on FR4-lossy substrate (30 x 20 x 1.6 mm^3) with dielectric constant of Ɛr = 4.3. Figure 4 depicts the fabricated antenna for experimental verification.

The reflection coefficient of the antenna has been analyzed using CST Microwave STUDIO simulator and verified using another electromagnetic simulator HFSS as shown in Figure 5. A 3.1–7.5 GHz frequency range below -10 dB of return loss S11 is obtained. The reflection coefficient (S11), measured in decibel (dB), can be calculated using the formula:

$$S_{11} = -20log_{10}\left|\frac{Z_{in} - Z_0}{Z_{in} + Z_0}\right|$$

Where Z0 is the characteristic impedance of the 50 Ω SMA port and Zin is the driving point impedance of the antenna. Figure 5 shows a comparison of the simulated reflection coefficient using both CST and HFSS. The results corroborate that there is a good agreement between the two simulations with a small variation as the two softwares use different numerical techniques, finite integration technique, a relative of FDTD for CST Microwave Studio and Finite Element Method (FEM) for HFSS [12].

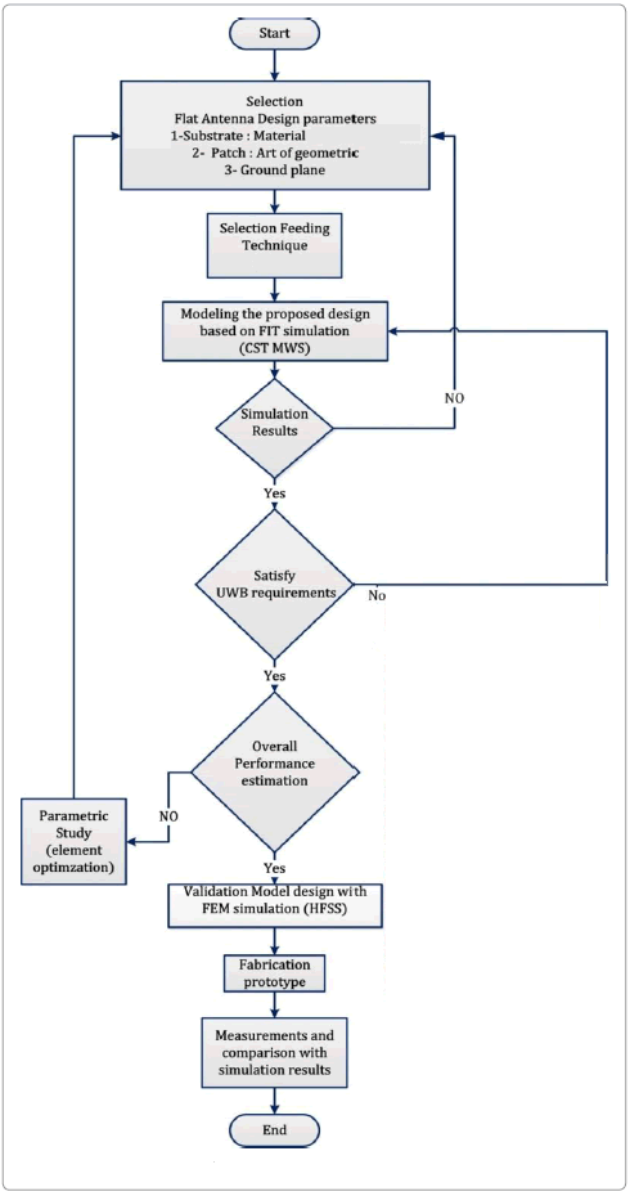

Figure 3 The flow chart of the propounded antenna's design methodology.

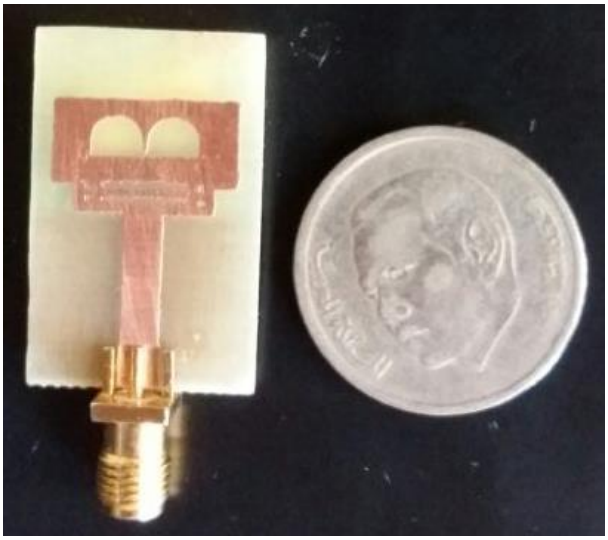

Figure 4 Photograph of the fabricated UWB antenna

The UWB antenna was measured after fabrication to examine the performance of the proposed approach. Measured reflection coefficient is achieved by vector network analyzer. The measured and simulated reflection coefficients of antenna are compared in Figure 6. From measured results, we can notice that the antenna is operating with a -10dB bandwidth from 3.1 to 7.5 GHz. A good agreement between simulation and measurement results is observed with a little discrepancy which is mainly owing to the fabrication margin. It could also be because to the impact of the feeding cable, feeding connector and the antenna fixation support as the structure is small.

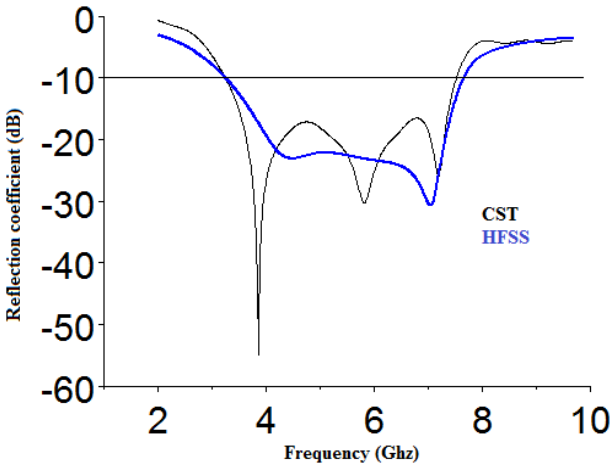

Figure 5 Simulated reflection coefficient of the propounded antenna

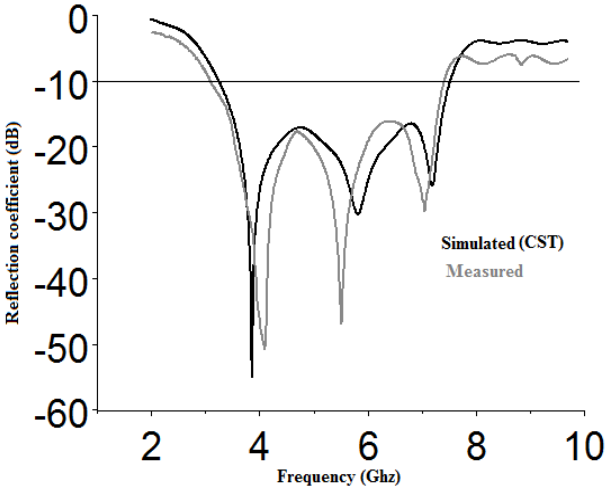

Figure 6 Measured and simulated reflection coefficient of the UWB antenna

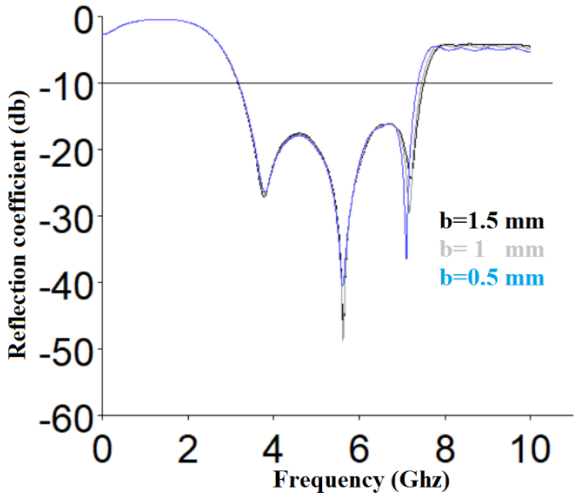
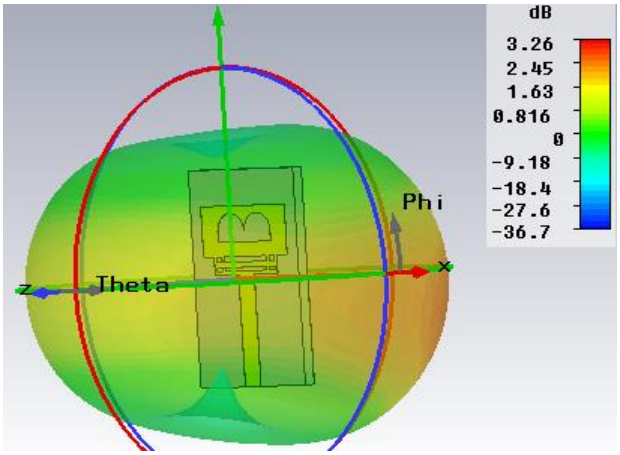
The electromagnetic solver, CST Microwave STUDIO, is used to numerically analyze and improve the antenna's configuration. Figure 7 presents the simulated results of the propounded antenna with the rectangular slot combined with semi-circle slots width, from 0.5 to 1.5 mm. It should be noticed that one variable at the time was varied, the others being constant. It is apparent that the bandwidth for UWB band decreases as the width decreases from 1.5 to 0.5 mm. Consequently, it is concluded that b= 1.5 mm is the optimal value for the bandwidth from 3.1 to 7.5 GHz, covering the whole UWB range with three resonant frequencies at 3.9, 5.95 and 7.3 GHz.





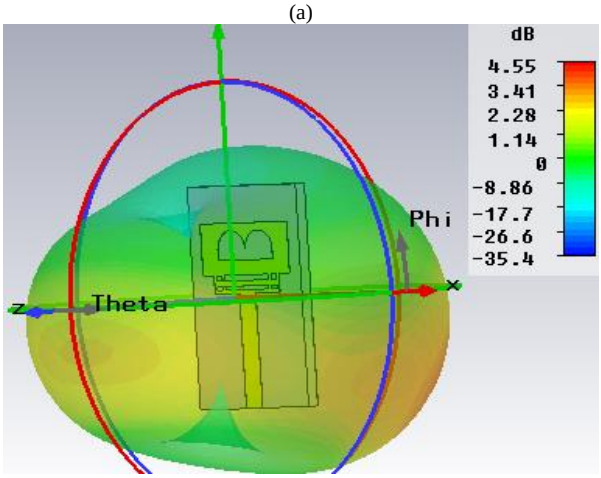


Figure 7 Simulated reflection coefficient response of the antenna as a function of "b". All other parameters are the same as listed in Table 1

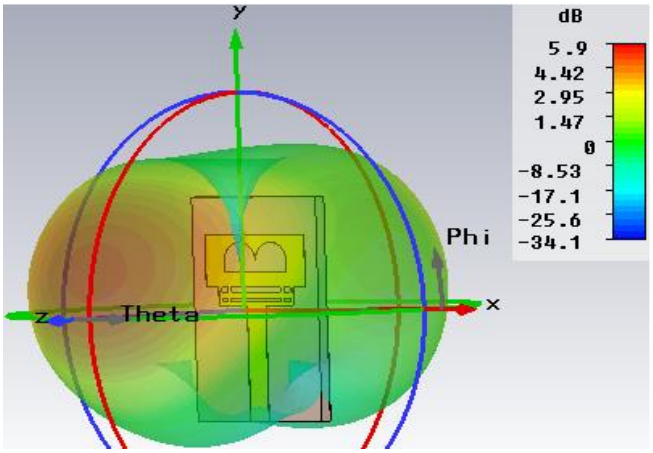

The propounded UWB antenna has an acceptable quasi omnidirectional radiation pattern needed to receive information signals from all directions. Figure 8 presents three-dimensional radiation patterns at three frequencies 3.9, 5.95 and 7.3 GHz. The gain of the antenna attain 3.26 dB at 3.9 GHz, 4.55 dB at 5.95 GHz and 5.90 dB at 7.3 GHz.

(a) (b)

(c)

Figure 9 Surface Current distributions at (a) 3.9 GHz, (b) 5.95 GHz and (c) 7.3 GHz

Surface current distribution has been depicted in Figure 9 and analyzed at discrete frequencies (a) 3.9 GHz, (b) 5.95 GHz and (c) 7.3 GHz, to give a physical perception and have a deeper understanding on the resonant behavior of the antenna. Figure 9 (a) and (b) shows that the surface current distributions are mainly flow and distributed though along the rectangular slots and the feed part. From Figure 9 (c), it can be observed that most of surface currents are concentrated on the edges of the interior and exterior of semi-circle slots. Effective coupling between different slots affords wide-band matched impedance bandwidth, therefore, the surface current is distributed evenly over the radiating patch. The maximum gain of the propounded antenna is presented in Figure 10. As expected, the antenna has a good gain over the whole operating frequency range with a maximum gain up to 5.9 dB.

The simulated radiation efficiency of the antenna is presented in Figure 11. It can be noticed that the antenna reaches a maximum radiation efficiency of 81% and more than 60% over the whole UWB frequency range.

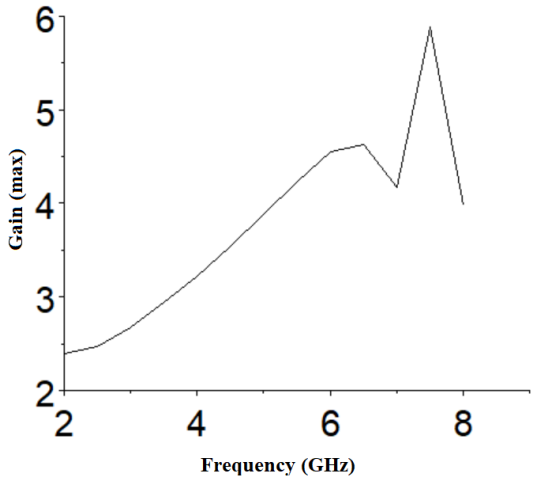

Figure 10 The gain of the propounded antenna

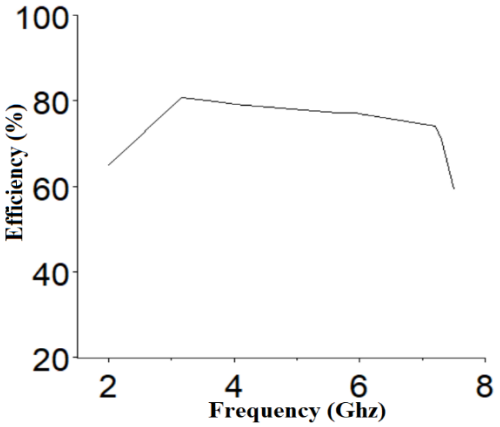

Figure 11 simulated radiation efficiency of the antenna

A comparison between our antenna and other published research is demonstrated in Table 2 in terms of their dimensions, bandwidth, gain and applications, in order to reinforce the concept of design. The almost stable radiation pattern with gain up to 5.9 dB makes our antenna suitable for being used for UWB applications.

4. Conclusion

The micro-strip patch antenna is easy to manufacture, replaceable, low profile and highly efficient. Such antennas are strongly recommended in satellite and wireless communication. In this paper, a new UWB patch antenna is presented with a wide bandwidth from 3.1 to 7.5 GHz with three resonant frequencies at 3.9, 5.95 and 7.3 GHz. The optimized structural parameters have been reached after many optimization and parameter sweeps on antenna performance. The propounded antenna can be used in multiple UWB applications that requires a wide bandwidth and reduced return loss at the operating frequency of the frequency range. The simulated results provide that, the maximum bandwidth attained numerically is 4.4 GHz due to the multiple slots used in the antenna. The results have revealed that our new fabricated antenna is definitely highly convenient for UWB applications such as high-resolution radar, military communication, communications and sensors, position location and tracking.

ABSTRACT

News companies have a need to automate and make the process of writing about popular and new events more effective. Current technologies involve robotic programs that fill in values in templates and website listeners that notify editors when changes are made so that the editor can read up on the source change on the actual website. Editors can provide news faster and better if directly provided with abstracts of the external sources and categorical meta-data that supports what the text is about. To make categorical meta-data a reality an auto-categorization model was created and optimized for Swedish articles written by local news journalists. The problem was that it was not scale-able enough to use out of the box. Instead of having this local model that could make good predictions of the text documents, the model is to be deployed in the cloud and an API interface is created. The API can be accessed from the tools where the articles is being written and therefore these services can automatically assign categories to the articles once the journalist is done writing it. To allow scale-ability to several thousands of simultaneously categorized articles and at the same time improving the workflow of deploying new models easier the API is uploaded to Sagemaker where several models are trained and once an improved model is found that model will be used in production in such a way that the system organically adapts to new written articles. An evaluation of Sagemaker API was done and it was concluded that the complexity of this solution was polynomial.

1 Introuction

Modelling data with machine learning algorithms has shown to give promising results in various of areas, for example image processing and robotics. The areas are growing and machine learning becomes more advanced for every day. Natural language processing is one area that is difficult and requires larger and deeper networks to perform. The larger a network is the more computational power is required to compute a prediction. For a system in production the speed and memory usage could be fatal to the incoming requests of the application. This article addresses the difficulties to take such a system from the model produced by the algorithm to a productified version utilized by a product or users in real time. The response time, memory consumption and computational power are of importance when these types of models will be available with minimal waiting- and downtime. This article addresses one way to scale the application to handle all requests from the user base of a media company distributed over 22 regions in Sweden and reasons behind possibilities to scale up to the entire Sweden user base of local news production line.

In a longer run the focus is also to use the categories metadata point in other products such as improving article personalization algorithms, data analytic of supply and demand of article categories. This article is an extension from Linden et al presented at Fedcsis conference 2018 [1]. The auto-categorization prediction accuracy are improved by parameter optimization since the last article and are now at 80 % and that is the underlying reason why the system is ready for an production environment. The classification model will categorize articles into different news topics and reply with a given confidence for each category. The while the journalists writes their articles in they would like to have categories in or close to real time.

2 Related Work

The novelty of this research, that concerns productification, is the idea to take the auto-categorization neural network

*Johannes Lindén, Holmgatan 10 Sundsall Sweden, 010-142 80 69 & johannes.linden@miun.se

model from its experimental phases all the way to a use case where it brings value. Several research projects has been done for managing and supporting big data pipelines, where live data needs to be processed by several organizations (for example analysis and business intelligence) [2]-[3]. The auto-categorization model perdictions needs a similar automatic data pipeline to uphold the load of each prediction and at the same time allow analysis of the result that will be brought back to the model in a feedback loop. Blaiszik et al made a scalable service that manages machine learning models through a structured API [4]. Blaiszik is using docker containers to wrap the model logic into an environment with controlled variables. This research approach is similar to Blaiszik but instead of using containers for only the models the idea is to have one container for the service as well. Cloud based services such as AWS Sagemaker or IBM's Watson has benefits as well as flaws explained in detail by Hummer et al that builds their own cloud service for training machine learning models [5]. According to Hummer's research it is essential for the AI expert to focus on the model itself and care less about the pipeline and how to set it up properly but Hummer also mentions the importance of having the settings available to tweak the service for special needs. For simplicity this research are using Sagemaker to deploy models in production since there is knowledge about other AWS services available and having all systems in the same cloud has other benefits of latency and authorization flexibility. An evaluation investigation in signal processing was issued that was written by Massimo Ravasi and Marco Mattavelli where they motivated the importance of the system complexity and the partitioning of hardware and software evaluation [6].

As for the auto-categorization model itself Payne et al have made an evaluation of their SVM classification algorithm which yields promising results in performance [7]. The model used in this research utilizes a bigger neural network to comprehend a larger problem domain. Rather than only focusing on a domain concerning digital archives it is focused on local news which could be very specific to each region of the country but could also be very general where regions have common information needs of local news.

3 Approach and Model

The proposed four step model in previous research that predicts categories of arbitrary text paragraphs are going to be the main model in this research that will conduct scalability experiments and propose a system structure of this machine learning model. See Figure 1 for an overview of previous implementation.

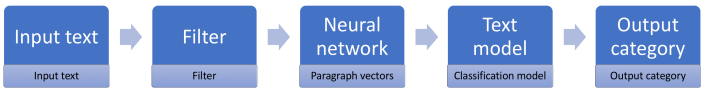

Figure 1: An overview of the model

The input is the algorithm parameters θ and a single document D, which is interpreted as a sequence of words $w_1, w_2, \cdots, w_n$. The output of the model is a set of category probabilities $c_1, c_2, \cdots, c_i, \cdots, c_m$ computed by 1.

$$c_i = P(\text{ith category}|D,\theta) \approx P(\text{ith category}|D) \quad (1)$$

In this research the model are used for example as shown in Figure 2, the article shown to the left in a web-browser will request a category from the trained auto-categorization model and retrieve a list of probable categories.

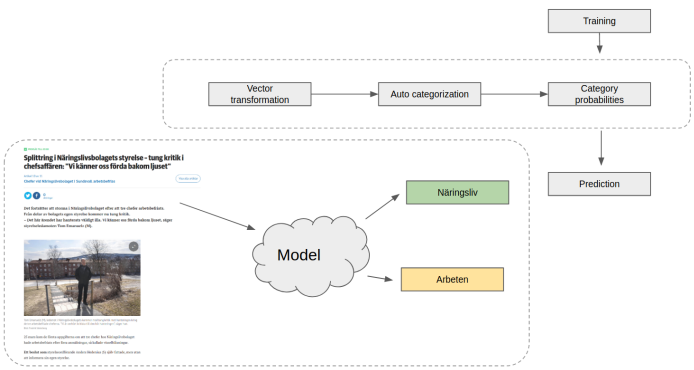

Figure 2: Auto-categorization in a real case scenario. While a user navigates to a article page the category of that particular article is determined based on the body/text within it.

The algorithm takes an unstructured sequence of words forming a text paragraph as input. Language of this model is Swedish and even though the text length could be of any length the articles that has been evaluated has the length between 5 to 600 words in the first step of Figure 1. Text paragraphs are filtered before training to not include articles with only links or empty texts since these articles are not describing what the article is about. Within an text paragraph some additional modifications is done which is step two in Figure 1. Non-alphabetic characters, exclamation and question marks are replaced by full stops. XML tags and its attributes are removed. Some additional optional modifications are left in the settings file to be turned on or off while using the system. Such modifications include Named Entity Recognition (NER) substitution of locations, organizations, names and time units, another modification are Part-of-speech (POS) tagger and Dependency parser which will filter out certain types of tagged words and leaf nodes [8]. POS and Dependency parser chosen in this research where Google SyntaxNet [9, 10]. Out of the resources mentioned in Nilson et al, we selected a treebank made by Jan Einarsson's project, which is well documented [11]-[12]. The other steps in Figure 1 are described in the following sections.

3.1 *Paragraph Vectors*

The third step in Figure 1 is a constructed one layered neural network model that will transform the filtered text paragraphs from previous step into vectors. The paragraph vectors are unique vectors that mapps the paragraph to a high dimensional vector space. A softmax activation function

makes sure that the elements are within the interval -1 to 1. The vectors are constructed in such a way that it is possible to relate a paragraph from the distance between another paragraph. The relation of two paragraphs can be obtained by computing the cosine similarity which will give a positive value when the documents are sharing similar contexts, a value close to zero when no relatedness could be found, and a negative number when the paragraphs appears in in opposite contexts [13]. The vectors can also use common subtraction and additions operations in case other related context will be retrieved, as shown in 2.

$$king - man + woman = queen \tag{2}$$

The paragraph vectors context awareness contains information about what makes a document category as shown in previous research [1]. The paragraph vectors are as before computed using the PV-DM algorithm which is an extension of the known word2vec algorithm bag of words (WV-BOW) [1, 14].

Experiments previously conducted showed that the PV-DBOW paragraph algorithm is reliable when implemented by the distributed memory vector concatenated with the distributed bag of words vector described by Mikolov et al [13].

3.2 Text Model

The paragraph representation vectors is input to the fourth step where the auto-categorization takes place. The categorization algorithms we proposed in previous research experiments where decision trees, random forest, multi layer perception and long-short term memory (LSTM). The one outperformed the others where the LSTM model which are used in this extended paper with the possibility to exchange to another model at any time through a settings parameter in the system. The output is the category belonging probabilities for each considered category described in 1. The LSTM model has a time parameter that each time sequence are used for a vector transformed sentence in the paragraph. Figure 3 shows the LSTM input format, each colored line is a sentence which are fed in per time-slot in the model for training .

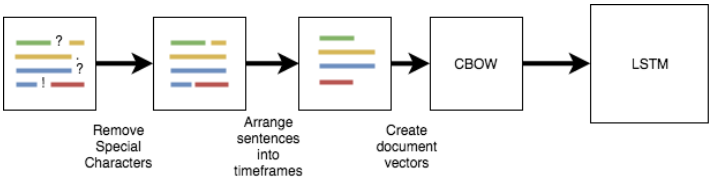

Figure 3: The input vector of the LSTM algorithm is shown above. It first applies the filter layer conditions, then divides the document into sentences to be used as input data for the CBOW algorithm that produces the document vectors.

LSTM models are based on the principles of recurrent neural networks (RNN). A RNN is constructed like a neural network with an input, hidden layers and a output layer. The RNN-cell can be visualised as shown in Figure 4. The activation function of an RNN is usually the *tanh* function. For each iteration, the model is trained by backpropagation through the network. The purpose of RNN is to have a short-term memory that remembers previous neurons. One of the first and simple constructions of RNN is the recurrent neural network language Model (RNN-LM). The hidden layer of an RNN-LM algorithm remembers the neurons one time-step back in the training history [15].

For different use-cases there are different variations of RNNs. Andrej Karpathy summarises the different networks that are used into different mappings [16]. One-to-one mapping is the original algorithm, for example the RNN-LM algorithm. One-to-many mapping when there is one input and several RNNs connecting to several outputs. This mapping can, for example be, used for image prediction with one image and several words that predict the image. Many-to-one mapping is where there are several inputs mapping to one output, this mapping can for example be used for classification. Many-to-many mapping is what Karpathy describes as two different mappings: one mapping that maps to an equal number of input and output RNNs (N-N), and another mapping that maps to a different number of inputs and outputs (N-M). The N-N mapping can, for example, be used to predict video sequences over time, while N-M mapping can be used for translation problems.

LSTM networks are a special case of RNN that tends to solve a problem in the original RNN. The long-term memory in RNN (the gradient descent) exponentially diverges to infinity or converges to zero in many cases and LSTM introduces an additional memory cell and forget parts of the information and therefore avoiding more cases of vanishing gradients. LSTM networks introduce three sigmoid layers and certain gates that only let parts of the information through to compensate for the vanishing gradient. The first sigmoid layer determines what information that is important from the previous LSTM-cell, the second sigmoid layer determines what information is important from the *tanh* layer in the current cell and the third sigmoid layer determines what information will be passed to the next LSTM-cell. The gates that open or close based on the input from the previous LSTM-cell either remove or add information to a cell state that is also passed through to the next LSTM-cell. The third sigmoid layer extracts a piece of information from the cell state to the output value [17, 18].

3.3 Output Category

Output category is the last, fifth, step of the model which determines the output categories. This step interprets the output of the categorization model and limits the categories to suggest via a threshold of the category probability. If the probability is higher than the average probability of seen paragraphs the category are recommended and sent to output of the model. Before the categories that will be replied is returned from the auto-categorization model the probabilities are normalized according to 3.

$$\frac{value - min(value)}{max(value) - min(value)} \tag{3}$$

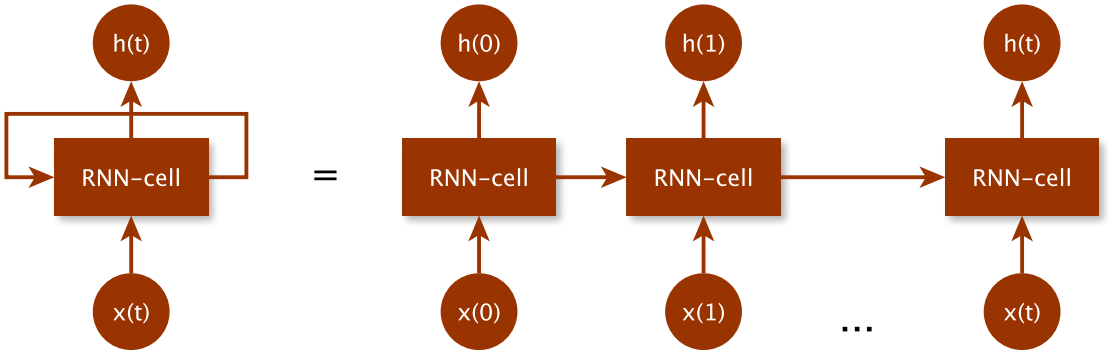

Figure 4: A recurrent neural network cell. The cell to the left is the general notation of the hidden layer in an RNN model. The right unfolded version is the representative of the RNN with a short-term length of t.

4 Architecture

The architectural approach consists of the system, the data pipeline and the neural network model. For making the auto-categorization available to use on texts written by the journalists all three pieces has to be in place. The procedure should be close to real time and this was accomplished by a system that could easily be scaled up to bigger machines with load distributed support for the user prediction requests. Figure 5 shows an overview of the system.

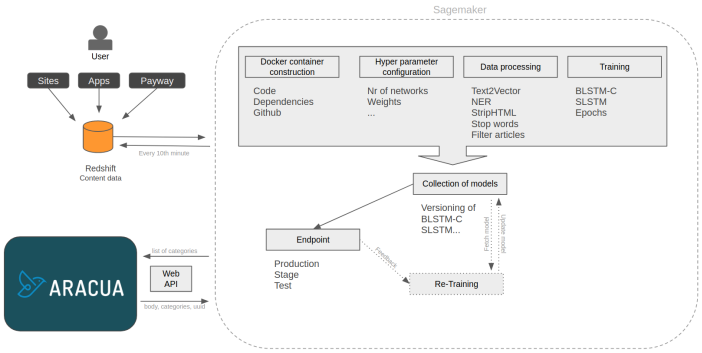

Figure 5: Architectural overview of production environment.

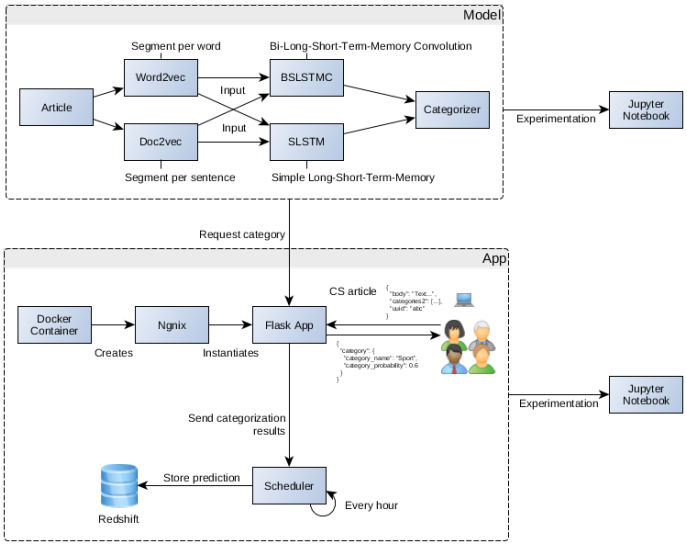

Figure 6: Architecture of the server system.

Aracua is the name of the system the journalists are writing their articles in, this system will request categories given the text of the article. Each categorization request is stored together with the previous category for further live evaluation purposes. The requests are stored in a AWS Redshift cluster to compare the final categories of each article with the suggested ones along the way while the journalists are writing the article [19]. In Redshift other services will have access to the auto-categorized categories to be used for example in personalization purposes. This section will further describe the deployment process of the model.

4.1 System

A Ngnix server was used for the system that can handle requests and reply the the model prediction of categories. The server instantiates python flask applications on demand when the load is high and one instance cannot keep up the clients requests as illustrated in Figure 6.

All runs inside a docker container to make it easy to increase the memory and processing power on an AWS EC2 instance if needed [20]. Each time a client requests categories for an article the user also sends the current categories on the article so that in a later step it is possible to evaluate an article over time as it is being worked on.

The predictions and articles are temporarily stored in memory to speed up the replies for the same article. A scheduled task is triggered every 10 minute or when number of articles in memory are larger than 1000 documents. The scheduler dumps these articles in memory to a persistent database where evaluation will be performed. The model is parameterized so that depending on the settings different models are being used for the prediction see Section 4.3.

4.2 Data pipeline

The system gets article contents that are being written by journalists from Aracua and stores them in a database. The articles are distributed on various of different places depending on the product that will use them. The auto-categorization product retrieves all articles and trains its models on these articles as described in Section 3. Each model that is trained is stored separately so that it is easy to switch models in production. A retraining process is started in production to dynamically improve the model for the articles. There are not only models for each environment (developement, staging and production) but also models for different versions and improved models as the time progresses.

4.3 Neural network model

The parameters that is used to train the model are stored in a configuration file. The configuration file contains what model structures that are going to be used, how long the training will take in terms of number of epochs, layer sizes pre-processing steps to be done, where the data is taken from and model stored to. Currently the following setup shown in Table 1 is used since it was shown to be the best one in previous experiments.

Table 1: Neural network model parameters

Param	Value
Layer size	3
LSTM timestep size	200
Document vector size	1000
Pre-processing steps	NER, StripHTML, Filter stop words, Part-of-speech

4.4 Hardware specifics

The evaluation conducted in this research is performed on an AWS Graviton Processor with two 64-bit Arm cores. The processor is caped at 2.3 GHz clock frequency, the memory is 16 GB and high network speed according to AWS specifications [21]. The computer used corresponds to the specification of ”ml.m4.xlarge” in Amazon Instance specifications[21].

5 Results

Figure 5 and 6 shows the resulting production system and how it works. The main result is that this system is used by thousands of journalists all over Sweden. Additional results of this extended article is to provide evaluation metrics of the system in terms of responsiveness to the journalists. Figure 7 shows how long the response time is in average given the number of clients trying to access the system at the same time.

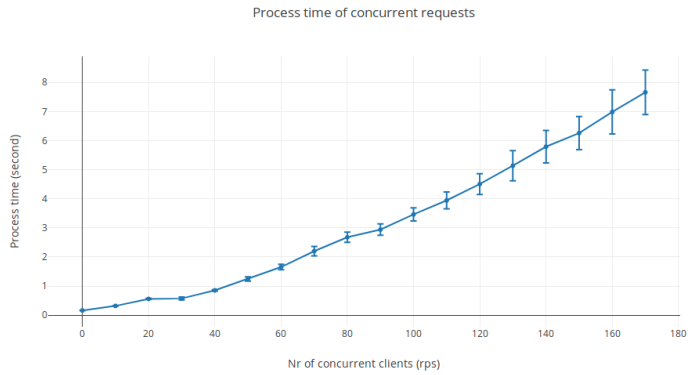

Figure 7: Process time of concurrent requests with standard deviation.

By analysing the number of characters an article body consists of when categorizing it is possible to say how much implications long articles have on the system, the resulting analysis can be seen in Figure 8.

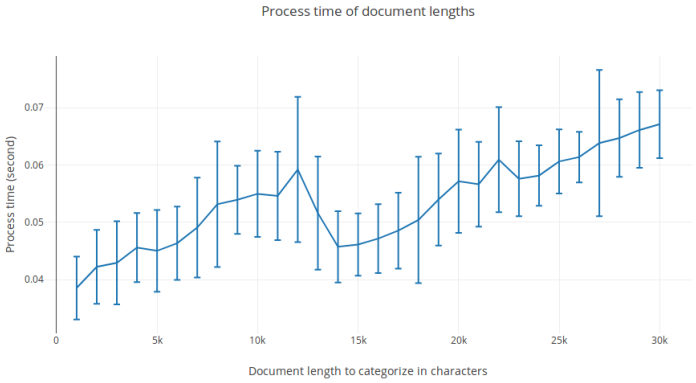

Figure 8: Process time of document lengths with standard deviation.

The training process is the process that initially takes the longest time of all in this research. Training a model with all articles of the categories in question takes up to 2.2 hours using a document vector embedding size of 600 elements as shown in Figure 9.

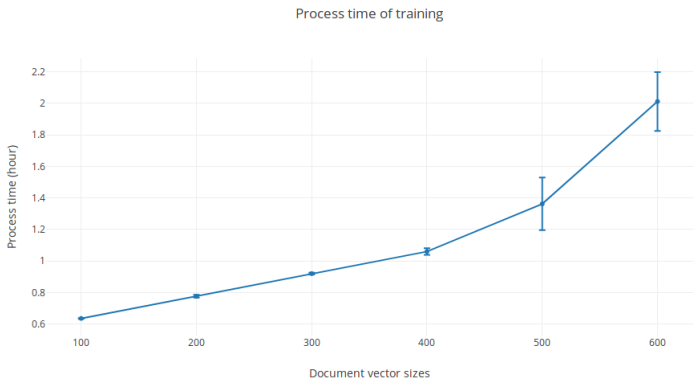

Figure 9: Process time of training with standard deviation.

6 Conclusion

In this article a proposition for a productification of a categorization algorithm that through a web API serves journalists with automatically categorized texts in their writing tool. The main question was if the performance of such model could be serving a large amount of users in their daily work and in that case how many users can it handle. It can be concluded that the number of concurrent requests have somewhat a linear time complexity but could potentially be exponential of higher orders for larger number of clients. Analysing the article length it can be interpreted to have an impact of the process time but would not be a problem for journalists since it is rare that they write long articles. Around 15 000 characters seem to be a good number of characters to have in an article. Training performance is growing with polynomial complexity and could be a risk as more categories are introduced and larger vector embedding needs to be considered. Future work for this project will be to include more categories with more complex algorithms which will use a wisdom of the many approach.

ABSTRACT

All forms of skin cancer are becoming widespread. These forms of cancer, and melanoma in particular, are insidious and aggressive and if not treated promptly can be lethal to humans. Effective treatment of skin lesions depends strongly on the timeliness of the diagnosis: for this reason, artificial vision systems are required to play a crucial role in supporting the diagnosis of skin lesions. This work offers insights into the state of the art in the field of melanoma image classification. We include a numerical section where a preliminary analysis of some classification techniques is performed, using color and texture features on a data set constituted by plain photographies, to which no pre-processing technique has been applied. This is motivated by the necessity to open new horizons in creating self-diagnosis systems for accessible skin lesions, due also to a huge innovation of cameras, smartphones technology and wearable devices.

1 Introduction

The World Health Organization recognizes skin cancer as one of the most lethal cancers that is spreading widely in many parts of the world in recent decades. Globally, each year between 2 and 3 million of non-melanoma skin cancers and 132,000 of melanoma skin cancers occur [1]. Cutaneous melanoma is still incurable. A successful treatment of skin lesion is heavily dependent on the timeliness of the diagnosis: it is crucial to detect and remove the skin lesion in the early stage. One of the major allert of this tumor is that, in the early stages, melanoma remains hidden, showing itself to be similar to other benign lesions. This aspect, combined with the aggressiveness and rapidity with which it expands, creates difficulties even for expert dermatologists; in addition, in its early phase, it is often underestimated [2]. Dermatologists, in clinical evaluation, in order to identify the tumor lesions of the skin, adhere to some reference protocols. Generally, they refer to the ABCDE protocol [3], the 7-point checklist [4] and the Menzies method [5]. If the investigations conducted leave doubts about the nature of the lesion, the specialist prescribes an analysis of the affected tissue by biopsy. Even today, the reliability of the diagnosis of melanoma can be improved with the support of latest-generation automated analysis tools. Although the human factor continues to be the main discriminating element for the diagnostic accuracy [2], on the other hand such tools could play a relevant role to support the specialist in the diagnosis procedure.
Therefore if, on one hand, it is evident the need to design sophisticated tools supporting the specialists in providing early and accurate diagnosis, on the other hand it is crucial also the necessity to develop low cost solutions alerting in case of suspicious skin lesions. Technology is driving a huge innovation in the healthcare domain and artificial intelligence is playing a key role in providing tools and applications supporting physicians in diagnosis and patient treatment. In particular, computer vision systems are revealing to be fundamental in medical image analysis, since they allow to have non-invasive diagnoses. The specific frameworks for the automatic analysis of skin lesions are constituted by the following fundamental steps: image acquisition, image processing and analysis, features extraction and classification.

This paper is an extension of work originally presented at the 9th International Conference on Information, Intelligence, Systems and Applications (IISA 2018). The goal of the original paper [6] was to offer insights into the state of the art in the field of melanoma image classification by both providing a review of the various features used in the elaboration of computer vision systems and focusing on those ones which appear to be the mostly used on the basis of the recent literature. Here a preliminary comparison between two different approaches (Support Vector Machine and Multiple Instance Learning)

[*]Corresponding Author:Ester Zumpano, DIMES - Department of Computer Science, Modelling, Electronic and Systems Engineering, University of Calabria, 87036, Italy & zumpano@dimes.unical.it

is proposed, pointing out the key role played by the feature selection (color and texture). In particular, this study was inspired by the good results obtained in [7], where the authors applied Multiple Instance Learning techniques for classifying some medical dermoscopic images drawn from the Ph^2 database [8], by using only color features. Our numerical experimentations, reported in this paper, showed that using only color features is not at all high-performance when the classification process is performed on a data base constituted by common plain photographies. On the other hand using in addition texture features provides reasonable classification results, especially if we consider that no pre-processing techniques were used.

This paper is organized as follows. In Section 2 we present the pathogenic mechanisms of the skin cancer, while in Section 3 we recall the main steps adopted in biomedical image processing. In Section 4, a preliminary numerical study is performed for classifying a set of 200 plain photographies (100 melanomas and 100 common nevi), using color and color/texture features. Finally some conclusions are drawn in Section 5, looking at possible future developments.

2 Skin lesions

The first layer of the skin is the epidermis, which is constituted by different types of cells, each of them characterized by specific biological chemical functions: *keratinocytes* have a mechanical function of protection from the external environment, *basal cells* have a reproductional function of the cells of the most superficial layer and *melanocytes* provide protection against ultraviolet rays throught the production of melanin.

Dermis is the second layer of the skin, and is constituted by dermal papillary and reticular dermis. It is located below the epidermis and has a thicker consistency (Figure 1). The third layer of the skin is the subcutaneous layer or hypodermis, and, as the dermis, contains many blood and lymphatic vessels and protects the underlying tissues and the internal organs [9].

The different biological structure of the various layers of the skin implies their specific optical properties. When a beam of white light hits the skin, one part is reflected, another part penetrates into the superficial layers and the last part is absorbed. The specific amount of light that is reflected or absorbed depends on genetic factors of the population including the specific phototype to which the individual belongs. Exposure to light triggers melanocytes that produce melanin which is activated as a particularly effective protective filter on shades of blue light.

Normally the melanin deposits are placed in the epidermis (nevi); in the case of malignant lesions, such as the feared melanoma, melanocytes produce excess melanin and these deposits tend to invade the underlying levels of the skin. The presence of melanin in the dermis is one of the most indicative factors in the presence of melanoma (Figure 2).

Further factors indicative of a malignant lesion are the increased blood flow at the periphery of the lesion, evidence of epithelial desquation and the low flow of blood within the lesion which appears with a bluish red hue. Precisely the color features provide clinical evidence for a suspicion of skin cancer. At this point the specialist prescribes a histology to make an explicit diagnosis. Figure 3 shows a common nevus (a), a dysplastic nevus (b) (which is a benign lesion) and finally a melanoma (c) [8].

3 Main steps in computer vision systems

In this section we will focus on the fundamental phases that characterize the automatic frameworks for image analysis. We will also refer to the most widespread techniques that characterize the various steps of an artificial vision system: acquisition, pre-processing, segmentation, extraction and selection of features (Figure 4). The classification would be the final step, which is not the main object

of this document, apart from some brief discussion in the numerical section.

Figure 4: Main steps in biomedical image processing

3.1 Image acquisition

The first step of computer vision systems is the acquisition of the digital image. The proliferation of techniques as well as the development of new software paradigms has found its way into the numerous techniques that have been presented by researchers and industrial stakeholders. Based on the corresponding pros and cons, each techniques results more suitable for specific cases and less for other ones. Among the mainly widespread techniques we report total cutaneous photography, dermoscopy, ultrasound, magnetic resonance imaging (MRI), confocal scanning laser microscopy (CSLM), positron emission tomography (PET), optical coherence tomography (OCT), multispectral imaging, computed tomography (CT), multifrequency electrical impedance and Raman spectra. The epiluminescence microscopy (ELM), also known as dermoscopy, allows an in-depth analysis of the surface texture of skin lesions as the technique makes the epidermis translucent. Transmission electron microscopy (TEM) is generally used to monitor the evolution of melanoma. Through an appropriate light source the layers of the skin become translucent and this makes possible to appreciate the vascularization of the lesion also analyzing the colorimetric variations of the pigmentation. Computed tomography (CT) is also used to assess the patient's subjective response, which also allows diagnosis to be made on suspicious lesions.

Positron emission tomography (PET) is a technique that involves the use of contrast fluids through the different absorption of cutaneous melanoma metastases [10]. In the presence of a tumor, the absorption of fluoro-deoxyglucose has a direct correlation with the rate of its proliferation and therefore with the degree of its malignancy. Alternative screening methods are the multifrequency electrical impedance [11] and the Raman spectra [12].

The biological characteristics of a healthy tissue are different from those ones of a diseased tissue. Using the Raman spectra, this different way of diffracting the light coming from a laser beam is exploited, obtaining useful information on the physical structure of the lesion. The spread of wearable devices as well as the enhancement of the smatphones cameras create the conditions for being able to realize applications for auto-screening potentially integrable in platform solutions, through which the patient can interact with specialists aiming at rapid and punctual diagnoses [13]. The increasing costs of health suggest to Governance bodies the adoption of dematerialized health models that can provide decision and responsibility processes, encouraging predictive and preventive analysis [14].

3.2 Image pre-processing

The presence of potential noise linked both to the instrumentation with which the image was acquired, and to the presence of undesired artefacts such as hair and dermatoscopic gel may imply inaccuracies in the diagnosis phase. The objective of the pre-processing phase is to optimize image quality: this phase has a strategic role and is decisive for the entire classification process. The primary task consists in separating the lesion area from the healthy skin. This operation results to be quite difficult as dermoscopic images often present irregular lighting, frames, gelatinous material and intrinsic skin features that make the identification of a lesion, for example trought edges detection methods, a difficult task. Therefore, anything that could affect the image needs to be localized and then removed, masked or replaced. Many techniques have been used in literature in order to perform this task, like image resizing, masking, removal of artefacts, transformation of images into various color spaces. Another important element that commonly penalizes the analysis of dermatoscopic images is the presence of hairs. Recent literature proposes various approaches to optimize images, which involve the use of morphological operators [15], or the detection of curvilinear structures [16] or envisaging a phase of image restructuration through painting [17].

Unfortunately, most of these techniques often leave behind undesirable blurring, invalidating an effective use of the color image. Zhou et al. proposed an algorithm able to carry out an accurate detection of curvilinear artefacts while preserving the lesion structure [18]. The presented approach is very effective for removing the dermatoscopic misuring stick and the hair, but on the other hand it requires high computational requirements. The pre-processing phase of an image can require several operations such as: enhancement, restoration and hair removal (Figure 5).

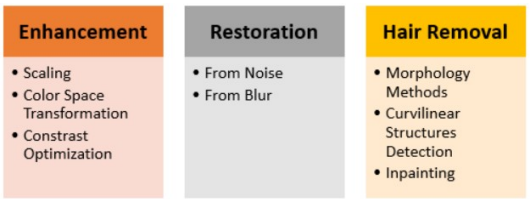

Figure 5: Fundamental steps and techniques for pre-processing

Among the various tools to remove unwanted artefacts, the filters are the most immediate ones. Several Computer Vision Systems dedicated to dermatology adopt filters by applying them directly to grayscale photos or on individual color channels in the case of color images [19, 20, 21].

Generally, for each type of unwanted artefacts, a specific strategy involving the use of dedicated solutions is adopted. Many effective methods use color space transformation to optimize both the quantization of color and of contrast, passing from RGB images to different color spaces for enhancing the variation of the color on the edges and inside the lesion.

The pre-processing phase follows antithetical goals. On the one hand, in order to contain the computational complexity, the objective is to identify a minimal number of colors to be used in image analysis. On the other hand, insufficient contrast would make edge detection very difficult. A solution adopted in many circumstances involves the use of histograms, with which it is possible to perform stretching operations to expand the pixel values in the interval [0, 255], or equalization to obtain a uniform distribution of the pixel values. The important task of appropriately enhancing the contrast between the image area where the lesion is contained and the background consisting of healthy skin can be obtained by compensating for irregular lighting through the use of monomorphic filters and high-pass filters. Adaptive and recursive weighted median filter are used to remove air bubbles and dermoscopic gels [22]. An interesting solution involves local processing carried out on a portion of pixels (generally 3x3), assigning the median to the central pixel. Using these techniques, it is possible to eliminate the noise by containing the alterations that may arise in the original image. The strategies referred to, as well as the other solutions presented in the literature, have as their final objective that of being able to favor the segmentation of the image and the extraction of functional features to the classification process. The strategies to be adopted depend on the nature of the considered images and of the impurities that must be managed [23].

3.3 Image segmentation

The analysis and identification of a lesion can be performed directly by specialists who rely on their experience or by using software solutions for image segmentation, such as IMAGEJ or EDISON (Edge Detection and Image Segmentation system). In fact, in melanoma detection, the main task of the segmentation process is to separate the skin lesion from the background consisting of healthy skin (Figure 6), in order to analyze color, structure, shape, texture and information related to vascularization of the lesion.

Figure 6: (a) dermatoscopic image (b) segmented lesion

The choice of the color space in which it is best to represent images is important, as it determines the rule of the various color channels. Consequently, it will be important to choose the appropriate segmentation algorithm that takes into account the modes of representation chosen for the images. Without the pretension to be exhaustive, some types of segmentation methods in this field are the following:

1. threshold-based, including the Otsu method, those that use the maximum value of the entropy and those that use histograms, such as the independent histogram search algorithm (IHP) [24];

2. region-based, including region growing and watershed segmentation;

3. pixel-based (aimed at labeling the pixel), both supervised methods such as the Support Vector Machine, unsupervised methods such as fuzzy c-means, and those with reinforcement such as artificial neural networks;

4. methods based on customized models, both adaptive and representable through deep multilevel networks.

3.4 Feature extraction

The goal of the segmentation process is to identify the region of the image that contains the lesion by discarding the pixels which are part of the background consisting of healthy skin. In this way the extraction and selection of the most appropriate features to be used for the melanoma detection by artificial vision systems will be favored. In particular, feature extraction implies the enhancement of some specific measures on portions of images: this fundamental step is not often sufficiently discussed and detailed in many researches. On the other hand, a recent study of the relevant features for artificial vision systems in melanoma detection can be found in [6]. As for the extraction of features, many different approaches have been proposed of the statistical and/or filtering type. Among the adopted methods to be mentioned, we cite the principal component analysis, useful for determining the geometric and the shape features, the co-occurrenze matrix [25], useful for the evaluation of texture features, the Fourier spectrum [18], the Gaussian kernels [26], and the transformation of the wavelet package [27], useful for performing image optimization and the extraction of boundaries aimed at reducing data redundancy [28]. In addition, many automated decision support systems implement the feature extraction by exploiting the traditional diagnostic analysis protocols such as the ABCDE system [25], the 7-point checklist [29], the 3-point checklist [30], the model analysis [31] and the Menzies method [32].

4 Numerical experimentations

In this section a preliminary numerical comparison between two different approaches (Support Vector Machine and Multiple Instance Learning) is reported, using color and color/texture features.

This study starts from some considerations related to the works [7, 33, 34]. In [33] the authors analyzed the role played by the color and the texture features, showing empirically that using only the color features outperforms the use of the texture features: very good results were obtained by means of different type of classifiers on a image data set drawn from the Ph^2 database [8], containing 200 melanocytic lesions images (80 common nevi, 80 atypical nevi and 40 melanomas). All the images of the database were selected on the basis of their quality, resolution and dermoscopic features. Good results were obtained also in [7] on the same data set Ph^2,

Table 1: 5-fold cross-validation

	Color			Color and texture

by applying Multiple Instance Learning techniques and using only color features.

On the other hand, the objective in [34] was to select the most important image features usable in melanoma detection. In this case, differently from [33] where a high quality data set was adopted, the authors performed their experimentations on a data set constituted by plain photographs publicly available from two online databases https://www.dermquest.coml and http://www.dermins.netl, obtaining very good results in terms of sensitivity (96.77%) and, consequently, in terms of F-score (90.91%). The key point of this work consisted in a very accurate pre-processing and segmentation steps.

On the contrary, the objective of our experimentation consists in simply evaluating the classification results, obtainable on 200 images (100 melanomas and 100 common nevi) drawn from the same database used in [34], but without performing any pre-processing step aimed at cleaning up the images from possible noises [23, 35]. This choice is motivated by the necessity to investigate on the possibility to create fast self-diagnosis systems for accessible skin lesions.

In particular, our experiments were performed by using three configurations of the data set, corresponding respectively to the 5-fold cross-validation, the 10-fold cross-validation and the leave-one-out validation.

For each configuration, initially only the color (RGB) features were used, adding, only successively, those ones related to the texture by means of the co-occurence matrix.

The following classification methods, each of them implemented in Matlab (version R2017b), were adopted:

- Support Vector Machine with linear kernel (SVM)[36];
- Support Vector Machine with RBF kernel (SVM-RBF) [36];
- MIL-RL [37].

Some words are to be spent about the MIL-RL method, proposed in [37]. Such a method belongs the class of the Multiple Instance Learning (MIL) algorithms. The MIL paradigm (see for example [38, 39]) is a relatively new approach for classification problems which fits very well on image classification, as shown in the recent works [40, 41] and, in particular, also for medical images and video analysis [42]. It differs from the classical supervised classification approaches, since it is aimed at classifying sets of items: such sets are called *bags* and the items inside the sets are called *instances*. The main characteristic of a MIL algorithm is that, in the learning phase, only the labels of the bags are known, while the labels of the

instances inside the bags are unknown. The MIL paradigm applies very well to image classification since in general an image (bag) is classified on the basis of some portions (instances) of it.

About the MIL-RL code, the same Matlab implementation adopted in [7] were used, while, for the SVM approaches with both linear and RBF kernels, the *fitcsvm* and *predict* subroutines for training the classifier and for computing the testing correctness, respectively, were utilized. Such subroutines are included in the Matlab optimization package.

The results of our experimentations are reported in Tables 1, 2 and 3, in terms of accuracy (testing correctness), sensitivity, specificity, F-score and CPU time. For each of these parameters and for each table, the best result was underlined. It is worth noting that the sensitivity is in general more important than the specificity because it measures the capability to identify positive patients. This is in fact taken into account in the F-score value.

Looking at the tables, it is possible to observe that using both color and texture features improves the results, with respect to using only color features. Moreover the better results are generally obtained in corresponding to the MIL-RL algorithm, whose F-score values are however comparable with those ones obtained by using the SVM with RBF kernel. On the other hand using the SVM-RBF is really faster than using the SVM with linear kernel or the MIL-RL approach.

5 Conclusions

In this work some numerical experimentations were performed to classify a data set constituted by plain photos of different sizes, some of which are low resolution images and others are blurred or with hairs. Although in [34] it has been shown that using some pre-processing methodologies on the images improves the classification performances, in our experiments we preferred do not use such techniques. In this way it was intended to operate in the worst conditions in order to compare the classification performances obtainable by using, on one hand, only color features (as proposed in [40, 41, 43]) and, on the other hand, color and texture features. The fact that the used data set consists of plain photographs, instead of high-quality dermatoscopic images such as those ones constituting the Ph^2 database, justifies the obtained classification performance.

Adopting additional sets of features together with more sophisticated algorithms providing nonlinear separation surfaces, such as in [44], opens up new possible scenarios for the implementation of efficient solutions, useful to provide a further support to specialists and, on the other hand, to have preliminary self diagnoses, since the diffusion of smartphones allows the possibility to take photos of one's own skin injuries. The use of medical solutions [45], as well as the possibility of creating Apps, BOTs and Educational Games [46], designed for different classes of population, are possible scenarios of interest.

ABSTRACT

The paper deals with hardware emulation of bio-inspired devices and nonlinear dynamic processes of complex nature by means of mixed-mode analog-digital emulators. The discretized state model of the emulated system serves for real-time calculation of dependent quantities. In contrast to input-output emulation known in control systems, the proposed approach emulates the ports of an electrical multiport network. The paper discusses the stability of the emulation process and the possibility of partitioning the system into two parts, one being emulated digitally and the other via an analog circuitry. The procedure is illustrated on the example of emulating the Fitzhugh-Nagumo model of neuron and the model of amoeba adaptation. The paper is an extension of our paper presented at the NGCAS 2018 conference in Valletta, Malta. The extended version deals newly with the choice of the integration method and provides a deeper stability analysis and more examples of emulation of biological models.

1. Introduction

Emulation consists in replacing a part of the electrical system with another system that has similar characteristics but is more convenient to implement. This technique has become popular in the field of electronic circuits with the (re)introduction of mem elements [1, 2]. For example, the memristors and other promising nanodevices for digital computational systems, massively parallel analog computations or elegant modeling of the neuron cells, are still in the experimental phase and are not available as off-the-shelf components. Emulation allows performing circuit experiments with equivalents of these novel elements and is also useful for demonstration and educational purposes [3].

The first emulators were proposed as analog circuits. Single-purpose emulators such as [4–6] are simple and elegant, but their disadvantage is the inability to change easily their characteristics. Emulators of memristive, memcapacitive and meminductive devices based on mutators provide large universality because they transform a nonlinear resistor, which can be easily modified, to the respective constitution relation of the mem element [7–8].

Another problem is the emulation of blocks with floating ports, which is difficult for purely analog emulators. Several two-terminal floating emulators were proposed [5, 9, 10]. However, all the emulators are based on grounded devices and are "floating" only in the case of neglecting parasitic parameters. In [11], a genuinely floating memcapacitor was proposed on the principle of switched capacitors. The first implementation of a floating resistive port using a mixed-mode system was proposed in [12] with the use of a digital potentiometer, whose resistance was controlled by a microcontroller by means of pre-programmed algorithms.

On the other hand, there are dynamic systems that cannot be emulated via the above single-purpose emulators. For example, the well-known Hodgkin-Huxley model of the cell membranes in a neuron is represented by a set of nonlinear differential equations [13]. The equivalent electrical model is a two-terminal device, consisting of a linear capacitor, two nonlinear memristive devices, and biasing sources [14]. Usually, these models contain large-value inductors and capacitors, which are not useful for practical laboratory experiments.

The demand for emulating general dynamic systems resulted in developing mixed-mode analog-digital emulators [15, 16]. They consist of a central digital unit, which controls one or more floating analog ports of three possible types: controlled voltage source, controlled current source, and digital potentiometer [17]. The independent port currents and voltages are digitally processed

[*]Corresponding Author: Zdenek Kolka, Brno University of Technology, Email: kolka@feec.vutbr.cz

according to the mathematical model of the emulated device, and the computed dependent quantities are used for controlling the analog ports. A great advantage of such an approach is the ability to change easily the emulated system by means of changing the software and the possibility of designing truly floating ports with the use of digital isolators without compromising the precision.

The paper summarizes our experience of the emulation of two complex nonlinear dynamic systems via the mixed-mode approach [15]. The problem of discretization analog system and its (in)stability, which occurs when connecting a digital emulator to an analog circuitry, is analyzed. The paper is an extension of our paper [1] presented at the NGCAS 2018 conference in Valletta, Malta. The extended version deals newly with the choice of the integration method and provides a deeper stability analysis and more examples of emulation of biological models.

2. Emulation Principle

2.1. Basic Setup

In general, the emulator represents a mixed-mode analog-digital system with m floating electrical ports. For the purpose of emulation, let us constrain ourselves to such systems where each port has an independent input quantity (voltage or current) and the other quantity (current or voltage) is computed as a response.

Thus, the emulator consists of a digital core, implemented in a microcontroller (MCU) or FPGA, and ports in the form of controlled current or voltage sources, Figure 1. Using A/D converters with a supporting circuitry, the core measures independent quantities, computes the response, and sets the dependent quantities using D/A converters, followed by reconstruction filters and corresponding controlled sources.

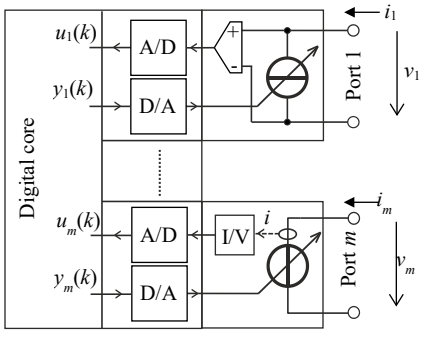

Figure 1: Multiport emulator shown with controlled current source at Port 1 and controlled voltage source at Port m.

The emulated system is generally a nonlinear discrete-time system of the n-th order with m inputs and m outputs, whose mathematical representation can be written as

$$\mathbf{x}(k+1) = \mathbf{f}(\mathbf{x}(k), \mathbf{u}(k)), \quad (1)$$

$$\mathbf{y}(k) = \mathbf{g}(\mathbf{x}(k), \mathbf{u}(k)), \quad (2)$$

where $\mathbf{x}(k) \in \mathrm{R}^n$ is the state vector, $\mathbf{u}(k) \in \mathrm{R}^m$ are the samples of independent (input) quantities, and $\mathbf{y}(k) \in \mathrm{R}^m$ are the dependent (output) quantities. The continuous functions $\mathbf{f}:(\mathrm{R}^n,\mathrm{R}^m) \to \mathrm{R}^n$ and $\mathbf{g}:(\mathrm{R}^n,\mathrm{R}^m) \to \mathrm{R}^m$ are generally nonlinear.

Figure 2 shows the time characteristics of a discrete-time system (1), (2) implemented in a real logical device and connected to a continuous-time circuit. The inputs $\mathbf{u}(k)$ are sampled with a period T and the outputs $\mathbf{y}(k)$ are available after the computation and transfer delay $t_c < T$. The analog circuit the emulator is connected to, which formally includes the anti-aliasing and reconstruction filters, responds to the new outputs $\mathbf{y}(k)$, and the response is sampled as the next input $\mathbf{u}(k+1)$.

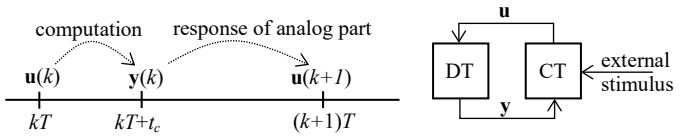

Figure 2: Timing of the emulation process (DT – discrete-time emulator, CT – continuous-time analog circuit).

2.2. Stability of Emulation

As shown in Figure 2, connecting the emulator to an application circuit creates a feedback system, which combines discrete-time and continuous-time parts. Let us consider the one-port case ($m = 1$). The stability of some fixed point of the system (1), (2) can be examined by linearizing the state description

$$\mathbf{x}(k+1) = \mathbf{A}\mathbf{x}(k) + \mathbf{B}u(k), \quad (3)$$

$$y(k) = \mathbf{C}\mathbf{x}(k) + Du(k), \quad (4)$$

where $\mathbf{A} \in \mathrm{R}^{n\times n}$, $\mathbf{B} \in \mathrm{R}^{n\times 1}$, $\mathbf{C} \in \mathrm{R}^{1\times n}$, and $D \in \mathrm{R}$ are real matrices.

Equations (3), (4) represent a single-input single-output linear system, which can be characterized by the z-domain input-output transfer function [18]

$$H(z) = \frac{Y(z)}{U(z)} = \mathbf{C}\frac{\mathrm{adj}[z\mathbf{I} - \mathbf{A}]}{\det[z\mathbf{I} - \mathbf{A}]}\mathbf{B} + D, \quad (5)$$

where "adj" denotes the adjoint matrix, $\mathbf{I}$ is the unity matrix, and $U(z)$ and $Y(z)$ are the z-transforms of the sequences $u(k)$ and $y(k)$.

The D/A converter generates a continuous-time signal $y(k) \to y(t)$, which stimulates the analog circuit, and the circuit response is sampled by the D/A converter as $u(t) \to u(k)$. The continuous-time circuit, which also includes the anti-aliasing and reconstruction filters, can be linearized around an operating point, which corresponds to the fixed point of the discrete system. The input-output small-signal transfer function will be

$$G_C(s) = \frac{U(s)}{Y(s)}, \quad (6)$$

where $U(s)$ and $Y(s)$ are the Laplace transforms of the continuous-time signals $u(t)$ and $y(t)$.

Considering the signal conversion $y(k) \to y(t) \to G_c \to u(t) \to u(k)$, the properties of the analog circuit can also be characterized in the discrete domain by means of the pulse transfer function [18]. For the zero-order hold (ZOH) D/A converter the transfer function will be

$$G(z)=\frac{U(z)}{Y(z)}=Z\left\{\frac{1-e^{-Ts}}{s}G_C(s)e^{-t_c s}\right\}, \qquad (7)$$

where $Z\{\bullet\}$ denotes the z-transform of the sampled impulse response of the continuous-time transfer function, $(1\text{-}e^{-Ts})/s$ is the transfer function of ZOH, and $e^{-t_c s}$ represents the processing delay t_c, which was formally added to the response of the analog circuitry. Note that (7) neglects the quantization introduced by real D/A and A/D converters.

Then the characteristic closed-loop equation will be

$$H(z)G(z)=1. \qquad (8)$$

The roots of (8) determine the stability of the emulation process.

The existence of two types of port (controlled current or voltage source, see Figure 1) is also dictated by the requirement of emulation stability. Let us consider a simple emulation of the resistor R_E by a controlled current source. Then the independent quantity will be the voltage ($u := v$) and the dependent quantity will be the current ($y := i$). The emulator transfer function (5) will be simply

$$H(z)=\frac{Y(z)}{U(z)}=\frac{I(z)}{V(z)}=\frac{1}{R_E}, \qquad (9)$$

i.e. $i(k) = v(k)/R_E$.

Let the emulator port be loaded with a physical resistor R. Considering a first-order reconstruction filter, but no anti-aliasing filter and no processing delay the small-signal transfer function (6) will be

$$G_C(s)=-R\frac{1}{1+s\tau_r}, \qquad (10)$$

where τ_r is the time constant of the reconstruction filter. The positive current i flows into the positive terminal of the emulator port, i.e. (10) has the negative sign.

The pulse transfer function (7) will be

$$G(z)=Z\left\{-\frac{1-e^{-Ts}}{s}\frac{R}{1+s\tau_r}\right\}=R\frac{1-c}{z-c}, \qquad (11)$$

where $c = exp(-T/\tau_r)$.

Substituting (9) and (11) into the characteristic equation (8) leads to

$$-\frac{R}{R_E}\frac{1-c}{z-c}=1. \qquad (12)$$

Considering the stability condition $|z| < 1$ for the root of (12) and with respect to the typical choice $\tau_r \approx T$, which gives $0 < c < 1$, we obtain the condition

$$R < R_E\frac{1+c}{1-c} \qquad (13)$$

for stable operation of the emulating process. Thus, if the Thévenin-equivalent resistance of the analog circuitry connected to the emulator port is higher than the limit (13), the system will oscillate, although the emulated device is a positive-value resistor. A more detailed analysis for other types of devices can be found in [19].

The example underlines the necessity for an emulation-stability analysis. A circuit that would be perfectly stable if realized from physical components may become unstable if some parts are emulated by a discrete-time system.

3. Demonstrations

3.1. Emulator Hardware

The emulator used for demonstrations is a two-port modification [17] of our emulator [15]. The system consists of the main board STM NUCLEO-F722ZE with a 32-bit MCU ARM Cortex-M7 with a single-precision floating-point unit connected to PC via USB. An add-on card implements two isolated ports, each with 16-bit A/D and D/A converters. The ports are fully floating, which is achieved by the use of integrated DC-DC converters and digital SPI isolators for converter control. The total parasitic capacitance of the floating part to the ground is about 11 pF.

A pluggable controlled voltage or current source can be connected to the ports as shown in Figure 3. The operating area of the four-quadrant voltage and current modules is ±3 V and ±3 mA. The emulator can easily achieve a sampling rate of 100 kHz. Depending on the software, it can emulate one or two independent floating devices or a general two-port network.

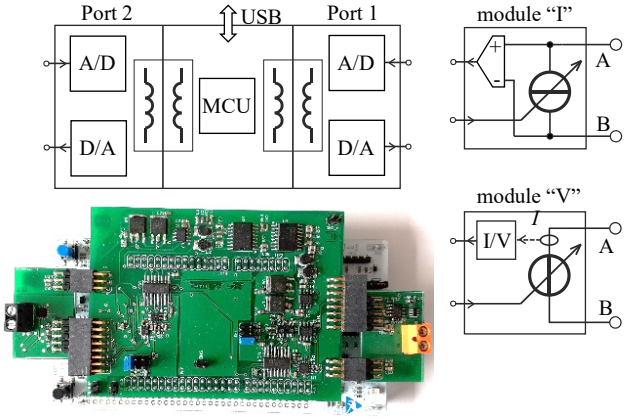

Figure 3: Emulator with pluggable IO modules.

3.2. FitzHugh-Nagumo Model

The FitzHugh-Nagumo (FHN) model of neuronal excitability [20] is a simplification of the well-known Hodgkin-Huxley model [13]. The model represents the prototype of an excitable system. When the input quantity exceeds some certain threshold, the system will generate a pulse. The two-dimensional FHN model is given in its normalized form as

$$\frac{d\upsilon}{d\tau} = \upsilon - \frac{\upsilon^3}{3} - w + j\,, \tag{14}$$

$$\frac{dw}{d\tau} = \frac{1}{\sigma}\left(\upsilon + a - bw\right), \tag{15}$$

where υ represents the normalized membrane potential, w is an auxiliary variable, j is a stimulus current, and τ is the model time. The model dynamics is determined by a set of three parameters with the usual values $a = 0.7$, $b = 0.8$, and $\sigma = 12.5$ [21].

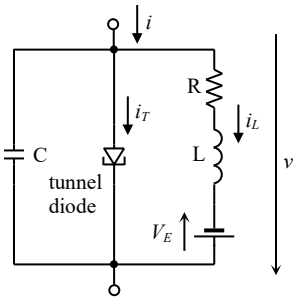

Figure 4: Equivalent circuit to (14) and (15) proposed by Nagumo [20].

The system (14), (15) can be represented by an equivalent electrical circuit shown in Figure 4 with a nonlinearity similar to that of the tunnel diode, which was proposed by Nagumo [20]. Let us consider the following mapping of FHN model quantities to the physical circuit in Figure 4:

$$v = \kappa_v\,\upsilon\,,\ i = \kappa_i\,j\,,\ i_L = \kappa_w\,w\,,\ t = \kappa_t\,\tau\,. \tag{16}$$

The transformation coefficients were chosen such that the variable υ will represent voltage in volts ($\kappa_v = 1$ V), j and w will be currents in milliamps ($\kappa_i = \kappa_w = 1$ mA), and one unit of model time τ will correspond to one millisecond of the physical time ($\kappa_t = 1$ ms), i.e. the dynamics will be speeded up a thousand times to get a convenient duration of generated pulses.

Considering (16), the parameters of the circuit elements will be

$$C = \frac{\kappa_t\,\kappa_i}{\kappa_v},\ R = \frac{b\,\kappa_v}{\kappa_w},\ L = \frac{\kappa_t\,\kappa_v\,\sigma}{\kappa_w},\ V_E = a\,\kappa_v\,. \tag{17}$$

For the chosen transformation coefficients we have $C = 1$ µF, $L = 12.5$ H, $R = 800$ Ω, and $V_E = 0.7$ V. The i-v characteristic $i_T(v)$ of the "tunnel diode" will be

$$i_T(v) = \kappa_i\left(\frac{(v/\kappa_v)^3}{3} - v/\kappa_v\right), \tag{18}$$

which corresponds to the first two terms of RHS of (9).

1) Direct Digital Emulation

Equations (14), (15) represent a dynamical system with the input current j and output potential υ. In accordance with the electrical model in Figure 4 the system can be emulated by a controlled voltage source. The output voltage $\upsilon(k)$ will be computed from the samples $j(k)$ of the measured current.

The real-time operation of the emulator requires the use of explicit integration methods with low numerical complexity [22]. Let us consider an ordinary differential equation of the n-th order in the form

$$\frac{d\mathbf{x}}{dt} = \mathbf{f}(\mathbf{x}, u)\,, \tag{19}$$

where $\mathbf{x} \in \mathrm{R}^n$ and u is a scalar input. Then the explicit multistep linear integration scheme can be formulated as

$$\mathbf{x}(k+1) = \mathbf{x}(k) + h\sum_{i=0}^{r-1}\gamma_i\,\mathbf{f}(\mathbf{x}(k-i), u(k-1))\,, \tag{20}$$

where r is the order of the method, h is the integration step, and γ_i are coefficients. For $r = 1$ we get the classical forward Euler method with $\gamma_1 = 1$, and for $r = 2$ the Adams-Bashforth method of the 2nd order (AB2) with $\gamma = \{3/2, -1/2\}$ [22].

The practical implementation of the multistep scheme (20) has a relative low numerical complexity as it requires just storing r-1 past values $\mathbf{f}(k\text{-}i) := \mathbf{f}(\mathbf{x}(k\text{-}i), u(k\text{-}i))$.

The computation of each step starts with the evaluation of RHS of (14), (15) for current values of the quantities

$$\mathbf{f}(k) = \begin{array}{|c|}\hline \upsilon(k) - \upsilon(k)^3/3 - w(k) + j(k) \\ \hline \left(\upsilon(k) + a - b\,w(k)\right)/\sigma \\ \hline \end{array}\,. \tag{21}$$

In the case of the Euler method the next step is

$$\begin{array}{|c|}\hline \upsilon(k+1) \\ \hline w(k+1) \\ \hline \end{array} = \begin{array}{|c|}\hline \upsilon(k) \\ \hline w(k) \\ \hline \end{array} + h\,\mathbf{f}(k) \tag{22}$$

and for AB2 we have

$$\begin{array}{|c|}\hline \upsilon(k+1) \\ \hline w(k+1) \\ \hline \end{array} = \begin{array}{|c|}\hline \upsilon(k) \\ \hline w(k) \\ \hline \end{array} + \frac{h}{2}\left[3\mathbf{f}(k) - \mathbf{f}(k-1)\right], \tag{23}$$

where $h = T/\kappa_t$. The coefficient $\kappa_t = 1$ ms scales the time axis so that the time unit in the original system (14), (15) corresponds to one millisecond in (22) and (23).

The emulator was configured as a current-controlled voltage source using the module "V", where the output quantity is the transformed state variable $v(k) = \upsilon(k)\ \kappa_v$ and the control quantity is $j(k) = i(k)/\kappa_i$. The sampling rate was set to 100 kHz.

Figure 5 shows the results of an experiment where the digital FHN model was "excited" by short pulses with an amplitude of 3 V, a width of 8 ms, and a period of 100 ms applied through a 10 kΩ resistor R_d. It can be seen that each pulse triggers a characteristic excursion, after which the system relaxes back to the equilibrium state.

The discretization and emulation of the continuous-time system bring two problems with the stability: the stability of the

integration method itself and the stability of the feedback emulation process as introduced in Section 2.2.

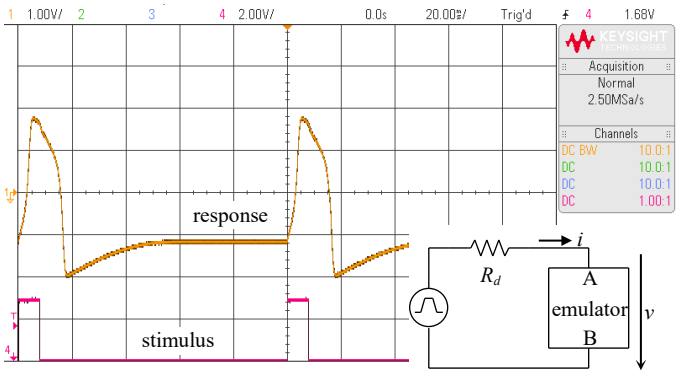

Figure 5: Response (channel 1 - orange) to excitation pulses (channel 4 - red).

In particular, it is known for explicit methods that an inappropriate choice of the integration step can lead to instability and an excessive truncation error [22]. Figure 6 shows a qualitative study comparing the performance of the methods (22) and (23) for the same setup as in Figure 5. For the 10 μs sampling period used, the results are indistinguishable from the nominal solution within the uncertainty introduced by the quantization by A/D and D/A converters. When the sampling period was increased to 500 μs, the waveform computed by AB2 showed numerical oscillations. Therefore, the first-order method was preferred in the experiments.

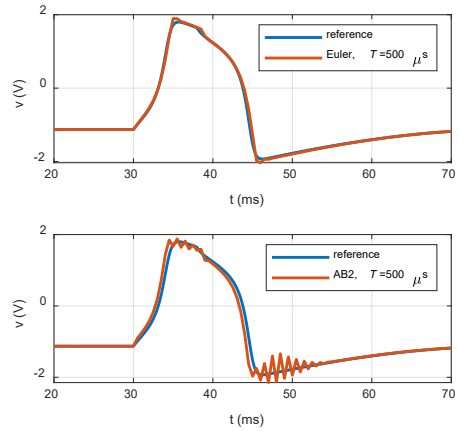

Figure 6: Comparison of forward Euler and 2nd–order Adams-Bashforth methods for large integration steps.

The stability of emulation as introduced in Section 2.2 can be qualitatively assessed based on the equilibrium stability analysis for $v = 0$, which corresponds to the OFF period of the signal source. The equilibrium of the FHN model can be obtained via solving the system (14), (15) for $d\upsilon/d\tau = 0$ and $dw/d\tau = 0$, and also by considering the relation $v = -R_d\, i$ determined by the driving circuit in Figure 5 during the OFF periods. After the transformation (16) the relation becomes $\upsilon\, \kappa_v = -R_d\, j\, \kappa_i$ and we obtain the system

$$0 = \tilde{\upsilon} - \frac{\tilde{\upsilon}^3}{3} - \tilde{w} - \frac{\tilde{\upsilon}\,\kappa_v}{R_d\,\kappa_i}, \tag{24}$$

$$0 = \tilde{\upsilon} + a - b\,\tilde{w}, \tag{25}$$

whose solution is

$$\tilde{\upsilon} = -1.129,\ \tilde{w} = -0.536\,. \tag{26}$$

Let us start with the forward Euler method. The equilibrium corresponds to a fixed point of the discretized system (22), because $\mathbf{f}_k = \mathbf{0}$ and thus $\upsilon(k+1) = \upsilon(k)$, $w(k+1) = w(k)$. The structure of the system (22) corresponds to (1), (2) and its linearization at the fixed point ($\tilde{\upsilon}$, $\tilde{w}$) leads to the following matrices (3) and (4):

$$\mathbf{A} = \begin{bmatrix} 1+h(1-\tilde{\upsilon}^2) & -h \\ h/\sigma & 1-hb/\sigma \end{bmatrix},\ \mathbf{B} = \begin{bmatrix} h \\ 0 \end{bmatrix},$$

$$\mathbf{C} = \begin{bmatrix} 1 & 0 \end{bmatrix},\ D = 0\,. \tag{27}$$

Using (5), the emulator transfer function is

$$H(z) = \frac{V(z)}{I(z)} = \frac{\kappa_v}{\kappa_i}\,\frac{zh\sigma - h(\sigma - bh)}{z^2\sigma + z[h\sigma(\tilde{\upsilon}^2 - 1) - 2\sigma + bh] + (bh - \sigma)[h(\tilde{\upsilon}^2 - 1) - 1] + h^2}\,. \tag{28}$$

The simulator uses a 1st-order reconstruction filter with the time constant τ_r and no anti-aliasing filter. The Laplace-domain transfer function between the output of the D/A converter and the input of the A/D converter corresponding to the application schematics in Figure 5 will be

$$G_C(s) = \frac{I(s)}{V(s)} = -\frac{1}{R_d}\,\frac{1}{1 + s\,\tau_r}, \tag{29}$$

where the negative sign stems from the chosen orientation of v and i.

Using the standard s- and z-transforms, the pulse transfer function can be easily obtained as [23]

$$G(z) = Z\left\{\frac{1 - e^{-Ts}}{s}\,G_C(s)\,e^{-t_c s}\right\} = -\frac{1}{R_d}\,\frac{(1 - cd)z^{-1} + c(d-1)z^{-2}}{1 - c\,z^{-1}}, \tag{30}$$

where $c = exp(-T/\tau_r)$ and $d = exp(t_c/\tau_r)$.

The time constant of the reconstruction filter was $\tau_r = T = 10$ μs, which smoothed reasonably its staircase output, and the processing delay was $t_c = 3$ μs. Then the roots of the characteristic equation (8) are as follows:

$$\lambda_{1,2} = 0.9978 \pm j\ 0.002289,\ \lambda_3 = 0.3692,\ \lambda_4 = -3.4988 \times 10^{-4},$$

which indicates a stable operation. It can be shown that the doublet $\lambda_{1,2}$ corresponds to the poles of (28) because the FHN model is driven by a high-resistance source, which behaves like a stimulation by a current source (see Figure 5). The doublet is close to the unity circle, reflecting the fact that the sampling rate is orders of magnitudes faster than the modeled dynamics, i.e. the update in each step is relatively low ($v(k+1) \approx v(k)$). The roots λ_3 and λ_4 are predominantly influenced by the chosen time constant of the

reconstruction filter and MCU processing delay, and represent fast-decaying artifacts of the emulation process.

To compute the z-domain transfer function (5) for higher-order integration methods, the difference equation (20) should be transformed to an equation of the 1st order.

In the case of the Adams-Bashforth method of the 2nd order the scheme (23) can be transformed to

$$\begin{bmatrix} v(k+1) \\ w(k+1) \end{bmatrix} = \begin{bmatrix} v(k) \\ w(k) \end{bmatrix} + \frac{h}{2}\left(3\mathbf{f}(k) - \tilde{\mathbf{f}}(k)\right), \tag{31}$$

$$\tilde{\mathbf{f}}(k+1) = \mathbf{f}(k), \tag{32}$$

where $\tilde{\mathbf{f}}(k)$ is the vector of RHS of (14) and (15) delayed by one period. Then the linearization of (31) and (32) leads to

$$\mathbf{A} = \begin{bmatrix} 1+\frac{3h}{2}(1-v^2) & -\frac{3h}{2} & -\frac{h}{2} & 0 \\ \frac{3h}{2\sigma} & 1-\frac{3hb}{2\sigma} & 0 & -\frac{h}{2} \\ 1-v^2 & -1 & 0 & 0 \\ 1/\sigma & -b/\sigma & 0 & 0 \end{bmatrix}, \quad \mathbf{B} = \begin{bmatrix} 3h/2 \\ 0 \\ 1 \\ 0 \end{bmatrix},$$

$$\mathbf{C} = \begin{bmatrix} 1 & 0 & 0 & 0 \end{bmatrix}, \; D = 0\,. \tag{33}$$

Repeating the same procedure as for the Euler method, we obtain the roots:

$\lambda_{1,2} = 0.9978 \pm j\,0.003594$,

$\lambda_3 = 0.3681$, $\lambda_4 = -0.0136$, $\lambda_5 = 0.0130$, $\lambda_4 = -3.0454 \times 10^{-4}$.

The doublet characterizes the emulated system dynamics and the other roots represent the artifacts of the discretization. Also in this case, the emulation is stable.

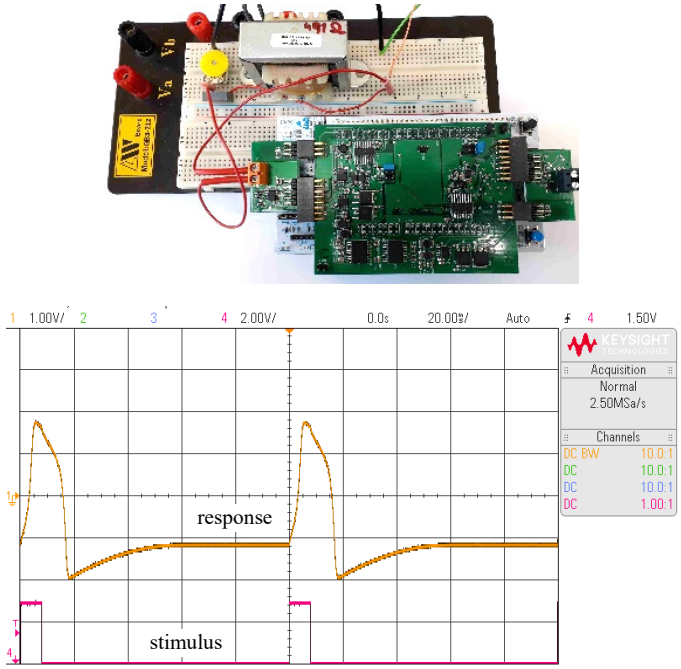

Figure 7: Hybrid circuit setup and response (orange) to excitation pulses (red).

2) Hybrid Circuit

In the hybrid approach the emulator is used to implement some parts of the model, while the rest of the model can be realized using standard electronic components as in Figure 4. In the case of the FHN equivalent circuit the emulator implements just the "tunnel diode". The cubic nonlinearity (18) was emulated as a voltage-controlled current source using the module "I".

Figure 7 shows the experiment setup on a breadboard and the response of the model for the same conditions as in Figure 5. The parameter L was changed to 16.2 H in this experiment to match the inductance of the available off-the-shelf choke.

Figure 8 compares the measured pulses with a PSpice simulation, the latter being regarded as a reference solution. All three waveforms overlap.

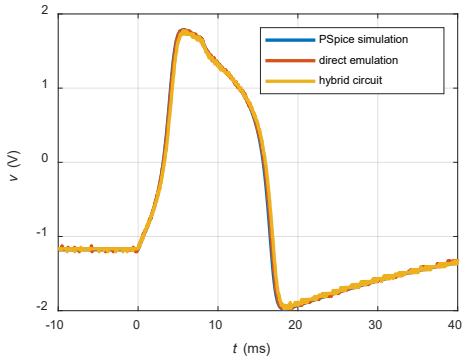

Figure 8: Comparison of the measured and simulated responses for L = 16.2 H (all waveforms overlap).

3.3. Model of Amoeba Adaptation

The amoeba can adapt to periodic environmental changes. An electrical model of the process was presented in [24], see Figure 9. The environmental conditions (temperature and humidity) are represented by a single quantity – the voltage $v(t)$, which is applied to the circuit. The response is the change in amoeba movement velocity represented by the voltage $v_c(t)$.

The memristor in Figure 9 is a voltage-controlled memristor with a threshold whose memristance R_M is governed by the following state equation [24]

$$\frac{dR_M}{dt} = f_A(v_M)\, f_W(R_M, v_M)\,, \tag{34}$$

where v_M is the voltage across memristor ($v_M = v_C$ here). The memristor activation function

$$f_A(v_M) = \frac{\beta - \alpha}{2}\left(|v_M + V_T| - |v_M - V_T|\right) - \beta v_M \tag{35}$$

is shown in Figure 9(b). The parameter α is the slope of the inner segment and β is the slope of outer segments.

The window function

$$f_W(R_M, v_M) = \theta(v_M)\theta(R_M - R_1) + \theta(-v_M)\theta(R_2 - R_M) \tag{36}$$

confines the memristance between the boundary values R_1 and R_2, and θ is the Heaviside step function.

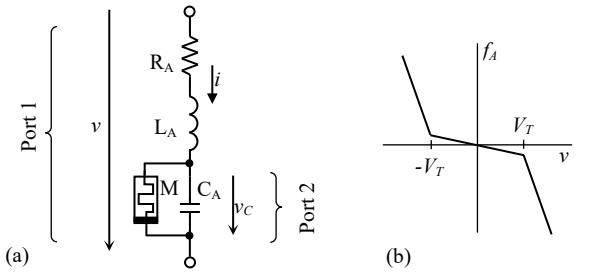

Figure 9: (a) Equivalent electrical model of amoeba's adaptation; (b) Activation function of memristor.

The model leads to a system of the 3rd order [25]

$$\frac{di}{dt} = \frac{1}{\kappa_t L_A}\left(-R_A i + v - v_c\right), \tag{37}$$

$$\frac{dv_c}{dt} = \frac{1}{\kappa_t C_A}\left(-\frac{v_c}{R_M} + i\right), \tag{38}$$

$$\frac{dR_M}{dt} = \frac{1}{\kappa_t} f_A(v_c) f_W(R_M, v_c), \tag{39}$$

where the parameters were identified as [24]: $R_A = 0.1\ \Omega$, $L_A = 2$ H, $C_A = 1$ F, $R_1 = 3\ \Omega$, $R_2 = 20\ \Omega$, $\alpha = 0.1\ \Omega$/Vs, $\beta = 100\ \Omega$/Vs, $V_T = 2.5$ V. The amoeba adaptation occurs on the time scale of ≈100 s, which is rather slow for laboratory experiments even with a digital memory oscilloscope. Therefore the time-axis scaling $\kappa_t = 10^{-3}$ was added to the equations. Now, one second of the model time corresponds to one millisecond of the real time.

The emulator was configured as a two-port network. The excitation voltage $v(t)$ is applied to Port 1 with the "I" module (controlled current source). Although the current i(t) is just an internal variable of the system (37)-(39), it can be generated at Port 1 to emulate fully the circuit from Figure 9(a). One ampere in the model corresponds to one milliampere in the emulated circuit. The model response based on $v_c(t)$ is generated at Port 2 with the "V" module. Alternatively, the output can be set as the memristance R_M to monitor the internal state of the model.

Equations (37)-(39) were discretized using the forward Euler method, similar to (22). The window function f_W was realized in the algorithm as a correction of the state variable R_M after each integration step. Whenever $R_M > R_2$, it is set back to R_2 and vice versa for the lower limit R_1.

The excitation voltage $v(t)$ represents environmental conditions of the amoeba. Favorable conditions correspond to a positive voltage and unfavorable conditions to a negative voltage. Long-term exposure to favorable conditions ($v > 0$) leads to $dR_M/dt < 0$ and after a sufficiently long interval the memristance R_M will be at its lower limit, i.e. $R_M = R_1$.

It has been observed that periodic intervals of unfavorable conditions make the amoeba adapt so that the organism can anticipate the intervals and decrease its velocity. The process can be demonstrated on an experiment from [24]. The "training" voltage waveform consists of three negative cosine pulses

$$v(t) = V_F + V_P \sum_{i=1}^{3} \left\{ \cos\left[\frac{2\pi(t - t_i)}{W_p}\right] - 1 \right\} \frac{w(t)}{2}, \tag{40}$$

where $w(t) = \theta(t - t_i)\theta(t_i + W_p - t)$ is a window function for masking the individual periods of the cosine function. The parameters used were $V_F = 0.1$ V, $V_p = 2$ V, and $W_p = 5$ ms. With respect to the time-axis scaling, the times of pulse starts for the irregular sequence were $t_i^{(irregular)} = \{10\text{ ms}, 19\text{ ms}, 34.5\text{ ms}\}$ and for the regular sequence $t_i^{(regular)} = \{10\text{ ms}, 19\text{ ms}, 28\text{ ms}\}$. The excitation signal was generated using the arbitrary waveform generator Keysight 33521B.

The output voltage on Port 2 was generated as [24]

$$v_{out}(t) = \min(v_C(t), V_F). \tag{41}$$

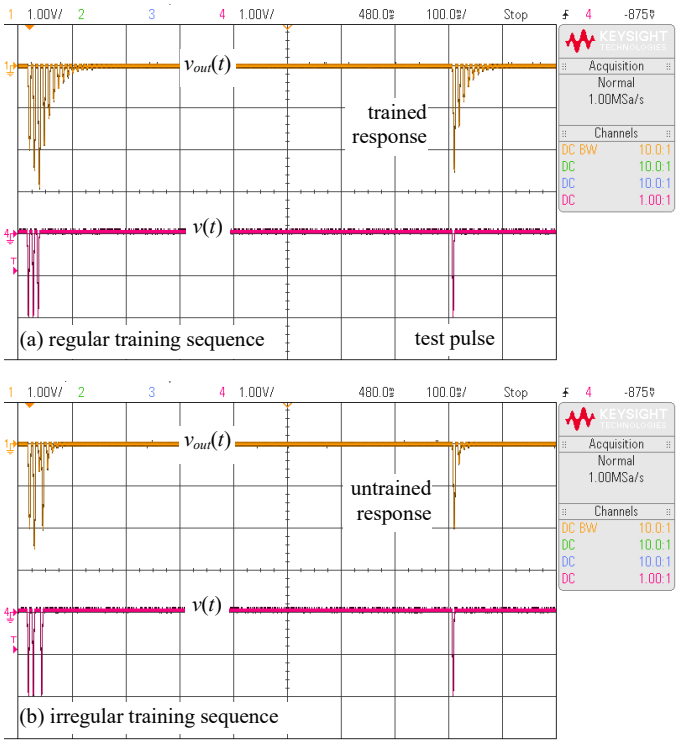

Figure 10: Excitation voltage (channel 4 – red) and amoeba response (channel 1 – orange) for (a) regular and (b) irregular training sequence.

Figure 10 shows the excitation voltage $v(t)$ and the response $v_{out}(t)$ generated by the emulator. The amoeba adaptation is represented in the model by the change of memristance R_M. The application of the irregular sequence of training pulses after a long period of favorable conditions (V_F) does not change the memristance significantly. On the other hand, the regular training sequence makes R_M increase to R_2 and the amoeba becomes "adapted". Both states can be tested by a single pulse at 800 ms after the training sequence start. The adapted response consists of several pulses of motion slowdown where the organism anticipates other unfavorable intervals. The response of the untrained organism is visibly smaller. Both results are in agreement with computer simulations in [24].

4. Conclusions

The results presented in the paper can be summarized as follows:

(1) Emulation provides the possibility of substituting an *m*-port network with a mixed-mode analog-digital system. The network modeled via multi-dimensional differential equations, which link terminal voltages and currents and internal state variables, can be emulated via digitally controlled current or voltage sources. The sources are controlled based on the port voltages or currents and the state variables via discrete-time equations of motion of the system being emulated.

(2) In some cases, it can be useful to emulate digitally only some key parts of the circuit, while the rest can be made up of (preferably passive) analog components.

(3) The combination of continuous-time and discrete-time blocks can bring stability problems, even in very simple circuits. The paper presents a methodology that can be used to assess the emulated system stability.

(4) Stability problems can be alleviated by an appropriate selection of the type of controlled source (voltage or current) which is used to realize each port. Details are given in our previous work [17].

(5) The paper presents a mixed-mode emulator with pluggable IO ports that has proven itself to emulate unconventional circuit elements (memristors, memcapacitors, meminductors, etc.) and also bio-inspired circuits. Especially in the case of models of biological systems it can avoid using bulky inductors and capacitors, which are common there.

Conflict of Interest

The authors declare no conflict of interest.

ABSTRACT

Current work demonstrates how open-source optimization library "Extremum" (OSOL Extremum) can be used to build feedback controller of a satellite. Proposed software was developed to as an attempt to eliminate current problems that are present in scientific area: black-box effect (i.e. there is no opportunity to explore source code, modify it, or simply verify), no code reuse (i.e. implemented procedures are accessible only within software that includes it), limitated application of modern optimization algorithms (i.e. number of optimization algorithms increases but most of them were verified only on synthetic tests). All of them lead to so-called reproducibility crisis.

1 Introduction

This paper is an extension of work originally presented in 2018 IV International Conference on Information Technologies in Engineering Education (Inforino) [1].

Optimization is a field of mathematics that is widely applied in engineering, e.g. optimal component design and control theory [2, 3, 4]. Traditionally, optimization algorithms are divided into two groups:

- analytic – these are determined algorithms which efficiency and convergence properties are proved; their main disadvantage is relatively poor performance which reduces the scope of applied problems that can be solved by them [5],
- (meta)heuristic – on the contrary, this group of algorithms has problems with the convergence of results: it is not guaranteed that an appropriate solution will be found, but these algorithms are much more computationally efficient and practically verified [6].

The current work consists of several parts:

- *Prerequisites – explains reasons which led to the OSOL Extremum development;*
- *Description of OSOL Extremum – provides information about software structure and technology stack;*
- *Synthesis of Feedback Control of a Satellite via the OSOL Extremum – describes mathematical task formulation;*
- *Application Results – demonstrates particular results of application of the developed software;*
- *Conclusion – summarizes the results and provides information about further research.*

2 Prerequisites

In order to understand why the development of a new software was performed it is necessary to describe its background. It will be explained in details in the following subsections.

2.1 Black-Boxing

This is the double-edged sword of software development. On the one hand, it allows one to use given tools without necessity to implement desired algorithm, but on the other - it deprives the opportunity to modify code the way you need it for the exact task. In other words, black-boxing makes all your software tools not as flexible as they can be. Also, you must be totally confident in the quality of the software that you use, because you have no opportunity to check confusing moments.

2.2 Code Reuse

Generally, academic scientists and software developers work differently. Mainly, scientists are more concerned to solve the given problem without any care about reuse of the scripts and software that they have developed. Programmers, conversely, think a bit differently: they use different programming concepts (e.g. object-oriented programming paradigm) in order to maximize the efficiency of written code in future. That gives an opportunity to create reusable tools speeding up further investigations.

2.3 Reproducibility Crisis

Last but not least, reproducibility crisis is general problem for the science. A lot of researches that are described in scientific articles cannot be verified or at least repeated. That happens because of the restrictions on the article size (i.e. there is no enough space to provide step-by-step description or to explain every moment in detail) and displaced informational focus (i.e. scientists are more concerned to present application results not the specification moments).

2.4 Section Summary

Mentioned problems lead to various limits in overall development speed. This coerces scientist to solve tasks that are out of his professional scope. One possible way to weaken effects of described problems is to develop open-source libraries that offer wide capabilities of API (application programming interface) including unified standard for algorithm creation, general testing environment, and huge spectrum of applied tasks.

Available open-source packages (e.g. python's scikit and scipy packages, R's specialized packages for optimization) partially solve described problems but mostly provide out-of-box tools. Also none of them fully support interval optimization algorithms and they are hardly connected to external programs. That is why it is important to develop library that can be used as set of building blocks for any desired algorithm.

3 Description of OSOL Extremum

This section provides information about OSOL Extremum presenting its main ideas and features. Source code of the library can be found on GitHub site [7].

3.1 Technology Stack

Software part of the developing library consists of modules that are developed using two program languages: Scala (main logic) and Python (for plotting, scripting, and non-math routines).

Scala belongs to multi-paradigm programming languages which support both object-oriented and functional features [8]. Object-oriented paradigm gives opportunity to develop inheritance hierarchy that simplifies code reuse a lot. Functional paradigm is often treated as more "native" to mathematicians because its main statements: treating functions as basic objects, data immutability, pure functions, and etc.). Mainly, these statements aimed to provide code stability decreasing places of potential code mistakes. Also. It should be noted that Scala runs on JVM platform, so it is easily maintained and distributed.

Python is a well-known language which is widely used by scientists of different specialization because of its relative simplicity and generous number of various packages (e.g. NumPy, SciPy, Matplotlib, and etc.) [9].

3.2 Library Structure

OSOL Extremum consists of several parts:

- implementation of basic required mathematical operations and objects, e.g. vector operations, function transformations, random number generators, and statistics calculation,
- general template for optimization algorithms that can be extended by other researches to implement desired method,
- block of implemented optimization algorithms,
- block of different tasks (including basic optimization tasks and complicated optimal control synthesis problems).

3.3 Current State and Future Goals

Current version of OSOL Extremum supports the following features:

- definition of basic optimization algorithm in a form of abstract template that supports wide range of running instructions, e.g. termination by max time or iterations and logging instructions,
- bunch of classical and modern optimization algorithms (including Random Search, Simulated Annealing, Cat Swarm Optimization, and Harmony Search) [5, 6],
- tools for the interaction with Simulink models.

In future it is planned to: implement more optimization algorithms, add support of interval optimization algorithms, add support of other modelling systems (e.g. Wolfram Mathematica), add support of other computational cores.

4 Synthesis of Feedback Control of a Satellite via the OSOL Extremum

This section will provide information how OSOL Extremum can be used to solve applied problem in the field of control theory.

4.1 Stage 1: Open-Loop Control Determination

Problem Definition. During the first stage it is required to solve the problem of optimal open-loop control determination.

Let's consider that the behavior of an object that is described by the following differential equation [10]:

$$\dot{x}(t) = f(t, x(t), u(t)), \tag{1}$$

where $t \in T = [t_0; t_1]$ is continuous time, T - system operational time, $x \in \mathbb{R}^n$ - system state vector, $u \in U \subset \mathbb{R}^q$ - control vector, U - set of admissible control values, $f(t,x,u) = (f_1(t,x,u), ..., f_n(t,x,u))^{\mathrm{T}}$ - continuous vector-function.

Initial state is given:

$$x(t_0) = x_0, \tag{2}$$

terminal state $x(t_1)$ should satisfy the following conditions:

$$\Gamma_i(x(t_1)) = 0, i = 1, ..., l, \tag{3}$$

where $0 \le l \le n$, $\Gamma_i(x), i = 1, ..., l$ are continuously differentiable, system of vectors $\left\{\frac{\partial \Gamma_i(x)}{\partial x_1}, ..., \frac{\partial \Gamma_i(x)}{\partial x_n}\right\}, i = 1, ..., l$ is linearly independent $\forall x \in \mathbb{R}^n$.

The only information which is used to form control is continuous time t. Hence, we consider open-loop control.

Set of admissible processes $D(t_0, x_0)$ is defined as a set of pairs $d = (x(\cdot), u(\cdot))$ which include trajectory $x(\cdot)$ and admissible control $u(\cdot)$ where $\forall t \in T : u(t) \in U$ that satisfy equations (1), (2), and (3).

On the set of admissible processes we consider cost functional

$$I(d) = \int_{t_0}^{t_1} f(t, x(t), u(t))\, dt + F(x(t_1)), \tag{4}$$

where $f^0(t,x,u)$ and $F(x)$ are given continuous functions.

In order to transform the given problem into the problem without terminal constraints we can use penalty function:

$$\bar{I}(d) = I(d) + \sum_{i=1}^{l} E_i(x(t_1), \varepsilon_i, p_i), \tag{5}$$

where

$$E_i(x, \varepsilon_i, p_i) = \begin{cases} (p_i \cdot \Gamma_i(x))^2 \text{ if } |\Gamma_i(x)| > \varepsilon_i \\ |\Gamma_i(x)| \text{ otherwise,} \end{cases} \tag{6}$$

are error functions, p_i and ε_i, $i = 1, ..., l$ are penalty parameters and maximum allowed errors accordingly.

The task is to find such a pair $d^* = (x^*(\cdot), u^*(\cdot))$ that

$$d^* = \mathrm{Arg} \min_{d \in D(t_0, x_0)} I(d). \tag{7}$$

To solve task defined by equation (7) it is suggested to propose parametric form of control and convert initial problem to a problem of parametric optimization. The control, which is obtained by such a procedure, is suboptimal.

Application of Optimization Algorithms. To apply optimization algorithms it is required to parameterize controls in any suitable vector form. Proposed approach was tested using several parameterization schemes:

- polynomial control: $(a_0, a_1, a_2, ..., a_s)^{\mathrm{T}} \Rightarrow u(t) = a_0 + a_1 \cdot t + a_2 \cdot t^2 + ... + a_s \cdot t^s$,
- piecewise linear control: $(a_0, a_1, a_2, ..., a_s)^{\mathrm{T}} \Rightarrow u(t) = \frac{\tau_{i+1} - t}{\tau_{i+1} - \tau_i} \cdot a_i + \frac{t - \tau_i}{\tau_{i+1} - \tau_i} \cdot a_{i+1}$, where $\tau_i = t_0 + i \cdot \frac{t_1 - t_0}{s}$ and $\tau_i \le t < \tau_{i+1}$.

The value of the cost functional is calculated by the numerical methods using Euler, Euler-Cauchy or Runge-Kutta formulas [11, 12].

To obtain numerical results it is proposed to use two techniques:

- simply generate polynomial control (this technique will be called direct),
- start with determination of controls in polynomial form (with few degrees of freedom) and then use obtained solution as a seed for optimization procedure with piecewise linear controls (this technique will be called sequential).

Transformation, which is used during sequential technique, can be easily done by calculation of values of polynomial control in nodes of uniform grid (demonstrated on Figure 1).

Described techniques differ in this way: direct requires less time to obtain control, sequential requires more time (because of two parts) but potentially generates more efficient controls (due to bigger number of degrees of freedom).

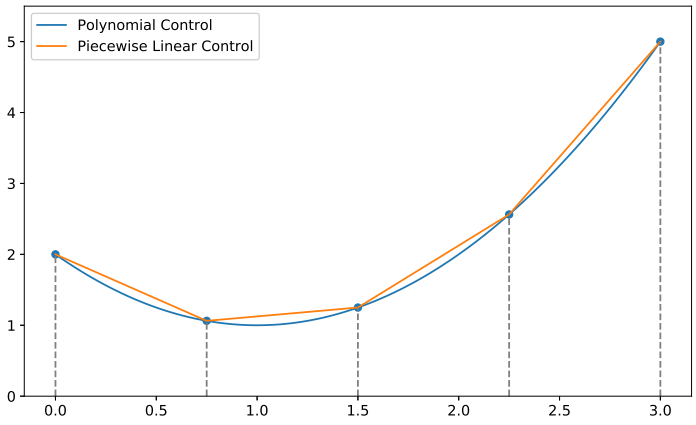

Figure 1: Conversion of polynomial control to piecewise linear one

Thus, initial task is transformed to the determination of optimal vector $(a_0, a_1, a_2, ..., a_s)^{\mathrm{T}}$. As the final result of the first stage set of suboptimal controls $\tilde{u}^{*,k}, k = 1, ..., K$ will be found, i.e. $\tilde{u}^{*,k}$ corresponds to initial state vector $x^k(t_0)$ (K is a number of totally observed initial conditions).

4.2 *Stage 2: Controller Construction*

Final form of the controller will be found during the final stage in a form of regressor. Current block consists of data preparation part and actually regressor construction.

Data Processing. During current phase initial data will be transformed and modified. There are various data processing procedures [13], e.g.

- **Cleaning**. This process ensures that only valid data will be used. In our case it is important to include this phase because on previous stage we use metaheuristic optimization algorithms which are not guaranteed to retrieve the best possible solution. Thus, we will eliminate from further consideration those controls which do not provide sufficient accuracy in the means of the final state error defined by equation (8).
- **Imputation** is widely used in machine learning. Mostly it is present in cases when there is a possibility of data loss. Considered case is determined so there is no need to include it.

- **Transformation**. During this phase data, which was previously cleaned, is transformed from raw format (in our case it is set of suboptimal controls) into format that is suitable for machine learning procedures. We will transform data to a table format.
- **Normalization** is required to standardize obtain data, e.g. nullify its mean values, normalize standard deviation, etc.

In terms of cleaning it is proposed to use only those controls which correspond to trajectories with relatively small terminal constraints errors, e.g.

$$\frac{1}{l} \cdot \sum_{i=1}^{l} |\Gamma_i (x(t_1))| \leq b, \tag{8}$$

where b is a bias value that can be treated as an acceptable level of average cumulative error.

Having set of suboptimal controls $\left\{\tilde{u}^{*,k}\right\}_{k=1}^{K}$ it is possible to find corresponding set of trajectories $\left\{\tilde{x}^{*,k}\right\}_{k=1}^{K}$ from equation (1). This information is sufficient to build initial dataset that will be considered as a base. Specifically, it is proposed to build dataset in a form of Table 1.

Table 1: Initial dataset template

j(index)	t	x_1	$\cdots$	x_n	u_1	$\cdots$	u_q
1	$t\Big\vert_{j=1}$	$x_1\Big\vert_{j=1}$	$\cdots$	$x_n\Big\vert_{j=1}$	$u_1\Big\vert_{j=1}$	$\cdots$	$u_q\Big\vert_{j=1}$
$\vdots$	$\vdots$	$\vdots$	$\cdots$	$\vdots$	$\vdots$	$\cdots$	$\vdots$

Such a table can be built for any selected control and then all obtained tables can be concatenated. Thus, we have K different trajectories from each of which we sample in N discrete time moments. Finally, it results into the following bounds for j index: $j = 1, ..., K \cdot N$.

Regressor Construction. Regression is a classical example of so-called supervised learning [14]. In a considered scope of optimal control determination we can treat controls (derived from optimization procedures during the first stage) as an ideal output. Time, and state values can be treated as the input. In other words, desired feedback controller can be treated in this way:

$$\hat{u}_i \left(t\Big\vert_{j=j^*}, x_1\Big\vert_{j=j^*}, ..., x_n\Big\vert_{j=j^*} \right) = u_i\Big\vert_{j=j^*}, \tag{9}$$

where $i = 1, ..., q$ and j^* - possible index.

From equation (9) it is obvious how to generate control for previously observed values but it is not clear what to do with new values that will arise in future. That is why machine learning is proposed to be used here - because of its ability to generalize information basing on finite set of observations [15, 14].

In current work it is proposed to build regressor using well known and widely applied Random Forests [16], which are already implemented in Python open-source library Scikit-Learn [17].

4.3 Section Summary

The core component of the described approach is application of optimization algorithms which can be realized via the OSOL Extremum. Following sections will demonstrate how the proposed approach can be applied to a real control problem.

5 Application Results

5.1 Description of Dynamic Model

To demonstrate the proposed approach the problem of satellite rotational motion dampening is considered [18]. After the conversion to non-dimensional variables system of differential equations, which describes solid body motion relative to centre of mass, will have the following form:

$$\begin{cases} \dot{p} = \frac{u_1}{6}, \\ \dot{q} = u_2 - 0.2 \cdot p \cdot r, \\ \dot{r} = 0.2 \cdot (u_3 + p \cdot q). \end{cases} \tag{10}$$

Control vector constraints are represented via intervals $\forall t \in [0; 1]$: $U = [-500; 500] \times ... \times [-500; 500]$.

Cost functional is given by the formula:

$$I(d) = \int_0^1 (|u_1(t)| + |u_2(t)| + |u_3(t)|)\, dt. \tag{11}$$

Initial values for p_0, q_0, r_0 will be taken from sets $\{-25, -20, ..., -5, 0, 5, ..., 20, 25\}$ (for direct optimization procedure) and $\{21, 22, 23, 24, 25\}$ (for sequential optimization procedure) which results into 11^3 and 5^3 possible combinations accordingly.

Terminal constraints are the same for any starting configuration:

$$p(1) = q(1) = r(1) = 0. \tag{12}$$

Parameters of error functions are also the same for any starting configuration:

$$p_i = 10^3, \varepsilon_i = 0.1, i = 1, 2, 3. \tag{13}$$

Thus, modified functional cost will have the following from:

$$\begin{aligned} \bar{I}(d) = \int_0^1 (|u_1(t)| + |u_2(t)| + |u_3(t)|)dt + \\ + E_1\left(p(t_1), 0.1, 10^3\right) + \\ + E_2\left(q(t_1), 0.1, 10^3\right) + \\ + E_3\left(r(t_1), 0.1, 10^3\right). \end{aligned} \tag{14}$$

5.2 Intermediate Results

For All graphics in this and following section horizontal axis is associated with dimensionless time, vertical axis provides information for target variable (also in dimensionless units).

All results in the current section were provided assuming $s = 2$ for polynomial control and $s = 10$ for piecewise linear.

Figure 2 demonstrates the obtained results during the optimization stage (for sequential technique).

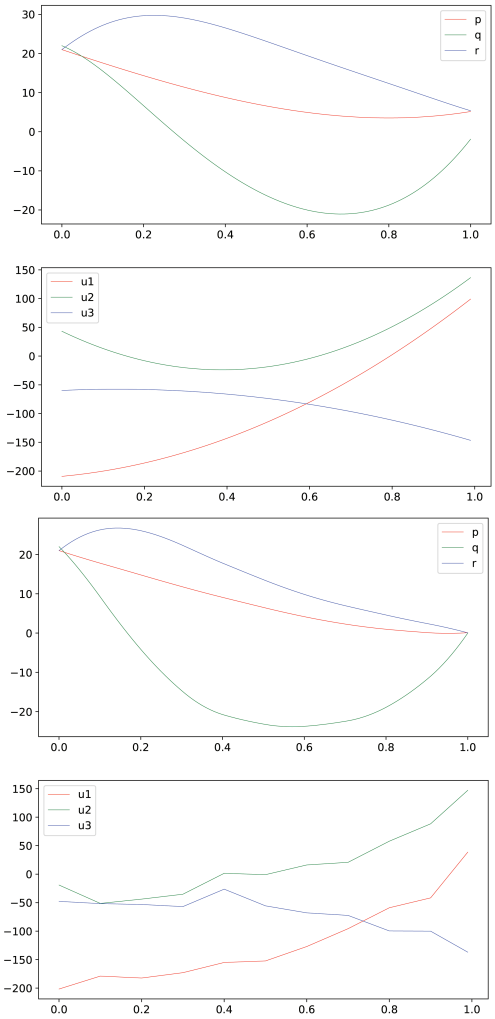

Figure 2: Results of sequential optimization procedure for initial conditions $p(0) = 21, q(0) = 22, r(0) = 21$

From the plot it is clear that during the first stage (generation of polynomial controls) some of them have corresponding trajectories with relatively big errors for terminal state. But it is successfully minimized during the construction of the piecewise polynomial control.

Better visual description of obtained controls can be obtained via bunch graphics demonstrated on Figure 3.

It should be noted that all columns will be scaled (except of the control columns), i.e. transformed to have maximum value equal to 1 and minimum - to 0.

5.3 *Final Results*

The following section will contain information about obtained regressors. Initial values are chosen in order not to duplicate previously used initial states. Each received trajectory was sampled $N = 101$ times in moments $t_i = 0.01 \cdot i$.

Direct technique. Example of application is demonstrated on Figure 4 and Figure 5.

Initial conditions: $p_0 = 24, q_0 = 16, r_0 = 16$.

Achieved terminal state: $p(t_1) = -0.067, q(t_1) = -0.065, r(t_1) = -0.094$.

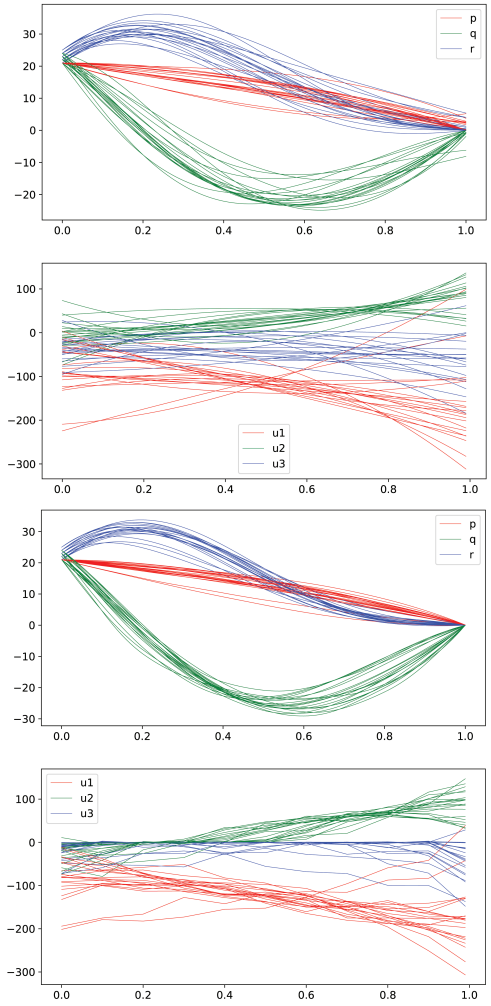

Figure 3: Bunches of trajectories and controls (for sequential optimization procedure)

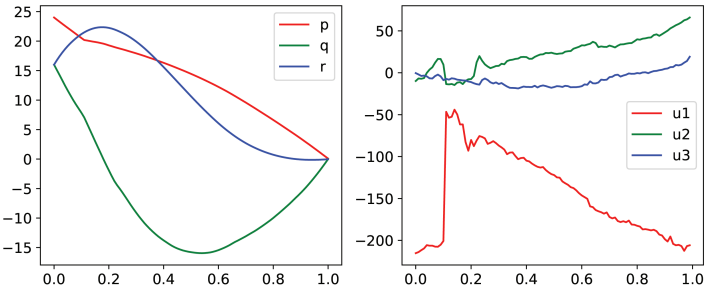

Figure 4: Example 1: trajectories and controls

Initial conditions: $p_0 = -9, q_0 = 13, r_0 = -24$.

Achieved terminal state: $p(t_1) = 0.096, q(t_1) = -0.008, r(t_1) = -0.019$.

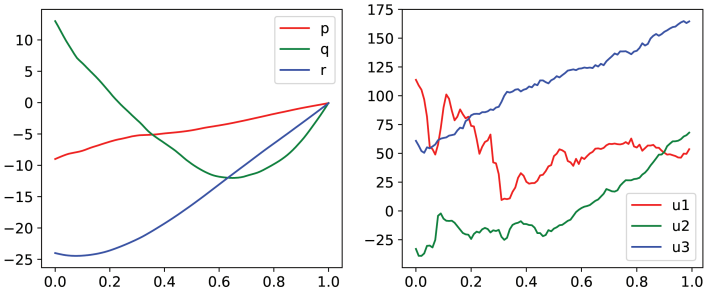

Figure 5: Example 2: trajectories and controls

Sequential technique. Example of application is demonstrated on Figure 6 and Figure 7.

Initial conditions: $p_0 = 24.7, q_0 = 23.3, r_0 = 21.1$.

Achieved terminal state: $p(t_1) = 0.101, q(t_1) = -0.063, r(t_1) = -0.002$.

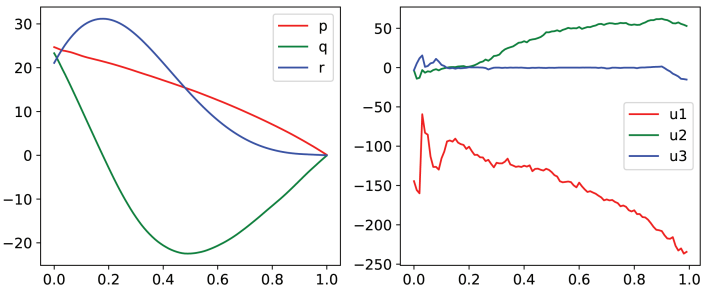

Figure 6: Example 3: trajectories and controls

Initial conditions: $p_0 = 21.1, q_0 = 21.2, r_0 = 21.3$.

Achieved terminal state: $p(t_1) = 0.09, q(t_1) = -0.067, r(t_1) = 0.058$.

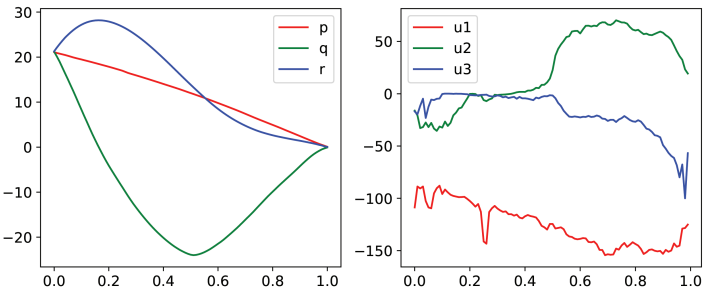

Figure 7: Example 4: trajectories and controls

From observed graphics it is evident that the proposed approach has a great potential to solve the problem of feedback control synthesis. Disadvantage of the proposed approach is that obtained controls are not smooth functions. Such particularity is treated as a disadvantage because it complicates the hardware implementation of the generated control and lowers durability of control mechanism due to the necessity of high-amplitude control adjustments.

6 Conclusion

Main results of the current work are the following:

- efficiency of the developed OSOL Extremum software complex was proved based on obtained solutions for tasks of open-loop control determination,
- proposed approach was tested on an applied task of satellite rotational motion dampening.

Further research is planned to be conducted in several different directions:

- find the way to make controls, that are generated by regressors, have smoother form,
- determine losses in efficiency in the terms of cost functional compared to other computational approaches (including analytic ones),
- find the way how to conduct proper comparative analysis and provide detailed comparison report with the existing software complexes in the terms of accuracy, computational efficiency, and algorithm coverage.

ABSTRACT

In this paper, we present a new Somewhat Homomorphic Encryption (SHE) scheme using computation over complex numbers. We then use Bootstrapping technique to make the scheme Fully Homomorphic (FH) and supports unbounded number of circuit depth. In addition to its homomorphic properties and security level, a main characteristic of the proposed new scheme is its simplicity as it is merely based on addition and multiplication operations over complex numbers. The new scheme is implemented under Python using SAGEMath library and evaluated. Then a crypt-analysis based on Approximate GCD problem is done. A comparison with the BGV, a well known Fully Homomorphic Encryption (FHE) scheme, shows that this new scheme is an efficient homomorphic encryption scheme.

1 Introduction

An encryption scheme is said to be FH, if it allows to perform addition and multiplication operations explicitly over the cipher-texts while performing implicitly the same operations over the plain-texts. This new type of ciphering is very required in cloud systems mainly when users treat the cloud as a third untrusted party. With Homomorphic Encryption (HE) the cloud is able to process over encrypted storage and the privacy of the user is preserved at the cloud side. In Figure. 1, we show the case of a mobile user sending an encrypted query to the cloud using HE, thus the cloud is able to process encrypted query over encrypted data to return an encrypted answer. The user can do the decryption.

The notion of homomorphism was first introduced by Rivest, Adleman and Dertouzo [1] as privacy homomorphism after the invention of RSA crypto-system [2]. The basic RSA crypto-system is a multiplicative homomorphic scheme that allows to perform multiplication operations over the cipher-texts. Give, for example, RSA public key, $p_k = (N, e)$ and cipher $c_i = (m_i)^e mod(N)$ for a plain-text m_i. It is simple to demonstrate that $\prod_i c_i = (\prod_i m_i)^e mod(N)$. Several works followed the RSA scheme. A state of art of HE is given in [3] – [6]. Some of the known homomorphic schemes are: Paillier crypto-system [7, 8], Domingo Ferrer crypto-system [9, 10] which is a HE scheme based on polynomial calculations. The Enhanced MORE [11] is another FHE based on matrix calculation and the NOHE [12] scheme is a lightweight FHE that profits from the simplicity and the homomorphic behavior of logic *NOT*. The most valued work in this domain was given by Craig Gentry in his Ph.D. thesis in 2009 [13, 14]. The work of Gentry was inspired from lattice based cryptography. Gentry first introduced a SHE scheme that supports a bounded number of operations over the cipher-texts. Then he developed a new refresh mechanism called Bootstrapping [15] – [19] to make the scheme FH and supports unbounded operations. An important FHE scheme is the BGV crypto-system developed by Brakerski, Gentry and Vaikuntanathan in [20, 21]. Since BGV scheme is also Somewhat Homomorphic (SH), Modulus Switching (MS) is a technique used with BGV to extend the circuit's depth during the evaluation procedure.

In this paper, our main motivation is to add a value in homomorphic encryption by designing a new simple and robust FHE based on simple complex numbers operations . We first build a new asymmetric SHE complex-based scheme, then we apply Gentry refresh mechanism (Bootstrapping). In comparison with BGV which is lattice based encryption, our scheme is simply based on complex addition and multiplication operations. In addition, Bootstrapping supports unbounded number of circuit depth in our scheme, while MS extends the BGV evaluation to a limited number.

The rest of the paper is organized as follows: in section 2, we present the basic concept of HE with the properties that can lead to a HE scheme. In section 3, we introduce our new FHE scheme built using complex numbers theory. In section 4 we consider our implementations for the new Complex-based scheme and the

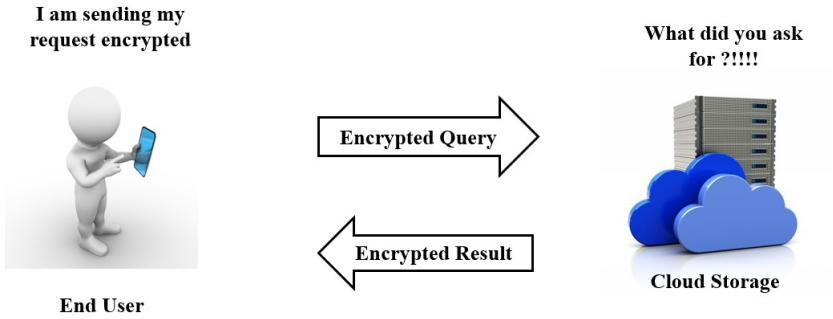

Figure 1: Cloud Scenarion Under Homomorphic Encryption

BGV scheme under Python using SAGEMath Library, followed by a crypt-analysis of our new scheme based on the Approximate GCD problem [22, 23, 24]. And finally the conclusion, comparison between the two schemes and future works are listed in section 5.

2 Homomorphic Encryption

In this work, we focus on asymmetric schemes. Consider an asymmetric scheme α, where p_k is the public key, s_k is the secret key, c_i is the ciphered text of a plain-text m_i. A homomorphic scheme has 3 different basic functions that are: $KeyGen_\alpha$ that generates (p_k, s_k), $Encrypt_\alpha(p_k, m_i)$ that outputs cipher-text c_i, $Decrypt_\alpha(s_k, c_i)$ that outputs the plain-text m_i.

2.1 Evaluation Function

In addition to the three basic functions listed above, a homomorphic scheme has also an evaluation function defined by $Evaluate_\alpha$ that takes as input the public key p_k, a circuit L and a tuple of cipher-texts $C = (c_1, c_2, c_3, ..., c_t)$, cipher of the input plain-texts vector $(m_1, m_2, ..., m_t)$. The evaluation function outputs a cipher-text Ψ given by:

$$\Psi = Evaluate_\alpha(p_k, L, C) \quad (1)$$

The scheme is homomorphic if we have: $\Psi = Encrypt_\alpha(p_k, L(m_1, m_2, ..., m_t))$.

2.2 Homomorphic Properties

When the circuit L performs a certain operation over the encrypted data as written in 1, the cloud is computing a predefined Boolean function f that can be written in a polynomial form. A polynomial form is a set of addition and multiplication gates. Thus to build a HE scheme we should satisfy these two basic properties:

1. Addition

$$Enc_\alpha(p_k, m_1) + Enc_\alpha(p_k, m_2) = Enc_\alpha(p_k, m_1 + m_2) \quad (2)$$

2. Multiplication

$$Enc_\alpha(p_k, m_1) \times Enc_\alpha(p_k, m_2) = Enc_\alpha(p_k, m_1 \times m_2) \quad (3)$$

where m_1 and m_2 are two plain-texts in $\{0, 1\}$ and $Enc_\alpha(p_k, m_i)$ is the encryption function.

3 Homomorphic Complex Scheme

In this section, we build our scheme using complex numbers. We first list the security parameters and then we detail our proposal.

3.1 Parameters

Based on a security parameter λ, different other parameters are generated as listed in [15] to build the new scheme:

1. γ: the bit length of the real and imaginary parts in the public key ($\gamma = \omega(\eta^2 log_2 \lambda)$).
2. ρ: the bit-length of the real and imaginary parts in the noise ($\rho = \omega(log_2(\lambda))$.
3. η: the bit length of the secret key ($\eta \geq \rho.\Theta(\lambda log_2^2(\lambda))$.
4. ρ': extra noise parameter.
5. τ: The number of public keys ($\tau \geq \gamma + \omega(log_2 \lambda)$).

3.2 Somewhat Homomorphic Complex Scheme Construction

The SH complex scheme construction is based on the following steps:

1. Secret key: The secret key s_k is defined by an η bit prime integer p.
2. Public keys: We build a public key bank (PK) formed of τ complex numbers having the following form:
   $PK = \{({p_{k1}}^h + i{p_{k2}}^h) = (({pq_1}^h + {\epsilon_1}^h) + i({pq_2}^h + {\epsilon_2}^h), 1 \leq h \leq \tau\}$.
   For each complex public key $({p_{k1}}^h + i{p_{k2}}^h)$, we build different parameters as follow:
   (a) random integer: $q_j^h \longleftarrow Z \cap [0, \frac{2^\eta}{p})$, random noise parameter: ${\epsilon_j}^h \longleftarrow Z \cap (-2^\rho, 2^\rho)$ where $j \in \{1, 2\}$.
   (b) $({p_{k1}}^h, {p_{k2}}^h)$ should have different parities.
   (c) $({\epsilon_1}^h, {\epsilon_2}^h)$ should have the same parity.

3. Encryption Function: The encryption of any bit m is given by the following equation:

$$c = Enc(p_k, m) = ({p_{k1}}^h + i{p_{k2}}^h) \times ({R_1}^h + i{R_2}^h) + {r_1}^h + i{r_2}^h + m \quad (4)$$

where $({p_{k1}}^h + i{p_{k2}}^h)$ is chosen randomly from the public key bank (PK), ${R_1}^h + i{R_2}^h$ is a random complex chosen such that $|{R_1}^h| <<< \frac{p}{6|{\epsilon_1}^h - {\epsilon_2}^h|}$, $|{R_2}^h| <<< \frac{p}{6|{\epsilon_1}^h + {\epsilon_2}^h|}$, ${r_1}^h + i{r_2}^h$ is a random complex chosen between $(-2^{\rho'}, 2^{\rho'})$ such that ${r_1}^h$ and ${r_2}^h$ have the same parity and $|{r_1}^h - {r_2}^h| \ll \frac{p}{6}$(Choosing the intervals of R_1^h, R_2^h, r_1^h, r_2^h is explained in the upcoming decryption section).

4. Decryption Function:
Following 4, we can demonstrate that $c = Enc(p_k, m) = ({p_{k1}}^h + i{p_{k2}}^h) \times ({R_1}^h + i{R_2}^h) + {r_1}^h + i{r_2}^h + m = (pq_1{}^h R_1{}^h - pq_2{}^h R_2{}^h + R_1{}^h \epsilon_1{}^h - R_2{}^h \epsilon_2{}^h + r_1{}^h + m) + i(pq_1{}^h R_2{}^h + pq_2{}^h R_1{}^h + R_2{}^h \epsilon_1{}^h + R_1{}^h \epsilon_2{}^h + r_2{}^h)$.
The decryption of the cipher c is done as follows:

$$\begin{aligned} Intermediate = real(c) - imag(c) = \\ p(q_1{}^h R_1{}^h - q_2{}^h R_2{}^h - q_1{}^h R_2{}^h - q_2{}^h R_1{}^h) + \\ R_1{}^h(\epsilon_1{}^h - \epsilon_2{}^h) - R_2{}^h(\epsilon_1{}^h + \epsilon_2{}^h) + (r_1{}^h - r_2{}^h) + m. \\ m = mod(modNear(Intermediate, p), 2). \end{aligned} \quad (5)$$

Where $modNear(x, p) = y$, such that $y \in (-\frac{p}{2}, +\frac{p}{2})$.
Decryption works as long as:
$\frac{-p}{2} \leq {R_1}^h({\epsilon_1}^h - {\epsilon_2}^h) - {R_2}^h({\epsilon_1}^h + {\epsilon_2}^h) + ({r_1}^h - {r_2}^h) + m \leq \frac{p}{2}$.
In addition $({\epsilon_1}^h - {\epsilon_2}^h)$, $({\epsilon_1}^h + {\epsilon_2}^h)$ and $({r_1}^h - {r_2}^h)$ are even integers.
The decryption condition is satisfied as long as: $|{R_1}^h| <<< \frac{p}{6|{\epsilon_1}^h - {\epsilon_2}^h|}$, $|{R_2}^h| <<< \frac{p}{6|{\epsilon_1}^h + {\epsilon_2}^h|}$, $|{r_1}^h - {r_2}^h| << \frac{p}{6}$ and each pair of $({\epsilon_1}^h, {\epsilon_2}^h)$, $({r_1}^h, {r_2}^h)$ is formed of two integers having the same parity.

3.3 Complex Homomorphic Properties

We show in this section that the proposed scheme satisfies the homomorphic properties. Given two cipher-texts c_1, c_2 respectively for 2 different plain-texts m_1, m_2 encrypted using the complex scheme listed in section 3.2.
$c_1 = ({p_{k1}}^h + i{p_{k2}}^h)({R_1}^h + i{R_2}^h) + {r_1}^h + i{r_2}^h + m_1 = (pq_1{}^h R_1{}^h - pq_2{}^h R_2{}^h + R_1{}^h \epsilon_1{}^h - R_2{}^h \epsilon_2{}^h + r_1{}^h + m_1) + i(pq_1{}^h R_2{}^h + pq_2{}^h R_1{}^h + R_2{}^h \epsilon_1{}^h + R_1{}^h \epsilon_2{}^h + r_2{}^h)$. $c_2 = ({p_{k1}}^t + i{p_{k2}}^t)({R_1}^t + i{R_2}^t) + {r_1}^t + i{r_2}^t + m_2 = (pq_1{}^t R_1{}^t - pq_2{}^t R_2{}^t + R_1{}^t \epsilon_1{}^t - R_2{}^t \epsilon_2{}^t + r_1{}^t + m_2) + i(pq_1{}^t R_2{}^t + pq_2{}^t R_1{}^t + R_2{}^t \epsilon_1{}^t + R_1{}^t \epsilon_2{}^t + r_2{}^t)$.

1. Addition

$$\begin{aligned} c_1 + c_2 = \\ (pq_1{}^h R_1{}^h - pq_2{}^h R_2{}^h + pq_1{}^t R_1{}^t - pq_2{}^t R_2{}^t + R_1{}^h \epsilon_1{}^h \\ - R_2{}^h \epsilon_2{}^h + R_1{}^t \epsilon_1{}^t - R_2{}^t \epsilon_2{}^t + r_1{}^h \\ + r_1{}^t + m_1 + m_2) + i(pq_1{}^h R_2{}^h + pq_2{}^h R_1{}^h + \\ pq_1{}^t R_2{}^t + pq_2{}^t R_1{}^t + R_2{}^h \epsilon_1{}^h + R_1{}^h \epsilon_2{}^h + R_2{}^t \epsilon_1{}^t \\ + R_1{}^t \epsilon_2{}^t + r_2{}^h + r_2{}^t). \end{aligned} \quad (6)$$

Decryption of $c_1 + c_2$ is obtained by calculating $mod(modNear(real(c_1 + c_2) - imag(c_1 + c_2), p), 2)$ having the following form:
$pQ_{add} + R_{add} + m_1 + m_2$ such that $R_{add} = {R_1}^h({\epsilon_1}^h - {\epsilon_2}^h) - {R_2}^h({\epsilon_1}^h + {\epsilon_2}^h) + {R_1}^t({\epsilon_1}^t - {\epsilon_2}^t) - {R_2}^t({\epsilon_1}^t + {\epsilon_2}^t) + ({r_1}^h - {r_2}^h) + ({r_1}^t - {r_2}^t)$.
Decryption works as long as R_{add} is even and $\frac{-p}{2} \leq R_{add} \leq \frac{p}{2}$.

2. Multiplication
Similar to addition, decryption of $c_1 \times c_2$ is obtained by calculating $mod(modNear(real(c_1 \times c_2) - imag(c_1 \times c_2), p), 2)$.
We can demonstrate that $real(c_1 \times c_2) - imag(c_1 \times c_2)$ have the following form:
$pQ_{mult} + R_{mult} + m_1 m_2$ such that $R_{mult} = ({r_1}^t {R_1}^h + m_2 {R_1}^h - {r_2}^t {R_2}^h)({\epsilon_1}^h - {\epsilon_2}^h) - ({r_1}^t {R_2}^h + {r_2}^t {R_1}^h + m_2 {R_2}^h)({\epsilon_1}^h + {\epsilon_2}^h) + ({r_1}^h {R_1}^t + m_1 {R_1}^t - {r_2}^h {R_2}^t)({\epsilon_1}^t - {\epsilon_2}^t) - ({R_1}^t {r_2}^h + {r_1}^h {R_2}^t + m_1 {R_2}^t)({\epsilon_1}^t + {\epsilon_2}^t) + ({R_1}^h {R_1}^t {\epsilon_1}^h - {R_2}^h {R_2}^t {\epsilon_1}^h)({\epsilon_1}^t - {\epsilon_2}^t) + ({R_2}^h {R_2}^t {\epsilon_2}^h - {R_1}^h {R_1}^t {\epsilon_2}^h)({\epsilon_1}^t + {\epsilon_2}^t) - ({R_1}^h {R_2}^t {\epsilon_1}^h + {R_2}^h {R_1}^t {\epsilon_1}^h)({\epsilon_1}^t + {\epsilon_2}^t) - ({R_2}^h {R_1}^t {\epsilon_2}^h + {R_1}^h {R_2}^t {\epsilon_2}^h)({\epsilon_1}^t - {\epsilon_2}^t) + {r_1}^h({r_1}^t - {r_2}^t) - {r_2}^h({r_1}^t + {r_2}^t) + m_2({r_1}^h - {r_2}^h) + m_1({r_1}^t - {r_2}^t)$.
Decryption also works as long as R_{mult} is even and $\frac{-p}{2} \leq R_{mult} \leq \frac{p}{2}$. We can simply demonstrate that R_{add} and R_{mult} are even since each couple of $({r_1}^h, {r_2}^h)$, $({r_1}^t, {r_2}^t)$, $({\epsilon_1}^h, {\epsilon_2}^h)$ and $({\epsilon_1}^t, {\epsilon_2}^t)$ is formed of two integers having the same parity, but having R_{add} and R_{mult} between $\frac{-p}{2}$ and $\frac{p}{2}$ is not always satisfied.
As a conclusion our new complex scheme is SH that supports a bounded number of addition and multiplication operations over the cipher-texts.

3.4 Making the Complex Scheme Fully Homomorphic

To make our complex scheme FH, we apply Bootstrapping [15, 17] in order to reduce the noise level after each operation. Starting from a complex cipher c, the plain-text m can be calculated following this equation $m \leftarrow [c^* - \lfloor \frac{c^*}{p} \rceil]_2$ where $c^* = real(c) - imag(c)$ since this decryption equation is much simpler than Equation. 5. First of all we can use Gentry's transformation to squash the decryption circuit. In this transformation we add to the public key some extra information about the secret key, and use this extra information to

post process the cipher-text c^*. The post processed cipher-text c^* can be decrypted more efficiently than the original cipher-text.

3.4.1 Bootstrapping:

Consider the evaluation procedure given in 1, we use instead of the arithmetic circuit L, the decryption circuit D_α of the SH scheme α. The main concept of Bootstrapping is that we have a cipher-text ψ_1 that encrypts m under p_{k1} that we want to refresh. s_{k1} is the secret key related to the public key p_{k1}. s_{k1} is encrypted under another public key p_{k2}. Let $\overline{s_{k1j}}$ be the encrypted secret bits j of s_{k1} under p_{k2}. Bootstrapping is given by this algorithm:

$$\begin{aligned} &Recrypt(p_{k2}, D_\alpha, < \overline{s_{k1j}} >, \psi_{1j}), \\ &Set \quad \overline{\psi_{1j}} \leftarrow Encrypt(p_{k2}, \psi_{1j}) \\ &Output \quad \psi_2 \leftarrow Evaluate_\alpha(p_{k2}, D_\alpha, \langle\langle \overline{s_{k1}} \rangle, \langle \overline{\psi_{1j}} \rangle\rangle) \end{aligned} \tag{7}$$

In 7, the function $Evaluate_\alpha$ takes as input the bits of s_{k1} and ψ_1, each encrypted under p_{k2} to evaluate homomorphically the decryption circuit D_α. The output ψ_2 is an encryption under p_{k2} of $Decrypt_\epsilon(s_{k1}, \psi_1) = m$. By applying 7, we are removing the error vector associated to the first cipher and adding another error vector. The progress is made as long as the second error vector in ψ_2 is shorter than the primitive in ψ_1.
In Figure. 2, we present the evaluation procedure of a circuit with high depth giving birth to a cipher c with a high noise level.
As given in Figure. 3, for a cipher c consider $D_c(sk) = Decrypt_{sk}(c)$, this operation is called squashing the decryption circuit (will be explained in the upcoming section) and $D_c(.)$ is a low depth polynomial in sk. Bootstrapping consists of evaluating $D_c(.)$ using the encryption of the secret key sk.

3.4.2 Squashing the Decryption Circuit:

Bootstrapping is possible as long as the decryption circuit is an arithmetical circuit of low depth. Squashing is the required transformation in making it possible as listed in[15, 16, 17, 18, 19]. Following Gentry's Squashing technique, we add three different extra parameters κ, θ, Θ that are function of the security parameter λ. $\kappa = \frac{\gamma\eta}{\rho'}$, $\theta = \lambda$, $\Theta = \omega(\kappa.log(\lambda))$. For a secret key $s_k^* = p$ and a public key p_k^* from the original complex homomorphic scheme α, we add to the public key a set $\overrightarrow{Y} = \{y_1, y_2, y_3, ..., y_\Theta\}$ of rational numbers in $[0, 2)$ with κ bits of precision, such that there is a sparse subset $S \subset \{1, 2, 3, ..., \Theta\}$ of size θ with $\sum_{i \in S} y_i \approx \frac{1}{p} (mod 2)$.
The secret key becomes the indicator of the subset S. The scheme of section 3.2 becomes FH complex by first applying the following modifications:

1. KeyGen:
   Generate $s_k^* = p$ and p_k^* as before. set $x_p \leftarrow \lfloor \frac{2^\kappa}{p} \rceil$. Choose randomly a Θ bit vector $\overrightarrow{s}$ with hamming weight θ, $\overrightarrow{s} = \langle s_1, s_2, ..., s_\Theta \rangle$ and let $S = \{i; s_i = 1 \text{ in vector } S\}$. Choose Θ random integers $u_i \in Z \cap [0, 2^{\kappa+1})$, $i = 1, 2, 3, ..., \Theta$ subject to the condition that $\sum_{i \in S} u_i = x_p mod(2^{\kappa+1})$. Set $y_i = \frac{u_i}{2^\kappa}$ and $\overrightarrow{Y} = \{y_1, y_2, ..., y_\Theta\}$. Hence each y_i is a positive number smaller than 2 with κ bits of precision after the binary point such that $[\sum_{i \in S} y_i]_2 = (\frac{1}{p}) - \Delta_p$ for some $\Delta_p < 2^{-\kappa}$.
2. Encrypt and Evaluate Algorithm:
   Generate the cipher-text $c^* = real(c) - imag(c)$ from a complex cipher c. Then for each $i \in \{1, 2, 3, ..., \Theta\}$, set $z_i \leftarrow [c^*.y_i]_2$ keeping only $n = \lceil log\theta \rceil + 3$ bits of precision after the binary point for each z_i. Output both c^* and $\overrightarrow{z} = \langle z_1, z_2, ..., z_\Theta \rangle$
3. Decrypt and Output Algorithm:

$$m \leftarrow [c^* - \lfloor \sum_{i \in S} s_i z_i \rceil]_2 \tag{8}$$

Lemma 1. *For every cipher-text $(c^*, \overrightarrow{z})$ that is generated by evaluating a circuit C, it holds that $\sum_i s_i z_i$ is within $\frac{1}{4}$ of an integer.*

Proof. Fix an arithmetic circuit L, public keys and secret keys generated with respect to the security parameter λ, with $\{y_i\}_{i=1}^\Theta$ the rational numbers in the public key and $\{s_i\}_{i=1}^\Theta$ the secret key bits. If we recall that y_i's were chosen that: $[\sum_i s_i y_i]_2 = (\frac{1}{p}) - \Delta_p$. We fix a circuit L, and t cipher-texts $\{c_i\}_{i=1}^t$ that encrypts the input to L and denote: $c = Evaluate_\epsilon(pk, L, c_1, c_2, .., ..., c_t)$, we need to establish this equation:

$$\lfloor \frac{c^*}{p} \rceil = \lfloor \sum_i s_i z_i \rceil (mod 2) \tag{9}$$

where $c^* = real(c) - imag(c)$ and the z_i's are computed as $[c^*.y_i]_2$ with only $\lceil log\theta + 3 \rceil$ bits of precision after the binary point, hence $[c^*.y_i]_2 = z_i - \Delta_i$ with $|\Delta_i| \leq \frac{1}{16\theta}$.
$[(\frac{c^*}{p}) - \sum s_i z_i]_2 = [(\frac{c^*}{p}) - \sum_i s_i [c^* y_i]_2 + \sum s_i \Delta_i]_2 = [(\frac{c^*}{p}) - c^* [\sum s_i y_i]_2 + \sum s_i \Delta_i]_2 = [(\frac{c^*}{p}) - c^*.(\frac{1}{p} - \Delta_p) + \sum s_i \Delta_i]_2$
$= [c^*.\Delta_p + \sum s_i \Delta_i]_2$. □

We claim that the final quantity inside the brackets has magnitude at most $\frac{1}{8}$. By definition, since c^* is a valid cipher-text output, the value $\frac{c^*}{p}$ is within $\frac{1}{8}$ of an integer. Together all these facts imply the lemma. To establish the claim, we first observe that $|\sum s_i \Delta_i| \leq \theta \times \frac{1}{16\theta}$. Regarding $c^* \Delta_p$, recall that the output c^* is obtained by evaluating the circuit L on the cipher-text c_i as listed in [15], for any polynomial P that implements the circuit L, for any $\alpha \geq 1$, if P's input has magnitude at most $2^{\alpha(\rho'+2)}$, its output magnitude at most $2^{\alpha(\eta-4)}$. In particular, when P's are fresh cipher-texts, which have magnitude at most 2^γ, P's output cipher-text c^* has magnitude at most $2^{\gamma(\eta-4)(\rho'+2)} < 2^{\kappa-4}$. Thus $|c^* \Delta_p| < \frac{1}{16}$.

3.4.3 *Practical Implementation of Squashing and Bootstrapping:*

For the squashed decryption circuit given in 8, the implementation of $\sum_{i\in S} s_i z_i$ (such that $z_i = (z_{i1}, z_{i2}, ..., z_{in})$ is a vector of $n = \lceil log\theta \rceil + 3$ bits, where $1 \leq i \leq \Theta$), can be done with lower computational complexity as implemented in [16, 19]. This new implementation is based on dividing the new secret key $\overrightarrow{s}$ in θ boxes of $B = \dfrac{\Theta}{\theta}$ bits each, where each box has a single bit having the value 1. This will lead us to obtain a grade school addition algorithm that requires $O(\theta^2)$ multiplications instead of $O(\Theta.\theta)$. The secret key $\overrightarrow{s}$ is divided into $s_{k,i}$, the i^{th} secret key bit in box k, where $1 \leq k \leq \theta$ and $1 \leq i \leq B$. The resultant equation is:

$$m \leftarrow (c^* - \lfloor \sum_{k=1}^{\theta} (\sum_{i=1}^{B} s_{k,i} z_{k,i}) \rceil) mod(2) \tag{10}$$

We denote that the sum $q_k = \sum_{i=1}^{B} s_{k,i} z_{k,i}$ is obtained by adding B numbers, only one being nonzero. The decryption equation is now:

$$m \leftarrow (c^* - \lfloor \sum_{i=1}^{\theta} (q_k) \rceil) mod(2) \tag{11}$$

Where the q_k's are rational in $[0, 2)$ with n bits of precision after the binary point. Another form of the decryption equation is given by:

$$m = [c^*]_2 \oplus [\lfloor \sum_{i=1}^{\Theta} s_i z_i \rceil]_2 \tag{12}$$

Based on 12, we can deduce that the parity of the plain-text m is related to the parity of the primitive cipher-text c^* and the parity of $[\lfloor \sum_{i=1}^{\Theta} s_i z_i \rceil]_2$.

In order to make this concept much clearer, a simple implementation of bootstrapping, using low values, is explained in the following example. Giving randomly $\Theta = 4$, $\theta = 2$, $B = \dfrac{\Theta}{\theta} = 2$, and a precision bit $n = 1$. The secret key $\overrightarrow{s} = [b_1, b_2, b_3, b_4]$ such that ($b_1 = 1$ and $b_2 = 0$) or ($b_1 = 0$ and $b_2 = 1$), ($b_3 = 1$ and $b_4 = 0$) or ($b_3 = 0$ and $b_4 = 1$) based on the implementation of 10. Initial values for evaluating the decryption circuit using the secret key $\overrightarrow{s}$ without encryption are $s_1 = [s_{11} \quad s_{12}] = [b_1 \quad b_2]$, $s_2 = [s_{21} \quad s_{22}] = [b_3 \quad b_4]$, the z values are taken just as an example $z_1 = [z_{11} \quad z_{12}] = [[10] \quad [01]]$, $z_2 = [z_{21} \quad z_{22}] = [[11] \quad [01]]$. We start by applying the evaluation procedure over the plain-texts by calculating $Sum = \sum_{k=1}^{\theta} \sum_{i=1}^{B} s_{k,i} z_{k,i} = \sum_{k=1}^{2} \sum_{i=1}^{2} s_{k,i} z_{k,i} = (b_1 z_{11} + b_2 z_{12}) + (b_3 z_{21} + b_4 z_{22}) = [b_1 \quad b_2] + [b_3 \quad b_3 + b_4] =$

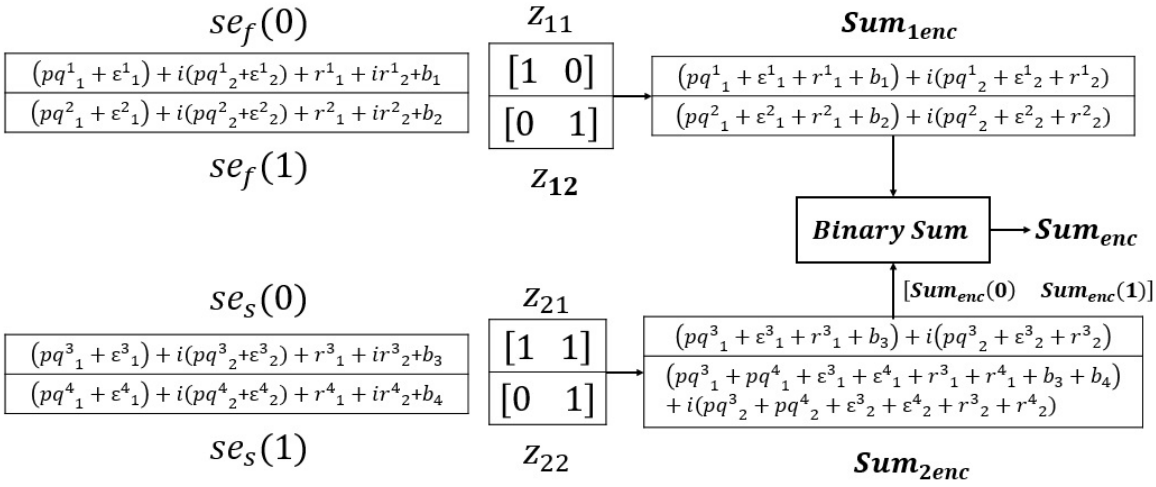

Figure 4: Circuit Evaluation over Cipher-texts.

$(Sum_1) + (Sum_2)$, then we apply the binary summation to calculate $Sum = Sum_1 + Sum_2 = [b_1 + b_3 \quad b_2 + b_3 + b_4 + b_1b_3] = [Sum(0) \quad Sum(1)]$ ($Sum(0) = Sum_1(0) + Sum_2(0)$ and $Sum(1) = Sum_1(1) + Sum_2(1) + Sum_1(0)Sum_2(0)$). As a result, the parity of $\lfloor Sum \rceil$ is given by $b_1 + b_3 + b_2 + b_3 + b_4 + b_1b_3$. Next step is to do the circuit evaluation over the complex cipher-texts. Let $se_f = [se_1 \quad se_2]$ be the cipher of the secret key $s_1 = [b_1 \quad b_2]$ and $se_s = [se_3 \quad se_4]$ be the cipher of the secret key $s_2 = [b_3 \quad b_4]$ using the encryption procedure listed in 4 with random values $(R_1^h + iR_2^h) = 1$.

$se_f = [se_f(0) \quad se_f(1)] = Enc(s_1) = [(pq_1^1 + \epsilon_1^1) + i(pq_2^1 + \epsilon_2^1) + r_1^1 + ir_2^1 + b_1 \quad (pq_1^2 + \epsilon_1^2) + i(pq_2^2 + \epsilon_2^2) + r_1^2 + ir_2^2 + b_2]$.

$$Sum_{enc} = \sum_{k=1}^{\theta}\sum_{i=1}^{B} se_{k,i}z_{k,i} = \sum_{k=1}^{2}\sum_{i=1}^{2} se_{k,i}z_{k,i} = Sum_{1enc} + Sum_{2enc},$$

where $Sum_{1enc} = se_f(0)z_{11} + se_f(1)z_{12}$ and $Sum_{2enc} = se_s(0)z_{21} + se_s(1)z_{22}$. An implementation of circuit evaluation over the cipher-texts is given in Figure.4.

As shown in Figure.4, after applying the binary summation over Sum_{1enc} and Sum_{2enc} we obtain $Sum_{enc} = [Sum_{enc}(0) \quad Sum_{enc}(1)]$ such that $Sum_{enc}(0) = p(Q_{0R} + iQ_{0I}) + (\epsilon_1^1 + \epsilon_1^3) + i(\epsilon_2^1 + \epsilon_2^3) + (r_1^1 + r_1^3) + i(r_2^1 + r_2^3) + \mathbf{b_1} + \mathbf{b_3}$.

$Sum_{enc}(1) = p(Q_{1R}+iQ_{1I})+(\epsilon_1^1\epsilon_1^3-\epsilon_2^1\epsilon_2^3)+(r_1^3\epsilon_1^1+r_1^1\epsilon_1^3-r_2^3\epsilon_2^1-r_2^1\epsilon_2^3)+(r_1^1r_1^3-r_2^1r_2^3)+b_1\epsilon_1^3+b_3\epsilon_1^1+b_1r_1^3+b_3r_1^1+(\epsilon_1^2+\epsilon_1^3+\epsilon_1^4)+(r_1^2+r_1^3+r_1^4)+\mathbf{b_1b_3}+\mathbf{b_2}+\mathbf{b_3}+\mathbf{b_4}+i((\epsilon_1^1\epsilon_2^3+\epsilon_2^1\epsilon_1^3)+(r_2^3\epsilon_1^1+r_1^1\epsilon_2^3+r_2^1\epsilon_1^3+r_1^3\epsilon_2^1)+(r_2^1r_1^3+r_1^1r_2^3)+b_1\epsilon_2^3+b_3\epsilon_2^1+b_1r_2^3+b_3r_2^1+(\epsilon_2^2+\epsilon_2^3+\epsilon_2^4)+(r_2^2+r_2^3+r_2^4))$.

Since $mod(modNear(real(Sum_{enc}(0)) - imag(Sum_{enc}(0)), p), 2) = b_1+b_3$ and $mod(modNear(real(Sum_{enc}(1))-imag(Sum_{enc}(1)), p), 2) = b_1b_3 + b_2 + b_3 + b_4$, as long as the encryption parameters are chosen such that the scheme is SH (i.e Sum_{1enc} and Sum_{2enc} are formed of complex ciphers that can be added and multiplied homomorphically as long as the scheme is SH). Based on all the calculations listed above, a fresh cipher-text of c^* can be written as:

$$fresh_{cipher} = \lfloor Sum_{enc}(0) + Sum_{enc}(1) \rceil + [c^*]_2 + \sum_j (p_{k_1}{}^j + ip_{k_2}{}^j)(R_1^j + iR_2^j) \quad (13)$$

4 Implementation and Security Analysis

In order to validate our work, first we did an implementation of our new Complex-based scheme, then we compared the evaluation of the logic circuit $C = (b_0 \oplus b_1) \bullet (b_2 \oplus b_3)$ using the two schemes: Complex and BGV.

As a brief overview of the BGV [20, 21], it is a FHE scheme that works over bit level and built using Lattice based cryptography. The security of this scheme depends on the hardness of Learning With Error (LWE) introduced by Oded Regev in [25], that relies on the complexity of solving a noisy linear system. Starting from a security parameter λ, we have a secret key $s \in Z_p^{[1,n]}$ and a cipher-text $c \in Z_p^{[n,1]}$. The hardness of LWE resides in taking the lattice dimension: $n \approx poly(\lambda)$ and the ring dimension: $p \approx poly(n)$ following [21, 25]. Homomorphic addition is achieved by simply adding the two cipher-texts, while homomorphic multiplication is done by calculating the Tensor product of the two different cipher-texts which increases the dimension exponentially. Key Switching (KS) is a new technique introduced to reduce the cipher dimension after each homomorphic multiplication. The basic BGV scheme is SH since the noise level will increase with circuit depth, therefore MS is another technique introduced to reduce the noise level after each arithmetic operation and extend to a higher circuit depth.

Finally a crypt-analysis of the new scheme is validated with the GACD attack. All simulations are done under Python with SAGE-Math Library using a machine having the following specifications (CPU: Intel Xeon, E5 – 2630, 2.40 GHZ, 8 CORES, 128 GB RAM).

4.1 Implementations and Results

1. **First Implementation** : First implementation with the new Complex-based scheme is done with three different security layers (**small**: $\lambda = 42$, $\rho = 26$, $\eta = 988$, $\gamma = 147456$, $\Theta = 150$, $\tau = 158$), (**medium**: $\lambda = 52$, $\rho = 41$, $\eta = 1558$, $\gamma = 843033$, $\Theta = 555$, $\tau = 572$), (**large**: $\lambda = 62$, $\rho = 56$, $\eta = 2128$, $\gamma = 4251886$, $\Theta = 2070$, $\tau = 2110$) with extra noise parameter $\rho' = \eta - \rho$, θ the hamming weight of vector $\overrightarrow{s}$ is equal to 15, n the precision after the binary point of each

Table 1: First Implementation Results

Parameters	*KeyBankGen*	*Encrypt*	*Decrypt*
small	0.136439000002 *s*	0.00102999999945 *s*	0.000683999998728 *s*
medium	2.732191 *s*	0.00130100000024 *s*	0.00339099999837 *s*
large	48.049091 *s*	0.00596199999927 *s*	0.0216390000023 *s*

Table 2: Second Implementation Results

Parameters	Complex mean execution time	BGV mean execution time
small	0.4102108 *s*	0.35041905 *s*
medium	2.8407822 *s*	2.42358273 *s*
large	27.40187732 *s*	38.52468052 *s*

z_i is taken as 4. Table. 1 shows in terms of execution time the generation of public key bank of τ complex public keys, 1 bit encryption and decryption.

2. **Second Implementation** : In the second implementation, we did the evaluation procedure of the logic circuit $C = Plain_{output} = (b_0 \oplus b_1) \bullet (b_2 \oplus b_3)$, (i.e. $Cipher_{Output} = ((c_0 + c_1) \times (c_2 + c_3)$, where $c_i = Enc(b_i)$, $for\ 0 \leq i \leq 3$) using the two schemes (Complex and BGV) with the same level of security λ. For BGV the three layers of implementation are (**small**: $\lambda = 42$, $n = 42$, $p \approx O(n^{20})$, $q \approx O(\frac{n^{20}}{2})$), (**medium**: $\lambda = 52$, $n = 149$, $p \approx O(n^6)$, $q \approx O(\frac{n^6}{2})$), (**large**: $\lambda = 62$, $n = 370$, $p \approx O(n^6)$, $q \approx O(\frac{n^6}{2})$). Table.2 shows a comparison in terms of mean execution time between the two implementations for 100 iterations (Evaluation procedure for the Compplex-based scheme is done with Bootstrapping mechanism while with BGV is achieved with KS and MS). In addition, results have shown that noise is efficiently reduced for the two schemes. One can see that for large case, the proposed Complex based-scheme performs better that BGV.

4.2 Security Analysis:

The crypt-analysis of the homomorphic encryption schemes will consider the techniques used to build such schemes. The security of the BGV-lattice based scheme relies on the hardness of solving LWE problems [25]. As for our new complex scheme, it uses mathematical operations and the typical attack in this case is General Approximate Common Divisor (GACD). Given a public key bank $PK = \{x_1, x_2, ..., x_\tau\}$ where $x_j = pq_j + r_j$ for $1 \leq j \leq \tau$, the basic idea of this attack is to reveal the value of the secret key p starting from PK. The secret key p can be revealed using different types of algorithms like the approximate GCD of two numbers discussed in [22], the approximate GCD of many numbers using the SDA algorithm [23] by applying a lattice based attack with *LLL* algorithm. Recently a new improved attack was introduced and implemented in [24], [19]. In our crypt-analysis, we tried to apply this new Approximate GCD attack. Given the public key bank $PK = \{x_j, 1 \leq j \leq \tau\}$, where $q_j \in [0, \frac{2^\gamma}{p})$ and $r_j \in [0, 2^\rho)$ are chosen uniformly and independently at random. The algorithm is as follows: For $j = 1, 2, ..., \tau$, let:

$$y_j = \prod_{i=0}^{2^\rho - 1} (x_j - i) \tag{14}$$

Equation 14 shows clearly that p divides the GCD $g = gcd(y_1, y_2, ..., y_\tau)$. To build this attack and depending on the choice of the (q_j, r_j), we will try to find a certain bound B not much larger than 2^ρ that with a high probability, all the prime factors of g except p are smaller than this bound B. The probability that all the prime factors of g except p are smaller than B is done based on [19]: "For every prime $p \geq B$ other than p, not all the x_j's are congruent to one of $(0, 1, ..., 2^\rho - 1) \quad mod p$". This happens with probability very close to $1 - (\frac{2^\rho}{p})^s$. Hence, the probability that all the prime factors of g except p are smaller than B is essentially given by the following Euler product:

$$P_{s,\rho}(B) = \prod_{p \geq B,\ p \neq p} (1 - \frac{2^{s\rho}}{p^s}) \tag{15}$$

Based on [19] and using the usual prime counting function $\pi(x)$ explained in [26], we can demonstrate that 15 converges to some positive number smaller than 1 and satisfies the following lemma:

Lemma 2. *For any $B > 2^{\rho + \frac{1}{s}}$, we have:*
$1 - P_{s,\rho}(B) < \frac{2s}{s-1} \times \frac{2^{s\rho}}{B^{s-1} log B}$

In our simulation, we picked $B = 2^{\frac{s+1}{s-1}\rho}$ and we got a success probability $P_{s,\rho}(B) > 1 - 2^{-\rho}$. The GACD attack is given by the pseudo code of Algorithm 1.

Algorithm 1 *GACD Attack*

procedure p=$GACD_(\eta,\gamma,\rho)$
$p \leftarrow random_prime(0, 2^{\eta})$
$s \leftarrow \rho \sqrt{\frac{s+1}{s-1}}$
$B \leftarrow \lfloor 2^{\rho} \rfloor$
$Fa \leftarrow Factorial(B)$
$x \leftarrow p \times random_integer(0, 2^{\gamma-\eta}) + random_integer(0, 2^{\rho})$
$i \leftarrow 0$
$g \leftarrow 1$
while $i < 2^{\rho}$ **do**
$g \leftarrow g \times (x - i)$
$i \leftarrow i + 1$
end while
$j \leftarrow 1$
while $j \leq s$ **do**
$x \leftarrow p \times random_integer(0, 2^{\gamma-\eta}) + random_integer(0, 2^{\rho})$
$i \leftarrow 0$
$z \leftarrow 1$
while $i < 2^{\rho}$ **do**
$z \leftarrow z \times (x - i)$
$i \leftarrow i + 1$
end while
$g \leftarrow Greatest_divisor_of_gcd(g, z)_prime_to_Fa$
if $\lfloor log_2(g) \rfloor \leq \eta$ **then**
Break
end if
$j \leftarrow j + 1$
end while
return g
end procedure

Due to the limited resources of our machine (CPU: Intel Xeon, E5-2630, 2.40 GHZ, 8 CORES, 128 GB RAM), the proposed GACD attack with the security levels related to λ is not feasible since the polynomial y_j given in 14 is of degree 2^{ρ} with coefficients of size γ and requires a memory of size $2^{\rho}\gamma$ bits. The required size of each level is: **small** : 1.125 Terra Byte, **medium** : 210759 Terra Byte, **large** : 34831286272 Terra Byte, while our machine is only 128 GB RAM.

5 Conclusion

In this paper, we profited from the simplicity of complex numbers properties by proposing a new SWE scheme based on complex numbers. We applied Gentry refresh mechanism to make our scheme FH. We then implemented our new scheme with the BGV using SAGEMath library. As a comparison with BGV, a well known FHE scheme, our new scheme is an efficient homomorphic scheme and performs better than BGV in terms of execution for large implementation. In addition, our scheme is simply based on simple complex operations rather than lattice based cryptography (homomorphic complex multiplication is done without dimension expansion rather than Tensor product) and Bootstrapping can support unbounded circuit depth, while MS used with BGV is limited to some circuit depth. Finally a crypt-analysis based on GACD attack is presented. Future work will consider the implementation of the GACD Attack given in section 4.2 with a more powerful machine in order to evaluate the approximate attack time.

ABSTRACT

Great efforts have been shown in the literature to improve the efficiency of photovoltaic (PV) systems. In this workpaper, authors present the development of a computational system based on free software that allows to estimate with an accuracy superior to 99.9 percent the performance of the PV array connected to a current inverter block, from the physical models behind. For this purpose, a solar radiation measures was made in the laboratory, and also voltage, current and temperature tests over the whole system, adding a storage interface and serial data transmission port to drive and process the data from a computer. Once the system was tested and calibrated in laboratory, the I-V experimental curves of the PV system were obtained in real time, in order to define the most important parameters: short-circuit current, open-circuit voltage, maximum current and voltage, in a natural environment. Those parameters were the input data to the computational tool based on Scilab, which allow estimate the performance of PV system described, solving the non-linear equations of the physical models used. The performance results were compared with a similar computational tool developed in Matlab, as well as with a commercial solar simulator used by the manufacturer of PV module. A highly accurate computational system based in Scilab was obtained allows to evaluate the efficiency and the filling factor of an array for different temperature and solar irradiance levels in real time.

1 Introduction

Great efforts have been made to improve the efficiency in electric power generation using photovoltaic (PV) systems, since the advantages in comparison with others alternative energy sources, being generally fixed systems, which do not require inputs or fuels for operate, just sunlight, which geographically is available in most cases.

This workpaper is an extensión of work originally presented in IEEE 2018 Open Innovations Conference (OI) [1], as a contribution on developing software to determine the behavior of photovoltaic arrays, e.g. [2, 3], in order to be able to size correctly a deployment in any cases: residential, commercial, industrial and even farming environments. Most of these software require license payment or the source code can not be modified. Even, the most recent and interesting works based in two-diode model simulation [4] – [9] use Matlab to evaluate the performing of photovoltaic arrays. However, this work shows the results of an alternative computational system, based on two-diode model used for polycrystalline silicon PV cells [10]– [13], that determines the performance of a cell under sunlight irradiance variations and hence the relevance of knowing the efficiency of the device under study. To achieve this goal, the behavior of a semiconductor in sunlight conditions have been considered as well as temperature changes, to determine the current density between the terminals of the cell, generally consisting of a n-type and p-type semiconductor materials, which are brought

[*]Héctor L. Núñez-Ramírez, Fundación Cendit - Caracas 01060A, +582128088275, hectornunez2002@gmail.com

togheter in the well-known n-p junction. The current of carriers under the photovoltaic phenomenon are deduced by means of the equations that describe the physical model that lead us to a non-linear equations system, which will be solved by software using different Scilab functions. The coefficients of equations have been determined through the most important parameters of any photovoltaic array: short-circuit current (I_{sc}), open-circuit voltage (V_{oc}), maximum current (I_{max}) and voltage (V_{max}), all of them determined experimentally in Photonic Laboratory of Cendit. Once the equations are solved, the I-V and P-V curves of the array under test are obtained, and they are compared with the results obtained using Matlab and the solar simulator facility from one manufacturer of the module under study. However, the results obtained include the performance of the DC-AC current inverter, which is part of the system, using a complete bridge configuration, PWM controller and LC filtering at the output. The computer system developed shows not only the I-V and P-V curves of the device under test but also shows the efficiency and the filling factor of whole set.

This workpaper was developed in five sections: Physical and Mathematical Modeling to focuses phenomena and equations according with the photovoltaic arrays used; Experimental Setup to describe the procedures performed in the laboratory to obtain the data required; Software Development with the scope of describe the tools used and the programming developed, as well as the use of the obtained experimental data; Results and Conclusions to analyze, compare, discuss and verify the operation of the computational tool presented.

2 Physical and Mathematical Modelling

The physical properties of a commercial photovoltaic array made of polycrystalline silicon was considered in this case, constituted by a n-p junction of semiconductor materials under the physical fundamentals of cells of this type described in [14, 15]. Isolated, each semiconductor material retains its neutral charge. The holes are the majority carriers in the p-type material and their positive charge is compensated by negatively-charged ionized acceptor atoms, while the electrons are the majority carriers in the n-type material where there is a large concentration of free electrons compensated by positively-charged ionized donor atoms. If both semiconductor materials are placed together, a very large difference in electron concentration occurs that causes an hole diffusion current from p-type material towards the n-type material as well as an electron diffusion current from the n-type material through the metallurgical junction to the p-type material, but the region close to the junction become free of mobile charge carriers, reason why this area is denoted as a depletion or space-charge region. The diffusion generates minority carriers in each region. The gradual depletion of the charge carriers generates a charge zone made up of acceptors and donor atoms, which is no longer compensated by the free mobile carriers. As quasi-neutral regions are denoted the regions around of the depletion zone, where the neutral charge is maintained (see figures 1 and 2).

In the depletion region, under equilibrium conditions and darkness, an internal electric field is formed which forces the charge carriers to move in the opposite direction to the concentration gradient, therefore, the diffusion current continues its flow, while the forces act on the charge carriers, compensate each other, then the diffusion and drift (due to the internal electric field created around the junction) currents that originate from the carriers are compensated, reason why the net current density is zero ($I_{drift} = I_{diffusion}$). When an increase in temperature occurs, electron-hole pairs are generated, provided that thermal energy can undo the bonds, increasing the minority carriers within the material, which causes a current density due to thermal-generation.

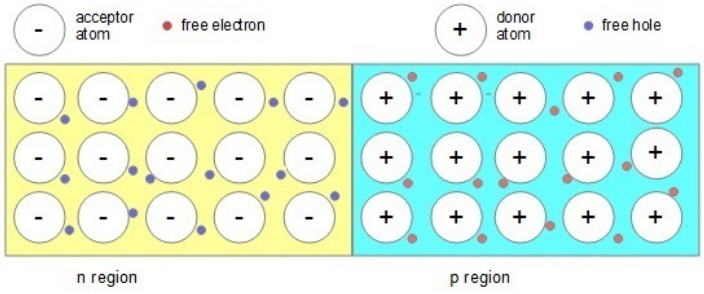

Figure 1: n-p junction (top: before junction).

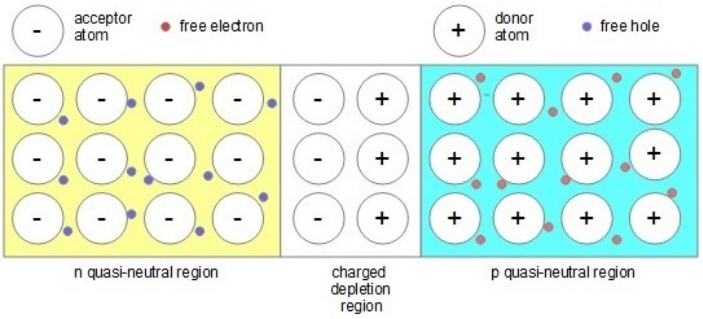

Figure 2: n-p junction (after junction).

The difussion currents (due to minority carriers) into n-type and p-type materials causes recombination currents since the minority carriers recombine with the majority carriers (the electron-hole pairs are undone). The recombination current is compensated by the thermal-generation current ($I_{rec} = I_{gen}$). The recombination strongly determines the performance of the photovoltaic cell, since the current that can be collected by the minority carriers within the semiconductor is reduced.

When the thermal equilibrium is broken, under illumination conditions, due to photons with enough energy (and frequency) to create an electron-hole pair, between the valence and conduction bands of the metallurgical junction, which increases the concentration of the minority carriers, is enabled the flow of holes from the n-type region to the p-type region, and vice versa in the case of the electrons. The flow of the photo-generated carriers determines a photo-generation current density (of intensity I_{ph}), which is added to the current density by thermal generation when the temperature increases within the material.

Based on the above, the behavior of the photovoltaic cell in darkness can be described as a currents balance due to recombinations and thermal generation phenomena, by 1:

$$I_{dark} = I_{01}(e^{qV/kT} - 1) + I_{02}(e^{qV/AkT} - 1) \quad (1)$$

where I_{01} and I_{02} are the saturation current in the quasi-neutral regions and the saturation current in the depletion region, respectively, q is the carrier's charge, k is the Boltzman's constant, T is the temperature, V is the built potential due internal electric field in the junction, A is the ideality factor between both regions. In this case, note that the exponential function is like the Boltzman Approximation, which has been demonstrated in the literature.

On the other hand, under illumination condition, the photogeneration current I_{ph} appears as shown in expression 2:

$$I_{total} = I_{ph} - I_{01}(e^{qV/kT} - 1) - I_{02}(e^{qV/kT} - 1) \tag{2}$$

with:

$$I_{ph} = [I_{sc} - K_i(T - Tr)](\frac{E}{1000\ W/m^2}) \tag{3}$$

where I_{sc} represents the short-circuit current, I_{total} corresponds to carriers net flow between the conducting terminals from the photovoltaic array, K_i is the short-circuit current coefficient, T_r represents the reference temperature and E is the irradiance.

The I-V and P-V curves, current-voltage and power-voltage respectively, can be obtained from equation (2), whose performance is shown in figure 3, where the I_{sc} is pointed at the left extreme when $V = 0$ and V_{oc} in the right extreme at $I_{total} = 0$.

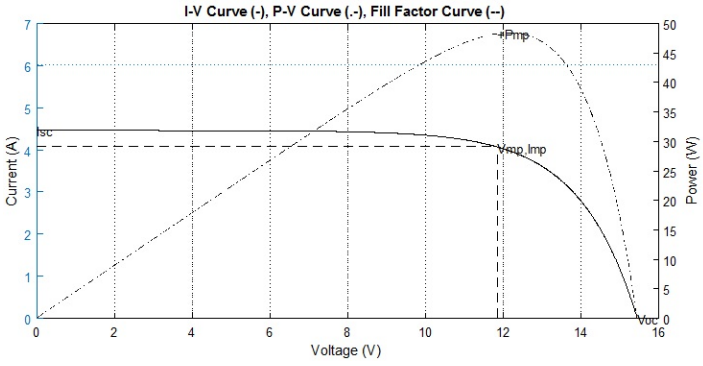

Figure 3: I-V Curve (blue), P-V Curve (red) and Fill Factor (yellow).

When the short-circuit condition is given, I_{max} not could be reached completly, in fact is a little lower due to the high resistivity presents between the ends of the junction, equivalent to a resistance in parallel to the current source and the diodes, denoted as shunt resistance (R_{sh}). In the other side, when the open-circuit condition is given the V_{max} not could be reached due to the ohmic losses in the union of the contacts with the ends of the n-p junction, denoted as resistance in series (R_s) to the current source and diodes.

$$I_{total} = I_{ph} - I_{01}(e^{\frac{q(V-I_{total}Rs)}{kT}} - 1) - I_{02}(e^{\frac{q(V-I_{total}Rs)}{AkT}} - 1) - (V + I_{total}R_s)/R_{sh} \tag{4}$$

The behavior of a single photovoltaic cell is given by the combination in parallel or series of a single photovoltaic cell, modifying expression (4) by the following:

$$I_{total} = N_pI_{ph} - N_pI_{01}(e^{q(V/N_s - I_{total}R_s/N_p)/kT} - 1) - N_pI_{02}(e^{q(V/N_s - I_{total}R_s/N_p)/AkT} - 1) - (N_pV/N_s + I_{total}R_s)/R_{sh} \tag{5}$$

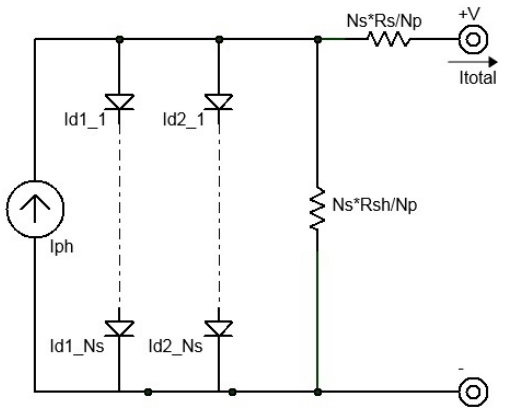

Figure 4: Equivalent circuit for a photovoltaic array.

where I_{ph} is represented by a current source and the current under darkness (I_{01} and I_{02}) by two diodes in parallel, justifying the ideal factor between both diodes denoted as A, N_p and N_s, are the number of cells (from the array) in parallel or series , respectively. The equivalent circuit to (5) is shown in Figure 4.

Using the short-circuit condition, $V = 0$ gives $I_{total} = I_{sc}$, then:

$$I_{sc} = N_pI_{ph} - N_pI_{01}(e_{qI_{sc}R_s/kT}) - N_pI_{02}(e_{qI_{sc}R_s/AkT}) - I_{total}R_s/R_{sh} \tag{6}$$

Meanwhile, using the open-circuit condition, $I_{total} = 0$ gives $V = V_{oc}$, then (5) changes to a:

$$0 = N_pI_{ph} - NpI_{01}(e^{qV_{oc}/N_skT} - 1) - NpI_{02}(e^{qV_{oc}/AN_skT} - 1) - (N_pV_{oc}/N_s)/R_{sh} \tag{7}$$

Combining (6) and (7) gives:

$$NpI_{sc} = I_{01}(e^{qV_{oc}/N_skT} - e^{qI_{sc}R_s/N_pkT}) - I_{02}(e^{qV_{oc}/AN_skT} - e^{qI_{sc}R_s/AN_pkT}) + (V_{oc}I_{sc}R_s)/R_{sh} \tag{8}$$

Differentiating (4) with respect I gives:

$$1 + qN_pI_{01}R_s/kT(e^{q(V/N_s + IR_s/N_p)/kT} + qN_pI_{02}R_s/kT(e^{q(V/N_s + IR_s/N_p)/kT} + R_s/R_{sh} \tag{9}$$

Under the open-circuit condition, $R_{s0} = -dV/dI$, then (9) changes to:

$$(R_{s0} - R_s)(\frac{qN_p}{kT}(I_{01}e^{\frac{qV_{oc}}{N_skT}} + I_{02}e^{\frac{qV_{oc}}{N_sAkT}}) + \frac{1}{R_{sh}}) - 1 = 0 \quad (10)$$

meanwhile, in the short-circuit condition, $R_{sh0} = -dV/dI$, then expression (9) changes to:

$$(R_{sh0} - R_s)(\frac{qN_p}{kT}(I_{01}e^{\frac{qI_{sc}R_s}{N_pkT}} + I_{02}e^{\frac{qI_{sc}R_s}{N_pAkT}}) + \frac{1}{R_{sh}}) = 0 \quad (11)$$

Substituting $I_{total} = I_m$ and $V = V_m$ in (5) and using Iph from (6) gives:

$$I_m(1+\frac{R_s}{R_{sh}}) = I_{01}(e^{\frac{qV_{oc}}{N_skT}} - e^{\frac{q(V_m+I_mR_s)}{N_pkT}}) + I_{02}(e^{\frac{qV_{oc}}{ANskT}} - e^{\frac{q(V_m+I_mR_s)}{ANpkT}}) + \frac{(V_{oc}-V_m)}{N_sR_{sh}} \quad (12)$$

Finally, to determine the values of I_{01}, I_{02}, R_s, R_{sh}, A, has been solved the equations system given by (8), (10), (11), (12), with the following conditions that regards the device under test:

$$R_{s0} = 0\ ;\ R_{sh0} = \frac{V_m}{I_{sc} - I_m} - \frac{V_{oc} - V_m}{I_m} \quad (13)$$

3 Experimental Setup

The values of V_{oc}, I_{sc}, V_{max} and I_{max} for the photovoltaic array setup in laboratory, were acquired from I-V curves gives via experimental, under controlled temperature and solar levels, making the necessary measurements and following what is indicated by flow diagram shown in figure 5.

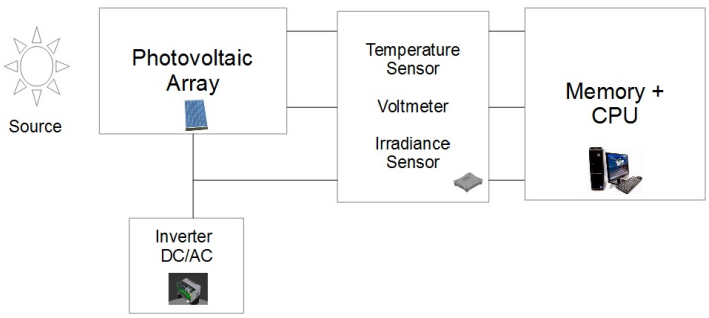

Figure 5: Flow diagram of experimental setup.

In fact, this data was acquired using a device developed in the laboratory based on PIC 18F2550, which has enough memory capacity to operate an SD memory card for data storage, as well as an RS485 interface for trasmission in real time to a computer. The device was based on the scheme proposed in [16]. The device is constituted by three sensors:
- A photodiode to measure the solar irradiance, using the BPW31.
- A temperature sensor, using the LM35.
- A voltmeter, using the ADC PIC module.

To calibrate the solar irradiance sensor, the TES 1333 was used, while for the temperature the infrared thermometer IDEAL 6165 and the multimeter Fluke 179 were used. For the acquisition of data, a script was generated in SCILAB to obtain the data via serial port, in order to plot in real time, for known conditions of irradiance (W/m2) and temperature (^{o} C), I-V curves using a variable load variable (max. 10 A). The figures 6 and 7 show some photos about the experimental setup.

Figure 6: Captures of experimental setup (UNERVEN array).

Figure 7: Captures of experimental setup (SIMENS array).

The technical specifications of photovoltaic (PV) module under test are indicated in table 1: Power (Max.), Voltage (Nominal), Series Cells (Ns) and Parallel Cells (Np).

Table 1: PV arrays under test (both polycrystalline).

Parameter	UNERVEN MSF	SIEMENS PC-2-JF
Power	195 W	35 W
Voltage	24 V	17 V
Ns	48	36
Np	1	1

The I-V curves for several solar irradiance levels during the useful solar day for each model of photovoltaic module under test are shown in figures 8 and 9.

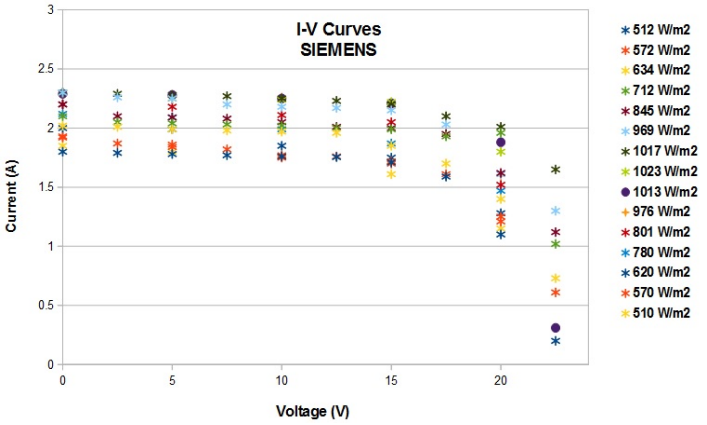

Figure 8: I-V experimental curves for UNERVEN SMF.

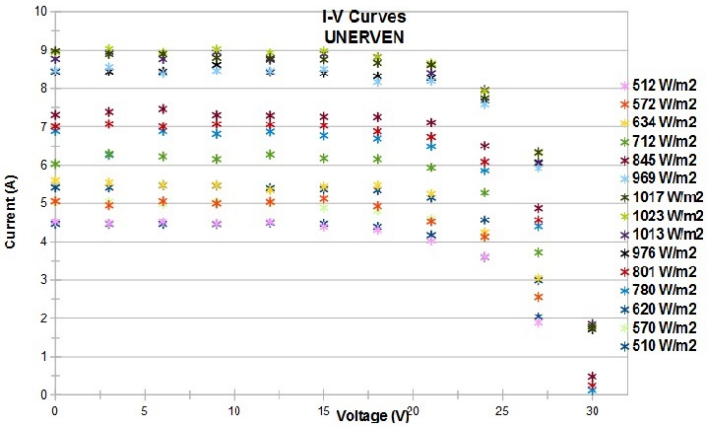

Figure 9: I-V experimental curves for SIEMENS PC-2-JF.

Table 2 shows the values obtained in laboratory for parameters: V_{oc}, I_{sc}, V_{max} and I_{max}, from photovoltaic arrays under test.

Table 2: Experimental values obtained.

Parameter	UNERVEN	SIEMENS
V_{oc}	30.25 V	23.18 V
I_{sc}	8.72 A	2.41 A
V_m	23.76 V	2.12 A
I_m	8.15 A	17.49 V

4 Software Development

A SCILAB script was developed to solve nonlinear equations system constituted by expressions (8), (10), (11), (12), using the function fsolve $[x_0, F]$, with x_0 defined as a vector with the initial values and F defined as a vector that describes equations mentioned before.

First of all, we have to define the equations to solve as a function:

$function[f] = F(x)$
$kB = value;$
$q = value;$
$T = value;$
$Voc = value;$
$Isc = value;$
$Vm = value;$
$Im = value;$
$Vt = value;$
$Rsh = value;$

$f(1) = x(1) * (exp(Voc/Vt) - exp(Isc * x(4)/Vt)) + x(2) * (exp(Voc/(x(3) * Vt)) - exp(Isc * x(4)/(x(3) * Vt))) - Isc + (Voc - Isc * x(4))/Rsh;$
$f(2) = -x(4) * ((x(1)/Vt) * exp(Voc/Vt) + x(2)/(x(3) * Vt) * exp(Voc/(x(3) * Vt)) + 1/Rsh) - 1;$
$f(3) = x(1) * (exp(Voc/Vt) - exp((Vm + Im * x(4))/Vt)) + x(2) * (exp(Voc/(x(3) * Vt)) - exp((Vm + Im * x(4))/(x(3) * Vt))) + (Voc - Vm)/Rsh - Im * (1 + x(4)/Rsh);$
$f(4) = -x(4) * ((x(1)/Vt) * exp(Isc * x(4)/Vt) + (x(2)/(x(3) * Vt)) * exp(Isc * x(4)/(x(3) * Vt)) + 1/Rsh) - 1;$
$end function$

Then, we have to define a script to solve the equations:
$x0 = [min_value; scale_factor; max_value];$
$y = fsolve(x0, F);$
$I1 = y(1);$
$I2 = y(2);$
$A = y(3);$
$Rs = y(4);$

The expression defined by (5) is a trascendental equation that was solved in this case using Xcos from Scilab. Figure 10 shows how the four terms in (5) are determined. For more details see [1].

In the last blocks a DC-AC converter has been included and using a full-bridge configuration and a LC filter in the out, with PWM control. For more details in [1].

The I-V and P-V curves generated in Scilab, under Standard Test Conditions (STC) from the mathematical two-diodes model used for each array under test: SIEMENS and UNERVEN, are shown in figures 11 and 12.

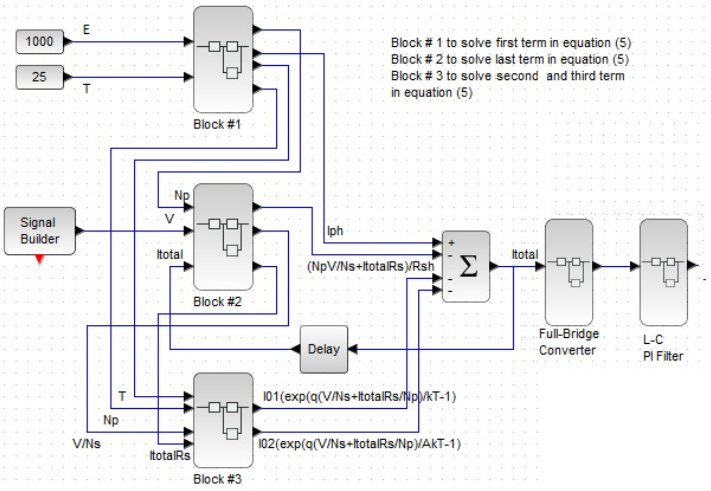

Figure 10: Xcos solution to simulate photovoltaic arrays with DC/AC inverter.

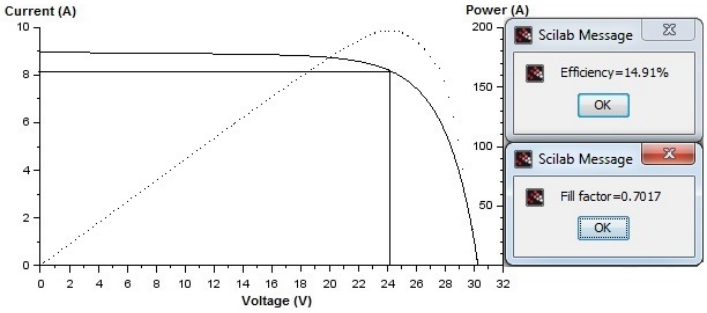

Figure 11: I-V and P-V curves through Scilab (PV array: UNERVEN).

