An anomaly based network intrusion detection system for Remote to Local (R2L) attacks is proposed in [15]. R2L attacks usually exploit a vulnerability in a service at the target machine to elevate the attacker's privileges. This attack is similar to the impersonation attacks occurring in clouds. The proposed detection system consists of two logical modules, the Packet Processing Unit (PPU) and the Statistical Processing Unit (SPU). The PPU has to extract service requests from the stream of packets on the wire to pass them to the SPU. The task of the SPU is to read the service

requests and extract suitable statistical input data. Requests are divided into several groups where each group contains request types with similar statistical properties such as Get and Post protocols. The requests of each group are then analyzed independently. The properties of a request used to determine its anomaly score include: type of request, length of request, and payload distribution. The anomaly score of a service request is the weighted sum of the three scores computed for each of the previously mentioned properties. Finally, the anomaly score is compared to a threshold that can be manually set by the security administrator. The presented detection system has detected all anomaly requests with a very slight false positive rate. Since the anomaly score technique proposed for network packets, we adjust it to detect impersonators in service clouds by computing the anomaly score of SOAP request messages exchanged between services.

In [14], the detection system concentrates on profiling the behavior of system processes by studying the set of system calls made by the program. The designed algorithm compares the sequence of system calls captured during online usage to the normal sequences profiles during the training phase. The detection accuracy was 72.2% with a false positive rate of 2.1%.

4. Impersonation Attack Detection Approach

When dealing with the impersonation attack detection, it is important to mention that we assume the impersonator has already obtained the required security parameters including the victim service's credentials, the security token, and the encryption keys to get involved in the cloud application and communicate with its services (explained above). We also assumed that the attack targets are only web services. Hence, SMDBs, detectors and other entities are assumed to be sufficiently secure.

When presenting the stolen identity, the impersonated service appears as a legitimate service with the same access rights as the victim service. Ideally, monitoring a service's behavior after being granted access is required in order to detect such attacks. We find that certain types of service activities can reveal the service intent. For instance, SOAP requests used for web service communication offer an interesting behavior to monitor. A service request contains the sender supplied data which is sent over the network to another provisioned service in the same application session to perform a single task on behalf of that sender, which is either a human user or another service. This data shows the intent of the service trying to gain secure information from different services in a very short period of time before the stolen security token expires and before the victim finds out about its stolen identity.

The developed approach composes of three steps. The output of each step represents the input to the next step (Figure 2):

A. Auditing services' messages by the auditing system during the training phase.

B. Profiling the request behavior of each service in a profile document before running the detection algorithms during runtime using log files.

C. Detecting any significant change between the profiled and live behaviors then verifying the identity of the malicious service by using the verification technique.

To assess the feasibility of our approach within the service cloud model, we craft an easy to understand case study with a deployed service cloud hosting 25 distinct web services with 15 tenants owning and offering these services. We implement a session manager randomly chooses among appropriate services and composes them to provision an application that satisfies a user's request. A service cloud receives the traveler requirements with the preferred maximum price and the cloud returns the most suitable travel package with allowed payment. Table 1 shows the services and tenants used in the case study to evaluate the proposed impersonation attack detection approach. The cloud employs different meta-services to manage the travel reservations. These services are a Travel Agency service, Transportation services, and Living services.

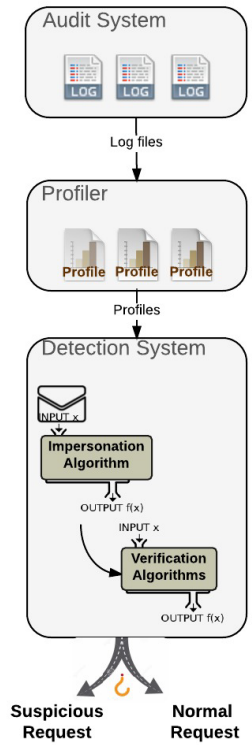

Figure 3: Impersonation detection approach

Table 1: The available services in the case study

Tenant Class	Web Services
Banks	CreditChecking, Payment, CreditCard, paymentService, CreditVerification,CreditPayment, CheckBalance
Airlines	FlightFinder, FlightService, CheapFlight, TicketFinder, FlightFinder
Car Rentals	RentalAgent, RentalService, CarRental, RentalService, RentCar
Hotels	RoomBooking, RoomLocator, Accom, AvaRoom, BookingService, FindRoom
Weather	WeatherRetriever, Forecast

The Session Manager (SM in Figure 1) dynamically provisions services from tenants into a service chain to simulate a travel management system as in Figure 4. Given a client request, the provisioned services buy a flight ticket to a specific destination at a specific time, reserve a hotel room, rent a car, retrieve the forecast for the desired travel dates, and pay the total price from the client's bank account. The resulting service chain consists of at least 9 services from at least 5 tenants.

4.1. Auditing System

In our service cloud architecture [3], the impersonation detection algorithm is distributed across a tenant scope, session or application scope, and cloud scope as depicted in Fig. 1. This distribution allows for load balancing among services logging events, tenants generating profiles of all of its hosted services, applications executing service chains to satisfy clients' requests and detect impersonation attempts, and the cloud verifying the extent of the attack.

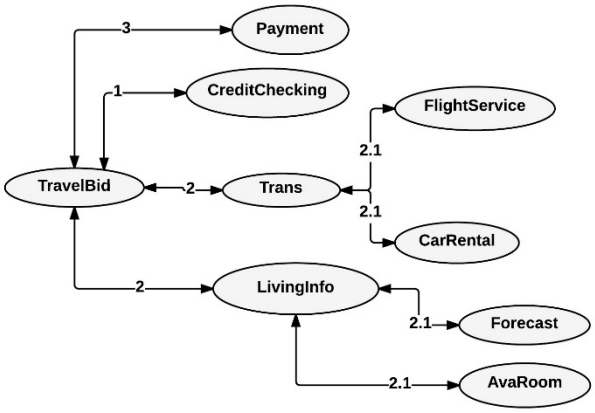

Figure 4: A scenario of Travel Package Bidder

Event logging at each service is done by its tenant's Auditor. The Auditor is a web service interceptor attached to each service to monitor its request and received messages. By intercepting SOAP requests, the Auditor is able to collect important information about the recipient to sufficiently check the sender's request behavior. Such information includes recipient services and their business classes, requested methods in these recipients, request size, and other critical details. The advantage of this approach is that the logging process created and managed independent of the service process code to protect the auditing process from intruders. Since the tenant auditor would not be able to log requests issued by the impersonated service, checking the victim service's log file for the suspicious events helps to detect the attack at early stages.

At the application scope, the STS log file retains messages communicated by the client and services as it manages the creation, delegation, validation, and cancellation of the security token. By logging these details, we can corroborate the STS log file with the victim service's log file (the service whose credentials have been stolen) to reveal any missing events [1] as significant evidence of an impersonation attack.

The cloud scope gathers centralized forensic investigation information and examines it for impersonation attacks. During the detection process, the cloud scope correlates alerts received from any affected application scope and compares the malicious request of the impersonated service with the victim service's log file. The final decision about the malicious request is logged by the cloud Auditor at the cloud scope.

4.2. Profiler

The detection system detects an impersonated service by comparing its observed request to its expected behavior using certain metrics that are defined in its profile. The expected behavior can be deduced during the training period. Since the manual creation of expected behavior is cumbersome, we use the training period for each service to collect information about its behavior. During training, the auditing system logs enough information about request events for each service. Extracted data about requests from a specific service's log file are not classified in advance, meaning that the frequent requests represent the general behavior of the service. Hence, during runtime, received requests are evaluated against a summary of the training data (i.e. profile) to measure the deviation from the normal behavior.

Profiling the services' behavior is done in two phases: profile generation and profile aging. Each phase is discussed in detail in next subsections.

4.2.1. Profile Generation

Instead of building the detection system by evaluating the received request during runtime against all requests in the sender's log file, we summarize these records in profile documents. Thus, the detection time dramatically decreases which leads to an improvement in the performance. The Profiler uses the logged data at the tenant scope to generate the service's request behavior profile. Then, SM makes the services' profiles available to the involved application detector.

The profiler depends on a statistical model to generate the request behavior profile from the service log file. This model consists of different attributes extracted from the SOAP request without processing its payload. Hence, the model reduces the cost of decrypting payloads of malicious requests that would be declined at the end. The used attributes are recipient's class, SOAP size, method, and historical incidents. We found these attributes sufficient to reveal any deviation from the normal request behavior.

1) Recipient's Class:

We hypothesize that each service has a logical "preferred" set of business classes where it sends requests based on its business purpose. For example, flight reservation services always communicate with different services in the banking and airline classes to buy a ticket for the client. In the statistical model, we compute how frequent the recipient's class has been accessed by the sender during the training phase. The probability of relevant frequency is used to compute the anomaly score (AS) of recipient's class as follows:

$$AS_{class} = - \log_2 (P[c]) \quad (1)$$

Equation (1) assigns higher anomaly scores to requests sent to recipients with less frequent classes. The probability P[c] represents the relative frequency that a request with class c has occurred during the training period of the sender. In order to prevent too high anomaly scores (or even infinite values) for the class that has been requested by the sender very infrequently (noise) or not at all during the training period, the probability of each request class needs to be set to a minimum value depends on the service characteristics and it might be adapted from time to time. Since this minimum value yields to a maximal anomaly score for classes that never received requests from the sender, it is necessary to maintain the same maximum anomaly score across all attributes of SOAP requests to keep the total anomaly score consistent.

2) SOAP Size:

The size of a SOAP request can be a good indicator of the reliability of its source. The structure of a SOAP request consists of optional elements that the service can include, such as SOAP Header and SOAP Fault. Usually, the size of the SOAP message does not vary much between requests that are generated by services in a certain class to a specific recipient. The situation looks different when requests carry input wanting to obtain information from the target recipient. For instance, the attacker may send a request with nested queries to get more information from the recipient's database. To assess this attribute properly, we correlate SOAP size with either the recipient service or class based on some properties of the observed request.

The sender's profile keeps track of all recipient services and their classes that have ever received requests from that sender along with the average size of these requests. If the current recipient of the observed request has been accessed by the sender over an acceptable rate of requests then the available information about the requests sent by the sender to this recipient would be sufficient to evaluate the size of the received request. Otherwise, the size of requests received by the current recipient's class (received by any service in this class) would be used to compute the size attribute.

We calculate the anomaly score for SOAP size as in [15], by using the mean (μ) and the standard deviation (σ) of the sizes of the requests that have been sent by the sender during its training period to either a specific recipient or class. These two values are stored in the sender's profile for each recipient and each class that has been previously accessed by the sender. The following formula is used to check the anomalousness of a request with size Z during run time. The anomaly score grows exponentially as the request size increases. In order to tolerate a reasonable amount of deviation of the size attributes, we set x variable as the base and multiply σ with a constant factor of y. The choice of x and y is the recipient's responsibility based on its features and needs. The x and y variables are stored in the application SMDB and available for the detection algorithm.

$$AS_{size} = x \wedge ((Z-\mu) / (y*\sigma)) \quad (2)$$

This equation assigns anomaly scores greater than x only to requests that have SOAP size longer than the average. This is consistent with our assumption that malicious request increases the total size of the soap message. We limit the maximum value of AS_{size} to the same value in AS_{class} to avoid having infinite anomaly scores.

3) Method

The WSDL file for a web service shows its business logic and policies. The business logic is represented by the operations or methods that are available for the client to call along with information about their required parameters, data types, maximum values etc. Since this information is publicly available, there is no reason for the attacker to restrict himself from calling any method while he has valid credentials. However, for the victim service, there should be a noticeable behavior towards the recipients' methods.

Assume the recipient is a credit card service with two methods; one to check the sufficiency of an input card number to cover a certain payment and another method to return the available balance of the received card number. If the recipient receives a call from the impersonated service to the balance returning method given information that the victim service is used to frequently call the sufficiency checking method then the detection system can consider this call as a serious flag of an impersonation attack.

To compute the anomaly score of the invoked method in the observed request, we correlate this method with the probability of relevant frequency of its service which is the current recipient of the request. However, the dynamic nature of the provisioning process in service clouds can lead to provisioning some services offering the same business service less frequent than others. For recipients that have been provisioned and accessed by the sender more than a predefined threshold, the anomaly score of their methods would be computed using their probabilities in equations (3) and (4) below.

The anomaly score (4) for the called method is calculated for each method in the recipient WSDL that was called by the sender using the conditional probability in (3) if P(rec) is greater than a preset threshold. The anomaly score is stored in the sender's profile. We also limit the maximum value of AS_{meth} to the same value in AS_{class} and AS_{size} to avoid having infinite anomaly scores.

$$P(meth|rec) = (P(meth \text{ and } rec))/(P(rec)) \quad (3)$$

$$AS_{meth} = - \log_2 (P[meth|rec]) \quad (4)$$

Other recipients with less provisioning probability do not have sufficient information about their methods in the sender's profile that can be used by the detection system to determine the anomaly scores of their methods. Hence, using equations (3) and (4) to compute the anomaly score of the invoked method for infrequent recipients would introduce a significant bias into the final anomaly decision. Instead, owners of infrequent recipients need to set anomaly scores to their methods representing their acceptable risk degree of revealing information by each method if it has been accessed by an impersonated sender.

4) Historical Impersonation Incidents

Since the cloud hosts many services owned and operated by different tenants, the cloud provider must not assume that all tenants are careful about the security configuration of their services. Thus, the detection system needs to consider the historical incidents of impersonations occurred for each service when examining its requests. The service profile provides the probability that the service historically reveals to be a victim of an impersonation attack.

To calculate the impersonation probability for each service, information about the historical incidents that occurred for the service is accumulated in the tenant SMDB. Then, Profiler exploits this information with the information extracted from the service log file about the total number of requests to compute the probability of the service being a victim of previous impersonation attacks:

$$P(s) = (\text{total impersonated requests}) / (\text{total requests}) \quad (5)$$

We use P(s) to compute the anomaly score for the service history in (6). We weight the probability to have a maximum value similar to other attributes. The higher the anomaly score of the service history the more likely that the service is currently involved in an impersonation attack.

$$5) \quad AS_{history} = P[s] * max \quad (6)$$

The behavior profile for each service has a summary of its request messages logged in its log file using equations (1)-(6). These values would be preserved in the tenant SMDB upon the service registration and provisioned to the relevant applications' SMDBs by the SM.

4.2.2. Profile Aging

When the detection system produces more false alarms than that logged for a previous period for a certain service, that means either the request behavior of this service has dramatically changed or the training data used to generate the profile became old and misrepresents the current behavior. Hence, we propose a strategy indicating when and how to update behavior profiles for services to increase the accuracy of the detection system.

We combine two conditions to determine the profile age and trigger an updating. The first one is a chronological condition for the profile to be updated periodically based on the service owner's policy. The updating process is automatically done at the tenant scope by Profiler using the service's log file. Secondly, when the detection system causes too many false alarms for a certain service before reaching the next updating cycle, the cloud scope (Figure 1) triggers the update at the tenant scope to use the most recent requests in the log file to model the service's profile.

During the updating period for a specific service, the service becomes unavailable for provisioning in cloud applications. Profiler checks the availability of enough requests in the service log file to replace the currently used training data since the last time this data has been collected. If there is enough data, the most recently logged requests are used to generate the profile. Otherwise all recent requests substitute the oldest requests in the training dataset. This method of aging has the effect of creating a moving time window for the profile data, so that the behavior is influenced strongly by the most recently observed behavior. Thus, the detection system adaptively learns services' behavior patterns; as services alter their behavior, their corresponding profiles change.

4.3. Detection System

Although any anomaly detection algorithm can be used to model normal behavior, the algorithm to be used for a significant amount of data in service clouds during real-time must be very efficient. Instead of ML algorithms, we develop an anomaly detection algorithm, which in our experiments leads to a high rate of accuracy and an acceptable performance overhead. In next sections, we explain in details our algorithms to detect suspicious requests and verify their owners' identities.

4.3.1. Detection Process

Inspired by the anomaly detection scoring system in [15], our algorithm does not detect data that represent an attack in the training period because it does not label such data as an anomaly; it assumes all data is normal. It is based on the premise that low probability values with a low likelihood of certain attributes are regarded as noise, and hence. Given that attack data is a minority of the training data then they would be recognized as attacks by the detection algorithm implicitly as low probability events and treated as anomalies at run time. "If attacks were prevalent and high probability events, then they are normal events, by definition" [18].

Upon each request, the application detector retrieves the sender's profile from the application SMDB to examine the impersonation attack. The deviation rate between the received request and the normal behavior is calculated by using the statistical model previously explained.

The total request anomaly score is a value that specifies the extent of the deviation of the received request from the expected values of anomaly scores specified by the sender's profile. It is a compound value derived from the attributes that have been computed in equations (1), (2), (4), and (6) and stored in the profile as follows:

$$AS = w_1\, AS_{class} + w_2\, AS_{size} + w_3\, AS_{meth} + w_4\, AS_{history} \quad (7)$$

The anomaly score for each attribute can be weighted to reflect its importance for the detection system using weight variables w1, w2, w3, and w4. This total score is compared to a threshold that can be chosen by the security administrator. A lower threshold means it is more likely that requests from impersonated services are detected with the disadvantage of an increasing number of false alarms. On the other hand, a higher threshold would allow for malicious requests to pass without detection.

ALGORITHM 1 performs the detection process. Line 24 indicates that the detector of the affected application sends the adequate information about the detected request to the cloud scope to take the proper action.

New services may not have a performance record in the cloud. If they are impersonated by attackers during the training phase; the detection system assumes their abnormal behaviors are normal behaviors. Therefore, once a new service arrives, the cloud must assume a certain amount of risk for some acceptable time if it provisions a new service into an application, given that the use of the new service can cause unrecoverable damage or too many false positives. Thus, the cloud needs to set constraints on the use of new services to determine their trustworthiness. In the proposed architecture (Figure 1), the SMDB of each tenant has an archive of the historical security incidents that have occurred on each service owned by this tenant. This history can be used by the cloud provider to evaluate the trustworthiness of the tenant in order to accept its new services in the provisioning process.

Each application has in its SMDB a white list of services that are within their training phase. The application detector skips checking this new service against ALGORITHM 1. Otherwise, the detector would generate an alert for each request instantiated by every new service which increases the false positive rate of the detection system.

```
ALGORITHM 1: IMPERSONATION_DETECTION
Input:
1.  Sender's profile (prof).
2.  Received request (req).
Output:
3.  Anomaly score (AS) for the received
request.
Begin:
4.  initialize soapSize, recipient, method,
class,μ,σ,AShist,ASmeth,ASclass,ASsize,
anomalyThreshold
5.  method =  req.getSoapAction()
```

```
6.  recipient = req.getRecipient()
7.  soapSize = req.getSoapSize()
8.  class = SMDB(recipient)
9.  if ( find(class in prof) {
10. ASclass= prof.get(ClassAS)          (1)
11. Ashist=prof.get(HistoryAS)          (6)
12. μ = get (Mean, prof)
13. σ = get (standardDeviation, prof)
14. ASsize=x^((soapSize-μ))/(y*σ)       (2)
15. if (find(recipient in prof)
16.     ASmeth=prof.get(MethodAS)       (4)
17. else
18.     ASmeth=max
19.     AS=w1*ASclass+w2*ASsize+w3*ASmeth+
        w4*AShist(7)
20.}
21.else {
22. AS= 0.4* 15 + 0.2* zero + 0.2* zero +
    0.2* zero }
23.if ( AS> anomalyThreshold)
24.  send alert to Cloud scope
25.else
26.  pass req
End
```

4.3.2. Verification Process

The impersonation detection algorithm gives an alert about a malicious request deviating from the normal behavior of the legitimate sender. To verify the identity of the suspicious sender, we use a verification technique. This technique confounds and confuses an impersonator into believing they have useful information when its identity is not verified. We integrate this technique with the service behavior profiling to secure the service in the cloud from being impersonated.

Upon registration, the verification technique requires each service to present a faked version of its response to the cloud SMDB. Then, the SMDB provisions this response to the applications that this service involved in. In addition, the cloud SMDB provisions a random code to each application for verification purposes. Hence, whenever a malicious request to the recipient service is detected by the application detector using ALGORITHM 1, the fake response is returned by the application detector in such a way as to appear completely legitimate and normal. The detector is the only party in the application has the privilege to access the code and fake responses reside in the application SMDB. Therefore, whenever a service has been impersonated, the attacker has no way to neither realize that the received response is faked nor use the application code to verify his identity.

When the sender is correctly identified as an impersonated service, it accepts the faked response since it does not have the ability to communicate with the application detector to distinguish between real and fake responses (Figure 5.A). As a result of this acceptance, the application detector terminates the application after a predefined period of time and delivers the information about the detected request as a security alert to the cloud scope for more investigation. The cloud scope then asks the tenant that owned the detected sender for its recent log file. If the detected request is not recorded in the original sender log file then the decision made by the application detector is correct otherwise it is a sign that the profile of the falsely detected needs to be updated.

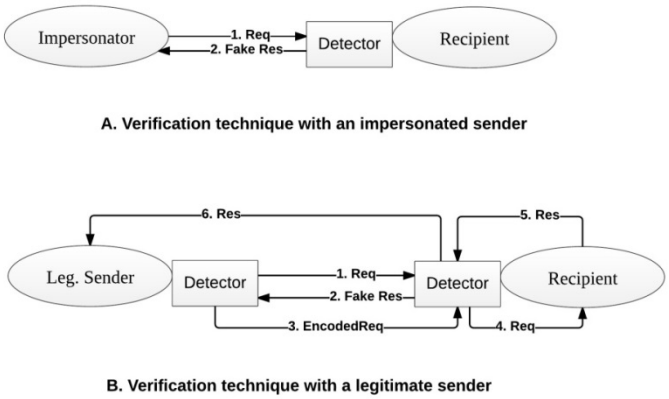

Figure 5: The verification process after detecting an impersonator

For the legitimate sender, the application detector would receive the fake response and readily recognize it and send the same request again along with the application random code to the same recipient (Figure 5.B). This encoded request is the application detector way to verify the sender's identity and issue a false positive alarm. The verification technique here serves two purposes: (1) validating whether the sender is authorized when abnormal request is detected, and (2) confusing the impersonator with useless information.

To incorporate the verification technique with the defined detection system, we need to change ALGORITHM 1 at line 24 to call ALGORITHM 2 instead of the cloud scope as follows:

VERIFICATION (req)

ALGORITHM 2 details how the detection system sends useless information as a response to malicious services. In line 5, the detector checks if the received request is a repeated request from a legitimate sender having the predefined code to verify its identity. In Line 7 the request is passed to the recipient after decoding it. Line 9 shows that the fake response for each service is extracted from the application SMDB. The fake response is passed in Line 10 to the sender.

```
ALGORITHM 2: VERIFICATION

Input:

1.   The malicious request (req).
Output:

2.   Detector's action against the malicious
  request.
Begin:

3.   sender = req.getSender()
4.   recipient = req.getRecipient()
5.   if (req.hasEncodedData) {
6.       Req.removeEncoded()
7.       pass req }
8.   else {
9.       fake_info= SMDB.getFake(recipient)
10.  pass fake_info  }
End
```

ALGORITHM 3 shows how the detector reacts when receiving a fake response by one of the application services. Line 4 declares that the detector uses a single code provisioned by the cloud scope to resend the legitimate requests. The detector deploys the verification technique either by sending or responding to the fake

response without getting the recipient service involved, which reduces the performance overhead and keeps the service black-boxed in the cloud without changing its internal code.

```
ALGORITHM 3: RECEIVING_FakeRes
Input:
1. fake response (res).
Output:
2. req: a new request holding the old request
and the code.
Begin:
3. if (res is fake){
4.   req.update(code)
5.   pass req }
6. else
7.   pass res
End
```

5. Results and Discussion

The developed framework is deployed in Azure cloud. JBoss server is used to deploy the web applications while Apache CXF Framework is used to develop web services and the STS. The application Detector and Auditor are implemented as CXF inbound and outbound interceptors attached to the STS in order to manipulate each SOAP request and response after being authenticated.

To generate behavior profiles for services in the Travel Agency case study, we deployed the framework 300 times to respond to client requests, randomly creating 300 service compositions (applications) from the available services. We used the resulting log files to generate profiles from while recording the generation time. The average time for each service to generate its behavior profile was about 3.2 seconds.

We have conducted three different tests on the designed case study: no attack check, anomaly check, and attack check. We have run the framework without attacks for legitimate services and anomalous services that are changed their behaviors without updating their profiles to measure the false positive rate. In addition, we designed several attacks to measure the detection accuracy rate of the detection algorithm. The designed tests have been deployed on randomly generated applications with a distinctive percentage of 94%. The anomaly threshold was ranging between 3 and 5. We used 0.4, 0.2, 0.2, and 0.2 to weight ASclass, ASsize, ASmeth, and AShistory respectively. The recipient's class anomaly score has slightly more weight since it primarily represents the business logic of the sender. The threshold is computed during the training phase and set to a value that would cause 10 false alarms per 100 applications when the system would receive the training data itself as input. A lower threshold would detect more attacks with the disadvantage of an increasing false positive rate. Hence, the threshold should be set to the lowest value possible provided the acceptable false positive rate. This decision depends on the type of traffic that is seen on the service clouds and SLAs between cloud providers and consumers deciding how many false alarms are considered acceptable [15].

For the test with no attacks, the framework responded with random applications to 100 client requests without involving any attacks. The services here behaved normally as in their profiles. The false positive rate was 1.7%. We have decreased the default threshold of 3 to 2.7 and the false positive rate slightly increases to 1.715%.

During the test with behavior anomalies, the same requests were tested on other random applications with some modifications on the legitimate services' behaviors. These legitimate services were enforced to dramatically change their behavior during runtime before the profile's update time. The changes included accessing new methods, sending large message sizes, and accessing rarely accessed classes. The false positive rate during this test was 28.75%. The false alarms have been exclusively caused by requests that called methods that had not been accessed during the training period. However, this result was generated without using the verification technique. With the verification technique, our detection system eliminated all false positives with a considerable performance overhead as depicted in Figure 6. The detection system needs to support variable security levels with different overhead for different applications. For example, if a banking application is running in the service cloud then there should be possibility to provide highly secure detection for this application by running the verification technique. In case of online games and voice over IP (VoIP) applications, performance and quality of service (QoS) could be of higher priority which requires disabling the verification technique.

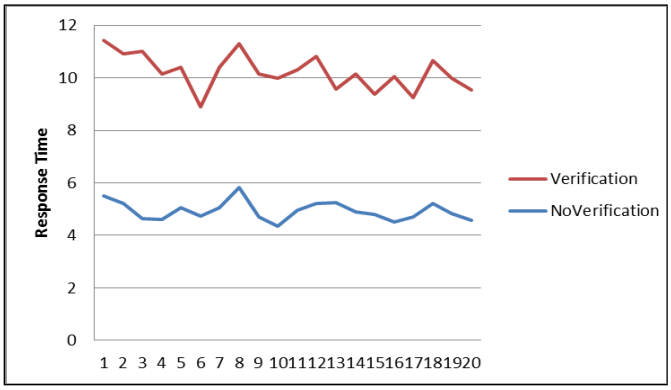

Figure6 : Verification technique overhead

After exploring the false positive rate, we attacked the case study in four distinct tests to measure accuracy. Each test had 100 client requests to initiate 100 different applications each has an impersonated service sending a malicious request to another service in the same application. The attacks mimicked the victim's behavior at different degrees. The victim services were meta-services since they have request behavior profiles while the tenants' services did not have profiles in this test. Any attack targeting a tenant's service would be detected immediately since the expected normal behavior for such services does not include sending requests to any service in the cloud. Table 2 lists the average anomaly scores for statistical properties of malicious requests and the detection accuracy of the impersonation attacks for all four cases. All tests were conducted twice; one with victim services having no historical impersonation attacks and one with a moderate history of attacks.

Table 2: The detection results for the attack tests

Test	Avg (ASclass)	Avg (ASsize)	Avg (ASmeth)	Avg (AShistory)	Accuracy
T1	6.6	1.1	1.9	0(1.5)	92%
T2	1.2	11.3	0.15	0(1.5)	67%(69%)
T3	1.2	11.3	6.2	0(1.5)	97%
T4	1.7	1.8	0.14	0(1.5)	0%

In the test T1, different impersonated services used the legitimate credentials of the victim services to send requests to services from classes that never been or rarely accessed by the victims before. The detection accuracy in this test was high (92%) because the Recipient's Class attribute has a highest weight in the anomaly detection equation among other attribute in the statistical model. However, any attribute can be differently weighted to reflect its security importance in the cloud.

T2 focused on revealing more information from the attacked services by embedding multiple queries in one request. 67% of the attacks have been correctly detected. On the other hand, the detection accuracy increased when the victim services had previously faced impersonation attacks. Furthermore, the detection accuracy reached 97% when the attacks targeted both the message size and the method at the same time as shown in T3 in Table 2. The last group of attacks fully mimicked the victim services which cannot be detected by the proposed detection system using the victim behavior profile. Thus, we need to extend the algorithm to cover such mimicry attacks in future work.

From the computational perspective, the presented algorithm accelerates the detection and profile update operations by implementing these operations in distinct scopes. The profile generation process is done before runtime at the tenant scope by the Profiler to reduce the computational load during the detection live time. The application scope holds the detection process during runtime by using the generated profiles. This results in shorter impersonator live time inside the cloud because it is limited to the active session lifetime at the application scope. As a counterpart, this approach needs a fast periodic update of the service's behavior profile and this introduces some overhead in the cloud network. Furthermore, the verification technique adds some overhead. We believe that updating the behavior profiles very frequently would decrease the need to trigger the verification technique which would eliminate much of the overhead.

Conclusions

The presented detection process depends on two parameters: the anomaly score computed by the detection algorithm using the behavior profiles of the services sending requests, and the fake response used by the verification technique to validate the malicious sender's identity.

In future work, some questions regarding the detection approach needs to be further investigated to improve the detection rate including: How much data is required in order to properly train each service? Should behavior profiles be based on individual service, or should services from the same class be grouped together?

Conflict of Interest

This manuscript is an extension of a conference paper that has been published in December 2016. All authors listed have contributed sufficiently to the project to be included as authors, and all those who are qualified to be authors are listed in the author byline. To the best of our knowledge, no conflict of interest, financial or other, exists.

ABSTRACT

This paper This paper presents a reliable method for image segmentation using a fuzzy inference system. The Fuzzy Membership function is applied on the YCbCr color space. Triangular membership functions are used in the input of the fuzzy system, Mamdani type fuzzy inference system is applied and for the output universe, singleton-type functions are used; to get the accurate output value, the Weighted Average Method (WAM) is applied. The YCbCr color space is used as feature space. One of the reasons being that it is standardized for the transmission and reception of digital video, (ITU-R Recommendation BT.601-5), and implemented by most of the sensors used in the acquisition of video. The fuzzy membership functions characterize the different membership levels between hue and Chroma from the YCbCr color model. The fuzzy inference system classifies data and generates regions of pixels with a homogeneous color level in the output images. The proposed method was also compared with another system segmentation using Euclidean distance applied to the RGB color space. The best results were obtained in the YCbCr color space. In such model, the changes of hue in presence of illumination variations are considered so that it has a better performance in the segmentation task. In addition, the processing time was lower in this color space.

1. Introduction

Color perception begins with a chromatic light source -which is electromagnetic radiation with wavelengths between 400 and 700 nm approximately. Part of the radiation, which is reflected on the surface of objects, is a scene and the resulting reflected light reaching the human eye, generates the feeling of color perception [1-4].

Brightness is the luminance or relative darkness of the color, hue is the color reflected or transmitted through an object and, saturation (also called chroma) represents the contribution of white color existing in proportion to the hue, or more precisely, the color purity [2]. This is the basis of the YCbCr color space.

The color segmentation in the computer vision field is important for pattern recognition and image processing tasks purposes. Segmentation is the process of partitioning an image into regions of interest (sets of pixels), with homogeneous features; namely, they can share one or more characteristics, such as shape, color, texture, lighting, etc.

The color of the shapes within an image can be used to simplify the identification and extraction of the regions of interest. They can be recognized as separate objects.

Image segmentation methods have recently been proposed, many of them based on Neural Systems and Fuzzy Logic. A segmentation system based on neural networks has been proposed by Ganesan et al. [5], they performed an unsupervised competitive neural network based in Kohonen's self-organizing maps (SOM). They used color satellite images. The images are segmented in RGB and HSV color space. The main problem of his work is the high computational cost because to obtain the value of a pixel, with the structure presented, 48 connections are necessary, increasing with this the number of operations. In addition, the weights of each node should be initialized before training data and

Email: aanzuetor@ipn.mx

the performance of the training depends on the initial data. If the initial data is not adequate, the process will have to be repeated.

The YCbCr color model has been used for skin detection and, in combination with the fuzzy model, has presented great performance for image segmentation [6, 7]. The Cb and Cr components determine the skin tonality. Tonalities are represented by histograms. Fuzzy inference models to determine the pixels representing the possible regions of skin within an image can be applied to them.

When looking for adaptability in fuzzy systems to model information in an unsupervised way, different proposals have been presented for the image segmentation using the classical algorithm of Fuzzy C-Means (FCM) [8-10]. G. Liu et al. [8] introduced a dissimilarity function by combining region-based and pixel-based distance function, in order to enhance the relationship between pixels which have similar local characteristics. This idea is retaken in this work, since, for the distribution of fuzzy sets, local information is considered.

Liu and Wang [11] developed a method of fuzzy color recognition and segmentation of robot vision scene based on the combination of fuzzy color quantization and edge extraction of HSV color space. This work was supported in part by the same idea; the triangular membership functions in the input of the system and the Mamdani-type inference are used. In contrast with the work mentioned above, we used YCbCr color space, fuzzy singletons are used as output function and the output value is obtained by the Weighted Average Method (WAM) [12, 13].

One of the reasons for using the YCbCr color space is that it is standardized for the transmission and reception of digital video, (ITU-R Recommendation BT.601-5 [14]), therefore, most of the sensors used in the acquisition of video implement it. We used a device that has as main output signals, the YCbCr color space, eliminating the need to perform the transformation to another color space and improving the response time.

The fuzzy singleton function and WAM are used to simplify the mathematical calculation of the output value for the fuzzy inference system.

Distribution of input membership functions for classification of hue is made on the Cb and Cr components of YCbCr color space (see Figure 1).

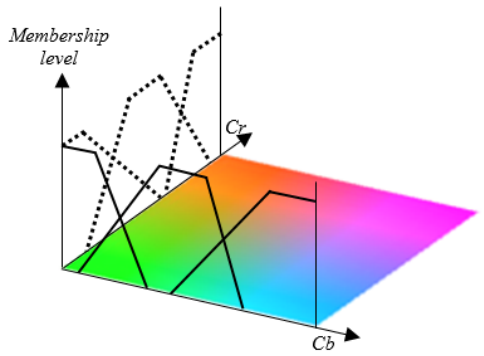

Figure 1: Distribution of membership functions in the space of chroma Cb and Cr

This paper is organized as follows. In Section 2, we give a brief introduction to the YCbCr color space. The basis of fuzzy logic is discussed in section 2. Section 4 presents the fuzzy rules used by the system. The application of segmentation system is presented in Section 5. The discussion of the results is made in Section 6. Section 7 presents the conclusions.

2. YCbCr Color Model

It is a nonlinear encoding of the RGB color model. The YCbCr model components determine the luminance and chrominance. "Y" is the contribution of light in the pixel; "Cb and Cr" are the blue and red chrominance components, respectively. The combination of Chroma values are different colors (color coordinate system), but the luminance value "Y" determines the brilliance of color, specifically, for low values of "Y" the colors will be dark; otherwise, the colors will look very bright with a hue close to white. The three cases for the variation of illumination "Y" are shown in Figure 2, as it can be seen, the color coordinate system changes its hue.

The YCbCr space is commonly used in vision-based hardware systems and digital video transmission. It is defined for standard-definition television and digital transmission purposes by the ITU-R BT.601. One of the main features of this model is that the brightness component "Y" is independent from the chroma components; because of this, this color space can be used to solve illumination variations in non-controlled environments.

The below mathematical expression is given following the recommendations of the ITU-R BT.601 standard (chapter 3.5.2 [14]) for a Cr and Cb re-normalized system.

Equation (1), describes the RGB color space conversion to the YCbCr space. Where matrix A represents the re-normalized coefficients of the horizontal vectors Y, Cb and Cr respectively. C is the matrix that re-measures the data, transforming the 220 and 225 levels, to 256 (8-bit digital representation). Before applying (1), the lowest value for Y, Cb and Cr is 16 and the highest value for Y is 235 and Cb, Cr is 240. After applying (1), the lowest value is 0 and the highest value is 255, for the three components. This mathematical procedure is similar to the function RGB2YCBCR included in the MATLAB's digital image processing toolbox. This value transformation, 256 values, will be used in this paper.

$$\begin{bmatrix} Y \\ Cb \\ Cr \end{bmatrix} = \begin{bmatrix} 16 \\ 128 \\ 128 \end{bmatrix} + \left([A^t \times C]^t \times \begin{bmatrix} R \\ G \\ B \end{bmatrix} \right) \quad (1)$$

Where:

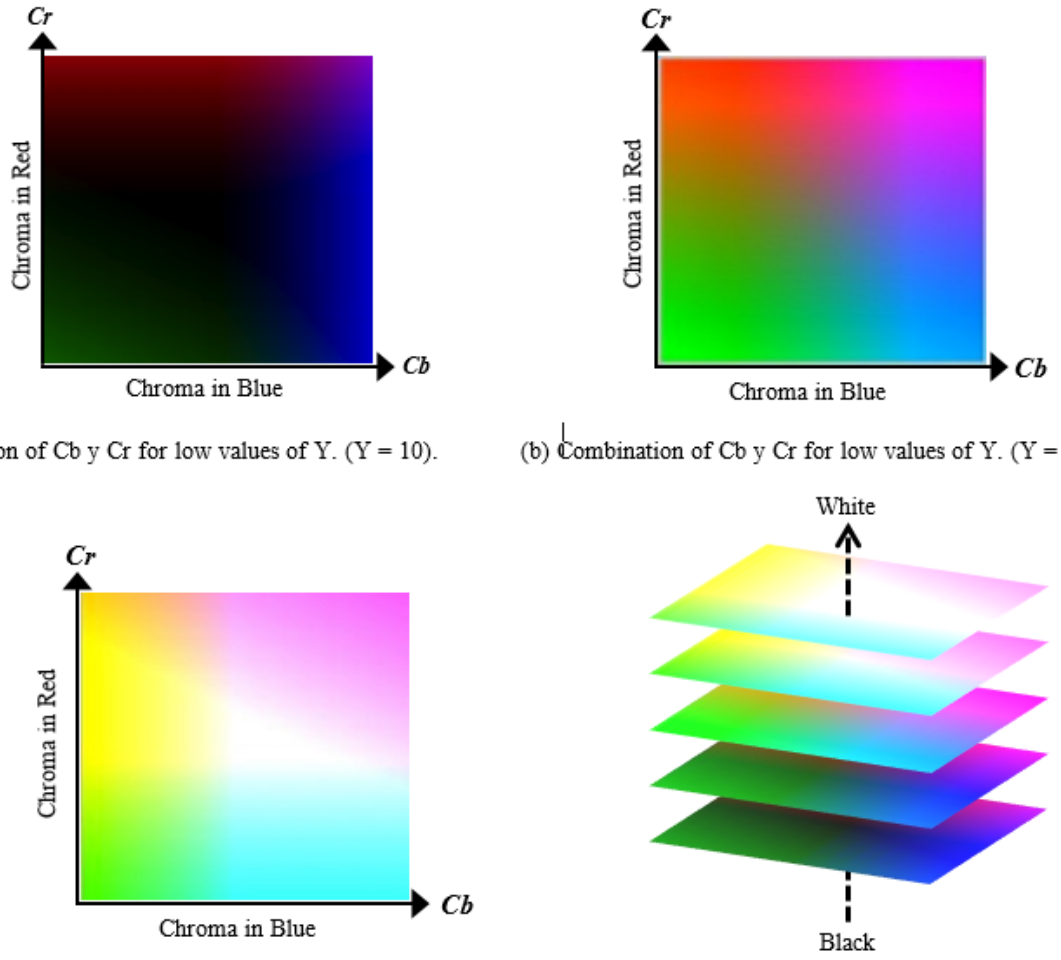
$$A = \begin{bmatrix} 0.299 & 0.587 & 0.114 \\ -0.169 & -0.331 & 0.500 \\ 0.500 & -0.419 & -0.081 \end{bmatrix} \quad (2)$$

$$C = \begin{bmatrix} {}^{220}/_{256} & 0 & 0 \\ 0 & {}^{225}/_{256} & 0 \\ 0 & 0 & {}^{225}/_{256} \end{bmatrix} \quad (3)$$

3. Fuzzy Logic

In the YCbCr color space, the transition between a color and another one does not have a defined borderline; namely, it changes gradually from one hue to another. Due to the fact that fuzzy systems work with uncertain data, this system is very appropriate.

A fuzzy set is associated with a linguistic value that is defined by a word, an adjective or a linguistic label. In the fuzzy set, the membership function can take values in the interval (0, 1), making



(a) Combination of Cb y Cr for low values of Y. (Y = 10).

(b) Combination of Cb y Cr for low values of Y. (Y = 128)

(c) Combination of Cb y Cr for low values of Y. (Y = 240).

(d) Colors through "Y".

Figure 2: Color coordinate system obtained by combination of Chroma. Value of low illumination (a), value of medium illumination (b), value of high illumination (c), colors through "Y"

a gradual transition between zero and one, and not discreetly one such as that in classical sets.

The fuzzy set in a universe of discourse can be defined as shown in (4).

$$color = \{(x, \mu_{color}(x) | x \in U)\} \quad (4)$$

Where $\mu_{color}(x)$ is the membership function of the variable x, U is the universe of discourse. The closer the color of the set membership to value 1, the greater the variable x belonging to the set color will be.

$$\mu(x) \begin{cases} 0 & if\ x \leq a \\ x-a/b-c & if\ a \leq x \\ 1 & if\ b \leq x < c \\ d-x/d-c & if\ c \leq x < d \\ 0 & if\ x > d \end{cases} \quad (5)$$

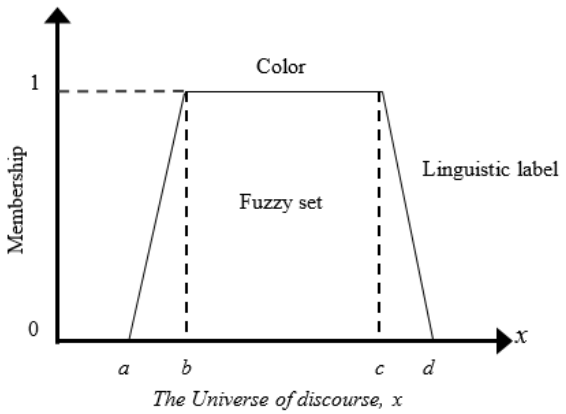


Figure 3: Definition of Trapezoidal Fuzzy Set

Equation (5) defined a trapezoidal fuzzy set type (see Figure 3) which describes the different membership levels [12]. The parameters (a, b, c, d) determined the slopes in the boundary lines of the fuzzy sets. As a fuzzy set, it can be inferred that the maximum level of membership is equal to one, the slope of a line determines the different membership levels and the non-membership is equal to zero. For this system, the overlap in the

fuzzy sets describes the inaccurate transition between the hues, as detailed in Figure 4.

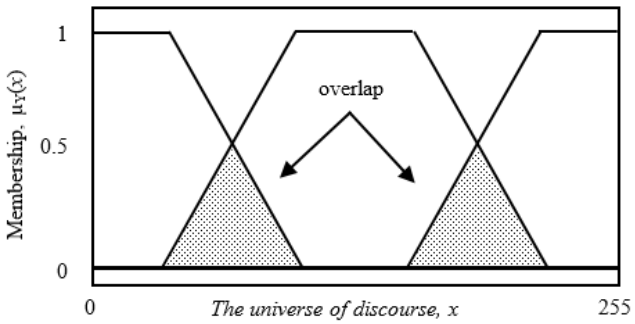

Figure 4: Overlap in fuzzy sets, inaccurate transition of the hue

4. Fuzzy Rules

A fuzzy system inference uses the expert's knowledge to generate a knowledge base, which will give the system the ability to make decisions. This knowledge base is modeled by creating a rule set, which generates the system output; in this case, it is the membership of pixels within an image above a set or another.

As mentioned, the component "Y" represents the contribution of light existing in a color. In Figure 5, a graphical diagram of the inference of nine fuzzy rules when the colors are considered dark can be seen. That is, when luminance "Y" has a low value. (The first nine rules in Table 1).

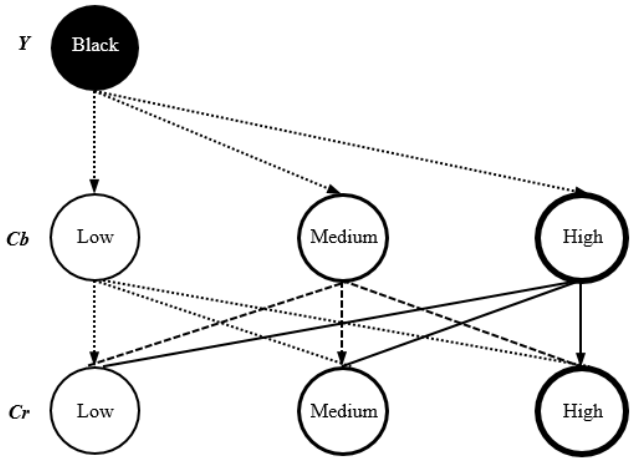

Figure 5: Graphic description of the fuzzy rules

In Table 1, we can see twenty-seven diffuse rules, which are all combinations when we consider three fuzzy sets for each component of the color space YCbCr.

To obtain a crisp output or output image (segmented regions), we need a defuzzification process. The inputs of the defuzzification process are the values of fuzzy membership functions Y, Cb, and Cr, and the output of the defuzzification process is a single number (or the value of one pixel). Many defuzzification techniques have been proposed in literature [12, 13]. The most commonly used method is the WAM (also named centroid). In WAM, the defuzzifier determines the weighted mean (or the center of gravity) of the fuzzy membership functions implicated in each of the knowledge base rules (Table 1). It is given by the algebraic expression in (6).

$$output = \frac{\sum_{i=0}^{n} \mu(A)_i . A_i}{\sum_{i=0}^{n} \mu(A)_i} \quad (6)$$

Where $\sum$ denotes an algebraic sum and A represents the different colors expected at the output, see Table 1.

Table 1: Combination that generate the knowledge base of fuzzy rules.

No. Rule	Description			Output
	Y	Cb	Cr	
1	***Black***	***Low***	***Low***	***Black***
2	***Black***	***Low***	***Medium***	***Black***
3	***Black***	***Low***	***High***	***Black***
4	***Black***	***Medium***	***Low***	***Black***
5	***Black***	***Medium***	***Medium***	***Black***
6	***Black***	***Medium***	***High***	***Black***
7	***Black***	***High***	***Low***	***Black***
8	***Black***	***High***	***Medium***	***Black***
9	***Black***	***High***	***High***	***Black***
10	Color	Low	Low	Green
11	Color	Low	Medium	Yellow
12	Color	Low	High	Red
13	Color	Medium	Low	Cyan
14	Color	Medium	Medium	Gray
15	Color	Medium	High	Crimson
16	Color	High	Low	Blue
17	Color	High	Medium	Violet
18	Color	High	High	Magenta
19	White	Low	Low	White
20	White	Low	Medium	White
21	White	Low	High	White
22	White	Medium	Low	White
23	White	Medium	Medium	White
24	White	Medium	High	White
25	White	High	Low	White
26	White	High	Medium	White
27	White	High	High	White

5. Segmentation of Hue Using Fuzzy Logic

The YCbCr color space has a color chart consisting of the combination of the Chroma belonging to the red and blue (Cb and Cr) and different levels of luminance (Y), see Figure 2.

For the universe set "luminance", we consider three linguistic labels, "Black" which represents the low contribution of light, "Color" where it is considered the optimal lighting to perceive the tone of a color, and "White" representing a high contribution of light, see Figure 6.

In order to reach the perception of color, the presence of luminance without reaching saturation will be necessary.

Different combinations of the components "Cb and Cr" typify the color. By taking this into account, the fuzzy sets are generated in their combination representing the different colors that the system can classify.

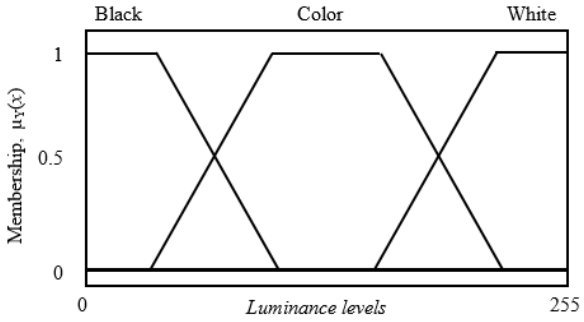

Figure 6: Fuzzy sets for the universe set. "luminance"; Y

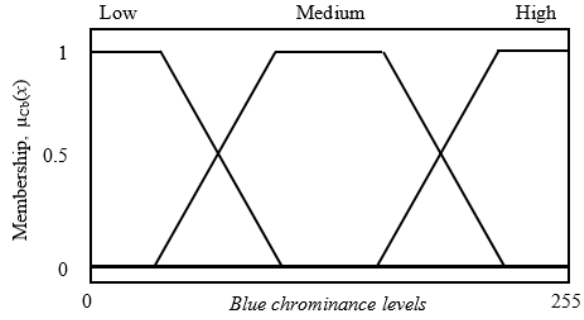
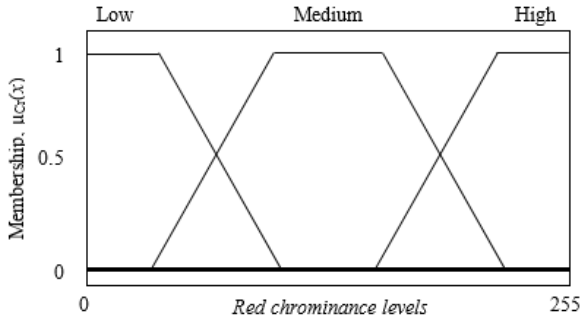
Three fuzzy sets are defined, each with their linguistic label respectively for each Chroma component. "Low" when the Chroma saturation in blue or red is low, "medium" when the Chroma saturation is medium, and "high" when the Chroma saturation is high, as detailed in Figure 7.



(a) Fuzzy sets for blue chrominance, Cb



(b) Fuzzy sets for red chrominance, Cr

Figure 7: Fuzzy sets of chrominance. (a) Blue chrominance *Cb*, (b) Red chrominance *Cr*

The values values (a, b, c, d), which are parameters of (5), represent the form of all the fuzzy sets in a universe set (see Figure 8). By varying these parameters, different slopes in the boundary lines of the fuzzy sets are generated, modifying the zone that represents uncertain data.

Also, it is possible to find a particular hue value by modifying these parameters. For example, if we are looking for red color and its different hue values (the red color region is in the upper left corner in the color palette as shown in Figure 8), it is necessary to expand the region covered by the "Low" set in "Cb" and the "High" set in "Cr", which means that the value of the parameter "a" in "Cb" should be increased and the value of the parameter "d" in "Cr" should be decreased. The region of interest is then amplified as shown in Figure 9.

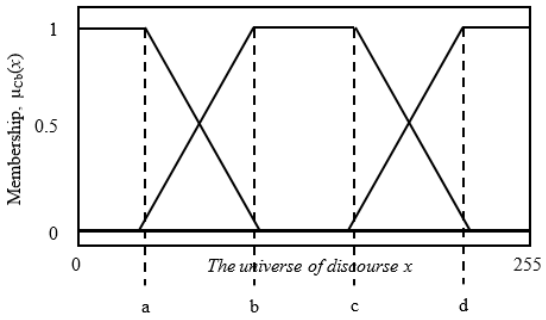


Figure 8: Parameters for controlling the distribution of the fuzzy sets (a, b, c, d)

The numerical values of (a, b, c, d) parameters, which are used in the fuzzy sets for red segmentation, are shown in Table 2.

Table 2: Value of the parameters (a, b, c, d) for the fuzzy sets of Y, Cb, Cr

	Y	Cb	Cr
a	30	95	85
b	60	105	95
c	200	195	145
d	235	205	155

One of the images tested with the proposed fuzzy inference system is shown in Figure 10. It contains an object with a red hue. In order to explain the different steps that the fuzzy logic segmentation system follows, a pixel will be taken from the processed image.

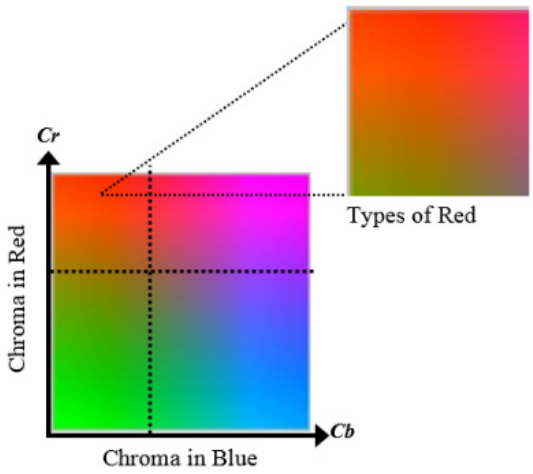

Figure 9: Color model YCbCr. Search of red in the color pallet of the chrominance (Cb and Cr)

This selected pixel corresponds to a reddish object, and it has the following values for Y=143, Cb=94 and Cr=188. The membership values obtained by processing the pixel described above are shown in Table 3.

The membership value shown in Table 3 are introduced in (4) to obtain the numerical values of the system output. Variables named "S" represent the output fuzzy sets (fuzzy Sigleton's), each of them are located at the expected output value; for example, S10 represents the red color, suggesting that the pixel in the output

image will have R = 255, G = 0, B = 0 as a numerical value *as long as* the numerical value obtained in (3) is similar to S10. Table 4 lists the values of all the fuzzy singleton's.

Table 3: Membership Value for Each Fuzz Set

Fuzzy Sets μ	Membership Value
μ_{BlackY}	0
μ_{ColorY}	1
μ_{WhiteY}	0
μ_{LowCb}	1
$\mu_{MediumCb}$	0
μ_{HighCb}	0
μ_{LowCr}	0
$\mu_{MediumCr}$	1
μ_{HighCr}	0

Table 4: Fuzzy Singletons Value (Output Functions)

	Output Numerical Value
S1	10
S2	33
S3	56
S4	79
S5	102
S6	125
S7	148
S8	171
S9	194
S10	217
S11	240

To form the output image, each pixel is is processed in the same way. The used method for image processing is shown in Figure 10. At first, the original image is in RGB color space (Figure 10 (a)). Then, the image is transformed into YCbCr color space (Figure 10 (b)) and finally, the fuzzy inference system is applied to the result image (Figure 10 (c)). It is worth noting here that the output singleton sets are represented again in RGB color space to be displayed on screen.

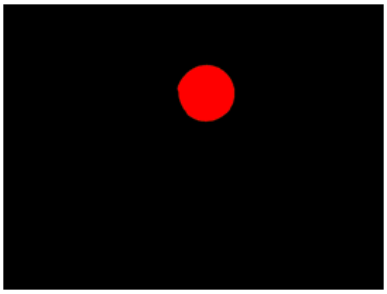
(b) YCbCr color space image. Choosing a point to be processed



(c)Output image obtained by the segmentation system

Figure 10: Graphic sequence of the fuzzy segmentation system (a), (b), (c)

6. Experimental Evaluation

To evaluate the effectiveness of the segmentation system by fuzzy logic, the segmentation of the green hue in the original image of Figure 11(a) was proposed. This photo was taken in the laboratory, in a closed room, under semi-controlled lighting conditions and the changes in illumination inside the photo can be noticed. The image contains a green area that simulates the conditions of a (small) soccer field, a red ball and white lines that define the green area.

This particular photo was chosen because our segmentation system will be a part of the vision system of a robotic prototype that serves as a football player.

The segmentation system was designed considering only the red, green and blue contributions in the RGB color space model, in order to define the color of an object and matching the results from the opposite system. The classification in the RGB segmentation was made by obtaining the Euclidian distance between each one of the image's pixels and the mean of the pixels (red, green, blue) that defines the green color of the image.

The code was developed based on Matlab programming language in its version R2010a (see Appendix A), on a computer with an Intel Core2 Duo T6400 2 GHz. Images were obtained with a Kodak Easy Share CD14 with a resolution of 1280x960, JPG format.

The execution time of the segmentation system when using RGB color space was of 1 min.15 sec. For YCbCr color space it was 55 sec.

The difference between the RGB and YCbCr execution times is mainly due to the fact that, in the RGB color space, each component contributes to obtain a color hue so that the three components are an input of the fuzzy system; in the YCbCr, the component "Y" determined, as a first step, if the pixel has low lighting (black), high lighting (white) or if the lighting is good

enough to perceive the hue of a color. The pixel Chroma components to determine the membership level are discussed only in the latter case.

Figure 11(c) shows the result of the segmentation of the RGB color space.

For segmentation in YCbCr, we transform the original image into this color space, due to fact that the image is in RGB color space, Figure 11(a), the rgb2ycbcr function was used for this purpose, which is part of the "image processing" toolbox of Matlab, (see Figure 11(b)). In Figure 11(d) the result of the segmentation can be observed.

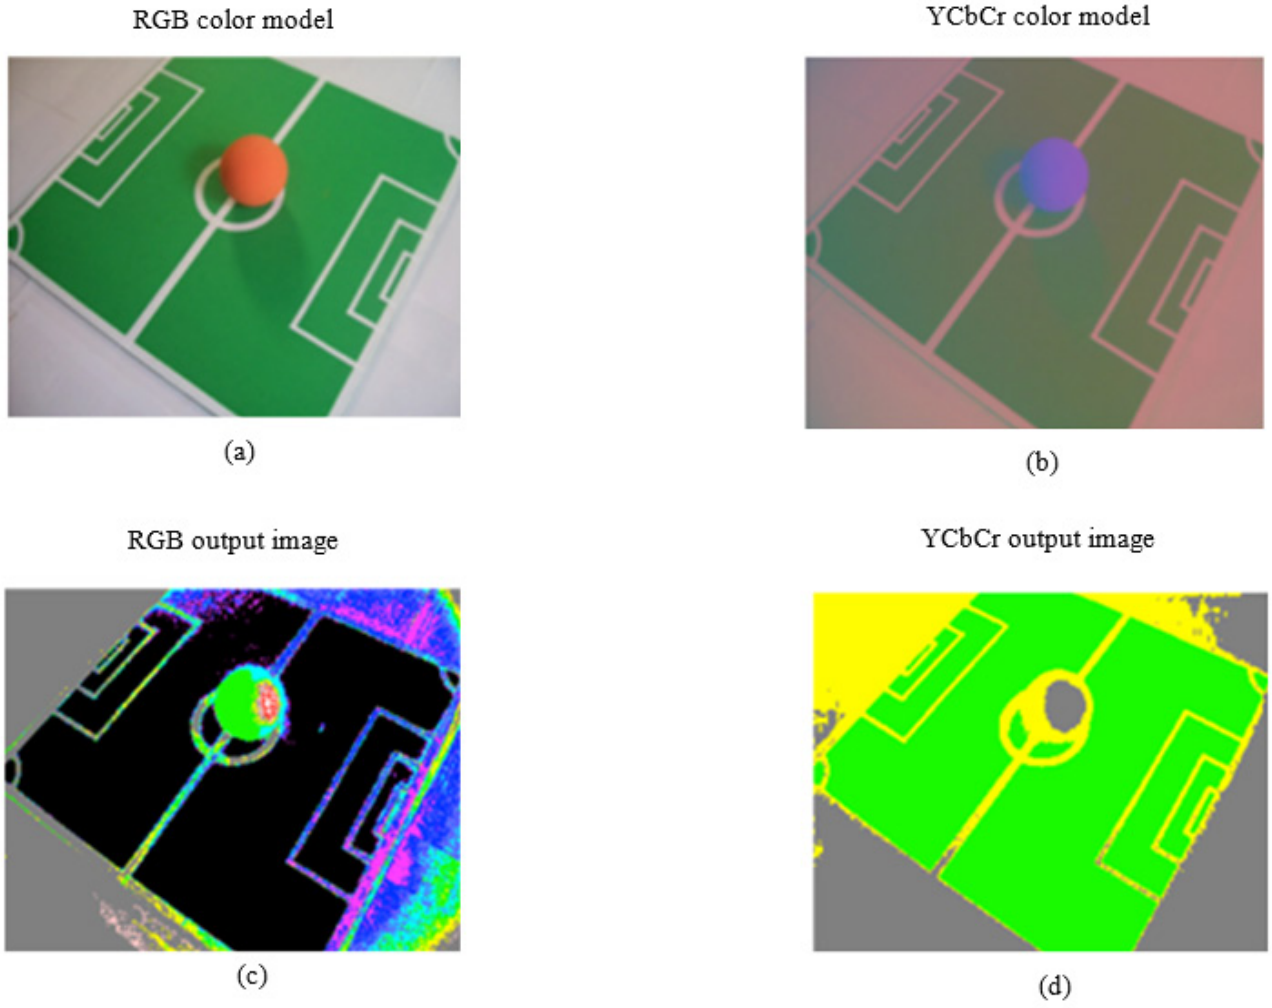


Figure 11: Segmentation process in the RGB and YCbCr color spaces, (a) Original image in RGB color space, (b) Original image transformation into YCbCr color space, (c) Segmentation of green color in RGB, (d) Segmentation of green color in YCbCr

The change in hue due to the variation of lighting was considered in the YCbCr color space, so that, when the images in Figure 11(c) and Figure 11(d) were compared, as expected, we observed a better performance of the segmentation system in YCbCr.

The variation of lighting is not considered for the RGB, so that, the pixels in the top center of the image Figure 11(c), were classified as non-green hue.

In Figure 11(a), three main regions can be seen, one of them is the green region (region of interest), and two more regions that are covered with yellow and gray pixels. The last two regions are the result of the membership levels to the fuzzy sets of the remaining pixels.

The values for the parameters (a, b, c, d) of the fuzzy sets which are used for the segmentation of green color in YCbCr are shown in Table 5.

Table 5: Value of the Parameters (a, b, c, d) for the Fuzzy Sets of Y, Cb, Cr

	Y	Cb	Cr
a	30	95	85
b	60	105	95
c	200	195	215
d	235	205	225

Another important point to mention is that the equations to conform the fuzzy sets are relatively simple and only require 4 parameters to generate the fuzzy sets that cover a universe set. We have taken advantage of this simplicity and it was implemented in a segmentation system in an FPGA.

A test showing how to generate an output image with three hues by adding the segmentation of green and red color from an input image is shown in Figure 12. The image obtained in Figure 12(d), may be used for classification and recognition of objects contained therein.

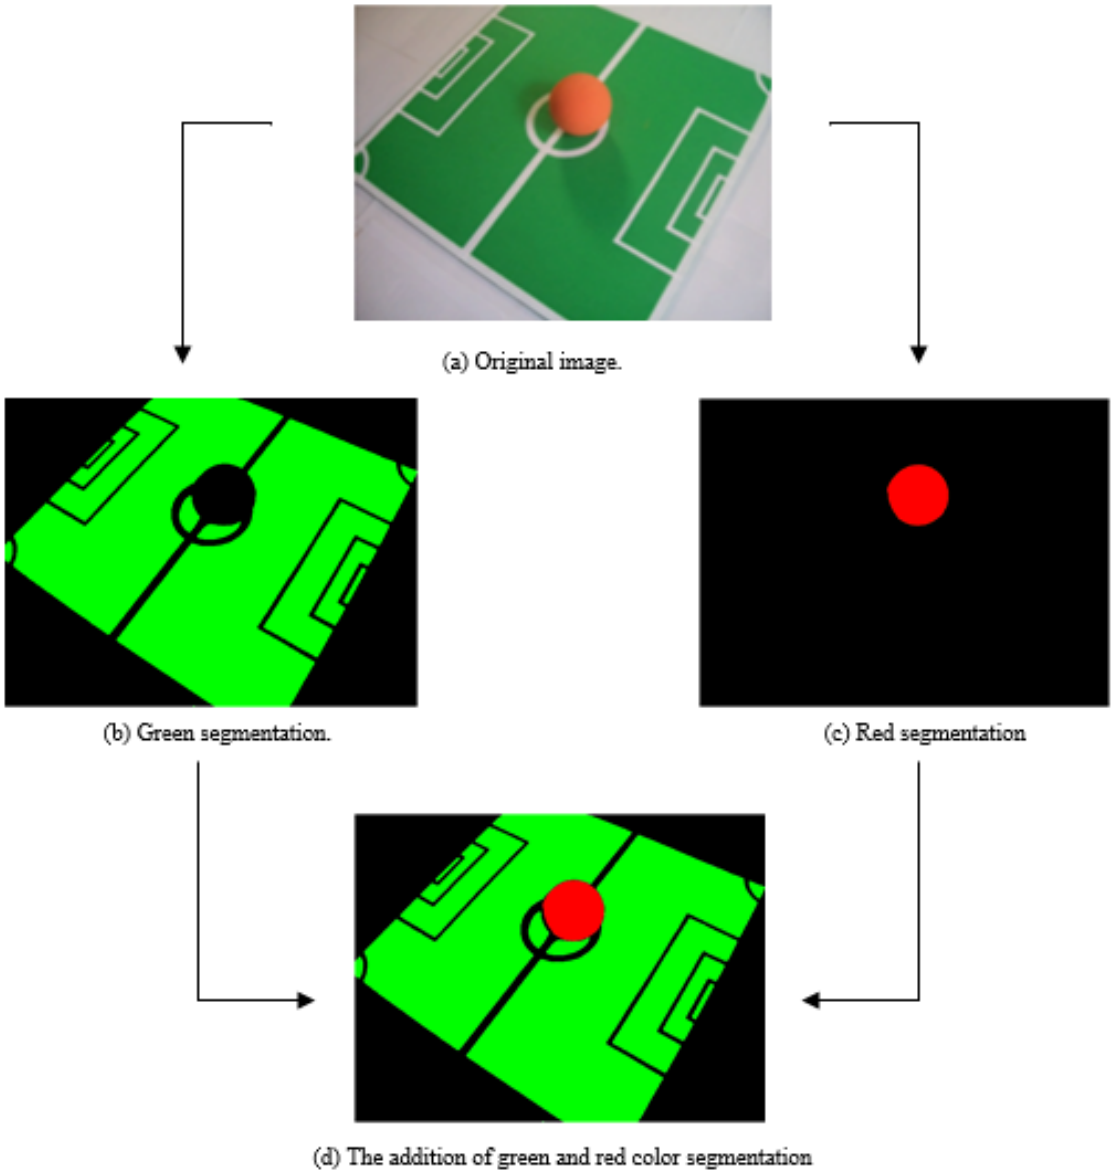

Figure 12: Segmentation process, (a) Original image, (b) Green segmentation, (c) Red segmentation, (d) Addition of b and c

7. Conclusion and Future Works

This paper proposes an application of *segmentation of regions in images* using fuzzy logic. It exploits the ability of fuzzy sets for modeling accurate data to interpret the transition from one hue to another by using the blue and red chromas in the YCbCr color space.

Trapezoidal sets are proposed for mapping of the chroma to membership levels and is considered the ITU-R Recommendation BT.601-5 in order that the system can be applied to most sensors for the acquisition of digital video.

The combination of the YCbCr color space with the fuzzy inference system demonstrated high adaptability to model different color hues, so different color hues can be segmented into an image.

By the simplicity of the equations, both to generate the fuzzy sets and the calculation of the value of the output of the system, it is possible to have a system of low computational cost and high speed to obtain a response.

MATLAB programing language was used in its version R2010A to develop the system and was applied in two color

spaces, RGB and YCbCr, execution times were 1 min. 15 secs and 55 secs, respectively.

Due to the simplicity of the formulas that are used to develop the fuzzy inference system, the implementation in hardware is feasible. In our laboratory, we have implemented the proposed system, using the Spartan 3E development board which contains an FPGA xc3s500e from XILINX Company. The proposed segmentation system has been applied in the object tracking and orientation of robots. Different colors and shapes have been presented to a robot and the execution times obtained allow working with images with continuous sequence.

Conflict of Interest

The authors declare that there is no conflict of interest regarding the publication of this paper.

Knowledge Discovery

ABSTRACT

The evolution of technology has changed the face of education, especially when combined with appropriate pedagogical bases. This combination has created innovation opportunities in order to add quality to teaching through new perspectives for traditional methods applied in the classroom. In the Health field, particularly, augmented reality and interaction design techniques can assist the teacher in the exposition of theoretical concepts and/or concepts that need of training at specific medical procedures. Besides, visualization and interaction with Health data, from different sources and in different formats, helps to identify hidden patterns or anomalies, increases the flexibility in the search for certain values, allows the comparison of different units to obtain relative difference in quantities, provides human interaction in real time, etc. At this point, it is noted that the use of interactive visualization techniques such as augmented reality and virtual can collaborate with the process of knowledge discovery in medical and biomedical databases. This work discuss aspects related to the use of augmented reality and interaction design as a tool for teaching anatomy and knowledge discovery, with the proposition of an case study based on mobile application that can display targeted anatomical parts in high resolution and with detail of its parts.

1. Introduction

This paper is an extension of work originally presented in International Conference of the Chilean Computer Science Society (SCCC) [1].

The computer is a facilitator of teaching for different sciences, since the static and two-dimensional image printed in the books can be added movement and a new dimension, allowing a better representation of scientific concepts and favoring meaningful learning. In this perspective, interactive digital graphics applications can aid in the teaching-learning process of concepts, contents and chemical skills as well as the knowledge discovery process, due to the fact of stimulating self-learning [2] [3]. In the Health area for example, we have a great concentration of studies looking for viable computational solutions for the most diverse types of information management problems. The analysis and cross-checking of information are able to provide evidence to understand the development of diseases, assist health students and professionals to make decisions to contain the epidemics and improve the care for patients, avoiding extra costs with hospitalizations.

The individuals that born after 1960 having grown up surrounded by all sorts of new technologies, and their minds have undergone cognitive modifications brought about by new technologies and digital media, which have propelled a new range of needs and preferences on the part of younger generations, particularly in the area of learning. Prensky [4] says that today's students and professionals represent the first generation to grow with the technology of interactive graphics applications. They spent their whole lives surrounded by emergent technologies such as augmented reality, ubiquitous learning (u-learning), mobile learning (m-learning), serious games and learning analytics for improving the satisfaction and experiences of the users in enriched multimodal learning environments [5]. As a result of this ubiquitous digital environment and the large amount of interaction with it, students today think and process information fundamentally different from their predecessors.

Email: isabel.siqueira@gmail.com

In the same way that the brains are programmed to acquire the ability to write and read, the constant use of digital technologies reprograms the brain to think from the logic of these devices. This means that a large part of the problem related to the learning of digital natives resides in the fact that it is very laborious to retrain the brain to construct thought from the linearity of reading and writing, and that this thought was already modified in function of Television and the advent of computer graphics [6]. According to Mazzarotto and Battaiola [7], three aspects are identified as possible implications of the use of such applications in the learning process: increasing learner motivation and interest in learning activity, increasing retention of subjects and improving skills Reasoning and high complexity thinking. The increase in motivation and interest would be the result mainly of the elements of curiosity, fantasy and control offered by the interactive graphic application. In addition to functionality and usability, users seek pleasure in the activity, and this search is key to choosing to purchase and use a product.

Visualization and interaction techniques can aid the analysis of data, since they amplify the process of insight on related data, transforming them and/or amplifying them in the form of images [8] [9]. When an image is analyzed, a cognitive process begins, where perceptual mechanisms are activated that aim to identify patterns and segment elements [10]. The correct mapping of data to images is crucial, since one can discard relevant information or exceed the amount of irrelevant information [11] [12]. Thus, it is noted that the graphical representation should limit the amount of information that the user receives, while keeping him/her aware of the total information space and reducing the cognitive effort [13].

In this context, Augmented Reality (AR) allow the viewing of virtual objects combined with scenes from real environments through computers equipped with a video camera, or even from portable devices, such as tablets and cell phones [14]. There are three basic ideas that make up AR: immersion, interaction and involvement. Immersion is linked with the feeling of being inside environments. Interaction is the computer's ability to detect user input and instantly modify the virtual world and actions on it. Involvement is connected with the degree of motivation for engaging a person with certain activity.

The health sciences have benefited from the power of these tools [15]. By employing virtual technology to teach anatomy, the challenges are different from traditional teaching with real anatomical parts and/or two-dimensional atlas (2D), since virtual anatomy requires three-dimensional (3D) visualizations with high resolution and interaction with them in real time [16] [17]. Students can use AR to build new knowledge based on interactions with virtual objects that bring underlying data to life [18]. Virtual objects can be manipulated in a direct way, which allows the user to interact with them in a free and natural way, as in the real world. This system not only helps students learn anatomical details, but also provides the enhancement of 3D structures that cannot be replicated by a 2D atlas. It is speculated that working directly with AR can help students learn the complex structure of anatomy better and faster than using traditional methods (cadaver dissection and the use of paper atlas).

Thus, AR can amplify the associations between anatomy-physiology and movement through its use in mobile devices, allowing greater flexibility of interaction with virtual anatomical models. However, there are not many software solutions involving AR and visualization of anatomy, human and animal, aimed at mobile devices and, among those that exist (see section 2), it is not possible to visualize and interact with detailed and segmented anatomical structures. In addition to these questions, it was identified that the response time of such tools, coupled with the quality of 3D models, does not favor their use in the classroom as an aid to teaching activities by teachers.

Based on these questions, this work aims to propose the use of AR to visualize segmented anatomical structures, in high resolution, detailing their parts textually next to the image and using cut planes, in mobile devices. Interaction questions with segmented anatomical pieces are also studied, in order to facilitate their study and learning with students in the areas of health sciences. Such proposals were validated in two case studies involving the anatomy of human bone structures and animal organs. The first case study has already been validated alongside potential users through usability testing while cognitive specialists evaluated the second case study.

This article is organized as follows. Section 2 presents works related to the topic discussed in this article. Section 3 describes the proposed tool while section 4 presents details of the validation experiment with users and results. Finally, section 5 presents the final considerations.

2. Related Work

Different studies and applications are being developed with AR focused on teaching concepts related to Health.

Ten years ago, Gomes et al. [19] were already investigating the application of AR for educational purposes in the area of Medicine. Using free tools (Linux and ArToolkit[1]), they presented examples of overlapping of organs on markers in real scenes, allowing the visualization and manipulation of the respective organ with differentiated aspects. To do so, they used sound allied to the image, making the learning more dynamic and realistic, although they did not explore mobile technology, mainly due to the technological restrictions of the time.

Safi et al. [20] indicate that, in relation to the monitoring of specific diseases, such as skin cancer, AR can help to monitor and identify problems early in order to initiate treatment or prevent disease progression. High-risk individuals may present with disturbing and abnormal skin lesions, and, in this context, AR can help the professional to quickly compare the results and the change of these lesions over a period of time based on the data (texts and images) of the patient. Minimally invasive surgeries may also be possible with AR, allowing surgeons to access information more quickly without having to shift their attention to the patient being treated. Vital statistics of this can be kept in their field of view while operating, without taking risks of distraction.

Coles et al. [21] present a virtual environment for training femoral palpation and needle insertion, the opening steps of many interventional radiology procedures. A novel augmented reality simulation has been developed that allows the trainees to feel a virtual patient using their own hands. The authors mimic the palpation haptics effect by two off-the-shelf force feedback devices have been linked together to provide a hybrid device that gives five degrees of force feedback. This is combined with a

[1] https://www.hitl.washington.edu/artoolkit

custom built hydraulic interface to provide a pulse like tactile effect. The simulation has undergone a face and content validation study in which positive results were obtained. During validation tests, experts in the field rated the device as closely reproducing the fine tactile cues of a real life palpation.

Reitzib [22] also agree with these observations, claiming that working directly with AR can help future professionals learn the complex structure of anatomy better and faster than using traditional methods (cadaver dissection and the use of paper atlas). Patient 3D images, constructed from 2D images of computed tomography scan and/or magnetic resonance imaging can be visualized overlapping their bodies with accurate visual information and real-time data retrieval.

Bacca et al. [23] contribute to existing knowledge in AR in educational settings by providing the current state of research in this topic. This research has identified relevant aspects that need further research in order to identify the benefits of this technology to improve the learning processes. In this context, the authors highlight some aspects as learning gains, motivation, interaction, collaboration and student engagement and positive attitudes. However, very few systems have considered the special needs of students in AR and there is a potential field for further research.

Jenny [24] employed Augment[2] software to defend her thesis involving the benefits of AR employed in the fields of Dentistry and Medicine. In dentistry, the AR was used in courses and in practical classes with the purpose of demonstrating dental models for the students and enabling them to compare their sculpture with reference models. It was observed that AR facilitated communication between teachers and students, clarifying the images and texts found in the textbooks.

In relation to the use of AR in Veterinary Medicine, there are still few published papers about it.

Parkes et al. [25] present a mixed reality simulator was developed to complement clinical training. Two PHANToM premium haptic devices were positioned either side of a modified toy cat. Virtual models of the chest and some abdominal contents were superimposed on the physical model. Seven veterinarians set the haptic properties of the virtual models; values were adjusted while the simulation was being palpated until the representation was satisfactory. Feedback from the veterinarians was encouraging suggesting that the simulator has a potential role in student training.

Lee et al. [26] developed an intravenous injection simulator, based on AR, to train veterinary students in the performance of canine venous puncture. The 3D models used were developed from images derived from computed tomography of beagle dogs, converted to stereo lithography format. Another application of AR in Veterinary Medicine is reported in [27] where the University of Liverpool School of Veterinary Science is using such technology to allow students to analyze the internal anatomy of animals from smartphones. The team developed a 3D image of an equine heart for the study in question.

In terms of applications, we have the application based on AR proposed by Chien et al. [15], which allows visualization of anatomical details in 3D, allowing users to disassemble, assemble and manipulate such details for educational purposes. In the article, the technologies employed are not informed and the application was not made available for mobile devices. On the other hand, the BARETA (Bangor Augmented Reality Education Tool for Anatomy) [28] system, in turn, combines AR with 3D models from rapid prototyping technology, aimed at teaching anatomy. Likewise, the project LearnAR[3] proposes an online tool, based on AR, aimed at teaching in health disciplines. Anatomy4D[4] is an application that was developed for mobile devices using AR concepts

The works discussed in this section do not allow the visualization of detailed and segmented anatomical as also parts individualized and intuitive interaction with them, a fact that motivates the researches of this work.

As conclusion of our study of related works, we observed that, although they address the use of AR in educational settings, they mostly focus on the specific applications for a human or animal body part. The visualization of detailed and segmented anatomical as also parts individualized and intuitive interaction with them is not well explored.

3. Segmentation and Visualization of Human and Animal Anatomical Structures with Augmented Reality

Understanding the complexity of human and animal anatomy something that requires a lot of time and study. It is noted that the teaching methods used are mostly based on 2D atlas studies in addition to the traditional use of cadavers or mannequin models, through which students learn the forms and the location of structures of the human/animal body, correlating them with their functions [16]. However, the use of corpses has been aggravated in terms of availability and storage due to the restricted time of access to the material [17]. Besides, the use of 2D atlases compromise the understanding of the real 3D structure of anatomical pieces while multiple needle and wire punctures can cause rapid degradation of mannequin models [21].

In the previous section, there is a series of papers discussing the use of RA as a possible solution for such questions, but there is not found a variety of solutions that allow the combination of AR to the segmented visualization of 3D anatomical parts, with intuitive interaction and support for use on mobile devices. Based on these observations, we propose a tool for collaborate with the

[2] http://www.augment.com/ technology/

[3] http://Learn.org

[4] http://site.daqri.com/project/anatomy-4

teaching area in Health and knowledge discovery that implements some functionality not observed in the related works studied.

3.1 Requirements Gathering

For the requirements gathering regarding the present research, were interviewed teachers who work in undergraduation disciplines of the area of Health involving the teaching of concepts of human and animal anatomy together with the accomplishment of the contextual analysis of the same acting in the classroom with their students. The institution where the case study was carried out has different resources used in the classroom, such as tablets and computers, which have software and virtual atlas applications of anatomy, embryology and histology, imaging resources - such as RX, tomography, Resonance, human models in resin that replace the use of corpses to study human anatomy, anatomy and histology books, among others. Active methodology techniques such as body painting and body projection are also used for visualization and learning dynamics.

As a pedagogical proposal for the teaching of anatomy in undergraduation Health courses, teachers point out that the use of AR may help to identify anatomical structures, amplifying the associations between anatomy, physiology and movement through their use in mobile devices, in order to allowing greater flexibility interaction with the anatomical models. Such benefits are amplified with the possibility of segmented and detailed visualization of anatomical parts, in high resolution, and with intuitive interaction in real time. Thus, the proposed visualization has such characteristics.

3.2 Segmented and Detailed Visualization

From the requirements gathering, the following features were defined for the proposed visualization:

- Visualization and interaction with the use of AR aimed at assisting the teaching of human and animal anatomy, based on real case studies, facilitating their adaptation and use in the classroom according to the demands and disciplines that involve the study of the anatomy;
- Support for use in mobile devices, in order to provide users with flexibility of use (students and teachers);
- Use of 3D models with adequate degree of definition and realism;
- Trace based on markers;
- Intuitive and easy-to-understand interface;
- Possibility of segmented and detailed visualization of a human and/or animal anatomical component.

Figure 1. 3D model of the humerus bone designed over real scene.

For reading 2D markings in real scenes through devices that have camera implementation, the framework Vuforia[5] was used. Vuforia accesses the database remotely, not overloading the execution of the application. The Vuforia was integrated with the game engine Unity[6] in order to generate the AR functionalities, connecting virtual images with real scenes and allowing interaction with them in real time. The 3D models were obtained from public repositories and/or builded in Blender[7] software from 2D pictures.

Four main views were made available:

- Simple anterior view;
- Simple posterior view;
- Detailed anterior view; and
- Detailed posterior view.

In the "previous view", the front part of the projected structure is shown (Figure 1) while in the "anterior view", the back part is seen. The difference of both to the detailed ones is that, in the latter, we have the description of the main bone accidents that compose a structure as showed in Figures 2 and 3. Clicking on any of the viewing options in the menu will trigger the camera of the mobile device that will capture the actual scene. As in all applications involving AR, after finding the marker in the scene, the 3D image of the structure, chosen from the menu, is incorporated into the scene. In the Figures 1 and 3, we employed a fiducial marker to facilitate the mapping of the abstract to the concrete experience for inexperienced user with the use of AR.

Besides these four views, a fifth view is being developed and improved: the cut plane view. Figure 4 shows two examples of cut plane views of segmented head structures.

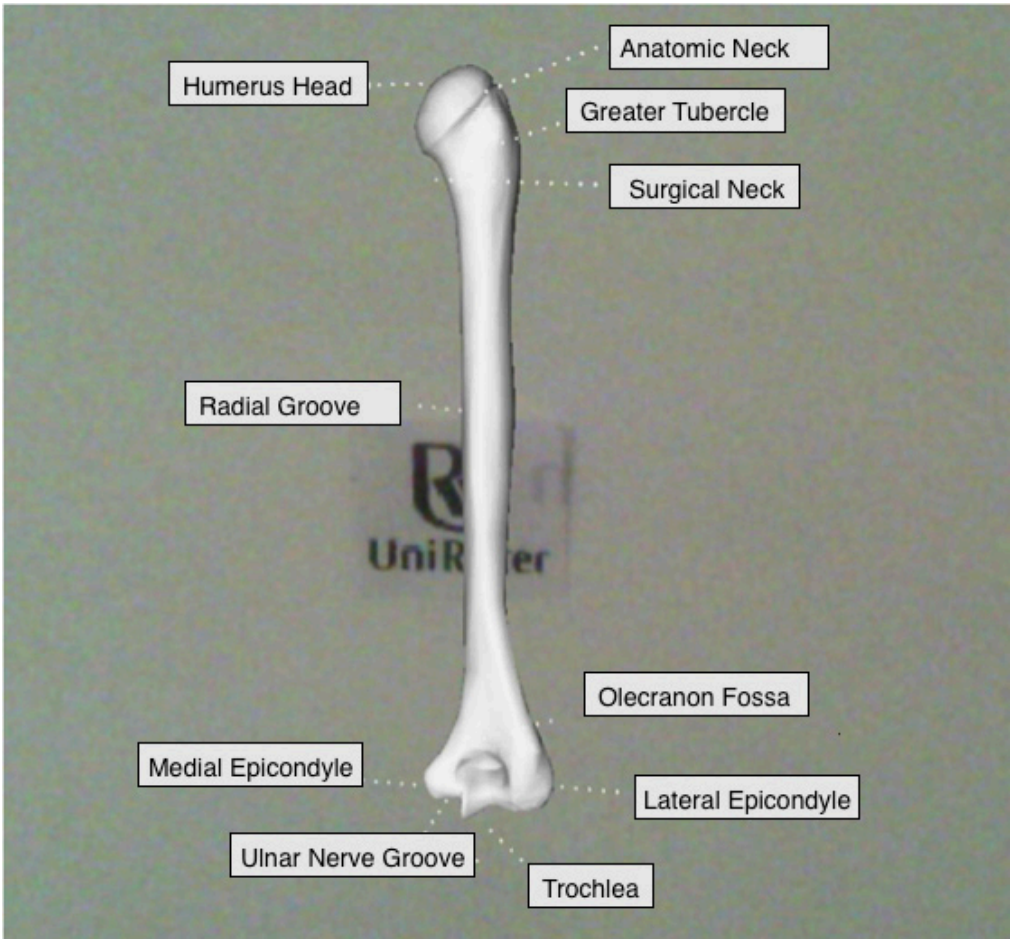

Figure 2. Image generated by AR with 3D model of the humerus bone with details.

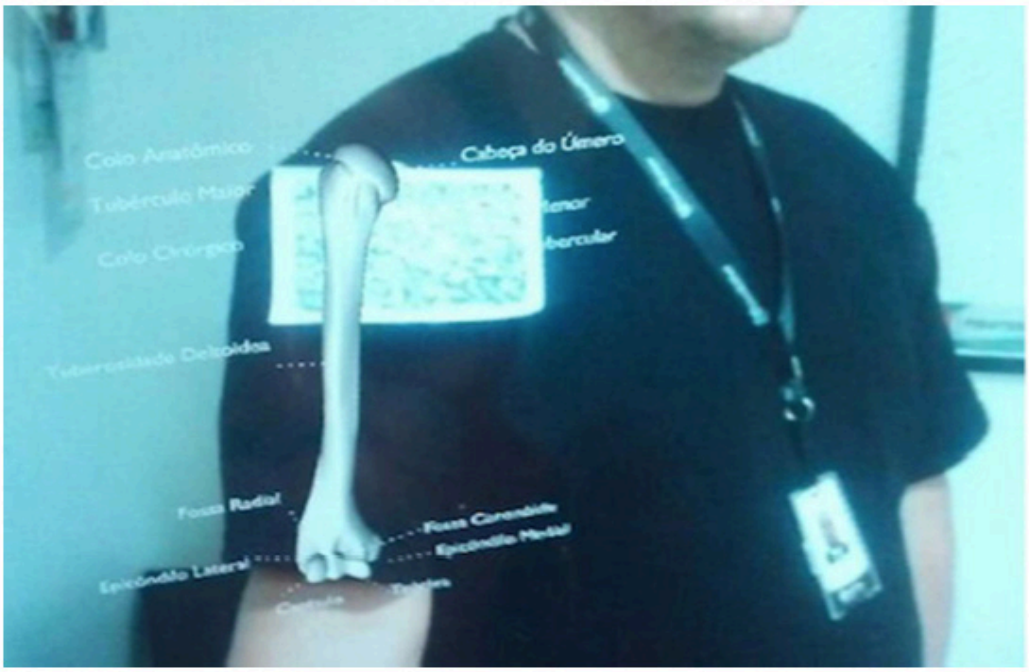

Image generated by RA with 3D model of the humerus bone on real scene with detailing.

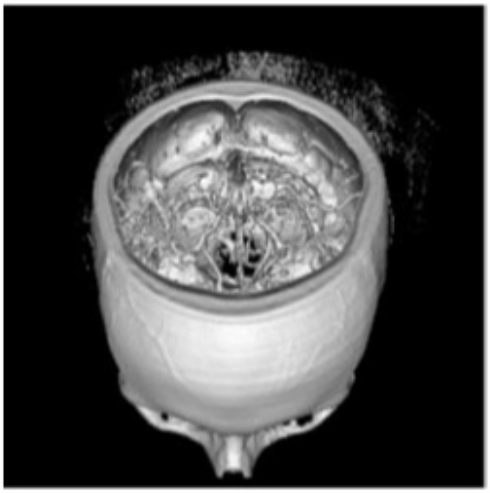

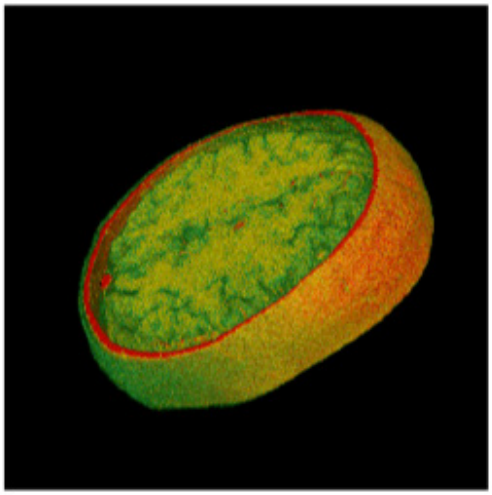

The interaction with the anatomic objects in the scene occurs by three basics geometrics transformations: translation, scale and rotation.

4. Validation and Results

The proposed objectives was validated by two evaluation experiment based on the human humerus bone (Figures 1, 2 and 3) and the cat liver, being the last one validated considering the 3D model texture and transparency in order to show the vascular structures (Figures 5 e 6).

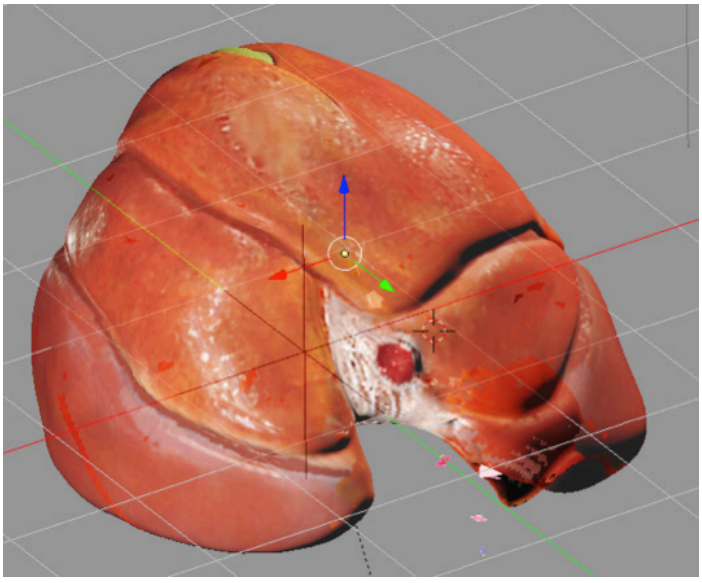

Figure 5. Texturized 3D model of a cat liver.

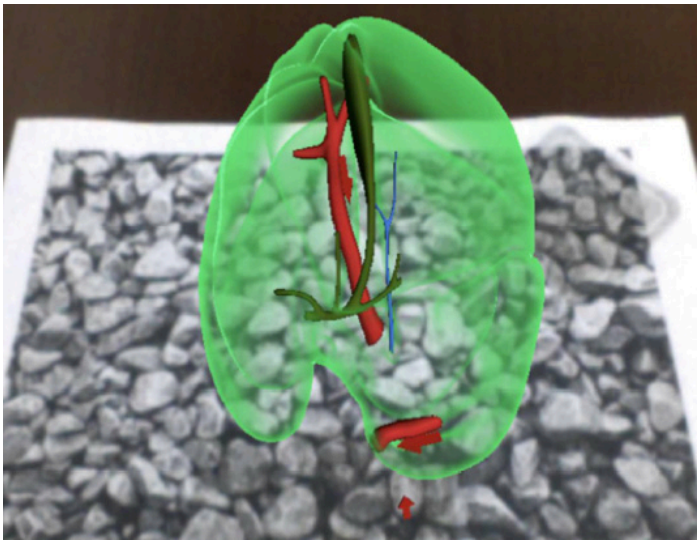
This experiment was based on tests of usability and has as hypothesis the following statement "The proposed application assists the teaching and the study of the human and/or animal anatomy".



In addition to the hypothesis, the evaluation criteria were:

• Efficiency: Does the application allow users to better visualize 3D anatomical structures on mobile devices with the visualization options of structures in a segmented and detailed way?

4.1 Case Study 1: Human Humerus Bone

4.1.1 Subjects

The application validation process had the participation of 5 (five) teachers and 23 (twenty-three) students of a Physiotherapy undergraduate course being 9 (nine) men and 14 (fourteen) women

between the ages of 22) And 45 (forty-five) years. Teachers have more than 20 (twenty) years of contact with the Physical Therapy area, and only 1 (one) of these had previously had experience with devices involving AR.

4.1.2 Procedure

The application was distributed to the subjects along with a manual explaining its operation. After testing the application free form, the group was submitted to a questionnaire composed of 5 (five) affirmations based on the likert scale composed by the assertions: "fully agree", "partially agree", "undecided", "partially disagree" and "fully disagree ". Users should choose only one alternative in each statement, representing the one that best matches their experience of using the application.

The questionnaire had the following statements:

1) The proposed application has an intuitive interface and simple handling and understanding.

2) The virtual visualization a segmented structure with individualized interaction helps in the understanding of its peculiarities in relation to the whole.

3) The possibility of AR visualization of a segmented part of the human or animal anatomy in mobile applications allows greater flexibility of user interaction during anatomy study.

4) The quality of the 3D rendered structure via AR provides a more immersive user experience when interacting with the virtual scene combined with the actual scene.

5) The visualization provided by the use of AR can aid the teaching and study of the anatomy more efficiently than traditional methods.

4.1.3 Results

From the validation experiment performed and discussed in the previous section, we set out to analyze the results and their discussion. In this sense, Figure 7 presents graphs with the distributions of the responses from each to each of the five statements described in the previous section.

As can be seen in Figure 7, the assertions ("fully agree" + "partially agree") make up 100% of the answers given to questions 1, 2, 3 and 4. Thus, it can be assumed that the proposed application is According to the evaluation criteria effectiveness and usability, presenting friendly interface and fulfilling its purpose by offering an intuitive interaction with the 3D representation of the humerus bone in this case study specifically.

Only affirmative 5 did not achieve full agreement - 30% of subjects were undecided on this question, probably because they needed more time to use the application in the classroom (the vast majority of participants in this experiment had never had contact with applications involving AR above).

Interquartile range (IQR) was also analyzed in order to summarize the data independently of the number of observations (Figure 8). It can be seen from the graph of Fig. 8 that the variability of the responses was almost nil with an IQR equal to 1.0 in statements 1, 2, 3 and 4 and with the value of 1.75 in affirmative 5, which confirms the convergence of users' opinions.

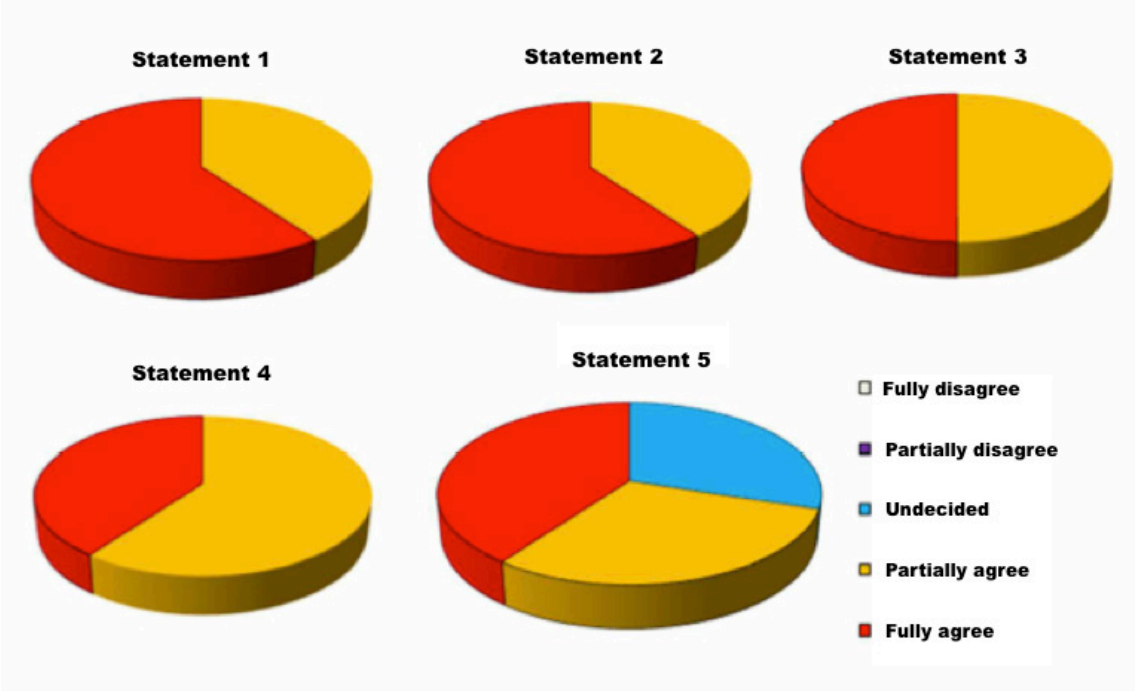


Figure 7. Graph with distribution of the users' answers to the questions proposed during the evaluation experiment for the case study 1.

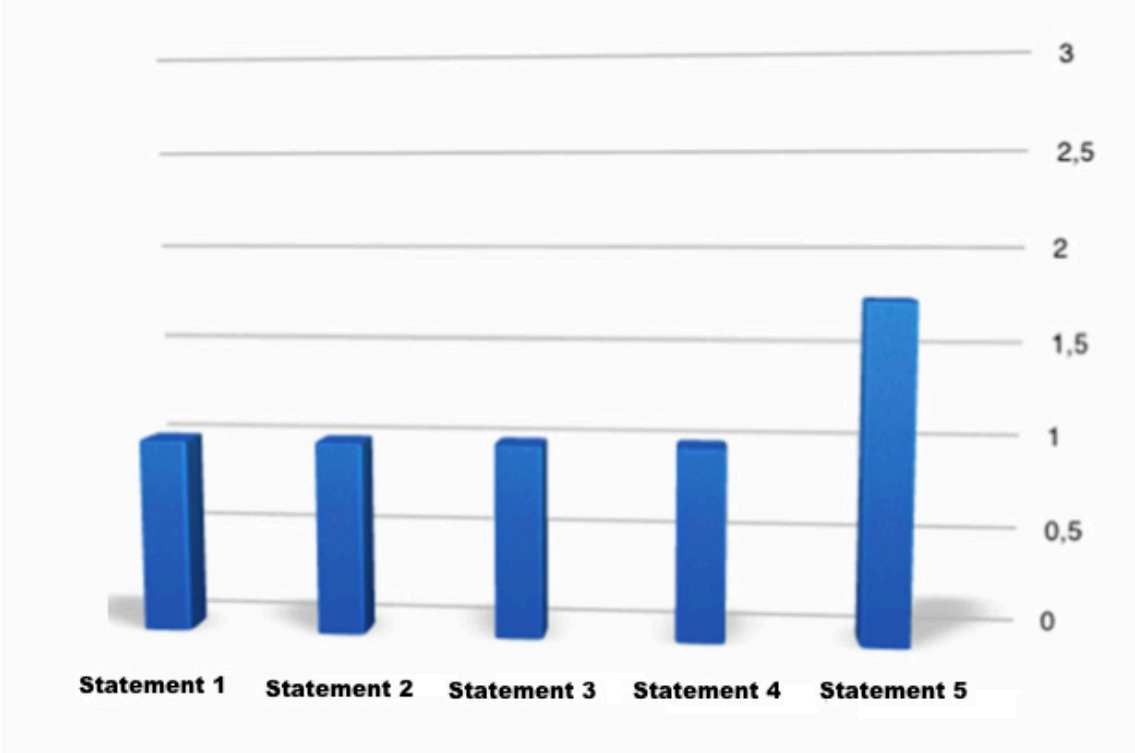

Figre 8. Graph with the IQR values of the users' answers to the questions proposed during the evaluation experiment for the case study 1.

4.2 Case Study 2: Cat Liver

4.2.1 Subjects

4.2.2 Procedure

The subjects were taken to a computer lab to be introduced to the AR based visualizations developed and interact with them. Initially, the functionality of the visualization was explained, presenting screens and form of interaction.

Ad the first validation experiment, subjects were then asked to start the visualization and, at the end, respond to a post-test questionnaire composed of eleven questions and based on the likert scale with the following assertions: “fully agree", "partially agree" "undecided," "partially disagree" and "fully disagree". Subjects should choose only one alternative for each question in order to express their experience of using the application.

The questionnaire had the following statements:

1) The use of AR motivates me to participate in animal anatomy classes.

2) Virtual and interactive 3D models help the study and understanding of anatomical models.

3) The ability to view and interact with 3D models over real scenes via mobile devices helps learning as it is not limited to using a PC/notebook or paper atlas.

4) The interaction with the 3D model is intuitive.

5) The time elapsed between application initialization and the initial display of the 3D model is satisfactory.

6) The response time of the application to the interaction with it is satisfactory.

7) I realize that the use of AR can be applied to other content related to my undergraduate course.

8) I recommend and approve the use of AR in my undergraduate course.

4.2.3 Results

As can be seen in Figures 9 and 10 (IQR), most subjects agreed ("fully agree" and "partially agree") with the statements (around 80).

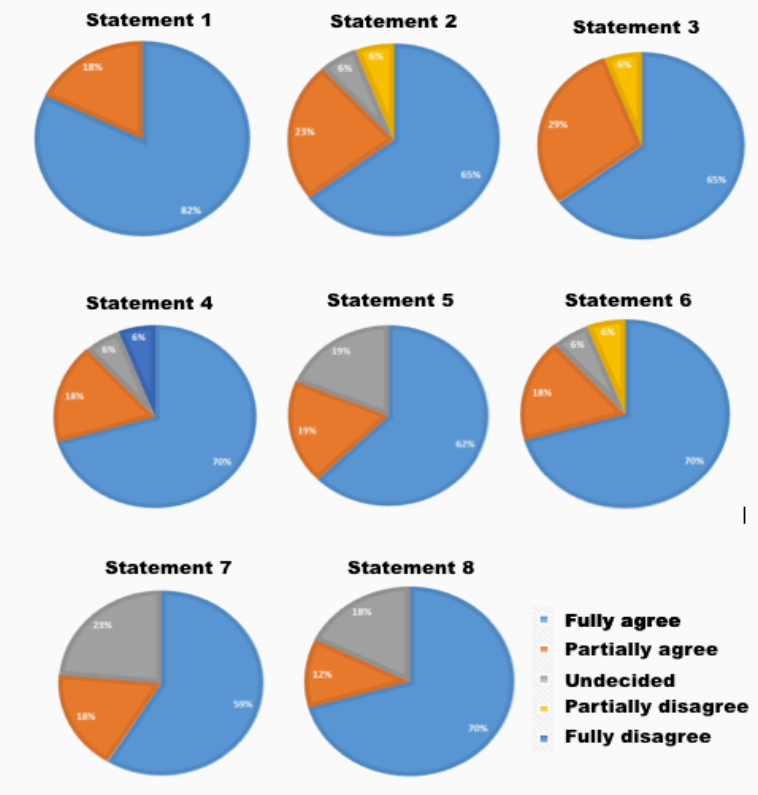

Figure 9. Graph with distribution of the users' answers to the questions proposed during the evaluation experiment for the case study 2.

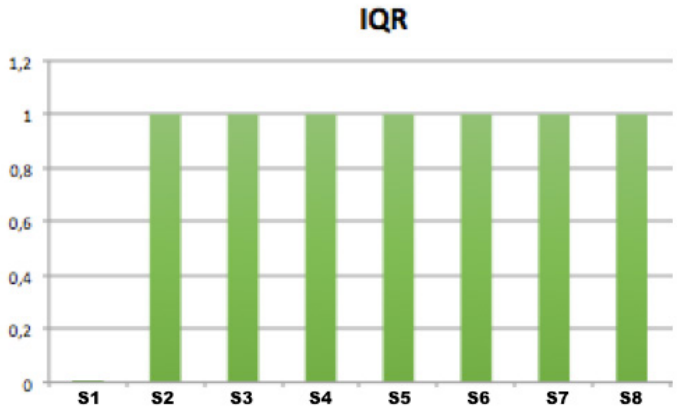

Figre 10. Graph with the IQR values of the users' answers to the questions proposed during the evaluation experiment for the case study 2.

Based on these results, it is observed that, in addition to the proposed criteria, the hypothesis raised was also confirmed in this first moment, although it is felt the need to vary the sample of subjects and extend the validation time of the application in the classroom. In general, it was noted that the users approved the application and that it can be used in the teaching of human and animal anatomy in order to assist students' learning in an interactive and visual way.

However, new experiments, with different anatomical pieces, still have to be performed.

This work presented a study about the investigation of an application of AR aimed at assisting the teaching of anatomy having, as case studies, the visualization of the human humerus

bone and a cat's liver. During its development, it can be noted that the AR is a technology that brings a differential to methods commonly employed in teaching anatomy in undergraduate courses in the area of Health, since it integrates virtual and real objects in order to contribute to a more realistic and interactive visualization of structures in the human body as well as knowledge discovery.

As pointed out by the users, the usability combined with the effectiveness of the use of the AR visualization contributed to a positive evaluation of the same and signaling the will to use it continuously in the classroom. The interface was considered easy to handle and understood by users and the application made it possible to 3D visualization with adequate degree of realism, segmented form and individual interaction, meeting the main requirements raised by the interviewees in the initial phase of this study.

Thus, it is envisaged that AR can bring a new approach to teaching anatomy, both for students and teachers, through its integration into mobile devices. This is a valid alternative to traditional methods of studying anatomy employing corpses, 2D atlases on paper and mannequin models.

In future work, it is intended to extend the application to holographic visualizations besides the construction of simulations of interaction with anatomical parts in virtual environments with support to the use of RV glasses.

Conflict of Interest

The authors declare no conflict of interest.

Acknowledgment

We thank all the teachers and students who participated in this work, from the requirements gathering to the validation experiment.

ABSTRACT

This paper is an extension of work originally presented in SYSCO CONF.We extend our previous work by presenting the initial results of the implementation of intrusion detection based on risk assessment on cloud computing. The idea focuses on a novel approach for detecting cyber-attacks on the cloud environment by analyzing attacks pattern using risk assessment methodologies. The aim of our solution is to combine evidences obtained from Intrusion Detection Systems (IDS) deployed in a cloud with risk assessment related to each attack pattern. Our approach presents a new qualitative solution for analyzing each symptom, indicator and vulnerability analyzing impact and likelihood of distributed and multi-steps attacks directed to cloud environments. The implementation of this approach will reduce the number of false alerts and will improve the performance of the IDS.

1. Introduction

Cloud computing is a new emerging model in Information technology which can enable ubiquitous, convenient, on demand network access to a shared pool of configurable computing resources released with minimal management effort and can rapidly be provisioned. It represents a new opportunity for both customers and service providers, by improving IT efficiency, agility and reliability to reduce the cost of IT technologies. This technology allows customers to create an elastic environment with a multitude number of services, optimize resources and offer an alternative way for renting computing and storage infrastructure services.

Cloud computing services are the most vulnerable target for intruder's attacks due to their distributed environment and the accessibility of cloud services via the internet threating data and services security.

Detect and deter attacks can be difficult task for security administrators. Therefore, the use of IDS (Intrusion Detection system) can help both cloud providers and security administrator in order to monitor and analyze network traffic.

The goal of using such system is to detect and prevent attacks, using different algorithm of detection. Nevertheless, analyzing and monitoring symptoms produces a multitude alarms with a huge number of false ones impacting the effectiveness of such systems. The distributed and open structure of cloud layers makes the implementation of traditional IDS inefficient to be deployed in cloud environment.

In the aim of reducing the number of false alarms this paper proposes a correlation approach by analyzing risks related to each attack pattern. The approach consists of calculating risk related to each attack steps by analyzing symptoms, indicators and vulnerability to define the attack risk score then yield alert. This paper propose to include customers as part of security protection. It demonstrate how the implementation of risks can decrease the number of false alarms. Our work is extended by presenting the initial results of the implementation of the approach in cloud computing specially in SaaS layer.

The remainder of the paper is structured as follows: in section II we present the prior work done in this field. Section III presents the intrusion detection system and risk assessment methodology, in section IV, we describe our proposed detection process based on attacks patterns analysis by risk assessment. Section V presents the initial finding results of the implementation of our approach to detect an SQL injection attack in SaaS layer .The last section of this article will present a conclusion and future works.

2. Related Works

Intrusion detection system has an important role in the security and perseverance of active defense system against intruder hostile attacks. Through the past few years several papers have been presented with the purpose of detecting malicious threat against cloud with different approaches. Security researchers need to have a seamless mechanism to integrate and analyze various information generated by heterogeneous sources implemented in cloud environment with the aim to detect intrusion and reduce false positive alerts. [1]

Kleber, schulter et al. [2] have proposed an IDS service at cloud middleware layer with an audit system designed to cover attacks that Network IDS and Host IDS cannot detect. In [3] authors presented an approach of detection using five major classifiers to characterize the nature of an attack, classification by attack vector, attack target, operational impact, informational impact and by defense, which provide the network administrator with information of how to mitigate an attack.

With similar methodologies to those used in the AVOIDIT [4] taxonomy, S. A. and J. Hamilton [5] developed an ontology-based attack model to assess the security of an information system from the angle of an attacker. Goal of the assessment process is the evaluation of attack effects. Thus, the difference of system performance before and after an attack is calculated. The process consists of four phases. The first step consists in identifying system vulnerabilities by using automated vulnerability tools. Such tools assess computer system, applications or network regarding their vulnerabilities and generate sets of scan results. In the second phase, the developed ontology is used to determine which attacks might occur due to the identified vulnerabilities. By querying the ontology, the possible effects are obtained. Finally, in the last phase the attack effect is calculated. In [6] authors proposed a taxonomy with four dimensions that provides a classification covering network and computer attacks. Their taxonomy provides assistance in improving computer and network security as well as consistency in language with attack description. The first dimension being attack vector is used to classify the attack. The second dimension classifies the target of the attack. The third dimension consists of the vulnerability classification number, or criteria. The fourth and final dimension highlights the payload or effects involved.

Massimo Ficco in [7] proposes a hybrid and event correlation approach for intrusion detection in cloud computing. It consists of detecting intrusion symptoms by collecting diverse information at several cloud levels to perform complex event analysis presented in an ontology.

In [15] song et al propose a model which is based on behavioral and contextual analysis. Authors present two sets of attributes to be used for anomalies detection contextual attribute and behavioral attribute based on a probabilistic analysis.

Wang et al in [16] present an approach for TCP/IP Reassembly in Network Intrusion Detection and Prevention Systems to be used as DPI (Deep Packet Inspection) for network intrusion monitoring.

For risk assessment several methods exist. In [8] author proposes a method for a probabilistic model driven risk assessment with security requirements. The security requirements and their causal relationships are represented using MEBN (Multi-Entities Bayesian Networks) logic that constructs an explicit formal risk assessment model that supports evidence-driven arguments. In [9] author proposes security ontology for organizing knowledge on threats, assets and safeguards measures. This work constructs classification for each of these groups and creates a method for quantitative risk analysis, using its own framework.

In our previous work [10] we presented a new intrusion detection approach based on risk assessment for traditional IDS.

Although all of the previous works present useful taxonomy and ontology that can provide an informative baseline for cyber intrusions and attacks analysis, they lack the details needed to analyze all symptoms of attacks which can provide many false positive alerts in cloud environment. Moreover, this work proposes a detection approach based on risk assessment analysis related to attack pattern initially presented in [1], which means that the data owner and cloud provider will participate in attacks analysis.

For example the same attack against two different clients of the same services may have different impacts. However, IDS will detect both connections as malicious actions. That's could bring IDS to miss the impact analysis, and generate many false alarms.

Our solution addresses this issue in cloud services through the implication of risk assessment in the detection and analysis processes.

3. Intrusion detection and risk assessment

This section presents the Intrusion detection systems, the correlation process and the risk assessment methodology.

3.1. Intrusion detection systems

An IDS (Intrusion detection system) is used for monitoring the network or a host for suspicious or malicious activities. Next to an IDS there is also an Intrusion Prevention System (IPS). An IPS will do more than just monitoring the traffic t will also prevent malicious activities from taking place. IDS/IPS perform a diagnosis of system security to detect all suspicious actions and discover various security breaches based on different algorithms of detection. IDS is used to detect flaws and the different possible threats that attempt to compromise the confidentiality, integrity or availability of a resource with a capability to block malicious attacks using functionalities of prevention.

Providing an analysis of all network traffic with IDS will catch intruders and block multiple suspicious actions threating the security of IT systems. But will also lead to a great number of false positives and can identify authorized users as intruders, especially in cloud environment where all resources are shared between customers.

In order to withhold attacks and reduce the number of false alerts and improve efficiency of IDS, our solution defines both CSP (Cloud Services Provider) and the customers as part of the monitoring process by implementing a risk agent related to all cloud layers (IaaS, PaaS, SaaS).

3.2. Risk assessment

Risk assessment is the process of identifying security risks related to a system and determining their probability of occurrence, their impact, and the safeguards that would mitigate that impact. Risks can be defined as the potential that a given threat will exploit vulnerabilities of an asset or group of assets to cause loss or

damage to the assets. The main objective of risk assessment is to define appropriate controls for reducing or eliminating those risks

Based on the 27005[11] standard risk is evaluated by looking at the probability of successful attacks and the consequent severity of that attacks.

Generally there are four steps of risk assessment. The four steps are as follow:

- Threat Identification
- Vulnerability Identification
- Risk Determination
- Control Recommendation

The general equation of risk determination is:

$$Risk = Impact * Likelihood \quad (1)$$

Impact: (or consequence) refers to the extent to which a risk event might affect the enterprise expressed in the terms of: Confidentiality, Integrity and Availability

Likelihood: represents the possibility that a given event occurs.

This equation (1) will be implemented in our approach with the aim to encourage customers to assess the security risks related to their information and to simplify the analysis of all detected events for intrusion detection systems in cloud computing.

4. Attack pattern analysis in cloud with risk assessment

An attack pattern is an abstraction mechanism for describing how a type of observed attack is executed. Following the pattern paradigm, it also provides a description of the context where it is applicable and then, unlike typical patterns, it gives recommended methods of mitigating [10].

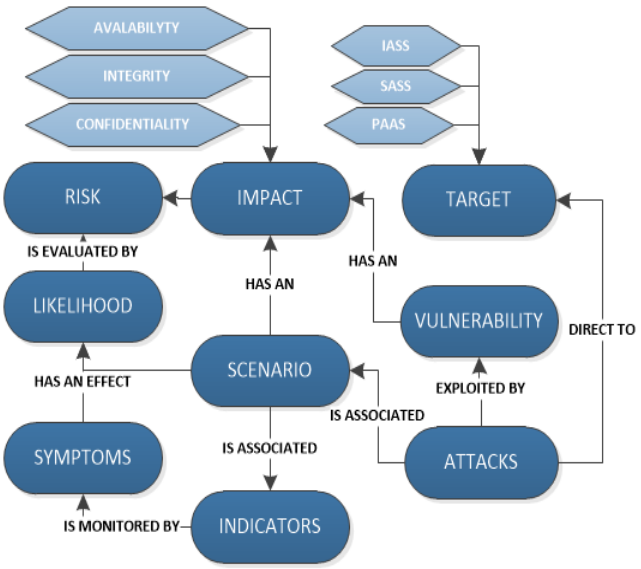

Figure 1: Attack ontology

Figure 1 shows a simplified view of our attack ontology designed to cloud environment.

When an attack occurs, it uses several paths (from reconnaissance to exploitation) by using scenarios defined in the process by indicators and symptoms, in the aims to gain unauthorized access to data. The analysis of impact simplifies the monitoring process and minimizes false-alarms.

Each attack scenario has an impact in either confidentiality, availability or/and integrity. The data owner on the risk-agent will define the impact of each indicator, symptom and vulnerability depending on the nature of the data.

The possibility that a given event will occur is defined as Likelihood. The risk score of the detected attack changes and simplifies the diagnostic of alarms (false positive or successful attack), in the same time symptoms and attack indicators scenario upturn the likelihood in the risk agent.

The analysis of attack pattern uses the risk agent to calculate the score of all indicators and symptoms then to define the nature of the packet. We propose a definition for risk (Re) as a product of the Probability (Pe) of a security compromise, a threat event, and its potential Impact or Consequence (Ie):

$$Re = Pe * Ie \quad (2)$$

The correlation is used to aggregate attack scenarios and symptoms produced by all the probes in the cloud environment.

Equation (2) represents the formula of risk assessment, the likelihood Pe, whereas (Ie) may be assigned a value on a numerical scale. Each indicator Is, Vulnerability Ve, Symptoms Sy have different impact. The value of Pe will be increased related to each detection of an attack pattern.

By using the formula of risk assessment of all suspicious actions we can get a risk score related to each attack:

$$Ra = 1/n \sum Ie * Pe \quad (3)$$

$$Ie = \sum (Is + Ve + Se + Sye) \quad (4)$$

The impact Ie and likelihood Pe of each symptom and attack will be defined by the data owner and cloud provider in a risk agent deployed in all cloud layers. The goal of such correlation is to get attacker's behavior and risk related to each action to by calculating impact and lure a potential attacker from critical system.

The value of Ra related to each attack will determine if the action is a successful attacks or a false positive depending of the sensitivity of targeted data related to risk values.

IDPSs serve four essential security functions: they monitor, analyze detect and respond to all suspicious activities as depicted in the functional layer.

The IDS/IPS detects intrusion by analyzing the collected data in all cloud layers based on knowledge base and the attack pattern ontology, calculates the risk of the attack then decides if it represents a suspicious action or a false-positive.

A software Agent is related with each probe defining the impact and likelihood of each detected symptoms. The risk server will determine the impact of each attack pattern then the risk of the attack. Implementing, such methodology can minimize the number of false-positive alarms and increase the effectiveness of Intrusion Detection System.

5. Implementation of approach

In this chapter we present the initial finding while implementing the discussed idea in cloud environment in the aims to decrease the number of false-alarms and to improve the reaction in the detection intrusion system in cloud.

5.1. Architecture of implementation

IDS implementation in cloud computing requires an efficient, scalable and virtualization-based approach. In cloud computing, user data and application is hosted on cloud service provider's remote servers and both cloud user and CSP (Cloud Services Provider) has a limited control over data and resources.

In the implementation of the proposed approach we have used OPENSTACK [12] as cloud platform with a collection of open source software project that developers and cloud computing technologist can use to setup and run their cloud compute and storage infrastructure.

SURICATA [17] was used as intrusion detection system which is a free and open source, fast and robust threat detection engine.

The simulation setup is a Cloud with different layers. We have chosen a fixed value in risk agent. The main goal is to analyze all actions based on the impacts and likelihoods of vulnerabilities and detected symptoms to evaluate the efficiency of our works.

The architecture of implementation and the used correlation process is presented in Figure 2:

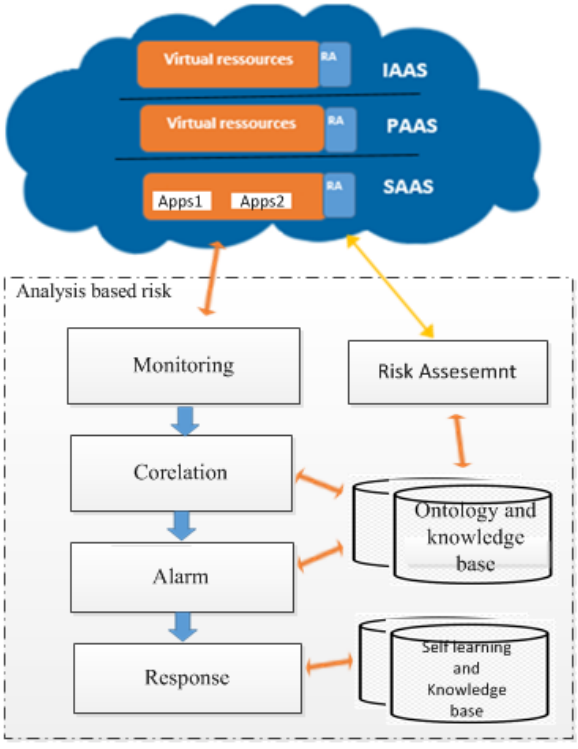

Figure 2: Architecture of implementation

5.2. Detection of SQL injection in SaaS

An attack based on SQL injection can be defined as an attack which consists of insertion of a SQL query via the input data from [13].

In this attack malicious user will use several steps to gain an access to a SaaS service and a successful SQL injection exploit can threat the confidentiality, integrity and availability of database. However the same attack in two application in a SaaS service could have different impact.

Based on the SQL injection attack pattern defined in [14] the scenario can be presented as below:

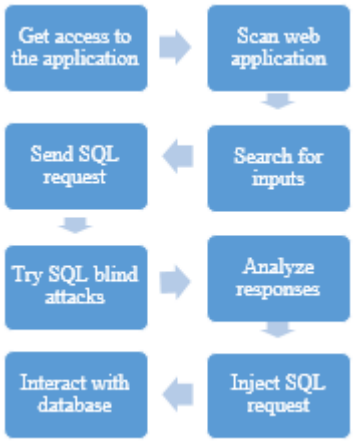

Figure 3: SQL injection attack pattern

In the scenario of implementation each cloud client must define a risk related to this attack pattern

- **Vulnerabilities**: Input validation ,Inputs are not properly validated by the application
- **Scenario** : Try different approaches for adding logic to SQL queries
- **Indicators** : Scan a website application, analyze responses positive or negative
- **Symptoms**: Use automated scan tools, try "Blind SQL Injection" techniques to extract information about the database, Send different requests

The Table below shows a simplified use of risk assessment used to estimate an SQL injection attack impact against two SaaS applications with a fixed values:

Attack pattern	Likelihood in app1	Likelihood in app2	Impact in app1	Impact in app2	Ra app 1	Ra app 2
Vulnerability	1	3	3	1	3	3
Scenarios	3	2	4	3	12	6
Indicators	2	2	4	3	8	6
Symptoms	2	3	4	1	8	4
Attack risks					7,75	4,75

Table 1: Attack analysis

Attack Pattern against SaaS services is composed of 4 attributes: Vulnerability, Scenarios, Indicators of attack and symptoms. Each attribute define an impact and has an initial value of likelihood determined by customers in risk agent.

Ra app 1 present the risk of each attribute, while attack risks is calculated using the equation (3). Table1 demonstrate how the same attack against two customers in the same Cloud service should have different impact.

The graphs below show results, before and after the use of risk analysis, obtained while exploiting the SQL injection vulnerability directed to two customers data in the same SaaS service with the use a static risk agent related to this attack pattern as presented in *table 1*.

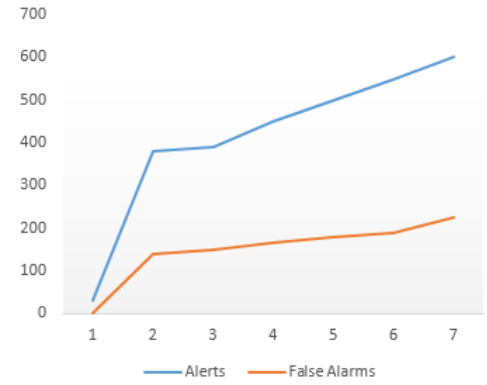

Figure 4: Number of false alarms before implementation

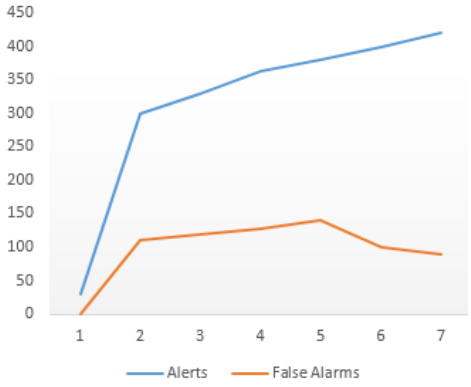

Figure 5: Number of false alarms after implementation

5.3. Discussion

The specific and complex characteristics of cloud computing environment make the implementation of intrusion detection system more difficult with the multitude of alarms and the huge number of false alarms. Therefore, there is a need of new approach of detection and analysis of malicious activities for both cloud consumers and CSP to check the effectiveness of the current security controls that protect data stored in cloud.

Figure 5 demonstrates how the implementation of risk assessment in cloud layer for two customers reduces the number of false positive alarms. With such an approach, the cloud consumers can check the effectiveness of the current security controls that protect an organization's assets and the service providers can maximize and win the trust of their cloud consumers if the level of risk is not high. Also the cloud consumers can perform the risk assessment to be aware of the risks and vulnerabilities present in the current cloud computing.

6. Conclusion and future works

Based on the observation that consumers must be involved in data protection and attack deterrence in cloud computing, this paper provides a novel approach in the disposition of intrusion detection system. We suggest a model to recognize and analyze malicious actions by using a risk assessment related to attack pattern.

The same attack should have different impact on different customer's data. This paper classifies attacks by target, symptoms, scenarios, impact and likelihood defining the attack pattern than estimate impact and risk related to all malicious activities against cloud services. Both CSP and consumer will participate in the correlation process. This classification will help to provide a methodology of analysis in depth of all suspicious actions in the aim to minimize the number of false alarms and increases the efficiency of intrusion detection system in cloud services.

The initial implementation for securing a SaaS service and detecting an SQL injection attack against two customers data's has demonstrated the efficiency of our approach in both decreasing the huge number of false alarms and increase the effectiveness of the IDS system.

Future works will be focused on the implementation of our approach to detect sophisticated attacks in all cloud layers with the implementation of distributing risk agent.

ABSTRACT

A method for optimal sizing of hybrid system consisting of a Photovoltaic (PV) panel, diesel generator, Battery banks and load is considered in this paper. To this end a novel approach is proposed. More precisely a methodology for the design and simulation of the behavior of Hybrid system PV-Diesel-Battery banks to electrify an isolated rural site in southern Algeria Illizi (Djanet). This methodology is based on the concept of the loss power supply probability. Sizing and simulation are performed using MATLAB. The technique developed in this study is to determine the number of photovoltaic panels, diesel generators and batteries needed to cover the energy deficit and respond to the growing rural resident energy demand. The obtained results demonstrate the superior capabilities of this proposed method.

1. Introduction

PV system size and performance strongly depend on meteorological variables such as solar energy, wind speed and ambient temperature and therefore, to optimize a PV system, extensive studies related to the metrological variables have to be done [1].

The performance of a PV module strongly depends on the sun light conditions. Standard sunlight conditions on a clear day are assumed to be 1000 W of solar energy per square meter and it is sometimes called ‘‘one sun’’ or a ‘‘peak sun’’. Less than one sun will reduce the current output of a PV module by a proportional amount [2,3].

The generation of electricity through a hybrid system combining several renewable energy sources is of great interest to developing countries, Such as the Maghreb countries. These countries have many isolated regions far from traditional electricity distribution networks. Thus the extension of these networks would be of an exorbitant financial cost. To solve this problem, exploiting the renewable energy potential of these countries must be a priority.

Hybrid PV/diesel systems have greater reliability for electricity production than using PV system alone because diesel engine production is independent of atmospheric conditions. The PV/ diesel system will provide greater flexibility, higher efficiency and lower costs for the same energy quantity produced. In addition, PV/diesel system as compared to only diesel system provides a reduction in the operation costs and air pollutants emitted to the atmosphere [4]. Currently, some research works are carried out focusing on optimal sizing of hybrid PV/diesel generator systems so that the number of PV modules, storage battery capacity and diesel generator capacity can be optimally selected. Hybrid PV/diesel systems can be classified into two categories: series topology and parallel topology. In the series topology, the diesel generator is connected in series with the inverter and therefore it is not able to supply the load directly while the load demand is covered by the storage battery. The disadvantages of this topology that such systems require large inverter size and low overall efficiency due to the series connection, as well as when the PV system is connected to the diesel generator it leads to a limited control of the diesel generator. However, these disadvantages can be avoided in the parallel topology whereas the diesel generator is in parallel with the inverter and can supply the load and the battery at the same time [4].

Rural electrification in the southern countries is based in most cases on solar homes systems with limited use. This gives an impression that photovoltaic systems aimed the poor. Diesel generators generate more electricity but suffer from the maintenance costs and the provision of oil [5].

*Corresponding Author: Adel Yahiaoui, City of Almond, Bougara, Blida, Algeria, +213 795 517 302 | Email: yahiaoui.industry@gmail.com

The hybrid combination of photovoltaic-battery-diesel systems requires technical knowledge, economic and preliminary studies for the design, optimizing the choice of a suitable load profile, assessing consumption and simulation performance before installation and implementation of the systems. Each aforementioned item requires data and computer tools to accomplish it.

Many papers are discussed on design of hybrid systems with the different components. In 2006 Eftichios Koutroulis et al presented a methodology for optimal sizing of stand-alone PV/WG systems using genetic algorithms [6]. They applied design approach of a power generation system, which supplies a residential household. In 2007 Yang developed a novel optimization sizing model for hybrid solar-wind power generation system [7]. In 2016 R. Hosseinalizadeh et al presented an economic sizing of a hybrid (PV–WT–FC) renewable energy system (HRES) for stand-alone usages by an optimization-simulation model: Case study of Iran [8]. In 2015 B. Guinot developed a Techno-economic study of a PV-hydrogen-battery hybrid system for off-grid power supply: Impact of performances' ageing on optimal system sizing and competitiveness [9]. Recently, Leong Kit Gan et al developed a hybrid wind–photovoltaic–diesel–battery system sizing tool development using empirical approach, life-cycle cost and performance analysis: A case study in Scotland [10].

An overall power management strategy is designed for the system to coordinate the power flows among the different energy sources. Simulation studies have been carried out to verify the system performance using practical load profile and real weather data in south Algeria. It is to mention that there are many similar regions around the world with this typical situation that can be expanded.

In this paper, a methodology of optimal sizing of hybrid power generation system is proposed. The main objective of this work is to determine the optimal number of PV panels, Battery banks and diesel generators. For this purpose a new sizing algorithm, called loss power supply probability (LPSP) is utilized. The obtained results show that the proposed methodology finds optimal sizing of hybrid power generation system with a quality energy services for the rural population through of a reliable network. The simulated result illustrates the good applicability and performance of the proposed method.

The rest of the paper is organized as follows: Section 2 presents the city of our study. Section 3 presents the modeling of the system considered. Section 4 discuses about the LPSP algorithm. Section 5 and 6 describes how the problem can be solved by using the proposed method and results. Conclusions are presented in Section 7.

2. The case of Djanet city

2.1. The selected site

The site selected for this study is a rural village isolated Saharan named "Djanet" present in figure 1. This village is located in the province of Illizi and consists of a small number of homes.

2.2. Meteorological data

The performances of photovoltaic modules are directly correlated to climatic data that is in principle the solar irradiation and the ambient temperature. These data are taken through the acquisition system measured to step time is 10 minutes. For each day of the year the kit provides for the acquisition of ambient temperature in degrees Celsius (°C), and solar incident in Watts per square meter illumination (W / m2). The annual assessment of the site's climatic characteristics is shown in Figure 2 and Figure 3.

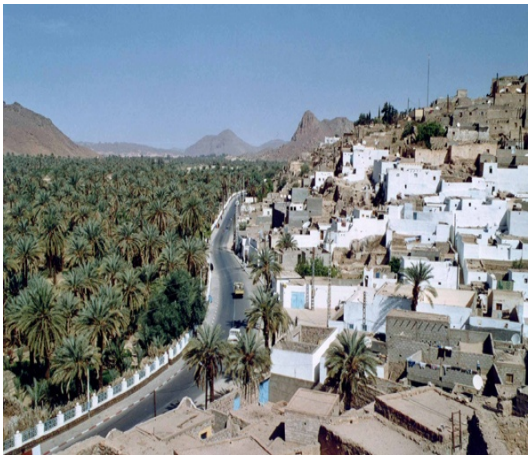

Figure 1: Geographical location of Djanet city in Algeria

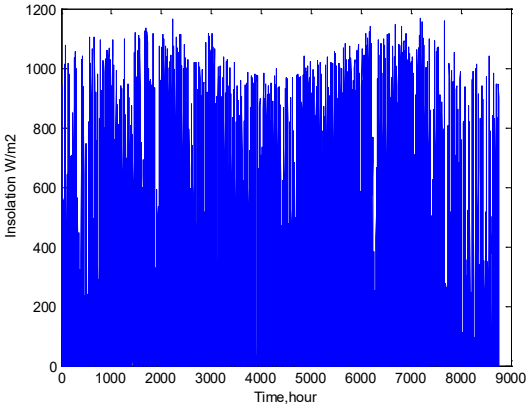

Figure 2: Annual insolation data for Djanet city

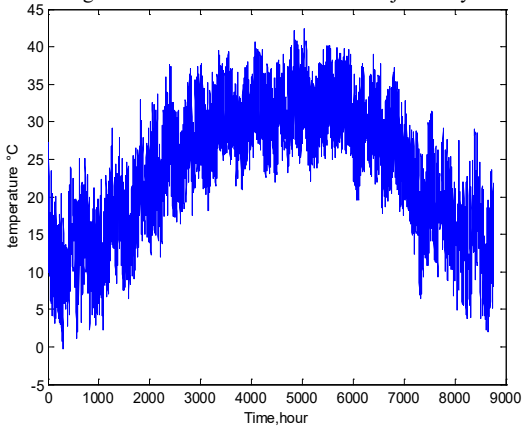

Figure 3: Annual temperature data for Djanet city

2.3. The load profile

The initial data in the implementation of a renewable energy production system as for any other energy system is the demand, which will be determined in relation to the and / or the loads to be supplied. This demand must be estimated as precisely as possible, both from a point of view of the powers called and from its temporal distribution, although it's often random nature makes this task very difficult.

The hybrid system considered is intended for supplying a load for domestic use. For our case study (Djanet city) in which there are ten dwellings, we consider a constant load profile throughout the year.

Figure 4 shows the distribution over the hours of the day of consumption of the conventional appliances used (lighting, refrigeration, TV, radio, ventilation); on which the difference between the quantities of energy consumed from one hour to another is seen. Hence, the importance of choosing economical appliances for isolated sites, to minimize installation costs.

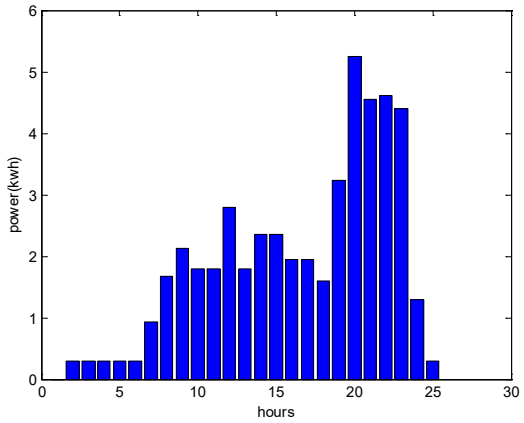

Figure 4: Curves of hourly load profiles.

3. Modeling of considered system

3.1. Photovoltaic system

Choosing a suitable model for simulation is very essential. The simple model of PV panel as a function of the area, the input variables of this model are solar insolation shown in Figure 1 and its efficiency. Detail equation of PV model can be described as follows [10,11,12]:

$$P_{pv}(t) = n.A_p.N_{pv}.G(t) \quad (1)$$

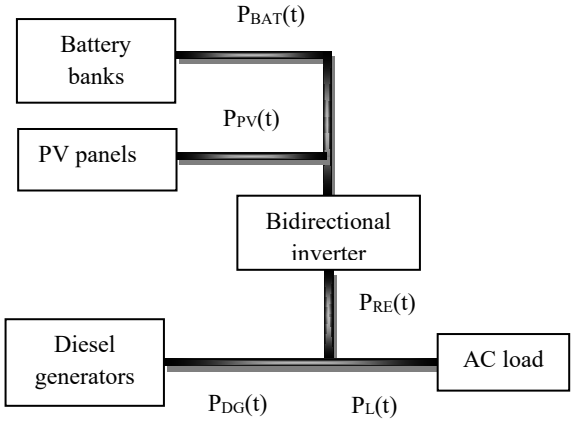

Figure 5: Configuration of the system

Where; n energy conversion efficiency, (%). A_p is the area of single PV panels, (m^2). N_{pv} is the number of PV panels. G (t) is the insolation data, (W/m^2).

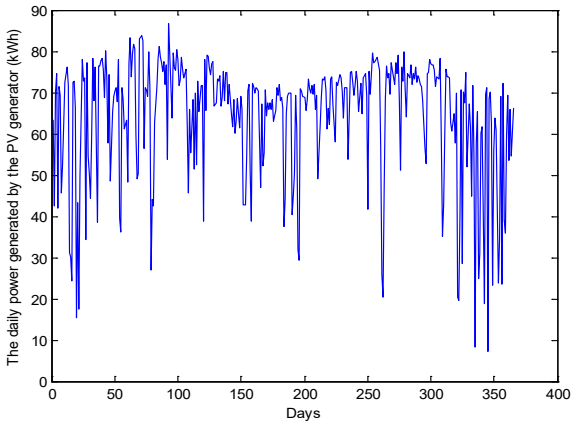

Figure 6: The daily power generated by PV modules

3.2. Battery Banks

Here, power from battery banks is required whenever The PV panels or Diesel generators (DG_s) are fail to supply load. Power from PV system through the inverter is hourly measured as follow:

$$P_{RE}(t) = \eta_{inv}.P_{pv}(t) \quad (2)$$

Where, η_{inv} is the inverter efficiency. Principles of charging and discharging scenarios are dependent on the state of P_{RE} and the load power demand at hour t ($P_L(t)$).

1. If the value of P_{RE} (t) > P_L(t) the remaining power will be used to charge battery banks by the following equation [13]:

$$C_{Bat}(t) = C_{Bat}(t-1) + \left(P_{pv}(t) - \frac{P_L(t)}{\eta_{inv}} \right) \eta_{Bat} \quad (3)$$

2. If the value of the P_{RE} (t) < P_L(t) insufficiency power will be supplied by diesel generators and/or the battery banks according to the following dispatch strategy:

- If the amount of power from battery banks is enough to handle the remaining power, the strategy allows the discharging process of battery banks with following equation [14]:

$$C_{Bat}(t) = C_{Bat}(t-1) + \left(P_{pv}(t) - \frac{P_L(t)}{\eta_{inv}} \right) \quad (4)$$

Where, C_{Bat} (t) is available battery banks capacity at hour t, C_{Bat} (t-1) is available battery banks at previous hour and η_{Bat} is yield of battery charging.

The value of C_B (t) could not be lower than minimum allowable energy level remained in battery banks, and it could not be higher than maximum allowable energy level during charging operations as follow [8,13]:

$$C_{Bmin} \leq C_B(t) \leq C_{Bmax} \quad (5)$$

- Whenever battery banks are fail to supply the remained power or the strategy does not allow for the battery banks to discharge, then diesel generator is started and battery banks will be neither charged.

$$P_{DG}(t) = P_L(t) - P_{RE}(t) \quad (6)$$

Where, $P_{DG}(t)$ is the output power from diesel generator unit.

3.3. Diesel generator

The fuel consumption of diesel generator unit is related with the rated power and its generated power. The fuel cost is calculated for a year as follows [15]:

$$AFC = C_f \sum_{t=1}^{Tend} F(t) \quad (7)$$

Where, F(t) is the hourly fuel consumption (liter /hour), based on load characteristic of the diesel generators. This parameter is calculated as follows [14]:

$$F(t) = (0.246 \times P_{DG}(t) + 0.08415 \times P_R) \quad (8)$$

Where, P_R is rated power of diesel generators, P_{DG} (t) is the power generated by diesel generators and C_f is the fuel cost per liter in US$/l.

4. Description of the LPSP method

A balanced system, the amount of energy supplied by the solar modules must at least compensate the amount of energy, depending on the place of installation, the season, and the particular conditions of consumption and use.

The sizing method presented consists in determining the optimum number of batteries and PV modules according to an optimization criterion, namely reliability, which is based on the concept of the LPSP (Loss of Power Supply Probability), It will allow us to dimension a realistic electricity production system supplying ten individual habitats for the Djanet site during a year.

Dimensioning a PV system means determining all the elements of the PV chain according to the loads such as the sunshine and the load profile. There is no fixed scale between consumption and generator size. There are several methods of dimensioning a PV system: by the hourly usability function, by the probability of energy loss, and by iterative methods ... etc.

LPSP is a probability technique introduced by AbouZahr and Ramakumar in 1990 the field of wind and photovoltaic generation systems [16, 17]. The probability of energy loss (loss of power supply probability) is widely used in the design and optimization of autonomous systems (stand-alone) wind-photovoltaic [18, 19, 20]. It is based on the concept of the LPSP, which is the probability that the system is experiencing a shortage at some time during a period of analysis, that is to say a state in which the system would not be able to provide energy to the load. From the information on the variability of resources and its correlation with the load, LPSP can be calculated. This method is particularly useful in assessing the behavior of an energy storage.

The 'LPSP' is defined as the fraction of the unsatisfied demand on that requested by the load. It expresses the rate of non-satisfaction of the load. Thus, this probability is defined as the sum of all unfulfilled demands 'LPS' on the total energy demanded by the load during a period of operation (For this study, T = 1 year), as follows [14] :

$$LPSP = \frac{\sum_{t=0}^{T} T_i}{T_p} \quad (9)$$

Where,

T_p is the period of study.

T_i is the duration corresponding to a power produced less than the demand.

5. Application of the LPSP to the PV installation

The first step before carrying out any dimensioning is to determine when we need electricity and to define our consumption which should not be underestimated or overestimated. This step requires a lot of reflection because an error at this stage will distort our results. So, at the outset, we choose the energy consumption profile, as well as the choice of an architecture of the system.

With the data from the first step, you will be able to know the number of photovoltaic modules needed to cover the electricity needs. To do this, it is necessary to calculate the energy that the modules must produce each day, and to know the sunshine of the region where the installation is located. The amount of electricity produced by the photovoltaic modules depends directly on this sunshine and therefore on the region.

Always the first step will also allow us to calculate the number of battery. The stored energy depends directly on the periodicity of your consumption.

The next step is to dimension the load regulator. This step does not involve any calculation, but there are a wide variety of regulators that differ according to their options, functions and power. It will therefore take time to choose the regulator best suited to your situation.

Another step is to choose the converter if this device is necessary, that is to say if our load is operating in AC mode. Indeed, the installation can already provide direct current 12, 24 or 48VDC.

6. Development of the proposed approach

The system configuration is shown in Figure 5; meanwhile, the flowchart of system operation is shown in Figure 7. The load demand is supplied by DGs, PV, and battery banks. The bidirectional inverter is required to supply power from battery banks to the load demand or feed surplus power from PV panels and DGs to the battery banks. Total power from battery banks, DGs and PV panels has to satisfy the load demand. The concept of operational strategy could be explained clearly as follow:

- If the load demand ($P_L(t)/ \eta_{inv}$) is less than the total power produced from photovoltaic panels ($P_{pv}(t)$), and the battery C_B is fully charged, then the banks of the battery are charged as amount as the capacity of the inverter and the excess power are dumped.

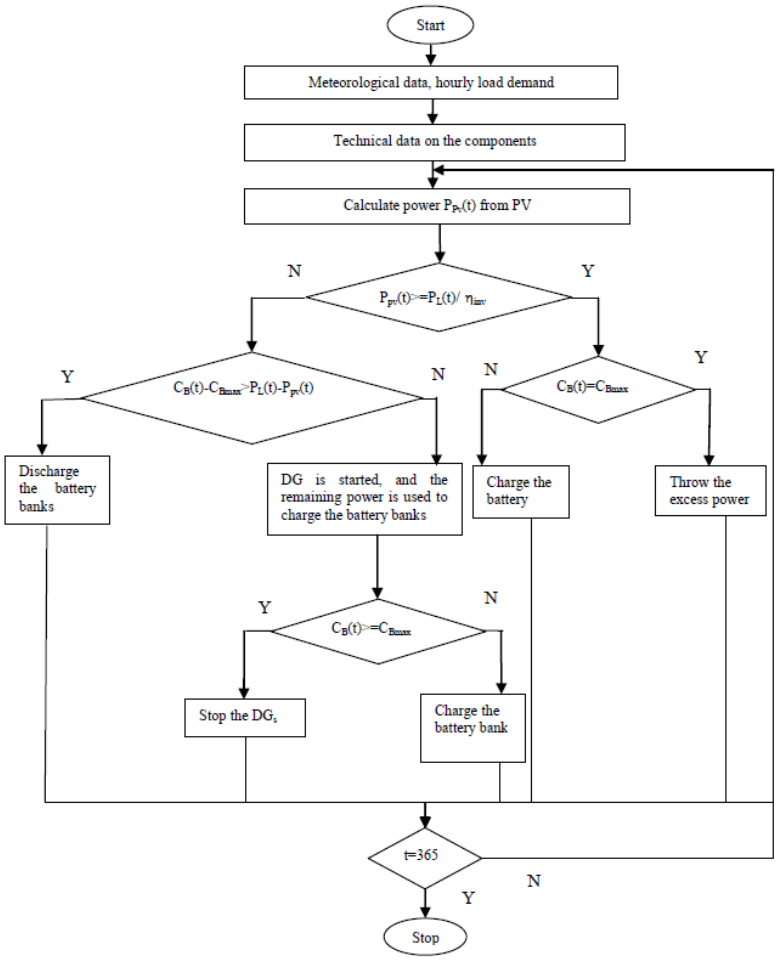

Figure 7: Flowchart of the algorithm for simulating hybrid system

- If the $C_B(t)$ is less than C_{Bmax} the excess power is used to charge the banks of the battery.
- If the load demand (P_L (t)/ η_{inv}) is greater than $P_{pv}(t)$ and C_B (t) of the banks of the battery is greater than C_{Bmin}, then the power of the insufficiency will be provided by the banks of the battery. Otherwise, if $C_B(t)$ of the battery banks equal C_{Bmin}, diesel generators are started to meet the demand for charging the banks of the battery.
- However, if the power of the inadequacy is greater than the capacity of the inverter, the battery banks are discharged in quantity that the capacity of the inverter, and then the diesel generators are started to meet the load demand.

7. Application and results

The main objective of this work is to determine the optimal configuration of the hybrid photovoltaic, diesel generator with storage to satisfy the power demanded by the load.

Several methods of designing hybrid energy systems have been carried out by researchers. The method we are going to use is based on a technical-economic analysis. We will first apply the LPSP

Table 1: Number of PV modules in terms of LPSP

LPSP	0.01	0.02	0.03
Number of PV modules	221	219	216
Number of batteries	120	105	90
Number of diesel generators	3	3	2

Table 2 : Monthly energy balance

	Energy produced by PV (kWh)	Average storage capacity (kWh)	Fuel consumption (Liter)	The operating hours of DG
January	1300	88.6046	6,33	1,00
February	1420	87.8545	0,00	0,00
Marche	1620	97.2668	0,00	0,00
April	1550	54.4687	88,62	14,00
May	1650	54.4379	82,29	13,00
June	1440	48.3240	151,92	24,00
July	1440	49.8778	177,24	28,00
August	1640	51.8210	88,62	14,00
September	1550	52.6139	101,28	16,00
October	1690	96.4810	0,00	0,00
November	1350	87.1510	0,00	0,00
December	1170	85.6003	0,00	0,00

Table 3 : Annual energy balance

Nature	Value
Annual PV Energy produced	17820 kWh
Average annual storage capacity	69,90 kWh
Annual fuel consumption	696,30 Liters
Annual energy produced by diesel generator	2200 kWh
Annual excess energy	4030,8 kWh

(Loss of Power Supply Probability) method. Then, using the optimal configuration that satisfies the demand obtained, consisting of the number of photovoltaic panels, number of batteries and diesel generators, we use the approach proposed in the previous section to simulate the hybrid system.

In our system, we chose LPSP = 0.03 which gives a number of PV modules equal to 216 Depending on weather conditions (light and temperature) and load profile, the number of photovoltaic modules is given in Table 1.

Table 4 : Daily production percentage

Nature	Percentage
Photovoltaic	94.4627 %
Diesel Generator	5.5373 %
Annual excess energy	1.5229%

Table 1 show that by increasing the value of the LPSP, the number of PV panels, battery banks and diesel generators is decreased. In other words, the variation of components depends on the LPSP.

It is thus possible to conclude from various simulations that the availability of photovoltaic panels plays a key role in the optimal system design and in the precise design of the energy production of the system.

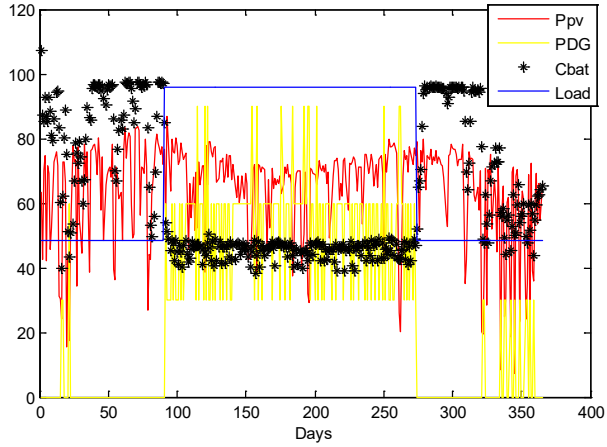

Figure 8. The energy management of hybrid system

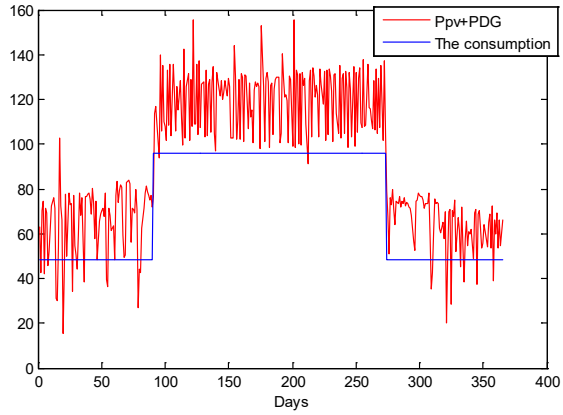

Figure 9: The daily power generated by PV panels and DG$_s$ compared with the consumption

The simulation results presented in this paper provides monthly, hourly and daily results, which allows us to make monthly and annual balance sheets. Figure 8 shows a monthly variation in the production of photovoltaic energy, diesel generators and average storage capacity respectively, we see that the two production pikes are for the months of April and September (iterations 93 and 279), and production is minimal in the month of December (in the iteration 345), these results affect the ability of storage, the relationship between the two parameters is proportional.

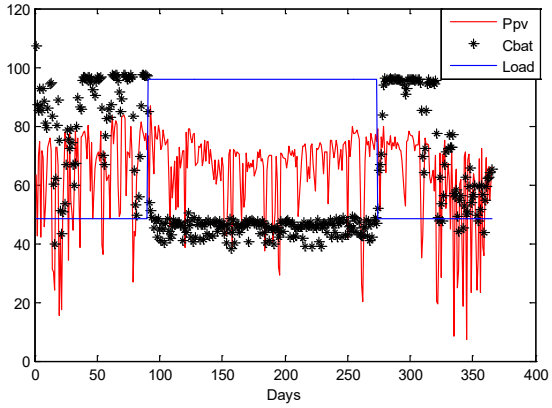

Figure 10: energy management of only PV system

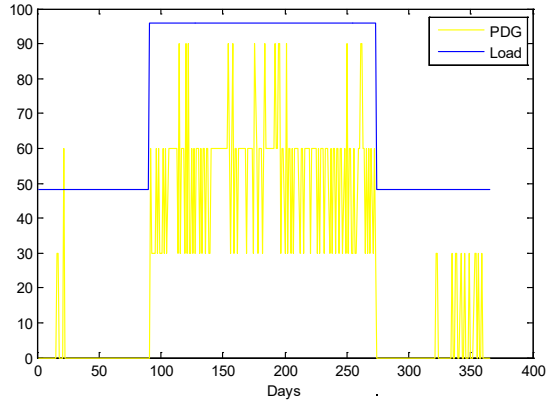

Figure 11: energy management of only DG system

The energy produced by the diesel generator, as shown in Table 3 vary from one month to another, they are highest in the months of April, May, June (in the iterations 92 to 272), and they are minimal in the months of January, February, March, April, May, October, November and December (in the iterations 1 to 91 and 273 to 365). Note that the results are synchronized by sunshine, temperature and load, we also find that the percentage of photovoltaic is important (94.4627%) by contribution to 5.5373% of the energy produced by the diesel generator.

The excess energy is low in the order of 1.5229%. The energy produced by the system during 12 months compared with the consumption is shown in Figure 9. it can be observed that the consumption is minimum in the months of January, February, March, October, November and December (in the iterations 1 to 88 and 274 to 365), which is causing a decrease in the total energy produced, and it increases proportionally with consumption in the rest iterations (months of April, may, June, July, August and September).

The simulation results of only PV system, only DG system are presented in Figures 10 and 11 respectively. From these results it can be concluded that the system is able to fully satisfy the load demand.

The design procedure resulted in determination of best configuration of the system.

The stand-alone hybrid PV-DG system with battery bank seems to be a motivational techno-economic solution to meet the energy demand of consumer.

8. Conclusion

This paper presents a new method based on loss power supply probability (LPSP) to solve the optimal sizing of a hybrid PV/Diesel/Battery system. The optimal number of PV panels, Diesel generators and batteries is determined using LPSP to supply the load. The main objective of this work is to examine the feasibility and performance to electrify rural community by the hybrid solution, then we realized that the operation of the system depends not only on the input and output variables which are the sunshine, the temperature and the load to be supplied but also the interdependence between different devices. An improperly sized system component can compromise which was verified by simulation results the proper functioning of the entire system. Thus, we can conclude that the combination of energy sources (PV-Diesel-Battery) is required to be able to cover the energy deficit and meet the growing energy demand of rural inhabitant. We believe that the technical and economic simulation results obtained were satisfactory and demonstrated the effectiveness of the studied hybrid system.

A successful hybrid system requires an energy saving approach and a rigorous design and installation of components that meet the need.

Conflict of Interest

The authors declare no conflict of interest.

Acknowledgment

The research work presented in this paper was jointly carried out by the Research Laboratory in Electrical Engineering and Automatics (LREA) at the University of Yahia Fares in Medea-Algeria and the Control Laboratory Processes (LCP) at the National Polytechnic School of Algiers-Algeria. We would like to thank all those involved in our project.

ABSTRACT

In this paper the design of a new 3D magnetic field (H-field) probe with a near-field scanning system is presented, then the near electromagnetic fields radiated by a Library RFID system is characterized. The proposed system is developed in order to determine the magnetic near-field emitted by electronic devices. The designed isotropic H-field probe consists of three orthogonal and identical loops each of diameter of 6 mm having 3 turns. The antenna factor of the designed probe is presented for a frequency range from 10 MHz to 1 GHz. The designed probe is tested and validated using a standard passive circuit as a device under test. An RFID reader antenna is also designed and simulated on HFSS (high frequency structural simulator) and the radiated magnetic field, obtained by simulations, is then compared to the real measured one above the fabricated circuit. The obtained levels are checked if they satisfy the European and ICNIRP Electromagnetic Fields Guidelines.

1. Introduction

The everyday use of devices and systems emitting radio frequency electromagnetic fields is continuously increasing. Some of these devices are operating in the vicinity of human body, in which people are in the near-field region of the radiating source, and they are exposed to electromagnetic fields. Radio Frequency Identification (RFID) systems are used today in wide variety aspects of everyday life. There are wide areas of RFID applications such as: cashless payments, transportation ticketing systems, residential door keys, antitheft protection systems, library systems [1] etc. RFID technologies are intended to recognize or identify remotely placed label on an object, animal or person. The system consists of the reader or RFID antenna and of a label (or tag) composed of a RFID chip and an antenna (e.g. pasted into a book in a library). The label is activated by a modulated electromagnetic wave processed by the reader with an antenna. It returns a signal to reader in one of the frequency bands allocated to the RFID applications: 125 to 150 kHz; 13.56 MHz; 433 MHz; 860 to 960 MHz; 2.45 GHz. The distances covered with systems can reach up to several meters [2].

Due to the development of such applications, there must be a study on the relationship between the exposure to electromagnetic fields and the health of humans. Near-field region is an important part that should be analyzed in this study. Even though there are different methods for field mapping, passive detection is always an economical way of measuring vector electromagnetic fields. Various researches have been done in the development and characterization of electric and magnetic probes. In [3] the results of a probe with a CPW fed transmission line in the frequency range of 0.1 to 0.3GHz is presented whereas in [4] a resonance suppressed magnetic field probe which operates in the 1-7GHz frequency band is presented. All these probes measure only one component of the electric or magnetic field at a time. Also, the larger size of these probes reduces the performance by reducing the spatial resolution as the size of the probe is inversely proportional to the spatial resolution of the probe [5].

It is necessary to have all the 3 components of magnetic or electric fields for accurate prediction of radiated emissions [6]. But it requires a large scanning time in order to complete one surface of a printed circuit board during the near field measurements. In [7] three dimensional (3D) near field scanner for IC chip level measurements is proposed. It consists of 3D near field scanner with a magnetic probe head. Two separate magnetic fields probe (to measure normal and tangential component of magnetic field) for measuring three dimensional fields in high frequency planar circuits is proposed in [8]. Still, these methods don't reduce the scanning time because each component has to be measured

[*]Corresponding Author: Kassem Jomaa, IMEP-LaHC Laboratory, Grenoble-Alpes University, Grenoble, France Email: kassem.jomaa@imep.grenoble-inp.fr

separately. In order to minimize the scanning time we propose a 3D scanning system consisting of a near field scanner and a 3D magnetic field probe.

In this work a new 3D magnetic field probe which measures the three components of the magnetic field simultaneously is designed and validated. It is used to measure the three magnetic field components of the radiated emissions from a device under test (DUT), over a broad range of frequencies. The near-field exposure assessment of the radiated field from RFID reader antennas used in Libraries is then studied. An RFID rectangular loop antenna operating at 13 MHz is designed and fabricated. The designed antenna is simulated on HFSS using finite element method (FEM) then the simulations are compared to the real measurements of the magnetic field near the antenna using the designed probe.

2. Probe Design

2.1. Magnetic field Sensors Theory

Electromagnetic field is a combination of two types of quantities: electric and magnetic fields. In the near-field regions they should be both measured since they are not related to each other as in the far-field region. So we have six field components three for each field, each one should be measured separately. In this work we will focus in the magnetic field measurement. Magnetic field passing through a loop generates a voltage across its terminals according to Faraday's law, which states that the induced voltage is proportional to the rate of change of magnetic flux through a circuit loop:

$$V_{emf} = -\frac{d\phi}{dt} = -\frac{d}{dt}\iint \vec{B}.d\vec{S} \tag{1}$$

Each single loop is capable to measure one component of magnetic field. For total magnetic field distribution three orthogonal components $\boldsymbol{H_x}$, $\boldsymbol{H_y}$, and $\boldsymbol{H_z}$ must be measured. The overall magnetic field $\boldsymbol{H_t}$ can be determined from the root sum square of these quantities:

$$H_t = \sqrt{H_x^{\,2} + H_y^{\,2} + H_z^{\,2}} \tag{2}$$

2.2. Design Probe

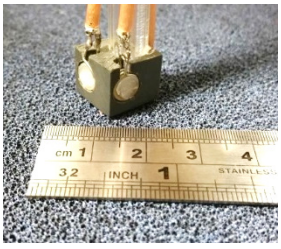

Fig. 1. 3D H-field Probe

The designed 3D ***H***-field probe consists of three orthogonal identical loops combined in a 1×1.2×1.3cm^3 plastic cube having their centers at the same plane (Fig. 1). Each loop has 3 turns with radius of 3mm. The terminals of each loop are connected to the channels of the Teledyne LeCroy oscilloscope (which also measures the frequency domain as a spectrum analyzer) through a coaxial cable. The difference between the loop centers was taken into account in post processing. The whole loop structure is attached to the robot arm in the scanning system.

2.3. Probe Calibration

Calibration is a process done to find the probe performance factor which is the antenna factor (AF). It is like a transfer function between the measured voltage across the loop and the magnetic field in the scanned geometry. The calibration of electromagnetic field probes needs to generate a reference field which intensity and spatial configuration are known with good accuracy inside a certain volume where the calibrated probe is placed.

Several probe calibration techniques are available nowadays. Transverse Electromagnetic (TEM) cells [9], waveguides, and also a 50 ohm simple microstrip line can be used.

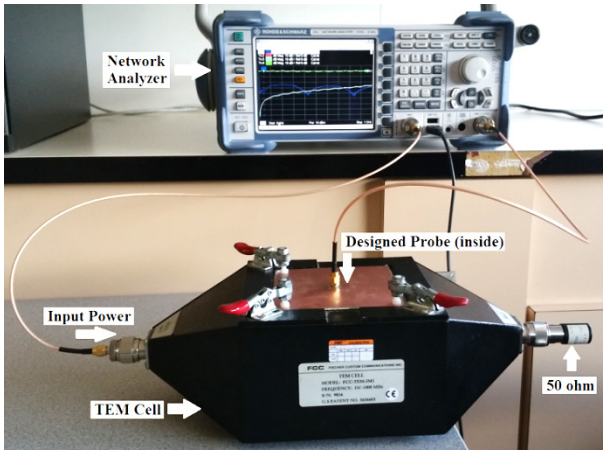

Fig. 2. Calibration Setup

In this work FCC-TEM-JM1 cell was used to produce calculable electric and magnetic field strengths. It operates in the transverse electromagnetic mode, so that both the ***E*** and ***H***-field components generated between the septum and outer conductor have the characteristics of a wave propagating in free space. The field strength can be calculated from the dimensions of the cell, its impedance at the measurement plane and the input power as shown in the equations below:

$$E[V/\mathrm{m}] = \frac{\sqrt{2.Z_c.P_{in}[\mathrm{watt}]}}{h[m]} \tag{3}$$

$$H[A/m] = \frac{E[V/m]}{\eta[\Omega]} \tag{4}$$

Where Z_c is the input impedance of the measuring instrument in ohms

P_{in} is the input power in watts

h is the distance in meters between the septum and the outer conductor of the TEM cell

η is the intrinsic impedance of the free space in ohms

$$\eta = \sqrt{\frac{\mu_0}{\varepsilon_0}} \tag{5}$$

The antenna factor then can be calculated by placing the probe inside the TEM cell and measuring the induced voltage $V_{ind.}$ across the loop terminals, according to the following equation:

$$AF[\mathrm{dB}\frac{A/m}{V}] = 20\log\left(\frac{H[\mathrm{A/m}]}{V_{ind.}[V]}\right) \tag{6}$$

Where $V_{ind.}$ is the induced voltage in the loop (in volts) and it is given by:

$$V_{ind.} = \sqrt{2.Z_c.|S_{21}|^2.P_{in}[watt]}.e^{j.\arg(S_{21})} \tag{7}$$

The AF of each loop in the proposed probe is shown in Fig.3 for a frequency range of [10MHz – 1GHz] along with the AF factor of a single loop.

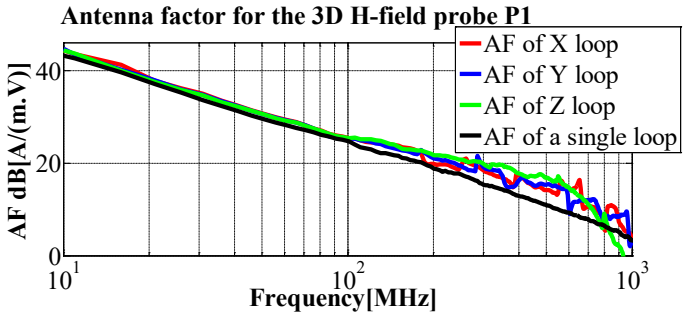

Fig. 3. Measured antenna factor versus frequency for the designed probe

The antenna factor varies from 44 dB(A/m.V) for low frequencies and up to 5 dB(A/m.V) at 1 GHz. Compared to the single loop AF, the antenna factor of each loop in the 3D probe has fluctuations above 200MHz . These are due to the coupling between the individual loops in the 3D probe. This factor is important to know the level of the field above the DUT when using the probe in the near-field measurement system.

3. Scanning System Validation

The 3D scanning system consists of a scanning robot, Teledyne LeCroy WaveRunner 640Zi oscilloscope, PC and the designed 3D H-field probe (Fig.4). The scanning robot is connected with the oscilloscope to the PC. The PC is programmed to control the movement of the robot and the data collection from the spectrum analyzer. The plastic arm of the robot holds the probe above the DUT. The movement of the robot arm can be precisely adjusted to 0.1mm/step by a 3D movable controller system. The output of the probe is connected to the 3 channels of the oscilloscope using coaxial cables. Since there is no preamplifier, the noise floor of the spectrum analyzer limits the measurements to frequencies above 10MHz.

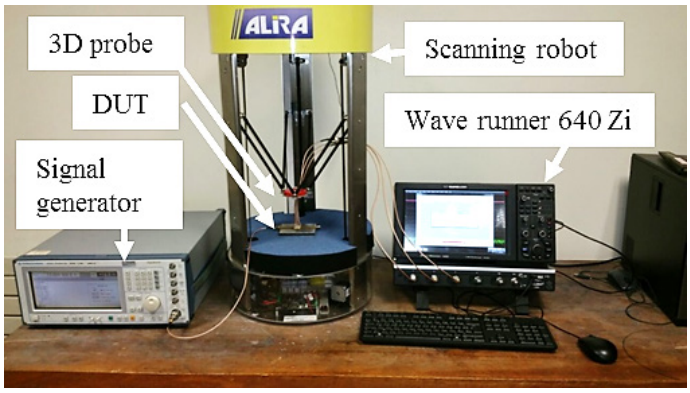

Fig. 4. Measurement System Setup

To validate the test bench, the magnetic near-field of a simple passive circuit used as DUT is measured and then the experimental results are compared to theoretical ones. The electromagnetic field components, depends on the geometrical parameters (Fig. 6) and the injected power of the DUT. A standard circuit that is consisting of a cylindrical conductor above a ground plane is used as the DUT. The DUT is terminated by 50 ohm load at one end and excited by a power of 16dBm by a signal generator at the other end (Fig. 5).

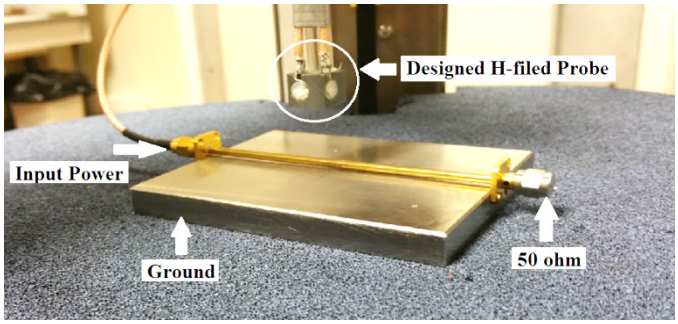

Fig. 5. Standard Validation Circuit

The magnetic field was computed using the expressions of the transverse electric and magnetic field components that are obtained by electrostatic calculation with the use of image theory [10]:

$$E_y = 8K\frac{yzn}{(y^2+(z+n)^2)(y^2+(\mathrm{z-n})^2)} \tag{8}$$

$$E_z = 4K\frac{n(y^2-z^2+n^2)}{(y^2+(z+n)^2)(y^2+(\mathrm{z-n})^2)} \tag{9}$$

$$H_y = -\frac{1}{\eta}E_z \tag{10}$$

$$H_z = \frac{1}{\eta}E_y \tag{11}$$

Where, $n = \sqrt{h^2-a^2}$ and $K = \dfrac{\sqrt{2PZ_c}}{\ln\left(\dfrac{h+n}{h-n}\right)}$

The propagating waves along the cylindrical conductor in the above circuit (Fig. 5) are characterized by a quasi-TEM mode. So we will only measure the transverse components of the magnetic field ($\boldsymbol{H_y}$ and $\boldsymbol{H_z}$).

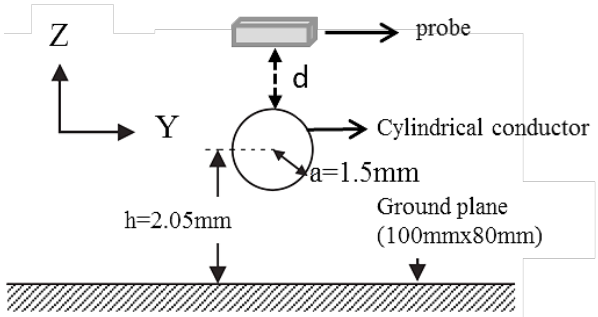

Fig. 6. Geometrical dimensions for the validation circuit

The ***z-axis*** is normal to the scanned plane, and the probe moves in the ***x*** and ***y*** directions measuring the magnetic field radiation from the DUT. Measurements were done at four different highs (4, 6, 8, and 10mm), and the scan was along ***y-axis*** with a step of 1mm. The computed theoretical field values are compared with the measured ones and they are presented in Fig. 7 and Fig. 8.

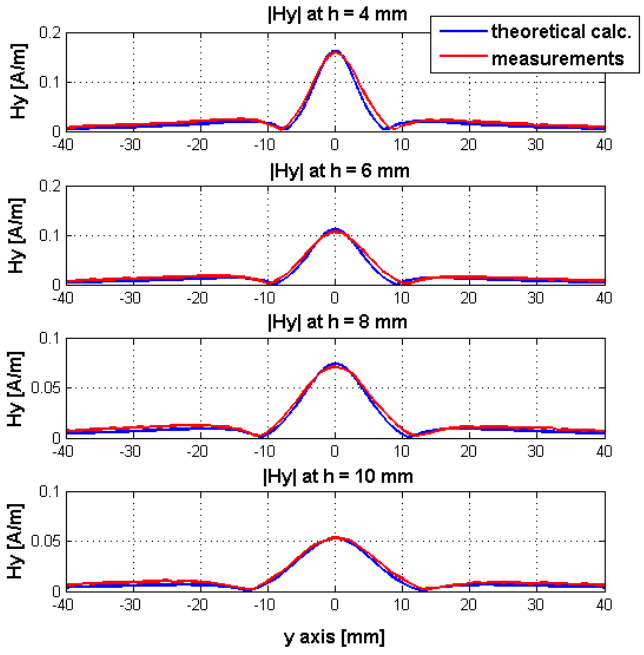

Fig. 7. Tangential H-field component H_y

Fig. 7 shows the tangential magnetic field component $\boldsymbol{H_y}$, while Fig. 8 shows the normal one $\boldsymbol{H_z}$. The comparison shows that the field measurements are in good agreement with the theoretical calculations for the 3D probe. Also good spatial resolution is obtained for the probes in measuring the magnetic field components.

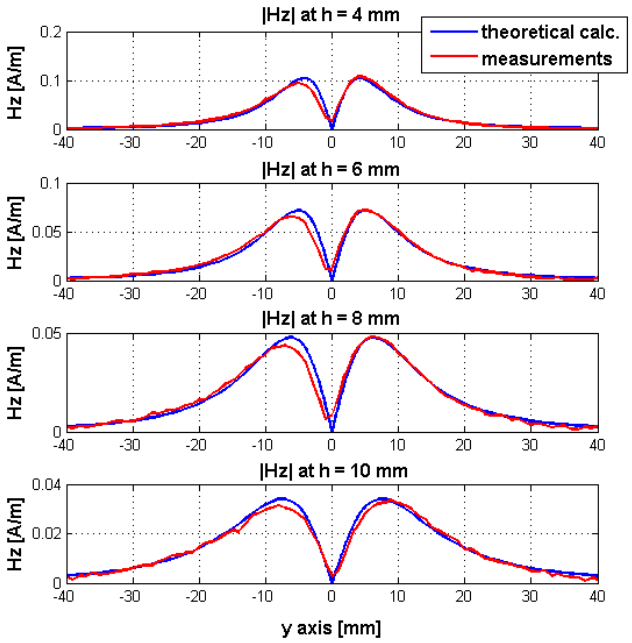

Fig. 8. Normal H-field component H_z

4. RFID System Characterization

4.1. RFID Loop Antennas

Most of the RFID readers are designed with loop antennas. Loop antennas feature simplicity, low cost and versatility. They are made of a loop of a conductor that may have various shapes: circular, triangular, square, elliptical, etc. They are widely used in communication links up to the microwave bands (up to 3GHz). They are also used as electromagnetic field probes.

Loop antennas are usually classified as electrically small and electrically large antennas. Electrically small loop antennas are those who have their circumference less than tenth of the wavelength ($C < 0.1\lambda$), while in electrically large antennas the circumference is near the wavelength ($C \approx \lambda$). Small loops are equivalent to a magnetic dipole and they have a far-field pattern very similar to that of a small electric dipole normal to the plane of the loop [11].

4.2. Designed RFID Antenna

In this paper, a rectangular small loop antenna operating at 13 MHz is designed. It is the typical RFID reader antenna used in library RFID systems. First the RFID reader antenna was designed and simulated using HFSS; it consists of 1-turn rectangular loop and a matching network. The rectangular loop has the dimensions of 140mm×140mm with a line width of 5mm.

The loop antenna has inductive input impedance; hence a parallel RC circuit should be used as a matching circuit. An impedance matching circuit was designed using surface mounted device (SMD) lumped elements to match the antenna to the 50Ω feed line at the operating frequency. Fig. 9 shows the corresponding circuit of the designed loop antenna, and Fig. 10 shows the 3D far field pattern where the loop lies in ***xy*** plane.

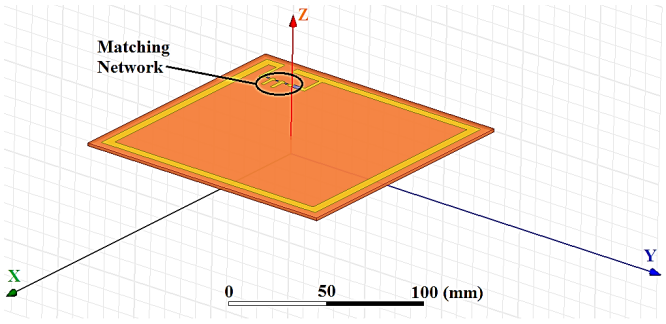

Fig. 9: Simulated RFID rectangular loop antenna

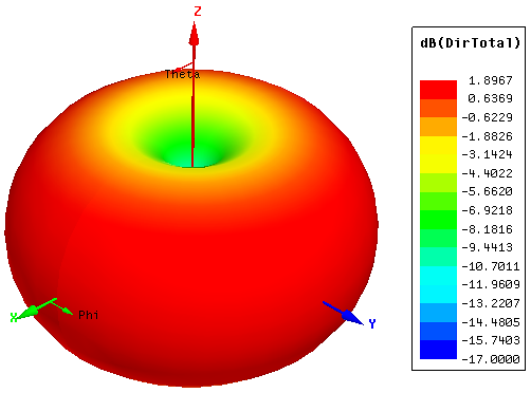

Fig. 10: 3D far field pattern of the designed antenna

The antenna prototype is then fabricated on a dielectric substrate FR4 with the dimensions of 150mm×150mm and 1.6mm thickness as shown in Fig. 11. The dimensions of the square loop are 140mm×140mm, and the width of the copper trace is 5mm.

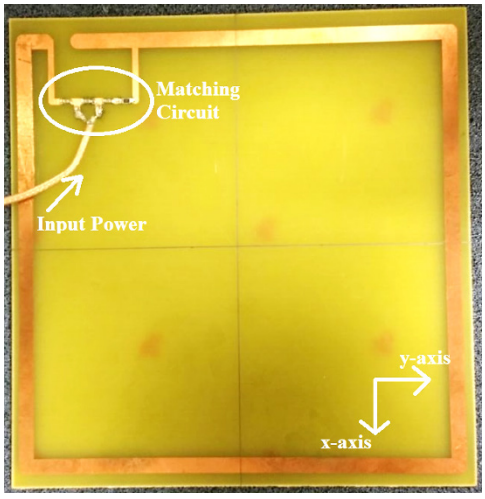

Fig. 11: Fabricated RFID loop antenna

The reflection coefficient measurement in Fig. 12 shows that the antenna resonant frequency is exactly at 13MHz. The measured reflection coefficient of the antenna is in good agreement with the simulation.

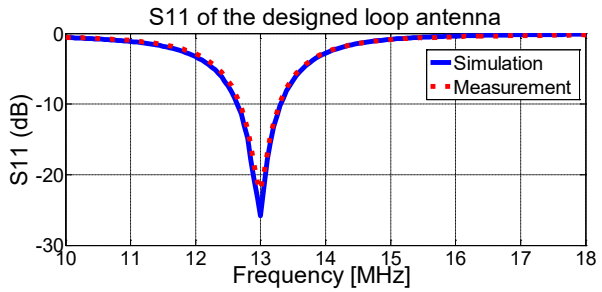

Fig. 12: Reflection coefficient of the designed RFID loop antenna

4.3. Characterization of the Designed RFID Antenna

The RFID antenna was excited with a ***CW*** signal having a source power of 10dBm, which is a typical power supply value for the RFID readers used in libraries applications [12]. The field mapping was done along ***y-axis*** and at two different heights (h=1cm & h=5cm) above the RFID reader loop antenna. These heights were chosen since they are the typical heights for the human exposure to library RFID systems. Then the measured magnetic field is compared with the simulated values and compared with ICNIRP guidelines for exposure limitations [13].

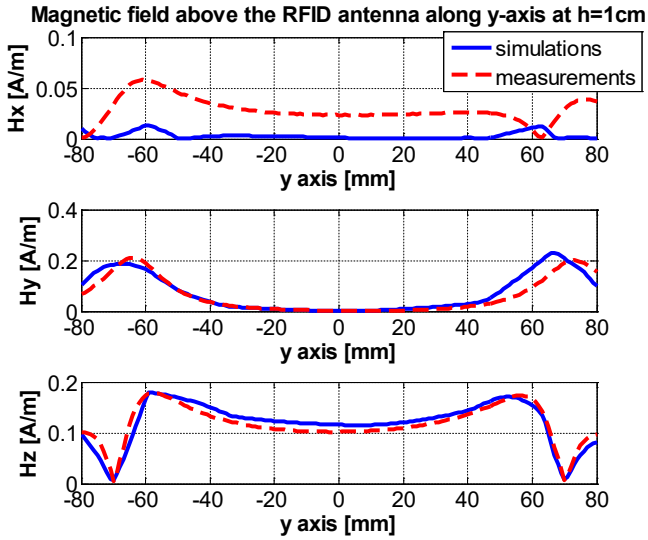

Fig. 13: Magnetic field strength above the RFID reader antenna along y-axis at height h=1cm

The magnetic field strength of the three components ($\boldsymbol{H_x}$, $\boldsymbol{H_y}$, and $\boldsymbol{H_z}$) at the two different heights above the RFID reader antenna is shown in figures Fig. 13 and Fig. 14. The simulation values obtained with HFSS are in good agreement with the measured ones, except the $\boldsymbol{H_x}$ component. This mismatch is due to the low level of $\boldsymbol{H_x}$ field if compared to the other components, so the coupling effect on the ***x*** component loop in the 3D probe is too high in this case. At h=1cm the $\boldsymbol{H_y}$ component has a maximum level of 0.2A/m while $\boldsymbol{H_z}$ has a maximum level of 0.18A/m where $\boldsymbol{H_x}$ has a level below 0.06A/m. At h=5cm the $\boldsymbol{H_y}$ component has a maximum level of 0.04A/m while $\boldsymbol{H_z}$ has a maximum level of 0.07A/m where $\boldsymbol{H_x}$ has a level below 0.02A/m.

At our operating frequency the reference level in the Guidelines is 0.2μT, which is equal to 0.16A/m in free space. This limit value refers to full body exposure for 6 minutes period. Considering the RFID reader used in library systems, there is a partial body exposure and the exposure lasts just for few seconds. So the obtained values at h=1cm which are little bit above the allowed ones (0.04A/m for $\boldsymbol{H_y}$ and 0.02A/m for $\boldsymbol{H_z}$) in the Guidelines are acceptable for this application. Moreover, the RFID reader antenna in Library systems is placed under a table so there is about 2cm between the antenna and the table surface.

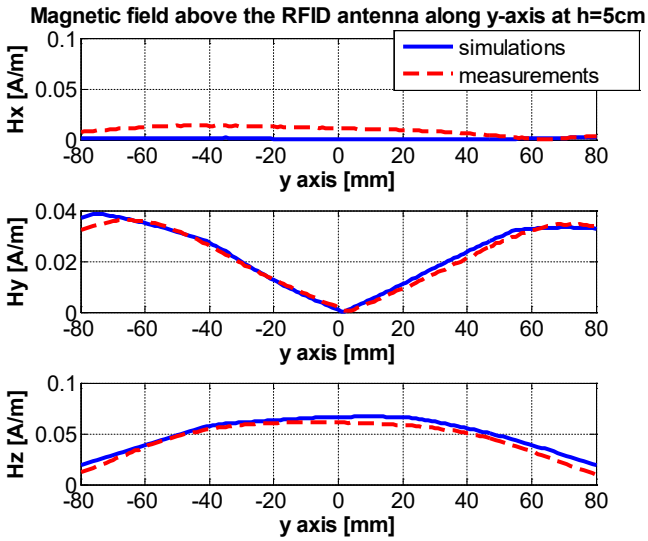

Fig. 14: Magnetic field strength above the RFID reader antenna along y-axis at height h=5cm

5. Conclusion

In this paper we have presented a near-field measurement system with a new 3D magnetic field probe design. The system consists of a 3D magnetic field probe, 3D scanning robot, and a digital oscilloscope. The designed probe was calibrated using a TEM cell, and the antenna factor between 10 MHz and 1 GHz was presented. The system was validated using a wire over a ground plane loaded with 50 ohm impedance. Good results were obtained for the used probe in measuring the magnetic field in the near region. Then an RFID reader loop antenna, used in Library RFID systems, was simulated and designed. The magnetic field strength near the designed antenna is then measured with the designed probe and analyzed. The simulations obtained with HFSS and the measurement results were compared to the action levels stated in ICNIRP Electromagnetic Fields Guidelines.

ABSTRACT

Nowadays, compliant micro-motion stages offer high positioning accuracy and repeatability. When assembled with conventional stages, the resulting dual-range positioning systems allow for nanometer scale accuracy within a centimeter scale working area. However, such systems invoke a high cost and large footprint. This paper presents a low-cost, compact compliant XY micro-motion stage where dual-range manipulation has been implemented in an effort to maintain the workspace area and increase the positioning accuracy. The method presented in this work employs the use of a large range/low resolution linear encoder to measure the position of the stage (coarse positioning), before using short range/high resolution capacitive sensors to correct the positioning error (fine positioning). This solution achieves a positioning accuracy close to 1μm within a workspace of ±2.2mm×2.2mm. The compliant stage has been machined from Aluminum 7075-T6 using Wire Electric Discharge Machining (WEDM). This material is well known for its large reversible strain and its suitability for compliant mechanisms.

1. Introduction

Due to advantages such as compactness, cost reduction and enhanced performance, compliant XY motion stages are promising alternatives to conventional linear stages. They have a wide range of applications, such as fibre alignment, semi-conductor positioning, scanners for an Atomic Force Microscope (AFM) and micro-assembly. Their inclusion in micro-motion applications has allowed for accuracy and repeatability values in the nanometre scale. Compliant stages have been reported to have no backlash; no friction; no noise emission and no need for lubrication. However, they also have several disadvantages such as non-linear behaviour and limited working area. A multitude of compliant XY motion stages have been reported in the literature [1-10], with a range of motion from $105 \times 105\mu m^2$ to $25 \times 25mm^2$ and a positioning accuracy from 10μm down to a few nanometres. Combining high accuracy and large workspace implies expensive metrology such as ultra-high resolution/large range sensors and actuators. The aim of this work is to use the concept of dual-range manipulation to achieve a positioning accuracy of a few micrometres within a workspace of a few millimetres, while keeping the cost as low as possible.

The concept of dual-range manipulation is to use two sets of actuators and/or sensors within the same system. The first set allows for positioning in a large workspace but has a low positioning accuracy. The second set covers a smaller workspace, just enough to compensate the positioning error of the coarse mechanism and has a high positioning accuracy.

The main advantage of dual-range manipulation is the cost reduction. It also avoids the need for complex calibration, tight manufacturing and assembly tolerances.

Most conventional dual-range micro-motion stages simply consist of two stages serially connected, simplifying their design and assembly. Some stages can achieve a very high absolute positioning accuracy over a large range of motion by using ultra-high resolution/large range sensors such as laser interferometers. However, this implies a high cost and often a large foot print. For instance, the stage designed in [11] consists of a piezo (PZT) actuated stage mounted on the top of a DC motor driven stage, resulting in a $300\times300mm^2$ workspace and a positioning accuracy of ±10nm. A 3-DOF stage was designed in [12] using linear motors for the coarse positioning and voice coil actuators (VCAs) for the fine positioning. The system has a workspace of $500\times500mm^2$ and can achieve nanometre scale accuracy, with a repeatability of 50nm. The positioning stage developed in [13] combines a 2-DOF coarse positioning stage driven by linear motors and a 6-DOF fine positioning stage driven by VCAs and magnetic bearings. The stage has a $300\times300mm^2$ workspace with an accuracy of 10nm and 15nm along the X and Y axes, respectively. The 3-DOF stage from [14] combines two linear motors and four PZT actuators, giving it a working range of $200\times200mm^2$ working range and an accuracy of 13nm. The stage designed in [15] also combines VCAs and PZT actuators. It can achieve an accuracy of ±20nm within a

*Corresponding Author: Xavier Herpe, School of Engineering and Physical Sciences, Heriot-Watt University, Edinburgh, UK | Email: xh28@hw.ac.uk

workspace of 25×25mm^2. Another 1-DOF stage was developed in [16] using a linear motor for the coarse motion and a VCA for the fine motion. The positioning accuracy achieved was 10nm within the working range of 300mm.

The high cost, high accuracy and large workspace of these stages are not justified for miniaturised product assembly applications. In addition, stacking two stages on the top of each other increases the moving mass and therefore slows the dynamic response

Other stages use high resolution/short range sensors such as capacitive sensors for the fine positioning. This solution involves cheaper equipment but allows for the same positioning accuracy. However, positioning is relative to the current coarse position of the stage. For instance, the 2-DOF stage developed in [17] consists of a PZT actuated stage mounted on top of a DC motor and a lead screw driven stage. It can reach sub-micrometre accuracy using capacitive sensors and has a workspace of 200×100mm^2. The 1-DOF stage designed in [18] uses a VCA for the coarse positioning and a PZT actuator for the fine positioning. The high resolution linear encoder used allows for a positioning accuracy of 20nm within a workspace of 80mm.

In some cases, the dual-range manipulation is carried out using a single compliant stage in which two sets of actuators and/or sensors are integrated. For instance, the 1-DOF stage developed in [19] consists of a PZT actuator directly mounted on a VCA with a positioning accuracy in the nanometer scale. For each direction of motion, the XY motion stage designed in [20] uses one PZT actuator connected between the base and a lever mechanism to amplify the motion and a second one connected between the lever mechanism and the stage for the fine positioning. The positioning accuracy achieved is 10nm but the workspace is only 119.7×121.4µm^2. Another compliant dual-range XY motion stage designed in [21] uses only two VCAs and two sets of strain gauges, one for the coarse positioning and one for the fine positioning. The resolution of the coarse motion is 8.52µm for a range of -1.94mm to 2.47mm; while it is 1.63µm for the fine motion in the range of -0.22mm to 0.31mm. The advantage of this solution is that once the stage has been calibrated, both coarse and fine positioning are absolute. However, the fine positioning mode cannot be used for the whole workspace.

This paper presents the design and testing of a dual-range micro-motion XY motion stage based on our previous work from [22, 23]. A novel coarse/fine positioning concept is used to achieve low cost high accuracy positioning. Firstly, the force-displacement characteristics of the stage are defined using Finite Element Analysis (FEA). The fabricated stage is then evaluated and the results are compared with FEA. Finally, the dual-range positioning system including the compliant stage is designed, fabricated and test results are presented. Unlike most of the available dual-range stages, this system uses the same actuator for both coarse and fine positioning in a parallel setup, resulting in a reduced cost, a reduced footprint and a faster response. This concept can be used for systems with larger workspace and with different types of sensor and actuator, so that the right cost/accuracy balance can be achieved.

Parameters	E (MPa)	σ_{max} (MPa)	P (kg/m3)	N
Values	71700	505	2810	0.33

2. Compliant XY Motion Stage Design

The structure of the compliant XY motion stage presented in this paper is based upon the stage designed in [22] and implemented in [23]. The dimensions of the beams are chosen to be 45mm in length to increase the range of motion, 6 mm in height to maintain a high stiffness along the Z-axis and 0.5mm in thickness to limit the force input requirement. As with most of the compliant stages reported in the literature, this stage is made of aluminium 7075-T6. This material is well known for its large reversible strain. In order to reduce the stress concentration, corners of 0.5mm radius have been added at both ends of the beams.

2.1. Force-displacement analysis

In order to size the actuators and define the travel range of the stage, FEA is carried out using ABAQUS.

Firstly, a buckling analysis is carried out, where the buckling point of the beams will determine the travel range of the stage. For short beams, the force required to cause buckling is often much higher than the force required to reach the material's yield strength. However, for longer or thinner beams, buckling can occur before the yield strength is reached. In the present case, buckling occurs at the inner beams (Fig. 1) when the stress at the centre increases suddenly and the difference between the input and the output displacement of the stage increases significantly. From Fig. 2, the buckling point is estimated to occur when the input displacement is around 4.05mm, corresponding to an input force of 351.3N.

To continue, a stress/strain analysis is carried out. An input displacement is gradually applied on one side of the stage until the yield strength of the material is reached. The output displacement, the maximum stress and the reaction force are recorded. In this case, the yield strength of 505MPa is attained when the input displacement is 3.24mm, corresponding to a reaction force of 208.1N. The yield strength of Aluminium 7075-T6 is therefore the main limit to the travel range of the stage. To ensure a long fatigue life and to limit the force input requirement, the travel range of the final design is limited to ±2.2mm × 2.2mm. This corresponds to an input force of approximately 70N.

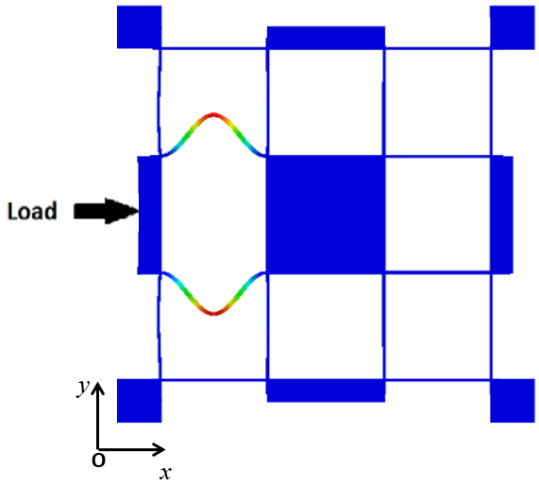

Fig. 1. Buckling point when a load is applied along X

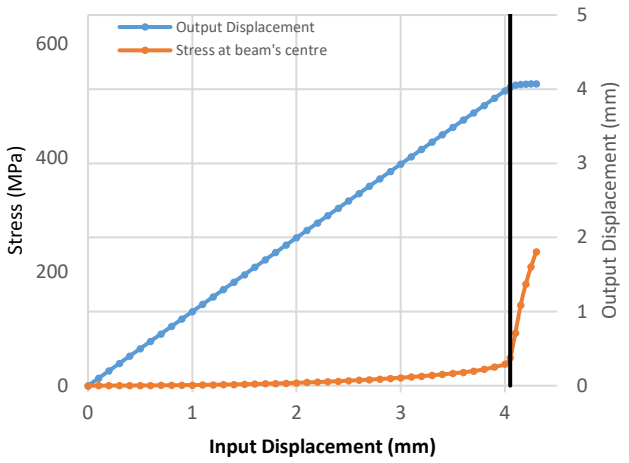

Fig. 2. Stress and output displacement response to a large input displacement

The output displacement is also compared with the input displacement. The axial deformation of the inner parallelogram beams causes the output displacement to be slightly different from the input displacement. The results show that for an input displacement between 0 and 2.2mm, the difference between the input and the output displacement can reach 5µm.

2.2. Coupling analysis

It is desirable for a compliant stage to have a minimal cross-coupling between the axes of motion. An analysis is therefore carried out to evaluate the parasitic displacement along the Y direction when a load is applied in the X direction. An input displacement of 2.2mm is first applied along the Y direction, as presented in Fig. 3. The maximum parasitic displacement is 65µm (Fig. 4), corresponding to a coupling of 3%. An input displacement of 2.2mm is then gradually applied along the X direction. The results show that the maximum displacement error along Y is 67µm (Fig. 5).

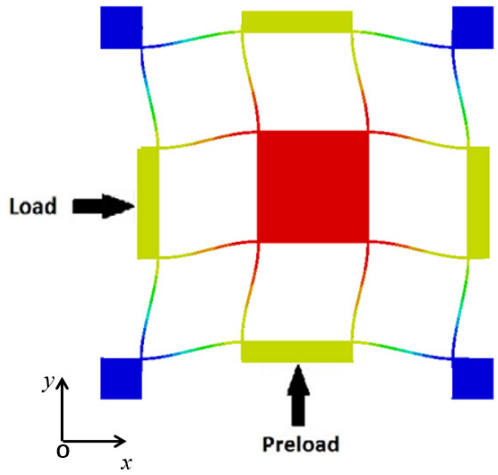

Fig. 3. Deformed XY motion stage with input displacement applied along X and Y directions

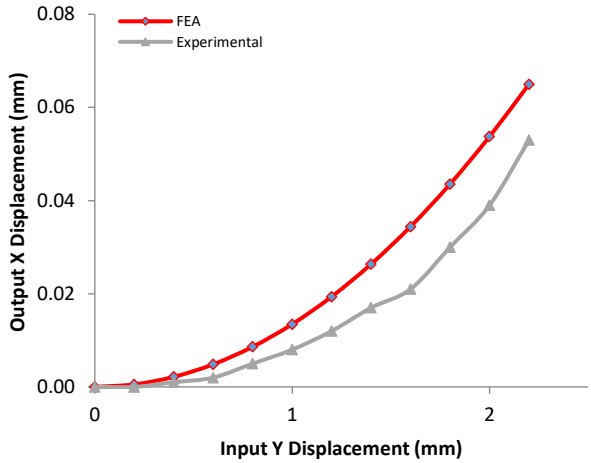

Fig. 4. Measurements of the parasitic displacement for single direction loading

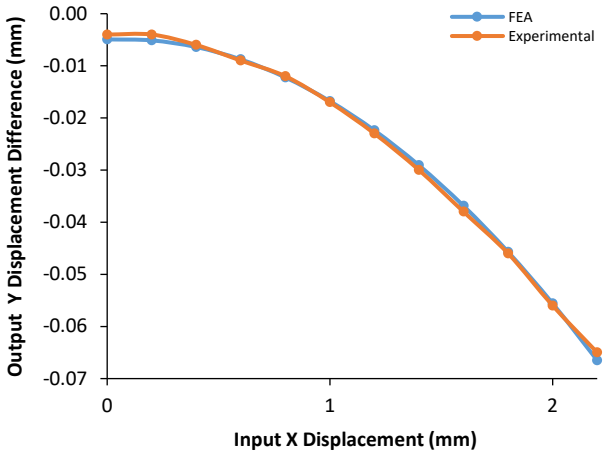

Fig. 5. Coupling error between X and Y

2.3. Dynamic analysis

In order to limit the effect of external vibrations, the first natural frequency of the compliant stage must be kept as high as possible. A high ratio between the first two natural frequencies and the third natural frequency is also desirable as it guarantees that the stiffness along the two directions of motion is much lower than the stiffness along all other directions, thus avoiding unwanted motion. The stiffness ratio of compliant stages usually lies between 2 and 5 [4, 5, 10, 24-26]. A dynamic analysis of the stage is carried out with ABAQUS using the Lanczos Eigen solver (Fig. 6). The first two modes correspond to simultaneous vibrations along both the X and Y-axes, which occurs at 55.8Hz. The third mode, corresponding to a rotation around the Z-axis occurs at 249.5Hz. Finally, the fourth mode, corresponding to vibrations along the Z axis occurs at a frequency of 313.3Hz. The ratio between the first two natural frequencies and the third one is greater than 4.

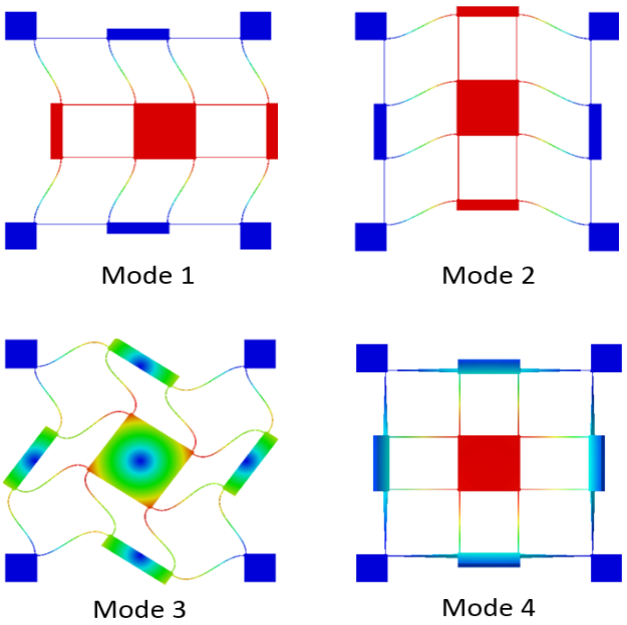

Fig. 6. Modal analysis results from FEA

3. Compliant XY Micro-motion Stage Fabrication and Testing

Most of the compliant stages reported in the literature are fabricated using Wire Electric Discharge Machining (WEDM). This technique allows for tight tolerances and a smooth surface finish. However, it is costly. Laser cutting and CNC machining were also considered but these processes are not suitable for machining 0.5mm thick beams. The first one would melt the beams and the second one would bend the beams because of the cutting force applied. The stage was fabricated using (Fig. 7). Corners of 0.5mm radius have been added to reduce the stress concentration. The stage is driven by two VCAs from Moticont (LVCM-051-064-02) with a 12.7mm stroke, 68.2N continuous force and a force constant of 21.6N/A. The moving coils are guided using high accuracy preloaded miniatures guides from SKF (LZMHS12-37T2P1). The VCAs are controlled by two Ingenia Pluto Drives, allowing for a position command resolution of 1.07µm over ±2.2mm along both directions using a 12-bit Analogue to Digital converter (ADC). The displacement of the actuators is measured using two linear encoders from Renishaw (ATOM4T0-150) with a resolution of 100nm.

3.1. Force-displacement test

A test is carried out to establish the relationship between the input displacement and the reaction force. The input displacement along the X-axis it maintained at 0mm while it is varied from 0mm to 2mm along the Y-axis. The linear encoders are used to measure the position of the VCAs. As the servo drives include a built-in current sensor, the force is derived from the current using the VCA's force constant. The results are shown in Fig. 8. The force error of the first few readings is due to the internal friction in the bearings and can be neglected. The maximum force error, occurring at 2mm, is 11.1% when compared with FEA.

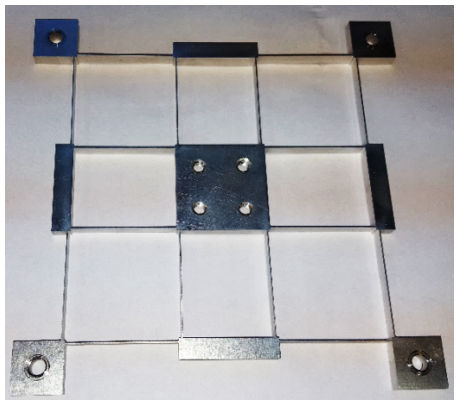

Fig. 7. Fabricated compliant XY micro-motion stage

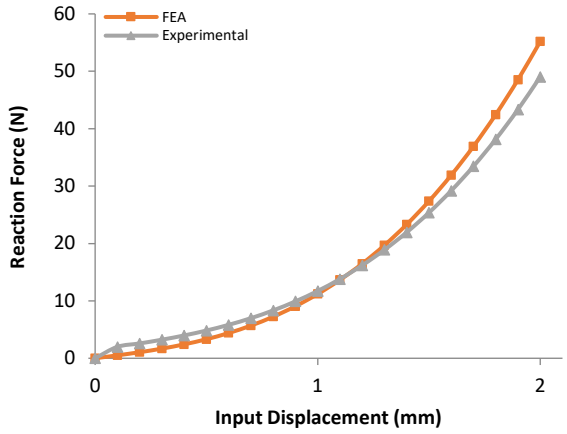

Fig. 8. Stiffness along a single direction

3.2. Frequency response analysis

In order to obtain the frequency response of the XY motion stage, a testing rig is set up to allow the stage to vibrate freely. An impulse is used to generate free vibrations which are measured along the X, Y and Z axes using a 3-dimensional accelerometer (ICP-T356A16), placed at the centre of the stage. The sensitivity of the accelerometer is 100mV/G and its output signal is processed by a Dual Channel Accelerometer Amplifier (FE-376-IPF) and recorded using a National Instruments data acquisition card (6008) with a sampling rate of 10kHz.

Labview is used to obtain the frequency domain response of each direction of motion using the Fast Fourier Transform (FFT). The testing rig setup is presented in Fig. 9. A peak in amplitude in each spectrum corresponds to the natural frequency along the corresponding direction of motion. The results are then compared with FEA, taking into account the mass of the accelerometer. The recorded resonant frequencies are 47Hz along the X and Y-axes and 267Hz along the Z-axis. When compared with FEA, the corresponding errors are 15.8% along the X and Y-axes and 14.8% along the Z-axis respectively. This error can be due to the mounts applying a small preload in the beams when being screwed.

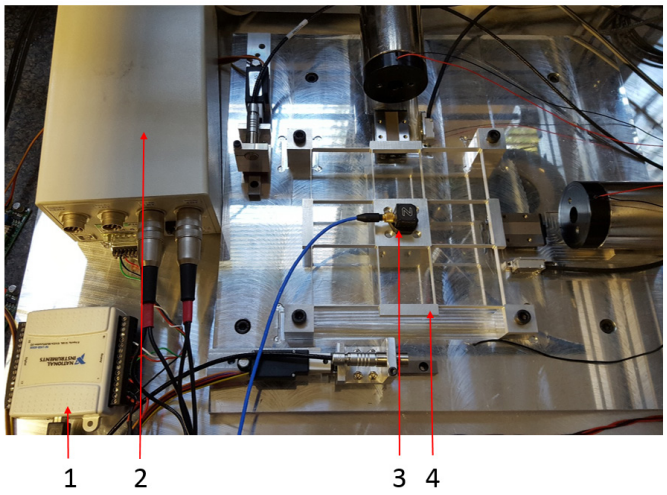

Fig. 9. Experimental vibration test setup. 1) Data acquisition card, 2) Amplifier, 3) 3D accelerometer, 4) Compliant XY motion stage

4. Dual-Range Positioning XY Micro-motion Stage

The assembled stage is presented in Fig. 10. It consists of a platform directly fixed to the centre of the compliant stage. Two small plates are mounted on the platform and are used as a target to measure the output displacement of the XY motion stage. The total moving mass is approximately 1kg.

4.1. Input Position Control

The input position control of the XY motion stage controls the linear displacement of the VCAs with a Proportion-Integral-Derivative (PID) loop using the two linear encoders as feedback. The output displacement (i.e. displacement of the moving platform) is measured with two capacitive sensor heads (CS1) from Micro-Epsilon with DT6110 controllers, giving a resolution of 100nm and a reading accuracy of 0.5µm over a range of 1mm. These sensors are mounted on a carrier and are moved along a guiding rail using two Firgelli L12-P micro linear actuators with a 10mm stroke and ±0.1mm repeatability.

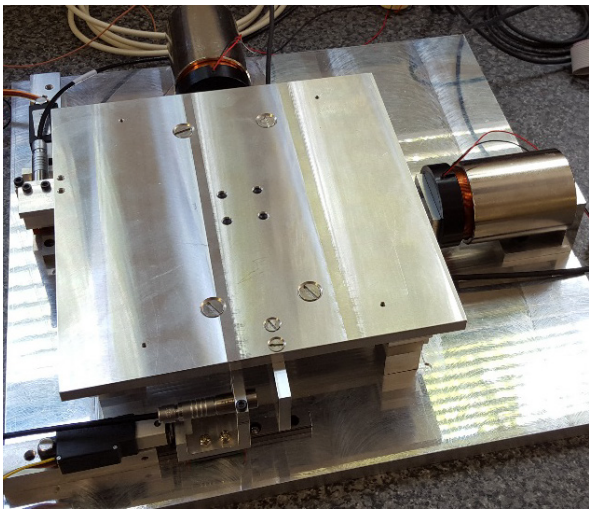

Fig. 10. Fabricated XY motion stage

The input displacements along the X and the Y directions are controlled with LABVIEW 2014 through the analogue outputs of a Labjack U6 Pro data acquisition card.

To begin with, a single direction displacement test is carried out over a range of 0mm to 2.2mm along Y. The results show that the difference between the input and the output displacement is 4µm and that the parasitic translation along the transverse direction is 53µm (Fig. 4), corresponding to a coupling of 2.4%.

A bi-directional loading test is then carried out. The input displacement of 2.2mm previously applied along the Y direction is maintained and an input displacement of 2.2mm is gradually applied along the X direction. The results are presented in Fig. 5. The first observation made is that the results are in accordance with FEA, where the maximum error is less than 3µm for 2.2mm input displacement. The second observation is that the maximum recorded parasitic displacement is 50µm.

4.2. Dual-range positioning

The observations made from the input position control test show that there is a coupling between the two axes of motion that cannot be predicted when moving the stage along both directions simultaneously. There is also a difference between the input and the output displacement of up to 14µm. To compensate for this positioning error, a set of high resolution sensors is added to the system in order to directly measure the output displacement of the stage. These sensors are mounted on a carrier and are moved along a guiding rail using two Firgelli L12-P micro linear actuators with a 10mm stroke and ±0.1mm repeatability. The dual-range positioning procedure for each direction of motion is as follow:

i. The stage is moved to its desired position in open-loop mode (coarse positioning)
ii. The high resolution sensors are moved close to the moving platform and the relative position is recorded and used as the initial position for the next step
iii. The positioning error is measured using an external system
iv. The stage is moved by the positioning error measured in closed-loop mode using the feedback from the high resolution sensors (fine positioning)

A second PID loop is added to control the output displacement of the stage using the readings from the high resolution sensors. The simplified plant model is presented in Fig. 11. The gains are tuned using the trial-and-error method and will be refined at a later stage if necessary.

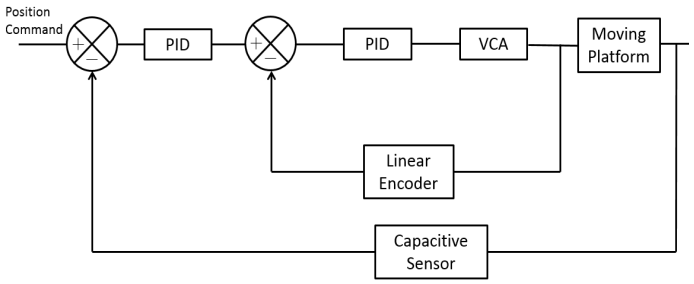

Fig. 11. Fine positioning control loop for the XY micro-motion stage

The external system used to measure the positioning error depends on the system in which the XY motion stage is integrated. This choice is up to the user. For instance, a high resolution vision system can be used to measure the position of the moving platform on which a calibration grid is placed. Alternatively, a coordinate measurement machine (CMM) was used in [23] to measure the positioning error.

Sensor selection

The choice of high resolution sensor is critical, however it involves a trade-off between the cost of the system and the measuring accuracy . Table 2 presents a qualitative analysis of the four types of sensors considered for this application based on quotations from RENISHAW®, KEYENCE Ltd. and MICRO-EPSILON Ltd. The most suitable solution in terms of this trade-off between cost and accuracy is the capacitive sensor. Therefore, the sensors used to measure the open-loop behaviour of the compliant stage are reused for the closed-loop control of the fine positioning, along with the linear actuators. The dual-range setup of the XY motion stage is presented in Fig. 12.

Testing

Since the capacitive sensors directly measure the position of the stage, they can be used to estimate the relative positioning accuracy. It is assumed that due to the nonlinear stiffness of the compliant stage, the force disturbance is higher for large displacements. Therefore, a test is carried out for an input displacement of 0mm along both directions and then for 2.2mm along both directions. The sensors' readings are recorded for a period of 20 seconds in fine positioning mode and the accuracy is estimated from the maximum amplitude of oscillation once the steady state is reached. Fig. 13 shows the steady state response along both directions for 0mm loading. It can be clearly seen that the maximum amplitude of oscillation is smaller than ±0.5µm, which is beyond the reading accuracy of the capacitive sensors. Fig. 14 shows the steady-state response for 2.2mm bidirectional loading. The amplitude of oscillation increases and reaches ±2µm. This oscillation is due to the nonlinearities arising from the compliant stage. Additionally, the resolution of the analogue to digital converter (ADC) used to read the position command sent by the data acquisition card is only 12-bits. This corresponds to an incremental position resolution of 1.12µm. Controllers with a higher resolution would allow for a higher positioning accuracy.

5. Conclusion

A compliant XY micro-motion stage made from Aluminium 7075-T6 was characterised and fabricated, with a travel range of ±2.2mm×2.2mm and a coupling of 2.4%. The simulation results in terms of working area and stiffness are in accordance with FEA. The maximum displacement error of the micro-motion stage measured in coarse positioning mode was 67µm. The concept of dual-range manipulation was therefore introduced using capacitive sensors for the fine positioning. The relative positioning accuracy was reduced to less than ±2µm in the worst-case scenario. This error can be reduced by using higher resolution motor controllers and sensors. Therefore, there is a great potential for compact, low-cost and high accuracy micro-motion using dual-range positioning. The stage will later be integrated in a hybrid miniaturised product assembly system.

ABSTRACT

Feature extraction is playing a significant role in bio-signal processing. Feature identification and selection has two approaches. The standard method is engineering handcraft which is based on user experience and application area. While the other approach is feature learning that based on making the system identify and select the best features suit the application. The idea behind feature learning is to avoid dealing with any feature extraction or reduction algorithms and to train the suggested model on learning features from input bio-signal by itself. In this paper, Self-Organizing Map (SOM) will be implemented as a feature learning technique to learn the model extract the features from the input data. Deep learning approach will be proposed by deploying SOM to learn features. In the proposed model, the raw data will be read then represented by using different signal representation as Spectrogram, Wavelet and Wavelet Packet.
The newly represented data will be fed to self-organizing map layer to generate features, and finally, the performance of the suggested scheme will be evaluated by applying different classifiers such as Support Vector Machine, Extreme Learning Machine, Evolutionally Extreme Learning Machine and Discriminate Analysis Classification. Analysis of Variance (ANOVA) and confidence interval for different classifiers will be calculated. As an improving step for the results, classifier fusion layer will be implemented to select the most accurate result for both training and testing set. Classifier fusion layer led to a promising training and testing accuracies.

1. Introduction

This paper is an extension of work originally presented in 2016 8th Cairo International Biomedical Engineering Conference (CIBEC) [1]. However, we will implement Self-Organizing Map as a feature learning technique after representing raw data by using different data representation techniques. Supervised learning is considered as highly limited technique despite being applied to various applications. Still, most of the applications require engineering handcraft extraction by using different algorithms. This means that the primary target is, to represent the data by using good feature representation. Whenever feature representation is good, classification error should be expected to be less.

However, engineering handcraft representation is still exhausting and time-consuming in addition to that, it depends on researcher experience. Many suggested feature learning techniques may be applied to enhance feature representation automatically and save time and effort. The chief governor on the performance of used feature learning technique is the classification error. The most approach for implementing feature learning belongs to deep learning concept. Deep learning started in 1986 when Rina Dechter presented the basics for first and second order deep learning [2]. Later, deep learning is considered as a branch of machine learning where, it depends on multilayer by implementing the algorithm, in each layer, to represent data. Each layer feature output should be the input to the next cascaded layer [3]. Each layer in deep learning is implemented by using a hidden layer of artificial neural networks [4], where features are being learned by using the artificial neurone as shown in fig 1 where a very simplified flow chart of deep learning steps. Deep learning learns features in a hierarchal concept. The learning is being processed layer by layer, and extracted notations are being learned from lower level layers [5]. Deep learning can be used in supervised learning by translating the data into useful representations and remove any redundancy in

*Marwa Farouk Ibrahim, 15 Broadway, Ultimo, NSW 2007, Australia, 0061405565739 & marwafaroukibrahim.ibrahim@student.uts.edu.au

representations or features. The significant advantage of deep learning is that it can be used in unsupervised learning, where data is unlabelled. Unlabelled data is more challenging than labelled one. Neural history compressors[6] and deep belief networks[7] are considered as an example for implementing deep learning for unsupervised learning.

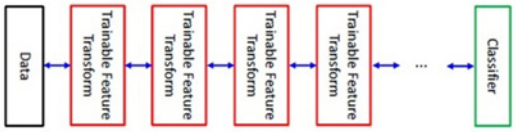

Fig.1. Deep Learning simplified steps

This paper is structured by giving a brief on previous work that was published in finger movement classification and deep learning implementation for the biomedical signal. Very simplified review on the self-organizing map and three bio signal representations (Spectrogram, Wavelet and Wavelet Packet) will be represented where, Discriminate Analysis, Support vector machine, Evolutional Extreme Learning Machine, and Extreme learning machine will be used as an evaluation step. Analysis of Variance (ANOVA) and confidence interval for different classifiers will be calculated. Finally, classifier fusion will be added to improve both training and testing accuracies.

2. Previous Work

In this paper, we will suggest a deep learning model that will be able to learn features by itself without utilising any feature extraction or reduction technique. The proposed model will be skilful in classifying between ten finger movements. Finger movement classification was presented previously in many types of research as in [8] where the researchers proposed a feature projection technique by implementing Fuzzy Neighbourhood Preserving Analysis (FNPA) with QR-decomposition. The primary purpose of Fuzzy Neighbourhood Preserving Analysis (FNPA) is to decrease the distance, to the maximum extent, between samples of the same class and increase it between samples of different classes. The researchers' purpose was to classify ten finger movements, and they verified average accuracy 91% by using only two channel electrodes. After that, other authors proposed a finger movement classification system. Where, they employed Spectral Regression Discriminant Analysis (SRDA) for dimensionality reduction, Extreme Learning Machine (ELM) for classification and smoothed the results by using majority voting method. They achieved classification accuracy 98% from two electromyography channels only [9]. Then the authors used the same data set collected by using two channel electrodes, which was considered a challenging task, to hire Spectral Regression Discriminate Analysis (SRDA) for dimensionality reduction, kernel-based Extreme Learning Machine (ELM) for classification and smoothed the results by using majority voting method [10]. Moreover, they applied Particle Swarm Optimization (PSO) to optimise the kernel based ELM. Later, other investigators suggested a model classifying between 9 finger movements (classes) by using two electrodes [11]. They implemented seven-time domain features and evaluated the system by applying Artificial Neural Network (ANN) and k- nearest neighbours (KNN) as classifiers. Other investigators suggested using Nonnegative Matrix

Factorization (NMF) technique to select accurate and dependable features. They employed neural networks for classification and calculated the accuracy for both simple and complex flexion where they achieved 95% for simple flexion and 87% for complex one [12]. After that other researchers suggested collecting surface electromyography signal using eight electrodes to classify between nine hand motions. They hired two different neural networks for classification. The first neural network architecture verified 83.43% accuracy while the second one achieved 91.85% [13]. Another experiment was published in [14] where the authors employed time-domain descriptors (TDD) to measure the power spectrum characteristics for electromyography signal which in turn reduced the computationally expensive feature construction traditional techniques. This suggested method improved the error percentage by 8% in comparison with other methods [14]. Another trial was published for recognising finger movements by using microneedle with average accuracy 94.9% [15]. On the other hand, many researchers claimed for implementing a general model that should be able to learn features by itself without employing any feature extraction and reduction techniques which led to deep learning clue. Many published experiments were done in hiring deep learning for biomedical data. As for example but not limited to, in [16] the authors developed a system by using an ensemble of convolutional neural networks to classify medical images. Convolutional neural networks were implemented for learning features by tunning and for classification as well. Other researchers suggested employing convolutional neural networks to learn features and developing low-level features only [17]. The authors in [18] developed a deep learning system to classify between different plaque constituents in Carotid Ultrasound. Later, the texture of lung pattern was analysed by implementing deep learning technique after employing convolutional neural networks [19]. Consequently, we can consider deep learning as a feature learning system where the system will extract the best features suit the application or in another word the system will learn features without employing any feature extraction or feature reduction algorithm. We will propose a deep learning model by engaging self-organising map in learning features from the represented bio signal. The bio signal will be represented using either spectrogram, wavelet or wavelet packet. We will evaluate the behaviour of our suggested model by hiring different classifiers as support vector machine, discriminant analysis, extreme learning machine and evolutionally extreme learning machine. Evolutionally extreme learning machine will lead to higher accuracy results than other implemented classifiers. Analysis of variance and confidence interval for different classifiers will be calculated as well. Finally, and as a development stage, classifier fusion layer will be added to select best local classifier. Accordingly, our proposed model will learn features by itself without hiring any feature extraction or reduction algorithm and verify well-accepted accuracy values. Moreover, implementing analysis of variance and confidence interval is considered as an in-depth step to understand the nature of the relation between our employed classifiers and to know our trustful range of accuracy results.

3. Self-Organizing Map

Self-Organizing Map is a typical artificial neural network which has two main characteristics. The first one is that it follows unsupervised learning technique to generate a lower dimensional copy of input training set. The new dimension of the data is typically two dimensions, and the new training set is called map. While the second characteristic is that it applies error correction by using back propagation technique or gradient descent and at the same time, keeps the properties for the input by using neighbourhood function [7]. Sometimes Self-Organizing Map is called Kohonen map in referring to Teuvo Kohonen who first invented it in 1980 [8]. Self-Organizing Map may represent the nonlinear version of principal component analysis [9]. The new two-dimensional data is considered as the features that will be used for classification steps. SOM is used in unsupervised learning. The network is being trained to generate features from the input data at the output instead of producing classes at the output. The input to the self-organizing map is the represented data either by spectrogram or wavelet or wavelet packet while the output is considered as the features. The classifier uses features produced from the self-organizing map as an input while; its output is the class equivalent to input data. Fig.2 shows the procedures of signal processing by using self-organizing map.

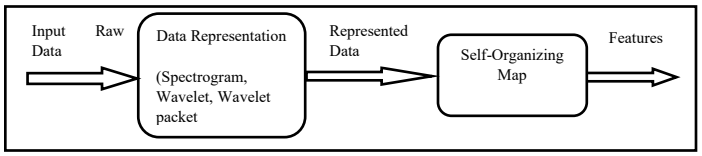

Fig.2. Procedures of SOM signal representation

Fig 3 shows the mapping of a point in the input space to its new point in the output space.

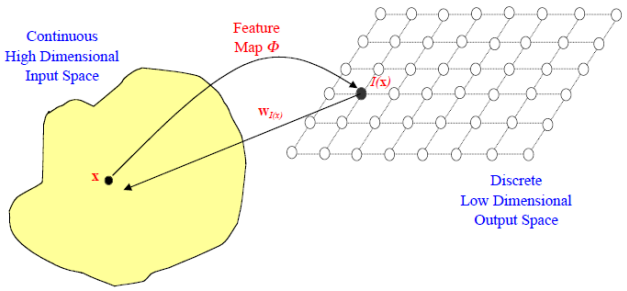

Fig.3. Mapping input space to output space in SOM

In this algorithm, the self-organizing map is being used to reduce the dimension of the data into lower and more useful representation. Consequently, self-organizing map enhances in extracting essential features or good representations of input data. So, the self-organizing map is in the context of feature learning where we have trained data. We will extract some features from training data then, apply the algorithm on the testing set and calculate the classification error.

4. Bio-Signal Processing

4.1. Bio Signal Representation

To improve the performance and to get lower classifier error, we suggest some signal representations can be done on the data before being introduced to the self-organizing map stage. The first data representation is to take the spectrogram of our input data. The spectrogram is to represent the spectrum of frequencies for our signal in a visual manner. Mathematically, Spectrogram can be calculated by taking the square of the magnitude of Short-Time Fourier Transform (STFT) or; it can be named short term Fourier transform. Short time Fourier transform is a Fourier-related transform, where it divides the long-time signal into shorter segments in time. These separated segments should be equal in length and then compute the frequency and phase for each segment separately. So, simply it is Fourier transform but for shorter segments than calculating it for the whole signal at one time[10]. The spectrogram output of the data is being trained by the self-organizing map to extract features then; these extracted features should be used in classification stage. Moreover, wavelet was applied as signal representation Wavelet is considered as small shifted and scaled partitions of the original signal. Fourier transform is representing the signal as a sinusoidal wave with different frequency while wavelet is representing the signal in the form of sharp changes. Wavelet allows us to capture better feature representation for abrupt changes in the signal. However, smooth representation by Fourier is useful in case of the smooth signal. We used Haar wavelet in our software. Fig.4 shows Fourier transform representation and wavelet representation. As a comparative study, we applied wavelet packet for the signal representation. We used six levels for sym10 at sampling frequency 2 kHz.

Fig.4. Fourier transforms representation and wavelet representation

4.2. Classifiers

We implemented four classification algorithms, where the first is Extreme Learning Machine (ELM), second is Discriminate Analysis (DA), third is Support Vector Machine (SVM), and the fourth is Self-Adaptive Evolutionary Extreme Learning Machine. We compared the accuracy for six different types of SVM (Linear SVM, Quad SVM, Cubic SVM, Fine Gauss SVM, Medium Gauss SVM and Coarse Gauss SVM) and picked up the most accurate result. Also, we compared Linear Discriminate Analysis (LDA) and Quadrature Discriminate Analysis (QDA) and selected the most accurate result. Fig.5 shows the suggested procedures for our implemented feature learning suggested model

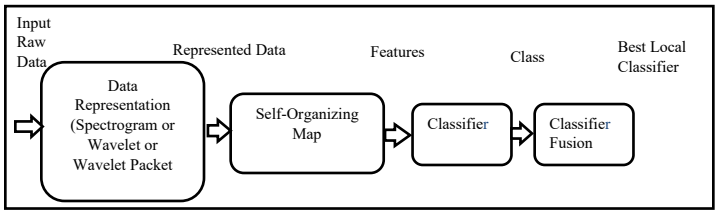

Fig.5. Procedures of Suggested Feature Learning Model

An extreme learning machine is being used in modelling complex systems either linear or nonlinear. The modelling algorithm uses gradient free fast convergence tool [20-23], for N observations $\{(x_i, t_i)\}^N$, where $x_i \in R^d$ and $t_i \in R^m$. ELM

chooses both the input weights and hidden biases in a random manner.

$$y_i = \sum_{j=1}^{L} \beta_j \, g(a_j . x_i + b_j) = t_i \quad , \; j = 1, \dots, N \qquad (1)$$

Where $a_j = [a_{j1}, a_{j2}, \dots, a_{jn}]^T \in R^d$ is the input weight, x_i is the input signal & $b_j = [a_{j1}, a_{j2}, \dots, a_{jn}]^T \in R \; (j = 1,2, \dots, L)$ is the bias. Those are the learning parameters of jth hidden node, $\beta_j = [\beta_{j1}, \beta_{j2}, \dots, \beta_{jn}]^T \in R^m$ is the output weight that relates output node and hidden node. Equation (1) can be simplified

$$H . \beta = T \qquad (2)$$

Where H is the hidden matrix and can be defined as

$$H = \begin{bmatrix} g(a_1 . x_1 + b_1) & \cdots & g(a_L . x_1 + b_L) \\ \vdots & \ddots & \vdots \\ g(a_1 . x_N + b_1) & \cdots & g(a_L . x_N + b_L) \end{bmatrix} \qquad (3)$$

So simply j th element of H represents the corresponding output vector of the jth hidden neuron with respect to ith input x_i , the values of H parameter is being selected in a random manner Subsequently, the estimate of the β_j^* , a_j^* , b_j^* parameters will be calculated using equation (4).

$$\|H(a_1^*, \dots, a_L^*, b_1^*, \dots, b_L^*)\beta^* - T\| = min_\beta \|H(a_1, \dots, a_L, b_1, \dots, b_L)\beta - T\| \qquad (4)$$

The cost function can be defined by the following equation

$$SSE = \sum_{i=1}^{N} \left[\sum_{j=1}^{L} \beta_j \, g(a_j . x_i + b_j) - t_i \right]^2 \qquad (5)$$

Where SSE is the sum square of error.

The least square solution of the $H . \beta = T$ can be determined as

$$\beta = H^{\dagger} T \qquad (6)$$

Where $H^{\dagger}$ is the Moore-Penrose generalized inverse of the hidden layer matrix H .

The self-adaptive evolutionary Extreme learning machine introduces the optimisation algorithm by applying differential evolutionary optimisation technique on objective function $f(\theta)$ by picking up a certain number of populations N_P and number of generation G until the targeted level of convergence obtained [24-28]. Where, the ith parameter can be defined as

$$\theta_{i,G} = \left[\theta_{i,G}{}^1, \theta_{i,G}{}^2, \dots, \theta_{i,G}{}^D \right] \; i = 1,2, \dots, N_P \qquad (7)$$

Where D is the described searching space.

The procedures of Differential Evolutionary can be defined as following

First, the cover parameter space should be initialized by using the following equation

$$\theta_{i,G} = \theta_{min} + rand(0,1) . (\theta_{max} - \theta_{min}) \qquad (8)$$

Where, θ_{min}& θ_{max} are the minimum and maximum boundaries respectively. The values of θ_{min}& θ_{max} are predetermined.

Second, generation of the new mutual vector by calculating difference vectors of randomly picked population vector. These can be calculated by one of four strategies

Strategy 1:

$$v_{i,G} = \theta_{r_1^i,G} + F . (\theta_{r_2^i,G} + \theta_{r_3^i,G}) \qquad (9)$$

Strategy 2:

$$v_{i,G} = \theta_{r_1^i,G} + F . \left(\theta_{best,G} - \theta_{r_1^i,G}\right) + F . \left(\theta_{r_2^i,G} - \theta_{r_3^i,G}\right) + F . (\theta_{r_4^i,G} - \theta_{r_5^i,G}) \qquad (10)$$

Strategy 3:

$$v_{i,G} = \theta_{r_1^i,G} + F . \left(\theta_{r_2^i,G} - \theta_{r_3^i,G}\right) + F . (\theta_{r_4^i,G} - \theta_{\mathrm{r_5^i,G}}) \qquad (11)$$

Strategy 4:

$$v_{i,G} = \theta_{i,G} + F . \left(\theta_{r_1^i,G} - \theta_{i,G}\right) + F . \left(\theta_{r_2^i,G} - \theta_{r_3^i,G}\right) \qquad (12)$$

Where r_1^i, r_2^i, r_3^i, r_4^i and r_5^i are mutually exclusive integers numbers which are randomly selected. $0 \leq F \leq 2$ is implemented to adjust the scaling difference, and the ruling parameter is randomly created as well within the range $0 \leq K \leq 1$.

Thirdly, the crossover is used to increase the varieties of the confused parameters vector with respect to mutant vector $v_{i,G} = [v_{i,G}{}^1, v_{i,G}{}^2, \dots, v_{i,G}{}^D]$ at generation G a trail vector $u_{i,G} = [u^1, u_{i,G}{}^2, \dots, u_{i,G}{}^D]$ is generated according to the following equation.

$$u_{i,G} = \begin{cases} v_{i,G}{}^j \; if \; (rand \; j \leq CR \; OR \; (j = jrand) \\ \theta_{i,G}{}^j \; Otherwise \end{cases} \qquad (13)$$

Where CR is the crossover rate to adjust the friction of the parameter values copied, rand j is jth evaluation of a uniform random number created in [0, 1] and jrand is randomly selected an integer from [1, D].

Fourthly, Selection is conducted using fitness function for each objective and corresponding trail vector, and the one at a lower value of fitness function is kept as population for the next generation. Then, second and fourth steps are repeated until the objective met or maximum iteration reached.

To overcome the restrictions of mutually selecting trail vector generation strategies and its associated ruling parameters, Self-Adaptive Evolutionary Extreme Learning Machine (SAEELM) is implemented to optimise the ELM output weight matrix using the following procedures

Initialize the hidden layer matrix

$$\theta_{i,G} = g\left(a^T{}_{1,(k,G)}, \dots, a^T{}_{L,(k,G)}, b^T{}_{1,(k,j)}, \dots, b^T{}_{L,(k,G)} \right) \qquad (14)$$

Where $j = 1,2, \dots, L$ are randomly generated, G generation, and $k = 1,2, \dots, N_P$ number of population, and then calculate the output matrix by using the following formula

$$\beta_{k,G} = H_{k,G}{}^{\dagger} T \quad (15)$$

$$RMSE_{k,G} = \sqrt{\frac{\sum_{i=1}^{N} \left\| \sum_{j=1}^{L} \beta_j \, g\left(a_{j,(k,G)} \cdot x_i + b_{j,(k,G)}\right) - t_i \right\|^2}{m.N}} \quad (16)$$

Where, $H_{k,G}$ and $\theta_{k,G+1}$ can be defined by using the following equations

$$H_{k,G} = \begin{bmatrix} g\left(a_{1,(k,G)} . x_1 + b_{1,(k,G)}\right) & \cdots & g\left(a_{L,(k,G)} . x_1 + b_{L,(k,G)}\right) \\ \vdots & \ddots & \vdots \\ g\left(a_{1,(k,G)} . x_N + b_{1,(k,G)}\right) & \cdots & g\left(a_{L,(k,G)} . x_N + b_{L,(k,G)}\right) \end{bmatrix} \quad (17)$$

$$\theta_{k,G+1} = \begin{cases} u_{k,G+1} \; if \; RMSE_{\theta k,G} - RMSE_{uk,G+1} > \varepsilon . RMSE_{\theta k,G}, \\ u_{k,G+1} \; if \; \left| RMSE_{\theta k,G} - RMSE_{u\,k,G+1} \right| < \varepsilon . RMSE_{\theta k,G} \\ \qquad and \; \left\| \beta_{uk,G+1} \right\| < \left\| \beta_{\theta k,G} \right\| \\ \theta_{k,G} \quad elsewhere \end{cases} \quad (18)$$

All trail vectors are $u_{k,G+1}$ created the $(G+1)^{th}$ generation are evaluated by implementing equation 16 with small tolerance ε.

The Analysis of Variance (ANOVA) was calculated for different classifiers. Where, we grouped average testing accuracies for three signal representation techniques (Spectrogram, Wavelet and Wavelet Packet) that result in P value equalled to 0.0613. The P value indicated that there was no practical difference between any of these four classifiers as P value was larger than 0.05 although its value was not that far from 0.05.

Moreover, the Confidence interval for each classifier was calculated with confidence score equals 60%. Generally speaking, confidence interval has two limits one is a higher limit, and the other is the lower one. We are confident in our result by level 60 % as long as testing accuracy, for each classifier, within our interval.

5. Implementation

In this section the data acquisition that we followed will be displayed and explained in more details and results will be discussed.

5.1. Data Acquisition

We used FlexComp Infiniti™ to collect the surface Electromyography signal. MyoScan™ T9503M Sensors were used to obtain two EMG. Those two sensors were put on the subject forearm as shown in Fig.6.

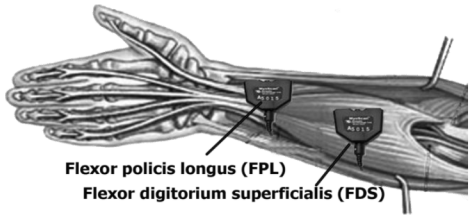

Fig.6. Placement of the electrodes

We have nine subjects where each subject was asked to do one of ten different finger movements for five seconds then take rest for other five seconds. Each movement was reiterated for six times. Then, the subject was asked to perform the same scenario for another finger movement class till finishing the whole ten finger movement classes. The signal was amplified by gain 1000 and sampled at the rate of 2000 sample per second.

The main target is to use collected EMG signal and feature learning technique and classify the finger movement for the subjects into ten classes. Fig.7 shows the targeted ten classes

Three-folded validations for data was used where the training set was 2/3 of the whole data, and the residual 1/3 was assigned for testing set.

The bio signal was filtered to remove any noise that might be superimposed on data. So, the implemented filter was to ensure that our processed signal is free from noise.

The average training and testing accuracy were calculated by simulating the system for each subject separately then summing the training or testing accuracy for all participants and dividing the result by the number of our subjects.

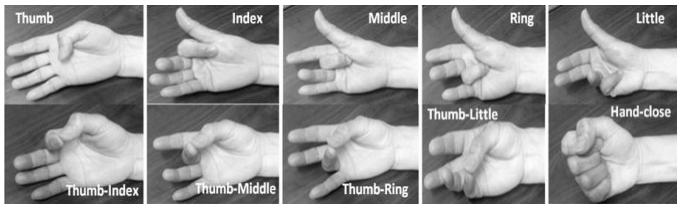

Fig.7. Ten different finger movements

5.2. Results

Table I shows training and testing accuracies for different signal representations and different classifiers

TABLE I. TESTING AND TRAINING ACCURACY

Signal Representation	Average Training Accuracy	Average Testing Accuracy	Classification Algorithm
Spectrogram	99.41%	81.54%	Support Vector Machine
Spectrogram	98.26%	83.29%	Extreme Learning Machine
Spectrogram	96.71%	91.11%	Evolutionally Extreme Learning Machine
Spectrogram	96.95%	83.13%	Discriminate Analysis
Wavelet	99.84%	85.11%	Support Vector Machine
Wavelet	98.03%	84.91%	Extreme Learning Machine
Wavelet	99.35%	93.14%	Evolutionally Extreme Learning Machine
Wavelet	98.61%	86.77%	Discriminate Analysis
Wavelet Packet	98.42%	90.47%	Support Vector Machine
Wavelet Packet	97.83%	87.96%	Extreme Learning Machine
Wavelet Packet	99.50%	94.44%	Evolutionally Extreme Learning Machine
Wavelet Packet	96.30%	89.98%	Discriminate Analysis

We went through different experiments by altering self-organizing map configuration until we reached the current configuration where the size of the two-dimensional map was 10x10, the layer topology function employed was 'hextop' and the neurone distance function hired was 'linkdist'. This configuration was to compromise between simulation time and accuracy level. These parameters were optimum regarding the accuracy level and the time consumed in simulation in which, increasing size of our map would recall higher simulation time without a tangible impact on accuracy level. The bio signal was filtered before signal representation stage and neural networks phase to guarantee a substantial barrier against noise level that might be superimposed on our collected bio signal.

The same set of data was introduced to a pattern recognition system, as shown in Fig.8, where we applied the traditional feature extraction and feature reduction techniques. The extracted features were slope sign change, zero crossing, waveform length, skewness, mean absolute value, root mean square and autoregressive. Also, we applied linear discriminant analysis as feature reduction method. The training accuracy was 96.60% and testing accuracy were 88.92%.

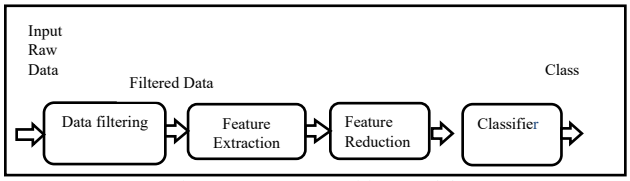

Fig.8. Pattern Recognition Model

It is evident from the results that are shown in Table I that using wavelet packet as a signal representation generated a higher testing accuracy than both wavelet and Spectrogram. Moreover, wavelet had a higher testing accuracy than Spectrogram and had a lower testing accuracy than wavelet packet. Support vector machine showed impressive classification ability for wavelet packet than its ability in spectrogram signal representation. Support vector machine testing accuracy for wavelet packet signal representation was very close to testing accuracy for discriminate analysis classifier but still higher. Moreover, support vector machine showed moderate classification ability for wavelet signal representation and poor classification ability for spectrogram signal representation. On the other side, Extreme learning machine excelled the other classification techniques for spectrogram signal representation. However, testing accuracy for spectrogram signal representation was very close to its value resultant from using Discriminate Analysis classifier. Discriminate analysis showed higher testing accuracy for wavelet signal representation than both extreme learning machine and support vector machine for the same data set and wavelet signal representation while, testing accuracy for wavelet signal representation by using support vector machine was higher than testing accuracy resultant from extreme learning machine for same wavelet signal representation but, close and lower than testing accuracy for discriminate analysis. The testing accuracies, for three signal representations, were moved to another higher level by implementing Evolutionally Extreme Learning Machine as a classifier and this is due to the optimisation algorithm that is being followed by this technique. The only drawback for evolutionally extreme learning machine was its simulation time as it was considered longer than the time consumed during simulation of an extreme learning machine. However, the high accuracy levels gained from evolutionally extreme learning machine was very encouraging to implement it.

We calculated the ANOVA value for four different classifiers. The P value resulted in 0.0613, which is slightly less than 0.05. Although the P value is slightly smaller than 0.05 However, it is yet indicating that there is no sensible difference between those four implemented classifiers

Table II shows the confidence interval for four different performed classifiers

TABLE II. CONFIDENCE INTERVAL for various CLASSIFIERS

Classifier	Confidence Interval High	Confidence Interval Low	Confidence Interval
Extreme Learning Machine	86.54%	84.24%	2.3%
Discriminate Analysis	88.29%	84.96%	3.32%
Support Vector Machine	87.89%	83.53%	4.36%
Evolutionally Extreme Learning Machine	93.71%	92.08%	1.63%

Fig.9. Shows the clustered column chart which is representing our confidence interval for our used classifier. The used confidence score is 60%. We are confident in our result by level 60 % as long as testing accuracy, for each classifier, within our interval. It is apparent from these results that evolutionally extreme learning machine has the narrowest range which is 1.63%. Support vector machine has the widest interval, which impacts the gap between higher and lower confidence interval. Moreover, the second widest interval is Discriminate Analysis which results in 3.32% and finally, extreme learning machine generates the second narrowest interval that is 2.3%.

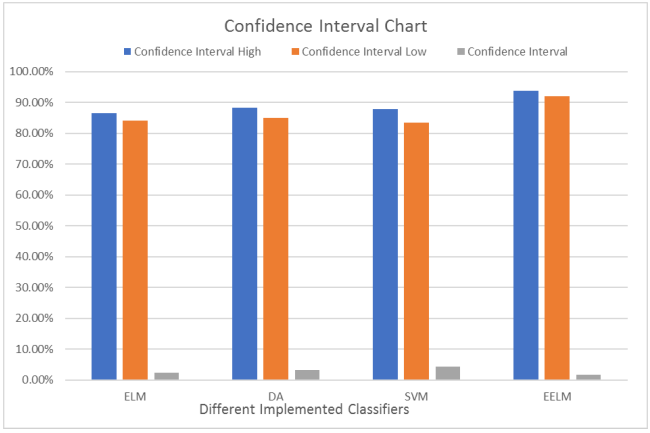

Fig.9. Confidence Interval

Classifier fusion layer was added where; it selected the best local classifier by using dynamic classifier selection algorithm. Both training and testing accuracies were improved as shown in Table III.

TABLE III: CLASSIFIER FUSION TESTING AND TRAINING ACCURACY

Signal Representation	Average Training Accuracy	Average Testing Accuracy	Classification Algorithm
Spectrogram	98.42%	93.07%	Classifier Fusion
Wavelet	99.35%	95.25%	Classifier Fusion
Wavelet Packet	99.73%	96.60%	Classifier Fusion

The testing accuracies were improved by adding classifier fusion where wavelet packet testing accuracy exceeded 96% while, wavelet testing accuracy became higher than 95%, and finally, spectrogram became more than 93%. In comparing Table III results with Table I results we can conclude that classifier fusion improved results. Fig.10 shows the number of learned feature for each data representation.

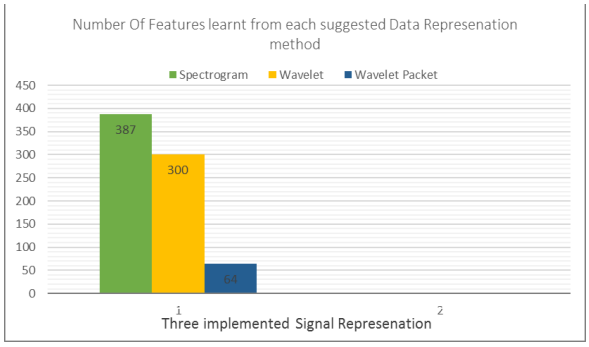

Fig.10. Number of learned features for each data representation

6. Conclusion

The self-organizing map was time-saving and easy feature learning technique, where it reduced dimensions of data without too much loss of the information and observations that should be associated with data. The self-organizing map was considered one of the types of neural networks which use dimension reduction (typically two dimensions) and back propagation for error correction. Although the simulation time was not long, we got a good testing accuracies.

Spectrogram, wavelet and wavelet packet helped in better representing raw data. Support vector machine showed good classification ability in Wavelet Packet while discriminate analysis showed an impressive result in wavelet signal representation and good ability for classification for Spectrogram although Extreme learning machine excelled in Spectrogram testing accuracy than using discriminate analysis.

Evolutionally extreme learning machine was considered a very real improvement for our accuracies percentages. This was due to the optimisation algorithm that existed in the model. As all testing accuracies, for evolutionally extreme learning machine, exceeded 90%. The only drawback for evolutionally extreme learning machine was its simulation time which was relatively longer than that consumed during implementing extreme learning machine. On the other hand, the accuracy values achieved by employing evolutionally extreme learning machine as a classifier was higher than those reached by hiring extreme learning machine in the classification stage.

ANOVA value was 0.0613 as calculated above. The value was not yet to be less than 0.05. However, it was very close to 0.05. This meant that there was no practical difference between classifiers. Despite this, we believed that using evolutionally extreme learning machine pushed ANOVA value to be as close as 0.05.

The confidence interval was calculated by confidence score 60%. And as shown above, the narrowest interval was for an evolutionally extreme learning machine. While the widest range for support vector machine. These intervals gave us an indication of how far we were confident in our resulting testing accuracy. And if the testing accuracy was in our range, so we would be confident in our result by 60%.

Classifier Fusion layer enhanced in increasing testing accuracies for the three used signal representations. Classifier fusion algorithm followed was selecting best local classifier. The only drawback for classifier fusion was increasing simulation time as it became relatively high than before. However, simulation time consumed by the self-organizing map as feature learning was short.

The average simulation time was around 20 seconds which was considered as a short time. However, it was very far from real time hands applications (150m seconds to 300 m seconds). As a future work we are planning to mix all features for three suggested data representation and select top useful features by applying indexing technique then use classifier fusion to combine between reaching real simulation time in real hands applications (150m seconds to 300 m seconds) and verifying high testing accuracies rate. Also, as a future work, we are planning to introduce raw data to our model without any signal representation to save simulation time and build a practical system.

ABSTRACT

In this paper, a delay-dependent controller based on the sliding mode concept is proposed to stabilize a networked robotic system in a decentralized synchronization scheme. In addition to being affected by communication time-delays between agents, and seen that external disturbances obviously affect any physical and dynamic system, an unsettling action resulting from measurement errors affects the position and the velocity state vectors of agents. Then, it has been proved that the synchronizing algorithm enables cooperative agents, acting in a disturbed environment, to efficiently accomplish a shared task and to compensate delayed communication data. The proposed controller has been implemented in a cooperative robotic system, where the controller proves its robustness face to disturbances.

1 Introduction

The need for robust robotic controllers, that respond to greater productivity and faster manufacturing devices, has been a hot topic in the last few years. This need obviously imposes high pressure on researchers to acquire secure and effective robots, especially with the increasing humanitarian and social exigency, which require interactions between robots and humans. Thence, this paper presents an extension of a research work originally presented in the 8^{th} International Conference on Modelling, Identification and Control [1]. Recently, several similar synchronization studies have been investigated in several complex mechanical systems, where flexibility and accuracy have been highly recommended [2], [3], [4], [5], [6]. There exist numerous samples of sophisticated technologies dedicated to modern life, such as material transporting [7], [8], advanced agriculture aggregation [9], building tasks [10], etc. Indeed, in light of the accelerated pace of development, there has become a growing demand for cooperative multi-agent robotic systems to serve contemporary industries and manufacturing applications [11], [12]. In this context, it has been proved that the flexibility and the maneuverability guaranteed by a cooperative robotic system are far beyond the working capacity of one single manipulator. In the other hand, the time-delay phenomenon obviously appears in nature [13], especially in several control systems (aircraft, chemical or process control systems) either in the control input, in the state or in measurements. In contrast to the ordinary differential equations, delayed systems are infinite dimensional in nature, and time-delayed data transmission presents in the most of cases, a source of instability. As an illustration, a state estimator is designed in [14] to a class of uncertain discrete-time Markovian jump neural networks, with time-varying delays, in order to estimate the network states through available output measurements. Indeed, the study presented in [15] seeks to resolve the problem of data packet dropout and transmission delays resulted by communication channels in the networked control system. So, great efforts have been invested in the synthesis of uncertain networked systems with time-delay, seen that the stability issue as well as performances of the system control with delay are both of theoretical and practical importance. However, in several robotic applications, the uncertainty may arise from many real-world sources such as errors of the robot modeling, unpredictable robot actuation, unpredictable movements in the environment, etc [16], [17]. As well, while robots are executing their assigned global task, some assumptions under which controllers were built may be invalidated: loads or robots may fail, the environment may change, etc. The cumulative effect of

[*]Fatma Abdelhedi, Sfax–Tunisia, fatma.abdelhedi@live.com

https://dx.doi.org/10.25046/aj020366

such uncertainty sources can be hard to manage during the task execution. Thus, to ensure a fluid response to the distributed multi-robot system, tradeoffs between multi-robot flexibility, time delay adjustment, uncertainty compensation, and task execution efficiency should be considered. To achieve it, we present the stability analysis of a robust control concept which combines the SMC design with a particular class of the graph theory, aiming to stabilize a networked robotic system.

2 Introduction to the SMC

While considering the SMC concept, the state trajectory evolution is divided into two parts [18]:

- from the initial state to the intersection with the sliding surface, this part is called "the reaching phase",
- from the intersection with the sliding surface to the origin, this part is called " the sliding phase".

During the reaching phase, the attractiveness condition of the sliding surface $\dot{S}(x)S(x) < 0$ is verified. This condition is global but it does not guarantee a finite sliding time. To ensure a finite sliding time, the condition becomes:

$$\dot{S}(x)S(x) < -\varepsilon_1 - \varepsilon_2|S| \;\; if \;\; S(x) \neq 0 \; and \; \varepsilon > 0 \qquad (1)$$

This sliding time can be imposed by choosing the sliding surface of the form:

$$\dot{S}(x) = \; -\mu S(x) - \mu\Omega \,\mathrm{sign}\,[S(x)] \qquad (2)$$

This expression, which has been adopted in this study, is a solution of a differential equation [19]. During the sliding phase ($S(x) = 0$ and $\dot{S}(x)S(x) < 0$), the closed loop system has the same behavior than $S(x) = 0$.
In general, for a system of order n which is described in the state space by:

$$\begin{cases} \dot{x}_i = x_{i+1} \;\; i = 1, ..., n-1 \\ \dot{x}_n = f(x,t) + g(x,t)u(t) \end{cases} \qquad (3)$$

the linear sliding surface according to the state has the form:

$$S(x) = Cx = \sum_{i=1}^{n} c_i x_i \qquad (4)$$

In the sliding phase, the looped system will have the same behavior as the system is described by:

$$\begin{cases} \dot{x}_i = x_{i+1} \;\; ; i = 1, ..., n-2 \\ \dot{x}_{n-1} = -\sum\limits_{i=1}^{n-1} c_i x_i \;\; ; c_n = 1 \end{cases} \qquad (5)$$

This is a linear system of order $(n-1)$ [20]. Thus, when the sliding regime is reached (after an interval t_g of time), the operating point is going to stay on the surface whose equation is $S(x) = 0$. Therefore, the looped system has an insensitivity to parameter variations of the system to be controlled.

3 Problem formulation and Mutual SMC synchronization concept

Let us consider p manipulator robots described by the following differential equation:

$$M_i(\ddot{q}_i) + C_i(q_i, \dot{q}_i)\dot{q}_i + G_i(q_i) \;\; = \;\; \tau_i \qquad (6)$$

for $i = 1 \cdots p$. Each robot has n degrees of freedom, for which:

- $q_i \in \mathbb{R}^n$ denotes the vector of measured displacements and i is the number of cooperative robots,
- $\dot{q}_i \in \mathbb{R}^n$ is the measured velocity vector,
- $\ddot{q}_i \in \mathbb{R}^n$ is the vector of articulatory acceleration,
- $M_i(q_i) \in \mathbb{R}^{n \times n}$ is the inertia matrix, which is symmetric uniformly bounded and positive definite,
- $C_i(q_i, \dot{q}_i)\dot{q}_i \in \mathbb{R}^n$ is the vector expressing the Coriolis and the centrifugal forces,
- $G_i(q_i) \in \mathbb{R}^n$ is the vector of gravitational forces,
- $\tau_i \in \mathbb{R}^n$ denotes the vector of external torques and forces applied at each joint.

The state vector is presented as: $x_i = \begin{pmatrix} q_i \\ \dot{q}_i \end{pmatrix}$, and its control vector is $u_i = \tau_i$. To achieve a coordinated control motion, a cross coupling synchronizing approach (that is derived from the graph theory [21]) has been applied to the networked system. Thus, the cross-coupled SMC concept is adopted in this work to control the whole multi-agent system, which in turn becomes considered as a single generalized system. The typical procedure for implementing such a control module is to first build a global error model in real time [3], based on the information feedbacks derived from all system members. In order to achieve this goal, we define the tracking error as follows:

$$\zeta_{1i}(t) = q_i(t) - q_d(t) \qquad (7)$$

where:

- $q_d(t) \in \mathbb{R}^n$ denotes the desired position of the robot.

The 'cross-coupling' concept consists in presenting a synchronization error with reference to the calculation of differences between position errors. This error is presented as follows [3]:

$$\zeta_{2i}(t) \;\; = \;\; \sum_{j \neq i}^{p} \Lambda_{ij}\,[q_i(t) - q_j(t-\tau)] \qquad (8)$$

where $\Lambda_{ij} = \Lambda_{ji}$ are symmetric positive-definite matrices which reveal an idea about the communication quality between the i^{th} and j^{th} agent. Finally, the

global error concerning each agent of the system is given by:

$$\varepsilon_i = \zeta_{1i} + \int_0^t \zeta_{2i}(\mu) d\mu \tag{9}$$

Let's consider the sliding surface:

$$s_i = \dot{\varepsilon}_i + \lambda_i \varepsilon_i$$

and let's define the control law:

$$u_i = u_{eq} + \Delta u \tag{10}$$

Hence, equality $\dot{s}_i = 0$ yields the following equivalent control expression:

$$u_{eq} = M_i\Big[\ddot{q}_{id} - \dot{\zeta}_{2i} - \lambda_i(\zeta_{2i} - \dot{\zeta}_{1i})\Big] + C_i(q_i, \dot{q}_i)\dot{q}_i + G_i \tag{11}$$

and the discontinuous control part becomes:

$$\Delta u = -M_i^{-1}\, K_i \,\text{sign}\,(s_i) \tag{12}$$

where K_i is a definite positive diagonal matrix.

Applying the control law (10) yields the expression of the differential with respect to time of vector s_i:

$$\dot{s}_i = -K_i \,\text{sign}\,(s_i) \tag{13}$$

The advantage of the adopted decentralized architecture is that it allows to each robot to have local information about relative positions of its neighbors. So each agent can communicate and share information with robots placed just nearby, according to the utilized cross coupling approach.

4 Stability analysis

To prove the stability of one agent in the system, we consider a Lyapunov function:

$$V_i \;=\; \frac{1}{2}\, s_i^T K_i^{-1} s_i \;> 0 \tag{14}$$

Its differentiation with respect to time gives:

$$\dot{V}_i \;=\; -s_i^T \,\text{sign}\,(s_i) \;< 0 \tag{15}$$

By considering the whole multi-agent system, the chosen Lyapunov candidate function becomes:

$$V = \sum_i^p V_i > 0$$

and after its differentiation with respect to time we obtain:

$$\dot{V} = -\sum_i^p s_i^T \,\text{sign}\,(s_i) < 0$$

This proves the stability of the overall system.

5 Convergence to the desired trajectory

It is clear that $s_i(t)$ goes to zero after the reaching phase ($t > t_0$). In the sliding phase, we have $s_i = 0$. That is for $t > t_0$:

$$\varepsilon_i(t) \;=\; \varepsilon_i(t_0) e^{-\lambda(t-t_0)} \tag{16}$$

$$\dot{\varepsilon}_i(t) \;=\; -\lambda \varepsilon_i(t_0) e^{-\lambda(t-t_0)} \tag{17}$$

It is obvious that:

$$\lim_{t \longrightarrow +\infty} \varepsilon_i(t) \;=\; 0 \tag{18}$$

$$\lim_{t \longrightarrow +\infty} \dot{\varepsilon}_i(t) \;=\; 0 \tag{19}$$

Then, we can write that for $t > t_1 = t_0 + \frac{5}{\lambda}$:

$$\varepsilon_i(t) \simeq 0\,, \;\; \dot{\varepsilon}_i(t) \simeq 0 \tag{20}$$

Let's assume that the following quantities are uniformly bounded for $t > t_1$:

$$\|q_d(t) - q_d(t-\tau)\| \;\leq\; m_1 \tag{21}$$

$$\|\dot{q}_d(t) - \dot{q}_d(t-\tau)\| \;\leq\; m_2 \tag{22}$$

$$\left\| \int_{t-\tau}^{t} q_d(\varsigma) - q_d(\varsigma - \tau) d\varsigma \right\| \;\leq\; m_3 \tag{23}$$

Let's write, for $t > t_1$, $\dot{\varepsilon} = 0$:

$$\begin{aligned} &\dot{q}_i(t) - \dot{q}_d(t) + \left(\sum_{j \neq i} \Lambda_{ij}\right)[q_i(t) - q_d(t)] \\ &- \sum_{j \neq i} \Lambda_{ij}\,[q_j(t-\tau) - q_d(t-\tau)] \\ &+ \sum_{j \neq i} \Lambda_{ij}\,[q_d(t) - q_d(t-\tau)] \;=\; 0 \end{aligned} \tag{24}$$

Denoting:

$$d_i(t) \;=\; \sum_{j \neq i} \Lambda_{ij}[q_d(t) - q_d(t-\tau)] \tag{25}$$

we can write that:

$$\dot{\zeta}_{1i}(t) + \left(\sum_{j \neq i} \Lambda_{ij}\right)\zeta_{1i}(t) - \sum_{j \neq i} \Lambda_{ij}\zeta_{1j}(t-\tau) + d_i(t) = 0 \tag{26}$$

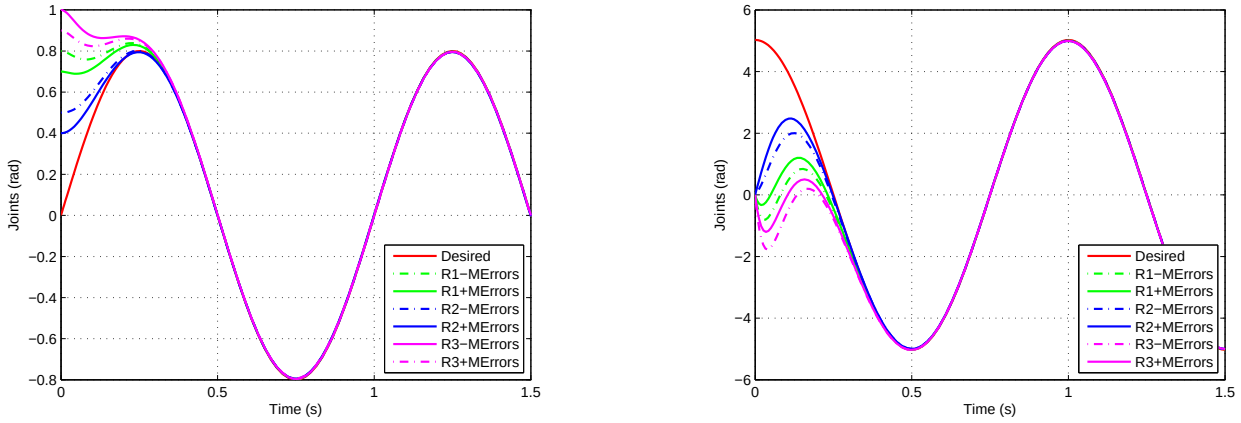
Let's define: $\zeta_1 = [\zeta_{1i}^T\; \zeta_{2i}^T \cdots\;]^T$ and $d = [d_1^T\;\; d_2^T \;\cdots\;]^T$. Then, we have:

$$\dot{\zeta}_1(t) = A\zeta_1(t) + B\zeta_1(t-\tau) + d(t) \tag{27}$$

where A is a block-diagonal matrix, for which each bloc-diagonal term is:

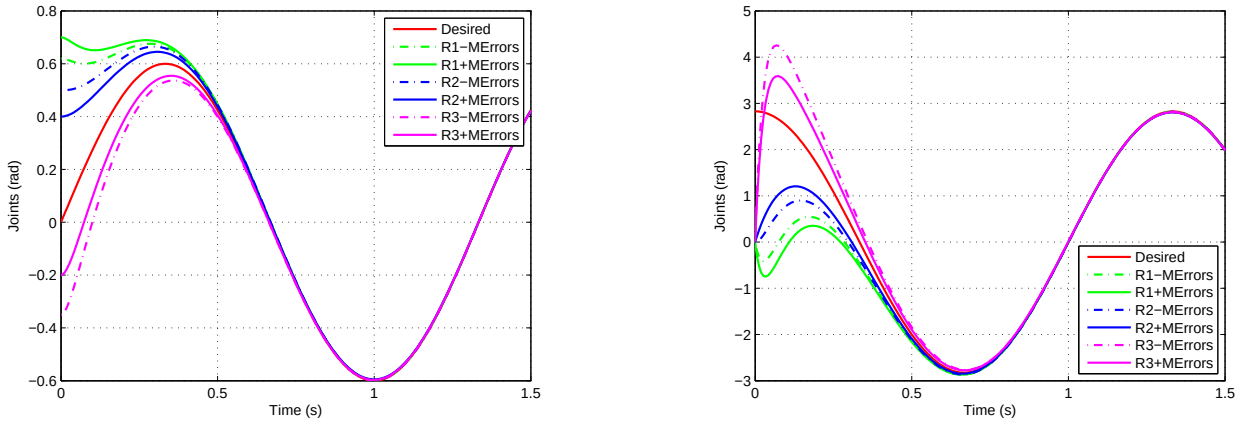
$$A_i = -\sum_{j \neq i}^{p} \Lambda_{ij} \tag{28}$$

which is a symmetric definite negative matrix. This shows that all eigenvalues of matrix A_i have strictly negative real parts. Consequently, A is a Hurwitz matrix.



(a) (b)

Figure 1: The 1^{st} joints SMC:(a) Trajectory tracking and position synchronization,(b) Velocity synchronization.



(a) (b)

Figure 2: The 2^{nd} joints SMC:(a) Trajectory tracking and position synchronization,(b) Velocity synchronization.

Table 1: Joints initiation and parameters

Articulation	Mass	Length
q_1	8 kg	0.4 m
q_2	6 kg	0.3 m
q_3	0.5 kg	0.3 m

Using properties of matrices A and B, and using the fact that $d(t)$ is uniformly bounded, we can deduce that $\zeta_1(t)$ is uniformly bounded [22, 23, 24]. This shows that $\zeta_{2i}(t)$ and:

$$\int_0^t \zeta_{2i}(t)dt = \varepsilon_i - \zeta_{1i}(t) \tag{29}$$

are uniformly bounded. This yields that:

$$\lim_{t \longrightarrow +\infty} \zeta_{2i}(t) = 0 \tag{30}$$

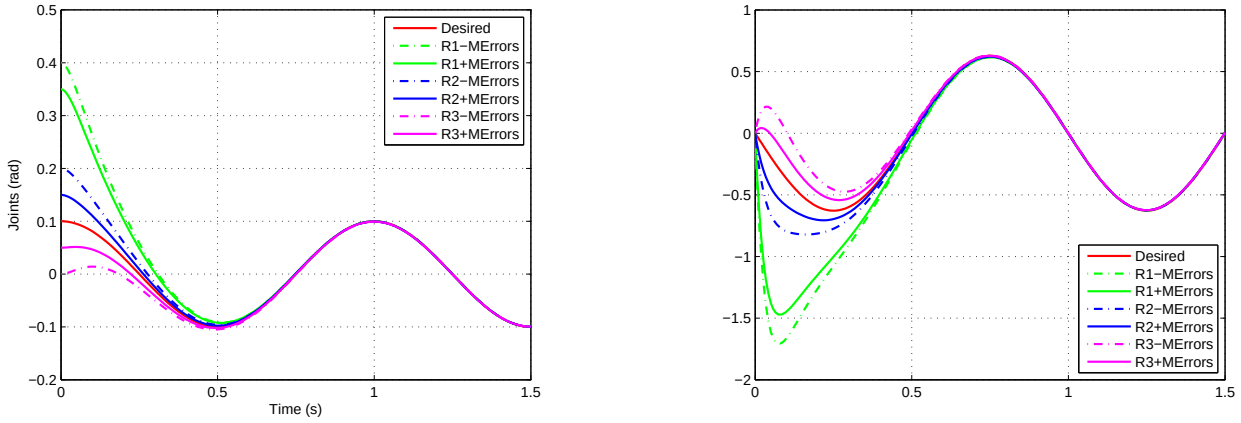
In consequence, we have, for $t > t_1$:

$$\varepsilon(t) = \dot{\zeta}_{1i} + \zeta_{2i} \simeq 0 \tag{31}$$

Finally, we can easily deduce that for $t > t_1$:
$\zeta_1(t) \simeq 0$. This proves that positions of al robots converge to their desired trajectory.

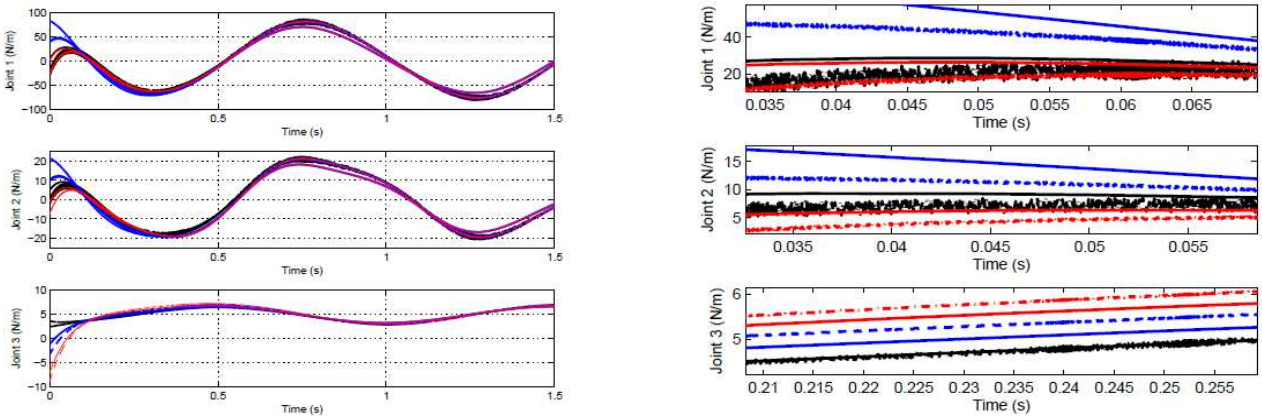
6 Application

Consider the SMC law applied to the networked robotic system for a trajectory tracking control task. Here, the cooperation is defined as a group of robots that work together to accomplish a required task, where resources are shared between all agents, and the action performed by each robot takes into account actions performed by others. The required behavior of the proposed synchronizing SMC is to handle measurement errors appearing in the controller of one robot in the system, the communication time delay lag between cooperative robot movements, and at the same time to retain all properties and system performances. So that, the designed controller must have a sufficient authority which is able to dominate the undesirable disturbances affecting one robot, and which



(a) (b)

Figure 3: The 3^{rd} joints SMC:(a) Trajectory tracking and position synchronization,(b) Velocity synchronization.



(a) (b)

Figure 4: (a) Applied torque behaviors: The black lines present behaviors of the robot affected by the measurement errors, (b) Enlarged scales: Dotted lines- In the presence of external disturbances. Continuous lines- Without external disturbances,

have been transmitted to other neighbors due to the feedback control sharing imposed by the cross coupling design. Dynamic parameters of the manipulator robot model are mentioned in Table I. We note that:

- R_i: designate the cooperative robots, $i = 1..3$.
- R-MErrors: presents the robot behavior without measurement errors (in the presence of a constant communication time delay z = 0.4s).
- R+MErros: presents the robot behavior in the presence of measurement errors affecting the position vector of the first robot R1 (in the presence of a constant communication time delay z = 0.4s).

Discussion: Simulation results present a comparison between behaviors of the time-delayed networked system acting with and without presence of measurement errors. The robust synchronization of the networked system, realized by the synchronizing SMC has been proved when the time delay rate is valued around 0.4 s, even in the presence of external disturbances. In fact, position and velocity behaviors of the multi-agent system are almost similar in both cases as shown in Figs.1, 2 and 3, despite the addition of measurement errors (at the position vector of the first robot) whose impact reaches 20% of its right value. So the global system addresses imposed perturbations and different positions of cooperative robots rapidly attain their desired trajectories. At the same time, the synchronization effect is clearly presented despite the existence of communication time delay between robots. Besides, the generated velocity curves also reflect the insensitivity of the proposed control approach to different perturbations applied to the system, as demonstrated in Figs.1(b), 2(b) and 3(b). This proves the robustness of the synchronizing SMC in achieving adequate motion control and meeting the efficiency requirement throughout a middle affected by a constant communication time-delay and relatively high valued external disturbances. Concerning the control input behavior, we note that the signum function (which is responsible to generate the chattering phenomenon) has been replaced by an approximating function (Hyperbolic tangent) in order to better present the disturbance effect on the system. This is justified by the fact that the high frequency sig-

nals resulted from the chattering phenomenon cover the measurement error impact, whose amplitude is much smaller in comparison with the chattering one. So in the absence of measurement errors, torques behave smoothly as shown in Fig.4(a) and obviously in Fig.4(b). However, it is clear that input torques are influenced by the presence of disturbances, where slight oscillating signals disrupt input torques of the affected robot, and lower disturbing signals appear in the torque behaviors of other agents not affected. This shows that each robot influences other teammates under the synchronizing control effect. So, feedbacks derived from unaffected robots help the affected agent to overcome external disturbances which he meets.

7 Conclusion

In this paper, we have developed an analytical approach to define adequate synchronizing stability conditions in the presence of constant communication delays, and illustrated them for a decentralized architecture of a class of networked robotic systems. This analysis shows that the overall system synchronization, even in a middle disturbed by measurement errors, can be successfully guaranteed by transmitting feedbacks between cooperative system agents. Obtained comparison between simulation results shows that the networked system can easily reach desired behaviors and move smoothly when the considered communication time delay is valued around 0.4 s, and the rate of measurement errors attain 20presence of low disturbing frequencies in the control torques of agents proves that the proposed controller addresses disturbances and guarantees a robust synchronized motion task.Further researches will involve consideration of the system convergence rate with respect to the time-varying delay functions, to the SMC constraints, and the limit rate of time delays which can be supported and compensated by such a variable structure controller.

ABSTRACT

In Interactive Learning Environment (ILE), the cognitive activity and behavior of learners are the center of the researchers' concerns. The improvement of learning through combining these axes as a structure of indicators for well-designed learning environment, encloses the measurement of the educational activity as a part of the learning process. In this paper, we propose a mathematical modeling approach based on learners actions to estimate the cognitive activity, learning behavior and motivation, in accordance with a proposed course content structure. This Cognitive indicator includes the study of knowledge, memory and reasoning. While, activity indicator aims to study effort, resistance and intensity. The results recovered on a sample of students with different levels of education, assume that the proposed approach presents a relation among all these indicators which is relatively reliable in the term of cognitive system.

1 Introduction and Purpose

In Interactive Learning Environment (ILE) the evaluation of learners is based on interactions analysis when accessing e-learning systems.
Several studies [1, 2, 3] look into calculation and deduction of indicators from analysis of interaction traces, in order to extract meaningful information about the learner activity and behavior, this allows tutors to observe, assess and regulate the activities of learners .
To some extent, the choice of data to analyse mainly depends on the objectives of observation, supposedly with individual or collective character, using quantitative or qualitative value, knowledge's study. The use of extracted knowledge from traces has enabled the development of several sectors such machine learning, artificial intelligence, e-learning and e-commerce. A concept that turns more and more to realization in real time [4, 5]. In fact, exploring traces as a background information identifies learners' navigation paths and reconstruct their activities. [6] demonstrate the relevance of navigation in systems oriented toward the elderly, indicating that linear navigation is more suitable for these users, through comparing two designs of the same email Web application with linear and hypertextual navigation styles. However, the use of traces is a common approach by focusing on the processing on digital traces; just a few works involves another kind of traces in this aspect of the research. [7] propose a system that evaluates the activity of learners using log files data, based on four indicators; classification indicator of learners based on their activity (weekly), indicator of activity of each learner throughout the course (weekly), learner classification indicator according to their performance (for each event) and performance indicator of each learner.
The active involvement of learners in their learning process can be reinforced by a meta-cognitive regulation strategy by alternating learning with repeated tests of their knowledge [8]. [9] propose that the computer support provided to the tutor enable him/her to follow up individually a collective activity in which the learner is engaged. In complicated learning conditions, learners have an increased commitment to learn with increased cognitive effort that would paradoxically result in more sustained attention [10, 11]. The voluntary efforts

*Corresponding Asmaa Darouich, asmaa.darouich@gmail.com

https://dx.doi.org/10.25046/aj020367

of the learner result in the acquisition of knowledge, however the quality of learning returns with added value, which positively influences cognitive performance.

Effort, or as [12] call, motivational excitement, occurs only if a number of conditions are met. First, there should be expectation that some behavior will lead to some desirable outcome values (task incentive). Secondly, the behavior must be difficult but considered to be at its capacity and justified by the potential gain. A concept that is very close to mental effort is the mental load [13].
The effort is expected to be associated with cognitive processes reflected by the Electroencephalography measurements. Where cerebral activity in default mode [14, 15] and cortical inhibition [16, 17] suggests that this measure reflects different levels of effort, with a high alpha for low effort levels.
The human cognitive system is a complex processing device capable of acquiring, conserving, processing and transmitting information. Cognition improves gradually from birth through the interactions of the child with his/her environment. Cognitive development appears punctuated by acquisitions that are necessary for the establishment of subsequent cognitive processes. Actually, cognitive science has identified four key factors for learning: attention, active learner engagement, feedback and consolidation [18]. These four factors are based on the functioning characteristics of the cognitive system and are deeply rooted at an early age.

On the basis of the [19] model, the cognitive architecture underlying the learning phenomena consists of working memory and long-term memory. In neuroscience, memory is defined as the ability to acquire, retain and restore information. Stimulated by more than a century of neuropsychological study, researchers have come to distinguish these forms of memory. Maintaining a certain amount of memory in short-term memory would eventually allow it to be transferred into long-term memory for more sustainable storage. This process would be facilitated by mental work of repetited information , hence the expression "working memory" [20]. The working memory can be defined as the temporary maintenance and the manipulation of information during the realization of cognitive spots. However, long-term memory can be seen as an adaptive function of the human being to his cultural, social and emotional environment [21].
Knowledge is an element of our memory that allows us to recognize the world around us, to interpret, to understand our environment, but also to act on it. Knowledge is mainly evaluated in the form of a simple reminder or through comprehension activities.
In the didactic of learning environments, knowledge given to be study always comes from an institutional demand and what individuals have to build are knowledge that will enable them to analyze a situation or to allow an action.
When designing a pedagogical scenario, knowledge derived from the psychology of learning, [22] presents human knowledge by categorizing it into six different formats, these formats corresponding to particular learning processes. Contrary to the proposal of [23], which updated the taxonomy of Bloom, these authors do not establish any hierarchy between the different knowledge formats and even consider that some knowledge does not exist according to certain formats.
Based on the idea that cognition groups together the various mental processes of perception, memorization and reasoning, [24] made an important contribution when it differentiates four types of cognitive reasoning: deductive reasoning, inductive reasoning, abductive reasoning and reasoning by analogy. However, reasoning takes the form of a cognitive process to produce a conclusion based on premises.
The studies conducted in the cognitive psychology help to structure behavioral models. However, the analysis of interactions provides a large amount of data approach that identify the motivational aspect as a point that cannot be detached from cognitive and activity aspect of learner. The number of definitions of the motivation term is almost a large topic. This happens because motivation represents a hypothetical construct and not a material entity, which means that we use observable manifestations to infer a state of motivation.
Motivation is not a skill, but a state of mind influenced by internal and external factors to the individual. [25] defines it as "the orientation of the conduct, the efforts deployed and finally the persistence of this effort over time". In a psychological perspective, [26] emphasizes the characteristics of the environment in which behavior is manifested: motivation is defined as the set of "physiological and psychological processes responsible for initiation, maintenance and cessation behavior and the appetitive or aversive value conferred on the elements of the environment on which this behavior is exercised ". The work environment is likely to influence motivation, and also the work environment of the worker and, more specifically, the social beliefs of the employee [27]. The work of [28] on the theory of objectives setting establishes that an individual is motivated when he is working towards a clear, challenging and meaningful objective for which he will have a feedback. The proponents of the theory of self-determination, on the other hand, consider that the individual is motivated by the needs of social belonging, competence and autonomy, which would be the most decisive need [29]. The theory [30] relates motivation to three variables: valence (value attributed to the result), instrumentality (relation between performance and retribution) and expectation (results) which combined, can induce

motivation. On the other hand, analysing resistance to learn is directly observable at a large scale as some students fail assessments on a course. [31] suggests, that this resistance manifests through a reduction in motivation, suggested by lateness or absence from sessions, or a reduction in participation in group exercises and discussions. The individual learning resistance is linked to his/her defense mechanisms as a set of actions that purpose to the reduction or elimination of any change in relation to the integrity and stability of his/her biopsychic [32].

This paper is an extension of work originally reported in Proceedings of the 11th International Conference on Intelligent Systems: Theories and Applications (SITA). Thereby, we expose firstly the methodology of structuring a course content on which we base our modeling indicators approaches [33]. Secondly we modeled cognition [34], activity and motivation [35] indicators also approached in [36], by addressing their structure that use navigation traces on a learning session, likewise as a concept of procedures integrated in the adaptive learning content system we named S-CAMO. Developing those approaches complete studies that use simpler types of indicators [1, 2, 3], which is not sufficient to reflect the learner profile in a general way. The last section expose the statistical validation of the proposed indicators modeling.

2 Educational collections for course structure

Conceiving a flexible learning content toward learner profile with his different needs requires and includes structured components.
We propose an educational collections Ct that offer the possibility of being redesigned under different personalization in proportion to the same degree of subordination of the collection to form a semantic model of dynamic content.
Following the conceptualization of a structured educational content ("As shown in Algorithm 1"), educational collections can be one of four types; A course Cr_i "(2)", a chapter Ch_j "(3)", a unit U_k "(4)" or an educational component Cpt_h "(5)" as a pedagogical concept Cp_h or a pedagogical activity Ap_h.

2.1 Pedagogical objective

The pedagogical objective O^{Ct} "(1)" of a collection is conceptualized from the objective to learn dimension Ld and the junction of the cognitive Cd with the knowledge Kd dimensions ("As shown in Figure 1").

$$O^{Ct} = \{Ld, Cd, Kd\} \quad (1)$$

14: $O^{Cr_i} = \{O^{Ch_j}\}_{j\in[1\cdots s]} = \{O^{U_k}\}_{k\in[1\cdots c]} = \{O^{Cpt_h}\}_{h\in[1\cdots n+m]}$

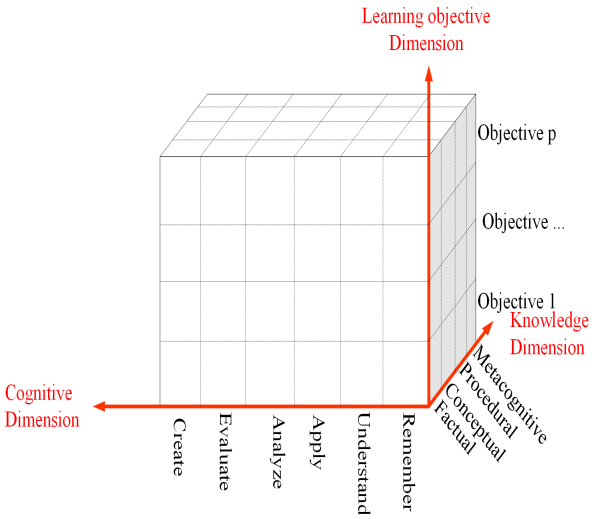

Figure 1: Pedagogical objective

Tutors create educational collections with taking into account the progress of the objectives to acquire throughout the learning process ("As shown in Algorithm 1"). By means of joining to each collection a learning objective, however, for each one is assigned one of the 24 levels ("As shown in Table 1") arranged by the junction of the knowledge type and the cognitive process identified in the revised Bloom Taxonomy [23]. Each level is represented by the coefficient $Pd(Ct)$ ("As shown in Table 1") which we propose is equal to the product of the value of the

knowledge type {1..4} and the value of the cognitive process {1..6} compared to all levels of the taxonomy.

Table 1: Coefficient of learning objectives

$Pd(Ct)$	(1)Factual	(2)Conceptual	(3)procedural	(4)Metacognitive
(1)Remember	1/24	2/24	3/24	4/24
(2)Understand	2/24	4/24	6/24	8/24

(5)Evaluate	5/24	10/24	15/24	20/24
(6)Create	6/24	12/24	18/24	24/24

3 Modeling Cognitive, activity and motivation indicators

In the framework of developing Cognitive, Activity and Motivation aspects of learners, deduced from navigation traces and consulting concepts presented in course content. As a fundament of an adaptive learning content, we detail these indicators that are updated each time the learner progresses and pass his unit test.

$$\left(C^{U_k}, A^{U_k}, M^{U_k}\right) \quad (6)$$

3.1 Navigation traces

The navigation traces are collected in the form of a web browsing data, the flow of these interactions data reflects the interaction of a learner ("As shown in Figure 3").
A trace $Tr^k(t_i)$ in a learning session with an index k regroups all interactions data captured at every time of consultation t_i, it is characterized by;

t: Duration of learning a unit.

N: Total number of traces visited when learning a unit.

$f_{Tr^k(t_i)}$: Frequency of consultation of an interaction trace.

$d_{Tr^k(t_i)}$: Duration of an interaction trace.

3.2 Cognitive indicator

The cognitive activity indicator "(7)" for a learner at a given unit is a component defined by a $3-tuple$ of explanatory variables related to that unit.

$$C^{U_k} = (D_{knowledge_{U_k}}, D_{memorizing_{U_k}}, D_{reasoning_{U_k}}) \quad (7)$$

$D_{knowledge_{U_k}}$: The knowledge degree is calculated after the learner accessed and proceeded to a unit as well as having passed this unit test T^{U_k} ("As shown in Figure 2). Indeed, a unit test is a transit from one unit to another in order to ensure the assimilation of the pedagogical objectives and knowledge presented to the learner related to each pedagogical component of this unit ("As shown in Algorithm 2"). However, the calculation of knowledge acquisitions follows a linear process in the learning activity.

Algorithm 2: Processing the level of knowledge $\{D_{knowledge_{U_k}}\}$

for each $U_k \in [U_1 \cdots U_c]$ **do**
  for each $[Cpt_1 \cdots Cpt_{n+m}]$ **do**
    for v' questions $Q_i^{Cpt_h}$ associated with the pedagogical component Cpt_h. Each acquisition Aq_{Cpt_h} of this pedagogical component Cpt_h is linked to a vector $[1..v'] \subset [1..v]$ of questions $Q_i^{Cpt_h}$. **do**
      if $\sum_1^{v'} R(Q_i^{Cpt_h}) \geq \frac{v'}{2}$, with $R(Q_i^{Cpt})$ as answers given by a learner **then**
        $Aq_{Cpt_h} = 1$, Cpt_h is acquired.
      else if
        then $Aq_{Cpt_h} = 0$, Cpt_h is non acquired.
      end if
    end for
  end for
  Calculate $D_{knowledge_{U_k}} = \frac{\sum_1^{n+m} Aq_{Cpt_h}}{n+m}$, $D_{knowledge_{U_k}} \in [0,1]$.
  if $\sum_1^{n+m} Aq_{Cpt_h} \geq \frac{(n+m)}{2}$. **then**
    T^{U_k} is assessed validated with $state_{D_{knowledge_{U_k}}} = acquired$ and learner is redirected to unit U_{k+1}.
  else if
    then T^{U_k} is assessed not validated with $state_{D_{knowledge_{U_k}}} = non-acquired$ and the learner is redirected to the same unit U_k.
  end if
end for
Save the learner degree and state of knowledge $\{D_{knowledge_{U_k}}, state_{D_{knowledge_{U_k}}}\}$.

$D_{memorizing_{U_k}}$: The memorization degree is the quantification of memorized knowledge in a unit U_k. This degree represents the sum of the acquisitions multiplied by the coefficient of objective of a pedagogical component to which they correspond, divided by the number of acquisitions to be acquired $(n+m)$ for each unit ("As shown in Algorithm 3").

Algorithm 3: Processing the memorization degree $\{D_{memorizing_{U_k}}\}$

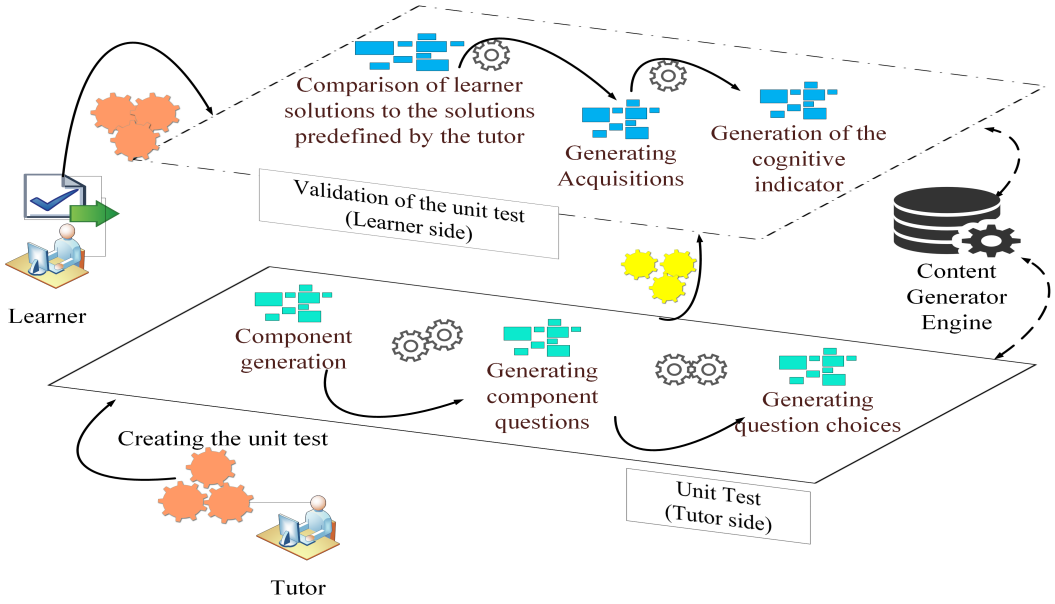

Figure 2: Generation of the cognitive indicator

1: **for** each $U_k \in [U_1 \cdots U_c]$ **do**
2: **for** each $[Cpt_1 \cdots Cpt_{n+m}]$ **do**
3: **for** All acquisitions Aq_{Cpt_h} of a pedagogical component Cpt_h **do**
4: **Calculate** $D_{memorizing_{U_k}} = \frac{\sum_{h=1}^{n+m} Aq_{Cpt_h} \times Pd(Cpt_h)}{\sum_{h=1}^{n+m} Pd(Cpt_h)}$
5: **end for**
6: **end for**
7: **end for**
8: Save the degree of memorization $\{D_{memorizing_{U_k}}\}$

$D_{reasoning_{U_k}}$**:** The reasoning degree refers to the ability of an effective knowledge understanding, proposed on a unit U_k, it represents the sum of all the given answers $R(Q_i^{Cpt})$ multiplied by their logical reasoning coefficient divided by the total number v of questions present in the unit test T^U (”As shown in Algorithm 4”).

Algorithm 4: Processing the reasoning degree $\{D_{reasoning_{U_k}}\}$

1: **for** each $U_k \in [U_1 \cdots U_c]$ **do**
2: **for** each $[Cpt_1 \cdots Cpt_{n+m}]$ **do**
3: **for** each $\{Q_i^{Cpt_h}\}_{i\in[1..v]}$, where $R(Q_i^{Cpt_h})$ is the learner's answer to the question $Q_i^{Cpt_h}$ **do**
4: **if** $\exists$ dependence between $Q_i^{Cpt_h}$ and $Q_{i-1}^{Cpt_h}$ **then**

$$P(Q_i^{Cpt_h} \mid Q_{i-1}^{Cpt_h}) = \begin{cases} 0, R(Q_i^{Cpt_h}) = 0 \,\&\, R(Q_{i-1}^{Cpt_h}) = 0 \\ \frac{1}{2}, R(Q_i^{Cpt_h}) = 1 \,\&\, R(Q_{i-1}^{Cpt_h}) = 0 \\ 1, R(Q_i^{Cpt_h}) = 1 \,\&\, R(Q_{i-1}^{Cpt_h}) = 1 \end{cases} \quad (8)$$

5: **else if** $\nexists$ dependence between $Q_i^{Cpt_h}$ and $Q_{i-1}^{Cpt_h}$ **then**
6:

$$P(Q_i^{Cpt_h} \mid Q_{i-1}^{Cpt_h}) = \begin{cases} 0, & R(Q_i^{Cpt_h}) = 0 \\ 1, & R(Q_i^{Cpt_h}) = 1 \end{cases} \quad (9)$$

7: **end if**
8: **Calculate** $D_{reasoning_{U_k}} = \frac{R(Q_1^{Cpt_h}) * P(Q_1^{Cpt_h}) + \sum_{i=2}^{v} R(Q_i^{Cpt_h}) * P(Q_i^{Cpt_h} | Q_{i-1}^{Cpt_h})}{v}$
where

$$P(Q_1^{Cpt}) = \begin{cases} 0, & R(Q_1^{Cpt_h}) = 0 \\ 1, & R(Q_1^{Cpt_h}) = 1 \end{cases} \quad (10)$$

9: **end for**
10: **end for**
11: **end for**
12: Save the reasoning degree $\{D_{reasoning_{U_k}}\}$.

3.3 Activity indicator

The activity indicator ”(11)” measures the degree to maneuver learning on a given unit. It is a component defined by $3-tuple$ of explanatory variables linked to this unit (”As shown in Figure 3”).

$$A^{U_k} = (Res_{U_k}, Int_{U_k}, Efr_{U_k}) \quad (11)$$

Res_{U_k}**:** Resistance to learn expresses the difficulty of learning all the pedagogical objectives presented in a unit.

$$Res_{U_k} = \frac{\sum_{j\in[1..N]} f_{Tr^k(t_i)}(j)}{N} * d^2_{Tr^k(t_i)}(j) \quad (12)$$

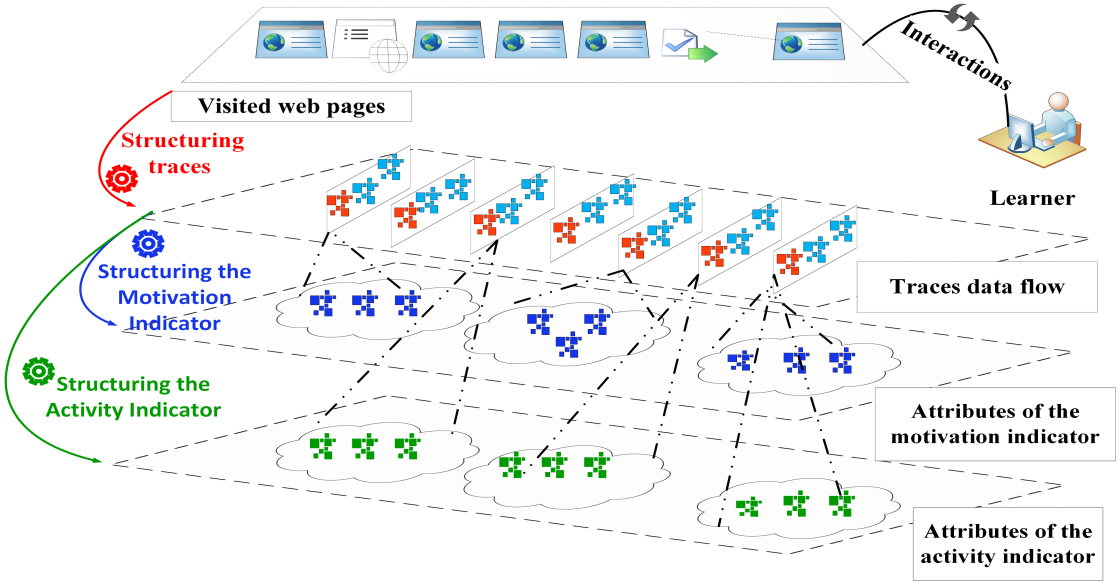

Figure 3: Structuring Activity and Motivation Indicators

Int_{U_k}: Learning intensity expresses the intensity to learn all the pedagogical objectives presented in a unit.

$$Int_{U_k} = N/t \tag{13}$$

Efr_{U_k}: Learning effort expresses the effort to learn all the pedagogical objectives presented in a unit.

$$Efr_{U_k} = Pd(U_k) * Res_{U_k} * {Int_{U_k}}^2 * t \tag{14}$$

3.4 Motivation indicator

The motivation indicator "(15)" measures the degree of motivation in learning all the pedagogical objectives presented in a unit ("As shown in Figure 3).

$$M^{U_k} = \sum_{j \in [1..N]} Pd(U_k) * \frac{f_{Tr(t_i)}(j)}{N} * \frac{d_{Tr(t_i)}(j)}{t} \tag{15}$$

4 Method

The perplexity of the proposed indicators modelization, depends on the reliability of the proposed scale. In fact, we implemented all procedures of our approach in an adaptive learning content system we named S-CAMO.

4.1 Learning environment

The system S-CAMO comprises the module "web navigation tracker" which is an extension that retrieves the data of navigation on the Internet between the time of the connection and the disconnection to the system. This extension will appear as an icon in the browser's menu bar, where the learner will have to enter his username and password and then log in. If the learner exists in the database, then the profile (Learner name, learner identifier) will persist in the local storage of "Google Chrome". However, just after installing this extension, authentication will remain active as long as the learner does not choose to disconnect manually. This extension detects and traces access to any web page in any open tab of the browser "Google Chrome", as well as verifies the learner's adhesion to each learning session opened in the platform, through the validity of its domain name. The extension sends the navigation or interaction data to the web server.

4.1.1 Interception of navigation data

For each successful authentication of a learner, the web service provided by the platform retrieves his identifier ("As shown in Figure 4). However, whenever the learner changes web page (url), the browser adds a new function that will be delegated to the extension level. The process of the new function includes:

1. The retrieval of the information of each navigation data which are url, the url parameters (parameter of the request), the title of the web page;

2. Testing and verifying the authentication at the platform, in order to send the information associated with this new intercepted and formulated navigation data.

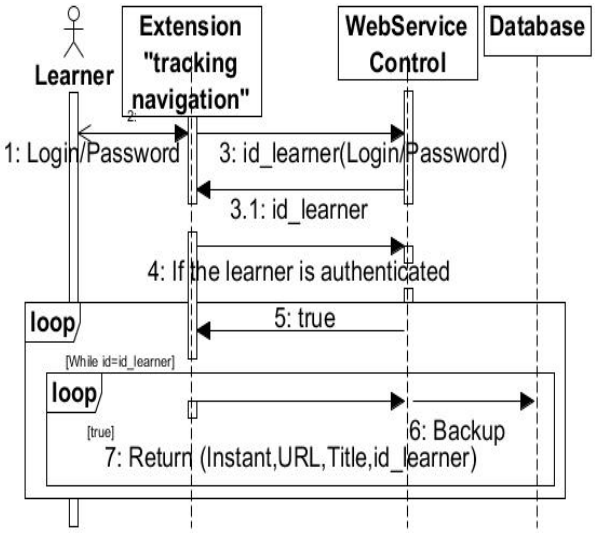

Figure 4: Process of intercepting a navigation trace by "web navigation tracker" module

4.2 Participants

The sample of learners on which the test was conducted is equal to 50 students, organized into 3 approximately equal groups. The group G_1 and G_2 contained 17 learners, while G_3 contained 16 ones. These learners were heterogeneous in relation to their level of education and had at least an associate degree.
Learners had a laptop, nevertheless, those who could not bring one, had at their disposal laptops or desktop laboratory. For the relevance of the study, we made sure that the module "web navigation tracker" was installed before the test.

4.3 Materials

We create a course ("As shown in Table 2") while respecting the learning content structuring described above, also to each educational collection was assigned a pedagogical objective.
All students followed the same course and performed the presented tests unit .

5 Task analysis results

This study recovers values of all indicators' variables according to the proposed approach, by studying the learners traits.
We have obtained the number of learners who have acquired or not the knowledge concepts presented at level of the chapter Ch_1 structure ("As shown in Table 3).

Table 3: Tests unit of chapter Ch_1 results.

$state_{D_{knowledge_{U_k}}}$	U_1	U_2	U_3
$acquired$	34	48	40
$non-acquired$	16	2	10

Table 4: Abbreviation of indicators variables

abbreviation	variables
$D_{knowledge_{U_k}}$	v_1
$D_{memorizing_{U_k}}$	v_2
$D_{reasoning_{U_k}}$	v_3
Res_{U_k}	v_4
Int_{U_k}	v_5
Efr_{U_k}	v_6
M^{U_k}	v_7

The three groups present approximately the same characteristics with respect to the educational components of the studied chapter. In fact, all groups reflect a strong correlation among the variables of the cognitive indicator relatively to all the tested units. All groups have no resistance to learn in relation to all units except for group G_1 who presents moderately a resistance to learn unit U_1. All groups have a low intensity to learn relatively all units, however more is the intensity to learn less there is a resistance. The effort to acquire knowledge and to memorize for the group G_1 remains average relatively to unit U_1 while it is low for groups G_2 and G_3, however there is no effort to reason for all groups for all units. All groups show moderate resistance linked to the effort to learn the unit U_2, however, the group G_1 has an effort related to the resistance at unit U_1. Unlike group G_2 and G_3 where resistance is not related to effort. As well as group G_3 has a resitance related to the effort at unit U_3 while group G_2 and G_3 where resistance is not related to effort. Intensity to learn is moderately low compared to all units. Motivation is weakly related to the variables of the cognitive indicator, it is moderately linked to the resistance to learn and weakly related to the intensity of work. All groups have a moderately weak relationship between motivation and effort .

6 Conclusions and discussion

The many aspects profile of learners serve on adapting their learning environment. However, the lack of holistic measures in learning environment make us propose a compilation of indicators by developing a theoretical conception that include the cognition, activity and motivation in a learning process.The study involve the measurement of the proposed indicators' structures, it reflects the behavior and trend of learners on processing information in learning interactions. In this context, we develop

an educational content structure which was already implemented and which mobilizes the achievement of the specific estimation of the updated indicators after each pedagogical unit. The results show specifically a high relation among the cognition attributes and a moderatly interrelated linkage among all the studied variables. We assume that the scale we have presented in this paper prove the efficiency of the proposed modelization.

ABSTRACT

Small animal modeling is an exciting research field where human pathogenic frameworks can be replicated in a controlled environment. Accurate Imaging is in high demand when modeling abnormalities and, magnetic resonance imaging plays a vital role due to its demonstrated lowest intrusion when compared with other imaging methods. However, the required high-resolution yields low-quality images and often, critical events are masked. In this manuscript, we improve the images in small animal frameworks by modifying the reception coils to parallelize the readings and by dealing with the mutual induction produced at the dimensions required for the studied subjects.

1 Introduction

Magnetic Resonance Imaging (MRI) has become a ubiquitous tool in imaging research and clinical radiology due to its capacity to provide non-invasive, in-vivo images, both in humans and in animal models. Small animals are widely used in disease research as their size make them particularly easy to manipulate; however, MR imaging is also significantly more challenging in smaller structures. The trade-off between the spatial resolution and signal-to-noise ratio (SNR) becomes exceptionally important when scanning small volumes.

Despite improvements in high field magnet technology at 7T and beyond, several factors reduce image quality so that larger fields may not mean better images. In particular, T1 lengthening, T2 shortening, and chemical shifts artifacts account for lowering the image quality well below theoretical expectations in high field magnets [1]. In contrast, parallel acquisitions improve image quality while avoiding all of these issues [2]. Simultaneous acquisitions require single receptors to be split into two or more simple loops while maintaining the field of view (FOV). This dimensional reduction is, initially, convenient because smaller receptors provide higher sensitivity and field stability [2], [3]. Nevertheless, when two or more coils share a common space, their mutual inductance (MI) [4] deteriorates the receptor characteristics of the coils to the point where images can not be produced.

Here we present strategies to increase the quality of MRI images in surface coils and to minimize the deteriorating effects of MI. The first involves a shared capacitor placed between adjacent loops that counteracts the rising MI at Larmor frequency (F_r). A second strategy, accomplished with pre-amplifiers, consists in diminishing the electrons' flow among the receptors, so the factor $L\frac{di}{dt}$ is reduced; therefore, MI declines as well. This last strategy is intended to deal with high order MI, which is likely to be an issue when reading parallelization involves more than two channels.

We also determine the effect of implementing these MI reducing strategies both, independently and combined by analyzing the SNR, the field stability and the sensitivity of the coils for the images produced.

2 State-of-the-art technology

The concept of reducing the coils' area to produce more efficient receptors, which was introduced by Roemer in [2] is both, attractive and challenging. It has numerous technical advantages, such as the possibility of creating adaptable devices that can fit almost any volume, while maintaining modularity [5]. A reasonable attempt at using multiple surface coils was presented by the Petals Project [6]. In that work, the receptor device consisted of a crown of resonant loops for hydrogen nuclei magnetized at 1.5T. The authors

[*]Fernando Yepes-Calderon, 1300 N. Vermont Av, Los Angeles-CA, USA & fernandoyepesc@gmail.com

https://dx.doi.org/10.25046/aj020368

elegantly avoided near (first order) and next to near (higher order) MI by placing a gap between receptors. One drawback of this approach is that images of the brain presented not only progressive in-depth deterioration, but also fuzzy regions between the "petals." In spite of these issues, the Petals Project work showed the validity of the multiple coil approach and provided an important step towards applicability, while demonstrating the flexibility of the device.

The reception capabilities of the coil circuitry are not only dependent on its electrical length, but also on its geometrical configuration. For example, in [7], planar devices were build for which proper decoupling was enforced at the cost of reduced flexibility. In humans, [5] designed an interfacing box that allowed to connect up to 16 coils with different shapes, generating images with good contrast, though with an FOV of $200cm^2$. Notwithstanding these high dimensions (a surface coil of $200cm^2$ is too big for scanning a rat or mice), the circuitry is stable due to the larger values of its reactive components. The dynamically adaptable tuning-and-matching box is feasible due to the relatively big size of humans, but its implementation with smaller devices has various drawbacks associated with the electrical length of connectors and their dependence on frequency. The problem of making coils invisible to each other in an array disposition is well depicted in [8], where the authors proposed a geometrical method by placing a butterfly coil in parallel with a loop component. Through this configuration, a 90° combination of signals isolated the array from second and superior order MI while critical overlapping accounted for first order MI. This implementation was accomplished by arranging commercial coils to suit the quadrature configuration and presents and alternative to the low impedance preamplifiers in Roemer's small coil strategy [2]. Yet in [7], the authors stated one more motivation to implement smaller receptors. Apart from offering better field stability and more in deep tissue penetration, its implementation, due to the inherent FOV reduction and the necessity to recover it, forces the use of parallel imaging (PI), which in turn reduces acquisition time. Following this initiative, several other authors looked into the so-called array coil. In particular, in [9] and [10], human array coils were designed for PI implementation, which allowed the use of standard reconstruction methods such as Simultaneous Acquisition of Spatial Harmonics (SMASH) [11], Sensitivity Encoding (SENSE) [12], Generalized Auto-Calibrating Partially Parallel Acquisitions (GRAPPA) [13], [14] and their improvements or variations [15]. The idea is that a complete positioning axis can go from being encoded in a voxel-by-voxel fashion to being wholly or partially encoded in one TR depending on the length of the array and its relative dimensions about the subject being scanned. Consequently, the acquisition time is dramatically reduced.

For small animal imaging, the reduced size of the subjects imposes new challenges. For example, circuits may be too long or of unsuitable geometries. Also, the dynamic components are smaller, making the circuitry less stable. In spite of these issues, array coils have been used for specific applications like in [16], where rodents are scanned at ultra-high magnetic fields. In this case, the images are read with a three-channeled device, but each channel has been built to detect a different element's nuclei, and therefore, their resonance frequency is different. Thus, MI is minimized by the selectiveness of the receptors. In one more small animal implementation, a novel imaging method capable of detecting redox-status, oxygenation and free radicals has also been introduced as a functional MRI strategy. This has been called Electron Parametric Resonance (EPR) [17], and is implemented through a 4-channel coil array. Here, the receptors are activated sequentially; thus, there is no need of MI decoupling methods.

The work presented here is a step toward creating operative MRI surface coils. Our model consists of a single loop coil that is replicated to build a two elements receptor. Once the coils share the same space, the MI affects the reading. Two strategies for avoiding MI are implemented. The first consists of a shared capacitor that counteracts the MI by resonating at the working frequency with the inductive effect; therefore, turning the induction circuit in a purely resistive device. The second strategy consists of adding a low impedance pre-amplifier to the parallel channels, so the read signals are transported as voltage instead of current; consequently, the induction principle of Faraday is minimized.

The design suits the small animal dimensions. At these sizes and working frequencies, one faces instability of the electronic components, high influence of geometry and the fact that even a simple cable can become any active component – a capacitor or an inductor – therefore making of the resonance condition, a moving target.

3 Materials and Methods

All experiments presented here were performed using a Biospec 4.7T MRI Bruker system, setup to enable the surface coil mode and PI. This system is usually sold with volumetric coils as the original acquisition device; Although, these antennas may be changed to suit animal dimensions. The software can be adapted to either use volumetric coils that have the emitter and the receptor on the same device or to use two different devices; thus making of the surface coil, the receptor device. Under the surface coil scheme, the emitter can be any of the individual coil sets provided by the manufacturer.

The new devices are Printed Card Board (PCB) loops designed using the Eagle software [18]. The associated circuitry was created following the procedure depicted in [19]. The devices were simulated and tested individually in a network analyzer (Agilent - E5062A-275) before coupling them to the MRI scanner. All coils were matched at 50Ω and tuned at

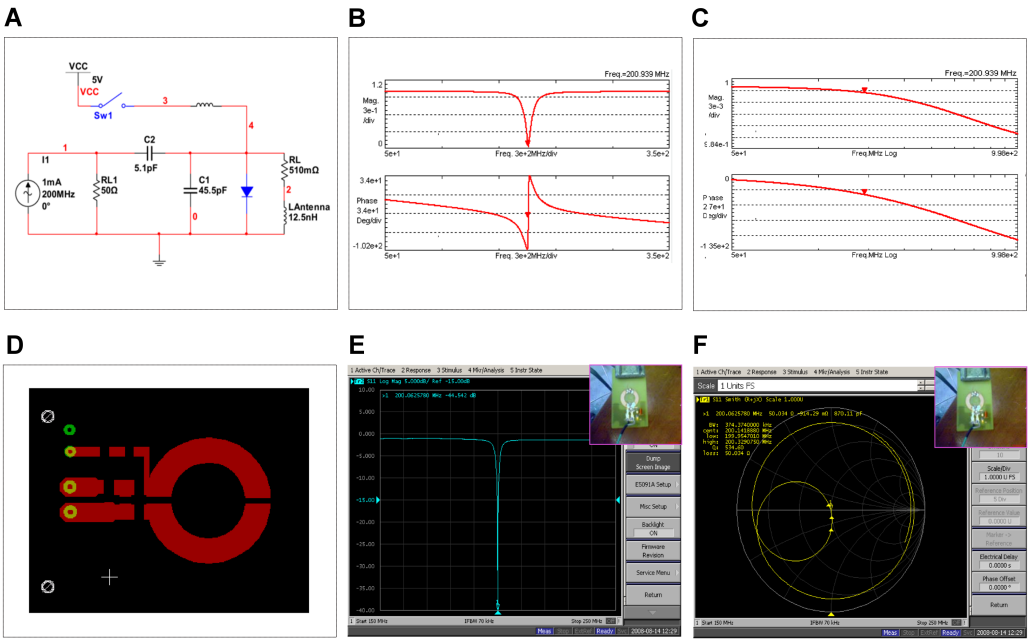

Figure 1: MRI single surface coil fabrication. **A**. Schematic of the circuit. **B**. Simulation of magnitude and phase responses of the circuit in A. **C**. The output of the circuit in magnitude and phase when the decoupling pin diode (line 4 in A) is on, providing protection to the coil against MRI RF pulsation. **D**. PCB of the real single surface coil. **E**. The amplitude response of the designed circuit read in the network analyzer around frequency F_r. **F**. Zero Index of signal reflexion in the coil's terminals depicted in a Smith diagram. The PCB in D, when mounted, is used to create the displays in panels E and F (see upper right corner of these two panels).

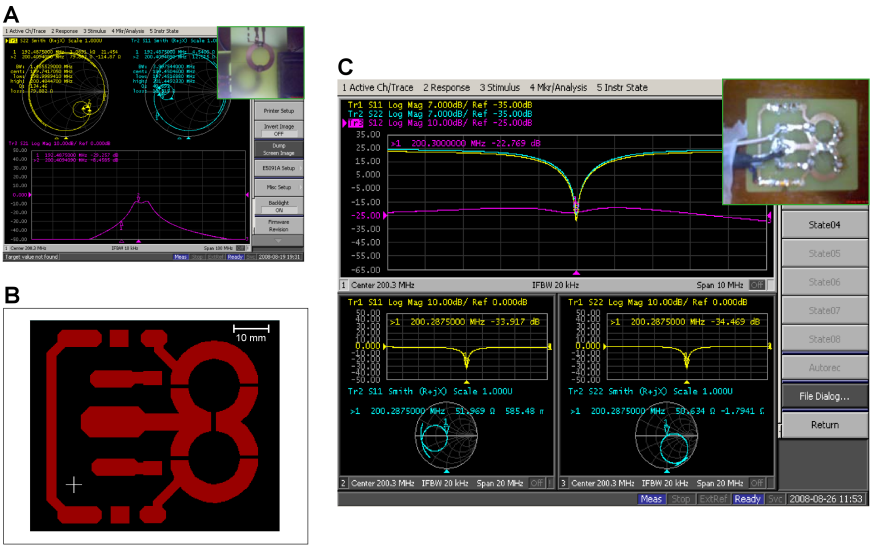

Figure 2: Two loops MRI receptor. **A**. Reduced emission/reception capabilities due to MI (see loops in the upper right panel). **B** PCB of the two-elements coil. **C**. Proof-of-concept: two coils magnetically separated by a shared capacitor. Here, the loops behave as if they were single devices, similar to the scheme in figure 1-E. The Smith diagrams show perfect matching and tuning in both loops

(f_r) which corresponds to 200.3 MHz, as dictated by hydrogen spins magnetized at 4.7T. The different devices that we tested consist of:

- **SD** → A single-loop coil, $15mm$ in diameter.
- **DD** → A two-elements coil with shared capacitor, $2x15mm$ in diameter.
- **SDWP** → A single-loop coil with low impedance amplifier, $15mm$ in diameter.
- **DDWP** → A two-elements coil with shared capacitor and pre-amplifiers, $2x15mm$ in diameter.

Figures 1 and 2 show the circuit design and simulation, as well as evidence of accurate tuning and matched properties for the SD and DD devices.

3.1 Reducing di/dt. The low-impedance pre-amplifier

The role of the low-impedance pre-amplifier is to reduce current flow trough the coils' terminals; therefore, the MI is also lowered [20]. The objective of this strategy is to obtain a circuit that has a high impedance on the coil side and, simultaneously, a low impedance at the preamplifier's terminals at frequency F_r. In order to accomplish this, the $\lambda/4$ concept described in [21] is used. Briefly, the $\lambda/4$ length happens to be the distance at which a coaxial cable like the one used for transmission inside the scanner, becomes the desired device (high impedance on one side, a low impedance in the opposite). Using the network analyzer and the Smith diagram, this length was found to be $21cms$.

The $\lambda/4$ cable is then plugged-in to the terminals of the two devices already created. Figure 3 shows the final setup of the receptors.

The images are created on phantoms using T1 contrast and multi-slice-multi-echo sequence (MSME-pvm) [22]. The repetition and echo times (TR and TE) are 261.4 and 10.7 ms, respectively, with a flip angle of 180°; isometric in-plane resolution of $0.136mm$; slice thickness of $2mm$; $35x35mm^2$ FOV; $256x265$ matrix, 8 slices for single loop coils, and 16 for the two-elements ones. The acquisition time is kept at 3.06 minutes for all experiments. The phantom for single loops coils consists of a circular syringe 15mm in diameter, while the two-elements devices scanned a syringe of 30 mm in diameter. Both phantoms contain a mix of water, salt (4.5%) and gadolinium. We performed six acquisitions per device. The five most centered slices in the volume of interest of each experiment are used to compute statistical comparisons (see Table 1).

3.2 Measures of coils performance and comparisons mechanisms

Measures of SNR, field stability, and visual depth were gathered from the acquired images. The SNR is obtained in the time-domain as the ratio between the signal - high-intensity pixels arranged in a circular fashion - and the standard deviation of the intensities in the background. The field stability was characterized by the horizontal profile while visual depth was obtained from the vertical profiles, where amplitude and signal decay are separately analyzed. All measures were done in axial views. A Shapiro-Wilk test was run over the data to determine the normality of the distribution. T-tests were performed on all the normally distributed data. However, the horizontal and vertical (amplitude and decay) profiles resulted in not normally distributed data, so we used the Mann-Whitney U test for statistical comparisons. Table 1

summarizes the factors we analyzed, the statistical tests, the comparisons we used and the questions that we addressed with each test. Statistical significance is assessed using a threshold of $p = 0.05$. All the statistics mentioned above were computed with SPSS.

4 Results

This section presents the results of applying the measurements described in Subsection 3.2. Color coding and labeling are provided; moreover, the colors are coherent throughout all sections for a fast association between the result and the device under test. The leftmost panel in each figure shows the regions where the data were gathered.

4.1 SNR comparisons

For each device, the SNR was measured by taking as signal a disk in the high-intensity region at the center of the image and, as noise, the standard deviation of intensities in the rest of the FOV.

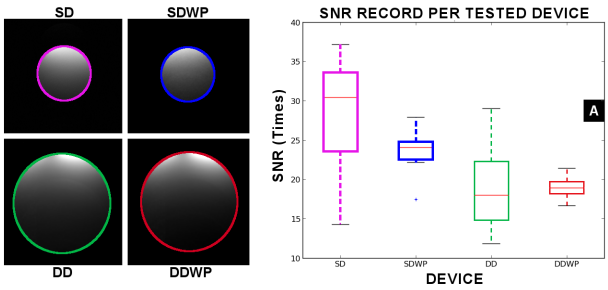

Figure 4: Panel A. Single loop devices exhibit a higher image quality as measured by the SNR, nevertheless it is in this group (the single devices) where the pre-amplifier generates the largest gap in quality when comparing with its counterpart (SDWP). Remarkably, in both, single and double device groups, the use of the pre-amplifier reduces the noise dispersion. In the double-loop devices, the pre-amplifier does not modify the SNR.

No statistical differences in SNR were found (t(14)=1.47, p=0.16) between SD ($\overline{x} = 28.54 \pm 7.95$) and SDWP ($\overline{x} = 23.44 \pm 3.48$). For the DD devices, the average for DD and DDWP were respectively 19.05 ± 6.35 and 18.99 ± 1.64. They were not statistically different from each other (t(10)=0.024, p=0.98).

4.2 Field stability

A Gaussian filter is applied to the original profile aiming to recover its low-frequency component, which is in turn, a measure of the field stability. The cutoff frequency is automatically extracted from the properties of the given profile by truncating its Fourier spectrum at 90% of the spectral energy content. Posteriorly, a homemade program iteratively looks for a polynomial that fits the filtered signal. The algorithm stops when the correlation coefficient reaches the value of 0.995, then, the index of the fitted polynomial is saved for each profile. In SD devices, the fitted polynomial found from 3 to 7 constraints, with an average of 5 for the two included devices. In DD devices, there is a natural increment of the tortuosity due to the boundary created by the two channels. The asymmetry in the profile was a constant in all the tested devices; we hypothesize this is due to a difference in the copper deposition in the construction process.

4.3 Visual depth

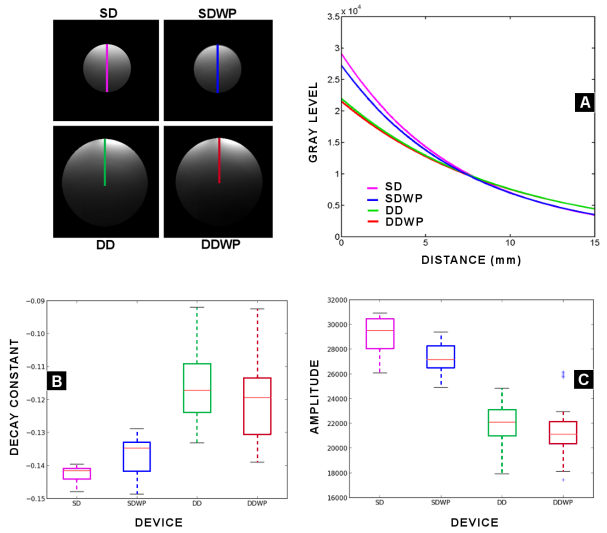

Figure 6: Comparison of vertical profiles. The vertical profile can be compared among all tested devices since the composition in the phantoms is the same for all devices regardless of their size. Panel A shows the decay while penetrating the phantom in all devices. Panels B and C show the data distribution in decay and amplitude respectively for each tested device.

In the single loop device, the use of the pre-amplifier reduces the dispersion in the decay constant. Nonetheless, the mean value for this decay is faster when the pre-amplifier is used. Both versions of the two elements loop allow the system to decay more slowly compared with their single loop counterparts. The amplitude in SD and DD devices can not be compared due to the loss of quality factor evidenced when looking at **Figures 1-E** and **2-C**. Additionally, the amplitude and the decay constant can be separated for this specific analysis since the peak amplitude of the signal depends solely on construction specifications while the signal decay is a function of recruited spins. Considering that the phantom contains the same solution for all tested devices, the signal decay can be use for comparing all built devices, but an amplitude comparison will be only fair if done intra-group.

Table 1: **Questions addressed and statistical tests performed**

Factor	Test	Comparisons	Addressed question
SNR	T-test	(SD-SDWP)	Is the quality of the images affected by addition of the pre-amplifier?
SNR	T-test	(DD-DDWP)	Is the quality of the images affected when the pre-amp and the shared capacitor are in place?
Horizontal	MWU	(SD-SDWP)	Is the field homogeneity affected by the pre-amp?
Horizontal	MWU	(DD-DDWP)	Is the field homogeneity affected by the pre-amp if another MI avoiding strategy is used?
Amplitude	MWU	(SD-SDWP)	Is the amplitude of the acquisitions affected by the use of the pre-amp?
Amplitude	MWU	(DD-DDWP)	Is the amplitude of the acquisitions affected when the pre-amp and the shared capacitor are in place?
Decay	MWU	(SD-SDWP)	Is the use of the pre-amp affecting the visual depth?
Decay	MWU	(DD-DDWP)	Is the visual depth affected when pre-amp and the shared capacitor are in place?
Decay	MWU	(SD-DD)	Is the visual depth of the coils increased when the inner diameter of the device decreases?
Decay	MWU	(SDWP-DDWP)	Is visual decay affected when two MI avoiding strategies are implemented together?

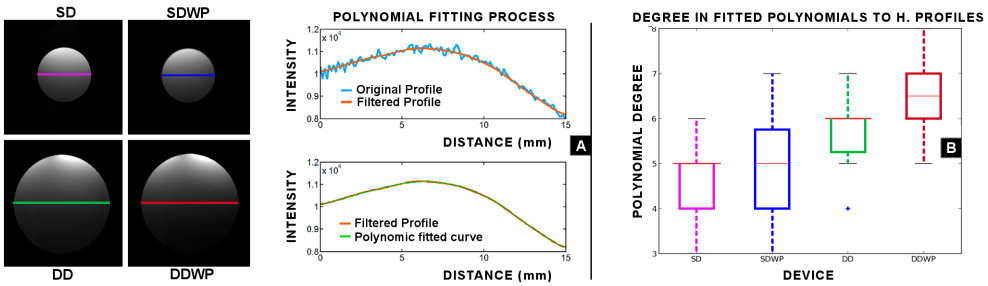

Figure 5: Panel A. Summary of the procedure for the horizontal profiles. Panel B. Distribution in tortuosity of the horizontal profiles in each device, measured as the degree of the first polynomial adjusted at 0.995 index of correlation

Decay	MWU	(SDWP-DDWP)	$(27222 \pm 1315.57),(21526.8 \pm 2375.99)$	0.001*	U=109.50, Z=5.03

The built devices are capable of MRI imaging, that should be and indubitable statement at this point due to the vast evidence presented with the Smith diagrams in **Figures 1** and **2**. However, we show in **Figure 7**, proof of the images that may be acquired with the sort of surface receptors designed and built along the development of the experiments that support the statements in this manuscript.

5 Discussion

Our hypothesis is that the DD devices behave similarly to the SD devices when MI is diminished or avoided, and this claim is validated in those experiments with no statistical differences. Hence, we focus the discussion on those trials that resulted in statistical differences, and on their practical implications. Refer to the entries labeled with * in Table 2.

A significant difference (U= 247.50, Z=3.22, p=0.001) is found between DD ($\overline{x} = 5.63 \pm 0.85$) and DDWP ($\overline{x} = 6.5 \pm 0.97$). The mean rank of DD was 32.25, and that of DDWP was 23.75. These results have a low practical impact since the horizontal dynamics can be controlled by software reconstruction. In this case, we used a geometrically driven algorithm to merge the two channels, but customized setups can be implemented to optimize the smoothness of the boundary [1]. Nevertheless, the high degree of the fitted polynomials, even in the single loop devices, suggest a lack of uniformity in the copper deposition of our devices. This is observable in figure 5-A, which belongs to the SD device. A perfectly build coil within a flat B_0 field should have a profile that can be modeled with a two-degree polynomial.

In the amplitude analysis, there was a significant difference ($p \leq 0.05$) between SD ($\overline{x} = 29096.36 \pm 1586.54$) and SDWP ($\overline{x} = 27222 \pm 1315.57$) (U= 731.00, p=0.0013). The mean rank of SD was 21.13, and the mean rank of SDWP was 39.87, suggesting that the use of the pre-amplifier negatively affected the reading capabilities of the device; However, the practical implications of this finding are null, since it affects the single loop devices where the pre-amplifier does not introduce any added value. The pre-amplifier was connected to a single loop device with the purpose of creating a fair counterpart to compare the outcomes of the DDWP device. More importantly, the pre-amplifier in DD devices does not result in statistical differences, a fact of high relevance towards applicability.

In the decay analysis, there is a significant difference ($U = 193.50, p < 0.001$) between SD ($\overline{x} = -14.24 \pm 0.002$) and SDWP ($\overline{x} = -0.1366 \pm 0.005$). The mean rank of SD decay is 21.95, and the mean rank of SDWP decay is 39.05. There is no significant difference ($U = 533.00, p = 0.22$) between DD ($\overline{x} = -0.115 \pm 0.010$) and DDWP ($\overline{x} = -0.119 \pm 0.012$). The mean rank of DD decay is 33.27, and that of DDWP decay is 27.73. These results imply that visual depth is affected by the pre-amplifier in the group of devices that are not affected by the MI. In contrast, the pre-amplifiers do not have a significant influence on the signal in DD devices, where MI exists.

There was also a significant difference ($U = 0.00, p < 0.00$) between SD ($\overline{x} = -14.24 \pm 0.002$) and DD ($\overline{x} = -0.115 \pm 0.010$). The mean rank of SD decay was 45.50, and the mean rank of DD decay was 15.50. The reduction of the diameter in the coils improves the reading capabilities of these devices. There was a significant difference ($p \leq 0.05$) between SSWP ($\overline{x} = -0.1366 \pm 0.005$) and DDWP ($\overline{x} = -0.119 \pm 0.012$); $U = 109.50, p < 0.001$. The mean rank of SDWP decay was 41.85, and the mean rank of DDWP decay was 19.15, which suggest that both strategies can be used together without affecting the quality of the images.

6 Conclusions

The small animal modeling field would be greatly benefited if accuracy in the visual monitoring methods is improved. An imaging setup with better outcomes would also yield more robust results, and the derived conclusions would be less questionable. In the end, animal experimentation is the only means that humanity has to test and study the progression of diseases and to anticipate the outcomes of procedures in living subjects. In this manuscript, we demonstrated that a better MRI receptor device, suitable to work at small animal dimensions is feasible. To this purpose, we implemented MI avoiding strategies and proved that they could be used together without significantly affecting the signal quality while enabling a more efficient use of the scanning time.

ABSTRACT

In modern day technology, the Information Society is at risk. Passwords are a multi-user computer systems usual first line of defence against intrusion. A password may be textual with any combination of alphanumeric characters or biometric or 3-D. But no authentication protocol is fully secured against todays hackers as all of them are Static in type. Dynamic authentication protocol is still a theoretical concept. In this paper, we are focusing on a concept of authentication technique which is actually dynamic in genre, i.e. the password here will change in t time (where t is as small as possible). This technique comprises of both hardware and software part. In this paper, we have covered the idea of generating an efficient algorithm that can work as the final in the Dynamic Password Authentication system. We have used standard deviation within statistics to generalize the possible password which is further secured by Feistel Block Cipher and Advanced Encryption Standard technique (AES), leading and following the said mathematics respectively. In order to allow the system to create variable password in the least time interval possible, we must make sure our process is not much complex.

1 Introduction

This paper is an extension of the research work named Secure Authentication with Dynamic Password presented in the IEEE IEMCON, , Vancouver, Canada, 2016. [1]

When it is the matter with network security, we have to be updated always. As for example, today we simply cannot afford any security system that includes a dilapidated protocol (as for example Caesar Shift Cipher). Security protocols are used to protect several different medium using passwords, which supposed to be known only to the users of the system. Textual password authentication system is the most widely used protocol, though it is not much secure against Shoulder Surfing Attack, Brute Force Attack [2]. Smartcard concept, 3-d password concept are not totally protected either [3], [4]. Biometric system may be the most powerful authentication system ever, but it is much costly [2]. Dynamic password authentication system is the latest system that has come in the field. In this work we have discussed about the cryptographic way to generate the dynamic password for the authentication protocol described in the said conference. [1]

The authentication protocol described in the conference is a combination of both the hardware and software. Here we are imagining a chip which will be used as the key to unlock different ids. According to the main work, we have taken a random textual password e.g. Password. The ASCII values of each letter acts as equivalence to mass where we have used Einstein's Theory on bending Space-Time Continuum because of Mass. Now we have placed the textual password (here Password) on 3-d box which is described by the X-Y-Z coordinates.[1]

Later we have used the concept of the eye. The EYE (technically a sensor) is the only object inside the 3-D box.

The EYE will actually take a random position inside the 3-D box (i.e. the X, Y, Z coordinates of it will be selected randomly). Now the EYE will trace the endings of the shifted parts in the plane by joining them.

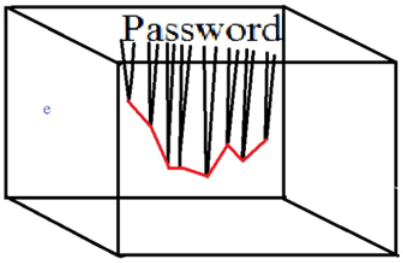

Fig.1: Traced path according as the position of the eye

If we manage to let the eye to change its position in t time (t is as small as possible), then during each time interval we will have a different path as shown.

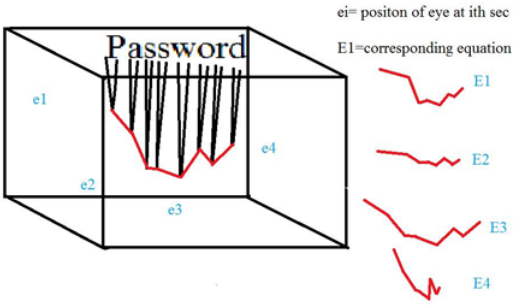

Fig.2: Traced path by the eye

Since at a certain time, the received traced path is the key of the real password, by changing the position of the EYE, and hence by getting different traced path in each time interval t, we gain the dynamically changeable password.

In this paper we have tried to make an algorithm that will be able to convert the traced path (technically a geometric figure) to a combination of binary digits (0 and 1). This expression gained at a certain time will be the password at that time interval. We will try to add some cryptographic concept in the algorithm to make a final defence in the system. The mathematical idea used to convert the geometric figure an expression of standard deviation (in decimal) will be both followed by and lead two different cryptographic concepts the first one is general Feistel Block Cipher concept,[5], [6] and the later one is AES (Advanced Encryption Standard) algorithm.

2 Security with Feistel Block Cipher Model

We will move further assuming that the textual password chosen by the user was Password. Before going to the generation of the password from the traced path, we need to find the coordinate of the points of the path, which we will do in this process. We will follow the general Feistel Block Cipher concept, i.e. at first, we will divide the plaintext into 2 equal parts say L and R. The plaintext will be the ASCII representation of the textual password. Hence we have the plaintext ASCII representation of Password 8097115115119111114100. [5],[6]

Now the string will be divided into 2 halves based on the length of it. If the length of the string is found even, the L, R will be of equal length. If the length of the string is found odd, the length of L will be 1 greater than that of R.

Here we have the length 22. Hence L will be 80971151151 and R will be 19111114100. Each digit in L and R are added and the results will be stored in R‘ and L‘ respectively. The addition of digits in L is 39 and the addition of digits in R is 20. Hence R‘ will store 39 and L‘ will store 20.

We will count (R‘ modulo 2) and (L‘ modulo 2). To find the axis of the traced path, we will follow a concept

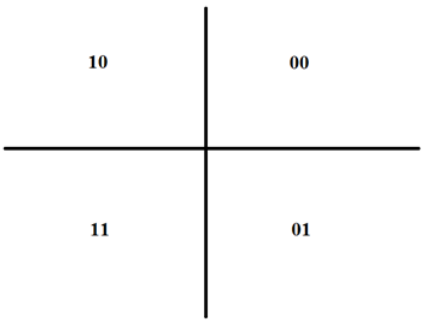

Fig.3: X-Z Coordinate Plane

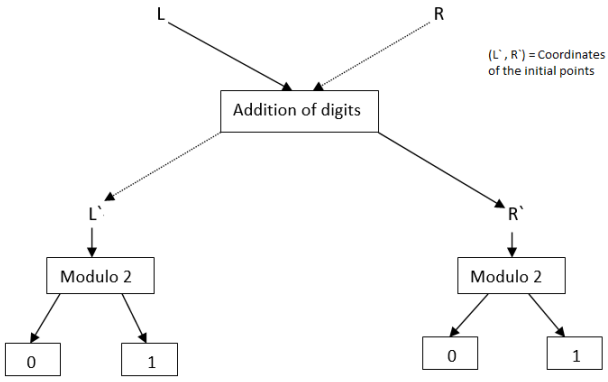
As for example if (L‘ modulo 2) is 1 and (R‘ modulo 2) is 1 then we will consider that the traced path will be in 3rdquadrant and proceed to the mathematics (hence 0 represents positive quadrant and 1 represents negative quadrant). The values of L‘ and R‘ will be the x-coordinate and z-coordinate of the initial point in the traced path respectively.



L` mod 2	R` mod 2	quadrant
0	0	first
0	1	forth
1	0	second
1	1	third

Fig.4: Feistel Block Cipher Model to get quadrant and initial coordinate

In our example, (L‘ modulo 2) is 0 and (R‘ modulo 2) is 1. Hence the traced expression will be in the 4thquadrant. The initial point will be (20, -39). It

should be mentioned that the graph, starting from a specific quadrant, may end in a different quadrant.

A case to be noted that in this concept we havent used Feistel Block Cipher completely. Here we havent used any key and there is no functioning it with L. Instead, we have changed both L and R to R‘ and L‘ respectively. The swapping of L and R to R‘ and L‘ is done only once instead of having several rounds.

3 Derivation of the Traced Path

Suppose there are n letters in the password. So, we have n corresponding extreme points in the x-z graph. Here, we connect each 2 consecutive extreme points to get one straight line. Thus, in total we get (n-1) of such straight lines, each having a definite equation f(z,x)=0. The equation of each straight line is provided by the system.

Our job is to find variance (similar to what is used in case of problems with large number of bodies)[7], and thus standard deviation for the distance of each part from x axis (z) for each of (n-1) Straight lines.

$$Variance = \sigma^2 = < z^2 > - < z >^2 \quad (1)$$

$< z >= \int_a^b z\rho(x)dx$ where (a, z_1), (b, z_2) are the two extremities of a Straight lines where $b > a$. Here $\rho(x)$ is the probability density such that $\rho(x)dx$ defines the probability of an individual being in the interval of (x,x+dx).

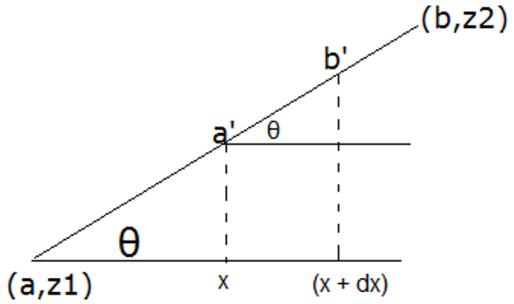


Fig.5: Derivation of traced path

Here, length of $a'b' = dxSec\theta$
Length of $ab = xSec\theta$
So,

$$\rho(x)dx = \frac{dx}{x} \quad (2)$$

Therefore,

$$< z >= \int_a^b \frac{zdx}{x} \quad (3)$$

$$< z^2 >= \int_a^b \frac{z^2 dx}{x} \quad (4)$$

Performing the integrations, we can have σ^2
Now, standard deviation= σ
Thus, we will have (n-1) no. of standard deviations for (n-1) of Straight lines.

Let, these standard deviations are σ_1, σ_2,..... $\sigma_{(n-1)}$

Let, $\sigma_k = \Sigma_{i=1}^{n-1} \frac{\sigma_i}{n-1}$, is the standard deviation.

Standard Deviation of those standard deviations is:

$$\sigma_p = \frac{\sqrt{\Sigma_{i=1}^{n-1}(\sigma_k - \sigma_i)^2}}{n-1} \quad (5)$$

σ_p is the password at that moment.

Come to think about it, for a password with n letters, there are $(26+10+30)^n = 66^n$ [26⟶ English letters, 10⟶numbers from 0 to 9, 30⟶special characters] no. of different possibilities, and thus 66^n no. of different combinations of Straight lines in z-x graph. Each of the point in z-x graph can arbitrarily be on each of the 4 coordinates. So, there are 4^npossibilities for each of 66^n different possibilities. Finally, the final standard deviation σ_p depends on the position of average of different σ_i. There are (n-1) of such partitions.

So, probability of a random password, matching the real password be:

$$Probability = \frac{1}{(66\times 4)^n \times (n-1)} = \frac{1}{264^n \times (n-1)} \quad (6)$$

For a 8 digit password, this probability is $\sim 6 \times 10^{-21}$

4 Final Security with AES Algorithm

This process is the final process in the whole system. Here we will use Advanced Encryption Standard (AES) to get the encrypted cipher text [8]. The cipher text will be the actual password in the dynamic password authentication system.

Reasons behind selecting AES encryption for our process:

(i) AES is one of the most efficient and strongest encryption systems.

(ii) Here we are not much concern of any decryption of the encrypted text (i.e. the password). Hence theres no necessity of choosing asymmetric encryption system like RSA. [9]

(iii) Comparing Twofish encryption system and AES encryption system, Twofish slightly leads in terms of security. But AES is faster than Twofish. Since our system gets high security due to the changeable password, we will allow it to change in the minimum time interval possible. Hence we are choosing AES for our authentication system. [10]

According to AES system, we will have a plaintext and key of 128 bits and there will be total 10 rounds- 9 regular rounds and 1 final round.

We will get the plaintext from the standard deviation of the previous mathematics.

Let the output from the mathematics is 6.4467. To have a plaintext of 128 bit (i.e. 16 bytes), the output is multiplied with pi (round 16 bytes decimal). Here

the output will be:20.25290535989732. Each digit excluding the point (2, 0, 2, 5, 2, 9, 0, 5, 3, 5, 9, 8, 9, 7, 3, 2) is considered and the corresponding binary digit in 8 bit is calculated (i.e. 00000010, 00000000, 00000010, 00000101, etc). Hence we have 128 bit plaintext.

To get the key, the textual password (here Password) is converted to binary. To get a 128 bit (16 byte) key the textual password will have to be of 16 letters. If the textual password is less than 16 letters then there will be a repetition of letters until it reaches 16 letters. If there is more than 16 letters then there will be excise of letters from right to left until it reaches 16 letters. At the end there will be text to binary conversion.

As for example, for the textual password Password since there is 8 letters, after updating we have PasswordPassword. Hence the key will be: 01010000 01100001 01110011 01110011 01110111 01101111 01110010 01100100 01010000 01100001 01110011 01110011 01110111 01101111 01110010 01100100.

Now we will move for AES algorithm.

The algorithm our system will follow can be described in the figure: [11]

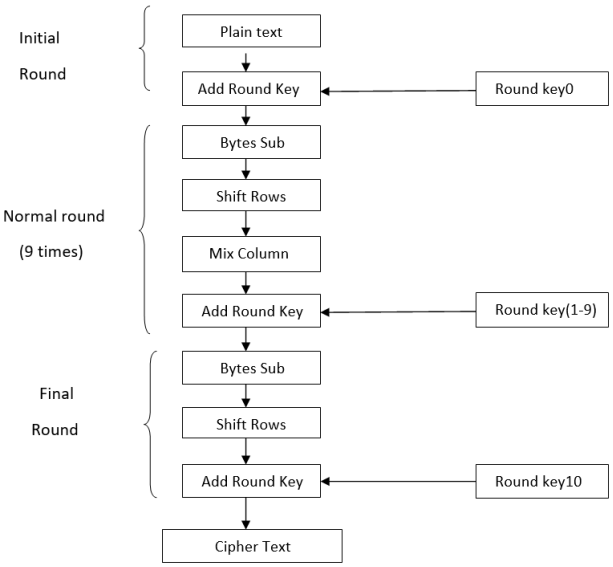

Fig.5: AES Algorithm

The cipher text we get after whole 10 rounds is the actual password of the system. It is to be noted that we havent done anything with decryption since we are not concerned with the decoding of password to original text.Since the password consists of 128 different characters each having 2 possibilities (0,1), the number of different possible passwords is 2^128.

5 Conclusion

In the main work we have already clarified that the concept is secured against most of the common security threats like Brute Force Attack, Timing Attack, Key Logger and Shoulder Surfing Attack. Moreover, it is shown that the Space and Time Complexity of the concept is less than some other common authentication techniques. The whole idea has been developed to make a secure yet simple concept, creating a user-friendly platform. The time interval t between two different traced paths will depend on the time required for the execution of the two encryption algorithms (Feistel Block Cipher and Advanced Encryption Standard technique), along with the completion of the standard deviation. Less is the t, greater is the possibility of having 2 different traced paths in a time interval T, hence greater is the security. The algorithms used in generating the binary password from the graphical traced path are recognised as some secure encryption techniques. Hence they can perform as the final defence as well. At the end we should mention that since we have worked with a completely theoretical concept, it should go through an experimental procedure to detect the flaws and disadvantages.

ABSTRACT

Network Virtualization, which allows the co-existence of various logical networks on shared physical infrastructure, has become popular in recent years. The optimal mapping of virtual resource to physical resource is a major issue in network virtualization. This problem, called virtual network embedding (VNE), has been well explored in the context of one physical domain, which is in practice operated by a single infrastructure provider (InP). However, the needs of virtual network (VN) is rapidly growing, and quite a number of VNs have to be established across multi-domain. For multi-domain VNE, infrastructure providers can no longer just solve their own single domain VNE problem, but have to cooperate to build the whole VN. Therefore, new challenge arises for the multi-domain VNE, compared to traditional single domain VNE. The existing investigations on this problem mainly focus on decomposing a VN to sub VN for each domain, but little attention has been paid to the joint relation between intra-domain and inter-domain (peering) links. In this paper, we propose a multi-domain link mapping method which combines the intra and peering link mapping so as to optimize the overall resource utilization. Our approach is easy to be deployed since it is based on current Internet architecture. Evaluation shows that our approach brings improvements related to existing methods.

1 Introduction

Network virtualization [1] is regarded as a solution to overcome some weakness of traditional network architecture. It makes easy to support various separated logical networks running over shared physical network. In virtualized network architecture, the service provider (SP) creates and manages virtual networks (VN) for end users,while infrastructure provider (InP) deploys the substrate network (SN) equipment and offers the necessary physical resources.

An important step of network virtualization is to establish VNs above SNs. This is referred as *virtual network embedding* (VNE). The VNE problem aims to find a mapping from the VN to SN in a way that objectives (*e.g.* cost) are optimized and constraints (*e.g.* bandwidth) are satisfied.

Large networks in current Internet architecture are organized by autonomous system (AS). An AS is one or several physical networks controlled by a single authority. In this article, we use the vocabulary of *"domain"* to denote the whole substrate network under the control of a single InP.

As VNs are getting more and more deployed, VNs in multi-domain will be more and more considered by potential VN users. Establishment of multi-domain VN is more difficult than the one on single domain for at least two reasons:

- First, a single domain VNE problem is mainly solved by linear programming (LP). If we had a complete vision of all the domains, a multi-domain VNE could be considered as a single domain VNE with a very large domain, so computationally harder to solve.
- More importantly, for various reasons (technical, commercial, etc.), the acquisition of full information in multi-domain is costly and often not possible. Only limited information is exchanged between InPs via protocols like BGP, so single domain approach cannot be re-used.

To address these challenges, multi-domain VNE

[*]Shuopeng Li, L2TI, Institut Galiléee Université Paris 13 Sorbonne Paris Cité Villetaneuse, France, li.shuopeng@univ-paris13.fr

https://dx.doi.org/10.25046/aj020370

frameworks are developed. Usually, there is a VN decomposition step followed by local sub VN mapping in each InP. Some authors introduced a broker-like additional actor, termed *Virtual Network Provider* (VNP) [2], between SP and InPs. The role of this VNP consists in assembling multi-domain information, decomposing VN and achieving the multi-domain VNE.

Existing solutions mainly focused on the decomposition of a multi-domain VN to each domain. One of the shortcomings in these frameworks is the lack of efficient link mapping method especially for the peering links which interconnect two domains.

In this paper, we propose an efficient framework of link mapping in multi-domain virtual network embedding context, which jointly consider the mapping of intra and peering links. In our approach, the peering links are mapped simultaneously along with intra domain links. Our approach is based on information usually disseminated by classical routing protocol (like BGP). Our simulation results prove that this solution results in better utilization of substrate resources.

The rest of this paper is organized as follows. Section 2 provides an overview of the related work. Section 3 presents our network model. Section 4 presents our multi-domain VNE solution. The evaluation results are shown in section 5. Section 6 concludes this paper.

2 Related Work

2.1 Single domain VNE

The problem of single domain VNE is NP-hard [3] [4]. A basic off-line approach is proposed in [5], which performs the embedding in 2 stages (node then link mapping). The Multi Commodity Flow (MCF) is introduced in [6] to embed the virtual links The method in [7] takes into account the virtual links in node mapping stage. It privileges such node mapping that reduce the length of substrate link path.

Since 2-stage VNE solutions are lack of cooperation, some solutions mapping nodes and links in the same stage have been proposed. An approach based on subgraph isomorphism detection is presented in [8]. An other model in [9] applies the Markov Random Walk to rank nodes and then embeds links and nodes by using back-tracking strategy based on breadth-first search. In order to meet the change of requirements over time, dynamic VNE is proposed in [10] .

2.2 Multi-domain information disclosure

Because of politic and efficiency reasons, InPs can't disclose their complete information to others, so it is critical to make clear the information disclosure policy.

The proxy VNP could get peering links location and resource information but intra-domain links cannot be assumed to be available to VNP [11].

In [12], three types of resource information in each domain are provided to VNP:

- Node: its location, available capacity and unit price.
- Peering link: its vertices, available capacity and unit price.
- Intra-domain link: a length-based price for connecting any two nodes in its domain.

Based on the information disclosure policy above, we will describe our network model in the next section.

2.3 Multi-domain VNE

Multi-domain VNE framework can be decomposed into three major components [13]:

(i) partitioning the VN request into each InP via multi-domain node mapping method,

(ii) establishing inter-domain connection (peering links) between InPs using inter-domain paths,

(iii) embedding each sub VN request in each InP using intra-domain algorithm.

Based on multi-domain information model introduced in previous section, some centralized multi-domain VNE solutions are proposed in [14][11][12][15].

Many of them mainly focus on the *first component*. In [14], the authors introduce the cost of mapping a virtual node to a domain and the cost of mapping a link between two substrate nodes. Their node mapping algorithm optimizes the total embedding cost. The approach in [12] adopts the node mapping method [7] on a full-mesh topology which complies with partial information disclosure policy.

The *second component* is not very well explored compared to the first component. Existing solutions use simple policies to establish peering links. In [14], each peering link is considered as a single VPN (Virtual Private Network) connection. In [12], the flow of peering links is unsplittable between two domains, while the intra-domain sub virtual links are splittable. The peering link path is determined by Dijkstra's algorithm on VNP layer. Since VNP layer topology is not modified over time because of cost efficiency, Dijkstra's algorithm based peering links have always the same path. This phenomenon will result in difficulty of later intra-domain mapping. In [11], a virtual node is first mapped to substrate peering node to determine the peering link and the InP it belongs to. This approach is suitable for traffic matrix based VN [16] but not topology based VN.

Since establishing peering links is a part of link mapping, the chosen peering nodes will probably influence the intra-domain paths. We believe that there exist some inter-dependencies between the 2nd and

3rd components. To this end, we propose a framework which maps peering links jointly with intra-domain links in each InP.

3 Network Model

We adopt the usual substrate and virtual network model [7]. In addition, we describe VNP layer information based on existing multi-domain information model.

3.1 Substrate Network

A domain InP_i is modelled as an undirected graph $G_i^S(N_i^S, L_i^S)$, where N_i^S is the set of substrate nodes in domain i, L_i^S is the set of internal substrate links. Each substrate node $n_i^s \in N_i^S$ is associated with a CPU capacity $cpu(n_i^s)$ and a geographic location $loc(n_i^s)$. Each substrate link $l_i^s \in L_i^S$ is associated with a bandwidth capacity $bw(l_i^s)$.

Assuming that the substrate network covers K domains, there are some peering nodes (border nodes) which have peering links with other domains. The peering nodes set is denoted by N_i^{SP} ($N_i^{SP} \subset N_i^S$). The peering links between InP_i (*i.e.* G_i^S) and InP_j (*i.e.* G_j^S) is denoted by L_{ij}^S. We denote by $P_i^S = \cup_{j=1}^K L_{ij}^S$ the set of all of the peering links of InP_i, and by P^S with $P^S = \bigcup_{i=1}^K P_i^S = \bigcup_{(i,j)\in(1...K)^2} L_{ij}^S$ the set of all of the peering links. The complete substrate network $G^S(N^S, L^S)$ is thus obtained as follows: $N^S = \bigcup_{i=1}^K N_i^S$, $L^S = (\bigcup_{i=1}^K L_i^S) \bigcup P^S$.

3.2 Virtual network

The virtual network is also modelled as an undirected graph $G^V(N^V, L^V)$, where N^V is the set of virtual nodes and L^V is the set of virtual links. Each virtual node $n^v \in N^V$ is associated with a CPU capacity demand $cpu(n^v)$, a geographic location $loc(n^v)$ and a distance constraint $dis(n^v)$ specifying how far a virtual node n^v can be placed from its $loc(n^v)$. Each $l^v \in L^V$ is associated with a bandwidth demand $bw(l^v)$. In addition, each virtual network G^V has a lifetime $t(G^V)$.

3.3 VNP layer model

VNP collects information provided by InPs. We assume that InPs provide exact information about their nodes, as well as the peering links. On the contrary, there is no exact information about the internal organisation of a domain. Similar to the existing solution [12], we assume that this information is given by InP for each couple of <node, peering node>, as if there was a *pseudo* direct link between these two nodes. Denote the set of these links by $L_i^P = \{l_{mn} / m \in N_i^S, n \in N_i^{SP}\}$, InP_i provides to VNP the set of linking cost C_i^P defined by

$$C_i^P = \{C(l_{mn}) / m \in N_i^S, n \in N_i^{SP}\}$$

where $C(l_{mn})$ represents a cost (distance, bandwidth, etc.) characterizing the link l_{mn}. This kind of information is actually what a routing protocol (BGP) reports to other AS.

Thus, the SN of an InP_i is *perceived* by VNP as a graph $G_i^P = (N_i^S, L_i^P)$. In this way, the whole substrate network that VNP perceives, referred as G^P, is defined as follows:

$$G^P = (\bigcup_i G_i^P) \bigcup P^S$$

i.e. the perceived vision for each domain and the exact vision of the inter-domain connections. With G^P, VNP can establish a kind of complete topology covering all the domains for achieving VN decomposition and link mapping.

4 Our proposition

To solve VNE in the context of multi-domain, we propose a novel algorithm that maps jointly intra and peering links.

We propose to handle each VN request with a 2-step process

- At the first step, VNP performs the node decomposition optimizing the node embedding.
- Subsequently, VNP performs a series of iterative downsizing VNE sub-solution, each of them optimizes both the intra and peering link mapping related to a domain.

The link mapping is determined, at each iteration, by the acting InP (called *mapper*). VNP is in charge of providing necessary information to the mapper. The generic work-flow of our algorithm is given by figure 1. The details are explained as below.

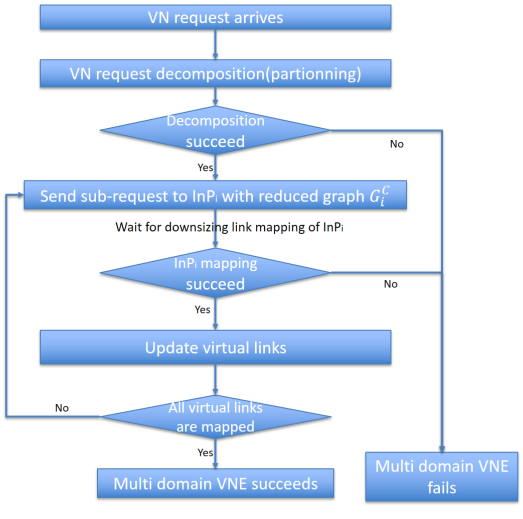

Figure 1: VNP workflow to embed a VN

4.1 Decomposition

Firstly, VNP decomposes the VN request with objective of minimizing the node mapping cost. In this stage, VNP associates each virtual node with a candidate set of substrate nodes that meet its $loc(n^v)$. VNP is free to use any multi-domain VN partitioning

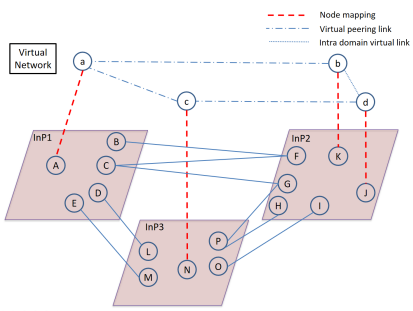

Figure 2: VN decomposition

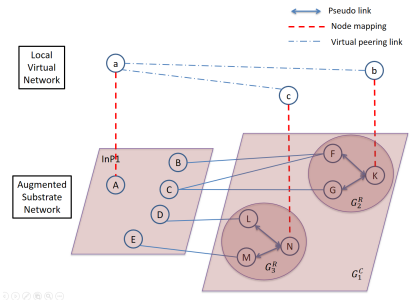

Figure 3: downsizing link mapping by InP_1

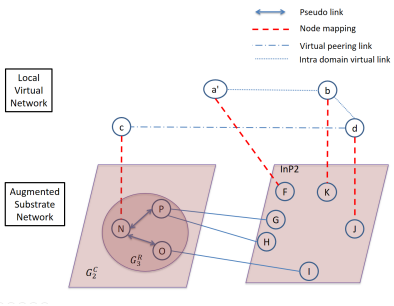

Figure 4: downsizing link mapping by InP_2

method (*e.g.* [14][12]). At the end of this stage, virtual nodes are embedded to different domains.

An example of VN decomposition is shown in figure 2. Three InPs are shown with their substrate nodes from A to P. They are connected via 2 or 3 peering links. Intra substrate links are not drawn. We suppose that a VN $\{a,b,c,d\}$ arrives. The VN decomposition step tells us that a, b, c and d are mapped to substrate nodes A, K, N and J, respectively. $\{a-b, a-c, c-d\}$ are virtual links which interconnect two different domains, while $\{b-d\}$ locates in only one domain.

4.2 An iterative downsizing VNE approach

Here we give a detailed presentation of the kernel of our proposal, which is formally given in algorithm 1.

4.2.1 Rationale

After VN decompostition step, since there is no domain who knows the complete information of any other one, embedding the virtual links which interconnect two different domains becomes an issue.

We notice that, VNP can build, for each InP_i, a reduced vision (denoted by G_i^R) from G_i^P. This vision contains all the peering links/nodes, as well as the substrate nodes on which a virtual node is embedded. Formally, $G_i^R = (N_i^R, L_i^R)$ where

$$N_i^R = N_i^{SP} \bigcup \{n_i^S \in N_i^S \,/\, \exists n^v \in N^V, M(n^v) = n_i^S\}$$

i.e., N_i^R is the union of all the substrate nodes supporting virtual nodes on domain i and all of its peering nodes. In a similar way, we define L_i^R as follows;

$$L_i^R = \{l_{mn} \in L_i^P / n \in N_i^R, m \in N_i^{SP}\}$$

i.e., L_i^R is the subset of L_i^P between N_i^R and N_i^{SP} containing only the links interconnecting a peering node and a node supporting a virtual node.

In order to achieve an efficient and pragmatic operation mode, we prefer that VNP plays its role of coordinator: It is VNP who decides which of the InP should have the privilege to map its peering links with others. It is also VNP who provides to the chosen InP (that we refer as *mapper*) the topology of the rest of the network according to its perception. In other words, the chosen InP (the mapper) extends its view to the rest of the network, by using the vision provided by VNP, the only one who has a kind of comprehensive view on all domains. In this way, the mapper obtains an augmented graph on which it will perform link mapping, including both its intra and peering links.

This process continues, domain after domain, until all of the virtual links are set. The selection criterion is the link utilization, the InP has most stringent link utilisation will be the first to map its peering links. The reason lies in that high link utilization denotes more constraints in the choice of path.

4.2.2 Building of the augmented graph

Let InP_i be the chosen mapper. Formally speaking, the vision of the other domains provided by VNP is $G_i^C = \bigcup_{j \neq i} G_j^R$, i.e. the reduced perceived vision of all the other domains. We only need to consider the case where all the domains are adjacent to the mapper. The case of a domain not adjacent to the mapper but to which the mapper has virtual links can be reduced to the adjacent case.

VNP communicates G_i^C to the mapper (InP_i) so that the latter can creates an augmented graph G_i^A, defined as follows:

$$G_i^A = G_i^S \cup P_i^S \cup G_i^C$$

This topology covers all of the accessible domains and can be used as a substrate graph on which the mapper performs VNE.

4.2.3 VN sub-request

VNP asks the mapper to perform a partial VNE, which concerns only the virtual links related to the mapper. We refer this partial VNE as a *sub-request* (L_i^{subv}). It is obtained from the current VN request by reducing it to virtual links related to the mapper.

4.2.4 An MCF-based link mapping

At this stage, the mapper gets an augmented vision of the whole substrate network, and a VNE sub request (L_i^{subv}), both from VNP. We have thus a classical VNE problem that we solve with the multi commodity flow

(MCF) based mapping algorithm (line 6 of algorithm 1).

At the end of this step, InP_i pre-allocates resources on the intra and peering links related to it and sends to VNP a virtual link update notification.

Let us illustrate it by our example. Assume in figure 2 that InP_1 is chosen as the 1st mapper. VNP builds the VNP-level graph vision $G_1^C = G_2^R \cup G_3^R$ (see figure 3) with G_2^R = ({*F*, *G*, *K*}, {*F-K*, *G-K*}) and G_3^R = ({*M*, *N*, *L*}, {*M-N*, *L-N*}). It builds also the sub-request L_1^{subv} = {*a-b*, *a-c*}, actually the virtual links *b-d* and *c-d* will be pruned since they haven't any extremity node supported by a substrate node in InP_1. VNP then sends G_1^C and L_1^{subv} to InP_1. The latter builds the augmented graph G_1^A which includes G_1^S (all the nodes and links in InP_1), the peering links (*B-F*, *C-F*, *C-G*, *E-M*), and G_C^1. InP_1 then applies the MCF-based algorithm to solve the embedding of L_1^{subv} on G_1^A.

4.3 Update and iteration

After each sub-request, the mapper (say InP_i) reports the results. In particular, it gives the results of the mapping of all of its inter-domain virtual links in the following manner.

Let $l^v(a,b)$ be the virtual link between a particular node $a \in InP_i$ and a particular node $b \in InP_j$, with $bw(l^v(a,b))$ as the required bandwidth. The MCF algorithm will map $l^v(a,b)$ into one or several paths. Denote by N^F the set of the peering nodes of InP_j through which a fraction of $l^v(a,b)$ is mapped. After the link mapping of InP_i, the set of virtual links $\{l^v(c,b)\}_{c\in N^F}$ is equivalent to the virtual link $l^v(a,b)$ with bandwidth demand:

$$\sum_{c\in N^F} bw(l^v(c,b) = bw(l^v(a,b))$$

It is to be pointed out that these links are totally inside inP_j and they replace $l^v(a,b)$.

As the mapping of InP_i is achieved, it will no longer appear as domain in the subsequent problem which contains only the remaining domains. However, the achieved mapping concerns only the links related to InP_i (intra as well as peering), the part of inter-domain virtual links on the other domains still has to be mapped. Each of such inter-domain virtual link related to the mapper can be transformed into the above described equivalent set which will be added to each concerned domain. For the sake of reading simplicity, we prefer to give an informal description here, instead of a formal one, which would generate some more heavyly-indexed notations.

In this way, we obtain a new VNE problem with:

- at the SN level, the retreat of InP_i and all the peering links related to it;
- at the VN side, the retreat of all the virtual links internal to InP_i and the replacement of all the inter-domain virtual links related to InP_i by their equivalent set which are added to corresponding domain.

This allows us to execute iteratively the downsizing mapping described in § 4.2. VNP repeats the process till its convergence which is *certain*, since the subset is reduced by at least one domain (the mapper) at each iteration.

Algorithm 1: Link mapping of InP_i as mapper

```
Input  : sub request virtual links L_i^subv
Input  : reduced perceived graph G_i^C
Output: virtual link update notification
1  begin
2      if L_i^subv = NULL then
3          return
4      end
5      create augmented substrate network
         G_i^A(N_i^A, L_i^A) ;
6      solve single domain VNE MCF problem;
7      foreach flow on substrate link l_mn do
8          if l_mn ∈ L_i^S ∪ L_ij^S then pre-allocate
             resource on link l_mn ;
9      end
10     send virtual link update notification;
11 end
```

In the example of figure 2 and 3, assume that InP_1 has chosen link *F-K* to map virtual link *a-b*. After sending its results to VNP, this latter deduces and creates a new virtual link *a'-b* with node mapping *a'* equal to *F*. This virtual link *a'-b* replaces virtual link *a-b*.