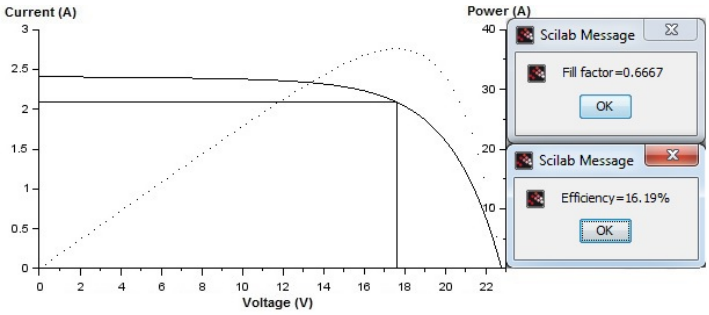

Figure 12: I-V and P-V curves through Scilab (PV array: SIEMENS).

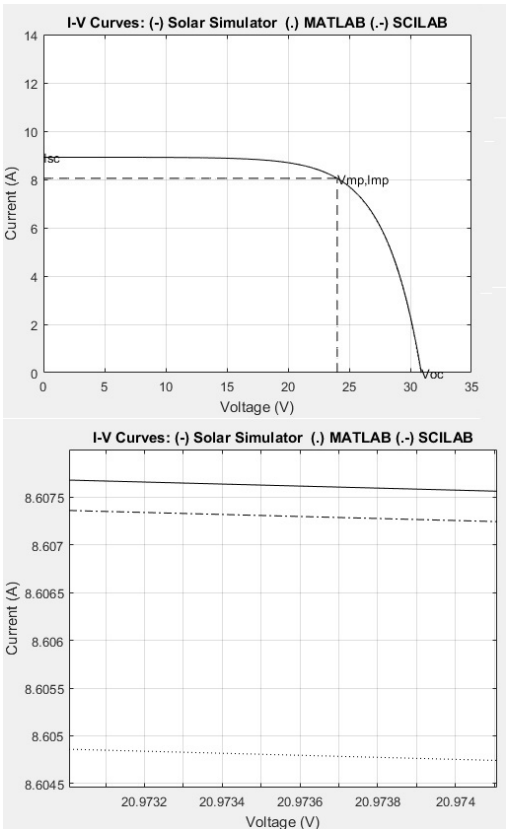

Figure 13: I-V Curves: Solar Simulator, Matlab, Scilab (PV array: UNERVEN).

5 Results

The I-V curves from different sources are shown in Figures 13 and 14: Solar Simulator (from UNERVEN, class A), Matlab Simulator (based on [1]) and Scilab Simulator, for each photovoltaic array under study on STC (1000 W/m^2 , 25 ^oC). The solid line and the dash-dotted line are very close to each other, even if some approximation algorithm was not used to solve the equations of two-diode model as in recent workpapers cited above.

The I-V curves for several solar irradiation levels using Xcos from Scilab for each photovoltaic array under study are shown in Figures 15 and 16. Again, the solid line and the dash-dotted line are very close to each other, with an accuracy superior to 99.9 percent.

6 Conclusions

A computational tool has been put to test in laboratory, based on a free software platform, which allows evaluate in real time the efficiency not only of a photovoltaic array, but also the effects generated by a DC-AC inverter coupled like a load to the system as in real enviroment, using in the develop the physic models cited. Test were coducted in two commercial photovoltaic arrays, and aditionally, the performance results were compared with other tools (licensed) reaching a high accurate.

In contrast with experimental tools used (Solar Simulator Class A from UNERVEN) and computational tool based on Matlab, using Scilab (free software) was improve the perfomance of photovoltaic arrays, even a real time estimation of fill factor and electrical efficiency as an additional feature respect to works cited above. works.

ABSTRACT

We present findings on classifying the class of executable code using convolutional, recurrent neural networks by creating images from only the .text section of executables and dividing them into standard-size windows, using minimal preprocessing. We achieve up to 98.24% testing accuracy on classifying 9 types of malware, and 99.50% testing accuracy on classifying malicious vs. benign code. Then, we find that a recurrent network may not entirely be necessary, opening the door for future neural network architectures.

1 Introduction

This paper is an extension of the work originally presented in the 2018 IEEE National Aerospace and Electronics Conference (NAECON) [1] .

Stakes are always escalating in the arms race that is malware detection. From personal security to breaches at large data centers, it is important to remain vigilant and always explore new methods for combating malware. Classifying executable code images may soon be one of the best methods for malware detection given all of the advances with neural networks in recent times, and we aim to further push the field by questioning the amount of information necessary and size of network necessary to make a judgment.

With our previous work, we proved in concept that using only the .text section of executable files, and not the data, is a possible avenue for malware detection. Using only the executable code allows for leaner, faster networks at the lowest possible level in the hardware stack. Unfortunately, one large issue with malware images is the extremely variable size of the input - code can be anywhere from minuscule to gigabytes in size so figuring out how to use one network to classify code of any size can be difficult. We previously used padding to standardize all files to one length, negatively impacting performance. In this work, we extend on our previous work by using a "windowing" method to allow for arbitrary-length, minimally processed input that achieves competitive performance in malware classification compared with seminal works. To do this, we use a variant of recurrent neural network called a ConvLSTM [2] that uses convolution in tandem with a recurrent architecture. With further investigation, however, we find that it may be possible to ditch the recurrent relationship altogether, opening the door for a multitude of possible architectures.

2 Related Work

Viewing executable code as an image has become a subject of interest for many studying malware detection and neural networks. We will present some of these works for comparison to our work, to both show the state of research and also how our work has some advantages and disadvantages to other methods. In particular, our method has minimal preprocessing of the images, unlike almost all other methods. To view executable code as an image, each byte of the file is taken and translated directly from hexidecimal to decimal. These values then become greyscale pixels, creating an image. Figure 1 shows an example.

Figure 1 shows the first 100 lines of a malicious image where each line of the executable code is translated to a line of greyscale pixels. We pad each line with 0's to the maximum line length. This format differs from some other formats, especially with the line padding and that we only use the .text section, or executable code, and no data. For many of the malware as image works, the results do not classify malicious vs. benign, but instead classifying which type of malware a file is. This is because obtaining and distributing a large number of malicious files is much easier than doing the same

[*]Corresponding Author: Michael Santacroce, santacml on GitHub, santacml@mail.uc.edu

for benign files. Additionally, it is in some ways a better test of the network to classify the type of malware than malicious or benign, as it can be considered a more difficult type of the same problem. If a network can classify the type of a file out of 10 or more classes of executable code, it should be easier to classify out of only 2 classes, in theory.

Figure 1: Example executable code as an image

In 2010, the authors of [3] used k-NN and feature extraction to achieve 98% accuracy on nearly 9,500 samples of 25 classes of malware. This is one of the earliest works that visualize malware as an image and shows that the concept is viable. The authors note some possible methods of avoiding detection such as inserting redundant bytes. Additionally, we note that this method includes a large amount of preprocessing for the malware images.

In [4], the authors process the images to a standard size and then use a densely-connected neural network to achieve 96.35% accuracy on 3131 files of 24 classes of malware. We note that in this work, excellent results are achieved on such a large number of classes of malware.

More than any other method, the ideas of malware image detection have been combined with the burst of developments with convolutional neural networks (CNNs). CNNs have become the go-to for image classification due to their ability to identify spatial relationships in data [5, 6, 7]. In particular, the Microsoft Malware Classification Challenge has spurred a large interest in using CNNs for malware detection [8]. For instance, the author of [9] used a CNN to acheive 95.24% accuracy on a test set of over 40,000 samples, and then used a residual network to achieve 98.21% accuracy on the same samples. The author also notes that the test set was limited to a certain size of binaries and that future work should expand to any length of binaries. In our own work, which this paper extends, we presented up to 88% accuracy in classifying malware on the same data from the Microsoft Malware Classification Challenge [1] . The largest issue from that work was the large amount of padding used. Instead of reducing or expanding images, we padded all images to be the same length. The upside of this method is that it loses no information, however, there were of course large amounts of padding for tiny images, affecting performance. Like in this work, however, we only used the .text section, proving it possible to only need limited information.

The authors of [10] use a convolutional, distributed network, topped with a recurrent neural network on over 2 million malicious files. The network uses bytes of the full executable without preprocessing and uses and embedding, pointing out the issues with preprocessing. The authors also note difficulties with RNNs due to the length of the sequence, as we also found. The network achieves a maximum of 94% accuracy and 98% AUC. This work is the most similar to ours, however, we expand in a few ways. Most importantly, we are only using the .text section of files, a much smaller subset of the total files. Next, we introduce the concept of breaking the malware image into windows, which would theoretically allow for processing only window at a time, saving large amounts of memory. Next, we apply the ConvLSTM architecture to the data which has not been done before, alleviating RNN issues. We also use global average pooling in one of the final network layers to improve generalization [11]. Finally, we are using a different dataset that is much smaller, but we do achieve better overall performance.

The best performance we could find was by the authors of [12], who combine a CNN and LSTM in ensemble, achieving 99.88% accuracy on 40,000 samples balanced equally between malicious and benign files. Then, when used on only the malicious files, they achieved 99.36% accuracy on 9 classes. Again, the input is the full disassembly of the executables and the input is again preprocessed. Additionally, the authors do not present the method of disassembly for the benign files. We will discuss in the next section some possible flaws with mixing these two types of dataset, of which there may be many.

Executable code as an image has become a hot area of research in recent years. In many of these works the images are preprocessed before classification, which might take a large amount of time or resources in practice depending on the operations, and may be bypassable by reverse-engineering the preprocessing. Additionally, all of the works we have seen use the full executable file for classification. By only using the .text section of an executable, classification can be done at a lower level in the hardware stack, with less memory, less time, and less context of what is running. We will address the issues of using arbitrary-length files by using minimal preprocessing and only using the executable code with a ConvLSTM architecture.

3 Network Input

In our previous work we generated our own data using malware obtained from a Windows installation and live malware found online [1] , number 240 total files split evenly between the two classes. There were a few issues with this dataset, namely, the limited size due to difficulty of acquiring samples and the overly-complex tokenization method. The tokenization of assembly resulted in a larger-than-needed vocabulary size and some preprocessing time which we attempting to limit as much as possible.

As a second test, we used the data from the Microsoft Malware Classification Challenge on Kaggle [8], which contains over 20,000 total malware files from 9 classes of malware. With this data, we are able to directly use the machine code and translate it into decimal per byte, which resembles other works as we have discussed. We will again evaluate performance on this dataset. Of these files, 10,869 had labels and then of those 10,375 were found to have .text sections that we could use, however, we quickly hit memory limits while testing longer files. To solve this, we had to limit to only files

that had under 50,000 lines of code, resulting in a total of 8,550 files, of which we used 6,500 training and 2,050 testing files. Because the final goal is classification of malware vs. binary code, however, we have generated an additional dataset consisting of 4,550 benign files from a default Windows installation that were disassembled using IDA pro. Again, due to the 50,000 line cutoff, we were only able to use 3,100 of these files. We then combined the benign data with randomly-chosen malicious files for a second dataset of only malicious vs. benign classification, consisting of 4,000 training and 1,000 testing files.

We will present results on both of these datasets to validate that our own benign files were not biased because of some concerns with the benign data format. While we are comfortable that the datasets are now fair to compare we will show those concerns and how we addressed them. Many benign files were initially identifiable by eye due to some certain characteristics, as in Figure 2:

Figure 2: First 100 lines of a benign code image

The first problem is that there seems to be a long portion of data bytes at the beginning of many benign files that only includes one or two executable bytes. In the Microsoft dataset, these sections are grouped to have many data bytes per line (up to 18). Next, many lines end in the same color pixel. This is because of how we extract data from the disassembled bytecode - once disassembled from IDA, we simply look at every line to see if it starts with ".text", signifying executable code. Then, we extract the hexadecimal bytes from that line until there are no bytes left. Many of these lines end in the byte "db", a signal from IDA that represents the variable size (a byte) and not code. For some reason these extra "db" tokens were never an issue in the Microsoft dataset as there is always some other non-hexadecimal token before them, causing them to be excluded in our extraction. We therefore excluded the "db" at the end of any line (which is always lowercase if it is not an actual byte in the code but added by IDA, so no innocent bytes were lost). With both of these issues it is possible we are disassembling the data differently than Microsoft did in the Kaggle challenge. Because the exact way that the Microsoft dataset was generated is unknown, we present results on both datasets with the assumption that our benign files are not, but may be, biased.

Unfortunately, malware or benignware can come in all sizes, so the question becomes how to approach classifying arbitrary-length files. Additionally, the files can reach extreme lengths, so a straight LSTM or RNN will experience difficulties in training. We therefore split the files into t windows by grouping every w lines of code. The number of windows forms the new number of timesteps, and the dataset can now be seen as an arbitrary-length sequence of images. An example is shown in Figure 3.

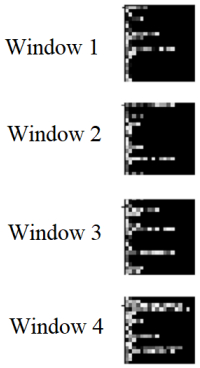

Figure 3: Malware Image Windows

Figure 3 shows a malware image split into windows (not to scale).

4 Network Architecture

Forming the malicious bytecode into an arbitrary-length, windowed format allows for input into a variety of network architectures. Before discussing the network architecture for the new input format, we first downsample and perform an embedding on the data. We previously experienced issues with the size of the input being too large to use at once, and even after purposely omitting files over a certain length, the networks would train in an unreasonably long amount of time. Therefore, we utilized pooling to downsample the input data [1] . While this is the only preprocessing we perform, which adds time to making predictions, we still perform downsampling on the data by randomly discarding 9 of every 10 lines. Along with the benefit of faster training and prediction we find that it does not negatively affect performance and actually improves testing performance in some cases, which we will discuss in the results section.

We also previously used embeddings to assist in feature detection, similar to natural language processing [10, 13], as the magnitude of the bytes have no intrinsic meaning. The embedding serves as a look up table where each singular value maps to a higher-dimensional space of values with less magnitude.

With the initial layer of an embedding, we now expand on the previously static, convolutional network. A natural pick for classification of these videos would be some kind of recurrent neural network given the time-varying nature and seeming temporal dependency of the problem. In fact, one large question we will pose throughout our work is if the windows are actually temporally dependent, in other words - does the previous window affect how we should see the next? Given the nature of the problem, it seems logical that this would be true, and is the assumption we made for beginning to explore architectures.

Convolutional LSTMs are a relatively recent form of recurrent neural network that have cropped up in a few field of study that involve both temporally- and spatially-related data [2, 14, 15]. In

Keras, this layer of a network is called ConvLSTM2d [16], meaning that it performs 2d convolution inside an LSTM. For comparison, A traditional LSTM uses the following equations:

$$\begin{aligned} i &= sigm(h_{t-1} \cdot U_i + x_t \cdot W_i) \\ f &= sigm(h_{t-1} \cdot U_f + x_t \cdot W_f) \\ o &= sigm(h_{t-1} \cdot U_o + x_t \cdot W_o) \\ g &= tanh(h_{t-1} \cdot U_g + x_t \cdot W_g) \\ c_t &= f \cdot c_{t-1} + i \cdot g \\ h_t &= o \cdot tanh(c_t) \end{aligned} \tag{1}$$

Where $W_{i,f,o,g}$ and $U_{i,f,o,g}$ are trainable weight vectors, and c_t and h_t are the hidden state and output, respectively. These equations can of course change and are only an example for comparison.

LSTMs can help alleviate "vanishing gradient" issues when training and therefore allow for training recurrent networks on much longer inputs than a vanilla RNN [17, 18]. We attempted to use a regular LSTM on input mawlware without windows and found that the model would not only take an extraordinarily long time to train, as expected due to the input length, but would not perform well. Even if a decent training accuracy was obtained the results would not translate to testing accuracy.

Recent works, including our own, have shown that classifying malware images responds well to convolution [1] . Therefore, instead of using a LSTM, it is possible to use the Convolutional LSTM (from now on, ConvLSTM). The ConvLSTM consists of nearly the same parts as a regular LSTM except that many dot products are simply switched to being convolution:

$$\begin{aligned} i &= sigm(h_{t-1} * U_i + x_t * W_i) \\ f &= sigm(h_{t-1} * U_f + x_t * W_f) \\ o &= sigm(h_{t-1} * U_o + x_t * W_o) \\ g &= tanh(h_{t-1} * U_g + x_t * W_g) \\ c_t &= f \cdot c_{t-1} + i \cdot g \\ h_t &= o \cdot tanh(c_t) \end{aligned} \tag{2}$$

Where $W_{i,f,o,g}$ and $U_{i,f,o,g}$ are trainable weight vectors, and c_t and h_t are the hidden state and output, respectively.

The ConvLSTM was introduced in 2015 by [2] as a way to capture both spatial and with temporal relations in precipitation forecasting, as opposed to an LSTM, which is only capable of capturing temporal relations. ConvLSTMs have since been used many times to capture spatio-temporal relations in data. In [15], they are used to build on feature extraction in gesture recognition, and in [19], the authors add to the ConvLSTM architecture for traffic accident prediction. More notably, in [20], the authors use a nested ConvLSTM for video classification. Our work can be seen as converting the malware to a video rather than an image, and taking inspiration from these works. In our case, the ConvLSTM captures spatial relations in blocks and functions of code and temporal relations between those blocks.

With the recurrent networks it was found best to use use two hidden recurrent layers, one that returns sequences and a second that does not. When a recurrent network in Keras has the parameter return_sequences set to true, the output of the layer is not just the final output but the output of each timestep, the result being a sequence of the same length. Using this parameter is useful as it allows the stacking of recurrent layers and therefore deeper networks.

While our models that use ConvLSTM found success, which we will discuss in the results section, we also found that they took up a large amount of time to train due to the complexity of the hidden state. Many modified RNNs were attempted by removing or adding various gates to the ConvLSTM hidden state until we tested a recurrent network that simply adds the previous hidden state to the current as so:

$$\begin{aligned} h_t &= x_t * W_t + b_t + h_{t-1} \\ y_t &= \sigma(h_t) \end{aligned} \tag{3}$$

Where σ represents the sigmoid function, W_i and b_i are trainable weight vectors, h_t is the hidden state, and y_t is the output at time t.

This network is about as minimal as a recurrent neural network can get and can be compared to a standard recurrent network where the hidden weight vector is set to all 1s. We call this the "MinConvRNN". In theory, one layer of this network that does acts the same as if each timestep was independently run through a small neural network and then summed afterwards. Because there are two hidden layers used and each timestep is returned for the first, however, the intermediate timesteps returned by the first hidden layer do not resemble a kind of distributed network.

We can perform backpropogation on the MinConvRNN for training through the widely-known procedure of BackPropogation Through Time (BPTT). We will perform BPTT on the MinConvRNN for completeness, however, gradients are calculated symbolically and automatically in our simulations, so these calculations are not stricly necessary. BPTT consists of unrolling the recurrent neuron into t neurons and repeatedly applying the chain rule. We will start by defining all parameters in Table 1, for any arbitrary objective function J.

Table 1: MinConvRNN Backpropogation Parameters

Variable Name	Purpose
x_t	Input at time t
h_t	Hidden state at time t
W_t	Weight vector at time t
b_t	Bias vector at time t
y_t	Output of neuron at time t
σ	Sigmoid Function
δ_t	$\frac{\partial J_t}{\partial y_t}$
J_t	Objective function value at time t

The goal of backpropogation is to find the partial derivative of the objective function with respect to a parameter. In this instance, $\frac{\partial J_t}{\partial W_t}$. Note that W_t for time t is a formality, and $W_i = W_j, \forall (i, j) \in t$, and the same for b_i. We begin by defining the base case of $t = 1$ such that $h_0 = 0$, making $h_1 = x_1 * W_1 + b_1$.

Then, we can define the partial derivative of J with respect to W_t using the chain rule:

$$\frac{\partial J_t}{\partial W_t} = \frac{\partial J_t}{\partial y_t} \cdot \frac{\partial y_t}{\partial h_t} \cdot \frac{\partial h_t}{\partial W_t} \tag{4}$$

We can define δ_t to be $\frac{\partial J_t}{\partial y_t}$ to simplify notation as the expression will change for a different J. We can then calculate the other terms directly as:

$$\begin{aligned} \frac{\partial y_t}{\partial h_t} &= \sigma'(h_t) \cdot 1 \\ \frac{\partial h_t}{\partial W_t} &= \frac{\partial x_t * W_t}{\partial W_t} \end{aligned} \tag{5}$$

We leave $\frac{\partial x_t * W_t}{\partial W_t}$ alone to simplify the expression, but we note it is computable. It is also known commonly known that $\sigma'(x) = \frac{\partial \sigma(x)}{\partial x} = \sigma(x) \cdot (1 - \sigma(x))$, and we will use $\sigma'(x)$ for simplification of expressions as well.

The full partial derivative at time t can then be defined as:

$$\frac{\partial J_t}{\partial W_t} = \delta_t \cdot \sigma'(x_t * W_t + b_t + h_{t-1}) \cdot \frac{\partial x_t * W_t}{\partial W_t} \tag{6}$$

Because W_t is the same $\forall t$ as stated earlier, we can compute the partial derivative for W for n timesteps as:

$$\begin{aligned} \frac{\partial J}{\partial W} &= \sum_t \delta_t \cdot \sigma'(x_t * W + b_t + h_{t-1}) \cdot \frac{\partial x_t * W}{\partial W} \\ h_0 &= 0 \\ t &\in [1, 2...n] \end{aligned} \tag{7}$$

For a recurrent neural network where only the output is considered, we could factor out δ_t from the sum. We can also perform a similar process to find the partial derivative for b for n timesteps as $\frac{\partial J}{\partial b} = \sum_t \delta_t \cdot \sigma'(x_t * W + b_t + h_{t-1})$, with the same conditions.

This partial derivative does not look too dissimilar to that of a basic recurrent neuron. The neuron is indeed recurrent in the sense that it is necessary to calculate h_{t-1} in order to calculate h_t, and that the gradient must be propogated starting with the initial output in the same manner. Regardless of these equations, however, the neuron as defined in Eq. 3 does not make intuitive sense. Taking the raw sum after convolution, in theory, might simply lead to an unbounded output in the hidden state that approaches ∞ (or $-\infty$) for all elements as the number of timesteps approaches ∞ , leading to all 1s (or 0s) in the output with the sigmoid activation.

As will be shown in the results, we found the MinConvRNN to largely match the performance of the ConvLSTM2d. The success of the MinConvRNN begs the question if a recurrent neural network is necessary, or in other words, if executable code as an image has a temporal dependency when it comes to classification. As will be presented in results, it is even possible to scramble the order of the input lines and achieve decent performance using the same net trained on ordered input lines. It seems unintuitive at first but a simple explanation is simply that a large amount of code is wrapped up in short functions. Depending on how large the window size is made, it is possible that each window encapsulates even multiple functions. Because the order in which functions are defined largely does not matter, there is not a strong temporal dependence between windows. A different explanation may be that even between windows, temporal dependency does not matter, and that the class of a file is largely determined by the types and quantities of commands issued, and not their order. Future work will need to investigate the temporal dependence of the data more closely as it will greatly affect how we classify malware with neural networks.

Regardless of the type, after the recurrent layers, the output has three dimensions. The first two dimensions can be average-pooled to reduce overfitting [11], and then connected with a final densely-connected layer for the output. The architecture of the network is shown in Figure 4.

5 Performance

We present results on both the Malware Classification Challenge dataset and the Malware vs. Benign dataset as discussed, starting with the Malware Classification Challenge dataset.

Table 2 shows the final results of the ConvLSTM2d and MinConvRNN networks. Both networks were trained until no further performance gains were seen.

Table 2: Results on Microsoft Malware Classification Challenge Dataset

Metric	ConvLSTM	MinConvRNN
Parameter Count	573,634	116,951
Train Accuracy	98.35%	97.28%
Test Accuracy	98.24%	96.39%
Time to Inference	~63.67ms	~23.73ms

In Table 2, it can be seen firstly that both networks performed competitively to other works. The MinConvRNN was purposely limited in size to have the same number of convolutional kernels as the ConvLSTM2d network, being 50 kernels of size 4 in the first hidden recurrent layer, and 25 kernels of size 3 in the second hidden recurrent layer. The network was kept the same size to demonstrate the relatively similar performance. While the ConvLSTM2d network did achieve better results, it has nearly 5 times the total number of parameters. Better results are certainly possible through tweaking the network size, activation functions, etc., but we see these networks as a proof-of-concept for future work that does not rely on recurrent networks given the performance of the MinConvRNN. Additionally, we note that the ConvLSTM2d takes nearly twice as long to make a prediction given an input due to the complexity of the hidden state. If we can cut out the recurrent nature of the network, the time to predict would drastically go down.

Table 3 shows Confusion matrix for the ConvLSTM2d network on the testing data, where the row is the actual class and the column is the predicted class. Of note is that one class in the dataset has an extremely low number of samples, class 5. Neither this network nor the MinConvRNN was able to correctly identify and class 5 samples. This might be addressed by using weighted categorical crossentropy, but again, we are presenting these results as a proof-of-concept.

Table 4 shows the confusion matrix for the MinConvRNN on the testing dataset, where the rows are the actual class and the columns are the predicted class.

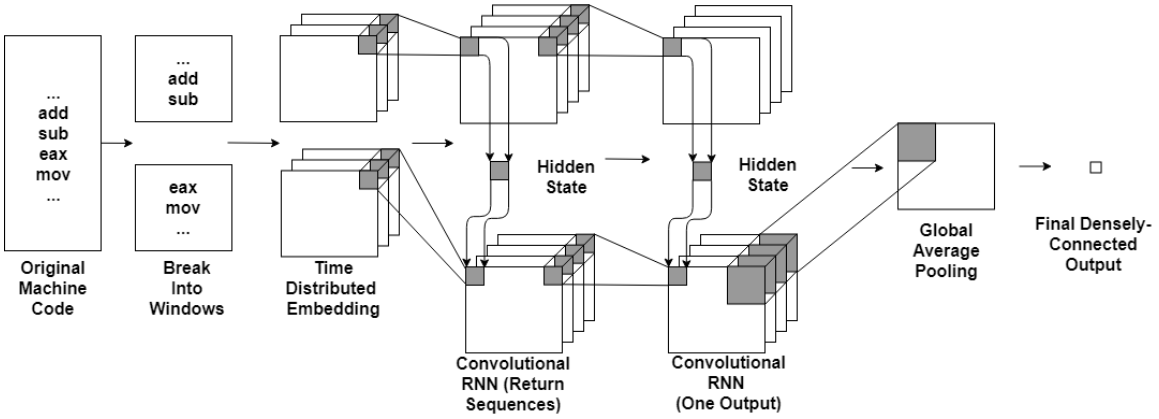

Figure 4: RNN for Malware Classification Architecture (for arbitrary hidden state)

Table 3: Confusion Matrix for ConvLSTM2d Net on Testing Data

	1	2	3	4	5	6	7	8	9
1	249	0	0	0	0	0	0	0	0
2	2	364	0	0	0	0	0	0	0
3	0	0	681	0	0	0	0	0	0
4	0	0	0	99	0	0	0	0	0
5	2	1	0	0	0	0	1	2	0
6	3	0	0	3	0	107	0	0	0
7	0	1	0	0	0	1	89	2	1
8	6	1	0	0	0	1	0	259	1
9	3	1	0	0	0	0	0	4	166

Table 4: Confusion Matrix for MinConvRNN on Testing Data

	1	2	3	4	5	6	7	8	9
1	245	0	0	0	0	0	0	2	2
2	3	356	1	0	0	2	0	3	1
3	0	0	680	0	0	0	0	1	0
4	0	0	1	98	0	0	0	0	0
5	1	0	0	1	0	1	0	2	1
6	1	0	0	4	0	105	0	2	1
7	0	1	12	0	0	1	80	0	0
8	13	2	0	1	0	0	0	252	0
9	4	1	5	1	0	1	0	2	160

Overall, we see performance for both networks, moreso the ConvLSTM2d, matching other works. The benefit to using these networks is the minimal preprocessing, the small size of the networks, and the minimal amount of input by only using the executable code.

Table 5 shows the results of the networks on the Malicious vs. Benign dataset.

Results on the Malicious vs. Benign Dataset are on par or better than the previous dataset. Despite reservations with the benign data as previously discussed we believe that the networks show competitive performance in classifying Malicious vs. Benign data to seminal works. The MinConvRNN again shows worse performance than the ConvLSTM, likely due to the smaller number of parameters. Considering that the network is smaller, the relative success of the MinConvRNN calls into question whether using a recurrent network is necessary.

Table 5: Results on Malicious vs. Benign Dataset

Metric	ConvLSTM	MinConvRNN
Parameter Count	573,634	116,951
Train Accuracy	99.78%	99.32%
Test Accuracy	99.50%	99.20%
Test Recall	99.37%	98.12%
Test Precision	99.58%	99.58%
Time to Predict	~91.16ms	~35.32ms

6 Future work

There are many topics of future work to expand on. In the big picture, the concept of a non-recurrent network would be interesting to test compared to the recurrent networks. It is possible to take more inspiration from video classification methods in this way. We have observed that a minimal recurrent network achieves decent performance, so with optimization, a purely time-distributed network that is aggregated afterwards may perform well.

With or without recurrent, it would be important to optimize the network, exploring activation function, weighted categorical crossentropy, cross-validation methods, and pruning methods. Performing an architecture optimization search would take much more work, but would improve the performance of the network.

There are also some flaws in our methodology, the largest being the limit of 50,000 line long samples. One possible method of removing this constraint is to reformat the data. The figures of malware code show that each line is padded with 0's to be the same length - this was done to preserve the ordering of the opcodes in relation to the data. This format, however, may be unnecessary and the code is often treated as one contiguous block in other works. The size of the input would be greatly reduced by removing the padding, which would not only allow for any length input, but also faster and possibly more accurate predictions. Additionally, it would also

ensure compatibility with the Microsoft and Benign datasets given the different maximum line lengths.

Finally, finding a way to extend the work to hardware would be great for evaluating the feasibility of the practical implementation of the networks. One possible method of using the malware-detecting-network in practice might be to deploy it in a custom chip or FPGA. While the network is likely too large for such acceleration now, with compression techniques, it may be possible to make the network fit. Putting the network in separate, purpose-built hardware would not only free up resources from the main system but also speed up the network considerable.

7 Conclusion

Malware detection will always be a vital part of computer systems. In recent times, classifying malware images made from the executable bytes of a file has become a possible route to take.

This extension of our previous conference paper again proves it is possible to classify malware with nothing other than the .text section of an executable, which contains the actual code that makes up the program. Additionally, we expand on the type of network for detection by creating windows out of the malware image. With this format, minimal preprocessing is required to feed the image into a convolutional, recurrent neural network, achieving competitive performance.

Additionally, we find that using a recurrent neural network may not be entirely necessary. By stripping the ConvLSTM2d of its components and making the MinConvRNN, we have shown that the temporal dependency between windows may not be necessary, opening the doors to new network architectures. Using the MinConvRNN is not the end of the story - it is highly likely that even leaner neural network architectures are possible for malicious assembly.

Conflict of Interest The authors declare no conflict of interest.

ABSTRACT

Recently, the trend of mobile communication network in Korea has been dramatically increasing the number of operating equipment for managing the explosion of wireless data traffic in 4G LTE network. This phenomenon has caused an increase in the operating cost to the mobile telecommunication service provider. Especially, the study about the reduction of the operating cost through the reduction of the power consumption in the power consumption area and the efficient operation method are under study. Through these studies, we consider the method to maintain the best service quality of mobile communication subscriber while minimizing the power consumption of LTE equipment, find out PSi & PSo algorithm that can realize this and verify it in commercial network. Applying this algorithm to a commercial network will save both power consumption and service experience of mobile subscribers to the best level, and it will be more effective in the 5G era that has already begun.

1. Introduction

This paper is an extension of work originally presented in *2018 International Conference on Information and Communication Technology Convergence (ICTC)* [1].

The world has already begun to enter the 5G world, and the first 5G signal in Korea has started to be transmitted. There are also many killer services available to satisfy customers' needs. This means that a lot of people are using smartphones and are getting into daily life. In the past, the use patterns of voice-based usage changed with data, and the network that accommodates customers changed quickly. As the LTE network matured, the frequency bandwidth and the number of equipment services are continuously increasing to accommodate the increasing subscriber traffic [2].

This provides a pleasant environment for various services and accommodates a growing number of subscribers, but the cost of operating of equipment has increased. SK Telecom's electricity costs account for about 30% of the total cost of operating a network, exceeding 30% in 2017, which is still rising. In 2019, electricity costs are expected to account for 35% of total operating costs.

This increase in network operating costs is bringing considerable stress to mobile telecom operators, and it is also evolving to a level that significantly affects corporate EBITDA [3]. As a result, each company has a great interest in reducing the cost of network operation, especially in the field of electric power. In previous mobile communication areas, there has been much interest in battery efficiency aspects such as SoC (System on Chip) upgrade [4] and C-DRX(Connected Mode Discontinuous Reception) [5]. Recently, attention has been focused on the reduction of power consumption of network equipment itself.

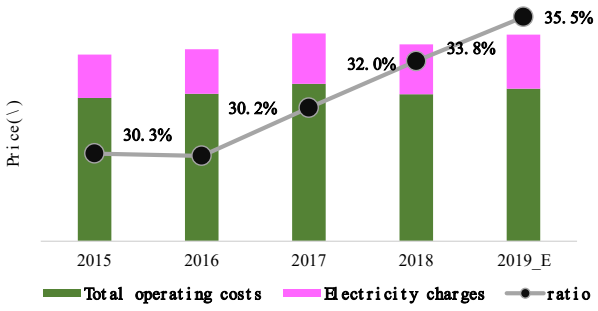

Figure 1: Electricity charges and ratio in operating costs

We used the power saving function of SK Telecom's NOKIA equipment to investigate how to reduce the power consumption of the network equipment itself. Through the derivation of optimal values of PSi and PSo, which are control variables for triggering

*Jongsin Kim, +8210-3768-6309, Email: kjs3838@sk.com

power saving to be explained later in detail, Consumption is decreasing. The optimal PSi and PSo values mean the point where the quality of the mobile communication subscriber can be maximized while minimizing the power consumption.

In this paper, we propose an operation algorithm that can reduce the power consumption of wireless network service equipment while providing optimal service without inconvenience to mobile communication subscribers. In this process, SK Telecom's commercial network is divided into several cases, and results are derived. The power saving function of the wireless network service equipment and the algorithms discussed in this study are used to reduce the actual power consumption.

2. Basic direction of power saving of LTE wireless network

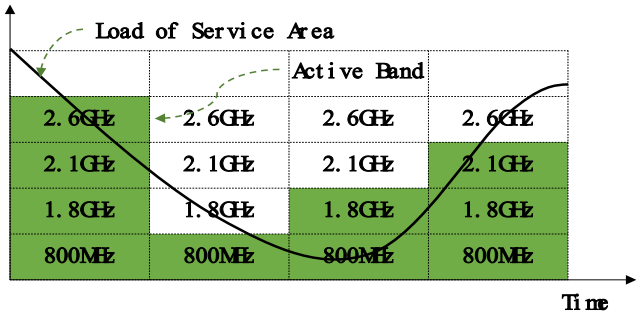

Table 1: Number of subscribers per 10Mbps

Freq. Combination	Number of eligible subscribers
800M	7.5
800M+1.8G	22.5
800M+1.8G+2.1G	30.0
800M+1.8G+2.1G+2.6G	52.5

Table 1 shows the number of subscribers per frequency configuration operated by SK Telecom. As shown in the table, the number of subscribers that can be accommodated for each frequency combination is linear. (However, in LTE network, the service required for voice, messaging, video, and FTP is different according to service type, but it is calculated based on 10Mbps speed for convenience.) In order to service many subscribers, more frequency and bandwidth are needed. On the contrary, it is not necessary to provide the frequency and bandwidth of mobile communication subscribers in every place. This is because the number of subscribers and traffic vary with time. In other words, the frequency and bandwidth need to be tailored to the region's maximum traffic, but not all-time full-band service. Taking operational efficiency in accordance with the traffic volume and characteristics of subscribers is a basic direction for power saving in LTE networks.

In order to reduce power consumption in LTE mobile communication, there is a method to utilize a SON (Self Organizing Network) [6] implemented by a mobile communication provider. As mentioned above, this study utilized the power saving function provided by NOKIA equipment.(Other vendors, however, offer similar functionality.) The basic concept of power saving is that when the same area is served by several frequencies, the subscriber traffic of the service area is judged as a combined load, and when this value is low, the power consumption is reduced by turning off the output of some frequencies.

As can be seen in Figure 2, when several frequencies are serviced in the same area, the number of subscribers and traffic varies with time, and thus the number of frequencies required varies. Typically, however, mobile operators have been providing full-band services in their area, which means that unnecessary power consumption is still happening. One thing to notice is that traffic loads do not change over time in all locations. It should be noted that the traffic varies according to the characteristics of the area and the subscriber, and thus the service quality of the mobile communication subscriber may be changed by such a change. In addition, it is necessary to avoid the factor that hinders the service quality of the mobile communication subscriber in this process.

3. PSi & PSo Algorithm

It is an ideal point of execution of power saving to minimize power consumption without affecting service quality of mobile subscriber. If you do not mind this ideal goal and run power saving, it is very likely that you will be shifting to negative side. When the service quality of the mobile communication subscriber is considered, the power saving level is lowered. On the contrary, if the power saving level is increased, the service quality of the subscriber is lowered. This means that when running power saving, you should not have to break down either your service quality or your power consumption. In this study, we have developed an algorithm that derives the optimal value between service level and power saving through three step approach.

① Power saving operation control variable regulation

② Subscriber service impact index calculation

③ PSi & PSo algorithm exploration

In order to find a clear power saving algorithm, we first define the control variables that can control the operation and clarify the input variables that the operator can set and control the algorithm. Then, in the step of measuring the change of the result, it is necessary to find an index capable of quantitatively judging the influence of the service of the mobile communication subscriber. After excavation, the amount of change must be analyzed through tracking and observation. After the analysis, we set the design direction of the algorithm by considering the determinants of the service impact. Finally, it is necessary to find a point that can maximize the power saving level while ensuring service quality for mobile phone subscribers. The PSi & PSo algorithm established and stipulated these step - by - step core requirements and repeated the process of setting and analyzing each variable and outcome indicator.

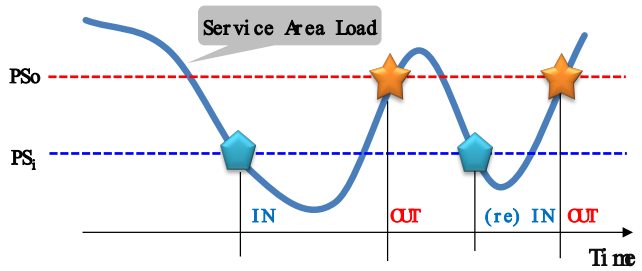

Figure 3: Power saving operation control variable

3.1. Control variables related to power saving operation

First, in order to control the power saving operation, PSi, which is the power saving operation start step and PSo, which is the step of canceling the power saving operation, are defined based on the total load value of the service area.

As shown in Figure 3, the load on the service area changes over time. There is no difference in the fact that there is a difference in the number of times the load increases and decreases in each service area, but changes with time. When the load of the service area falls below a certain level in consideration of this variability, the power saving mode is entered (IN), and the value of this moment is defined as PSi. Conversely, when the load of the service area rises to a certain level or more, power saving mode is released (OUT), and the value of this moment is defined as PSo. When the power saving mode is entered (IN), the equipment of the specific frequency is turned off, and the remaining frequencies that are not off are able to handle the traffic of the subscriber, and power consumption is reduced from this moment. When the subscriber and traffic increase and the load is increased at the moment, it is necessary to turn on the frequency that was turned off to secure the proper capacity. Is turned on. From this moment on, power consumption is not reduced. Two variables, PSi and PSo, allow specific frequencies to be turned on or off to accommodate changing traffic in the service area. However, frequent entry (IN) and release (OUT) to the power saving mode may occur depending on changing traffic and load, which negatively affects the service quality of the mobile communication subscriber. In this paper, we try to find a way to maximize the reduction of power consumption through power saving operation and to minimize the influence of service quality of subscribers in the process.

3.2. Definition of subscriber service impact indicators

Although there are various indicators for calculating the service quality in the mobile communication network, it is necessary to adopt the connection rate (%) and the truncation rate (%) that can comprehensively judge the quality of voice and data service. A new index CEI (Customer Experience Index) is calculated by multiplying two indicators and calculated by the following formula.

$$\text{Call Connection Rate}(\%) = \frac{Number\ of\ Connection\ Successful}{Number\ of\ Connection\ Attempt} \times 100 \quad (1)$$

$$\text{Call Drop Rate}(\%) = \frac{Number\ of\ Call\ Drop}{Number\ of\ Connection\ Successful} \times 100 \quad (2)$$

$$CEI(\%) = Call\ Connection\ Rate \times (100 - Call\ Drop\ Rate) \quad (3)$$

Equation 1: Estimation of the calculated index

Let's look at Equation 1. As shown (1), it is possible to determine the success rate when the mobile communication terminal attempts to connect to the wireless network for the first time, and the truncation rate can be determined based on the connection rate of the mobile communication subscriber. It is possible to judge the situation in which the connection is released irrespective of the will of the user. (1) and (2), the environment of the service to be connected to the first wireless network, and the maintenance level of the connected state after the connection, and calculates the instant when the mobile communication subscriber attempts to connect to the network through the CEI of (3). It can be used as an indicator to represent the quality from the moment to the end.

3.3. PSi & PSo algorithm

PSi and PSo, which are the control variables of power saving, are classified into three phases (high, mid, and lower) and the conditions for each stage are defined as follows.

Table 2: Understanding of PS control variable condition

Division	Step	Condition
PSi (Entry Variable)	High	Difficult to Entry
	Mid	Normal to Entry
	Low	Easy to Entry
PSo (Release Variable)	High	Easy to Release
	Mid	Normal to Release
	Low	Difficult to Release

Combining the three stages of PSi and the three stages of PSo, it can be combined the following nine cases. PSi & PSo value means integrated load of one site.

Table 3: Test Case by PS Control

Division	PSo(High): 30	PSo(Mid): 40	PSo(Low) : 50
PSi(High): 20	Case1	Case2	Case3
PSi(Mid): 30	Case4	Case5	Case6
PSi(Low): 40	Case7	Case8	Case9

Each case was tested in the commercial network of Namwon and Jangsu in Korea, which provides CA service of SK Telecom. The results of changing the PSi and PSo are summarized by the above CEI and the time when the equipment is off and not operated, and the cumulative calculated power saving value is added. Also, the values of PSi & PSo set in each case are arbitrarily set, and they are set to a wide range in order to derive the optimal value.

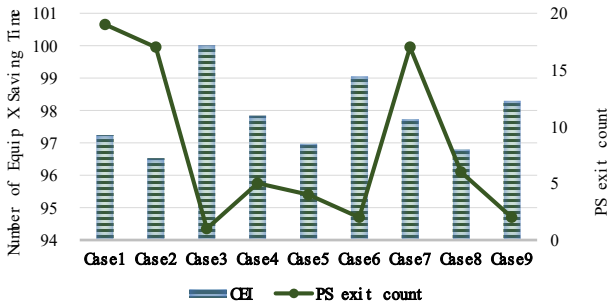

Figure 4 : Power saving exits and CEI by case

As shown in Figure 4, it can be seen that the CEI value varies depending on the case under test. And it can be clearly seen that it is inversely proportional to the number of times the power saving

mode is abandoned. In other words, the more frequent the entry and exit into the power saving mode, the more negative the service quality of the subscribers. Conversely, the lower the number of exits (the longer stay in power saving Mode), the less negative impact on the service quality of the subscriber can be interpreted. Case # 3, 6, and 9 had the fewest number of exits, and the service quality of the subscriber was maximized. As a result, it can be seen that adjusting the PSo to make it difficult to exit in power saving mode and reducing the number of exits has contributed to the optimum result preserving the CEI value.

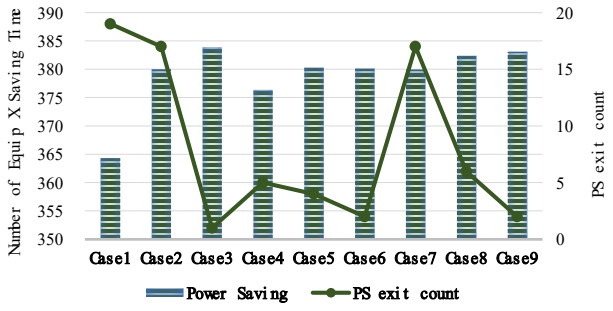

Figure 5 : Power saving level according to the number of power saving mode exits per case

The power saving level can be interpreted as PSi, which determines the entry, rather than the PSo condition, which interferes with the mobile communication subscriber experience when interpreting Figure 4 and Figure 5. In Case # 1, 2, and 3, which are difficult to enter, the power saving level is low and the condition of entry is high in Case # 7, 8, and 9.

3.4. Expanded application of PSi & PSo algorithm

The optimal values of PSi and PSo were selected as 20 and 50 respectively in SK Telecom. NOKIA developed a function to monitor the power consumed by mobile communication service equipment in real time. As a result of using this function, it is possible to save 0.12kW when 1 hour off of 2.6G equipment. We extended it to the commercial network in 2019 and saved about $ 93,000 over five months. Also, it is confirmed that CEI, which is an indicator of service quality, is maintained within the normal range.

As mentioned above, the lower the number of exits to the power saving mode, the lower the service quality of the subscriber can be prevented. As a result of applying power saving to 2.6G equipment in Jeju region of Korea, we found a device with maximum mode change count of 66 times. The site has a lot of tourists, and the traffic load is very volatile. There are two options for these areas. In order to maintain the service quality of the subscriber, it is necessary to abandon the power saving or set the PSi value low to make it difficult to enter the power saving mode (IN), thereby performing the power saving only for the necessary time. The author chose to give up power saving in the area. It is also important to reduce electricity consumption by reducing electricity consumption. However, it is because the company regards the service quality of its subscribers as more important. If one day the company's policy changes and minimizes operating costs become more important, it can turn into a situation where power savings can be applied to these areas and the service quality degradation of subscribers can be tolerated to some extent.

SK Telecom will continue the power saving in order to reduce the electricity cost to operate the network. However, it considers the quality preservation of service subscribers as the top priority and repeats the process of continuously checking the PSi & PSo algorithm and deriving the optimum value will be.

4. Conclusion

The PSi and PSo algorithms for the power saving method that maximize the reduction of power consumption while maintaining the service quality of the mobile communication subscriber are discussed. In order to derive the results, we have divided into 9 cases and the optimal value of PSi and PSo in the area managed by the author can be derived as PSi = 20 & PSo = 50. This number will vary depending on the traffic conditions in each region served. We concluded that we can adjust the power saving mode deviation to minimize PSo and access the ideal result of power saving execution if the PSi-controlled entry operation is easily set up. Although this study investigated algorithms for power saving, we did not discuss the various ISSUEs that can occur when applying this algorithm to commercial networks and the values that should be prioritized by each company's policy. This is because it depends on the value and philosophy of the mobile service provider and operator adopting this algorithm. However, the load fluctuation differs according to the service area and the load level that can be tolerated during the power saving execution may be different between the mobile communication company executing the same and the organization within it. Thus, the task of identifying the optimal value for the demand level is left as an additional research area. In addition, this approach has a weak point that it can partially obstruct the service quality of the mobile communication subscriber during the process, but it has a strong point that it is possible to draw conclusions that can be immediately expanded through direct execution in the commercial network.

Based on the results of this study, the operators who are interested in the reduction of the electricity cost among the network operation cost will be able to execute immediately because they have obtained the initial value and the method that maximizes the power consumption reduction while minimizing the quality deterioration of the subscriber.

ABSTRACT

The study proposed a self-driven guidance walker through user-oriented integration design. The common two-wheel drive performs left and right turn. By reducing the weight of the walker body, the durability of the battery can be increased. Secondly, we use a foldable structure so that the walker can be conveniently stored in a small space. A small number of sensors are required to reduce the complexity of signal processing. The front sensors of the walker are infra-red and ultra-sonic detectors, which determine and evade obstacles. The walker handle has three to five force sensors. The combination of the pressure data from these sensors can be used to determine the intent of the user, like turning or stopping.

1. Introduction

With the significant improvements in health science; the population of the senior citizens over 65 years old will be 15% by the year 2025 in Taiwan. Visually impaired persons often encounter difficulties in living an independent life. They need assistive devices to reduce visual obstacles.

Most of the seniors prefer to stay at home. When visually impaired people are unable to complete activities in their lives, they cannot participate in social activities. The assistance is vital for them to participate in ordinary life. Postmenopausal changes decrease the ability for visually impaired women to maintain postural stability [1]. Elderly blind persons had a slower walking speed, shorter stride length and longer time of gait [2].

In [3], the author addresses the motivation of elders to initiate exercise. The elderly are less active than the general population. Fear of injury is a common concern. Therefore, an exercise environment and regimen must be safe. Gradual exercise progression, increasing duration and frequency is significant. People should have the ability to exercise independently [4]. They should be able to maintain a sense of safety throughout the exercise.

1.1. Smart environment

Wireless technology evolved in recent years, designers can bring it to people with accessibility and ergonomic thinking. Many products found are based on a technology perspective and are less conceived from a user perspective. Article [5] suggests a way of deploying ubiquitous computing to cope with these difficulties. A friendly environment reveals itself by talking to the user with a ubiquitous module prototype.

Smart cane [6] offers voice and vibration alert. There is an antenna at the front of the guide stick to sense the RFID tag in the room. The guide wand transmits the signal to the blind person. Sometimes the contents of the tag cannot be read for a fast moving stick.

1.2. Active assistants

Active assistive walker usually has navigation ability. CMU developed robotic assistant in 2002 which lead the users to the destination. An active assistant gather environmental information, achieve obstacle avoidance with sensors. More sensors could increase the processing load and system cost.

An extended Kalman filter is applied to mobile robot navigation in a public environment which relies on geometric beacon [7]. Leonard et al. [8] used the geometric beacons for mapping and localization. The depth camera's data provides indoor localization. Received signal strength (RSS) constructs the radio maps through different data sets and the environment's coordinates [9].

Another study of Tsukiyama [10] proposed a monitoring system of solitary elderly based on urination, kitchen work, and physical cleanliness. The system monitors health status by using water flow sensors attached to faucets. Semi-autonomous control provided simple access through a handheld device. In case of problems, the robot contacts informal caregivers using teleoperation [11]. Another study [12] predicts the possible

* Fang Lin CHAO, Email: flin@cyut.edu.tw

movement according to the output of the force sensor, the direction of motion conveyed by varying the center of mass elevation. A semi-passive walking robot designed using antagonistic actuation [13] with two pairs of legs, parallel links, and one torso. The robot could walk on horizontal surfaces while hung on the bar to prevent falling. The toe length is sensitive with lateral distance, and gait pattern of robot locomotion [14]. Gait function can be used as reference data in the control process. A passive exoskeleton developed with a clutch-spring mechanism and calf muscles. The engaging and disengaging timings were optimized through simulation for extending knee joint application [15].

The active assistants face the challenge of a trade-off between computing power and weight. The pursuit of the function increases the power consumption. Excessive functionality also makes the user unable to learn or unable to afford it. Heavy parts and large battery are also challenges for this to be implemented in living situations.

2. Concept design and prototyping

We proposed the concept design of an active walker with less weight [16, 17] to fulfill the need of the elderly. Smartphones have remote access and communication ability through the USB or Bluetooth connection.

2.1. Design process

Many of the previous designs focused on special features. From the user interviews, we found that such a model is large in size and complicated to construct, which makes it difficult to use. Complex functions also result in increased power consumption and battery drain. Here, conceptual design proposed from the perspective of human factors with an appropriate function, size, and weight.
Figure 1 shows the design process, and user reflection was collect with ergonomic consideration. The design process set a priority of design goal and tradeoffs of product concepts to confirm feasibly.

The digital model creates a prototype 3D printing which utilized in user evaluation. Electrical parts and interface module are placed with mechanical elements. An existing smartphone app has a built-in position sensor and voice notice. The measured data and user's feedback results are collected to adjust the pressure sensing parameters to acquire better control.

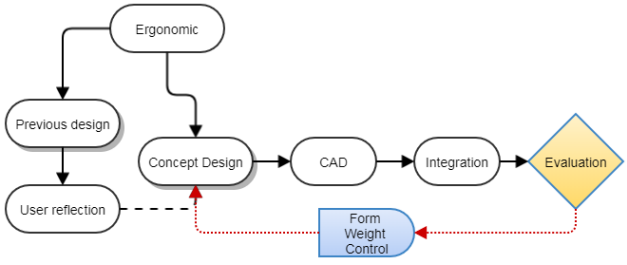

Figure 1: The design process of the people-oriented electromechanical integration design

As shown in figure 1, the ergonomic consideration ensures user's requirements and functional integration. Evaluation test confirms the product features through a series of measurements.

2.2. Electrical components and sensors

The electronic parts and mechanical components are combined to achieve appropriate functions through system integration. The electrical components primarily follow sensing and control circuits.

The walker's body has sensor units placed in front to determine and evade obstacles. The block diagram (Figure 2) shows the existing technologies such as motor controllers and sensors, which have widely been used in different fields. We proposed a link between pressure sensing and user intent.

2.3. Mechanical parts and chassis

The structural and mechanism components are configured with CAD system. The walker's handle (Figure 2) has pressure monitor sensors. The handle sensors located corresponding to palm and finger contact areas. The pressure gathered from the distribution of charges with thin-film sensors. The pressure distribution helps to verify the current status of the user and adjust the walker's speed (Figure 3).
The relationship between the visually impaired and the walker is like the way people lead them.

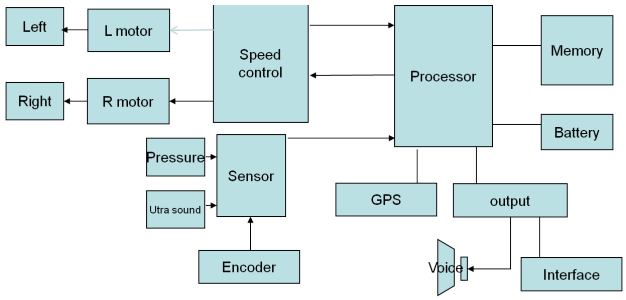

Figure 2: Functional block diagram using a smartphone to control, some software builds in the mobile app. via the Bluetooth interface.

The user configures the parameters of the walker to fit an individual's need. Typically, the handle has three to five sensors. The combination of the data from these sensors can determine the intent of the user (turning or stopping).

Figure 3: Perspective view of walker leads the visually impaired in the moving target.

3. Ergonomic design

The ergonomic design follows some rules; detail concerns: 1) the adjustable handle accommodates users of different heights within weight limit; 2) easy control and reduces the applied force; 3) fashionable style that is apart from handicap stereotypes.

3.1. Overall image

Primary purpose of the assisted walker is to take a walk with the visually impaired. Through the pre-set path and speed, the assisted walker allows the elderly to be involved in minor exercises in daily life, hence promoting a healthier lifestyle. The image of handicap is subjective to the acceptance of users. They are sensitive to negatively perceived in a social context. The form of the assisted walker is more aesthetically pleasing to customers, which may remove some of their mental pressures in purchasing and using the walker.

3.2. Weight and dimension

In [16] participants performed different lifting tasks, with three lifting heights. The working heart rate of the participants showed a significant difference during lifts. One of the design targets is to make it less heavy so that an individual can lift it comfortably. Put the user's needs to the forefront, the weight of the walker was reduced to avoid injury and easy to carry. So we need to choose to remove unnecessary elements and function.

The weight of the car is 23Kg referring to the requirements of airline baggage which is a reasonable load for user. The parts are selected and configured under the premise of this weight limit.

3.3. Way of control

Safety is an important consideration for the elderly. To avoid the sudden rotation caused by the interference of walking, we set the stop button near the thumb. When the elderly consciously can't follow or is too fast, they can manually stop the helper to prevent potential danger.
A user may choose the assistive mode and listen to the related information. Seniors face usability issues related to physical, mental, and cognitive impairments. Most of the elderly have limited experience with technology.

Observing the guidance for blind people is helpful for walker design. Usually, people follow the below steps to activate by a sighted person.

Offer an elbow and back up to the person's outstretched hand. Walk at a comfortable pace by remaining a slightly behind.

Keep arms bent at a 90-degree angle. The visually impaired person will remain a half step behind as you begin walking.

Stop when you need to turn around and tell your follower. He or she will release your arm and wait until you offer it again.

Imagine that when we assist the elderly in crossing the road, we also support him or her on one side; so this is a more natural form of assistance. We choose one-handed operation; the prerequisite is that the elderly can still walk normally. It also avoids interference with the machine while holding both hands.

4. Evaluations

The measured pressure determines the user's intention. The implement procedures are described in Figure 4.

4.1. Moldable clay

Moldable clay was used to demonstrate deformation during initial test. The handle was wrapped with clay evenly. The deformation of clay is related to the pressure distribution during usage.

User's operations would be recorded in the change of shape to determine possible positions of sensors.

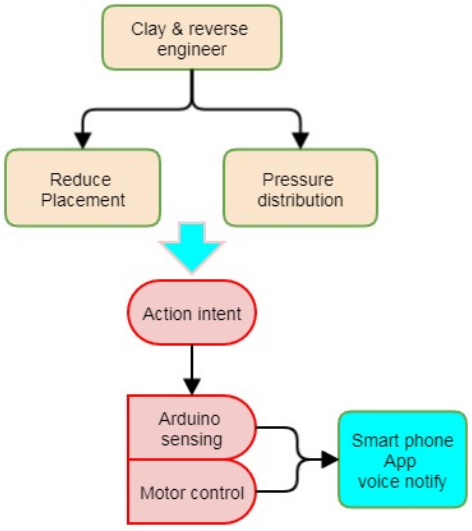

Figure 4: The ergonomic study and implement procedures

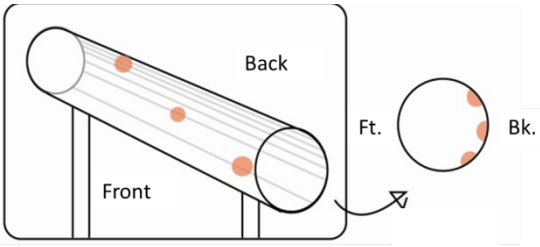

Figure 5: The side view of the pressure detector located on the handle (red dots are high-pressure area). The leading edge (Front or Ft.) is the direction of movement, and the trailing edge (Bk.) is the side of user.

There is less variation among the elderly in terms of palm-size. We choose the positions of sensors according to the magnitude of geometrical change (Figure 5).
When the old man is led forward, he may be towed and fall if the walker runs fast. If the walker turns quickly, the users also have challenges to follow. The sensors acquired the intent and conditions of the elder; so that the robot can adjust its speed.

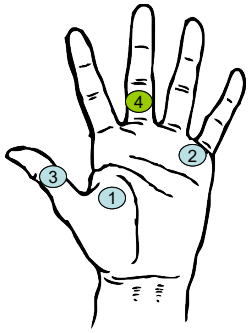

Figure 6: Sensor contact location

4.2. Pressure distribution

As shown in Figure 6, a user holds the handle during a walk. We adjusted the speed and direction of movement based on the pressure distribution. The purpose is to understand the appropriate location to detect the action intently. In this experiment, the driver

did not have a built-in processor and measurement device, so an external sensor and wire is employed to transmit directly to the host PC for subsequent design.

Figure 7: Measurement of pressure distribution.

We will start with five sensors and then re-evaluate that of fewer sensors (3 or 4) in a suitable position based on the pressure distribution observed from the clay.

Five sensors

We collect walking data of five sensors with five participants (Figure 7) to identify the pressure distribution. The measurements is based on the following situations.

- Condition 1： Right-hand control, go forward and intend to turn left,
- Condition 2： Right-hand control, go ahead and expect to turn right,
- Condition 3： Right-hand control, go forward and plan to stop.

The measured results are listed in Table 1-3.

Table 1: Pressure of left turn

User	Thumb	Index	Middle	Ring	Little
A	Low	High	Medium	Low	Low
B	Medium	High	Low	Low	Low
C	Low	High	Low	Low	Low
D	Low	Low	Low	Low	Low
E	Low	Low	Low	Low	Low

We find some variation in Table 1-3, such as:

- Table 1: the index finger of participant A.B.C is different from that of participant D and E.
- Table 2: the little finger pressure of participant E is different from that of others.
- Table 3: the index finger pressure of participant B is different from that of others.

Table 2: Pressure of right turn

User	Thumb	Index	Middle	Ring	Little
A	High	Low	Low	Medium	High
B	Medium	Medium	Low	Low	High
C	High	Low	Low	Low	High
D	High	Low	Low	Low	High
E	High	Low	Low	Low	Low

Table 3: Pressure of sudden stop

User	Thumb	Index	Middle	Ring	Little
A	Low	Medium	Medium	Medium	Medium
B	High	Low	Low	Low	Low
C	Low	High	High	High	High
D	Low	High	High	High	High
E	Low	High	High	High	High

Discussion

Depending on the size of the participant's hand, some users apply pressures by the palm, which made the finger pressure to be less apparent. This variation causes a limitation of using pressure data to determine the user's intent.

The way to overcome this difference is to reduce the unnecessary sensors and to tailor the handle's shape according to the size of the user's hand. Just as people buy a shoe with a specific size, the handle's shape needs to fit the user's hand.

The personal handle can be printed in a 3D facility at a reasonable cost — the specific handle shape made according to the clay model, and adjusted 3D model by reverse engineering. Afterwards, the sensors are then placed in the correct position of the handle.

Three / four sensors

The price of the sensor is high, so we hope to know the possible placement position with a limited number of sensors. Three and four sets of sensors placed to record the user's main motion intent sequentially. The user holds the handle and records the pressure at each position. Based on observations, we infer the position of the sensor that is suitable for the user.

The measurement of three/four sets of sensor placement summarized in (Figure 8, 9). The position for the three sets of sensors for different users is not exactly the same, which is due to the difference in the size of the palm and personal holding habits.

According to the three intentions we want to distinguish (scenario: left turn, right turn, and stop), the test results of the three sensors (Figure 8). We found that the three values at sensor 1 are identical; there is a significant difference in sensor 2; the right turn is similar to the stop at sensor 3. Although the sensor 2 is able to

resolve the three intents, in order to improve the reliability of the results, we continue to try four sensors.

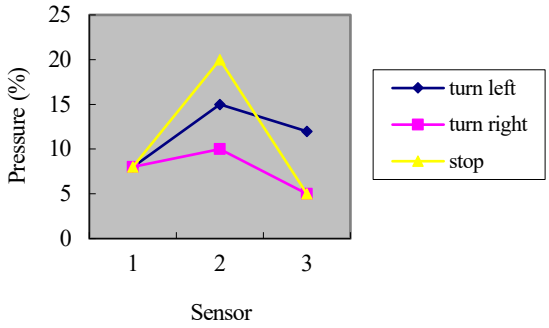

Figure 8: Pressure test results when using three sensors. The three lines represent the values of the pressures presented at each sensor when three actions are performed (left turn, right turn, and stop). The pressure sensing distribution is different when performing three actions.

The fourth pressure sensor was added to the first section of the finger joint (the leading edge of the walking handle). As shown in Figure 9, the test results of the four sensors are shown in the figure. We found that the three values of intent at sensor 1 are identical; there is a notable difference at sensor 2; the right turn is still similar to the stop at sensor 3; there is a significant difference at sensor 4. The sensor 2 and 4 are able to verify the three intents reliably.

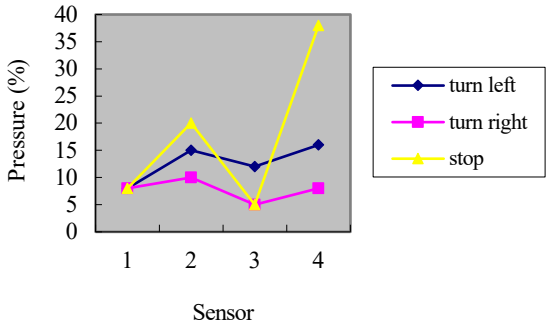

Figure 9: Pressure test results when using four sensors. The three lines represent the values of the pressures presented at the four sensors when performing three actions (left turn, right turn, and stop). The difference in pressure sensing distribution is more obvious when performing three kinds of actions.

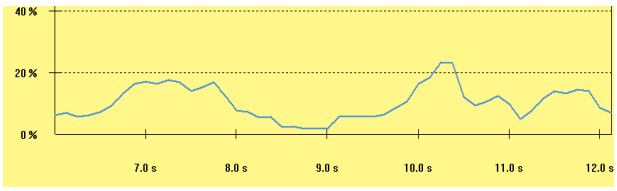
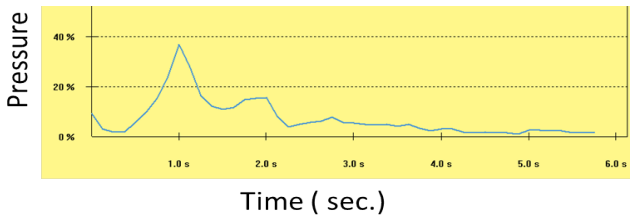


4.3. Pressure variation with time

Thin-film sensor applied to acquisition the pressure variation with time — f sensors placed on the different contact area. The sensor is 0.208mm thick and 14mm in width and sensing diameter is 9.53 mm (Figure 10). The sampling rate is 20 Hz and the data is fetched through the serial port.



The measured pressure is plotted in Figure 11; the maximum force occurs in two situations: while turning, or when the walker hits an object. The maximum value does not last long (0.3-0.4 sec.). The result of the fourth sensor near the middle finger is shown in Figure 11(a), it can be found that in the temporary stop operation situation, the value of the fourth sensing zones becomes significantly more extensive, and scenarios can be separated. The measured data show that the 'stop' scenario, the sensor provide good variation to distinguish it at 10.6 sec. Figure 11(b) has a gently varying waveform showing a continuous force-applying state, and a glitch shows a collision.

Figure 10: Thin-film sensor and configurations

(a)

(b)

Figure 11: Sensor's responses: (a) the second sensor during turns left, (b) the fourth sensor during the collision and stop.

We divide the value of the sensor into three different levels; low-level (< 5%), high-level (>14%), the median level in between. If the signal maintained at the same level for a certain period, the phenomenon presented a user's action. The maximum pressure value maintained for 0.3 sec during turning moment (Figure 11.a).

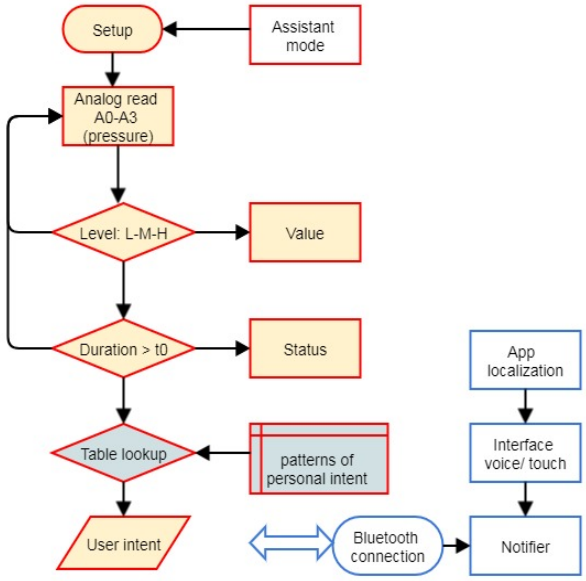


Figure 12: Flow chart of the Arduino sensing module

4.4. Implementation

The sensing module of the walker can implement with Arduino, which connects the four pressure sensors to the analog input pins of A0 to A3 (digital value 0-1023). The percentage of the Y-axis on the left side of Figure 11(b) represents the maximum measured value of the pressure sensor. We set a high pressure zone is above 14% (digital value 143), and a low pressure zone is below 5% (digital value 51), and a medium zone between the two (range 5%-14%). For example, in 2sec time (sampling rate is 20 Hz), the high pressure value is in the range of 0.75 seconds to 1.3 seconds, 1.75 seconds to 2.0 seconds; the low pressure time is between 0.1 seconds and 0.45 seconds, and the rest is medium pressure value. When maintaining the same level for a period of time, we can compare the pressure distribution of the four pressure sensors to predict the user's intention. The sensing module determines the rotation or deceleration through a logic judgment and controls the rotation speed of the motor through the voltage value of the output pin (Figure 12). There are many applications on the phone that handle positioning and navigation. The sensing module can also be connected to the mobile phone via Bluetooth, and the action to be performed is notified to the elderly by the voice of the mobile phone without being overwhelmed.

5. Conclusions

The walker is suitable for elderly in public environments, such as hospitals or retirement homes. The concept design emphasized on ergonomic features; such as weight reduction, folding, sensing the user's intent, and the like. Physical prototype and hardware circuit implementation is ready-to-expand Arduino module to perform force sensing. The smart phone app helps the elderly to move in a safe environment.

Conflict of Interest

The authors declare no conflict of interest.

ABSTRACT

Convolutional LSTMs are widely used for spatiotemporal prediction. We study the effect of using different activation functions for two types of units within convolutional LSTM modules, namely gate units and non-gate units. The research provides guidance for choosing the best activation function to use in convolutional LSTMs for video prediction. Moreover, this paper studies the behavior of the gate activation and unit activation functions for spatiotemporal training. Our methodology studies the different non-linear activation functions used deep learning APIs (such as Keras and Tensorflow) using the moving MNIST dataset which is a baseline for video prediction problems. Our new results indicate that: 1) the convolutional LSTM gate activations are responsible for learning the movement trajectory within a video frame sequence; and, 2) the non-gate units are responsible for learning the precise shape and characteristics of each object within the video sequence.

1 Introduction

Problems in video prediction (spatiotemporal prediction) are important in both research and industry. Examples include human action recognition [1], spread of infections, medical predictions [2], weather forecast prediction [3], and autonomous car video prediction systems [4, 5].

Spatiotemporal (e.g. video) datasets are challenging to predict due to the spatial and temporal information which the datasets carry through time. In sequence prediction problems, the prediction at the current step depends primarily on the previous history. Making a near future prediction requires an computational tool that is able to discover both the long and short-term dependencies in the data. Initially, recurrent neural networks (RNN) [6] were proposed to model data which was sequential in nature. However, straightforward RNNs have major drawbacks. RNNs suffer from the vanishing/exploding gradient problem which prevents them from learning long-term data dependencies [7–9]. There are several gate-based RNN models that attempt to solve this classic problem. These include the long short-term memory unit (LSTM) [7], peephole LSTM [10], gated recurrent unit (GRU) [10], and minimal recurrent unit (MRU) [11].

This paper studies the LSTM architecture as an attractive architecture architecture to perform spatiotemporal (video) prediction. In addition, Gref et al. [12] empirically showed that the LSTM is the most efficient recurrent architecture to solve for speech recognition, handwriting recognition, and polyphonic music modeling [12]. The LSTM has the highest number of gates compared with other gated units [9–11]. Furthermore, the choice of the activation function for gate and non-gate units within the LSTM has an essential effect on the the LSTM's function [12].

This work studies gate activations and non-gate activations within the LSTM architecture. In most APIs the gate activations and non-gate activations are known as recurrent activations and unit activations, respectively. To solve image and video related problems, different convolution-based models are used such as in Kalchbrenner et al [13], Elsayed et al. [5], Lotter et al. [4], Finn at al. [14], and Wang et al. [15]. However, the most widely used architecture for video prediction to-date is the convolution LSTM. Hence, we performed our experiments on a convolution-based LSTM (convolutional LSTM) network model [4]. We studied the effect of different gate activation and unit activation

https://dx.doi.org/10.25046/aj040234

functions through the learning process of the convolutional LSTM architecture [3]. Our experiments use the convolutional LSTM found in the Keras deep learning framework [16]. Training was performed on the moving MNIST dataset as the most commonly used benchmark for video prediction problems [17].

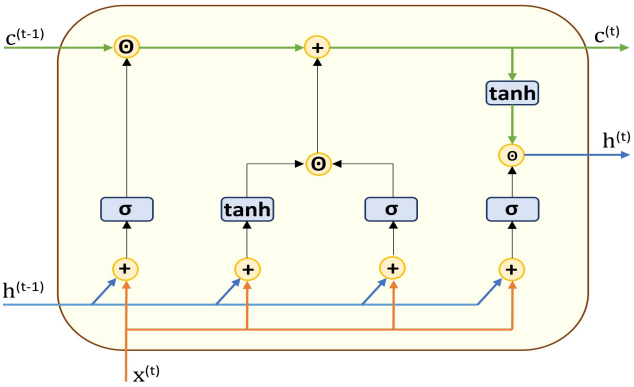

Figure 1: The unrolled LSTM architecture. The memory-state and output lines are time-evolving and labelled c and h, respectively. The CEC is indicated by the plus sign on the c line. The level of description is coarse enough so that this could either depict a standard LSTM or a convolutional LSTM.

In our empirical study, we worked with a model than what was needed for optimal prediction. Specifically, it had fewer parameters. This reduction allows us to more clearly see the effect of gate and unit activations on the convLSTM model without contamination by influences of other high-effect parameters. For example, it avoids saturation effects on the model accuracy which helps to see changes in activation function effects [18]. Our study compares different activation functions on a simple convolutional LSTM model for spatiotemporal (video) prediction task. We investigated the responsibilities of the convolutional LSTM gates and unit activations over the training process. Furthermore, we found the most appropriate function to be applied for the gates and for the unit activation for solving video prediction problem.

2 Convolutional LSTM

The LSTM [7] is the first gate-based recurrent neural network. As noted earlier, it was motivated by the need to mitigate the vanishing gradient problem and did so by using the principle underlying a constant error carousel (CEC) [7] to improve the learning of long-term dependencies. This was implemented by adding a memory-state line to the architecture (Figure 1). This memory-state line can retain (remember) the recurrent values over arbitrary time intervals. Gres et al. [8] added a forget gate to the LSTM cell to allow information to be removed from (forgotten) the memory-state line. This gate was trainable so that the module could learn when stored information was no longer needed. Gers et al. [10] improved the design by adding so-called peephole connections from the memory cell to the LSTM gates. The peephole connections enable the memory line to exert control over the activation of all three of the gates. This helps the LSTM block to avoid vanishing gradients and also helps learning of precise timing in conjunction with Constant Error Carousel (CEC) [8]. The CEC is the key ingredient mitigate the vanishing gradient problem.

LSTMs are used in several application areas including speech recognition [19,20], language modeling [21], sentiment analysis [22], music composition [23], signal analysis [24], human action recognition [1], image caption generation [25], and video prediction [3,4,17,26].

The convolutional LSTM (convLSTM) was introduced in 2015 by Shi et al [3] for weather precipitation forecast prediction task. This is an enhancement to the LSTM discussed previously. The crucial change is that the data within the module takes the form of a multichannel 2D feature map (image stack). The convLSTM improves predicted video on data sets of evolving precipitation maps compared to the non-convolutional LSTM. Apparently, it captures spatiotemporal correlations better than non-the standard variant [3,17].

An unrolled convLSTM module in Figure 1 can be either standard or convolutional because it does not make the relevant internal operations and weights explicit. Like the standard LSTM, the architecture has three gates indicated by the activation functions labeled σ. These are the forget, input, and output gates [9]. There are two non-gate units which are labeled with tanh activation functions. The convLSTM gates (input, forget, and output) have the ability to multiplicatively attenuate the outputs of tanh units and the value on the $c^{(t-1)}$ line. The forget gate attenuates information deemed unnecessary from the previous cell memory state $c^{(t-1)}$. $h^{(t-1)}$ is the convLSTM cell output at time $t-1$, and $h^{(t)}$ is the output of the convLSTM cell at time t. $x^{(t)}$ is the current video frame target at time t. $c^{(t-1)}$ and $c^{(t)}$ are the memory cell states at consecutive times.

The following equations calculate all of the gate and the unit values based on the Gers et al. [8] LSTM combined the convolutional model of Shi et al. [3]. These operations should be compared with Figure 2.

$$i^{(t)} = \sigma(W_{xi} * x^{(t)} + U_{hi} * h^{(t-1)} + b_i) \quad (1a)$$

$$g^{(t)} = tanh(W_{xg} * x^{(t)} + U_{hg} * h^{(t-1)} + b_g) \quad (1b)$$

$$f^{(t)} = \sigma(W_{xf} * x^{(t)} + U_{hf} * h^{(t-1)} + b_f) \quad (1c)$$

$$o^{(t)} = \sigma(W_{xo} * x^{(t)} + U_{ho} * h^{(t-1)} + b_o) \quad (1d)$$

$$c^{(t)} = f^{(t)} \odot c^{(t-1)} + i^{(t)} \odot g^{(t)} \quad (1e)$$

$$h^{(t)} = tanh(c^{(t)}) \odot o^{(t)} \quad (1f)$$

The the input, forget, and output gate activations s are denoted $i^{(t)}$, $f^{(t)}$, and $o^{(t)}$. σ denotes logsig. The gates have activation values falling in the interval $[0,1]$ where 1 means completely open and 0 means completely closed. $g^{(t)}$, is the current input. $c^{(t)}$ represents the current memory module state. $h^{(t)}$ represents the current output. b_i, b_g, b_f, and b_o are biases for the respective gate. W's and U's are the feedforward and

recurrent weights, respectively. "⊙" denotes element-wise multiplication, and "∗" denotes the convolution operator.

Figure 2 shows the arithmetic operational level of the convLSTM architecture where the convLSTM components and their corresponding weights are shown explicitly.

3 Activation Functions

As explained earlier, gate units usually have sigmoid (range $[0,1]$) activation functions and non-gated units usually have *tanh* activation functions. This paper studies the effects of using different activation functions for these units. This section reviews the most common activation functions used. All of the functions discussed are nonlinear.

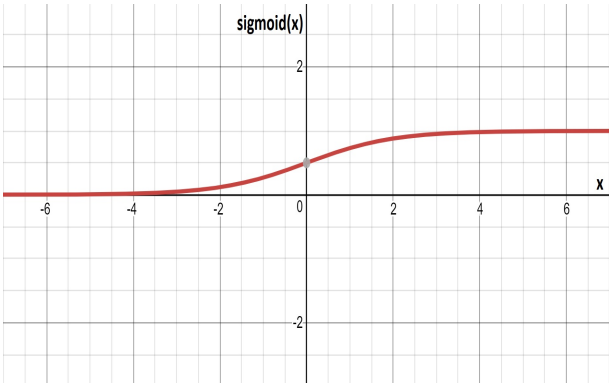

Figure 3: The curve of the logsig (σ) function.

3.1 Logsig Function

The logistic sigmoid (logsig) function [27] is shown in Figure 3. It is given by the following equation:

$$f(x) = \sigma(x) = \frac{e^x}{e^x + 1} = \frac{1}{1 + e^{-x}}, \tag{2}$$

The logsig is commonly denoted by $\sigma(x)$, where $x \in (-\infty, \infty)$ and $\sigma(x) \in (0,1)$. The logsig is historically common in network models because it intuitively represents the firing rate of a biological neuron. The logsig is still used in recurrent models for gating purposes. The input value is usually known because it appears in the feedforward sweep of the network. Because of this, its derivative can be computed efficiently as shown in (3).

$$f'(x) = \sigma'(x) = f(x)(1 - f(x)) \tag{3}$$

3.2 Hard-Sigmoid Function

The hard-sigmoid (hardSig) function is considered a noisy activation function. HardSig approximates logsig function by taking the first-order Taylor expansion around zero and clipping the result according to function's range $[0,1]$. Hardsig appears in Figure 4 and is calculated as follows:

$$hardSig(x) = \max(\min(0.25x + 0.5, 1), 0) \tag{4}$$

This function allows a crisp decision for the gradient during function saturation phase to be either fully on or fully off. In the non-saturation range near zero, hardSig is linear. This helps avoid vanishing gradients [28].

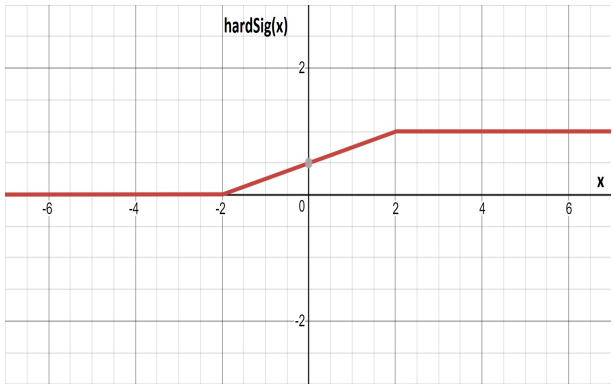

Figure 4: The curve of the hardSig function.

3.3 Hyperbolic Tangent Function

tanh is a saturating activation function. It is typically used as the recurrent activation function in RNNs [6].

In some cases, tanh is considered as cheaper for gradient evaluation in comparison to the logsig function. The function graph appears in Figure 5 and is specified by (5):

$$\tanh(x) = \frac{\sinh(x)}{\cosh(x)} = \frac{e^x - e^{-x}}{e^x + e^{-x}} = \frac{e^{2x} - 1}{e^{2x} + 1} \tag{5}$$

$$tanh'(x) = 1 - tanh^2(x) \tag{6}$$

A convenient property of the tanh activation function is that calculating its first derivative from a known input value is easy as seen in Eqn. (6).

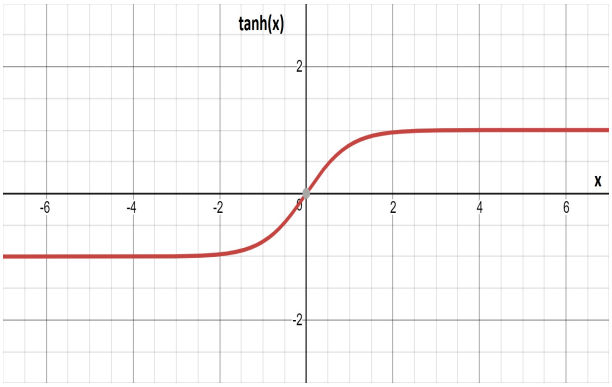

Figure 5: The curve of the Hyperbolic Tangent function.

3.4 SoftSign Function

The SoftSign function was introduced in [29]. Its grahp is given in Figure 6 and is specified by:

$$SoftSign(x) = \frac{x}{1 + |x|} \tag{7}$$

The SoftSign function range is $(-1, 1)$ and the function domain is $x \in (-\infty, \infty)$. The first derivative of SoftSign also can be evaluated simply as the following:

$$SoftSign'(x) = \frac{x}{(1 + |x|)^2} \tag{8}$$

SoftSign is an alternative function to hyperbolic *tanh*. In comparison to *tanh*, it does not saturate as quickly, improving its robustness to vanishing gradients.

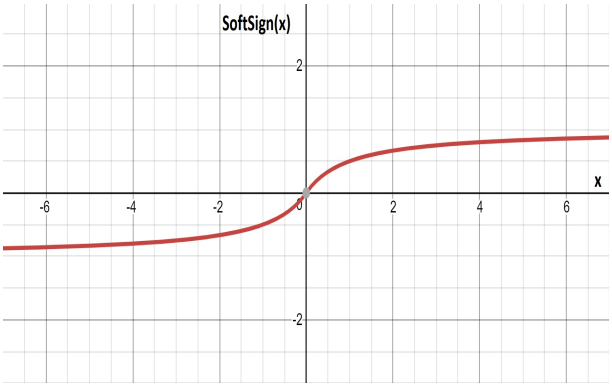

Figure 6: Curve of the SoftSign function.

3.5 ReLU Function

The rectified linear unit (ReLU) is very efficient compared to other activation functions. It was proposed in [30]. For $x \geq 0$ it is the identity function and appears in Figure 7. ReLU is defined by:

$$ReLU(x) = max(x, 0) \tag{9}$$

Its has domain $x \in (-\infty, \infty)$ and range $[0, \infty)$.

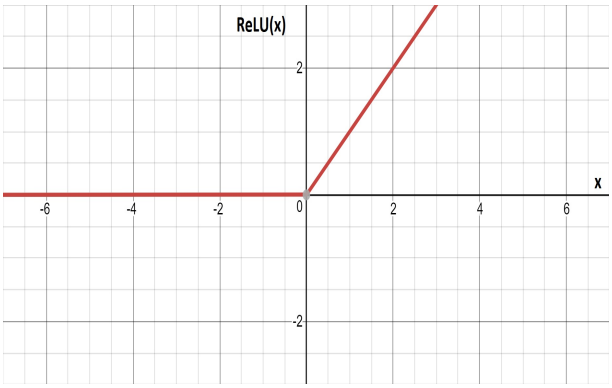

Figure 7: The curve of the ReLU function.

3.6 SoftPlus Function

The SoftPlus function (Figure 8) was proposed in [31]. It modifies the ReLU by applying a smoothing effect [29] and is defined:

$$SoftPlus(x) = \ln(1 + e^x) \tag{10}$$

with $x \in (-\infty, \infty)$ and range $(0, \infty)$. Its derivative is:

$$SoftPlus'(x) = \frac{1}{1 + e^x} \tag{11}$$

Like the SoftSign function, the SoftPlus function is used only in specific applications.

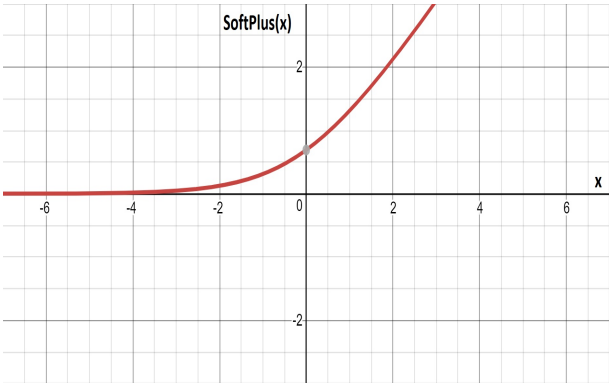

Figure 8: The curve of the SoftPlus function.

3.7 ELU Function

The exponential linear unit (ELU) was introduced in [32] to avoid a zero derivative for negative input values. The ELU achieved better classification accuracy than ReLUs [32] and is defined by:

$$ELU(x) = \begin{cases} \alpha(e^x - 1), & \text{if } x < 0 \\ x \quad , & \text{otherwise} \end{cases} \tag{12}$$

Its domain and range is $(-\infty, \infty)$. Assuming that $\alpha = 1$, its graph is shown in Figure 9 .

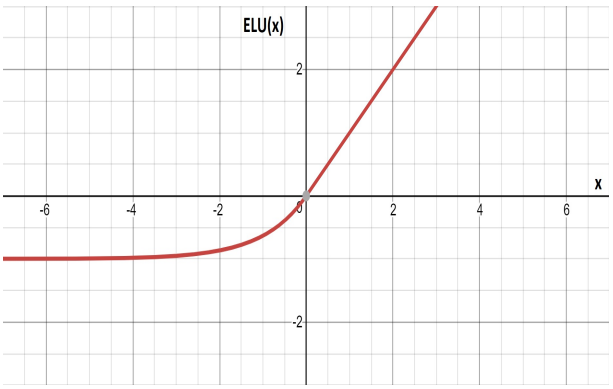

Figure 9: The curve of the ELU function.

3.8 SELU Function

The scaled exponential linear unit (SELU) an ELU function modified with two hyperparameters. Its definition follows:

$$SELU(x) = \lambda \begin{cases} \alpha(e^x - 1) & , \quad \text{if } x < 0 \\ x\,, & \text{otherwise} \end{cases} \tag{13}$$

Its domain is the same as the ELU function, but its range is limited to $-(\lambda\alpha, \infty)$. λ and α are hyperparameters that depend on the mean and variance of the training data. If the data is normalized to $\mu = 0$ and $\sigma = 1$, then $\lambda = 1.0507$ and $\alpha = 1.6732$ whose graph appears in Figure 10.

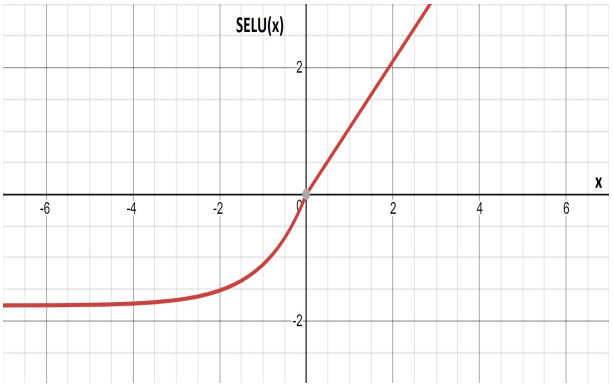

Figure 10: The curve of the SELU function.

The first derivative of SELU is calculated as shown below:

$$SELU'(x) = \lambda \begin{cases} \alpha e^x & , \quad \text{if } x < 0 \\ 1\,, & \text{otherwise} \end{cases} \tag{14}$$

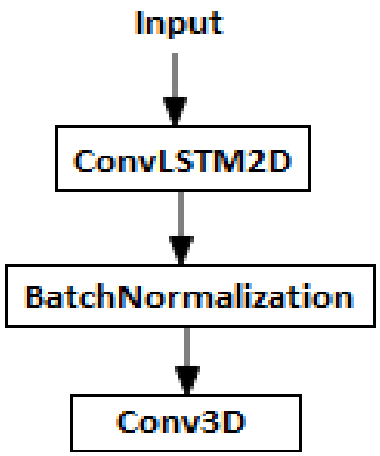

Figure 11: The model architecture used in our experiments.

4 Experiments and Results

This section the results of comparing different activation functions for both the gate units and non-gate units. We chose the functions described in the previous section. They are commonly available in deep learning frameworks. We explore the question of which activation function is best as a gate activation and which is best as a unit activation for convolutional LSTMs in an unsupervised context. Moreover, we want to understand the differential behavior of the gate and non-gate units as a result of training.

We calculated several measures: training loss, validation loss, elapsed training time, and appearance of the predicted video frames compared with ground truth. We did our experiment and analysis on the moving MNIST [17] as explained in the introduction. The moving MNIST dataset consists of 10,000 different video sequences. Each sequence has a length of 20 frames. Each frame is 64×64 pixels and contains two randomly selected handwritten digits from the standard 28×28 MNIST dataset. The two digits move randomly within the frame [17].

4.1 Framework

Our framework uses Shi's et al. [3] convLSTM. Because we had limits on our computing power, our test were serendipitously performed using a small model with insufficient learning capacity for fully accurate predictions. However, this did let us more clearly see the effects of the activation function manipulations. The reduced capacity models helped us avoid ceiling effects so that we could see differential performances in the activation functions.

The model is implemented using the Keras API [16] and appears in Figure 11. It consists of three layers. The first layer is a convLSTM with 40 size 3x3 kernels. The next layer is batch normalization. Finally, we used $3 \times 3 \times 3$ kernel to get the video output shape. Table 1 provides details of the model parameters.

The Adam optimizer [33] was used with initial learning rate $r = 0.001$, $\beta_1 = 0.9$, $\beta_2 = 0.999$. The cost

Table 1: Description of the proposed model architecture used in this study.

Layer (type)	Output Shape	Param Number
ConvLSTM2D	(None, None, 64, 64, 10)	4000
Batch Normalization	(None, None, 64, 64, 10)	40
Conv3D	(None, None, 64, 64, 1)	271
Total params	4,311	
Trainable params	4,291	
Non-trainable params	20	

function was MSE [34].

Each input was a 20-frame video randomly sampled from moving MNIST [17]. As previously mentioned, the amount of input data is 10,000 videos each of length 20 frames. We used 9,500 for training and 500 for validating.

The task is proposed for sequence to sequence video prediction. A sequence of five future frames were predicted using the previous five frame sequence. Because of the reduced learning capacity mentioned at the beginning of this section, the trained network could predict only the two temporally closed frames clearly and the rest were unclear because of the reduced learning capacity in the model.

We used an Intel(R) Core i7 – 7820HK, 32GB RAM, and a GeForce GTX 1080 GPU. Training was for ten epochs in each experiment. In each epoch, we fit 475 batches where each batch size was set to 20 for our model experiments. All parameters were held constant over all experiments except for the recurrent activation function that was being tested.

4.2 Results

Our results pertain to the relative performance of varied activation functions for gate and non-gate units.

4.2.1 Results for Gate Activation Functions

For a fair comparison of different gate activation functions, we only changed the gate activation functions and preserved the remaining parameters with the same initializations and values during each experiment. The gate effects were studied collectively because we used the default convolutional LSTM module in found in the Keras API. The API allowed us to change all the gate functions at once (not each gate separately) for setting up an experiment.

For this experiment, the gate activation functions apply to all three gates gates described in Eqns 1a, 1c, and 1d. Accordingly, only functions with range $(0, 1)$ are eligible. Thus, this experiment only compared the logsig and hardSig functions.

Table 2 shows the performance results, including average elapsed training time (in minutes), MSE loss (Loss-MSE) for training, validation loss (Val-loss-MSE), percent accuracy (Accuracy) for $n = 3$, and the standard error (SE) for training loss ($n = 3$). The elapsed training time using the hardSig activation is higher than the logsig function by about ten percent. We are not sure why this happens. In Table 2, both logsig and hardSig have nearly exactly the same MSE and MAE.

Figure 12 shows the training and validation loss for the logsig and hardSig activation functions. From the figure, one can also see that the loss average difference between the training and validation runs using the hardSig function is smaller than the logsig function.

We also examined the differences between the accuracy of both training and validation runs using the logsig versus hardSig functions. The average ($n = 3$ for all data points) accuracy values for each function appear in Figure 13. Blue represents training and yellow represents validation accuracy. Both logsig and hardSig functions have similar validation and training accuracy It is also temporally time. The hardSig shows a more comparable accuracy among the training and validation curves. Moreover, hardSig curve does not contain frequent validation accuracy drops down as in logsig curve.

Figure 14 visually shows the prediction results for both the sigmoid and hardSig gate activations of the model. The first row shows ground truth. The two rows below show predictions using the logsig versus hardSig gate activation functions. Both logsig and hardSig are comparable. From the figure, both functions show that the model attempts to learn the digit movement trajectories as shown in each of the prediction frames. The 'double exposure' appearance indicates that the prediction retains the object's previous location within the predicted frame. Despite the double exposure look, digit shape is preserved. Moreover, the hardSig function shows better prediction accuracy than the sigmoid. This agrees with the Gulcehre et al. [28] theory stating that noisy activation functions are better than their non-noisy counterparts.

This experiment suggests the gate activation functions of the convolutional LSTM play a role learning the movement trajectories.

4.2.2 Results for Non-gate Activations

Our second experiment analyzes which activation function is best to use for non-gate units (input-update and output activation) as seen in Eqns. 1b and 1f. We applied the same setup and initialization as in the first experiment except that we retained all the convLSTM parameters. Only the set of possible unit activation functions were manipulated. Gate activations were

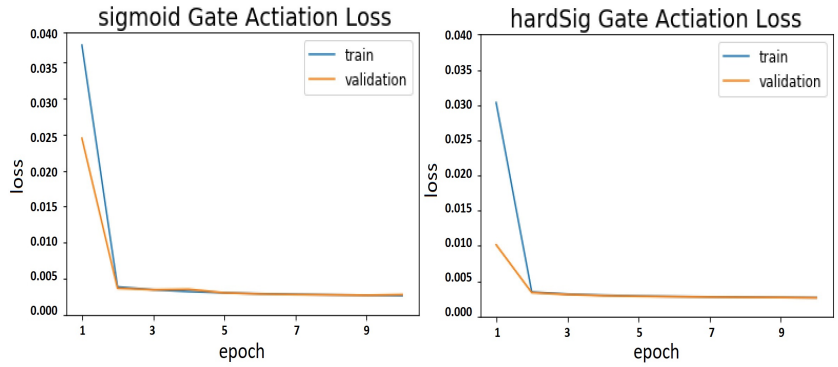

Figure 12: Training and validation loss for each gate activation function over each training epoch. In the left figure, all three gate units used the logsig activation. In the right figure, all three gate units used the hardSig activation function.

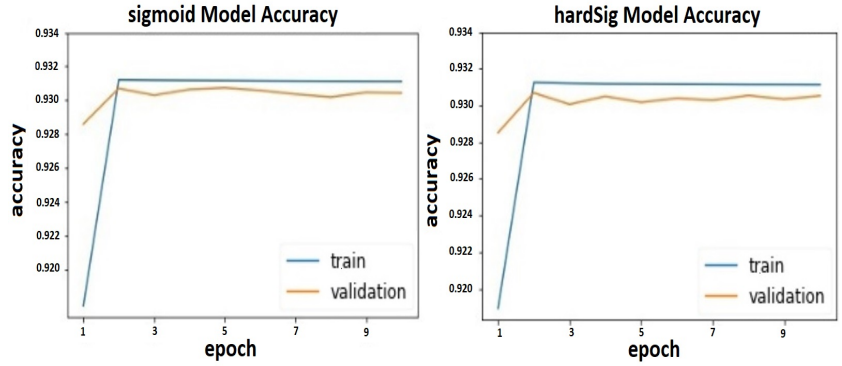

Figure 13: Training and validation accuracy for each gate activation function over each training epoch.

Table 2: Gate Activation Effect on the ConvLSTM Training Process.

Activation function	Training Results					
	Time (Minutes)	*Loss (MSE)*	*Val-loss (MSE)*	*Mean Absolute* Error (MAE)	*Accuracy (Percentage)*	*SE (Loss)*

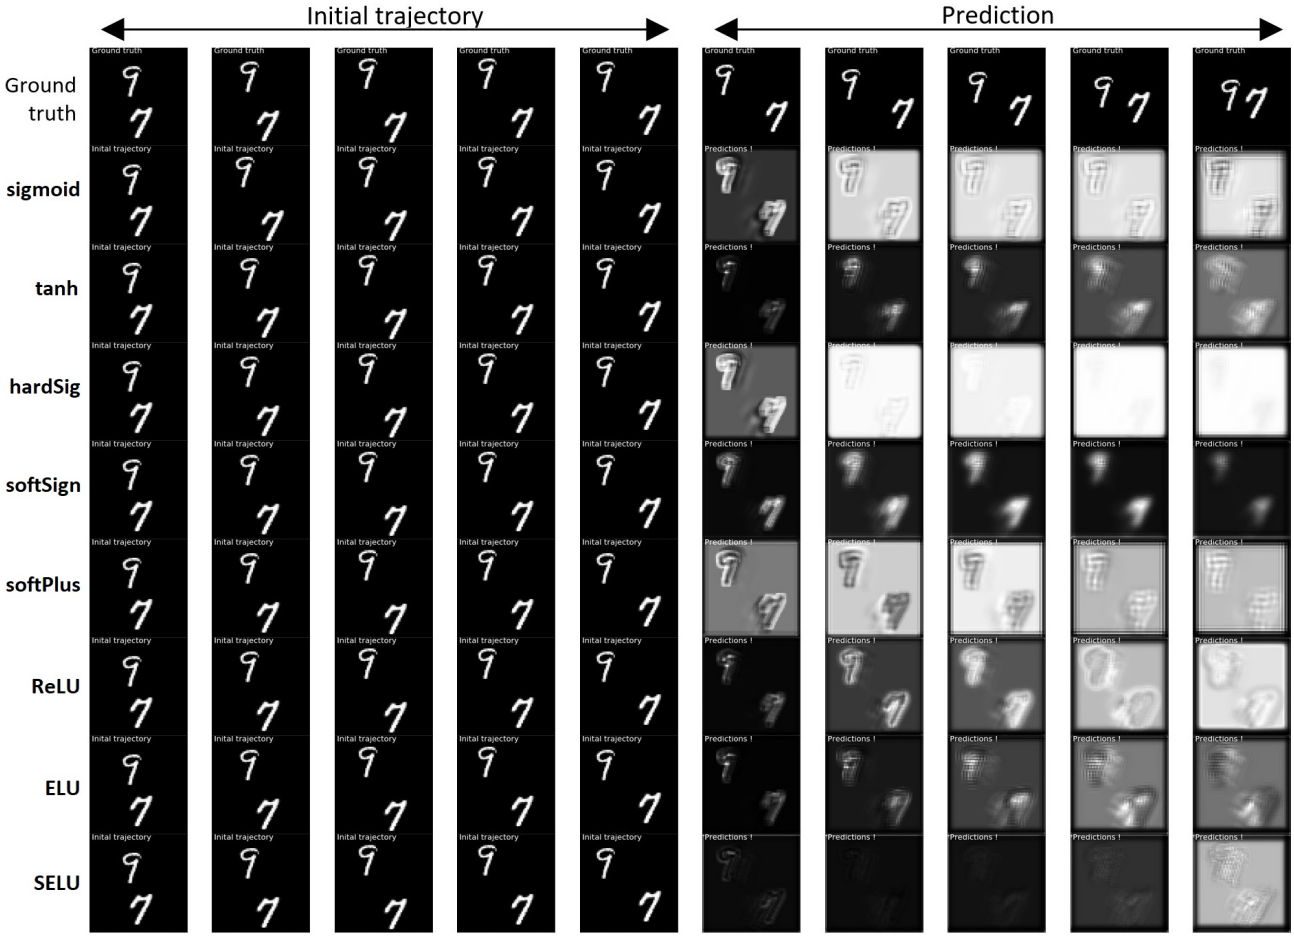

Figure 15: The initial trajectory and predicted frames for each non-gate unit activation function. Although there is shape distortion, the movement directions seem to be preserved.

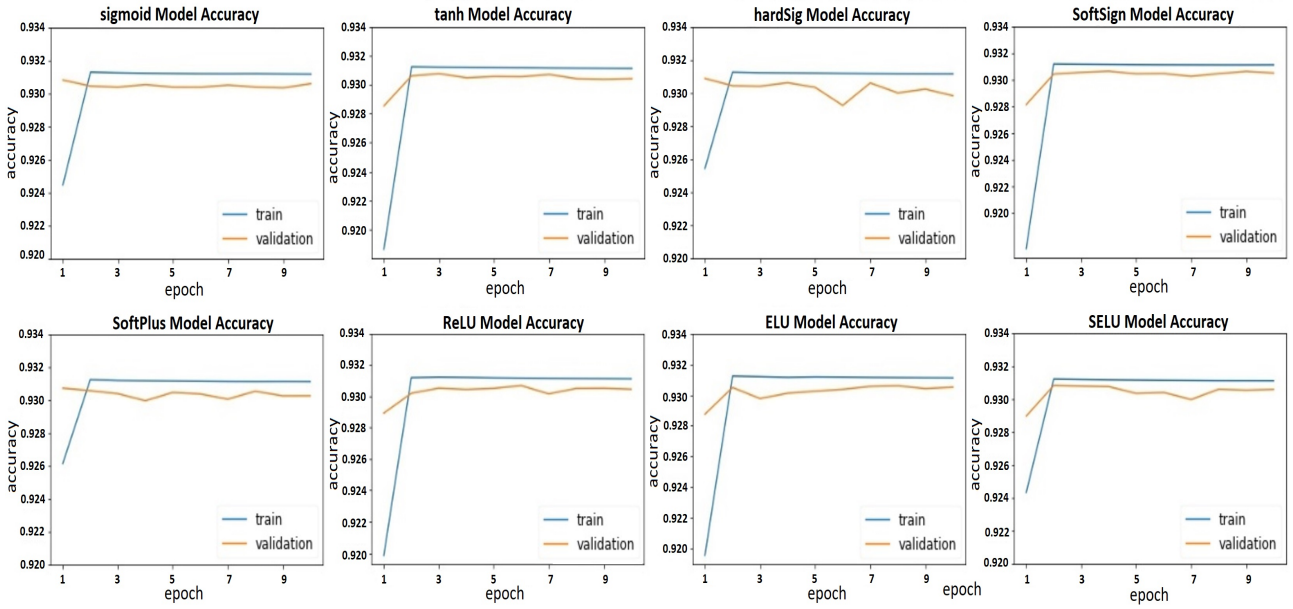

Figure 16: Training and validation accuracy non-gate unit activations. All tested functions are shown for each training epoch.

always set to hardSig. This happens to be the default recurrent activation in the Keras convLSTM API.

There is no restriction on the range of the unit activation function selection compared to the gate activation. Therefore, we tested all eight of the functions from Section 3. Table 3 shows average training time, training loss, validation loss, validation mean absolute error, training accuracy, and standard error of training loss ($n = 3$). The units of training and validation loss are MSE.

Table 3 shows that the elapsed training time of the functions is overall about the same and the highest training time (SELU) is about two minutes longer than the rest. Loss was calculated using MSE and is about the same for all tested functions.

Accuracy of the training and validation tests appears in Figure 16 where the hardSig has the lowest validation accuracy because the accuracy degraded over time. In addition, it has a significant average difference between both the training and validation accuracy curves. For the SoftPlus, SELU, ReLU, and ELU diagrams, there is a notable unstable validation accuracy compared to the training accuracy. However, the most stable validation accuracy for the other tested functions is found when the activation was sigmoid, tanh, or the softSign function. However, the average difference between training and validation accuracies for logsig is higher than the tanh and softSign.

The predicted videos as compared with ground truth for the non-gate unit functions is shown in Figure 15. The lowest visual accuracy occurs when the SELU function is used. The hardSig, logsig, ReLU, and softPlus functions show roughly the same visual prediction results. These functions were unable to maintain, the object's outline, the background, or object's color. The ELU function could not retain the digit outline through time. The softSign function was able to maintain the shape of the objects but it maintained the object's location with reducing their actual sizes. It also suppressed object movement. The tanh preserved the object shape and movement.

In important insight can be seen by looking at the differential visual prediction results in Figure 15. Although changing the non-gate activation functions changes the shape distortion, the predicted movement accuracy seems to be the same across the different activation functions. This indicates that non-gate units play more of a role in predicted shape than in predicting movement direction. In contrast, we saw the opposite pattern with the gate activation functions.

As seen in Figures 14 and 15, prediction accuracy should be improved for practical applications. The intent of our work was to study differential activation function effects. Prediction accuracy can be improved by enhancing the model architecture by increasing the number of the convolutional LSTM layers and adding regularization techniques such as dropout [35]. Further improvements can be obtained by adding more channels to each layer, increasing the number of training epochs, adjusting the input batch size, and adjusting the hyper-parameters. Moreover, using an information flow propagation transfer algorithm (such as predictive coding [4, 36, 37]) to data between the multilayered hierarchy could significantly increase the prediction performance.

5 Conclusion

We found that the choice of gate unit activation function, when used in the convLSTM video prediction problem, affects acquisition of the digit's movement trajectory throughout the video frame sequence. The role of the non-gate unit activation is to enhance the object's shape and determine its details. Only activation functions with range $[0, 1]$ are eligible as a gate activation functions. The convLSTM exhibited the best

prediction performance when the gate activation used the hardSig function and it had the best prediction visual results. In addition, the relation between training and validation accuracies was stable. The model also obtained better predictions when the tanh function was used as the non-gate activation. The tanh has similar training loss and training time to the other functions examined in our experiments.

ABSTRACT

Vision-based defect detection techniques are widely used for quality control purposes. In this work, an efficient deflectometry based detection system is developed for semi-specular/painted surface defect detection. This system consists of a robotic arm that carries a screen/camera setup and can detect defects on large surfaces with different topologies, such as a car bumper, by traversing its profile. A hybrid pipeline is designed that utilizes multi-threading for optimal resource utilization and process speed. Specific filters are also designed to remove spurious defects introduced by acute curvature changes and part edges. The system was successful in consistently detecting various defects on small test samples as well as on large bumper parts with varying topology and color and can accommodate inherent ambient lighting and vibration issues.

1 Introduction

Quality control is a crucial factor in manufacturing industry as it affects customer satisfaction, reduces production cost and increases profitability. In the automotive industry, vehicles are usually assembled from parts shipped by various original equipment manufacturers (OEM) to the assembly plant. Example of these parts includes front and back bumper covers, side fenders, and other exterior parts which are normally manufactured and painted to specific colour before being shipped to another plant for assembly. These outer body parts are made by Thermoplastic PolyOlefin (TPO) injection moulding process. This process consists of three main steps: moulding, cleaning, and painting. Defects may induce during any of these processes, which results in part rejection or rework, causing loss of revenue. As such, it is essential to perform a full inspection of every part. This inspection process is usually carried out by human inspectors. It is a costly and a labour intensive job which requires multiple inspection lines for high volume yield. Further, the defect judgement is very subjective, which results in inconsistencies. As a result, overall productivity and quality are diminished. This paper presents a system for inspecting automotive painted semi-specular exterior body parts and is an extension of work originally presented in 15th Conference on Computer and Robot Vision (CRV 2018) [1]. This extended version includes expended testing and analysis.

There are a series of challenges that impact the development of an inspection system for this task, including:

1. Parts are in motion while they are inspected on the production line. The vibrations induced from this motion makes profiling the surface harder.
2. The inspection process must fit within the existing production cycle time.
3. The part being inspected vary in curvature, size, shape and material, with different specular characteristics.
4. The visibility characteristic of the defect depends on the external lighting conditions. Designing a proper lighting environment for such a system is a challenging task due to high reflection coefficient of the test surface [2].
5. Each type of defect varies in shape and size, and experienced inspectors even miss some defects.

In recent years, vision-based surface inspection systems have found a burst of application in areas such as defect detection in aluminium sheets [2], locomotive

rail tracks [3], liquid crystal displays (LCDs) [4], plastic objects [5], sphere parts [6], agricultural food produce [7], fabric and textile industry [8] etc. However, defect detection and surface profiling of a specular surface remains a challenging problem due to the reflective nature of the surface. Profilometry is a widely used approach for characterization, reconstruction and inspection of such surfaces. Profilometry approaches can be generally divided into contact and non-contact methods. Contact-based profilometry, such as stylus profilometer, scanning tunnelling microscopy, scanning force microscopy, coordinate measuring machine (CMM), etc., is a high-resolution method. The measurement accuracy is in the order of nanometers and is considered as a gold standard for surface finish measurement. This approach is independent of surface characteristics or shape and also works well in dirty environments. As a result, it can be used for both specular and non-specular surface measurement. However, being a direct contact method, it may damage high finish inspection surfaces such as painted automotive parts and its operating speed is also sluggish.

Non-contact profilometry methods are used for high-speed surface scanning and 3D reconstruction [9]. Over the years, many different non-contact profilometry techniques are developed, such as common structured light projection, phase shifting interferometry, deflectometry, digital holographic microscopy, etc. These approaches are based on the inhomogeneous reflection of light from defects. The visibility of defects can be enhanced by the use of a structured light source. In common structured light projection method, the specular surface is coated with a thin layer of powder to make it behave like a diffused surface [10] and then fringe pattern profilometry is used for analysis. This additional coating changes the surface geometry so cannot be reliably used for surface defect detection. On the other hand, interferometry is highly accurate but requires a reference and is not suitable for complicated free-form surfaces. Further, the field of view is limited, so it cannot be used for large surfaces. Hence, deflectometry is recently used for measuring a large object with varied surface topology. A sinusoidal fringe pattern is widely used as a structured light source in deflectometry analysis [11]. In smooth defect-free regions, imaging process obeys specular reflection while the incident rays are dispersed in defected areas. As a result, an acute gradient variation is observed in defect bearing regions, which is used for defect segmentation. These approaches have a lower measurement accuracy (in micrometres range) compared to contact profilometry approaches. Since these approaches are surface dependent, so are affected by the testing environment as any dirt or external dust particles will affect the obtained results.

A new defect detection system is presented in this paper, which is based on the deflectometry principle. The developed system can overcome the practical challenges of a production line. Controlled lighting and camera configurations are designed to counterpoise vibration effects. Various filters are used to segment the region of interest and eliminate false defects due to edge effect and abrupt curvature changes. Finally, to track parts while going through the production line, the system is designed to be mounted at the end of a robotic arm. The proposed system is validated by field testing in an operational automotive painting booth.

The remainder of this paper is organized as follows: Section 2 provides a brief review of the deflectometry principle as it is the foundation of the defect detection system. Section 3 describes the proposed system and explains the working of its different components. Section 4 depicts the system setup and presents implementation details. Section 5 archives the obtained experimental results with analysis. Finally, Section 6 summarizes the findings of this research and highlights some areas of future development.

2 Deflectometry Principle

In this section, we will provide a brief overview of the deflectometry principle, which forms the basis of the proposed system's working principle. The use of deflectometry is actively explored by researchers for the measurement of objects with an abrupt slope change or large size. Many different deflectometry methods are proposed for surface profilometry and defect detection. Some of these include Moier deflectometry [12–16], Ronchi method [17, 18], laser scanning deflectometry [19–21], and phase measuring deflectometry (PMD) [11, 22–24].

PMD technique is used in this paper as it is highly accurate and provides continuous data for surface profiling. It has a large dynamic range and can give full-field measurements. This technique is first developed by Horneber et al. [25]. Over the years, researchers have modified PMD to measure different specular objects [11, 26, 27]. PMD is also successfully applied for specular and semi-specular surface defect detection [28–33]. However, various challenges arise while implementing deflectometry to inspect a larger part like a car bumper which are successfully addressed in the developed system.

2.1 Phase-shifting Deflectometry

In deflectometry, the topographical information of a specular surface is obtained by analysing the reflections of a structured light source. A sinusoidal fringe pattern, displayed on an LCD screen located at some distance from the specular test surface, acts as the light source. The attached camera setup captures the reflections of the deformed pattern from the test surface. By applying phase-shifting and phase-unwrapping algorithms, useful information is extracted from these deformed fringe patterns which are used for surface profile construction. A phase varying single frequency pattern is generally used for deflectometry analysis. A pixelated version of such a multi-phase single frequency pattern is defined as [34]:

$$f(x,y) = \frac{G}{2}\left[1 + \sin(2\pi f \frac{x}{p} + n\frac{2\pi}{7})\right] n = 1..7 \quad (1)$$

where, $f(x,y)$ is the displayed pattern intensity at (x,y) pixel location, G is the maximum of the image intensity range, f is the frequency of the displayed pattern, p is the total pixels in a time period and n is the number of phase-shifted patterns selected.

These phase-shifted patterns are one-by-one displayed on the LCD screen, and their reflections are captured from the specular surface. The intensity of the captured pattern is given by (2) [35].

$$I(x,y) = A(x,y) + B(x,y)cos(\phi(x,y)) \quad (2)$$

where $I(x,y)$ is the captured image intensity, $A(x,y)$ is the ambient light intensity, $B(x,y)$ is the amplitude of the modulated fringe pattern and $\phi(x,y)$ is the desired phase measurement.

The measured phase is directly related to the surface topology. Computing this phase at each pixel location will create a surface phase map. Captured surface reflections of the phase-shifted patterns are used to calculate this phase map by applying Windowed Discrete-Fourier Transform (WDFT). For seven phase-shifted single frequency patterns, the closed-form solution is represented by the following relation [36]:

$$\phi = \tan^{-1}\left[\frac{(I_1 - I_7) - 3(I_3 - I_5)}{4(I_4) - 2(I_2 + I_6)}\right] \quad (3)$$

where $I_{1,\ldots,7}$ correspond to the captured reflections of the seven phase-shifted patterns displayed on the LCD screen. The phase map ($\phi(x,y)$) is in $0 - 2\pi$ range, so a phase unwrapping step is needed to recover the actual phase with the inclusion of appropriate multiples of 2π [37]. Then the absolute derivative of the phase map is computed with respect to pattern variation axis (x-axis) as defined by the following equation [33]:

$$D_y(x) = \left|\frac{\mathrm{d}\left|\phi(x)\right|}{\mathrm{d}x}\right| \quad (4)$$

here, $D_y(x)$ is a continuous function which represents line topography for the corresponding y^{th}-axis.

The effect of this differential operation is the attenuation of low-frequency signal information and accentuation of high-frequency contents induced due to the presence of defects in the specular/semi-specular surface. As a result, $D_y(x)$ remains almost constant in defect-free regions, whereas an acute variation is observed in defect-bearing areas.

3 Defect Detection System

Use of deflectometry for big automobile bumper inspection brings its own set of challenges. Its impractical to examine the entire part surface in one scan. Therefore, it is divided into smaller segments based on the reflection of the displayed pattern. Since external light sources impact the detection results, controlled lighting setup is constructed to minimize the effect of these external factors. Figure 1 shows the image processing pipeline used. Captured surface reflections are pre-processed before deflectometric defect detection operation. Several false positives are observed due to the topographical variation in the test surface. A set of spurious defect removal filters are designed to eliminate these false positives. Camera shutter speed, aperture and robotic motion are adjusted to reduce vibration effects and eradicate motion blur. Since the detection operation is carried out in small segments, the results are then combined and localized on test parts. Finally, defect characteristics are gathered and archived in the designed database which can later be used for display or higher level decision making for process improvement. The following sections provide additional details on the functionality of different components.

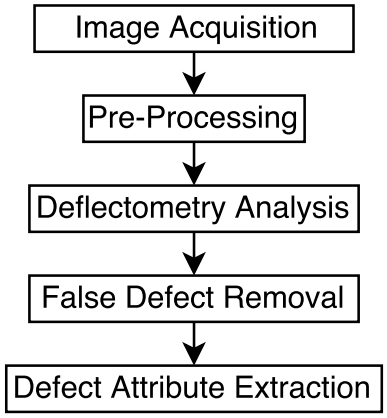

Figure 1: Defect detection scheme

3.1 Capturing and Pre-processing

Figure 2 and Figure 3 show the process involved in capturing and pre-processing of images. OpenGL library is used for the rendering of seven phase-shifted sinusoidal patterns. The patterns are generated only once during the run-time using pattern screen resolution and then stored in memory as 2D matrices. Later on, these stored patterns are displayed one-by-one for deflectometry analysis. The reflection of these patterns is captured from the part surface by an attached camera. Pattern display and capture of surface reflections are carried out sequentially. Once a set of seven surface reflections is captured, a pre-processing thread is initiated to compute the phase map and find its derivative. It is noted that a single phase-map-derivative image is created for each segment. While the pre-processing step is running, the next set of seven patterns are ready to be displayed on the screen and captured by the camera. This multi-threading approach reduces cycle time through parallel computation.

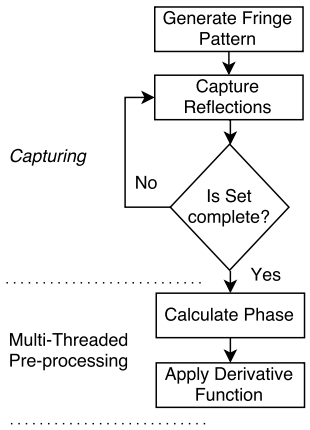

Figure 2: Sequential image capture and mutli-threaded pre-processing steps

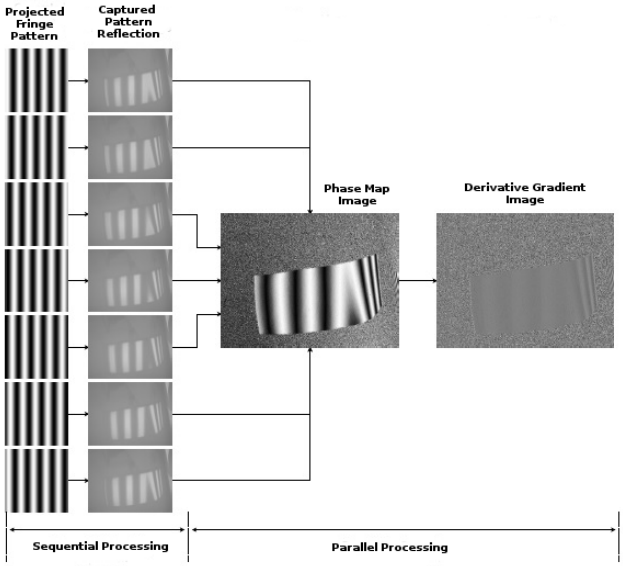

Figure 3: Surface reflection capturing and phase-map-derivative image generation

Once the Capturing and Pre-processing steps are completed, a defect detection thread is initiated, which extracts defect information from the phase-map-derivative image. Defect detection process can be divided into three main stages; Fringe region segmentation, Defect pool and spurious defect elimination and Defect attributes extraction and registration.

3.2 Fringe Region Segmentation

A fixed focus camera at a defined distance from the test surface is used in this study. As a result, the camera captures a fixed size image that may contain both the fringe projected region and non-fringe region. Further, the size of the reflected pattern varies with the surface curvature; the reflected pattern shrinks as the surface become convex. As a result, the first step in the defect detection process is to crop the fringe pattern projected region from the phase-map-derivative image.

The obtained phase-map-derivative image in the previous step is thresholded and smoothed with a Gaussian kernel. The resulted blobs are eroded to remove uneven corners and then selected based on size to create a mask. This mask is used to extract the fringe projected region as shown in Figure 4, which is later used for defect detection.

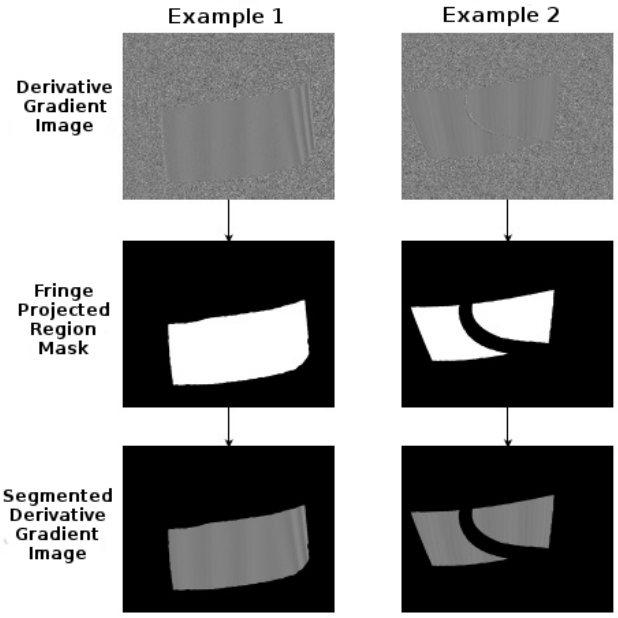

Figure 4: Fringe region extraction from the generated phase-map-derivative image

3.3 Defect Pool and Spurious Defect Elimination

Once the fringe projected region is extracted, thresholding and edge detection are used to create a defect pool. This defect pool consists of possible true and false defects. False defects are a combination of tiny defects below the accepted size criterion, edge defects and defects due to abrupt curvature changes. Three different filters; Size/Noise filter, Surface curvature filter and Edge filter are designed to remove these false defects. These filters work in parallel to remove these defects as depicted in Figure 5.

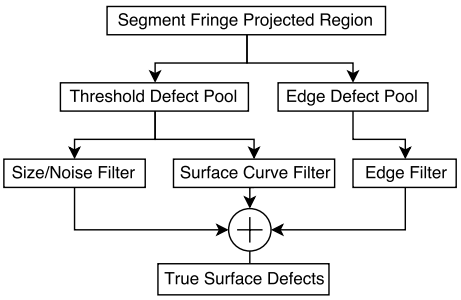

Figure 5: Processing and false defect removal

A size based filter is designed to remove tiny noise like defects. It is observed that after thresholding, several very small defects are detected in the binary image. This filter removes all those defects which are below the given size criterion. The second filter removes the false defects from the curved region. This filter uses parallel lines to determine the curved region in

the captured surface reflection. A Canny edge detection operation followed by Hough transform is used for these lines detection. The angle variation of the detected lines is exploited to determine the curved region from where the defects are removed. The last filter removes spurious defects in the edge region, which are the result of the application of WDFT. It makes use of both curved region information and defect pool generated by Canny edge detection operation to segregate defects produced due to edge effect.

The application of these filters results in three separate images that contain only legitimate defects. Later on, all these defects are aggregated together to form an image which shows all the valid defects in the inspected region as depicted in Figure 5. Application of these filters on a typical gradient image is shown in Figure 6.

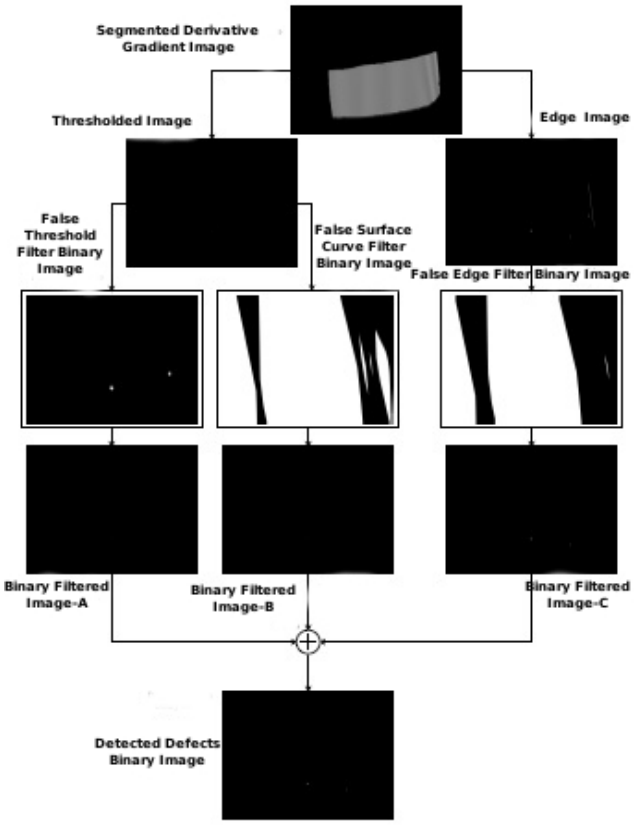

Figure 6: Application of false defect filters on defect pool

3.4 Defect Attributes Extraction and Registration

Once all the true defects are found, defect attributes such as size (in terms of pixels), bounding region and centroid location are determined. To extract these characteristics, close by defects are first fused by a morphological dilation operation. Later on, a contour-finding operation is performed to separate different defects and then above mentioned attributes are computed for each found contour.

These attributes are also recorded in the appended database, which can be used in future for tracking, decision making or other process adjustments. The results are also overlaid on a part image for physical defect localization which is saved in a directory for immediate use. All these different steps are delineated in Figure 7.

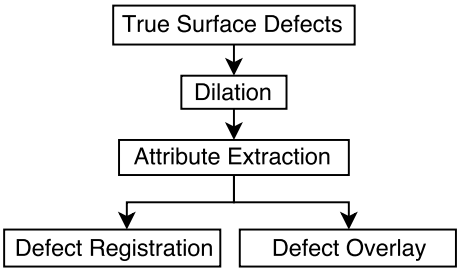

Figure 7: Defect attributes extraction and display

4 Implementation Details and Experimental Setup

4.1 System Architecture

Figure 8 shows the entire system implementation. Since the system is expected to inspect large parts, a robotic arm is used where the pattern screen and camera are mounted on the end-effector. The system includes several additional components to enable robot movement for full part inspection such as positioning of the robot end effector, generation of inspection patterns and administrative operations such as results registration and display.

The defect detection process consists of both sequential and parallel operations. As a result, a hybrid computational framework is designed. It is evident in Figure 8 that individual steps need to be completed to proceed to the next component for processing, so parallel operations (multi-threading) are only used for computationally expensive processes. First of all, robot positions the LCD pattern screen tangent to the surface to be inspected. Then seven phase-shifted sinusoidal fringe patterns are sequentially displayed on the screen, and the attached camera captures corresponding surface reflections. These surface reflections are pre-processed, and defect detection operation is applied to find the surface abnormalities. These two steps, pre-processing and defect detection, are computationally expensive, and multi-threading is used here. This multi-threading operation can be activated/deactivated by the frontal administrative control panel. All detected defect information is stored in the designed database system that can be accessed remotely. All these steps are controlled by a front end administrative control panel, which also displays a sample test part image on which detected results are overlaid. It also provides the option to configure features such as directory paths for registering captured and processed images, the number of segments to divide the test surface and displays the progress of the detection operation.

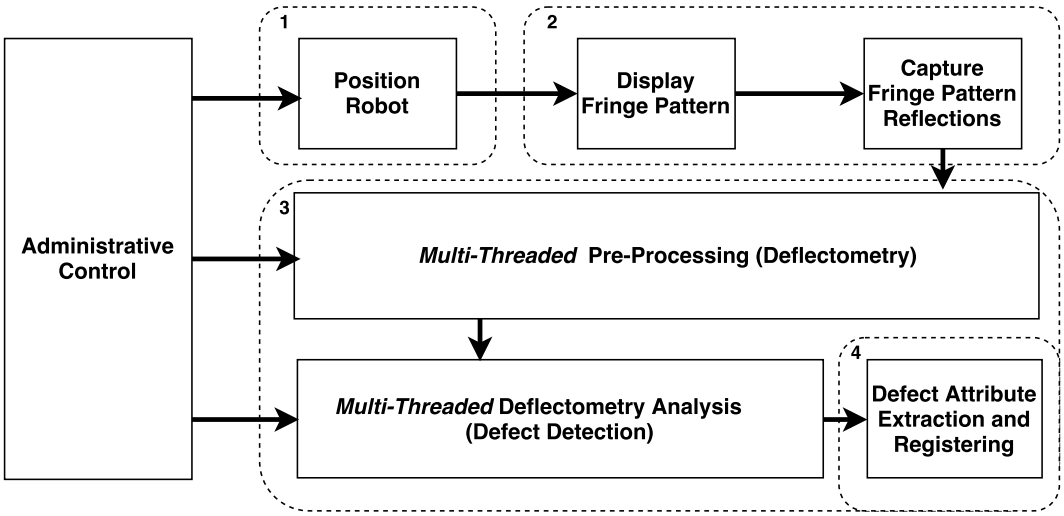

Figure 8: Schematic of implemented defect detection system

4.2 Experimental Setup

4.2.1 Overall Setup

Testing was conducted at the Robotics Institute @ Guelph lab. The experimental setup is shown in Figure 9. The test parts were placed on a carrier similar to the ones used at the part manufacturing facility. The carrier was stationary during the testing. A KUKA KR 16-2 KS industrial robotic arm is used to carry the screen/camera setup to transverse the large bumpers under test. The robotic arm was programmed to move in a predefined path to inspect each segment and hence the whole part. This operation controls the movement of the screen/camera setup. A controlled lighting environment was enforced where the pattern screen is the only source of illumination. Any direct light source incident on the part whose reflection reaches the camera will create a blind spot in the gradient image. The test surface should also be free of any dust particles as they will produce a dispersed reflection of light and will appear as a defect. A 40 inch commercial TV screen is used as the pattern screen. The computing system consists of an Intel Core i7-6700 3.40 GHz processor and has 16 GB RAM and Nvidia GTX960 graphics card running on 64-bit Windows 10 OS. The detection code is written in C++ using Qt Creator 5.6, OpenCV 3.2 and OpenGL libraries. The camera is connected via high-speed USB 3.0 connection and pattern screen is interfaced with an HDMI cable.

4.2.2 Camera Setup

A monochrome Point Grey 3.2 MP (GS3-U3-32S4M-C) camera with a 12.5 mm Fujinon lens HF12.5HSA-1 (LENS-50FS-125C) is used. The camera is attached to a specially designed fixture on the side of the pattern screen so that it looks in the middle of the projected pattern on the test sample, as seen in Figure 10. A fixed focus camera, as already mentioned, is sharply focused on the test surface, which is approximately 40 cm away from the camera. Once the robot starts traversing the surface topology, a distance of 35 cm to 45 cm is maintained so that the image remains within the camera's depth of filed and hence sharply focused.

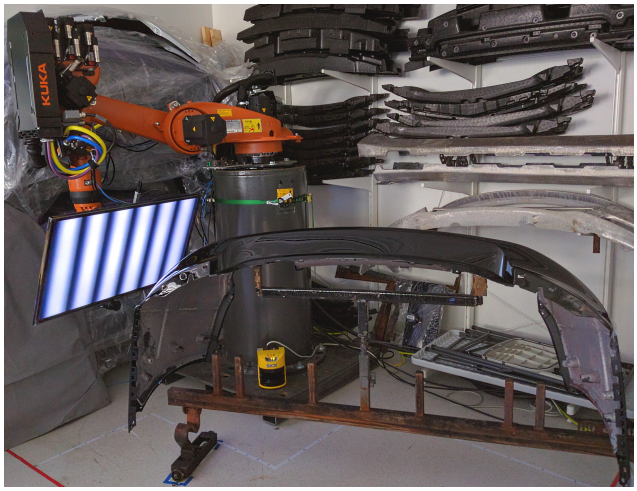

Figure 9: Experimental setup

Figure 10: Camera view

4.3 Surface Segmentation

It is virtually impossible to inspect the full test part in one capture due to its large size. There are two reasons for this. Firstly, there is a lot of variation in the surface topology of the test surface, and the pattern screen should be tangent to it to capture the displayed pattern. Secondly, only a limited payload both in terms of size and weight can be attached to the robot end effector. Hence, a huge screen which can project the pattern on the full part cannot be used. As a result, the test surface is partitioned in small regions based on the reflected pattern as shown in Figure 11.

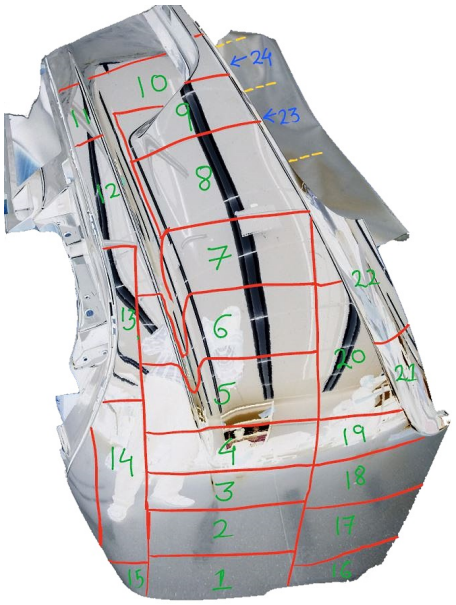

Figure 11: Bumper segmentation for inspection

Seven phase-shifted sinusoidal patterns are projected on each region, and the attached camera captures corresponding reflections. There is some overlap in the captured surface reflections among adjacent segments that accommodate for some variation in part placement. These different regions are then appended together to localize the identified defects on the entire test surface.

4.4 Test Specimen

Ten test samples are used in this study. These samples are provided by an OEM exterior body parts manufacturer. These are large SUV/Minivan bumpers of 5.5 ft long, 1.5 ft high and 2.5 ft deep, as shown in Figure 11. These bumpers are of different colours and are rejected due to the presence of various surface defects. These defects are marked on the test parts by expert human inspectors working at the manufacturing facility. In addition to these defects, some more defects are artificially created to augment the defect database used as ground truth (GT). Since the bumpers are symmetric, we only needed to inspect one half of each bumper. In real production, two robots can be used to examine the whole bumper. Each tested part is divided into 24 small segments as depicted in Figure 11.

5 Results and Analysis

Two sets of experiments are performed to evaluate the performance of the developed painted surface defect detection system. In the first study, small defect samples are used to verify the effectiveness of the deflectometry principle in detecting various defects. Once, the efficacy of the deflectometry principle is validated on these small samples; large parts are tested. Large parts have their own set of challenges in terms of size, sudden curvature change, throughput etc.

5.1 Small Test Samples Preliminary System Validation

Different type of surface defects such as dirt, cold sludge, fisheye, blister etc. occur during moulding or painting process. Small test samples bearing these defects are used to validate the effectiveness of the detection principle. Some of the sample parts are shown in Figure 12. These small parts are mounted on a tripod in front of pattern screen, as shown in Figure 13. The parts are placed 40 cm away from the camera, which captures the surface reflections. A set of seven sinusoidal fringe patterns with a phase shift of $2\pi/7$ are generated to display on the LCD screen and then their reflections are captured. These surface reflections are analysed to reconstruct the surface profile. During this testing, the fringe projected area is manually segmented for deflectometry analysis. This process is depicted in Figure 14 and the results are tabulated in Table 1. Here, detection accuracy represents whether a defect is successfully detected by the developed system.

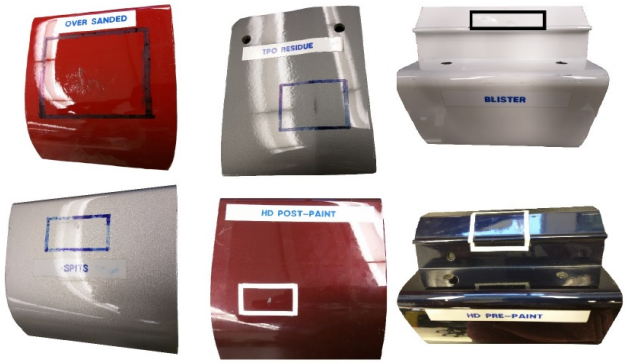

Figure 12: Some typical surface defect samples

Figure 13: Camera with fringe pattern screen and test part on tripod

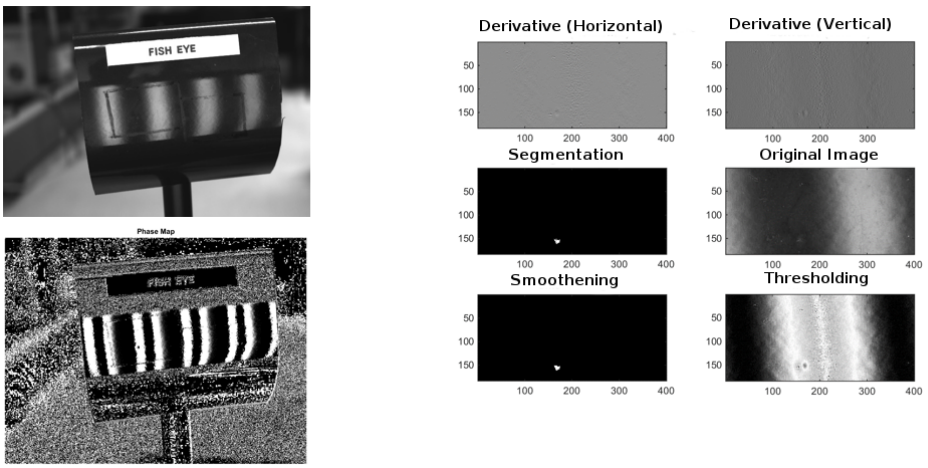

Figure 14: Fisheye defect detection

Table 1: Small sample defect detection results

Sr. No.	Defect Type	No. of Samples	Detection Accuracy
1.	Dirt	2	100%
2.	Cold Slug	4	75%
3.	Spits	1	100%
4.	Fish Eye	2	100%
5.	Flash	2	100%
6.	Blister	3	100%
7.	TPO Protusion	2	100%
8.	Over Sanded	3	100%
9.	Hot Pre-paint	1	100%
10.	Overflame Torch	2	100%
11.	Water Spots	1	100%
12.	TPO Residue	3	100%
13.	Popping	1	50%
14.	HD Post Paint	3	100%

These results indicate that the developed system mostly detects the studied defects although some low detection performance is observed for cold slug and popping defects. Popping defects are salt-and-pepper noise like small defects that occur when the solvent or air trapped in paint film escapes during the drying process. This creates a lot of tiny defects clustered in a small area. A 50% popping defect detection accuracy indicates that approximately half of these tiny defects are detected, but it is enough to declare the part defective.

5.2 Large Parts Defect Detection

Following the experimental setup outlined in section 4, various large bumpers are tested by the developed system. The developed framework was successful in detecting most of the manufacturing as well as the artificially created defects. Some of these detection results are shown in Figure 15.

Results are reported in two tables. The segment-wise results are given in Table 2 while body part color based results are reported in Table 3. These results are reported in terms of recall, precision and F-measure. Equal weighting of recall and precision is considered for computing F-measure. These metrics are defined as follows:

$$Recall = \frac{TP}{(TP+FN)} \tag{5}$$

$$Precision = \frac{TP}{(TP+FP)} \tag{6}$$

$$F-measure = 2 \times \frac{(Precision \times Recall)}{(Precision + Recall)} \tag{7}$$

where TP is true positive, FP is false positive and FN is false negative. Ground truth data to compute these measures is provided by the part manufacturer.

By reviewing the results, we can deduce that the performance of the defect detection system varies depending on part colour and segment location. The performance of the algorithm is lower in segments 8, 9 and 10 where precision drops significantly to 0.46, 0.43 and 0.30, respectively. These segments contain highly curved sections which drastically distorts the projected pattern resulting in a higher number of FP. This can be improved by tuning the system differently on a per region basis to accommodate the different variations in surface curvature. The results by part colour show that the performance of the detection system is compromised on white parts. White surfaces reflect all light incident to it, so the algorithm becomes more sensitive to surrounding light. Besides, the contrast of the projected pattern is muted by white parts affecting the visibility of defects on the part surface. The combination of these factors reduces the accuracy of the algorithm on white parts.

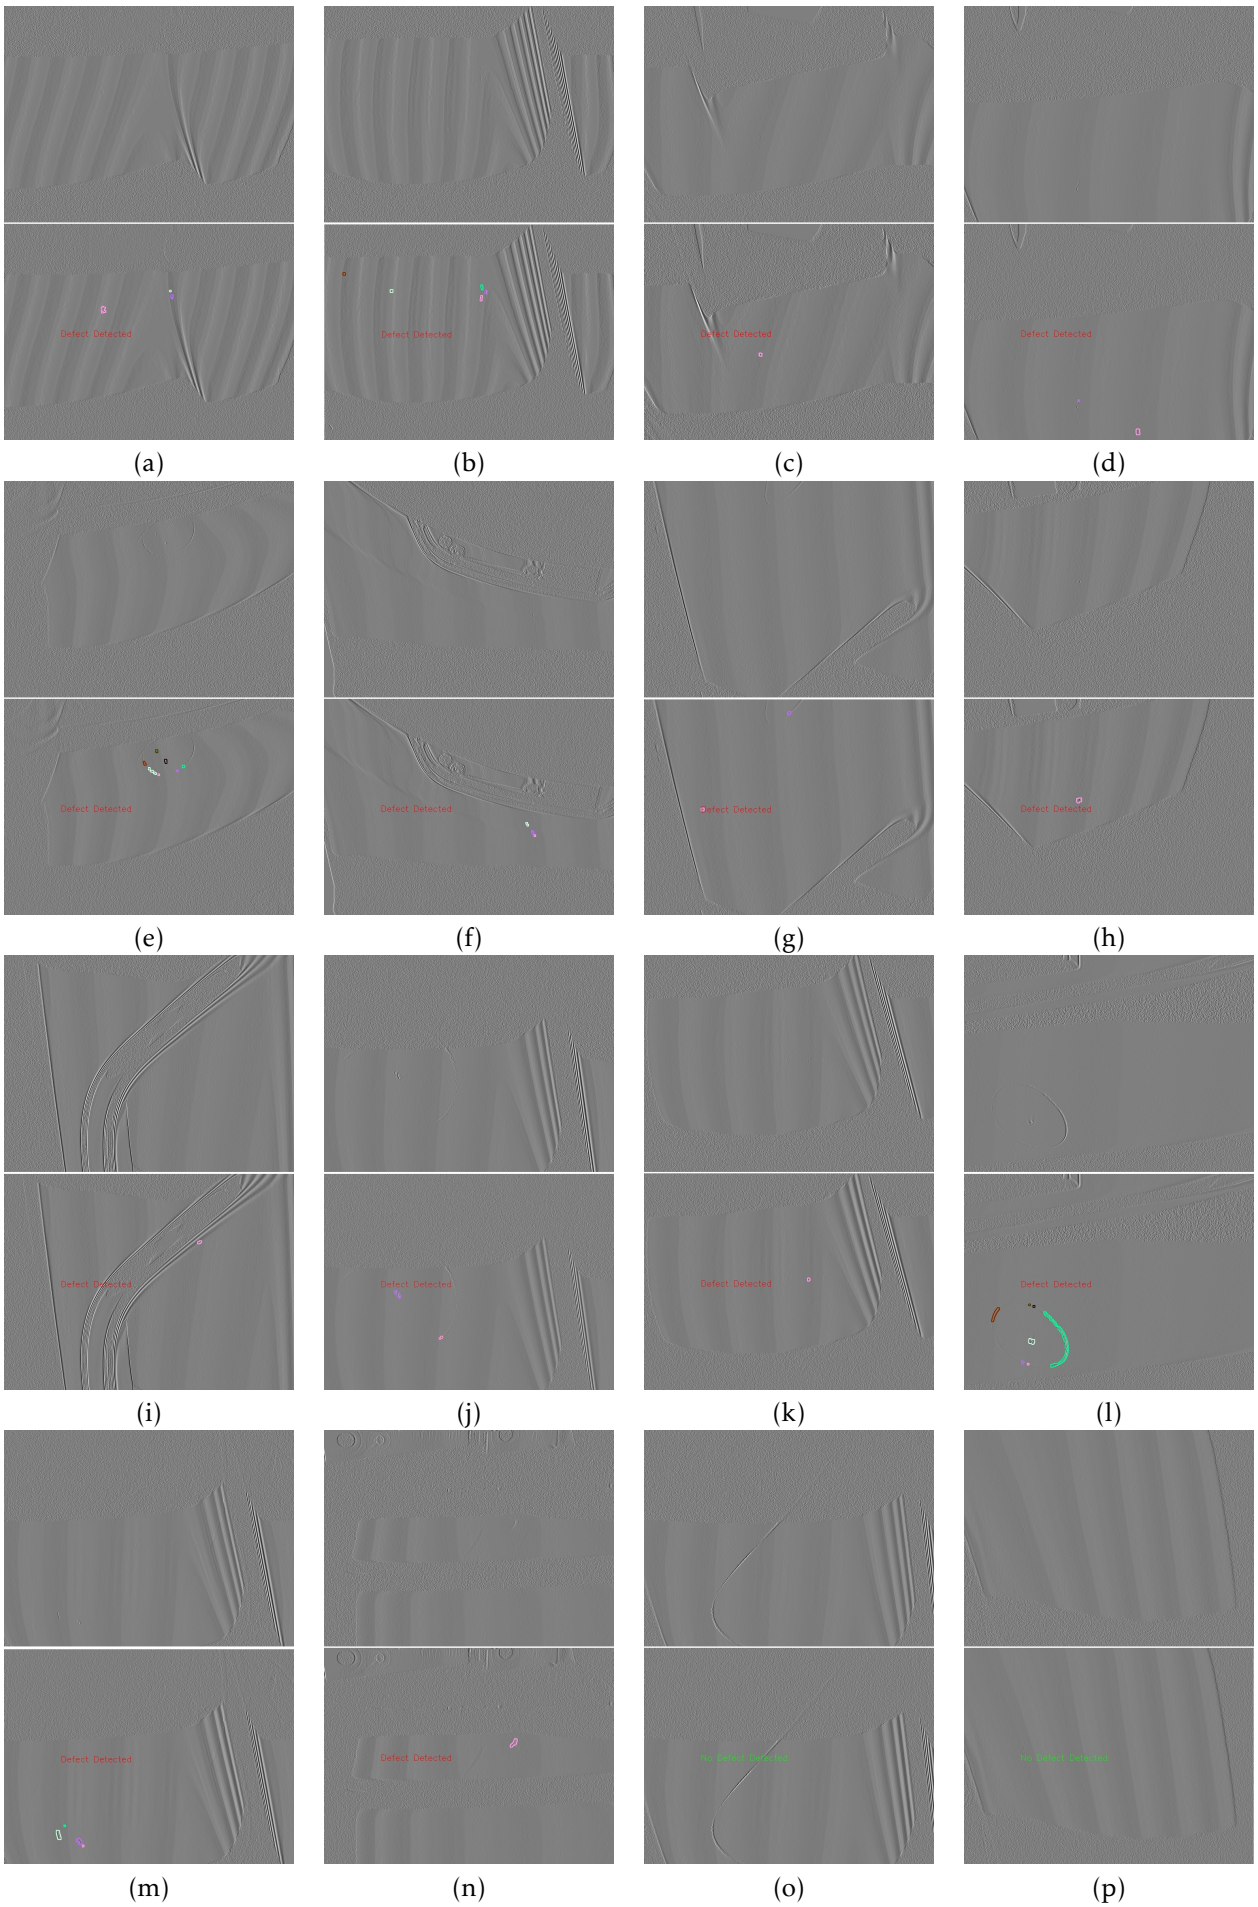

Figure 15: Some defect detection results on large bumpers First row: Gradient image, Second row: Detected defect ((o) is an example where defect is not detected as it is not enclosed by fringe region and (p) is an example of a defect free region)

Table 2: Defect detection results by segment

6 Conclusion

A deflectometry based defect detection system is presented in this research paper. The developed system has successfully detected large and subtle defects on large painted automotive parts. The system analyses gradient variation in the measured phase for defect detection and does not require an existing dataset or pre-training for its functioning. The use of robotic arm lends it the capability to inspect varying surface geometries. The system examines the whole part by operating on individual segments. These defects are then aggregated to localize them on the full part.

The system successfully detected various manufacturing defects induced during moulding and painting processes on small test samples as well as on large automotive bumpers. For large bumper testing, additional algorithms are designed and used to extract the region of interest, as well as eliminate spurious defects detected due to edge effects and abrupt curvature changes. The algorithm processing takes approximately 0.35 seconds per segment, and this doesn't include the time that it takes the robotic arm to move between segments.

It is noted that the implemented framework can only detect defects if they are enclosed by a fringe projected region from all sides. It is possible to use multiple cameras to reduce the number of segments and speed-up the inspection process. A colour fringe pattern could potentially be used to improve the system's performance on light coloured parts. Use of a phase shifted coloured pattern can be explored as it will alleviate the requirement for a stationary part-camera/screen system by eliminating the need for multiple phase-shifted patterns.

ABSTRACT

Peer-to-peer (P2P) energy trading is a mechanism that allows people to share locally the energy they have generated from distributed renewable resources (DER), to generate profit form the unused resources and to reduce the cost for electricity for the household and in the community itself. This calls for the design of new energy markets, accompanied with the development of comprehensive exchange strategies, which reflect both the consumer?s preferences and the heterogeneity of the renewable sources. The paper presents a study of the behavior patterns of individual prosumers using bidding strategies based on the State-of-Charge of the battery and two different pricing algorithm, one with fixed prices and one based on the battery price of each standalone system as well as the effect such patterns have on a local energy market with solar panels, fuels cells and batteries. The evaluation is achieved by the use of a prototype based on the Open Energy Systems (OES), a community in Okinawa, Japan, made of 19 interconnected houses with residential storage, photovoltaic cells and AC grid connection. In order to simulate heterogeneity, a fuel cell, modeled after Ene-Farm, is added to the original configuration. Each house has a power flow management system, which uses a priority-based algorithm to maintain demand-response efficiency, capable of scheduling the operating hours of the available fuels cells. The energy market is based on Zaraba, a continuous double auction algorithm used by the Japanese Stock Exchange, in which prosumer can bid for a desired amount and price of electricity for a 30-minutes time slot in the future The preliminary numerical evaluation is based on the results from several simulations using different versions of the bidding agent.

1 Introduction

This paper is written as an extension of the work titled "Energy exchange strategy for local energy markets with heterogeneous renewable sources", presented at the 2018 IEEE International Conference on Environment and Electrical Engineering and 2018 Industrial and Commercial Power Systems [1] in Palermo, Italy.

In the recent years a huge surge in the usage of renewables worldwide [2]. The growth of the solar photovoltaic capacity installations in particular is remarkable, nearly double those of wind power and adding more net capacity than coal, natural gas and nuclear power combined. This trend can be seen not only on global scale since the dropping prices for energy storage and Feed-In Tariffs(FIT) [3] has led to an increase in the adoption of solar energy by individual consumers. Additionally, the efforts of countries like Japan, have contributed to the improvement of the efficiency and reducing of the cost for Distributed Renewable Resources (DER), making on-site energy sources such as fuel cells more popular with consumers [4]. However, the current centralized nature of both the grid infrastructure and the electricity markets is preventing residential customers from participating and taking full advantage of cheaper renewables. The successful implementation of blockchain technology for peer-to-peer (P2P) trading in the Brooklyn Microgrid [5], has not only led to a surge in the adoption of the technology in the development of local energy markets but to new and innovative approach towards designing such markets. Still the increased heterogeneity of the microgrids as well as the needs of the individual prosumers are yet to be addressed.

The paper [1], on which the research presented here is based, studied the impact of introducing a new power source,

[*]Borislava Spasova, 3-14-13 Higashigotanda, Tokyo 141-0022, Japan, +818044094144, b.spasova@gmail.com

in this case a hydrogen fuel cells, on already existing on a local energy market with renewables and batteries. The prototype, used for the analysis was built upon and existing system, the Open Energy Systems (OES) [6], operating it real world microgrid in Okinawa, Japan. OES consists of 19 autonomous subsystems, equipped with photovoltaic cells, energy storage and loads and interconnected via DC power bus. The system, currently used by the OES microgrid, has a well-defined exchange algorithm [7], designed to enable energy exchanges between all of the connected subsystems. However, no financial rewards are attributed to the prosumers and the energy is essentially exchanged for free.

The subsequently developed prototype aimed to change that by developing a market-based trading platform which can provide financial incentives for trading and thus enabling all the prosumers to be active participants in the local energy market and to make better use of the generated renewable energy. Such approach contributes to the an increase in the self-sufficiency and the sustainability of the community itself and expands the possibility for developing decentralized energy market to reflect on the decentralized nature of the P2P exchange. Usually trading platforms require the submission of an order bid, using an internal bidding strategy, which may or may not be fully matched, or be matched only partially, with someone else?s bid using a perviously agreed matching method. The matching can be done centrally by aggregating all requests, determining a common market clearing price (MCP) in order to maximize trading volume for a given timeslot. Another approach is to use auctions, a method often used for trading goods, mainly non-fungible goods e.g. E-bay. Continuous or real-time trading, characteristic for spot markets, is used in this prototype as it provides both speed and liquidity. The bids, used here, require for the desired amount and price of the energy for exchange to be set in advance. Both parameters are determined by the individual prosumer's exchange strategy, which is based on the State of Charge (SoC) of the available battery. A version of the algorithm was already in operation in the OES system, proving to be working well for the for subsystems with solar panels and batteries. In order to further test the SoC-based exchange strategy, a hydrogen fuel cell was added to the original configuration of the subsystems in simulated environment. The fuel cell came to the attention of the authors, due to it rising popularity among Japanese households. Unlike the the fluctuating output of the solar panels, it provides stable generation level which coupled with well devised prediction of consumption patterns can contribute to the building of off-grid communities, completely self-sufficient and independent from the utility grid.

The study presented 2018 IEEE EEEIC and I&CPS showed the broader effects of the SoC-based exchange strategy have on a community with heterogeneous power sources and the strategy itself has a very simplistic pricing algorithm which didn't account for the actual price of the energy being exchanged. As a result, a new pricing method was added, based on the price of the energy, stored in the battery of each individual subsystem. This paper presents a quantitive evaluation of the effects of this change on the developed market as well as on the behavior of predetermined prosumers' groups, created based on the daily consumption average. Examining more detailed behavioral patterns allows for better understanding of each prosumer's needs which can enhanced the development of more customized bidding strategies. Moreover, it opens the possibilities to design a more diverse community, where each standalone system can use different set of power sources, to serve as testing environment in order to achieve more realistic results.

The evaluation, presented in this paper, is based on a study of the effects of SoC-based bidding strategy with simple pricing algorithm and pricing algorithm based on the current price of the energy, contained in the battery of each standalone subsystem, on the local market and on the individual prosumer. It is achiebed by comparing the results, obtained by the simulation with the OES community, with the two bidding strategies. Furthermore, the presented strategies are evaluated in the context of a single member of a prosumers' group to better understand how changes in the bidding system can affect the individual prosumer.

Section 2 of this paper introduces the basic concepts used in the development of the solution and provides a look into the current state of P2P energy trading and existing blockchain based markets. Section 3 gives a more detailed information about the observed community and the selected prosumers' groups. Section 4 provides an overview of the prototype's design and the concrete implementation which is used for the quantitative evaluation. Finally, Section 5 will focus on the analysis of the simulations' results followed by final remarks and discussion of future works.

2 Research background

This paragraph will introduce existing solutions for energy exchange between interconnected subsystems. Many studies focus on the exchange strategies between interconnected microgrids and the main grid. The research, presented by Asimakopoulou [8], suggests a Leader-Follower strategy for energy management of Multi-Microgrids, achieved with the use of bilateral contracts between microgrids and a large production unit. Wang [9] proposes a control strategy for networked microgrids and distribution systems. Other authors such as Matamoros and Gregoratti [10, 11] has focused on developing an optimization framework for a distributed energy trading algorithm between islanded microgrids. They were also among the first researchers to give a solution for direct trading between microgrids although due to the lack of clear separation between the microgrids' internal power management strategy and their exchange strategy the proposed system didn't offer many possibilities of implementing self-interest-based internal strategies.

Such opportunity was offered by Wang [12, 13, 14] who proposed a two-layered optimization method that separates internal and external strategy and helps avoiding undesired power injections and reduces peak consumption. This proposal creates new opportunities for collabotation between self-interest microgrids. Other papers [16, 17] prefer the use of Game Theory for the trading algorithm, while Nunna [18] came up with an multi-agent approach for power trading between microgrids using demand-response and distributed storage.

Dimeas' paper [19] proposed a *multiagent system* (MAS) approach, that allows independent agents,*Buyers* and *Sellers*, to submit *Bids* for *EnergyPackages* according to *GridPrices*. Other papers also discussed this kind of approaches [20, 21, 22] but mainly from a theoretical point of view without physical prototype.

Starting with Nakamoto's white paper on Bitcoin [23], Blockchain has received both academic and industry interest for being the first scalable method to successfully decentralize P2P exchanges. It can be applied not only for cryptocurrencies, but also for various other use cases as for instance in the energy sector, notably the here-addressed P2P energy trading [24]. Using Blockchain for trading was first address by Transactive Grid Project [25] which demonstrated the concept of the Brooklyn Microgrid [26], [5]. Later many projects such as Grid+ [25], NRGCoin [27], Bankymoon, Daisee, D3A and Energo Labs [28] followed but so far few pilots and prototypes are completed and the one that are focus more on developing functioning energy market from the perspective of retailers and producers and not from the customer's perspective.

As stated in previous works [1], a prototype, following the Wang's approach was developed, which focuses on developing a platform for trading between members of one microgrid. The base concept design allows in the future to expand the market by trading with neighbouring microgrids as well. For research purposes, a prototype was developed, having explicit separation between the internal strategy for energy management and the trading algorithm, defined in the external strategy built-in in its base design. Such division aims to address both the lack of incentive and the decision coupling issue which is particularly affects cases where blockchain is used without separating external and internal logic beforehand. The systems aims to create environment where different energy exchange strategies can be used to better reflect the different targets set by prosumers when using renewable energy. The internal strategy, is tasked with managing the demand-response efficiency of each subsystem and with evaluating the system needs for buying and selling energy, implemented by the priority-based internal agent and the bidding agent, respectfully. The external strategy is the software implementation of the local energy market, used in this study.

Moreover, unlike the other studies, introduced in the paragraph, this research focuses on the small prosumers and aims to create local energy market where each player can use a customized bidding strategy that is best suited to their needs. In order to achieve that, a better understanding of the behavior of different types of prosumers is needed. This paper deepens the study of the market by observing the effects a small change in the bidding strategy can have on the individual prosumer.

3 Application in real world microgrid

This section will provide more detailed information on the real world microgrid, used for the evaluation and on the prosumers' groups, designed based on the recorded consumption data in the microgrid for the year 2015.

3.1 Microgrid Architecture

The OES is a bottom-up, distributed electric power system that mainly uses renewable energy sources. It presents an alternative way of exchanging energy in-between energy subsystems in order to manage energy fluctuations within the community. Supply and demand are balanced autonomously without impacting the utility grid and thus energy autonomy is increased with minimal infrastructure costs. The concept and feasibility of OES have been demonstrated in a decentralized, peer-to-peer microgrid in Okinawa, Japan. The microgrid has been operating there since late 2014 and consists of 19 houses, each equipped with their own subsystem with photovoltaic cells, residential energy storage in a form of 4.8 kWh batteries, dc nanogrid and loads. All the subsystems are connected via dedicated, shared DC power bus as well as communication line which allows energy exchanges within the community. The subsystem use a direct current (DC) procedure for exchange, combined with pure peer-to-peer (P2P) communication infrastructure and exchange algorithm [7]. All the houses also have connection to the utility (AC) grid, which can be used as an auxiliary power supply when no other energy supply is available. Bidirectional dc-dc converters are used as an interface between subsystems: they allow for an effective control of the power flow and can be used as an abstraction of the internal subsystem design. This way, dc power can be exchanged within a community to help balancing demand-response requirements without requiring global knowledge or control.

In order to test the system capabilities in simulated environment with heterogeneous power sources, a fuel cell is added to the to the configuration of each standalone subsystem. The fuel cell, used here is largely based on Ene-Farm, a hydrogen fuel cell for home use, that has been gaining popularity in Japan. Ene-Farm is an energy system that can extract hydrogen from natural gas, usually supplied though underground pipes in most major cities in Japan, or propane gas (LPG), usually supplied to a residence via external tanks part of the building design. The hydrogen is then used in combination with ambient oxygen to generate electrical power and at the same time to capture the residual heat which in turn is used to heat up water. Ene-Farm was chosen here for both its wide spread use and its high efficiency ratio.

The extended topology of the observed microgrid, very similar to the real world one, can be seen on Figure 1.

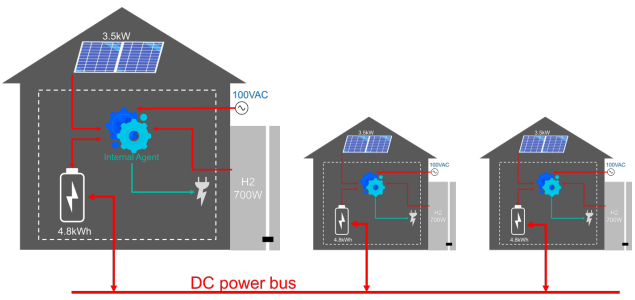

Figure 1: Sample subsystem configuration and general microgrid architecture of the chosen microgrid

3.2 Prosumers' groups in the OES community

During the process of design and development of the prototype the daily consumption of all 19 members of the OES community for the entire year of 2015 was examined in detailed. Furthermore the solar generation patterns we also mapped for the same period of time. Based on the analysis, the OES consumers were divided into three main groups, defined by their individual average daily consumption for the observed period, using the generated output from the fuel cell and the solar panels patters a baseline indicator. The groups are as follows:

1. Group 1: High consumers, with observed daily average consumption of more than 700 watts;
2. Group 2: Average consumers, with daily average consumption in the range of 350 to 700 watts;
3. Group 3: Low consumers, with daily average consumption of less than 350 watts.

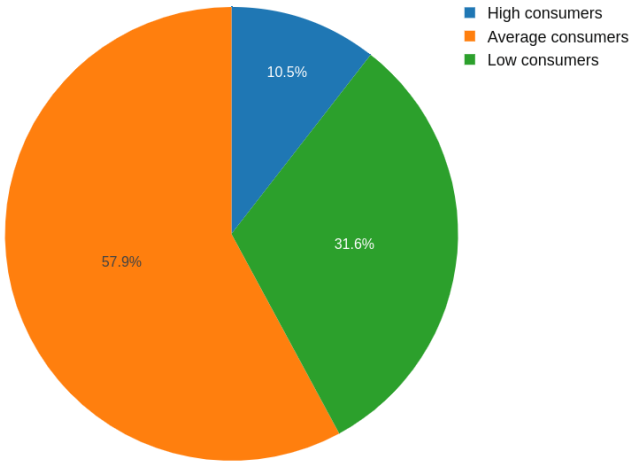

Figure 2: OES prosumers distribution, based on their consumption

Figure 2, shows that more than 50% of the consumers in the OES community are in the second category, a trend that remained unchanged for the entire year 2015. Moreover, no noticeable changes in the members of Group 2 was observed throughout the year. One notable exception was registered in April 2015 when a user moved from Group 3 to Group 1 due customers moving into previously uninhabited house.

Dividing the community into categories, based on such a crucial factor as consumption, helps further the understanding of the community and the prosumers themselves because it provides an effective way to analyze the behavior of different types of consumer since members of one category tend to exhibit similar behavior within an acceptable margin of error. That will allow for the development of different strategies aimed to satisfy the needs of variety of customers.

4 Prototype design and implementation

The prototype, presented here, is developed based on the Open Energy Systems (OES), a real world microgrid operating in Okinawa, Japan. This section will provide an overview of the basic premises and concrete algorithms used in the development of the proposed solution.

4.1 Design assumptions and limitations

During the development of the prototype, presented here, several simplification were incorporated in the design. The following paragraph focuses only on the ones that have major implication for the research, subject of this paper. For more detailed list, please refer to the cited paper [1].

1. No losses, including conversion and transmission losses, are taken into account during the powerflow management;
2. Projected transmission losses, however, are taken into consideration in the pricing algorithm;
3. Initial investment in the renewable source is disregarded when calculating the energy price;
4. Each subsystem is equipped battery, used for absorbing imbalances in the network;
5. The price of the battery is calculated for $\forall t \in \mathcal{T}$, where $\mathcal{T}$ is time series.
6. The price of the battery is calculated as a sum of the amount charged in the battery from each power source multiplied by the predefined energy price of the source and then divided by the current amount of energy in the battery. The formula can be seen bellow.

$$bp = \frac{\sum_{i \in \mathcal{N}} \mathrm{PS}_{i,t}^{\mathrm{amount}} * \mathrm{PS}_{i}^{\mathrm{price}}}{currentcapacity} \quad \forall t \in \mathcal{T} \qquad (1)$$

7. Users are charged when storing energy in the battery, not when discharging the stored energy for the consumption
8. It is presumed that the data, provided by the power meters and the controllers, can be trusted;
9. The DC line capacity is set as 2.5 kw for all subsystems;
10. Japanese yen is selected as main currency for all the financial transactions, due to the microgrid location;
11. The battery is charged solely from the renewable sources;
12. There is no Feed-in to the utility grid

4.2 Prototype design

The following paragraphs will give a short description of the internal and externals strategies, focusing on the bidding component of the former. For more information about the chosen algorithms, please refer to the cited paper [1].

4.2.1 *Internal strategy*

The internal strategy, used in this paper, is tasked with managing the demand-response efficiency of each subsystem and with evaluating the system needs for buying and selling energy. It is comprised of two main components: priority-based agent and bidding agent, each implementing different side of the internal agent. They are designed to work independently using only the same data in order to increase encapsulation. More information about the basis of the algorithms cam be found in the paragraphs bellow.

Priority-based internal agent: The internal agent is responsible for scheduling the power flows to and from the modules, configured for each individual subsystem. It is designed for standalone house equipped with residential storage, energy sources and loads. The fundamental premise built into the design of the system is inherent flexibility when it comes to changing the number and types of the installed power sources. Essentially the system allows for various sources such as photovoltaic and fuel cells, wind turbines, standard electricity grid, etc. to be added to the configuration at any moment, given that each source is a assigned a priority level, a parameter used to control when it is going to be used, and a price for electricity for kWh. The priority is normally determined by factors such as energy price and cost for curtailment. In the current system the priority is set as follows: fuel cell output; solar generation; battery; utility grid. In this case power sources with what is considered an expensive curtailment, like fuel cells, are given higher priority in order to fully utilize their generation even though the cost for electricity for other sources such as solar tends to be much lower. Once the priority is defined, the algorithms uses it to satisfy the demand-response requirements by accessing the available energy from each source until the demand is satisfied. If after using all the power from the renewables, the demand is still not satisfied, the system gets the remaining necessary power from the AC grid. If there is still available renewable energy after the demand-response requirements are satisfied, it is charged to the battery if there is enough capacity, the remaining energy is curtailed. As it can be seen, in this system, the battery plays a dual role as both a power source and a load. The role of the agent is to maintain internal power balance at any moment:

$$P^{batt}_{i,t} = \sum_{n=1}^{\infty} P^{ps}_{n,i,t} + P^{ac}_{i,t} + P^{trade}_{i,t} - P^{load}_{i,t} \quad \forall t \in \mathcal{T}, i \in \mathcal{Z} \qquad (2)$$

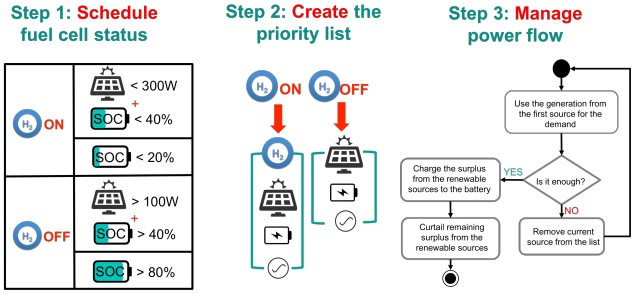

Figure 3: Scheduling conditions and simplified workflow of the internal agent.

Following the research presented in previous works [1] a scheduling component was added to the functionality of the internal agent. This software module is tasked with scheduling the operating hours of power sources with constant output like a fuel cell. The module analyzes the future energy requirements and gives command to shut down or turn on the fuel cell. Fuel cells of the Ene-Farm type require 30 minutes to stop and start operation therefore the default conditions are set based on the solar generation output and the SoC of the battery to take into account the future state of the system.

Figure 3 shows the basic workflow of the priority-based internal agent with the defined configuration. As shown the fuel cell is scheduled to shut down when the SoC of the battery is higher that 80%, which is more than enough to satisfy any upcoming changes in the consumption and to reduce to risk of curtailment from this power source. Even if the SoC is lower, if there is an observed spike in the solar generation, the fuel cell also turn off to enable the solar generation to be fully absorbed by the battery, thus utilizing better the generation and lowering the bidding price. In the opposite scenario, the fuel cell is scheduled to resume operations, when the SoC falls under 20% in order to prevent the activation of the connection to the utility grid, which has much higher price than the fuel cell generation. For the same reasons, the fuel cell turns on, when there is a decline in solar generation whether due to reduced solar radiation caused by weather conditions or during nightfall. This conditions help reduce the electricity cost for the household by decreasing the reliance on the utility grid.

Bidding agent: The bidding agent is a module that is installed together with the internal agent and is tasked with generating a sell or buy bid for the next timeslot and dispatching it for matching. Each bid consists of desired amount of electricity for a certain price for kWh. The amount is determined based on a detailed analysis of the status of each subsystem which includes the number and type of configured power sources, e.g. batteries, PV, fuel cell, etc., and current consumption and generation patterns. This is then used by a pricing function to determine the future need for electricity and is reflected in the bids that follow.

The bidding strategy, subject to evaluation of this paper, uses the State-of-charge (SoC) of the installed battery to predict the amount of electricity that will be needed for the next 30-minute timeslot but with two different pricing algorithms. The ***base*** amount, seen in Figure 4a,b, refers to the minimum amount of electricity available for exchange, calculated as a function of the DC line capacity and the trading timeslot duration to avoid line congestion.

In the case of the previously used bidding strategy, the prices are fixed based on the prices for the electricity, paid by the customer, as seen on Figure 4a. It is assumed that the lower the SoC level, the more inclined is the prosumer to buy electricity. Since all systems are connected to the AC-grid, the highest price for the electricity in the market was designed to always be less than the price of the grid. Similarly, there is a higher incentive to sell the generated renewable energy when the battery is getting full. The price in this case is set as a minimum price at which electricity can

be sold while still generating profit. This pricing, although well designed for the original OES configuration, is not as effective in the presence of a stable power source such as fuel cell, because of the difference in the price for energy, generated from the solar panels and from Ene-Farm.

Battery SoC (%)	Sell Bid		Buy Bid	
	price (yen/kWh)	amount(watt-hour)	price (yen/kWh)	amount(watt-hour)
<=20			25	(base) x4
20 - 40	30	base	20	(base) x3
40 - 60	20	(base) x2	10	(base) x2
60 - 80	15	(base) x3	5	base
>= 80	10	(base) x4		

a)

Battery SoC (%)	Sell Bid		Buy Bid	
	price (yen/kWh)	amount(watt-hour)	price (yen/kWh)	amount(watt-hour)
<=20			25	(base) x4
20 - 40	bp + 40%	base	20	(base) x3
40 - 60	bp + 35%	(base) x2	10	(base) x2
60 - 80	bp + 30%	(base) x3	5	base
>= 80	bp + 25%	(base) x4		

b)

Figure 4: Bidding prices and amounts for State of Charge (SoC)-based bidding strategy with simple pricing algorithm(**a**) and pricing algorithm based on battery price (**b**).

The new pricing algorithm, shown on Figure 4b, takes into account the price of the electricity, currently stored in each individual subsystem, noted as ***bp*** in the table. It currently affects only the sell bid with the price similarly decreasing with the increased incentive to sell. The percentage is based on a projected transmission loss of nearly 15% which in the case of the studied community is paid by the Seller.

4.2.2 *External Strategy:*

The external strategy represents the software implementation of the local energy market, used in this study. At the core of the market is the matching algorithm, a simplified version of the Zaraba method, which is a continuous double auction algorithm used by the Japanese Stock Exchange. The trading is done in real time, with multiple sell and buy bids received for the duration of each 30-minute timeslot. They are match on on first-come first-served basis with the most beneficial counter bid being chosen each time as a counterpart. At the end of the timeslot the agreed deals are sent to the internal agent to execute the physical exchange and all the unmatched bids are invalidated.

Since the DC losses are neglected, we assume that the sum of all energy trading must be equal to zero:

$$\sum_{i \in \mathcal{Z}} \mathrm{P}_{i,t}^{\mathrm{trade}} = 0 \quad \forall t \in \mathcal{T} \tag{3}$$

4.2.3 *Virtual Wallet:*

In order to keep an accurate record of all financial transaction, including detailed information about the used energy from the renewable sources and from the grid, cost of the energy charged to batter and cost/revenue from the energy trading, each subsystem has a virtual wallet. The data, kept in the wallet, is accessible via simple user interface which provides basic analysis and monthly reports.

5 Simulation Setup and Results

For numeric evaluation purposes, this study uses the results of multiple simulations, obtained using prototype, comparatively similar to the OES Simulator [7], written in Python 3.6. The prototype provides a software approximation of the internal power flow of each system and of the community. All the implemented algorithms are consistent with the descriptions given in the previous section and in other works [1]. The following subsection will display the general configuration of studied subsystems, the data, provide information of the scope of the data used as an input for the simulator and will discuss the results of the performed tests.

5.1 *Input Data and Configuration*

In order to further the research, shown in previous works [1], the simulation uses the same dataset for the consumption and solar radiation, recorded for 19 houses, part of OES in Okinawa, Japan, in the duration of year 2015 with 10 minutes granularity. The bidding is done for a 30-minutes timeslot in the future, which amounts in total to 48 trading timeslots per day.

Each subsystem in the community has the following configuration of modules:

1. ***Solar panels*** with average area of 20 m^2, with estimated panel yield of 19% and 75% performance ratio. Since the initial investment is not taken into consideration in the estimate, the price for solar energy is set to 0 yen for kWh.

2. ***Fuel cell*** with factory output of 700 watts and predefined price for electricity of14 yen for kWh, based solely on the price of the fuel used, since the initial investment is also disregarded during calculations.

3. ***Utility grid,*** used as an auxiliary power source with no power limitations. The price for electricity is considered 30 yen for kWh, which is an approximation of the real price of the electricity in Japan. This is necessary due to the varying prices for different regions as well as different usage categories.

4. ***Battery*** with capacity of 4.8kWh, charged at 50% with energy price of 10 yen for kWh, used only in the first iteration of the algorithm. For the remaining of the simulation, it is calculated in the beginning of each iteration, how much energy was charge it in the previous cycle and from which renewable source.

5. ***Wallet*** with 100,000 Japanese yen available.

5.2 Results

In order to evaluate the added functionality presented in this paper, two simulations are performed, each using different bidding strategies as listed below:

1. SoC-based bidding strategy, described in the cited paper [1].

2. SoC-based bidding strategy with pricing algorithm based on the battery price of each standalone system, presented in this paper.

All simulations are performed using a only selected potion from the available dataset with length of 1 calendar month, in this case August 2015. To simplify the visualization of the results, only one week, from August 2nd to August 9th, is taken for the analysis of the whole market. That particular week is chosen because of the variety of weather conditions that occurred during that period. The selected timeframe consisting of several sunny days and two partially cloudy day is chosen. In order to better study the behavior pattern of the individual participants, only data from 1 day, August 5th 2015, with daily generation close to the month's average is examined.

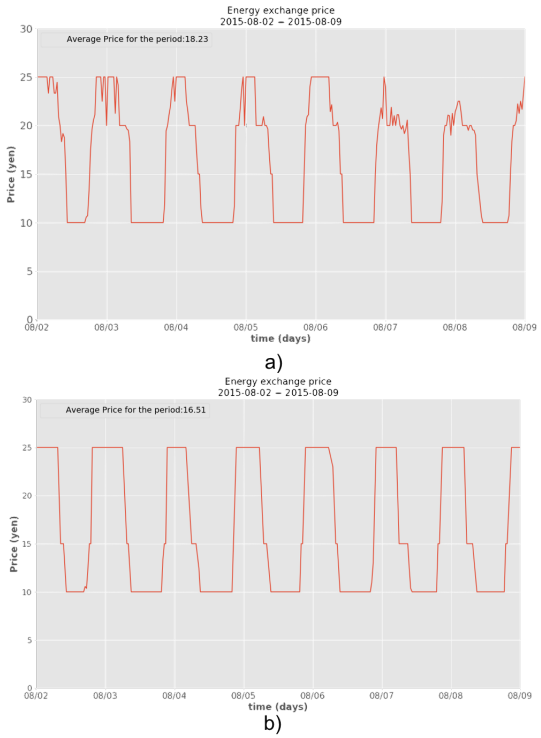

Figure 5: Market price within a community, comprised of standalone houses with solar panels and fuel cells, SoC-based bidding strategy with fixed pricing(**a**) and SoC-based bidding strategy with pricing algorithm based on the battery price (**b**)

5.2.1 Community overview

This section will provide a detailed analysis of the effects of the new bidding strategy on the entire community before focusing on selected members of the predefined prosumers' groups. The second portion of the analysis can be seen in the next section. Detailed analysis of the results of the simulations showed 55% decrease in the number of deals with the new bidding strategy. This is due to less available matches in the preferable price range of the prosumers which makes them less willing to either sell or buy energy if it is not beneficial for them. This has had an effect on the market price as well as seen on Figure 5.

Fig. 5b shows that the pricing algorithm, has led to predictable patterns for market price, with stable peaks that indicate higher prices in comparison with the case of fixed pricing, Fig. 5a. Most influenced by the new pricing algorithm are the high consumers which show 10% decrease in energy spending. Average consumers and low consumers with daily average consumption more than 100 watts spent 7% less for electricity for the same period of time while systems with daily average consumption of less than 100 watts registers a surplus increase of 10%.

Despite the lower number of deals, there has been observed in 10% increase in the utilization of solar generation due to a drop in the consumption of electricity from the AC grid. The numbers are based on the numeric evaluation of the results though a slight reduction the curtailment peaks can be seen on Figure 6. The increase is due to more customized bidding strategy and shows that better focus on customers' energy requirements and implementing them into individual bidding strategy can be used as a foundation for building self-sustainable community. There is no visible curve for the Fuel cell curtailment since it remains 0 for the entire period due to the efficiency of the scheduling component of the internal agent.

5.2.2 Analysis of individual prosumers from the predefined groups

The analysis of a selected members of the groups, described above, provides a deeper understanding of the results shown above. Consumers of all groups showed slight in the usage of the energy stored in their battery which is a contributing factor for the slight decrease in the solar curtailment.

For a Group 1 consumer the increase has led to lowering the usage of the AC grid, shown on Fig. 7, while for consumer from Groups 2 and 3, the difference is compensated by using less electricity directly from the Fuel cell, shown on Fig. 8 and Fig. 9 respectively. The solar usage remained unchanged. Since solar energy is considerable cheaper than the one from AC or Fuel cell it can be considered as a factor in the general lowering of the energy cost.

Deeper analysis of the sources of energy for the battery further shows that the new pricing algorithm has contributed to the higher utilization of the solar energy. Although the results shows very little change for customers of Group 1, Fig. 10, in the case of customers from both Group 2 and 3, Fig. 11 and Fig. 12 respectively, shows increased charging from the solar generation while the no energy has been bought from the market. That scenario shows better management of the energy and of the trading which is more consistent with the system requirement of this two types of consumers since both should have enough energy so be entirely self-sufficient and participate in the market only to sell their excess energy. The graph of the energy exchanged through the DC bus gives even better idea of what is happening. As we can see on Fig. 14 for customers of Group 2 and Fig. 15 for customers of Group 3, there is a distinctive

lack of spikes that indicate buy deals, which shows that in the case of the simple SoC strategy we have moments early morning and late evening where prosumers with enough energy are forced to buy from other prosumers electricity on higher prices because they have previously sold their for lower price. Reversed pattern can be observed for customers of Group 1, Fig. 13, because their have electricity demand that on average exceeds their generation by 50% so they should not be selling energy in those periods of time as well.

Although the effects on the community are only marginal, the new pricing method had shown significant shift in the patters of all of the observed individual customers. Further customization can provide better results and can make the prosumers more competitive in the market but in the context of their individual needs.

6 Conclusion

This study shows the impact of enhanced pricing algorithm, which accounts for the price of the electricity contained in the battery of standalone systems, part of a local energy market with renewables and batteries. The evaluation is done by analyzing the results, generated by a prototype with the use of real data from a full-scale microgrid in Okinawa, Japan. The microgrid represents a community of 19 houses each equipped with residential storage, photovoltaic cells, fuel cell and AC grid connection. All the houses are connected via dedicated, shared DC power bus which allows them to exchange energy with their neighbors. A continuous double-auction algorithm, used by the Japanese Stock exchange, is used for the implementation of the trading platform. Each house can bid on the local market, using a State-of-Charge based bidding strategy. Similar to previous works [1], some simplifications were taken during the development of the simulation platform, including neglecting all losses and ignoring the price of the energy, stored in the battery when calculating the desired exchange price. The effects of the incorporation of the losses in the algorithm are yet to be studied but it is expected that such change will cause an increase in the market price. The topic is currently being investigated and will be a subject to future works.

This paper focuses on studying how including the battery price in the pricing algorithm affects different types of consumers and the community as a whole. The results show that increasing the customization leads to higher utilization of the renewables and further reduces the cost of electricity for consumers with daily average consumption higher than 100 wats. Since this was achieved with customizing a single parameter, it is the opinion of the authors that further analysis of the behavior of the individual system is need in order to create bidding strategy, tailored to each prosumer. It is the opinion of the authors that a well design exchange strategy should allow for the customers to set individual goals such as maximizing profit, maintaining independence from the utility grid, reducing energy waste, etc. It should implement a prediction algorithm which accounts for consumption and generations patterns and include weather predictions for better evaluation of the energy needs. Furthermore, with the wide spread of renewables and distributed renewable resources (DER), more diverse communities are likely to appear so further tests in the community with standalone systems with various configuration power sources can serve as a testing environment to achieve more realistic results.

Conflict of Interest The authors declare no conflict of interest.

Acknowledgment This paper would not have been possible without the continuous support of the Okinawa Institute of Science and Technology and H.Kitano. The authors would like to thank A.Werth and M.Hoshino, for their contribution in forming these ideas.

ABSTRACT

In this paper, a frequency-tunable antenna is proposed based on a previous antenna which has a ladder shape and a size of 120 x 50 mm^2. It is fed using a coaxial cable and it is operational at 700 MHz which is in the UHF band with a bandwidth of 30 MHz. Varactors, having a very low resistance value and a wide range of capacitance values, are implemented on the surface of the antenna which achieves tunability in the DTV applications band used for mobile handheld devices. By using such varactors, the electromagnetic characteristics of this antenna could be changed by changing its electrical length. Multiple cases are studied; either adding a varactor on each step of the ladder antenna or adding only one varactor in a certain well justified position. The operating frequency is swept in different ranges where all of the obtained frequencies could be used for digital TV broadcasting on mobile devices.

1. Introduction

Digital TV broadcasting is now the median of exchanging information and that is thanks to the progress in digital TV technology in the form of wireless devices as well as the ways of sending and receiving signals. The new mobile devices have an attractive feature which is to allow users to watch TV on their own handheld devices; however, this feature presents some challenges in the field of designing antennas for this purpose. The antenna has to have a small size to fit in the devices and a high performance to satisfy interested users.

This paper is an extension of the work originally presented in the conference paper entitled "Ladder Shape Microstrip Patch Antenna", [1]. It is known that the operational frequency and the size of the antenna are inversely proportional. Since our targeted frequency is in the UHF band, it is then obvious that the size of the antenna operating in the high MHz range will increase. One advantage in the design process is that the designer is capable of slightly sacrificing the efficiency of the antenna because digital TV is a receive-only system in which lower total efficiency is acceptable as stated in [2].

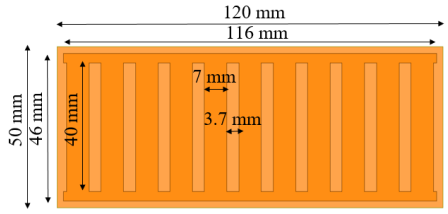
Other than the fact that the antenna has to have a small size, it has to have good impedance matching conditions also. This is where the designer is required to add a matching circuit in the purpose of achieving the best possible power transfer between the amplifier and the antenna, which leads to the optimal antenna efficiency. Also, the designer has to take into account the fact that all the used components in the matching circuit add some losses to the design, which affects the whole performance of the system.

In the literature, there exists many papers that present designs of digital TV broadcasting antennas for mobile handheld devices. Some of these antennas are the grating monopole antenna, [3], having dimensions of 240 x 35 mm^2 and operating between 458 MHz and 960 MHz, the asymmetric fork shaped monopole antenna, [4], having dimensions of 245 x 35 mm^2 and operating between 451 MHz and 912 MHz, the coplanar waveguide-fed dipole antenna, [5], having dimensions of 241 x 58.5 mm^2 and operating between 430 MHz and 1180 MHz and the monopole slot antenna, [6], of dimensions 128 x 51 mm^2 and operating at 600 MHz. In [7], two small microstrip antennas and one planar inverted F antenna are proposed. These antennas are used in the TV band for transmission of cognitive radios. The three of them operate between 700 MHz and 900 MHz. Some new references could be found in the literature such as [8] in which the authors designed and fabricated a flexible printed active antenna having a meander line shape for the DTV reception. It has a size of 180 x 50 mm^2 and a wide operational band ranging from 510 MHz to 790 MHz due to the usage of coplanar waveguide feeding technique. This antenna has an omnidirectional radiation pattern and a maximum gain of about 18 dB. A compact 46 x 46 mm^2 antenna is designed in [9] covering a wide band from 490 MHz to 720 MHz. The bandwidth enhancement is achieved by changing the size of the ground plane of the antenna and the size reduction

* Maria Moussa, Email: mnm33@mail.aub.edu

is achieved by incorporating the meander line shape in the radiating patch.

In [1], the goal was to design a small antenna for digital TV after modifying the antenna proposed in [10], which is also a ladder shaped antenna but operational at 90 GHz. Considerable modifications were done on the latter one to function in the MHz frequencies despite the fact that wireless devices impose some size constraints on the antenna. The resulting patch antenna has the shape of a ladder and a size of 120 x 50 mm^2 which overrides some of the antennas presented in the literature. Many of the ladder dimensions were studied in [1] to try to improve the matching conditions. The software used for the design and simulation of the antenna is HFSS. It is then fabricated and tested. The simulated and measured results showed good agreement. It has a narrow operational bandwidth of 30 MHz only ranging from 685 MHz to 715 MHz, which do not cover the whole UHF band channels. The solution proposed for that issue is to add surface mounted varactors to the ladder patch antenna to be able to tune the operational bandwidth. A DC bias voltage should be applied to the varactors to change their capacitance values and hence achieve frequency tunability to different UHF channels.

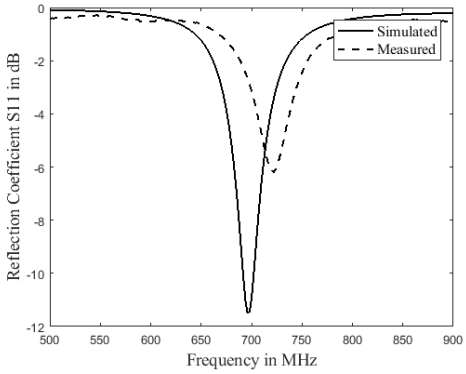


In the upcoming wireless communication systems, reconfigurable antennas are used widely for many reasons. A re-configurable antenna could have the ability of changing many of its characteristics. Frequency, radiation pattern, bandwidth and polarization could be altered to adapt to the environment, [11], using a reconfigurable antenna. Besides their re-configurable capability, re-configurable antennas contain many other features such as reduced cost, size miniaturization and multipurpose functions and they use microstrip antennas as a platform. In addition, recent systems must be able to receive signals over a wide range of frequencies so they require, as stated in [12], either wide-band or tunable narrow-band antennas. The requirement of receiver filters is relaxed because tunable narrow-band antennas, in contrary to broadband antennas, provide frequency selectivity. Tunable antennas, [13], are of interest for wireless communication systems because they could substitute multiple antennas operating at different frequencies, which will reduce the implementation size and its cost as well as the complexity of the system. Another advantage presented by such antennas is the ability to reject the interference from services coexisting in the spectrum. Slot antennas are one of the common types of antennas used in frequency tuning because varactors or switches could be used easily to change their resonant frequency. The frequency tuning is achieved by varying the effective length of the slots using varactor diodes embedded across the slots. Therefore, a tunable antenna could be obtained by loading the patch antennas with varactor diodes, [14], thus having a change in the resonant frequency of the patch.

The authors of [15] present a slot antenna that uses switches to change its electrical length and obtain an effective wide bandwidth. A small patch antenna that could be tuned to different frequencies, ranging from 800MHz to 900 MHz, is designed in [16], this antenna uses variable capacitors and transistors. A radio baseband processor sends commands to a digital control unit implemented in the antenna to control it. In [17], two lumped variable capacitors, also known as varactors, are placed in properly chosen positions on a slot antenna. The antenna is changed to a dual-band antenna having two operational frequencies that could be controlled individually.

In this paper, the varactors are placed according to three different scenarios. The first thing done is to plot the current magnitude on the surface of the antenna in [1] and indicate the points where it is the highest and the lowest. The first scenario is designed by placing a varactor component where the current gets cancelled out, which is in the middle of each ladder step. The two other scenarios are designed by choosing two different points where the current is circulating with high magnitude. These two points appeared to be on the side strip connecting the ladder elements at the same side of the feeding point, one between the third and the fourth element and the other one is between the fourth and the fifth ladder element. Two designs were tested for the second and third scenarios; first, the copper strip facing the varactor had to be removed to avoid short-circuiting the inductors and drive the current to pass through the varactor. The second design was done by removing all strips similar to the one facing the varactor from the ladder patch. All the proposed designs were fabricated and tested and good agreement was obtained between the simulated and the measured reflection coefficients.

2. Original Ladder Antenna: Design and Fabrication



The antenna in [1] is designed with a size of 120 x 50 mm^2 on an FR4 epoxy substrate with a dielectric constant of 4.4 and a thickness of 1.6 mm. All the dimensions of the antenna are shown in Figure 1(a).

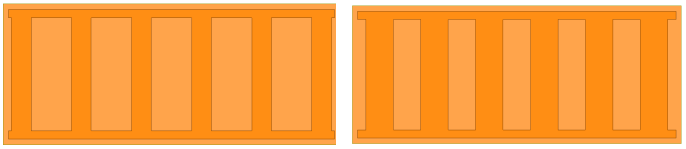
(a) Dimensions.

(b) Prototype.

(c) Simulated and measured S_{11}.

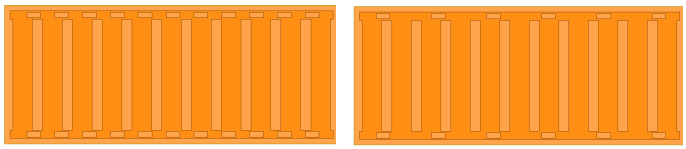
Figure 1: Original ladder shape antenna.

The substrate has a rectangular shape of length 120 mm and a width of 50 mm. The patch has also a rectangular shape of length 116 mm and a width of 46 mm which means that it is smaller than the substrate by 2 mm from each side. The ladder is composed of eleven copper rectangular steps of length 40 mm and of width 7 mm with a spacing of 3.7 mm between each two steps. Finally, the width of each of the two side strips connecting the eleven steps is 3 mm. As already said, the antenna is fed using a coaxial cable and the position of the feeding point was chosen to be in the middle of one of the side strips connecting the ladder elements. A parametric study was done before making the best choice of the feeding position to get the best possible performance of the antenna. The fact that this antenna occupy the entire space of the PCB does not affect the addition of other antennas necessary for the functionality of the device because most of the antennas designed now are very small strip antennas and could use different PCBs.



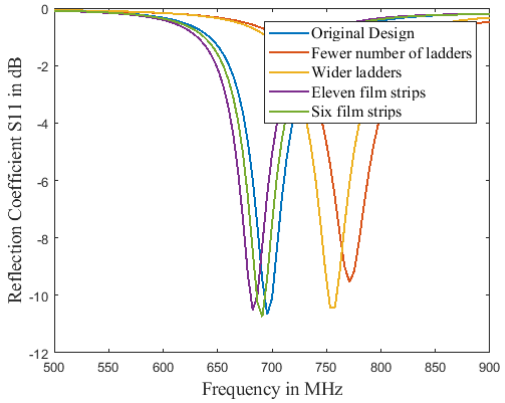
After the fabrication of the antenna as shown in Figure 1(b), measurements were done on its reflection coefficient. Both the simulated and the measured S_{11} are shown in Figure 1(c). There is a good agreement between the simulated and the measured results. The value of -6 dB is the threshold of acceptable S_{11} values for TV antennas therefore the antenna is found to be operational at 700 MHz with a bandwidth of 30 MHz.

The reflection coefficient of the antenna shows that it has a narrow band covering only one TV channel. However, to be able to cover a wider bandwidth in the UHF band, many solutions could be proposed one of which is the use of surface mounted varactors and changing their capacitance values which allows the tuning of the operational frequency of the antenna to different UHF channels.



3. Optimization Approaches

To improve matching conditions at 700 MHz, four approaches were tested in [1]. The first approach, Figure 2(a), was to decrease the number of ladder steps to six. The second, Figure 2(b), was to use the design obtained after applying the first approach and increase the width of the steps to 10 mm which is an increase of 43% of their original width. The third approach, Figure 2(c), was to reuse the original design and subtract eleven slots of size 5 x 2 mm^2 from both, upper and lower, side strips connecting the steps making them look like film strips. The final approach tested, Figure 2(d), was to decrease the number of slots subtracted to six and check their influence on the reflection coefficient. The four approaches mentioned are combined with Figure 2(e) that shows the reflection coefficients of the antennas obtained after applying these approaches as well as that of the original antenna simulated using Ansoft HFSS.



No major improvement is shown in the reflection coefficient of the antenna. Instead, resonant frequency is shifted away from 700 MHz in the four cases. Therefore, since the chosen frequency is 700 MHz and also thanks to the simplicity of the design and its easy fabrication, the antenna of the original design is the one chosen to be fabricated and measured. The network analyzer used to do the measurements is the "FieldFox RF Analyzer N9914A" from the Keysight Company. A small acceptable difference between the simulated and the measured S_{11} could be noticed and it is caused by some fabrication losses therefore, the ladder antenna fabricated is a good candidate to be used for TV applications.

(a) Approach 1. (b) Approach 2.

(c) Approach 3. (d) Approach 4.

(e) Simulated S_{11} of the above approaches.

Figure 2: Investigated optimization approaches.

4. Frequency Tunable Ladder Antenna Scenarios: Designs and Fabrication

The addition of varactor diodes along the current path leads to changing the electrical length of the patch and hence the operating frequency. It all depends on the capacitance value of the varactor; for some capacitances the electrical length increase and the resonant frequency decrease and for some other cases, the inverse occurs.

To plainly explain the effect of the capacitance on the transmission line length, it is necessary to introduce the Smith Chart. The Smith Chart is a way of graphically determining transmission line parameters rather than mathematically. Consider a transmission line, it has an impedance which is usually a complex number expressed by (1) where R is the resistance and X is the reactance and can be plotted on the smith chart using the resistance and the reactance circles. A complete circle on the Smith Chart represents a half wavelength transmission line. One of the important applications of a Smith Chart is the length calculation of a short-circuited piece of transmission line to provide a required capacitive or inductive reactance. The addition of a series RC circuit will change the impedance of the transmission line by adding R to its real part and X_c, calculated using (2), to its imaginary part.

$$Z = R + jX \quad (1)$$

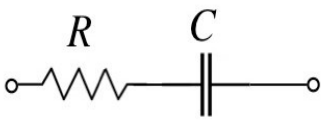
$$X_c = \frac{1}{2\pi f C} \quad (2)$$

f is the frequency in Hertz and C is the capacitance in Farads. Any change in the position of the transmission line impedance point on the Smith Chart, caused by adding matching circuits such as a series RC circuit, will lead to a change in the electrical length of the transmission line as well as its impedance which modifies its matching conditions. The electrical length will either increase or decrease, therefore the operational frequency which is directly related to it, will also change. The distance traveled by a current signal along a transmission line is expressed in relation to its source frequency. The wavelength calculated by (3), where c is the speed of light, is this distance considered for a given frequency.

$$\lambda = \frac{c}{f} \quad (3)$$

In the two suggested scenarios, the varactors are connected serially across a slot subtracted from the radiating patch, which means between two halves of the patch as in [18] and [19]. According to [20], the tunability of the antenna is therefore achieved by cutting small slots from the copper lines and inserting varactors in their place.

The diode model used here is a serial connection between a capacitor and a resistor as shown in Figure 3. The resistor has a very small value of 0.01 Ω. The capacitance of the varactor that is used, 1SV325, is varied between 7 pF and 80 pF when a reverse voltage between 0V and 6V is applied.



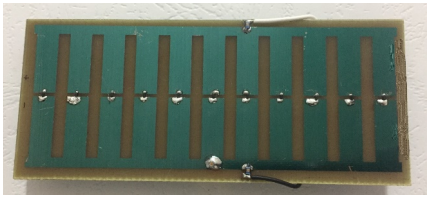


Figure 3: Used configuration of the varactor model depending on resistance R and capacitance C implemented in series.

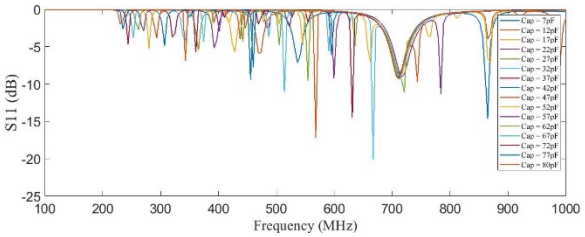
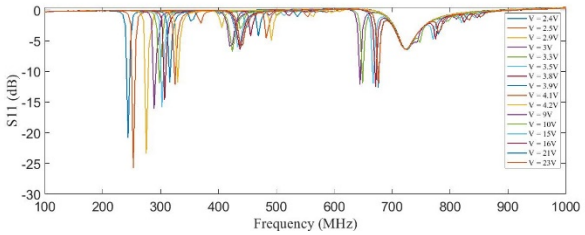


In what follows, the simulated reflection coefficients are presented for some capacitance values ranging between 7 pF and 80 pF. The measured reflection coefficients are captured while varying the DC bias voltage. It is varied between 0V and 6V for the case of only one varactor added to the surface of the ladder patch antenna represented by scenarios 2 and 3 in the following figures. However, the voltage could be varied in a greater range for the antenna of scenario 1 that has a varactor added to each of its ladder steps because the varactors are in a parallel connection to each other so the voltage would be divided across all the varactors.

Figure 4(a) represents the first antenna scenario where eleven varactors are added each in the middle of one of the steps, with the simulated S_{11} in Figure 4(b) and the measured S_{11} in Figure 4(c).



In the second antenna scenario, the varactor is added between the third and the fourth ladder step. Figure 5(a) represents the first design of the second scenario with only one copper strip removed. The simulated S_{11} is represented in Figure 5(b) and the measured S_{11} in Figure 5(c).

(a) One Varactor in the middle of each ladder step.

(c) Measured Reflection Coefficient.

Figure 5: Scenario 2 - Design 1.

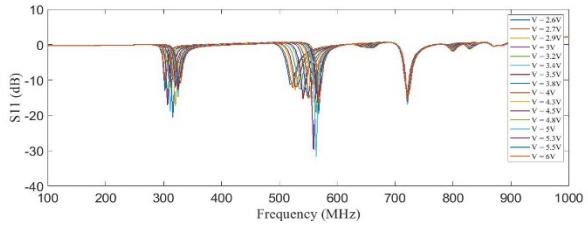

Figure 6(a) represents the second design of the second scenario with all copper strips removed. Its simulated S_{11} is represented in Figure 6(b) and the measured S_{11} in Figure 6(c).

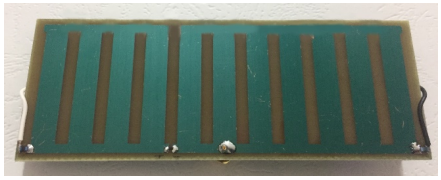
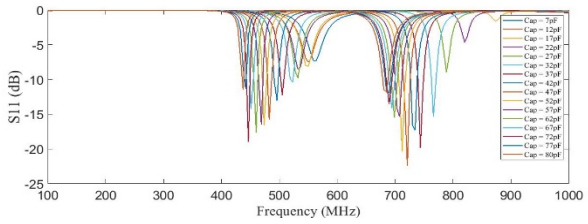
(a) One Varactor between the third and the fourth step with all copper slots removed.



(b) Simulated Reflection Coefficient.



(c) Measured Reflection Coefficient.

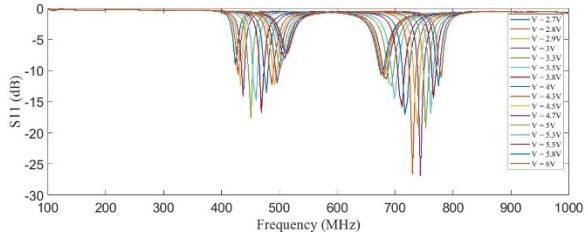


Figure 6: Scenario 2 - Design 2.

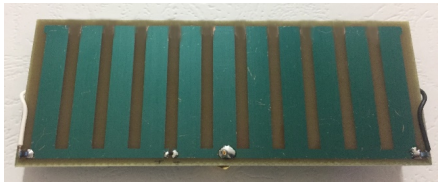
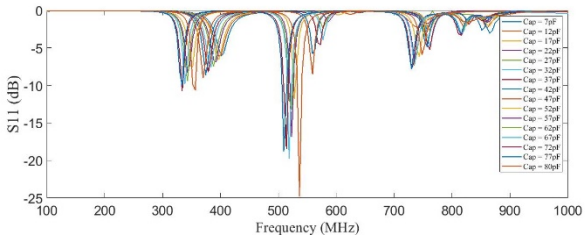
(a) One Varactor between the fourth and the fifth step with one facing copper slot removed.

(b) Simulated Reflection Coefficient.



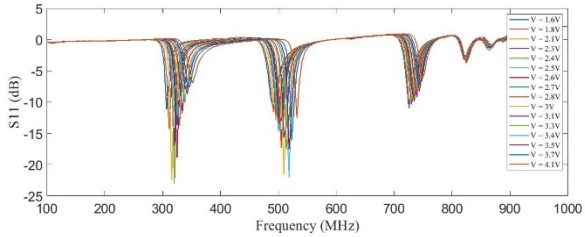
(c) Measured Reflection Coefficient.

Figure 7: Scenario 3 - Design 1.



In the third antenna scenario, the varactor is added between the fourth and the fifth ladder step. Figure 7(a) represents the first design of the last scenario where only one copper strip is removed. The simulated S_{11} is represented in Figure 7(b) and the measured S_{11} in Figure 7(c).

Figure 8(a) represents the second design of the last scenario with all copper strips removed. Its simulated S_{11} is represented in Figure 8(b) and the measured S_{11} in Figure 8(c).



In the figures showing the simulated and the measured reflection coefficients for all the antennas deigned, a slight difference could be noticed. This difference is due to the fabrications inaccuracies as well as the losses that could be encountered in the measurement process. However, it is well shown that all the tunable frequencies fall in the same frequency ranges when comparing simulated and measured results for each design.

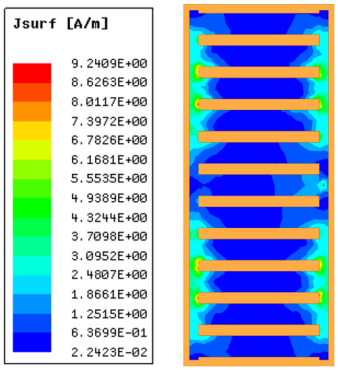
(b) Simulated Reflection Coefficient.

(c) Measured Reflection Coefficient.

Figure 8: Scenario 3 - Design 2.



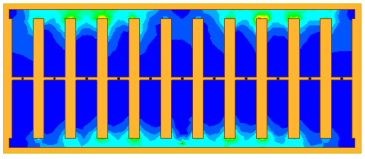


Figure 9: Current distribution for antenna [1].

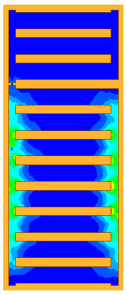

5. Current Distribution

Figure 9 shows the current distribution on the surface of the ladder patch antenna in [1] at the resonant frequency 700 MHz. It is shown that the current magnitude is not equal in all of the points on the patch; the current on the ladder steps is lower than the one circulating on the side strips connecting them. This is obvious since the current is being canceled out in the middle of the steps because of the fact that it is traveling in opposite directions.

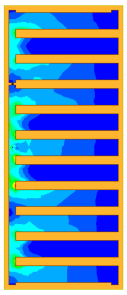

Figure 10 represents the current distribution on the surface of the ladder patch for the five tunable designs discussed above at 700 MHz frequency.

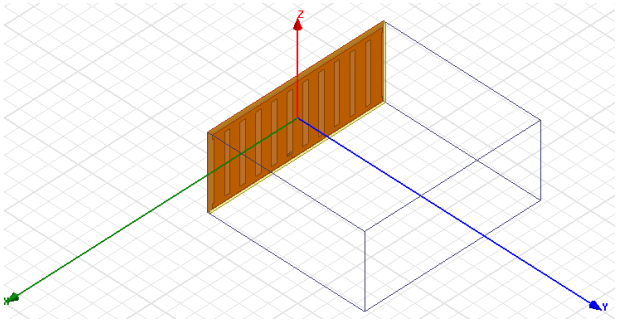
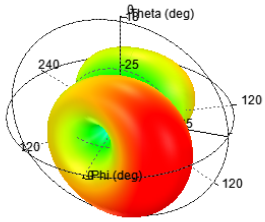
(c) Scenario 2 - Design 2.

(d) Scenario 3 - Design 1



(e) Scenario 3 - Design 2

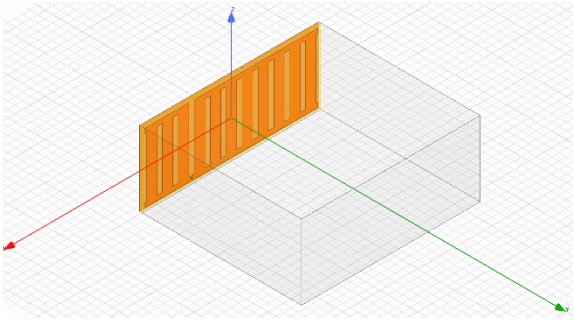
Figure 10: Current distribution for the tunable antennas.



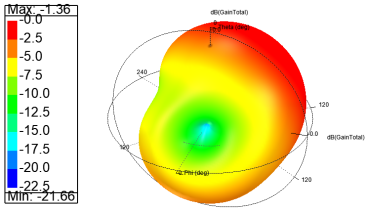
6. Radiation Characteristics

Figure 11(a) shows antenna [1] positioned in the xyz-plane. The three-dimensional radiation pattern of the antenna is shown in Figure 11(b). The main lobe of the antenna is directed in the plane formed by theta equals 90° and phi equals 45°.

Figure 12(a) represents the first antenna design of the second scenario which is having the varactor placed after the third step and removing the copper strip facing it. Two plots of the radiation pattern are presented in Figures 12(b) and 12(c) for resonating frequencies 840 MHz and 870 MHz respectively. Both plots show that the main lobe changed its direction when compared to that of antenna [1].



(a) Antenna [1] in the xyz plane.



(b) 3D Radiation pattern.

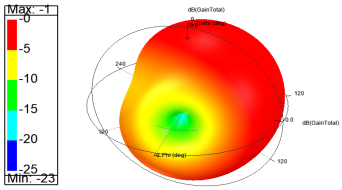


Figure 11: Antenna [1] - Radiation Characteristics.

(a) Antenna of scenario 2 - Design 1.

(b) 3D Radiation pattern at 840 MHz.

(c) 3D Radiation pattern at 870 MHz.

Figure 12: Antenna of scenario 2 - Design 1 - Radiation Characteristics.

It is shown that the gain of this antenna is negative; that is due to its small size compared to what it should have been for operational frequencies in the UHF band. For 700 MHz frequency, the wavelength is around 400 mm however the length of this antenna is 120 mm, which means that the current is circulating on a path that is much smaller than what it should be. However, as

already stated in the introduction, this antenna is considered as a receive-only system in which efficiency could be sacrificed more than in a transmit-system.

7. Conclusion

The antennas presented in this paper are an extension of the ladder-shape microstrip patch antenna design presented in the conference paper [1]. When comparing the antenna presented in [1] to other antennas in the literature designed for the same purpose, it shows good improvement in terms of the compactness of its size. It has a length of 120 mm whereas other antennas are of length 240 mm, [3], and 245 mm, [4]. Even though its size suits most of the mobile phones used in the market, this antenna has one drawback which is its narrow operational bandwidth of 30 MHz.

The proposed solution in this paper is to transform this antenna into a frequency tunable antenna by adding varactors onto its surface. A slight change in the geometrical shape of the antenna will create new current paths and new radiation edges which will introduce multiple shifts in the resonant frequency. According to [21], the position of the varactors obviously affect the current flow path, so to tune the obtained resonant frequency, changing these positions is a must.

The varactors are placed in certain positions that achieve frequency tuning while keeping sufficient matching conditions with minimal perturbation. The antennas presented in this paper resonated on new sets of frequencies falling between 200 MHz and 1 GHz, which allows them to be used for Digital TV broadcasting applications on mobile handheld devices.

These antennas have a negative gain because of their small size according to their frequency of operation however, many techniques could be used to improve the antenna gain such as changing the substrate and using a different material having lower losses such as air, adding parasitic patches or meandering edges, cutting parts of the ground plane, etc…

Simulation tool

ABSTRACT

Digitization forces industry players to adapt to transforming market situations and buyer behavior. Technological advances, buyer power, and sharpened competitive intensity imply that businesses are confronted with the menace of commoditization. For companies to perform successfully in the market, outdated business models ought to be rethought and new business models should be created. Unique selling propositions and differentiation through research, innovation, and holistic stakeholder involvement help industry players to master the change. A tool was built to support businesses facing the consequences of digital transformation: the Business Model Builder. This research paper explores the steps of creating a software version of the analog Business Model Builder. The digital twin enables firms to simulate the iterative adaptation of business models to permanently changing market circumstances and customer demands on an ongoing basis. The user of the tool can edit single variables, understand interrelations, and see the effect on the outcome of the business case, e.g., earnings before interest and taxes or economic value added. Accordingly, the simulation offers the opportunity to have a dynamic view of the business model where any variances of input parameters are reflected in the business case. Thus, profitability, feasibility, and functionality of a business model can be validated, tested, and reviewed in the digital simulation tool.

1. Introduction

Digitization has an impact on most industries, value-creating architectures, and business models based upon them. The impact depends on the market and can – in several cases will – make current business models outdated.

Digitally connecting devices – TVs, household appliances, watches, etc. –, the Internet of Things creates chances for new business models in B2C commerce. Nevertheless, they need to be created and implemented as a first step. Furthermore, the Internet of Things substitutes business models in the B2B segment [1].

To adjust current business models to the transforming market situations, or to come up with new business models, the Business Model Builder was developed within the cooperative research project "low-carbon city" [2] – a project, state subsidized by the German Federal Ministry of Education and Research from August 2016 to December 2018 (references 02K12A150 and 02K12A151). The Business Model Builder represents a digital tool that depicts the modules, drivers, and interrelations vital for the development or modification of business models.

2. Methodology

The creation of the digital twin simulating a business model design tool follows three major steps: conceptualization and design of the analog Business Model Builder, identification of interdependencies within the tool, and coding of the software-supported version to create the digital twin.

3. Digitization Process of the Tool

To customize single elements of a business model during its development, and to reveal consequences of changes on the other elements, the Business Model Builder is designed using application software. This software builds a digital twin of the business model. A digital twin stands for to a digital replica of a business model [3, 4].

This digital duplicate of the business model simulates adaptations or improvements of e.g., a product involved in the

* Kira Rambow-Hoeschele, Email: kira.rambow-hoeschele@t-online.de

business model. This includes testing the effects on function, handling, visual appearance, etc.

Internal links and databases in the background of the application enable to digitally show how adjustments of individual elements impact other ones. Additionally, the business case is calculated in the tool.

Not merely does the digital version of the Business Model Builder provide an iterative and efficient creation of business models, it also provides real-time information. Through the real-time depiction, transformations of business models can be reviewed in a convenient way.

4. Reference to Existing Work and Theories

Over time, the term "business model" has changed and has been defined in various ways. In order to fully comprehend the concept, it is therefore necessary to look at the past definitions as well as future requirements that business models need to fulfill. Business models illustrate a business idea as well as the ways and means by which the idea can be successfully implemented [5]. A business is defined as a product or service that owns a market presence and creates market- and resource-based synergies through collaboration with other entities [6].

Other researchers define the term "business model" as the synthesis of how a company selects its customers, how it defines and differentiates its products, how it structures its internal and external activities, how it uses its resources, how it enters the market, how it creates customer value, and how it earns profits [7]. A business model represents the complete system of how customer value is created and how it is monetized [8]. For several researchers, the elements of value propositions as well as customer segments are of high importance. Moreover, key resources and key activities that are necessary to create customer value as well as revenue streams are considered vital.

According to Timmers, a business model is "an architecture for the product, service and information flows, including a description of the various business actors and their roles and a description of potential benefits for the various business actors and a description of the sources of revenues" [9].

Business models can also be seen as planning and analysis tools. Companies dominating their markets therefore constantly adapt, refine, and develop current or new business models in order to remain competitive [10].

With the new economy boom at the beginning of the current century, the term "business model" was transferred to the business world, as competition was no longer defined as produces and services competing against each other but rather as a clash among various business models [11].

This led to changes in thinking about how to conduct business and where to best allocate resources in order to maximize competitiveness and value creation, since companies no longer possessed competitive advantages due to a superior product or service but rather through the design of complex and advanced business models. Instead of producing a good and simply selling it to the market, the business model needs to tell a reasonable story that is applicable to today's accelerated and more volatile business environment [12].

Moreover, a business model can be defined as a business concept that is applied in the real world. A business concept identifies what value the business is providing to its stakeholders. Also, a business concept is an architecture that should describe how value is generated for customers and business partners. This architecture should include the different steps of value creation. Moreover, it should show how the business model will be able to generate revenues and profits to enable decision makers to identify the value of business ideas and the sustainability of their long-term success [13].

Most researchers see the term "business model" as a simplified depiction of business activities. However, the understanding of the importance of certain aspects of the business model varies [14–17].

Osterwalder and Pigneur define a business model as "nothing else than the value a company offers to one or several segments of customers and the architecture of the firm and its network of partners for creating, marketing, and delivering this value and relationship capital, in order to generate profitable and sustainable revenue streams" [18].

To visualize and to test the realization of business models, they developed the so-called "Business Model Canvas." This is a tool for business model development that can also be used as a checklist to provide an overview of the tasks and requirements that need to be accomplished in order to turn the idea into a real-life business. It is especially helpful to create a common basis for all stakeholders that are involved in the business development process [19].

The concept consists of nine different components that should depict the model in regard to all important parts: customer segments, value proposition, channels, customer relationship, revenue streams, key resources, key activities, key partnerships, and cost structure.

The customer segments component includes consumers as well as businesses. This building block enables a clearer understanding of who the different parties are that are being served by the business. It provides clarity about whom value should be created for and how important those parties are for the business. The different customer segments can be structured according to their needs, their behavior, their specific characteristics, their financial buying power, and their preferred channels.

The value proposition consists of products or services that create value for specific customer segments. This value provided can differ with regard to its nature. It might include performance optimization, branding, work simplification, or entirely new products or services.

The customer relationships component describes how the business interacts with its customers to showcase how it can gain and retain customers. It shows how the relationship between the customer and the company is formed and what kind of relationship they have when conducting business.

The channels component includes all sorts of customer touchpoints as well as the different channels that are used to communicate with the customer and that are needed to distribute and sell the product or service.

Key activities include all important activities that are necessary for the entity in order to conduct business. This includes the processes that are needed to create and provide the value proposition to the customer, that are necessary to build and retain customer relationships, and that are used to reach all markets that are relevant for the business idea.

Key resources include all kinds of resources of physical, financial, human, or intellectual natures. This component gives an overview of all resources that are necessary to conduct the business.

In the key partnerships component, the network of all partners and suppliers that are needed for the business idea is described. This might include strategic alliances, joint ventures, and buyer-seller relationships.

Moreover, in the cost section of the business model canvas, all kinds of key fixed and variable costs are displayed in order to identify the biggest cost drivers that will affect the profitability of the business.

One of the most pivotal components of this model, however, is the revenue part. This section, in which the actual revenue streams are explained, will ultimately provide guidance on whether the business will be successful or not. This might include revenues from sales, rental services, leasing contracts, advertisements, commissions, or subscription fees.

In the following section, several innovative business model ideas are described. Some have existed for a long time in the business world, while others are comparably new, being enabled through technological developments such as e-commerce.

5. Innovative Business Model Approaches

One business model example is the sale of products or services with optional add-on features. This model enables the customer to buy a basic product at a lower price and then be charged a higher amount for additional options. Examples of such business practices can be seen in a variety of businesses such as the airline industry, the automotive industry, or the software industry [20].

A relatively new business model is revenue generation through affiliate links. Through the usage of such links, companies receive a commission based on the generation of sales of products or services through those links. Such business practices are used in e-commerce businesses, e.g., through review or price comparison websites generating additional sales channels for producers [21].

Another prominent business model, especially in the e-commerce sector, is based on auctions. This model enables customers to set the price, leading to higher ambiguity for the seller. Whereas the seller might be able to achieve higher returns in comparison to a traditional sales approach, the business risk increases as the predictability of revenues decreases [22].

Moreover, some companies use a barter approach to acquire new customers by providing free samples of their product. This is often found in the area of consumable products, where potential customers receive a small sample to convince them to convert to paying customers who buy the real product [22].

Bundling and cross-selling approaches capture customers through ecosystems of products and services that, once a customer is acquired, make it rather difficult for them to leave the ecosystem again. Often, technology firms provide a software and hardware ecosystem that enables the customer to synchronize devices and use services on a variety of devices [23, 24].

Another innovative business approach is crowdfunding. This enables companies to make investments they would not have been able to make without the financial support of a broad variety of sponsors [25].

Crowdsourcing business models can be found in a variety of industries. Some companies only try to focus on their specific area of expertise and follow a crowdsourcing approach instead of a vertical integration approach, leading to potential cost savings and more flexibility [26].

Moreover, some companies base their business model on customer loyalty. Many of those companies earn revenues through the collection and analysis of data that is gained from customers who profit from customer loyalty programs, paying with their data [27].

An additional business model that has been developing over the past decades with the rise of digital technology is digitalization. Many businesses have been successful in providing digitized content to customers instead of more resource-intensive and less flexible physical content [28].

Furthermore, the development of the internet created higher market transparency for customers as well as companies and established new ways for producers to earn revenues through direct selling. By leaving out intermediaries, businesses can turn profitable and establish new market opportunities that had not existed before [29].

E-commerce business models are currently transforming the retail business and a variety of industries in ways that have not been seen before. Through lower costs, targeted advertising, broader product offerings, and further advantages, these businesses threaten many well-established companies [30].

Other businesses use flat-rate business models that require users to pay a specific amount in order to use a product or service to an unlimited extent. This has been visible in the online media world, e.g., for music or movie streaming [31].

Additionally, companies use franchising models that enable large scaling effects. After a concept has been developed and a brand established, e.g., in the food industry, local business owners pay for the usage of and supply from the brand [32].

A business model that is frequently visible in the web services industry is the freemium model. This allows customers to use a product in a basic form or for a limited time and offers a premium version that must be paid for [33].

An alternative business model that is often used in the web services industry is hidden revenues. Through the display of advertisements or promotions of complementary products, companies are able to generate revenues [31].

Also, many companies track, analyze, and sell customer data collected through a variety of channels in order to earn revenue. This model is especially used by social media platforms [34].

Intellectual property that might have not been commercialized in the past can be monetized through licensing. Many software firms base their business models on this architecture [33].

Furthermore, through easier accessibility and lower costs due to digitization, long-tail business models have been created that offer products and services that include not only mass products but also niche products that have now become profitable due to economies of scale and lower barriers of entry into a market [35].

Another business model, which became attractive to companies over the past decade, is mass customization, allowing customers to buy products that are mass-produced but customized for them. This has been enabled through technological developments in production, e.g., 3D printing, as well as automation of processes and further technologies. Exemplary industries are the automotive sector as well as the technology hardware sector [36].

Moreover, through lean startup approaches and the reduction of certain product features, no-frills business models have enabled market entry for lower-cost products. A variety of consumable product companies have been established that focus on specific, highly demanded features of a product while leaving out less important features in order to reduce price and increase product attractiveness as well as market attractiveness [37].

Other companies might use open source business models that allow external parties to improve the product. This is a commonly used approach in the software industry, where developers use certain tools that are more adaptable than standard software [38].

An approach that creates flexibility in regard to pricing is the "pay what you want" business model. This architecture can be found in, for example, the cultural sector or the web application sector [39].

With an increased usage of data analytics, pay-per-use business models have become more viable over the past years. Mobility services providers have been using this business model extensively [31].

The razor and razor blade business model architecture is also seen quite frequently in today's consumables industry. Oftentimes, a basic product is provided at a low cost or even free. However, when a replacement of particular parts is needed, the purchase of those parts is more cost-intensive for the customer [33].

A very prominent business model, especially in the web-based industry, is a subscription architecture. This enables companies to earn recurring revenues that might lead to less price-sensitive customers who accept their current costs due to automatic payments. They thereby receive products or services periodically, such as consumables, media, or clothing [40].

Finally, everything-as-a-service (XaaS) business models have been seeing an increasing presence over the last years. In particular, in the software industry, product purchases have been transformed into consuming a service [41].

Those briefly introduced business models are only examples of currently existing business models and should not be seen as an exhaustive list. However, they give a good indication of the variety and complexity of business models that exist nowadays. The aforementioned business models are not only used exclusively but are often implemented as a combination of different models. Due to the potential complexity of business models, it is of high importance to use a development approach that is comprehensive, easy to understand, and flexible to changes.

6. Comparative Analysis of Business Model Definitions and Elements

The creation of a business model consists of multiple connected subcomponents, which build several components, which again join up to form modules. The business model building tool presents the individual elements of a business model and their underlying logic. The Business Model Builder is shown in low granularity in Figure 1.

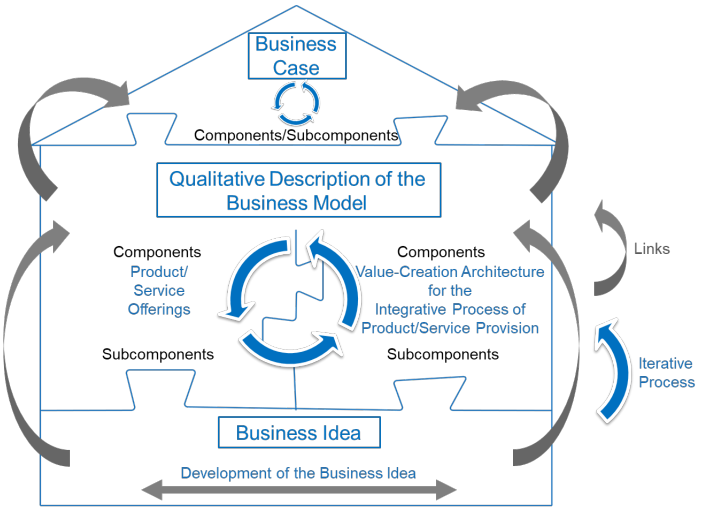

Figure 1: Business Model Builder Depicted in Low Granularity

The application of the Business Model Builder provides the user with business-specific yield numbers indicating the anticipated commercial performance of a business model. The application and field test of the analog Business Model Builder were a success [1].

There have been some former approaches for the creation of business models, e.g., from Gassmann et al. (2013) [42], Schallmo (2013) [43], Osterwalder and Pigneur (2011) [19], or Timmers (1998) [9]. These approaches often consist of diverse checklists, which are mainly grounded on theoretical concepts.

Including all important business model elements, a comparison and evaluation of established business model definitions took place (Figure 2) [7, 9, 10, 13, 15–18, 29, 40, 42–47].

Business models are built of several single elements with differing effect on the outcome of the business case. Various approaches for the creation of a business model can be chosen. For the digitization process of a business model creation tool, nonetheless, it is relevant to individually list all parts. This breakdown eases converting the impact and interrelationships of the single parts into a digital tool since precise relations can be assigned.

To comprehensively include all characteristics required for the development of the digital twin, the Business Model Builder was developed, originating from and enhancing former concepts.

As mentioned earlier, a checklist lacks some details for the complete development of a business model. Every business model requires a well-considered idea as its basis. Several checklists and related concepts still need to examine the soundness of a business idea and review the concept for its resistance. More than fifty percent of new business formations fail [48]. A key reason are unsustainable business ideas [49].

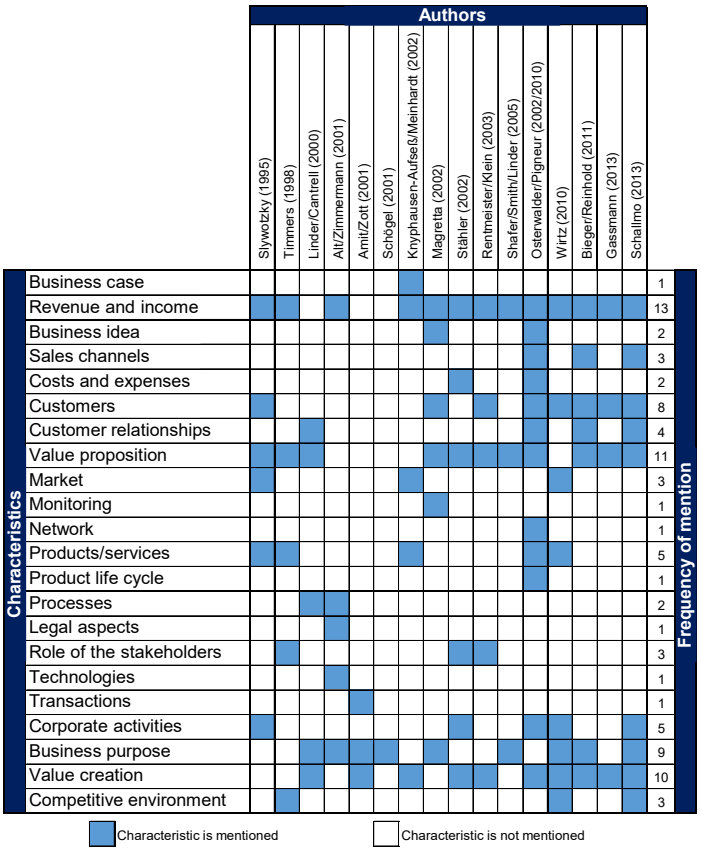

Figure 2: Comparative Analysis of Existing Business Model Theories

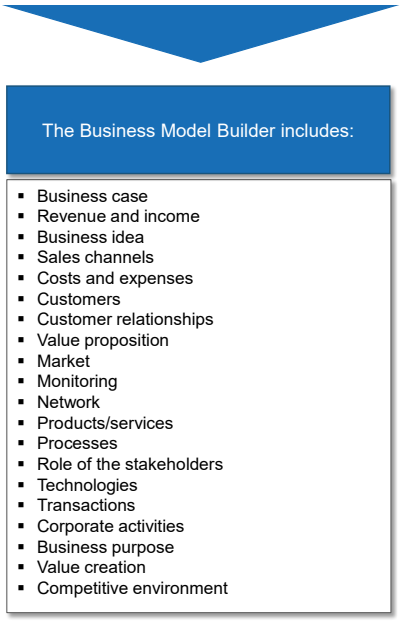

Figure 3: The Business Model Building Tool Extends the Existing State of Knowledge

Figure 3 shows that the Business Model Builder involves all characteristics that are vital for the success of a business model. The tool structures the elements to give a thought-out overview pursuing a distinct logical pattern. The goal of this tool is to enable effective creation of business models.

Compared to the concepts reviewed in Figure 2, the business model building tool follows an explicit architecture to allow for an adjustment of customer demands during and after the process of developing the business model. Pivotal advantages are that the application of this approach is both dynamic and iterative.

Some existing software-supported tools for the creation of business models offer the visualization of the business model elements. However, interrelated effects among the parts are not yet disclosed and precise figures, e.g., of the business case, are not yet calculated.

The software-based version of the business model building tool bridges this gap by paying attention on how individual parts impact each other. Also, business-specific earning numbers are calculated as a result. The digital tool of the Business Model Builder represents a self-contained, cohesive system.

7. Research and Innovation Approach

Within the state-subsidized project, various business ideas were created with the aid of the Business Model Builder for the loading of electric vehicles with self-produced electricity, generated by photovoltaic plants.

The single elements of the Business Model Builder are shown in Figure 4. The subcomponents of the tool form components, which sum up to condensed modules. These modules build on one another. Derived from the current state of research, the order of the subcomponents represents a recommendation on how to develop the business model step by step.

7.1. Module 1: Business Idea

The first module works as an idea filter for business ideas identified as fruitful. The value proposition is investigated from the customer's point of view and reviewed with regard to an implementation in the market.

7.2. Module 2: Qualitative Description of the Business Model

This module comprises of the components product/service offerings as well as creation of offerings / value creating architecture, characterizing the business model under development or revision.

At the end of this process, a definite product/service offering is determined, including a rise in quantity and price on one side and a defined value creating architecture with respective quantities and specific costs on the other side

7.3. Module 3: Business Case

The core of this module is the measurement of how performant a business model will be. The success is quantified by key performance indicators, e.g., earnings before interest and taxes or economic value added. The basis, therefore, includes selling volume and price as well as production volume and costs from the second module. The business case – as a quantified business model – can also serve as the foundation for negotiations with investors, for instance.

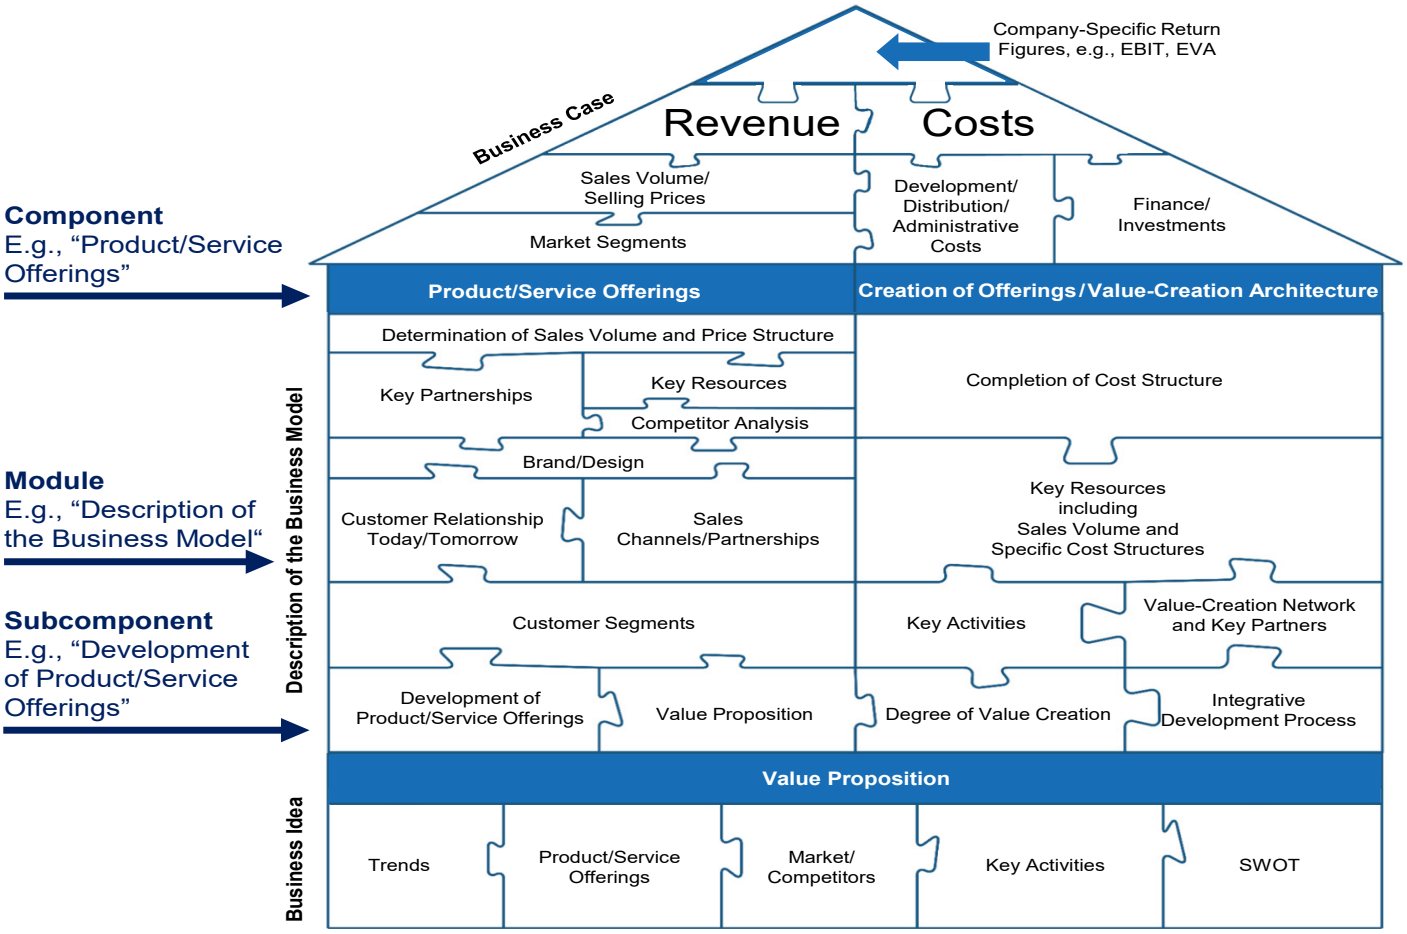

Figure 4: Business Model Builder Depicted in Fine Granularity

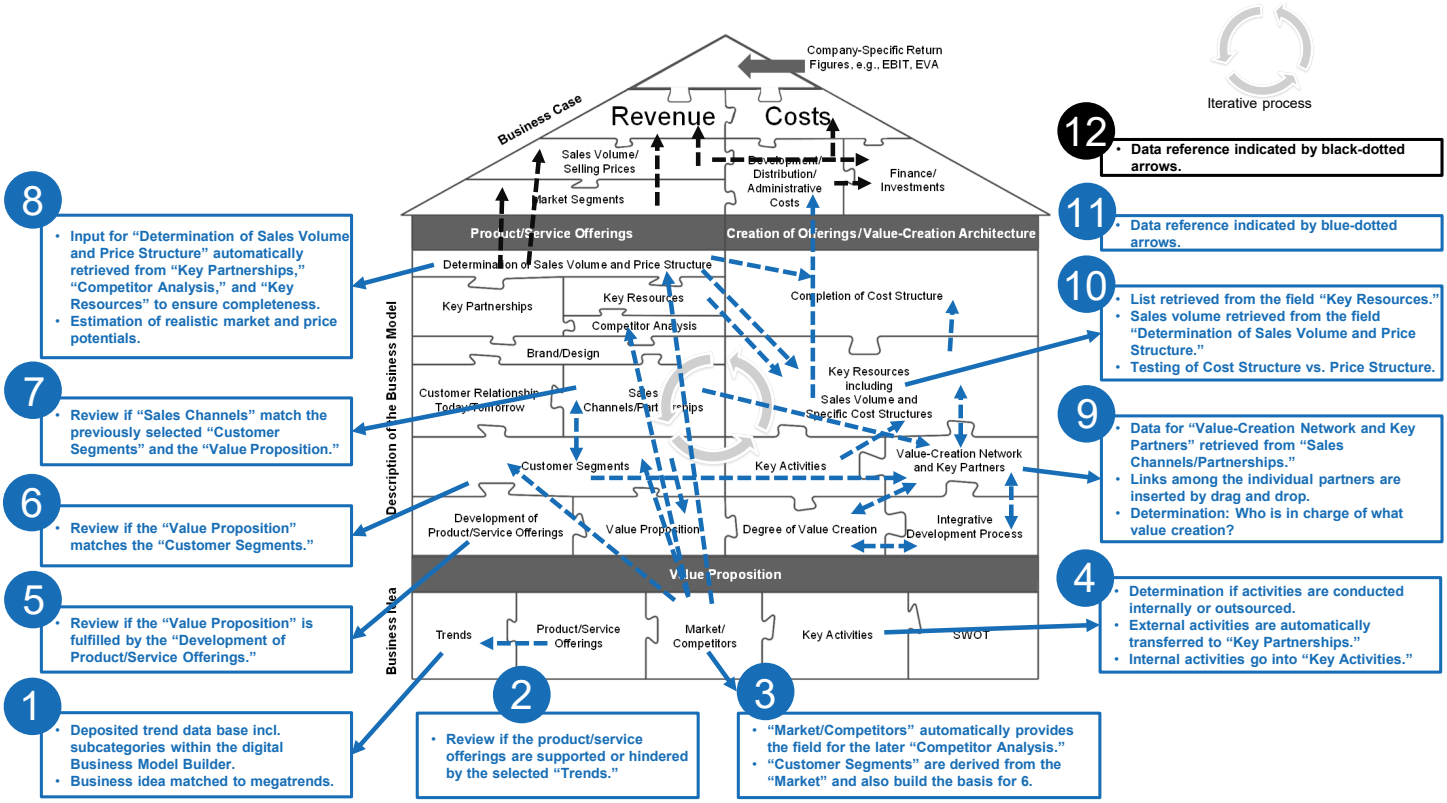

Figure 6: Interdependencies Within the Software-Supported Version of the Business Model Builder

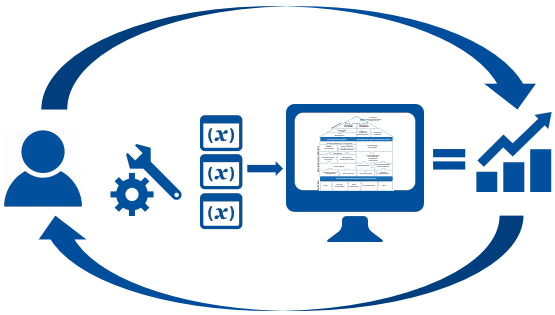

8. Conceptualization of the Tool and Its Digital Twin

The Business Model Builder is designed such that interrelated elements are linked and that effects from changes in one part on another part are revealed. Depending on the input variable, a change can also affect the business case.

The digitization of the Business Model Builder facilitates complex analyses. As multiple elements of the tool depend on other elements and are automatically updated through the links, impact on business results is easily uncovered and visualized.

Figure 5 depicts the schematic setup of the software-based tool. The user is responsible for the input of the elements. The elements automatically match as well as offset against each other. Hence, the operational results are automatically calculated.

Besides, the tool checks the user's input for plausibility and impact on other business model elements. In case of a mismatch, the user is given an error warning, and they are asked to reassess and correct the data entry.

9. Digitization Process of the Tool and Elaboration of Interrelations Among Elements

To digitize the business model building tool, it is pivotal to define which elements are freely definable, which import data from deposited databases, and which are the result of interrelated elements. The details of the interdependencies are shown in Figure 6. For the creation of this tool, all elements are studied for their impact on other elements involved. After the definition of these links, the attendant effects are programmed within the application software. This automizes the steps for the iterative business model development.

Providing an example, the first subcomponent in the tool is the trends. The trends are drawn from an external database. Thus, the user assigns their business idea to a megatrend at first. Subsequently, the idea is assigned to the macrotrends related to the megatrend. Later, the trends chosen are collated with the subcomponent "product/service offerings" to check the content of these subcomponents is consistent.

In addition to the yield numbers, the software-based version of the tool generates a digital twin of the business model. This offers convenient further editing of the business model. For instance, if the figures of the business case calculation lead to a "no go" decision, the subcomponents of the business model can be edited so that yield numbers finally result in a "go" decision. The digital Business Model Builder offers users to gradually adapt and improve the digital twin over the total lifetime.

10. Findings

Digitizing the Business Model Builder, an instrument is developed enabling users to create new, or innovate current business models in a convenient and structured manner with the desired granularity. In the software-based version of the business model building tool, the elements are automatically interconnected. Hence, business models can be modified, and results can be simulated. The tool can holistically depict the complete lifecycle of business models. Thus, various scenarios can be simulated with little expenditure of human labor and time.

11. Limitations

At this phase of the research project, the coding of the digital twin is taking place. As a next step, pilot testing will be implemented to test the application under real-world conditions, collect feedback, and potentially revise and adjust the tool. Only after the rollout will it be possible to see the impact of how the digitized Business Model Builder enhances effectiveness and efficiency of businesses.

12. Conclusion

Digitization pushes businesses aiming for sustainable commercial success to adapt business models to new market situations or create new business models when the former ones become obsolete through technological change. The Business Model Builder was developed to serve this demand. As digital version, the tool enables the permanent iterative adaptation of business models to transforming market circumstances.

The software-based version of the tool allows firms to set up their current business models in a digital twin. In this way, firms have the possibility to conveniently simulate amendments to business models and review their profitability, functionality, and feasibility. Furthermore, new business models can be created, validated, and tested. The digital tool offers established businesses as well as start-ups the option to iteratively adapt their business models to continuously transforming market situations and customer demands over a lifecycle. The tool's mission is to support firms in growing sustainably, in generating and keeping unique selling propositions to stand their ground in the market, and in achieving durable success in the world's markets.

Flame attenuation, narrow channels

ABSTRACT

The article of given research presents the mathematical and computer modeling of flame attenuation in narrow channels for different fire extinguishing and explosion suppression compositions. Such kind of flame distribution and attenuation could be considered for different media and channels but in this case it was considered for narrow channels. The effect on the combustion reaction is possible with gas mixture components concentration reducing, cooling the combustion zone and slowing down of chain reactions with the help of a phlegmatizing or inhibiting substances, of which the most universal and perspective are powder materials. Therefore, a necessary condition for solving the problems of developing effective flame arresters is to find common indicators and properties of substances that can become criteria for their phlegmatizing ability. The computer model in MatLab was created for methane allowing the choice of diameter and length of channel and velocity of explosion suppression composition, showing the dependence of temperature on length of channel.

1. Introduction

This paper is an extension of work originally presented in 2018 IEEE International Conference" Management of Municipal Waste as an Important Factor of Sustainable Urban Development" (WASTE). The influence of flame propagation as a result of heat losses from the reaction zone is the main factor of ensuring explosion safety for combustible gas systems. Thermal losses make it impossible to spread the flame beyond certain boundaries of composition and instrumental conditions. The mechanism of thermal losses plays a leading role in solving the emerging problems of explosion safety. The objective is to provide a general introduction to the Mechanics of heat transfer, together with its elementary applications to Solid and Fluid Mechanics. As result it would assimilated the principal concepts and laws governing the kinematics and dynamics of deformable media. In addition, this research should understand the application of this theory to the cases (i) of infinitesimal Thermo-Elasticity, and (ii) of Newtonian and perfect Fluid Mechanics [1-4].

2. Description of Problem

Mathematical and computer modeling provided a medium of exchange for the diverse disciplines (Mechanics and IT) utilizing mathematical or computer modeling as either a theoretical or working tool. Equal attention was given to the mechanics, methodology and theory of modeling with an attempt to advocate either mathematical or computer modeling, or a combination of the two, in an integrative form [5-7]. When burning in a narrow channel, the key to the mechanism of thermal losses from the reaction zone is the conductive heat conductivity to the walls of the channel. In this case, the reaction zone of obviously explosive gas systems is cooled. In sufficiently narrow channels, heat loss is possible, leading to quenching even of the most rapid-blowing known explosive systems. This feature combustion in narrow channels used in flame arrestors with narrow channels separating apparatus in which possible initiation foci combustion fire-retardant protected by the surrounding space, filled with a potentially explosive environment. The gas and flame have no other way out of the dangerous apparatus.

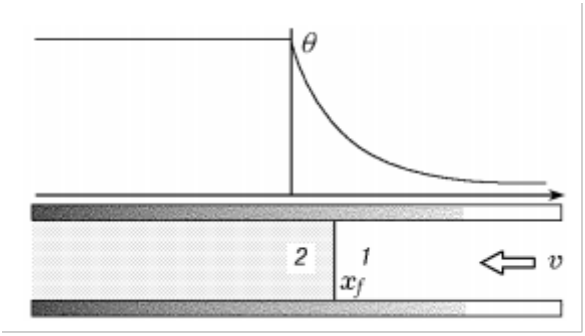

Figure 1: Flame attenuation in narrow channels

The Figure 1 shows a diagram of a flame in a flat channel. As in the classical formulation, approximations are used about the constant density, heat capacity, and thermal conductivity of the gas.

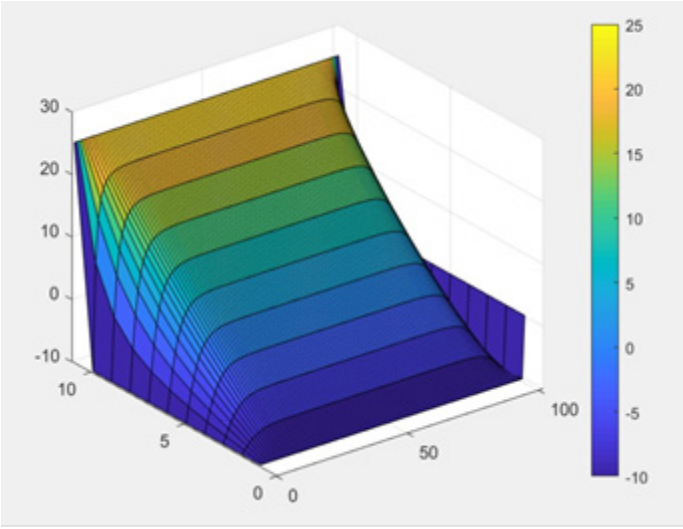

Figure. 2: Temperature distribution from wall to center of channel

This Figure 2 represents the temperature distribution from wall to center of channel. Identifying the relevant heat transfer processes on a heating when the foamed insulation sheet of channel is placed on inner surface and on the outer surface of channel. To avoid singular solution, the round configuration of channel is preferred.

3. Flame attenuation, mathematical modeling

Processes with heat regeneration include filtration combustion of gases, where the flame can stabilize in microchannels between the solid phases, even if the dimensions of the microchannels are substantially smaller than the critical diameter determined from the initial temperature. Combustion in this case is possible provided that the gas phase is surrounded by walls with a temperature exceeding the ambient temperature. This work can be considered as a continuation of the classical works on flame propagation taking into account the transfer of heat from the combustion products to the fresh mixture by an inert medium due to its high thermal conductivity.

Combustion of gas in a channel with heat exchange is the simplest example of a system with a convective heat recovery method. A characteristic feature of combustion in such a system is the thermal interaction between the combustion products and the fresh mixture through the heat-conducting wall. In this linear configuration, unlike devices with special combustion chambers, the flame stabilizes inside the inlet tube. This mechanism of flame stabilization is typical for small-sized systems with recirculation of heat. Studies of the dynamic behavior of a flame in a system with counter-current heat transfer make it possible to study the characteristics of combustion in systems with heat recovery, and also covers a whole series of new phenomena.

It is necessary to solve the Cauchy problem for the one-dimensional heat equation (a second-order partial differential equation that describes the temperature distribution in a given region of space and its variation over time) using parallel programming tools. The problem is solved for a homogeneous heat equation (the system is insulated) on the interval [0, L]: One-dimensional dimensionless equations for temperature have the form

$$\frac{\partial T_{1,2}}{\partial t} = \frac{\partial^2 T_{1,2}}{\partial x^2} + V\frac{\partial T_{1,2}}{\partial x} - \Omega(T_{1,2} - \theta(x))$$

Here the dimensionless time t is measured in units of correlation between thermal properties of gas in channel and adiabatic velocity of gas, i.e. æ/Vb², the dimensionless spatial coordinate x is in units of æ/Vb, where æ is the thermal diffusivity of the gas, and Vb is the adiabatic velocity of the flat flame. The channel wall temperature θ and the gas temperature T are measured in terms of the adiabatic flame temperature Tb [8-10].

The subscripts 1 and 2 refer to the fresh mixture and combustion products, respectively. The gas velocity V is measured in units of Vb. The dimensionless heat transfer parameter $\Omega = 4Nu/Pe^2$ is related to the Nusselt number $Nu=\alpha d_o/\lambda g$ and the Peclet number $Pe=Vbd_o/æ$, which are determined for the channel of height d_o (here α is the heat transfer coefficient; λg is the thermal conductivity of the gas). The boundary conditions for equations (1) far from the flame have the following form:

$$x \to +\infty:\ T_1 \to \sigma,\ C_1 \to 1,\ \theta \to \sigma$$
$$x \to -\infty:\ T_2 \to \Theta,\ \theta \to \Theta > \sigma$$
$$\sigma = \frac{T_0}{T_b},\quad \Theta = \frac{T_w}{T_b}$$

where T0 is the initial temperature of the fresh mixture, Tw is the wall temperature at the hot end of the channel.

Thus, Equation (1) together with boundary conditions (2) at the ends of a narrow channel determines the spread of the flame in the channel. In this case, the temperature distribution in the channel is calculated (the flame temperature of the combustible gas and its mixture before and after mixing, the temperature of the channel walls and their combination are taken into account) as a function of time. Also, the differential equation of the second order includes the velocities and accelerations of the temperature change. The gas characteristics were calculated from some physical parameters: thermal diffusivity of the gas, dimensionless heat transfer parameter (as correlation of numbers of Nusselt and Peclet), heat transfer coefficient; the thermal conductivity of the gas. Thus, taking into account the boundary conditions (2), the boundary value problem was modeled and coded in Matlab.

4. Numerical calculations in MatLab

The numerical realization of heat transfer process was implemented in MatLab, and Adomian Decomposition Method was used for calculation of components of displacement of parts

of fire extinguishing powders and burning reagents. This calculation needs to use some special functions for discretization of components of temperature.

The basic mechanisms of combustion of gases in systems with heat recirculation can be clarified from the study of combustion of gases in a narrow channel with a controlled wall temperature. Therefore,

studies of gas combustion in micro-channels with controlled wall temperature are necessary for understanding processes in both microsystems with heat regeneration, where the heating of the combustible mixture of gases occurs due to the heat of the exhaust combustion products, and for the development of new technologies that use combustion of gases in various media. The small dimensions of the channel in which combustion occurs allow the creation of an almost uniform temperature distribution in the cross section. Experiments show that the temperature gradient in the walls of the channel, which was created by an external heat source, remains practically constant, both with the combustion of gas inside the channel and without burning. These observations make it promising to use a microchannel with a temperature gradient to study the structure of the flame and to test existing models with detailed kinetics of chemical reactions.

Burning studies usually consider gas flows in which transport phenomena and chemical reactions play an important role. In order to analyze the combustion process, in addition to the chemical transformations of the substance, it is necessary to take into account the phenomena caused by the release of heat. If we take into account the interconnectedness of the above processes, then the complexity of the theoretical analysis of combustion becomes obvious.

Advances in the theory of combustion of gases were associated, first of all, with the use of simple and at the same time realistic mathematical models.

Software Package of given formulas are special calculations that can contain class folders, function, and class definition files, and other packages. The names of classes and functions in Matlab are scoped to the package folder. A package with name" TED in channels" (Thermoelastodynamics in channels) is unique. Function and class names must be unique only within the package. Using a package provides a means to organize classes and functions. Packages also enable you to reuse the names of classes and functions in different packages.

The proposed code of the software product allows you to transparently change the approaches to calculation, change the parameters to be set. Explicit schemes for solving the differential equation are proposed. Also in Matlab, visualization of the computational process was carried out.

The Graphical User Interface GNUI requires the following parameters:

- Diameter of channel (in m),
- Velocity of motion gas or fluid (in m/sec),
- Length of channel (in m).

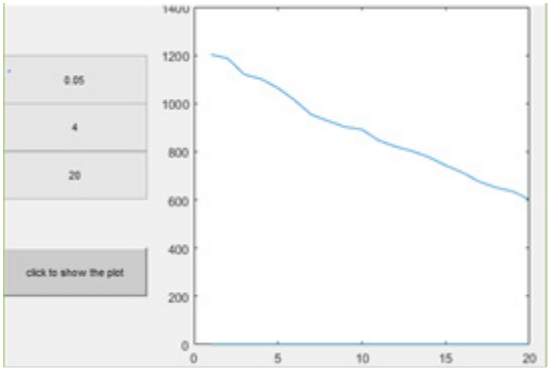

Figure 3: Visualization of flame attenuation in narrow channels in TED in channels

Figure 3 represents the Interface of package and input/output parameters. The graph of the dependence of the change in the combustion temperature of methane on the length of a narrow channel clearly indicates a decrease in temperature during motion away from the flame front, which confirms the physical nature of the problem and the correctness of the chosen mathematical model.

Thus, a mathematical model of flame burning in a narrow channel has been developed, the properties of burning and quenching of gas or liquid in a narrow channel have been studied, depending on the combustion temperature and the flame propagation velocity in the channel. In this case, the inhibitory properties of the substance, flame propagation in thin channels are investigated [11-13]. Based on the 2-D model, a computer model was created in MatLab14. This model requires the specification of some input parameters and provides a graphical representation of the temperature dependence of the length of the channel. The computer model allows you to transform and supplement the subsequent calculations.

As a result of computer modeling of combustion processes in a system with convective heat recirculation, confirmed by some experiments, it was shown that

- in this system

a) it is possible to sustain combustion in a channel with a diameter less than critical,

b) combustion with velocities greater than the normal velocity of the free flame and gas temperature may exceed the adiabatic temperature of the free flame,

c) the flame is resistant to external influences caused by a change in the ambient temperature, changes in the gas flow rate and other factors.

The possibility of flame stabilization in a straight channel with a temperature gradient in the walls, which is created by the combustion products, is shown. These results allow us to conclude that this system is promising for creating, for example, micro-burners.

- A new type of instability has been discovered in the combustion of gas in micro-channels with a longitudinal temperature gradient in the walls of the channel. A feature of this type of flame instability is the presence of an inhomogeneous velocity profile of the gas in the channel and heat exchange with hot walls. The range of values of the gas flow rate at which this type of instability manifests itself is found. It is shown that in a radial channel this type of instability leads to the formation of rotating flame structures, in particular, a spiral flame detected in experiments.

5. Conclusion

The mathematical model of flame attenuation in narrow channels for different fire extinguishing and explosion suppression compositions is given. Such kind of flame distribution and attenuation could be considered for different media and channels but in given research it was considered for narrow channels. The effect on the combustion reaction is possible with gas mixture components concentration reducing, cooling the combustion zone and slowing down of chain reactions with the help of a phlegmatizing or inhibiting substances, of which the most universal and perspective are powder materials. As in the classical formulation, approximations are used about the constant density, heat capacity, and thermal conductivity of the gas. Caushy task

for a second-order partial differential equation that describes the temperature distribution in a given region of space and its variation over time was solved. The numerical realization of heat transfer process was implemented in MatLab, and Adomian Decomposition Method was used for calculation of components of displacement of parts of fire extinguishing powders and burning reagents. The interface with input/output parameters was launched and tested. A package with name" TED in channels" (Thermoelastodynamics in channels) enables to reuse the names of classes and functions in different packages.

Biaxial anisotropy

ABSTRACT

Birefringence is a known property of anisotropic media where incidence of a single propagating wave on a biaxial boundary gives rise to what scientists refer to as an ordinary wave and extraordinary wave. This article explores the anisotropic electromagnetic theory that gives rise to the phenomenon of birefringence focusing on both ordinary and extraordinary plane wave propagation. The dispersion equation in an unbounded anisotropic medium leads to a fourth order polynomial solution for the wave number which is shown to be the root cause of birefringence. Finally, a derivation of the unique properties for a partially filled biaxial rectangular waveguide that serves to suppress wave propagation in the vertical direction will negate the effect of birefringence in the case of the first propagating mode.

1. Introduction

At the invitation of the associate editors of the Advances in Science, Technology and Engineering Systems Journal (ASTESJ), the author presents the following manuscript on an in-depth theoretical expansion of a conference paper previously submitted in the Applied Computational Electromagnetics Society (ACES) Symposium proceedings in 2018 [1]. Originally, the author only discussed the explanation of the suppression effect of anisotropic birefringence inside a rectangular waveguide in brief, and the author feels that scientific interest in the subject warrants a more in depth theoretical examination of the phenomenon. The author has also presented other portions of the theory relating to anisotropic wave propagation in a second publication [2]. Therefore, the author is happy to contribute an expansion on this aspect of the anisotropic birefringence theory to a special issue of ASTESJ at the invite of the associate editors. The article will focus on how the derivation of the anisotropic wave equation in a biaxial anisotropic medium leads to birefringence through a fourth order dispersion equation. The final section will explain how constraints on the boundary conditions of modes in rectangular waveguides can negate the effect of birefringence.

Scientists have understood electromagnetic wave propagation in homogeneous anisotropic optical media since the 1950s. At optical frequencies, one has to rely on naturally occurring crystalline media with anisotropic properties. However, as early as 1958 Collin showed that at microwave frequencies, where the wavelength is much greater, it is possible to fabricate artificial dielectric media having anisotropic properties [3].

Recently engineered materials have come to play a dominant role in the design and implementation of electromagnetic devices and especially antennas. Metamaterials, MetaFerrites, and magneto-dielectrics have all come to play a crucial role in advances made in both the functionality and characterization of such devices. In fact, a movement towards utilizing customized material properties to replace the functionality of traditional radio frequency (RF) components such as broadband matching circuitry, ground planes, and directive elements is apparent in the literature and not just replacement of traditional substrates and superstrates with engineered structures. A firm theoretical understanding of the electromagnetic properties of these materials is necessary for both design and simulation of new and improved RF devices.

Inherently, some of these engineered materials have anisotropic properties. Previously, the study of anisotropy had been limited mostly to the realm of optical frequencies where the phenomenon occurs naturally in substances such as liquid crystals and plasmas. However, the recent development of a separate class engineered materials at microwave frequencies has encouraged the study of electromagnetic anisotropy for RF applications. Low loss anisotropic magneto-dielectrics greatly expands the current antenna design space. Anisotropic media provide unique properties not available using isotropic media. These include a high effective refractive index reducing the electrical size of wavelengths in a medium, relatively low magnetic loss at MHz

frequencies, and lower density and weight than traditional isotropic ferrite materials. Anisotropic media can be up to five times less dense than traditional ferrites while exhibiting magnetic properties with lower loss tangents. Relevant work in this area includes plane wave solutions to propagation in anisotropic media [4-6]. Researchers have also performed modal decomposition of rectangular waveguides filled with anisotropic magneto-dielectrics along with in depth analysis of cut-off wave numbers and field distributions [7, 8].

An anisotropic electromagnetic medium defines permittivity ($\underline{\underline{\varepsilon_r}}$) and permeability ($\underline{\underline{\mu_r}}$) as separate tensors where the values differ in all three Cartesian directions ($\varepsilon_x \neq \varepsilon_y \neq \varepsilon_z$ and $\mu_x \neq \mu_y \neq \mu_z$). This is known as the biaxial definition of anisotropic material which is more encompassing than the uniaxial definition which makes the simplifying assumption that $\varepsilon_x=\varepsilon_y=\varepsilon_t$ and $\mu_x=\mu_y=\mu_t$. The anisotropic definition also differs from the traditional isotropic definition where ε_r and μ_r are the same in all three Cartesian directions defined by a single value. Anisotropic media yield characteristics such as conformal surfaces, the focusing and refraction of electromagnetic waves as they propagate through a medium, high impedance surfaces for artificial magnetic conductors as well as high index, low loss, and lightweight ferrite materials. The following sections aim to discuss in more detail some RF applications directly affected by the incorporation of anisotropic media and will also present a rigorous derivation of the wave equation and dispersion relationships for anisotropic magneto-dielectric media. All results agree with those presented by Meng, et. al [7, 8]. Furthermore, setting $\underline{\underline{\mu_r}} = \underline{\underline{I}}$, where $\underline{\underline{I}}$ is the identity matrix, yields results that agree with those presented by Pozar and Graham for anisotropic dielectric media [6, 9].

2. Applications of Anisotropy in Radio Frequency (RF) Devices

Traditionally, the study of anisotropic properties for RF was limited to a narrow application space where traditional ferrites exhibiting natural anisotropy were the enabling technology. These types of applications included isolators, absorbers, circulators and phase shifters [10, 11]. Traditional ferrites are generally very heavy and very lossy at microwave frequencies and those are the two main limiting factors narrowing their use in RF devices; however, propagation loss is an important asset to devices such as absorbers. Anisotropy itself leads to propagation of an electromagnetic wave in different directions. This phenomenon is already important in devices such as circulators and isolators [10]. For phase shifters and other control devices, changing the bias field across the ferrite controls the microwave signal [11]. However, newer versions of some of these devices, utilizing FETs and diodes in the case of phase shifters, rely on isotropic media to enable higher efficiency devices.

As early as 1958, Collin showed that at microwave frequencies, where the wavelength is larger, it is possible to fabricate artificial dielectric media having anisotropic properties [3]. This has led some to investigate known theoretical solutions to typical RF problems, such as a microstrip patch antenna, and extend them utilizing anisotropic wave propagation in dielectric media [5, 6]. The anisotropic dielectric antenna shows interesting features of basic antenna applications featuring anisotropic substrates. While these solutions establish a framework for electromagnetic wave propagation in anisotropic media, they simplify the problem by necessarily setting $\mu_r=1$ and only focusing on dielectric phenomena of anisotropy.

The proliferation of metamaterials research over the last few decades exemplifies the growing interest in the area of artificial media [12-22]. Metamaterials incorporate the use of artificial microstructures made of subwavelength inclusions implemented with periodic and/or multilayered structures known as unit cells [13]. These devices operate where the wavelength is much larger than the characteristic dimensions of the unit cell elements. One characteristic feature of some types of metamaterials is wave propagation anisotropy [14]. Applications such as directive lensing [15], cloaking [16], electronic beam steering [17], metasurfaces [18], anisotropic oscillators [19], and optics [20] among others all utilize anisotropic media as the enabling technology. More recent research focuses on the proper modeling schemes for computational electromagnetics [21] or examining phenomenon such as scattering off of anisotropic objects [22].

A class of engineered materials exists, known as MetaFerrites, that exhibits positive refractive index, anisotropy, and magneto-dielectric properties with reduced propagation loss at microwave frequencies compared to traditional ferrites. These materials show the unique ability to provide broadband impedance matches for very low profile antennas by exploiting the inherent anisotropy to redirect surface waves thus improving the impedance match of the antenna when very close to a ground plane. Designers have demonstrated antenna profiles at 200 MHz to 500 MHz on the orders of a fortieth of a wavelength using these anisotropic media with over an octave of bandwidth and positive realized gain [2, 23].

3. Anisotropic Wave Equation

The recent development of low loss anisotropic magneto-dielectrics greatly expands the current antenna design space. Here we present a rigorous derivation of the wave equation and dispersion relationships for anisotropic magneto-dielectric media. All results agree with those presented by Meng, et. al [7, 8]. Furthermore, setting $\underline{\underline{\mu_r}} = \underline{\underline{I}}$, where $\underline{\underline{I}}$ is the identity matrix, yields results that agree with those presented by Pozar and Graham for anisotropic dielectric media [6, 9]. Incorporating a fully developed derivation of anisotropic properties of both $\underline{\underline{\varepsilon_r}}$ and $\underline{\underline{\mu_r}}$ expands upon the simplification imposed by both Pozar and Graham that uses an isotropic value of $\mu_r=1$. An expansion on the results of Meng, et. al given in section 4 develops the waveguide theory including a full modal decomposition utilizing the biaxial definition of anisotropy versus their simplified uniaxial definition. The derivation of anisotropic rectangular waveguide resonance in section 6 differs from that of Meng, et. al by addressing the direct relationship between boundary conditions and the existence of birefringence. Furthermore, the analysis of anisotropic properties is not restricted to double negative materials, which is the case for the Meng, et. al studies.

In order to solve for the propagation constants we will need to formulate the dispersion relationship from the anisotropic wave equation. This allows us to solve for the propagation constant in the normal direction of the anisotropic medium. We start with the anisotropic, time harmonic form of Maxwell's source free equations for the electric and magnetic fields

$$\nabla x\underline{\boldsymbol{E}} = -j\omega\mu_o\underline{\underline{\boldsymbol{\mu}}}_r\cdot\underline{\boldsymbol{H}}, \tag{1}$$

$$\nabla x\underline{\boldsymbol{H}} = j\omega\varepsilon_o\underline{\underline{\boldsymbol{\varepsilon}}}_r\cdot\underline{\boldsymbol{E}}, \tag{2}$$

where ω is the frequency in radians, ε_o is the permittivity of free space, μ_o is the permeability of free space, $\underline{\boldsymbol{E}}=\underline{\boldsymbol{x}}_oE_x+\underline{\boldsymbol{y}}_oE_y+\underline{\boldsymbol{z}}_oE_z$, and $\underline{\boldsymbol{H}}=\underline{\boldsymbol{x}}_oH_x+\underline{\boldsymbol{y}}_oH_y+\underline{\boldsymbol{z}}_oH_z$. We define $\underline{\underline{\boldsymbol{\mu}}}_r$ and $\underline{\underline{\boldsymbol{\varepsilon}}}_r$ as

$$\underline{\underline{\varepsilon}}_r = \begin{bmatrix} \varepsilon_x & 0 & 0 \\ 0 & \varepsilon_y & 0 \\ 0 & 0 & \varepsilon_z \end{bmatrix}, \tag{3}$$

$$\underline{\underline{\mu}}_r = \begin{bmatrix} \mu_x & 0 & 0 \\ 0 & \mu_y & 0 \\ 0 & 0 & \mu_z \end{bmatrix}. \tag{4}$$

Combining (1-4) yields

$$\begin{aligned} &\underline{x}_o\left(\frac{dE_Z}{dy}-\frac{dE_Y}{dz}\right)+\underline{y}_o\left(\frac{dE_X}{dz}-\frac{dE_Z}{dx}\right)+\underline{z}_o\left(\frac{dE_Y}{dx}-\frac{dE_X}{dy}\right), \\ &\quad = -j\omega\mu_o\left(\mu_xH_X\underline{x}_o+\mu_yH_Y\underline{y}_o+\mu_zH_Z\underline{z}_o\right) \end{aligned} \tag{5}$$

$$\begin{aligned} &\underline{x}_o\left(\frac{dH_Z}{dy}-\frac{dH_Y}{dz}\right)+\underline{y}_o\left(\frac{dH_X}{dz}-\frac{dH_Z}{dx}\right)+\underline{z}_o\left(\frac{dH_Y}{dx}-\frac{dH_X}{dy}\right). \\ &\quad = j\omega\varepsilon_o\left(\varepsilon_xE_X\underline{x}_o+\varepsilon_yE_Y\underline{y}_o+\varepsilon_zE_Z\underline{z}_o\right) \end{aligned} \tag{6}$$

Using the radiation condition, we assume a solution of $\underline{\boldsymbol{E}}(\underline{\boldsymbol{r}})=\underline{\boldsymbol{E}}(x,y)\exp(-jk_zz)$. Now isolate the individual components of (5) by taking the dot product with $\underline{\boldsymbol{x}}_o$, $\underline{\boldsymbol{y}}_o$, and $\underline{\boldsymbol{z}}_o$ respectively. This operation yields the following equations

$$dE_z/dy - jk_zE_y = -j\omega\mu_o\mu_xH_x, \tag{7}$$

$$jk_zE_x - dE_z/dx = -j\omega\mu_o\mu_yH_y, \tag{8}$$

$$dE_y/dx - dE_x/dy = -j\omega\mu_o\mu_zH_z. \tag{9}$$

The same procedure assuming a solution of $\underline{\boldsymbol{H}}(\underline{\boldsymbol{r}})=\underline{\boldsymbol{H}}(x,y)\exp(-jk_zz)$ for (6) yields

$$dH_z/dy - jk_zH_y = j\omega\varepsilon_o\varepsilon_xE_x, \tag{10}$$

$$jk_zH_x - dH_z/dx = j\omega\varepsilon_o\varepsilon_yE_y, \tag{11}$$

$$dH_y/dx - dH_x/dy = j\omega\varepsilon_o\varepsilon_zE_z. \tag{12}$$

Equations (7-12) allow us to solve for the transverse field components of the electric and magnetic fields in terms of the derivatives of H_z and E_z as

$$E_x = -\frac{j}{k_o^2\mu_y\varepsilon_x-k_z^2}\left(\omega\mu_o\mu_y\frac{dH_z}{dy}+k_z\frac{dE_z}{dx}\right), \tag{13}$$

$$E_y = \frac{j}{k_o^2\mu_x\varepsilon_y-k_z^2}\left(\omega\mu_o\mu_x\frac{dH_z}{dx}-k_z\frac{dE_z}{dy}\right), \tag{14}$$

$$H_x = \frac{j}{k_o^2\mu_x\varepsilon_y-k_z^2}\left(\omega\varepsilon_o\varepsilon_y\frac{dE_z}{dy}-k_z\frac{dH_z}{dx}\right), \tag{15}$$

$$H_y = -\frac{j}{k_o^2\mu_y\varepsilon_x-k_z^2}\left(\omega\varepsilon_o\varepsilon_x\frac{dE_z}{dx}+k_z\frac{dH_z}{dy}\right). \tag{16}$$

Now that we have relationships for the transverse field components, we can solve (1) and (2) for $\underline{\boldsymbol{H}}$ and $\underline{\boldsymbol{E}}$ respectively

$$\underline{H} = -\underline{\mu}_r^{-1}\cdot\left(\nabla x\underline{E}\right)/\left(j\omega\mu_o\right), \tag{17}$$

$$\underline{E} = \underline{\varepsilon}_r^{-1}\cdot\left(\nabla x\underline{H}\right)/\left(j\omega\varepsilon_o\right). \tag{18}$$

Taking the cross product of both sides and substituting (1) for $\nabla x\underline{\boldsymbol{E}}$ and (2) for $\nabla x\underline{\boldsymbol{H}}$ yields [8]

$$\nabla\times\underline{E} = \nabla\times\underline{\varepsilon}_r^{-1}\cdot\left(\nabla x\underline{H}\right)/\left(j\omega\varepsilon_o\right), \tag{19}$$

$$\nabla\times\underline{H} = -\nabla\times\underline{\mu}_r^{-1}\cdot\left(\nabla x\underline{E}\right)/\left(j\omega\mu_o\right), \tag{20}$$

$$\nabla x\underline{\mu}_r^{-1}\cdot\left(\nabla x\underline{E}\right) = -k_o^2\underline{\varepsilon}_r\cdot\underline{E}, \tag{21}$$

$$\nabla x\underline{\mu}_r^{-1}\cdot\left(\nabla x\underline{E}\right) = -k_o^2\underline{\varepsilon}_r\cdot\underline{E}. \tag{22}$$

Equations (21) and (22) represent the vector wave equations in an anisotropic medium.

4. Dispersion Equation for H_z

We expand the $\nabla x\underline{\boldsymbol{H}}$ term of (22) in terms of (13-16), and take the dot product with $\underline{\underline{\boldsymbol{\varepsilon}}}_r^{-1}$

$$\begin{aligned} \nabla x\Bigg[&\frac{\underline{x}_o}{\varepsilon_x}\left(\frac{dH_Z}{dy}-\frac{dH_Y}{dz}\right)+\frac{\underline{y}_o}{\varepsilon_y}\left(\frac{dH_X}{dz}-\frac{dH_Z}{dx}\right) \\ &+\frac{\underline{z}_o}{\varepsilon_z}\left(\frac{dH_Y}{dx}-\frac{dH_X}{dy}\right)\Bigg] = k_o^2\underline{\mu}_r\cdot\underline{H} \end{aligned}, \tag{23}$$

Evaluating (23) and taking the dot product with the $\underline{\boldsymbol{z}}_o$ direction allows us to isolate the H_z component of the magnetic field on the right hand side of the equation

$$-\frac{1}{\varepsilon_y}\frac{d^2H_z}{dx^2}-\frac{1}{\varepsilon_x}\frac{d^2H_z}{dy^2}+\frac{1}{\varepsilon_y}\frac{d^2H_x}{dxdz}+\frac{1}{\varepsilon_x}\frac{d^2H_y}{dydz} = k_o^2\mu_zH_z, \tag{24}$$

Setting E_z=0, if we differentiate (13) by $d^2/dxdz$ and (14) by $d^2/dydz$, keeping in mind that $d/dz = -jk_z$, we arrive at the following result

$$\begin{aligned} &\frac{k_z^2}{\varepsilon_y\left(k_z^2-k_o^2\varepsilon_y\mu_x\right)}\frac{d^2H_z}{dx^2}+\frac{k_z^2}{\varepsilon_x\left(k_z^2-k_o^2\varepsilon_x\mu_y\right)}\frac{d^2H_z}{dy^2} \\ &\quad -\frac{1}{\varepsilon_y}\frac{d^2H_z}{dx^2}-\frac{1}{\varepsilon_x}\frac{d^2H_z}{dy^2} = k_o^2\mu_zH_z \end{aligned}, \tag{25}$$

Combining the d^2H_z/dx^2 and d^2H_z/dy^2 terms in (25) gives the following second order differential dispersion equation for H_z

$$\frac{k_o^2\mu_x}{k_o^2\mu_x\varepsilon_y-k_z^2}\frac{d^2H_z}{dx^2}+\frac{k_o^2\mu_y}{k_o^2\mu_y\varepsilon_x-k_z^2}\frac{d^2H_z}{dy^2}+k_o^2\mu_zH_z = 0. \tag{26}$$

5. Dispersion Equation for E_z

We expand the $\nabla x\underline{\boldsymbol{E}}$ term of (21) in terms of (13-16), and take the dot product with $\underline{\underline{\boldsymbol{\mu}}}_r^{-1}$

$$\begin{aligned} \nabla x\Bigg[&\frac{\underline{x}_o}{\mu_x}\left(\frac{dE_z}{dy}-\frac{dE_y}{dz}\right)+\frac{\underline{y}_o}{\mu_y}\left(\frac{dE_x}{dz}-\frac{dE_z}{dx}\right) \\ &+\frac{\underline{z}_o}{\mu_z}\left(\frac{dE_y}{dx}-\frac{dE_x}{dy}\right)\Bigg] = k_o^2\underline{\varepsilon}_r\cdot\underline{E} \end{aligned}. \tag{27}$$

Evaluating (27) and taking the dot product with the $\underline{z}_o$ direction allows us to isolate the E_z component of the magnetic field on the right hand side of the equation

$$-\frac{1}{\mu_y}\frac{d^2E_z}{dx^2}-\frac{1}{\mu_x}\frac{d^2E_z}{dy^2}+\frac{1}{\mu_y}\frac{d^2E_x}{dxdz}+\frac{1}{\mu_x}\frac{d^2E_y}{dydz}=k_o^2\varepsilon_z E_z . \quad (28)$$

Setting H_z=0, if we differentiate (15) by $d^2/dxdz$ and (16) by $d^2/dydz$, keeping in mind that $d/dz = -jk_z$, and plug the results into (28), then we arrive at the following result

$$\begin{gathered}\frac{k_z^2}{\mu_y\left(k_z^2-k_o^2\mu_y\varepsilon_x\right)}\frac{d^2E_z}{dx^2}+\frac{k_z^2}{\mu_x\left(k_z^2-k_o^2\mu_x\varepsilon_y\right)}\frac{d^2E_z}{dy^2}\\ -\frac{1}{\mu_y}\frac{d^2E_z}{dx^2}-\frac{1}{\mu_x}\frac{d^2E_z}{dy^2}=k_o^2\varepsilon_z E_z\end{gathered} . \quad (29)$$

Combining the d^2E_z/dx^2 and d^2E_z/dy^2 terms in (38) gives the following second order differential dispersion equation for E_z

$$\frac{k_o^2\varepsilon_x}{k_o^2\mu_y\varepsilon_x-k_z^2}\frac{d^2E_z}{dx^2}+\frac{k_o^2\varepsilon_y}{k_o^2\mu_x\varepsilon_y-k_z^2}\frac{d^2E_z}{dy^2}+k_o^2\varepsilon_z E_z=0 . \quad (30)$$

6. Suppression of Birefringence in a Rectangular Waveguide

Birefringence is a characteristic of anisotropic media where a single incident wave entering the boundary of an anisotropic medium gives rise to two refracted waves as shown in Figure 1 or a single incident wave leaving gives rise to two reflected waves as shown in Figure 2. We call these two waves the ordinary wave and the extraordinary wave. For low order modes, and especially the first mode, a rectangular waveguide suppresses the birefringence inherent to anisotropic media by suppressing propagation in the vertical direction. This suppression assumes that the dimensions of the waveguide are such that the horizontal dimension is at least twice the size of the vertical dimension [10]. To see how the geometry of the waveguide acts to cancel out the extraordinary wave, we need to solve for k_z from our dispersion equations.

Equations (26) and (30) yield the following solutions in unbounded anisotropic media restricted by the radiation condition (previously stated in section 3)

$$E_z(x,y,z)=E_o e^{-j\left(k_x x+k_y y+k_z z\right)}, \quad (31)$$

$$H_z(x,y,z)=H_o e^{-j\left(k_x x+k_y y+k_z z\right)} . \quad (32)$$

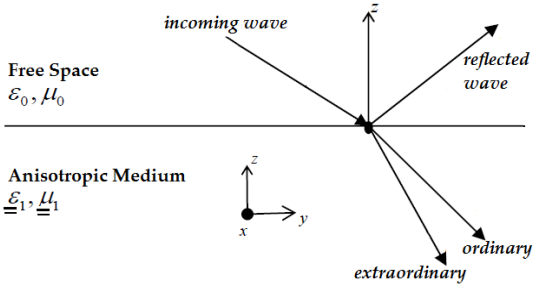

Figure 1: Free space plane wave incident on an anisotropic boundary [9].

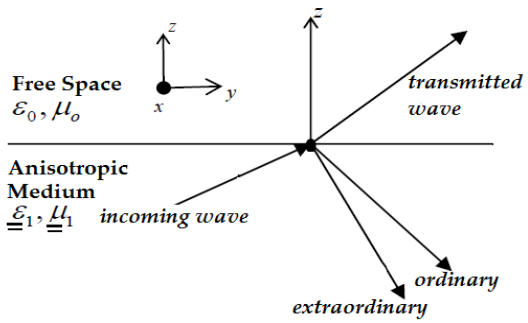

Figure 2: Anisotropic plane wave incident on a free space boundary [9].

Plugging (31) into (30) (equivalently we could substitute (32) into (26)) yields a polynomial equation whose solutions give the values of k_z in the anisotropic medium. Noting that $d^2/dx^2 = -k_x^2$ and $d^2/dy^2 = -k_y^2$, (30) simplifies to

$$\frac{k_o^2k_x^2\varepsilon_x E_z}{\left(k_o^2\mu_y\varepsilon_x-k_z^2\right)}+\frac{k_o^2\varepsilon_y k_y^2E_z}{\left(k_o^2\mu_x\varepsilon_y-k_z^2\right)}-k_o^2\varepsilon_z E_z=0 . \quad (33)$$

Dividing out the $k_o^2E_z$ term and multiplying through by both denominators gives us the following factored polynomial

$$\begin{gathered}\left(k_o^2\mu_y\varepsilon_x-k_z^2\right)\left(k_o^2\mu_x\varepsilon_y-k_z^2\right)\varepsilon_z-k_x^2\varepsilon_x\left(k_o^2\mu_x\varepsilon_y-k_z^2\right)\\ -\varepsilon_y k_y^2\left(k_o^2\mu_y\varepsilon_x-k_z^2\right)=0\end{gathered} . \quad (34)$$

Finally, multiplying out (34) yields a fourth order polynomial whose roots yield the four values of k_z describing the ordinary wave and extraordinary wave in the positive and negative propagation directions

$$\begin{gathered}k_z^4\mu_z+\left[k_x^2\mu_x+k_y^2\mu_y-(\varepsilon_x\mu_y+\varepsilon_y\mu_x)k_o^2\mu_z\right]k_z^2\\ +\left[k_o^4\varepsilon_x\varepsilon_y\mu_x\mu_y\mu_z-k_o^2k_x\varepsilon_x\mu_y\mu_x-k_o^2\varepsilon_y k_y\mu_x\mu_y\right]=0\end{gathered} . \quad (35)$$

Equation (35) is directly responsible for the existence of the two ordinary and extraordinary waves that are characteristic of the birefringence phenomenon. In an isotropic medium, the resulting polynomial for k_z is a second order polynomial, which yields only the values for the positive and negative propagation of the single ordinary wave. A fourth order polynomial allows for positive and negative propagation of both the ordinary and extraordinary wave shown in Figures 1 and 2.

The suppression of birefringence requires (35) to reduce to a second order polynomial. This is clearly not possible in an unbounded anisotropic medium as currently formulated. However, the boundary conditions in a rectangular waveguide assume that the first resonance suppresses the propagation constant in the vertical direction [10]. In other words, k_y=0 and d^2/dy^2=0, and this completely eliminates the second E_z term in (33). This simplifies (34) to

$$-\frac{k_o^2k_x^2\varepsilon_x}{k_o^2\mu_y\varepsilon_x-k_z^2}E_z+k_o^2\varepsilon_z E_z=0 , \quad (36)$$

which resembles the form of the traditional second order wave equation. Solving for k_z thus leads to the following second order polynomial

$$k_z^2 = \varepsilon_x \left(k_o^2 \mu_y - k_x^2 / \varepsilon_z \right). \quad (37)$$

Since (37) yields the positive and negative square root of the right-hand-side as the two solutions for k_z, this indicates the existence of only a single propagating wave. The suppression of the k_y term in the first resonant mode of the rectangular waveguide yields a second order differential equation for the wave number in the propagation direction, thereby eliminating the property of birefringence for this case. For a practical validation of this theory, the author would point the reader to reference [2]. This paper shows an antenna application that exploits the suppression of anisotropic birefringence to facilitate wideband impedance matching of a cavity backed antenna.

The reader should remember that (37) applies only to the first order resonance mode of the rectangular waveguide. As higher order modes are introduced propagation birefringence will exist for some modes depending on the boundary conditions. A similar analysis should be carried out for each propagating mode.

Conflict of Interest

The authors declare no conflict of interest.

ABSTRACT

This paper analyzes the process of reactive power compensation using thyristors switched capacitors TSC topology based on multiterminal switch during the starting of induction motor. The paper explains the control principle of this TSC topology which depends on the multiterminal switch. To actively track the required reactive power for the dynamic load and to perfectly transit from it from one level to other, proper control system is established. MATLAB/SIMULINK is used to develop a simulation model to prove the dynamic performance of the proposed TSC during the compensation of reactive power required for induction motor during starting.

1. Introduction

This paper is an extension of work originally presented in 2018 X International Conference on Electrical Power Drive Systems (ICEPDS) under title (Performance Assessment of Thyristors Switched Capacitors during Reactive Power Compensation of Dynamic Load) [1]. It is well known that; the induction motors are the most broadly utilized motors in the world due to their high rigidness [2]. The powers of the used induction motors vary from the fraction of kilowatt up to several megawatt [3]. The induction motors require reactive power during their operation either they are supplied from conventional AC source or through drive system [4]. But, the connection of reactive power compensators with the induction motors improves the power system quality where they are supplied [5]. The compensation of the reactive power may be achieved by the connection of fixed capacitor on the terminals of the induction motor. But, this method doesn't adapt the requirements of the motor for the various operation modes. The application of dynamically changed reactive power supply improves the power factor for wider operation range particularly during the starting of the motors [6]. The induction motors speed may be changed using dynamically changed reactive power source [7].

Several references [8,9] study the usage of conventional static VAR compensators needed by the induction. The production of harmonics is an essential demerit of the conventional SVCs. Therefore, they require the application of filters [10,11]. The switched-based SVC present a vital solution to remove the harmonics during the control of the reactive power. But, it should be considered that, the switched SVCs have discrete performance during the control of reactive power; consequently, they require different control and design methodology to obtain the smoothest characteristic [12].

This research analyzes the process of reactive power compensation for the starting of induction motor depending on switched SVC. The thyristor switched capacitors TSC which has 25 discrete steps of operation is the type of SVC applied in this study. The design of such TSC topology requires special design to dynamically change the developed capacitive reactive power. The control methodology applied for the TSC topology is established to regulate the proper amount of reactive power during the starting of the induction motor. The detailed induction motor model is illustrated to study the effect of the SVC on its operation. By using MATLAB/SIMULINK package, Simulation model of the whole system is established to demonstrate the TSC performance during the compensation of reactive power.

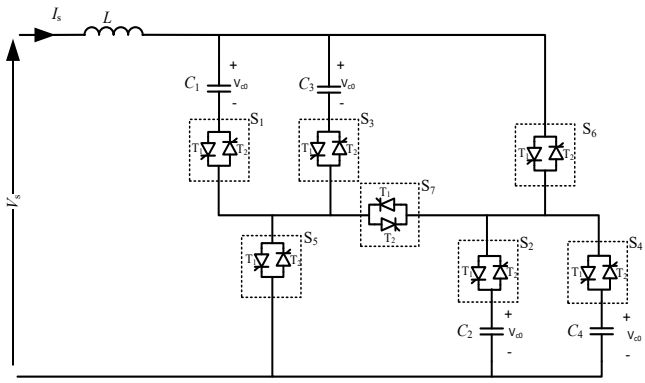

Figure 1: TSC produces 25 discrete levels of capacitive reactive power

2. Principle of operation of multiterminal switch TSC

Figure 1 illustrates the proposed TSC scheme which can produce 25 level of operation by providing 25 different equivalent capacitances [13]. In compared with binary TSC and for the same number of capacitors, the developed scheme produces more steps of operation where the binary TSC only produces 16 steps [14]. Therefore, the developed TSC provides more flexible operation to produce capacitive reactive power while there is no need for application of thyristor-controlled reactor TCR for reactive power regulation. The proposed TSC topology produces zero harmonics during its operation.

Table 1 demonstrates the several equivalent capacitances produced by the proposed TSC. The connected reactor L in the topology is important related to the reduction of current rate of change [15] and related to the restoring of the stored energy on capacitors back to the source [13].

The proposed TSC parameters is obtained depending on an optimization technique which assures the most smooth variation of the distinct characteristic [16,17]. The developed capacitive reactive power has discrete characteristic as shown in Figure 2. The function of control system of this topology is the determination the required reactive power in another words the required susceptance. Therefore, the control system should regulate the operation state of each switch of the seven switches to produce specific capacitance as in Table 1. The TSC reactive power control system needed by induction motor at starting will be explained in section 4.

As shown in Table 1, some of the equivalent capacitance include series connection of certain capacitors. The series connection of capacitors during generation of certain levels of reactive power leads in appearance of permanent different DC voltages on capacitors after termination of the reactive power level generation. To change the equivalent capacitance to another level, the capacitors which were connected in series on previous stage should be discharged. The discharging process should be completed in very short time to make the system response faster. The discharging of capacitors achieved by regenerative method by recovery the capacitors stored energy to the power supply. The

recovery process can be accomplished by connection of reactor L shown in the scheme Figure 1.

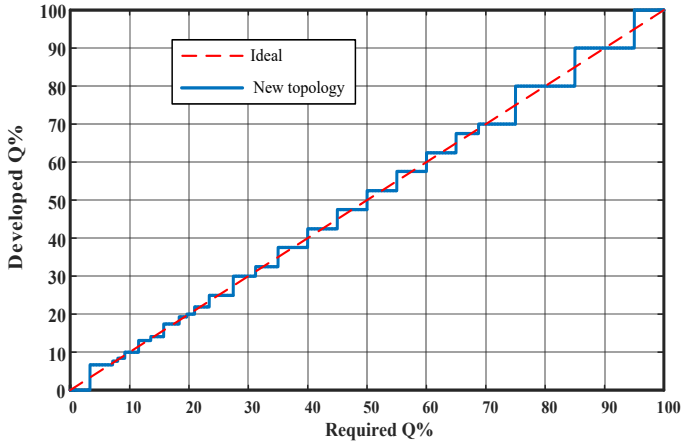

Figure 2: The characteristic of the proposed TSC

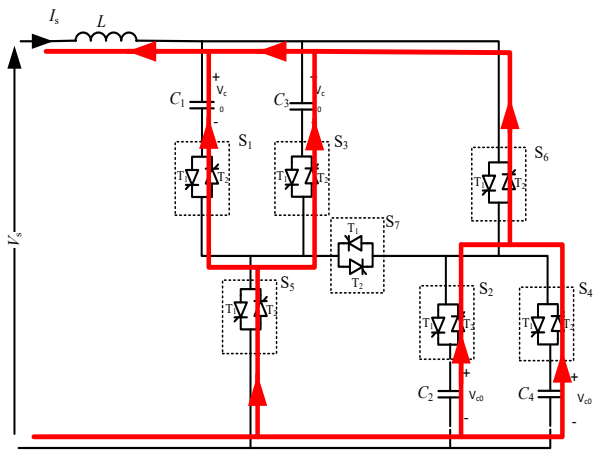

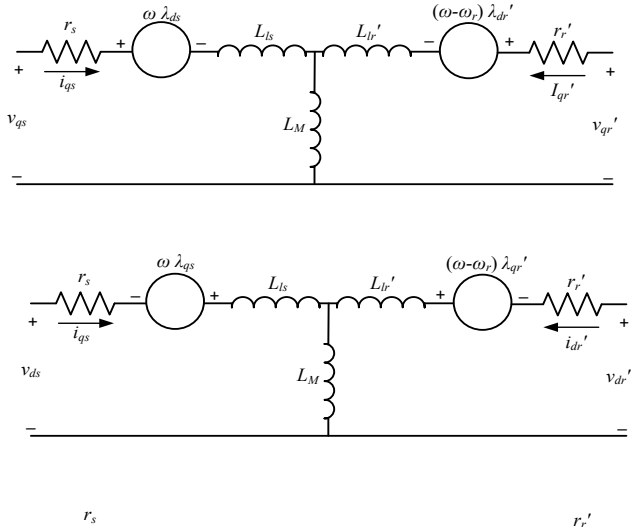

Figure 3: Discharging path for positively charged capacitors of TSC

To discharge all capacitors, the time presents a critical factor, So, in this study, the TSC system is designed to discharge the capacitors in very short less than quarter of the voltage period. The added reactor and any combination of capacitors is considered resonance circuit. By the help of this resonance circuit, the stored energy on capacitors can be recovered to the power source. Figure 3 illustrates the discharging path for the charged capacitors. The regeneration can be completed within time less than the one quarter of the entire period [14]. The semiconductor switches in this scheme has a vital rating related to the maximum amplitude of current during discharging. The inductance value and firing angle to start the process affect the performance of discharging process. The resonance frequencies ω_k relates between the inductance L and the total capacitance C_{eq} by the following relation:

$$\omega_k = \frac{1}{\sqrt{L\,C_{eq}}} \tag{6}$$

The frequency ω_k determines the time of the discharging time which should be fewer than one-quarter of the fundamental period. So, the relation between ω_b and ω_k is as the following, while $k > 4$:

$$k = \frac{\omega_k}{\omega_b} \tag{7}$$

Therefore, the inductance is obtained consistent with the subsequent relation:

$$L = \frac{1}{\left(k\,\omega_0\right)^2 C_{eq}} \tag{8}$$

In this study, k is set at 24. The total required capacitance is determined consistent with the reactive power requirement of the induction motor as will be explained in section 5.

3. The Detailed Dynamic Model of the Induction Motor

The three-phase induction motor consists of six windings; three windings are in the stator and three are in the rotor. The equations of the stator voltage are as the following:

$$\begin{bmatrix} v_{as} \\ v_{bs} \\ v_{cs} \end{bmatrix} = \begin{bmatrix} R_s & 0 & 0 \\ 0 & R_s & 0 \\ 0 & 0 & R_s \end{bmatrix} \begin{bmatrix} i_{as} \\ i_{bs} \\ i_{cs} \end{bmatrix} + \frac{d}{dt} \begin{bmatrix} \lambda_{as} \\ \lambda_{bs} \\ \lambda_{cs} \end{bmatrix} \tag{1}$$

where, v_{as} , v_{bs} and v_{cs} are the voltages on the stator windings, R_s is stator resistance and λ_{as}, λ_{bs} and λ_{cs} are the linkage fluxes of the three windings. The flux linkage can be described as the following

$$\begin{bmatrix} \lambda_s^{abc} \\ \lambda_r^{abc} \end{bmatrix} = \begin{bmatrix} L_{ss}^{abc} & L_{sr}^{abc} \\ L_{rs}^{abc} & L_{rr}^{abc} \end{bmatrix} \begin{bmatrix} i_s^{abc} \\ i_r^{abc} \end{bmatrix} \tag{2}$$

where subscript 'r' specifies rotor and 's' specifies stator. Moreover, L_{ss}^{abc} and L_{rr}^{abc} are stator and rotor inductance matrixes. As well known, both of L_{sr}^{abc} and L_{rs}^{abc} are stator and rotor mutual inductance matrixes which have time variant parameters. To solve the dynamic equation (1), some difficulties should be faced. So, the using of transformation theory through Klark matrix (equation (3)) presents a solution to solve the dynamic model.

$$\left[T_{qd0}(\theta)\right] = \frac{2}{3} \begin{bmatrix} \cos\theta & \cos\left(\theta - \frac{2\pi}{3}\right) & \cos\left(\theta + \frac{2\pi}{3}\right) \\ \sin\theta & \sin\left(\theta - \frac{2\pi}{3}\right) & \sin\left(\theta + \frac{2\pi}{3}\right) \\ 0.5 & 0.5 & 0.5 \end{bmatrix} \tag{3}$$

The voltage equations after transformation are presented as in the following equation.

$$\left[V_{sqd0}\right] = R_s\left[i_{qd0}\right] + p\left[\lambda_s^{qd0}\right] + \omega\begin{bmatrix}0 & 1 & 0\\ -1 & 0 & 0\\ 0 & 0 & 0\end{bmatrix}\left[\lambda_s^{qd0}\right] \quad (4)$$

where λ_s^{qd0} is the stator windings flux linkage, i^{qd0} the arbitrary reference frame currents and ω is the rotational speed reference frame. The arbitrary reference frame equivalent circuits for symmetrical three-phase induction motor are illustrates in Figure 4.

It is common to present the parameters of machines and power system in ohms, per-unit or percent of base impedance, so, it will be more suitable to express both of flux linkage and voltage equations in terms of reactances instead of inductances as in the following equations [1, 2, 3].

$$v_{qs} = r_s i_{qs} + \frac{\omega}{\omega_b}\psi_{ds} + \frac{p}{\omega_b}\psi_{qs} \quad (5)$$

$$v_{ds} = r_s i_{ds} - \frac{\omega}{\omega_b}\psi_{qs} + \frac{p}{\omega_b}\psi_{ds} \quad (6)$$

$$v_{0s} = r_s i_{0s} + \frac{p}{\omega_b}\psi_{0s} \quad (7)$$

$$v'_{qr} = r'_r i'_{qr} + \left(\frac{\omega - \omega_r}{\omega_b}\right)\psi'_{dr} + \frac{p}{\omega_b}\psi'_{qr} \quad (8)$$

$$v'_{dr} = r'_r i'_{dr} - \left(\frac{\omega - \omega_r}{\omega_b}\right)\psi'_{qr} + \frac{p}{\omega_b}\psi'_{dr} \quad (9)$$

$$v'_{0r} = r'_r i'_{0r} + \frac{p}{\omega_b}\psi'_{0r} \quad (10)$$

$$\psi_{qs} = X_{ls} i_{qs} + X_M\left(i_{qs} + i'_{qr}\right) \quad (11)$$

$$\psi_{qs} = X_{ls} i_{ds} + X_M\left(i_{ds} + i'_{dr}\right) \quad (12)$$

$$\psi_{0s} = X_{ls} i_{0s} \quad (13)$$

$$\psi'_{qr} = X'_{lr} i'_{qr} + X_M\left(i_{qs} + i'_{qr}\right) \quad (14)$$

$$\psi'_{dr} = X'_{lr} i'_{dr} + X_M\left(i_{ds} + i'_{dr}\right) \quad (15)$$

$$\psi'_{0r} = X'_{lr} i'_{0r} \quad (16)$$

$$T_e = \left(\frac{3}{2}\right)\left(\frac{P}{2}\right)\left(\frac{1}{\omega_b}\right)\left(\psi'_{qr} i'_{dr} - \psi'_{dr} i'_{qr}\right) = T_l + Jp\omega_r \quad (17)$$

where ω_b is the base electrical angular velocity used to calculate the reactances. The flux linkages λ in equation 4 are converted to ψ flux linkages per second. ω_r is the rotational speed of rotor. X_l is leakage reactance and X_M is the mutual reactance. T_e and T_l are electromagnetic and load torque respectively. J is the inertia for motor and load. By using the previous dynamic equations, the motor can be analyzed using any simulation package such as MATLAB/SIMULINK used in this paper. All variable states of the induction motor can be determined by this model specially the variables estimate the required reactive power.

4. Control System of Reactive Power for the Operation of Induction Motor

Figure 5 shows the block diagram of the control system for the proposed TSC to regulate the reactive power of the motor. The voltages and currents of the motor terminal are measured to get the feedback signals. Therefore, the amount of capacitive reactive power is determined. The corresponding amount of susceptance B can be estimated from both of terminal voltage and reactive power. Consequently, the required susceptance presents the input of TSC lookup table characteristic in Table 1 and Figure 2. One step of the 25 steps is the lookup table output. The changing of the developed

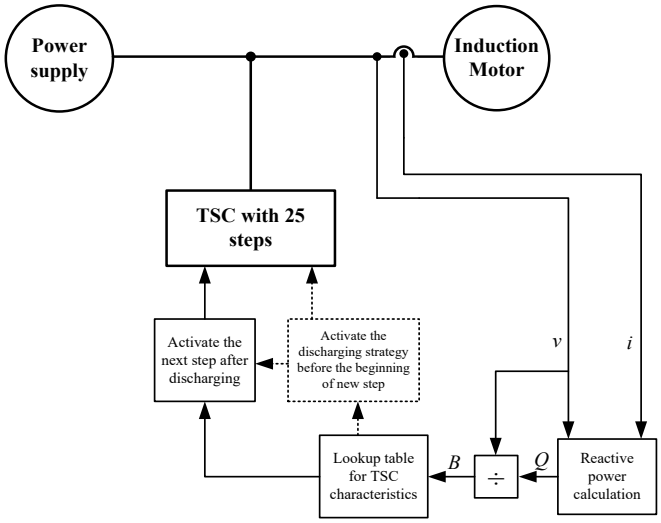

Figure 5: The block diagram for the TSC control system for reactive power compensation

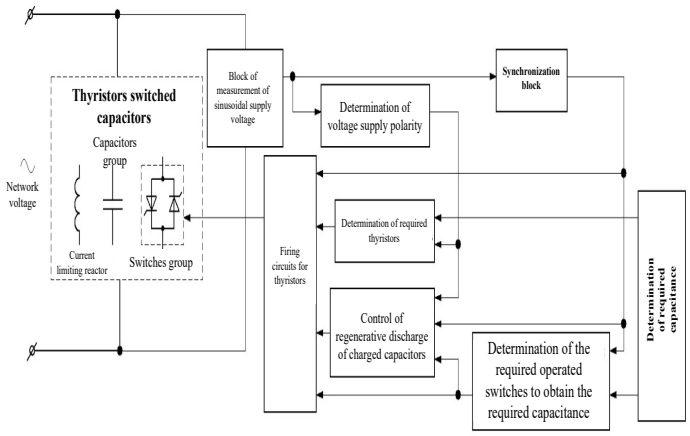

Figure 6: Block diagram of new topology of TSC control system

steps from look up table activates the capacitors discharging process once before the implementation of the following step [13]. Figure 6 illustrates the proposed TSC control system for both implementation of any susceptance and the activation of the discharging process [14].

When the discharging process is activated, the produced capacitive reactive power equals zero. If the next step is activated after the discharging process, the SVC continues the production of reactive power. The control proposed algorithm depends on the tracking of the required reactive power for the motor to produce it by the TSC. The transfer function describes the performance of the TSC can be described as:

$$\frac{B_{TSC}}{B_{ref}} = \frac{e^{-sT_d}}{1 + s\,T_b} \tag{18}$$

where B_{TSC} is the produced susceptance, B_{ref} is the reference susceptance, T_d is the dead-time and T_b is the delay-time [18].

5. Simulation Results of the compensated motor by TSC

In this study, the reactive power compensated induction motor by the proposed TSC is simulated depending on MATLAB/SIMULINK package. The reactive power compensation is imitated throughout the induction motor starting to illustrate the performance of effective control system proposed to regulate the reactive power. Figure illustrates the parallel connection of the TSC in parallel with the motor. The line-to-line voltage of power supply equals 400 V. The induction motor has the following ratings: nominal power of 37.3 kVA, 400 V line-to-line voltage, 50 Hz, 4-poles. The motor has the following parameters: r_s = 0.087 Ω, X_{ls} = 0.302 Ω, r_r' = 0.228 Ω, X_{lr}' = 0.302 Ω, X_m = 13.08 Ω and inertia constant J = 8 kg.m2.

The ratings of the connected TSC are as the following: rated line voltage of 400 V and rated power of 243 kVAR capacitive. Although the power rating of the TSC is much higher than the rating of the motor itself, the TSC reactive power is enough to compensate the reactive power required by the motor during starting. At free running, the TSC can compensate the reactive power of several connected motors because the required reactive power by the motor is reduced by the speed increment.

If the induction motor starts running, the TSC starts to compensate the reactive power compensation with the full rating then the compensated reactive power is gradually decreased. The TSC control system adjusts the reactive power by producing the maximum reactive power presented by level number 25 (Figure 2 and Table 1) at zero speed. At no-load, the required reactive power by the motor is reduced to lower level presented by level number 2. The motor with and without TSC is simulated to illustrate the TSC influence on the motor performance. The motor needs around 12 seconds to reach its full speed; consequently, the emulation period is 15 seconds which are sufficient to study the influence of the reactive power compensation on the motor performance. Figure 7 shows the supply reactive power in two cases; compensated and uncompensated motor. The using of TSC enables to reduce the total apparent power produced by the power source. Figure 8 shows the produced capacitive reactive power if the motor is compensated. Figure 9 illustrates the step of operation required to produce the corresponding reactive power. Several benefits are achieved by the reactive power compensation. The first advantage is shown in Figure 10; the compensation causes the reduction of the line current of the power source. The second benefit is the enhancement of the motor terminal voltage as illustrated in Figure 11. Therefore, the enhancement of voltage causes the increasing of motor acceleration as illustrated in Figure 12. Due to the reduction of the supply current, the internal losses of the motor are reduced where the internal winging resistance equals r = 0.5 Ω as in Figure 13. The changing of the compensation level leads to the appearance of spikes in the system response. The transition needs one full period to discharge the installed capacitors as explained in section 2.

The power factor of the system is improved due to compensation. This is due to the reduction of the phase shift between the voltage and current as illustrated in Figure 14

As explained earlier, the transition between two steps of reactive power requires the discharging process to be activated. To discuss this interval, the instantaneous waveforms of currents and voltages are illustrated. Throughout the changing of the developed steps from 25 to 24, Figure 15(a) shows the waveform of supply voltage and its produced current. As shown in the figure, the phase shift between current and voltage is around zero. In steady state, the waveform of the supply current is pure sin wave except some distortion during the transition period. The time span of the distorted current equals about one period. As shown in Figure 15(b), the phase shift between the TSC current and the supply terminal voltage is 90° lead. During the transient period, the TSC supplies zero current except spike current owing to the process of capacitors discharging. Furthermore, Figure15(c) illustrates that the voltage and the motor current are not in phase; therefore, the power factor below unity. Nevertheless, the usage of TSC enhances the power factor to unity by reducing the phase-shift between the voltage and current.

6. Conclusion

TSC has been developed as a reactive power supply to produce the required reactive power for the induction motor during starting period. The circuit topology of the proposed TSC is introduced to control the reactive power with 25 discrete steps. The principle of operation and characteristic of the proposed TSC scheme is analyzed to produce compensation system suitable for dynamically changed load. The induction motor and TSC dynamics have been introduced to analyze the dynamic performance of the whole system. The control system block diagram is constructed to track the needed reactive power for the motor. The concept of regeneration of capacitive unit energy has been explained to assure the dynamic reactive power production for the TSC. The design parameters of the TSC have been determined to produce the required reactive power and to carry out the discharging process effectively. using MATLAB/SIMULINK package, simulation and model have been developed for the whole system contains induction motor, the TSC and its control system. The simulation results demonstrate the efficiency of the proposed TSC topology during the reactive power compensation needed by the induction motor through the dynamic performance. The control system efficiently controls the TSC response to actively produce the proper reactive power.

Tsunami wave source
Sea surface displacement
Orthogonal decomposition

ABSTRACT

Source parameters of tsunami waves are an essential part of any modern tsunami warning system. Recalculation of a measured time series (wave profile obtained by a seabed-based pressure sensor) in terms of initial sea surface displacement at tsunami source is among the most (or) one of the promising approaches to be applied in a warning center. The "orthogonal decomposition", that was proposed and studied earlier by the authors, is numerically studied here. Realistic shape of sea surface displacement and digital bathymetry of the southern part of Japan are used. To study functionality of the proposed approach, wave profiles are obtained by the sensors of DONET – Dense Oceanfloor Network system for Earthquakes and Tsunamis – pressure gauge network of Japan. We stress on the quality of tsunami source parameters reconstruction as well as on time required. As observed, just a part of the first wave period is enough for robust determination of such source parameters as amplitude and total volume of water. Results of numerical tests are summarized in tables and then discussed.

1. Introduction

This paper is an extension of work originally presented in OCEANS'18 MTS/IEEE Kobe/Techno-Oceans 2018, May 28-31, Kobe Japan [1].

Typical tsunami warning system includes the following parts: wave generation, propagation over the water area under study, and inundation of a dry land. Aiming to achieve real time tsunami danger prediction, we address the question of fast determination of tsunami source parameters. Having such information, there are several software packages for numerical simulation of wave propagation and inundation mapping. Here we refer the reader to MOST (Method of Splitting Tsunami – official tool of the NOAA UnS tsunami warning centers), see [2-4], and TUNAMI, see [5,6].

In any case numerical simulation of wave propagation requires the initial data, say initial sea bed displacement at tsunami source. In this paper we address the question of rather fast reconstruction of the sea surface displacement at tsunami source. As an input data we use direct measurements of the wave profile (time series), obtained at any sensor system. As is well known, a number of deep-water pressure recorders are located all around Pacific Ocean, they measure and send such data via satellite channels. Among these systems we would like to mention the USA DART (Deep-ocean Assessment and Reporting of Tsunami) buoys (https://nctr.pmel.noaa.gov/Dart/), and DONET (Dense Oceanfloor Network system for Earthquakes and Tsunamis) pressure gauge network system, which is under construction in Japan (https://www.jamstec.go.jp/donet/e/).

Our goal is to recalculate these direct measurements of the water column over a single sensor (which is nothing but a curve of the wave profile) in terms of 2D function of initial sea surface displacement at tsunami source. In general mathematical statement it is not possible to solve this problem. So, we use the so-called "Calculation in Advance" inversion strategy [7]. It has been proposed to cover the subduction zone (area of possible tsunami sources) with the system of *100x50* km rectangles (typical size of the seabed displacement zone for tsunamigenic 7.5 M earthquake). In case of Alaska-Aleutian subduction zone there are 50 of such Unit Sources (UnSs), composed in two alongshore lines. Then a typical (for this region) shape of the initial sea-bed displacement, normalized with an amplitude of *0.57* m, is used at each UnSs as tsunami wave source. Propagation of such wave from all the UnSs were numerically calculated (in advance) over the entire Pacific

[*]Mikhail Lavrentiev & mmlavrentiev@gmail.com

Ocean according to the approximation of shallow water system. As a result, a database of the calculated tsunami wave profiles, generated by the source of the same initial shape at all UnSs, is available for all grid points of the Pacific Ocean.

Now, having the measured (real) wave profile at certain sensor location, one can approximate this curve with the help of linear combination of calculated wave profiles from a number of UnSs, picking up at the same point of sensor location. In other words, the problem is to determine the amplification coefficients for the UnSs such that the corresponding linear combination of UnSs (say, a Composed Source – CS) provides a good approximation of the initial sea-bed displacement.

The similar approach named SIFT – Short-term Inundation Forecasting for Tsunamis (https://nctr.pmel.noaa.gov/Pdf/SIFT_3_2_2_Overview.pdf) is used by NOAA (USA) for wave height assessment in grid points of computational domain. As well as in the method presented here, on the basis of "computations in advance" of the tsunami height distribution from the set of Unit Sources the authors [7] reconstruct the CS. Unlike the method presented here, by search of set of coefficients in linear combination of UnSs, the SIFT system uses the combinatory search of values of coefficients giving a discrepancy minimum between real and calculated tsunami wave series in several tsunami detectors. Such approach requires a lot of processor time if CS consists from more, than 5 UnSs. There is no such a shortcoming of the approach here proposed, where CS restoration time practically does not depend on quantity of UnSs involved. By the way, authors of this article also took part in development of an algorithm for source inversion in the SIFT forecasting system.

This approach has been many times tested against the field observations after near field and trans-oceanic events. Amazing agreement has been observed by comparison of computed wave, generated by a calculated CS, and measurements taken at various gauge stations. Nowadays, all subduction zones around Pacific, Atlantic, and Indian Oceans were covered with such systems of UnSs unit sources (https://nctr.pmel.noaa.gov/propagation-database.html); synthetic marigrams at every grid point from every source have been saved in a specialized database. One of the problems is to choose the aforementioned amplification coefficients in an automated mode. The orthogonal decomposition approach to handle this was proposed in [8] and then tested in [1,9]. It happens that even a part of the first wave period is enough to determine the CS – the set of amplification coefficients. In this paper we continue to study the problem of robust determination of sea surface displacement at tsunami source by a part of the wave profile.

The paper is arranged as follows. We first describe the proposed orthogonal decomposition algorithm and provide the mathematical ground behind it. In the numerical section we briefly describe digital bathymetry in use and the parameters of realistic CS, which has a feature of the reconstructed source of historical event of 1707 [10]. Then we provide the obtained numerical results in the form of a table. Finally, numerical results are discussed.

2. Orthogonal decomposition algorithm

2.1. Mathematical ground of algorithm

Here we provide the brief explanation of the algorithm for reconstruction of the CS. More detailed description one can find in [8].

Let *f(t)* be the marigram – time series, obtained at any particular sensor (DART buoy, bottom cable sensor of DONET, or other). We will use notations $f_k(t), (k = 1, \dots, N)$ for simulated wave profiles, calculated (according to the linear or nonlinear shallow water approximation) at the same point of sensor location, by direct numerical modeling of the tsunami wave propagation. It is understood, that the subindex *k* refers to a tsunami wave initiated by the normalized sea surface initial profile of a given shape from the *k*-th UnSs. We assume that all these functions, $f_k(t)$, are linearly independent. We are looking for coefficients, b_k, for the linear combination of these functions, which provide the best approximation of the function *f(t)* in L_2 norm:

$$\int_0^T \left(\sum_{k=1}^N b_k f_k(t) - f(t)\right)^2 dt \ \rightarrow min \qquad (1)$$

So, we consider the problem of optimal approximation of a given function, *f(t),* by the linear combination of the finite subset of functions from the system $\{f_k(t)\}$. Suppose that the system is orthogonal and normalized according to:

$$\left(f_i(t), f_j(t)\right) = \int_{t_0}^T f_i(t) f_j(t) dt = 0, \text{ if } i \neq j \qquad (2)$$

$$\left(f_i(t), f_i(t)\right) = 1. \qquad (3)$$

Here t_0 stands for the time moment when the wave approaches the closest receiver, *T* is the time of the latest (of all receivers) full period on marigram which is concerned as the end of the second phase of tsunami. For sensors which are more distant off the coast than a source, the second phase of tsunami is positive, and for those which are closer to the shore, it is negative.

As is well known in the Fourier series theory, the coefficients of such optimal approximation are nothing but the Fourier coefficients of expansion of *f(t)* in a series with respect to $\{f_k(t)\}$ (see, for example, [11]).

2.2 Algorithm description

Based on the statement above, the following algorithm was proposed in [8] and tested in [1,9] for searching the coefficients of the linear combination allowing optimal approximation of the given function. It includes three steps.

(a) The calculated set of "marigrams", $\{f_k(t)\}$, from the unit sources should be orthogonalized and normalized, according to equations (2)-(3).
(b) The measured marigram, *f(t),* should be expanded to the Fourier series with respect to obtained orthonormal system of functions.
(c) The so-determined Fourier coefficients should be recalculated in terms of initial functions $\{f_k(t)\}$.

Let us transform the given system $\{\mathrm{f_k}\}$ to the corresponding ortho-normal system, $\{e_k\}$, with respect to the scalar product (2). Let

$$\mathrm{e_1} = \mathrm{f_1} \qquad (4)$$

Suppose that pairwise orthogonal nontrivial functions $\mathrm{e_1}, \mathrm{e_2}, .., \mathrm{e_{k-1}}$ are already constructed. We will look for the function $\mathrm{e_k}$ in the form:

$$\mathrm{e_k} = \mathrm{f_k} + \mathrm{l_{k,1}e_1} + \dots + \mathrm{l_{k,k-1}e_{k-1}} \qquad (5)$$

i.e. we obtain the next function, e_k, as the linear combination of the new function, f_k, and the already constructed ortho-normal ones, $e_1, e_2, .., e_{k-1}$. The coefficients, $l_{k,1}, l_{k,2}, .., l_{k,k-1}$, in formula (5) should be found from the conditions that the new function, $e_k = f_k + l_{k,1}e_1 + .. + l_{k,k-1}e_{k-1}$, is orthogonal with all the previous ones, $e_1, e_2, .., e_{k-1}$, and normalized. Thus, the coefficients in (5) are calculated according to:

$$l_{k,i} = -\frac{(f_k, e_i)}{(e_i, e_i)}, \ (i = 1, \cdots, k-1) \qquad (6)$$

As is well known in calculus, the optimal L_2 approximation, according to criteria (1), of a given function f by the linear combination of orthogonal and normalized functions, e_k

$$f_appr = \sum_{i=1}^{k} a_i e_i \qquad (7)$$

is achieved at the Fourier coefficients, a_i, of the function *f(t)*, decomposition with respect to the system e_k:

$$a_i = \int_{t_0}^{T} f(t)e_i(t)dt \Big/ \int_{t_o}^{T} e_i^2(t)dt \qquad (8)$$

So, to solve the original problem (1), we only need to provide the coefficients (8) in terms of the original basis functions f_k.

It is just an algebraic exercise to conclude that the desired coefficients, b_k, in expression (1), are calculated through the given coefficients, a_k, from the formula (8), as follows:

$$\begin{cases} b_k = a_k, \\ b_{k-1} = a_{k-1} + a_k F(L', k, k-1) \\ b_{k-2} = a_{k-2} + a_{k-1}F(L', k-1, k-2) + a_k F(L', k, k-2) \\ b_i = a_i + \sum_{j=i+1}^{k} a_j F(L', j, i) \end{cases}$$

$$F(L', j, i) = \begin{cases} 0, \ \text{if } j = i, \\ l_{j,i}, \ \text{if } j = i+1, \\ l_{j,i} + \sum_{k=i+1}^{j-1} l_{j,k} F(L', k, i), \ \text{if } j \neq i, \ j \neq i+1. \end{cases}$$

So, the proposed algorithm to approximate the given marigram, *f(t),* by the linear combination of synthetic marigrams, $\{f_k(t)\}$, *k=1,...,N*, in order to achieve minimal L_2 difference (1), is as follows.

We first transform the system $\{f_k(t)\}$ to the orthogonal system, $e_k(t)$, and normalize it according to formulae $(4) - (8)$.

Then the recorded marigram, f(t), is decomposed to the part of Fourier series with respect to obtained orthogonal and normalized (see (1), (2)) basis, $e_k(t)$, by the formula (8).

Finally, the obtained Fourier coefficients, a_i, are recalculated in terms of coefficients, b_i, of the original linear combination (1), by means of (9).

3. Numerical experiments

Numerical experiments were arranged in the area around the south-east coast of Japan (eastern Kyushu, Shikoku islands and Kii peninsula. Geography, bathymetry and location of UnSs and CSs in this region are shown in Figure 1.

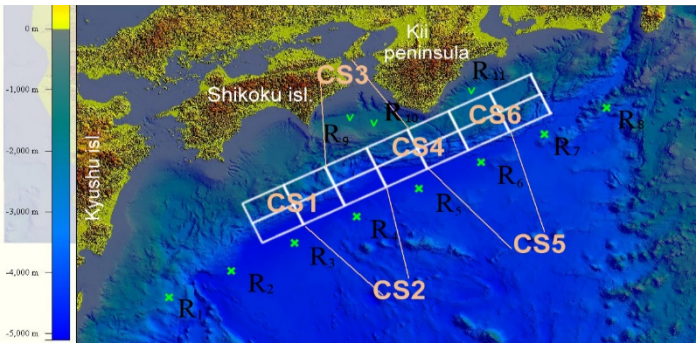

Fig. 1. Digital bathymetry of the water area under study. White rectangles show positions of model tsunami sources. Green crosses (R1-R8) indicate locations of artificial sensors. Green check marks (R9-R11) show the selected sensors of DONET.

3.1. Digital bathymetry

Numerical experiments were arranged at the gridded bathymetry around Eastern Kyushu, Shikoku Island and Kii Peninsula (southern part of Japan), built on the basis of Japanese bathymetric data produced by the Japan Oceanographic Data Center (JODC), presented in Figure 1. This digital gridded bathymetry has the following characteristics:

Size of array is 3000 x 2496 nodes;

Grid steps are 0.003 and 0.002 degrees (which means 280.6 and 223 meters, respectively);

Domain covers the area approximately between 131° E and 140° E, 30° N and 35° N.

3.2. Composition of tsunami source

In the course of numerical calculations model tsunami sources were formed of UnSs of *100x50* km in size located in two rows along the coast (Figure 1). Each of the six composed sources (CS), having the sizes of 200x100 km, is presented as the linear combination of four UnSs with given amplification coefficients *(1.4; 1; 1.5; 1.1).* For this set of coefficients, the maximum surface elevation in the source area is equal approximately to 3 m, and minimum water level there is estimated as -1.5 m (Figure 2). Bigger coefficients correspond to UnSs more distantly located off the coast. Numbering of CSs begins with UnSs which are at the western edge the source area (Figure 1). Two of them (the first and the last) are indicated in Figure 1. The ocean bottom displacement in the CS used for computations is shown in Figure 2.

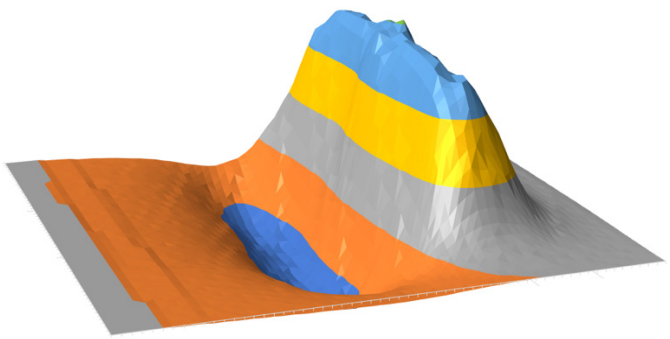

Fig. 2. Shape of the initial surface displacement at the Composite Source used for numetical experiments.

We assume precision of 10% as the value of reasonable accuracy of the tsunami height estimation. This value allows to determine parameters of the wave near the shore with the same precision, which is enough for the rapid tsunami hazard evaluation. It means that maximum difference between the initial and calculated surface displacement is less than 10 cm for a typical initial displacement height of 1 m. Accordingly, the deviation of 1 m is considered acceptable in case the wave height is 10 m.

As a rule, a part of the wave profile from the beginning to the zero level after the highest amplitude point (see Figure 2) is sufficient to reconstruct the amplification coefficients with a particular precision. So, we tried to determine how smaller could be a part of wave profile to keep the error in reconstructed ISSD amplitude within 0.1 discretization. The location of the model tsunami source centers for numerical calculations are chosen according to estimation of the source of the major tsunami, expected, according to [10], in the near future in the Nankai subduction zone (Figure 3 is taken from [10]). The size of the model sources corresponds to a tsunamigenic earthquake of magnitude 8.0.

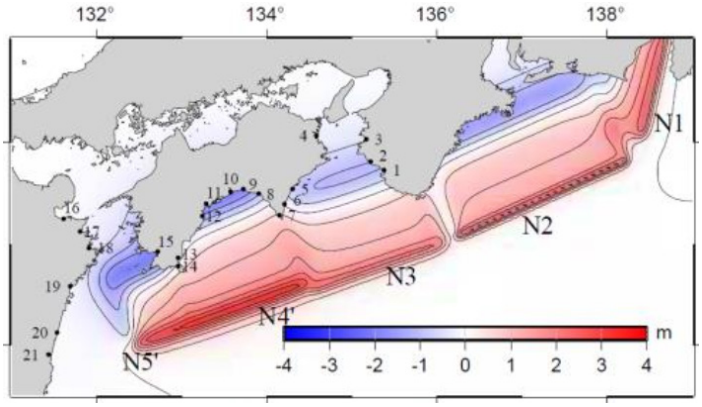

Fig. 3. The expected distribution of the initial water surface displacement in the tsunami source at the Nankai subduction zone, [10].

3.3. Positions of sources and sensor network

The virtual sensors network consists of one row of virtual deep-water wave detectors, installed along the Nankai Trough (R_1-R_8, indicated by green crosses in Figure 1). In addition, 3 sensors of DONET were also included to observation network system for source restoration in our numerical experiments. These sensors are indicated in Figure 4 as black squares, R_9, R_{10} and R_{11}. Reconstruction of a source means determination of coefficients in the linear sum of UnSs composing CS.

3.4. Numerical experiments

As a result of numerical experiments, the tsunami wave signal from each of the six locations of CS (see Figure 1) was recorded by 11 detectors, R1-R11, given in Figures 1 and 4. By means of the described method, the minimum length of a wave signal, sufficient for determination of coefficients in the linear sum of UnSs (Necessary Part of Wave Profile – NPWP) have been determined with the required accuracy. These lengths as a percentage to length of the full wave period which means complete first two phases (positive and negative) of a wave are summarized in Table 1. The first column shows receiver's number (1-11). In the second column one can find the Composed Source number (1-6). In the third and the fourth columns the length in seconds of NPWP and the full wave period are presented, respectively. Column number 5 gives the length of NPWP in percentage of the full tsunami period. The last two columns present the NPWP ending time instance and the wave arrival time to a shore.

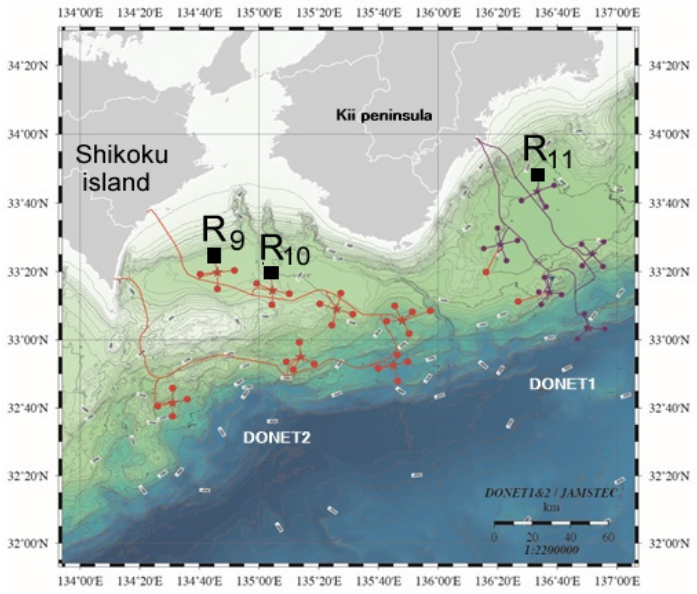

Fig. 4. Configuration of DONET-1 and DONET-2 system at the south-east of Japan (https://www.jamstec.go.jp/donet/e/). The existing sensors are in violet and sensors under construction are indicated in red. Black squares show three sensors, which positions were used for artificial sensors.

The duration of NPWP counted from the moment of wave arrival at receiver. More important for us is the end of NPWP on the record (column 6 in the Table 1). This record starts simultaneously with the initial ocean surface displacement. It is the same moment as regarded as zero in tsunami travel time. So, if NPWP (on record) is less than the tsunami travel time to the coast, then we have some time for reconstruction of CS and for estimation of the expected wave height near a shore.

Table 1: Numerical tests Parts of the entire wave profile (in percents), enough to determine the source parameters

Receiver	CS	NPWP, sec	Period, sec	NPWP, % of full wave period	Time required for accuracy to be achieved (from the generation moment), sec	Wave arrival time to a shore, sec

Numerical experiments showed that in most cases use of even a wave record only from one sensor allows to restore the source (coefficients in the linear sum of UnSs) with the required accuracy, using only a part of a wave signal (less than a half of its full period). From the results presented in Table 1 it is visible that for each CS there are several sensors, processing of a wave signal from which allows to restore the source with the required accuracy even before arrival of a wave to the nearest coast. In particular, for CS1 those are detectors R1, R2, R9, R10 and R11. For CS2 those will be sensors R1, R2, R3, R9, R10 and R11. And so on.

4. Discussion

The fact that among such sensors there is always a tsunami detector which is included to observation system DONET (Figures 1 and 4) is important. In these sensors (R9-R11) the first phase of tsunami on the wave record is negative (surface inundation), and then the surface elevation is coming. Finally, we can conclude that with the help of observation network described the tsunami warning system is able to estimate expected wave heights along the coast before its arrival there.

By results of the numerical experiments given in table 1 one can notice that the length of NPWP for restoration of some CSs by records of some sensors exceed 80% of the full period of a wave. Though, in most cases duration NPWP does not exceed 50 percent of the tsunami period. In particular, more than 80 percent of the full wave period is required for sufficient-quality restoration of CS having number 1 by means of sensors R1 and R6. The CS3 by means of sensors R3 and R6. And, at last, CS5 on the basis of measurements by sensor R4. For the last case the length of NWDP reaches 98.6 percent of wavelength. From Figure 1 it is visible that in all these cases the sensor is located in the direction of a long axis of CS (a rectangle 200 x 100 km) or near it. It means that such relative positioning of the CS and the tsunami detector negatively affects speed and quality of restoration of coefficients in a linear combination of UnSs composing the source. CSs are most successfully restored using wave records taken from the detectors which are located in the direction of a short axis of the source.

5. Conclusion

The numerical method which was used for calculating the direct initial value problem on propagation of tsunami generated by a UnSs have been many times tested on exact solutions and on real tsunami data. So, correlation between initial surface displacement at the UnSs and synthetic marigrams in receivers seems to be reliable. According to the mathematical model the increase in height of Unit Source by N times causes the proportional growth of wave height in all grid-points of computational domain.

As a result of this research it is shown that at the reasonable relative location of the area of the possible tsunami sources and deep-water tsunami detectors for correct restoration of the composed source it is enough only a part of the recorded wave signal. At the same time, a part of a wave signal, necessary for restoration, can be used by the restoration algorithm even before arrival of a wave to the coast. It gives the chance for quick solution of a direct problem of the tsunami propagation from the initial water surface displacement to estimate the expected wave height along the entire coast. Besides the carried-out numerical

experiments will allow find optimal positions for installation of the new deep-ocean tsunami detectors capable to restore the composite tsunami sources more quickly.

ABSTRACT

3D-printing technologies have greatly influenced the field of fabrication of medical devices. In particular, Fused Deposition Modeling 3D printing has emerged as one the most popular and most promising technologies for fabricating upper-limb prostheses. Over the last years, a variety of types and designs of 3D-printed hand prostheses have been created and are commercially available. However, there are no standards or established procedures for testing these devices. Available information regarding their long-term performance and functionality is very limited. This paper presents a case study of mechanical testing methods applied to a specific design of an upper-limb prosthesis. The device and its subassemblies were subjected to flexion test in hyperextension and abduction conditions, fatigue/wear test, and tensile test. The experimental results are presented and examined. Testing procedures, adaptations and recommendations are described and discussed to demonstrate ways of generating reliable data that serve for comparison among different hand prostheses designs.

1. Introduction

The fabrication of medical devices is one of the most influenced fields by 3D printing technologies advances. Particularly, in the last years, 3D printed hand prostheses have emerged as a promising low-cost alternative, compared to conventional hand prostheses, to fulfill the need for these devices in developing countries [1]. Currently, Fused Deposition Modeling (FDM) is one of the most common and inexpensive technologies for fabricating functional end-use parts by 3D printing, including hand prostheses. However, FDM has a disadvantage related to the anisotropy generated by the process and its corresponding effect on mechanical properties. A material fabricated by 3D printing shows a ductile behavior in the orientation of the bead deposition, but a brittle one in the perpendicular orientation. Therefore, FDM printed components are susceptible to fracture in the building orientation; a failure mechanism called delamination. While the effect on mechanical properties of many fabrication parameters such as layer height, infill pattern, density, nozzle diameter, build plate temperature, printing orientation and velocity [2, 3, 4, 5, 6, 7] has been evaluated using 3D-printed test specimens, little advances have been made in testing and characterizing entire components fabricated using FDM 3D-printing.

Although the popularity and the use of 3D printed hands keep increasing, there is a lack of standards for fabrication and testing of these devices and very limited information available in terms of their long-term performance and functionality. Existing hand prostheses standards and testing procedures are not directly applicable, even for currently commercial multi-fingered and dexterous hand prostheses, because they were conceived mainly for conventional hook prostheses. Moreover, hand prostheses manufacturers use their design-specific tests to provide full specifications of their commercial products.

In this context, different researchers have explored the possibility of adapting existing methods and implementing variations, according to their investigation's objectives and available resources, to evaluate the performance of open-source and specific models of 3D printed upper-limb prostheses. Tests have been conducted to evaluate mechanical properties such as tensile strength, impact resistance, flexural strength, and fatigue

* Renato Mio & Email: r.mioz@pucp.edu.pe

resistance, both in the whole prostheses and sub-assemblies, with parameters (test velocity, applied load, number of cycles, etc.) that resemble conditions of activities of daily life (ADL). A review of these tests has been presented by the authors in the conference BIBE 2018 [8] and is summarized as follows.

Tenim [9] and Koprnicky [10] analyzed the mechanical behavior of phalanges of prosthetic hands employing hyperextension (see Figure 1a) and lateral bending test and cyclic flexion-extension test (see Figure 1b). The bending tests were intended to evaluate the maximum load that a phalange can withstand and extrapolate the results to compute the maximum load that can be carried by all of the fingers of a prosthetic hand. These bending tests have been also applied to individual fingers from robotic grippers [11]. Furthermore, the purpose of the cyclic flexion-extension test was to measure the endurance of a finger under the application of several fatigue cycles and to determine the mode of failure under this condition (e.g. damage of one of the finger components or wear of the flexion cables channels). In addition, Crisco and Wolfe [12] analyzed the finger biomechanics and proposed testing procedures to mimic the conditions to which a prosthesis is subjected to when conducting activities of daily living. While the ASTM F1781 standard [13] provides some guidance for finger fatigue test, Joyce and Unsworth [14] have proposed a set of parameters to be applied, such as the flexion-extension load magnitude: 10-15 N, pinch load: 100 N, the angular amplitude of the motion: 0-90 degrees, and the frequency: 1.5 Hz.

Among the tests to which prosthetic hand subassemblies could be subjected to, the ISO 22523 standard [15], annex A, proposes the distal tensile test (see Figure 1c). In this test, a hand subassembly is induced to perform a power grip on a 19 mm diameter cylindrical object. As schematically observed in Figure 1c, the object is pulled away, forcing the fingers to extend or to break. In this way, it is possible to establish the maximum load that the prosthesis can withstand without failure. Additional tests involving grasping movements with a cylindrical object have been proposed in [16, 17, 18]. Cylindrical grip test is of key importance because it mimics the movement conditions of most of the body-powered hand prostheses, i.e. opening and closing of all of the fingers at the same time. Furthermore, the ISO 22523 standard describes the procedures to conduct hand or wrist flexion tests in the case of transradial prostheses.

This paper presents a case study of mechanical testing methods applied to an upper-limb prosthesis. The study is focused on the 3D-printed D1M Hand (acronym in English for Dando Una Mano, *Giving a Hand*) [19] (see Figure 2). The D1M hand was designed for transmetacarpal or partial hand amputations and was fabricated by the FDM 3D printing process. Due to its design and functionality the D1M hand was subjected to finger flexion test (in the hyperextension and abduction/adduction directions) to measure individual finger maximum load, finger cyclic flexion-extension to measure individual finger durability, and hand tensile test to measure the maximum possible load that the hand can withstand while performing a cylindrical grasp. Schematic drawings and a description (references, conditions, outcomes, and objectives) of these tests are shown in Figure 1 and Table 1 respectively.

This work complements the one presented by the authors in BIBE 2018 [8]. This manuscript includes a summary of the design and fabrication process of the D1M hand, the experimental details and testing procedures description; with particular emphasis placed on the machine adaptations for positioning and supporting the tested hand and finger samples, and the discussion of obtained results.

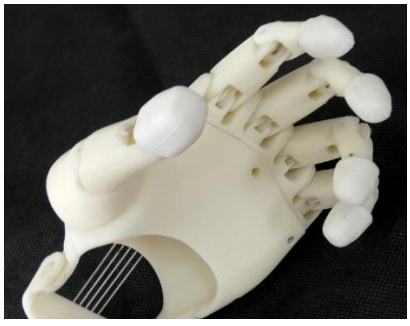

Figure 2: D1M hand prosthesis prototype. Image from [19].

2. Experimental Procedure

The mechanical tests were performed using universal testing machines. The D1M hand was fabricated using a commercially available desktop 3D printer. The use of commercially accessible equipment will allow the experimental procedures to be replicated and the results to be compared with those obtained by other researchers. The assemblies and accessories presented in this work can be modeled in CAD software and then minor modifications can be made to accommodate different designs. Validation of the printing parameters and methodology was performed with detailed testing applied to the D1M hand.

Table 1: Description of the mechanical resistance tests applied to the D1M Hand (adapted from [8]).

Type of test	*Test description*			
	Based on (guide or standard)	***Test conditions***	***Recorded outcomes***	***Objective***
Finger flexion	ISO 178, ASTM 790 and the works of Tenim [9] and Koprnicky et al. [10]	Velocity of the test: 1% the gage length per minute. Finalize when: Maximum deflection is 5% or failure. Different tests: Hyper-extensive and lateral loading.	Displacement and force against time.	Estimate the mechanical strength of the fingers to withstand forces that over-extend (hyper-extensive loading) or bend the fingers laterally (lateral loading). The target load value is 30 N according to [20]
Finger cyclic flexion-extension	ISO 14243-1 and the works of Tenim [9] and Joyce et al. [14].	Cyclic loading frequency: 1.5-2 Hz. Finalize when: achieve 1,200,000 cycles or failure of whichever component. Load at the MCP joint: 10 - 15 N. Pinch force: 100 N. Finger base joint range of motion: 0 - 90 degrees.	Cycles can achieve the prosthesis until the failure. Wear of the components measured by weight difference before and after the test.	Calculate the number of cycles the prosthetic finger can withstand. The target value is 1,200,000 cycles (equivalent to 4 years of use) according to [21]
Hand tensile test	ISO 22523-2006, annex A.8.2 [15]	The prosthesis grasps a 100mm x diameter 19 mm cylinder. An external force pulls the cylinder out of the hand. Preload: 10 N Load: increases at a rate of 1 – 10 N/s until failure.	Displacement and force against time.	Estimate the maximum payload of the whole prosthesis when performing a cylindrical grasp.

2.1. Fabrication of the D1M hand prosthesis

The D1M hand was fabricated by FDM 3D printing with an Ultimaker 3+ Extended machine; the material employed was acrylonitrile butadiene styrene (ABS). Table 2 shows the general 3D printing process fabrication parameters that were applied to all of the main components (fingers, palm and forearm).

The prosthesis was designed based on the anthropomorphically structure of the user and the functionality of the 4 linkages mechanism [19]. ABS is an optimal polymer for this use because of its strength and low density. As mentioned previously, the mechanical resistance of the 3D printed hand depends on the manufacturing orientation, caused by the intrinsic anisotropy of the manufacturing and its deposition of consecutive layers. For this reason, optimal printing orientation for each component was chosen based on factors such as maximizing the area of the critical cross-section under stress (to prevent delamination) and attaining the best surface quality with no support material for important geometrical features (like shaft supports). Table 3 and Figure 3 shows the orientation of each component of the hand and its printing parameters. In addition, it was observed that for the palm less infill density is placed than in the fingers, because in the continuous use of the prosthesis it was identified that the fingers were critical pieces, due to the small thickness in the lace. Many other existing hand prostheses designs also come with suggested infill percentages, which adds another variable influencing the resulting mechanical properties of the resulting device. With the purpose of finding the exact technical specifications of the prosthesis, mechanical tests were performed based on the experimental parameters found in the literature.

2.2. Experimental Procedure on D1M hand

Three different tests were conducted in the D1M hand: first the hand tensile test, chosen because the main actions performed by upper limb prostheses require a cylindrical grip; then, finger flexion tests were performed in order to know the maximum weight that an individual finger can resist; and finally, the finger fatigue / wear test to estimate the prosthesis' durability and the wear due to its use. These tests required the design of custom fixation components to be placed between the hand components and the testing machine.

Table 2: 3D Printing parameters for the components of the D1M Hand.

Parameter	**Value**
Nozzle Temperature	230 °C
Build plate Temperature	100 °C
Printing speed	65 mm/s
Layer height (Z-axis resolution)	0.2 mm
Wall thickness	1.2 mm
Infill pattern	Linear

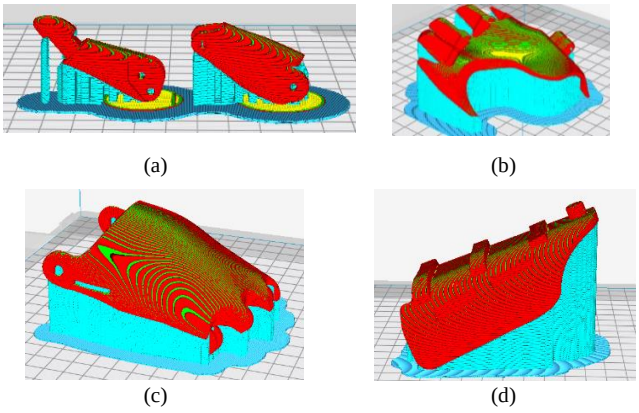

Table 3: 3D Printing Parameters specific to each component.

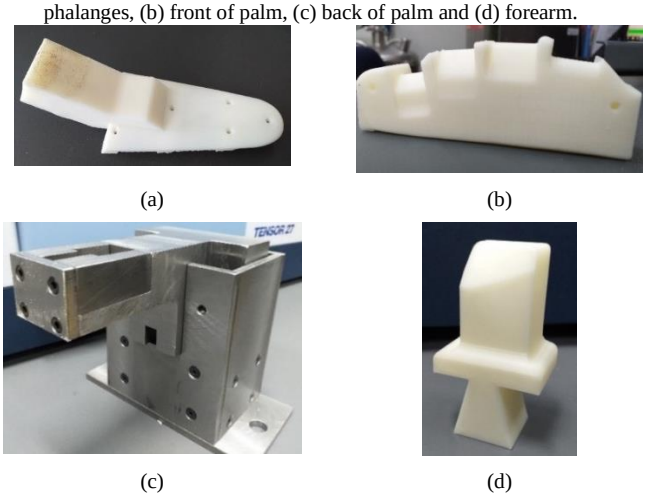
Piece	**Layer thickness [mm]**	**Infill [%]**	**Angle orientation**	**Figure**
Finger	0.1	50	17° and 25°	Figure 3a
Palm (front side)	0.2	30	28°	Figure 3b
Palm (backside)	0.2	30	15°	Figure 3c
Forearm	0.2	50	32°	Figure 3d

2.2.1. Hand tensile test



The tensile test was performed in the whole hand assembly to evaluate the maximum load that the prosthetic hand can withstand when it is performing a cylindrical grasp movement. The test was conducted using a Zwick Roell Z050 tensile test machine with the test parameters defined by ISO 22523:2006 [15]. Three whole hand assemblies were tested. As shown in Figure 4a, a flat area accessory to connect the machine jaws with the hand was fabricated, it also served to keep the assembly aligned with the axis on which the machine exerts force. This accessory was printed in ABS and 100% filling density was used. Additionally, a grasping device (see Figure 4b) was fabricated to allow the prosthesis to make a cylindrical grip. On the other hand, a support device was added to maintain the wrist flexion needed to close the fingers around the grasping device. To ensure that the test can reproduce a real-use condition, the prosthesis must be tested while

activated with its fingers closed. For this reason, a pair of accessories were designed to keep the prosthesis locked as if it were activated by a user exerting force with the stump. A steel accessory (see Figure 4c) was manufactured to support the hand and withstand relatively high loads without deforming. In addition, an accessory acting as a support point of the inner part of the palm was printed (see Figure 4d). Figure 5 shows the complete assembly to perform the testing.

(a) (b) (c) (d)

Figure 4. Accessories for the optimal fix between the prosthesis and the testing machine.

The test is performed until the failure of any component (or until the prosthesis stops holding the grip due to the deformations that occur in the threads that cross the phalanges).

2.2.2. *Finger Flexion test*

Flexion tests were conducted in the fingers to evaluate their maximum load-carrying capacity. The tests were carried out simulating two conditions: a finger extended in a horizontal plane (hyperextension test), and a finger extended in a vertical plane (abduction test). The tests were performed using a Zwick Roell Z0.5 multi-test machine. Three samples of middle and little fingers (longest and shortest finger of a hand, respectively) were subjected to each condition of the test. The test speed was proportional to the length of the finger, which in turn depended on the test condition. For the hyperextension condition, the test speed was 6.6 mm/min and 4.6 mm/min for the middle and little finger, correspondingly. For the abduction condition, the speed was 7.3 mm/min and 5 mm/min for the middle and little finger respectively. Three accessories were needed for this test: the general coupling, the secondary coupling and the bending punch. Figure 8a shows the assembly designed in the CAD software. The general coupling (see Figure 6) was fixed on the machine table and housed the secondary coupling and the finger. The secondary coupling (see Figure 7) varied depending on the size of the finger and the type of test (hyperflexion or abduction). The bending punch was fabricated from a sheet of steel and had a U shape in order to avoid the slip with the 3D printed finger, as shown in Figure 8b.

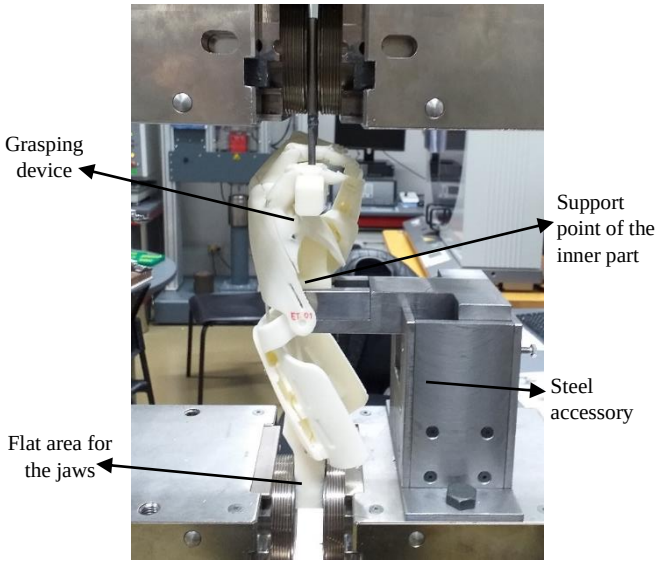

Figure 5. The complete assembly of the hand tensile test. Arrow indications correspond to the accessories shown in Figure 4.

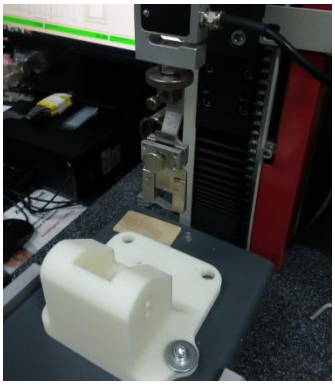

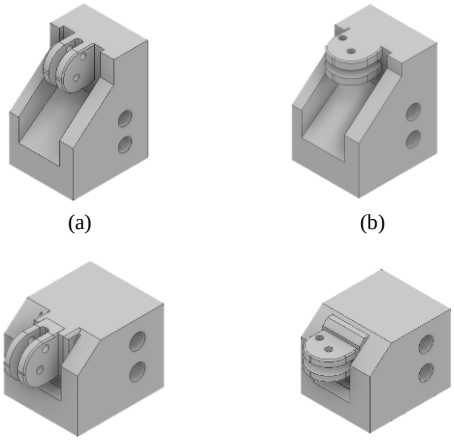

Figure 6. 3D printed coupling made of white ABS and punch that exerts the bending force.

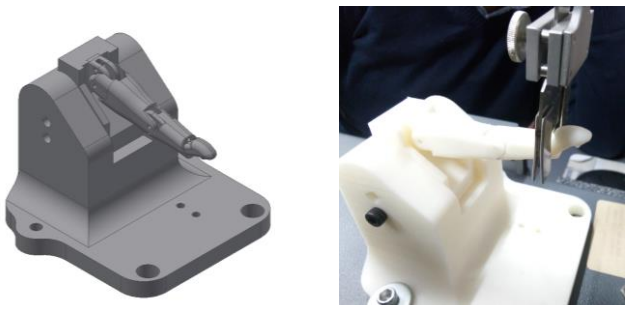
2.2.3. *Finger fatigue/wear test*

The fatigue/wear test was performed to evaluate the capacity of the index finger assembly (3D printed phalanx, wire and pins) to perform a cyclic pincer grasp movement and measure the possible wear between the threads and the internal channels of the prosthesis, and the metal pins with the phalange holes. A Zwick Roell Z0.5 machine was used for the test, subjecting samples of the index finger to 24000 cycles in flexion mode. The test load variation was from 2 N to 80 N to ensure the force in the fingertip of 15N (as suggested in [21]), with a displacement speed of 1000 mm/min. The wire that pulls the mechanism to operate the finger was placed in the machine's jaw (see Figure 9) and was connected with the finger through a bronze pulley (see Figure 10b) that also that also serves as an alignment tool. Then the finger was set up in



a 3D printed holder to facilitate the test and a sensor (a Force Sensitive Resistance sensor with a magnitude range: 100 g – 10 kg) was positioned in the area of contact with the fingertip in order to evaluate the pincer grasp load (see Figure 10a).

Three samples were tested and, besides analyzing their capacity to withstand cyclic loads, the wear resistance of the assembly was evaluated by weighing the samples before and after the test.

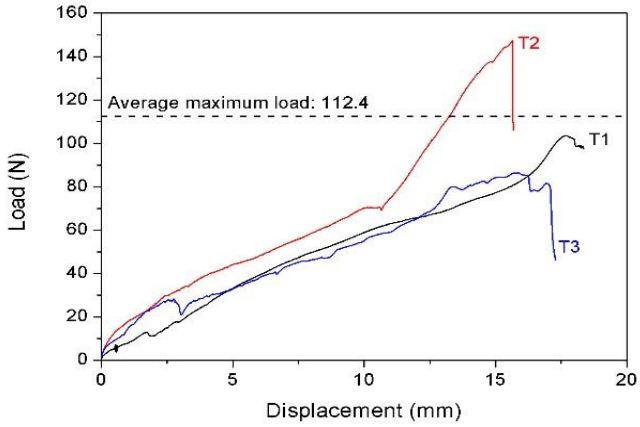

Figure 11: Tensile test curves for the D1M prosthetic hand samples

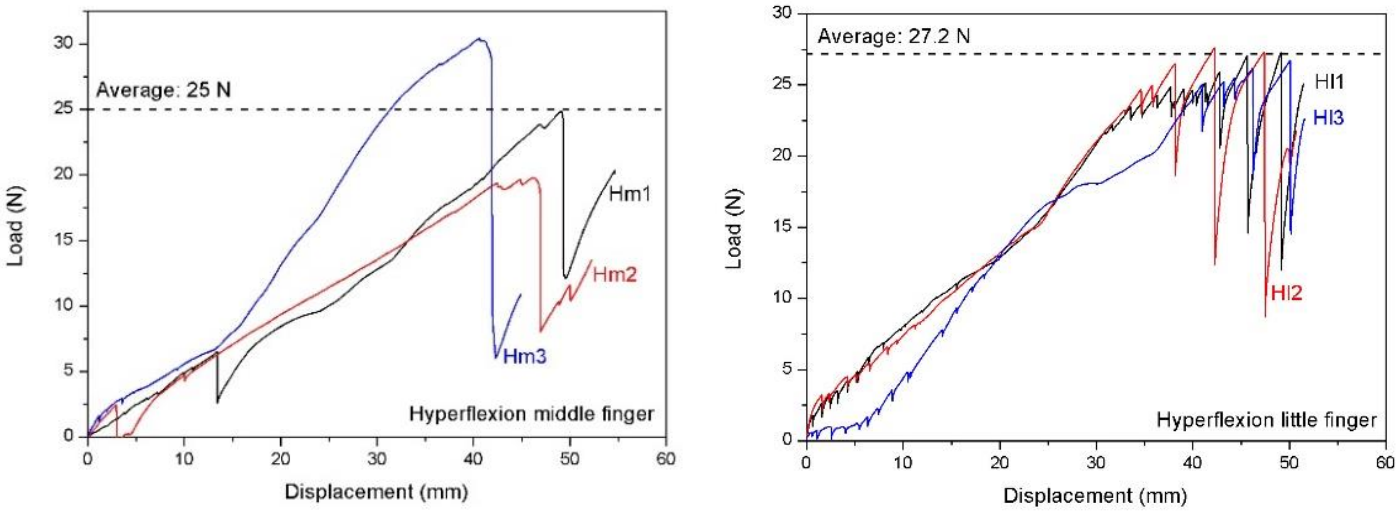
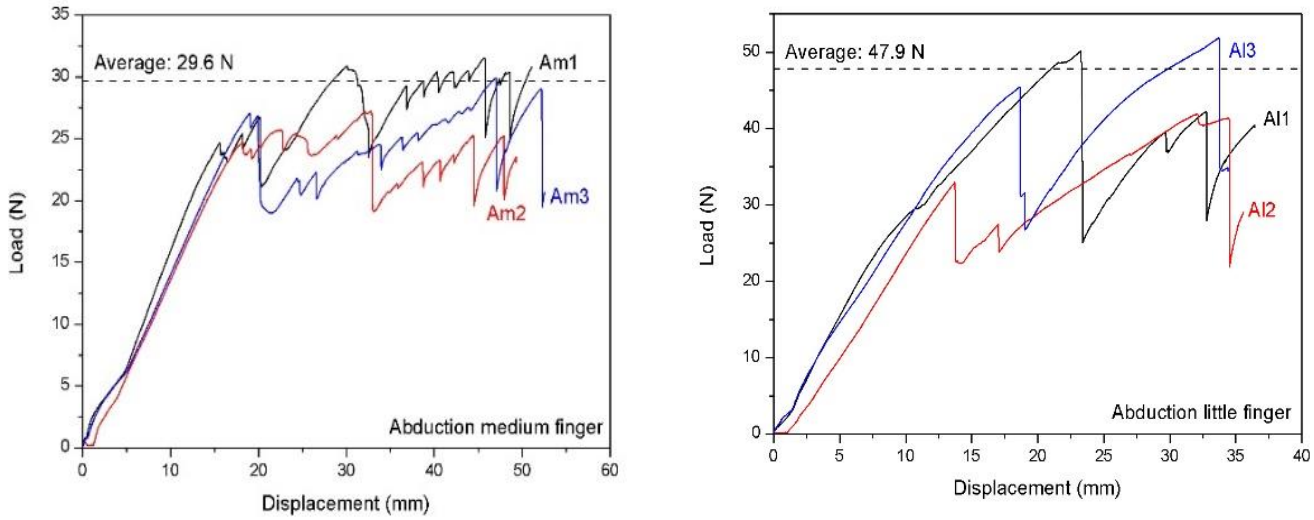


3. Results and Discussion

3.1.1. Hand tensile test

Figure 11 shows the load-displacement curves for the tensile test in the three assembled prosthetic hands (samples T1, T2 and T3). The average maximum tensile load that the hand can withstand before failure is 112.4 N. Discontinuities in the curves and differences in behavior for each sample could be attributed to factors inherent to the 3D printing process, and to re-accommodation events of the hand assembly through the test due to the elastic and plastic deformations experienced by the wire.



3.1.1. Finger Flexion test

Figure 12a and Figure 12b show the load-displacement curves for the middle and little finger samples obtained from the flexion tests in hyperextension condition (hyperflexion). The average maximum load for the middle and little finger in hyperflexion mode is 25 N and 27.2 N, correspondingly. The average maximum displacement is 50.6 mm for the middle finger and 51.3 mm for the little one. Although the average maximum load and the average maximum displacement values are similar for both fingers, the dispersion among the obtained values is bigger for the case of the middle finger. Figure 13a and Figure 13b present the load-displacement plots for the middle and little fingers obtained from the flexion tests in abduction condition. The average maximum load for the middle finger in hyperextension and abduction condition is 25.0 N and 29.6 N, correspondingly. For the little finger, the average maximum force is 27.2 N in hyperextension mode, and 47.9 N in abduction condition. The little finger can withstand bigger loads in both test conditions due to the fact that the length in cantilever mode is shorter, compared to that for the middle finger. The test curves exhibit discontinuities due to re-accommodation of the finger assembly. Table 4 presents the set of tested samples and the corresponding designation.

(a) (b)

Figure 12. Finger hyperextension test curves for the middle (a) and little (b) fingers of the D1M hand. The horizontal dashed lines represent the average of the maximum load values.

(a) (b)

Figure 13. Finger abduction test curves for the middle (a) and little (b) fingers of the D1M hand. The horizontal dashed lines represent the average of the maximum load values.

As shown in Figure 14a, failure of the fingers in hyperextension occurs at the link of the proximal phalanx. On the other hand, failure in the abduction condition takes place at the MCP joints, as observed in Figure 14b; cracks nucleate in this area and propagate producing misalignment of the pins. This mechanism might be the reason why significant variations in the load-displacement curves beyond the linear region are evidenced (see Figure 15). Despite being thinner and thus having a smaller cross-sectional area for load distribution, the little finger can withstand a greater load than the middle finger due to the shorter moment arm from its base to the fingertip, which should be taken into consideration for the design.

In the case of the fatigue test, after 24000 cycles of loading, no component from the finger assembly (3D printed pieces, metallic pins, and wires) show any type of failure. Table 5 shows the weight of the fatigue/wear test samples before and after the test. A relatively small difference in weight was recorded as a result of the cyclic load and wear on the contacting parts, the average percentage of variation of weight was 0.05%. The 24000 cycles represent a period of 27 days of use of the prosthetic hand, considering that an average person performs 3680 grasp movements per day [22] and that a prosthetic hand user employs it 4 hours per day [23]. Based on the obtained results, the expected annual weight loss of the D1M hand would be 0.67%, which is a low value when compared to the wear rate for common materials. Figure 16 shows one of the fatigue test samples after the test; the encircled area highlights the ABS material particles resultant from the wear on the contacting parts.

Table 4: Designation of test specimens.

Test type	Sample	Number of samples	Samples designation
Hyperflexion	Middle finger	3	Hm1, Hm2 and Hm3
Hyperflexion	Little finger	3	Hl1, Hl2 and Hl3
Abduction	Middle finger	3	Am1, Am2 and Am3
Abduction	Little finger	3	Al1, Al2 and Al3

Table 5. Weight of fatigue/wear test samples before and after the test.

Sample	Weight (g)		Weight loss (%)
	Before test	After test	
1	6.7117	6.7109	0.012
2	6.7090	6.7020	0.104
3	6.8066	6.8040	0.038

Figure 16: Fatigue test sample

4. Conclusions

In this work, mechanical testing methods for upper limb prostheses were adapted and applied to a specific design, the D1M hand. Details of the experimental procedure have been described and test results have been discussed. The maximum tensile load that the D1M prosthetic hand can withstand is 112.4 N. Furthermore, maximum flexion strength of fingers in hyperextension and abduction conditions is 27.2 N and 48 n, respectively. It was also determined that after 24000 cycles of flexion no component of the fingers assembly of the D1M prosthetic hand exhibits any type of failure.

Obtained mechanical resistance tests results can be utilized to compare future experimental and simulation results. Moreover, our findings and the case described contribute in generating data for the 3D-printed prostheses community since standardization is needed in order to evaluate properties and performance of existing and future designs, which will allow for objective comparison between them and the continuous improvement of their mechanical specifications.

Conflict of Interest

The authors declare no conflict of interest.

ABSTRACT

We have suggested an architecture of the second-order all-pass active RC-filter (ARCF), based on three differential difference amplifiers (DDA's), which provides full set of amplitude-frequency responses (AFR's) (low pass filter (LPF), high pass filter (HPF), band pass filter (BPF), rejection filter (RF)). We have given the basic equations, which allow ARCF's. The results of computer simulation of the LPF, HPF, BPF and RF's are discussed. In case of small volume production it is possible to produce the given ARCF in a form of specialized structural arrays, in which LPF, HPF, BPF and RF characteristics are realized by using one of the seven inputs, to which the processed signal is supplied, and four outputs, from which the said signal is outputted. The ARCF is noted, because its transfer ratio and pole frequency are not changed, when the pole Q-factor is adjusted.

1. Introduction

All-pass active RC-filters (ARCF), which provide amplitude-frequency responses (AFR) of low-pass filter (LPF), high-pass filter (HPF), band-pass filter (BPF), rejection filter (RF) [1-16] at different outputs, are attractive for production in a form of special structural crystals [17,18] in conditions of small volume specific type of electronic equipment. At the same time, the application of promising electronic component base in ARCF, for example, differential difference amplifiers (DDAs) [19-33], which provides new properties of frequency selection devices of this class, is of considerable interest.

The present article's purpose and novelty are analysis of all-pass ARCF's new structure's properties [34]. The filter is provided with independent adjustment of base parameters (for example, with digital potentiometers or passive elements' digital switching. A full set of LPF, HPF, BPF, RF's characteristics are implemented by switching seven inputs, on which the signal is supplied, and four outputs, form which the said signal is outputted.

2. ARC-Filter Base Architecture's Properties

There is a circuit of the suggested all-pass ARC-filter (LPF, HPF, BPF, RF) on Fig. 1 [34]. It provides an independent adjustment of pole Q-factor, when pole frequency and transfer ratio, which depend on other elements' parameters, are constant. The independent adjustment is achieved by controlling resistors' resistance. It significantly simplifies a process of frequency selection devices' trimming and adjustment, based on the suggested ARCF circuit. The buffer amplifier (BuffAmp) in scheme Fig. 1 is implemented on a base of traditional operational amplifiers (OpAmps) or DDA, it provides a wide range of R3, R4 resistors' resistance change.

All types active RC-filters' (LPF, HPF, BPF, RF) generalized transfer function is written as (the filters are implemented on the circuit, given on Fig. 1):

*Corresponding Author: Nikolay Butyrlagin, Don State Technical University, Russia | Email: butyrlagin@gmail.com

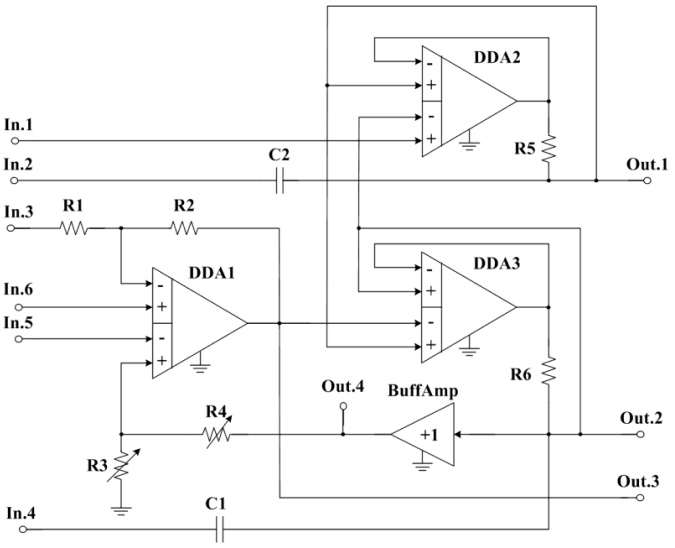

Figure 1: Suggested ARC-Filter's Circuit

$$F(p)=\frac{a_2p^2+a_1p+a_0}{b_2p^2+b_1p+b_0}, \quad (1)$$

where a_i, b_j are equation (1) numerator's and denominator's coefficients, which depend on components' parameters and inputs and outputs in circuit on Fig. 2.

A set of transfer function's numerator coefficients a_i defines a type of ARC-filter (LPF, HPF, BPF, RF).

There are transfer functions' (1) numerator coefficients ai, which are realized in particular ARCF of the Fig. 1 connection circuits, given in Table 1.

The sensitivity functions of the basic parameters of ARCF (Fig. 1) easily correspond to formulas (1) and Table 1.

In the proposed ARCF schemes, typical schemes are applicable, including digital potentiometers or digital switching passive elements, which are described in detail in [35, 36].

The implemented filters' (LPF, HPF, BPF, RF) transfer functions' (1) denominator coefficients b_j relate to elements of the circuit on Fig. 1 by the following equations:

$$b_0=\frac{1}{\tau_1\tau_2}, \quad b_1=\frac{KK_4}{\tau_1}1, \quad b_2=1, \quad . \quad (2)$$

Here the following notation are used in formulas (1), (2):

$$K=\frac{R_3}{R_3+R_4}, \quad K_1=\frac{R_2}{R_1}, \quad K_2=K_3=K_4=1+\frac{R_2}{R_1}, \quad (3)$$
$$\tau_1=R_6C_1, \quad \tau_2=R_5C_2,$$

where R_{ij} are resistance of ij-resistor, C_1, C_2 are capacitance of capacitors C1 and C2.

The active RC-filters, shown in Table 1 and defined as $LPF^{(+)}$, $HPF^{(+)}$, $BPF^{(+)}$, $RF^{(+)}$, have the pole Q-factor, transfer ratio's and pole frequency's independent adjustment properties. Here the pole Q-factor adjustment does not change the filter's transfer ratio and its pole frequency. These filters have the greatest practical interest.

The active RC-filters, defined in Table 1 as LPF, HPF, BPF, RF, do not have the Q-factor, transfer ratio's and pole frequency's independent adjustment properties. Here the transfer ratio and pole frequency coefficients may change, when the pole Q-factor is changed.

The active RC-filters, defined in Table 1 as $LPF^{(-)}$, $HPF^{(-)}$, $BPF^{(-)}$, $RF^{(-)}$, have an amplitude-frequency response slope, which corresponds the first-order transfer function. It limits application scope for these circuit solutions.

There are variants of ARCF Fig. 1 inputs and outputs application on Fig. 2-Fig. 6, they provide AFR different modifications' implementation. In this case, connecting a signal source, for example, to the first input (In.1) assumes that unused inputs are connected to a common bus.

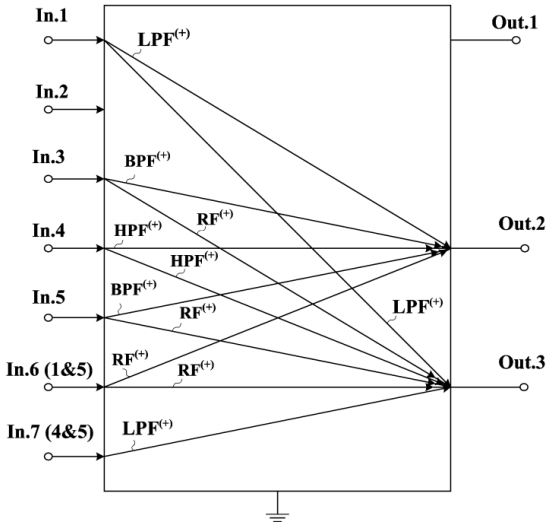

Figure 2: ARCF (Fig. 1) Inputs and Outputs Application Variants, which Provide $BPF^{(+)}$, $RF^{(+)}$, $LPF^{(+)}$,$HPF^{(+)}$ Implementation with Pole Q-Factor Independent Adjustment

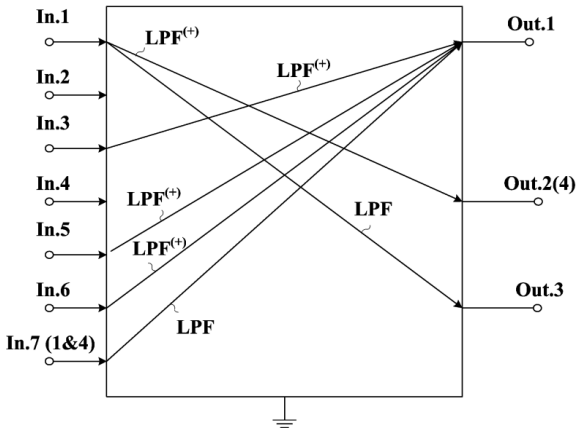

Figure 3: ARCF (Fig. 1) Inputs and Outputs Application, which Provide Low-Pass Filters $LPF^{(+)}$ and LPF Implementation

In.6 AFR curves Fig. 12b	LPF$^{(+)}$ $a_2 = a_1 = 0$ $a_0 = \frac{K_2}{\tau_1\tau_2}$	BPF $a_2 = a_0 = 0$ $a_1 = -\frac{K_2}{\tau_1}$	RF$^{(+)}$ $a_2 = K_2$ $a_1 = 0$ $a_0 = \frac{K_2}{\tau_1\tau_2}$
In.1&4 AFR curves Fig. 13b	LPF $a_2 = a_1 = 0$ $a_0 = \frac{KK_4}{\tau_1\tau_2}$	RF$^{(+)}$ $a_2 = 1$ $a_1 = 0$ $a_0 = \frac{1}{\tau_1\tau_2}$	RF $a_2 = KK_4$ $a_1 = 0$ $a_0 = \frac{KK_4}{\tau_1\tau_2}$

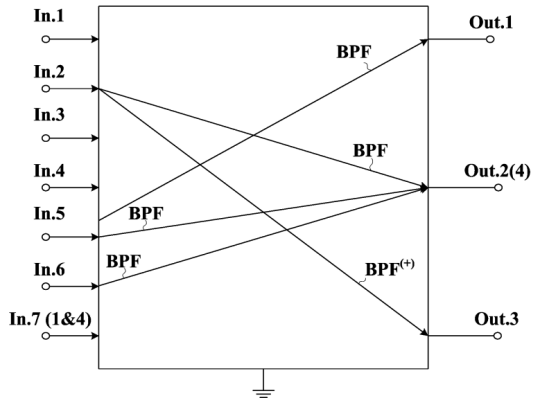

Figure 4: ARCF (Fig. 1) Inputs and Outputs Application, which Provide Band-Pass Filters $BPF^{(+)}$ and BPF Implementation

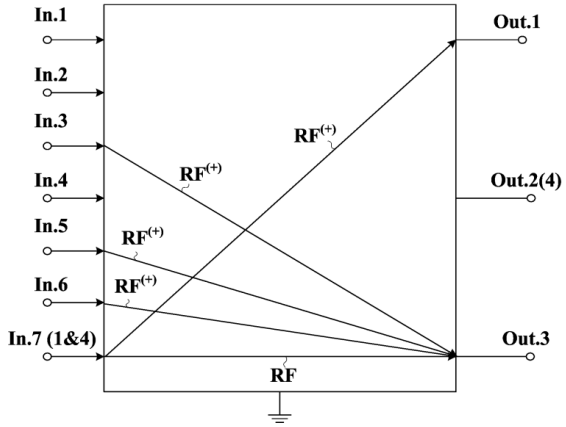

Figure 5: ARCF (Fig. 1) Inputs and Outputs Application, which Provide Rejection Filters $RF^{(+)}$ and RF Implementation

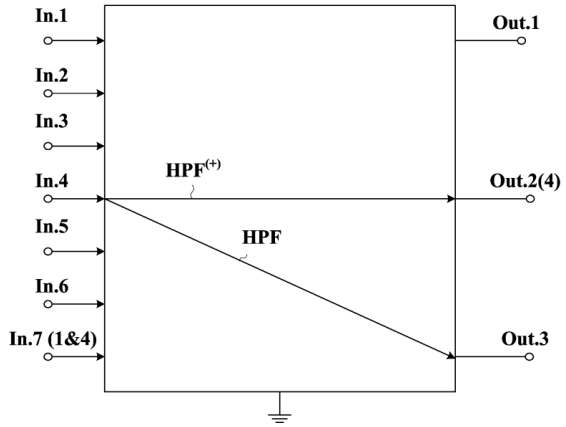

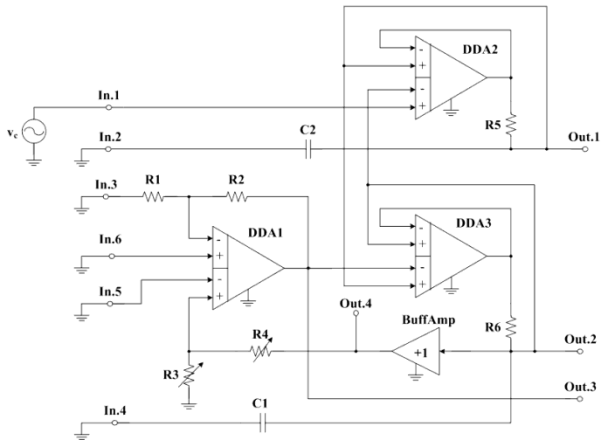

Figure 6: ARCF (Fig. 1) Inputs and Outputs Application, which Provide High-Pass Filters $HPF^{(+)}$ and HPF Implementation

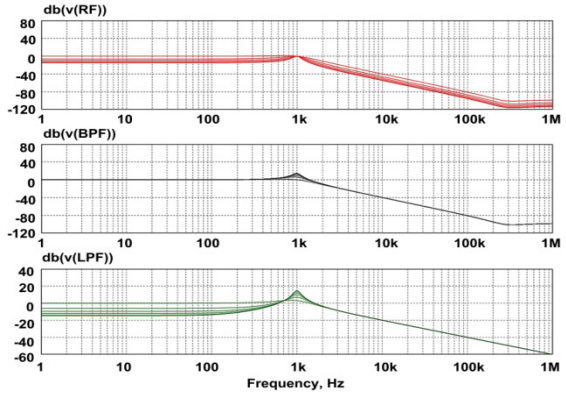
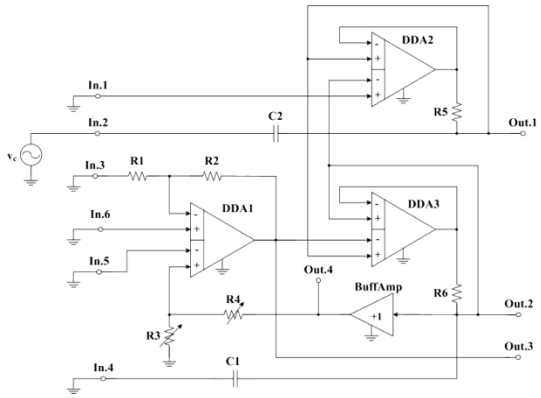


The computer simulation of the ARCF Fig. 1 different modifications, which correspond Fig. 2-Fig. 6, was made in MicroCap on AD830 DDA. It has confirmed the above properties of the suggested ARCF's circuit solution.

3. Low-Pass Filter $LPF^{(+)}$

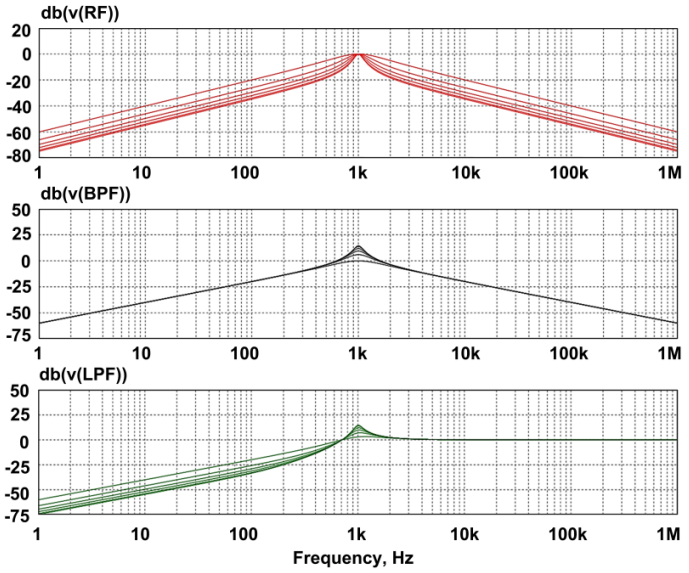
ARCF's inputs (Fig. 1) are connected according to the circuit, given on Fig. 7a, it provides amplitude-frequency responses of $HPF^{(-)}$&$BPF^{(-)}$, $LPF^{(+)}$, LPF on outputs Out.1, Out.2(4), Out.3.

(a)



(b)

Figure 7: Special ARC-Filter's Switching Circuit (a) and its AFRs (b)

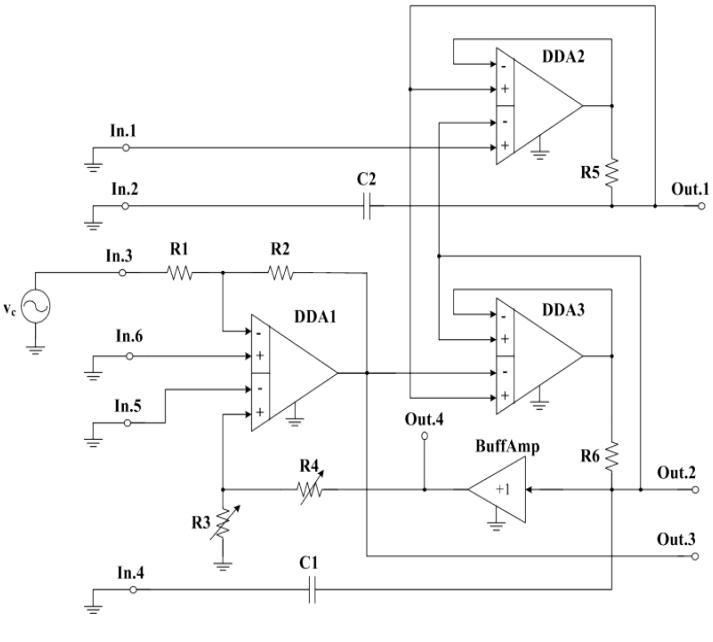


Analysis of the AFR's curves (Fig. 7b) has shown, that transfer ratio and pole frequency are not changed in $LPF^{(+)}$, implemented for output Out.2(4), when the pole Q-factor is adjusted (by changing R3 and R4 resistors resistance). At the same time, the pole frequency in this circuit can be tuned using resistors R5 and R6.

4. Band-Pass Filter $BPF^{(+)}$

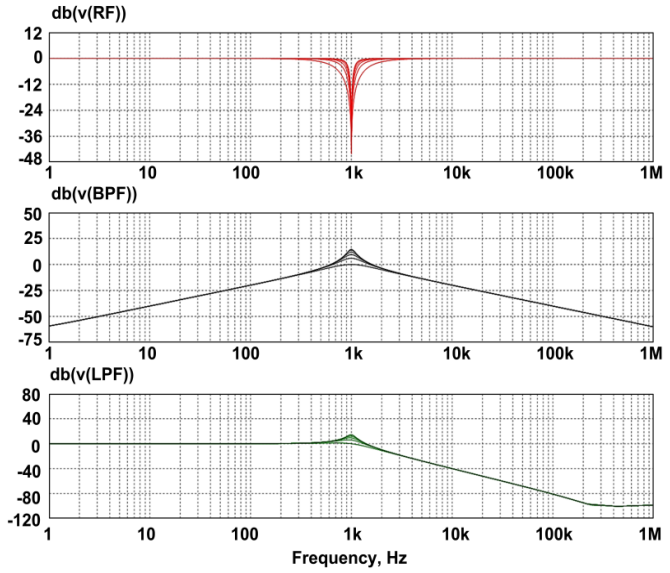
ARCF's inputs (Fig. 1) are connected according to the circuit, given on Fig. 8a, it provides amplitude-frequency responses of $HPF^{(-)}$&$BPF^{(-)}$, BPF, $BPF^{(+)}$ on outputs Out.1, Out.2(4), Out.3.

(a)



(b)

Figure 8: Special ARC-Filter's Switching Circuit (a) and its Amplitude-Frequency Responses (b)



Based on the BPF(+)'s AFRs curves (Fig. 8b) for output Out.3, can be concluded, that transfer ratio and pole frequency are not changed, when the pole Q-factor is adjusted (by changing R3 and R4 resistors' resistance). In this case, the pole frequency in this circuit can be tuned with resistors R5 and R6, and the transfer ratio change with resistors R1 and R2.

5. Rejection Filter RF(+) and Low-Pass Filter LPF (+)

ARCF's inputs (Fig. 1) are connected according to the circuit, given on Fig. 9a, it provides amplitude-frequency responses of LPF(+), BPF, RF(+) on outputs Out.1, Out.2(4) and Out.3.