Now, the new problem (figure 4) contains only InP_2 and InP_3. Assuming that the InP_2 is chosen as mapper, the same process continues and our problem is eventually reduced to a single domain which is the last step of our algorithm.

4.4 Reject of virtual request

The resources are definitively allocated only if all the computation on different domains succeed. A COMMIT message is then sent by VNP to InPs so as to validate the resource reservation. Should a mapper report a failure, a DEALLOC message would be sent by VNP, which stops the process (VNE failure) and allows each domain to deallocate pre-allocated resources.

5 Reinforcement of our method

As mentioned at the end of 4.2.1, we choose the link utilization criterion to determine mapping sequence. This choice simplifies the algorithm, but may fail to get the optimal solution. In this section, we propose a reinforcement of our algorithm, which waives the constraint of sequence selection.

Fundamentally, domains are peers. From a domain's point of view, there are actually 2 "domains" : a single domain (itself) and a outside domain (others). Using our downsizing algorithm, a domain tries its best to map its intra and peering virtual links, but how does the outside domain (others) map the remaining virtual links? We notice that after the first

downsizing mapping, the problem is reduced to a multi-domain VNE on the outside domain (others) because the first mapper has mapped its own intra and peering virtual links. Following the downsizing logic, the problem will finally be reduced to a 2 domain VNE, on which a better solution can be easily found. Therefore, We first study the case of only 2 domains, and then we move to K domains VNE.

5.1 Two domain basic method

First, we consider the case of 2 domains. Assuming that the multi-domain VNE problem consists of 2 domains (denoted by InP_1 and InP_2), there are obviously 2 possible mapping sequences.

- First Solution $S_{1->2}$: InP_1 starts up the mapping processus as mapper and then InP_2 solves a single domain VNE.
- Second solution: $S_{2->1}$: InP_2 starts up the mapping processus as mapper and then InP_1 solves a single domain VNE.

These two solutions are sent to VNP, which compares the embedding cost of these solutions. The final solution of the 2 domain basic multi-domain VNE (denoted by $MDVNE(2)$) is the better one among the 2 solutions above:

$$S_{MDVNE(2)} = min\{S_{1->2}, S_{2->1}\}$$

Algorithm 2: $MDVNE(K)$

```
   Input  : VN request
   Output: embedding cost
   Output: mapping solution
1  begin
2      foreach InP_i do
3          link mapping of InP_i as mapper;
4          get embedding cost C(mapper);
5          if K > 2 then
6              solve MDVNE(K − 1) ;
7              get embedding cost C(others);
8          end
9          else
10             solve MDVNE(2);
11             get embedding cost C(others);
12         end
13         InP_i solution cost
             C(i) = C(mapper) + C(others) ;
14     end
15     return minimum C(i) and correspond
         solution;
16 end
```

5.2 Towards K domain solution

From the 2 domain basic method, K domain multi-domain VNE (denoted by $MDVNE(K)$) can be determined by a recursive algorithm. The detail of $MDVNE(K)$ is shown in Algorithm 2.

The multi-domain is fundamentally divided into 2 elements, a mapper and the others. The former is mapped using our downsizing method (line 3 in Algorithm 2), and the later is reduced to a K-1 domain problem (line 6 in Algorithm 2), until the basic 2 domain problem. The cost of the candidate is the sum of cost of the 2 elements (line 13 in Algorithm 2). The minimum cost candidate will be adopted as the mapping solution.

6 Performance Evaluation

We implemented a discrete event simulator to evaluate the performances of our method. The optimization problem is solved by IBM CPLEX library. Since we are basically interested by the link mapping, all the evaluated methods work with the same node decomposition by using the greedy algorithm of [6].

6.1 Evaluation Environment

The substrate networks are generated by GT-ITM tool [17]. 3 domains are generated. Each domain consists of 50 nodes and 100 links. The 3 domains are interconnected by 26 peering links. The CPU capacity of each node is chosen in [50,150]. The bandwidth capacity is selected in [50,100] for intra links and in [300,400] for peering links. The cost of the pseudo link between a border node and an intra node is chosen to be the inverse of the bandwidth capacity of the shortest path between these two nodes.

The virtual networks are also generated by GT-ITM tool. The virtual nodes of each VN follow a uniform distribution between 3 and 8. The virtual nodes are interconnected with probability 0.4. The CPU and bandwidth demands are uniformly chosen in [0,20]. The VN request arrival process is Poisson with arrival rate $\lambda \in (2...6)$ requests per 100 time units. The life time of each VN follows an exponential distribution with an average of 1000 time units. Each simulation lasts for 20000 time units.

6.2 Compared methods

We compare the following 3 methods :

(i) $lu-ciplm$: Link utilization coordinated intra and peering link mapping. This is our first method.

(ii) $r-ciplm$: Reinforced coordinated intra and peering link mapping. This is our second method.

(iii) *shen* [12]: This approach computes separately intra and peering links. The latter is determined according to Dijkstra's algorithm.

We used the following metrics for comparison:

- *VN request acceptance ratio*: the ratio of the accepted VN request over the total arrived VN requests;

- *Average link utilization*: the link utilization is the total allocated link resource over the total substrate resource. The allocated resource $\mathscr{U}$ is given by:

$$\mathscr{U} = \sum_{l^v \in L^V} \sum_{l^s \in L^S} bw(l^s, l^v)$$

where $bw(l^s, l^v)$ denotes the bandwidth committed on the substrate link l^s to embed the virtual link l^v.

- *Total revenue*: The revenue of a VN as the weighted sum of bandwidth and CPU:

$$\mathscr{R} = \beta \sum_{l^v \in L^V} bw(l^v) + \alpha \sum_{n^v \in N^V} cpu(n^v)$$

where α (resp. β) is the unit revenue for cpu (resp. bandwidth). .

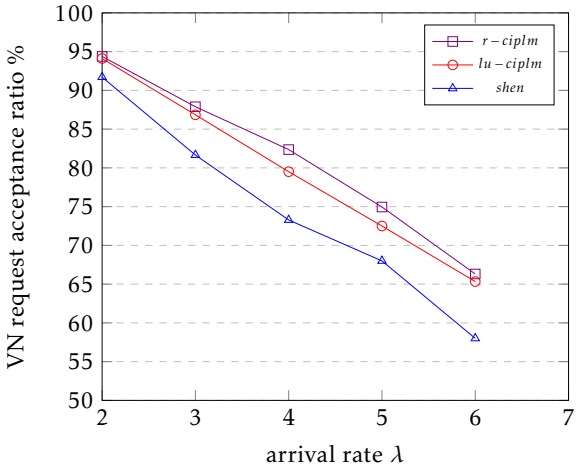

Figure 5: Acceptance ratio

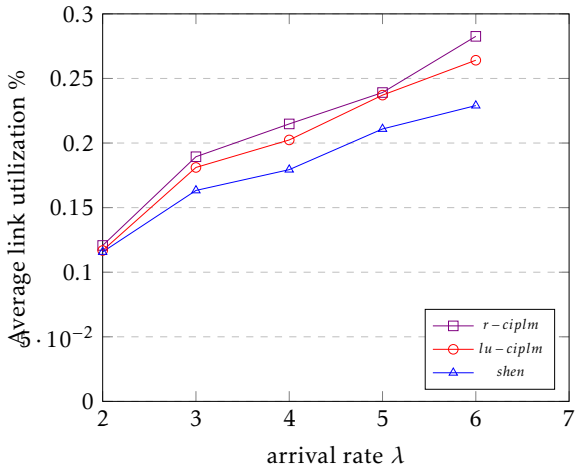

Figure 6: Average link utilization

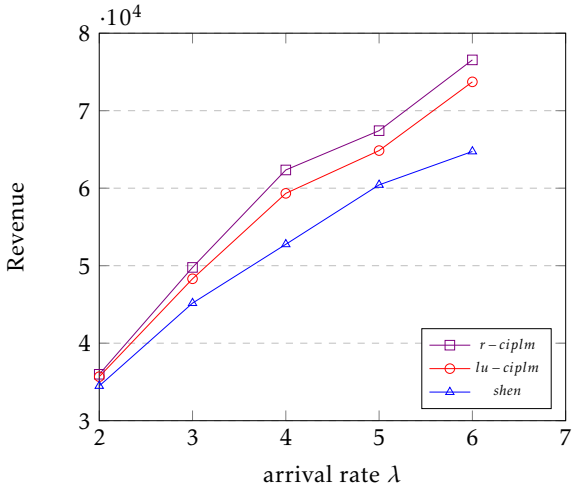

Figure 7: Total revenue

6.3 Result analysis

The simulation results are shown in Figure 5, 6 and 7. The VN request acceptance ratio is shown in Figure 5. The link utilization and revenue are shown in Figure 6 and Figure 7, respectively. We got the following observations:

- $r-cilpm$ is the best, followed by $lu-ciplm$, and then *shen* over all the three metrics.
- The difference between $lu-ciplm$ and *shen* is always significant.
- The difference between $r-ciplm$ and $lu-ciplm$ is not always significant.

To summarize:

- Our approaches are better than that of *shen*. Indeed, mapping jointly intra and peering links increases the efficiency. Our methods improve the performance. In these cases, traffic is splitted and sent to less loaded links, achieving in this way a better utilisation of the overall residual bandwidth.
- The out-performance of $r-ciplm$ is small compare to $lu-ciplm$. $r-ciplm$ ensures a cost-efficient mapping solution for every VN. The peering links are mapped jointly with the right domain, which leads to a better resource allocation. However, the peering links in $lu-cimplm$ are sometimes not perfectly mapped because link utilization does not always give the best mapping sequence.

7 Conclusion

Network virtualization attracts more and more attention in future network architecture, since it allows the (dynamic) building of a network suited to end-users need, without modifying the underlay infrastructures. Part of them will be built over several infrastructures run by different operators.

The virtual network embedding, which aims at establishing the optimal virtual networks on substrate networks, is a key issue in network virtualization. The fact of partial information makes the multi-domain VNE quite different from the single-domain VNE and this problem remains a challenge. Some multi-domain VNE solutions have been proposed in literature. Most of them focus more on VN decomposition into sub VN requests for each domain, so that the single-domain VNE can be applied subsequently. Few attention has been paid on the mapping of peering (inter-domain) links.

In this paper, we propose a novel multi-domain VNE algorithm which aims to optimize the peering link mapping. For this, we introduce a coordinator (VNP, VN Provider). The latter has the privilege to get a comprehensive vision of all of the domains as well as the peering links. It performs VN decomposition, then coordinates the optimized mapping of both intra and peering links, domain after domain, in an iterative (and converging) manner. The optimization is achieved by applying the MCF algorithm on an augmented graph related to each domain. Simulation shows that our approach optimizes the substrate resource utilization compared to existing method. Besides, our method is easy to deploy in current Internet architecture.

ABSTRACT

Cloud computing is one of the largest emerging utility services that is expected to grow enormously over the next decade. Many organizations are moving into hybrid cloud/hosted computing models. Single cloud service provider introduces cost and environmental challenges. Also, multi-cloud solution implemented by the Cloud tenant is suboptimal as it requires expensive adaptation costs. Cloud Federation is a useful structure for aggregating cloud based services under a single umbrella to share resources and responsibilities for the benefit of the member cloud service providers. An efficient security model is crucial for successful cloud business. However, with the advent of large scale and multi-tenant environments, the traditional perimeter boundaries along with traditional security practices are changing. Defining and securing asset and enclave boundaries is more challenging, and system perimeter boundaries are more susceptible to breach. This paper to describe security best practices for Cloud Federation. The paper also describes a tool and technique for detecting anomalous behavior in resource usage across the federation participants. This is a particularly serious issue because of the possibility of an attacker potentially gaining access to more than one CSP federation member. Specifically, this technique is developed for Cloud Federations since they have to deal with heterogeneous multi-platform environments with a diverse mixture of data and security log schema, and it has to do this in real time. A Semantic-less Breach detection system that implements a self-learning system was prototyped and resulted in up to 87% True-Positive rate with 93% True-Negative.

1 Introduction

As an increasing fraction of computing services move to the Cloud, there will be a proliferation of software characteristics, service models, and deployment options. Many organizations are moving into hybrid cloud/hosted computing models. A Cloud Service Provider (CSP) goal is to maximize its market share among the potential Service Providers (SP). Accommodating variable demands for computing resources requires an immense capacity, as it calls for providing for the maximum demand. In some cases, this drives them to underutilization of massive datacenter deployments. In other situations, the CSPs suffer over-utilization because of a miss in the market share, load and reliability projections. Both cases lead to sub-optimal utilization.

From the SPs perspective, they are most interested in availability and adaptability. The former refers to reliable service conditions that make its services available to the users it serves. The latter relates to the Vendor lock-in risk[1]. Single CSP provides a sub-optimal solution to the SP thus multi-cloud become an attractive solution. However, multi-cloud solution implemented by the SP requires expensive adaptations to the CSP's tools and service constructs that may vary among different CSPs.

Cloud Federation is a new paradigm that allows many CSPs to utilize computing resources optimally[2, 3]. Also, it allows SP to avoid the Vendor lock-in risk and provide service availability that can not be provided by a single CSP. No matter what the architecture, there is a need for to ensure the security and information assurance to users. Cloud Federation is an advantageous structure for aggregating cloud based services under a single umbrella to share resources and responsibilities for the benefit of the member cloud ser-

https://dx.doi.org/10.25046/aj020371

vice providers. Federation is useful not only for sharing resources amongst cloud service providers but also for providing enclaves for interactions to perform domain-specific missions such as electrical grids and supply chains.

The Federation will need to assure that data transfers amongst the Federation's CSPs are secure. The Federation will, above all, need to detect any anomalous behavior occurring in transactions and resource sharing. In addition to the growing number of security tools, there is a need to log and identify security issues requiring attention early on in the process. In particular, breach detection in inter-cloud data transfer and communications is a particularly serious issue because of the possibility of an attacker potentially gaining access to more than one CSP federation member.

This paper to describe security best practices for Cloud Federation. The paper also describes a tool and technique for detecting anomalous behavior in resource usage across the federation participants. Specifically, this method is developed for Cloud Federations since they have to deal with a heterogeneous multi-platform environment with a diverse mixture of data and security log schema, and it has to do this in real time. This Semantic-less tool is described below after a description of the context of the issue.

The reminder of paper is organized as follows, Section II (Federated Cloud) discusses a new inter-cloud structure. It also describe some of the terminology used in this paper; Section III (Cyber Security Challenges in Federated Cloud) describes the core challenges of such inter-cloud system in a multi-layer model; Section IV (Semantic-less Breach Detection) discuss the tool we suggest for detecting the behavior of the anomalous system that runs in the Cloud Federation; Section V (Evaluation) discuss the breach-detection tool prototyped; Section VI (Analysis) analyze and present the prototype results; finally, Section VII (Conclusions) summarizes the main results and ongoing developments.

2 Federated Cloud

Organizations that serve and process a large number of simultaneous users and the user's often large quantities of data are termed "cloud computing services." These services enable convenient, on-demand, network access to a shared pool of configurable computing resources. The following section describes cloud federation and the reasons for its formation. It serves as background for the security design and breach detection mechanism we propose in a later section.

Cloud computing is occupying a rapidly growing market share of IT resources. IT related spending toward workload processing increased 32.8 percent in 2014, 29 percent in 2015, 34.1 percent during 2016, and expected to grow 42 percent during 2017[1]. Also, from environmental perspectives, grid energy powered by hydrocarbons are increasingly devoted to the growing power needs of cloud computing data centers. Carbon emission generated by data centers is growing from a 2011 level of 21.3 MtCO2e and expected to rise to 39.1 MtCO2e by 2020[2].

This makes cloud computing one of the fastest growing consumers' utility services, one that is projected to grow an order of magnitude in the next decade. [2] propose a new paradigm that will allow multiple cloud providers to utilize computing and energy resources optimally. From the customer's perspectives, the organization's total-cost-of-ownership is expected to shift from capital-expense-based, e.g., on-premise deployments to operational-expense-based, e.g., cloud service subscriptions. Thus, there is a need to create an efficient and transparent eco-system that allows the organization to match IT expenses with its planned cost structure.

Federated Clouds demonstrate a new paradigm that will allow multiple cloud providers to utilize optimally computing resources. It will do this by (1) lowering the data center's deployments per provider ratio, share and (2) scheduling available energy via aggregators and (3) lastly to employ, where appropriate, more renewable and carbon-free energies. It will quantify results and baseline the efforts based on work at the data centers within a single cloud provider. The federated cloud demonstrates the utility software container-based paradigm for achieving dense and elastic containerization technologies. It is centered on several discreet Linux Containers (LXC) managed by a Kubernetes resource management system [3] that acts as the governance engine. Moreover, the proposed solution scales out and optimizes cross-data centers and cross-regional deployments by computing and suggesting a cross-cloud provider's collaboration via a cloud aggregator. Furthermore, it suggests operating data centers employing maximum intermittent green energy sources[2]. Yet all of these advantages will be for naught if federation services cannot be supplied securely in the face of growing sophistication and quantities of cyber security threats. It is therefore essential that risks to data, computing resources and communications are managed such that the value of services provided exceeds the losses arising from cyber breaches.

2.1 Architecture

The Cloud Federation architecture is comprised of multiple CSPs, a Clouds-Coordinator, and a Clouds-Broker system. These are defined below.

Clouds-Coordinator. Acts as an information registry that stores the CSPs pricing offers and demand patterns. Clouds Coordinators periodically update the CSPs availability and offering prices. Also, a Clouds-Coordinator will help to employ, where appropriate, more renewable and carbon-free energies [3].

Clouds-Broker. Manages the membership of the CSP constituents. Both CSPs and SPs will use the Clouds-Broker to onboard the Cloud Federation. Also, Clouds-Broker will acts on behalf of the SP for resource allocation and provisioning requests. Clouds-Broker also provides a continuous ability to deploy SP software, configuration, and data to one or more CSP, so it provides the SoS IT agility goal.

3 Cyber Security Challenges in Federated Cloud

The Cloud Federation has a global scale software and hardware infrastructure. We describe a progressive layers security model starting from the physical security of data centers, progressing to the hardware and software that underlies the infrastructure, and the constraints and processes to support the Cloud Federation operational security. The following section describes the Cloud Federation cyber security design throughout the data processing life cycle at a Cloud Federation. e.g., enables secure communication with tenants (SP) and its customers or control plane communication including CSP, Cloud-Brokers, and Clouds-Coordinator.

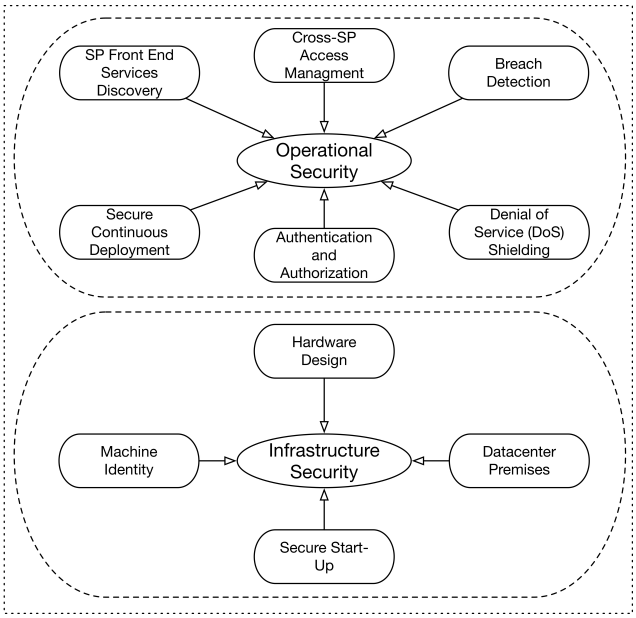

Figure 2: Cloud Federation Cyber Security Model includes two core layers, infrastructure security and operational security

Figure 2 describes the cyber security layers offered by the Cloud Federation. The following paragraph briefly describes the security elements corresponded with each layer[4]. Our extended cyber security model will emphasize the operational security with unique breach detection methodology. This was done since the operational security corresponds to the perimeter security of an enterprise system and the interface to the Federation members. Also, it will suggest a system for encryption of both inter microservices communication with emphasis on cross-CSP for tenants' workloads.

3.1 Infrastructure Security

The required baseline security level needed for cloud federation constituent's systems is referenced in Figure 1. It includes deployed facilities and computer systems managed by the CSPs or the Federation. The larger CSP's often exceed these baselines.

Datacenter Premises. CSPs design and build its data centers based on its expected computing capacities and service reliability manifested by their SLA and the redundancy levels of sub systems[4, 5]. The datacenter incorporates various components of physical security protections. Access to such facilities is governed by the CSP security operations. It uses technologies such as biometric identification, metal detection, metal detectors, and CCTV solutions[6].

Hardware Design. CSPs data centers run computing server machines fed by power distribution units and connected to a local network that is all connected to the edge of the wide network. The computing, digital storage, and networking equipment require a standard that ensures the required audit and validation of the security properties by components[7, 8], e.g., hardware security chip [9].

Machine Identity. confirms that any participating computing server in Cloud Federation can be authenticated to its CSP machine pool throughout a low-level management services[9]
Secure Start-Up. Ensures that CSPs servers are booting the correct software stack. Securing underlining components such as Linux boot loaders, OS system images and BIOS by cryptographic signatures can prevent an already compromised server from being continuously compromised by an ephemeral malware.

3.2 Operational Security

Operational security comprises the business flows between the SP with the cloud federation and the CSP it uses for processing workloads. The following section briefly discusses the required cybersecurity measures needed for SP and CSP business scenarios in a cloud federation.

Cross-SP Access Management: SP workloads are manifest in two workload types, (1) short-lived workloads. i.e., jobs that are terminate upon completion, and (2) long-lived workloads. i.e. services. The former workload might require connectivity to external services during its processing. The latter might expose serving endpoints to other services. e.g., short-lived jobs might require persistent storage to write its job results hence connecting to BigTable[5] storage server provisioned by other CSPs, which, in turn, require access management that uses credentials and certificates

[4]We extrapolate Google Cloud security model from https://cloud.google.com/security/security-design/
[5]https://cloud.google.com/bigtable/

stored within the Cloud Federation.

SP Front End Service Discovery: Long-lived workloads might expose public facing endpoints for serving other workloads or end-user requests. SP front-end services require publishing endpoints to allow other workloads within or external to the cloud Federation to discover their public facing entry point and this requires service discovery capabilities. Service discovery endpoints, and the actual service endpoints, are prone to risks such as Denial of Service attacks or intrusions originated by an attacker. We argue that current solutions offered by individual CSP's are sub-optimal because of the target scope of the intrusion. i.e., assuming an attack probability for a given CSP, running several CSPs reduces the risk by a factor of the number of CSPs. Later sections will formulate the risk function and show how cloud-federation minimizes those challenges by using the semantic-less breach detection system and show how most risks originate by crossing machine boundaries.

Secure Continues Deployment: Continuous Deployment (CD) is the function that allows cloud-native applications to get updated through an automated pipeline that is initiated by a new or updated code submission, compiled, tested through various quality gates until it is certified for deployment of the production systems and deployed seamlessly. Continues deployment enables cloud applications to innovate faster and safer no matter what number of machines are in the service pool. A secure continuous deployment service requires secured SP code and a configuration repository that authenticates to the target computing resource regardless of the CSP network segmentation. Traditional network segmentation, or fire walling, is a secondary security mechanism that is used for ingress and egress filtering at various points in the local network segment to prevent IP spoofing[10, 11]

Authentication and Authorization. In a federated cloud architecture, deployed workloads might require access to other services deployed by the federation. The canonical example will be an end user request service deployed in the Federation that triggers another micro-service within the SP architecture. Such cascading requests require multilayered authentication and authorization processes. i.e., a micro-service calls another micro-service and authenticate on behalf of the end user for audit trails supported by the end-user authentication token and the cascading micro-service tokens generated throughout the end user request. Figure 3 depicts the data flow during a call initiated by SP Micro-Service that runs in one of the federation's CSP denoted by CSP_i and CSP_j. A call initiated from SP_n that was provisioned in the federation as ms_n. The call destination runs on a different and sometimes the same SP. Let SP_m denote the destination SP. The call payload is encrypted by SP_n private key. The call arrived at an SP_m endpoint and checked for admission. SP_m admission control decrypts the call payload using SP_n public key that was submitted throughout the on-boarding process to the Cloud Federation. It is verified for authenticity and authorization of allowed call-sets. If admitted, SP_m calls and process the get_data() call and sends back the response to the originating SP, SP_n.

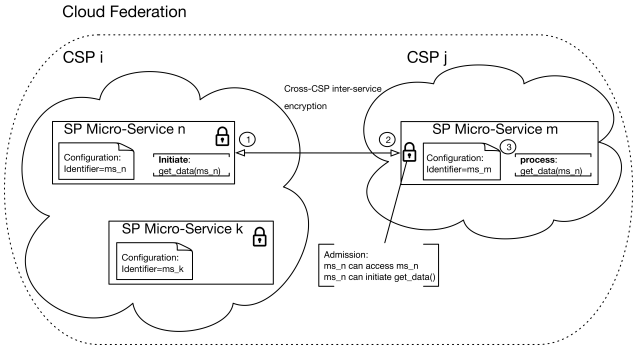

Figure 3: Authentication and authorization in Cloud Federation Cross-SP model

Breach Detection: The Cloud federation comprises various workload types that are owned by different autonomous organizations. Breach detection includes a complex data processing pipeline that integrates system signals originated from specific users of a CSP service as well as the potential cloud federation tenants. System signals are comprised of network devices as well as signals from infrastructure services. Only in recent years, after the growing numbers of data breaches and liabilities arising from losses,[12, 13, 14] have organizations started to incorporate business related metrics for breach detection[15]. Both data pipelines need to generate operational security warnings of potential incidents. The output of such warnings usually alerts security operations staff to potential incidents that require the relevant team's triage and response as appropriate.

Such methods are sub-optimal in a Federated Cloud for two main reasons: (1) different data sets are owned by different organization departments that are not integrated physically, schematically or semantically, (2) Lack of unification of both data sets as accomplished by fusion requires a complex transformation of both data sets semantics into a single data set. The above situation exacerbated when migrating the workload to the cloud as it introduces another orthogonal data set that contributes to complexity. The following sections propose a method for breach detection that collapses the three silos into a cohesive semantic-less data set that will enhance the Cloud Federation services detection breaches to an extent limited by available data and their investment in detection .i.e. allowing methods to the tenants to incorporate more data about their workload for more automatic detection.

4 Semantic-less Breach Detection

Malware infected cloud-computing-workloads introduces three core risks for organizations (1) Service unavailability, (2) Data breach , and (3) Data corruption. There is a need for breach detection system that helps to determine whether a workload is infected as well as the type of exploited risk type as enumerated above. Breach detection system effectiveness is influenced by a number of factors. We focused on the human social factor and the emergent public cloud offering. The following paragraph describes the important

factors required for optimized breach detection. This mode of breach detection has to span the heterogeneous schema employed by the various federation members.

4.1 The Human Social Factor

Enterprise IT is typically organized into silos. e.g., IT operations, network operations, database administration, and product engineering. The silos goal is to allow field-based ownership. Usually, silo teams are governed by different management hierarchies, communication styles, and vocabularies i.e. *semantics*. As as far as cyber security goes, semantics manifest by a particular interpretation of intrusion or breach. e.g., malware sending data to C&C might not impact the normal operation of a workload. Thus, product owners are oblivious to that risk while network operations detect unusual egress or ingress traffic usage patterns.

Enterprise IT workloads deployed as SP workload requires adopting unified cyber security best practices that overcome the different management hierarchies, communication styles, system security pans, data scheme, semantics and, vocabularies. The next paragraph shows how Federated Cloud helps enterprise IT improve its cyber security resiliency by offering a prediction tool that allows SP to apply proactive policies to mitigate potential threats.

4.2 The Cloud Federation Factor

Public Cloud services exacerbate the organization's human factor risk by introducing an additional silo that is often separated from the organization it serves. Public cloud operations are agnostic to its tenant's workload semantics by definition. CSPs configure their multi-tenancy to allow business with conflict of interest to run its workload on the same platform. Such practices and policies, augment the lack of cohesive view required for optimized malware detection.

Workloads deployed in public cloud services are not limited to known machine boundaries as traditional on-premise models offer. Although CSPs feature cyber security mechanisms that attempt mimicking the traditional computing workload hosting, workloads artifacts are under the CSP control. As such, the cloud client workloads might be compromised. Thus, there is a need for another cyber security dimension for the SP workload that overcomes the lack of control when running in the cloud.

We proposed a unique self-learning methodology that removes the need for tenant information that streamlines semantic-less information from the various software stacks of the Cloud Federation, including both tenant metrics and control-plane metrics. Also, it streamlines training data of security incidents shared in collaborative platforms outside the Cloud Federation. We also argue that a Cloud Federation optimizes such collaboration and self-learning process. We prototyped a system that implements such self-learning system that resulted in up to 87% True-Positive rate with 93% True-Negative.

Workload data and usage patterns form a critical path for the SP business success. The leakage of some of the workload data and usage patterns impose a threat to the SP business. This challenge represents a new threat of organizational espionage as well as attacks on the SP service that impacts SP business continuity. Therefore, sharing semantics breaks the isolation between the two systems and might hold the hosting system accountable for security attacks in CSP or Cloud Federation platforms. Also, transforming every workload semantics into a coherent model that aggregates numerous SP workloads requires a significant amount of investment. SPs will be reluctant to make such an investment, especially since it doesn't produce income. Therefore, this method has a low likelihood of being implemented. Therefore, enabling a method that eliminates SP investment and business risks is a key for the breach detection system success. Finally, a Cloud-Federation provides a centralized view of cross-CSP operations. Such centralized view allows SP workload deployment to different CSPs to gather a rich data set that will be available for malware identification and later, for predictive analytics. We suggest a method that captures computing resources usage and intra federation traffic and infers potential breach or disruption to proactively alerts CSP security stakeholders about suspicious cyber instances.

4.2.1 From Workload Semantics to Semantic-less

Cloud workloads are broadly composed of two types: online system, and offline system. The former provides low-latency, read/write access to data. For example, a web user requests a web page to load online and serve within a fraction of a second. The latter provides batch-like computing tasks that process the data offline, which is reported later to users by the system servers; for example, the search results based on a pre-calculated index. Offline production workloads are usually comprised of mainly unstructured data sets, such as click stream, web graph, and sensors data[2, 3].

The semantic-less detection will address the polymorphic malware case as its data stream are abstracted from computing activity. More specifically, a tenant's workload in a federated cloud manifested by software containers that are limited to not more than (1) namespace per tenant for isolation and (2) limited to a resources control groups(aka cgroup)[6] Control groups are the mechanism for limiting computing server host CPU, Memory, Disk I/O and Network I/O usage per namespace. That is the foundation of Linux Containers, which alludes to the existing methods of measurements of the metrics set, CPU, memory and I/O usage. We call this set the behavioral attributes set. Access to cgroup and namespace configuration and control is available on the host level i.e. the host OS that runs the multi-tenant workloads i.e. a control-plane component.

4.3 Data Collection

Both Cyber Security leaders and national agencies agree that addressing emerging cyber risks require sharing cyber attacks retrospects and their historical behavior, and discovered vulnerability reports as a foundation for collaboration, predictive time series analysis, risk quantification and risk allocations all leading to safer cyber services [16, 17]. Incidents are often documented in unstructured reports that

[6] https://www.kernel.org/doc/Documentation/cgroup-v1/cgroups.txt

require a manual analysis to identify trends[18].

To assess whether or not a system was breached, it is required to establish malicious system behavior patterns and then decompose those patterns into generic computing system metrics that can later be classified as harmful or safe. The following paragraph includes the source datasets we chose to assess the initial malicious patterns and their detectability by our method. We continued by decomposing the data and removing the tenant semantics. That allows a generic pattern of malicious activity dataset that can be used as a training data for the supervised model.

4.3.1 Source Datasets

We choose the National Vulnerability Database (NVD)[19] and the Vocabulary for Event Recording and Incident Sharing (VERIS) [20]. Both datasets included thousands of reported incidents spanning across various categories. Our model focuses on (1) Unauthorized access attempts, (2) Suspicious Denial of Service, and (3) Data Stealing Malicious Code, including ransomware instances. We filtered the incidents that conform to the categories and performed a qualitative assessment of the identified breach impacts. Lastly, for simplicity, we appllied an additional category that distinguishes the target component reported, service-based or client-based. We included only the service-based incidents. i.e., reported incidents that clearly targeted desktops and workstations were not included in defining tenant semantic structures.

We applied filters for training data accuracy. Filters for VERIS dataset included server workloads as indicated in Section 4.2.1, i.e., Authentication Server, Backup Server, Database Server, DHCP Server, Directory Server(LDAP, AD), Distributed control system, Domain Name Server, File Server, Mail Server, Mainframe Server, Web Application Server, and Virtual Machine Server[20]. Assets operating systems were filtered to Linux and Unix as such operating systems are more prevalent in servers than Windows, MacOSX, and mobile device operating systems.

VERIS dataset includes incident actions. We filtered the action types that fit the paper focus workloads. i.e. Brute Force, Cache Poisoning, Cryptanalysis, Fuzzing, and HTTP Request Smuggling attacks. We excluded Buffer overflow cases as such attacks can be prevented in deterministic methods and common in Windows-based operating systems[21]. The dataset size following the refinement is 5015 incidents. Table 1 summarizes the dataset we used for the training data.

Malware Category	modus operandi	Number of Incidents
Brute Force	Exhaustive effort of data encryption	946
Cache Poisoning	Corrupt data is inserted into the cache database e.g., DNS	894
Cryptanalysis	Exhaustive effort of data encryption	750
Fuzzing	Injects random bad data into an application to break it	946
HTTP Request Smuggling	Exhausting a proxy cache by sending HTTP requests	639
Data stealing malware	Data transmitting across unencrypted network	840

Table 1: Summary of datasets used

4.3.2 Removing the Tenant Semantics

Our approach attempts to detect anomalies in both control-plane and tenant activities that conform to suspicious patterns. In Section 4.3 Data Collection, we defined a categorical dataset that adheres to real incident data. This data applies to potential breaches for server-based workloads. We stipulate, for the purposes of this paper that such server-based workload will obey similar suspicious patterns when deployed in the cloud.

In this paragraph, we transformed the categorical dataset into a multivariate time series data that can be used for supervised anomaly detection. The multivariate set is comprised of general operating system observations that do not include any workload semantics but could be used for contextual anomaly detection. The contextual attributes are used to determine the position of an instance on the entire series. We showed that, based on collected incident data, the conversion of behavior patterns to multivariate time-series satisfies effective breach detection of any malware, conventional or polymorphic.

We gathered the operations reported in the incident reports (Table 1) and inferred about the operating system resources consumed during the malware lifespan. Table 2 depicts the relationship between the malware characteristics and operating system usage. Figure 4 describes a workload sample, video-on-demand. It shows the common pattern of the operating system resources usage that will be used as multivariate time series data sequences. The Evaluation section describes in more details the nature of the data and how it translates into meaningful time series data.

Malware Category	OS Resources Patterns
Brute Force	Extensive CPU, Memory, I/O to disk or network
Cache Poisoning	Extensive I/O to disk or network
Cryptanalysis	Extensive I/O to disk or network
Fuzzing	Network I/O Ingress
HTTP Request Smuggling	Network I/O Egress
Data stealing malware	Network I/O Egress

Table 2: Dataset Classification

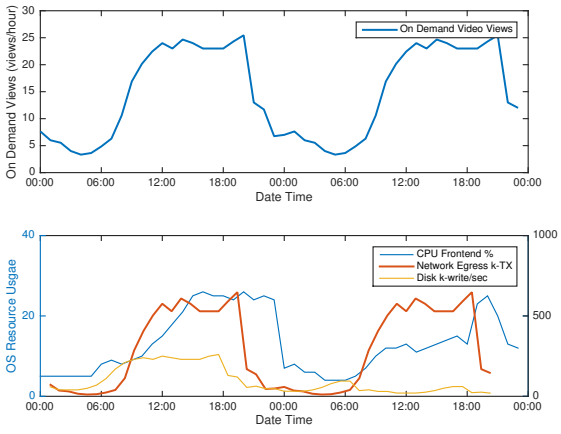

Figure 4: Workload semantics sample transformed into semantic-less training sequences

4.3.3 Prediction Methodology

We used the data gathered in Table 2 for formulating the anomaly detection problem of polymorphic malware[22]. The detection approach includes three distinct methods: (1) Detecting anomalous sequences in OS usages time series events, (2) Detecting anomalous subsequences within OS usages time series, and (3) Detecting anomalous OS usages events based on frequency. Let T denote a set of n training sequences based on OS usage generated by CSPs, SPs, and the Federation control plane. Also, S denote a set of m test sequences generated based on Table 2, we find the anomaly score $A(S_q)$ for each test sequence $S_q \in S$, with respect to T. T mostly includes normal OS usage sequences, while S includes anomalous sequences.

The semantic-less tool output produces a score for a scanned training sequence T using Regression. i.e., forecast the next observation in the time series, using the statistical model and the time series observed so far, and compare the forecasted observation with the actual observation to determine if an anomaly has occurred[22]. For simplicity, our model uses TensorFlow[23] for regression calculation. Our tool is not limited to that tool or the regression type.

5 Evaluation

We prototyped Cloud Federation system that mimics that properties analyzed in section 2, Cloud Federation. The prototyped system includes the component that is depicted in Figure 1. For the scope of the prototype, we enabled semantic-less metrics from both SPs and CSPs to improve correlation efficiency. CSP data sharing limits the effectiveness of any cyber analytical technique and, in practice will represent a compromise between improved cyber security and CSP privacy and confidentiality. With that proviso, in the following section, we evaluate a computer load coordination system component that manages on-demand streaming, generates T, a set of n training sequences based on OS usage generated by CSPs, SPs, and the Federation control plane. We chose on-demand video streaming as Video streaming is expected to constitute up to 85% of Internet consumers traffic within a few years[24]. Also, we showed that video-on-demand streaming follows a pattern of usage that can be monitored for breach detection that can help on-demand SP to seamlessly improve their consumer's privacy and provide their studio's safe e-commerce platform.

5.1 Experiment Planning

Below is a simulation of a cross-regional platform that is comprised of control-plane, workload-plane and coordinating components. This will be embodied in a resource allocation system (Kubernetes). This system provisions resources to be a priority of being near, users. The control-plane enables an effective compute resource provisioning system that spans across different public cloud providers and regions. Also, it collects operating systems usages for both the SP workload and control-planeThe coordinating components will accept user-workload demands as well as green energy availability from various regions and opportunistically seek to process streaming workloads using compute resources provisioned by green energy resources. The workload-plane will be comprised of edge streaming servers that process the end-user on-demand video streaming. It will be built on standard Apache HTTP[7] servers that run on the edge location.

The control-plane software infrastructure is based on Kubernetes[8], it facilitates internal discovery between Apache HTTP server instances so instances can connect across different cloud boundaries and regions. This architecture provides an open architecture that enables continuous monitoring. In a real world federation the data load may require several big data nodes and substantial compute capacity. This paper is a demonstration and proof of concept on a finite scale to permit model and parameter tracking and adjustment.

5.2 Execution

5.2.1 The System Preparation

The prototype experiment included the setup of three virtual datacenters deployed in different regions: (1) Central US, (2) West US and (3) East US. The clusters were sized based on US population distribution[9] by regions i.e. 20% for West US, 40% for East US and 40% Central US. The cluster sizes for West US, Central US, and East US are 3, 7 and 7 machines respectively. Each machine is standard 2-CPU cores with 7.5GB of memory.

The control-plane comprised of Kubernetes API server and controller-manager. The controller coordinator component will need to allocate resources across several geographic regions to different cloud providers. The API server will run a new federation namespace dedicated for the experiment in a manner that such resources are provisioned under a single system. Since the single system may expose external IPs, it needs to be protected by an appropriate level of asynchronous encryption[10].

For simplicity, we use a single cloud provider, Google Container Engine, as it provides a multi-zone production-grade compute orchestration system. The compute instances that process the user workloads are deployed as Docker containers that run Ubuntu 15 loaded with Apache HTTP server. For simplicity, we avoided content distribution by embedding the video content to be streamed in the Docker image. We ran 52 Docker containers that span across the three regions and acted as Content Delivery Network edges.

5.2.2 Baseline and Execution

The baseline execution included data populations for video streaming. The data population was achieved by the Kubernetes Jmeter batch jobs. The loader jobs goal is to generate traffic that obeys the observed empirical patterns depicted in

Figure 4. The system usage for both control-plane and SP capture, through cAdvisor, a kubernetes resource usage, and performance analysis agent. The agent, from every node in a cluster, populates system usage data to Heapster, a cluster-wide aggregator of monitoring and event data [11].

We labeled the system usage with the semantic-less dimensions, Network egress was measured by thousands of transmitted packets (k-TX), Disk writes per second (k-write/sec) and CPU usage per container (%). The Heapster aggregated the data based on the labels that are later pushed to centralized database, influxDB. We also used the influxDB HTTP API to inject randomized system usage data according to the three labels, CPU, network and disk usage. Those considered as the anomalous sequences $S_q \in S$. We used Figure 4 as a baseline sequence that randomized using NumPy[12]. The randomization followed the malicious usage patterns described in Table 2.

The execution required a TensorFlow session that looped through the dataset multiple times, update the model parameters and obtain the anomaly score $A(S_q)$ for each test sequence $S_q \in S$, on T. The breach and anomaly detection was performed using the following data streams and learning algorithms.

5.2.3 Limitations

We used influxDB because of its seamless integration with Kubernetes Monitoring system. However, our approach is not limited to influxDB or other database systems for that matter. We used TensorFlow for regression and anomaly score calculation. We did not use long training sequences. The maximum duration spanned across 48 hours. Training with longer sequences using long-running jobs and TensorFlow model checkpointing would improve our results. Our test content variety was limited and fixed. That might impact the generated tests sequences stability. Larger content variety would require longer training sequences for optimal detection.

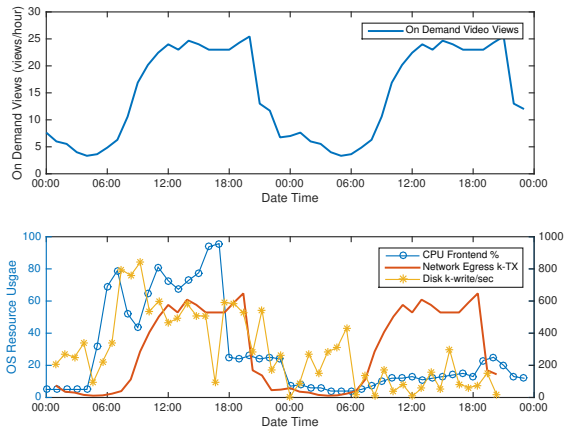

Figure 5: A Ransomware Anomalous Workload semantic-less sample

6 Analysis

The prototype included two core datasets, normal (Figure 4) and malicious (Figure 5). The CPU usage in the normal dataset fit the viewing patterns at the first half of the run. The second half required less CPU due to the caching mechanism applied in the Apache HTTP server that alleviates the need for the CPU when served through a cache. The Disk write pattern manifested similar content caching schema. The network egress ratio was not impacted by the caching schema.

The malicious dataset used the malware classification table (Table 2). Figure 5, shows a semantic-less behavior for ransomware malware that attempts to encrypt data while serving workload. Suspicious signals denoted by a star and o markers for CPU and disk write respectively. Based on the dataset classification, ransomware requires no network egress but CPU for data encryption and writing back to disk the encrypted payload. Our prototype included similar patterns depicted in Table 2 with a similar approach as done for ransomware.

Our model yielded a series of anomaly scores $A(S_q)$ for $S_q \in S$ anomalous patterns. We considered a potential breach of cases of anomaly and when regression produced a sufficient variability factor, i.e., a value that is not close to zero.

7 Conclusions

Security practices traditionally focus on prevention and tightening perimeter boundaries. However, with the advent of disparate, distributed, large scale, multi-tenant environments such as the proposed Cloud Federation, the traditional perimeter boundaries along with traditional security practices are changing. Defining and securing asset boundaries is more challenging and the system perimeter boundaries are more susceptible to breach. In this paper, we proposed a proactive approach for detecting a breach in a cloud workload. Such method requires no upfront investment from the monitored services. Upfront investments are often one of the main barriers to securing cloud service. Our tool eliminates such need and uses general system usage patterns that help to predict potential breach proactively.

Conflict of Interest The authors declare no conflict of interest.

Transient Stability

ABSTRACT

The Static Var Compensator (SVC) is used to improve the stability of the power system because of its role in injecting or absorbing the reactive power in the electrical transmission lines. The Power System Stabilizer (PSS) is also a control device which ensures maximum power transfer and thus the stability of the power system enhancement. The PSS has been widely used to damp electromechanical oscillations occur in power systems. If no adequate damping is available, the oscillations will increase leading to instability. The present work is an original contribution to the problem of transient stability in the electrical power system, the authors have made some efforts to illustrate the flexibility and the importance of inserting the SVC alone or with the PSS the fact that maintain the characteristics of the system within acceptable limits in a very short time. The results show that the system has been developed successfully in terms of transient stability in a bi-machine transmission system only with the presence of PSS when a single-phase fault has been occurred, while the presence of SVC is more than essential when a three-phase fault is occurred.

1. Introduction

Today's world is continuously growing so that generation distribution and transmission of power are also simultaneously required to increase in same manner to fulfill the requirement. Power system stability may be broadly defined as that property of a power system that enables it to remain in a state of operating equilibrium under normal operating condition and to regain an acceptable state of equilibrium after being subjected to a disturbance [1].

Stability of this system needs to be maintained even when subjected to large low-probability disturbances so that the electricity can be supplied to consumers with high reliability. Certain system disturbances may cause loss of synchronism between a generator and the rest of the utility system, or between interconnected power systems of neighboring utilities. Various control methods and controllers have been developed over time that has been used for this purpose.

Recently, there has been a surge of interest in the development and use of FACTS controllers in power transmission systems. These controllers utilize power electronics devices to provide more flexibility to AC power systems. The most popular type of FACTS devices in terms of application is the SVC [2]. This device is well known to improve power system properties such as steady state stability limits, voltage regulation, and damp power system oscillations [3]. The SVC is an electronic generator that dynamically controls the flow of power through a variable reactive admittance to the transmission network, also the SVC regulates voltage at its terminals by controlling the amount of reactive power injected into or absorbed from the power system [4]. When system voltage is low the SVC generates reactive power (SVC capacitive). When system voltage is high, it absorbs reactive power (SVC inductive) [5].

It is known that the power-system stabilizers PSS for generators and the supplementary controllers for flexible ac transmission system (FACT) devices are efficient tools for improving the stability of power systems through damping of low-frequency modes [6], where the frequency of these modes ranges from 0.2 to 2.5 Hz [7]. Power System Stabilizer (PSS) devices are responsible for providing a damping torque component to generators for reducing fluctuations in the system caused by small perturbations [8].

In some cases, when the use of PSS cannot provide sufficient damping for inter-area power swing (0.1-0.7Hz), SVC damping controller is an alternative effective solution. The SVC

supplemented with damping controller and PSS on synchronous generators are applied to increase the probability of stability [9].

Generally, it is important to recognize that machine parameters change with loading make the machine behavior quite different at different operating conditions. Since these parameters change in a rather complex manner, a set of stabilizer parameters, which stabilizes the system under a certain operating condition, may no longer yield satisfactory results when there is a drastic change in power system, stabilizers PSS should provide some degree of robustness to the variations in system parameters, loading conditions, and configurations [10, 11]. The basic structure of PSS is operating under typical control generator while the basic structure of SVC is operating under typical bus voltage control [13].

This paper is an extension of work originally reported in Proceedings of the International Conference on modeling, identification and control [12]. Firstly we start with an introduction containing an overview of the system under examination, in section two we have given a detailed description of the proposed system, section three is divided into two parties the first one shows the results obtained and discuss the impact of PSS when a single-phase fault is occurred whereas the second one discuss the impact of the SVC when a three-phase fault occurred, finally we have drawn an overall conclusion which reveals the most important point to consider from the current work.

2. System Description

The proposed power system works under abnormal system conditions and has the following characteristics see Figure 1.

- Two synchronous generators
- Two power transformers of 13.8 kV / 500 kV.
- Three bus bars.
- A transmission line of 500 kV and 700 km.
- Two PSS and two AVR (Automatic Voltage Regulator).
- The SVC characteristics: 200 Mvar.
- A purely resistive load of 5000 MW.

Note that the load center is modeled by (5000 MW) resistive load which is fed by the remote of (1000 MVA-plant M1), and a local generation of (5000 MVA-plant M2). A load flow has been performed on this system for G1 and G2 with generating rate of (950 MW and 4046 MW) respectively while the line carries (944 MW) which is closed to its surge impedance loading (SIL = 977 MW). The shunt compensated used in this research is with rate of (200 Mvar) to maintain system stability after faults [14].

The SVC does not have a power oscillation damping (POD) unit. G1 and G2 are equipped with a Hydraulic Turbine and Governor (HTG), excitation system, and Power System Stabilizer (PSS). Two standard types of stabilizer models can be connected to the excitation system: Generic model using the acceleration power (Pa which is the difference between mechanical power (P_m) and electrical output power (P_{eo}) and Multiband model which uses a speed deviation (dw) [14].

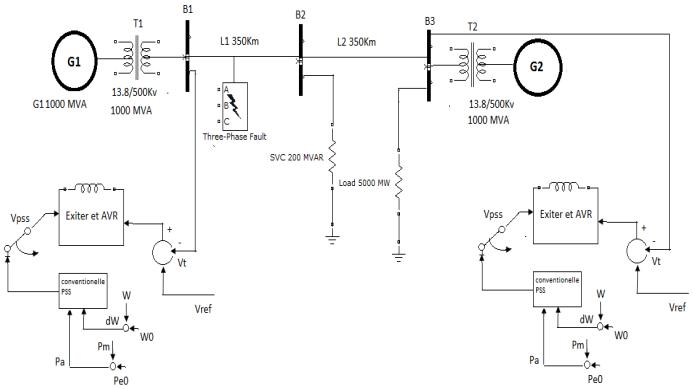

Figure 1. The Simplified Diagram of the Multi-Machine Power System with SVC and PSS

3. Problem Statement

3.1. PSS Modeling and Damping Controller Design

The operating function of a PSS is to produce a proper torque on the rotor of the machine involved in such a way that the phase lag between the exciter input and the machine electrical torque is compensated [15]. The block diagram of the ith PSS with excitation system is shown in Figure 2, where ($\Delta\omega_i$) is the deviation in speed from the synchronous speed which is the input signal. The output signal of the PSS is used as an additional input (ΔU_i) to the Excitation System block [16]. The three basic blocks of a typical PSS model are: The first block is the stabilizer Gain block, which determines the amount of damping. The second is the Washout block, which serves as a high-pass filter. The last one is the phase compensation block, which provides the desired phase-lead characteristic to compensate for the phase lag between the AVR input and the generator electrical (air-gap) torque [17].

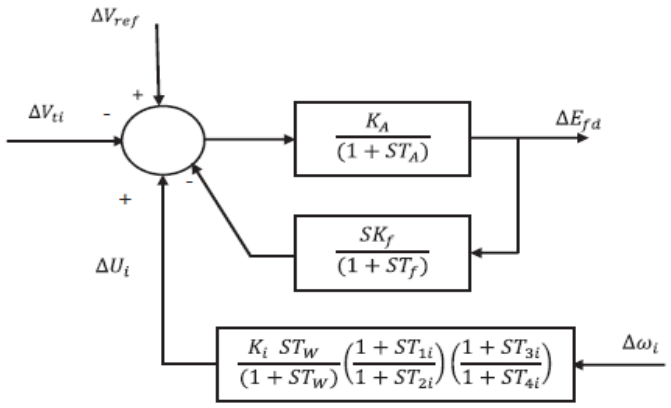

Figure 2. Block diagram of ith PSS with excitation system [16]

3.2. SVC modeling and damping controller design

A Static Var Compensator (SVC) is composed of a fixed capacitor in parallel with a thyristor controlled reactor (FC-TCR), this model consists of a harmonic voltage source in series with a variable source admittance [18]. The SVC adjusts the susceptance in each phase by controlling the conducting angles of the thyristor controlled reactor [19]. Also it can control the unbalanced loads more effectively and can enhance the transient stability of the system by inserting or absorbing instantaneous currents to or from the system [20].

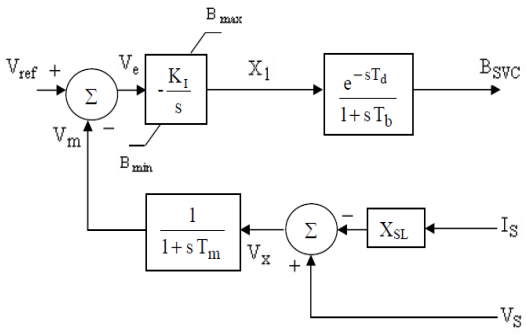

Figure 3. SVC Control Model

The equations describing the SVC controller are:

$$V_m = \frac{1}{T_m}(V_X - V_M) \quad (1)$$

$$X_1 = -V_e K_I \quad (2)$$

$$B_{SVC} = \frac{1}{T_b}(X_1 - B_{SVC}) \quad (3)$$

$$V_e = V_{ref} - V_m \quad (4)$$

$$V_X = V_S - X_{SL}.I_S \quad (5)$$

$$\begin{cases} X_1 = B_{\min}; X_1 < B_{\min} \\ X_1 = B_{\max}; X_1 > B_{\max} \end{cases} \quad (6)$$

Where

B_{min}: is the minimum susceptance

B_{max}: is the maximum susceptance

B_{SVC}: is the Static Var Compensator susceptance

K_I: is the proportional gain

T_m: is the measuring time

V_m: is the measured voltage

V_X: is the voltage at X position

V_{ref}: is the reference voltage.

X_l: is the line reactance

X_{SL}: is the slope.

4. Simulation Results and Discussion

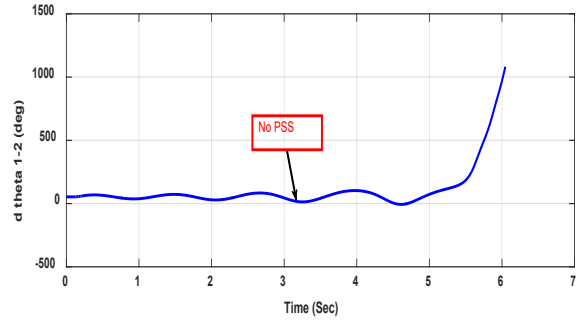
This work illustrates modeling of a simple transmission system containing two hydraulic power plants. A Static Var Compensator (SVC) and Power System Stabilizers (PSS), In order to observe the impact of PSS and SVC on the power system stability a single-phase to ground fault and a three-phase fault have been applied on the first section of the line (L1) see Figure 1.

4.1. Single-Phase Fault - Impact of PSS - No SVC

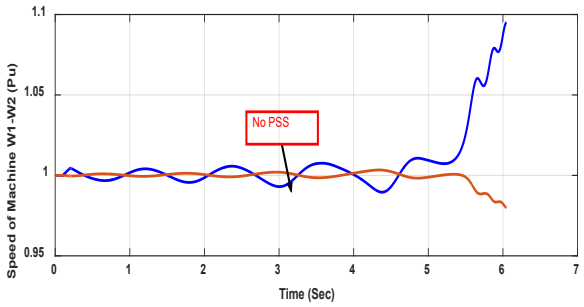
In this part the SVC is set to operate in fixed susceptance mode with (Bref=0) this is equivalent to putting the SVC out of service. Also a single-phase to ground fault have been applied at t=0.1 s and eliminated at t=0.2 s.

4.1.1. PSS out of service

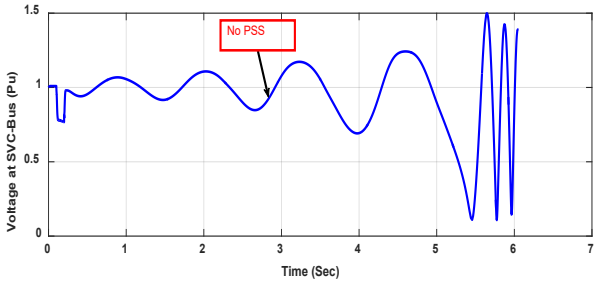
Figure 4 shows the obtained graphs without the impact of the PSS, if a single-phase fault is applied, immediately the system tends to support the oscillations, then these oscillations increased more and more, so that the system loses its steady state.



(a)



(b)

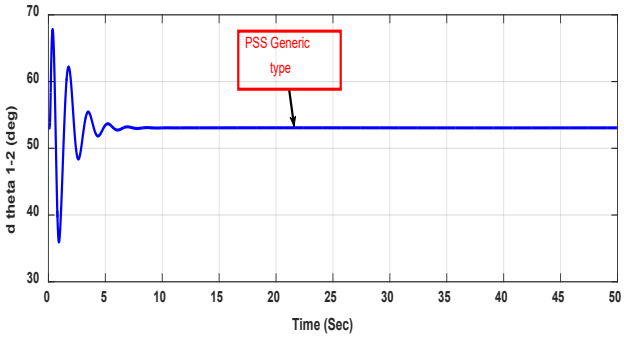


(c)

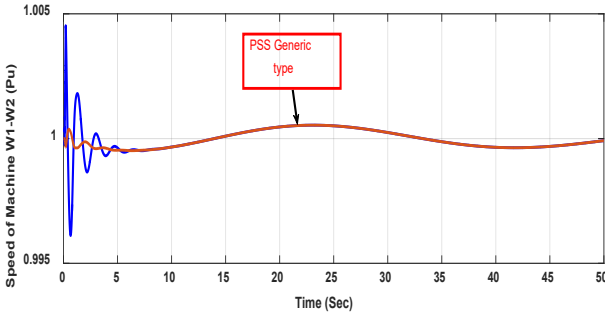
Figure 4. Impact of PSS for 1-phase fault (without PSS): (a) Rotor angle difference d_theta1_2 between the two machines, (b) Machine speeds of G1and G2, (c) Voltage at SVC-Bus.

4.1.2. PSS Generic type in service

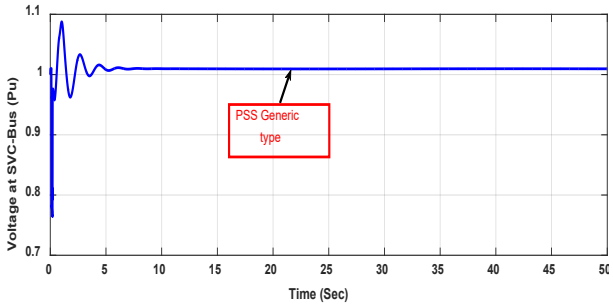
Figure 5 shows the impact of PSS Generic type, if a single-phase fault is applied, Figure 5(a) shows the Rotor angle difference d_theta1_2 between the two machines, it is found that the angle is approximately (50°) at the fault clearing time, Figure 5(b) shows that machine speeds (W1, W2) for G1 and G2 respectively converge to 1 Pu, so the machine speeds oscillate at the same time for low frequencies at 0.025Hz. Figure 5(c) shows that the voltage at SVC-bus is constant.



(a)



(b)

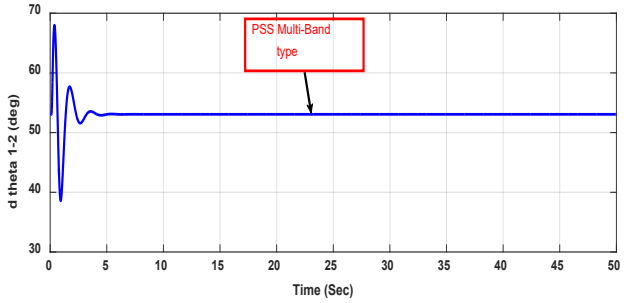


(c)

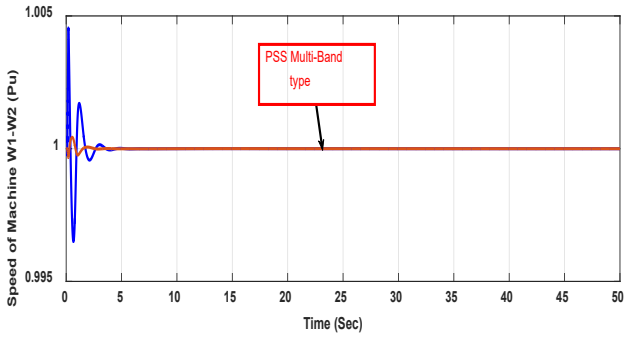
Figure 5. Impact of PSS for 1-phase fault (with PSS Generic type): (a) Rotor angle difference d_theta1_2 between the two machines, (b) Machine speeds of G1and G2, (c) Voltage at SVC-Bus.

4.1.3. PSS Multi-Band type in service

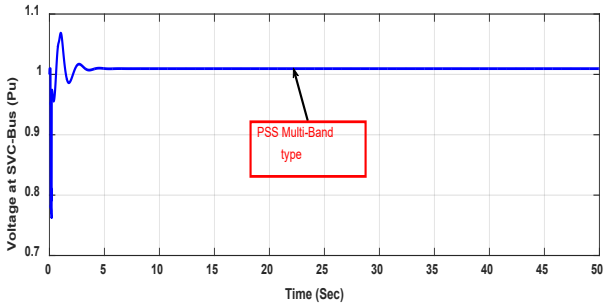
Figure 6 shows the impact of PSS Multi-Band type, if a single-phase fault is applied, the same results shown above with PSS Generic type have been drawn, however the Multi-Band type can attenuate not only the frequencies of 0.8Hz but also 0.025Hz .



(a)



(b)



(c)

Figure 6. Impact of PSS for 1-phase fault (with PSS Multi-Band type): (a) Rotor angle difference d_theta1_2 between the two machines, (b) Machine speeds of G1and G2, (c) Voltage at SVC-Bus.

Now the results have been assembled in the same graph to allow comparison between a various cases (without PSS, with PSS Generic type and with PSS MB type.

The first trace of Figure 7 shows the rotor angle difference d_theta1_2 between the two machines. Power transfer is maximum when this angle reaches 90°, this signal is a good indication of system stability. If d_theta1_2 exceeds 90º for too long a period of time, the machines will lose synchronism and the system goes unstable.

The second trace of Figure 7 shows the speed oscillation of machine G1 notice that machine 1 speed increases during the fault because during that period its electrical power is lower than its mechanical power.

The third trace of Figure 7 shows the positive sequence voltage at the SVC bus, we notice that as soon as the fault has been applied the voltage grows to reach 1.08 then this peak is followed by oscillations.

In the blue waveforms we can clearly see that, if there is no PSS than system can't be able to sustain stability and lose it synchronism (see Figure 7). In the red waveforms notice that when we use PSS Generic type system becomes stable but there is low frequency oscillation present (see Figure 7). In the magenta

waveforms we notice that when we use PSS MB type system may be stable with no low frequency oscillation.

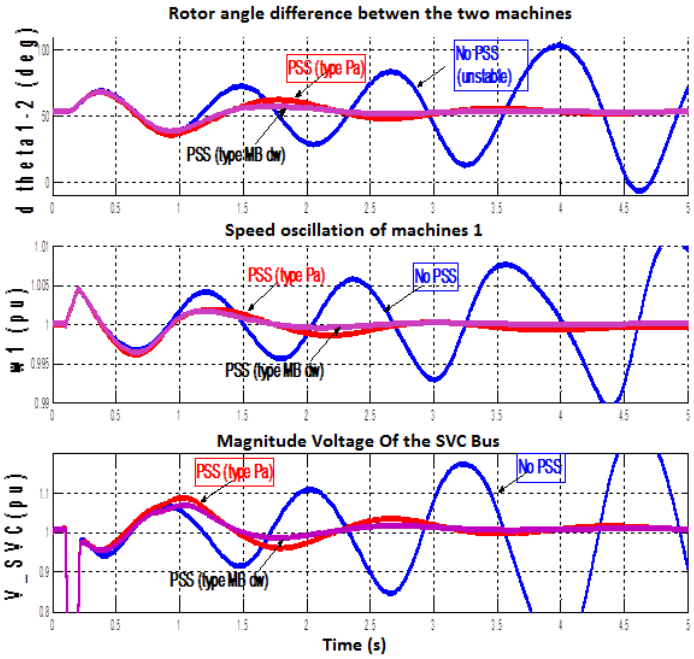


Figure 7. Impact of PSS for 1-phase fault (without SVC)

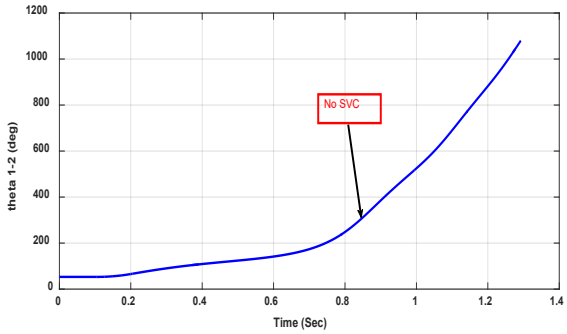
4.2. Three-Phase Fault - Impact of SVC

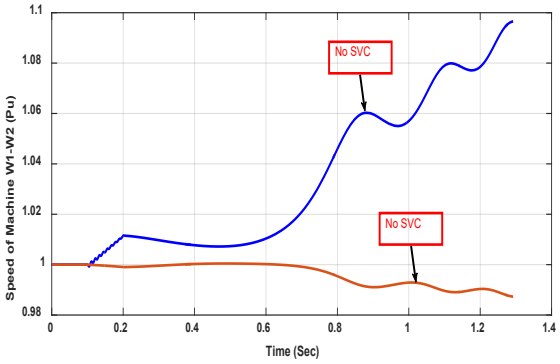
This part contains two tests, in the first one the SVC is set to operate in fixed susceptance mode with (Bref=0) this is equivalent to putting the SVC out of service. The second one, the SVC is set to operate in voltage regulator mode; however, the PSS Generic type has been maintained in service. Also a three-phase to ground fault have been applied at t=0.1 s and eliminated at t=0.2 s.

4.2.1. SVC out of service

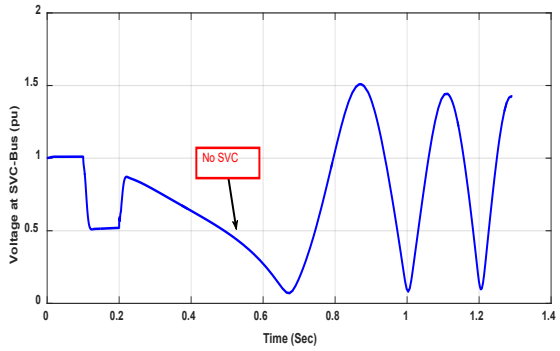
Figure 8 shows the obtained graphs with PSS Generic type in service and without the impact of the SVC (fixed susceptance mode Bref=0), if a three-phase fault is applied, immediately the system tends to support the oscillations, then these oscillations increased more and more, so that the system loses its steady state.



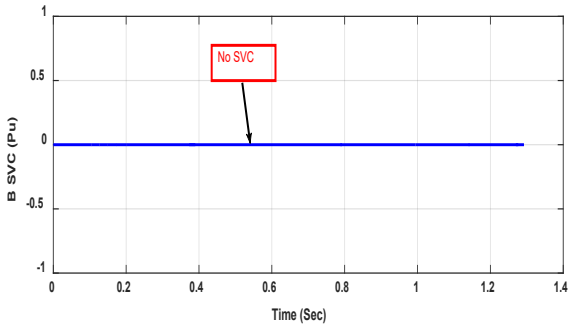
(a)



(b)



(c)

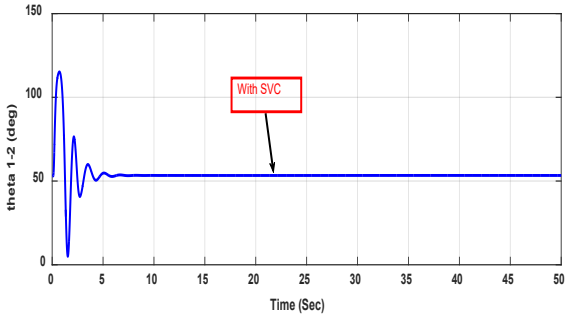


(d)

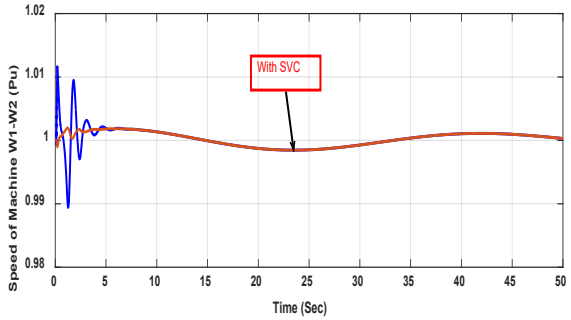
Figure 8. Impact of the SVC for 3-phase fault. (without SVC): (a) Rotor angle difference d_theta1_2 between the two machines, (b) Machine speeds of G1and G2, (c) Voltage at SVC-Bus, (d) Susceptance of SVC

4.2.2. SVC in service

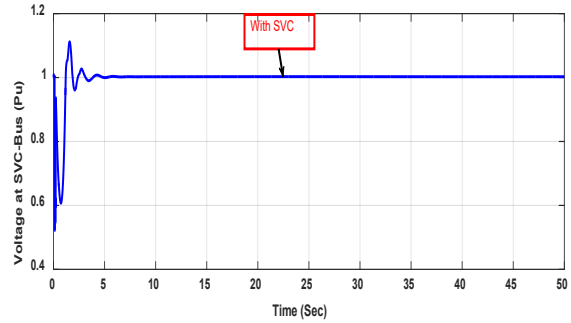
Figure 9 shows the impact of SVC (voltage regulation mode), if a three-phase fault is applied. Figure 9(a) shows the rotor angle difference d_theta1_2 between the two machines, it is found that the angle is approximately (70°) at the fault clearing time. Figure 9(b) shows that machine speeds (W1, W2) for G1 and G2 respectively converge to 1 Pu. Figure 9(c) shows that the voltage at SVC-bus is constant and equals to 1 Pu. Figure 9(d) shows that the SVC tends to support the voltage stability by injecting the reactive power into the transmission line whenever is needed (measured voltage differs from the reference voltage).



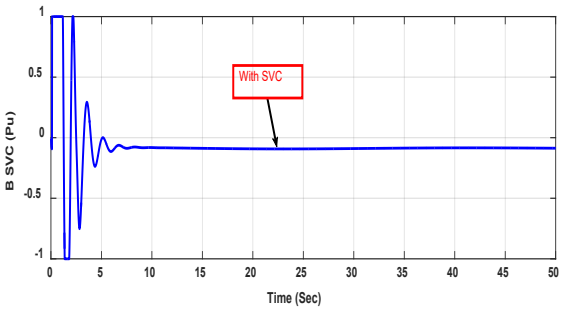
(a)



(b)



(c)



(d)

Figure 9. Impact of the SVC for 3-phase fault. (with SVC): (a) Rotor angle difference d_theta1_2 between the two machines, (b) Machine speeds of G1and G2, (c) Voltage at SVC-Bus, (d) Susceptance of SVC

Now, the results have been assembled in the same graph to allow comparison between the two tests (without SVC and with SVC).

Here we show that if there is three-phase transient fault than without SVC, both PSS are not able to maintain the stability. By looking at the red waveforms we should observe that the two machines quickly fall out of synchronism after fault clearing. In order not to pursue unnecessary simulation, the Simulink 'Stop' block is used to stop the simulation when the angle difference reaches 3*360degrees.

Now the SVC is set to operate in voltage regulation mode. The SVC will now try to support the voltage by injecting reactive power on the line when the voltage is lower than the reference voltage (1.009 pu). In steady state the SVC will therefore be 'floating' and waiting for voltage compensation when voltage departs from its reference set point.

The results of these studies show that the SVC has an excellent capability in damping power system oscillations and enhances greatly the dynamic stability of the power system. We also note that the stabilization time is minimal.

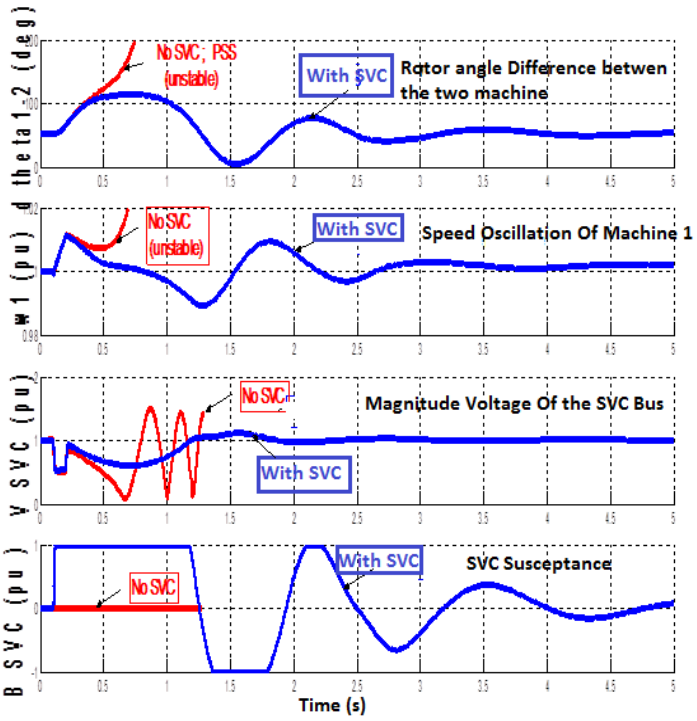


Figure 10. Impact of the SVC for 3-phase fault

5. Conclusion

From simulation results of the proposed model we can conclude:

- The proposed model is oscillatory and instable with absence effects of (PSS) and SVC.
- The selective of (PSS) are capable of proving sufficient damping to the steady state oscillation and transient stability voltages performance over a wide range of operating conditions and various types of disturbances of the system used in proposed model.

- If there is Single line to ground fault than the PSS able to sustain the stability, but using SVC the angle deviation is reduced.
- If there is three phase transient fault then without SVC both PSS are not able to maintain the stability.
- Compare working two types of (PSS), the multiband type oscillation is quickly damped than generic type.

ABSTRACT

Smart city projects are quickly evolving in several countries as a feasible solution to the urban organization to provide sustainable socioeconomic growth and solve problems that arise as the populations of these cities grow. In this sense, technology application plays an important role in enabling automation of processes, improving the citizen's quality of life and reducing the costs of public services for municipalities and enterprises. However, automation initiatives of services such as electricity, water, and gas which materialize by the so-called smart grids, have emerged earlier than smart city projects, and are consolidating in several countries. Although smart grid initiatives have arisen earlier to projects of smart cities it represents a subset of the great scenario of IoT that is the vision in which the smart city projects are based. The time difference from developments between these two initiatives made the alternatives of communication technologies for infrastructures construction of communication followed different paths. However, in view of the great scenery of IoT is desirable to determine technologies that provide convergence of a single urban communication infrastructure capable of supporting all applications, whether they are typically IoT or traditional smart grid applications. This work is a review which presents and discusses the two main technologies which are currently best positioned to play this role of convergence that is RF Mesh and LoRaWAN. The strengths and weaknesses of each one of them are also presented and propose that in actuality LoRaWAN is a promising option to offer the required conditions to take on this convergent position.

1. Introduction

The first initiatives of smart grids have begun about ten years ago, in the year 2007. At that time the discussions about the intensive use of technology to automate public services in urban centers were very preliminary. In this context, technology options for building communications infrastructure was only scoped to support smart grid projects to the specific demands of utilities in segments such as electricity, water, and gas. In the specific case of the electric sector applications that motivated these initiatives were remote metering of consumption, automation of distribution networks, demand control, and to become viable an automated environment capable of enabling distributed generation development based on renewable sources [2, 3].

More recently, after the first smart grid projects implementation on a large-scale basis, initiatives of intensive use of technology for automation of public services in urban environments has emerged. These initiatives have defined smart city projects that use the concept of Internet of Things (IoT) as a technology to support the communication infrastructure. This new vision has stimulated technologies development aimed to meet applications with a particular profile, such as low data rate and tolerance of high latency. Smart grids typical applications were not primarily in focus [4, 5]. In this way, these two initiatives have created the conditions for industry to develop two different and parallel approaches regarding communication infrastructure. But it didn't take long for the vision about the need for convergence arises.

Considering this new scenario smart grid applications represents a subset in the bigger context of smart cities. As the industry developed initially without this convergent and integrated vision between smart grid applications and smart city the next step was the industry of smart grid communication systems expands the scope to cover other smart city applications. In the other hand, the IoT communication systems industry began to focus their products

on meeting the demands typically smart grid with all its peculiarities.

In terms of well-established platform, RF Mesh assumed an outstanding position for smart grid projects. Regarding IoT applications, although there are currently various proposals under development, the technology that has to emerge as the most suitable for IoT and smart grid at the same time is LoRaWAN [6, 7].

This paper presents a review of the main technical requirements for smart grids, the main features of these two prominent technologies (RF Mesh and LoRaWAN) and makes a comparison between them. The goal is to discuss the possibilities of LoRaWAN to take on the role of convergence and interoperable option between different manufacturers required to support demands of smart cities and smart grids.

2. Smart Grid Requirements

The challenges faced by the electricity sector in all world markets have brought about deep changes in all three segments of the industry: generation, transmission, and distribution. From the point of view of the growing demand for electrical energy and urgency in environmental issues comes leveraging the renewable generation technologies development and transforming the traditional centralized array into distributed.

Transmission systems also go through a process of change. Search for technical solutions that reduce system losses is one of the actions. Another change is transmission lines construction to connect efficiently the new array of generation and ensure a suitable protection system [8].

Distribution segment might be the one that has been more challenged to promote changes in their way of operating. The distribution plant that was static becomes endowed with computational intelligence to promote operational gains and improvement of service quality indices, as well as add new services and features to consumers. The concept of smart grids represents this new way to operate and maintain the electrical system. It requires a telecommunications network overlaps grid interconnecting the systems to a centralized computer system. Smart grids add value to the entire industry, but the segments in which its application is most intensive is in distributed generation and mainly in the distribution system [8, 9].

Applications affected by this technological innovation are the consumption measurement and distribution operation. This new concept involves smart metering and Distribution Automation (DA), which evolves into the Advanced Distribution Automation (ADA), which allows the system to reconfigure them in the case of network failure. There are also other applications such as automation of street lights and asset management of the electrical system. Both smart metering and DA have specific technical requirements with regard to telecommunications support systems. As presented in the following items, it demands more stringent parameters from the point of view of data rate available and network latency tolerance.

2.1. Smart Metering

Smart metering means consumption measurements automation eliminating any human intervention in the process. Measuring routines are possible in real-time, every 15 minutes, every hour or in larger intervals. Smart metering processes uses an Advanced Metering Infrastructure (AMI).

Besides the main function, remote metering can provide electricity network, quality parameters and service availability together with the data collected from the SCADA systems of distribution substations.

The parameters contribution of quality and availability extracted from smart meters working as remote sensors enhances the diagnostic map of operation centers due to its capillarity and represent the points of service delivery [9].

2.2. Demand Response (DR)

The main motivation for the control of electrical energy demand is to adjust it to the generation capacity, transmission, and distribution, especially during peak times. In the case of mismatching down between available energy in the system and the total demand, actions are necessary to adjust it and try to balance the electricity system. In the context of smart grids, this interaction between consumers and the distributor of electric energy is possible in real-time.

The main source of consumer information is the smart meter that communicates with the utility systems via a communication network. In this same communication network, the load control takes actions on actuators installed in the facilities of consumers with the goal of providing the necessary adjustments in the consumption level. As the information system for the actions of demand response is the smart metering system, the technical requirement of AMI systems will meet DR's systems as well.

2.3. Distribution Automation (DA)

The basic idea of distribution system automation is to allow management (supervision and control) of network elements remotely from an operations center [9]. This concept is applicable to sub-transmission and distribution substations and distribution network using Automatic Reclosers (ARs).

In the case of DA, actions must be taken by an operator who performs a fault diagnosis and tries to restore as much as possible of network segments [4, 5].

Advanced Distribution Automation (ADA) gives more automatic actions by sending supervisory information to a centralized computer system. This system shall take decisions autonomously to open and close ARs in order to restrict the scope of a failure and restore a maximum number of possible network segments [9].

With regard to the requirements of communications network, three aspects are crucial: maximum data rate available, network availability, and low latency especially in the case of the ADA.

2.4. Other Applications

In addition to typical smart grid applications such as smart metering and distribution automation, there are new demands directly related to electric power sector. Among them are: assets management automation and street light automation. Supervision and control of the street lighting are already a reality in various cities around the world and has been usually supported by RF Mesh networks designed for smart grids. Regarding asset management (transformers, current transformers/potential transformers, capacitors, etc.), increasingly arise projects aimed at

accelerating the information flow to empower management processes. Asset management processes more efficient represent gains in logistics, inventory optimization, and improvement of operational and financial results of companies.

With regard to requirements of telecommunications systems, both streetlight and assets management automation do not require any specific characteristics different of those observed in smart grid applications. Thus, a network Field Area Network (FAN) or Neighborhood Area Network (NAN) designed for smart metering and DA applications will be also capable of supporting them. In this sense, these new applications in the context of a smart grid network reinforce the convergence around a single IoT platform. The question is which technology is best suited to take on this role. Although RF Mesh is in theory capable of supporting all these applications they have a typical IoT profile and suggest the use of a communications infrastructure more adherent to this scenario.

2.5. Telecom infrastructure

Telecommunication infrastructure to support smart grid applications is divided into Outdoor RF Concentrator Devices, and Network Interface Cards (NICs). Concentrators are RF equipment installed on Telecom towers, top of buildings or even poles and are responsible for communicating with endpoints and concentrated those located within its covered area. The NICs are interfaces embedded on endpoints and are responsible for communicating with nearest RF Concentrator and make the interface with endpoint device's application.

Outdoor RF infrastructure is usually divided into private and public networks. Public networks are those provided by third parties, generally, Telcos that share infrastructure with several other users. These are services like mobile network (GPRS, 3G, 4G) and Internet. Private are those in which a network or a network segment dedicated to the exclusive use of a single user. It can be considered private assets those acquired and operated by the company itself or contracted third-party companies, such as telecommunications operators. These are examples of services contracted to third parties: MPLS, dedicated circuits, satellite services, among others [10].

The main options currently available for utility companies to construct private telecommunication networks for smart grid applications are:

i Backbone layer: Optical Systems, and SHF Point-to-Point Radios.

ii Backhaul layer: WiMAX, LTE, and Point-to-Multipoint Radios.

iii Access layer (FAN/NAN): RF Mesh and LoRaWAN, which are the focus of this work.

Considering the criticality of smart grid applications an aspect that needs increasingly be observed in the infrastructure construction of telecommunications and information technology (IT) is the information security.

With regard to communication technology selection to meet the requirements of high availability (on the order of 99.9% or higher), performance, and security are more under control of distribution company if the infrastructure is its own [8]. Table 1 presents the typical requirements of a smart grid network. [8, 9, 11].

Table 1: Typical Smart Grid Requirements – Access Layer

Smart Grid Requirements				
	Smart Metering/DR	DA	ADA	Asset Management/ Street Light
Frequency Range (FAN/NAN)	≤ 2.4 GHz	≤ 2.4 GHz	≤ 2.4 GHz	≤ 2.4 GHz
Transmission Mode	Bidirectional	Bidirectional	Bidirectional	Bidirectional
Maximum Data Rate per Terminal	10 kbps	10 kbps	100 kbps	Best effort
Average Latency End to End	≤ 2 s	< 1 s	< 160 ms	Best effort
Mobility of Endpoints	Not Required	Not Required	Not Required	Required (AM)
Geolocation	Important	Important	Important	Required (AM) Important (SL)

With respect to the defined values for the parameters, it is interesting to define the concept of "best effort". This term refers to the traffic on IP network information according to the features that are available at a given moment, without any compromise with the service quality standards.

Therefore, the information flow on the network will occur in a way that is possible. This operation mode is used to meet applications not sensitive to certain parameters.

In this work, the requirements selection studied and compared to the technologies considers the most critical factors to ensure the minimum acceptable performance by type of application. Each technical aspect listed in Table 1 is presented below with their respective most relevant comments and their impact on smart grid applications.

i Frequency Range (FAN/NAN): The frequency band of operation of wireless systems that support the applications of smart grids is preferably not licensed and must be in such a way that meets the commitment between the longer range with the lowest possible transmission power and less sensitivity to obstructions between transmitter and receiver. Although the unlicensed frequency bands are much more susceptible to disturbance from other systems, they offer the great advantage of not requiring licensing processes before the telecommunications sector regulators, which also impacts in reducing the cost of the project, does not require payment of licenses for the use of the frequency spectrum. The range of the frequency spectrum in most markets that meet these requirements is in the range of 450 MHz to 2.4 GHz. Regarding disturbances caused by other systems operation in unlicensed frequency bands, the technologies used in smart grids applies countermeasures such as signal encoding, frequency-hopping, among others.

ii Transmission Mode: Applications of smart grids imply an interaction between the endpoint and the operation center of electric power distributors for sending a data requested

in the same way as AMI and asset management automation and lighting, or for confirmation of reception and confirmation of a remote command execution just like in the case of the DA/ADA and DR. This makes two-way communication is a mandatory requirement in smart grid support technologies.

iii Maximum Data Rate per Terminal: This parameter indicates the maximum throughput of each endpoint. The data transmission rate in a communication network based on wireless technologies can vary according several factors, of which the main ones are the frequency range, the transmission power, the level of obstruction to the radio frequency signal propagation, the load of traffic to be transmitted over the network in a given time interval, and network latency. Although a typical smart grid application requires a throughput ranging from 1 Kbps to 100 Kbps by endpoints depending on the application, higher values of data transmission rate enable implementation of more elaborate projects and the traffic of more detailed information between the endpoint and the operation center.

iv Average Latency End to End: The delay in data transmission in a communication infrastructure has a critical rate depending on the type of application to be supported. Real-time applications or those which require a quick response time of endpoints, latency must assume values as low as possible. In the case of smart grids, most critical applications are DA and ADA in particular. Another scenario in which communication network latency is a critical factor is when a polling based system requests information from a large number of endpoints. The total time of a polling cycle and information collection from all endpoints need to occur within a certain period of time acceptable and pre-defined in order to make the process feasible. This is the case of the smart metering of consumers and demand control (DR). In some cases, the number of endpoints to be measured and controlled can reach tens of million.

v Mobility of Endpoints: Mobile communications are important to utilities mainly for voice and data communication between the field teams and operation centers. These applications are supported by communication technologies specifically developed for this purpose and are different from those designed to meet the applications that are part of the scope of this work. Although typical applications of intelligent network (AMI, DR, and ADA) do not require communication platform mobility, automating asset management, which is a very important application for the utilities, as commented previously requires this feature to allow the ability to monitor the assets displacement until the positioning at the place of installation and commissioning.

vi Geolocation: Electricity energy distribution networks need georeferenced systems due to its extension and capillarity. This feature is essential for the operation and maintenance of the electricity grids and provides necessary visibility for operation centers to the actions of operation and dispatch processes of service orders to the field teams. The Geographic Information System (GIS) is computational systems responsible for positioning the assets and grid lines itself on the map. In the context of smart grids, a communication platform on which it is possible georeferencing of communications network elements and endpoints represent an important functionality. This feature enables a smart metering platform to work as a sensor network, allowing the mapping of massive or punctual failures. For distribution automation application a georeferenced communications network is an important tool for the network operation according to the DA or ADA vision. For the projects of automation of the asset management geolocation is essential. Associated to the mobile possibility of terminals it is possible to follow and locate a particular asset since the warehouse to its positioning and start-up in the distribution network. Another interesting application of this feature in the plant communication to the public lighting service that allows lamps location on their respective poles.

Based on these main technical features evaluation of communication technology in comparison with the requirements of the smart grid applications, it is possible to determine the adequacy of this particular technology in order to meet the demands. The goal should be map options that provide the wide scope and service convergence in order to optimize the investments required for infrastructure construction, and operation and maintenance costs.

In the following items will be discussed the main features of the two options of communication network technology in the access layer that stand out today: the already established RF Mesh and the emerging LoRaWAN. In the case of LoRaWAN is evaluating its suitability for smart grid applications. Then a comparison is made between these two technologies showing the advantages and disadvantages between them.

3. RF Mesh

This technology for construction of private wireless networks is based on mesh topology in which each network element is a repeater. In this way, each element can be accessed directly from an access point or via another network terminal element through one or several hops. The basic topology of an RF Mesh Network is presented in Fig. 1. It is based on the IEEE 802.15.4g standard in the physical layer, IEEE 802.15.4e standard in the link layer, MAC sublayer, and the IETF 6LoWPAN Protocol on sublayer LLC [10, 11].

For the purposes of the network address, the IPv6 protocol is used which is able to address 3, 4x1038 different IPs. An IP address is associated with a terminal device so that should not exist on the same network one IP address associated with two different terminal devices.

RF Mesh aims to be a technology based on open standards to ensure interoperability between networks and devices from different manufacturers. To operate in this way should be adopted the protocol stack as shown in Fig. 2 [11, 12, 13].

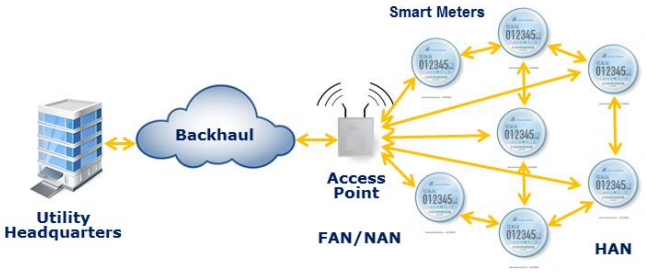

Fig. 1: Basic RF Mesh network topology

The RF Mesh standard was adopted by Wireless Smart Utility Networks Alliance (WI-SUN Alliance). WI-SUN Alliance is a global non-profit organization to promote industry solutions based on open standards and interoperable wireless networks. Officially formed in April 2012 has a mission to test and certify interoperability among different vendors. The focus is smart utility networks and smart cities. It has approximately 95 companies including utilities, government institutions, products manufacturers, and software companies [11]. The current movement of Wi-SUN seeks to expand the scope of its activities to meet IoT services.

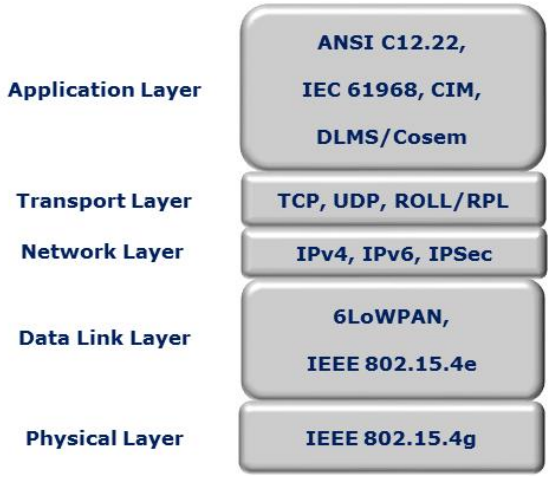

Fig. 2: Wi-SUN Alliance RF Mesh protocol stack

For utility applications, RF Mesh is a fully established technology and of proven effectiveness. The sum of the number of points serviced by the network deployed in several countries reaches over a hundred million. From the point of view of the technical and functional feature, RF Mesh was set to meet the requirements of utility companies' essential applications, such as smart metering and distribution automation, in the case of the electric sector companies [14].

The main characteristics are presented in Table 2 [11, 13, 14]. Data were based on theoretical information that was confirmed through field measurements on an RF Mesh network deployed in seven electric power distribution companies of CPFL Energia Group in State of São Paulo, Brazil deployed for smart metering of all its C&I customers and distribution automation.

Table 2: Main RF Mesh features

RF Mesh Features	
Application	Smart Grid (Smart Metering, DA) and Public Lighting. IoT in development.
Topology	Mesh
Frequency Range	863-876 MHz/915-921 MHz (Europe) 865-867 MHz (India) 902-928 MHz (North America and Brazil) 470-510 MHz (China) 920-928 MHz (Japan) 917-923.5 MHz (Korea)
Maximum Data Rate per Terminal	10-100 kbps
Average Latency	700 ms per hop (recommended up to 3 hops)
Maximum Aggregation per Concentrator	10,000 terminals
Urban Range (without repetition)	3-5 km
Rural Range (without repetition)	10-15 km
Technology Maturity Level	Smart Grid: Established IoT: In development
Mobility of Endpoints	Possible with restrictions
Geolocation	Not possible

Some highlights should be made regarding the technical RF Mesh specifications. First is related to the frequency band. The 900 MHz band is non-licensed in most markets. It dispenses with the obtaining of an operation license from the regulator agency of the telecommunications industry. The counterpart is the interference possibility, but that is outlined using advanced modulation techniques. Another aspect is the coverage area. It is a very interesting frequency range to bypass obstacles and provides a very convenient compromise between transmission power and available bandwidth.

The second point is about the network latency that is related to the topology. Mesh topology offers the advantage of range extension and creation of alternative routes automatically, on the other hand, can cause increased latency in the network. For smart metering applications, this feature does not represent a problem but produce an undesirable impact for DA applications. In order to overcome this restriction for DA applications, RF Mesh designs usually build specific paths in the network or use additional specific network elements, which lead to the rise of network costs. Endpoints can connect to the central Server via any network concentrator. This provides mobility in all coverage areas, but with restrictions in the sense that there is a trend of increase routing information traffic due to neighbor endpoints interaction.

4. LoRaWAN

This newly created technology won momentum with the LoRa Alliance foundation in March 2015. This non-profit organization gathers currently about 330 companies from various countries of the world between telecom operators, equipment manufacturers, semiconductor manufacturers, software companies, computer companies and consulting firms [15].

LoRaWAN is a fully convergent technology based on open standards, low-cost, and was designed from the start to build urban platforms for it. Thus the scope of application is very comprehensive. Among the possible applications are smart grids for utilities, including companies of the electric power sector. The offer of embedded devices grows constantly and includes portable device monitoring, public and patrimonial security solutions, management of urban infrastructure, healthcare, and smart meters [16].

Unlike RF Mesh topology LoRaWAN has a star topology which simplifies the operation, and significantly reduces traffic on network destined to routing information. On the other hand, it does not count with the coverage possibility of extension through the relay on the neighboring terminal device. This loss of functionality as well as being convenient for the context of it does not represent a problem due to the fact a LoRaWAN concentrator device has an average cost of approximately 5 times less than a Mesh RF concentrator.

As the frequency range of operation is also located on non-licensed 900 MHz spectrum, covered area tends to be very similar to RF Mesh. Advanced modulation techniques and access (CDMA) are also used to make the network virtually immune to interference and increased sensitivity of LoRAWAN embedded interfaces on endpoint devices [6, 17].

If a coverage expansion is needed, it can be done by using additional concentrators in RF shadow regions without causing a significant rise in project costs, considering the margin of investments reduction if compared to RF Mesh. Fig. 3 shows the reference topology of LoRaWAN and Fig. 4 the protocol stack [18].

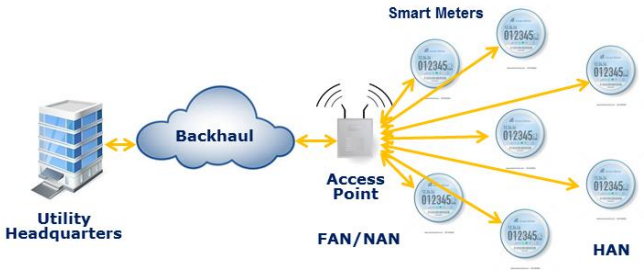

Fig. 3: Basic topology of LoRaWAN network

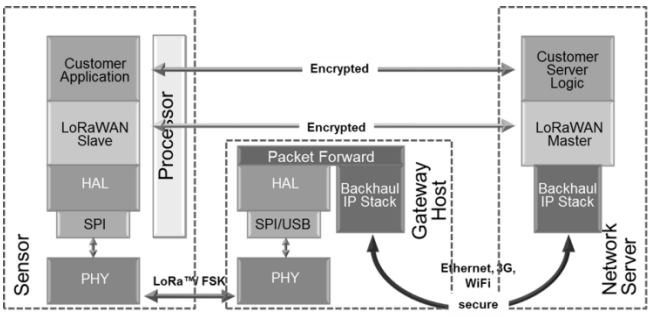

Fig. 4: LoRaWAN protocol stack

A prominent feature of this technology is the extremely low power consumption. The NICs in LoRaWAN endpoint devices are capable of detecting RF signals with power up to 20 dB below noise level consuming a minimum of electric energy. These LoRaWAN NICs can operate autonomously with the same internal battery for 10 to 20 years. This feature is extremely interesting to equip the utility's smart meters.

Regarding the performance characteristics given in Table 3 [6, 17, 19] it is observed significant advantages such as data rate available per terminal, uniform latency due to multiple hops absence to connect endpoints to a concentrator and aggregation capacity of terminals per concentrator. In the current version of LoRaWAN, this feature is 50% higher if compared to RF Mesh current version.

Table 3: Main LoRaWAN features

LoRaWAN Features	
Application	IoT, Smart Cities, Smart Grid (Smart Metering. DA needs to be studied)
Topology	Star
Frequency Range	867-869 MHz (Europe and India) 902-928 MHz (North America and Brazil) 470-510 MHz (China) 920-925 MHz (Japan and Korea)
Maximum Data Rate per Terminal	50 kbps
Average Latency	1 s
Maximum Aggregation per Concentrator	15,000 terminals
Urban Range (without repetition)	2-5 km
Rural Range (without repetition)	10-15 km
Technology Maturity Level	In positioning
Mobility of Endpoints	Possible
Geolocation	Possible

A highlight needs to be made regarding DA applications. Although the theoretical data suggest that this application can also be supported further studies must be done considering all requirements. It is necessary to consider the various situations of communication networks and the topology of distribution grid to determine a recommendation more assertive. The LoRAWAN suitability to any situation of DA projects still needs to be proven. A LoRAWAN differential is the three different classes of service available to allocate the applications according to its technical requirements [20]. Follows below a summary description of these three classes of services:

i. Bidirectional end-devices (Class A): The terminal's uplink transmissions are based on an ALOHA-type protocol. The downlink from the server can only be made in two short receive windows that open after the uplink transmission. This class is that it provides the lowest consumption of energy in the terminal. It can be used for street light, smart meters of the residential segment and Asset Management.

ii. Bidirectional end-devices with scheduled receive slots (Class B): A pre-programmed transmission window is opened, which is managed from a timing signal (Beacon) that indicates when the receiver is ready to receive. It can be more convenient for smart metering of a C&I customer, smart metering substations located at the border of distribution and sub-transmission networks, or to load firmware updates of smart meters.

iii. Bidirectional end-devices with maximal receive slots (Class C): A transmission window continuously opens for transmission. This class is best suited for the possible allocation of the applications (Reclosers) and sub-transmission management systems based on SCADA.

Mobility is an inherent feature of technologies designed for IoT. In this sense, LoRaWAN is totally suitable for applications that require this functionality, such as asset management.

In the following item, a comparison is made between these two technologies for construction of smart grids FAN/NAN. The objective is to determine if LoRAWAN represents an appropriate option considering its technical characteristics of data rate available, low complexity, the guarantee of interoperability among different vendors, and mainly by its convergence around the IoT applications for smart cities.

5. Technologies Comparison

As demonstrated on items III and IV both technologies RF Mesh and LoRaWAN meet the requirements for the most part of smart grid applications. There is no restriction to use LoRaWAN for smart metering. An exception must be made for distribution automation (DA/ADA) in the case of LoRaWAN that still must be better studied. Table 4 presents a comparison between RF Mesh and LoRaWAN considering the parameters studied on this work.

Especially with regard to network latency, it is needed to evaluate boundary conditions about the possibility to use this technology, due to the fact that its performance on this item operates on the borderline of the requirements. For ADA the use of LoRaWAN in the current version of technology presents an even greater constraint also with regard to maximum permissible latency. For these two applications, a solution would be the use of technologies in Backhaul layer able to perform this function. In this scenario, the endpoint of distribution automation would be accessed and serviced directly by this layer of the network, without using the access layer LoRaWAN. Possible telecommunications technology for DA/ADA would be LTE, WiMAX, Point-to-Multipoint radio systems, or even an RF Mesh System specifically designed for this purpose or serving as a Backhaul solution for a LoRaWAN urban network. Table 4 presents a comparison of technical features of these two Network Access Layer technologies. It is proven the requirements compliance for smart metering and other applications such as street light and assets management automation.

Even if a restriction is observed for distribution automation applications, there is a boundary condition to be used which would be to build a network specifically designed to support this application while maintaining other smart grid services via LoRaWAN.

Table 4: RF Mesh X LoRaWAN Comparison

RF Mesh x LoRaWAN		
	RF Mesh	LoRaWAN
Topology	Mesh	Star
Maximum Data Rate per Terminal	10-100 kbps	50 kbps
Average Latency	700 ms per hop (recommended up to 3 hops)	1 s
Maximum Aggregation per Concentrator	10,000 terminals	15,000 terminals
Outdoor RF Concentrator Average Cost per Terminal	US$ 0,50	US$ 0,07
Technology Maturity Level	S.G: Established IoT: In development	In positioning
Mobility of Endpoints	Possible with restrictions	Possible
Geolocation	Not possible	Possible

One relevant advantage of LoRAWAN technology is the fact that is a fully convergent technology, open standards-based, low-cost, and ready to meet all IoT applications in the context of a smart city project. It is desirable that investments in a smart city platform meet all applications and services with an IoT vision, in order to optimize resources and simplification of telecommunications infrastructure. The LoRAWAN technology simplicity is another important aspect in comparison with RF Mesh. The fact that each terminal accesses directly a concentrator excludes the need for complex routing protocols present on RF Mesh. In the context of IoT, this functionality is not even desirable. There are various situations in which it is not even appropriate a terminal access a concentrator through another terminal.

Mesh topology provides the advantage compared to star topology extending the coverage area through NICs that act as a repeater. The endpoints of a neighborhood area network (NAN) can be aggregated in one NIC closer to the concentrator. If a failure event or unavailability of a NIC acting as an aggregator, another one can assume that role. Star topology does not have this functionality, but as discussed earlier, it does not represent a problem for the IoT scenario and offers the advantage of becoming latency uniform of the network. This occurs because star topology does not have hops among endpoints to access a concentrator as happens with RF Mesh.

The endpoints mobility is possible in both technologies. Endpoints of LoRaWAN and RF Mesh are not necessarily bound to a specific concentrator, but in RF Mesh there is a trend of increase traffic of routing information. In this sense, mobility is possible with restrictions. RF Mesh was initially designed to support applications such as smart metering, DA and street light, in which mobility is not an essential issue. Thus, this feature was not initially a priority. However, new smart grid applications with an IoT profile like asset management require a communication network capable of supporting mobility.

The geolocation possibility is an important aspect to be considered in the communication technology selection designed to support applications on smart grids. Utilities use georeferenced systems in their operational processes in order to plot on maps, geographical areas of distribution plant and locate through geographical coordinates their electrical grid assets. Geolocation becomes an important functionality for a communication network that aims to automate these assets, whether for operational processes or management. In this sense, LoRaWAN presents a significant advantage over the RF Mesh. Even though the studies point to restrictions on the use of LoRaWAN for DA, the ability to georeference smart meters in measuring plant extends its functionality to a sensor network which is able to geographically map failures occurrence in delivering of electric power. In addition to this application, the geolocation associated with communications mobility plays a key role in the projects of automation of management of electrical assets.

With regard to the frequency of operation and coverage, both urban and rural environments are well served by both technologies. They have similar characteristics and meet the requirements of the smart grids. However, considering a wider vision in the context of possible partnerships between utilities and municipalities to attend public services, a real scenario points out to the communication infrastructure construction in which coexist technologies such as LoRaWAN in the Access Layer, RF Mesh with mainly functions of Backhaul Layer besides LTE, WiMAX, PMP radios and Optical Fiber systems. Eventually, it will be necessary to complement the coverage with contract services from Telcos based on the public platform of NarrowBand IoT (NB-IoT) for RF shadow regions of the proprietary networks in which the investment on the part of the utilities and municipalities to cover those regions are not financially viable.

Data rate available per terminal in RF Mesh is typically 10 kbps, but some versions go up to 100 kbps. For IoT applications including smart grid, the data rate required by applications rarely exceeds this value. LoRaWAN technology that offers a maximum data rate per terminal of 50 kbps also meets this requirement. Certainly, the data rate effectively available at each point of the coverage area of a concentrator will depend on the level of obstruction to RF propagation, and the distance between the endpoint and the concentrator. In this sense optimization of effective data rate available on each endpoint will depend on the RF design.

Aggregation capacity is a parameter that defines how many endpoints can be connected using a single concentrator device. This implies directly in RF design which will affect the total cost of outdoor RF infrastructure and distribution of this cost per endpoint.

Outdoor RF Concentrator Average Cost per Terminal considers one RF concentrator distribution average cost among endpoints and the maximum aggregate capacity per concentrator. The cost of embedded NICs in the endpoint is not included. A comparison shows that LoRaWAN presents a lower cost in part due to the fact that the average price of the LoRaWAN concentrator device is about 5 times lower than in RF Mesh. Another fact is that aggregation capacity is higher reducing in about 7 times the cost of RF concentrator devices per endpoint.

The maturity level of technologies is different, mainly due to the time of startup of each one: Wi-SUN Alliance in April 2012 and LoRa Alliance in March 2015. This suggests that although the LoRaWAN is advancing fast in various markets, there is still much to be developed. The great interest of the industry demonstrated in just 1 year of organization, especially due to the adequacy of LoRaWAN on IoT projects makes the future of this very promising technology. On the other hand, RF Mesh is well established for the smart metering and automation. Although LoRaWAN is suitable for smart metering, there is an uncertainty regarding its support for distribution automation due to its high latency.

The next steps which certainly will follow from now on point out to an increasing engagement of industry; services companies, including utility sector; government entities; research agencies and academia. Studies of new applications that can be supported by LoRaWAN are advancing in various countries. In the context of smart grids, main applications that require focus to adjust this technology are related to electric grid automation.

6. Conclusion

Smart city projects in the urban environment introduce innovation in the infrastructure services provisioning, making applications accessible directly and fast anywhere. In this context, the concept of Internet of Things (IoT) plays a key role in the telecommunications platform construction that do these projects implementation possible on a large-scale basis. Smart grid initiatives for utilities represent part of this big scenario of smart cities.

Construction of a platform for IoT becomes reality by private and public networks combination, including the Internet as the main platform. Formation of private networks for IoT has two technologies that stand out currently: RF Mesh and LoRaWAN. In this sense, it is desirable to determine an option that provides smart grid and other smart city applications convergence around the same technology. In order to support smart grid applications, utility companies have widely adopted RF Mesh that aims to be an open and interoperable option to build private networks. Regarding interoperability that is essential for IoT projects, RF Mesh has yet work to be done.

For IoT services including smart grids the emerging technology LoRaWAN represents a really convergent alternative which also adopts open and interoperable standards, but at a lower cost if compared to RF Mesh. LoRaWAN technology provides the features necessary to take on the role of an adequate alternative infrastructure to support all smart cities applications, including smart grids. An exception must be made for DA and ADA, which needs to be better studied and tested under a LoRaWAN platform.

A boundary condition would be a separate network deployment specifically designed for this purpose. Another possibility is to build a LoRaWAN Backhaul network also capable of supporting DA and ADA. The currently available technology options that could play this role are WiMAX, LTE, Point-to-Multipoint Radio Systems, or even an RF Mesh System.

Finally, taking into account what was studied on this work it is recommended that utility companies that have not invested yet in a smart metering network based on RF Mesh should consider LoRaWAN inclusion as a possible option in their projects. This can help to find a viable way to build a smart grid infrastructure, taking into account the new context of smart cities, in order to provide a greater gain in scale, preparing the path for possible partnerships between companies providing public services and municipalities. The ultimate goal as well as to make feasible business plans that enable the projects, is to provide citizens quality public services based on technology-intensive application, at the lowest cost as possible.

Conflict of Interest

The authors declare no conflict of interest.

Progressive edge-growth (PEG) methods

ABSTRACT

This paper focuses on optimizing the decoding complexity of the progressive-edge-growth-based (PEG-based) method for the extended grouping of radio frequency identification (RFID) tags using a hybrid iterative/Gaussian elimination decoding algorithm. To further reduce the decoding time, the hybrid decoding is improved by including an early stopping criterion to avoid unnecessary iterations of iterative decoding for undecodable blocks. Various simulations have been carried out to analyse and assess the performance achieved with the PEG-based method under the improved hybrid decoding, both in terms of missing recovery capabilities and decoding complexities. Simulation results are presented, demonstrating that the improved hybrid decoding achieves the optimal missing recovery capabilities of full Gaussian elimination decoding at a lower complexity, as some of the missing tag identifiers are recovered iteratively.

1. Introduction

Checking the integrity of groups containing radio frequency identification (RFID) tagged objects or recovering the tag identifiers of missing objects is important in many activities to find missing tagged objects. Autonomous verification of a group of RFID tags is an essential feature in RFID systems, because it ensures standalone operations as well as scalability, privacy and security. This can be achieved by treating a group of tag identifiers as packet symbols which are encoded and decoded as in binary erasure channels (BECs). This paper is an extension of work originally presented in [1], by optimizing the decoding complexity of the progressive-edge-growth-based (PEG-based) method for the extended grouping of RFID tags while achieving significant missing recovery enhancements compared to other extended grouping methods presented in [2–4].

Various decoding algorithms are devised to recover erasures over BECs, each with different performance and complexities. The most prominent decoding algorithms are maximum likelihood (ML) and iterative (IT) decoding algorithms. ML decoding for a BEC can be implemented as Gaussian elimination (GE), which provides the optimum decoding in terms of erasure recovery capabilities at the price of high decoding complexity [5]. On the other hand, IT decoding based on belief propagation features a linear decoding complexity, but it remains suboptimal in recovering erasures, as it is affected by the existence of short cycles [6, 7]. This suggests a hybrid (HB) decoding strategy which combines the above-mentioned IT with GE decoding algorithms in order to compromise between performance and complexity. References [8–12] proposed and implemented HB decoding algorithms in BECs with the basic idea of employing IT decoding first. If the IT decoding fails to recover all the erased symbols, the GE decoding is activated to complete the decoding process and resolve the simplified system. The GE decoding algorithm can fully recover the erasures in the simplified system if the columns of the decoding matrix are linearly independent. This paper focuses on optimizing the decoding complexity of the PEG-based method using an HB decoding algorithm. To further reduce the decoding time, the HB decoding is improved by including an early stopping criterion to avoid unnecessary iterations of iterative decoding for undecodable blocks. Simulation results are presented, demonstrating that the improved HB decoding achieves the optimal missing recovery capabilities of full GE decoding at a lower complexity, as some of the missing tag identifiers are recovered iteratively.

The remainder of this article is organized as follows. A brief overview of ML and IT decoding algorithms is provided in Section 2. Section 3 introduces the early termination of IT decoding, while Section 4 presents the improved HB decoding. Section 5 evaluates the performance achieved with the improved HB decoding using simulations. Conclusions and future work follow in Section 6.

2. Maximum Likelihood and Iterative Decoding Algorithms

2.1. Maximum Likelihood Decoding Algorithm

The ML decoding algorithm on the BEC involves solving a system of linear equations and finding the unknowns (erasures) in

$$TID_{k`}\ A_{k`} = TID_k\ A_k \quad (1)$$

where $TID_{k`}$ and $TID_k$ are the arrays of lost and known symbols (tag identifiers), respectively. Similarly, $A_{k`}$ is the matrix which contains the columns of A related to $TID_{k`}$, while $A_k$ is the matrix which contains the columns of $A$ related to $TID_k$. A system of linear equations has a unique solution, if and only if the columns of $A_{k`}$ have full rank (i.e. they are linearly independent). This ML decoding can be implemented as GE by reducing $A_{k`}$ to row echelon form. The process of the algorithm consists of two steps. The forward elimination step first reduces the system to an upper triangular form, which can be done using elementary row operations. The algorithm continues with a backward substitution step. It recursively resolves erased symbols until the solution is found. The last symbol of an upper triangular matrix is given the value of the symbol on the right-hand side. Then, this value is replaced in all the equations in which it is included. GE provides the optimum decoding in terms of erasure recovery capabilities at the price of the high decoding complexity of $O(n^3)$, where n is the number of variables [13]. GE is used to represent ML throughout this article.

2.2. Iterative Decoding Algorithm

IT decoding algorithms or message-passing algorithms are commonly used in BEC decoding [14]. IT decoding based on belief propagation features a linear decoding complexity of $O(n)$, but it remains suboptimal in recovering erasures over the BEC, as it is affected by the existence of short cycles [6, 7]. IT decoding algorithms consist of solving (1) by recursively exchanging messages along the edges of a Tanner graph between variable nodes and check nodes. All parity check equations having only one erased symbol are found, and the erased symbols are recovered. Then, new equations which have only one erased symbol may be created and used to recover further erased symbols. The decoding process is as follows:

1) Each variable node v sends the same message $M_v \in \{0, 1, e\}$, where e denotes the erased symbol, to each of its connected check nodes.
2) If a check node receives only one e, it replaces the erased symbol with the bitwise exclusive or XOR of the known symbols in its check equation.
3) Each check node c sends different messages $E_{c,v} \in \{0, 1, e\}$ to each of its connected variable nodes v. These messages represent the results of the previous step.
4) If the variable node of an erased symbol receives $E_{c,v} \in \{0,1\}$, the variable node updates its value to the value of $E_{c,v}$.

The IT decoding iterates the above process until all the erasure symbols are recovered successfully or until a predetermined maximum number of iterations (I_{max}) has passed without successful decoding [15].

3. Early Termination of Iterative Decoding

Early termination of IT decoding has been extensively researched within correcting errors introduced by channels. At each iteration, the IT decoding detects decodable blocks by checking parity check constraints. If all parity check constraints are satisfied, the decoding terminates. Otherwise, the decoding always completes $I_{\max}$ iterations for undecodable blocks. The decoding time and complexity increases linearly with the number of decoding iterations. To avoid unnecessary decoding iterations when processing undecodable blocks, a proper stopping criterion is required to terminate the decoding process early and therefore to save decoding time and power consumption [16]. Different early stopping criteria have been proposed for IT decoding, aiming to detect undecodable blocks and to stop the decoding process in its early stage. These criteria can be divided into two types. One type utilizes log-likelihood ratios (LLRs), for example the criterion in [17]. It identifies undecodable blocks using variable node reliability, which is the addition of the absolute values of all variable node LLRs. The decoding process is stopped if the variable node reliability remains unchanged or is decreased within two consecutive iterations. This is a consequence of the observation that a consistent increase of the variable node reliability is expected from a decodable block. The criterion is disabled if the variable node reliability is larger than a channel-dependent threshold. Similar criteria have been proposed in [18–20] which monitor the convergence of the mean magnitude of the LLRs at the end of each iteration to identify undecodable blocks. The other type of criteria are those which observe the numbers of satisfied or unsatisfied parity check constraints; for example the criteria in [21] and the improved criterion in [22] compare the numbers of satisfied parity check constraints in two consecutive iterations. If they are equal, the decoding process is halted. On the other hand, the criteria in [23, 24] use the number of unsatisfied parity check constraints to detect undecodable blocks.

4. Improved Hybrid Decoding Algorithm

In the HB decoding process, the decoding time of IT decoding for undecodable blocks becomes longer as the decoding iterates for $I_{\max}$. Figure 1 shows the iteration histogram as a function of the missing amounts experienced for two variants of group sizes, including 49 and 169 tags. I_{max} is set to 50 and 200, respectively. It is explicit that as the number of missing tags increases, iteration for $I_{\max}$ starts to occur due to the existence of undecodable blocks. This can clearly be seen in the region where IT decoding has failed, for example when recovering more than 15 and 70 missing tags from a group of 49 and 169, respectively. Therefore, the taking into account of an early stopping criterion, which adaptively adjusts the number of decoding iterations, arises as an attractive solution to avoid unnecessary iterations and thus to save decoding time. Since the main advantage of HB decoding is to reduce GE complexity, the frequency of GE decoding usage should be as small as possible,

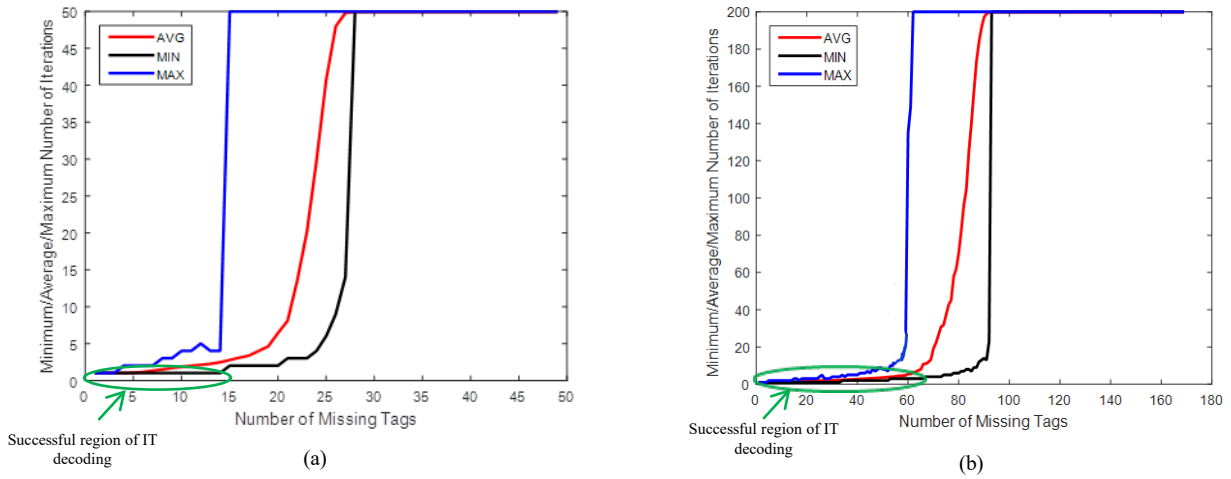

Figure 1. The iteration numbers required for decoding different group sizes: (a) $n = 49$; (b) $n = 169$ where $j = 3$ for the PEG-based method

even for a large number of missing tags. When GE decoding is utilized, the size of the simplified system should also be as small as possible. This suggests a stopping criterion for the PEG-based method which permits partial decoding of undecodable blocks up to a point where IT decoding cannot recover any missing tag identifiers. The proposed criterion can distinguish between decodable and undecodable blocks. It does not cause any computation overheads, as it utilizes the information available during the decoding process. Algorithm 1 outlines the improved HB decoding algorithm. The input is the received codeword $y = [y_1, y_2, \dots, y_n]$ of the transmitted codeword $x = [x_1, x_2, \dots, x_n]$ where $x_i \in \{0,1\}$ and $y_i \in \{0, 1, e\}$ for $i = 1 \dots n$. The output is $M = [M_1, \dots, M_n]$ where $M_i \in \{0, 1, e\}$. Let S_j denote the set of symbols in the j-th check equation of the code, n_e is the number of erasures at the input to the decoder, and $E_{j,i}$ is the outgoing message from the check node j to the variable node i. The improved algorithm is based on the observation of the checksum of erasure symbols n_e^I at the end of each iteration I. It halts the decoding process if the checksum remains unchanged or does not decrease within two consecutive decoding iterations, as in Step 24. This results from the observation that decodable blocks exhibit a consistent decrease in checksum values.

5. Simulation Results

This section gives an account of the various simulations which have been carried out to analyse and assess the performance of the PEG-based method under the improved HB decoding, both in terms of missing recovery capabilities and decoding complexities.

5.1. Missing Recovery Capability Analysis

To illustrate the performance of the improved HB decoding in recovering missing tags, Figure 2 shows the average error rate as a function of the number of missing tags for different values of group sizes n where the column weight j varies between 3 and 4. It can be clearly shown that increasing j greatly increases the performance of the improved HB decoding in recovering missing tags. The main reason for this behaviour is that a large value of j produces a large number of rows and thus increases the rank of the matrix. For example, if five tags are missing from a group of n = 25, all their identifiers can be recovered with at least j = 3 under the improved HB decoding. However, if ten identifiers are missing, the column weight needs to be adjusted to 4 in order to achieve 100% reliable recovery (0% error rate). Table 1 compares the missing recovery capabilities of the simulated PEG-based method under the improved HB decoding algorithm with other extended grouping methods presented in [2–4]. It is clear that the improved algorithm achieves significant missing recovery enhancements compared to other extended grouping methods. It can be concluded from the results that the improved HB decoding achieves the optimal missing recovery capabilities of full GE decoding, since the remaining systems of IT decoding containing short cycles are solved with GE decoding. The results also reveal that the recovery performance of the improved HB decoding increases by increasing the group size. This results from the fact that the PEG-based method accounts for short cycles in Tanner graphs by maximizing the local girth, i.e. the length of the shortest cycle, at variable nodes, which is more achievable when the group size is large [1]. Applying the improved HB decoding to groups of 25 and 49 tags, for example, results in the recovery of missing tags of up to 48% and 65%, respectively, of the group size, with a 0% error rate. On the other hand, for groups of 121 and 169 tags, the recovery capabilities increase to 72% and 74.5%, respectively.

5.2. Decoding Complexity Analysis

The relative complexities of the improved HB decoding are analysed in terms of decoding time. The decoding time is measured on a 2 GHz Intel i7 processor. The entire decoding complexity is equal to the complexity of IT decoding plus that of GE decoding if short cycles exist. This is mainly determined by the efficiency of the first stage of IT decoding; the better the performance of the IT decoding, the less the complexity and thus the time of the improved HB decoding. During the decoding process, IT decoding is first applied on the parity check matrix. If the IT decoding fails, GE decoding is activated to solve the remaining systems with a complexity less than the complexity of decoding the original matrix.

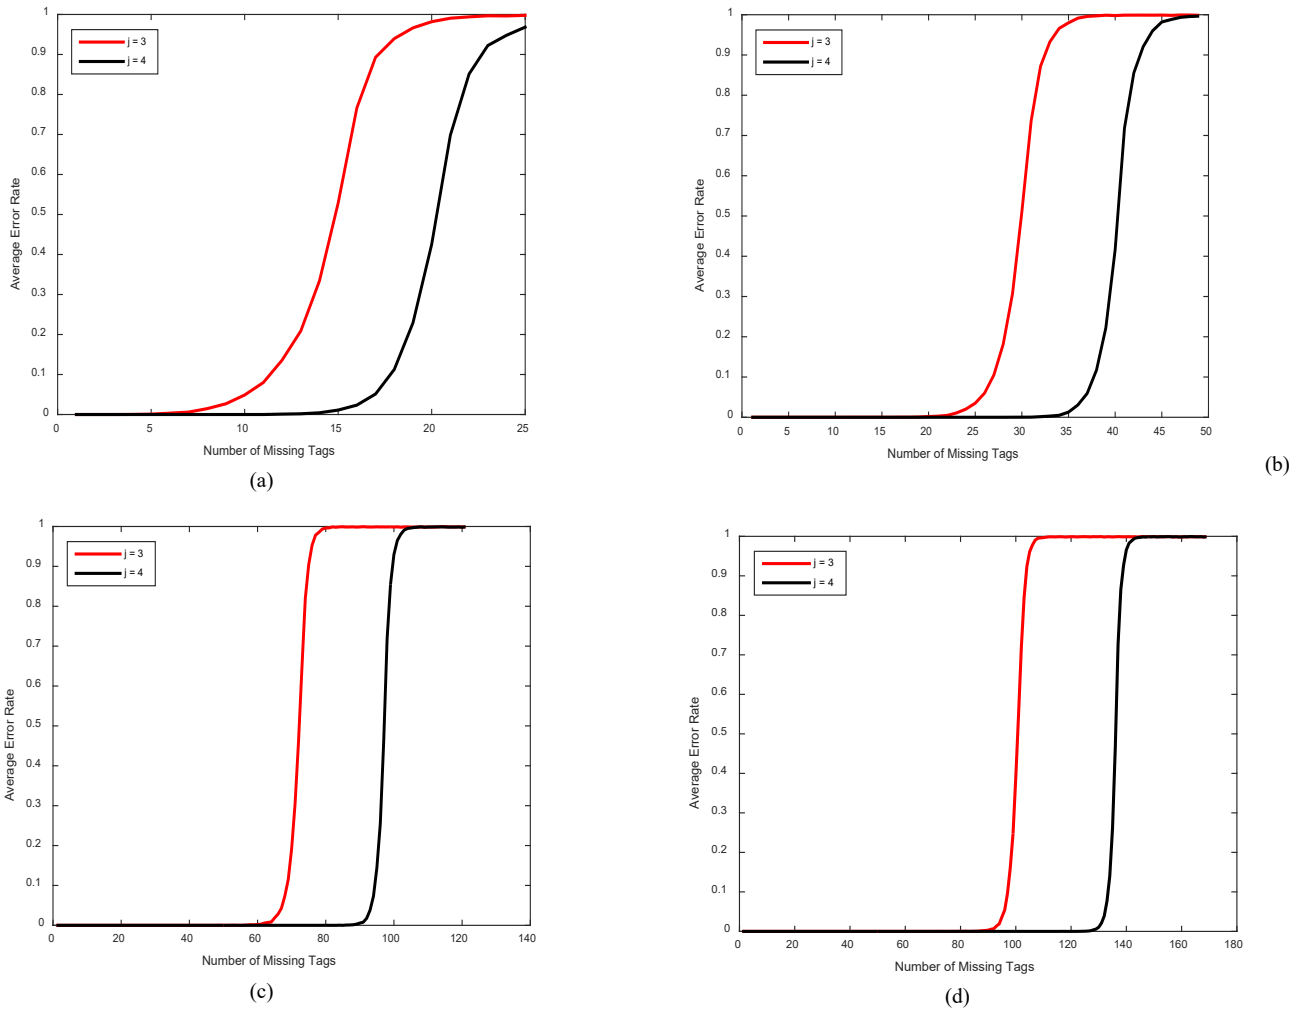

Figure 2. The average error rate for different group sizes: (a) n = 25; (b) n = 49; (c) n = 121; (d) n = 169 using the PEG-based method under the improved HB decoding

Table 1. Comparisons of missing recovery capabilities of the PEG-based method under the improved HB decoding algorithms with other extended grouping methods

(49, 4, 5)	[2]	3	(169, 4, 5)	[2]	1
	[3]	7		[3]	9
	[4]	8		[4]	16
	PEG-based method under GE decoding	32		PEG-based method under GE decoding	126
	PEG-based method under HB decoding	32		PEG-based method under HB decoding	126

Two experiments are conducted:

1) Decoding time measurements when IT decoding fails and thus GE is required. This is the worst case from a decoding point of view.

2) Decoding time measurements as a function of the number of missing tags to compare two cases, one where IT decoding is successful and the other where IT decoding fails and GE is needed.

5.2.1. Decoding Time when Gaussian Elimination is Required (Worst Case)

Figure 3 illustrates the decoding time during the GE process of the improved HB decoding for a group of 49 and 169 tags where $j = 3$. By changing the number of missing tags, the resulting average simplified system size changes, which affects the decoding time. The figure illustrates this time as a function of the simplified system size and the related histogram. The region where IT decoding recovers some missing tag identifiers is only considered in this analysis. However, in the second region, where IT decoding cannot recover any missing tag identifiers, GE decoding time is equal to that of full systems. The improved algorithm efficiently decreases the average decoding time of GE decoding, because the complex GE decoding is only utilized when required over a simplified system resulting from IT decoding. For a group of 49 tags, the histogram demonstrates that the maximum decoding time remains below 2 ms related to an average decoding time of 1.8 ms. When the group size increases to 169 tags, the GE decoding time also increases, following a $O(n^3)$ law. It can clearly be seen that the maximum decoding time remains below 13 ms related to an average decoding time around 12 ms. In contrast, GE decoding on full systems, as illustrated in Figures 5 and 6 (presented in the next section), is slower, especially for a large group of tags. For a group of size 49 and 169 where $j = 3$, it is evident that the decoding time lasts on average 2 and 15 ms, respectively.

To illustrate the impact of the proposed early stopping criterion on decoding time, Figure 4 shows iteration numbers which are taken for various missing amounts to be compared to those of the conventional IT decoding depicted in Figure 1. One can observe that the proposed stopping criterion greatly reduces the average number of iterations in the region where IT decoding is not successful. Figure 4 shows that undecodable blocks need at most 17 and 33 iterations, respectively, when recovering more than 15 and 70 missing tags from a group of 49 and 169.

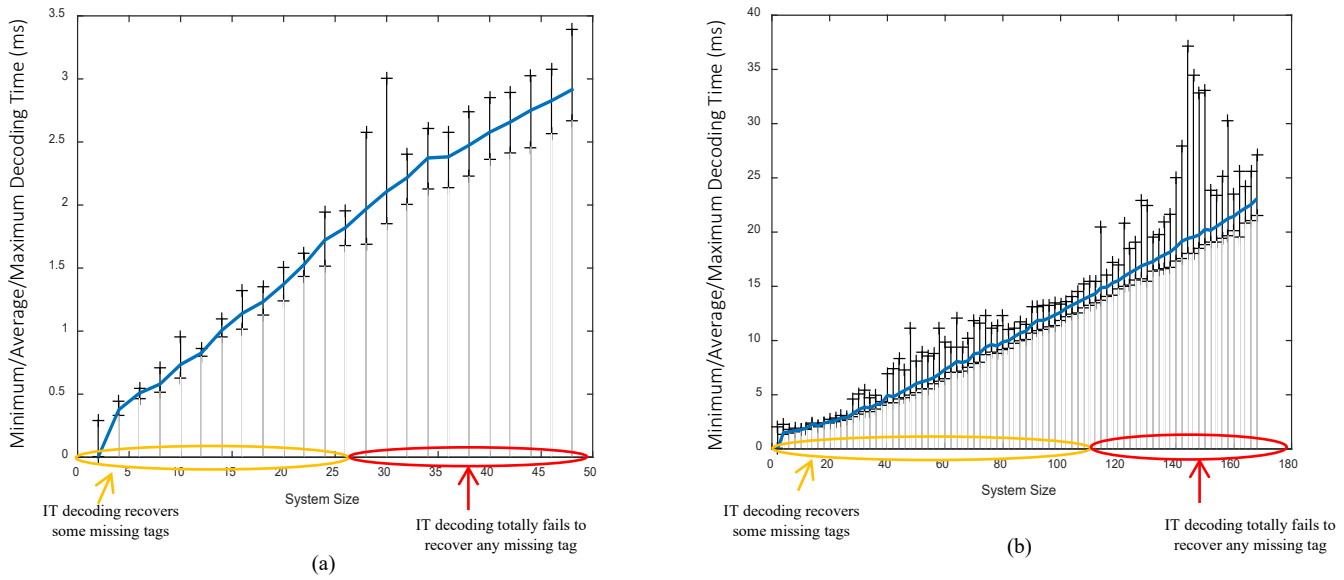

Figure 3. Histogram of GE decoding time with respect to the simplified system size for different group sizes: (a) $n = 49$; (b) $n = 169$ where $j = 3$ for the PEG-based method

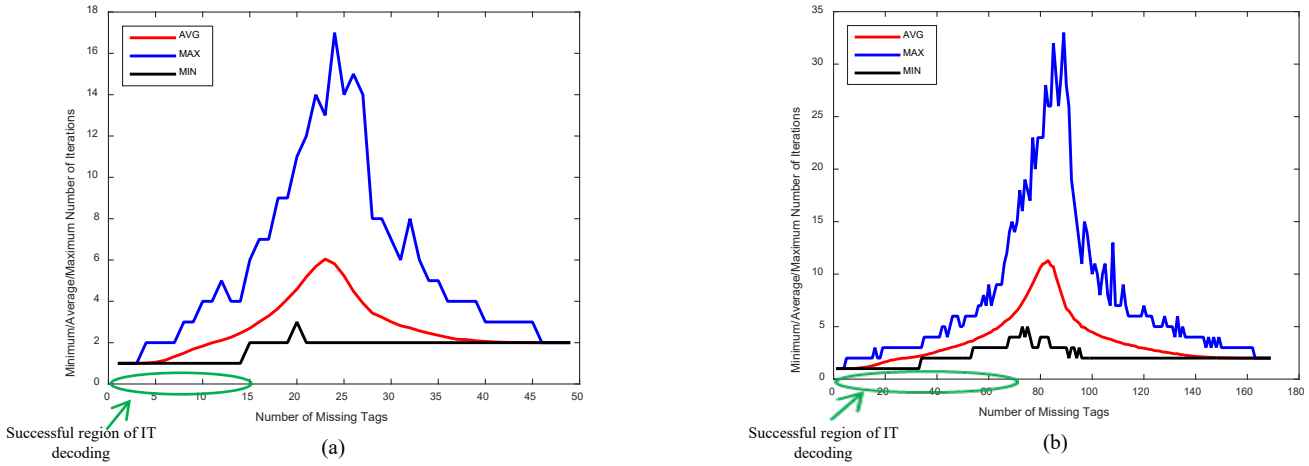

Figure 4. The enhanced iteration numbers required for decoding different group sizes: (a) $n = 49$; (b) $n = 169$ where $j = 3$ for the PEG-based method

5.2.2. *Decoding Time of the Improved Hybrid Decoding*

Figures 5 and 6 show the average decoding time as a function of the number of missing tags for different values of n where j is equal to 3 and 4 under the IT, GE and improved HB decoding algorithms. It is obvious that the decoding time depends on the missing amounts experienced. With small numbers of missing tags, the decoding time of the improved HB decoding is fast and is similar to that of IT decoding. This is clear in a region where IT decoding is successful. As the number of missing tags increases, the decoding time of the improved HB decoding also progressively increases, because GE decoding is more and more often required. This can be seen in the curves: after the successful region of IT decoding, the average decoding time of HB decoding increases progressively, since IT decoding turns out to be ineffective, and the size of the simplified system increases accordingly. Then, above a certain threshold which depends on the missing recovery capabilities of IT decoding, the decoding time of the improved HB decoding gradually approaches the full GE decoding. Since the entire decoding time of the improved HB decoding is equal to the decoding time of IT decoding plus that of GE decoding, the improved HB decoding algorithm can easily be tailored to satisfy operational requirements. More precisely, the IT decoding phase can be avoided when the aforementioned condition is met, to save HB decoding time. It is clear that the n and j parameters also have major impacts on the decoding time. As n or j increase, the improved HB decoding time increases too. This is due to specific phenomena. The complexity of IT decoding depends on the number of XOR operations, which is determined by the number of variables in each equation, whereas the complexity of the GE decoding depends on the number of linear equations and the number of variables. Therefore, by increasing n or j, the number of operations required by the IT and GE decoding algorithms is increased accordingly. If decoding time is an issue with a large n value, choosing a smaller j value is possible. If the HB decoding time is compared with the GE decoding time for

the full system, it can be concluded that the HB decoding is faster for small to medium numbers of missing tags even when GE decoding is required.

6. Conclusions and Future Work

This paper has focused on optimizing the decoding complexity of the PEG-based method using a hybrid iterative/Gaussian elimination decoding algorithm. The hybrid decoding is improved by including an early stopping criterion to avoid unnecessary iterations of iterative decoding for undecodable blocks and thus saving decoding time. Simulation results have been presented showing that the improved hybrid decoding algorithm achieves the optimal missing recovery capabilities of full Gaussian elimination decoding, since the remaining systems of iterative decoding containing short cycles are solved with Gaussian elimination decoding. This recovery performance significantly increases with an increase in the group size of tags. It has been shown that the proposed stopping criterion greatly reduces the average number of decoding iterations for undecodable blocks and therefore reduces decoding time when compared to the conventional IT decoding algorithm. The improved algorithm is very efficient in decreasing the average decoding time of Gaussian elimination decoding for small to medium amounts of missing tags up to a certain threshold which depends on the missing recovery capabilities of IT decoding. This makes the improved hybrid decoding a promising candidate for decoding the PEG-based method for extended the grouping of RFID tags.

For future work, more investigation is needed into the joint use of the two decoding algorithms according to missing amounts and group sizes.

Monitoring in virtual environments

ABSTRACT

One of the great challenges in distance-learning is to follow the actions of the teachers/tutors and also the actions of students during the process of teaching and learning. This article presents the FAG Tool integrated with the LMS Moodle was developed to help managers of the Distance Education environment to monitor the actions of teachers/tutors and also teachers/tutors in the follow-up of student actions. Through the techniques of Business Intelligence (BI) and Learning Analytics (LA), the tool generates analytical reports and dashboards, presenting a holistic and transversal view, being this vision the differential of this tool. The use of FAG allows teachers/tutors to monitor the participation of all their students in all virtual rooms under their responsibility and thus take corrective measures in the teaching and learning process, such as reducing the risk of avoidance. For the managers, it can be considered as a support tool for decision making regarding the faculty, maintaining or not the teacher/tutor in the process of teaching and learning or even be a base to enlarge or reduce their classes depending on their performance in the virtual environment. Through the use of the FAG, this decision-making can happen during the teaching and learning process and not only after the end, as is usual, because the reports are easy to understand and present accurate information in time to ensure the success of the teaching and learning process.

1. Introduction

This publication is an extension of the article entitled "Management support tool in virtual leaming environments using MoodIe as a case study" that is published in 2016 XI Latin American Conference on Learning Objects and Technology (LACLO)[1].

Distance education is a widely used teaching modality in the teaching and learning process [2]. In this modality of teaching, there are several actors, and the teacher is responsible for motivating and stimulating the learning process in order to transform the information into knowledge by the students, who are considered active subjects in this process [3]. The tutor is responsible for guiding the student, explaining and clarifying questions related to the subject and participating in the evaluation activities [4] and the distance-learning environment and process manager is responsible for planning, organizing, directing and controlling [5]. In this work the role of a teacher and a tutor will be considered as a single role, called, teacher/tutor, since not necessarily a course needs a teacher and a tutor. This decision is related to three situations: digital fluency of a teacher, an excessive number of students enrolled and teachers availability of time to carry out and follow the course.

Nothing prevents a teacher from acting as a tutor in online courses [6]. In order to guarantee better results in the process of distance teaching and learning, one of the needs is the monitoring process of teachers/tutors' actions, often done by a manager of many or all courses of an institution. Usually, the management reports provided by an LMS are confusing, offering scattered data that do not allow a global view of the observed processes, thus hindering efficient management and decision-making [7]. Among the several existing LMSs Moodle will be used, once it is an LMS widely used in thousands of institutions in the world and consequently a

very safe and very tested system. Moodle offers Learning Analytics (LA) tools that can be defined as a set of tools geared to the measurement, collection, analysis and reporting of student data in order to improve the teaching and learning process through analysis of generated data. These tools generate analytical reports and/or graphs of specific resources as classrooms or participants. In this way, the importance of this work is the identification of an auxiliary tool that, integrated to Moodle LMS, offers a better follow-up of the students' participation, besides an efficient monitoring of the actions of the teachers/tutors in relation to all the activities and contexts in which they work.

Section 2 presents concepts related to the knowledge area of work, such as Business Intelligence (BI), Learning Analytics (LA), some Moodle tools associated with LA, as well as the Pentaho BI and Qlik Sense Cloud tools, which will be used in the case study. Section 3 will present the methodology and case study. Section 4 presents the tool developed to solve the problem detected in the case study and partial result. In section 5 the conclusion will be presented and in section 6 future works will be proposed. Finally, bibliographical references are presented.

2. Concepts referring to the knowledge area of work

2.1. Business Intelligence (BI)

BI is a tool that assists in the selection, presentation and analysis of data, is a set of processes, technologies and tools necessary to transform data into information, information into knowledge [8].

Throughout their existence, organizations generate and store a large amount of data related to the activities performed, thus making it necessary to apply BI techniques in the strategic decision-making process, since mistaken decisions can jeopardize the future of an organization. In this scenario, there are also educational institutions, which need to be able to subsidize the optimization of their decision-making processes [9].

2.2. Business Intelligence Architecture Components

They are components that aid in the visualization and manipulation of large amounts of data:

- Data warehouse (DW): is defined as a database that serves as a repository of an organization built for the purpose of generating reports and business analysis [10].

- ETL (Extract Transform Load): The ETL process consists of reading the data from one or more databases, the process of which is called the extraction, after the extraction has the conversion of the extracted data to the form that is required, in order to be loaded on a date warehouse or other database, called transformation and finally the loading of the data in the data warehouse [11]. The ETL feeds DW and BI, and if this process does not work properly, the BI will not have the necessary information [12].

- OLAP (On-Line Analytical Processing): OLAP tools enable online generation of information in the form of reports, rankings, ad-hoc queries (uniquely mounted by the user), etc. [13].

The OLAP technology allows making an instance of the data in a multidimensional view, thus allowing the presentation of the information in different perspectives [19]. OLAP information is stored in subsets called information cubes, updated periodically from the DW, according to Figure 1.

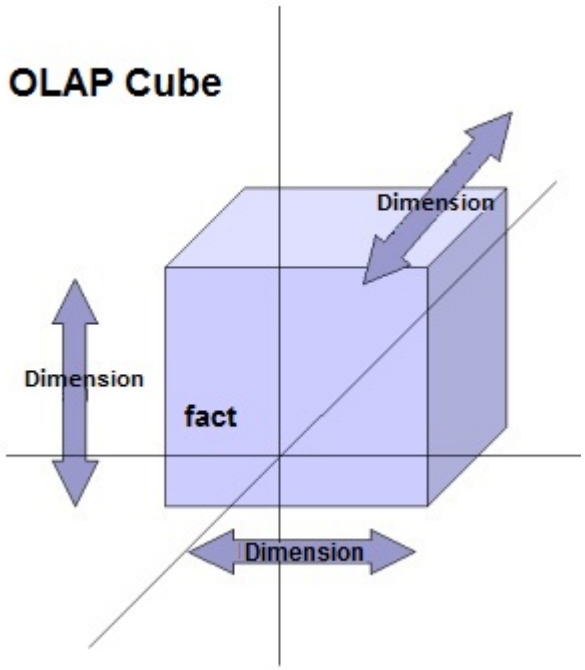

Figure 1. OLAP cubes

2.3. Business Intelligence in Learning Management System (LMS)

The concept of Business has changed. With the adoption of LMS in the learning support, the volume of information to be managed by teachers/tutors and also by the managers of LMSs systems increases, which makes it difficult to manage in these environments [14]. A derivation of the principles of BI used in information systems applied to the educational field, called Learning Analytics [15].

2.4. Learning Analytics (LA)

The term Learning Analytics appeared for the first time in 2009 in The Horizon Report. It is a field of research that is growing and presents several tools implemented in educational environments aim to offer educators resources so that they recognize and evaluate their educational process [17-18].

The main objective of the learning analysis is to generate information for those who create learning situations, such as teachers/tutors, managers and educational institutions [8]. It is a powerful way to inform students, teachers/tutors and managers about student performance and the progress of the learning process [19].

2.5. Learning Analytics (LA) in Moodle

Among the tools with LA resources offered by the Moodle can be cited:

- GISMO: consists in a visualization tool used to analyze the learning process of students comprehensively, which gives a view of the whole class and not just a specific student or a specific resource. It is useful to teachers/tutors.

- MOCLog: it is a set of tools used to analyze and present Moodle data. The development of this tool was based on GISMO,

through this tool users have access to summary reports of interactions related to actions in resources and tools, such as questionnaires [16].

- Learning Analytics Enhanced Rubric (LAe-R): consists a plugin created for Moodle LMS being an advanced classification method used for the careful evaluation. Contains some related criteria and classification levels associated with data from the analysis of student interaction and learning behavior in a course such as access time to learning materials, message numbers, and others [17].

In addition to the tools presented there are other ways to see the trends, analysis, and data on the platform from Moodle 2.8, among them:

- Event monitoring: Issue notifications to administrators and teachers/tutors when certain events occur in Moodle;

- General statistics: this is a plugin that generates site graphics and course reports, including user login, countries, preferred languages, number of courses per category, number of courses per size and registered users;

- Comprehensive report (site-wide Report): they are accessed by administrators are reports of the entire site;

- Compromise Analysis: The Engagement Analytics module provides information about student progress in the course, choosing activities that will be monitored by Moodle;

- Activities (Logs): These are reports that can be viewed by administrators;

- Forums Reporting Charts (Report Graph Forum): Displays the interactions in a single Forum activity and creates a targeted graph;

Through the tools with LA resources offered by Moodle it is not possible to extract analytical and consolidated reports containing information about all the rooms under the responsibility of a certain teacher / tutor, which makes it extremely difficult for the EaD manager to group information from room to room, considering That, most of the time, a teacher/tutor participates in several rooms simultaneously.

2.6. Pentaho BI

The Pentaho Open BI platform is a suite of open source applications for creating BI solutions, distributed through the open source Pentaho Public License (PPL). The Pentaho suite is one of the most used and reputed in the market [18].

The most important Pentaho modules that will be used in this work are:

- Pentaho Data Integration (PDI): one of the most powerful components responsible for the ETL process, is a collection of tools designed to fill the Data Warehouse with data [22].

- Platform Pentaho User Console (BiServer): an analysis platform that will run under a Tomcat server in a MySQL database, Linux environment.

- Pentaho Report Designer: tool that allows you to generate reports in a consolidated and analytical way.

2.7. Qlik Sense Cloud

The Qlik Sense Cloud platform focuses on self-service, lets you quickly create views.

The tool does not work with inflexible cubes, it creates a large file with all associations, so any table can be "fact" or "dimension" and all relevant data is available in RAM, a technology known as AQL (Associative Query Logic), Different from OLAP, where it is necessary to define the necessary dimensions and metrics [20].

Qlik Sense Cloud lets you share Qlik Sense applications in the cloud for free. It is a Software as a Service (SaaS) service or program as a service[20].

The great differential of this tool, besides the ease of generating graphical reports is that it adapts to tablet and smartphone[21].

3. Methodology and case study

For the development of the work the following steps were performed:

- Extraction of real data of Moodle, referring to the disciplines of four undergraduate courses that occurred in the second half of 2015, being, Human Resources Management, Management Process Management, Administration and Accounting Sciences. Statistics of the interactions of teachers/tutors with students in the tools were presented: forum and questionnaire, as well as student participation, through a case study.

- Analysis of the results obtained in order to verify the problems pointed out by the bibliographic research.

- Implementation of the tool using the platforms Pentaho BI and Qlik Sense Cloud.

The name of the teacher/tutor will be omitted, and in the case study, it will be referenced as tutor "A".

The data were obtained from the three disciplines, under the responsibility of tutor "A", named: MKP - Personal Marketing, MTA - Methods and Techniques of Applied Research and PO - Organizational Psychology. These disciplines were chosen by totaling a larger number of registered students.

3.1. Profile of tutor "A" in the courses and disciplines analyzed

The responsibilities of teachers/tutors in this environment:

- Track students' daily access,

- Attend the Doubts at Forum within 24 hours of posting,

- Post informational and alert messages in the News Forum,

- Prepare and distribute the programmatic contents of the course according to the specific program specified in the course plan, respecting the academic calendar of the institution,

- Prepare and publish activities that can be:
  - o Questionnaires,
  - o Evaluation forums,
  - o Online types or file uploads,
- Give feedback on activities,
- Prepare and correct the evaluations.

In addition, teachers/tutors are encouraged to motivate the participation of students by sending weekly messages, alerting them to the timing of the proposed activities and orienting them in the studies. The more classes the teacher/tutor has under their responsibility, the more time they will have to spend to fulfill those responsibilities.

3.2. Follow-up of student participation and tutor actions "A" in the subjects MKP, MTA and PO

Table 1 presents an overview of student participation (access) in the three virtual rooms, under the responsibility of tutor "A". Students who, at least once, accessed the virtual room in the last month of the course in December 2015 were considered active ".

Table 1. Participation of students (accesses) in virtual rooms

Discipline	Students				
	Total amount	Active amount	(%)	Never attended the course amount	(%)
MKT	34	27	79,4%	0	0,0%
MTA	188	172	91,5%	11	5,8%
PO	95	88	92,6%	3	3,1%

Figure 2 presents the analytical report offered by Moodle, referring to student accesses, in a specific room where the teacher/ tutor acts.

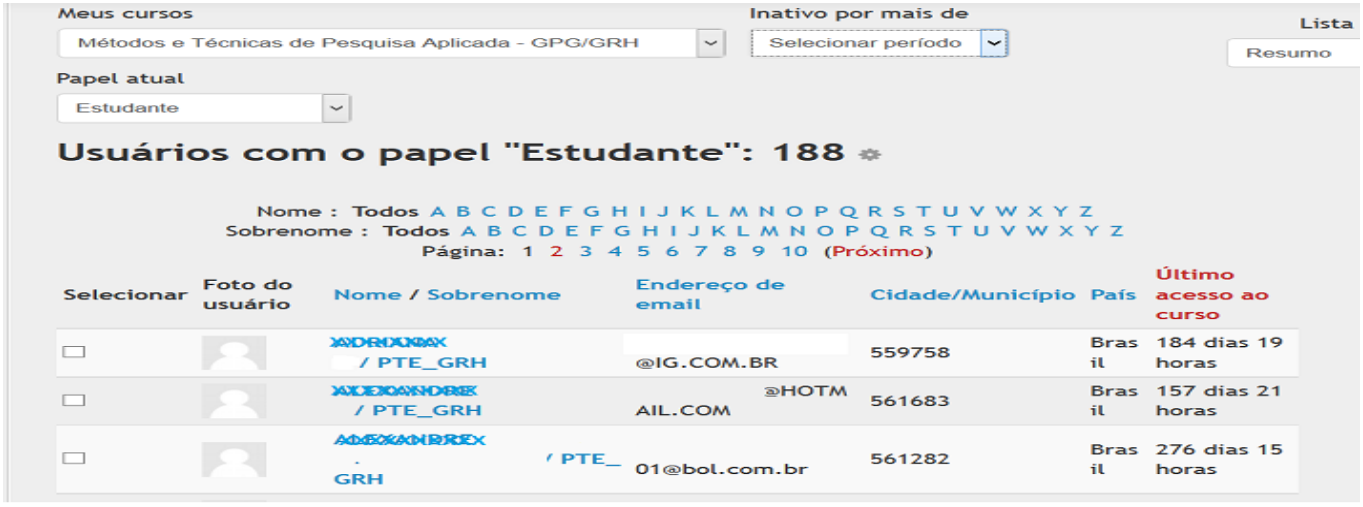

Figure 2. Students access

This report is offered by Moodle LMS, however, the teacher/ tutor must access each virtual room under his responsibility, issue the report and check the last access of the students registered in it. There is no cross-sectional view.

Table 2 presents an overview of the participation of students in the Forum of News, in the three virtual rooms, the responsibility of tutor "A".

Table 2. Participation of students in the News Forum

Discipline	Students		
	Total	Access	(%)
MKT	34	17	50,0%
MTA	188	38	20,2%
PO	95	21	22,1%

Table 3 presents an overview of students' participation in the Doubt Forum, in the three virtual rooms, under the responsibility of tutor "A".

Table 3. Student participation in the Doubts Forum

Discipline	Student		
	Total	Access	(%)
MKT	34	23	64,6%
MTA	188	62	32,9%
PO	95	33	34,7%

Figure 3 presents the analytical report regarding the accesses in the News Forum by students in a specific room that the teacher /tutor acts.

The report extracted from Moodle regarding student access in the Doubt Forum is identical to the one shown in Figure 3.

It is important to note that all participants of the course receive the messages that are posted in the forums also by e-mail and, since it is not possible to count the accesses to the e-mail messages, only the accesses in the virtual classrooms were considered.

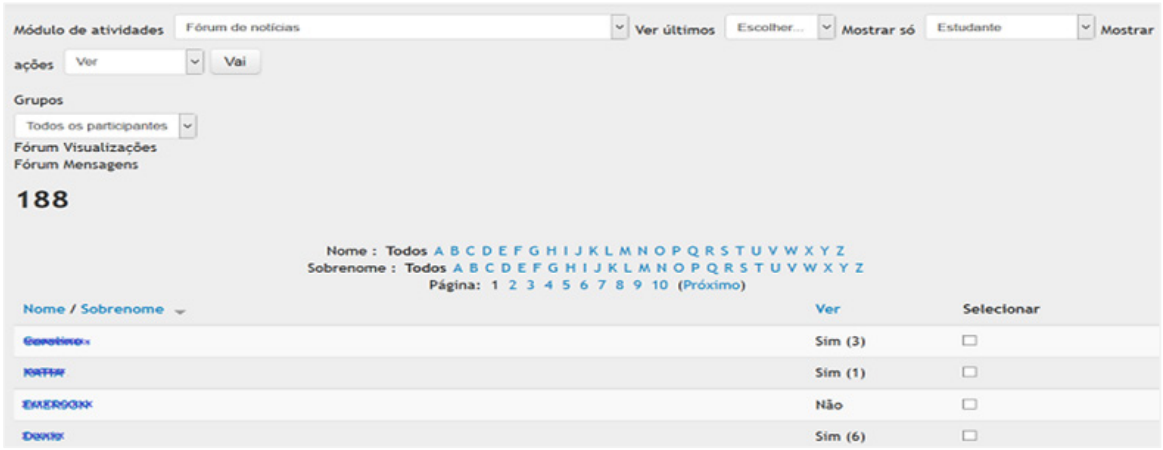

Figure 3. Student Accesses in the News Forum

Figure 4 presents the report made available by Moodle, regarding the participation of students in the activities of the questionnaire type, of a specific room in which the teacher/tutor acts.

Table 4 presents an overview of students' participation in Questionnaire-type activities in the three virtual classrooms, under the responsibility of tutor "A".

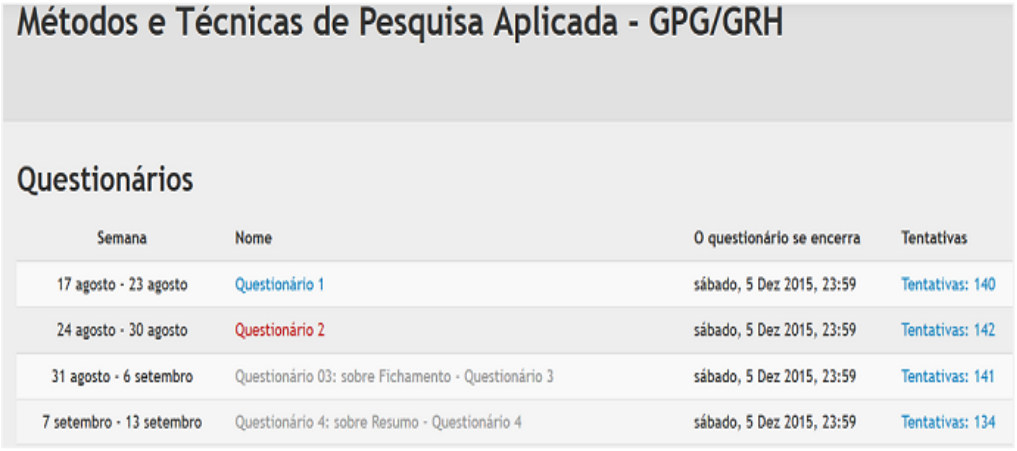

Figure 4. Participation of students in the activities of the Questionnaire type

Table 4. Participation of students in the activities of the Questionnaire type

Table 6. Participation of tutor "A" in the Forum of News

	MKT	MTA	PO
Messages posted to the News Forum	4	4	4

3.3. Analysis of extracted data

It is observed in the study, through Figures 2, 3 and 4, that Moodle allows the extraction of reports of inactive students for more than one period, specified in the system, student participation in forums, activities, however, are not easy interpretation.

The teacher/tutor used the News Forum tool to keep the students informed about the events in the course, such as term of activities, calendar of tests, alerts and also this Forum was used for messages of welcome to the students, however, In the case of tutor "A" only four messages were posted in the News Forum of each virtual room, which is considered little due to the importance of this tool in transmitting information to students. Access to this News Forum is important because it is published relevant topics such as: notices, alerts, important dates, deadlines, etc.

One of the main roles of tutors is to be responsible for explaining and clarifying issues related to the discipline [4]. The tool used for this purpose in the examples presented was the Doubts Forum. In the presented results it was observed that the participation of the teacher/tutor was representative, through the messages posted in the Doubts Forum, in the sense of commenting them, the participation of the students was not significant, according to the number of messages posted by them.

In this study, the teacher/tutor offered twelve evaluation questionnaires during the course and, through the BOX Activities, was able to extract information on how many attempts were made in each questionnaire, but difficult to interpret.

The monitoring of the actions in Moodle becomes very laborious for both the teacher/tutor and the manager since it is necessary that these monitoring must be done in each virtual classroom in which the tutor acts, in isolation, for later the information be grouped and provided an overview of the actions.

The same deficiency of the environment is verified for the environment manager and learning processes, which does not have a way to obtain a visualization of the actions of the teachers / tutors in a global way, grouping all the virtual rooms under their responsibility, being necessary that they access each Virtual room in isolation and extract the information of your interest.

A competent tutorial action could minimize many flaws in this process of teaching and learning, and allow the manager to make decisions regarding the faculty during the course, so it is interesting that:

- The teacher/tutor is monitored weekly through access statistics in virtual rooms;
- Messages are posted in the News and Doubts Forums;
- Evaluation activities are posted weekly, such as: questionnaires, online tasks, file submission task and discussion forums.

4. Monitoring tool for students and teachers/tutors

A Fag tool was developed integrating 2 software: BI Pentaho and Qlik Sense Cloud. Integrated into the Moodle LMS and this tool is responsible for generating analytic and consolidated reports that show a transversal view of all system's actors (students and teachers/tutors) and the interaction between these actors with the system. It is important to notice that this is the main contribution of the tool: provide a wide and transversional vision system's vision. Figure 5 shows the architecture of the FAG Tool.

From these reports, it is expected that:

- The teacher/tutor can act quickly and efficiently in his / her role of motivating and stimulating student participation;
- distance-learning environment and process managers improve the time in decision making regarding the faculty and can achieve better results in distance-learning.

4.1. Fag Tool Architecture

Figure 5 shows the architecture of the developed FAG tool. The data source used is MySQL, extracted from Moodle LMS, which represents the data layer. In this layer, it was necessary to move the useful data for the generation of reports and dashboards to an intermediate data repository called the data warehouse (DW), this process is called ETL (Extraction, transformation and load). Performed through the Pentaho BI tool and scheduled to run in the D-1 period, updating the DW always with the data from the previous day.

From DW, the software Pentaho BI and Qlik Sense Cloud were used to generate the analytical reports and dashboards presenting a holistic and transversal view of the participation of students and teachers/tutors LMS Moodle.

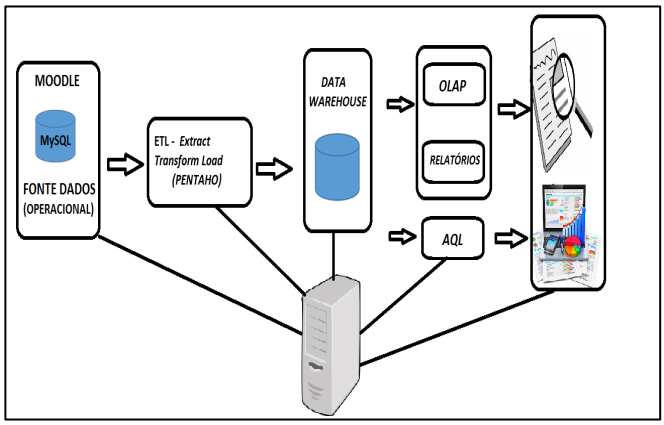

Figure 5. Fag tool architecture

4.2. Partial result

In this section, it will be presented some analytical reports generated by the tool, in addition to the dashboards, all with a holistic and transversal view. Figure 6 presents the percentage participation report of students linked to the courses of the selected teacher/tutor.

The system manager selects the desired teacher/tutor, the related courses are listed with the number of students enrolled, the number of active students and consider as active the students who accessed the course in the last 30 days and calculated and displayed the % of student participation in each course.

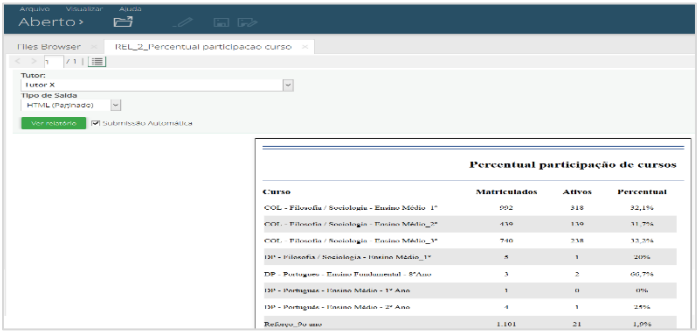

Figure 6. Percentage of student participation report

Figure 7 presents the report with the participation percentage of students in the weekly activities proposed by the teacher/tutor.

The teacher/tutor selects his / her name, the respective courses are listed, the number of students enrolled and the number of students who did not perform any of the weekly activities proposed and is calculated and displayed the percentage of effectiveness, that is, percentage of students who Carried out all the proposed weekly activities.

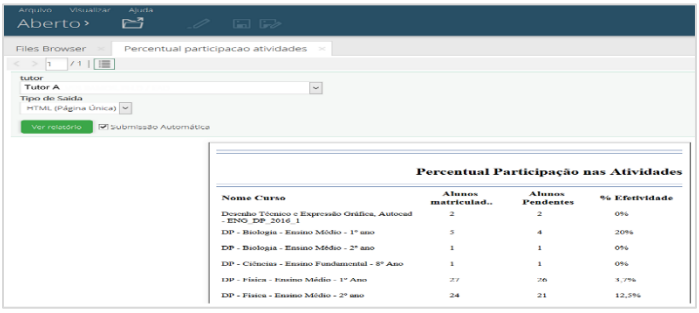

Figure 7.Percentage of participation in weekly activities

Figure 8 presents the report with the percentage of students who have, never attended the course.

The teacher/tutor selects his / her name, lists the respective courses linked to him/her with the number of students enrolled, the number of students who have never attended the course, it is calculated and displayed the percentage of students who never attended the course and in sequence Are listed name and email of students who have never attended the course, if the number of students they have never accessed is greater than zero.

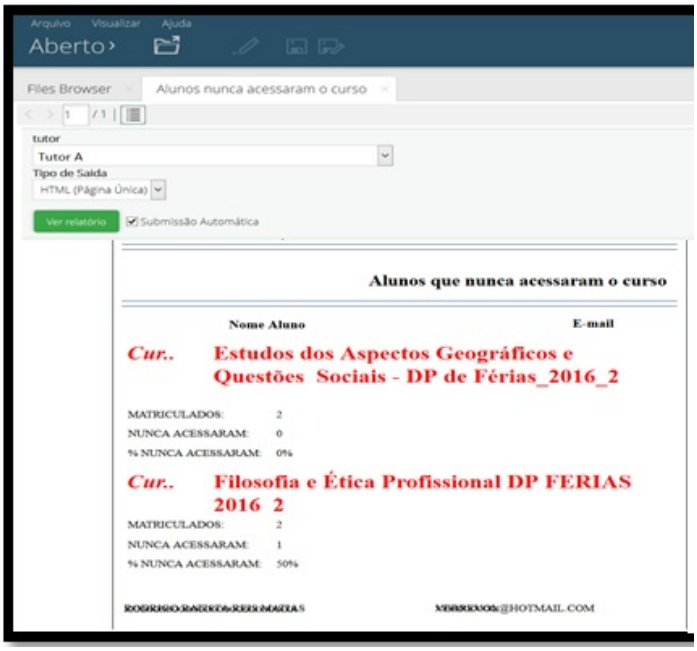

Figure 8.Percentage of students who have never attended the course

Figure 9 shows the report with the total time of access of the teacher/tutor.

The system manager selects the desired teacher / tutor and the month, the corresponding teacher / tutor courses are listed with the days of the week and the time in hours, minutes and seconds, which the teacher / tutor has connected to each course linked to his or her profile in that selected month.

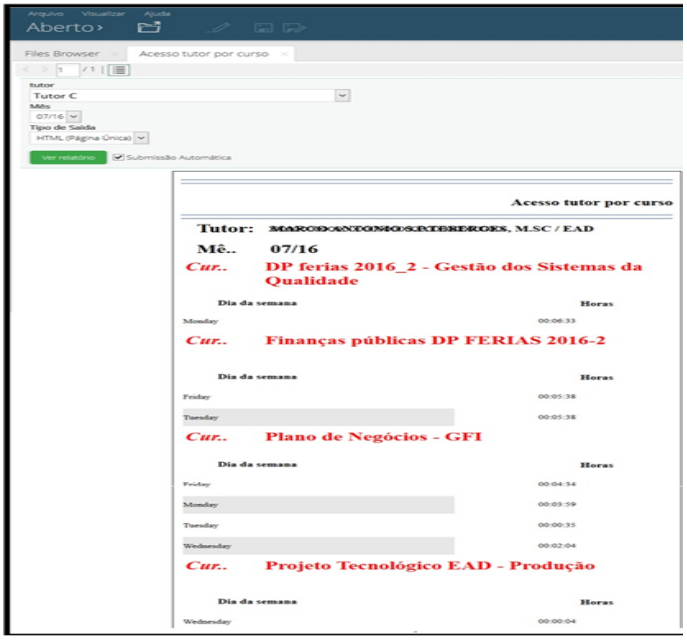

Figure 9.Total time of teacher/tutor access

Figure 10 presents to the system manager a dashboard with the total number of students enrolled in Moodle LMS (Qtd. Students), users in the role of teachers / tutors and the registered courses, as well as a graph that shows the students who have accessed the courses for teachers / tutors in the last 30 days.

Through queries that use AQL technology, a specific teacher/tutor can be selected and information automatically updated according to the courses linked to that teacher/tutor, according to Figure 11.

Through the Tutor dimension, the courses are related to the selected teacher/tutor (Tutor A), the number of students enrolled in the courses linked to it (144), and the graph with the number of students who have accessed the courses in the last 30 days and the list of names, e-mail and courses of the respective students.

In addition to the selection of the teacher/tutor, one can select a specific course linked to it, consequently, the information will be updated, as shown in Figure 12.

According to Figure 12, the vision for the COURSE dimension is presented and it can be observed that in the Course "COL - Filosofia / Sociologia – Ensino Médio_1_2016 " selected, of the teacher/tutor "Tutor B", 290 students are enrolled and of these students 246 attended the course in the last 30 days, therefore, they are considered active.

In addition to the selection of teacher/tutor and courses, the tool also allows verifying the accesses in the course linked to the teacher/tutor, through the selection of the access date (s), according to Figure 13.

This shows the number of students who have accessed the selected course linked to the teacher/tutor on that specific date (s), in addition to the students' names and emails. The result is also displayed in graphic form.

The Forums view illustrated in Figure 14 shows the percentage of students who accessed the Doubts and News Forums through the FORUMS dimension.

The view with the dimension QUESTIONS selected shows the percentage of students who accessed the Doubts Forums.

The vision with the NEWS and COURSE dimension selected presents the percentage of students who accessed the News Forum in the selected course.

The view News Forum with the dimension STUDENT selected presents the courses in which "Student A" is linked and the percentage of accesses in the News Forums in each course.

The view with the dimension QUESTIONS and COURSE selected presents the percentage of students who accessed the Doubts Forum in the selected course.

The Forums view with NEWS dimension selected shows the percentage of students who accessed the News Forums.

The view Forum of Doubts with the dimension STUDENTS selected presents the courses in which "Student A" is linked and the percentage of accesses in the Doubt Forums in each course.

The Tutor Management view presents the average time of access of the teachers/tutors to the courses in Moodle LMS.

The tool also presents the general average time of access of the teachers/tutors to the courses per day of the week or the general average time of access of the teachers/tutors to the courses when selecting the name of the tutor in the dimension TUTOR.

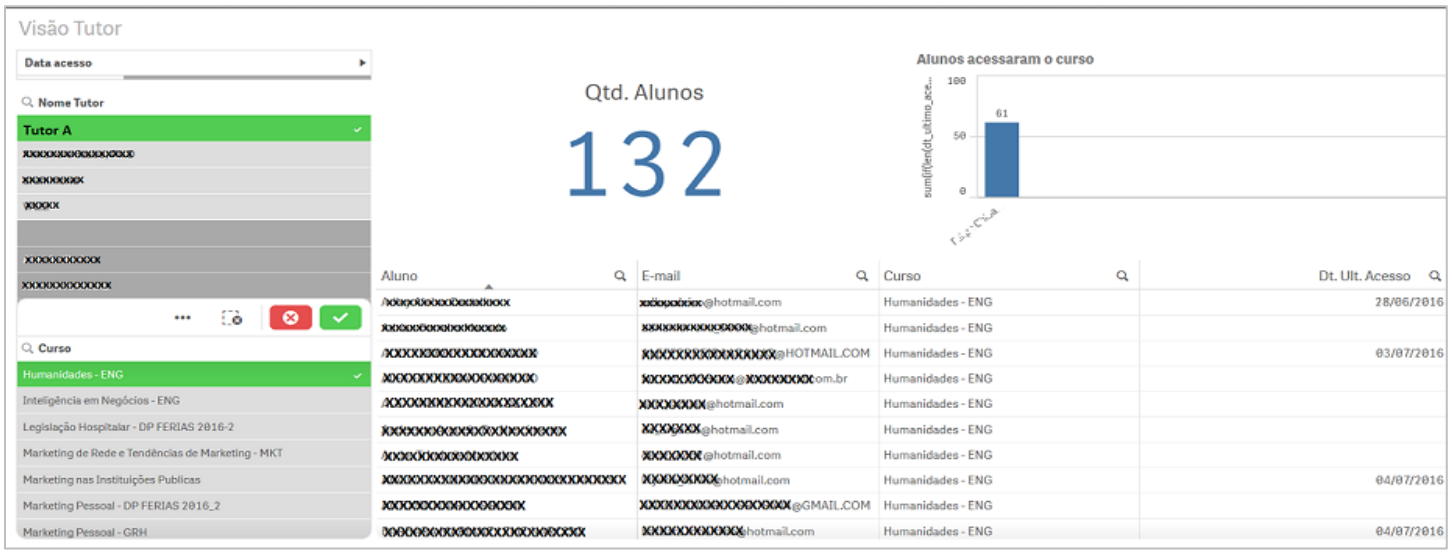

Figure 10. Vision of the participation of the students linked to the courses in Moodle LMS

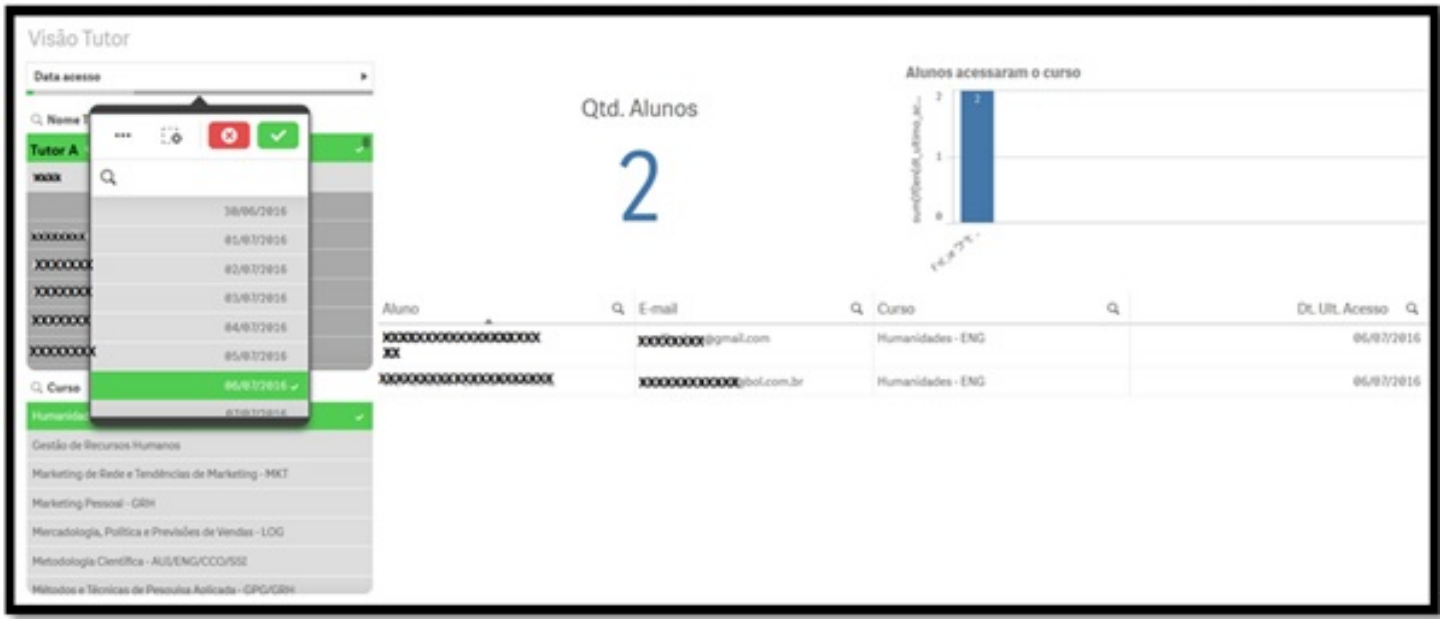

Figure 13.Participation of students in selection of a teacher/tutor, course linked to him and date (s) of access

Figure 14.View Forum Leaders

5. Conclusion

In this study was present some Moodle LMS's tools showing that they do not provide resources to the teacher/tutor to efficiently monitor the participation of the students and nor does it provide the tools necessary for educational process managers to monitor the actions of teachers/tutors in all activities that are involved.

The work also presents a tool - FAG that provides reports, through the use of BI techniques, to automatically generate analytical and consolidated views and necessary dashboards for both the teacher/ tutor in relation to student participation as well as the system manager in relation to the actions of the teachers/tutors, simultaneous in all the courses or rooms linked to them in Moodle LMS.

The FAG tool, integrated to Moodle LMS, provides information in a very simple and fast way, minimizing the time needed to obtain meaningful information and thus facilitating the interpretation work of the teachers/tutors, through the holistic and transversal view.

Using the FAG tool, teachers/tutors are able to verify the participation of the students in activities of the Questionnaire type, in Forums of doubts and news, as well as access to the courses. By using this information, it is possible to stimulate students participation, motivating them and reducing the level of avoidance and dropout.

The managers, through the reports offered by the FAG tool, are able to monitor the actions of teachers/tutors, identifying their participation in many activities like Forums of doubts, publication of activities, time of access to the courses and interaction with students.

The FAG Tool assists teachers/tutors in the follow-up of students' participation in the courses related to them and also supports the LMS's managers in the decision making in a timely and assertive way, improving the management process in LMSs systems.

6. Future Work

As future work, it is suggested to create plug-ins in Moodle LMS to be added to the LA resources offered by the platform. In addition, it is suggested the creation of a parametric measurable tool that will allow the generation of the visualizations in any LMS, through the creation of scripts that use parameters, thus to be able to feed the DW with the necessary information.

SEMMA

ABSTRACT

Among the most popular methodologies for development of data mining projects are CRISP-DM and SEMMA, This research paper explains the reason why it was decided to compare them from a specific case study. Therefore, this document describes in detail each phase, task and activity proposed by each methodology, applying it in the construction of a MODIS repository for studies of land use and cover change. In addition to the obvious differences between the methodologies, there were found other differences in the activities proposed by each model that are crucial in non-typical studies of data mining. At the same time, this research determines safely the advantages and disadvantages of each model for this type of case studies. When the MODIS product repository construction process was completed, it was found that the additional time used by CRISP-DM in the first phase was composed in the following phases, since the planning, definition of mining goals, and generation of contingency plans, allow developing the proposed phases without inconvenience. It was also demonstrated that CRISP-DM is presented as a true methodology in comparison with SEMMA, because it describes in detail each phase and task through its official documentation and concrete examples of its application.

1. Introduction

This paper is an extension of work originally presented in 11CCC IEEE 2016 [1].

Within the set of business intelligence technologies is data mining, which in itself is a phase of the KDD process, and is responsible for the data preparation and the interpretation of the results. Keeping in mind that KDD is a process that has a high level of complexity, it was necessary the use of methodologies that allow a systematic approach in the construction of data mining projects, today there are two methodologies for the information treatment that are avant-garde in their models. The SAS company suggests the use of SEMMA methodology, likewise in 1999, a large consortium of European companies, NCR (Denmark), AG (Germany), SPSS (England) and OHRA (Netherlands) joined forces to develop a free distribution methodology called CRISP-DM (Cross Industry Standard Process for Data Mining) [2]. Those methodologies structure the data mining project in phases that are interrelated, converting the process into iterative and interactive.

The CRISP-DM methodology structures the life cycle of a data mining project in six phases [3], which interacts with each other in an iterative way during development of the project as shown in Figure 1. The methodology in a general description is organized in phases, where each phase is structured in several generic tasks of second level, and these make a projection towards specific tasks that described the actions that should be developed [3]. E.g., if the second level has the generic task "data cleaning", the third level indicates the tasks that have to be developed for a specific case, such as "numerical data cleaning" or "categorical data cleaning". Finally, the fourth level includes a set of actions, decisions and results of the data mining project in question.

On the other hand, the SEMMA methodology takes its name from the different stages that lead the process of information exploitation, sample, explore, modify, model, and assess. The methodology is itself a cycle whose internal steps can be performed iteratively according to the needs. SEMMA provides an easy-to-understand process that allows the development and maintenance of information exploitation projects [4].

Both methodologies structurally have similarities, e.g., the specific task of data cleaning, however they differ in several aspects, like tasks, activities and phases, e.g., in CRISP-DM there

*Corresponding Author: Herman Jair Gómez Palacios, Department of System Engineering, Mariana University, 520002, Colombia
Email: hjgomez@umariana.edu.co

is a phase dedicated to problem understanding in terms of business, defining objectives, resources, roles, etc., for setting data mining goals, while SEMMA proposes to directly access the data to be analyzed, defining a sample and applying techniques of data mining without considering the business objectives. Therefore, this causes certain differences in the data mining process, and this document aims to identify them.

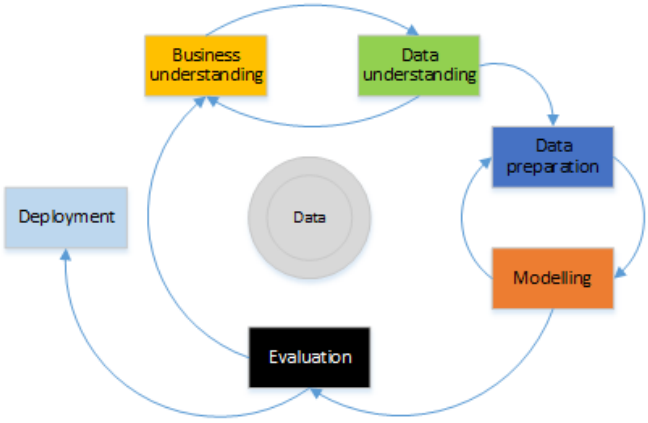

Figure 1: CRISP-DM methodology phases. Adaptation of: Chapman, P. [3].