(a)

(b)

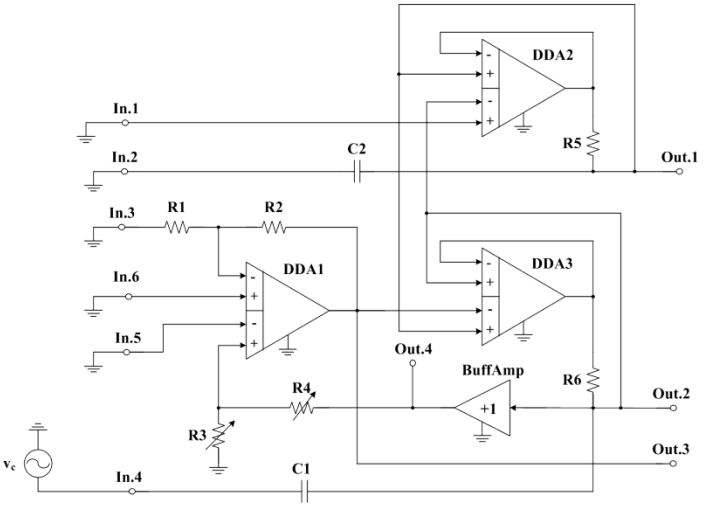


Figure 9: Special ARC-Filter's Switching Circuit (a) and its Amplitude-Frequency Responses (b)

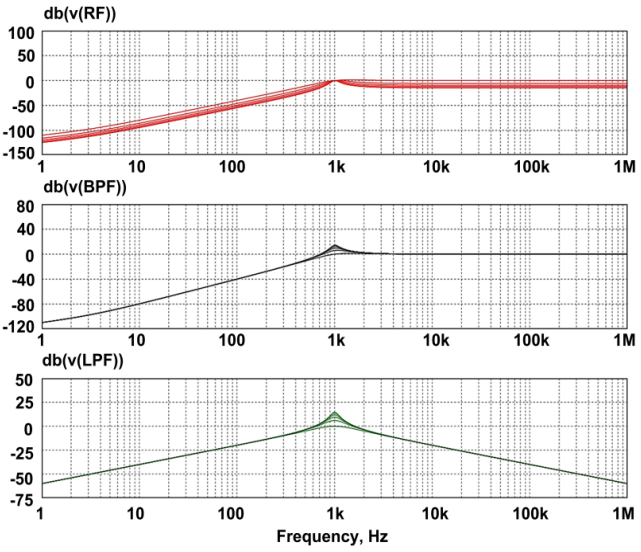
So the ARC's curves (Fig. 9b) show, that transfer ratio and pole frequency are not changed in the implemented LPF(+) and RF(+) for outputs Out.1 and Out.3, when the pole Q-factor is adjusted by changing R3 and R4 resistors' resistance. The pole frequency in this circuit can be tuned with resistors R5 and R6, and the transfer ratio with resistors R1 and R2.

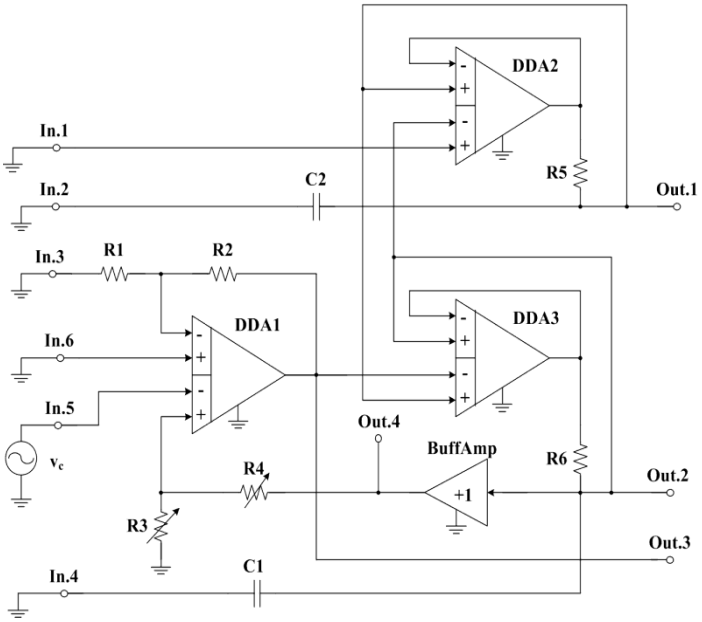


6. High-Pass Filter HPF(+)

ARCF's inputs (Fig. 1) are connected according to the circuit, given on Fig. 9a, it provides amplitude-frequency responses of BPF, HPF(+) and HPF on outputs Out.1, Out.2(4), Out.3.

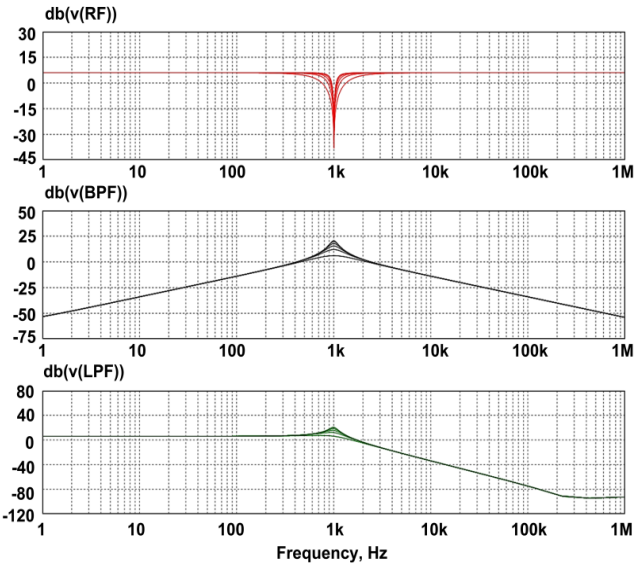
It should be noted that when the pole Q-factor is adjusted, the transfer ratio and pole frequency of HPF(+) for output Out.2(4) are not changed, which follows from AFR on Fig. 10b. At the same time, the pole frequency in this circuit can be tuned using resistors R5 and R6.

(a)



(b)

Figure 10: Special ARC-Filter's Switching Circuit (a) and Amplitude-Frequency Responses (b)

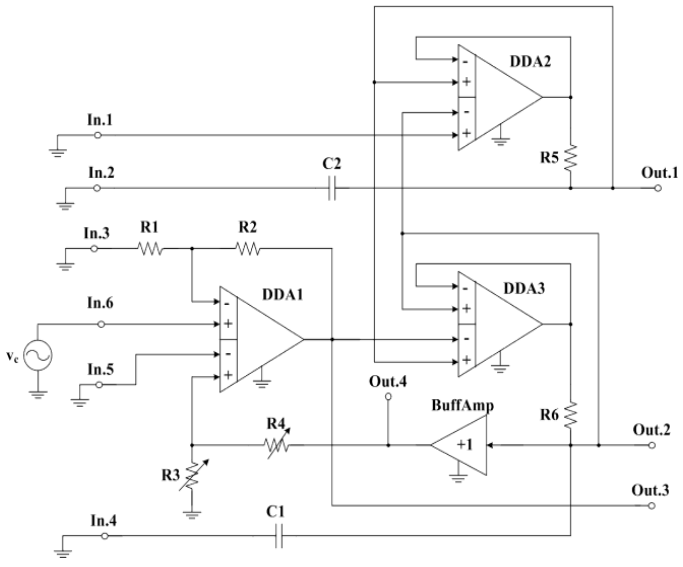


7. Low Pass Filter LPF(+) and Rejection Filter RF(+), Inverting Input Signal

ARCF's inputs (Fig. 1) are connected according to the circuit, given on Fig. 11a, it provides amplitude-frequency responses of LPF(+), BPF, RF(+). on outputs Out.1, Out.2(4), Out.3.

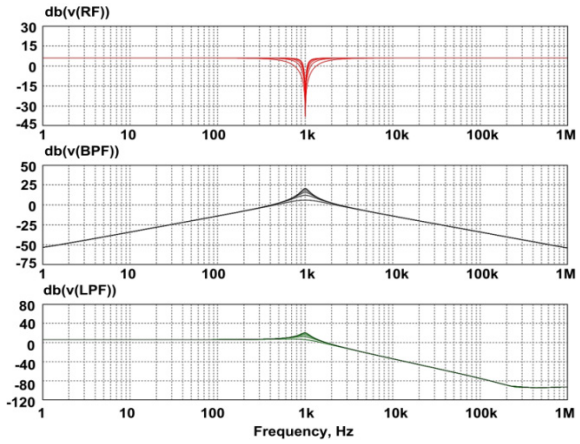
The given AFRs' curves' (Fig. 11b) analysis has shown, that the transfer ratio and pole frequency in LBF(+) and RF(+) for outputs Out.1 and Out.3 are not changed, when the pole Q-factor is adjusted by changing R3 and R4 resistors' resistance. At the same time, the pole frequency in this circuit can be tuned with resistors R5 and R6, and the transfer ratio with resistors R1 and R2.

(a)



(b)

Figure 11: Special ARC-Filter's Switching Circuit (a) and its Amplitude-Frequency Responses (b)

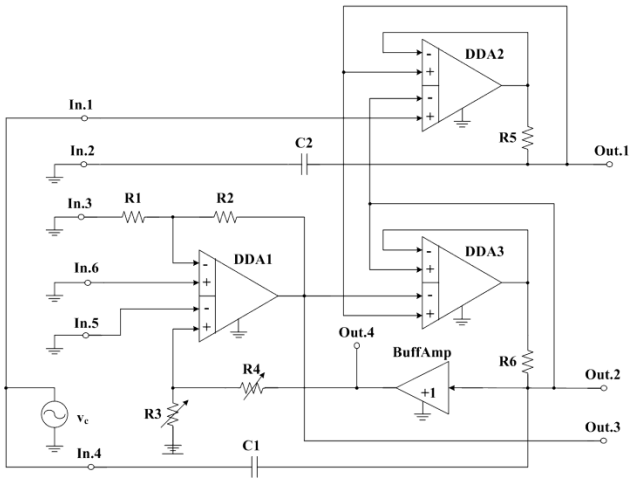


8. Low Pass Filter LPF (+) and Rejection Filters (+), Non-inverting Input Signal

ARCF's inputs (Fig. 1) are connected according to the circuit, given on Fig. 12a, it provides amplitude-frequency responses of LPF(+), BPF, RF(+) on outputs Out.1, Out.2(4) and Out.3.

When the pole Q-factor is adjusted (by changing R3 and R4 resistors resistance), the transfer ratio and pole frequency of LPF(+) and RF(+) (for outputs Out.1 and Out.3 correspondently) are not changed. At the same time, the pole frequency in this circuit can be adjusted using resistors R5 and R6, and the transfer ratio using resistors R1 and R2.

(a)



(b)

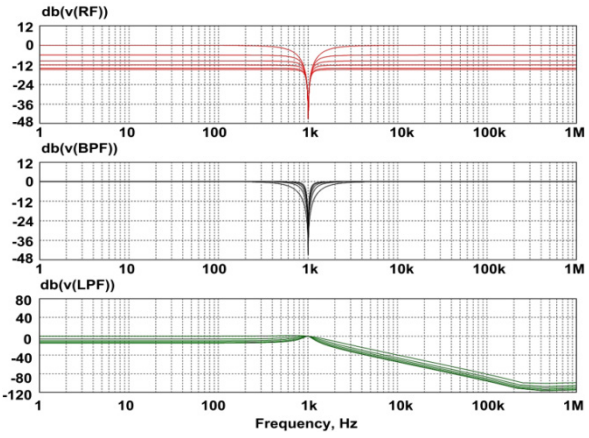


Figure 12: Special ARC-Filter's Switching Circuit (a) and its AFRs (b)

9. Rejection Filter RF(+)

ARCF's inputs (Fig. 1) are connected according to Fig. 13a, it provides amplitude-frequency responses of LPF, RF(+), RF on outputs Out.1, Out.2(4), Out.3.

(a)

(b)

Figure 13: Special ARC-Filter's Switching Circuit (a) and its Amplitude-Frequency Responses (b)

From the analysis of the AFRs' curves (Fig. 13b), it may be concluded, that the transfer ratio and pole frequency are not changed in the RF(+), implemented for output Out.2(4), when the pole Q-factor is adjusted (by changing R3 and R4 resistors resistance). At the same time, the pole frequency in this circuit can be tuned using resistors R5 and R6.

10. Conclusion

We have developed a structure of all-pass ARCF with pole Q-factor, transfer ratio and pole frequency independent adjustment for the whole spectrum of amplitude-frequency responses of the second-order filter (LPF, HPF, BPF, RF) implemented. This is a significant advantage of the considered circuit design solutions in comparison with the known ARCF of this class. We recommend using the suggested ARCF as a specialized chip of a structural array because of its universality. It is possible to implement a wide range of frequency selection devices in the said ARCF, because the signal source is connected to one of seven inputs and four outputs.

Conflict of Interest

The authors declare that there is no conflict of interests regarding publication of this paper.

ABSTRACT

Perishable inventory management contributes simultaneously to society and the economy, by reducing food wastage and capitalizing on the freshness of goods. For this reason, countless mathematical models have been developed for their effectiveness and cost-efficient management. Yet, the majority of these models can only optimize systems for a limited time frame, allowing for small gains in operations management, but failing to change the recurring patterns in inventory levels. System dynamics (SD) modelling shifts emphasizes these patterns and the recurring decisions that make them. Moreover, the framework has generated insight for other supply chain cases that could not have been derived from a short-term perspective. Thus, the current study now seeks to apply the SD framework in modelling perishable inventory systems, in designing policies that benefit the environment and the economy by reducing waste production and increasing the viability of goods reaching the customer. In particular, it evaluates the impact of opposing issuance policies (i.e. First-In-First-Out (FIFO) and Last-In-First-Out (LIFO)) on perishables to demonstrate the potential of SD in improving perishable inventory management. The simulated results share the sentiments of optimization models, that FIFO will ultimately generate less wastes and incur less material costs. Yet, the simulations also reveal implementing FIFO will result in larger fluctuations in inventory levels, which imply greater inconsistency in age-based quality. These suggest that LIFO would be preferable for quality-sensitive products, while FIFO would be preferable for cases sensitive to waste production. The current study demonstrates the efficiency of system dynamics in generating insight beyond that which can be derived from the existing mathematical models. Future studies may likewise extend this approach in the evaluation of policies on the use of technology in perishable inventory systems, which are the prevalent in present literature.

1. Introduction

In inventory models, perishability is a physical property of inventories that results in the eventual expulsion of these goods from the system as waste [1]–[3]. In terms of social and commercial impact, studies on the management of perishables have prevailing importance. Products necessary to sustain human life, such as food and healthcare, possess this characteristic [4], [5]. In particular, the case of blood banks has received much attention from studies on perishable inventories. Due to the instability of supply and short validity of blood units, a precise and quantified means of managing these inventories are much needed [4], [6]. Blood banks are a strong example of how perishability as a product characteristic can complicate inventory systems, and can be used to generate insight on how other perishable products are best to be managed [6].

Perishability complicates the traditional inventory and supply chain models. The typical components of such models are profit and sustainability measures, capacity constraints, and demand

[*]Corresponding Author Phoebe Ching, phoebe_ching@dlsu.edu.ph

distributions [7], [8]. However, policies that prove optimal for non-perishables are not necessarily optimal for perishables [5], [6]. In some models, perishability is represented as the deterioration of product quality [5], [9]. This can affect demand or the allowable pricing, thereby sharply differentiating the scenario described from inventory systems that do not differentiate between fresh and aged inventories. The transition of inventories from a state of salability to wastes is another differentiating factor. The production of wastes affects system capacity [10], [11], and any wastes generated may incur disposal costs [11], [12]. In this case, perishability affects key system constraints and parameters. Some studies on this subject have been dedicated to studying the differences between perishable and non-perishable systems. These have proven that the differences between perishables and non-perishables result in different optimal policies for each kind of inventory.

The majority of studies in this area are optimization models. From the models themselves, decisions on production quantity and product timing can be determined for a given set of parameters. In turn, managerial insights on managing inventory given similar parameters can be derived from the quantitative behavior of the variables. The optimization of inventory systems is a continuously growing body of research, with models growing in scale and complexity, or through the incorporation of new components such as technology enhancements [3], [13]. Aside from this, research efforts are also being invested in identifying the most efficient algorithms for the model [9], [14]. All in all, advancements in this area are geared towards achieving greater accuracy and numerical exactness. However, a weakness of this approach could be that the emphasis on these aspects of modelling shifts the focus away from insight-generation. While the models are becoming increasingly adept at describing specific scenarios, it may be noted that real inventory systems are constantly subject to external change. Thus, regardless of the level of exactness that is achieved by these models, its direct applicability to real systems will always be limited.

In response to these issues with current modeling approaches, applying the system dynamics methodology can augment these through (1) its applicability to large-scale systems which mathematical modeling may be inefficient for [15], (2) its emphasis on patterns of behavior over numerical exactness [16], [17], and (3) its limitation to constant system elements, as opposed to designing in response to external factors [18], [19]. The first two attributes make system dynamics apt for identifying key areas for solution implementation. Specifically, it can be used to identify the most influential variables in the system. This is insightful for future studies, which can delve more specifically in those areas. The third attribute aids in generating insight for recurrent managerial policies as opposed to period-specific decisions. These are more aligned with real managerial practices which, where rules and guidelines are favored to specific values.

In this study, the system dynamics (SD) methodology is applied to the case of perishable inventory systems. This is done for the purpose of demonstrating how the SD methodology can be applied in designing managerial guidelines, with proof that use of these guidelines will generate significant improvement for the system. As SD has already generated insights for general supply chain settings [20], [21], this study now investigates how perishability can alter the results, given that perishability has been proven to be a significant differentiating factor in previous studies [22]–[24]. Through its high-level perspective, the current study aims to identify impactful areas for solution development in the perishable inventory scenario. In this way, it can contribute to the area of study with suggestions for future studies focusing on these specific areas.

2. Literature Review

2.1. Inventory System Dynamics

There seems to be a limited research concerning inventory system dynamic (ISD) studies, thus there is potential to address multiple unexplored research gaps [19]. The challenge then is to find a purposeful gap to address, and justifying why system dynamics (SD) methodology would be more appropriate over methods that allow for more quantitative accuracy and optimization. In this respect, a review of the existing ISD studies is conducted to (1) learn the research objectives that prompted the use of SD, (2) understand how the ISD study relates to other inventory models using different methods, (3) understand how managerial and policy-making insights are derived from such studies, and (4) determine the main contribution of individual ISD studies.

In a literature review on SD applications in renewable energy supply chains, Saavedra 2018 observed that related studies seems to have objectives of either (1) improving understanding of the supply chain; or (2) developing modelling and simulation approaches. As a framework for understanding, SD is effective in depicting complex cause-and-effect chains and various sectors through its diagram-based modelling approach. From its diagramming methods alone, insight can be derived from the network of interrelationships between variables. On the other hand, as a simulation tool, the effectiveness of SD in providing insight is still being validated. This is due to its lack of quantitative accuracy and the lack of studies in this area.

Generally, a well-accepted method of applying SD is to use the diagramming approach to identify problematic areas, and apply sensitivity analysis to determine the most efficient area for solution [25]. This is the approach taken by studies seeking to apply the SD framework in a specific context. On the other hand, in studies that assess the methodology itself, SD has been coupled with various methods to augment its lack of numerical soundness, and the lack of perspective in other modeling approaches [19].

Given its frequent applications in sustainable supply chain models, there is often a part of SD studies that compares its methods with the likes of operations research and life cycle assessment (LCA), and validates that it can produce insights beyond those that can be derived from other modeling approaches. In comparing supply chain models using SD with those using other methodologies, Saavedra 2018 concluded that a major difference between SD and LCA is its focus on the behavioral patterns of variables within a model, such as the intermittency and variability of its values. On the other hand, the focus on LCA is on aggregate performance, such as the total volume of emissions [18].

The SD methodology also allows for a wide range of variables to be modeled and simulated efficiently, given its lack of numerical

exactness. In a literature review, it was observed that most SD supply chain models had a macroscopic perspective consisting of economic and environmental impact. Next in quantity were SD studies with an inter-organizational scope, and last were studies with an intra-organizational scope. On the contrary, for operations research-based studies, the order from highest to lowest volume of publications is intra-organizational, inter-organizational and macroscopic [19]. This can alter the kinds of policies that may be developed and simulated using each method.

SD can be a means of extending optimized parameters into concrete policies, particularly in cases with multiple parameters of a different nature. Song 2018 created a model to simulate the application of optimized parameters for technology, environment, energy and economy in a system where they are interrelated. These parameters were derived using data envelopment analysis (DEA), which augments the lack of numerical accuracy in most SD models. SD then strengthens the policy-making approach by highlighting the physical relationship between variables.

Scenario analysis, such as applying different parameters to represent different cases, is a quick means of validating the model's logic and policy development. In validation, it allows for multiple real-life case parameters to be applied to prove the validity of the causal relationships and the completeness of the model. In policy-making, a number of alternative solutions can also be generated and simulated, by shifting model parameters [18].

Overall, SD studies have contributed to the field of study with insight for how certain resources can be managed with optimal results [25]; knowledge on the opportunities and limitations of simulation methods [18]; and the creation of hybrid models combining SD with more math-based methodologies [19].

2.2. Perishable Inventory Systems

Perishable Inventory Systems (PIS) have received much attention in literature as early as the 1990s, up until recent time [5]. Earlier studies simply sought to incorporate 'perishability' as an attribute of inventory. Nonetheless, more recent studies seek to determine the kinds of managerial strategies and policies that may be applied to perishable inventories [2], [26]

In a literature review conducted in [5], studies from 2012 to 2015 were segregated according to the different policies being implemented in each study. It was found that the top policies being studied during that period were (1) credit and payment policies, (2) supply chain information sharing, and (3) pricing and markdown problems. There were notably few studies on the use of the introduction of advanced monitoring technology, and on classic issuance policies (i.e. FIFO, LIFO).

Since then, there has been an increase in models on the integration and use of monitoring technology in perishable inventory systems. [6] have introduced the use of RFID technology in monitoring of unit age and cost to the dual-sourcing problem for perishables. This was evaluated against fixed and exponential product lifetime scenarios, to gain insight on specific potential applications for this strategy. More recently, [3] have developed an IoT-based model for monitoring perishables in shared storage. Given the potential for cross-perishability, which refers to the increase or decrease in deterioration rate resulting from shared storage, information monitoring in this manner could then allow for lowering of deterioration costs, inventory level, and quality loss for the system. On a two-stage optimization model for pricing and replenishment of PIS, the recommended extension is also the incorporation of RFID and point-of-sales data in decision-making [7].

It seems to be reasonable for research to progress in this direction given the rise of Industry 4.0 [27], [28]. However, the implementation of advanced systems, similar to the aforementioned, are still dependent on fundamental decisions in inventory management. This is evidenced by the way that these technologies are modeled in conjunction with inventory management policies from classic literature [29]. Yet, these policies are still among the top policies being studied from 2012 to 2015, as identified by [5].

Over the years, there have been few changes to the performance functions used for perishable inventory models which enable ease of comparison. Financial measures such as profit and cost are still used in almost every PIS study. The percentage of profit growth or cost reductions resulting from the implementation of certain policies is typically used as the measure of performance in these cases [4], [6], [26]. Profit can be affected by perishability through the decline of demand alongside quality [30]. It can also manifest as disposal costs [2], [8] and wastes [7].

Wastes differ from financial measures as they are a physical outcome of the PIS policy. By quantifying waste production, a model can also be assessed for its sustainability [10], [11]. The minimization of waste, separate from its contributions to cost, is used as an objective in a number of studies [5]. In this way, the model can differentiate between financial and physical outcomes, given that the volume of wastes would not always be economically relevant in all cases.

Another physical outcome of PIS policy is the service level, or the ability to meet customer demand [28]. In the model of [7], service level is the probability of stockout in the replenishment cycle resulting from the policy. Monitoring the service level of PIS prevents over-emphasis on cost efficiency, in a more tangible way than revenues. Aside from this, the model of [4] has made use of the average age of inventories being sold, to represent the quality of the products.

The perishable nature of inventories in PIS is represented as a finite lifetime. This leads to wastes at the end of the product lifetime [11], [12], and declining demand over time for a specific unit [5], [9], [31]. In most PIS models, a scenario analysis is conducted for various rates of deterioration. Generally, the higher the deterioration rate, the greater the amount of waste [7]. However, this can also vary depending on the stochastic distribution of a product's lifetime, and the kind of policy being implemented. The model of [6] demonstrates that dual-sourcing can produce greater cost savings in cases where lifetime is fixed with a shorter average, and when lifetime is exponentially distributed with a longer average.

Generally, a number of policies have proven effective in managing PIS, with immediate improvements in cost and material efficiency. Optimization models demonstrate how such policies can be applied with optimal results for a given set of parameters.

However, the existing methodologies have proven to be inefficient for policy-to-policy comparison, given the variability in model structures and sensitivity to parameters. Thus, the basis of determining best practices based on the existing studies could still be improved.

2.3. FIFO and LIFO Issuance Policies

Issuance policies are an integral part of an inventory management problem. In general, the parameters under study in such a problem are pricing, inventory costs, and deterioration rate [7], [32]. These parameters are present in almost all studies and are used to evaluate specific policies being applied, or intended for application, on real inventory systems. These policies can include issuance policies (i.e. FIFO and LIFO), which relate to the order at which goods of the same kind at different ages are dispatched to the customer. Based on the review of Janssen (2016), issuance policies appear to be an overlooked area in literature. However, based on the current review that was conducted, it seems that most studies include issuance policies as a parameter, instead of treating it as a focus of the study. The review of literature in this area is thus segmented in two ways: (1) studies considering issuance policies as a parameter, and (2) studies explicitly focused on evaluating or identifying optimal issuance policies.

Using a policy as a parameter means that it can be changed to allow the analyst to see various scenarios. [23] sought to determine how the centralization of inventory could be beneficial in managing a perishable supply network. Specifically, the case under consideration was a blood supply chain with inventory located at a single blood bank and being supplied to multiple hospitals. FIFO was explicitly modeled for this case, as this is the standard for inventories in the healthcare service industry. [10] adapted a modeling and simulation analysis methodology determine the impact of a closing day constraint for the inventory of stores. The objective of the study was to determine if the existence of a closing day would lead to more aged inventory as closing day approach, as is the case in real grocery store inventories. It was found that the closing day constraint did result in simulated behavior being closer to the real behavior of inventories. In another study, [11] assessed the quantitative impact of micro-periodic inventory management policies, for how these may potentially improve costs and waste production. Under this approach, a single day was broken into morning, midday, afternoon and evening periods. This likewise made use of a mixed FIFO and LIFO approach. It was found that costs were reduced significantly from micro-periodic management, as compared to daily planning.

One reason why a mixed approach is taken in most studies is so that the exact impact of each policy will not have to be considered. This recognizes that there are, in fact, real differences between the effects of applying each policy, particularly on perishables. The models that explicitly analyze the issuance policies seek to determine what these effects are and how they can be managed most effectively to meet the goals of the system. [12] compared the viability of FIFO and LIFO for managing perishable inventories using a modified Economic Manufacturing Quantity. Said model was modified to give consideration for fixed order quantity and joint ordering policies. This revealed that LIFO could prove optimal under linearly decreasing price structures. This finding is relevant given that it is generally accepted that FIFO has superior performance on perishables [19], [23].

In most cases, issuance policies are modeled as a two-warehouse problem. Under LIFO, the first inventories to be sold would come from the rented warehouse; while under FIFO, the first sales are taken from the owned warehouse. A model for this problem was developed by [32], who assessed each issuance policy for its overall costs, given deterioration and holding costs. It was found that FIFO was less expensive when the cost parameters were lower for the owned warehouse than in the rented warehouse. As this is the case for most entities, it may be concluded that the study recommends FIFO under LIFO given the parameters that were considered. [9] extends the study of issuance policies for two-warehouse inventory systems to the use of modified FIFO (MFIFO) and modified LIFO (MLIFO) policies. Under the MFIFO rule, the FIFO rule is followed as far as the inventory in demand is available. When unavailable, the backorder gets assigned to the lowest priority level in the next period [28]. The model was structured in such a way that allowed for easy comparison between policies by relaxing a few constraints. It was found that when deterioration rate was different between the rented and owned warehouses, holding cost could make a significant difference in the optimality of each policy.

MFIFO and MLIFO are already evolutions of the existing issuance policies. It is understood that FIFO and LIFO each have weaknesses, and thus improvements can be made in their exact rules. [31] proposed the development of a new issuance policy entitled Allowance-in-Fraction-Out which has specific rules for when to apply FIFO and LIFO. This is likewise applied to the two-warehouse inventory problem, wherein the decision to switch is based on the fraction of rented warehouse inventory to owned warehouse inventory. Across various cases of deteriorating behavior, value of information, and perishability, it was found that the mixed method could have benefits in transportation costs and the occurrence of sub-replenishments.

In recent literature, most studies treat issuance policies as a parameter. Moreover, most studies assume a mixed issuance policy structure to protect the model from the effects of using any specific policy. However, this suggests that inventory will be taken randomly from a company, which is understandably not the case in inventory systems. The most advanced study in this area seeks to determine the appropriate rules for using FIFO and LIFO, and managing their negative repercussions. This would imply that further study is needed of the explicit behaviors of FIFO and LIFO to determine how they may be managed productively.

3. Methodology

In this study, the system dynamics (SD) methodology is used to model a perishable inventory model, and simulate the application of certain policies and methods. This method is efficient for analyzing patterns of behavior, as it emphasizes long-term patterns over quantitative accuracy [16], [17]. It is also efficient in expanding the scope of a model to encompass all variables that could have significant feedbacks on the key variables under study [20]. SD emphasizes the importance of feedbacks in a system, showing how the system's behavior is actually the result of these internal feedbacks, and not external factors [16]. In problem solving, this maintains the focus on constant factors,

rather than externalities which may or may not be present. In this way, the SD methodology is well-suited for evaluating policies in the long-term, and managing any negative repercussions that may result from their application.

The SD framework is applied with the intention of designing policies that will improve the sustainability and quality goals of the system. Most perishable inventory models attempt to address sustainability goals by having waste minimization as one of its objectives [30], [33]. The connection of waste minimization to sustainability implies that through waste reduction, resource consumption is also reduced. On the other hand, quality goals can be met in terms of age-based quality, by minimizing the time a unit spends in the system from production to sale [4]. Age or, conversely, freshness is an apt representation of quality for perishables given the fact that (1) perishables are typically fast-moving consumer goods which vary little from unit to unit, and (2) perishables will definitely degrade in some way over time, making age a significant component of quality, even if it is not the sole component.

The SD methodology classifies variables as stock, flow, auxiliary or exogenous based on their role in the model. Stock variables accumulate over time based on previous values; flow variables represent this rate of accumulation; auxiliaries serve as the transition of stocks to flows; and exogenous variables are parameters whose values are externally determined. A discussion of how the variables were classified, and of their respective equations is given in Section 3.1. Following this, the variables determined in Section 3.1 are organized in a causal loop diagram in Section 3.2. This represents the relationship of the variables in an enclosed system. The variables and loop structure are then integrated in a stock-flow model for simulation and analysis in Section 3.3.

3.1. Variables Definition

Stock variables are those which increase or decrease in relation to their value in a previous period. This can be used to represent inventory levels which physically change over time. In this model, inventory is divided into two categories based on age. Hence, there is a variable representing Fresh Finished Goods Inventory (FFGI) and Previous Finished Goods Inventory (PFGI) respectively, as levels. By logic, FFGI is a function of production, sales, and leftover inventory in the current period (t). Since it is not an option to dispose freshly-produced goods in this model, there is no difference between the equation for FFGI in the perishables and non-perishables case.

$$\text{FFGI}(t) = \text{FFGI}(t\text{-}1) + \text{Prod.}(t) - \text{Sold F. Inv.}(t) - \text{Held Inv.}(t) \quad (1)$$

PFGI represents inventory carried over from previous periods. In the perishable's scenario, a fraction of inventory becomes waste at the end of each period. Mathematically, these differences between the perishables and non-perishables case are given in equations 2 and 3 respectively.

$$\text{PFGI}(t) = \text{PFGI}(t\text{-}1) + \text{Held Inv}(t) - \text{Sold P. Inv}(t) - \text{Wastes}(t) \quad (2)$$

$$\text{PFGI}(t) = \text{PFGI}(t\text{-}1) + \text{Held Inv}(t) - \text{Sold P. Inv}(t) \quad (3)$$

Aside from variables that physically change in value, stock variables are also apt for representing human cognition in system dynamics models. Cognition is influenced by the occurrence or lack thereof of certain events. In consequence, these strengthen or weaken a certain idea, which in turn produces reactions affecting the other variables in the system. Such variables are usually not included in modeling as there is no definite metric to represent them. However, the soft emphasis on numerical accuracy in system dynamics allows for such variables to bear the same weight as tangible variables (i.e. inventory, cashflow).

In this model, there are two cognition variables, both represented as 'perception'. One of these is Perceived Quality (PQ), representing the customer's flawed knowledge on the actual quality of goods produced by the producer. System dynamics recognizes the feedback delay in perception of performance, which results in there appearing to be no effect despite efforts toward improvement. PQ changes by a positive or negative value, depending on whether the quality in recent periods has been good or bad. However, PQ itself will always be a normalized value as the change happens in relation to previous values of PQ. Conversely, Perceived Demand (PD) represents the producer's flawed knowledge on the actual volume of customer demand. In real applications, this would represent the degree of error in demand forecasts [34]. Likewise with PQ, PD changes by a positive or negative value depending on the recent demand values.

The change in the value of stock variables at each period is defined as a flow variable. A stock can have inflows that add to its value, and outflows that reduce its value. In the case of FFGI, the inflow rate is Production (Prod), while the outflow rates are Held Inventory (Held Inv) and Sold Fresh Inventory (Sold F. Inv). Prod is based on the value of PD, which represents the use of forecasts in deciding on production quantities [32], [35].

$$\text{Prod}(t) = \text{PD}(t) \quad (4)$$

Held Inv is equal to the current value of FFGI, as all fresh inventory that is not sold will be carried over to the next period as PFGI. Held Inv represents the transition of FFGI into PFGI by being an outflow of the former into the latter. The also represents the aging of products in the system. In essence, there are only two age classes of goods--fresh and previous. While this may not capture the exact age of the inventory pieces, it is nonetheless sufficient to show the impact of FIFO and LIFO. Further segmentation by age group may further complicate the model without generating additional insight to compensate for the effort.

$$\text{Held Inv}(t) = \text{FFGI}(t) \quad (5)$$

FFGI and PFGI each have outflows in the form of sales, and the equations for these vary between the FIFO and LIFO cases given that the former prioritizes selling PFGI while the latter prioritizes selling FFGI [Parlar et al, 2011]. These are Sold Fresh Inventory (Sold F. Inv) and Sold Previous Inventory (Sold P. Inv). Mathematically, the prioritized inventory class is directly influenced by Customer Demand (Cust Dem), while the deprioritized class is a function of the sales for the prioritized class. The equations for the FIFO case are given in equations 6 and 7; and those for LIFO are given in equations 8 and 9.

$$\text{Sold F. Inv}(t) = \text{MIN}(\text{MAX}(\text{Cust Dem}(t) - \text{Sold P. Inv}(t), 0), \text{FFGI}(t)) \quad (6)$$

$$\text{Sold P. Inv}(t) = \text{MIN}(\text{Cust Dem}(t), \text{PFGI}(t)) \quad (7)$$

$$\text{Sold F. Inv}(t) = \text{MIN}(\text{Cust Dem}(t), \text{FFGI}(t)) \quad (8)$$

$$\text{Sold P. Inv}(t) = \text{MIN}(\text{MAX}(\text{Cust Dem}(t) - \text{Sold F. Inv}(t), 0), \text{PFGI}(t)) \quad (9)$$

For PFGI, there is an additional outflow in the form of Wastes. This variable is only present in the perishables case, as inventory can only be accumulated in the case of non-perishables. The variable Wastes is a function of the residual PFGI and a given rate of deterioration:

$$\text{Wastes}(t) = (\text{PFGI}(t) - \text{Sold P. Inv}(t)) / \text{DelayP} \quad (10)$$

For the cognition variables Perceived Demand and Perceived Quality, it was previously mentioned that the change could be positive or negative depending on the recent values of the perceived information. These changes are the flow variables Change in Perceived Demand (CIPD) and Change in Perceived Quality (CIPQ). Mathematically, a positive change would result if the current value is greater than the perceived value, and a negative change if otherwise. In effect, the current values are normalized against previous values. A feedback delay is used to represent the limited influence on current values against long-standing perception. In equation form:

$$\text{CIPD}(t) = (\text{QOGS}(t) - \text{PQ}(t)) / \text{DelayPQ} \quad (11)$$

$$\text{CIPQ}(t) = (\text{Cust Dem}(t) - \text{PD}(t)) / \text{DelayPD} \quad (12)$$

Aside from stock and flow variables, a system dynamics model contains auxiliary variables. These are components of flow variables. It can serve as a means of breaking down potentially-complex equations for flows, both for ease of understanding and to highlight the behavior of specific components. Auxiliaries are derived from the behaviors of stock variables, and can link these to flows in the model. Unlike stock variables they are not a function of their previous value. While they do not change the overall system behavior, they are nonetheless important for clarity in representation.

The model contains three auxiliary variables: Quality Multiplier (QM), Customer Demand (Cust Dem), and Quality of Goods Sold (QOGS). QM is an example of an auxiliary that exists for ease of understanding. Its value is equal to the value of Perceived Quality (PQ), yet the conversion is made to show the logic in making PQ part of the function of Cust Dem. Hence:

$$\text{QM}(t) = \text{PQ}(t) \quad (13)$$

Cust Dem is a function of two variables, QM and a randomized demand value that is exogenous to the system (Natural Range of Customer Demand, NRCD). In effect, the perception of good quality positively influences demand by a margin, while the perception of poor quality has an inverse effect. As indicated by its usage in the previous equations, customer demand is the actual amount of purchases made by the customer in a single period. This consequently affects the sales variables, Sold Fresh Inventory and Sold Previous Inventory. The equation for this variable is given as:

$$\text{Cust Dem} = \text{NRCD} * \text{QM}(t) \quad (14)$$

QOGS represents the quality of goods sold for a current period. In this model, the quality of the perishable product is solely based on freshness. Its value is derived from the amount of Sold Fresh Inventory (Sold F. Inv) in relation to Customer Demand (Cust Dem). Higher proportions of Sold F. Inv in Cust Dem would thus equate to better quality. As information on the quality of the producer's goods is transmitted to the customer through sales, QOGS has a direct but gradual influence on PQ [30], [36].

$$\text{QOGS}(t) = 1 - \text{Sold P. Inv}(t) / \text{Cust Dem}(t) \quad (15)$$

The variables that are not directly influenced by any variable in the model are exogenous variables. The belief that the system's behavior is primarily influenced by the feedbacks between its endogenous variables, rather than exogenous variables, are at the core of the system dynamics methodology. Hence, exogenous variables are typically represented by constant parameters, as proof that their value is of minor significance to the system's behavior.

Feedback delays are a common example of an exogenous variable. These represent delays in the transmission of information across the system. In equation form, these are variables that limit the flow of information to a cognition variable. In this model, these delays exist in the flow variables for Perceived Quality and Perceived Demand, as Delay in Perception of Quality (DelayPQ) and Delay in Perception of Demand (DelayPD). Physical delays are another common exogenous variable, representing rates of transition from one state to another. In this model, the physical delay is the Delay in Perishing (DelayP). This delays the transition of inventory into wastes, according to a supposed validity period.

An exogenous variable is also used to represent additional sectors of the system that can be simplified for ease of analysis. This can be done when the variables included in that sector are not explicitly being analyzed. In this model, the Customer Demand (Cust Dem) is understandably an outcome of Perceived Quality. Yet, it is also influenced by the availability of other options in the market; the demand of the customer's own customer; and numerous other factors depending on the specific case and scenario. In effect, Cust Dem will have a degree of variability due to these other variables. To represent this, a Natural Range of Customer Demand variable is introduced as a random variable with a given range.

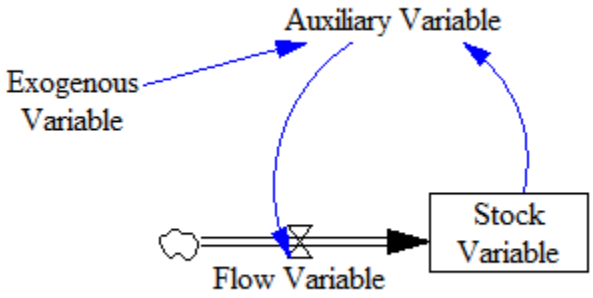

Figure 1: Basic Structure of a System Dynamics Model.

3.2. Interactions Between Endogenous Variables

The greatest differentiating factor of the SD methodology is that it organizes variables into feedback loops. This follows the principle that a system's behavior is influenced more by the system's internal reactions than any external factor. A visual representation of the role of each kind of variable in a feedback loop is given in Figure 1. All loops include at least one stock variable, which shows how the current outcomes of a system result from behavior in a previous period. This progression of cause and

effect leading from past to current behavior is demonstrated through a progression of auxiliary variables. It is shown in Figure 1 that auxiliary variables are the link from stock variables to flow variables, which mathematically means that the past values of a variable would change its next-period values. Finally, the exogenous variables are externally-determined and not influenced by any other variable in the system. Hence, there is no feedback leading to an exogenous variable.

To demonstrate the cause-and-effect relationships in a SD model, variables are arranged in causal loops without differentiation between variables. The purpose of this is to emphasize the feedbacks within the system prior to explicit modeling. In developing the causal loop diagrams for this study, it became apparent that there would be different causal loops for the FIFO and LIFO cases respectively, due to the difference in inventory type affected by sales. Specifically, demand directly impacts aged inventory in the FIFO case, and fresh inventory in the LIFO case. Aside from this, both cases have the same loops, representing a common PIS structure to enable comparison.

In PIS models, demand changes based on the age of inventory given the fact the that goods are deteriorating over time [5], [9]. In this model, a quality variable determined by age is positively linked to demand, meaning that demand will increase as quality improves. Quality is positively affected by the quantity of fresh inventory, and negatively affected by the quantity of aged inventory. This is how the reduction in demand caused by low-quality or aged goods is interpreted in the model. The resulting demand has a delayed impact on production, representing how demand from previous periods can determine production levels in the coming periods through forecasts. Production quantities then add to the level of fresh inventory, and fresh inventory becomes aged inventory, by natural progression [4], [11], [37].

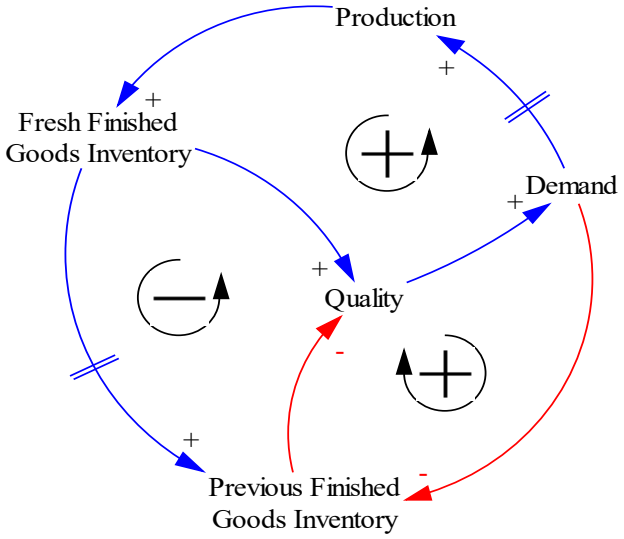

Figure 2: Causal Loop Diagram for FIFO Scenario.

The amount of positive or negative relationships in a feedback loop determine the 'positivity' or 'negativity' of that loop. Even numbers of negative relationships create a positive loop, which prompts positive exponential growth in the variables involved. Odd numbers create a negative loop with negative exponential growth. In system dynamics, systems are understood to be composed of these positive or negative loops, which balance each other out. Following this perspective, the LIFO scenario is more balanced than the FIFO scenario, as it contains equal amounts of positive or negative loops. This suggests that behavior is more consistent under the LIFO scenario, than the FIFO scenario.

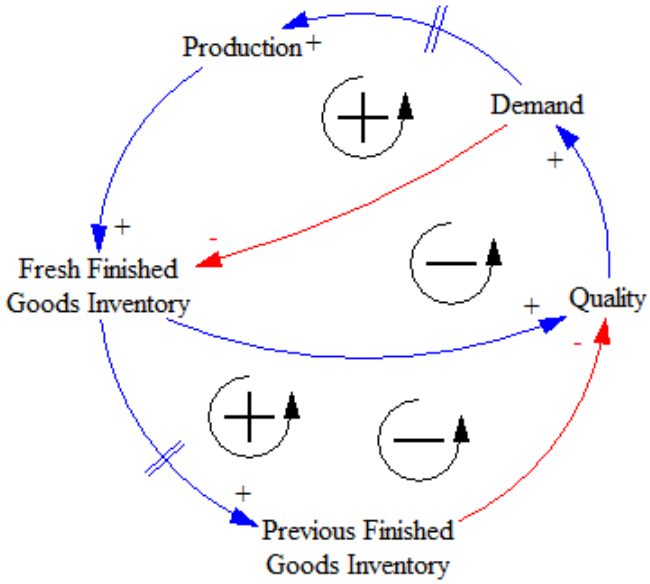

Figure 3: Causal Loop Diagram for LIFO Scenario.

3.3. Simulation Model Development

Using VensimPLE software, a system dynamics (SD) model was developed to simulate the postulated behaviors of each variable and analyze their interactions. The general form of the SD model is shown in Figure 4. This shows the variables identified in Section 3.1 in their proper form, and arranged in the feedback loops derived in Section 3.2. There are three major sections in the model: (1) the physical inventory system, which is also the main problem variable under study, (2) the perception of quality, representing the impact of the physical system on human receptors, and (3) the perception of demand, representing the human decisions which govern the physical system. These form a single loop that determines the behavior of the system.

The model parameters are feedback delays, which can be adjusted to represent various scenarios. The Delay in Perishing represents the validity period of the goods, which can vary depending on the nature of the goods. In PIS for blood banks, this parameter strongly impacts system behavior given the brief and stringent validity period of the inventory [23]. For disaster relief operations where goods are hardier, the impact of this parameter is less strong, given that the goods are practically non-perishable [2]. For the same reason, there are few disaster relief supply chain studies which consider waste and disposal.

The Delay in Perceived Quality represents how evident differences in quality may be to the customer. Smaller batch sizes and proximity to the end-customer can equate to shorter delays. In retail settings, which have this characteristic, demand is typically a function of quality [11]. On the other hand, upstream suppliers consider perishability in terms of waste and disposal costs, as opposed to impact on demand [23], [28].

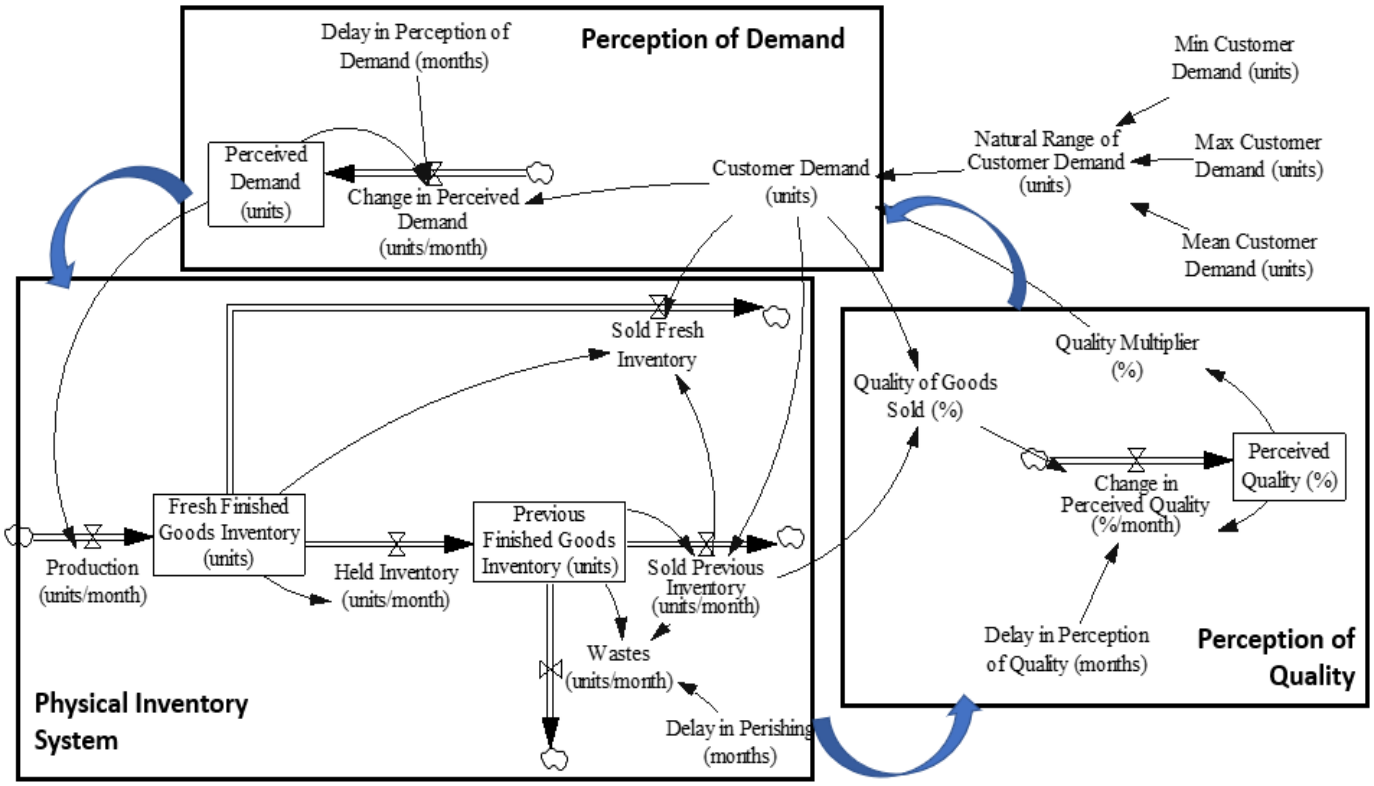

Figure 4: Structure of Inventory System.

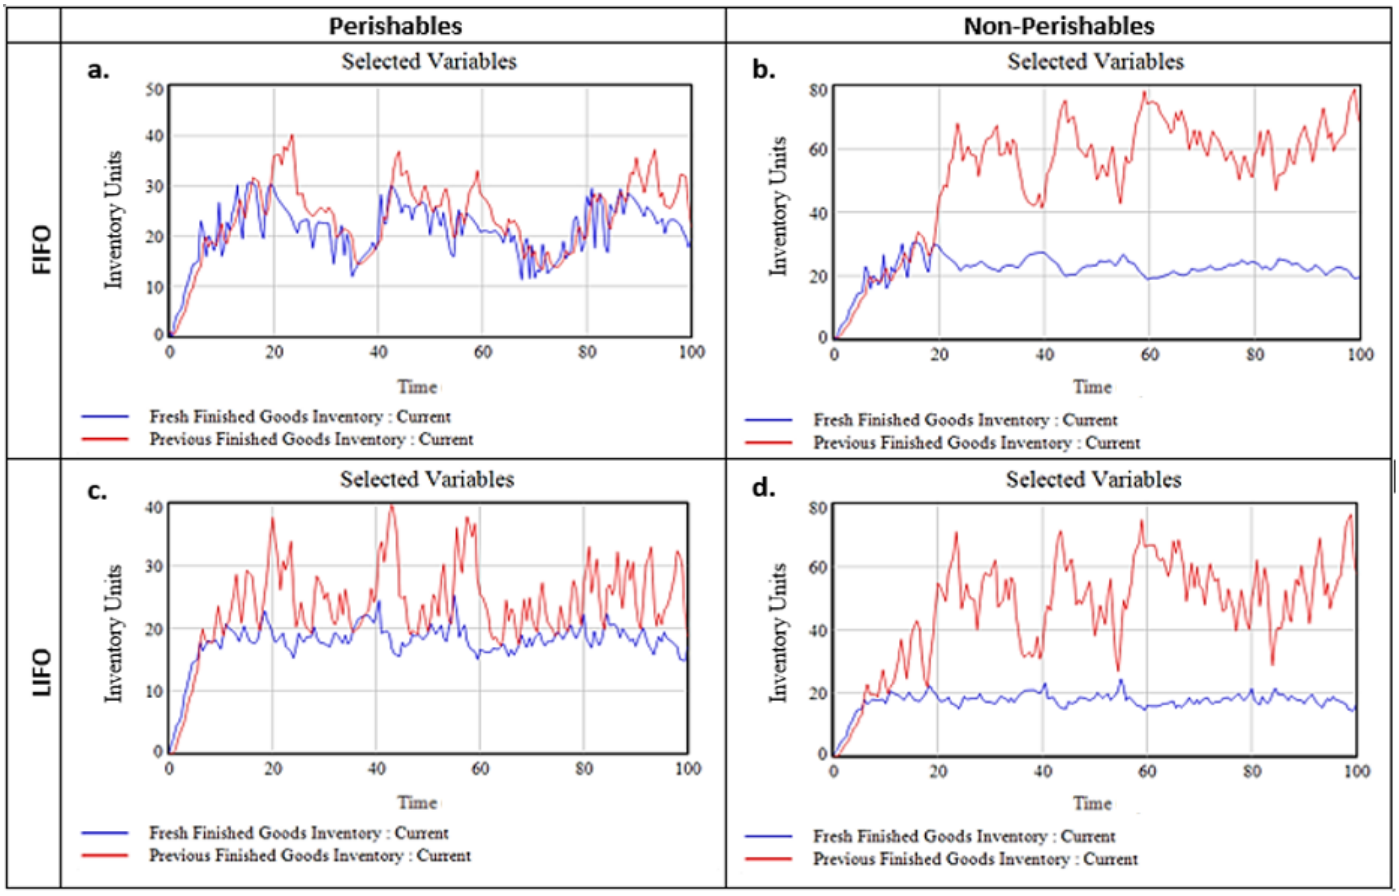

Figure 5: Simulated Fresh and Aged Inventory Levels.

The Delay in Perceived Demand represents inaccuracies in the forecasting techniques with regards to real demand. There are countless studies on forecasting techniques and replenishment policies, and each have proven effective in specific contexts and following specific demand distributions. In such cases, the policies are evaluated by the resulting service level [4], [7]. The current model extends this to examine the reactions between the performance of the policy and other components of the system.

Following the structure in Figure 4, four models were created for each of the following scenarios: (1) FIFO applied to perishables, (2) FIFO applied to non-perishables, (3) LIFO applied to perishables, and (4) LIFO applied to non-perishables. The main difference between the perishables and non-perishables scenarios is the lack of a Waste outflow for aged non-perishable inventories. In this case, the only possible outflow is through sales. Given that the emphasis of this study is on perishable inventories, the policies that may trigger the disposal of non-perishables are not considered.

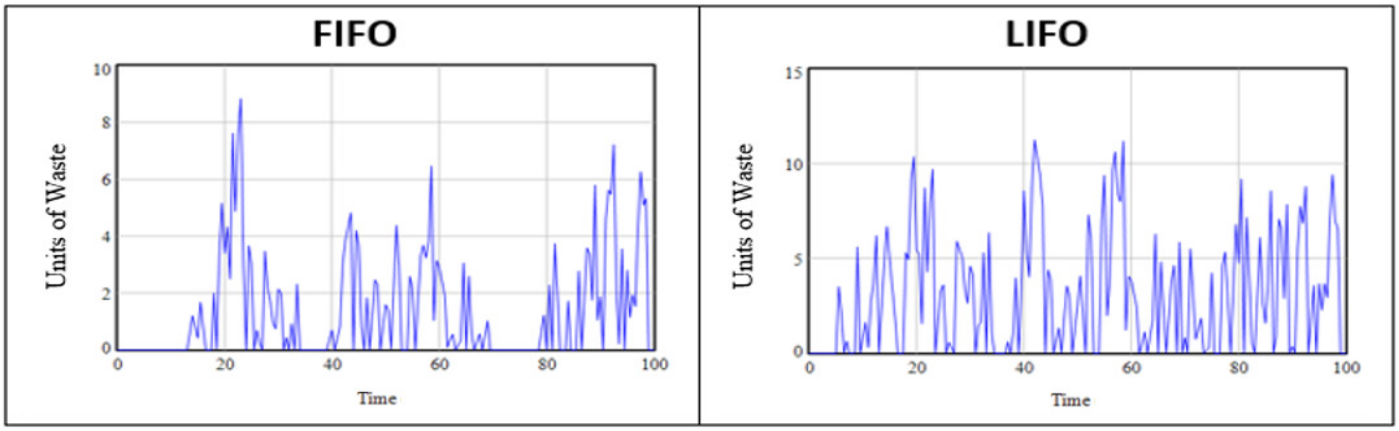
By logic, FIFO and LIFO differ based on the priority of inventories to be sold. These differences were given in equation form in Section 3.1 and in diagram form in Section 3.2. It is necessary to generate a different model to represent each case given that the feedback relationships differ. Hence, this is not a case of merely adjusting parameters to represent a case, but making adjustments to the model parameter. Aside from priority of sales, the structure of the model given in Figure 4 is maintained for all versions, to allow for the results to be comparable with one another. The simulation results depict values for the behavior of variables over time. This is analyzed in graphical form to assess the model for patterns and identify areas for problem-solving.

4. Simulation Results

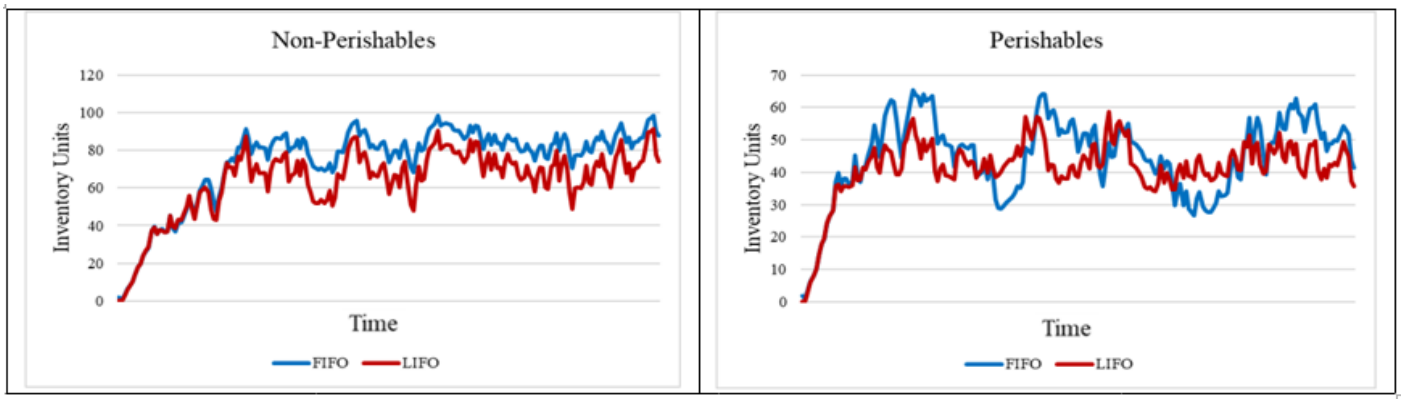
All inventory models have the objective of minimizing inventory levels, whether directly or indirectly. In optimization models, inventory levels are often linked to cost objectives through holding costs and disposal costs [15], [35]. In this way, minimal inventory levels becomes the most economic scenario for an inventory system. In simulation methodologies, inventory is physically monitored with the unstated understanding that it affects other performance indicators, such as cost and wastage [5], [7]. The system dynamics methodology is aligned with this perspective. This study likewise monitors physical inventory levels as a performance measure, and evaluates its effect on outcome and quality.

As mentioned in Section 3.1, the perishable aspect of inventory is modelled by the transition of goods from a fresh state (Fresh Finished Goods Inventory) to an aged state (Previous Finished Goods Inventory). The model differentiates between inventory in only two ways, fresh and aged, based on their impact on the system. The system dynamics methodology is an efficient means of monitoring and analyzing such variables for this purpose. In mathematical models, inventory is represented in a very exact manner, indexed by time of production and sale [28], [31]. This can take the focus away from the more important implications of inventory.

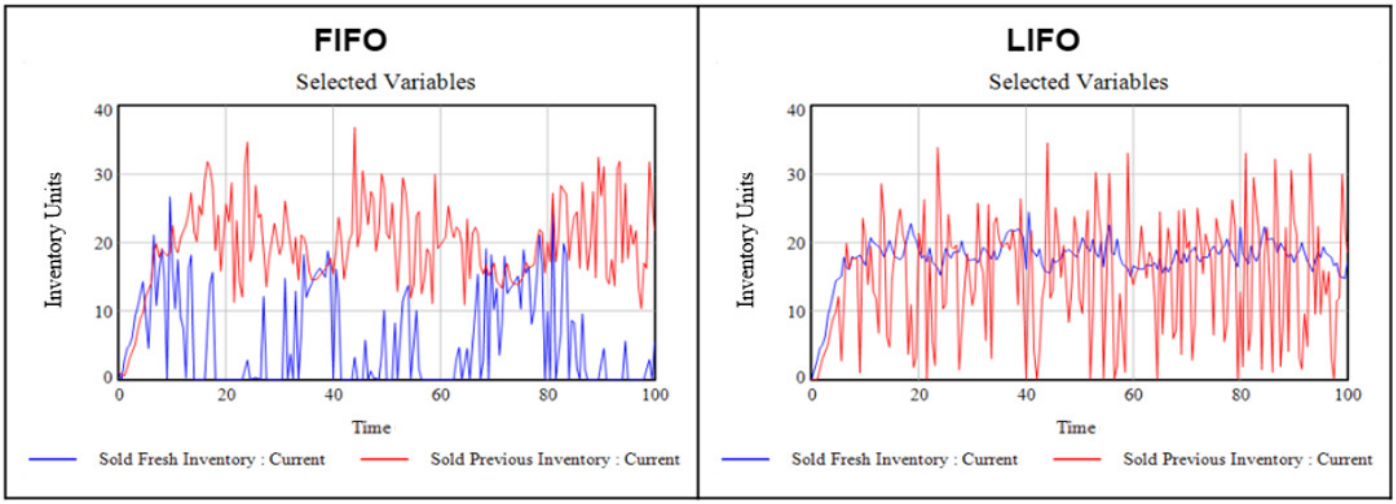
Four scenarios are simulated: FIFO applied to Perishables, FIFO applied to Non-Perishables, LIFO applied to Perishables, and LIFO applied to Non-Perishables. Each scenario is evaluated by its resulting inventory level. The analysis can be segmented into three parts: (1) A comparison between the Perishables and Non-Perishables scenarios for logic-checking, (2) A comparison of the FIFO and LIFO scenarios for policy evaluation, and (3) Determining the optimal issuance policy to apply to perishable inventories.



4.1. Comparison of Perishables and Non-Perishables Scenarios



In Figure 5, sections a and c contain the simulated inventory levels for the perishables scenario, while sections b and d contain the results for non-perishables. In all cases, inventory levels exhibit oscillating behavior which is aligned with the behavior being demonstrated in other inventory models and supply chain industry studies [36]. The perishables and non-perishables scenarios differ in the long-term trend being demonstrated by inventory under each case. Under the non-perishables scenario, inventories exhibit an upwards trend, indicating the tendency for inventories to accumulate. Under the perishables scenario, inventory levels are stable in the sense that they exhibit no upwards or downwards trend. The volume of inventory in the perishables scenario is naturally regulated by the potential for wastes, which prevents accumulation. On the other hand, there is no negative feedback to control the volume of inventories in the non-perishables scenario, resulting in accumulation.



The simulated behavior for non-perishables is aligned with the behavior of most forecast-based non-perishable inventory systems. There is evidence to support this in the management of mechanical parts inventory, which has a large amount of excess [38], [39]. The accumulation may also be attributed to the fact that production quantity was based solely on sales forecasts, without any regard for current inventories. This mimics decision-making for perishables more closely. Since goods manufactured in one period do not have the same external value as goods manufactured in a different period, past inventory cannot be fully utilized to supply current demand. Therefore, decision-making parameters such as current inventory and safety stock generally carry more weight in models for non-perishable inventories.

The simulated behavior for perishable inventories follows the behavior of traditional inventory models (e.g. EOQ), which oscillate without any positive or negative trend. Inventory accumulates because of inaccuracies in forecast. Yet, because a fraction of perishable inventories become waste at the end of each period, inventories cannot accumulate. Instead, excess inventory from inaccuracies in in forecasting eventually leave the system as waste. This is not favorable given that the amount of inventory that become Wastes are just excess in a different form. It may only be said that inventory is more effectively-handled under the perishable scenario if the volume of its Wastes is not increasing in the same way excess inventory does for non-perishables. The simulated behaviors for waste, although oscillating, exhibit no increasing trend (see Figure 6). For these reasons, it may be concluded that perishable inventories do not have as strong of a tendency towards overproduction.

It may be concluded based on the simulated results for Previous Finished Goods Inventory that the main issue in the management of perishable inventory is not preventing surpluses and shortages. Under common inventory management policies, perishability as a product characteristic results in an inventory system that is less

prone to such outcomes. Inventory models with the objective of determining an optimal stockout level could thus be redundant, or even counterproductive to the system's natural ability to regulate itself. On the other hand, the system could benefit from the minimization of its peak inventory levels, or all-around variability.

As the simulated behaviors follow the trend described by real industry data and by literature, the ensuing analysis can be deemed valid. A comparison may now be conducted between the FIFO and LIFO policies given the system structure. Based on the simulated values in Figure 5, it is apparent that the choice of issuance policy hardly makes a difference on inventory levels. On the other hand, there are clear differences between the FIFO and LIFO scenarios in the perishables case.

4.2. Comparison of FIFO and LIFO Scenarios

Generally, inventory levels are higher under the FIFO case. This is true for both the non-perishables and perishables cases. Figure 7 shows that in, the non-perishables case, inventory levels

exhibit the same upwards trend. Yet, once the values stabilize, the FIFO case will begin to exhibit consistently higher inventory levels. Its highest point and lowest point upon stabilization are higher than inventory at any point in time under LIFO. This is different from the case of perishables, where inventory levels have higher maximum peaks under FIFO but also lower LIFO peaks. However, based on the simulations, it would appear that FIFO exhibits higher inventory levels more often than it exhibits lower inventory levels.

The higher inventories under FIFO may be attributed to the extent of feedback delay between production and demand. In the causal loop diagrams in Figure 2, there are multiple delays between Fresh Finished Goods Inventory and Demand under FIFO. This signifies that there are multiple delays between demand and production for forecasts based on it are actually sold. Hence, there is a higher propensity for overproduction or underproduction. In these cases, the problem is leaning towards overproduction given that current inventories are not considered in deciding on the quantity to produce in the next period.

Based on the review of studies on PIS, there are more models were FIFO proved to be optimal than otherwise. These models are optimization models with the primary objective of minimizing costs. The potential for waste production is incorporated in the form of disposal costs or deterioration costs, which align the sustainability and economic objectives for the system. It is understandable for FIFO to be optimal following this perspective, as FIFO results in the lower minimum inventory values. However, in actual inventory systems, stable inventories are preferred over fluctuations.

In literature, the case where LIFO proved to be optimal was the case where prices decreased linearly for each period that the inventory unit remained in the system. This would suggest that when quality affects revenues, LIFO becomes preferable. This is because the profit earned per unit would be more consistent. The key benefit to be derived from LIFO is consistency. In this model, quality affects revenues by acting as a multiplier to demand. Results showed that inventory levels were less variable for both perishables and non-perishables, which aligns with the suppositions from previous studies that LIFO can result in greater consistency.

4.3. Evaluation of FIFO and LIFO Applied to Perishables

For perishables, product quality is partially determined by the age of inventories. Hence, the volume of fresh and aged inventories can have an impact on demand. In this model, quality is given as the fraction of fresh inventories in relation to total inventories. Previously, it was mentioned that the levels of fresh and aged inventories that result from FIFO and LIFO respectively different greatly for perishables. This means that the use of FIFO and LIFO can also significantly alter the quality of perishable goods being sold.

It has been mentioned that LIFO may promote greater consistency in an inventory system. This also manifests in the current model where quality is more consistent under LIFO due to the fact that the levels of both fresh and aged inventory are more consistent. Consistent quality also results in greater consistency of sales. Figure 8 contains the simulated values for sales of inventory, where it may be observed that Sold Fresh Inventory, which is the primary contributor to sales in LIFO, is high consistent.

Under FIFO, sales of fresh and aged inventories both fluctuate. Specifically, the two inventories have an inverse relationship, as the sales that cannot be met with aged inventories will satisfied with fresh inventories. The fluctuations in quality also lead to fluctuations in demand, which feedbacks to inventory levels. When demand is high, it can prompt the production of new inventory, which has a negative effect on demand as the goods will be aged by the time they are sold. This problem is aggravated by the fact that there the production quantities derived from past demand will be misaligned with actual demand. When demand is rising, production will be higher, and conversely, when demand is dropping, production will be lower. This is the result of feedback delays between demand and production.

There are also feedback delays upstream, in the customer's perception of quality. The current model differentiates between actual quality and perceived quality, by the logic that there is a delay in the recognition of quality change when it comes to inventories. In most inventory models, the perception of quality and its resulting change in demand is instantaneous. However, this relationship is only descriptive of settings such as retail stores where customers see the physical units individually and its quality instantaneously affects the probability of purchase [8], [40]. This is not the case for entities where purchases are made in bulk, such as the manufacturing or warehousing settings. In such cases, the individual quality of units have little value in the system, which is evident by the miss-outs from sampling procedures [3]. There are also delays due to the fact that not all inventory units are assessed prior to production, and thus any information on quality would only be known after production or through customer returns [41].

FIFO exhibits longer cycles between the arrival and sale of an inventory unit. In the short term, this will result in (1) less wastes and lower inventory levels for the manufacturing firm, and (2) instances when sales may be lower in the periods during and following the end of an inventory cycle, when the leftover units have aged. The trade-offs can be managed with a classical optimization model that can balance waste generation with freshness. On the other hand, the long-term impact of FIFO in the supply chain is inconsistent quality. This complicates reordering decisions downstream in the supply chain, by adding variability to product lifetimes. This in turn heightens the amplitudes of bullwhips being exhibited by the inventory levels of a supply chain. Therefore, in the long term, FIFO promotes variability and greater efforts being made by members of a supply chain to manage it.

LIFO has the opposite effect on inventory levels in the short term; and will result in more consistent quality in the long term. While this lessens the complexity of decision-making for the members of the supply chain, there is nonetheless the issue of waste to be addressed. The consistent generation of waste would require greater efforts in waste management. On a positive note, the consistent waste generation would also regularize the demand for waste management, and through that require the standardization of waste management procedures. Currently, the efforts to minimize waste and the natural variability of production add complexity to decisions on when and where to set up waste management

facilities. Given the high investment required by such facilities, this generally results in there being insufficient infrastructure for this purpose. In this sense, the consistency promoted by implementations of LIFO would be beneficial, by giving a clearer perspective on the volume of waste management activity that would be needed.

5. Conclusion

In this study, classic FIFO and LIFO issuance policies were assessed for their impact in a perishable inventory system. The performance of these policies was evaluated in terms of their ability to meet sustainability and quality goals. Specifically, it aimed to improve sustainability through waste reduction and quality by maximizing the freshness of inventories in the system. While similar studies had been made in the past, the present study viewed the problem from a different approach, through the development of a system dynamics (SD) framework. Using the SD framework emphasizes the patterns of the inventory levels, rather than its exact values, allowing for the generation of insights that can be generalized regardless of lifetime variability.

A simulation model was developed comprising of three major sections that eventually form a general single loop: (1) The physical inventory system, (2) The perception of quality, and (3) The perception of demand. Furthermore, feedback delays such as delays in perishing, perceived quality, and perceived demand were also considered. FIFO and LIFO models for both perishables and non-perishables products were then formed with the presence of Waste outflow variable as a distinguishing factor between non-perishables and perishables model.

Comparing the perishables and non-perishables scenario yielded that for all cases, inventory levels exhibit an oscillating behavior. Non-perishables showed upward trend due to accumulation of inventory since quantity to be produced relies solely on sales forecasts and that current leftover usable inventory was not factored in as to how much quantity is to be produced for the next period. This is to emulate perishables inventory systems wherein external values of goods differ per period. On the other hand, perishables seem to have no upward for downward trend and seem to follow the behavior of traditional inventory models like EOQ. Perishable inventories do not have strong tendency towards overproduction. Wastes is not increasing the same way excess inventory does for non perishables. Based on these observations, it may be counterproductive to determine the optimal stockout level of perishable goods since it seems to have its way of regulating itself.

A comparison of the FIFO and LIFO scenarios showed that LIFO is preferable when revenues are heavily influenced by quality since LIFO promotes greater consistency in inventory system. Consistency in quality brings consistency in profit earned per unit and this was explicitly observed in Sold Fresh Inventory which is a primary contributor to the sales in LIFO.

On the other hand, FIFO exhibits higher inventory levels which is attributed due to feedback delays between production and demand. Furthermore, FIFO system tends to lean towards overproduction since current leftover inventories were not factored into the decision for the amount or quantity to be produced for the next period. Also, fluctuations were observed in FIFO for both sales in fresh and aged inventories - as evidenced by its inverse relationship - lead to fluctuations in demand. Although FIFO may be more optimal for minimizing costs and inventory levels once wastes is treated as disposal costs or deterioration costs, actual inventory systems still prefer stable inventories rather than constant fluctuations. FIFO is preferable for cost-sensitive or waste-sensitive cases, while LIFO is preferable in quality-sensitive cases.

The results of this study demonstrate the ability of SD to produce insights in addition to those that can be derived from optimization models. While the current study applied SD on classic inventory management policies (i.e. FIFO and LIFO), literature on perishable inventory models comprise various new policies and technologies that can be assessed more extensively using the SD framework. In particular, information technologies such as RFID and IoT have been proposed as means of monitoring the age-based quality of perishables with better accuracy, yet there is still the question of how to use this feedback effectively in decision-making. The current study serves as a starting point for future studies applying SD in evaluating and improving policies that will prove useful in a wide variety of cases.

One of the major contributions of this study is its demonstration of the SD framework as a means of modelling and simulating policy outcomes that are difficult to, or cannot be specifically quantified. This is very relevant to the field as it recent literature centers on the application of information technology in inventory management. The effects of greater accuracy and shortened feedback granted by information technology are not directly quantifiable, making it a suitable extension of this policy. The study also contributes by providing insight on what the long-term implications of issuance policies could be, particularly in the area of sustainability. While it may appear that FIFO is the most efficient in terms of cost and waste generation, LIFO actually has more positive long-term implications by reducing complexity in supply chain decisions, and standardizing waste management efforts.

weak convergence,
strong convergence,
common fixed points

ABSTRACT

In Banach spaces an iteration algorithm for two finite families of total asymptotically quasi-nonexpansive maps is introduced. Weak and strong convergence theorems of this algorithm to approximation common fixed points are proved by using suitable conditions. As well as, numerical example by using Mat-lab is given.

1. Introduction and Preliminaries

This paper was originally published in the Conference: 2018 International Conference on Advanced Science and Engineering (ICOASE), Iraq [1]. It is well known that the concept of asymptotically nonexpansive introduced by Goebel and Kirk [2]. Additionally, every asymptotically nonexpansive map of a Banach space has a fixed point is proved. In [3], Petryshyn and Williamson proved the weak and strong convergence for quasi-nonexpansive map by using a sufficient and necessary condition. Alber [4], a new class of asymptotically nonexpansive is introduced. As well as, approximating methods for finding their fixed points are studied. In 2014, G. S. Saluja [5] established the strong and weak convergence for approximating common fixed point for generalized asymptotically quasi-nonexpansive maps in a Banach space.

Very recently, In [6], the authors proposed an implicit iteration for two finite families of generalized asymptotically quasi-nonexpansive maps. As well as, some strong convergence theorems are established. It is useful to point out our findings in this area which appeared in [7].

Let B be a non-empty closed convex subset of a real Banach space M and T be a self-map of B. The set of all fixed points denoted by F(T). A self-map T from B into M is called nonexpansive map [2] if

$$\|Ta - Tb\| \leq \|a - b\| \; for \; all \; a, b \in B$$

and is called quasi- nonexpansive map [6] if $F(T) \neq \emptyset \; and$

$$\|Ta - a^*\| \leq \|a - a^*\|$$

for all $a \in B$ and for all $a^* \in F(T)$.

A Banach space M is satisfying:

- "Opial's condition if for each sequence (a_n) in M, is weak convergence to a implies that $\lim_{n\to\infty} inf\|a_n - a\| < \lim_{n\to\infty} inf \; \|a_n - b\|$ for all $b \in M \; with \; a \neq b$".
- "Kadec-Klee property if for each sequence (a_n) in M is weak convergence to (a) together with $\|a_n\|$ converges strongly to $\|a\|$ imply that (a_n) is strong convergence to a point $a \in M$ [7]".

The aim of this paper, an iterative scheme for two families of total asymptotically quasi-nonexpansive maps is established. The strong and weak convergence theorems of this scheme for approximation of common fixed points in Banach space by using suitable conditions are established. For this purpose, let us recall the following definitions and lemmas.

Definition (1.1): "A map T is named asymptotically nonexpansive [1] if there is a sequence (f_n) in $[0, +\infty)$ with $\lim_{n\to\infty} f_n = 0$ and $\|T^n a - T^n b\| \leq (1 + f_n)\|a - b\|$, for all $a, b \in B, n = 1,2,..$.

*Salwa Salman Abed, Email: salwaalbundi@yahoo.com

If $F(T) \neq \emptyset$ there is a sequence (f_n)in $[0, +\infty)$ with $\lim_{n\to\infty} f_n = 0$ and $\|T^n a - a^*\| \leq (1 + f_n)\|a - a^*\|$,
for all $a \in B, a^* \in F(T)$ and $n = 1, 2, \ldots$.Therefore, T is named asymptotically quasi-nonexpansive map [10]".

Definition (1.2): "A map T is named total asymptotically nonexpansive map [4] if there are null sequences of postive real numbers $(f_n)_{n=1}^{\infty}, (g_n)_{n=1}^{\infty}, n \geq 1$ and nondecreasing continuous function $\psi: [0, \infty) \to [0, \infty)$ with $\psi(0) = 0$ such as $\forall a, b \in B$

$$\|T^n a - T^n b\| \leq \|a - b\| + f_n \psi\|a - b\| + g_n".$$

T is named total asymptotically quasi-nonexpansive map if $F(T) \neq \emptyset$, there are null sequences of postive real numbers $(f_n)_{n=1}^{\infty}$, $(g_n)_{n=1}^{\infty}, n \geq 1, \sum_{n=1}^{\infty} f_{in} < \infty$ and $\sum_{n=1}^{\infty} g_{in} < \infty$, and nondecreasing continuous function $\psi: [0, \infty) \to [0, \infty)$ with $\psi(0) = 0$ such as $\forall a \in B$ and $a^* \in F(T)$
$\|T^n a - a^*\| \leq \|a - a^*\| + f_n \psi\|a - a^*\| + g_n$.
If $g_n = 0, \forall n = 1, 2, \ldots$ therefore T is asymptotically quasi-nonxpansive map.

Definition (1.3)[11]: "Let B be a nonempty closed convex subset of a Banach space M. A self-map T is named uniformily K-Lipschitzain if there exists a constant $K > 0$ such that $\|T^n a - T^n b\| \leq K\|a - b\|, \ \forall a, b \in B$.

Definition (1.4)[12]: "A map $T: B \to M$ is named demi-closed with respect to $b \in M$ if for each sequence (a_n) in B, (a_n) is weak convergence to a and $T(a_n)$ is strong convergence to b. Hence $a \in B$ and $T(a) = b$. If $(I - T)$ is demiclosed which means if (a_n) is weak convergence to a in B and $(I - T)$ is strong convergence to 0. Therefore $(I - T)(a) = 0$".

Note: Now to explain the relation between the above definitions:

$$\begin{array}{ccccc} Nonexpansive & \Rightarrow & Asymptotically\ nonexpansive & \Rightarrow & Total\ asymptotically\ nonexpansive \\ \Downarrow & & \Downarrow & & \Downarrow \\ Quasi-nonexpansive & \Rightarrow & Asymptotically\ quasi-nonexpansive & \Rightarrow & Total\ asymptotically\ quasi-nonexpansive \end{array}$$

Lemma (1.5)[13]:" Let M be a uniformly convex Banach space and $0 < L \leq t_n \leq K < 1, \forall\, n \in N$. Presume that (a_n) and (b_n) are two sequences of M such as:

$$\lim_{n\to\infty} \|a_n\| \leq r, \lim_{n\to\infty} \|b_n\| \leq r \ \ and \ \ \lim_{n\to\infty} \|t_n a_n + (1 - t_n) b_n\| = r$$

hold for some $r \geq 0$. Thus $\lim_{n\to\infty} \|a_n - b_n\| = 0$".

Lemma (1.6)[14]: "Let $(\mu_n)_{n=1}^{\infty}, (\sigma_n)_{n=1}^{\infty}$ and $(e_n)_{n=1}^{\infty}$ be sequences of postive numbers accomplishing the following inequality:

$$\mu_{n+1} \leq (1 + \sigma_n)\mu_n + e_n \ , \forall\, n \geq 1$$

if $\sum_{n=1}^{\infty} \sigma_n < \infty$ and $\sum_{n=1}^{\infty} e_n < \infty$, then $(\mu_n)$is bounded and $\lim \mu_n$ exists. In additional if, $\liminf_{n\to\infty} \mu_n = 0$ then $\lim_{n\to\infty} \mu_n = 0$".

Lemma (1.7)[15]: "Let B be a nonempty convex subset of a uniformly convex Banach space. Therefore there exists a strictly nondecreasing continuous function $f: [0, \infty) \to [0, \infty)$ with $f(0) = 0$ such as for each Lipschitzain map $T: B \to B$ with Lipschitz constant K:

$$\|tTa + (1 - t)Tb - T(ta + (1 - t)b\| \leq Kf^{-1}\left(\|a - b\| - \frac{1}{K}\|Ta - Tb\|\right),$$

$\forall\, a, b \in B$ and $\forall t \in [0,1]$".

Lemma (1.8)[12]: "Let M be a uniformly convex Banach space and its dual M^* accomplishing the Kadec-Klee property. Presume that (a_n) bounded sequence in M such as $\lim_{n\to\infty} \|ta_n + (1 - t)p_1 - p_2\|$ exists $\forall\, t \in [0,1]$ and $p_1, p_2 \in W_w(a_n)$, thus $p_1 = p_2$".

2. Main Results

Let B be a nonempty closed convex subset of a Banach space M and $\{T_j, S_j, \forall j = 1, 2, \ldots, k\}$ be two families of total asymptotically quasi-nonexpansive self-maps. We define the iteration algorithm (a_n) as follows:

$$\begin{aligned} &a_1 \in B \\ &a_{n+1} = (1 - \alpha_{jn}) S_j^n a_n + \alpha_{jn} T_j^n b_{jn} \\ &b_{jn} = (1 - \alpha_{jn}) S_j^n a_n + \alpha_{jn} T_j^n b_{(j-1)n} \\ &b_{(j-1)n} = (1 - \alpha_{(j-1)n}) S_{j-1}^n a_n + \alpha_{(j-1)n} T_{j-1}^n b_{(j-2)n} \\ &\cdot \\ &\cdot \\ &\cdot \\ &b_{2n} = (1 - \alpha_{2n}) S_2^n a_n + \alpha_{2n} T_2^n b_{1n} \\ &b_{1n} = (1 - \alpha_{1n}) S_1^n a_n + \alpha_{1n} T_1^n b_{0n} \end{aligned} \qquad (1)$$

Where $b_{0n} = a_n$ and $(\alpha_n)_{n=1}^{\infty}$ are sequences in [0, 1].

Lemma (2.1): Let B be a nonempty closed convex subset of a normed space M and $T_j, S_j, j = 1, 2, \ldots, k$ be two family of total asymptotically quasi-nonexpansive self-maps of B. Presume that $F(T_j, S_j) \neq \emptyset$ and the sequence (a_n) be as shown in step (1). Then:
i- There are sequences (u_n) and (v_n) in $[0, \infty)$ such as $\sum_{n=1}^{\infty} u_n < \infty, \sum_{n=1}^{\infty} v_n < \infty$ and
$\|a_{n+1} - a^*\| \leq (1 + u_n)^{j+1}\|a_n - a^*\| + v_n^{j+1}$,
$\forall\, a^* \in F(T_j, S_j)$ and $\forall\, n$.
ii- There exist constants $J_1, J_2 > 0$ such as
$\|a_{n+p} - a^*\| \leq J_1\|a_n - a^*\| + J_2$, $\forall\, a^* \in F(T_j, S_j)$
and $n, p = 1, 2, \ldots$..
If there is $Z > 0$ such that $\psi(\lambda_j) \leq Z\lambda_j, j = 1, 2, \ldots, k$.
Proof: i- Let $a^* \in F, u_n = \max_{1\leq j\leq k} f_{jn}$ and $v_n = \max_{1\leq j\leq k} g_{jn}$.

Now, we have

$$\begin{aligned} \|b_{1n} - a^*\| &= \|(1 - \alpha_{1n}) S_1^n a_n + \alpha_{1n} T_1^n a_n - a^*\| \\ &\leq (1 - \alpha_{1n})\|S_1^n a_n - a^*\| + \alpha_{1n}\|T_1^n a_n - a^*\| \\ &\leq (1 - \alpha_{1n})\{\|a_n - a^*\| + f_{1n}\psi\|a_n - a^*\| + g_{1n}\} \\ &\quad + \alpha_{1n}\{\|a_n - a^*\| + f_{1n}\psi\|a_n - a^*\| + g_{1n}\} \\ &\leq (1 - \alpha_{1n})(1 + f_{1n}Z)\|a_n - a^*\| + (1 - \alpha_{1n}) g_{1n} \\ &\quad + \alpha_{1n}(1 + f_{1n}Z)\|a_n - a^*\| + \alpha_{1n} g_{1n} \\ &\leq (1 + f_{1n}Z)\|a_n - a^*\| + g_{1n} \\ &\leq (1 + u_n)\|a_n - a^*\| + v_n \end{aligned}$$

Assume that $\|b_{jn} - a^*\| \leq (1 + u_n)^j\|a_n - a^*\| + v_n^j$
Therefore,

$$\|b_{(j+1)n} - a^*\| = \|(1 - \alpha_{(j+1)n}) S_{j+1}^n a_n + \alpha_{(j+1)n} T_{j+1}^n b_j - a^*\|$$

$$\leq (1-\alpha_{(j+1)n})\|S_{j+1}^n a_n - a^*\| + \alpha_{(j+1)n}\|T_{j+1}^n b_j - a^*\|$$
$$\leq (1-\alpha_{(j+1)n})(1+f_{(j+1)n}Z)\|a_n - a^*\| + (1-\alpha_{(j+1)n})g_{(j+1)n} + \alpha_{(j+1)n}(1+f_{(j+1)n}Z)\|b_j - a^*\| + \alpha_{(j+1)n}g_{(j+1)n}$$
$$\leq (1-\alpha_{(j+1)n})(1+u_n)\|a_n - a^*\| + v_n + \alpha_{(j+1)n}(1+u_n)(1+u_n)^j\|a_n - a^*\| + \alpha_{(j+1)n}(1+u_n)v_n^j$$
$$\leq (1+u_n)^{j+1}\|a_n - a^*\| + v_n^{j+1}$$

Thus, by induction, we obtain

$$\|b_{jn} - a^*\| \leq (1+u_n)^j\|a_n - a^*\| + v_n^j \quad (2)$$

for all $j = 1,2,\dots,k$.

Now, by (2), we get

$$\|a_{n+1} - a^*\| \leq (1-\alpha_{jn})\|S_j^n a_n - a^*\| + \alpha_{jn}\|T_j^n b_{jn} - a^*\|$$
$$\leq (1-\alpha_{jn})(1+u_n)\|a_n - a^*\| + v_n + \alpha_{jn}(1+u_n)(1+u_n)^j\|a_n - a^*\| + \alpha_{jn}(1+u_n)v_n^j$$
$$\leq (1+u_n)^{j+1}\|a_n - a^*\| + v_n^{j+1}$$

ii- By using part (i), we get

$$\|a_{n+p} - a^*\| \leq (1+u_{n+p-1})^{j+1}\|a_{n+p-1} - a^*\| + v_{n+p-1}^{j+1}$$
$$\leq e^{(1+u_{n+p-1})^{j+1}\|a_{n+p-1}-a^*\|} + e^{v_{n+p-1}^{j+1}}$$
$$\leq e^{(j+1)u_{n+p-1}\|a_{n+p-1}-a^*\|} + e^{(j+1)v_{n+p-1}}$$
$$\leq e^{(j+1)\sum_{k=1}^{n+p-1}u_k}\|a_n - a^*\| + e^{(j+1)\sum_{k=1}^{n+p-1}v_k}$$
$$\leq J_1\|a_n - a^*\| + J_2.$$

Setting $J_1 = e^{(j+1)\sum_{k=1}^{n+p-1}u_k}$ and $J_2 = e^{(j+1)\sum_{k=1}^{n+p-1}v_k}$.

Lemma (2.2): Let B be a nonempty closed convex subset of a normed space M and T_j, S_j , $j = 1, 2, \dots, k$ be two families of total asymptotically quasi-nonexpansive self-maps of B. Presume $F(T_j, S_j) \neq \emptyset$ and (a_n) be as shown in step (1). Therefore, $\lim_{n\to\infty}\|a_n - a^*\|$ exists for all $a^* \in F(T_i, S_i)$.

Proof: By Lemma (2.1.i)

$$\|a_{n+1} - a^*\| \leq (1+u_n)^{j+1}\|a_n - a^*\| + v_n^{j+1}$$
$$\leq (1+u_n)\|a_n - a^*\| + v_n$$

and $\sum_{n=1}^{\infty}u_n < \infty, \sum_{n=1}^{\infty}v_n < \infty$. So by Lemma (1.6.i), we get $\lim_{n\to\infty}\|a_n - a^*\|$ exists for all $a^* \in F(T_j, S_j)$.

Lemma (2.3): Let B be a nonempty closed convex subset of a Banach space M and T_j, S_j , $j = 1, 2, \dots, k$ be two families of Lipschitzain and total asymptotically quasi-nonexpansive self-maps of B. Let (a_n) be as shown in step (1). Therefore, for all $a_1^*, a_2^* \in F(T_j, S_j)$, the limit $\lim_{n\to\infty}\|ta_n + (1-t)a_1^* - a_2^*\|$ exists for all $t \in [0,1]$.

If there is $Z > 0$ such that $\psi(\lambda_j) \leq Z\lambda_j, j = 1, 2, \dots, k$.

Proof: By using Lemma (1.6),we have $\lim_{n\to\infty}\|a_n - a^*\|$ exists $\forall a^* \in F(T_j, S_j)$ and (a_n) is bounded. Let $\gamma_n(t) = \|ta_n + (1-t)a_1^* - a_2^*\|$, $\forall t \in [0,1]$.

Therefore, $\lim_{n\to\infty}a_n(0) = \|a_1^* - a_2^*\|$ and $\lim_{n\to\infty}a_n(1) = \|a_n - a_2^*\|$ exist by Lemma (2.2).

Then, for $t \in [0,1]$ and for all $a \in B$, we define the map $R_n: B \to B$ by:

$$b_{1n} = (1-\alpha_{1n})S_1^n a_n + \alpha_{1n}T_1^n b_{0n}$$
$$b_{2n} = (1-\alpha_{2n})S_2^n a_n + \alpha_{2n}T_2^n b_{1n}$$
$$\vdots$$
$$b_{jn} = (1-\alpha_{jn})S_j^n a_n + \alpha_{in}T_j^n b_{(j-1)n}$$
$$R_n a = (1-\alpha_{jn})S_j^n a_n + \alpha_{jn}T_j^n b_{jn}$$

Now,

$$\|R_n a - R_n c\| \leq (1-\alpha_{jn})\|S_j^n a - S_j^n c\| + \alpha_{jn}\|T_j^n b_{jn} - T_j^n d_{jn}\|$$
$$\leq (1-\alpha_{jn})(1+f_{jn}Z)\|a-c\| + (1-\alpha_{jn})g_{jn} + \alpha_{jn}(1+f_{jn}Z)\|b_{jn} - d_{jn}\| + \alpha_{jn}g_{jn}$$
$$\leq (1+u_n)\|a-c\| + v_n$$
$$\leq (1+f_nZ)\|a-b\| + g_n$$

with $\sum_{n=1}^{\infty}u_n < \infty$, $\sum_{n=1}^{\infty}v_n < \infty$ and $s_n = 1 + u_n$, it follows that $s_n \to 1 \; as \; n \to \infty$.

Setting $W_{n,m} = R_{n+m-1}R_{n+m-1}\dots R_n$ and $b_{n,m} = \|W_{n,m}(ta_n + (1-t)a_1^* - (tW_{n,m}a_n + (1-t)a_1^*)\|$.

Thus,

$$\|W_{n,m}a - W_{n,m}b\| = \left\| \begin{matrix} R_{n+m-1}R_{n+m-2}\dots R_n(a) \\ -R_{n+m-1}R_{n+m-2}\dots R_n(b) \end{matrix} \right\|$$
$$\leq s_{n+m-1}\left\| \begin{matrix} R_{n+m-2}\dots R_n(a) \\ -R_{n+m-2}\dots R_n(b) \end{matrix} \right\| + v_{n+m-1}$$
$$\leq \prod_{j=n}^{n+m-1}s_j\|a-c\| + \sum_{j=n}^{n+m-1}v_j$$
$$= A_n\|a-c\| + \sum_{j=n}^{n+m-1}v_j$$

for all $a, c \in B$, where $A_n = \prod_{j=n}^{n+m-1}s_j$, $W_{n,m}a_n = a_{n+m}$ and $a^* = a^*$ for all $a^* \in F(T_i, S_i)$.

Hence,

$$\gamma_{n+m}(t) = \|ta_{n+m} + (1-t)a_1^* - a_2^*\|$$
$$= \left\| \begin{matrix} tW_{n,m}a_n + ((1-t)a_1^* - a_2^* + W_{n,m}(ta_n + (1-t)a_1^*) - a_2^* \\ +a^* - a^* \\ -W_{n,m}(ta_n + (1-t)a_1^*) - a_2^* \end{matrix} \right\|$$
$$\leq b_{n,m} + \|W_{n,m}(ta_n + (1-t)a_1^*) - a_2^*\|$$
$$\leq b_{n,m} + A_n\gamma_n(t) + \sum_{j=n}^{n+m-1}v_j$$

By using Lemma (1.7), we have

$$b_{n,m} \leq Kf^{-1}(\|a_n - a^*\| - \frac{1}{K}\|W_{n,m}a_n - W_{n,m}a^*\|)$$
$$\leq Kf^{-1}(\|a_n - a^*\| - \frac{1}{K}(\|a_{n+m} - a^*\| - \|W_{n,m}a_n - a^*\|)$$

and $(b_{n,m})$ converges uniformly to zero. Since $\lim_{n\to\infty}A_n = 1$ and $\lim_{n\to\infty}v_n = 0$, we get

$$\lim_{n\to\infty}\lim_{m\to\infty}sup\gamma_{n+m} \leq \lim_{n\to\infty}\lim_{m\to\infty}b_{n,m} + \lim_{n\to\infty}inf\gamma_n(t) = \lim_{n\to\infty}inf\gamma_n(t)$$

Thus, $\lim_{n\to\infty}\gamma_n(t)$ exists for all $t \in [0,1]$.

Theorem (2.4): Let B be a nonempty closed convex subset of a uniformly convex Banach space M, T_j, S_j , $\forall j = 1, 2, \dots, k$ be two families of Lipschiztain and total asymptotically quasi-nonexpansive self-maps of B and the sequence (a_n) be as shown in step (1). If there is $Z > 0$ such that $\psi(\lambda_j) \le Z\lambda_j, j = 1, 2, \dots, k$. Then, $\lim_{n\to\infty}\|T_j^n a_n - a_n\| = 0 = \lim_{n\to\infty}\|S_j^n a_n - a_n\|$, $\forall j$.

Proof: By Lemma (2.2), $\lim_{n\to\infty}\|a_n - a^*\|$ exists. Assume that

$$\lim_{n\to\infty}\|a_n - a^*\| = e, \qquad \forall e \ge 0.$$

If e=0, the proof is straight forward.

Now, suppose $e > 0$. We get

$$a_{n+1} = (1 - \alpha_{jn})S_j^n a_n + \alpha_{jn}T_j^n b_{jn}$$

and

$$e = \|a_{n+1} - a^*\| = \|(1 - \alpha_{jn})(S_j^n a_n - a^*) + \alpha_{jn}(T_j^n b_{jn} - a^*)\|.$$

Since $\|S_j^n a_n - a^*\| \le K\|a_n - a^*\| \le e$

and $\|T_j^n b_{jn} - a^*\| \le K\|b_{jn} - a^*\| \le K\{(1 + u_n)^j\|a_n - a^*\| + v_n^j\} \le e.$

Therefore, by Lemma (1.5), we get

$$\lim_{n\to\infty}\|S_j^n a_n - T_j^n b_{jn}\| = 0$$

Next,

$$\begin{aligned}\|b_{jn} - a_n\| &\le (1 - \alpha_{jn})\|S_j^n a_n - a_n\| + \alpha_{jn}\|T_j^n b_{(j-1)n} - a_n\| \\ &\le (1 - \alpha_{jn})(1 + f_{jn}Z)\|a_n - a_n\|(1 - \alpha_{jn})g_{jn} \\ &\quad + \alpha_{jn}(1 + f_{jn}Z)\|b_{(j-1)n} - a_n\| + \alpha_{jn}g_{jn} \\ &\le g_{jn} + \alpha_{jn}(1 - \alpha_{(j-1)n})(1 + f_{jn}Z) \\ &\quad \|S_{j-1}^n a_n - a_n\| + \alpha_{jn}\alpha_{(j-1)n}(1 + f_{jn}Z) \\ &\quad \|T_{j-1}^n b_{(j-2)n} - a_n\| \\ &\le g_{jn} + \alpha_{jn}(1 - \alpha_{(j-1)n})(1 + f_{jn}Z)g_{jn} \\ &\quad + \alpha_{jn}\alpha_{(j-1)n}(1 + f_{jn}Z)(1 \\ &\quad + f_{(j-1)n}Z)\|b_{(j-2)n} - a_n\| \\ &\quad + \alpha_{jn}\alpha_{(j-1)n}(1 + f_{jn}Z)g_{(j-1)n} \\ &\quad . \\ &\quad . \\ &< \infty\end{aligned}$$

Since $Z > 0, \sum_{n=1}^{\infty} f_{jn} < \infty$ and $\sum_{n=1}^{\infty} g_{jn} < \infty$, hence $\lim_{n\to\infty}\|b_{jn} - a_n\| = 0$.

Then,

$$\begin{aligned}\|S_j^n a_n - a_n\| &\le \|S_j^n a_n - T_j^n b_{jn}\| + \|T_j^n b_{jn} - a_n\| \\ &\le \|S_j^n a_n - T_j^n b_{jn}\| + K\|b_{jn} - a_n\| \to 0 \\ &\quad as\ n \to \infty.\end{aligned}$$

And

$$\begin{aligned}\|T_j^n a_n - a_n\| &\le \|T_j^n a_n - S_j^n a_n\| + \|S_j^n a_n - a_n\| \to 0 \\ &\quad as\ n \to \infty.\end{aligned}$$

Theorem (2.5): Let B be a nonempty closed convex subset of a Banach space and T_j, S_j , $j = 1, 2, \dots, k$ be two families of total asymptotically quasi-nonexpansive self-maps of B. Presume that $F(T_j, S_j) \ne \emptyset$ and (a_n)be as shown in step (1)is strong convergence to a common fixed point of T_j and S_j iff $\lim_{n\to\infty} inf\ d(a_n, F) = 0$, where $d(a, F) = inf_{a^* \in F}\|a - a^*\|$.

Proof: To show $\lim_{n\to\infty} inf\ d(a_n, F) = 0$ implies that (a_n) is strong convergence to a common fixed point of T_j , $S_j, j = 1, 2, \dots, k$, since by (2)

$$\begin{aligned}d(a_{n+1}, F) &\le (1 + u_n)^{j+1}d(a_n, F) + v_n^{j+1} \\ &\le (1 + u_n)d(a_n, F) + v_n\end{aligned}$$

By Lemma (1.6), we get $\lim_{n\to\infty} a_n$ exists and $\lim_{n\to\infty} inf a_n = 0$.

Hence, $\lim_{n\to\infty} a_n = 0$.

Next, to prove the sufficiency, firstly show that (a_n) Cauchy sequence. By using Lemma (2.1.ii), we get

$$\|a_{n+p} - a^*\| \le J_1\|a_n - a^*\| + J_2 \qquad (3)$$

$\forall a^* \in F(T_j, S_j), n = p = 1,2, \dots$

Since $\lim_{n\to\infty} a_n = 0, \forall \epsilon > 0, \exists N$ such that

$$d(a_n, F) \le \frac{\epsilon}{3J_1} - \frac{J_2}{J_1}, \qquad \forall n \ge N$$

therefore, there is $l \in F(T_i, S_i)$ such that

$$\|a_N - l\| \le \frac{\epsilon}{2J_1} - \frac{J_2}{J_1} \qquad (4)$$

From (3) and (4), $\forall n \ge N$, we get

$$\begin{aligned}\|a_{n+p} - a_n\| &\le \|a_{n+p} - l\| + \|a_n - l\| \\ &\le J_1\|a_N - l\| + J_2 + J_1\|a_N - l\| + J_2 \\ &\le J_1\frac{\epsilon}{2J_1} - J_2 + J_2 + J_1\frac{\epsilon}{2J_1} - J_2 + J_2 \\ &= \epsilon\end{aligned}$$

Then, (a_n) is a Cauchy sequence and converges to $c \in M$.

Lastly, to show that $c \in F(T_j, S_j)$, for any $\epsilon^* > 0$, there is N_1such that

$$\|a_n - c\| \le \frac{\epsilon^*}{2(2 + f_jZ)} - \frac{3g_j}{(2 + f_jZ)}, \forall n \ge N_1 \qquad (5)$$

Since $\lim_{n\to\infty} a_n = 0$ implies that $N_2 \ge N_1$ such that $d(a_n, F) \le \frac{\epsilon^*}{3(4+3f_jZ)}, \forall n \ge N_2$.

Thus, $\exists\ l_1 \in F(T_j, S_j)$ such that

$$\|a_N - l_1\| \le \frac{\epsilon^*}{2(4+3f_jZ)} \qquad (6)$$

From (5) and (6) for any $T_j, \forall j = 1, 2, \dots, k$, we obtain

$$\begin{aligned}\|T_j c - c\| &\le \|jc - l\| + 2\|T_j a_{N_2} - l_1\| + \|a_{N_2} - l\| \\ &\quad + \|a_{N_2} - c\| \\ &\le \|c - l_1\| + f_j\psi\|p - l_1\| + g_j + 2\|a_{N_2} - l_1\| \\ &\quad + 2f_j\psi\|a_{N_2} - l\| + 2g_j + \|a_{N_2} - l_1\| \\ &\quad + \|a_{N_2} - c\| \\ &\le (1 + f_jZ)\|c - l_1\| + 2(1 + f_jZ)\|a_{N_2} - l_1\| + 3g_j \\ &\quad + \|a_{N_2} - l_1\| + \|a_{N_2} - c\| \\ &\le (1 + f_jZ)\|a_{N_2} - c\| + (1 + f_jZ)\|a_{N_2} - l_1\| \\ &\quad + 2(1 + f_jZ)\|a_{N_2} - l_1\| + 3g_j + \|a_{N_2} - l_1\| \\ &\quad + \|a_{N_2} - c\| \\ &\le (2 + f_jZ)\|a_{N_2} - c\| + (4 + 3f_jZ)\|a_{N_2} - l_1\| \\ &\quad + 3g_j \\ &\le (2 + f_jZ)\frac{\epsilon^*}{2(2 + f_jZ)} - 3g_j + 3g_j \\ &\quad + (4 + 3f_jZ)\frac{\epsilon^*}{2(4 + 3f_jZ)} \\ &= \epsilon^*\end{aligned}$$

Therefore, $\|T_j c - c\| = 0\ \forall i$ which means $T_j c = c, \forall j = 1, 2, .., k$.

By using the same above argument we can prove $\|S_j c - c\| = 0, \forall j$.Thus $c \in F(T_j, S_j)$.

Theorem (2.6): Let B be a nonempty closed convex subset of a uniformly convex Banach space and $T_j, S_j, j = 1, 2, \dots, k$ be two families of Lipschitzain and total asymptotically quasi-nonexpansive self-maps of B. If M accomplishes Opial 's condition and the maps $I - T_j$ and $I - S_j, j = 1,2, \dots, k$ are demiclosed to zero, therefore (a_n) be as shown in step (1) is weak convergence to a common fixed point of T_j and $S_j, j = 1, 2, .., k$.

Proof: Let $a^* \in F(T_j, S_j)$. By Lemma (2.2), $\lim_{n\to\infty} \|a_n - a^*\|$ exists.

By Theorem (2.4), we have

$$\lim_{n\to\infty} \left\|T_j^n a_n - a_n\right\| = 0 = \lim_{n\to\infty} \left\|S_j^n a_n - a_n\right\|$$

for j=1, 2,…, k. Since by the supposition the maps $I - T_j$ and $I - S_j, \forall j = 1,2, \dots, k$ are demiclosed to zero, therefore $T_j a^* = a^*$ and $S_j a^* = a^*$, that means $a^* \in F(T_j, S_j)$.

Next, to prove (a_n) converges weakly to a^*. Assume there is other subsequence $(a_{ni})\ of\ (a_n)$ is weak convergence to $b^* \in F(T_j, S_j)$ and $a^* \neq b^*$. By using the same argument as above we can show that $b^* \in F(T_j, S_j)$.

Now, to prove the uniqueness, assume $a^* \neq b^*$. Therefore, by using Opial 's condition, we obtain:

$$\begin{aligned}\lim_{n\to\infty} \|a_n - a^*\| &= \lim_{nj\to\infty} \left\|a_{nj} - a^*\right\| \\ &< \lim_{nj\to\infty} \left\|a_{nj} - b^*\right\| \\ &= \lim_{ni\to\infty} \|a_{ni} - b^*\| \\ &< \lim_{ni\to\infty} \|a_{ni} - a^*\| \\ &= \lim_{n\to\infty} \|a_n - a^*\|\end{aligned}$$

This is contradiction, therefore $a^* \neq b^*$. Hence, (a_n) is weak convergence to a^*.

Theorem (2.7): Let B be a nonempty closed convex subset of a uniformly convex Banach space and $T_j, S_j, j = 1, 2, \dots, k$ be two families of Lipschitzain and total asymptotically quasi-nonexpansive self-maps of B. If the dual space $M^*\ of\ M$ has the Kadec-klee property and the maps $I - T_j, I - S_j, j = 1,2, \dots, k$ are demi-closed to zero, therefore, (a_n) be as shown in step (1) is weak convergence to a common fixed point of T_j and S_j.

Proof: As showed by Lemma (2.2), that $\lim_{n\to\infty} \|a_n - a^*\|$ exists. Since (a_n) is bounded in B and M is reflexive. Therefore, there exists a subsequence $(a_{ni})\ of\ (a_n)$ which is weak convergence to a point$a^* \in B$. By Theorem (2.4)

$$\lim_{n\to\infty} \left\|T_j^n a_n - a_n\right\| = 0 = \lim_{n\to\infty} \left\|S_j^n a_n - a_n\right\|$$

∀j=1, 2, …, k .

Since by the supposition the maps $I - T_j$ and $I - S_j, \forall j = 1,2, \dots, k$ are demi-closed to zero. Thus, $a^* \in F(T_j, S_j)$. Now, to prove (a_n) is weak convergence to a point a^*. Presume that (a_{nk}) is other subsequence of (a_n) that is weak convergence to a point $b^* \in F(T_j, S_j)$. By using the same argument as above, we obtain $b^* \in F(T_j, S_j)$.

Therefore, by Lemma (2.3) $\lim_{n\to\infty} \|ta_n + (1-t)a^* - b^*\|$ exists for all $t \in [0,1]$.

By Lemma (1.8) $a^* = b^*$. As a result, the sequence (a_n) is weak convergence to the point $a^* \in F(T_j, S_j)$.

The following corollaries are special cases

Corollary (2.8): Let B be a nonempty closed convex subset of a Banach space and $T_j, S_j, j = 1, 2, \dots, k$ be two families of total asymptotically nonexpansive self-maps of B. Presume that $F(T_j, S_j) \neq \emptyset$ and $\sum_{n=1}^{\infty} f_n < \infty, \sum_{n=1}^{\infty} g_n < \infty$.

Presume that (a_n) be as shown in step (1) is strong convergence to a a common fixed point of T_j and S_j iff $\lim_{n\to\infty} inf\ d(a_n, F) = 0$, where $d(a, F) = inf_{a^* \in F} \|a - a^*\|$.

Corollary (2.9): Let T_j, S_j, B, f_j and $g_j,\ j = 1, 2, \dots, k$ be as in corollary (2.8). Therefore (a_n) be as shown in step (1) is strong convergence to $a^* \in F(T_j, S_j)$ iff $(a_{ni})\ of\ (a_n)$ that converges to a^*.

Corollary (2.10): Let B be a nonempty closed convex subset of a uniformly convex Banach space and $T_j, S_j, \forall j = 1, 2, \dots, k$ be two families of Lipschitzain and total asymptotically nonexpansive self-maps of B. If the dual space $M^*\ of\ M$ has the Kadec-klee property and the maps $I - T_j$ and $I - S_j, \forall j = 1,2, \dots, k$ are demi-closed to zero, therefore (a_n) be as shown in step (1) is weak convergence to a common fixed point of $T_i\ and\ S_i$.

Corollary (2.11): Let B be a nonempty closed convex subset of a uniformly convex Banach space and $T_j, S_j, \forall j = 1, 2, \dots, k$ be two families of total asymptotically nonexpansive self-maps of B. If M accomplishes Opial 's condition and the maps $I - T_j$ and $I - S_j, \forall j = 1,2, \dots, k$ are demi-closed to zero, therefore, (a_n) be as shown in step (1) is weak convergence to a common fixed point of $T_j, S_j, \forall j = 1, 2, .., k$.

Corollary (2.12): Let B be a nonempty closed convex subset of a Banach space and $T_j, S_j, j = 1, 2, \dots, k$ be two families of asymptotically quasi-nonexpansive self-maps of B. Presume that $F(T_j, S_j) \neq \emptyset$ and $\sum_{n=1}^{\infty} f_n < \infty$. Presume that (a_n) be as shown in step (1) is strong convergence to a common fixed point of T_j and S_j iff $\lim_{n\to\infty} inf\ d(a_n, F) = 0$, where $d(a, F) = inf_{a^* \in F} \|a - a^*\|$.

Corollary (2.13): Let B be a nonempty closed convex subset of a uniformly convex Banach space and $T_j, S_j, \forall j = 1, 2, \dots, k$ be two families of Lipschitzain and asymptotically quasi-nonexpansive self-maps of B. If the dual space $M^*\ of\ M$ has the Kadec-klee property and the maps $I - T_j$ and $I - S_j, \forall j = 1,2, \dots, k$ are demi-closed to zero, therefore, (a_n) be as shown in step (1) is weak convergence to a common fixed point of T_j and S_j.

Corollary (2.14): Let B be a nonempty closed convex subset of a uniformly convex Banach space and $T_j, S_j, \forall j = 1, 2, \dots, k$ be two families of Lipschitzain and asymptotically quasi-nonexpansive selfmaps of B. If M accomplishes Opial 's condition and the maps $I - T_j$ and $I - S_j, \forall j = 1,2, \dots, k$ are demi-closed to zero, therefore, (a_n) be as shown in step (1) is weak convergenve to a common fixed point of T_j and $S_j, \forall j = 1, 2, .., k$.

3. Numerical Example

We illustrate our results by the following

Example (3.1): Let $T_j, S_j: R \to R, \forall j = 1, 2, \ldots, k$ be two maps such that $T_j a = \frac{2a}{3^j}$ and $S_j a = \frac{46a}{2^j}, \forall\, a \in R$. Choose $\alpha_{jn} = \frac{n}{4(n+1)}\ \forall\, n$ with initial value $a_1 = 15$. Let (a_n) be the sequence. According to Table 1 and Figure 1, it eases to sight that (a_n) converges to the fixed point $a^* = 0$.

Table 1: Numerical results corresponding to $a_1 = 15$ for 36 steps.

n	Iteration (1)	n	Iteration (1)
1	15.0000	**13**	0.0184

12	0.0332	**24**	0.0000

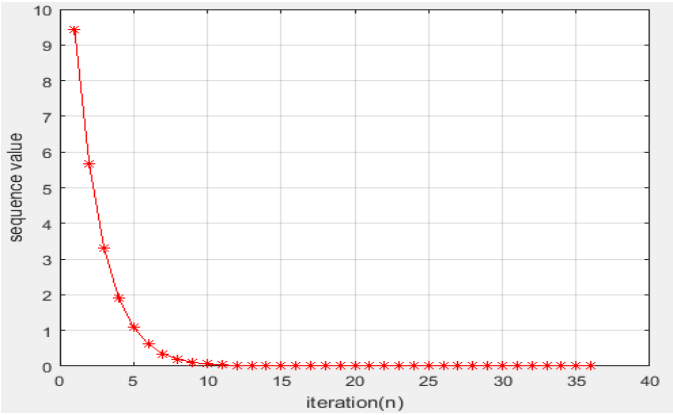

Figure. 1. Convergence behavior corresponding to $a_1 = 15$ for 36 steps.

4. Conclusion

We study the strongly and weakly convergence of new type of finite-step iteration processes under total asymptotically quasi-nonexpansive maps, see Theorems (2.4)-(2.6). Our results are generalizing and unifying the results of others who have been referred to in the references.

5. Open Problem

Recently, S.S. Abed has been defined as the following type of generalizations of total asymptotically quasi-nonexpansive[16]: Let $\mathcal{A}$ be a subset of real Banach space a set–valued map $G: \mathcal{A} \to 2^{\mathcal{A}}$ is called the general asymptotic set-valued if for each $x \in \mathcal{A}$ there exists null non- negative real sequences $\{a_n\}$ and $\{b_n\}$ such that

$$\mathfrak{D}(G^n x, G^n y) \leq \|x - w\| + a_n\, \mu(\|x - w\|) + b_n \qquad (7)$$

for any $y \in \mathcal{A}$, $w \in G^n y$ and $\mu: R^+ \to R^+$ with $\mu(0) = 0$. One can study convergence theorems in (1) and in [17, theorem (11)] for families of general asymptotic set-valued maps. As well as possible to demonstrate new results in the case of other spaces as a modular space [18].

Acknowledgment

The authors wish to express his thanks to the referees for their helpful advice.

ABSTRACT

Knowledge Based Systems play a very important role, within Healthcare, with a primary goal of supporting a high quality service at an optimal cost. A widely accepted knowledge acquisition technique is through the use of Business Rules in a natural language like format. As clinical terminology is centric to HealthCare, a large percentage of these rules use industry standard codes to describe clinical concerns. Usually there is a large number of codes to denote the various clinical processes and procedures within Healthcare. These can translate to a combinatorially explosive number of Business Rules within the HealthCare IT system. It is common practice to leverage a Rule Engine to execute these rules and produce decisions within the system. A Rule Engine accepts a collection of rules called a ruleset. Within Healthcare Insurance, these rules and rulesets embody regulatory, policy and contractual concerns. To effectively manage this huge body of rules and rulesets, it is typical for Knowledge Based Systems to reuse rules across rulesets. Further, the knowledge required to author these rules and constructing comprehensive rulesets is specialized and requires deep expertise within the domain. Further, this also requires an expertise with authoring unambiguous business rules and operating the Rule Management Systems or Knowledge Based Systems. There is a need for the continuous Governance of these rule based knowledge assets for the organization. Typically knowledge experts in this field have a decade or more of experience. An emergent challenge or trend witnessed within the industry is that the experienced knowledge workers are retiring and their positions are being replaced by people not as experienced. This paper proposes techniques to build a layer of intelligent capabilities that can transform the methods for the automation, creation and maintenance of knowledge artifacts, that can aid and support the inexperienced knowledge workers with the effective management and administration of these assets within a Healthcare system.

1 Introduction

Healthcare domains are characterized by a rich knowledge accumulated through a combination of science, technology, experience, innovation within the industry and standardization through regulatory entities. Given the high cost of administration of health care, it is common practice to be reliant on a strong infrastructure of insurance to fund the high costs of administering healthcare. Further, there is a strong demand and pressure for absorbing scientific and technological advances within the field into operational practice within a short period of time. There is a high risk of adverse practice effects, fueling the necessity for standardization of practice, within the industry. This paper is an extension of the paper titled *Intelligent discovery features for EDM and MDM Systems* originally presented at 2018 IEEE 22nd International Enterprise Distributed Object Computing Workshop (EDOCW) [1]. This paper further extends the concepts beyond the discovery features described in the original paper. It further formalizes these concepts into a set of foundational patterns, called *intelligent foundations*, with a view to providing automation towards hard to scale and hard to automate human labor intensive processes around business rule mining and knowledge manage-

ment. This paper further lays down a formalized foundation of ingredients to construct recipes for building intelligent virtual knowledge working software agents to aid a new breed of digitally savvy, but functionally inexperienced workforce.

1.1 Healthcare in the United States

In the US, healthcare can be broadly categorized into the *Provider* i.e. the clinical entity viz., hospitals, doctor's offices, clinics etc. that provides the clinical services and the *Payor* i.e. the funding entity a.k.a insurance companies that pays for these services. The cost of healthcare is expensive and exorbitant to the general population. In addition it is highly susceptible to litigation, which further acutely drives up the cost. Healthcare insurance infrastructure is predominantly operated by the private sector, through a combination of "for profit" and "not for profit" entities. Stereotypically, healthcare insurance within the US is offered as a benefit, to employees of companies. The employers purchase health insurance for their employees through customized benefit plans, from healthcare payor companies. The health insurance costs are more affordable when bought in bulk for larger groups of people and is often referred to as the "group discount". This is due to the fact that the risk of "adverse selection" is significantly lowered. The cost of insurance is high for the average citizen seeking to buy it [2], [3], [4], [5]. Recent reforms in healthcare have attempted to introduce competitive pricing through the notion of healthcare exchanges at competitive rates. The general gist of this is to be able to provide insurance for healthcare to citizens, who otherwise cannot participate in employer health benefit plans either due to lack of employment or lack of availability of the benefit from the employer. In the US, there is a specialization of insurance products for *Medical* healthcare, *Dental* healthcare and *Vision* healthcare.

1.2 Background

The work presented in this paper and the original foundational paper is part of an evolving case study in the practical application of data science, analytics and visualization techniques that can automate the process of knowledge analysis and mining at a Dental Insurance company. Delta Dental of Michigan, Indiana and Ohio is the leading provider of dental benefits, serving the mid-western part of the US, with a subscriber base of nearly 15 million members throughout the states of Michigan, Indiana, Ohio and it's growing base of other affiliated states in other parts of the US. The company has witnessed a strong growth over the last decade of it's 60+ years of history. A key factor for this growth is it's highly automated insurance and benefits administration software platform, that achieves an industry enviable 95% auto adjudication rate (the percentage of claims that are entirely processed by the software platform with no human intervention). The cornerstone of the software platform is a sophisticated rule management system called BRIDE, which enable the domain *knowledge workers* or Subject Matter Experts (SMEs), to author, test and manage the operational rules, using highly configurable *Domain Specific Languages* and a semantically rich *Business Vocabulary* [6]. The BRIDE platform is an innovative homegrown product which is the result of original collaborative work by the author and other fellow contributors, which is elaborated in a published conference paper [7]. The knowledge externalized into BRIDE as operational *Business Rules*, can be translated and deployed to any forward chaining production rule engine format [8].

1.3 Motivation

The process of deciding to pay a claim a.k.a *adjudication* in the healthcare claims arena, requires a deep understanding of healthcare clinical knowledge. Within the dental healthcare space, it is not uncommon to manually adjudicate complex and costly dental procedures, by dental experts who have had prior hands on experience with the clinical aspect of the science. Further a second dimension of expertise is to understand, the payor's business policy as it pertains to the interpretation of allowances and coverages. As a consequence, a typical knowledge worker has decades of experience within the industry and/or company. However, these experts are now reaching retirement age and will be transitioning their responsibilities to younger and lesser experience functional specialists. This provides strong motivation to build *"intelligent capabilities"* into the platform, that can automate laborious manual processes and to provide a decision support system for generating or recommending rules to the knowledge workers as they author these rules. This will be elaborated further in subsequent sections.

1.4 Organization

This paper is organized as follows. In 2, we will explore the characteristics of knowledge sources, their nature and consequences, within the context of healthcare claims processing and adjudication. We will cast a wider net to describe how the patterns presented by these problems can be applied to other functional verticals with similar characteristics. This will then provide a segue to 3, where the subject of *intelligent capabilities* will be explored with a viewpoint of automating manually intensive tasks and to provide seamless decision support to the act of *rule/knowledge mining*. In 4, we will explore the subject of building intelligent foundations and capabilities with the backdrop of the BRIDE [7] case study, that can support a growing and diverse eco-system of artificial intelligence. In 5 we will discuss inherent challenges in addressing the intelligent automation of knowledge/rule mining. This will naturally set the stage for discussion of future research/work, in 6. We will finally provide a meaningful conclusion for the work in 7.

2 Knowledge Characteristics

Knowledge/Rule Mining through traditional means can be a manually intensive process. Traditional Rule-based Information Systems, rely on the ability of human experts, to author high quality, non-ambiguous system enforceable rules. Further, knowledge rich areas such as clinical domains, yield a high number of such rules. These rules exhibit symptoms of combinatorial explosion, when certain influencing parameters change. These parameters are commonly influenced by external forces, such as customer needs, advances in science, market trends, regulatory mandates , adherence to standards etc. Second, the complexity of the rules can be high. In certain cases automation of the business logic, through procedural programming techniques can yield, very large (in the order of 10K lines of code), extremely complex programs [9]. The maintenance cost of such programs increase dramatically over time. In the face of such complexity, a system of externalized rules provides significant cost savings and improved agility to change. However, the system of rules that are mined out from large legacy procedural language programs is iterative in nature and is best achieved in a phased manner.

The original paper [1], outlines the complexities of the problem, especially around the mining, discovery and management of business domain knowledge as externalized business rules, into six different categories viz., *Volume and Growth Complexity*, *Organizational and Reuse Complexity*, *Rule Logic Complexity*, *Domain and Subject Matter Complexity*, *Healthcare Complexity*, *Healthcare Consolidation Complexity*. In this section we will contrast these with other intrinsic characteristics surrounding *Knowledge* and their relevance within surrounding eco-systems.

Healthcare systems operate around a hub of knowledge. This hub is surrounded by a triad of pillars, *People*, *Process* and *Technology*, which is depicted in 1. The *People* realm represents the Clinical knowledge workers, Business User Community, Claims/Insurance Practitioners etc., and their collective knowhow. The *Process* realm represents the organization's conscious act of documenting the knowhow with a view to standardizing, documenting and repeating them in a predictable fashion. The *Technology* realm reflects the collective collage of automation software, which in the case of the Healthcare Payor business, could be the Claims Processing System, Benefits Administration System, Accounting System etc. The company's knowledge assets live in the hub of these three pillars. We will now proceed to examine the characteristics of knowledge which intersects with each of these pillars. We will further examine the influences of introducing *intelligent foundations* to *Knowledge Management* and how it helps to preserve the most valuable assets of the organization i.e *knowledge*.

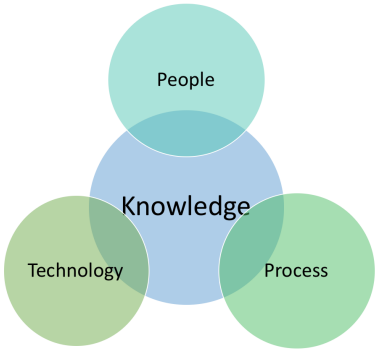

Figure 1: Knowledge Hub

2.1 Documented Knowledge

Documented Knowledge as the name suggests, represents all documented artifacts describing business processes, policies, contracts etc. Documented knowledge, exists in a variety of formats for different audiences. Healthcare is a highly regulated domain and is subject to a variety of audits. Non-compliance with regulation and audit findings present dire consequences, in the shape of costly penalties and potential litigation. Hence, it is crucial to maintain detailed documentation of processes, contracts and such. The basis of *Documented Knowledge* is depicted in 2.

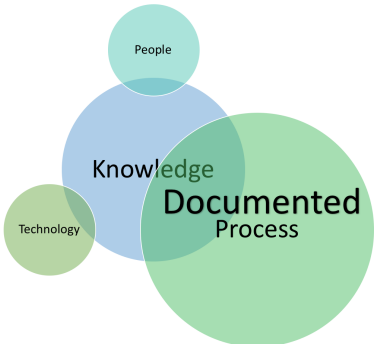

Figure 2: Documented Knowledge

Documented Knowledge, has the following consequences.

1. Footprint of *Documented Knowledge* can be huge and verbose. As it grows over time, the maintenance and upkeep of it becomes increasingly labor intensive and costly. As a result it is necessary to have quick and correlated discovery available to navigate the knowledge bases.

2. *Documented Knowledge* through traditional means is not *interactive* and *adaptable* to different audiences and contexts. Unlike *tribal* knowledge where knowledge workers can decide to provide a detailed explanation or high level overview depending on the appropriate audience and context, documented knowledge needs to be captured at varying levels of abstraction.

3. The knowledge can become outdated quickly, i.e. the knowledge bases if not updated periodically

can lose its accuracy, and hence its efficacy and value. To derive continual value from this source of knowledge, proper controls need to be put in place to effect the timely update of these knowledge resources.

4. Being textual and descriptive, semantics can get distorted. To mitigate this, the documented knowledge bases need to be reviewed and updated periodically by knowledge workers.

But if done right, this is an important source of knowledge and as such an asset to the enterprise. We will further explore how building a foundation of intelligent capabilities within the Knowledge Based Systems will capture the documented knowledge at the source of knowledge, through explicit means i.e. where the users can document aspects of pertinent contextual knowledge and implicit means where the underlying system learns, predicts and creates knowledge content.

2.2 Tribal Knowledge

Tribal knowledge is any undocumented information that is not commonly known by others within a company. It can also be thought of as the collective wisdom of the organization. It is the sum of all the knowledge and capabilities of all the people [10]. In a highly specialized functional domain such as healthcare, detailed nuances of claims adjudication procedures, interpretation of high level organizational policy or adaptation of external regulatory stances or standards can reside in this domain. Typical knowledge workers, with decades of experience in the field and more importantly experience administering the knowledge, within the domain within the same company are a very rich source of such knowledge. The origins of *Tribal Knowledge* in the *People* domain is depicted in 3.

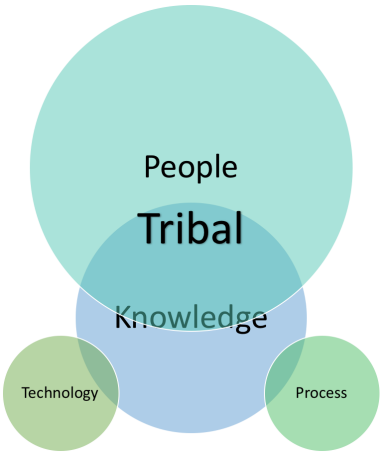

Figure 3: Tribal Knowledge

This form of knowledge has the following consequences.

1. There is a high risk of erosion, as the people holding them leave the organization through attrition or retirement. This presents a strong motivation to build intelligent systemic capabilities that can tap into this rich source of tacit knowledge and be able to capture and leverage where possible, within the organization.

2. Traditional methods for capturing or documenting the knowledge i.e. transforming it into *Documented Knowledge*, in entirety is challenging at the least.

3. Tribal Knowledge can be clouded by subjective influences.

4. Some aspects of tribal knowledge pertains to the expertise or experience of the knowledge workers and their innate ability to leverage different sources of knowledge. This can be very contextual and situational by nature and unless well integrated into the knowledge management platform can become very hard to assimilate and correlate contextually. Hence, there is a very strong need to not only capture knowledge, but to artfully disseminate, correlate and index it for easy and fuzzy discovery.

The industry at large has been undergoing a significant generational workforce transition [11], which puts a heavy burden on the organization to effectively transition the tacit tribal knowledge held by the seasoned "baby boomer" generation, to a younger inexperienced generation. Special attention needs to be paid towards building a foundation of *Artificial Intelligence*, that can aid in the seamless capture from the older generation while effecting a smooth transition with interactive decision support capabilities back to the newer generation joining the workforce. On the other side of the coin, there is a strong need to attract and retain digitally-savvy, millennial and post-millennial generations of workers [13], while training them to be future knowledge workers.

2.3 Knowledge Systemization

We will now examine the concept of *systemization* of knowledge. This is the act of capturing the knowledge into a software system with a view of automating it. This can be achieved with one of two approaches.

1. In this approach, the knowledge is programmed and automated into software applications that capture the essence of the knowledge. We will call this the *Black Box* approach, for the obvious reason that the knowledge is now buried deep within the implementation of a software system, as depicted in 4.

   This approach while being non-transparent to the non-programming business user community, at least does captures the knowledge within the bounds of a software. In theory this knowledge could be mined out (albeit painfully) and documented. However, there are some drawbacks.

(a) The organization might not own the software system, which implements the business logic. In this scenario the organization has limited control on the mining effort at a later stage and has to entirely depend on the owning vendor of the software to mine out their business logic as metadata.

(b) The software system is programmed in a legacy technology, with limited technical resources who understand the technology. This presents the same consequences challenges of erosion as posed by *Tribal Knowledge*, described earlier in 2.2

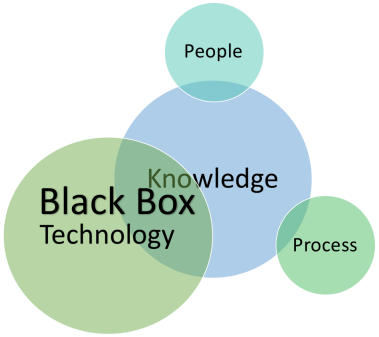

Figure 4: Blackbox Knowledge

2. This approach can be described as the act of formally capturing the knowledge in a *Knowledge Management System*. The most tangible forms of knowledge are *business rules* and *business policies* as these tend to be precise statements describing aspects of the business. Within the healthcare payor space, these are typically captured as operational rules that can be automated. Such knowledge is *externalized* into a Rule Management System a.k.a Decision Management System as operational rules intended for consumption by a software system for automation, but more importantly externalized to be human readable and comprehendible by non-programming savvy users. We will call this the *White Box* approach, as this knowledge is *externalized* and is now transparently available to be understood and manipulated by the organization. The knowledge is externalized and managed under *Knowledge Management*, as shown in 5.

   Externalization of the knowledge, presents the following benefits.

   (a) Externalization as described above, makes the organization more *agile*, as they now have the ability to change the operational business rules without making systemic changes which require a software release cycle. Further these changes can be directly controlled by the end business users, rather than the Information Technology community within the organization.

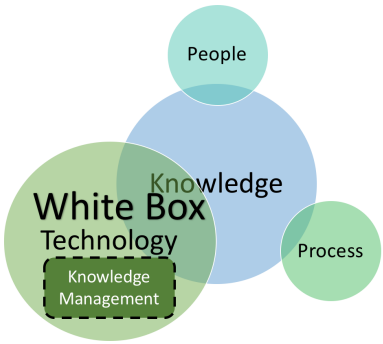

Figure 5: Whitebox Knowledge

3. Externalization of knowledge makes the organization's operation more transparent, but more importantly explainable as opposed to the *Black Box Approach*.

   However, these are some consequences of knowledge externalization that need to be considered.

   (a) The number of externalized operational rules and policies could be large. Further, these rules are combined into large rulesets can present a combinatorially explosive [7], difficult to manage scenario over time. It takes highly experienced rule authors and knowledge workers well versed in the science and the organization's business operations, to effectively manage this, over time. This exposes the organization to the risk of knowledge erosion.

   (b) While the externalized knowledge is more transparent and explainable, to be able to comprehend far reaching cause and effect, the underlying system needs rich traceability capabilities [12], to provide detailed comprehensive explanations to the business users. This provides the deep motivation for *Intelligent Foundations* and providing an intelligent way to manage knowledge and sets up the business case for a *Virtual Knowledge Worker*, that is capable of answering deep *knowledge* questions, something that can aid and support the new younger generation of *digitally savvy* knowledge workers.

2.4 Intelligent Foundations

As discussed in 2.2, transition of the labor force [11], and catering to a diverse workforce with different knowledge assimilation requirements [13], presents a big challenge. This bolsters the case to build sophisticated and *intelligent capabilities* to address these needs. The intelligent capabilities will be elaborated further in 3. In this section, we will introduce the concept of *intelligent foundations*. Building such a foundation can then enable *intelligent capabilities*, that can rapidly train a new generation of young workforce, on the deep knowledge expertise. This is depicted in 6. The idea is as *Tribal Knowledge* erodes in an organization, the

new business users can learn rapidly, thereby restoring the tribal knowledge held by the people who leave the organization.

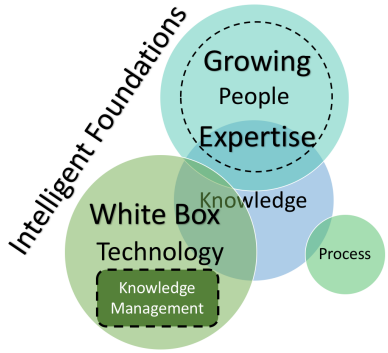

Figure 6: Intelligent Foundations

These *Intelligent Foundations*, can also be articulated as *capability* statements. We define a capability as a simple statement that describes an *ability* or feature of the system. Here are the ten foundational capabilities, at a high level, that enable building more specific intelligent capabilities around knowledge analysis, management and intelligent automation. These will be discussed in more depth in 4, against the backdrop of a case study, within BRIDE [7].

1. *Discovery:* Ability to fuzzily discover diverse artifacts
2. *Tagging:* Ability to *tag* or decorate knowledge artifacts with manual and generated metadata.
3. *Visualization:* Ability to graphically visualize *affinity* between artifacts
4. *Classification:* Ability to classify artifacts based on characteristics
5. *Correlation:* Ability to build correlation between different artifacts
6. *Event Processing:* Ability to generate, process and react to system and user events, within the platform.
7. *Recommending:* Ability to recommend action to take based on correlation between artifacts
8. *Language Processing:* Ability to absorb, disseminate and score keywords from textual content/documentation at detailed inflection points
9. *Generation:* Ability to generate new content
10. *Learning:* Ability to learn from data patterns and from human feedback

2.5 Knowledge Governance

Healthcare as discussed earlier is a highly regulated, knowledge rich domain. There is a strong need to formalize, document and more importantly *govern* the knowledge, which refers to choosing structures and mechanisms that can influence the processes of sharing and creating knowledge [14], surrounding the detailed aspects of administration, business rules, business policy and processing. Within healthcare the business rules around administration are driven by different motivations, varying from regulatory, industry standardization, organization policy to client contractual customizations. Understanding and cataloging the various business rules and associated knowledge artifacts, contributes to better organizational management of the same. This consequently enhances the documented process knowledge surrounding them. By building intelligent capabilities around integrating and automating aspects of *Knowledge Governance* into the Knowledge Management System, aids in better administration of the governance process. Further it centralizes and promotes the use of the externalized knowledge across all three pillars i.e. *People*, *Process and Technology*, in a seamless fashion. This is shown in 7 .

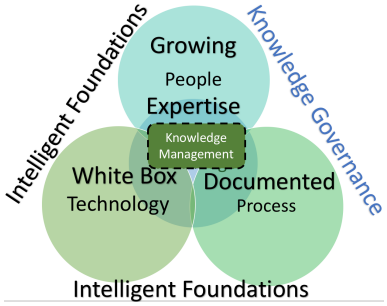

Figure 7: Intelligent Foundations with Governance

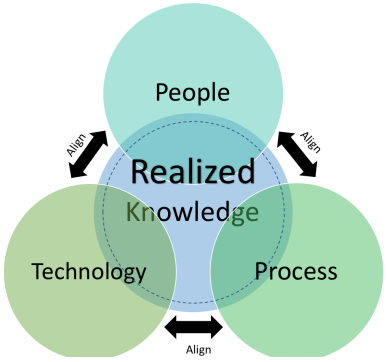

Figure 8: Realized Knowledge

A big goal is to better *align* knowledge sources across the three pillars of knowledge and unify them as a net sum of *Realized Knowledge*, as shown in 8. The introduction of *Intelligent Foundations*, coupled with *Knowledge Governance* strives to achieve that [15].

3 Intelligent Capabilities

In this section we will describe a subset of *Intelligent Capabilities* that are built on top of the set of ten foundational intelligent capabilities i.e. *intelligent foundations*

described in 2.4. These *Intelligent Capabilities* cover the vast gamut of functions needed to effectively manage a complex, vast, functionally diverse and growing footprint of externalized knowledge, as seen in healthcare. A logical viewpoint of this framework is shown in 9.

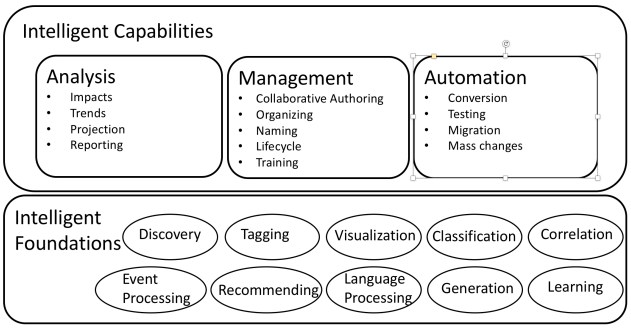

Figure 9: Intelligent Knowledge Management Framework

The capabilities are broken up into these broad categories viz., *Analysis*, *Management* and *Automation*. We will elaborate each of these broad categories of capabilities.

3.1 Analysis

Analysis covers the most important and far reaching capability across the organization. Practically every *business user* would need access to some or all aspects of this capability to perform their job effectively. As mentioned earlier, authoring operational *business rules* is a central part of knowledge externalization. With healthcare, some of the most complex rules are around *clinical terminology*.

To illustrate this further, we will contrast this with a Dental Insurance use case. With dental health insurance, clinical rules are specified using ADA (American Dental Association) mandated CDT (Current Dental Terminology) Procedure Codes. The knowledge workers are making changes to these rules as contractual benefits with customers change, or when the ADA releases a new version of the CDT, each year. Each Dental Procedure has a nomenclature that describes the procedure using key clinical terminology. When a certain aspect of dental clinical science changes, the ADA makes appropriate changes to the CDT to -

1. Introduce new Procedure Codes to reflect new clinical procedural advances
2. Retire obsolete Procedure Codes

In the United States, all healthcare business participants are mandated to be HIPAA (Health Insurance Portability and Accountability Act) compliant. In Dental Insurance, among other things, this means that Dental Providers (Dentists, Dental Offices) and Payors (Dental Insurance companies) are CDT compliant. This translates to the Dental Insurance adjusting thousands of dental clinical rules to reject or adjudicate claims based on the correct/appropriate dental procedure code being submitted.

These are some of the more fine-grained use cases within the *Analysis* capability.

1. *Impact Analysis:* Sometimes there are business rule changes across segments or the whole book of business, to specific areas of treatment, caused by a variety of reasons. These reasons, for example can be one of the following:
   (a) Periodic ADA CDT version changes that are introduced on a yearly basis.
   (b) Changes to a large client's contractual benefits on renewal, on a periodic basis.
   (c) Introduction of a new line of business or product.
   (d) Regulatory mandates.
   (e) Corporate directional changes.

   There is a strong need, for an ability to analyze and make micro-level operational rule changes based on macro-level shifts in function. To be able to do this the system needs the ability to correlate and analyze impacts across varying granulation of knowledge assets.
2. *Trend Analysis:* Trend Analysis can offer up useful insights to the organization and is intrinsic to the collective knowledge it holds. Here are some examples of trend analysis.
   (a) *Reuse Trending:* As mentioned in 2, certain knowledge rich domains, can have combinatorially explosive rules under certain conditions. Therefore there is a need to provide appropriate tools for managing the analysis of trends to minimize the explosion of such rules through intelligent optimization and reuse.
   (b) *Metric Trending:* The collection of accurate metrics leads to better knowledge governance and quality of rules/knowledge that yield better business decisions. For example, within the dental claims adjudication arena, we would like to analyze the most popular rules and be able to see seasonal or long term trends in their usage. Another useful analysis is to study the trending of the auto adjudication metric, which is the percentage of adjudicated claims that do not require any form of manual expert intervention, as this directly ties to the cost of administration.
   (c) *Volatility Trending:* It is important to understand how frequently a knowledge artifact or rule changes. These can lead to deeper questions that would help analyze - are there seasonal influences to the change ? Are these changes reflective of changes to the book of business ? Can we use this as a future predictor of like phenomena?

(d) *Variance Trending:* When looking at a collective body of knowledge artifacts for example, an entire set of rules, there is typically a variant component and an invariant component. This form of trending is again useful as a future predictor to study correlational causal effects with underlying books of business. For example the variance trending for Government Contracts can differ from Contracts, underwritten for small commercial clients, or clients within a certain vertical industry like car manufacturers or the demographic makeup of a certain group of underwritten people within a group.

(e) *Complexity Trending:* Are knowledge artifacts (i.e. rules, rulesets, policy, key terms etc.) within a certain sub-domain of the business growing in complexity ? This form of trend analysis helps identify and proactively address the management of such artifacts.

(f) *Obsolescence Trending:* It is not uncommon to *retire* knowledge artifacts i.e. business rules or policies, over time and this form of trending can be an indicator in correlating the obsolescence of knowledge with evolving the book of business. In a certain sense this is similar to the volatility trending, discussed above, however obsolescence of knowledge can provide certain key insights and indicators around directional change for the organization, especially around obsolete business models or outdated processes, which are valuable.

3. *Projection Analysis:* Projection Analysis is the ability to analyze existing knowledge artifacts, to generate or "project" inductively, through inferred heuristics, gained from historical correlation of associated historical contextual changes to the corresponding changes of knowledge artifacts. This technique of analysis provides an approach for both the system and humans within the knowledge economy to project or generate knowledge artifacts based on the correlated data. This correlated data can further be used to generate features, to develop future state capabilities such as machine learning based on the generation and validation of projections based on correlation between characteristics of knowledge artifacts and high-level characteristics.

4. *Reporting Analysis Results:* With *Intelligent Capabilities*, built on AI foundations of fuzzy discovery, classification and correlation, business users can now be empowered to gather insights with deep drill down capabilities. It is important however to be able to package the results of ad-hoc analysis sessions into interactive reporting that can be exported and shared to a broader audience or community within the organization. It is also important to be able to provide interactive *data visualization* features, packaged into this capability. By combining multiple *Intelligent Foundation* concepts, new users can be onboarded and trained on complex interrelated concepts in a more effective, timely and continual manner.

3.2 Management

Traditionally, management of knowledge assets within an organization requires deeply experienced multifaceted knowledge workers, well versed in the domain terminology and the functional vertical. In addition, the knowledge workers tasked with authoring externalized business rules, need to possess traits that can translate complex functional subject matter into clearly articulated, unambiguous business rules and policies. Lastly, they need to be adept at navigating a complex knowledge management system, replete with a rich interconnected set of business vocabularies and complex features for other life cycle functions of knowledge management. The *Intelligent Capabilities* around management can be broken up into these following broad areas:

1. *Collaborative Knowledge Authoring:* This capability is at the heart of any Knowledge Management System, and to a large extent determines the success and efficacy of such a system. With traditional means i.e. with no *intelligent foundational* capabilities, a big part of the success and efficacy of the external knowledge hinges on the skills of the knowledge workers to deliver the quality. By building this capability on an intelligent foundation, new possibilities abound. For example here are a few plausible use cases, that leverage intelligent management capabilities. With a *collaborative* approach, the system collaborates seamlessly, with the users and facilitates collaboration amongst participating knowledge workers

   (a) *The authoring tool provides a guided wizard like experience for complex rules.* For example, for new business rule authors who are not familiar with the intricacies of the detailed business vocabulary of a complex domain, the act of authoring a complex business rule that achieves a granular operational business decision can be a daunting task. In such scenarios, a high level, questionnaire driven wizard can step the business rule author through the act of authoring.

   (b) *The authoring tool provides impromptu training sequences for guided authoring.*An extension of 1a, described above could show a step by step progression of an authored business rule to the new business rule author. This will help train that business rule author to learn the intricacies of the business domain vocabulary and it's associated key terms. Further, such sessions could be

recorded for future playback as interactive help topics.

(c) *The authoring tool provides help based on correlation with keywords used in key business vocabulary.* This feature is another interactive training feature for the authoring tool to train new users. Further, while this use case is centric to the day to day management of knowledge, it can be used as a key analysis feature, that can help the business rule authors to do integrated impact and correlation analysis as they author business rules, policies and other knowledge artifacts.

(d) *The authoring tool disseminates complex authored rules to catalog and correlate keywords to contextual help topics.* As new knowledge assets i.e. Business Rules, Policies etc., are created inside the Knowledge Management System, new business terms and language could be introduced. A consequence of this is that only small segments of the business community are aware of the semantics and impact of the newly introduced terminology. This bolsters the case for cataloging and correlating this information at the point of entry, into the management system. This could make the system smarter through the continual layering of correlational metadata.

(e) *The authoring tool provides a means for a community of knowledge workers, to collaboratively author related knowledge artifacts, concurrently by providing push notifications of changes and preventing conflicting or inconsistent changes to occur.* This capability leverages the intelligent foundations in 6, (the seminal book [16] provides a sound introduction to the science of events). Using this, the platform is capable of sending push notifications of user edit events, to different users, analyzing sequences of events, to make inferential decisions about dynamically constraining certain situational edit operations for certain knowledge assets, by certain participating knowledge workers.

2. *Knowledge Organization:* To manage the combinatorially explosive growth of knowledge assets, there is a compelling need for a sophisticated organization method that promotes the optimal reuse of knowledge assets. To be able to effectively reuse common knowledge assets like business rules, the first barrier to overcome is the ability to discover (rather fuzzily) that such a business rule or a *similar* business rule does exist. In the absence of this, a lot of duplicate or near duplicate knowledge assets are created. Organization of knowledge is key to enabling knowledge recall, management, mining and last but not the least Governance. We will now consider the organization of knowledge from the following vantage points.

(a) *Structure and Granulation:* Here we need to consider how the knowledge is structured and abstracted. Typically the knowledge artifacts can be structured in a hierarchical fashion, from most granular to least granular (i.e. high-level to low-level). Further each level of granulation can have several viewpoints. For example in dental insurance, the highest level of knowledge can be emblematically represented in a client/customer contract, which in turn, can be represented as a ensemble of *business policy* statements, which are high level statements of business purpose, that are driven through a combination of regulatory, contractual and administrative concerns.

These business policies are implemented through sets of operational *business rule* statements, that enforce the intent of the policy, within the Claims Administration platform. The breakdown of artifacts from a high-level perspective to a low-level perspective has to be well thought through and it is desirable to follow some form of a structured dissemination, based on some pre-established categorization. For example, the clinical adjudication policies are administered through a set of well established *treatment categories* within BRIDE [7]. This helps in managing combinatorial explosion of rule artifacts through a controlled reuse of pre-existing configurations of sets of rules. In the absence of such a categorized structure, there would be significant redundancy and duplication in structure as each hierarchical structure would end up duplicating, sub-structural elements of it's hierarchy. However, in spite of this form of structured organization duplication and redundancy can be introduced due to the lack of *discovery*, as discussed in 2.4.

Lastly, to achieve these hierarchical structures of granulated knowledge artifacts with reuse, the underlying domain structures share a many to many correlation amongst each other, which are elaborated in more length in [7].

(b) *Ownership* This is an important aspect of *Knowledge Governance*, that can influence the level of reusability discussed in 2a. With a growing consciousness and need for privacy, customers and clients are increasingly unwilling to share common data. Within, the consolidating healthcare payor space, this presents some interesting consequences.

Within the dental insurance space, the collective knowledge i.e. policies and rules

gained to preempt Fraud, Waste and Abuse, can be a shared asset, as these knowledge assets are gained through collective experiences. But to effectively leverage the shared operational knowledge, the historical claims *data*, across customer boundaries are needed to effectively adjudicate them. But privacy considerations and constraints can explicitly govern and prevent us from leveraging cross-customer data and knowledge, across boundaries, thereby limiting the potential to act on opportunities, that can minimize claims utilization.

Another consequence of ownership is that there are strict rules, that can be driven by a contractual agreements that dictate, who *owns* the knowledge and who has the rights to view, use or change them, under specific conditions. This poses interesting challenges to sharing and pooling of knowledge assets

(c) *Correlation and Connectivity* To effectively organize knowledge, we need the ability to *correlate* and *connect*, pieces of knowledge assets. This introduces the important notion of *traceability* [12], which provides the users the ability to perform key activities such as root cause analysis, answer audit questions and explain processing and/or adjudication reasoning to customers and other stakeholders. Correlation can be achieved through the following three means or mechanisms.

i. *Structural* This is the strongest and most basic form of correlation and connectivity that can be built to correlate different knowledge assets, explicitly correlated through well defined data and object models relationships. Within the BRIDE eco-system [7], different knowledge assets such as Rule Stores, Rule Packages, Rule Packets, Rules etc. are correlated in this fashion, which lends to easy organization.

ii. *Manual or Explicit* This form of correlation is weaker, but equally important. This allows the business users to explicitly tag or store metadata about various knowledge assets. These can be used to connect and organize knowledge assets based on the explicitly defined metadata.

iii. *Derivative or Implicit* This form of correlation builds on the above two forms of correlation. Here, we leverage smart algorithms to derive, infer, classify, tag, index, store, visualize and report additional correlations.

3. *Knowledge Artifact Naming:* As mentioned earlier, the detailed or granular knowledge assets i.e. operational business rules and policies can grow combinatorially. The business users usually would like to introduce some mnemonic naming conventions to better organize and catalog the knowledge base. Hence, introducing capabilities to automate naming of newly introduced knowledge assets that adhere to user introduced naming conventions make sense. Further smart automated algorithms that manage the naming and cataloging of the knowledge assets especially when knowledge assets split, morph or converge, make the continued governance of such assets, over time, error and conflict free. Here are some of the explicit advantages or automation opportunities that can be realized by automated enforced mnemonic naming conventions.

(a) Infer stereotypical characteristics of knowledge assets based on the mnemonic name

(b) Projection and generation of *new* knowledge content based on mnemonic name of close affinity.

(c) Proactive discovery of semantically like knowledge assets based on mnemonic name similarities

4. *Knowledge Lifecycle Management:* From a systemic standpoint knowledge assets need to honor constraints placed by systems. In addition, knowledge externalization and development processes need to synthesize knowledge asset development and lifecycle with systemic software development, especially for emergent areas of knowledge externalization and management. In doing so, at a very high level, knowledge assets goes through the following main lifecycle phases:

(a) *Creation:* This is where the knowledge asset is generated.

(b) *Change:* This is when the semantics or content of the asset morphs.

(c) *Culmination:* This is where the knowledge asset loses relevance and is retired or terminated.

Within an environment, certain knowledge assets, such as business rules and rulesets have their own miniature lifecycle, before they are utilized by the automated system. For example BRIDE [7], has the following lifecycle

(a) *Author:* The business rule is authored or edited within the BRIDE Guided Editor.

(b) *Translate:* The authored business rule is translated to a format that can be interpreted by an *Rule Engine* [8]. This action is implicit for the standard use cases within BRIDE i.e. the Business User does not need to explicitly translate the rule, but it is tied into the Authoring phase of the lifecycle.

(c) *Deploy to Sandbox* The overarching *Rule Package*, that contains the *Rule Packet*, that contains the *Rule*, is deployed to a safe sandbox, where the business users can test the rules.

(d) *Deploy to System* The overarching *Rule Package* is deployed to the System, where the operational business processes can consume the decisions, made by these rules.

It is a common practice for knowledge based systems in organizations to have different environments. Broadly the environments can be categorized into:

(a) *Production:* This is where the knowledge is applied to day to day operational business processes. New business rules and policies for established areas i.e. business decisioning services can still be developed here by the business users without any software or systemic development impacts. The BRIDE system supports this type of configuration, wherein the Business Rule authors enjoy such autonomy, wherein they can fully develop, test and deploy new operational knowledge assets *Rule Packages* [7], to the running production Claim Administration Platform.

(b) *Non-Production:* This is where the organization develops, tests and validates the effects of newly introduced knowledge on the overall system. For emergent areas of knowledge externalization, the process entails the development of a standardized set of *Business Vocabulary* [6], that are mapped to an underlying implementation model, that integrates well with the other systemic components. Non-production environments can vary in number and purpose depending upon the organization's software and automation capability development processes. For example, here is a list of plausible non-production environments:

i. *Production Dry-run and Training Environment:* Intended for the Business Users to run live simulations, where they can do large scale application of knowledge without impacting live production business processes.

ii. *User Acceptance Testing Environment:* Intended for Business Users to run full scale end to end software release testing regiments, applying emergent areas of knowledge externalization and applying existing large knowledge bases with large scale impact changes.

iii. *Integration Testing Environment* Intended for component level integration testing of new and existing knowledge bases with systemic components.

iv. *Development Environment* Intended for the development of business vocabulary and unit testing it's effects in a limited sense.

Finally, as knowledge assets take birth in different environments i.e. *Production* or *Non-Production*, there is a strong need to be able to migrate these assets from one environment to another in a safe and secure manner, without loss of integrity and fidelity. The BRIDE system [7], supports these capabilities in full, which enable the business knowledge workers to autonomously migrate and administer these knowledge assets.

5. *Knowledge Training:* It is crucial to have succession planning amongst knowledge workers, to avoid large scale dissipation of knowledge. With this capability the Knowledge Management System, uses intelligent foundations 1, 2, 4, 5, 8 and 10 described in 2.4 to absorb knowledge topics about the use and context of knowledge assets, to fuzzily discover, classify, correlate, disseminate and analyze language, learn and recommend actions to the knowledge worker in a proactive fashion.

3.3 Automation

As the externalized knowledge bases, grow, evolve and diversify within the organization, there is a strong need to *automate*, aspects of analysis, management and lifecycle management. We will now explore the intelligent capabilities needed to support this.

There are several tasks in the lifecycle that the knowledge workers have to do to externalize and create knowledge assets and related collateral. The biggest task is the process of authoring business rules and policies. Business Rules in particular are more challenging, for the following reasons:

1. The business logic captured by a single business rule could be complex and if not authored properly will not enforce the policies accurately or worse, introduce errors in claims processing and adjudication. Another consequence is they could introduce unforeseen loopholes that can be exploited by Fraud, Waste and Abuse scenarios.

2. There could be a high number of business rules due to combinatorially explosive sets of conditions. The knowledge workers have to expend significant analysis effort to analyze if there are gaps or conflicts in the logic and implementation. As a consequence, there could be a lot of duplicate, equivalent or subsumed business rules that get created over time, by knowledge workers, as there were no sophisticated discovery mechanisms present to discover them.

3. The business rules need to be carefully assembled into sets of rules, to form executable rulesets.

Many of the rules in a ruleset can have overlapping conditions and prioritization of rules within a ruleset matter. Between business rules in a ruleset there could be partial or complete overlaps of logic called subsumption. The knowledge workers need to make sure that these are minimized and restricted, only allowing some legitimate partial overlaps.An error in configuration of these rulesets causes errors in processing. The BRIDE system [7], provides a sophisticated system of configurations such as *Rule Packages* and *Rule Packets*. The Rule Packages are deployed as executable rulesets, that can be executed by a Rule Engine [8].

Here are some of the more fine-grained use cases within the *Automation* capability.

1. *Automating Conversion:* Consolidation and Digital Transformation are driving organizations to consolidate and transform their business operations. Within the healthcare payor space, healthcare insurance companies are seeking to move their operations to either:

   (a) Homegrown healthcare administration platforms of healthcare insurance companies.

   (b) Commercially available healthcare administration platforms.

   The process of mining, converting and automating the knowledge i.e. Business Rules and Policies, of an insurance company on to a new benefits administration platform, is a risky, time-consuming and expensive process. There is a high risk of failure for the business and if not implemented accurately, there are hidden and ongoing costs introduced due to sub-optimal claims utilization, which can run the company out of business. Traditional methods for mining the knowledge from legacy systems [9] are manual, subjective and error-prone. The conversion process is dependent on multiple documented knowledge sources and is heavily reliant on knowledge workers who have had prior experience with the systemized knowledge, within the legacy platform. The challenges posed by traditional manual methods are:

   (a) It is dependent on knowledge workers intimately familiar with knowledge sources in the legacy platform.

   (b) It is ad-hoc and situational to the conversion project or customer.

   (c) It is time-consuming, typically a couple of years or more.

   (d) It is labor intensive, i.e. needs focused effort from a dedicated team of skilled knowledge workers.

   (e) It is not scalable to handle conversions of large magnitude or multiple parallel conversion efforts.

Partially automated approaches to *mining* information from legacy platforms entail, writing customized conversion programs/scripts that perform extraction and transformation of the knowledge to a mapping schema or file. The knowledge workers can then, manually analyze the data in the mapping data source and manually author the knowledge assets, into the target platform. Unfortunately, this again poses the same challenges except for challenge 1a, which is automated through the conversion program.

This is where more comprehensive and intelligent automation capabilities help solve the problem. As a case-study, using intelligent automation capabilities, the conversion effort was dramatically reduced from two or more years to under six months. The case study leveraged building automation capabilities that relied on an ensemble of *intelligent foundations* viz., 1, 2, 3, 8, 5 and 9, from 2.4.

Figure 10, depicts the steps to automate the mining and conversion of knowledge.

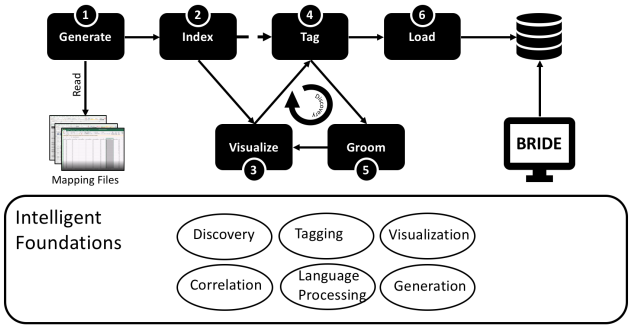

Figure 10: Automated Conversion Process

The conversion automation process is described through a sequence of six steps described below:

(a) *Generate:* This is the first step, that analyzes the conversion data in the Mapping File and generates business rules, organizing them into rulesets, which for BRIDE [7] entail, organizing them into *Rule Packages* made up of reusable *Rule Packets*, containing the *generated* business rules. The generation algorithm follows the structural organizational rules mandated by BRIDE to stereotype the packets and rules with the appropriate *Treatment Category*. The generated artifacts are assigned a generated systemic naming convention in this step. The complex normalized data in the mapping files are put through a sequence of file transformations.

(b) *Index:* The intermediate data that is generated by the above step is then loaded in an ElasticSearch database, which is a search engine based on the Lucene library, to enable

them for easy and fuzzy discovery. This enables the intelligent foundation of *Discovery*, for the steps detailed below.

(c) *Visualize:* Once loaded, custom data drilldown visualization programs aid the knowledge workers to analyze and proof the generated knowledge assets. In this step we use intelligent foundations of Visualization, Discovery and Correlation..

(d) *Tag:* In this step, specialized algorithms analyze the generated business rules and elicit important parametric data to tag the knowledge asset. The two fundamental intelligent foundations used here are Tagging and Language Processing.

(e) *Groom:* This is the phase of feedback for the algorithm to learn from knowledge workers, more specialized scenarios, to enable more accurate auto generation of knowledge assets. In addition, this is a process that is well integrated into the overall conversion capability to allow the knowledge workers to work collaboratively with the automated conversion process.

(f) *Load:* This is the phase, where the generated rules are loaded into the BRIDE knowledge platform, into the *authored representation* [8]. Techniques such as rule parametrization (i.e. the variant information from rules are externalized as rule parameters) and mnemonic rule template selection are used to select the appropriate rule template and the parameters are substituted using macro substitution. Alternatively, more sophisticated intelligent builder approaches can be employed, wherein the authored representation for the rule can be generated based on structure of the generated rule, which can be gleaned by a command pattern generated during the *Generate* phase. Finally, the knowledge workers can resume normal knowledge management activity with the generated rules within BRIDE.

Figure 11, depicts the anatomy of an index for a Rule. This is created during the *Index* process, from the outputs generated from the *Generate* step. In addition to the generated rule, the additional metadata generated during the *Tag* phase sets the stage for the subsequent grooming and accurate and automated loading into BRIDE knowledge base.

Figure 12 depicts the anatomy of an index for a Rule Packet. The basic structural data for the Rule Packet is created during the the *Generate* phase. The intelligent conversion algorithm blends in manually authored rules by knowledge workers with the generated rules, to construct a fully functional subset of rules that constitute a Rule Packet for a given Treatment Category. Further during the *Tag* phase, there is an abstraction phase of the algorithm that filters only relevant or important tags from rules that are emblematic of characterization for the Rule Packet. Lastly, the algorithm generates a descriptive name for the Rule Packet that facilitates easy discovery for knowledge workers for higher level activities such as contract implementations.

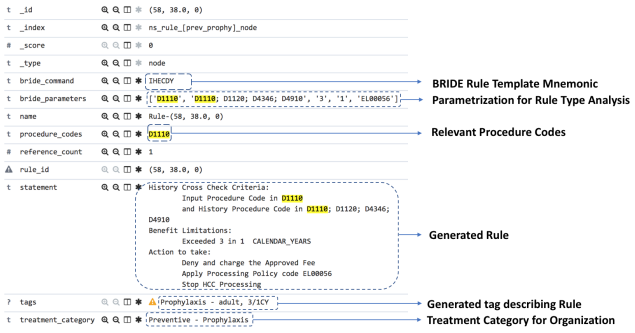

Figure 11: Anatomy of a Rule Index

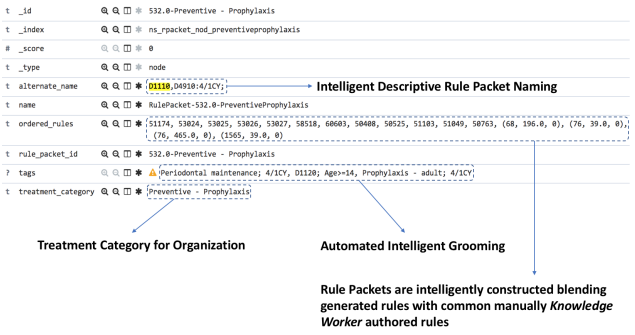

Figure 12: Anatomy of a Rule Packet Index

2. *Automating Testing* With rapid growth of knowledge assets within the platform, especially in the form of operational business rules, there is a compelling necessity for having an intelligent automation technique that can analyze rules within a ruleset and generate appropriate test scenarios. For example within the BRIDE [7] framework, there are over 17,000 test cases in just one area of adjudication rules. These are test cases that have been created by knowledge workers during their testing phase of knowledge management. A significant chunk of these test cases were generated from live claim processing data scenarios. However, with a strong and steady growth of operational business rules, more sophisticated techniques are needed to conquer the scale problem. Here are some use cases that explain this capability further:

(a) An automated test scenario creation algorithm intelligently interprets semantic tags about the rule parameters collectively con-

tained within a ruleset to generate test data and scenarios.

(b) As new rules are authored and included into a ruleset, an algorithm amends or augments test scenarios to test out new semantic consequences of the change.

(c) As knowledge workers decide to edit rules, an algorithm that can analyze the impacts from a test scenario perspective interactively communicates consequences of the change to the knowledge worker. This is a capability that can grow in the degree of sophistication.

3. *Automating Migration:* As we discussed in 4, it is typical for knowledge workers to manage knowledge assets across multiple *production* and *non-production* environments. Within BRIDE, select knowledge workers can elevate their role to an administrator, to perform critical administrative functions of knowledge asset management. *Migration* of knowledge assets across environments is one such function, that needs to be done with care.

   Here are a few challenges with administering this function, where the administrator is performing these tasks manually.

   (a) The number of physical environments can grow within an organization, over time. With consolidation the number of knowledge tenants in a multi-tenant environment, further impact the number of environments to manage.

   (b) The number of knowledge assets to migrate across environments grow. This puts an increased burden on the knowledge administrator to keep knowledge assets consistent across environments.

   (c) Not all environments, especially not all tenants may share the same assets i.e. business rules, policies, business vocabulary, test scenarios etc.. This introduces increased complexity for the migration path of these assets.

   (d) Maintenance in target environments can impede or impact the migration of knowledge artifacts. This problem is very similar to supply chain inventory and inventory movement, within Supply Chain Management.

   (e) Associated management functions such as deployment need to occur in target environments, post migration. This puts an extra burden on the administrator to ensure that these activities occur in a timely fashion.

   Strong intelligent foundations can help with the automation of pieces of this important function. Here are a few of the scenarios, that can help intelligently automate this function and reduce the dependency and burden on the knowledge worker.

   (a) Tag and inventory knowledge assets with migration specific metadata that is human and more importantly system consumable. This can enable intelligent algorithms to proactively audit, report and govern knowledge assets, migrating to target environments. Here intelligent foundation 2 is primarily leveraged.

   (b) Restrict the migration of knowledge artifacts to target environments that are undergoing maintenance or is being reserved for some focused activity. This prevents undesirable collisions and interference with activities in the target environment. Here the intelligent foundation 6 is leveraged.

   (c) Automatically include related artifacts impacted by the inclusion of a knowledge asset within a migration manifest. Knowledge Assets are intricately related, sometimes explicitly and structurally, but other times through correlation as explained in 2a. Hence movement of such knowledge assets should do the necessary impact analysis to ensure consistency and integrity of the knowledge assets. Here intelligent foundation 5 is primarily used. In addition, intelligent foundation 7 can be leveraged when the inclusion needs to be reported or recommended to the knowledge worker performing the administrative role.

   (d) The *Automated Migration Assistant* participates as a *virtual knowledge worker* in the target environment, as described in 1e. Here the intelligent foundation 6 is leveraged.

4. *Automating Mass Changes:* Sometimes it is necessary to make large scale or *mass* changes to knowledge assets. For instance, a large number of business rules need to be changed because a key business policy changed or the semantics of a key business term changed.

   Through traditional methods, this would mean knowledge workers need to track down every single relevant knowledge asset that are impacted by the change and modify them to reflect the macro-change. A classic example of this are new yearly versions of the *Common Dental Terminology*, released by the *American Dental Association*.

   Here by leveraging all the 10 intelligent foundations, intelligent capabilities that automate making mass changes can significantly reduce human labor, erroneous edits and significantly reduce cost.

4 BRIDE Case Study

4.1 Background

Delta Dental of Michigan, Indiana and Ohio is the leading provider of dental benefits within the midwestern part of United States. The company has been in business for over 60 years and has witnessed a dramatic growth within the last decade. The reason for this dramatic growth is a highly automated and sophisticated benefits administration software platform, powered by BRIDE [7], a powerful homegrown, elegant Enterprise Decision Management System. BRIDE houses the company's growing pool of complex, externalized operational business rules which allows the company to automate the vast majority of it's claims adjudication process allowing it to scale it's business footprint to unprecedented levels, while keeping operation costs at an optimal level. The current metric for measuring this automation level is called *"Drop to pay"* or *"Auto Adjudication Rate"*, which is currently hovering at around 96%, which is an industry leading score.

To keep up with the fast growth, it was necessary for the BRIDE platform, at inception to introduce industry leading capabilities for surfacing full life cycle rule management functions, such as authoring, testing, deployment, migration, such that non-technical knowledge workers and subject matter experts could entirely manage these with little to no involvement form the IT Department. Over the last decade the BRIDE platform has kept up with innovation, by expanding the capabilities and staying a step ahead of the business needs.

The BRIDE ecosystem organizes its knowledge artifacts in a structured, highly reusable and componentized fashion. A logical view of the domain model for BRIDE at a high level is depicted in refbrideDomainModelFig.

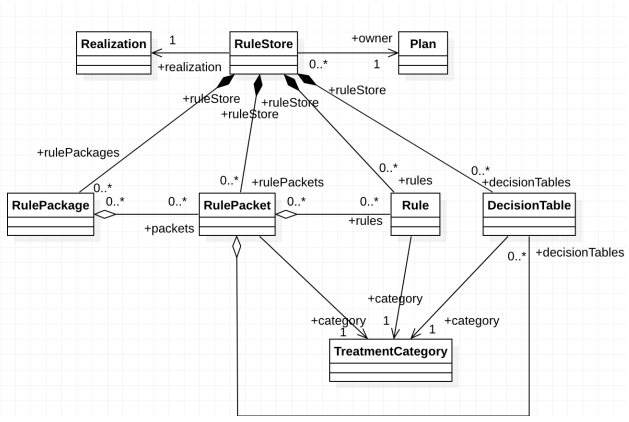

Figure 13: Highlevel BRIDE Domain Model

The core BRIDE constructs [7] are:

1. *Plan:* Represents a Dental Insurance Owner, that owns the rule artifacts.

2. *Rule Store:* A repository for storing rule artifacts, each rule store holds the reusable rule artifacts that can be reused within it, in a structured and constrained manner.

3. *Realization:* Represents an area of business functionality that require specialized terminology to externalize and articulate operational business rules using a structured vocabulary. There are over 30 areas of business functionality for the dental insurance domain so far, ranging from several detailed aspects of claims administration to billing, rating and actuarial applications. This is a growing body of knowledge as opportunities for automation and externalization are identified.

4. *Rule Package:* Represents an *executable* set of rules, that can be executed in a forward chaining, fact inferential rules engine [8]

5. *Treatment Category:* A mechanism to categorize finely granular rule artifacts. Within the clinical domains, the treatment category construct allows the business to categorize specialized clinical rules to literal clinical treatment categories as recommended by clinical standard bodies such as American Dental Association. For non-clinical domains, the treatment category construct is repurposed to category sub functional constituent components of processing.

6. *Rule Packet:* Represents a subset of rules for a given treatment category. Each Rule Packet is stereotyped for a treatment category and should only contain Rules of that same treatment category.

7. *Rule:* Represents a reusable authored production rule (i.e. a rule containing conditions followed by actions) authored in a "Domain Specific Language" using an english-like vocabulary. It is also the most

The next wave of innovation within the BRIDE platform introduces the application of *Artificial Intelligence* techniques to effectively address a new, growing breed of current and anticipated challenges. The work done on developing some of these capabilities has gone towards shaping and developing the concepts discussed in this paper.

The approach to building this new wave of innovation, has been to implement a strong foundational architecture i.e. *"Intelligent Foundations"*. We will discuss these foundational capabilities, their motivation, the architectural choices and application, subsequent sections.

4.2 Discovery

"Ability to fuzzily discover diverse artifacts" As the number of rule artifacts have grown over time, in spite of the ability to reuse rules a lot of unneeded redundancy and duplication have proliferated causing the knowledge base of operational rules and rulesets to

bloat. A major reason for this has been attributed to *discoverability*.

Within the original architecture, the BRIDE system provided SQL based searches against a relational database backdrop of the BRIDE schema. With this, the knowledge workers could search for specific rules with key terms and vocabularies and see their association with rule packets and rule packages. This was a bottom up search. They could also search for Rule Packages with specific Rule Packets in their configuration. With this they could search for full or partial rule package configurations, generate a report and then drill down. In spite of these rich search capabilities, discovery was not sufficient to prevent the proliferation of redundant rule assets overtime. Here are the main reasons why this alone is not sufficient:

1. *Layered Reuse Complexity:* BRIDE uses a layered reuse paradigm for constructing Rule Packages that eventually translate to executable rulesets. While this approach in and off itself is a sound from a component reuse vantage point, the major complexity is the inability of the traditional search functions to get a comprehensive and 360°view of the Rule Package.

2. *Naming Complexity:* With the componentized approach promoted by BRIDE, the knowledge workers set about building reusable Rule Packets, which in essence were combinations of rules, within treatment categories. In the interest of providing meaningful names that described Rule Packets, the knowledge workers resorted to lengthy descriptive names that sought to summarize the semantics of emblematic rules contained within the Rule Packet. However, this approach is highly manual, lacks predictable standardization and is not sufficient to describe huge and complex Rule Packets.

3. *Variational Complexity:* The characteristics of specific clinical domains require blending of specific clinical terminology that by the very nature can lead to a combinatorial explosion of sorts. With the nuances and subtleties in books of business and the semantic authoring flavors introduced by different knowledge workers there were subtle variations of sequences of rules, individual rules that were introduced over time. Some of these were made deliberately to support the variational needs of the requirements. Yet, others were made unknowingly introducing inconsistencies in approach. These were challenging to discover.

ElasticSearch, is a search engine built on the Lucene library. Nowadays, it is a common trend with modern IT architectures to leverage this tool to enable and enhance fuzzy discoverability. Data can be loaded or *indexed* into ElasticSearch as JSON (JavaScript Object Notation) documents. Subsequently this data can be discovered through a textual search of terms or fields contained in the JSON documents loaded and the tool will return all documents that match or nearly match textual patterns searched.

With complex natural language rules, this enables easy discoverability of these assets in a fuzzy fashion, that traditional relational queries do not allow. But this alone is not sufficient as the knowledge workers not only need to discover individual rules based on key business terms and vocabularies, but they also need to be able to discover the connections between rule artifacts, their levels of similarity and the characteristics of their similarities. With that there are five intelligent foundations that need to be applied in conjunction to fully realize the benefits of *discovery*. How these intelligent foundations collaborate is shown in 14. To understand these relationships:

1. *Language Processing* is used to disseminate the textual data in policies and rules, filtering key business terms and builds important metadata for *Correlation*.

2. *Classification* runs advanced algorithms, leveraging data created by *Correlation* to build more detailed correlation data.

3. *Tagging* is the default mechanism for storing metadata generated during *Correlation* and *Classification*

4. *Classification* and *Correlation* builds the foundation for *Discovery*.

5. *Visualization* helps makes sense out of *Discovery*, especially when there is a large amount of interdependent, connected data.

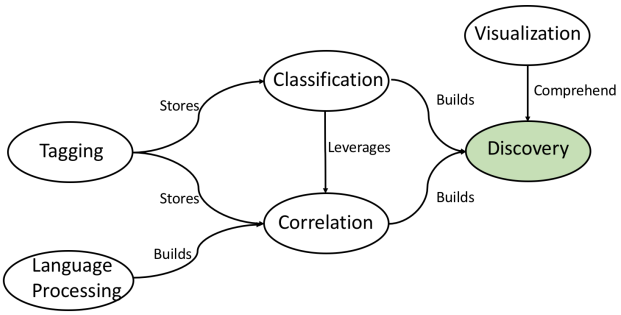

Figure 14: Collaborative Foundations for Discovery

4.3 Tagging

"Ability to tag or decorate knowledge artifacts with manual and generated metadata."

The basic implementational notion of a tag is to assign a key and description tuple to an artifact of interest. However sometimes, there can be more than one tag to decorate the artifact with. Therefore, it makes sense to introduce these key concepts:

1. *Tag Aggregation (Tagregation):* A Tag Aggregation is a composite structure of sub aggregations and Tags.

2. *Tag:* A Tag is simple key and description.

3. *Taggable Artifact (ITagArtifact)* A Taggable Artifact is any entity that needs tagging metadata.

The logical domain models for the basic tag constructs and taggable artifact constructs are shown in 15 and 16. The actual implementation of tags with the artifacts is more relevant when indexed into ElasticSearch for discoverability. A JSON representation of a Rule with a sample of extracted tags, used for discovery, is shown in 17. In this example, the tags for dental procedure codes used in the rule are, extracted to the tag "procedureCodes". Similarly, other useful correlational metadata could be extracted.

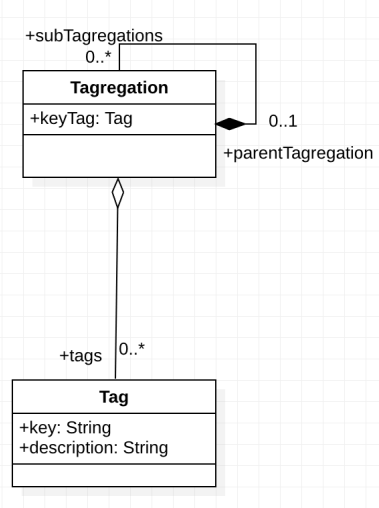

Figure 15: Tagging Domain

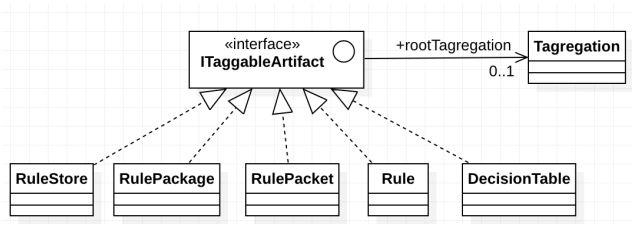

Figure 16: Taggable Artifact Domain

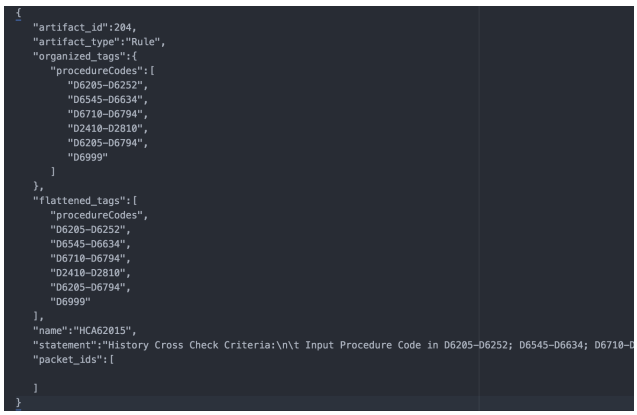

Figure 17: JSON of a Tagged Artifact

4.4 Visualization

"Ability to graphically visualize affinity between artifacts"

To enhance the discoverability of the knowledge assets data visualization is an effective method of analysis. Here a few different visualization techniques have been leveraged, with the correlation and classification data collected through tagging. Knowledge assets as a graph visualization with color coded edges to depict the different types of classifications, is depicted in 18. This is an effective way to discover common trends and patterns. The original workshop paper [1], outlined six different affinity classification measures, which are shown in this visual with different colors. This kind of visual is very useful for identifying common clusters of affinitive rules within an area and the nature of their affinity. There has been significant research and work on the efficacy of applying topological data analysis techniques, to use cases within healthcare [17]

Figure 18: Color Coded Clustered Affinity Visualization

An edge configuration for the same visual is shown in 19. This shows the nodes on the circumference and different colored edges criss-cross connecting the different nodes which represent the rule artifacts. The advantage of this visual is that useful, metadata can be shown on the edges, on hover that aid immensely during knowledge analysis.

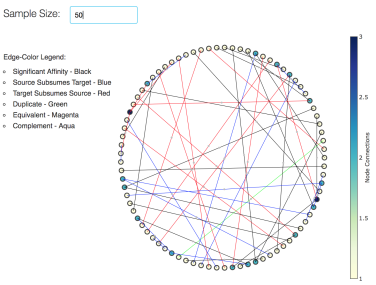

Figure 19: Color Coded Edge Affinity Visualization

A common themed rule asset, is picked out from a crowd of assets, in 20. This form of visualization is useful in identifying an emblematic asset for a certain area.

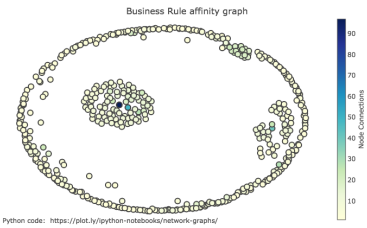

Figure 20: Clustering to identify baseline rule

A term cloud visualization is shown in 21. This is a very useful visualization for performing impact analysis based on key term correlation. In conjunction with correlation of key terms across rule and knowledge assets, it is possible to do end to end impact analysis.

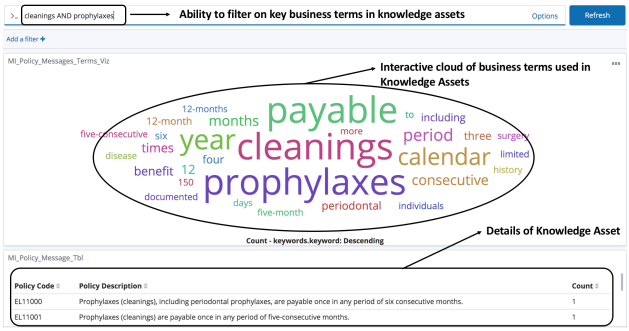

Figure 21: Interactive Term Cloud Visualization

A few observations when building data visualizations are:

1. It is useful to provide a way to filter based on category. This helps with narrowing sample sets and separation of concerns.

2. It is useful to provide a way to configure the size of a sample set. With certain types of analysis the knowledge workers are seeking understand common trends, to make informed decisions about management and governance.

3. It is useful to provide a mechanism for searching or filtering for combinations of terms. This aids in narrowing down the analysis. The visualization in 21, provides this mechanism.

4. It is useful to provide a detailed drill down capability on visualizations where possible. This allows the knowledge worker to identify the concrete knowledge assets with a single visual.

4.5 Classification

"Ability to classify artifacts based on characteristics"

Several sophisticated algorithms were developed to study the affinities between business rules and to classify them. Techniques to classify rule and knowledge assets ranged from naive simple bag-of-words to more sophisticated variations that combined bag-of-words with correlation to relevant master data assets. In the original workshop paper six different classifications were developed, comparing business rules, which were:

1. *Duplicate:* When two rules were exact duplicates with different names. These were top candidates for elimination and consolidation.

2. *Equivalent:* When two rules were semantically the same but had conditions that were in a different order. The classification algorithm here was shallow and only checked for conditions or actions in a different order. Deeper semantic analysis of rules will be able to identify equivalent rules beyond these narrow confines, creating the opportunity for better cleanup of these redundant rules.

3. *Complement:* These were specific to this area of rules where clinical procedures were complemented across the input and history procedures, to provide a complete adjudication coverage. Often times, claims are submitted out of order and these kind of rules analyze logical completeness. The scope for these can be expanded to cover other clinical criteria such as teeth, tooth surfaces etc. in the future. Further this pattern can be applied to other functional verticals to analyze logical completeness.

4. *Subsumption:* Here there were captured as two classifications i.e. Source subsumes Target and Target subsumes Source. Here again deeper semantic analysis can analyze more subtle aspects of subsumption, like analyzing inclusive procedure patterns etc. In the absence of these deeper analysis capabilities, come subsumptions could miss this classification.

5. *Significant Affinity:* Here the algorithm used a threshold of score similarity to identify rules that were closely affinitive with each other. However this was pretty effective and did capture rules that were significantly affinitive with each other.

4.6 Correlation

"Ability to build correlation between different artifacts"

This has been a centric intelligent foundation, for connecting different concepts together, to perform associative analysis and impact analysis. The implementation of correlation relied on algorithms, that analyzed, indexed and decorated knowledge assets with metadata in the form of tags and/or first class correlative attributes, in specific cases. Within the BRIDE case study we implemented correlation for three forms of correlation and connectivity as explained in 2c. Here are a few architectural aspects to consider, while integrating this intelligent foundation within the Knowledge based system.

1. Correlative algorithms need to run close to point of knowledge. There is an inherent risk of running correlation algorithms in a batch fashion

as morphing data conditions could either miss certain temporal correlation or miss transient changes that can be critical information to capture.

2. The initial correlations should be captured at well designed intermediate sink points and should be verbose enough to not miss seemingly inconsequential details, that might add value at a later point. Intermediate logging could be an option for such an architectural implementation. Generating and storing changes as events is another option.

3. The correlation algorithms should be designed in an idempotent fashion where possible, especially with the dimension of temporality. There are use cases that might require the regeneration and storage of correlation, especially during software upgrades and patching.

4. Even though, for the most part correlation of knowledge assets do not include PHI (Personal Health Information) or PII (Personal Identification Information), there are some corner cases where indirect correlation of operational data that have such concerns might crop up. One example of this is the reverse engineering capability of BRIDE for test cases from live data. In such cases de-identification and regular purge of such correlation need to occur to address security concerns.

4.7 Event Processing

"Ability to generate, process and react to system and user events, within the platform"

This intelligent foundation forms the basis of a very important infrastructural capability. As stated earlier, it can be leveraged for Collaborative Authoring. But it can also be leveraged for Correlation and Connectivity. Within the BRIDE case study, this is currently on the roadmap but has not yet been implemented. However, a lot of work is projected on the roadmap to innovate this intelligent foundation, especially for capturing fine grained operational execution metrics to aid correlation, for machine learning and machine training purposes.

4.8 Recommending

"Ability to recommend action to take based on correlation between artifacts"

Within the BRIDE case study this was implemented as an explorative proof of concept, wherein the system could recommend close rules based on the current authored content. While this could be foreseen as a useful feature in and off itself, this is barely scratching the surface. The BRIDE case study, hopes to leverage this intelligent foundation for deeper more sophisticated scenarios, which can be the subject of another paper.

4.9 Language Processing

" Ability to absorb, disseminate and score keywords fro textual content/documentation at detailed inflection points"

Within the BRIDE Case Study, this intelligent foundation has been used to disseminate policy descriptions, and procedure code descriptions, to correlate business rules and other artifacts such as Rule Packages, Rule Packets, Rules, Benefit Plans etc, with key term correlation. The Language Processing capabilities with Python and NLTK give a good starting point to filter out key business terminology, which can then be used to correlate. Again there is not more to report here from a case study perspective as we are in very early stages of fully realizing and leveraging this intelligent foundation.

4.10 Generation

"Ability to generate new content" Within the BRIDE Case Study, this intelligent foundation was used to automate conversion as discussed in 1. However, this is just one use case or application of this intelligent foundation. However, there are some other scenarios where Generation can help.

1. Perform mass changes to rules. As mentioned earlier the ADA, publishes a new version of the CDT every year. With the ability to generate new or change existing content, based on high level heuristics, it will be possible to automate the mass changes to Rules.

2. Generate new rule templates based on mnemonic naming patterns that are generated based on high level heuristics. Within the BRIDE Case Study, this was exercised in a limited purview, as new rules had to be generated based on the conversion data.

3. Automatically generate test cases based on rule content. Based on semantic analysis of knowledge and rule artifacts, intelligent generators can automate the act of building test cases on the fly and saving them for regression purposes.

4.11 Learning

"Ability to learn from data patterns and from human feedback"

This has not yet been implemented within BRIDE, but it is there in the roadmap. This is an area of future work and builds on the other intelligent foundations.

5 Automation challenges for Knowledge-intensive systems

In this section we will consider some of the challenges around automation, for knowledge intensive systems. In 3.3, automating the task of authoring was identified as a the biggest opportunity for automation. Within

the BRIDE case study, automating conversion was one of the biggest opportunities. Automating the process of knowledge acquisition, reduced the time effort from 2 years to a few months. However, there are some inherent challenges with automation of the rule mining and authoring process. They are:

1. *Standardization :* For an automated rule conversion process to work repeatedly, the data for that area of functionality needs to be standardized into a well thought out canonical format.

2. *Specificity:* It is not uncommon for the quality of knowledge mined out from legacy blackbox systems to contain a lot of noise and inconsistencies that are specific to the legacy system. Further the nature of the inconsistencies can vary across different target systems and conversion initiatives. The automation processes while being streamlined should allow for custom transformation rules that can be externalized and customized for each conversion effort.

3. *Semantics:* The interpretation of standard benefit clauses implemented in rules in the legacy source system could have different semantics and might need specialized handling or transformation into the target system's knowledge base.

4. *Inconsistencies:* Sometimes there are misinterpretations of documented high level policies and contracts in the source legacy system, that are being converted. Technically one point of view amongst knowledge workers is to rectify these during the conversion process. Yet, this can have dire behavioral regressions on the target system, post-conversion. These kind of situations, need to identified during the automated conversions, traced back to the source and have a good explanation facility. Whether this method *can* be formalized consistently to bolster the efficacy of such automation efforts, remains a tantalizing proposition.

5. *Universal applicability:* For the BRIDE case study, the automated mining and generation process is fairly well established for a specific area of adjudication rules, that had the most number of rules and artifacts, that could not have been authored manually. But, whether this automated process can be streamlined and applied universally to other areas of rule mining is the subject of future work. This could be an area of research in the future.

6 Future Work

The paradigm of *intelligent foundations* to knowledge based systems holds great promise and potential. Especially within healthcare these techniques are making some significant differences. However there are areas that need further research and elaboration. Current state of the art AI techniques involve an ensemble of methods. Intelligent Foundations, strives to formalize and document a set of reusable patterns, language and processes to effectively apply them on a large and universally diverse setting. This paper was born out of a case study to address seemingly unsolvable and hard to automate and humanly unscalable problems. Here are some high level areas for future work.

1. *Universal application of techniques:* One area of future work is to continue the rigorous formalization of the techniques described here for universal application to other diverse verticals.

2. *Identifying more intelligent foundations:* While this paper attempted to do a reasonable job in identifying key intelligent foundational capabilities and building a framework for intelligent knowledge base systems, there is a significant opportunity for more research and elaboration, to further refine and enhance this concept and framework. Future work should continue to investigate other intelligent foundations that can introduce other intelligent capabilities that make the reality of a *virtual knowledge worker* real.

3. *Exploration of intelligent capabilities:* While this paper, outlined a few of the capabilities that can be built atop these intelligent foundations, there are more to be discovered and documented. This will motivate AI researchers to apply techniques to effectively solve the one real problem i.e. make healthcare cost effective to the general populace.