The case study proposed for the comparison focuses on the construction of a MODIS repository for studies of land use and cover change. Considering that vegetation is a primary indicator of the state of an ecosystem because of its fundamental role in the water and carbon cycles [5], in addition, photosynthetic activity is a measure of the transformation of radiant energy into chemical energy, and any observable change in it may indicate alterations in the environment [5]. An agile and low-cost way to monitor large areas and analyze vegetation behavior is the use of vegetation indices obtained from remote sensors, e.g., from the MODIS sensor.

MODIS (MODerate resolution Imaging Spectroradiometer), which is one of the most important for the monitoring of the processes of change in the earth for its spatial and spectral characteristics. The MODIS sensor was designed by an interdisciplinary team of scientists with extensive experience in remote sensing. This team worked for about 10 years to finally define requirements for data collection, calibration and processing [6]. This sensor produces a total of 648 tiles, which about 290 are classified as soil and therefore produce vegetation indices [7]. However, a vegetation index can be defined as a parameter calculated from reflectance values at different wavelengths, and is particularly sensitive to vegetation cover [8]. According to the previous definition, the variation of the vegetation index over time allows to determine if a field in terms of coverage or biomass is better or worse according to its historical values.

This study was used the MOD13Q1 products generated by the sensor on board the TERRA satellite, and as an alternative was used the MYD13Q1 products from AQUA satellite. The NDVI (Normalized Difference Vegetation Index) was used as an index to estimate the quantity, quality and development of vegetation based on measurement, by means of remote radiation sensors of certain bands of the electromagnetic spectrum that vegetation emits or reflects [7]. The EVI (Enhanced Vegetation Index) also was used, which is considered to be the most robust vegetation index, because it is more robust compared to the contribution of soil and atmospheric influences [7].

From the files downloaded for the study area, the first three products were extracted (NDVI, EVI and VI Quality); the quality of the data present in the spectral bands will determine the quality of the studies of land use and cover change. The reason why it is necessary to carry out a cleaning process following the steps proposed by a recognized methodology of data mining, where the quality of the data before applying mining techniques is essential. Therefore, it was decided to make a comparison between the CRISP-DM and SEMMA methodologies to determine the most appropriate for non-typical data mining studies such as the one referred to in this research. Thus the process was developed with a high level of detail phases, tasks and activities of each methodology, and it was finally possible to obtain the best quality of the MODIS products that would be used in studies of land use and cover change.

2. Research background

Nowadays, some worldwide researches are based on the MODIS sensor, e.g., to temporal and spatial comparison of the frequency of heat sources as a fire indicator in Colombia in recent years [9], as well as in techniques of data mining, physical and statistical models, based on satellite remote sensing methods [10], also in remote sensing systems that allow exploring diverse fields such as agricultural, forestry, or to evaluate land use and cover change [11]. However, in the found referents, it was evident the insufficiency of researches in which to guarantee the highest quality of the data to be used, following a data mining model, and even less if it is included in studies of land use and cover change using MODIS products. On the other hand, although there are several comparative studies between different models of data mining, including CRISP-DM and SEMMA [12, 13, 14], it is not clear which to use for researches that obtain data from MODIS products.

3. Methodology

The area of analysis of this research includes the territory of the department of Nariño; therefore the MODIS products downloaded correspond to tile h10v08. The tiles are distributed within a Cartesian system, starting at the position (0, 0) corresponding to the upper left corner and ending at the position (35, 17), corresponding to lower right corner [6]. The coverage area of each tile is 10x10 deg. The rows are defined by the letter "v" and the columns by the letter "h", in this way is possible to make a suitable selection of the area of interest.

The MODIS products that work with vegetation indices are those corresponding to the MOD13 and MYD13 series, from which were selected those that provide a spatial resolution of 250 meters and a temporal frequency of 16 days, to finally obtain 355 MOD13Q1 products from the years of 2000 to 2015. For the identification of MODIS products with excellent quality for studies of land use and cover change, CRISP-DM and SEMMA data mining methodologies were applied faithfully following each phase, task and activity suggested.

With respect to the download, reprojection, transformation, cleaning and storage of MODIS products, some “scripts” were used in all cases to optimize the process, among them ModisDownload [15]. The scripts were created for the statistical program R, which is free (GNU) and through the RGDAL and Raster libraries can directly process the HDF files. The scripts

make use of the MRT reprojection tool, which were granted free of charge by NASA, this tool allows the download, reprojection, conversion and integration of MODIS products [16], in addition to extracting the layers from each of them.

4. Result

The detailed process of the application of the mining methodologies presented in the previous sections is described below, and the similarities and differences between both models, are presented in a parallel, spotlighting the key elements of phases and previous tasks.

4.1. Phase 1

The development of this first phase in CRISP-DM is known as "Business Understanding" [3], which allows obtaining a greater level of understanding of the case study, this being a key component to construct the MODIS repository for studies of land use and cover change, because it is possible to plan a project and define clear and concrete data mining goals.

Task 1: denominated by CRISP-DM as "Determining business objectives" [3], in this general task the methodology suggests knowing what the client wants to obtain, thus giving the analyst a business perspective. In this first task the objectives were defined, based on the context, area of the problem and current solution, therefore the objective was: to classify regions in the department of Nariño in agricultural, forest and livestock, as defined by the IGAC [17]. Task 2: the methodology defines it as "Assess situation" [3], which is done by taking into account the inventory of resources (hardware, knowledge and data), identification of requirements, assumptions, constraints, risks and contingency plans, as well as including the costs and benefits of the study. For this research, it was identified among other elements: the different alternatives for the acquisition of MODIS products, among which standout 1) Reverb, online tool for the discovery of scientific data of the earth; 2) USGS Global Visualization Viewer which is a tool for searching and downloading satellite data 3) LP DAAC Data Pool, which allows direct access to MODIS products. In addition to these free tools provided by NASA, there are payment tools and scripts developed by experts with free access, the latter being the best alternative for the project. Task 3: CRISP-DM defines it as "Determine data mining goals" [3], in the specific tasks the data mining objectives and the evaluation criteria of the model are determined, which for the case study were respectively: identification of types of regions in Nariño, according to kind of vegetation found and the evaluation of the accuracy of the model compared with real data provided by IGAC - Nariño. Task 4: is known as "Produce project plan" [3], and is the last general task proposed by CRISP-DM for the first phase, in the specific tasks, the project plan was constructed through a table in which it stands out for each phase: time, resources, risks and contingency plans that are required for the successful project implementation, and to create the table, all the information obtained in previous tasks was required. Therefore the planning of the phases necessary to construct the repository of MODIS products can be visualized in the Table 1.

On the other hand, SEMMA in its first phase "Sample" [4], proposes to extract a sample of the total data, in this way allowed to make a previous analysis of the problem of mining. For the case study it was obtained that:

For data access, it was defined for this study that it would work with the MOD13 algorithm, specifically with the MOD13Q1 products, because in addition to be suitable for studies of land use and cover change, they do not produce pixels on oceans or soil under water. The study population was 355 HDF files and 1065 products of interest; B) to establish a small sample, 10 percent of the total population was chosen, therefore the sample size was 107 products; C) to form the sample was chosen a simple random method, obtaining 28 NDVI, 53 EVI and 26 VI Quality layers. For the extraction of the first three layers (NDVI, EVI and VI Quality) of interest in the case study, the MRT tool was used, as well an R script that optimizes the process.

Table 1: Project planning

Phase	Resources	Risks	Contingency plans
Business understanding	Documentation about MOD13Q1 product. Documentation about vegetation indices. Documents of IGAC from Nariño. Visualization tool: Quantum GIS	Limited information in Spanish about these topics.	English and Portuguese documentation
Data understanding	Website with products for soil studies as LP DAAC Scripts to download, reprojection and conversion of MODIS products. Tool to reproject and convert MODIS products (MRT). Environment and R programming language to execute the scripts.	Bugs or limitations in the scripts.	Manual FTP downloading.
Data preparation	NDVI, EVI and VI Quality products. Environment and R programming language to execute the scripts. PostgreSQL - PostGIS to store the layers. Programming language: Python	MODIS products that cannot be used.	Downloading MODIS products from AQUA satellite.

At the end of the phase, it is concluded that CRISP-DM benefits the achievement of results because it allows for fully understanding of the problem in terms of the business and its equivalent in terms of data mining, even proposes to make a detailed plan that guarantees the success in the process.

4.2. Phase 2

In CRISP-DM the second phase is known as "Data Understanding" [3]. In this phase the methodology proposes data selection criteria, obtains and explores them, in a way that identifies the elements that determine their level of quality.

Task 1: denominated by CRISP-DM as "Collect initial data" [3], where the following criteria were defined: 1) Products of the MOD13 series with a resolution of 250 meters. 2) The study region should contain the area of Nariño (available in the h10v08 tile). 3) Download available products between February 2000 and June

2015 (for a total of 373 files in HDF format). For the download of MODIS products it is necessary to keep in mind parameters of the script to select a specific date, or a range of time; The coordinates to specify the tile to be downloaded, or several tiles when joining several coordinates; The script named "ModisDownload" of free access, originally created by Naimi [15], later adapted and improved by the community, uses the GDAL library, which allows reading and writing raster data compatible with spatial references, also the reading of vector data and HDF extension files belonging to the MODIS products. The MRT reprojection tool is free and developed by NASA [16]; this tool allows the download, reprojection, conversion and integration of MODIS products, in addition to the extraction of the layers of each product. The HDF files were obtained from the website: land data products and services LP DAAC [16]. The execution of the script was done per year and the time required to download the products of a particular year was 161 minutes. The total time for the download of all MODIS products was 2310 minutes. Adding the download time of AQUA sensor products would add 126 minutes. Task 2: known in the methodology as "Describe data" [3], for the case study was determined the description of the type and range of values of the attributes and the volume of the data (1119 files in TIF format and reprojected to the coordinate system accepted in Colombia. The files correspond to first three layers of the MOD13Q1 products). Task 3: named by CRISP-DM as "Explore data" [3], focused on the VI Quality product, which allows the determination of the quality of the data processed per pixel in the layers, using parameters such as the usability of the pixel, amount of aerosol, detection of adjacent clouds, atmospheric correction, among others. Task 4: defined as "Verify data quality" [3], it was decided to work with the first VI Quality layer parameter, identifying special values and cataloging its meaning (Table 2).

Table 2: Description of the VI Quality parameter used

Bits	Parameter Name	Value	Description
0-1	VI Quality	00	VI produced with good quality.
		01	VI produced, but checks other QA.
		10	Pixel produced, but most probably cloudy.
		11	Pixel not produced due to other reasons than clouds.

The "Explore" phase [4] of SEMMA was developed with an exploration of the sample data, allowing complement the initial understanding of the problem, later the process was restarted and applying for all the data, thus sufficient inputs were available for the next phase. For the case study, the MODIS products of interest were the first three: NDVI, EVI and VI Quality. For the NDVI and EVI layers the valid range of values is -2000 to 10000 and its scale factor is 0.0001, which means that the values of 10,000 in a raster should be multiplied by 0.0001 in order to achieve the current value. As for the data quality criteria, the first four attributes of the first parameter of the Quality VI layer were chosen as indicated in Table 2.

The first phase of CRISP-DM is very important because it offers clarity on the problem to be solved and how to do it, whereas SEMMA does it, but in a very superficial way depending on several later phases of this, nevertheless SEMMA has as advantage that work with a smaller amount of data (however this first phase is optional). Regarding the data selection and evaluation criteria, the CRISP-DM methodology proposes to define them in the third task of the first phase, however, each of them had to be reviewed and improved in several of the following tasks in the same phase. Through the criteria it was possible to optimize the process of data selection and the cleaning of data. In SEMMA the definition of selection criteria was quite questionable at the beginning, and each criterion had to be improved and corrected in the course of the tasks and even in the following phases.

4.3. Phase 3

This phase is known as "Data Preparation" [3] in CRISP-DM, it is composed of four general tasks and the same number of specific tasks.

Task 1: named by CRISP-DM as "Select data" [3], allows determining which data will be included for the study and the criteria to exclude the data with low quality. For SEMMA, this task is called "Transformation and selection of data" [4] and consists, as in CRISP-DM, of identifying the data to be used in the next task, however SEMMA did not consider the inclusion of MYD13Q1 products, thus obtaining 1065 files, unlike the 1119 obtained by CRISP-DM, despite this, the development of the task was similar in the two methodologies and described below.

For each downloaded MOD13Q1 product the first three layers (NDVI, EVI and VI Quality) were extracted, by means of the adaptation of the script developed by Golicher [18], to transform the image to the TIF format and at the same time reproject it to the coordinate system accepted in Colombia, obtaining a total of 1119 new files. The VI Quality product allows determining the quality of the data processed per pixel, identifying which data has an excellent quality, an intermediate quality, a low quality and which cannot definitively be used [7]. For the case study it defined the first 4 bits of the VI Quality layer described above in Table 2, determining that the total of non-usable pixels will be the result of the sum of the probably clouded pixels and the pixels not produced, Therefore, if this value exceeds 30% of the pixels in the image, it should be discarded [19].

In order to determine the quality of each image for the NDVI and EVI products, the calculation was performed by adapting the script developed by Lydholm [20] for the statistical program R. The process was performed by each VI Quality layer, determining the number of non-usable pixels in the study region and keeping in mind an analysis is not possible if the amount of unusable data exceeds 30% [19].

In the script, the necessary libraries were loaded to use methods to create raster images and functions to handle HDF files. The next step was to set the directory in which the TIFF files corresponding to the Quality VI layer are located. After extracting the addresses of each of the files in the list, it was proceeding to work each of them in an iterative structure to determine if the quality of the associated layers has a value greater than 70%. Finally, the directory was set to store the images under the accepted quality value.

In the script was also defined an iterative structure which used the list of addresses of the files with the VI Quality layer obtained in the previous steps, for each VI layer, a raster file was generated and stored in memory, then, a function was defined that It will take the first bits inside the raster, transform them to integers and reverse them. Then, the previous function was used in each raster, thus obtaining the total amount of pixels with a high, medium and low quality. These are pixels with such a high amount of clouds that they cannot be used, and pixels not produced or not usable for other reasons. On the other hand this also determines the amount

of pixels corresponding to land, ocean, land under shallow water (rivers) and land under moderately deep water (lakes).

Once the parameters for each raster previously defined in Table 2 were obtained, it was extracted, transformed to a percentage and adds the values corresponding to cloudy and non-produced pixels. Then a logical expression was used to determine if the previous sum is greater than 30, if it is true, a text file was generated with the date of the VI Quality layer analyzed as its name, and inside it stored the quantity of pixels of high quality, average quality, pixels probably cloudy and unprocessed. Likewise in the following line its equivalent in percentage, the sum of the last two values and finally the exact name of the file containing the VI Quality layer. This text file allows the investigator to know in detail why that particular image was discarded by the script. After this, a PNG image (Figure 2) was generated with the analyzed raster and stored in the specified destination at the beginning of the code.

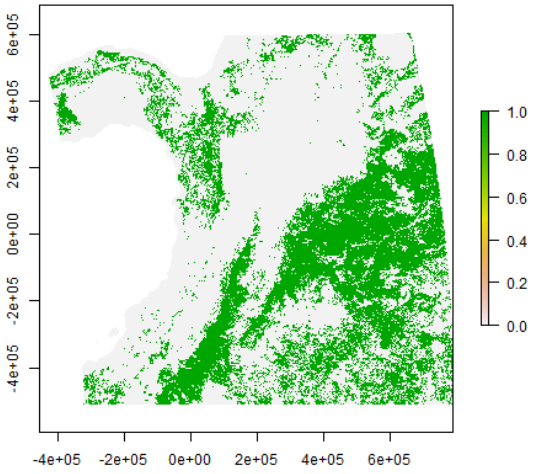

Figure 2: Image generated by the R script of the VI Quality layer on June 10, 2015.

However, due to the size of the MODIS tile and considering that the study region was smaller than the size of the image, it was decided to re-evaluate the images discarded by the script, therefore it was constructed in such a way that it generates a report with the images that did not exceed the minimum of non-usable pixels, besides an image in PNG format with the date of the VI Quality layer analyzed, in which represented in a green color are the clouds present in the region, and a text file with the quality values. Delegating responsibility to the researcher to decide which were still valid and which should definitely be withdrawn from the study.

Sometimes the script discarded the two images obtained in the same month, leaving several months in a year without data to analyze, for this reason the MODIS products generated by the sensor in AQUA satellite were downloaded and used for those special months. This situation had already been foreseen in the first phase of the CRISP-DM methodology, so that a contingency plan was included in the overall planning of the data mining project and it was carried out in this phase.

B) Task 2: named by CRISP-DM and by SEMMA as "Clean data" [3, 4], this task classified the MOD13Q1 products with the sufficient quality to perform studies of land use and cover change, and the products to be discarded. In contrast to SEMMA, in the CRISP-DM methodology, the MYD13Q1 products were established as a contingency plan in view of the risk of running out of products in a particular month. In the following section, the task is presented considering the contingency plan.

Keeping in mind the selection criteria, (percentage of usable pixels, spatial and temporal resolution, and MODIS product type) it was obtained: 746 images, which were valid images only 534 therefore the quantity of discarded images was 212. The time required for this process was 2804 minutes, being the process that required most time during the entire investigation. By year the time used was about 179 minutes; in addition the time for the 18 images of the satellite AQUA was about 147 minutes.

Table 3 and Table 4 present the data cleaning report for two years in particular, highlighting in gray the images that despite reporting a higher percentage of unusable pixels to be accepted can be used in the study region. Also highlighted in orange are the months in which all images were excluded, thus the MYD13Q1 products were downloaded and analyze the result of the process can be seen in Table 5 and in Table 6.

Task 3: named by CRISP-DM as "Construct data" [3], after completing this task, the structure of the tables that store the data resulting from the previous task were obtained. For SEMMA, this task is called "Construction of the repository" [4] and actually covers in its development in the fourth task of CRISP-DM, because it not only identifies the structure of the repository, it also builds it. In CRISP-DM that process is divided into two tasks, therefore the description of the third task of SEMMA corresponds to two sections dedicated to third and fourth task of CRISP-DM.

PostGIS was used for the construction of the repository, because is a spatial extension of PostgreSQL, that in addition to be a spatial database compatible with "OpenGIS Simple Features for SQL" [21], it allows us to manage spatial objects (roads, rivers, forests, etc.) as objects of the database, allowing to calculate relationships between objects that are very difficult to model without using spatial objects [21], such as proximity, adjacency, containment, among others. The database was created in PostgreSQL, however a PostGIS extension must be added to the DBMS so that it recognizes, e.g., raster type attributes.

Table 4: Data cleaning process MOD13Q1 between 2014 and 2015 (Part 2)

Item	Pixel produced, but most probably cloudy		Pixel not produced due to other reasons than clouds		No usable pixels (%)	Exclude
	Quantity	(%)	Quantity	(%)

Considering that database will be filled with identical information, it was inappropriate to create a single table that contains them; the best way to handle large amounts of data is by partitioning tables. In order to perform the partitioning of tables, a parent table must be created, which will later inherit the characteristics of the child tables [22]. For the case study corresponds to one table per year and vegetation index.

Task 4: named by CRISP-DM as "Integrate data" [3], this task allows the combination of data resulting from previous tasks. For the case study it was necessary to use the structures defined in the repository construction as described below.

To create the database, a script was developed based on Golicher's approach [18], the Python-built script for this work allowed defining one table per year, inheriting the characteristics of the main table, and allowing the entry of a layer in TIF format for each table depending on the year in which it was obtained. At the end of the process, 15 tables were obtained from the NDVI vegetation index and another 15 tables from the EVI vegetation index. Finally, a total of 32 tables were obtained, each with an average number of records of 1517.

In the script used, the corresponding libraries to handle SQL statements and file handling were loaded. Later, it selected the folder in which the files for the NDVI or EVI vegetation index were stored, then a list was extracted with all the files and was classified according to the year of each layer, finally, an iterative expression was built which runs the data by each year, beginning in the year 2000 and ending in the year 2015. In the iterative structure a new table was created with the name of the vegetation index and the respective year, a restriction of dates in such a way as prevent entering different values than the selected year. The other attributes are inherited from the main table, finally, it was proceeded to define another cycle that will be responsible for filling each record of the table with the corresponding indices (usually two for each month). In the next iterative expression, each product NDVI or EVI was evaluated, creating a temporary table with the raster of each one, for this the command program "raster2pgsql" offered by PostgreSQL was used, including the parameters and access data for the required database. Then, a new attribute of date type was added to the temporary table to insert the exact date of the MODIS product. Data of the temporary table was transferred to the table defined in the previous cycle. Finally, if it leaves the iterative structure, it means that for that particular year, all the corresponding layers have already been registered; therefore an index can be defined per year.

5. Conclusion

The data cleaning process for MODIS products in studies of land use and cover change using the CRISP-DM methodology, was easier than SEMMA, mainly because CRISP-DM is presented as a true methodology of data mining with detailed phases, tasks and activities. Also, it has documentation produced by typical case studies which the methodology was applied; guaranteeing that CRISP-DM methodology for the cleaning of the MODIS products would work without any problems. Another important point in the success of the application of CRISP-DM was the preliminary tasks that clearly defined the process, including predictions about possible problems in the data cleaning stage.

It should also be noted that the use of R scripts helped and optimized the process of cleaning, downloading and reprojection of MODIS products, because the time invested in each phase of the methodology was smaller than the one invested on the traditional way. It can also be concluded that managing a high level for understanding the problem was a key to build the MODIS repository for studies of land use and cover change, because it defined a clear and concrete mining goals, where the CRISP-DM methodology dedicates an entire phase to transform the problem in terms of data mining.

On the other hand, SEMMA is designed to work with the SAS® Enterprise Miner™ tool, and all available documentation focuses on this tool, therefore, when working with non-typical mining cases as the case study presented in this article, the amount of SEMMA disadvantages increase, demonstrating that SEMMA is not suitable for applying in a similar studies as presented in this manuscript. In contrast, CRISP-DM methodology is recommended when attempting to perform a data mining project, because it has all the available documentation, detailed phases, tasks and activities, and the development of the first phase, that facilitate the problem understanding and its transforming to a data mining problem. It is a better approach if the knowledge of the

problem in terms of business is insufficient and if the problem does not fit within the typical cases solved with mining techniques.

For future work, it is recommended to use all available MODIS products obtained from the sensor in the TERRA satellite and from the sensor in AQUA satellite. Both satellites combined generate four images every month, however, according to the results it was common that in the months with worse weather in Colombia, sometimes all the images were discarded by excessive cloudiness for those months.

It is also worth noting that the time for the data cleaning process was quite long, mainly due to the physical characteristics of the computer used, then, the best way to optimize the process would be through a computational cluster of high performance, improving computing capacity and it would significantly reduce the total time invested at the end of the data cleaning process, and in general of the whole study. In the same way, it is suggested to optimize the scripts used in the research, making them more efficient, allowing to analyze all the required years in a single execution, and to facilitate the inclusion of different phases in sequence and in parallel. Finally, a suitable graphical interface for scripts would be very helpful for researchers who need them, facilitating their use and improving their "usability".

Conflict of Interest

The authors declare no conflict of interest.

Acknowledgment

The authors wish to express their gratitude to department of systems engineering and to department of environmental engineering of Mariana University, also to all the individuals who have been sources of help throughout the research period.

ABSTRACT

One of the most important roles of the wireless sensor networks (WSN) is to avoid wiring costs, be self-sustainable and be able to function for several years. However, due to the slow progress in battery technology, power continues to be a limited resource in wireless sensor communication and electric energy storage remains to be an important issue. On the other hand, if batteries must be replaced often, many remote sensing applications may become impractical. Therefore, batteries with long life on the order of several years are needed. This paper is an extension of work originally presented in The 5th International Conference on Electronic Devices, Systems and Applications to investigate further the power requirements for wireless data transfer between two nodes using batteries with different capacities (55 mAh, 550 mAh and 5500 mAh). In particular, the effect of a propagation medium such as air, distilled water and engine oil on the wireless communication inside a one meter long metallic pipe was investigated. Our first result shows a successful transmission of wireless signal through air, distilled water and oil medium with very low transmission losses. The second result shows that an increase in the battery capacity will increase the two-node wireless sensor operation time even in different propagation medium. This result can be used to determine the required battery capacity for extending the WSN operation time.

1. Introduction

Pipelines in oil and gas industries constitute generally the most economical way to transport large quantities of oil, refined oil products or natural gas. The management of oil and gas transport in a pipeline is a challenging task with the rapid growth of the required length of pipelines. Challenges such as oil and gas leaks, pipeline corrosion, wax precipitation and environmental pollution are treated with highest priority in oil industries. Hence, the most common and important applications of WSN in oil industry are related to real-time monitoring of the production performance through process control, safety, and rigorous maintenance operations [1, 2].

Because of its crucial importance, the continuous operation of a WSN is essential and must be maintained at all time. The lifetime of a WSN can be defined as the life of the shortest living node in the network. However, depending on the application, the density of the network, and the possibilities of the network reconfiguration, it can also be defined as the life of some other (main or critical) nodes [2]. In order to prolong a WSN life, it is required to reduce the energy consumption of the nodes as much as possible [3].

However, for many important WSN applications, such energy option is not feasible, and specific power-management strategies are necessary for WSN nodes that are powered by non-rechargeable batteries. Energy consumption still remains one of the main obstacles to the development of WSN technology, especially in cases where long and reliable network operation is required [3].

In most cases once the WSN has been deployed, it is impossible to replace each and every battery present in the network after discharge. One important challenge in the design of a large WSN is energy efficiency where the design of a WSN should extend its life without sacrificing its reliability [4].

*Corresponding author: Abdellatif Bouchalkha, Physics Department, Khalifa University of Science and Technology, P.O. Box 127788, Abu Dhabi, United Arab Emirates | E-mail: abouchalkha@pi.ac.ae

To reduce the overall energy consumption of the network, one should use some power management (PM) techniques at the level of the sensing, communication, or processing unit. Another option is to consider using some energy harvesting techniques to extend the WSN operation time [5].

The main goal of this paper is to study the power consumption of a two-node wireless sensor communication for batteries with different capacities. Two experiments were considered for this study. The first one was the free space wireless communication in open air without metallic pipe and the second one was the wireless communication inside a metallic oil pipe acting as a waveguide. The measurement results showed that the data can be transmitted successfully through air inside a pipe with very low transmission loss. It was also shown that an increase in the battery capacity increases the two-node wireless sensor operation time. This result can be used to determine the required battery capacity for extending the wireless sensor system life time.

2. Linear Network

The architecture and proposed work for a general WSN may not be suitable for linear WSN applications such as monitoring pipelines. This requires a good review and a thorough study of the applications needing linear WSN to determine the specific design requirements for it.

There are several advantages for using linear alignment of nodes to provide protection and monitoring of linear topology such as oil, water, and gas pipelines. Some of these advantages include faster and less costly network deployment in addition to the ability to introduce flexible multi-hop routing which can overcome intermediate node failures.

In a linear distributed detection system, an initial sensor starts the detection process and make decisions then transmit both the data and the decisions to its neighbor as shown in Figure 1. Based on the received decisions from their predecessors, the succeeding sensors again form decisions and transmit them together with the data until the final sensor or gateway node is reached [6].

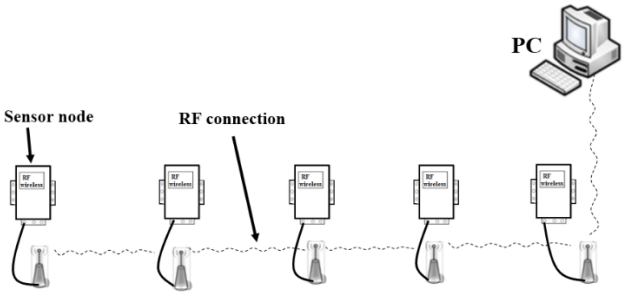

Figure 1.Linear structure of wireless sensor network.

Since the pipeline network extends generally along a line, it is important for the network to be continuously connected to collect and transfer information from the sensor nodes distributed over the pipeline to the control station. It will also be required to transfer control commands to the actor and sensor nodes, which are often located inside the pipeline. The sensor network architectures generally used for reliable communication in pipeline systems are based on wired networks, wireless networks, or a combination of both. Typical applications [7, 8], include the case of sensors embedded in the outer surface of a pipeline. This linear sensor arrangement is the result of their linear topology.

Linear WSN is a special category of WSN where the nodes are placed in a linear form. Kevin et al., [9] gave two different definitions for the network topology model of a linear WSN. The first definition describes it as a connected non-cyclic diagram where each node has exactly one or two distinct neighbors. The two nodes with only one neighbor are referred to as the endpoints of the network. While the second definition presents it as a linear network topology containing N nodes where each node can communicate with other nodes up to a number M of hops [10, 11].

Lin et al., [12] have proposed an application of linear network in power transmission lines. In this case, they used a clustering algorithm to balance energy consumption and leverage hybrid media access control for monitoring the power transmission lines. This proposed technique makes the system complex to implement and less responsive. Akbar et al. [13], in their contribution to linear WSNs, proposed another technique. This consists of mobile sinks, and courier nodes that work underwater in a 3-D linear formation which minimizes energy consumption as well as accurately computing required routing information. Such 3-D linear system is, though accurate in routing, yet also too complex for real-time sensing and monitoring. This is especially the case for the implementation in mission critical applications such as pipeline monitoring.

Linear WSNs may be simplistic in topology but the decision of routing and deployment of nodes to conserve resources is not as simple as it may seem to be. A detailed hierarchical and topological classification and implementation of linear sensor networks is provided by Jawhar et al., and Liu et al., [14, 15]. In both cases it is difficult to implement in pipeline monitoring due to the surrounding harsh environment. Therefore, certain design requirements and research issues need to be addressed and investigated, given that few research papers have discussed the special requirements for linear WSN. These requirements have strong impact on the network performance.

On the other hand, extending the network lifetime is still a critical issue in many WSN cases. Different research groups have discussed this issue [16, 17], from the point of view of network power management software and protocol but not in terms of extending battery lifetime.

In this paper, we investigate the wireless transmission between two consecutive nodes to address the issues related to wireless communication in a linear WSN for long pipelines. The results of this work are very useful and can be extended to a multi-node linear system in the future.

3. Battery life

The two most important properties of a battery are its voltage level and its capacity (expressed in Ampere-hour, Ah) which represents the amount of energy stored in a battery. For an ideal battery, the voltage stays constant over time until the moment when it is completely discharged. Ideally, the battery's capacity remains the same for any load. However, in a real situation, the voltage of a battery drops during the discharging phase and the

effective capacity of a real battery is lower under a higher load. In this case, the high current draw decreases the battery capacity in a nonlinear behavior. In the case of an ideal battery, it would be easier to calculate the battery life L in the case of a constant load as follows [18, 19].

$$L = \frac{C}{I} \quad (1)$$

Where C is the battery capacity and I is the load current.

The above simple relation does not hold for predicting the life of a real battery due to the various nonlinear effects neglected. A better and still simple approximation for the battery life calculation under constant load can be obtained from Peukert's law. The later gives an expression for the capacity of a battery in terms of the rate of discharging. As a result, when the rate of discharging increases, the battery's available capacity decreases. The formula for Peukert's law can be expressed in different forms with the most common one used is shown below [19, 20]:

$$L = H\left(\frac{C}{IH}\right)^{k} \quad (2)$$

Where;

L – The time, in hours, that the battery will last for a given rate of discharge.

H – The discharge time in hours.

C – The battery capacity in Amp-hours based on a specified discharge time.

I – Current in Amp.

k – Peukert exponent parameter which is a unique number for each battery.

4. Experimental setup

4.1. Wireless communication experiment

The wireless transmission experimental setup is shown in Figure 2. This setup consists of two wireless communication nodes using a fixed digital data set provided by an analog input voltage. The two nodes are standard ZigBee terminals powered by a lithium battery and communicating in the frequency range 2.4-2.5 GHz. The digital data is transmitted by the transmitter terminal and received by the receiver terminal which is interfaced to a PC through a National Instrument NI-ELVIS DAQ. An IP Modem Configure-F8114 and the SScom32E software were used for collecting data on the computer. The principle of operation is that the PC sends a command to the wireless ZigBee terminal F8114 connected through RS232 to a PC to communicate with wireless terminal F8914 and read its digital output data. The communication was established via simple dipole antennas to ensure unidirectional transmission between the two terminals. These directional antennas help reduce the effects of interference as well as extend the communication range between the two terminals. The dipole antennas have an impedance of 50 Ω, a gain of 3 dB and a length of 125 mm. The data is then processed by the PC which is connected as shown in Figure 2.

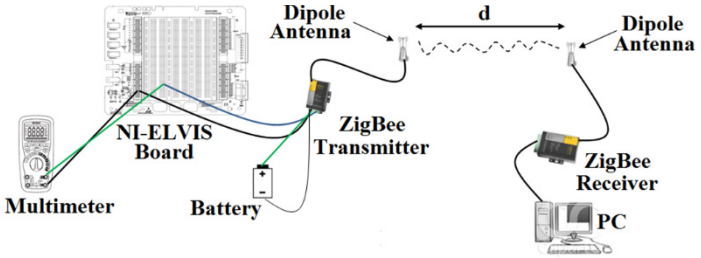

Figure 2. Wireless communication setup

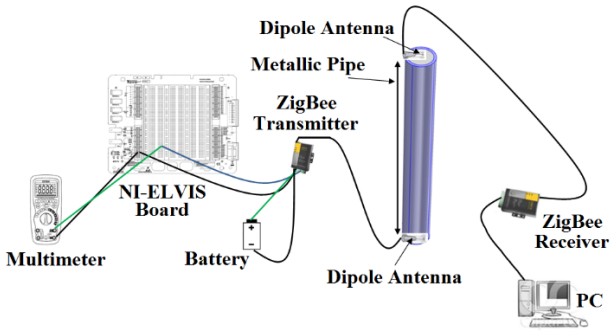
The transmitter/receiver terminal uses the standard ZigBee communication protocol which is based on offset quadrature phase shift keying to transmit digital data [21]. The acquired data was in hexadecimal (HEX) format which was then converted to decimal (DEC) format. The corresponding value was then calculated, as described in the manual of the F8914 ZigBee Terminal.

For the study of the effect of a different medium on the wireless communication, we used a one meter long hollow metallic pipe made of iron as shown in Figures (3a) and (3b). We have also used the pipe as a waveguide for transmitting and receiving data wirelessly between the two dipole antennas driven by the two ZigBee terminals. The diameter and the thickness of the pipe were respectively 0.1 m and 0.003 m. The metallic pipe was placed between the two antennas and filled, alternatively, with distilled water or engine oil. The initially analog voltage data was transformed to ZigBee format and sent through these different mediums. The received values for air, distilled water, and oil mediums were recorded and compared to the transmitted values as will be shown later in Figure 5. The temperature was also kept constant at approximately 21±0.5 °C throughout the experiment.



(a)

(b)

Figure 3. Experimental setup for wireless communication in a mettalic pipe as a diagram (a) and the actual laboratory setup (b).

4.2. Wireless node power requirement experiment

A common way of specifying the energy capacity of the wireless sensor is to provide the battery capacity as a function of elapsed time until it is fully discharged. The experimental setup used in this part is shown in Figure 4.

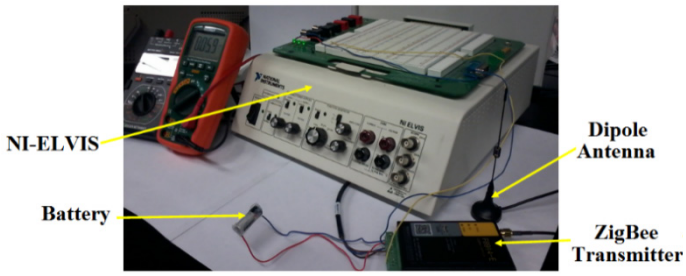


Figure 4. The battery voltage measurement setup.

In this case, we maintained a good communication between the transmitter and receiver terminals but measured the load voltage of the battery connected to the transmitter as a function of the elapsed time. Three different batteries with different nominal capacities (*55 mAh, 550 mAh and 5500 mAh*) were used in our experiment. The power level of the transceivers was kept constant at 2.82 mW and the distance between the transmitter and receiver was fixed to either 1 m or 9 m.

The analog voltage value was converted to digital value first then transmitted wirelessly. The transmission was done continuously and after each transmission the battery voltage was recorded. The battery voltage level measurements were conducted at regular time intervals at the transmitter side. The communication between the emitter and the receiver was maintained and checked before each measurement to make sure it is successful.

5. Results and discussions

5.1. Two-nodes communication in different mediums

The results from the wireless communication experiment described earlier are shown in Figure 5. This experiment was conducted to establish wireless communication and compare the transmitted and received data between the two ZigBee terminals. From the figure it can be clearly seen that the voltage data was successfully transmitted through the three different mediums namely air, distilled water and engine oil with very low relative transmission losses. It can also be seen from Figure 5 that the wireless transmission is independent of the medium inside the pipe and the digital data was well received as expected and confirmed. This is a good confirmation that digital data transmission has experienced practically no losses even through a wide range of different propagation mediums such as air, distilled water and engine oil.

In oil wells, we are always monitoring the temperature and the pressure downhole as the most critical parameters. In general, the temperature is high and can easily reach 150 °C. In order to validate the above results, we have adjusted the previous experimental setup to transmit and receive real measured temperature data. The experimental setup used is shown in Figure 6 with wireless transmission through the 1 meter metallic pipe. In this case we have replaced the constant voltage value by a temperature sensor immerged in a variable temperature water bath. The temperature sensor used is a type K thermocouple (Chromel/Alumel) with a temperature range of -30 °C to 300 °C and an output voltage range of -6.4 mV to 54.9 mV.

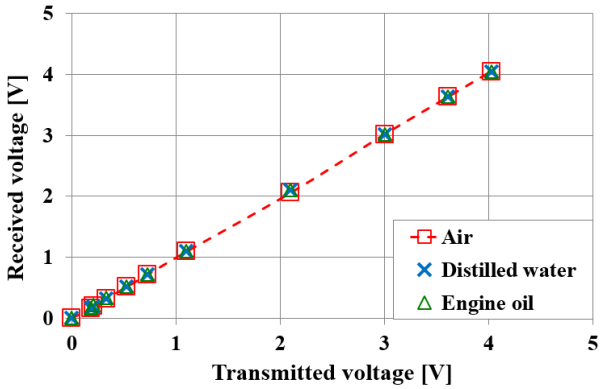

Figure 5. Comparison between the wirelessly transmitted and received voltage in a 1 meter long mettallic pipe for the different cases indicated.

The multimeter used is capable of measuring very low voltages across the two wires of the thermocouple as shown in Figure 6. The measured voltage was multiplied by the Seebeck constant to get the corresponding temperature [22]. This temperature was recorded as the input temperature. Since the thermocouple voltage was very low, it was fed to an AD620 instrumentation amplifier before the wireless transmittion and further processing. The received wireless signal is transformed back to temperature data and the results are shown in Figure 7.

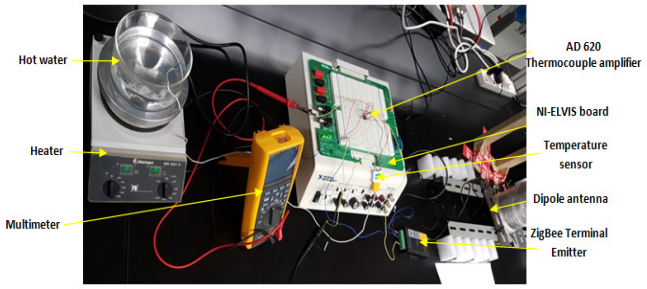

Figure 6. Wireless communication setup with Temperature sensor (Thermocouple K)

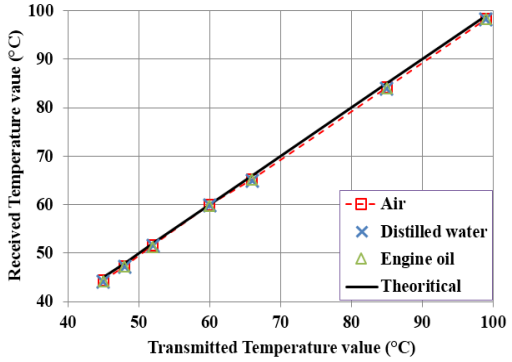

Figure 7. Comparison between the wirelessly transmitted and received temperature data in a 1 meter long mettallic pipe for the different cases indicated.

From Figure 7, it can be seen that the temperature data is successfully transmitted through air, distilled water and oil mediums with very low transmission loss. The maximum

temperature limit of 100 ºC is due to water evaporation temperature. Higher temperatures could be reached with other fluids such as oil if needed. From the graph we can estimate the error on the transmitted temperature to be about 0.7 % at 100 ºC. This is very close to the expected K-type thermocouple uncertainty of 0.75 % at the same temperature. In comparison with the previous experiment, using constant voltage, where the error was negligible, we can conclude that the observed error in transmitting temperature data was mainly introduced by the thermocouple.

5.2. Battery life measurements

For the power requirement and battery life study, we consider the first results using a single battery B1 with a nominal capacity of 55 mAh. Figure 8 shows a comparison between the battery voltage level as a function of continuous wireless transmission time and distance between the nodes for the battery B1. The wireless transmission was conducted in air with and without a metallic pipe. Using the Terminal ZigBee powered by B1 with a distance of 1 m between the transmitter and receiver, we observed that the battery B1 had lasted for about 79 hours of continuous transmission. This is in good agreement with the value of 81 hours listed by the manufacturer. This is due to the special cutoff voltage of 8.8 V below which this battery is considered to be non-reliable.

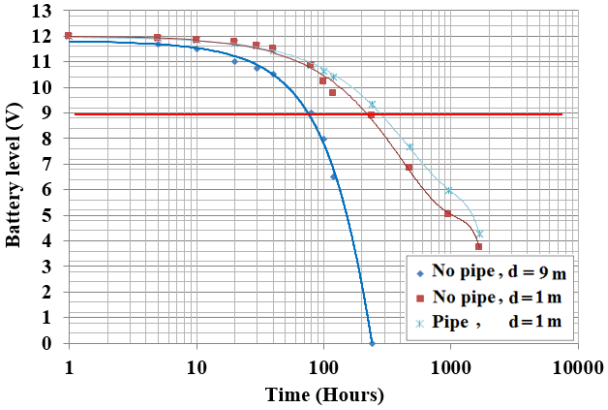

Figure 8. Comparison between the battery voltage level as a function of continuous wireless transmission time and distance between the nodes for the battery B1 with 55 mAh nominal capacity . The transmission was conducted in air with and without a metallic pipe.

It is also observed from Figure 8 that the distance between the nodes has an important effect on the data transmission. From the figure we can see that when the distance was changed from 9 m to 1 m without using the metallic pipe, the battery lasted for about 250 hours as opposed to 79 hours with the 9 m distance. This increases the battery life by a factor of 3. On the other hand, we noticed that using the metallic pipe as a cylindrical waveguide has also enhanced the battery life. This is due to the reduced attenuation effect from the open environment and the enhancement due to the waveguide effect making the transmission more directional. In this case according to Figure 8, the battery life measured for the wireless transmission in the metallic pipe under the same conditions was about 300 hours. Comparing the two results we can see that we have achieved a battery life enhancement of at least 20 % for this particular case. This is quite encouraging and will be investigated and optimized further in our future work.

In order to investigate further the battery life as a function of its capacity, we have chosen to conduct additional experiments with two other batteries B2 and B3 with higher nominal capacities of 550 mAh and 5500 mAh respectively. These experiments were conducted in open air for batteries B1, B2, and B3 as indicated in Table 1. The temperature of the environment was kept the same at around 21±0.5 °C and the distance between the transmitter and receiver was fixed to 9 m.

Table 1. Battery life measured at the cutoff voltage of 8.8V with B4 and B5 as indicated.

Battery	Nominal capacity (Ah)	Battery life (years)
B1	0.055	0.009
B2	0.55	0.02
B3	5.5	0.16
B4 [23]	34	1
B5 [24]	700	20

The battery voltage level measurements at the wireless transmission node were recorded as a function of the continuous transmission time for the three different batteries B1, B2, and B3. The results are shown in Figure 9 with a cutoff voltage of 8.8 V as discussed earlier. From the graph we immediately notice that the battery life was longer for the higher capacity batteries as expected and confirmed by our measurements. We also notice that the measured battery voltage decreases more slowly for the batteries with larger capacities (B2 and B3) hence providing longer battery life according to the indicated cutoff voltage of 8.8 V.

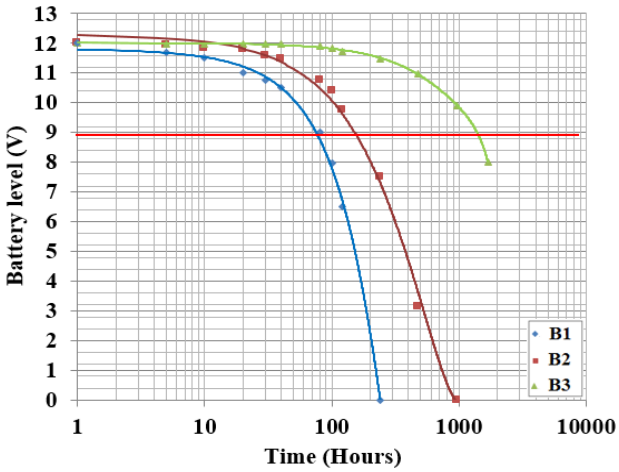

Figure 9. Comparison between the battery voltage level as a function of continuous wireless transmission time for the batteries B1, B2, and B3 with nominal capacities 55, 550, and 5500 mAh respectively, in open air for a fixed distance of 9 m between the two nodes.

For the battery B2 with nominal capacity 550 mAh, it's observed that the life of transmission is about twice greater than that of the battery B1 with nominal capacity 55 mAh. In addition, we found that the battery B2 lasted for about 170 hours of continuously transmitting data before reaching the minimum required cutoff voltage of 8.8V. For the third battery B3 with the nominal capacity of 5500 mAh, it was observed that after 1400 hours, the transmitter has consumed only 17 % of the battery's capacity. In Table 1 we report the measured battery lives of the three different batteries obtained from Figure 9 at the cutoff voltage of 8.8 V.

The results in Table 1 were used to obtain the very useful graph shown in Figure 10. Note that the data for batteries B4 and B5 were obtained from the literature [23, 24]. The curve in Figure

10 is obtained from Equation (2) with I = 2.3 mA and k = 1.25 as the average value for most lead acid batteries [25]. Notice the good agreement between the measured and calculated battery life.

The graph in Figure 10 can be used to predict and estimate the remaining battery life at any moment in time during battery operation. This is quite useful for WSNs that require long-term operation with single batteries. As shown in Figure 10, the requirement for a specific battery life can also be determined. For example, a 15 years operation time can be reached with a 500 Ah capacity battery while a 10 years operation time requires a 320 Ah capacity battery as shown in the figure below. From the literature review and the available products in the market, these battery lifetimes are now accessible and currently used in certain applications. This, certainly, makes our predictions very useful to the users of these batteries. With our plot in Figure 10, one can estimate the remaining time for these long-life batteries and plan the required battery replacements.

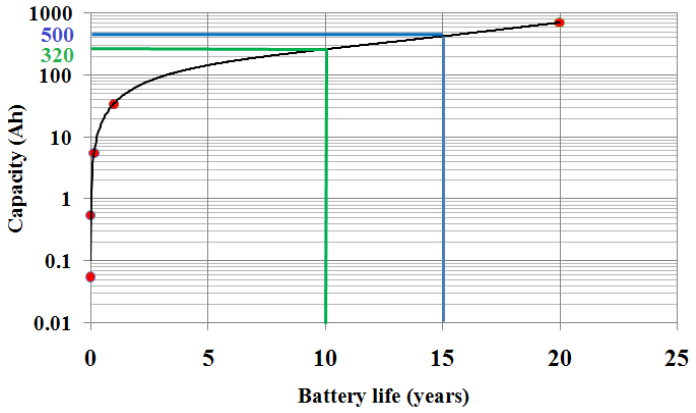

Figure 10. A plot of the different battery capacities as a function of their corresponding life. The line is a theretical curve fit as discussed in the text.

In summary, we conclude that the transmitting WSN nodes will perform well with long life batteries and small discharge time such as the case of the high capacity batteries. Also, from the measurement results, the digital data is successfully transmitted through air, distilled water, and engine oil mediums with very low transmission loss relative to air. We can conclude and confirm that the wireless transmission is well established and was not affected much by the two different mediums considered in our study which are distilled water and engine oil compared to air. We have also shown that the wireless transmission in a metallic pipe contributed at least 20 % more to the battery life of the wireless transmitter according to our current experimental setup. On the other hand, our results are more general and could be adapted to different types of wireless sensor networks to predict and monitor the required battery power.

6. Conclusion

In this paper, we have presented the study of a two-node wireless communication considering both the medium of propagation and the power requirements. The two terminals used were ZigBee terminals with dipole antennas placed at the ends of a metallic pipe filled with air, distilled water or engine oil. Our experimental results showed that efficient communication between the two wireless nodes was well established in air, distilled water and engine oil at the standard communication band of 2.4-2.5 GHz.

We have also presented the wireless sensor power requirement study and the required battery life for sustained wireless communication of a continuously transmitting node. The study of the battery life allowed us to estimate the required battery capacity for a specific long-term wireless sensor operation. For example, for a 15 years operation time one needs a battery of at least 500 Ah capacity. This estimation can be conducted for any specific wireless node power requirement. This study enables predictions concerning the service life for long-term use of batteries. The experimental results showed that the rate of energy discharge varies from one battery to another and can be quite long for large capacity batteries. When the battery capacity is large, it ensures good life of the wireless sensor transmission and the WSN.

This work is the first phase of a big project that will be continued and implemented. We would expect to extend our work in the future to include other components such as temperature sensors, pressure sensors, gateways and other models for wireless sensor networks. This will be mainly targeting the oil pipeline monitoring for addressing specific flow assurance challenges. We will also investigate further the 20 % battery life enhancement observed in the case of the guided wave conditions that we setup in the metallic pipe.

ABSTRACT

This paper presents a novel dual-band rectenna for RF energy harvesting system. This rectenna is created from a dual-band antenna and a dual-band rectifier which operates at GSM bands (900 MHz and 1800 MHz). The printed monopole antenna is miniaturized by two meander-lines. The received signal from the receiving antenna is rectified by a voltage double using Schottky diode SMS-7630. The rectifier is optimized for low input power level of -20dBm using harmonic balance. Prototype is designed and fabricated. The simulation is validated by measurement with power conversion efficiency of 20% and 40.8% (in measurement) at the input power level of -20dBm. The proposed rectenna has output voltage from 183-415 mV. From the measured results, this rectenna provides the possibility to harvest the ambient electromagnetic energy for powering low-power electronic devices.

1. Introduction

Nowadays, with the development of semiconductor, microelectronic and wireless technology, the wireless electronic devices are getting more compact, wireless, low-power and highly autonomous (i.e.: sensor nodes in Wireless Sensor Networks). In general, almost all electronic devices are powered by batteries, resulting in some disadvantages such as larger size and weight of device, regular maintenance due to limited battery lifetime, which can be more challenging and expensive if the device operates in severe or even difficult to access environment. Therefore, the ambient energy harvesting techniques are proposed as a solution.

The energy existing in the natural environment is of many different kinds, each has a different power density in ambient environment and requires a suitable harvesting technique, such as solar energy (100 mW/cm^2), thermal energy (60 µW/cm^2), ambient RF energy (0.0002 – 1 µW/cm^2), energy from vibration (200 µW/cm^3), etc. Among these energy harvesters, the ambient RF energy harvester has drawn considerable interests in recent years because of some advantages such as continuous RF energy source, low profile, low cost, simple fabrication and compatibility with MMIC (Monolithic Microwave Integrated Circuit).

In recent years, various rectenna designs have been published for RF energy harvesting applications. They can operate at single-band [2,3] , dual-band [4-7], multi-band [8], or broadband [9-11]. A narrow band rectenna can give a higher power conversion efficiency (PCE), but the amount of harvested power is low, whereas a multi-band rectenna can has the lower PCE, but more harvested power. The promising solution is to design a dual-band or multi-band rectenna to maximize PCE at the specific frequencies where maximum ambient signal level is available [12]. However, most of designs use an input power level higher than the real power level of RF energy in ambient environment. The spectrum surveys in [13-15] indicate that the RF energy in the downlink channels of GSM-900, GSM-1800, UMTS-2100 and TD-LTE bands is dominant in ambient environment with an expected input power level of -20dBm, that is presented in Fig. 1.

In this work, a dual-band rectenna operating at GSM 900 MHz and 1800 MHz is proposed. The rectenna consists of a dual-band monopole antenna miniaturized by two meander-lines, and a voltage doubling circuit using SMS-7630 Schottky diode to rectify the received signal from the antenna. The RF – to – DC conversion efficiency is optimized for low input power level of -20dBm using Harmonic Balance (HB) simulation in ADS software [17]. Each part of the rectenna is designed and tested separately, and then integrated in a circuit to evaluate the overall performance.

(b)

Fig. 1. RF power receive: (a) Outside shopping mall [13]; (b) Distributed RF power density in ambient [16]

2. Receiving Antenna Design

The fabricated antenna is shown in Fig. 2. The proposed antenna has dimension of 46 mm of length, 30 mm of width. The used material for substrate is Rogers RO4003 with dielectric constant of 3.55 and thickness of 0.8 mm.

This structure is inspired from the antenna design in [17,18] . Paper [18] presents a low-profile dual-band printed Inverted-L (IL) shaped monopole antenna with Parasitic Inverted-F (PIF) shaped element in the ground plane for 2.4/5.2/5.8 GHz WLAN applications, the overall size of this antenna is 40 mm x 30 mm. We can apply directly the technique in [18] to obtain an antenna operating at GSM 900 MHz and 1800 MHz, but the size of antenna will be increased considerably. Therefore, the miniaturized technique in [19] is used to reduce the size of our structure. In [19], a miniaturized antenna using meander-line strips with the overall size of 32 mm x 32 mm is presented for operating at GSM-850, GSM- 900, UMTS-2100, WiMAX-2.3 and WiMAX-3.3 bands. However, the gain of this antenna is quite low almost for all frequency bands, even negative in GSM bands. Our antenna has dual-band with gain of 1.46 dB, 1.91 dB at GSM 900 and GSM 1800.

The return loss and far-field characteristics of the developed antenna are shown in Fig. 3 and Fig. 4. As Fig. 3, the return loss of antenna between simulation and measurement are not similar.

The measurement result is not well matched at GSM 900MHz and shifted a little toward the right at GSM 1800 MHz. This can be explained that as the coupling between two meander-lines in practice weaken or lost, the meander-line for GSM 900MHz was not appropriately excited. Therefore, antenna efficiency is not as high as we expected. This aspect must be improved in the next work.

3. Rectifying Circuit Design

The structure of a classical rectenna is shown in Fig. 5. A rectifier consists of a harmonic filter, an impedance matching network to maximize the power transfer from the receiving antenna to AC – to – DC conversion circuit, a conversion circuit converting the received signal by antenna to DC signal, a DC filter to smooth DC signal and to bring the harmonic signal back to rectify and a resistive load. However, this proposed rectifier does not use the Harmonic filter.

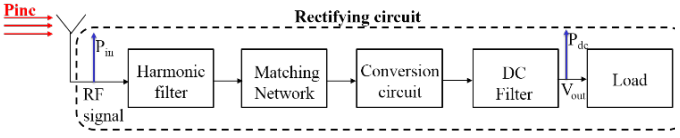

Fig. 5. Structure of rectenna

The RF signal is rectified by a voltage doubling circuit using Schottky diode. The topology of voltage double and the model of diode are shown in Fig. 6. The voltage double consists of two stages, the first one includes capacitor C_1 and diode D_1 clamping the negative part of input signal and the second one includes capacitor C_2 and diode D_2 for peak rectification. C_1 is used in order to block the harmonics generated by the diode (due to its nonlinear behavior) and return to the receiving antenna to avoid the unwanted radiation. C_2 plays a role as a DC filter, and also storages energy, which would be then replaced by a dual radial stub DC filter. The output voltage is defined as:

$$V_{out} = 2*(V_{in} - V_d) \quad (1)$$

Where V_{out} is output dc voltage, V_{in} is input voltage, V_d is forward voltage of diode.

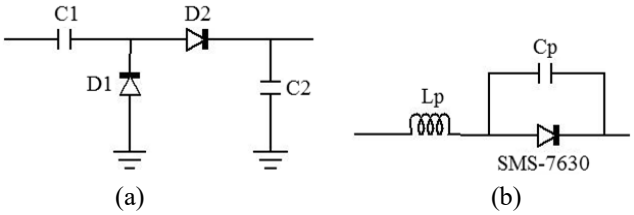

Fig. 6. (a) Voltage double circuit; (b) Diode SMS-7630 model

The diode is the most important component in the design of a rectifying circuit. As shown in paper [20], diode SMS-7630 is chosen. SPICE model parameters of diode SMS-7630 are taken from [21]. The parasitic phenomenon due to package of diode is considered by a parasitic inductor $L_p = 0.7$ nH and a parasitic $C_p = 0.045$ pF. First, the impedance matching network can be (made from?) implemented by lumped elements or distributed elements. In our project, we use a dual-stub matching network to match the receiving antenna and the rectifier at two frequencies. Fig. 7 illustrates the impedance matching network after the total size reduction by meander-line. Fig. 8 shows simulated result of matching network. The good impedance matching is achieved at GSM 900 MHz and GSM 1800 MHz, proving the capability of the dual-frequency matching circuit.

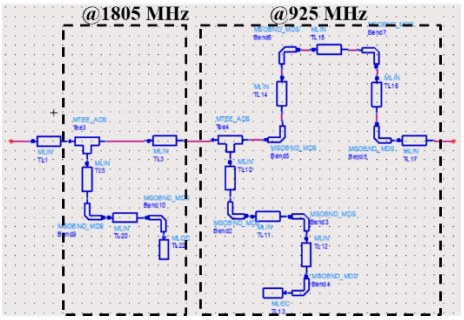

Fig. 7. Impedance matching network

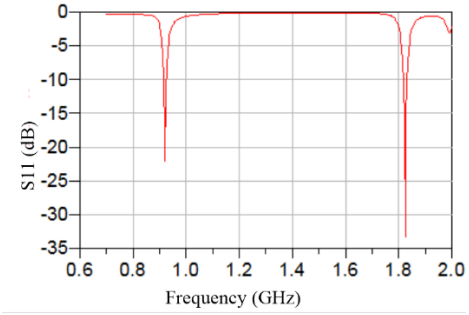

Fig. 8. Simulated result of matching network

Second, a DC filter helps smoothing the DC signal as well as bringing the harmonics back to rectify and its filtering characteristics. The DC filter with dual radial stub has the function of attenuating the fundamental frequency of GSM 900 MHz and 1800 MHz. Besides, the second and the third harmonics are well filtered with less than -3dB transmission coefficient S21 (cf. Fig. 9).

The rectifying circuit is simulated by Harmonic Balance (HB) and Large Signal S-Parameter (LSSP) simulation of ADS in . It is optimized for low input power level of -20 dBm at 925 MHz and 1805 MHz (two frequencies begin the downlink channels of GSM 900 MHz and 1800 MHz, respectively). An optimized load of 8.2kΩ is selected for maximum conversion efficiency. The Fig. 10 shows the photograph of the fabricated rectifier with the total sizes of 10 cm x 6.5 cm. The substrate Roger 4003C is used.

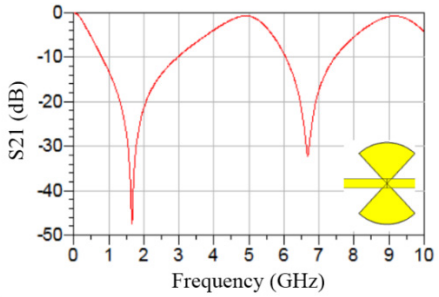

Fig. 9. DC filter and its characteristic

The measured and simulated results indicate that at the low input power level of -20 dBm, the rectifier operates at two frequencies of 925 MHz and 1805 MHz with conversion efficiency of 30.4% and 20%, and output voltage of 158 mV and 128 mV, respectively.

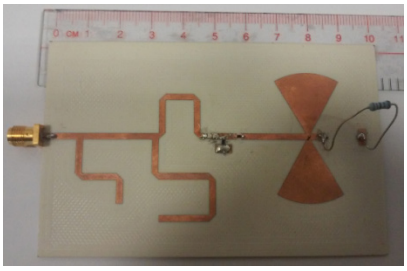

Fig. 10. Photograph of the fabricated rectifier

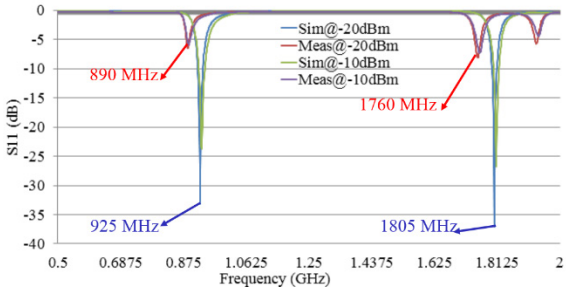

Fig. 11. Return loss of rectifier with difirent incident power level

Fig. 11 plots the measured and simulated return losses (S11) of rectifier at different input power levels. The measurement results are shifted a little toward the left and not well matched. It can be explained by two reasons. Firstly, the dielectric constant of Rogers RO4003 can vary from 3.38 to 3.55. When the dielectric constant increases, the resonant peak shifts to lower frequency. Secondly, it can be due to diode model, especially the junction capacitance *Cj* [20]. By increasing *Cj*, we find that the resonant frequency shifts to lower frequency and the power conversion efficiency degrades drastically.

Fig. 12 presents the results of efficiency and output voltage of the dual-band rectifier when varying incident power level from – 20 dBm to 5 dBm. The maximum output DC voltage is 3.3 V with an input power incident of 0 dBm. However, the incident power of GSM900 and GSM1800 can never be 0 dBm. Table I compares the simulated and measured results at the input power level of -20 dBm.

As the results are shown in Table I, the measured efficiency is haft of simulation result. The inaccurate diode model can be the reason as described above. However, this circuit gives the acceptable output voltage with the low input power level. The exact diode is expected to give higher power conversion efficiency.

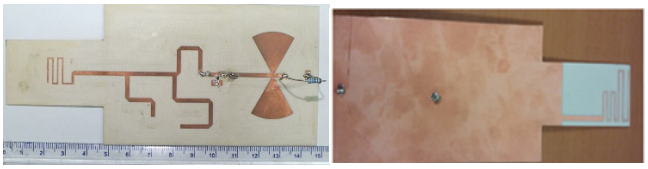
4. Rectenna performance

The receiving antenna and rectifier are designed and evaluated separately. Then they are integrated into the rectenna prototype that is fabricated and evaluated, as presented in Fig. 13:



(a) (b)

Fig. 13. Photograph of the fabricated rectenna
(a) Top view; (b) back view

The rectenna measurement is performed in an anechoic chamber as in Fig. 14. The receiving antenna is fixed in front of the transmitting antenna, the received RF power of antenna, P_{RF}, will be measured by spectrum analyzer. After that, the receiving antenna will be replaced by rectenna at the same position, the output voltage of rectenna (V_{out}) will be measured by a voltmeter. The conversion efficiency of rectenna $\eta_{RF\text{-}DC}$ is defined as the ratio of the DC power P_{DC} and the RF power P_{RF}:

$$\eta_{RF-DC} = \frac{P_{DC}}{P_{RF}} \times 100\% = \frac{V_{out}^2}{R} \times \frac{1}{P_{RF}} \times 100\% \qquad (2)$$

The results of rectenna are presented in Fig. 15 and Fig. 16. Our rectenna recovers the voltage from 183 mV to 415 mV when it is placing near the mobile and in ambient environment (cf. Fig. 16). The efficiency of rectenna is 40.8% and 20% at 1834 MHz and 890 MHz, respectively, with incident power of – 20 dBm.

Table II shows the comparison of various rectifiers published in several literatures. This work provides a dual-band design with higher conversion efficiency. As observed from the table, this work provides a dual-band design with higher conversion efficiency compared to others at the input power level of -20 dBm. However, the total size is bigger than [16,22-24] and smaller than [7] because of the large dimension of DC filter and dual-band coplanar receiving antenna.

N/a *is not available*
η is conversion efficiency of rectenna
** is the distance calculated by the wavelength*

The rectenna efficiency is quite high compared to rectifier efficiency at section 3. This can be explained by the effect of ground layer of rectifier to monopole antenna performance when the antenna is integrated into rectifier. This aspect is being discussed and reviewed in our current research. Nonetheless, these results demonstrate the potential application of this rectenna in autonomous sensor or self-powered electronic device where additional storage of energy circuit is required.

5. Conclusion

A dual-band rectenna was designed and tested in ambient environment. Simulation results show that the presented rectenna can achieve good voltage. Measurement results on a prototype rectenna show that the operating frequency was well-matched; the rectenna harvests the maximum of 415 mV in ambient environment, which implies that the proposed rectenna is suitable for autonomous sensor application. However, as we mentioned in Section 2, the receiving antenna of this rectenna can be optimized in the future researches to give higher efficiency. A super capacitor can be inserted into the circuit to store energy that is harvested by our rectenna.

ABSTRACT

This paper proposes a novel intelligent technique that has been designed to optimise the performance of Software Defined Networks (SDN). The proposed hybrid intelligent system has employed integration of intelligence-based optimisation approaches with the artificial neural network. These heuristic optimisation methods include Genetic Algorithms (GA) and Particle Swarm Optimisation (PSO). These methods were utilised separately in order to select the best inputs to maximise SDN performance. In order to identify SDN behaviour, the neural network model is trained and applied. The maximal optimisation approach has been identified using an analytical approach that considered SDN performance and the computational time as objective functions. Initially, the general model of the neural network was tested with unseen data before implementing the model using GA and PSO to determine the optimal performance of SDN. The results showed that the SDN represented by Artificial Neural Network ANN, and optmised by PSO, generated a better configuration with regards to computational efficiency and performance index.

1. Introduction

Over the past few years, upon entering the era of 'big data, there has been a change in the traditional internet traffic to a more complex traffic form. This complexity has required the increased flexibility and scalability of the modern data centre. In addition to the utilisation of numerous device types within the same area and an increase of advanced network applications, it is now possible for a multitude of end-point devices to share and exchange varying network traffic patterns. As a result, there is a need for a change in the infrastructure of the current network in order to modernise it in line with these differing network traffic patterns. As such, a new approach has been proposed [1].

In the recent years, hybridisation or combination of different machine learning and adaptation techniques has been employed for a large number of new intelligent system designs. The main aim of integrating these techniques is to overcome individual limitations and to achieve synergetic effects [2]. These techniques including, Neural Networks (NNs), the Adaptive Network Fuzzy Inferences System (ANFIS) are used for mapping and modelling purposes. Whilst evolutionary based optimisation approaches, such as

the Genetic Algorithm (GA) and Particle Swarm Optimisation (PSO) have been applied widely to produce powerful and optimised intelligent systems [3].

In many modern systems, artificial intelligence methods, such as intelligent transportation, have taken on notable roles. This adoption of new technology has encouraged the consideration of improvements in the conventional computer networks. The SDN paradigm's abstraction concept and AI techniques have a complex relationship that can be utilised to develop network elements with adaptive behaviours that can also introduce contemporary mechanisms that can overcome the common network issues as well as new issues related to SDN [1].

*Corresponding Author: Ann Sabih, Electronic and Computer Engineering Department, College of Engineering, Design and Physical Sciences Brunel University London, United Kingdom, Email: Ann.Sabeeh@brunel.ac.uk

Recently, with the fast development of the Internet, network topology, and number of applications have been changed gradually, which has led to be more complicated in structures and functions. A network based on the traditional TCP/IP architecture faces many challenges, especially the router, as the network core, takes on too many efforts to deal with. As a result, the validity and efficiency of data forwarding is being threatened. Hence, we need to find a new kind of network architecture to solve the existing problems. To this end, the study of future networks is proceeding all over the world, and the Software Defined Network (SDN) is one of them [4]. SDN is an architecture enabling rapid innovation, while hiding much of the complexity of the networking design. As such, it is a promising solution for network virtualisation that decouples control from the forwarding or data plane [5]. In doing so, it can provide the capability of remote and centralised control of the network forwarding-plane through the network control-plane.

SDN, as a network platform, has been studied widely in the literature and many researchers have proposed soft computing methods to model and optimise the network. Yilan and et al. [6] provided a genetic algorithm for solving the bandwidth-constrained multi-path optimisation problem in the SDN. Gao and et al. [7] contributed a Particle Swarm Optimisation algorithm to solve the control placement problem that takes into consideration both the latency between controllers and their capacities. Zhang and Fumin [8] explored applications of the SDN technique in the direction of the automation of network management, the unified control of optical transmission and IP bearing, smooth switching in a wireless network as well as network virtualisation and QoS assurance. Risdianto and et al. [5] evaluated the performance of an SDN-based virtual network on different virtualisation environments, including operating system based virtualisation, hardware-assisted virtualisation, and par virtualisation. Sgambelluri and et al. [9] proposed novel mechanisms that have been specifically introduced to maintain working and backup flows at different priorities and to guarantee effective network resource utilisation when a failed link is recovered. Ionita and Victor-Valeriu identified a method of avoiding DDoS attacks in the SDN environment. These scholars utilised a cyber defence system to assess risk that was structured around the neural network and the biological danger theory. This demo platform is able to achieve full packet capture in the SDN in addition to mitigating any attacks, providing it is considered necessary by the central command component. The benefit of these packet captures is that they can be utilised for forensic analysis to identify the attacker [10].

A novel open flow controller, which was structured around the intracerebral neural network was suggested by Wu and Huang in order to generate a independent media handover with wireless operation. As such, binary decisions are made by the controller that are determined by the link control parameters. These are instantly generated and gathered from the trained neural network, which is reliant on the interactions between mobile speed and the wireless link performance parameters. Using a mutated PSO, these authors managed to train the fundamental controller equation for the media independent handover that is interspersed with the intracerebral neural network's sigmoid and radial activation functions [11].

A hybrid intelligent system is proposed in this paper to optimise the performance (i.e. throughput, delay) of the SDN. The proposed system includes ANN to model inputs (flows of the flow tables)-outputs (throughput and delay) of the network. After, the evolutionary algorithms have been employed to find the optimal set of inputs that maximise this performance. This method grants to lessen the burden of SDN switch by making the network controller adaptively providing the rules/flows to the switches instead of making the switch suspends for the controller events every period of time.

2. Software-Defined Networks

It was previously noted that a software-defined network (SDN), could be centrally organised around the principle of the compartmentalisation of the control plane and data plane. The SDN is a budding architecture that is promoted by the ONF due to its ability in forwarding functions and network control decoupling. This decoupling allows the direct programming of the network control and the abstraction of the underlying infrastructure for applications and network services. The networking devices have their intelligence removed in this architecture and positioned within a centralised controller, which manages the functionality of the entire network. Software based SDN controllers also have this centralised network intelligence allowing them to maintain a global view of the network. This allows the infrastructure devices to take on a forwarding role that is able to process incoming packets. This role is determined by a set of rules generated instantaneously by the controller within the control layer that is based on some predefined program logic. A remote commodity server is a usual manner in which these controllers are run. A secure connection allows communication with the forwarding elements utilising a standardised command set. A high-level architecture for SDN is presented by Open Networking Foundation ONF [12], that has three main layers, application, control and infrastructure layers that are vertically split as detailed in Figure 1

As demonstrated by [9], the SDN controller serves to maintain the stream tables so as to engage in the management of every stream that is conveyed through the system. Application layer service requests are mapped by the SDN control layer into defined commands and directives to data plane switches. The SDN control layer then supplies applications with data plane topology and activity information. As such, the control layer acts as either a server or a collaborating set of servers, which are recognised as SDN controllers.

The OpenFlow procedure can be regarded as an open SDN specification that is constituted of a pair of foundational elements: first, the OpenFlow switch and, second, the controller. The former facilitates the execution of the data plane while the latter realises

the control plane. It should be noted that the OpenFlow procedure as a totality is employed by the interchange that takes place with regard to the controller and the switches via a safe channel. The OpenFlow switch and controller communicate via a safe channel that is realised in the context of a distinctive practice and, according to [10], this is also referred to as OpenFlow. The controller transmits a Flow Table towards the OpenFlow switches and each stream passage in the former element is constituted of a regulation crafted from an organisation of fields, thereby coordinating the approaching bundles. It is notable that this is an activity that characterises the issue of how the coordinating parcels can be prepared, for example, by transmitting on a specific yield port.

In addition, a number of counters are employed in order to collect information relating to the stream. In a similar way, each passage can be linked to alternative information, one case of this being the requirement level and the hard and idle timeout of the pair of timing devices.

The bundle is captured and conveyed to the controller that employs the safe channel in those instances where a switch receives a parcel that is not engaging in the coordination of the passages that have been introduced. Having captured the bundle, the activity of the OpenFlow switch is regulated by the controller as a result of the overhaul of its Flow Tables, thereby transmitting the coordinating parcels to the end point [8]. One implication of this is that the relative casings are not required to partake in the controller another time as a result of the potential initiation of the Flow Tables' reformulation [3].

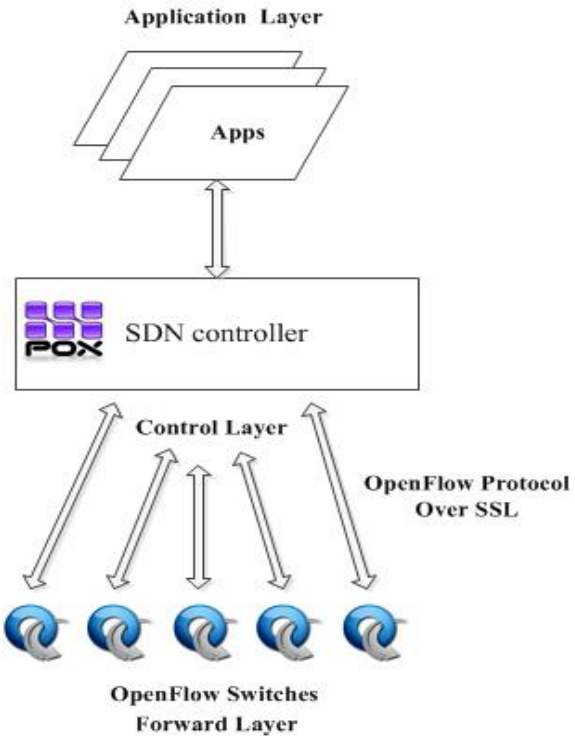

Figure 1. The software-defined network's architecture

3. Artificial Intelligence

3.1. Neural Networks

A branch of artificial intelligence, disseminated at a considerable pace in recent times owing to its suitability with regard to the modelling and forecasting ability it has in relation to dynamic systems, is the artificial neural network (ANN). In light of their promising potential, ANNs have emerged as a central branch of research into artificial intelligence. The registration of the input-output relationships of nonlinear and synthesis systems have been identified as one of the key advantages offered by ANNs and, notably, this relationship can be straightforwardly, rapidly, and cost- and time-effectively discerned by lowering the error with regard to the network output(s) and the actual output(s). A defining feature is that, following the appropriate preparation of the network, outputs can be estimated within a very short space of time (namely, in a matter of seconds). Frameworks that centre on artificial neural networks are currently seeing effective application in a range of areas – a few examples being including adaptive control, laser applications, nonlinear system identification, robotics, image and signal processing, medical areas, pattern recognition, error detection, process logging, and renewable and sustainable energy areas – in order to surmount obstacles faced by engineers [11]. The only appropriate connections in a feedforward neural network structure are between the outputs and inputs of each layer. As such, there are no connections between the outputs of one layer and the inputs of the same or previous layers [13].

3.2. Evolutionary Algorithms

Taking inspiration and motivation from natural processes and, in addition, basing the developments on factors relating to iterative and probabilistic processes, a range of evolutionary algorithms – including genetic algorithms (GAs), particle swarm optimisation (PSO), and simulated annealing – have been formulated in recent years. The primary purpose of such developments is for application in optimisation issues. Two multi-purpose and frequently employed algorithms include GA and PSO, and these are utilised in every domain [12].

- **Genetic algorithm**: Formulated by Holland (1975), GAs are self-modifying global optimisation probability search algorithms, the fundamental concept of which was inspired by the genetic mechanisms that form the basis of the theory of Darwinian natural selection and biological evolution. GAs operate by simulating the biological processes that are observed in the natural world as driving the phenomena of genetic and evolutionary development; according to the concept of natural selection, GAs provide solutions to deep problems by employing code technique and reproduction processes [13]. GAs has been extensively employed in a variety of domains with considerable efficacy in recent years, and this is primarily attributed to their almost universal relevance and promising results. The difference between the more traditional search algorithms and GAs[4] is that the latter have numerous candidate solutions rather than just one partial or candidate solution. With GAs, each problem's candidate solution is portrayed by a data

structure that is termed an 'individual'. There are two parts to each individual; these are the chromosome and the fitness. An individual's chromosome is constructed from genes with each value assigned to the gene being referred to as alleles. These individuals combine to form a population, the size of which remains constant for the duration of the search for most GAs. Out of the current population, a number of 'parent' individuals are selected, based on their fitness, which are allowed to create offspring. Individuals with above average fitness have a higher than average chance of selection for parenting. Following selection, the parents are subjected to a number of reproductive operators, such as crossover and mutation. Those subjected to crossover have a copy of their genes taken to create an offspring's chromosome. This is comparable to the creation of living organisms that are created from a genetic mixture of both parents from sexual reproduction. However, only one parent is required for mutation. In this manner, the offspring is often an almost exact replica of the parent but with a few altered genes. Following the generation of the offspring, their represented candidate solutions can be evaluated, and the offspring's fitness is determined. As the population size remains largely static, before the offspring can be incorporated into the population, it is necessary for some individuals in the current population to be removed, or die. Removal of individuals is often decided from their fitness with those individuals with a below average fitness being more likely to be selected for removal than those with an average or above average fitness. Again, this is reminiscent of the evolution of living organisms and is termed natural selection. As such, those individuals that display better fitness are allowed to procreate and live longer. Interestingly, this process of fitness selection means that the original population does not need to be very good. Indeed, it is often the case that each individual in the initial population represents a randomly generated candidate solution; however, the repetitive application of natural selection and reproduction allows GAs to generate rapid and efficient solutions [13].

- **Particle Swarm Optimisation**: First developed by Kennedy and Eberhart (1995) [14] and built on by the researchers several years later (Ibid, 2001) [15], PSO algorithms have been applied with enormous success in optimising a broad range of applications [16]. PSO operates by locating all individuals and particles (usually in the range of 10-100) in randomised positions and, following this, intending that each particle engages in random motion in a determined direction in the search space. Following this, the direction of each particle is incrementally modified in order to proceed according to the optimal previous positions, thereby identifying more favourable positions on the basis of specifications or an objective function (i.e. fitness). The original particle speed and location are chosen randomly and, in turn, the velocity formula presented below is used to provide updates:

$$V_{c_i+1} = wV_i + C_1R_1 \times (Pb_i - x_i) + C_2R_2 \times (Gb - x_i) \quad (1)$$

Contrastingly, the new particle is computed by summing the new velocity to that which precedes it, as presented below:

$$x_{i+1} = x_i + V_{c_i+1} \quad (2)$$

Where: Vc denotes the particle's velocity; X denotes the particle's position; R1 and R2 are independent random variables uniformly distributed in [0, 1]; C1 and C2 are the acceleration coefficients, and w represents the inertia weight. The particle's new velocity can be calculated by employing Eq. 13, and the information required includes the previous velocity, the distance of the particle's present position from its optimal position (Pb), and the global best position (GB). Following this, on the basis of Eq. 14, the particle is conveyed to a new location in the search space and, notably, the way in which every particle performs is evaluated in relation to a predetermined objective function known as the performance index.

4. Equation Simulation and Results

4.1. SDN Simulation

SDN simulation has been performed using the Mininet platform which is the common emulation for SDN which is used by researchers to collect all datasets of inputs and outputs. Mininet has the ability to imitate various types of system components, for example, have, layer-2 switches, layer-3 switches, and interfaces. In addition, simulation experiments were carried out using POX controller with OpenFlow 1.0 and monitoring of the flows was required for all events. Regarding which, in order to build the learning system, the SDN controller gives the orders to SDN switch to monitor the flows, and the switch keeps on monitoring them to detect the events. When the flows are monitored, the entire events whether they occur only frequently or periodically are stored in the database to be used in the ANN learning system. The flows/inputs include the rules coming from the controller. In turn, the output will be represented by the system throughput and the network delay. Consequently, the data which are collected from the ANN learning system is considered as being an efficient input to the optimisation algorithms. This paper presents a new method to minimize the load of the SDN switch by making it changing adaptively by the controller, instead of wait for the event all the time.

4.2. SDN Identification

When the ANN training started, the dataset had been preprocessed by normalising them into the range between -1 and 1. The dataset of the inputs and outputs was divided randomly into three subsets: a training set, valediction set and testing set. The first subset was for establishing the gradient as well as updating the network weights and biases. The error regarding the second subset was observed during the training development. The validation error is usually reduced in the initial training phase, as is the training set error. Nevertheless, when the network overfits the data, the error in the validation set invariably starts to rise. In the current case, the network parameters were saved at the minimum of the validation set error.

Input values need to be normalised in the range [-1, 1], which corresponds to the minimum and maximum actual values. Subsequently, testing the ANN requires a new independent set (test sets) in order to validate the generalisation capacity of the prediction model. A multilayer feedforward network was implemented to estimate the performance of the SDN. In order to obtain a maximum accuracy of prediction, the network was trained in different topologies. For each network architecture, the training was run ten times for various random initial weights and biases using the Levenberg Marquardt algorithm (LMA). After investigating the performance of different architectures using the exhaustive search method, the best trained ANN with one hidden layer was found to consist of 17 neurons in this hidden layer, which gives the comparably better performance of MSE, with 2.488 ×10-8, see Figure.. 2. While, Figure 3 shows the performance of the network as a mean square error (MSE) versus the network architecture for the single hidden layer. Also, Figures 4 and 5 show the simulated and predicted SDN performance for both the training and test sets. It is noticed that the ANN model is efficiently accurate and the network is accepted as a general model to be integrated, as the next step, with GA or PSO so as to produce the proposed intelligent hybrid system.

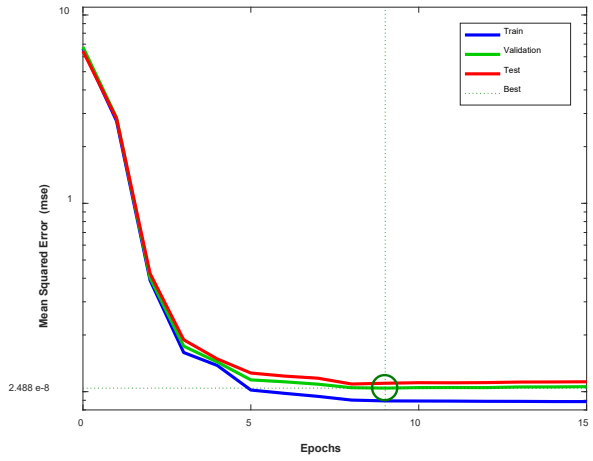

Figure 2. the progress of the ANN performance.

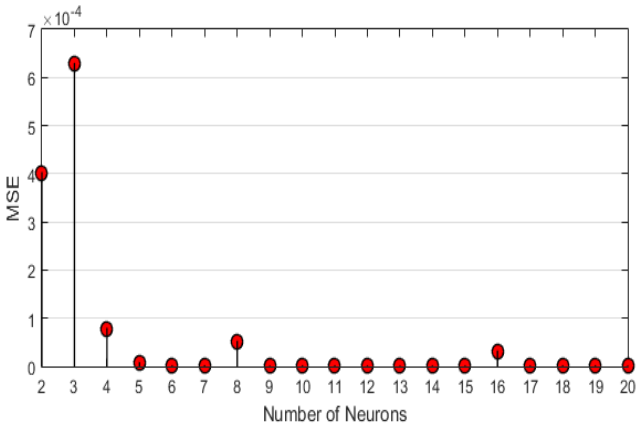

Figure 3 Performance of a single hidden layer ANN

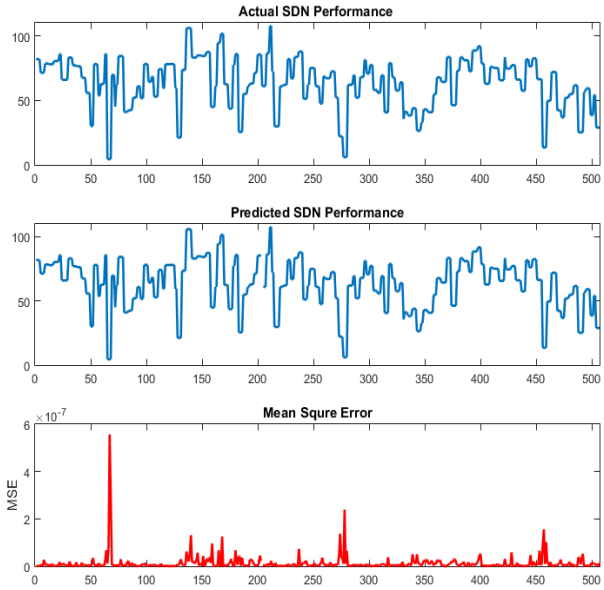

Figure 4 Comparing predicted with actual SDN performance for the training sets

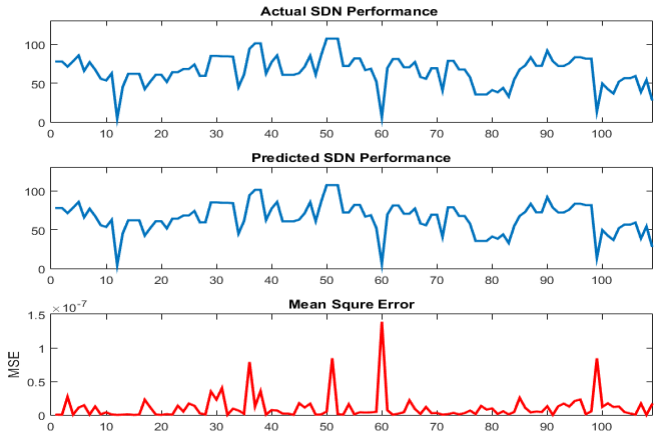

Figure 5 Comparing predicted with actual SDN performance for the testing sets

4.3. SDN Optimisation

GA and PSO were integrated separately with the trained ANN model to select the optimal set of inputs that make the network work as efficient as possible. Figure 6 shows the architecture of the system including the trained general ANN model as well as PSO and GA as an optimizer.

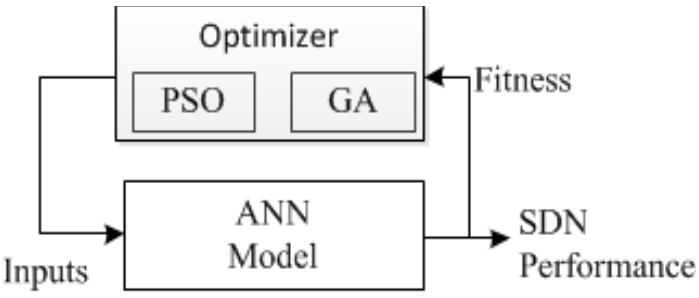

Figure 6 The architecture of the proposed method

TABLE I. PERFORMANCE AND COMPUTATION TIME COMPARISONS FOR GA AND PSO

Optimisation method	SDN Performance %	Computation Time (min)
PSO	96.321	3.23
GA	94.846	6.75

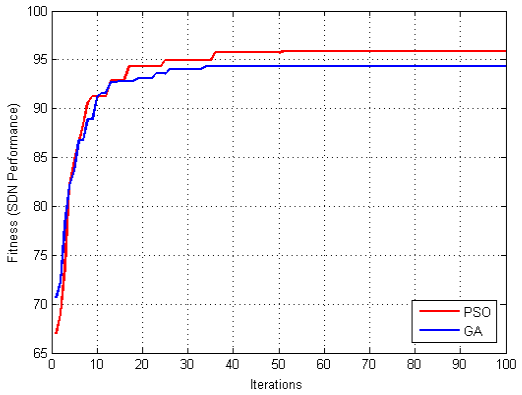

Figure 7 Convergence comparison of GA and PSO

The simulation experiments were carried out by MATLAB platform. PSO was employed to find the optimal structure of the network, and the best operational parameters of this and the GA algorithm were chosen after extensive simulations, which were set as follows:

- Size of the population or swarm: 50
- Maximum iterations or generations (max) :100
- Cognitive acceleration (C1): 1.2
- Social acceleration (C2): 0.12
- Momentum or inertia (w): 0.9

A comparison of the results of the SDN performance is provided in Table 1 and Fig. 7. PSO has outperformed GA regarding the performance, and computational time, the convergence is faster with fewer iterations, and the obtained fitness is higher. However, the results provided were obtained after running PSO/GA 20 times.

5. Conclusion

This paper has presented a novel hybrid intelligent system for the modelling and perfecting of the Software Defined Network (SDN). This involved the training of an artificial neural network (ANN), which had a single layer in the hidden zone, to map the inputs and network performance. An acceptable MSE was shown by the network that was demonstrated as being below 2.466×10^{-8}. The application of unseen data as a test set to the trained ANN model proved its generality; this ANN model was then coordinated with evolutionary algorithms (EAs) to create the presented intelligent hybrid system. In order to optimise the EA, PSO and GA were utilised in order to identify the optimal input set for the SDN. This optimisation was based on the fitness function of the individuals. The comparison results showed that PSO was a more effective option in terms of computational time, convergence and performance.

ABSTRACT

This paper presents a literature review on data flow error detection and recovery techniques in embedded systems. In recent years, embedded systems are being used more and more in an enormous number of applications from small mobile device to big medical devices. At the same time, it is becoming important for embedded developers to make embedded systems fault-tolerant. To make embedded systems fault-tolerant, error detection and recovery mechanisms are effective techniques to take into consideration. Fault tolerance can be achieved by using both hardware and software techniques. This literature review focuses on software-based techniques since hardware-based techniques need extra hardware and are an extra investment in cost per product. Whereas, software-based techniques needed no or limited hardware. A review on various existing data flow error detection and error recovery techniques is given along with their strengths and weaknesses. Such an information is useful to identify the better techniques among the others.

1. Introduction

In general, a critical aspect of any computer system is its reliability. Computers are expected to perform tasks not only quickly, but also correctly [1]. Recent trends in embedded systems attract industries to use them more and more in day-to-day life for an increasing number of applications. Application areas include, but are not limited to, mechatronic industries, medical equipment, smart energy consumers, mobility. Reduced size and reduced supply voltage make systems more susceptible to disturbances. Since there are more systems in use and the environment becomes more harsh, a system failure or a system crash is more likely to occur. A system failure could lead to serious consequences such as human injury, environment pollution and a huge amount of money loss for industries [2].

The rise in usage of electronics under harsh conditions significantly increases the probability of all kinds of disturbances from the environment. Such disturbances are glitches, electromagnetic interference, temperature variations, etc. [3–6]. It is proven that decreasing the size and supply voltage of the components in circuits and increasing their complexity leads to less reliable systems [7]. The corresponding systems are susceptible to soft errors (bit flips) which are typically transient. Transient faults do not cause any permanent physical damage and can be restored by overwriting the introduced bit flip or by a system restart. Still these faults are categorized as systematic faults since given the exact same circumstances these faults will re-appear in exactly the same way. Because the environment changes, transient faults don't occur continuously, unlike design and manufacturing faults [1,8,9].

Errors in embedded systems can cause unusual behavior and degrade systems integrity and reliability [7]. A number of hardware and software techniques have been developed to make embedded systems fault-tolerant against transient faults [10,11]. Fault tolerance is a two step process. The first step is fault detection, indicating that somewhere in the system fault has occurred. The second step in the process is fault recovery, restoring the system from fault state to the normal state [12].

Today, fault tolerance is mainly achieved via hardware solutions. Such hardware-based solutions are hardware redundancy approaches to meet the requirements of the reliability. Such hardware redundancy techniques are expensive since they have to be implemented on every product produced. A commonly used hardware-based technique for error detection in embedded systems is N-modular redundancy. This technique uses N (N>2) parallel modules for comparing the original and redundant process results. This hardware redundancy technique introduces a 100* (N- 1)% performance and memory overhead but does achieve a fault coverage of 100% [12,13]. To reduce the overheads in hardware-based fault tolerance techniques different software-based redundant techniques have been proposed and implemented [12,13]. Such software solutions would lead to a more cost-efficient solution in many situations. Due to its

*Venu Babu Thati, KU Leuven; Spoorwegstraat 25; 8200 Brugge, Belgium

flexibility and cost, software-based solutions are used in a number of applications. Software redundancy increases the system's reliability but requires extra memory space and processing time to execute redundant instructions [15]. A number of software-based data error detection and recovery techniques have been proposed and implemented in literature for fault-tolerant embedded systems [1,7,8,12–22].

According to recent studies, soft errors are one of the primary sources of failure in embedded systems [7,16,23–25]. These soft errors (bit flips) may further affect the system during program execution, leading to a faulty system. Such bit flips have an effect on data flow or control flow of the program. Generally, data flow errors lead to corruption of variables in the program causing a wrong intermediate or output result. In contrast, control flow errors lead to a jump in the program execution order [26–29]. This review paper focuses on various data flow error detection and recovery techniques existing in literature to make embedded systems fault-tolerant against bit flips. Since a number of data error detection and recovery techniques exist in literature, it is important to review and identify the strengths and weaknesses of each of these techniques for a fault-tolerant embedded system. Figure 1 gives an overview of the software-based data protection techniques that will be discussed in this paper.

The remainder of this paper is organized as follows: Section 2 describes and reviews the different data flow error detection techniques. Section 3 describes and reviews the different error recovery techniques. Section 4 provides future work plans and Section 5 concludes this paper.

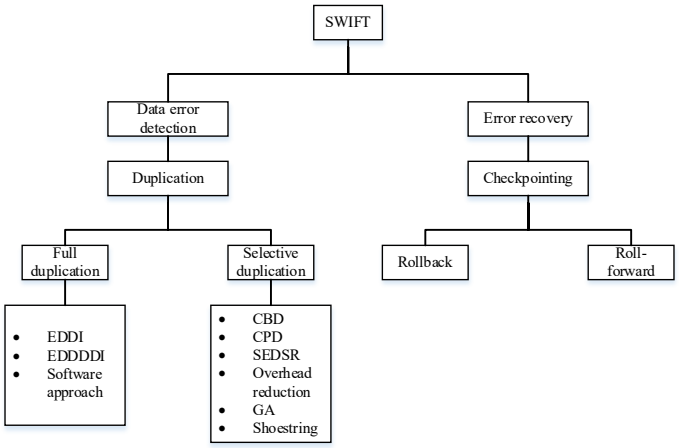

Figure 1. Overview of software-based data protection techniques.

2. Related Work

Soft errors usually occur due to heavy radiation, power supply distortion, environmental temperature fluctuations, and other factors. The introduced soft errors can corrupt the data of the program in execution. To counter this data corruption, a number of data flow error detection and recovery techniques have been proposed in literature [1,7,8,12–17,19–21]. In previous work [4], we listed several data flow error detection techniques and discussed their reported results. The contribution of this review paper is 1) that we list not only detection techniques but also recovery techniques, 2) that we discuss the considered techniques more in depth and 3) that we give several strengths and weaknesses per technique. The provided strengths and weaknesses have been determined based on the technique's inner working and reported results. By looking at the strengths and weaknesses of each of the technique presented under error detection and error recovery, one can easily identify the better technique immediately with clear reasoning.

3. Data Flow Error Detection

This section presents and reviews various existing data flow error detection techniques such as EDDI (Error Detection by Duplicated Instructions), ED^{4}I (Error Detection by Diverse Data and Duplicated Instructions), Software approach, CBD (Critical Block Duplication), CPD (Critical Path Duplication), SEDSR (Soft Error Detection using Software Redundancy), Checking rules, GA (Genetic Algorithm) and Shoestring approach. Strengths and weaknesses of each of these techniques will be discussed. All of the presented data flow error detection techniques are software-based.

Duplication is the basic mechanism involved in data error detection techniques [4]. A number of data flow error detection techniques have been developed based on a unique duplication mechanism for better fault coverage or lower overhead in terms of memory consumption. The duplication can be applied at various levels such as a full duplication and selective duplication [1,4,7,8,12–15,17,18]. Full duplication techniques and selective code duplication techniques are discussed in Sections 2.1 and 2.2 respectively.

In order to evaluate the data error detection techniques, authors of the corresponding techniques [1,7,12–17] have chosen various case studies for the experiments. Bubble sort, quicksort, insertion sort, and matrix multiplication are the most used case studies in previous research in this field [13,16,17,26,30]. Of course, some of the techniques uses other case studies such as FFT, differential equation solver, mean, vortex, etc. Further, a fault injection mechanism has been used to inject the faults in hardened case studies for validation. All of the provided information in Table 1 and Table 3 such as error detection techniques, case studies, injected faults, detected faults, fault coverage, performance overhead, and memory overhead are considered from literature [1,7,12 – 17]. Fault coverage, performance overhead, and memory overhead are defined in (1), (2), and (3).

$$Fault\ coverage = \frac{Number\ of\ detected\ faults}{Number\ of\ injected\ faults} \quad (1)$$

$$Memory\ overhead = \frac{Final\ memory - Initial\ memory}{Initial\ memory} \quad (2)$$

$$Performance\ overhead = \frac{Final\ time\ - Initial\ time}{Initial\ time} \quad (3)$$

3.1. Full Duplication

This section presents various existing full duplication techniques for data flow error detection. The basic mechanism involved in all of the full duplication techniques is duplicating the entire code and comparing the original and duplicated output to detect errors. Full code duplication has been performed in different ways for different techniques as in [7,13,15,31].

Table 1. Representation of error detection technique with case studies, case studies length, injected faults and detected faults from literature [1,7,12–17].

Error detection technique	Case studies used	Case studies length (in lines)	Injected faults	Detected faults

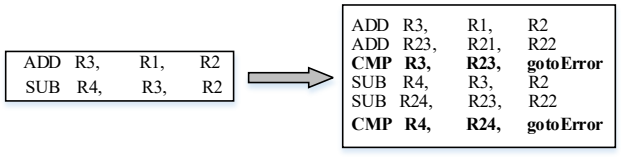
Error detection by duplicated instructions

EDDI is one of the most often used error detection techniques in research [12]. The EDDI technique states three different instructions for program execution: a master instruction (MI), a shadow instruction (SI), and a comparison instruction (CI) [13], as shown in Figure 2b. Figure 2a represents two different master instructions. The master instruction is the original instruction of the source code, while the shadow instruction is the duplicated instruction added to the source code. Validation of correct operation is accomplished by comparing registers and memory values of master instructions and those of shadow instructions. In Figure 2b, first three instructions refer to MI, SI, and CI. If there is any mismatch between the master and shadow output, the comparison instruction reports an error. To achieve the highest fault detection ratio, EDDI is applied at the assembly level [8,13]. In order to evaluate the effectiveness of the proposed technique, quicksort, matrix multiplication, insertion sort, and FFT were used as case studies.



a) Original instructions b) Transformed instructions

Figure 2. Master, shadow, and comparison instructions representation.

Strengths

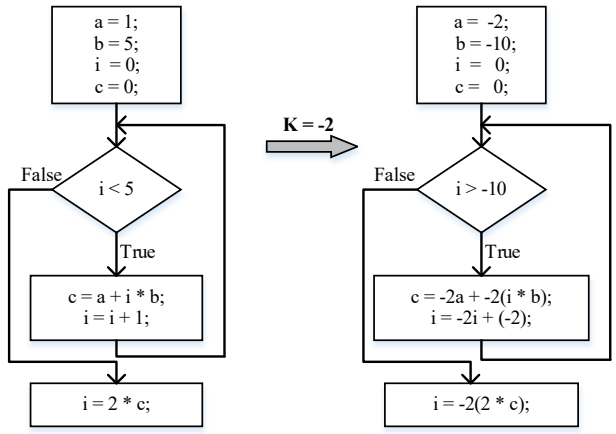
With the final computation results from MI and SI in the program, the error can be detected by placing a comparison instruction. The EDDI technique achieves nearly 98.8% [13,16] of fault coverage by placing a redundant comparison instruction after each MI and SI in the program. The remaining percentage of undetected errors comes from the faults that create an infinite loop in the program. EDDI is one of the techniques that has highest fault coverage in this field.

Weaknesses

Since it is a full duplication technique, all of the instructions presented in the program need to be duplicated. Next to the original (MI) and duplicated (SI) instructions, a comparison instruction has to be placed to report errors. Since each of the original instructions is converted to three instructions, so performance and memory overhead of EDDI are 104.7% and 200% [13,16], as shown in Table 3.

Error detection by diverse data and duplicated instructions

ED^{4}I detects errors by executing two different programs, the original and a transformed (duplicated) program, and comparing their results. The comparison gives an error if the original and duplicated programs do not lead to the same result. The transformation of ED^{4}I technique representation is shown in Figure 3, where $x' = k.x$ for integer numbers is used. Where k is the fault detection probability of the program, $\boldsymbol{x}$ is the original program and $\boldsymbol{x'}$ is the transformed program [7]. In the presented ED^{4}I technique, the optimum value for k that maximizes the fault coverage probability is calculated. After performing the validations with case studies, the authors identified that $k = -2$ is the optimum value to have a maximum fault detection. EDDI and ED^{4}I techniques are comparable because of their common case stuides.



a) Original program b) Transformed program

Figure 3. Original and transformed program with k = -2.

Strengths

The ED^{4}I technique presents a transformation algorithm for the program that transforms an original program (integers or floating point numbers) x to a new program $\boldsymbol{x'}$ with diverse data. This technique achieves a 96.1% [7,16] fault coverage when using the optimum value for k. This result is approximately equal to that of the EDDI technique, as shown in Table 3.

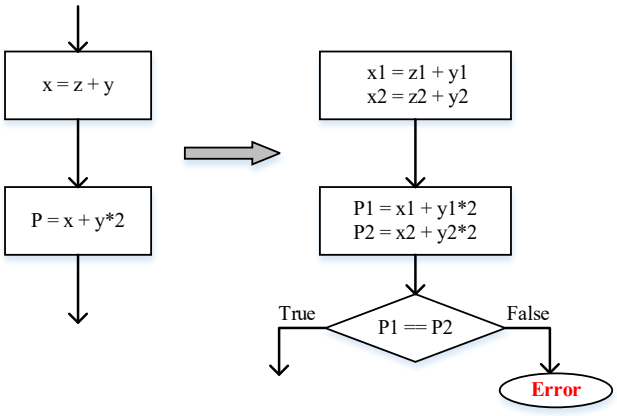
Weaknesses

As in EDDI, ED^{4}I also needs to duplicate the entire original program with diverse data. This technique requires a number of redundant instructions for duplication and comparison, which causes an increment in overhead. The performance and memory overhead imposed by this technique is nearly 126.6%

and 160% [16], as given in Table 3. ED^{4}I transformation is only good for either integers or floating point numbers, but not for both. For example, if a program has mixed data types such as floating point numbers and integers, in that case, we need multiple transformations with different *k* values for each type. The drawback of such a multiple transformations is that it will introduce a more performance and memory overhead.

Detecting soft errors by a pure software approach

The error detection mechanism in the proposed technique is based on a set of transformation rules. These transformation rules are classified into three basic groups: 1) error affecting data, 2) error affecting basic instructions, and 3) error affecting control instructions to detect the errors [31]. Error affecting data rules are used to detect data flow errors, whereas error affecting basic and control instructions rules are used for control flow error detection. In error affecting data, the motive is to identify and define a dependency relationship between variables of the program. Furtherly, classifying them into intermediary variables and final variables based on their role in the program [31]. From Figure 4a, variables *x*, *y*, and *z* are classified as intermediary variables, which are used for other variables operation. Whereas variable *P* is classified as a final variable, which does not participate in any operations. After each write operation to the final variables, both original and duplicated values are compared for a consistency check, if any inconsistency is identified an error detection procedure is activated. By applying the different transformation rules to each of the original variables, this technique is able to detect errors that occur in data, basic instructions, and control instructions.



a) Original program b) Transformed program

Figure 4. Transformations rules targeting error affecting data in a sample program [31].

Strengths

The presented technique is mainly based on a set of transformation rules. Error affecting data rules are used to detect data flow errors with full duplication scheme. Fault coverage achieved with this technique is 100% [31], because of duplicating the entire program and comparison after each write operation to the final variables. Software approach is one of the techniques that has highest fault coverage in this field.

Weaknesses

Usage of more redundant instruction for duplication and the comparison lead to increase in overhead. The appeared performance and memory overhead in this technique are 244% and 362% [31], as shown in Table 3.

3.2. Selective Duplication

This section presents a number of existing selective code duplication techniques for data flow error detection. The main difference with full duplication techniques is that selective duplication techniques first analyze the program to detect the most important parts and only duplicate those important parts. Defining and identifying the important part of a program can be done in different ways, leading to different techniques [1,12,14–17].

Error detection by critical block duplication

The presented selective code duplication technique is named CBD. The CBD technique follows three different steps to detect data flow errors. The first step is, to identify the critical blocks in the control flow graph. These critical blocks are the most vulnerable in the program because its output has an influence on the other blocks. The second step is to duplicate the identified critical blocks. The final step is to compare the original and duplicated critical blocks to detect errors. The authors of this proposed technique introduced a simple way for critical block detection from the example of control flow graph, as shown in Figure 5. A block that has the most number of outgoing edges to the other blocks in the control flow graph is considered, as a critical block [12]. In Figure 5, block 1, has three outgoing edges to the other blocks, whereas others have less than three. In this case, the highlighted block 1 is identified as a critical block. Furthermore, the critical block, block 1, is duplicated and compared to the original block. If any mismatch is identified between the original and duplicated instructions, it will report an error.

Strengths

In Section 2.1, we have reviewed various full duplication techniques and their advances in fault coverage. But, because of increased performance and memory overhead, it seems that full code duplication is not a good option. Limiting the code duplication scope is useful in real-time and general purpose applications where cost is the primary factor. In CBD, performance and memory overhead are decreased because they use less redundant instructions for duplication and comparison. The appeared performance and memory overhead in this technique are 50% and 101.6% [12], as shown in Table 3.

Weaknesses

With regards to CBD, redundant instructions are inserted only in the critical block, so there is a possibility of missing undetected errors in other blocks leads to a reduction in fault coverage. The achieved fault coverage with CBD technique is only 73.5% [12]. Another major drawback of this technique is that it is a compiler and/or case study dependent and could just act as a full duplication technique. For example, let's consider a control flow graph with 8 basic blocks, 5 of them have two outgoing branches and other 3 have only one. Since 5 of them are critical blocks, they are expected to have at least 80% of the code. Such a control flow graph with CBD approach is duplicating 80% of the original program.

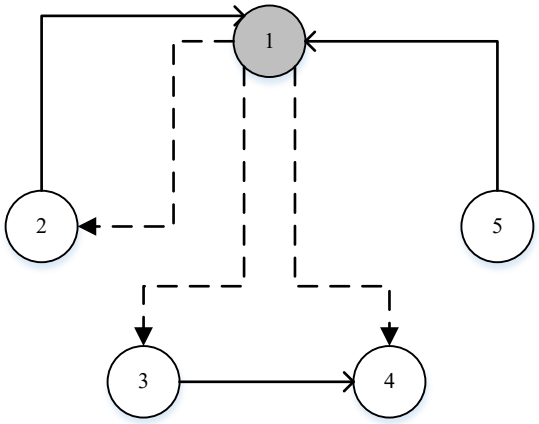


Figure 5. Example of control flow graph with CBD [12].

Error detection by critical path duplication

In this CPD technique, the data flow graph is used instead of using the control flow graph. The data flow graph is used to derive the interconnection of variables and their dependencies and effects on each other. In a data flow graph example, nodes represent the operands and vertices represent the variables of the program, as shown in Figure 6 [14]. The basic idea behind this technique is to identify and duplicate the critical path in the data flow graph. The first step is, to identify the critical path in the data flow graph. The authors of [14,17,32] who proposed CPD technique introduced a simple principle for critical path detection. The longest path in the data flow graph is considered as a critical path because of the great possibility of error occurrence on that long path. According to the principle proposed by the authors, the longest path in the data flow graph is identified and kept in the box, as shown in Figure 6. Next, the identified critical path will be duplicated and the comparison instructions will be placed after each write operation in the final variables. If the final variables in the program are not equal to each other, it reports an error.

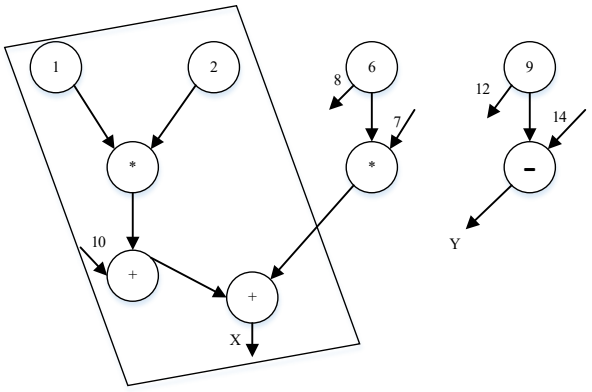

Figure 6. Example of data flow graph with CPD [14].

Strengths

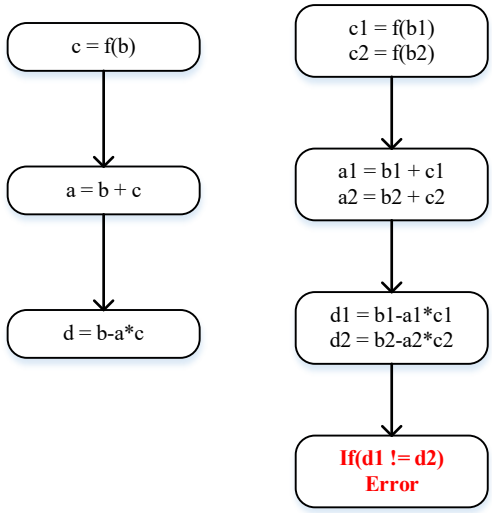
With regard to CPD, only instructions presented in the critical path are duplicated to detect the data flow errors with minimum overhead. In CPD, performance and memory overhead are decreased because they use less redundant instructions for duplication and comparison. The appeared performance and memory overhead in CPD are 60% and 103% [14], as shown in Table 3.

Weaknesses

As far as CPD is concerned, redundant instructions are inserted only in the critical path, so there is a possibility of missing out on the undetected errors in the other small paths in the data flow graph. This lead to reduce in a fault coverage. Fault coverage achieved with CPD is only 73.3% [14]. In CPD, creating a data flow graph is much harder in assembly than C and C++. It is also difficult to perform the duplication and maintain the control flow graph in order when only data flow graph is given.

Soft error detection using software redundancy

This technique is named SEDSR. In this technique, the critical block is duplicated as in CBD. As in [12,17], the critical block is the block with the most number of outgoing edges to the other blocks in the control flow graph, as shown in Figure 5. In this technique, critical block variables are further divided into two categories: (1) middle variables: important in computing the other variables and (2) final variables: they don't perform any computations [17]. In the critical block, a redundant comparison instruction is placed after the final variables to compare these parameters in original and duplicated blocks. Figure 7a represents the sample (original) program of the critical block and variables *a, b,* and *c* are considered as the middle variables and *d* is considered as the final variable. Figure 7b is the duplicated version of a sample program with comparison instruction for the critical block. If any mismatch between original and duplicated variables is identified during the comparison, an error is reported and the program execution is halted. SEDSR and CBD techniques are comparable because of their common case studies.



a) Sample program b) Duplicated program

Figure 7. Sample program of critical block with duplication and comparison [17].

Strengths

SEDSR is one of the critical block duplication techniques. In comparison with CBD, in this technique, the critical block variables are not directly duplicated but furtherly classified into two types such as middle variables and final variables. In SEDSR, by placing a comparison instruction after writing to the classified final variables detect a lot of errors. Fault coverage achieved with this technique is 94.85% [17], which is increased in comparison to the CBD, as shown in Table 3.

Weaknesses

As in CBD, this technique also considers only the critical block with further improvements in the process over CBD, as mentioned in strengths. At the same time, performance and memory overhead are increased because of placing extra comparison instructions. The imposed performance and memory overhead in SEDSR are 112.3% and 134.6% [17], they are increased in comparison to the CBD. Since SEDSR has a similar kind of duplication mechanism as in CBD, this technique is also a compiler and/or case study dependent and could just act as a full duplication.

Overhead reduction in data- flow software-based fault tolerance techniques

The aim of this technique is to provide low overhead with the same level of reliability as in EDDI, ED^{4}I , and Software approach [7,13,31]. This technique provides an alternative implementation of software-based techniques. The alternative overcomes the drawback of the massive overhead introduced by other techniques for soft error detection. In the presented technique, a set of rules for the data protection are explained as shown in Table 2 such as, 1) global rules: each register used in the program should have its replica, 2) duplication rules: (a) duplicating all instructions except branches, (b) duplicating all instructions except branches and stores, and 3) checking rules: to compare the values of a register with its replica at different positions [15]. Such rules are applied to various methods with the choice to detect the errors. Table 2 explains the purpose of each rule. Checking rules (overhead reduction), EDDI, and ED^{4}I techniques are comparable because of their common case studies.

Table 2. Checking rules description [15].

Global rules	(Valid for all techniques)
G1	Each register used in the program has a spare register as a replica
Duplicated rules	Performing the same operation on the registers replica
D1	All instructions except branches
D2	All instructions except branches and stores
Checking rules	Compare the value of a register with its replica
C1	Before each read on the register
C2	After each write on the register
C3	Before loads, the register that contains the address
C4	Before stores, the register that contains the data
C5	Before stores, the register that contains the address
C6	Before branches

Strengths

Different methods are implemented in this technique by considering the choice of duplication and checking rules, as shown in Table 2. A couple of methods have equal fault coverage with changes in overhead. Selecting the right checking rules is important because they have an influence on fault coverage and overhead. The method with highest fault coverage and lower overheads is considered as the best method. In this technique, the best method has a fault coverage of 95% with performance and memory overhead of 72.3% and 82% [15]. The appeared performance and memory overhead in this technique are decreased in comparison to the EDDI, and ED^{4}I techniques, as shown in Table 3.

Weaknesses

Compared to full duplication error detection techniques such as EDDI, and ED^{4}I, this technique has slightly reduced fault coverage. Fault coverage achieved with this technique is 95% because of using less number of redundant instructions with the choice of checking rules in comparison to the EDDI and ED^{4}I techniques.

Method for hardening a program against soft error using genetic algorithm

In this technique, GA has been used to identify the most vulnerable blocks of the program through input data [16]. The identified vulnerable blocks have to be strengthened against errors through duplication and comparison. The proposed technique follows three different steps to detect errors as shown in Figure 8. Those three steps are, 1) preprocessing of the input program: with regard to the results obtained from the related researchers such as [33,34], a considerable number of program instructions does not have any effect on the program output results. This step includes a method called program slicing [35], which eliminates some of those instructions that do not have an impact on the program output results. The first step improves the speed of proposed GA in the second step, 2) identifying the most vulnerable blocks: GA has been proposed to identify vulnerable blocks. GA takes the source code of the program as an input to find out the smallest subset of the basic blocks which are more vulnerable. The most vulnerable blocks are identified based on initial population, selection, crossover, mutation, evaluation, and replacement processes introduced in GA, as clearly explained in [16], and 3) strengthening the identified vulnerable blocks: based on the required level of reliability, most vulnerable blocks in the program are strengthened against errors [16], is shown in Figure 8.

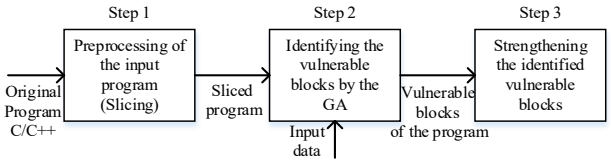


Figure 8. Representation of proposed method [16].

Strengths

Due to initial preprocessing and then selective vulnerable block duplication and comparison, the presented technique uses a less number of redundant instructions. Usage of a less number of redundant instructions decreases its performance and memory overhead. Performance and memory overhead presented in this technique are 24.3% and 60.3% [16].

Weaknesses

As other selective duplication techniques presented in this section, this technique considers only the most vulnerable blocks in the program for duplication. By duplicating only the vulnerable blocks in the program, most of the faults can be detected but not all. There is a possibility of undetected errors in the other normal blocks which lead to a reduction in fault coverage. Fault coverage achieved with this is technique is 82% [16].

Shoestring: Probabilistic soft error reliability

In the program, any instruction that can potentially influence global memory is considered as a high-value instruction [1]. In fact, if it consumes a wrong input, they are likely to produce outputs that result in user-visible corrupted results. In this

technique, high-value instructions are defined as the most vulnerable instructions and will have a huge impact on program output. Shoestring technique contributes in different issues for detecting the errors. Such issues are: 1) a transparent software solution for addressing soft errors, 2) a new reliability-aware compiler analysis, and 3) a selective instruction duplication that leverages compiler to identify and duplicate a small subset of vulnerable instructions [1]. Code duplication begins by selecting a single high-value instruction, from the set of all high-value instructions in the program. The selected single high-value instruction then proceeds to duplicate and then compare with comparison instruction. Duplication process is terminated when no more producers exist for duplication or the producer is already duplicated. Then the inserted comparison instructions are used for checking the errors. In Figure 9, the shaded parts represent the code duplication chains and the dashed circles indicate high-value instructions.

Strengths

Shoestring is a minimally invasive software solution, which results in very low overhead. Since duplicating and comparing only high-valued instructions, less number of redundant instructions are used which leads to decrease in overhead. Performance and memory overhead introduced in this technique are 20.16% and 40% [1], these are better than any other techniques in this field.

Weaknesses

Shoestring approach initially identifies the most unsafe instructions, as high-value instructions. Only duplicating and comparing the high-valued instructions, produce better overhead. At the same time, fault coverage is reduced because of possible undetected errors in the unduplicated instructions. Fault coverage achieved with this technique is 80.6 [1]%.

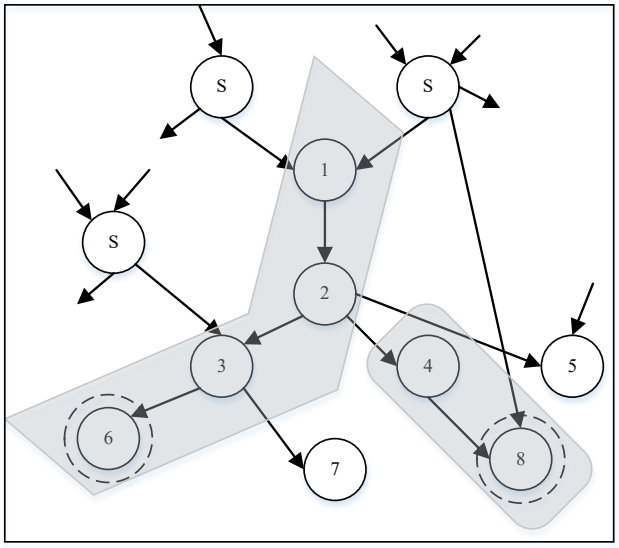

Figure 9. Example of data flow graph illustrating shoestrings code duplication chains [1].

4. Error Recovery

Error recovery techniques have been implemented to recover from the identified errors to keep systems in an error-free state with minimum overhead. Error recovery is generally based on the checkpointing concept [19–21,36]. Checkpoints are saved at regular intervals in the program based on the program execution behavior.

This section presents and reviews general checkpointing techniques for rollback error recovery and roll-forward error recovery. Strengths and weaknesses of rollback and roll-forward error recovery policies with checkpointing techniques are discussed.

4.1. Rollback Error Recovery

Rollback error recovery is one of the most used error recovery policies to recover the errors by using the checkpointing techniques in embedded systems. Bashiri, et al. propose a checkpointing technique for rollback error recovery. In rollback error recovery, in the case of an error, the processor state is restored to the error-free state with lower overhead [21]. In general, cost, performance, and memory overhead are primary factors for any error recovery technique.

The primary step for developing an error recovery technique is defining the correct error model. In [21], the proposed technique is based on control flow error model. During compilation time, the program is partitioned into basic blocks. The basic block is a set of instructions in a program without a jump instruction. Thereafter, an error detection mechanism needs to be added to the basic blocks presented in the program. Figure 10 shows the example of placing checkpoints in the control flow graph of the program. Usually, the checkpoint is stored in memory for rolling back the system with an immediate effect whenever an error is detected. Such a memory must be a fault-tolerant memory. The checkpoint contains the content of the registers, stack pointer and memory locations like stack region, constants, and variables [21]. For the considered benchmark programs such as bubble sort, matrix multiplication, and linked list copy, a checkpoint capturing is inserted to each of the basic blocks individually.

For example, a control flow graph is constructed with six blocks based on the program. Then checkpoints are added to the blocks based on the program execution order as shown in Figure 10. Since there will be a possibility of error occurrence before the first checkpoint location, it is mandatory to put a checkpoint at the beginning of the program. Remaining checkpoints are placed at the locations based on the program's vulnerability. In Figure 10, locations of the second and third checkpoints contain the vulnerable information. During the program execution time, whenever an error is detected, a detection mechanism informs the recovery routine and recovery routine recovers the error from the previously restored checkpoint. To evaluate the presented checkpointing technique, a pre-processor has been implemented that selects and adds the checkpoints to blocks [21].

Strengths

Bashiri, et.al, proposes a general checkpointing technique for rollback error recovery to recover from detected errors. The advantage of rollback error recovery is that if the error is detected, the processor state is restored into error free state without using the spare processor. The number of redundant instructions needed for rollback error recovery is very low. In the presented checkpointing technique for rollback error recovery, appeared memory overhead is low and also a cost efficient.

Weaknesses

In the presented checkpointing technique for rollback error recovery, whenever an error is detected, immediately the system

must rollback to its previous checkpoint of the corresponding program. Due to the fact that considerable time overhead is the main drawback of the rollback error recovery, as shown in Table 4. This technique is not fit for the typical time critical applications.

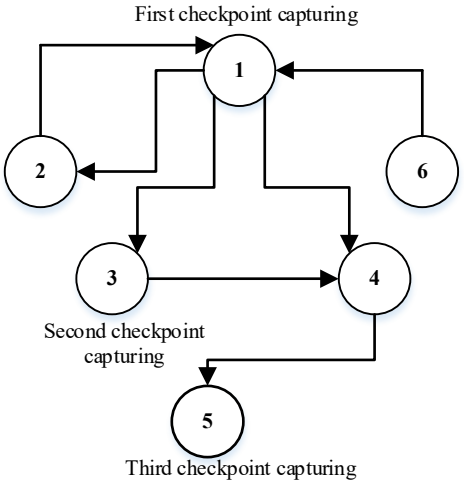

Figure 10. Periodic checkpointing representation in control flow graph.

4.2. Roll-Forward Error Recovery

Roll-forward error recovery is another error recovery policy to recover the errors. Roll-forward schemes are developed to increase the possibility that a given process completes within a given time. In that case, a couple of roll-forward schemes uses a spare processor for removing the rollback to save the time. At the same time, in time critical applications, redundancy is an important factor to consider because of cost, power, memory, and other factors. However, both schemes for roll-forward recovery with and without spare processor are discussed in this section.

Roll-forward recovery with dynamic replication checks (with spare processor)

The presented roll-forward recovery scheme uses dynamic replication checks to detect errors and is named RFR-RC (Roll-Forward Recovery with dynamic Replication Checks). This scheme is organized based on the isolated checkpoint intervals. For any isolated checkpoint intervals, a task is executed on two independent processors such as processor P1 and processor P2 as shown in Figure 11 [20]. In the presented scheme, at every checkpoint, the duplicated task records its state in the storage and the recorded state is forwarded to the checkpoint processor. Thereafter, at the end of the checkpoint interval, the checkpoint processor compares the two states from the processors. If the compared checkpoint states match with each other, the checkpoint will be committed and both the processors P1 and P2 continue their executions into the next checkpoint interval [20,21]. During the comparison, if any mismatch is detected, a validation step starts immediately. During the validation process, processors P1 and P2 continue their execution. At the same time, a spare processor is occupied to retry the last checkpoint interval using the previously committed checkpoint. Once the spare processor is ready with its process, the state is compared with the previous states of processors P1 and P2. The faulty processor among two processors such as P1 and P2 will be identified after this comparison. Then the identified faulty processor state will be made identical to that of the other processor. Now, both processors duplicating the task need to be in the correct state. As from the assumption [20] of single independent faults, a further validation process is not required.

Strengths

In the presented RFR-RC scheme, a spare processor is used to save time. With an extra processor, there is no need of rolling back to restore the system from error state. In RFR-RC, during the validation, the spare processor is used to identify the faulty processor and recovery action will be taken immediately. Appeared time overhead in RFR-RC scheme is decreased in comparison to the rollback scheme and RFR-BC scheme, as shown in Table 4.

Weaknesses

Because of using a spare processor to avoid the rollback, the cost is getting high. Memory overhead appeared in this technique is increased in comparison to the rollback recovery scheme.

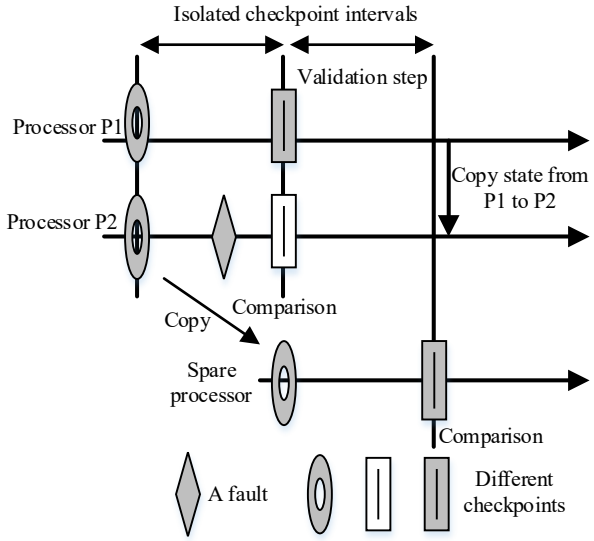

Figure 11. Roll-forward recovery in RFR-RC scheme [19,20].

Roll-forward recovery with behaviour-based checks (without spare processor)

In order to avoid the rollback, self-checks have been inserted to identify the faulty processors [20]. Such a self-detection methods are behaviour-based checks, such as control flow monitoring, detecting an illegal instruction, and memory protection. In [20,37], a new scheme has been proposed and implemented for roll-forward recovery named RFR-BC (Roll-Forward Recovery with Behavior based Checks). The proposed scheme uses a process pair approach to avoid the rollback to reduce the time. The intuitive idea presented in this scheme is, whenever an active task fails, the spare task becomes active to provide the necessary services [20]. The information sending through the active and spare task do not differ. However, information passing through the spare task need to be verified by the acceptance test before sending. Thereafter, the states of two processors (processor1 and processor 2) are verified at the end of a checkpoint interval to declare passing the test is committed, as shown in Figure 12.

Basically, acceptance test for sending the information validates a couple factors such as timing, coding, reasonableness, structural and diagnostic checks [20,38]. In the presented scheme, checkpointing is used for fault identification and roll-forward error

recovery. Whenever a faulty processor is located, then its state is made identical to the checkpoint state of the error-free processor. Because of this, both processors (processor1 and processor 2) will be in the correct state at the beginning of the next checkpoint interval. Figure 12 demonstrates the REF-BC scheme.

Strengths

RFR-BC scheme in roll-forward recovery does not need a spare processor as in RFR-RC to avoid rollback. In the RFR (Roll-Forward Recovery) schemes, the continuity of the executing program will be maintained so that the recovery delay will be removed [20,21]. The advantage of RFR-BC scheme is that time overhead is decreased in comparison to the rollback scheme, as shown in Table 4. It is also a more cost efficient solution compared to RFR-RC because of no spare processor.

Table 3. Results of the presented data error detection techniques from literature [1,7,12–17].

Error detection technique	Case studies used	Fault coverage (%)	Performance overhead (%)	Memory overhead (%)
EDDI	Insertion sort	99	113.90	200
	Quicksort	98.2	89.3	200
	Matrix mul.	99.2	111.1	200
	(Average)	**(98.8)**	**(104.7)**	**(200)**
ED^{4}I	Quicksort	96.4	110	164
	Matrix mul.	95.9	133	170
	Insertion sort	96.2	137	146
	(Average)	**(96.1)**	**(126.6)**	**(160)**
Software approach	Constant mod-ulus algorithm	100	244	362
CBD	Bubble sort	78.54	51	94
	Matrix mul.	71.53	57	109
	Quicksort	70.57	42	102
	(Average)	**(73.5)**	**(50)**	**(101.6)**
CPD	Differential equation solver	73.3	60	103
SEDSR	Bubble sort	95.01	112	127
	Matrix mul.	93.95	121	146
	Quicksort	95.59	104	131
	(Average)	**(94.85)**	**(112.3)**	**(134.6)**
Checking rules	Bubble sort	95.6	70	82
	Matrix mul.	96	82	89
	Dijkstra's	93.5	65	75
	(Average)	**(95)**	**(72.3)**	**(82)**
GA	Bubble sort	82	23	64
	Regression	80	24	57
	Quicksort	84	26	60
	(Average)	**(82)**	**(24.3)**	**(60.3)**
Shoestring	Vortex	92	12	31
	Crafty	75	24	48
	Gap	75	24.5	41
	(Average)	**(80.6)**	(20.16)	**(40)**

Table 4. Results of the presented error recovery techniques from literature [19– 21,36].

Method	Time overhead
Rollback recovery	31.1%
Roll-forward recovery (RFR-RC)	1.23%
Roll-forward recovery (RFR-BC)	2.08%

Weaknesses

In the RFR-BC, appointed self-check detection has an inaccurate error coverage and can't detect certain types of faults such as faults causing infinite looping. Time overhead with RFR- BC scheme is increased in comparison with the RFR-RC scheme for roll-forward recovery.

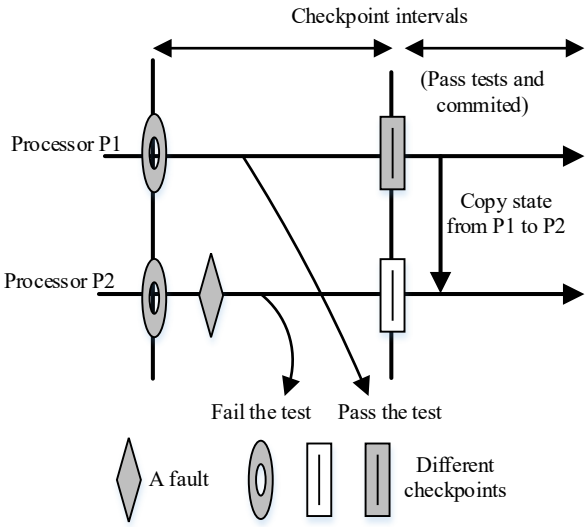

Figure 12. Roll-forward recovery in RFR-BC scheme [19,20].

Table 5. Strengths and weaknesses comparison of error detection methods.

Error detection technique	Strengths	Weaknesses
EDDI	The EDDI technique achieves high fault coverage by placing a comparison instruction after each MI and SI in the program.	Each of the original instruction is converted into three instructions, so performance and memory overhead is increased.
ED^{4}I	This technique achieves a high fault coverage when using the optimum value for *k*.	Good for either integers or floating point numbers, but not for both.
Software approach	Fault coverage achieved with this technique is very high because of duplicating the entire program.	More number of required instructions for duplication and comparison lead to increase in overhead.
CBD	Performance and memory overhead are decreased because they use less redundant instructions for duplication	This technique is a compiler and/or case study dependent and could just act as a full duplication technique.
CPD	Due to less number of instruc-tions required for duplication, performance and memory over-head is decreased.	In CPD, creating a data flow graph is much harder in assembly than C and C++.
SEDSR	In SEDSR, by placing a comparison instruction after writing to the classified final variables detect a lot of errors.	This technique is also a compiler and/or case study dependent and could just act as a full duplication.
Checking rules	The appeared performance and memory overhead in this technique are decreased in comparison to the EDDI, and ED^{4}I techniques.	Fault coverage achieved with this technique is reduced because of using less number of redundant instructions with the choice of checking rules.
GA	Because of selective vulnerable block duplication, the presented technique uses a less number of redundant instructions.	There is a possibility of undetected errors in the other normal blocks which lead to a reduction in fault coverage.
Shoestring	By duplicating and comparing only high-valued instructions, leads to decrease in overhead.	Fault coverage is reduced because of the possible undetected errors in the unduplicated instructions.

Table 6. Strengths and weaknesses comparison of error recovery methods.

Error recovery	Strengths	Weaknesses
Rollback error recovery	If the error is detected, the processor state is restored into error free state with out using spare processor.	Time overhead is the main drawback of the rollback error recovery, because of its rollback.
RFR-RC	Time overhead in RFR-RC scheme is decreased.	Usage of a spare processor to avoid the rollback, the cost is getting high.
RFR-BC	RFR-BC scheme in roll-forward recovery does not need a spare processor as in RFR-RC to avoid rollback.	Self-check detection has an inaccurate error coverage and can't detect certain types of faults.

5. Future Work

The strengths and weaknesses given in this paper for each technique were determined theoretically, by analyzing the technique and determining what data flow errors they detect, which they neglect and which overhead the techniques introduce.

To guide researchers and embedded systems engineers, we will perform an experimental comparison of the mentioned techniques. This experimental comparison will allow to evaluate the techniques on the same base: same hardware, same case studies, and same fault injection process. We'll perform this comparison both for data flow detection techniques and data flow recovery techniques. The outcome of the experimental comparison will allow other applicants of the techniques to quickly determine which existing technique is the best, in general or for their application.

Finally, we'll use the gathered data from the experimental comparison to develop a technique that can detect and recover from data flow errors, without introducing abnormal overhead.

6. Conclusions

This review paper lists and reviews various data flow error detection and recovery techniques existing in literature in the field of embedded systems. Each of the considered data error detection and correction technique has been discussed in terms of strengths and weaknesses. The discussion is summarized in Tables 5 and 6.

After thoroughly reviewing the strengths and weaknesses of error detection techniques, we have found that some of the techniques such as *ED^4I, EDDI and Software approach* are good for fault coverage but come with high overhead both in memory and performances. On the other hand, some other techniques such as *CBD, CPD, GA and Shoestring* are good for overhead but come with a reduction in fault coverage. At the same time, there exist a couple of techniques such as *SEDSR and Checking rules* which are good for fault coverage with satisfactory overhead.

As error recovery is concerned, based on the identified strengths and weaknesses from the methodology, we have found that *checkpointing technique for rollback error recovery* is better if memory overhead is the main concern. *Checkpointing technique for roll-forward error recovery schemes* are better if time overhead is the main concern.

Conflict of Interest

The authors declare no conflict of interest.

In-Vehicle Infotainment

ABSTRACT

The paper presents a prototype Head Up Display interface which acts as an interactive infotainment system for rear seat younger passengers, aiming to minimize driver distraction. The interface employs an Augmented Reality medium that utilizes the external scenery as a background for two platform games explicitly designed for this system. Additionally, the system provides AR embedded information on major en route landmarks, navigational data, and local news amongst other infotainment options. The proposed design is applied in the peripheral windscreens with the use of a novel Head-Up Display system. The system evaluation by twenty users offered promising results discussed in the paper.

1. Introduction

Head-Up Display (HUD) interfaces are currently emerging as an increasingly viable alternative to traditional Head-Down Displays (HDD). HUDs present fresh opportunities for the presentation of information using symbolic and/or alphanumeric representation. By occupying larger estate directly on the driver's field of view, they can provide crucial information swiftly and without distracting the driver. As such they can enhance significantly a driver's information-retrieval capacity and response times in near collision situations [1,2,3].

Prototype HUD design interfaces and devices have significantly mitigated this issue of the driver's attention being diverted from his/her field of view, as shown in previous studies [3,4 & 5]. Yet, the requirements of the passengers' user group have not been adequately explored. In particular, rear seat passengers, specifically children, can seek to attract their parents' attention during long distance trips or whilst commuting. Such actions have a detrimental impact on the driver's attention, and could potentially lead to an accident. A UK survey that collected 2000 British parents' opinion about their children's behaviour whilst they were driving reported findings of around 62% of the parents feeling more at ease without their children in the car, 43% feeling tense and irritated with their children, and about 55% admitting that they were prone to losing their temper while driving long distance [6]. Furthermore, some parents used mirrors, not to check external road conditions, but to glance at and check their children's behaviour in the back seat.

This action could lead to hazardous driving and could potentially cause traffic collisions [7,8]. In light of the aforementioned facts and observations this project aims to collate and explore the current state of technology in infotainment car devices, as a base for launching the design and evaluation of the Human-Computer Interaction (HCI) for applications to rear-side HUD displays. The latter would enhance passenger's entertainment in the vehicular environment and provide visual and auditory information regarding the external environment. The utilization of HUD draws from our previous experiments with collision avoidance interfaces that achieved significant results towards the reduction of the collision probability in adverse weather conditions [4,5,9].

Overall, the paper is structured as follows: The paper introduces the target group and current driver distraction issues. The above form the framework requirements used for the development of the proposed HUD interface. In turn the paper presents a description of the proposed system and related design considerations. The evaluation process and results of twenty users are discussed. Finally, conclusions are summarized and a future plan of work is presented.

2. Current In-Vehicle Distraction Issues and Solutions

Previous studies have observed that long-distance journeys in a car, constrain family members in the confined vehicle space for extensive periods of time. Typically, the adult members of the family are trying to keep the younger passengers occupied through various activities such as chatting, singing songs or playing on mobile phones [7]. Adults and children, however, frequently have different expectations during travel time, with children being inclined to expect the time to be enjoyable and playful, whilst adults prefer it to be relaxing and quiet [7]. Children usually start becoming bored and losing interest after about 30 minutes of long distance driving, resulting in negative feelings of parents as noted above, with 60% of parents dealing with these situations by lying about the journey time and 70% choosing to buy food and drinks in an attempt to divert attention and thus resolve the situation [6].

Despite of these, recent studies also demonstrate that an increasing number of families with dependent children choose to take their children to school by car or to travel long distances with the family [7,8].

Evidently the in-vehicle interactions between the passengers, particularly the younger ones, can distract a driver's attention and increase dramatically the collision probability. As such, the following section will present a potential solution to this issue that could be mutually beneficial for both the driver and passengers.

A number of electronics and automotive manufacturers have made tentative plans and experiments in order to maintain the rear passengers occupied during long distance traveling or commuting. Early examples include "Backseat Playground" designed in 2009 by Mobility Studio in Sweden. The game aims to improve the travel experience for the passengers. The most significant feature of the game was to combine the game's sounds with the actual travel location sounds, to enhance the experience of the game, and many participants pointed out that this feature was so vivid that it made them confuse the virtual game with the actual geographical location. Hardware including a pocket PC, microphone, magnetometer, gyroscopes, headphones, laptop, GPS and wireless LAN were used to achieve this feature [10].

The game utilizes landmarks and transforms then into an imaginary land occupied by virtual creatures and treasures. The system utilizes a gaming device which operates by pointing it towards road objects as they pass by. The players can play individually or collaborate with other players in meeting road traffic. Although it has many mini stories, the whole game is more suitable for travelling for a short time, with an increase in distance travelled leading to the story becoming more unclear and potentially confusing [10].

In 2011 "nICE" was designed by a German University aiming to increase the communication experience during travel time. This application was specially designed for BMW; in 2008 BMW already had some in-car entertainments devices, such as DVD, TV and music. This game uses headphones (for the driver who can decide to join in or not) and two touch pads (for front and back seat passengers or children) to play and which can link with each other with a wireless connection. The game is a picture puzzle game; there are pictures in the application album, and the passenger can randomly choose one and begin the game. Each picture has a missing part and the player needs to solve the mini puzzle game to earn these missing parts, for instance, a music quiz, drawing pictures and a labyrinth game. Passengers can choose particular mini game which they are good at, and win the game as a team [11].

In 2013, "Mileys" was developed as an in-vehicle game designed particularly for families traveling long-distance journeys [7]. The aim of the game was to educationally enrich the driving time by providing geographical and location orientated information. The game employs AR technology, GPS, radar and mobile phone interaction in order for users to present and access the provided information. In the game, parents can see the location of the character Miley, which they can position de novo at a location or find Mileys already planted or dropped by other people. At the same time, children use a radar device to search different positions in order to find the exact location and in the process, talk to their parents. When the family reach the location, children can use the phones to pick up Miley and a secondary objective is to keep the character's health high with safe and steady driving. Once/if the health runs out, the children will get their final score and the character Miley will be dropped and wait for the next player to pick it [7].

3. Head-Up Display vs Head-Down Display

The HUD systems typically comprise a projection unit embedded on the vehicle dashboard. The projected image is in turn inverted with a set of mirrors directly positioned in front of the projector, and reflected on the windshield area. The area of the windscreen that receives the projection is covered with a transparent surface, namely the combiner, which enables the correct depiction of the projected colours and shapes. Depending on the system calibration, the image can be superimposed on the environment, seemingly appearing at approximately 1.5m to 2.5m ahead of the windscreen [12, 13]. This is deemed as an ideal projection distance in order to avoid the cognitive capture effect which forces the human eye to focus between two different layers, that in turn results in degradation of human attention and performance [14,15]. Evidently, the HUD systems adhering to the aforementioned design requirements can improve significantly the driver's response times in accident situations [1,2, 9, 13,15].

In contrast the information depicted on the vehicle's dashboard is known as Head-Down Display (HDD). The HDD by default, forces the user to take their eyes from the road, and focus momentarily on the lower section of the vehicle (dashboard) which accommodates multiple infotainment displays [15,16,17,18]. A plethora of studies have analysed the drivers' cognitive load in different scenarios involving vehicle instrumentation, navigation systems, radio, CD and mobile phones amongst other devices [16,17,18,19]. The conclusions of such studies suggest a high collision probability whilst the driver

operates any of the aforementioned in tandem to the main driving task [1,2,4,20, 21].

In our case, we opted for a HUD system in order to enable the younger passengers to look out of the window and experience the route. The HUD in this case can offer an Augmented Reality gaming environment that could mix the Computer-Generated Image (CGI) game characters with the real environment and create different gameplay experience on each drive [22, 23]. Additionally, the HUD offers the capability to project succinct educational information regarding the landmarks and areas viewed during the car-travel. The software and hardware system requirements are presented analytically on the following sections.

4. Proposed System Solution

Significant attempts to enhance the rear passengers commuting experience via in vehicle game solutions have been described in section 2, however, the issue of passenger infotainment in a vehicular environment remains largely unsolved [24, 25]. Previously suggested solutions and research projects have managed to identify various interactions and patterns that could possibly occupy the rear passengers, they were, however, not offering a holistic approach that could adapt to different ages and interest groups.

The proposed system aims to offer a combination of activities for the rear passengers in order to avoid in-vehicle distractions that could affect driver's performance and concentration. The system is designed to facilitate both educational and entertainment activities with particular focus on the younger passenger age group.

4.1. Software requirements:

The HUD system is comprised of a generic interface that allows the rear-passengers to access information in real-time through the navigation GPS. The navigation type of information can vary from maps and navigation, distance covered, estimated time of arrival and highlighted on-route landmarks (i.e monuments, churches, castles etc.). The latter can be accessed in real-time, through online connectivity.

The landmark related specifics can be superimposed through the side HUD to the landmarks approached en route providing succinct information. This aims to keep the rear passengers occupied throughout the travelling time whilst educating them with regards to the surrounding environment. Additionally, the system offers an overview of the vehicle functions such as speed, consumption, revs amongst other, that might be of interest to the passengers.

The second arm of the interface offers the entertainment suite which entails games, movies, internet, music and audiobooks. The audio related data can be provided by individualized headsets so as to avoid further in vehicle sound distractions. On the entertainment section we have primarily targeted the younger audience with a set of onboard games that could be augmented in the external window scenery. As such we have developed (a) a platform flying game and (b) a historic Augmented Reality (AR) game.

Fig. 1: Prototype HUD interface and offered activities.

In the first game the user commands a superhero flying over the scenery whilst avoiding and shooting back a flying villain. As the scenery constantly changes both rival characters' battle in different terrains and weather conditions (figure 2).

The second game aims to entice the upper age limit of the passengers as it utilizes the external scenery and landmarks as temporary objects for the game. The game employs the external scenery of a real castle (i.e. Stirling Castle) for the duration that the user can see the castle through his/her window. In turn the user has to complete a set of challenges, such as assaulting the castle with the use of a 3D catapult. If the catapult shots are successful, the user gathers some points and continues to the next landmark and task.

This can obviously be altered depending on the country, landmarks and activities that the user wishes to access and interact with. In this paper we examine the overall user experience in regards to the HUD interface and the first game.

4.2. Hardware requirements:

The projected interface is presented on a rear passenger side window HUD system. The selection of the particular surface was chosen as it is in close proximity to the passengers and can utilise the external environment and scenery for augmented reality and geotagged application. Also, the side windows on any vehicle offer a large area for any type of data projection without requiring additional monitors. The utilisation of this highly neglected surface within the vehicle additionally offers an interactive projection field within arm's distance.

In the Virtual Reality Driving Simulation laboratory (VRSD Lab) a dedicated High Definition (HD) mini projector was employed to project the HUD interface and context on a custom transparent film positioned on the top of the glass window. The mini projector superimposes both the external view and the HUD interface (game and generic interface) in a side window of a full scale vehicle as presented in Figure 2. This method offered a realistic projection of the HUD.

Due to cost limitations and time constrains, a suitable micro projector was not a viable option at this stage. An alternative system would have been the transparent screen by Samsung [26],

however for the same reasons as stated above it was not feasible to use it for this experiment.

Fig. 2: The figure presents the screenshot of the HUD interface and projected Augmented Reality en route to Stirling Castle in Scotland.

Prior to selecting the particular projection method alternative emerging technologies have been investigated. The Virtual Reality (VR) option was a simple and easier option yet it was isolating and depriving the user from experiencing the environment view and the route.

Furthermore, the bulky Head Mounted Display (HMD) is not ideal for younger users as they might suffer significant neck injuries in an abrupt braking situation. The more advanced Augmented Reality (AR) option of Microsoft HoloLens was also excluded for the same concerns related to cost and safety of the system in a vehicular environment by younger passengers.

A second side HD projector was mounted externally on the ceiling. The latter projector was projecting a video recorded footage from a 45 minutes' drive nearby the Stirling Castle. The interface was designed to provide geospatial information related to the en route landmarks.

Notably the Stirling Caste is visible on the background for the duration of each trial whilst the user can operate the interface. The interface provides related educational and historic information, local news and weather amongst other information.

The overall simulation is run by a custom server PC in a Cave Automatic Virtual Environment (CAVE) which uses five HD 3D projectors that create a full surround driving environment surrounding a real-life Mercedes A Class vehicle as presented in the Figure 3 & 4 below.

The vehicle has rebuilt and rewired steering wheel and pedals compatible with the Unity3D game engine. The vehicle has also a central vibration system which enhances the motion feeling. A 5.1 surround audio creates the vehicle and environment sounds. The internal mini projector provides the required audio feedback for the HUD interface and the related infotainment activities.

The physical interaction with the HUD interface is either through gesture recognition software or typical game pad device. The first is utilizing a Leap Motion device and the second an XBOX controller described succinctly below.

4.2.1 Leap Motion Interaction:

Prior to the main user trials, the Leap Motion device was tested in a desktop PC environment and received positive feedback in preliminary trials. The particular device was chosen as an ideal system to interact with the provided interface as it was not involving any handheld devices [27].

In the main trials the Leap Motion was positioned with an adhesive tape on the door inside plastic section, underneath the car window in close proximity to the user. Although the system performed well the users' experienced arm fatigue as their right hand was operating the system without any support. This was in contrast to the desktop environment that offered the table as arm rest for the focus group users.

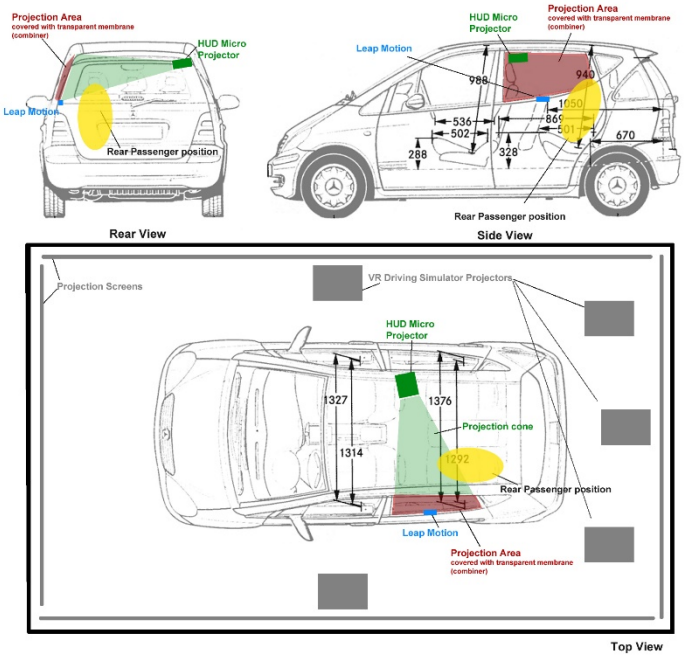

Fig. 3: Explanatory design of the HUD system and the VR Driving Simulator environment.

The game developed for the Leap Motion involved a cartoon style battle between a hero and a villain as depicted in Figure 2. The hero, controlled by the user was operated by pointing with one finger and moving the flying hero in four directions (up, down, forwards and backwards). The aim of the game was to fly the hero and avoid the fireball projectile shot by the villain. As the real environment background was changing en route their battle was taking place in different real locations. To activate a different app of the bottom menu the user had to point and push the button choice (without touching the window glass). The particular gestures were simple and efficient [28,29] however the duration of the actions and the position of the user within the vehicle, resulted in users' arm fatigue.

The game was developed in Unity3D game engine, exclusively for the evaluation of the proposed HUD system.

4.2.2 XBOX controller Interaction:

The typical XBOX controller was chosen as an alternative to the Leap Motion. The handheld controller aimed to counteract the fatigue issues and offer a familiar and faster interaction medium. The controller's drawback was mainly the handheld nature of the system. This could be a potential issue in an abrupt braking as the inertia of the device could result in injuries of the passengers.

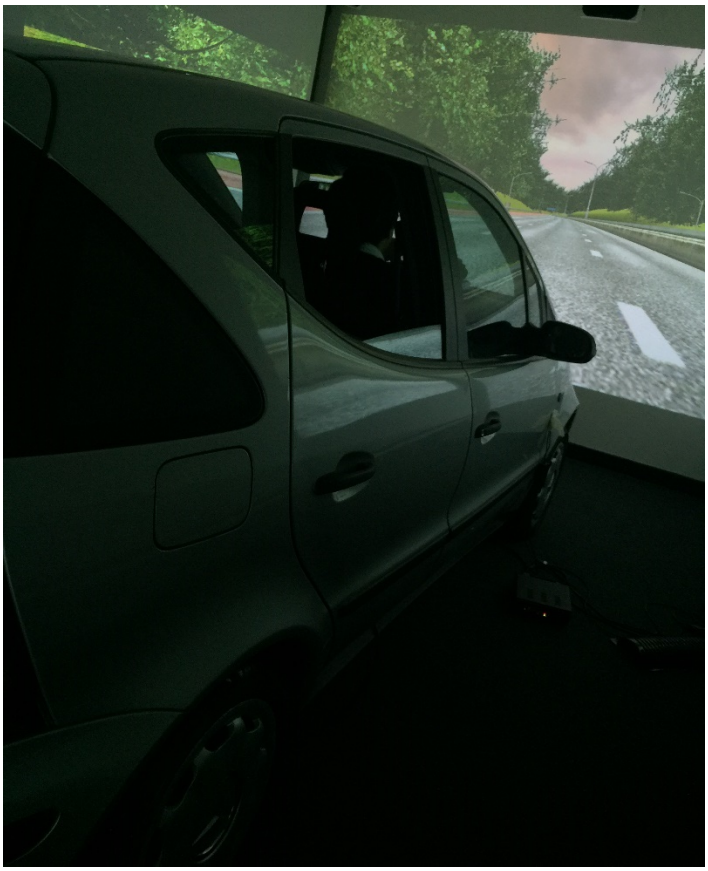

Fig. 4: Screenshot of the GCU VR Driving Simulator in action.

5. System Considerations

Adhering to the situations noted above, the proposed in-vehicle games should be able to entice the users to play for the duration of long distance runs whilst providing interesting information for the surroundings [4]. Due to the nature of these games, the in-vehicle activities should abide to a number of considerations in order to have the expected positive results according to Broy's research [10].

The preservation of driving safety, is a primary consideration, as the risk of the game distracting the driver by sound or virtual effects should be minimized.

Secondly, in-car games are not like traditional games or computer games, as they require a different playing environment, and should function steadily and effectively in a vehicular environment. As such the particular games should be simple and forgiving to minor movements that might occur due to road imperfections. Additionally, by utilizing the Augmented Reality (AR) provision of a HUD they could adapt to the external environment and create interesting and memorable game experiences [10, 11, 24, 30]. Interestingly this was highlighted by numerous remarks of our users in the simulation environment. Consequently, by utilizing the external environment the games do not require a full 3D gaming background in order to operate.

Additionally, motion sickness should also be taken into account, as some passengers feel uncomfortable when they read during travel, so it may be more comfortable and effective to use pictures and/or sound to present the information [9, 10]. Furthermore, Brunnberg provided evidence to suggest that, due to high speed travel, the view from the rear seat will pass by very quickly. It is therefore difficult for the device to identify and present the information, and this may be one of the most difficult technological challenges to be faced and overcome during the design process [9]. It should also be noted that passengers of different age groups (young children, teenagers, parents) have varying levels of ability in terms of reading and understanding; hence, the game's level of difficulty needs to be carefully considered [10].

Based on the aforementioned rear-passenger population differences the provided geospatial information should also be targeting the interest of the different age groups. As such we deemed essential to present local and international news as well as different educational data in different levels of detail and complexity for different ages. Additionally, the various movies or games which the HUD can project have been optimised for different age audiences. As such for the toddlers we incorporated simple platform games, popular kids' movies and indicative, simplified information for the external environment. For primary school pupils and teenagers, we introduced games and movies adhering to their preferences and age according to current top ten lists from relevant magazines and online publications. For adult passengers, we provided a collection of different online newspapers, news channels, weather channels mind games and contemporary movies. However, these were utilized as demonstration material of the system in a simulation environment. On a real-life commercial application, we would envisage the use of online applications to feed constantly the infotainment database and a small capacity Hard Disk Drive (HDD) that could maintain a selection of favourite movies and audio playlists.

Based on the aforementioned considerations, some in-car games have already been designed for short-distance drives situation as previously discussed. "Backseat Playground", "nICE" and "Mileys" use special equipment, phones or touchpads to play the games [7]. Similar studies have been conducted, in 2011 and 2012, by Toyota and General Motors (GM) respectively, utilizing enhanced versions of their backseat entertainment systems. Notably, GM used motion and optical sensor technology to transfer the rear seat window into a gesture touch panel [11,12,24].

However, there has been limited - if any at all - employment of HUD and gesture recognition technology, which could offer a more immersive and subtle way of interaction for the users. The ultimate purpose of this combination is to offer attention seeking infotainment to the passengers so as to reduce the level of distraction for the driver. All the current systems mentioned above have their own features and utilize their interfaces with multiple types of equipment, but without gesture recognition and typical console controls. Hence, the above, highlights the need for a new passenger infotainment and communication system that could alleviate the level of distraction of the driver.

6. Evaluation & Results

The evaluation process followed a threefold approach. Prior to commencing the main user trials we had to identify the nature of games that could be developed, projected and played in long duration within a vehicle environment. As mentioned above the idiosyncratic characteristics of these games offer new opportunities of Augmented Reality (AR) gameplay yet create a number of questions related with the type of games that could maintain passengers' attention and avoid motion sickness effect due to the vehicle's movement.

6.1. Focus Group

For this reason, a focus group of five users (3 male, 2 female) age 30 to 40 years of age was formed to test different popular games, aiming to identify the most suitable category for the vehicular environment.

The categories of games tested by a focus group prior to developing our own HUD games highlighted the difficulty of playing games that move in different directions to the vehicle's motion. The games tested were in categories of first person, action adventure, platform and table game.

The platform games following the vehicle's direction were perceived as easier to play without creating any motion sickness effect. In contrast, single person games that require from the user to move in 3D dimensions were confusing and tiring for the focus group users.

6.2. Main User Evaluation

The main evaluation was performed by 20 users varying from 4 to 13 years of age. The users tested the overall system. This paper focuses primarily on the game section of the overall interface evaluation. Two custom platform games were tested. Both games used the Leap Motion hardware in order to create gesture recognition interactions.

The results of the evaluation trials in this age group were promising and yielded a great deal of positive and useful feedback as presented in Figure 5. The first AR game received consistent approval and positive reactions from the participants. Yet certain issues were also pointed out, mainly regarding the gesture recognition system which required significant stamina from the users in order to operate it. This issue arose primarily from the demanding task of maintaining the arm lifted in order to operate the game on the side window. As an alternative, the system can be operated with a console wireless controller in order to avoid arm fatigue.

Notably, 90% of the participants rated the game highly. Furthermore, analyzing all the comments, gesture control is the focal point, with 80% of the participants enjoying the function of gesture control in the game, and 50% of those with no prior gesture control experience describing the gestures as hard initially, but acceptable and appropriate after a period of familiarization.

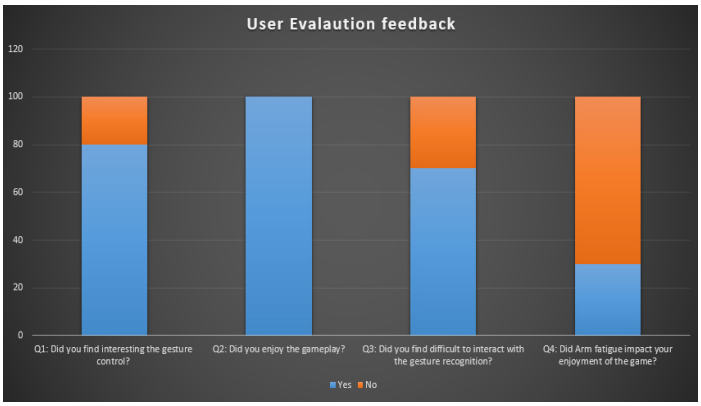

Figure 5: User evaluation feedback on main four usability questions.

Interestingly, despite expecting users to identify arm fatigue as the main problem caused by the hand gestures, the overwhelming response from the users was that arm fatigue did not significantly affect the participants' enjoyment of the game. 70% of the participants did not consider arm fatigue as an influencing factor in their enjoyment of the game. This result is not only contrary to the initial expectation but is also in contrast to the result of the test with the younger age group.

Although the participants did not think that arm fatigue affected their enjoyment in the game, they suggested that a pause button could be useful in extensive duration game-play. Finally, the HUD system and AR game managed to captivate the audience for the duration of the first level (10 minutes per level) and in some cases the users continued in the subsequent game-levels, achieving the 100% target for occupying the passengers for the duration of a typical long distance commute or trip [11].

6.3. Secondary User Evaluation and Driving Patterns

The aforementioned result had evidently a direct benefit to the driver's attention throughout the simulations. An indicative driver pattern driving the simulator with a toddler at the rear seat with and without the passenger HUD can be observed in Figure 6. This secondary trial aimed to identify the emerging driving patterns of the parent drivers during a short distance commute.

The simulation followed our previous work and challenged the driver to respond either by braking abruptly or performing collision avoidance maneuver, in a number of potential collision situations [1,2,4]. The simulation tested the parent/driver response times and collision occurrences with and without the use of the passenger HUD interface.

The simulation environment was a 3D photorealistic representation of an existing motorway section (M8) between Glasgow and Edinburgh. This smaller user trial involved 5 parents and their children. The driving patterns emerged from the five simulations which presented distinct similarities. The most interesting was that the use of the passenger HUD prevented any collisions as the driver was not concerned with the activities of the rear passengers.

In turn the children were preoccupied with the HUD interface for the duration of the simulation and were particularly interested in the custom platform games. In contrast the absence of the HUD activities on the simulation without the system, challenged the patience of the younger passengers which in turn distracted their driver/parent. However, this third part of the user trials was constrained by a number of factors.

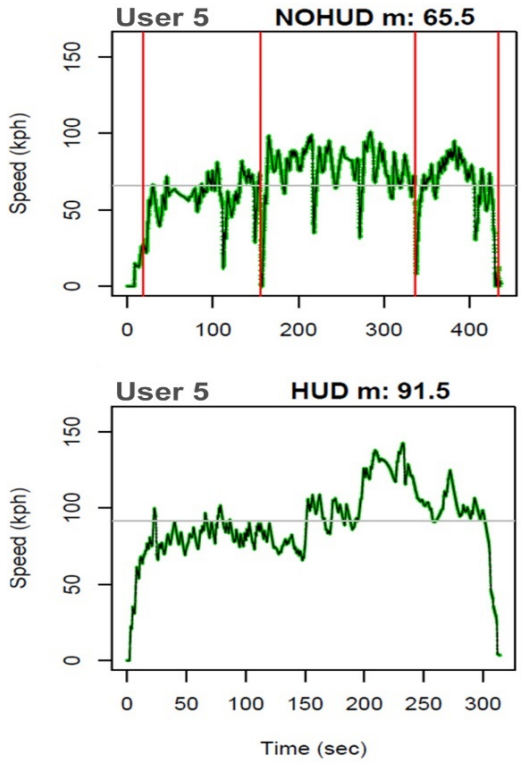

Figure 6: Indicative driving patterns recorded with and without the HUD interface. The Red vertical lines present the collisions occurred.

Primarily it was a difficult task to obtain both parents and toddler participants to run the simulation. Secondly it is very difficult to recreate in a short time the effect of boredom that can frustrate the younger age passengers. Furthermore, the VR Driving Simulator itself kept the young users occupied mitigating any boredom factor for substantially longer than in a typical everyday commuting environment.

Future multiple user trials will be required with the same users in order to create a familiarity with the VR Driving Simulator in order to avoid the third factor that affects the younger users' routine behaviour.

Additionally, users that are immune to motion sickness could potentially drive the simulator for longer trial times (i.e. two hours driving) for obtaining more accurate data. Acknowledging these three limitations, the HUD managed to maintain the rear seat vehicle occupants' attention and keep the parent-driver preoccupied with the driving task.

7. Conclusions & Future Work

This paper presented the design consideration, development and evaluation of a prototype Human Computer Interaction design for automotive HUD designed to entertain and inform the young passengers in the rear seat younger passengers. To facilitate an appraisal of the system, the experiment hosted two different games that utilized gesture recognition and typical console controls.

The results indicate that the participants were satisfied with the game's performance, with 80% of the participants having enjoyed the function of gesture control in the game, and half of the players who had no gesture control experience thinking that the gestures were hard at the start, but were acceptable and enjoyable after a period of familiarization. The problem of arm fatigue caused by hand gestures was highlighted in the experiments, even if not considered severe by the participants.

Yet, despite the positive outcomes of the presented work, it is apparent that the games need to be customized for the particular environment and take into consideration the duration of the trips, counteract the road-surface disturbances and adapt to the external weather conditions. Our tentative plan for future work entails the update of the games' and HUD interface's functionality in order to comply with the aforementioned observations and results. Consequently, further testing of the updated HUD system will be required in order to determine the optimal system parameters that will allow the system to facilitate lengthy interactions with minimal fatigue.

The motion sickness experienced by some users was not evaluated in this particular trial as this was not the aim of the particular experiment. However, we are interested to identify the motion sickness triggering mechanisms of this side window HUD interface in future trials explicitly designed to quantify this issue. In turn we plan to revise our interface in order to mitigate and reduce this side effect.

Additionally, we plan to introduce an interface indication for short breaks between HUD applications. This potentially will provide some time for the user's body to recover from the tilted position.

Finally, longer simulations and trials might be required in order to determine the passenger HUD's efficiency in quantitative trial with simulations of real life scenario.

ABSTRACT

The presence of microaneurysms(MAs) in retinal images is a pathognomonic sign of Diabetic Retinopathy (DR). This is one of the leading causes of blindness in the working population worldwide. This paper introduces a novel algorithm that combines information from spatial views of the retina for the purpose of MA detection. Most published research in the literature has addressed the problem of detecting MAs from single retinal images. This work proposes the incorporation of information from two spatial views during the detection process. The algorithm is evaluated using 160 images from 40 patients seen as part of a UK diabetic eye screening programme which contained 207 MAs. An improvement in performance compared to detection from an algorithm that relies on a single image is shown as an increase of 2% ROC score, hence demonstrating the potential of this method.

1. Introduction

This paper is an extension of the algorithm originally presented in the International Conference on Signal Processing Theory and Applications (IPTA 2016) [1]. This work adds a combination of spatial information from two retinal images for microaneurysm (MA) detection. Diabetic Retinopathy (DR) is one of the most common causes of blindness among working-age adults [2]. Signs of DR can be detected from images of the retina which are captured using a fundus camera. Microaneurysms (MAs) are one of the early signs of DR. Several algorithms for automated MA detection from single 45 degree fundus images have been proposed in the literature. However, in many Diabetic Eye Screening Programmes, including the UK National Health Service Diabetic Eye Screening Programme (NHS DESP) [3], at least 2 views of the retina are captured including both optic disc centered view and the fovea centered images (Figure 1). These images overlap together and thus have common MAs that appear in both views (with variability in contrast). Despite the availability of both views, the algorithms that have been proposed have only taken into account the information contained in a single image. In this paper an increase in detection accuracy is achieved by fusing the information from two views of the retina.

Algorithms reported in the literature lie broadly in two categories: supervised and unsupervised techniques. Supervised techniques make use of a classifier to reduce the number of false detections. This classifier requires training on an additional training set in order to generate a classification model. Unsupervised methods do not require a classifier and hence no training step is needed.

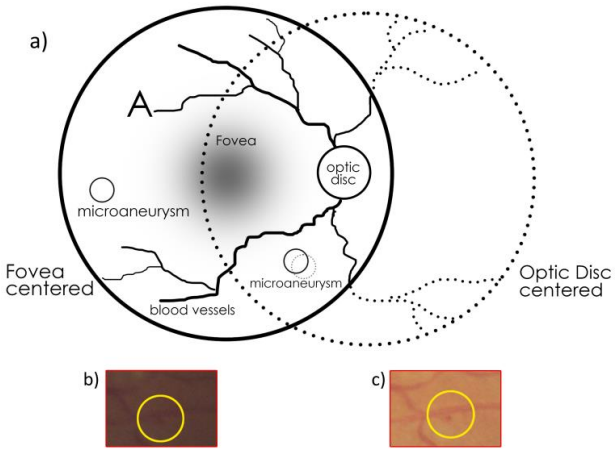

Figure 1. a) A conceptual diagram of the 2 spatial views of the retina (optic disc and fovea centered). The patches in b) and c) demonstrate how the same microaneurysm in different views of the retina can have a varying level of contrast.

The majority of the proposed methods in the literature fall under the supervised category. Most of the algorithms consist of three main stages: 1) Preprocessing 2) MA Candidate Detection and 3) Classification. The preprocessing phase corrects the image

[*]S.A. Barman, Kingston University, UK | E-mail: s.barman@kingston.ac.uk

with respect to non-uniform illumination and enhances MA contrast. MA Candidate Detection detects an initial set of candidates that are suspected to be MAs. While it is possible to stop here and report the detected results, a third phase is usually included in the algorithm to reduce the amount of false positives. This is the candidate classification phase and it classifies the detected candidates from phase 2 as either true or spurious.

A variety of classification techniques have been reported in the literature such as Linear Discriminant Analysis (LDA) [4] K-Nearest Neighbours (KNN) [5]–[8], Artificial Neural Networks [9], [10], Naive Bayes [11] and Logistic Regression [12]. There are a number of unsupervised methods that do not rely on a classifier include [13]–[16]. The obvious advantage of an unsupervised method is that they do not require a training phase. Some initial candidate detection methods that have been proposed are Gaussian filters [4]–[6] or their variants [8], [17], [18], simple thresholding [15], [16], [19], Moat operator [20], double ring filter [9], mixture model-based clustering [21] 1D scan lines [13], [14], extended minima transform [11], [22], Hessian matrix Eigenvalues [7], [23], Frangi-based filters [24] and hit-or-miss transform [10].

All the aforementioned methods were based on detection from a single colour image. Even though extra information may be available from another view of the retina, these algorithms are not designed to incorporate this extra information. A few methods have addressed the problem of detecting or measuring change from multiple images for the purpose of disease identification. Conor [25] performed vessel segmentation on a series of fundus images and measured both vessel tortuosity and width in these images. This was done in order to find a correlation between these measures and some signs including Diabetic Retinopathy. Arpenik [26] used fractal analysis to distinguish between normal and abnormal vascular structures in a human retina. Patterson [27] developed a statistical approach for quantifying change in the optic nerve head topography using a Heidelberg Retinal Tomograph (HRT). This was done for measuring disease progression in glaucoma patients. Artes [28] reported on the temporal relationship between visual field and optic disc changes in glaucoma patients. Bursell [29] investigated the difference in blood flow changes between insulin-dependent diabetes mellitus (IDDM) patients compared to healthy patients in video fluorescein angiography. Narasimha [30] used longitudinal change analysis to detect non-vascular anomalies such as exudates and microaneurysms. A Bayesian classifier is used to detect changes in image colour. A "redness" increase indicates the appearance of microaneurysms. Similarly, an increase in white or yellow indicates the appearance of exudates. While the problem of analysing "change" and "progression" of disease has been studied in the literature, to the best of our knowledge, the combination of a spatial pair of retinal images for the improvement of detection of MAs has not yet been explored.

The objectives of the present work are: 1) To present a novel method for combining information from two views of the retina (optic disc centered and fovea centered) and 2) Evaluate this method using a dataset of spatial image pairs. Following this introductory section, the methodology of the proposed method will be explained. Section 3 will discuss the details of the dataset and the methods employed for evaluating the proposed method. Results will be presented and discussed in Section 4. Final remarks and conclusions will be presented in Section 5.

2. Methodology

2.1. Method Overview

Figure 2 illustrates the overview of the proposed method. A way to compare MA candidate detection using the combined image versus the 2 singular images from the same patient was needed. A previous method [1] was used for the detection of candidates and measuring the probability of each candidate being true or spurious. The method was explained in detail in [1] and will be summarised in the following paragraph.

The previous method worked on the detection of microaneurysms from a single colour fundus image. The method was based on 3 stages: Preprocessing, MA candidate detection and classification. In the preprocessing phases, noise removal was performed and the image was corrected for non-uniform illumination by subtracting it from an estimate of the background. Salt and pepper noise was also removed during this stage. The vessel structure was removed from the image since vessel cross sections usually cause many false positive candidate detections. In the MA candidate detection phase a Gaussian filter response was thresholded in order to receive a set of potential candidates. Each candidate was region grown in order to enhance the shape of the candidates (to match the original shape in the image). Finally, during the classification stage, each region grown candidate was assigned a probability p between 0 and 1 representing the classifier's confidence in it being a true candidate or not. Each probability p can be thresholded at an operating point α to produce t such that:

$$t = \begin{cases} 1 \text{ if } p > \alpha \\ 0 \text{ otherwise} \end{cases}$$

Where $t = 1$ means that the corresponding candidate will be classified as true and $t = 0$ means it will be classified as spurious and removed from the candidates set.

The previous method has been adapted to work on 2 images of different spatial views. As shown in Figure 2, the 2 images are run through the algorithm as normal. This produces a set of 2 scores ($scores^{(1)}$ and $scores^{(2)}$). The intention is to combine these 2 scores together. However, before fusing the scores a way to find correspondences between candidates is needed. Therefore the images need to be aligned first (Image Registration) and then finding a match between corresponding candidates is needed (Candidates Matching). Each of the matched candidate's scores can then be combined to produce a single set of scores for both images. This combination should increase the confidence in some true MA candidates, and will hence improve the final algorithm after the final scores are thresholded with an operating point α.

In the following sections the Image Registration, Candidates, Matching and Fusion of Scores stages are described in greater detail.

2.2. Image Registration

Image registration is the process of aligning two images so that their corresponding pixels lie in the same space. One image is considered to be the *reference image* and the other image (known as the *moving image*) is transformed to be aligned to the reference image. A global transformation model was used which means that a single transformation was applied across the entire moving image. This has the advantage of simplicity and efficiency, but may not be as accurate as localised registration techniques. Since the goal of this paper was to introduce a proof of concept with regards to combining spatial information during microaneurysm detection, the accuracy achieved was sufficient for this purpose. More accurate registration techniques will be investigated in future work.

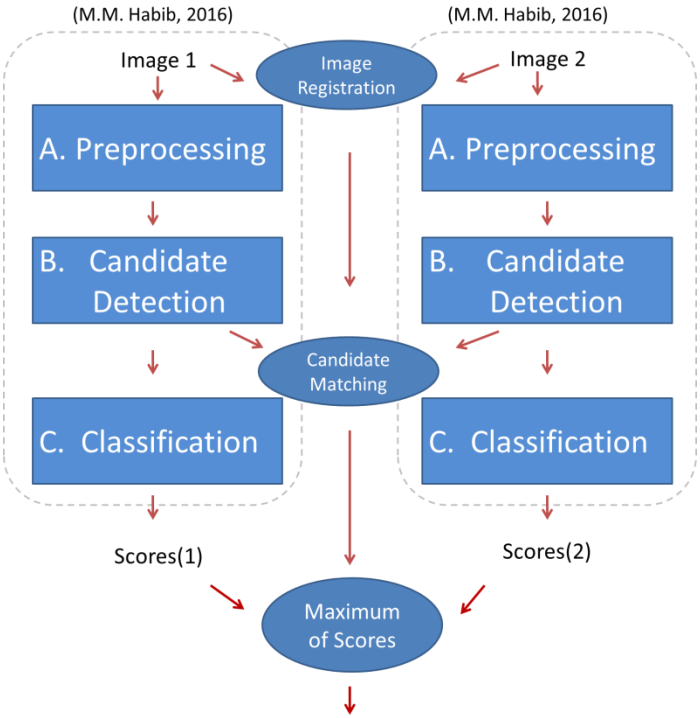

Figure 2. An overview of the proposed methodology.

A manual registration technique was employed where corresponding 'control points' were selected from each image. These control points were used to solve the global transformation model equations and find the transformation parameters (Figure 3). Corresponding points were annotated in each pair of images (as specified by Table 1).

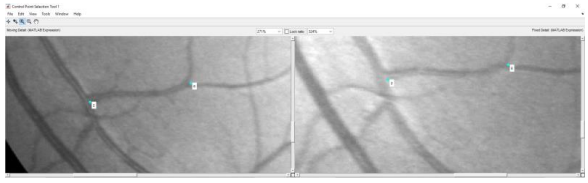

Figure 3. The manual control point selection process for the image registration phase.

Based on the literature, four transformation models were evaluated: These include Similarity [31], Affine [32], [33], Polynomial [34], [35] and RADIC [36], [37].

The transformation model parameters were estimated using the six control points that were manually selected on each pair of images. These control points were picked on each image's vessel cross sections since it was easiest to identify corresponding points at these areas. Figure 4 shows samples of checkerboard patches selected at random from the registered image pairs. In general it was difficult to identify the most accurately registered model by visual observation of the patches alone since there was an observed discrepancy in performance across rows.

In other words, none of the transformation models perfectly aligns the vessels in all four patches. Hence, a more objective method for selecting the model was needed. This will be discussed in Section 3.2.1.

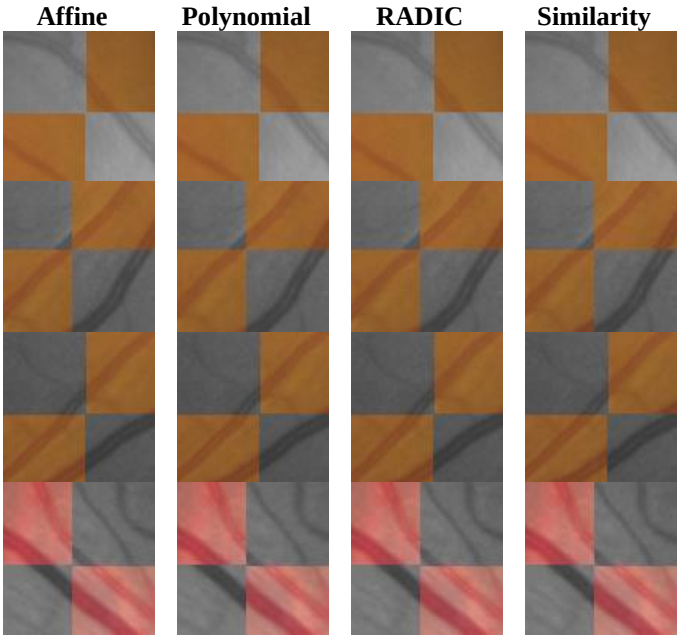

Figure 4. Sample checkerboard patches showing registration of multiple transformation models.

Table 1 The number of control points needed for each transformation model

Transformation model	No. of control points needed
Similarity	2
Affine	3
Polynomial	6
RADIC	3

2.3. Candidates Matching

Once both images were aligned the candidates detected from both images lie in the same coordinate space and hence can be matched by their location. In order to account for some inaccuracies in the registration, we used the following method to find matches between 2 candidates:

Given two aligned images I_1 and I_2, each candidate R detected in I_1 needs to be matched to one of the candidates detected in I_2. We start by finding the centre of candidate R and define a circular search region with radius r around R. A match is made with the candidate in I_2 whose center lies closest to R. If no candidate in I_2 is found in this region, no match will be made. This procedure is repeated for all candidates in I_1. In our case we defined r to be 15 pixels which is twice the size of an average candidate in our dataset

(Figure 5). This offers more tolerance to account for potential inaccuracies in the image registration.

More formally, let $P \in \{p_1, p_2, \ldots p_n\}$ be the set of candidates detected from the image I_1 and $Q \in \{q_1, q_2, \ldots q_m\}$ be the set of candidates detected from image I_2. Our goal is to find a set of correspondences $C = \{\{p_{r_1}, q_{s_1}\}, \{p_{r_2}, q_{s_2}\}, \ldots \{p_{r_l}, q_{s_l}\}\}$ (where $r_i \in [1..n]$ and $s_i \in [1..m]$) which represent the correspondences between these candidates. Note that some candidates would not have any correspondences and in this case they would not be a member of any set pair in C. In practice either P or Q are picked as a 'reference set' and matches are found from the other set. For instance, if we pick P as a reference then for each p_i we find a corresponding match from Q and add it to C if any exists. But we would not do vice versa – Q would not be used as a reference, and this is done for consistency, since we want to have consistent matches in order to make the fused scores consistent.

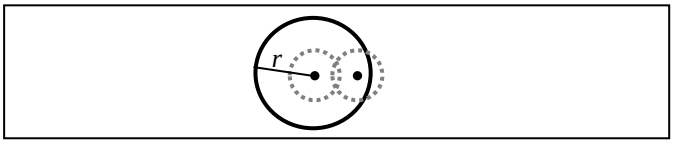

Figure 5. An illustration of the tolerance added while matching 2 candidates. The dashed circles represent two candidates from two views of the retina. It is assumed that they are misaligned due to registration inaccuracy. The solid circle represents a tolerance region around the first candidate and using this method a match is made.

Figure 6 shows an example of correspondences found after following the procedure above. The first row in the figure (a, b) shows a colour image pair while the second row in the figure (c,d) represents the green channel extracted from each image in the first row. Note that the candidates are matched from the image on the right column (b, d) to the image on the left column (a, c). The annotation numbers represent the matches from P to Q (A visual representation of C). Candidates annotated with "-1" in the right image represent a candidate that has no correspondence in the other image (no match found in C). The blue circle in the figure represents a true candidate. It can be seen that a match has been found between the true candidate in (b) and its corresponding candidate in (a). Furthermore, it is observed that the candidate has a much higher contrast in the right image than it does on the left one. The MA candidate is still visible in the left image but it much more subtle. Nevertheless, a combination of information from both candidates will give us higher confidence that is a true candidate.

In fact, human retinal graders often switch between both views of the retina when they have suspicions regarding one candidate. The existence of signs in both images would give graders more confidence about it being a microaneurysm. The process of matching in the proposed method attempts to replicate this.

2.4. Scores Fusion

Given that correspondences have been established between candidates and that each classifier has produced scores for each candidate we now need to find a final fused set of scores that represent a combination of information from both images. Suppose we have two matched candidates a and b from images I_1 and I_2 respectively. Furthermore, assume that I_2 is our reference image – i.e. we are currently interested to classify the candidates in I_2. We define the function fuse as follows (Figure 7):

$$\text{fuse}(a,b) = \begin{cases} \max(a,b) \; if \; \beta_1 < b < \beta_2 \\ b, \text{otherwise} \end{cases}$$

Where β_1 and β_2 are algorithm parameters specified between 0 and 1. In other words, given 2 matching candidates, the maximum of both their scores is taken only if b lies between the two threshold parameters (β_1 and β_2). The parameters β_1 and β_2 are used to limit the number of false candidates that get their scores maximized in the final set. This is because maximization of scores should only be done for true candidates

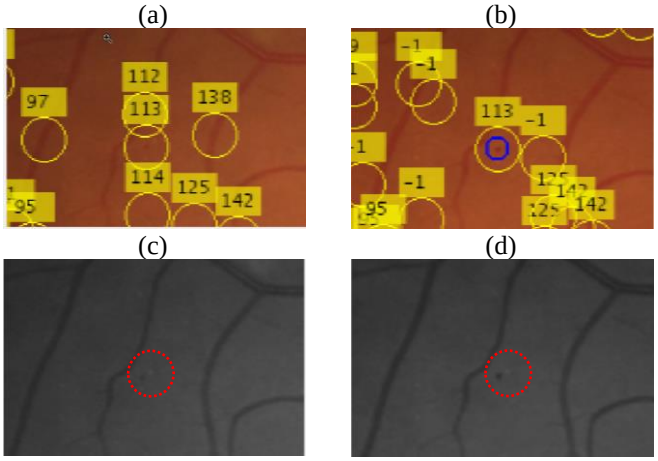

Figure 6. An example of the candidate detection result. a) A colour image from an optic disc centered image. b) The fovea centered view of (a). (c) The green channel image of (a). d) the green channel image of (b). The numeric annotations on (b) represent the result of the matching operation with a). '-1' represents no match. Candidate #113 is a true candidate and it has been correctly matched in both images (b). The candidate has variable contrasts in both images as can be seen in (c) and (d). The matching will hence improve the confidence regarding this candidate.

If a candidate in a reference image has no match in the other image then its score is simply copied over to the fused set (Figure 7). Once the fused score set is computed we can perform a final threshold at an operating point α to find the final set of classifications as described in Section 2.1.

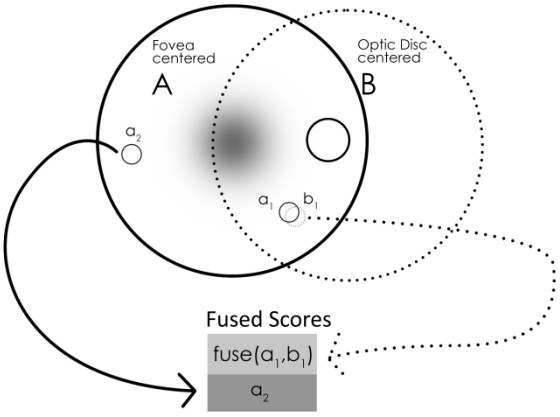

Figure 7. The method employed for the scores fusion phase. β_1 and β_2 are parameters set for the model.

3. Results

3.1. Dataset

The dataset used for evaluation consists of 40 patients imaged imaged as a part of UK NHS DESP. 4 images are available for each patient: fovea and optic disc centered images for 2 eyes. Hence there are 4 images per patient. The total amount of images is 160 images (Figure 8). The images were captured using different fundus cameras (including Canon 2CR, EOS and Topcon cameras) and hence were of different resolutions (Table 2) however they all had the same aspect ratio of 1.5. Moreover all the images had the same field of view (45 degrees).

The images in the dataset were split into 80 images for training the model and 80 images for validating it. The training set consisted of 112 MAs and the testing set consisted of 95 MAs.

Research Governance approval was obtained. Images were pseudonymized, and no change in the clinical pathway occurred.

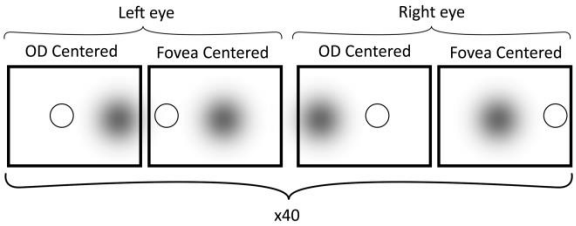

Figure 8. An illustration of the types of images available in the spatial dataset. OD centered – optic disc centered.

The same test set was used to validate both the proposed technique that takes into account spatial information and the normal technique. The classifier model was generated using the training set and the same model was used for both cases of with and without spatial information. To clarify, the same model was used to generate the scores for both the single-image method and the spatial-information method.

Table 2 The image resolutions of the dataset. All the images had an aspect ratio of 1.5.

Image Resolution	Count
3888 x 2592	24
2592 x 1728	48
3872 x 2592	12
4752 x 3168	32
4288 x 2848	20
3504 x 2336	24
TOTAL	160

3.2. Evaluation

In this section details regarding the evaluation of the registration transformation model and spatial information combination phases are presented. Section 3.2.1 details the selection of the appropriate transformation model objectively. Section 3.2.2 will describe the process for evaluating the spatial information combination and present its results.

3.2.1. Registration

As shown in Figure 4 it is difficult to decide which transformation model achieves best performance. Therefore we need a more objective measure of registration performance. During the registration we have a reference image I_r and a moving image I_m which is transformed to be in the coordinate space of I_r. After the image is transformed to the coordinate space of I_r we define an overlapping region as all the pixel coordinates where both I_r and I_m exist (overlap).

The Centreline Error Measure (CEM) [36] quantifies the mean of the minimum distance between each pixel along the centreline of the reference image and the closest pixel in the moving image. Given a set of coordinates in the reference image that lie on its vessel centreline (Figure 9) and are on the overlapping region of the two images: $V=\{v_1, v_2, \dots, v_N; v_i \in (x,y)\}$. Similarly, let $U=\{u_1, u_2, \dots, u_L; u_j \in (x,y)\}$ be the set of points on the moving image that lie on its vessel centreline and belong to the overlapping region. Let $t(p)$ be a transformation that transforms a point p from the moving image space to the reference space. We calculate the centreline error metric for a transformation $t(p)$ on the moving image as follows:

$$CEM = \frac{1}{L}\sum_{i=0}^{L-1} \left| M(\boldsymbol{u}_i) - t(\boldsymbol{u}_i) \right|$$

$$M(\boldsymbol{u}_i) = \underset{j=1..N}{\operatorname{argmin}}\ d(\boldsymbol{v}_j, t(\boldsymbol{u}_i))$$

Where $d(\boldsymbol{x}, \boldsymbol{y})$ represents the Euclidean distance between coordinates $\boldsymbol{x}$ and $\boldsymbol{y}$. Therefore the CEM calculates the average distance between each point on the reference image and the nearest points on the registered moving image (in the overlapping region).

A box and whisker plot of CEM values for each registration model in the same view was plotted in Figure 10. This plot is helpful to summarize the data since it shows the median value and the spread of the values (upper-quartile, lower quartile and the highest and lowest value). Based on this plot it is observed that while the polynomial model contains some of the lowest CEM values (highest accuracy) compared to other models, the distribution of its values also contain the highest spread (as can be seen by the height of the polynomial 'box', as well as the highest and lowest values). This can also be seen by the number of outliers in the polynomial plot. This high variance in values is also expressed by the standard deviation of the values as can be seen in Table 3. This suggests the undesirable "instability" of the polynomial model. We also see that the lowest standard deviation values are exhibited by both the affine and the similarity models (with the similarity model having a slightly lower standard deviation). Both the mean and standard deviations of these models are similar to each other which makes their performance comparable. The similarity model was selected since its values exhibited the lowest standard deviation.

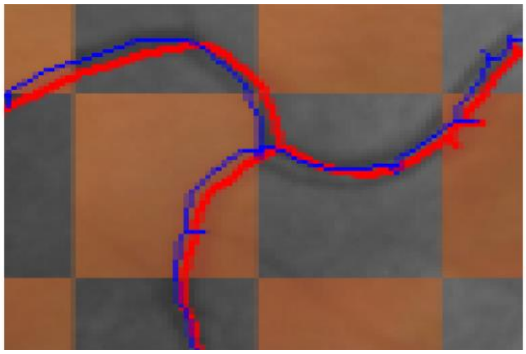

Figure 9 An example of overlapping vessel centerlines for computing Centerline error after registration. The distance between each red pixel and the nearest blue pixel is computed and the average of all distances is a measure of alignment accuracy.

Table 3 Centerline Error Metric (CEM) mean and standard deviation values for various transformation models. Std – Standard deviation.

	Similarity	Affine	Polynomial	RADIC
Mean	4.40	4.50	4.74	4.49
Std	1.51	1.536	3.82	1.536

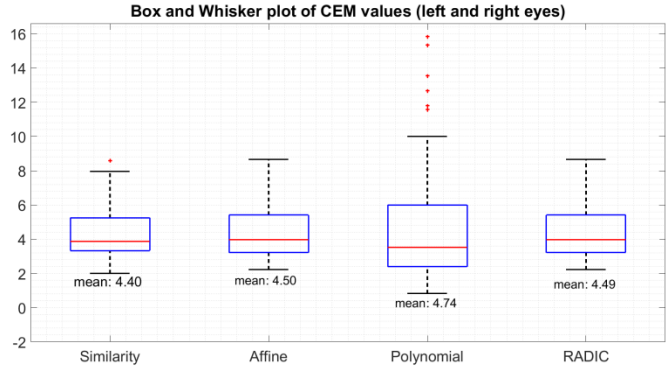

Figure 10. A Box and Whisker plot of the Centerline Error Measure (CEM) values

3.2.2. Spatial information combination

The method for fusing the scores has been discussed in Section 2.4. In order to evaluate the effectiveness of this method we need a baseline method to compare against. The baselines in our case would be the original proposed method that detects the candidates from a single image [1]. The goal was to provide a direct comparison between the performance when spatial information is accounted for and when it is not accounted for. The method used to compare [1] with the proposed method of this paper was as follows:

1- A tree ensemble model was generated using the training set.
2- Features were generated from the validation set and the ensemble model (decision tree ensemble) was used to assign scores to each candidate in the 80 images of the validation set.
3- In the case of the original image that used single images, an FROC (Free-Receiver operating) curve [38] was generated using these scores alone. This is the solid curve in Figure 11.
4- To incorporate spatial information, each image pair (optic disc centered and fovea centered) had their corresponding candidate scores fused as explained in the methodology section. The fused scores were then evaluated *collectively* for each image pair and this was used to generate the FROC curve in Figure 11.

The parameters for scores fusion were $\beta_1 = 0.4$ and $\beta_2 = 0.95$. Automating the process of selecting these parameters is left for future work. We see a slight increase after spatial information is incorporated. This increase can be captured quantitatively using the ROC score measure [39]. This score measures the sensitivity values at various x-axis intervals. The measured ROC score shows an increase of 0.02 after adding spatial information, which is a 2% increase. This increase can be explained intuitively as follows: Some candidates appear very subtle in the optic disc centered image, especially at the edge towards around the fovea region. This is because the retina is spherical and would get distorted during image acquisition. This distortion would affect the candidates towards the edge of the image. But these same candidates would appear more clearly in the Fovea centered image. This is because the same candidates now lie in the centre of the captured image, and hence their appearance will be obvious in the image. Intuitively, we expect the classifier to give higher scores to the more obvious candidates in terms of appearance. However, when the scores are fused, we take the maximum score of both candidates, and this will give us a higher score for the more subtle candidate that was originally given a lower score. This is why the FROC curve for the fused candidates shows a better performance.

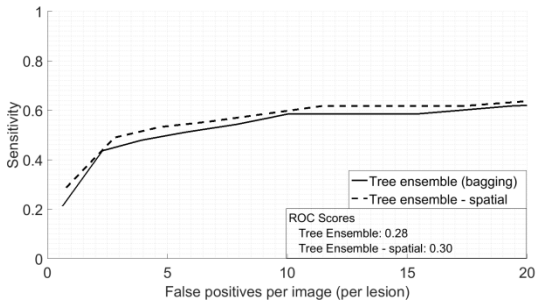

Figure 11 A comparison of performance between the technique applied to single images (solid) and after incorporating spatial information (dashed)

Figure 12 shows this intuitive concept by showing a plot of the corresponding pairs of scores. The figure shows a correspondence of scores for the test set where "score 1" and "score 2" on the axes refer to the methodology scores in Figure 2. Furthermore true candidates are labelled in blue while false detections are labelled in orange. Let us assume Score 2 is the reference image and that the candidate scores are being matched to score 1. Since in our case $\beta_1 = 0.4$ and $\beta_2 = 0.95$ we are only interested in this cross section from the score 2 axis. If we look to the extreme right of the graph we will see some candidates that have received scores within this range in the score 2. These receive higher scores along the x-axis. Hence, the maximum of both scores in the fused set will improve their scores and this will result in a higher FROC curve.

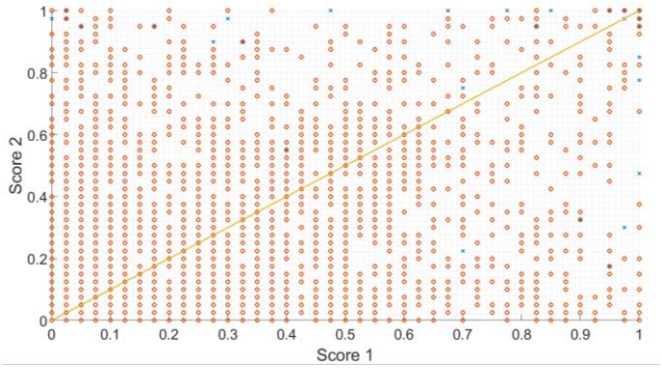

Figure 12 The scores from each corresponding spatial pair of images (these are the same scores as illustrated in Figure 2). True candidates are labelled in blue while false detections are labelled in orange. The orange line represents the linear line for the equation x=y.

The additional processing involved is the time for Image Registration, Candidates Matching and Score Fusion. These are the blue ellipse stages in Figure 2. The image registration is dependent on the algorithm of choice. In this work since it is based on manual control points the overhead is the control point selection and the time to solve a series of equations. An automated registration method may require an optimisation step and hence more time will be required for this step [40]. Given a spatial image pair, let m be the number of candidates detected in one image, and n be the number of candidates detected in the other image. The candidates matching step requires calculating the distance between each pairs of candidates detected in both images and hence has a complexity of $O(m \times n)$ (using Big O notation). The Score Fusion phase will fuse the scores together from one image (n fusions) and then fuse the scores from the other image (m fusions) and therefore will have a complexity of $O(m + n)$. In practice, on a core i5-4590 @ 3.30GHz CPU with 8GB RAM and an SSD hard drive, the time per image for each of the three stages was as follows:

1. Image Registration: 0.02 s
2. Candidates Matching: 1.30s
3. Scores fusion: 0.001s.

The sum of the above timings is 1.321s. The total time for test dataset was computed and then the average value per image pair was found. The average time per pair for the entire process was 4.141s. This means that the average overhead is about 32% of the time required per image (1.321s out of 4.141s). This does not take into account the time for manual control point selection, however, automated registration will be implemented in future work. Methods for optimising the speeds of the other stages are also left for future work.

4. Conclusions and Future Work

In this work a novel algorithm that combines spatial information from two views of the same retina for the purpose of microaneurysm (MA) detection is proposed. Most of the published work in the field of MA detection has been on detection from a single fundus image. The problem has been redefined to assume that two are available and the objective is to use the information from both to detect the microaneurysms in both images. The clinical application of this work would be its incorporation into diabetic eye screening programmes, thereby assisting the National Health Service in the detection of diabetic retinopathy. Screening in England has a recommendation of at least 2 images per eye so the assumption that two views are available would be valid in this context. ETDRS grading [41] is based on a categorical variable. Accurate counts of abnormalities could lead to a more refined grading/risk prediction using a continuous variable, or more accurate estimates of ma turnover that may better predict progression of disease. Accurate alignment of images would be an essential prerequisite to allow such scoring systems to develop. We propose a method for aligning the images, detecting candidates, matching candidates from both views and then combining the information from both views to perform microaneurysm detection from both views simultaneously. The proposed method was evaluated on a Diabetic Eye Screening Programme dataset of 160 images that contained 207 microaneurysms. The combination of information from multiple images was shown to increase the performance in comparison to depending on single images only. An account of the computational overhead required for the combination of information is also presented. Some of the limitations of the present work are: 1) The computational overhead required for the additional steps of the proposed method, 2) The accuracy of the registration method can be improved, 3) The control point selection of the image registration step can be automated to reduce manual labour work and 4) The scores fusion stage can be further improved to reduce more false positives and increase true positive detections. Future work will involve an exploration of other ways to combine information from spatial images, including multi-image features, or mosaicing images together to enhance the contrast of subtle MAs. Furthermore, this concept will be extended to include temporal images of the same patient as well.

Conflict of Interest

The authors declare no conflict of interest.

ABSTRACT

In this paper, a novel approach for collision avoidance for indoor mobile robots based on human-robot interaction is realized. The main contribution of this work is a new technique for collision avoidance by engaging the human and the robot in generating new collision-free paths. In mobile robotics, collision avoidance is critical for the success of the robots in implementing their tasks, especially when the robots navigate in crowded and dynamic environments, which include humans. Traditional collision avoidance methods deal with the human as a dynamic obstacle, without taking into consideration that the human will also try to avoid the robot, and this causes the people and the robot to get confused, especially in crowded social places such as restaurants, hospitals, and laboratories. To avoid such scenarios, a reactive-supervised collision avoidance system for mobile robots based on human-robot interaction is implemented. In this method, both the robot and the human will collaborate in generating the collision avoidance via interaction. The person will notify the robot about the avoidance direction via interaction, and the robot will search for the optimal collision-free path on the selected direction. In case that no people interacted with the robot, it will select the navigation path autonomously and select the path that is closest to the goal location. The humans will interact with the robot using gesture recognition and Kinect sensor. To build the gesture recognition system, two models were used to classify these gestures, the first model is Back-Propagation Neural Network (BPNN), and the second model is Support Vector Machine (SVM). Furthermore, a novel collision avoidance system for avoiding the obstacles is implemented and integrated with the HRI system. The system is tested on H20 robot from DrRobot Company (Canada) and a set of experiments were implemented to report the performance of the system in interacting with the human and avoiding collisions.

1. Introduction

In future work environments, robots will work alongside to human, and this raises big challenges related to the robustness of these robots in detecting people, interacting with them and avoiding physical accidents. Different collision avoidance techniques have been implemented for mobile robotics. In Bug algorithms [1], when the robot meets an obstacle in the navigation path, it will implement either a complete rotation around the obstacle (Bug1), or it will rotate around the obstacle till it sees again the goal location (Bug 2). The robot will then continue its movement to the goal. Other methods takes into consideration the robot's dynamics, such as dynamic windows approach (DWA) [2]. In DWA, after specifying the distances of each obstacle from the robot, it will consider only the velocities that the robot can use and decelerate before colliding with the obstacles. The robot will then select the velocity vector that is closest to the goal location. Other methods uses reactive techniques, in which the robot relies merely on the

sensor's information and the motion update is related to the new measurements that are obtained from the sensors. An example of these methods is potential field [3], vector field histogram [4], and nearness diagram [5]. Nearness Diagram simplifies the collision avoidance task by using a divide and conquer strategy; the robot splits the navigation area into sectors, and combines the sectors that don't include obstacles together to define the navigable regions. Based on this information, the robot will consider only the regions that are wide enough for the robot to navigate, and it will select one of five scenarios for selecting the region and avoiding the obstacles; the robot will then calculate the angular and linear velocities for passing the selected region.

Recently, many human-robot interaction systems have been realized in robotics. Wearable sensors are fixed on certain parts of the people to provide the robot with the motion of their bodies, and it will then execute physical reactions as a result of the interaction. Cifuentes et al. implemented a human-tracking system that allows the robot from following the human [6]. In this system, the robot will use LRF sensor to track the leg's motion of the human. Furthermore, an inertial measuring unit IMU is fixed on the trunk of the user to extract its motion and rotation. The robot moves in front of the person and adjusts its direction and velocity based on the sensory data from LRF and IMU.

3D vision is another common method to obtain the interaction with the humans. As an example of these sensors is the Kinect. Boubou implemented an interaction system to define nine actions for the humans (wave, sit, walk, stand, pick up, stretch, forward punishing, use hammer, and draw a circle) [7]. To define the gestures, a histogram of oriented velocity vectors HOVV algorithm is implemented. The HOVV will analyze the velocity and orientation of each joint of the body and build a velocity vector for each of these joints. The vectors will be then represented in a spatial histogram. The implemented histogram will be used to describe the activity of the person. Other human-robot interaction systems could be done by voice recognition [8], brain-signals [9], and face recognition [10].

In the literature, it is found that several collision avoidance systems show good performance in avoiding obstacles. Still, in these systems, when the robot meets humans in the path, it will consider them as dynamic obstacles. When the robot moves in social environments such as laboratories, hospitals and restaurants, these systems won't work efficiently since the people and the robot will get confused regarding the motion direction that each of them has to follow. Furthermore, these systems can't solve the bottleneck problem in which the robot and humans meet in narrow areas such as corridors and small rooms, so none of them is able to generate the collision-avoidance path due to the limited navigation area. Out of this, a collision avoidance system has been implemented. The system provides a mutual responsibility for both the robot and the people in avoiding each other. When the robot meets humans, it will send a voice message asking the people to interact. If a person interacted with it, the robot will move based on the gestures that were provided by the user. If no people interacted with the robot within a certain time, it will generate the collision avoidance path autonomously, taking into consideration generating the collision-free path that is closest to its original path.

Since this system is based on the interaction between the human and the robot, it will be called Cooperative Collision Avoidance system based on Interaction (CCAI).

This paper will be organized as follow: chapter 2 will show the human-robot interaction system. In chapter 3, the collision avoidance system will be explained, while chapter 4 will show the experimental results for the system.

This paper is an extension for the work originally presented in Mechatronika conference [11]. In this paper, deep experiments have been implemented to check the performance of the human-robot interaction and the collision avoidance systems and the results have been reported.

2. Human-Robot Interaction System

Human-Robot interaction (HRI) is defined as the ability of the robot from recognizing the humans, understanding their activities and implementing certain responses as a result of this interaction [12]. In the proposed system, the HRI will serve the task of collision avoidance. Thus the HRI will be based on gesture recognition. Kinect 2.0 sensor (Microsoft, USA) will be used for detecting the humans and extracting their joints' coordination. This sensor has a RGB camera and an infrared camera. The combination of these two cameras provides the robot with a 3D vision of the work environment. The sensor uses time-of-flight to measure the distance between the sensor and the objects. The Kinect 2.0 provides a skeleton frame, which includes the skeletal data for up to 6 people to the robot. 3D dimensions for 25 joints express each skeleton. Fig 1. shows the skeletal representation for the used gestures in this work. To implement the human-robot interaction, seven gestures are used in this system:

- Stop: the robot will stop as long as the stop gesture is raised.
- Move right: The robot will generate the collision-free path to the right side of the person.
- Move left: The robot will generate the collision-free path to the left side of the person.
- Move forwards: The robot will move toward the person as long as the "move forward" gesture is raised.
- Move backwards: The robot will move backwards as long as the master person raises the "move backwards" gesture.
- Master select: when several people are in the path of the robot, the robot will not know to which person it has to interact, since

two or more people might give different orders to the robot. To overcome this problem, "Master Select" gesture is assigned. When a person in a group raises the right arm 180°, the robot will know that it has to interact with this person and will ignore the gestures of other people in the work area.

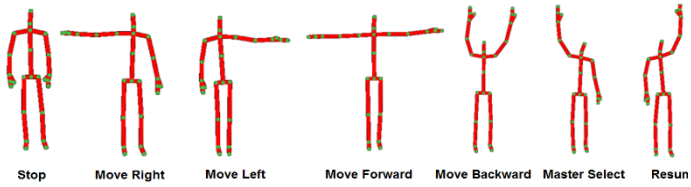

Figure 1: The gestures that are used for interaction with the robot

The Kinect sensor provides only the dimensions of the human's joints, without describing the gestures. Thus, to build the gesture recognition system, the "y" values for the right & left elbows, the right & left wrists and the "y, z" values of the neck joints were extracted. Furthermore, machine learning (SVM) and artificial intelligence (BPNN) models were trained to define the gestures. To train the models, a training set of 448 samples is constructed, and the k-fold cross validation algorithm is used to train the models. Additionally, it is worthy to mention that the HRI system took into consideration that in real environments, the robot and the human might not be located face-to-face. Thus, the training set is extracted with different deviation angles between [-40°, 40°].

3. Cooperative Collision Avoidance

In previous collision avoidance systems, the robot will search for the closest collision-free path to the goal location, without taking into consideration the motion direction of the human. Since the human will also try to avoid the robot, both participants will get disordered about the correct direction that each of them has to go. This situation can cause problems when the robot navigates in social areas which include several people leading to a collision when both the human and the robot decide to use the same collision-avoidance direction. To overcome this situation, a new method for the collision avoidance is proposed which is called *Cooperative Collision Avoidance System based on Interaction (CCAI)* since both the robot and the human will cooperate in generating the collision-free path via interaction. Fig. 2 shows the flow chart of the proposed system.

In the proposed collision avoidance system after identifying people in the path the robot will send a voice message "Robot in the path", alarming the people that the robot is moving in the same area. The people can move away from the robot's path, or be prepared for interaction. If the human remain in the path, the robot will stop keeping a certain distance from the people (2m), asking them for interaction by sending a voice message "Interact". Then the following situations can occur.

- If a user raised the right arm activating the "master gesture", the robot will execute the orders provided by the user.
- If no human interacted with the robot, it will plan a collision-free path autonomously, taking into consideration the goal location.
- If the human moved away from the path of the robot, it will complete its path to the goal without changing its direction.
- If there is no available path that the robot can go through, it will send an alarm message "no free path" to inform the people that they have to keep a free path for the robot so it can generate a new collision-free path.

Fig. 3 shows three human in front of the robot; non of them interacted with it. The robot will then implement the collision avoidance path by searching for the regions that the robot can pass through. Then, it will select the region that is closest to its original path obtained from the global navigation system [13]. Since the robot has two available regions (R1, R2), it will select the region R2 since it is the closest to the original orientation to the goal.

In contrary, when the user interacts with the robot, it will follow the orders provided by the master via gestures. The red colored person in fig. 4 activated the "master person", and asked the robot to move to the left. The robot will then select the region R1 since there is no free space between the persons P1, P2, and the region R2 is not located to the right of the master person.

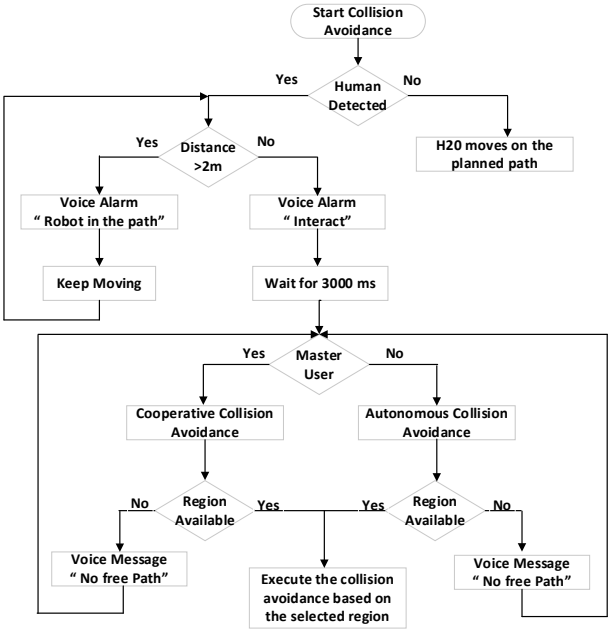

Figure 2: The flow chart of the collision avoidance system

To calculate the collision-free path, the robot has to search for all available regions that the robot can pass safely. Here the robot distinguishes between the terminal regions that are located to the

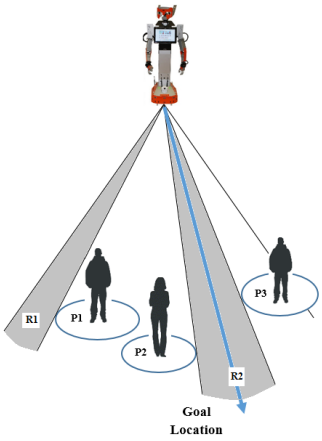

Figure 3: Selecting the CA region based on the goal location

right/left of the last person in the group, and the regions that exist between the people.

In the first step, the robot detects the positions of the people, and calculates the relative distances between them. For the middle regions between the people, the robot calculates the width of the available distance between them:

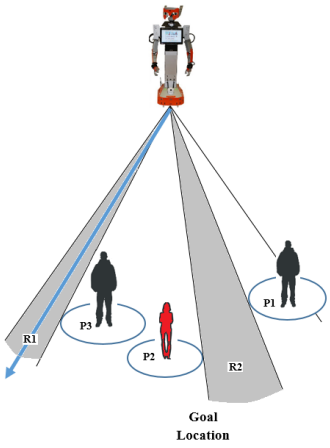

Figure 4. Selecting the CA path based on HRI

$$R_{av}^{i} = X_{p}^{i+1} - X_{p}^{i} \; where: i = 1, .., n-1 \qquad (1)$$

where n represents the number of people detected by the Kinect sensor.

Furthermore, the robot estimates the minimum region width required for the robot to pass without collision:

$$R_{\min\,(mid)}^{i} = 2 \times r_r + r_p^{i+1} + r_p^{i} + d \qquad (2)$$

Where:

r_r robot's radius.

r_p^i the distance between the shoulder and the neck of the user i obtained from Kinect sensor.

d the safety distance around the robot.

In the next step, the robot checks the possibility of generating the avoidance path to the right and left of the most right/left people in the group. This calculation is done by considering the maximum detection angle of the sensor (70°), so the robot will compare the width of the region between the terminal person and the last point that the sensor can detect for the given depth, as it could be found in fig. 5, which shows the calculation of the region for the right-terminal person.

The following equations are used to get the width of the right-terminal region:

$$\delta_n = \sin^{-1} \frac{X_p^n}{Z_p^n} \qquad (3)$$

$$Z_{temp}^{n} = Z_p^n . \cos \delta_n \qquad (4)$$

$$X_{term}^{n} = Z_{temp}^{n} . \tan 35 \qquad (5)$$

where

Z_p^n: The distance of the person n from the robot

X_{term}^n: The last point that the Kinect sensor can detect for the given depth Z_p^n

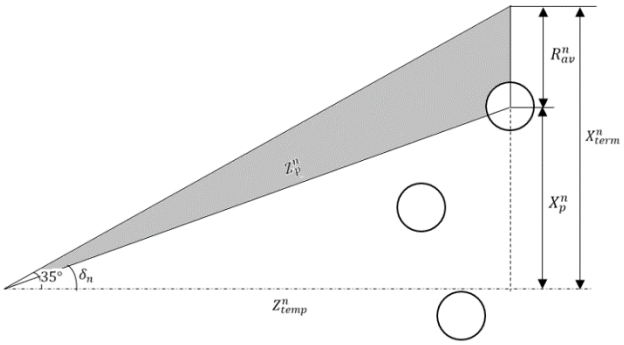

Figure 5. Calculation of available terminal region

The available region is given as:

$$R_{av}^{n} = \left| X_{term}^{n} - X_{n}^{p} \right| \qquad (6)$$

The same calculations are done to get the width of the left terminal region. The robot will then calculate the minimum width of the terminal regions that the robot can pass through:

$$R_{\min}^{n} = r_r + r_p^n + d/2 \qquad (7)$$

$$R_{\min}^{0} = r_r + r_p^0 + d/2 \qquad (8)$$

The candidate valleys are the regions that are wider than the minimum required width:

$$V = \sum_{i=1}^{n-1} R_{av}^{i} + R_{av}^{0} + R_{av}^{n} \quad if \; R_{av}^{i} > R_{min}^{i}, R_{av}^{0} > R_{min}^{0}, R_{av}^{n} > R_{min}^{n} \qquad (9)$$

If $V = \emptyset$, the robot couldn't find a free walking area between the group of people, and it will send the voice message "no free path" to alarm the people to move and keep enough area for the robot to pass as it could be found in fig. 2.

If $V \neq \emptyset$, the robot will select the valley depending on whether the master user asked the robot to go to a certain direction, or in case that no people interacted it will select the valley that is closest to its path. To calculate the collision-free path for the selected valley, the robot distinguishes between the terminal valley and the intermediate valley. Fig. 6 shows the calculation of the collision avoidance path for an intermediate valley using the following equations:

$$x_{ca} = \frac{x_p^{i+1} - x_p^i}{2} \quad (10)$$

$$Z_f = Max\{Z_i, Z_{i+1}\} \quad (11)$$

$$\psi = \sin^{-1}\frac{x_f}{z_f} \quad (12)$$

$$Z_{temp} = Z_f.\cos\psi\ \theta_{ca} = \tan^{-1}\frac{x_{ca}}{Z_{temp}} \quad (13)$$

$$\theta_{ca} = \tan^{-1}\frac{x_{ca}}{Z_{temp}} \quad (14)$$

$$Z_{ca} = \frac{X_{ca}}{\sin\theta_{ca}} \quad (15)$$

$$d_{ca} = Z_{ca} + r_r + r_f + d \quad (16)$$

where:

x_{ca}: The middle of the selected valley.

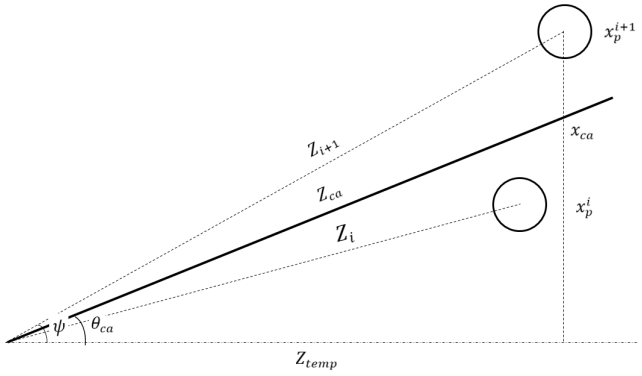

Figure 6. Calculating the collision-free path

Z_f: The distance of the farthermost person from the robot in the selected region.

θ_{ca}: The robot's orientation toward the valley.

ψ: The angle between the robot's horizontal axis and the farthermost person in the selected region.

Z_{temp}: The horizontal distance between the robot and farthermost person.

Z_{ca}: The distance between the robot and middle of the Region.

d_{ca}: The travelled distance to pass the people.

For the terminal valleys, the robot uses the following equations for the most right person:

$$x_{ca} = X_p^n + r_p^n + r_r + d/2 \quad (17)$$

$$Z_{ca} = Z_p^n \quad (18)$$

$$\theta_{ca} = \sin^{-1}\frac{x_{ca}}{Z_{ca}} \quad (19)$$

$$d_{ca} = \frac{x_{ca}}{\tan\theta_{ca}} + r_p^n + r_r \quad (20)$$

And for the most left person:

$$x_{ca} = X_p^0 - r_p^0 - r_r - d/2 \quad (21)$$

$$Z_{ca} = Z_p^0 \quad (22)$$

$$\theta_{ca} = \sin^{-1}\frac{x_{ca}}{Z_{ca}} \quad (23)$$

$$d_{ca} = \frac{x_{ca}}{\tan\theta_{ca}} - r_p^n - r_r \quad (24)$$

Calculating the angular and linear velocities is based on the width of the selected valley:

$$v = v_{max}.\frac{\log_{10}\theta_r}{\log_{10}\theta_{max}} \quad (25)$$

$$\omega = \omega_{max}.\frac{\log_{10}\theta_r}{\log_{10}\theta_{max}} \quad (26)$$

Where θ_{max} the maximum vision angle of the Kinect sensor and equal 70°, θ_r the width of the selected region in degrees.

4. Experimental Results

The experiments have been implemented to check the performance of the HRI and the collision avoidance systems.

4.1 The experiments for the human-robot interaction

The experiments over the HRI were implemented on two steps. The first step, the experiments were applied to compare the performance of the SVM and BPNN and find out the best model that could fit the HRI system. After finding out the optimal model that can classify the training data, the HRI is tested for different gestures and different people to find the success rate of the implemented HRI system.

The goal of using the L_SVM and BPNN is to find the optimal model that could be used to recognize the gestures of different people with different heights and deviations from the Kinect level. To do so, a training set is implemented to train the models. Each training vector is composed of the "y" values of the right and left elbows, the "y" values of the right and left wrists, and the "y, z" values for the neck joint. The training data is collected from four people with different heights [152-187] cm. Each person is asked to do 112 gestures with distances [1.7, 4] m from the Kinect, with deviation angle [-40, 40]. Thus the total training set is 448. The L_SVM is trained for different penalty values, while the BPNN is trained for different number of hidden neurons.

To implement the training, the K-fold cross validation model is used with k=8.

4.1.1 Training the L_SVM model

The L_SVM is trained to find out the best penalty value that provides minimum error over the test set. The model is trained for penalty values $c = e^n\ where\ n \in [-10,70]$. Table I shows the training results.

Table I. The training results of L_SVM model

C	Total Error	Average Error	Success Rate (%)	Train time (ms)	Test Time (ms)	No. Support Vectors
$4.5 \times 10^{-5}, 0.0067$	379	47.3	15.53	[103, 112]	<1	21
0.0183	335	44.3	20.9	102	<1	21
0.0497	156	19.5	65.17	88	<1	21
0.135	33	4.12	92.64	71	<1	21
0.367	8	1	98.2	68	<1	21
1, 2.718	9	1.125	97.99	49.56	<1	21
7.389	**8**	**1**	**98.2**	**45**	**<1**	**21**
$20.08, 9.2 \times 10^{29}$	16	2	96.4	[41,53]	<1	21

From table I it can be seen, that the best penalty value that shows minimum error is at c=7.389 with 8 misclassified training samples for the 8 folds.

4.1.2 Training the BPNN model

The BPNN model is trained to find the best number of hidden neurons. The learning rate is set to $\eta = 0.15$. The model has five input neurons, three output neurons, while it is trained and tested to find the best number of hidden neurons with the range [3, 15]. Table II shows the experimental results for training the BPNN.

Table II. The training results of BPNN model

No. Hidden neurons	No. Errors	Training Time (ms)	Test Time (ms)
3	0	94	<1
4	0	137	<1
5	0	92	<1
6	**0**	**126**	**<1**
7	0	135	<1
8	0	113	<1
9	0	117	<1
10	0	119	<1
11	0	122	<1
12	0	133	<1
13	0	122	<1
14	0	162	<1
15	0	161	<1

From table II, it could be concluded that despite of the number of hidden neurons, the model could correctly classify the whole test data successfully with no errors. Furthermore, in comparison with table I, it could be found that despite of the number of hidden neurons, the BPNN outperforms the implemented SVM model. Thus, the BPNN model is selected in the HRI system with a number of hidden neurons equal to 6.

4.1.3 Test the HRI system

After selecting the optimal model for the HRI system, further experiments have been implemented in real work conditions to check the performance of the HRI. To do so, five people with different heights and physical shapes were asked to do tests. Each person is asked to implement 18 gestures with different deviation angles [-40°, 40°]. Table III shows the experimental results for the HRI system.

Table III. The test results for the HRI

Person	No. Experiments	Height	False Gesture	State Transition
1	18	165	1	0
2	18	170	1	3
3	18	177	0	1
4	18	179	0	1
5	18	181	0	1

Out of 90 experiments, two gestures were misclassified. These misclassifications occur due to false measurements for the joints' locations by the Kinect sensor. Furthermore, state transition means the Kinect couldn't detect the person that is located in front of it, and it required from him to move or shake their bodies to be detected from the sensor.

4.2 The experiments for the collision avoidance system

As mentioned in chapter 3, the robot uses the equations (25), and (26) to adjust its velocity based on the width of the selected region. Fig. 7 shows simulation for the velocity controller for different maximum linear and angular velocities taking into consideration that the maximum angular view for the sensor is 70°. Furthermore, to check the validity of the implemented system, several experiments were implemented for each function. H20 humanoid robot from DrRobot Company is used in the experiments.

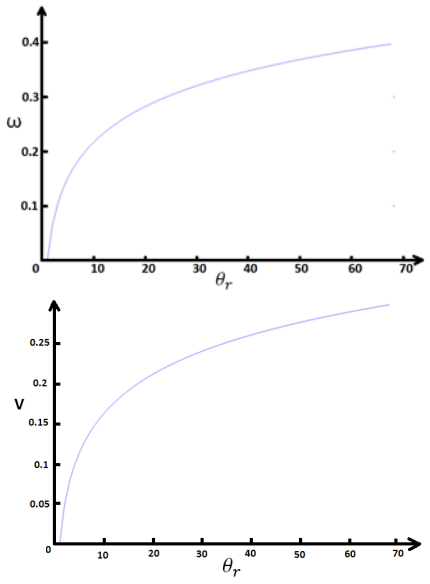

Figure 7: The simulation result for the velocity controller

4.2.1 Tests for the move forward/backward

The experiments for the move forward/backward gesture were implemented for different velocities $V_{max} = 0.1, 0.2, 0.3$. Two experiments were implemented for each velocity, one for each function. The experiments show that the robot could detect people, interact with the master and execute the orders based on the raised function. Fig 7. Shows an example of the cooperative collision avoidance in which the master asked the robot to move forward, and then he asked it to move to the right.

4.2.1 Tests for the move right/left

Fig 7. shows an example of the "move right" function after using the "move forward" gesture. To test the move right/left functions, 6 experiments were implemented. Table IV summarizes these experiments. V_{max}, ω_{max} represent the maximum linear and angular velocities that the robot uses in case that no obstacles in its path. Region candidates represent the possible steering angles that the robot can use to pass the detected regions. Heading angle represents the steering angle that the robot uses after selecting the region that the robot will go through it. (d) represents the distance that the robot will travel to pass the region. θ_r is the width of selected region. v, ω are the linear and angular velocities for the robot obtained from the velocity controller. Time represents the time that the robot needs to pass the people.

As it could be found, the robot will detect the whole navigable regions that are located at the right or left of the master person, depending on the direction that he/she ordered the robot to move. Then, it will calculate the steering angle and the distance that it has to move to pass the region. The robot will also consider the width of the selected region to calculate the linear and angular velocities.

4.2.2 Tests for the autonomous collision avoidance

As discussed before, in case of no human interaction the robot will generate the collision avoidance autonomously without any interaction. To test the function, additional six experiments were implemented to check the performance of the autonomous collision avoidance system. Table IV shows the experimental results for the system. Waypoint represents the original heading angle that the robot had to move if there are no people in the path.

The robot could successfully define the navigable regions, and select the region that is closest to its original path, by comparing the regions' angles with the angle of the waypoint. Furthermore, it could be seen that the robot could successfully define the steering angle and the distance that it has to move to pass the region. Furthermore, the velocity controller will adjust the robot's linear and angular velocities based on the width of the selected region.

4.3 Discussion and comparison with other systems

As it could be found in the experiments over the HRI system, the system is able to classify the whole gestures with a success rate 100%. Furthermore, the implemented system is able to detect and define the gestures even when the user is deviated with [-40°, 40°] from the straight line between the user and the robot. Other systems which are based on analyzing the geometrical displacements of the joints as in [14] and [15] will fail in such situations.

Although many collision avoidance systems proved a good performance in avoiding dynamic and static obstacles, all of these systems considered the humans as dynamic obstacles. This is a short come if we consider that in cluttered social environments, robots will navigate between many people who will share the location, and this could lead for both of them to get confused due to the lack of the interaction between them. Furthermore, the previous collision avoidance systems didn't solve the bottleneck problem which could occur in narrow corridors and rooms, so the robot can't generate collision avoidance paths due to the lack of space. Additionally, it is possible in certain situations that the human needs to interrupt the motion of the robot, and control it when needed.

The implemented system solved the bottleneck problem, by using the move forward/backward gestures. Thus, the master can lead the robot to another area which is wide enough to avoid each other. Furthermore, when there are several people in the path of the robot, a person can raise the "master select" gesture, and provide the robot the direction that it has to move, so the other group of people can go to another direction, and no motion conflict will occur. Besides to the interactive collision-avoidance features, the system is also able to generate the collision-avoidance path autonomously in similar concepts that other collision avoidance systems follow.

Future work will focus on detecting the static obstacles and integrate it to the implemented collision avoidance system, so the robot can avoid both the static, dynamic and human obstacles.

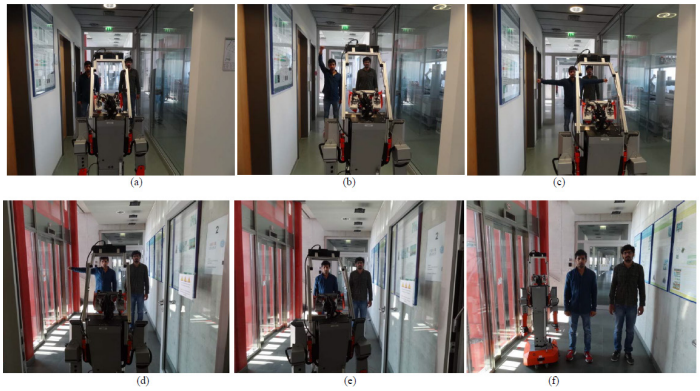

Figure 8: The cooperative collision avoidance, (a) the robot meets people in narrow path and ask them to interact, (b) the user raises his right arm to inform the robot that he will be the master, (c) the master person orders the robot to move forward, (d) the robot moves forward till it reach to a wide area and the user asks the robot to implement the collision avoidance to the right, (e, f) the robot adjusts its motion and moves to the free region to the right of the master

(a) (b) (c)

Figure 9: the autonomous collision avoidance, (a) the robot detects two people in the path and defines three navigable regions, (b) since no people interacted with the robot, it will select the region that is closest to its original path, (c) the robot calculates the path, pass the people and keep moving to the goal location.

Table IV: The experimental results for the move right/left functions

No.	Function	V_{max} m/s	ω_{max} rad/s	Region Candidate	Region Candidate	Heading Angle	d(m)	θ_r (°)	V (m/s)	ω (rad/s)	Time (s)

ABSTRACT

The sector of telecommunications is experiencing a large growth and rapid change in developing applications due to the variety of technologies, to increase the number of users and to arrival services varied from the high demand of the service quality such as streaming, web navigation. In this regard, the 3rd Generation Partnership Project (3GPP) organization has greatly motivated to develop Next Generation Network (NGN). Indeed, telecom operators are forced to make a portfolio of available services more efficient to ensure customer loyalty. This article aims to propose an incorporation a layer above the quality of service (QoS) controller based on Fuzzy Logic to determine the guaranteed levels of QoS and levels of criticality. It describes a new approach of multi criticality in order to ensure the integrity in IP Multimedia Subsystem (IMS) networks. This approach is based on the recent model of integrity Totel. The proposed approach is tested and evaluated using Fuzzy Inference System to simulate levels of criticality for determining an adequate QoS level that ensures the customer's needs. The simulation results describe the comparison between three membership function Triangle, Trapezoidal, Gaussian also describes the comparison between the methods of defuzzification to find whose gives better results and has more efficient in the aspect of chance value for levels of QoS and levels of criticality.

1. Introduction

The sector of telecommunications is undergoing a profound and rapid change in developing applications due to convergence towards Telecom, Internet, Multimedia and continual technological innovations. The IMS architecture towards all-IP domain supporting at all services voice, video and data. Thus, according to IMS network convergence, the issue of maximizing the resource use and the continuity of QoS and Quality of Experience (QoE) for satisfying the user's requirements has gained importance to find success or failure of applications and services. This quality shows performance metrics in terms of perspectives for the service user. Indeed, the IMS architecture is composed of several entities types of session initiation protocol (SIP) servers to process SIP signaling packets of the IMS domain: Proxy Call Session Control Function (P-CSCF), Interrogating CSCF (I-CSCF), and Serving CSCF (S-CSCF).

Thus, IMS architecture also defined entities for QoS management, which are Policy Control Rule Function (PCRF) and Policy Charging Enforcement Function (PCEF). Although, due to the high-quality IMS services, it is not possible to guarantee a QoS for IMS services at anytime, anywhere due to the increase of user numbers and to their mobility.

This paper is an extension of work originally presented in conference on Intelligent Systems Theories and Applications (SITA) [1]. The goal of this article is to propose a policy of integrity implementation that allows a security policy integrated on IMS architecture. This integration is based on Totel model. Our contribution described a new approach for multi criticality on IMS architecture to ensure the integrity and to verify the exchange between different software entities. Furthermore, to dynamically find the level of criticality of customers for offering QoS appropriated to their needs by using Fuzzy Logic for decision-making according to multi criteria such as environment, equipment and the importance of customers. This approach is introduced by simulation using Matlab.

This paper is organized as follows. In section 2, we briefly review related work. We summarize basic standards and mechanisms, integrity models, Fuzzy Logic in Section 3. The proposed contribution and discussion architecture presented in Section 4. Section 5 concludes this paper, sums up and explains the next steps.

2. Related works And Motivation

2.1. Related works

Recently, the increase in mobile usage data and the new application emergence has greatly motivated the 3GPP organization for working on the IMS network. Various studies made to enhance the QoS in IMS networks [2, 3, 4, 5, 6, 7] due to the network convergence on account to several issues including security, mobility, and QoS management. Some works, focus on detecting problems of degradation of service. Others provide methods for QoS Management [2]. Basic mechanisms for management of QoS in the IMS are presented by 3GPP specification [8, 9]. The 3GPP approaches based on the phase of provisioning services by offering stable and dynamic solutions for the resources according to the type of service. The goal of this approach is to find the needs of each service in terms of QoS requirements. Although, these approaches focus on the phase of providing service, without taking into consideration the customer type, which influenced on the overload of network [10].

In paper [11], the authors propose a technique of causal map for monitoring the resources to identify the fault cause via the technique of map causal [11]. The aims of this solution is to detect a failure by identifying the probable cause. This approach allows monitoring resources and not services flows [5].

The paper [13], propose a platform SLM&M (service Level Management & Monitoring) for services monitoring, it is based on indicators collected directly over the network. However, before deducting the requirements provisioning service to users, these indicators are analyzed using thresholds defined in the Service Level Agreement (SLA) of each client. The aim of this solution is to detect only the degradations without including the corrective actions in real-time.

In paper [2], authors propose a new approach INQA (IMS Network QoS Architecture) that is presented at SLM&M platform to supervise and monitor a service in the real-time according to key performance (KPI) and quality indicators (KQI). The aim of this solution is to project enhanced Telecom Operation Map (eTOM) in the context of IMS network by integrating entities in a multi-technologies context using web technology; more particularly service oriented architecture SOA and simple object access protocol SOAP [12].

In [14], authors discuss three types of SLA, which are SLAs Customer, SLAs Supplier/Partner, and SLAs Interns. A service provider for offering products to the customer intends SLAs Customer. This type of SLA is generally subject to a formal contract between the customer and the service provider. SLAs Supplier/Partner are intended for suppliers who are designed to ensure whether performance targets met for the service components provided by a supplier and for derived from a partial or total contractual agreement between suppliers. An agreement for all customers using the services delivered by the service provider. SLAs Interns are designed primarily to target services and working resources. They are intended to service elements or groups of service elements and are described as the agreements between organizational functions within the business operators.

Paper [13], proposes the verification of SLA using eTOM process [15] for monitoring services. The aim of this verification is to identify the appropriated QoS, which is determined in the SLA contract from the information collected by the network entities. Four steps, structures this verification: Performance Indicators Collection [13], Mapping quality indicators, Comparison between quality indicators and SLA, and Report overall service and resource. In the performance indicators collection step, a key performance indicator KPIs is identified by Packet Loss (%), Delay (ms), and Bandwidth (kb/s). Unlike indicators of performance, quality indicators are correlated to the service, these indicators are MOS-V (Mean Opinion Scores Video) [16] and MOS-A (Mean Opinion Scores Audio) [17]. The following step is a comparison between quality indicators and SLA to verify the negotiation of SLA. Lastly, a report on the resource during service provisioning and its status are created for detecting the type of SLA execution.

2.2. Motivation

In IMS network, SLA execution takes two forms: Normal SLA Execution and SLA execution with a violation. The Normal SLA Execution detects the exceeded thresholds or failure of a component and the manager intervenes. However, the SLA execution with violation restores services and QoS operation of Video service on demand (VoD).

To enhance an SLA security policy and to control the exchange between different entities, the proposed approach is to integrate a layer called integrity verification communication in IMS architecture for applying integrity policy [1] in terms of criticality [1]. To achieve this goal, the Totel model of integrity is adopted to improve a new approach of multi criticality using multi-criteria for decision-making and to guarantee QoS needs according to the level of criticality of users. This proposition is integrated into INQA and SLM&M architecture as illustrated in Figure 1. It is composed of two layers: assurance and monitoring. The assurance layer is dedicated for verification process of SLA according to several entities of eTOM process. The monitoring layer is dedicated for supervising; it is composed of a set of functional processes for ordering services and other execution scenarios of a resource. It is divided into two parts: A distributed part that is a set of agents and probes that are able to recover all data in real-time. Moreover, a centralized part is dedicated to synchronization.

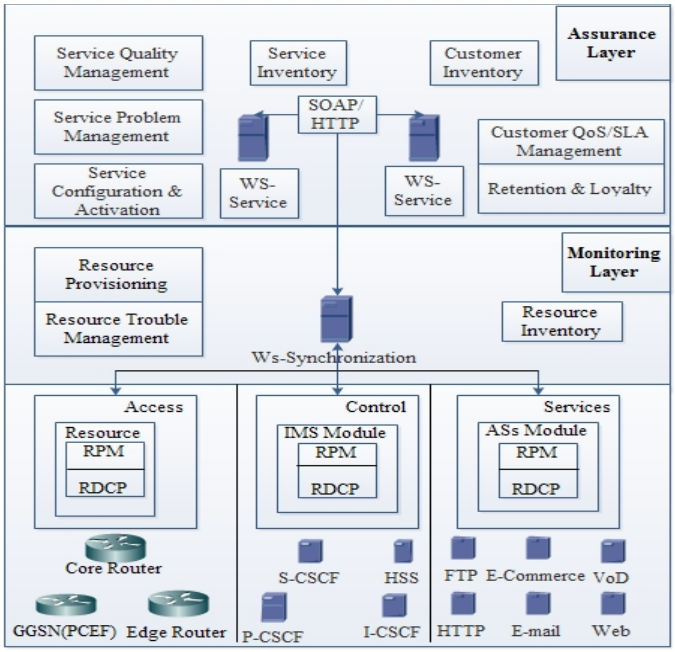

Figure 1: *Architecture SLM&M and INQA [2]*

3. Overview

An access control model intended to abstract the policy and handle its complexity, to verify the consistency of the security policy and detect possible conflicts. It is based on essential model and mechanisms, integrity policy, IMS, Fuzzy Logic, which will be outlined in this section.

3.1. Survey of integrity

Computer security in critical infrastructure is designed to control access and manipulate data by using the mechanisms of authentication, integrity, authorization, in order to protect a system against the vulnerabilities and failures. One basic element of security is integrity. It is a key for checking the trust change of data by using verification mechanisms such as integrity models. These models keep data safe and trustworthy by protecting system data from any intentional or accidental changes. For a long time in computer systems, this concept was used for three goals: to prohibit unauthorized users from making any changes to data or programs, to prohibit authorized users from making unauthorized modifications and finally to prevent internal and external consistency of data and programs [18]. Integrity models allow quantifying the integrity in term of credibility or criticality [19]. Credibility can be considered as an integrity fact, since it is defined as the character of something that can be believed, on what trust can be placed. The measure indicator of credibility is based on reliability, internal actions, and reputation. However, criticality is the characteristic of a system that does not tolerate failures and must secure its properties even through internal and external events. This sensitivity is related to system importance on the socio-economic development of a nation, and the grave consequences that could emerge from a service interruption caused by any inadvertence or malicious source [19].

3.2. Integrity Models

The models of integrity policy are:

- The policy defined by Bell & Lapadula that addresses confidentiality of data systems. It is based on two properties: Simple Integrity (No read down) and Integrity* property (No Write up) [21]. For simple integrity property, the subject can only read objects at its own integrity level or above. On the other side the Integrity* property, the subject can only write objects at its own integrity level or below.
- The Chinese Wall policies aim is to protect the financial system from illicit manipulation. It consists of three levels of abstraction object: Objects that contain information about only one company, Company data set (CD), and the conflict of interest (COI). CD is an object collection related to a certain company. COI is a class containing the data sets of competing companies [22].
- The policy defined by Clark & Wilson is designed for commercial aims and focuses on data integrity preservation. Indeed, each data item can only change using a certified procedure, which keeps its integrity. Furthermore, it is dedicated to verifying data items and certify their integrity. This model can be interpreted as two integrity levels: data are classified into Unconstrained Data Items (UDI) and Constrained Data Items (CDI). This model defines two notions: the transactions and separation of duties. The first notion states that information may only be treated through Transformation Procedures (TPs) which support the involved data integrity. Additionally, integrity Verification Procedures (IVPs) can be verified modification integrity data. The system keeps lists of a relation between these entities which allowing UDIs into CDIs transformation according to TPs and IVPs [23]. Unlike Biba policy, two ways influenced the policy defined by Clark & Wilson: a data who gives integrity level should keep its integrity level only if it is manipulated by a procedure validated to at least the same level. Moreover, the information flow passage from a lower to the highest level is possible only if it is validated to certify that the data has a high integrity level.
- Totel model is based on the object-oriented approach. It aims to offer a usable and flexible generalization of the other models mentioned above for providing kinds for objects with defined properties. Figure 2 presents the software architecture proposed in Totel's Model. It is based on objects classification in order to give a strict information flow to check integrity policy and to manipulate the mechanisms of information integrity upgrade. Authors in [24, 25] defined three object types: **Single Level Objects (SLOs):** are single constant integrity level. This king contains information and creates flows using its internal data at different levels of integrity. **Multi Level Objects (MLOs):** are intended for providing more flexibility by being able to offer some services at any integrity level. They are validated to a given integrity level and can accept data from any level. They are modified dynamically and restoring it at the beginning of the next invocation. To achieve this aim, the authors prove that these objects have no memory. At each invocation, these objects will be created from scratch. **Validation Object (OV):** provides information with a sufficient certified integrity level to

allow flow from low to high integrity level. Furthermore, it runs fault tolerance mechanisms to produce high integrity outputs. The software architecture described a Trust Computing Base (TCB), which is composed of operating system micro and kernel integrity. The goal of TCB is to control all communications in the system, prevent unauthorized rising flows by authorizing only ascending flows, and sending it to a validation object.

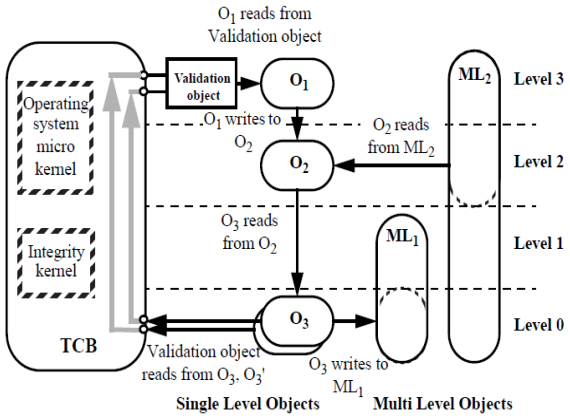

Figure 2: Illustrations of the integrity policy rules [25]

3.3. Integrity Based IMS architecture

In IMS networks, the integrity protection is applied between user equipment (UE) and the P-CSCF for protecting the SIP signaling according to several steps: Firstly, UE and P-CSCF negotiate the integrity algorithm for the session. Secondly, these entities agree on key of security, which is based on AKA algorithm and they verify that data originates received. Finally, the replay and reflection attacks must be mitigated. The integrity algorithm defined in IMS architecture is HMAC-MD5-96 or HMAC-SHA-1-96. This algorithm should be supported by UE and the P-CSCF. The protection indicator of integrity to decide the registration is as follows: (1) REGISTER request from the UE needs to be authenticated. (2) The S-CSCF should be known about the integrity protection applied to a message. (3) The p-CSCF lies an indication in the REGISTER request to inform the S-CSCF that the message was integrity protected for verifying if the message of integrity is the same or not. (4) For all other REGISTER requests, the P-CSCF attached an indication in order to verify that was not integrity protected or ensures that there is no indication about integrity protection in the message [5].

3.4. Fuzzy Logic

Fuzzy Logic is a technique that provides mechanisms to handle nonlinear uncertainties that exist in physical systems. It introduced by Lotfi Zadeh [26]. It is applicable in several applications [27]. Fuzzy sets represent objects collection, which is characterized by a membership function. The membership function is a type variable, which uses words instead of numbers to represent its knowledge in fuzzy systems that express a conditional rules statement [28]. The linguistic variables are parameters that are used to control the system and to show their performance. It is divided into levels. Fuzzy operations are the same operations in classical sets, which are union, intersection, containment, and complement. Fuzzy rules consist of three parts antecedent, fuzzy proposition, and consequence. Fuzzy inference system (FIS) is the regrouping of fuzzy rules, the linguistic variables of membership functions and fuzzy reasoning [27]. The FIS is designed for constructing complex and nonlinear relationships between the input and output. There are many FIS used in applications such as Mamdani, Tsukamoto, and Sugeno [30]. The difference between these types of FIS is in the aggregation and defuzzification processes. The Mamdani FIS method is used in our case because it has widespread acceptance and it has the most commonly used of the three FIS [30]. To implement an FIS, four steps to follow fuzzification, rule evaluation, aggregate output, and defuzzification.

4. Contribution And Discussion

The approach of multi criticality on IMS networks aims applying of a policy of security in terms of criticality. The proposed contribution is to integrate a layer called Integrity verification communication in Test Bench [2] as shown in Figure 3. This integration is based on Totel model. Even though, in the IMS network, the entities of the controller have much knowledge of the network. Although, the administration of real-time services is a difficult task given the fluidity of the network to be ensured at any time. That is why, the contribution approach is to integrate a layer of security policy to monitor business processes [2] responsible for the implementation regarding verification and correction scenarios to ensure the integrity of the exchanged messages. Using Totel Model, for integrity policy presents an advanced innovation in terms of QoS management in IMS network compared with the other models [20, 21, 22, 23]. These models prohibit the passage flow from a lower level of criticality to the highest level of criticality. On the other hand, in IMS network; the users are mobile devices, have different preferences such as environment, equipment …

For this effect, the communications should be circulated in both ways from less critical tasks to more critical tasks. The proposed contribution is based on an object-oriented, the SLO objects described levels of QoS and the MLO objects described levels of criticality of customers. In [24], the authors have specified that the MLO allow changing their level of criticality at any invocation method to control and accept data from lower or equal level. These objects have no memory, and are created at each invocation, which influences execution duration and reduces network performance; also, the identification of the exacted values for these thresholds is very difficult. For this reason, the concept of Fuzzy logic is used to determine dynamically criticality levels for users according to several criteria: customers, equipment, and environment. This technique allows a significant gain in terms of determining appropriate QoS to the users' levels of criticality.

4.1. Integration of fuzzy logic in the multi criticality approach

There are many main components of soft computing such as Fuzzy Logic, Neural Networks, Probabilistic reasoning [29] and Genetic algorithms [31]. The most important one is Fuzzy Logic.

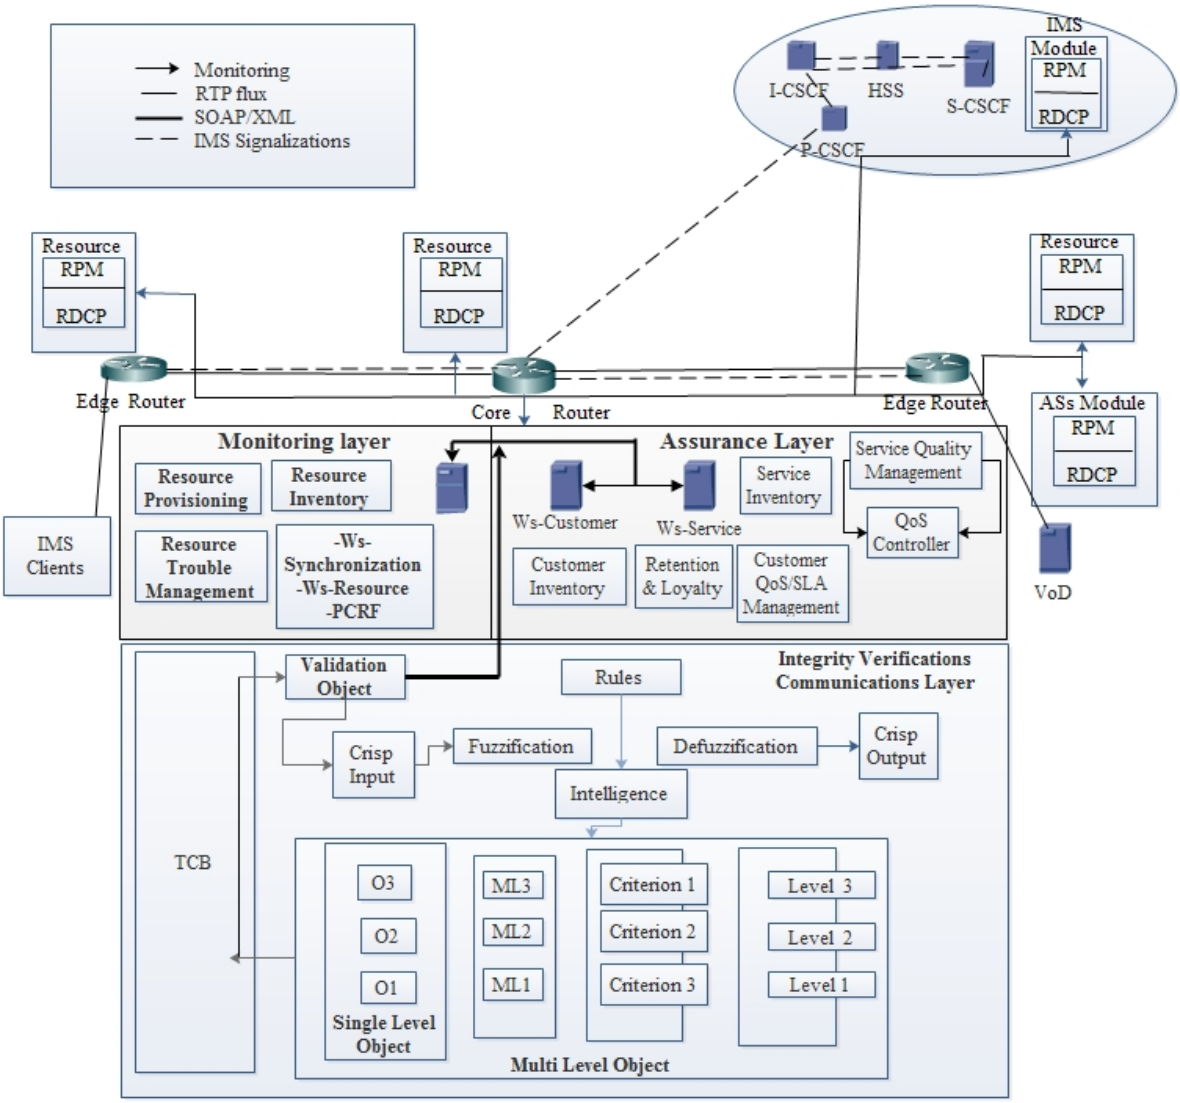

Figure 3: Architecture proposed [1]

It incorporates modeling, control management, forecasting and performance estimation. Also, it used on several applications. The integration of multi criticality approach, based on fuzzy logic as shown in Figure 3 has several advantages while estimating a QoS considering the increasing or decreasing levels of criticality of customers, levels of QoS services and optimizing costs. However, this approach is a key to satisfaction both QoS and QoE of customers' needs.

4.2. Use Case of Fuzzy Logic

The simulation results are based on Matlab tools. The fuzzy logic tool allows users to create Fuzzy inference for estimating conclusions problems. To simulate a system, the system is built through the Graphical User Interface (GUI) Tools. Five GUI tools are being executed to have simulations for the input and output of our system: building, editing FIS, Membership function, Rules, and reviewing Rule and surface. The viewer Rule and surface are being used for a survey with FIS editor.

FIS Design

Fuzzy Logic is based on Fuzzification, rule evaluation, aggregation, and defuzzification as mentioned previously. The simulation is based on Mamdani method, which is the most frequently used method [30]. This method allows a system to work in an easy and simplified mathematical way as described in Figure 4.

For modeling the control system, the FIS design considers three parameters: Environment, Equipment, and Customer to define the chance value of SLOService and levelOfCriticality MLO. Customer input presents a degree of importance of users according to their activities in the IMS network. Equipment input presents categories of mobile use. Environment input presents areas when users placed. SLOService describes a QoS and LevelOfCriticality describes levels of criticality for the customer.

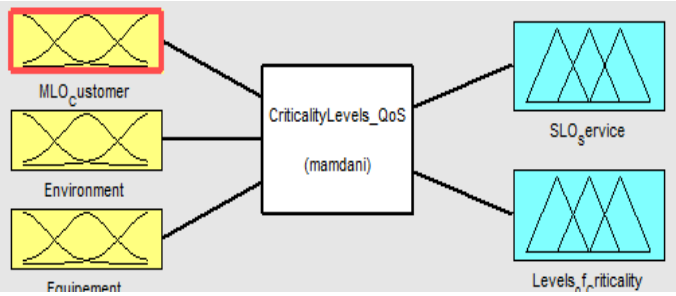

Figure 4: Fuzzy Inference System for CriticalyLevels_QoS

Each parameter is divided into three linguistic value levels: Average, Good, and very Good for Customer input, and Dense Urban, Urban, Suburban for Environment, and category 1, category 3, category 5 which present bit rate for Equipment. Moreover, Matlab Fuzzy Logic tools included several types of membership functions such as triangle, Trapezoidal, Gaussian, sigmoidal and S-shape. In the next step, some simulations are found to determine the important membership functions between Gaussian, trapezoidal and Triangle whose gives a good result in the aspect of chance value for SLOService and MLO.

The variable linguistic for input parameters is presented by a Gaussian membership function as illustrated in Figure 5, Figure 6 and Figure 7.

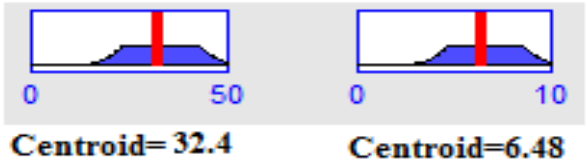

Figure 11: Centroid Point for Defuzzification

Analysis and examples for trapezoidal and Triangle membership function

The following simulation describes a comparison between Gaussian, triangle and trapezoidal membership function. The linguistic variable for the middle level (good, Urban, category3) is presented by the triangle membership function, while the other levels are presented by Trapezoidal membership function as illustrated in Figure 12, Figure 13 and Figure 14.

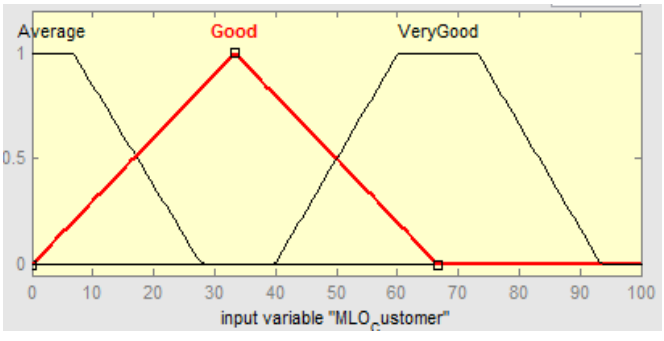

Figure 12: Fuzzy set of Customer

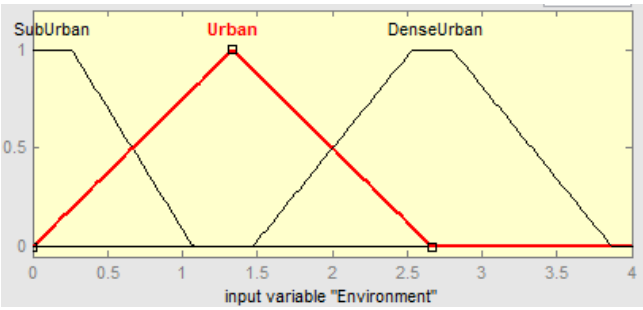

Figure 13: Fuzzy set of Environment

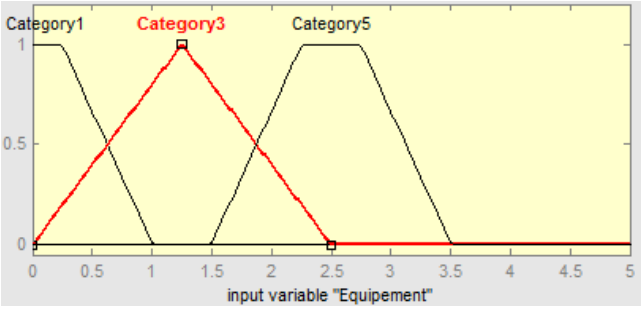

Figure 14: Fuzzy set of Equipment

To give our incidence feature of flexibility, the linguistic variable for chance value is divided into 9 levels following as VeryLow, Low, ratherLow, LittleMedium, Medium, HighMedium, ratherHigh, High, VeryHigh for levels of criticality and veryWeak, Weak, littleLow, LittleMedium, Medium, HighMedium, littleHigh, High, VeryHigh for levels of QoS as illustrated in Figure 15 and Figure 16.

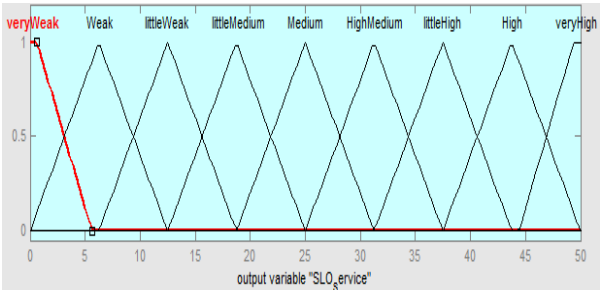

Figure 15: Fuzzy set of SLOsService

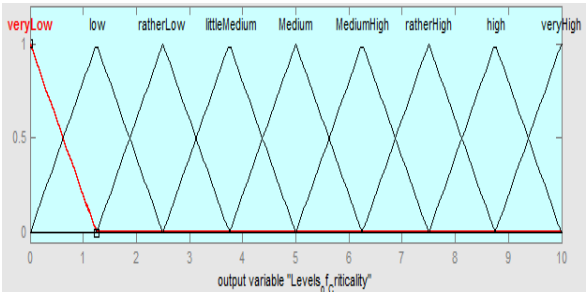

Figure 16: Fuzzy set of SLOsService

According to this result, the degree that is determined by a Triangle and Trapezoidal membership functions is more specific than a membership function of Gaussian. In addition, Triangle and Trapezoidal membership functions are more useful than the other types because their degree is more easily determined. Table 3 illustrates IF-THRN rules. The following Figure 17 described a result obtained for defuzzification by triangle and trapezoidal membership function.

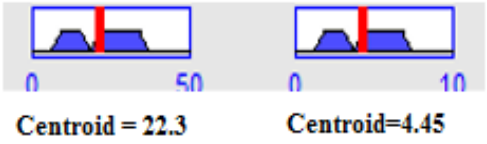

Figure 17: The centroid point

25	VeryGood	SubUrban	Category5	VH	VH
26	VeryGood	SubUrban	Category3	High	High
27	VeryGood	SubUrban	Category1	LH	rH

For SLOService QoS: Low: veryWeak(VW)-weak-LittleWeak (LW), Medium: LittleMedium (LM)-Medium (M)-HighMedium (HM), High: LittleHigh (LH)-High-HighMedium (HM). For LevelsOfCriticality MLO: Level1 (low level of criticality): veryLow (vL)-Low-ratherLow (rL), Level2-3(Medium Level of criticality): LittleMedium (LM)-Medium (M) - MediumHigh (MH), Level4 (High level of criticality): ratherHigh (rH) - high- veryHigh (vH).

Analysis and examples for different defuzzification methods:

Our analysis result takes into consideration two cases:

Case 1: Low quality of service and Low Level of Criticality.

Case 2: Excellent quality of service and High Level of Criticality.

Case1: if (customer is average) and (Environment is SubUrban) and (Equipment is Category1) then (LevelofCriticality is veryLow) and (SLOService is veryWeak), which is described in Rule viewer and illustrated in Figure 18.

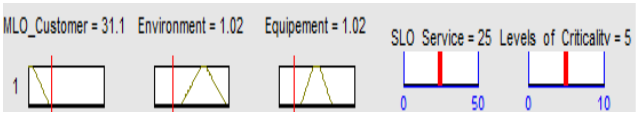

Figure 18: Rule Viewer for case 1

While, the values for MLO_Customer as average (31.1), Environment 1.02 and Equipment 1.02, then SLOService is 25 and Level of criticality is 5. In this case, the Level of criticality is low and the level of QoS also is Low. Therefore, the activity of users is average, the environment is suburban and the equipment is category1, which bit rate is low. Thus, the level of criticality and QoS are low. According to this result of defuzzification, the service of VoD is delivered. This value is obtained by using COG method. The proposed approach of multi criticality is based on several criteria for making decision problems. For this reason, the FIS incorporates three inputs and two outputs. In this case, a 3D surface cannot show the relations between all output criteria: SLOService and levelofCriticality. In such a case, several 3D fuzzy surfaces are illustrated in different examples in Figure 19. Each surface corresponds to one scenario and allows the sensibility of the SLO and LevelsOfCriticality output with Customer and Environment input. Three main methods of defuzzification methods such as COG (Centroid of Gravity), MOM (Mean value of maximum), and LOM (Largest value of Maximum) are simulated by using 3D surface viewer as illustrated in Figure 19. A method COG returns a maximum of aggregation solutions. MOM method takes as a solution the average of the most likely values output. In addition, LOM method returns the maximum value, which is determined from membership functions.

Table 4 defines the results of comparative for three methods of defuzzification such as COG, MOM and LOM. Rule number 9 describes case 1 that represents a low quality of service (SLO) which value of COG method is 13.6, MOM is 6.25 and LOM is 9. In addition, the value of low Level of Criticality (MLO) using COG method is 2.92, MOM is 0.25 and LOM is 0.5.

From the result above, The COG method returns the maximum chance values for providing the more stable results among the other methods (MOM and LOM), considering the variations in the set conclusion which are graphically illustrated in Figure 19. From these figures, also the same results are concluded, the COG defuzzification methods take into a consideration several values for input that represented by different color as compared to MOM and LOM method. Thus, the concluded result is that the COG method gives a better result than MOM and LOM methods.

Table 4: Output values obtained for different defuzzification method

S. No	Input			Output SLO			Output MLO		
	Ct	**Ev**	**Eq**	**C**	**M**	**L**	**C**	**M**	**L**

15	50	2.37	0.56	31.3	37.5	40.5	6.27	7.5	8.1
16	50	0.64	4.43	25	25	25	5	5	5
17	50	0.64	2.54	37	48.5	50	7.44	9.7	10
18	50	0.64	0.56	31.3	37.5	40.5	6.26	7.5	8.1
19	85	3.54	4.43	25	25	25	5	5	5
20	85	3.54	2.54	47.7	48	50	9.49	9.6	10
21	85	3.54	0.56	40.6	40.8	48	8.12	8.15	9.6
22	85	2.37	4.43	25	25	25	5	5	5
23	85	2.37	2.54	47.8	48.3	50	9.51	9.65	10
24	85	2.37	0.56	40.6	40.8	47.5	8.12	8.15	9.5
25	85	0.64	4.43	25	25	25	5	5	5
26	85	0.64	2.54	47.8	48.3	50	9.51	9.65	10
27	85	0.64	0.56	40.6	40.8	47.5	8.12	8.15	9.5

Ct (Customer), Ev (Environment), Eq (Equipment), C (COG), M (MOM), L (LOM).

Figure 19 shows that the environment and type of customer are low, thus resulting of SLO and MLO is Low, this is why the result is different for three defuzzification methods. A service VoD can be transmitted with low quality for a customer whose have a low level of criticality.

Case2: if (customer is VeryGood) and (Environment is DenseUrban) and (Equipment is Category5) then (LevelofCriticality is veryHigh) and (SLOService is veryHigh) as described in Rule viewer and illustrated in Figure 20.

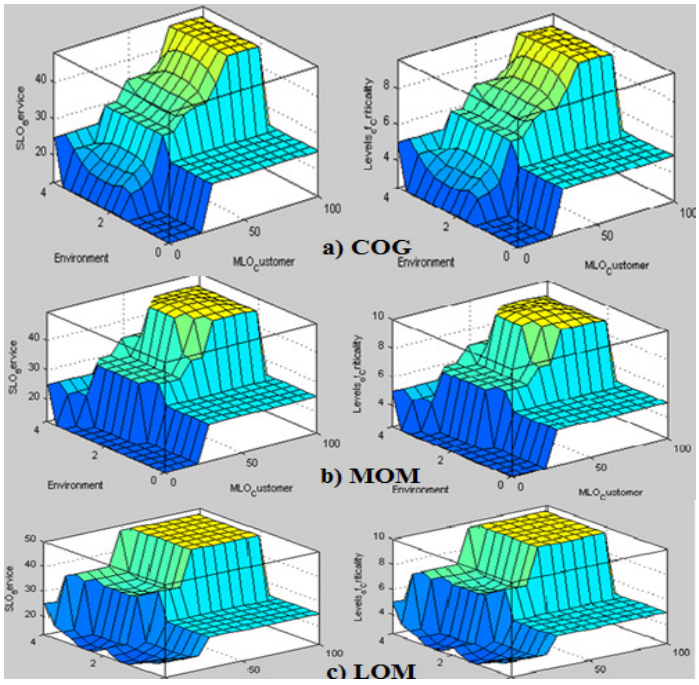

Figure 19: Surface viewer with method: a) COG, b) MOM and c) LOM

Figure 20: Rule Viewer for case 2

In case 2, the value of the Customer is 82.6, Environment is 3.23 and Equipment is 3.14. For SLOServices the value is 47.5 and LevelOfCriticality is 9.53. The analysis determined that the QoS is Excellent and the level of criticality is high. This means that using the parameters above, the service VoD can be transmitted with excellent quality for a customer whose have a high level of criticality. The case 2 is illustrated with rule 19 in Table 4, which describes DenseUrban environment, veryGood type of customer and high category of mobile, thus resulting in high SLO and MLO this is why the result is approximately the same for three defuzzification methods: GOC, MOM, and LOM, which are 25 for SLO output and 5 for MLO output. A service VoD can be transmitted with high quality for a customer whose have a high level of criticality.

From the above examples in case 1 and case 2, the COG defuzzification method gives better results in the aspect of SLOService and LevelsOfCriticality. This can be seen with the surface viewer and the rule viewer as presented in the above examples using different rules. In this section, the proposition aims are to design some control mechanisms, for solving problems of QoS during multimedia service transmission by using an intelligent controller, in order to determine dynamically levels of criticality of customers. This controller is analyzed by using Fuzzy Controller Language (FCL), the input of FCL is determined and the most appropriate membership functions and defuzzification method are founded for determining better crisp values in the aspect of SLOService and LevelsOfCriticality in IMS network. In addition, the methods for membership function (Gaussian, Triangle, and Trapezoidal) and methods for defuzzification: GOC, LOM, and MOM are compared. The 3D surface viewer is used for describing the comparison offered by three methods. Through these analyses, the COG method, triangle, and trapezoidal membership functions give better results in all analyzed cases.

5. Conclusion

In this paper, the proposed approach of multi-criticality is based on Fuzzy Logic to ensure integrity on IMS architecture, in order to determine levels of criticality dynamically by using multi-criteria: Environment, Equipment and Type of customer for making the decision to offer a level of QoS of VoD. It is based on Totel model. From the simulation results, the triangle and trapezoidal membership functions give better results than Gaussian membership also COG method of defuzzification is more efficient than MOM and LOM methods. Future works, will be focused on the technical approach of Totel model using technologies web SOA, make a VoD by using openIMS, and will be focused on the prediction of the indicators for storing the antecedents' cases of degradation, furthermore another aspect of QoE will be discussed.

ABSTRACT

This paper describes the concept and configuration of a novel automated safety vehicle stop system, and a future prospect of the study. Intrinsic sudden death may cause traffic accident since such accidents sometimes involve not only the driver but also other traffic users such as passengers and pedestrians. Cardiovascular disease (CVD) is considered as a serious driving risk factor. The pain and others effects of cardiac events degrade driver's performance, and CVD causes ischemia brought by the CVD induces incapacity of driving. In the automated safety vehicle stop system, which our research group has developed, steer-sensors collects bio-signals and a camera captures the driver's posture to monitor driver's incapability. When the driver loses his or her driving capability, the system takes over the maneuver of the vehicle and automatically drives to a safety spot by observing the traffic environment. An emergency scenario was used to demonstrate the system verifying its potential.

1. Introduction

The association of driving and physical disorder has been researched for many years. Driving requires both physical and cognitive functions. Beside the effects of long time driving and many cognition stressors, deterioration of driving performance by physical disorder increases the risk of accidents [1]. Although multiple technologies such as adaptive cruise control and emergency braking embedded in the vehicle have decreased the stress of driving on the driver, the number of intrinsic sudden death in traffic accident is still high over the years (Table 1).

Table 1. Autopsy report of intrinsic sudden death of driver

Author	Location	Period	Driver reported as intrinsic sudden death	
			Number	Percentage
West et al. (1968)[2]	USA (California)	1963-1965	155/1026	15%
Osawa et al. (1998)[3]	Japan (Western Kanagawa)	1992-1997	15/188	8%
Oliva et al. (2011)[4]	Canada (Quebec)	2002-2006	123/1260	9.7%
Tervo et al (2013)[5]	Finland	2008-2009	55/488	11.3%

Cardiovascular disease (CVD) and cerebrovascular disease are the most common causes of sudden natural death while driving[6][7]. The effects of cardiovascular disease, such as myocardial infraction, are not immediately but gradual, so that the driver can somehow step on the brake and/or maneuver the vehicle to the side of the road. The pain of cardiac events distracts driver's concentration, and ischemia brought by CVD induces impairment of awareness, recognition, eyesight, physical strength, and others functions.. Syncope is the sudden and transient loss of consciousness. The aftereffect of some serious arrhythmias is syncope that may lead to the lost control of the vehicle. The association of driving and CVD has been investigated for many years [2][8][9]. In Japan, Motozawa et al [6] have reported that among the autopsies results of Transportation Bureau of National Police Agency (Japan), the main cause of death is ischemic heart disease. In European countries, meta-analysis has shown that CVD patients have 23% higher risk of accident involvement than drivers without CVD [10]. Many other researches also pointed out that CVD drivers have higher risk of accidents than healthy drivers [11][12][13][14].

Table 2. Percentage of CVD death among intrinsic sudden death at wheel

Author	Location	Period	Intrinsic death caused by CVD (%)
West et al. (1968)[2]	USA (California)	1963-1965	94%
Copeland (1987)[18]	USA (Florida)	1980-1984	82%
Oliva et al. (2011)[4]	Canada (Quebec)	2002-2006	36.8%
Tervo et al (2013)[5]	Finland (Uusimaa)	2008-2009	17.8%

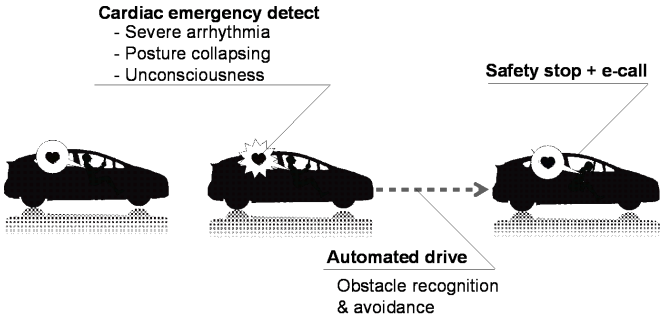

Figure 1. System objective

Various authorities have issued guidelines to detail the criteria for declaring an individual with CVD safe to drive [15][16][17]. Although these methods help decrease the number of death at wheel caused by CVD, drivers still have high potential to get cardiac emergencies behind the wheel, as shown in Table 2. Development of the system that prevents from the CVD-derived accident is essential besides developing the regulations.

This study aims to develop a system that prevents traffic accidents caused by physical disorders. The system detects driver's incapacity by collecting various types of bio-signals and driver's ergonomic factors: electrocardiogram (ECG), photoplethysmogram (PPG), and blood pressure (BP), by using steer-sensors. A driver agent using a camera in front of the driver monitors the driver's posture. The system will take over the maneuver of the vehicle when the driver lost his capacity to drive, and automatically drive to a safety spot by sensing the traffic environment. Figure 1 shows the objective of the research. The following sections describe the concept and the configuration of our first prototype system, The prototype system was designed focusing on cardiac emergencies, and a future prospect of the study.

2. System configuration

The system is composed by the following units: Steering wheel-type bio-signal sensor (Steer-sensor), which is for the cardiac emergencies, Driver's ergonomic factors and driver agent assist to confirm situation, and Automated driving system will take over the vehicle to maneuver to safety spot.

2.1. Bio-signal sensing and cardiac emergency detection

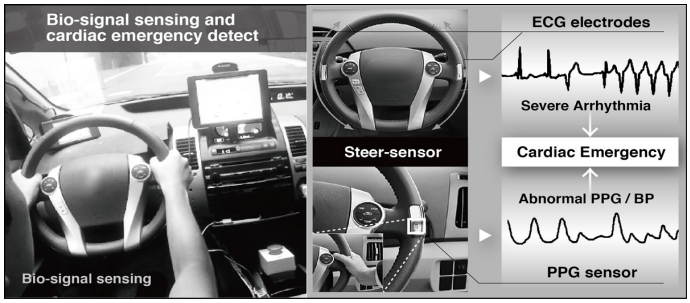

Figure 2. Bio-signal sensing by the steer-sensor and cardiac emergency detection

The collected bio-signals are essential data to detect CVD-event. The electrodes are placed on the outer side of the wheel. ECG and PPG signal are collected by gripping the steering wheel with both hands. Figure 2 shows the position of the both sensors on the wheel. The PPG sensor is located at the place where the base of right thumb touches when a driver grips the wheel in the usual manner. BP is estimated from the pulse transit time (PTT) measured by the ECG and PPG. Further detail is referred to [19][20].

Combining the characteristics of following patterns: 1) tachycardia or bradycardia, 2) abnormality of QRS complex, 3) irregularity of R-R or P-Q intervals, 4) abnormality of BP; the type of cardiac emergency is estimated. Depending on the type of arrhythmias, the normal heart rate will be affected and heart rate might be faster or slower or erratic. These abnormal states of heart rate will affect the control capacity of the driver. When the life-threatening arrhythmias such as ventricular tachycardia (VT), ventricular fibrillation (VF), Torsade de Pointes, or cardiac arrest with the abnormal PPG and BP are detected, the system triggers the emergency signal to the later unit.

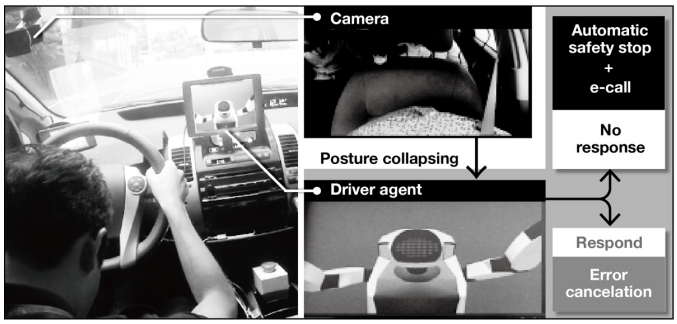

Figure 3. Posture collapsing detection

2.2. Driver's ergonomic factor and driver agent assist

When the system detects an abnormality in driver's bio-state sent from the prior unit, the driver's posture is captured by the driver-monitor camera settled in front of the driver (Figure 3). Some arrhythmias cause pain and/or numb in the chest and shoulder, some make driver feel dizzy or faint. In most of the cases, drivers with serious trouble feel uncomfortable in their chest first and then eventually lose their normal driving posture. A driver agent is installed inside the vehicle to give instruction and alerts while driving.

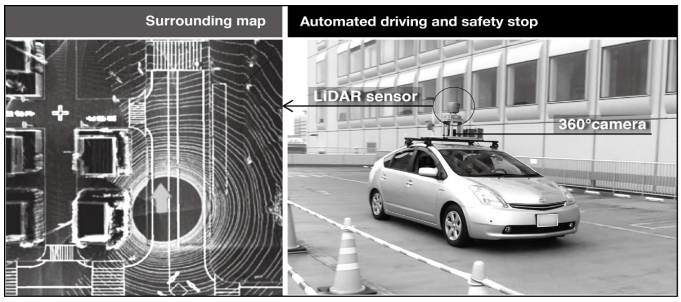

Figure 4. **Automated driving and safety stop**

By using driving instruction model, the driver agent handles cameras data and driving records to monitor driver's driving performance and give instructions if needed to improve driving behavior. If the driver's abnormal posture is detected, the driver agent alerts the driver. The alerting is settled in order to avoid the misdetection of the arrhythmia and posture collapsing. Autonomous drive is activated by the absence of response to the alert for certain duration, and then emergency call (e-call) is taken. Further detail of the driver agent is referred to [21].

2.3. Automated driving system

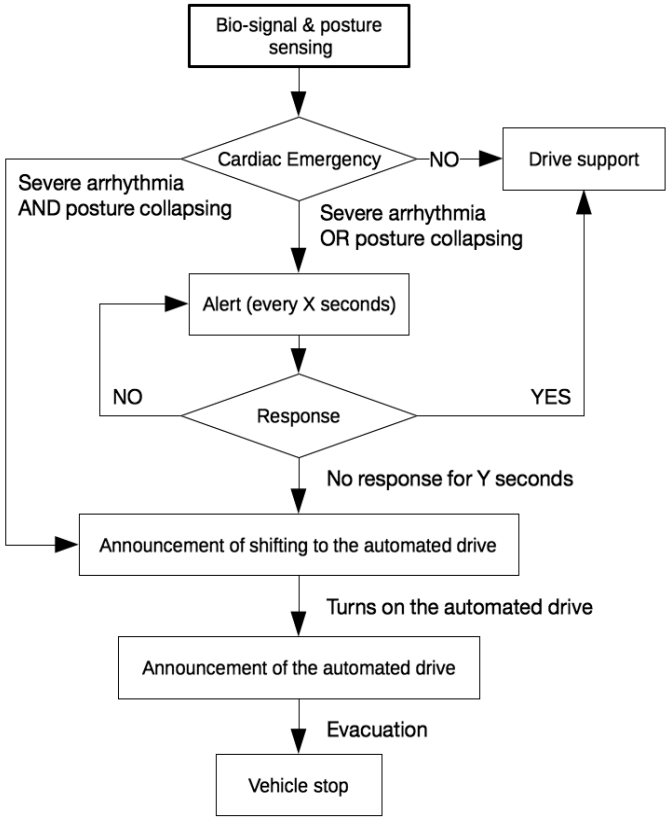

Figure 5. Decision-making procedure of the manual-to automated shift

Various sub-systems in the automated driving system enable the vehicle capture to the surrounding environment: by a LiDAR sensor (HDL-64E, Velodyne LiDAR, Inc.), 360 degrees camera (Ladybug 5, Point Grey Research, Inc.), Grasshoper 3 cameras and Javad RTK sensors receive global positioning information from satellites as shown in the Figure 4. By combining Velodyne LiDAR sensor and Ladybug 5, the system obtains 3D point-cloud data for localization and mapping, and is also used to measure the distance to surrounding objects and moving objects. The Grasshoper can be used to detect traffic lights. The system enables to estimate the position with the precision of 0.1m. This configuration allows the vehicle to drive and avoid obstacles on the road after taking control from the driver. Further detail is referred to [22].

When the driver's critical state is confirmed and trigger signal is sent from prior units, the automated driving mode is activated. The system recognizes the surrounding of the vehicle and automatically finds a safety spot to park the vehicle. Figure 5 shows the decision-making procedure of the manual-to-automated shift.

3. Demonstration

The prototype of the system has been demonstrated at TOC Ariake, Tokyo, Japan in 28th August 2015. A well-prepared scenario was set to demonstrate the working prototype: The driver is driving with normal state then the abnormal state is injected to the system to simulate the critical situation.

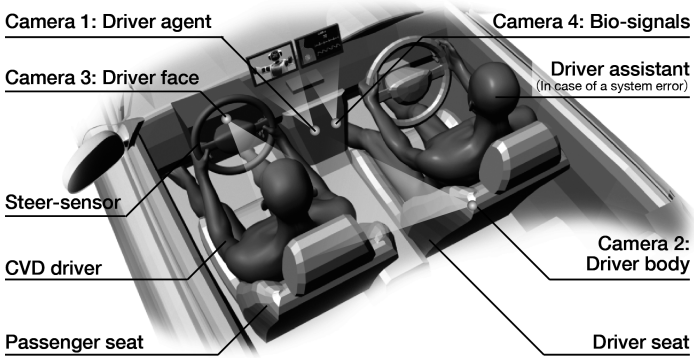

Figure 5. Interior layout of the demonstration

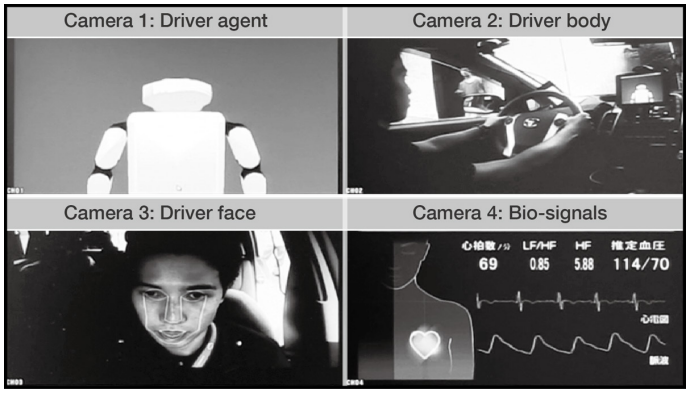

Figure 6. Captured images by the cameras at the demonstration

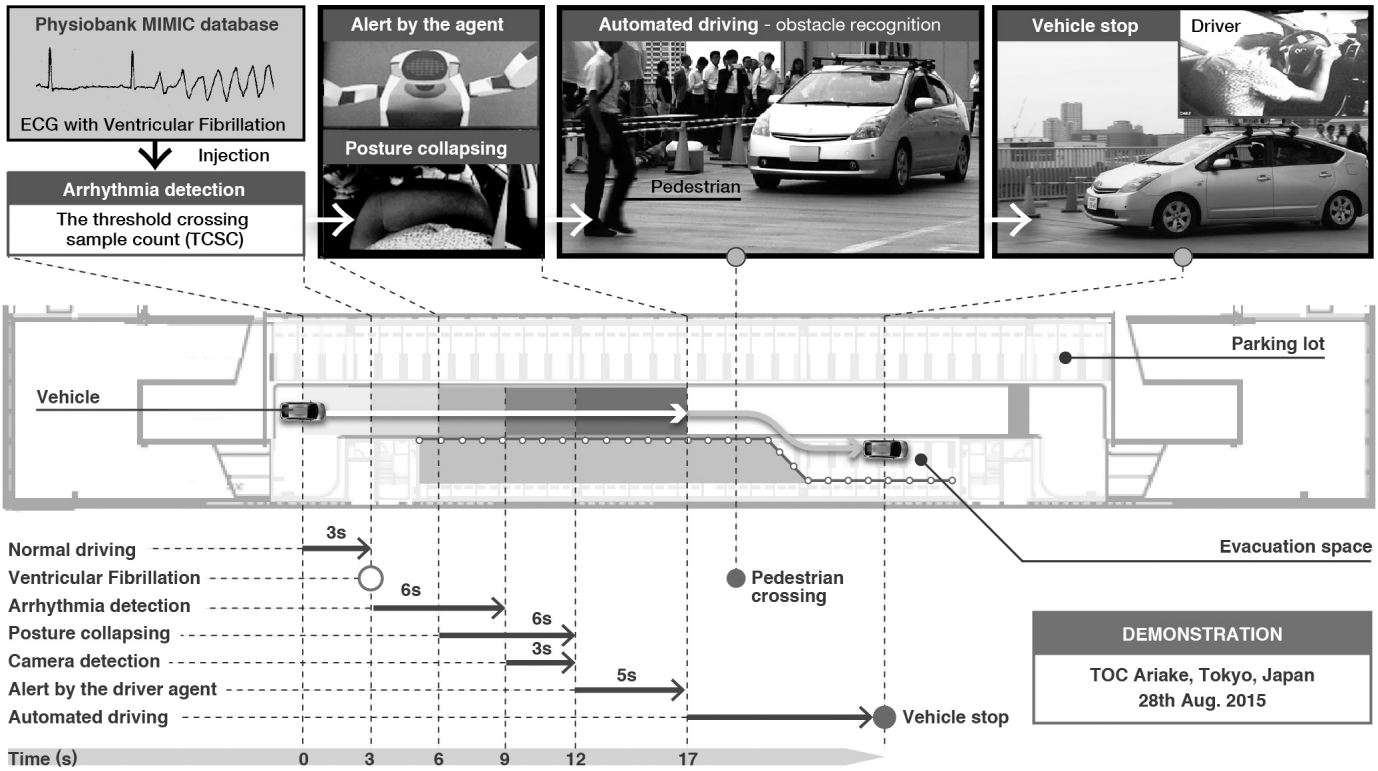

Figure 7. Scenario of the demonstration conducted at TOC Ariake, Tokyo, Japan in 28th August 2015

Normal ECG data was collected by the sensor, then the ECG with ventricular fibrillation (VF), obtained from PhysioBank MIMIC database [23], was used for simulation of the emergency situation.

The threshold crossing sample count (TCSC) [24] was implemented for the VF detection. Considering the safeness of the demonstration, the steer-sensor and the driver-monitoring camera were settled on the passenger seat as shown on the Figure 5. The assistant driver on the driver seat will take countermeasures in case of system errors during the transition of manual-to-autonomous driving and while automated driving. Four cameras were settled to monitor the conditions of inside the vehicle: two for capturing driver's face and posture, one for driver agent and one for driver's bio-signals.

The captured images (Figure 6) were sent to the monitor placed in front of the audience wirelessly. The scenario of the demonstration is illustrated in the Figure 8. It started from normal driving with the speed of 20 km/h, it took about 3 seconds to let the vehicle reached the designated velocity and all systems worked in normal state. Soon after the simulated VF was injected, the arrhythmia detection and cameras worked simultaneously to catch the emergency situation. The posture collapsing of the driver were detected by the face recognition. In the meantime, the agent gave an alert to the driver to confirm the situation. Then the system automatically turned on the automated driving when it confirms the driver's critical state. In the scenario, a pedestrian crossed in front of the vehicle while the system turned into the automated mode. It successfully recognized the pedestrian and stopped while he was crossing the road. Soon after it confirmed no obstacles ahead; it drove to the safety spot (Evacuation space on the Figure 8) and stopped the vehicle. All the procedures after the VF injection were done automatically.

4. Discussion

European automobile manufacturers have developed the related system in recent years [25]. Their system prevents frontal crash and lane departures by an adaptive cruise control and a lane-keep assist when a driver lost his capacity to drive by a physical disorder. It also alerts the driver by an indicator and warning brakes, and evacuates the vehicle with hazard lumps when there is no response from the driver. The similar demonstration has shown at the 22nd ITS world congress, Bordeaux, France, in October 2015 [26]. Driver's incapacity was detected by a camera and automatically stopped the vehicle on the shoulder of a road at the demonstration. Although the related system is well designed for the countermeasures for incapacitated drivers, the future studies require detection methodologies of the driver's incapacity at earlier stage. Even a few seconds of beforehand detection decreases the risk of crash. Since the bio-signals indicate the abnormality of the driver before he/she gets incapacity, our system has a potential for minimizing the crash risk. The prototype of the system using bio-signal detection was successfully demonstrated its function at the prepared scenario.

The demonstration, however, also revealed its limitations and problems. Tests with conventional ECG sensor has showed that the driving condition actively adds noise to the signal. Moving artifacts due to body motion were sometimes detected as severe arrhythmias, resulting in misdetections. Since the steer-sensor generates more noises on the ECG than conventional sensors, that uses adhesive electrodes, the waveform of the PQRST complex easily gets distorted. Therefore, it requires additional methodologies on the conventional arrhythmia detection. Moreover, gripping the wheel by both hands all the time is not practical in the real driving scenes, so that it requires

accompanying sensors such as capacitive ECG sensor or wearable PPG sensor to compensate the signal distortions or the signal losses or combine with other technologies to compensate signal when the driver drives with one hand. As shown in the Figure 7, the duration of uncontrolled vehicle is 14 seconds and the initial velocity when the arrhythmia started was 20 km/h (5.6 m/s). Thus, the distance the vehicle kept moving is 78 meters. In unconsciousness state, the driver can step on the gas pedal or steer the vehicle out of the lane. Both of above situations will eventually lead to accident. It is needed to shorten the detection time of both arrhythmia and posture collapse. Normally, if the driver feels any discomfort while driving he/she will apply brake and slow down. But others might suffer more serious situation and collapse before the accident happen. In that case, it is important to develop methodology to predict arrhythmia before it happen. In addition, it is not always safe to stop the vehicle at a certain spot. Further investigation of coping behavior in the emergency situation is essential for the development.

5. Conclusion

The study demonstrated the concept of the automated safety vehicle stop system for cardiac emergencies. The prototype system has shown potential benefits to both patients and normal healthy people. But the system contains many limitations requiring their solutions: the sensor quality and investigation of emergency management on the various driving situations. Moreover, detecting driving incapacity requires not only bio-signals but also other risk factors such as driving performance, driver's state, driver's medical history etc. Currently, we are focusing on the effects of the driving situations, the effects of physical stress and cognitive stress on CVD patients and healthy subjects. These topics are dedicated to our further studies.

ABSTRACT

Jaw cyst is one of the most common pathology observed in the field of dentistry. Early detection of the cystic lesion will help the surgeons to take appropriate therapeutic measures after a thorough diagnostic procedure. One of the challenging task for surgeons is to differentiate the cysts from the other pathologies. The appearance of these pathologies on a radiograph is a complex and confusing task due to the close similarity between the cysts and tumors which is a difficult to differentiate just by its appearance. Hence to resolve this problem, a computer aided classification algorithm is needed for accurate classification of cysts. The work presents a new approach for the determination of the presence or severity of the jaw bone disease aiding the diagnosis and radiotherapy planning. This paper presents texture characterization for the dental panoramic images. The transposed images are analyzed using Gray level co-occurrence matrix(GLCM). The textural properties such as entropy, contrast, correlation, energy and homogeneity are determined for both cyst and non-cystic images. The results obtained are fed to the classification model to classify the given image into normal or abnormal images containing cyst. Support vector machines are chosen for image classification. Image dataset of 30 were used in training and validation. The image set consists of 20 abnormal images and 10 normal images used in image classification.

1. Introduction

Digital dental x-rays are the most preliminary step in imaging various dental anomalies. Dental x-rays also referred as orthopantomograph is the radiographic examination of jaws and the supporting structure across the teeths [12]. Using this equipment, the area of interest in the jaw are scanned in few seconds, often happen to be distorted by the noise and have inhomogeneous distribution, due to this, few regions are blurred making it difficult to interpret certain features from the raw images. Orthopantomography being a two dimensional imaging modality is riddled with problem of superimposition of anatomical structures. In this approach, the limitations are overcome by using specific image processing algorithm to retrieve more information from the original image.

A cyst in the jaws occurs most frequently than any other part of the body. The most frequent manifestation of jaw cysts is swelling followed by the combination of swelling and pain. The swelling associated with the cysts causes facial deformation adversely affecting the patient's psycho-social status. A definitive diagnosis can be made by age gender and prevalence of cyst. If the cysts are not detected at an early stage, it may lead to tumors**.** Jawbone cysts are classified based on the odontogenic or nonodontogenic, epithelial or non-epithelial, inflammatory or developmental in origin. The distribution of jaw cysts in the ordinary population according to the diagnosis are radicular cysts, dentigerous cysts, odontogenic keratocyst(OKC), eruption cysts, nasopalatine duct and traumatic bone cysts to name a few. Diverse cysts or cysts like lesions appear in maxillofacial region. According to the study, radicular cysts (RC) and dentigerous cysts(DC) are the commonest of all the cysts [1][2].

2. Image Processing Chain

Image processing chain consists of preprocessing, segmentation, feature extraction and classification [9]. First the dental x-ray images are preprocessed based on image enhancement technique namely contrast stretching. Next, it involves segmentation of cysts and lesion using level sets method. In addition to this, certain features are extracted based on texture statistical distribution using gray level co-occurrence matrix (GLCM). In this step the texture properties such as energy correlation, contrast, entropy and homogeneity are analyzed and given as an input for classification. Image classification is made using support vector machines (SVM) to classify the presence or absence of cysts for the given image set. Figure 1 show the block diagram of the image processing system.

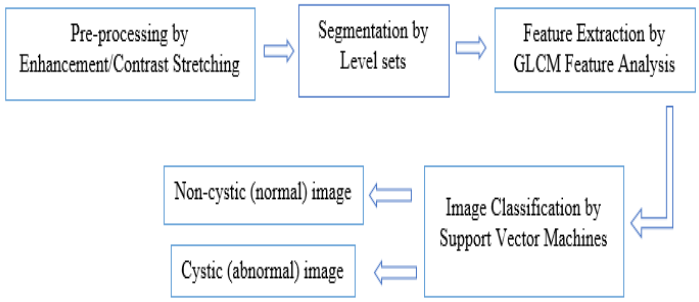

Figure 1: Block diagram for the classification of Cysts.

2.1. Preprocessing

Pre-processing represents the lowest level of abstraction at the images where both input and output are gray scale intensity images. Pre-processing deliberately reduces the information content of the image [13]. If the entropy of the images is measured, the preprocessed image typically has low information content compare to the original image. Therefore, the aim of preprocessing is to reduce the noise and improve the quality of image highlighting few important features which is necessary for further processing in segmentation and recognition tasks [4]. Image pre-processing is classified into two categories such as image enhancement and image restoration techniques. In this paper the raw dental images are scanned by digital dental x-rays are preprocessed based on one of the enhancement techniques called contrast stretching. Contrasting the image, possibly increase the brightness so that the transformed image can be better interpreted. Usually digital dental x-rays images have limited band of gray levels. So the gray level transformation corrects the brightness by setting up the two image contrast between two brightness values p1 and p2. Using the proper brightness threshold, the contrast of the image can be improved and significantly recognizing low level features which is distorted due to poor illuminance properties [3].

2.2. Segmentation by Level Sets

The main idea behind this level sets segmentation is to represent the initial contour of the object as the zero level set function which is defined by the level set function defined in the higher dimensions [12]. The level sets function is evolved using partial differential equations (PDF) [10]. This method presents many advantages in which the contour described by the extent level set function has the flexibleness to interrupt and merge naturally during the evolution. [5].

The level set method is a curve evolution technique for detecting interfaces and shapes in the images. In level set method initially the contours are set as zero level set of higher dimensional function called as level set function. firstly, geometrical shaped contour and iterations are defined and after given number of iterations the contour spreads over the region of interest for the object boundaries to be extracted. [5].

The level set evolution function is defined as the gradient flow minimizing energy functional based on the term distance regularization and basically it has energy functional that tends to move the zero level set function to obtain the desired object boundaries and its location. This level set function(LSF) created with the signed distance profile near the zero-level set function give rise to the new technique called as distance regularized level set function(DRLSE). The numerical errors accounted induced during computation of the level sets are reduced with the effect of distance regularization term.

In traditional level sets methods, level sets functions create instability and causes numerical errors with the irregularities developed during its evolution. Hence to avoid such errors, a mathematical approach called initialization is used [6]. Figure 2 illustrates the segmentation of cystic region carried out by the level sets algorithm for 110 number of iterations.

2.3. Texture Analysis

Feature extraction is a method to extract the desired features and representing the data for further processing. This plays a crucial part in machine vision in understanding and describing the objects extracted after segmentation [11]. The resulting representation can be used as an input for classification techniques to classify the medical data into normal or abnormal. In this step, the features pertaining to the dental images are extracted using statistical texture analysis. Texture is represented as the spatial distribution of gray levels in the neighborhood pixels. Each pixel is characterized by its position and tonal properties referred as texture elements or texels. Thus image texture is described by the spatial relationship and its primitives. Texture constitute the repeated pattern of local deviations in the image intensity finely distinguishing the objects subjectively at the given resolution. Hence the general rule is to group this connected or similar set of pixels occurring repeatedly in the image region satisfying certain the gray level properties is assigned as textured region. Typically,

texture deals with the properties representing the surface or shape of an object. In this phase the dental x-ray images are analyzed based on one of the statistical texture description using co-occurrence matrix called gray level co-occurrence matrix(GLCM) [3].

Texture is spatial quantity which is represented by the two dimensional matrix known as gray level co-occurrence matrix. The occurrence matrix gives the interdependencies of the gray level intensities to extensively analyze texture [3].

The gray level co-occurrence matrix P[i, j] is defined as how frequently the pixels with the gray level i and j are occurring in the window separated by the distance vector[6]. Distinct features are extracted by GLCM are entropy, energy, contrast correlation and homogeneity for the dental panoramic images. This GLCM estimates the similarity measures among these co-occurrence matrices and five features are selected for this course of study which are discussed in this paper.

Entropy defines the randomness present in an image. It is a measure of disorder of an image. It is inversely proportional to the energy of GLCM. If the image is inhomogeneous, the GLCM matrix P will have small values. Hence entropy will be low if energy is high in the GLCM matrix. It is difficult to understand subjective wise as mathematically it given by

$$E_{entropy} = \sum_i \sum_j p(i,j) \log (p(i,j)) \qquad (1)[8]$$

Energy cost for the uniformity of the image representing second angular moment. A monochrome or homogeneous image usually has less gray level distributions hence a co-occurrence matrix, P will predominantly have high values for energy feature. In this context, Energy is, the opposite of entropy. Image exhibits its distinct energy forces acting internally and externally on the images[8]. In this sense, Energy is useful in representing orderliness. That is the reason for finding Energy in texture measures.

$$E_{energy} = \sum_i \sum_j p(i,j)^2 \qquad (2)[8]$$

Contrast is accounted for difference moment of the co-occurrence matrix P representing the local variations and brightness distribution in the image.

$$E_{contrast} = \sum_{n=0}^{N_g-1} n^2 \{\sum_{i=1}^{N_g} \sum_{j=1}^{N_g} p(i,j)\} | i, j | \ (3)[8]$$

Homogeneity represents inverse difference moment. This term attains the highest values when most of the GLCM elements are concentrated towards the main diagonal of the GLCM matrix P. Hence it is inversely proportional to the GLCM contrast.

$$E_{homogeneity} = \sum_i \sum_j \frac{1}{1=(i,j)^2} p(i,j) \qquad (4)[8]$$

The correlation feature is a measure of gray-level linear dependencies in the image [7].

$$E_{correlation} = \sum_i \sum_j \frac{(i,j)p(i,j) - \mu_x \mu_y}{\sigma_x \sigma_y} \qquad (5)[8]$$

Table 1: Feature extracted for cystic images

Features /Images	Image1	Image2	Image3	Image4	Image5

2.4. Image Classification

Image classification is one of the application of medical image processing and has a great significance in the field of pattern recognition. Most of the times, the jaw bone cysts and lesions have close similarity which is hard to differentiate just viewing the images where the patient is allowed to undergo deferential diagnosis. Hence this common problem can be taken as classification problem where the main purpose of classifier is to differentiate the normal and abnormal pixels based on the texture features. Support vector machines is one of the most successful method proved for pixel classification

Support vector classification is one of the advance approach used in statistical recognition which is computationally faster than other classifiers. SVM designs a model which group the pixels into normal and abnormal pixels yielding binary classification. In this approach, the optimal classification can be obtained by increasing the margin or the empty space between the two classes. The width of the margin is defined as the distance between the discrimination hypersurface in n-dimensional feature space and the closest training patterns which are known as support vectors. Thus support vectors specify the discrimination function in hyperplane. Earlier SVM is employed for dealing only linear classification yielding two separate classes. Later this limitation was overcome by supporting non linearity classification where combing two separate classes yielding multi class classification [3].

Support vector classification involves designing a model for two separable classes. Hence training is required for the classifier where the kernel function is chosen appropriately to yield better performance of the classifier [7]. A large amount of training data set is required for the learning algorithm to obtain high accuracy. Figure 3 shows the basic steps involved in generic classification algorithm.

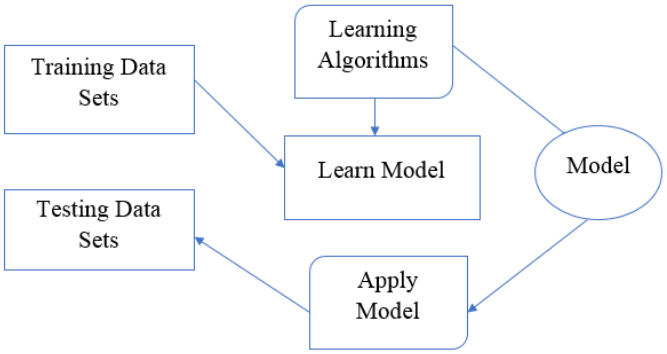

Figure 3: Model for building Generalized Classification

3. Conclusion

Dental x-ray images exhibit complex nature with respect to distribution of pixel intensities. This paper presents a new algorithm for determination of texture using on co-occurrence matrix(GLCM). The selection of feature plays a vital role in any classification. Five distinct features are extracted using GLCM namely energy, contrast, entropy, correlation and homogeneity. These features are given to the classifier to classify into presence or absence of cysts for the given dental image. The classification is made by support vector machines. This yield a binary classification which group the given image set into cystic(abnormal) image or non-cystic(normal) image. Totally 30 images were used for training and testing the classifier, in which 20 images are abnormal (or cystic images) and 10 (non-cystic) images are normal. The proposed classification algorithm accounted for 68% of accuracy. Hence to improve the accuracy large dataset are used to train the network which constitute the future scope of this proposed work.

Conflict of Interest

The authors declare no conflict of interest.

ABSTRACT

The availability of traffic data and computational advances now make it possible to build data-driven models that capture the evolution of the state of traffic along modeled stretches of road. These models are used for short-time prediction so that transportation facilities can be operated in an efficient way that guarantees a high level of service. In this paper, we adopted a state-of-the-art machine learning deep neural network and the divide-and-conquer approach to model large road stretches. The proposed approach is expected to be a tool used in daily routines to enhance proactive decision support systems. The proposed approach maintains spatiotemporal correlations between contiguous road segments and is suitable for practical applications because it divides the large prediction problem into a set of smaller overlapping problems. These smaller problems can be solved in a reasonable time using a medium configuration PC. The proposed approach was used to model 21.1- and 30.7-mile stretches of highway along I-15 and I-66, respectively. The resulting predictions were better than predictions obtained using partial least squares regression.

1. Introduction

The growing economy and an increasing number of vehicles on the road have brought about traffic problems that increase travelers' inconvenience. Traffic congestion features prominently among these problems, and has become an everyday concern in many urban areas, bringing with it negative environmental effects. During periods of congestion, cars cannot run efficiently, resulting in air pollution, carbon dioxide (CO_2) emissions, and increased fuel use. In 2007, wasted fuel and lost productivity cost Americans $87.2 billion. This number reached $115 billion in 2009 [1]. Congestion also increases travel time. In 1993, driving under congested conditions caused a delay of about 1.2 minutes per kilometer of travel on arterial roads [2]. Since then, this problem has grown worse, as evidenced by a report from the Texas Transportation Institute that indicates that the number of wasted hours due to traffic congestion increased fivefold between 1982 and 2005 for Americans.

In the past, the solution to these problems was constructing new roads, but that era of build-out ended due to its social and economic effects. Subsequently, Transportation Management Centers (TMCs) were deployed to solve traffic problems. Most of these TMCs operate in reactive mode, applying management strategies only after conditions in their regions change. Today, due to advances in technology, applying predictive traffic control strategies offers a cost-effective solution to improving traffic flow. Predictive traffic control is a proactive approach where traffic problems, such as congestion, are anticipated and countermeasures are applied prior to their occurrence.

Data-driven, short-term prediction of traffic characteristics, such as flow, density, and speed, is essential for applying predictive traffic control strategies. However, because of unstable traffic conditions and complex road settings, short-term prediction is not a straightforward task [3]. Applying mathematical models that are based on macroscopic and microscopic theories of traffic flow is difficult so data-driven modeling is considered a good approach to model complex traffic characteristics. Thanks to computational advances that make data collection and processing easy and rapid, a promising research area based on data-driven algorithms has emerged.

The use of deep learning neural networks for traffic state prediction was demonstrated to be promising by Elhenawy and Rakha [4]. In this paper, we describe new research on the prediction of traffic speeds and flows for basic freeway segments using a data-driven approach. Predictions are based on the current traffic state data, weather conditions, visibility levels, and seasonal predictors (i.e., day of the week and time of the day). State-of-the-art deep neural networks were trained and tested to predict traffic states for a larger spatial and temporal horizon. The proposed approach allows for identification of traffic problems up to 2 hours in advance, and implementation of solutions up to several miles away. In order to make the proposed approach suitable for practical applications at TMCs, a principal component analysis (PCA) was used to reduce the dimensionality of the inputs to the deep neural network. Moreover, we used the divide-and-conquer approach to divide the large prediction problem into a set of smaller overlapping problems.

Following the introduction, in Section 2 related work is discussed. Section 3 defines the short-term prediction problem. Section 4 briefly presents a background of the methods used in this paper. The model calibration is described in Section 5. The study sites and the preprocessing of the traffic state data are discussed in Section 6. In Section 7, the results of the experimental work are outlined. Finally, the paper's conclusions and recommendations for future work are described in Section 8.

2. Related Work

Over the past few decades, traffic characteristic prediction models have been developed by researchers from different areas, such as transportation engineering, control engineering, and economics. The developed prediction approaches can be classified into three broad categories: parametric models, nonparametric models, and simulations. Parametric models include time-series models, stochastic differential equations, etc. Nonparametric models include a variety of techniques that range from simple methods like k-nearest neighbor (k-NN) to complex support vector regressions (SVR) and artificial neural networks (ANNs).

The time-series technique is a parametric model used widely in traffic flow prediction. The autoregressive integrated moving average (ARIMA) model was used very early to predict short-term freeway traffic flow [5]. After that, different advanced versions of ARIMA were used to develop more-accurate prediction models. Voort et al. integrated the Kohonen self-organizing map and ARIMA into a new method called KARIMA, which uses a Kohonen self-organizing map to cluster the data and then models each cluster using ARIMA [6]. Lee et al. used a subset ARIMA model for the one-step-ahead forecasting task, which returned more stable and accurate results than the full ARIMA model [7]. Williams and Hoel used seasonal ARIMA (SARIMA) to analyze data from two freeways, and the results showed that one-step seasonal ARIMA predictions outperformed heuristic forecast benchmarks [8].

Due to both the highly nonlinear nature of traffic characteristics and the availability of data, nonparametric methods have also attracted researchers' attention. For traffic flow prediction, there are many versions of the k-NN algorithm that show a good prediction accuracy. Davis and Nihan argued that k-NN can capture linear and nonlinear relationships and is therefore able to model the nonlinear transition between free-flow and congested traffic [9]. However, the results of their empirical study showed that k-NN was no better than a simple univariate time-series forecast. Sun et al. considered the traffic prediction model as a nonlinear system with historical and current traffic characteristics as inputs and future traffic characteristics as outputs [10]. They used the local linear regression model to approximate the nonlinear relationship between system inputs and outputs to predict future traffic characteristics. Young-Seon et al. proposed a short-term traffic flow prediction algorithm combining the online-based SVR with the weighted learning method for short-term traffic flow predictions [1]. ANN is considered one of the best tools to model highly nonlinear relationships between inputs and outputs, and many papers have adopted different ANN models, such as the Bayesian neural network [11] and radial basis function neural network [12], for predicting traffic flow. For more information, Vlahogianni et al. [13] provide a good review of the proposed techniques as well as the challenges of short-term prediction.

Recently, a number of algorithms have been developed to train neural networks with many hidden layers. These deep learning neural networks are state-of-the-art machine learning techniques used to solve complex problems. However, this technique requires a huge amount of data for the training to return good results. In recent years, deep neural networks have attracted the attention of researchers in the transportation field as a super-tool to model traffic evolution. Huang et al. used a deep belief network to learn the important features for flow prediction and then passed those features to the regression output layer [14]. In another paper, the problem of traffic forecasting at peak hour and after an accident is approached using a generic deep learning framework based on long short term memory units [15]. Polson and Sokolov used a deep neural network to predict traffic flow, demonstrating that the deep neural network is capable of giving precise short-term prediction at the sharp traffic flow regime [16]. Lv et al. used a stacked autoencoder model to learn features that capture the nonlinear spatial and temporal correlations from the traffic data, then forwarded these features to the output layer to predict the traffic flow [17]. In an another recent study by Ma et al., spatiotemporal speed matrices were considered as images and used to train a convolution neural network, and then this network was used to predict large-scale, network-wide traffic speed with high accuracy [18].

3. Problem Definition

In this research, we are interested in predicting the traffic states of several segments of a freeway for up to a 2-hour horizon. This is not an easy task, since the evolution of traffic states is a complex spatiotemporal process. In order to define our prediction problem, we first define the spatiotemporal speed/flow matrix, S_{IxT}, where I is the number of the stretch's segments and T is the day's time intervals. The spatiotemporal traffic state prediction problem can be stated as follows. Let s_i^t be the observed elements of the spatiotemporal state matrix at the time interval $t = 1, 2, \dots, t_0$ and segment $i = 1, 2, \dots, h$ of the studied stretch of road. Given the spatiotemporal observed traffic state submatrix that ends at time t_0, the forecasted weather conditions, and the visibility level, our goal is to predict the spatiotemporal traffic state submatrix that spans the time interval $[t_0 + 1,\ t_0 + \Delta]$ for some prediction horizon Δ.

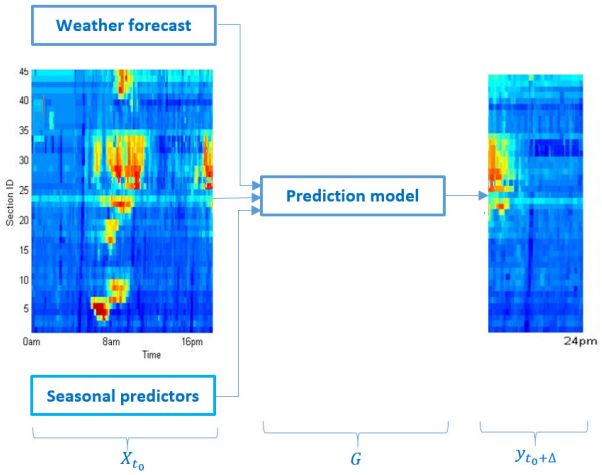

Figure 1. Illustration of the problem where a model is needed to predict the speed evolution in time (x-axis) and space (y-axis).

The general form of the solution for the problem above is shown in Equation 1 [19];

$$y_{t_0+\Delta} = G\left(X_{t_0}, e_{t_0}, \Theta\right) + e_{t_0+\Delta} \quad (1)$$

where:

G	the chosen model
$y_{t_0+\Delta}$	the prediction at horizon Δ
X_{t_0}	the inputs' predictors, including the observed elements of the spatiotemporal state submatrix at the time interval t_0, time of day, day of week, and the forecasted weather conditions and visibility
Θ	estimated model parameters
$e_{t_0+\Delta}$	errors (unexplained variability) due to the absence of factors we cannot observe

We propose using a deep neural network for this prediction problem for the following three reasons. First, the stochastic nature of the input-output data makes it possible to find two different responses for the same input. In other words, the response corresponding to any input predictor is a distribution rather than a single point in the response space. Second, the spatiotemporal response is multivariate and the input-output relationship is nonlinear. Third, there is no closed mathematical form (model) that can be used to explain the relationship between the input predictors and the response.

4. Methods

4.1. Discriminatively Pre-Trained Deep Neural Networks

In machine learning, ANNs are powerful tools used to estimate or approximate unknown linear and nonlinear functions, and are used for both classification and regression problems.

An ANN consists of an input layer, hidden layers, and an output layer. Each layer consists of several processing units, called neurons. In this paper, we used a multi-layered, feed-forward ANN, which is commonly used for classification/regression analysis. In a multi-layered, feed-forward ANN, the neurons make use of directed connections, which allow information flow in the direction from the input layer to output layer. A neuron k at layer m receives an input x_j from each neuron j at layer $m-1$. The neuron adds the weighted sum of its inputs to a bias term, then applies the whole thing to a transfer function and passes the result to its output toward the downstream layer. Given the training dataset, the ANN can use a learning algorithm such as back propagation to learn the weights and biases for each single neuron [20]. In general, training a deep neural network that has more than one hidden layer is challenging because the gradient vanishes as it propagates back. Over the past 10 years or so, many algorithms have been proposed to train deep neural networks, the discriminative pre-training method being one of the most simple [21]. The discriminative pre-training algorithm starts by training a neural network that has only one hidden layer. The input predictors and the responses are used in the supervised pre-training. Once the one-hidden-layer network has been trained, the algorithm inserts a new hidden layer before the output layer. The expanded whole network keeps the weights and biases of the input layer and the previously pre-trained hidden layer as initial weights for the next pre-training cycle. This algorithm continues growing the network until the desired depth is reached. Finally, the whole network is fine-tuned using a backpropagation algorithm.

4.2. Partial Least Squares Regression

Multiple linear regression (MLR) is a good tool to model the relationship between predictors and responses. MLR is effective when the number of predictors is small, there is no significant multicollinearity, and there is a well-understood relationship between predictors and responses [22]. In many scientific problems, the relationship between predictors and responses are poorly understood, and the main goal is to construct a good predictive model using a large number of predictors. In this case, MLR is not a suitable tool. If the number of predictors becomes too large, an MLR model will over-fit the sampled data perfectly but fail to predict new data well.

When the number of the observations is less than the number of predictors, the chance of multicollinearity increases and ordinary MLR fails. Several approaches have been proposed to overcome this problem. For instance, principal component regression is used to remove the multicollinearity by projecting X into the orthogonal component and then regressing X's scores on Y. These orthogonal components explain X but may not be relevant for Y.

Partial least squares regression (PLSR) is a more recent technique that generalizes and combines features from principal component analysis and MLR. It is used to predict Y from X and to describe their common structure. PLSR assumes that there are a few latent factors that account for most of the variation in the response. The general idea of PLSR is to try to extract those latent factors, accounting for as much of the predictors' X variation as possible, while at the same time modeling the responses well. A number of variants of PLSR algorithms exist, most of which estimate the coefficients of the linear regression between X and Y as $Y = X\tilde{\beta} + \widetilde{\beta_0}$. Some PLSR algorithms are designed for the case where Y is a column vector, while others are suitable for

the general case, in which Y is a matrix. One example of a simple PLSR algorithm is the nonlinear iterative partial least squares (NIPALS) algorithm [23].

4.3. Principal Component Analysis (PCA)

The stretch-wide prediction problem is a multivariate problem that may involve a considerable number of correlated predictors. PCA is a popular technique for dimensionality reduction that linearly transforms possibly correlated variables into uncorrelated variables called principal components.

PCA is usually used to reduce the number of predictors involved in the downstream analysis; however, the smaller set of transformed predictors still contains most of the information (variance) in the large set. The principal components are the Eigenvectors of the dataset covariance matrix. The following steps show how to find k principle components given N data vectors in the space R^n where $k \leq n$.

1. Normalize input data vectors.
2. Compute the covariance matrix S for the normalized dataset.
3. Compute the Eigenvectors and the associated Eigenvalue of the covariance matrix S.
4. Sort the Eigenvectors in order of decreasing Eigenvalues.
5. Reduce the size of the data by choosing the first k Eigenvectors.
6. Construct a good approximation of the original dataset by multiplying the transpose of the matrix consisting of the k Eigenvectors with the original data matrix.

The first principal component is the normalized Eigenvector, which is associated with the highest Eigenvalue. The first principal component represents the direction in the space that has the most variability in the data, and each succeeding component accounts for as much of the remaining variability as possible.

5. Model Calibration

5.1. Divide-and-Conquer Approach

One major challenge in traffic state short-term prediction using the spatiotemporal state matrix is the dimension of the predictor and response vectors and the large number of required parameters that must be estimated. As the stretch of road grows, the deep neural network needs a great deal of time for training or suffers from memory problems. To deal with these issues, this study adopts a divide-and-conquer approach model.

The divide-and-conquer paradigm suggests that if the problem cannot be solved as is, it should be decomposed into two or more small problems of the same type, which are then solved. The final solution to the difficult big problem is the combination of solutions to the smaller problems.

We applied divide and conquer in a straightforward manner to our prediction problem by dividing the input predictors of the spatial-temporal state matrix into smaller overlapping windows. The same method was applied to the responses, as shown in Figure 2.

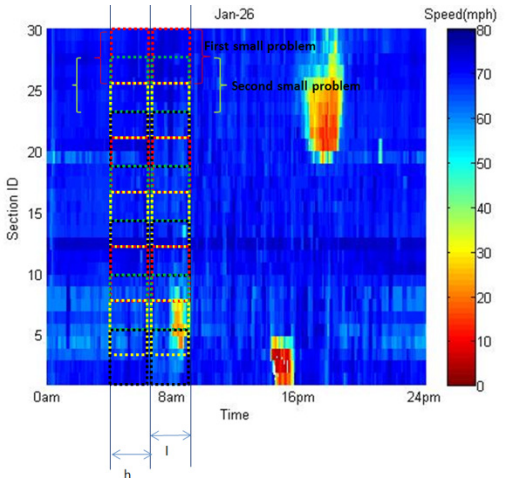

Figure 2. Illustration of divide-and-conquer approach, where l is the prediction horizon and h is the width of the predictors' windows.

The overlap of the windows is important for determining a smooth predicted speed. In the experimental work done in this paper, we set the window length equal to four segments and the overlap between contiguous windows equal to two segments. Because of this overlap between windows, each segment has two predicted traffic states at the testing phase, and the final predicted traffic state for overlapped segments is the average.

5.2. Training and Testing Phase

The model calibration process consists of a training phase and a testing phase. In the training phase, the deep neural network's weights are estimated using the training dataset. In the testing phase, the constructed deep neural network's accuracy is tested using an unseen dataset called the testing dataset. The training phase in our approach includes the following steps:

1. Partitioning (dividing) the whole stretch into small windows, each with four segments.
2. Preparing the X and Y matrices for each window by reshaping the traffic state, weather, and visibility inside the windows, with widths of h and l respectively.
3. Shifting the window to the right and repeating Step 2 to get another raw X and Y, as shown in Figure 3.
4. Using PCA to find $\bar{X}$, which is the scores of the matrix X.
5. Using $\bar{X}$ and Y matrices as the inputs and outputs, respectively, to train the one-hidden-layer neural network. Once the one-hidden layer network is trained, the algorithm discards the output layer and keeps the first hidden layer with its trained weights. Then, it stacks another hidden layer with a new output layer on top of the first layer and randomly initializes the weights of the new layers. The grown network is retrained again using the same $\bar{X}$ and Y matrices. This algorithm continues growing the network until the desired depth is reached. Finally, the whole network is fine-tuned using the backpropagation algorithm.

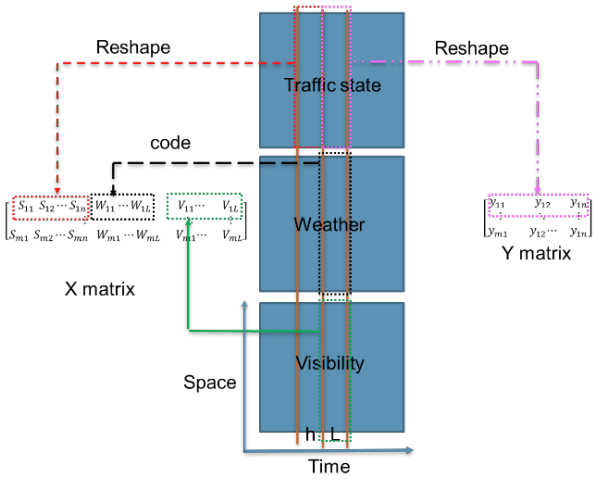

Figure 3. Illustration of preparing *X* and *Y* matrices for one window.

The testing phase is always simpler and does not require a great deal of time. This phase includes passing the testing data through the neural network after reducing it using the same principal components. The last step in testing is putting the predicted pieces together to find the prediction for the whole stretch.

6. Case Study

The performance of the proposed algorithm was tested on two real datasets collected from Interstate 66 (I-66) in Virginia and Interstate 15 (I-55) in California. This section describes the study sites and the preparation of the data.

6.1. Virginia Study Site

The selected I-66 eastbound study site is located between Gainesville and Arlington in Northern Virginia. There are 36 segments along the selected 30.7-mile stretch of freeway. This corridor has four lanes in each direction, with the leftmost lane designated as an HOV-2 lane during morning and afternoon peak hours. This is the major commuting corridor between Northern Virginia and Washington, DC. INRIX probe data from 2011 to 2013 were used to develop the prediction models, and data reduction was conducted to extract the daily traffic speed matrices. One-minute average speeds (or travel times) are available in the raw data for each roadway segment. Initially, the daily speed data were sorted by time and location from the raw data into a two-dimensional matrix. In order to reduce the stochastic noise and measurement error, the speed matrices were aggregated by 15-minute intervals. The missing data in the aggregated speed matrices were estimated using the moving average from a 3 × 3 window.

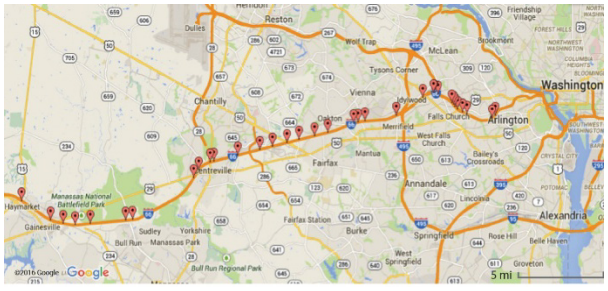

Figure 4. Virginia study site (I-66) (source: Google Maps).

6.2. California Study Site

The 2013 and 2014 loop detector data from I-15 southbound were used to develop traffic prediction models for the California study site. The layout of the I-15 freeway corridor and the locations of loop detectors are presented in Figure 4. There are 43 loop detectors along the 21.1-mile stretch of the corridor. Data reduction was conducted on the loop detector data collected from the test site to extract the daily traffic data matrices of speed and flow. The speed and flow matrices were 15-minute aggregated matrices.

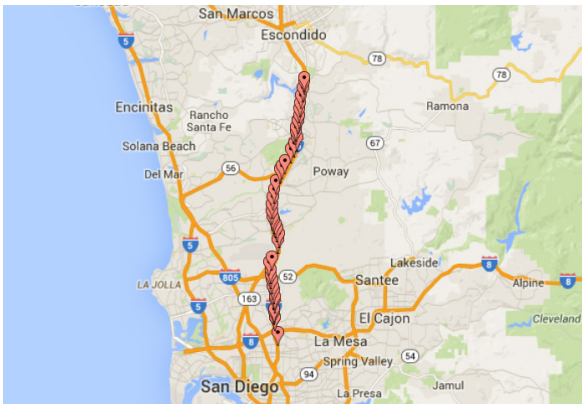

Figure 5. California study site (I-15) (source: Google Maps)

7. Prediction Experimental Results

This section describes the evaluation criteria and then shows the experimental results of the proposed traffic state prediction for the Virginia and California study sites.

7.1. Evaluation Criteria

Relative and absolute prediction errors were calculated to compare the models using shallow networks, those using deep neural networks, and those using PLSR. The relative error was computed as the Mean Absolute Percentage Error (MAPE) using (2). This error is the average absolute percentage change between the predicted and the true values. The corresponding absolute error is presented by the mean absolute error (MAE) using (3). This error is the absolute difference between the predicted and the true values.

$$\mathrm{MAPE} = \frac{100}{\mathrm{IxJ}} \sum_{j=1}^{J} \sum_{i=1}^{I} \frac{\left|y_i^j - \hat{y}_i^j\right|}{y_i^j} \tag{2}$$

$$\mathrm{MAE} = \frac{1}{\mathrm{IxJ}} \sum_{j=1}^{J} \sum_{i=1}^{I} \left|y_i^j - \hat{y}_i^j\right| \tag{3}$$

where:

J = total number of observations in the testing data set

I = total number of elements in each observation

y = ground truth traffic state

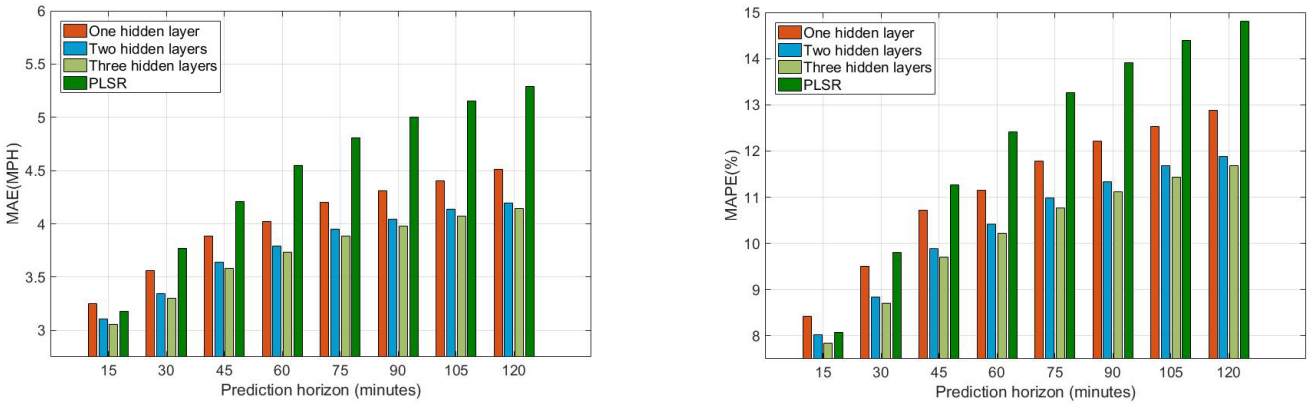
$\hat{y}$ = predicted traffic state

In the following experimental work, leave-one-out validation was used to cross-validate the prediction errors. During each fold

of the leave-one-out validation, one month was kept out for testing and the other months were used to train the model such that each month was used only once for testing. The leave-one-out validation subsequently reported the final prediction errors as the average errors of all folds.

7.2. I-66 Results

In this section, we present the results of applying the PLSR model, shallow network model, and deep neural network model to predict the speed for up to 120 minutes in the future for the I-66 stretch. The dataset for the I-66 road stretch contained only speed data. The input to the neural network is the score matrix $\bar{X}$, which is obtained from the predictors' matrix X using PCA. In our previous study [24], we trained different one-hidden-layer networks with different numbers of neurons, ranging from 3 to 31, in the hidden layer. The different networks were compared using the MAPE and MAE, and the results showed that nine neurons was a good choice. Accordingly, in this experimental work, the number of neurons in each hidden layer was set equal to nine. The MAPE and MAE for the speed at different prediction horizon are shown in Figure 6.



(a) (b)

Figure 6. Speed prediction errors for I-66 in Virginia: (a) MAE; (b) MAPE.

expected to be high, and the variability in the response could be explained using a linear model such as PLSR. However, as the prediction horizon increased, the relationship between the predictors and responses became nonlinear and the PLSR did not predict well. The neural network, on the other hand, had the ability to estimate a nonlinear function, and predicted well. It should also be noted that, as the number of hidden layers increased, the average errors decreased. In order to visually inspect differences among the four models, we plotted the average of the errors of all folds and estimated the 95% confidence interval, as shown in Figure 7.

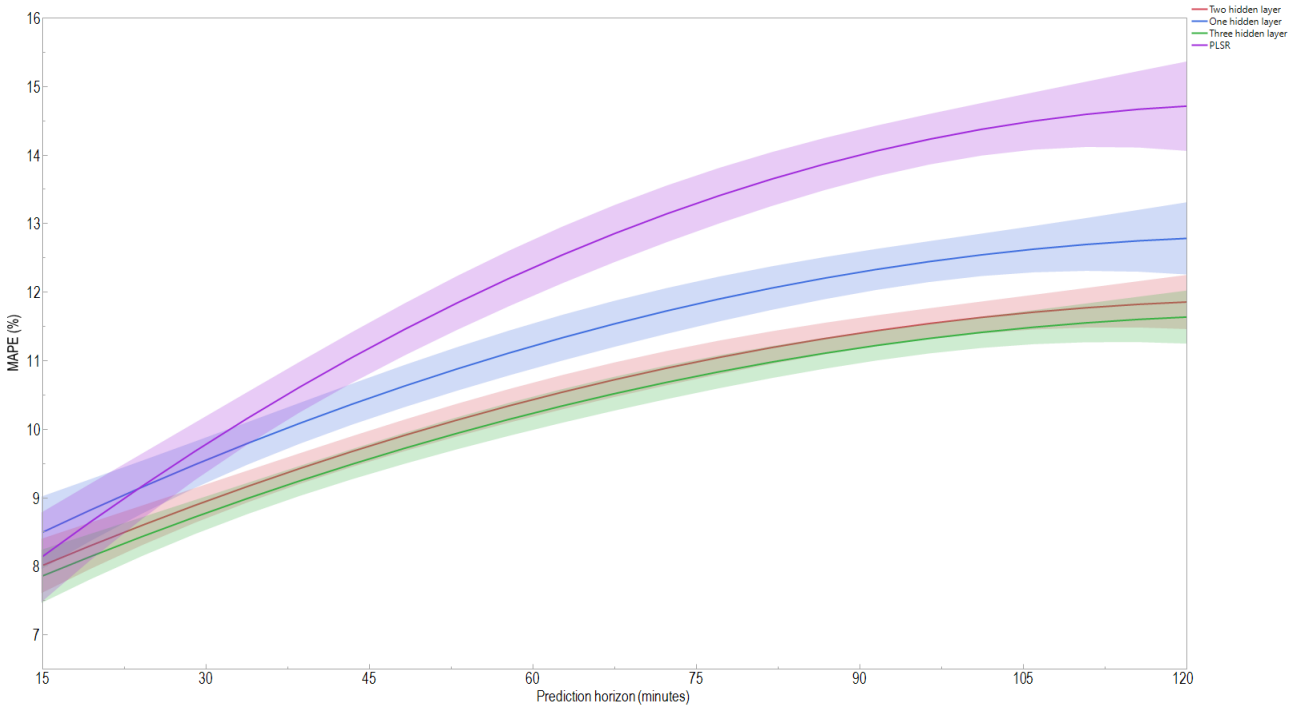


Figure 7. The speed MAPE and 95% confidence interval for the four developed models I-66 in Virginia).

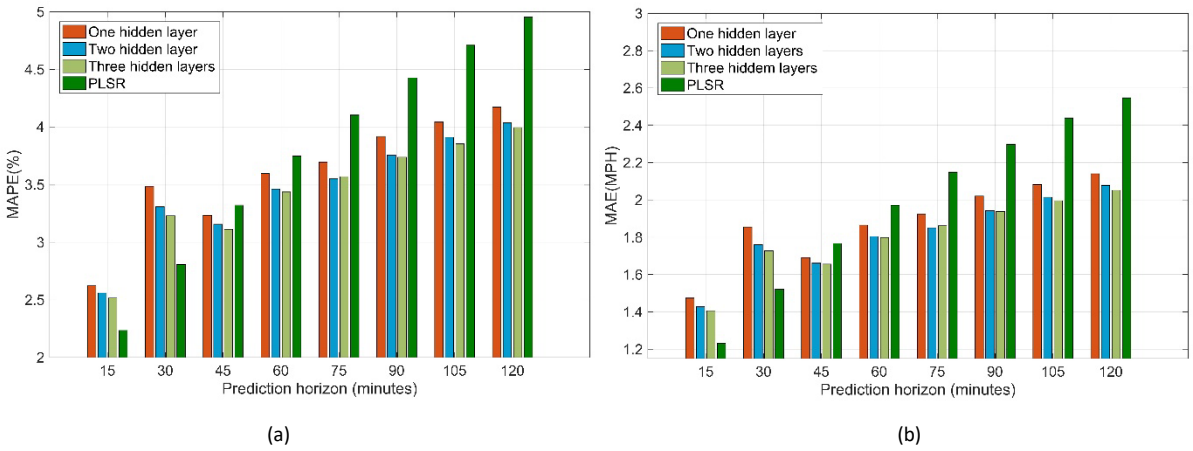
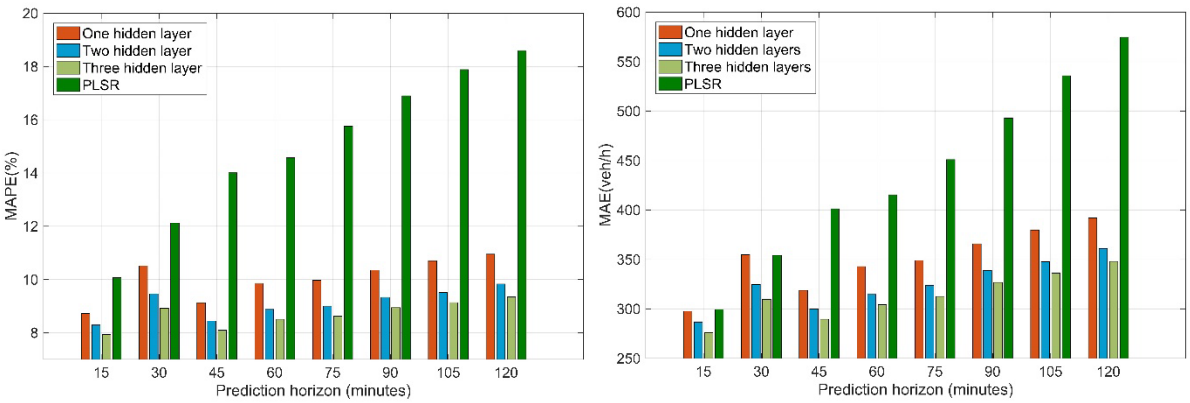


(a) (b)

Figure 8. Speed prediction errors for I-15 in California; (a) MAPE; (b) MAE.



(a) (b)

Figure 9. Flow prediction errors for I-15 in California; (a) MAPE; (b) MAE

As shown in Figure 7, at the 15-minute prediction horizon, all models are quite similar where their four confidence intervals intersect. At a larger prediction horizon, we can group the four models into three different groups. The first group includes the PLSR model; the second group includes the one-hidden-layer neural network model; the third group includes both the two- and three-hidden-layers neural network models. This figure suggests that the three-hidden-layers neural network is the best model, particularly at the 120-minute prediction horizon, as its confidence interval does not intersect with the one-hidden-layer neural network's confidence interval.

7.3. I-15 Results

In this section, we discuss the results of applying the proposed approach to a different dataset to predict the traffic states (speed/flow) for up to 120 minutes in the future for the studied stretch if I-15. We modeled the traffic state using shallow network models, the PLSR model, and deep network models. The prediction errors for both speed and flow at different prediction horizons are shown in Figure 8 and Figure 9, respectively.

Figure 8 compares the shallow network and the two deep networks for the speed prediction, with the top panel showing the MAPE and the bottom panel showing the MAE. The PLSR model is shown as well for the sake of comparison. As the figure illustrates, the deep neural networks had smaller prediction errors compared to the shallow neural network. Moreover, the three-hidden-layers network did not remarkably reduce the average prediction error. However, the confidence intervals of the various models still need to be considered before deciding on a preferred model. Figure 8 also shows that at the 15-minute and 30-minute prediction horizon PLSR performed quite well, as there was high correlation between the input predictors and the responses. However, for the longer prediction horizons, neural networks returned better results than PLSR.

The flow prediction errors shown in Figure 9 indicate that the deep neural network had smaller prediction errors compared to the shallow neural network. Moreover, the three-hidden-layers network had the lowest prediction errors. Figure 9 also shows that the prediction errors for PLSR were the worst among all the models, especially for the long prediction horizons.

differentiate between the models with close average errors. In this figure, we can visually inspect whether the four models are, in fact, different by plotting the average of the errors of all folds and estimating the 95% confidence interval.

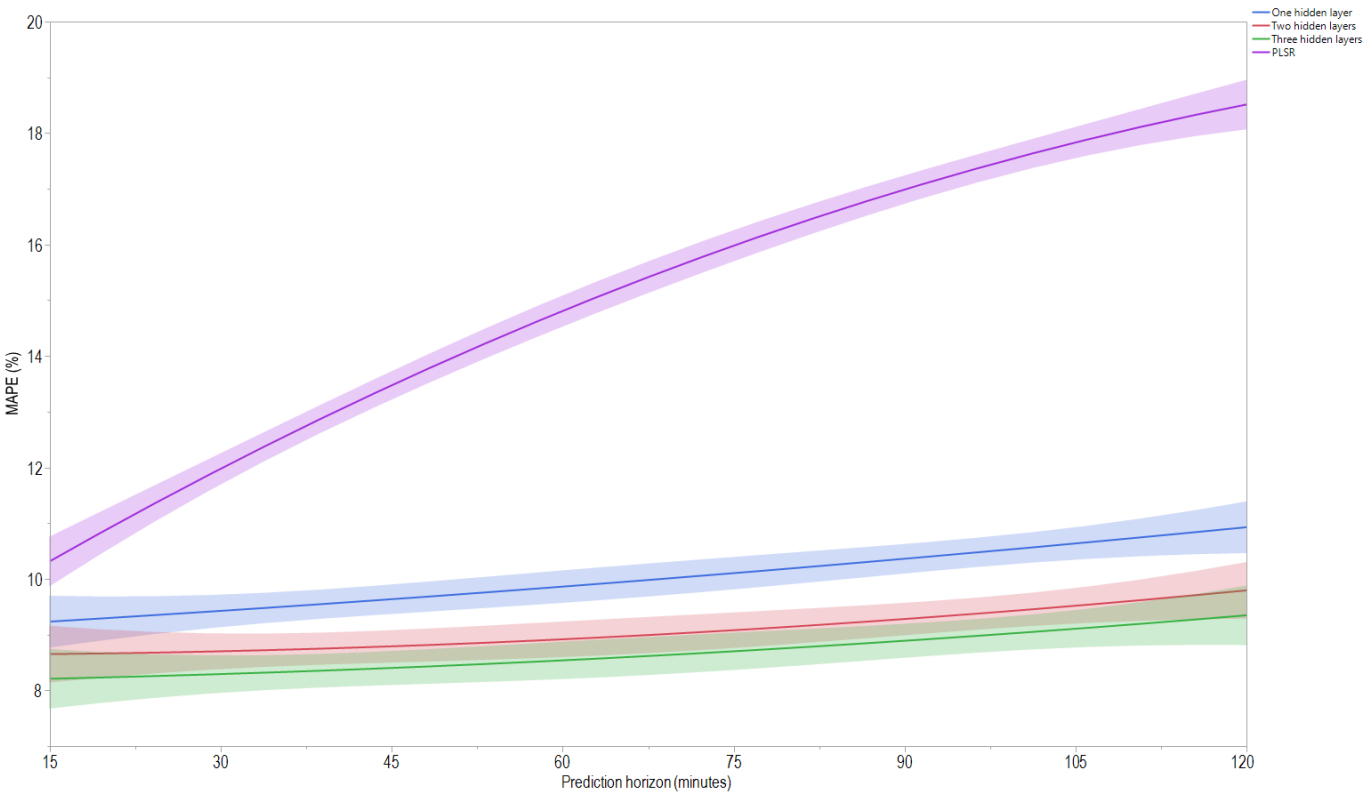


Figure 10. The flow MAPE and 95% confidence interval for the four developed models (I-15 in California).

As shown in Figure 10, the confidence intervals of the two- and three-hidden-layers neural networks intersect, indicating that they are not significantly different. However, the three-hidden-layers model is preferred because it does not intersect with the one-hidden-layer model at the 15-minute prediction horizon, and its confidence interval is far from that of the one-hidden-layer model's confidence interval.

8. Conclusions and Future work

In this paper, we adopted discriminatively pre-trained deep neural networks to build a traffic state short-term prediction model. We compared a shallow neural network, a two-hidden-layers neural network, a three-hidden-layers neural network, and PLSR. The four models were used to predict traffic states for two different freeway road stretches. We used the divide-and-conquer approach to overcome the central processing unit time and memory requirements for long roadway stretches and large prediction horizons. The models were compared using MAE and MAPE measures. Experimental results showed that the three-hidden-layers neural network was the best model for traffic state short-term prediction and that PLSR was the worst among the four models. However, PLSR performed well at the 15-minute prediction horizon, as evidenced by its high correlation between the responses and predictors at that horizon.

Adding other factors, such as work zones and incident information, to the prediction models is planned in future studies. Adding these factors may explain some of the variability that cannot be accounted for using the current prediction models.

Note that the models proposed in this paper do not consider the response of travelers if they are receiving predicted traffic information disseminated by the agencies operating the network. Studying the interaction of informed travelers and including travelers' responses as an input factor to the prediction models is an area for further work. Another area for future work is network-wide traffic prediction, for which models to predict the traffic on different roadway segments in a network will be developed. For network-wide prediction, we can make use of newly available technologies along with new big data techniques to integrate travel behavior and enhance traffic predictions. Moreover, online learning algorithms that continue to learn from each new incoming observation are needed to capture the dynamics of traffic patterns inside cities, which change over time.

ABSTRACT

Wheelchair controller design is very important for handicapped users such as quadriplegia, amputee, paralyzed and elderly. The safe use, easiness, and comfort are an important factor that can directly affect the user's social efficiency and quality of life. In this paper, the design, implementation, and test of a new low-cost hybrid wheelchair controller for quadriplegics and paralysis patient have been proposed. Two sub-controllers are combined together to build the hybrid controller which are the voice controller and the head tilt controller. The voice controller consists of two voice recognition (VR) modules. The first module uses the dynamic time warping (DTW) and the second used both the hidden Markov model (HMM) and the DTW to process the user's voice and recognize the required commands. This controller has been tested with three global languages English, German, and Chinese at two different noise levels 42 and 72 dB. The voice controllers can be used for motion commands as well as for controlling other parameters like lights, light signals, sound alarm, etc. The second sub-controller is the head tilt controller. It consists of two sophisticated orientation detection modules BNO055 to detect and track the user's head and the wheelchair-robot orientation. The controller has an auto-calibrated algorithm to calibrate the user head orientation with reference wheelchair orientation to adjust the control commands and the speed of the system motors in case of ascending or descending a hill or when passing non-straight roads. The head tilt controller was tested successfully for indoor and outdoor applications.

1. Introduction

Quadriplegia, paralyzed, hand amputees and elderly users lost the ability to control their hands and they need a special control system to use an electrical wheelchair which is normally controlled via joystick. Thus, they still need the help of others to move and realize their daily activities. Nowadays the population of this type of users increases dramatically due to rapid increases in accidents and elderly people. The main goal of the presented work is to help this type of patients to control the electrical wheelchair without the need of others help. The active body regions for quadriplegia patients include the head, neck, shoulders and some chest muscles. One of the effective control signals in this body regions is the user's voice. It can be used as a simple solution to control the intelligent application using voice recognition (VR) technology. The VR technology means the processing and converting of the user audio signal to an electrical signal, which can be used by a computer or microcontroller as a control signal. Two main strategies have been used to build VR-based systems. The first uses a computer program to implement the voice recognition and then the computer controls the target system. The second uses embedded modules to implement the VR tasks. In the proposed work the second approach is preferred due to small size, low cost, and less power consumption [1-6].

Other signals which can be used for quadriplegia patients can be acquired from the user's skin surface in the active body regions that are still under the user control such as shoulders, face and head

scalp using different bio-signal acquisition techniques, like electromyography (EMG) [7-8], electroencephalography (EEG) [9-10], and electrooculography (EOG) [11]. These methods have many drawbacks. The bio-signals are highly affected by the interferences and noises from the power sources and also from other body bio-signals [12-14]. The acquisition of the EEG, EMG, and EOG need to use and connect the user's body with special electrodes which may be uncomfortable and limit the user motion.

Head tilts and body movements have been used by other researchers. User's head tilts around basic axes x, y and z-axes were used to control the motion of the wheelchair. Several scenarios have been used to achieve this goal. Ultrasound and infrared sensors and detectors have been used to track the head motion with reference to the sensor array [15-18]. Cameras and optical sensors have been used to detect the head orientation and used it as a control signal [19]. Nowadays, accelerometer, micro electrical mechanical system (MEMS) based inertial and orientation sensors are used to detect the objects motion and gesture recognition [20-24]. Most of the above work used open loop control systems with thresholds for the control commands. Some applications use fixed speed for each motion command which is not sufficient for a real-time application.

In this paper, the design, implementation, and test of a hybrid low-cost controller for wheelchairs have been proposed. It has two sub-controllers which are the voice and head tilts to give the user more flexibility in the selection of the comfortable control method. The presented work is innovative in the sense that it uses two different voice recognition modules that are combined together in the voice controller. At the same time, the head tilts controller uses two orientation detection modules to calibrate the control commands of the user's head with the wheelchair reference orientation in case of ascending or descending a ramp. The proposed solution is safe, comfortable, and easy to use compared with previous other solutions which used only the head orientation without taking in consideration the wheelchair orientation and the road slope.

The system has a simple design. A headset with microphone is used to pick up the voice commands and send them to the voice recognition modules VR1 and VR2. Also, the first orientation module is fixed on the headset to detect the user's head tilts and send the orientation data to the microcontroller to take the required control commands. The user can simply control the wheelchair by his voice using specific commands or he can use his head tilt to the front, back, left, right and middle for forward, backward, left, right and stop commands respectively. The system uses the powerful ARM EFM32GG990F1024 microcontroller (Silicon Laboratories Inc., USA) which makes the system work standalone, without the need of using any computers and also enables a low cost, small size, and low energy consumption design.

2. Methodology

The system consists of two input units and two output units connected to the core microcontroller. The input units are the two VR modules for voice controller and also the two orientation detection modules for the head tilts controllers. The output control signals will be sent to the motor driver unit of the wheelchair to implement the motion commands and to the system LCD display to show the system status and the active controller. The microcontroller is responsible for receiving the data from the input unit, processing the received data, taking the required control commands and sending them to the output units. Fig. 1 shows the block diagram of the system. All system units will be explained in detail in next sub-section.

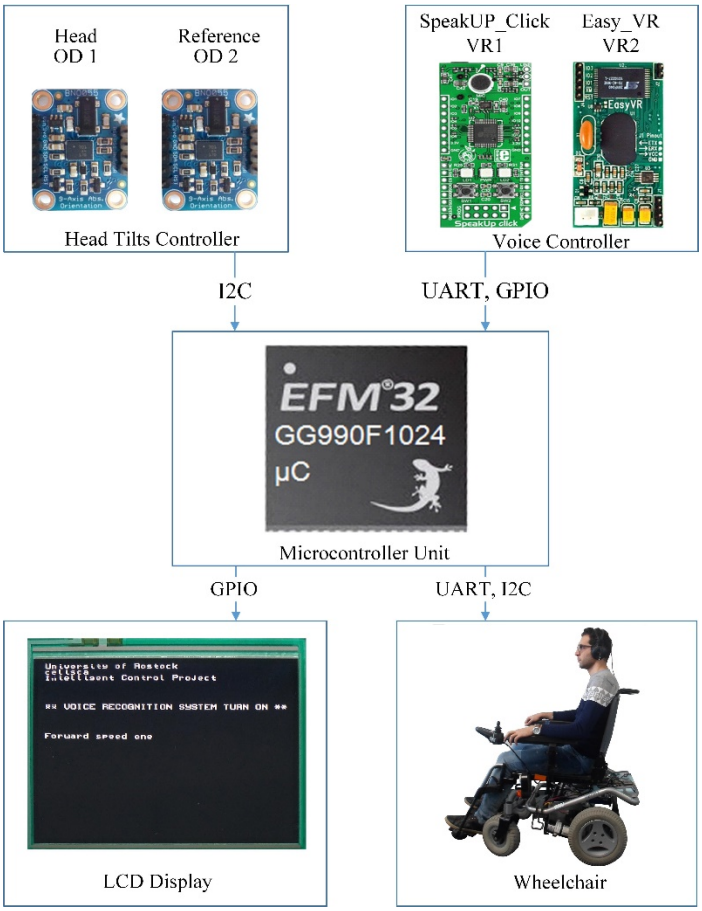

Fig. 1: Block Diagram

2.1. Microcontroller Unit (MCU)

The Silicon Labs EFM32GG990F1024 ARM microcontroller, has been selected as the core processor for the presented system. The low energy consumption (200 µA/MHz in running mode; 50 µA/MHz in sleep mode), makes it one of the most energy efficient microcontrollers. The EFM32GG990F1024 has a 32-bit central processing unit (CPU) and can operate at the speed of up to 48 MHz. The main reason and embedded features for selecting this microcontroller are:

- 5 universal synchronous/asynchronous receiver/transmitter UART/USART ports are available and can be used separately. Tow UART ports have been used for communication with the voice recognition modules. Also, another UART port is used for the communication with the motor driver unit. The remained UART/USART ports can be used for future system requirements.

- The controller has Two I²C bus interfaces: The proposed system requires only one I²C bus for communication with the two BNO055 orientation modules. The remaining I²C interface can be reserved for future works.
- 3 pulse counters: the system requires two pulse counters to communicate with the motor encoders to calculate the speed feedback of the system motors.
- Wake up time: It has a short wake-up time of 2 µs. The wake-up time is the time required to change the energy mode from different sleep modes to active mode.

Several other unique embedded features have been built in the EFM32GG990F1024 microcontroller found elsewhere [25].

2.2. Voice Controller

The voice controller consists of two voice recognition modules which are the VR1: SpeakUp Click module (MikroElektronika D.O.O., Serbia) and the VR2: Easy VR module (Veear, Italy). The two modules VR1 and VR2 connected together with the main MCU and build a strong voice controller. The voice controller uses both, dynamic time warping (DTW) and hidden Markov model (HMM) algorithms to perform the voice processing and it can work with speaker dependent SD or speaker independent SI voice recognition modes. This controller has already been tested with Jaguar lite robot. In this paper, the same controller will be integrated with a wheelchair. More details about the previous work and the used module can be found elsewhere [4, 6, 26-28].

2.3. Head Tilts Controller

The head tilts controller consists of two BNO055 orientation detection modules (Bosch Sensortec, Germany). The BNO055 module consists of 3 triaxial MEMS sensors which are an accelerometer, a gyroscope, and a magnetometer. All 3 sensors are combined with a 32-bit microcontroller in a single package to produce a nine degree of freedom (9DOF) orientation detection module. The module output has different data formats and measuring units such as Euler angles, quaternion vector, linear acceleration, gravity vector, and magnetic field strength [29]. The Euler angles have been used in the proposed system to measure the user's head and the reference wheelchair orientation.

2.4. Motors Driver Unit and Motors

Meyra Ortopedia Smart 9.906 (MEYRA GmbH, Germany) has been used for system tests. The Meyra wheelchair uses CAN bus for communication between the joystick and the motion controller. In the presented work, the original joystick control system has been replaced with the voice and head tilt controller. Sabertooth 2x32 Amp (Dimension Engineering LLC., USA; see Fig. 2) has been used for the wheelchair motor driving. It communicates with the main ARM microcontroller using a UART bus (settings: 115,200 kbps, N, 8, 1).

Two DC motors SRG0531 (AMT Schmid GmbH & Co. KG, Germany) have been used to drive the wheelchair. Each motor has a gearbox including a helical gearset on the input side and spur gear set on the output side. The operation voltage of the motor is 24 V with a rated power from 220 to 400 Watt. The total load capacity is 160 kg and it can run with an output speed from 105 to 200 RPM (revolutions/minute). The motor operates at low-level noise which is less than 58 dB. It has an electromagnetic brake work with 12/24 V [30].

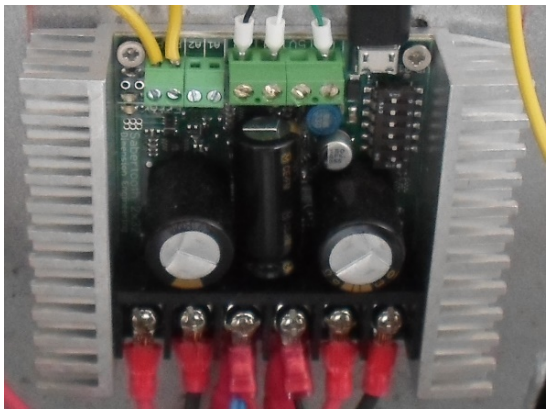

Fig. 2: Sabertooth 2x32 motor driver unit

3. System Description

The microcontroller communicates with the voice controller modules VR1 and VR2 via the general-purpose input/output GPIO pins and UART communication ports respectively. The voice command is picked up and feeding to the VR1 and VR2 using a sensitive microphone with an internal impedance of 1 k Ohm at 1 kHz, frequency range of 50-13000 Hz and a sensitivity of -34 dB. The VR modules process the voice commands and send the recognition results to the microcontroller. “OR” function has been used to combine the recognition results of the VR modules which allow the system to response when any one of the both VR modules recognizes correctly. A false positive (FP) cancellation function has been programmed and added to the “OR” function to cancel the voice recognition results if the two modules show a different command recognition. The FP cancellation function converts the FP errors to a false negative FN error which mean the system cannot recognize the voice command.

The head tilts controller can be activated using the voice command “Orientation”. Two BNO055 orientation detection modules have been used to track and read the orientation data of the user's head and the wheelchair. The first module is fixed on a headset for reading the head orientation; the second is fixed on the wheelchair chassis to read the reference wheelchair orientation. The user's head tilts around the principal axes x and y activates the control commands of the head tilt controller. The orientation detection modules have been programmed to send orientation information in Euler angles format (Pitch, Roll, and Yaw) to the microcontroller using inter-integrated circuit I²C bus.

The use of the second module for reference orientation detection plays an important role in the control commands calibration in the case of ascending or descending a hill. The microcontroller will compare the tilt angles (Euler angles) of the

user's head with the wheelchair tilt angles instead of comparing with ground original (x, y, and z) axes. This increases the system safety, and easy use when the system passes through ramps or non-straight roads. When only the head orientation module is used for controlling the wheelchair without using the reference wheelchair orientation, the user needs to increase the head tilt angle proportional to the value of hill slope angle in the ascent and vice versa the descent to compensate the hill slope. The same procedure happens in case of a side slope in the road. The user needs to increase the head tilt more to the right when the slope of the right side is greater than left and vice versa. In the presented system only two Euler angles have been used which are the Pitch and Roll for motion control. The Yaw angle has been neglected to allow the user turn his head free around the z-axes when he is driving the wheelchair.

3.1. System motor controlling

The wheelchair speed and direction control have been implemented through controlling the left (M2) and the right (M1) motor rotation speed and direction. The head tilts controller controls the speed of the wheelchair motors depending on the x, and y position of the user's head with reference to the origin point (x=0°, y=0°). If the user increases his Pitch tilt angle in the x-axis and keeps the Roll at -5°<y<5°, the both wheelchair motors will rotate in the forward direction at the same speed. If the user tilts his head in the forward direction with right side tilt (see Fig. 3) to move the wheelchair forward with a right curve direction. In this case, the left motor (M2) speed will increase (M2= x + y) and the right motor (M1) speed will decrease (M1= x - y) depending on the value of the head tilt in the x and y-axes. The same procedure applies when the user needs to go forward with a left curve where the speed of the right motor will increase and the speed of the left motor will be decreased. A similar situation will be applied for backward commands.

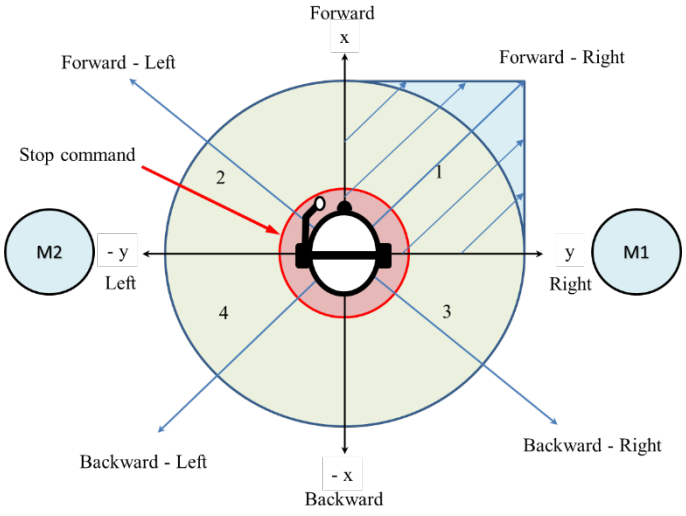

Fig. 3: Head tilts control motor speed

The user can rotate the wheelchair left or right at the same point by tilting his head left or right and keeping the value of the x-axis at -10°<x<0°. The forward command is activated when the Pitch head tilt angle become at 0°<x<25°. This tilt range will keep acceptable user viewing in the front direction. The backward command is activated when the Pitch tilt angle become at -45°<x<-10°.

3.2. Sub-Controller selection

The system design allows the user easily to select and change between the voice and head tilt as a motion controller. The system will start by listening for the user voice command to activate the required controller. If the user wants to select the voice controller hen need to give the voice command “voice”. The voice controller controls the motion of the wheelchair using a group of motion commands which are forward, left, right, stop, backward, speed one and speed two. Another group of voice commands has been used for activating the control of lights, signals and sound alarms which are light-on, light-off, signal-on, and signal-off. When the user needs to activate the head tilts controller he must give the voice command “orientation”. Then the wheelchair motion is guided by the user’s head tilts and the voice controller will still be used to turn on the lights, light signals, and sound alarms. The user can change the motion controller at any time by giving a voice command with the name of the required controller (“voice” or “orientation”). Fig. 4 shows the flowchart of the presented system.

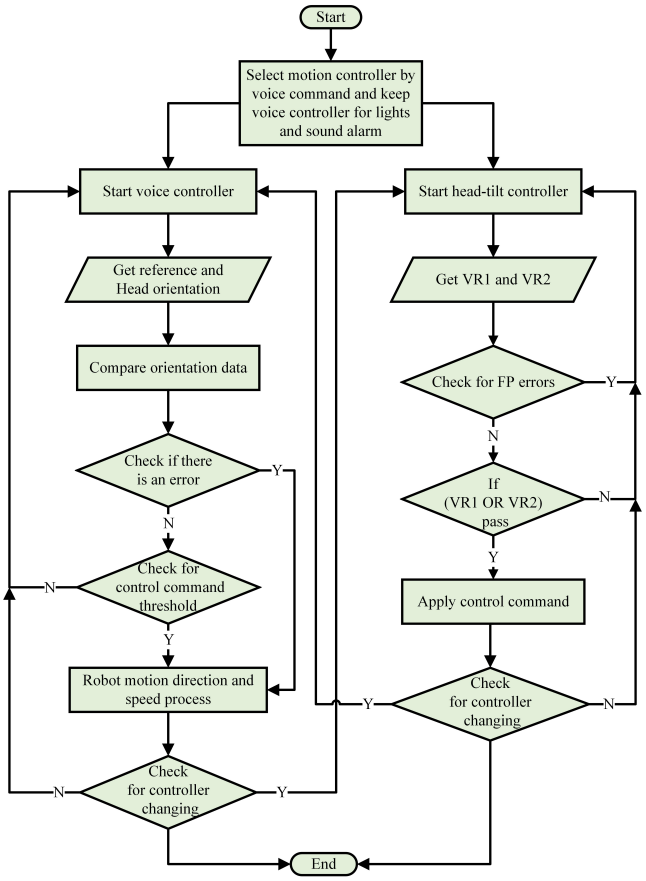

Fig. 4: System flowchart

4. Experimental Results

4.1. Voice Controller

In the previous work, the voice recognition modules VR1 and VR2 have been tested individually and also combined with "AND" and "OR" algorithms [6] in two different noise level environments with 42 dB and 72 dB. Seven voice commands to control the motion of the wheelchair have been selected for the test which are: forward, left, right, stop, backward, speed one and speed two (more detailed results can be found elsewhere [4, 6]).