4. *Automation of conversion and generation of knowledge content:* Lastly, this is a major challenge as current methods are fairly ad-hoc, human and expert intensive. While prevalent data science methods and machine learning techniques seek to solve *"well defined"* problems, the challenge of replacing or augmenting the loss of a human subject matter expert by *emergent* system capabilities is an alien concept. The automation of conversion, rule mining and generation holds great promise and should open up rich areas of research.

7 Conclusion

As stated earlier, this paper came out of a case study, but introduces concepts that hold great potential. The work motivating this paper is a project to modernize and improve the *state of the art* of the BRIDE platform. The case study for automation and generation of rules and knowledge artifacts into the BRIDE platform has been instrumental in practically implementing and proving out a majority of the *intelligent foundations* discussed in this paper. The primary goal has been to, introduce elements of Artificial Intelligence at a grass root level that can provide an ambitious shift in capabilities. *Intelligent Foundations for Knowledge*

Based Systems, provide a perfect foil for solving the giant problem of generational shift, which seems to be driving Digital Transformation.

Conflict of Interest The author declares no conflict of interest.

Acknowledgment The author would like to acknowledge the executive leadership at Delta Dental for sponsoring and fueling the innovation, and for their continual commitment and support for the BRIDE platform, which remains a source of inspiration and innovation to the organization.

A B S T R A C T

This paper is an extension of work originally presented in 2018 Global Smart Industry Conference (GloSIC). Researches are devoted to the development of Smart technology for complex objects control and prediction on the basis of a distributed Honeywell DCS control system of the TengizChevroil enterprise using the example of a technological process of medium pressure gas cleaning. The article describes how on the basis of the multi-algorithm approach there was developed a modified algorithm based on modern artificial intelligence methods in order to select informative features (principal component method, Random Forest algorithm, particle swarm algorithm) and artificial immune systems (clonal selection) solving the image recognition problem and predicting the state of a complex control object. There was conducted a comparative analysis of the simulation results using the example of real production data (daily data of sensors from an average pressure absorber).

1. Introduction

Nowadays, the efficiency of industrial enterprises depends on many factors: material and technical support (installation of modern production equipment, modernization and reconstruction of the existing technical base), economic factors (growth of production and raw materials costs), management factors (information support for decision-making), and etc [1]. Therefore, modern researches in the field of development of automated complex objects control systems are aimed at increasing the reliability and at reducing the influence of various negative factors on the production process.

The implementation of modern Smart technology enables the possibility to improve production by effective prediction of the technical state of the equipment and the timely resolution of problems at the stage of their occurrence in real time. A characteristic feature of the complex objects control is the need to process a huge array of production data, as well as prediction and decision-making under the condition of parameters uncertainty.

In order to solve such problems at the complex objects control process, there were proven modern methods of artificial intelligence with the following advantages: the ability to process multidimensional data, self-organization and relative ease of implementation.

Widespread use has control systems based on neural networks (NN). For example, in [2] there is presented the use of a decentralized robot control system based on a neural network. There were proposed four decentralized control systems which can identify the dynamics of the robot's movement. Training of each neural network is performed online using the advanced Kalman filter. The researches [3] are devoted to the development of a combined adaptive neural network and to the nonlinear prediction model for production processes control.

The effectiveness of the proposed method was tested on a system of reactors with continuous mixing. In work [4] there is presented a PID controller based on a neural network for the pH neutralization process control system. The classical PID control cannot adapt to changes in the process, and therefore a PID controller with a signal neuron was developed. The simulation results showed the reliability and adaptability of the proposed control system.

In addition to neural networks there are used swarm intelligence (SI) algorithms for complex objects control. For example, in work [5] there is presented the application of the

*Corresponding Author Zarina Samigulina, e-mail: zarinasamigulina@mail.ru
www.astesj.com
https://dx.doi.org/10.25046/aj040312

particle swarm algorithm (PSO) for the optimal choice of process control parameters. In researches [6] there was used an ant colony optimization at setting the PID controller for a conical tank. The proposed approach has shown better results compared to setting of a closed loop based on the Ziegler-Nichols method and to setting of a controller in a closed loop system. In work [7] there is presented the development of a control system for autonomous mobile robots based on a bee colony algorithm and a genetic algorithm. Researches [8] are devoted to applying the method of bacteria movement optimization at the development of a PID controller by a two-wheeled robot with a two-way movement mechanism for a working environment with limited space.

Also there is widely used an approach based on fuzzy logic for complex objects control. Another study a control system for mobile robots with nonholonomic wheels moving on a plane on the basis of a fuzzy controller in order to achieve a given trajectory of motion. The problem of rounding obstacles is considered. Parameters of PID controller are calculated on the basis of fuzzy logic. There are presented simulation results based on a real vehicle. The researches are devoted to cascade control based on a fuzzy PID controller for a conveyor for weighing materials. The article presents a non-linear model of a conveyor system of continuous weighing, taking into account the delay time of material transportation. There has been developed a PID controller based on fuzzy logic with two control loops: an internal speed control loop and an external mass flow control loop. The results of simulation and experiment show that the proposed algorithm for fuzzy PID control can improve the quality of material mass flow control in an industrial conveyor system of continuous weighing using a programmable logic controller.

In work [9] there is proposed an innovative approach for fuzzy control systems setting with low parametric sensitivity based on the Gray Wolfs Optimization Algorithm (GWO). The servo system is controlled on the basis of the Takagi-Sugeno-Kang fuzzy PI controller (TSK PI-FC). The GWO algorithm is used in solving the optimization problem. Article [10] is devoted to an optimized fuzzy-genetic algorithm (F-GA) for controlling the process of production of aluminum foam with open pores. The application of the F-GA method allows to take into account the uncertainty associated with the model and the statistical variability of the production process within one model.

Nowadays, the researches in the field of the use of the bio-inspired approach of artificial immune systems (AIS) for complex objects control are also promising. In work [11] there is presented AIS application at PID controller parameters setting for nonlinear control systems. Researches [12] are devoted to the development of a complex object control algorithm based on an adaptive artificial immune system. The simulation was carried out on the example of a reactor with a mixing function. The article [13] provides an AIS application for control a group of robots. The work [14] is devoted to the use of a meta-heuristic AIS for signal evaluation in identifying the contour of the angle control of an unmanned aerial vehicle. In the article [15] there is used the AIS algorithm for preliminary signal processing at detection of failures for autonomous underwater vehicles. Article [16] is devoted to applying the AIS approach (negative selection algorithm) in order to control the combustion process in the chamber with the implementation on the microcontroller. In researches [17] there was developed an immune reconfigurable controller based on four modules for the immune system modeling: the observation process, response, mechanism of memory and self-training. The proposed algorithm is able to detect drive failures and to provide failure-tolerant control for the systems with multiple inputs and outputs.

In addition to bioinspired methods, machine learning algorithms for complex objects control and solving the problem of identifying informative features have become widespread. The most promising is the Random Forest (RF) algorithm. For example, in [18], RF is used to detect defective plates by chemical characteristics in the production of semiconductors. The article [19] presents the use of algorithms for machine learning of RF, decision trees, etc. in heavy industry for analysis of large amounts of production data. The work [20] is devoted to the use of the Random Forest algorithm in sensor failures diagnostics. The algorithm is used to reduce memory requirements in the process of assessing the state of the equipment in real time.

Therefore, the analysis of the literature proves the relevance of the development of modern Smart technologies and prediction of complex objects control based on industrial enterprises using artificial intelligence methods.

The following structure of the article is proposed. The second section contains the formulation of the research problem. The third section presents the development of Smart technology for complex objects control and prediction based on the Honeywell Experion Process Knowledge System (PKS) distributed control system (DCS) and the approach of artificial immune systems; reviewed the operation of the DCS at the Tengizchevroil enterprise, and presented the general structure of the Smart technology. The fourth section is devoted to the development of a modified algorithm of artificial immune systems. The fifth section describes the multi-agent Smart system for complex object prediction and control under industrial operation conditions. The sixth section contains the simulation results. Description of a real complex medium-pressure absorber, its principle of operation, readings from sensors, etc. The simulation results are presented in the form of graphs, as well as a comparative analysis of the effectiveness of the proposed algorithms. The conclusion describes the main findings and a list of references.

2. Problem statement

Since the complex objects control with the presence of parameters uncertainty in the conditions of industrial operation is a time-consuming task due to the need to process multidimensional data in real time, the use of promising heuristic algorithms of artificial intelligence is important.

The research problem statement is formulated as follows: it is necessary to develop a modern Smart technology for complex industrial objects control based on a multi-algorithm approach. Within the framework of the multi-algorithm approach to synthesize a modified algorithm of artificial immune systems in order to solve the problem of prediction and control. In order to organize an autonomous, flexible and decentralized control system based on the proposed technology, it is necessary to develop a multi-agent Smart system for implementation in real production based on TengizChevroil enterprise, with the aim of working with Honeywell PKS distributed control systems.

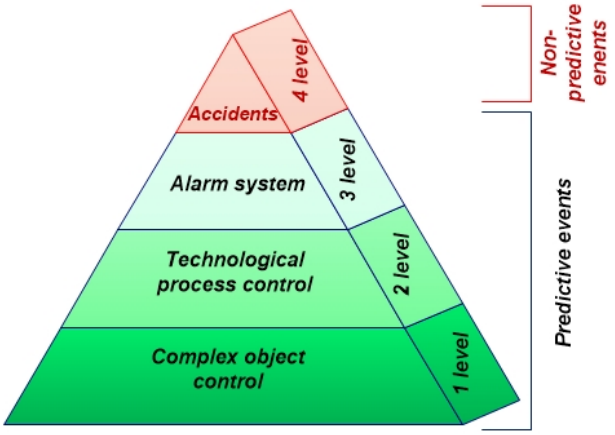

Figure 1: Honeywell DCS process control system with independent protection levels

3. Development of Smart technology for complex objects prediction and control on the basis of a distributed control system and an artificial immune systems approach

3.1. Distributed control system at TengizChevroil enterprise

TengizChevroil is the largest company engaged in the development and production of oil in the territory of the Republic of Kazakhstan together with the American company Chevron. In TengizChevroil there is used modern industrial equipment from Honeywell, in particular, Honeywell PKS distributed control systems (DCS). Nowadays, the Experion PKS system is the best in the field of distributed control systems and received an award from the magazine "Control Engineering". The company created a consortium for emergency situations control, aimed at exploring the causes of emergency situations and developing solutions aimed at reducing them. Therefore, the researches on improving the quality of equipment at the enterprise are relevant.

The Honeywell PKS distributed control system contains several independent levels of protection (Figure 1), designed to work with predictable and unpredictable events [23].

Predicted events include the following levels of independent protection:

1 level. Maintains "normal" operating conditions of the process. The distributed control system is engaged in the collection and processing of technological parameters, as well as their adjustment to ensure a given mode.

2 level. This level requires decision-making from the operator if the alarm is triggered and the first level is unable to maintain normal operating conditions of the control object.

3 level. This level indicates that the control object has left the "normal conditions" of operation mode and a controlled stop is required. The Safety Instrumented Systems (SIS) is activated. The SIS security system also includes: Emergency Shutdown System (ESD), Fire & Gas System (F&G), Safety Shutdown System (SSD) и т.д.

4 level. The level refers to unpredictable events, such as the occurrence of fires, gas leaks and other major accidents. A distributed system cannot predict the occurrence of such accidents, but it is designed for quick response and minimization of damage.

Information on the operation of the technological process is stored in the historical module (History Module, HM) of Honeywell DCS [23]. Developed Smart technology is aimed at working with the predicted events of the Honeywell DCS, with obtaining data for processing using the HM.

3.2. Smart technology based on Honeywell PKS distributed control system

Let consider the general structure of the proposed Smart-technology for complex objects prediction and control. The Honeywell PKS distributed control system consists of nodes described by controllers, operator consoles, control devices, data storage equipment, etc. The information transfer between nodes occurs through a local and universal control network. Information is collected in a historical module that is connected to a local control network, and a process history database is formed here.

The developed Smart-technology is designed to work with the predicted events of Honeywell PKS (Figure 1). The process history database containing current information on the behavior of a complex control object (readings from sensors, monitoring systems, etc.) is processed on the basis of a multi-algorithm approach (Figure 2).

Then a database of optimal parameters is formed for prediction and control on the basis of AIS algorithm, clonal selection. Depending on the nature of the processed data in the modified algorithm based on the AIS method, the most effective algorithm is selected that shows the best predictive result.

Further in the paper, as an example, we will consider the complex control object of the Tengizchevroil enterprise: a fragment of the Installation 300 for cleaning gases from acidic components [21].

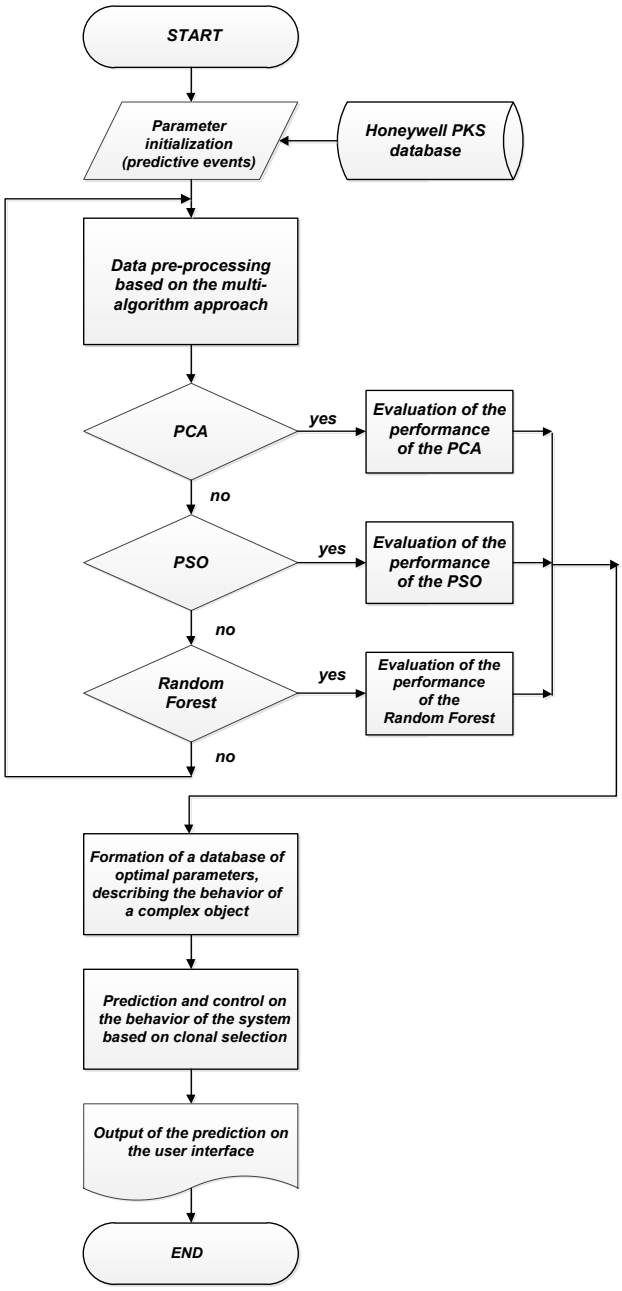

Figure 2: The structure of the developed Smart technology for complex objects prediction and control based on Honeywell PKS

4. Modified artificial immune algorithm based on clonal selection

Nowadays, the approach of artificial immune systems is a promising area of research. This method has the following advantages: adaptability, memory, dynamic arrangement of elements, ability to self-organization, etc. There are several main areas of AIS research: negative selection algorithms (NSA), immune system algorithms (INA), danger theory algorithms (DTA), and clonal selection algorithms (CSA) [22].

Let consider in more detail the clonal selection algorithm [23-25]. When a foreign antigen enters the body, special cells B-lymphocytes produce antibodies A_b. Each cell produces only one type of antibody that is relatively specific for the antigen. At binding antibodies (receptors), as well as using T-helper cells, the antigen stimulates B cells to multiply and to mature into plasma cells. Different cell divisions produce clones, by which there is meant a set of cells that are descendants from a single cell. Plasma cells most actively produce antibodies B-lymphocytes that divide rapidly. Antibodies A_b divide much more slowly. Lymphocytes can also differentiate in addition to plasma cells into long-lived memory cells - B - memory cell. Memory cells circulate through the body through the blood, lymph and tissue. In a secondary immune response, they can turn into large lymphocytes capable of producing antibodies with high affinity. These cells are pre-selected for the specific antigen that stimulated the primary response. The clonal selection algorithm is based on the following operations: selection, cell cloning and mutation. The selection procedure is carried out for cells with higher affinity and subsequent cloning, while other cells undergo a mutation process, which helps to improve their quality.

The clonal selection algorithm is presented as follows [23]:

Algorithm 1

Step 1. Generation of a set of possible solutions P, composed of a subset of memory cells M, added to the remaining population P_r.

$$P = P_r \cdot M \tag{1}$$

Step 2. Determination of the best individuals n, the population P_n based on the value of affinity (affinity).

Step 3. Cloning of n best individuals of a population, with the generation of a temporary population of clones C.

Step 4. Representation of a clone population to a hypermutation procedure, where hypermutation is proportional to the affinity of the antibody and antigen. Creation of a population of mature antibodies C^*.

Step 5. Repeated selection of improved individuals from the population C^* in order to form a set of memory M. Some members of the population P may be replaced by other improved population individuals C^*.

Step 6. Replacement of antibodies d by the new ones. Cells with lower affinity have a higher probability of replacement.

Modern methods of artificial intelligence are well established for the development of complex objects control systems, but unfortunately these approaches are not universal, and need to be customized for specific cases, taking into account the features of the object and the system parameters. The quality of forecasting and management directly depends on the processed data. The higher the quality of the data is, the more accurate is the forecast. Therefore, the application of the multi-algorithm approach is actual, within the framework of which the procedure of preliminary production data processing is carried out on the basis of modern statistical and intellectual algorithms. As a result of

research several methods are considered. Algorithms that will give the best predictive result are used for further research. Preliminary production data processing within the framework of the proposed Smart technology is carried out on the basis of the following approaches:

- Statistical approach - factor analysis and principal component method;

Statistical approaches are often used to process production data. In order to solve the problem of reduction of non-informative parameters during the study of complex industrial facilities, factor analysis (principal component method) has proven itself well. Among the advantages of factor analysis we can note the ability to analyze hidden (latent) relationships between parameters, as well as the relative simplicity of implementation [26]. As a disadvantage there should be noted the difficulties in the interpretation of the obtained results.

The algorithm of factor analysis consists of the following steps. The entire data set must be rotated counterclockwise, with the first axis associated with the maximum dispersion, and each subsequent one with the others. According to the results of the data rotation, the parameters that lie closer to the origin of coordinates are subject to reduction, as uninformative.

- Swarm intelligence - particle swarm optimization algorithm;

Let consider the concept of swarm intelligence (SI) [27]. The term SI was proposed by Beni and Wang in application to cellular robots and implied the collective behavior of a decentralized self-organizing system. Then it was used in the theory of artificial intelligence and describe the social behavior of living organisms (particle swarm method, ant algorithm, bee algorithm, wolf pack algorithm, bat algorithm, etc.).

In the proposed Smart technology, in the framework of the multi-algorithm approach, a particle swarm optimization algorithm is considered in detail.

A feature of the PSO method is that during each iteration, the solution is evaluated using the objective function to determine its suitability [28]. Each solution is represented as a particle in the search space. Particles move in the search space in order to find the maximum value of the objective function. As the particles move, each particle has a position in the search space, speed, and an individual best position. The PSO algorithm consists of the following steps [26, 27]:

Algorithm 2 Particle Swarm Optimization

Step1 . Initialization of a particles swarm.

Step 2. Evaluation of the suitability of each particle.

Step 3. Calculation of historically optimal positions of individuals.

Step 4. Calculation of historically optimal positions of the swarm.

Step 5. Speed and position update of particles according to the equation of speed and position. Repeat of this iteration until the stop condition is reached.

The speed of each particle is calculated by the formula:

$$\upsilon_i(t+1) = \varpi\upsilon_i(t) + c_1 \cdot r_1 \cdot (\hat{x}_i(t) - x_i(t)) + \\ + c_2 \cdot r_2 \cdot (g(t) - x_i(t)) \quad (2)$$

where i - particle index; ϖ - inertia coefficient $0.8 \le \varpi \le 1.2$; c_1, c_2 - acceleration coefficients ($0 \le c_1, c_2 \le 2$); r_1, r_2 - random values lying in the range $0 \le r_1, r_2 \le 1$; $\upsilon_1(t)$ - particle speed in time t; $x_1(t)$ – particle position in time t; $g(t)$ – the best swarm solution in time t.

The change in the position of each particle of the swarm is calculated by the following formula:

$$x_i(t+1) = x_i(t) + \upsilon_i(t+1) \quad (3)$$

The advantages of the PSO algorithm include: a simple implementation; small amount of adjustable parameters; parallel computations are possible; with a certain setting has the ability to fast convergence; no matches and mutations; has small requirements for computer memory and fast calculation speed; can be used in case when the representation of a mathematical model is impossible.

- Random Forest (RF) algorithm, etc.

Nowadays, the RF algorithm is a promising method of machine learning, capable of solving the problems of image recognition, prediction and selection of informative features [28]. A random forest is created on the basis of decision trees and has the same set of hyperparameters, while in RF the process of searching for the root node and the separation of object nodes is performed randomly [29, 30]. The more trees in the forest, the more accurate the simulation result are.

The advantages of the RF algorithm are following: there is no risk of retraining of the model; the algorithm has flexibility and high accuracy; no need to scale data; individual decision trees can be trained in parallel; data processing ability with a large amount of attributes, etc.

The operation of the Random Forest algorithm is presented below:

Algorithm 3 Random Forest

Step 1. Arbitrary selection of f signs from the total number of F signs.

Step 2. Calculation of a *node* among f features using the best separation point.

Step 3. Separate a *node* on child nodes using the best partition.

Step 4. Repeat steps 1-3 until reaching the value of the number one.

Step 5. Creation of a forest by n repeating of the steps 1-4 in order to create the n number of trees.

Based on the previously discussed methods, the modified AIS algorithm based on clonal selection can be described as follows (Figure 2).

Algorithm 4 Modified artificial immune algorithm

1. Connection to the historical module of the Honeywell PKS distributed system.
2. Data collection (readings from sensors) describing the behavior of a complex control object.
3. Formation of a database of system parameters.
4. Pre-processing of the obtained database, rationing, centering and filling in the missing data.
5. Formation of the optimal set of parameters due to the reduction of non-informative data based on the multi-algorithm approach.
5.1 Reduction of non-informative parameters based on the statistical approach, the principal component method.
5.1.1 Evaluation of the performance of the PCA algorithm.
5.1.2 Formation of a database of optimal parameters DB_PCA, describing the behavior of a complex object.
5.2 Reduction of non-informative parameters based on swarm intelligence, particle swarm algorithm.
5.2.1 Evaluation of the performance of the PSO algorithm.
5.2.2 Formation of a database of optimal parameters DB_PSO, describing the behavior of a complex object.
5.3 Reduction of non-informative parameters based on the Random Forest algorithm.
5.3.1 Evaluation of the performance of the Random Forest algorithm.
5.3.2 Formation of a database of optimal parameters DB_RF, describing the behavior of a complex object.
6. The solution of the problem of image recognition on the basis of clonal selection. Processing the received databases (DB_PCA, DB_PSO, DB_RF) and prediction.
6.1 Selection of an efficient algorithm that shows the best prognostic result.
6.2 Decision-making on the complex object control.

The proposed technology in industrial operation is most conveniently implemented on the basis of a multi-agent approach. Further there is presented a developed multi-agent Smart system for complex objects prediction and control.

5. Multi-agent object control Smart-system

Nowadays, multi-agent systems (MAS) are widely used in the field of industrial automation and artificial intelligence. A multi-agent system consists of independent agents with autonomy, decentralization, and flexibility. At developing complex industrial systems using MAS, the process of modeling and control is greatly facilitated. The paper [31] presents the MAS technology for organization of a flexible production process of customized products, through cooperation between companies, for the integration of heterogeneous production systems. Article [32] presents the use of a multi-agent artificial immune system for detecting and classifying network intrusions. Researches [33] are devoted to a decentralized multi-agent control system based on artificial immune systems. This system consists of the following target agents: the agent of self-organization, the agent of interaction, the agent of following specific goals and has the properties of flexibility, the ability of agents to work autonomously, the ability to optimally distribute the system resource, multifunctionality and self-organization.

Based on the foregoing, the development of a multi-agent Smart system for complex objects control at TengizShevroil for the integration of the developed modified artificial intelligence algorithms into production is relevant. Figure 3 shows the structure of the multi-agent Smart system.

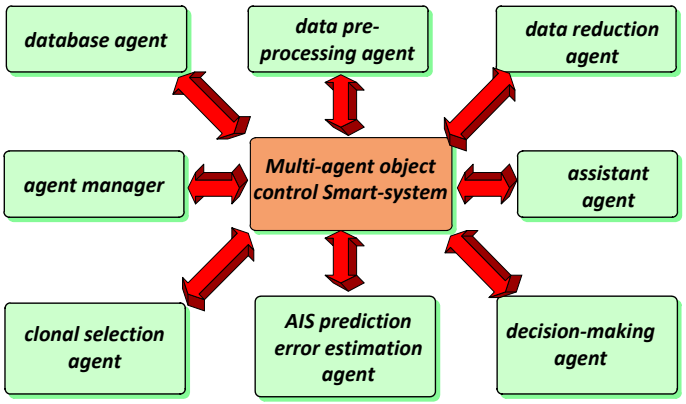

Figure 3: Structure of multi-agent smart system for complex objects control

Table 1 describes the main agents and their functions.

Table 1: Functions of agents of multi-agent smart system

Agent name	Function of the agents
Database agent	A database agent is needed to organize data readout from the Honeywell PKS historical module of the distributed control system. The generated database consists of sensors and monitoring systems, which allow to assess the state of the technological control object (normal operation, work with deviations, an accident, etc.).
Data preprocessing agent	The agent of preliminary data processing is responsible for rationing, centering, filling in the missing data in the database of parameters of the control object. The agent interacts directly with the database agent.
Data reduction agent	The data dimension reduction agent performs information processing based on the multi-algorithm approach for reducing non-informative parameters describing the behavior of a complex object.
Clonal selection agent	The agent implements the approach of artificial immune systems, the clonal selection algorithm for prediction of the behavior of a complex object.
AIS prediction error estimation agent	This agent is designed to select the algorithm with the best predictive result.
Decision-making agent	The decision support agent generates recommendations for process control based on the obtained data on the results of the

	prediction based on the modified AIS algorithm.
Assistant agent	The agent contains reference information about the algorithms and principles of data processing. Assistant functions are necessary for correct input of information into the system.
Agent manager	Agent Manager coordinates the work of other agents.

6. Simulation results

6.1. Technological process of oil gases cleaning from acidic components at installation 300

Researches were conducted on the real production data of the TengizChevroil company. The enterprise consists of several complex technological lines (CTL) and installations (Figure 4).

As the control object we will consider the Installation 300, which is intended for the petroleum gases cleaning from acid components: hydrogen sulfide, carbon dioxide and carbon dioxide. Acidic components are removed using a solution of diethanolamine [21]. The raw materials of the U300 are high and medium pressure oil gases coming from Installation 200 (U200) intended for gas separation. The final products of the U300 are: purified high-pressure gas entering the Installation 700 for fractionation; refined medium pressure gas returned to the U200 for compression; acid gas with a high content of hydrogen sulfide, is sent to the installation 400 for the production of sulfur. In general, the U300 consists of the following main components: high-pressure gas cleaning, medium-pressure gas cleaning, dietalomine regeneration, amine filtration, chemical supply, etc.

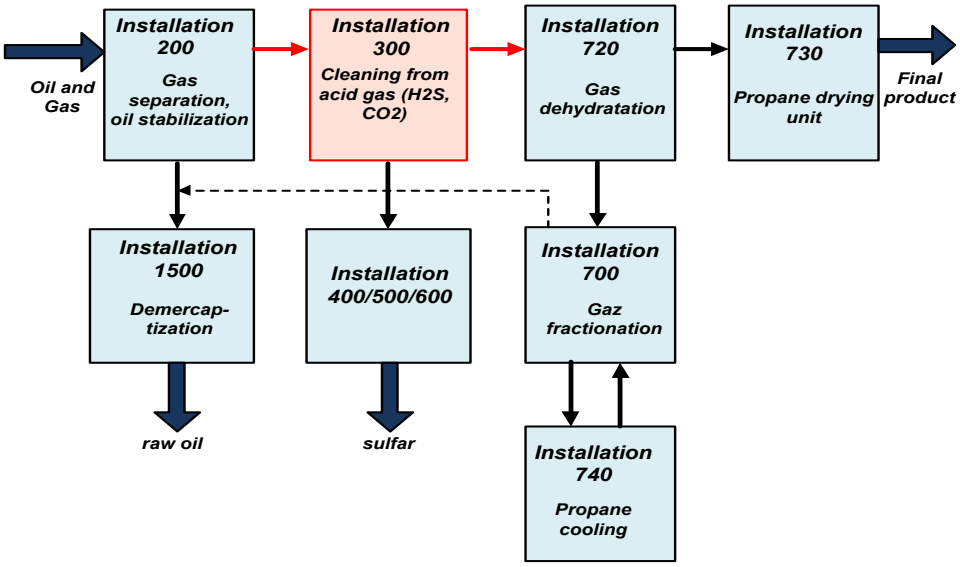

Figure 4: The structure of the Tengizchevroil enterprise

Table 2: Specification of medium pressure gas cleaning equipment

Designation on the diagram	Unit Name
D-302	Medium Pressure Absorber
F-328	Medium Pressure Separator and Coalescer
F-324	Medium Pressure Filter-Separator
F-320	Separator
F-319	Separator
F-303	Saturated Amine Tank
F-203	Low pressure separator
GC-200	First stage line
GC-201	Second stage suction line
EA-302	Regenerator reboolers (4 heat exchangers)
EA-304	Regenerated / saturated amine heat exchanger

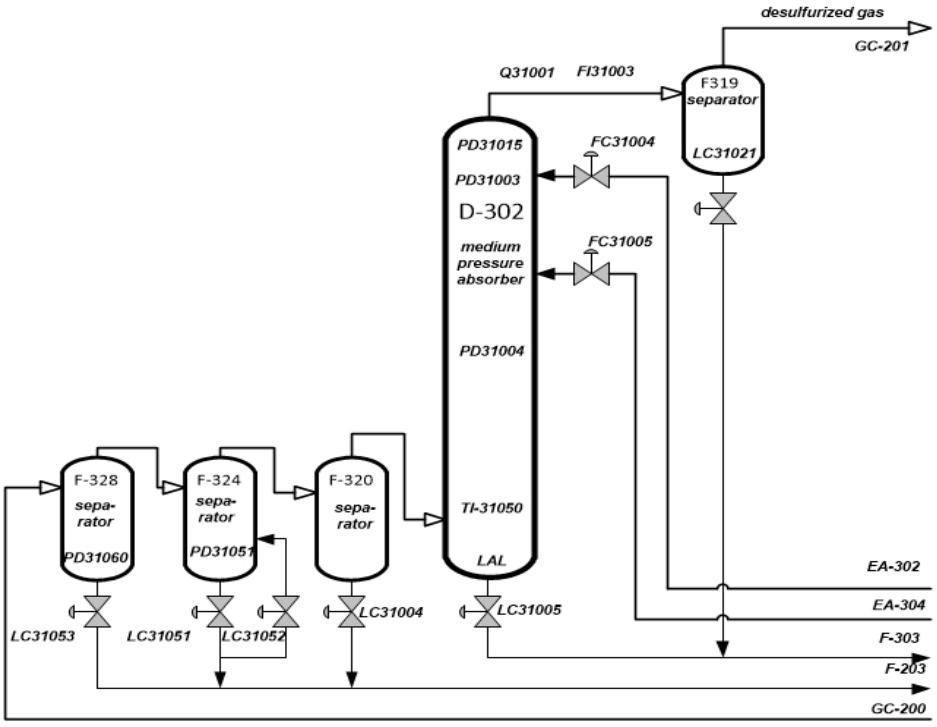

Figure 5: Fragment of the U300 technological scheme, medium pressure gas cleaning

The technological process of medium pressure gas cleaning in the absorber D-302 (medium pressure absorber) was chosen as a complex control object.

6.2. Medium Pressure Gas Cleaning of the Installation 300

Let consider a fragment of the U300, a medium pressure gas cleaning process (Figure 5, Table 2). The flow of raw gas enters the medium pressure absorber D-302 from the U200. In separators F-328, F-324, F-320 the hydrocarbon condensate is removed from the raw gas and transferred to the low-pressure separator F-203. This process is controlled by level controllers: LIC31053, LIC31051, LIC31052 and LIC31004.

Next, gas from the F-320 enters D-302. In the medium pressure absorber, the absorption process of H_2S and CO_2 also takes place due to the contact with two streams of the solution of regenerated diethanolamine [21], the temperature of which should not be lower than 540° in order to prevent condensation of hydrocarbons. In a medium pressure absorber, a pressure is approximately 24.5 bar. Gas temperature is measured using TI31050.

The absorber D-302 in the upper part consists of 11 valve plates, the pressure drops on which are measured using PDI31015, PDI31003 and PDI31004. In the case of a high pressure differential, plates may be blocked or foamed in the absorber. In order to prevent foaming, the antifoam injection points are located on the supply line of the regenerated amine in the column to the flow regulators: FIC31004 and FIC31005. The output of saturated dietalomine to the F-303 receiver is regulated by the LIC31005 regulator.

Next, the purified gas passes through an F-319 separator, where about 99% of the amine solution is removed in droplet particles of 10 microns and more in size and discharged to F-303. The output of the amine solution in F-303 is controlled by the LIC31021 level controller. Sulfured gas from F-319 is directed to the suction line of the second stage of GC-201. The consumption of diethanolamine in the upper section is regulated by the flow regulator FIC31004, and in the lower section by the FIC31005. The consumption of purified gas from D-302 is measured using FI31003, the concentration of H_2S is measured by QRAH31001. A total of 457 sensors are located on the U300, information from which is collected on the basis of the distributed Honeywell DCS control system. Sensor specifications are presented in Table 3.

As an example, let consider daily measurements from the U300 medium-pressure gas cleaning unit. A fragment of the parameters database is presented in Table 4.

6.3. Simulation of the developed Smart technology on the example of a complex object of the medium pressure absorber

Modern distributed control systems, such as the Honeywell DCS during the operation collect a huge amount of production data, the processing of which in industrial operation conditions is a complex task. Particular attention is paid to industrial safety, in connection with which there are different priorities of the alarms: emergency, high, low, logging and sending to the printer, writing to the log, sending to the printer and no action [21]. In this case, there are three alarms states: on, off, disabled. Therefore, for the application of the developed Smart technology there are selected 5 classes, depending on the state of the object for an alarm:

1 class. The alarm priority - emergency, the alarm state is on;
2 class. The alarm priority - high, the alarm state is on;
3 class. The alarm priority - low, the alarm state is off;

Table 3: Specification of sensors for the U300 circuit fragment, medium pressure gas cleaning block

…	…	…	…	…	…
800	74,379	51,453	220,456	…	25,648

4 class. The alarm priority - writing to the log and sending to the printer, the state of the alarm - prohibited;
5 class. The alarm priority - no action, the state of the alarm is prohibited.

Remark. The creation of classical mathematical models for complex control objects is a time consuming task. As a mathematical model for research, there is considered a time series consisting of records from the medium-pressure absorber sensors.

As a modeling environment, modern Rapid Miner software products and WEKA operators were used. Let consider a fragment of the DB_D302 database describing the state of the complex control object of the absorber D-302 at medium pressure gases cleaning on the U300 consisting of 12,000 copies of data. Figure 6 shows the visualization of results from the DB_D302 database sensors According to the 4th algorithm, the database DB_D302 is pre-processed.

Then, within the framework of the multi-algorithm approach, the PCA algorithm is applied in order to reduce the low-informative features that characterize the behavior of the complex control object *D-302.* Figure 7 shows the simulation results in the form of a graph of attributes ranking by degree of importance, as well as the visualization of the *DB_D302* database after the non-informative parameters reduction. Similarly, the reduction of low-information descriptors is performed using the Random Forest algorithm (Figure 8) and the PSO swarm intelligence algorithm (Figure 9).

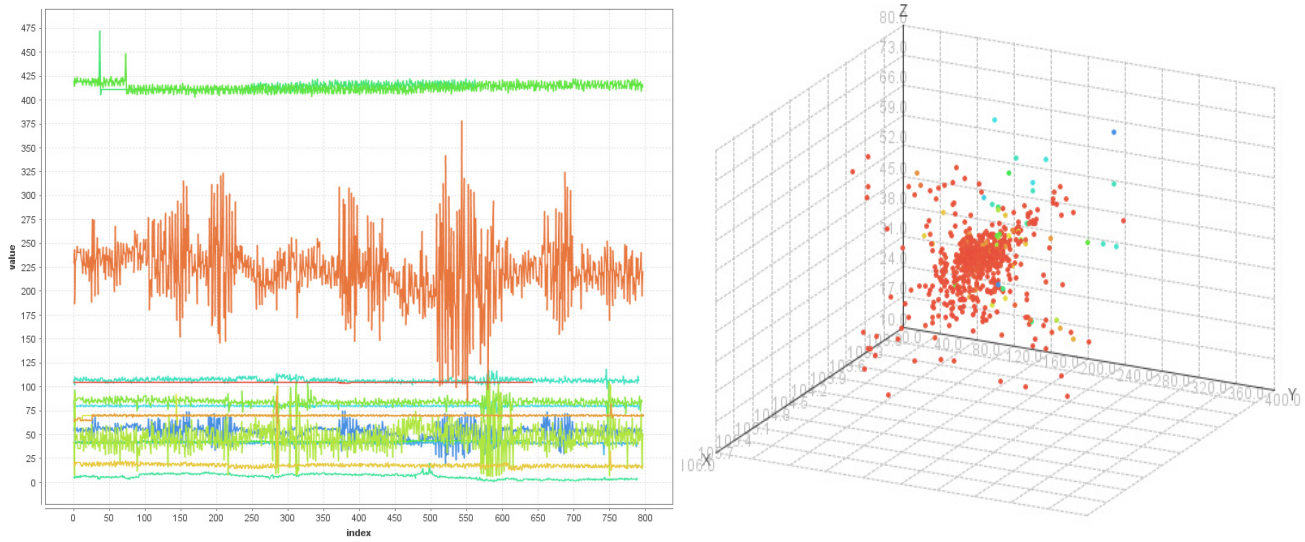

Figure 6: Fragment of *DB_U300_D302* database visualization in 2D and 3D form

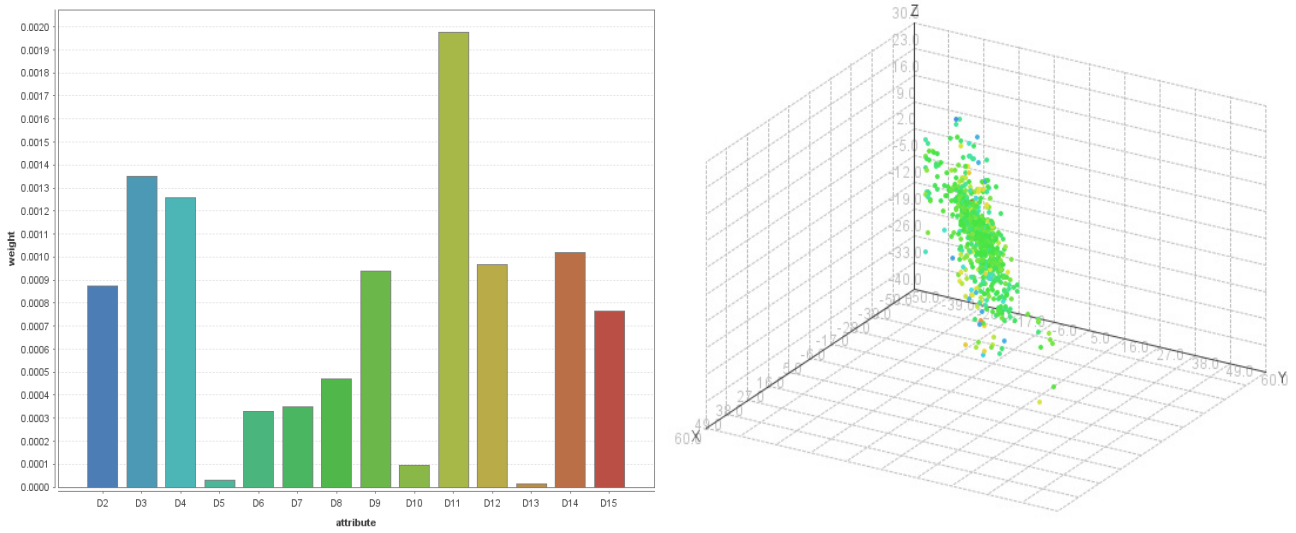

Figure 7: Low-informative parameters reduction using PCA

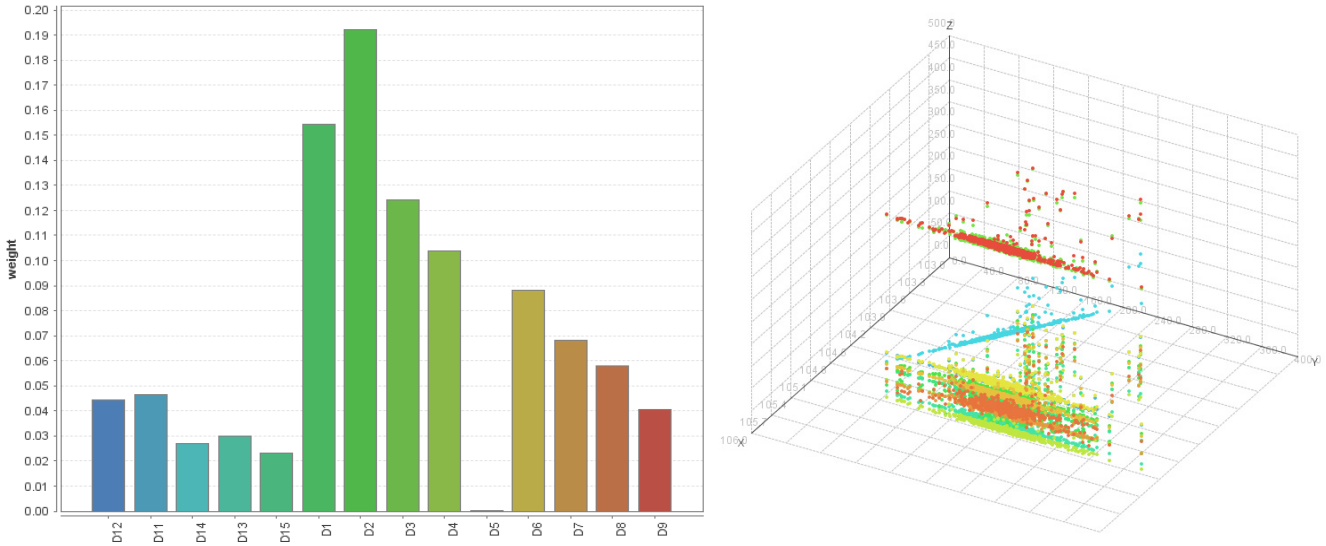

Figure 8. Low-informative parameters reduction using Random Forest

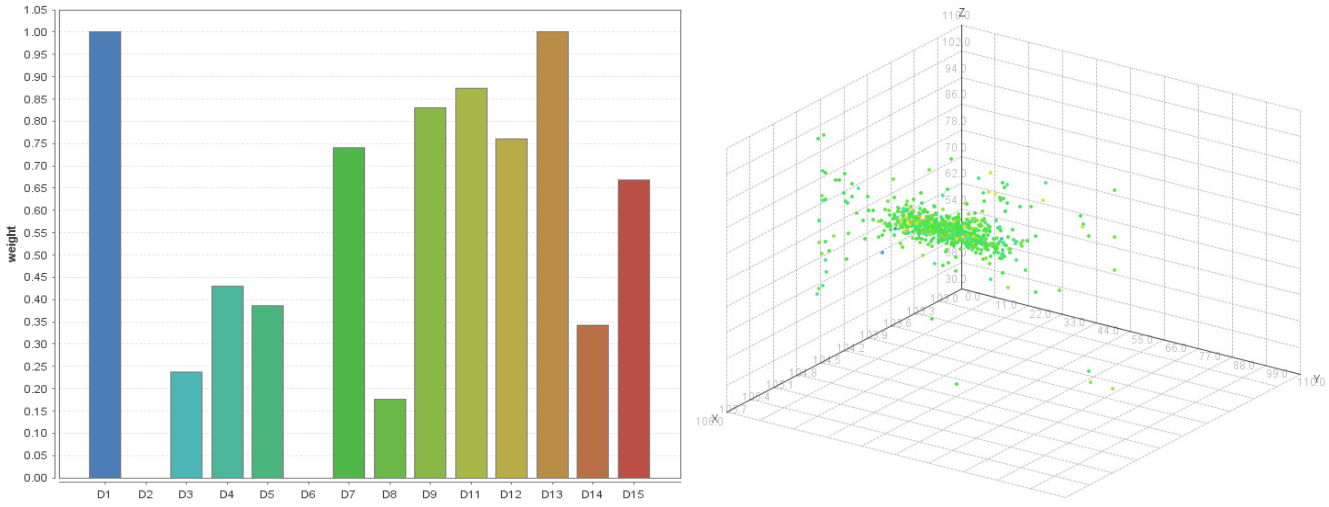

Figure 9. Low-informative parameters reduction using PSO

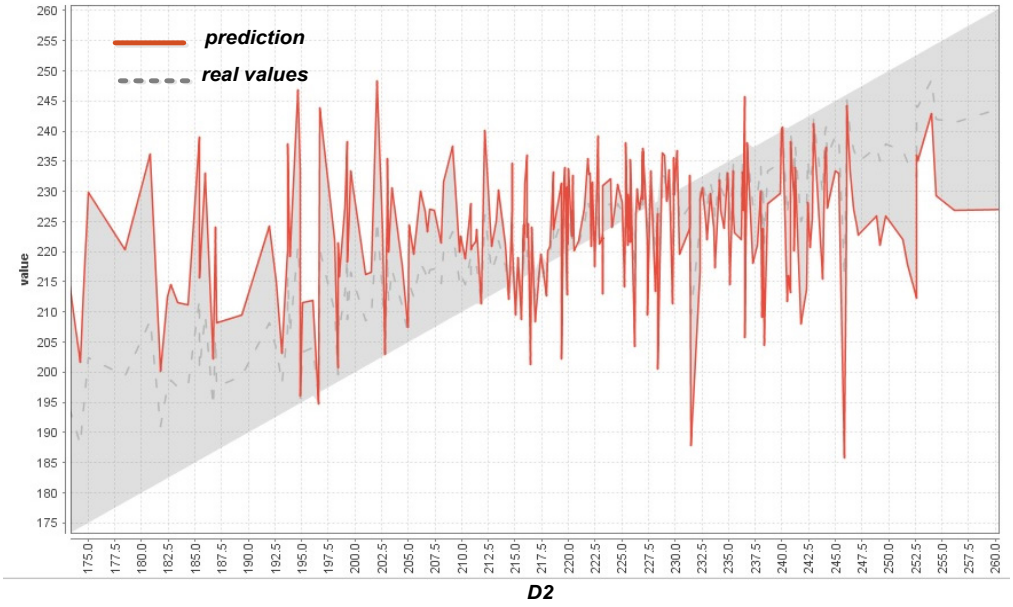

Figure 10. Prediction based on modified algorithm *PSO - Clonal Selection*

Further, according to the 4th algorithm, after the selection of informative features, the task of classification is solved using the AIS algorithm, based on clonal selection. A comparative analysis of the simulation results is presented in Table 5.

Table 5: Comparative analysis of image recognition results based on clonal selection

Feature selection method	PCA	RF	PSO
Performance of feature selection	87,67%	95,45%	94,56%
Runtime of feature selection	1 min 25 sec	7 min 34 sec	1 min 4 sec
Performance of clonal selection classification	85,53%	86,74%	93,67%
Runtime of feature selection	56 sec	2 min 59 sec	34 sec

Because the Honeywell DCS distributed control system from the Installation 300 collects a huge amount of production data, the required time to simulate multidimensional data is a necessary criterion for evaluating the effectiveness of the modified algorithm.

In the case of the use of intelligent algorithms in the development of control systems, it is impossible to use classical sustainability criteria in order to assess the effectiveness of the developed Smart technology. The effectiveness of the heuristic algorithms is carried out using the calculation of such parameters as [35]:

- *accuracy* - accuracy (relative amount of correctly classified examples, percentage of correct predictions);
- *classification_error* - the percentage of incorrect predictions;
- *kappa* - kappa statistics calculation;

- *weighted_mean_precision* - weighted average value for each class of measurement accuracy;
- *spearman_rho* - rank correlation between actual and predictable labels using Spearman's rho measure, which shows a linear relationship between two variables;
- *kendall_tau* - rank correlation using Kendall's tau measure, showing the strength of the relationship between two variables;
- *absolute_error* - average absolute deviation of the predicted values from the actual value;
- *relative_error* - average absolute deviation of the forecast from the actual value divided by the actual value;
- *relative_error_lenient* - average relative error, which shows the average absolute deviation of the forecast from the actual value divided by the maximum of the actual value and the forecast;
- *relative_error_strict* - average severe relative error;
- *normalized_absolute_error* - normalized absolute error;
- *root-relative-squared error* - averaged relative quadratic error, etc.

Table 5 shows the final accuracy parameter showing the percentage of correct predictions by the proposed methods.

Therefore, according to the research results within the multi-algorithm approach, the best prognostic result for solving the problem of prediction and control of the process of medium-pressure gases cleaning based on real data of the control object D-302 is a modified algorithm *PSO - Clonal Selection*. A visualization of a fragment of the prediction results based on the *PSO - Clonal Selection* algorithm is presented on Figure 10.

7. Conclusion

As a result of the research, there was proposed a Smart technology for complex objects control based on Honeywell's distributed control system and an artificial immune system approach. The scientific novelty of the proposed technology is following:

1. The technology allows the prediction and control of complex objects of the oil and gas industry based on the intellectual analysis of historical data obtained from the distributed control system of Honeywell DCS.

2. There was developed a modified algorithm of artificial immune systems on the basis of a multi-algorithm approach in order to improve the quality of prediction of the behavior of complex objects under industrial operation.

3. There has been created a multi-agent Smart system that allows the integration of the proposed modified artificial intelligence algorithms into real industrial control systems.

4. Presented the simulation results on the basis of a real complex facility of the TengizShevroil enterprise (medium pressure absorber) of a fragment of the installation line 300 for gas cleaning from acid components.

Therefore, the proposed Smart technology allows the implementation of artificial intelligence algorithms based on real industrial production, in case when the classical methods of control theory are not efficient and unsuitable for working with large amount of data.

Conflict of Interest

The authors declare no conflict of interest.

Acknowledgment

The work was carried out under the grant of the KN MES of the Republic of Kazakhstan on the topic: AP05130018 "Development of cognitive Smart-technology for intellectual complex objects control systems based on artificial intelligence approaches" (2018-2020).

ABSTRACT

Physical computing is important for ICT (information and communication technology) Education and other informatics education such as software education since physical computing can provide learning-by-doing education for students. It is also a strong tool to increase students' programming ability using various type of physical computing tools like a robot. In physical computing, it is necessary to have evaluation metrics for learners in order to test students' progresses and environmental safety, etc. However, in the literature, there is little work for evaluation metrics for learners. In this paper, for the proposed evaluation metrics for learners developed in the previous research, the usefulness and validity are discussed and justified with statistical analysis. The final 23 evaluation metric will be very useful in actual physical computing education.

1. Introduction

This paper is an extension of work originally presented in ICTC2018[1].

Physical computing refers to downloading data from the real world to a digital device, processing it in the form of software, and then outputting the results to a monitor, LED or various devices. To put it more simply, computers and the real world are talking through data. The main content of the physical computing was developed by artists dealing with New Media Art. This is because it was necessary to understand computers in order to create works in the field of media art using images or light.

Physical computing is the foundation of the Internet of Things field. The basic nature of the Internet of Things is that it recognizes its surroundings through sensors and shares or processes the necessary information over the network, so it can be said to be an important technology that forms the Internet of Things.

On the other hand, for students who are new to programming, physical computing can be a good way to learn how computers and programs work. For example, students can learn about computers by assembling blocks directly, controlling robots by assembling and controlling them, or using sensors and outputs that can be easily detached to measure the quality and temperature of air which makes it easier for them to understand the principles of machine and programming.

Simplified coding programs and computer devices help students learn about physical computing. Instead of advanced programming languages such as C, students can learn programming simply by using block-coding software called Scratch. And instead of dealing with complex computer parts, students can understand the principles of computers by assembling microcomputer boards such as Arduino and Raspberry Pies, as well as various sensors and outputs to complete their own machine.

With this characteristic that the virtual world and the real world can exchange information, it is expected that the software industry will play an important role in the future thanks to the fact that it is the basis of the Internet of Things field that recognizes the surrounding environment and processes the necessary information, and that it can be approached with a simple and active image in terms of programming education.

In physical computing, evaluation metrics for learners are very important. Those metrics are very useful in evaluating learners' progresses, teaching-learning models, class materials, etc. However, in the literature, there is little research work on evaluation of learners in physical computing. The purpose of this paper is to develop evaluation metrics of learners in physical computing and justify them based on rigorous statistical analysis.

The rest of this paper is organized as follows. In Chapter 2, related works for physical computing are introduced. In Chapter3, evaluation metrics of learners are proposed and discussed. In Chapter 4, statistical analysis is presented for those evaluation

*Corresponding Author: Woochun Jun, Seocho Dong, Seocho Gu, Seoul, Korea, wocjun@snue.ac.kr

metrics. Finally, in Chapter 5, conclusions and further research issues are presented.

2. Related Works

2.1. Evaluation standards of Physical Computing

In this section, literature review works for evaluation standards for robot computing and physical computing are introduce.

In [2], achievement criteria of robot computing are proposed as below. In their work, criteria of robot computing is classified into 5 categories, understanding of robot, robot experience, robot motor control and sensor experience, control of sensor and creation of works, project in daily life, respectively.

[Step 1] Understanding Robot

(1) Definition of robots

I can understand and explain the basic elements of robot definition.

(2) Robot type and composition

I can understand the kinds of robots used in real life and the parts and applications that make up them.

(3) Robot operating principles

Robots understand how they react through external input or recognition and know how they work.

[Step 2] Robot Experience

(4) Robotic rules and safe use

I can understand the basic rules for building robots and how to use them safely.

(5) Understanding robot behavior

It is able to know necessary procedures for robot operation such as connecting devices and turning them on with variety of robots.

(6) Fabricate simple motion robot

Robotic behavior can be created in the order presented through simple block programming. It can also be created by modifying robot movements by applying various themes.

(7) Brief description of operation robot

Simple block programming can create robot behavior and explain the contents of the procedure.

[Step 3] Robot Motor Control and Sensor Experience

(8) Understanding Rotational Motion

Understanding the motor, learning about the operating procedure, principle of rotation, and component control required for member operation can be understood and simple robot rotation operation can be created and understood.

(9) Various robot-driven work production

Based on the principle of motion and understanding of the robot's driving procedure, various robots can be used to make a drive. I can also learn how to control the precise movement of a robot.

(10) Utilization of robot drive works

I can explain to my friends how the robot drives, how the robot is programmed in order, and its functions. It develops social relationship cooperation and communication skills through sharing of works and expression activities (recognition of goal achievement, sharing of error-solving experiences, etc.).

(11) Creation of simple sensor robot works

I can create a robot or device that can control behavior combined with simple sensors. It can make robots or devices using one of several sensors, including light sensors, ultrasonic sensors and sound sensors.

(12) Brief description of sensor robot work

I can identify the types of sensors used in my life, understand the characteristics of sensors, and describe robots or devices with sensors. I can express to my friends the design, function and programming procedures of a robot or device-driven work combined with one sensor. It develops social relationship cooperation and communication skills through sharing of works and expression activities (recognition of goal achievement, sharing of error-solving experiences, etc.).

[Step 4] Control of Sensors and Creation of Works

(13) Produce various sensor robot works

I can create and program controllable robot or device works by combining various sensors that can solve problems found in my life. It can also create works and explain them logically according to the programming sequence according to the purpose and purpose of production.

(14) Description of the various sensor robot works

I can describe the function, use and programming procedures and methods of robot or device work combined with various sensors. It also develops social relationship cooperation and communication skills through works sharing and expression activities (recognition of goal achievement, sharing of error-solving experiences, etc.).

(15) Rule Design and Robot Fabrication

Understanding the conditions for compliance with the rules, understanding the algorithms that can perform them, and designing the parts and devices needed to drive can be designed to operate through programming that applies algorithms to create robots or devices and perform them.

[Step 5] Project in Daily Life

(16) Designing Robot Works in Life

I can think about topics that can solve life problems and design algorithms and creative works that can define necessary parts and functions and control them by individuals or teams.

(17) Making Robot Works in Life

A creative work can be created through programming with algorithms applied to create robots or devices designed by individuals or teams and to perform defined functions according to topics that can solve life problems.

(18) Sharing and Expression of Robot Works

To solve problems found in life, creative works created by individuals or teams can be shared with friends, and better improvements can be found and expressed. In addition, better algorithms can be found, supplemented and shared to perform functions.

2.2. Educational Effects of Physical Computing

In [3], they presented EPL and physical computing curriculum using Entry and sensor boards that can be easily learned and used by elementary school students. The results of this study showed that both the comparative groups applying the problem-oriented EPL curriculum and the groups applying the additional problem-oriented EPL curriculum and the physical computing curriculum have significant effects on the improvement of students' computational thinking skills. Specifically, the problem-oriented EPL curriculum and the physical computing curriculum using the sensor board contributed to increasing learner's problem-solving skills, and showed that they are more effective in terms of improving satisfaction and computational thinking-related problem-solving skills when the physical computing education is combined with the programming training alone

In [4], high school students in the industrial field were trained in programming Android applications that control Arduino using app computers and analyzed the changes in students' creative and fusion thinking abilities. To this end, they designed a teaching course based on a creative problem-solving model and an integrated thinking model. Studies have resulted in significant improvements in diffuse thinking and motivational factors among the subcomponents of creative problem solving. In addition, according to the results of a survey by students on integrated thinking, many students answered that they can devise IoT systems that can be applied to their daily lives based on the knowledge learned through this class. Thus, the education of physical computing using app computers and Aduinos could be seen to have a positive effect on students' ability to think creatively and diversely.

On the other hand, other research works showed benefits of physical computing in ICT education [5-7].

3. Development of Evaluation Metrics for Learners

3.1 Design Principles

In order to development of evaluation standards of learners in physical computing, the following principles are adopted [1].

First, student-oriented activity is emphasized. Second, process-oriented activity is emphasized. Third, cooperative activity is encouraged rather than individual study in physical computing. Fourth, attitudinal and emotional experience or achievement are included.

In overall, evaluation standards are developed based on educational philosophy called constructivism [8]. Constructivism has the following major characteristics. First, it is assumed that there is no objective knowledge in the real-world. It means that every can make his or her own knowledge depending on his or her way of thinking or view. Second, it encourages social interaction. In other words, cooperative works are encouraged for study. Third, it also emphasizes problem-solving ability for authentic problems. Authentic problems mean that problems can happen in our daily life.

3.2 Evaluation Metrics

The following evaluation standards of physical computing are proposed in [1].

Table 1. Evaluation Standards of Learners

Division	Standards
Study Guidance	-Do students know study objective in advance or in the beginning of the activity? -Do students know any prerequisite or background information necessary for the activity? -Do students know the necessary equipment or teaching aids for the activity? -Do students know study materials for the physical computing activity?
Cooperation	-Does each student have a proper role in physical computing activity? -Is any leader in the group? -Are ways of communication good enough during activity?
Safety	-Do students know safety instruction for the activity? -Do students break or ruin any parts in the activity?
Output	-Do students finish the activity and produce output? -Is output good enough as expected or incomplete? -Are students supposed to have a change to expression their review or impression of the activity?
Report	-Do students write a memo or report during the activity? -Do students produce a final report after end of the activity?
Attitude	-Are students polite in the process of activity? -Does any student cause a brawl and stop the activity?
Time	-Do students spend right time for the whole class? -Do students spend too much time in specific activity of the class?
Emotion	-Are students satisfied with the activity? -Are students interested in physical computing activity? -Do students have some confidence on the subject after activity?
Theory	-Do students know the principle or theory of the physical computing activity? -Can students link the theory with physical computing activity?

4 Statistical Analysis

4.1 Design of Analysis

Verification of the reliability of the tool to measure the importance of evaluation metrics for learners in physical computing showed that Cronbach α was 0.90 and was reliable, as shown in Table 2.

Table 2. Reliability of Measurement Tool

Item Number	Cronbach's α
23	0.90

The data collected in this study were analyzed using the Statistical Package for the Social Science (SPSS) WIN 25.0 program. The analyzer method calculated Cronbach α to verify the reliability of the measuring instrument. In addition, the average and standard deviation were obtained in order to find out the importance of the evaluation standards of learners in the physical computing, and the correlation was conducted to understand the relationship between the sub-areas of the evaluation metrics of learners in the physical computing.

4.2 Analysis Results

-Descriptive Statistics

The average and standard deviation of questions asked about the importance of evaluation metrics of learners in physical computing are as shown in Table 3.

Table 3. Results of Descriptive Statistics

Evaluation Standard	AVG.	SD
1. Do students know study objective in advance or in the beginning of the activity?	3.66	1.10
2. Do students know any prerequisite or background information necessary for the activity?	3.16	1.14
3. Do students know the necessary equipment or teaching aids for the activity?	2.91	1.17
4. Do students know study materials for the physical computing activity?	2.84	1.11
5. Does each student have a proper role in physical computing activity?	3,88	1.04
6. Is any leader in the group?	3.22	1.21
7. Are ways of communication good enough during activity?	4.22	1.01
8. Do students know safety instruction for the activity?	4.56	0.72
9. Do students break or ruin any parts in the activity?	3.50	1.30
10. Do students finish the activity and produce output?	3,41	0.95
11. Is output good enough as expected or incomplete?	3.16	0.92
12. Are students supposed to have a change to expression their review or impression of the activity?	4.06	0.91
13. Do students write a memo or report during the activity?	2.97	1.23
14. Do students produce a final report after end of the activity?	2.94	1.19
15. Are student polite in the process of activity?	4.13	0.91
16. Does any student cause a brawl and stop the activity?	3.69	0.90
17. Do students spend right time for the whole class?	4.34	0.70
18. Do students spend too much time in specific activity of the class?	3.31	1.09
19. Are students satisfied with the activity?	4.28	0.68
20. Are students interested in physical computing activity?	4.41	0.67
21. Do students have some confidence on the subject after activity?	4.19	0.93
22. Do students know the principle or theory of the physical computing activity?	3.56	1.11
23. Can students link the theory with physical computing activity?	3.66	1.04

Where AVG and SD stand for average and standard deviation, respectively.

4.3 Sub-area of Descriptive Statistics

The results of the average and standard deviation of the sub-area of the importance of the evaluation metrics of learners in physical computing showed that the average of the importance of the evaluation metrics of learners in physical computing was 3.65, as shown in Table 4.

Among the sub-categories of the importance of learners' evaluation metrics for physical computing, the average was 4.29, followed by "safety" 4.03, "attitude" 3.91, "time" 3.83, "cooperation" 3.77, "theory" 3.61, "output" 3.54 and "student guidance" 3.14 and "report" 2.95 were the lowest.

Table 4. Results of Descriptive Statistics of Sub-area

Evaluation Standard Area	AVG.	SD
Student Guidance	3.14	0.97
Cooperation	3.77	0.92
Safety	4.03	0.86
Output	3.54	0.67
Report	2.95	1.17
Attitude	3.91	0.78
Time	3.83	0.68
Emotion	4.29	0.58
Theory	3.61	1.02
Overall Evaluation Metrics	3.65	0.56

Where AVG and SD stand for average and standard deviation, respectively.

As shown above in Table 4, among the sub-areas of the learners' evaluation metrics in physical computing, the importance of 'emotion' is highest and the importance of 'report' is lower than that of other areas.

4.4 Correlation Analysis

The results of the correlation between the sub-area of evaluation metrics of learners in physical computing and the entire evaluation metrics are shown in Table 5.

Where * p<.05, *** p<.001

As shown above in Table 5, student guide(r=.661, p<.001), cooperation(r=.802, p<.001), safety(r=.716, p<.001), output(r=.419, p<.05), report (r=.764, p<.001), attitude(r=.696, p<.001, time(r=.614, p<.001), emotion(r=.616, p<.001), and theory (r=.606, p<.001) showed a statistically significant static correlation with evaluation metrics of learners in physical computing. Therefore, the higher the importance of student guidance, cooperation, safety, output, report, attitude, time, emotion, and theory, the higher the importance of evaluation metrics of learners in physical computing.

Table 5. Results of Correlation Analysis

Area	Correlation Value
Student Guidance	0.661***(0.000)
Cooperation	0.802***(0.000)
Safety	0.716***(0.000)
Output	0.419*(0.017)
Report	0.764***(0.000)
Attitude	0.696***(0.000)
Time	0.614***(0.000)
Emotion	0.616***(0.000)
Theory	0.606***(0.000)

5 Conclusions and Further Research Issues

Physical computing is very important in current ICT education and software education since it can provide learning-by-doing activity for learners. In other words, learners can enjoy the physical computing activity and have interests and motivation in physical computing class. Physical computing becomes very popular as ICT education is extended in the future.

In physical computing, evaluating learners is very essential in checking learners' study progress. Also, evaluating learners is also important in developing teaching-learning models in classrooms, study contents, etc. In the literature, there is little work on evaluation standards or metrics of learners. In the previous research work, new evaluation standards are developed and proposed. Through statistical analysis, overall evaluation standards are justified to use in physical computing.

In this research, based on previous research work, the purpose of the work is to justify the results one more time. Using descriptive statistics and correlation analysis, overall 23 evaluation metrics of learners are verified.

The immediate research issues are as follows. First of all, it is necessary to develop more detailed evaluation metrics depending on physical computing tools such as robots, toy, etc. Second, it is also necessary to develop evaluation standards or metrics for study materials. It is not known yet how to develop study materials in physical computing. That is, we need the general design principles and detailed guidelines.

Conflict of Interest

The authors declare no conflict of interest.

ABSTRACT

The task of fuzzy mathematical modeling of the composition of a polymer composition is singled out and formulated, as one of the types of chemical-technological systems for creating the theoretical foundations for managing the physicochemical properties of the material produced from this composition. Fuzzy data on the technical functions and concentration of individual ingredients that included in the composition in the form of fuzzy numbers are used as the initial formalized information at modeling the polymer composition. As a result, a parametric space is formed that describes the multicomponent system under study. The index of compliance of each parameter of the polymer composition with the requirements for the physicochemical properties and quality of the polymer material is calculated. This allows you to go to the relative dimensionless real values. Weighted voting procedure is used as an aggregate function. The obtained numerical value reflects the integral measure of the compliance of the chemical-technological system with the requirements for the polymer composition.

An example of the choice of ingredients of the polymer composition by calculating using fuzzy numbers is presented. In addition to the formulation of the problem, the study develops the mathematical software for the intellectual system supporting the research and production activities of the chemical technologist to substantiate the decision to choose a polymer composition.

Accepted abbreviations: PC — polymer composition, CTS — chemical-technological system, PCM — polymer composite material, FS — fuzzy set, IS — information system, DNA — Deoxyribonucleic acid

1. Introduction

This study is an extension of work originally presented in International Russian Automation Conference [1]. The study gives a new vector of application of fuzzy mathematics methods in the analysis of complex multifactor technical systems, including chemical-technological system (CTS), for their identification and pre-experimental research. These systems, as a rule, are described by fuzzy information: the presence of linguistic descriptions, intervals, lack of data, incompatible research results, conflicting expert opinions, etc. Under these conditions, mathematical modeling using this information also has a fuzzy nature and a multiplicity of solutions. Nevertheless, the use of fuzzy mathematics, fuzzy modeling allows at the preliminary stage to choose the optimal and economical strategy of the experiment and evaluate the expected technical result, which is directly related to product quality. It should be noted that the use of fuzzy set (FS) for the preparation of initial information in the simulation of CTS has recommended itself from the positive side, as a form of theoretical

analysis of polymer composition (PC) and finding the relationship between the components and properties of the polymer system as a whole. Here, a prerequisite is the identification and ranking of the technical functions of the ingredients of the PC. Managing the properties of polymer composite material (PCM) is an important task of chemical technology, it can be extended to: oil and gas processing (primary separation, refining, age hardening), petrochemical and organic synthesis, biotechnology, the technology of high-molecular substances, the technology of processing plant and animal raw materials and etc. [2].

The formation of the PC optimization problem and its solution is based on the "composition – property – quality – application" dependence and provides for the selection of a certain number of ingredients with the necessary technical functions using fuzzy modeling. In this paper, this idea is extended to the PCM analysis.

Raw PC, in other words, mixtures, are complex systems. They are based on polymer matrices in which various ingredients are added. The interaction between such matrices, their structure and composition also depend on the chemical and technological processes of their processing. PC-derived composites are also complex heterogeneous systems and can be divided into five leading classes:

1. Matrix, consisting of a continuous phase (matrix) and a dispersed phase (discrete particles) (dispersed — hardened composite materials).
2. Compositions with fibrous fillers.
3. Mixed compositions.
4. Compositions having an interpenetrating structure of two or more continuous phases.
5. Layered PCMs.

Considering the special interest of researchers and the market of consumers of polymer products to nanotechnology, let us mention the polymer matrix of the "polymer matrix – additive (filler)" composition, in which 2D and 3D nano-ingredients are used as fillers — graphene and carbon nanotubes. Here, mathematical modeling can be conducted based on the analysis of ingredients in the direction of predicting the level of physical and mechanical properties, depending on the number and size of nanoparticles and the parameters of the polymer matrix of a stable configuration. This direction is at the beginning of development, therefore, in most cases, problems are solved on the basis of experiments [3, 4]. Here the applicability of fuzzy mathematics is quite possible when calculating and analyzing results. Thus, the PC is ultimately a multi-component, inhomogeneous system, the characteristics of which do not allow to calculate the exact values of technical effects by its component. The versatility of the situation emphasizes the fact that in addition to a large set of active and inactive fillers, modern technology with a different purpose gives rise to the use of new modifying additives, a brief description of which is proposed below. In parentheses are their possible concentrations in the PC.

Light stabilizers allow for a long time to maintain the original color of the product and its mechanical strength, providing protection from ultraviolet rays. Here you can point to derivatives of benzonitrizol, benzophenol, nickel and cobalt salts of substituted phenols, etc. It has been established experimentally that they are effective even at very low concentrations (0.1 –5.0%).

Antioxidants prevent thermo-oxidation and slow down destruction during extrusion and injection molding. Also, these additives are used to protect the polymer when processing in aggressive environments. The mixtures compounds of phenols and phosphides (0.1 – 2.0%) are the most popular here.

Plasticizers are low molecular weight organic substances that, when introduced into the composition at the preparation stage, reduce the interaction between adjacent macromolecules. At the same time, common plasticizers include esters of organic and inorganic acids, such as dibutyl phthalate, di-(2-ethylhexyl) phthalate, dibutyl sebacate, tricresyl and tributyl phosphate, refined products, (petroleum oil), coal and wood materials (cumarone indene resin, rosin, etc), epoxidized vegetable oils, etc. The temperature of decomposition of plasticizers should be higher than the processing temperature of PC (0.1 – 45.0%).

Combined additives (light stabilizer + antioxidant + dye, etc.) are widely used in the production of agricultural films. They allow to use the polymer for its intended purpose after recycling (0.1 – 45.0%).

Flame retardants are the most important additive limiting the flammability of PCM. Special flame retardants are used for the production of non-combustible and low-flammable films, sheets and molded products. They are divided into three large groups:

- chemically interacting with the polymer;
- intuminescent;
- additives mechanically miscible with polymer.

Flame retardants are most often halogen-containing and phosphorus-containing compounds, as well as metal hydroxides and other inorganic compounds (0.1 – 3.0%).

Antistatics can get rid of the static effect. For example, in the manufacturing of cases for audio and video equipment. Commonly used antistatic agents include alkylamines (up to 3.0%).

Slip agents are an internal lubricant in a polymer matrix that reduces melt viscosity, improves extrusion performance, makes the surface smoother, shinier and glossy, and reduces the coefficient of friction of products. Active ingredients are derivatives of higher fatty acids (depending on technology).

Anti-blocking additives prevent sticking, that is especially important in the production of polypropylene films. The packages made of a film with such additives are easily opened. Package walls do not stick together. Active ingredients are silicic acid or amide waxes (0.1 – 0.3%).

Antislips are additives that are similar in properties to antiblocking. They give the surfaces of the films roughness. They are used in the manufacturing of packaging, bags for packing bulk products and other products. One of the antislips is ultra high molecular weight polyethylene (0.1 – 0.3%).

Antiseptics prevent the biological destruction of PCM (up to 2.0%).

Nucleates affect the supramolecular structure of the polymer matrix, making it more fine-grained. At the same time, the

crystallization time is significantly reduced, the product is cooled faster. In addition, the effect of greater transparency of the films is created. Nucleates are used exclusively for polypropylene (0.1 – 0.3%).

Foaming additives are used to manufacture porous polypropylene and polyethylene products. The structure of the matrix is loosened, the extensions disappear with the introduction of additives. They are designed to produce decorative films used in the packaging of gift sets, as decorative ribbons, gaskets in cork and other purposes (depending on the requirements of technology).

Modifier in the production of stretch films. It gives them the effect of additional elasticity, and for some polymers, including polypropylene, impact resistance (no information).

This list is rapidly replenishing and expanding today, for example, so-called processing additives that improve the economy and technological parameters of processing activities (in each case individually) can be singled out separately.

Today, PC theory is an attempt to solve the problem of how the final physicochemical properties of finished products depend on the composition, chemical-technological and physical-technical parameters. The ultimate goal here is to obtain materials with desired properties. To achieve this goal it is necessary, setting the final properties of the designed material or product, to know the parameters of their manufacture.

General requirements for PC ingredients are as follows:

a) thermodynamic compatibility with the polymer matrix should be ensured, preferably before the formation of a molecular solution;

b) should not be volatile;

c) do not bleed out of the polymer matrix;

d) should be nontoxic, chemically and thermally resistant.

As an example (Table 1) [5], we consider the composition (in weight parts) of an electrically insulating PC from the Russian patent which is well illustrating the multifactorial nature of the identification problem and the versatility of PCM ingredients. And this is not the most difficult PC.

Therefore, for PCM ingredients, their effect on the polymer matrix is empirically determined. And to obtain a PC with the desired set of properties, both polymer matrices and individual ingredients are selected. The complexity of the problem is obvious, as is the complexity of the system.

It should be noted that for particular cases of the theoretical analysis of the properties of PCM, many CTS analysis methods are used: discriminant, factorial, regression, etc., to identify the control actions and calculate their consequences, while operating in numerical spaces [6 – 8]. But in the presence of nonnumeric, for example, linguistic parameters, such methods become of little use and require additional efforts to harmonize the source data and mathematical methods. Comparing and critically analyzing the existing mathematical approaches [2, 6 – 9] we can conclude that an important part of this problem is overcome by using FS for describing both numerical and nonnumeric parameters. The solution of the problem itself is carried out by methods of fuzzy mathematics. Important elements of the latter are increasingly being applied in the scientific analysis of the CTS [10 – 13].

Table 1: Composition of a Polymeric Composition (in Weight Parts)

Components	No.

* PVC S-70 – polyvinyl chloride polymer matrix, Russian brand S-70.

In connection with the above, let us point out that the management of PCM properties is possible in various theoretical and further practical ways, such as:

1) pre-experimental heuristic identification,

2) the choice of the polymer type,

3) changes in production technology of polymer used as a matrix (polymerization, polycondensation, modification, crystallization, structuring),

4) regulation of the concentration and technical functions of the ingredients,

5) variation of composition and structure.

Among the newer modern experimental approaches to the management of PCM properties through the "composition – properties" relationship, for example, layer-by-layer deposition of polymers can be specified to control the conductivity of ophthalmic preparations through lenses [11], the regulation of technology to control the physicochemical properties of PCM [12 – 16], or increase, in the particular case, of the structural stability of such a biopolymer as DNA, when counter-ions are neutralized with the help of polyamines [15]. From what has been said, it is clear that controlling the properties of the polymer matrix, whether it be an olefin or DNA, is a separate scientific and technological task. Here, we have not found any works on the application of FS for the theoretical analysis of the polymer matrix — a full-scale experiment is fully used. So we have attributed points 4, 5 to the above list to our problems.

Here, the use of fuzzy analysis for the study of polymer systems and their particular case of PCM and comparison of mathematical procedures of fuzzy analysis [16, 17] made it possible to formulate the task of managing the properties of PCM and to obtain particular methods of its solution. Let us make the restrictions related to the subject area of this article and introduce it into the framework of the general task of studying CTS, while considering the PC as a system consisting of an undefined set and their number. Mathematical modeling and optimization of this CTS will be carried out under the conditions mentioned above, multicriteriality, incompleteness and vagueness of the initial information. This information can include the knowledge, experience and intuition of a specialist expert, which provides the basis for managing these systems — one of the main modern vectors of their development. We repeat that the identification of optimal and compromise technical solutions at the early stages of the formation of a plan for laboratory research and pilot product releases in world practice is known [18, 19], but it is still an urgent task focused both on the creation of new equipment and technology, and on the savings of intellectual and material resources. In principle, the problem of analyzing fuzzy data is relevant for analyzing the internal problems of the intelligent systems themselves, which are oriented toward interaction with both researchers and the consumer. As an example, one can cite a system for analyzing linguistic information for predicting the commercial attractiveness of goods [20] and other areas using problems with fuzzy data [21, 22].

The work of creating a fuzzy model is multidimensional and complex. It can be noted that in chemistry and technology, PCM tasks with fuzzy data are most of all:

- selection of compositions,
- evaluation of new materials properties,
- design of competitive technologies,
- consideration of possible environmental damage,
- safety accounting, etc.

Describing the problem of modeling CTS in this part, it is necessary to proceed from the fact that the very formulation of the problem of fuzzy modeling, computer implementation of calculations and their effectiveness can have, as discussed above, the nature of the set, which is largely determined by the formalization of the source data (parameters and conditions) and the adequacy of the test results obtained during the simulation. At the same time, depending on the level of fuzziness and the type of model obtained, the solutions may have different significance [22].

Let us add that modern research focused on processing fuzzy information uses the following route: "raw data – fuzzification – analysis – defuzzification – result". At the same time, they formulate variables, including linguistic ones, and, using conventional methods of fuzzing terms, go to FS and further, as for example, in [23] analyze the resulting data model in a mathematical package [24]. Also fuzzy components are explored using intelligent systems. Since the considered approach focuses on certain subject areas, the formalization of information is carried out in accordance with the requirements of these areas using a mathematical apparatus. This is often beyond the power of ordinary users of intelligent systems. In such cases, it is offered either detailed manuals, or to fully automate the process.

We performed the real work, which is the software of the information system (IS) summarizing the information available in this part and using our own experience in solving such fuzzy problems. Here it will be possible, firstly, to automate the initial processing of the raw data (to carry out the fuzzification process) and, secondly, to analyze the solutions for the information support of researcher work. The second part is focused on a wide range of chemical-technological tasks, such as: classification, identification, examination and management of the CTS. The specific analysis methods discussed below are focused on relative data and have no substantive substantiation; therefore, they can be applied in other fields of science and technology. We also point out that to solve the problems of our profile, we used the latest advances in the field of FS analysis [25 – 29], interval mathematics [30], and others [31], however, a universal method for processing fuzzy data, we have not found neither in Russian nor in foreign practice, although research in this direction is being actively conducted, as an analysis of scientific and technical literature of recent years shows.

This paper takes into account the complexity of the system and the PCM analysis and is aimed at developing a methodology for formalizing the source data in the form of fuzzy numbers, defining a library of mathematical models for selecting ingredients from a given set. Ultimately, information is provided for the quantitative support of the decision to choose PCM. Also, the typing of the source data will allow to unify and algorithmize the process of automated analysis of the results of the experiment.

2. Research objective

Now we will set a more specific task of forming the initial data, and then the mathematical method of calculation. We point out the conceptual fuzziness that exists and arises when describing the PCM:

- the technical functions of the ingredients are not presented;
- in the description of the ingredients of their concentration in the PC are given in the form of intervals;
- the level of action of the technical function of additives is characterized linguistically and is not related with their concentration in PCM;

- the possible relationship between the physicochemical parameters of the additives themselves and PCM and the positive or negative chemical interaction between them is not indicated.

Considering these fuzzinesses, which are more practical in practical technologies, the description of the data about the PCM by fuzzy numbers and operations with them by the methods of fuzzy mathematics will be adequate techniques. In general, the quality management of PCM will be carried out according to the scheme proposed in Figure 1 using fuzzy data analysis techniques.

Note that the main requirements for the PCM are formulated by consumers (customers) and process engineers, taking into account industrial capabilities and needs, on their part introduce additional requirements. If the former determine the range and tolerances of physicochemical, mechanical, ergonomic, environmental and other operational characteristics; the latter proceed from technological limitations, polymer matrix synthesis processes (polymerization, polycondensation, modification) and processing: (melting, mixing, casting, molding, stamping, extrusion, etc.) The formulation of such requirements is made by experts in the relevant fields, and, in many cases, is cited in reference data sources.

We assume that the basic consumer requirements already exist. It is necessary to construct the composition of the PCM that best meets these requirements and select ingredients with certain technological and technical functions.

The management of the design and analysis process of the PCM itself is carried out by assessment and selection of:

- polymer matrix,
- ingredients (including fillers),
- coordination of concentrations,
- justification of processing technology.

These actions need to be carried out in concert, since the nature of each polymer matrix determines a unique combination of possible ingredients and their content. You can get far from optimal low-potential low-quality PCM even choosing a polymer matrix with good physico-chemical characteristics and using an unsuccessful set of ingredients.

The following route is proposed for creating an original technical solution:

1. The choice of the polymer matrix is carried out on the basis of the analysis of the achieved level of technology by a variable method from the available kits, most often from the brand kits.
2. Determination of technical functions and concentrations of ingredients and their combinations is carried out through technical expertise.
3. Specific representatives are selected from the known ingredients, taking into account the available possibilities, and the compliance index for each of them is calculated.
4. PC is numerically evaluated based on the properties of the selected components by calculating the PC compliance index and, if necessary, proceeds to step 1.

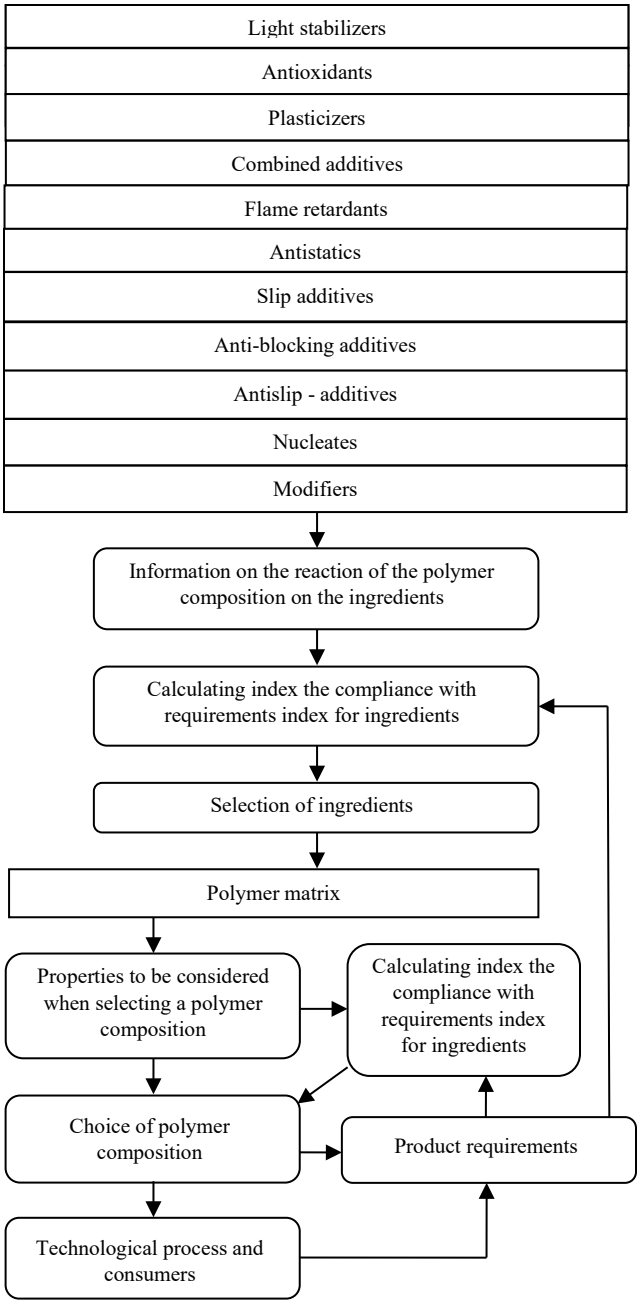

Figure 1: Control Scheme of the Physicochemical Properties of PCM and the Quality of Polymer Products

5. The decision is made on further actions: the choice of the polymer matrix, the specific composition of the PC, the individual ingredient, changes in the technological regime, etc.

Actions under item 1 are related to the experience of the technologist and researcher, the availability of information and material resources. They are obvious and, we believe, comments do not require. The actions under item 2 can be implemented either by designers or directly by process engineers — experts in the field of chemistry and PCM technology. It can also use reference books, databases and knowledge bases or knowledge systems created on the basis of generalization of subject information. In any case, the technology of these actions goes far beyond the scope of this article and is not discussed in detail here.

This article discusses in more detail the steps in paragraphs 3, 4 and 5 related with solving the problems of evaluating the technical functions of ingredients in a given set for designing a PC, in the context of the decision to choose its composition. A solution to the problem of optimal PC selection using a given polymer matrix and variability of additives is also proposed. In the simplest case, it is CTS type "one polymer matrix + one functional additive" or "polymer matrix + filler + functional additive". In the latter case, the "polymer matrix + filler" is considered inseparably. Then we will complicate the task.

We formulate the general task of determining compliance with the requirements of an abstract technical object and present the main points of its solution method, to assess the quality of the additive used to form a PC, and then the quality of PCM.

Let $Q = (Q_{ij})$, $i = 1, \ldots, n$, $j = 1, \ldots, m$ be the matrix of input data describing the results of measurements or calculations of m characteristics of n representatives of a certain class of chemical systems $s_1, \ldots, s_n$, $Q_{ij} \in Q_j$, where Q_j is a set of values representing numbers, sets, words, etc.

Here and below, we will illustrate the reasoning with an example of the choice of a flame retardant for a polymer matrix presented in the form of a fibrous substrate (Table 2). At the same time, since this is not significant for the description of the mathematical methodology, the names of chemical compounds, as well as the dimension of physicochemical parameters will be omitted. The point is that it is necessary for those given in Table 2 data to evaluate the PC system being formed and in some sense choose the best option. The choice of flame retardant as an illustration of FS application in this case is related to its technical function (see above) and cannot be considered accidental or abstract. The fact is that in the practice of chemistry and chemical technology of high-molecular compounds, imparting noncombustibility of PCM or a significant decrease in combustibility is one of the most urgent tasks, along with increasing the durability of polymer products.

Table 2: Abstracted Characteristics of Industrial and Laboratory Flame Retardants [25]

Compound no., i	Q_{i1}	Q_{i2}	Q_{i3}
0 (Reference, q/δ)	*1.0/8*	*1.5/8.5*	*21/10*
1	*19*	*12.1*	*9*
2	*18*	*10.7*	*9*
3	*18*	*3.7*	*14*
4	*6 – 10*	*6 – 10*	*15*
5	*18*	*2*	*9*
6	*3*	*3*	*10.6*
7	*1.0 – 1.2*	*2.67*	*15*
8	*1.0 – 1.2*	*1.5 – 2*	*9 – 11*

It is clear that the method discussed below can be applied to any flame retardant, and in general, to an ingredient, both from the list discussed above and any other using any polymer matrix. The solution of the problem is divided into several stages, including: analysis of the initial data Q, construction of fuzzy numbers U, formalization of requirements in the form of fuzzy numbers, comparison of U with formal requirements, choice of PC, decision making.

3. Analysis of the source data

3.1. Method Description

The purpose of this stage is to bring different types of data to one type in the form of a segment. We use the operator proposed earlier [31], i.e. define the operator A, for this:

$$A(Q_{ij}) = [q_{ij1}; q_{ij2}],\ q_{ij1}, q_{ij2} \in \mathbb{R},\ q_{ij1} < q_{ij2},$$

where $\mathbb{R}$ — set of real numbers.

It is not possible to define this operation precisely, since in practice Q_{ij} can be represented in any form, but first you can describe the solution for the most typical forms by creating a library of data models, and later, if necessary, expand the library, which will allow you to adapt the proposed approach to almost any type of source data. Consider the most common cases.

1. Q_{ij} — real number.
2. Q_{ij} — set of real numbers.
3. Q_{ij} — linguistic value.

For all these cases, it is proposed to use the following operator.

$$A(x) = \begin{cases} A_1(x), \text{ если } x \in \mathbb{R} \times \mathbb{R}^+ \setminus \{0\}, \\ A_2(x), \text{ если } x \in \Re, \\ A_3(x), \text{ если } x \in t, \end{cases}$$

where

$$A_1: \mathbb{R}\times\mathbb{R}^+\setminus\{0\} \to \Im,\ \Im = \{[a; b] |\ a, b \in \mathbb{R},\ a < b\},$$

namely,

$$A_1(x, y) = [x - y; x + y],\ x \in \mathbb{R},\ y \in \mathbb{R}^+\setminus\{0\};$$

$$A_2: \Re \to \Im,\ \Re = \{X |\ X \subset \mathbb{R}\},$$

namely,

$$A_2(X) = [\inf X; \sup X],\ X \subset \mathbb{R};$$

$$A_3: t \to \Im_1,\ \Im_1 = \{[a; b] |\ [a; b] \subset [0; 1]\},$$

namely,

$$A_3(t_k) = [e_{k-1}; e_k].$$

Operator A_3 requires additional explanations on the set of terms t. Let be $Q_{ij} \in t = \{t_k |\ k = 1, \ldots, r\}$, and terms t_k are such that $t_1 \prec \ldots \prec t_r$, where $\prec$ is an ordering relation. We split the segment $E = [0; 1]$ into r parts in accordance with the terms t_k, while maintaining the same order, i.e.

$$E = \bigcup_{k=1}^{r} E_k ,$$

where $E_k = [e_{k-1}; e_k]$, $k = 1, \ldots, r - 1$, $E_r = [e_{r-1}; e_r]$, $0 = e_0 < e_1 < \ldots < e_r = 1$.

Illustrating with compound no. 1 from the example under consideration (Table 2), we obtain, for example, for parameter no. 1

$$Q_{11} = 19, \delta_{11} = 1,$$

$$q_{111} = 18, q_{112} = 20,$$

i.e.

$$A_1(19, 1) = [18; 20].$$

Further, similar to [25], fuzzy numbers are given for q values:

$$u_{ij}(x) = \exp\left(-\frac{\ln 2}{\delta_{ij}^2}(x - q_{ij})^2\right),$$

where $q_{ij} = (q_{ij1} + q_{ij2})/2$, $\delta_{ij} = (q_{ij2} - q_{ij1})/2$, $x \in \mathbb{R}$. Main provisions of fuzzification described in [25] are given in a more generalized form in clause 3.2.

As a result, a matrix of fuzzy numbers $U(x) = (u_{ij}(x))$, $i = 1, \ldots, n, j = 1, \ldots, m$ (Table 3) is obtained.

Further it is necessary to formalize the requirements for representatives of the class of systems. In the context of our example it is necessary to formalize the operational requirements for PCM, for which can serve properties defined in statics and in the dynamics, for example degradation, such as durability and biodegradability. The latter is a time challenge. Characteristics must be expressed quantitatively and / or qualitatively. For further actions, we proceed in the same way as [31], namely, let us set a hypothetical fire retardant s_0, possessing such characteristics that fully meet the operational requirements (Table 2, fire retardant 0). At the same time, the characteristic q_{0j} reflects the required value, and δ_{0j} is the tolerance value, within which the value of the corresponding characteristic satisfies the requirements.

Table 3: Values of the Elements of the Matrix $U(x)$ Calculated from the Table 2

No. compound, i	q_{i1}/δ_{i1}	q_{i2}/δ_{i2}	q_{i3}/δ_{i3}
0 (Reference, q/δ)	*1.0/8*	*1.5/8.5*	*21/10*
1	*19/1*	*12.1/0.1*	*9/1*
2	*18/1*	*10.7/0.1*	*9/1*
3	*18/1*	*3.7/0.1*	*14/1*
4	*8/2*	*8/2*	*15/1*
5	*18/1*	*2/0.1*	*9/1*
6	*3/1*	*3/0.1*	*10.6/0.1*
7	*1.1/0.1*	*2.67/0.01*	*15/1*
8	*1.1/0.1*	*1.75/0.25*	*10/1*

3.2. Computational experiment

To evaluate systems from a given class, we use the method described in [25], which consists of the following.

Let $S = \{s_i | i = 1, \ldots, n\}$ is a set consisting of n objects. For each object s_i, m characteristics $Q_{ij}, j = 1, \ldots, m$ are defined. Depending on the conditions of use, the set of considered characteristics may expand and contract, up to the introduction of chemical, biological, ergonomic and other properties. We select the reference object s_0 and its characteristics Q_{0j}, and s_0 can be either an element of the set S or not, it depends on the specific conditions of the problem and the preferences of the research or expert opinion. The characteristics of Q_{0j} are selected in such a way that s_0 is optimal in terms of the requirements for the quality of the object.

It is required to rank the elements of the set S according to the given m characteristics for compliance with the standard.

For each characteristic Q_{ij} we construct a FS, $\hat{Q}_{ij}$, $i = 1, \ldots, n$, $j = 1, \ldots, m$. To do this, we define the variables x_j with the range of values of G_j. Let the values of the variable x_j, satisfying the characteristic Q_{ij}, make up the segment X_{ij}. Then

$$X_{ij} = A(Q_{ij}).$$

We select the membership function μ_{ij} for the criterion Q_{ij}. Based on the construction of the set X_{ij} we find that in the q_{ij}, function has a maximum point, within the set X_{ij} the membership function takes values greater than 0.5, and outside X_{ij} it is less than:

$$\mu_{ij}: G_j \to [0; 1],$$

$$\mu_{ij}(q_{ij}) = 1,$$

$$\mu_{ij}(x_j) \geq 0.5 \Leftrightarrow x_j \in X_{ij}.$$

As a membership function, you can, for example, use the following functions:

$$\mu_{ij}(x_j) = \exp\left(-\frac{\ln 2}{\delta_{ij}^2}(x_j - q_{ij})^2\right), i = 0, \ldots, n, j = 1, \ldots, m.$$

As a result, we get FSs

$$\hat{Q}_{ij} = \{x_j | \mu_{ij}(x_j)\}, i = 0, \ldots, n, j = 1, \ldots, m.$$

We'll calculate the degree of equality ν_{ij} of the corresponding FS [26] to determine to what extent the characteristic of the object si is close to the characteristic of the reference object s_0:

$$\nu_{ij} = \max_{G_j} \min(\mu_{ij}(x_j), \mu_{0j}(x_j)), —$$

and the value 1 will correspond to absolute equality, and 0 to absolute inequality.

Further using the aggregate function (as such, we can take, for example, weighted voting), we'll obtain an integral estimate ν_i of the correspondence of the set of object characteristics s_i of the set of object characteristics s_0.

We'll calculate the degree of equality ν_{ij} of the corresponding FSs [32], using this method in our experiment, in order to determine to what extent the characteristics of flame retardant no. i is close to the characteristic reference no. 0:

$$\nu_{ij} = \max_{\mathbb{R}} \min(u_{ij}(x_j), u_{0j}(x_j)).$$

For the membership functions of the reduced form [33], we have obtained that the maximin value is reached at the point:

$$\nu_{ij} = u_{0j}(x_{ij}^*),$$

where $x_{ij}^* = \left(q_{ij}\delta_{0j} + q_{0j}\delta_{ij}\right)/\left(\delta_{0j} + \delta_{ij}\right)$, $i = 1, \ldots, n, j = 1, \ldots, m$.

For example,

$$x_{11}^* = \left(q_{11}\delta_{01} + q_{01}\delta_{11}\right)/\left(\delta_{01} + \delta_{11}\right) =$$

$$= \left(19 \cdot 8 + 1 \cdot 1\right)/\left(8 + 1\right) = 17,$$

$$\nu_{11} = u_{01}(x_{11}^*) = \exp\left(-\frac{\ln 2}{\delta_{01}^2}(x_{11}^* - q_{01})^2\right) =$$

$$= \exp\left(-\frac{\ln 2}{14^2}(16.867 - 1)^2\right) \approx 0.0625,$$

similarly, $\nu_{12} \approx 0.349$, $\nu_{13} \approx 0.438$.

Having conducted a weighted vote, we'll obtain an integral assessment ν_i of the correspondence of the set of object characteristics s_i to the set of object characteristics s_0:

$$\nu_i = \sum_{j=1}^{m} \alpha_j \nu_{ij},$$

where $\alpha_j \geq 0$, $\sum_{j=1}^{m} \alpha_j = 1$. The weights α_j are selected in accordance with the level of importance of each of the characteristics and are determined by the expert in the subject area so that the PC fully meets consumer requirements, technological process, etc. It is accepted here $\alpha_1 = \alpha_2 = 0.33$, $\alpha_3 = = 0.34$. The results of calculations based on the data Table 2 are presented in Table 4.

Table 4: Evaluation of Fire Retardants to Compliance with Operational Requirements

Fire retardants no., *i*	ν_i
1	*0.28*
2	*0.33*
3	*0.60*
4	*0.76*
5	*0.51*
6	*0.81*
7	*0.93*
8	*0.83*

Thus, the no. 7 fire retardant is preferable from the point of view of the presented requirements.

The proposed computational model can form the basis for automated data analysis when choosing the optimal CTS, including with the participation of experts. The approximate route of operation of such an IS is shown in Figure 2. Here, the requirements for the evaluated objects (PCM) are set directly in the IS interface when formulating the initial task, allowing specialists to quickly adjust its formulation in the context of the research.

When generating generic CTS evaluation tasks, it is possible based on known experimental data to form a library (database) of expert assessments (along with the data model library), which will relieve the user of the IS from having to obtain or collect expert assessments and fully automate the evaluation process of a specific CTS.

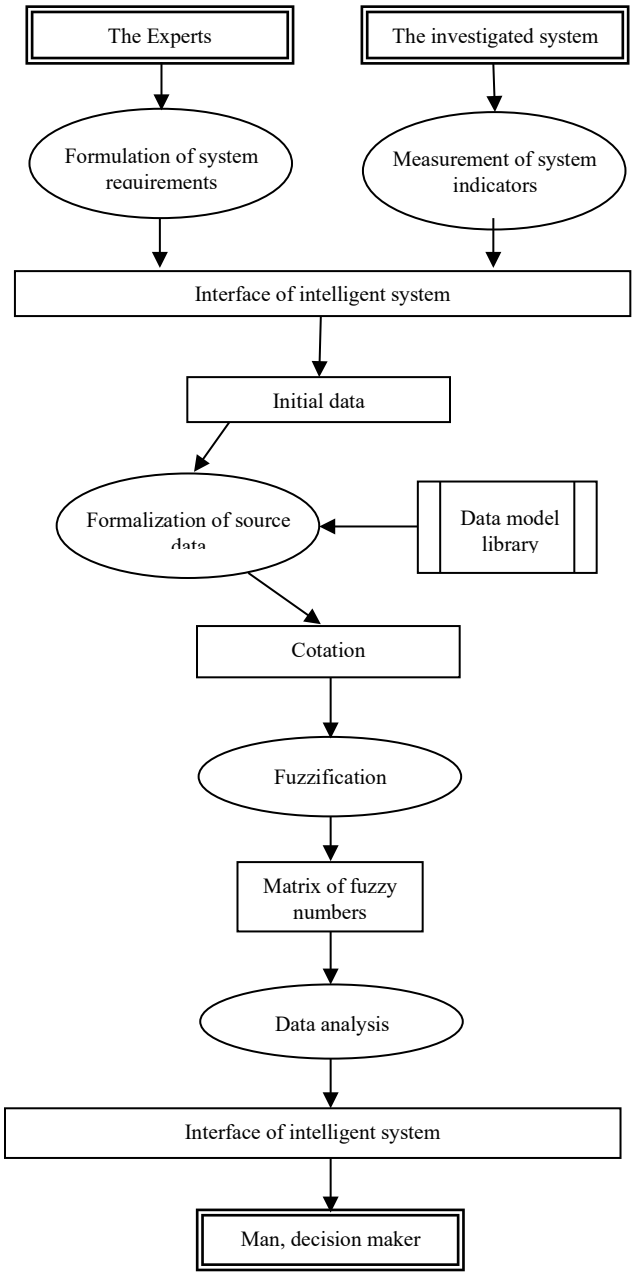

Figure 2: Scheme of the Information Flow in the IS

4. The optimal choice of a single additive for the polymer composition

4.1. Method Description

Let p_k, $k = 1, \ldots, l$ — be polymeric matrices, s_{ik}, $i = 1, \ldots, n$ — the additives for p_k. As mentioned above, by Q_{0j} we denote the value of the j-th property, which the PC should possess.

After modifying the polymer p_k by adding s_{ik} its properties become equal Q_{ikj}, $i = 1, \ldots, n$, $k = 1, \ldots, l$, $j = 1, \ldots, m$.

Further we get fuzzy numbers

$$u_{ikj} \text{ based on } X_{ikj} = A(Q_{ikj}),$$
$$u_{0j} \text{ based on } X_{0j} = A(Q_{0j}), \quad (1)$$

where $i = 1, \ldots, n$, $k = 1, \ldots, l$, $j = 1, \ldots, m$.

To select one additive and one polymer matrix we calculate

$$\nu_{ikj} = u_{0j}(x^*_{ikj}), \quad (2)$$

where $x^*_{ikj} = \left(q_{ikj}\delta_{0j} + q_{0j}\delta_{ikj}\right) / \left(\delta_{0j} + \delta_{ikj}\right)$, $i = 1, \ldots, n$, $k = 1, \ldots, l$, $j = 1, \ldots, m$ and

$$\nu_{ik} = \sum_{j=1}^{m} \alpha_j \nu_{ikj} . \quad (3)$$

In the end, choose the additive $s_{i_0 k_0}$ and polymer matrix p_{k_0}, where $(i_0, k_0) = \arg \max_{\substack{(i,k),\\ i=1,\ldots,n,\\ k=1,\ldots,l}} \nu_{ik}$.

4.2. Computational experiment

We present a study of PC with alternative polymer matrices of polyurethane elastomer and polycaproamide and use a set of fire retardants presented in Table 5, for an extended demonstration of the capabilities of the fuzzy data analysis method. The number of flame retardants for simplicity of notation is the same as in the Table 2, but this is not essential for the method and, in general, the amount of additives for each polymer matrix can be different. In addition, the reference value, that is, additive number 0, is left the same as in Table 2. This is essential for the considered mathematical method of PC analysis.

Table 5: Background Characteristics of Fire Retardants for Elastomer Matrix [34]

Compound no., i	Q_{i1}	Q_{i2}	Q_{i3}
0 (Reference, q/δ)	*1.0/8*	*1.5/8.5*	*18/10*
1	*12.7*	*17.1*	*20*
2	*8.5*	*8.5*	*18*
3	*20.6*	*20.7*	*20*
4	*18.7*	*18.7*	*17*
5	*6.2*	*6.2*	*16*
6	*18.0*	*22.1*	*17*
7	*28.1*	*27.0*	*20*
8	*4.4*	*4.4*	*10*

Let p_1 be polycaproamide, and p_2 — polyurethane elastomer, data on additives to which are given in Table 2 and Table 5 respectively. After the fuzzification of the initial data using (1), we obtain the fuzzy numbers u_{i1j} (Table 3) and u_{i2j} (Table 6) for p_1 and p_2, respectively.

Table 6: Parameters of Elements of the Matrix $U(x)$ Calculated on the Data of Table 5

Compound no., i	q_{i1}/δ_{i1}	q_{i2}/δ_{i2}	q_{i3}/δ_{i3}
0 (Reference, q/δ)	*1.0/8*	*1.5/8.5*	*18/10*
1	*12.7/0.1*	*17.1/0.1*	*20/1*
2	*8.5/0.1*	*8.5/0.1*	*18/1*
3	*20.6/0.1*	*20.7/0.1*	*20/1*
4	*18.7/0.1*	*18.7/0.1*	*17/1*
5	*6.2/0.1*	*6.2/0.1*	*16/1*
6	*18.0/0.1*	*22.1/0.1*	*17/1*
7	*28.1/0.1*	*27.0/0.1*	*20/1*
8	*4.4/0.1*	*4.4/0.1*	*10/1*

Applying to the data Table 3 ($k = 1$) and Table 6 ($k = 2$) formula (2) we obtain the values ν_{ikj}, $i = 1, \ldots, 8$, $k = 1, 2$, $j = 1, 2, 3$. Next, using (3), we obtain ν_{ik}, $i = 1, \ldots, 8$, $k = 1, 2$, are given in Table 4 for $k = 1$ and in Table 7 for $k = 2$.

Table 7: Evaluation of Elastomer Fire Retardants in Compliance with Operational Requirements

Fire retardants no., i	ν_{i2}
1	*0.45*
2	*0.71*
3	*0.35*
4	*0.34*
5	*0.81*
6	*0.33*
7	*0.34*
8	*0.77*

Among the data Table 4 and Table 7 find the maximum value of *0.93*, which corresponds to the addition of s_{71} and the polymer matrix p_1.

Thus, a specific recommendation was received on the flame retardant, which is part of the PC. Extensive work is needed to formulate a recipe based on these recommendations. This, for example, the definition of other components or their part in the PC, which allows you to take the first step in developing a new PCM in an automated way. Here we note that the proposed analytical method also has the possibility of choosing additional components for PC design. This is covered below.

Above (see Table 1) we have already indicated that thanks to the growth and expansion of consumer requirements, the complexity of polymer systems are increasing simbatically. Therefore, identification tasks are also becoming more complex.

Consider the complicated task of choosing several ingredients (additives) for PC design.

5. Selection of several additives for PC

5.1. Method description

Let it be necessary to choose one polymer matrix from the set p_k, $k = 1, \ldots, l$ and $r \le n$ additives for it from s_{ik}, $i = 1, \ldots, n$.

To do this, we define r properties $Q_{j_1}, \ldots, Q_{j_r}$, to improve which the choice of r additives is directed.

For each polymer matrix p_k, we define a set of additives $s_{i_s k}$ ($i_s \in \{1, \ldots, n\}$, $s = 1, \ldots, r$, $k = 1, \ldots, l$) such that the additive $s_{i_s k}$ provides the best property value Q_{j_s} among the additives $s_{1k}, \ldots, s_{nk}$. However, some numbers may coincide with each other if the same additive provides the best values for several properties at once. In this case, for the modification, not r, but a correspondingly smaller amount of additives is used, but the result will correspond to the set task — the same r properties are improved.

Next, we obtain ν_{ik}, $i = 1, \ldots, n$, $k = 1, \ldots, l$ as it was described in Section 4 and define

$$\nu_k = \sum_{s=1}^{r} \alpha_{j_s} \nu_{i_s k} . \quad (4)$$

Determine the number

$$k_0 = \arg \max_{k=1,\ldots,l} \nu_k$$

and choose a modification of the polymer matrix p_{k_0} a set of additives $s_{i_1 k_0}, \ldots, s_{i_r k_0}$.

5.2. Computational experiment

To demonstrate the capabilities of the method presented here, we will use the same data (Table 2 and 5) and the same notation as above. Since the formulas for calculating the same, the values of ν_{ik} are also given in Table 4 and 7.

Table 8: Values of the Degree of Compliance of the Characteristics of Additives to Consumer Requirements to PCM

Compound no., i	$k = 1$			$k = 2$		
	ν_{i11}	ν_{i12}	ν_{i13}	ν_{i21}	ν_{i22}	ν_{i23}
1	*0.0625*	*0.349*	*0.438*	*0.235*	*0.102*	*0.994*
2	*0.0843*	*0.452*	*0.438*	*0.552*	*0,.632*	*0.950*
3	*0.0843*	*0.956*	*0.755*	*0.0173*	*0.0316*	*0.994*
4	*0.712*	*0.767*	*0.814*	*0.0365*	*0.0625*	*0.912*
5	*0.0843*	*0.998*	*0.438*	*0.752*	*0.813*	*0.867*
6	*0.966*	*0.979*	*0.480*	*0.0472*	*0.0187*	*0.912*
7	*1.0*	*0.987*	*0.814*	*0.000427*	*0.00226*	*0.994*
8	*1.0*	*0.999*	*0.5*	*0.885*	*0.924*	*0.5*

Let $r = 2$, and $j_1 = 1$, $j_2 = 2$. To determine i_1 and i_2, ν_{ikj} values are needed that were not of immediate interest previously and were omitted from the examples of calculations. Now we bring these data to Table 8

To find i_1 for $k = 1$, we find the largest among the ν_{i11} values. This is *1*. This value is achieved for two supplements. We take $i_1 = 7$. Similarly, we get $i_2 = 8$. Acting in the same way, for $k = 2$ we define $i_1 = 8$, $i_2 = 8$.

Next, we calculate by (4)

$$\nu_1 = \alpha_1 \nu_{71} + \alpha_2 \nu_{81} = 0.33 \cdot 0.93 + 0.33 \cdot 0.83 \approx 0.58,$$

$$\nu_2 = \alpha_1 \nu_{82} + \alpha_2 \nu_{82} = 0.33 \cdot 0.77 + 0.33 \cdot 0.77 \approx 0.51.$$

The value $\nu_1 \approx 0.58$ indicates that for $k = 1$, the PC has a higher degree of compliance with the requirements. As a result, we choose a PC based on textile fiber ($k = 1$) with additives no. 7 and 8 (Table 2). Thus, a specific recommendation on the main additional component of the PC is also received here. The formation of a complete recipe based on these recommendations has the peculiarity that the proposed composition is already a multi-component system, but still has an incomplete character and requires more design and experimental work to implement the full "task-practice" algorithm. This, as well as noted above, can be the definition of additional components, their concentration in PC, technological and operating conditions. Calculations should be considered as a quantitative justification for the decision to develop a new PC. With the development of these approaches it is possible to create an automated system.

6. Conclusion

Summarizing the above, we note that often the CTS design problem arising at the initial stages is the task of choosing the best or, in a certain sense, optimal variant from the set of admissible ones. They must meet the specified requirements on the "composition – property – application" platform. When you try to get a solution in terms of incomplete and fuzzy information about the object of design, there is a high probability of incorrect or inaccurate multiple solutions. Therefore, the use of a clear strategy can minimize this probability, also reducing the cost of design and practical implementation of a technical solution.

The approach proposed in this article to mathematical modeling using fuzzy information in the field of chemical technology is essentially the mathematical support of a profiled IS. The formation of a database of models within the system allows us to bring the linguistic resources of the user interface to a new level of interaction using language environments more similar to natural languages and setting the input data in a form that is quite familiar to the researcher.

We should also note that only one of the most important aspects of using fuzzy simulation of PCM is shown here. It is aimed at using information in the form of fuzzy numbers when choosing PC components from a uniform set. As can be seen from the above results, the analysis of experimental data is well algorithmized and can be implemented as an IS of a chemist-researcher and a chemist-technologist. The above mathematical calculations are illustrated by the example of PCM design in general methodical terms, so they can be transferred to other natural and engineering systems in which multicomponentity is the main feature.

The development of the proposed computational methods creates theoretical foundations for the formalization and automation of the process of quality management of technical systems. In this case, it is possible to attract highly qualified experts only once to customize methods for solving specific tasks. The necessary step in this case is the formation of a library of settings and the solution of basic ("zero") tasks. This will further allow you to work offline.

At the same time, the expert has several roles in stock:

- to identify the links between informal entities of the subject domain and formal entities of the theory of FS;
- the formation of an optimal set of requirements that a quality product must meet;
- applied to the PCM — selection of the PC composition according to the selected requirements.

This information will further allow to formalize the initial data of the subject area in terms of the theory of FS and use them in calculations, when upon receipt of an order from the consumer a set of requirements for PCM is automatically generated, and then estimates of formed requirements for specific candidates for PC components are calculated. Then a decision is made on the technical implementation of the composition, which ensures high quality of PCM. The analysis given here is given as a possible prospect for the development of the applied use of fuzzy mathematics tools in engineering. The stated essence of the method shows its role and value in solving the problem of quality management of PCM and other technical systems.

At the same time, we selectively point out the nearest additional applied work-analogues and areas in which methods for analyzing fuzzy information are being developed. These are economics [35], management systems [27], analysis of leasing projects [36], traffic optimization [37], occupational studies [38]. As a prospect, it can be viewed as technical compositions of medicinal and cosmetic forms, building and drilling mixtures and solutions, alloys, and some colloidal systems. As a nontrivial and nontechnical one, it is possible to propose to consider personnel recruitment tasks, for example, for diplomatic or other complex, for example, artistic work, from a certain number of applicants with a quantitative assessment of personal data and interview results. The basis for this is [39, 40]. True, the fully successful outcome of the future work of candidates cannot be guaranteed — one thing is a technique, the other is people-specialists. The risk factor, as in polymer and other systems, remains, but it is much higher.

Conflict of Interest

The authors declare no conflict of interest.

Sympathy Expression Method
Body Motion

ABSTRACT

Recently, educational-support robots have been attracting increasing attention as studying-support gadgets. Previous studies used the sympathy expression method in which the robot expressed emotions in sympathy with the learners; however, the robots considered in those studies expressed only facial emotions. Presently, there is no study that uses body movements together with facial expressions in the sympathy expression method. Thus, in this paper, we examine the effects of two types of robots that have different method of expressing emotions on learners in two experiments.

1 Introduction

Recent developments in robotics have prompted an increase in educational-support robots that assist in studying. For instance, a robot supports students at school [1] or helps them to learn the English language[2]. Koizumi introduced the robot as a "watching over" in situations where children learn while discussing the programming that controls the assembly and motion of the car robot by the Lego block [3]. Our research focus on educational support robots to learn with people. The serious problem that these robots face is that the learner gets tired of the robot because they find the behavior of the robots to be monotonous [4], [5]. To address this problem, previous researches developed a sympathy expression method that allows a robot to express emotions sympathetic to learners [6]. Through the subject experiments, the previous research reported that the robot using empathy expression method reduced the monotonicity of learning and reduced tiredness. However, sympathy expression method has been studied only for a robot that expresses emotions by changing facial expressions. In the area of human-robot interactions, conventional research stated that body motions of robots are useful in the interactions between humans and robots as well as in expressing emotions [7]. Thus, sympathy expression method using both facial expression change and body motion may be better than one based only on facial expression change. This paper reported the Experiment1 to measure the short-term impression and the Experiment2 to measure studying effects and long-term impression.

2 Sympathy expression method

The sympathy expression method is based on Russell's circumplex model of affect (shown in Fig.1). This method can be used to express emotions in the circumplex model using the correct answer vector $\vec{A}$ and the incorrect answer vector $\vec{B}$; thus, the learners believe that the robot sympathizes with them. If learner correctly answers the question, the robot expresses emotions using $\vec{A}$; in contrast, the robot expresses emotions using $\vec{B}$ for incorrect answer. $\vec{A}$ moves in the area $0 \leq L_A \leq 1.0$ and $-90° \leq \theta_A \leq 90°$. $\vec{B}$ moves in the area $-1.0 \leq L_B \leq 0$ and $-90° \leq \theta_B \leq 90°$. $L\cos\theta$ refers to the axis of "Pleasure-Displeasure." $L\sin\theta$ refers to the axis of

"Arousing-Sleep." The emotion vectors move as follows [6].

if (learners solve the problem correctly)
$L_A \leftarrow L_A + 0.2$
$L_B \leftarrow L_B + 0.2$
else
$L_A \leftarrow L_A - 0.2$
$L_B \leftarrow L_B - 0.2$
if (the time of answer $<$ reference time)

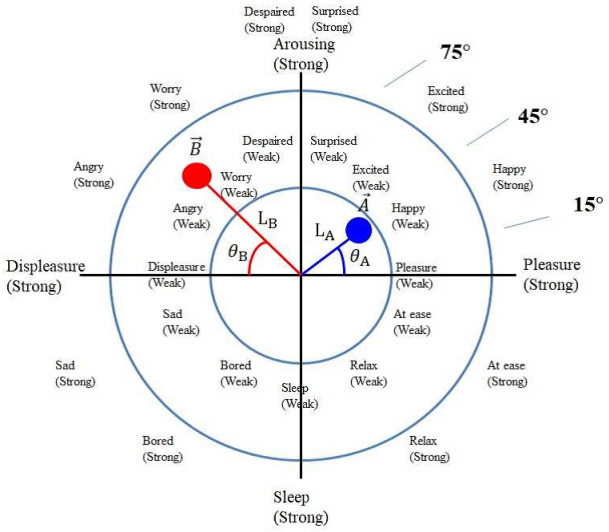

Figure 1: Sympathy expression method

if (learners solve the problem correctly)
$\theta_A \leftarrow \theta_A + 15$
else
$\theta_B \leftarrow \theta_B + 15$
else
if (learners solve the problem correctly)
$\theta_A \leftarrow \theta_A - 15$
else
$\theta_B \leftarrow \theta_B - 15$

In these experiments, the reference time is decided by the answer time in the earlier question. In the 1st question of studying, reference time is decided by the average answer time before studying. However, in first studying, reference time is 60. All robots utilized in these experiments were assumed to have the same sympathy expression method to enable a fair comparison.

3 Robot

3.1 Overview

In this study, we used a tablet robot ,"Tabot", whose head consists of tablets. as shown in Fig. 2. Tabot can express a lot of facial expressions by expressing the agent on the screen of the tablet.. It has 14 degrees of freedom: the neck has 3 degrees of freedom, the arms have 10 degrees of freedom, and the legs have 1 degree of freedom. So, it can do many body motions. It can express many emotions by combination of body motions and facial expressions. In these experiments, 2 Tabots were utilized for reducing the effects of the shape of robot.

Figure 2: The Tabot used in the experiment

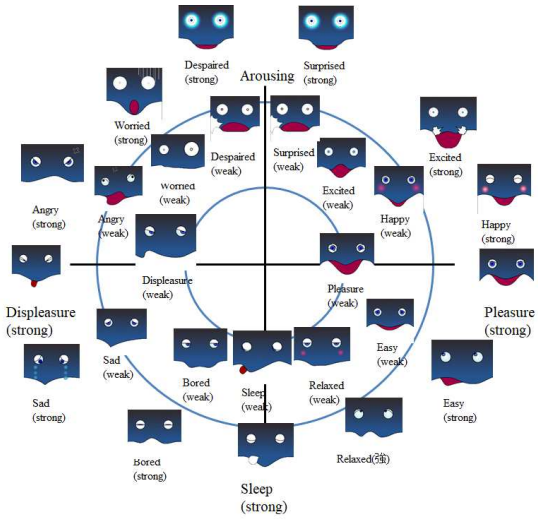

Figure 3: Facial expression

3.2 Facial expressions and body motions

The face displayed in its tablet and the changes in Tabot's facial expressions were developed based on a specific design. Two types of facial expressions were used to express the emotions corresponding to each emotion in the circumplex model. Fig. 3 shows example of facial expression of the Tabot. Conversely, Tabot's body motions were created on the basis of [8] and [9], which discussed the relation between human emotion and physical activity. Two types of body motions can be used to express each emotion and the corresponding emotions in the circumplex model. The body motions and facial expressions that expressed the same emotions were combined. We implemented

facial expression as well as a combination of facial expressions and body motions such that emotions can be communicated precisely to the learners. Fig. 4 shows example of combination of facial expression and body motion of the Tabot.

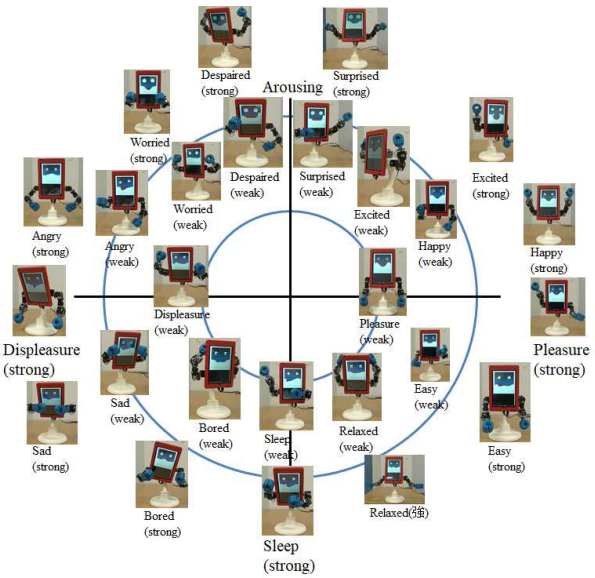

Figure 4: Combination of facial expression and body motion

4 Experiment 1

4.1 Method

The subjects learned with the robot comprising the sympathy expression method and a studying system. When a subject answered a question, the studying system displayed a correct or a incorrect response. Subjects learned by answering the questions displayed in the studying system. 4 university students and 8 graduate students in the science stream were gathered for this experiment. The participants had never used a Tabot previously. The twelve learners used two types of robots. The first type of robot was called "Robot-Facial-Group", which expressed emotions using only facial expressions. The second type of robot was called "Robot-Combination-Group", which used both facial expressions and body motions. The robots were used in a random manner. The subjects answered 20 questions in each group.

The upper side of Tabot's tablet displayed facial expressions. The lower side of the robot's tablet displayed studying systems. Tabot expressed emotions when the studying system gave either a correct or a incorrect response.

4.2 Overview of the studying system

We used the studying system (Fig. 5) for math questions called "Synthetic Personality Inventory 2 (SPI2)." SPI2 is used as a recruitment test for employment. Moreover, it uses junior high school level math questions. Therefore, university students do not require knowledge for SPI2.

Subjects first log in with an account number. Fig. 5(a) shows a menu of the study contents (i.e.,math questions). The column used for choosing the number of questions is shown under the study items. When a learner selected "20," 20 questions were shown randomly. Subsequently, repeating the same selection would display different twenty questions that could be repeated until all 100 questions are displayed. Thus, it enables learners to answer all the questions within the chosen study item. When a subject selected a study content and the number of questions, the studying screen (Fig. 5(b)) appeared and the studying process began. The subject answered the question from the selection list. Subsequently, the system displayed whether it was the correct answer as shown in Fig. 5(c). When the subject selected "Next" as shown in Fig. 5(c), the system moved on to the next question. When the subject selected "Result" as shown in Fig. 5(c), or solved all the questions, the system moved on to the results page (Fig. 5(d)), which presented the number of correct answers. When the subject selected "Study again," the menu of the studying items was displayed (Fig. 5(a)). When the subject selected "Study incorrect answers," the study page presented questions that were answered incorrectly (Fig. 5(b)).

4.3 Evaluation criterion

Impression evaluation used the rating scale method, which is a quantitative evaluation of impressions as shown in Fig.6. The rating scale method has 14 questions; it uses a range of values, e.g, "Friendly - Friendless," "Emotional - Intelligent," "Be pleased with me - Be not pleased with me," and "Enjoying studying - Not enjoying studying". The scores of the rating scale method range from 1 to 7. In Fig. 6, the left score is 7, and the right score is 1. In each group, subjects answered this questionnaire at the end of studying. Furthermore, subjects answered a questionnaire on the general comments about impressions. We defined the sum of scores of all questions as the score of good impressions. We conducted paired t-test for impression evaluation.

4.4 Result

Fig. 7 indicates the average impression score in two groups. This graph indicates the score of the Robot-Combination-Group is better than that of the Robot-Facial-Group. The result of paired t-test showed that the good impression score of the Robot-Combination-Group is significantly different from that of the Robot-Facial-Group. These results show that the robot that expresses emotions using both body motions and facial expressions can give learners a better impression than the one that expresses emotions using facial expressions only.

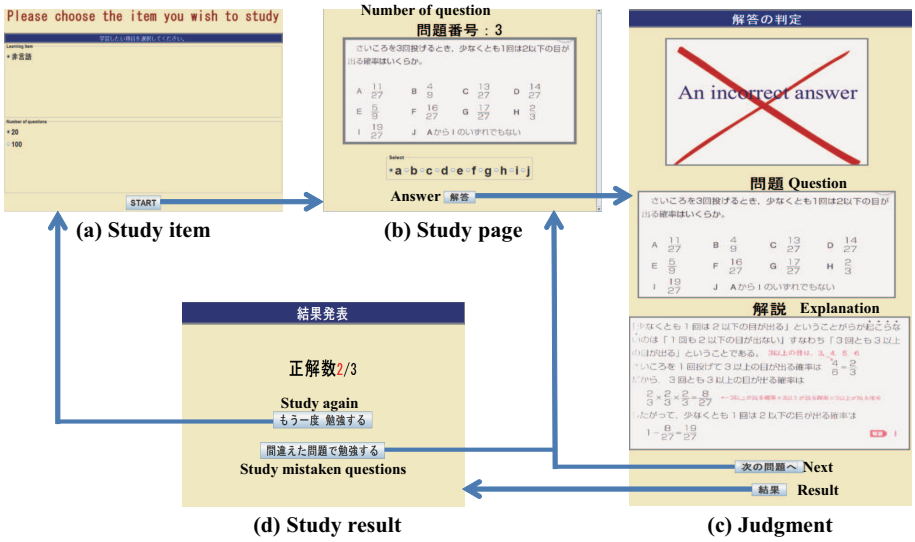

Figure 5: studying system

4.5 Discussion

The result of the experiment indicate that the sympathy expression method that expresses emotions using both body motions and facial expressions can give learners a better impression than a method that expresses emotions using facial expressions only. In the general comments column, somebody stated, "It was difficult for me to look at the robot's facial expressions." This implies that it is possible for some learners to not notice that the facial expression of the robot was changing because they concentrated on the questions of the studying system. Therefore, the impression made by the Robot-Combination-Group was quite different from that made by the Robot-Facial-Group.

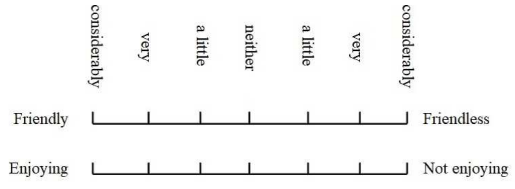

Figure 6: Examples of the rating scale method

5 Experiment 2

5.1 Method

The subjects learned with a robot comprising a sympathy expression method and a studying system. When a subject answers question, the studying system shows a correct or incorrect judgment. Subjects learned by answering the questions which were displayed by the studying system.

20 university students who had never studied with Tabot previously were gathered for this experiment. 20 subjects were divided into two groups of 10 students each; "Robot-Facial-Group" and "Robot-Combination-Group." The subjects in Robot-Facial-Group studied with Tabot, which expresses only facial expressions. The subjects in Robot-Combination-Group studied with Tabot, which expresses a combination of facial expressions and body motions. These subjects were instructed in math by the studying system for 40 minutes, 2 or 3 times a week, for 1 month. Thus, they studied 12 times in a month. During the studying of 1st and 12th time, subjects used studying system on their own to measure their ability before and after studying. These are the pre-test and the post-test scores. From the 2nd time to 11th time, subjects learned using the studying system with the Tabot.

The upper side of Tabot's tablet showed facial expressions. The lower side of Tabot's tablet showed the studying system. Tabot expressed emotions when the studying system gave a correct or an incorrect response.

The robot and studying system used in this experiment is the same as those used in Experiment1.

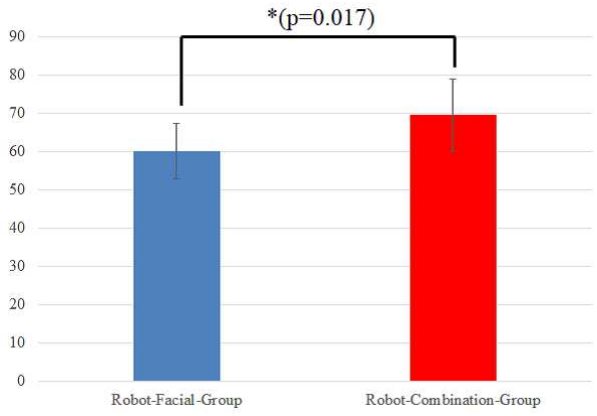

Figure 7: Impression score in experiment1

5.2 Evaluation criterion

Studying effect was calculated based on the improvement score got by difference of the pre-test score and post-test score. Each of these scores was calculated by

100 questions shown by the studying system. Impression evaluation was calculated in rating scale method, that is same as Experiment1. In all groups, subjects answered the questionnaire after the 11th studying. We defined the sum of scores of all questions as the score of good impressions. We conducted a Welch's t-test to improve the studying effect and the impression evaluation. To admit a significant difference based on the fact that p values is 5%, we adjusted the significance level (p = 0.025) using the Bonferroni method.

5.3 Result

5.3.1 Improvement score

Fig. 8 indicates the pre-test average score and the post-test average score in two groups. Fig. 9 indicates the average improvement score in two groups. Fig.9 indicates that the score of the Robot-Facial-Group is higher than the score of the Robot-Combination-Group. We conducted Welch's t-test to compare the studying effects. The results show that there was no significant difference in the improvement score between the two groups.

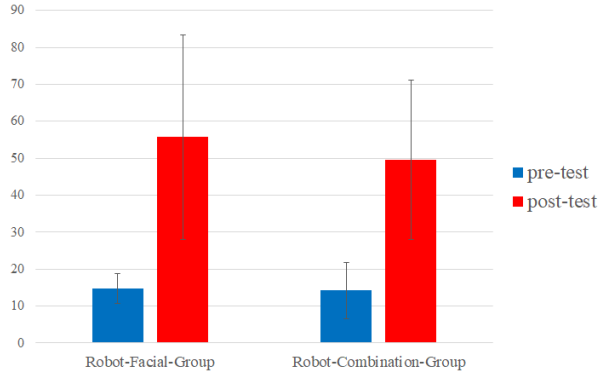

Figure 8: Score of pre- and post-test

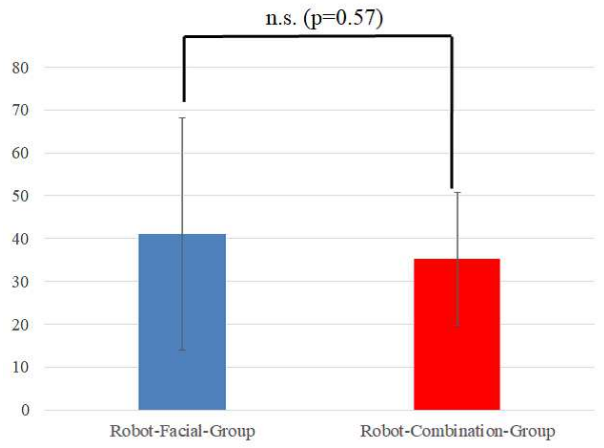

Figure 9: Improvement score

5.3.2 Questionnaire

Fig. 10 shows the average impression score in two groups. This graph shows that the average impression score of the Robot-Combination-Group is higher than that of Robot-Facial-Group. We conducted Welch's t-test to compare the impression scores. The results showed there was no significant difference in the impression score between the two groups.

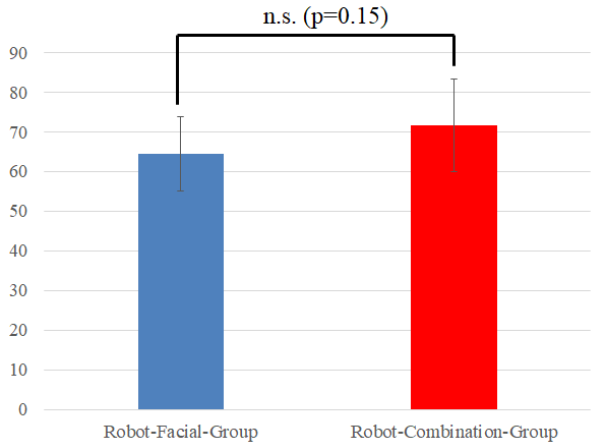

Figure 10: Impression score in Experiment2

5.4 Discussion

The result of studying effect indicates that it is higher in Robot-Facial-Group than in Robot-Combination-Group. Table.1 shows the number of answering questions in Robot-Facial-Group. Table.2 shows the number of answering questions in Robot-Combination-Group. The average number of answering questions is shown in Fig. 11. The answering questions were defined as the number of answered questions in each studying session. The average number of answering questions shows that its number was higher in Robot-Facial-Group than in Robot-Combination-Group. The time to express emotion by body motion is longer than the time to express emotions by facial expression change. Thus, the fact that the robot cannot move to the next problem while expressing emotion produced the difference in the average number of answers between the two groups. Moreover, we determined that the studying time in Robot-Combination-Group was shorter than that in Robot-Facial-Group. We believe that it is possible that the studying effect can be influenced by the number of answering questions.

In contrast, the result of the questionnaire shows that the robot in the Robot-Combination-Group gave a better impression than that in the Robot-Facial-Group. Therefore, the body motion of the robot manifested emotion efficiently as reported in conventional research [7]. Therefore, we believe that learners felt the more sympathy from the robot expressing emotions using body motions than from the robot expressing emotions using facial expressions only.

However, in this experiment, we could not find significant difference in the impression score between the two groups. Thus, we calculated the percentage of the expressed emotions. Fig. 12 shows the percentage of emotions expressed in the Robot-Combination-Group. It shows that only three types of emotion out of 28 were

often expressed by robots in the Robot-Combination-Group. Therefore, learners may feel that robots in this group always expressed the same emotion. Therefore, robots that expressed emotions using body motions and facial expressions did not show any significant difference compared to the robots that expressed emotions using facial expressions only.

Table 1: The number of answering questions in Robot-Facial-Group

No.	2nd	3rd	4th	5th	6th	7th	8th	9th	10th	11th
1	36	29	41	48	52	51	50	59	61	70

6 Conclusion

This paper examined the effects of sympathy expression method using body motion and facial expression in short-term and long-term experiments. We used "Tabot", a tablet-type robot that has a tablet head. Tabot has a sympathy expression method. In the experiment we performed, we used two types of' Tabot; robots that express emotions using facial expressions only and those that use a combination of body motions and facial expressions to express emotions. The results of Experiment1 suggest that the robot that expressed emotions using body motions and facial expressions prompted more impression to the learners than the robot that expressed emotions using facial expressions only. The results of Experiment2 suggest that robots that express emotions using facial expressions can better prompt learners to improve their studying effect than those that express emotions using the combination of body motions and facial expressions. Moreover, we determined that the robots that express emotions using facial expressions and body motions prompted more impression to the learners than those that express emotions using facial expressions only. However, robot that express emotions using body motions and facial expressions has issues relating to the time of expressing emotions and the kind of emotions they expressed.

In the future, we plan to improve the algorithm for sympathy expression in a way that solves the problem of time of expressing emotions and the kind of emotions expressed by the robot.

Edge computing

ABSTRACT

Cloud computing is an exceptional paradigm, which is facilitating the developments and utilization of resources over the internet. Fog computing operates at the edge of the network saving bandwidth, by not sending all information to the cloud, while edge computing does processing of data at the edge of the cloud. Edge computing reduces the distance data must travel on the network. The unique relationship between cloud, fog and edge computing makes research in these areas mandatory. Deciding on a specific area of research as regards these subjects could be a bulky procedure for a scientist. Therefore, reviews and paper studies for recognizing potential research gaps are required. A systematic mapping study is utilized in giving a summary of the conducted research in a particular study area. The objective of this paper is to conduct systematic mapping studies on cloud, fog, edge/mobile devices management, hierarchy models and business models. The results showed that publications that discussed process in relations to the field of study is 14.04% out of the 114 papers included. Also method contributed 24.56%, model had 42.98% and tool contributed 18.42%. Furthermore, evaluation research in terms of the field of study was 27.5% out of 120 papers included. Also, validation was discussed in 17.5% of the papers, solution was 32.5%, philosophical was 5.83%, experience was 15.83% and opinion was 0.83%. The clearly highlighted gaps ought to inspire more enthusiasm for additional research by both researchers and industry practitioners.

1. Introduction

The Cloud is a parallel and appropriated computing system comprising of interconnected and virtualized computers that are powerfully displayed as a unified computing resource, which is dependent on service level approvals set up through dealings between service providers and users [1]. Cloud computing is basically interconnected computers and applications used to deliver services over the Internet. When systems are connected in this manner, device management also becomes paramount. Cloud computing is presently delivering services at all layers hence, there is everything as a service, but there are three primary services in the cloud which are Software-as-a-Service (SaaS), Platform-as-a-Service (PaaS) and Infrastructure-as-a-Service (IaaS). In SaaS, major cloud service provider (CSP) like Salesforce.com offer custom-built applications for users on the internet, hence the user do not need to bother about installation and license. In PaaS, the user develops and deploys his application through the infrastructure made available by the CSP. In IaaS, the user utilized resources on the CSP infrastructure on a pay as you go basis. The CSPs have massive data centers with state of the art system; hence, the user can start up without the cost of infrastructure. Although the CSPs strive in providing effective and trustworthy services on the cloud, there are also issues of trust [2]. The effectiveness of cloud computing becomes very evident as services improve and expand regularly, due to the fundamental applications running on the cloud [3,4]. In addition, there are four cloud computing models namely the private, public, community and hybrid models. Private clouds provide organizations infrastructures that are hosted on premises or off premises making use of in house staff. Private clouds are considered more secure. Public clouds provide massive elastic, on-demand pool of resources to the users through the CSP

*Corresponding Author: Isaac Odun-Ayo, Contact No. +234 802 88 29456, Email: isaac.odun-ayo@covenantuniversity.edu.ng

infrastructure. Community cloud make services available to institutions that share infrastructure but operate independently. Hybrid clouds provide the potential to host core applications on private cloud and auxiliary applications on public clouds. However, due to the process of virtualization and multitenancy on the cloud, there are concerns about security [5,6].

Fog and edge computers carry out storage and processing at the edge of the cloud. This saves bandwidth and makes usage simple. However, there are technologies that must be used to monitor these applications data and services operating within and at the edge of cloud computing. Edge computing is characterized by proximity to end users, zone geographical distribution, and support for high mobility and value addition for customer IoT services [7]. Mobile edge computing aims at reducing both network latency and resource demand by shifting computing and storage capacities from the Internet cloud to the mobile edge [8]. In [9], the cloud system is described with a 3-layer hierarchy, the cloud computing infrastructure layer, the edge computing or mobile clouds, which are utilized in vertically integrated applications where a part of the processing and analytics happens on the edge device while the cloud is used for coordination and data retrieval [10]. The service measurement index framework discussed in [11] is a business model that provides an understanding of CSP rankings, and has 7 major characteristics namely: accountability, agility, assurance, financial, performance, security and privacy and usability [11].

Systematic mapping studies provides a platform for categorizing research using a scheme and structure indicating the frequency of research in such an area and the results are presented visually on a map. Systematic mapping requires less effort: yet provides a more coarse-grained overview in the area of study [12]. This enables the coverage of the research field to be determined. The systematic process in this work was accomplished using three facets: the topic, contribution and research facets. The topic facet extracts key consideration from the scope of study. The contribution facet deals with method or mode of the work, while the research facet considers the nature of research such as evaluation or opinion. While the goal of this study is to conduct a systematic mapping study, the rest of the paper is organized as follows: Section II examines the related work. Section III examines the materials and methods, Section IV presents the results and discussion and Section V is the conclusion and suggestion for future work.

2. Related Work

In [13], the authors explored the developing stage of a systematic mapping study by identifying the software designs present at the requirement engineering stage of the project, and providing a comprehension of the roles played by these patterns based on basic parameters required in the development process. A protocol was developed for the study with basic steps to enable the replication of their work by the research community, which results in confirming the validation of the research. For this paper, ACM DL, IEEExplore, SCOPUS, and Web of Science digital libraries were utilized, and the guidelines laid down in [12] were adhered to.

In [14], the authors dwelled on describing the protocol for a systematic map, in relation to domain-specific languages (DSL). The authors focused on channeling their work on the advanced apprehension of the DSL domain of research, while emphasizing on trending researches and subsequent expectations, and utilizing the requirements for conducting a systematic review, all within the interval of July 2013 to October 2014.

The authors in [15] analyzed the utilization of concept maps in Computer Science, which resulted in a systematic map focused on gathering and analyzing previous articles on concept maps. This resulted in a thorough examination of concept maps, with emphasis on learning and teaching supports. Also, the searching process involved the utilization of backward snowballing and manual methods, and search strings applied on SCOPUS, ScienceDirect, Compedex, ACM DL, and IEEExplore digital libraries.

In [16], the researchers examined how games related methods are implemented in software engineering, and how these methods assist specified software engineering knowledge domains. Based on publications from 1974 to 2016, the authors utilized 156 primary studies, which were centered on using and evaluating games in software engineering education. The mapping procedure was done in line with the guidelines provided in [12].

In [17], the authors did a mapping of power system model by providing a summary of power system models and its subsequent usage by European organizations in terms of analysis of their modeling features and identification of modeling gaps. 228 surveys were sent out to power experts for data extraction, while 82 questionnaires were eventually completed and utilized for the mapping.

In [18], a mapping study of domain-specific languages was conducted with a primary interest in the type of contribution and research, and the area of focus. By exploring reputable articles from 2006 to 2012, a mapping study was conducted by defining research questions, conducting the search, and extracting the data.

In [19], the authors focused on searching studies on “legal theory” and “legal concepts”. The selected studies were grouped on contributions in terms of language, tool, method, and model. The other steps include identification of the used legal theories in legal core ontologies building process, identification of focus with a clear recommendation on the use of two ontologies, and analyzing each highlighted research for conclusive findings about legal and ontological research.

In [20], the researchers gave a summary of an empirical research in software cloud-based testing in the process of building a classification scheme. The authors examined functional and non-functional testing techniques, their applications, and their peculiarities. Sixty-nine (69) primary studies out of seventy-five (75) research articles were utilized for a rigorous statistical analysis, and an eventual quantitative result. Most articles utilized a singular experiment approach for evaluating their expected result.

In [21], the authors presented a comprehensive review of knowledge management in organization with a focus on the potential role of Information Technology (IT) in the process. They further discussed several important issues bordering on the process of managing knowledge and the role of IT in propelling and assisting these processes. Also, emphasis was made on the need to support in creating, storing, transferring and applying knowledge in organizations.

In [22], the authors discussed the usefulness and limitations of systematic literature review in information system and social sciences. They are of the opinion that the general stand that systematic literature review provide a holistic and superior approach to literature review is not only questionable but also unacceptable. In their argument and justification of this, they concluded that caution and restrains should be exercised when choosing systematic literature review as it could undermine critical engagement with literature and the scholarly nature of academic work.

In [23], the authors discussed the lessons learned from utilizing a systematic literature review process on software engineering domain. The authors summarized the review process, highlighted the reviews of other authors and finally extracted and discussed findings as regards applying this practice to software engineering domain.

In [24], the researchers opined that research reviews must pay close attention to rigorous methodology that is required of primary researcher. The author further conceptualized the research review as a scientific enquiry involving five stages that parallel those primary research, which includes: formulating the problem, collecting data, evaluating the data points, analyzing and interpreting the data, and lastly, presenting the results. All the functions; sources of variance and the other potential treats to validity with each stage are discussed.

In [25], the authors provided useful insights to researchers for carrying out literature review. They suggested synthesizing trends and patterns while preparing to write literature review, among which includes: the purpose and voice before beginning to write must be considered, then consider how to reassemble the notes as well as create a topical outline that traces the argument in the literature review. All of these provides the guidelines for developing a thorough and coherent literature review.

In [26], the researchers assessed the effectiveness of a systematic literature review, which recommends evidence-based software engineering methods for aggregating evidence. The authors utilized manually searched Journals (10) and conference proceedings (4). Of the twenty (20) significant articles considered, eight (8) articles focused on research trends rather than evaluating the technique utilized, and seven (7) systematic literature reviews focused on estimating the cost. The quality of systematic literature reviews was fair with only three scoring less than 2 out of 4.

In [27], the authors have an opinion that the evaluation of the approaches of systematic mapping, as carried out by researchers, is needed in identifying the improved guidelines that are centered on the experiences from existing systematic maps and literature reviews. In the affirmative, the authors carried out a systematic mapping study and considered a few practices of the systematic review guidelines. They discovered that amongst the extensive number of studies carried out, various guidelines were utilized and integrated, leading to multiple methods of conducting systematic mapping studies.

In [28], the authors stressed the importance of literature review in scientific enquiry and the need to avoid standing on the shoulders of dwarf literature search, which remains a point of concern for enhancing a productive literature review. The authors further discussed the difficulties of literature search in the ever-increasing dynamic setting of data frameworks, and proffer solutions on how these difficulties can be dealt with.

In [29], the authors presented the systematic mapping study of high-performance computing and the cloud which based their work on the concepts of [27]. This study provided six classes of studies in the areas of architecture, virtualization, application, optimization, design and implementation, and performances in relation to the focus of study. The selected studies were applied on the contribution facet such tool, method, and model. In addition, the selected studies were used on the research facet which dealt with evaluation, validation and solution research.

In [30], the researchers examined the systematic mapping study of cloud resources management and scalability in brokering, scheduling, capacity planning and elasticity. The classification scheme in relation to resource management, discussed scalability, brokering, scheduling, capacity planning, elasticity, and resource sharing. The selected studies were applied on the contribution facet such metric, tool, method, and model. In addition, the selected studies were applied to the types of research.

3. Materials and Methods

The systematic mapping study is a useful tool for both researchers and practitioners alike. A mapping study provides a visual representation of scope of work in a particular discipline. This study was carried out utilizing the guidelines on systematic mapping studies, as seen in [12]. Systematic mapping study involves replicating a process for deducing and interpreting accessible materials, in line with a research objective [31]. This important process (Figure 1) involves defining the research question and outlining the scope of the review. Next is screening the articles to select the important ones and key wording the abstract of the articles, with the goal of creating a classification scheme. Finally, the last step involves extracting the data, which ultimately leads to creating the systematic map. At every stage of the process there was an outcome which was refined for better overall output of the systematic map.

3.1. Definition of Research Questions

The goal of a systematic map is to provide more insight into the quantity and type of work being conducted in a particular discipline. It may also be necessary to know the places where such work were published. These issues help in determining the appropriate research questions to apply to the study in this paper.

The research questions are:

RQ 1: What areas are addressed and what number of articles are covered in the highlighted areas of the research topic?

RQ 2: What sets of articles are published in the highlighted areas and what are their evaluations and originality?

3.2. Conduct of Research for Primary Studies

For the purpose of getting papers for this study, four (4) major digital libraries based on their impact factor of conferences and journal publication were utilized. Table 1 contains the digital libraries and their corresponding uniform resource locator (URL).

Table 1: Electronic databases used for the systematic mapping study

Electronic Databases	URL
ACM	http://dl.acm.org/
IEEE	http://ieeexplore.ieee.org/xplore
SCIENCE DIRECT	http://www.sciencedirect.com/
SPRINGER	http;//www.springerlink.com/

The search string was designed based on population, outcome and intervention of the papers. The keywords used in the research was gotten from all parts of the structure of this study's title; the search string is as follows:

(TITLE (cloud) AND KEY (cloud) AND (TITLE-ABS-KEY) (fog) OR TITLE-ABS-KEY (edge and mobile) OR TITLE-ABS-KEY ("devices management") AND (KEY (Models) OR TITLE (models)

The searches were performed on the electronic database, which involves utilizing the designed search string above on document metadata to guarantee the inclusion of significant articles. For this study, findings from relevant databases relating to cloud computing and computer science were utilized, and a total of 120 papers were relevant to be included out of an underlying pursuit comprising of 1339 papers. This study covered the period 2001 – 2018. The list of primary studies utilized for this work is at the Appendix.

3.3. Screening of Papers for Inclusion and Exclusion

The importance of selection criteria is identifying and incorporating all papers relevant to the study. This was a vital aspect of the study. It was essential to use the inclusion and exclusion criteria to eliminate irrelevant articles as regards to cloud, fog, and edge/models device management. In addition, the criteria was utilized in removing all materials not providing answers to the research question. Some abstract usually mention only one aspect of the focus of study without further details and such papers are also excluded. This study also excluded panel discussions, editorials, prefaces, presentation slides, summaries and tutorials. It was pertinent to consider articles that had the main focus and able to also provide some secondary details. The main focus of this study was devices management and models as it relates to cloud, fog, and computing. Therefore, the inclusion and exclusion process was done using details depicted in Table 2.

Table 2: Inclusion and exclusion criteria

Inclusion criteria	Exclusion criteria
The abstract explicitly mentions cloud, fog, edge, mobile devices management, hierarchy models and business models. Furthermore, discussions in this area are meant to achieve cloud management.	The paper lies outside the area of cloud computing as it identifies with cloud management. The paper does not contribute to issues of management in the cloud.

3.4. Keywording of Abstracts

Keyword of abstracts is an important process in systematic mapping, used to design the classification scheme for the study and involves the following stages as shown in Figure 1.

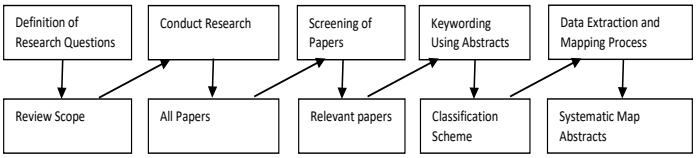

Figure 1: The systematic mapping process [27]

Key wording was useful in decreasing the required time for designing a classification scheme for cloud management and model studies. Also, key wording ensured that only the significant papers were considered in the scheme. The abstracts were studied in order to extract concepts and keywords relating to the focus of this study. Therefore, keywords from different publications were combined together to give satisfactory knowledge about the nature of the contributing research. This was eventually utilized in determining the facts or categories of the study.

A cluster of keywords were finally used in this paper to determine the categories and the eventual systematic map. In this paper, the three categories focused on topics based on all aspect of the title of the study. The second facets discussed the types of contributions in relation to metric, tool, method, process and model [12]. The third facet concentrated on research types such as evaluation and validation.

3.5. Research type Facts with Category and Description

A study of this nature will be inadequate without all the categories outlined. The following is the classification of research methods, which was utilized for the third facet, as listed in [32]:

1. **Validation of research:** The utilized methods are unique but not yet executed, either in form of an application or experiments.
2. **Evaluation research:** The methods have been executed and analyzed with a proof of concept. Outcomes are examined in terms of advantages and disadvantages.
3. **Solution proposal:** The method offers an essential solution to a problem; the benefits and application of such results are also outlined.
4. **Philosophical papers:** The papers discuss techniques that provide new methods of solving a problem in relation to concepts and framework.
5. **Opinion papers:** The research papers do not apply any known methods, but simply expressed the opinion of individuals.
6. **Experience papers:** This paper relates the personal experience of the researcher. It offers insight into how something was done

These categories were considered adequate and sufficient to be used in the classification scheme of this study, as to research facet. The papers included in this study were all examined based on the various research categories.

3.6. Data Extraction and Mapping Studies

Relevant articles were sorted into a classification scheme at the key wording stage. This next step allowed data extraction from the primary studies. The method of extracting data shaped the nature of the classification scheme. The procedure for extracting data was achieved on Microsoft Excel tables. The Excel tables contained the various groups of the classification scheme. The frequency of publications in each category was extracted to different tables. The frequency of publications in each category was combined into a table either contenting the topic/contribution category or the topic/research category. The analysis was focused on presenting the frequencies of articles based on the entries made into the various Excel tables. The essence was to identify which aspect of device management and models as it relates to cloud, fog and edge/mobile computing were given more emphasis in this study This enabled the determination of gaps and made it easy to identify areas for further research.

Based on the results extracted to the Excel tables, bubble plots were subsequently utilized in presenting the frequency of the articles using a map. The map included a two x-y scatter plot with bubbles at the crossing point of the classifications. The size of the bubble coordinates corresponds to the quantity of articles in such combined categories. There were two quadrants based on the three facets under consideration. Each quadrant provided different visualized maps on the basis of the intersection of the topic category with either the contribution or research category. The different facets could be considered simultaneously, providing an overview of the results of the study.

4. Results and Discussion

The analysis of the result is meant to present the frequencies of publication in each category, and to identify which category has been emphasized in past research [12]. The essence of this was the identification of gaps and the possibility of researching further. From the analysis, gaps were identified by using the systematic map, which showed topic areas where there was dearth of study, and indicated the areas that were explored as regards articles. In this systematic study, high-level categories was utilized in assessing the primary studies, which was used to create the systematic map.

4.1. Topic and Contribution Facet

The topics extracted at the classification scheme in this field of study comprise of the following:

1. Architecture
2. Application
3. Implementation
4. Networking
5. Mobile computing
6. Embedded systems

The list of primary studies used for checking the topics against the types of contributions is at Table 3. The systematic map is shown at Figure 2. The contribution facet shows the type of contribution to the field of study. The results showed that publications that discussed process in relations to the field of study was 14.04% out of the 114 papers included. In addition, method contributed 24.56%, model had 42.98% and tool contributed 18.42%. There were no contributions at all from metric.

Models discussion contributed 42.98% of the papers reviewed. In relation to the topics, model had 5.22% in terms of architecture, 12.28% in terms of application, and 3.51% in the area of implementation, 10.53% in the area of networking, 3.51% in the aspect of mobile computing and 7.89% on embedded system. Other aspects of topic and contribution aspect are reflected in Figure 2.

4.2. Type and Research Facet

The list of primary studies used for examining the topics against the types of research is at Table 4. On the x-axis of the right quadrant of Figure 2 are the results of the types of research conducted with respect to the field of study. The result indicated that evaluation research in terms of the field of study was 27.5% out of 120 primary studies. Also, validation was discussed in 17.5% of the papers, solution in 32.5%, philosophical in 5.83%, experience in 15.83% and opinion in 0.83%.

Solution proposal constituted 32.5% of the papers examined in this field of study in relation to the topics. Solution proposal had 1.67% in terms of architecture, 8.33% in terms of applications, 5% in relation to implementation, 11.67% with respect to networking, 3.33% in terms of mobile computing and 2.5% in terms of embedded system. Other aspects of research and topic contribution is as shown in Figure 2.

4.3. Major Findings

From Figure 2,

a. It can be identified from the visual map that there were more publications on implementations and mobile networking that discussed metric with 26%, more publication on applications that examined model with 12.28%, more papers on architecture that discussed method with 6.14% and more work on embedded systems examining process at 6.14%.

b. Similarly, on the left quadrant of Figure 2, there were more articles on mobile computing that discussed evaluation research with 9.17%, more publications on application that examined validation research with 5%, more work on network in terms of solution proposal at 11.67%, more publication on mobile computing in terms of philosophical paper with 3.33%, more materials on application in term of experience papers and only one opinion paper related to embedded system.

c. On the other hand, this study had shown that there were no discussions at all relating to metric in this field of study. There were no papers on architecture in terms of tool. There were no articles on implementation and networking in terms of process. In addition, there was no work on architecture, application, and networking in the area of philosophical papers.

d. Furthermore, publications on application topic as it related to tool, mobile networking and implementations

Table 3: Primary studies for topic and contribution facet

Contribution Facet / Topic	Metric	Tool	Model	Method	Process
Architecture			30, 37, 80, 92, 93, 95,	18, 42, 60, 77, 84, 90, 116,	4, 8,
Application		28,	25, 36, 39, 38, 45, 48, 54, 57, 71, 78, 82, 85, 115, 119,	5, 11, 14, 86, 94,	105, 108,
Implementation		13, 19, 26, 101, 118, 120	50, 55, 87, 100,	2, 43, 46,	
Networking		22, 24, 29, 31, 33,	7, 9, 12, 15, 16, 91, 96, 98, 103, 104,106, 112,	20, 41, 47, 70, 79, 83,	
Mobile computing		3, 6, 10, 23, 109, 110,	27, 32, 34, 35	2, 73, 75, 76, 89, 99	44, 53, 56, 58, 71
Embedded Systems		49, 61, 62,	1, 64, 65, 66, 67, 68, 74, 115, 119	81	17, 21, 51, 52, 97, 113, 114,
Percentage	**0.0%**	**18.42%**	**42.98%**	**24.56%**	**14.04%**

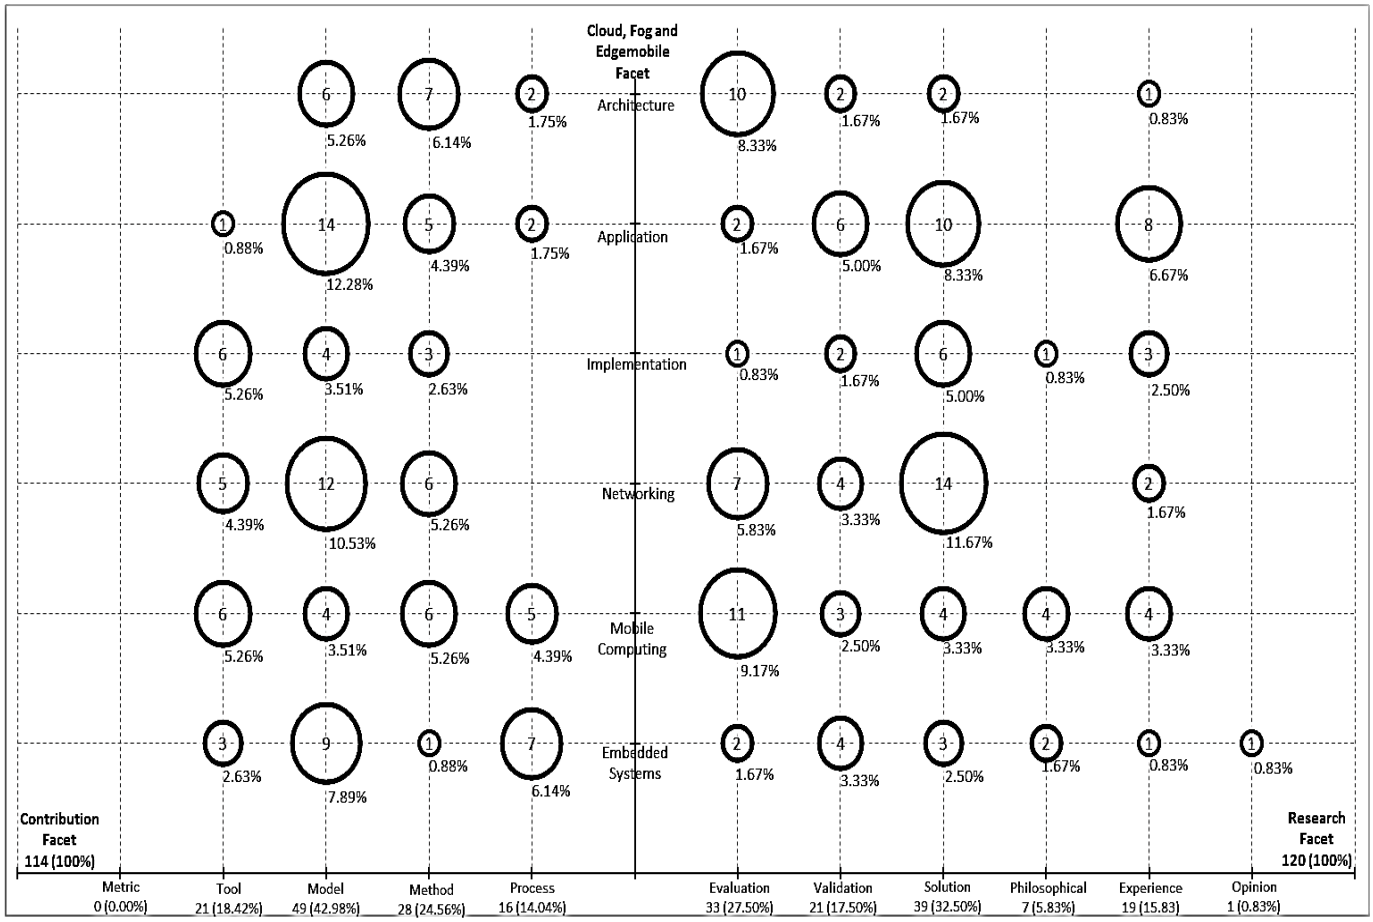

Figure 2: Systematic map of cloud fog, and edge/mobile devices management, hierarchy and business models

Table 4: Primary studies for topic and research facets

Research Facet / Topic	Evaluation	Validation	Solution	Philosophical	Experience	Opinion
Architecture	4, 8, 37, 42, 60, 80, 84, 90, 95, 116	18, 30	92, 93		77	
Application	78, 102	11, 14, 59, 63, 105, 108	5, 36, 39, 38,48, 54, 82, 85, 115, 119		25, 28, 45, 57, 69, 71, 86, 94	
Implementation	2	13, 87	19, 26, 43, 46, 118, 120	101	50, 55, 100	
Networking	7, 20, 22, 24, 29, 31, 33	41, 47, 88, 91	9, 12, 15, 16, 49, 61, 62, 70, 104,106, 112, 96, 98, 103		79, 83	
Mobile computing	3, 6, 10, 23, 34, 35, 75, 99, 111, 113, 114	76, 89, 107	40, 44, 73, 117	53, 56, 58, 72	27, 32, 109, 110	
Embedded Systems	1, 65	17, 21, 51, 52	64, 81, 97	66, 67	74	68
Percentage	**27.50%**	**17.50%**	**32.50%**	**5.83%**	**15.83%**	**0.83%**

in terms of model, embedded systems were the least having, 0.88%, 3.51%, 0.88% and 1.75% respectively.

e. In terms of the topic and research types, implementation topic in relation to evaluation research, implementation and architecture in relation to solution proposals, implementation with respect to philosophical paper, architecture and embedded systems in terms of experience papers had the least publications with 0.83%, 1.67%, 0.83% and 0.83% respectively.

From the foregoing, the visual appeal of a systematic map assists in summarizing and offering researchers with the likelihood of stimulating interest in the results.

The different categories combined together makes the bubble plot more useful. It is imperative to state that the creation of a systematic map in the absence of a successive systematic review is valuable in itself. This is because the systematic map enables the identification of research gaps and shortage of publication in this field of study. This paper provided six classes of studies namely architecture, application, implementation, networking, mobile computing and embedded systems, which could be discussed as regards to either tool, model, method, metric and process or evaluation, validation, solution, philosophical and opinion research. The few aforementioned areas, along these lines, are suggested for additional research, and the rundown of primary studies would likewise help meaning researchers.

5. Conclusion

Cloud computing is providing opportunities in different areas of human life. More areas of cloud research are opening up on a regular basis. This has led to increasing studies and consequent publications in cloud computing. There are volumes of research effort that is useful both to the cloud users and cloud providers alike. The aspect of devices management and models in relation to cloud, fog, edge and mobile computing has continued to receive attention. Despite the large quantity of publications in this field of study, the systematic map has shown that there are shortage of publications in this field of study. The visual representation provided by the systematic map enhances decision on areas of further research. This systematic mapping study has been able to identify some areas where there were less emphasis on the topic, based on the categories used in the scheme. This paper has therefore contributed to knowledge by highlighting the different aspects of the study with gaps, and recommending them for further studies. Also, further research could be carried out to validate this study or resolve contradictory issues. In summary, this study created a systematic map that could be advantageous to the cloud community, and will assist researchers in uncovering the critical gaps that were not previously explored.

Conflict of Interest

The authors declare no conflict of interest.

ABSTRACT

The IEEE 802.11n wireless local-area network (WLAN) has been extensively deployed around the world due to the flexibility, lower cost, and the high-speed data transmission capability at 2.4 GHz ISM band. However, in the WLAN deployment, one key challenge is to optimize the channel assignment of access-points (APs) under the small number of partially overlapping channels (POCs) to reduce radio interference, particularly for the channel bonding. In POCs, the frequency spectrums of adjacent channels are partially overlapped with one another, which will result to low throughput for concurrently communicating links using them. The accurate throughput estimation of a link is critical in the optimal WLAN deployment. Previously, we studied the throughput drop estimation model using the receiving signal strength (RSS) from the interfered link for two concurrently communicating links under POCs. In this paper, based on measurement results, we have extended this model for three concurrently communicating links. The accuracy of this model extension is verified by comparing the estimated results with the measured ones.

1 Introduction

Nowadays, the *IEEE 802.11 wireless local-area network (WLAN)* has been used across various sectors around the world, due to the unlicensed frequency bands in wireless medium and availability of low-cost devices [1]–[3]. It is suggested that WLAN has become a crucial business and the common asset [4]. For the access to the Internet using WLAN, a host is connected to an *access point (AP)* wirelessly, where the AP is connected to the Internet with wires. Therefore, a host can move randomly in the network area with the current association. As the data transmission speed increases due to technological advancements, WLAN has proved popular even for static settings of personal computers in offices and homes [5].

The IEEE 802.11 WLAN can function in two unlicensed frequency bands [6, 7]. One is the 2.4 GHz *Industrial, Scientific, and Medical (ISM)* band, and the other is the 5 GHz *Unlicensed National Information Infrastructure (U-NII)* band.

For either band, the IEEE 802.11 standards define the small number of channels for use. Each channel has 22 MHz width, conventionally called a 20 MHz channel. The frequency gap between two adjacent channels is merely *5MHz*. Thus, the spectrums of adjacent channels are partially overlapped with one another, called the *partially overlapping channels (POCs)*. Figure 1 shows the 2.4 GHz spectrum with 40 MHz channels to illustrate the POCs in IEEE 802.11n.

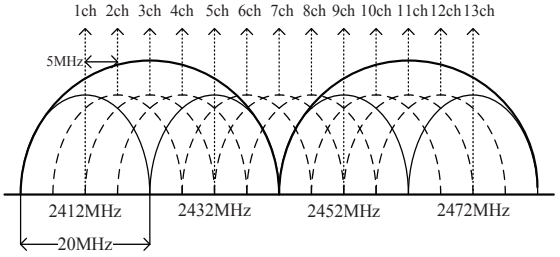

Figure 1: 40MHz channels at 2.4 GHz band.

While the IEEE 802.11 WLANs referred to in this paper use the unlicensed frequency bands, *the Industrial, Sci-*

*Corresponding Author: Nobuo Funabiki, Dep. of Elect. and Comm. Eng., Okayama Univ., Okayama, Japan, Email: funabiki@okayama-u.ac.jp

entific, and Medical (ISM) 2.4 GHz band and *the Unlicensed National Information Infrastructure (U-NII) 5 GHz band*, the 802.11y is licensed to use [8]. The unlicensed IEEE 802.11ad, which represents modifications of IEEE 802.11 physical layer (PHY) and medium access control layer (MAC) [9], provides the very high speed, which is equivalent to the fiber optic. However, its short range limitation coupled with the expensive hardware makes the global adoption of IEEE 802.11ad to be low [10].

Similarly, the IEEE 802.11af is advantageous due to its long-range transmission and low power consumption. However, it requires expensive band-specific hardware, which is not readily available in the global market where it is primarily used in US and Canada. In addition, since it utilizes the frequencies for unused TV channels, they may not be available everywhere [11].

The proposed model in this paper targets WLANs on the IEEE 802.11n unlicensed frequency band. Since this protocol has been widely adopted, the related devices are much easily and cheaply available, compared to those of emerging standards of the IEEE 802.11ad and IEEE 802.11af.

At the 2.4 GHz band, 13, 20MHz POCs are possible, which indicates that the number of *orthogonal channels (OCs)* is four at most. Since orthogonal channels do not overlap with one another, APs assigned OCs are not interfered for the medium access, if any pair of nearby APs do not operate on the same OC.

Currently, the *IEEE 802.11n* is most used in WLAN due to the high-speed data transmission capability at the 2.4 GHz band using the *channel bonding* that combines two neighboring 20 MHz channels together to form one 40 MHz channel as shown in Figure 1, [12]–[14]. Then, the number of OCs is reduced to at most two, and the channel assignment using OCs to the APs without interference cannot be avoided. [15] has shown that channel bonding improves performance, although it may increase frequency competition with adjacent LANs.

To overcome this limitation of the OC assignment in WLAN, it has been reported that the POCs will be beneficial to enhance the performance by fully utilizing the available spectrum [16, 17]. Then, the *throughput estimation model* under POCs is essential to identify the proper POC assignment to the APs while evaluating the performance accurately. Specifically, in a dense WLAN, the model must consider the *throughput drop* caused by the interference that each AP suffers from the neighboring APs on the adjacent POCs.

Previously, we have studied the *throughput estimation model* for a single communicating link, which consists of the *log-distance path loss model* and the *sigmoid function* [18]. Then, we move to estimate the *throughput drop* caused by the interference for two concurrently communicating links under POCs [19]. It is examined according to the *receiving signal strength (RSS)* from the interfering link and the *channel distance (chD)* between the two links.

The proper use of POCs should be considered for the full utilization of the limited frequencies, since there are limited orthogonal channels available in the IEEE 802.11n protocol with the channel bonding. Besides, the estimated throughput should be directly used as the metric for selecting POCs by estimating the network performance, since the interference does not exhibit the exact performance of the network, which has been observed in this paper.

Our model considers the channel bonding and POCs, to directly estimate the throughput from the channel distance and the RSS of the interfering AP. From the estimated throughput, the POC assignment can be optimized under the channel bonding.

Besides, in our previous studies [20, 21], we considered the indoor network environment inside a building for the target field, since WLANs are usually deployed there. A lot of environmental factors, such as wall attenuations and multipath effects, can affect the throughput performance. To accurately estimate the throughput, we have developed the throughput estimation model that consider the environmental factors.

In this research work, we extend the *throughput drop estimation model* for three concurrently communicating links under POCs. Firstly, we conduct extensive measurements of *receiving signal strength (RSS)* and throughputs under three links. Then, we extend the model based on the measurement results.

To confirm the effectiveness of our proposal, we compare the estimated throughputs by the model with the measured ones, and through simulations. It has been demonstrated that the proposal can estimate the throughput for three interfered links under POCs with the considerably high degree of accuracy.

The rest of this paper is organized as follows: Section 2 describes related works. Section 3 discusses the implementations of the auto-channel selection in vendor AP devices and the significance of the throughput estimation model. Section 4 reviews our previous studies. Section 5 presents experiments with three concurrently communicating links under POCs. Section 6 proposes the model extension for them. Section 7 evaluates the proposal with experiments and simulations. Section 8 introduces the application to the channel assignment. Section 9 concludes this paper with future directions.

2 Related Works

In this section, we discuss specific works related to our proposal. A significant amount of research works have addressed the problem of interferences in WLAN to improve the throughput performance by applying partially overlapping channels.

In [22], Mishra et al. revealed that the orthogonal channel assignment to APs in WLAN is inefficient in a network field, if a substantial number of access points are deployed there. In such a case, the number of APs in the network field is higher compared to that of orthogonal channels, hence any AP could exist in the interference ranges of other APs as indicated in [23].

In [24], Mishra et al. also noted that partially overlapping channels have previously been avoided due to their interferences. However, through their model and measurements, it is demonstrated that the careful use of some POCs does not only improve the spectrum utilization but also the throughput performance.

In [25], Feng et al. proposed POCs as a means of reducing interference from the traditional use of OCs. Through

testbed experiments, they reported that POCs offers better flexibility in wireless frequency allocation, and can increase overall network performance. Similarly, in [26], Zhang et al. proposed the use of POCs for interference management which outperforms the OCs.

In [27], Zhao et al. observed that with increased frequency reuse which has been reported in POCs, the network capacity can be scaled up through activating more APs in the network field as the expected distance from the users to their connected APs becomes smaller. However, it is reported that since POCs are partially overlapped with each other, one AP may suffer interference from multiple other APs. They conclude by proposing a need to have a maximum and a minimum bound for the number of APs based on the size of the network field and the number of POCs available.

In [28], Mukherjee et al. explored the AP selection, channel assignment, and the host association. They reported that the three aspects are critical in maximizing the throughput in WLAN, where the appropriate combination of both non-overlapping channels and POCs can further improve the overall throughput of the network.

In [29], Tewari et al. emphasized that multiple overlapping transmissions cause low network performance due to high interference from the limited non-overlapping channels. They have proposed a combined power control and POC assignment, where the former reduces the AP's transmission and the interference range while the latter improves spatial reuse.

In [30], Zhao et al. demonstrated that the effect of interference on the network performance depends on the channel separation and the degree of frequency overlap among the interfered APs. In particular, it is noted that two interferes cause higher performance deterioration than a single interfere, but less than twice the interference caused by a single interfere or the summation of interference from the two interferes.

Furthermore, in [31], Su et al. measured the interference among the APs when POCs are used from the perspective of the physical characteristics of the communication. They reported a clear distinction between in-range and hidden terminal interferences with POCs, where the latter has worse throughput performance due to high packet loss.

In [28], POC interference is evaluated by considering the interference factor defined in [32]. Where more than one APs interferes, [27] [28] and [29] considers summation of interfering signal powers at the target node. However, since the MAC protocol lowers the data transmission rate of the target AP depending on the level of interference with individual interfere, calculating the summation may fail to identify a real value of interference.

At present, there is no research work that has proposed the throughput drop estimation model for multiple interfering APs under POCs that considers the channel distance and the interfering RSS.

3 Auto-channel Selection Implementations and Model Significance

In this section, we survey implementations of the auto-channel selection in vendor AP devices, and discuss the significance of the throughput estimation model under it.

The auto-channel selection is the dynamic adjustment mechanism of the assigned channel to the AP, in order to avoid radio interferences from other WiFi devices. Each AP vendor has its own implementation approach.

In [33], Cisco describes their implementation of the auto-channel selection, where the AP operating in the 2.4 GHz band with 11 POCs can be set only to one of the three orthogonal channels of 1, 6, and 11 under the non-bonded channels with the *(20 MHz)* width. It means that up to three APs can be assigned the channels. The assignment for other POCs must be done manually.

However, when the channel bonding with the *(40 MHz)* width is applied, which is commonly used in IEEE 802.11n WLANs to improve the throughput performance, the AP can have only one choice of channel 3, since all the other channels are partially overlapping with it. It means that the auto-channel selection cannot work for the channel bonding.

On the other hand, our proposal can assign any POC to the AP with the channel bonding by considering the throughput drop from the other up to two interfered links.

Besides, from our experimental observations, the orthogonal channels can interfere with each other when the APs are closely located together, which would further affect the auto-channel selection in the Cisco Meraki APs.

Furthermore, Cisco's approach scans for a possible channel change after every 15 minutes, in addition to the three necessary situations: 1) a new AP joins the network, 2) the network administrator manually runs the auto-channel), and 3) the currently assigned channel fails to work. This would lead to the performance overhead, since the services of an AP must be stopped when channel change is applied. To avoid the frequent service stops, our approach changes channels of APs when an AP joins or leaves the network.

In [34], Fujitsu reports the auto-channel selection such that the total interference is minimized, where the details of the implementation are not given. However, the interference index is not a good metric to evaluate the throughput performance, because the interference and the throughput performance are not proportional as our paper reported. Instead, the throughput drop of each link from the other interfered links should be evaluated to more accurately estimate the network performance under a lot of interfered links.

In [35], Buffalo implements the auto-channel selection that tries to find the non-interfered channel for a new AP. By scanning all the channels, it selects a non-interfered channel if it exists. However, they also reported that the channel selection performs poorly, if no non-interfered channels exist. In real network environments, as demonstrated in our paper, several APs coexist together where any channel is interfered by an existing AP. On the other hand, our proposal is applicable in such real cases.

Similarly, in [36], Vodafone limits the auto-channel selection only to the non-interfered channels or the least interfered channel. In [37], Google WiFi works on the similar principle by selecting an orthogonal channel.

It should be pointed out that the proposed throughput estimation model can be incorporated into an auto-channel selection mechanism to improve the resulting performance of WLAN. Our model considers the channel bonding, POCs, and the direct throughput estimation. Therefore, we believe

that this model can improve the auto-channel selection. In future works, we will compare the performance by our model with existing auto-channel selections.

4 Review of Throughput Estimation Model

In this section, we review our previous works.

4.1 Motivation of Empirical Model

In [5], Reis et al. indicates that most of physical protocol explorations with respect to interference may adopt simple abstract models with multiple assumptions, including that the signal propagation obeys a simple function of the distance, the radio coverage area forms a circle, and the interference range is twice of the transmission range. Unfortunately, experimental data using a real WLAN have shown that all of these models appear to be largely inaccurate [38, 39].

In contrast to a physical model, an empirical model is based on observations on actual network environments. Thus, the empirical model for interference in WLAN is expected to be more descriptive and accurate compared to a physical model. Therefore, we have developed the empirical throughput drop estimation model for multiple-link concurrent communications based on experimental results.

4.2 Definitions of Three Distances

The *channel distance*, the *physical distance*, and the *link distance* are defined to illustrate the throughput estimation model under partially overlapping channels.

4.2.1 Channel Distance

The *channel distance* (*chD*) of the two links is defined as the least channel difference between the channels of these links. For instance, if the two links are activated with the same channel, then *chD* is 0, and they will be entirely overlapped. When one link is assigned *channel 3* and another link is *channel 5*, *chD* is 2, in this case, these channels are overlapped by 50% for 20MHz, and by 75% for 40MHz. The largest *chD* is 12 for 20MHz and 8 for 40MHz, in which any frequency overlapping does not exist theoretically.

4.2.2 Physical Distance

The *physical distance* (*phD*) is defined as the Euclidean distance between the two links. As it represents the separation distance among the interfering links, the farther the two links are placed, that is, the higher the physical distance is, the interference will become lesser. By increasing the physical distance between the links, the signal interference between them fades due to the path loss and the absorption by obstacles on the path.

4.2.3 Link Distance

The Euclidean distance between the sender and the receiver of the link is defined as the *link distance*. The longer link distance generally reduces RSS at the receiver and degrades the throughput.

4.3 Throughput Estimation Model

Generally, the throughput of a link will be affected by a variety of factors like the modulation and coding scheme (MCS), the transmission power, the transmission distance, and the channel interference [13, 40], which have made it hard for the theoretical calculation of the throughput. In [18], we proposed the throughput estimation model for the single link communication based on empirical results. This model first estimates the *receiving signal strength (RSS)* at the host using the *log-distance path loss model* [41]. Next, it estimates the throughput from the RSS using the *sigmoid function*.

4.3.1 Received Signal Strength Estimation

Firstly, the Euclidean distance *d (m)* between each link (AP/host pair) is calculated by:

$$d = \sqrt{(AP_x - H_x)^2 + (AP_y - H_y)^2} \tag{1}$$

Here, AP_x, AP_y and H_x, H_y denotes the x and y coordinates for the AP and the host respectively.

Then, *RSS* at the host from the AP is estimated by:

$$P_d = P_1 - 10\alpha \log_{10} d - \sum_k n_k W_k \tag{2}$$

Here, P_d denotes *RSS* (dBm) at the host, P_1 does *RSS* at the $1m$ distance from the AP where no obstacle exists, α does the path loss exponent, *d (m)* does the Euclidean distance calculated between the AP and the host, n_k does the number of *type_k* obstacles found on the path between the AP and the host, and W_k represents the signal attenuation factor (dB) for *type_k* obstacle.

4.3.2 Throughput Estimation

From P_d, the throughput is estimated by;

$$tp_{ij} = \frac{a}{1 + e^{-(\frac{(120+P_d)-b}{c})}} \tag{3}$$

where tp_{ij} denotes the estimated throughput ($Mbps$) and, a, b, and c are constant coefficients.

4.4 Throughput Drop Estimation Model for Two-Link Concurrent Communications

In [19], we proposed the *throughput drop estimation model* to consider the frequency interference between concurrently communicating adjacent two links using interfering channels. The *throughput drop* of the target link can be estimated by the receiving signal strength at the receiver, called the *interfering RSS*, (RSS^i), from the interfered link, and the channel distance *chD* between the two links:

$$tpD(RSS^i, chD) = p(chD) \times \ln(q(chD) + RSS^i) + r(chD). \tag{4}$$

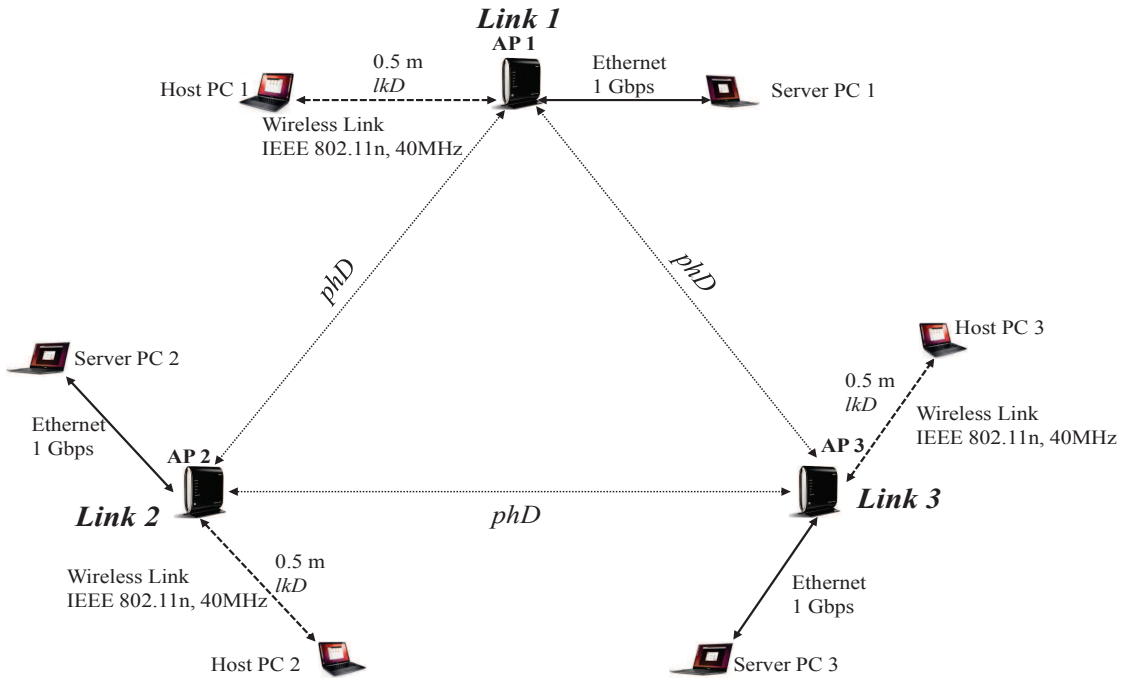

Figure 2: Measurement setup.

where $tpD(RSS^i, chD)$ represents the estimated throughput drop ($Mbps$), and $p(chD)$, $q(chD)$, and $r(chD)$ represent constants determined by the channel distance (chD).

The values of the three constants p, q, and r in the model were obtained from the throughput drop measurement results for every channel distance. Table 1 shows them.

Table 1: Constants for each channel distance.

channel distance	p	q	r
0	27	88.17	-20
1	27	87.36	-20
2	27	89.00	-22
3	25	94.50	-22
4	33	92.00	-56
5	34	92.00	-57
6	45	91.00	-98
7	45	88.00	-100
8	40	75.50	-80

Then, the throughput estimation model under POCs for two interfered links is modified by:

$$tp^i_{ij} = tp_{ij} - tpD(RSS^i_j, chD^i_j) \quad (5)$$

where tp^i_{ij} represents the throughput of the target link from node i to node j under the interference from the interfered link, tp_{ij} does the throughput of this link estimated by the original model, RSS^i_j does RSS from the interfered link at node j, and chD^i_j does the channel distance between the two links.

5 Experiments in Three-Link Concurrent Communications

In this section, we present the experiment results to examine the extension of the throughput drop estimation model for three concurrently communicating links.

5.1 Experiment Setup

Table 2 indicates the necessary devices and software used in the experiments. It is noticed that if different devices are used, the parameter values of the model will vary accordingly.

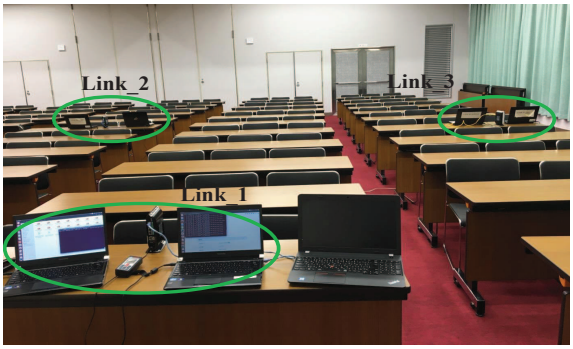
Table 2: Measurement devices and software.

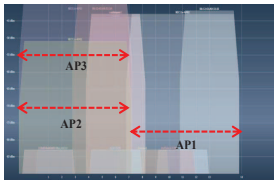
Access Point (*all links*)	
maker/ type	NEC WG2600HP
protocol	IEEE 802.11n
operating band	2.4 GHz
frequency width	40 MHz
host PC (*all links*)	
maker/ type	Toshiba dynabook R731/B
operating system	Ubuntu 14.04 LTS
processor	Intel Core i5-2520M 2.54 Ghz
network adapter	Intel HM65 Express chipset
server PC ($link_1$)	
maker/ type	Toshiba dynabook R731/B
processor	Intel Core i5-2520M 2.54 Ghz
operating system	Ubuntu 14.04 LTS
network adapter	Intel HM65 Express chipset
server PC ($link_2$, $link_3$)	
maker/ type	Fujitsu lifebook S761/C
processor	Intel Core i5-2520M 2.5GHz
operating system	Ubuntu 14.04 LTS
network adapter	Mobile Intel QM67 Express

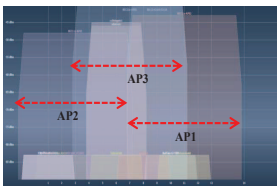
Figure 2 shows the topology of three links ($link_1$, $link_2$ and $link_3$) in experiments. The server PC connects to the AP through the Gigabit Ethernet, and the host PC is connected to the AP by the 11n wireless link. The host is 0.5m from its connected AP, and each AP is 5m from the other AP. The maximum transmission power is selected for any AP with the equal antenna gain [16]. The *minimax AP setup optimization approach* in [18] is applied to maximize the throughput for each link. The *iperf 2.05* [42] is used to generate the TCP traffic between the server and the host.

5.2 Experiment Fields

The experiments were carried out in indoor fields on the 2nd floor of *Graduate School of Natural Science and Technology Building* and the 3rd floor of *Engineering Building #2* in Okayama University. Each field consists of several rooms, walls, and floors, which can affect the throughput through the multi-path effect. RSS^i and the throughputs are measured while increasing the physical distance, *phD*, between the two APs and their channel distance, *chD*. By using *Homedale* [43], the frequencies of the links under measurements and the external interfering links are recorded. Figure 3 shows the site while Figure 4 reveals the frequency utilization for measurements, where several channels are highly utilized by non-target APs.







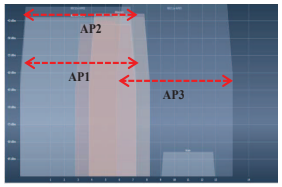


Figure 3: Experiment in Graduate School Building.

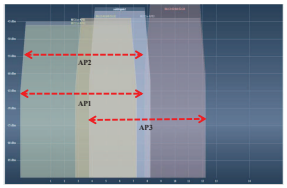

(a) AP1= ch11, AP2 = ch3, AP3 = ch3

(b) AP1= ch11, AP2 = ch3, AP3 = ch7

(c) AP1= ch3, AP2 = ch3, AP3 = ch8

(d) AP1= ch3, AP2 = ch3, AP3 = ch10

Figure 4: Frequency utilization in experiments.

5.3 Experimental Results

For AP_1 (and AP_2 for three links), the bonded channel 3 is always assigned. For AP_2 (AP_3 for three links), the assigned channel is changed from 3 to 11 one by one, so that the channel distance *chD* increases from 0 to 8. The throughput was measured at the same time for all the links. The experiments were conducted on weekends and at night on weekdays to reduce the interference from other Wi-Fi devices.

Figures 5 and 6 show measured individual and average throughput under concurrently communicating two links and three links, respectively. The individual throughput fluctuates, because the contention among the links is not well resolved by the current *carrier sense mechanism* [44], which may cause the unfair channel occupation among them. Thus, in this paper, we use the average throughput among them for the single link throughput.

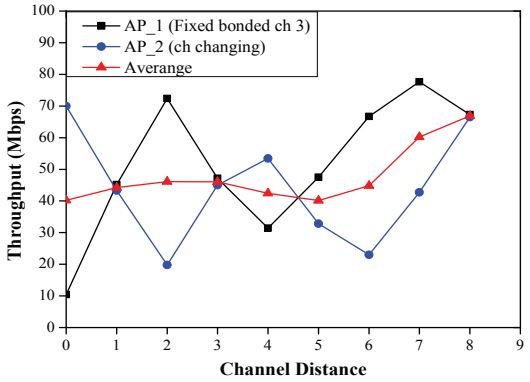

Figure 5: Throughput results for two links.

Figure 6 demonstrates that when the three APs are assigned the same channel, one AP takes the entire medium, which makes the others have the lower throughput. As *chD* increases, the throughput of AP_3 will enhance gradually, due to the reduced channel interference.

In this experimental setup, the measured maximum throughput of one link is about 140$Mbps$ under no interference. Then, it drops significantly to about 40$Mbps$ under two links, when the channel distance is smaller than seven. Furthermore, it drops to about 20$Mbps$ under three links.

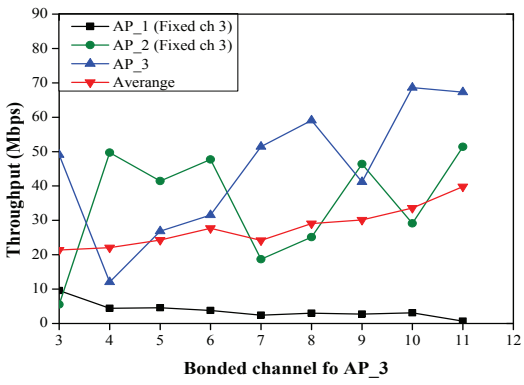

Figure 6: Throughput results for three links.

5.4 Observations from Experiment Results

According to the evaluation, it is observed that for the target link, the interference from the first interfering link causes the larger throughput drop (from 140$Mbps$ to 40$Mbps$), and the interference from the second causes the smaller drop (from 40$Mbps$ to 20$Mbps$). That is to say, when the target link is interfered by the first link, the rate adaptation mechanism lowers the transmission rate by adopting the robust MCS. Then, the second interfering link further lowers the rate by adopting the more robust MCS [30][31]. Here, the rate can be lowered exponentially in MCS.

6 Model Extension for Three-Link Concurrent Communications

In this section, we present the extension of the throughput drop estimation model for three concurrently communicating links based on experimental results.

6.1 Idea of Throughput Drop Estimation under Three Links

As observed before, the throughput drop from multiple interfering links can be estimated one by one through calculating each drop using the model in Section 4.4 in descending order of the interference. That is, the drop from the link with the largest interference is first estimated, assuming the original maximum throughput. Then, the drop from the link with the second largest interference will be estimated, assuming the maximum throughput has been reduced by the first drop.

6.2 Throughput Drop Estimation Procedure

The throughput of the target link $link_{ij}$ under three-link concurrent communications is evaluated by the following procedure:

1. Estimate the throughput of each of the three concurrently communicating links using the original model in Section 4.3.
2. Estimate the throughput drop tpD from each of the two interfering links using Eq. (4) in Section 4.4.
3. Sort them in the descending order: let tpD^{1st} and tpD^{2nd}.
4. For the largest interfering link, adjust tpD^{1st} by the maximum speed of the AP of the target link, because different APs have different throughput performances:

$$tpD^{1st}_{adj} = tpD^{1st} \times \frac{tpM^{AP}}{140} \quad (6)$$

where tpD^{1st}_{adj} represents the adjusted throughput drop by the largest interfering link, and tpM^{AP} does the maximum throughput for the AP of the target link.

Then, the throughput tp^{1st}_{ij} of the target link after considering the drop by the first link interference is estimated by:

$$tp^{1st}_{ij} = tp_{ij} - tpD^{1st}_{adj} \quad (7)$$

5. For the second largest interfering link, adjust the tpD^{2nd} by;

$$tpD^{2nd}_{adj} = tpD^{2nd} \times \frac{tpM^{AP} - tpD^{1st}_{adj}}{140} \quad (8)$$

Then, the throughput tp^{2nd}_{ij} of the target link after considering the drop by the second link interference can be estimated by;

$$tp^{2nd}_{ij} = tp^{1st}_{ij} - tpD^{2nd}_{adj} \quad (9)$$

In [31], Su et al. observed that the throughput drop by the accumulated interference from two interfering links is greater than that from a single interferer, but less than the sum of the drops from the individual interference. The second interfering link will cause a smaller drop than the first one. This observation also supports our throughput drop estimation model for concurrently communicating three links.

7 Evaluations of Model Extension

In this section, we evaluate the throughput drop estimation model for three concurrently communicating links under POCs and the channel bonding through experiments and simulations.

7.1 Experiment Results in One Room

First, the devices and one-room field in Sections 5.1 and 5.2 are used in experiments.

7.1.1 Channel Assignments

In experiments, the bonded channel 3 is always assigned to AP_1. Then, the either channel of 3, 7, and 11 is assigned to AP_2. To AP_3, the assigned channel is moved from 3 to 11 one by one so that the channel distance is changed. The throughputs are measured at the same time for all the links.

7.1.2 Throughput Results

Figures 7, 8, and 9 show the measured average throughput among the three APs when the channel 3, 7, and 11 is assigned AP_2, respectively.

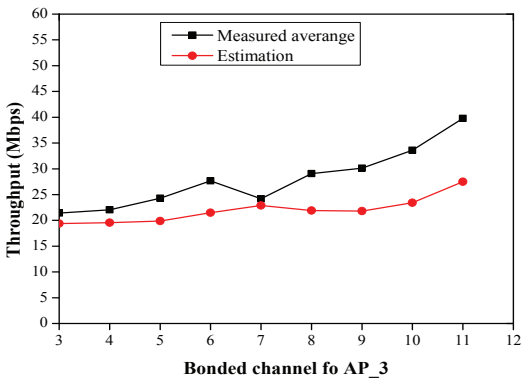

Figure 7: Throughput results in one room for AP_1:ch3, AP_2:ch3.

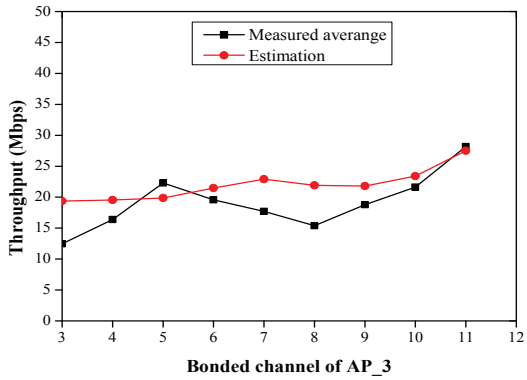

Figure 8: Throughput results in one room for AP_1:ch3, AP_2:ch7.

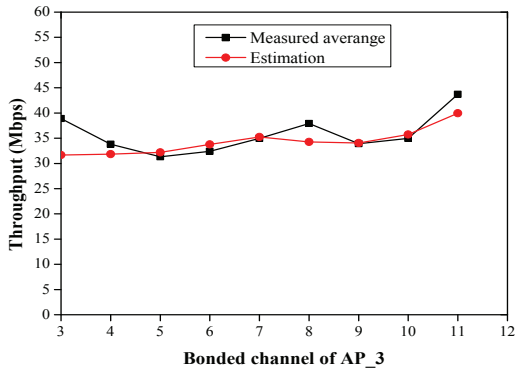

Figure 9: Throughput results in one room for AP_1:ch3, AP_2:ch11.

When the three results are compared, Figure 8 indicates the lowest throughput among them, because AP_2 is interfered with both AP_1 and AP_3. Figure 9 presents the highest throughput in general, because AP_1 and AP_2 are not interfered. On the other hand, Figure 7 shows that as the channel distance increases, the throughput will raise as the reduction of the interference between (AP_1 and AP_2) with AP_3.

Then, the estimated throughput is calculated by the proposed throughput drop estimation model, and is compared with the measured throughput. Figures 7- 9 demonstrate that these throughput are similar in any case. Thus, the accuracy of the proposed model for three concurrently communicating links is confirmed.

7.2 Experiment Results in Three Rooms

Next, the experiments are conducted using three rooms on the 3rd floor of *Engineering Building #2* to examine the accuracy of the model.

7.2.1 Experiment Field

The physical distance between the APs is changed by locating each AP in a different room from the previous experiments, as revealed in Figure 10. By locating each AP in a separate room, the overall interference between them is reduced. The link distance between the AP and its associated host is set 0.5m or 4m. The channel assignments in Section 7.1.1 are adopted.

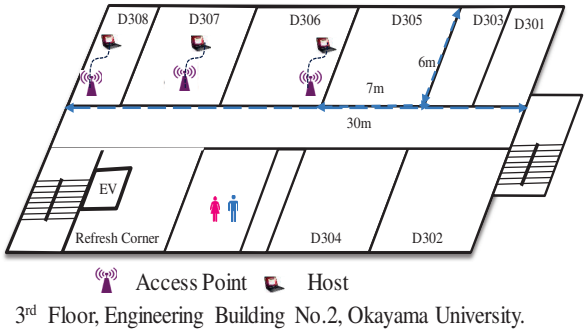

Figure 10: Three room topology.

7.2.2 Throughput Results with 0.5m Link Distance

Figures 11 - 13 show the measured and the estimated throughput results when the link distance is 0.5m. These throughput turns out to be similar at any channel distance, which confirms the accuracy of the proposed model. At the same time, they are higher than the ones in Figures 7- 9, since they are less interfered here.

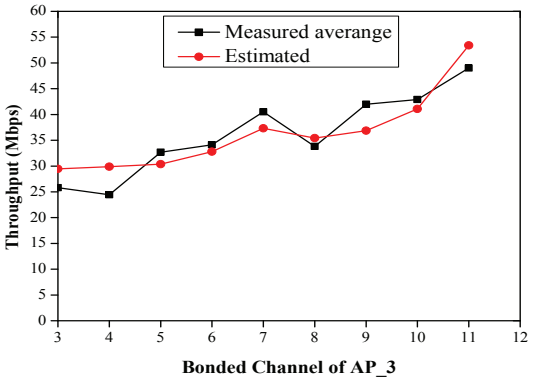

Figure 11: Throughput results in three rooms with 0.5m link distance for AP_1:ch3, AP_2:ch3.

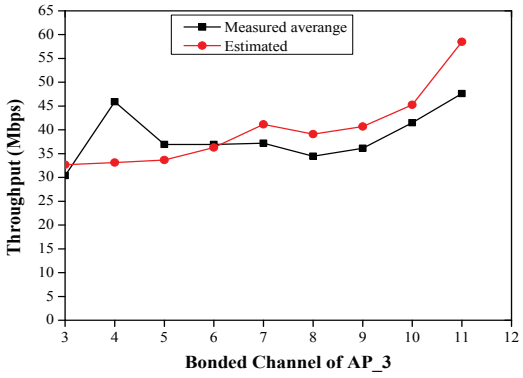

Figure 12: Throughput results in three rooms with 0.5m link distance for AP_1:ch3, AP_2:ch7.

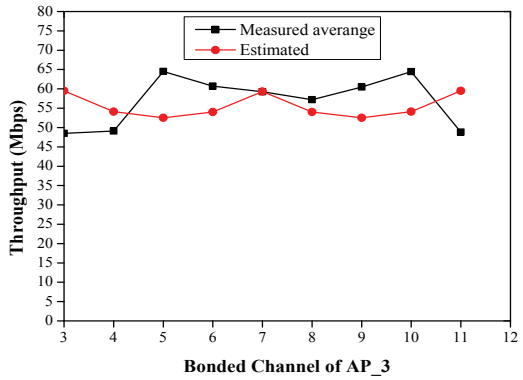

Figure 13: Throughput results in three rooms with 0.5m link distance for AP_1:ch3, AP_2:ch11.

7.2.3 Throughput Results with 4m Link Distance

Figures 14- 16 show the measured and the estimated results when the link distance is 4m. In Figures 15 and 16, they are similar at any channel distance. Thus, the accuracy of the model is verified in the larger link distance as well. However, in Figure 14, the measured throughput is lower than the estimated one at each channel distance. This is because the interference from non-target APs in the field is stronger around the channel 3, as shown in Figure 4. It is a must to conduct experiments in environments with less interference, which will be included in future works.

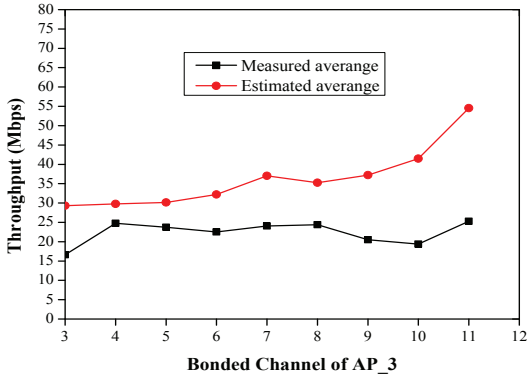

Figure 14: Throughput results in three rooms with 4m link distance for AP_1:ch3, AP_2:ch3.

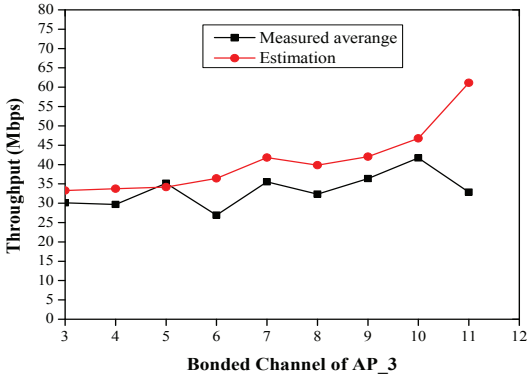

Figure 15: Throughput results in three rooms with 4m link distance for AP_1:ch3, AP_2:ch7.

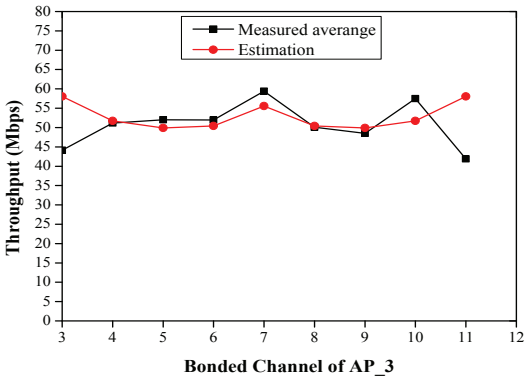

Figure 16: Throughput results in three rooms with 4m link distance for AP_1:ch3, AP_2:ch11.

8 Application to Channel Assignment

In this section, we discuss the application of the proposed throughput drop estimation model to the POC assignment to the APs.

8.1 Modification of Channel Assignment Phase

The channel assignment phase of the *active AP configuration algorithm* in [45] is modified to assign POC using the proposed model. Specifically, the formulations for this phase are revised from the previous one in [45] as follows:

8.1.1 Modification of Input

The number of partially overlapping channels is adopted in place of the number of orthogonal channels for C.

8.1.2 Modification of Output

The partially overlapping channel assigned to every active AP is adopted rather than the orthogonal channel assigned to every active AP.

8.1.3 Modification of Objective

The total interfered communication time E_3 is modified to consider partially overlapping channels by:

$$E_3 = \sum_{i=1}^{N} [IT_i^i] \tag{10}$$

where IT_i^i denotes the interfered communication time under partially overlapping channels for AP_i.

Under POCs, the link speed drop by the interfered links needs to be examined in the throughput estimation model. Therefore, IT_i^i can be simply given by:

$$IT_i^i = \sum_{j \in AH_i} \frac{1}{tp_{ij}^{2nd}} \tag{11}$$

where AH_i denotes the set of hosts associated with AP_i.

Our current throughput estimation model for partially overlapping channels only examines the interference between three links. In this paper, we assume that the target link is interfered by the two strongest interfering links, while the other interfering links may have negligible effects. This can be supported by the results in Section 5.4, where the highest interfering link causes the large drop and the second link causes the far small drop.

8.2 Evaluations by Simulations

First, we evaluate the performance of the POC assignment via simulations.

8.2.1 Simulation Platform

The *WIMNET simulator* [46] is adopted for simulations. Table 3 sums up the parameters for simulations [45].

Table 3: Simulation Parameters in WIMNET Simulator.

parameter	**value**
packet size	2360 bytes
max. transmission rate	150 Mbit/s
propagation model	log-distance path loss model
rate adaptation model	sigmoid function
carrier sense threshold	−85 dBm
transmission power	19 dBm
collision threshold	10
RTS/CTS	yes

8.2.2 Results for Random Topology

To evaluate the performance in various network environments for WLAN, first, the *random topology* is considered. As shown in Figure 17, in this topology we consider a network field of size $800m \times 200m$, where two rooms are located, each of length $400m$. Eight APs and 25 hosts are allocated randomly.

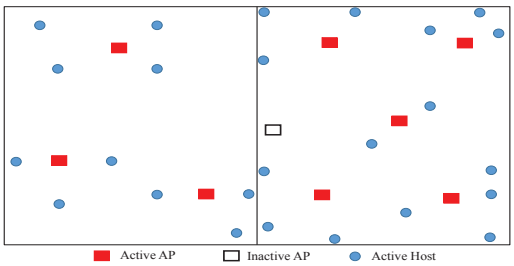

Figure 17: Random topology for channel assignment.

.

Then, the minimum host throughput and the overall throughput are compared between the POC assignment and the conventional OC assignment through simulations. Two channels (3, 11) are used for the OC assignment all the time. On the other hand, three channels (3, 7, 11), six channels (3, 5, 7, 8, 9, 11), and nine channels (3, 4, 5, 6, 7, 8, 9, 10, 11) are used for the POC assignment. Table 4 shows the results.

Table 4: Throughput results for *random topology*.

channel assignment	OC	POC		
# of channels	2	3	6	9
min. host throu. (Mbps)	7.12	9.16	8.42	8.63
overall throu. (Mbps)	174.56	196.74	197.04	198.46

8.2.3 Results for Regular Topology

Next, the *regular topology* in the third floor of Engineering Building #2 at Okayama University is considered. The room size is either $7m \times 6m$ or $3.5m \times 6m$. Eight APs and 55 hosts are regularly allocated, as signified in Figure 18.

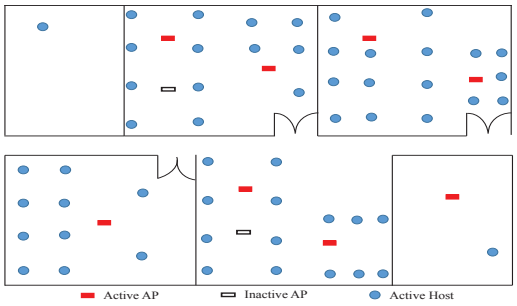

Figure 18: Regular topology.

The same two, three, six, and nine channels as for *random topology* are considered. Table 5 shows the minimum host throughput and the overall throughput for them.

It is noted that in both topologies, as the number of POCs is increased, the overall throughput will enhance by reducing the interference while maintaining the minimum host throughput.

Table 5: Throughput results for *regular topology*.

channel assignment	OC	POC		
# of channels	2	3	6	9
min. host throu. (Mbps)	2.68	3.11	3.06	3.15
overall throu. (Mbps)	147.76	170.88	168.76	173.49

8.2.4 Results for Regular Topology with Large APs

Finally, in Figure 19 we evaluate the model by simulations in a new instance by increasing the number of APs from 8 to 10 in the regular topology. The number of hosts remains as 55.

The evaluation in a real environment using the testbed is more important to confirm the effectiveness of the model. Thus, it will be in our future studies.

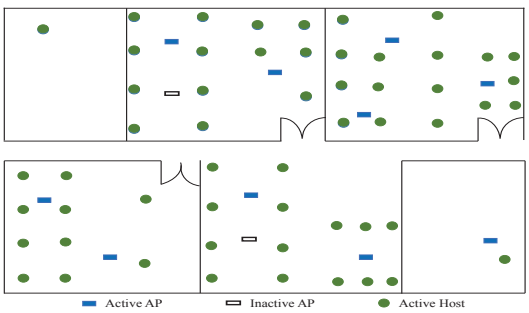

Figure 19: Regular topology for 10 APs.

Table 6 shows the results. As the number of APs increases, the total performance also increases, because more hosts can be located nearer to the APs, which increase the throughputs of them.

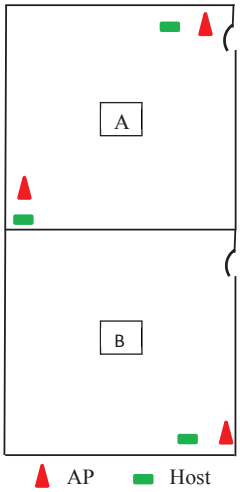

Table 6: Throughput results for *regular topology on 10 APs*.

channel assignment	OC	POC		
# of channels	2	3	6	9
min. host throu. (Mbps)	3.97	4.66	4.49	4.55
overall throu. (Mbps)	218.24	250.72	247.29	251.24

8.3 Evaluations by Experiments

Lastly, the throughput of the POC assignment is evaluated through experiments using the *two-rooms topology* in Figure 20. Two channels 3 and 11 are used for the OC assignment, and three channels 3, 7, and 11 are for the POC.

Table 7 shows the simulation and measurement results. This table indicates the following: 1) the POC assignment improves the overall throughput, and 2) the estimated throughput is well coincident with the measured one. The accuracy of the throughput estimation model and the effectiveness of the POC assignment are confirmed.

(a) Two-rooms topology

Figure 20: Two-rooms topology.

Table 7: Throughput results for *Two-room topology*.

channel assignment	OC	POC
# of channels	2	3
measurement (Mbps)	146.36	158.2
simulation (Mbps)	143.5	157.31

9 Conclusion

In this paper, we presented the *throughput drop estimation model* extension for concurrently communicating three IEEE 802.11n links under *partially overlapping channels (POCs)* and the *channel bonding*. Also, we proposed the model application to the POC assignment to the access-points in WLAN. Through extensive experiments and simulations, we confirmed the accuracy of the model and the effectiveness of the POC assignment. In future, we will upgrade this model for four or more interfering links. Then, we will evaluate it in a variety of network scenarios, such as for dense WiFi environments.

ABSTRACT

Recently, there is an enormous research on the smart campus concept due to the revolution of the IoT technologies. The motivation of this paper is to: reinforce the safety on campus, reduce the cost, and take one step forward toward a University smart campus. In this paper, we are not only proposing a framework that would act as an instantaneous responder, but we also provide a glimpse of the evolving research on smart campus. In addition, we explore the challenges, and highlight the future work regarding this on-the-spot responder system.

1. Introduction

The smart campus concept has been the main focus of many researchers recently due to the valuable insights gained toward developing smart cities. The university campus theoretically is a small city where it delivers variant services to variant users. There are several factors that attract the investigators to study the smart campus including: delivering high quality services, protecting the environment, and saving the cost. The internet of things is a fundamental part of the smart campus, and it is inescapable getting it invoked.

The internet of things is a communication paradigm that gained its tenacity from its capability of connecting variety of everyday life objects to the internet. These objects include, but not limited to, sensors, robots, security locks, alarms, drones, appliances, smart grid systems, office equipment and so on. Even though IoT is in its early stages, there are many applications and standardization that has been developed in many domains including: home automation, smart grids, water and waste management, traffic control, smart vehicles, healthcare assistance, and industrial automation. Moreover, the realization of the IoT network is facing two main challenges. First, technical challenges because of IoT novelty and heterogeneous nature. Second, business challenges due to the lack of complete and approved business model that would encourage investments.

In this paper, we are proposing a safety and security framework based on the IoT which would enhance the safety on a university campus. The work in this paper is not only an extension of the investigation originally presented at the 2016 International Conference on Future Internet of Things and Cloud (FiCloud) [1], but we also propose a new system, and identify the limitations and research opportunity in this field.

The safety on a university campus is a growing concern among the campus community across the U.S. and across so many other countries due to the horrific crimes and mass shooting committed, lately. Regardless of whether the campus is rural or urban, large or small, significant number of people on campus seems to be reluctant to walk out at night alone [2]. According to Clery Center for security on campus [3], the crimes committed by students on campus is about 80% of the overall crime number. For example, Tennessee State University (TSU) is considered about an average in crime rates [4]; However, there were recent cases which saddened TSU community such as the shooting in 2015 that killed one, and injured three students [5]. Figure 1 shows statistics of the crimes committed on post high school education campuses in the United States over the period of 2015 to 2017 [6]. Our proposed system will not only enhance the safety, but also it would reduce the cost, make efficient use of resources, and

*Alghamdi Abdullah, Assistant Professor, IS Dept., NU, Najran, Saudi Arabia.
Email: aaalghamdi@nu.edu.sa

become one step closer toward a smart campus by utilizing the recent advances in technology.

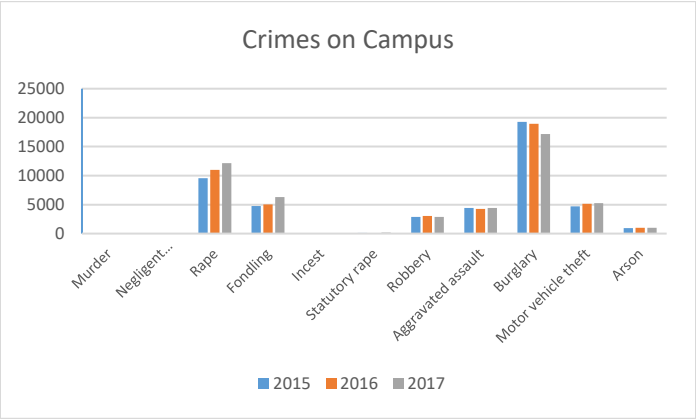

Figure 1 Statistics of The Crimes Committed on more than 11000 Campuses [6].

2. Smart Campus and Its Applications

The smart campus market springs from being a diverse environment regarding the services conveyed and the recipients of these services. The impact of conveyed services is not limited to the academic aspect, but also the social, financial, and environmental aspects. We can categorize the current research in smart campus into four main areas: intelligent buildings, campus smart grid, learning environment, and other applications. Figure 2 shows the context of a smart campus, its impacts, and many examples of its applications. On the rest of this section, we will present the research being done toward achieving a smart campus.

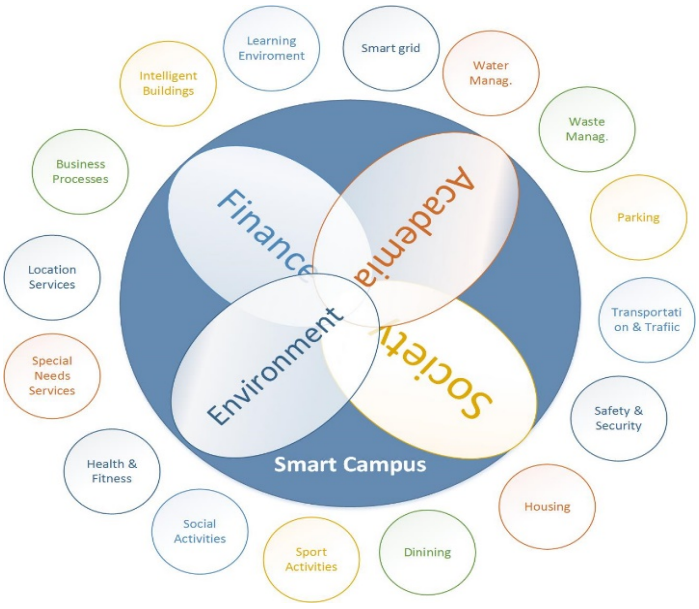

Figure 2 Impacts and Applications of Smart Campus Concept [1].

2.1. The Intelligent Buildings

Given that there is no de facto guide which would lead the people in the construction industry on how to build an intelligent building, a novel approach would be the plan to achieve the stakeholders' goals [7]. The planners need to focus on two main aspects. First, Information and Communication Technology (ICT) infrastructure where at least one fast backend network is needed for both business and building systems. Servers and variant sensors are essential part of the automation process of buildings. Sensors routine includes, detecting carbone dioxide levels in buildings, monitoring building stress, adjusting temperature, turning off the services in empty spaces, and measuring humidity and pollution levels [8,9]. Second, reporting and collaboration between various department is crucial to improve business processes and workflow, and it can be done by sharing information and reports, and enhancing communication [7]. The reports include building occupancy, staff attendance, patterns of utility usage, real-time warnings, energy usage, and so on. Knowing that the productivity gets increased by boosting the comfort of the community on campus, the stakeholders would make that as one of their goals [10].

2.2. Campus Smart Grid

Smart grid "is an opportunity to use new information and communication technologies (ICTs) to revolutionize the electrical power system" [11]. There are many universities adopting smart grids such as Oregon State University, which integrated Synchrophasor technology to have better monitoring and alarming system; however, the optimized results are not realistic due to the fact that this technology is relatively new and needs further studies [12]. In case of failures with SCADA, Santos *et al.* [13] suggests an automation process of power restoration using Open Platform Communications (OPC) protocol, and to characterize detection, isolation, and self-healing. Examining demand patterns, implementing a self-organized mapping (SOM), which is favored load profiling algorithm, and analyzing the current grid to provide a methodology and recommendations for smart microgrid in a university campus are discussed in [14,15]. Web-based systems on a cloud platform are introduced in: [16] for the analysis of energy consumption and behavior patterns, [17] for the purpose of controlling the demand response, and [18] for forecasting of future demand using machine learning (ML) models. Bracco *et al.* [19] propose a quantifying method for the usage of primary energy, predict CO2 emissions cut, and assess the cost reduction at the University of Genoa campus. Finally, IoT made it possible to control and monitor the energy consumption by users, identify energy draining devices, and suggests actions to optimize their behavior.

2.3. The Learning Environment

Given that the primary ambition of e-learning systems is to provide an articulated learning environment for learners based on their aspirations, knowledge, and talent, Wang *et al.* [20] characterize the learning process in an intelligent environment as a recursive process of four stages: learning, assessment, interaction, and analysis. Several papers published in this area including [21] which proposes students profiling based on their behavior over on-campus social network to provide a context-based personalized learning experience to achieve a ubiquitous learning (uLearning); however, additional study in terms of

learners' behavior and content design would exaggerate the benefit of such system. Microsoft and MIT started a research collaboration to achieve an intelligent campus, so called (MIT iCampus) [22]. This collaboration resulted in developing several intelligent systems including: class communicator system (CCS) to overcome communication issues between instructors and students, and class learning partner (CLP), and to provide an exercises and instant feedback during the class. Finally, given that mobile phones, tablets, laptops, and other wearable devices are among the most prominent devices that have influenced this universe [23], and utilizing them in education is inevitable.

2.4. Other Applications

Even though they do not get enough attention, there are plenty of other applications where IoT can be utilized to dramatically change campus to a smart one such as: waste and water management, parking, voting, safety and security, and so on. Regarding waste management, many papers published recently including [24-26] which generally suggest planting sensors at the bins, and waste trucks that collect real-time data for analysis, and a system would use the collected data to suggest better cleaning schedule and a superior and cost-effective route for waste contractors.

One the other hand, Mudumbe and Abu-Mahfouz [27] present a user-centric smart water management system which represent consumption in visual graphs to increase awareness. Gabrielli *et al*. [28] describe a sustainable prototype for smart metering devices and the associated network. Despite the feasibility of the project, the focus of their experiment is to build a sustainable metering device. Moreover, the authors [29,30] demonstrate: a parking guidance system for the parking building, and an electronic voting system that uses RFID technology for the authentication process, respectively.

Keeping in mind that most of recent work is focused on energy, learning environment, and intelligent buildings, the safety and security did not attract the attention of researchers; however, the intrinsic need of: better safety, instantaneous response to emergency, and cost effective solution on campuses actuated our team to investigate this area.

3. Safety and Security System

In this section, we will describe our system in details. At first, we will show the overall architecture of the system followed by the technique that will be used to deploy the sensors. Considering four different types of undesirable incidents: gun possession, assault, burglary and firing arms, we will show how to detect such suspicious activity. After that, we will show how to detect and track the suspect until the backup team arrives to the scene.

3.1. System Architecture

The safety and security system work with a variety of devices including: cameras, microphone sensors, glass break sensors, Raspberry Pi boards (RPis), a drone, and a server connected to the safety and security Operation Control Center (OCC) on campus. Figure 3 shows the general architecture of the system. To avoid overwhelming one server by making it process all the data collected by sensors across the campus, we would use the RPis to accomplish a distributed data processing architecture. Taking advantage of its cheap cost, the RPis would be used to process images, voices and other collected data by attached sensors. In case of detecting suspicious activity, the RPi would notify the server which will identify the location of the RPi using table for mapping the RPi's ID and its predefined location. The server would trigger the alert, identify the fastest route to the incident location, and instruct the drone to observe the situation, and wait for further actions.

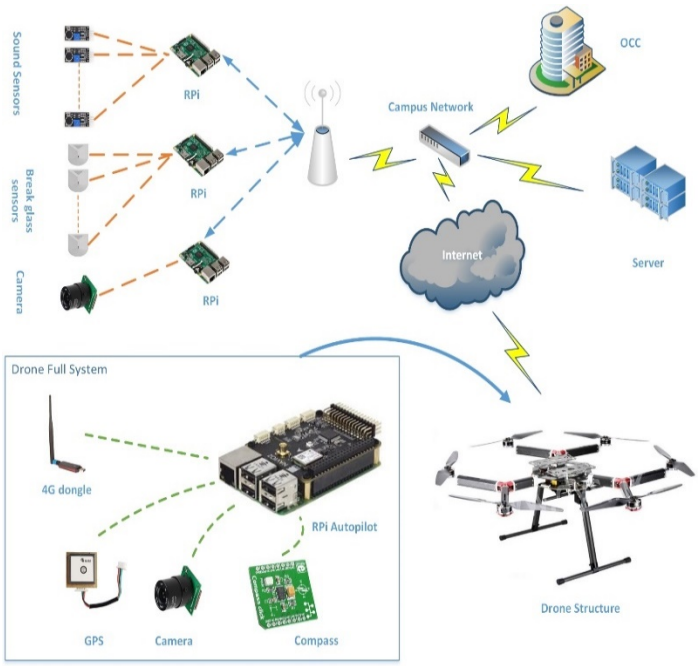

Figure 3 System Architecture

A sophisticated and robust drone need to be used as an instantaneous responder to observe the situation, and send live updates to the OCC for assessment and evaluation. The drone's autopilot would be attached to: a 4G dongle for internet connection, a GPS, a camera, and a compass.

3.2. Sensors Deployment

Since we have different types of sensors and our system depend on them, we need to deploy them carefully. The deployment technique is planned attentively to achieve two goals: to be cost effective regarding the number of sensors, and to avoid degrading the effectiveness of the system by deploying less sensors than required. The cameras would be deployed at parking lots, sidewalks, and buildings' entrances. The glass break sensors need to be deployed inside the buildings. Because one sensor covers around 25 feet, we would deploy one sensor per room wherever applicable. Finally, we decided to choose a microphone that covers 20 to 30 feet in a spherical area such as QSPMIC microphone by Q- See.

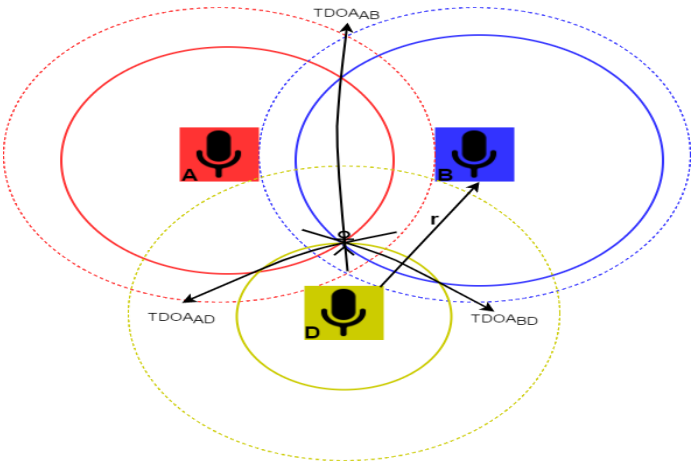

Figure 4 Sound Sensors Deployment

Figure 4 shows the way of planting the sound sensors where every sensor is planted at the end of the previous sensor coverage. Thus, the horizontally and vertically distance between sensors is equal to the radius of the coverage area (r). The sound source location can be determined using the Time Difference of Arrival (TDOA) or Multilateration (MLAT) method [31]. TDOA is an algorithm used to determine the location of the sound source by calculating the differences in arrival time of the sound at spatially separated sensors. The time difference of arrival of sound at different sensors must be known and processed at the central location. When the possible distance of the source from each sensor is drawn, it creates a hyperbolic curve. The location of the sound source lies in the intersection of all the hyperbolas from different sensors. This method works quite accurately for relatively static sources. If dynamic sources to be tagged, modified TDOA can be used [32].

3.3. Suspicious Activity Detection

The proposed system considers four different undesirable incidents to prove its effectiveness which are: gun possession, assault, burglary, and firing arms. The following paragraphs will study these scenarios in details.

Gun possession would be caught using the cameras distributed all over the campus parking lots, entrances, and sidewalks. The Raspberry Pies (RPis) attached to cameras would be able to detect guns automatically using Convolutional Neural Networks (CNNs) [33]. CNN is the state of the art technology in computer vision and it has been proven as a reliable architecture in object detection, giving its high accuracy with sufficient training. CNN is a special case of Neural Networks that apply the convolution operation to an input image for the purpose of feature extraction; however, the usage of the convolution operation demands high computational time, which is a challenge in our environment, knowing that we are using limited, low-energy devices. Fortunately, Iandola *et al.* [34] were able to achieve a smaller CNN architecture that performs the same accuracy as the AlexNet-level on ImageNet with fifty times fewer parameters, and they named it SqueezeNet. As a result, the SqueezeNet can be used on almost any controller or embedded computers. On RPis, it takes SqueezeNet approximately 2 seconds to process an image, which is enough time to: detect a person with a gun on a sidewalk, issue an alarm on the building, automatically close the inner doors of buildings, and notify the safety and security OCC on campus. Using a significant number of images of different types of guns, the SqueezeNet would be trained. The trained model would be deployed on the RPis wherever the cameras are applicable. After the detection of the gun, the RPis would alert the server. Using the predefined mapping between RPis and locations, the server would be able to instantaneously deduce the location of the gunman, plan the fastest route for drone, and instruct the drone to find and tracking the gunman until a backup team arrives to the scene.

There are some cases where the gun would not be detected by the distributed cameras. Therefore, we introduce another method for detection which is by detecting the sounds of firing arms. Usually, firing the arms and assault crimes are accompanied by sounds such as the sounds of gunshots and yelling for help. In case of any of these undesirable incidents happened, the microphones attached to RPis would catch the accompanied signals, and pass it to the neural network to identify if there is any suspicious activity. Since the CNN is proven to be effective in speech recognition [35], likewise, the SqueezeNet architecture would be used here too. Gunshots and yelling for help spectrograms would be used to train the network, and the pre-trained model would be deployed on the RPis. Similar to the previous scenario when the detection happens, the RPis would notify the server. Then, the server would identify the location of the incident and instruct the drone to observe the situation.

For burglary detections, we are using a glass break sensors which are connected to RPis. By listening to acoustical frequencies generated when a glass gets broken, the sensor would alert the RPi over the wireless which would lead to issuing an alarm to the server. Because the RPi mapped the sensor with its location on the building, the server would send the drone to that location to give real-time updates of the broken window. This would be important in case the burglar tried to run away because the drone can always detect and track people on the scene. Meanwhile, the OCC room should have sent a backup team to that room to investigate the situation.

3.4. Target Detection and Tracking

As soon as the drone arrives into the scene, it has to detect and track the suspect. To add more capability, our algorithm would allow two methods of detection: manually and automatically based on the situation. Figure 5 shows the general flowchart of target detection and tracking process. Upon the arrival of drone, it would start: capturing videos frames, notifying the OCC with updates, and analyzing the captured frames for detection of the suspect. Knowing that CNN requires high computation demand, Histogram Oriented Gradient (HOG) [36] would be used to detect upright persons in the scene. Because we need to reduce the computation overhead of the RPi on drone, we would analyze only five frames out of the twenty-five frames per

second that the camera can detect. If there is more than one upright person on the scene, the system would allow the OCC to decide which one to track. Otherwise, the drone will track the detected target. Regardless of the method used to detect the target, the drone will keep the target on its camera frame center, while the OCC will get real-time updates of the location which would be shown on an interactive map. Because we don't want to overwhelm the drone's connection to the internet, the OCC will get few captured frames only.

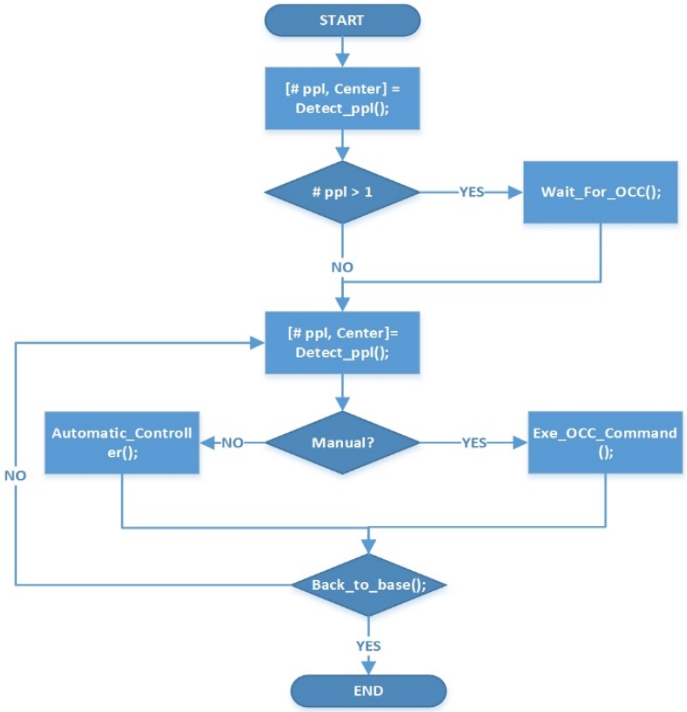

Figure 5 Target Detection and Tracking Flowchart

For the tracking, our system would allow the manual tracking of the suspect where the OCC officer can remotely control the drone without the need for frames analysis; however, this would require a high speed internet because the OCC needs a live streaming to be able to remotely control the drone. In case of automatic tracking, the optical flow method and its estimation using the Lucas-Kanade method will be used to track the suspect at the first frame only of every second [37,38]. The method works as the following: consider a pixel *I(x,y,t)* at the first frame, and it moves by distance *dx, dy,* in the frame that is compared to which is taken at *dt*. Because we are tracking the same person on real time, we assume the intensity does not change.

$$I(x, y, t) = I(x + dx, y + dy, t + dt) \quad (1)$$

by taking Tylor series approximation, and dividing by *dt*, we get:

$$f_x u + f_y v + f_t = 0 \quad (2)$$

$$f_x = \frac{\partial f}{\partial x}; \quad f_y = \frac{\partial f}{\partial y} \quad (3)$$

$$u = \frac{dx}{dt}; \; v = \frac{dy}{dt} \quad (4)$$

Then, using the Lucas-Kanade method, the final solution will be:

$$\begin{bmatrix} u \\ v \end{bmatrix} = \begin{bmatrix} \sum_i fx_i^2 & \sum_i fx_i fy_i \\ \sum_i fx_i fy_i & \sum_i fy_i^2 \end{bmatrix}^{-1} \begin{bmatrix} -\sum_i fx_i ft_i \\ -\sum_i fy_i ft_i \end{bmatrix} \quad (5)$$

Then, the drone will move to the desired direction to make u, and v in its frame center. This method will be repeated once every second. Because we are capturing from the drone, the capture has a wide area where the suspect is in the center of the frame. It is less likely that the suspect will be able to go beyond the area of the drone's camera in one second. So, we are processing one frame per second only, and to avoid overwhelming the RPi with computation demands. Figure 6 illustrates the detection and tracking process, and the movement of the drone.

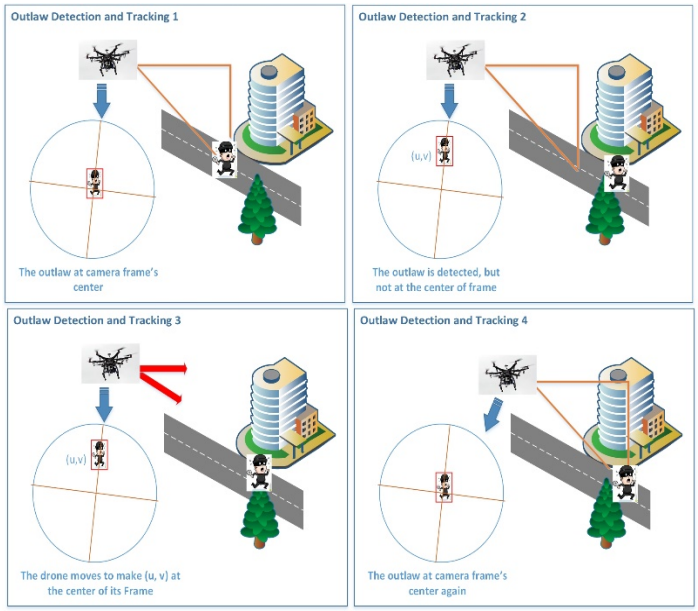

Figure 6 Target Detection and Tracking

4. Challenges and Future Work

Basically, the proposed safety and security framework inherited the obstacles that are facing the smart campus market which we can summarize in three areas: technical, financial, and political.

The technical barriers can be observed from the following perspectives: security, privacy, and configuration [1]. Being able to planet a massive number of low-energy and wirelessly connected devices on campus and meeting the security requirements is a problematic task due to the heterogeneous and intensive communication environment. Giving that we are utilizing various types of sensors, the privacy of people on campus is an issue where we need to be absolute that nobody can misuse the system to invade the people's privacy. Adopting the safety and security system on campus would result in using hundreds if not thousands of sensors which can be an enormous burden to configure them manually. Certainly, new ways of the automated configuration of IoT devices need to be thoroughly investigated.

In general, the smart campus market is facing financial difficulties giving that the limited resources of universities, regardless of immature experiences here and there. Even though the proposed system would save the university tons of many regarding the number of security officers on the long term, the initial investment is an impediment to the implementation of this system.

Regarding political hindrances, this system would need a waiver of some restrictions for unmanned aerial vehicles (UAV) by the Federal Aviation Administration (FAA), in the United States or such agencies in other countries, such as: the maximum altitude of 400 feet above ground level, visual line of sight, daylight only operations and some others [39]. Also, the system may face forceful opposition from people on campus and nearby neighborhoods regarding the invasion of their privacy. Even though it is almost inconceivable, the opposition of anti-tech security officers is a possible hindrance that needs to be considered.

After finalizing the implementation, our work opens the doors for researchers to improve the capability of this system to achieve optimum performance. The detection of outlaws during night-time and tracking them is a possible area of improvement. Moreover, the profiling of crimes respecting the hotspots, timings, and frequent suspicious activities using data collected by sensors would provide copious information about the crimes. The refined information would lead to crimes' prediction and prevention, eventually. Reducing the time between incident and arrival of drone is another area of improvement. Arming the drone with stun gun shocks could be considered for improvement. In addition, finding ways to avoid outlaws targeting the drone such as working on a bulletproof drone structure and trying to balance that with the speed of the drone is another area of improvement.

5. Conclusion

After presenting the recent work in smart campus technologies using IoT, we proposed a safety and security framework tailored to fit any university campus that would like to take advantage of recent advances in technology. The proposed framework would act as an instantaneous responder to incidents that could happen on campus. The proposed system is a good tool that would not only detect the incidents, but also it can track the outlaws even outside the campus until a backup team arrive to the scene. Also, we discussed the challenges of the system from three different perspectives: technical, and financial, and political. Finally, we highlighted the future work for this system to achieve its optimum performance.

Conflict of Interest

The authors declare no conflict of interest.

Islamic Critical Reflection
Research and Development

ABSTRACT

The use of technology in the learning process has become the most significant point in helping teachers reaching the objectives of the learning. This study focuses on the use of multimedia by novice teachers in comprehending the internship program's guidance. The Islamic Critical Reflection model is a new and innovative model in the field of education which development is a result of integration between Islamic value and science. This study aims to answer problems related to the internship supervision which occurs among novice teachers. The multimedia application in the form of Flash Macromedia is developed using Islamic Critical Reflection model for internship program of novice teachers at the Tarbiyah and Teacher Training Faculty UIN Sunan Ampel Surabaya. The research design of this study is Research and Development. It includes the process of collecting information, designing a product, validating the design, improving the design, piloting the product, re-revising the product, trying out the product, revising further and creating products for large numbers. The results of this study indicate that the products produced by Macromedia Flash application integrated with Islamic Critical Reflection Model for Tarbiyah and Teacher Training Faculty of UIN Sunan Ampel Surabaya's internship program are feasible to use. The results are from the experts' analysis and users' trials. Experts involved in the validation of this product are Islamic Education specialists, application experts, educational technology experts, and curriculum expert.

1. Introduction

UIN Sunan Ampel Surabaya has a vision and mission that is hoped to be reached through the milestones between the period of 2019-2045. The milestones are described in the UIN Sunan Ampel Surabaya's Development Master Plan 2019-2045 [1], [2]. One of the biggest duty of UIN Sunan Ampel Surabaya and also of other higher education institutions managed by the Ministry of Religion is to integrate knowledge and religion as the differentiator between the institutions with those managed by the Ministry of Education.

Higher education nowadays has more challenging responsibility in preparing its students to be ready for the 4.0 industrial revolution. This preparation can be managed by an internship program for novice teachers. It is because this module is an integration between theory and practice done at schools. This program aims to prepare students to be professional teachers.

* Evi Fatimatur Rusydiyah, Jl. A. Yani 117 Surabaya, +62 8121635409 & evifatimatur@uinsby.ac.id

Within this context, UIN Sunan Ampel has done many adaptation programs. One of the programs is designed to train novice teachers in mastering teaching skill that is intact and integrated. Therefore, after graduating, novice teachers who have taken the internship module are hoped to be ready for teaching [3], having a positive identity as a teacher, and acquiring more knowledge in the field of teaching [3]. It is possible because the internship program has several elements that are involved: supervisor, mentor teacher, and novice teacher.

The challenge is that the internship program that is running at the moment is considered to be not effective and not efficient yet in its guidance system. The problem that is emerged is the unstructured guidance program within each element. The evaluation and reflection in the internship program have only been partially conducted without a thorough involvement of various weakness points. The result is, there is no comprehensive information toward the development of novice teachers during the internship program. This condition then resulted in less competent novice teachers. Whereas, this internship program is designed to

be the prime program the faculty can offer, and also designed to be the educational core program.

To resolve the problem, Tarbiyah and Teacher Training faculty strives to develop a supervision system through critical reflection approach in the internship program. The technique implemented is the 3-2-1 technique with Islamic values as the base of its integration. Therefore, the process will facilitate teaching and learning, and it would be central to the teacher's development. The implementation of the 3-2-1 technique is done within the discussion process between the supervisor, mentor teacher and novice teacher. The three elements provide three positive inputs of what was found during the internship. After that, two negative inputs are presented and followed by a solution [4]. The Islamic Critical Reflection approach is used during supervision. It is based on Surah Al-Hujurat verse 6-8.

In this research, the concept is made in the form of the application using Flash Macromedia. Included in it, is the first supervision until the eighth. In other words, this research aims to develop a multimedia application with Islamic Critical Reflection for the Novice Teacher Internship Program.

In this research, multimedia as a tutorial application in facilitating teacher mentors, lecturers, and students in carrying out practical activities in field experience, so that they can understand the steps of supervision they will do for each. For teacher mentors, they will understand what they must provide in each supervision. For lecturers, they can understand what must be done when they are supervised. Likewise, for students, they will understand what they should get every time the lecturer supervises. Therefore this multimedia is not used for the learning process in the classroom, but this multimedia is used as a tutorial application in making supervising steps clear.

With the application, it is hoped that the novice teacher's professionalism is improving in the way that novice teachers can critically reflect and integrate it with Islamic values and pedagogical knowledge. "Critical reflection involves concern about the broader issue of teaching and learning*"* [5] is the notion that Murray and Kujundiz hold. They explained that [6] "critical reflection involves a process of analyzing, reconsidering, and questioning experiences within a broad context of issues such as analyzing assumption about teaching, raising awareness about the context of teaching. They imagine alternative ways of thinking".

The concept is visualized in the form of flash Macromedia. The application is developed through the Technology Acceptance Model (TAM). TAM model modification is done by Venkantesh [7] by adding trust variable with the title: Trust enhances Technology Acceptable Model which evaluating the relationship between TAM variable and trust. TAM other modification is Trust and Risk in Technology Acceptance Model (TRITAM) that uses trust and risk variable named TAM variable [8]. This model is one of the models developed from the theory of using a system of technology. It is considered to be the most affected in explaining personal acceptance towards the benefit and information technology used as a system [9].

One research that is related to the novice teacher program is Toman et al., [10]. It develops reflective thinking method and determines the novice teacher reflective thinking level. In 2007, Mathew discussed how mentor teacher creates opportunities for the novice teachers to developed reflective practice during the internship at school [11]. Gonen [12] in the research that was aimed to evaluate the experience that caused some changes after reflection is done. Moreover, it was also aimed to figure out what experience gained by the novice teacher after receiving guidance from the mentor teacher [12].

The importance of this research is for both the mentor teacher and the novice teacher understand the supervision process thoroughly, especially in implementing the 3-2-1 reflective principal as a part of novice teacher professional development. Novice teacher will be more confident with the guidance process that used Islamic Critical Reflection. Mentor teacher will also work professionally in guiding novice teacher.

2. Design

This research is aimed to develop an application in the form of Macromedia flash to be used in the internship program. This multimedia application is used to make an understanding of the duties of lecturers, mentor teacher,, and novice teacher when conducting internship program as a tutorial in supervising. Therefore this application is not used in class as media teaching-learning but is used in the supervision process. According to Borg and Gall [13], this research is categorized as Research and Development (R&D) research.

Steps that are generated from the process are understood to be the R&D cycle. They are consisted of studying research findings, developing the product, testing the product, and revising it to improve its weaknesses.

The R & D design used in this study is as follows.

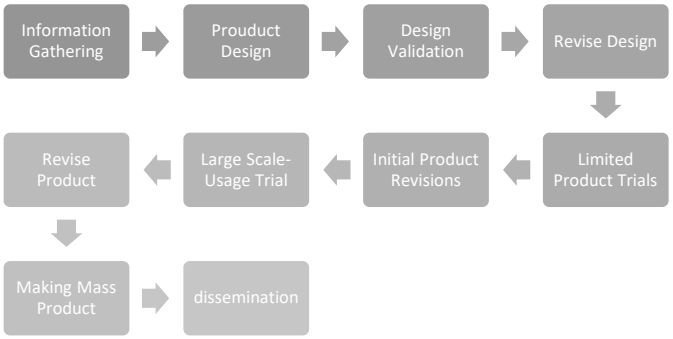

Figure 1. R & D flow

The R & D steps as referred to in the figure are information gathering, product design, design validation, revise design, limited product trials, initial product revisions, large-scale usage trials, revise product, making mass product, and dissemination [13]. These steps are a guide for researchers to conduct this research.

The test subjects in this R & D are stakeholders involved in implementing the practice of the field experience. The

stakeholders are 50 partner schools of the Tarbiyah Faculty UIN Sunan Ampel Surabaya which are occupied by field experience, 50 supervisors, and 150 mentor teachers.

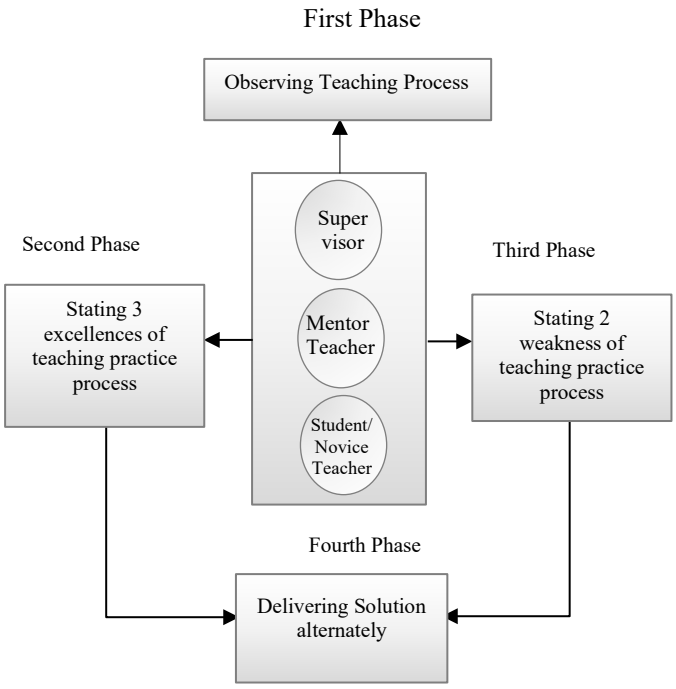

Figure 2: Islamic Critical Reflection Model

The product produced is based on the Islamic Critical Reflection model. This is a distinction as UIN Sunan Ampel integrated its learning process to Islamic principles and research [14], [10], [12]. The steps in Islamic Critical Reflection are observation, advantages, deficiency, and solution. The scheme can be seen in Figure 2.

The instrument which is used to measure the product is the Technology Acceptance Model (TAM). It is to explain personal acceptance towards the benefit and the use of information technology as a system [9]. After the application is made, the validity test was conducted. The experts to validate were ones who are expert in Islamic Education, Technology Education, and Curriculum. Operational suitability of the product was conducted in ten different primary schools and secondary school in Surabaya and Sidoarjo, East Java. The questionnaire was the main instrument for this stage.

3. Finding and Discussion

As in the R & D design above some of the findings in this study are as follows:

3.1. Gather Information

Information about the implementation of internship program in schools was conducted on Sunday, May 13, 2018 through a Focus Group Discussion (FGD) which was attended by 47 good tutors who were in Ibtidaiyah Madrasah, Madrasah Tsanawiyah / Middle School, Islamic Senior High Schools/ Vocational Schools in the region Surabaya and Sidoarjo and 41 Supervisors at the Sunan Ampel State Islamic University (UINSA). The FGD results show the need for understanding the concept of how the guidance model can improve the quality of UINSA internship's students who are qualified, the need for easy access that can be reached by students, civil servant teachers and Field Supervisors about guidelines for implementing effective and efficient internship program.

3.2. Stage of Product Design

On June 5, a Forum Group Discussion (FGD) was held which was attended by experts, namely educational technology experts, multimedia experts, Islamic education experts, and curriculum design experts from development products including a model of student assistance with Pamong Teachers and Field Advisors with 3-2-1 (triad meeting) which is visualized in Flash Media Media multimedia. On June 10, an FGD was held which was attended by experts again by presenting users. This FGD designed a product that will be formed in the internship application development model using Islamic studies on how to provide critical assistance based on an Islamic approach.

At this stage it was found, the practice of field training needs to be done with a reflective approach in communicating to convey information. This 3-2-1 approach is an implementation of Islamic teachings, that motivating students must be done politely with techniques to promote positive aspects rather than negative aspects. Likewise, the technique 3-2-1 strengthens the process of training students in finding solutions based on an analysis of their strengths and weaknesses [6]. Therefore approach 3-2-1 is an approach that leads to the analysis of the theory of critical reflection.

The 3-2-1 approach is also supported by the pyramid theory of human needs from Malow [15]. Humans in their lives have different needs, those needs from the high to the low. The lowest needs are the need to acknowledge oneself, then the need for compassion, love and love, then the need for security, and the highest needs are physiological needs. The higher the education of a person the higher the level of recognition desired [16]

Figure 3: Preliminary Display of the Pre Service Teacher Interference Model Application through the Islamic Critical Reflection Approach

3.3. Stage of Validation Design

The validators involved in this study were 1) Islamic religious education experts, multimedia experts, learning technology

experts, and curriculum experts. The results of the validator are as follows.

Islamic Education Expert

The application was developed through several steps. The first one is the observation step based on the basic Islamic teaching, which is Surah Al Maidah verse 17 and surah Al-Anam verse 46 about observing the process as one of Allah's power. In observing the novice teacher, mentor teacher could see how a novice teacher is going through a process in becoming a professional teacher and how a novice teacher is going through a process to be better.

The second and third step is to give a positive and negative suggestion. The second and the third step is the feedback from the supervisor, mentor teacher, and novice teacher. They all work together to suggest positive points. The inspiration for this step is Surah Al Baqarah verse 219, Surah Al Haj verse 28, Surah Al Isra' verse 14 and Surah Al Ankabut verse 3. Based on the verses, it can be concluded that as a supervisor, a mentor teacher, and a novice teacher, all the three elements have to deliver the truth, which is: conveying positive points to understand the deeper meaning, to contemplate, to evaluate the positive and the negative sides. Contemplation is designed by giving three positive characters and two negative experience.

The fourth step is the solution stage. It is based on Surah Al Baqarah verse 153, Surah Al Baqarah verse 109, Surah Al Ahzab, verse 70-71. All of the surah mentioned gives a clue that supervisor, mentor teacher and novice teacher have to show positive attitude such as to talk politely.

To ease the user in operating the application, guidance and summary result were provided thoroughly as it is seen in Figure 4.

Rangkuman

Praktik Pengalaman Lapangan II (PPL) di Fakultas Tarbiyah dan Keguruan UIN Sunan Ampel Surabaya adalah suatu rangkaian kegiatan untuk menerapkan berbagai teori kependidikan yang

Figure 4: Application Guidelines And An Application Summary

The Macromedia flash application consists of application guidelines, internship material, supervision stages, stages on supervision using the 3-2-1 technique. The third is to show the positive sides of the novice teacher's teaching. The second is to show the weaknesses of the novice teacher's teaching, and the first one is the solution. The 3-2-1 technique was used in a discussion and is conducted when the supervisor supervises the novice teacher. The 3-2-1 technique will be used not only by the novice teacher but also as a supervisor.

The result of the research is suitable with Maslow concept about human need pyramid. It is said that human need recognition. The recognition needed is toward self-actualization, affection, safety, and psychological needs [15]. Those needs are basic human needs. It also supported by several research: Schulte dan Marthann [17], Medcalf et all[18], Emad [19] dan Sari dan Dwiarti [20]. These research found out that motivation has a significant effect on work and study achievement.

The result of this 3-2-1 reflection technique is hoped to shape the novice teacher's self-confident. The teaching and learning will result in positive, and novice teacher can find their professionalism through reflecting every meeting. Therefore, they will be a professional teacher.

Application Analysis

The application that has been made was measured for its suitability using TAM indicator which consists of Perceived of Usefulness with its sub-indicators as follow: *1) Make Job Easier; 2) Work More 3)* Increase Productivity *4)* Effectiveness 5) Improve job performance *(6)* Useful. The second indicator is Perceived ease of use with its sub-indicator as follow: *1)* Easy to learn *2)* Controllable *3)* Clear and understandable *(4)* Flexible*, 5)* Easy to become skillful *(6)* easy to use [21]. This research also used an application that was developed based on the human-machine interaction [22] indicator by Davis [23] and Hendrawati [24]. It has several indicators, such as *learnability, efficiency, memorability, errors, and satisfaction.*

Through the application, it is gained several positive aspects as follow: the application could give guidance for a supervisor so that the supervisor could use it easily. It could also aid the supervisor's understanding in guiding a novice teacher. It helps the supervisor to improve novice teachers' professional competencies. This application is designed to present steps in supervising internship programs using the 3-2-1 technique effectively. This, in return, beneficial for faculty, supervisors and lecturers, novice teachers, school and stakeholders to develop teachers' professionalism.

Based on the application analysis, it is found out that the application design using buttons that are familiar for users is compatible with these Operating System: Windows, Linux, and Android. This development supports Koral and Emel [25], also Akar and Güzin [26] who suggest that technology acceptance relates to content comprehension which becomes the focus. It is also stated by Konak et al. [27] who stated that technology acceptance affects collaborative work. The same notion explained by Davis [21] and Hendrawati [24] who figured that technology acceptance had affected intrinsic motivation to occur.

As the previous research, information technology system acceptance could be explained within group work. The bigger the group who receive the information technology system, the bigger its practice would change. The group would also tend to use or try something new that could be used or developed in an information technology system

3.4. Education of Technology analysis

Education technology is a knowledge which relates to theory and practice on how to design, develop, implement, organize, and measure the education process to reach the educational aim. One

of its important components is a reflection. Reflection is a stage in an educational process so that the goal is reached. Therefore, reflection is used as one of the stages in this application so that it would affect novice teacher positively.

This condition is the same as several research which stated that every novice teacher has a reflective thinking skill [10]. Novice teacher has contributed positively towards the teaching skill that is developed to think reflectively [11]. Reflective needs to be applied when conducting an internship [12].

The same notion goes to video animation. The message is delivered effectively using video. The research that was conducted by Duygu Sonmez and Meral Hakverdi-Can [28] explained that video and application could affect users' comprehension in teaching reflectively.

The result of this study support the research by Mohd dan Elmagzoub A [29], Komalasari, et al. [30], Djamas, et al. [31], and Richter research's [32]. These researchers found out that learning through application brings a positive effect to the learning result. In this research, it was also found that the mentor teacher understood it more on how to do supervision job during the internship. Likewise the results of research conducted by DeVore et al. [33], Linton [34], Hamdi, et al. [35] Syurigin and Krasnova [36], Lailiyah et al. [37] and Darmawan [38].

3.5. Curriculum Analysis

During the internship program, eight supervisions were conducted. The internship was for two months on holiday between July and September every year [3]. The first supervision is an introduction, observation, school introduction, and sit in with mentor teacher as a complete model. The three activities were conducted in the first week within the supervision activity.

The second supervision is a practical observation which was guidance teaching (with the composition of mentor teacher took up 75% and novice teacher took up 25%) and conference (discussion between mentor teacher, supervisor and novice teacher) on a learning process that has been conducted and lesson plan preparation. Other points that were discussed were: practical guidance teaching (mentor teacher took up 50%, and novice teacher took up 50%), and conference (discussion between mentor teacher, supervisor, and novice teacher) about the learning process that has been conducted and lesson plan preparation. The second supervision was done in the second week.

The third supervision was a practical observation on guidance teaching (mentor teacher took up 25%, and novice teacher took up 75%) and a conference (discussion between mentor teacher, supervisor, and novice teacher) on the learning process that has been conducted and lesson plan preparation. This supervision was conducted in the third week of the internship program.

The fourth supervision is a practical observation on independent teaching and a conference (discussion with a mentor teacher, supervisor and novice teacher) on the learning process that has been conducted and lesson plan preparation. This was done in the fourth week.

The fifth supervision is on the fifth week. The supervision was a practical observation on independent teaching and a conference (discussion between mentor teacher, supervisor, and novice teacher) on the learning process that has been conducted and lesson plan preparation.

The sixth supervision is a practical observation on independent teaching and a conference (discussion between mentor teacher, supervisor, and novice teacher) on the learning process that has been conducted and lesson plan preparation. The seventh supervision is a practical observation on independent teaching and a conference (discussion between mentor teacher, supervisor and novice teacher) on the learning process that has been conducted and lesson plan preparation. This was conducted during the sixth week during the internship program. The eighth supervision was an observation on presentation preparation about the internship result and the finishing of the report. This was done in the sixth week.

The activities above can be visualized in a Macromedia flash application. This application was used in order to aid internship guidance comprehension in the means of attractive visual for users. Not only that, the internship guidance scheme as part of the curriculum becomes more organized and systematic. This is because each supervision has a clear aim and target and therefore, could improve the professionalism of novice teacher [16]. This process could be said as a professionalism improvement process by providing review activity in the reflection during the conference. This is also understood as the implementation of democracy in education [39].

The basis of this development and research is on the analysis of curriculum expert. The result was the internship curriculum design that will influence professionalism achievement of a novice teacher. This is as what Capka [40] has found that the curriculum design could influence student professionalism in the field of accountancy. Another research was by Jasperson [41] which stated that the internship curriculum with reflection principles could improve students' self-development. The same result was concluded by Johnson [42] who found that the internship process contributes to student's carrier development after graduation.

4. Conclusion

Internship model application development for novice teacher using the Islamic Critical Reflection was conducted based on four experts. The Islamic religion education expert stated that this application represents Islamic teaching principles as the basis of educational theory development. Application expert stated that this application meets the easiness and readability aspect of TAM (Technology Acceptance Model). Education technology expert stated that educational aspect through reflective teaching is used for feedback to improve the professionalism of novice teacher. It is found in this application. Curriculum expert stated that the cycle of 2-month supervision in this application is a good way in improving novice teacher's professionalism Conflict of Interest.

ABSTRACT

This paper considers active disturbance rejection control (ADRC) as a new control approach for pH neutralization process. The pH process is challenging to control due to its sensitivity to disturbance, nonlinear dynamics, and time-varying characteristics. Special attention is paid to the impact of disturbances typically exists in the chemical process. First, the pH neutralization process nonlinear model is presented, then the active disturbance rejection control is described briefly and a pH neutralization process closed-loop control system is designed on its bases, and investigated with simulation. More robust and better disturbance rejection performances are achieved compared to the control technique of feedback linearization (FL).

1. Introduction

This paper is an extension of work presented initially in 2018 15th International Computer Conference on Wavelet Active Media Technology and Information Processing (ICCWAMTIP) [1]. Control of pH neutralization in the chemical and biotechnological industries is a typical process [2]. The pH of this effluent must be retained within environmental boundaries, before discharging the effluent streams from wastewater treatment plants. Tight pH control is also critically required in pharmaceutical production. However, owing to the high nonlinearity of the pH process, robust and high performance pH process control is often difficult to obtain [3-5]. The process gain of these processes can differ from a small range of pH values to several orders of magnitude. Thus it can exhibit severe static nonlinear behavior.

So far, many authors have proposed, developed, and implemented different control techniques to overcome this problem. The classical PID controller is the first technique applied to control the pH [6-8]. In the field of industrial applications, the PID controller is considered as the most popular controller types, but it has been unable to satisfy the growing demand for efficiency, speed, and accuracy. Nonlinear control techniques also have been applied [9-21]. Other works involve intelligent control technique [22, 23]. In general, most of the above methods require an adequate model, which could not be easy to obtain, add to that the complexity of the controller design based on the above approaches. Hence, pH neutralization process requires a new approach to control it.

In [24-26], Han introduced the powerful control technique active disturbance rejection control (ADRC) and simplified and identified in [27]. The states and disturbance can be estimated in the ADRC before an error can occur, which can ultimately attain early compensation and disturbance resistance. Since it was introduced, the ADRC method has gained worldwide attention and broad implementation and has become common after its linear form has appeared [28]. In many fields, ADRC has been implemented effectively, benefiting from its full control characteristics as fast system response, large scale adaptation, and small overshoot [29].

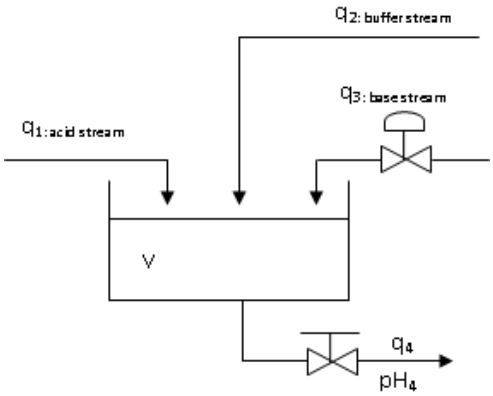
In this technique, a unique state observer is used to estimate what is called total disturbance. The uncertainties in the dynamics of the internal process and the disturbances of the output are considered as total disturbances. This observer is called the extended state observer (ESO), and it can track the state-space model's extended state, which can achieve this goal. The plant's state-space model should include only the model estimate. A linear model in a state-space form may be an estimate for a nonlinear system [29].

This work proposes a different control technique based on estimating the disturbances and actively rejecting it for pH neutralization process. All the disturbances typically presented in pH process are lumped together in one signal called total disturbances. The extended state observer tracks these disturbances and the control law cancels it.

The organization of this paper is as follows. The pH process's model is given in section 2. Section 3 briefly presents the technique

* Mohanad Hamad Eljack Elameen, mohanadeljack@gmail.com

of feedback linearization. Section 4 shows the ADRC control system for the pH process. Section 5 gives the simulation results, and section 6 gives a general conclusion.



2. Model of pH Process

Figure 1 shows a schematic diagram describing the pH process. The process consists of an acid flow rate (q_1), buffer flow rate (q_2), and the base flow rate (q_3) mixed in the tank. pH_4 represents the output of the process, where q_3 represents the control input. By using the conservation equations of the reaction invariants and equilibrium relations, a dynamic model has been derived. Set tank volume (V), Ideal mixing, constant density, and full ion solubility are considered as assumptions for modeling. The system's chemical reactions are:

$$H_2CO_3 \leftrightarrow HCO_3^- + H^+,$$

$$HCO_3^- \leftrightarrow CO_3^{2-} + H^+,$$

$$H_2O \leftrightarrow OH^- + H^+$$

The reaction's equilibrium constants are

$$K_{a1} = \frac{[HCO_3^-][H^+]}{[H_2CO_3]},$$

$$K_{a2} = \frac{[CO_3^{2-}][H^+]}{[HCO_3^-]},$$

$$K_w = [H^+][OH^-]$$

The chemical balance is formed using the reaction invariant concept [30]. The invariants concentrations are (i=1,2,3,4):

$$W_{ai} = [HCO_3^-]_i + [H^+]_i - 2[CO_3^{2-}]_i - [OH^-]_i,$$

$$W_{bi} = [HCO_3^-]_i + [CO_3^{2-}]_i + [H_2CO_3]_i,$$

where W_{ai} is a charge-related quantity, and W_{bi} is the carbonate ion concentration, and they are independent of the extent of the reaction. The concentration of the hydrogen ion is calculated from:

$$W_{ai} + W_{bi}\frac{\frac{K_{a1}}{[H^+]_i} + \frac{2K_{a1}K_{a2}}{[H^+]_i^2}}{1 + \frac{K_{a1}}{[H^+]_i} + \frac{K_{a1}K_{a2}}{[H^+]_i^2}} + \frac{K_w}{[H^+]_i} - [H^+]_i = 0.$$

The hydrogen ion $[H^+]_4$ with the following relationship calculates the pH of the effluent stream:

$$pH_4 = -log_{10}([H^+]_4)$$

The dynamic model is given by the vessel's material balance:

$$V\frac{dW_{a4}}{dt} = q_1(W_{a1} - W_{a4}) + q_2(W_{a2} - W_{a4}) + q_3(W_{a3} - W_{a4}),$$

$$V\frac{dW_{b4}}{dt} = q_1(W_{b1} - W_{b4}) + q_2(W_{b2} - W_{b4}) + q_3(W_{b3} - W_{b4}).$$

This put the process model in a state-space form as

$$\dot{X} = f(x) + g(x)u + p(x)d \quad (1)$$

where

$$u = q_3, \quad x = [W_{a4}\ W_{b4}]^T, \quad d = [W_{a1}\ W_{b1}]^T,$$

$$f(x) = \begin{bmatrix} -\frac{q_1}{V}x_1 + \frac{q_2}{V}(W_{a2} - x1) \\ -\frac{q_1}{V}x_2 + \frac{q_2}{V}(W_{b2} - x2) \end{bmatrix},$$

$$g(x) = \begin{bmatrix} \frac{1}{V}(W_{a3} - x1) \\ \frac{1}{V}(W_{b3} - x2) \end{bmatrix}, \qquad p = \begin{bmatrix} \frac{q_1}{V} & 0 \\ 0 & \frac{q_1}{V} \end{bmatrix}.$$

Note that Eq. (1) is linear in p, and the unknown parameters are presented in the vector d. The relation between the state variables x and the output y is nonlinear as shown by

$$c(x, y) = 0, \quad (2)$$

where

$$c(x, y) = x_1 + 10^{y-14} - 10^{-y} + x_2 c_{x2}, \quad (3)$$

$$c_{x2} = \frac{1 + 2 \times 10^{y-pk_2}}{1 + 10^{pk_1 - y} + 10^{y-pk_2}},$$

$$pk_1 = -log_{10}k_{a1}, \quad pk_2 = -log_{10}k_{a2}.$$

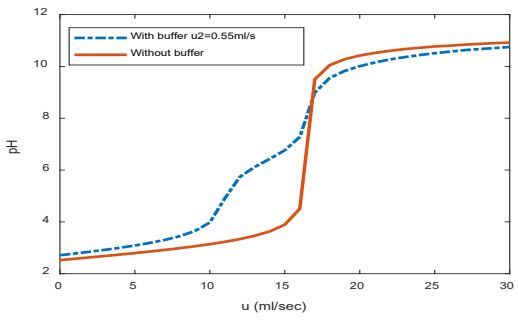


Figure 2: The dynamics of the pH process

Table 1 shows the nominal values of the parameters.

Table 1. Model Parameters Nominal Values

Parameter	Nominal value
V	2900 ml
K_{a1}	4.47×10^{-7}
K_{a2}	5.62×10^{-11}
$[q_1]$	0.003 M HNO3
	5×10^{-5} M H2CO3
$[q_2]$	0.03 M NaHCO3
$[q_3]$	0.003 M NaOH
	5×10^{-5} M NaHCO3
q_1	16.6 ml/s
q_2	0.55 ml/s
q_3	15.8 ml/s
pH_4	7.00
W_{a1}	0.003 M
W_{b1}	5×10^{-5} M
W_{a2}	-0.03 M
W_{b2}	0.03 M
W_{a3}	-3.05×10^{-3} M
W_{b3}	5×10^{-5} M
W_{a4}	-4.50×10^{-4} M
W_{b4}	5.5×10^{-4} M

Figure 2 shows the static dynamics of the pH process, which shows strong nonlinearity.

3. Feedback Linearization Technique

For the severely nonlinear system expressed in (1-3), a nonlinear controller based on feedback linearization (FL) technique is first designed.

Consider the following nonlinear system

$$\dot{x} = f(x) + g(x)u, \quad y = h(x) \tag{4}$$

The objective is to find a linear differential relation between a new input v and the output y. The system has a relative degree r if

$$L_g L_f^i = 0 \qquad 0 \le i \le r - 2 \tag{5}$$

$$L_g L_f^{r-1} h(x) \neq 0$$

where Lf in the direction of f is the Lie derivative. Suppose the system above has a relative degree of r and is linearizable, then the input transformation

$$u = \frac{v - L_f^r h}{L_g L_f^{r-1} h} \tag{6}$$

hence, the relation between y and v is linear as

$$y^{(r)} = v \tag{7}$$

For the pH process, by differentiating (3) using (1) we get

$$\dot{y} = -c_y^{-1}(x,y)c_x(y)[f(x) + g(x)u + p(x)d] \tag{8}$$

where

$$c_x = \frac{\partial c(x,y)}{\partial x} = [c_{x1} \quad c_{x2}],$$

c_{x1}=1,

$$c_{x2} = \frac{1+2\times 10^{y-pk_2}}{1+10^{pk_1-y}+10^{y-pk_2}}.$$

$$c_y = (\ln 10) \times \left\{ x_2 \left(\frac{10^{pk_1-y} + 10^{y-pk_2} + 4 \times 10^{pk_1-pk_2}}{(1 + 10^{pk_1-y} + 10^{y-pk_2})^2} \right) + 10^{y-14} + 10^{-y} \right\},$$

Since $-c_y^{-1}(x,y)c_x(y)g(x) \neq 0$ for all x and y of interest, the relative degree $r = 1$, and the linearization relation is

$$u = \frac{v + [f(x) + p(x)d]c_y^{-1}(x,y)c_x(y)}{-c_y^{-1}(x,y)c_x(y)g(x)}$$

Now, assume v is the output of a PID controller in the form

$$v = k_P e + k_I \int e + \dot{y_{sp}} \tag{9}$$

where $e = y_{sp} - y$ and y_{sp} is the reference signal, k_P is the proportional gain, k_i is the integral gain.

The control structure of the FL controller is shown in Figure 3.

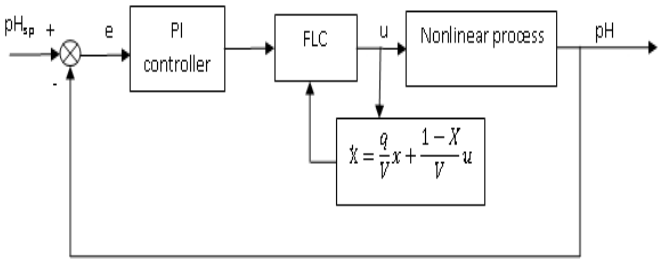

Figure 3: The control structure of the FL controller

4. ADRC Solution for the pH Process

It is shown that the control structure using the feedback linearization method is very complicated. To simplify the control design, ADRC is designed. It is shown that all the nonlinear and time-varying terms under ADRC are components of the total disturbance that need to be estimated and rejected, making the design and structure much more straightforward.

4.1. Conventional linear ADRC

We can rewrite the system described in (1) as

$$\dot{y} = f + bu \tag{10}$$

where f is the total disturbance, and b is the coefficient of the output change rate to the control variable step and varies all through the process. Now, ADRC task is to estimate f in real time and cancel it in the control law, which putting the extended state observer as a choice tool from the modern control theory. Define

the cases as $x_1 = y$ and $x_2 = f$, where the extended state is represented by x_2; then, Eq. (10) rewritten as

$$\begin{bmatrix}\dot{x}_1\\ \dot{x}_2\end{bmatrix} = \begin{bmatrix}0 & 1\\ 0 & 0\end{bmatrix}\begin{bmatrix}x_1\\ x_2\end{bmatrix} + \begin{bmatrix}b\\ 0\end{bmatrix}\dot{f}$$

$$y = x_1 \tag{11}$$

An ESO can be constructed to estimate the states

$$\begin{bmatrix}\dot{z}_1\\ \dot{z}_2\end{bmatrix} = \begin{bmatrix}0 & 1\\ 0 & 0\end{bmatrix}\begin{bmatrix}z_1\\ z_2\end{bmatrix} + \begin{bmatrix}b\\ 0\end{bmatrix}u + \begin{bmatrix}\beta_1\\ \beta_2\end{bmatrix}(y - \hat{y})$$

$$\hat{y} = z_1 \tag{12}$$

where β_1 and β_2 represent the gains of the observer.

The total disturbance $z_2$will be estimated by a well-tuned observer in Eq.(12), and the control law

$$u = \frac{-z_2 + u_0}{b} \tag{13}$$

where u_0 is a virtual control signal, then Eq.(10) reduced to

$$\dot{y} = u_0 + (f - z_2) \approx u_0 \tag{14}$$

which can be easily controlled using a proportional controller.

$$u_0 = k_p(r - z_1) \tag{15}$$

Here k_p is the controller gain and r is the reference signal.

The structure of the ADRC is shown in Figure 4.

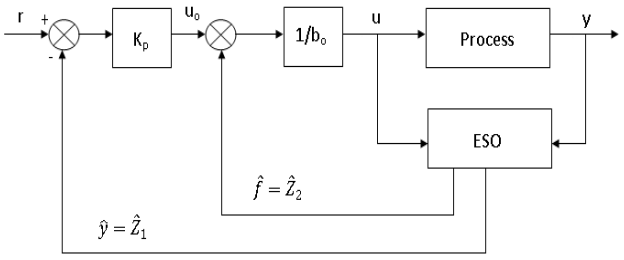

Figure 4: ADRC structure for a first-order process

The gains of the observer are chosen as $\beta_1 = 2\omega_{ob}$ and $\beta_2 = \omega^2_{ob}$ to put the observer poles at $-\omega_{ob}$. In the same way, the controller gains are selected as $k_p = \omega_c$ to put the pole of the control loop at $-\omega_c$. ω_{ob} and ω_c are called the observer bandwidth and controller bandwidth, respectively.

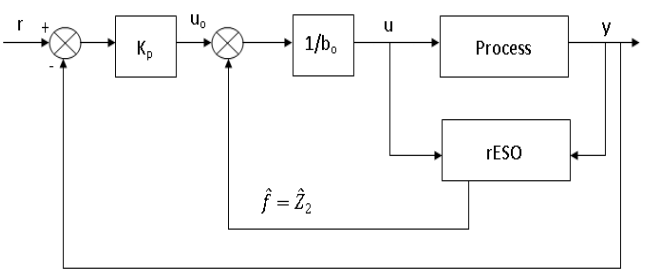

Figure 5: ESO based reduced-order ADRC

4.2. Reduced-order ADRC (rADRC)

In the ADRC, a second-order ESO is used to obtain the extended state compensation estimate; however, redundancy occurs when the state's first component can be directly measured [31]. A reduced-order state observer is employed, as shown in Figure 5.

The state observer of reduced-order for x_2 is

$$\dot{z}_2 = -\omega_{ob}z_2 - \omega_{ob}bu + \omega_{ob}\dot{y} \tag{16}$$

where ω_{ob} (>0) determines the convergent rate of the ESO. To avoid intensifying measurement noises by direct numerical differentiation of signal y in (16), we define a new state as

$$z = z_2 - \omega_{ob}y \tag{17}$$

Therefore (16) may be rewritten as

$$\dot{z} = -\omega_{ob}z - \omega_{ob}{}^2 y - \omega_{ob}bu \tag{18}$$

which combined with

$$z_2 = z + \omega_{ob}y \tag{19}$$

constitutes the reduced-order ESO. The remaining controller design is the same as those above.

5. Simulation Results

A comparison between the performances of the designed FL and ADRC controllers is carried out through simulation. The change in buffer and feed stream flow rate is regarded as a disturbance to the system and shown in Fig. 6. The ADRC parameters are shown in Table 2.

Table 2. ADRC controller parameters

ADRC	$\omega_{ob} = 5$	b = 0.05	$\omega_c = 10$
rADRC	$\omega_{ob} = 0.9$	b = 0.05	$\omega_c = 10$

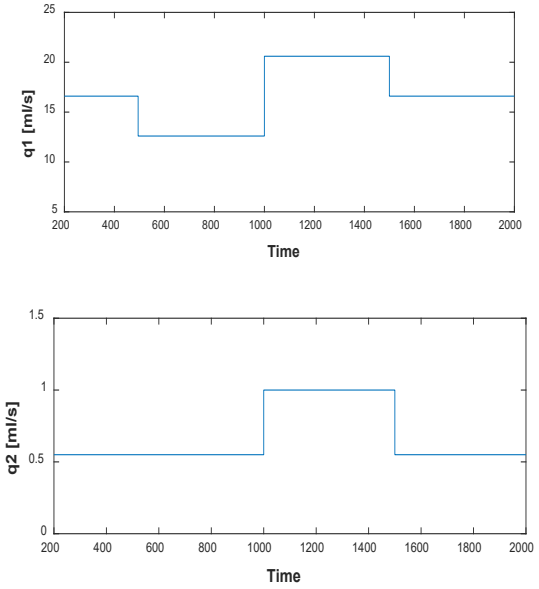

Figure 6: The change of buffer and feed stream flow rate

There are two cases considered in this simulation.

A. Constant Parameters

First, let us look at the case of the constant parameter. The efficiency of both disturbance rejection (Figure 7) and setpoint tracking (Figure 8) is examined to evaluate the effectiveness and robustness of the control system. A comparison to the FL controller carried out to illustrate the advantages of the ADRC as well as the rADRC. It can be observed from Figure 7 the superiority of ADRC and rADRC over the FL controller. We can see from Figure 8 that ADRC tracks the change in setpoint very well, and rADRC tracks it even better, while the FL controller shows some overshoot with longer settling time.

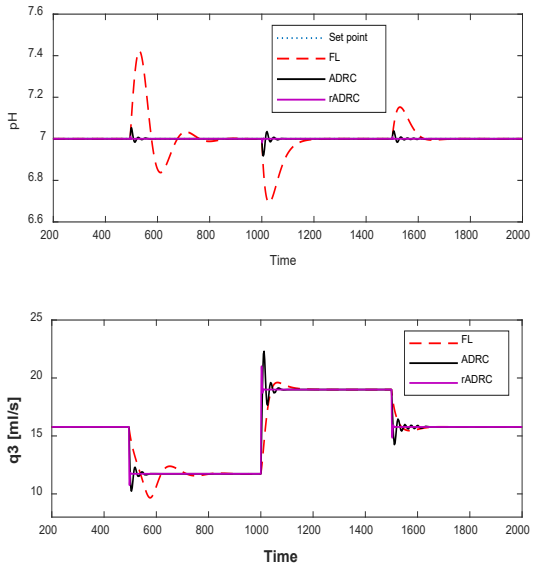

Figure 7: The performance of disturbance rejection

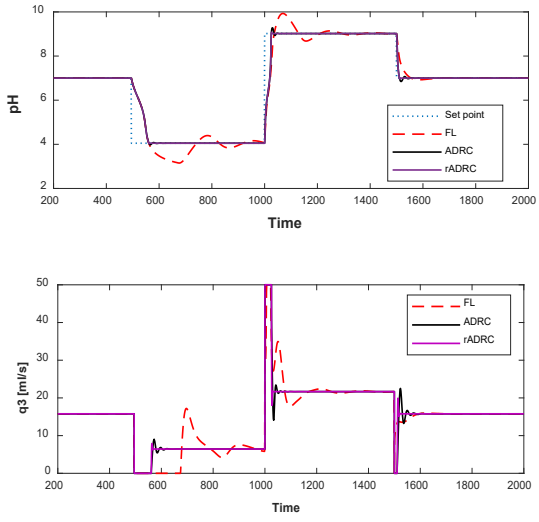

Figure 8: The performance of setpoint tracking

B. Variations in the parameters

The parameters changes are discussed In this case. They are regarded and handled as a system's internal disturbance. Figure 9 shows the changes in the concentrations of the feed stream.

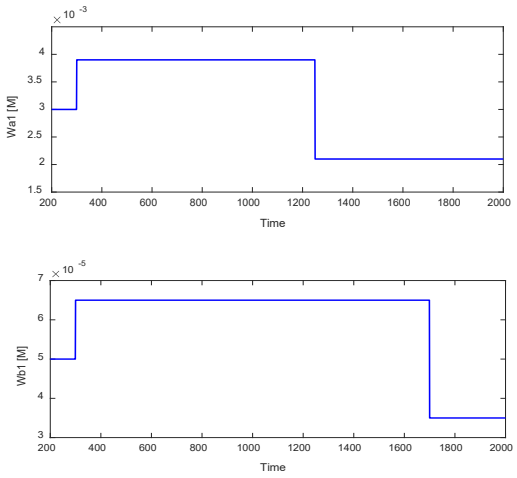

Figure 9: Variations in the concentration of the feed stream

Figure 10 shows the performance of the disturbance rejection, while Figure 11 shows the performance of the setpoint tracking. We can see obviously that ADRC and rADRC are superior to the FL controller.

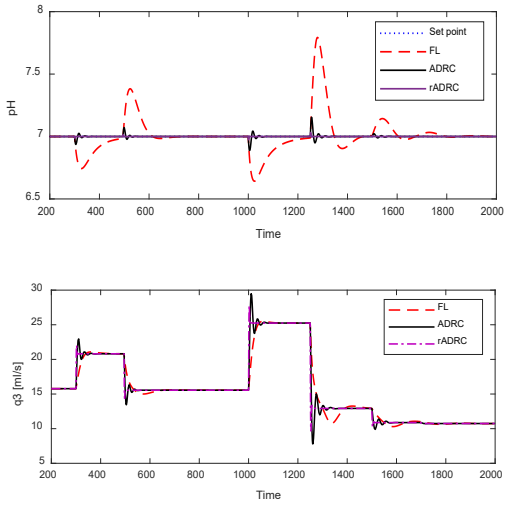

Figure 10: The performance of disturbance rejection with variation in parameters

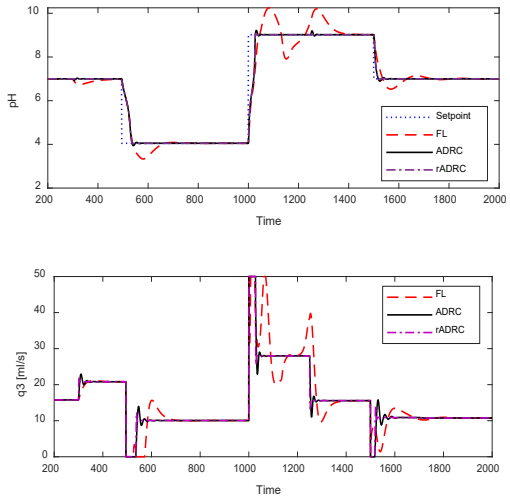

Figure 11: The performance of setpoint tracking with variation in parameters

6. Conclusion

A novel control technique (ADRC) for a pH process is presented in this paper. ADRC is an excellent solution to the process that needs a high performance controller to overcome the modeling errors and disturbances. ADRC's pH simulation studies showed a major enhancement over nonlinear FL control. For more analysis, a reduced-order ADRC was designed and proved that it has the most significant performance in regulating the pH in the existence of the input and external disturbances. The ADRC method is a strong algorithm, particularly in rejection of disturbances. Compared to FL control technique, design and tuning are much more straightforward.

Conflict of Interest

The authors declare no conflict of interest.

Face sketch recognition
Face sketch synthesis
VGG-Face network

ABSTRACT

Face sketch recognition aims at matching face sketch images to face photo images. The main challenge lies in modality discrepancy between face photo and sketch images. In this work, we propose a new facial sketch-to-photo recognition approach by adopting VGG-Face deep learning network, with which face images can be represented by compact and highly discriminative feature vectors. Different from existing VGG-Face based methods which directly match face sketches to photos, we firstly transform the gallery photos to sketches for decreasing the modality difference. Experimental results on multiple face photo-sketch datasets indicate the superiority of our method.

1. Introduction

Face sketch to photo recognition is a key branch of face recognition to address the lack of face photos, which has wide application in forensics [1]. If crime happened, and only incomplete information is obtained about the suspect because of the bad quality of monitoring videos, face sketches which drawn by the artists with the description of witnesses are used to identity the possible suspect. The police can shrink the range of suspects by searching the law enforcement face databases or surveillance cameras with the drawn face sketch images [2].

Face sketch to photo recognition approaches can be mainly classified into common space projection approaches and local feature descriptor approaches. Common space projection approaches attempt to transform facial images from various modalities to common subspace where the modality difference is reduced. After that, facial photos and sketches could be directly identified in the common space. Lin et al. [3] translated heterogeneous features to common feature space with common discriminant feature extraction (CDFE). In [4], Lei et al. proposed a subspace learning framework named coupled spectral regression (CSR) for heterogeneous face recognition. Then, they improved the CSR algorithm through learning a mapping from all modalities to all samples [5]. In [6], Sharma et al. employed partial least squares (PLS) algorithm to project heterogeneous facial images into common subspace. Mignon et al. [7] proposed to learn a discriminative latent space by using cross modal metric learning (CMML) method. In [8], Kan et al. suggested a multiple view analysis algorithm, with which the dependencies from intra-view and inter-view can be utilized to obtain a discriminant subspace for heterogeneous face recognition. However, the space projection based methods may lose the underlying information of the source images and lead to degradation of the recognition effect.

Local feature representation approaches aim at extracting robust and modality-invariant face feature representations from the heterogeneous face images. In [9], Klare et al. put forward a face sketch recognition approach with a local feature discriminant analysis (LFDA) framework which taking advantage of multiscale local binary pattern (MLBP) [10] and scale invariant feature transform (SIFT) [11]. In [12], Zhang et al. suggested a coupled information theoretic encoding based local face descriptor for face sketch to photo recognition. And later, the coupled information theoretic encoding algorithm was modified to the random forests by using various sampling methods. Galoogahi et al. [13] put forward a facial feature descriptor named local radon binary pattern (LRBP) for face sketch recognition, which firstly projects the face images into the radon space and then encodes them with the local binary patterns (LBP). In addition, a local face descriptor based on histogram of averaged oriented gradients (HAOG) is suggested by Galoogahi et al. to decrease the modality difference [14]. In [15], Lei et al. put forward a heterogeneous face

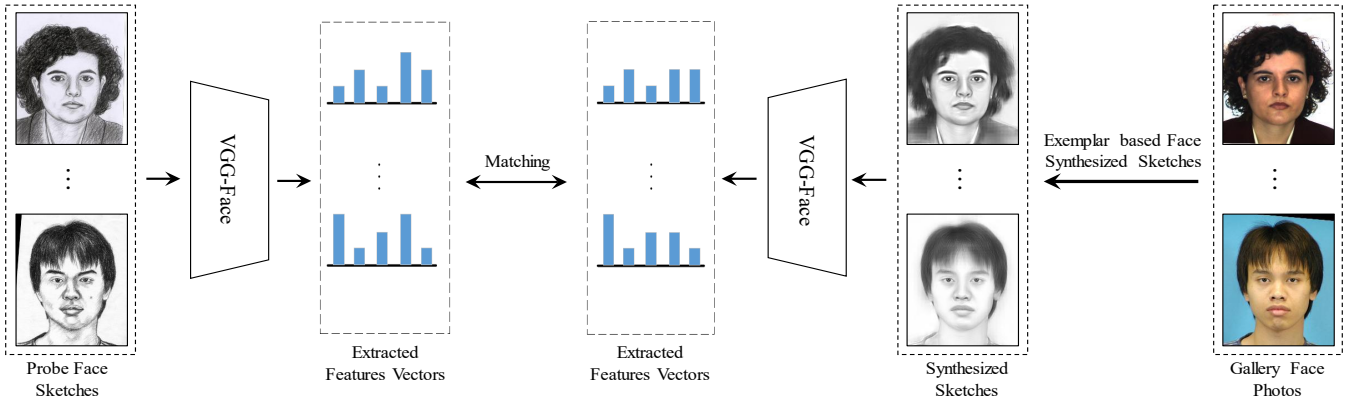

Figure 1. The illustration of the proposed face sketch recognition approach.

recognition method based on discriminant image filter learning. Alex et al. [16] suggested a local difference of Gaussian binary pattern algorithm for heterogeneous face recognition. However, when extracting the face feature representation, the local feature descriptor based approaches lose the sight of the holistic spatial structure of face, which is important for face sketch recognition.

Moreover, because of the huge differences between the face photo and sketch images, it is difficult for traditional homogeneous face recognition approaches to achieve good performance by directly matching the sketches to photos. In this paper, we transform the photo images into sketch images by adopting an exemplar-based sketch generation approach to decrease the modality difference between face photo and sketch images. In [17], Parkhi et al. presented a deep learning network, namely VGG-Face, which is able to map a face images to a compact space where distances can be used for measuring the face similarity. Peng et al. [18] mentioned that it can be adopted for face sketch recognition. Motivated by its efficient performance, we adopt it to extract the discrimination face feature representation in this paper. With the VGG-Face network, the feature vectors which represent the corresponding face images can be obtained. The illustration of the proposed approach is showed in Figure 1.

2. Related Works

2.1. Exemplar-based Sketch Generation

The exemplar-based face sketch generation approach needs a group of training dataset which contains some face photo-sketch pairs. First, each test photo **T** is divided into several image patches with overlapping between adjacent patches. Then, for each test photo patch **t**, several number of closest photo patches are chose from the training photo images which are cut image patches with the same approach. At the same time, we can get *K* corresponding sketch candidate patches with the obtained photo patches. Finally, the sketch patches are generated by combining the *K* candidate sketch patches with the corresponding weighting coefficients. The sketch generation operation can be represented as follow:

$$\min_{w} \| \mathbf{t} - \mathbf{X} \cdot \mathbf{w} \|_2^2, \ \ s.t. \ \mathbf{1}^T \mathbf{w} = 1 \tag{1}$$

where **X is** the *K* selected photo patches from training data. **w** is the weighting vector to combine candidate sketch patches.

Then we can obtain the target sketch patch ***s*** by:

$$\mathbf{s} = \mathbf{Y} \cdot \mathbf{w} \tag{2}$$

where **Y** represents the corresponding sketch patches of the test photo patch **t**.

2.2. VGG-Face Networks

The VGG-Face networks [17] are built on the basis of VGG-Very-Deep-16 convolutional neural network (CNN) architecture. The VGG-Face networks consist of a series of convolutional, pool, and fully-connected layers. The first eight blocks are convolutional layers and the remaining three blocks are fully-connected layers. For each convolutional layers, a ReLU activation layer is followed. The output dimensions of the first two fully-connected layers are 4096 and the output dimension of final fully-connected layer is 2622. The filters of convolutional layers are with size of 3×3 while the pool layers perform subsampling with a factor of two. Figure 2 displays the framework of the VGG-Face model.

In the proposed method, a pretrained VGG-Face model with 37 basic layers is utilized to extract deep face features. The pretrained model is trained on a big face dataset which has 982,803 images from 2622 subjects. The pretrained VGG-Face model only can recognize the people in the training dataset, however, we are able to extract face features from its bottleneck layers for any face images by forwarding the face images through the whole networks. The extracted features are highly discriminative, compact, and interoperable encodings of the input face images. When the face features are obtained from the bottleneck layers of the VGG-Face model, the sketch to photo matching can be performed based on these obtained face features. In this paper, the MatConvNet toolbox, which provides the pretrained implementation of the VGG-Face model, is utilized to extract deep face features.

3. The Proposed Method

In this paper, we presented a new facial sketch-to-photo recognition approach with the VGG-Face network and face sketch generation. The proposed method mainly consists of face image preprocessing, face sketch synthesis, and face sketch recognition three steps, which will be described later.

3.1. Face Image Preprocessing

Face photo and sketch images vary in properties, e.g. varying resolution, pose, and deformation. We firstly normalized all the

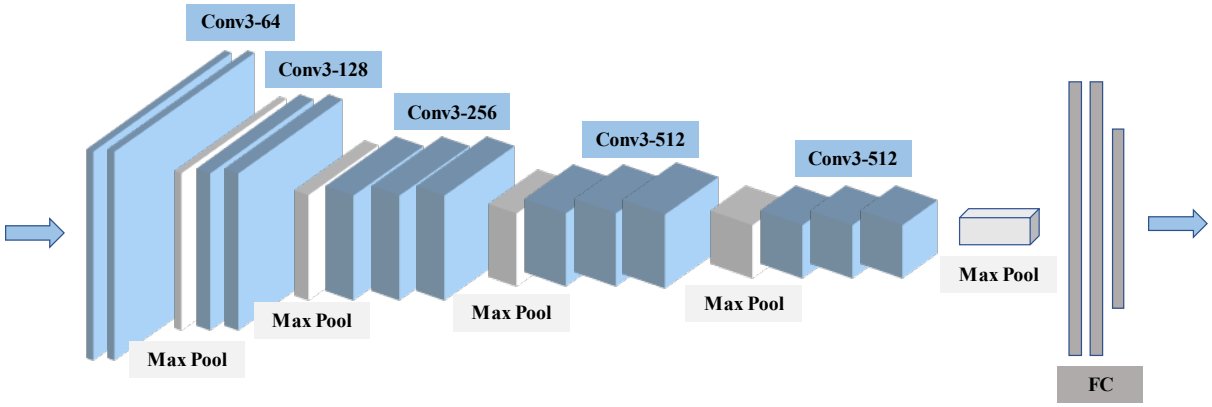

Figure 2. The VGG-Face CNN architecture.

sketch and photo images by fixing the coordinates of eyes centers. The common-used Dlib library was used to detect eyes position, and then translation, rotation, and scaling operations are conducted to align face images based on the detected eyes coordinates. Figure 3 shows some samples of original and preprocessed face photo and sketch images.

3.2. Face Photo to Sketch Synthesis

Assuming there are M geometrically aligned training photo-sketch pairs. We first divide these photo images and sketch images in training data into patches. Then, we reshape every patch to a vector. For each patch position, the searching area is extended c pixel around the patch. Thus, we can obtain $(2c+1)^2$ patches in the searching area for each patch position. We will obtain $(2c+1)^2M$ face photo and sketch patches from the training data, respectively. We employ the random sampling algorithm for selecting K face photo patches $\mathbf{U}^{(i,j)} \in \mathbf{R}^{2p^2 \times K}$ and sketch patches $\mathbf{V}^{(i,j)} \in \mathbf{R}^{2p^2 \times K}$ from training data. (i, j) is the patch position at the m-th row and the n-th column. Each image patch can be reshaped to a d-dimensional column vector.

For each test photo patch $\mathbf{t}_1^{(i,j)}$, we can compute the reconstruction weight by using equation (3):

$$\min_{\mathbf{w}^{(i,j)}} \| \mathbf{t}_1^{(i,j)} - \mathbf{U}^{(i,j)}\mathbf{w}^{(i,j)} \|_2^2 + \lambda \| \mathbf{d}^{(i,j)} \square \mathbf{w}^{(i,j)} \|, s.t. \mathbf{1}^T \mathbf{w}^{(i,j)} = 1 \quad (3)$$

where $\mathbf{d}^{(i,j)} \in \mathsf{R}^{K\times 1}$ represents the L2 distance of the test photo patch $\mathbf{t}_1^{(i,j)}$ and the selected photo patches $\mathbf{U}^{(i,j)}$ from training data, $\mathbf{w}^{(i,j)} \in \mathsf{R}^{K\times 1}$ represents the weighting coefficients of the test photo patch $\mathbf{t}_1^{(i,j)}$.

Equation (3) has the closed-form solution:

$$\begin{aligned} \mathbf{w}'^{(i,j)} &= (C^{i,j} + \lambda \mathrm{diag}(\mathbf{d}^{(i,j)})) \setminus \mathbf{1} \\ \mathbf{w}^{(i,j)} &= \mathbf{w}'^{(i,j)} / \mathbf{1}^T \mathbf{w}'^{(i,j)} \end{aligned} \quad (4)$$

where $\mathbf{1}$ represent a column vector, its elements all are 1. $C^{i,j} = (\mathbf{U}^{(i,j)} - \mathbf{1}\mathbf{t}_1^{(i,j)^T})(\mathbf{U}^{(i,j)} - \mathbf{1}\mathbf{t}_1^{(i,j)^T})^T$ is the covariance matrix, $\mathrm{diag}(\mathbf{d}^{(i,j)})$ is a diagonal matrix which is extended from $\mathbf{d}^{(i,j)}$.

By linearly combining K selected sketch patches of the training data and the weighting coefficients $\mathbf{w}^{(i,j)}$, the result sketch block

Figure 3. Facial photo-sketch examples in CUFS dataset and CUFSF dataset.

$\mathbf{s}^{(i,j)}$ could be generated:

$$\mathbf{s}^{(i,j)} = \mathbf{V}^{(i,j)}\mathbf{w}^{(i,j)} \quad (5)$$

We can generate the final target sketch with overlapping area averaged when get all the target sketch patches,. Fig. 3 shows some generated examples with the exemplar-based face sketch generation. From Figure 3, we can observe that the modality difference between the sketch image and the transformed sketch image smaller than the photo image.

3.3. Face Sketch Recognition with VGG-Face Network

After the photo images are generated to sketch images, the VGG-Face network was adopted to get the facial feature vectors of synthesized sketch images. We then call the synthesized sketch images gallery, and the test face sketch images probe.

We extract the face features by utilizing the VGG-face networks which is provided by the MatConvNet toolbox. The VGG-face architecture is composed of several convolution layers with 3×3 filters, several pooling layers with a factor of 2, and 3 fully-connected layers. In VGG deep networks, the early layers are

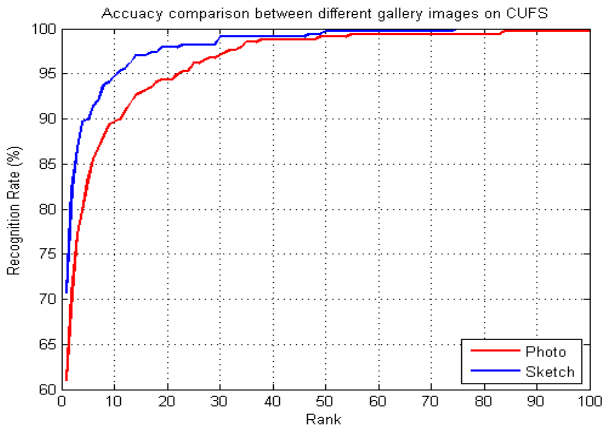

Figure 4. Performance comparison by using different gallery images.

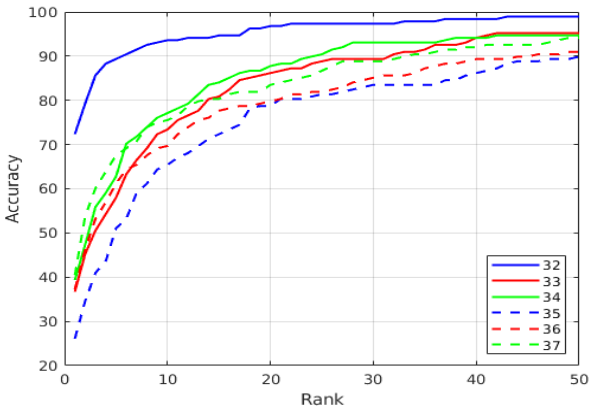

Figure 5. Performance comparison by different VGG-Face layers.

the low-level representation for input images such as edge and corner, the intermediate layers represent mid-level features like parts, and the high-level representations exist in the last layers. In order to find the optimum high-discrimination face features for face sketch-to-photo recognition, we selected activation maps from 32nd layer to 37th layer as the deep feature representation. The performance comparison results, which will be analyzed in the experiment section, indicated that the 32nd layer obtains the highest recognition accuracy. In this case, each face image was represented by a 25,088-dimension deep feature vector.

By using the well-trained VGG-Face network model, we can map all the sketch images in gallery into 25,088-dimension feature vectors. And a same length feature vector can be obtained by using the pre-trained network for each input probe image. We use the squared Euclidean distance of the face feature vectors to calculate the facial similarities. Face images from the different subjects have large distances while facial images of the same person have small distances. Hence, the face sketch recognition can be regarded as a nearest neighbor classification problem. The illustration of the proposed face sketch recognition method is shown in Figure 1.

4. Experiments and Results

4.1. Datasets

Two public available datasets are adopted to assess the recognition effect of the proposed approach: the CUHK dataset (CUFS) and the CUFSF dataset [19]. The CUFS dataset is composed of facial images from 3 datasets: the CUHK student dataset (188 subjects), the AR dataset (123 subjects), and the XM2VTS dataset (295 subjects). The CUFSF dataset has 1194 subjects of FERET dataset. In CUFS and CUFSF datasets, there are one photo image and one sketch image for each subject. All the face photo and sketch images are normalized and cut to with size of 250×200. The first two rows of Figure 3 shows the examples of photo-sketch pairs from these two datasets. The first three columns are face images of CUFS and the final column are face images of CUFSF. The first row are the original face sketches and the second row are the face photos. The final row are the generated sketches.

4.2. Experiments

First. we evaluated the recognition effect between adopting face photo images as gallery and adopting the generated sketch images as gallery. Figure 4 shown the comparison results, from it we can see that using the synthesized sketch images as gallery obtained better recognition performance. The results indicated that modality difference of the face photo and sketch images was narrowed down after synthesizing face photos to sketches.

We extracted last several layers from the VGG-face networks as the deep face features for recognition. To compare the performance by different layers, the experiment on CUHK student sub-dataset was conducted with same distance measurement. The result shown in Figure 5 indicated that the 32nd layer obtains the highest recognition accuracy. Thus, the feature vectors extracted from 32nd layer were set as the face representation in this paper.

Three existing approaches are compared to assess the recognition effect of the proposed approach, namely the HOG based approach, the DCP based approach [20] and the Light-CNN based approach [21]. Figure 6 (a) and (b) shown the comparison results on the CUFS and CUFSF datasets. Table 1 shown the rank-1, rank-5 and rank-10 recognition accuracies on CUFS and CUFSF datasets. From them, it can be seen that the proposed approach achieves the best recognition performance, compared to other methods. For the CUFS dataset, even though it is easy for other approaches to obtain high recognition performance, but our approach is the quickest one achieving 100% accuracy. The CUFSF dataset is more difficult due to the face photo images are taken under various illumination conditions. In addition, the face sketches exist shape deformation compared with the photos in CUFSF dataset. But the proposed approach still achieves the best recognition accuracy. In summary, the proposed face sketch to photo recognition approach is effective and practical.

5. Conclusions

In this paper, we presented a face sketch-to-photo recognition approach based on deep feature representation. The face photos were synthesized to face sketches to decrease the modality gap of the face photo images and sketch images. After that, the VGG-Face network was employed to extract feature representation for each face image. With the extracted face features, the face similarity can be measured directly. Experimental results on the CUFS and CUFSF datasets indicated the superiority of the proposed approach. The proposed approach in this paper is our preliminary research and only the pre-trained VGG-Face network was adopted. In the future, we plan to develop high-performance networks for face photo to sketch recognition.

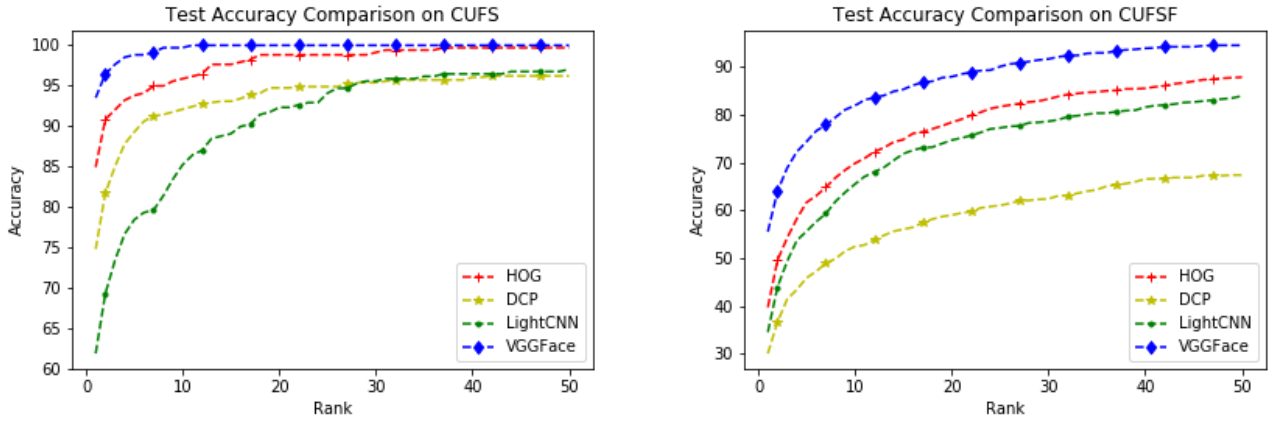

Figure 6. The comparison of recognition accuracies by different approaches on the CUFS and CUFSF datasets.

Table 1. Recognition accuracy (%) by different methods.

Methods		HOG	DCP	LightCNN	Proposed
CUFS	Rank-1	84.91	74.75	61.83	**93.49**
	Rank-5	93.79	89.27	78.40	**98.81**

Planning in Dairy Industry

ABSTRACT

The most important biological factors, mainly determining the economic efficiency of milk production, are the productivity potential and the level of viability of cows. The aim of the work is to predict the bio-economic effects in a heterogeneous population of dairy cows taking into account the decrease in the length of productive life with increase in milk productivity. In the considered model situation, with an increase in the productivity of cows, the total profit per cow per year increases, while the profitability of production may decline. The developed algorithms are supposed to be used for solving the problems of optimizing the management of the dairy cow herd and planning technological development in animal husbandry.

1. Introduction

Used abbreviations and terms: PL is length of productive life (the number of consecutive lactations of 305 days each); PP is the potential of productivity, VP is the viability potential, CR is constitutive resistance, dry period is the period from the end of lactation to calving; calving period is lactation period + dry period.

Due to the reduction in the total size of dairy cattle population, the rate of decline in milk production in the Russian Federation is not compensated by a positive trend of increasing the average productivity of cows. The use of imported breeding material on a large scale and the use of intensive industrial technologies in milk production are accompanied by a decrease in the level of biodiversity, an increase in "productivity diseases", a decline in reproduction, a deterioration in the quality and safety of the products obtained. Similar problems in the field of dairy cattle husbandry have arisen in recent decades in other countries, since the high productivity of cows is often associated with an increased frequency of culling. [1, 2]. Therefore, to ensure profitability and overall sustainability of milk production, it is necessary to intensify research in the field of biology of the viability and productive longevity of cows [2 - 4]. It is necessary to search for biological traits and technical tools for the collection and transmission of information for early prediction of the health status of lactating cows at the earliest possible stages of postnatal life [2, 3].

Previously, it was shown that for early assessment and prediction of viability in groups of dairy cows, the trait of constitutive resistance can be used as an integral indicator reflecting the effects of age-related decline in protective forces [5], as well as the reciprocal of the rate of cows culling in first lactation. An analysis of empirical data reveals the presence of heterogeneity in terms of survival parameters in populations of various animal and human species. The data from bio-medical studies show that the patterns of mortality in a population considered as one whole may differ significantly from the mortality frequencies in the constituent subpopulations [6, 7]. There are data indicating the heterogeneity of dairy cattle populations on survival parameters [8, 9]. In the context of the stated approach, the main factors determining the lifetime productivity of cows are PP and VP. Age dynamics of milk production in groups of cows with different PL is determined by a specific combination of these factors.

From the viewpoint of planning the development of the dairy industry, it is important to have methodological tools for a comprehensive assessment and forecasting the influence of the most critical factors in the selection, reproduction and housing condition of dairy livestock. In this paper, as a starting point in this direction, we propose a pilot model for predicting bio-economic effects when varying a set of factors, including milk

*Corresponding Author: Gennadii G. Cherepanov, Institute of Animal Physiology, Biochemistry and Nutrition, Borovsk, Kaluga region, 249013, Russia, Email: 8961242110@mail.ru

production potential and the rates of disposal of the herd in a heterogeneous population of dairy cows. When setting the initial data, an empirically fact of a decrease in PL with increasing milk production was taken into account, especially pronounced in highly productive cows.

The aim of this work is the systematization of previously identified empirical patterns and the development of a pilot numerical model for predicting the bio-economic effects in a dairy cows population which is non uniform in terms of PP and VP.

2. Determination of The Numerical Values of Parameters using Empirical Data

2.1. Milk Production Potential

To estimate the potential of milk production in the *i*-th homogeneous group, cumulative 305 d milk yield data are used for consecutive lactations, $y_{mi}(t)$, ranging from 4 ($t = 4$) to the last completed lactation t_{imax}. Age dynamics of 305 d milk yield is described by a three-component multiplicative function

$$y_{mi}=A_i \times\exp(-\exp(-bt))\times D^t{}_t \qquad (1)$$

in which A_i is a potential maximum lactation yield (productivity potential, PP), the exp(-exp(-bt)) function describes an age-dependent increase in the ability to form milk with a gradual reaching a plateau level, the function D^t (constitutive resistance, CR, D<1) describes an age-related decrease in the ability to maintain lactation activity in the *i*-th group. The maximum yield is always less than A by an amount depending on the rate of decline of the CR. At small values of D, the peak of milk yield for lactation occurs earlier and the cows drop out of the herd more quickly.

Earlier, when analyzing empirical data on cows of the Kholmogor and Black-and-White breeds, a linear positive relationship was found between PL, expressed by the number of last lactations t_{imax}, and the value of D_i in groups [5]. Thus, the value of D has the meaning of viability potential (VP), estimated from the age dynamics of 305 d yields in groups. The value of the parameter b in the second component of formula (1) varies within small limits (0.4–0.5) and for proximate calculations it was assumed to be 0.45.

2.2. *Potential of Viability*

The presence of a positive relationship between PL and the "initial" value of the CR in the analysis of the age dynamics of milk yield agrees qualitatively with the identified relationship between PL and the viability index estimated from the dynamics of cows leaving the head (culling by sum of reasons). Culling rate is described by the Gompertz function:

$$y_c(t)=\Delta S(t)/(S(t)\times\Delta t)=B\times\exp(ct) \qquad (2)$$

where $S(t)$ is the cohort size at the moment of time t, $\Delta S\ (t)$ is the reduction of the cohort size for the period of time Δt. For lactating cows, time is usually expressed as the number of the current lactation and $\Delta t = 1$. Parameters B and c can be determined not in cohorts (in groups of animals born during the same period of time), but according to the data of age structure of the herd (cross-sectional study).

The mean PL (T, the average number of lactations in a cohort) can be estimated from empirical data using an analytical expression [10]:

$$T=\exp(B/c)\times\mathrm{Ei}(B/c)/c \qquad (3)$$

where Ei(.) is a special function (integral exponent).

For use in zootechnic practice, we can use the truncated Gompertz distribution, which does not take into account a small number of longevity record holders. Our numerical simulation showed that in the range of values B = 0.04–0.3, c = 0.2–0.8, the maximum PL value is approximately 2 times larger than the average PL i.e. $t_{max}\approx 2\ T$ or $T = t_{max}/2$ [8].

The value of the initial rate of disposal y_{c1} in formula (2) means the difference between the number of cows in the first and second lactation divided by their number in the first lactation. When analyzing production data on the age structure of the dairy herd, in particular, on five breeds of the USA and on eight farms of the Leningrad region, the existence of a positive linear dependence of T on the value of $1/y_{c1}$ was revealed [5]. Therefore, the value of $1/y_{c1}$ has the meaning of predictor of longevity, as measured by the dynamics of the disposal of cows from the population, herd or cohort [8].

The function, inverse to the intensity of disposal, is characterized by a decrease in the viability with age ("resistance to mortality" according to Gompertz). Thus, at t = 1, the "initial" disposal intensity $y_{c1} = B\ e^c$ is determined, and the reciprocal, $1/y_{c1} = B^{-1}\ e^{-c}$, has the meaning of the initial viability level.

3. Forecasting Milk Production Efficiency

3.1. Baseline Data for The Forecast

In the model situations under consideration, there are four groups with consecutive values A = 24, 20, 16, 12 thousand kg (the average for the lifetime milk yield is 12.4; 11.0; 9.35; 7.64 thousand kg); T = 2, 3, 4. 5 (t_{max} = 4, 6, 8, 10 lactations); D = 0.95; 0.91; 0.89, 0.88. An additional list of source data may include a large number of indicators. In this case, this list includes the calving period 13 months and the main cost indicators, including feed costs, the price of sold milk and culled cows (delivery at a meat processing plant, utilization of carcasses of sick cows, etc.).

3.2. Intermediate Calculations and Target Forecast

The initial data for each group are calculated:
- the average lifetime cumulative 305 d milk yield over 10 completed lactations (y_m);
- the number of replacements of the culled cow on the heifer for the total number of 10 lactations ($Nr = 10/T$);
- calendar term corresponding to 10 lactations (years);
- revenue from sold milk over 10 lactations with price of 30 rubles per 1 kg of milk, thousand rubles (milk income, $m.inc = 30 \times ym$);
- revenue from sold culled cow over 10 lactations, thousand rubles (realization income, $real.inc = cow\ price \times Nr$);
- total revenue, thousand rubles (*income, inc = inc.m+ real.inc*);

- the average price of grown or purchased heifers, thousand rubles (heifer cost, *Hc*);
- the cost of growing or purchasing heifers, thousand rubles (reproduction expenses, *repr.exp.* = *Hc* × *Nr*);
- the cost of maintenance and technological spending per cow for the whole period, thousand rubles (technological expenses, *t.exp.* = *12* × *year*);
- feed costs for milk production per 10 lactations, thousand rubles (feed expenses, *f.exp* = *0.6* × *inc.m*);
- the sum of expenses, thousand rubles (*s.exp* = *repr.exp* + *t.exp* + *f.exp*);
- profit, thousand rubles (income over expenses, *IOE* = *inc.);*
- profitability (% rentability, *rent*).

The adopted forecasting scheme assumes a certain method of combining in the same algorithm two heterogeneous data, i.e. the age dynamics of productivity and the longevity of cows. In the literature, there is no description of such an algorithm, and there are also no systematic empirical data necessary for detailed analysis. The simplified calculation method used in this work for ten 305 d lactations at one value of calving interval is as follows. Since the average daily milk yield values are used in groups, to obtain a forecast of the calendar period for 10 lactations per cow place, you can use the above ratio $T = t_{max}/2$. For example, at $T =$ 5 it is necessary to have two periods, i.e. 2 cows with 5 lactations and 4 dry periods (100 months of lactation, 24 months of dry period). At the same time, in the case of culling, a new primiparous cow is transferred to this place, one period of dry period is missed, and the total calendar period for which the cost of one cow per year is calculated for this group is 10.3 years. For the next three groups, these values are 10, 9.9, 9.5.

4. Results and discussion

The results of calculating the profitability of milk production for 4 model groups (subpopulations) with different values of the productivity potential, the average PL, the cost of raising or importing young stock and the main technological costs with an interval of 13 months are given in Table 1 and Figure 1 and Figure 2.

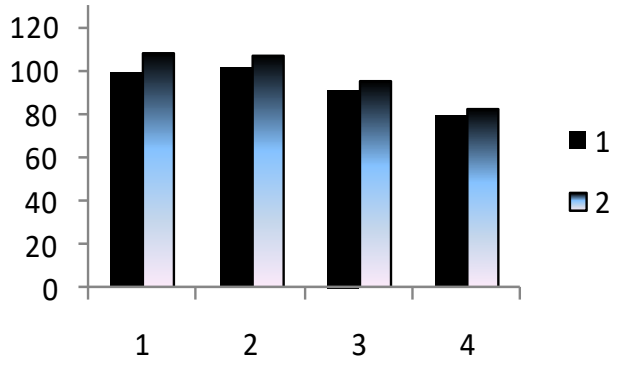

Figure. 1. Total profit per cow per year in the production of milk in four groups of cows with the values of the parameters listed in Table. In groups 1, 2, 3, 4, the average milk yield per life is 12.4; 11.0 9, 35, 7.64 thousand kg.; the calving period is 13 months. The average price of a culled cow sold in option 1 is 10, in option 2 it is 30 thousand rubles.

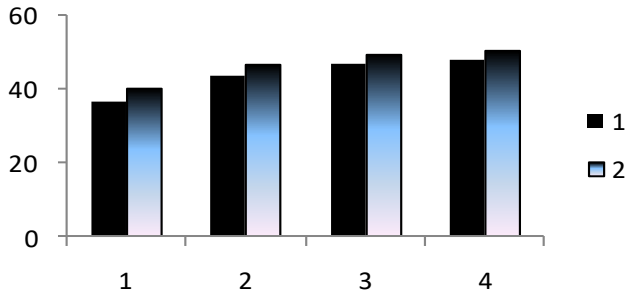

Figure. 2. Profitability of dairy raw materials production (revenue per milk and from sale of culled cows / sum of expenses) in four groups of cows with the values of the parameters listed in Table. In groups 1, 2, 3, 4, the average milk yield per life is 12.4; 11.0; 9.35; 7.64 thousand kg.; the calving period is 13 months. The average price of a culled cow sold in option 1 is 10, in option 2 it is 30 thousand rubles.

In the considered model situation, with an increase in the productivity of cows, the total profit per cow per year increases, while the rentability of production decreases.

To predict bio-economic effects in real conditions (including in terms of long-term planning), it is necessary to take into account the variability of interrelations and a wide range of possible values of parameters. In this work, seven factors were considered, the numerical value of which can vary widely, which is the case for different regions of the Russian Federation. At the same time, four gradations of two factors (level of productivity and viability index) were taken into account with two levels of one additional factor. At this stage of the study, the operability of the formulated concept and the pilot prediction model were tested. With a positive assessment of the results of the first stage, the expansion of the empirical base becomes urgent, i.e. obtaining a sufficient amount of production data while improving the calculation algorithm.

In the extended version of the model, additional indicators may be introduced into the calculations, including the reproduction parameters of the dairy herd. Since, at high levels of milk production, there is a shortage of the young animals number, to preserve the livestock population size the complex methods are developed (separation of bull-sires semen, induction of superovulation, *in vitro* fertilization, transplantation and embryo cloning), which increase the cost of reproduction of the dairy herd. To provide enhanced herds reproduction, the choice of the most appropriate method depends largely on the conditions of the territorial distribution of specific farms, as the initial data in the forecasting can vary greatly for small farms in the regions and for large industrial complexes with intensive technologies located near large urban agglomerations. Therefore, in order to rationalize management decisions, multivariate model calculations are required.

Researchers working in the field of studying the dynamics of human populations have identified the need to identify subpopulations in order to correctly predict demographic processes [11, 12]. In the process of breeding work in animal husbandry, similar problems arise, since an early assessment of the breeding value of parents for productive longevity of offspring is important. For bull-sires, one of the options for such an assessment may be

Table. Baseline data and results of the prediction of the bioeconomic efficiency of milk production in groups that differ in productivity potential (A) and viability (D).

Notes: notations are given in the section 3.2.

the inverse of the rate of disposal in first lactation, measured in a group of daughters [13]. When using the latest genomic, bioinformatics and telecommunication technologies, there are ample opportunities for solving such problems. The use of microelectronic sensors and wireless communication allows to increase the amount of information captured during screening surveys throughout the animal's life, which can dramatically increase the possibilities for monitoring and forecasting multifactorial bio-economic effects.

At this stage, it is important to compare the initial prerequisites of our calculations with known ideas and concepts related to the problems of populations viability. The concept of constitutive resistance as the main determinant of productive animal longevity, used in this work, is in many ways consistent with the concepts of creod according to Waddington [14] and primal health of Odent [15]. There is evidence that metabolic diseases occurring in later life may arise *in utero* as a result of suboptimal intrauterine conditions. The process by which prenatal defects lead to permanent changes in tissue structure and function, and finally to low birthweight, is known as developmental programming; i.e. placental insufficiency invariably affects embryonic development and health in later life [16]. So, the level of viability in heifers is being formed epigenetically in the prenatal and postnatal periods when exposed to internal and external factors. Our data indicate that the value of cow PL depends on the "initial" level of viability indicators (at the beginning of the reproductive period). The existence of this dependence is indicated by empirical data and, as carried out by calculations, a similar relationship follows from the general properties of the Gompertz function, traditionally used in analyzing the survival of populations.

5. Conclusion

The most important biological factors, mainly determining the economic efficiency of milk production in dairy farms, are the productivity potential and the level of cow viability formed to the age of reproductive activity. The length of the productive life of cows largely depends on the initial level of viability indicators. Currently, the average group potential levels of productivity and viability can be determined from indirect information – the data of age dynamics of 305 d milk yields and intensity of cows culling in first lactation.

From the viewpoint of planning the development of the dairy industry, it is important to have methodological tools to predict the influence of the most critical factors in the selection, reproduction and housing condition of dairy livestock. In this paper, we tested the operability of the general approach and the algorithm of numerical simulation using discrete scales and data approximation by the Gompertz function. The results showed that in the considered model situation, with the increase of the average of lifetime milk yield, the total profit per cow per year increases, while the profitability may decline. According to the authors, there is reason to assume that the identified consistent patterns reflect a general trend, at least in a qualitative sense, since empirically established facts and regularities are taken into account in the set of initial data.

After expanding the volume of empirical data, setting parameters and modification of algorithm taking into account the features of real objects, the proposed forecasting model is supposed to be used to optimize the herd management and forecast scientific and technological development in dairy cattle husbandry.

ABSTRACT

Clustering is a branch of data mining which involves grouping similar data in a collection known as cluster. Clustering can be used in many fields, one of the important applications is the intelligent text clustering. Text clustering in traditional algorithms was collecting documents based on keyword matching, this means that the documents were clustered without having any descriptive notions. Hence, non-similar documents were collected in the same cluster. The key solution for this problem is to cluster documents based on semantic similarity, where the documents are clustered based on the meaning and not keywords. In this research, fifty papers which use semantic similarity in different fields have been reviewed, thirteen of them that are using semantic similarity based on document clustering in five recent years have been selected for a deep study. A comprehensive literature review for all the selected papers is stated. A comparison regarding their algorithms, used tools, and evaluation methods is given. Finally, an intensive discussion comparing the works is presented.

1. Introduction

Clustering is a problem of unsupervised learning; the main task is to group a set of objects in a manner that the group of objects in the same collection called the cluster are more similar (in meaning) to each other than those in the other cluster [1][2]. Document clustering or (text grouping) is a block analysis application on text documents, has applications in automatic organization of document, filtering or fast information retrieval and subject extraction [3][4]. The text group divides a set of text documents into different categories so that the documents in the same category group describe the same subject. Text clustering is an essential function in the text mining process [5]. Problem of Description clustering is one of the key issues for the traditional algorithm of document clustering. The objects can cluster in traditional algorithm, but the result of clustering cannot give description concept. It is therefore necessary to find a way to resolve the problem of grouping the document description in such a way to meet the specific needs of document clustering [6]–[8].

For conceptual and meaningful collecting of documents into groups (clusters), it is necessary to exploit the semantic relationships between words and concept in the documents [9]. For this case semantic similarity is needed. The term semantic similarity is a specific measure for several pamphlets/concepts in contrast with the similarity that capable of roughly- calculations with respect to represent grammar (such as the format of the string). For this reason, the mathematical instruments are depended for asset estimation semantic association among language units and ideas or examples, by means of a numerical description obtained by comparing information that supports its meaning or description of its nature [10]–[12].

It is often confused with the term semantic relatedness and semantic similarity. The semantic relationship involves any relationship between two periods, whereas the semantic similarity only includes a relationship “is a” [13]. For example, "car" and “bus" are similar, but is related to “driving" and “road”. By determining topological similarity, Semantic similarity can be estimated using the ontology to determine the distance between concepts/term [14][15].

For semantic similarity purpose between concepts many tools are used, the most common one is the WordNet. The term of WordNet Is the lexicons of the English language database. It’s collecting the words into a group of synonyms named syn-sets, provides general, short info and register a different semantic relationship between these sets of synonyms. Especially WordNet is suitable for similarity procedures, because it regulates nouns and

[*]Rowaida Khalil Ibrahim, Email: rowayda.gravi@gmail.com

verbs in the hierarchy of "is a" relation [16]. Several tools for finding semantic similarity between concepts and words have been proposed in our literature but most of them have been used WordNet. For this paper we reviewed many papers that used semantic similarity but we choose only thirteen systems in these five recent years that using semantic similarity for clustering propose and we give some important information of each of them. Our paper organized as follow: in section 2 it's a literature review of papers, in section 3 we give table of discussion of all that systems we reviewed before, then we conclude all work in section 4.

2. Literature Review

The main framework of the approach addressed by [17] consists of three modules, first one is Page Counts based measures, second Snippets and third is taxonomy-based approach. for page count four co-occurrence standard measures are used namely (WebOverlap, WebJaccard, WebPMI and WebDice), after the page count of two words are calculating then checking the context of those two words locally by using snippets based on probability measure to find out the pattern exist between both words. Also, they have used taxonomy-based measure (LEACOCK and CHODOROW (LCH) [18], WU & PALMER (WUP) [19], and RESNIK [20]) that using WordNet for finding and computing similarity between words (X and Y). then for combination the result using tow class of Support vector Machin (SVM and libSVM). The term of dataset used for evaluation, for training propose using MEN dataset [21] Selecting synonymous word pair at random from dataset and create non-synonymous for each one. However, for testing propose using MC approach [22], and RG [23], WordSimilarity-353 (WS) [24]). And using WEKA [25] for testing and training of the SVM with suitable demonstrating approach LibSVM and the qualified prototypical via determining the division ratio is about 70.51%. The results of accuracy were obtained near by 72%.

As explained in [26], the approach in this paper at first finding similarity between tow documents then extend to between two document sets, after that using clustering and classification to group the documents based on similarity measures .the proposed measure of similarity called (similarity measure for text processing) SMTP and the classification algorithm used are KNN based (SL-KNN) single label classification, KNN based (ML-KNN) multi label classification and for clustering algorithm using K-mean Clustering and (HAC) Hierarchical Agglomerative Clustering. The result checks the SMTP similarity measure's effectiveness that applying in text application (SL-KNN, ML-KNN, K-mean and HAC). Also, Compare SMTP performance with other five metrics, Cosine, Euclidean, IT-Sim, Extended Jaccard (EJ) and Pairwise-adaptive (Pairwise) by using different k value and using evaluating measures like (AC (Accuracy), EN (Entropy)). It shows that the similarity measure usefulness may rely on: 1) the format of feature, e.g., tf-idf or word count; 2) application of domains, e.g., image or text; and 3) classification or clustering algorithm. In addition, the term of datasets which are used for evaluating are three different datasets WebKB download from internet, Reuters-8 [27], and RCV1 [28]. Finally, in each case the result show the proposed measure SMTP have better performance.

In [29], the system approach for clustering the text document is an ensemble approach by using concept from Wikipedia. Two kind of clustering used, First approach is Partitional Clustering (lexical document clustering (LDC)) have three main phases are (Clustering term, finding documents lexical seed and Clustering text documents), in phase1 for the clustering purpose the fuzzy c-means algorithm is used to collecting the columns of matrix the (document-term matrix) hence the Fuzzy c-means collect the document-terms into k term clusters then in phase2 extract the documents representative, that are using as seeds in order for clustering all documents later, finally in phase3 based on those document seeds of each cluster term the centroid of document will be computed. Then the distances among the centroids and documents are used for clustering the documents. Second approach is Ensemble clustering ELSDC (Ensemble Lexical-Semantic Document Clustering) the main phases are (clustering term and topic key term selection, lexical seed documents extraction, find documents seeds, tagged and by using the consensus method collecting the documents). In phases 1 and 2, is same as of (LDC) but in phases 3 and 4, BOC and BOW are used for documents representation. The relevant concepts extract from Wikipedia by wikify module. The Naive Bayes classifier is the component of consensus method, by using documents in the same cluster in both clustering they are trained. The final cluster is generated after the remaining document are classified. However, the feature selection Var-TFIDF method are used for both approaches.

The experimental result has two rounds, in first round find comparison between LDA model and lexical document clustering (LDC) algorithm, the LDA's main idea is that the document can be rate as a distribution probabilistic on the underlying themes seen each subject as the terms of probability distribution. The C++ implementation are used for the LDA model; in this round It has been shown that the LDC can generate results similar to the LDA model on some real text data sets based on the representation of the duration document. In second round of experiments, find comparison between LDC and proposed ensemble algorithm (ELSDC). Show the benefits of incorporating Wikipedia concepts into document clustering. For evaluation proposed using Normalized Mutual Information (NMI) hence It measures the amount of information obtained from the categories given to a group of clusters, and has a maximum value of one clustering process when re-create the layers perfectly and the minimum it is zero. Also, for experiment propose eight datasets are used (20Newsgroups (News-sim3, News-rel3 and 20ng-whole), Reuters-21578, Classic4 is created from SMART data repository, WebKB, SMS Spam Collection and Cade is gathered from the content of Brazilian web pages).

As show in [30], extracting document feature and document vectorization to find similarity between Arabic webpages and showing the semantic annotation. The main steps in proposed approach are, in the first step Extraction of main class features using (Arabic VerbNet). The second one is document vectorization according to semantic feature by two solutions (semantic class probability distribution or Semantic class density) and in third step doing clustering and annotation. the model is work as follow the annotated document is take to be classified and all opinion word will be recognized by using semantic feature extraction and all the word will be aggregate to give semantic annotation to the document. The result gathered tow experiments, at the first one is

showing comparison between clustering only using K-mean (standard) and clustering using K-mean with semantic class density however, k-mean with semantic probability distribution and this is done by using evaluation measures (purity, MICD and DBI) hence the purity show that the clustering with vectorization signifies with high score, MICD tend that proposed model is out perform than standard k-mean and DBI show that proposed model appear to have smaller value than standard is mean that is better performance. The Runtime of standard k-mean is longer than the time consumed for tow solutions k-mean with vectorization. The second experiment showing annotation by using Mean score among cluster with both vectorization solution and Mean ratio among corpus (MRAC) also with two solution of vectorization. However, the datasets used for evaluation propose are collected corpus from the archives of online Arabic newspaper and VerbNet download from internet.

In [31], the approach of semantic clustering the text documents by using lexical chain and WordNet. The proposed approach in this paper are work as follow, at first the polysemy and synonymy are two main problem that effect the representation of text, this problem is solve by using WordNet based on Word sense disambiguation, after that introducing the lexical chain to capture the main theme of text and find the relationship between the word sense, then is show that the method can find a true number of clustering which is useful for finding the number of k that use in K-mean clustering algorithm. Finally, for experimental propose the paper show the comparison between all three (Base, DC, DCS) and with another system like ASG03 [32], LMJ10 [33] and CSF11 [34], hence Base is mean (all nouns) the system use all basic preprocessing techniques, i.e. term set extraction, stop words removing, stemming word and identification of nouns from term set but without performing WSD. However, DC is (disambiguated concepts) corresponding to the Base, but with preforming WSD and finally DCS (disambiguated core semantics) also corresponding to the DC, but adds the core semantics extraction process and is the proposed method.

In addition, in this paper for evaluation propose using Reuters-21578 corpus dataset and the evaluation measure using purity, entropy and F1-measure. Finally, the result show that in all experimental scheme the LMJ10 is the worst and the term of dimensionality reduction the feature account that derived from ASGO3 is lower than the number of base and the reduction of DSC is between 10% and 40% hence that the CSF11 greater than 74%, as well as the cluster quality obtained using the core semantic feature is better than using all nouns and using disambiguated concept (or at least comparable to) however the performance of using the disambiguation concepts is better than using all nouns, This suggests that the proposed disambiguation standard can solve the problem in a highly commendable and volatile manner, improve quality to a certain extent, and that the features of the semantic strings produced by the DCS approach do not only reduce the number of semantic concepts without losing much information, also adequately the main topic of the document that helps the clustering.

As [9], the model of clustering proposed in this paper incorporate Coreference resolution and exploit semantic relationship among the words by tackling polysemy and synonymy problem using WordNet and semantic similarity. The proposed approach consists of five modules are (Coreference Resolution, Preprocessing, Synonymy Identification and Sense disambiguation, Feature Selection and Bisecting k-means) modules. the purpose of those five model are, at first Coreference Resolution is the process of identifying Coreference words that occur in the document, then the propose of preprocessing model to transform the document in more suitable form and this is done in three steps (POS tagging ,Stop word Elimination and stemming),after that Sense Disambiguation and Synonym Identification deal with polysemy and synonymy problem in document and the model use WordNet for this propose, then the feature selection done by weighing the words in document using tf-idf, finally the documents are clustered by using Bisecting K-mean. For experimental propose the paper using four classic Datasets (CACM are 60 Documents, CISI are 44 Documents, CRAN are 44 Documents, and MED consists of 52 Documents) and for evaluating the quality of cluster using purity. The result show comparison between Base and proposed model hence the Base is the model without (the Coreference resolution, sense disambiguation and pruning term), after comparison the term of purity result show that the proposed model is observed that achieve 30% of improvement in clustering purity, that the purity rate of Base configuration is 0.55 hence the proposed model is 0.8.

As [35], Based on style Similarity and structure Clustering Web Pages, the model which used in this paper is DOM (Document Object Model) tree. The approach using two main measures, one of them for structural similarity to find similarity on DOM using TED (Tree Edit Distance) for HTML pages and another one using (Jaccard similarity measure) for CSS which called Stylistic similarity on style sheet information, after that based on those similarity measures using (Near neighbor clustering technique) for clustering propose, however to combine this information using Jarvis and Patrick method (shared nearest neighbors) [36]. It is a respectable feature aimed at aggregating Internet pages built for pairs similarity metrics. For evaluating propose using different threshold value of near neighbor at first using 90% edge for resemblance toward luxury near neighbors' pamphlets and 90% threshold for communal close towards combine clustering then altered the threshold to 95% until found the optimal threshold. The result show that when the threshold was 90% total number cluster was 12, and when it was 95% the total was 24 cluster as well as when it was 85 the total number of clusters was only 5, so after few trails they found that for test dataset the optimal threshold for both resemblances and intersection for communal close parties was near by 85%. As it declares that the result is positive as early evaluation.

As [37], the approach based on Hierarchical agglomerative clustering method (HAC) that is based of conceptual annotation of documents. The key steps of approach are: (1) pairwise calculation of the initial similarity matrix (2) Explanation of newly cluster and updating the matrix of similarity (3) post processing of HAC tree result. The approach chooses to rely on Lin Measure for pairwise similarity and on Base Match Average (BMA) for GroupWise semantic similarity, the proposed method uses GroupWise semantic similarity to compute the pairwise similarities between document for creating the label-base similarities matrix. When two clusters are agglomerative a new cluster are creating then automatically compute the annotation for this new cluster and then the label-based matrix are iteratively update, finally using

postprocessing of the tree hierarchy to take the branch lengths advantage in the tree to only keep the most meaningful cluster. For evaluation propose using (HSC heavy semantic clustering and LSC light semantic clustering) approaches for comparison with baseline (classical HAC with naive cluster annotation) by using Normalized Robinson-Foulds Distance measure hence the lower the distance the higher resemblance. The result after comparison between approaches (HSC, LSC and baseline) the HSC and LSC clearly outperform the baseline but for runtime the baseline was faster. then it shows the comparison of approaches (LSC, Baseline) with postprocessing and without post processing (pp and nopp) show that both are bad without postprocessing, finally it evaluating cluster labeling between our clustering labeling (CL), naive merge annotation (baseline) and expert also, the result show CL is better. And the dataset which used for evaluating propose was derived from WordNet-based disambiguation version of the aforementioned bookmark annotation [38] however, all resources and result of this paper are available at [39].

As [40], the approach for semantic document clustering based on the graph similarity. Graph is mainly used information from WordNet to the degree of semantic similarity between 150,000 of the most common in English terminology. The proposed approach at first Adds all the documents in to the similarity graph, then the distance between a pair of documents is measured by evaluating the paths between them, where a path in the graph can go through several terms that are semantically similar. The idea is to creating a node for each document and connecting this node to the graph, then to find the semantic similarity between the two documents will be measured by calculating the distance between the two nodes, and using three choices for the distance metric: the cosine, linear or logarithmic. Finally, for clustering propose using K-mean algorithm to cluster a set of documents and the algorithm relies on a way for computing the distance between two documents. The term of experimental result, the dataset of documents from Reuters-21578 benchmark and using F-measure for evaluating. The end of evaluating after applying the K-mean algorithm in three different distance metrics (cosine, linear and logarithmic) at first the result show that Using the similarity graph can lead to both higher precision and recall. And with Noting that using the linear or logarithmic similarity metric did not make a difference. The reason is that the two metrics apply different monotonic functions on the average of the sum of the forward and backward paths. Applying these monotonic functions has no effect on the ordering of the distances between nodes and on the clustering result.

In [41] paper the approach named (An Ontology-based and Domain Specific Clustering Methodology for Financial Documents). The main steps in approach are (preprocessing and feature extraction, sense word disambiguation, representation document and clustering). The approach works as follow: at step1 the preprocessing and data extraction is responsible to extract text from document in order to transform word in to more meaningful form and this is done in three steps (Stop Word Removal, Noun Extraction and Lemmatization). In step2 word sense disambiguation the correct sense for the noun are identified and this is done by using (WordNet ontology/database and an information content file) and in this study two disambiguation techniques are used which used different external information to remove ambiguity, used one technique (Brown Content File) which is the default for measuring Resnik and other technical used (file content financial information) that is proposed in this study. In step3 the document representation the features are represented as term frequency (TF or tf) vector to be prepare for clustering. Then, in step4 clustering is the final step which clusters the document vector by using algorithm and in this approach two kind of algorithms are studies (K-mean and sequential Information Bottleneck).

The dataset which used in this study was downloaded from EMMA [42] online repository using 446 documents, EMMA documents are classified under the US jurisdiction and their sectors or purposes and have achieved three types of labeling settings according to the categories provided by EMMA (setting1: purpose at the same time called sector as the class label, setting2: class label as state and setting3: class label as mixing of both state and sector). Then for evaluating propose in this study using purity for external evaluation to evaluate the cluster performance. The result showing the purity rate of both algorithm K-mean and sIB based on three settings also showing comparison as follow: 1) comparison between all term and noun only, Although the names are selected, the number of features is reduced significantly, the purity values of both algorithms do not have a considerable difference; 2) comparison between tf-idf of nouns and without tf-idf, it shows that with tf-idf better purity; 3) comparison between no disambiguation and with disambiguation, both methods of disambiguation have yielded good results, but the finest result produced with one the used financial information content file. Moreover, based on experimental results, the sIB algorithm can be determined as the most appropriate algorithm for aggregation.

As explained in [43], The system called WMDC (Wikipedia matching document classification) several steps are used in this approach. First, select knowledge and concept from Wikipedia. Second, using heuristic selection to pick up related concept. Third, finding similarity between document using combination of (Semantic similarity based on Wikipedia machine and Textual similarity based on keywords matching), and choosing K-mean algorithm for classification in this approach because of its efficiency and accuracy. Also, the evaluation experiment in this paper are divided in to two part. First part, focus on effectiveness of heuristic selection Rules, hence three rules are used to pick up the related concept of word (Rule1: all title, Rule2: all keyword and Rule3: any keyword) for evaluating efficiency of those three rules using selectivity measure and evaluating quality by using relevance. Second part, evaluating the effectiveness of approach.

Using Purity for measuring the accuracy of document classification and for evaluating the efficiency of approach using (vector construction time). The datasets used in this paper are Wikipedia dataset which download directly from internet and published in 2011-10-7, and document dataset from Reuters-21578 divided in to 82 cluster by removing those cluster with documents less than 15 and more than 200 only 30 cluster reminding to enhance the experimental effect. The result in this paper show that after using 4 different thresholds 0,0.5,0.10 and 0.15 for evaluating all rules of heuristic selection given that the smaller rule of selectivity is better efficiency and higher rule of relevance is better quality. then as the overall given that the proposed approach can accurately find out the related concept for a given document. Then the same threshold used for purity and (vector construction time) for evaluating classification accuracy and efficiency it concluded

that the proposed approach can improve the efficiency of language and for the corresponding Wikipedia under the precondition of not compromising the accuracy classification of the document.

As in [44] the system called SEMHYBODC related to (Fuzzy C-Manners). The methodology of clustering works as follow: At first the documents are annotated by "KIM" plugin before clustering. Then the documents are clustered using FPSOFCM (FPSO+FCM) and concept weight is calculated. The term of weight is recalculated through the steps specified in SEMHYBODC algorithm. And the Accuracy of clustering is computed using measures such as cluster purity and compared with various other hybrid approaches. after evaluating by using F-measure and purity the result show that, using swarm intelligence for clustering is not suitable for large dataset because the computational time is more but it give better accuracy in order to solve this problem a hybrid approach combine with algorithms such as PSO and FCM, however the PSO is combine with K-mean it's also leads to optimal solution but the time for computational is still higher, then as finally result the FPSO+FCM it show improvement over another algorithms like K-mean, Fuzzy C-means and Hybrid, It is combined with the ability to search from the globalized and fast algorithm PSO convergence algorithm FCM. It is used as a result of the initial seed FPSO algorithm FCM, which is applied to the purifying with generate concluding outcome. For evaluating propose webpages are collected from internet.

As explain in [45] many methods of clusters are operate based on similarity between documents as well as we explained before in our literature but in this paper the semantic similarity used for clustering the articles. The approach which proposed in this paper are at the first step the semantics of articles based on participating the entities in these articles, build three vectors of representations for each article: One calculates the average vector for all entities, one also with all entities but excluding citations and the other with only citation entities. Once the article vectors are generated, the next step is to identify clusters of articles based on vectorization using (k-mean) Clustering and using the Louvain (Network-based clustering methods) for community detection. For experiments the both clustering methods are using the Astro dataset [46]. At first four solutions of clustering are collected, namely CWTSC5, STS-RG, UMSI0 and ECOOM-BC13 for the pseudo-ground-truth based on adjustF1 that the best K are choosing which gives a highest score of adjustF1 also using adjustedF1 score to evaluate the results of clustering as well from the Louvain method.

The result shows the quality scores of three cluster based on pseudo-ground-truth (no citation, only citation, all entities) and OCLC Louvain then gives the average Adjusted Mutual Information scores (AMI) between current solution and the all four other solutions named, STS-RG, UMSI0, CWTS-C5 and ECOOM-BC13. It indicates that, if citations are used only, the resulting combinations correspond to other solutions of clustering than those if not using citation whose adjusted F1 score is also the lowest. Not surprisingly, the other clustering solutions depend heavily on citation information. So, even if they use different methods of citations, the citation information is still bringing enough agreement between them. Use all entities to represent articles has highest score adjustedF1 and agree with most others. Also, find AMI results among these three solutions and groups based on the Louvain method. Again, the cluster based on citation only agree with the results of Louvain almost as much as using cluster that use all entities. In accordance with these measures, they decided to use all entities as a major choice of characteristics, and to maintain 31 sets as key results for K-Means, which is named OCLC-31.

3. Discussion

The table below show the survey of approaches that using semantic similarity based on clustering. The table give a number of papers each paper has specific method and different tools are used for each of this method as well as provide information of each paper given different options like Measures for similarity and evaluation propose and algorithms for clustering or classification also, provide datasets that used by each paper.

As show in the survey, most of the method using WordNet, the term of WordNet as we mentioned before in introduction is the lexicons of the English language database, as well as in information system the WordNet was used for a number of proposals, for example (information retrieval, word sense disambiguation, text classification automatically, summarization of text automatically, machine translation and also can used for crossword puzzle generation automatically) [47] but one of the WordNet most common application is using to determine the similarity between words as we seen in all that method which are using WordNet the main propose was used for (word sense disambiguation) that deal with polysemy and synonymy problem. However, rather than WordNet there are another tool are used like Wikipedia or Kim Plugging also, there are method based on clustering, similarity graph or even network. Also, most of people using K-mean algorithm for clustering hence it's a must popular clustering algorithm that grouping the documents using a similarity metric that is based on keywords matching, and its useful for huge variables for this reason most of time computationally the k-mean is faster than hierarchical clustering but if keeping (K) small, and another advantage is it can make a tighter cluster [48]. However, many of research using bisecting K-mean because it can deal with large dataset also its very satisfactory quality of clustering with low cost. And another algorithm used as shown in surveys like fuzzy c-mean, HAC, Naïve base classifier, near neighbor, sIB, Louvian method and using PSO with clustering algorithm for optimization propose.

As it can be seen that other measures are used like tf-idf its mean (term frequency-inverse document frequency) it's using as weighting factor the main job is determine how much important the word is to the document in corpus or in group [49], as we seen in survey most of paper used this measure for feature selection. Also, other measures are used like Var-TFIDF, heuristic selection etc. for evaluation and experimental result many types of dataset are used and there are specific measures that using for evaluation purpose most popular one is Purity hence its very simple and primary evaluation measure that using for validation to determine the quality of cluster [50], however there are another one like F-measure, Entropy etc. the main propose are to determine the performance of cluster.

Table 1: Summery of Approaches Using Semantic Similarity Based On Clustering

No.	papers	Date	Method	classification and clustering Algorithm	Evaluation measures	Other Measures	Dataset
1.	L. Sahni, et al. ,[17]	2014	Semantic similarity between words using WordNet	SVM	Training the model by determining a split ratio of about 70.51%.	using 4 co- occurrence measures, probability measure and measures-based approach (LCH, WUP and Resnik)	using MEN dataset for training and 3 Benchmark datasets for testing propose
2.	Y. S. Lin et al. ,[26]	2014	Text classification and clustering	SL-KNN, ML-KNN, k-means and HAC	Accuracy and Entropy in (tf-idf, word count, Z-score)	SMTP proposed measure	Three data sets namely RCV1, WebKB and Reuters-8
3.	S. Nourashrafeddin et al. ,[29]	2014	Document clustering using Wikipedia	fuzzy c-means and Naive Bayes classifier	Normalized Mutual Information (NMI)	Var-TFIDF	using 8 datasets 1-20Newsgroups (News-sim3, News-rel3 and20ng-whole). 2-Reuters-21578. 3- from data repository SMART creating Classic4. 4-WebKaB. 5-SMS Spam Collection 6- Cade from Brazilian web pages content is gathered
4.	H. M. Alghamdi et al ,[30]	2014	Arabic VerbNet	K-Mean	Purity, Mean intra cluster distance (MICD) and Davis Bouldin Index (DBI)	using Mean score among cluster, Mean ratio among corpus (MRAC) for Annotation	Corpus collected from online Arabic newspaper archive
5.	T. Wei et al. ,[31]	2014	Text clustering Using WordNet version 2.0	Bisecting k-mean	Purity, Entropy and F1-measure	Using Lexical chains	Reuters-21578 corpus
6.	S. S. Desai and J. A. Laxminarayana ,[9]	2016	Document clustering Using WordNet	Bisecting K-mean	Purity	Tf-idf for feature selection	using 4 classic Datasets 1-60 Documents from CACM, 2- 44 Documents from CISI, 3-44 Documents from CRAN, 4- 52 Documents from MED
7.	T. Gowda and C. Mattmann ,[35]	2016	Webpage clustering using (DOM)tree	Near Neighbor Clustering technique	using different value of threshold	TED and JS	Dataset from a popular weapons classifieds site
8.	N. Fiorini et al. ,[37]	2016	Semantic clustering using WordNet	HAC	Normalized Robinson-Foulds Distance	lin Measure, BMA, post processing	Derived from WordNet-based disambiguation version
9.	L. Stanchev ,[40]	2016	Document clustering Based on similarity Graph	K-mean	F-measure	cosine, linear, and logarithmic	Reuters-21578 benchmark
10.	C. Kulathunga and D. D. Karunara,[41]	2017	Document Clustering Using WordNet and information content file	K-mean and sIB	Purity	Tf-idf	EMMA
11.	Z. Wu et al. ,[43]	2017	Document clustering Using Wikipedia	K-mean	Selectivity, relevance, purity and vector construction time	Heuristic selection	Wikipedia Dataset published from internet and document dataset from Reuters-21578
12.	J. Avanija et al. ,[44]	2017	Document Clustering using KIM plugging tool	Fuzzy C-mean with PSO and K-mean with PSO	Purity and F-Measure	Tf-idf	Web pages collect from internet
13.	S. Wang and R. Koopman ,[45]	2017	Article clustering based on Network	K-means and Louvain method	F1-measure and adjustedF1	vectoring	Astro dataset

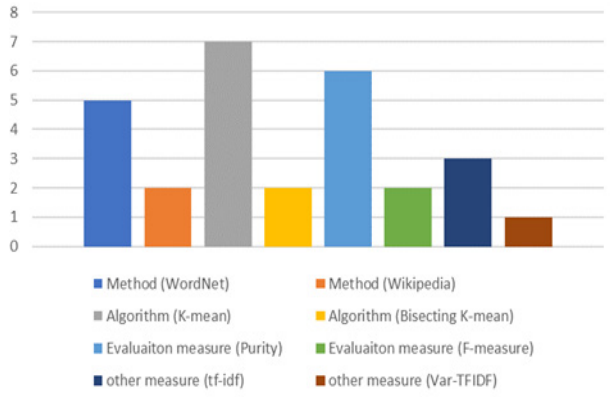

Figure 1: Showing the usage number of main features (Methods, Algorithms and measures).

4. Conclusion

In this paper, after we reviewed all that papers, we conclude that each paper has specific approaches and various tools and measures are available for each approach, and as it can be seen that most popular steps are used in approaches were preprocessing to transform the document in better format and different steps are used in preprocessing like removing stop words, stemming, tokenization etc., word sense disambiguation are used for solving the synonymy and polysemy problems and feature selection another important step that many of approaches was using tf-idf for this case and there was another like Var-TFIDF, heuristic selection etc. however one of the most popular tools used is WordNet the English dataset for meaningful clustering, then clustering done by using clustering algorithms also the most usage one was K-mean algorithm because of its simplicity to use and can give tighter cluster as well as there is another like bisecting K-mean, fuzzy c-mean, hierarchical agglomerative clustering etc. finally, as we see that the main goal of all approaches trying to a chive a better efficiency, accuracy and quality of clustering. after using the experimental measure for evaluating propose like (Purity, F-measure, Entropy etc.) in all case show that the semantic clustering giving a better performance.

ABSTRACT

From the collection of supervised machine learning technique, an ensemble procedure is used in Random Forest. In the arena of Data mining, there is an excellent claim for machine learning techniques. Random Forest has tremendous latent of becoming a widespread technique for forthcoming classifiers as its performance has been found analogous with ensemble techniques bagging and boosting. In the present work we have proposed an algorithm, Aggrandized Random Forest to detect fraud from credit card transactions/ATM transactions with high accuracy considering both balanced and imbalanced dataset, comparatively to the defined classification algorithm Random Forest in Data mining.

1. Introduction

The statistical analysis, machine learning, artificial intelligence, database techniques and pattern recognition concepts have magnified the origin of Data mining. Traditional techniques may be inapt due to enormity of data, high dimensionality of data, heterogeneous and dispersed nature of data. In this era, data mining is prevalent in the field of commerce, trade, science, architecture, education and medication fair to remark a few. The area of data mining applications we come across are the mining of genome sequencing, market exchange, clinical experiments and in the transactions of credit card. With the immense of devices gifted of accumulating data, Big data is now used more widely with the collection of data attractively and cheaply.

Frauds existing in tax return, claims of insurances, usage of cell phones, credit card transactions etc. represent substantial problems for corporate and the government but spotting and foiling fraud is not so modest task. Frauds are claimed to be an adaptive crime, so it desires distinct means of intellectual data mining algorithms which are coming raised in the field of investigation to sense and prevent fraud. These are methods that exist in the areas of machine learning, statistical analysis and knowledge discovery databases. These methods in different zones of fraud crimes do offer appropriate and fruitful solutions.

There are mainly two procedures used for fraud detection statistical performances and artificial intelligence. Fraud supervision is a knowledge-intensive activity. The main AI

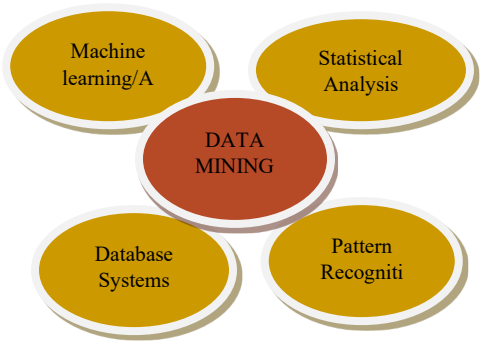

Figure 1. Applications of Data Mining.

Techniques used in the analysis of detecting fraud management include:

- Data mining is the process where facts are classified, clustered and segmented and connotations and

*Jisha.M. V, Nehru Arts and Science College, Thirumalayampalayam, Tamilnadu -641105. Contact No-9745222933 & jisharudhra@gmail.com

instructions in the agreed data are mechanically found that may indicate stimulating patterns, together with those correlated to fraud.

- Expert systems will help to scramble know-how to perceive scam in the way of rules.
- Pattern recognition sense estimated patterns, classes or clusters of mistrustful deeds either routinely or to match assumed inputs.
- Machine learning methods to mechanically find features of frauds.
- Neural networks learn doubtful patterns from samples and used advanced to detect them.

Other techniques such as Bayesian networks, Link analysis, Decision trees and sequence matching are also used for fraud detection.

In field of data mining and knowledge discovery, to handle the problems it is mainly classified into two types supervised learning and un-supervised learning respectively. Supervised learning is further sub-classified depending on the properties of the response variable into classification and regression methods. If the response variable is categorical and discrete, it is classification problems. Otherwise, if the response variable is continuous, it is regression problems. There are different Classification methods for detecting fraud from large data transactions. Selecting Random Forest, Support Vector Machine, Logistic regression and K-Nearest Neighbors [1], our previous work of comparative analysis of these algorithms detected Random Forest to be the best having high accuracy to detect fraud from credit card transactions/ATM card transactions [1].

In this paper, we have given an introduction to Random Forest in section II, description of smote sampling model in section III, about ROSE function in section IV, Theoretical description in section V, proposed algorithm in section VI, followed by Conclusion and References.

2. Introduction to Random Forest

Random Forest can be used to resolve regression as well as classification problems. The dependent attribute or variable is continuous in regression and in classification problems it is categorical. Random Forest is a very influential ensembling machine learning algorithm in which decision tree works as the base classifiers, forming multiple decision trees and then merging the output generated by each of them. Decision tree is a classification model in which it classifies each node with maximum information gain. This search is continued until all the nodes are beat or there is no more information to gain. Decision trees are very modest and informal to know models; however, their predictive power is less, thus called as weak learners [1].

Random Forest works as an ensemble of random trees. It syndicates the yield of multiple random trees and then to originate up with its own output. Random Forest as similar to Decision Tress [1] but will not select all the data points and variables in each of the trees. It arbitrarily assembles data points and variables in each of the tree that it produces and then it is united to arrive at the output at the end. It takes away the prejudice that was encountered in a decision tree model. Also, it improves the predictive power significantly [2].

Random forest stays a tree-based algorithm which take in building several trees (decision trees), were the manipulator generates the number of trees. The elective of all created trees fixes final classifying outcome.

3. Smote Sampling Method

Stereotypically, there are several classification problems that have been anticipated to organize formerly disregarded observations, which will be situated, or recognized set to be tested by application of a classifier is then trained by earlier prearranged observations called training dataset. Numerous typical classifiers are anticipated to deal with this type of snags such as tree-based classifiers, discriminant analysis and logistic regression.

Unbalanced data cause problems in many of the learning algorithms. This is due to irregular quantity of cases that is posed by each class of the problem. Synthetic Minority Over-Sampling Technique algorithm (SMOTE) is used for handling these unbalanced classification problems.

The Smote function can be called as defined, when it discourses the unbalanced problems with the creation of a new smote data set. Alternatively, it returns the ensuing model by routing a classification algorithm on the new data set [3].

Smote (form, data, perc. over = 200, k = 5, perc. under = 200, learner = NULL, ...)

Definition of the arguments-

Form designates the prediction problem. *Data* holds the actual unbalanced dataset. *Perc. Over* is method of over-sampling that finds a figure that initiatives the verdict of how many further cases from the minority class are generated. *Perc. Under* is an under-sampling where among each case made from the minority class, it specifies an amount that initiate the choice of the number of further cases from the majority classes are designated [4,5]. *K* is a quantity signifying the number of adjoining neighbors that is further used to produce the new instances of the minority class. *Learner* is set to Null by default. It acts as a string with a tag of a function that outfits a classification procedure that will be useful in the ensuing smote data set.

The two important constraints that switch the quantity of over-sampling of the minority class and under-sampling of majority class are perc. Over and perc. Under respectively. Perc. Over will approximately a numeral above 100, thereby perc. Over/100 innovative samples of this class are considered for the minority class. If perc. Over value is below 100 then for an arbitrarily selected proportion of the cases, a single case is created and fit into the minority class on the original dataset. The perc. Under constraint panels part of the cases of majority class that erratically selected as the final balanced dataset. With respect to the count of newly engendered minority class cases, the result is obtained [3], [5].

Designed for each existing minority class, ‘n’ new-fangled instances will be formed which is measured by the parameter perc.

Over. The instances will be generated by using the parameter K that holds the count of neighbours [3], [6].

We arrive directly to the classification model from the resulting balanced dataset by using the above-mentioned function [5]. Overall, this function will either return Null value or a new dataset depending on the usage of smote function. If not, the learner parameter will return the classification model [5].

4. Rose: A Package for Binary Imbalanced Dataset

Imbalanced learning signifies the problematic of supervised classification if a class behave erratically over the sample dataset. The Rose, Random Over Sampling Example [7] tackles these problems with its on functions embedded in the package. The class imbalance circumstances are persistent in the multiplicity of applications and fields; this issue had received considerable attention recently [8]. There originate the scarcity of software and procedures clearly meant to handle imbalanced data so to have the non-expert users adopt it. In the R environment, there exist Caret package to validate as well as select classification and regression complications. It highlights the issue of imbalance class as down-sample and up-sample [6][8]. It is worth indicating DMwR (Torgo,2010) which gives an estimation of any classifier, thereby handles imbalanced learning.

The *ROSE* package was motivated to enhance the performance of an imbalanced setting of binary classification providing both standard and more refined tools [7]. Menardi and Torelli at 2014 had developed the smoothed bootstrap-based method. By aiding the phases of model estimation and assessment ROSE [7] relieved the gravity of the effects of an unbalanced distribution of classes.

5. Theoretical Background

5.1. Ensemble Classifiers

An ensemble contains a set of independently trained classifiers whose predictions are combined for categorizing new instances [2].

Bagging [9] and Boosting (Robert E Schapire,2003) are two popular methods for producing ensembles. Bootstrap gathering samples stands for the process called Bagging. As portion of ensemble, if "n" individual classifiers are to be produced from a given original dataset of size "m" then n distinct training set of size m is engendered using sampling. In bagging multiple classifiers created are not dependent on each other. In boosting, from the training dataset each sample is allotted weights. The classifiers generated by boosting is dependent on each other.

5.2 Definition of Random Forest

Random Forest classifier comprise group of tree-structured classifiers $t(x, \Theta_n)$ n=1,2…. , where the Θ_n are self-regulating identical scattered random vectors and every tree casts a unit vote for the most popular class at input x, [2][10].

Once the forest is trained or constructed, each tree give rise to new instance which is recorded as vectors and is joined. The new instance is taken by considering the class having the maximum votes. Nearly one-third of original instances are left, after sampling with replacement of every tree the bootstrap sample set is drawn. The new instances obtained is the out of bag (OOB) data. Out-of-bag error estimation is calculated considering every individual tree's OOB dataset in the forest.

Illustrating Accuracy of Random Forest:

The Generalization error (Pe^*) of Random Forest is Use "(1)",

$$Pe^*=P_{x,y}(mg(X, Y))<0 \quad (1)$$

where mg (X, Y) is margin function. The margin function measures the level to which the average count of votes at the point (x, y) for the exact class surpasses the average votes of any further class. Here x is the predictor vector and y is the classification.

The Margin function is Use "(2)",

$$mg\ (X, Y) =\alpha v_k I(h_k(X)=Y)\ \max j_{=y}\alpha v_k I(h_k(X)=j) \quad (2)$$

Here, I is the indicator function.

Boundary is directly proportional to confidence in the classification.

Benefit of Random Forest is specified in terms of the predictable value of Margin function Use"(3)".

$$B=E_{X,Y}\ (mg\ (X, Y)) \quad (3)$$

A function of mean correlation amongst base classifiers and average strength results in the generalization error of ensemble classifier (Prenger. R, et al,2010). If the mean value of correlation is low an upper bound for generalization error is Use"(4)",

$$Pe^* \leq \rho\ (1- B^2) / B^2 \quad (4)$$

6. Aggrandized Random Forest.

For this work, we have used large dataset of about three lacs of credit card transactions. The classification algorithm is built in the R platform. The proposed algorithm is named Aggrandized Random Forest, which have an increase in its accuracy by 3.06 % for balanced data and an increase of 3.30% for imbalanced data, compared to the previous work as shown in Table.2.

Aggrandized Random Forest is proposed by considering the random forest as the base classifiers with bagging approach and compared with the existing random forest. It is analyzed that Bagged Random Forest gives better results.

Here, we have used the ROSE package of R, to train the imbalanced data set. The functions in ROSE [7,8] have improved the capacity of generalization and reduced the risk conceded by other oversampling methods. As will be expounded, the ROSE technique can be truly considered, which reduces the repetition of instances. In accuracy evaluation step, the overall accuracy may yield misleading results, thus the aggrandized random forest has been evaluated in rapports of class -independent extents such as precision, recall, F-measures etc., as mentioned in the Table.1.

The required library functions in R,

```
library(caret)
library(caTools)
```

library (ROSE)
library (random Forest)

6.1. The Usage of ROSE Function:

ROSE (formula, data, N, subset = options("subset") $subset, seed)

Defining the arguments:

Formula represents the object of class formula where the class label representing the route is allotted with a sequence of routes thru the predictors. The interaction among predictors or their transformations is mentioned by a message. *Data* argument when not specified the variables are taken from environment. It is an optional argument. *N* indicates the anticipated trial proportions of the ensuing dataset. By default, the length of the response variable in formula is considered. *Seed* argument is assigned a single integer value to indicate seeds and preserve the trace of the produced sample [7].

rf.predict1<-predict(rf.model1,newdata = test)
plot(rf.model1) as plotted "As in Fig.2(b)".

6.3. Confusion Matrix.

After the performance of a classifier, we can engender confusion matrix grounded on the prediction results where each column of the matrix represents the instances in a predicted class, while each row represents the instances in an actual class.

The table consists of two rows and columns that gives the count of true positives (TP), false positives (FP), true negatives (TN) and false negatives (FN). The minority class is the positive class and the majority class is the negative class "As in Figure.3".

	Predicted Positive	**Predicted Negative**
Actual Positive	True Positives	False Negatives
Actual Negative	False Positives	True Negatives

Figure 3. Confusion matrix representation.

6.3.1 The Confusion Matrix for The Proposed Algorithm.

Confusion matrix to evaluate OOB error rate "As shown in Figure.4".

Actual class	**Predicted class**		**Class error**
	0	1	
0	97821	648	0.006580751
1	639	98186	0.006465975

Figure 4. OOB estimate of error rate: 0.65%.

6.3.2. Confusion matrix for balanced dataset and imbalanced dataset

The "Figure 5 (a)" represents the confusion matrix for the balanced dataset, and "Figure 5 (b)" represents the confusion matrix for imbalanced dataset, where we could get true positive value, false positive, false negative and true negative value to calculate the parameters precision, recall, f-measure, sensitivity and specificity. Thereafter, the analytical measures are calculated accordingly.

Actual class	Predicted class	
	0	1
0	42468	42
1	201	42732

Figure 5(a). For balanced data.

Actual class	Predicted class	
	0	1
0	85284	31
1	11	117

Figure 5(b). For unbalanced data.

6.4. Analytical Measures Used for Comparing the Proposed and Existing.

There are several factors which is used to the detect the best performance of the algorithm. The presentation of the proposed system is evaluated using the analytical measures such as precision, recall, f-measure etc. [1].

- Precision = TP/(TP+FP)
- Recall = TP/TP+FN)
- F-Measure = 2 *(precision * recall) / (precision + recall)
- Sensitivity= TP/FP
- Specificity=TN/FN

Along with the above-mentioned factors, the other evaluated factors are Accuracy, Kappa, prevalence, detection rate, detection prevalence, P -value, Positive Pred. value, Negative Pred. value, Mcnemar's Test P- Value, AUC etc.

Precision measured by the count of true positives divided by the sum of true positives and false positives.

Recall measures the figure of the true positives divided by the sum of true positives and false negatives.

The *F-Measure* indicates the stability between precision and recall values.

Kappa statistics characterize the range to which the data is collected correctly.

Sensitivity refers to the comparison of the count of acceptably recognized as fraud to the amount incorrectly listed as fraud. It is the ratio of true positives to false positives.

Area Under the Curve (AUC) is used to analyze the performance of classification models capable to predict the classes accurately [11,12].

Detection rate is mainly reflected in confusion matrix. This parameter will vary according to the dataset.
Detection rate=TP/(TP+FP+FN+TN).

Specificity indicates the same concept with genuine transactions, or the assessment of true negatives to false negatives.

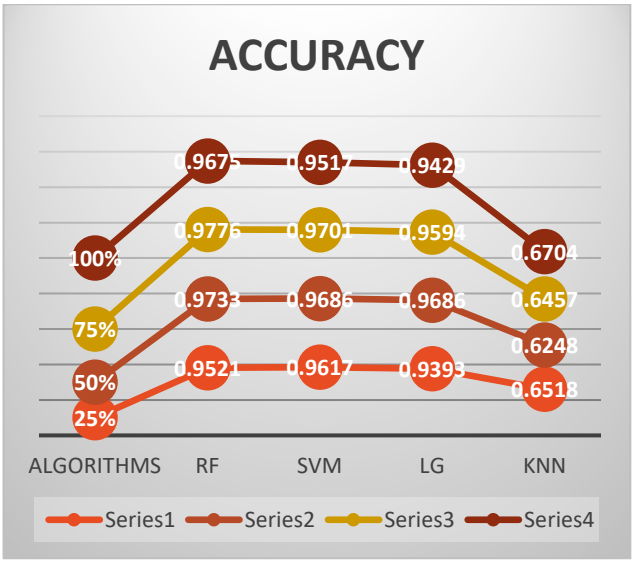

Figure 6. Accuracy of the comparative study of previous work for detecting 100% fraud in the dataset [1].

The previous work was a comparative study of different classification algorithms such as Random Forest [12-15], SVM, K-nearest neighbor and Logistic Regression [1] to detect fraud from credit card transaction. It was found that the Random Forest Algorithm [15] is best in detecting the fraud with an accuracy of 0.9675 "As shown in Figure.6".

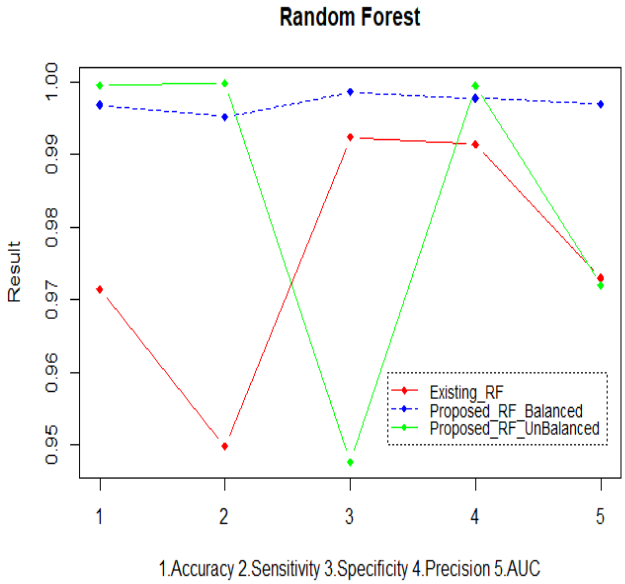

Figure 7. Performance of the proposed Random Forest

Table 1. Comparison of Analytical Measures for the Aggrandized Random Forest Results with Those of the Existing Random Forest.

Factors	Existing Random Forest	For Balanced Dataset	Imbalanced Dataset

The overall performance of the Aggrandized Random Forest with balanced and imbalanced dataset is evaluated with the existing random Forest, and found to have more accuracy, sensitivity, F-measure, precision, etc. The Table 2 gives the improvement of the proposed algorithm.

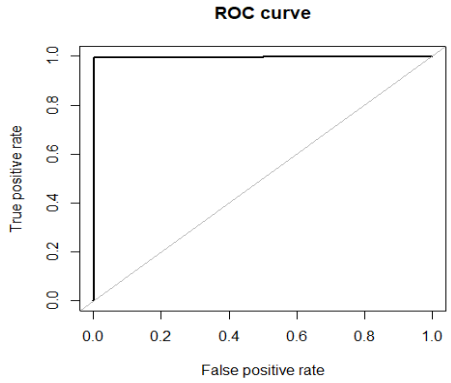

Figure 9(a). ROC of balance dataset.

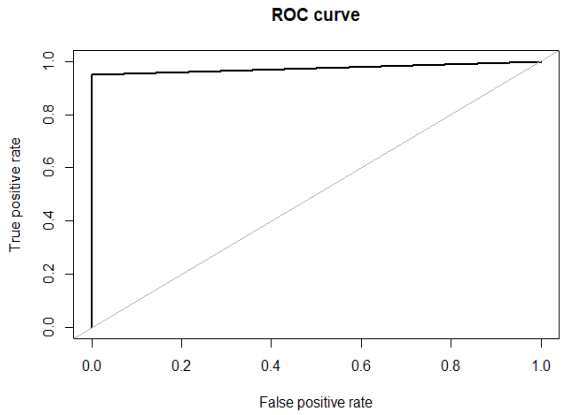

Figure 9(b). ROC of imbalanced dataset.

7. Conclusion

In this paper, our proposed algorithm Aggrandized Random Forest is developed in R platform, having a better accuracy of 0.9972 for balanced and 0.9995 for imbalanced data. The results show that for an imbalanced data, Random Forest outstrips other classification techniques and henceforth stays excessive scope for developing improved Random Forest. Using random forest as a base learner can achieve good outcome in the domain of Imbalanced data.

Panorama

A B S T R A C T

Image stitching is a process of creating a panoramic image by combining multiple images that have overlapping regions of the same scene. It is a challenging topic in image processing, multimedia, and medical applications. The proposed system can be applied in medical applications for scoliosis operations and other long limb operations. The problem of the traditional x-ray machine is the narrow view. So, it can't produce the large view of body x-ray image in a single frame. Therefore, this problem is solved by combining two or more x-ray images into a panorama one. This paper proposes a system which automatically stitches the x-ray images and produced a panorama x-ray image. The proposed stitching method is based on feature based approach, ORB (Oriented FAST and Rotated BRIEF). In feature detection stage, Oriented FAST approach is used. In feature description stage, Rotated BRIEF approach is applied. The two important criterias for determining the stitching performance are stitched image quality and processing time. Therefore, the aim of my proposed system is to produce a panorama x-ray image with high resolution and low processing time based on feature extraction approach. We compared our proposed method with three different features detectors. SIFT, SURF, and Harris corner detectors were tested and measured the rate of correct features detection and computation time. Finally, we measured the quality of result images that produced by stitching system of different feature based methods. According to the experimental results, ORB approach can produce high quality panorama image with least processing time.

1. Introduction

Image mosaicing or stitching is creating a panorama image by stitching or mosaicing many images that have overlapping points of the same view. A panorama is a large view of a scenery. It can be obtained by merging many pictures that have overlapping parts of the same scene. Image stitching is very popular in many applications such as construction of large view map, stitching arial images or satellite images and mosaicing radiography images in medical applications. In medical applications, it is needed to view the whole body x-ray images. The large view of x-ray images helps the surgeons to diagnose a disease for example long leg alignment operation, scoliosis patients etc. The traditional x-ray machine cannot produce large view x-ray image. Therefore, our proposed system can be applied in medical applications to view a panorama x-ray image.

Image stitching methods can be divided into two groups. They are direct method and feature based. Direct based method minimizes pixel to pixel mismatching, pixel based approach [1]. Feature based methods find distinctive features and then matched each other between two input images. The robust detectors can extract important characteristics (for example robust in translation, scale, noise and rotation). There has been great progress in medical images stitching system using features based approach. They are SIFT (Scale Invariant Feature Transform) [2], SURF (Speedup Robust Feature detector) [3], HARRIS detector [4] [5], Principal Component Analysis SIFT (PCA-SIFT) [6], and FAST (Features from Accelerated Segment Test). A good feature detector can be choose depending on the nature of the problem. Two main stages in feature based methods are the registration stage and the stitching stage.

The aim of this paper is to develop high quality image stitching system with low processing time. The proposed system contains five main stages. They are preprocessing, feature detection and

description, feature matching, Homography estimation and images stitching. This paper is an extension of work originally presented in 2018 International Conference on Intelligent Informatics and Biomedical Sciences [7].

The rest of this paper comprise of five parts. Part 2 presents the background of research work. Part 3 contains the briefly reviews of three features detection approaches. In Part 4, the proposed image stitching methodology is discussed. In Part 5, the results of proposed system are explained. Finally, Part 6 discusses the conclusion and the future works.

2. Background

Recently there has been done many researches works in image stitching using feature based approaches. Many researchers tried to develop the feature based methods that can detect reliable and repeatable features than traditional methods. But there still a great challenge in image stitching. There are many features detectors that were used in images stitching such as SIFT, SURF, Harris etc. Harris corners fail in image scaling and SIFT is the longest processing time [8].

According to the literatures, there are mainly two methods for image stitching. They are direct based approach and feature based method. Direct methods calculate the camera parameters by minimizing an error function based on the intensity difference of the overlapped region. Transformation matrix is calculated based on intensity difference. Direct based methods give accurate registration, but they fail in image scaling, illumination change and noise. Compared to feature based method, it requires a good initial estimation to achieve transformation matrix which is a major weak point of this method.

Feature based method detects different features, for example edges, points, corners, lines, or other shapes and calculates the relationship between these features. Compared to direct method, it is strong to light change, scale, affine transformation, noise, and orientation of the image. It takes care of locality around detected features to describe that feature as feature descriptor. In feature based method, all main features in an image pair are compared with that of every feature in other image by using the descriptors [9].

There are many feature detector methods exist that are used in medical images stitching system. Feature based approach is suitable for any movement of scene happened in image because of its robustness. This method is very faster, and it has the capability to identify a panorama image by detecting the neighbor correlation between two images. But, feature based techniques rely on accurate recognition of image features.

By using direct based approach, there had been done researched for medical images stitching. Among them, cross correlation was mostly applied because it can be developed using the FFT (Fast Fourier Transform) for stitching two images of the same size. But the weak point is high in costs [10].

There has been great progress in image stitching using feature based approaches. SIFT, SURF, and Harris detectors were mostly used [11]. Gong was presented an image stitching method. In feature extraction, SURF detector was used. The weak point is that it can't detect correct features in image with noise [4] [5]. Singla presented images stitching using x-ray images by combining SIFT and SURF [12]. RANSAC (Random Sample Consensus) algorithm was used to select the correct features points but high in computation complexity. Adel et al. [13] compared many feature based detectors. They showed that ORB was the fastest in processing time compared with other detectors.

Many researchers have been proposed the medical images stitching using feature based approach, but ORB method has not been applied yet. Therefore, this research work is the first work of biomedical images stitching using ORB feature based approach. The proposed system used ORB method in feature detection and description. The correct features points were chosen by using RANSAC algorithm. Homography matrix was estimated by applying the four feature pairs. As a final, the system mosaiced the two x-ray images together using Homography matrix. In blending stage, weight average method was used to eliminate the seam. The proposed system can be used in medical applications to help for surgeons to diagnose the diseases and to save time.

3. Feature Detection and Description

3.1. SIFT

SIFT (Scale Invariant Feature Transform) is an algorithm for local feature extraction and descriptor representation. The SIFT features are robust in image scale and rotation [3]. In SIFT algorithm, there are three major stages. These stages are key point or interest points detection, orientation assignment, and key point descriptor. Key point detection used difference of Gaussian function (DOG) to detect feature points which are invariant to scale and rotation. In orientation assignment stage, one or more orientations are assigned to each key point. In key point descriptor stage, a vector descriptor is developed for each key point.

3.2. SURF

Bay et al. developed the SURF algorithm [1]. SIFT and SURF algorithms process a little different way in detecting features. SIFT creates an image pyramids and then filters each layer with Gaussians by increasing sigma values and taking the difference. SURF makes a stack without down sampling. By using integral images, SURF filters the stack using a box filter approximation of second order Gaussian partial derivatives. Integral images allow the computation of rectangular box filters in near constant time [6].

3.3. Harris

Harris and Stephens presented a corner detector, which is called Harris detector [14]. This detector is widely used to detect feature points and corners. To find the corners in the input image, Harris method takes look at the average intensity which is directional. The intensity change in the small specific area called window around an interested point. The point where the average intensity strongly high changes as compared to the previous one direction is called as a corner point.

4. Methodology

The proposed methodology of x-ray images stitching is shown in Figure 1. There are five main stages in our proposed system. They are preprocessing, feature extraction and description, feature matching, Homography estimation and images blending. Our

proposed system accepted input x-ray images that have overlapped regions and recognized overlapped areas of the images by extracting the ORB features of those images and stitched them automatically to generate the final large view image. In our proposed system, there are two main components, namely overlapped area searching and stitching the images using the searched overlapped area. By using ORB features, the system can find the overlapped areas of the images efficiently. Moreover, the system can stitch the images to produce the seamless high resolution image with low processing time.

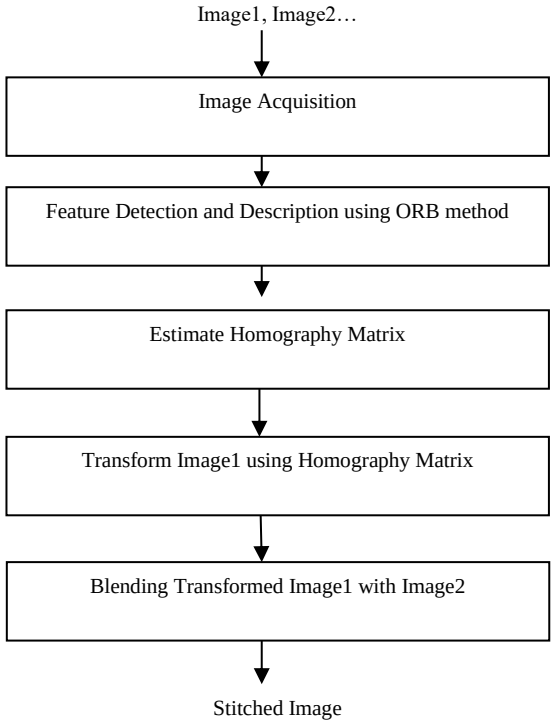

Figure 1. Proposed Images Stitching System Using ORB Feature Based Approach.

4.1. Image Preprocessing

The preprocessing step is an essential step in image processing. First, the original DICOM format is converted into JPEG format to reduce the image size. We used 100 x-ray images with 50 pairs of overlapped images as the input images. It is required about 15-30% of overlapped regions to be stitched. The samples of the input x-ray images are illustrated in Figure 2.

4.2. Features Extraction and Description

Our proposed images stitching system used ORB feature based approach. ORB approach is a combination of Oriented FAST detector and Rotated BRIEF descriptor. Oriented FAST is used to detect feature points and Rotation BRIEF is used to generate descriptors. The speed of FAST and BRIEF are very fast, so ORB has advantages in speed. The good point of this algorithm is fast and having rotational invariance and reducing sensitivity to noise. Figure 3 and Figure 4 show the extracted ORB features of input x-ray images.

4.2.1. Oriented FAST Detector

Both FAST algorithm and BRIEF algorithm do not have scale invariance. FAST detector can detect the features that are translation and rotation invariance, insensitive to noise and high reliability. But the feature points do not have information about direction. Therefore, ORB algorithm uses the Oriented FAST algorithm to detect the feature points which has direction information. Using intensity centroid method, it can calculate the direction of the corner and produce features with direction information.

$$m_{pq} = \sum_{x,y} x^p y^q I(x,y)$$

From Equation 2, we can know the center of gravity or centroid.

$$C = \left(\frac{m_{10}}{m_{00}}, \frac{m_{01}}{m_{00}}\right) \quad (2)$$

The orientation of the vector from corner to center of gravity can be calculated by using Equation 3.

$$\theta = \arctan\ 2(m_{01}, m_{10}) \quad (3)$$

4.2.2. Rotated BRIEF Descriptor

BRIEF produces binary descriptors by binary coding method. The binary descriptor is simple and storage space is smaller than SIFT and SURF.

$$\tau(\mathrm{p};\mathrm{x},\mathrm{y}) = \begin{cases} 1 \text{ if } & \mathrm{p(x)} < \mathrm{p(y)} \\ 0 & \text{otherwise} \end{cases} \quad (4)$$

Where p(x) is the pixel intensity at that point. The feature descriptor is defined as follows:

$$f_n(P) = \sum_{1 \le i \le n} 2^{i-1} \tau(P; Xi, Yi) \quad (5)$$

n BRIEF pairs (a1, b1), ……., (an, bn) can be written as a matrix S as follows:

$$S = \begin{bmatrix} a_1 & \cdots & a_n \\ b_1 & \cdots & b_n \end{bmatrix}$$

A rotated version of $\boldsymbol{S_\theta}$ can be computed by using Equation 6.

$$\boldsymbol{S_\theta = R_\theta S} \quad (6)$$

Where, S_θ is the test position for the binary pixel after rotation. θ is the rotation angle, R_θ is the rotation matrix of the main direction.