In the presented work, 8 new voice commands have been used to 1) select the motion controller, 2) control the maximum speed of the wheelchair and 3) control the lights. The used commands are: voice, orientation, speed-one, speed-two, light-on, light-off, signal-on, and signal-off. Since the voice controller was tested before [4, 6], the SD voice recognition mode has been selected to control the wheelchair, which is the best choice for medical and rehabilitation application. It makes the wheelchair respond only to a specific user and not respond to any person saying the same trained commands.

"OR" with FP cancellation function has been used in the voice controller tests. The function has been tested before and the results show that the VR accuracy has been increased ≈ 3% and the FP error has been reduced to ≈ 0% with FN error rate of 5.2 % in 72 dB noisy environments [4, 6].

The voice commands "forward", "speed one" and "speed two" have been used when the head tilt controller is activated to control the user's head tilts to speed ratio. This is important to let the user increase or decrease the system speed sensitivity proportional to the head tilts angle value. The "forward" voice command sets the tilt to speed ratio as 0°-25° tilts angles have a 0-2 km/h speed with ≈ 80 m/h speed for each individual tilt degree. The command "speed one" increases the speed ratio to (0°-25° / 0-4 km/h) with ≈ 160 m/h speed for each tilts degree. The command "speed two" increases the tilts to speed ratio to (0°-25° / 0-6 km/h) with ≈ 240 m/h speed for each tilt degree. Fig. 5 shows the tilt to speed ratio of the tested voice commands.

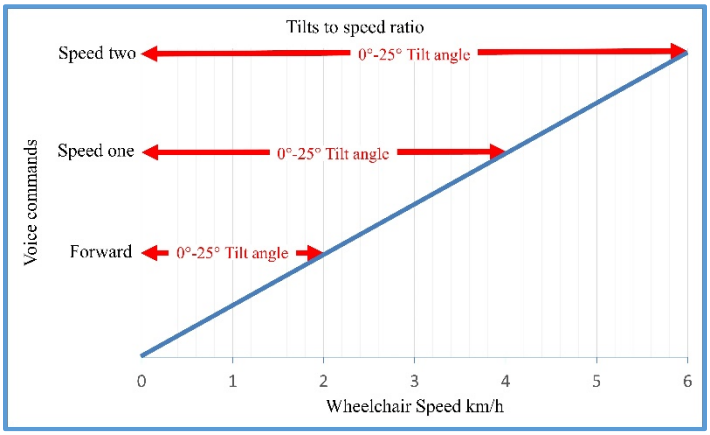

Fig. 5: System tilts to speed ratio

4.2. Head Tilts Controller

The head tilts controller has been tested for indoor as well as for outdoor environments.

4.2.1. Indoor Head Tilts Controller Tests

Several different tasks have been executed to test the system for the indoor motion control. The first task is used to test each control command for the head tilts controller. The users performed the test two times. The first is without previous training and the result titled NTU, and the second is after training the user for approximately 30 minutes and titled TU. Seven control commands have been tested by the users using head tilts around the x and y-axis. The tested commands are: forward, backward, left, right, stop, forward-left, forward-right. Each user tests each control command 10 times. The system speed to tilts ratio has been fixed at 2 km/h which is the primary system speed to tilt ratio. The test results before and after 30 mints training for the control command tests are explained in Fig. 6.

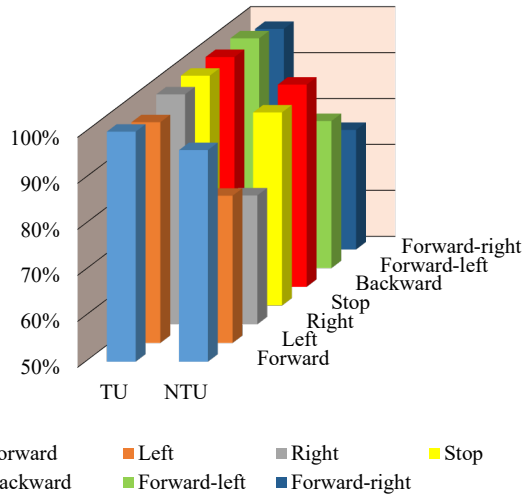

Fig. 6: Commands success rate of the head tilt controller for trained user TU and non-trained users NTU

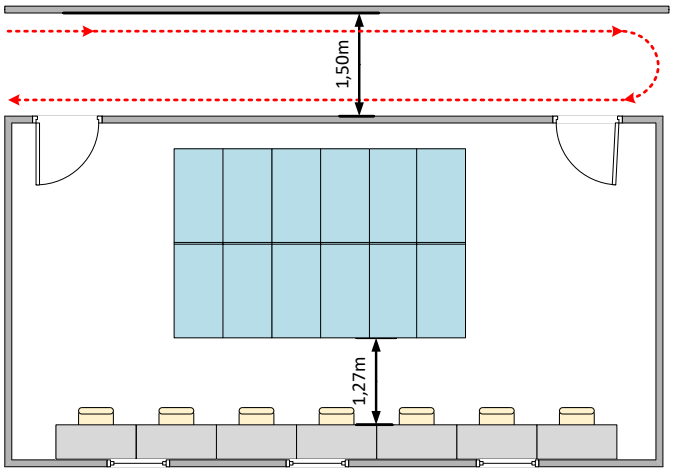
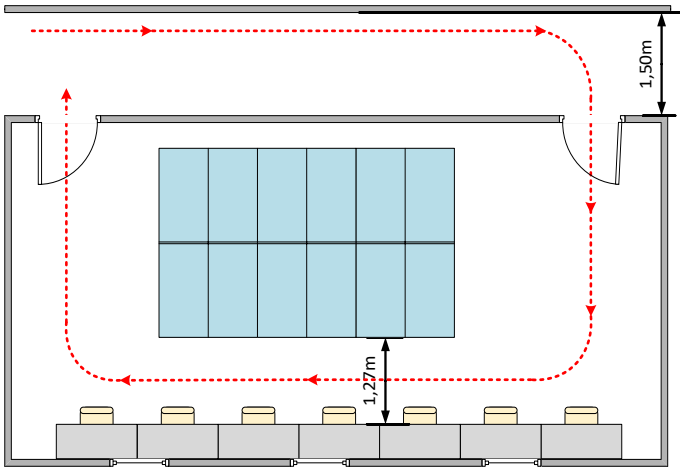
The results in Fig. 6 show the control commands success rate. The success rate is the correct implementation of the tested command in speed and direction from the start to the end point. The test results revealed that the success rate is increased when the user is trained before using the system.

The second test for indoor environments is used to check the flexibility of driving the wheelchair at a narrow area. This test includes implementing two tasks which are: 1) driving the wheelchair through a narrow corridor and 2) driving the wheelchair through a furnished hall. The test has been performed in a laboratory environment at the University of Rostock. Five trained users implemented the two tasks of the test 5 times. The results show a successful implementation of the two tasks using

the head tilts controller. All 5 users completed the tasks 1 and 2 without collisions and followed the required paths correctly. Fig. 7 shows the test paths.



1- Passing a narrow corridor



2- Passing a pathway in furnished hall

Fig. 7: Tasks for system indoor tests

4.2.2. Outdoor Head Tilts Controller Tests

The auto-calibrated algorithm of the head tilts controller has been tested for outdoor environments. The test was designed to check the performance of the algorithm, especially in the case of ascending or descending a hill. The algorithm is used to cancel the effect of road slope on the user's head tilt angle. The tests was performed on a small narrow and long ramp with a height of 80 cm and a slope angle of 7 degrees. The test included two tasks, the first is to pass the ramp without activating the algorithm while the second is to pass the ramp with the auto-calibrated algorithm. Five users performed the test using fixed tilt to speed ratio of 25° tilt angle to 2 km/h for both tasks.

The test results revealed that the auto-calibrated algorithm enhances the performance of the head tilts controller for driving the wheelchair while passing the ramp and makes it similar to driving the wheelchair with normal head tilt angles on a straight road. The test of the system without activating the auto-calibrated algorithm for ascending a hill show that the control of the wheelchair is more difficult. In the ascending of the hill the user needs to tilt his head 7 degrees more down (same ramp slope) compared to the motion with the auto-calibrated algorithm to compensate the hill slope (7°) and vice versa. Fig. 8 shows the tests of the system with and without the auto-calibrated algorithm.

a) Without auto-calibrated algorithm, 7° more in the head tilts

b) With auto-calibrated algorithm

Fig. 8: System tests for passing an 80cm height and 7° slope angle ramp with and without the auto-calibrated algorithm.

4.2.3. Hysteresis and Wrong Head Orientation Function

During the test of the system, the head tilt controller is faced with a harmful situation with hysteresis around the stop command area. This problem occurs when the user brings his head into the stop area and moves his head involuntarily out of the stop area for less than 50 ms without intending the system to move. This problem makes continuous discrete motion-stop commands that can cause concern and bother the user and also unwanted motion may occur. A new function has been added to the head tilt controller to avoid this hysteresis by increasing the number of measurements for the desired control command from the head orientation sensor. Instead of using only one readout in the range of 0º<tilt angle<25º for the forward command, the system uses 10 continuous measurements at the region of 0º<tilt angle<25º for the forward command tilt area in order to implement the forward command. This procedure cancels the effect of the involuntary head movement and makes the start of the motion more smoothly.

Another function has been built and embedded in the head tilt controller to stop the system and protect the user if the head orientation goes out of the programmed range of the control commands tilts angles. The function stops the wheelchair and suspends the control commands of the head tilt controller until the headset returns to the center stop region (0°>x>-10°, 5°>y>-5°). This function protects the user when the headset falls down or the user loses consciousness.

The two functions have been tested with the system and the results revealed a successful performance for both of them. The hysteresis function increased the reaction time of the system ≈ 50 ms in the initial motion only which do not really affect the system performance.

4.2.4. Orientation Sensor Error Handling

Orientation sensor error handling is one of the most important tasks in the present study since the system's motion can cause the loss of the instantaneous updating of orientation data. This can affect the microcontroller performance and may cause restarting or hanging in the system. An error handling function has been programmed to avoid missing orientation data. The error handling function tracks changes in the orientation data and sends alert information to the user if there are any communication problems with orientation modules. It also resets and recalibrates the orientation sensors after a limited number of unchanged readings.

The function has been tested with the system and the test results show a success rate of 100% for tracking the information data, resetting and calibrating the orientation detection modules. Fig. 9 shows the flowchart of the system's error handling function.

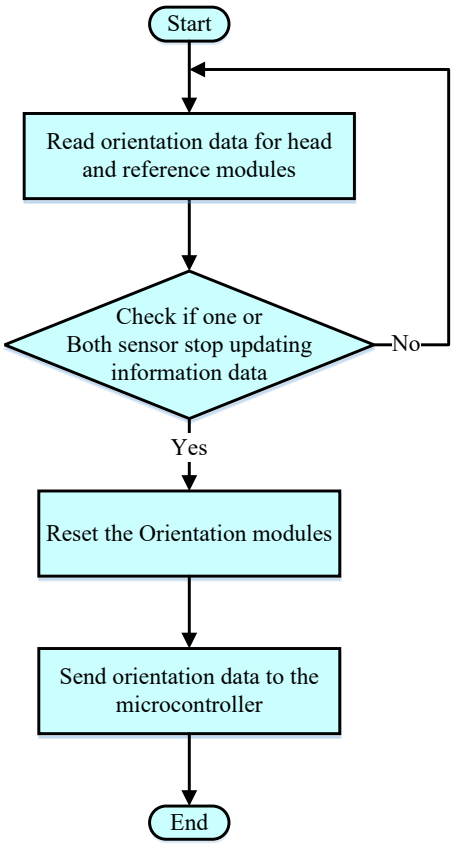


Fig. 9: Error handling function of the head tilts controller

5. Conclusions

In this paper, the design, implementation, and testing of a hybrid wheelchair controller for quadriplegic and paralysis users has been proposed. Two sub-controllers, which are the voice and head tits controller, have been used to allow the user to select and change the active controller for more comfortable wheelchair driving. The test results of the voice controller revealed that it has a better performance using "OR" and FP cancellation function compared with "AND" and individual tests. The results revealed a ≈ 3% increase in the VR accuracy which reached 98.2% in 42 dB noise environments with a 0% FP errors and 1.8% FN errors which are important features for biomedical and rehabilitation application. The voice controller is ideal for the control of lights, light signals, sound alarms, rather than control the wheelchair motion, especially in narrow indoor areas.

The head tilts controller tests revealed that it can be used for both indoor as well as outdoor environments. The indoor tests showed accurate control and good performance in a narrow area with a successful implementation of task 1 and task 2. The outdoor tests showed that the system is ideal for non-straight roads and especially for ascending and descending a hill with the auto-calibrated algorithm.

Hysteresis, wrong head orientation function and orientation sensor error handling function have been successfully added to the head tilts controller. All the functions have been tested and the results show that they enhance the performance of the controller and make the driving of the wheelchair more safe and comfortable.

The head tilts controller tests revealed that previous training of the user is required before using it to have a better human system interaction, good adaptation, and enhancing the system performance.

The voice and the head tilt controllers have been combined together successfully, the user can select or change the wanted controller easily using voice commands.

ABSTRACT

This work depicts the preparation of Ni-C ultrafine composite from used engine oil. The used oil was emulsified with detergent loaded with Ni $(OH)_2$. The loaded emulsion was sprayed on electric plasma generated between two C electrodes to a DC main 28 V and 70-80 A. The purged Ni-doped carbon fume was trapped on a polymer film moistened with synthetic adhesive to fix the trapped smoke. Characterization of the deposit was made using SEM. XRD examined the crystal morphology. Carbon density in the cloud was calculated. The average size and thickness of the deposited composite is 120-160 nm. Aliphatic hydrocarbons readily decompose to gaseous products. Solid carbon smoke originates from aromatic compounds. Plasma heat blasts the oil in short time to decompose in one step.

1. Introduction

Teng [1] reported the use of plasma arc technology to produce fluid of carbon ultrafine particles dispersed in distilled water. Carbon is simultaneously heated and vaporized in a chamber furnace. Carbon vapor was cooled to prepare a carbon/water ultrafine slurry. The problem of heat dissipation from electrical appliances became a significant issue. To ameliorate this problem, there are four approaches commonly taken [2] enlarged the heat exchanger area and structure, [3] fabricated the heat exchanger using materials with higher thermal conductivity, [4] increased the working fluid flow rate to the heat exchanger, and [5] improved the heat transfer performance of the heat exchange working fluid. *Akoh* [6] prepared superfine fluids using the VEROS method. Teng [7] improved the VEROS technique and developed successful and effective preparation of Ag, Fe fine fluids. Bo [8] showed that plasma-enhanced chemical vapour deposition (PEVCD) has emerged as a key method to generate vapor-gas; and determine the development of VG with required properties. The paper summarized the state-of-the-art research on PECVD growth of VG ultrafine sheets. It provided guidelines on the design of plasma sources and operation parameters. Also to offer a future good challenges that would help commercial applications of VG. The authors studied the influence of feedstock gas temperature and pressure on VG growth. The effect of pretreatment and the growth of VG patterns on cylindrical and carbon ultrafine tube (CNT) substrates was shown. After discussion conclusion showed challenges and future directions for PEVCD growth of VG.

In the year 2014, defects-free graphene and with highest electron mobility was successfully prepared. Mayer [9] used adhesive tape to separate graphene sheets from graphite. It was reported that hydrazine followed by annealing in argon/hydrogen gases was successful to reduce graphite oxide. It was shown that almost intact carbon framework allowed efficient removal of functional groups. Some molten salts attack graphite particles to form a variety of carbon ultrafine structures including graphene [10]. Hydrogen cations, dissolved in molten lithium chloride, were discharged and intercalated and peeled to graphene sheets [11]. The graphene ultrafine sheets produced displayed a single-crystalline structure with a lateral size of several hundred ultrafine meters and a high degree of crystalline and thermal stability [12]. In 2014 defect-free, not oxidized graphene-containing liquids were made from graphite using mixers that produce local shear rates greater than 10×10^4 [13]. Mubarak [14] reported that the chemical vapor deposition (CVD) had been found a potential way to produce high quality and at high yield of CNTs. El Mel et al., [15]

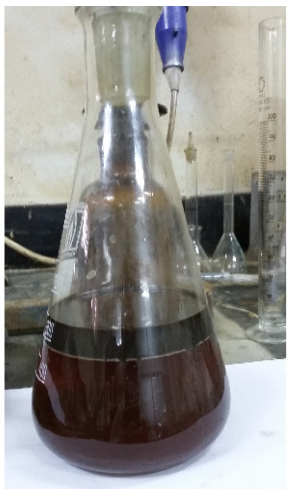
Industrial nitrogen gas was used as a propellant to spray the emulsified oil on the plasma. The gas was supplied in cylinder with the following specifications

Nitrogen and trace inserts	99.998%
Oxygen	< 0.001%
Density (g cm^{-3})	1.2506
Sp. Gravity (g.cm^{-3})	0.9737
Viscosity (g $cm^{-1}s^{-1}$)	$1.809x10^{-4}$

The chemicals used are technical pure grade. Nickel hydroxide salt was synthetically prepared by precipitation by adding 10% ammonium hydroxide to nickel sulfate solution. The precipitated $Ni(OH)_2$ was filtered, washed and dried.

2. Emulsification of the used engine oil

About 100 g of the used engine oil was placed in a conical flask of a thermostated agitator maintained at 80°C. The flask was fitted with an electrical mechanical stirrer. After the oil has acquired the required temperature, sodium sulphonate detergent containing nickel hydroxide suspended in distilled water was added step wise while stirring for 4 hours. The emulsion was then transferred to a separating funnel and left over night.



3. Method of preparation of the Ni-doped carbon ultrafine particles.

Determination of the extent of engine oil emulsification was determined by weighing the separated portion of the not emulsified oil. Fig. 2 shows partial (2a) and full (2b) emulsification of the used oil. Fig. 2 her

4. Methods of measurement of the physic-chemical properties

Determination of nickel in the oil suspension or in the prepared composite was carried out by dissolving 1 g of the oil or 250 mg of the catalyst in 1 N nitric acid. Nickel content was determined using spectrophotometer Unicom 7400 Fig.3 shows a schematic diagram of the Electric Plasma device used for thermal decomposition of the engine oil. Particle size and shape of the product were determined using the light-scattering size analyzer, SEM. Crystal morphology was examined by X ray diffraction (XRD).

5. Results

The specifications of the engine oil are given in Table 1. It can be seen that the spent oil has lower viscosity, foam and gelation index and higher phosphorus content.

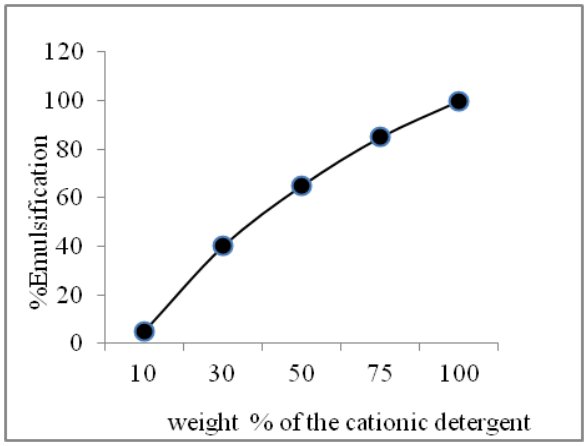


Fig. 4 shows the extent of emulsification of the spent engine oil (SEO) as affected by the weight of commercial anionic detergents containing 10 % Ni as $Ni(OH)_2$. It is seen that the extent of emulsification of the spent engine oil increases linearly with the corresponding increase of the detergent. Anionic detergent is far efficient to emulsify engine oil as compared to the cationic detergent to emulsify the spent engine oil.

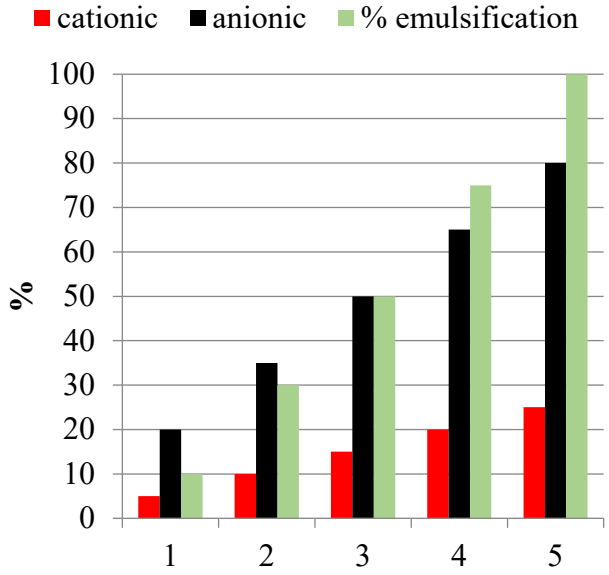

Fig 5 Effect of detergent type on the extent of emulsification of spent engine oil.

Table 3 shows the mean value of the weight of carbon particles disseminated in the cone of a plasma heat as a function of the weight of inserted oil and the dimensions of the cone.

Fig.8 shows the XRD diffraction patterns of nickel-carbon composite species It is seen that the diffraction peaks of Ni confirm the existence of well crystalline Ni metal. Raman spectrum of Ni doping C appeared with I_D/I_G=0.63

Fig. 9 shows the weight of the deposited carbon -Ni composite on the polymer film as a function of the weight of the sprayed engine oil as a function of the weight of the sprayed emulsified engine oil.

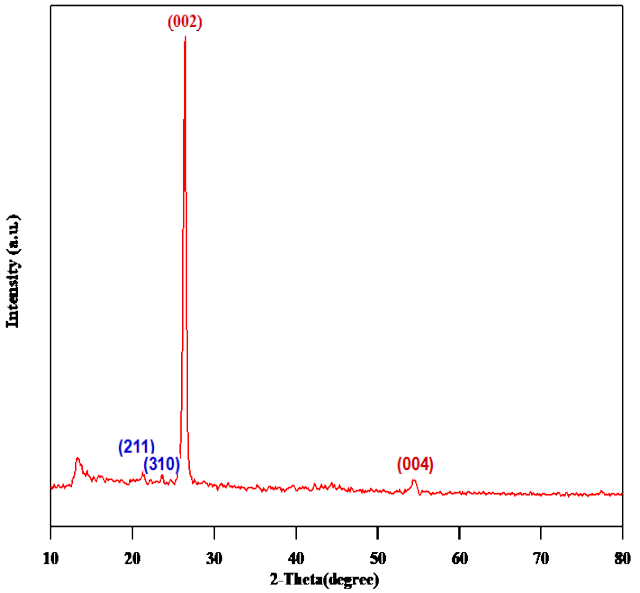

Fig. 8 The XRD diffraction patterns of nickel-carbon composite species It

It can be seen that the weight of the deposited C-Ni amounts to 10 ug/cm2 and increases gradually with the increase of the weight of sprayed engine oil up to 350 mg whereby the maximum WCNIO is attained (45.5 ug/cm2). Fig. 10 shows the SEM of the deposited C-Ni composite material.

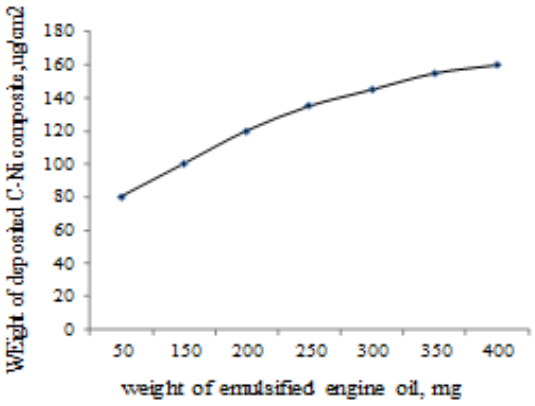

Fig. 9 The weight of the deposited C-NiO (W_{CNiO})

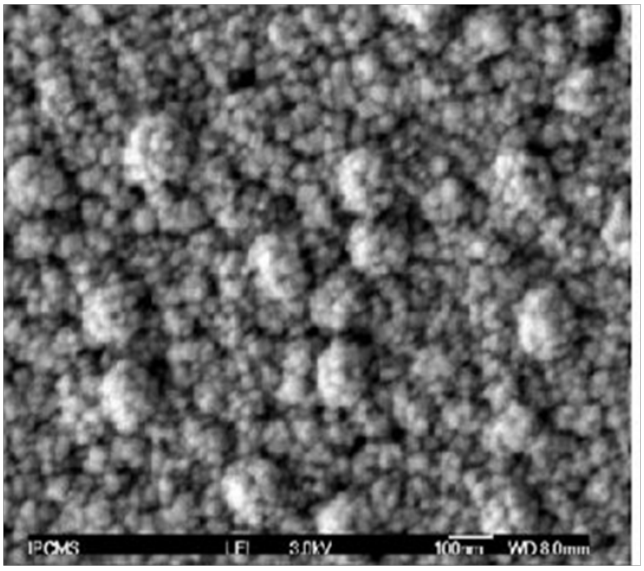

Fig. 10 SEM photograph of the deposited C—Ni composite

6. Mathematical Model

A mathematical model has been proposed to simulate the formation of C-Ni particles in the hood of the plasma heat vicinity based on the following assumptions:

1. The chemical analysis of the used engine oil (O_u) and the projected plasma heat at the hood vicinity (hv) are kept constant throughout the experiments.
2. Solid carbon particles generate at a constant weight percentage of 27.5 % of the weight of the oil as determined experimentally.
3. The weight of carbon generates in nearly no time; $Wt_c = 0.275\ Wt_o$.
4. Ejection of the emulsified engine oil takes place in the plasma core at a constant discharge rate for a given driving pressure.
5. No extra air was fed into the hood vicinity of the plasma arc
6. The carbon particles dissemination is distributed symmetrically at a given horizontal level in the hood.

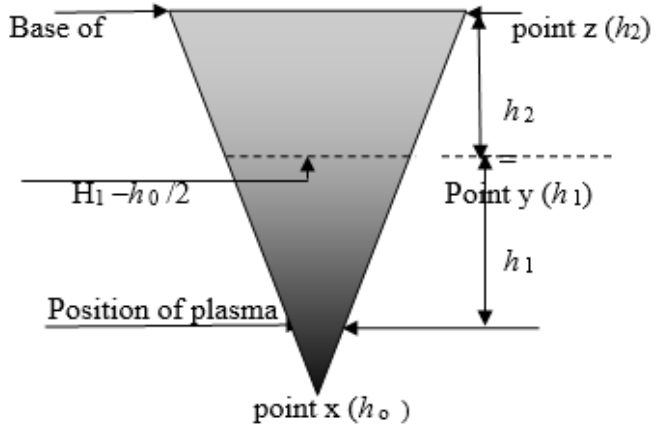

Fig. 11 A Schematic proposal of the caron-Ni smoke in the blasma hook.

The average concentration of C-Ni / cm^3 in the hood at a given horizontal level H_x =

$$\frac{0.275\ (Wt_o)_p}{V_{Hx}} \qquad (1)$$

Volume V of a right cone (hood) with a height H,

$$V = 1/3\ \pi\ r^2 H_x \qquad (2)$$

Wt_o is the weight of discharged oil at constant pressure p.
The average C-Ni concentration/ cm3 in the hood:

$$\frac{0.275\ (Wt_o)_p}{1/3\ \pi\ r\ h_x} \qquad (3)$$

Carbon particles disseminate in the hood volume under a convection model of heat transfer. Convection above a hot surface occurs because hot air expands and becomes less dense and rises upwards. Convective transfer involves the combined processes of diffusion (conduction) and advection transfer by bulk fluid flow. Natural buoyancy forces alone are entirely responsible for the C-Ni fluid motion upon heating the mass transfer of carbon.

Where k is a transfer coefficient, A is the total surface area of the carbon particles, T_p is the temperature at the plasma core and T_{Hx} is the temperature at the level Hx in the hood. The convective transfer coefficient is dependent upon the physical properties of the fluid (here air). Values of h have been measured and tabulated in the literature for commonly encountered fluids and flow of situations [18]. The mathematical presentation model of the release, development and change of air-born solid fluid (C-Ni particles) as a function of variables such as time, temperature, pressure, distance, and concentration has been processed using "the experimental design" program. Results are under publication elsewhere

7. Discussion

Engine oil is composed of hydrocarbons, poly alpha olefins (PAO), and poly internal olefins(PIO). The organic compounds consisting entirely of carbon and hydrogen [17]. The oil contains 73-80% weight/weight aliphatic hydrocarbons (primarily alkanes and cycloalkanes with l-6 rings); 11-15% monoaromatic hydrocarbons; 2-5% diaromatic hydrocarbons; and 4-8% polyaromatic hydrocarbons. Additives for lubrication, (≈ 20% of the oil), consist primarily of zinc diaryl, molybdenum disulfide, zinc dithiophosphate, metal soaps, and other organo metallic compounds. The Canadian Environmental Protection Agency reported that up to 15% of the additives are detergents and dispersants [18]. Other used mineral-based crankcase oil may contain compounds of barium, phosphorus, zinc, and some chlorine and bromine as a result of oil additives [18]. Inorganic compounds of sulfur, aluminum, arsenic, calcium, chromium, copper, iron, magnesium, manganese, potassium, silicon, sodium, tin are detected. Organic solvents of toluene, benzene, xylene,and ethylbenzene are present although most of the organic compounds may be destroyed during combustion of crankcase oil as fuel [19]. In general, sources of dirt, sand and dust from the air, soot, contaminate unburned fuel in the motor oil. Water if detected is formed from condensation of the combustion products. Particulates of metal wear that the oil filter

cannot trap together with the corrosion by-products and degraded additive elements [20, 21]. All these contaminants enter the engine oil and creat more wear debris and cause more damage than they would separately.

Heating engine oil at high temperatures undergoes a decrease in viscosity grade and degradation reactions of multi sequence order. Decomposition begins with the formation of compounds having more simple molecular chemical formulae. According to the infrared spectra, the paraffinic-naphthenic fractions of new and used oils are substantially similar to each other. The aromatic fractions of the used oil contain oxygen groups that can be removed only by catalytic hydro treating [22]. The aromatic fractions contain oxygen groups detrimental to the thermal-oxidative stability of the oil. [23]. The decomposition process proceeds in a multi sequence order to finally produce the free elements of the engine oil (C, H, O). In 1959, Chevron developed a new method of refining base oils (Hydro cracking) where many of the paraffin and wax molecules are broken up into mineral oil molecules. The process removed the aromatics, sulphur and nitrogen compounds from the oil [22,23].

In 1993, Chevron invented the Hydro-Isomerization process, where wax and paraffin molecules are reshaped into useful lubricants instead of simply being broken up into smaller molecules. In 2004 accounts for almost half of all base oils [22]. Iso-dewaxing produces much higher-performance oil and allowed to start with low quality oil. In addition, oil manufacturers add what's called an additive package [23]. Additive packages contain several different chemicals with different purposes.

Results of weight loss upon charring of oil emulsion revealed that NiO may catalyze one or more of the decomposition reactions. The temperature of the electric plasma exceeds some thousands and it promotes decomposition reactions to complete to end in one step in nearly no time. Generated carbon fumes, doped with nickel, deposit on a cold surface of polyurethane film positioned over the spark zone. Frequent deposition of C-Ni composite on the polymer surface would form a layer with measurable thickness. Thickness development is a time dependent process. The particle size and shape are critical for to build up the composite layer. Characterization of the crystal structure of the deposit was carried out by SEM. Crystal morphology was examined by XRD. Results revealed that the thickness of the deposited composite film was few microns. The average size of the crystals of composite ultrafine material ranged from 50-90 nanometer whereas thickness of the layer was 120 – 160 nm depending on the experimental conditions. Finer size was obtained with a rate of oil discharge of 0.5 g/min. It increases with the increase of the oil discharged rate ≥ 5 g oil/min. Results were explained in the premise of a model which assumes that engine oil decomposed in a multistep reactions ending with the formation of ultrafine carbon fumes doped with nickel vapor. The weight % of the solid fumes generated from decomposition process of the engine oil amounts to 65%. The mathematical model given in page 3 estimates the hypothetical weight of carbon disseminated in the experimental test rig. It was studied based on multi sequence reactions. Results will be published later on.

8. Conclusion

The output results conclude the following.

1. Used engine oil is a useful material that can be utilized to prepare C-Ni composite.
2. The plasma heat is an effective heat source to decompose the used engine oil.
3. Decomposition process is a multi-sequential reaction involving generation of solid carbon particles and gaseous products.
4. Plasma decomposition blasts oil to undergo decomposition in nearly no time and in less decomposition reactions.
5. The particle size of the produced carbon -Ni was 50-90 nm whereas the thickness of the formed layer amounts to 120-160 nm
6. Doping of carbon ultrafine particles with Ni has been successfully carried out by loading the oil emulsion with Ni Hydroxide.

ABSTRACT

In order to increase the diagnosis accuracy of schizophrenia (SCZ) disease, it is essential to comprehensively employ complementary information from multiple types of data. It is well known that a network is a general method for analyzing relationships between patients, with its nodes representing patients and its edges showing relationships between them. In this study, we constructed a fused network using three types of data including genetic, epigenetic and neuroimaging data from a study of schizophrenia patients. We developed a network-based prediction approach taking advantage of the whole network of patients rather than just individual clusters in the network. The majority neighborhood of a node in the network was exploited as a feature for discriminating SCZ from healthy controls. Compared with other 9 graph-based label prediction methods, our network-fusion based label prediction method shows the best performance according to the prediction accuracy. The prediction power of our proposed method was also tested under different parameters settings and an optimal parameter was found for achieving the best performance. The method is also computationally efficient and can be extended to identify other clinical outcomes.

1 Introduction

This paper is an extension of work originally presented in the IEEE International Conference on Bioinformatics and Biomedicine (BIBM 2016) [1].

Currently, there is a lack of objective ways for the diagnosis of schizophrenia (SCZ) [2]. It is generally diagnosed according to criteria set in either the American Psychiatric Associations fifth edition of the Diagnostic and Statistical Manual of Mental Disorders (DSM 5), or the World Health Organizations International Statistical Classification of Diseases and Related Health Problems (ICD-10). These criteria use the self-reported experiences of the patients and report abnormalities in their behaviors, followed by a clinical assessment by a mental health professional. However, symptoms associated with schizophrenia occur along a continuum in the population and must reach a certain severity before a diagnosis is made [3]. Although in psychiatry as in all of general medicine there is an irreducible element of the subjective [4], we should try our best to reduce the subjective part of medical and psychiatry practice. This goal is well recognized by the National Institutes of Mental Health as well [5].

Like many other complex diseases, SCZ is caused by a combination of genetic, biological, and environmental factors, creating a difficult challenge for diagnosis and defining subtypes. In addition, SCZ is a highly heritable disorder [6]. The current belief is that there are a number of genes that contribute to susceptibility or pathology of SCZ, but none of them exhibits full responsibility for the disease. It is believed that SCZ is caused by a number of genetic and environmental factors [7].

Recently, high-throughput studies are rapidly accumulating a wealth of 'omics'-scale data, which enable comprehensive monitoring of a biological system. Meanwhile, there are remarkable medical images accumulated in hospitals, such as images from functional magnetic resonance imaging (fMRI). fMRI

is a fairly new tool that has been used to measure brain activation utilising the dependency of the magnetic properties of haemoglobin on the amount of oxygen it carries. Blood-oxygen-level-dependent (BOLD) signals measure the alterations in cerebral blood flow that mark functional brain activity [8]. The intrinsic BOLD contrast makes fMRI an invaluable non-invasive instrument for the investigation of the underlying physiological disturbances that lead to manifest psychiatric disorders. It is anticipated that successful application and analysis of fMRI in neurological disorders can be used to characterise and diagnose mental illnesses such as Alzheimers disease, SCZ, bipolar disorder, mild traumatic brain injury and addiction.
It is a valuable way to combine genetic, epigenetic and imaging data for the diagnosis of SCZ disease. Many studies have demonstrated that the integration of fMRI and SNP information will give a more comprehensive analysis of schizophrenia. For example, Yang et al. [9] proposed a hybrid machine learning method to identify schizophrenia patients from healthy controls by combining genetic and fMRI data, and this method achieved better classification accuracy than using either data alone. Castro et al. [10] developed a multiple kernel learning approach that employed both the phase and the magnitude of complex-valued fMRI data for the classification, showing improved classification accuracy compared with using only the magnitude of fMRI data. Cao et al. proposed a sparse representation clustering (SRC) model [11, 12] to simultaneously select SNPs and fMRI voxels as biomarkers for schizophrenia followed by a classifier such as support vector machine (SVM). The integrative model was tested on 20 SCZ patients and 20 healthy controls, demonstrating that the complementary information from both fMRI and SNP data can be utilized to improve diagnosis [13].

The above mentioned SCZ studies, however, only used two types of data: SNPs and fMRI data. DNA methylation is one of several epigenetic mechanisms and can be used by cells to control gene expression. There are a number of mechanisms controlling gene expression in eukaryotes, but DNA methylation is a frequently used epigenetic signaling tool, which can fix genes in the "off " position [14]. In addition, the integration methods used in the above mentioned research directly used features extracted from data as predictors. Alternatively, network-based classification methods mainly employ the topological features as predictors. With the rapid development of systems biology, network-based classification or prediction methods have been widely used [15, 16, 17, 18, 19, 20, 21].

In our study, we combined three types of data including SNPs, DNA methylation and fMRI to construct networks, which were subsequently be fused for diagnosis of SCZ. Specifically, for each type of data, we first constructed a patient network, called a single network. Thus for three types of data, we constructed three single networks. Then we fused two or three single patient networks into one subject network. As a result, we created four fused networks: three fused networks from the combinations of two data types and one fused network from three data types. Finally, we employed the neighborhood majority of the nodes in the network to predict unknown labels, that is, identifying whether a subject is a schizophrenia patient.

2 Data Preparation

In this study, participant recruitment and data collection were conducted at the Mind Research Network. Three types of data (SNP, DNA methylation and fMRI) were collected from 208 subjects including 96 schizophrenia patients (age: 34 ± 11, 22 females) and 112 healthy controls (age: 32 ± 11, 44 females). All of them were provided written informed consents. Healthy participants were free of any medical, neurological or psychiatric illnesses and had no history of substance abuse. By the clinical interview of patients for DSM IV-TR Disorders or the Comprehensive Assessment of Symptoms and History, patients met criteria for DSM-IV-TR schizophrenia. Antipsychotic history was collected as part of the psychiatric assessment. After a series of quality controls, we selected 184 subjects, including 80 SZ cases (age: 34 ± 11, 20 females and 60 males) and 104 healthy controls (age:32 ± 11, 38 females and 66 males). After pre-processing, 27,508 DNA methylation sites, 41,s236 fMRI voxels and 722,177 SNP loci were obtained for the subsequent biomarker selections [22, 23, 24, 25, 26, 27].

2.1 SNPs data collection and preprocessing

A blood sample was obtained for each participant and DNA was extracted. Genotyping for all participants was performed at the Mind Research Network using the Illumina Infinium HumanOmni1-Quad assay covering 1,140,419 SNP loci. Bead Studio was used to make the final genotype calls. Next, the PLINK software package(http://pngu.mgh.harvard.edu/~purcell/plink) was used to perform a series of standard quality control procedures, resulting in the final dataset spanning 722,177 SNP loci. Each SNP was categorized into three clusters based on their genotype and was represented with discrete numbers: 0 for 'BB'(no minor allele), 1 for 'AB' (one minor allele) and 2 for 'AA' (two minor alleles).

2.2 DNA methylation data collection and preprocessing

DNA from blood samples was assessed by the Illumina Infinium Methylation27 Assay. A methylation value, beta (β), represents the ratio of the methylated

probe intensity to the total probe intensity. A series of quality controls (QC) on the beta values were applied to remove bad samples and probes, such as 1) Beta value QC: Change any beta value to NaN, if p>0.05. 2) Bad sample/ bad marker removing: Samples with >5% of missing (NaN) values; markers with >5% of missing (NaN) values. This resulted in the identification of good methylation data from 224 subjects, 27,508 markers (some have missing values <5%). After QC, we used the K nearest neighbor (KNN) method [28]to impute for the missing values.

2.3 fMRI data collection and preprocessing

The fMRI data were collected during a sensorimotor task, a block-design motor response to auditory stimulation. During the on-block, 200msec tones were presented with a 500 msec stimulus onset asynchrony (SOA). A total of 16 different tones were presented in each on-block, with frequency ranging from 236 Hz to 1318 Hz. The fMRI images were acquired on Siemens 3T Trio Scanners and a 1.5T Sonata with echo-planar imaging (EPI) sequences using the following parameters (TR = 2000 msec, TE = 30 msec (3.0T)/40 msec (1.5T), field of view = 22cm, slice thickness = 4mm, 1mm skip, 27 slices, acquisition matrix = 64×64, flip angle =90°.). Data were pre-processed in SPM5 (http://www.fil.ion.ucl.ac.uk/spm) and were realigned, spatially normalized and resliced to $3 \times 3 \times 3mm^3$, smoothed with a $10 \times 10 \times 10mm^3$ Gaussian kernel to reduce spatial noise, and analyzed by multiple regression considering the stimulus and their temporal derivatives plus an intercept term as regressors. Finally the stimulus-on versus stimulus-off contrast images were extracted with $53 \times 63 \times 46$ voxels and all the voxels with missing measurements were excluded.

3 Methods

3.1 Overview

We employed a network-based semi-supervised learning (SSL) scheme, which improves the predictive power by using unlabeled data [29, 30, 31, 32]. It is compuationally efficient and the learning time depends nearly linearly on the number of network edges. Also, the accuracy is comparable with other methods such as kernel-based methods with a longer learning time [18, 33]. Moreover, the network structure can facilitate the interpretation of gene-gene interactions and/or region- region connections in the brain [34, 35, 36], which is one of the advantages of network-based SSL.

Based on a fused network, our label prediction method mainly consists of three procedures: network construction, network fusion and label prediction using network-derived features.

3.2 Network Construction

Based on the features selected from SNPs, DNA methylation and fMRI data, a subject network can be constructed. Suppose we have n samples and m measurements (e.g., DNA methylation). A subject similarity network is represented as a graph $G = (V, E)$. The vertices V correspond to the subjects $\{x_1, x_2, ..., x_n\}$ and the strengths of the edges E are the weighted value of the similarity between subjects. The edge weights are represented by an $n \times n$ similarity matrix$\mathbf{W}$, with each W_{ij} indicating the similarity between subjects x_i and x_j. $\rho_(x_i, x_j)$ is represented as the Euclidean distance between subjects x_i and x_j. In order to calculate edge strength, a Gaussian function was taken on the Euclidean distance between subjects:

$$W_{ij} = \begin{cases} exp(-\frac{\rho(x_i,x_j)^2}{\sigma^2}), & \text{if } i \sim j \\ 0. & \text{otherwise} \end{cases} \quad (1)$$

If i is in $j^{'}$ s K-nearest-neighborhood and vice versa, nodes i, j can be connected by an edge. In our study, we constructed three individual networks for SNPs, DNA methylation, and fMRI data.

3.3 Network Fusion

We fuse multiple networks into one network, using mean fusion in our study. Multiple networks, denoted by $G^m = (V^m, E^m, w^m), m = 1, 2, 3, \ldots, N$, are constructed from multiple types of data. They have the same network nodes and the edge strength in the fused network is the mean value of edge strength of all individual networks.

$$G = (V, E, w),\ with\ V = \cup_m V^m, E = \cup_m E^m,$$
$$and\ w(i,j) = \frac{1}{N} \sum_{m=1}^{N} w^m(i,j). \quad (2)$$

Using this graph fusion method, we fused two or three single patient networks into one subject network. As a result, we created four fused networks: three fused networks from the combinations of two data types and one fused network for three data types.

3.4 Label Prediction Based on Neighborhood Majority

A network is a map of interactions, with the links measuring the association between objects or subunits. A labeled subject is marked either by 0 or 1, representing two possible labels: healthy or disease, respectively. The edges have an essential role in influencing the propagation between the subjects to predict the true label of the unknown subject. We assumed that the labels of two subjects are more likely to be the same if the two subjects are more closely related to each other. Therefore, the labels can be predicted based on the similarities between subjects

with their genomic profiles and/or imaging features. Edges in network-based SSL represent the similarities between subjects that can be extracted from different data including SNPs, DNA methylation and fMRI data (Figure).

Network-based classification methods can be classified into two types [21]: direct annotation schemes, which infer the class label of a node based on its connections in the network, and module-assisted schemes, which first identify modules of related nodes and then annotate each module based on the known labels of its members. Neighborhood counting is a simple and direct method for label prediction, which determines the label of a subject based on the known label of subjects lying in its immediate neighborhood. Here, we used neighborhood majority to predict the unknown labels. We first calculated the neighborhood majority of a query subject. Then, the subject is assigned the same type of label as the one of its immediate neighbors with greatest neighborhood majority (Figure).

For a query subject i, the majority of its immediate neighbors can be defined as:

$$M_k = \sum_{j=1}^{N_k} W_{ij} \tag{3}$$

where k represents subject class index and N_k is the number of subjects in class k. Then the label of subject i is defined as:

$$y(i) = y(arg\max_k M_k) \tag{4}$$

4 Results and Discussions

We employed a network-based classification method to predict whether new subjects are schizophrenia patients. After preprocessing the three types of collected data: SNPs, DNA methylation and function MRI data, we chose 184 subjects with all three types of data. We used 5-fold cross validation to evaluate our prediction method. A two-step feature selection method was applied to the labeled data sets. At first, for SNPs and DNA methylation data sets, we preselected the features based on the genes in KEGG pathways and this procedure yielded 14,875 SNPs and 6,935 DNA methylation sites. Then, for three types of data, we utilized the t-test to select the significantly differential features ($p \leq 0.01$) between normal and disease status. The preselected features were used to construct a subject-subject network. A single-type network was built for each data type. That is, three single-type networks were generated. Next, a network fusion method was used to build fused networks from two or three single-type networks. Thus we can get four fused networks: three fused networks from the pairwise combinations of two data types and one fused network from three data types. In our previous study [37], it has been shown that the technique of data fusion will improve the classification performance of network based classifiers. Therefore, in this paper, we focus on the study of the fused network from three types of data. Based on the fused network, we utilized nodes' features in a network to predict the label of a testing subject. This process is illustrated in Figure. Our prediction method is called MMN, which is a majority-neighborhood-based classification method by mean fusion.

We also compared the performance of our model with that of several other network based classification methods, with fixed parameter settings ($\sigma^2 = 510, and K = 20$). We compared 10 network based methods, whose differences consist in the procedure of network fusion and the algorithm of classification. For network fusion, two alternative methods are the mean fusion as used by our model, and Similarity Network Fusion (SNF) [38]. For classification procedure, we used five different classification methods: majority-neighborhood based classification (MN), which is adopted by our model, spectral clustering (SPC) [39, 40], support vector machine (SVM) [41], local and global consistency (LGC) [32], and label propagation (LP) [42]. SPC is a module-assisted classification approach based on spectral clustering, which is efficient in capturing global structure of a graph [43]. SVM utilizes 11 node features extracted from the network for label classification, and these 11 node features are: betweenness centrality, closeness centrality, degree centrality, Bonacich Power centrality scores, the (Harary) graph centrality, information centrality, the load centrality, the vertex prestige scores, the stress centrality, and clustering coefficients [44]. LGC utilizes both the local and the global consistency of a new patient in a patient-patient network for classification. LP predicts the clinical outcome of the new patient based on a network structure called label propagation. Thus, we have 10 different models, which are MMN (our model), SMN, MSPC, SSPC, MSVM, SSVM, MLGC, SLGC, MLP, and SLP, respectively. To evaluate the performances of these 10 network-based label prediction methods, we computed some widely used metrics, e.g., true positive rate (TPR), true negative rate (TNR), negative predictive value (NPV), false positive rate (FPR), false negative rate (FNR), false discovery rate (FDR), accuracy (ACC), and F1 (F1 = 2TP/2TP+FP+FN) of each method. The classification performances of all these models are listed in Table 1.

From these results it is evident that our model, MMN performs significantly better than other network based classification methods, in terms of some key metrics, e.g. ACC, FDR, etc. Also, it seems that those mean fusion based methods (MLP, MLGC, MMN, MSPC, MSVM) works slightly better than thef corresponding SNF based methods (SLP, SLGC, SMN, SSPC, SSVM), which demonstrates the advantage of mean fusion over SNF. In summary, mean fusion is more suitable than SNF for classification, and MMN works significantly better than other graph-based

Table 1: The performances of different graph-based label prediction methods

Methods	TPR	TNR	NPV	FPR	FNR	FDR	ACC

methods.

At first, we want to compare two different network fusion methods: mean fusion and SNF [38]. For each classification approach, we used both network fusion methods. So according to the network fusion, the 10 prediction methods implemented in our study are all grouped into pairwise comparisons. For example, in SLP and MLP, the first letter S in the method symbol SLP denotes SNF fusion method and the first M in the method symbol MLP means mean fusion approach. It is the same for other pairs of prediction methods: SLGC and MLGC, SMN and MMN, SSPC and MSPC, SSVM and MSVM. Table 1 shows the performances of different prediction algorithms between two network fusion methods. As can be seen in Table 2, for the prediction methods based on LP and LGC, there are no differences in performances between two network

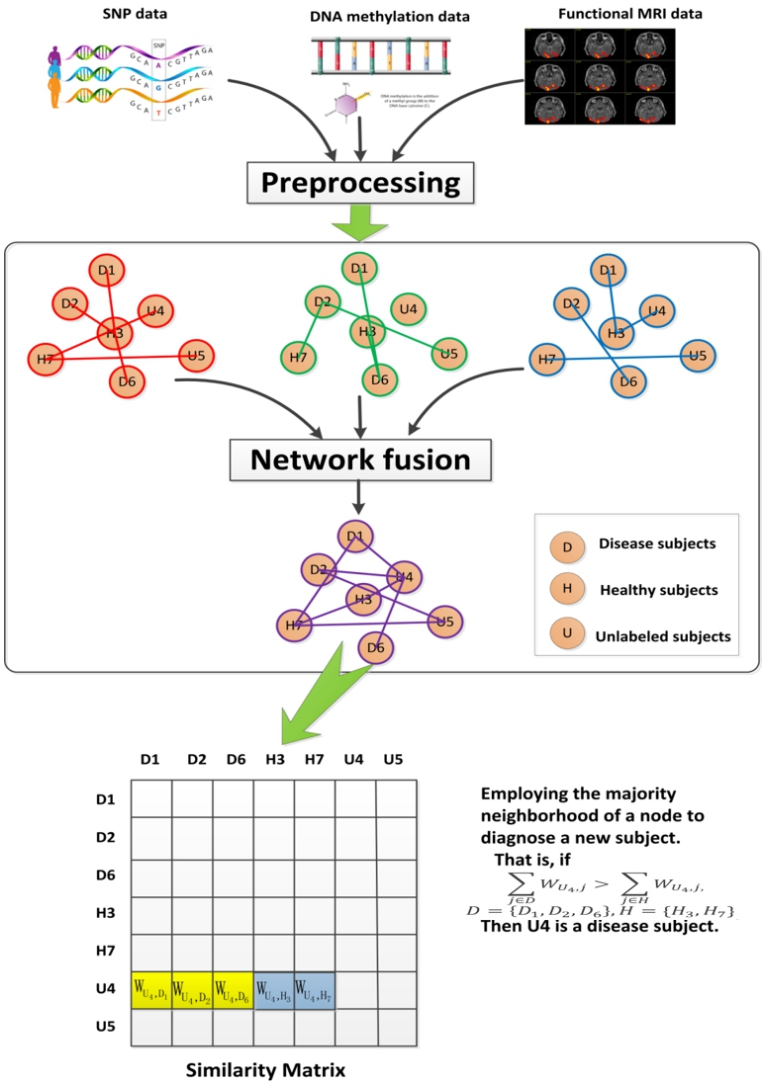

Figure 1 The Schematic of Schizophrenia Diagnosis

fusion approaches. For SSPC and MSPC, the only one group of module-assisted prediction methods, their accuracies are close to each other and neither got good performance. The results are similar to another pair of prediction methods: SSVM and MSVM. The major difference between SPC-based pair is that the mean-fusion-based method MSVM obtained higher accuracy than SNF-based method SSVM. However, the comparison results between SMN and MMN differ greatly from other graph-based prediction method pairs. For each of the performance metrics, MMN performs better than SMN, especially the ACC. Actually, the network fusion method used in this study uses uniform weight, i.e., equal weight for each of multiple individual networks. In the future, we will try to develop a weighted mean fusion method, which can assign an optimal weight for each individual network.

Above all, our prediction method MMN performs the best among all those graph-based label prediction methods and it is computationally efficient.

When computing the edge strength for constructing networks, there are two parameters σ, K related to

the prediction accuracy. When selecting an optimal σ, we fixed the parameter K (K=20) and evaluated the performances with σ^2 ranging from 100 to 950. The results are shown in Table 2 and we can see that when σ^2 is too small or too large, the prediction accuracy decreases and MMN performs best with $\sigma^2 = 510$. When selecting an optimal K, σ^2 was fixed at 510 with K changing in the range 7, 9, 12, 18, 20, 37 corresponding to 1/25, 1/20, 1/15, 1/10, 1/9, 1/5 of the number of the samples. As shown in Table 3, our methods achieves the best accuracy with $K = 20$, which is about 1/10 of whole sample (nodes) size.

5 Conclusions

We combined SNPs, DNA methylation and fMRI data into a single comprehensive network using a simple network fusion approach. A network-based label prediction method was applied to the network for predicting schizophrenia patient. Compared with other 9 graph-based label prediction approaches, our prediction method shows the best performance. However, our network fusion method used a uniform weight based combination of each network and in the future we will find an optimal weight based method to improve the prediction accuracy. In addition, Kim et al.[19] incorporated genomic knowledge when integrating multi-omics data for predicting the clinical outcome of cancer, which improved the predictive power. Therefore, we will also incorporate other prior knowledge into the construction of patient connection networks.

Conflict of Interest The authors declare no conflict of interest.

IR-drop

ABSTRACT

With silicon technology further scaling, the switching activities together with GHz operation frequency greatly affects the power integrity by generating large IR-drop noises. Excessive IR-drop causes functional failures such as timing failure, abnormal reset and SRAM flipping. The PGN needs to be optimized to reduce IR-drop. The traditional EDA optimization routine repeats the steps such as generating layout, extracting parameter and simulation, which greatly increases the cost of integrated circuit design. This paper proposes a novel fast optimization flow optimizing the PGN based on the improved Gauss-Seidel method (IGS), which calculates the accurate IR-drop distribution according to the initial voltage distribution and the 3-D parasitic resistance distribution of PGN. The proposed optimization flow compares the calculated IR-drop distribution with the IR-drop distribution constraints, and changes the parameters of power straps until the performance of PGN meets the requirement of constraints without full chip simulation, which reduces the time cost of PGN optimization. This paper also provides the comparison between the IGS-based optimization flow and traditional EDA optimization routine. The difference of IR-drop distributions calculated by the proposed optimization flow and traditional EDA optimization routine is less than 4.7%. And the PGN optimization time has been reduced by 96.2% on average for ITC99 benchmark s9234, s13207, s35932 and b19. According to the results and analysis, the IGS-based optimization flow is reliable to improve the performance of PGNs.

1 Introduction

For advanced technologies like 28nm and below, billions of CMOS gates are integrated into a modern SOCs. As a result, the density of power ground network (PGN) has been greatly increased, which causes extra IR-drop. Due to the parasitic resistance and inductance of PGN, as well as the high current consumption, IR-drop can reach multiple hundreds millivolts, which becomes a significant challenge for IC design and test [1]. Excessive IR-drop causes functional failures such as timing failure, abnormal reset, and SRAM flipping. Hence, it is necessary to optimize the PGN and reduce IR-drop. The details of PGN optimization routine, which improves its performance, consists of two parts, including the calculation of the IR-drop distribution for different PGN parameters, and checking whether the performance of PGN meets the IR-drop constraints.

The traditional optimization routine of PGN is based on EDA tools such as Synopsys IC Compiler™ and Cadence EDI™, which uses full chip simulation to calculate the IR-drop distribution. However, when the parameters of PGN are changed, the traditional EDA optimization routine repeats the steps such as generating layout, extracting parameter and simulation, which greatly increases the cost of integrated circuit design. Therefore, it is difficult to calculate the IR-drop distribution for the PGN in a short time. Also, EDA tools only understand 1-D IR-drop constraints,

https://dx.doi.org/10.25046/aj020391

which is the maximum allowable IR-drop value. For example, when the IR-drop constraint is a 2-D IR-drop distributions, EDA tools cannot understand the constraint and determine whether the calculated IR-drop distribution meets the requirement of the constraint. So the traditional optimization routine cannot provide efficient and high quality PGN optimization results. Therefore, the optimization flow with ability efficiently calculating IR-drop distribution and comparing the performance of PGN with complex IR-drop constraints is of great value.

1.1 Previous Work

Several types of optimization methods to reduce IR-drop have been presented in literatures. The optimization methods proposed in [2] and [3] reduce the IR-drop by adjusting power straps such as changing the place of power straps, increasing the density of power straps where current noise is high, and amplifying the power strap area. However, the excess power straps lead to serious placement and routing problem for chips. Also it is technically difficult to increase power straps in the tape-out process. [4] presents the analysis method of Graphene-Based power distribution networks. A Walking pads method is presented in [5] and [6], which reduces IR-drop by changing the position of power supply pads according to critical path. But the changed power pads lead to distribution problem. Also, the optimization methods based on TSVs have been analysed. A thermal-aware power network design method for the power pad optimization is presented in [7]. [8] and [9] present the optimization method to reduce IR-drop by modifying the parameters and position of TSVs, which highly increases the area of chips. The optimization methods presented in [10] and [11] change the size of TSVs to reduce IR-drop. However, the size of TSVs is constant in the 28nm technologies. The optimization method presented in [12] inserts compensation cells when the delay of critical path exceeds the allowed value to reduce IR-drop. All the researches mentioned above reduce IR-drop and optimize the PGN of chips finally. But there are a few disadvantages of these methods as follows.

- These methods reduce IR-drop based on other parts of integrated circuits rather than the PGN, which leads to appended problems such as clock delay and increasing area power dissipation.
- These methods ignore the effect of power straps in PGN, which have a non-negligible impact on the IR-drop. Power straps take a large area of PGN, whose width and density are adjustable.
- These methods are used to reduce IR-drop instead of optimizing PGN, so they cannot optimize the PGN according to the IR-drop constraints.

Previous work refers to the Random Walk algorithm in [13], which is widely used to calculate the voltage distribution. And the Representative Random Walk algorithm presented in [14] establishes a relatively simple conductance model according to the width and density of the real PGN, then calculates the IR-drop distribution of the model, which is efficient to estimate the IR-drop distribution. But this algorithm cannot get accurate IR-drop distribution and calculate the voltage of each node in PGN. [15] presents the multiple triple method, which costs too much computing resource due to the high integration of the PGN. The Gauss-Seidel Method is presented in [16] to calculate the IR-drop distribution using recursive calculation. But this method only calculates the IR-drop distribution of the 2-D PGN and ignores the conductance of power rails and TSVs. Thus it cannot calculate the IR-drop distribution of the real PGN accurately. An IR-drop measurement system on chips is presented in [17]. This method adds a sensor on the basic circuit to measure the power supply noise. The unit level sensor provides a accurate IR-drop distribution of power rails, which produces extra noise. Also, the method adding a fully digital on-chip distributed sensor network is presented in [18]. The extra sensor network monitors the power supply noise across the chip continuously and generates a trace for diagnosis of the noise-induced failure. These methods spend a lot of time to repeat the full chip simulation, and change the circuit configuration. And they cannot provide a accurate voltage distribution of PGN to meet the requirement of IR-drop constraints automatically. So they cannot be used in the actual PGN.

1.2 Contributions and Paper Organization

In this paper, a novel fast optimization flow based on the improved Gauss-Seidel (IGS) method is proposed. The IGS method takes the conductance of power rail and TSV into consideration compared with the Gauss-Seidel method presented in [16]. The proposed IGS-based optimization flow has the following advantages.

- It optimizes the PGN by adjusting the parameters of power straps.
- It uses improved Gauss-Seidel method to calculate the IR-drop distributions for different power straps without repeating the steps such as generating layout, extracting parameter and simulation.
- It calculates the voltage of each node in the PGN accurately.
- It automatically optimizes the PGN with less manual operation and full chip simulation compared with the traditional EDA optimization routine, which saves a lot of time.
- It can provide satisfactory parameters of power straps according to 2-D IR-drop constraints.

This paper is organized as follows. In Section 2, the IGS method is presented to calculate the IR-drop of the PGN. The novel fast optimization flow of the PGN is presented in Section 3. The analysis of the results is shown in Section 4. Finally, the conclusion is presented in Section 5.

2 The Improved Gauss-Seisel Method

2.1 The Gauss-Seidel Method for the 2-D Conductance Network

In this part, the Gauss-Seidel method, which calculates the IR-drop distribution for the 2-D conductance network, is presented. Figure 1 shows a representative node i and the neighboring nodes j in a 2-D conductance network. The conductance between the node i and j is defined as $g_{i,j}$, and the voltage of node i is defined as V_i. The leakage current of node i is defined as I_i. According to the Kirchhoff Voltage and Current Law, the following equation is educed, in which N_i represents the gather of neighboring nodes of node i:

$$V_i = \sum_{j \in N_i} \frac{g_{i,j}}{\sum_{j \in N_i} g_{i,j}} V_j - \frac{I_i}{\sum_{j \in N_i} g_{i,j}} \tag{1}$$

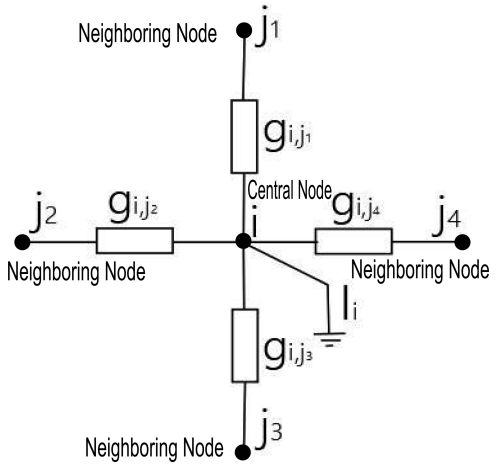

Figure 1: A representative node in the 2-D conductance Network with four neighboring nodes.

So the voltage of node i is calculated according to the leakage current of node i and the voltages of all neighboring nodes. Equation (1) is applied to all the nodes in the 2-D conductance network. A typical structure of power straps is shown in Figure 2. This model considers the network composed of power straps as the 2-D conductance network. And the intersection of power straps is regarded as a node in the calculation. The total number of nodes in the model network is N^2. The conductance between the neighboring nodes *(i,j)* and *(k,l)* is defined as $G_{(i,j)} = \sum_{(k,l) \in N_{(i,j)}} |g(i,j)(k,l)|$. And $V_{(i,j)}$ represents the gather of neighboring nodes of node *(i,j)*. The voltage of nodes in the 2-D conductance network is calculated as:

$$V_{(i,j)} = \sum_{(k,l) \in N_{(i,j)}} \frac{g_{(i,j)(k,l)}}{G_{(i,j)}} V_{(k,l)} - \frac{I_{(i,j)}}{G_{(i,j)}} \tag{2}$$

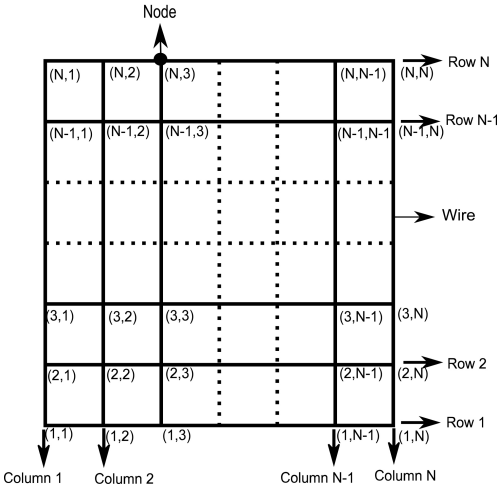

Figure 2: A typical structure of the 2-D conductance network.

The voltage distribution of the conductance network depends on the node leakage current, the voltages of neighboring nodes, and the neighboring conductance. The voltage of each node in the 2-D conductance network is calculated via Equation (2). Algorithm 1 details the Gauss-Seidel method, which uses recursive computation to calculate the voltage distribution. The leakage current of each node and the conductance between neighboring nodes should be provided before calculation. The initial voltages of nodes connected to power pad is VDD, which is constant, and the initial voltages of other nodes is 0. According to the initial voltage distribution and the conductance network, the voltage distribution of the first time recursive computation is calculated via Equation (2). In this way, the new voltage of every node is presented. The second time recursive computation is based on the voltage distribution calculated by the first time recursive computation. So this method provides a accurate voltage distribution with multiple recursive computation.

Algorithm 1 The GAUSS-SEIDEL Method in the 2-D conductance network

1: Calculate related conductance value and leakage current;
2: $V^{(0)}$=the initial value;
3: **for** each $n \in [1, P]$ **do**
4: **for** each $(i,j) \in Q$ **do**
5: $V_{(i,j)}^{(n+1)} = \sum_{(k,l) \in N_{(i,j)}} \frac{g_{(i,j)(k,l)}}{G_{(i,j)}} V_{(k,l)}^{(n)} - \frac{I_{(i,j)}}{G_{(i,j)}}$
6: **end for**
7: **if** max(abs($V^{(n)} - V^{(n-1)}$))< e ; **then**
8: break
9: **end if**
10: **end for**

Combining Algorithm 1, the first time recursive computation is finished in Line 4, and the new voltage distribution is applied to the second time recursive computation. In the process of recursive computations, the dynamic range of some parameters like the total leakage current, the total area, and the total conductance of the chip should be determined. In Algorithm 1, the parameter P on the Line 3 is the maximum times of recursive computation, which is set by users. The parameter Q represents all nodes in the power straps. The parameter e is the judgment factor to set the end of recursive computation. If the difference between adjacent computation is less than e, the recursive computation stops. The result calculated by the last time recursive computation is the output of Algorithm 1. Also, the parameter e can be used to adjust the accuracy and the time consumption of the recursive computation. With smaller judgment factor, the calculated voltage distribution is closer to the real distribution, i.e., the result is more accurate. And the results shows that the maximum value of the difference between the results calculated by the IGS-based optimization flow and traditional EDA optimization routine. Also, the smaller judgment factor leads to the increase of the iterations, which causes more time consumption of the recursive computation. However, the Gauss-Seidel Method ignores the conductance of power rails and TSVs, which influences the accuracy of voltage distribution.

2.2 The Improved Gauss-Seidel Method for the 3-D Conductance Network

The basic structure of the PGN is shown in Figure 3, which consists of three parts including power straps, TSVs, and power rails. In the PGN, the power straps connected to TSVs supplies power to TSVs. And some power rails are connected to the logic gates to feed the gates. In the actual PGN structure, the power straps can be placed in different metal layers while power rails only can be placed in one metal layer, which does not influence the analysis and calculation. This paper chooses a double layers PGN to analyse as shown in Figure 3. The leakage current only exists in power rails. The power straps and power rails with different width and density, as well as the TSVs, lead to complex conductance distribution. So the improved Gauss-Seidel method is proposed to calculate the IR-drop distribution of the 3-D PGN. The Gauss-Seidel method calculates the voltage distribution of the PGN, which is regarded as a 2-D conductance network. But the actual PGN has a 3-D structure consisting power straps, TSVs and power rails. Compared with the Gauss-Seidel method, the improved Gauss-Seidel method adopts a 3-D conductance network as the computation model to calculate the IR-drop distribution of the PGN, which is closer to the real structure of the PGN.

The first step of Algorithm 1 is calculating the conductance between neighboring nodes and the leakage current of nodes in the 2-D PGN. It is also suitable for the algorithm of the 3-D PGN. The initial voltage of power straps directly connected to the power is VDD, which is a constant in recursive computation. The initial voltage of other power straps is 0, which updates in each recursive computation. The total leakage current is measures by EDA tools, which exists in the power rails directly connected to logic gates. It is an important content to accurately calculate the equivalent conductance of metal lines in the related PGN, which depends on the volume and resistivity of metal lines. The resistivity of metal lines is provided in the standard library of chips. Figure 4 shows the equivalent transformation between the 3-D PGN and the conductance network. Each metal line is equivalent to a conductance and the metal lines network is equivalent to a conductance network. And the intersection area is regarded as a node in the equivalent transformation. The equivalent conductance networks are added to the basic conductance network to constitute the complete conductance network. And a 3-D conductance network is built in this way. There are three kind of nodes in the real PGN. The nodes formed by the horizontal and vertical power straps are defined as $node_a$. The nodes formed by the power straps and TSVs are defined as $node_b$, The nodes formed by power rails and TSVs are defined as $node_c$. And the conductance between $node_a$ is defined as g_a. The conductance between $node_b$ is defined as g_b and the conductance between $node_c$ is defined as g_c. The conductance of TSVs between $node_b$ and $node_c$ is already provided as a constant.

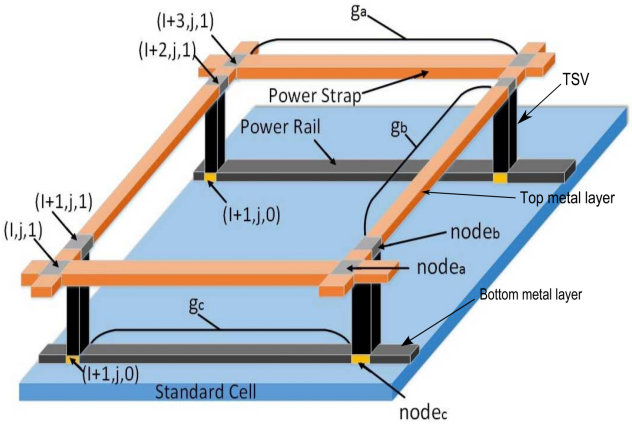

Figure 3: A two metal layers construction of the PGN consisting of power straps, TSVs and power rails.

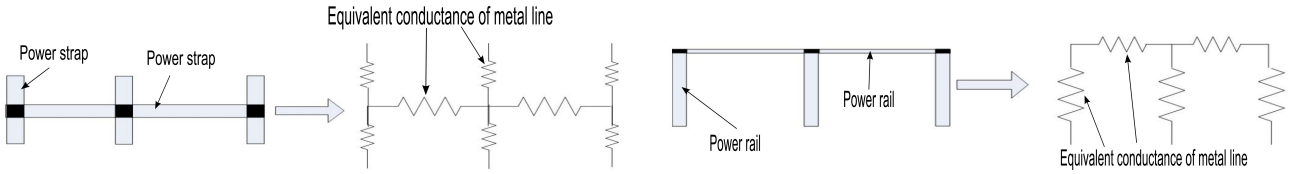
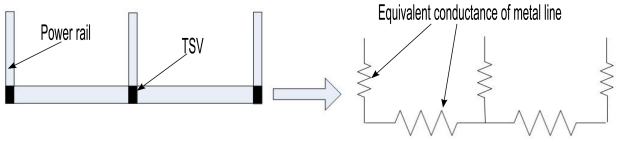
To calculate the conductance distribution of the PGN, the total length and density of power straps should be provided. The total length of power straps is set to L and the density is set to N. The distance of neighboring $node_b$ is defined as l_{rail}. The width of power straps is defined as W. And the width of power rails is defined as w. The electrical conductivity of the metal lines is defined as k. Then the conductance is calculated as:

$$g_a = k \cdot \frac{N-1}{L} \cdot W \tag{3}$$



(a) The equivalent conductance of metal lines at the power straps intersection.

(b) The equivalent conductance of metal lines at the intersection of power straps and TSVs.



(c) The equivalent conductance of metal lines at the intersection of power rails and TSVs.

Figure 4: The equivalent transformation between the 3-D PGN and the conductance network.

$$g_b = k \cdot l_{rail} \cdot W \tag{4}$$

$$g_c = k \cdot \frac{N-1}{L} \cdot w \tag{5}$$

The total length of chips and total leakage current, which are measured by EDA tools, are required to calculate the voltage distribution of chips. The parameters of power straps are constant except the width and density. In the PGN, which is placed in the 3-D system of coordinate as shown in Figure 3, the power straps and power rails are placed in different layers, which are connected by TSVs. The nodes in the power straps are defined as *(i,j,1)* and the nodes in the power rails are defined as *(i,j,0)*. The conductance between neighboring nodes *(i,j,k)* and *(l,m,n)* is defined as $G_{(i,j,k)} = \sum_{(l,m,n)\in N_{(i,j,k)}} |g(i,j,k)(l,m,n)|(k,n = 0,1)$. And $N_{i,j,k}$ represents all the neighboring nodes of node *(i,j,k)*. The leakage current only exists in power rails, so $I_{(i,j,1)} = 0$ and $I_{(i,j,0)} \neq 0$. The voltage of nodes in the power straps is calculated as:

$$V_{(i,j,1)} = \sum_{(l,m,n)\in N_{(i,j,1)}} \frac{g_{(i,j,1)(l,m,n)}}{G_{(i,j,1)}} V_{(l,m,n)} \tag{6}$$

And the voltage of nodes in the power rails is calculated as:

$$V_{(i,j,0)} = \sum_{(l,m,n)\in N_{(i,j,0)}} \frac{g_{(i,j,0)(l,m,n)}}{G_{(i,j,0)}} V_{(l,m,n)} - \frac{I_{(i,j,0)}}{G_{(i,j,0)}} \tag{7}$$

The voltage distribution is calculated via Equation (6) and (7). Algorithm 2 details the steps of the improved Gauss-Seidel method, which uses recursive computation to calculate the voltage distribution of the actual PGN. The conductance and leakage current of chips are provided before the algorithm.

The initial voltage of nodes connected to the power pad is VDD, which is a constant in the recursive compute process. And the initial voltage of other nodes is 0. According to the initial voltage distribution and the conductance distribution, the result of first time recursive computation is calculated via Equation (6) and (7). In this way, the new voltage distribution of the PGN is presented. Then the voltage distribution calculated by the first time recursive computation is applied to the second time recursive computation. By such analogy, the improved Gauss-Seidel method provides a accurate voltage distribution with multiple recursive computation. As well, the parameter P on the Line 3 is the maximum times of recursive computation, which is set by users. The parameter Q_1 represents all nodes in the power straps, and the parameter Q_2 represents all nodes in the power rails. The parameter e is a judgment factor to set the end of recursive computation in Algorithm 2. If the difference between adjacent computation is less than e, the recursive computation stops. The result of last time recursive compute is the output of Algorithm 2.Similar to the Algorithm 1, the judgement factor of Algorithm 2 determines the computational accuracy and the time consumption of the recursive computation. And the efficiency of the IGS method is inversely proportional to the value of the judgment factor. And the efficiency is proportional to the node number of the PGN as shown in Figure 4.

3 The Novel Fast Optimization Flow Based on the Improved Gauss-Seisel Method

To optimize the PGN efficiently, a novel fast optimization flow based on the improved Gauss-Seidel method is proposed, which calculates the voltage distribution for the PGN automatically without repeating full chip simulation. This proposed optimization flow optimizes the PGN according to IR-drop constraints, which considers the conductance of power rails and TSVs. The flow diagram of this optimization flow is shown in Figure 5 and the specific steps are detailed in Algorithm 3. The proposed IGS-based optimization flow involves a three-part process of measurement, calculation and verification. The optimization process is divided into three steps. Firstly, EDA tools are used to measure the total length and leakage current of chips. Secondly, the dynamic range of power strap parameters is limited, and the IR-drop distribution of power straps is calculated by the improved Gauss-Seidel method. Finally, this proposed optimization flow understands the 2-D IR-drop distribution constraints, and compare the IR-drop distribution calculated by the IGS method and the IR-drop constraints to verify whether the performance of the PGN meets the constraints. The detailed steps of this optimization flow are described below.

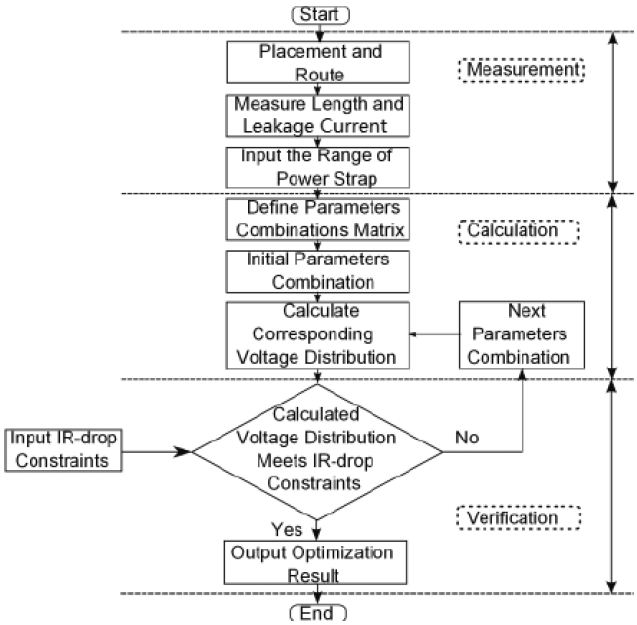

Figure 5: The flow diagram of the novel fast optimization flow diagram based on the improved Gauss-Seidel method.

3.1 Measuring the Total Length and Total Leakage Current of Chips

At the beginning of the proposed optimization flow, the total length and total leakage current of chips are provided to calculate the voltage distribution and the conductance of the PGN, which is measured by EDA tools directly. As the total leakage current is a constant when chips work at a unique frequency, EDA tools are used to place and route only once in the proposed optimization flow.

3.2 Voltage Distribution Calculation

The PGN of chips consists of three parts including power straps, power rails and TSVs as shown in Figure 3. The width and density of power rails are invariable while the width and density of power straps are adjustable. And the IR-drop can be reduced by adjusting the width and density of power straps. Before the optimization, the maximum density and minimum density of power straps are defined as $N_{\max}$ and $N_{\min}$. And the maximum width and minimum width of power straps are defined as $W_{\max}$ and $W_{\min}$. So the parameter group of power straps (W_α, N_β) should satisfy the condition that $W_\alpha \in (W_{\min}, W_{\max})$ and $N_\beta \in (N_{\min}, N_{\max})$. Each parameter group represents a kind of power strap distribution of the PGN.

To traverse all possible parameter groups, the traverse gradients of the power strap width and density are defined as Δw ($\Delta w \ll |W_{\min} - W_{\max}|$) and Δn ($\Delta n \ll |N_{\min} - N_{\max}|$). The traverse gradients are determined by the actual requirements of the optimization process, which determine the optimization precision. The object of the optimization flow is to detect the PGN with satisfactory power straps, whose performance meets the requirements of the IR-drop constraints. All parameter groups are listed in a matrix as follows:

$$\begin{bmatrix} (W_{\min}, N_{\min}) & (W_{\min}+\Delta w, N_{\min}) & \cdots & (W_{\max}, N_{\min}) \\ (W_{\min}, N_{\min}+\Delta n) & (W_{\min}+\Delta w, N_{\min}+\Delta n) & \cdots & (W_{\max}, N_{\min}+\Delta n) \\ (W_{\min}, N_{\min}+2\Delta n) & (W_{\min}+\Delta w, N_{\min}+2\Delta n) & \cdots & (W_{\max}, N_{\min}+2\Delta n) \\ \vdots & \vdots & \ddots & \vdots \\ (W_{\min}, N_{\max}) & (W_{\min}+\Delta w, N_{\max}) & \cdots & (W_{\max}, N_{\max}) \end{bmatrix}$$

The first element $(W_{\min}, N_{\min})$ in matrix is the initial parameter group. Combining the parameter group with the total width and total leakage of chips measured by EDA tools, the voltage distribution is calculated using the improved Gauss-Seidel method.

3.3 Verifying Whether the Voltage Distribution Satisfies IR-drop Constraints

The IR-drop constraints provide the minimum allowable voltage of IR-drop distribution in the PGN, which is presented in Algorithm 3 as $V^{(MIN)}$. And the $V^{(IGS)}$ in Algorithm 3 indicates the minimum value of the IR-drop distribution calculated by the IGS method. If the result calculated by the IGS method meets the requirements of the IR-drop constraints, the corresponding parameter group is the result of the optimization flow, otherwise the next parameter group is applied to the IGS method to calculate the IR-drop distribution until the satisfactory IR-drop distribution is obtained.

Output Optimization Result;

The way to compare the IR-drop distributions calculated by the IGS method and the IR-drop constraints depend on the contents of the IR-drop constraints. For example, if the IR-drop constraints only contain the maximum allowable value of IR-drop distribution, the maximum value of the IR-drop distribution calculated by the IGS method should be extracted. And if the maximum value of the calculated result is less than the maximum allowable value of IR-drop distribution, the proposed optimization flow stops and outputs the satisfactory power strap parameters of the PGN, otherwise the optimization flow continues. The proposed IGS-based optimization flow can understand the 2-D IR-drop distributions constraints such as the area ratio of different IR-drop region, and determine whether the calculated IR-drop distribution meets the requirement of the constraints. Because of the feature of the PGN, the increased width and density of power straps causes the decrease of the power strap equivalent resistances, which reduces the IR-drop finally. Therefore, when a satisfactory PGN is determined, the performance of PGNs with the wider and greater density power straps also meets the requirements of the IR-drop constraints. So the result of the proposed optimization flow is not unique. For the convenient comparison in the next section, the result of the proposed optimization flow is the PGN with the minimum parameter group, which satisfies the IR-drop constraints. But in actual conditions, all PGNs with wider and greater density power straps are acceptable.

Benchmark	Gate Number	Leakage Current
s9234	2027	152mA
s13207	2573	76.19mA
s35932	12204	114.29mA
b19	67619	152.1mA

Table 1: Logic Gate Number and Leakage Current of Benchmarks

4 Experimental Results

4.1 Benchmarks Under Test

The experiments are based on the 28nm Synopsys Cell Library. In the experiment, the recursive parameter e is set to $10^{-7}V$ to ensure the accuracy of the IR-drop distribution. The experiments are performed on ITC99 benchmark s9234, s13207, s35932 and b19, which are presented on ISCAS conference as the dedicated test circuits. The number of logic gates and leakage current of the selected benchmarks are shown in Table 1. And the selected benchmarks have different sizes from thousands to ten thousands to testify the wide suitability of the IGS-based optimization flow. The power panels are placed at the center, which are connected to the power straps directly. The VDD is set to 1.05V. The working frequency of the benchmarks is set to 125MHz. The IR-drop is calculated by multiplying the equivalent conductance and the leakage current of the node. And the wavelength of the 10GHz electromagnetic wave is 3cm. So the size of the chips is the small electrical size even the operation frequency reaches 10GHz. As a result, the equivalent conductance of the PGN is approximate in the 0.1 10GHz range. At different operating frequencies, the IGS-based optimization flow uses EDA tools to measure the leakage current at step one, which is determined by the operating frequency. And the measured leakage current is the input of the following steps. So the change of the operating frequency does not influence the application of the proposed optimization flow. The benchmarks are optimized according to 2-D IR-drop distribution constraints on the area ratio of different IR-drop region, and the details of the contributions are shown in Table 2. The rule of setting IR-drop distribution constraints is based on the requirements of the blocks on chips. There are a few IP cores in the SoC, which are sensitive to the slack. As a result, the IR-drop of the area with these IP cores needs to be limited strictly. So the IR-drop constraints sets a large IR-drop value of the area with sensitive

components and a small IR-drop value of other area.

The accuracy of improved Gauss-Seidel method is analyzed to validate the reliability of the proposed optimization flow. The PGNs are optimized by the IGS-based optimization flow and traditional EDA optimization routine according to the IR-drop constraints. The IR-drop distributions calculated by two methods are compared to verify the efficiency of the proposed optimization flow. The time overhead of two optimization methods is also compared.

4.2 Verifying the Accuracy of Improved Gauss-Seidel Method

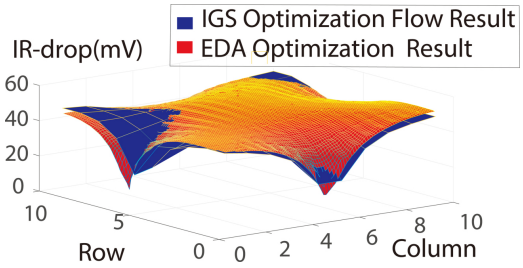
The proposed optimization flow is based on the improved Gauss-Seidel method. The IR-drop distribution, which is calculated by the improved Gauss-Seidel method, is a key factor to identify the performance of the PGN, so the accuracy of the improved Gauss-Seidel method determines the reliability of the proposed optimization flow. The IR-drop distributions of PGNs calculated by the improved Gauss-Seidel method and traditional EDA optimization routine are compared with the same IR-drop constraints to find the coherence of two methods. If the difference of two results is acceptable, the improved Gauss-Seidel method can be used to calculate the IR-drop distribution directly. Each benchmark is optimized by both optimization routines in the same condition. The IR-drop distributions of the PGN, which are calculated by the IGS method and traditional EDA optimization routine, are shown in Figure 6. Because of the different size of benchmarks, the IR-drop distributions are put into three dimensional coordinates to compare respectively.To highlight the gaps of the IR-drop distributions, the difference between two results is also presented in Figure 6. in Figure 6, X axis and Y axis denote the position of the nodes in power straps, and Z axis refers to the IR-drop value and the percentage of the difference as noted. The maximum value of the difference between the two results calculated by the IGS method and traditional EDA optimization routine is less than 4.7%, which proves that there is a high coherence between the two results. So the IGS method can calculate the IR-drop distribution of the PGN accurately.

Figure 7 shows the IR-drop distributions of the PGNs optimized by the IGS-based optimization flow and traditional EDA optimization routine according to the 2-D IR-drop constraints. The maximum value of the difference between two results is less than 5%. The result shows that the IGS-based optimization flow optimizes the PGN according to the IR-drop constraints on the area ratio of different IR-drop region successfully.

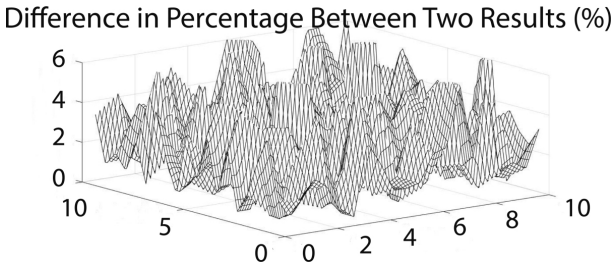
4.3 Analysis of Optimization Results and Time Overhead

In the optimization example, the width and density range of the power straps are set to $N_{\min} = 10$, $N_{\max} = 30$, $W_{\min} = 0.2um$, $W_{\max} = 2um$. And the variation gradient of the parameter groups is defined as $\Delta w = 0.02um$ and $\Delta n = 1$. The 2-D IR-drop distribution constraints on the area ratio of different IR-drop region are set to prove the effectiveness of the optimization flow based on the improved Gauss-Seidel method. The optimized PGNs of the proposed optimization flow are compared with traditional EDA optimization routine results to analyze the accuracy of optimization flow as shown in Figure 7. The optimization results and time overhead of two optimization methods are shown in Table 3. The maximum difference of width between two optimization methods is 7.4%, and the density of PGNs optimized by the proposed optimization flow is the same as the density of PGNs optimized by traditional EDA optimization routine. So the IGS-based optimization flow provides highly consistent results with traditional EDA optimization routine, and is reliable to optimize the PGN according to the IR-drop constraints.

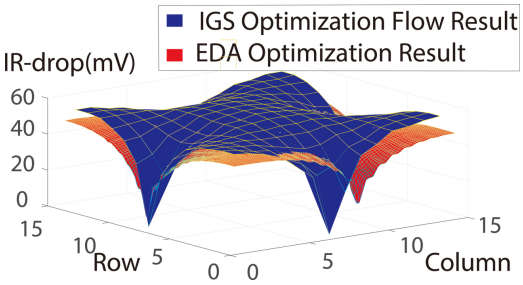
Time overhead is an important factor to judge the validity of the proposed optimization flow. The time overhead analysis of the optimization flow based on improved Gauss-Seidel method and traditional EDA optimization routine is shown in Table 3. In Table 3,



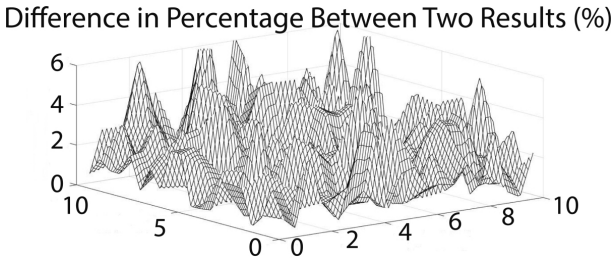
(a) The IR-drop distributions calculated by the IGS optimization flow and traditional EDA optimization routine for s9234.



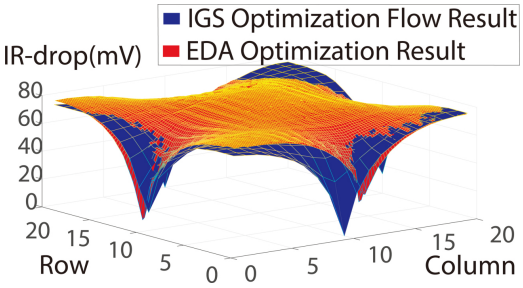
(b) The difference in percentage between the IR-drop distributions calculated by the IGS optimization flow and traditional EDA optimization routine for s9234.



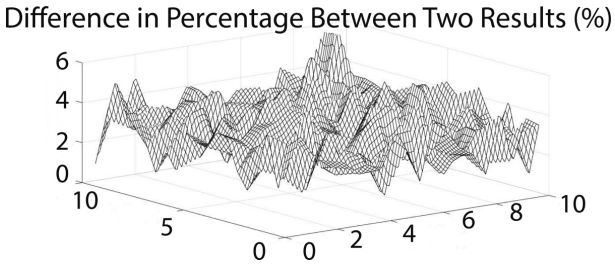
(c) The IR-drop distributions calculated by the IGS optimization flow and traditional EDA optimization routine for s13207.



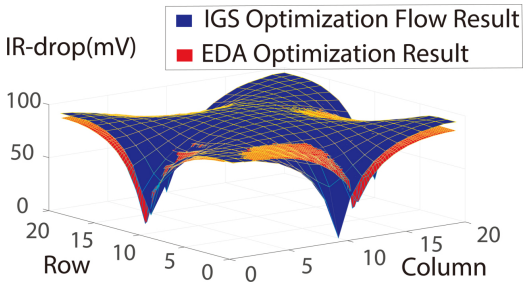
(d) The difference in percentage between the IR-drop distributions calculated by the IGS optimization flow and traditional EDA optimization routine for s13207.



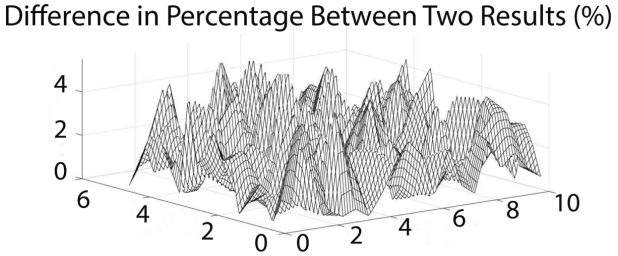
(e) The IR-drop distributions calculated by the IGS optimization flow and traditional EDA optimization routine for s35932.



(f) The difference in percentage between the IR-drop distributions calculated by the IGS optimization flow and traditional EDA optimization routine for s35932.



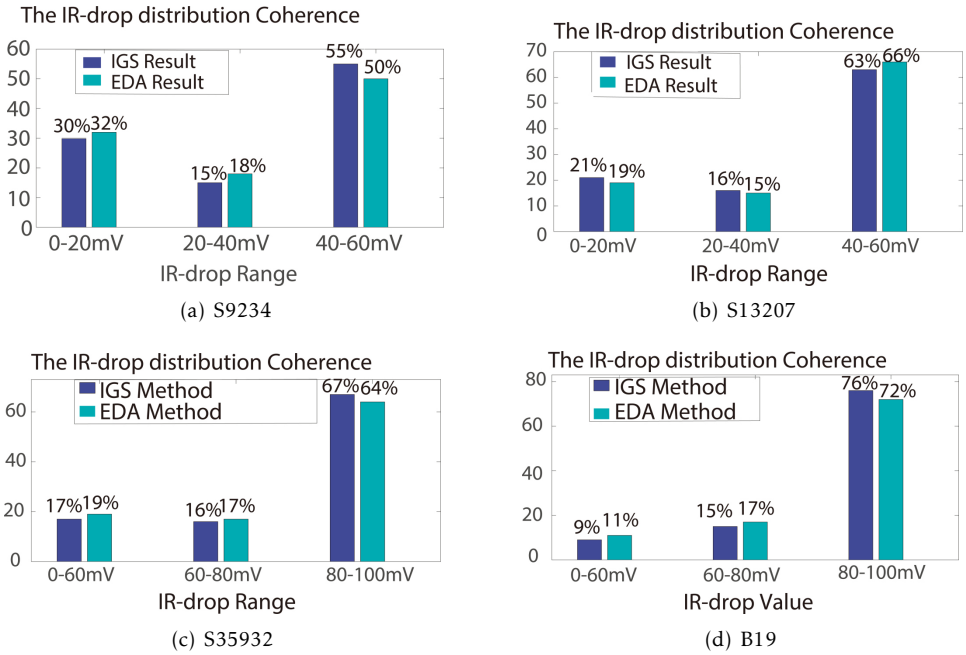
(g) The IR-drop distributions calculated by the IGS optimization flow and traditional EDA optimization routine for b19.



(h) The difference in percentage between the IR-drop distributions calculated by the IGS optimization flow and traditional EDA optimization routine for b19.

Figure 6: The IR-drop distributions calculated by IGS and traditional EDA optimization routine as well as the difference between two results for benchmark s9234 s13207 s35932 b19. It shows that the IGS result is close to the standard result provided by traditional EDA optimization routine. And the maximum value of difference is less than 4.7%, so the IGS method is reliable to calculate the IR-drop distribution.

the time consumptions of the IGS-based optimization and traditional EDA optimization routine are listed in Column 7 and 8. And the number of steps of the traditional EDA optimization routine is listed in Column 9, while the IGS-based optimization flow needs only one step to get the optimization result. To get an appropriate optimization result, traditional EDA optimization routine repeats the steps such as generating layout, extracting parameter and simulation when the parameter group of power straps is changed, which greatly increases time overhead. The optimization flow based on the improved Gauss-Seidel method only



(a) S9234 (b) S13207 (c) S35932 (d) B19

Figure 7: The IR-drop distribution coherence between the IGS calculation and traditional EDA optimization routine results for benchmark (a) s9234 (b) s13207 (c) s35932 and (d) b19. The maximum IR-drop difference is within the range of 5%, which shows the proposed IGS method successfully optimizes the PGN to satisfy the IR-drop constraints.

uses EDA tools once for place and route in the whole process. So when benchmark has a large size, traditional EDA optimization routine optimization spends a lot of time. For example, the time overhead of the proposed optimization flow to optimize benchmark b19 is 165.2s. Considering the universal judgment factor, the computation time does not increase significantly. But traditional EDA optimization routine spends 630s to simulate the full chip once, and spends 6930s to finish the optimization. The PGN optimization time has been reduced by 96.2% on average for ITC99 benchmark s9234, s13207, s35932 and b19 by the IGS-based optimization flow. The improved Gauss-Seidel method adopts a 3-D conductance network as the computation model to calculate the IR-drop distribution of the PGN, which is closer to the real structure of the PGN. In the application of the proposed optimization flow, the IGS-based optimization flow works together with the EDA tools, and the IR-drop constraints can be set flexibly and multiply. The IGS-based optimization flow can understand the complex IR-drop constraints, and optimize the particular area with the sensitive components emphatically to avoid the problems such as timing failure, abnormal reset and SRAM ?ipping. On the premise of increasing the complexity of the IR-drop distribution constraints, the time consumption is reduced by 15 to 40 times compared to the traditional EDA optimization routine to optimize the benchmark s9234, s13207, s35932 and b19. So the proposed optimization flow can improve the accuracy of the IR-drop distribution calculation compared with the past work, and avoid the functional failure by setting complex block-wise IR-drop constraints.

5 Conclusion

In this paper, a novel fast optimization flow of PGNs based on the improved Gauss-Seidel method is presented. In this optimization flow, the improved Gauss-Seidel method is provided to calculate the IR-drop distribution of the PGN according to the initial voltage distribution and the parasitic resistance distribution of the PGN. The IR-drop distributions calculated by IGS method and traditional EDA optimization routine are compared to verify the accuracy of IGS method. The difference between two results is less than 4.7%, which proves that the IGS method is reliable to calculate the IR-drop distribution of the PGN. The proposed IGS optimization flow can understand 2-D IR-drop distribution constraints and provide highly consistent results with traditional EDA simulation routine. And the IGS optimization flow only uses EDA tools once for place and route once in the whole optimization process while traditional EDA simulation routine repeats the steps such as generating layout, extracting parameter and simulation when the parameters of power straps is changed. So the IGS optimization flow saves 96.2% of the traditional EDA simulation routine time overhead on average for benchmark s9234, s13207, s35932 and b19.

GNSS / Glonass Positioning
Urban Areas

ABSTRACT

Reliable, available and accurate localization of people and vehicles is one crucial requirement for intelligent transportation systems (ITSs). This has led to a variety of technical approaches in recent years. Towards an exact positioning via Global Navigation Satellite Systems (GNSSs) the visibility of satellites is an important factor. In this paper, we review the literature regarding the positioning under non-line-of-sight conditions and analyze a range of topics from explicit modeling to empirical data collection. The variety of research indicates a growing interest in robust localization in urban areas. Furthermore, we develop a taxonomy of the technical design for GNSS applications dealing with non-line-of-sight and a typology of the measuring instruments. Both is based on an extensive analysis and review of the state-of-the-art. In doing so, we characterize the current research road map. Thus, the goal of this work is to provide a starting point in terms of the state-of-the-art for further research activities in robust GNSS positioning and the opportunity for technological innovations to ITS.

1 Introduction

This paper is an extension of work originally presented in the international conference on Intelligent Transportation Systems 2016 [1].

Localization and navigation are two key features for our industrial and globally connected world. Reliable knowing the ego position at any time around the globe – in real-time – is a necessary prerequisite for many applications, which include movement from one point to another. One particular field is the area of autonomous driving (AD) which opens up a lot of new and interesting applications. AD as a system innovation involves technological, social and infrastructural changes. Right now, several technical systems have been presented that operate on level two (partial automation) of the SAE[1] scale. In order to reach the next level of automation, that also involves higher awareness of the automated vehicle, further technological innovations are needed. Here, robust and reliable GNSS is considered a key-technology. Moreover, the ongoing progress of urbanization causes a steady extension of satellite based navigation to urban canyon environments [2]. Within inner cities, users would like to navigate seamlessly without any obstacles in both outdoor and indoor [3].

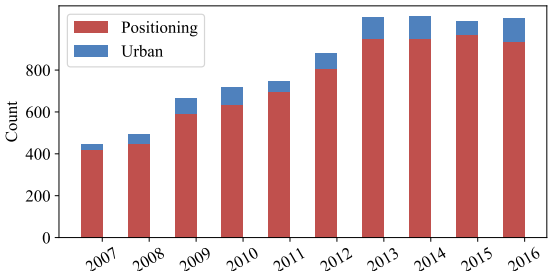

Figure 1: Number of relevant GNSS publications from 2007 to 2016.

However, the dense urban area causes several errors to satellite navigation-based positioning and thus decreases the potential for various positioning applications [4]. Due to the fact that the urban environment provides perfect surfaces for reflections, non-line-of-sight (NLOS) situations are a source for the worst errors in cities. This effect is also known outside of cities such as airports [5] or in harsh natural environments such as mountains or forests with dense foliage.

https://dx.doi.org/10.25046/aj020392

Traditional approaches are not able to identify and eliminate several stochastic and deterministic errors in satellite based navigation under both, urban and indoor, conditions [6], [7]. In [8] various approaches to address the urban canyon problem by minimizing the negative influences to the navigation solution are described. Moreover, [4] presents four different methods for improving positioning performance and categorizes in

- usage of several common radio signals such as radio signals, Wi-Fi or new technologies such as Long Term Evolution (LTE) or 5G,
- integration of different sensors such as dead reckoning (DR), mainly low-cost inertial sensors and odometry data from vehicles [9],
- techniques for the detection or modeling of the surrounding environment of the localization object [10], [11], [12], [13].

However, no cost-efficient system which provides a reliable sub-meter-level positioning in urban areas based on one single method is known, today. Consequently, we expect that future applications will combine multiple solutions to increase the accuracy and reliability. That means the most sophisticated localization system requires the combination of the single advantages of heterogeneous techniques within one system.

According to [14], the main aspects of cost-efficient GNSS-based localization system are *availability* (e. g. by using more satellite systems [15]), *accuracy* [16] and *reliability*. Some approaches improve one particular aspect without evaluating the potential negative influence to the other criteria. We believe, than an innovative localization system should strive to increase all three aspects at once while keeping costs at a reasonable level. For this reason, navigation and real-time positioning in challenging environments still requires a lot of efforts in research [17] and industry.

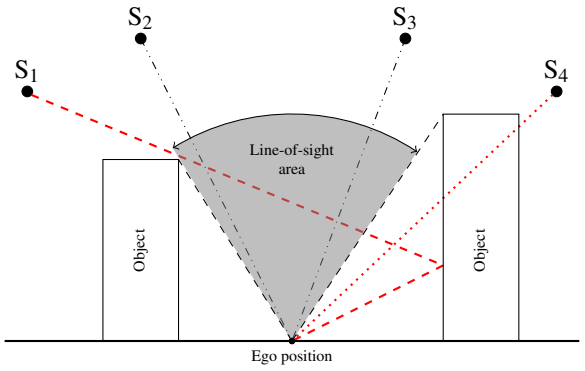

Figure 2: A typical situation in an urban area. The reception of each satellite signal depends on the position of the receiver and the satellite with respect to each other. Satellites S_2 and S_3 are in line-of-sight (LOS), satellite S_4 is blocked and satellite S_1 has non-line-of-sight (NLOS). This is a schematic representation of the electronic waves emitted by the satellites.

Based on [18], we focus on intelligent urban positioning (IUP) which includes new techniques for the detection of non-line-of-sight (NLOS) signal propagation. Thus, we will outline the current roadmap of scientists who deal with GNSS positioning under NLOS conditions. Within this survey, we intend to present a systematic overview of relevant data for NLOS handling. An explicitly in-depth assessment by benchmarking of the entire techniques is not aimed. However, we discuss topics such as measurement data generation. This survey is motivated, by the development of conference proceedings and journal publications of GNSS positioning as depicted in Figure 1, which has been stagnating since 2013. In fact, we present a subproblem of GNSS localization: the techniques for handling NLOS as well as the evaluation methods of the scientists. The paper is structure as as follows: in section 2 we first describe the NLOS phenomena by itself in order to prepare the introduction of an appropriate taxonomy. In section 3, we present a taxonomy of different NLOS handling techniques and evaluation methods. In the subsequent section an outlook to future trends and new approaches is given. The paper closes with a comprehensive conclusion in section 5.

2 Non-Line-of-sight

When using GNSS localization there are various influencing factors, which might decrease the quality of a position estimate in urban scenarios. [8] claims two important challenges: Multipath and NLOS situations. Both phenomena appear in several application domains where electromagnetic wave propagation between a sender and a receiver is used. This includes the signal reflection from surrounding buildings, a poor satellite visibility or an unfavorable satellite constellation. For the sake of clarity, we deliberately distinguish between *multipath* and *NLOS*. If a satellite signal is received via multiple paths at the antenna, that is, via the direct path (also known as line-of-sight or LOS) and the NLOS path, it is characterized as multipath. If it is solely received via the reflection path it is simply characterized as NLOS. In inner cities with high buildings and narrow streets the receiver performance is usually affected by both, multipath and NLOS. Thus, both effects are the dominant sources for unwanted disturbances [19]. Figure 2 depicts a typical situation within an urban canyon. It is worthwhile to mention, that advanced antenna concepts (e.g. based on dual polarization [20], antenna arrays [21] or choke ring designs) are able to exclude the NLOS part from a multipath signal. However, this no longer works if only the NLOS signal is received. Moreover, these effects cannot be removed by differential techniques [7]. Thus, an efficient and explicit estimation/identification step is required.

In [14] the NLOS problem is divided into eight individual sectors. Based on the aforementioned work, we abstract three different levels: the technical design for the detection of NLOS; the objective of the approach itself; and the application domain (see Figure 3).

- The *technical design* level consists of four different sub-levels—*error analysis*, *hardware sensors*, *environmental modeling*, *fault detection/outlier classifi-*

cation. This level summarizes all technical implementations and designs.

- *Objective* includes the sub-levels *handling* and *scope*. It describes how the contained information within the NLOS signal is used. For example, if it is just ignored or exploited to a certain extend. Moreover, we separate between *autonomous* (stand-alone) and *cooperative* architectures.
- The level *application domain* comprises the main areas where GNSS-based localization techniques are used for the positioning process.

In the subsequent text, we use the combination of technical design and the level of objectives (especially handling) as categories for our survey. This includes the analysis of current NLOS methods under the aspects of availability, accuracy and reliability.

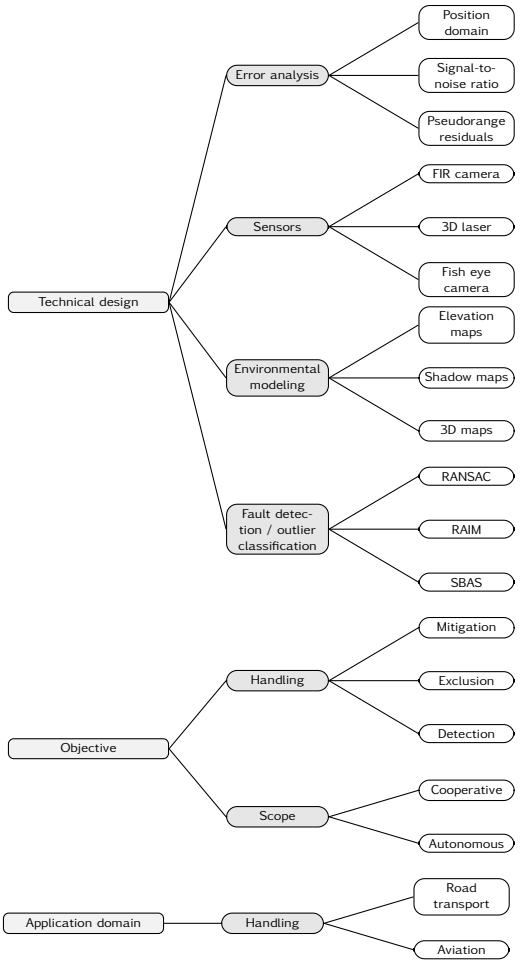

Figure 3: Overview of created taxonomy in reference to [14].

3 Classification & Taxonomy

In this section we will create a taxonomy, in which the levels of handling, objectives and techniques are linked (see Figure 3). Based on these levels, we will assign different research activities. In addition, we provide two further categorizations based on an inductive approach. We summarize current research approaches, which lead us to the taxonomy stages. For the sake of clarity, we present a table which categorizes the evaluation methods found in literature. Finally, we present an overview that summarizes current approaches which address NLOS.

3.1 Taxonomy of NLOS Handling Approaches including Techniques

After analyzing the literature, we came to the conclusion that there are four different high-level solutions to the NLOS problem. This includes: *ignorance* of the NLOS effect, *mitigation* of NLOS signals, *identification* of NLOS signals as well as *avoiding* NLOS. The latter one is equivalent to avoiding to go to cities or denied environments. Ignorance means, the disregard of multipath effects and NLOS signals at all. Although, this approach is not constructive in the sense of a modern localization system as highlighted in the introduction section, we included it for the sake of completeness. By mitigation we subsume approaches which basically assume that the effect of multipath can be minimized through the usage of improved features of hardware. In contrast, there is the field of identification. Here, we include approaches which aim to identify NLOS signals in order to use this information for further processing. In a second step, the identified NLOS signals can be eliminated or exploited.

It is worth mentioning that some approaches use different methods but generate similar results. For example, the sub-level *receiver-based correlator design* might mitigate the influence of NLOS without exact identification of the defect signal, while a similar work, which belongs to the sub-level *modified receiver processing strategy*, performs an identification followed by a subsequent elimination of that signal from the positioning process.

Mitigation

The work of [22] proposes two categories of mitigation techniques: antenna design and receiver-based correlator design. We augment this classification with two additional categories in our taxonomy, that is, *weighting* and *using quality parameters*. Due to the nature of these techniques, the algorithms are only able to decrease the influence of the NLOS error to the positioning solution without explicitly modeling which signals are received under NLOS or LOS conditions. Hence, they are for example not suitable for explicit modeling of pseudorange signal characteristics.

- Receiver-based correlator - different designs or implementations of the correlator at the HF-level are a key feature of work within this category and can be found in [23] and [24].
- Antenna design - based on a special design of the antenna, the NLOS part within a multipath signal can be extracted before the signal arrives the receiver. Representatives of this approach are: [8], [25], [26], [27] and [28]. Recurring on [8], six antenna designs can be distinguished, where the angle of arrival measurement (AOA)is rated the most performant technology.

Although the AOA principle provides a high performance, it is worth mentioning that this antenna design is not widely adopted yet.

- Weighting - refers to the so-called elevation cut-off angle for different satellites. In general, low elevated satellites are more affected by NLOS than satellites with a high elevation. For this reason measurements from these satellites will be excluded before a position solution is computed. Implementations of that technique can be found in [29] and [30].
- Using quality parameters - the approaches in this category indirectly use different indicators such as signal-to-noise ratio (SNR), Doppler frequency, etc. to assess the probability of a measurement being a NLOS signal. Based on a user-defined threshold in this domain, the potential NLOS signals are either excluded or tagged in order to apply a weighting. Implementations of this can be found in [31], [32], [33], [34], [35], [36] and [37].

Identification

We split the top-level category identification (as proposed by [8] and [38]) into the sub-levels *elimination* and *exploitation*. For both sub-levels, the identification of NLOS signals is a necessary condition. Regarding the elimination of NLOS signals, the concept initially presented in [4] is extended with a further category named *environmental modeling*. Thus, the final four sub-levels of the category elimination are:

- Environmental modeling - describes the explicit modeling of potential external influences such as buildings or infrastructure of cities: [12], [39], [18], [40], [41], [42], [43], [44], [45], [46], [47], [48], [49], [50], [51]. We also propose to include approaches such as a sky-positioning camera within this category.
- Integration with inertial navigation systems (INSs) - combines the benefits of two heterogeneous systems into one localization system: [14], [52], [53], [54], [55], [56], [57], [58].
- Modified receiver processing strategies - describes approaches were the receiver architectures is modified in order to achieve better signal processing aspects: [59], [60], [61], [62], [63], [64], [65], [66], [67], [68].
- Using multi-constellation GNSS - for increasing the overall amount of available satellite signals to choose from and thus improving the dilution of precision (DOP) metric: [13], [69], [70].

The level exploitation includes a large amount of approaches and consequently comprises several categories. The handling-technique is used to obtain further important information about accuracy, availability and reliability. Accordingly, the technique is appropriately utilized. This changes the view of NLOS: from a negative effect to an important information provider. Also, we have gathered techniques that allow to provide necessary information. In [43], the two categories *signal-to-noise ratio* and *shadow matching* are proposed. The category *signal delay matching* (SDM) was introduced in [4]. The other categories are taken from [14] and augmented with different collections of papers as shown in the following listing. It should be highlited, that recent research approaches usually propose a combination of the individual techniques. The categories of the sub-level exploitation are divided in:

- Signal-to-noise ratio - approaches sorted to this category aim to use the information about different SNR levels in several environments: [27], [47], [71], [72], [73], [74].
- Ray tracing - this technique uses several models (e.g. 3D city models) to predict an intersection of the LOS signal path with a building between a satellite and the receiver. In case of an intersection, the probability for NLOS is considered high: [4], [22], [71].
- SDM or signal delay matching - describes a technique to predict and observe parameters such as delta code phase delay. The observed parameter is then compared to a known model as shown in [4].
- Shadow matching - shadow matching is a pattern matching approach which utilizes a 3D city model in order to predict whether a satellite will be visible or not. Based on the decision whether a signal was directly received, the most likely position candidate from the 3D map can be selected: [11], [75], [76], [77], [78], [79] and [80].
- 3D building model - this level encompasses all approaches based on 3D building models which do not rely on ray tracing or shadow matching: [4], [22], [71], [81], [82], [83].
- Consistency checking - The rationale behind this approach is, that LOS measurements usually produce a more consistent navigation solution (e.g. in data fusion systems) than NLOS measurements [8]. Therefore, different combinations of satellite signals are used to compute individual position candidates which are afterwards compared to each other or another reference: [29], [84], [85], [86] and [87]. The technique of innovation filtering is also included in this category [8].
- Pseudorange residual - the least squares method aims to minimize the residuals produced by all considered measurements. The result is a more consistent (i.e. balanced) positioning solution as shown in [71].
- Carrier phase - this category is similar to the SNR level. However, this time the observed parameter is the carrier phase [88].
- Time delay and Doppler frequency - This category is similar to the SNR level. However, this time the observed parameters are the time delay and Doppler frequency: [89], [90] and [91].

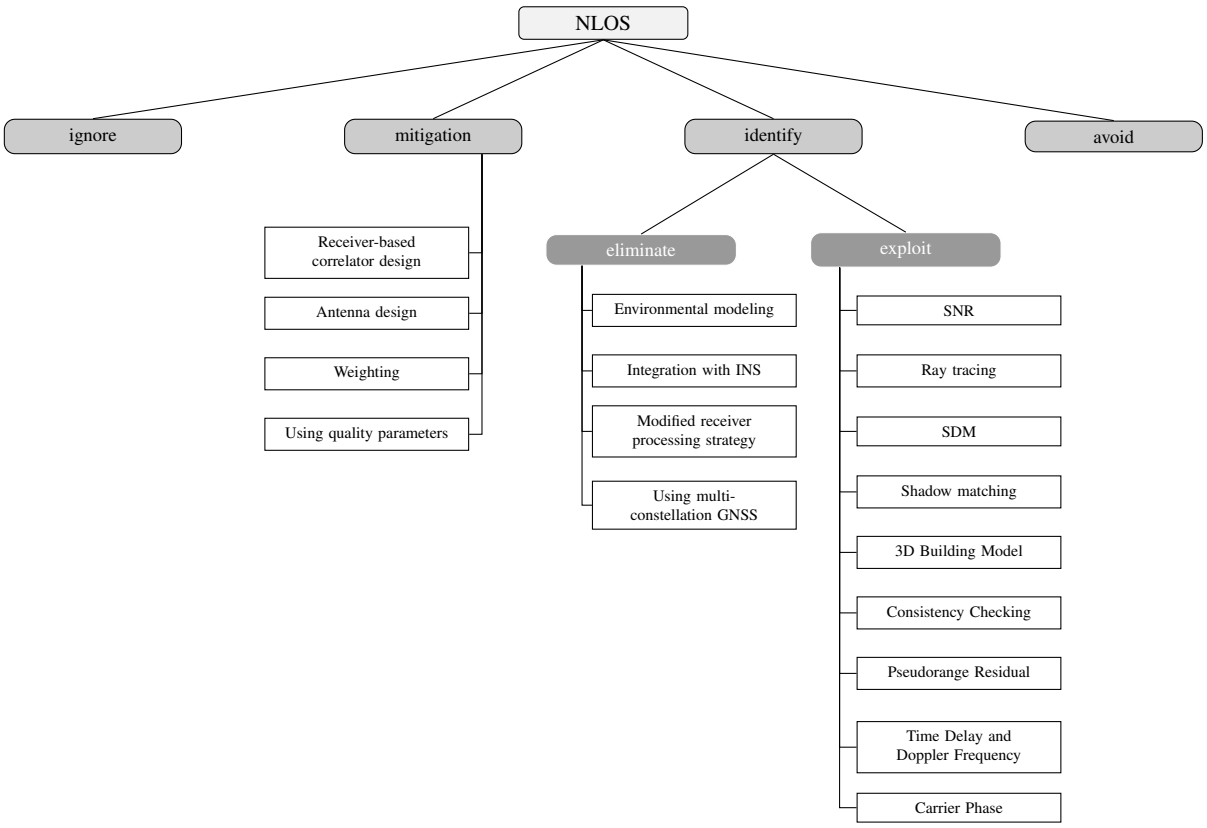

Figure 4: Classification of the NLOS problem into four different levels. Additionally, the level identify is divided into the two sub-levels eliminate and exploit. The different sub-levels are inspired by [4], [38], [8], [14] and extended by own categories.

Some approaches found in literature cannot be clearly assigned to one of the aforementioned categories. Moreover, papers which cover more than one technique are also missing at this stage. For the sake of completeness, we would like to add these papers to this survey. For example, techniques which utilize cooperative methods to exchange GNSS raw data in order to mitigate the influence of degraded satellite signals can be found in [92] and [93]. Other approaches try to detect jumps of the mean value within the measurement domain over time [94]. Moreover, various forms of receiver autonomous integrity monitoring (RAIM) have been investigated [95]. A further class of complex algorithms utilizes Dirichlet process mixtures (DPM) for multipath mitigation [96], [97].

3.2 Evaluation Methods

In the introduction, we mentioned the characterization of the scientific road map in the context of NLOS. Similarly, to the handling methods, we now want to present the analysis of the evaluation methods. At this point, we ask ourselves how the technical approaches for NLOS mitigation, identification and modeling are assessed. Therefore, we provide an overview of the used experimental setups. The focus is clearly on papers, which address NLOS or multipath handling. We proceed in an inductive manner. This means, we try to derive relevant categories from the reviewed papers. Within 53 papers we found static and dynamic measurement campaigns, which were destined for either vehicles (trucks, aircrafts, drones, cars, etc.) or persons. Moreover, these measurement campaigns can be categorized into simulation and real-world data collections. Table 1 illustrates our results and allows a classification. The row *no information* summarizes items that do not report the evaluation method. The classification is focused on real-world data collection for vehicles. We observed that real-world data collection campaigns for persons is constantly increasing since 2013. In contrast, simulations are underrepresented in connection with the exploration of identification and mitigation strategies of NLOS. We assume different obstacles in the process of transferring real world phenomena into a simulation model. The influences and dependencies between constantly changing environments during a dynamic maneuver are highly complex. Hence, the majority of the investigated papers use real-world data to cover most relevant side effects. During the characterization of the evaluation methods we also realized that a comparison of the results can hardly be produced. This is mainly due to a lack of a common dataset, which allows consistent benchmarking of the used methods and techniques.

3.3 Recent solutions for positioning under NLOS conditions

In this section, we will look at the different categories of our Survey for current research projects. Similarly, we test the statement by [8] that the combination of techniques is essential. The study of the reviewed work showed 7 research projects in the period from 2013 to 2015, which dealt with the NLOS problem. The methodology of the programs can

be classified into the field of identification. Based on this current research, we analyzed solutions in form of technical design, scope and data collection. Due to this sampling we found:

- one approach with a cooperative scope [56]. This approach was evaluated by simulation.
- six approaches, which are specialized in environmental modeling with 3D ([4], [18], [22], [43], [47], [71]). Here, real-world data was collected. Thus, building boundary data, digital terrain models and building models were used.

Table 1: Types of Measurement Data

Real Data collection	**Static measurement**	**Dynamic measurement**
Via vehicle	[8], [14], [33], [50], [80], [98], [99]	[4], [14], [30], [33], [35], [92], [47], [48], [50], [51], [58], [67], [68], [70], [74], [81], [82], [83], [85]
Via person	[18], [22]	[43], [49], [66], [71]
(No information)	[28], [29], [31], [32], [34], [37], [73], [84], [86], [87], [88]	
Simulation	**Static measurement**	**Dynamic measurement**
Via vehicle	[90]	[14], [27], [56], [68], [91], [94]
Via person (No information)	[25], [41], [89], [95]	

Furthermore, this analysis reveals that these projects used a combination of technical designs in order to identify the NLOS signal. For example, [18] used building models, consistency checking, signal geometry and signal strength information within one algorithm. In addition, we were able to determine which criteria were used to evaluate the research projects. In all studies, accuracy was the main objective, while some studies focused on the availability aspect as well. Only four studies addressed the performance indicator reliability.

Furthermore, an assumption from our introduction was confirmed. Thus, the costs represent a significant influencing factor on the techniques, which were used. Four out of the seven research programs address the low-cost aspect: [4], [18], [43] and [47]. For this reason, we conducted further meta-analysis on the criteria for NLOS handling techniques by investigating the following sources: conference proceedings as well as journal publication from the years 2013 to 2016. It became clear that accuracy was given to 59%, availability to 27% and reliability to 14% as observation and influencing factors for the assessment of NLOS approaches. Figure 5 illustrates this evolution. In addition, we observed an increase in low-cost conditions for NLOS techniques since 2014. Basically, these criteria can be considered evaluation standards for a common benchmarking of NLOS handling techniques.

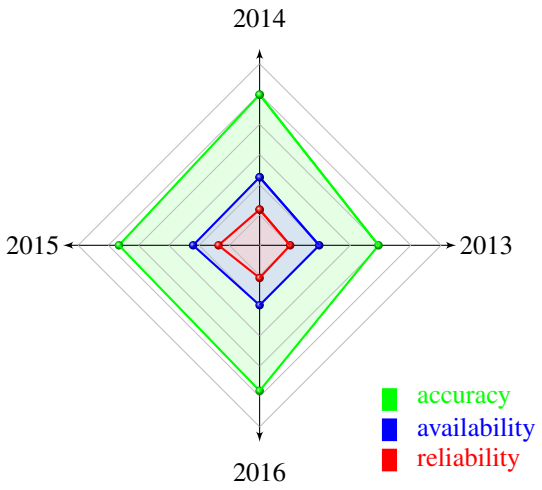

Figure 5: Evolution of evaluation criteria from 2013 to 2016.

4 Current Development

Despite the steadily growing field of satellite navigation for pedestrians, in combination with other techniques a seamless navigation independent from the environments, the majority of usage is for various vehicles on roads. This fact is shown in the rows for vehicle of Table 1. On the other hand, there are some gaps of research and experience with satellite-based navigation for pedestrians. Another fact is the ongoing development of autonomous vehicles in the near future. A reliable and accurate navigation system is one of the enabling-technologies for improved mobility. For this purpose the vehicle have to trust the navigation solution, independently of harsh environments or good visibility of satellites. In theory, there are several techniques to fulfill this task. However, we expect that the combination of multiple approaches will result in a safe navigation system that can be used in case of outage or partial degradation of a sub-system.

Although, this survey paper focuses on an analysis of the state-of-the-art of GNSS positioning under NLOS conditions, we would like to mention that there are a couple of national and European initiatives which aim to improve satellite navigation in challenging areas. For example, the goal of the German research project *smartLoc*[2] is to develop a robust positioning algorithm based on the factor graphs framework as used in the robotics community. The main motivation is to enable low-cost receivers to be used in urban areas by deliberately modeling the LOS and NLOS statistics inside of the navigation algorithm. By that ap-

[2]http://www.smartLoc.eu

proach, an appropriate integrity as well as an improve accuracy is expected. The algorithm is designed to explicitly handle temporal mulit-modalities of the GPS pseudoranges as caused under NLOS conditions. Similarly, the European research project *InDrive*[3] proposes to use a software GNSS receiver in combination with a Bayesian data fusion framework in order to estimate and identify NLOS signals already at the correlator level. In contrast to a standard GNSS receiver which typically solely emits one PVT solution per epoch, the *InDrive* concept allows to provide multiple solutions in case of temporal ambiguities. Due to the probabilistic interface on the output side, later stages (e.g. inside of a complex system architecture as in autonomous vehicles) can be used to finally select the most appropriate solution candidate based on further information (e.g. from digital maps or other exteroceptive sensors).

5 Conclusion

In this paper we addressed a specific segment or phenomenon of robust localization: NLOS. With our survey approach, we intend to present a systematic search for specific data relevant to the NLOS handling. Starting from the work presented in [14] and an analysis of several papers we have developed a taxonomy of handling NLOS in GNSS positioning. Thereby we integrated the fields of handling, the technology used and the intended objective. Afterwards, we identified types of evaluation methods and analyzed which are primarily used. Finally, we looked at current research programs and their technical design, data collection, handling, scope and application domain.

The output of Table 1 and the classification in Figure 4 give a good impression of the usage of satellite-based navigation. The majority of the reviewed papers are related to outdoor environments for any kind of vehicles. Many of them used real-world data to compare their solutions. As the used reference data (ground truth) is not the same within the data sets, an absolute comparison regarding the algorithmic performance is difficult. Hence, a quantitative comparison of the various solutions should be addressed in future work. Then, we applied the taxonomy of handling and evaluation methods to current research projects. It became clear that cooperative handling approaches as well as real-data measurements belong to the current standard. In addition, we were able to characterize the evaluation criteria of the researchers for their chosen technique and to outline an essential condition for the technique. Thus, we could determine the current researcher roadmap for dealing with NLOS. The roadmap is defined by the choice of several cooperating NLOS handling techniques in coordination with the respective research objective (mitigation, exploitation or elimination). Then, the evaluation of this technique is carried out under the conditions of low-cost, due to the availability, accuracy and reliability of the GNSS localization system. Real data are usually used for this purpose. In the future, we would like to use a common dataset to benchmark the used methods and techniques. These steps are needed to create technological innovations for our industrial and globally connected world - especially for system innovations in the area of ITS.

ABSTRACT

This paper discusses a step climbing strategy using a wheelchair and a teleoperated care robot that avoids collisions between the wheelchair's front wheels and the step wall. In our method, the two vehicles are connected and use the velocity difference between them to climb steps. Since the wheelchair's front wheels, or another part of the wheelchair, tend to collide with the step being mounted while the wheelchair front wheels are in the lifted position, we investigated a system that permits switching between teleoperation and autonomous control to avoid this problem. In our proposed system, the wheelchair step climbing process is performed under autonomous control, while the robot step climbing process is performed under teleoperation control by a remote caregiver. Theoretical analysis and accompanying calculations were performed to clarify the most suitable lifting position for wheelchair front wheels when climbing, and our experimental results show the overall effectiveness of this system.

1 Introduction

This paper is an extension of work originally presented in *The 2016 IEEE International Conference on Simulation, Modeling, and Programming for Autonomous Robots* [1].

For disabled people, using wheelchairs is an effective means for locomotion. However, since it is difficult for wheelchairs to negotiate steps, user movements are often restricted. Some reasons for the wheelchair's difficulty include driving wheel slippage and/or vehicle imbalance. Numerous research programs aimed at improving wheelchair mobility on steps have been conducted, and the following potential solutions have been investigated: additional legs [2], multiple wheels and variable wheelbases [3], a combination of an adjustable center of gravity (COG) and multiple wheels [4], tracked vehicles [5], an additional driving wheel system [6], and changing the wheelchair posture to facilitate climbing [7]. In addition, Yoshikazu Mori studied a new step climbing and descending strategy using a manual wheelchair equipped with linear actuator mechanisms and a light portable ramp [8].

This study's research group has previously investigated a cooperative step climbing method that can be used by a robot and a manual wheelchair connected via a passive link [9], and by using a teleoperated robot controlled by a caregiver through an intranet and a conventional or electric drive wheelchair [10][11]. Our step climbing system, which is capable of reducing the burden imposed on the caregiver, takes advantage of the wheelchair user's ability to judge external information (e.g., obstacles and distances between vehicles and steps), and the caregiver's ability to teleoperate the system through an intranet.

To operate this step climbing system, both the wheelchair user and the caregiver will need sufficient training, particularly for the period when the wheelchair's front wheels are close to the step, which is where the risk of a collision between the wheels and step is high. Furthermore, since this system uses autonomous control during the wheelchair step climbing process, it was necessary to implement a support system that can switch between teleoperation and autonomous control.

While the primary purpose of this paper is to describe our proposed support system for avoiding collisions between the wheelchair front wheels and step during stair ascents [1], we will also describe the concept behind our step climbing method, and provide a detailed theoretical analy-

sis, similation and the results of an experiment describing its use.

Other reports of multiple vehicles cooperating to cross irregular terrain include those of Asama *et al.* [12], who considered a forklift system, and Gaston *et al.* [13], who studied stair climbing robots using a mechanism similar to that of Asama *et al.*

Based on our preliminary measurements of the friction coefficients for the robot under wet and dry conditions on asphalt, concrete, wood, and interior flooring, the ground surface considered in this research was assumed to have a friction coefficient within the range of 0.6 to 0.9. The heights of steps located at the entrances of typical buildings and other structures were also measured, and a target step height of 120 mm, which accounts for more than 80% of the observed heights, was set.

This remainder of this paper is organized as follows: Section 2 describes the concept of cooperative step climbing, and Section 3 describes the robot and wheelchair used. Section 4 describes the step climbing process, and Section 5 provides a theoretical analysis of our proposed method. Section 6 describes an experiment using our proposed system and the results, and our conclusion is given in Section 7.

2 Concept behind wheelchair care robot

As described above, since it is difficult for wheelchairs to climb steps, wheelchair user movements tend to be restricted. Most wheelchairs have two casters employed as front wheels and two driving rear wheels, and the center of gravity of a wheelchair with a seated user is high. Thus, when a wheelchair attempts to climb a step, high potentials for driving wheel slippage (Figure 1 (a)) and/or tipping over the vehicle (Figure 1 (b)) arise. In addition to step climbing situations, wheelchair users face difficulties at numerous other times. For example, it is difficult for a wheelchair user to open a door (Figure 2 (a)) or pick up an object that is on the floor or placed on a high shelf (Figure 2 (b)). Thus, under most current circumstances, most wheelchair users need a human assistant. However, taking care of a wheelchair and its user is hard work.

(a) (b)

Figure 1: Reasons why wheelchairs are weak against steps: (a) driving wheel slippage, and (b) possibility of tipping over when the rear wheels transverse the step

(a) (b)

Figure 2: Obstacles for wheelchair users other than step climbing: (a) door opening, and (b) picking up objects

The aim of this research is to create a teleoperated robot system that can be used by caregivers to provide assistance to vulnerable but esteemed persons (such as their elderly parents) from a distant location. In the next section, we will begin by evaluating a method for avoiding collisions between the front wheels of a wheelchair and a step wall.

3 Wheelchair and robot

The robot used in this research is “Tateyama”, which is a wheeled robot developed in this laboratory (Figure 3).

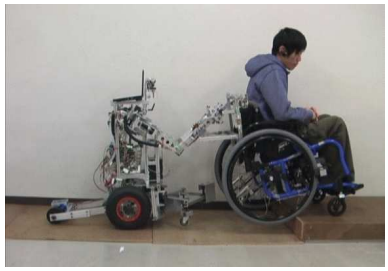

Figure 3: The wheelchair and robot

Table 1: Robot specifications

Overall length	230 to 800 mm
Overall height	747 mm
Radius of front wheels (r_{Bf})	25 mm
Radius of middle wheels (R_B)	145 mm
Radius of rear wheels (r_{Br})	19 mm
Wheelbase (WB_f)	190 to 440 mm
Wheelbase (WB_r)	270 mm
Distance of center of gravity from the middle wheel axes (l_{rB})	93 mm
Height of the mass above the middle wheel axes (h_{mB})	286 mm
Distance of Joint 2 from the rear axes (l_{LB})	90 mm
Height of Joint 2 above the rear axes (h_{LB})	532 mm
Mass of the robot’s body	55 kg
Mass of upper links (from Joint 2 to 4)	2.55 ×2 kg
Mass of forearm links (form Joint 4 to hand)	0.8 ×2 kg
Length of Link 2 (l_2)	330 mm
Length of Link 4 (l_4)	300 mm
Length of the hand (l_6)	105 mm
Length from Joint 4 to the connecting position (l_{4C})	370 mm

Table 2: Wheelchair specifications

Overall length	1060 mm
Overall height	985 mm
Radius of front wheels (r_A)	63 mm
Radius of rear wheels (R_A)	300 mm
Wheelbase (l_A)	430 mm
Hand rim position (l_{LA})	250 mm
Distance of center of gravity from the rear wheel axles (l_{rA})	149 mm
Height of mass above the rear wheel axles (h_{mA})	371 mm
Height of push-handle (h_{LA})	435 mm
Mass (wheelchair + driver) (M_A)	92.7 kg

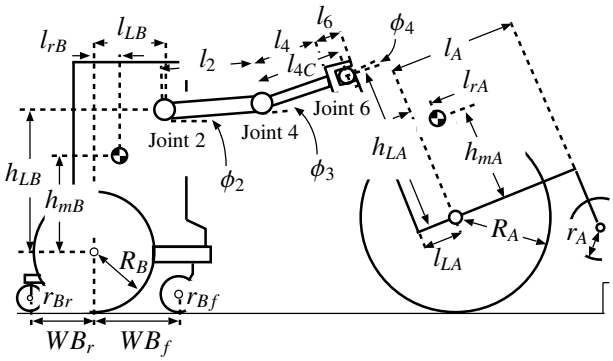

Figure 4: Model of wheelchair and robot

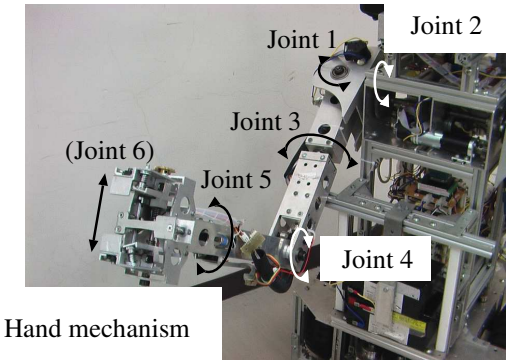

Figure 5: Robot manipulator

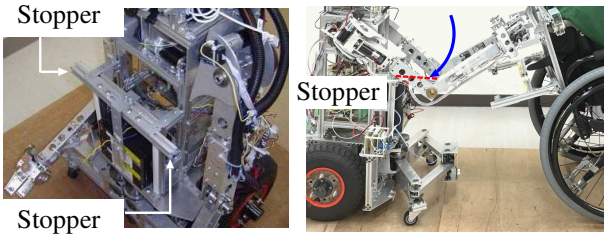

(a) (b)

Figure 6: Rotary motion control of the robot shoulder using the robot body: (a) Front body of the robot, and (b) side view of stopper on the robot chest

The process begins with the wheelchair and robot deployed in a forward-and-aft configuration to traverse the step (Figure 4). When the wheelchair and the robot encounter a step, the robotic hands grasp the rotary shaft of the wheelchair push handle [14]. Table 1 and Table 2 list the specifications of the robot and wheelchair, respectively. The wheelchair and robot move at a constant speed (0.76 km/h). This robot is equipped with three pairs of wheels, and each pair consists of left and right wheels. The front pair are casters, whereas the middle and rear pairs are driving wheels. The front and rear pairs can be folded.

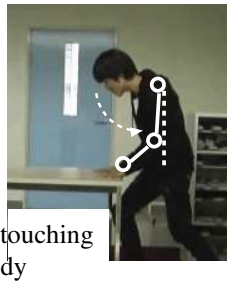

Figure 7: Human pushing an object

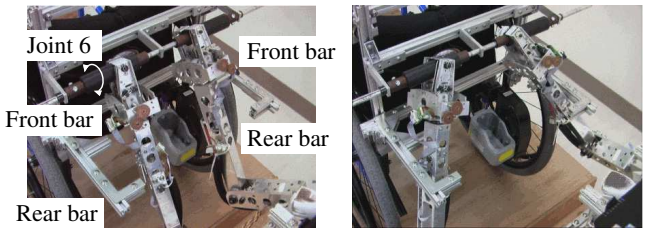

(a) (b)

Figure 8: Sides of the robot: (a) in wheelchair climbing position, and (b) in robot climbing position

(a) (b)

Figure 9: Stopper actions: (a) lifting the robot wheels, and (b) preventing the robot from falling down

The robot has manipulators attached to the left and right joints of its upper half. Since each arm has five degrees of freedom (5-DOF) and the hand has 1-DOF, the arm has a total of 6-DOF (Figure 5). In this paper, the length of the upper arm link (from Joint 2 (shoulder) to Joint 4 (elbow)) is l_2; the length of the forearm link (from Joint 4 to Joint 6) is l_{4C}. The manipulator joint angles are -90 deg $\leq \phi_2 \leq +90$ deg and $0 \leq \phi_3 \leq +100$ deg. The right and left hands each have two fingers (Joint 6) in order to grasp and hold items (Figure 5).

The robot is equipped with a stopper mounted on the front part of its body (Figure 6 (a)), as described below, and is capable of limiting the passive rotational travel of the manipulators when it is pushing the wheelchair (Figure 6

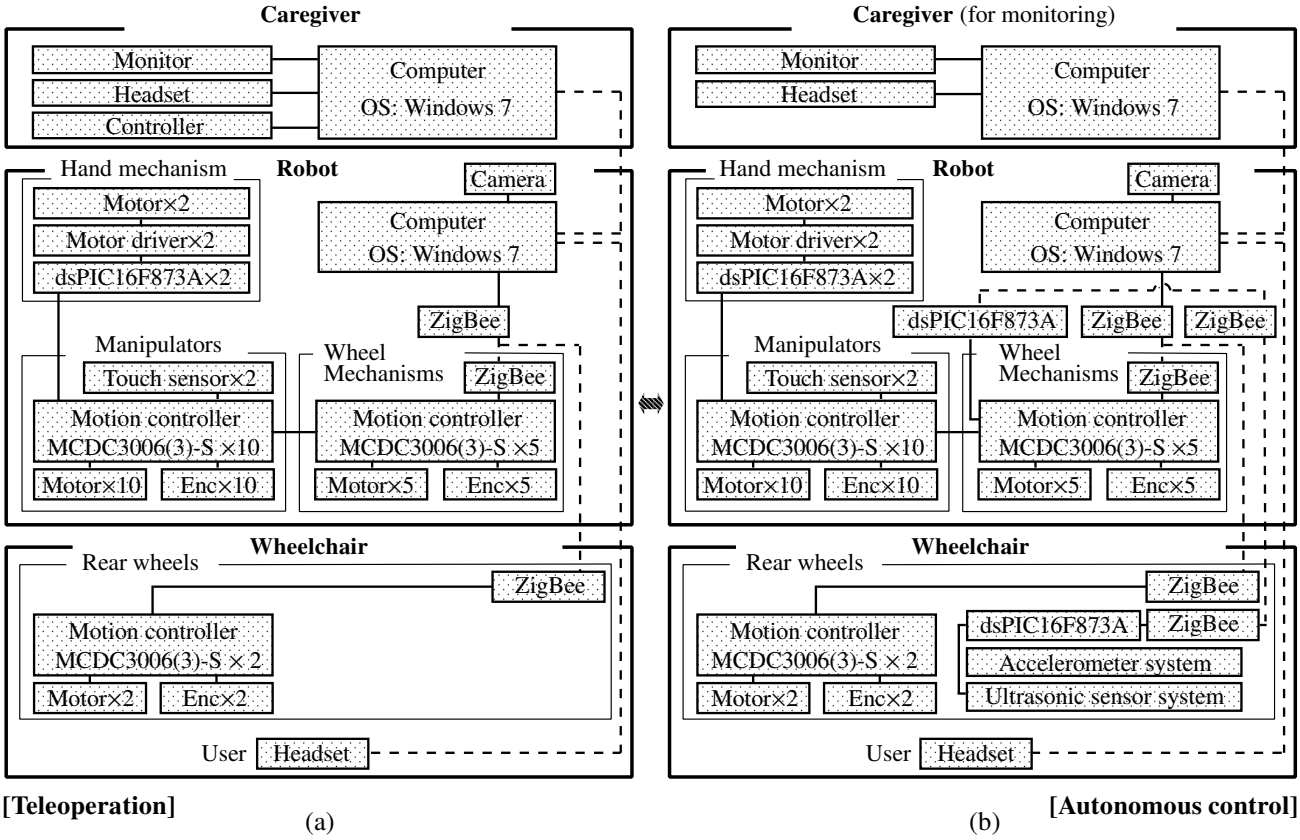

Figure 10: Working devices of the entire system: (a) teleoperation mode, and (b) autonomous control mode

(b)). This enables the robot to imitate the operation of a human pushing an object (Figure 7). The robot does not need to exert force around the shoulder axes because its upper arms push against the chest (i.e., the stopper) when pushing the wheelchair [11]. The motors mounted on the robot are connected to Faulhaber MCDC3003-S and MCDC3006-S motion controllers (Faulhaber-Global, Schnaich, Germany). These are connected to a notebook personal computer (PC) mounted on the robot. The shape of the Integral-ME wheelchair (NOVA, Carson, Ca) used in this study is typical among wheelchairs available on the market (Figure 3). The rear-wheel drive wheelchair is equipped with a TRD-1 electric drive unit (Acritech Co., Ltd.). Two motion controllers are added for the electric drive unit. The motion controllers on the wheelchair are connected to the notebook PC installed on the robot via a ZigBee wireless communications module. The wheelchair has a push handle mechanism on its back (Figure 8 (a)) that is equipped with a rotary shaft in order to permit passive rotation of the handle. When the robot hands grasp this shaft, the two vehicles are connected. The stopper of the wheelchair is composed of front and rear bars. During the robot climbing process, the sides of the robot are opened, and the right and left manipulators are inserted into the stopper (Figure 8 (b)). The dual manipulators of the robot are equipped with touch sensors that allow them to detect contact with the stopper. The robot pushes the front bars by using the forearm links of the manipulators to lift its front wheels (Figure 9 (a)). The rear bars are used to prevent the robot from tipping over backward when its center of gravity shifts behind the contact point between the middle wheels and the ground (Figure 9 (b)).

The robot control mode can be switched between network-based teleoperation and autonomous control by the caregiver. In Figure 10, (a) is a system configuration diagram that shows the working device in the teleoperation mode, and Figure 10 (b) shows the system diagram of the autonomous control mode. These system configuration diagrams show only the working devices in each mode. When engaged in wheelchair step climbing, this system uses the autonomous control. For robot step climbing, the system uses the teleoperation mode.

3.1 Teleoperation

The robot is equipped with a camera, and the video imagery transmitted from it and the Motion Manager 5 operating window are displayed on the robot's notebook PC. The screen on this notebook PC uses RealVNC (RealVCN Ltd., Cambridge, UK) software to transmit imagery as-is over the intranet to the display of the caretaker's PC (robot operator). The caregiver can control the robot by operating Motion Manager 5 (Faulhaber-Global) from his PC. The caregiver and the wheelchair user both wear headsets. The caregiver's headset is connected to his/her PC, and the chair user's headset is connected to the robot PC via Bluetooth. The caregiver and the wheelchair user verbally telecommunicate via the Skype (Microsoft Corp., Redmond, Wa) communication application. Keyboard commands, which are activated by pushing the buttons of a joypad, correspond to the controller manipulations necessary to teleoperate the robot. Switching between teleoperation and autonomous control is carried out by the controller.

3.2 Autonomous control

To lift the front wheels of the wheelchair, the robot stops while the wheelchair drive continues moving (see Section 4). However, network teleoperation is difficult for this process because the wheelchair's raised front wheels tend to collide with the step when they are in near proximity with each other (Figure 11).

An accelerometer system and an ultrasonic sensor system were added onto the chair, and a support system for the caregiver was created. The accelerometer system detects the incline of the chair, and the ultrasonic sensor system measures the distance between the chair and the step.

Both sensor systems are connected to the robot's PC by a ZigBee wireless communication module. Since the support system for the caregiver is capable of performing the wheelchair step climbing process automatically, the caregiver (robot operator) does not need to control the vehicles in the autonomous control mode. However, the caregiver can watch the live video from the robot's camera, and the wheelchair user and the caregiver are in direct verbal communication, so if the vehicles encounter a problem, the caregiver switches from autonomous to teleoperation control to handle it.

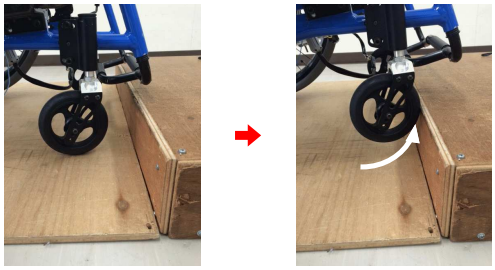

Figure 11: Collision between the front wheels and step

4 Step climbing process

When the vehicles encounter a step, the robot hands grasp the rotary shaft of the wheelchair's push handle mechanism, thus linking the two vehicles [14]. Joints 2, 4, and 6 are allowed to rotate passively (Figs. 5 and 8). In this study, Stages 1 and 2 signify the processes in which the wheelchair front and back wheels, respectively, ascend the step. Similarly, Stages 3 and 4 signify the processes in which the robot front and other wheels, respectively, climb the step.

Both vehicles move automatically during the wheelchair step climbing process (Stages 1 and 2) by using the caregiver's support system. After that, the caregiver switches from autonomous control to teleoperation, and the robot step climbing process (Stage 3 and 4) is carried out. The ascent process is described below (the states shown in Figure 12 correspond to (1) through (16) below.

[Stage 1]

(1) From Stage 1 to Stage 2, the vehicles are under autonomous control. The wheelchair and the robot move forward until the ultrasonic sensor system detects a suitable position where the wheelchair front wheels do not collide with the step. (2) The robot stops and the wheelchair continues forward until the accelerometer system detects the wheelchair inclination level that would place the front wheels on the step. (3) At this point, the wheelchair center of mass is in front of the contact point between the rear wheels and the ground. If it shifts to behind the contact point as the wheelchair tilt increases, the stopper of the robot limits the passive rotation around Joint 2, which prevents the wheelchair from tipping over backward (Figure 6 (b)). (4) Both vehicles move forward, and the front wheels of the wheelchair are placed on the step.

[Stage 2]

(5) Both vehicles continue to move forward. (6) The back wheels of the wheelchair come into contact with the step. (7) The robot continues to push the wheelchair so that the rear wheels of the wheelchair climb up onto the step. The robot supports the wheelchair during this process to prevent the wheelchair from tipping over backward. (8) Both vehicles move forward, and the wheelchair's rear wheels climb the step.

After the wheelchair's rear wheels have reached the upper level of the step, the robot control mode is switched from autonomous to teleoperation control by the caregiver. The caregiver directs the vehicles to stop.

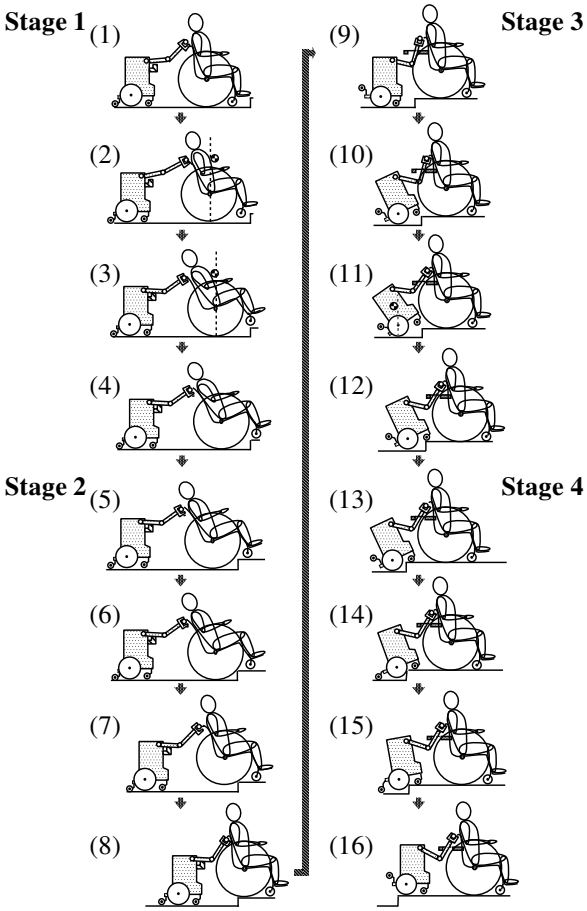

Figure 12: Step climbing process (Stages 1 through 4)

[Stage 3]

(9) The robot's front and rear wheels are folded, its

sides are opened, and the manipulator forearm links are inserted into the wheelchair stopper (Figs. 8 (a) and (b)). The wheelchair stops while the robot moves forward, and the manipulator forearm links comes into contact with the front bars of the wheelchair stopper (Figure 9 (a)). (10) The robot continues to push the wheelchair using the forearm links, and the front wheels of the robot are lifted. (11) When the robot center of mass shifts behind the contact point between its middle and the ground, the robot's tilt increases and it begins to tip over backward. However, at that point, part of the manipulator forearm links come into contact with the rear bars of wheelchair stopper, which limits the extent of rotation (Figure 9 (b)). Thus, the wheelchair prevents the robot from tipping over backward. (12) Both vehicles move forward, and the front wheels of the robot are placed on the upper level of the step.

[Stage 4]

(13) Both vehicles continue to move forward. (14) When the robot middle wheels come into contact with the step, the wheelchair pulls it forward. The robot rear wheels are lowered and provide climbing help. Then, the robot middle wheels begin to climb the step. (15) Both vehicles continue to move forward. (16) The robot middle wheels can now climb the step. Once the robot middle wheels have reached the upper level of the step, both vehicles are stopped, and the robot's rear wheels are folded upward.

5 Theoretical Analysis

When the distance between the step and the wheelchair is too short to lift the front wheels, the wheels will collide with the step (Figure 11). In this section, we clarify the requirement for avoiding a collision between the chair front wheels and the step.

In Figure 13, Σ_B is the basic coordinate system for the robot and wheelchair, where p_0 is the origin as well as the contact position between the robot middle (driving) wheels and the ground. The position of the step edge is p_{se}, where p_i (i = 1–7) are the joints (p_1: axes of the robot middle wheels, p_2: shoulder joints, p_3: elbow joints, p_4: robot hands (location where the hands hold the wheelchair push handle), p_5: axes of the wheelchair rear wheels, p_6: axes of the wheelchair front wheels and, p_7: the tread of the wheelchair front wheels).

The position vectors for the joints in system Σ_B are expressed as ${}^B\boldsymbol{p}_i = [x_i \;\; z_i]^T$ ($i = 1-7$). The position vectors of the step edge are ${}^B\boldsymbol{p}_{se} = [L \;\; h]^T$.

In the local coordinate system, in the case that Σ_i parallels Σ_0, ${}^0\boldsymbol{p}_1 = [0 \;\; R_B]^T$, ${}^1\boldsymbol{p}_2 = [l_{LB} \;\; h_{LB}]^T$, ${}^2\boldsymbol{p}_3 = [l_2 \;\; 0]^T$, ${}^3\boldsymbol{p}_4 = [l_{4C} \;\; 0]^T$, ${}^4\boldsymbol{p}_5 = [l_{LA} \;\; -h_{LA}]^T$, ${}^5\boldsymbol{p}_6 = [l_A \;\; -R_A + r_A]^T$, and ${}^6\boldsymbol{p}_7 = [r_A \;\; 0]^T$ (Figure 13).

Moreover, ϕ_i is the angle of Σ_i formed by Σ_{i-1}. In this system, ϕ_1 is zero in *Stage 1* because Σ_1 parallels Σ_0, and ϕ_3 is zero when the wheelchair is pulled by the robot because the elbow joints are controlled passively. In addition, $\phi_5 = 0$ is always zero because Σ_5 parallels Σ_4. Hence, the wheelchair inclination is $\Sigma_{k=1}^{5}\phi_i = \phi_2 + \phi_4$.

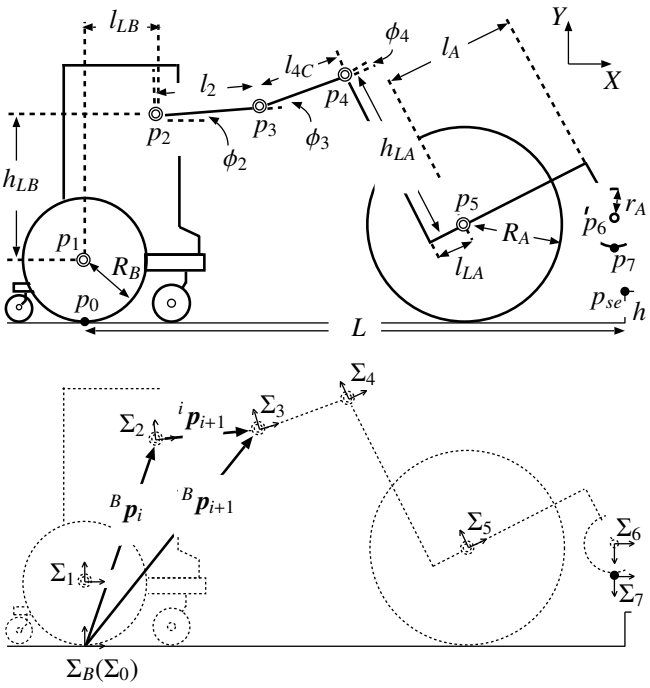

Figure 13: Wheelchair and robot model

In the basic coordinate system Σ_B, the homogeneous transformation matrices ${}^B\boldsymbol{T}_5$, ${}^B\boldsymbol{T}_6$ are given below.

$$ {}^B\boldsymbol{T}_5 : \begin{bmatrix} \cos\phi_{24} & -\sin\phi_{24} & x_5 \\ \sin\phi_{24} & \cos\phi_{24} & y_5 \\ 0 & 0 & 1 \end{bmatrix} \tag{1} $$

$$ {}^B\boldsymbol{T}_6 : \begin{bmatrix} \cos\phi_{246} & -\sin\phi_{246} & x_6 \\ \sin\phi_{246} & \cos\phi_{246} & y_6 \\ 0 & 0 & 1 \end{bmatrix} \tag{2} $$

Here, $\phi_{24} = \phi_2 + \phi_4$, $\phi_{246} = \phi_2 + \phi_4 + \phi_6$. Equations (3) and (4) show the positions of the wheelchair rear and front wheels axes, ${}^B\boldsymbol{p}_5 = [x_5 \;\; y_5]^T$, ${}^B\boldsymbol{p}_6 = [x_6 \;\; y_6]^T$, respectively.

$$ {}^B\boldsymbol{p}_5 : \begin{bmatrix} x_5 \\ y_5 \end{bmatrix} = \begin{bmatrix} \cos\phi_{24} & -\sin\phi_{24} \\ \sin\phi_{24} & \cos\phi_{24} \end{bmatrix} \begin{bmatrix} l_A \\ -h_{LA} \end{bmatrix} + (l_2 + l_{4C}) \begin{bmatrix} \cos\phi_2 \\ \sin\phi_2 \end{bmatrix} + \begin{bmatrix} l_{LB} \\ h_{LB} + R_B \end{bmatrix} \tag{3} $$

$$ {}^B\boldsymbol{p}_6 : \begin{bmatrix} x_6 \\ y_6 \end{bmatrix} = \begin{bmatrix} \cos\phi_{24} & -\sin\phi_{24} \\ \sin\phi_{24} & \cos\phi_{24} \end{bmatrix} \begin{bmatrix} l_A + l_{LA} \\ r_A - R_A - h_{LA} \end{bmatrix} + (l_2 + l_{4C}) \begin{bmatrix} \cos\phi_2 \\ \sin\phi_2 \end{bmatrix} + \begin{bmatrix} l_{LB} \\ h_{LB} + R_B \end{bmatrix} \tag{4} $$

Similarly, from a calculation of the transformation matrix ${}^B\boldsymbol{T}_7$, ${}^B\boldsymbol{p}_7 = [x_7 \;\; y_7]^T$ is given below.

$$ {}^B\boldsymbol{p}_7 : \begin{bmatrix} x_7 \\ y_7 \end{bmatrix} = r_A \begin{bmatrix} \cos\phi_{246} \\ \sin\phi_{246} \end{bmatrix} + \begin{bmatrix} \cos\phi_{24} & -\sin\phi_{24} \\ \sin\phi_{24} & \cos\phi_{24} \end{bmatrix} \begin{bmatrix} l_A + l_{LA} \\ r_A - R_A - h_{LA} \end{bmatrix} + (l_2 + l_{4C}) \begin{bmatrix} \cos\phi_2 \\ \sin\phi_2 \end{bmatrix} + \begin{bmatrix} l_{LB} \\ h_{LB} + R_B \end{bmatrix} \tag{5} $$

Here, when ${}^B\boldsymbol{p}_7$ is the bottom position of the wheelchair front wheels, $\Sigma_{k=1}^{6}\phi_i = -90$ deg. Hence, $\cos\phi_{246} = 0$ and $\sin\phi_{246} = -1$.

Meanwhile, $y_5 = R_A$ in Stage 1 because y_5 is the height of the wheelchair rear wheel axes (Figure 13). Hence, Equation (6) is obtained from (3).

$$l_{LA}\sin\phi_{24} - h_{LA}\cos\phi_{24} + (l_2 + l_{4C})\sin\phi_2 + h_{LB} + R_B = R_A \quad (6)$$

Thus,

$$\sin\phi_2 = \frac{h_{LA}\cos\phi_{24} - l_{LA}\sin\phi_{24} + R_A - R_B - h_{LB}}{l_2 + l_{4C}} \quad (7)$$

and

$$\cos\phi_2 = \sqrt{1 - \sin^2\phi_2} \quad (8)$$

Equation (6) is substituted for y_7 of (5) when ${}^B\boldsymbol{p}_7$ is the bottom of the front wheels.

$$y_7 = -r_A + l_A\sin\phi_{24} + (-R_A + r_A)\cos\phi_{24} + R_A \quad (9)$$

where

$$\sin\phi_{24} = \sqrt{1 - \cos^2\phi_{24}} \quad (10)$$

From Equations (9) and (10), we obtain Equation (11).

$$\cos\phi_{24} = \frac{(R_A - r_A)(R_A - r_A - y_7) + l_A\sqrt{2(R_A - r_A)y_7 + {l_A}^2 - {y_7}^2}}{(R_A - r_A)^2 + {l_A}^2} \quad (11)$$

We substitute $y_7 = h$ for Equation (11) if the system detects the step height h, and can then ascertain the necessary minimum inclination of the wheelchair in order to put the front wheels on the step.

When the height of the front wheel axes is lower than the step height, the requirement needed to avoid a collision between the wheelchair front wheels and the step is Equation (12) (Figure 14 (a)).

$$\|{}^B\boldsymbol{p}_s - {}^B\boldsymbol{p}_6\| > r_A \quad (0 < x_6 < L,\ 0 < y_6 < h) \quad (12)$$

Here,

$${}^B\boldsymbol{p}_s = [L \ \ y_6]^T \quad (13)$$

is a vector whose horizontal position is on the step wall (L), and the height is the same as the wheelchair front wheel axes (y_6).

Similarly, when the front wheel axes are above the step, Equation (14) shows the requirement to avoid a collision (Figure 14 (b)).

$$\|{}^B\boldsymbol{p}_{se} - {}^B\boldsymbol{p}_6\| > r_A \quad (0 < x_6 < L,\ h \le y_6) \quad (14)$$

Then, using Equations (12) and (14), the system avoids a collision between the wheelchair front wheels and the step by detecting the chair inclination ($\phi_2 + \phi_4$), the distance from the step (L), and the step height (h).

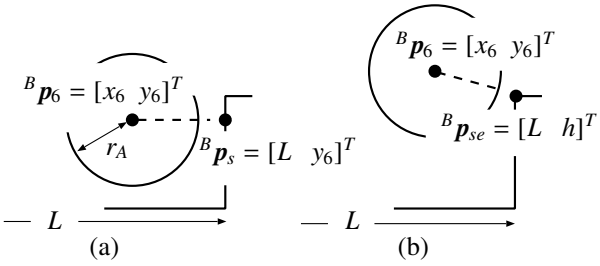

Figure 14: Collision between the front wheels and a step. (a) $0 \le y_6 \le h$, (b) $h < y_6$

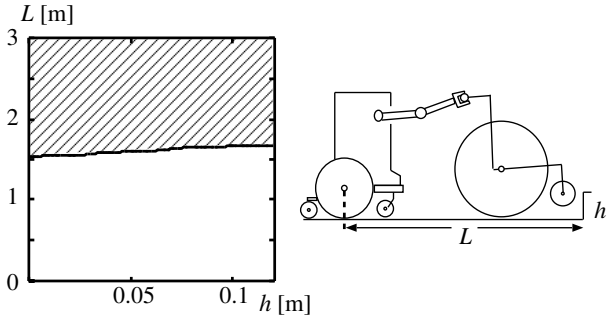

Figure 15: Step height and distance capable of avoiding collision

The requirement for avoiding a collision between the wheelchair front wheels and the step (Equation (12), Figure 14 (a)) is more difficult than the case where the front wheel axes are above the step (Equation (14), Figure 14 (b)). Thus, we performed a numerical calculation to clarify the lifting position of the front wheels using Equation (12). Equation (12) is solved using (4), (7), (8), (10), (11), and (13). Here, y_7 is the minimum bottom height of the front wheels (Figure 13) needed for the system to lift the wheels up to the step height (h).

Substituting $y_7 = h$ for Equation (12), the shading in Figure 15 shows a combination of the step height (h) and the distance (L) that enables it to avoid the collision, where the horizontal axis indicates h (step height) and the vertical axis indicates L (distance from the robot's rear wheel axes to the step wall). By selecting the distance (L) in the shadings when the step height is (h), the wheelchair front wheels can avoid collision during climbing.

6 Experiment

An experiment was carried out in a situation involving a step 120 mm high and a friction coefficient $\mu = 0.72$. The wheelchair user was on one floor of the National Institute of Technology, Toyama College, and the caregiver (robot operator) was on another floor. The movement speeds of the vehicles were constant (0.76 km/h). The wheelchair user and the robot operator were both able-bodied adult males. We assumed that the system knew the step height was below 120 mm.

In Stages 1 and 2, when using autonomous control, the wheelchair front wheels did not bump into the vertical wall of the step and the front wheels and rear wheels were able to traverse the step successfully (Figure 16). Here, $L = 2.07$ m. Operation changed from autonomous to teleoperation control following Stage 2, and the caregiver was able to move the robot forward into a suitable position for climbing the step. Next, the robot successfully climbed the step (Stages 3 and 4). In Stages 3 and 4, the system was operated by the caregiver who was watching video imagery from the robot's camera. However, the operation was difficult because the robot inclined during its step climbing process and the mounted camera lost sight of the wheelchair. This and other experiments have shown that we need to construct

a fully autonomous control system that can handle robot climbing as well as wheelchair climbing.

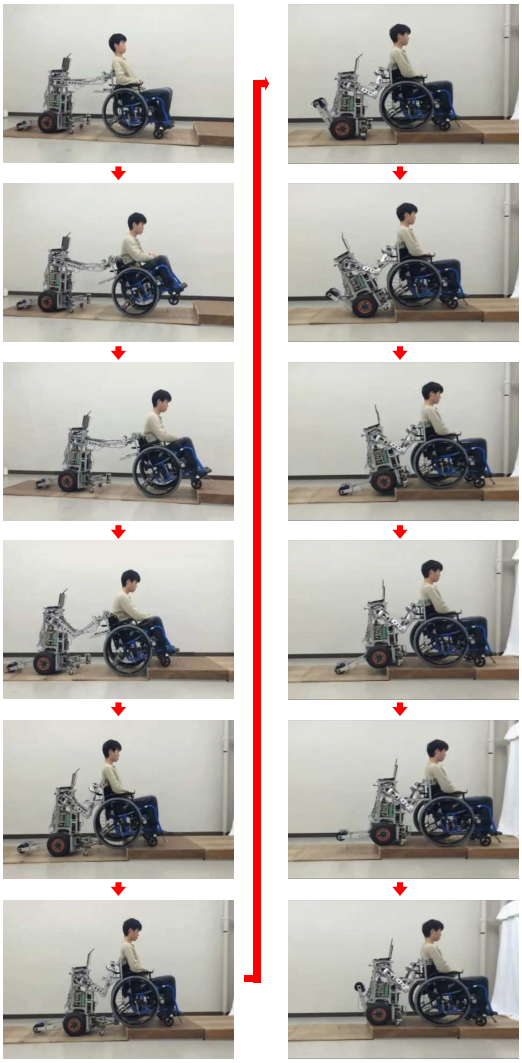

Figure 16: Step climbing experiment

7 Conclusion

This report describes a support system for a robot operator that can be used to perform wheelchair step climbing. The support system was designed and constructed in a way that permitted switching between teleoperation and autonomous control. We then conducted a theoretical analysis to show the requirements for preventing the wheelchair's front wheels from colliding with the step, which involved a numerical calculation to clarify the position for lifting the wheelchair's front wheels.

In experiments carried out with the system, autonomous control for wheelchair step climbing and teleoperation control for robot step climbing were both demonstrated to be effective. However, teleoperation control by a caregiver was complicated by the need to watch video imagery from the robot camera. This indicates that the system needs autonomous control system for the robot as well.

Nevertheless, it is notable that our theory for collision avoidance between the step wall and wheelchair's front wheels during the step climbing was confirmed, and that both vehicles were able to climb a step using the theory and system.

In the future, we will construct a fully autonomous control system will be able to perform step climbing for both the wheelchair and the robot, and we will analyze a suitable step climbing trajectory for both vehicles.

ABSTRACT

In this paper first discussion approach will stress out the integration of model predictive control in maximum power point tracking MPPT and as progressing a second approach identified as fuzzy logic controller FLC and perturb & Observe P&O algorithms are analyzed. All are interrelated to MPPT model for a photovoltaic module, PVM, to search for and generate the maximum power; in this case what's called P_{max}. As per the first technique the focus is on the optimal duty ratio, D, for a series of multi diverse types of converters and load matching. The design of the MPPT for a stand-alone photovoltaic power generation system is applied where the system will consist of a solar array with nonlinear time varying characteristics, and a converter with appropriate filters. The integration of model predictive control will be addressed first in this paper. The second fold will implement an MPPT system that use the FLC and compare it with a P&O) algorithm through the utilization of Simulink.

1. Introduction

It has been obvious that maximum power point tracking algorithm is currently playing a vital role to enhance the efficiency of the solar panel as less than 40% of energy incident is being converted into electrical energy. Due to the growing dependency and the increasing need in acquiring electricity, and due to the limitations in supply and the uprising prices of conventional sources (such as the continuous increase in electrical bills, generation, distribution, and maintenance of the electrical plants, fluctuating petroleum prices, etc.), photovoltaic (PV) energy vitality turns into a promising option as it is inescapable, openly accessible, environmentally promising, and has less operational and upkeep costs. Along these lines, the interest of PV era systems is by all accounts expanded for both standalone and grid-connected modes of PV systems. As a result, an efficient maximum power point tracking (MPPT) technique is vital for tracking the MPP at all environmental conditions and then push forward the PV system to functionally be operable at that MPP point. Undesirably, photovoltaic generation systems have two note-worthy issues: the conversion efficiency in electric power generation is somehow low (normally below 17 percent particularly under low irradiation conditions), and the amount of electric power generated by solar arrays changes persistently with climate conditions. Numerous MPPT methodologies have been recommended in the literature; the Perturb and Observe (P&O), the Incremental Conductance (IC), the Artificial Neural Network, and the Fuzzy Logic methods, etc. It has been noticed that the efficiency of the PV is influenced by the following two parameters: the panel's irradiance and temperature which are stochastic and unpredictable. In any PV module a DC/DC converter is accountable for transferring maximum power to the load.

Unfortunately and since the MPP point must be sought, this can be achieved in either computation models or search algorithms. Figure 1 illustrates an MPPT module diagram.

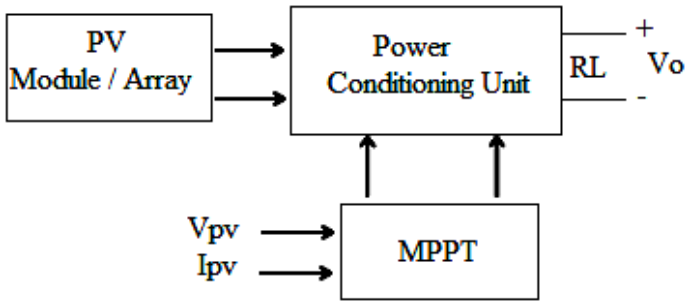

Figure1.MPPT module diagram

We have to stress out that the voltage across the power conditioning unit (DC-DC converter) is fed to get an isolated load. The input-output (I/P-O/P) voltage relationship for converter conduction mode is given by duty cycle. As a result, the forthcoming of this paper is an extension of a previous research outcome that was originally presented in the International Conference on Smart Systems and Technologies (SST 2016) to recompense for the parametric variations that took place due to the effect of temperature and irradiance variations, where a controller was utilized to be adaptive to environmental changes. The extension of the already published paper will be expanded towards proposing an innovative fuzzy logic controller (FLC) for DC–DC converters that yield to an effective element of MPPT system so that it integrate itself into enhancing the photovoltaic modules to work under changeable operating conditions as well as dealing with the nonlinear properties of DC-DC power converters [1].

2. Overview of model predictive control

MPC is a model in view of line control approach with the following accompanying modules: a prediction horizon, a receding horizon procedure, and a regular update of the model and re-computation of the optimal control input [2,3,4,5]. A block diagram of MPC system is shown in Figure. 2. A process model is used to predict the current values of the output variables. The residuals, the differences between the actual and predicted outputs, serve as the feedback signal to a Prediction block. The predictions are utilized as a part of two types of MPC calculations that are performed at each sampling instant: the first is the set-point calculations and the second is the control calculations.

The set points for the control calculations, which are called targets, calculated from an economic optimization based on a steady-state model of the process, conventionally, a linear model. In MPC the set points are customarily computed each time the control calculations are conducted.

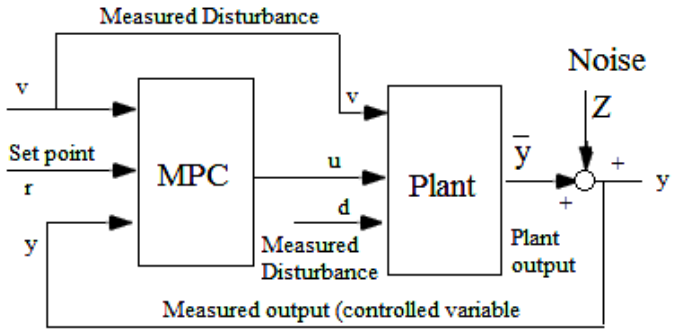

Figure 2.Block diagram for MPC

3. Nonlinear predictive control

The basic principle of model predictive control is shown in Figure 3. At a denoted time (t) certain measurements are provided, which will trigger the controller to predicts the future dynamic behavior of the system over a prediction horizon *Tp* and furthermore determine (over a control horizon *Tc*≤ *Tp*) the input under the condition a predefined open-loop performance objective is optimized.

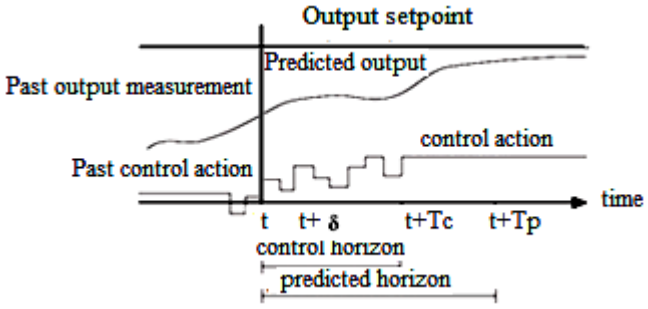

Figure 3.Principle of model predictive control

When neither disturbances exist nor mismatching model plant presence is evident, and if the optimization problem could be solved for infinite horizons, then we can apply the input function found at time t=0 to the system for all times $t \geq 0$.As a matter of fact, this is not feasible generally. Because of the factors of disturbances and the stressing model-plant mismatch, the real system behavior is going to differ from the predicted behavior. To integrate a feedback scheme, the open-loop manipulated input function acquired will be ready for implementation as the next measurement becomes available. The time difference between the recalculation/measurements can vary, however often it is assumed to be fixed, i.e. the measurement will take place every δ sampling time-unit. Using the new measurement at time (t + δ), then the whole process for the prediction and optimization is going to be repeated to find a new input function with the control and prediction horizons moving forward. Knowing that in Figure 3 the input is depicted as arbitrary function of time. For numerical solutions of the open-loop optimal control problem it is often necessary to parameterize the input in an appropriate way. This is normally achieved by employing a finite number of basic functions; as an example the input could be approximated as piecewise constant over the sampling time δ. The computation of the applied input (based on the predicted system behavior) permits the inclusion of constraints on states and inputs as well as the optimization of a given cost function. In general the predicted system behavior will differ from the closed-loop one; and thus further cautionary should be taken into account to achieve closed-loop stability.

We consider the stabilization problem for a class of systems described by the following nonlinear set of differential equations:

$$\dot{X}(t) = f\big(x(t), u(t)\big), \quad X(0) = x_0, \qquad (1)$$

subject to input and state constraints of the form:

$$U(t) \in \mu \ \forall t \geq 0 \ \ x(t) \in X, \mu \ \forall t \geq 0 \qquad (2)$$

Where x (t) $\in X \subseteq \mathbb{R}^n$ *and* $u(t) \in \mu \subseteq \mathbb{R}^m$ denotes the vector of states and inputs, respectively. The set of feasible input

values is denoted by X. In the simplest form $\mu$and X are given by box constraints of the form:

$$\mu: = \{u \in \mathbb{R}^m | Umin \leq u \leq Umax\} \quad (3)$$

$$X: = \{x \in \mathbb{R}^n | Xmin \leq x \leq Xmax\},$$

Here u_{min}, u_{max} and x_{min}, x_{max} are given constant vectors.

We assume that the purpose of the control object (1) is to ensure that the equalities

$$\lim_{t\to\infty} \|x(t) - r_x(t)\| = 0;$$

$$\lim_{t\to\infty} \|u(t) - r_u(t)\| = 0 \quad (4)$$

Where a given vector functions; $r_x(t)$ and $r_u(t)$ define a desired motion of the object.

We introduce the concept of quality control, setting a functional to control the movement of the object (1).

$$J_{0=} J_0\,(x(t), u(t)) \quad (5)$$

Any optimal control problem is to find such a control action of a given class (if the task takes into account the feasible set U), which ensures the achievement of goals (4) taking into account the constraints $x(t) \in X$ and $\forall t \in [0, \infty)$ and minimizes the functional (5).

To explain the basic tenets of the theory of predictive control, along with a mathematical model (1) of the control object, a system of differential equations of the form:

$$\dot{\bar{X}}_i(\tau) = \bar{f}\big(\tau, \bar{x}(\tau), \bar{u}(\tau)\big)\bar{x}\big|_{\tau \dot{=} t} = x(t) \quad (6)$$

Is considered, where$\bar{X} \in E^n$ - the state vector, $\bar{u} \in E^m$- the vector control, $\tau \in [t, \infty)$. We assume that the function $\bar{f}$has the same properties as the function f and vectors,$\bar{X}$and$\bar{u}$taking the value of the admissible sets,$X$and $u$respectively.

In addition, let us assume that the function $\bar{f}$ is set in such a way that for any admissible control$\bar{u}(\tau) \equiv u(\tau)$ vector functions $x(\tau)$ and $\bar{x}(\tau)$, satisfy the system (1) and (6) respectively; and are close to each other at a rate for each $\tau \in [t, \infty)$.

The system of differential equations (6) is called predictive model in relation to the mathematical model (1) of the control object.

A practical view of photovoltaic energy conversion station is presented in Figure 4, where the source of energy, represented by the solar array PHVS with filter C delivers power to DC-DC power converter, such as buck, boost or buck-boost converters; which depends on specific architecture of the entire system to select one of the above-mentioned types. For instance, if PHVS is considered to supply power to a DC distribution network (i.e. a space station power network) than power interface will provide conditioned DC power. In case the main utilization was for smart-home application with AC power distribution network then independently controlled DC-AC inverter with built in PWM control may be used. The interface links between PHVS and the consumer grid may include other elements such as energy-storage devices (i.e. batteries or super capacitors), which require specific controllers to run "charge-discharge" mode of operation. We have to bear in mind that control designs for interfaces devices are ignored.

The objective of DC-DC converter on PHV station MPPT system is to regulate the output voltage V_0 (Figure 4) under wide range of operations and PHV nonlinearity characteristics, caused by existing atmospheric conditions and load variation. The controller task is to deliver output signal D (Figure 4) to follow MPPT [6] and constraints of the circuit.

DC-DC boost converter schematic is in a view of lumped parameter circuits used for control design and represented in Figure 5.

The coil non-linearity's is neglected, and the switch is also considered ideal. At each switching instant, the stray inductor and parasitic capacitor are also neglected. After this assumptions the lumped parameter switched model X_l represent the linear inductance value associated to the coil L, which losses are accounted for r_l, x_c , $and r_c$ represent capacitance and equivalent series resistor of C.

Output load presented by resistor R_0. The switching stages of the converter are formalized through the switch S, representing the dual operated semiconductor component [7]. The converter operation characterizes by switching period T_s (corresponding frequencyf_s).

The DC component of the output voltage regulated through the duty cycle D[k], (Figure. 4), which is defined by:

$$\mathrm{D[k]} = \frac{t_1[k]}{T_s} \quad (7)$$

Where $t_1[k\,]$ represents the time interval during the k[th] switching period;T_s during which S is in the position 1 for the boost converter, connecting to the supply U_s.