4.3. Features Matching

After detecting the ORB features, the next stage is features matching. In this step, hamming distance is applied to find the matched features. The results of features matching stage are shown in Figure 5 and Figure 6.

4.4. Compute Homography Matrix

After features matching, the next stage is Homography estimation. The RANSAC (Random Sample Consensus)

algorithm is used to eliminate the wrong matched features and to compute the Homography matrix. The matching relationship of the images are found by using transformed Homography matrix.

4.4 RANSAC (Random Sample Consensus) Algorithm

RANSAC algorithm has three stages. In the first step, it chooses four random feature pairs. Second, it produces the Homography matrix for those selected feature pairs. In the third stage, it calculates an error measure pairs using Homog (8) matrix.

4.4.1. Homography Estimation from Point Correspondences

For two images that have a correspondence between 4 points, homography matrix can be expressed as below:

$$\begin{bmatrix} x_i' \\ y_i' \\ 1 \end{bmatrix} \cong \begin{bmatrix} a & b & c \\ d & e & f \\ h & i & 1 \end{bmatrix} \begin{bmatrix} x_i \\ y_i \\ 1 \end{bmatrix}$$

It is required 2 linear equations and 8 unknowns for each correspondence. Therefore, it is needed 8 linear equations for 4 correspondences. Two linear equations can be calculated by Equation 7 and 8.

$$ax_i + by_i + c - x_i'(hx_i + ky_i + 1) = 0 \quad (7)$$

$$dx_i + ey_i + f - y_i'(hx_i + ky_i + 1) = 0$$

In these equations, x_i' and y_i' are coordinates of changed stitched image.

(1) (2)

(3) (4)

Figure 2. The example input images that used in our proposed system.

4.5. Images Blending

The final stage of images stitching is images blending. The aim of this step is to adjust the pixels intensity and to eliminate the visible seams. In this stage, the weighted average method is applied. Figure 7 and Figure 8 show the result images of our proposed system.

Figure 7. Final knee stitched image.

5. Results

The proposed system is the automatic images stitching system using medical x-ray images. Our proposed images stitching system is based on feature based approach. In feature detection and description, ORB method was used. The good point of ORB approach is rotation invariant, robust in noise and speed in processing time. We compared our proposed method with three different detectors, SIFT, SURF and Harris. According to the experiments, we can prove that our proposed method is the best in processing time and performance accuracy compared with three features detector methods. We examined the accuracy of our proposed method using 100 x-ray images. Our input samples consist of spine, lower limb and upper limb x-ray images. As the inputs images, our proposed system needs two overlapped x-ray images to be stitched. It is needed about 15-30% of overlapping regions to be stitched. The sample dataset was received from Department of Medicine, Aung Hospital, Lashio in Myanmar. Our proposed system can be used in medical applications such as scoliosis operations. The tested equipment to run for our proposed method is a computer with Core i7 CPU 2GHz and RAM 4GB. Table 1 and 2 describe the comparison of features extraction performance that tested with SIFT, SURF, Harris and ORB. Table 3 shows the comparison of quality measurement of the ORB method and other feature based image stitching methods using MSE and PSNR values. According to this table, images stitching using ORB method has lager PSNR value and smaller MSE value compared with other feature based methods. From experimental results, ORB can detect correct features points with lowest processing time. Therefore, ORB method is suitable for real time applications.

Image Stitching Using SIFT	146.47	26.51	8.012932
Image Stitching Using SURF	186.75	25.91	0.65411
Image Stitching Using Harris	216.31	23.67	0.75314

6. Conclusion and Future Work

In this paper, we proposed automatic images stitching system using feature based approach. In features detection and matching, ORB features were used. The proposed method was tested with 100 x-ray images with 50 overlapping pairs. The main goal of our proposed system is to develop a high quality images stitching system with low processing time. The contribution of our proposed system is that it is the first work of medical images stitching system using ORB approach. The proposed system was compared with other feature based images stitching algorithms, SIFT, SURF and Harris. The final image quality measured between the ORB algorithms and other feature based methods were computed using MSE and PSNR values. Experimental results show that the ORB algorithm can produce high quality seamless image mosaic of medical images with low processing time.

Our proposed method tends to be extended for 3D image stitching, 2D images stitching with moving objects and using hybrid of feature based with direct based approaches to get better results as a future work.

Conflict of Interest

The authors declare no conflict of interest.

Acknowledgment

The authors highly appreciate the Asian University Network (AUN/SEED-Net) for their financial support to contribute this research. Moreover, we also thank ‘Aung’ Hospital, Lashio, Myanmar, for the x-ray images used in this study.

ABSTRACT

An experimental transmission between two XBee modules using Radio over Fiber technique is demonstrated. Data issued from an XBee module coded on a wireless microwave carrier at 2.44GHz is transmitted through an optical link of 25.24 km. The optical transmission is based on an external modulation scheme over a dispersive channel. Frequency response of the external modulation scheme is determined by simulation and experimentally. In particular, the chromatic dispersion of the optical fiber associated to its length allow the generation of a pass-band filter whose bandwidth is used to code the RF signal. The recovered RF signal exhibits a SNR of 27dB. Obtained results allow proposing this RoF scheme as a good contender for data transmission.

1. Introduction

This paper is an extension of the work originally presented at the 15th International Conference on Electrical Engineering, Computing Science and Automatic Control [1]. Now, the main contribution of this extended work resides in the fact that we are describing the mathematical procedure that allows determining the frequency response of the electro-optical system used for the transmission. Besides, the theoretical behavior of the optical communication system is validated by simulations. This work is situated on the field of Radio-over-Fiber (RoF), a technique that allows joining radio frequency and electro-optic methods. RoF emerges as a promising solution to fulfill the capacity and mobility of access networks providing high data rate, high capacity and a mobility proposal to transmit information [2-4]. Given that the transmission of information is via light through optical fibers, it is evident that its inherent advantages are exploited, such as low losses, immunity to electromagnetic interference and especially the huge bandwidth available. Figure 1 shows a basic RoF scheme composed by a RF-to-Optical stage, an optical link and an Optical-to-RF stage. The RF signal modulates the light (either directly or externally). The modulated light travels across the optical channel. Finally, the light is turned into its electrical form where it can be radiated by an antenna providing wireless coverage in zones of difficult connection such as shopping centers and subterraneous places [5].

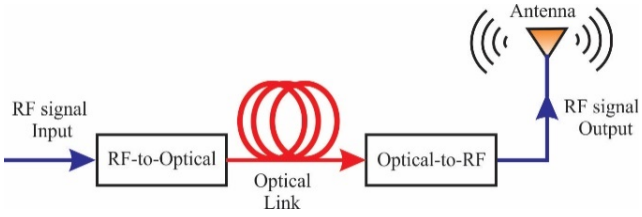

Figure 1. Basic diagram of a RoF system

RoF technology is a candidate that aims to alleviate the bandwidth restrictions for 5G Mobile, delivering wireless data signals via optical fiber channels. [6]. Thus, RoF allows supporting secure, cost-effective coverage as well as excellent capacity mobile-wireless access for oncoming services. Some drawbacks inherent to RoF are due to the distortion and noise derived by the non-linear features of the components employed in the optical network as the optical sources, the chromatic dispersion and photodetectors. For this reason, to mitigate sources of noise and

*Ignacio Enrique Zaldívar Huerta , Luis Enrique Erro #1, Sta. María Tonantzintla, Puebla, México, zaldivar@inaoep.mx

misstatement, intensity-modulation-direct-detection is advisable [7]. In this regard, we propose and experimentally demonstrate a RoF scheme using an optical communication system in the modality of external modulation for the transmission and distribution of a RF-signal. Furthermore, it is demonstrated that the chromatic dispersion (considered as a drawback in this type of systems), is used in an advantageous manner to the generation of notch filters. On the other side, it is known that an XBee is an electronic device whose operation is based on the network transport protocol IEEE 802.15.4, it is able to generate wireless paths to establish communication between devices (http://xbee.cl/que-es-xbee, https://www.digi.com/products/xbee-rf-solutions/xctu-software/xctu). In this sense, XBee modules that use the ZigBee protocol find applications in RoF networks [8, 9]. In this experimental proposal, a wireless signal delivered by an XBee module is used as test signal. A baseband modulation Gaussian Frequency Shift Keying (GFSK) signal at 2.44GHZ is generated by an XBee. This electrical signal modulates an intensity electro-optic modulator. This work is structured as follows. In Section 2, is given the principle of operation of the optical communication system at external modulation and also numerical simulations are presented. In Section 3, experimental set-up of the RoF is described. At the end, a short conclusion is given in Section 4.

2. Principle of Operation

Figure 2 depicts the block diagram the optical communication system in the modality of external modulation used in this work. Basically, it is constituted by a single-mode laser diode as optical source, a Mach Zhender-Intensity Modulator (MZ-IM), a Single Mode-Standard Fiber (SM-SF), as well as a Photodiode (PD).

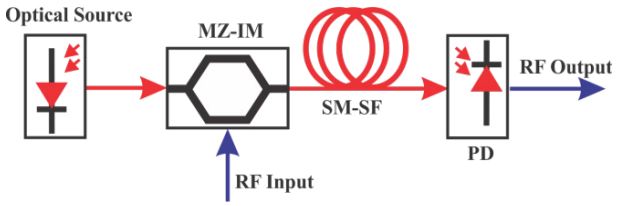

Figure 2. Block diagram of the model used

In the following, a full mathematical analysis explaining the behavior of the model is given. In order to exploit the chromatic dispersion exhibited by the SM-SF, it is necessary to assume that the single-mode laser diode emits at 1550nm. It is demonstrated that the chromatic dispersion (D) and the length (L) of the optical link play an important role that allow the system to act as photonic notch filter.

Mathematically, the optical spectrum of a single-mode laser diode (for example a DFB) can be modeled by a Gaussian envelope centered at an angular frequency ω_0 as [10]

$$S_0(\omega-\omega_0)=\frac{2S_{max}}{\Delta_\omega\sqrt{\pi}}exp\left(\frac{-4(\omega-\omega_0)^2}{\Delta_\omega^2}\right) \quad (1)$$

where S_{max} is the maximum power emission and Δ_ω is the Full Width at Half Maximum of the spectrum that can be expressed in terms of $\Delta\lambda$. Eq. (1) can be simplified, defining $a=4/\Delta_\omega^2$ and $W=\omega-\omega_0$, resulting in

$$S_0(W)=\sqrt{\frac{a}{\pi}}S_{max}exp(-aW^2) \quad (2)$$

The Fourier Transform (FT) of Eq. (2) is the spectral density of the optical source, thus

$$\{S_0(W)\}=\int_0^\infty S_0(W)exp(-j2\pi ZW)dW \quad (3)$$

Defining $Z=v_m\beta_2L$, and expressing the propagation constant $\beta_2=-D\frac{\lambda^2}{2\pi c}$, defining $\omega_m=2\pi v_m$, and $dW=d\omega$, then

$$\mathcal{F}\{S_0(W)\}=\int_{-\infty}^{\infty}\sqrt{\frac{a}{\pi}}S_{max}exp(-aW^2)\,exp(-j2\pi ZW)dW \quad (4)$$

Equation (4) is solved considering that the FT of a Gaussian function $f(t)=exp(-at^2)$ is [11]

$$\mathcal{F}[exp(-at^2)]=\sqrt{\frac{\pi}{a}}exp\left(-\frac{\omega^2}{4a}\right) \quad (5)$$

Rewriting Eq. (4) and considering a, and Z we find

$$\mathcal{F}\{S_0(W)\}=S_{max}exp\left(-\frac{(\pi v_m\beta_2L\Delta_\omega)^2}{4}\right) \quad (6)$$

When $S_0(W)$ is narrow, the frequency response of the system is

$$H(v_m)=cos\left(\frac{\pi v_m^2\lambda^2DL}{c}\right) \quad (7)$$

The squared of the modulation frequency v_m^2 makes the system behave like a non-periodic notch filter.

The notch frequencies f_i, for which Eq. (7) becomes zero, are determined by

$$f_i=\frac{1}{\lambda}\sqrt{\frac{1}{2}\frac{(2i-1)c}{DL}} \quad (8)$$

where λ is the central wavelength in nm, D is in ps/nm·km, c is speed of light in nm/s, and L is the length of the optical link in km.

Equation (7) is numerically evaluated by using MATLAB for the frequency range 0-25GHz, considering: λ=1550nm, c=2.9979x10^{17}nm/seg, L=25.24km, D=15.81ps/nm·km.

Moreover, substituting λ, c, L, and D in Eq. (8), the first and second notch frequency values are f_1=12.50GHz and f_2=21.65GHz, respectively.

Figure 3 shows the result of this numerical evaluation. The result of this evaluation is corroborated by a block level simulation using VPIphotonics software® (http://www.vpiphotonics.com/index.php), and plotted on the same graph. This software is provided with a full library of electro-optics components whose properties can be easily manipulated, therefore, the degree of reliability for the results is high.

From this graph, it is clearly appreciable that the separation between consecutive notches is not constant and decreases as the frequency increases. The bandwidth at -3dB for the low-pass band and for the first lobe (band-pass) are in the order of GHz. The common point between both curves is their tendency. Note that both curves converge to the values of 12.50GHz and 21.65GHz

as stablished by Eq. (8). The justification to use 25km is because the current transmission lengths are designed to meet 20 km, as is determined by an international standard [12].

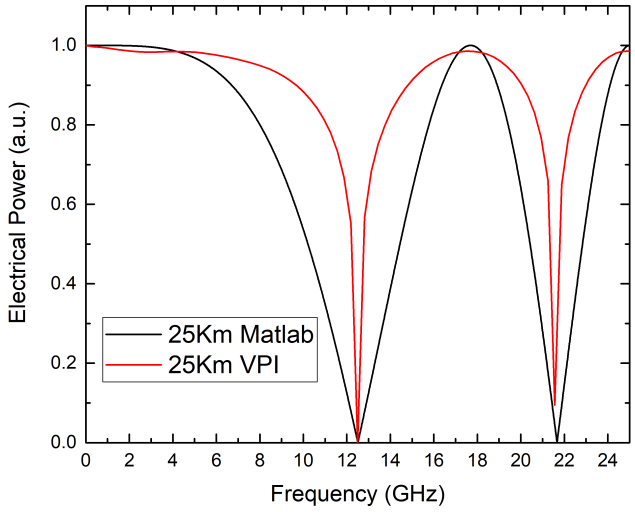

Figure 3. Simulated frequency response using MATLAB and VPI photonics software.

3. Experimental Results

Initially, a test communication between two XBee devices is carried out. Later, a characterization of the optical communication system is done. Finally, the performance of the system composed by a couple of XBee modules over a RoF link is accomplished.

3.1 Test of the XBee devices

XBee is a trademark of radio devices capable of supporting communication protocols as ZigBee, 802.15.4, and Wi-Fi, among others [9]. Figure 4 depicts an XBee network. One module plays the role of Coordinator whereas the other of an End Device.

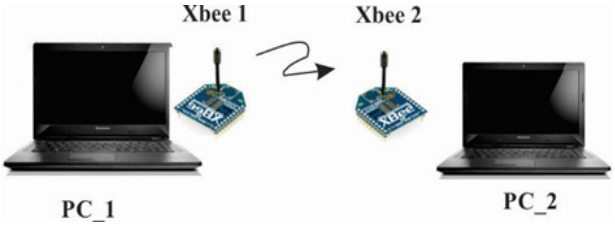

Figure 4. Network generated by using two XBee modules.

The Coordinator handles out addresses and manages the network The End Device is responsible for joining existing networks, transmitting and receiving information. In this work, two XBee modules (XBee-PRO model ZNet 2.5 OEM, indoor range 100m, operating frequency 2.4GHz, transmit power output 18dBm) are used. Both devices are provided with an omnidirectional antenna (Gain 2.15dBi, frequency range from 2.4 to 2.4835GHz) and an USB adapter (Sparkfun XBee Explorer Dongle) that allows the connection via serial communication. The communication between these devices is achieved by using the platform XCTU. Figure 5 shows this interface (https://www.digi.com/products/xbee-rf-solutions/xctu-software/xctu). Data to be transmitted by PC_1 (Coordinator) are coded at the frequency of 2.44GHz and then radiated via an antenna and decoded by PC_2 (End Device).

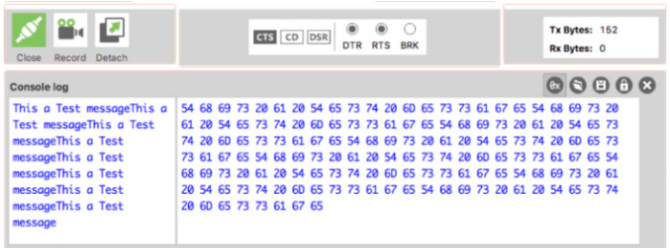

Figure 5. Screenshot showing the interface to control the Coordinator.

Figure 6 shows the spectrum of the emitted radio frequency signal at 2.44GHz measured by an Electrical Signal Analyzer (ESA) exhibiting a SNR value of 55dB. The baseband data is coded within the side lobes.

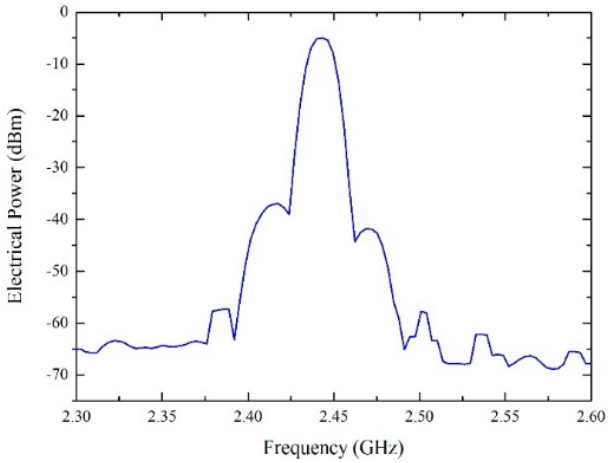

Figure 6. Electrical spectrum corresponding to the Coordinator

3.2 Experimental Frequency Response

Figure 7 illustrates the experimental bench used in this work. It is well known that the use of multimode optical fibers is reserved for short distances, such as in local area networks. Because, we are interested to emulate a FTTH-PON, whose typical length is in the order of 20km [12], thus the use of single-mode optical fiber is mandatory, due to its characteristics of extremely low-losses. Furthermore, most of commercial electro-optical devices (optical sources, optical modulators, photodetectors, etc.) operating at the commercial wavelengths of 1300 and 1550 nm, are supplied with this type of fiber. From the comments above described, SM-SF is used in this experiment. In the next sub-section, a detailed description of the optical communication system is given.

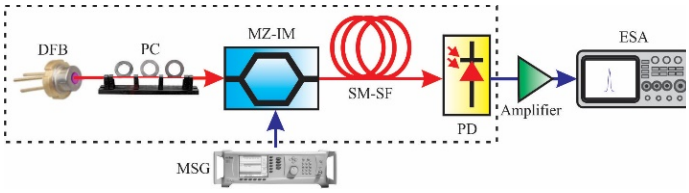

Figure 7. Optical communication system externally modulated

First, the optical spectrum of a DFB (NX8508-55, Side Mode Suppression Ratio SMSR=40dB, linewidth 0.1nm) is recorded by means of an Optical Spectrum Analyzer. According to the datasheet, this optical source has its own internal optical isolator to avoid reflections, therefore a good optical stability is guaranteed. Figure 8 shows the optical spectrum for an operation current of

20mA exhibiting a central wavelength λ_0=1553.5nm. The shape of the optical spectrum corresponds to Eq. (1).

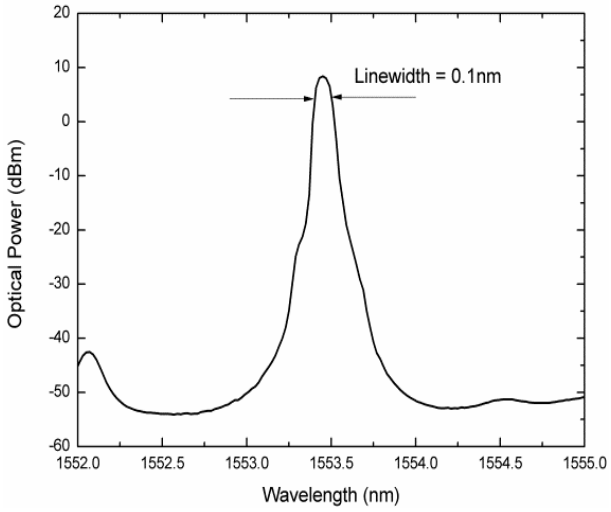

Figure 8. Optical spectrum of the DFB laser source used

Once the characteristics of the optical source are known, the light generated by the DFB is modulated via the electro-optic MZ-IM (insertion loss of 2.7dB, BW-20GHz, operating wavelength 1530-1580 nm, Vπ=7.5 V). The Polarization Controller (PC) device allows optimizing the optical power level at the output of the modulator. The RF signal used to modulate the light is provided by a Microwave Signal Generator (MSG) through a sweep in frequency range of 0.01-13 GHz at a power of 0 dBm. The modulated beam is injected to a reel of SM-SF (D=15.81ps/nm·km @ 1550nm, α=0.22dB/km, L=25.24 km). The light that emerges of the optical fiber is turned to its corresponding electrical signal by the PD (Miteq, BW-13GHz, Responsivity=0.9Amp/Watt). This signal is submitted to a process of amplification (Minicircuits, ZVA-183-S+ Ultra-Wideband Amplifier, 0.7-18GHz, Gain 26dB) and finally visualized in the screen of the ESA. Figure 9 corresponds to the measured frequency response where the simulation curves have been superimposed. Since the frequency emitted by the XBee Module is at 2.44GHz, the low-pass band will be used to code the transmission of the RF signal.

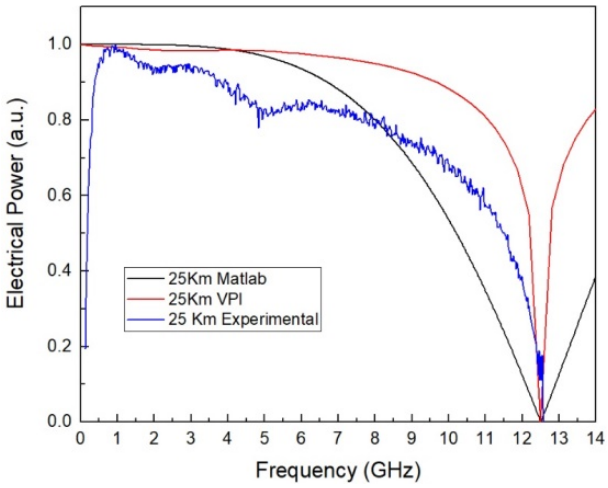

Figure 9. Comparison between simulated and experimental results

From this graph, it is noticeable that the response is restricted by the BW of the PD.

3.3 *Experimental RoF Transmission*

Figure 10 shows the test bench for carry out the transmission of the signal issued from the XBee module. The main difference to the scheme shown in Fig. 7 is that now the MSG is replaced by the coordinator module connected to PC_1 generating the information to be sent (an electrical signal at 2.44GHz at -6dBm) that is emitted from Antenna 1. Antenna 2 receives this signal which is amplified and launched to the RF port of the MZ-IM to modulate the optical signal. The modulated light is injected to the SM-SF. At the end of the link, the modulated light is converted into electric signal by the PD. Subsequently, amplified and separated by a power divider. A percentage of the recovered signal is evaluated by the ESA and the remainder is connected to the Antenna 3 where is emitted. An anechoic chamber is used to guarantee isolation between the signals emitted by antennas 1 and 3. Lastly, antenna 4 captures the signal to be handled by the second XBee module coupled to computer number 2 (PC 2), recovering in this manner the original transmitted message. Figure 11 corresponds to the measured electrical spectrum corresponding to the recovered signal with a SNR of 27dB.

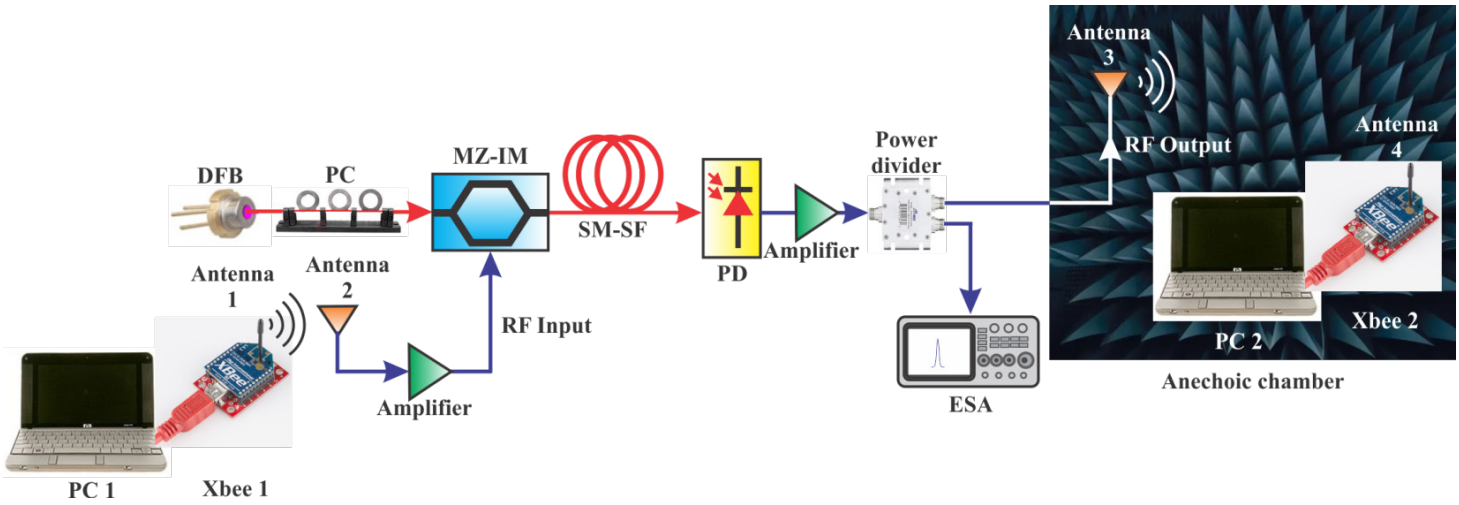

Figure 10. Experimental scheme assembled to test the RoF XBee transmission system

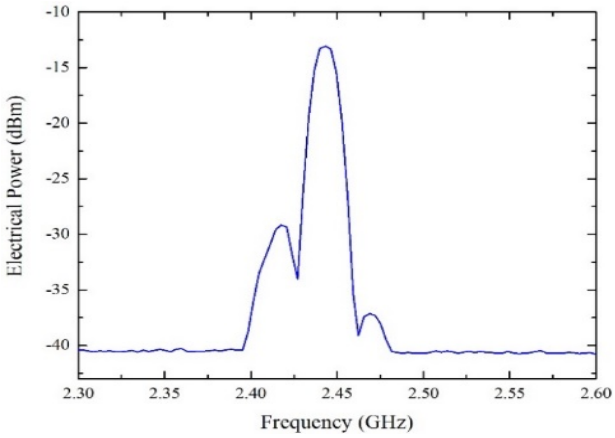

Figure 11. Recovered spectrum corresponding to the output of the system

4. Conclusion

In this work, we have experimentally demonstrated an efficient communication between two XBee modules using the RoF technique. The optical transmission was carried out by using an external modulation scheme. A full mathematical analysis explaining the principle of operation of an optical communication system was given. The relationship that allows determining the frequency response of the optical communication system was evaluated by a numerical simulation achieved in Matlab. Later, a block level simulation of the optical system was carried out by using VPIphotonics software corroborating the previous results. One thing to keep in mind is that the usage of an optical source whose central wavelength is 1310nm associated with SMSF allows the cancellation of the chromatic dispersion effect [12]. However, in this work, we have used a DFB laser whose central wavelength is around 1550nm and SM-SF; thus, the chromatic dispersion value was considerable. This effect, as well as, the length of the optical link has an important role to determine the electrical bandwidth of the system as it was evident in Eq. (7) and Eq. (8). The frequency response was composed by a low-pass band as well as a series of bandpass or notches. In particular, the first lobe was used for the transmission of a wireless signal of 2.44GHz issued by the XBee module. Optical transmission was successfully achieved through an optical link of 25.24Km. The recovered RF signal exhibits a SNR of 27dB. Considering that the electrical bandwidth can be tailored in function of the length of the optical link, it is possible to assure the possibility to accommodate future services distributed by means of RoF schemes using a larger bandwidth. Furthermore, another interesting feature of this RoF system is that, at the end of the link, data can be distributed by antennas to several customers. Direct and external modulation can be used to implement a D-RoF system in our case we have opted for external modulation using a Mach Zehnder modulator (MZM) to modulate a DFB laser in order to generate a simpler configuration [13]. As future work, we propose the use of a VCSEL as optical source in order to benefit of its properties as threshold currents of very few mA and facilitate the coupling with optical fibers [14].

ABSTRACT

Agriculture, being the vital sector, contributes to India's GDP by 18%. It is necessary to enhance the production in this sector with minimal need of resources to get the good yield of crops. It in turn boosts up the necessity of automation in the field of agriculture. This paper discusses about the experimental study which includes the invasive/non-invasive method to sense the approximate supply of macro nutrients such as Nitrogen, Phosphorous & Potassium to the plants. The nutrient content of leaf is sensed by the usage of optical sensors. The results have been obtained based on the sensor data carried out for the sample test leaf. Thus, the level of the estimated nutrient contents is indicated by three different ranges such as Low (L), Medium (M) and High (H). A mathematical model is developed for nutrient measurement especially for nitrogen and validated with SPAD meters for the measurement of nitrogen content. The other macro nutrients were also estimated, and the entire system is tested at different test conditions with the support of UASD in the field of University of Agricultural Science.

1. Introduction

As there is an increase in population and the per capital income, the demand for crop yield is drastically increasing with the advancement in technological growth. It is necessary to identify the severe problems involved in crop yield and address the challenges [1]. Even though there is much advancement in the field of science and technology still farmers across the country adopt the traditional practices. The availability of the resources in the process of farming is one of the most important aspects in eco-system. In addition to this nutrient are very important resources for the plants that give structure to the leaf. Since the population growth of the nation is getting enhanced, this creates a necessity to increase the food production. Supplying the appropriate amount of fertilizers and water becomes evident in enhancing the plantation yield as a whole. The basic nutrients provided to the plants are Nitrogen (N), Phosphate (P), and Potassium (K) in the ratio of 4:2:1. On the other hand due to the lack of awareness and quick measurement techniques, the farmers oversupply nutrients and water to plants, leading to destruction of the crops. Especially the excessive supply of nitrogen nutrient to the crops causes the chemical to evaporate and create oxides of nitrogen (NOx) mainly nitric oxide and nitrogen dioxide into the atmosphere. The formed NOX contributes to the formation of smog and acid rain, affecting ozone layer resulting to global warming. Hence there is a necessity for efficient use of nitrogen broadly known as Nitrogen Use Efficiency (NUE).

The fertilizers should be supplied in appropriate manner so that good number of crops can be obtained without any defects. The exact amount of fertilizers will be supplied based on the type of crop, its growth status and the quality of fertilizers or soil. The growth of the plant depends upon absorption and consumption of the nutrients. One of the major challenges in agriculture in order to get the optimized plant yield is reducing the amount of water consumption and fertilizers [2]. Different nutrients are available in the market for plantations. They are scattered to the plantation area for better crop output. Nitrogen related chemicals are distributed in abundant volume as they play an active role in managing an edulcorated premises in the field. Also, potassium and phosphorous aids in plant growth. The growth stage of the plant can be managed in a better way by maintaining proper supply of these nutrients. But many times, unnecessary supply or inadequate supplies of nutrients are evident in all field area leading to environmental hazards and wastage of crop yield. In association with the technology, a smart way has to be established to accurately measure the nutrient content and supply concrete chunk of fertilizers.

*Shraddha Balayya Hiremath, Email: shraddha_h@bvb.edu

The conventional methods of Chlorophyll and Nitrogen analysis require the destruction of the leaf sample. It is also time-consuming and expensive process. The above techniques cannot satisfy the requirements of precision farming. Non-destructive optical techniques based on absorbance and reflectance of light by leaves have been proven as alternative time-saving and simple techniques to quantify Chl in a number of agricultural species such as birch (*Betula pendula Roth.*)[3], [4], wheat (*Triticum aestivum L.*)[5] and potato (Solanum tuberosum L.), maize (*Zea mays L.*)[6] and soybeans (*Glycine max L. Merrill*.), sorghum (*Sorghum bicolor L. Moench*.) and pigeonpea (*Cajanus cajan L. Millsp*.). Strong relationship between CCI and nitrogen was also reported in sugar maple (*Acer saccharum Morsh*.) (Van den Berg and Perkins2004) [7], [8], and rice (*Oryza sativa L*).

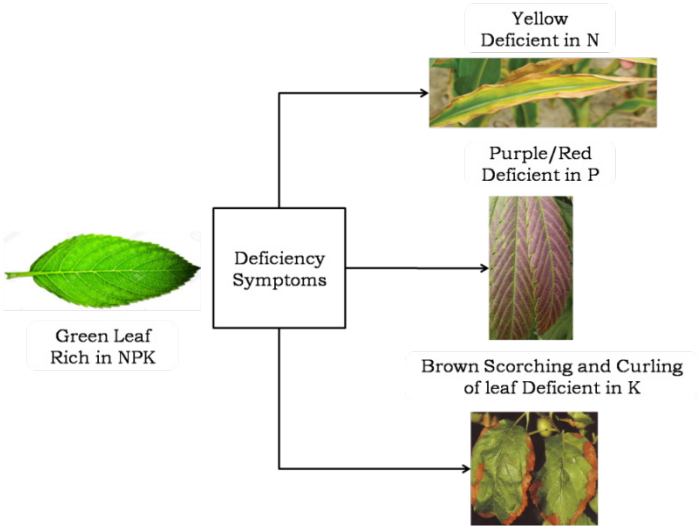

Figure 1: Change of color showcasing nutrient deficiency in leaf

From Figure 1, it is apparent that the deficiency in nutrients results in an outcome in the form visual look of the leaf which proves to be a nutrient deficient plant [9]. The deficiency symptoms in plants completely depend upon the color of the leaf. They are as follows,

- If the color of the leaf results in yellow, it proves to be deficient in N
- If the color of the leaf results in purple/red, it proves to be deficient in P
- If the leaf results in brown scorching and curling of leaf, it proves to be deficient in K

Finally, if the leaf appears to be completely green at its initial and later stages of growth, it results to be rich in all the three macro nutrients.

Methodology carried out to detect the approximate value of nutrients is by the study of spectral reactance of the leaf of the plant. The reactance alters at different stages of the plant growth on the grounds of variation in nutrient content [3]. In particularly the nitrogen is absorbed by the plant through atmosphere and is closely proportional in a linear fashion with chlorophyll. Hence the penetration and reactance of the leaf with light modulates with variation of the color of the leaf from green to yellow. On the other way the different macro nutrients are directly sourced from the soil of the plants.

The techniques present for nutrient and moisture content in plant are:

- Invasive Method
- Non-invasive method

Invasive technique uses destructive method for measurement of nutrients. The invasive methods used for measuring micro and macro nutrients for soil, leaf and irrigation water are:

- Electro-chemical method.
- Ion-selective electrode method.

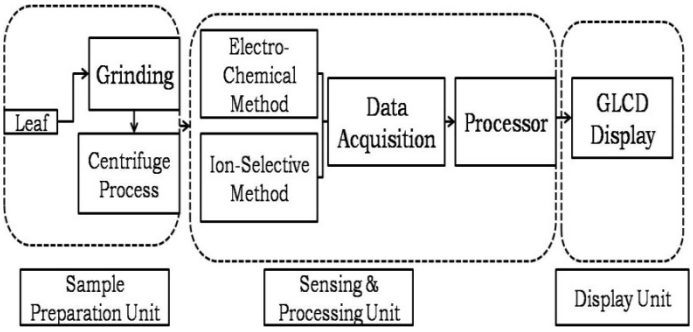

Figure 2: Architecture for Invasive Method

The overall system level block diagram for Invasive technique is depicted in Figure 2. It comprises of the various blocks such as sample preparation unit, sensing & processing unit and display unit. The sample preparation unit consists of sample leaf which is grinded into small pieces and further sent to the centrifuge process where in the sedimentation principle is used to separate the denser substances from less dense ones. The sensing and processing unit inculcates two different methods such as electro-chemical method and ion-selective method to acquire the data from previous unit. The data is further processed and given to the display unit in order to display the required data. The architecture for Non-invasive method is shown in Figure 3. The non-invasive technique uses non-destructive method for measurement of nutrients. This method uses non-contact type of sensors. The optical based sensors with the appropriate wavelength are selected for measuring the nutrients. The output obtained from optical sensor is processed using an embedded system and displayed. Based on the concentration of the nutrients an automatic alarm signal is generated for an inadequate concentration of particular nutrients which in turn controls the switching ON and OFF of the existing drip irrigation system.

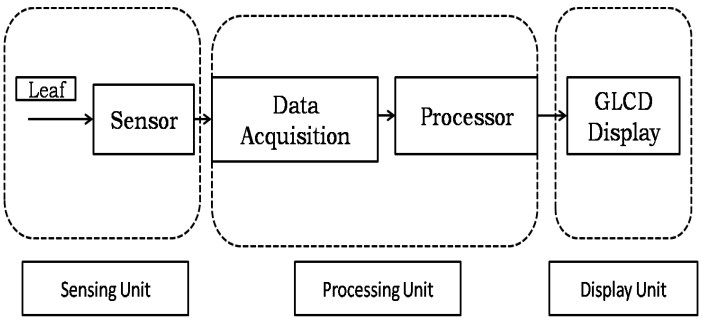

Figure 3: Architecture for Non-invasive Method

In order to quantify the spectral absorption optical sensor was used termed as TCS230.A waveform is generated as a result of the sensor which is later sampled to quantify the changes in nitrogen nutrient in leaf [10]. Different plant families exhibit variations mathematically involving Chlorophyll content Index (CCI) and entire quantity of chlorophyll/nitrogen content [11], [12]. For the product under design a self reliant mathematical model is developed for the species under consideration to a belonged zone. The main feature of the system should include its portability and user friendly behavior.

The organization of the paper is as follows. Section II discusses the implementation details of the system involving nitrogen, phosphorous and potassium detection. Section III discusses the results obtained for each nutrient and lastly section IV concludes the observational study.

2. Proposed Methodology and Implementation

This section describes about the implementation carried out to detect the three essential macro nutrients in plants such as Nitrogen, Phosphorous and Potassium. Two techniques were implemented for stress measurement of different nutrients.

1. Non invasive technique for detection of nitrogen and phosphorous.

2. Invasive technique for detection of potassium nutrient.

Intermediate sub models were built to reach the set goals. Different methods to improve the efficiency by the means of which precision and smart fertigation is obtained is discussed. This part of the paper also confers about different system models that are developed in order to achieve the set goals. It also discusses various methodologies of optimizations to the built models that are adopted to lock the constraints on various criteria's and approach by which appropriate nutrient distribution is carried out.

2.1. Nitrogen Detection

This segment of paper describes the details of nitrogen detection in maize leaf using non-invasive technique by discussing the system architecture proposed and implemented, formulating a mathematical model and optimization. Figure 4 shows the structural view of estimating the content of nitrogen in maize plant. It consists of various sub blocks such as color sensor, Pulse modulation wave processing, ADC block, and comparator and display device. The color sensor was used to sense the color of the leaf. Depending upon the color the amount of nitrogen will be estimated. Constant light source was provided to the leaf. The sensor output will be in digital domain. The color of the leaf changes accordingly with the frequency of the output wave. Visible light and infra red are the two light sources which were considered for experimentation. Different set of readings were obtained depending on the lighting conditions. The digital output obtained from the color sensor is provided from the controller for the signal to be processed. The frequency, wavelength of light reflected from the processed data was calculated with the help of algorithm. The frequency obtained is directly proportional to the reflectance of light that in turn changes with the content of chlorophyll of the leaf. Different frequency values are obtained as per the change in the color of the leaf. The relationship between obtained and reference frequency is gained by using mathematical model.

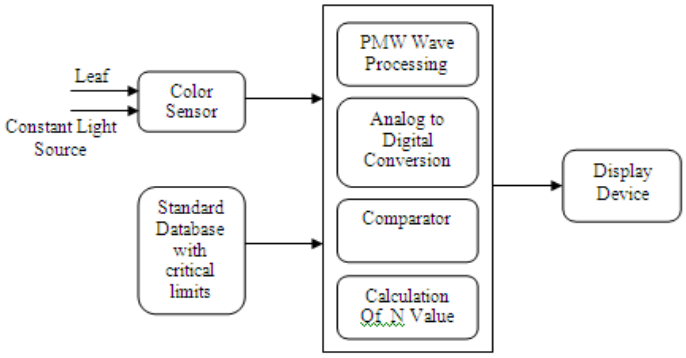

Figure 4: White box of N detecting sub module

The data set for the worst value was aggregated for analytical measurement from UASD College. Based on these values and also the value obtained from the system were compared and the assessed value of nitrogen in percentage of the leaf is unveiled and authenticated.

2.1.1. Mathematical Modeling

There are several authoritative systems in the market which act as chlorophyll meters. SPAD 502 meter is one such device that is made use in this project to act as a reference for spectral assessment of the leaf [13], [14]. Figure 6 provides an insight of the methodology undertaken to arrive at the inter-relationship between the standard device and the device under design.

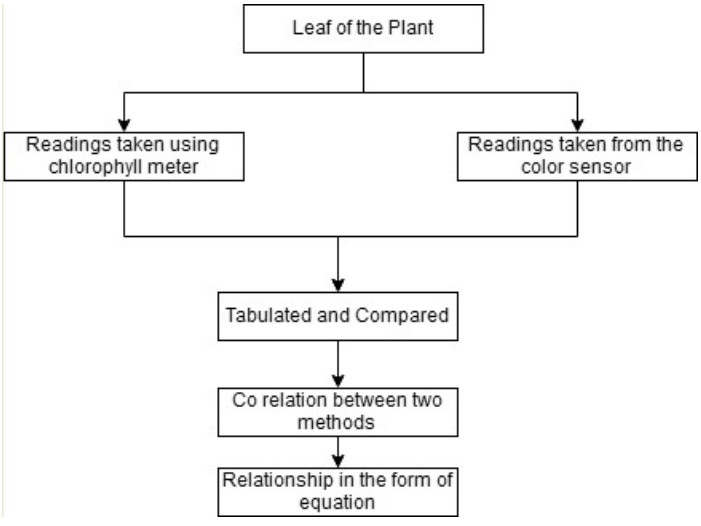

Figure 5: Method to arrive at the relationship between SPAD meter and color sensor

The readings of the leaf using both the devices were taken under different environmental conditions.

Equation (1) describes a linear inter-relation between the data from meter and the color sensor observed by plotting the graph.

$$Sensor = a * SPAD + b \quad (1)$$

Parameter 'a' & 'b' in Equation 1 constitutes to the slope and intercept respectively. This produces a dedicated mathematical model for nitrogen estimation. While creating a data from the reference meter, the readings were taken from all the different areas of the leaf at various locations. The same technique was also carried out while collecting the leaf data using color sensor

The data tabulation of SPAD meter and N_Sensor plot characterizes non- uniformity and was proportional in an inverted manner with each other revealing no patterns. An in-built function in MatLab i.e. fit function was exploited to fit the curve obtained with the help of polynomial of degree. The equation procured after the fitting procedure is as depicted in Equation 2 which shows inverse proportionality relation between the two data sets. Later stage involved modification of Equation 2 in terms of N_Sensor as exemplified in Equation 3.

$$SPAD = (-1.7393)N_sensor 93.83 \quad (2)$$

$$N_sensor = (-0.5748)SPAD + 93.83 \quad (3)$$

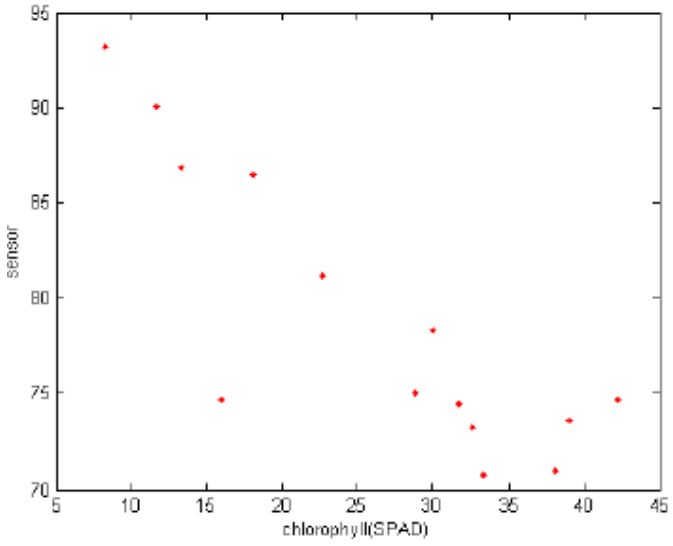

Figure 6: Relationship between chlorophyll content in SPAD and chlorophyll content in sensor

2.1.1. Optimization

Taguchi's technique acts as a reference and narrates a systematic approach for planning and conduction of experiments most effectively when there are numerous parameters related to the end results [15]. Hence the most appropriate data is collected which provides valid and objective conclusions as shown in Figure 7. Figure 8 depicts the inclusion of this approach to obtain different features.

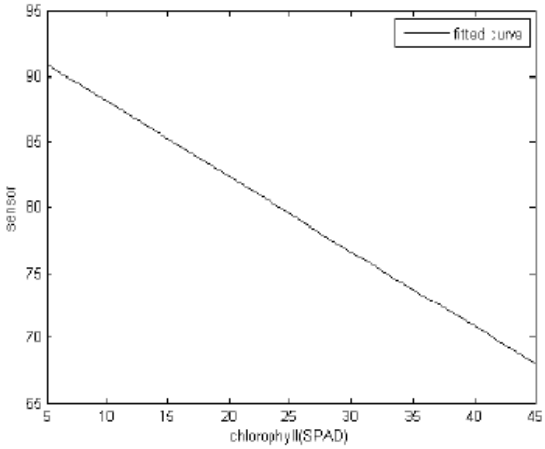

Figure 7: Best fit curve displaying the connection between SPAD device and chlorophyll

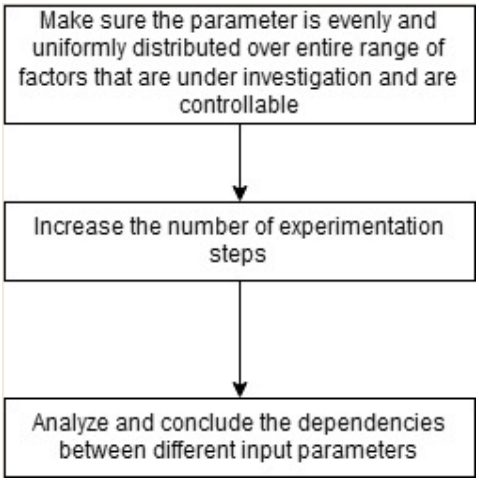

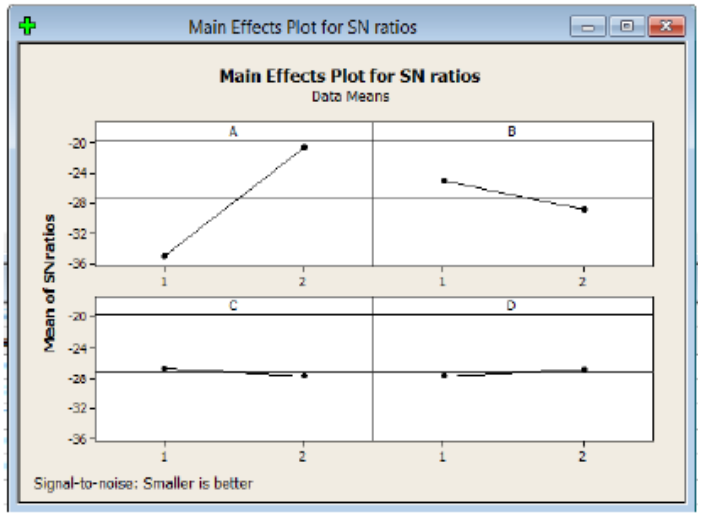

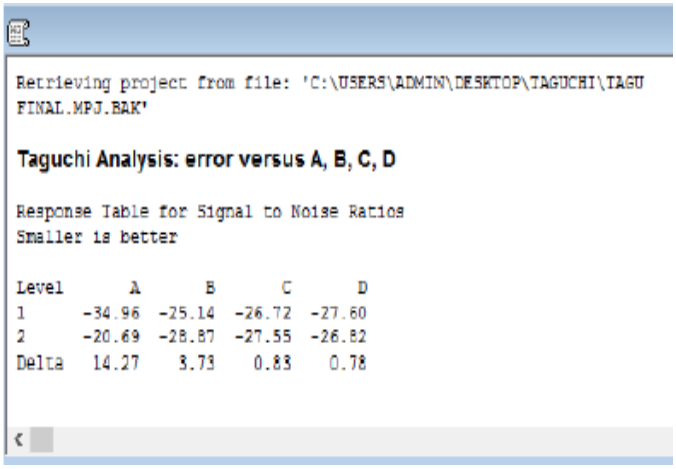

Figure 8: Features list requirement

The signal to noise ratio was plotted and the sensor error was defined as shown in below Figure 9.

In terms of achievement a lower range of the ratio of signal and noise should be present. Hence the gilt edge level of data set should be chosen in that range which has very least level of ratio of noise and signal. After above mentioned experimentation the best result is achieved at 5Volts present at second level with the distance of 1cm and at the lower range of frequency of first level. This also covered a large area at 2nd level as shown in Figure 10. A thorough study was investigated to identify the major design factors affecting the quality of the results using ANOVA technique. The outcome of this investigation led to the conclusion that voltage variation mainly influences the results compared to other design parameters.

2.2. Phosphorous Detection

This is another essential nutrient required in large quantity for the yield to enhance their productivity [16]. As per the observation, this nutrient has absorbance peaks in red regions with the wavelength ranging from 600nm to 700nm. It has no transmission in the near infra-red region. Hence the design in selection of the sensor is enabled such that the emission in light in preferably in the visible region. At the later stage of the sub system an optical filter id designed based on the wavelengths of interest that has to be passed. For this work the wavelength taken into account are beyond 665nm.

To calculate the nutrient amount approximately in the maize, crop a conceptual model was developed as depicted in Figure 11. The instrument used to calculate the phosphorous amount is equipped with series of electro-luminescent diodes that eradicates light with greater intensity in the visible range. The output of the designed system produces the range of phosphorous content in three levels – High, Medium and Low. The specimen of interest is exactly positioned between transmitter and receiver. Later the optical sensor detects the reflectance of those wavelengths.

Table 1: Set Threshold Values on Experimental Basis

Threshold Value	Nature of Leaf
2	No Green
3	Green

Table 2: Readings Obtained for Phosphorous

Readings	Approximate Phosphorous Content
> 3.4	Sufficient
< 3	Deficient

Table 1 discusses about the threshold value set based on the numerous readings that differentiates between green and non-green leaf. Table 2 discusses about the obtained readings which provides an approximate phosphorous content. The advantage of the device under investigation is, it identifies the change in Phosphorous content in an approximate manner well before it is visible by naked eye.

2.3. Potassium Detection

This nutrient is considered as the quality nutrient which is required in large amounts for proper growth as well as reproduction of the plants. The detailed block diagram for detecting the potassium content in coconut leaf is shown in Figure 12.

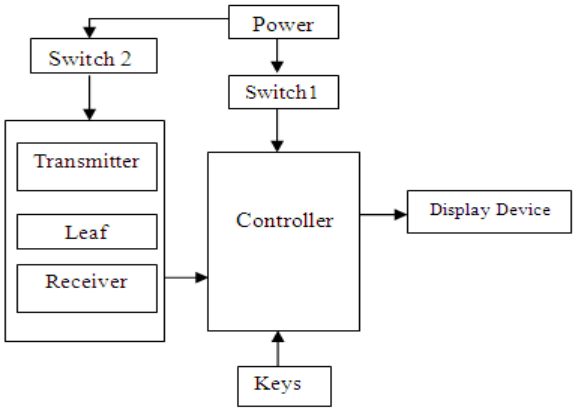

Figure 11: Functional Block Diagram

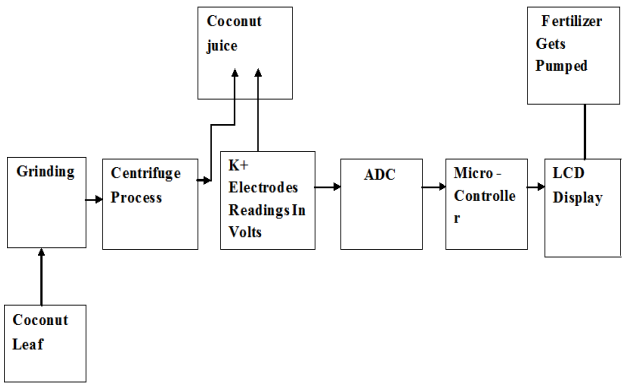

Figure 12: Functional Block Diagram

An experiment was conducted on coconut leaf to estimate the potassium content. One of the invasive techniques, ion selective electrode method was carried out for estimating the nutrient content. In this approach a K^+ electrode is used and the approximate amount of K^+ in a standard unit of PPM is determined.

Table 3: Source- Visible light; Measuring parameter- Nitrogen in maize leaf

3. Results and Discussion

This part of the study details about the tabulation of results obtained from the designed system for nutrient management in plants. Initial sub sections discuss the detection of nitrogen and phosphorous content in maize plant using non-invasive technique and the last sub section describes the results obtained for potassium content in coconut leaf using invasive technique. An IoT application was built to store the acquired data onto the cloud for further analysis. The created home page with experimental values is been listed.

3.1. Nitrogen Detection

SPAD meter is used as a reference device to carry out the investigation work. The data was recorded and the average of sensor data was calculated for each segment of the leaf. There is a need to compare a wide range of chlorophyll data which is obtained from the spectroscopy. The readings were considered from different segments of the leaf. The most important observation was that the content of chlorophyll was decreased at the center portion of the maize leaf. As it is apparent that leaf's nitrogen content directly varies with the content of chlorophyll in it. Thus, there is a linear relation between the two. Exploiting this mathematical relation maize leaf nitrogen content is calculated. Tests are conducted during day and night for validating the impact of sunlight on the designed sensor. The sensor is also validated for different sources of light particularly visible and infrared light as depicted in Table 3 and 4

T

Figure 13: Prototype showing high nitrogen in maize leaf

Figure 13 exhibits the proof of concept of the sub-component implemented.

3.2. Phosphorous Detection

For proof of concept the specimen leaf of maize plant was taken into account. A total of 10 leaves were procured on random basis for analysis. The test was conducted on the leaf using two methods for validation. The work carried out mainly concentrates on developing a strong interdependency between nutrient levels of phosphorous and reflectance numbers in two regions i.e. red and NIR range. [17].

Figure 14 & 15 displays the values obtained by the component under design and web page that includes the real time readings.

Figure 14: Home Page

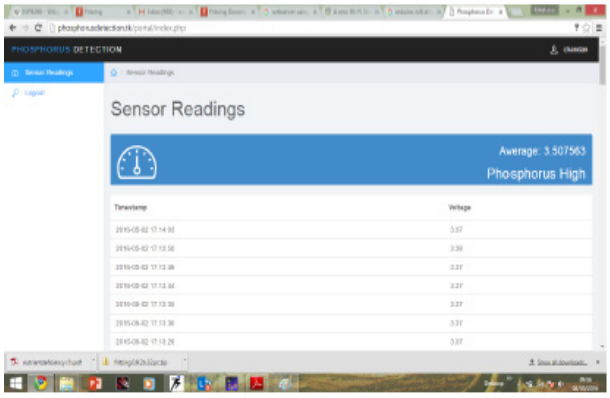

Figure 15: Dash Board

3.3. Potassium Detection

The measuring device initially requires preparation of coconut leaf extract that involves grinding followed by centrifuge process. The electrodes are used to estimate the reading in volts and the data is refined using signal conditioning circuits. The controller processes the conditioned data and displays the results of the nutrient content in terms of High (H), Medium (M) and Low (L). Table 5 displays the results obtained by ion selective method for potassium content in the coconut leaf. There was a linear relationship between the electrode output readings and concentration in PPM. This method of detecting the potassium content was further corroborated by taking the coconut leaf samples for UAS Dharwad which was categorized into less potassium content, medium content and rich in potassium. Using these leaves the results were obtained that stated the potassium content as per its presence in the leaf.

Table 5 : Results Obtained for Potassium Nutrient

Electrode Output in Volts	Concentration in PPM
0.2	4.503
0.4	20.28
0.6	106.204
0.8	478.3
1.0	2154.43
1.2	9703.49

4. Conclusion

Irrigation and fertigation play a pivotal role in better yield of crops. Excessive usage of fertilizers, in particular nitrogen leads to evaporation of this chemical which in turn creates global warming. Hence this impacts the environment. The projected work assesses the quantity of the nutrient present in the leaf approximately in the scale of high, medium and low. Three nutrients are addressed which are treated as macro nutrients. The nitrogen and phosphorous was tested and validated for maize plant where as potassium nutrient was initially experimented from coconut leaf. The entire work is based on the spectral analysis which was conducted in isolation for N and P and by inculcating non-invasive method of stress detection. Compared to conventional procedure, sensor-based reasoning of nutrients contributes to large spectrum of readings. Different optimization techniques were involved and among them Taguchi's approach was used in nitrogen detection.

A server is created to observe the real time data remotely. An invasive technique was also subjected in the proposed work for detecting potassium content in coconut leaf by using ion selective electrode method which was found to be time consuming and involving huge devices for making the required solution.

ABSTRACT

An optimization method using a semi-analytical approach is detailed in this paper to design a wideband multilayer meander-line polarizer. It consists of the transmission line equivalent circuit study to find the best values of the shunt components that allow the maximum transmission and a 90 phase difference between two orthogonal components over the entire bandwidth, followed by a simulated annealing algorithm to optimize the polarizer's dimensions by converging the values of the shunt components found earlier, to some rigorous empirical formulas of the equivalent admittances.
To validate the proposed method, a wideband (6-18 GHz) four layer's meander-line polarizer is optimized and manufactured. The polarizer prototype is stacked to a horn antenna operating at the same frequency band and tested. The experimental results verify that the linear waves of the horn antenna alone were converted to circular ones when the multilayer meander-line polarizer is stacked to it.

1. Introduction

This paper is an extension of work originally presented in the 48th European Microwave Week [1] where a four layer's wideband (6 – 18 GHz) meander-line polarizer has been optimized and simulated with different patch antenna for validation.

As well known, the polarizer is a passive broadband device, used to change the polarization properties of an Electro-Magnetic (EM) wave. Combining antennas with those devices to change the polarization of the wave is very useful. A well-designed polarizer permits to change the antenna polarization and to propagate a different polarization without any significant variations in the pattern performance [2]. The Meander-Line (ML) polarizer is the most popular device used to change the Linear Polarized (LP) waves into the Circular Polarized (CP) ones [3]. It is a multilayer structure made of several printed ML sheets spaced by about one-quarter wavelength apart. The principle of operation is to convert an incident wave into two equal components at ±45º as summarized in [4]. One component passes through a structure equivalent to a broad-band shunt-inductive filter while the other passes through a broad-band shunt-capacitive filter. the other component, by about 45º.

The ML polarizer has been proposed in [4], and improved in [5]. Later, [6-9] gave analytical formulas to compute the phase delay and characterize the polarizer's grating layer. Transmission Line (TL) theory together with Method of Moments (MOM) based algorithms has been used by [7, 10-13] to analyze the ML polarizer.

In this paper, the basic principle of the ML polarizer is described in section 2. Section 3 describes the detail of the optimization procedure which includes the TL equivalent circuit and Simulated Annealing (SA) algorithm. Finally, in section 4, the four layer's wideband (6 – 18 GHz) meander-line polarizer studied previously in [1] is used as a case study. The optimization study is presented, followed by experimental validation using a wideband horn antenna covering the same bandwidth.

2. Meander Line Polarizer: Basic Principle

The ML polarizer is a multilayer structure (Figure 1). Each layer consists of MLs printed on a low-loss dielectric substrate and separated by a spacer respecting one-quarter wavelength apart. The

*Wafa Abdouni-Abdallah, Emirates Technology and Innovation Center, Khalifa University, Main Campus, Abu Dhabi, UAE, +971 690 3881, wafa.abdouni@etic.ac.ae

spacer could be air (vacuum) or any kind of low loss material such as foam or dielectric substrate.

The principle of operation is to convert an incident wave into two equal and perpendicular components at ±45 degrees as summarized in [3]. The ML polarizer's layer is placed in the *xy*-plane in such a way that the meander axes are all oriented at an angle Ψ = 45 degrees with respect to the incident electric field $\boldsymbol{E_{inc}}$ along the *y*-axis (Figure 2).

The incident electric field $\boldsymbol{E_{inc}}$ will be decomposed into two orthogonal components: one parallel and the other one perpendicular to the ML axis, noted respectively $\boldsymbol{E_{\parallel}}$ and $\boldsymbol{E_{\perp}}$. As well known, a CP wave can be obtained by designing a ML polarizer that introduces a differential phase shift of 90^0 between the components $\boldsymbol{E_{\parallel}}$ and $\boldsymbol{E_{\perp}}$ while keeping their magnitudes identical over the entire required frequency bandwidth. Right-hand or left-hand circular polarizations can be easily obtained by switching the orientation angle $\boldsymbol{\Psi}$ from $+45^0$ to -45^0.

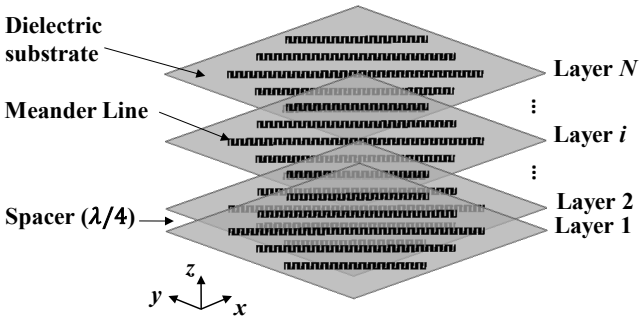

Figure 1: N-Layers ML polarizer design

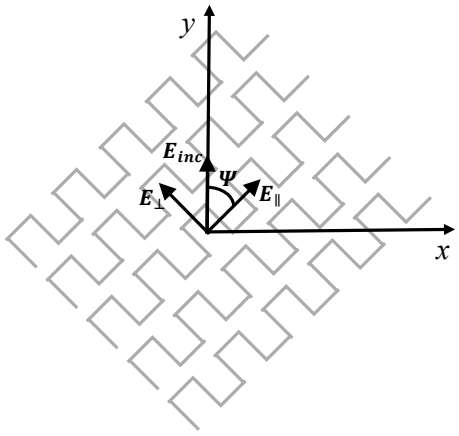

Figure 2: Incident field ($\boldsymbol{E_{inc}}$) exiting the polarizer layers with the parallel $\boldsymbol{E_{\parallel}}$and the perpendicular $\boldsymbol{E_{\perp}}$ components resulted.

The difficulty in the design of a meander-line polarizer is to determine the inductive and capacitive impedances of the grating for the $\boldsymbol{E_{\parallel}}$ and $\boldsymbol{E_{\perp}}$ polarizations with respect to frequency and constitutive dimensions of the meander line.

An optimization method is developed to optimize the ML polarizer's dimensions and described in detail in the below section. It consists of a semi-analytical analysis based on the combination of TL circuit theory and SA algorithm and allows to find the dimensions of the MLs that keep the magnitude of the components $\boldsymbol{E_{\parallel}}$and $\boldsymbol{E_{\perp}}$ identical with a phase differential shift of 90º over the desired frequency bandwidth.

Our method of optimization has the advantage of avoiding the heavy computations and simulations used in [13] to solve the TL circuit and the unit cell of each layer. This implies a large reduction in the computation time.

- The TL equivalent circuit is solved using the optimization tool of ADS. This tool has the advantage of optimizing the shunt elements of all the layers at one simulation and avoid the heavy computation of the transmission matrices of each layer then the scattering transmission parameters and finally optimize the shunt elements using quasi-Newton algorithm as used in [13].
- SA algorithm is used to optimize the physical dimensions of the MLs. This algorithm optimizes the dimensions and minimize the absolute values of the differences between the theoretical admittances introduced by Chu and Lee in [14], and their lumped-element counterparts optimized by solving the TL circuit using the optimization tool of ADS. This method avoids the full-wave analysis of the unit cell and all the steps described before which are used in [13].

3. Meander Line Polarizer: Optimization and validation Procedures

3.1. TL Equivalent Circuit Model

As summarized in [4], the incident electric field $\boldsymbol{E_{inc}}$ will be decomposed into two orthogonal components $\boldsymbol{E_{\parallel}}$ and $\boldsymbol{E_{\perp}}$. One component passes through a structure equivalent to a broad-band shunt-inductive filter while the other passes through a broad-band shunt-capacitive filter. The phase shift through either filter should have almost the same slope, so that if the differential phase shift is 90º at one frequency in the common passband, it remains close to 90º everywhere in the common passband.

The TL equivalent circuit of the N-layers ML polarizer excited by an incident wave along *y*-axis (Figure 1) can be represented as shown in the Figure 3 where η_0 is the characteristic impedance of the vacuum ($\eta_0 = \sqrt{\mu_0/\varepsilon_0}$) with μ_0 and ε_0 the permeability and the permittivity of vacuum, respectively. The parameters h_{d1}, h_{d2}, …, h_{dN} and $\varepsilon_{r_{d1}}$, $\varepsilon_{r_{d2}}$, …, $\varepsilon_{r_{dN}}$ are respectively the thickness and the relative permittivity of the 1st, 2nd, …, *N*th layer. The parameters h_{s1}, h_{s2}, …, h_{sN} and $\varepsilon_{r_{s1}}$, $\varepsilon_{r_{s2}}$, …, $\varepsilon_{r_{sN}}$ are respectively, the thickness and the relative permittivity of the 1st, 2nd, …, *N*th separator. The L_{eq_1}, L_{eq_2}, …, L_{eq_N} and C_{eq_1}, C_{eq_2}, … , C_{eq_N} are respectively the lumped inductance and capacitance equivalents of the 1st, 2nd, …, *N*th periodic strip lines on each layer.

The input parameters of the TL model of ML polarized are: the frequency bandwidth (center frequency f_0), the number of layers and the relative permittivity and thickness of each dielectric substrate and separator. This model must be solved by optimizing the shunt components L_{eq_1}, L_{eq_2}, …, L_{eq_N} and C_{eq_1}, C_{eq_2}, …, C_{eq_N} which verify the maximum transmission coefficients (S_{21} and S_{43}) in term of magnitude (~0dB) while

attaining 90^0 differential phase shift between both components for the CP properties.

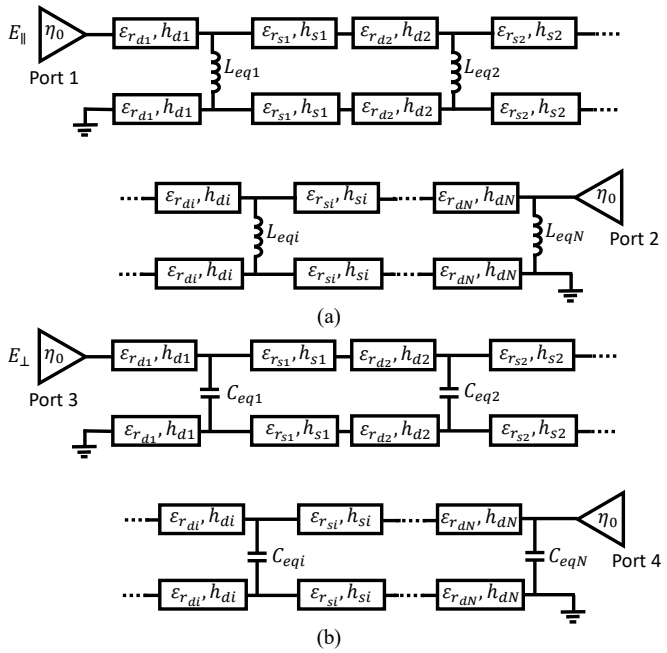

Figure 3: Transmission Line equivalent circuit for N-Layers ML polarizer observed by (a) the parallel wave $\boldsymbol{E}_\parallel$ and (b) the perpendicular wave $\boldsymbol{E}_\perp$.

3.2. Simulated Annealing Algorithm

Simulated Annealing is a mathematical equivalent of the thermodynamic annealing. The energy of the particle in thermodynamic annealing process can be compared with the cost function to be minimized in optimization problem. The particles of the solid can be compared with the independent variables used in the minimization function. The Simulated Annealing Algorithm is detailed in [15].

The MLs dimensions must be optimized to verify that the impedance equivalent of each layer is equal to the one found by solving the TL circuit model.

Chu and Lee in [14], presented rigorous empirical formulas of equivalent admittances for parallel ($Y_\parallel$) polarization $\boldsymbol{E}_\parallel$ and perpendicular ($Y_\perp$) polarization $\boldsymbol{E}_\perp$ of the ML, dependent on the dimensions a, b, h, and w (Figure 4).

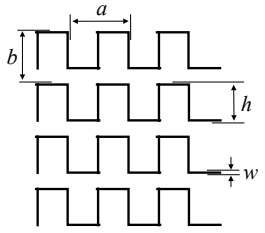

Figure 4: Polarizer's dimensions

The SA algorithm is used to optimize the best values of the ML dimensions of each layer i by making the admittances values ($1/j\omega L_{eq_i}$ and $j\omega C_{eq_i}$), found using the TL circuit model, equal to the ones given by Chu and Lee ($Y_{\parallel_i}(a_i, b_i, h_i, w_i)$ and $Y_{\perp_i}(a_i, b_i, h_i, w_i)$). In other word, for each layer i, the dimensions a_i, b_i, h_i, w_i are optimized to minimize the difference between the admittances ($\delta_i \approx 0$ and $\delta_i' \approx 0$) as shown in the equation (1).

$$\begin{aligned} &\left|Y_{\parallel_i}(a_i, b_i, h_i, w_i) - \frac{1}{j\omega L_{eq_i}}\right| \le \delta_i \\ &\left|Y_{\perp_i}(a_i, b_i, h_i, w_i) - j\omega C_{eq_i}\right| \le \delta_i' \end{aligned} \quad \text{for } i = \{1, \dots, N\}. \quad (1)$$

The optimization procedure is summarized in Figure 5.

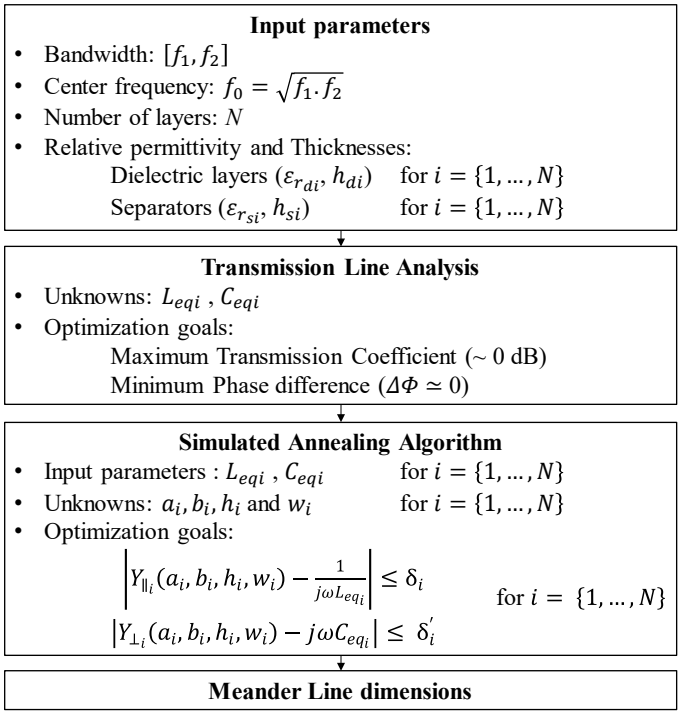

Figure 5: Optimization Procedure Summary

4. Case Study: 6-18GHz Four Layers ML Polarizer

A four layers ML polarizer covering the bandwidth from 6 GHz to 18 GHz is studied in this section.

4.1. Polarizer Optimization

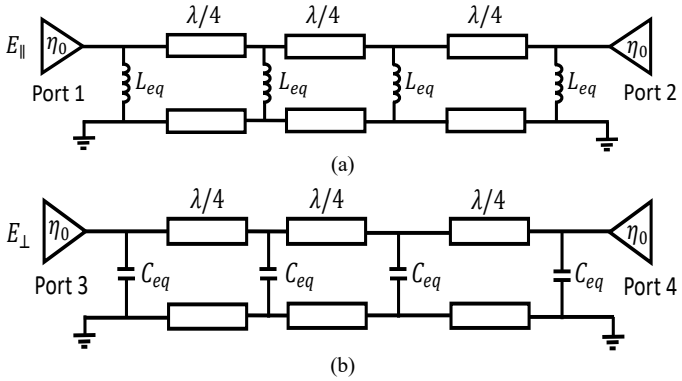
The optimization procedure starts by defining the input parameters which are the frequency bandwidth [6-18GHz], center frequency f_0 = 10.4GHz, number of layers N = 4, relative permittivity and thickness of the dielectric substrates ($\varepsilon_{r_{di}}, h_{di}$) and separators ($\varepsilon_{r_{si}}, h_{si}$) for $i = \{1, \dots, 4\}$.

To simplify the TL equivalent model, the equivalent circuit was studied with one-quarter wavelength apart ($\lambda/4$) air separators and without considering the substrate effect since a very thin substrate ($h_{di} = 0.127mm$) with low permittivity and low loss (Rogers RT/duroid 5880 ($\varepsilon_{r_d} = 2.2, Tan\delta_d = 0.0009$)) is used.

The choice to have the same MLs dimensions (i.e. same L_{eq} and C_{eq}) for each layer was also made to make the system integration simple and flexible. The TL equivalent circuit of the four layers ML polarizer is shown in the Figure 6.

The optimization tool of ADS is used to find the best values of the equivalent inductance and capacitance to verify the maximum transmission coefficients (S_{21} and S_{43}) in term of magnitude (~ 0dB) and 90^0 differential phase shift between them

over the entire bandwidth. The optimum values are: C_{eq}=3 fF and L_{eq} = 0.494 pH.



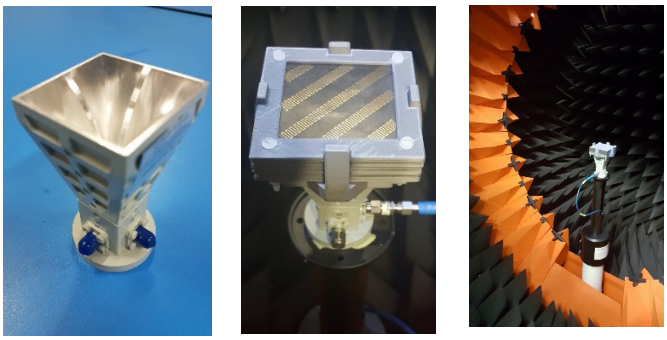


Figure 6: TL circuit model of the four layers Meander Line polarizer observed by the (a) parallel wave ($\boldsymbol{E}_{\parallel}$) and the (b) perpendicular wave ($\boldsymbol{E}_{\perp}$).

The ML dimensions (a, b, h, and w) are optimized using the SA algorithm, as detailed previously, by making the admittances values ($1/j\omega L_{eq}$ and $j\omega C_{eq}$), found using the TL circuit model (Figure 6), as close as possible to the ones given by Chu and Lee (1). The optimum values found are a = 2.17mm, b = 13.08mm, w = 0.446mm and h = 5.151mm.

4.2. Polarizer test with 6-18GHz Horn Antenna

To verify the performance of ML polarizer, a wideband horn antenna (6 to 18 GHz) shown in figure 7(a) is used. The four ML layers of the polarizer were fabricated. A mechanical support was designed and realized using a 3D printer to maintain the quarter wave length distance between each layers and the antenna. The picture of the polarizer attached to the antenna is shown in figure 7(b). Figure 7(c) shows the antenna with the ML polarizer under test in the near field anechoic chamber StarLab (by Microwave Vison Group), available in IETR.

(a) (b) (c)

Figure 7: Picture of (a) horn alone - (b) horn with ML-Polarizer – (c) horn with ML-Polarizer under test

The measurements were performed for the horn antenna alone and with the ML polarizer excited in vertical polarization. The reflection coefficients of the horn antenna alone (without the ML polarizer) and with the ML polarizer are plotted in Figure 8.

Both reflection coefficients are very close, which proves that the ML polarizer doesn't mismatch the antenna except at the around 6GHz, where the reflection coefficient is measured around -6.5dB.

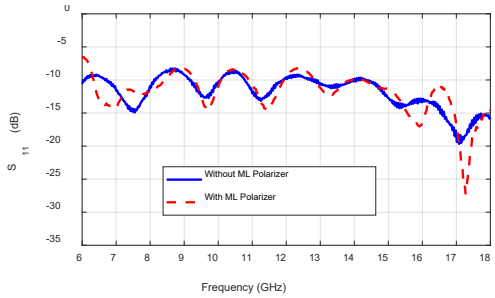

Figure 8: Reflection coefficients of the horn antenna with and without the ML polarizer

The co-polarization and cross-polarization of the Electrical filed (E_θ and E_ϕ) are plotted for different frequencies in the figures 9-15.

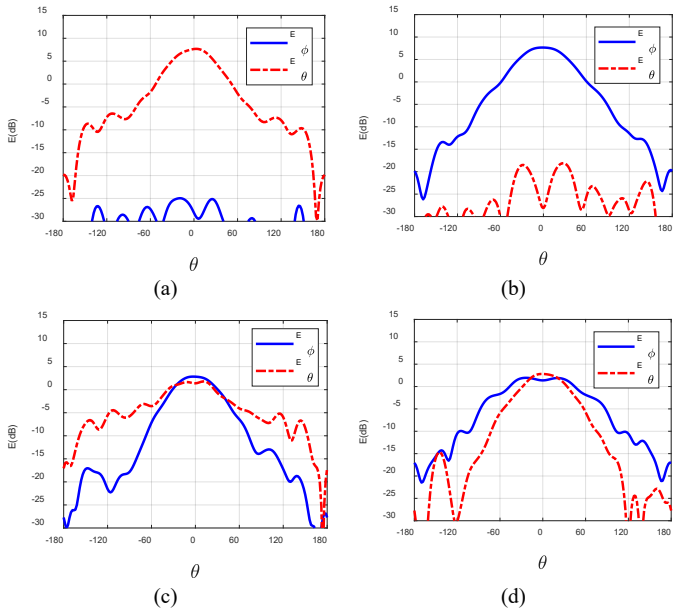

Figure 9: Measured E_θ and E_ϕ at 6 GHz for the horn antenna alone in both planes (a) $\phi = 0^0$ and (b) $\phi = 90^0$ and for the horn antenna with the ML polarizer in both planes (c) $\phi = 0^0$ and (d) $\phi = 90^0$.

In figure 9, the E_θ and E_ϕ components of horn antenna alone and with ML polarizer are plotted at 6 GHz in both planes ($\phi = 0^0$ and $\phi = 90^0$). The results seem to show that the horn antenna initially excited for a vertical polarization (Figure 9 (a) and (b)) is radiating a circular polarized wave when it is stacked with the ML polarizer (Figure 9 (c) and (d)). At the boresight, the difference between the co and cross components of the horn antenna measured alone is more than 28 dB while it reduces to 1dB when the horn antenna is measured with the ML polarizer. The measured Axial Ratio (AR) of the horn antenna with the ML polarizer at this frequency is around 6dB (Figure 16). Therefore, the ML polarizer is converting the linear polarization waves into elliptical polarized ones. The measured insertion losses are around 2.5dB (Figure 17) which is due to the mismatch of the antenna with the ML polarizer at this frequency (Figure 8).

The E_θ and E_ϕ components of the horn antenna alone and with ML polarizer are plotted in figure 10 – 14 for the frequencies from 8GHz to 16GHz. The vertical polarized waves of the horn antenna alone are perfectly converted to circularly polarized ones when it is stacked to the ML polarizer with the maximum AR of

2.9 dB at 8GHz (Figure 16). The insertion losses are less than 1.4 dB with the minimum of 0.24 dB at 14 GHz (Figure 17).

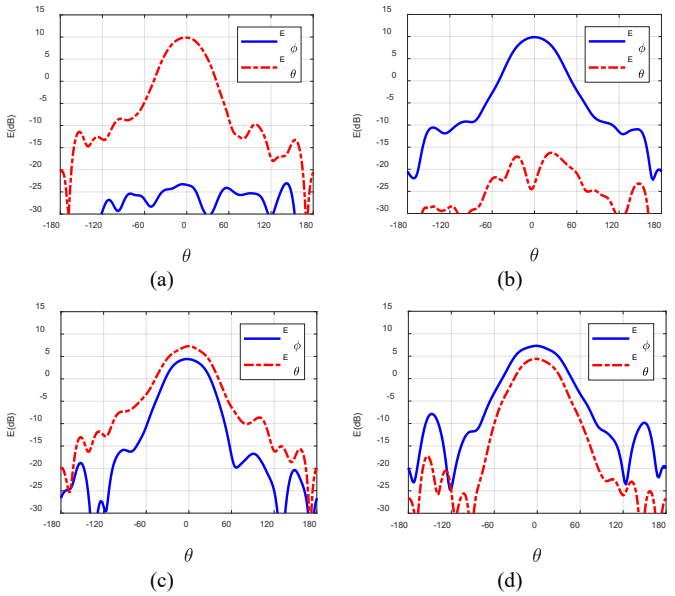

Figure 10: Measured E_θ and E_ϕ at 8 GHz for the horn antenna alone in both planes (a) $\phi = 0^0$ and (b) $\phi = 90^0$ and for the horn antenna with the ML polarizer in both planes (c) $\phi = 0^0$ and (d) $\phi = 90^0$.

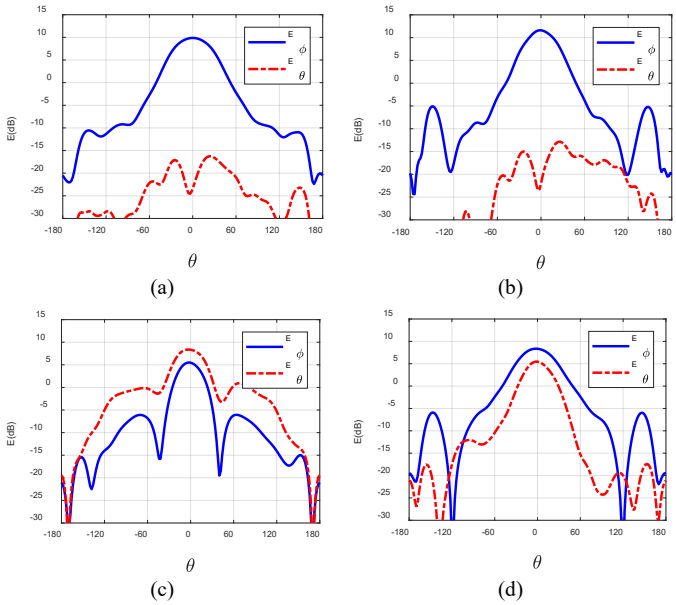

Figure 11: Measured E_θ and E_ϕ at 10 GHz for the horn antenna alone in both planes (a) $\phi = 0^0$ and (b) $\phi = 90^0$ and for the horn antenna with the ML polarizer in both planes (c) $\phi = 0^0$ and (d) $\phi = 90^0$.

The measured results at 18 GHz are plotted in figure 15. At the plane $\phi = 0^0$, some ripples are observed in the pattern of the co-component when the antenna is measured with the ML polarizer. This comportment is not reproduced at the other cut plane ($\phi = 90^0$) where the directive radiation pattern shape is preserved. The measured Axial Ratio (AR) of the horn antenna with the ML polarizer at this frequency is around 5.4 dB (Figure 16). Therefore, the linearly polarized waves of the horn antenna alone are converted to elliptical polarized waves. The measured insertion losses are around 0.6 dB (Figure 17).

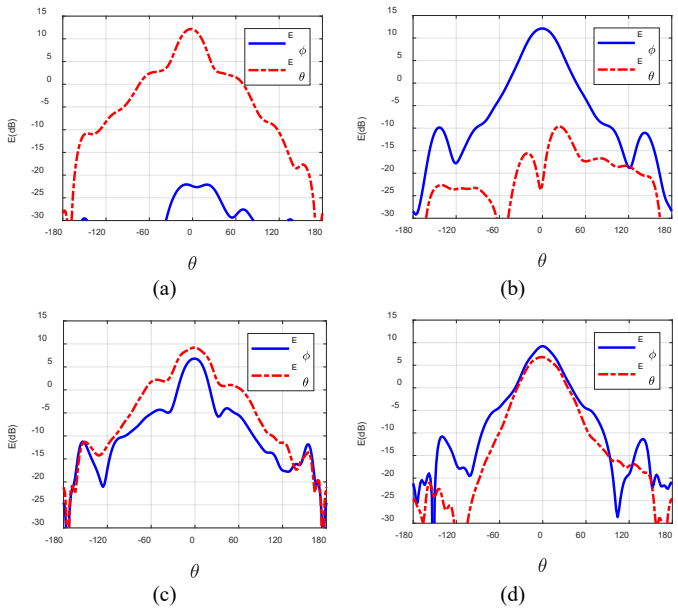

Figure 12: Measured E_θ and E_ϕ at 12 GHz for the horn antenna alone in both planes (a) $\phi = 0^0$ and (b) $\phi = 90^0$ and for the horn antenna with the ML polarizer in both planes (c) $\phi = 0^0$ and (d) $\phi = 90^0$.

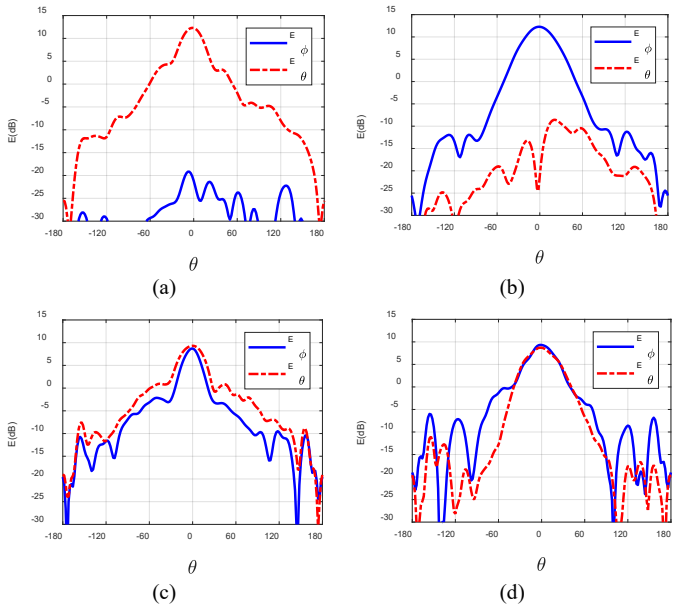

Figure 13: Measured E_θ and E_ϕ at 14 GHz for the horn antenna alone in both planes (a) $\phi = 0^0$ and (b) $\phi = 90^0$ and for the horn antenna with the ML polarizer in both planes (c) $\phi = 0^0$ and (d) $\phi = 90^0$.

The measured values of the AR at boresight are reported in figure 16 versus frequency for the horn antenna with the ML polarizer. The AR is less than 3dB at the frequency band between 8 GHz and 16 GHz. Therefore, the ML polarizer converts the linear polarization of the horn antenna to a circular one. In both ends of the frequency band (6 GHz and 18 GHz), the ML polarizer converts the linear polarization of the horn antenna to an elliptical one.

The total electrical fields (E_{tot}) values at boresight are reported in figure 17 versus frequency for the horn antenna alone and with the ML polarizer. This figure shows clearly that the E_{tot} of the horn

antenna with the ML polarizer is following the same allure as the E_{tot} of the horn antenna alone variation with some insertion losses.

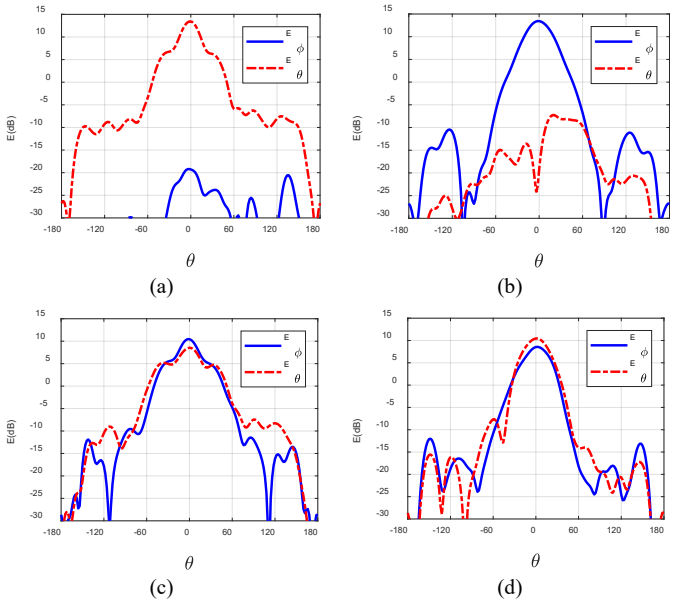

Figure 14: Measured E_θ and E_ϕ at 16 GHz for the horn antenna alone in both planes (a) $\phi = 0^0$ and (b) $\phi = 90^0$ and for the horn antenna with the ML polarizer in both planes (c) $\phi = 0^0$ and (d) $\phi = 90^0$.

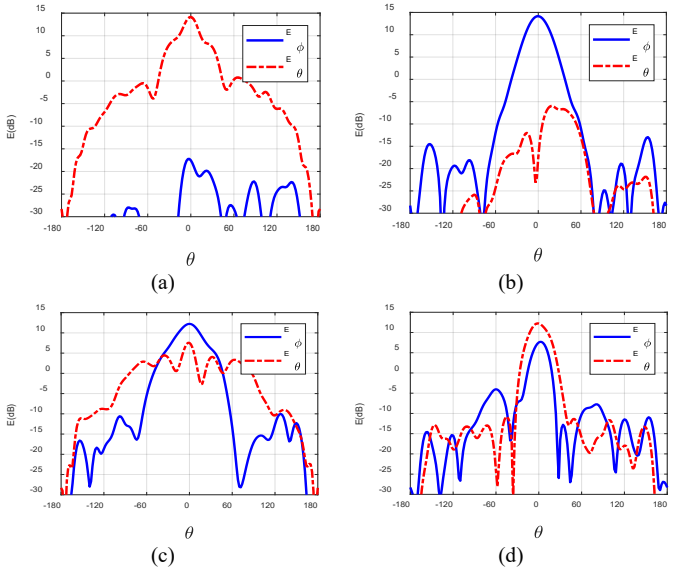

Figure 15: Measured E_θ and E_ϕ at 18 GHz for the horn antenna alone in both planes (a) $\phi = 0^0$ and (b) $\phi = 90^0$ and for the horn antenna with the ML polarizer in both planes (c) $\phi = 0^0$ and (d) $\phi = 90^0$.

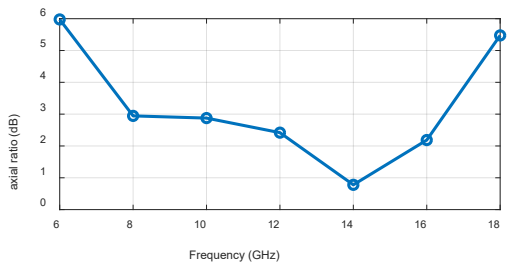

Figure 16: Measured Axial Ratio (***AR***) versus frequency for the horn antenna with the ML polarizer

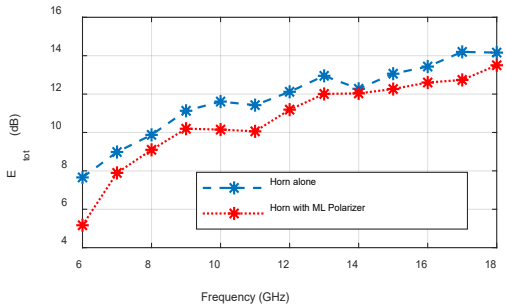

Figure 17: Measured total electrical field (***E_{tot}***) versus frequency for the horn antenna alone and with the ML polarizer

In almost the entire bandwidth, except at 6 GHz, the insertion losses are less than 1.5dB with the minimum of 0.24 dB at 14 GHz. The maximum insertion losses (2.5dB) are measured at 6 GHz which is due to the mismatch of the horn antenna with the ML polarizer.

5. Conclusion

An optimization Method of Wideband Multilayer Meander-Line Polarizer using a Semi-Analytical approach is described in this paper. The originality of this method lies in the optimization of: i) values of the shunt equivalent inductance L_{eq} and capacitance C_{eq}, determined by the ADS software - ii) ML dimensions (a, b, h and W) using the SA algorithm. This method was applied to optimize a four layers wideband (6 – 18 GHz) ML polarizer as study case.

The optimized polarizer was manufactured and a wideband Horn antenna covering the same bandwidth was used for the testing. The test consists of the measurements of the horn antenna vertically polarized without and with the ML polarizer. Good measured results were observed where the linear polarization of the antenna was converted to a purely circular one in almost the entire frequency band (8 GHz – 16 GHz, corresponding to an octave). In both ends of the frequency band (6 GHz and 18 GHz), an elliptical polarization was achieved with a maximum axial ration of around 6dB.

At 6GHz, the axial ratio is around 1dB but the insertion losses are around 2.5dB which is due to the mismatch of the horn antenna with the ML polarizer at this frequency. At 18 GHz, the axial ratio is around 5dB and the insertion losses are around 0.6 dB.

The future work will be devoted to the study of five layers ML polarizer to improve the performances, and especially at both ends of the frequency band.

ABSTRACT

This study introduces the implementation of fuzzy set theory to solve machine layout design issues, in order to handle vague information, using a genetic algorithm with tournament selection as the selection operator. The material handling inputs, including frequency and volume of materials that move between machines, were the parameters regarded as fuzzy numbers. The experimental results came from 2 case studies in a manufacturing system. In the first case, examining the difference in shapes of the triangular membership functions of input data, the total distances were reduced from 38.45 m to 29.72 m, a 22.71% reduction in distance. In the second case, examining the uncertainty of fuzzy data by an expert, the total distances were reduced from 103.45 m to 82.45 m, a 20.03% reduction in distance. It was found that given the uncertainty in input data, a shorter total material handling distance might not give a lower cost. The selection operator of tournament selection can compete effectively to converge to near the optimum solution. This can, therefore, be an alternative technique in managing manufacture.

1. Introduction

Facility layout design plays a large part in business competition. Facilities can be machines, workstations, construction sites or departments, depending on the type of business. Costs can be reduced by having an appropriate layout. However, it is a complex problem. One of the essential goals of the design is to minimize total material handling costs, which are affected by many factors, such as types of materials, processing and production flow. Especially in the manufacturing industries, some produce not just one product but a variety of goods.

Moreover, in reality, the factors that affect material handling costs are vague and fuzzy. In a manufacturing system, they are dependent generally on the seasons, product variety and business growth. In order to engage with this ambiguity, there are levels of the vagueness of information, and the decision is usually made under uncertainty [1]. Fuzzy sets theory is a suitable concept to deal with this situation [2-6]. Therefore, this paper extends the research to understand the effects when the values in fuzzy sets are predictable and if they are extremely vague.

In many manufacturing industries, there can be several products manufactured in a factory, and each product can have different routes through machines or workstations. Production efficiency depends highly on this kind of problem in production planning [7]. Production costs can be reduced by 10–30% when the facility layout is more effective [8]. Shorter handling distances of materials' flow between workstations are required for faster transfer times within a factory floor.

The inputs necessary to design a facility layout for an actual production system are usually imprecise. Besides, the issue is considered a complicated situation because of the choice of products, materials, processes and other factors involved with the business. These factors are also time-dependent, such as customer orders and product growth, so the cost of material handling between machines usually changes. Different methods [9-12] have been presented for solving these kinds of problems; however, uncertain and ambiguous data inputs have been paid little attention [13]. Therefore, the fuzzy set theory is applied in this paper.

Many researchers have proposed different ways to solve this complex problem. In choosing the solution, the aim should be to achieve maximum efficiency, and there should be a simple method for finding the answer. Drira, et al. [14] gathered techniques and methods used for solving machine layout problems. Several methods can be used in the analysis of these problems, such as branch and bound, dynamic programming, simulated annealing, tabu search, genetic algorithms, ant colony, intelligence methods.

To find a solution with accurate answers to a complex problem, the costs of solving are very high [15]. Thus, it is better, rather, to have a method that can solve the vague problem obtaining an

*Wanwanut Boongsood, Email: wanwanut@sut.ac.th

acceptable answer with less time and cost than that with high accuracy and high cost. Since mathematical modeling techniques used to solve the facility layout design problem are complicated, challenging, and time-consuming, the issues require a powerful technique [5].

For the problems of machine layout design, the genetic algorithm is one popular method for finding answers, or approximate answers [16]. The Simple Genetic Algorithm (SGA) applies the principle of evolution and natural selection, by which the best individuals are selected to generate answers for the next generation. To calculate the answer by SGA is fundamental to solving the optimization problem. Many studies adopting this method have been released [14].

Conventionally, Genetic Algorithm (GA) includes these steps: generate an initial population, select high potential chromosomes to be parents, crossover and mutate parents' chromosomes to produce offspring chromosomes. Since there are a couple of genetic operators used in GA steps, improving the results fulfilling genuine applications can be achieved by adopting some of these operators (see [17-19] and [20]). The action of selecting high potential chromosomes to be parents called the selection process is the operation that has been broadly studied. Tournament Selection (TOS) and Roulette Wheel Selection (RWS) are general ways for making a selection. It was suggested that TOS is more effective than RWS [21-23]; the consequence is that a reasonable answer can be reached faster.

The research of Vitayasak [24] on fuzzy methods is interesting. The fuzzy approach can help manage uncertainty in practice, which may arise from a lack of information, not having enough data for the application, or the data not yet being available [25]. The experience of experts in reasoning or decision making in the human situation can help analysis and help manage uncertainty. The fuzzy theory is a theory of uncertain boundaries. Currently, it is widely used in the study of problems containing uncertain information [26].

It is important for machine layout design decision making and an efficient way to deal with inaccurate and vague information. Kritwattanakorn, et al. [27] used the RWS method for the selection approach in GA and suggested not to apply mutation for machine layout problems. However, based on the suggestions given by some research [21-23], the TOS method seems to be superior in finding a solution qualitatively (for instance, minimizing the total material handling cost) and obtain answers faster and closer to the optimum. In our paper presented initially to a conference [28], we related to the research of Kritwattanakorn, et al. [27] that not to apply mutation, used TOS for selection, and showed how to deal with the vagueness of information and assist solving problems taken from earlier research works [25, 26]. Our proposed method performed corresponding to the work presented by Jinghui, et al. [21] that using TOS is competitive in terms of solution quality and achieving minimization faster.

However, realistically, there are also levels of the vagueness of information. To understand the effects when the values in fuzzy sets are predictable and if they are extremely vague, in this study, the tournament method was used in the selection process for the genetic algorithms solving the machine layout problem. Material handling information was considered employing fuzzy uncertainty. An original layout and new layouts constructed from three GA based approaches were compared for 2 case studies. The first was the case where fuzzy information was thought predictable, examining different forms of skewed shapes. In the second case, the fuzzy data was obtained from a process expert in a new factory when asked to give the possible values for each variable. Thus the fuzzy sets were utterly formless. Every approach in the study was programmed and run with Visual Basic for Applications in Microsoft Excel for determining the layout, distance, and cost.

2. Methods

The fitness function, which is a particular type of objective function, is required for the GA algorithm to execute optimization. In this paper, the objective (1) is to minimize the total costs of material handling. This objective has been chosen by many researchers [29-31] in determining facility layouts. The function can be written as

$$Minimize\ C = \sum_{i=1}^{M} \sum_{j=1, i \neq j}^{M} f_{ij} c_{ij} d_{ij} \quad (1)$$

$$f_{ij} = \mathrm{F_{ij}} \times \mathrm{V_{ij}} \quad (2)$$

where C represents the total cost of the material handling system.

f_{ij} is the flow of materials in the production system.

c_{ij} is the unit cost of material handling between machines *i* and *j*.

d_{ij} is the rectilinear distance between the centroids of machines *i* and *j* (see for instance Fig. 1, where the distance between machines B to E is equivalent to $\Delta x + \Delta y$).

M is the total number of machines.

F_{ij} is the frequency flow between machines *i* and *j*.

V_{ij} is the volume flow between machines *i* and *j*.

In the calculation, minimize C is the objective, the variables used in consideration in this paper, $\mathrm{C_{ij}}$ and $\mathrm{d_{ij}}$ are considered as crisp numbers, and f_{ij} is information that is uncertain.

In general, $f_{ij} = \mathrm{F_{ij}} \times \mathrm{V_{ij}}$. However, in this study the information was considered both as if it is fuzzy to compare with the conventional idea, and as if it is crisp. Thus, when the frequency and the volume of material flows are considered as fuzzy numbers, they will be represented as $\mathrm{F'_{ij}}$ and $\mathrm{V'_{ij}}$, respectively, and the material handling flow as a fuzzy number is f'_{ij} (3).

Since the total cost, C, is a crisp number, f'_{ij} needs to be converted back to be an exact number. This method is called defuzzification, see (4).

$$f'_{ij} = \mathrm{F'_{ij}} \otimes \mathrm{V'_{ij}} \quad (3)$$

$$\mathrm{Defuzzification}(f'_{ij}) = f_{ij} \quad (4)$$

However, in some cases, the materials frequency and volume flow information are exact numbers, so they need to be converted

to a fuzzy number. This method is called fuzzification (5) when X is a number.

$$Fuzzification(X_{ij}) = X'_{ij} \quad (5)$$

The framework:

- Data input: the data input includes the production routing of each product (P_I, P_{II}, P_{III} ...), number of machines (N), sizes of machines (width, w_n, and length, l_n), shop floor area (W is width and L is length), frequency of material flow per round (F'_{ij}), volume flow per unit (V'_{ij}), unit material handling cost between locations of machines (c_{ij}) and distance between machines (d_{ij}), population size (v) and the number of generations to simulate (G).
- Step 1) Fuzzification: The uncertain flow frequency of materials, f_{ij} which is the function of F_{ij} and V_{ij} , was converted to fuzzy numbers (f'_{ij}).
- Step 2) Fuzzy computing: Fuzzy arithmetic was used.
- Step 3) Defuzzification: In order for the next step following the GA approach, crisp numbers are essential for calculation. The fuzzy number f'_{ij} was required to be transformed into crisp numbers.
- Step 4) Genetic algorithm: The sub-processes in the adapted GA are shown in Fig. 2.
- Stop: The calculation stops when conditions are met as in Fig. 2.

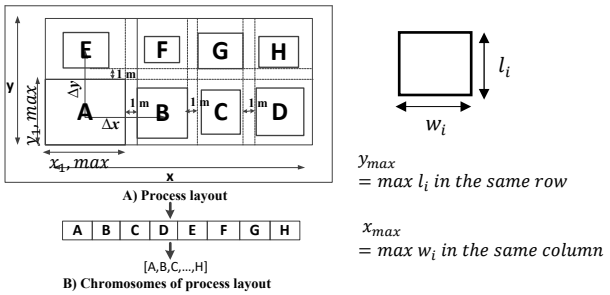

Figure 1: Chromosomes representation.

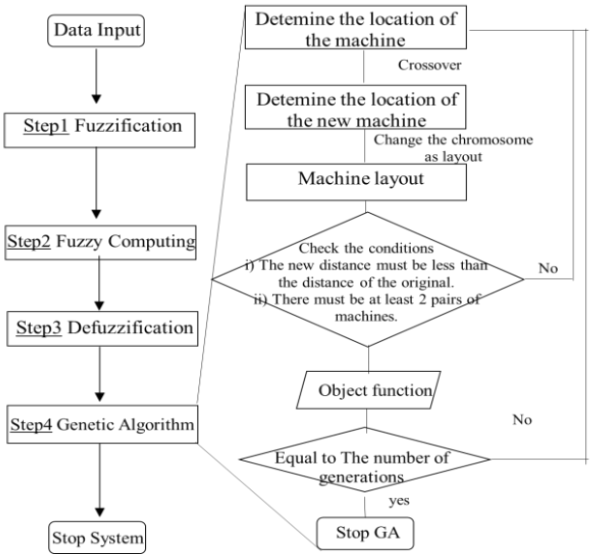

Figure 2: The framework.

2.1. Fuzzy number

Fuzzy numbers are the foundation of fuzzy set theory [2]. They are an extended form of real numbers that do not refer to one single value, but a set of possible crisp numbers. The fuzzy technique is used to represent data with uncertainties.

2.1.1. The shape of membership: Triangular fuzzy numbers (TFNs), graphically represented as Fig. 3, are used in this research. They are suitable because of their computational advantages and commonly used for subjective description [6].

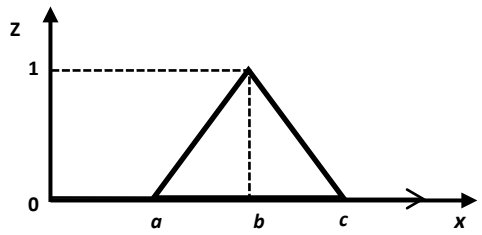

Figure 3: Triangular fuzzy number.

The membership function of a TFN can be explained by:

$\mathbf{Z(x)}$ is the grade of membership,

where $Z(x) > 0$ when $a < x < c$

$Z(x) = 0$ when $x \leq a$ *or* $x \geq c$

$Z(x) = 1$ when $x = b$ *"highest grade of membership at the modal value."*

Therefore,

a = the lowest possible value,

b = the most likely possible value,

c = the highest possible value in the fuzzy set.

2.2.2. Fuzzification: First, it is necessary to convert the input information to fuzzy numbers and calculate them using fuzzy operators. For input data F_{ij} and V_{ij}, the fuzzy sets of F'_{ij} and V'_{ij} are

$$F' = [\mathrm{F_L}, \mathrm{F_M}, \mathrm{F_H}] \quad (6)$$

$$V' = [\mathrm{V_L}, \mathrm{V_M}, \mathrm{V_H}] \quad (7)$$

$\mathrm{F_L}, \mathrm{F_M}$ and $\mathrm{F_H}$ are the lowest, most likely, and highest possible values of the frequency flow and $\mathrm{V_L}, \mathrm{V_M}$ and $\mathrm{V_H}$ are the lowest, most likely and highest possible values of the volume flow, and their grades of membership are between 0 and 1. If, for example, the total material flow frequency of all products is possibly 20 times and the total material flow volume is approximately 5 units each time, the material flow F could be a set of numbers with the most likely value of 18 such as [16, 18, 19] as well as V could be [3, 5, 6].

2.1.3. Fuzzy arithmetic: The operations [32] can be indicated by

Fuzzy addition $\oplus$:

$$\mathrm{F} \oplus \mathrm{V} = [\mathrm{F_L} + \mathrm{V_L} \ , \ \mathrm{F_M} + \mathrm{V_M} \ , \ \mathrm{F_H} + \mathrm{V_H}] \quad (8)$$

Fuzzy multiplication $\otimes$:

$$F \otimes V = [\min(F_L V_L, F_L V_H, F_H V_L, F_H V_H), F_M V_M, \max(F_L V_L, F_L V_H, F_H V_L, F_H V_H)] \quad (9)$$

With the above example values

$$F \otimes V = \begin{bmatrix} \min(16\times 3,\ 16\times 6, 19\times 3,\ 19\times 6), 18\times 5, \\ \max(16\times 3,\ 16\times 6, 19\times 3,\ 19\times 6) \end{bmatrix}$$

$$= \begin{bmatrix} \min(48, 96, 57, 114), 90, \\ \max(48, 96, 57, 114) \end{bmatrix}$$

$$= [48, 90, 114]$$

2.1.4. Defuzzification: Before entering the GA procedure, the fuzzy numbers for the material flow must be changed to crisp numbers using the fuzzy weight method [33].

$$f_{ij} \cong f'_{ij} \quad (10)$$

$$f_{ij} \cong \{[(0.5 \times (a + c)) + b]/2\} \quad (11)$$

therefore, $f_{ij} = \{[(0.5 \times (48 + 114)) + 90]/2\}$

$=85.5$

2.2. Genetic algorithm

The objective function (1) is used in this paper to find the optimum value by applying the genetic algorithm. The suggested GA has been modified from the Simple Genetic Algorithm (SGA) [16]. It begins with an initial set of random solutions for the problem being considered. The set of these alternatives is called the population. The population's individuals are called chromosomes. The objective function evaluates the results from the chromosomes. The chromosomes showing high potential is then carried out to be a part of the new generarion. In the crossover phase, a chromosome is chosen, along with the checking conditions, to produce the offspring. The details follow.

2.2.1. Initialization: GA approach begins with creating an initial population, $\boldsymbol{v}$. In our cases for solving machine layout problems, the genes represent the machines, and the chromosomes are for the layouts. Thus, the initial population can be converted from the "prior to improvement" process layout, see Fig. 1 (B) for an example.

2.2.2. Fitness evaluation: This is the procedure for assessing the chromosome's value. The chromosome that is more likely to be selected for the reproduction process would be selected by taking the proportionate fitness into consideration. The objective function of the fitness function, as presented in (12), can be described by total distance, in order to minimize the total costs of the material handling in the machine design issue.

$$\text{Total distance: } d_{ij} = \sum P_I + P_{II} + \cdots + P_k \quad (12)$$

Every material handling distance of product P is computed from the machine routing when each row or column of the machines is 1 m apart, as shown in Fig. 1. Assuming that there are 3 products required to be manufacture in a plant, as shown in Table 2, thus k=3. The machines have to be arranged on the floor plan to determine the total distance derived for a chromosome. The machines were arranged onto a certain floor area of W × L. The difference between the number of columns and rows of the machines was 1 at most.

2.2.3. Selection: This step decides which chromosomes should be parents in the reproduction process to generate offspring for the next generation.

Tournament selection (TOS): The simple tournament selection method [14] was used in this research. First, it divides the population into groups. Next, in each group, n chromosomes are randomly selected. The next generation of parents shall then be assigned from the chromosomes that make the most efficient solution in their groups. There were 2 groups in a tournament in this work. Each group had 3 chromosomes (n = 3), then the best chromosomes in each group were chosen as the next generation of parents.

2.2.4. Crossover: A new solution, namely offspring, is created by the crossover process. In this work, a crossover point, as shown in Fig. 4, was randomly chosen. After the crossover process, 2 conditions were checked. For condition 1, at least 2 pairs of machines in the chromosome must be operated side-by-side. For condition 2, after simulating the machines onto the shop floor area, and the new distance derived from the offspring must be reduced in comparison to the distance achieved by the layout of the parent.

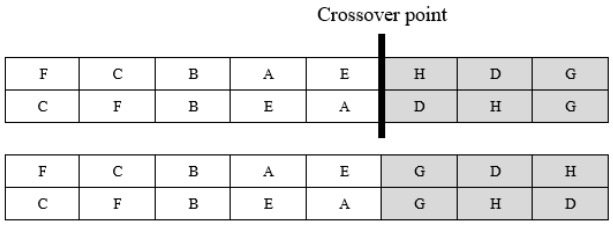

Figure 4: One point crossover process.

2.2.5. Mutation: The mutation process is one in which genes are randomly selected and their positions in the chromosome are swapped to generate additional offspring. It is a traditional step in conventional GA. Kritwattanakorn et al. [27], however, proposed that the mutation should be disregarded in this kind of problem. They have found it produced machines positioned further away while they should be put side by side when considering routing and lastly produced poor outcomes.

2.2.6. Stop: The proposed GA procedure was looped until the given number of generations was met, see Fig. 2.

3. Example

Two layout problems were studied in this research. The details are as follows:

- Case 1: This case uses original information from the manufacture of plywood furniture. There were 3 products and 8 machines in the same shop floor area. Table 2 shows the production routing for each product. Table 3 exhibits the sizes of the machines. The material handling information was initially received as crisp numbers.
- Case 2: This case studied a bus manufacturer. The fuzzy material handling information was given when their

process experts were asked for the values in the fuzzy sets of material flow between machines. There were 12 products and 8 machines. Table 4 shows the production routing of each product, and the machine sizes are shown in Table 5.

Since GA is widely applied for solving machine layout problems, the layouts constructed by different approaches were compared as listed. A summary of GA based approaches is shown in Table 1.

1. Initial layout (unknown approach)
2. SGA [16]
3. Modified GA with RWS and additional conditions (Kritwattanakorn et al. [27])
4. Modified GA with TOS and additional conditions (proposed approach)

Table 1: Summary of GA based approaches.

No	Information	Selection	Crossover	Mutation	Special Conditions
1	Crisp	Unknown (Initial layout)			
2	Crisp	RWS	One point	One point swap	No
3	Crisp	RWS	One point	No	Yes, see 2.2.4
4	Fuzzy	TOS	One point	No	Yes, see 2.2.4

Here the proposed GA approach used Thai Baht (32.50 THB = 1 USD), the number of the initial population, v, was 10, and the number of generations, G, was 100 given to stop the loop. The machine layout design problems were solved using VBA in MS Excel running under Windows 8 OS, on an Intel (R) Core (TM) i7-4500U 1.8GHz Ram 4 GB device.

Table 2: Products and production routing for case 1.

Product	Production Routing

G	1.22	1.25
H	1.20	1.22

4. Results and Discussion

4.1. Case 1: When the level of fuzziness was considered predictable.

In case 1, the costs from layouts exposed by the existing methods including: from the SGA method [16], the adapted GA that applied GA with RWS selection and without mutation [27], and the proposed method in this study using 6 different fuzzy data sets combined with the GA approach (Fig. 5). The case studies used various fuzzy set differences of 0%, 15%, 30%, and 50% fuzziness for the frequency flow and volume flow. The fuzzy set with the difference of 0% represents a crisp number.

A	1.20	1.50
B	1.20	1.50
C	1.70	1.50
D	1.20	1.40
E	1.50	1.20
F	1.30	6.00
G	1.20	1.00
H	3.50	2.00

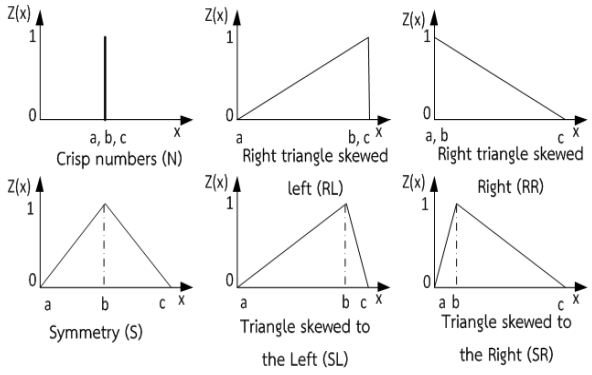

Figure 5: Data sets representing fuzzy numbers.

The results in Fig. 6 show that the total costs vary if the input information is uncertain or fuzzy. If there is the high difference between the lowest and highest possible values, the total costs increase or decrease considerably, such as for the right triangle skewed right (RR), the highest possible value gives a high total cost, but the lowest possible value gives a low total cost. The costs increase or decrease depending on the nature of the skew. If the input information is skewed fully to one side (such as RR and SR), it is likely to make the total costs higher, but if the input is skewed to the minimal side (such as RL and SL), it shows the opposite impact.

Table 6: Results of case 1 with different fuzzy types.

Difference	Fuzzy Type	F', V'	Total Cost (USD)
0% [a]	N	[20, 20, 20], [5, 5, 5]	914.46
15%	S	[18, 20, 22], [4, 5, 6]	923.61
	RL	[17, 20, 20], [4, 5, 5]	841.30
	RR	[20, 20, 23], [5, 5, 6]	1,001.34
	SL	[18, 20, 21], [4, 5, 5]	861.88
	SR	[19, 20, 22], [5, 5, 6]	976.19
30%	S	[17, 20, 23], [4, 5, 6]	955.61
	RL	[14, 20, 20], [3, 5, 5]	781.86
	RR	[20, 20, 26], [5, 5, 7]	1,101.93
	SL	[16, 20, 22], [3, 5, 6]	868.74
	SR	[18, 20, 24], [4, 5, 7]	1,005.91
50%	S	[15, 20, 25], [3, 5, 7]	960.18
	RL	[10, 20, 20], [2, 5, 5]	731.57
	RR	[20, 20, 30], [5, 5, 8]	1,234.52
	SL	[13, 20, 23], [2, 5, 7]	884.74
	SR	[17, 20, 27], [3, 5, 8]	1,067.63

a. Crisp number

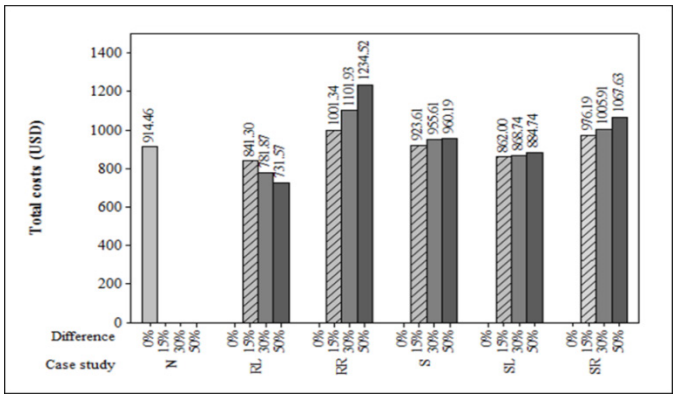

Figure 6: The relationship between various fuzzy data sets and the total cost.

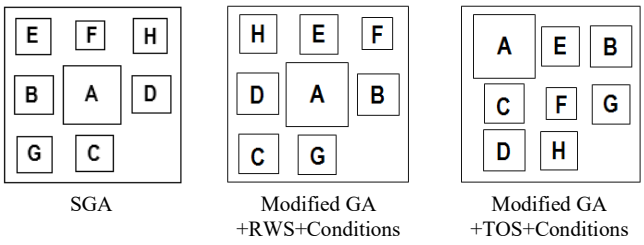


From the findings of this case, it can be seen that the suggested technique shows total costs that increase or decrease depending on the flow of the material handling system in the production. These findings agree with the existing research works [9-12] that information is essential for making a decision on layout planning and design, and fuzzy sets is an appropriate idea in dealing with imprecise information [25, 26].

Table 6 shows the outcomes of the 4 different methods and their layouts for the machines are shown in Fig. 7. Table 6 demonstrates the results of total costs and distances. Before arranging the layout, the total cost initially was 1,179 USD and the total distance was 38.45. The proposed method with a different variation of 15% in fuzzy data input (due to natural associated vagueness) has a total cost of 923.61 USD and a total distance of 29.72 m. It can reduce the total cost by 21.66% and the distance by 22.71%. Both the traditional GA (SGA) method [16] and the Kritwattanakorn et al. method [27] give total costs and distances greater than the proposed method.

Table 7: Comparison of the different approaches in case 1.

Approach	Total cost (USD)	Total Distance (m)
Unknown (initial layout)	1,179.00	38.45
SGA	1,060.92	34.48
Modified GA+RWS+Conditions	978.46	31.80
Modified GA+TOS+Conditions *	923.61	29.72

* Fuzziness at 15 % difference

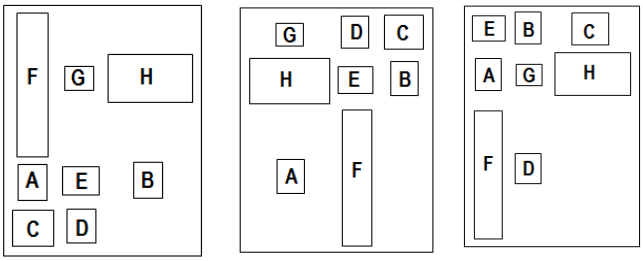
SGA | Modified GA +RWS+Conditions | Modified GA +TOS+Conditions

Figure 7: Layouts of machines obtained using different methods for case 1.

4.2. Case 2: When the level of fuzziness was extremely vague.

In fact, the shape of fuzzy sets might not be specific. This study used a bus manufacturer as an example. They are a family run business. Machines were laid out based on the experience of the systems expert, not an analysis of manufacturing data. Table 8 shows the frequency and volume of material transport between machines, by letting the expert respond what were the minimum, modal, and maximum values, as for the machine layout design input.

Table 8: Fuzzy data input of case 2.



Machine	Frequency flow (F')	Volume flow (V')
M1-M5	[3, 10, 16]	[5, 16, 22]
M1-M6	[6, 8, 14]	[7, 10, 24]
M1-M7	[3, 4, 7]	[8, 12, 18]
M2-M3	[1, 1, 1]	[0, 2, 2]
M2-M4	[3, 6, 8]	[6, 8, 14]
M2-M5	[2, 2, 4]	[7, 8, 13]
M2-M8	[1, 3, 4]	[1, 2, 2]
M5-M3	[3, 6, 8]	[6, 8, 14]
M5-M6	[2, 2, 5]	[6, 11, 15]
M7-M8	[2, 2, 2]	[3, 4, 6]

Table 9 shows the results that the totals cost of material handling can be considerably lowered. The costs generated from the layouts obtained from the method described in this paper were compared competitively with the initial machine layout and 2 existing methods. The machine layouts can be seen in Fig. 8. Table 9 compares the approaches. The total cost and the total distance before arranging being 84.22 USD and 103.10 m, respectively. The proposed method, with fuzzy data input acknowledged from the product experts, has a total cost and distance of 66.40 USD and 82.45 m, correspondingly. The total cost and distance can be reduced by 21.16% and 20.03%.

Even if the total cost obtained from the proposed method was higher than SGA [16] and the method with RWS (Kritwattanakorn et al. method [27]), the total distance was the shortest. This emphasizes the effect of fuzziness of information on decision making. More attention should be paid to uncertainties of data.

Table 9: Comparison of the different approaches in case 2

Approach	Total cost (USD)	Total Distance (m)
Unknown (initial layout)	84.22	103.10
SGA	48.56	92.40
Modified GA+RWS+Conditions	41.24	90.25
Modified GA+TOS+Conditions	66.40	82.45

SGA | Modified GA+RWS+Conditions | Modified GA+TOS+Conditions

Figure 8: Layouts of machines obtained using different methiods for case 2.

5. Conclusion

Acknowledgment

ABSTRACT

Due to the recent development of information and communication technology, such as sensor technology, IoT technology, and smart technology, interest in maker education is increasing. Maker education offers students experience-based education that allows them to make their own results, giving them various interests and motivations. Recently, various research results on maker education have been under way. However, there is little research work on the teaching aids selection criteria for maker education. The purpose of this study is to justify the teaching aids selection standards that are developed in the previous research works. In the previous research work, 14 selection standards were developed in a total of eight areas. In this work, through rigorous statistical analysis, justification of the 14 standards are verified. The findings are expected to help a lot in future policy proposals and related research on maker education.

1. Introduction

This paper is an extension of work originally presented in ICTC2018[1].

Various changes are taking place throughout the industry following the recent advent of the 4th industrial revolution era. Information-oriented industries are emerging at the forefront of the industry in the existing product-oriented manufacturing industry structure. The changes are prompting the acceleration of the modern knowledge and information society, calling for, among other things, interest in and understanding of the information-oriented society.

This change in the industrial structure also calls for many changes in public education in schools. In particular, interest in information education such as information collection, analysis, and processing is increasing in schools as the knowledge and information society accelerates. Information education is evolving into a software education form, especially from Information and Communication Technology Education, which started from 2000 in Korea. While the human image sought in ICT education was the core part of a computer-savvy user, the human image sought by the government in 2015 became the producer or manufacturer who could actually make software [2].

Maker education began in the early 2000s with the U.S. as the Do-It-Yourself Movement [3]. The DIY movement aimed to produce and use the necessary items in everyday life and also to share the necessary processes and products with each other. The DIY movement evolved into the Maker Movement, which, combined with the Maker Space, was ultimately born into Maker Education [4].

Meanwhile, according to [5], maker education was defined as follows by relating it to information education (or software education). In [5], maker education is a new type of educational paradigm to foster so-called "maker geeks" who can create things themselves. In other words, what students have imagined autonomously is produced directly using digital devices. It was also defined as process-oriented project education rather than the results that lead to the sharing of knowledge and experience learned in this process.

Maker education is in the spotlight as an experience-type education that can increase students' interest and motivation for learning. It is also receiving attention at the schools in a typical form of convergence education, combined with various subjects, such as science and practical subjects. In addition, various forms of hands-on exhibitions and contests are attracting interest from students and parents, and teachers are given various training opportunities to encourage interest in maker education.

Along with the spread of maker education, academic research is under way on various maker education. However, in order to carry out actual maker education on the schools, there is a lack of standards on how to choose teaching aids, which is the core of the maker education, among other things Generally, teaching aids are

*Corresponding Author: Woochun Jun, Seocho Dong, Seocho Gu, Seoul, Korea, wocjun@snue.ac.kr

tools used in class activity. The typical teaching aids in class are scissors, colored paper, glue, and so on. In maker education, the typical teaching aids includes 3D printers, 3D pens, cutting tool, sewing machine, and so on. Teaching aids are either raw materials or making tools like a machine tool. In maker education, teaching aids are essential for class activity. Thus, choosing right teaching aids in maker education is very important in successful class.

The purpose of this study is to justify teaching aids selection standards that are developed in the previous research works. That is, for those 14 selection standards, rigorous statistical work is done and selection standards are proved to be useful in schools.

The rest of this paper is as follows. First, in Chapter 2, related works are presented. In Chapter 3, the existing 14 selection standards are introduced. In Chapter 4, statistical analysis is presented for selection standards. Finally, in Chapter 5, conclusions and further research issues will be discussed.

2. Related Works

This chapter presents an overall relevant study of maker education. First, the typical characteristics of maker education can be summarized as follows [6].

First, knowledge can be organized through interaction with objects or people through direct-creating activities. In addition, outputs created directly by learners can induce social participation through various sharing, thereby providing a meeting place for various participants to communicate together through common tasks.

Second, it can provide self-directed and cooperative learning. Makers are engaged in maker activities, choosing their own themes from areas of personal interest and social issues. In addition, working on cooperative projects can lead to mutual respect and communication through cooperative learning.

Third, it provides an environment for making activities. In other words, the maker education will require a maker space for direct production activities and a variety of teaching aids and materials. The maker space needs an environment with the tools needed for the maker's activities.

Fourth, maker education requires a position as an inventor and creator as a learner. In other words, students go through the process of choosing their own themes through making activities. Through this process, learners experience creative problem solving.

Fifth, in maker education, a teacher will act as a helper. Maker activities are basically activities that can improve students' creative thinking and problem-solving skills. In addition, since students decide on their own topics, tools, methods, etc., they should provide a free learning environment and a free environment for evaluation regardless of the outcome's success or failure. Therefore, a teacher's role should be a learning guide or facilitator.

Sixth, students can start with personal participation in maker education and continue with social participation. This is because the maker education can share and open information with other learners through personal problem solving, starting from social issues and creating experiences, and to see if personal and social problems can be solved through product sharing.

On the other hand, a recent study by [7] developed and presented a measure of the ability of making as part of the software coding- based maker education program for scientific gifted children. The Matching Capacity Scale means the competency that students who participate in the maker education should have, and the makeup competency measures presented in [7] are as follows. Overall, the making capabilities comprise three core competences: analysis capabilities, design capabilities, and implementation capabilities. Specifically, analysis capability refers to the ability to collect data and analyze problems, and design capability corresponds to the ability to generate and refine ideas for problem resolution, and to come up with solutions through sharing ideas. Finally, implementation capability refers to the ability to select a tool for problem solving, generate results through active participation and evaluate results. The three core competences were divided into more detailed sections to provide specific capabilities.

Table 1. The Original Selection Standards

Number	Standard	Detailed Criteria
1	Safety	-There should be no risk of safety accidents. -Material that can be harmful to health should not be used
2	Subject Compatibility	-It should be available for various educational activities -It should be possible to integrate with other teaching materials and learning materials.
3	Multi-purpose	-The teaching aids must support various functions through the connection of built-in or additional parts.
4	Ease of Manipulation	-(Teacher) It should be easy to use in class by simple training. -(Student) It should be easy to use after simple teaching and learning about how to use.
5	Economics	-It should be easy to buy within budget items of the school. -Parts can be easily procured within reasonable time and price.
6	Universal Design	-It should be designed for the older, people with mental and physical disabilities. -It should provide alternative functions for main functions
7	Gender Equality	-It should be used regardless of gender.
8	Durability	-Failure or breakage should not occur even if students repeatedly use. -It should be able to withstand the minor impact (collision, drop, etc.) that occurs between educational activities.

3. Development of Teaching Aids Selection Standards

3.1 Design Principles

The selection standards for teaching aids in maker education are developed through the following principles [1].

First, it is in line with the general teaching aids selection criteria used in primary and secondary schools. That is because the teaching aids used in maker education are essentially one of the teaching aids.

Second, it is based on the selection criteria for the physical computing education, which is mainly used in recent software education.

Third, the universal design principle is adopted so that it can be used by anyone. In other words, care is taken to make it easier for anyone, regardless of age, gender, age, ordisability.

3.2 The Original Selection Standards

In [1], the original selection standards of teaching aids in maker education are proposed. The following table 1 show the initial standards.

4 Statistical Analysis

4.1 Design of Analysis

Verification of the reliability of the tool to measure the importance of teaching aids selection standards in maker education showed that Cronbach α was 0.77 and was reliable, as shown in Table 2.

Table 2. Reliability of Measurement Tool

Item Number	Cronbach's α
14	0.77

The data gathered in this work were analyzed using the Statistical Package for the Social Science (SPSS) WIN 25.0 program. Cronbach α is used to verify the reliability of the measuring tool. In addition, the average and standard deviation were calculated in order to find out the importance of the selection standards in maker education, and the correlation analysis was conducted to understand the relationship between the sub-areas of selection standards and selection standard in maker education.

4.2 Analysis Results

-Descriptive Statistics

The average and standard deviation of questions asked about the importance of teaching aids selection standards in maker education are as shown in Table 3.

4.3 Sub-area of Descriptive Statistics

According to the results of the review of the average and standard deviation in the sub-areas of teaching aids selection standards in maker education are shown in table 4. The average importance of the selection standards for the teaching aids in maker education was 4.13, and the selection standards for the teaching aids were important.

Among the sub-areas of the standards for selection standards for teaching aids, “safety” 4.84, followed by "ease of manipulation" 4.52, "durability" 4.30, "economics" 4.28,"subject compatibility" 4.05, "gender equality" 4.00 and "multi-purpose" 3.78, with the lowest "universal design."

As above, it is shown that “safety” is the highest in the sub-areas of the teaching aids selection standards in maker education, and that “universal design” is less important than other areas.

Table 3. Results of Descriptive Statistics

Standard	AVG	SD
1. There should be no risk of safety accidents.	4.84	0.37
2. Material that can be harmful to health should not be used.	4.84	0.37
3. It should be available for various educational activities	4.13	0.91
4. It should be possible to integrate with other teaching materials and learning materials.	3.97	0.82
5. The teaching aids must support various functions through the connection of built-in or additional parts.	3.78	0.94
6. (Teacher) It should be easy to use in class by simple training.	4.41	0.80
7. (Student) It should be easy to use after simple teaching and learning about how to use.	4.63	0.61
8. It should be easy to buy within budget items of the school.	4.38	0.66
9. Parts can be easily procured within reasonable time and price.	4.19	0.86
10. It should be designed for the older, people with mental and physical disabilities.	3.06	1.16
11. It should provide alternative functions for main functions	3.00	1.14
12. It should be used regardless of gender.	4.00	1.19
13. Failure or breakage should not occur even if students repeatedly use.	4.28	0.85
14. It should be able to withstand the minor impact (collision, drop, etc.) that occurs between educational activities.	4.31	0.69

Where AVG and SD stand for average and standard deviation, respectively.

4.4 Correlation Analysis

The results of a review of the correlation between the sub-areas of the standards for teaching aids selection standards in maker education and the whole teaching aids selection standards in maker education are shown in Table 5.

Safety (r=.455; p<.01) and subject compatibility (r=.627, p<.001), multi-purpose (r=.548, p<.01), ease of manipulation (r=.391, p<.05), economics (r=.534, p<.01), universal design (r=.725, p<.001), gender equality (r=.824, p<.001), and durability (r=.453, p<.01) showed a statistically significant static correlation with the importance of the standards for teaching aids selection

standards in maker education. Therefore, the higher importance of safety and subject compatibility, multi-purpose, ease of manipulation, economics, universal design, gender equality, and durability of the standards for teaching aids selection standards in maker education, the higher importance of the standards for teaching aids selection standards in maker education.

Table 4. Results of Descriptive Statistics of Sub-area

Evaluation Standard Area	AVG.	SD
Safety	4.84	0.27
Subject Compatibility	4.05	0.73
Multi-purpose	3.78	0.94
Ease of Manipulation	4.52	0.63
Economics	4.28	0.61
Universal Design	3.03	1.07
Gender Equality	4.00	1.19
Durability	4.30	0.69
Overall Selection Standards	4.13	0.43

where AVG and SD stand for average and standard deviation, respectively.

5 Conclusions and Further Research Issues

Along with the development of various information and communication technologies and smart technologies, maker education is receiving attention at schools due to the increase in the number of available teaching aids at schools. Maker education is an experience-based education in which students directly participate in designing and analyzing the work they want to produce, and finally participate in production, which has the advantage of generating interest and motivation for students. Maker education is also very popular as a project-oriented cooperative study because teachers and students can participate and discuss the entire process of producing works together.

The role of the teaching aids in maker education is very important and the interest and academic performance of students in the whole class, depending on how they choose the teaching aids, also affects safety issues. However, there has been no standardized research or guideline on the standards for teaching aids selection standards in maker education.

The purpose of this study is to justify the teaching aids selection standards that are developed and proposed. In the previous research, 14 selection standards are developed and analyzed statistically. In this research, with more rigorous statistical analysis, the justification of the results is verified.

The immediate further research issues are as follows. At first, it is necessary to present more detailed selection standards depending on tools of maker education such as 3D printer. Also, it is also necessary to present more integrated and extensive selection standards for both maker education and software education. This is because there is no clear limit between maker education and software education.

Conflict of Interest

The authors declare no conflict of interest.

The Detailed Value Chain Model
The Elementary Management Cycle
Educational domain knowledge content

ABSTRACT

The aim of this paper is to develop the educational domain management knowledge content identification and knowledge updating method, based on formal descriptions of enterprise management information interactions. This is very important because the progress of modern science leads to the emergence of new factual or conceptual knowledge. There is a need for proper methods that allow, first, to study and make decisions regarding the relevance of the content, and then take practical steps on the content and possibly of the corresponding structure adaptation. The authors suggest a systematic solution for this problem. The hierarchical Detailed Value Chain Model and Elementary Management Cycle model of educational domain knowledge content identification and updating is formally described, computerized process measures are proposed. The paper provides a method for updating the knowledge of the analyzed domain, referred to as "enterprise domain", based on enterprise modelling in terms of management information interactions. A method, whose formal DVCM and EMC descriptions are provided in BPMN notation, was designed, allowing to develop a two-level (granular) model for describing knowledge of educational domain management information interactions. In implementing this model and its algorithms in technological terms, a subsystem of enterprise knowledge has been created in a knowledge-based CASE system (computerized knowledge-based IS engineering), performing the function of a domain knowledge database.

1. Introduction

This paper is an extension of work originally presented in 2018 2nd International Symposium on Multidisciplinary Studies and Innovative Technologies (ISMSIT) [1].

Meeting modern, constantly evolving educational enterprise needs requires enterprise integration with information technologies and computerized information systems (IS) that would be able to adapt to organizations' enterprise changes. In the context of this paper enterprise is understood as a educational institution.

Among different IS development approaches one of the most promising is model-driven approach, which aims to utilize formal domain knowledge to perform, adjust and manage and engineering process. One of the earliest stages of IS development life-cycle is enterprise modelling, which becomes especially important in applying model-driven IS development methodology (MDE – Model Driven Engineering) and its methods [2]. The aim of enterprise modelling is to create an enterprise model of an

[*]Jurij Tekutov, Email: jurij.tekutov@yahoo.com

organization, which would help to deal with issues of an analysed domain. The concept of Model Driven Architecture (MDA) defines IS development process as a three-level model (CIM – the Computation Independent Model, PIM – the Platform Independent Model, PSM – the Platform Specific Model) interaction, whose purpose is to directly link enterprise modelling and further stages of IS analysis, design and implementation. Thus, from enterprise modelling professionals' point of view MDA concept [3, 4] should be thought of as an effort to integrate enterprise modelling methods with full life-cycle Computer-Aided Systems Engineering (CASE) technologies characterized by the bottom-up approach, i.e. from engineering methods to enterprise modelling methods for IS engineering needs. Hence, modern IS development methodologies pay increasingly more attention not only (and not as much) to software and IS engineering methods, but rather organizations' enterprise modelling issues, i.e. domain knowledge mapping.

IS engineering methods (IS life-cycle stage models) based on intra-enterprise engineering, the basis of which is subject area (domain) pattern model, are called knowledge-based methods [5]. The purpose of MDE-based computerized IS engineering enterprise model is to systematize and formalize knowledge on a certain analysed domain (subject area). IS engineering methods are emerging that seek to integrate knowledge about operational functions, processes, rules in CASE systems and use them in intellectualizing IS development process. There have also been attempts to apply domain knowledge content creation and updating methods [6] from similar areas, such as e-learning, Business Intelligence systems [7, 8], business rule modelling [9].

The analysis of IS engineering stages (1. traditional IS engineering, 2. computerised software engineering, 3. computerised IS engineering (including enterprise modelling), 4. knowledge-based IS engineering) reveals the key features of the variations in the IS engineering process (methods, knowledge sources, software types). Hence, it enables to define the key characteristics of the knowledge-based IS engineering methodology and the composition of the basic components. In traditional computerized IS engineering a system is created empirically, by first collecting, analysing and specifying consumer needs. Works linked to knowledge-based IS development allow to take software development to a higher level of abstraction, partly automate these processes and use the models in other systems. Business activity modelling, the improvement of knowledge formalization and the application of the conceptual modelling in developing the IS are the key things for the further development of the IS engineering methods. In knowledge-based computerized IS engineering a system is created using an enterprise knowledge base and domain knowledge stored in it. It is believed that the main characteristic of knowledge-based IS engineering is a subsystem of domain knowledge, which is based on an organization's enterprise model and is designed to acquire knowledge on a computerized domain. Such knowledge acquisition subsystem should perform the functions of a storage of domain knowledge, required for the creation of IS project models. The following structure for a subsystem was proposed: enterprise model and enterprise metamodel (formalized enterprise management knowledge structure).

Domain knowledge acquisition subsystem should become the essential component of a knowledge-based CASE measure, intellectualizing the whole process of IS development. The creation of such subsystem is one of the most urgent scientific problems addressed in this paper. The development of knowledge-based IS engineering methods requires an internal approach to business process modelling, which should be based on the internal business process logic – the causal links between business processes, i.e. necessary and sufficient components of activity elements and interactions between them (the activity goals of material processes, information processes and structural information units). Therefore, the above-mentioned diagram shows the managerial information exchange (in proposed modified Value Chain Model).

In our previous works it was proposed that the development of these systems should be performed by focusing on Value Chain Model (VCM) [10], since computerization involves enterprise management functions and processes, as well as interactions between organization's functional areas, which are revealed by the VCM. In computerizing enterprise, a research of informational interactions between enterprise management functions and processes is performed, requiring further decomposition of value chain elements, i.e. further VCM modification is performed [11], a Detailed Value Chain Model (DVCM) is created. Hence, knowledge-based IS development is based on knowledge on enterprise management, which defines fundamental attributes of enterprise management information interactions. In previous work [12] was shown the enterprise management information interaction is specified as an Elementary Management Cycle (EMC), linking enterprise management function and process by a feedback loop. The novelty of the work is the application of the expanded VCM and the EMC to manage operational knowledge; after defining the assessment criteria, such management model allows to objectively assess and constantly improve the knowledge content of the subject area.

This paper elaborates a proposed domain management knowledge modelling method, which is based on formal DVCM and EMC descriptions presented in a BPMN notation. Educational domain has been chosen intentionally, on the basis of methodological terms. In academic field IS development typically starts with enterprise management function analysis, in which enterprise management information interactions are important. The analysed higher education study domain is multivariate, dynamic and requires constant knowledge content updating. Only by actualizing study programme structure and knowledge content in a timely manner is it possible to properly take into account changing needs and requirements from all stakeholders.

This paper is devoted to the actual topic of modern university management. Improving the quality of higher education and the corresponding management approaches are very important. The authors propose to apply the proven methods of enterprise management. This is a very promising decision, because, firstly, such business-oriented models have proven their effectiveness, and then such models are focused on practical solutions.

Previous works. One of the pioneers of analysing study programme development as an IS engineering process were MOCURIS – Modern Curriculum Development in Information Systems at Master Level project promoters, who offered in their works a model study programme design method [13]. They have

introduced the notion of study programme engineering, defined study programme architecture and by analyzing a study programme as a system of courses and modules, they have applied the standard IS engineering process to develop a Master‘s study programme. Using this method, a large IS-related Master's programme specification document was created, which would act as a guideline for developers of certain programmes, courses and modules. However, already in the project fundamental flaws of this method became evident. Such programme development process could only be effectively implemented by the authors, meanwhile, the resultant artefact (textual specifications document) because of its technicality, complexity and size was unsuitable to perform the main function of requirement specification which is to ensure communication of all process participants and coordinate their work. After analysing requirement identification, localization and specification (granularity) issues, it was found that these limitations are inherent in traditional non-automated requirement engineering processes. Therefore, other researchers (including the authors of this paper) have suggested to automate this process by creating a study programme requirement engineering system on the basis of CASE measures [14]. With a direct involvement of the authors, such a system has been created and applied for the development of new study programmes [15, 16]. However, in a fast changing environment timely study programme modernization, quality assurance and knowledge content updating become especially relevant. It all requires effective feedback from all stakeholders. To solve the issues mentioned in this paper, a DVCM has been used, ensuring constant information feedback, which sends descriptive data (attributes) to the enterprise management function and retrieves management decisions to direct enterprise process. The method is implemented by creating an enterprise knowledge database in IS engineering CASE system, which is designed on the basis of a computerized educational domain enterprise model.

The creation of knowledge content specification includes the collection of domain knowledge, its preparation and analysis, verification and validation. In this paper domain knowledge is understood as a dynamic set of knowledge attributes, described according to requirements as a system of facts, principles and theories related to a specific professional activity. In other words, knowledge attribute set is an expression of a domain in current context. Enterprise modelling can be assigned to requirement collection and analysis stage. Then enterprise models are transformed into requirement specification for the system being

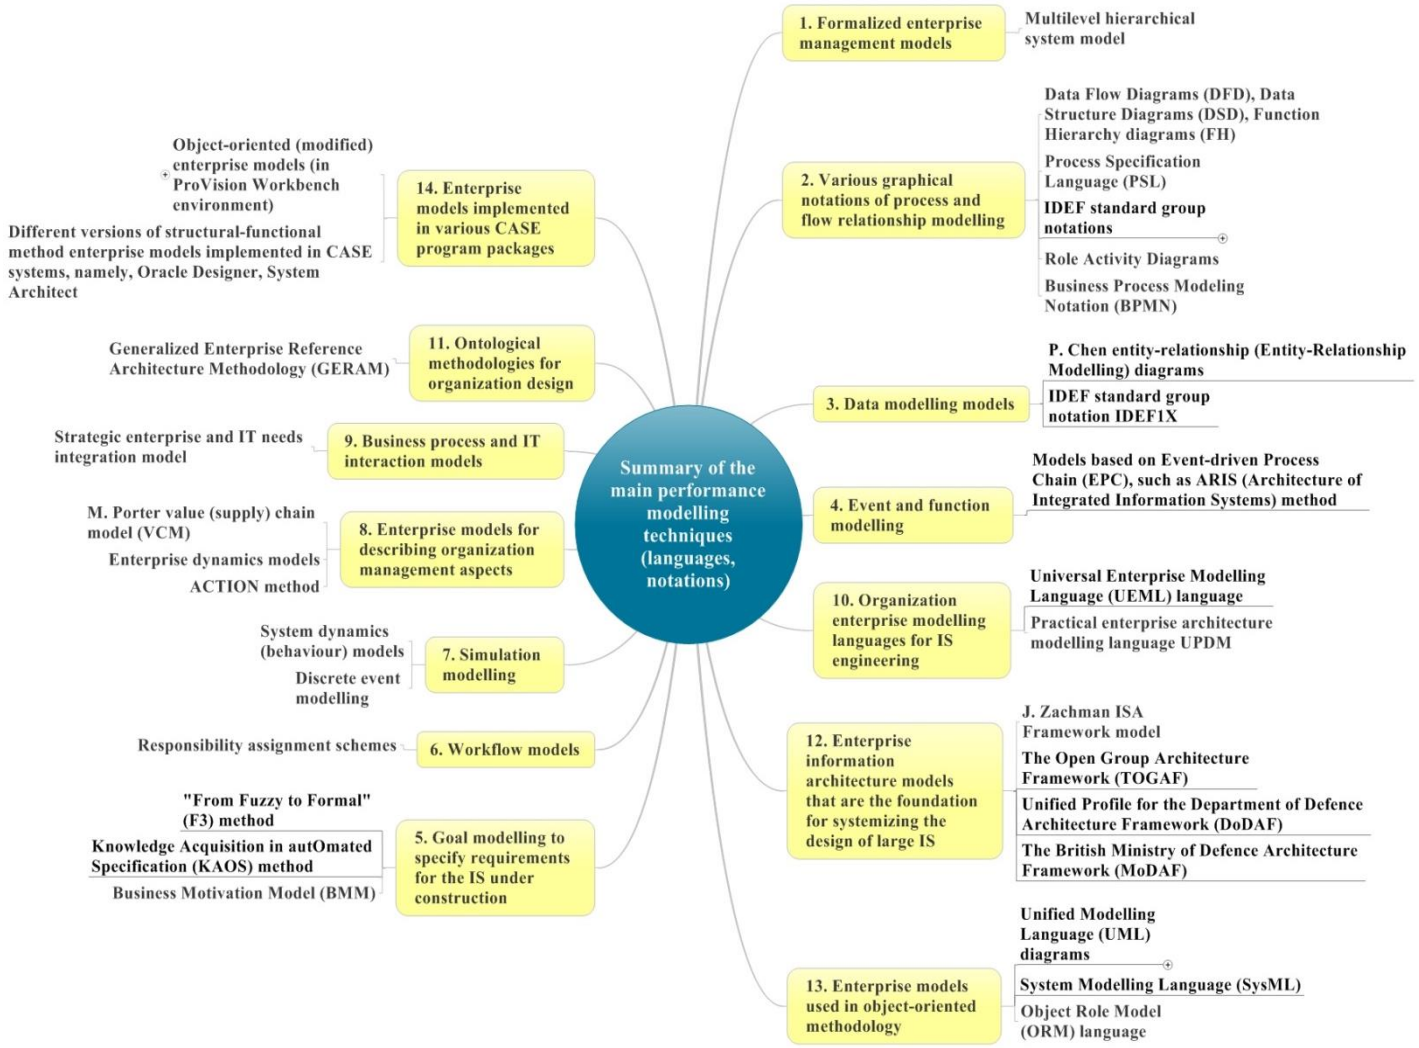

Figure 1. Concept map of enterprise modelling techniques (languages, notations) (using *Mindjet MindManager Pro™* tool)

developed. Systems (for example, domain knowledge content) and separate component specifications are produced during IS engineering process. The most important step in every effective domain knowledge management process is the writing down of the requirements identified during the selection. It helps to ensure accurate communication and management of the requirements during their development. Documents are an understandable form for requirement recording. These documents provide a basis for context identification and requirement collection, yet are not very useful in supplementing and modifying requirement information.

The main aim of this paper is to develop the educational domain management knowledge content identification and knowledge updating method, based on formal descriptions of enterprise management information interactions.

The remainder of the paper is structured as follows: Section 2 reviews domain modelling methods in terms of knowledge content modelling. Section 3 introduces the created educational domain management knowledge modelling method, based on enterprise management information interactions. The application of a Detailed Value Chain and Elementary Management Cycle model for knowledge content description and updating is demonstrated. The created educational domain management knowledge content identification and knowledge updating computerized process model are laid out in Section 4.

2. The Analysis of Current Domain Modelling Methods in Terms of Knowledge Content Modelling

Due to the fact that many new enterprise modelling approaches, methodologies and methods were recently created, a separate research area has occurred, called enterprise modelling.

Therefore, there is a need to systematize the variety of these methods in order to select the most convenient way of modelling management activities. To facilitate this selection a concept map of different enterprise modelling techniques (languages, notations) [17-23] was designed (Figure 1).

Enterprise models are divided into the following categories: business process models, data flow models, data models, business objective models, control flow models, management process models, knowledge management processes [24]. Widely known enterprise modelling methods are structural-functional modelling (Data Flow Diagrams or DFD), business process modelling languages, BPMN (Business Process Modeling) notation, IDEF (Integration of computer aided manufacturing DEFinition) set of standards and enterprise modelling language UEML (Unified Enterprise Modelling Language), and business architecture modelling language UPDM (The Unified Profile for DoDAF/MODAF). Well known enterprise modelling methodologies and standards are CIMOSA, GERA, EPC, DoDAF, MODAF, MDA [23]. However, amongst them one can rarely find those that would model enterprise in terms of management, i.e. performance management information components and their interactions.

When comparing modern enterprise modelling methods (languages, notations), it is becoming clearer that enterprise modelling needs to have capable methodologies because it has to be ensured that all necessary structures can be modelled. For this purpose, the above mentioned concept map can be used, that shows primary and systematized information and provides references to all other required sources of domain modelling methodologies. When analysing known enterprise modelling methods (notations, languages) in terms of domain management, it is becoming clearer that only a few methods can actually evaluate management information interactions that are necessary to manage domain from a theoretical perspective.

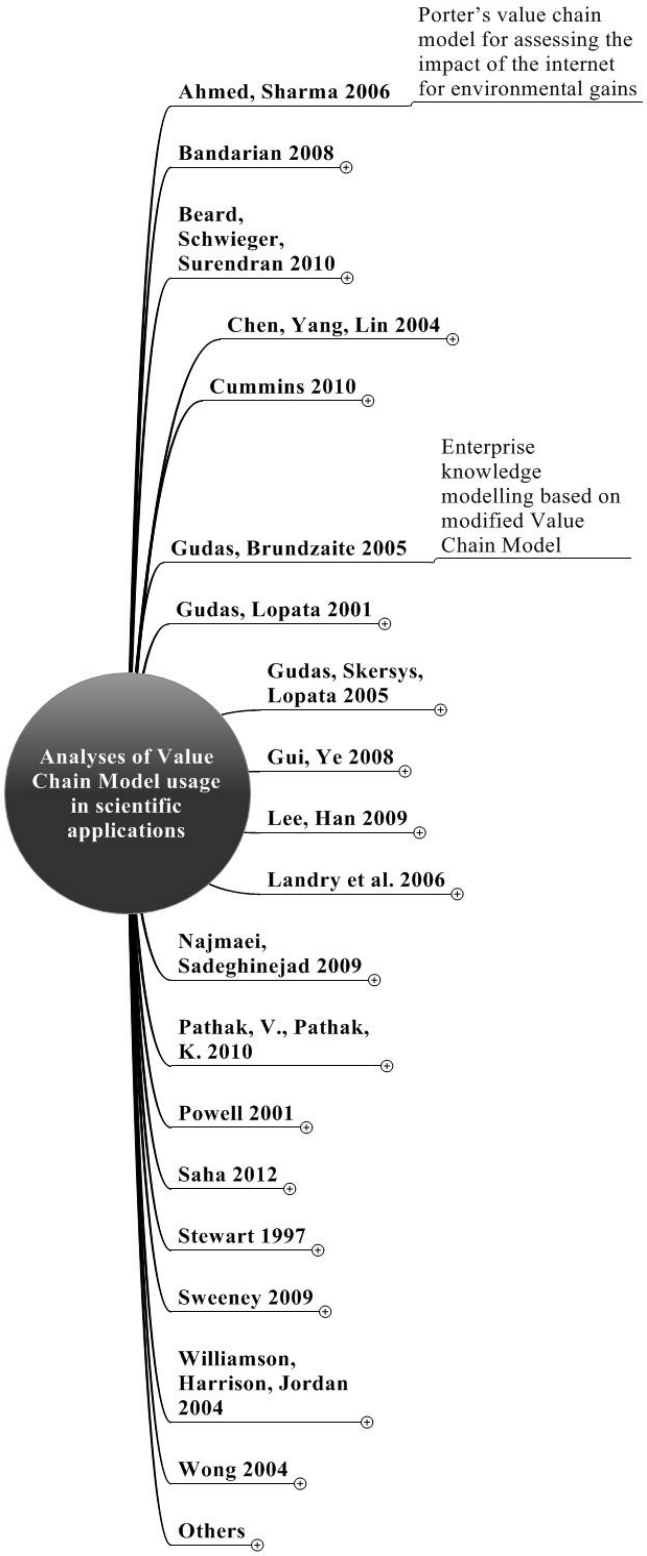

Figure 2. Conceptual map of Value Chain Model in scientific applications

In organizational management practice Value Chain Model (herein referred to as VCM), created by Porter, is popular and has been used in many works (Figure 2) [26-42].

The concept map (Fig. 2) illustrates examples of the application of VCM in scientific research (other examples of the analysis can be accessed by clicking on the plus sign in the concept map in Mindjet MindManager™ environment): Porter's value chain model for assessing the impact of the internet for environmental gains [26]; Enterprise knowledge modelling based on modified Value Chain Model [40]; others.

The structured DVCM is used to identify the information transactions between Management Functions and Enterprise Processes. Detailed Value Chain Model (DVCM) embodies a procedural approach to enterprise consisting of: primary activities (operational processes) and support activities (operational functions). The formal description of DVCM is as follows:

$$DVCM = \{(Fi) x (Pj)\} \quad (1)$$

Where: (F1,…, Fi,…., Fn) – a set of Enterprise Management Functions, (P1,…, Pj,…., Pm) – a set of Enterprise Processes, x – relationship between a set of Management Functions {F} and a set of Enterprise Processes {P} (management information transactions $(Fi \times Pj)$.

The interrelationship between primary and secondary business processes explored in Gudas, Lopata [43] identified a different nature of these 2 enterprise activities: secondary processes possess informational nature and are referred to as enterprise (management) Functions; while primary processes are concrete (non-informational) and are named enterprise (material) Processes. This paper presents more detailed content of Function Fi since it defines a sequence of definite types of interacting information activities directed to control Process Pj.

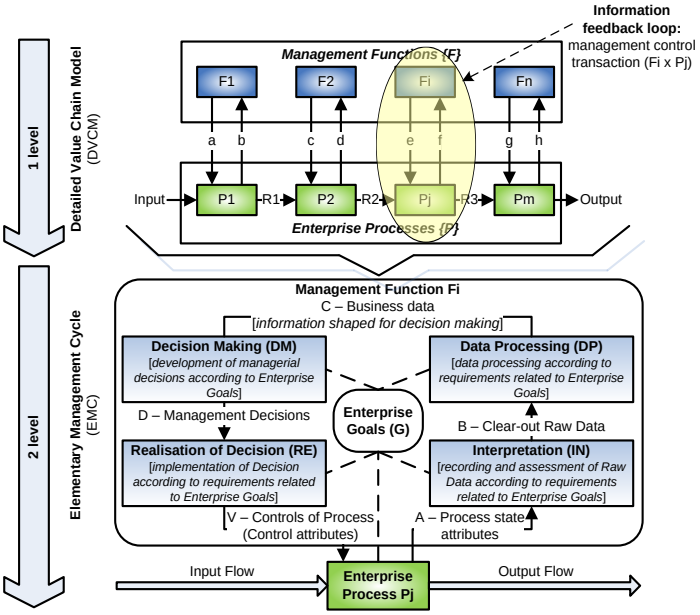

Figure 3. The formalized model of the interaction between the Function Fi and Process Pj (Elementary Management Cycle – EMC) in modified (structured) DVCM

In brief, the concept of EMC is a formalized description of the Enterprise management control as the interaction between the Function and the Process – as two core components of enterprise from the control point of view. On the basis of these findings, the Value Chain Model is modified. The decomposition of the information interactions $(Fi \times Pj)$ in the DVCM between the Management Function Fi and Enterprise Process Pj is defined as Elementary Management Cycle (EMC) on the lower level in Figure 3. The interaction between the core elements a Function and a Process is formally assumed as a Control Process with the Feedback Loop between the Function Fi and the Process Pj. The two levels of granularity: 1) the Detailed VCM (DVCM) and 2) the Elementary Management Cycle (EMC).

A detailed model of the informational interactions between the Function Fi and Process Pj can be defined by:

$$EMC(Fi,Pj) = \begin{pmatrix} Pj(A,G) \rightarrow IN(A,B,G) \rightarrow P(B,C,G) \rightarrow \\ M(C,D,G) \rightarrow RE(D,V,G) \rightarrow Pj(V,G) \end{pmatrix} \quad (2)$$

Where A – state attributes of the process Pj, needed in terms of G; B – systemized (interpreted) primary data, needed for the enterprise management function Fi in terms of G; C – enterprise data, formed by data processing DP, prepared for decision making DM and needed in terms of G; D – goal-congruent management decision formed by the decision making process DM; V – goal-congruent effects of management on the process Pj, formed by the realization process RE.

The expanded DVCM and EMC was printed in the general format [15, 16]. As proposed in works [44, 45], the Elementary Management Cycle (EMC) is the basic construct of Enterprise Management modelling, it refines the components of management (control) cycle as well as content of management information transformations. The mandatory steps (Interpretation – IN, Data Processing – DP, Decision Making – DM, Realisation of Decision – RE) of the EMC are defined as information transferring processes focused on the control of the content of the Management Functions Fi. The Management Function Fi consists of a sequence of definite types of goal-driven information transformation activities (steps of EMC) aimed to control a state of an Enterprise Process Pj. For example, in the structure of an EMC: Pj (A, G), Pj (V, G) – Technological Process (managed object), its input (I) and output (O) are Material Flows. Material Flows are defined by state attributes of a specific Process Pj, which are necessary to perform a specific enterprise management Function Fi in combination with enterprise Goals (G).

Based on this general model, the authors have proposed a specialised model for particular problem domain.

3. Educational Domain Management Knowledge Modelling Method, Based on Enterprise Management Information Interactions

Educational domain management knowledge modelling method, based on enterprise management information interactions, was created in order to identify the discrepancy between the existing knowledge model and the actual domain knowledge model. The resulting method is designed to create a two-level

(granular) knowledge description model for the analyzed educational domain management information interactions, to form current knowledge and domain knowledge models and to perform the analysis of knowledge models. The computerisation of the organisational activities involves an examination of the information interactions between the management functions and the business processes, which requires the decomposition of the value chain elements, i.e. the VCM is modified and a Detailed Value Chain Model (DVCM) is created. Thus, the knowledge-based IS development is performed based on that business management knowledge which defines the key features of business management information interactions. A business management information interaction is specified as an Elementary Management Cycle (EMC), which links the business management function and the business process through a feedback circuit. A two-level subject area management knowledge model was selected. The two levels of knowledge description are:

1. First level of detail – DVCM that identifies information interactions.

2. Second level of detail – a detailed model of each management information interaction by applying EMC.

Such model is believed to be sufficient in all cases of activity knowledge modelling. The decomposition of the organisational system business management functions and the business processes can be continued up to the required level of detail of the business management function.

Paper comprise known approaches to create educational domain content knowledge models updated existing. Model is created on to levels that combines DVCM and EMC model presenting the transformation of the existing and the domain knowledge models on the basis of management information interactions", BPMN notation (Figure 4).

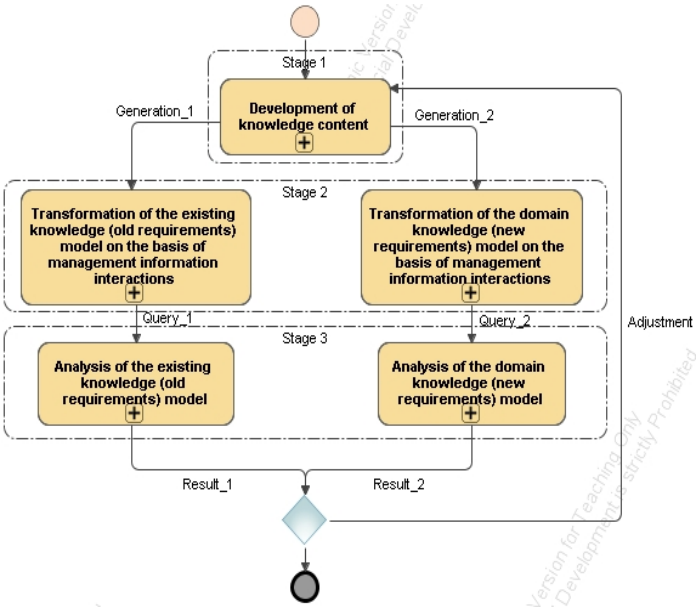

Figure 4. A principal scheme of educational domain management knowledge modelling method (BPMN notation)

Development of knowledge content (Figure 5) involves structural, functional, quality and other requirements.

The method is elaborated in a specific domain – higher education study programme design and updating. In terms of the current domain (for example, programme structure), the smallest structural component is a study module. Module composition is described in terms of attributes. To establish a system hierarchy, modules are combined into study blocks (subject groups). Main blocks are defined in the general requirements for study programmes (component_1 in Fig. 5). Functional (study content) requirements are defined by the purpose, stage and objectives of a study programme that are defined in regulatory documents and derived from other requirement sources (component_2 in Fig. 5).

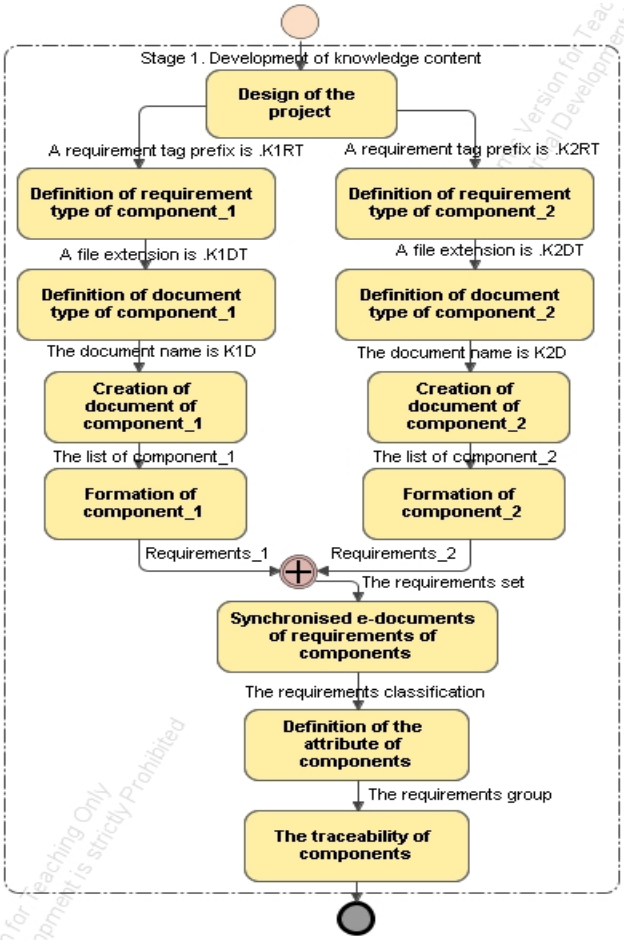

Figure 5. Part of the method (Stage 1 "Development of knowledge content", BPMN notation, using *MagicDraw*^{TM} tool)

Designing a knowledge base on the basis of DVCM and EMC. Management knowledge model based on DVCM and EMC is created in two stages (Figure 6):

1. On the basis of the Detailed Value Chain Model (DVCM) identifying management Functions and their information resources.

2. Each intersection between management Function and Process is modelled in detail as the managed process by creating their Elementary Management Cycle (EMC) models.

1st stage of designing a management knowledge model and a knowledge base. Designing a knowledge base on the basis of the Detailed Value Chain Model (DVCM) requires to evaluate not only DVCM structure, but also all the informational attributes

(data) of interactions between management Functions and Processes:

1. Analyze the general case of the Detailed Value Chain Model (DVCM) which is the formalized DVCM structure.

2. Verify that management Function hierarchy exists.

3. Verify that Process hierarchy exists.

4. Verify that data (information attributes) related to each intersection between a management Function and a Process exists.

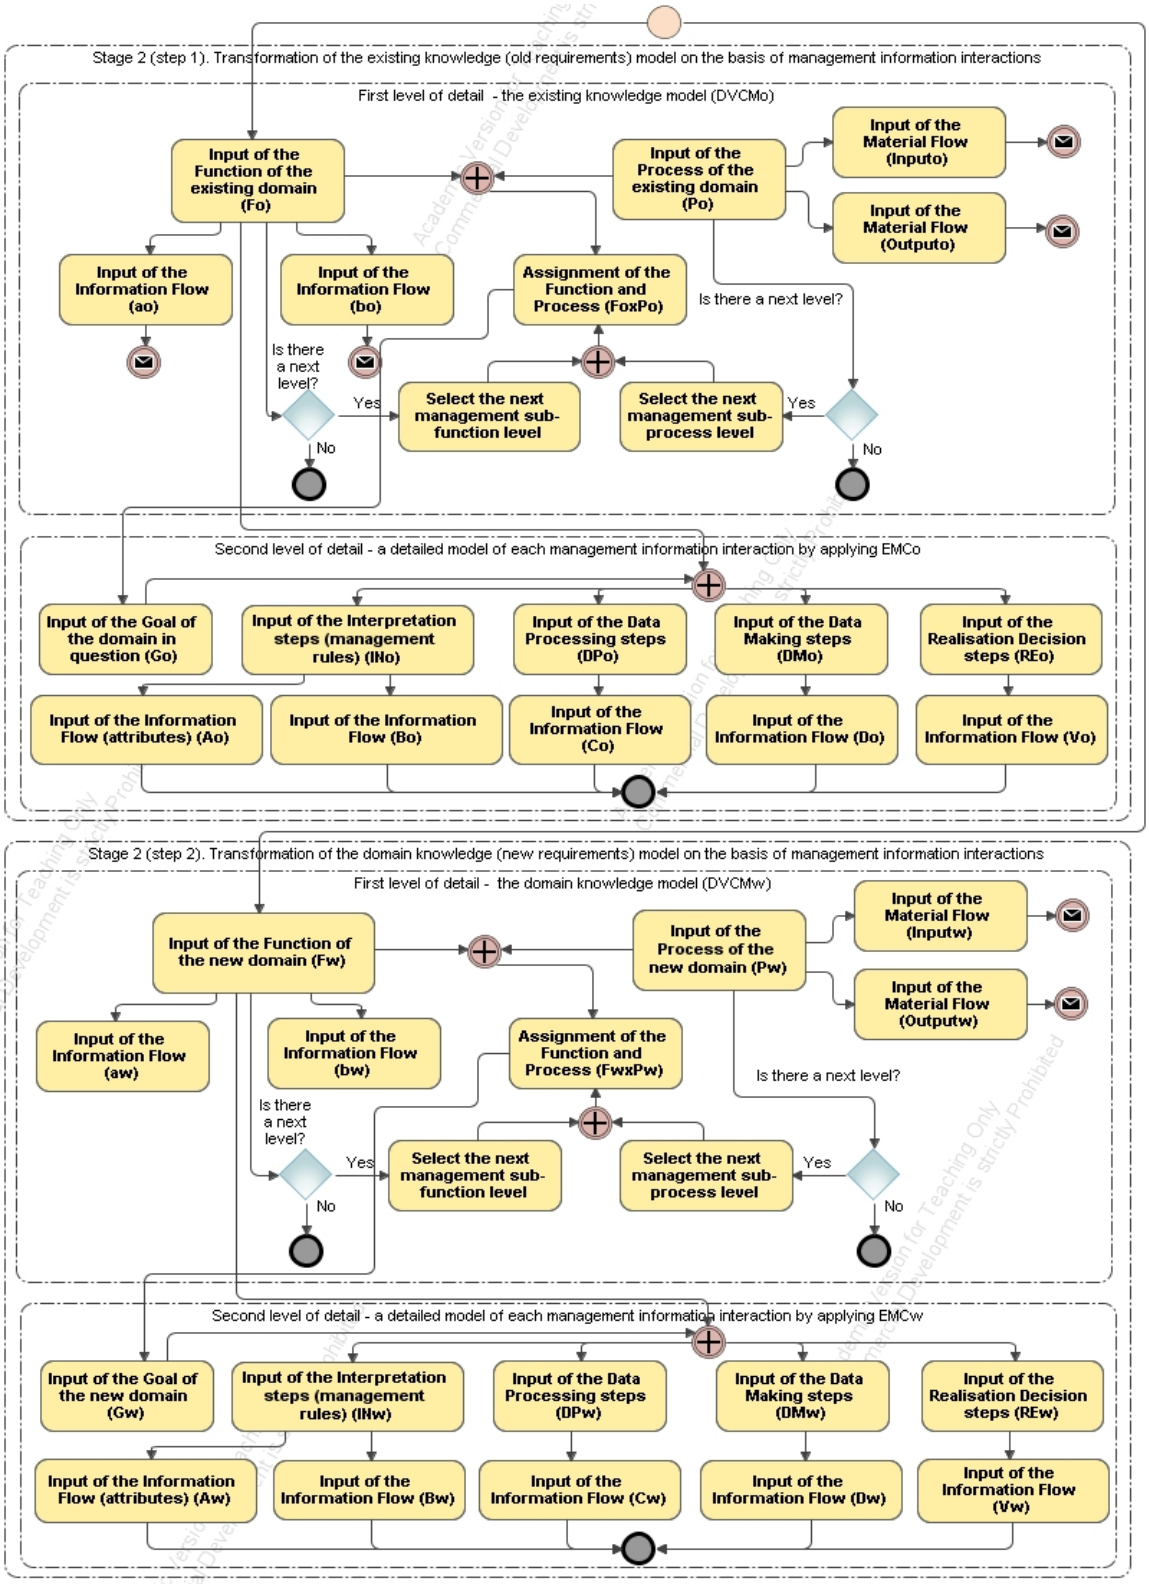

Figure 6. Part of the method (Stage 2 "Transformation of the existing and the domain knowledge models on the basis of management information interactions", BPMN notation)

2nd stage of designing a management knowledge model and a knowledge base. The resulting management knowledge model does not assess the internal structure (informational transformations performed by the enterprise management Function itself) of management Functions, i.e. information interactions between the structural parts (components) of a management Function. Next, the internal structure of each management Function is modelled on the basis of Elementary Management Cycle (EMC) description:

1. Select a specific management Function and Process pair (intersection) identified with DVCM, that will further be modelled as a managed process (formally described EMC).

2. Create an Elementary Management Cycle (EMC) model of the selected management Function and Process intersection by identifying (naming) all EMC components: IN, DA, SP and RE processes, related goals G, information flows between EMC components.

3. Illustrate DVCM and EMC through domain entity class model.

4. Develop a prototype of a knowledge base.

When requirements documents are created and linked together while the requirements themselves are kept in the Knowledge Base (KB), an opportunity appears to automate requirements analysis by using computerized systems (Figure 7). Within the selected CASE tool (IBM Rational RequisitePro™) special visual environments (so called views) for knowledge analysis are selected. It is possible to review knowledge (requirements) presented in different views in parallel by using various matrices or hierarchical structures (trees) where requirements with their attributes and/or traceability links between different requirement types are represented. For example, one of the problems of requirement analysis is the determination of requirements attributes.

When applying the visual environment of Attribute Matrix, it is possible to comfortably revise all the requirements of a particular type and attributes related to them. When analyzing a current domain (for example, study programme), the following actions with the matrix are performed: the establishment and editing of a requirement title, text, attributes and traceability links; the saving of matrix query; matrix printing. Filtering and sorting functions can also be applied to analyze requirements, thus maximizing the informational value of each requirement. By choosing one or several attributes and/or traceability signs (indicators), it is possible to perform requirement filtering and sorting, therefore, selecting the necessary requirements or forming new categories of them. In particular, it is used to design the architecture of a study programme and it's structural components (study blocks and modules).

Modification of a structured Value Chain Model to identify educational domain knowledge content. To reflect these needs the authors have proposed a new problem domain life cycle model, which is based on modified VCM. This specialised model is presented in Figure 8.

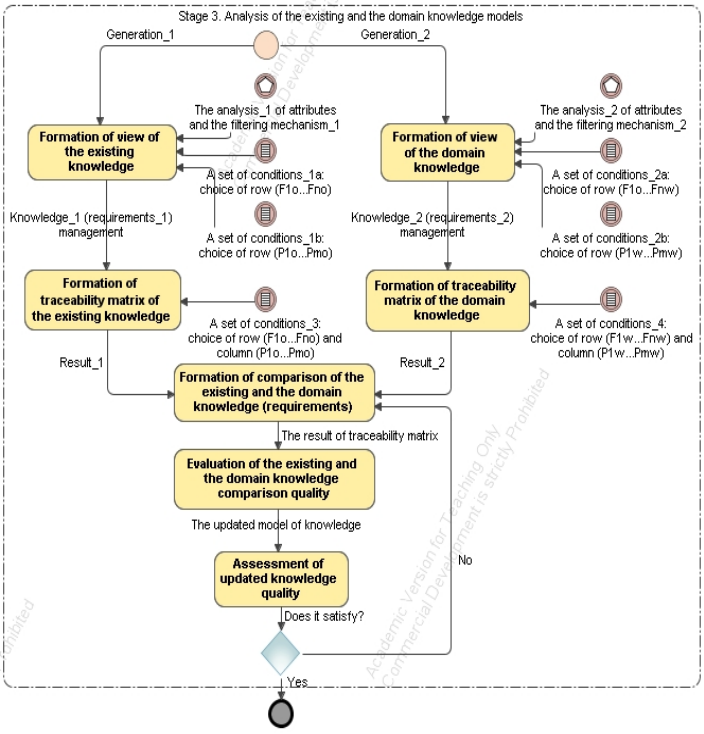

Figure 7. Part of the method (Stage 3 "Analysis of the existing and the domain knowledge models", BPMN notation)

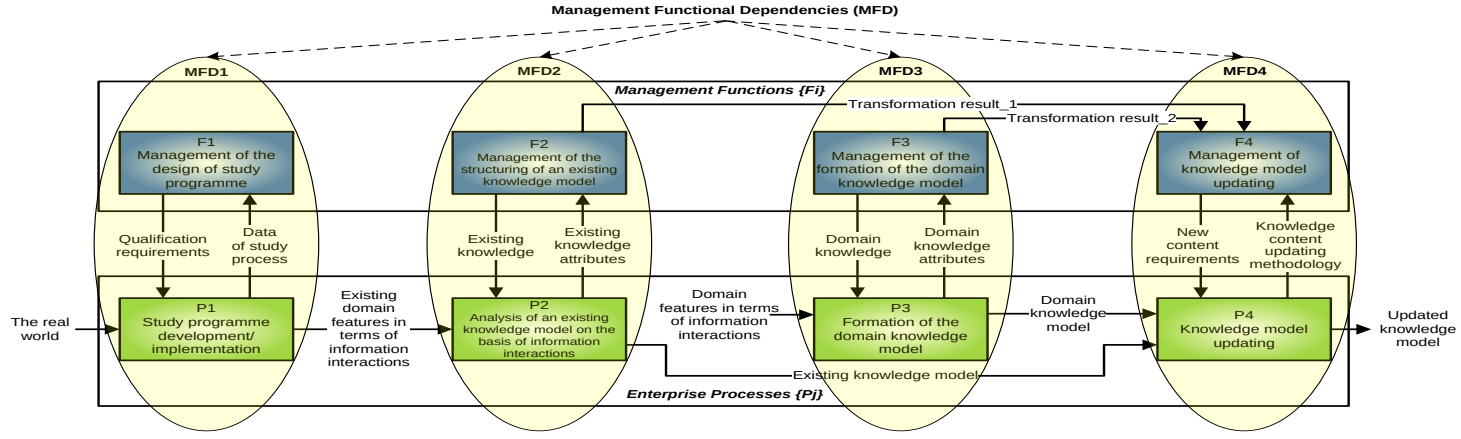

Figure 8. Informational model of educational domain knowledge content identification process

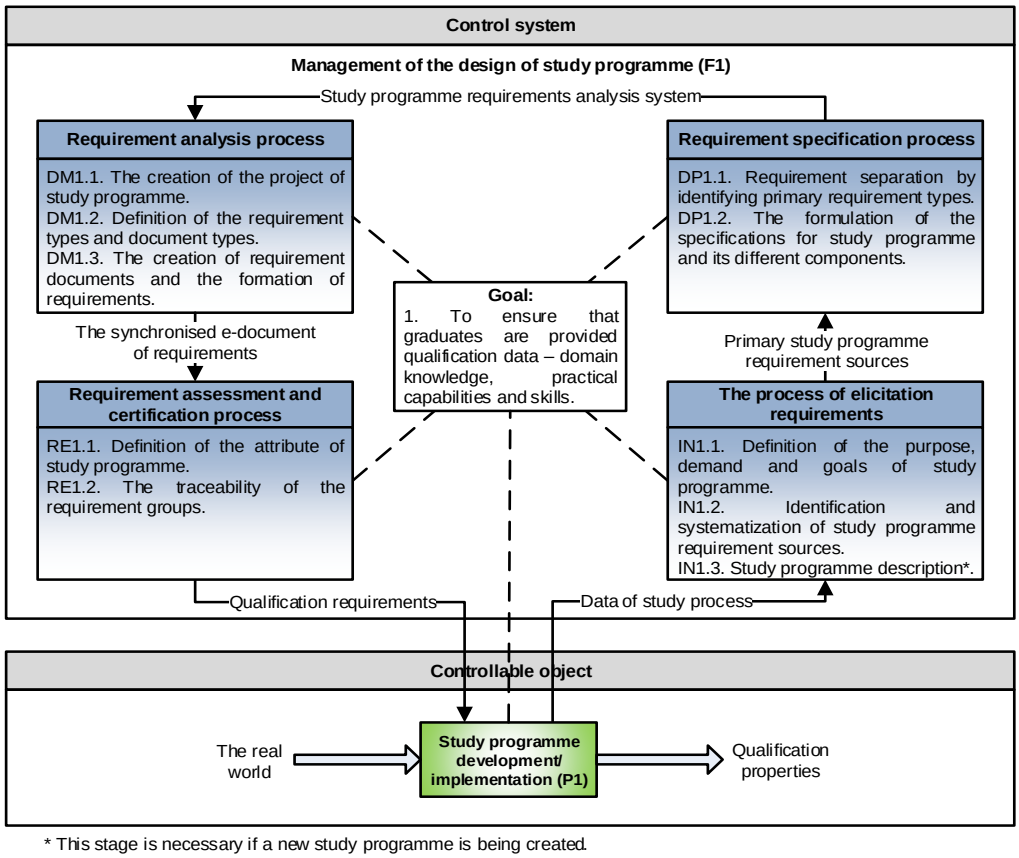

Figure 9. The Formalised Model of the Interaction between the *Function F1 = "Management of the design of study programme"* and the *Process P1 = "Study programme development/ implementation"*

Each interaction between management Function Fi and Process Pj $(Fi \times Pj)$ identified with DVCM is seen as a managed process that implements a specific Management Functional Dependence (MFD).

For example, the formalised model of the interaction between the Function F1 = "Management of the design of study programme" and the Process P1 = "Study programme development/ implementation" (see Fig. 8) is presented in Figure 9.

It is important to mention that any specific EMC does not end, it continues with each new domain process cycle. Thus, the current domain is developed based upon the spiral principle with the renewal of the quality in general. In particular, the steps (rules) and the attributes (data) of the transformation of current domain management information were identified.

4. Educational Domain Management Knowledge Content Identification and Knowledge Updating Computerized Process Model

This section provides a principal scheme of knowledge content identification and educational domain knowledge updating model, on the basis of which a knowledge-based specification is performed. A particular enterprise Management Functional Dependency is the aggregate of the necessary information interactions among specific enterprise management Function components, specified by a particular Elementary Management Cycle.

Construction of a principal scheme of knowledge content identification and domain knowledge updating model. A principal knowledge content identification and domain knowledge updating model scheme is provided in Figure 10.

When analysing the principal knowledge model scheme, it can be stated that management Function model, in this case, becomes a scenario that defines mandatory information interactions, necessary to computerize all tasks that constitute management Function.

The identification of the existing (old) knowledge which are documented before and the new subject area knowledge related with problem domain is presented in two upper DVCM in Figure 11.

Mapping and comparison of the old and the new knowledge allow to construct a modified DVCM producing a set of updated knowledge.

A technique of knowledge analysis is used for comparison between $DVCM^o$ and $DVCM^w$. Comparison of these two (($DVCM^o$ and $DVCM^w$) domain models allow to identify the changes of problem domain content (i.e. identify the actual changes of knowledge about domain) and to construct a derivative new Detailed VCM ($DVCM^N$) encompassing all actual domain knowledge components. Afterwards the $DVCM^N$ is used for identification of new knowledge requirements. Traceability Matrix shows the relation of two knowledge sets (Figure 12).

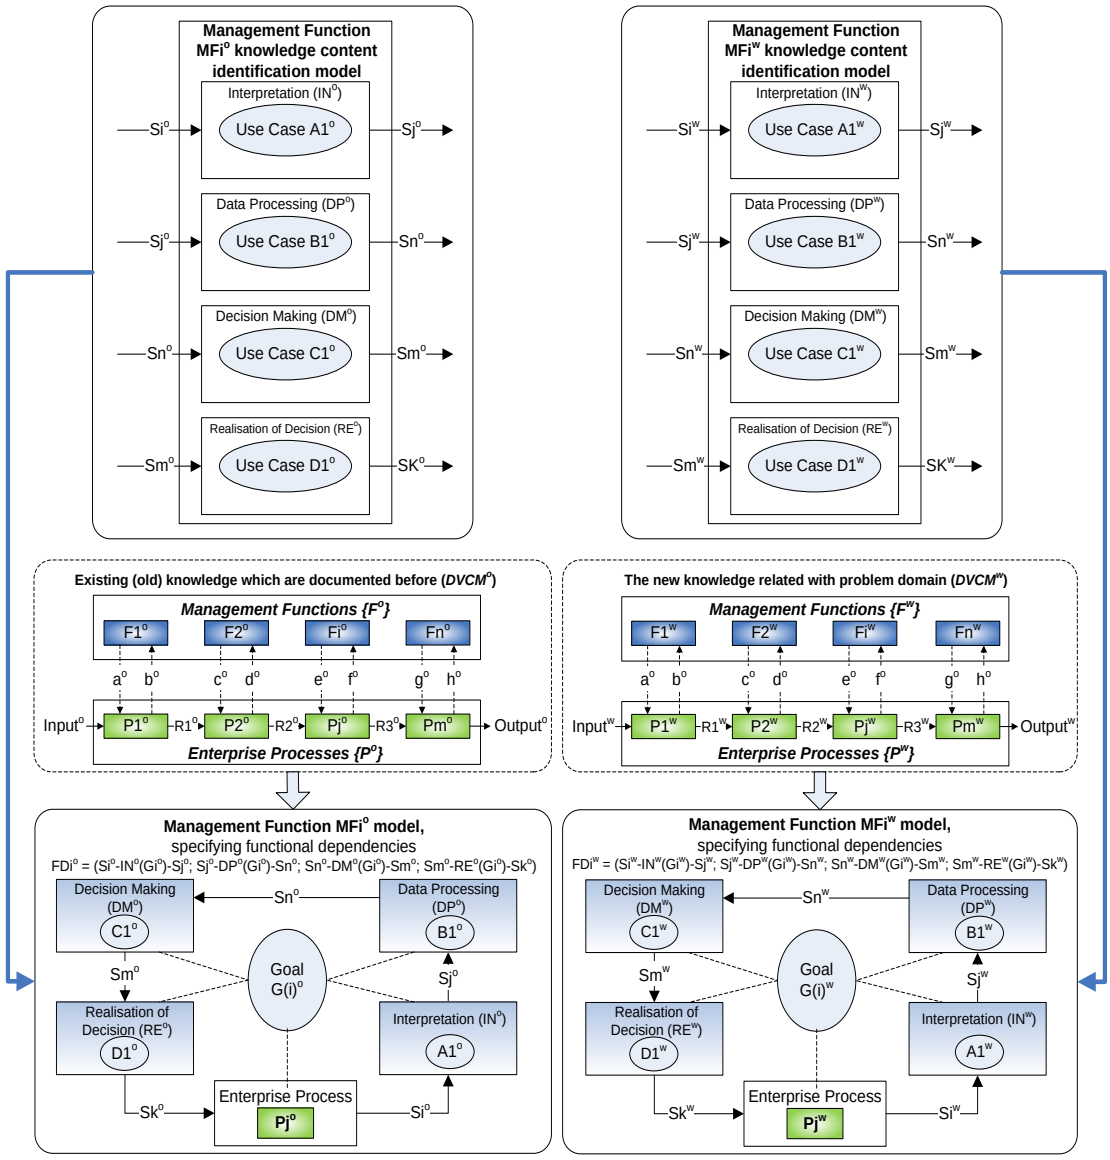

Figure 10. A principal scheme of knowledge content identification and domain knowledge updating model (based on enterprise management function)

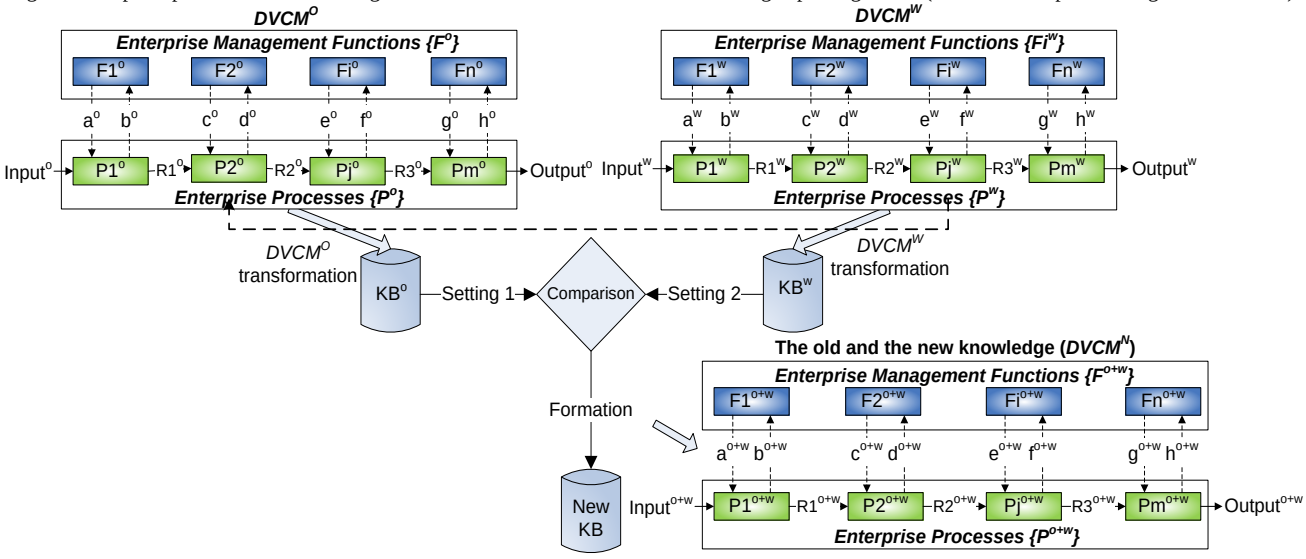

Figure 11. The identification of the existing and the new knowledge (here: $DVCM^o$ – the old knowledge; $DVCM^w$ – the new knowledge; $DVCM^N$ – the renewed domain content model))

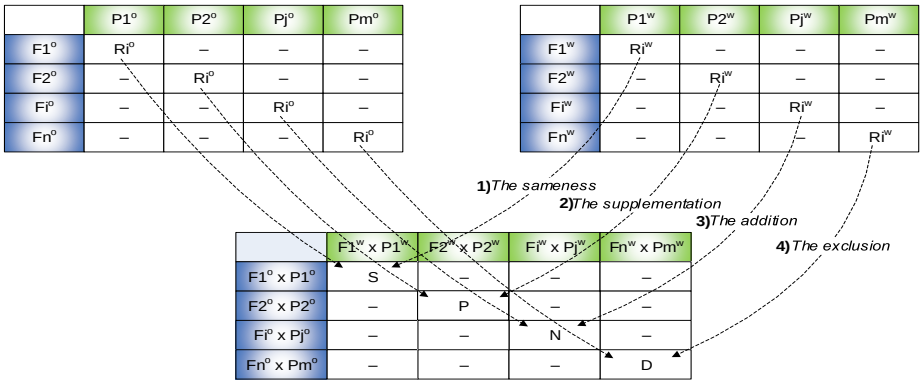

Figure 12. The relations between existing (old) and the new knowledge (requirements) (where $R_1^o, R_2^o, ..., R_i^o$, $R_1^w, R_2^w, ..., R_i^w$ – the existing and new managed process results)

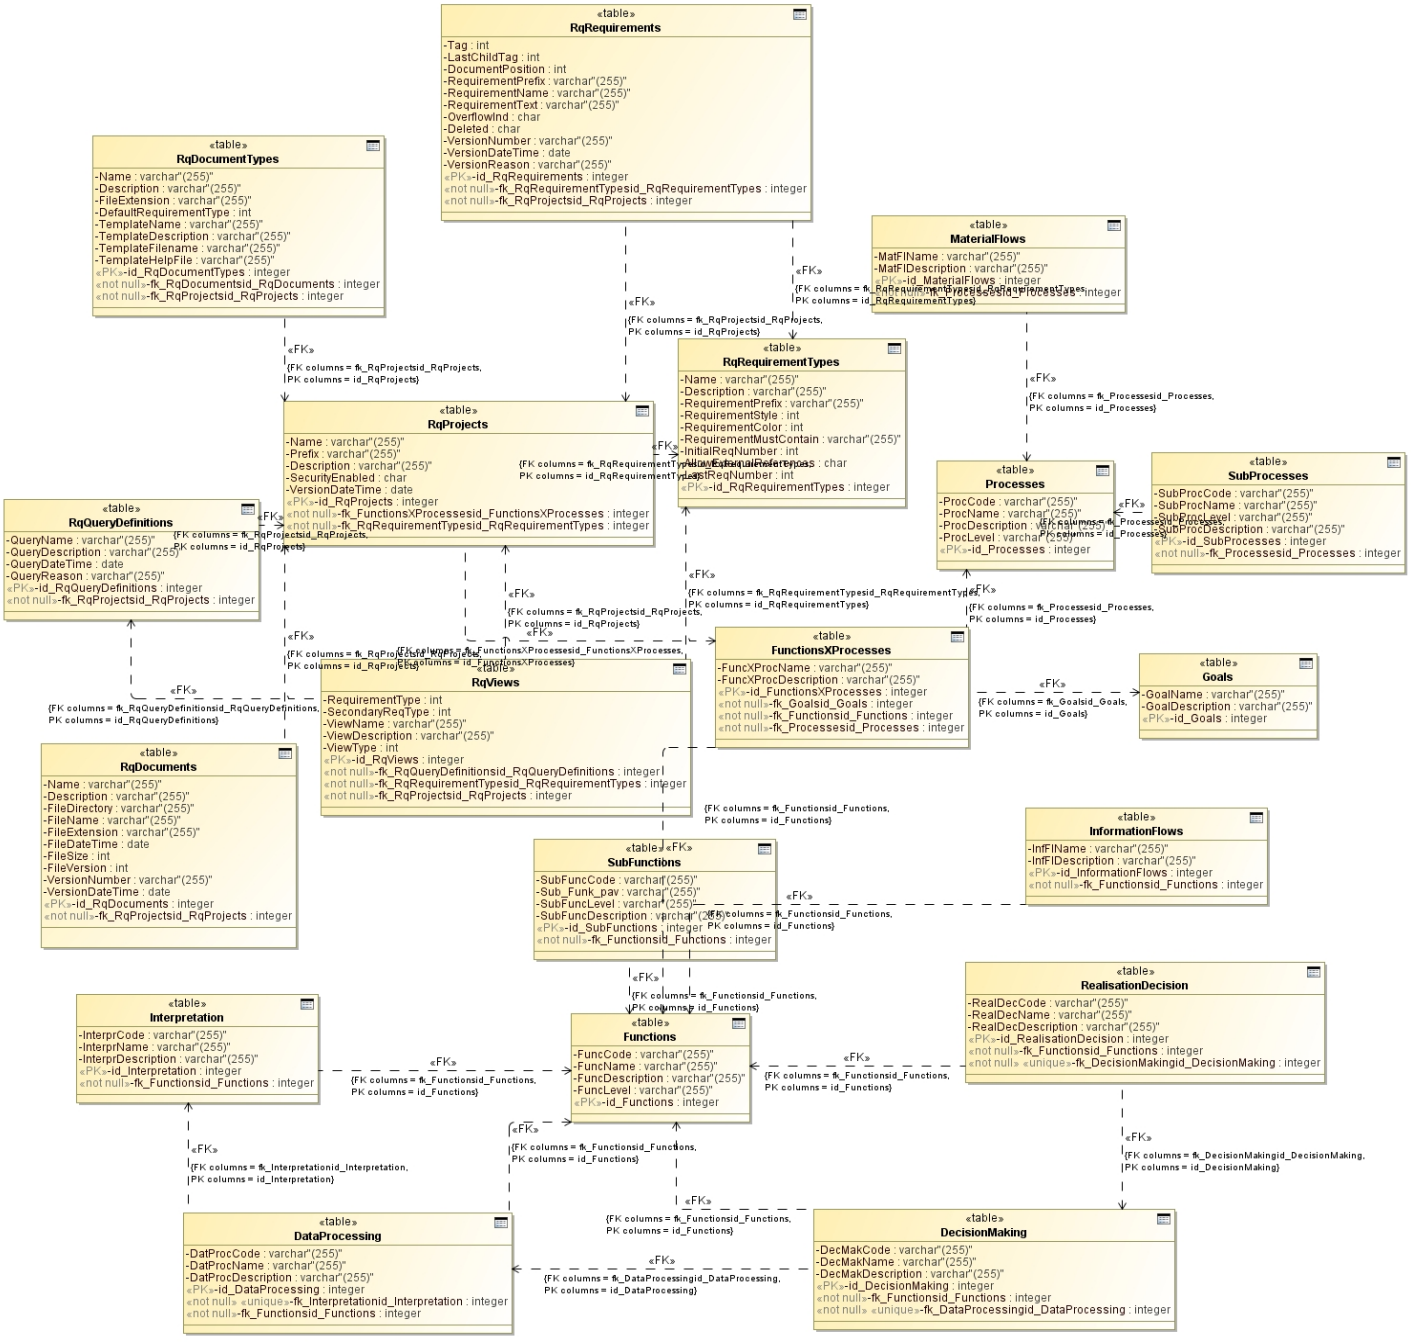

Figure 13. Subject area entity class model (physical data model)

There are several situations that can be identified: 1) the sameness of knowledge (equal requirements, knowledge remains unchanged, denoted by S); 2) the supplementation of existing knowledge with lacking new subject area knowledge (current knowledge only partially covers new requirements and should be supplemented, denoted by P); 3) the addition (inclusion) of new domain knowledge (denoted by N); 4) the exclusion of present knowledge from the current domain (no longer meets subject area requirements, competency becomes less important, denoted by D).

Implementation of the knowledge repository. Implementation of the knowledge repository of proposed model for current domain requirement improvement and knowledge content updating. Subject area entity class model (physical data model) is presented in Figure 13 (using MagicDraw^{TM} CASE tool). The solution is implemented by extending the requirement management system by knowledge-based components.

Requirement management is performed on the basis of IBM Rational RequisitePro^{TM} tool, meanwhile, the structure of a knowledge base is based on Detailed Value Chain and Elementary Management Cycle.

Subject area entity class model of the knowledge repository specifies DVCM and EMC elements which can be a function (consisting of information activities: Interpretation, Data Processing, Decision Making and Decision Realization), a process, a material flow, etc. Thus, the current domain parameters derived from DVCM and EMC together with requirements are stored in the knowledge databases and can be used for solving specific problems of expected application areas.

5. Conclusions

After conducting theoretical and experimental research, the following scientific and practical conclusions were drawn:

After analysing domain modelling methodologies and methods (languages, notations), it was found that a knowledge based enterprise modelling method for identifying organization's operational objectives, as well as the informational interaction between a controlled object and a controlling system forming control feedback, can be based on a Detailed Value Chain Model.

The Detailed Value Chain Model (DVCM) is defined as a problem domain content model. The peculiarity of the DVCM is refinement of the Management Functions {Fi} and Processes {Pj} as an obligatory component types of problem domain knowledge content. Management Functions (F) possess information transformations; while Enterprise Processes (P) are concrete material transformations.

The educational domain management knowledge modelling method was designed, allowing to create a two-level (granular) model for describing knowledge of domain management information interactions: the highest level Detailed Value Chain Model is further elaborated into a set of Elementary Management Cycle models; the chosen hierarchical structure allows to create new structural knowledge models and to update existing ones.

The work goes beyond formal presentation; the method is applied in a specific domain, which requires constant knowledge content updating – higher education study programme construction and updating. The flexibility of the proposed solutions should be noted – the possibility to integrate the created domain knowledge base into a study programme requirement management system, by identifying knowledge management processes and implementing a knowledge subsystem in an existing CASE system environment. Its approval provided results relevant and useful for the members, employees and professionals of academic community in higher education institutions, working on improving existing study programs and seeking to ensure their quality.

Conflict of Interest

The authors declare no conflict of interest.

Important note of applied research

This paper contributes to the applied scientific research at Klaipeda State University of Applied Sciences “Application of Enterprise Management Models in Knowledge-based Information Systems Engineering”. Area: sustainable environmental development; Field: Innovative Technologies; Branch (topic): Smart Information Technology, TMV-027.

ABSTRACT

In this paper, an optimal discrete-time sliding mode control is proposed for single-input single-output nonlinear systems with input constraints. The sliding surface is designed on the basis of particle swarm optimization algorithm in order to optimize the system response characteristics while ensuring the follow-up of reference model in presence of constraints. Moreover, the controller is developed such that the elimination of chattering phenomenon, the finite-time convergence and the stability of the closed-loop system are guaranteed. Performed on an inverted pendulum system, simulation results demonstrate the effectiveness of the proposed approach over the discrete-time sliding mode controller using the saturation function and the discrete-time second order sliding mode controller in terms of fast response.

1 Introduction

This paper is an extension of work originally presented in 2018 15th International Multi-Conference on Systems, Signals and Devices (SSD) [1]. Due to the increasing use of computers in control applications, discrete-time sliding mode control (DSMC) has been extensively developed since its appearance with Milosavljevic in 1985 [2]; see, for example, [3–9]. However, the finite sampling time negatively impacts the robustness of continuous-time sliding mode control to external disturbances, parametric uncertainties and modeling errors [10–12]. In fact, the control input remains constant during the sampling period so that it can not be changed when the trajectory of system state crosses the sliding surface. This is at the origin of chattering phenomenon that may badly affect control devices and system performances [13].

Introduced by Gao in 1995 [14], the quasi-sliding mode concept consists to drive the state trajectory to cross the sliding hyperplane in finite-time, to move with a non-increasing zigzag motion and to remain within a specified layer. Thus, the above-mentioned drawback can be reduced but not eliminated. Several approaches was proposed in the literature to overcome it. In [15–17], the saturation function is used as smooth one instead of the sign function which is the origin of discontinuity. In [18–20], discrete-time second order sliding mode control (DSOSMC) was proposed for linear and nonlinear systems. In [21, 22], a piecewise-constant control is used to generate the discrete-time sliding mode. It ensures that the chatter effect is avoided and the system state trajectory convergences to the sliding surface after a finite-time interval.

In the following, an optimal discrete-time sliding mode control (ODSMC) is proposed for single-input single-output (SISO) nonlinear systems with input constraints. Particle swarm optimization (PSO) algorithm is employed to search the sliding vector to which corresponds the optimal response characteristics of the closed-loop system and its behavior follows the reference model. Developed by Eberhart and Kennedy in 1995 [23], PSO algorithm is based on food searching behavior of animals societies having no leaders in their swarm such as bird flocks and fish schools. Its main advantages are the easiness of implementation, the robustness in controlling parameters and the good efficiency in solving nonlinear, nondifferentiable and large search space problems [24, 25]. Regarding the control law, it is designed in such a way that chattering phenomenon is eliminated, the convergence to the sliding manifold is ensured in finite-time and the system dynamics are stable while respecting constraints.

The efficiency of the proposed controller will be demonstrated by applying it to an inverted pendulum system and by comparing it to DSMC controller using the saturation function and to DSOSMC controller with an arbitrary choice of control parameters and without taking into account the

input constraints.

This paper is organized as follows. The DSMC and DSOSMC controllers are developed for SISO nonlinear systems in sections 2 and 3. Section 4 is devoted for the design of the proposed ODSMC controller. The inverted pendulum system is represented in section 5. Section 6 illustrates numerical simulation results. Concluding remarks are given in section 7.

2 Discrete-time Sliding Mode Control

Consider a class of discrete-time SISO nonlinear system described by

$$\begin{cases} x(k+1) = F(x(k)) + H(x(k))\,u(k) \\ y(k) = Cx(k) \end{cases} \tag{1}$$

where $x(k) \in \mathbb{R}^{n\times 1}$ is the state vector, $u(k) \in \mathbb{R}$ is the control input, and $y(k) \in \mathbb{R}$ is the system output. $F(x(k)) \in \mathbb{R}^{n\times 1}$ and $H(x(k)) \in \mathbb{R}^{n\times 1}$ are vectors of nonlinear functions and C is the output matrix. Let's admit that H and its pseudo-inverse H^{+} are both bounded.

The sliding function is defined as follows

$$s(k) = c^T e(k) \tag{2}$$

where $e(k) = x(k) - x_d(k)$ is the tracking error and $c^T \in \mathbb{R}^{1\times n}$ is the sliding vector chosen such that the sliding dynamic $s(k) \equiv 0$ is asymptotically stable.

The reaching law is given by

$$s(k+1) = (1 - qT_s)\,s(k) - \varepsilon T_s \,\mathrm{sat}(s(k), \varphi) \tag{3}$$

where $0 < 1 - qT_s < 1$, $\varepsilon > 0$, T_s is the sampling period and sat is the saturation function defined as follows

$$\mathrm{sat}(s, \varphi) = \begin{cases} \frac{s}{\varphi} & \text{if } \left|\frac{s}{\varphi}\right| \le 1 \\ \mathrm{sign}(s) & \text{else} \end{cases} \tag{4}$$

with $\varphi > 0$ is the boundary layer width of s and sign is the sign function.

Using the reaching law (3) and the forward expression of the sliding function (2), the control law $u(k)$ is given by

$$\begin{aligned} u(k) = \left(c^T H(x(k))\right)^{-1} (& (1 - qT_s)\,s(k) \\ & - \varepsilon T_s \,\mathrm{sat}(s(k), \varphi) - c^T F(x(k)) + c^T x_d(k+1)) \end{aligned} \tag{5}$$

3 Discrete-time Second Order Sliding Mode Control

The sliding function defined in [19, 20] is given by

$$\sigma(k) = s(k) + \beta s(k-1) \tag{6}$$

with $\beta \in [0, 1[$ in order to ensure the stability of $\sigma(k)$.

The control law is given by

$$u(k) = u_{eq}(k) + u_d(k) \tag{7}$$

where $u_{eq}(k)$ is the equivalent control used to force the system state to evolve on the sliding manifold and $u_d(k)$ is the discontinuous control used to ensure the robustness.

Setting $\sigma(k+1) = \sigma(k) = 0$, the equivalent control $u_{eq}(k)$ is determined from the following relation

$$s(k+1) + \beta s(k) = 0 \tag{8}$$

Hence, It is given by

$$\begin{aligned} u_{eq}(k) = \left(c^T H(x(k))\right)^{-1} (& - c^T F(x(k)) \\ & + c^T x_d(k+1) - \beta s(k)) \end{aligned} \tag{9}$$

The discontinuous control $u_d(k)$ is expressed as follows

$$u_d(k) = u_d(k-1) - \varepsilon T_s \mathrm{sign}(\sigma(k)) \tag{10}$$

4 Optimal Discrete-time Sliding Mode Control

4.1 Design of Sliding Surface

The sliding vector c^T is determined using the PSO algorithm in order to ensure the optimization of the closed-loop system response characteristics and the follow-up of the reference model in the presence of constraints on control input.

PSO algorithm starts with population of np n-dimensional particles. The i^{th} particle of the swarm has a position $x_i = [x_{i,1}, \ldots, x_{i,n}]$ and a velocity $v_i = [v_{i,1}, \ldots, v_{i,n}]$. Its previously best visited position and the global best particle in the swarm are denoted by $pbest_i = [pbest_{i,1}, \ldots, pbest_{i,n}]$ and $gbest$ respectively. The velocity and the position of each particle are updated as follows

$$v_{i,j} = w\,v_{i,j} + \alpha_1 r_1 \left(pbest_{i,j} - x_{i,j}\right) + \alpha_2 r_2 \left(gbest_j - x_{i,j}\right) \tag{11}$$

$$x_{i,j} = x_{i,j} + v_{i,j} \tag{12}$$

with $i = 1, \ldots, np$ and $j = 1, \ldots, n$. w is the inertia weight, $\alpha_{1,2}$ are positive constant so-called the acceleration coefficients and $r_{1,2}$ are random parameters uniformly distributed within $[0, 1]$ at each generation.

PSO is used to generate the sliding vector that minimizes the following cost function

$$cost = \lambda_1 t_r + \lambda_2 t_s + \lambda_3 M_p + \lambda_4 E_{ss} \tag{13}$$

where t_r is the rise-time, t_s is the settling-time, M_p is the overshoot, E_{ss} is the steady-state error and λ_q , $q = 1, \ldots, 4$, are their corresponding weights.

As illustrated in Table 1, the iterative process is repeated until stopping criterion is met.

Table 1: Description of PSO algorithm

Step 1	**Parameter settings**
	Set the population size np, the minimum and maximum bounds $x_{min} = [x_{min,1}, \ldots, x_{min,n}]$ and $x_{max} = [x_{max,1}, \ldots, x_{max,n}]$, and the acceleration coefficients $\alpha_{1,2}$.
Step 2	**Initialization**
	Initialize the particle's position x_i^0, $i = 1 \ldots np$, randomly and uniformly within bounds.
	Initialize the particle's velocity v_i^0 and the particle's best position to its initial position, i.e. $pbest_i^0 = x_i^0$.
	Set $gbest$ equal to the global best particle.
Step 3	**PSO algorithm**
	WHILE stopping criterion is not met DO
	Update the particle's velocity and position
	FOR $i = 1$ to np
	FOR $j = 1$ to n
	$v_{i,j} = w\, v_{i,j} + \alpha_1 r_1 \left(pbest_{i,j} - x_{i,j}\right) + \alpha_2 r_2 \left(gbest_j - x_{i,j}\right)$
	END FOR
	$x_i = x_i + v_i$
	END FOR
	Update the particle's best position
	FOR $i = 1$ to np
	IF $f(x_i) \prec f(pbest_i)$
	$pbest_i = x_i$
	END IF
	END FOR
	Update the global best position
	FOR $i = 1$ to np
	IF $f(pbest_i) \prec f(gbest)$
	$gbest = pbest_i$
	END IF
	END FOR
	END WHILE

4.2 Design of Control Law

The control law is designed such that the chatter effect is avoided, the state trajectory convergences to the sliding surface after a finite-time interval and the closed-loop system is stable while respecting control constraints.

The forward expression of the sliding function (2) can be rewritten as follows

$$\begin{aligned} s(k+1) = s(k) &+ c^T \left(x_d(k) - x_d(k+1)\right) \\ &+ c^T \left(F(x(k)) - x(k)\right) + c^T H(x(k)) u(k) \end{aligned} \tag{14}$$

Setting $s(k+1) = 0$, the equivalent control u_{eq} is expressed by

$$\begin{aligned} u_{eq}(k) = -\left(c^T H(x(k))\right)^{-1} &\left(s(k) + c^T \left(x_d(k) - x_d(k+1)\right)\right. \\ &\left. + c^T \left(F(x(k)) - x(k)\right)\right) \end{aligned} \tag{15}$$

Consider that $\|u(k)\| \leq u_{max}$, the constrained control is given by

$$u(k) = \begin{cases} u_{eq}(k) & \text{if } \left\|u_{eq}(k)\right\| \leq u_{max} \\ \frac{u_{eq}(k)}{\left\|u_{eq}(k)\right\|} u_{max} & \text{else} \end{cases} \tag{16}$$

Suppose that

$$\left\|c^T \left(x_d(k) - x_d(k+1)\right) + c^T \left(F(x(k)) - x(k)\right)\right\| \leq \delta,$$
$$\left\|\left(c^T H(x(k))\right)^{-1}\right\| \leq \eta$$

and

$$u_{max} > \delta\eta \tag{17}$$

with $\delta > 0$ and $\eta > 0$.

It follows that

$$\begin{aligned} &\left\|u_{eq}(k)\right\| \leq \left\|\left(c^T H(x(k))\right)^{-1}\right\| \\ &\left\|s(k) + c^T \left(x_d(k) - x_d(k+1)\right) + c^T \left(F(x(k)) - x(k)\right)\right\| \\ &\qquad \leq \eta \left(\|s(k)\| + \delta\right) \end{aligned} \tag{18}$$

For $\|u(k)\| > u_{max}$, the forward expression of the sliding function (14) is expressed by

$$\begin{aligned} &s(k+1) = s(k) + c^T \left(x_d(k) - x_d(k+1)\right) \\ &+ c^T \left(F(x(k)) - x(k)\right) + c^T H(x(k)) \frac{u_{eq}(k)}{\left\|u_{eq}(k)\right\|} u_{max} \\ &= \left(s(k) + c^T \left(x_d(k) - x_d(k+1)\right)\right. \\ &\left. + c^T \left(F(x(k)) - x(k)\right)\right) \left(1 - \frac{u_{max}}{\left\|u_{eq}(k)\right\|}\right) \end{aligned} \tag{19}$$

For stability analysis, the Lyapunov function is chosen as follows

$$V(k) = \|s(k)\| \tag{20}$$

Thus, the Lyapunov difference is given by

$$\Delta V(k) = \|s(k+1)\| - \|s(k)\| \tag{21}$$

Using (17)

$$\begin{aligned} &\|s(k+1)\| \\ &= \left\|s(k) + c^T \left(x_d(k) - x_d(k+1)\right) + c^T \left(F(x(k)) - x(k)\right)\right\| \\ &\left(1 - \frac{u_{max}}{\left\|u_{eq}(k)\right\|}\right) \\ &\leq \|s(k)\| + \left\|c^T \left(x_d(k) - x_d(k+1)\right) + c^T \left(F(x(k)) - x(k)\right)\right\| \\ &- \frac{u_{max}}{\left\|\left(c^T H(x(k))\right)^{-1}\right\|} \\ &\leq \|s(k)\| + \delta - \frac{u_{max}}{\left\|\left(c^T H(x(k))\right)^{-1}\right\|} \\ &< \|s(k)\| \end{aligned} \tag{22}$$

Hence, $s(k)$ decreases monotonically. From (18), the equivalent control $u_{eq}(k)$ will belong to the constrained domain, i.e. $\left\|u_{eq}(k)\right\| \leq u_{max}$, in finite time and therefore it will bring the system trajectory to the sliding manifold $s(k) = 0$ on which the dynamics of the closed-loop system are stable.

5 Inverted Pendulum System

As shown in Figure 1, the inverted pendulum system consists of a pendulum amounted on a cart at a frictionless pivot point. The pendulum is of mass $m = 0.1$kg and length $2l = 1$m and the cart is of mass $M = 1$kg [26]. u is the force applied to the cart that lies within the range of ± 10N and $g = 9.81\text{m/s}^2$ is the gravity acceleration. The generalized coordinates are x and θ which represents the horizontal movement of cart and the rotation of pendulum respectively [27].

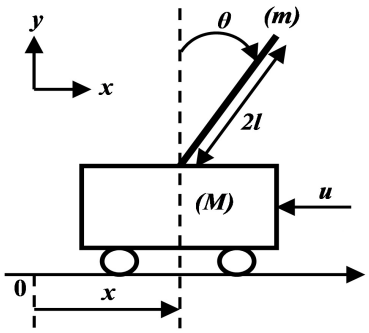

Figure 1: Schematic of the inverted pendulum system

Let $x = \begin{bmatrix} x_1 & x_2 \end{bmatrix}^T = \begin{bmatrix} \theta & \dot{\theta} \end{bmatrix}^T$ be the state vector. The dynamic equations are given by

$$\begin{cases} \dot{x}_1 = x_2 \\ \dot{x}_2 = f(x_1, x_2) + h(x_1, x_2)\, u \\ y = x_1 \end{cases} \tag{23}$$

with

$$f(x_1, x_2) = \frac{(M+m)\, g \sin x_1 - mlx_2^2 \sin x_1 \cos x_1}{\frac{4}{3}(M+m)\, l - ml\cos^2 x_1}$$

and

$$h(x_1, x_2) = \frac{\cos x_1}{\frac{4}{3}(M+m)\, l - ml\cos^2 x_1}$$

Using for discretization the Euler forward method defined by

$$\dot{x} \cong \frac{x(k+1) - x(k)}{T_s},$$

the discrete-time model of the inverted pendulum system is expressed as follows

$$\begin{cases} x_1(k+1) = x_1(k) + T_s x_2(k) \\ x_2(k+1) = x_2(k) + T_s f(x_1(k), x_2(k)) \\ \qquad\qquad + T_s h(x_1(k), x_2(k))\, u(k) \\ y(k) = x_1(k) \end{cases} \tag{24}$$

6 Numerical Simulation Results

For $T_s = 0.05$s, the reference model is chosen as follows

$$x_d(k) = \begin{bmatrix} \frac{\pi}{30} \sin(kT_s) & \frac{\pi}{30} \cos(kT_s) \end{bmatrix}^T \tag{25}$$

The initial conditions are given by

$$x(0) = \begin{bmatrix} 0.2 & 0 \end{bmatrix}^T, x_d(0) = \begin{bmatrix} 0 & \frac{\pi}{30} \end{bmatrix}^T \tag{26}$$

The sliding vector and the reaching law parameters for DSMC controller are respectively

$$\begin{gathered} c^T = \begin{bmatrix} 5 & 1 \end{bmatrix}, \\ q = 2,\ \varepsilon = 10,\ \varphi = 0.5 \end{gathered} \tag{27}$$

The parameters of DSOSMC controller are chosen as follows

$$\varepsilon = 0.02,\ \beta = 0.5 \tag{28}$$

Using the PSO algorithm, the cost function to minimize is the following

$$cost = 0.9t_s + 0.1t_r \tag{29}$$

The population size, the acceleration coefficients, and the minimum and maximum bounds of particle's position are given respectively by

$$\begin{gathered} np = 100,\ \alpha_{1,2} = 2, \\ c_{min}^T = \begin{bmatrix} 0.5 & 0.5 \end{bmatrix},\ c_{max}^T = \begin{bmatrix} 10 & 10 \end{bmatrix} \end{gathered} \tag{30}$$

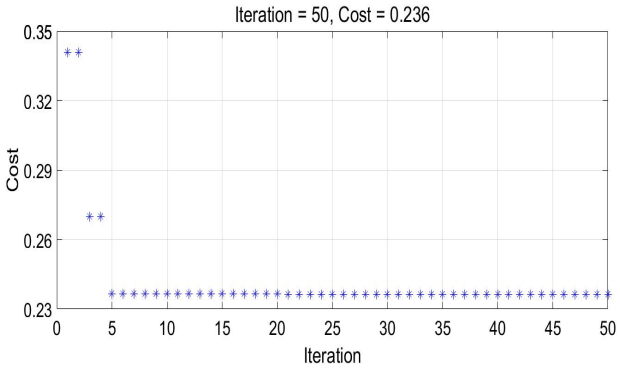
The following linear decreasing inertia weight is used [28, 29]

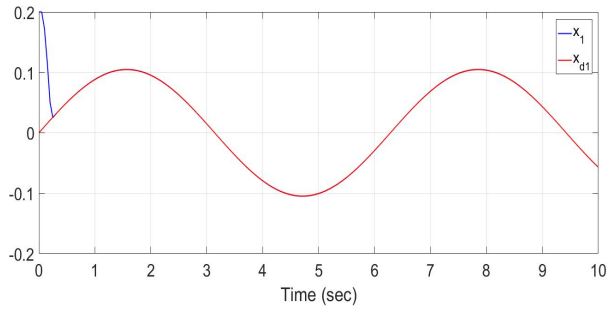
$$w = w_{max} - (w_{max} - w_{min})\, \frac{iter}{iter_{max}} \tag{31}$$

where $w_{max} = 0.9$ and $w_{min} = 0.4$ are the initial and final values of the inertia weight respectively, $iter$ is the current iteration, and $iter_{max}$ is the maximum number of iterations.

Figure 2 illustrates the evolution of the cost function (29) corresponding to ODSMC controller. It shows that PSO algorithm ensures a rapid convergence of the cost function to its minimum value of 0.236s corresponding to the following sliding vector

$$c^T = \begin{bmatrix} 7.085 & 0.5 \end{bmatrix} \tag{32}$$





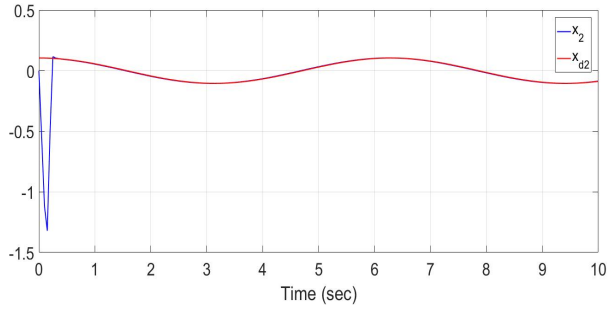


Figure 2: Evolution of the cost function for ODSMC

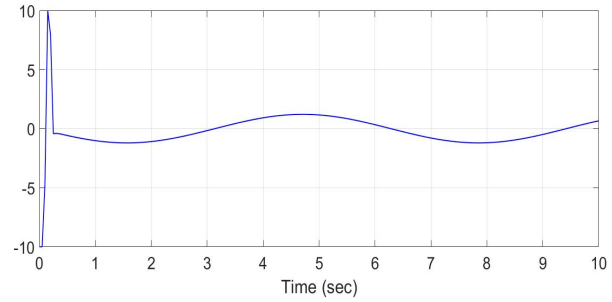

Figure 3 shows numerical simulation results of ODSMC controller using the sliding vector (32). Figures 3a-3b present the state variables $x_{1,2}(k)$ and their corresponding references $x_{d1,2}(k)$. They show that the developed controller ensures the follow-up of the reference model and the stability of the closed-loop system in the presence of control input constraints. Figure 3c depicts the constrained control input $u(k)$. It shows that chatter effect is avoided. Figure 3d illustrates the sliding function $s(k)$. It shows that the state trajectory converges to the sliding surface in finite time.

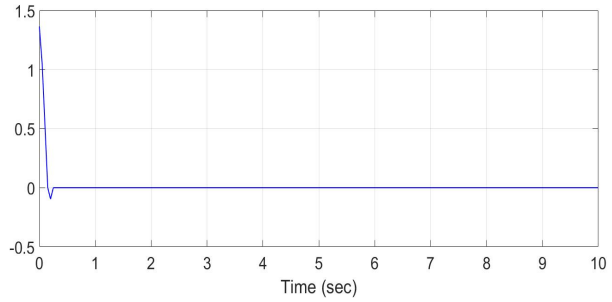
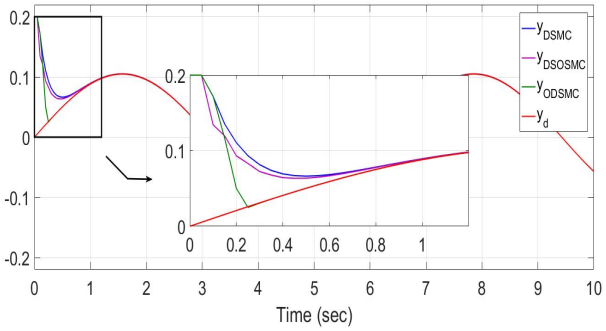


(a) State variable $x_1(k)$ and its reference $x_{d1}(k)$

(b) State variable $x_2(k)$ and its reference $x_{d2}(k)$

(c) Control input $u(k)$



(d) Sliding function $s(k)$

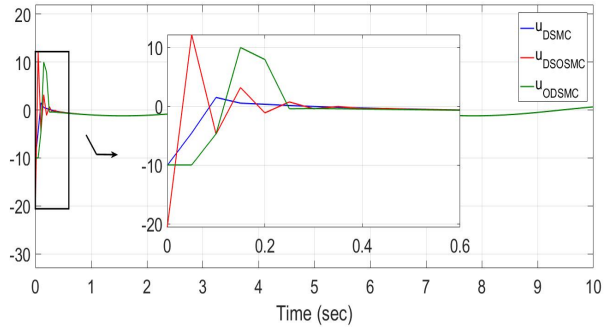


Figure 3: Simulation results for ODSMC controller.

Figure 4 illustrates a comparison between DSMC with saturation function, DSOSMC and ODSMC controllers. Figure 4a presents a comparison of system responses $y(k)$. It shows that all controllers ensure the follow-up of the reference model. Yet, the ODSMC controller ensures the fastest response time while respecting input constraints. Figure 4b depicts a comparison of control inputs $u(k)$. It shows the effectiveness of the applied controllers in avoiding the chattering phenomenon. Moreover, the developed algorithm has lower values of control input in the initial phase than DSOSMC controller.

The results are summarized in Table 2. Actually, It shows that the developed ODSMC ensures the best results with the least rise and settling times of 0.14s and 0.24s respectively, and with lower values of control input than DSOSMC controller whose corresponding minimum and maximum input values are −20.6N and 12.18N respectively. Figure 4 and Table 2 demonstrate that ODSMC controller outperforms DSMC and DSOSMC controllers.

(a) Comparison of system responses

(b) Comparison of control inputs

Figure 4: Comparison between DSMC with saturation function, DSOSMC and ODSMC controllers.

Table 2: Summary table of numerical results

	Settling time (s)	Rise time (s)	u_{min}	u_{max}
DSMC	1.07	0.39	-10.07	1.5
DSOSMC	1.03	0.37	-20.6	12.18
ODSMC	0.24	0.14	-10	10

In this study, Matlab 2016a was used for the implementation of all algorithms.

7 Conclusion

This work presents an optimal discrete-time sliding mode controller for nonlinear SISO systems subject to input constraints. The particle swarm optimization algorithm is employed to determine the sliding vector for which the response characteristics are optimal and the closed-loop system model follows the reference model. Furthermore, the control law which is designed based on the equivalent control concept guarantees the avoidance of chattering phenomenon and the finite-time convergence of system trajectory to the sliding

manifold on which the system dynamics are stable while respecting constraints. Simulation results demonstrate the efficiency of the developed controller in ensuring the fastest response comparing to discrete-time sliding mode controller using the saturation function and to discrete-time second order sliding mode controller. Future work will be to develop the proposed controller to multi-input multi-output nonlinear systems and to verify its effectiveness by experiments.

ABSTRACT

This article is addressed to show the results of hybrid dynamical modeling in the form of PWA (piecewise-affine) and equivalent MLD (mixed-logical dynamical) model for multi-restricted areas avoidance of an autonomous system. It is a problem of determining the optimal moving trajectory from plant's initial position to some desired position while avoiding some restricted areas (obstacles) between them. In order to calculate the optimal input value capable of generating the optimal trajectory, the model predictive control (MPC) approach was utilized by minimizing an objective function of state/output prediction subject to the formulated hybrid dynamical model. To illustrate the formulated model and its responses, some computational simulations were performed in a three-dimensional state using two/three box-shape restricted areas. From the simulation results, the optimal trajectory was achieved, and the plant avoided the restricted area.

1. Introduction

Dynamical equation models, which comprise of the linear, complex, and hybrid dynamical system, play an important role in engineering the control systems. There are thousands of published research articles developed to analyze the dynamical model of some new engineering systems such as the mobile robot [1, 2], autonomous vehicles, car-like robot, etc. This research deals with an independent system with some known initial state and its corresponding output value with plant's initial position. The plant utilized moves to a decided state known as target position with minimal "effort" where some restricted states are not allowed to be passed through by the plant. The term "effort" in some cases is defined as the shortest path, while an obstacle is a restriction in space movement which should be avoided by the plant. The pioneer mathematical model utilized in this state was developed in [3] by formulating a piecewise affine model which corresponds to the restricted and normal sets. There are some published articles which described the restricted use of some systems, such as vehicles and mobile robots [4–9]. The more complicated problem comprises of several plants which are controlled by applying a multi-agent concept like flocking scheme, which was used in [10,11].

In some cases, the objectives of restricted area avoidance are not only avoiding the obstacle but also determining the optimal trajectory used to determine the final or target point. In this problem, an optimal control method based on mathematical optimization was implemented to solve the technique. For example, a particle swarm algorithm was applied in [12,13]. It is reasonable to utilize an optimization-based method because it will generate the ace result to the problem. Beside of optimal control problem, numerous inconsistencies were solved using the optimization approach which was also used to describe its profitability such as facility location optimization and the colony algorithm for knapsack.

In the system theory, a newly developed strategy is the hybrid dynamical model which comprises of different types of Piecewise-affine (PWA), discrete hybrid automata (DHA) and Mixed Logical Dynamic (MLD) models [14]. To analyze and control a hybrid model, in [15], a toolbox was developed which comprises of some MATLAB functions on model formulation and controlling. For example, the PWA model written in HYSDEL programming language can be converted into MLD using the MATLAB routine "*mld"* in the hybrid system toolbox. Furthermore, the MLD model which consists of trajectory tracking problems tends to be solved by applying a classic control method scheme MPC (model predictive control) and modifying the state prediction along with its corresponding objective function which was carried out in [16,17]. Many research articles applied this control method in agriculture field [18,19], as well as in controlling mechanical vehicles [20], boiler-turbine [21], and spacecrafts [22].

This research therefore aims at solving the problem associated with the restricted area inherent the three-dimensional states. First, the PWA model was formulated to determine whether the dynamical system of the plant is in a normal or restricted area.

Next, the PWA system is converted into equivalent MLD using HYSDEL and hybrid toolbox. Furthermore, by using predictive control method for the MLD model, the optimal input was generated to obtain the moving trajectory, which was initialized at the plant's starting point to its target position. Some computational simulations are performed to illustrate and visualize the results.

2. Dynamical System

Let vector $x(k) = \left(x_1(k), x_2(k), \cdots, x_n(k)\right)' \in \mathsf{R}^n$ denotes the state of a plant where k denotes the time instantly. Therefore, the dynamical model of the observed plant is a linear time-invariant system modeled as illustrated in the equation below

$$\left.\begin{aligned} x(k+1) &= Ax(k) + Bu(k) \\ y(k) &= Cx(k) \end{aligned}\right\} \tag{1}$$

where $u \in \mathsf{R}^p$ and $y \in \mathsf{R}^m$ are input & output vectors respectively, and the notations *A, B, C,* and *D* are real constant matrices. The control method used in this paper is applicable, the controllable and observable assumptions are held by (1).

2.1. Restricted Area Avoidance Scheme

The position to the output vector *y is defined without losing the generality property*. Let the initial position of the plant is obtained by $y(0) = y_0 = Cx(0) = Cx_0$. The value of the output, i.e., plant's position *y* have to maneuver and reach some desired target position denoted by y_f which corresponds to target state x_f, $y_f = Cx_f$, where in the output's domain, some sets such as $R_1, R_2, \ldots, R_r \subset \mathbb{R}^m$ are not allowed to be utilized by *y*. Let $R = \left(R_1 \cup R_2 \cup \cdots \cup R_r\right) \subset \mathsf{R}^m$, *y* is restricted to be in *R,* then $y \notin R$ should be held. To handle this condition, the dynamics of the system is formulated as a hybrid system.

The formula is illustrated as follows, w.l.o.g., let $y(k) \in \mathbb{R}^3$ with two restricted sets, R_1 and R_2 illustrated in Figure 1. The problem is how to determine the optimal trajectory used by the plant to maneuver (or move) from its initial state to the target position. The term "optimal" is interpreted as minimal effort (or energy or work or other similar things) used by the plant. The optimal trajectory shown in Figure 1 illustrates a moving trajectory from the initial to the target point.

The non-restricted sets are known as the normal area where the dynamics of the plant corresponds to (1). Alternatively, the dynamics which corresponds to the restricted set is defined as

$$\left.\begin{aligned} x(k+1) &= x(k) \\ y(k) &= Cx(k) \end{aligned}\right\} \tag{2}$$

which means that the dynamical model is used to prevent the plant from being located in the restricted area. The formulation of the hybrid dynamical model where the plant is prevented from entering the restricted area is illustrated by Figure 2 by assuming $x(k) \in \mathbb{R}^3$ and $y(k) = x(k)$.

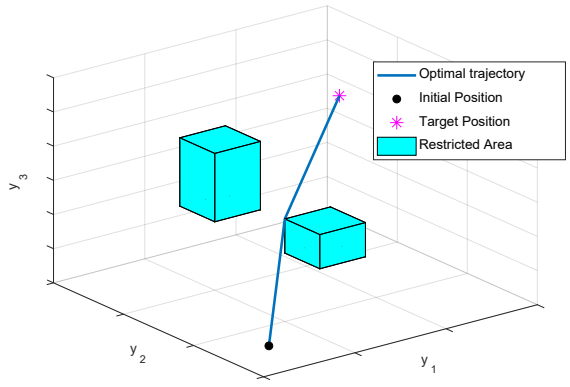

Figure 1: Two box-shape restricted areas illustration

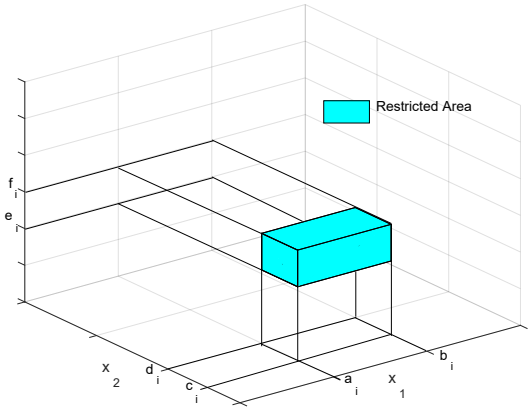

Figure 2: Restricted area labeling

Let the restricted sets (area) R_i, $i = 1, 2, \ldots, k$, and the normal set (area) denoted by *N,* then these sets are written as

$$\begin{cases} R_i : \{(x_1, x_2, x_3) : a_i \le x_1 \le b_i, c_i \le x_2 \le d_i, e_i \le x_3 \le f_i\} \\ N \ : \text{otherwise.} \end{cases}$$

2.2. PWA to MLD Hybrid Model

The hybrid model in the PWA model of the plant for restricted area avoidance purposes is formulated as

$$\left.\begin{aligned} x(k+1) &= \begin{cases} Ix(k), & x \in \text{restricted area} \\ Ax(k) + Bu(k), & x \in \text{normal area} \end{cases} \\ y(k) &= Cx(k) \end{aligned}\right\} \tag{3}$$

with *I* denotes an identity matrix with the appropriate dimension. To apply the predictive control method to this system, the MLD model is, first of all, converted into the form of

$$\left.\begin{aligned} x(k+1) &= Ax(k) + B_1u(k) + B_2\delta(k) + B_3z(k) \\ y(k) &= Cx(k) + D_1u(k) + D_2\delta(k) + D_3z(k) \\ E_2\delta(k) + E_3z(k) &\le E_1u(k) + E_4x(k) + E_5 \end{aligned}\right\} \tag{4}$$

with some initial state $x_0 = x(0)$ where $z(k)$ is an auxiliary state. The notation $\delta(k)$ is a binary valued state describing the mode of the system (mode 0 assuming it is on the normal area and 1 when restricted). The matrices A, B_i, C, D_i and E_i for all i are real constant generated by the conversion process, which is conducted using *mld* MATLAB function embedded in hybrid system toolbox given in [23] by writing the PWA system in HYSDEL, then generating the matrices for the equivalent MLD model.

2.3. Predictive Control Approach

The equation used to determine the optimal input to enable the output vector (position) reach the target point using minimal effort is represented as a terminal state optimal control problem. Furthermore, the predictive control approach is used to obtain the optimal input by letting $x(k|t)$ as the state value predicted at time instant $(k+t)$ which is resulted by applying input value $u(k+t)$ into equation (4) where the corresponding output value is predicted at time instant $(k+t)$, $y(k|t)$. The optimal input will be calculated by solving the minimal value "cost" function of output prediction as follows:

$$\min_{[u,\delta,z]^T} J = \left\| Q_y y(T|t) - y_f \right\|_w + \sum_{k=0}^{T-1} \left[\left\| Q_u u(k) \right\|_w + \left\| Q_y y(k|t) - y_f \right\|_w \right] \tag{5}$$

subject to:

$$\begin{cases} x(0|t) = x(t); y(0|t) = y(t); \\ y(k+1|t) = Cx(k|t) + D_1 u(k) + D_2 \delta(k|t) + D_3 z(k|t); \\ E_2 \delta(k|t) + E_3 z(k|t) \le E_1 u(k) + E_4 x(k|t) + E_5; \\ u_{\min} \le u(k+t) \le u_{\max}, k = 0,1,2,3,...,T-1; \\ x_{\min} \le x(k+t|t) \le x_{\max}, k = 0,1,2,3,...,T; \\ y_{\min} \le y(k+t|t) \le y_{\max}, k = 0,1,2,3,...,T-1; \end{cases}$$

where T is called the horizon control period, Q_u and Q_y are symmetric and positive definite matrices used to weight the input u and output y respectively. These symmetric and positive definite properties are applied to guarantee the objective function J is convex. This is expressed in the notation $\|Qy\|_{w=2} = y^T Qy$ where $\|Qy\|_{w=\infty} = \|Qy\|_\infty$. This predictive control scheme resulting in a mixed integer quadratic optimization problem and in our simulation, *miqp* MATLAB function, which is also embedded in hybrid system toolbox, is utilized to solve. Finally, the optimal values of $u(k)$ for all k are used by the system. For restricted area purposes, the term y_f in (5) is the final/target position where the dynamics of x is (4) which equivalents to (3).

3. Simulation Results

Given a plant with three-dimensional state

$$x(k) = \left[x_1(x), x_2(k), x_3(k) \right]^T \in \mathsf{R}^3$$

and output vector $y(k) = x(k)$ which can be described as the position in a three-dimensional Cartesian coordinate system. Let the initial state be $x_0 = x(0) = \left[1,1,1\right]^T$, which corresponds to the initial position $y(0) = \left[1,1,1\right]^T$.

                     THEN x2 ELSE x2+u }; z3 = {IF
                     (da3&~db3)&(dc3&~dd3)&(de3&~df3)
                     THEN x3 ELSE x3+u }; }
                     CONTINUOUS {x1 = z1;
                                 x2 = z2;
                                 x3 = z3; }
                     OUTPUT { y1 = x1;
                              y2 = x2;
                              y3 = x3; } } }
```

Listing Code 1: PWA model (7) with two restricted areas in HYSDEL

Then the dynamic of the plant in the normal area is

$$\left.\begin{aligned} x(k+1) &= \begin{bmatrix} 1 & 0 & 0 \\ 0 & 1 & 0 \\ 0 & 0 & 1 \end{bmatrix} x(k) + \begin{bmatrix} 1 \\ 1 \\ 1 \end{bmatrix} u(k) \\ y(k) &= x(k) \\ x(0) &= \begin{bmatrix} 1 \\ 1 \\ 1 \end{bmatrix} \end{aligned}\right\}. \tag{6}$$

Suppose there are two restricted sets R_1 and R_2 defined visually as two boxes

$$R_1 : \left\{ (x_1, x_2, x_3) : 3 \le x_1 \le 5, 3 \le x_2 \le 4, 3 \le x_3 \le 5 \right\}, \text{ and}$$

$$R_2 : \left\{ (x_1, x_2, x_3) : 0 \le x_1 \le 3, 7 \le x_2 \le 9, 5 \le x_3 \le 7 \right\}$$

where the rest of state space is normal, then the PWA model of this system is stated as

$$x(k+1) = \begin{cases} x(k) & , x \in R_1 \cup R_2 \\ \begin{bmatrix} 1 & 0 & 0 \\ 0 & 1 & 0 \\ 0 & 0 & 1 \end{bmatrix} x(k) + \begin{bmatrix} 1 \\ 1 \\ 1 \end{bmatrix} u(k), & \text{otherwise} \end{cases} \quad (7)$$
$$y(k) = Cx(k).$$

The PWA model in HYSDEL has already been written (See Listing Code 1) and converted it into MLD model (4) resulting in the following matrices $B_2 = D_2 = zeros(3,15)$, $B_3 = C = I_3$, $A = B_1 = D_2 = D_3 = zeros(3,3)$, and E_1, E_2, E_3, E_4, and E_5 because their dimension is sufficiently large.

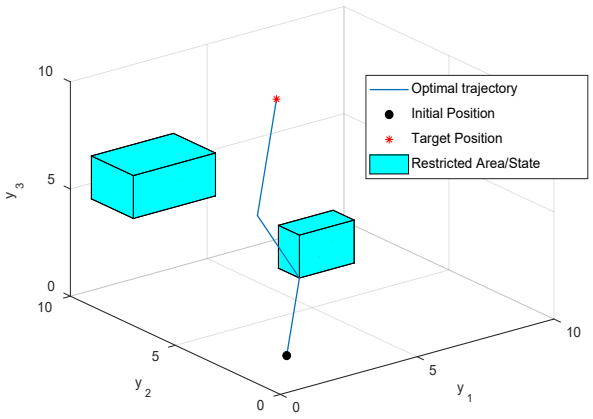

Figure 3: Optimal moving trajectory generated by the controller

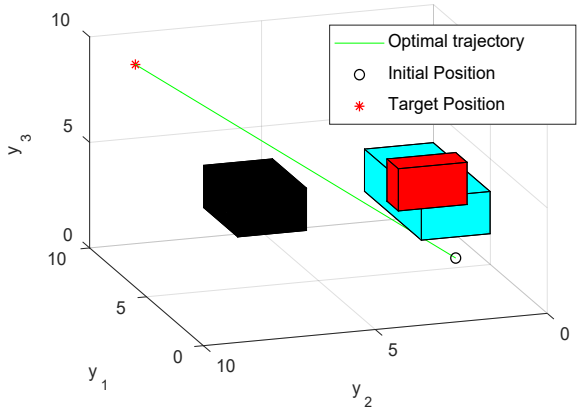

Figure 4: Optimal moving trajectory with three box-shape restricted area

By solving (5) with w=2, the optimal input values are obtained, and by applying them into (7), the optimal moving trajectory from its initial position to its target/final position as show in Figure 3 of the output values are obtained. From Figure 3, it is observed that two restricted areas were restricted and avoided by the system's moving trajectory, as illustrated in the two boxes. For further simulation, another box was added. The result is shown in Figure 4 and is similar to the optimal moving trajectory, which was generated by the controller to prevent the restricted areas.

4. Conclusions

The multi-restricted area which avoids the problem associated with the autonomous linear system was considered dynamic with the region formulated as a hybrid model and the optimal trajectory calculated. From the computational simulation, the obtained system's moving trajectory was generated by the controller, and the given restricted areas were avoided. Further research works will develop the shape of the restricted area into other shapes like polytope to control the inconsistencies associated with irregular shapes. Other control methods will be considered and compared to determine the best in performance.

Collision Risk Index
ANFIS

ABSTRACT

Collision risk index has been studied as the required quantitative values for decision-making of collision avoidance between ships. Recently, inference methods of the collision risk were proposed on the basis of the fuzzy theory because of being possible to collect data in real time. Existing fuzzy inference system was composed of only simulation results using virtual navigation situation. In this study, we obtained the fuzzy inference rule based on ship near-collision data via the adaptive neuro fuzzy inference system. Proposed fuzzy inference rule expressed various collision risk index in order that a ship could avoid collision with an encounter ship at appropriate distance and time. It would support for navigators to make an appropriate decision for collision avoidance with encounter ships.

1. Introduction

Despite the efforts to prevent accidents, marine accidents has been occurring without interruption. According to the statistics of KMST(Korean Maritime Safety Tribunal), 10,991 marine accidents have occurred in the last five years from 2014 to 2018. Out of these accidents, 1,132 marine accidents have occurred in collision resulting from lack of look-out and violation of CORLEGs(International Regulations for Preventing Collisions at Sea) [1]. Accordingly, collision accidents can cause structural hazard, loss of human life and property, and ocean pollution due to oil and cargo spills. Thus, since the demand on system to support the safe navigation of ships has been increased, collision avoidance algorithm has been proposed.

Collision avoidance algorithm starts from assessing the collision risk. In order to assess the collision risk in the early days, the concept of a ship domain proposed by [2] was used to assess the collision risk. This concept is succeeded by [3], [4] and [5] in several shapes, the methods of determining ship domains have evolved with time [6,7,8-10]. Nonetheless, it still doesn't contain time-related information.

Since it has been possible to obtain DCPA(Distance of the Closest Point of Approach) and TCPA (Time to the Closest Point of Approach) in real time, inference method of the CRI(collision risk index) on the basis of the fuzzy theory has been proposed. In [11], the author connected DCPA and TCPA to the CRI using interviews of navigators by showing virtual navigation situation on simulator. In [12], the authors reconstructed the FIS (Fuzzy Inference System) using non-dimensionalized DCPA and TCPA. In [13], the researchers calculated the CRI by including VCD (Variance of Compass Degree) into input parameter proposed by Lee and Rhee.

On the basis of the proposed FIS [11,12,13], various studies have been conducted. In [14], the author designed an estimation algorithm of the collision risk among approaching multiple ships by using the fuzzy theory, and verified performance on the basis of the AIS (Automatic Identification System) maritime traffic data. In [15], the author proposed an evaluation algorithm of the collision risk in order that VTSO (Vessel Traffic Service Operator) was able to analyze the collision risk among ships in advance. In [16], the author proposed a model of predicting ship collision risk based on the FIS considering the general patterns of collision avoidance. Furthermore, the FIS has been applied to collision avoidance system in the field of development for an USV(Unmanned Surface Vehicle). The USV developed for multipurpose of ocean observation and surveillance could flexibly change an action space according to the collision risk, which was inferred by using obstacle information on a basis of fuzzy inference [17]. In [18], the researcher used the FIS as a point of time for generating and sending messages in order that efficient information exchange for collision avoidance was possible between autonomous ship and manned ship.

But the proposed FIS [11,12,13] had the limitation which was relied on the empirical factors of navigators. Hence, in [19], the

*Corresponding Author: Ho Namgung, Email: ngh2009@mmu.ac.kr

author suggested the FIS considering ship's characteristic in virtual navigation situation on simulator without interviews of navigators. Nonetheless, because of membership functions and rules determined by simulation results, the existing FIS still have significant limitation not reflecting on information of actual collision situation between ships.

To overcome the limitation of the existing FIS [11,12,13,19], this study proposed an improved fuzzy inference rule by learning actual near-collision data extracted from the AIS via ANFIS (Adaptive Neuro Fuzzy Inference System). Section II described inference methods of the collision risk using the FIS and decision of near-collision. Section III suggested the fuzzy inference rule obtained by learning ship near-collision data via ANFIS. Subsequently, performance of the proposed FIS comparing with the existing FIS was validated and discussed in section IV. Finally, a summary of the work and the conclusion drew in section V.

2. Materials

2.1. Calculation of the CRI using FIS

The FIS inferred the CRI based on the fuzzy theory using DCPA and TCPA. DCPA referred to a minimum distance through a target ship when own-ship and a target ship were encountered. TCPA was an expected time to arrive at the point where DCPA occurred at the ship's present location. Figure 1 is presented that ships V_1 and V_2 passed the minimum distance between ships at TCPA t_c. The time from current time to t_c was TCPA, and the distance between own-ship and a target ship at estimated time from the t_c was DCPA.

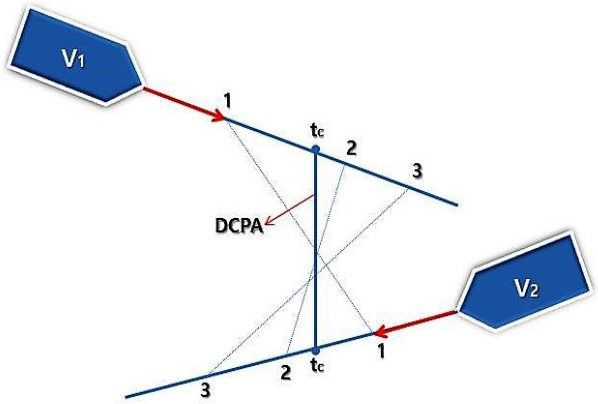

Figure 1: Calculation DCPA and TCPA

Figures 2 and 3 show the fuzzy membership function of TCPA/(L/ V) and DCPA/L, where L was a length of ship and V was a ship speed. In order to increase precise on the FIS, letting DCPA and TCPA to be dimensionless by using a length and a speed of ship was conducted[12]. The CRI can be expressed as values from -1 to 1. Negative values in TCPA mean that a target ship passed through own ship, i.e., safe situation by being out of the collision risk.

Inference rule of state variables used in the FIS are Small (S), Medium (M), B (Big), P (Positive), and N (Negative). Table 1 shows a part where collision risk was determined in order that an input and an output can express the inference rule as a two-dimensional matrix. In other words, it is determined by a condition part of the $i-$th inference rule out of all the inference rules. The CRI at the conclusion as numerals in the fuzzy inference table as show in equation (1).

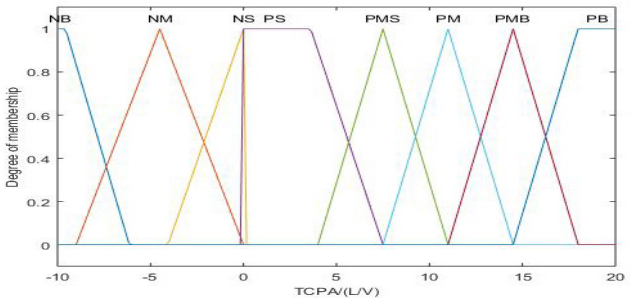

Figure 2: Fuzzy membership function of TCPA/(L/V)

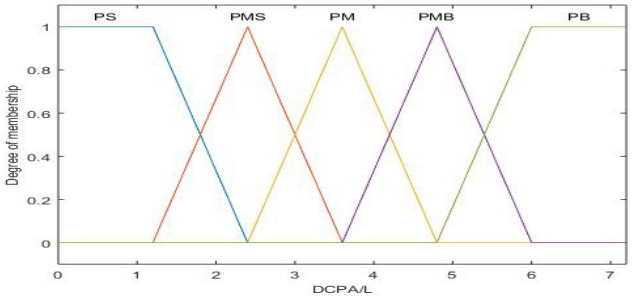

Figure 3: Fuzzy membership function of DCPA/L

$$\text{Collision Risk(CR)} = \frac{\sum_{i=1}^{n} CR_i \cdot a_i}{\sum_{i=1}^{n} a_i} \quad (1)$$

Where,

n = number of reasoning rules,

CR_i = singleton value of conclusion part of $i-$th rule,

a_i = contribution factor of conditional part of $i-$th rule.

Table 1: Fuzzy inference table

Division		TCPA/(L/V)							
		NB	NM	NS	PS	PMS	PM	PMB	PB
DCPA /L	PS	-0.2	-0.6	-1.0	1.0	0.8	0.6	0.4	0.2
	PMS	-0.2	-0.2	-0.6	0.8	0.6	0.4	0.2	0.2
	PM	-0.2	-0.2	-0.2	0.6	0.4	0.2	0.2	0.2
	PMB	-0.2	-0.2	-0.2	0.4	0.2	0.2	0.2	0.2
	PB	-0.2	-0.2	-0.2	0.2	0.2	0.2	0.2	0.2

A point of time for an action of collision avoidance[12,13,19] was determined as follows. In case of a give-away ship, more than 0.6 of the CRI mean an action of collision avoidance. A stand-on ship takes an action of collision avoidance in case of more than 0.8.

2.2. Decision of Ship Near-Collision

Because the number of actual collision accidents was very small, it was significantly difficult to construct a model for evaluating the collision risk based on previous marine accidents [20]. Therefore, near-collision, which was a situation in which there was the danger of collision between ships approaching each other, but with no collision eventually occurring, either due to

deceleration, or evasion by the change of course, was used. In order to detect a number of near-collision, ship domain was utilized for decision of near-collision as criteria not overlapped between ship domains [21,22]. Thus, in this study, near-collision was decided according to proposed methods using ship domain.

Ship domain [2] size with ellipse can be divided into two types as follows. In the sufficient sea area to freely navigate with 10 to 16 knots, the ship domain was composed of 8 L and 3.2 L, where L is ship length. In the constrained sea area such as narrow channel or harbour, the ship domain was composed of 6 L and 1.6 L by reducing speed until 6 to 8 knots. Figure 4 shows ship domain size[2].

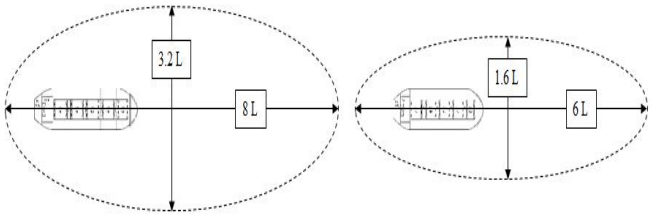

Figure 4: Ship domain size

Ship near-collision based on ship domain with ellipse can be decided in shown as Figure 5.

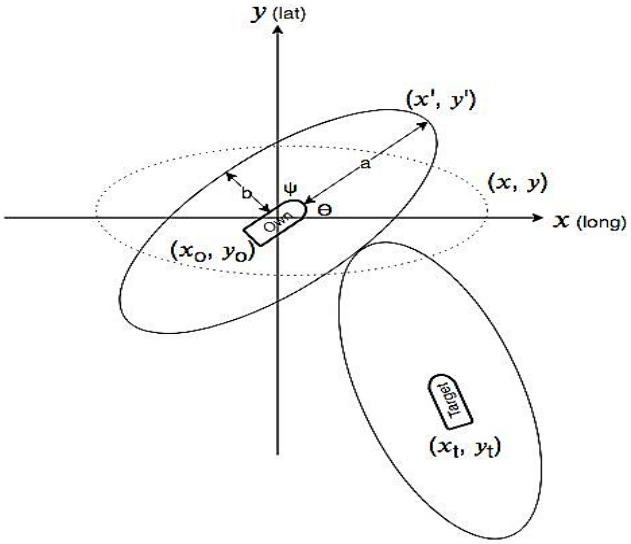

Figure 5: Near-collision between ship's ellipse dimensions

Own ship's ellipse area is parallel to the axis x at the position (x_O, y_O), and can be expressed with a long radius (a) and a short radius (b) in the shape of a dotted line. As an ellipse of position is able to be changed in accordance with own ship's course, rotation of ellipse is necessary corresponding to course. A long radius a and angle of intersection θ of bow direction on the axis x are decided according to ship course angle φ as equation (2). Calculation of rotated own ship's ellipse follows equation (3).

$$\theta = \begin{cases} |90^\circ - \varphi| \ (\varphi \leq 180^\circ) \\ |270^\circ - \varphi| \ (\varphi \geq 180^\circ) \end{cases} \quad (2)$$

$$\frac{(\cos\theta \times (x' - x_O) + \sin\theta \times (y' - y_O))^2}{(a \times L_O)^2} + \frac{(\sin\theta \times (x' - x_O) + \cos\theta \times (y' - y_O))^2}{(b \times L_O)^2} = 1 \quad (3)$$

3. Inference Rule based on Near-Collision via ANFIS

3.1. Procedure for Configuration of the Fuzzy Inference Rule

Procedure for configuration of the fuzzy inference rule presented in Figure 6 can be divided into four steps. A defined action of collision avoidance was defined in first step. Second step designated appropriate distance corresponding to an action of collision avoidance. Third step enlarged an area of the ship domain based on designated distance, and extracted DCPA, TCPA and CRI when ship domain enlarged by level was overlapped. The fuzzy inference rule by learning ship near-collision data via ANFIS was suggested in fourth step.

3.2. Set on the Collision Risk Index

The CRI was set by enlarging the ship domain corresponding to appropriate distance for collision avoidance through definition of an action of collision avoidance by level.

First step defined an action of collision avoidance corresponding to level, and set appropriate distance by level. According to the classification of encounter situations[23,25], an action of collision avoidance was divided into Collision(C), Dangerous(D), Threat(T) and Attention(A). Table 2 defines an action of collision avoidance by level.

Table 2: Definition of an action of collision avoidance by each level

Level	Definition
Collision (C)	· Both ships almost have collision
Dangerous (D)	· Both ships must conduct the best cooperation an action for collision avoidance
Threat (T)	· A give-way ship must conduct an action of collision avoidance · A stand-on ship can take an action for collision avoidance
Attention (A)	· A give-way ship must conduct an action of collision avoidance · A stand-on ship must keep own course and speed

In order to set appropriate distance according to the defined level, it is necessary to take into consideration a give-way ship and a stand-on ship's distance for an action of collision avoidance.COLREGs requested a specified light intensity to show the minimum distance of the ship lighting[23]. The mast light is 6 nm(nautical miles), side light is 3 nm and stern light is 3 nm. Comparing the minimum distance of the ship lighting with an encounter situation for an action of collision avoidance, the mast light and the side light are able to be checked on head-on and crossing situation, and the stern light are able to be checked on overtaking situation.

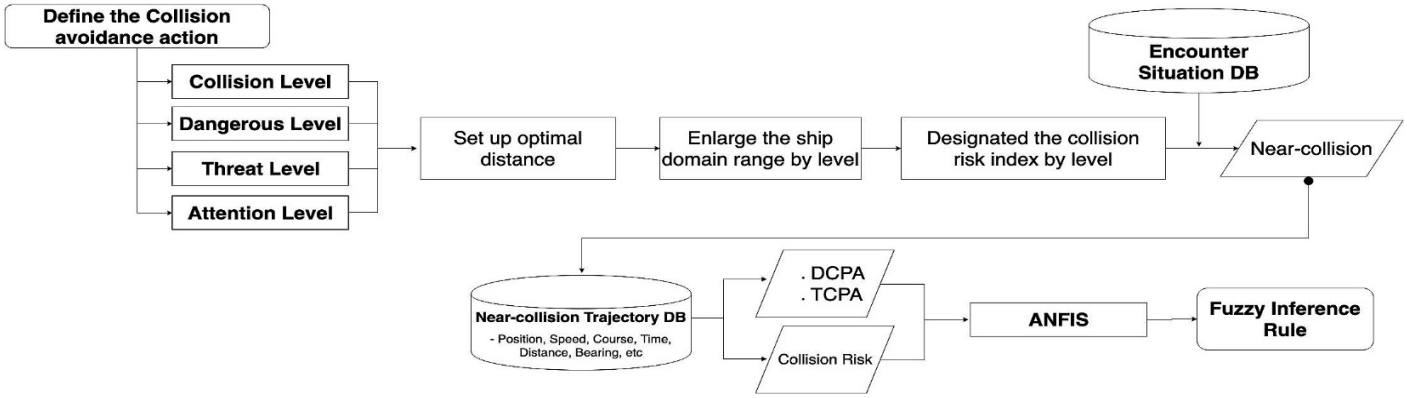

Figure 6: Procedure for configuration of fuzzy inference rule using ship near-collision data

Results of navigator's interviews[24] showed 6 nm, 3 nm and 1nm on the head-on situation, crossing and overtaking situation, and the minimum safe distance. Cockcorft, A. and Lameijer, J.N.F.,(2011) [25] advised the minimum safe distance for collision avoidance as 1 nm in sight of one another and 2 nm in restricted visibility. And, for a collision situation involving two power-driven ships, the minimum distance suggested for an action of collision avoidance were 2 to 3 nm.

Therefore, an action distance of collision avoidance for Collision(C) level was not set due to occurred situation of collision between ships. An action distance for Dangerous(D) level was set as 1 nm in order to pass safely between ships through both ship's cooperation navigation. An action distance for Threat(T) level was set as 2 nm in order that a stand-on ship takes an action of collision avoidance by continuously observing an action of a give-way ship's collision avoidance. At this distance, a give-way ship still has an obligation for collision avoidance. An action distance of Attention(A) was set 3 nm due to initial beginning of the collision risk between ships.

Second step sets the CRI corresponding to enlarged the ship domain based on designated distance by level. In order to enlarge the ship domain, we used the ship domain ($8L \times 3.2\,L$)[2] as standard, considering limited ship speed suggested in each sea area. The standard ship length was set as 70 meters due to having different lengths[2].

In case of overlapping the ship domain ($8\,L \times 3.2\,L$) set in encounter ships, each ship had extra distance 0.3 nm. At this time, the sum of extra distance was 0.6 nm. This was due to actual collision accident was not occurred. However, since distance of the overlapping ship domain was less than the minimum safe distance 1 nm, it could mean that both ships almost had collision. Hence, ship domain ($8L \times 3.2\,L$) was set corresponding to Collision(C) level. Based on this approaching methods, ship domain size was adjusted corresponding to designated distance by level.

The existing FIS had the range of the CRI from -1.0 to 1.0. But in this study, we composed of the range of the CRI from 0.0 to 1.0 except for negative sign. The CRI of Attention(A) level was set 0.0 due to initial beginning of the collision risk between ships. Other levels were designated by dividing 1.0 to the three parts. Accordingly, the CRI of Collision(C) level was 1.0 due to the meaning of having collision between ships, and Dangerous(D) level and Threat(T) level were set as 0.66 and 0.33 due to gradually increasing the CRI by times. Table 3 shows the range of the CRI, ship domain size and the minimum safe distance by proposed level. Overlapping situation between ship domains is presented in Figure 7.

Table 3: The range of the CRI, ship domain and safe distance by proposed level

Level	NM	Ship domain	CRI
C	-	$8\,L \times 3.2\,L$	1.0
D	$0.6 < \text{NM} \leq 1.0$	$13.2\,L \times 5.28\,L$	$0.66 \leq \text{CRI} < 1.0$
T	$1.0 < \text{NM} \leq 2.0$	$26.4\,L \times 10.56\,L$	$0.33 \leq \text{CRI} < 0.66$
A	$2.0 < \text{NM} \leq 3.0$	$39.6\,L \times 15.84\,L$	$0.0 \leq \text{CRI} < 0.33$

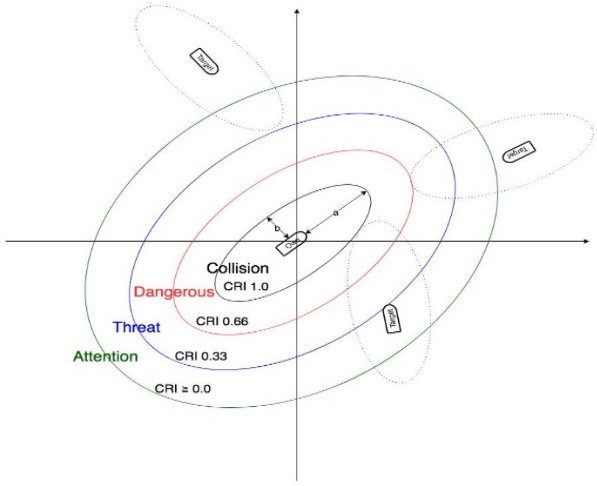

Figure 7: Overlapping situation of ship domain by proposed level

3.3. Ship's Trajectory Data by Level

By setting enlarged ship domain based on Collision(C) level to both ships, ship's trajectory data were extracted when overlapped. This was for comparing and analyzing the information generated from initial beginning of the collision risk to occurring to near-collisions. At this time, ship domain of both ships were set by having the same size in order that enlarged ship domain applied to both ships corresponded to the designated distance when overlapped. To collect ship's near-collision data, Mokpo sea area

was designated. 97 cases out of a total of 154 ships had encounter situations. Results of near-collision by setting ship domain ($8\,L \times 3.2\,L$) as Collision(C) level was a total of 49 cases. Figure 8 is shown as ship's near-collision trajectory.

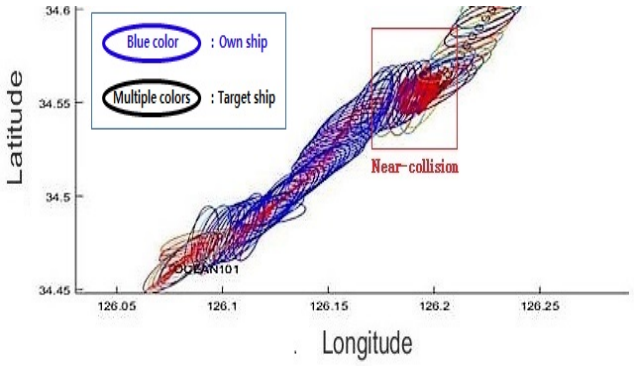

Figure 8: Ship near-collision trajectory

By extracting a total of 196 near-collision ships occurred in each level, we corresponded to the CRI of proposed level. DCPA and TCPA was extracted based on ship's trajectory near-collision data when near-collision by level occurred. At this time, the DCPA was non-dimensionalized by using ship length L, and the TCPA was non-dimensionalized by using ship length L divided by the ship speed V. Table 4 shows the trajectory data of ship near-collision by level.

Table 4: The trajectory data of ship near-collision by level

Level	DCPA/ L	TCPA/(L/V)	CRI
Collision (C)	0.12	0.74	1.0
	0.09	1.93	1.0
	0.17	1.13	1.0
Dangerous (D)	0.48	0.49	0.66
	0.41	2.98	0.66
	0.68	4.41	0.66
Threat (T)	1.07	7.28	0.33
	1.06	9.89	0.33
	0.72	0.81	0.33
Attention (A)	1.29	7.22	0.1
	1.43	3.09	0.1
	2.27	13.3	0.1

3.4. Inference Rule of Collision Risk

3.4.1. Structure of ANFIS

The ANFIS[26] is one of the neuro fuzzy systems for the fuzzy modeling and control proposed by Jang. Configuration of inference rule of the collision risk was as follows. First step designated DCPA/L and TCPA/(L/V) as input parameter, and the CRI as output parameter. At this time, DCPA/L and TCPA/(L/V) were composed of a total 4 of MF(memberships function). Table 5 shows input and output parameter set in MF.

Table 5: Categorized input and output parameter

No.	Input		Output
	DCPA/ L	TCPA/(L/V)	CRI
	Inputmf	Inputmf	Outputmf
1	Collision	Collision	Outputmf 1
2		Dangerous	Outputmf 2
3		Threat	Outputmf 3
4		Attention	Outputmf 4
5	Dangerous	Collision	Outputmf 5
6		Dangerous	Outputmf 6
7		Threat	Outputmf 7
8		Attention	Outputmf 8
9	Threat	Collision	Outputmf 9
10		Dangerous	Outputmf 10
11		Threat	Outputmf 11
12		Attention	Outputmf 12
13	Attention	Collision	Outputmf 13
14		Dangerous	Outputmf 14
15		Threat	Outputmf 15
16		Attention	Outputmf 16

Second step composed of fuzzy inference rule by learning input and output parameters via ANFIS. Figure 9 shows ANFIS structure configured by using MF of input and output parameters.

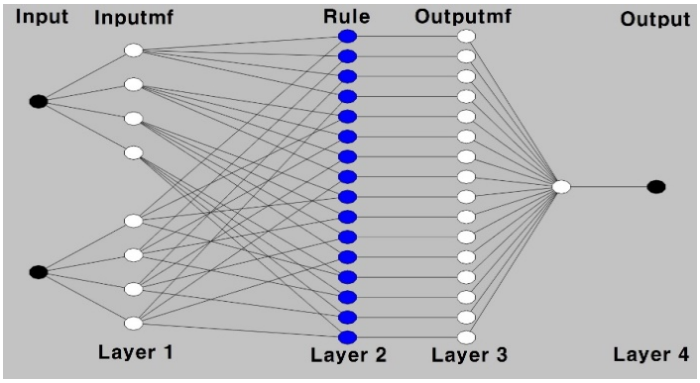

Figure 9: Structure of ANFIS

DCPA/ L and TCPA/(L/V) were designated as premise parameter x, y and CRI was designated as consequent parameter f_i. By using consequent coefficient a, b, c inference rule was composed as shown in equation (4).

$$Rule_i : If\ x\ is\ \mu_{\left(\frac{DCPA}{L}\right)i}\ and\ y\ is\ \mu_{\left(\frac{TCPA}{\left(\frac{L}{V}\right)}\right)i,}$$

$$\text{then } f_i = a_i x + b_i y + c \qquad (4)$$

3.4.2. Inference Rule through Learning Algorithm

The ANFIS can be trained by the backward propagation algorithm and the hybrid learning algorithm. In the backward propagation algorithm, the errors are propagated backward and the premise parameters are updated by gradient descent. At this time, consequent parameters are fixed. In the hybrid learning algorithm, the premise and consequent parameters are updated by least-

squares method and gradient descent. In this study, we used the backward propagation algorithm for maintaining the CRI designated by level. Therefore, surface of CRI through learning by the backward propagation algorithm was represented non-linear as shown in Figure 10.

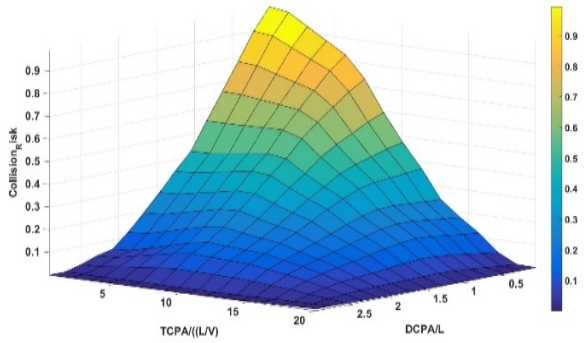

Figure 10: Surface of the CRI

Inference rule of the CRI proposed by learning near-collision data via ANFIS was presented in Table 6.

Table 6: Fuzzy inference rule for membership function

Division		DCPA/*L*

4. Result and Discussion

4.1. Result

To validate performance of the proposed fuzzy inference rule by comparing with the existing fuzzy rule, two ships navigating at Mokpo sea area were selected from AIS data. One of which was designated as own-ship and the other was designated as a target ship. An encounter situation and near-collision situation are presented in Figures 11 and Figure 12. When the encounter situation occurred within 10 nm, own-ship begun calculating the CRI with DCPA and TCPA. The CRI calculated from four types of inference rule was presented in Table 7 and Figure 13.

At the initial encounter situation between own-ship and a target ship, the FIS[12], FIS-VCD[13], FIS-SC[19] and FIS-NC proposed in section III indicated the CRI 0.29, 0.67, 0.32 and 0.11, respectively.

When it comes to TCPA and distance, the FIS-SC and the FIS-NC were gradually increased until near-collision situation according to reduction of TCPA and distance. Whereas, the FIS and the FIS-VCD were not gradually increased until near-collision situation. In case of the FIS, after it obtained the CRI until 0.94, the same CRI was kept until near-collision situation. In case of the FIS-VCD, unlike the FIS, the FIS-SC and the FIS-NC, it depended on how much the VCD was obtained due to input parameter DCPA, TCPA and VCD. As shown in Table 7, as the VCD got closer at 0, the CRI was increased.

When it comes to a point of time for action of collision avoidance of a give-way ship, distance for action of collision avoidance via the FIS, the FIS-VCD, the FIS-SC and FIS-NC represented about 7.2 nm, about 9.8 nm, about 6.1 nm and about 7.7 nm, respectively. At this time, TCPA represented about 10.7 minutes,15.8 minutes, 7.7 minutes and 11.7 minutes, respectively.

When it comes to a point of time for action of collision avoidance of a stand-on ship, distance for action of collision avoidance via the FIS, the FIS-VCD, the FIS-SC and FIS-NC represented about 5.1 nm, about 7.2 nm, about 1.7 nm and about 6.1 nm, respectively. At this time, TCPA represented about 7.4 minutes,10.7 minutes, 2.5 minutes and 7.7 minutes, respectively.

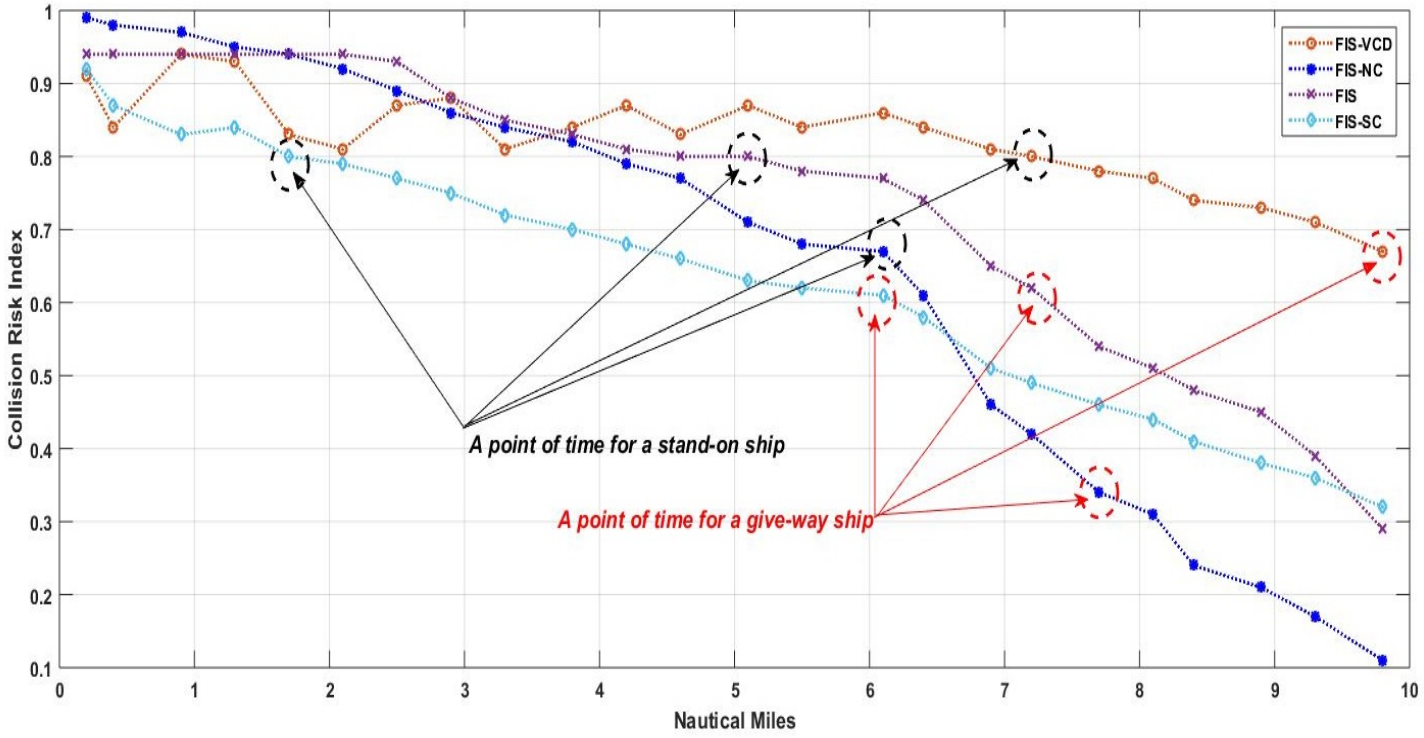

Figure 13: Comparison with the different CRI corresponding to distance

4.2. Discussion

In section 4.1, it could be seen that the exiting rule[12,13,19] and the proposed rule were able to obtain the CRI in the encounter situation between own-ship and a target ship according to values of input parameter. However, a point of time for action of collision avoidance was different according to type of the encounter situation. In case of a give-way ship, the FIS, the FIS-VCD and the FIS-SC defined that own-ship must take an action when the CRI exceeded more than 0.6. In case of a stand-on ship, own-ship must take an action for collision avoidance when the CRI exceeded more than 0.8. On the other hand, when the CRI exceeded more than 0.33, the FIS-NC proposed that a give-way ship must take an action for collision avoidance. In case of a stand-on ship in the FIS-NC, a point of time for collision avoidance was when the CRI was more than 0.66. Therefore, in this section, a point of time for action of collision avoidance via the FIS, the FIS-VCD, the FIS-SC and the FIS-NC were discussed according to the "A guide to the collision Avoidance Rules[25]", as well as a review of the various values obtained from inference rules.

According to [25], it states that ship should take an action for collision avoidance within about 5 to 10 minutes of TCPA or within about 2 to 3 nm of minimum distance. As shown in Table 7 and Figure 13, a give-way ship using the FIS, the FIS-VCD, the FIS-SC and the FIS-NC can obtain outer distance 2 to 3 nm and enough TCPA for taking an action. whereas, in case of a stand-on ship, the only the FIS-SC didn't obtain the requested distance and TCPA. it means that ship using the FIS-SC have no choice but to take into consideration collision risk at all times.

In terms of the CRI expression, even though the FIS had enough distance and TCPA until near-collision situation, it indicated the same CRI from 0.94 to near-collision situation. In case of the FIS-VCD, it relied on the only VCD. For this reason, unlike the FIS, FIS-SC and FIS-NC, the only the FIS-VCD already exceeded more than threshold at the initial encounter situation. On the other hand, the FIS-SC and the FIS-NC expressed the various CRI according to input parameters. It means that the CRI calculated from the FIS-SC and the FIS-NC reflected original information(DCPA, TCPA) well. Accordingly, because priority of multiple ships can be designated via the various CRI, these would be possible to not only take an appropriated action of collision avoidance between ships, but also among multiple ships.

For this reason, a ship using the FIS-NC can take an suitable action in any encounter situations because it reflects all of aspects, i.e., appropriated distance and TCPA according to the various CRI. However, it didn't reflect various factors, e.g., weather condition, ship size, congestion of navigation area and so on.

5. Conclusion

Although the FIS using DCPA and TCPA have been reported previously, they have largely relied on the use of either interviews of navigators or ship's characteristic in virtual navigation situation. These approaches tend to have the limitation not reflecting on information of actual collision situation between ships. Therefore, in this paper, we proposed the fuzzy inference rule based on near-collision via ANFIS by applying an action of collision avoidance corresponding to the CRI by level. For a configuration of fuzzy inference rule, steps was conducted as follows. An action of collision avoidance was defined, and distance to conduct an action of collision avoidance was set; (i). By enlarging ship domain based on designated distance by level, DCPA, TCPA and CRI were extracted when overlapped; (ii). Fuzzy inference rule was proposed by learning near-collision data via ANFIS; (iii). The results of applying proposed fuzzy inference rule to actual navigation area expressed the various CRI corresponding to the required distance and TCPA in order that navigators can make a decision appropriately. Accordingly, the proposed fuzzy inference rule not only overcame these issues, but also offered performance more outstanding than the existing fuzzy inference rule. However, it didn't reflect weather condition, ship size, congestion of navigation area, and so on. In further study, it is required to improve and validate the inference rule of the CRI taking consideration into drawbacks.

ABSTRACT

The article proposes a Digital Predistortion (DPD) methodology that substantially meliorates the linearity of limited range Mobile Front Haul links for the extant Long-Term Evolution (LTE) and future (5G) networks. Specifically, the DPD is employed to Radio over Fiber links that contrive of Vertical Cavity Surface Emitting Lasers (VCSELs) working at 850 nm. Both, Memory and Generalized Memory Polynomial models are implied to Single Mode (SM) and Multi-Mode (MM) VCSELs respectively. The effectiveness of the proposed DPD methodology is analyzed in terms of Normalized Mean Square Error, Normalized Magnitude, Normalized phase and Adjacent Channel Power Ratio. The demonstration has been carried out with a complete (Long Term Evolution) LTE frame of 10 ms having 5 MHz bandwidth with 64-QAM modulation configuration. Additionally, the effectuality of the proposed DPD technique is evaluated for varying levels of input power and link lengths. The experimental outcomes signify the novel capability of the implied DPD methodology for different link lengths to achieve higher system linearization.

1. Introduction

This paper is extension of the work originally presented in 2018 IEEE International Topical Meeting on Microwave Photonics (MWP) titled "Experimental evaluation of digital predistortion for VCSEL-SSMF-based Radio-over-Fiber link" [1]. The fifth generation (5G) technology is envisaged to provide faster internet access with low latency, cost effectiveness and pervasive mobile coverage [2-3]. Radio over Fiber (RoF) is a pertinent technology to deal with exorbitant requirement of bandwidth multivariate wireless services both for outdoor and indoor scenarios [4-6], and is regarded as a significant technology for the next generation networks [7].

In particular, RoF technology can provide an essential platform for building centralized/cloud radio access network (C-RAN) which should be able to control the centralized base band units (BBU) coming from different base stations and remote radio heads (RRHs) [8].

The interconnectivity of these BBUs with RRHs is economically viable with the distribution network known as the 'fronthaul' [9-10]. The RoF technology is then a suitable candidate for the fronthauling due to its inherent capillary properties. Figure 1 shows the C-RAN utilizing optical fronthauls (OFHs).

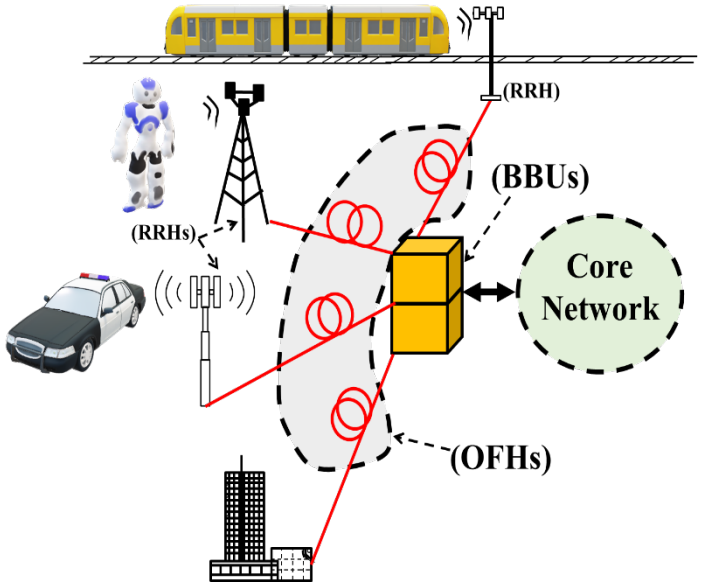

Figure 1: Basic C-RAN architecture showing optical fronthauls (OFHs)

Within these short-medium reach networks, OFHs based on the RoF technology can be realized utilizing Standard Single mode

Fiber (SSMF) or also Multimode Fiber (MMF) [11]. In both cases, a possible solution which keeps low levels cost and power consumption can be obtained utilizing Vertical Cavity Surface Emitting Lasers also known as VCSELs which emit in the first optical window (wavelength λ=850 nm) as the optical source.

While the use of VCSELs operating at short wavelengths is a relatively consolidated choice finding application e.g. in combinations with Plastic Optical Fibers within in-building networks [12-13] or in combination with MMFs within data centers [14], care must be taken in front of the possible impairments due to the multimodal behavior of SSMFs that operate at the 850 nm [15]. The presence of multimodal behavior would indeed be absent if expensive VCSELs operating at 1.3 μm and 1.55 μm were utilized , in which the major SSMF-related impairments could just be ascribed to optical nonlinear effects and/or to chromatic dispersion [16-17]. However, appropriate countermeasures have been proposed, which can prevent this last impairment cause to be critical [18-19].

Besides the cited OFH, VCSEL-based RoF systems can be found in multivariate scenarios, being utilized for radio astronomic signal transmission [20], multi service indoor wireless signal distribution [21], or machine learning detection [22].

In all these cases, a cardinal issue is represented by the impairments of the opto-electronic devices and particularly the whole VCSEL based Radio over Fiber system. Such nonlinearities, that arise due to relatively stable causes like nonlinear attributes coming from laser diode and perhaps from photodiode [23]. These nonlinearities can also arise due to little dynamics of VCSELs [24], e.g., when high Peak-to-Average Power Ratio (PAPR) signals are transmitted and can have an important role especially for multi-channel transmission. They indeed can cause high in and out of band distortion, which leads to higher interference among near channels.

In order to minimize the nonlinearities in RoF transmission, different methodologies have been proposed that comprises of digital and analog electrical techniques [25-27]. Among them, Digital Predistortion (DPD) has been regarded to be effectual method that leads to reduction in nonlinearities of RoF systems. The primary intension behind this method exploits a digital predistorter (PD) which has inverse and nonlinear profile as that of the Radio over Fiber system. Consequently, when cascaded with the RoF system, it will lead to linearization of the overall cascaded system. DPD linearization technique using memory polynomials based on Volterra series has been applied to Non linear RoF link [26-28]. Similarly, the Digital Predistortion technique based on canonical piecewise-linear (CPWL) function was proposed for intensity modulated/direct detection RoF system [29]. All the aforementioned techniques apply the distortion compensation considering the RoF systems as "black box".

In our previous work reported in [1,30], we demonstrated the novel implementation of DPD implied to considered radio over fiber link which was based on single mode (SM) based VCSEL for LTE applications utilizing Memory Polynomial (MP) architecture. The highlighted results were obtained in back-to-back (B2B) configuration, i.e. utilizing a SSMF fiber patch-cord of a few meters length.

In this paper, the novelty of the current work is summarized as follows: (1) for the first time, the evaluation that was performed in [1] is extended by considering the same SM VCSEL-based RoF system, not in B2B configuration, but equipped with SSMF spans of different lengths; (2) Moreover, also Multimode (MM) VCSEL-based RoF systems are analyzed, utilizing different lengths of MMFs, (3) in addition, to the DPD technique based on Memory Polynomials (MP) utilized in [1], another architecture named as Generalized Memory Polynomial (GMP), is utilized as well, which in general shows an improved effectiveness with respect to MP; (4) the DPD is trained and tested near to threshold to check the efficacy of the proposed technique.

As a performance index evaluation, the link linearity improvements are observed by calculating the Adjacent Channel Power Ratio (ACPR), Normalized Mean Square Error (NMSE), spectral regrowth, Normalized Magnitude (AM/AM) and Normalized phase (AM/PM). The paper is arranged as follows. In Section 2, modeling methodology is highlighted while Section 3 outlines the predistortion learning architecture. Section 4 discusses the estimation algorithm while Section 5 explains briefly the characterization and experimental setup. Section 6 presents the results in detail. Finally, conclusions are drawn in Section 7.

2. Modeling Methodology

The architecture of the predistortion technique is shown in Figure 2 which utilizes Indirect Learning Architecture for the estimation of PD training coefficients [31-34]. Since the statistic of the waveform will remain the same over time, therefore, it can be assumed that system nonlinearity is not time varying and the training of the predistortion can be applied in an off-line practice. This will not only reduce the expenditures and over heads of the predistorter but also avoids the need of an identification algorithm. The identification of DPD is performed in one step. Hence, a linear estimation of PD coefficients result in straightforward identification.

At first, the training phase calculates the predistorter coefficients. At this point, the RoF system output $y(n)$, becomes input $z(n)$ to the Pre-Distorter Training block which is defined as $z(n) = \frac{y(n)}{G}$ where G denotes the gain of the system. The coefficients appraisal can be made using least-squares-based algorithm and is described in Sec. 3. The convergence point of the training is achieved by minimizing the error function. Eventually, the computed training coefficients are employed to the predistorter referred as Digital Pre-Distorter in Figure 2. The predistorter models utilized are derived from the classical Volterra series.

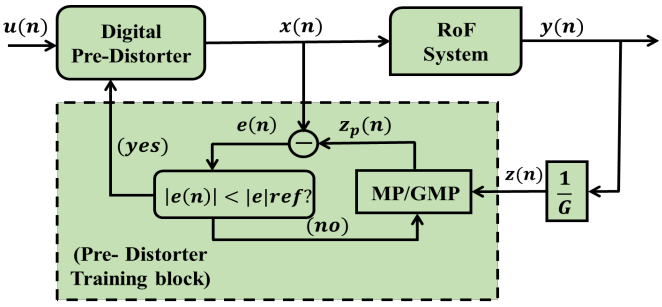

Figure 2. DPD identification for RoF utilizing ILA

3. Digital Predistortion Model

A. Memory Polynomial (MP) Model

Memory Polynomial (MP) model is referred as an inverse non-linear model that has been exploited previously as a powerful model for both, inverse and direct modeling of power amplifier

(PA) nonlinearities. Applying this model for RoF has an additional advantage since memory less model might have problems to characterize the electro-optical (EO) conversion phenomena accurately [34]. The MP model is generally referred as a compromise between memoryless nonlinearity and full Volterra series due to presence of diagonal memory. The output in this case is referred as:

$$z_p(n) = \sum_{k=0}^{K-1} \sum_{q=0}^{Q-1} c_{kq} z(n-q) |z(n-q)|^k$$

Here K represents order of non-linearity, Q is referred as the memory depth, z represents the predistorter input sequence and c_{kq} denotes the model coefficients.

B. Generalized Memory Polynomial (GMP) Model

The use of Generalized Memory Polynomial (GMP) model has been widely utilized for the linearization of PAs [35]. However, GMP has not been yet evaluated for RoF with varying lengths. The GMP model basis functions possess memory for both, for the diagonal terms as well as for the crossing terms i.e., $x(n-q)|x(n-r)|^{k-1}$, where $q \neq r$. The output of the post inverse block $z_p(n)$ modeled with GMP can be expressed as:

$$\begin{aligned} z_p(n) = & \sum_{k=0}^{K_a-1} \sum_{q=0}^{Q_a-1} c_{kq} z(n-q) |z(n-q)|^k \\ & + \sum_{k=1}^{K_b} \sum_{q=0}^{Q_b-1} \sum_{r=1}^{R_b} d_{kqr} z(n-q) |z(n-q-r)|^k \\ & + \sum_{k=1}^{K_c} \sum_{q=0}^{Q_c-1} \sum_{r=1}^{R_c} e_{kqr} z(n-q) |z(n-q+r)|^k \end{aligned} \quad (2)$$

where $z_p(n)$ and $z(n)$ represents the DPD output and input respectively. Similarly, $c_{kq}; d_{kqr}$ and e_{kqr} denotes the complex coefficients for the signal and the envelope; signal and lagging envelope and signal and leading envelope respectively. k represents the index of nonlinearity, and q, r represents the indices of the memory. While K_a, K_b, K_c are the maximum orders of nonlinearity, Q_a, Q_b, Q_c are the memory depths, while R_b and R_c exhibits the lagging and leading delay tap lengths, respectively. GMP has been applied choosing K_a=K_b=K_c= K, Q_a=Q_b=Q_c= Q and $R_b = R_c = R$.

The main objective of the predistorter is to minimize the error ($e(n) = z_p(n) - x(n)$) between the $z_p(n)$ and the input x of the RoF system.

4. Estimation Algorithm

There are number of least squares (LS) algorithm for estimation of model coefficients that take the linear weighting of nonlinear signals [36]. The formulation of the estimation initiates with collecting the coefficients e.g., c_{kq}, d_{kqr} and e_{kqr} in to a $R \times 1$ vector $\boldsymbol{v}$. R represents the total number of coefficients. $\boldsymbol{v}$ means a signal whose time will sample over the same period. Considering (2), coefficients c_{21} denotes the signal $x(n-1)|x(n-1)|^2$. $\boldsymbol{Z}$ characterizes the collection of all such vectors into a Nx R matrix. Once the convergence condition is obtained, the output of the predistorter training block becomes: $z_p(n) = x(n)$ and hence $z(n) = u(n)$. For total samples N, the output can be written in the following way:

$$\boldsymbol{z_p} = \boldsymbol{Zv}$$

Where $\boldsymbol{z} = [z(1),..,z(N)]^T$, $\boldsymbol{z_p} = [z_p(1),..,z_p(N)]^T$, while $\boldsymbol{v}$ displays a $R \times 1$ vector that contains the coefficients c_{kq}, $d_{kqr}$and e_{kqr}.The LS solution will then become a solution for the equation expressed as:

$$[\boldsymbol{Z}^H \boldsymbol{Z}]\hat{\boldsymbol{v}} = \boldsymbol{Z}^H \boldsymbol{x} \quad (4)$$

The LS solution in (4) should minimize the cost function

$$C = \sum_{n=1}^{N} |z_p(n) - x(n)|^2 \quad (5)$$

The advanced variations to Volterra series in form of MP, GMP and others increases the effectiveness of predistortion. However, this advanced variation can come in to existence by increasing the memory depth and nonlinearity order. However, this will extortionate the computational complexity and this has to be weighed against other simpler expediencies. Moreover, the performance would generally be more efficient if the predistortion model has higher number of coefficients. This means that while selecting the model and its complexity, a smart tradeoff between complexity and performance can be made accordingly. The effect of increase in complexity will be shown in Sec. 7.

5. Experimental Setup

The experimental test bed utilized for demonstrating and validating the proposed DPD technique is shown in Figure 3. The baseband LTE signal of 5-MHz with 64 QAM modulation format is emulated through a domestic software on MATLAB compliant with 3GPP release TS 36.104 V15.2.0 [37]. The signal is oversampled at 38.4 MSa/s. After this, the sampled sequence of signals passes through the DPD block, which is then RF-transformed at 800 MHz by a Vector Signal Generator (VSG) (see Figure 3) and is then sent to the optical link.

There are two different optical links that are considered for testing DPD sequentially. In the first, a Single Mode VCSEL (Optowell), that operate at 850-nm, which is followed by a fiber span (SSMF) and a PIN photodiode, having 2.5 GHz bandwidth and responsivity factor of 0.6 A/W. The SSMF for varying lengths has been utilized so that the effect of length on the DPD technique can be observed. In the second a 850-nm MM VCSELs in combination with MMFs was tested, maintaining the same photodetector of the other link.

The reason performing the test with reference to the two RoF configurations is related to the fact that each one of them presents aspects that, according to the particular applicative context, may make it preferable with respect to the other. The SM-VCSEL-SSMF based link can indeed feature convenience in terms of cost and flexibility, because of the lower cost per meter of SSMF with respect to MMF, and because of the huge transmission bandwidth of the SSMF. The MM-VCSEL-MMF based link can take advantage of a typically higher dynamic range and

emitted/coupled power of the MM-VCSEL over MMF with respect to the SM-VCSEL over SSMF case.

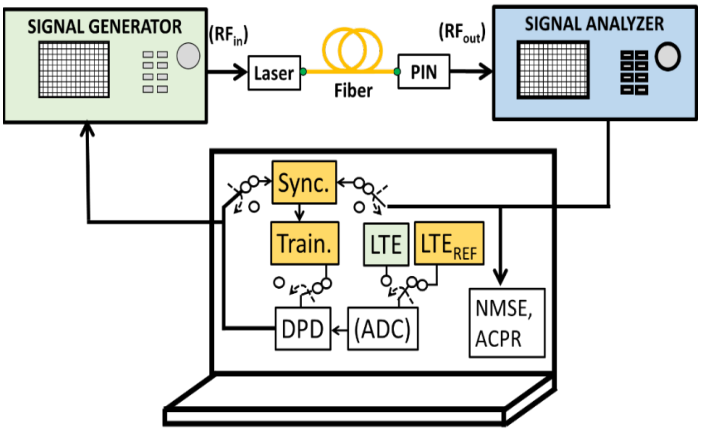

Figure 3. Experimental evaluation comprising of DPD training and application phase.

The reason performing the test with reference to the two RoF configurations is related to the fact that each one of them presents aspects that, according to the particular applicative context, may make it preferable with respect to the other. The SM-VCSEL-SSMF based link can indeed feature convenience in terms of cost and flexibility, because of the lower cost per meter of SSMF with respect to MMF, and because of the huge transmission bandwidth of the SSMF. The MM-VCSEL-MMF based link can take advantage of a typically higher dynamic range and emitted/coupled power of the MM-VCSEL over MMF with respect to the SM-VCSEL over SSMF case.

The process of predistortion is carried out in two steps. The first step is referred as a training phase. In training phase, the parameter identification for predistorter is carried out as referred in Figure 2. During the training phase, reference LTE frames are utilized (see LTE$_{REF}$ block in Figure 3). Primarily, input and output signals are synchronized i.e. time aligned (see Sync. in Figure 3). This block finds the time delay estimation by utilizing the Synchronization Signals (Primary and Secondary) accessible in the LTE framework. Then, the predistorter coefficients are procured through the PD models utilized (see Train. in Figure 3).

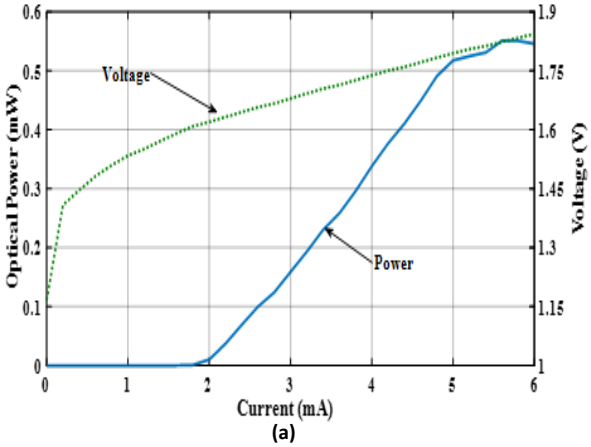
In the second step i.e. the testing phase, the training coefficients obtained in previous step are utilized to apply DPD in MATLAB. This means that all switches are turned to opposite position in Figure 3 and the testing is done for LTE frames followed by sampling, pre-distortion, and then uploaded to the Vector Signal Generator (VSG). Finally, they are channelized through the optical link and performance metrics are compared with the one without predistortion. It must be noted that the DPD testing and validation is not only evaluated for the reference LTE signals that were used not only for training, but also for generalized LTE frames.

As mentioned, the quantities utilized to evaluate the effects of the DPD introduced are ACPR and the NMSE. At first, the efficiency of the proposed methods are presented by the ACPR that computes the distortion components outside the useful bandwidth. It is expressed as [1]: (6)

$$ACPR_{dBc} = 10\log_{10}\left[\frac{\int_{ab_l}^{ab_u} S(f)\,df}{\int_{ub_l}^{ub_u} S(f)\;df}\right]$$

where ab_l and ab_u are the lower and upper frequency limits of the adjacent channel; ub_l and ub_u are the frequency bounds of useful bands. $S(f)$ denotes Power Spectral Density (PSD) of the output signal $y(n)$.

NMSE is defined as follows [27]:



$$NMSE_{dB} = 10log_{10}\left[\frac{\sum_{n=1}^{N}|x(n)-z_p(n)|^2}{\sum_{n=1}^{N}|x(n)|^2}\right] \quad (7)$$

The NMSE value is estimated between $z_p(n)$ and $x(n)$ of the RoF where N embodies the total signal length.

Exploiting these definitions, ACPR and NMSE are calculated for the predistorted and without predistortion output signals. The comparison of the evaluated quantities is presented in the next section. The description of the specifications utilized are given in Table 1.

6. Results and Discussion

The efficacy of the linearization method is appraised and brought into discussion in this section. A primary attention should be given while selecting the parameters of the predistorter such as

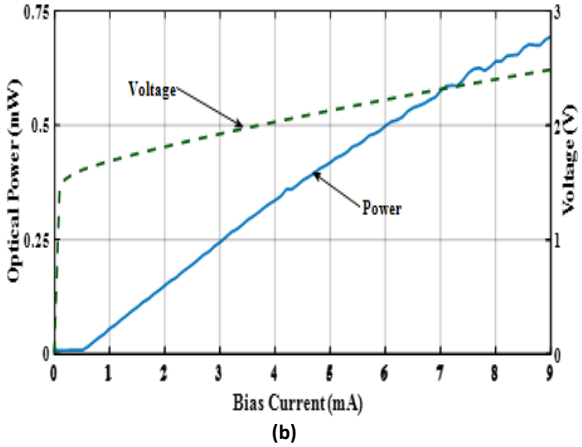


Figure 4. L-I-V characterization utilized in the evaluation of DPD experiments for (a) SM-VCSEL and (b) MM-VCSEL.

memory depth (Q) and nonlinearity order (K) (see Sec. 5 for the details).

Table 1: System Parameters

Optical Link Component	Parameters Values
Laser	**SM-VCSEL** Wavelength= 850 nm $I_{Bias} = 4\ mA$ $I_{Threshold} = 2\ mA$ RIN = -130 dB/Hz **MM-VCSEL** Wavelength= 850 nm $I_{Bias} = 4\ mA$ $I_{Threshold} = 0.8\ mA$ RIN = -125 dB/Hz
Fiber	**SSMF** Maximum Length = 1.5 Km Attenuation = 2.5 dB/km **MMF** Maximum Length = 1 Km Attenuation = 2.5 dB/km
Photo-detector	Responsivity = 0.6 A/W Bandwidth = 2.5 GHz

The L-I-V characteristic curve of SM-VCSEL and MM-VCSEL utilized are illustrated in Figure 4 (a) and (b) respectively. In SM-VCSEL, the maximum saturation current (I_s) is 5 mA while threshold current (I_{th}) is 2 mA. The bias point (I_{bias}) is chosen at 4 mA.

Similarly, In case of MM-VCSEL, the (I_s) is 8 mA and threshold current (I_{th}) is 0.8 mA. The bias point (I_{bias}) is chosen to be 4 mA. The signals having higher PAPR will give rise to higher distortions owing to small dynamics. The PAPR of signal utilized is 9.1 dB.

As explained in Sec. 5, the predistorter complexity is dependent upon the model and order of Q and K chosen. In order to show the trend of this fact, Figure 5 elaborates the experimental NMSE results for different choices of Q and K using both models.

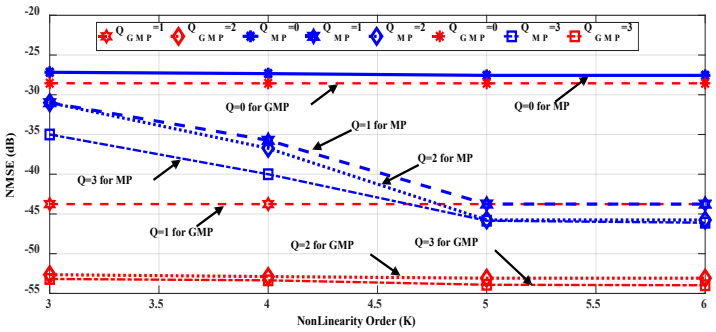

Figure 5. Normalized Mean Square Error results with varying values of memory depth Q and Nonlinearity Order K.

The evaluation in Figure 5 has been done for varying orders of Q (0, 1, 2 & 3) and non-linearity K (3, 4, 5 & 6) by applying a higher RF input power (0 dBm). It can be perceived that GMP results in higher reduction of NMSE in comparison to MP at lower orders of K. From this initial finding, the optimal values $Q = 1,2$ and $K = 3$ are chosen, resulting from a tradeoff between performance achieved and complexity required to the system.

In addition to NMSE, to show the effect of increasing complexity of the proposed distorter, keeping the value of $R = 1$ fixed, Figure 6 represents the ACPR for MP ($Q = 1,2$ and $K = 3$) and GMP ($Q = 1,2$ and $K = 3$) for 1 Km of SSMF. It is perceived that ACPR for MP model doesn't satisfies 3GPP ACPR requirement for MP (both $Q = 1,2$ and $K = 3$) after -5 dBm of input power. While, GMP with $Q = 1$and $K = 3$ satisfies the requirement, however, it is exactly on the borderline at 0 dBm of RF input power.

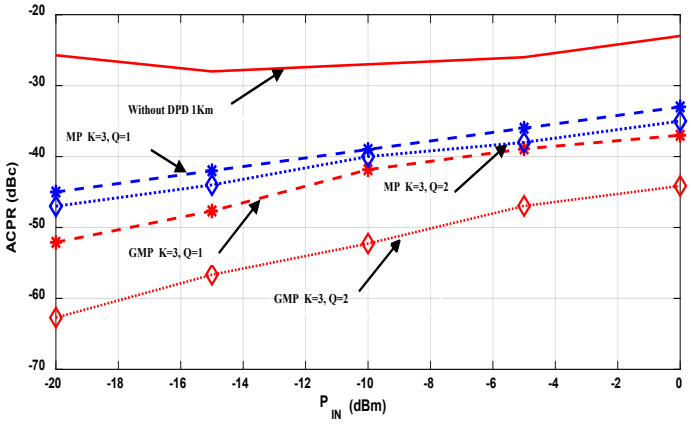

Figure 6. ACPR outcomes vs. input RF power. (Q=1,2, R=1 and K=3 for MP & GMP).

Considering GMP with $Q = 2$ and $K = 3$, the ACPR is well below the requirement set by 3GPP, hence the higher complexity enhances the performance. This demonstration shows that the performance can be enhanced at the cost of higher complexity of the PD model.

Similarly, the Power Spectral Density (PSD) of the received sequence is analyzed when both models are implemented. The length is fixed to 1 Km and RF input power is 0 dBm. The results have been arranged for comparison of MP and GMP with same order of K and Q.

Consider Figure 7(a), the DPD for received output signal is demonstrated for both models by fixing K=3 and Q=1. It is noticeable that GMP has higher reduction in spectral regrowth reduction as compared to MP. Then, in order to highlight the effect of increasing the complexity order, the PSD of GMP and MP are compared for K=3 and Q=2 in Figure 7 (b). This shows that DPD for K=3 and Q=2 is stronger as compared to K=3 and Q=1 due to which spectral regrowth reduction in latter case is higher. Similarly, GMP for K=3 and Q=2 results in ACPR of -44 dBc as compared to -37 dBc when GMP is utilized for (K=3 and Q=1). This substantiates that GMP has better ACPR reduction than MP. This conclusion seems justified due to the fact that GMP carries memory not only in the diagonal but also in the crossing terms.

In light of this discussion and results in the Figure 5, 6 and 7, GMP with optimal values $Q = 2$ and $K = 3$ keeping $R = 1$ fixed have been selected from a tradeoff between performance achieved and complexity required to the system.

In Figure 8 (a) and (b), the ACPR experimental outcomes for several RF input powers (P_{in}) are reported for SM-VCSEL with SSMF and MM-VCSEL with MMF respectively. First consider Figure 8 (a), there are three different cases discussed: Patch cord (Back to back), 1 Km fiber length and 1.5 Km fiber length case. By increasing the length of the fiber, the leakages in adjacent channels rise and therefore the worsening occurs with higher lengths. By employing linearization, it can be seen that fiber length with different lengths have different linearization profiles. For instance, let's consider 1.5 Km length case, the ACPR without linearization at 0 dBm is -18 dBc, and with linearization employed, it is reduced by 22 dBc to -40 dBc.

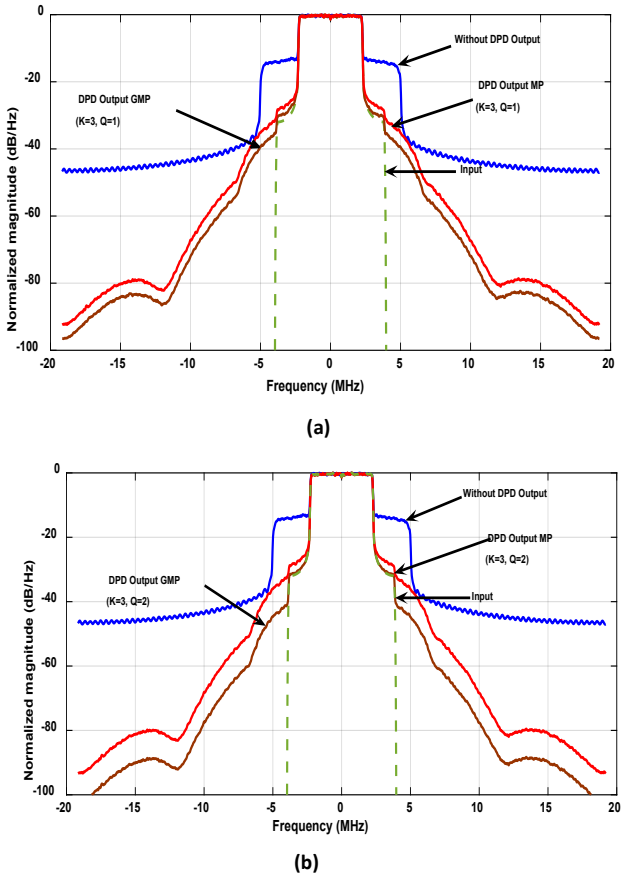

Figure 7. PSD evaluation of output signal without and with DPD (MP/GMP) 0 dBm for 1 Km SSMF with SM-VCSEL having: (a) Q=1, R=1, K=3 and (b) Q=2, R=1, K=3.

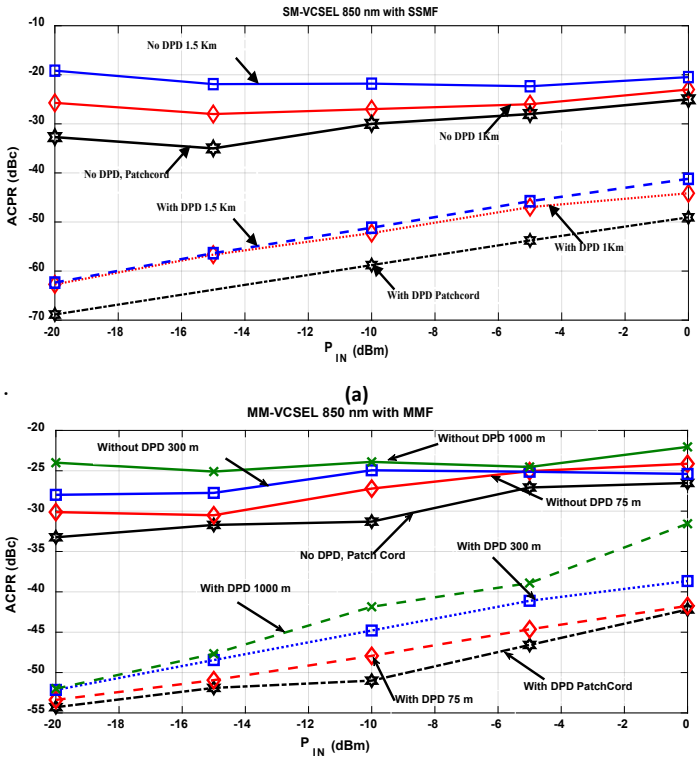
In case of Figure 8 (b), four different lengths have been shown up to 1 Km. For 1 Km length, the uncorrected ACPR at 0 dBm is around -22 dBc while the linearization results in a significant reduction to -36 dBc.

It can be deduced from the trend in Figure 8 (a) and (b) that the proposed DPD technique linearizes the length cases as well. Indeed, linearizing the laser nonlinearity is primary aim of the short link lengths, however, in addition to an optical channel consisting in a fiber patch cord (few meters of length), the proposed technique works efficiently for longer fiber lengths.

It must be put into evidence that linearization method has been evaluated for conditions which are very critical such as high PAPR and I_{bias} close to the threshold with optimal values of K and Q. If these critical conditions are relaxed, this will lead to better linearization performance of the predistorter.



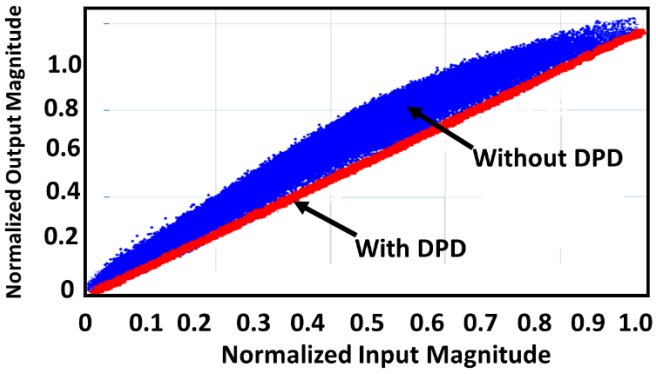


Figure 8. ACPR results vs. varying input signal power using (Q=2 and K=3 for GMP) for (a) SM-VCSEL with SSMF and (b) MM-VSEL with MMF.

Figure 9 represents the AM-AM and AM-PM statistics with and without the linearization employed for the RoF link consisting of 1 Km SSMF and SM-VCSEL. It can be seen that after DPD, the AM/AM is now a straight line and the phase difference is reduced to within 2 degrees.

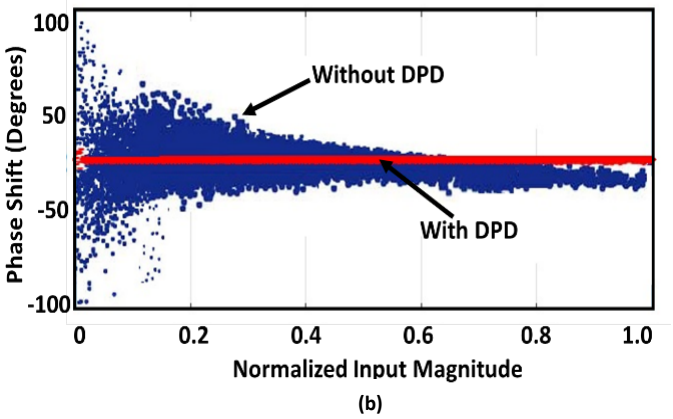

Figure 9. (a) AM-AM and (b) AM-PM plots for SM-VCSEL at 1 Km of SSMF for 0 *dBm* of input RF power with and without DPD.

Table 2 reports the results of the proposed technique, referred to 1 Km of link length with 0 *dBm*. The results are summarized for MP and GMP with K=3 and Q=2 in terms of ACPR and NMSE. The suggested technique linearizes the SM-VCSEL link and MM-VCSEL.

Table 2. Linearization performance for proposed DPD (P_{IN}= 0 *dBm, Link length= 1 Km*)

Model	*SM-VCSEL*		*MM-VCSEL*	
	NMSE (dB)	*ACPR (dBc)*	*NMSE (dB)*	*ACPR (dBc)*
Without DPD	-19.86	-20	-17.63	-22.04
With GMP (K=3, Q=2)	-41.548	-44	-33.18	-36
With MP (K=3, Q=2)	-31.25	-35	-30.14	-29

Indeed, Table 2 suggests that linearization with GMP is better than MP for link length of 1 Km (SM for SM-VCSEL and MM for MM-VCSEL). The reduction in ACPR and NMSE for SM-VCSEL is 22 and 20 dB respectively. While, for MM-VCSEL the improvement in ACPR and NMSE is 14 and 16 dB respectively. This suggests that for SM-VCSEL, the linearization is better than MM-VCSEL for same parameters of data. The improvement for MM-VCSEL is different from SM-VCSEL because the nonlinearities of two lasers are different. It should be noted that MM-VCSEL can achieve higher linearization by selecting appropriate sets of coefficients.

Note that in an applicative scenario, the process of DPD may be positioned at the Central Office (CO), e.g. where BBUs are placed (see Fig. 1) and compensate the RoF Downlink nonlinearities. A periodical re-training of the Digital Predistortion system is in this case necessary, requiring however a negligible time with respect to the time of normal operation of the RoF system. Various methods can be validated for enforcing the periodical training phase. Namely, if a RoF Uplink is applied, the nonlinearities in this case be compensated by a digital post distorter block located at a correspondent CO [38]. By utilizing this method, the RoF downlink nonlinearities can be accumulated at BBU which will decrease the cost and complexity of remote antenna unit.

The time devoted to the periodical re-training of the Digital Predistortion system would in any case remain negligible with respect to the time of normal operation of the RoF system, still allowing its adoption in real applicative scenarios. Similarly, it is possible to utilize an additional photodiode in a base station and feedback the laser nonlinearities and approximating that laser is the main cause of nonlinearity in the RoF link.

Note also that the proposed predistortion method can be applied also to LTE signals of larger bandwidth. The polynomial models nonetheless would require higher values of K & Q with respect to the case presented in the submitted work.

Considering the LTE signal bandwidth and higher modulation format, they would result in a higher PAPR of the transmitted RF signal [39]. At the same time, the increase in bandwidth also determines a correspondent increase in the overall base-band memory of the system to be taken into account by the model.
The polynomial models proposed can still be applied in these operating conditions. They nonetheless would require higher values of the K & Q with respect to the case presented in the submitted work.
These requirements would impact the cost of the DPD implementation, which would be higher due to the higher sampling rate of ADCs, and higher computing capabilities of FPGAs.

7. Conclusions

This article proposes a Digital Pre-Distortion mechanism for linearizing VCSEL based RoF links with different characteristics specifically link lengths. The proposed technique demonstrates a digital predistorter based on MP and GMP. The experiments have been prosecuted for systems based on SM-VCSEL followed by SSMF and on MM-VCSEL followed by MMF. The signal transmitted was a 5-MHz Bandwidth 64 QAM LTE signals and different link lengths have been considered. The performance has been explored in terms of ACPR and NMSE showing that for a link length up to 1 Km, both SM-VCSEL and MM-VCSEL can be linearized in good proportion. Particularly, utilizing SM-VCSEL, GMP results in 22 dBs of reduction in ACPR while MM-VCSEL results in 14 dBs of reduction in spectral regrowth. The results testify an encouraging link performance with low complexity of the predistorter model. It has been demonstrated for the first time that GMPs achieves superior linearization as compared to MP for link lengths up to 1.5 Km.

Electricity Theft Detection
Convolutional Neural Network (CNN)
Recurrent Neural Network (RNN)
Bidirectional Long Short Term Memory (BiLSTM)

ABSTRACT

The major problem in electric utility is Electrical Theft, which is harmful to electric power suppliers and causes economic loss. Detecting and controlling electrical theft is a challenging task that involves several aspects like economic, social, regional, managerial, political, infrastructural, literacy rate, etc. Numerous methods were proposed formerly for detecting electricity theft. However, the previous works considered only the one dimensional (1-D) energy consumption data which apprehended the periodicity and were found inefficient in storing and retrieving the memory that resulted in a lower accuracy rate of detection. Hence, this research study intends Convolutional Neural Network combined with Bidirectional Long Short Term Memory based Recurrent Neural Network (CNN-RNN-BiLSTM) for overcoming the aforementioned problems in the detection of electricity theft. The CNN captures the global variables of 1-D data and identifies the non-periodicity and periodicity of 2-D electricity consumption records. RNN-BiLSTM extends the memory storage capacity of the neural network with bidirectional flow of information, thereby allowing learning order dependencies. The proposed method results of the predicted values of the electricity theft show better accuracy rate with reduced time during the training phase and reduced number of epochs. The proposed model helps to discriminate the customers for preventing fraudulent activities in the usage of electric power. The validation of the proposed method is carried out by comparing the method with the existing Support Vector Machine (SVM) and multi-class SVM models. The comparative results prove that the proposed CNN-RNN-BiLSTM model of electricity theft detection works efficiently.

1. Introduction

Electricity has become a basic need in our life. Losses often occur during the transmission, generation, and distribution of electricity. The losses in the electricity supply to consumers, refer to the quantity of electricity introduced into the distribution and transmission grids that are unpaid by the users. The losses of electricity can be classified into technical losses (TLs) and Non-Technical losses (NTLs) [1]. Advanced Metering Infrastructure (AMI) they enable energy companies to obtain active energy, phase current and voltage, apparent energy, and Reactive lead from smart meter deployed at home [2]. Smart meters (SM) collect the active energy from the real-time, and reveal the user habits and behavior at home to forecast the financial loss. For example, if the daily energy is low, then the user is not at home. To disclose the theft detection is addressed in this work. Smart meters allow functions to perceive Non-Technical Loss (NTL), which was very difficult in previous days. Now SM even out functions that often measures the energy consumption (EC), and gives the better perceptive of customer consumption behavior [3].

Non-Technical losses occur due to loads and conditions when the Technical losses calculation become unsuccessful to consider or due to the triggering of the external factors. Non- Technical losses are tedious to evaluate since these losses are not frequently considered by the system operatives and therefore have no verified data existed [4]. One of the fundamental NTLs is the theft of electricity. This theft involves bypassing of the electricity meter,

* Corresponding Author: Priyamvada Chandel, Central Power Research Institute, Bhopal, India. Email Id: priyamvada@cpri.in

hacking the meter, or tampering the meter reading [5]. Electricity theft results in a great revenue fall of power company because of the surging electricity, the dense load of electrical systems, and it brings threats to public safety.

In many developing countries, at many distribution feeders, electricity theft is openly visible. In the past, indiscriminate machine learning methods have been employed for detecting electricity theft. However, convenient variables are created from meter readings, and the performance will be optimal [6]. The existing methods have some concerns that need to be addressed further. For Artificial Intelligence (AI) based methods, due to the difficulty in building a labeled dataset of electricity thefts, the application of classification methods is limited. Since the clustering algorithms are unverified, tampered load profiles with normal figures cannot be identified, ensuing in low accuracy of prediction. For the state-based methods, the measurement data and system information acquisition are much more difficult to obtain [7]. For deep learning approaches, since the scalability of the framework is arbitrary, the network can end up being unstable. Furthermore, the weights fed to the layers of the network have the underfitting of the model that tends to increase the number of epochs for training the model. Epoch is defined as the number of iterations related to the samples of the dataset. For training a network with a large dataset and a reduced number of epochs, memory storage becomes an important concern for the classification model of the network.

2. Literature Review

This section includes a survey of electricity theft detection methods proposed by researchers formerly. The studies can be categorized into hardware-based and non-hardware based solutions to the detection of electricity theft. Non-hardware based solutions include AI and machine learning techniques.

Nizar et al. applied the Extreme Learning Machine (ELM) for electricity theft detection [8]. The ELM-based technique extracts forms of customer behavior using their previous consumption data in kWh and perceives abnormal deeds. The performance of the classifier was compared with OS-ELM and SVM for validation. However, the classification rate of testing phase was found low for this approach.

In [9], the authors recommended a multi-class SVM which was trained to identify a sample of load profiles whether it is malicious or normal. This paper addressed and solved the imbalanced training by generating a synthetic dataset. The algorithm also uses silhouette plots to identify the different distributions in the dataset. One limitation of the machine learning approach is that it is vulnerable to contamination attacks.

In [10], the authors proposed an optimum-path forest (OPF) based unsupervised NTL detection methodology and compared with other popular clustering methods including k-means and GMM. OPF has attained the most accurate results while considering both the applications on two datasets composed of industrial and commercial profiles of irregular and regular consumers. However, clustering techniques are not cost-effective.

In [11], the researcher suggested for distribution lanes from current and real power measurements using linear regression technique; subsequently, NTL of all lane is measured in accordant with the estimated resistance value to find the electricity theft. Limitation of this method is that correlating more than two independent factors with dependent factor becomes complicated in the linear regression model.

In [12], the authors proposed for distribution load transformer is employed in detecting meter tampering using state estimation-based technique. The variation in the measured values and the estimated values is assessed to make suspicious details of consumers with metering issues. Customer meter data in conjunction with intelligent devices measurements in smart distribution grid are used for DSE and NTL detection without additional meter investment at points of delivery.

In [13], the researchers presented a probabilistic methodology NTL assessment in the distribution system. The sensitivity of technical loss when related to the load variation is derived, and the probabilistic distributions of total loss and technical loss are evaluated. This approach is suitable only for countries that have scarce resources and is not suitable for smart grid applications.

In [14], the authors recommended a deep-learning-based real-time technique for the finding of electricity thefts was projected. This paper utilizes real-time data and its state vector estimator (SVE), and computes the occurrence vector and state vector and the topology of the power system, and a detection scheme based on broad belief network assist the SVE identifies the false data injection (FDI). However, possible FDI attacks are not imposed on the network.

In [15], the researchers proposed Principal Component Analysis (PCA) based Theft Detection system to identify energy theft in AMI. This approach was then compared with SVM classifier to validate the supremacy of PCATD performance. But the results obtained from PCA are found to be inconsistent under change of constraints.

The study conducted in [16] detect the anomalous behavior in customer-defined patterns using an SVM classifier. However, the study relied on monthly measurements of the demand, and the detection window is approximately taken for two years. Additionally, the algorithm was found to show low performance while detecting any theft cases that are not viewed as unexpected variations.

Beyond the concept of machine-learning algorithms, techniques based on game-theory have been applied in [17], identified the fraud was executed between the utility company and fraud-committing consumers. The primary problem with these approaches is the struggle in the formulation of practical and realistic utility functions for the players involved.

In [18], the authors proposed a model that exploits the time-series nature of the customers' electricity consumption to implement a Gated Recurrent Unit (GRU)-RNN. As an improvement to RNN, random search analysis in the learning stage has been adopted. In [19], the authors suggested a deep neural network (DNN)-based customer-specific detector, that implements a sequential grid search analysis in its learning stage for tuning hyperparameters. Wide-ranging investigations are performed based on openly accessible originally energy consumption database of 5000 customers. These approaches suffer from inefficient memory for storage and retrieval.

In [20], the author proposed DNN with transfer entropy measure-based anomaly detection for both sensor measurements and innovative sequences, that can be assessed in a data-driven fashion without relying on a model of the underlying dynamic system. The results of the simulation indicated that the method takes a longer time for computation.

In [21], the authors recommended a novel data analysis method for detecting false data injection attack mitigation (FDIA) based on a data-centric model using the margin setting algorithm. The performance of the suggested methodology is presented employing the six-bus power network in a measurement system of the wide-area environment through simulation. However, it handles only a limited data for the period of the identification process.

In [22], the authors proposed to identify cyber-attacks in Cyber-Physical systems using a novel unsupervised approach, combining LSTM-RNN for behavioral-based intrusion detection. This model not only identifies the attacked sensor, but also detects the irregularities in the CPS. The limitation of this method was that the ability to validate the false positives was found less.

In [23], the authors proposed ANN-based intrusion detection. The MLP is trained to employ packet traces of internet, and then it is evaluated based on its capability to resist DoS/DDoS attacks. The study spotlight on the normal and threat patterns classification on an IoT Network. But the mean absolute error obtained for MLP was found to be high.

3. Proposed Methodology

In this section, the Electricity Theft Detection and Implementation using CNN-RNN-BiLSTM model are discussed. The advancement of the methodology proposed such work consists of the following fundamental stages:

- To construct a network for ensuring enhanced storage of memory along with cache memory and for the retrieval of the system.
- To build a balanced system for reducing the training time and epochs.
- To detect electricity theft in the Indian distribution system.

Electricity Theft Detection

Electricity Theft Detection study is categorized into two types: Data-driven solution and Hardware-based solution. The hardware-based solution met with failure due to severe weather conditions and difficulty in maintaining the devices. The data-driven solution has attained more attention

nowadays. The data-driven is planted on data fusion from sensors and AMI. The methodology uses SM data for convolution.

Data attributes

The following are the important attributes of electricity consumption behavior from 41 meters dated 1/1/2017 to 16/2/2018 with the frequency of every 15 minutes that the users consume energy daily. The attributes namely; R, Y, B phase current and voltage, active energy, apparent energy, reactive lag, reactive lead, PF, and label.

CNN

A CNN structure transforms the input work into an output work using a stack of the discrete layer. CNN comprises of an input layer, multiple hidden layers, and output layer; whereas the hidden layer embraced of pooling layer and convolutional layer [24]. The receptive field is the zone of the input matrix that influences a precise unit of the network. The convolutional layer which comprises of the less receptive field and it can extend up to full depth of

input, and it is composed of kernels or filters. Each filter is convolved using height and width of input at onward pass, and it produces the 2D activation map of the filter. The pooling layer reduces the parameters, network computation, and controls the overfitting. The pooling function employed in the proposed method is maximum pooling.

The pooling layer accepts the volume of size $W \times H \times D$, and produces a volume of size $W' \times H' \times D$.'

$$W' = \frac{W-e}{s+1} \quad (1)$$

$$H' = \frac{H-e}{s+1} \quad (2)$$

$$D' = D \quad (3)$$

Where e is the spatial extent and s is the stride. The pooling layer operates independently on every depth of the input slice and resizes it in the spatial dimension. Due to these advantages, the CNN network is used for extracting the convolution features efficiently.

RNN

In RNN the memory formed through recurrent connection. In feedforward networks, inputs are connected, and it is also independent. It exhibits vital behavior for sequential classification in a time sequence. Consider an input classification $X = (X_1, ..., X_T)$, a standard RNN evaluates the hidden vector classification $h = (h_1, ..., h_T)$ and output vector classification $Y= (Y_1, ..., Y_T)$ by repeating the below equations from t = 1 to T [25]:

$$h_t = H(W_{xh}X_t + W_{hh}h_{t-1} + b_h) \quad (4)$$

$$y_t = W_{hy}h_t + b_0) \quad (5)$$

where,

W - weight matrices (e.g., W_{xh} is the input-hidden weight matrix),

b - denote bias vectors (e.g., b_h is the hidden bias vector) and

H - hidden layer function. H is usually a sigmoid function.

Bidirectional LSTM (BiLSTM)

Long Short Term Memory (LSTM) Recurrent Neural Networks (RNN) have been solved the problem of vanishing gradients in RNNs. The LSTM structure composed of memory blocks and block consists of three multiplicative units such as input, forget and output gates and one or more self-associated memory cells. The multiplicative units afford incessant analogs of reading, write, and rearrange functions for cells. An LSTM is similar to RNN, but the main difference is the memory blocks are

used in the hidden layer instead of nonlinear units. To avoid the vanish-gradient issue and to access and store data for a long time of period, the multiplicative gates used in LSTM. Consider that the input gate rests closed (0) the cell will not be overridden by the fresh inputs, and can be set accessible for the next sequence, by opening the output gate.

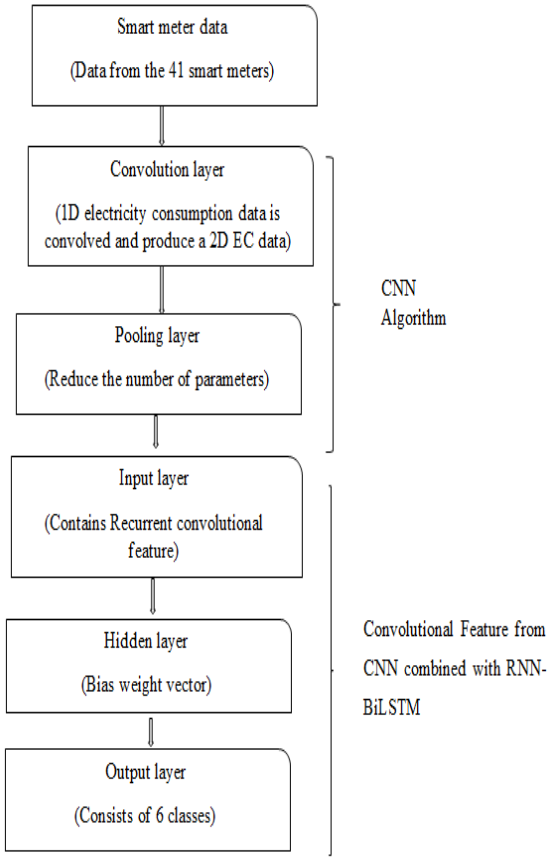

Figure.1: Methodology of CNN-RNN BiLSTM

Traditionally RNN has the problem for vanishing and exploding the gradients. The issue is due to the weight proportional to the gradient of error. During backpropagation, gradients multiply with small values leads to earning smaller values. LSTM does not suffer from any gradients, and it also controls the cell state retains in memory and passes the output. An activation function is a function that defines the output of each node. A sigmoid activation function is used in the design. A sigmoid activation function is an 'S' shaped curve function that ranges between 0 and 1.

$$\mathrm{i} = \sigma(\mathrm{xtUi} + \mathrm{st} - 1\mathrm{Wi}) \quad (6)$$

$$\mathrm{f} = \sigma(\mathrm{xtUf} + \mathrm{st} - 1\mathrm{Wf}) \quad (7)$$

$$\mathrm{o} = \sigma(\mathrm{xtUo} + \mathrm{st} - 1\mathrm{Wo}) \quad (8)$$

where,

xt is the input data sequence, the i-input gate is the gate that allows the input data to enter the network, the f-forget gate is responsible in deciding whether to keep the data or delete the data which is no longer useful, and o-output gate produces the output to be sent to the hidden state. The formula for each gate is formulated using the weight matrix (W), time sequence (U) and a sigmoidal activation function to push the values between a certain interval.

CNN-RNN-BiLSTM

This paper proposes a CNN-RNN-BiLSTM method for the detection of electricity theft. A hybrid wide and deep CNN and RNN is proposed with memory extension rendered by BiLSTM network. The Wide CNN component can capture the convolution features of 1-D electricity consumption data. And the Deep CNN module can recognize the non-periodicity and periodicity of the electricity consumption records.

BiLSTM based RNN offers enhanced memory storage with bidirectional information flow, and make the retrieval and the memory storage and recovery are possible for long term dependencies. The retrieved layer occurs with six classes.

The architecture of the proposed system

Fig 1 shows the flow diagram of the proposed CNN-RNN-BiLSTM prediction model. Data from 41 smart meters are collected and given to the Convolution layer. The convolutional layer convolves the 1-D electricity data and produces 2-D electricity consumption data. And the pooling layer reduces the number of parameters. This working flow of Convolution and Pooling layer is depicted in Fig 2. L is the number of attributes, M is the number of feature values from the convolution layer and pooling layer. Attributes considered in work are phase voltages, phase currents, active energy, apparent energy, reactive lag, reactive lead, and power factor.

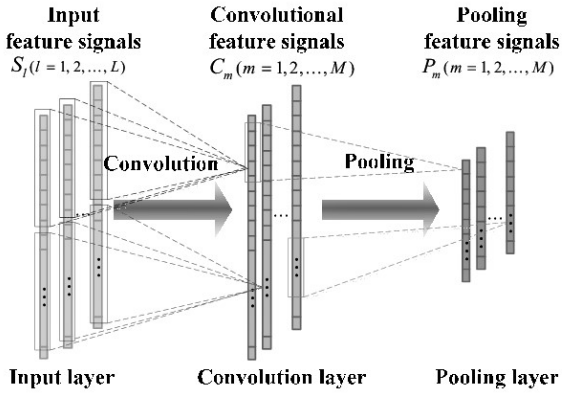

Figure. 2 Convolution and Pooling layer

The length of the input vector f is n, and that of the kernel g is m. The convolution of input vector and kernel function $f * g$ is defined as:

$$(f * g)(i) = \sum_{j=1}^{m} g(j) \cdot f(i - j + \frac{m}{2}) \quad (9)$$

These convolved values passed through max pool layer. The maximum value obtained from pooling layer is chosen as the convolution feature. The convolution features are loaded onto the input layer of RNN. The general structure of RNN is given in Fig 3.

RNN consists of 3 layers, namely, Input layer, Hidden layer, and Output layer. Input cells get convolution features and pass to the hidden or recurrent layer. It consists of neurons x1, x2, x3, etc.,

which gets the input data sequences. The hidden layer contains the hidden units h1, h2, etc., which hold the activation functions that define the output of the neurons in the recurrent layer. The neurons in the output layer y1, y2, etc., will send the predicted values of electricity theft as the output. Each cell of RNN in the proposed prediction model is a BiLSTM memory cell, whose structure is displayed in Fig 4.

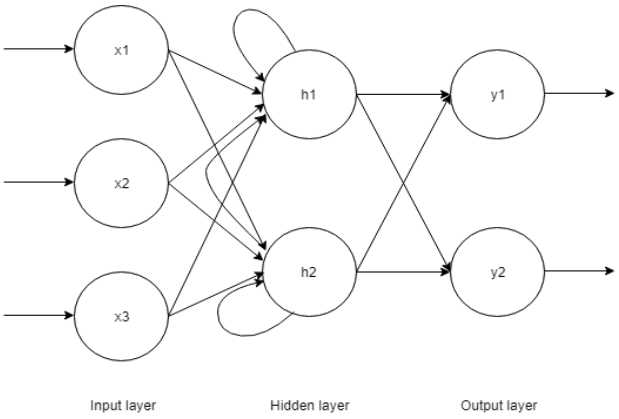

Figure 3. Structure of RNN

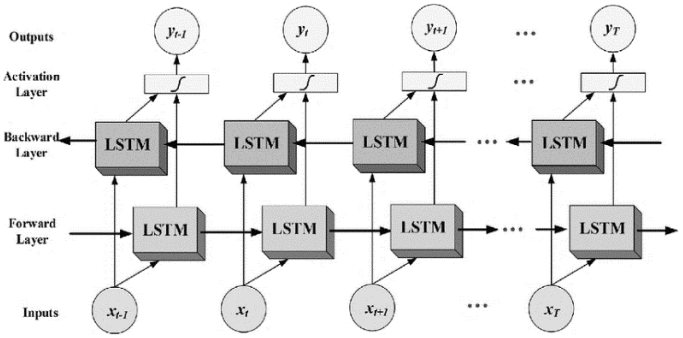

Figure 4. Structure of BiLSTM

The information flow in a BiLSTM is bidirectional, unlike the LSTM. BiLSTM cells acquire bidirectional long term dependencies among time steps or sequential data. These previous long term dependencies are useful for predicting the next state.

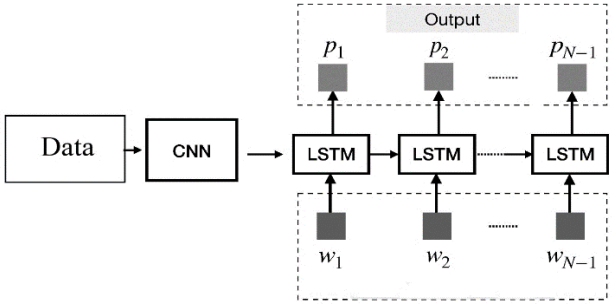

Figure. 5 CNN-RNN-BiLSTM

Fig. 5 shows the architecture of the proposed CNN-RNN-BiLSTM prediction model. Input data is sent to CNN for convolution. Convolution features extracted using CNN are sent to RNN-BiLSTM. The outputs of the model are the detected values of electricity theft.

The voltage and current threshold values for different tamper types are given in Table 1.

Table 1. Occurrence threshold values for different Tamper types

S. NO	TAMPER TYPE	OCCURRENCE THRESHOLDS
1	Link Miss phase-wise	Vx < 60 % Vref and Ix > 5 % Imax
2	CT Bypass	Iavg> 2% IBasic and Ix >2.5% IBasic
3	CT Open phase-wise	Vx > 60% Vref and Ix< 0.5% Imax
4	Current Unbalance	Vavg > 60% Vref and Iavg > 1:
5	Voltage Unbalance	Vavg > 66 % Vref
6	Current Reversal phase-wise	Vavg < 60% Vref and Net PF > -0.5:

Six classes are achieved based on Vref=240V, Ibasic=10A, Imax=40.0A, Iavg=Average of three-phase currents and the tampers are link miss-phase wire, CT bypass, CT open phase-wise, current unbalance, voltage unbalance and current reversal phase wire.

4. Result and Discussion

Evaluation of the proposed energy theft detection using abnormal conditions scheme is done using MATrix LABoratory (MATLAB) The energy usage data comes from Smart Meter Data.

Table 2. Results obtained

Class Labels	Six classes of fault types
No. of Observations	6000
Control classes	[5x1] double
Correct Rate	0.9712
Error Rate	0.0288
Classified Rate	1
Specificity	0.9929
Sensitivity	0.9990
Positive Predictive Value	0.9640
Negative Predictive Value	0.9998
Positive Likelihood	139.7162
Negative Likelihood	0.0010
Prevalence	0.1608

4.1. Experimental Data

Dataset taken for this study is the real-time data communicated by 41 numbers of three phases four-wire smart meters having a unique number, and the data is sent to the Data Collection Unit (DCU) of Chhattisgarh State Electricity Board Raipur. Totally 231637 data for every 15 minutes' interval of time from 1/1/2017 to 16/2/2018 is considered.

4.2. Testing

Then the network is tested using the 6000 data. Each label consists of 1000 data. The tested results are obtained from MatlabR2018a are given in Table 2.

The Fig.6 shows the confusion matrix accuracy of 97.1%.

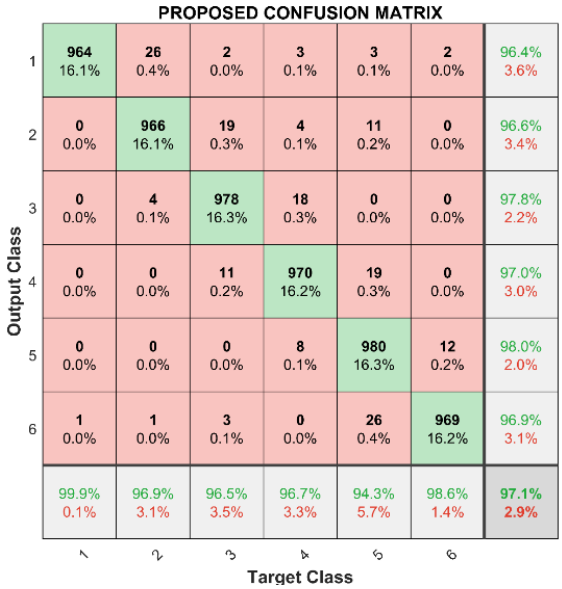

Figure 6. Proposed confusion matrix

4.3. Parameter Study

The Fig.7 shows the accuracy and loss of RNN-BiLSTM.

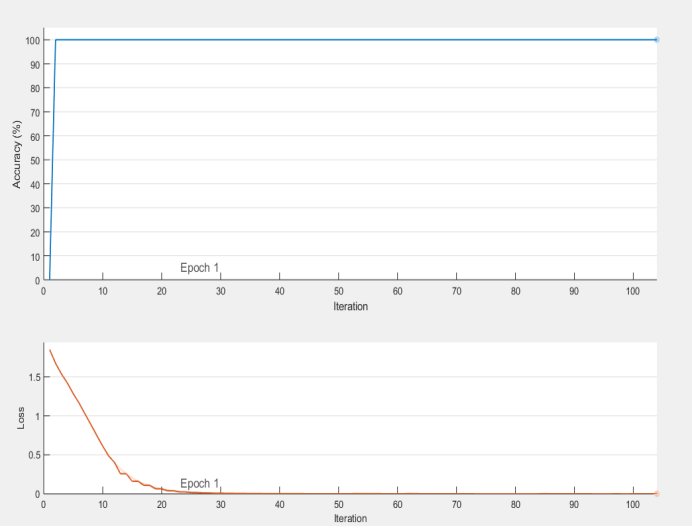

Figure 7. Accuracy and loss of RNN-BiLSTM

First Smart meter(SM) data are taken as label and balanced. Using the Convolutional Neural Network (CNN), the convolution feature of dataset is extracted. In CNN, we used two layers called Convolution and pooling layer to extract the convolution feature. Here, CNN works well for identifying simple patterns within the smart meter data, which will be employed to form higher complex patterns within higher layers. A one dimensional CNN is very efficient to derive the location of feature from shorter (fixed-length) sections of the entire data set and where the location of the feature within the section is not of high significance. The extracted feature from the convolutional feature is used in the RNN-BiLSTM network to predict the class of fault. In RNN-BiLSTM networks, information can be accessed both in forward and reverse direction. These forward and reverse feature in RNN-BiLSTM have to access the past as well as the future information. This has been effectively employed in many practical applications like language translation, future prediction, image captioning, etc., Using the Bidirectional LSTM we feed the learning algorithm with smart meter data once from the beginning to end and once from end to the beginning. There are debates here, but it usually learns faster than one-directional approach, although it depends on the task

Here the loss (error) reduces from 2 to 0, and the accuracy shows increase the value from 0 to 100. Hence it shows our proposed CNN-RNN-BiLSTM shows the efficient accuracy of 100% for the original Training Dataset.

The proposed system is compared with the existing technique and proved the accuracy of 97.1%. Table 3 given below represents the compared result of the proposed with the existing methods, and Fig. 8 represents the accuracy score of the proposed method [27]:

Table.3 Validation of proposed system

Algorithm	Arguments	Accuracy Score
Combined CNN model	100 epochs	0.9267
Single CNN model	100 epochs	0.9218
Simple DNN model	100 epochs	0.9145
Linear SVC	kernel: linear function	0.9178
Random Forest	Max depth: 7	0.9164
Logistic Regression	penalty: L2	0.9141
Proposed Model	Convolution BiLSTM	**0.9712**

The sensitivity, specificity, and accuracy for the proposed CNN-RNN BiLSTM are calculated using the confusion matrix which comprises of False Positive (FP), True Positive (TP), False Negative (FN), and True Negative (TN). Accuracy, sensitivity, and specificity are calculated using the following formulae.

$$Accuracy = \frac{TP+TN}{TN+FN+TP+FP} \quad (10)$$

$$Specificity = \frac{TN}{TN+FP} \quad (11)$$

$$Sensitivity = \frac{TP}{FN+TP} \quad (12)$$

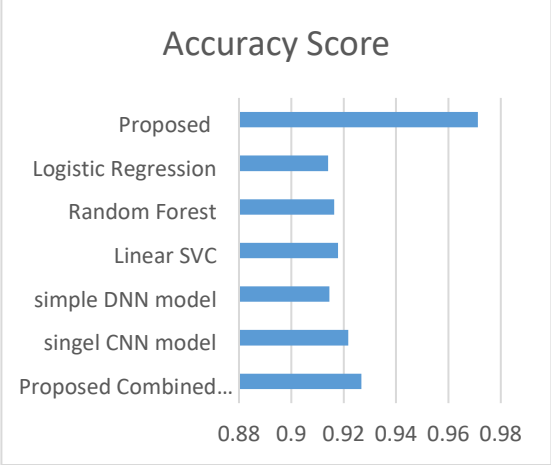

Figure 8. Accuracy score of CNN-RNN BiLSTM

The calculated values are found to be high for the proposed classifier. The specificity, sensitivity, and accuracy obtained for the proposed method are 99.29%, 99.9%, and 97.12% respectively. Fig 9 shows the performance assessment of the proposed framework:

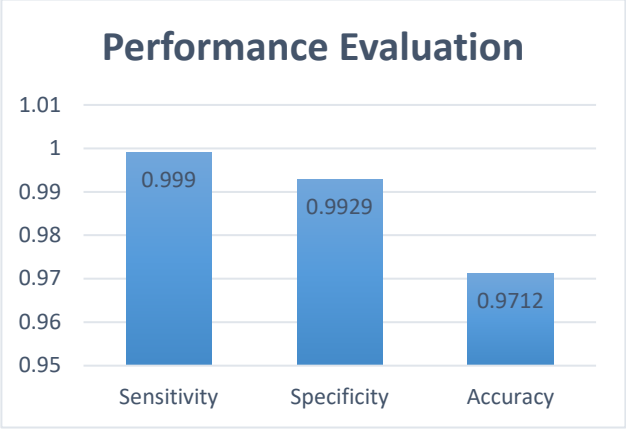

Figure 9. Performance evaluation of CNN-RNN BiLSTM

The performance of the proposed CNN-RNN-BiLSTM is compared with existing methodologies in the literature. Table 4. provides the comparative analysis of the performance parameters of the proposed model with two other models, namely, Support Vector Machine (SVM) and Multi-class SVM.

Table. 4 Performance comparison table

Method	**Accuracy (%)**
SVM [16]	60
Multi-class SVM [9]	94
Proposed	**97.1**

From the table, it is inferred that the proposed CNN-RNN-BiLSTM theft prediction model has better performance compared to the existing models.

5. Conclusion

In this paper, the detection scheme of theft using the abnormal changes in electric values measures in the smart meter is proposed. The proposed electricity theft detection model is based on the combination of CNN and RNN-BiLSTM network, which detects whether the metering data has an abnormal behavior or not. The model predicts the abnormalities in consumer's power consumption behaviors and classifies the behavior based on six classes. The proposed neural network model achieved an accuracy of 100% in training phase and 97.1% in testing phase. The use of technique proposed in this paper will help power utilities to predict theft in lesser time and higher accuracy. Hence in the future, this theoretical approach to the detection of electricity is to be tested for real time practical application. And the use of hybrid spike neural network for electricity theft detection model is presumed to improve the performance of detection effectively.

Conflict of Interest

The authors declare no conflict of interest.

Low-level features

ABSTRACT

Music genre classification is an important multimedia research domain, including aspects of music piece representation, distances between genres, and categorization of music databases. The objective of this study was to develop a model for automatic classification of musical genres from audio data by using features from low-level time and frequency domains. These features can highlight the differences between different genres. In the model, feature selection is performed using a genetic algorithm (GA), and the resulting dataset is classified using the k-nearest neighbor (KNN), naive Bayes classifier (NBC), and support vector machine (SVM) learning methods. Tenfold cross-validation is used to obtain the optimal f-measure value. In this study, the data were obtained from the GTZAN genre collection datasets. In the performance evaluation, it was found that the GA-based feature selection strategy can improve the F-measure rate from 5% to 20% for the KNN, NBC, and SVM-based algorithms. In addition, the proposed SVM-GA algorithm can exactly better than other comparison algorithms.

1 Introduction

Music genre classification is used to categorize musical data into suitable categories based on shared characteristics. In the modern era, numerous musical genres are appreciated, such as blues, classical, country, disco, hip-hop, jazz, metal, pop, reggae, and rock. New technologies and globalization have been beneficial for the evolution of music, leading to the emergence of world music. These developments have increased research interest in music information retrieval (MIR), a field of automatic music management including music recommendation [1], music mood classification [2], and musical instrument classification [3]. As musical genres are most commonly used to manage music databases, a previous study investigated the extraction of audio features and techniques for classifying musical genres [4, 5, 6, 7]. However, genre classification has remained a challenge[8, 9], as it requires systems that are capable of performing automatic grouping [10] and querying retrieving data from large a music data set [8]. The identification of commonalities between genres requires feature extraction [11]. In the case of audio files, combinations of relevant features are used for modeling the musical genre [4]. These features may include timbral texture, rhythmic content, and pitch content [12]. Musical genres have been modeled using different features including short-term Mel-frequency cepstral coefficients (MFCCs) [13, 14], and Daubechies wavelet coefficient histograms (DWCHs), depending on the required application. Features are selected to improve performance and accuracy [15]. Achieving optimal feature selection and extracting appropriate features and dimensions of the features reduction are very challenging tasks [16, 17]. There are many different approaches that have been proposed to classify music genre, such as data mining [18, 19], deep learning strategy [20, 21, 22, 23, 24], and machine learning stretegies such as hidden Markov model, AdaBoost, and support vector machine [25, 26, 27, 28, 29, 30, 31, 32, 33, 34].

In addition to the above, musical genre classification problems can be solved with constant evolutionary algorithms [35]. Among them, a genetic algorithm (GA) based optimization has become a widely used approach for optimizing the selection of relevant features [36, 37, 38, 39, 40].

https://dx.doi.org/10.25046/aj040221

Among the several methods developed for musical genre classification, the performance of classification algorithms has become the benchmark [41]. In this paper, we propose a model for musical genre classification using low-level time and frequency-domain features for short and mid-term feature extraction. In this model, feature extraction is performed using a GA, and musical genre classification is conducted using a range of machine learning algorithms, including the K-Nearest Neighbor (KNN) [42], Nave Bayes Classifier (NBC) [43], and the Support Vector Machine (SVM) [25] were used for music genre classification. In the performance evaluation, it was found that the GA-based feature selection strategy can improve the F-measure rate from 5% to 20% for the KNN, NBC and SVM-based algorithms. In addition, the proposed support vector machine genetic algorithm (SVM-GA) algorithm can exactly better than other comparison algorithms

The remainder of this paper is organized as follows. Section 2 provides background information and discusses related studies. The proposed algorithm is presented in Section 3, and its performance is evaluated in Section 4. Finally, the conclusions and future research are presented in Section 5.

2 Literature review

The primary challenge in genre identification is selecting features for extraction from audio data [8]. Audio data comprise a series of samples that together represent an audio signal. Classification cannot simply be applied to the audio samples. In previous studies, audio analysis has been prominently performed by extracting numerical values for representative features. In music signals, these features correspond to primary dimensions such as pitch, rhythm, harmony, melody, timbre, and spatial location. Low-level features, such as temporal, energy, and spectral features, are some of the most prominently used features in sound signal analysis. In audio signal analysis, low-level features are generally extracted from the time and frequency domains [44]. Moreover, 11 sets of low-level time- and frequency-domain features are prominently used.

2.1 Time-domain audio features

In general, time-domain features are directly extracted from samples of audio signals. The features include short-term energy, short-term zero-crossing rate, and entropy. These features provide a simple approach to analyzing audio signals, and combining these features with sophisticated frequency-domain features is generally essential.

(1) Energy: The sum of squares of signal values, normalized by the respective frame length.

(2) Zero-Crossing Rate: The rate at which the sign of the signal changes within a particular frame.

(3) Entropy of Energy: The entropy of the normalized energies of subframes, which can be interpreted as a measure of abrupt changes in the signal.

2.2 Frequency-domain audio features

The discrete Fourier transform (DFT) is extensively used in audio signal analysis, because it provides a convenient representation of the frequency content distribution of a signal as a sound spectrum. Numerous audio features are based on the DFT of a signal. These are termed frequency-domain (or spectral) audio features.

(1) Spectral Centroid: The center of gravity of a spectrum.

(2) Spectral Spread: The second central moment of a spectrum.

(3) Spectral Entropy: The entropy of the normalized spectral energies for a set of sub-frames.

(4) Spectral Flux: The squared difference between normalized magnitudes of the spectra of two successive frames.

(5) Spectral Rolloff: The frequency below which 90% of the magnitude distribution of a spectrum is concentrated.

(6) MFCCs: MFCCs are used to capture short-term, spectral-based features. The logarithm of the amplitude spectrum based on a short-time Fourier transform is derived for each frame. Frequency bins are then grouped and smoothed using Mel-frequency scaling to ensure that they agree with predetermined concepts. MFCCs are generated by decorrelating Mel-spectral vectors by using a discrete cosine transform.

(7) Chroma Vector: A chroma vector is a 12-element representation of spectral energy, wherein bins represent 12 equal-tempered pitch classes of Western music (semitone spacing).

(8) Harmonic: Harmonic features represent beats, and the harmonic ratio and fundamental frequency are two harmonic features.

Although studies have been conducted on music genre classification, the most accurate results have been achieved using the GTZAN dataset. A comprehensive set of features was proposed for the direct modeling of music signals [4]. When these features were employed for genre classification by using KNNs and Gaussian Mixture models (GMMs), an accuracy rate of 61% was achieved. A novel feature extraction method was proposed for musical genre classification, wherein DWCHs are combined with machine learning classification algorithms, including SVMs and linear discriminant analysis [14]. An accuracy of 78.5% was obtained with this method. Feature integration methods and late information fusion were examined in a previous study [12], by using majority voting for classification of all short-time features. A novel feature integration technique using an autoregressive (AR) model was proposed. This approach was reported to exhibit superior performance to that obtained by the use of mean variance features. Another study [45] addressed musical genre classification from a multilinear perspective. Multiscale spectro-temporal modulation features were extracted on the basis of an auditory cortical processing model, which provided an accuracy of 78.2%. Nonnegative matrix factorization was used to obtain a novel description of the

timbre of musical sounds[13]. A spectrogram was factorized, which provided a characteristic spectral analysis. Gaussian Mixture Models were then applied, to achieve a reported accuracy of 74%. An ensemble approach [37], involving the use of multiple feature vectors and time and space decomposition strategies was also reported in a previous study. In the study, time decomposition was performed using feature vectors, which were extracted from music segments obtained from the beginning, middle, and end of the original signal. The study also employed four machine learning algorithms, namely NBC, decision trees, SVMs, and multilayer perceptron (MLP) neural nets, which provided a maximum accuracy of 65.06%. In an alternative approach [46], a method based on the classification accuracy of an SVM classifier was proposed for selecting training instances. These instances comprised feature vectors representing short-term, low-level characteristics in an audio signal. This method was reported to provide an accuracy of 59.6%. An invariance of MFCCs to musical key and tempo was explored in a previous study[47]. The study indicated that MFCCs encode both timbral and key information. An accuracy of 69.3% was achieved by applying GMMs. The acoustic signal feature can be derived using a mathematical model that represents the acoustic signal [39]. In this approach, features were selected using a GA. Classification was then performed by generating an adjusted KNN classifier. The reported accuracy was 67.6%. In a previous study, a subspace cluster analysis process was used to automate the construction of a classification tree[48]. Experimental results validated the tree-building algorithm, and the study provided a new research direction for automatic genre classification. Several machine learning algorithms were employed, such as KNNs, J48, logistic regression (LOG), LibSVM with a radial basis function kernel, MLP neural networks, and sequential minimal optimization (SMO) SVM with a polynomial kernel. This method was reported to achieve an accuracy of 72.9%. Another study[49] proposed automatic musical genre classification by using spectral, time-domain, tonal, rhythmic, sound effect, and high-level descriptors. An analysis was conducted using KNNs, an SVM, and a GMM, with a resulting accuracy of 79.7%.

3 Methods

3.1 Feature extraction

Feature extraction is a crucial step in audio analysis, because it is also required in other pattern recognition and machine learning tasks. Extraction is performed in the following two steps: short- and mid-term processes. In short-term feature extraction, the input signal is divided into brief windows (or frames), and the number of features is computed for each frame, generating a sequence of short-term feature vectors from the entire signal. In mid-term extraction, statistical analysis is generally applied to these short-term feature sequences to obtain the signal. Several statistics, including mean, median, standard deviation, standard deviation by mean, max, and min, are derived for each short-term feature sequence. The data are then normalized to avoid the introduction of anomalies and minimize redundancy

3.2 Machine learning methods (naive Bayes classifier (NBC), K-nearest neighbor (KNN), support vector machine (SVM)) combined with genetic algorithm (GA)

Fig. 1 shows the system design. GA optimization is combined with the KNN, NBC, and SVM learning methods. The fitness function uses the largest f-measure value derived using machine learning, and is evaluated using 10-fold cross-validation. The system then derives the maximum fitness.

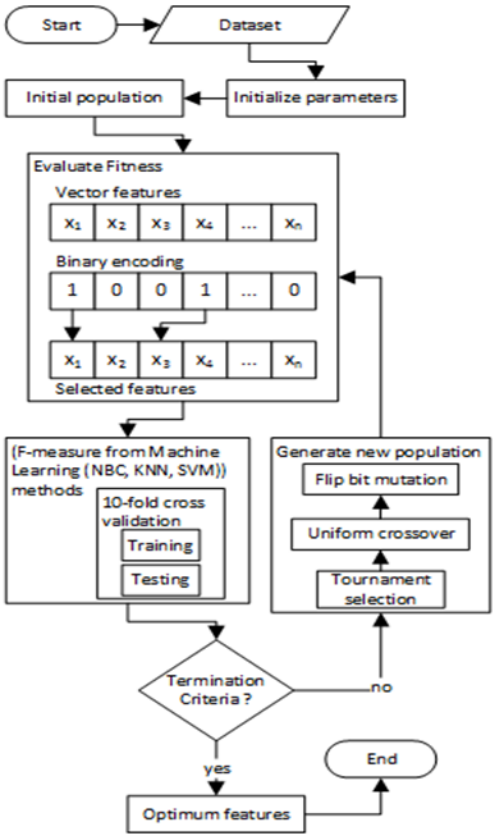

Figure 1: Machine learning methods (NBC, KNN, SVM) combined with GA

(1) The dataset is a feature vector containing normalized data. All necessary parameters are initialized. The initial population is generated and encoded in binary $\{0,1\}$. Individual solutions are randomly generated to form the initial population $P = \{S_1, S_2, S_3, \cdots, S_n\}$; $S_1 = S_2 = S_3 = \cdots = S_n = \{G_1, G_2, G_3, \cdots, G_n\}$. Here S is a solution and G_n represents features, where $G_n \in \{0,1\}$; feature labeled 0 are not used, whereas those labeled 1 are used.

(2) The fitness of each solution (S) is evaluated using the highest f-measure value for musical genre classification conducted through the KNN, NBC, and SVM learning methods, following the 10-fold cross-validation method. The highest fitness value indicates the optimal classification result.

(3) After all fitness values are obtained, tournament selection is used to select parents. This prominently used method probabilistically selects genomes for recombination; the selection is based on fitness. The algorithm

randomly selects genomes from the population to compete in tournaments of user-selected size T. The genome with the highest fitness value in each tournament is selected for recombination.

(4) A uniform crossover is primarily used for problems, wherein elements in the genome are independent of each other. In this case, the locations of genes relative to each other in the genome do not influence fitness. The probability of crossover per gene is set by the user. The uniform crossover process generates a solution in the (t+1)th generation by randomly selecting genes from each of the winners, corresponding to the relevant locations.

(5) A matrix of 1s and 0s is generated, and mutation is applied individually to each element. The probability of mutation per gene is set by the user. The selected values are interchanged such that 1s become 0s (and vice versa).

(6) Crossover and mutation then generate a new population (solution), whose fitness value is reevaluated.

(7) The process is stopped when the required criteria are satisfied; otherwise, the fitness is reevaluated.

(8) The GA then identifies the optimal solution, which in this case is a set of optimal features.

3.3 Evaluation

For the proposed method, selected audio files were used as validation data in this study. Each file was tested through cross-validation for ensuring its allocation to the accurate class. The result was presented in a confusion matrix summarizing accurately and inaccurately classified cases. The f-measure value was calculated from the matrix to determine the optimal classification. The harmonic mean of precision and recall was used as the f-measure value, with the highest f-measure value indicating the most accurate classification.

4 Experimental results

4.1 Environment setting

The data used in this study comprised instrumental music files from the GTZAN genre collection datasets[4]. The data were obtained from the following source:[1]. The dataset comprised 1000 30-s music files in an audio format at a sampling rate of 22050 Hz in 16-bit mono. Samples were classified into the following 10 musical genres: blues, classical, country, disco, hip-hop, jazz, metal, pop, reggae, and rock. The raw data were obtained from audio data files. The data were preprocessed by converting the data files into a numerical form before the execution of feature extraction. A total of 11 sets of low-level time- and frequency-domain features were extracted.

All experiments were performed over 15 independent runs and conducted using MATLAB 2016b with the parallel toolbox. The experiments were conducted on a standard laptop with an Intel i5-3320M 2.60-GHz CPU and 4-GB RAM.

4.2 Without feature selection

4.2.1 Experimental results obtained using KNN

As presented in Table 1, the KNN method performed data execution in less than 1 second in all experiments, with the F-measure mean (Fmean) time being 0.87s and a standard deviation (Fsd) time of 0.03s, yielding an Fmean of 66.2%. The difference between the best F-measure (Fbest) and the worst F-measure (Fworst) was not significant, at 1.4%. Moreover, the Fsd value was negligible, at 0.5%. For classification, the f-measure range was 65.5% to 66.9%. In the results shown, the performance of KNN is less than 70%, but very quickly classifies the music data, owing to the fact that KNN does not need the training process..

[1] http://marsyasweb.appspot.com/download/data_sets

Table 1: Results obtained by KNN without feature selection

Fbest		Fworst		Fmean		Fsd	
Value	time(s)	Value	time(s)	Value	time(s)	Value	time(s)
66.9%	0.67	65.5%	0.83	66.2%	0.83	0.5%	0.03

Table 2: Results Obtained by NBC without Feature Selection

Fbest		Fworst		Fmean		Fsd	
Value	time(s)	Value	time(s)	Value	time(s)	Value	time(s)
59.1%	9.07	56.8%	8.90	58.0%	8.93	0.6%	0.08

Table 3: Results Obtained by SVM without Feature Selection

Fbest		Fworst		Fmean		Fsd	
Value	time(s)	Value	time(s)	Value	time(s)	Value	time(s)
77.0%	14.37	75.3%	12.36	76.2%	13.16	0.005%	1.69

4.2.2 Experimental results obtained using NBC

Table 2 shows the NBC results. The Fmean time for data execution was 8.93s, with an Fsd time of 0.08s for each experiment and an Fmean of 58%. The difference between Fbest and Fworst was not significant, at 2.3%. Fsd was also very small, at 0.6%. For classification, the f-measure range was approximately 56.8% to 59.1%. In the results show, the performance of NBA is less than 60% and even slower than the KNN.

4.2.3 Experimental results obtained using SVM

Table 3 shows the SVM results. For all experiments, the Fmean and Fsd times for data execution were 13.16 and 1.69 s, respectively, with an Fmean of 0.762 (76.2%). The difference between Fbest and Fworst was 0.017 (1.7%), which was nonsignificant. Moreover, the Fsd value was 0.005 (0.5%), which was negligible. The f-measure range for classification was 0.7530.770 (75.3%77.0%).

4.3 With GA feature selection

4.3.1 Parameter Setting

The previous result shows that KNN is the best algorithm for F-measure and computation times. Thus, in this section we will try to import the GA-based feature selection strategy into these three algorithms. The basic parameter settings of all experiments are listed in Table 4. All experimental results are collected from 15 independent runs, each of 100 iterations.

Table 4: GA parameter settings

Parameter	Setting
iteration	100
population	15
crossover rate	90%
mutation rate	1%
selection operator	tournament
crossover operator	uniform
tournament size	2
Number of features	204

4.3.2 Experimental results obtained using KNNGA

From Table 5, it can be seen that KNN-GA required less than 5s for data execution in each experiment. The Fmean time of 4.74 s and Fsd time of 0.43 s gave an Fmean of 71.3%. The difference between Fbest and Fworst was not significant, at 1.2%. Fsd was also very small, at 0.3%. For classification, the approximate f-measure range was 70.8% to 72%. . In summary, we found that the GA-based feature selection will improve the 5% F-measure rates with the KNN approach.

4.3.3 Experimental results obtained using NBCGA

From Table 6 it can be seen that, for data execution, the NBC-GA required a fairly long Fmean time of 61.46 s. With the Fsd time of 8.50 s for each experiment, this gave an Fmean of 66.8%. The difference between Fbest and Fworst was not significant, at 0.9%. The Fsd was also insignificant, at 0.3%. The f-measure range for classification was approximately 66.4% to 67.3%. In summary, we found that the GA-based feature selection will improve the 10% F-measure rates with the NBC approach.

4.3.4 Experimental results obtained using SVMGA

As can be seen from Table 7, SVM-GA required a fairly long Fmean time for data execution, of 125.614s. With an Fsd time of 44.29s from each experiment, the Fmean was 79.5%. The difference between Fbest and Fworst was not significant, at 1.1%. The Fsd was also very small, at 0.3%. The f-measure range for classification was approximately 79.0% to 80.1%. In summary, we found that the GA-based feature selection will improve about the 3-5% F-measure rates with the SVM approaches.

4.3.5 Convergence Rates of KNN-GA, NBC-GA, and SVM-GA

The graphs in Figs 2, 3, and 4 reach steady state because they include a stop criterion at the 100th iteration when the process ended.

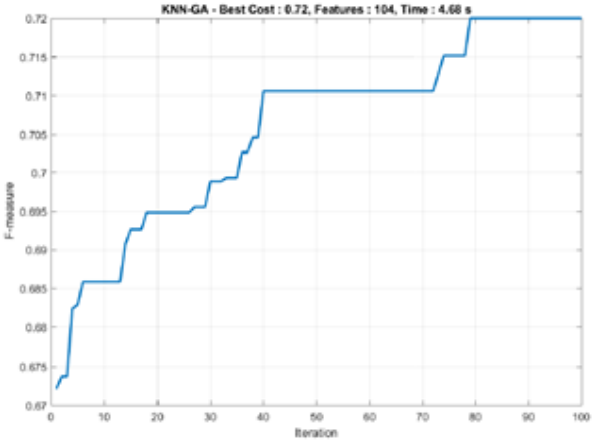

Figure 2: Convergence rates of KNN with Genetic Algorithm

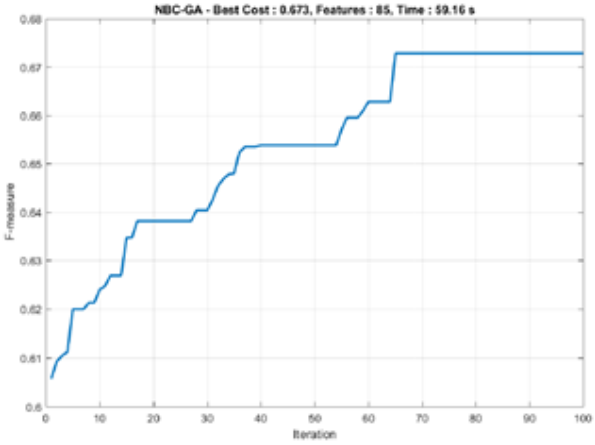

Figure 3: Convergence rates of NBC with Genetic Algorithm

Table 5: Results Obtained by KNN with Feature Selection

Fbest		Fworst		Fmean		Fsd	
Value	time(s)	Value	time(s)	Value	time(s)	Value	time(s)
72.0%	4.68	70.8%	4.66	71.3%	4.74	0.003%	0.43

Table 6: Results Obtained by NBC with Feature Selection

Table 7: Results Obtained by SVM with Feature Selection

Fbest		Fworst		Fmean		Fsd	
Value	time(s)	Value	time(s)	Value	time(s)	Value	time(s)
80.1%	121.19	79.0%	123.46	79.5%	141.05	0.3%	44.29

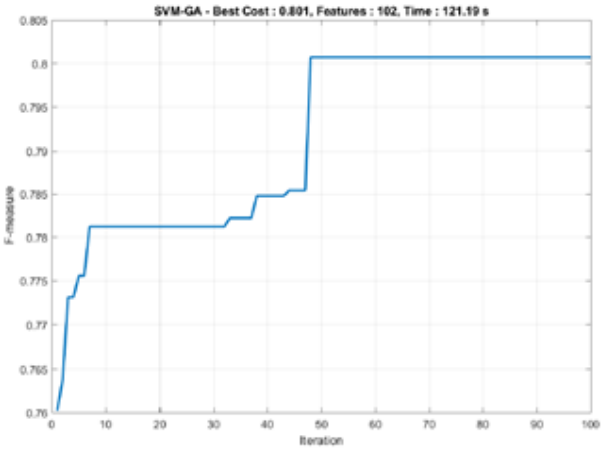

Figure 4: Convergence rates of SVM with Genetic Algorithm

4.4 Comparison of F-measure values

The performance is assessed based on Eq. 1.

$$\Delta F_M = \left(\frac{F_{new} - F_{orig}}{F_{orig}} \right) \times 100\% \quad (1)$$

Here, ΔF_M denotes the improvement of the F-measure values, Δt_{avg} denotes the improvement of computation time, F_{new} denotes the F-measure values of the KNN, NBA, and SVM algorithm performing the genetic algorithm feature selection, and F_{orig} denotes the KNN, NBA, and SVM algorithms without performing any feature selection strategy, and t_{avg} is the computation time in seconds.

Table 8 shows that the average increase in the Fmean value was approximately 7.24% for KNN-GA, approximately 13.27% for NBC-GA, and 4.23% for SVM-GA. However, in order to perform the feature selection strategy, the computation time was increased to between 500% and 871%. In summary, the feature selection increases the quality of the solution, but with a massive increase in computation time, especially with SVM-GA, which requires spending more than 10 times the computation time..

4.5 Comparison of results in this study with those in previous studies

Previous results showed the ability of a GA to improve the quality of result classification by reducing features. The existing algorithm performs poor quality classification (approximate Fmean 59%66%). Moreover, by feature selection using the GA, the quality classification can be improved until Fmean is 67%80%. In this section, we compare the proposed algorithm with other algorithms to verify the performance or proposed algorithms. Table 9 compares the accuracy of different methods with our proposed algorithms, KNN-GA, NBA-GA, and SVM-GA, using the highest measure achieved by each. All studies used the same GTZAN Genre Collection Data Sets [4]. The KNN-GA method from the current study produced an Fbest value of 72%, which is better than the comparison algorithms of [4, 39, 47, 48]. The NBC-GA method produced an Fbest value of 67.3%, which exceeded that reported in [4]. The SVM-GA method produced an Fbest value of 80.1%, which exceeded previous studies. In summary, the GA combined with the SVM method can obtain a better solution than other algorithms.

5 Conclusions and Future work

In this study, automatic musical genre classification was conducted by combining GA optimization with three machine learning methods. This approach entails using low-level time- and frequency-domain features. The features are extracted using short- and mid-term processes. The optimal classification accuracy levels achieved in the study were determined to be comparable to those achieved by other state-of-the-art musical genre classification algorithms. However, the feature selection strategy will consume a massive amount of computation time. As part of our future research, we aim to investigate three aspects: 1) applying other meta-heuristic methods such as particle swarm optimization (PSO) to select low-level features; 2) combining deep-learning techniques such as CNN with a meta-heuristic algorithm to improve the accuracy of classification results; and 3) decreasing the computation time by using feature reduction mechanisms to make the algorithm perform more effectively.

Table 8: Comparison of f-measure values

Measure	KNN-GA		NBA-GA		SVM-GA	
	ΔF_M	$\Delta\, t_{avg}$	ΔF_M	$\Delta\, t_{avg}$	ΔF_M	$\Delta\, t_{avg}$
Fbest	7.08	598	12.18	552	3.87	743
Fworst	7.49	461	14.46	546	4.68	898

Sliding mode control

ABSTRACT

This article presents a bridge crane nonlinear dynamic model in 2-dimensional space, and then given a novel adaptive fuzzy-sliding mode controller based on combining sliding mode control with fuzzy logic and Lyapunov function. Firstly, the article proposes an intermediate variable to link signal between two slide surfaces, related to trolley movement and payload swing. Then the fuzzy controller, compensative controller and parameter adaptive update law for the bridge crane are defined. The asymptotic stability of the proposed bridge crane control system is proven based on Lyapunov stability theory. Simulation results show that the adaptive fuzzy-sliding mode controller ensures the trolley follows the input reference with the short settling time, eliminating steady error, and anti-payload swing, anti-disturbance.

1. Introduction

The bridge crane is a lifting machinery which commonly used in industry and transportation to move goods from one location to another. The bridge crane consists of three main components: hoist, trolley and beam, corresponding to three movements: lifting and lowering the cargo of the hoist (mounted on the trolley), horizontal movement of the trolley (on the beam), and vertical movement of the beam (on the factory frame). Goods (refer to as payload) are linked to cargo hoist by the cable and hanger. This connection causes the vibration of the payload when the crane moves. This is undesirable - causing unsafe operation of the crane, reducing the accuracy in controlling the cargo transport of crane, reducing the crane operation.

In some cases of actual crane operation, it is often focused on controlling the exact position of the trolley, after lifting the payload. In this case, the bridge crane is studied as a trolley movement in the 2D space, created by the horizontal movement of the trolley and the verticality of the cable. Common works on position control of the trolley are often based on state feedback control, PID control [1, 2], LQR control [3], PID combined with fuzzy [4-7], PID adjusting parameters [8] and obtain certain results. In [1], the state feedback controller is combined with the integral part to eliminate the steady error. The work [4] presents a controller PID combined with the fuzzy-sliding mode control. These controllers are designed based on the linear model of the crane and the existing of payload oscillation.

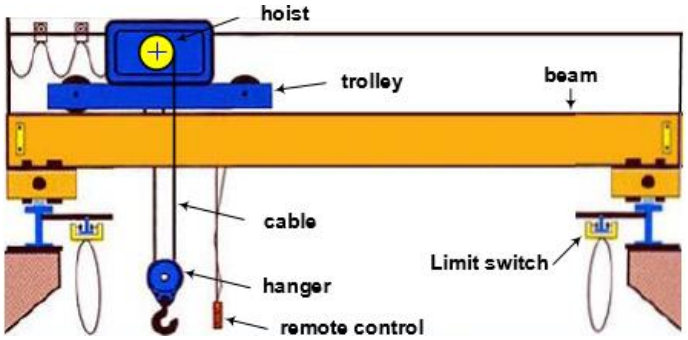

Figure 1. Bridge crane movement in 3D: trolley-0x, beam-0y, hoist-0z.

In recent times, the researches have taken into account the nonlinearity of the crane based on back stepping [9], nonlinear control [10, 11], sliding mode control [12], sliding mode control combined with fuzzy logic [13], partial linear feedback control [14], sliding mode control combined with partial linear feedback [15], sliding mode control combined with adaptive fuzzy control [16], or neural network [17]. These controllers have enriched the crane control strategy, ensuring that trolley follows the reference trajectory with small static error and small payload oscillation. However, these control algorithms are quite complicated, require a large amount of computation, the deployment of them on hardware devices is difficult and not considering the impact of

noise in the working environment of the crane, such as the impact of the wind.

This article presents a nonlinear mathematical model of a crane in two-dimensional space (2D bridge crane model). On that basis, an adaptive fuzzy-sliding mode controller is designed for 2D crane model based on the sliding mode control principle combined with fuzzy logic and Lyapunov function, ensuring that the trolley moves quickly, following set reference and eliminating payload oscillation, anti-disturbance. The rest of this article is organized as follows. Section 2 introduces the bridge crane dynamic model. Section 3 deals with the design of controllers for the bridge crane 2D. Section 4 presents the simulation results. Finally, section 5 presents conclusions.

2. Bride crane dynamic model

The motion of the bridge crane in the two-dimensional space *Oxz* as shown in Figure 2, where: *x(t)* is the position of the trolley moving in the *Ox* direction, *α(t)* is the oscillation angle of the payload. Assuming that the cable is a rigid rod and connected with a cargo hanger, the cable length is constant and the cable mass is negligible; ignore the trolley friction when moving; consider payload as the point $P(x_p,z_p)$ with mass m_p; trolley with mass m_t; F_x is the force driving a trolley in the *Ox*-direction, g is the gravitational acceleration.

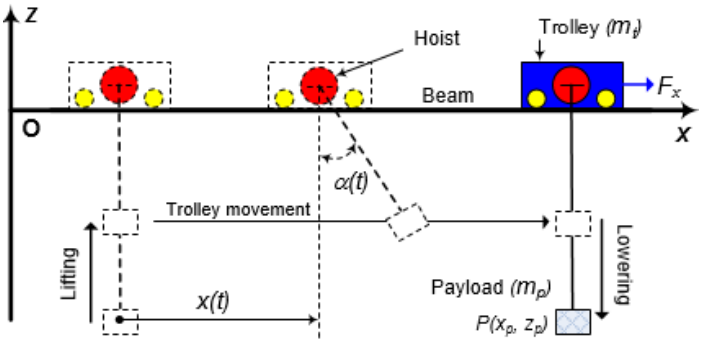

Figure 2. Bridge crane trolley movement in 2D

The dynamic model of bridge crane is defined based on energy conservation law. The total kinetic energy K and the potential energy T of the system are determined as follows:

$$K = K_{trolley} + K_{payload} = \frac{1}{2} m_t \dot{x}^2 + \frac{1}{2} m_p (\dot{x}_p^2 + \dot{z}_p^2)$$
$$; \; x_p = x + l\sin\alpha \; , \; z_p = -l\cos\alpha \qquad (1)$$
$$T = T_{trolley} + T_{payload} = -m_p g l \cos\alpha$$

Lagrange function is determined by the following formula:

$$L = K - T \qquad (2)$$

The mathematical equation describing crane dynamics is determined from the Euler-Lagrange equation, with $q = [x, \alpha]^T$, $\tau = [F_x, 0]^T$, as shown below

$$\frac{d}{dt}\left(\frac{\partial L}{\partial \dot{q}}(q, \dot{q})\right) - \frac{\partial L}{\partial q}(q, \dot{q}) = \tau \qquad (3)$$

After transforming, we obtain the mathematical equation describing the dynamics of crane:

$$\begin{cases} (m_t + m_p)\ddot{x} + m_p l(\ddot{\alpha}\cos\alpha - \dot{\alpha}^2 \sin\alpha) = F_x \\ \ddot{x}\cos\alpha + l\ddot{\alpha} + g\sin\alpha = 0 \end{cases} \qquad (4)$$

The system of equations (4) is separated into 2 subsystems, describing 2D bridge crane dynamics in the state space, including: system A describes the trolley movement; system B describes the payload oscillation.

$$A: \begin{cases} \dot{x}_1 = x_2 \\ \dot{x}_2 = f_1(x) + g_1(x)u \end{cases} \qquad (5)$$

$$B: \begin{cases} \dot{x}_3 = x_4 \\ \dot{x}_4 = f_2(x) + g_2(x)u \end{cases} \qquad (6)$$

where:

$$x_1 = x(t); x_2 = \dot{x}(t); x_3 = \alpha(t); x_4 = \dot{\alpha}(t); u = F_x$$

$$f_1(x) = \frac{m_p l x_4^2 \sin x_3 + m_p g \sin x_3 \cos x_3}{m_t + m_p \sin^2 x_3}$$

$$g_1(x) = \frac{1}{m_t + m_p \sin^2 x_3}$$

$$f_2(x) = -\frac{(m_t + m_p) g \sin x_3 + m_p l x_4^2 \sin x_3 \cos x_3}{(m_t + m_p \sin^2 x_3) l}$$

$$g_2(x) = -\frac{1}{(m_t + m_p \sin^2 x_3) l}$$

The 2D bridge crane model is a nonlinear system. When the trolley moves, the payload oscillation will appear, so that as the proposed controller not only ensures the trolley follows the reference trajectory but also quenching payload oscillation, in order to ensure safe operation and accurate cargo transportation.

3. Adaptive fuzzy-sliding mode controller design for the bridge crane

3.1. Sliding mode controller

In this research, mathematical model of 2D bridge crane is described by equations (5) and (6), corresponding to system A, system B.

The goal here is to synthesize a controller $u = u(\underline{x})$ so that the outputs $\underline{x}(t) = [x, \alpha]^T$ of the crane (5) and (6) follows on the input reference $\underline{x}_d(t) = [x_d, \alpha_d]^T$ i.e. the steady error:

$$\underline{e}(t) = [e_1(t), e_2(t)]^T \to \underline{0}$$

with $e_1 = x_1 - x_{1d}$;