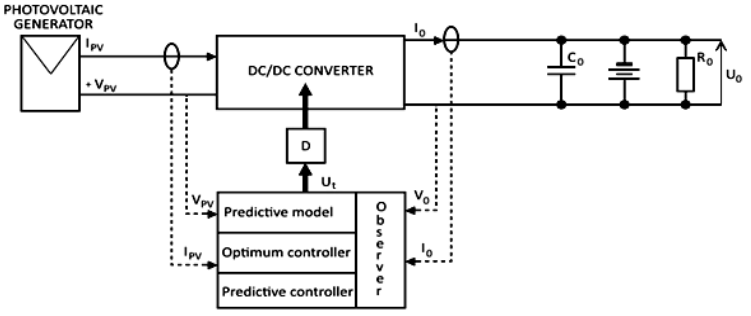

Figure 4.Photovoltaic station model predictive control block diagram

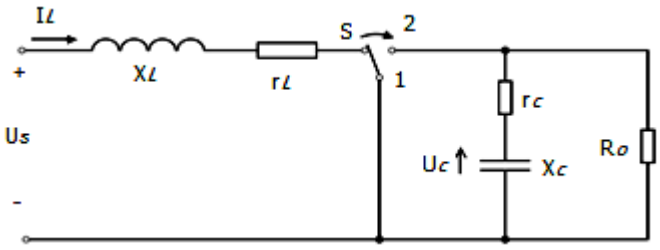

Figure 5 Lumped parameter model of the boost converter

$$x(t) = [i_l(t) \quad u_c(t)]^T \tag{8}$$

as the state vector, where $i_l(t)$ is the inductor current and $u_c(t)$ is the capacitor voltage, and with a given duty cycle D[k] for the k[th] period, the systems can be described by the following continuous-time state-space equations:

$$\dot{x}(t)=G_1 x(t)+g_1 u_s(t), \quad kT_s \leq t < (k + D[k]) \text{ when } S=1 \tag{9}$$

$$\dot{x}(t) =G_2 x(t)+g_2 u_s(t) (k + D[k]) \; T_s \leq t < (k+1)T_s \text{ when } S=0$$

Where G_1, G_2, g_1, g_2 are given by:

$$G_1 = \begin{bmatrix} a_{11} & a_{12} \\ a_{21} & a_{22} \end{bmatrix} \text{ For the boost converter.} \tag{10}$$

Output of the converter u_o is equal to

$$u_o(t) =B_1^T x(t), \quad kT_s \leq t < (k + D[k])T_s,$$

$$u_o(t) =B_2^T x(t), \quad (k + D[k])T_s \leq t < (k +1)T_s \tag{11}$$

$$B_1=\begin{bmatrix} 0 & \frac{r_0 \; r_2}{r_0+r_c} \end{bmatrix}^T \tag{12}$$

$$B_2 =\begin{bmatrix} \frac{r_0 \; r_2}{r_0+r_2} & \frac{r_0}{r_0+r_c} \end{bmatrix}^T \tag{13}$$

4. Fuzzy logic controller approach for photovoltaic Station

A standout amongst the most noteworthy problems in PV module and MPPT effectiveness is DC-DC converter. As of late, there has been expanding eagerness for the advancement of proficient control procedures to enhance dynamic conduct of DC–DC converters by utilizing conventional PID based controllers and fuzzy logic controller (FLC), and other well dealt and known controllers which have been utilized to control buck, boost, and buck–boost converters.

Carrying out, many leaders in this domain have additionally proposed to utilize the FLC in circumstances where it could be valuable in (1) there is no exact mathematical model for the plant and (2) there are experienced personnel whom they can control a plant and give subjective control rules in regards to vague and fuzzy instances. The tracking of the maximum power point is of twofold: (a) through rough search, with a major move to improve the response of the MPPT controller, (b) the fine phase where the step is small, thus ensuring the system stability and decrease the maximum oscillations around the MPP [8].

As we move towards the components of fuzzy logic controller we need to address the three major components of FLC which are Fuzzification (input variables) that encompass transforming crisp values into grades of membership for linguistic terms of fuzzy sets; Fuzzy Inference which is involved in the transformation from a given input to an output using fuzzy logic inference rules; and Defuzzification which converts the degrees of membership of output linguistic variables into numerical values [9]. A general view of fuzzy inference system is shown below in figure 6.

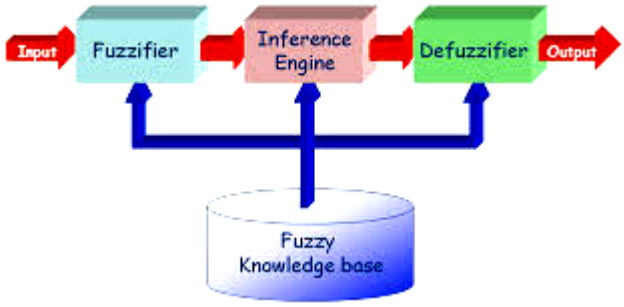

Figure 7 demonstrates the block diagram of fuzzy logic controller that is intended to control the DC-DC power converter with respect to MPPT of a photovoltaic system. Referring to Figure. 7 the inputs (error (e) and the difference in error (de) of the system are defined as follows [10] :

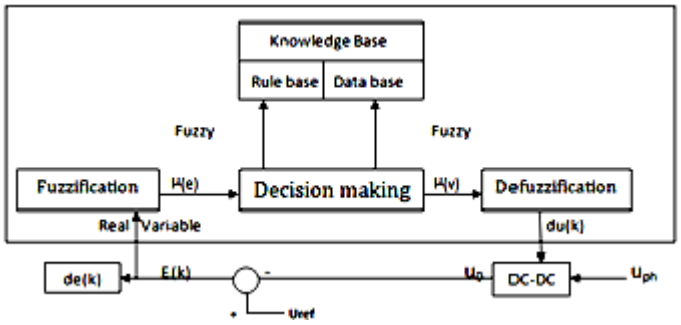

Figure 7.Fuzzy logic controller diagram

$$de(k) = e(k) - e(k-1) \tag{15}$$

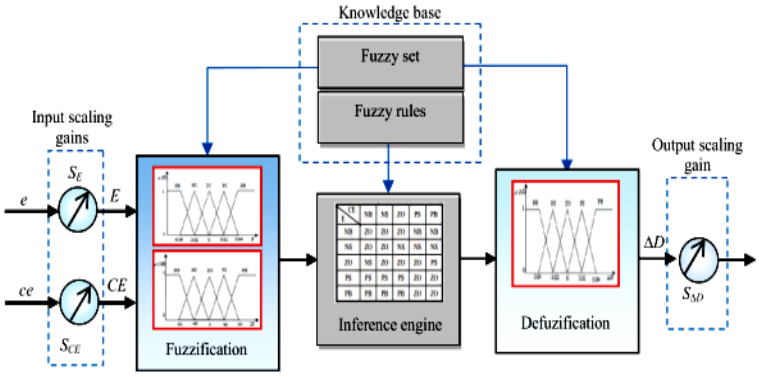
Knowing that U_{ref} = reference output voltage, U_0= *DC*–DC converter actual output voltage (at k[th] sampling time).

The fuzzy logic controller (FLC) output is considered as a change in duty ratio; *du (k).*

Where, duty ratio *d (k)*, is expressed at the k[th] sampling time as follows:

$$d(k) = d(k-1) + du(k) \tag{16}$$

A more detailed structuring of a fuzzy logic controller is shown below in figure 8.



5. Simulations and results for FLC and P&O MPPT techniques

A new adaptation and simulation of a PV system using fuzzy logic controller with an MPPT is addressed. As shown in figure.8, the input variables (*E*, *CE*) of the fuzzy controller are resulting from the actual signals (*e*, *ce*) through applying a product term in consequent scale gains (S_E, S_{CE}), which get converted in the form of linguistic variables utilizing fuzzy subset.

A sample of fuzzy rules are shown in table 1 and used to control the buck converter in a form to reach the maximum power point MPP of the photovoltaic PV generator, where the entries are a sort of fuzzy sets in the form of error (E), change of error (*CE*) and change of duty ratio (ΔD) to the converter.

Table 1. Fuzzy rules

E	CE				
	NB	**NS**	**ZO**	**PS**	**PB**

ZO	NS	ZO	ZO	ZO	PS
PS	PS	PS	PS	ZO	ZO
PB	PB	PB	PB	ZO	ZO

Figure 8 shows an approach for a main PV model structure composed of PV array, a DC-DC converter in the form of buck or step down converter along with MPPT controller which is connected to a load. This setup is manipulated inside the Matlab/simulink setting. Sunntech STb134.12/Tp represented the PV and its technical data is showing in table 2. Six PV modules connected in series formed the PV array which its total capacity is 810 W. The 105v DC input voltage was stepped down to 48v to fit the battery voltage level using a buck converter [11-14].

In addition, and to implement the fuzzy logic controller FLC, FL toolbox in Matlab/Simulink will be selected and the simulation of fuzzy logic controller for MPPT to be conducted and as we progress an evaluation comparison with a Perturb & Observe (P&O) for MPPT controller was performed.

Table 2.PV module specs

Electrical specifications	**Values**
Open-circuit voltage	22.3 V
Short-circuit voltage	8.20A
Optimum operating voltage (V_{mpp})	17.5 V
Optimum operating current (I_{mpp})	7.71A
Maximum power at STC (P_{max})	135W
Current temperature coefficient of Isc	(0.055 ±0.01) %K
Voltage temperature coefficient	-(75±10) mV/K

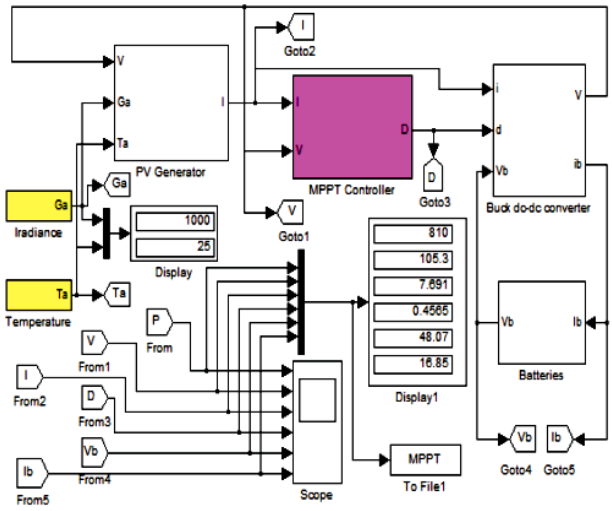

Figure 8a. Simulink implementation of the stand-alone PV system

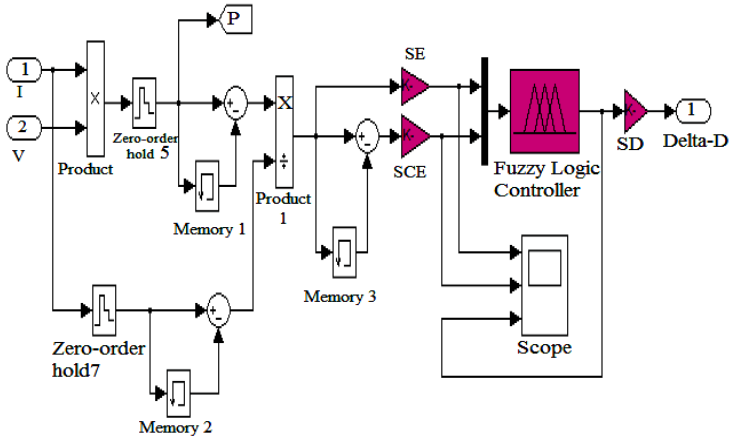

Figure 8b. FLC MPPT algorithm

Figure 9 demonstrates the outcome of the simulation result of PV generator O/P power, operating current & voltage, and eventually the duty ratio "D" through the use of a buck converter and these results were obtained at a standard test conditions (STC)

among the fuzzy logic controller "FLC" and the P&O based MPPT. To take the discussions a step forward obviously the outcome of the FLC MPPT had reduced clearly the response time of the PV system. On the other hand as we compare the above to P&O MPPT system P&O showed an impact of energy losses. Figure.9b is derived from comparing the MPPT signals at a frequency of 10HZ "STC". As we used the P&O technique there was an evidence of a continuous oscillation at the operation point and this was due to the incessant perturbation that took place at the operating voltage to reach the maximum power point "MPP". As compared to the FLC technique such oscillation wasn't existing in FL based MPPT technique, whereas the signals of the other parameters which were namely the power "P", voltage "V", current "I", and duty ratio "D" continued to stay constant, which would cause an impact on the reduction of power loss.

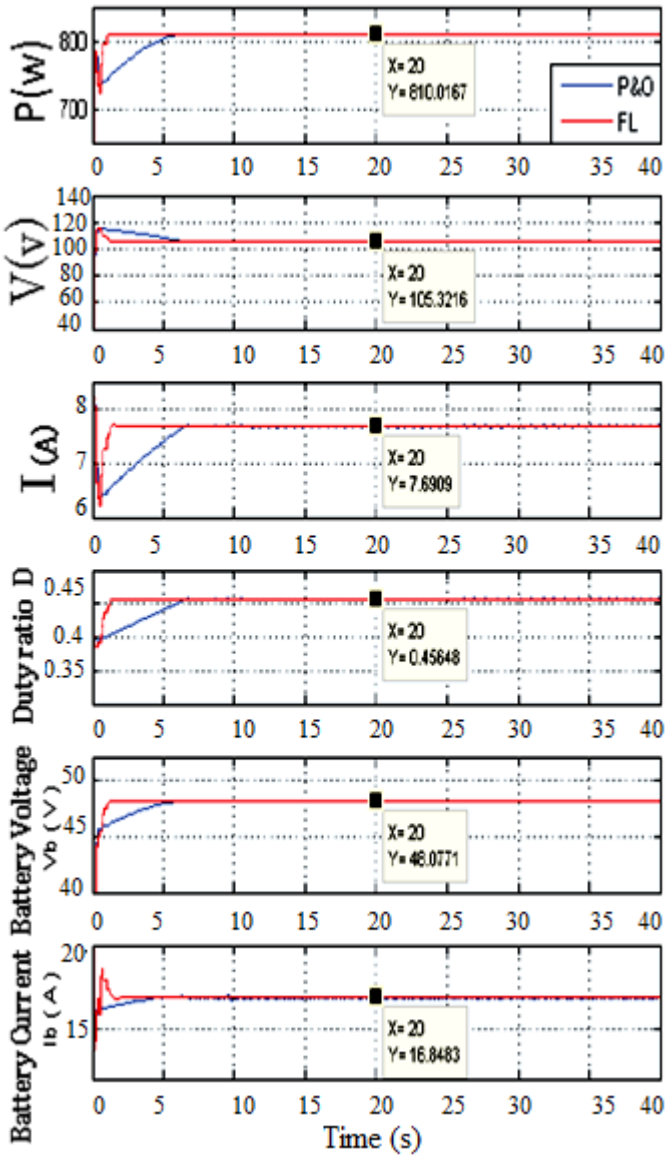

Figure 9a. Comparing P&O and FL signals

Figure 11 displays the simulation of the increase in cell temperature from "25°C" to "50°C" which was taking place at a "2 sec" time period.

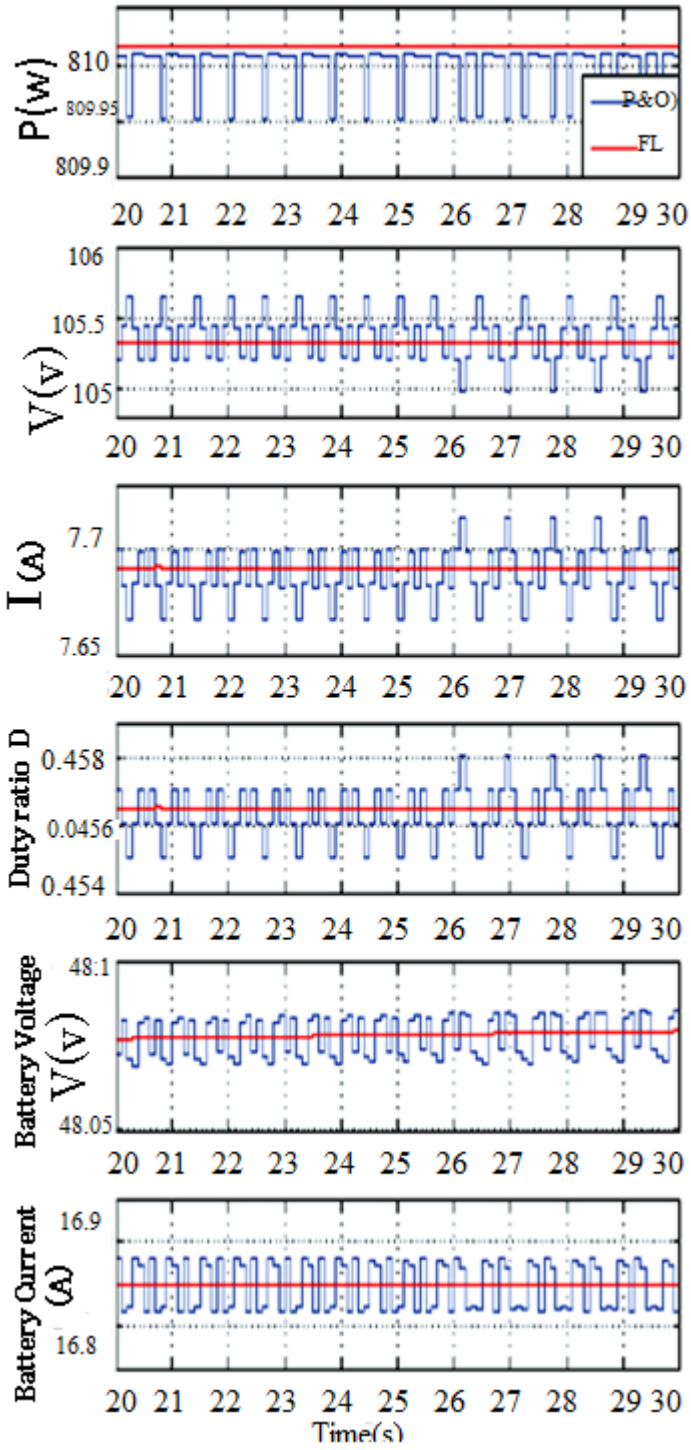

Figure 9b.Comparing MPPT methods at 10Hz frequency at the (STC) condition

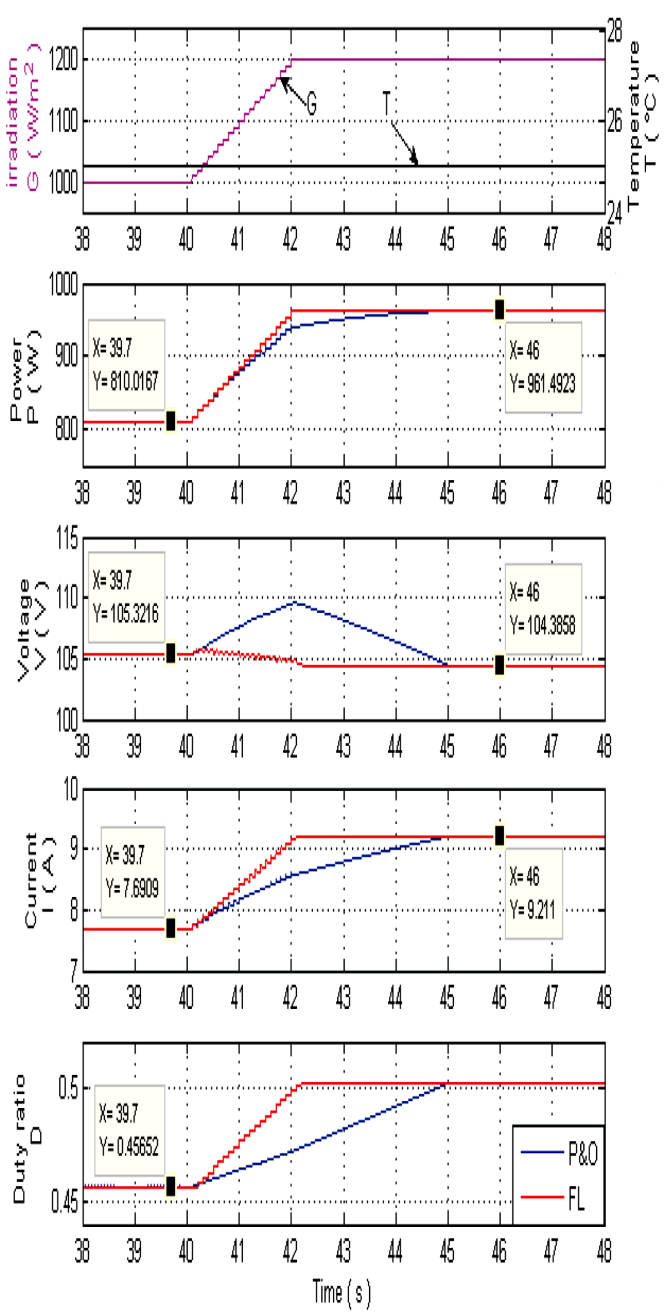

Figure 10. FL and P&O methods at fast increasing irradiation

From the simulation results we can clearly see that irradiation stayed constant on a 1000w/m2 value. In nutshell, Figure 11 shows that the output power with a decreased linearity as we applied both MPPT algorithms namely the fuzzy logic and Perturb and Observe. At the same time P&O MPPT method resulted in low deviation from the maximum power point MPP.

6. Conclusion

The employment of MPPT for PV stations and their applications were addressed in the form of two schemes; a first scheme was an adaptation of a model predictive control (MPC) for a PV station that is considered to be a promising technique to maximize the efficiency of the power utilization.

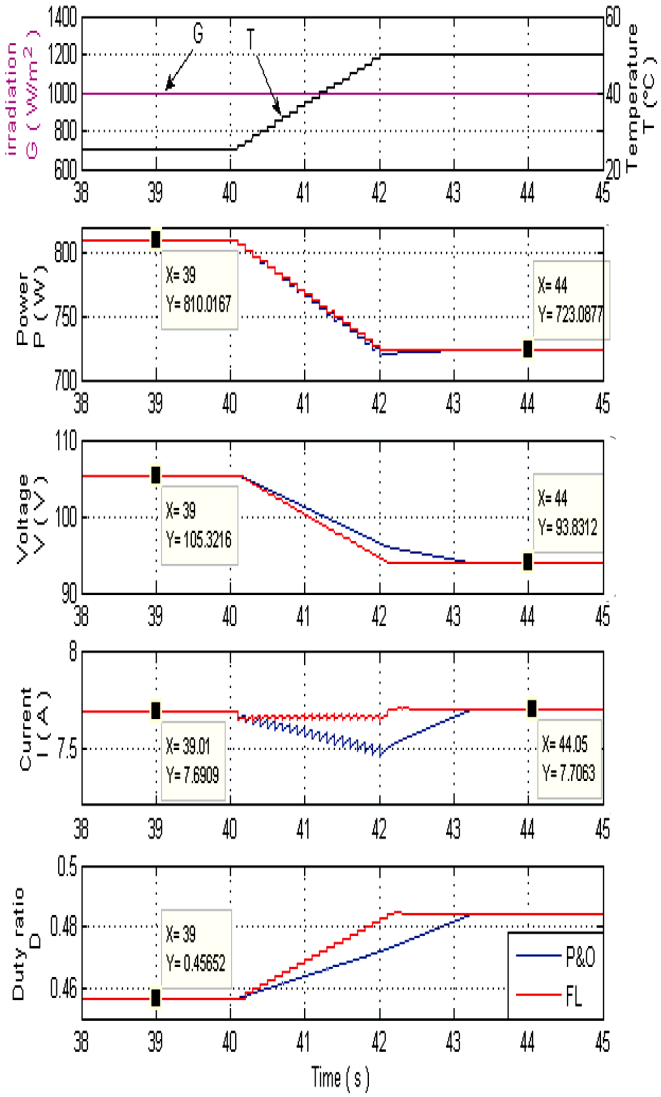

Figure 11. FL and P&O methods at fast increasing temperature

The second scheme of the paper was focusing on the implementation and simulation of fuzzy logic controller for MPPT to seek the maximum power point and comparing it to P&O. From the simulation results, FLC provided a reliable response as compared to the P&O controller in regards to main performance of MPPT.

The analysis of human sit down position is a research area allows for preventing health physical problems in the back. Many works have proposed systems that detect the sitting position, some open issues are still to be dealt with, such as: Cost, computational load, accuracy, portability, and among others. In this work, we present an alternative approach based on an embedded system to acquire the position-related variables and machine learning techniques, namely dimensionality reduction (DR) and classification. Since the information acquired by sensors is high-dimensional and therefore it might not be saved into embedded system memory, for this reason the system has a DR stage based on principal component analysis (PCA) is performed. Subsequently, the posed detection is carried out by the k-nearest neighbors (KNN) classifier between the matrix stored in the system and new data acquired by pressure and distance sensors. Thus, regarding using the whole data set, the computational cost is decreased by 33 % as well as the data reading is reduced by 10 ms. Then, sitting-pose detection task takes 26 ms, and reaches 75% of accuracy in a 4-trial experiment.

1. Introduction

The area of analysis and detection of human sit down during workdays and in classrooms has been explored by several studies that uses electronic devices and a wide range of sensors. Mostly, such studies aim at detecting of sitting static positions and determining their influence on the normal development of daily activities [1] [2]. In [3], authors explain that keeping bad/incorrect postures habits may cause attention problems, and loss of motor and brain skills for problem solution and decision making, as well as physical health problems such as muscle rigidity, fatigue and muscle pain [4]. The recognition/detection of sitting poses can be conducted by develop mainly two approaches: Image-processing-based and sensor-based approach [5]. The latter requires presure sensors able to be located on different weight-supporting surfaces by taking into account the pressure distribution over the whole surface.

The most common human positions in chair have been categorized in different manners. For instance, in [6], after performing several experiments, it is determined that there are 10 typic poses. Another study [5] considers 5 poses to develop the detection system. Despite that different systems have been proposed for sitting-pose detection, some open issues are still to be dealt with, such as: Cost, computational load, accuracy, portability, and among others.

In this work, we present an alternative approach based on a embedded electronic system to acquire the position-related variables and machine learning techniques, namely dimensionality reduction (DR) and classification. To design our detection system, we start with a comfortable chair that helps a user to readily reach a good posture so that his/her body keeps the natural state wherein the spin position and the space between the vertebrae do not change and the muscles of the waist and back relax. Otherwise,

*Paul Rosero-Montalvo, Ibarra-Ecuador, roseropal@utn.edu.ec

when changing to an incorrect position, intervertebral discs are narrowed and ligaments are stressed causing pain and discomfort [7]. The correct chair selection si necessary to be taken int account the human height, for this reaseon it must be able to adjust in order to provide a support for the user's lumbar region to be able to execute his task with comfort [7].

The selection is done of set of poses is highly dependent on the detection system design. Particularly, we set 4 poses detected through direct visualize method.

Once data are acquired by installed sensors inside the chair seat, we perform a data analysis stage using machine learning techniques. Such a stage involves a classification step using the well-known K-Nearest Neighbors (K-NN) multilabel classifier that depends of a metric used for the calculus of the Euclidian distance between two points for select the k neighbors nearest in terms of p attributes [11]. As well, due to the high dimension of acquired data (four dimensions) , we perform a DR step based on Principal Component Analysis (PCA) [8]. To implement our system, we opt by an Arduino platform because it is not only a powerful embedded system but is by construction highly versatile. In addition, there is a great amount of free code available at internet [9] [10] [12].

The electronic system proposed is aimed at detecting different poses that student may make during studying time. It works as follows: we use strength and ultrasonic sensors, which send the information to an embedded system. Such sensors are appropriately located and distributed on the chair.

The microprocessor inside the arduino does not have sufficient resources to storage big size of data and limited RAM memory for reading program, also the system is embedded to the chair and does not have communication for a computer. For this reason, we need to development a stages of machine learning.

To process the acquired data, we first apply PCA to represent the initial data –arranged into a data matrix - in lower-dimensional space [13]. Subsequently, we perform the KKN [14] [15] algorithm on the reduced data matrix. Doing so, we determine the poses that users (students) have made during a pre-established time period. To assess the accuracy of our system, we perform quantitative comparisons with a standard system running the same algorithms over the original higher-dimensional data matrix. As a result, regarding using the whole data set, the computational cost is decreased by 33 % as well as the data reading is reduced by 10 ms. Then, sitting-pose detection task takes 26 ms, and reaches 75% of accuracy in a 4-trial experiment.

The remaining of this paper is structured as follows: Section II, on one hand, presents the design of the electronic system and explains the data acquisition process. On the other hand, it outlines the data analysis made to detect sitting poses. Section III gathers the obtained results. Finally, Section IV draws the concluding remarks and future work.

2. Materials and Methods

The design of the Human Position detection in a chair system proposed in this work can be divided into two main stages: Acquisition and data analysis. An explaining diagram of the proposed system is shown in Figure 1.

2.1. Considered sitting poses and data settings

To establish the poses to be considered for our study, we use direct observation for setting the types of sitting made by a study group. The analysis is done over a University student group, who are monitored during their studying activities at library, as shown in Figure 2. As a conclusion, we find that there is a sitting pattern evidenced in 4 poses, similarly as proved in another study [16].

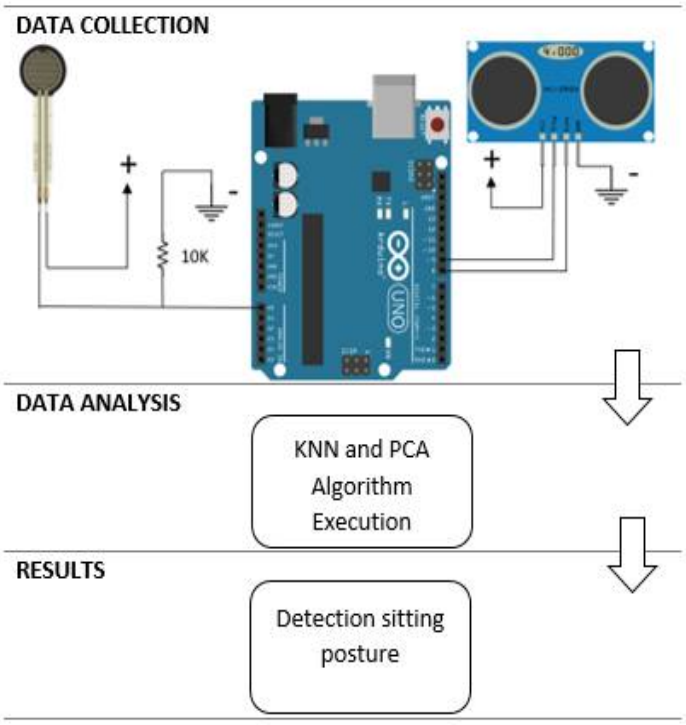

Figure 1. Explaining diagram of the proposed system. It mainly involves stages for data collection and analysis.

Figure 2. Sample picture of the student's type of sitting. Four poses are determined: Upright (red), leaning forward without back support (yellow), bowed forward (green), and tilted backwards (blue)

Table I gathers the name and description of all the considered poses. Figure 1. Comparatively, Poses **a)** (in red) and **c)** (in green) are better than the remaining ones since they have lumbar support, preventing from extra loads on the intervertebral discs of the spine, while relaxing the hip and back muscles.

TABLE I. DESCRIPTION FOR THE POSITIONS

#	Pose	Brief description
a)	Upright	The back and thighs form an angle of 90◦.
b)	Leaning forward without back support	The lower back have no support. Slope of up to 40º.
c)	Bowed forward	It has lumbar support. Slope of up 40º.
d)	Tilted backwards	Upper back against the chair backrest. Relaxed.

Data are acquired from observing 7 students (4 men and 3 women). Each of them is monitored for a while and making the 4 considered poses depicted in Figure 3. Our system linearly picks samples over a period of 1 minute. The processor works at 16MHz with own clock.

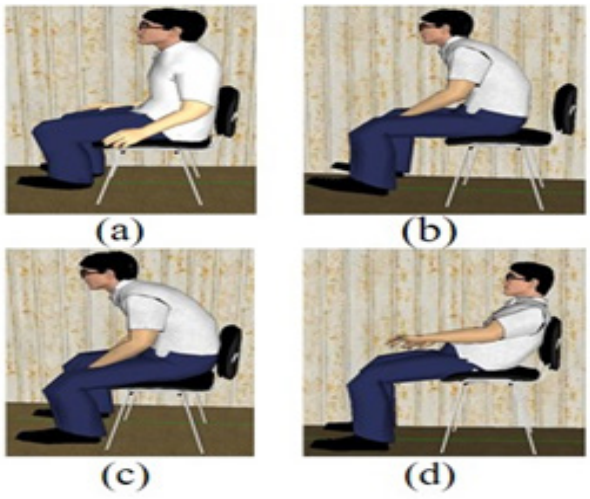

Figure 3. Sitting poses to be performed by the students from study group.

2.2. Electronic System Design

We design the circuit using as a main element the Arduino 1 R3 as embedded system. Three strength sensors (FSR-402) and one ultrasonic sensor (HCSR-05) are connected to Arduino through a transmission line that carries data while the user is sitting on strength sensors surface. Sensors are utilized as follows: Strength sensors are placed together on the chair being adapted inside the seat, while the ultrasonic sensor is placed on top of backrest as shown in Figure 4

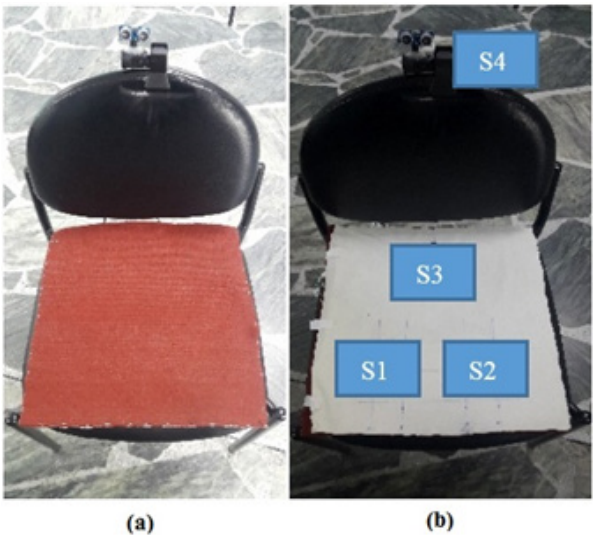

Figure 4. Sensor distribution on the chair. The figure shows the front (a) and backhand (b) view of fabric.

2.3. Data Analysis

The acquired data are arranged into a data matrix **M** (training set) which is **m** x **n**, where m is the number of samples or data points and n is the number of attributes or variables representing each data point. Initially, since 4 sensors are used, we get **n** = 400 and **m** = 4 for the higher-dimensional matrix **M**. Then, such a matrix is reduced by using PCA [10]. Particularly, we extract a new, 2-dimensional matrix. Over the reduced matrix, we run a K-NN classification algorithm. It depends on a metric used as a distance to measure how similar are the data points. Here we consider the Euclidean distance [11]. The data matrix **N** (test set) which is **j** x **l**, where j=100 and l=4.

Since strength sensors tend to be very sensitive, during data collection, the outliers must be clearly identified, especially those generated in the descent to the chair and sitting movements before establishing a fix sitting pose. We perform a manual outlier removal procedure. A total of 100 data points per position are considered for training the system. PCA is used to find the most relevant variables following a variance criterion. We obtain that sensors 3 and 4 represents the 86.66% of the data representation (see Figure 5). To perform the DR procedure, we set the resultant dimension as 2. So, we can draw 2D scatter plots as shown in Figure 6.

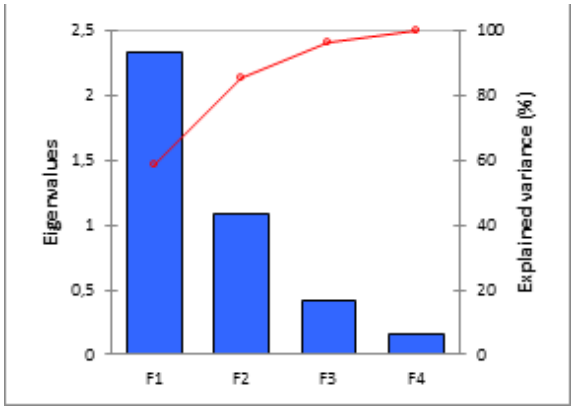

Figure 5. Eigenvalues bar diagram and explained variance plotting for the original higher-dimensional data matrix

The considered variables are those for the strength sensor S3 and proximity sensor S4. Another matrix size reduction should still be performed to prevent from saturating the RAM of the microcontroller [17] [18]. Following a K-NN scheme the number of rows (samples) can be reduced by excluding the data points being close from the average data distribution. Doing so, we get that the new number of rows becomes 80. Here we name the new, reduced matrix is named S that shows at the figure 6

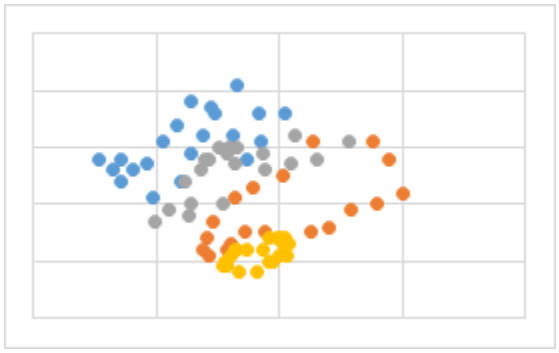

Figure 6. Scatter plot of reduced matrix. Each color represents one of the considered classes (poses) as follows: Pose 1 in blue, pose 2 in orange, pose 3 in gray and pose 4 in yellow.

The **S** matrix is stored in the embedded system RAM, in this way is faster the access to registers in relation to data EEPROM memory, but the CPU had overload when integrated all sensors and KNN algorithm. For this reason, we implemented a restart system after the electronic system has classified each five same times the user postures on the chair.

The flow diagram of the implemented approach is graphically described in Figure 7.

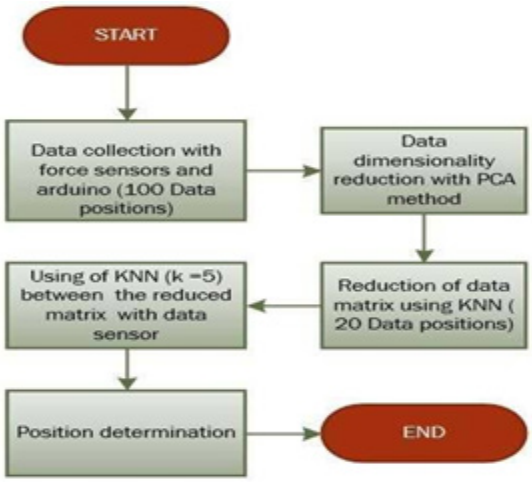

Figure 7. Flow diagram of the proposed data classification approach used for sitting-pose detection

The most important part in this work, is the embedded KNN algorithm inside an 8-bit microcontroller. After obtain the reduced matrix in 82 points with a position label, it necessary create a hexadecimal type file which must compilate in RAM memory. In the principal program, we call the file to read and compare each matrix's point with new data acquired for the accelerometer sensor and determinate the shorter distance and predict the position with the matrix label. The picture 8 shows a pseudocode that describes the K-NN function implemented [19].

```
KNN ALGORITHM
Include position's database //Insert database in hexadecimal format with four positions and twenty data
//points each one. Database sin mxn points where m=82 and n=4.
Integer column, row // variables for the matrix lecture
Integer cont_vector;// vector count variable
Double data_x, data_y, data_z // data acquisition variables of the matrix
Double lecture_x, lecture_y, lecture_z // data acquisition of the accelerometer
Double knn_dist // distance variable
Vector [5] five_less_distance; // knn vector
  Begin
        Read for accelerometer x, y, z in lecture_x, lecture_y, lecture_z
        Repeat
              Repeat
                    Case column
                          Case 0
                                Store in data_x
                          Case 1
                                Store in data_y
                          Case 2
                                Store in data_z
                    End cases
                    knn_dist=((data_x-lecture_x)^2+(data_x-lecture_x)^2+(data_x-lecture_x)^2)^1/2
                    Repeat
                          If vector less distance at position 0 is greater than position n + 1
                                Change positions.
                                Remember label by position
                          Repeat cont_vector <5
              Column < position
        Row < position database row length
        Repeat
              Print label saved in the top 3 positions
        Result <3
        Wax variables
        end
```

Figure 8. K-NN pseudocode write in C language

3. Results

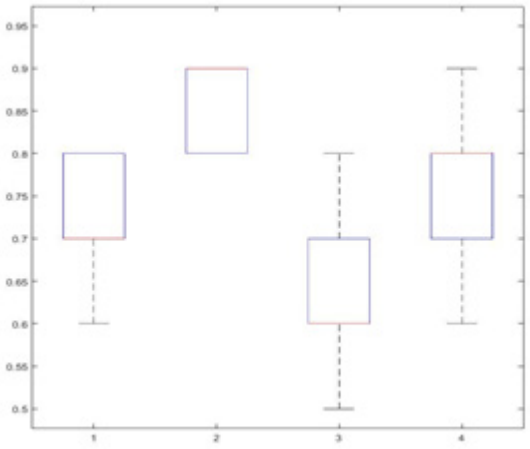
The tests were conducted on both a standard computer (PC) and the proposed system. Ten data points per pose taken at random were tested considering the matrices ***N*** and ***S***. The former matrix is only tested on the PC.

Results were obtained for all the analyzed poses a. Using matrix ***N***, for pose 1, an average accuracy rate (AAC) of 72% success rate was reached. Likewise, for poses 2, 3 and 4 the AAC was 86%, 63% and 77%, respectively. Figure 9 shows the ACC boxplots. Given its simplicity, the system outcomes are comparable with those reported in literature. As a result, the rules for x and y to reduce the dimension were:

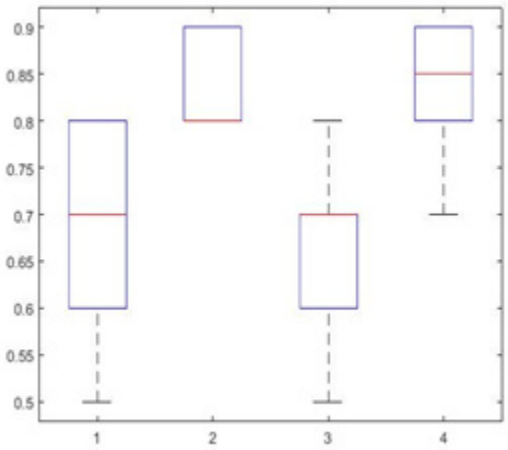
$$x = \sum_{i=0}^{t} (-0.0945 * i) + (0.7541 * i) + (0.6487 * i) + (-0.0384 * i),$$

and

$$y = \sum_{i=0}^{t} (-0.0232 * i) + (0.0274 * i) + (0.0239 * i) + (0.9991 * i) .$$



Using ***S***, AAC is of 68% for pose 1, 83% for pose 1, 67% for pose 3 and 83% for pose 4. These results can be graphically appreciated in Figure 10.



Results regarding memory usage of the embedded system processor are significant good. When inputting the higher-dimensional matrix ***M*** 99% of the flash memory of 8Kbytes is used, and therefore there would not be enough space for typing more script lines. On the contrary, using the lower-dimensional matrix ***S***, only the 30% of the memory is used, leaving enough to add lines of programming space. As a result, regarding using the whole data set, the computational cost is decreased by 33 % as well as the data reading time is reduced by 10 ms. Then, sitting-pose detection task takes 26 ms, and reaches 75% of accuracy in a 4-trial experiment.

4. Conclusions and Future Work

This work presents an alternative approach to deal with the problem of sitting-pose detection, which is based on a sensor network to acquire the position-related variables and machine learning techniques. Particularly, dimensionality reduction (DR) and classification techniques are considered. In this regard, both K-NN and PCA show to be suitable.

For future work, other issues are to studied such as real-time applications, computational load optimization and the use of different classification techniques to reach better performance.

ABSTRACT

Using smart parking systems has become very important, and particularly so for metropolitan areas, because of the benefits for drivers in many aspects, such as time, frustration, stress, and anger, in addition to the increased consumption of fuel while searching for a vacant parking space. This paper proposes a review of recent advances in sensing and communication technology concerning smart parking systems. It includes a brief study of the selected topics and provides an implementation process of those selected systems. Moreover, this work proposes a design approach for a smart car parking system prototype based on utilizing CCTVs (nodes), it is also illustrates the algorithms used for computer vision detection through simulation and real environments, as the system has been deployed in both these environments. Furthermore, the system has been tested and evaluated by stakeholders via a user-centred design process by applying a qualitative research; the promising results demonstrate the effectiveness of our prototype. Finally, this paper discusses the benefits of engaging the stakeholders to develop the prototype.

1. Introduction

Installing a parking system at any car park can be expensive, but recently, many researchers have been exploring techniques, such as vehicular ad hoc networks (VANET), or integrated RFID with Wireless Sensor Networks (WSN). As the Internet of Things (IoT) has evolved, further possibilities to provide services have emerged. Here, IoT can connect objects, such as smart-phones, sensors, and actuators, as nodes (in our case, CCTV cameras). The development of IoT may transform a number of domains dramatically, for example, automation, transportation, healthcare, and financial services. IoT can also be applied to new concepts and developments for smart homes to provide improved comfort, security, and quality of life. Some parking systems need extensive infrastructure investment, for example, digging holes in the ground at each parking spot to install a sensor. However, we are proposing an approach that can utilise an existing system instead, i.e., CCTV (node) coverage. The proposed system has many advantages. Firstly, it is cost efficient, as it is using the existing CCTV cameras (nodes). Secondly, no infrastructure changes are needed for the parking lots. Finally, and according to the interviews with stakeholders that were done during the evaluation process using the User-centred Design (UCD) method, the prototype can be useful for small and large parking areas whether the parking area is active or not where the user can easily identify and locate the vacant parking spots on the fly. This paper presents a prototype of a low-cost and flexible smart parking monitoring system using an embedded micro-web server, with IP connectivity for accessing and controlling devices and appliances remotely [1].

2. Contributions

We introduce a novel IoT parking system porotype based on computer vision and build a model of the system operation.

The general approach to design a usable Interactive Technology (IoT) smart parking system for stakeholders (end-users). The methodology for accomplishing this goal was to apply User Centred Design (UCD), which included observation, surveys with stakeholders, and in-depth interviews with users. This article and research contribution covers different aspects:

- It review and presents a related works of different parking systems.
- Design, implement, verify, validate, test and evaluate a smart parking system utilizing CCTVs (camera nodes) facilitating provision of mobile services in indoor and outdoor environments within a university campus as an example.

*Corresponding Author: Muftah Fraifer, Interaction Design Centre -Dep of CSIS, V94 T9PX, Ireland | Email: muftah.fraifer@ul.ie

- In the field of IoT, facilitating the parking systems process by enabling a camera (thing) to be a smarter thing using a Galileo board (microprocessor) by providing a solution by links smart objects to the Internet.
- In the field of HCI, the knowledge and insights about UCD and how it can be put into practice to design a usable and effective IoT Parking System.

3. Related Work

To provide an overview of the different technologies used by others, the following is a summary of the systems we have reviewed. Foshini et al. discussed the design and implementation of an M2M application in the field of road traffic management study which used an integrated IoT retractable bollard barrier management system to allow vehicular access to restricted city areas, based on a standard infrastructure and software components [2]. Pala and Nihat used RFID for finding the nearest vacant parking space and reporting to the driver [3]. Tang et al. developed a system using crossbow motes that have a low unit cost; the system enabled a car to detect entry to the car park and guide the driver to an empty parking space by signs displayed to the driver [4]. Benson et al. proposed that an RF transceiver and micro controller system could monitor the availability of car-parking spaces and send this information to drivers and car park administrators [5]. Funck et al. proposed a system using CCTV cameras fitted in car parks to automatically detect car parking spaces. However, all these methods have the problem that sometimes they are not accurate [6]. Panayappan et al. described a parking system using VANET, which located available parking spaces. The system depended on roadside units to relay parking messages and GPS coordinates to locate parking positions [7]. Kianpisheh et al. presented a smart parking system using ultrasonic sensors. For each individual car park, a sensor was fixed in the ceiling above each parking space. Such ultrasonic sensors operate based on echolocation. The sensor emits a sound, which is reflected back to the sensor; the presence of a vehicle changes the timing of the reflection [8]. Mathur et al. discussed a centralized solution, with cars equipped with ultrasonic sensors driving past parking spaces to collect occupancy data and upload the data to a database; the cars that require parking query the database [9]. In 2010, Hazrin et al. proposed a smart parking using SMS services to communicate with drivers. A parking reservation system was developed whereby users could reserve a parking spot with an SMS message, including GPS information [10]. Bong et al. proposed a system with image processing algorithms, the motivation being to minimise the cost. The system was called Car-Park Occupancy Information System (COINS) [11]. Klappenecker et al. modelled a parking lot as a continuous-time Markov chain. The parking area was modelled as a grid, and schemes for information aggregation and dissemination over the grid were proposed [12]. Jain et al. proposed a system with a Gate-PC Controller and Embedded Gate Hardware, RFID System, Modular Parking Management Platform [13]. Lee et al. proposed the use of a combination of magnetic and ultrasonic sensors for the accurate and reliable detection of vehicles in a parking lot, also describing a modified version of the Min-max algorithm for the detection of vehicles using magnetometers [14].

4. Research Methodology and Background

Our general approach is based on UCD. This includes observations of user behaviour, surveys with stakeholders, and in-depth interviews with users (ranging from the parking users to system operators and facilities management staff).

This is carried out in parallel with technical probes, i.e., incremental development and integration of system components. At present, we have a low-fidelity prototype where parking and CCTV nodes are emulated in an office environment (using toy cars) and then actual parking spaces. We explore the desired services informed and shaped by our user groups. We strive towards using open source software as far as possible, and in our preliminary sketches of the system, we may also be using Google APIs, including both maps and calendar functions that can be used for reserving parking spaces based on the user's planned activity on campus. It is thought that a minimally intrusive system that users' experience as augmenting their activity may be more likely to succeed. To address this, we are using part of the University of Limerick campus as a living lab to engage with users and evaluate a range of services. The campus has full coverage with open Wi-Fi, 3G, CCTV and a range of architecturally complex spaces with buildings interspersed with car parking [1].

5. Hardware and Software Requirements

- Micro-controller Intel Galileo board or, as in our case, desktop computer with Linux.
- CCTV cameras (nodes) A,B,C, etc.
- Parking Server Computer (PS).
- Software components with Java and Intel OpenCV library, Parking Server PS (LAMP stack)

Figure 1 below shows a Galileo board, which is used to run the OpenCV code directly. Also, the code can be compiled and run using the live-video streaming link for the live scene of the parking areas to monitor the parking status in real time.

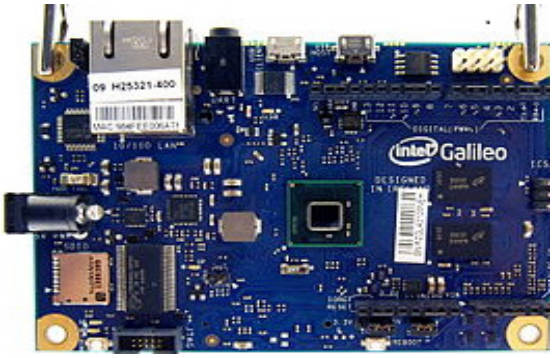

Figure 1: Galileo board

6. Application Architecture Layers

From the high level of the IoT based smart parking system; there are three main layers ; As shown in Figure 3.

- Application layer: the main purpose of this layer is data processing and service providing.
- Transmission layer: which is about transferring data over long distances and for wide areas.
- Perception layer: the system aims to collect and process the data from the physical world (in our case is using computer vision technology)

Figure 2 : Prototype CCTV camera node with the cover shield to protect the Galileo board

7. Design Goals

Based on our literature review and having access to the existing infrastructure on campus, we set out to explore a smart parking system based on CCTVs/Web-cams (nodes) that can provide drivers with convenient and simple parking service information. The prototype has been evaluated and tested using stakeholders, and the UCD process has been used to gather the end-users' needs and requirements. The process is also used to improve the prototype iteratively.

The system must fulfil a range of criteria. Firstly, it has to provide real-time navigation support to the driver, for example, by utilizing Google maps. Secondly, it has to provide a friendly parking information service to both the parking user and the parking facility's operator/owner. Finally, using CCTV cameras (nodes) for this purpose as well as for security purposes, it is an economical option. The main function the system will perform is to gather information about the parking status in real-time, and help drivers to navigate directly to vacant parking spaces [1]. Figure 3 and Figure 4 shows (admin GUI) when run the system in outdoor and indoor environments

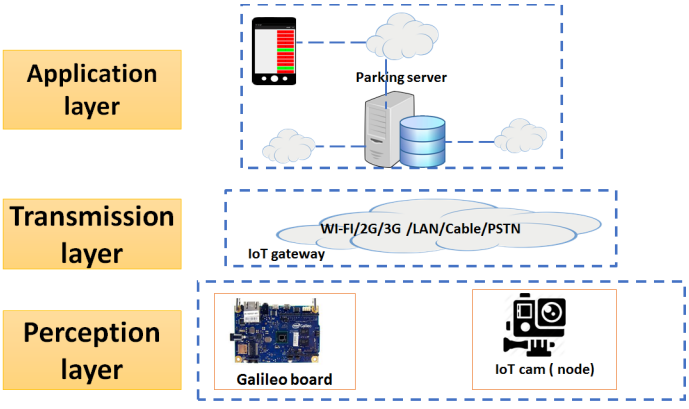

Figure 3: smart parking IoT application architecture

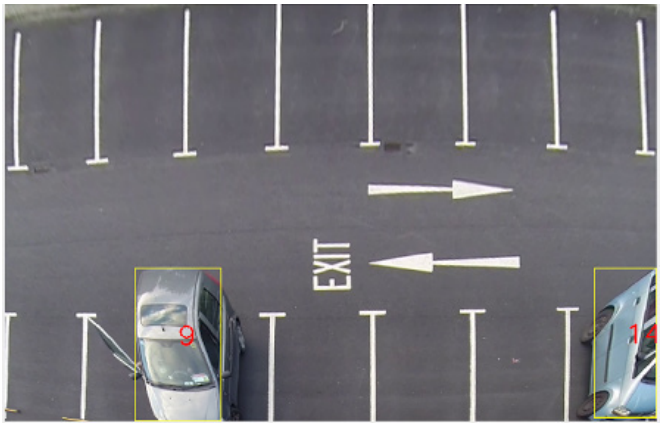

Figure 4: snapshot of testing scenarios in out-door environment covered by one node from admin GUI (monitoring (parking status on real-time)

8. User-Centred Design and its Influence on our Porotype

The UCD methodology in this process is used as a framework of processes in which the needs of stakeholders of a product or service are given extensive attention at each stage of the design process. It begins by defining the problem, which in our case is congestion during peak times and the effect on drivers, as it appears difficult for the driver to find a parking spot [1].

Another aspect to this research-study is carried out to explore the approach of UCD with a focus on stakeholders' involvement in the development of a smart parking technology prototype. We tried to alleviate this everyday issue of finding a parking space through the proposed prototype. Although some of the stakeholders' suggestions may involve some costs, the stakeholders have been identified and a thorough investigation of their needs has been conducted. By performing tasks and needs analyses, designers can develop alternative design solutions to be evaluated by users. The data analysis was based on a qualitative content analysis from a interaction design perspective.

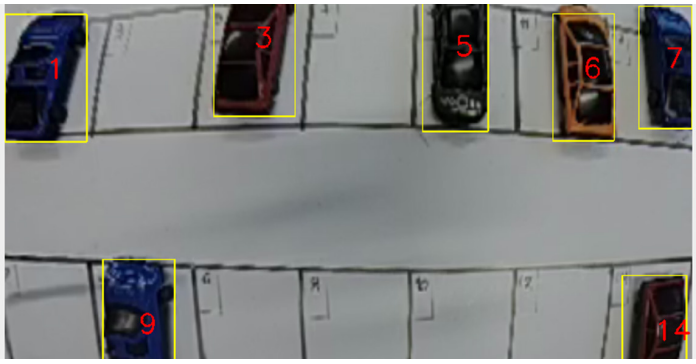

Figure 5: snapshot of Testing scenario in in-door environments from admin GUL (monitoring (parking status on real-time)

9. Prototype of the Proposed System

There are three main components:

- firstly, an app installed on the user's smartphone that connects the user with a parking server (PS);

- secondly, an IoT cams (which in our prototype is a Web Camera) nodes that is connected to a microcontroller (Intel Galileo);
- and lastly, a PS (Parking Server) hosting a database.

When the user installs the app on their Smartphone, they are given unique ID. The app can also hold a user's profile and preferences including all the information entered by the user during the registration with the system and the server. This allows the app to provide services that match a user's parking preferences with actual available spaces in the actual parking scenario at UL [1].

Our main scenario is the aforementioned openly accessible areas. Each parking lot is divided into areas that are covered by nodes, as shown in Figure 4 below.

Our prototype uses IoT camera nodes. An IoT cam can be set to report changes to the scene as a grid of polygons. At the same time, the user can interact with the system through the app. The IoT cam uses a DHCP connection to connect with the PS, which is on a fixed IP.

A simple blob-detection algorithm (using Intel's OpenCV library) is used for computer vision, which monitors and reports changes in a defined grid of polygons (i.e. if parking spaces are vacant or occupied). IoT cams connect to the PS, which aggregates the data and updates the database of available car parking spaces in close to real-time. It should be possible to define and redefine parking areas by system operators. The system will operate in close to real-time, so we can aim to improve the parking experience rather than forcing and regimenting it. Status information regarding the parking area within the coverage of any IoT cam (nodes) is continuous, and changes are sent to the PS. We are using both scenarios (indoor and outdoor environments); the first is only to test the feasibility of the system, which depends on toy cars in a model parking lot, as shown in Figure 3, while the second prototype was tested on real cars with an actual car parking area, as shown in Figure 4 (both snapshots were taken from admin GUI). The camera, in a simulated environment (CCTV), is fixed in position with a side view of the parking space. The height of the camera must be sufficient to obtain a clear plan view of the parking

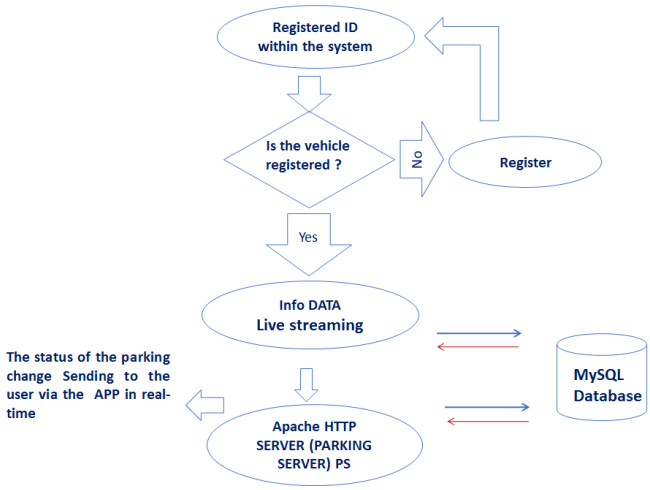

Figure 6: The operations triggered by the car-in and car-out events.

space, as in Figure 1. The IoT cam is positioned with an angled view of the parking space acquiring a fixed scene [1].

10. Interaction with MySQL Database

We are using a LAMP server as the open-source platform, which uses Linux as the operating system, Apache as the Web server, MySQL as the relational database management system, and PHP for scripting.

The system has real-time communication between the mobile app and the server, using a RESTful API. Each car park can be identified with labels, for instance, (Node A, Space 1, 2, 3, 4 etc.), so when a driver enters the parking area, they can easily identify each parking space. The main technique of the system is to monitor the system through IoT cams, while the video is processed by analysing the live streaming of data and changes are stored in a MySQL database. Figure 7 illustrates the UML use-case diagramor the interaction of the prototype Open CV Algorithms (1)(2)(3)(4).

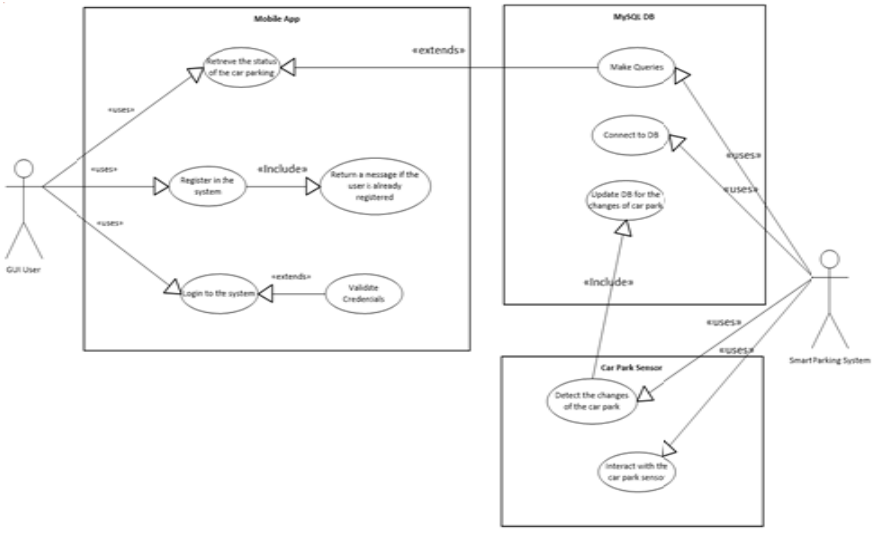

Figure 7: UML -USE CASE Diagram for the protpype

11. OpenCV Algorithms and Senescing Techniques

- The code depends on the OpenCV library, which has been used for video processing, to detect vacant parking spaces.
- The code retrieves frames from streaming video by applying a prospective transform Matrix on source images.
- For each pixel (x,y) of the destination image, the functions compute the coordinates of the corresponding "donor" pixel in the source image and copy the pixel value. A perspective transformation is then applied to the image. The function ***warpPerspective*** transforms the source image using the specified [3x3] matrix:

$$dst(x,y)=src\left(\frac{M_{11x}+M_{12y}+M_{13x}}{M_{31x}+M_{32y}+M_{33x}},\frac{M_{21x}+M_{22y}+M_{23}}{M_{31x}+M_{32y}+M_{33}}\right) \quad (1)$$

Where:

src: input image
dst: output image
M : 3x3 transformation matrix.

- Image loading, including erosion, smoothing, noise reduction, blurring, contrast fix, and brightness are applied to the uploaded images to get a uniform output from the camera input image.

$$dst(x,y)=\min_{(x',y'):\mathbf{element}\,(x,y)\neq 0} src(x+x'+y+y') \quad (2)$$

- We are using the ISODATA method (Iterative Self Organizing Data Analysis Technique) for thresholding of image segmentation to get a high degree of accuracy and to consistently find the contours for each polygon (car) [2].
- A fixed-level threshold is applied to each array element. (THRESH BINARY)

As below

$$dst(x,y)=\begin{cases} maxval & if\ src(x,y) > thresh \\ 0 & otherwise \end{cases} \quad (3)$$

src : input array (single-channel, 8-bit or 32-bit floating point).
dst : output array of the same size and type as src.
thresh: threshold value.

maxval: maximum value to use with the THRESH BINARY and THRESH BINARY INV thresholding types.

- One layer of the algorithm has been applied to detect vacant spaces in the parking lot using a contour method (rectangular detection) to identify the number of cars in the parking lot. The findRect method matches the detected shapes to the shape of a parked car, detecting the cars as rectangles.
- Rectangle X and Y coordinates as in (4), where variables are points, namely, first point and second point, and then a rectangle is drawn around the image.

$$Point\ (x,y) \rightarrow Point2f\ (x* 2^{-shift}, y*2^{-shift}) \quad (4)$$

- This data is sent to the MySQL database through a MySQL connector, with a list of all parking areas, number of possible spaces, etc., so the system can count how many parking spots are available. Using the marked parking spaces as bearings, the code can identify the central position of a car as illustrated in the pseudocode below.

12. Illustration the stages of Implementation of the Code

The algorithm passes through different stages; starting by getting the prospective transform matrix of the image. Then the code retrieves frames from streaming video using the prospective transform Matrix as clarified in the pseudo code below.

Pseudo code for the detection algorithm

```
// If a contour is detected in the parking spot, the contour
represents a parked car (occupied parking spot)
If (contours.size() != 0 )
{

 // checking each contour
 For (int idx = 0; idx < contours.size(); idx++)
  {

   //To get the boundaries of the rectangular contour.
   Rect contourRect=Imgproc.boundingRect(contours.get(idx));

   // If bounding rect is between the two aspect ratio x,y.
  If
  ((contourRect.width < min_x)||(contourRect.height <
min_y)||(contourRect.width > max_x)||(contourRect.height >
max_y))
  continue;

   // To get the aspect ratio.
  double ratio = [(double)contourRect.height
/(double)contourRect.width];
  if ((ratio < x)||(ratio > y))
  continue;
  If (the detected contour is a car)
  End If
   {
  // Draw a rectangle of the car.
  R = rectangle of car,
  // Get the position of each car. Pi = central position of car(i),

  // Give each occupied parking spot an ID.
  ParkID(i) = occupied_parking_spot(i),
  End If
  End for

 }
}
```

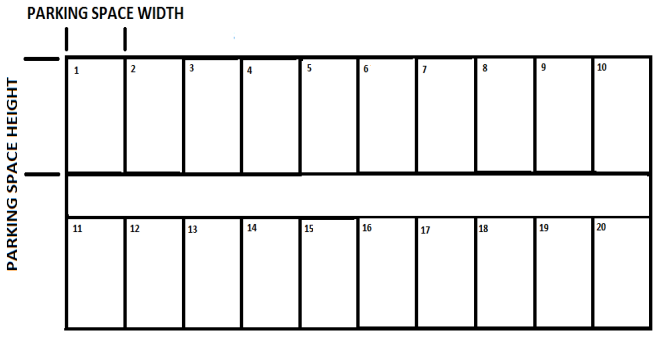

Figure 8: OpenCV algorithm design

13. System Implementation

A smart parking system based on CCTV (computer vision) has been proposed and tested in this paper. There are two Java applications; one is called ***SPSystemApp*** (OpenCV) and the other is called ***SPMobileApp*** (GUI). The interaction between them is via the MySQL database. The main purpose of the first application is to detect the status or changes of the car park and send this information periodically to the database in real time. At the same time, the GUI retrieves these changes for the user.

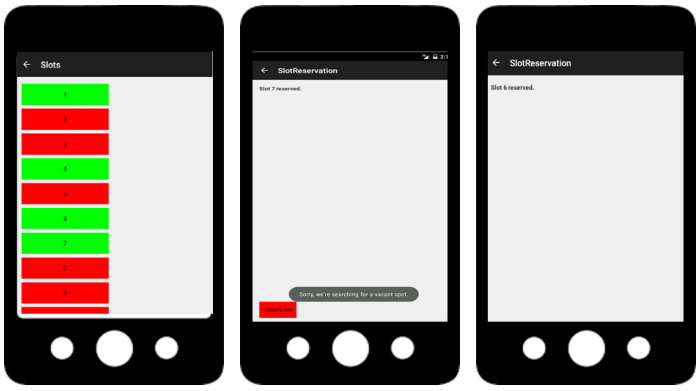

Figure 9: a,b,c Shows (a snapshots)AVD with a reservation scenario (it shows the interactive process by giving another parking spot

Figure 3 shows the implementation of the system, which shows red and green buttons where the user can reserve the parking space. The test cases used to evaluate the functionality of the system are listed in Table 1.

Table 1. Testing the system with different functions

Test scenario	Result
MySQL connector can make a database update record according to status change	Pass
Can the user reserve a specific parking space	Pass
View the number of available parking spots in real-time	Pass
Parking area status will update info to PS when a car leaves the car park	Pass
Able the user to register in the system using GUI	Pass
Ability to do several tasks (Registration/reserve)	Pass

14. The System and its Maximum Effectiveness

Regarding the implementation of the work of the system on the Galileo board (microcomputer); Which distinguishes its use during its work in real time in addition to being a small board next to each camera (node) and do not need to connect video over the Internet to a central computer, where the delay here in the live broadcast to nearly half a minute or more. What also distinguishes our use of the motherboard in this system is the possibility of operating it in a real car par. We used a special cover to protect the processor from atmospheric conditions as shown in the picture. Again, we want to clarify that this article came as part of a research with several purposes to demonstrate the proof of concept and the prototype of the system of a complete illustration of the general perception to take advantage of the work of cameras not only in the parking lot, but also anywhere to include temporary parking on both sides of roads and others Through our experience of the reality of the work of the system and found that its work is in the best conditions and give good results identical to the reality of the case in terms of the number of cars and their location and the possibility of detection by the system if the speed of the Internet is not less than 120 Mbps ; to be able to stream data with a smooth and fast way to emulate reality and thus the quality of images through video broadcast in real time of the parking lot , which is dedicated to a particular camera (node) or more. Also, The image resolution required is no less (1400X960) pixels .To enable the system to operate with acceptable efficiency. The system handles (capturing, analyzing and grabbing frames from the connected nodes) up to 22 frames per second ; This is what distinguishes using OpenCV in this research.

15. System Requirements and Implantation Techniques

The system can detect vacant spaces using two different methods. The first method is using the IoT-Cam, where it pushes any changes in vacancy to the server (the microcontroller/server (in this scenario) while the PS can get the parking area status. The second way is using smart cameras that just capture an image, and all the processing happens on the server where the server can get an image from the camera providing the server is able to get smart camera status.

The IoT cameras (web cameras nodes) are connected via Wi-Fi to the Internet, so we can get the IP-number for live streaming of the video, which covers a certain area of the parking space; When the code is executed online, it assigns the link to the IoT cam to get the video stream analysed on the Galileo board or via the Linux machine..

16. System Reliability in Different Scenarios

Below is a collection of screenshots for application during use; The captured images were placed within the Android framework for clarity. Several scenarios have been considered; For example, the first user booked a certain parking place number 7 as in Fig x.a ; Upon arrival he found the place vacant, In this scenario, the user has only to click on the button called a complaint. Although such

behavior is unlikely to occur. Because it will usually apply fines to prevent such violations as any other system which provides services to the public as it shows in Fig x.b Which shows a second option to the user automatically.

14.a System Efficiency

With regard in the reliability of our prototype. The system has been tested for several different times and for several different scenarios. The first tests were done in the laboratory (indoor environments) .While other tests were conducted in a real atmosphere. The tests carried out in the selected paper for the conference were carried out with a group of stakeholders and the number of them was 12 completed in the laboratory. All tests were ethically proven, and approved by ethical committee in the university. In terms of tests and reliability of experimental system. The system worked well and especially when the cars in both cases (toys and real) was properly parked. We noticed that those cars that are not parked along the lines of the stand cannot be detected by the system. The dark atmosphere makes the system fail to perform its functions, so we mentioned the need to light the parking lot in order to increase its efficiency. It is worth mentioning here. We connected the system to one of the cameras in a nearby parking lot .by Enabling VLC media player for Real Time Streaming Protocol (UDP); latency was quite high somethings, So there is some delay in the video displayed directly.

Based on the speed of the Internet and the quality of the images transmitted from the parking lot be the quality of the system and its efficiency and reliability.

We noticed that the system is delayed in this scenario to approximately 35 to 45 seconds. Sometimes the image is frozen in a fixed format as a result of the speed of the Internet or low performance of the processor. As the main purpose of this research is to clarify the potential of the work of the system in ideal circumstances.

14.b Various Activities for Application and Features Available

Regarding the real implementation process of the system, the stakeholders themselves, who are students, staff, and visitors contributed voluntarily from the experience of the system in practice. This is what distinguishes this work. As the method used in the design process is User-centred Design (UCD).The images below illustrate the practical tests of the system [10a] [10b] [10c] Low-fidelity prototype (paper prototyping) technique was used; as it is a method in the UCD process to ensure that stakeholders meet with satisfaction and acceptance. Then; The application is designed to run on the Android system. In a simple way, the application contains several activities. The most important is the possibility of registering in the system.

Where it is easy for the subscriber to enter his personal data including the number plate of his/her car. The car number has been added to its registration rules through suggestions for some stakeholders to follow the violators of the parking laws that want to apply such a system to facilitate the service to find a vacant position. The second activity relates to the possibility of seeing vacant positions in real time with the advantage of the possibility of reserving a particular position. The application is linked to a database as described above.

And each interaction with the system appears in the picture short message as shown in the figure below.

As previously reported, all trials were completed as shown in the table below. All the tests were in the appropriate conditions in terms of speed of the Internet and the quality of cameras and the weather and lighting. In addition to the emphasis on who was driving cars for the purpose of testing the need to be in a straight position parallel to the place allocated and not be tilted even a little and these are one of the biggest disadvantages of the system now.

17. Graphical user interface GUI for User and Admin

The system has a car parking mobile app as a key component, with a user interface for everyday use. Through the app, car parking information and services can be delivered to the user in a functional and user-friendly way and that are relevant to the user's present goals and location and according to the user's dynamic profile. Below is a collection of screenshots of the application during use.

Figure 10: GUI shows the status of parking area

When a user registers with the system, they are given a unique ID. The emulator used (an Android Virtual Device (AVD)) as in Fig[9] and Fig[10, 11].also the figure below shows real the app on a real device .

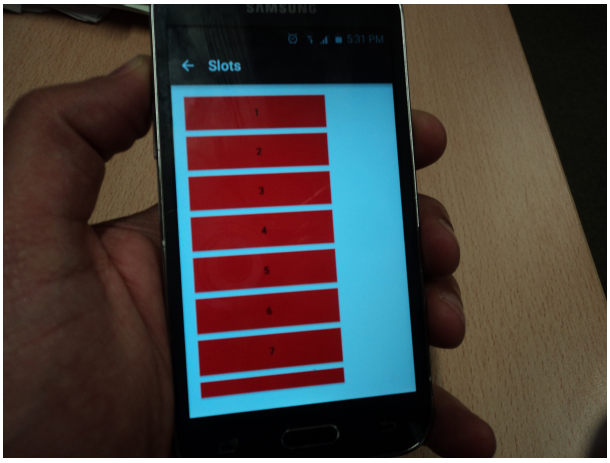

Figure 10 run the app on real device

Also, should someone else have deliberately or by mistake taken a pre-booked space, the system is currently able to allocate the user another parking space by the user clicking on the complain button as illustrated below in Figure 8(a,b,c) where red indicates an occupied and green a vacant spot.

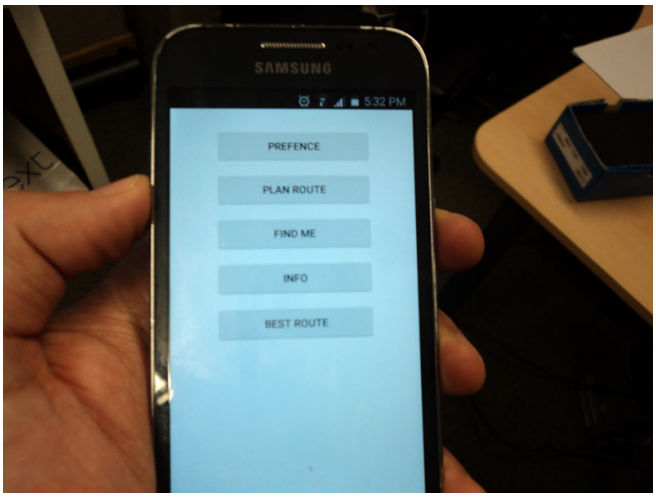

Figure 11 : run the app on real device for registration process

The figure below shows different snapshots of the admin GUI which is designed to help the system administrator to monitor the work and performance of the system.

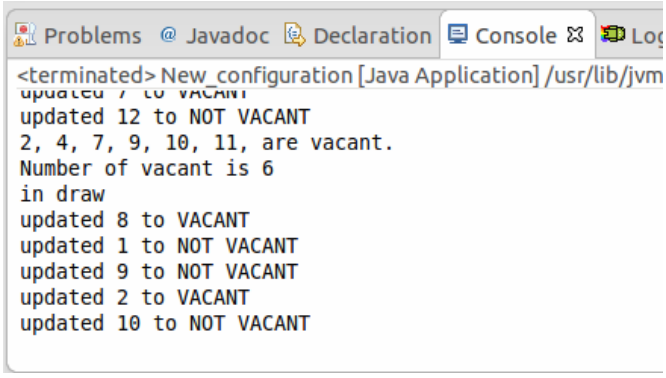

Figure 12 : Snapshot 1 of the admin GUI (monitoring parking status on real-time)

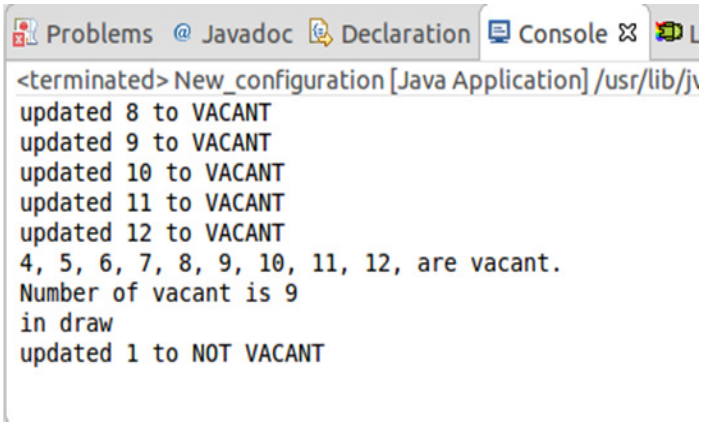

Figure 13: snapshot 2 of admin GUI (monitoring parking status on real-time)

18. Discussion

This smart parking system requires cooperation from multiple users searching for parking spaces at the same time, but there is no barrier to the parking spots. In addition, there are some situations where the system may not work. So far, the system is not designed for use at night, as the car park in our scenario is a scarce resource only during office-hours. If night-time operation was required, night vision cameras or artificial illumination would have to be used. [1]

To create a potentially successful parking locator system, we first considered user needs and requirements [15]. Users are not a homogenous group, and an individual user's goals can change rapidly. The heterogeneity of users may range from residents/workers, short/long-term visitors, deliveries, services and emergency access. As a whole, users may engage in a range of disparate and dynamic activities and roles. In addition, accidents and temporary disruptions that may render dedicated parking spaces temporarily unusable, which presents the problem of getting the system quickly updated to reflect any changes.

In addition, if a car is parked across two spaces, then the system may detect this as two separate shapes, neither of which is the correct shape to be a car and may be ignored [1].

19. Evaluation and Testing Our Prototype upon Empirical Study via Qualitative Research

In particular, intended smart parking solutions for urban environments necessarily and primarily need to involve all the stakeholders in an early phase of the solution development. The stakeholders involved in the UCD process were in general enthusiastic, and they were happy to be able to contribute to the system development. That is in line with research that found that users who are involved in the process indicated that the system was designed to meet their needs. The prototype was evaluated and tested in two iterations using the UCD methodology. The first iteration on the UCD process was informed by 15 participant interviews. This qualitative study builds on a case study to propose a methodological framework for the implementation of a smart parking IoT system.

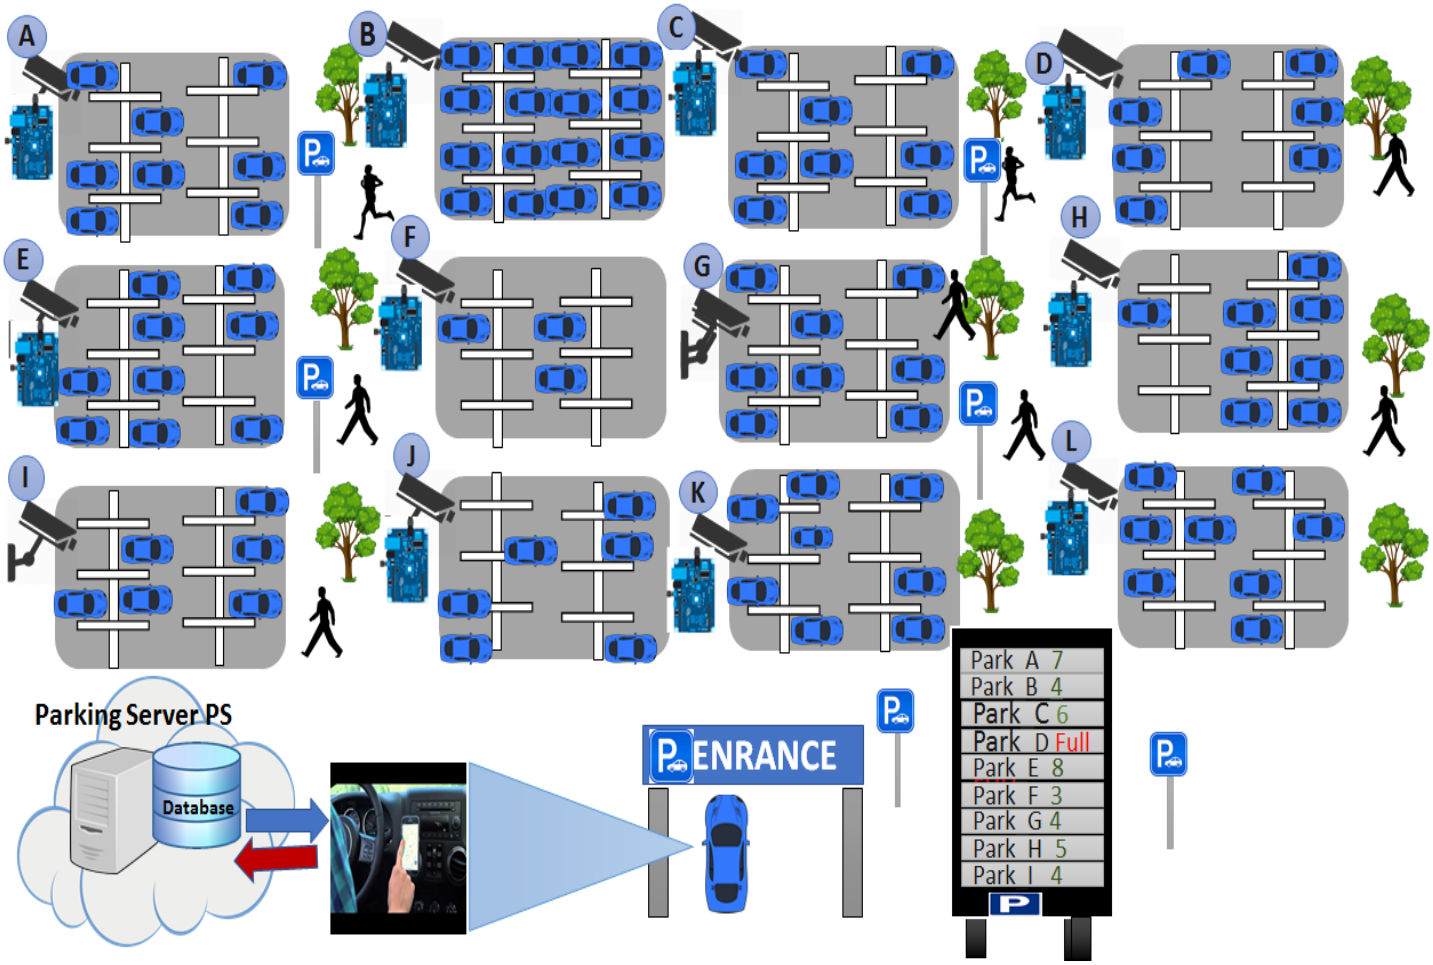

Figure 14: General outline of the IoT prototype using different nodes

The majority of participant stakeholders were impressed by the prototype and believed that the system would be useful, at least to alleviate the issue of finding parking spaces. They believed that even if the system is able to tell the users that there are no vacant spaces available, which would be useful information instead of the driver wasting time and fuel searching for a space when none is available. However, they had a variety of ideas regarding how to improve the prototype. We took this into consideration in the figure (9) above as a general prospective for our IoT parking system prototype.

20. Empirical Study and Ideas from Stakeholders Used to Improve the Prototype:

Our findings from the empirical data indicate that there is a real need for a smart parking system to alleviate the issues when finding a parking spot. Some stakeholders suggested letting all drivers know about the fully occupied parking areas via large information screens while others suggested using small screens connected to our prototype instead of the apps at each parking space/area to help the drivers avoid crowding and congestion. In addition, some recommended utilising large screens at each entrance to the university to provide information to the drivers. Also, interviewees recommended enabling the user to click on a button to confirm that he/she has arrived. Furthermore, stakeholders suggested applying rules about carpooling to convince the students and staff to set up a car-sharing system (a website would be created to support this). Moreover, some suggested using the system to cover all the parking spaces to let the driver know about the parking status. Besides, some stakeholders advised strongly against using a reservation option in the app. (It should be used to get information about the status of parking spaces, they believed, so they need it only to allow them to go directly to the less occupied ones). And to make the system more accurate, there was a suggestion from stakeholders regarding security staff - many stakeholders suggested that there was a need for crew safety, which are employed by the Buildings and Estates department to intervene if a driver finds someone has taken his/her place.

Finally, the ultimate problem may emerge from users, whose mistakes or deliberate ignorance may challenge the system. This raises the question of whether the system serves the users or if the users are serving the system. While it is technically possible to design a system that leaves almost no room for a user's ad-hoc behaviour, such a system may be too complex to be deployed (e.g. physical barriers preventing entry or exit from unauthorized individual locations) [1].

21. The Final Visualization of our Model System

According to the qualitative research with stakeholders, we can conclude that the system would be beneficial for two cases. On the one hand, it would be useful when the parking area is large and by guiding a driver to vacant spaces. Figure 4 represents the model, and a general perception of the system in the final image was that different size lots are desired so the user can easily can recognize the vacant parking space. On the other hand, it is also beneficial in a case when a parking area is small and active.

Conclusion and Future Work

To conclude, the objectives of this research have been achieved. The aggravation involved in searching for vacant parking spaces can been minimised by informing the driver about the status of parking areas. Although much work has been done on smart parking, the work reported in this paper is based upon IoT cams (nodes). We propose a novel architecture for low cost and flexible smart parking using CCTVs (nodes). The system is intended to use previously installed CCTV cameras at any parking space instead of using dedicated systems, which would be more expensive.

Upgrades are currently being done to ensure better reliability and scalability for the proposed system. Some adjustments are being done which focus on making the algorithms effective to cover more parking spots. More iterations of UCD will be applied to the process regarding evaluation of our prototype in order to improve the quality of service. Also, In our future work, we will consider the security aspects of our prototype system as well as implement the system in large scales in real environments.

Conflict of Interest

The authors declare no conflict of interest.

Acknowledgment

The authors would like to thank our colleagues in Interaction Design Centre- IDC in UL for their support in pursing this work. We also would like to acknowledge the support of the Ministry of Higher Education and Scientific Research-Tripoli for their funding of the project. Also, part of the article is taken from our previous work as referenced in [1].

We propose the use of the pitch rate of free-form speech recorded by smartphones as an index of voice disability. This research compares the effectiveness of pitch rate, jitter, shimmer, and harmonic-to-noise ratio (HNR) as indices of voice disability in English, German, and Japanese. Normally, the evaluation of these indices is performed using long-vowel sounds; however, this study included the recitation of a set passage, which is more similar to free-form speech. The results showed that for English, the jitter, shimmer, and HNR were very effective indices for long-vowel sounds, but the shimmer and HNR for read speech were considerably worse. Although the effectiveness of jitter as an index was maintained for read speech, the pitch rate was better in distinguishing between healthy individuals and patients with illnesses affecting their voice. The read speech results in German, Japanese, and English were similar, and the pitch rate showed the greatest efficiency for identification. Nevertheless, compared to English, the identification efficiency for the other two languages was lower.

1. Introduction

This paper is an extension of the work originally presented in IEEE Engineering in Medicine and Biology Society(EMBS) 2016 [1], with the main addition being the evaluation of German and Japanese samples, in addition to the previously evaluated English data.

In recent years, the widespread use of smartphones has created interest in pathological analysis that utilizes voice data [2-4]. Voice analysis by smartphones has the advantages of being non-invasive and requiring no specialized equipment; therefore, it can be performed easily and even remotely.

It is known that changes in voice characteristics due to various illnesses can be observed. For example, patients with Parkinson's disease often also suffer from dysarthria and stuttering. Additionally, patients with illnesses affecting the vocal cords or larynx may have hoarse voices.

To date, jitter, shimmer, and the harmonic-to-noise ratio (HNR) have been proposed as indices to describe the degree of voice disability [5–8]. Previous research on the use of these indices in the analysis of illness has shown that patients with depression pronounce vowels with higher shimmer and jitter values. Additionally, it has been shown that the frequencies of the first and second formants of depression patient speech are lower than those of healthy individuals [9]. In other research, the Lyapunov exponents and Kolmogrov entropy of the voices of depression patients were measured using chaos analysis methods [10]. Additionally, Zhou et al. have proposed new feature values derived from the Teager energy operator for the classification of voices under stress [11].

Research in the relationship between mental illness and voice has been conducted by analyzing the speaking rate [12-14], as well as the switching pause and percent pause [13, 15] of depression patients.

The objective of this study is to identify and evaluate characteristics that can be used to discriminate between voices of healthy individuals and those of disorder patients based on voice recordings of free-form speech.

[*]Shuji Shinohara, The University of Tokyo, 7-3-1 Hongo Bunkyuo-ku Tokyo 113-8655 Japan, +81-3-5800-9168 & shinokan99@m.u-tokyo.ac.jp

https://dx.doi.org/10.25046/aj020397

For this purpose, we focused on pitch degradation as an index representing sonic perturbations in patients' voices. As a measure of this feature, we devised the concept of the pitch rate to express the ease of pitch detection in voices.

2. Materials and Methods

2.1. Voice acquisition

For the voice evaluations, we used the Disordered Voice Database and Program, Model 4337, from KayPENTAX, a division of Pentax Medical Inc. This database contains recordings of the voices of approximately 700 persons (healthy individuals and patients), with two types of sounds from each individual: the long-vowel sound "ah" (lasting approximately 3 s for healthy individuals and approximately 1 s for patients) and a read speech from the "Rainbow passage" (approximately the first 12 s).

The voice recordings of read speech from 715 individuals contain samples from 53 healthy individuals and 662 patients. The voice recordings of long vowels from 711 persons include samples from 53 healthy individuals and 658 patients. The various disorders in the patients are (duplication observed): hyperfunction (288), paralysis (77), Anterior-Posterior squeezing (182), gastric reflux (54), vocal fold edema (46), and ventricular compression (109). The format used for recording had a sampling frequency of either 25 kHz or 50 kHz with 16-bit quantization.

Conventionally, long-vowel sounds are used in the evaluation of jitter, shimmer, and HNR.

Among the data of 658 patients, no jitter, shimmer, or HNR could be detected in 13 patients regarding the long-vowel sound "ah". Therefore, we used the data of 698 persons, including 53 healthy individuals and 645 patients.

The long-vowel sound "ah" does not change fundamentally between languages. In contrast, reciting a passage involves language differences based on the actual words used and pronunciation. In our research, we used the read speech of passages in Japanese and German, in addition to English, to investigate the language dependence of the proposed indices. Details regarding German and Japanese speech are provided below.

German speech was evaluated using the "Saarbruecken Voice Database" (http://stimmdb.coli.uni-saarland.de/) from the Institute of Phonetics of Saarland University. This voice database is available for free download, and it includes samples from over 2000 people. In our research, we used the samples of healthy individuals and patients with dysphonia saying "Guten morgen, wie geht esIhnen?" ("Good morning, how are you?") from this database. The number of voice files used was 632 from healthy individuals and 101 from patients with dysphonia. These samples had a sampling frequency of 50 kHz with 16-bit quantization.

Japanese speech was evaluated using voice samples from "Assessment of Motor Speech for Dysarthria" [16]. This CD contains voice samples from patients with dysarthria caused by various illnesses and from healthy individuals. All samples included recordings of readings from Aesop's fable "The North Wind and the Sun"; however, the samples from dysarthria patients also contained free-form speech. For this reason, the patient files were classified into a read-speech group and a free-form speech group. For consistency, only the read-speech samples of "The North Wind and the Sun" were used in the comparisons between patients and healthy individuals. Meanwhile, the free-form speech samples were compared to the read-speech samples of the same patients and evaluated to determine the presence of any differences between them. In this collection of samples, speech samples of the same patient were categorized and saved under multiple illnesses, so the duplicate voice files were erased. As a result, the total number of voice files from healthy individuals and patients was 6 and 35, respectively. These voice files had a sampling rate of 44.1 kHz with 16-bit quantization.

2.2. Evaluation method

Using the aforementioned data, we calculated the pitch rate, jitter, shimmer, and HNR, and compared the results of healthy individuals and patients. To evaluate the performance of each index in discriminating between patients and healthy individuals, we used the area under the curve (AUC) in the receiver-operating characteristic (ROC) plot, the sensitivity, and the specificity.

2.3. Evaluation index

We used the Praat software version 5.4.10 (http://www.fon.hum.uva.nl/praat/) to analyze the jitter, shimmer, and HNR. While shimmer measures the fluctuations in voice loudness, jitter measures the fluctuations in voice pitch and is affected by the tension and hardness of the vocal cords. The HNR is a measure of stability of the harmonic structure and indicates voice disorders, in particular, the degree of hoarseness. In this study, we used ppq5 for jitter, apq5 for shimmer, and harmonicity for HNR. In addition to these evaluation indices, we have introduced the pitch rate, which was devised by us, as an index for voice disability.

2.4. Pitch rate

Conventionally, jitter, shimmer, and HNR have been used as the measure representing the disturbance of the periodicity of speech waves. However, these cannot be measured with respect to the portion of the data in which the fundamental frequency cannot be detected. Furthermore, we focused on the ease of detection of the pitch rather than its value. The pitch detection ratio (pitch rate) is defined as the percentage of frames in which the fundamental frequency can be detected.

In normal voice recordings, there are silent intervals between utterances. In these intervals, the pitch cannot be detected. This means that the pitch rate is affected by the length of such intervals.

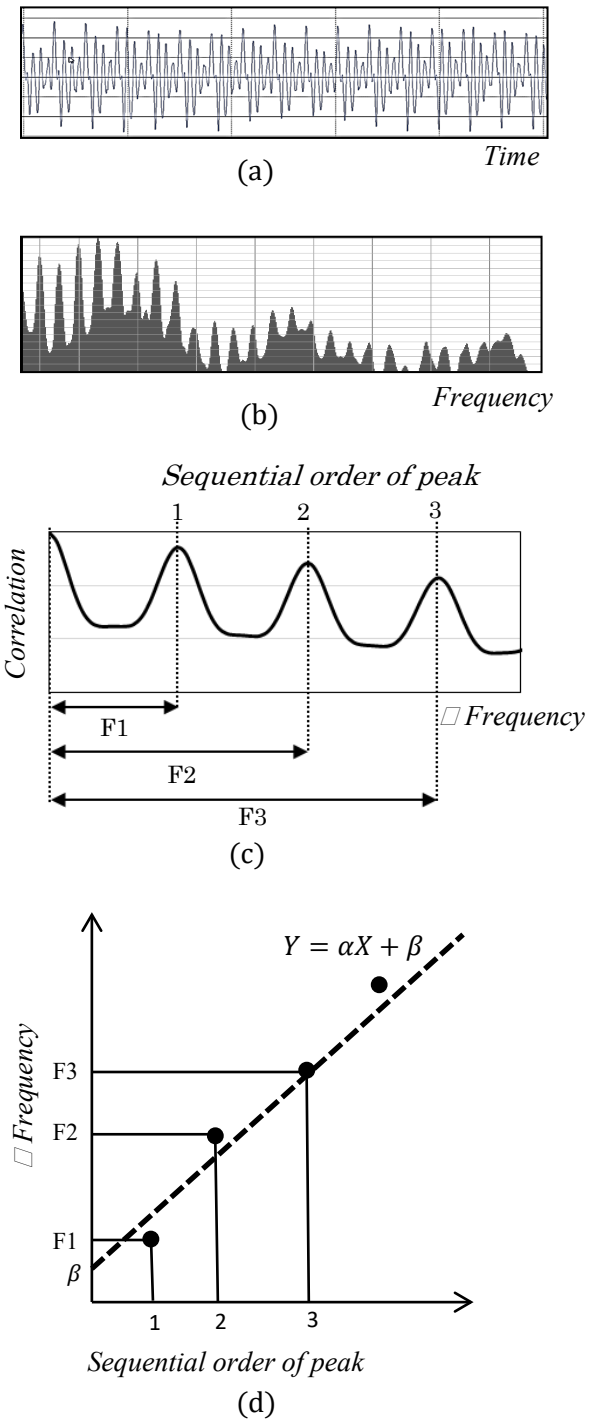

Figure 1. The pitch detection process. Details are listed in the text. (a) Voice signal, (b) frequency spectrum, (c) autocorrelation of the frequency spectrum, (d) plot of peak number and frequency shift exhibiting linear regression.

Therefore, to calculate the pitch rate, the data of these intervals must be excluded from the voice data. For this purpose, we used the Sensibility Technology software, version 3.0 (AGI Inc., Tokyo, Japan) [17-19].

After the speech interval data were extracted, the data were separated into frames of length L. However, each frame was offset from the previous frame by L/4 (i.e., 3/4 of each frame overlapped with the previous frame). We set L to equal 46.44 ms, which corresponds to 512 data points at a sampling rate of 11025 Hz.

The pitch was calculated for each frame using the methods described below [20, 21]. First, the voice signal waveform (Figure 1a) was processed by a fast Fourier transform (Figure 1b). Next, the Fourier spectrum autocorrelation was calculated, and the corresponding peaks were determined. Each peak was assigned a sequential number, and the change in frequency, ΔFrequency (i.e., F1, F1, F3…) was determined (Figure 1c). Lastly, the peak number was plotted on the X axis, the change in frequency was plotted on the Y axis, and a linear regression of the form $Y=\alpha X+\beta$ was determined (Figure 1d). If the linear regression had a coefficient of determination R larger than the threshold θ_1, and the absolute value of the y-intercept β was smaller than the threshold θ_2, then the pitch was considered as detected. Furthermore, if the pitch was detected, the slope of the linear regression α represented the pitch value.

$$pitch\ detection = \begin{cases} 1(detected)\ if\ R > \theta_1\ and\ |\beta| < \theta_2 \\ 0(not\ detected) \qquad otherwise \end{cases} \quad (1)$$

The pitch rate of every speech interval was determined by dividing the total number of frames by the number of frames in which the pitch was detected (which were subsequently analyzed). The frames that were analyzed were selected by the following methods. First, the value of the average power of the entire speech interval was determined. Next, the average power of each frame was calculated; if it was at least θ_3% higher than the average power in the entire speech interval, the frame was selected for analysis. In the research presented in IEEE EMBS 2016, we established a threshold for the absolute power was to select frames for analysis: if the average power of a frame exceeded this threshold, that frame was selected for analysis. However, in this study, we defined a relative value for this threshold. It must be noted that because of this change, the number of values provided in the Results section is different from that stated in IEEE EMBS 2016.

After the pitch rate was calculated for each speech interval, the average pitch rate of all speech intervals included in the voice files was determined; this average value was considered as the pitch rate for the corresponding voice files.

While jitter and shimmer are measures representing small disturbances of the periodicity within the range in which pitch can be detected, the pitch rate can be described as a measure representing a large disturbance of periodicity, such that the pitch cannot be detected.

If the intensity or the pitch varies continuously, the jitter and shimmer are affected. On the other hand, even if the intensity or the pitch fluctuates, the pitch rate is not affected, as long as the fluctuations are sufficiently small to detect the pitch. That is, the pitch rate is robust against fluctuations. Even if the amplitude, period, or the harmonic structure is greatly disturbed, the pitch rate diminishes. That is, the pitch rate can be described as a compositive index that included jitter, shimmer, and HNR. Therefore, it can be considered to be a rough indicator in comparison with conventional indicators.

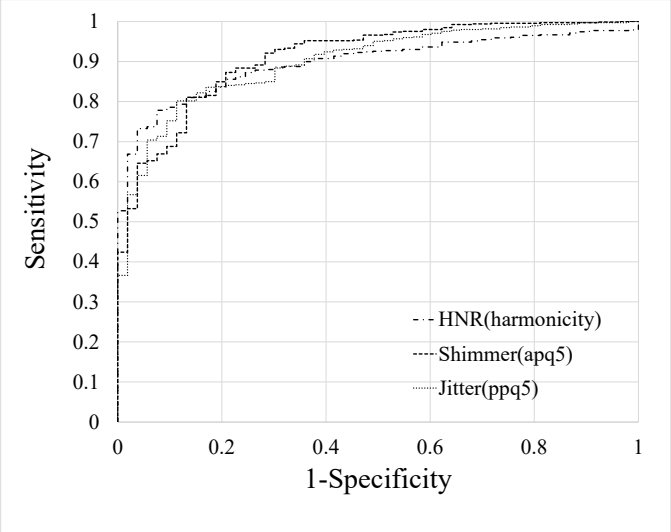

Figure 2 ROC curves used for discriminating between healthy individuals and patients using the jitter, shimmer, and HNR in the data of the long-vowel sound "ah".

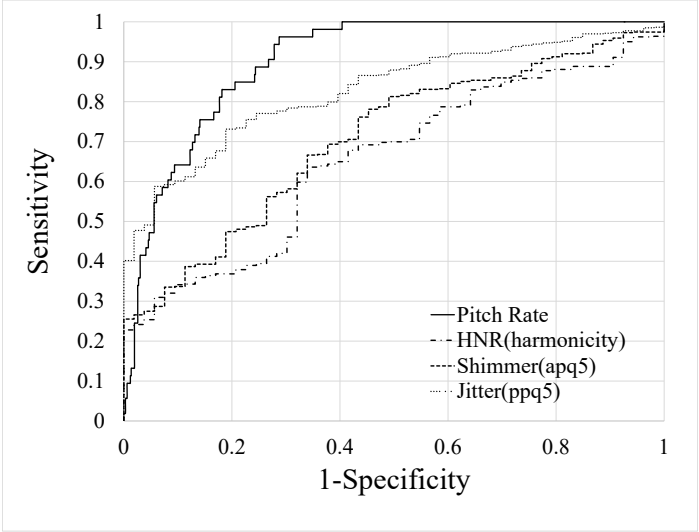

Figure 3 ROC curves used for discriminating between healthy individuals and patients using the pitch rate, jitter, shimmer, and HNR in the "Rainbow passage" read speech data.

The purpose of this study is to distinguish patients based on free-form speech rather than long-vowel sounds. Because more uncertainties are included in free-form speech compared with long vowels, we consider that a rough indicator is more adequate for free-form speech.

3. Results

3.1. Ability to discriminate based on long-vowel sound

TABLE 1. The mean values for healthy individuals and patient in the data of the long-vowel sound "ah"

Index	*Healthy Individuals (n=53)*	*Patients (n=645)*	*P-value*
Jitter (ppq5)	0.0016±0.00066	0.0061±0.0078	$1.23\cdot10^{-39}$
Shimmer (apq5)	0.012±0.0062	0.039±0.0293	$7.04\cdot10^{-55}$
HNR (harmonicity)	23.94±2.86	15.18±6.19	$4.76\cdot10^{-34}$

Table 1 shows the mean values for healthy individuals and patients in the data of the long vowel sound “ah”.

With respect to jitter, the mean values for healthy individuals and patients were 0.0016 (Number of Subjects (n) = 53, Standard Deviation (SD) = 0.00066) and 0.0061(n = 645, SD= 0.0078), respectively. Based on the t-test, significant differences were observed between the two groups ($t(695) = -14.05$, $p = 1.23\cdot10^{-39}$).

Regarding shimmer, the mean values for healthy individuals and patients were 0.012 (n = 53, SD = 0.0062) and 0.039 (n = 645, SD = 0.0293), respectively. Based on the t-test, significant differences were observed between the two groups ($t(329) = -19.01$, $p = 7.04\cdot10^{-55}$).

With respect to the HNR, the mean values for healthy individuals and patients were 23.94 (n = 53, SD = 2.86) and 15.18 (n = 645, SD = 6.19), respectively. Based on the t-test, significant differences were observed between the two groups ($t(97) = 18.77$, $p = 4.76\cdot10^{-34}$).

Figure 2 shows the ROC curves, which demonstrate the discrimination between healthy individuals and patients using these indices. The horizontal axis represents 1-specificity (false positive rate) and the vertical axis represents sensitivity (true positive rate).

Table 2 shows the AUC for the ROC curve, sensitivity, and specificity for these indices. The best discriminability was achieved by the shimmer in terms of AUC and sensitivity and by the HNR regarding specificity. For all the indices, the AUC was approximately 0.9, showing a strong discriminability between healthy individuals and patients.

TABLE 2. The discriminability of the indices (for the long-vowel sound "ah")

Index	*AUC*	*Sensitivity*	*Specificity*
Jitter (ppq5)	0.900	0.802	0.887
Shimmer (apq5)	0.911	0.811	0.868
HNR (harmonicity)	0.897	0.778	0.925

3.2. Ability to discriminate based on read speech in English

TABLE 3. The mean values for healthy individuals and patients in the data of read speech of "rainbow passage"

Index	*Healthy Individuals (n=53)*	*Patients (n=662)*	*P-value*
Pitch rate	0.903±0.047	0.643±0.25	$8.98\cdot10^{-39}$
Jitter (ppq5)	0.0084±0.0016	0.014±0.0076	$2.84\cdot10^{-39}$
Shimmer (apq5)	0.042±0.010	0.057±0.026	$4.55\cdot10^{-14}$
HNR (harmonicity)	13.12±2.18	11.41±3.48	$1.91\cdot10^{-6}$

Regarding the total speech time, the average values of healthy individuals and patients were 10089.23 ms (n = 53, SD = 734.33), and 9270.70 ms (n = 662, SD = 1394.42), respectively. As a result of the t-test, there was a significant difference between them (t(86) = 7.15, p = $2.71 \cdot 10^{-10}$).

Table 3 shows the mean values for healthy individuals and patients in the data of read speech of “Rainbow Passage”.

With respect to pitch rate, the mean values for healthy individuals and patients were 0.903 (n = 53, SD = 0.047) and 0.643 (n = 662, SD = 0.25), respectively. Based on the t-test, significant differences were observed between the two groups (t(394) = 22.285, p = $8.98 \cdot 10^{-39}$).

With respect to jitter, the mean values for healthy individuals and patients were 0.0084 (n = 53, SD = 0.0016) and 0.014 (n = 662, SD = 0.0076), respectively. Based on the t-test, significant differences were observed between the two groups (t(321) = −15.09, p = $2.84 \cdot 10^{-39}$).

With respect to shimmer, the mean values for healthy individuals and patients were 0.042 (n = 53, SD = 0.010) and 0.057 (n = 662, SD = 0.026), respectively. Based on the t-test, significant differences were observed between the two groups (t(117) = −8.58, p = $4.55 \cdot 10^{-14}$).

Regarding the HNR, the mean values for healthy individuals and patients were 13.12 (n = 53, SD=2.18) and 11.41(n=662, SD=3.48), respectively. Based on the t-test, significant differences were observed between the two groups (t(75) = 5.166, p = $1.91 \cdot 10^{-6}$).

TABLE 4. Discriminability of the indices (for read speech of "rainbow passage")

Index	*AUC*	*Sensitivity*	*Specificity*
Pitch rate	0.902	0.962	0.713
Jitter (ppq5)	0.827	0.588	0.943
Shimmer (apq5)	0.706	0.761	0.566
HNR (harmonicity)	0.655	0.636	0.660

Figure 3 shows the ROC curves, which demonstrate the discrimination between healthy individuals and patients using these indices.

Table 4 shows the AUC for the ROC curve, sensitivity, and specificity for these indices. The pitch rate had the best values for the AUC and sensitivity. However, the jitter had the best value for specificity. Compared to Table 1, the AUC for the shimmer and HNR was considerably reduced.

3. 3. Ability to discriminate based on read speech in German

Regarding the total speech time, the average values of healthy individuals and patients were 1561.81 ms (n = 632, SD = 331.24) and 1920.62 ms (n = 101, SD = 488.37), respectively. As a result of the t-test, there was a significant difference between them (t (115) = −7.13, p = $9.67 \cdot 10^{-11}$).

TABLE 5. The mean values for healthy individuals and patients in the data of read speech of "Guten Morgen, wie geht es Ihnen?"

Index	*Healthy Individuals (n=632)*	*Patients (n=101)*	*P-value*
Pitch rate	0.826±0.094	0.701±0.180	$6.55 \cdot 10^{-10}$
Jitter (ppq5)	0.0101±0.0028	0.0122±0.0056	0.00039
Shimmer (apq5)	0.036±0.012	0.045±0.019	$4.48 \cdot 10^{-5}$
HNR (harmonicity)	14.89±2.29	14.47±3.27	0.22

Table 5 shows the mean values for healthy individuals and patients in the data of read speech of “Guten Morgen, wie geht es Ihnen?”.

With respect to the pitch rate, the mean values for healthy individuals and patients were 0.826 (n = 632, SD = 0.094) and 0.701 (n = 101, SD = 0.180), respectively. Based on the t-test, significant differences were observed between the two groups

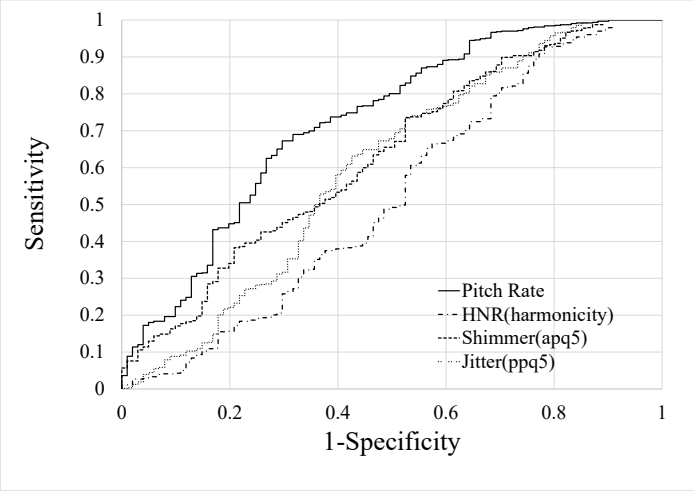

Figure 4 ROC curves used for discriminating between healthy individuals and patients using the pitch rate, jitter, shimmer, and HNR in data containing read speech of "Guten Morgen, wie geht es Ihnen?"(German).

(t(109) = 6.78, p = $6.55 \cdot 10^{-10}$).

With respect to jitter, the mean values for healthy individuals and patients were 0.0101 (n = 632, SD = 0.0028) and 0.0122 (n = 101, SD = 0.0056), respectively. Based on the t-test, significant differences were observed between the two groups (t(632) =−3.66, p = 0.00039).

Regarding shimmer, the mean values for healthy individuals and patients were 0.036 (n = 632, SD = 0.012) and 0.045 (n = 101, SD = 0.019), respectively. Based on the t-test, significant differences were observed between the two groups (t(112) = −4.25, p = $4.48 \cdot 10^{-5}$).

With respect to the HNR, the mean values for healthy individuals and patients were 14.89 (n = 632, SD = 2.29) and 14.47 (n = 101, SD = 3.27), respectively. Based on the t-test, no significant differences were observed between the two groups (t(116) = 1.230, p = 0.22).

As shown above, in all indexes other than the HNR, there were significant differences between healthy individuals and patients.

Figure 4 shows the ROC curves, which demonstrate the discrimination between healthy individuals and patients using these indices.

TABLE 6. Discriminability of the indices (for read speech of "'Guten Morgen, wie geht es Ihnen?'")

Index	*AUC*	*Sensitivity*	*Specificity*
Pitch rate	0.725	0.672	0.703
Jitter (ppq5)	0.598	0.734	0.475
Shimmer (apq5)	0.628	0.736	0.475
HNR (harmonicity)	0.519	0.927	0.218

Table 6 shows the AUC for the ROC curve, sensitivity, and specificity for these indices. For the AUC and specificity, the pitch rate was the most suitable. In terms of sensitivity, the HNR showed the best value. However, the value of the AUC tended to be lower than in the case of English.

3.4. Ability to discriminate based on read speech in Japanese

Regarding the total speech time, the average values of healthy individuals and patients were 26144.17 ms (n = 6, SD = 2995.73) and 18676.11 ms (n = 35, SD = 5145.64), respectively. As a result of the t-test, there was a significant difference between them (t(39) = 3.43, p = 0.0014).

TABLE 7. The mean values for healthy individuals and patients in the data of read speech of " Kitakaze to Taiyo "

Index	*Healthy Individuals (n=6)*	*Patients (n=35)*	*P-value*
Pitch rate	0.831±0.051	0.668±0.232	0.00078
Jitter (ppq5)	0.011±0.0026	0.013±0.0084	0.12
Shimmer (apq5)	0.040±0.014	0.0625±0.035	0.013
HNR (harmonicity)	13.64±2.46	11.85±3.59	0.25

Table 7 shows the mean values for healthy individuals and patients in the data of read speech of "Guten Morgen, wie geht es Ihnen?".

Regarding pitch rate, the mean values for healthy individuals and patients were 0.831 (n = 6, SD = 0.051) and 0.668 (n = 35, SD = 0.232), respectively. Based on the t-test, significant differences were observed between the two groups (t(36) = 3.67, p = 0.00078).

With respect to the jitter, the mean values for healthy individuals and patients were 0.011 (n = 6, SD = 0.0026) and 0.013 (n = 35, SD = 0.0084), respectively. Based on the t-test, no significant differences were observed between the two groups (t(26) = −1.61, p = 0.12).

Regarding shimmer, the mean values for healthy individuals and patients were 0.040 (n = 6, SD = 0.014) and 0.062 (n = 35, SD = 0.035), respectively. Based on the t-test, no significant differences were observed between the two groups (t(19) = −2.76, p = 0.013).

With respect to the HNR, the mean values for healthy individuals and patients were 13.64 (n = 6, SD = 2.46) and 11.85 (n = 35, SD = 3.59), respectively. Based on the t-test, no significant differences were observed between the two groups (t(39) = 1.17, p = 0.25).

As shown above, there was a significant difference between healthy individuals and patients only in the pitch rate.

Figure 5 shows the ROC curves, which display the discrimination between healthy individuals and patients using these indices.

TABLE 8. Discriminability of the indices (for read speech of "Kitakaze to Taiyo")

Index	*AUC*	*Sensitivity*	*Specificity*
Pitch rate	0.752	0.833	0.686
Jitter (ppq5)	0.562	1	0.343
Shimmer (apq5)	0.733	1	0.486
HNR (harmonicity)	0.624	1	0.314

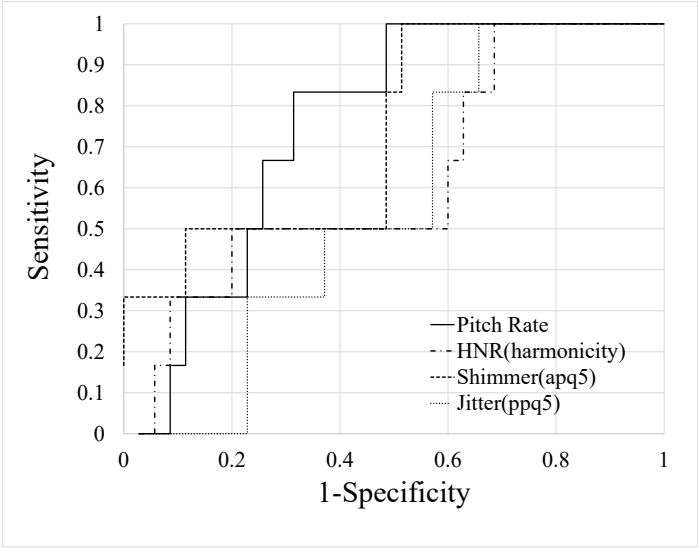

Figure 5 ROC curves used for discriminating between healthy individuals and patients using the pitch rate, jitter, shimmer, and HNR in the data containing read speech of "Kitakaze to taiyo" (Japanese).

Table 8 shows the AUC for the ROC curve, sensitivity, and specificity for these indices. For the AUC and specificity, the pitch rate was the most suitable. The sensitivity was 1 for all indices other than the pitch detection rate. As with German, the value of the AUC tended to be lower than in English.

Patient speech in Japanese included both read speech and free-form speech; these were separated manually. The differences between free-form speech and the recitation of a passage were investigated using these voice samples.

With respect to jitter, the mean values for reading and free-form speech were 0.013 (n = 35, SD = 0.007) and 0.013 (n = 35, SD = 0.008), respectively. Based on the t-test, no significant differences were observed between the two groups (t(68) = −0.304, p = 0.762). The correlation coefficient between them was 0.88.

With respect to shimmer, the mean values for reading and free-form speech were 0.059 (n = 35, SD = 0.030) and 0.067 (n = 35, SD = 0.034), respectively. Based on the t-test, no significant differences were observed between the two groups (t(68) = −0.95, p = 0.348). The correlation coefficient was 0.88.

With respect to the HNR, the mean values for reading and free-form speech were 12.30 (n = 35, SD = 3.23) and 11.65 (n = 35, SD = 3.56), respectively. Based on the t-test, no significant differences were observed between the two groups ($t(68) = -0.806$, $p = 0.423$). The correlation coefficient was 0.85.

With respect to pitch rate the mean values for reading and free-form speech were 0.668 (n = 35, SD = 0.232) and 0.582 (n = 35, SD = 0.277), respectively. Based on the t-test, no significant differences were observed between the two groups ($t(68) = 1.41$, $p = 0.162$). The correlation coefficient was 0.79.

4. Discussion and Conclusion

In this article, we propose a method for predicting whether a voice sample belongs to a healthy individual or a patient based on the pitch rate of a speech interval in English, German, and Japanese speech. Similar studies conducting comparative analyses of healthy individuals and patients have been performed using the same samples [22, 23]. However, those studies utilized voice samples of the long-vowel sound "ah." Instead, our research focused on the detection of illness via a smartphone using free-form speech in the form of reciting a set passage.

As shown in Table 2, in the case of the long-vowel sound, the jitter, shimmer, and HNR all resulted in an AUC of approximately 0.9, showing that these indices have good discriminability. However, as shown in Table 4, in the case of read speech, the discriminability diminished. In particular, for the shimmer and HNR, the AUC decreased considerably, to approximately 0.7 or lower.

In contrast, in the case of read speech, the pitch rate resulted in an AUC exceeding 0.9, demonstrating better discriminability between healthy individuals and patients than the conventional indices. However, in the case of the long-vowel sound, the pitch rate for both healthy individuals and patients was approximately 1.0, making it unsuitable for discrimination between healthy individuals and patients.

As stated above, the AUC of the pitch rate for the English passage was 0.902, which was a favorable outcome. In German and Japanese, the pitch rate showed the highest identification efficiency, as was the case in English. However, the AUC values were 0.725 and 0.752 for German and Japanese, respectively, which is more than 0.15 lower that the AUC value for English. In English, the average pitch rate values for healthy individuals and for patients were 0.903 and 0.643, respectively. The corresponding values in German were 0.826 and 0.701 and in Japanese 0.831 and 0.668, respectively. These results demonstrate that the healthy individual pitch rates in German and Japanese are lower than the healthy individual pitch rates in English and the patient pitch rates in German and Japanese are higher than the patient pitch rates in English. Differences in patient pitch rates may be due to differences in the severity of illnesses among the patients in the databases.

However, the question of why healthy individuals reciting in English have a higher pitch rate than in the other two languages remains. This could be owing to the characteristics of the languages, and the differences in the contents of the recited passages could also be a factor. Furthermore, the different sampling frequency used for each database and differences in the noise from the recording environment could be factors contributing to the pitch rate discrepancy.

Regarding the difference in the speech contents, in German, for example, the passage used was a greeting used in daily life, which is close to free-form speech. The influence of these differences was examined in Japanese patient speech through a comparison of free-form speech and read speech. The results showed that all indices—jitter, shimmer, HNR, and pitch rate—had a strong correlation of about 0.75 to 0.85 between free-form speech and read speech. In addition, there was a significant difference between free-form speech and read speech only in the pitch detection rate. The average value of the pitch detection rate was 0.582 in the case of free-form speech and 0.668 in case of read speech, and the free-form speech tends to be lower. Perhaps the German pitch detection rate is lower than that of English because the content of the speech is close to free conversation.

Additionally, the average total speech time for the German passage used was 1561.81 ms for healthy individuals, which is extremely short compared to the English passage (10089.23 ms) and the Japanese passage (26144.17 ms). However, because the average pitch rate value was calculated for each utterance, the difference in the total length of the voice samples is not expected to have an effect on the results.

The thresholds θ_1, θ_2, and θ_3, used for the pitch rate calculation algorithm described in section 2.4 had the same value for every language. In a separate pilot study, it was determined that if the thresholds are set at an appropriate value for each separate language, the AUC for German and Japanese exceeds 0.8. Therefore, these thresholds may need to be tuned separately for each language. These points will be further evaluated in future studies.

Although we have demonstrated that for read speech, the pitch rate has high discriminability, it must be noted that read speech and everyday conversation in telephone calls are not equivalent. In the read speech data used here, both the healthy individuals and the patients read the same sentences. However, in everyday conversation, the content is diverse. For example, the percentage of consonants varies in each case and the pitch rate decreases when there are more consonants. It has been reported [24] that compared with read speech, spontaneous speech can better classify patients with major depressive disorders. We believe that further studies are required on the effects of the speech content on the pitch rate or the differences between read speech and spontaneous speech.

Although long vowels can be recorded by using a smartphone, it is necessary that day-to-day recording is performed regularly. It has been reported [25] that the frequency of voice recording in such conditions gradually decreases compared with telephone calls.

In this study, we used the algorithm proposed in [20, 21]. The pitch rate itself is naturally affected by the performance of the algorithm. However, if the algorithms are used to process the same pitch, although there may be variations in the absolute pitch rate values, we believe that the relative magnitude relationship between healthy individuals and patients will not change. This means that it is likely that differences in the algorithm do not adversely affect the discriminability between healthy individuals and patients. This is also a topic for future study.

In this study, each analysis was performed for well-recorded speech signals using a PC processor. However, when analyzing real speech recorded in real conditions using smartphones, the analysis might be influenced by the audio transducer or processor of the smartphone. These points are under verification.

The voice database used in the study contained data from patients with diverse disorders. It can therefore be argued that although we have suggested an index to broadly discriminate between healthy individuals and patients, this index cannot be applied to diagnose a specific disorder. In the future, we aim to develop algorithms for diagnosing specific disorders.

Conflict of Interest

The authors declare no conflict of interest.

ABSTRACT

The host immune system is a key player in anticancer therapy response and resistance. Although the impact of host immune response in the 'war against cancer' has been studied and it has been the basis for immunotherapy, understanding of its role in attenuating the action of conventional anticancer therapies is an area that has not been fully explored. In spite of advances in systemic therapy, the 5-year survival rate for adenocarcinoma is still a mere 13% and the primary reason for treatment failure is believed to be due to acquired resistance to therapy. Hence, there is a need for identifying reliable biomarkers for guided treatment of lung and colon adenocarcinoma and to better predict the outcomes of specific anticancer therapies. In this work, gene expression data were analyzed using public resources and this study shows how host immune competence underscores the efficacy of various anticancer therapies. Additionally, the result provides insight on the regulation of certain biochemical pathways relating to the immune system, and suggests that smart chemotherapeutic intervention strategies could be based on a patient's immune profile.

1. Introduction

Cancer immunology has been studied and researched over many years to unravel the key mechanisms that determine therapeutic synergy or antagonism for cancer patients based on individual host immune environments. Traditional chemotherapy and other targeted therapies have been effective in combating many types of cancer. However, the efficacy of these interventions is determined by off-target effects within the host immune system [1]. Review of the literature shows that host immune response is key to the success of anticancer therapies through a process known as immune-surveillance [2].

Studies have shown that type-1 interferon can convert tumor associated macrophages (TAMs) into tumor-antagonizing macrophages by up-regulating the expression of dendritic cells in breast cancer. This results in increased CD8+ T cell population with reduced tumor growth and metastasis. As such, the combination of chemotherapy together with drugs that repolarize TAMs may be exploited to achieve greater patient responses and prevent resistance mechanisms within the immune system [3]. Some chemotherapeutics skew the polarization of macrophages directly, or indirectly via regulating cancer cell secreted factors [4]. FOXP3 expressing regulatory T cells (Tregs) are well-known for their immunosuppressive function in tumors [5]. They are a subset of CD4+ T cell population, which are involved with adaptive immune response. Tregs are known to be sensitive to cyclophosphamide and their depletion improves the potency of platinum-containing chemotherapeutic drugs against lung adenocarcinoma [6].

Another study has shown that Interleukin-17 (IL-17) producing CD4+ T cells limit the ability of 5-Flouro Uracil (5-FU) to delay the growth of subcutaneous thymoma cells. In contrast, IL-17 elevates the therapeutic efficacy of doxorubicin in sarcoma. Hence, the mode of action of these CD4+ T cell is paradoxical and depends widely on the cancer type [6]. However, their manipulation may be a useful strategy to determine the efficacy of chemotherapy.

Host immune response is known to significantly regulate the response of anti-angiogenic therapies [7]. Studies suggests that TAMs counteract the potency of anti-angiogenic agents; one such example is anti-angiopoietin 2 (ANGPT2), which decreases the blood vessel density of tumor and promote its remission. Interestingly, it also prevents the TIE2-expressing macrophages from associating with endothelial cells [8]. Together, these findings support the rationale for combining anti-angiogenic drugs with macrophage-targeting strategies to increase the efficacy of the former, particularly in tumors that develop resistance to anti-VEGF therapy. Despite the scientific progress in the field, a complete understanding of the role of the host immune system's response in improving the efficacy of anticancer therapies is greatly needed. There has been no systematic analysis carried out to evaluate the efficacy of different anticancer treatments based on host immune profile and subsequent application of this knowledge to develop reliable biomarkers to predict how well patients will respond to a treatment interventions.

Lung cancer continues to be the leading cause of death in industrialized countries and most commonly occurring disease among smokers. It can be broadly categorized into small cell lung cancer (SCLC) and non-small cell lung cancer (NSCLC). About 80-89% of patients suffer from the latter with most common being lung adenocarcinoma (LUAD), which has the average survival rate of 12-15% [9]. It develops on the outer parts of the lung or 'in-situ' and tends to grow slower than other types of cancer resulting in late-stage detection and a paucity of late stage treatments.

Colon adenocarcinoma (COAD) is the third most common cause of cancer mortality worldwide and fourth in the United States. Even though the 5-year survival rates have improved over the last 3 decades with ~95% in stage-I, it still remains low for stage III (~61%) and reaches only 8% for patients in stage IV. The treatment regimen involves mainly two classes of chemotherapy-alkylating agents and antimetabolites. However, the therapy is often insufficiently effective, with some patients exhibiting strong chemo-resistance. Therefore, host immune-competency plays a vital role to promote immunosurvelliance and disease regression [10].

Chemotherapy is one of the most common interventions for cancer care. It uses certain drugs to kill cancer cells or to stop them from growing and spreading to other parts of the body. This therapy works by damaging the DNA inside the nucleus of the transformed cells. While some drugs damage cells at the point of cell division, others damage the cells during DNA replication prior to division. Based on these differences in the mechanism of action, the chemo drugs can be classified into three main therapy types [11]:

(i) Alkylating agents: This class of drug directly targets DNA to repress a cell from reproducing. These drugs are not cell cycle specific and can be used for wide range of cancers.

(ii) Antimetabolites: This class of drug interferes with DNA and RNA synthesis by substituting for the normal building blocks of nucleotides. These agents damage cells during the S phase of cell cycle, when the cell's chromosomes are being copied.

(iii) Mitotic inhibitors: This class of drug is primarily derived from plant alkaloids and other natural products, and they operate by stopping mitosis in the M phase of the cell cycle by disrupting microtubule formation.

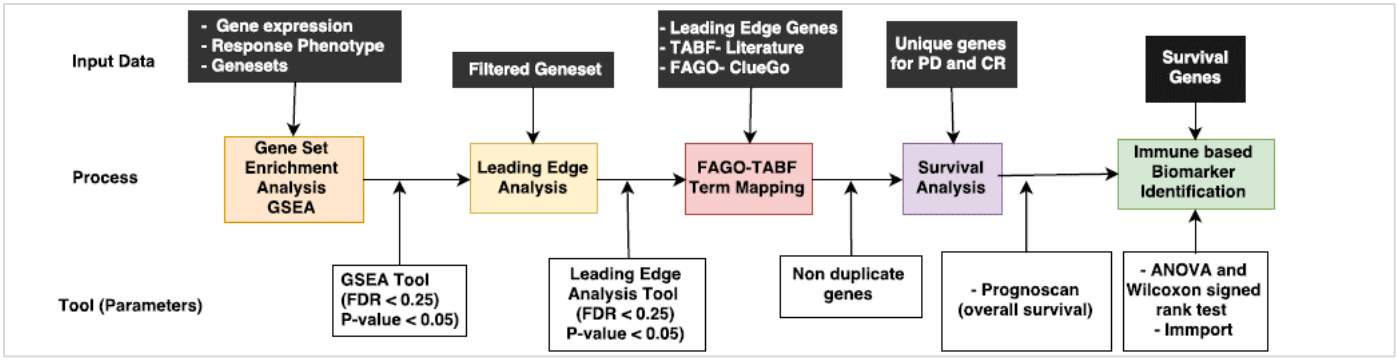
(iv) Anti-Angiogenesis: This class of drug is most widely used in the domain of vascular-mediated therapy [12], which is another class of treatment strategy that involves the impairment of tumor nutrition by targeting tumor blood vessel.

The single gene analysis method has been instrumental in our understanding of cell-biological processes, especially in elucidating the correlation between mutation and cancer. However, with increased understanding of the disease etiology, we have come to realize that it is not usually a single gene but a set that contribute to the clinical manifestation of cancer. Hence, it is more relevant to study the changes initiated by a set of genes, which can dramatically alter various cell biological and metabolic pathways. Along this vein the commonly used approaches to analyze a geneset are by over representation or aggregate score calculation. The latter is more reliable as it calculates the aggregate score for each geneset based on the gene-specific scores for that geneset and overcomes the limitations of over-representation analysis, which relies on the cutoff used in generating the geneset and can vary considerably depending on the gene list [13].

High throughput data like RNA-seq and microarray have fueled knowledge-based approaches like Gene Set Enrichment Analysis (GSEA), with access to publically available datasets for gene expression and clinical outcomes from TCGA. GSEA is widely used in studies that compare and contrast two conditions (for example disease vs. normal states) and usually focuses on a handful of genes that are either up or down regulated in the process. Therefore, in the present study we used GSEA to extract significant information at the level of functionally related geneset between the two clinical conditions (Fig 1.).

While GSEA provides a 'bird's eye view' of interactions between the drug treatment and the geneset significantly overrepresented in the phenotype being compared, not all the members in the geneset contribute equally to attain significant enrichment. As described by Subramanian et al., there are leading edge subsets of genes within the set that appear in the ranked-list before the point at which the running sum reaches its maximum deviation from zero [14]. These sets of genes are called 'leading edge genes' as they contribute more to the enrichment score of a geneset during geneset enrichment analysis. A gene that is in many of the leading edge subsets is more likely to be of higher significance or interest compared to other genes. called 'leading edge genes' as they contribute more to the enrichment score of a geneset during geneset enrichment analysis. A gene that is in many of the leading edge subsets is more likely to be of higher significance or interest compared to other genes.

In the current study, we used publically available datasets from TCGA for lung and colon adenocarcinoma samples along with the therapy regimen and response type - *Progressive Disease* (PD) (ineffective therapy with continued growth and spreading of cancer), and *Complete Remission* (CR) (state of disappearance of all signs of cancer in response to a treatment regimen) - to come up with putative biomarkers specific for both cancer types and different anticancer therapies using GSEA. Finally, to determine the prognostic ability of these biomarkers, we performed survival analysis.



2. Material and Methods

2.1. Data Access and Processing

The Cancer Genome Atlas (TCGA) public resource was used to download RNAseq gene expression datasets (level 3) for lung adenocarcinoma (LUAD) and colon adenocarcinoma (COAD). The expression set was quantified using RSEM method (RNA-seq by expectation maximization). Additionally, the genesets were obtained from MsigDB (http://software. broadinstitute.org/gsea/msigdb), which was explicitly integrated with the GSEA tool [15]. Five geneset categories, namely, *hallmark, canonical pathways (CP), GO genesets (C5), oncogenic signatures (C6) and immunologic signatures (C7)* were selected from the MsigDB collection, which included genes involved in cancer, immunology and biochemical pathways. The information relating to therapeutic interventions including drug name and response type for these patients was obtained from Nationwide Children's Hospital, which serves as the Biospecimen Core Resource (BCR) for TCGA.

The clinical data for lung adenocarcinoma consisted of four therapies discussed in the previous section, whereas alkylating agents and antimetabolites were the most preferred intervention for colon adenocarcinoma [16]. The drug information and patient response were then mapped with gene expression data using the TCGA ID as the primary identifier as shown in Table 1.

Table 1. Four therapy-classes were identified based on the information obtained from BCR for TCGA- LUAD tumor samples. Each named-drug used on the patients are listed under respective therapy-class.

Alkylating Therapy	Mitotic Inhibitor	Antimetabolite	Anti-angiogenesis
Cholrambucil, carmustine, dacarbazine, temozolomide, altretamine, cisplatin, carboplatin, oxalaplatin	Taxol, Ixabepilone, vinblastine, vinorelbine	5- Flourouracil, capecitabine, floxuridine, gemcitabine	Avastin, sunitnib

2.2 GSEA

2.3 Leading Edge Genes

We performed leading edge analysis on the enrichment results from GSEA, to identify genes that were significantly enriched across the PD vs. CR in LUAD and COAD. The leading edge analysis was carried out for genesets that were significantly enriched in the GSEA (FDR < 0.25, p-value < 0.05) across different geneset categories (C5, CP, hallmark, C7 and C6) and for all anticancer therapies. The leading edge genes obtained from the analysis were merged for each geneset category into the PD upregulated and CR upregulated groups.

2.4 Functional Association of Leading Edge Genes with GO terms (FAGO)

In order to extract functional annotation for the leading edge genes we used ClueGo, a Cytoscape plugin [17] that gives biological interpretation and systematic organization for a large list of genes. The list of leading edges genes for each anticancer therapy (for both PD and CR separately) was provided to ClueGo to obtain a list of gene-clusters that are functionally associated with a specific GO functional categories including biological processes (BP), cellular component (CC), molecular function (MF) and immune based terms. From a large list of GO terms, the terms that had significant p-value and high percentage term association were extracted and labeled as *'functionally associated GO terms'* (FAGO). There were several repetitive terms which performed similar function. Merging of all such FAGO terms helped us in downstream analysis.

2.5 Therapy Associated Biological Functions (TABF)

Each anticancer therapy has a different mechanism of action to stop the cancer cells from growing; each mechanism evokes perturbations in a complex system with several immunological processes and biological pathways involved. To evaluate the efficacy of each intervention, a comprehensive understanding of the mode of drug-action and the processes/pathways affected is necessary. Therefore, we searched the literature for concepts related to action mechanism in each drug category which were known to affect the efficacy of the therapy. These concepts/terms were labeled as '*therapy associated biological functions'* (TABF).

2.6 Mapping of TABF with FAGO terms

To identify relevant biological function affected by a therapy, we integrated TABF term for each therapy with related FAGO terms. While TABF term provided experimental evidence through the literature, FAGO defined concepts used to describe gene function. For instance, STAT3 signaling is known to be involved with tumorigenesis in all chemotherapies [18]. Here *'STAT3 Signaling'* is TABF and it is mapped with all the related GO terms (FAGO terms) present in PD.

2.7 Extraction of Unique Genes and Survival Analysis

The genes associated with mapped FAGO–TABF terms were retrieved for both disease outcome phenotype (PD and CR) as well as for all therapy groups. The duplicate gene entries were discarded and the list of genes from each therapy were compared to determine common and mutually exclusive genes between all therapies in both phenotypes (PD and CR). Survival analysis was performed for genes unique to each therapy using PrognoScan - a survival prediction tool with a collection of publicly available cancer survival data [19]. A list of genes specific to each treatment and phenotype was provided as input for the PrognoScan tool [20]. The survival performance was evaluated based on p-value, where a value < 0.05 indicated good overall survival while a greater value indicated poor survival. The genes obtained from survival analysis were further evaluated for immune related function using Immport which is a comprehensive list of immune related genes [21].

2.8 Study of Expression Variance for Biomarker Prediction

We performed statistical tests (ANOVA and Wilcoxon signed rank test) to detect putative biomarker genes whose expression significantly varied across the two phenotypes (PD vs CR) for each anticancer therapy in LUAD and COAD samples.

3. Results

3.1. Data

As shown in Table 1. 129 samples along with therapy information were obtained from BCR-TCGA for LUAD. Alkylating agents had the highest number of samples (60) due to its wide drug target spectrum, whereas 42 samples were divided amongst alkylating agents and antimetabolite therapy for COAD with clinical outcome (PD vs. CR) as shown in Table 1 with almost equal number of samples.

3.2. Gene Set Enrichment Analysis (GSEA)

Gene sets were filtered based on the p-value cutoff (<0.05) and FDR (<0.25), and we found significantly higher enrichment for complete remission in all four therapies for LUAD as reported in Table 2. High enrichment of oncogenic signatures (C6) in CR phenotype were reported for antimetabolite (PD: 0, CR: ~53%), mitotic inhibitor (PD: ~5%, CR: ~24%) and anti-angiogenesis (PD: 0, CR: ~58%). No significant enrichment was recorded for canonical pathway (CP) in both PD and CR for alkylating agents. However, in COAD oncogenic signature geneset (C6), PD phenotype was highly enriched in both therapies and a similar trend was observed for the hallmark geneset category as shown in Table 2. That said, the C7 category (immunogenic signatures) was equally enriched in PD and in CR for alkylating agents. Between lung and colon adenocarcinomas, we found higher overall enrichment for PD in COAD as opposed to LUAD.

Table 1. Distribution of LUAD and COAD samples based on therapy and outcome (PD vs CR) obtained from BCR-TCGA.

Therapy	Lung adenocarcinoma (LUAD)			Colon Adenocarcinoma (COAD)		
	Progressive Disease	Complete Remission	Total (Therapy wise)	Progressive Disease	Complete Remission	Total (Therapy wise)
	PD	CR		PD	CR	
Alkylating Agent	13	47	60	7	12	19
Antimetabolite	7	26	33	13	10	23
Mitotic Inhibitor	5	10	15	-----	-----	-----
Anti-angiogenesis	6	15	21	-----	-----	-----
Total(Response Type)	31	98	129	20	22	42

Table 2. Enrichment percentage for significantly enriched (p< 0.05, FDR < 0.25) genesets from GSEA across PD vs. CR in each anticancer therapy for LUAD and COAD samples.

Lung Adenocarcinoma (LUAD)	Progressive disease (PD)					Complete Remission (CR)				
	C5	C6	C7	CP	Hallmark	C5	C6	C7	CP	Hallmark
Alkylating agent	0	4.20%	0.30%	0	26%	1.4%	7.4%	0.4%	0.0%	6%
Antimetabolite	0.2%	0	0	0.9%	0	0.2%	51.3%	1.2%	9.9%	20%
Mitotic Inhibitor	1.9%	4.8%	2.4%	10.7%	38%	8.2%	24.3%	4.7%	8.2%	32%
Anti-angiogenesis	2.5%	0.0%	1.7%	1.4%	14%	10.9%	57.7%	3.8%	5.8%	36%
Colon Adenocarcinoma (COAD)	Progressive disease (PD)					Complete Remission (CR)				
	C5	C6	C7	CP	Hallmark	C5	C6	C7	CP	Hallmark
Alkylating agent	9.2%	20.6%	7.5%	4.0%	16.0%	0.0%	0.0%	8.2%	5.2%	0.0%
Antimetabolite	5.9%	23.2%	6.6%	2.7%	22.0%	1.2%	0.0%	0.1%	0.1%	2.0%

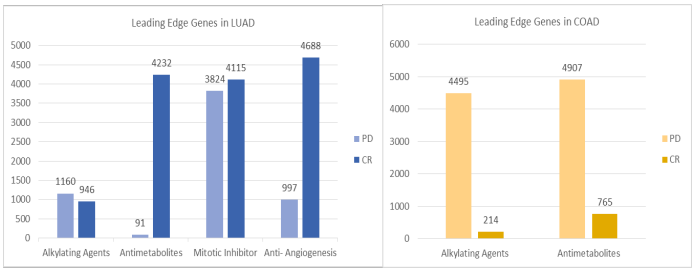
3.3. Leading Edge Genes

This trend was reversed in the case of COAD, where large number of leading edge genes enriched across PD for both the alkylating agents (PD:4495, CR:214) and antimetabolite therapies (PD:4907, CR:765) as shown in Figure 2. This result is consistent with the GSEA results shown in Table 2.

3.4. TABF-FAGO term mapping

We next sought to identify the functions associated with the genes within various enriched genesets. The *Functionally Associated GO-terms* (FAGO) for all the genesets were obtained, using ClueGO analysis. The number of genes associated with each of the GO terms is shown in Table 3. Majority of the FAGO terms belong to biological processes (BP) or immune-related processes

for both LUAD and COAD. The TABF terms and mapped FAGO terms are reported in Tables 1-12 in Appendix I section and have been explained in detail in the discussion section.



3.5. Survival analysis and Biomarker Discovery

The set of non-repetitive genes from each TABF-FAGO term mapping was extracted for survival analysis. However, due to the interest in seeking specific biomarkers for each therapy, only genes that were unique and non-overlapping between the anticancer therapies were extracted. The result showed 120 common leading genes across all four therapies for CR and 0 genes common across PD in LUAD. Similar to the analysis of genes unique to the therapy, analysis of these 120 common genes was also completed as shown in Figure 3. However with COAD data, both alkylating agents and antimetabolite therapies target the cell cycle and are involved in its disruption, which explains the large number of overlapping genes for both PD (103 genes) and CR (l107 genes) as shown in Figure 3.

Table 3. The number of FAGO terms mapped with TABF terms in each GO term category for all the anticancer therapies across PD and CR for LUAD and COAD samples.

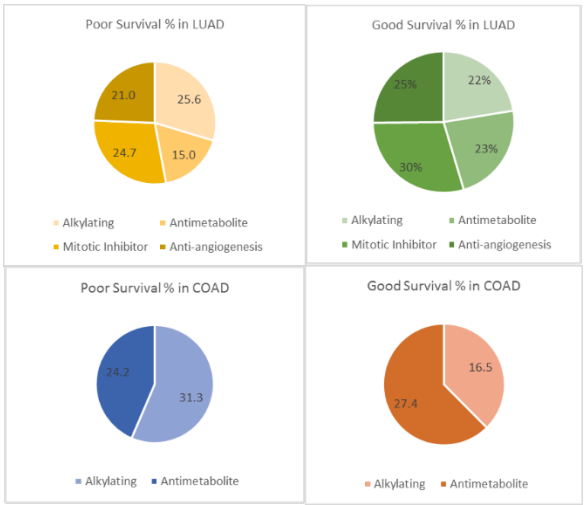
Simultaneously, the number of immune-related genes in each case using a comprehensive list of known immune related genes from Immport was evaluated. Results show a good percentage of immune related genes. Of all these total genes involved in good and poor survival, ~39% genes (in CR) ~48% genes (in PD) for LUAD, and ~42% genes (in PD) and ~14.6% (in CR) for COAD were related to immune response as shown in Table 4.

3.6. Expression Variance

The gene expression data was used in statistically analyzing expression variance across the PD vs. CR for all survival genes using ANOVA and Wilcoxon ranked test. The immune-related genes, which showed significant expression variance (p-value < 0.05), are presented in Table 5 for LUAD and Table 6 for COAD. In lung adenocarcinoma, the data resulted in 2 immune-related biomarkers for alkylating agents and 6 for antimetabolites, 17 gene biomarkers for mitotic inhibitors, and 33 gene biomarkers



for anti-angiogenesis, as shown in Table 5. For colon adenocarcinoma, 5 biomarkers for alkylating agents and 8 expression biomarkers for antimetabolites were seen in Table 6. The expression biomarkers are represented as boxplots in Figure 5 and Figure 6, where a clear distinction between PD upregulation compared to CR for DEF126 in alkylating genes are seen for LUAD, while JUNB has very high overall expression with high variance for PD as compared to CR. In antimetabolites, we found a good differentiation in expression for two groups: PD vs. CR response phenotype, for all the 6 genes including SIVA1, DNM1 and TNFRSF14, which shows a significant variance with high expression for CR as shown in Figure 5. The highest number of gene expression biomarkers were found in mitotic inhibitors, with a mixture of PD and CR upregulated genes with immune-based function. SRGN, MAPT, ABR, NPBL, STXPB1, NFE2L1, AATF, and VEZF1 were genes with striking difference in expression across PD and CR. The anti-angiogenesis therapy had 17 genes with striking expression variance, with 3 genes upregulated for PD and 14 for CR. A significant expression variance was seen across PRAKAA2, F13A1, NUPR1, RAPGEF4 and STK38L in PD compared to CR.

In COAD, we found 35 significant immune-related biomarkers - NPPB, S100A3, PPBP, LCNL1, PRDX2, TNFRSF11A, S100G, LEFTY1, IL13RA2, CXCR1, S100A12, FAM3C, CCK, PSMD14, PROK2, IL20RB, S100A9, WNT5A, TNFRSF11B, INHBC, APLN, MALT1, IFNE, RLN2, KLRC2, NCR1, KLRC3, PSPN, CRLF3, IL15, CDH1, COLEC10, GAST, SP1, and CRABP2 were upregulated for PD while two genes, IL18RAP and IL24, were significantly upregulated for CR in alkylating agents. In antimetabolite therapy, 8 immune-related biomarkers were indicated: EIF2AK2, FABP5, FCN2, HRAS, IL10, NAMPT, SEMA4G, and TAP2 were upregulated for PD, and three genes, IGF2R, NOV, and IL17C, were upregulated for CR as shown in Figure 6.

Table 4. The number of survival analysis genes with known immune function for PD and CR in all the therapies for LUAD and COAD.

Lung Adenocarcinoma						
Therapy	Progressive Disease (PD)			Complete Remission (CR)		
	Poor Survival	immune related	immune %	Good Survival	immune related	immune %

4. Discussion

4.1. GSEA and Leading Edge Analysis

In this work, we used the public dataset from TCGA for lung and colon adenocarcinoma patients who were treated with different anticancer drugs. Due to the lack of sufficient pre-cancerous samples, this study investigated the efficacy of the treatment outcomes, which were PD and CR. Since alkylating agents were the most commonly used drug therapy for non-small cell lung cancer (NSCLC) [22] compared to other therapeutic agents, we obtained a high number of study samples for patients treated with drugs in this therapeutic category. Anti-angiogenesis therapy is relatively new in contrast to the other three therapies [23], and consists of around 20 compounds being tested - only a few of them have been FDA-approved for commercial use, which explains the relatively small sample size for this therapy class. As for colon cancer, chemotherapy (alkylating agents and antimetabolite drugs) is the preferred choice of treatment.

A geneset enrichment analysis on two datasets to evaluate pathway level differences between the two clinical responses, i.e. PD vs. CR, is presented in this study. In case of LUAD, higher enrichment for CR samples was seen as opposed to PD in all five geneset categories. Since the disease under study is cancer, the result explains the large number of genesets enriched for C6, which is an oncogenic signature category based on MsigDB as shown in Table 2. Also this pattern was consistent across the leading edge analysis, where we selected the genes that significantly contributed towards the enrichment signal of a geneset. Overall enrichment for CR was higher than PD for LUAD as shown in Figure 2.

This pattern was reversed for COAD where PD samples were more enriched than CR, as presented in Table 2, and reflects upon the chemoresistant nature of this cancer type. This result was translated further to explain the higher leading edge genes enriched for PD as compared to CR as shown in Figure 2. Moreover, oncogenic signatures were highly enriched compared to other geneset categories. However, unlike LUAD, a significantly higher enrichment percentage for immunogenic signatures (C7) was also observed, which suggests a more immuno-active behavior of COAD. This is supported by the report from Tougeron et al., [24] which described the immune response as vital factor in the progression of colon cancer, and there exists a close association between the prognosis of the disease and the rate of tumor-infiltrating lymphocytes. These results are concordant with a number of TABF-FAGO terms related to immune response function, as shown in Table 3.

4.2 TABF- FAGO term mapping

The results from Table 3 show the number of FAGO terms obtained from ClueGO analysis and mapped with TABF terms for both complete remission (CR) and progressive disease (PD). In this section we will try to comprehend these associations and their biological interpretations.

4.2.1 Alkylating agents – Complete Remission

a. Lung adenocarcinoma

The TABF-FAGO term mapping results for alkylating agents can be comprehended from its mechanism of action. Cytotoxicity is one of the most highly correlated topics between cancer and immune system. It is a process involved in cell toxication which trigger processes like apoptosis, necrosis, and cell lysis. Alkylating agents, as described earlier, are cytotoxic agents that target the process of cell division. The host immune system has its own set of agents that cause cytotoxicity. The main ones are lymphocytes, cytotoxicity T-cells and natural killer cells. The recent review from Kulawik [25] explains the role of cytotoxic T-lymphocytes in antitumor response in lung adenocarcinoma. The host immune system also plays a crucial role in the antitumor response with a population of CD8+ and CD4 + lymphocytes [26], neutrophils [27], NK-T, B and T cells triggering the process of apoptosis [28]. The process is often amplified with the help of macrophages and dendritic cells which contributes towards antigen presentation for a successful cytolytic attack [29]. Therefore, the TABF terms found from the literature, were categorized as: *cell cytotoxicity, macrophage activation, immune response and myeloid cell activation, regulation of T cell and lymphocyte activation*, and *B cell proliferation and activation.* These terms are known to contribute synergistically towards the efficacy of alkylating therapy and are known to show tumor remission. This explains FAGO terms related to cytotoxicity in complete remission and TABF-FAGO term mappings involved with activation of T-cell, B-cell, macrophage activation, and immune response as shown in Table 1- appendix.

Targeting some signaling pathways can prevent DNA damage response and increase the efficacy of chemotherapy. While signaling pathways are essential for normal stem cells, their dysregulation can lead to tumorigenesis [30]. They form a complex interconnected network and can be crucial in regulating the cell structure, apoptosis and macrophage polarity [31]. This explains signaling pathway related term mapping, upregulated in complete remission for alkylating agents. The process of leukocyte activation and differentiation is connected with inflammatory response, which is beneficial in normal cells, and leukocytic adhesion to endothelial tissues marks the beginning of the inflammation process. But as much as these processes are important in the normal cell functioning, they can be the reason of poor survival in cancer and their regulation is crucial for improved efficacy of chemotherapy specifically alkylating agents [32]. The negative regulation of tumor promoting leukocytes is therefore one of the most important processes in improving the efficacy of this intervention. The role of leukocytes and lymphocytes is paradoxical and their balance mediates the process of tumor regression or promotion [33].

Cytokines are secretory proteins that are involved in the regulation and activation of immune cell. The role of host-derived cytokines is insightful in understanding the cytokine-tumor cell interactions in the inhibition of cancer development. According to the review by Dranoff [34], host-derived cytokines can suppress tumor formation by controlling infection, inflammation and immunity. Our results were consistent with cytokine-associated FAGO terms upregulated in CR for alkylating therapy. The review also talks about IL-12 cytokine production by macrophages and dendritic cells inhibiting chemical carcinogenesis. We found chemical carcinogenesis pathway enriched in progressive disease while cytokine-related FAGO terms were upregulated to the opposite response (CR), which further validates and justifies our results. The host immune response can be categorized into two broad categories: innate and adaptive, where the former is the first line of defense and involves the activation of macrophages, neutrophils, granulocytes etc. while the latter activates B and T cell response and production of immunoglobulins [35]. The activation of adaptive immune response and immunoglobulin production with the process involving somatic recombination have shown to sensitize tumors to alkylating drugs and increasing the drug efficacy [36] which further explains TABF-FAGO term mapping in CR for LUAD**.**

b. Colon adenocarcinoma

Bracci et al., [37] discussed in-depth the relevance of host immune-competency for improved efficacy of chemotherapy. There are evidences of enhanced T and B lymphocytes in the spleen of animal model with colon cancer showing synergistic association with chemotherapy drugs like oxaliplatin, gemcitabine and 5-FU which explains the upregulation of B and T lymphocyte activation, proliferation and other terms related to the activation of immune system in CR for both alkylating agents and antimetabolite therapy. Mitochondria organization is a key player in release of cytochrome-c with subsequent activation of caspase-9 and -3 which reduces cell cycle progression and carcinogen activation, as well as promoting immunosurvelliance [38]. Furthermore, non-coding RNA processing is often associated with improved response to chemotherapy in colon cancer and are directly involved in DNA methylation, histone modification and gene silencing. In turn, they are epigenetically targeted for repression of cancer and improved drug therapy [39]. All these biological processes explain the upregulation of FAGO terms in Table 2- appendix.

4.2.2 Alkylating Agents – Progressive Disease

a) Lung adenocarcinoma

We obtained 18 FAGO terms that were successfully mapped with the TABF terms as shown in Table 3-appendix. Holland-Feir Cancer Medicine (6th ed.) [40] presents a complete review on alkylating agents and the factors affecting its efficacy. Alkylating agents induce cell cytotoxicity but its potency is determined by the host system. One such finding is the host response to alkylation damage by arresting the cell in the G2 phase of the cell cycle which in turn activates the DNA repair process, where cells enter the mitotic phase despite alkylation damage, which leads to therapy resistance. A human tumor cell line has been shown to exhibit G2 arrest in response to alkylating damage, resulting in resistance to nitrogen mustard [41] which clearly explains the upregulation of FAGO term*: regulation of cell cycle G1/S phase transition* in PD for lung cancer. In some cases, transcription factors involved in DNA transcription initiation are released in response to genotoxic stress (agents involved in DNA damage), which stimulate RNA polymerase and promote RNA binding. This eventually leads to mRNA synthesis and the process is called gene activation, further stimulating DNA repair mechanisms by the host system and promoting defense against alkylating agents

[42]. We found related FAGO terms upregulated in PD as shown in Table 3- appendix, which strongly correlates with the findings discussed above.

The relationship between inflammatory response and cancer progression was first discovered in the 19th century by Rudolf Virchow and is one of the most widely studied phenomena. There exists an established connection between leukocyte chemotaxis and inflammation. The movement of leukocytes from blood to tissue in response to inflammatory stimuli was observed by Metchnikoff in 1891. During inflammation, leukocytes migrate to the site of inflammation to fulfill their role in defense response [43]. Pathways involved in inflammation and wound healing have shown to be associated with promoting tumorigenesis, with increased resistance to anticancer treatments. Interestingly, there also exists a strong link between complement activation and inflammation. Generally, the complement cascade system is activated to defend a host against microbes during an inflammatory response. The activation of complement and its role in tumor progression is evident in studies conducted for different cancer types, including lung adenocarcinoma [44], breast [45] and thyroid cancer [46]. Consequently, we observed similar processes from ClueGO results where genes involved in inflammation, complement activation and defense response were activated in PD alongside genes responsible for positive regulation of leukocyte chemotaxis.

b) Colon adenocarcinoma

Colon cancer is strongly linked with inflammatory microenvironment composed of intestinal epithelial cells, immune cells, etc. which determine the fate of the intervention. Moreover, cytokines acts as a mediator between the host immune response and malignant cells that activate oncogenic transcription factor STAT3 which is a major activator in cancer inflammation and promotes cell cycle progression [47]. Holohan et al., explains the role of JAK-STAT signaling pathway in cell proliferation, tumor progression, and chemo-resistance [48]. We found the upregulation of several interleukin factors, e.g. IL-1, 2, 4, 6, and 10, in progressive disease for colon cancer. IL-6 is a major player in inflammatory response in COAD that interacts with the membrane-associated gp130 subunit and activates Janus kinases (JAKs) with downstream effects on STAT3 [49], which explains their role in tumor progression as shown in Table 4-appendix.

IL-6 can increase resistance to various chemotherapeutic drugs [50, 51] by preventing apoptosis and downstream signaling of MAPK cascade [52]. Moreover, the release angiogenesis growth factors greatly influence the drug response in solid tumors and evidence suggests their involvement in cancer cell survival in the presence of chemo drugs [53]. Furthermore, IL-1b is a pro-inflammatory cytokine which can modulate the response of different drug transports [54]. Tumor necrosis factor is a major inflammatory cytokine and is well known for its role in tumor progression and drug resistance. Therefore, the upregulation of this term in the PD category for alkylating agents is well explained [55]. Mccubre et al., discusses the effect of the ERK-signaling cascade in promoting tumorigenesis and resistance to doxorubicin treatment [56]. All these points support our results from TABF-FAGO term mapping for PD in alkylating agents in Table 4-appendix [57].

4.2.3 Antimetabolite – Complete Remission

a) Lung adenocarcinoma

Antimetabolites are another class of chemotherapeutic drug that inhibit the action of metabolites and interfere with DNA and RNA growth [58]. They replace the normal compounds in the cell, resulting in disrupted cell division and specifically targeting the synthetic phase of cell cycle [59]. Since antimetabolites disrupt cell division and DNA damage, the TABF and FAGO terms upregulated for complete remission were very similar to alkylating agents. We found FAGO terms related to cell cytotoxicity upregulated in CR, and the majority of the FAGO terms were similar to alkylating agents.

Naïve CD4+ T cells can be categorized into four main lineage: T helper cells -1, 2, 17 and Treg cells [60]. Th2 promotes tumor growth and Th1 produce cytokines like interferon gamma, which causes cytotoxic T lymphocytes (CTL) proliferation, resulting in tumor elimination and potentiating the action of chemotherapy [61].The host immune milieu is rich in cytokine and chemokines which can produce immune-stimulatory effects. For instance, type-I IFNs can enhance the stimulation of dendritic cells which activate Th1 and inhibits Treg activity [62]. Therefore, we saw FAGO terms associated with Th cell activation and cytokines in Table 5-appendix.

Signaling pathways are popular targets and critical to the success of an anticancer therapy [63]. For instance, activated PI3K/Akt/mTOR pathways can regulate cell proliferation, growth, and survival, and are important targets for the development of potential antitumor agents [64]. According to Wang et al [65], the activation of signal transduction pathways enhances the cellular response to drug treatment. Hence, we found various signaling pathways terms associated with CR.

The link between skeletal system development and the immune system has been recognized recently with an interdisciplinary field studying and embracing the relationship under the name of "osteoimmunology". Studies have also shown that osteoimmunology can be a potential target for anticancer interventions as several systems that are related to host immune response are actually related to skeletal function. Such information has been useful to understand the improved efficacy of anticancer drugs, especially antimetabolites [66]. Receptor activator of NF-kB (RANK)/RANK Ligand (RANKL)/Osteoprotegerin (OPG) system is involved in the regulation of osteoclastogenesis, which influences immune, cardiovascular, endocrine, and nervous systems. They stimulate the antigen-specific immune response and are involved in dendritic cell maturation and survival [67, 68]. Hence, this clearly explains the upregulation of TABF-FAGO association in Table 5-appendix.

b) Colon Adenocarcinoma

We observed the upregulation of terms related to T cell lymphocyte activation, proliferation and positive regulation of immune response, a consistent pattern for CR category in all chemotherapies for both lung and colon cancer. Additionally, we

found histone modification terms enriched in CR. Histone modifications are crucial to gene regulation processes by compacting DNA. Histones are often involved in maintaining the balance between euchromatin and heterochromatin by undergoing post-translational modification at the amino terminal ends. These modifications, e.g. methylation, acetylation, ubiquitination, etc. [69] are correlated with the efficacy of chemo drugs in numerous types of cancer (prostate, breast, colorectal, lung) and hematological malignancies. All these TABF terms with their mapped FAGO terms are presented in Table 6-appendix.

4.2.4 Antimetabolites – Progressive Disease

a) Lung adenocarcinoma

Almost 90% of genomic DNA is transcribed into RNA, but only 2% of this RNA is protein-coding; the remaining "dark matter" genomic content is transcribed into non-coding RNA (ncRNA) and has been implicated with biological significance particularly in cancer. According to Liu et al. [70], ncRNAs play a crucial role in tumor progression and resistance to chemotherapy. Expression of metastasis-associated lung adenocarcinoma transcript 1 (MALAT1), a long non-coding RNA (lncRNA) is associated with resistance to chemotherapy and poor prognosis in patients in non-small cell lung cancer [71]. Another interesting study was conducted by Mader and colleagues [72] that showed increased expression of thymidylate synthase (TS) resulted in resistance to antimetabolite drug –5 fluorouracil (5-FU), to incorporate with RNA. Our results for progressive disease were in consensus with the discussion as shown in Table 7 -appendix.

b) Colon adenocarcinoma

The upregulated terms in the PD category for antimetabolite therapies were similar to alkylating agents - *IL1 production, tumor necrosis factor production, inflammation,* and *ERK cascade*. This is explained by their both being chemotherapy drugs with similar modes of action. Slow growth of tumors or G0-G1 cell cycle promotes resistance against antimetabolite drugs, which explains the connection between the upregulation of G1/s , G2/M phase transition and the progression of disease in Table 8 -appendix. Furthermore, literature based study shows TNF-alpha increase post-drug recovery and tumor survival in colon cancer from 5-FU (antimetabolite drug) by obstructing S phase entry [73].

4.2.5 Mitotic Inhibitors – Complete remission

Mitotic inhibitors are derived from natural plant alkaloids. They disrupt microtubules involved in mitotic cell division process [74]. Even though the mechanism of action for this therapy is very similar to alkylating agents, it was interesting to see that the immune response varied with some unique FAGO – TABF term mapping. The terms that were similar to alkylating agents were: *T cell and lymphocyte activation, B cell activation, positive regulation of immune response* and *cell signaling*. The terms similar to antimetabolite therapies were related to *system development and KEGG signaling pathways*. Interestingly, we found some striking differences. Firstly, innate immune response was more active as compared to adaptive when compared to alkylating agents and antimetabolites. Secondly, we found significant upregulation of FAGO terms related to cyclic adenosine monophosphate (cAMP) processes, which is attributed to the fact that cAMP plays a fundamental role in cellular response. Regulation of cAMP pathways is associated with ion metabolism and apoptosis [75]. They are also known to intermingle with other signaling pathways like calcium [76], JAK/STAT inhibitors [77], and RAK-mediated MAPK kinases to modulate cell processes [78]. The upregulation of cAMP-related pathways is favorable for the action of antimitotic drugs [79] which justifies the upregulated FAGO terms in CR as shown in Table 9 -appendix.

Another paradoxical phenomenon that was observed in antimitotic agents was the upregulation of an inflammatory response in CR unlike the other therapies. Even though inflammatory response is often associated with tumor regression, in some cases it can enhance the action of antimitotic agents. Host macrophages secreting inflammatory cytokines have been shown to induce the expression of inducible nitric oxide synthase (iNOS). This potentiated the effect of paclitaxel to regress cancer in solid tumors and promoted apoptosis [80]. Since inflammatory response is a critical stage in the wound healing process [81], we could see that wound healing was upregulated alongside inflammatory response in CR as shown in Table 9 –appendix.

Another contradictory observation was upregulation of interleukin-10 (IL-10) which is an anti-inflammatory cytokine that downregulates cytokine production. The effect of host IL-10 in tumor progression or regression has been debated over a long time. While studies have shown that regulatory T cells (Treg) produce IL-10 which downregulates immune response [82], this is inconsistent with Mumm et al's [83] claim that IL-10 reduces tumor development by inducing cytolytic molecules in CD8+ T cells and IFN- gamma dependent mechanisms. The review by Teng et al. [84] talks about the significance of stable IL-10, which can be beneficial in the regressing tumor. So far, there has not been any strong evidence showing a positive correlation between host IL-10 expression and survival of cancer patients. Our results in Table 9 -appendix highlights the above discussion.

4.2.6 Mitotic Inhibitors – Progressive Disease

The key highlight in the PD category was the upregulation of terms: *antigen presentation and transporter-associated with antigen processing (TAP)*, which are known for their multidrug resistance in cancer. The experiment conducted on a human cancer cell line by Izquierdol and colleagues [85] present a strong correlation between TAP expression and resistance (~ 2 fold) to the antimitotic drugs doxorubicin and vincristine. Mitotic checkpoints and response to DNA damage have shown resistance against these drugs, as they sense microtubule attachment to kinetochore. According to Wang et al. [65], the activation or dysregulation of these mitotic checkpoints and DNA damage response leads to continued cell division and increased resistance to taxol (antimitotic drug). Table 10 -appendix shows the FAGO terms upregulated in PD for mitotic inhibitors.

4.2.7 Anti-Angiogenesis

Angiogenesis is the formation of new blood vessels and is known to play an essential role in tumor growth, as blood vessels supply oxygen and nutrients for the cancerous cell's nourishment. Angiogenesis inhibitors bind to the vascular endothelial growth

factor (VEGF) and prevent them from binding to the receptor in order to facilitate the process of vasculogenesis [86].

a) Complete Remission

The mechanism of action for this therapy is different from the other three types of chemotherapies discussed previously. There is a strong link between host immune response and anti-angiogenesis therapy. T-cell activation and VEGF share an antagonistic relationship where the latter inhibits the production of T cells by interfering with thymus development [87]. Therefore, T-cell activation has a positive effect on anti-angiogenesis therapy. To back up this hypothesis, we have the case study of semaphorins, axon guidance molecules belonging to the class of transmembrane proteins which are known to play a role in immune response and organ morphogenesis. Class IV semophorin (Sem4A), expressed on dendritic and B-cells, enhance T-cell activation and differentiation [88]. Toyofoku and colleagues demonstrated in their experiments that mice lacking Sem4A exhibit enhanced angiogenesis in response to VEGF or inflammatory stimuli [89]. Therefore, deeming Sem4A as an inhibitor of VEGF and angiogenesis. Our results are concurrent with the above discussion and presented in Table 11- appendix.

Hypoxia is a process of oxygen depletion in cells which induce pro-angiogenic factors along with inflammatory response. According the study conducted by Brustugun [90], hypoxia caused treatment failure in lung carcinoma. Resistance to gefitinib, extensively used in EGFR-mutated lung cancer, is also induced by hypoxia via upregulation of growth factor. Blocking chronic inflammation can prevent pro-tumor polarization and contribute to anti-angiogenesis effect. Therefore, we see the process of negative regulation of hypoxia upregulated in CR. Even though the wound healing process is connected with an inflammatory response, in the case of anti-angiogenesis therapy response wounding is seen to contribute to increased efficacy. Activated host healing response is a crucial process after the extensive surgery of solid tumors. Interleukin-6 (IL-6) can act as an inflammatory cytokine and also as an anti-inflammatory cytokine [91]. There are other cytokines (IL-20) that possess anti-angiogenesis properties [92] and their regulation enhances the efficacy of the therapy as reflected in Table 11- appendix.

b) Progressive Disease

We observed several immune-related terms upregulated in progressive disease for anti-angiogenesis therapy. We discussed the role of VEGF and other growth factors in promoting angiogenesis, which results in tumor progression. The results in Table 12 from appendix section show the upregulation of all these pathways which induce therapy resistance. MHC and antigen presentation are associated with a multidrug resistance class of proteins especially in lung cancer; the overexpression of the transporter protein is known to induce high resistance to therapy [93]. But further investigation is needed to understand their involvement with cancer progression and resistance. The review conducted by Zaidi and Merlino [94] talks about the paradoxical role of interferon gamma in producing immune response against tumors while also producing tumorigenic effects under certain conditions. Hence, response to interferon gamma has a role in reducing drug efficacy and promoting tumor progression. Innate immunity can release angiogenic factors and promote tumor angiogenesis. Therefore, the release of inflammatory cytokines by the host innate immune system can further diminish the response to drug therapy [95]. The activated DNA repair mechanism has shown resistance to cetuximab/Erbitux (an anti-angiogenesis drug) used to treat EGFR-expressing tumors [96]. Table 12 in appendix shows upregulated FAGO terms mapped with all the biological functions discussed above.

4.3 Survival analysis and Biomarkers

The prognostic ability of genes specific to each therapy were tested using survival analysis. We found several genes with significant overall survival for both LUAD and COAD as shown in Table 4, which further validates the role of host immune response and therapy outcome. As for the common genes across different therapies, there was no complete overlap of genes for LUAD in PD; this result is obvious, as all four therapies have different modes of action. But, interestingly, there was an overlap of 120 genes for CR, shown in Figure 3, with one gene (IL4R-interleukin 4 receptor) that showed significant expression variance and survival for lung adenocarcinoma. The role of IL4R has been paradoxical in cancer immunology and has often been debated. In our results, IL4 was seen to be involved with complete remission when treated with any of the three therapies: mitotic inhibitors, anti-angiogenesis and antimetabolite. This was validated further with the experimental evidence of overexpressed IL4R contributing towards remission in lung cancer patients [97].

However, in colon cancer, the two treatments under study have similar cell cycle targets. Hence, we found more overlapping genes between alkylating agents and antimetabolites as shown in Figure 3. While we found only 4 genes (FAM3C, CRLF3, CETP, VAV3) that showed significant survival and expression variance as shown in Figure 6, the first three showed higher expression for disease progression, while VAV3 was seen as CR upregulated. We also found literature evidence of VAV3 as one of the molecular signatures for colon cancer [98]. IL-17 is often associated with tumor promotion and acts as a pro-angiogenesis factor, while in some cases it has also been regarded as tumor suppressing, as shown by experimental studies from Kryczek et al. [99]. Therefore, its role has remained undefined. However, in our results, we found IL-17 to contribute towards complete remission in antimetabolite therapy for colon cancer.

5. Conclusion

The era of translational medicine has opened new horizons for personalized therapeutic interventions and spurred the development of novel prognostic therapy-based biomarkers for each patient's individual immune profile. It is now evident that the tumor–host immune interaction dictates the magnitude, quality and efficacy of most anticancer strategies. Despite this, in our knowledge, no systematic analysis has been performed to study expression and pathway-based differences of multiple anticancer therapies depending on patient's immunocompetence.

In this study, we used expression based analysis to come up with biomarkers with prognostic validity for different anticancer therapies in two cancer datasets, LUAD and COAD. We found many gene biomarkers, unique to a cancer type or therapy, which were either associated with the progression or remission of the intervention. Additionally, we also found a number of

overlapping genes across different therapies, of which some had a controversial status towards cancer promotion or regression. Our results predicted the outcome of therapy resistance alongside its improved efficacy to some extent. The scope of this study went further to understand some of the pathways and their mode of mechanism in-depth for different therapies in both cancer types. However, one major limitation of this study is the absence of experimental validation for these biomarkers even though the majority of the indicated genes in our results have corresponding correlations within the literature. Therefore, such information would be highly valuable for translational medicine and in making an accurate intervention choice.

This work is an extension of our previous conference paper published at BIBM IEEE 2016 [100].

Conflict of Interest

The authors declare no conflict of interest.

Appendix I

Table 1. TABF-FAGO terms upregulated in CR for alkylating agents (LUAD)

TABF Terms	FAGO terms upregulated in CR for Alkylating Agents
Cell cytotoxicity	positive regulation of leukocyte mediated cytotoxicity, regulation of leukocyte mediated cytotoxicity, natural killer cell mediated cytotoxicity, leukocyte activation involved in immune response, positive regulation of leukocyte activation, leukocyte differentiation, regulation of leukocyte differentiation, positive regulation of leukocyte mediated immunity, regulation of leukocyte mediated immunity, leukocyte proliferation, positive regulation of leukocyte differentiation, myeloid leukocyte differentiation, granulocyte migration, neutrophil chemotaxis
Marcophage Activation	macrophage differentiation
Immune Response and Myeloid Cell Activation	positive regulation of immune response, myeloid dendritic cell activation, activation of immune response, myeloid cell activation involved in immune response, mast cell activation, positive regulation of immune effector process, regulation of production of molecular mediator of immune response
Regulation of T cell and Lymphocyte Activation	positive regulation of lymphocyte differentiation, positive regulation of T cell differentiation, positive regulation of alpha-beta T cell activation, lymphocyte activation involved in immune response, alpha-beta T cell differentiation, CD4-positive, alpha-beta T cell differentiation involved in immune response, regulation of alpha-beta T cell differentiation, activated T cell proliferation, thymic T cell selection, regulation of T cell differentiation, regulation of lymphocyte activation, positive regulation of lymphocyte activation, T cell activation, lymphocyte differentiation, T cell differentiation, regulation of lymphocyte differentiation, regulation of T cell proliferation, positive regulation of T cell proliferation, T cell proliferation, regulation of alpha-beta T cell activation, T cell costimulation, positive regulation of lymphocyte mediated immunity, regulation of lymphocyte mediated immunity, lymphocyte mediated immunity
B cell Proliferation and Activation	regulation of B cell activation, B cell mediated immunity, B cell activation, B cell proliferation
Signaling pathways	Fc-epsilon receptor signaling pathway, Fc receptor signaling pathway, immune response-regulating cell surface receptor signaling pathway, immune response-regulating signaling pathway, immune response-activating signal transduction, antigen receptor-mediated signaling pathway, immune response-activating cell surface receptor signaling pathway, cell-cell signaling, cell surface receptor signaling pathway, cell-activation, cell migration, cell chemotaxis, Chemokine signaling pathway
Negative regulation of leukocyte and lymphocyte activation	negative regulation of leukocyte activation, negative regulation of lymphocyte activation, negative regulation of leukocyte differentiation
Cytokine activity	cytokine activity, cytokine receptor activity, cytokine receptor binding, Cytokine-cytokine receptor interaction, cellular response to cytokine stimulus, regulation of cytokine production
Adaptive Immune Response and Immunoglobulin Production	response based on somatic recombination of immune receptors built from immunoglobulin superfamily domains, adaptive immune response based on somatic recombination of immune receptors built from immunoglobulin superfamily domains positive regulation of adaptive immune response based on somatic recombination of immune receptors built from immunoglobulin superfamily domains, regulation of immunoglobulin mediated immune response

Table 2. TABF-FAGO terms upregulated in CR for alkylating agents (COAD)

TABF Terms	FAGO terms Upregulated in CR for Alkylating Agent
ncRNA processing	ncRNA metabolic process, RNA processing, RNA splicing, mRNA processing, gene silencing by RNA
mitochondrion organization	mitochondrial transport, mitochondrial transmembrane transport, mitochondrial electron transport, NADH to ubiquinone, mitochondrial respiratory chain complex I assembly, mitochondrial ATP synthesis coupled proton transport
activation of immune response	myeloid cell activation involved in immune response, adaptive immune response based on somatic recombination of immune receptors built from immunoglobulin superfamily domains, negative regulation of production of molecular mediator of immune response
T cell differentiation, proliferation, activation, lymphocyte aggregation	regulation of lymphocyte mediated immunity, lymphocyte costimulation, T cell mediated immunity, regulation of T cell proliferation, positive regulation of alpha-beta T cell activation, regulation of CD4-positive, alpha-beta T cell activation
B cell homeostasis	regulation of B cell proliferation, positive regulation of B cell proliferation, B cell proliferation

Table 3. TABF-FAGO terms upregulated in PD for alkylating agents (LUAD)

TABF Terms	FAGO Terms upregulated in PD for Alkylating agents
G1/S cell cycle regulation	regulation of cell cycle G1/S phase transition
Response to DNA damage	DNA-templated transcription, initiation intrinsic apoptotic signaling pathway in response to DNA damage, response to cycloheximide, transcription elongation from RNA polymerase I promoter
Leukocyte chemotaxis	positive regulation of leukocyte chemotaxis
Defense response	defense response, antibacterial humoral response, wound healing
Inflammation	inflammatory response
Complement activation	complement activation, alternative pathway
KEGG pathways in cancer	viral carcinogenesis, cancer carcinogenesis
Glutathione metabolism	Glutathione metabolism

Table 4. TABF-FAGO terms upregulated in PD for alkylating agents (COAD)

TABF Terms	FAGO terms Upregulated in PD for Alkylating Agents
negative regulation of immune response	negative regulation of production of molecular mediator of immune response, negative regulation of adaptive immune response, negative regulation of immune effector process
Interleukin production	interleukin-1 beta production, interleukin-1, 2,4 ,6 10 production
angiogenesis	positive regulation of angiogenesis, regulation of angiogenesis, blood vessel development
MAPK cascade	regulation of MAPK cascade, positive regulation of MAPK cascade
ERK1 and ERK2 cascade	positive regulation of ERK1 and ERK2 cascade,
cell proliferation/ differentiation	positive regulation of cell differentiation, positive regulation of mononuclear cell proliferation, cell differentiation, regulation of cell proliferation
cytokine production	regulation of cytokine biosynthetic process, cytokine-mediated signaling pathway, cellular response to cytokine stimulus, negative regulation of cytokine secretion
Inflammatory response	acute inflammatory response, chronic inflammatory response
negative regulation of wound healing	response to wounding, negative regulation of response to wounding, regulation of wound healing
interferon-gamma production	regulation of interferon-gamma production, positive regulation of interferon-gamma production
positive regulation of tumor necrosis factor production	chemokine production, positive regulation of tumor necrosis factor production, regulation of tumor necrosis factor superfamily cytokine production

Table 5. TABF-FAGO terms upregulated in CR for antimetabolites (LUAD)

TABF Terms	FAGO terms Upregulated in CR for Antimetabolite
Cell Cytotoxicity	leukocyte differentiation, negative regulation of leukocyte migration, leukocyte activation involved in immune response, monocyte chemotaxis, myeloid leukocyte differentiation, positive regulation of leukocyte migration, regulation of leukocyte chemotaxis, positive regulation of leukocyte chemotaxis, positive regulation of leukocyte activation, regulation of production of molecular mediator of immune response, regulation of leukocyte mediated immunity, positive regulation of
Cytokine and Chemokine Regulation	cytokine receptor activity, cytokine activity, cytokine receptor binding, chemokine receptor activity, Cytokine-cytokine receptor interaction, Chemokine signaling pathway
Adaptive Immune Response	regulation of adaptive immune response, regulation of adaptive immune response based on somatic recombination of immune receptors built from immunoglobulin superfamily domains,
Regulation of T cell and Lymphocyte Activation	T cell activation involved in immune response, T cell differentiation involved in immune response, alpha-beta T cell differentiation involved in immune response, regulation of lymphocyte mediated immunity, regulation of T-helper 1 type immune response, stem cell differentiation
Cell Signaling	cell surface receptor signaling pathway, G-protein coupled receptor signaling pathway, cell-cell signaling, Phospholipase D signaling pathway, PI3K-Akt signaling pathway, immune response-
KEGG Signaling pathway	Rap1 signaling pathway, Calcium signaling pathway, G-protein coupled receptor signaling pathway, Phospholipase D signaling pathway, PI3K-Akt signaling pathway
System development	cardiovascular system development, skeletal system development

Table 6. TABF-FAGO terms upregulated in CR for antimetabolite (COAD)

TABF Terms	FAGO terms Upregulated in CR for Antimetabolite
system development	nervous system development, anatomical structure morphogenesis, embryonic morphogenesis, embryonic limb morphogenesis, regulation of growth, organ growth, aorta development
histone modification	histone lysine methylation, histone H3-K9 modification, histone H3-K9 methylation, histone H3-K36 demethylation
T cell proliferation activation, leukocyte differentiation, lymphocyte differentiation	leukocyte cell-cell adhesion, leukocyte aggregation, lymphocyte aggregation, positive regulation of leukocyte proliferation, T cell proliferation, lymphocyte activation involved in immune response, leukocyte activation involved in immune response, positive regulation of leukocyte migration, positive regulation of lymphocyte proliferation
positive regulation of immune response	myeloid cell activation involved in immune response, regulation of production of molecular mediator of immune response, positive regulation of production of molecular mediator of immune response, positive regulation of innate immune response, positive regulation of immune effector process

Table 7. TABF-FAGO terms upregulated in PD for antimetabolites (LUAD)

TABF Terms	FAGO terms Upregulated in PD for Antimetabolite
RNA Processing	RNA processing, RNA 3'-end processing
ncRNA processing	ncRNA metabolic process

Table 8. TABF-FAGO terms upregulated in PD for antimetabolite (COAD)

TABF Terms	FAGO terms Upregulated in PD for Antimetabolite
JAKSTAT cascade	positive regulation of JAK-STAT cascade, tyrosine phosphorylation of STAT protein, regulation of tyrosine phosphorylation of STAT protein
G1/s , G2/M phase	cell cycle G1/S phase transition, cell cycle phase transition, mitotic cell cycle phase transition
Interleukin-1 production	interleukin-1 beta production, regulation of interleukin-1 secretion, positive regulation of interleukin-1 production
Inflammtion	inflammatory response, acute inflammatory response, production of molecular mediator involved in inflammatory response, regulation of inflammatory response
ERK cascade	regulation of ERK1 and ERK2 cascade
IFN production	response to interferon-gamma, interferon-gamma production
cytokine production	regulation of cytokine production, response to cytokine, cytokine secretion, cellular response to cytokine stimulus, cytokine-mediated signaling pathway
cellular response to tumor necrosis factor	Tumor necrosis factor superfamily cytokine production

Table 9. TABF-FAGO terms upregulated in CR for mitotic inhibitor (LUAD)

TABF Terms	FAGO terms Upregulated in CR for Mitotic Inhibitor
KEGG signaling pathway	signaling receptor activity, MAPK signaling pathway, Calcium signaling pathway, NF-kappa B signaling pathway, Phosphatidylinositol signaling system, Jak-STAT signaling pathway, cell surface receptor signaling pathway, G-protein coupled receptor signaling pathway
B cell activation	B cell proliferation, B cell activation,B cell differentiation
Innate immune response	positive regulation of immune response, activation of immune response, regulation of innate immune response
regulation of T cell and lymphocyte activation	T cell activation,T cell differentiation, alpha-beta T cell activation, alpha-beta T cell differentiation,CD4-positive, alpha-beta T cell differentiation,T cell selection, activated T cell proliferation,T cell differentiation in thymus, regulation of T cell activation, positive regulation of T cell activation, regulation of T cell differentiation, positive regulation of T cell differentiation, regulation of alpha-beta T cell activation, lymphocyte proliferation, lymphocyte activation involved in immune response, regulation of alpha-beta T cell differentiation, positive regulation of alpha-beta T cell activation, response to interferon-gamma, positive regulation of immune effector process, T cell proliferation, regulation of T cell proliferation, positive regulation of T cell proliferation, lymphocyte costimulation, T cell activation involved in immune response
Regulation of cAMP	cyclic nucleotide metabolic process, cyclic purine nucleotide metabolic process, cAMP metabolic process, cAMP biosynthetic process, regulation of cAMP biosynthetic process, positive regulation of cyclic nucleotide metabolic process, positive regulation of cAMP metabolic process
Inflammatory response	Inflammatory response
Cytokine Production	response to cytokine, Cytokine-cytokine receptor interaction, regulation of cytokine production, macrophage cytokine production, positive regulation of macrophage cytokine production, macrophage cytokine production, positive regulation of macrophage cytokine production

Table 10. TABF-FAGO terms upregulated in PD for mitotic inhibitors (LUAD)

TABF Terms	FAGO terms Upregulated in PD for Mitotic Inhibitor
Negative regulation of cell death	negative regulation of cell death, negative regulation of apoptotic process, negative regulation of programmed cell death
Mitotic Checkpoint and DNA damage response	DNA damage checkpoint, mitotic DNA damage checkpoint, negative regulation of cell cycle G1/S phase transition, mitotic G1 DNA damage checkpoint

Table 11. TABF-FAGO terms upregulated in CR for Anti-angiogenesis (LUAD)

TABF Terms	FAGO terms Upregulated in CR for Anti-angiogenesis
Negative regulation of inflammatory response	regulation of inflammatory response, negative regulation of inflammatory response
macrophage activation	macrophage differentiation
Negative regulation of angiogenesis	regulation of vasculature development, regulation of angiogenesis, negative regulation of angiogenesis
myeloid cell activation	myeloid cell differentiation , myeloid leukocyte differentiation, regulation of myeloid cell differentiation
regulation of T cell and lymphocyte activation	T cell activation, regulation of T cell activation, T cell differentiation, lymphocyte differentiation, regulation of lymphocyte activation, regulation of lymphocyte activation, lymphocyte proliferation
Apoptosis	cell death, apoptotic process
Cell signaling	cell surface receptor signaling pathway, cell-cell signaling, cell-substrate adhesion, cell-cell adhesion
Organ morphogenesis	skeletal system development, cardiovascular system development, heart development, embryo development, organ morphogenesis
B cell proliferation and activation	B cell activation, B cell differentiation
Regulation of interleukin 6	interleukin-6 production, tumor necrosis factor production, regulation of interleukin-6 production
Regulation of cytokines	cytokine activity, cytokine receptor binding, cytokine metabolic process, Cytokine-cytokine receptor interaction
Wounding	Response to wounding
Hemopoiesis	hemopoiesis, regulation of hemopoiesis, negative regulation of hypoxia
Regulation of leukocyte	myeloid leukocyte differentiation, regulation of myeloid cell differentiation, regulation of myeloid leukocyte differentiation, negative regulation of leukocyte differentiation, regulation of leukocyte chemotaxis

Table 12. TABF-FAGO terms upregulated in PD for anti-angiogenesis (LUAD)

TABF Terms	FAGO terms Upregulated in PD for Anti-angiogenesis
Angiogenesis	Angiogenesis, anatomical structure morphogenesis
Growth Signaling Pathway	epidermal growth factor receptor signaling pathway, vascular endothelial growth factor receptor signaling pathway
Negative regulation of apoptosis	negative regulation of cell death, negative regulation of programmed cell death, cell division, cellular macromolecular complex assembly, chromosome organization, cellular macromolecule catabolic process, cell cycle, cell cycle process, chromosome segregation, cellular developmental process, cell migration, regulation of cellular process
Antigen Processing & Presentation	antigen processing and presentation of endogenous peptide antigen, antigen processing and presentation of exogenous peptide antigen via MHC class I, TAP-independent, antigen processing and presentation of exogenous peptide antigen, antigen processing and presentation of exogenous peptide antigen via MHC class II, antigen processing and presentation of peptide antigen via MHC class I, antigen processing and presentation of exogenous peptide antigen via MHC class I, antigen processing and presentation of endogenous peptide antigen
Regulation of innate immune response	activation of immune response, immune response-regulating signaling pathway, regulation of innate immune response, positive regulation of innate immune response, activation of innate immune response, organ or tissue specific immune response
DNA repair	DNA ligation, DNA metabolic process, DNA repair, translation
Defense Response	response to radiation, cellular response to stress, defense response to Gram-positive bacterium, response to other organism
KEGG pathways in cancer	Pathways in cancer

ABSTRACT

This paper is an extension of work originally presented at the 2nd International Conference of the Portuguese Society for Engineering Education and aims to describe an interdisciplinarity teaching experiment involving three subjects of the scientific area of Mathematics and a fourth one in the area of Management. Using only one project, the students developed skills, in an integrated way, in the fields of the subjects involved. The structure of the project is described in detail. It is shown how the knowledge obtained in the different subjects is needed and how it connects together to answer the proposed challenges. We report the progress of the students' work, the main difficulties and the skills developed during this process. We conclude with a reflection on the main problems and gains that may arise in similar projects.

1. Introduction

This paper is an extension of work [1], originally presented at the 2nd International Conference of the Portuguese Society for Engineering Education.

The Bologna reform aims to make the European Higher Education more comparable and compatible, unifying three different levels of study, for Bachelors, Master and Doctoral awards, across all member countries [2, 3].

This reform seeks to promote the student-centred approaches and the effective implementation of more active learning practices [4].

According to these authors, the Bologna process emphasizes that efforts should be made to include learning activities with "meaning" for students, providing them additional motivation. These authors state that one of the methodologies to achieve these objectives is based on interdisciplinary project approaches [4].

This paper aims to describe an interdisciplinarity teaching experiment involving three subjects of the scientific area of Mathematics and a fourth one in the area of Management, in a Portuguese school of engineering.

Societal, environmental, economic, and philosophical problems are often so complex that it is impossible to fully understand them from a single perspective. Multiple viewpoints can help to solve these complex problems and challenges by converging synergistic team efforts [5].

In line with this idea, many employers recognize the need to hire graduates that are able to work as members of a team as well as being able to understand certain core disciplinary competencies and to adapt to different contexts. Because of that, in recent times the theme of interdisciplinarity has gained popularity in different circles. Despite the skepticism in some education environments, the supporters of its application to school contexts have been increasing, especially with its introduction in university curricula and research agenda [5, 6].

In this field, Klein, quoted by Jacobs [5], makes an important clarification of concepts, presenting a distinction between multi- inter- and trans-disciplinarity that we highlight below: The multidisciplinarity is made by a juxtaposition of knowledge,

*Amélia Caldeira, Rua Dr. Bernardino de Almeida, 431, 4249-015 – Porto (Portugal), acd@isep.ipp.pt

methodologies or information from different disciplines even though the knowledge structure and the identity of the original disciplines remains unquestionable; on the other hand, interdisciplinary approaches emphasize integration and interaction, promoting the disciplinary transformation at methodological and theoretical levels; finally, in transdisciplinary approaches, research questions and practices are framed by problems arising from the life-world and studied in different points of view [5, 7].

"*Interdisciplinarity is a means to integrate knowledge and methods in the interest of problem solving*" [6]. Crossing disciplinary boundaries is particularly important for a future engineer because she/he will be called to solve complex problems. This requires not only crossing boundaries horizontally (across subjects) but also vertically (across experts, policymakers, practitioners, and the public) [8, 9, 10].

The advantages of interdisciplinarity studies are widely accepted by teachers and researchers. Some authors refer that interdisciplinary works use the knowledge that comes from different curriculum areas that offer different perspectives on a particular problem, making the curriculum more compact and more consistent. Furthermore, interdisciplinary works provide the students with relevant, challenging and enjoyable learning experiences [5, 6].

Chettiparamb [6] refers that "*Interdisciplinary pedagogy fosters in students a sense of self-authorship and a situated, partial and perspectival notion of knowledge that they can use to respond to complex questions, issues or problems. While it necessarily entails the cultivation of the many cognitive skills such as differentiating, reconciling, and synthesizing […] it also involves much more, including the promotion of student's interpersonal and intrapersonal learning.*"

Despite this, some authors believe that collaboration is often more truly interdisciplinary in social science and humanities disciplines than in technological ones because these disciplines require that researchers work more closely to agree on methods and interpretations [11]. Notwithstanding this, interdisciplinary approaches are critical to solving the most pressing technological challenges. An evidence of this is the fact that interdisciplinary is progressively more valued by the courses' accrediting agencies [7].

In alignment with these ideas, some universities have developed some interdisciplinary design courses with the goal of improving students' abilities to operate across disciplines and improve their preparation for work [12].

This paper aims to present the results of an interdisciplinary teaching experiment performed in the Electrical Engineering – Power Systems degree of the School of Engineering – Polytechnic of Porto (ISEP). The goal of this experiment was to carry out an interdisciplinary project involving four subjects of the first year of the degree, three of which from the scientific area of Mathematics - Mathematics I (MATE1), Mathematics Laboratory I (LMAT1), Linear Algebra and Analytic Geometry (ALGAN) - and one subject in the area of Management: Working Methods in Engineering (MTENG).

The subjects concerning the first semester of the first year program as well as the respective European Credit Transfer and Accumulation System (**ECTS**) [13,14] are listed in Table I.

TABLE I. COURSE REQUIREMENTS (1ST YEAR/1ST SEMESTER)

SUBJECTS	ECTS	Contact hours
Experimental Physics	5	4
Introduction to Electrotechnics	6	4
Linear Algebra and Analytic Geometry	5	4
Mathematics I	5	4
Mathematics Laboratory I	3	2
Working Methods in Engineering	6	4

Using only one project work, we intended to create the opportunity for students to develop skills, in an integrated way, in the fields of the involved subjects. Students were challenged to perform a set of tasks by applying concepts and skills developed in the four aforementioned subjects. Specific objectives were proposed for this work in each subject.

The experiment took place during twelve weeks in the first semester of the first year of the degree.

Students were assessed by three outcomes: one report, one oral presentation with discussion and a MatLab© script. All teachers were involved in the assessment of the report and the oral presentation. The MatLab© script was mainly assessed by the Mathematics Laboratory I (LMAT1) teacher.

Students faced initial difficulties in dealing with the interdisciplinary challenge, and with developing the soft skills required in the project. The main challenges were:

- to gain experience in team work as means to solve the interdisciplinary problems;
- to acquire insight into their own behaviour and understand how it influences collaboration in the team;
- to acquire and understand their competence and realize how it may be used for the benefit of the team.

This led to considerable gains in learning, so we will make a reflection on these gains and the benefits of carrying out a single project involving different subjects. We explore the main objectives of this interdisciplinary work, as well as the methodology and its main results.

We conclude this text with a reflection on the main lessons learned as well as with some suggestions for future interdisciplinary work involving these or other scientific areas.

2. The project

Interdisciplinary projects are encouraged and very welcome in the degrees of ISEP. Using some past experiences, a group of four teachers – responsible for three subjects of the scientific area of Mathematics and a fourth one in the area of Management – proposed to the students of the Electrical Engineering – Power Systems degree an interdisciplinary work.

2.1. Organizing the project

The purpose of this project was to give an integrated view of the several subjects of Mathematics, as well as to develop in students a number of soft skills that are pointed out as fundamental by the employers of graduated students.

In interdisciplinary research, success depends largely on the personality and attitudes of researchers. Useful characteristics are:

- curiosity about, and willingness to learn from other subjects;
- flexibility, adaptability, creativity;
- an open mind to ideas coming from other subjects and experiences;
- good communication and listening skills;
- an ability to bridge the gap between theory and practice;
- a good team worker.

The following additional abilities are very important:

- understanding (not necessarily in depth) across the project's main subject domains;
- understanding application areas, namely, Electrical Engineering, for project outcomes;
- respect for other subjects and some understanding of their general principles;
- focus on practical results, to overcome differences among subjects.

These abilities are highly relevant to achieve a good project management.

In addition to this, specific objectives were proposed in each subject.

In the subject of Working Methods in Engineering, the project had as objective to develop skills in the areas of:

- Project management competences, including planning and project control;

- Write technical reports using an appropriate structure and technical language;

- Communicate in public effectively, using technical data to support the message;

- Communication. Namely developing the capacity to reach consensus, make decisions and manage conflicts.

Mathematics Laboratory I is inserted in the first semester of the first year of the Degree in Electrical Engineering - Electric Energy Systems' syllabus. It is a scientific subject of the Mathematics area that intends to provide the skills for solving typical problems in engineering algebraically and numerically, using numerical methods (see, for example, [15] and [16]) and computer algebra systems.

As main goals of this subject, it is intended that students obtain reasoning and abstraction skills in order to:

- implement methods of algebraic and numeric resolution of problems;

- model engineering problems related to the degree mathematically;

- acquire critical sense, deductive reasoning, and graphic interpretation;

- be critical in the use of computer algebra software and numeric tools;

- do the integration between the nuclear subjects of Mathematics and Electrical Engineering.

As specific goals it is intended that a student should be able to:

- implement methodologies for solving problems using the algebraic and numeric tools (Matlab, Python and/or Matlab clone);

- understand the benefits and limitations of the algebraic and numeric tools (Matlab software, Python and/or Matlab clone);

- find and implement alternative methodologies to solve the problems;

- understand the several ways in which error can be introduced in the solution of the problem;

- solve equations of one variable numerically;

- use iterative methods in finding the solution sets of linear systems;

- evaluate derivatives and integrals numerically.

The subject contents were: the software introduction and error analysis; numerical methods for solving equations; methods for solving systems of equations and numerical differentiation and integration.

Mathematics I is a traditional one variable analysis subject (see, for example, [17] and [18]) with the following objectives:

- to characterize and manipulate real-valued functions in one variable;

- to use the techniques of differential calculus;

- to understand the notion of primitive of a function and to compute the primitive of functions using several methods;

- to understand the concept of definite integral and to use it to compute areas;

- to work with series of real numbers and with Taylor series, realizing its importance and its application to Engineering problems.

Linear Algebra and Analytic Geometry aims to complement and consolidate the mathematics training of students gained during their academic life and develop the abstraction and reasoning ability of students. The subjects of ALGAN also aims the development of a mathematical language and the acquisition of critical spirit. It intends to give basic training in linear algebra and analytic geometry in order to enable the creation and solving mathematical models applied to Engineering (see [19]).

After attending the subject of ALGAN, students should be able to:

- perform basic operations on matrices, compute determinants and solve matrix equations;

- use matrices and determinants in the resolution and discussion of systems of linear equations;

- identify and generate vector fields and check linear dependence on the vectors; identify linear transformations and compute the associated matrices, eigenvalues, and eigenvectors;

- give analytical expressions for lines and planes; study intersections of lines and planes and identify geometrical spaces that satisfy some pre-determined conditions.

Teams of four students were formed in the beginning of the scholar year, in the classes of Mathematics Laboratory I (LMAT1). Students were invited to form the teams according to their preferences. There was a consensus among the students in the formation of the groups and there was no need for direct intervention of teachers in this process. Students without LMAT1, but attending one of the other three subjects, would not have an interest in participating in this project, as it needed a lot of support given in the classes of LMAT1. For these students, an alternative assessment was defined.

A total of eighty one students participated in this project. Each team received a project worksheet. The worksheets were not equal for all teams, but they proposed similar tasks.

2.2. Planning for implementation of the tasks(weekly)

An overview of the project milestones and tasks is shown in Table II. Task 1 included the study of a real-valued function of one real variable and solving some equations numerically. This was performed during the four weeks of October, the first month of the project.

A preliminary report was delivered at the end of the second week of November. This was followed by the task of solving systems of linear equations using algebraic and numerical methods. The preliminary report of this task was delivered at the end of the first week of December.

Finally, the problem involving sequences, Taylor series and symbolic and numerical integration was addressed in the second and third weeks of December. The preliminary report about this task was delivered at the end of the third week of December. The final report was delivered in the last week of December.

TABLE II. TASKS SCHEDULING (WEEKLY)

Tasks	October	November				December				January (2016)	
	During 4 weeks	1st	2nd	3rd	4th	1st	2nd	3rd	4th	1st	2nd
MATE 1 Task1: Real-valued function of a real variable											
LMAT 1 Task1: Solve equations numerically											
ALGAN Task2:Solve systems of linerar equations											
LMAT 1 Task2:Solve systems of linerar equations numerically											
MATE 1 Task3: Sequences/ Series/Integration.											
LMAT1 Task 3: Numerical integration											
MTENG Preparation of the Report											
Results/ display resolution: task 1											
Results/display resolution: task 2											
Results / display resolution: task3											
Report delivery											
Presentation/Discussion											

2.3. Main tasks developed in the project

The tasks proposed to the students include three groups of questions. The first task to be developed in this project involved real-valued functions of one real variable. The voltages across the capacitor component were studied. Thus, the charge/discharge of the capacitor, $q(t)$, in the RLC circuit (Fig. 1) was given. The analytic expression involved various exponential functions, for example,

$$q(t)=\frac{57024\left(e^{\frac{\sqrt{43}\,t}{6}}+e^{-\frac{\sqrt{43}\,t}{6}}\right)+\frac{374112}{\sqrt{43}}\left(e^{\frac{\sqrt{43}\,t}{6}}-e^{-\frac{\sqrt{43}\,t}{6}}\right)}{6}e^{-\frac{7t}{6}}$$

$$-(192\,t+19008)\,e^{-\frac{t}{12}}.$$

$$v_C(t)=\frac{q(t)}{C} \qquad v_L(t)=L\frac{di}{dt}.$$

$$i=\frac{dq}{dt}.$$

The values for resistor, inductor, and capacitor are given, respectively, by

$$R = 7\Omega \;\; L = 3H \qquad C = 2F.$$

Some questions concerning real-valued functions were addressed at the beginning:

$$v_{LC}(t) = v_L(t) + v_C(t)$$

60%

0.05

0.0005

In the second task, an electrical circuit was given (see Figure 2). The circuit has different meshes. Using the Kirchhoff's laws for electrical circuits the students formulated the linear equations system to determine the currents in the circuit meshes.

A linear equations system was obtained. Then, the students were challenged to solve the system using algebraic methods such as Gaussian elimination and the Cramer's rule. After the use of these two algebraic methods, the students solved numerically the system of linear equations, using the iterative Jacobi and Gauss-Sidel methods. Here, it was provided the opportunity of comparison between the results obtained from algebraic and numerical methods. Furthermore, this approach gave to the students the opportunity to compare the performance of the two numerical methods.

The last task concerned an integral calculus problem where symbolic integration was not possible. Therefore, the problem should be solved using Taylor series/polynomials, in order to obtain an approximation of the integral. In addition, the Simpson and trapezoidal rules were proposed to obtain the integral, using numerical quadrature. We focus that these tasks led to the simultaneous use of algebraic and numerical methods. The function was $l(x) = 3\, e^{-\frac{x^2}{4}}$ and the problem was to calculate the definite integral

$$I = \int_{-2}^{2} l(x)dx.$$

At first, it was computed the Taylor series of l and, next, the numerical series that allows computing the value of I. The convergence of the numerical series was also studied.

After that, other two approximations of I were calculated:

- on the one hand, approximating $l(x)$ by its Taylor polynomial of degree n (n specified) and the value of the corresponding integral;

- on the other hand, using the trapezoidal and Simpson's rules.

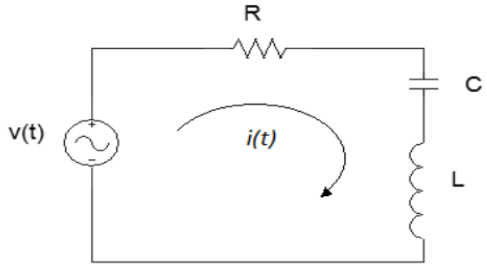

Figure 1: RLC circuit analyzed in Task 1.

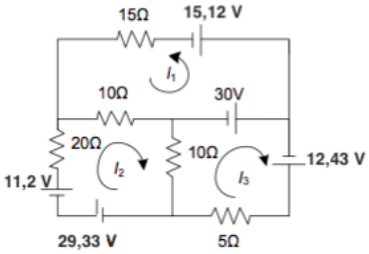

Figure 2: Electrical circuit solved in Task 2.

2.4. Interdisciplinarity

The interdisciplinarity present in the project proposed to students is shown in the flowchart in Fig.3. The linear equation system obtained from Kirchhoff's voltage law application is commonly addressed on LMAT1 and ALGAN. Algebraic methods, such as Gaussian elimination and Cramer's rule, had been studied in ALGAN. Numerical methods, such as Jacobi and Gauss-Sidel iterative methods, were implemented in LMAT1. The issue of real-valued functions of one real variable, including the voltages across the capacitor component or the charge/discharge of the capacitor in the RLC circuit, was addressed in MATE1 and in LMAT1.

The study of real-valued functions was done analytically in the MATE1 subject. Some equations were solved numerically in LMAT1. The numerical methods used were the bisection and Newton–Raphson methods. Another topic involves the integration of functions without any symbolic primitive. This problem was addressed in MATE1 and LMAT1. Taylor series/polynomial were used to find an approximation of the integrand function and so to obtain an approximation of the integral. In LMAT1, the Simpson and trapezoidal rules were used for numerical integration. The management and guidance for performing the reports and presentations were carried out in the MTENG subject. This general issue had also the contribution of all participant subjects.

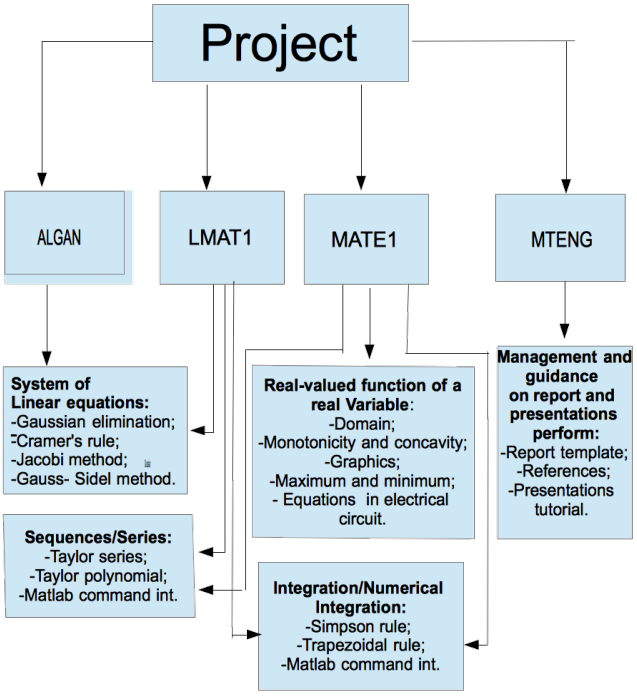

Figure 3: Topics and problems split into four different subjects

Prerequisite skills needed for the execution of the project are rather minimal. Students are required to have Mathematics education of secondary school. They should have some knowledge of basic electrical circuits. Some programming experience in Matlab or other higher-level language is helpful, but not required.

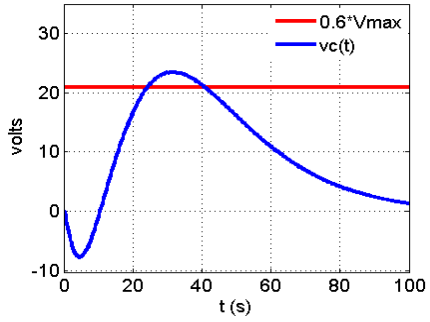

Figure 4: Graphic interpretation used in Task 1.

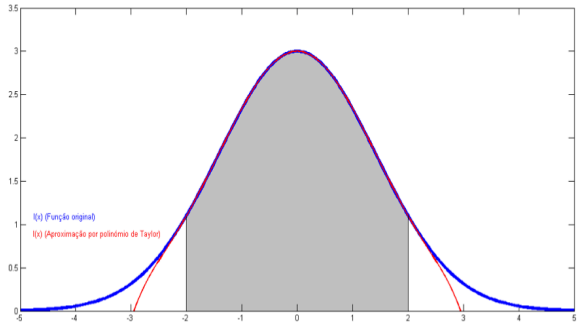

Figure 5: Numerical Integration.

We also highlight the use of the software MatLab© and its symbolic and numeric toolboxes to support the study. Furthermore, the graphical interpretation done by the students was improved by exploiting the graphical capabilities of the software. For instance, the graph presented in Fig. 4 (obtained with MatLab©) provides a better insight of the equation to be solved numerically while the graphic presented in Fig. 5 provides an insight concerning the integral to be computed.

The students were faced with questions where it is necessary to choose between numeric and algebraic approaches. They should analyze the advantages and disadvantages of each other.

2.5. Using the Moodle platform

The use of a communication platform between teachers and students is essential for work coordination. There are several platforms available, but at ISEP it is implemented the Moodle platform, so we used it.

The *Moodle* platform was used for communication with students, providing supporting material and for the delivery of the final work. A proper space, accessible to all persons involved, was created in this platform to help the management of the process of delivery of the final work and its logistics.

2.6. Transferability to other interdisciplinary projects

This work emerged from a group of teachers' desire and the conviction that this kind of project brings significant gains for students. These are challenged to integrate the knowledge that is often presented to them in a disintegrated way giving the idea of knowledge fragmentation. But this type of work presents challenges, not only for students, teachers are also challenged to think globally, to overcome the limits of their subject, to integrate its specific knowledge with other areas and to coordinate their work with other teachers.

Everyone involved in this experience - teachers and students – shares the opinion that it should be repeated and, furthermore, there should be conditions to transfer it to other contexts and to other areas. In order to facilitate this transferability, we leave some practices that we consider essential to the success of future experiments in this context:

1. Project Planning - Phase essential to the success of the project. It should involve communication between teachers from different subjects in order to i) describe goals for each subject, ii) define tasks to be developed by students, iii) define moments and assessment tools and respective criteria, iv) prepare the project worksheet and v) set a plan of regular control meetings.

2. Project presentation to students - The project must be presented to students in detail, in the context of class, through the delivery of a project worksheet which should include i) project goals, ii) detailed tasks and deadlines iii) materials and tools necessary for the tasks implementation and iv) assessment moments, tools and respective criteria.

3. Teams definition - teams should be defined at the beginning of the work by the students.

4. Teachers monitoring - Teachers should accompany the group throughout the implementation of the project, acquainting themselves from problems that arise and supporting students to solve it.

5. Coordination of the teaching staff - It is essential that teachers talk to students well-coordinated. For this purpose, project control meetings are very important.

6. Communication Platform for teachers / students - The use of a communication platform (in this case, the Moodle) seems to us essential to the success of the project.

7. Final Assessment - It is important that, in the end of the project, teachers and students have time to evaluate the process in which they were involved and reflect on the key lessons learned and define adjustments for the project replication.

8. The presence of all teachers in the oral presentation of projects – If we want to convey the message of interdisciplinarity, it is important that teachers are an example of commitment and networking.

3. Results and Conclusions

The Bologna reform brought new challenges for teachers and students of higher education. More student-centered teaching and crossing the frontiers of knowledge through interdisciplinary projects are examples of these new challenges [2, 3, 4]. In this paper, we intend to present the results of an interdisciplinary project carried out in an engineering school in the north of Portugal.

The results obtained by the participating students were generally positive. Students' involvement in the project was notorious. This involvement may be justified by the fact that, as Jacobs [5] and Chettiparamb [6] refer, interdisciplinary works provide the students with relevant, challenging and enjoyable learning experiences which may influence their degree of motivation and commitment in performing the tasks. In fact, the percentage of relative involvement of each student in the project was evaluated by his partners in the group. This information was asked to students in the moment of presentation and discussion of each team work.

As mentioned by Chettiparamb Interdisciplinary projects force students to integrate subjects that were apparently independent. The interdisciplinarity has implied a change of students' attitudes in the search for the development of integrated knowledge [6].

With this kind of challenge, students had the opportunity to develop a reflexive thought to overcome difficulties and, in this way, to develop knowledge and skills [5, 6].

In fact, many different skills have been developed by students throughout the execution of this project. As an example, we can point out the ability to work with others, to solve problems and conflicts, to integrate knowledge from different fields, to write a report using the citation rules and also the ability to make public presentations. As some authors have argued this kind of skills are very important for a future engineer that will be called to solve complex problems that require crossing boundaries [7, 11].

This type of work also puts great demands on the teachers involved in the project, particularly in terms of flexibility to integrate knowledge. Nevertheless, we think that the results in terms of benefits to the students justify all efforts that can be done to develop interdisciplinary work.

The results of the assessment of this project were used to evaluate students in the different subjects. The weight given to this project by each subject was different from subject to subjects. As each subject has established different goals to achieve with this interdisciplinary project, it has also defined its own assessment criteria as well as the weight of the project in the overall evaluation of the subject. This weight was 10% of the overall evaluation of the subject for ALGAN, 20% for MATE1 and LMAT1, and 35% for MTENG.

At the beginning of the oral presentation and discussion of the teamwork, each element of the team was asked to answer an auto assessment question. This question had to do with the perception that each element of the team had about the percentage of contribution of each element to all the work done.

In the report and in the oral presentation, students answered, in generally, correctly to what was asked. We can mention that the function studied on the first task was not an ``academic" one (easy to analyse). They had to do research work and discuss it with the MATE1 teacher.

The exception was the last task (subsection 2.3) where students were asked to approach a definite integral by two different processes (numerical integration and using Taylor polynomials). The students' weakness was that they did not have the critical spirit to comment on the results obtained. For example, in one team of students, the results obtained by the two processes were very different. They did not realize that they should have compared the results and make conclusions.

By the end of the project, students' opinions regarding the challenge they had faced were assessed using a questionnaire. The students were asked to give their opinion about the nature of the project and its objectives (question 1); about their satisfaction concerning their personal involvement in the project (question 2); about the impact of the project in motivating them to learn mathematics related subjects (question 3); about the opinion on the overall assessment of the project (question 4), and about the project contribution to develop personal and team work skills (question 5). Students were also asked to provide general feedback on the project as well as to identify strengths and weaknesses. Except for this last open question, all the other questions were assessed using a Likert scale, being 1 "somewhat satisfied", and 5 "very satisfied". Thirty-six students answered the questionnaire. The average score was over 3.9 considering all the questions, reaching 4.1 in those questions where students assessed the objectives of the project, and 4.2 in the ones concerning students' opinion about the project contribution to the development of personal and team work skills (Fig. 6). As for strengths, students highlighted the relevance of the project for developing those skills and also for learning and consolidating mathematics-related subjects.

Although many of the respondent students did not mention any weakness, some pointed out the workload, and the short time period to develop the work as aspects to be improved in future editions. With that information in mind, we may conclude that students recognized the importance of this project not only to develop personal and teamwork skills but also to consolidate knowledge of the several subjects involved in the project.

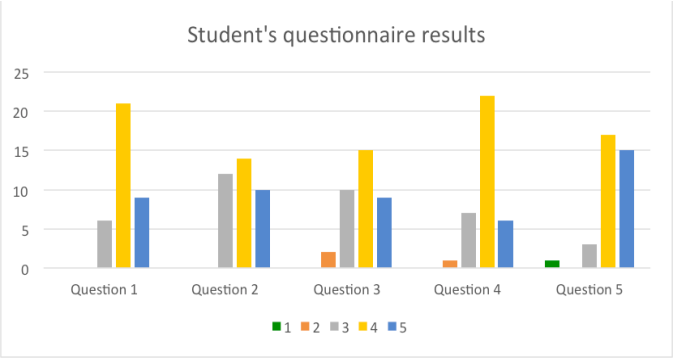

Figure 6: Students' questionnaire results

Despite the major benefits that this project has brought to the students, we are aware of the need to improve some aspects regarding planning and execution. At this stage, the coordination between the different involved teachers, the support provided to students during the project execution, and the management of the time students have dedicated to the project are the most challenging aspects and those with major impact on the success of the final project.

Taking into account the characteristics of this project and the context of the degree in which it is integrated (Electrical Engineer) it is important, in future experiences, to involve the subjects of Experimental Physics and Introduction to Electrotechnics. Their absence was one of the weaknesses of this experiment.

Other aspects to improve in new editions of the project are:

- to implement changes in the Moodle platform configuration to ensure a greater dynamic on the interaction between the members of each group, a greater dynamic on the interaction between students/teachers during the period of development of the work, and also to facilitate team work in online learning;
- to provide better conditions in online learning experiences, including team work will thus prepare students as effective members of teams in a virtual workplace of the future;
- to include a final report from every member identifying their contribution to the project;
- to provide some more class time for meetings because at the nowadays it is very hard for students to manage their schedules;
- to make the workload reasonable and the goals clear.

To conclude, it should be referred the intention of the authors to implement this project in other ISEP first degree courses (such as Electrical and Computer Engineering or Mechanical Engineering).

Conflict of Interest

The authors declare no conflict of interest.

Gait characterization

ABSTRACT

This paper presents a developed low cost system for human gait analysis. Two web cameras placed in opposite sides of a treadmill are used to acquire images of a person walking at different speeds on a treadmill, carrying a set of passive marks located at strategic places of its body. The treadmill also has passive marks with the color chosen to contrast with the ambient dominant color. The body joint angle trajectories and 3D crossed angles are obtained by image processing of the two opposite side videos. The maximum absolute error for the different joint angles acquired by the system was found to be between 0.4 to 3.5 degrees. With this low cost measurement system the analysis and reconstruction of the human gait can be done with relatively good accuracy, becoming a good alternative to more expensive systems to be used in human gait characterization.

1. Introduction

This paper is an extension of the work originally presented in 2016 IEEE International Conference on Industrial Engineering and Engineering Management (IEEM2016) [1]. The study of the human gait has been done in medical science [2-5], psychology [6, 7], and biomechanics [8-15] for more than five decades. Recently it has generated much interest in fields like robotics [16], biometrics [17] and computer animation [18]. In computer vision, recognizing humans by theirs gaits has recently been investigated [19]. The human gait is a pattern of human locomotion and can be described by kinetic or kinematics characteristics [20]. Gait signatures are the most effective and well defined representation methods for kinematic gait analysis. Gait signatures can be extracted from motion information of human gaits and have been used in computer graphics, clinical applications, and human identification [21-23].

Furthermore, gait data can be used to assess pathologies in a variety of ways. For example, stride parameters such as walking speed, step length and cadence provide an overall picture of gait quality.

Given the growing need for such analysis equipment, this paper presents a low cost system developed to characterize human gaits as an alternative to much more expensive solutions [24, 25], taking the advantage of requiring much less space for its installation (about 5 times less).

The organization of this paper is as follows: Section 2 describes the developed acquisition system and its setup. The static and dynamic performance tests are described in Section 3. The results of repeatability tests are presented in Section 4 and the conclusions in Section 5.

2. Acquisition System

The developed acquisition system is based on computer vision and tracks passive marks (circles with 4 cm of diameter) of a color chosen to contrast with the surround colors.

The system is mainly composed by one treadmill and two web cameras, one located on the right, and another on the left side of the treadmill, see Figure 1. Each one covers one side of the walking person.

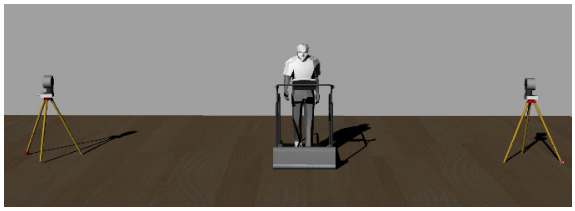

Figure 1. Layout of the developed system.

[*]M. Crisóstomo, Inst. of Syst. and Rob, Dep. of Elect. and Comp. Eng, Univ. of Coimbra, 3030-290 Coimbra, Portugal, Tel. +351 9130520256, mcris@isr.uc.pt

The web cameras used have the following characteristics: CMOS 640×480 (VGA) sensor, maximum of 30 frames per second, USB 2.0 interface.

The cameras are placed at a height of 1.15 m and at a distance of 2.35 m from the treadmill. Each camera is aligned and centred to the treadmill and to the opposite camera.

After laying out the system components, the following procedures need to be followed to extract human joint angles trajectories:

A – Calibrate and align both cameras;

B – Place detection marks on the person;

C – Calibrate both sides of the pelvis;

D – Synchronize both side videos;

E – Process video frames, correct the depth of the marks, and extract joint angles.

A. Cameras Calibration and Alignment

Next it is described the cameras calibration and alignment procedures.

A.1. Cameras Calibration

When using low cost video cameras, image distortions must be considered and it is mandatory to calibrate the cameras using standard calibration procedures.

Image distortions are constant and with a calibration and remapping they can be corrected [26]. Next, it is explained the basic topics of camera calibration: radial and tangential distortion, and the perspective transformation model.

A.1.1. Radial Distortion

The radial distortion is corrected using:

$$x_{corrected} = x(1 + k_1 r^2 + k_2 r^4 + k_3 r^6) \quad (1)$$

$$y_{corrected} = y(1 + k_1 r^2 + k_2 r^4 + k_3 r^6) \quad (2)$$

$$r^2 = x^2 + y^2 \quad (3)$$

where k_1, k_2, and k_3 are the radial distortion coefficients. Therefore, for an old pixel point at (x, y) coordinates in the input image, its position on the corrected output image will be $(x_{corrected}, y_{corrected})$. The presence of the radial distortion manifests in the form of the "barrel" or "fish-eye" effect.

A.1.2. Tangential Distortion

Tangential distortion occurs because the camera lenses are not perfectly parallel to the imaging plane. It is corrected by:

$$x_{corrected} = x + \left[2 p_1 xy + p_2 (r^2 + 2x^2)\right] \quad (4)$$

$$y_{corrected} = y + \left[p_1 (r^2 + 2y^2) + 2 p_2 xy\right] \quad (5)$$

where p_1 and p_2 are the tangential distortion coefficients. All the five distortion parameters were calculated using the Matlab camera calibrator app.

A.1.3. Perspective Transformation Model

For the units conversion the following formula (in homogeneous coordinate system) is used:

$$\begin{bmatrix} x \\ y \\ w \end{bmatrix} = \begin{bmatrix} f_x & 0 & c_x \\ 0 & f_y & c_y \\ 0 & 0 & 1 \end{bmatrix} \begin{bmatrix} X \\ Y \\ Z \end{bmatrix} \quad (6)$$

where the intrinsic camera parameters f_x and f_y are the camera focal lengths and (c_x, c_y) is the optical center expressed in pixels coordinates.

The process of determining all these nine parameters is the calibration. Calculation of these parameters is done through basic geometrical equations, and it depends on the chosen calibrating object, which was a classical black-white chessboard.

A.1.4. Camera Calibration Parameters Calculation

To do the calibration was used the Matlab camera calibrator app (Figure 2). The first step is to input images of a checkerboard calibration pattern. For accurate results it is recommended to use between 10 and 20 calibrating images, from each camera, and, in this case, 11 images were used (Figure 3). The checkerboard was used as calibrating object because its regular pattern make it easier to be detected automatically.

After inputting the checkerboard square size, the app will detect the checkerboard in all calibrating images. Then it is possible to inspect the results. This is helpful to find incorrect detections, and remove bad images for calibration.

After this, the calibration parameters can be calculated and if necessary images with biggest errors can be rejected and substituted by another ones to try to minimize the overall mean error.

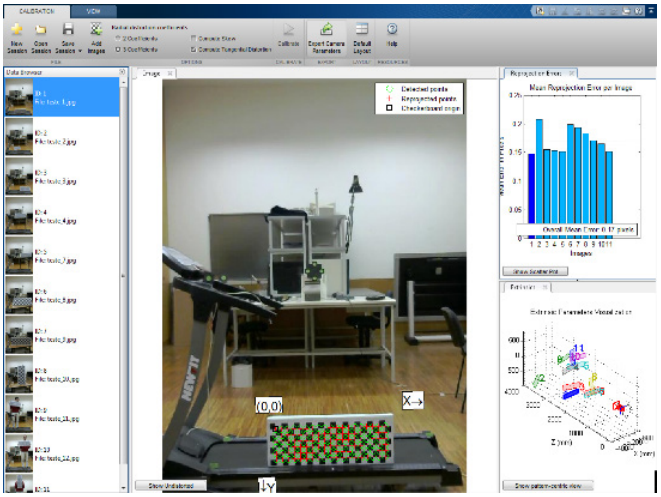

Figure 2. Matlab camera calibrator app.

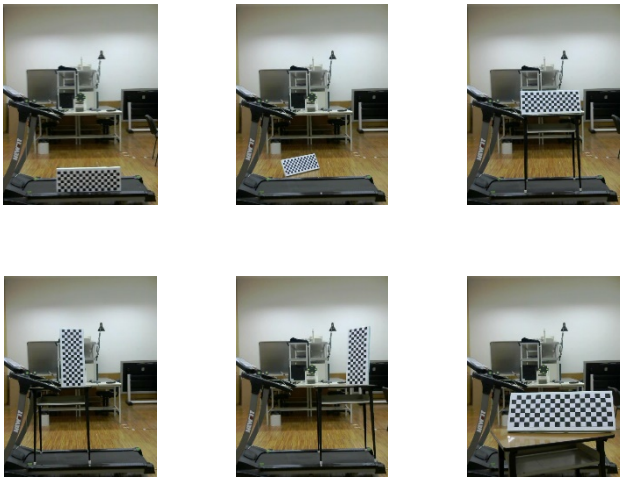

Figure 3. Some of the images used for camera calibration.

The obtained distortion coefficients for left camera are

$$Radial_{coef.} = [-0.0171 \quad 0.4642 \quad -1.4012]$$

$$Tangential_{coef.} = [-0.0048 \quad -0.0010]$$

and the intrinsic parameters (in pixels) are

$$focal_{length} = [f_x \quad f_y] = [809.5672 \quad 811.7467]$$

$$optical_{center} = [c_x \quad c_y] = [247.9749 \quad 296.3430]$$

For the right camera, the obtained distortion coefficients are

$$Radial_{coef.} = [0.1228 \quad -1.3171 \quad 6.2424]$$

$$Tangential_{coef.} = [-0.0054 \quad -0.0068]$$

and the intrinsic parameters (in pixels) are

$$focal_{length} = [f_x \quad f_y] = [819.1826 \quad 818.3655]$$

$$optical_{center} = [c_x \quad c_y] = [232.5183 \quad 332.3357]$$

A.2. Alignment of Cameras

Since there are two cameras and a treadmill between them, it is required to align each system component with each other to guarantee a good performance [27]. For that, it was developed a software module that measures the distance, in pixels, between six reference marks on the treadmill, and those marks viewed by the camera. Since the focal distance of the cameras and the distances between the treadmill and each camera are known, the location where the six marks should appear in the image can be calculated.

Now, it is necessary to do a manual fine alignment of the cameras in order to overlap each calculated mark position with its respective detected position in the image. Then, it is calculated the larger distance between these marks, and the goal is to ensure that the maximum distance is less than four pixels.

B. Placing Detection Marks on the Person

After the alignment of both cameras, it is necessary to attach 10 marks on each side of the walking person. Marks 1, 2, 3, A, 5, 6 and 8 correspond to joints in the human body: shoulder, elbow, wrist, pelvis, knee, ankle and finally finger toes, see **Error! Reference source not found.**.

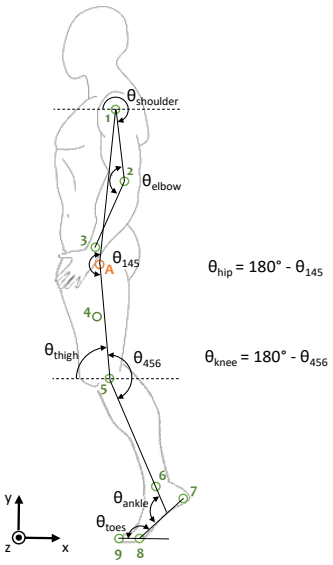

Figure 4. Joint angles definition and marks placement on the left side of a walking person.

C. Pelvis Calibration

Initially, the walking person must carry twenty marks (ten on each side) placed on him, Figure 5, but after the *"pelvis calibration"* procedure, the pelvis marks (A in Figure 4) are removed, and the pelvis joint marks will be inferred by the extra marks placed on the upper legs (mark 4 in Figure 4).

Considering the marks do not move during data acquisition, marks 4 can be removed and their positions inferred from the positions of the other two marks. This procedure is necessary because the arm and hand occlude the pelvis marks (marks A) during gait data acquisition. Figure 5 shows the software module window for the pelvis calibration.

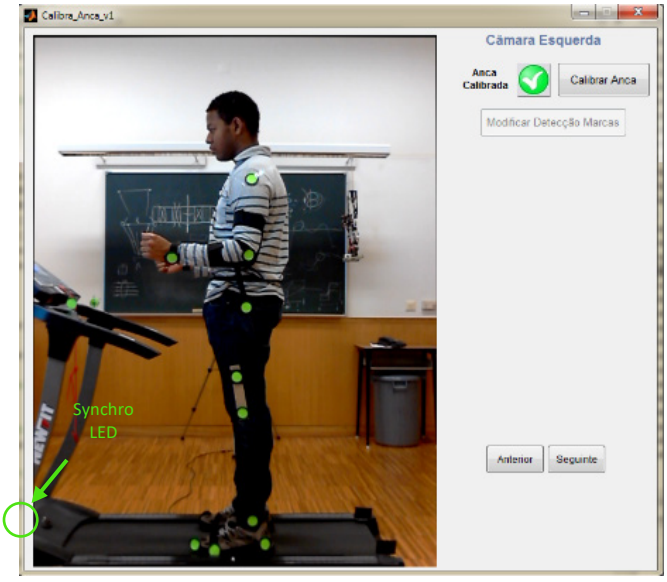

Figure 5. Left side pelvis calibration software module and synchronization LED position.

D. 3D Construction and Synchronization

To obtain 3D human gait data, it is required to cross synchronized both side's images [28]. To synchronize cameras, there is a white synchronization LED that blinks and that is visible by both cameras (Figure 5). The video acquisition starts first, and then the synchronization LED starts blinking. The synchronization procedure is automatic and is done when processing the acquired videos, and is necessary because cameras do not start exactly at the same time and the image acquisition rate is not exactly the same for both cameras and has fluctuations.

So, it is necessary to detect on both side videos when the synchronization LED turns ON and OFF, checking if the number of frames between LED ON and OFF cycles in both videos is the same. If they are not, the marks trajectories of the side with less frames are interpolated so that both side trajectories have the same number of data. When the number of frames in deficit is equal to or greater than three, the stride where this deficit occurs is considered not okay, and is discarded. This way, both side's videos can be crossed to extract 3D gait data.

To reference both camera images in space, there are two marks in the treadmill that are visible for both cameras (Figure 7). Both side images have their reference relative to these marks. This way it is ascertained not only the sagittal angles but also transversal and frontal rotation angles of the trunk, shoulders and pelvis.

It is necessary to add depth to the person's right and left planes, so, since the distances between all marks are measured (Figure 6), it is possible to convert those metric distances to pixels. To do this the required measures are: person height; shoulders width; arm and forearm lengths; hip width; thigh and leg lengths; distance between both ankles, and between both knees when in normal walking; great toe length; foot hinge finger to heel distance; and ankle to foot base distance. Other data are collected too, like age, gender and weight. Therefore the calculation of Body Mass Index (BMI) can be done.

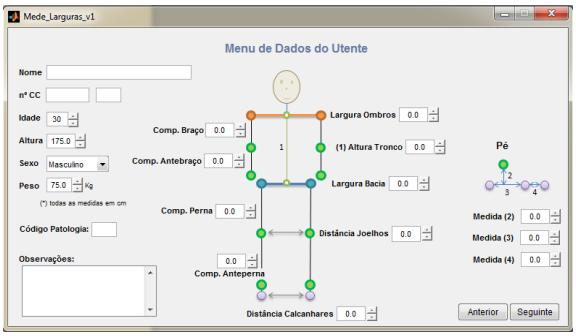

Figure 6. Menu to input the walking person data.

After these measurements and pelvis calibration the person walks about 6 minutes on the treadmill to be accustomed to it [29], and only after the person feels at ease with the treadmill use, the gait data acquisition can start (Figure 7).

Figure 7. Right side view of a person during gait data acquisition showing the 9 green marks on the person and the 2 on the treadmill.

E. Processing of Video Frames, Correcting the Depth of the Marks, and Extracting Joint Angles

After gait data acquisition, all saved data is loaded, and computed to extract the desired angle trajectories.

In this phase all frames are loaded to pass through a color segmentation process where all marks are extracted from the original videos, and the respective image coordinates are determined, [30, 31]. This segmentation is adjustable for every mark color.

The trajectories of all marks have been smoothed by using a zero lag Butterworth filter with a cut-off frequency of 6 Hz [9, 32]. Since for speeds below 5.5 Km/h, 99.7 % of the signal power is contained in the lower seven harmonics (below 6 Hz), the use of a 6 Hz cut-off frequency is considered to be adequate for the tests.

After being determined the coordinates of each mark for all video frames and after the noise reduction is done, each joint angle trajectory can be obtained.

Afterwards it is possible to visualize, for the entire duration of the test, the person 3D animated skeleton with all joints and links.

Stride detection makes possible stride grouping. Each stride is defined when the right foot starts going from up to down. After, the same foot stops moving forward and begins to move backward. I.e., forward to backward movement is first flagged, and after that, when upward to downward movement is detected, this instant corresponds to a new stride detection. Each stride detection ends the previous stride and starts a new one.

Figure 8 shows a window where the saved data can be viewed and analyzed.

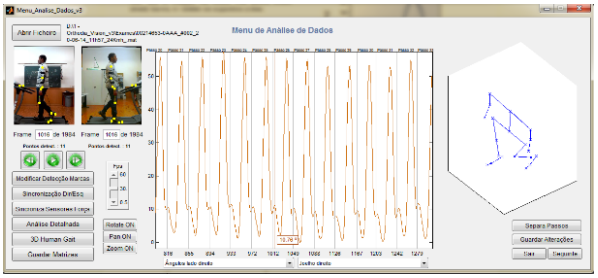

Figure 8. Menu to display collected data and respective joints angles.

In this window it can be seen: both sides videos, the location of each detected mark (yellow circles in video frames), the angle values for all recorded person strides, a 3D animated skeleton of the person for each frame, and other options, like zoom, pan, rotate, RGB levels for mark detection, intensity threshold for synchronization LED detection, export data, etc.

At the end, all collected data can be exported and opened in another window (Figure 9), where all strides are grouped and the 17 mean joint angles profile, and their respective standard deviation (in green) are seen.

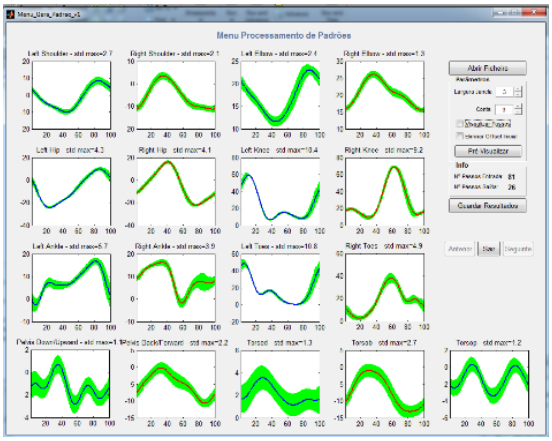

Figure 9. Window showing the mean, the standard deviation and other indicators from recorded data.

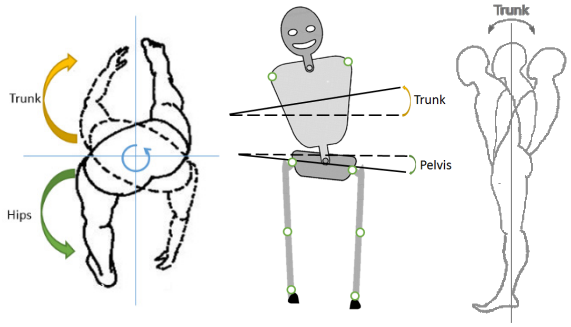
Beyond the angles referred to in **Error! Reference source not found.** it is also possible to extract other angles: backward/forward pelvis and trunk, downward/upward pelvis and trunk, and posterior/anterior trunk, as can be seen in Figure 10.



a) b) c)

Figure 10. a) - Backward/Forward Trunk/Pelvis angle.
b) - Downward/Upward Trunk/Pelvis angle.
c) - Posterior/Anterior Trunk angle.

The one side marks placed on the arm and leg are in different planes (see Figure 11). Instead of considering every mark in the same plane, it was made a depth correction [33]. I.e., using the physical characteristics of the person in test (Figure 6), the difference distances between the planes were calculated. Combining the values calculated before with the physical system setup distances, the points outside of the reference plane β (like knee, ankle and every foot points) were projected to it, permitting a more accurate calculation of the angles.

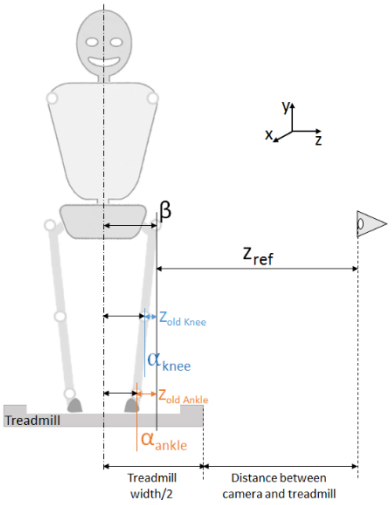


Figure 11. Position and metric relationship between reference plane and marks planes.

Involved variables can be viewed in Figure 12.

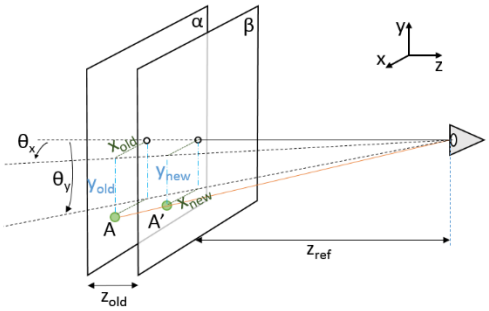

Figure 12. Variables used to correct the depth of certain points.

The reference plane β contains the pelvis mark point (see Figure 12).

Consider a point A with coordinates (x_{old},y_{old}) on the plane α parallel to the reference plane. The new coordinates of the point A (x_{new},y_{new}), on the reference plane β, A', are obtained by

$$\begin{bmatrix} x_{new} \\ y_{new} \end{bmatrix} = \frac{z_{ref}}{z_{ref} + z_{old}} \cdot \begin{bmatrix} x_{old} \\ y_{old} \end{bmatrix} \quad (7)$$

It must be mentioned that the image referential has to be at the centre of the image, and not at a corner of the image, like usually is. I.e., all of the points have to be referenced to the centre of the image.

The above procedure is executed for all points, except for pelvis point (since it is the reference point), and finally has to be done their re-reference for previous origin (original referential).

With these transformations, more accurate results are achieved.

3. Performance Tests

Static tests were performed using a static planar dummy (with known joint angles) located in three different positions on the treadmill (see Figure 13). Those angles were measured using the

software and compared with the real ones to determine system static errors. Also, a dynamic test was done, where a person walked on the treadmill at different speeds. The trajectories of the joint angles were then analysed and their standard deviations were calculated to check if they were as expected, having literature trajectories as reference. A comparison between these angle profiles and the literature normal profiles was also done.

3.1 Static Tests

To determine the maximum static system error, some tests were made using a planar dummy placed at three different positions upon the treadmill: at the front, at the center, and at the rear (see Figure 13).

Figure 13. Static dummy placement, for static error determination (right view).

The planar dummy consists of two styrofoam plates with marks located as the joint positions of a human. The plates were carefully positioned in order to achieve a vertical inclination identical to that of a human (see Figure 14b). The traced and measured angles are shown in Table 1 and Table 2. These angles are defined in Figure 14.

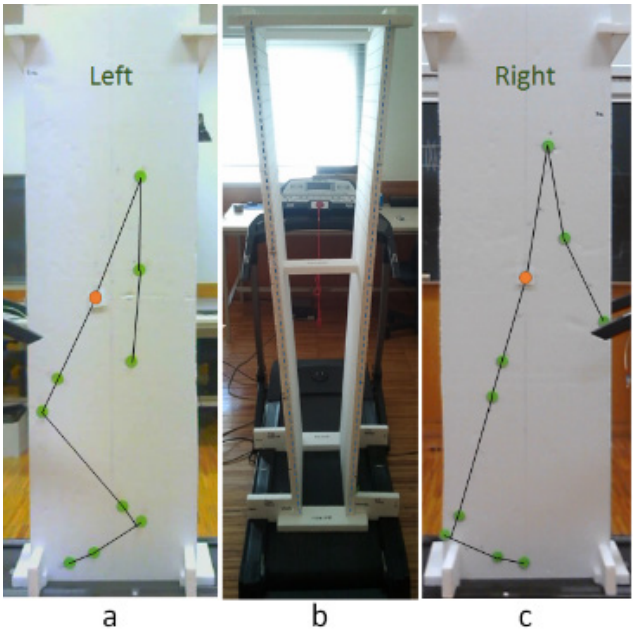

Figure 14. Planar dummy with known joint angles: a) left view; b) front view; c) right view.

The tests were made at the three referred positions upon the treadmill to be clear that there is neither a significant error at each location, nor a relation between the location and the error.

Each test lasted 3 minutes at 30 fps, which resulted in 5400 frames. In the total of the 3 tests this corresponds to 16200 analysed frames, which are more than enough to represent accurately the precision of the system in steady state.

After analysing the results it is concluded that there was no relation between the position of the dummy on the treadmill and the error of the measurements. Table 1 and Table 2 present the maximum errors obtained in all tests.

Table 1. Measured left and right sagittal angles, and respective errors, in degrees.

Angle (degrees)	Left				Right			
	Real value	Mean meas. value	Mean absolute error	Max. absolute error	Real value	Mean meas. value	Mean absolute error	Max. absolute error
Shoulder	20	20.4	0.4	0.7	-20	-19.6	0.4	0.6
Elbow	-5	-4.3	0.7	1.0	-15	-15.5	0.5	0.7
Trunk	-20	-21.0	1.0	1.2	10	9.7	0.3	0.5
Hip	-5	-3.7	1.3	1.8	5	6.1	1.1	1.5
Knee	65	64.3	0.7	1.0	0	-0.3	0.3	0.6
Ankle	-95	-97.2	2.2	2.3	-85	-83.0	2.0	2.3
Toes	-10	-11.2	1.2	1.7	-10	-9.4	0.6	0.9

Table 2. Measured crossed angles and respective errors, in degrees.

Angle (degrees)	Real value	Mean meas. value	Mean absolute error	Max. absolute error
Downward/ Upward Trunk	11	8.8	2.2	2.2
Backward / Forward Trunk	23	24.1	1.1	1.2
Downward / Upward Pelvis	9	7.3	1.6	1.8
Backward / Forward Pelvis	-9	-5.6	3.4	3.5
Posterior / Anterior Trunk	-5	-5.3	0.3	0.4

These tests show a relatively low static absolute error, with a maximum of 3.5 degrees obtained on crossed angles and 2.3 degrees on sagittal plane angles.

3.1 Dynamic Tests

A healthy person did a gait data acquisition, walking at different speeds. This person is a 30 year old male, 1.85 m tall, and weighs 87 kg.

Table 3 shows the maximum standard deviation of all angles for the different speeds of the treadmill.

Table 3. Maximum standard deviation of all angles for all dynamic tests, in degrees.

Speed [Km/h]	1.1	2.7	4.1	5.4
R. Shoulder	2.0	1.8	2.2	2.9
L. Shoulder	3.4	1.8	2.8	2.0
R. Hip	2.3	1.9	2.5	3.6
L. Hip	1.8	1.3	2.2	2.3
R. Knee	3.0	2.3	2.7	3.2
L. Knee	3.4	4.3	**6.1**	5.2
R. Ankle	2.0	1.3	1.6	2.4
L. Ankle	2.0	1.7	3.0	3.0

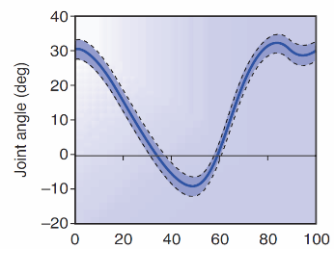
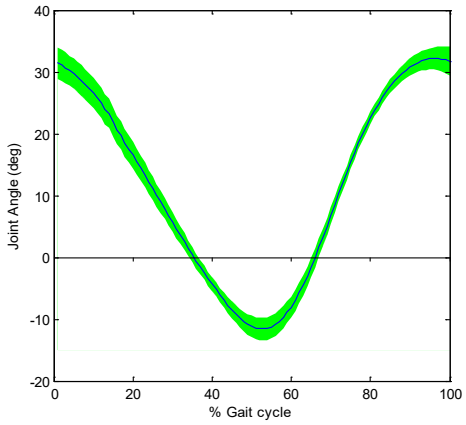
The maximum standard deviation of these tests is 6.1 degrees, which is similar to the value registered in [34].

Figure 15a shows the patterns of hip angles for the right side of a healthy person [35]. Figure 15b shows the measured values of the hip angle for the right side of a healthy person using the developed system.



a)



b)

Figure 15. a) Normal pattern of the right hip angle, and its standard deviation [35]; b) Measured right hip angle, and its standard deviation (in green) for a 4.1 km/h gait of a healthy person.

From Figure 15 it is seen that the measured values for the right hip have similar appearance to the pattern of this angle seen in the literature [35], except at the final phase of the gait cycle, where the pattern has a small nuance and our measurements do not. This nuance may be justified by the walking speed to obtain those pattern graphs, which is not mentioned in [35].

4. Repeatability Tests

Two more tests were done, where a person walked at the treadmill at different speeds and in two distinct sites. The whole system was completely installed and uninstalled in two different sites, and the same person did the gait acquisition twice, at the same speeds. The data were compared with each other, to check if both results are similar.

Figure 16 shows the mean measured values for both tests (solid lines) and their standard deviations (dashed lines). The curves obtained in both tests are similar, and their offsets are very low. The existing difference may be derived from the manual placement of each mark, which can vary, depending, for instance, on the dressing of the person.

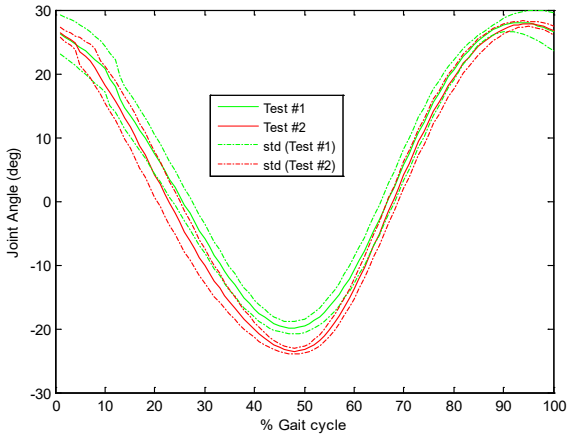


Figure 16. Right hip mean angle trajectories (solid lines) for two independent tests at 5.4 km/h gait speed, and their respective standard deviations (dashed lines).

To quantify the similarity of the results of these two tests, the following differences D_i were defined as

$$D_i = \frac{\min(\alpha_{2i} - (\alpha_{1i} \pm \sigma_{1i})) + \min(\alpha_{1i} - (\alpha_{2i} \pm \sigma_{2i}))}{2} \quad (8)$$

where

– i varies from 1 to 100, and represents the current percentage of the stride phase;
– α_{1i} is the angle i value of test #1;
– α_{2i} is the angle i value of test #2;
– σ_{1i} is the standard deviation of test #1 with index i;
– σ_{1i} is the standard deviation of test #2 with index i.

The Root Mean Square of D is then

$$RMS_D = \frac{1}{n}\sqrt{\sum_{i=1}^{n=100}(D_i)^2} \quad (9)$$

Table 4 presents the RMS_D values calculated with (9).

Table 4. Root mean square of the difference, in degrees, between two similar test sets, with the same walking person, at different sites.

Speed [km/h]	Shoulder		Hip		Knee		Ankle	
	Right	Left	Right	Left	Right	Left	Right	Left
1.1	0.6	0.7	0.5	0.9	0.3	1.6	0.2	0.3
2.7	0.0	0.4	1.8	1.9	1.0	1.3	0.4	0.0
4.1	0.9	0.0	0.6	**2.1**	1.1	0.1	0.2	0.1
5.4	0.2	0.9	1.3	1.2	1.5	1.1	1.1	0.1

Speed [km/h]	Pelvis bf [1]	Pelvis du [2]	Trunk bf [3]	Trunk du [4]	Trunk pa [5]
1.1	2.3	0.9	0.4	0.4	0.2
2.7	**5.0**	1.9	0.3	0.2	1.2
4.1	3.0	1.9	0.1	0.2	0.0
5.4	4.1	1.4	0.5	0.5	0.9

[1] Pelvis backward/forward, [2] Pelvis downward/upward,
[3] Trunk backward/forward, [4] Trunk downward/upward,
[5] Trunk posterior/anterior.

It is seen that the maximum RMS difference on sagittal plane angles is 2.1 degrees for the left hip at 4.1 km/h, which is a reasonable repeatability error that is compatible with the maximum absolute error measured on static tests. For crossed angles the maximum error is 5.0 degrees at backward/forward pelvis angle at 2.7 km/h, which is a maximum error of about twice the maximum static absolute error. This is acceptable since these crossed angles are determined by crossing right side points with left side points.

With these repeatability tests it is confirmed that precision was not affected by the portability of the system.

5. Conclusions

A system for acquisition and analysis of the human gait was developed and can be used for various applications such as physiotherapy, pathology identification and rehabilitation. It presents a mean error of about two degrees, what is perfectly acceptable for human gait characterization, once the human gait presents deviations above six degrees relatively to mean values [34]. The limitation of this system is the precision on crossed angles, which, because of their side cross nature, have an error of about five degrees. However, this is not relevant for the proposed purpose of human gait characterization.

A concurrent system has a maximum error of about 0.3º, seven times lower than the presented system. However, the presented system costs about 2,500 €, is significantly cheaper than concurrent systems (20 to 40 times), presenting a high quality/price ratio.

The presented system is a simple effective solution for human gait data acquisition and characterization, with a good precision, costing much less than current systems, and having the advantage of requiring much less space for installation setup.

ABSTRACT

The heat transfer process from a 6.4 Watt blue light flexible phototherapy mattress to a human hand has been studied. The intended use of the mattress is the provision of neonatal jaundice phototherapy during Kangaroo Mother Care (KMC) or skin-to-skin care. The heat transfer process has been studied with temperature and heat flow sensors inside an expanded- polystyrene spheroid 25mm of thickness where the phototherapy mattress's non emitting surface is in contact and folded around the hand while the light radiates outwards, to the polystyrene spheroid. The effective thermal capacitance of the phototherapy mattress was calculated as 3.4 J/ºK, the mattress-to-hand thermal conductance was found to be 0.25 W/ºC, the maximum temperature gradient between the mattress and the palm of the hand was 10ºC and the maximum power absorbed by the hand, 2.5W. The palm of the hand skin-to-core temperature gradient was 0.5ºC. It is expected that when used in KMC only one half of the hand skin surface would be in contact with the phototherapy mattress so that the effective thermal conductance to the hand in this conditions would be 0.125 W/ºC. Further study is suggested to include sweating effect of the hand.

1. Introduction

This paper is an extension of the work originally published in 2016 Healthcare Innovation Point of Care Technologies Conference [1], that paper was about the development and thermal assessment of a 1 Watt flexible blue light emitting diode (LED) array designed to apply neonatal jaundice phototherapy simultaneously with Kangaroo Mother Care (KMC) or skin-to-skin care, to benefit from both, well stablished, medical interventions in neonatal healthcare, KMC improves temperature stability of the neonate [2] while blue light irradiance is effective for treating neonatal jaundice [3], some studies like Samra's [4] showed the effectiveness of the simultaneous application. Before starting to use the device on neonates, the authors assessed the thermal performance of this form of phototherapy using two silicone polymer, thermally controlled mannequins, one of a neonate and the other of a mother. Results showed that the power transferred from the phototherapy mattress to the neonatal mannequin was 0.395 Watt, and the temperature increase in the contact surface (back of the neonatal mannequin) was 2.75ºC above its axillari temperature. The average blue light phototherapeutic irradiance obtained over the neonatal mannequin's back was 350 uW/cm^2, even if this irradiance is not considered intensive phototherapy; it approximately doubles that of white light fluorescent phototherapy devices.

Figure 1 shows the experimental setup with mannequins in [1], it is important to remark that the phototherapy mattress was held over the neonate's back by means of a long bandage acting as a belt around the mother and the baby, with no intervention of the mother's hand. In fact, a real mother would hold the phototherapy device to the baby's back with one hand to make sure the baby don't fall back.

Figure 1: The intended use of the flexible phototherapy mattress in [1]

Luis Jimenez, Av. Huayna Capac 184, Cusco – Peru. Tel +51 984988933
Email: wl_jimenez@yahoo.com

The present study's aim is to understand how the mother's hand would exchange heat with the phototherapy device; at first one might expect that the hand would act as an extra heat source contributing to the temperature increase of the phototherapy mattress and also that of the neonate. A closer look would make us realize that the mother temperature is physiologically controlled to 37ºC and that it would have a heat sinking effect when the phototherapy mattress temperature is above the mother temperature.

It is expected that with the hand's sinking effect, the power of the phototherapy mattress could be incremented safely to obtain a higher phototherapeutic irradiance over the neonate's skin. In this work we built a 6.4 Watt phototherapy mattress that has the same dimensions and flexibility as the one described in [1]. Experiments with this mattress around a volunteer's hand and the whole arrangement inside an expanded polystyrene spheroid are performed. Also, Simulink models are developed to obtain the effective thermal conductance from the phototherapy mattress to the human hand.

The thermal conductance we will obtain will allow us to have a design parameter to boost phototherapy irradiance keeping skin temperatures of the mother and the baby in a safe range.

2. Review of related work

An example of a medical device emitting light to a tissue, used in contact with the skin is the pulse oximeter; it is for measuring oxygen saturation non invasively, the difference with the phototherapy device of this work is that it only has two diodes and the power dissipated by the device is low compared to the phototherapy mattress of [1]. Medical device regulation agencies test the thermal safety of pulse oximeters over a person's finger that is inside an incubator at 37ºC [5]. Finally the temperature reached by the pulse oximetry sensor is measured, it has to be at most 4 degrees above body core temperature to get the authorization. The same temperature safety criteria has been applied in [1].

Researchers like Sienkiewicz [7] have quantified the amount of heat that is transferred from a hand submerged in water that is maintained between 37 to 40 degrees. In our case, the phototherapy mattress will not be used underwater, so the conditions for our study are different. Ducharme [6] studies the effect of blood circulation over heat transfer from body limbs to the environment. A review of Taylor [8] provides various thermal heat transfer parameters for hands and feet. An application of hands heat transfer is developed by Heller and Grahn [9], they develop a device that allows to reduce body core temperature rapidly cooling the hands by means of a glove that facilitates perfusion and allows a person to recover faster after exercise and to be able to exercise again.

Heat transfer between a hand and objects has been studied for human-computer interfacing in [10] as short contact time transients. The present work has to consider much longer times because Kangaroo Mother Care sessions last at least two hours as recommended by WHO in [11].

Heat flow from fingers to objects and Peltier pumps have been measured with thin film sensors as in the work of Guiatni and Kheddar [12], we use a similar sensor type as will be described below.

Also, thin film heat flow sensors have been used to measure heat transfer in processes that reached steady state, requiring more than 30 minutes to settle as in [13] where heat flow from human skin or from mannequins to water has been measured, they recommended to apply a thermal compound between the sensor and the material.

In the present work we don't require steady state to occur because modeling will consider heat capacity of the materials. The human hand will be treated as a constant temperature object with a thermal conductance to be determined experimentally.

3. Materials and Methods

3.1. Materials

The phototherapy mattress of this work is an arrayo of blue light emmitting diodes (LEDs) over an aluminium, duct reparing adhesive tape. Five flexible LED strips are placed in parallel separated 1 cm from each other over the adhesive tape. The phototherapy mattress dimensions are 10 x 25 cm and it weights 50 g. A 2110 Keithley desk multimeter has been used to measure DC current and voltage resulting that the mattress requires 6.4 Watt from a 12 Volt power supply. To assess the heat sinking effect of the hand that holds the phototherapy mattress, a semi-adiabatic experimental setup has been designed, it uses a hollow expanded polystyrene spheroid formed by two symmetric halves of 25mm of thickness hold together by adhesive tape for the experiments as shown un figure 2.

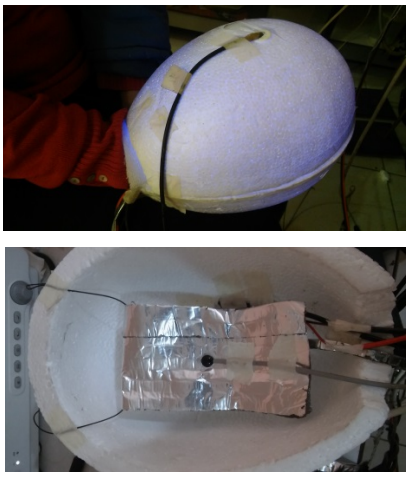

Figure 2: The prolate spheroid for the experiments with phototherapy matress inside

The polystyrene spheroid is prolate , c measures 14 cm, the perpendicular axis a measures 10.25 cm; for the internal surface of the spheroid c is 11.5 cm and a is 7.75 cm due to the thickness of the spheroid (2.5 cm). For the experiments, the phototherapy matress is folded in two at the middle of its longest size and sensor are placed inside the spheroid. The weight of the spheroid is 50 g.

The temperature of the phototherapy mattress is measured with a physiological monitor (Star 8000 –Comen Medical), its range is 0 to 50ºC with 0.1 ºC resolution; the metallic flat surface of the temperature sensor has been fixed to the aluminium tape back surface of the phototherapy matress with a drop of cyanoacrylate adhesive.

A temperature logger based on 5 LM35 sensors records the polystyrene spheroid inner wall temperature in two opposite points, another sensor is inserted in the outer wall of the spheroid as shown in the upper photograph of figure 2. Annother sensor is at the room air temperature. The last temperature sensor is for the experiment with the hand, it is fixed to the skin of the palm of the hand with a drop of cyanoacrylate adhesive. The resolution of this logger is the same as the physiological monitor and its temperature values have been calibrated with the physiological monitor. To measure the heat flow (in Watts/m^2) we use a thin film heat flow sensor, model HF4 from Omega Engineering Inc.; it has a sensitivity of 2 uV/(Watt/m2). The microvolt output is measured with a 2110 Keithley multimeter connected to a computer as a voltage logger. In the experiment without the hand, the heat flow sensor has been installed over the inner surface of the spheroid with adhesive tape at the borders, caring not to cover the thermocouple array with the tape as shown in figure 3. For the experiment with the hand, the heat flow sensor has been fixed over the palm of the hand with a drop of cyanoacrylate adhesive in each corner of the flow sensor. In both cases, a thin layer of thermally conductive cream has been applied between the heat flow sensor and the surface of interest.

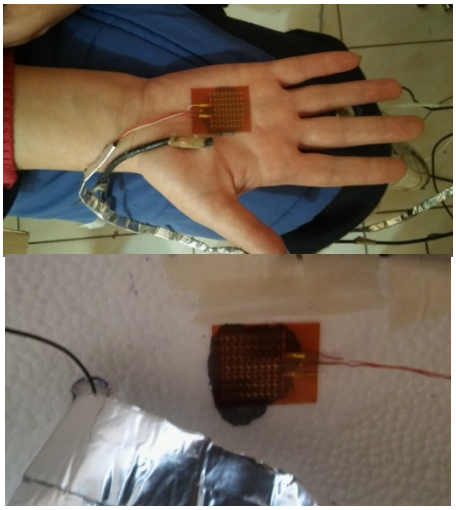

Figure 3: The heat flow sensor HF4 and temperature sensor LM35 fixed to the palm of a hand and to the polystyrene spheroid internal surface.

3.2. Methods

We use a thermal modeling method common in power electronics design, specifically the continued fraction or Cauer model [14].

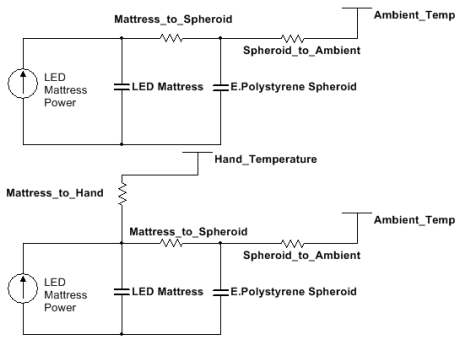

Figure 4: Simplified thermal models for the experiments.

In figure 4 the upper circuit represents the simplified thermal models for the first experiment (without the hand) and the lower circuit represents the experiment with the hand ; the main objective is to determine the thermal conductance between the LED mattress and the human hand.

The first is experiment is to study the thermal behavior of the phototherapy mattress inside the polystyrene spheroid without the hand inside, this is to find the effective thermal specific heat of the mattress, the effective thermal conductance (convective plus radiative) between the phototherapy mattress and the polystyrene spheroid and the effective thermal conductance between the polystyrene spheroid and the surrounding ambient air. The mattress has been kept hanged up inside the polystyerene spheroid and folded in two as shown in figure 5 with the two folded light emmiting surfaces parallel to the hemispheres that form the spheroid that is also kept vertically hanged up by a cotton thread as shown.

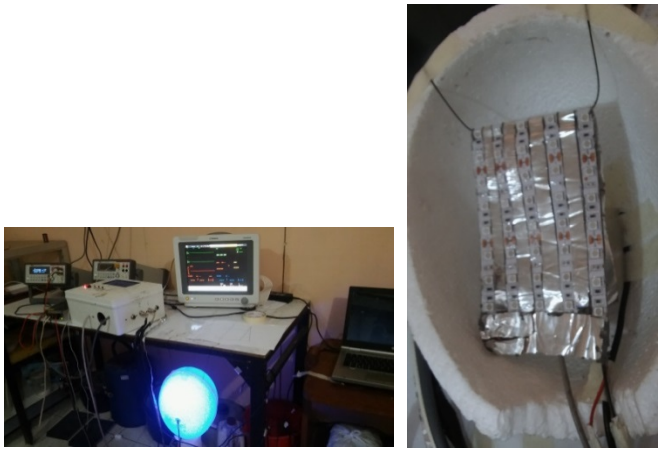

Figure 5: Phototherapy mattress hanged up and folded in two for the experiment without the hand.

The second experiment is the experiment with the hand of a healthy volunteer 48 years old and 70 Kg weight, the total surface area of his hand was measured as 0.024 m^2; the two halves of the polystyrene spheroid have been cut in the southern pole to allow the forearm to pass remain outside while the hand is inside the spheroid as shown in figure 6.

Figure 6: Experimental setup for the experiment with the hand.

3.3. Conductive, convective and radiating heat transfer:

- The effective thermal capacity of the phototherapy mattress will be determined in the experiment without the hand; as soon as the mattress is turned on, electrical power minus the radiative power emitted as light by the mattress begins to heat it, increasing the mattress temperature with approximate constant slope the first two minutes.

- The thermal specific heat of expanded polystyerene spheroid is assumed as 1500 J/(Kg ^{o}K). With this value and the known weight (50g), the spheroid's thermal capacity is 75J/^{o}K so the temperature slope related to power is 0.0133 ^{o}K/(Watt second) that will be used in the to model the experiments.
- Thermal conductance of the spheroid is calculated knowing the thermal conductivity of expanded polysterene assumed 0.035W/m^{o}K . The approximate surface of the spheroid is calculated from its dimensions: averaged internal and external dimensions: c_av=12.75cm, a_av=9cm. As the thickness of the spheroid is 25mm, the thermal conductance Gspher= 0.354 W/^{o}C; the heat loss of the spheroid to the surrounding air is assumed purely convective assuming low radiative losses, it will be proportional to the temperature difference between the core of the spheroid and the surrounding air temperature. Experimentally, the core of the spheroid temperature is calculated as the average of the inner and outer wall temperatures of the polystyrene spheroid given by the temperature sensors.
- The convective heat loss from the phototherapy mattress to the surrounding polystyrene spheroid is assumed proportional to the temperature difference between the mattress and the spheroid core temperature. The unknown convective thermal conductance will be adjusted by trial and error to make the Simulink model match the results of the experiment without the hand.
- The human hand and the phototherapy mattress are in contact in the second experiment, so, power transfer from the mattress to the hand can be modeled by a constant heat conductance so Pcond= Gcond*(Tmattress-Thand) where power will be in Watts, temperatures in degrees celsius and thermal conductance Gcond in Watt/oC. The effective value for Gcond will be determined so the model matches the results of the experiment with the hand.

3.4. Simulink model of the experiment without the hand

Two Simulink models are proposed to compare and adjust some unknown model parameters to match modeling results to the experimental results. The two models use an integrator to model temperature of the phototherapy mattress (output of the integrator); the input to the integrator is the net power received followed by a gain representing the inverse of the heat capacity of the mattress (initially unknown but this parameter will be set according to the results of the experiment without the hand as described in the previous section). Another integrator is used to model the core temperature of the polystyrene spheroid. The Simulink model for the experiment without the hand is shown in figure 7.

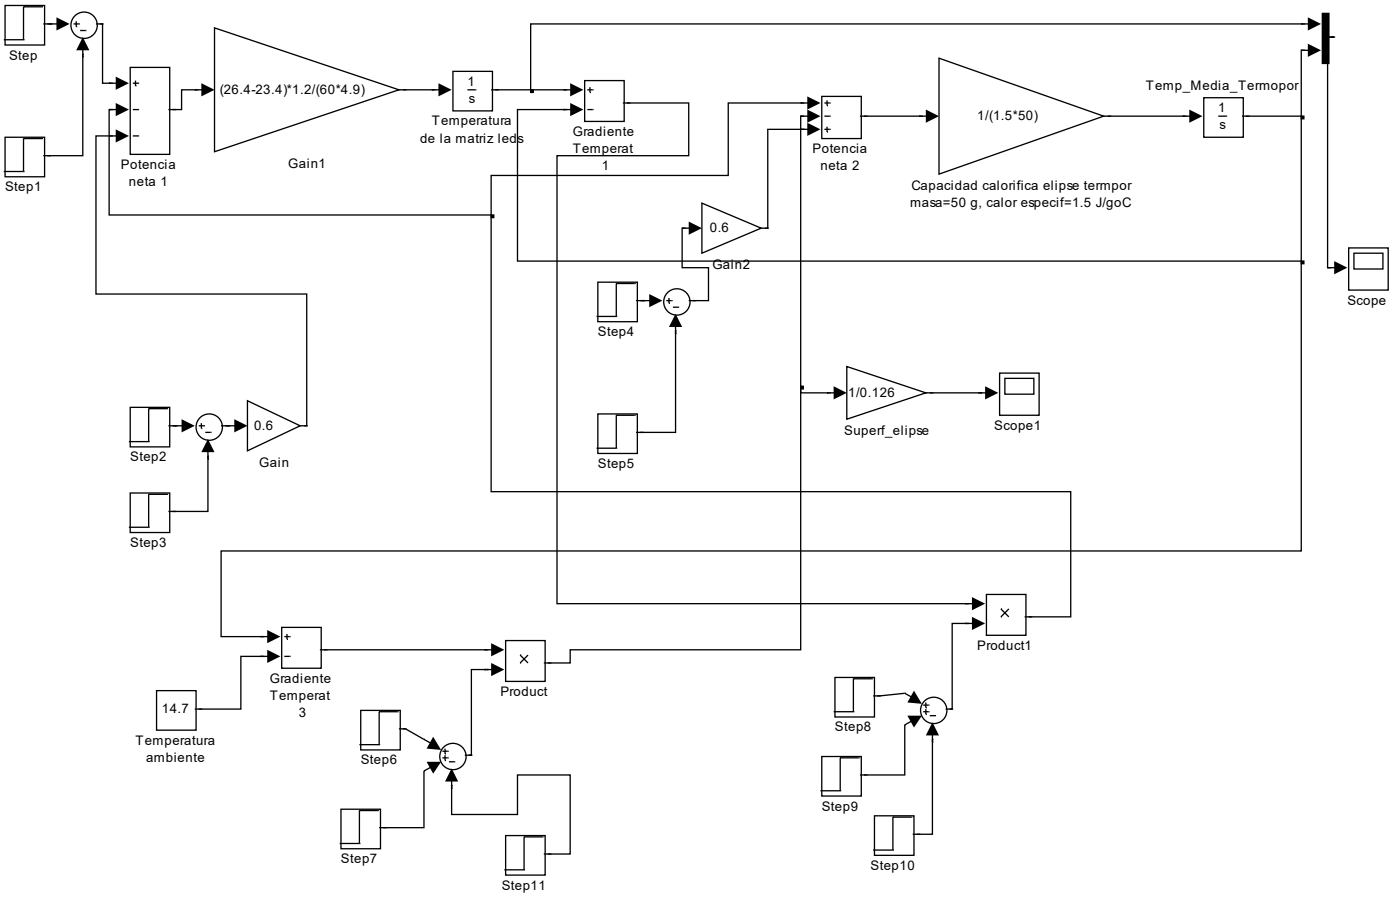

Figure 7. Simulink model for the experiment without the hand.

Step and Step1 sources model the electric power applied to the mattress (6.4 Watt) that starts in zero seconds and finishes in 960 seconds. Part of this power converts to blue light irradiance that goes directly from the LEDs to the polystyrene spheroid. The power corresponding to this irradiance is modeled by Step2 and Step3 sources and has to me substracted from the electrical power because it does not contribute to heating the phototherapy mattress; inversely the same irradiance power modeled by Step4 and Step5 sum directly as power gain to the spheroid. Gain 1 models the inverse of the thermal capacity of the phototherapy mattress, this parameter is adjusted later to match experimental results. The blue light irradiance and the corresponding power are calculated with experimental data from the heat flow sensor described above and the known interior surface area of the spheroid. The upper left integrador is for the mattress temperature and the upper right integrator is for the polystyrene spheroid whose gain at the left represents the inverse of its heat capacitance.

The power loss from the spheroid to the surrounding air is modeled by the temperature gradient with respect to the constant air temperature of 14.7 ºC (in the lower left of figure 7) and the Simulink block product, that models the thermal convective conductance together with Step6, Step7 and Step11 sources (a time variant approach is used to increase the convective conductance that is 0.354 W/ºC from 0 to 480seconds to 0.454 W/ºC from 480 to 1440 seconds to match experimental data, after this time, conductance returns to the original value of 0.354 W/ºC until the end of the simulated experiment time. Two values of conductance have been necessary because with only one conductance the difference between simulation and experiment mattress temperatures was too high.

The same approach of time variant convective conductance from the phototherapy mattress to the spheroid is implemented by the block Product1 and the Step8, Step 9 and Step10 sources. The power loss from the phototherapy mattress to the spheroid is proportional to the temperature gradient between the mattress and the spheroid (the substraction of the outputs of both integrators) and the conductance that is adjusted to match the experimental data. It is necessary to state that the phototherapy mattress has been turned off when its temperature approached 50oC because of the temperature maximum range of the physiological monitor used to record the mattress temperature. The Simulink model has been adjusted to reflect what happened in the experiment at this respect.

3.5. Simulink model of the experiment with the hand

The Simulink model for the experiment with the hand is shown in figure 8. The range of temperatures observed in the experiment with the hand allows the model to be accurate enough with a constant conductance (0.15 W/ºC) for the mattress to spheroid and a constant conductance (0.454 W/ºC) for the spheroid to ambient; these values are the same that were obtained in the model without the hand. Also, the same thermal capacity of the mattress is used (Gain block entering the integrator). The main difference here is the "hand effect" that is represented by a heat transfer proportional to the temperature gradient between the mattress and the hand, the hand is being represented by constant temperature of 36.5 ºC according to the experiment data. The gain block following the gradient represents the thermal conductance between the phototherapy mattress to the palm of the hand.

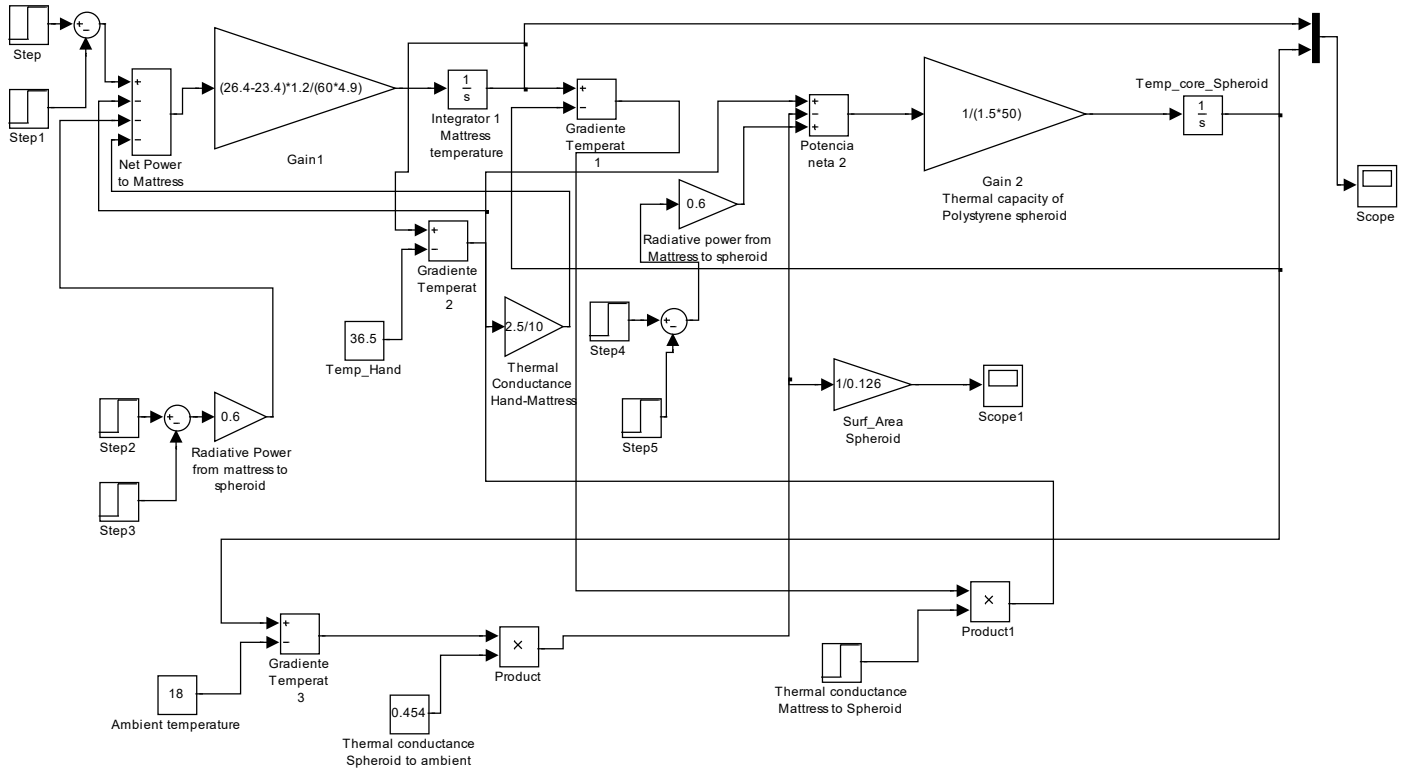

Figure 8. Simulink model for the experiment with the hand.

4. Results

4.1. Results of the experiment without the hand.

The initial temperature of the mattress and polystyrene spheroid were 18.2 ºC and 14.8ºC respectively, the electrical power provided to the phototherapy mattress was 6.4W during 16 minutes until its temperature achieved 49.5 ºC and power was turned off manually to zero. The exponential curve of the mattress temperature is of the charging capacitor type, the same occurs to the polystyrene spheroid core calculated as described in section 3.3.

Figure 9 shows the experimental data obtained with the first experiment (wihout the hand): Tmattress, Tcore_spheroid, Heat flow in W/m^2 , measured in the inner wall of the polystyrene spheroid, and also, the simulated mattress temperature with the Simulink model with the parameter values adjusted by trial and error to obtain a match between the experiment and simulation.

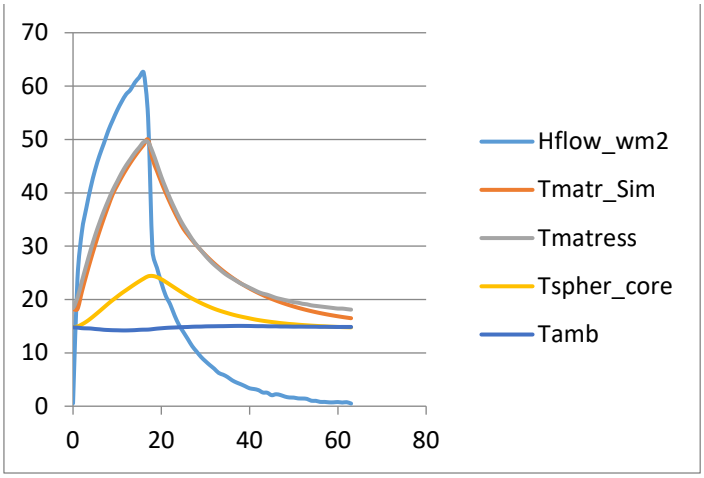

Figure 9. Simulink model for the experiment without the hand.

The first interesting result is the heat flow waveform at the spheroid inner wall showing an immediate transfer of radiating power from the phototherapy mattress because of the step increase from 0.5 to 23 W/m^2 , this justifies the radiating power sources in the Simulink model. There is the same type of variation when the phototherapy mattress is turned off.

Next, the phototherapy mattress temperature is showed in grey color overlaps closely the orange color simulated temperature of the mattress, this has been obtained adjusting by trial and error the model parameters to the next values: The thermal conductance of the mattress to the spheroid is not constant trough the simulation time with a value of 0.12 W/ºC the first 8 minutes, then 0.15 W/ºC until the 24th minute and returning to 0.12 until the end of the experiment. An average thermal conductance value of 0.135W/ºC from the mattress to the spheroid could be used for design purposes in future studies.

Also in the simulation, the thermal conductance from the polystyrene spheroid to the ambient is not constant neither, with values: 0.354 W/ºC and 0.454 W/ºC the same intervals of time indicated above. The thermal capacity for the phototherapy mattress in the simulation is obtained from the first minute of the mattress temperature ramp of the experiment giving a value of 3.4 J/ºK and knowing the 50g mass of mattress, the effective specific heat of the mattress results 68 J/KgºK. For reference, the calculated thermal capacity of the polystyrene spheroid is 70 J/ºK.

The temperature of the mattress during the experiment is limited only because the power has been turned off before it reached 50ºC. It is expected that the hand in the next experiment would be a limiting factor for the phototherapy mattress temperature.

4.2. Results of the experiment with the hand.

Figure 10 shows the results of the experiment with the hand with time in minutes. The first minutes are with the mattress turned off, so The heat flow sensor has been fixed with adhesive tape in the borders to the palm of the hand. The negative values mean heat is flowing from the hand to the outside and positive values that heat flows into the hand. The light yellow curve is the heat flow in W/m2 and show that while the matress is off, an average heat flow of 3.5W/m2 goes from the hand to the mattress that is folded around the hand, during this time the hand is hotter than the mattress by about 1.5ºC (34.5ºC-33ºC).

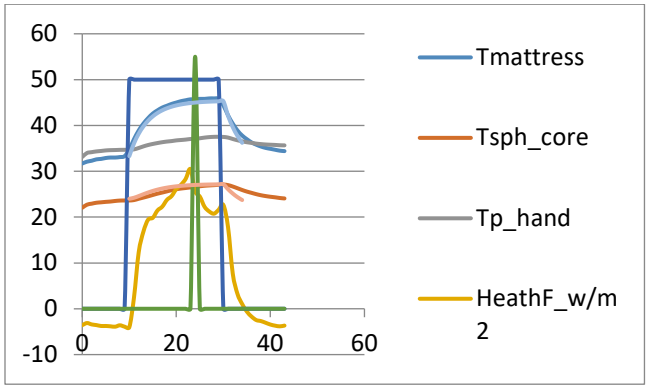

Figure 10. Results for the experiment with the hand.

When the mattress is turned on, the heat flow rapidly changes sign while the mattress's temperature rises but, this time, limited by the temperature of the hand that remains below 37.5ºC so, the phototherapy mattress reaches 45.8 ºC asymptotically. In the later part of the temperature rising, an occlusion of the brachial artery is produced with the help of the physiological monitor by means of the non invasive blood pressure measurement (NIBP) procedure, this causes a temporal descent of the heat flow to the hand that recovers just before the phototherapy mattress is turned off for the latest part of the experiment. The waveform of the heat flow to the hand during the heating phase is irregular, peaking before the occlusion. The Simulink model for this experiment takes most of the parameters from the previous model without the hand. To match the results of the simulated mattress temperature to the experiment with the hand, the thermal conductance between the mattress and the hand has been found by trial and error to be 0.25 W/ºC, there is a close match between simulation and experimental results (curves Tmattress and Tmat_simul). The volunteer reported he felt his hand started to sweat when the mattress temperature rose above 39ºC and felt thermal discomfort after the NIBP occlusion.

5. Discussion

Regarding neonate-mother mannequin pair in kangaroo mother care, in [1] the contact point between the 1Watt phototherapy mattress and the back of a thermally regulated neonatal mannequin was 2.75 ºC above the mannequin

temperature, but now for a 6.4W device, the temperature of the palm of a real hand incremented only 0.5ºC above core temperature (37ºC), so, the real hand has a much higher ability to sink power from the phototherapy device due to blood perfusion in the hand compared to a silicone rubber mannequin. It can be expected that the back of a real neonate as a blood perfused tissue that can sweat would be more able to absorb heat than the mannequin in [1].

Comparing the temperature of the phototherapy mattress in both experiments (Figures 8 and 9) , without the hand it rises up to 50ºC with no limit, contrary to this, in the experiment with the hand, it acts as a heat sink that limits the mattress temperature below 45ºC. The effective thermal conductance of 0.25 W/ºC and the approximate 10 ºC temperature gradient between mattress and hand gives about 2.5W absorbed by the hand. But the measured heat flow to the palm of the hand with the heat flow sensor was 25 W/m^2; when considering a hand with 0.024 m^2 surface, a total power of 0.6Watt would be absorbed by the hand, the difference (2.5W- 0.6W) might be explained by the sweating of the hand.

Our results are in agreement to Taylor [8] that indicates a maximum theoretical transfer of 12W to both hands with 1ºC skin to core temperature gradient (we obtained 2.5W to one hand with 0.5ºC skin to core temperature). We suggest to extend this study to understand the sweating effect, measuring relative humidity inside the expanded polystyrene spheroid. Finally with this results, in Kangaroo Mother Care (KMC) position, the hand of a mother holding the phototherapy mattress would have a contact surface with the mattress of approximately 50% of the surface in this experiment (only the palm, not the hand's dorsum), so the expected conductance would be 0.125 W/ºC in KMC.

6. Conclusions

The effective thermal capacitance of a 6.4 W phototherapy mattress and the thermal conductance from it to a human hand have been calculated from confined experiments inside a polystyerene spheroid, this thermal model parameters will be used in a future clinical study of heat transfer processes involving a similar phototherapy mattress and real mothers providing Kangaroo Mother Care to neonates requiring jaundice phototherapy.

The ability of a thin film heat flow sensor based on thermocouple arrays to measure radiating heat transfer has been confirmed, it opens the way to use it to study heat transfer processes where clinical radiant warmers are used.

Conflict of Interest

The authors declare no conflict of interest.

Acknowledgments

The authors wish to thank Universidad Nacional de San Antonio Abad del Cusco and Hospital Regional Cusco for supporting this study through the project "Effectiveness of blue light irradiance adapted to Kangaroo Mother Care in neonatal jaundice treatment"

Network security implements various strategies for the identification and prevention of security breaches. Network intrusion detection is a critical component of network management for security, quality of service and other purposes. These systems allow early detection of network intrusion and malicious activities; so that the Network Security infrastructure can react to mitigate these threats. Various systems are proposed to enhance the network security. We are proposing to use anomaly based network intrusion detection system in this work. Anomaly based intrusion detection system can identify the new network threats. We also propose to use Real-time Big Data Stream Processing Framework, Apache Storm, for the implementation of network intrusion detection system. Apache Storm can help to manage the network traffic which is generated at enormous speed and size and the network traffic speed and size is constantly increasing. We have used Support Vector Machine in this work. We use Knowledge Discovery and Data Mining 1999 (KDD'99) dataset to test and evaluate our proposed solution.

1. Introduction

Network security is of increasing importance than ever with increased usage of network-based computing resources. Several network security mechanisms like encryption, firewalls, cryptography, access control, authentication, and intrusion detection are used to provide network security. These techniques are used to detect and prevent the malicious activities and network attacks. Network intrusion detection is an essential task for any network based computing environment. Network Intrusion Detection system continuously monitors the network traffic and perform in-depth packet analysis for malicious activities and attacks in real time. Once the intrusions are detected, appropriate actions can be taken to mitigate the threat against the computing and network resources. Currently, computer networks are generating a huge amount of data traffic at enormous speed and this data generation speed is continuously increasing. Network traffic also contains different types (variety) of data. Network traffic satisfies all the three V's of big data; volume, velocity, and variety. The focus of this paper is to propose a network intrusion detection mechanism that can deal with all the 3 V's of big data.

This paper is an extension of work originally presented in 2016 IEEE 7th Annual Information Technology, Electronics and Mobile Communication Conference (IEMCON) [1]. In original work, we have used anomaly-based approach for network intrusion detection. Anomaly based approaches use machine learning algorithms to identify the abnormal behavior from the normal data traffic. We have used statistical approaches for feature reduction and support vector machine with the linear kernel for the classification process. We also have proposed an Apache Storm topology for the real-time big data streaming application. The current work uses Radial Basis Function (RBF) kernel for the support vector machine. This paper discusses the class imbalance problem and its possible solutions. We also discuss multiple techniques to reduce the false positive and false negative rates in the context of network intrusion detection system.

Mostly, network intrusion detection system follows one of the two major detection mechanism; Anomaly-based network intrusion detection and Signature based network intrusion detection. Some researchers also have proposed hybrid approaches. Each detection approach has its own strengths and weaknesses.

1.1. Signature Based Network Intrusion Detection

Signature based or misuse intrusion detection systems have better detection rate as compared to anomaly based systems in case of known network attacks. This type of intrusion detection systems scans predetermined signatures in network traffic packets and recognizes predefined patterns of network intrusions and attacks.

*Muhammad Asif Manzoor, Faculty of Engineering and Applied Sciences, University of Regina, SK, Canada, AsifManzoor@uregina.ca

The signature based system cannot detect new potential threats until their signature is added to the database. During the time, when a new threat is detected and its signature is applied, these systems cannot detect the new threats. Malicious strings in TCP/IP packets, abnormal flag combination, request for non-existing services, and intrusion attack signature are few of the approaches [2], [3] used to design signature based network intrusion detection systems.

1.2. Anomaly Based Network Intrusion Detection

Anomaly based system try to capture the behavior of incoming network traffic. These systems establish a baseline model for normal user/network behavior against the abnormal behavior. This model is created by analyzing the network traffic over a period of time and train the system to classify the normal traffic and malicious traffic. The baseline model reflects the valid activities of applications, hosts, users, and network. All the incoming network traffic is scanned using the defined model to classify it into normal and intrusion network packet. Alarms are raised for all the packets which are classified as intrusions. Anomaly based detection systems are good to detect new network threat at the cost of increased false alarm rate (both false positive and false negative detection). Despite this problem, anomaly based detection is an indispensable method due to increase in new type intrusion attacks.

The rest of paper is organized as follow, anomaly based intrusion detection systems are review in section II. Section III provides the detailed description of KDD 99 data set and also discusses the pre-processing techniques used in this work. Implementation details and methodology is discussed in Section IV. Experimental results are discussed in section V. Class imbalance problem and false positive/negative problem for network intrusion detection are discussed in Section VI and the paper is concluded in Section VII.

2. Literature Review

Machine learning algorithms are used to design anomaly based intrusion detection system. Both unsupervised and supervised learning methods are used in this domain. Although many intrusion detection methods are proposed using various different machine algorithms we will review Artificial Neural Network (supervised learning) and K-Mean Nearest neighbor (unsupervised learning) based approaches.

Artificial Neural Networks are used by many researchers as supervised learning algorithm to train the intrusion detection technique. Rapake et al. [5] proposed to use numbers of system calls that are executed on the host machine. These numbers are utilized for neural network training. Han and Cho [6] proposed to use evolutionary neural networks to detect anomalies based on learning the behavior of the program. Authors have used 1999 DARPA IDEVAL data set to evaluate their proposed method. Liang et al. [4] proposed to apply Fisher feature selection algorithm on KDD 99 dataset for performance enhancement. Authors used artificial neural networks to develop their intrusion detection system.

K-Mean Nearest Neighbor (KNN) is a clustering algorithm based on unsupervised learning method. Wang et al. [7] used KDD 99 dataset and defined new features based on density, cluster centers, and nearest neighbors. KNN is used to classify the normal traffic and network intrusion. Li et al. in [8] combined KNN algorithm with Particle Swarm Optimization (PSO) to design hybrid system. The K-mean algorithm suffers from premature convergence. PSO algorithm helps to avoid premature convergence in the proposed method. Xian et al. [9] proposed to unite fuzzy KNN algorithm with clonal selection algorithm to design network intrusion detection. Jiang et al. [10] used incremental KNN algorithm to detect intrusions. Authors used outlier factor to calculate the deviation degree of the cluster in this work.

Multiple network intrusion detection systems are proposed using data mining algorithms. Han et al. [11] used data mining approach to detect intrusions. They have analyzed attributes of network traffic protocol to identify misuse signature. They also have analyzed network packet contents for intrusion signatures. Qin and Hwang [12] proposed internet trace technique which discards few non-functionary frequent episodes rules dynamically. These episode rules are utilized to recognize abnormal sequences in network traffic connections. Otey et al. [13] develop a general purpose tunable algorithm to detect outlier/anomalies. The proposed algorithm can work with mixed attribute dataset as well dynamic and streaming data sets. KDD 99 intrusion dataset is one of the dataset used to test and evaluate the proposed tunable algorithm.

Gondal et al. [14][14] determined center of clusters on basis of diversity. These Diversity-based centroids are used to develop network intrusion detection system. Xiao et al. in [15] used Bayesian Network Model Averaging in their proposed work and compared it with Naïve Bayes classifier and Bayesian Network classifier. Authors have evaluated their work over NSL-KDD dataset.

Jeong et al. [16] proposed in their work to used Discrete Wavelet Transform to extract the features from network traffic. Principal Component Analysis (PCA) is applied to the extracted features to identify principal components and a visual analytics tool is proposed for intrusion detection. Le et al. [17] used deep learning approach in their network intrusion detection system. Authors explored various optimizers with Long Short-Term Memory Recurrent Neural Network.

Table I: Details of Dataset

	Training	**Testing**
Normal	97280	60623
Probe	4107	4166
DoS	391458	229853
U2R	52	13939
R2L	1124	2478
Total	494021	321026

Table II: Network Attacks and Categories

Category	Network Attacks
Denial of Service (DoS)	back, land, neptune, pod, smurf, teardrop, **apache2, mailbomb, processtable**
Probe	ipsweep, nmap, portsweep, satan, **mscan, saint**
User to Root (U2R)	ftpwrite, guespasswd, imap, multihop, phf, spy, warezclient, Warezmaster, **httptunnel, named, sendmail, snmpgetattack, xlock, xsnoop**
Remote to Local (R2L)	bufferiverflow, loadmodule, perl, rootkit, **ps, snmpguess, sqlattack, worm, xterm**

3. Knowledge and Discovery 1999 Dataset (KDD 99)

Knowledge and Discovery 1999 Network Intrusion Detection dataset (KDD 99) [18] is used in this work to test and evaluate the performance of the proposed method. KDD 99 is publicly available dataset and widely used by various researchers. The complete KDD 99 dataset contains around five million records for training and 3 million records for testing tasks. Due to the large size of the original dataset, smaller version of KDD 99 dataset is frequently used for evaluating intrusion detection systems. This smaller version contains 10% of testing and training records. We also have tested our intrusion detection system using smaller dataset. KDD 99 dataset contains normal records as well as malicious records. Twenty two types of attacks are included in training dataset along with normal network packets. Seventeen additional attacks are added to the testing dataset and can be used to determine whether the proposed algorithm can detect new attacks or not. Network attacks are divided into four categories; Denial of Service (DoS), Probe, User-to-Root (U2R), and Remote-to-Local (R2L). Table I provides the distribution of training and testing dataset into normal and intrusion packets. KDD 99 dataset consists of 494021 training records and 311029 testing records. The division of network attacks into categories is given in Table II. Network attacks in bold are new attacks added to testing dataset only.

Each record has 41 attributes; description of these attributes is given below:

- 9 basic and single connection derived (SCD) header features,
- 9 time based multiple connection derived (MCD) header features,
- 10 host based multiple connection derived (MCD) header features, and
- 13 content based features collected from traffic payloads.

3.1. Pre-Processing

KDD 99 data set is pre-processed in order to make it appropriate for the machine learning algorithm. The second reason for the pre-processing is to enhance the intrusion detection rate. Pre-processing is performed in three steps.

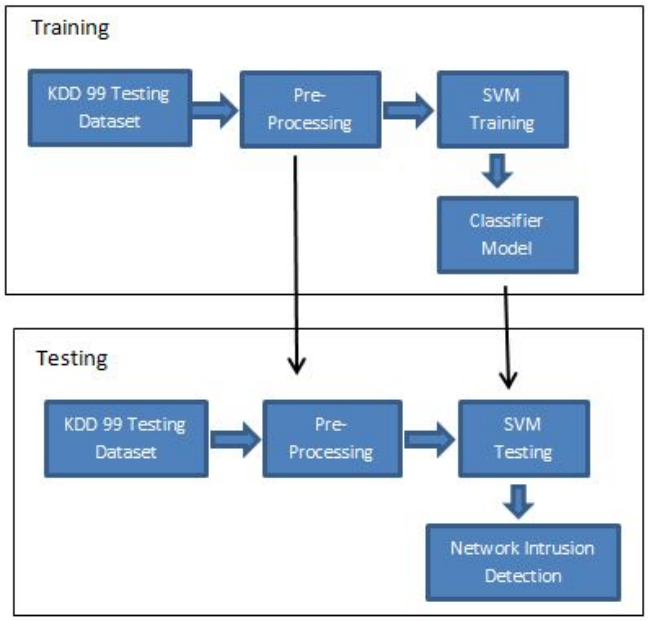

Figure 1: Network Intrusion Detection System Architecture

1. Each record in the dataset consists of numeric as well as categorical attributes. Textual data is used for categorical attributes. Support vector machine algorithm requires numeric data (either discrete or continuous). The first step in pre-processing is to convert this categorical attributes to numeric attributes. The dataset contains three categorical attributes while rest of the thirty eight attributes are numeric. Every category of an attribute is assigned a specific number.

2. Next, we have normalized all the numeric attributes in the training dataset. Testing dataset attributes are normalized using ratios determined for training dataset, so both (training and testing) subsets are normalized with same ratios. Normalization process converts all attributes to the same range; hence each attribute has a similar effect during the training process. The normalization process also significantly reduces the training time for support vector machine algorithm.

3. We applied statistical operations on the training dataset to reduce the features. Same features are dropped from testing dataset. These dropped attributes had a negative impact on the performance of network intrusion detection system. Reduce the number of attributes have a positive effect on the computation time.

4. We have used LibSVM library for SVM implementation; it requires training and testing data in a specific format. Lastly, we have converted the dataset to LibSVM compatible format.

4. Methodology

The architecture of Support Vector based Network Intrusion Detection system is given in Figure 1. KDD 99 training data set is pre-processed and Support Vector Machine (SVM) algorithm is applied to build a model. Pre-processing information determined for the training dataset is used to pre-process the training dataset. SVM model built during the training process is used to predict the category during the testing process.

4.1. Support Vector Machine

Support Vector Machine algorithm [19] is developed to solve binary classification problems. SVM is supervised learning algorithm which can be used for classification and regression problems and it is based on statistical learning approach. The fundamental idea of SVM is to identify hyperplanes (decision boundaries) between two categories based on the training data and one providing the maximum separation between two categories is selected as shown in Figure 2. This hyperplane provides the optimal separation between two categories. The identification of optimal hyperplane is considered as an optimization problem. Testing examples are projected and the category is predicted based on their position with respect to the optimal hyperplane. Cover's theorem [20] states; if linearly non-separable dataset is transformed using non-linear kernel function then it is probable that the transformation process will generate linearly separable dataset in higher dimensional space. Support vector machine also uses different types of non-linear kernel function to create linearly separable dataset and increase classification performance.

Let we have a training dataset S= $\{(x_1, y_1), (x_2, y_2),\ldots, (x_n, y_n)\}$, where $x_i \in R^n$ and it represents input feature vector and $y_i \in \{-1, 1\}$ is the category. Let weight and bias of hyperplane is given by w and b. The non-linear Kernel function is applied on training dataset to transform it into linearly separable categories and $\varphi(x)$ is used to represent it. The hyperplane between the two categories can be defined as:

$$w.\varphi(x) + b = 0 \qquad (1)$$

The optimization problem for calculation of w and b is:

Minimize

$$\varphi(w) = \tfrac{1}{2} \|w\|^2 \qquad (2)$$

Subject to

$$y_i(w.\varphi(x) + b) \geq 1$$

New variables ζ_i (slack variable) and C (regularization constant) are included in above optimization problem:

Minimize

$$\varphi(w,\zeta) = \tfrac{1}{2} \|w\|^2 + C\sum_{i=1}^{N} \zeta_i \qquad (3)$$

Subject to

$$y_i(w.\varphi(x) + b) \geq 1 - \zeta_i, \zeta_i \geq 0$$

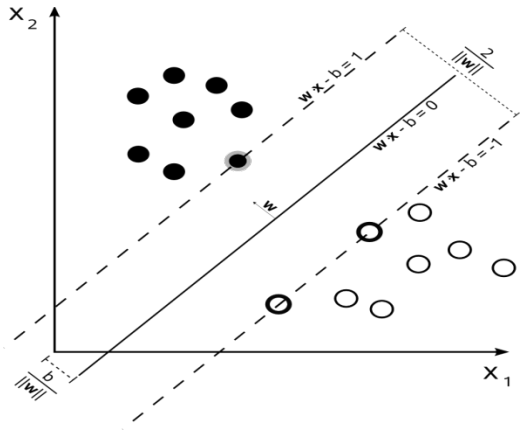

Figure 2: Decision Boundary with maximum margin

Where ζ is used to relax the hard margin constraint and C is used to manage the trade-off between classification error and maximal margin of separation.

Multiclass SVM is often constructed using basic binary SVMs to deal with real world problems like pedestrian detection [21], medical diagnosis [22], sentiment analysis [23] and many others. For multiclass SVM, 1-vs-1 [24] and 1-vs-all [25] are two approaches used to build basic binary SVMs.

We have used LibSVM [26] Java API in this work for SVM implementation. LibSVM provides both regression and classification implementations. We have used C-SVM approach to classifying the network traffic data into normal and intrusions. Radial Basis Function (non-linear kernel function) is used in this work for transformation into higher dimensional space. The value of gamma used here is 1 and the value of C is 6. As kernel implementation is part of LibSVM library; hence we are considering it a part of SVM training process and not a part of pre-processing. Finally, we have used the 1-vs-1 multiclass approach in this work.

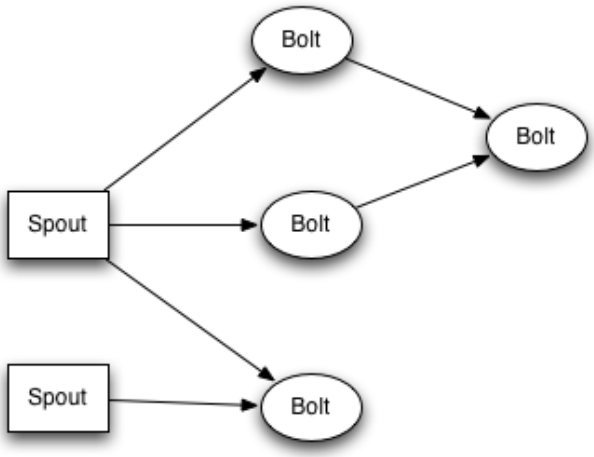

Figure 3: Apache Storm Topology

4.2. Apache Storm

Apache Storm is a scalable distributed framework that can be easily configured on cloud services or clusters. It is developed to process real-time big streaming data. Spouts and bolts are the basic building blocks for Apache Storm applications. Spouts are used as data sources; data is forwarded in form of tuples to the bolts. Bolts are the computation unit of the Apache Storm. Bolts process and evaluate the incoming tuples and can forward the results in form of tuple to other bolts for further processing. Spouts and bolts are combined to form a topology. Topologies are directed acyclic graphs and used to develop Apache Storm applications. An Apache Storm topology is shown in Figure 3. The edges of the topology show the flow of data. Bolts and spouts are vertices in the topology. We can create many instances of every bolt and spout to speed up the processing.

Apache Storm framework offers distributed and fault tolerant computing. An Apache Storm cluster is shown in Figure 4. The cluster consists of one or multiple worker nodes and only one master node. Worker nodes are named as supervisors while the master node is named as nimbus. Apache Storm also requires ZooKeeper cluster to provide coordination between the master node and worker node(s).

The proposed Apache Storm topology is given in Figure 5. This topology has one spout and three bolts. The detail of the bolts and spout is given below:

1. **Input Reader (Spout)** is the only data source in this topology. KDD 99 dataset is stored in a text file. This spout reads the KDD 99 dataset and each record is forwarded as a tuple to the next bolt.
2. **Data Pre-Processer (Bolt)** receives the tuples from Input Reader and performs pre-processing as explained in Section 3. It converts the categorical data to numeric data, perform normalization and feature reduction. Finally, it converts the data into LibSVM compatible format.

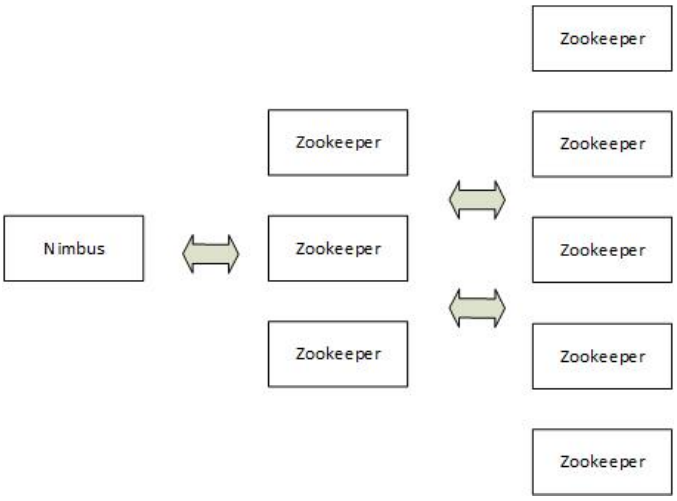

Figure 4: Apache Storm Cluster

Figure 5: Apache Storm Topology

3. **Support Vector Machine (Bolt)** performs the classification process for the network intrusion detection system.
4. **Result Aggregator (Bolt)** is the last processing unit in this topology. It aggregates the classification results. It stores these results on a text file for further analysis.

5. Experimental Results and Discussion

5.1. Experimental Setup

Apache Storm 0.9.6 is configured on Ubuntu 12.04. All the experiments are performed on 3.4 GHz Intel Core i7 processor with 16.00 GB of memory.

5.2. Evaluation and Analysis

We have used KDD 99 intrusion detection dataset to test our SVM based method. The testing dataset contains 18729 records belonging to new network intrusion attacks (17 new network attacks included) which are not included in the training dataset. Whereas 292300 records belong to network intrusion attacks which are also part of the training dataset. The accuracy for intrusion detection of the proposed method is 98.03% when only known attacks are considered (Network attacks used during training process). This intrusion detection rate drops to 92. 60% when all the network attacks are considered during the testing process. All the discussion, following this point, will be based on the complete testing dataset. The classification results for complete dataset (new network attacks included) of the proposed intrusion detection method are given in Table III. A simplified confusion matrix is given in Table IV; which only divides the classification results into normal and malicious network traffic.

Table III: Confusion Matrix for Network Intrusion Detection System

	Normal	Dos	Probe	R2L	U2R
Normal	60294	66	225	7	1
DoS	6571	223266	16	0	0
Probe	760	441	2965	0	0
R2L	12849	91	72	927	0
U2R	2462	3	0	7	6

Table IV: Simplified Confusion Matrix

	Normal	Attack
Normal	60294	299
Attack	22642	227794

The performance of the can also be determined using False Positive Rate (FPR), False Negative Rate (FNR), Precision and Recall. These four performance evaluators are calculated below using simplified confusion matrix (Table IV).

FPR = FP / (FP + TN) = 22642 / (22642 + 227794) = 0.09

FNR = FN / (FN + TP) = 299 / (299 + 60294) = 0.005

Precision = TP / (TP+FP) = 60294 / (60294+22642) = 0.73

Recall = TP / (TP+FN) = 60294 / (60294 + 299) = 0.995

For a good classification rate, FPR and FNR must be close to zero while Precision and Recall must be close to one. Other than Precision, all other performance parameters indicate good classification performance.

Normal traffic and DoS attacks are recognized correctly mostly. Whereas Remote to Local (R2L) and User to Root (U2R) are the two categories which are recognized incorrectly most of the time. Class imbalance is the main reason behind this shortcoming. R2L and U2R have the least number of training samples. Similarly, probe attack category also has relatively less training examples. While remaining two categories have the majority of the training examples; around 98.9% of the dataset. This class imbalance creates biased results during the training process. We will discuss few techniques to solve class imbalance problem in the next section.

The proposed network intrusion detection system is supposed to handle real-time streaming data traffic. The training process is done offline and it is not a real-time task. This system can process roughly 13,600 packets in a second for testing/prediction purposes. This processing speed is achieved with a single general purpose computer. The processing speed can be further increased by using a cluster of dedicated servers. This processing speed is a good indicator for real-time big streaming data scenario.

Support Vector Machines are machine learning algorithm used for supervised classification tasks whereas Apache Storm is development platform used to develop real-time big streaming data processing applications. Apache Storm supports multiple languages for coding. We have used Java in our work. The proposed system achieves good classification results along with a good processing speed.

6. Performance Enhancement for Network Intrusion Detection Systems

Class imbalance refers to the uneven representation of classes in training dataset. The skewed distribution causes performance degradation for many machine learning algorithms [27]. The methods to solve class imbalance problem are generally divided into two categories; data level and algorithm level solutions.

6.1. Data Level Approach

Data level approaches apply different techniques to the dataset before training process. It can be considered as pre-processing step to accommodate the class distribution. Sampling, under-sampling, and over-sampling, is a data-level approach to managing class distribution. Over-sampling duplicates the records from the minority category whereas under-sampling removes records from the majority category to minimize the imbalance ratio between different categories in training data.

Yen et al. [28] proposed to use cluster based approach to solve the class imbalance problem by selecting representative data. Clusters are used to identify the representative data to achieve better prediction rate for minority categories. Yu et al. [29] used vector quantization to under-sample the majority class and constructed representative local models. Synthetic Minority Over-Sampling Technique (SMOTE) [30] is an adaptive data-level approach for over-sampling. It computes the probability distribution to model minor categories and use this probability distribution to add new examples to the smaller classes. Guo and Viktor [31] proposed to combine boosting and data generation to over-sample the minority classes. This approach is named as DataBoost-IM algorithm.

6.2. Algorithm Level Approach

In algorithm level approach, specialized machine learning algorithms are used to tackle class imbalance problem.

One of the techniques used is to develop modified version of the basic learning algorithm which can manage imbalanced classes. z-SVM [32] and GSVM-RU [33] are modified version of SVM to manage imbalanced class distribution. z- SVM tries to maximize g-mean value by moving hyperplane using a parameter z. GSVM-RU uses granular computing to enhance the classification accuracy.

Another algorithm level approach is to use cost sensitive learning; whenever a misclassification occurs, an expensive cost is imposed on the classifier. Cao et al. [34] proposed Particle Swarm Optimization (PSO) based cost sensitive artificial neural network for imbalanced data classification.

7. Conclusion

Network intrusion detection is an important component of network management and it is a defense mechanism for network security. Anomaly based intrusion detection detects anomalous behavior or new network attacks which signature-based intrusion detection cannot. Higher processing speed is required to handle incoming real-time data traffic. The proposed Network Intrusion detection system can process 13,600 packets in a second on a single general purpose computer. Apache Storm based network intrusion detection system can achieve higher processing by deploying a cluster of computers. Data pre-processing techniques are implemented to reduce the number of feature; which reduces the training and testing time and increased the classification accuracy.

In this paper, we outline the machine learning based method for anomaly based intrusion detection. We propose to utilize support vector machine as supervised learning algorithm to classify the incoming network traffic into normal and network intrusion attacks (DoS, Probe, R2L, U2R). KDD 99 intrusion detection dataset is used in this work. The data set is pre-processed in order to make incompatible with support vector machine

algorithm as well as with LibSVM library. The experimental results show the feasibility of the proposed intrusion detection method. The performance can be further enhanced by solving class imbalance problem as discussed in section 6. This paper suggests using Support Vector Machine for classification process and Apache Storm as development platform to develop network intrusion detection system to handle big data characteristics of the network data traffic.

ABSTRACT

Higher Education Institutions (HEIs) employ Learning Management Systems (LMSs) primarily for greater efficiency, profitability, technological advancement or survival. The predominantly used LMSs, Moodle and Blackboard account for in excess of 60% usage by the top HEIs. However, the individual international regions do not necessarily bear the percentages of the overall total. Gaps are identified in optimality in course delivery within online learning when one studies LMSs and their functionalities. Advanced Distributed Learning (ADL) Initiative which was established to standardize and modernize training and education management and delivery, developed and recommended usage of Sharable Content Object Reference Model (SCORM) 2004 and later versions. SCORM 2004 which provides for flexibility in sequencing and navigation for learner-centric course delivery is not supported in any version of the more prevalently used LMSs. It is believed that most people have a preferred way in processing information. We propose codifying one or more Learning Style Instruments (LSIs), diagnosing the preferred teaching approach(es) and dominant/existing learning styles within a batch of learners, then providing course delivery as a best-fit per learner. As a proof of concept, OLeCenT allows the input of one or more course learning paths with real-time learning and automatic reconfiguration of the course path where a new trend or pattern is identified. OLeCenT identified disparity in teaching-learning and provided a mechanism towards improving online learner-centric course delivery. OLeCenT also identified comparative levels of similarities among learners and instructors even where they are deemed to be of different teaching-learning styles/mechanisms.

1. Introduction

For the formative years, the primary mode of knowledge transfer was through the face-to-face mode of delivery. Eventually knowledge was captured in writing which provided an alternative to the usual face-to-face delivery. As technology developed, new ways were found to transfer knowledge. This paper is an extension of work originally presented in Future Technologies Conference 2016 which describes a tool to enhance learning [1]. The development of technology also made available the combination of different forms of learning [2-3]. Amidst these, the need for the initial and most established mode of delivery still has its significance [4-6].

Whether through face-to-face or alternative means of course delivery, differences between the learners' approach to learning or styles of learning and the teacher's teaching mechanism or approaches within a batch of learners and teachers may lead to various rates of learning and a non-optimal level of learning in the overall batch of learners [7-9]. Identifying where there is a teaching-learning style mismatch and solving same can help achieve a resultant increase in the level of learning, and should free a teacher to more ably deal with special cases such as learners with special needs or develop varied course material and course delivery mechanisms to assist additional learners.

We examine teaching-learning in Higher Education Institutions, discuss theories of teaching and learning, and analyze the usage of learning mechanisms or styles in Learning Management Systems. These are used to propose OLECENT, an approach in view of learner-centric course delivery. We describe

*Carl Beckford, Department of Computing, University of the West Indies, Mona, Kingston 7, Jamaica, 876-702-4455, carl.beckford@uwimona.edu.jm

the features, results and benefits of the derived artifact, OLeCenT, an e-Learning Tool towards optimising the teacher-learner interaction [10-11].

2. Teaching-Learning in Higher Education Institutions

2.1. Teaching-Learning using Learning Management Systems

Learning Management Systems (LMSs) are used worldwide by Higher Education Institutions to assist with efficiency in course delivery or management [12-13]. There are different types of LMSs, which all work slightly differently but ultimately perform the same or similar functions and can deliver the same learning materials with different levels of efficiency [14]. Higher Education institutions tend to have one of the following three categories of LMSs in operation: off-the-shelf or proprietary, open source, or bespoke [15].

In an analysis of top universities in each international region, home-grown self-used systems accounted for about 17%, Sakai accounted for about 10% and Canvas accounted for only 5%. Usage of 40% and 21% by Moodle and Blackboard respectively confirm the dominant players in the LMS market. However, the individual regions do not necessarily bear the percentages of the overall total; for example, top universities of Latin American reflect a 100% usage of Moodle [16].

A detailed review of the four named systems was done based on features related to direct or indirect relevance to the level of learning, the finite number of human teachers, and resources or system design which may affect positively or negatively the teaching-learning process. In view of [17-30], Table 1 reflects the comparison of LMS features that are important in mitigating the problem of course delivery being static or erroneously less learner-centric.

Noteworthy are the features of Learning Management Systems that are not fully offered by any of the predominantly used learning environments. These are:

1. Provide for assessment of learning and teaching styles
2. Offer course delivery path/workflow to each learner to match learner's dominant learning style
3. Provide options for learner to receive course delivery in his non-dominant or other learning styles
4. Allow input and usage of text unique to courses
5. Allow for integration of activity simulation where practical knowledge is to be transferred
6. Allow instructor to modify course path according to students' expectations and/or indications from course beginning to end, in terms of transfer of knowledge and necessities for emphasis for repeats
7. Provide for assessment which equates to or exceeds the traditional mode but matches the style of learning
8. Provide for learner-centric scheduling of synchronous activities where such include online activities

Other LMSs or tools had some features but were significantly lacking in others. E.g. Intelligent Tutoring Systems (ITS) represents some of the knowledge and reasoning of good one-to-one human tutors, as it attempts to simulate a human tutor's behaviour and guidance [31].

Table 1: Comparison of LMS Features that are important in mitigating the Problem of Course Delivery being Static or becoming less Learner-Centric

Feature	Learning Management Systems			
	Black board	***Canvas***	***Moodle***	***Sakai***
Improvement for lack in the traditional with use of tools in the online environment				
Provide diagnostic assessment of learning/teaching styles				
Restrict and/or provide sections of course path based on pre-entered conditions or complex access criteria	√		√	
Modify course delivery path/workflow to match dominant learning style in batch of learners	√	√	√	√
Offer course delivery path/workflow to each learner to match learner's dominant learning mechanism / style				
Provide options for learner to receive course delivery in his non-dominant or other learning styles				
Automatically determine loss of learning of learners prior to assessment(s)	√	√		
Alert instructor and/or learner of loss of learning	√	√	√	√
Allow instructor to instantly assess student comprehension	√	√	√	√
Provide instructor with a view of the student's perspective	√		√	
Allow students to understand their own progress towards mastering key outcomes		√		
Equitable benefits to all types of courses and maintain/improve on tools in the traditional				
Allow input of all types of course material	√	√	√	√
Allow input and usage of text unique to courses	●		●	
Provide for use of external tool seamlessly within the learning environment	√	√	●	●
Allow for integration of activity simulation where practical knowledge is to be transferred	●	●	●	●
Align content items to objectives and goals	√			√
Allow students to add personal course artefacts that improved their learning	√	√		
Provide for Collaboration	√	√	√	√
Allow for student feedback outside of those pre-determined by instructor	●	√	√	●
Allow instructor to modify course path according to students' expectations and/or indications	●			
Provide for assessment which equates to or exceeds the traditional mode but matches the style of learning				
Integration of administrative information or functionalities that may aid in learning				
Allow input of teaching-learning schedule of course	√	√	√	√
Use teaching-learning schedule for notifications	√	√		
Provide for learner-centric scheduling of synchronous activities where such include online activities				●

Feature	Learning Management Systems			
	Black board	***Canvas***	***Moodle***	***Sakai***
Mitigate falsehood especially in assessment	√			
Allow HEI to offer course to learners worldwide through MOOC		√		
Permit customization so that HEIs can add according to holistic or long-term learner profile			√	√

Key: √ - feature is fully offered
● - feature is partially offered
blank - feature is not offered

2.2. Limitations of Learning Management Systems

There are documented common complaints about Learning Management Systems. Whereas all are genuine complaints, the only complaint that is identified to be of significant interest for this research is that LMSs do not fit in the existing administration workflows [32]. A key reason to implement a LMS is to support efficient training administration. So, if this isn't working for you, then it is a real problem [32]. We concur with [32] that when selecting a LMS, the HEI should be sure to map the existing administration and end user workflows, and use these maps to communicate your LMS implementation requirements. However, we purport that the LMS implementation requirements should be guided by best practices as well as best-case possibilities available in view of existing skills, resources, and achievements.

Blackboard's market strategy over the years (acquisition), Moodle's significant growth, and the arrival of Canvas (the first significant new product in this space in at least 8 years) tell interesting tales [33]. The various Learning Management Systems have delved into course management and delivery, and some have aimed for improved learning. Not many have designed or implemented a system to manage learning in view of the learner's behavior or learning style. The emergence of MOOC platforms, which for the high-profile MOOC initiatives such as Coursera and edX are homegrown products may be the ideal platform to have self-paced managed learning where learning is tracked and attempts made during the learning process to enhance the level of learning.

It is possible that Learning Management Systems (LMS) are not equivalently suited for all types of courses [34]. Where a course's primary aim is to transfer knowledge with respect to a practical achievement of a task, as opposed to a description or narrative view of an issue. This view could be used to support the view that LMSs may be more advantageous to certain types of courses. Among respondents who were engaged in a programming course delivered with use of a LMS, the communication and discussion aspects of the course were rated among the highest and guidance to solving problems among the lowest [34]. Although LMSs are deemed beneficial, they fall short in some aspects specific to computer science education, in particular programming. A Learning Management System lends itself to web-based learning environments by enabling the management of courses, delivery of content and lectures, assessment and tracking of student engagement with the course. The implementation of a worldwide networking course by Cisco Networking Academy which seeks to transfer the knowledge about a practical task should provide some encouragement for what is possible for other course content such as computer programming.

We are in the midst of learner-centric shifts in education, and the drivers for these changes are social and economic, not just technological [35]. A distinction is made between competency based learning (CBL) which focuses on learning outcomes rather than competency based education (CBE) which is based on time. The emphasis on the knowledge transfer to the learner being the guide for success is an essential aspect of old, existing or new Learning Management Systems.

A Delta Initiative analysis points out that most of the core Learning Management Systems were developed between 1997 and 2004, and there really has not been many new pedagogical capabilities added since that time. Instead, innovation has been driven by a horizontal expansion of business areas, e.g. interoperability with peripheral systems for portals, portfolios, ERP integration, and the ERP systems themselves [33]. As interoperability is achieved, improvements in pedagogical capabilities are achieved. The advancement of technology and the use of computing resources could assist in this way.

In referring to examinations or other forms of assessments, students have a strong tendency not to learn for life, but "to the test" [36]. A mismatch or misalignment [37] in form or content between examination tasks and learning objectives will lead to students engaging in the wrong learning activities and acquiring the wrong competences [36]. Multiple-choice tests are perhaps the most infamous example of such mismatch and the associated detrimental effects, decried for fostering surface learning and student disengagement [38]. Such a mismatch is likely to alienate students and erode their learning motivation [36]. The possibility of mismatch or misalignment suggests the need for LMSs that ensure that learning motivation is not eroded, course delivery is competence-oriented [39], as well as a LMS that mitigates the mismatch between examination tasks or other course delivery activities and learning objectives.

There are three functional areas the LMS is designed to support: Course Administration, Communication and Collaboration, and Custom Educational Content. One of the most important things an academic technologist can deliver to faculty is to show them how the LMS can be used for more than just a platform for course administration but to teach in new ways [33]. This implies that (1) there may be ways provided by the LMS to teach or improve teaching exists but are not being employed, (2) there may be new ways of teaching that may be inspired and developed with use of a LMS that have not been explored, (3) there may be new ways of teaching that are inspired by external factors to the LMS, maybe through the face-to-face environment, that may be developed as new features to the LMS.

Amidst the many Learning Management Systems and even the smaller number of those that are used predominantly by HEIs, Columbia University has used aspects of at least six of these, namely Sakai, Moodle, Angel, Canvas, eCollege and Coursera [33]. The change from one LMS to another suggests a feature, functionality, improvement or enhancement in at least one aspect of course administration, communication and collaboration, and providing educational content, which was in one system above another. Therefore as technology develops and the area of e-learning or online learning expands, newer functionalities and enhancements may become possible.

3. Consideration of Learning Styles in Learning Management Systems

Education has always had new ideas about learning and teaching. Educators are asked to use new curricula, new teaching strategies, and new assessments. They are directed to prepare students for the new state standardized test or to document and assess students' work through portfolios and performance assessments [40]. While classroom teaching and management strategies are well documented, the online learning environment presents different challenges and benefits [41]. Teaching in an online environment requires a special set of teaching skills since many of the strategies and tactics associated with best teaching practices are somewhat constrained by the primarily text-based environment [41]. Implicitly, teaching could be taking place in the online environment yet learning is not taking place or certainly not at the level at the perception of the teacher or instructor.

3.1. Theories of Teaching and Learning

Many theories of teaching and learning have been purported and/or established. Some of these are Cognitive Load Theory of Multimedia Learning, Maslow's Hierarchy of Needs, Cognitivism, Experiential Learning (Kolb), Constructivism, ADDIE Model, ARCS Model of Motivational Design, and Multiple Intelligences Theory [42].

Cognitive Load Theory of Multimedia Learning discusses that there are three types of cognitive load: extraneous cognitive load, intrinsic cognitive load, and germane cognitive load. The intrinsic cognitive load embodies the idea that all instruction has an inherent difficulty associated with it. This inherent difficulty may not be altered by an instructor. However many schemas may be broken into individual "subschemas" and taught in isolation, to be later brought back together and described as a combined whole [43, 44]. It is important that systems of learning provide for segmentation or combining of learning units to facilitate the intrinsic cognitive load. Extraneous cognitive load, is under the control of instructional designers. Where possible, the ideal LMS provide for the setup and automation of learner paths. Extraneous cognitive load and intrinsic cognitive load are not ideal; they result from inappropriate instructional designs and complexity of information. Germane cognitive load is coined as "effective' cognitive load, caused by successful schema construction. Each of the cognitive loads are additive, and instructional design's goal should be to reduce extraneous cognitive load to free up working memory [43]. The ideal LMS should model aspects of the human cognitive architecture, and provide for ease of use by course designers in their endeavor to apply sound instructional design principles.

Abraham Maslow's theory, Hierarchy of Needs is a motivational theory in psychology that argues that while people aim to meet basic needs, they seek to meet successively higher needs in the form of a hierarchy. Maslow presented the idea that human actions are directed toward goal attainment. Any given behavior could satisfy several functions at the same time; for instance, going to a pub could satisfy one's needs for self-esteem and for social interaction [45]. Maslow's Hierarchy of Needs has often been represented in a hierarchical pyramid with five levels. The four levels (lower-order needs) are considered physiological needs, while the top level is considered growth needs. The lower level needs need to be satisfied before higher-order needs can influence behavior [45]. Development and implementation of a learning system or tool must consider that the body of learners as well as instructors and teachers would tend to follow Maslow's Hierarchy of Needs.

The theory of Cognitivism says that the learner is viewed as an information processor (like a computer). Cognitivism focuses on the inner mental activities – opening the "black box" of the human mind is valuable and necessary for understanding how people learn [46]. The ideal learning system should provide for some capture of each learner's learning mechanism/style/intelligence. In view of the theory, ensuring that stimuli exist within a Learning Management System will contribute to the system being more learner-centric.

The theory of Constructivism says that learning is an active, constructive process. The learner is an information constructor. People actively construct or create their own subjective representations of objective reality. New information is linked to prior knowledge, thus mental representations are subjective. Knowledge is constructed based on personal experiences and hypotheses of the environment [46]. This theory is used to support the proposal that the system should provide for basic information access needs such as system user-friendliness and ease of use, to allow for ease of transition in a learner using the system to increase the level of learning. The theory says that learners continuously test the hypotheses of the environment through social negotiation. Each person has a different interpretation and construction of knowledge process. The learner is not a blank slate but brings past experiences and cultural factors to a situation [46]. Past experiences and cultural factors is used to support for a diagnostic mechanism that ascertains learner preferences or other factors that may influence learning. Constructivism assumes that all knowledge is constructed from the learner's previous knowledge, regardless of how one is taught [46]. Thus, even listening to a lecture involves active attempts to construct new knowledge.

Constructionism builds up the theory of Constructivism. Constructionism is 'learning by making'. Constructionism shares constructivism's connotation of the learning. It then adds the idea that this happens especially felicitously in a context where the learner is consciously engaged in constructing a public entity [47]. The theory of constructionism proposes that learning may be enhanced through kinesthesia. A Learning Management System should facilitate kinesthetic learning objects.

The theory of Multiple Intelligences identifies seven distinct intelligences. The theory says that we are all able to know the world through language, logical-mathematical analysis, spatial representation, musical thinking, the use of the body to solve problems or to make things, an understanding of other individuals, and an understanding of ourselves. Our educational system is heavily biased toward linguistic modes of instruction and assessment and, to a somewhat lesser degree, toward logical-quantitative modes as well [42]. It is argued that the broad spectrum of students would be better served if disciplines could be presented in a numbers of ways and learning could be assessed through a variety of means. It may seem impossible to teach to all learning styles [42]. However, as we move into using a mix of media or multimedia, it becomes easier. As we understand learning styles, it becomes apparent why multimedia appeals to learners and why a mix of media is more effective [48, 42]. The theory of multiple intelligences satisfies the many types of learning preferences that one person may embody or that a class embodies.

3.2. Teaching and Learning Styles

Learning styles are ways of learning presumed to allow individuals to learn best [49,50]. It is believed that most people have a preferred way in processing information [51]. There are a number of instruments developed for determining learning styles. Some of these are Witkin's Field-Dependence/Field-Independence, Kolb's Experiential Learning Model (ELM) and Learning Style Inventory (LSI), Hunt et al.'s Conceptual Level Model, Dunn et al.'s Learning Styles Inventory (LSI), Fleming et al.'s VARK Model, C.I.T.E Learning Styles Instrument, and Gregorc Learning Style Model [52]. Learning styles has a bad press. It seems that they are lauded and then attacked on an almost cynical basis [53]. This is probably because it is very difficult to measure learning (in part because it is difficult to define learning in useful ways), especially if one wants to know when learning happens or to what it can be ascribed. The critics of learning styles say things like 'Knowing ones learning style does not improve learning.' However knowing one's learning style can be beneficial if learners take the next step, and consider how and when they learn as part of a reflective meta cognitive process, with action to follow [53].

Predominantly, it was stated that there were three learning styles, namely auditory, tactile/kinesthetic and visual [54,55]. Currently it is more accepted that there are more than three learning styles [48,31]. There are discussions whether intelligences are styles or whether they should be considered as learning styles [56]. Gardner says that intelligences are not the same as learning styles. Intelligences are mental computers of varying strength, while styles are the ways in which individuals putatively approach diverse tasks [42]. The prevalently used instruments were chosen for the research, with consideration given to the level of their accessibility. Consequently, the learning styles models discussion includes Fleming et al.'s VARK Model, Kolb's Experiential Learning Model (ELM) and Learning Style Inventory (LSI). C.I.T.E Learning Styles Instrument was incorporated primarily due to its accessibility.

3.2.1 VARK Model of Learning Style

The VARK Model evolved from the VAK Model. The Visual, Auditory and Kinesthetic (VAK) learning style model is a common and widely-used model of learning style. According to this model, most people possess a dominant or preferred learning style; however some people have a mixed and evenly balanced blend of the three styles of visual learners, auditory learners and kinesthetic learners. In summary visual learners tend to learn through seeing and think in pictures, auditory learners tend to learn through listening and have highly developed auditory skills, and kinesthetic learners tend to learn through moving, doing and touching and expressing themselves through movement [38]. With use of an appropriate instrument, the ideal Learning Management System should provide for ascertaining the difference in styles of the learners; this should aid in the system's provision of a learner-centric course delivery.

VARK is an acronym for Visual, Aural, Read/Write and Kinesthetic. The VAK inventories had been around for years until expanded by the inventor of the model. The inclusion was a second 'visual' modality for Read/Write learners. From observation some students have a distinct preference for the written word whilst others preferred symbolic information as in maps, diagrams, and charts [53]. These two preferences were not always found in the same person. He also said that there is more acceptance of this distinction today than in the 1980s [53]. Fleming's VARK Model is suggesting that the visual and auditory/aural aspects of the previous VAK model did not capture ideally the read/write practices or preferences that were exemplified by some learners. The Learning Management System that is best suited for the learner should be able to distinguish a learner who is visual, aural or other or combinations of these styles.

3.2.2 Kolb's Learning Style Model

The Kolb's Experiential Learning Model and Learning Style Inventory (LSI) has been called the Kolb Learning Style Model, a 9-fold classification of learning styles with combinations of feeling, watching, thinking and doing/acting scored as a 12-item self-report questionnaire [51]. Kolb's learning theory sets out four distinct learning styles (or preferences), which are based on a four-stage learning cycle. The model offers both a way to understand individual people's different learning styles, and an explanation of a cycle of experiential learning that applies to us all. Kolb says that ideally (and by inference not always) this process represents a learning cycle or spiral where the learner 'touches all the bases', i.e., a cycle of experiencing, reflecting, thinking, and acting. Immediate or concrete experiences lead to observations and reflections. These reflections are then assimilated (absorbed and translated) into abstract concepts with implications for action, which the person can actively test and experiment with, which in turn enable the creation of new experiences [51]. The current Kolb Learning Style Model reflects an enhancement to a former version of the model [57]. As knowledge concerning learning styles increases and learning style theory, mechanism and instruments improve, there should be flexibility in a Learning Management System to facilitate ease of adaptability to the changes.

Kolb explains that different people naturally prefer a certain single different learning style. Various factors influence a person's preferred style, notably in his experiential learning theory model (ELT). The discussion on experiential learning theory is not included as it should not affect the approach for Learning Management Systems and the use of this approach [51]. The determination of a learning style is done by the following of a protocol or rules that govern the assessment process. The ideal learning environment that provides mechanism for assessing learners should provide for the seamless creation and modification of rules per learning style and per learning style instrument that may vary with an institution's selection of learning style approach. Knowing a person's learning style enables learning to be orientated according to the preferred method. Everyone responds to and needs the stimulus of all types of learning styles to one extent or another - it's a matter of using emphasis that fits best with the given situation and a person's learning style preferences [51, 58].

Whereas there has been support for the Kolb Model, there has been some criticism. The concept of learning styles has been criticized by many and experts suggest that there is little evidence to support the existence of learning styles at all. One large scale study looked at more than 70 different learning style theories and

concluded that each lacked enough valid research to support its claims [59]. In a 2008 article, educator Mark K. Smith argued that Kolb's model is supported only by weak empirical evidence and that the learning process is actually far more complex than the theory suggests. He also noted that the theory fails to fully acknowledge how different experiences and cultures may impact the learning process [59]. Additionally, [60] says that despite the various refinements of Kolb's inventory, the instrument still appears to possess several weaknesses which limit its use, including low reliability, questionable validity, and low predictive powers. The instrument presupposes that individuals can only possess one learning style. Their study says that although the four modes suggested by Kolb may be valid, little evidence is provided to confirm Kolb's two dimensions. They suggest three unidimensional factors, where the resulting learning style, will be based on one's relative position on each of the three dimensions [60].

Amidst the criticisms, [60] states that in 2005 amidst a list of 71 learning style models, Kayes chose Kolb's model as the most influential learning style model. Kolb Model has still been in usage across the world [61]. Kolb's Experiential Learning Model (ELM) and Learning Style Inventory (LSI) is the preferred model for inclusion in a Learning Management System. Notwithstanding, the ideal learner-centric Learning Management System should provide for setup of multiple learning style instruments and capability to select or activate the one(s) to be used per institution, per course or per period.

3.2.3 Teaching Style

By experimenting with innovative strategies intended to help students learn who formerly had not been successful, [62] found out that most methods and/or resources appeared to work with some students but not others. It was said further that in many cases, those who were successful with a particular method or set of materials had essentially similar characteristics. Repeatedly, data revealed that when taught through methods that complemented their learning characteristics, students at all levels became increasingly motivated and achieved better academically. If it is true that 90 percent of all instruction is conducted through either lecture or lecture discussion, it is no wonder that so few students achieve as well as we believe they should [62]. The research by Dunn & Dunn suggests that similar to how learners may favour a particular learning style or mechanism, a teacher or instructor may favour a particular style, mechanism or approach in providing knowledge or information to the learner.

Dunn & Dunn says that for decades, supervisors have been evaluating faculty in an effort to isolate those characteristics that produce effective instruction. Their efforts have been misdirected by weaknesses both in their assumption and their basic designs [62]. The attitude teachers hold towards various instructional programs, methods, and resources as well as kinds of youngsters they prefer working with constitute part of their "teaching style". Teachers can assess themselves with an instrument that simultaneously identifies their teaching style and reveals the areas that need to be expanded to respond to additional characteristics [62].

In summarizing the paper, Learning Styles/Teaching Styles: Should They… Can They Be Matched? [62] answers the question "Why not just match teachers with students?". The paper purports that the fallacy is this (a) learning style and teaching style characteristics do not always cluster into such neat packages; (b) students are not consistently one way or the other – nor are teachers; (c) neither traditional nor informal teachers are necessarily excellent, and it is possible to match a student's learning style and a teacher's teaching style and still not provide that youngster with an effective teacher; and (d) given the practical, "how-to" skills for teaching students through their individual learning styles, most teachers can become effective with most students and, simultaneously, provide a humanistic care, nurturing atmosphere [62].

We have concurrence with the views of [62]. However, within a Higher Education Institution, where the human teacher may be the primary source of course delivery, he/she is not necessarily provided with the resources of time to ensure that all avid learners being taught at a particular time are at their highest level of learning.

The analysis was done on a BTEC Applied Science course to determine whether student-centred learning activities improve learning outcomes [63]. The research states that deeper learning was significantly improved after instructional teaching as opposed to student-centred teaching. In the research, preferences for teaching style were also obtained from the students [63]. This research indicates that teaching style is a contributing factor to the level of learning. Where a Learning Management System is able to provide a teaching style – learning style match, the learning process may be aided. However, within a Higher Education Institution, where the human teacher may be the primary source of course delivery, he/she is not necessarily provided with the resources of compensation or training to ensure that all avid learners being taught at a particular time are at their highest level of learning.

In the discussion of teaching style, one may imagine the teacher or instructor being a computer software program or general form of Computer-Assisted Instruction (CAI) [64]. Of note to this research is the Intelligent Tutoring System (ITS) in Learning. We make note of [65] in their work for argument-making in higher education. The best result of 81.74% in classification correct rate was obtained when all grade classes were used [65]. It was said that while CAI may be somewhat effective in helping learners, they do not provide the same kind of personalised attention that a student would receive from a human tutor. One-to-one tutoring allows learning to be highly individualized and consistently yields better outcomes than other methods of teaching. Unlike previous CAI systems, ITS represents some of the knowledge and reasoning of good one-to-one human tutors, and consequently can coach in a much more detailed way than CAI systems. ITS does not just provide feedback such as correct or wrong answers for the student's mathematics solution but it also provides details of the misconception that the student face. The Student Model assesses student's knowledge and makes a hypothesis on the conceptions and reasoning strategies employed by the student to achieve his/her knowledge state [66]. Findings suggest participants' learning capacity of the introductory statistics could be improved successfully when CAI used as a supplement to regular lecture in teaching introductory statistics course [64].

The mechanism without the rules of Kolb's Model was attainable without a cost. For the C.I.T.E. Learning Styles

Instrument, both the mechanism and detailed rules for implementation were available.

3.3. Current Status of LMSs incorporating Learning Styles and Sequencing

The Advanced Distributed Learning (ADL) Initiative was established in 1997 to standardize and modernize training and education management and delivery. To meet its mission, the ADL Initiative developed the Sharable Content Object Reference Model (SCORM) and the ADL Registry. The release in 2009 is SCORM 2004 4th Edition. ADL supplies resources for SCORM 1.2, SCORM 2004 3rd Edition, and SCORM 2004 4th Edition. ADL recommends use of SCORM 2004 4th Edition [67]. Some consider the Experience API (Tin Can API) released in 2013 with currently in excess of 170 adopters, to be the successor to SCORM [68].

Further, the IMS Global Learning Consortium (IMS GLC) is a global, nonprofit, member organization that strives to enable the growth and impact of learning technology in the education and corporate learning sectors worldwide. Consequently, IMS develops Learning Tools Interoperability (LTI) to allow remote tools and content to be integrated into a Learning Management System (LMS). In addition to LTI, IMS GLC developed another standard, Common Cartridge. IMS Common Cartridge (IMS CC) provides a standard way to represent digital course materials for use in online learning systems so that such content can be developed in one format and used across a wide variety of learning systems, as well as enable new publishing models for online course materials and digital books that are modular, web-distributed, interactive, and customizable.

The three standards described, namely Sharable Content Object Reference Model (SCORM), Learning Tools Interoperability (LTI) and Common Cartridge have been employed in learning management systems in varied levels. The main systems in use which provide such functionality are Blackboard which is proprietary, and Moodle, Canvas, Sakai which are open source.

SCORM 2004 is not supported in any version of Moodle. Parts of the API have been implemented, but sections such as Navigation and Sequencing, which will assist in learner progress and assessment detailed tracking, have not been implemented. Moodle has announced that development on native SCORM 2004 support in the system has stopped. They further suggest that where a fully certified SCORM 2004 Player in Moodle is desired, Rustici Software have a Moodle plugin which connects to their commercial SCORM Cloud service turning Moodle into a fully compliant SCORM 2004 LMS [42].

Where there is a human teacher as the primary source of course delivery, he/she is not necessarily provided with the requisite resources to ensure that all avid learners being taught at a particular time are at their optimal level of learning. From the concept of levels of learning by [10] and the discussion of optimal learning by [11], the optimal level of learning is the highest level of learning achievable in a given time and nature of the uptake function; we consider the nature of the uptake function to include the learner, learning environment and learning style [69]. Learners are expected to comprehend the material within the mode made available by the teacher. All learners in a particular batch tend to be governed by the path of learning carved out by the teacher in his/her expertise and experience. Whereas the teacher has the knowledge to be transferred and is better able to determine the path to be taken based on prior batches of students, the flexibility does not exist at the point of learning for a change of path or delivery mode. There is also often disparity between the mode employed for course delivery and assessment, such as oral versus written or electronic versus hardcopy. Hence, as the number of learning styles may increase as the population within a batch of learners increases, there is an increasing tendency away from the optimal level of learning, amidst the finite or a limited number of course delivery paths and human teachers, and the current design of learning management systems.

4. OleCenT – The Online Learner-Centric Tool

4.1. The OLeCenT Approach to Course Delivery

In the interest of a positive effect on the level of learning, we propose OLeCenT, a tool for learner-centric course delivery in the online environment. OLeCenT may be integrated with a Learning Management System for enhanced course administration. We embrace the integration of learning styles to achieve a maximal matching [70] with the teaching styles. Teaching-learning in higher education institutions is examined with an analysis being done on course delivery in view of learning styles. We suggest how instructional design may be applied amidst a standard and specification for web-based e-learning with emphasis on how learning takes place.

4.1.1 The Underlying Theories of the OLeCenT Approach

We are influenced by [71] that computing impacts the three necessities of teaching-learning, namely basic skills instruction, advanced skills instruction and assessment of student progress, as well as the types of learning. We discuss the learner-centric tool by examining teaching and learning styles in a graph theory context.

4.1.1.1 OLeCenT and Graph Theory

By examining teaching and learning styles in a graph theory context, we propose an approach for course delivery, and describing elements and standards of the learner-centric model. The learner-centric tool may be designed for any of the sets of learning styles. We propose [51] Learning Styles Inventory 9-fold classification of concrete experience (feeling), reflective observation (watching), abstract conceptualization (thinking), active experimentation (doing), diverging (feel and watch), assimilating (think and watch), converging (think and do), accommodating (feel and do) and perception continuum (feel, watch, think, do). This model provides flexibility in terms of basic learning styles and diverse combinations of these styles. It is believed that this 9-fold classification engulfs others such as the seven stated in the classification by [48].

We propose that in the context of all teaching and learning styles, the relation for teaching-learning styles is a bijective function [70]. A teaching-learning style is a teaching style that provides greatest learning for (matches) a particular learning style, and vice versa. Considering a teaching-learning unit such as a course or a session of learning where knowledge transfer is the aim, there is a set of teachers and a set of learners. Correspondingly, there are sets of teaching styles, learning styles, and teaching-learning styles (the matching between a teaching style and a learning style).

Let G be a directed, bipartite graph with disjoint vertices T (the set of teaching styles, t_1, t_2, ...) and L (the set of learning styles, l_1, l_2, ...) in which the edges are directed from T to L (Figure 1). We propose that in any teaching- learning unit, optimal learning occurs where there is a maximal matching [70] for G with all elements of L having a pre-mapping (maximal matching with surjectivity) (Figure 1a, Figure 1b.) even where a complete matching does not exist (Figure 1b). Optimal learning may exist even where there is no surjective (onto) mapping as the same may exist where a teaching style exists in a teaching learning unit which has no mapping to a learning style in that unit (Figure 1b). Where there is a complete matching, that is with all teaching styles having a matching (Figure 1a, Figure 1c), non-optimal learning may still occur (Figure 1c) as all learning styles may not be catered to. For large learning groups with the number of learning styles tending towards maximum, invariably there are learning styles not mapped and far from optimal learning (Figure 1d). For learner-centric course delivery in e-learning, we propose that maximal matching with surjectivity for the teaching-learning styles is attainable with use of the learner-centric tool and how the LMS is implemented.

4.1.1.2 OLeCenT and the Push-Based Model

The push-based (build-to-stock) model of supply chains is built on the basis that the supplier or provider of goods or service knows best as to what goods or service are needed [72]. This build-to-stock model schedules production based on best guesses of demand and the availability of raw material in inventory. Considering the teachers' "raw material" or availability of teaching styles, some HEIs operate in a push-based model where the course content is provided in a mode as a best guess of demand. We propose that the pull-based approach (demand-driven) be used in course delivery where the customer orders trigger events in the supply chain [72]. The desire for learning should not be what triggers what is taught (course content) but rather the learning style (for the course content) should trigger events for the material to be provided in a particular style.

The pull-based model is similar to the self-examination mentioned by [71] in the PRECALC project or may be likened to diagnostic and formative assessments with benefits for the current year or summative assessments with benefits for the ensuing year. Research provided for the three initially proposed as the existing learning styles, namely visual, tactile, and kinesthetic [71]. The learner-centric tool also provides for learning styles which are combination of these as well as other forms of learning styles [51]. Further, formative and summative assessments primarily tend to be used to assess for knowledge gaps or knowledge acquisition respectively, rather than for an assessment of teaching style(s) to be employed. Even where these are used for this purpose, it must be noted that benefits can only accrue subsequent to the time of assessment.

4.1.1.3 OLeCenT and Supply-Demand Theory

The learner-centric tool should cause a lessening of the gap between teaching and learning styles within a batch of learners. Some learners should be more comfortable with the course material as it is received in a manner closer to the type of learning to which they are adept. The avid learner is not first required to "translate" course material from another teaching-learning style to ensure his/her optimal learning. Learners within the same batch benefit during the teaching-learning process as opposed to the trend where changes are put in place for subsequent batches

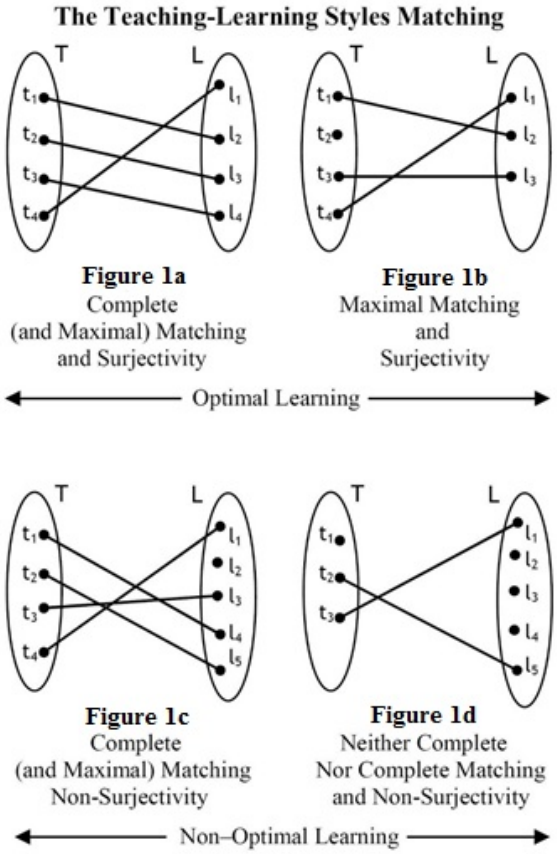

Figure 1: The Teaching Styles (T) and Learning Styles (L) Matching reflecting when optimal learning (7a and 7b) or non-optimal learning (7c and 7d) is achieved. The figure shows various combinations of complete matching, maximal matching and surjectivity

of learners. This is because the tool implements discovered trends or learning patterns of the current learners. The provision of learning objects specific to an individual's learning style should minimize the need to complement or supplement their learning with non-LMS sources. There is therefore a seamless integration required for fluidity of learning and a mitigating of the teachers' concerns for the use of material without approval.

In examining market mechanism, [73] states that the supply curve tells us how much producers are willing to sell at various prices, and the demand curve tells us how much consumers are willing to buy at these prices. The two curves intersect at the equilibrium point [73] where quantity demanded is equal to quantity supplied. In our study the aim is for optimal learning collectively and individually. Applying the supply and demand curve principle within a course and considering how much (teaching styles) teachers are willing, able or allowed to provide, and how much (learning styles) learners are willing to adopt, we propose that there exists a teaching-learning equilibrium (A) where teaching-learning tends to operate. With the learner-centric tool the level and speed of learning should increase and there should be an upward movement of the teaching-learning equilibrium point (A → B) (Figure 2). Figure 2 is constructed based on the following assumptions: (1) as the number of teaching styles increases, ceteris paribus, the level of learning increases because there is a higher likelihood that a learner will find a matching teaching style (T_1), and (2) similarly as the number of learning styles increases,

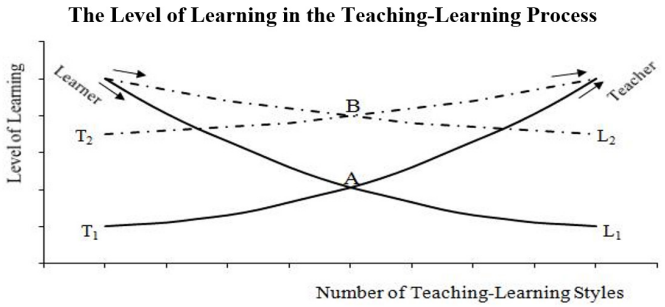

Figure 2: Relation between the Level of Learning and the Number of Teaching-Learning Styles for the human Teacher and the Learner in the Teaching-Learning process

ceteris paribus, the level of learning decreases (L_1). The tool provides a shift in both teaching (T_2) and learning (L_2) curves.

The graph shows expectations before (solid) and after (dashed) the use of a learner-centric course delivery tool. The teaching-learning styles axis represents the teaching styles for the teacher graphs (T_1 and T_2), and the learning styles for the learner graphs (L_1 and L_2).

4.1.2 Standards of the Learner-Centric Tool

One of the essential elements of the learner-centric tool is the emphasis placed on the learners and the determined learning style(s). We propose that in instructional design, learning style should drive course delivery and correspondingly course assessment (Learning Style → Course Delivery → Assessment). We apply Bloom's taxonomy and suggest examples of measurable learner outcomes to assess the learner-centric tool. The Instructional System Development model is adopted with specifics stated for the tool. We then state not only that the learner-centric tool is SCORM compliant but also how the SCORM categories should be used with the learner-centric tool.

4.1.2.1 Educational Objectives

Bloom's Taxonomy of Educational Objectives is widely used for organizing levels of expertise. Reference [10] states the three overlapping domains of educational objectives as cognitive, psychomotor and affective and based on the expected knowledge transfer within a course, the specific domain is identified. We propose the application of Bloom's Taxonomy to determine the learner's expertise in using the learner-centric tool. The learners' values, attitudes or interests are affected by the course delivery technique embracing teaching-learning styles, therefore the domain of affective goals is the most relevant to assess the learners' expertise and the effectiveness of the learner-centric tool. We determine each learner's level of expertise by assessing which measurable learner outcomes have been attained. The levels of expertise are listed in the order of complexity (Table 2). The collective summary of the learners' expertise suggests the effectiveness of the tool.

4.1.2.2 Instructional Design

Instructional Design models are used to define instructional systems. There are more than one hundred instructional design models, but almost all including the Instructional System Development (ISD) Model are based on the generic ADDIE model [74]. The ISD model is the most well-developed [71, 75] and contains similar phases as the ADDIE model, namely Analysis, Design, Development, Implementation and Evaluation. The phases are sequential sets of activities where the output of each serves as input to the subsequent phase. The learner-centric tool is defined below using the Instructional System Development model. The activities in the various phases for the learner-centric tool do not replace the actual activities for the instructional system but rather complement same. Consequently, good instructional design is expected of the system and these are only superseded where there is a conflict with the activities of the learner-centric tool.

Table 2: Measurable Learner Outcomes for Assessing Learners' Levels of Expertise in Using the Learner-Centric Tool, based on Bloom's Taxonomy for Affective Goals [10]

Level of Expertise	Measurable Learner Outcome
Receiving	Given an option, the learner chooses to use the learner-centric tool.
Responding	The learner uses optional features of the learner-centric tool such as some of the formative assessments.
Valuing	The learner seeks out in other learning environments, similar techniques employed by the learner-centric tool.
Organization	The learner finds differences with the method of learning (such as with the learning outcome) within the learner-centric tool, and the normal face-to-face mode of learning or the LMS without the learner-centric tool. The learner attempts to resolve the mental conflict(s).
Characterization by a value or value complex	The learner decides to encourage other learners to make use of the learner-centric tool.

4.1.2.2.1 The Analysis Phase

For the analysis phase the aim is to identify existing deficiencies before the teaching-learning exercise between what is desired and what is existing. The analysis is needed not only for the first delivery of the course content but for each delivery of the same. In addition to the analysis concerning desired outcome and existing knowledge and skills, the tool aids in the discovery of gaps between teaching skills and learning skills. Both teacher and learner are tested to determine teaching-learning skills matching. The human teachers for the course are tested and the teaching styles noted for each teacher as being preferred and/or practiced. Learners are tested with the aim of determining the prevalent learning style and the list of all learning styles in the set of learners. These are grouped into categories of dominant and existing learning styles. The teaching and learning styles resulting from the tests are put in a matrix and used to extract the levels of matching. An analysis document and file are produced with a listing of levels of each teaching-learning style match, levels of each unmatched learning style or combination of learning styles, and unmatched teaching style(s). The results from the analysis may be used by the HEI without the tool but these are generated specifically for and form the basis of the next phase for the design of the tool.

4.1.2.2.2 The Design Phase

In the design phase, the design document is produced to describe the learning objects to be created based on the results from the analysis phase. For each teaching-learning unit (such as material relating to a particular topic of a course), there are specific learning objectives including assessment(s) and corresponding learning objects. For each learning objective, it is determined which teaching-learning style learning objects are to be created to compensate for each teaching-learning style match and unmatched learning style or combination of learning styles. Some learning styles may require more learning objects than others for optimal learning. It is noted which learning objects per learning objective and learning style, already exist in the repository. Priorities are stated for all non-existent learning objects with greater values being given to those for the unmatched learning styles combinations. In LMSs, course designers indicate the workflow of teaching-learning units and the learning objects which relate to the teaching-learning units as well as the direction and timing for display. This exercise continues for the learner-centric tool. Additionally, the designer indicates these workflows per learning style; the actual order of teaching-learning units may vary based on the learning style. The course designer also documents rules as to which learning objects should be omitted based on other options chosen. The rules also indicate the conditions on which to allow the learner-centric tool, based on its learning, to assist in the workflow of the teaching-learning process.

4.1.2.2.3 The Development Phase

The creation of the learning objects is done in the development phase. Within this phase, based on the priorities indicated in the design document, learning objects are created. HEIs may choose not to create learning objects for teaching-learning style matches based on the lack of time before delivery and/or the lack of compensatory resources. However, this decreases the effectiveness of the learner-centric tool. For unmatched learning styles, where the levels indicate that the majority of the learners fall in this grouping, the learning objects are loaded into memory cache. The memory cache is a specialized memory storage used to optimize data transfers resulting in faster and more efficient data retrieval. Based on the workflow, direction and timing of the teaching-learning units and the learner's current place in the garnering of the course material, the loading of objects into cache is done at run-time as the learner accesses the course environment. The loading of objects into cache is important primarily where learning objects are large or may significantly increase retrieval time. The setting up of the rules given in the design document in the learner-centric tool is done at this juncture. The developer also ensures that the tool has the facility for the learner to set the timing of their learning sessions with the possibility for teacher override. The learning objects created are ensured to be SCORM 2004 Compliant.

4.1.2.2.4 The Implementation and Evaluation Phase

As it relates to instructional design, the implementation phase speaks to the delivery of the course material to the learner. All developments are put into operation and are expected to follow whatever rules were setup. Within the evaluation phase, one ensures greater efficiency and effectiveness based on the results garnered from implementation. The usage of the learning objects per learning objective per learning style is compared to the expected levels indicated in the analysis document. Where the learner-centric tool was allowed to assist in the workflow based on its learning, a determination is made whether the tool appears consistent with the learners' desires. This information influences decisions in subsequent analyses. Some of the other control mechanisms are the usage pattern of the objects loaded into memory cache, and the level of reuse of the objects.

4.1.2.3 Standards for Web-based e-Learning

The learner-centric tool is SCORM 2004 4th Ed. Compliant but may be developed with less effectiveness to be compliant with other editions of SCORM 2004. The Sharable Courseware Object Reference Model (SCORM) is a collection of standards and specifications for web-based e-learning [76]. The parts of SCORM 2004 are the Run-Time Environment, the Content Aggregation Model (CAM) and the Sequencing and Navigation (SN). The CAM has three parts: the Content Model, the Metadata and Content Packaging. The Content Model describes the relationships between course modules and provides for Sharable Content Objects (SCOs) and assets; the Metadata is used to describe the content into some common vocabulary. The SN governs how navigation between SCOs is handled by the LMS through the definition of rules known as the Sequencing Definition Model [67].

We state only the aspects for which there is uniqueness for the learner-centric tool. We recommend that the learner-centric course delivery tool uses SCORM 2004 with the following:

1. The teaching-learning style learning objects (the learning objects per learning objective and learning style) are represented as the (SCORM) assets. [Content Aggregation Model – Content Model]
   The SCO is the combination of these assets (learning objects) for a learning objective. A recursive definition would be more appropriate for accomplishing the needs of the learner-centric tool but to achieve reuse, SCORM defines that a SCO is not allowed to reference other SCOs.
2. In a grouping of learning objects per learning objective, one or more of these learning objects may or may not be used in an instance of accomplishing the learning objective, based on the learning style(s) of the learners. [Content Aggregation Model – Content Model]
3. The Meta-metadata category stores the teaching-learning styles relevant to the object. Its usage is therefore mandatory. [Content Aggregation Model – Metadata]
4. The usage of the General, Lifecycle, Relation, and Classification categories are optional but recommended. [Content Aggregation Model – Metadata]

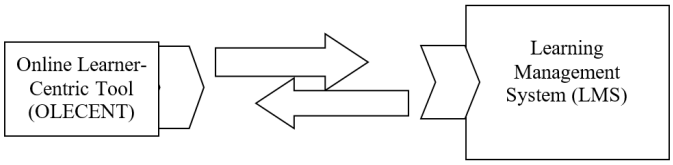

Figure 3: The Online Learner-Centric Tool (OLeCenT) - Learning Management System (LMS) Interface

5. The Sequencing Rules category outlines the workflow between the teaching-learning style learning objects. [Sequencing and Navigation Specification – Sequencing Definition Model]
6. The following categories are also mandatory: Rollup Rules, Rollup Controls, Objectives, Delivery Controls and Navigational Controls. Completion Threshold Controls is mandatory for SCORM 2004 4th Edition only. [Sequencing and Navigation Specification – Sequencing Definition Model]
   The categories of Sequencing Control Modes, Constraint Choice Controls and Limit Conditions are not mandatory but their usage are advantageous based on the implementation and application of the learner-centric tool.

All other aspects of or necessities for SCORM which tend to be common to all SCORM compliant tools are applied: the LMS launches all content in a web browser and is required to implement an API, all of the relevant course data is stored in a XML file, and all content is to be transferred in a folder or a ZIP file called a package interchange file (PIF) [76, 67].

The Online Learner-Centric Tool (OLeCenT) is designed to interface with a Learning Management System (LMS) (Figure 3), thereby course delivery and administration is still managed by the LMS, but enhanced by the learner-centric delivery provided through OLeCenT.

4.2. Components of OLeCenT

The tool has four components, namely Diagnostic Analysis, Repository and Workflow Setup, Learning Administration, and Learner-Centric Assessment and Evaluation (Figure 4). Diagnostic Analysis allows for the setup of one or more Learning Style Inventories as well as the diagnostic assessments of the teacher(s) and learner(s). Repository and Workflow Setup receives and updates learning objects of different types for a single unit of learning as well as setup a designated workflow of how the learning objects are ordered for delivery of the course content per learning style. Learning Administration generates learner course paths and Assessment and Evaluation provides for formative and summative assessments in consideration of each student's teaching-learning style.

4.2.1 Diagnostic Analysis

The Diagnostic Analysis component incorporates two (2) major processes, namely Setup Learning Style Inventory (LSI)

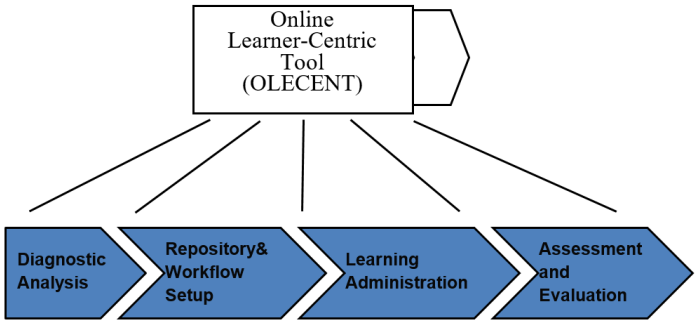

Figure 4: Components of OLECENT

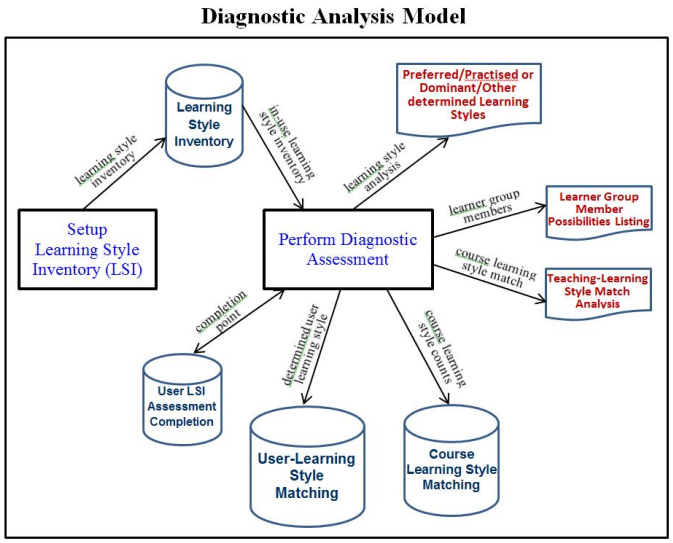

Figure 5: Diagnostic Analysis Model

and Perform Diagnostic Assessment (Figure 5). The tool is designed to allow for any learning style mechanism that has measurable notations. OLeCenT uses learning style indexes throughout its implementation and therefore translates the terms, codes and notations of specific learning style instruments to the OLeCenT learning style indexes.

The tool provides each teacher and learner with a diagnostic assessment to ascertain the teaching-learning style(s) and preferences; it uses this information to inform the human teacher (where existent) of the learning style make-up of the class and teaching-learning style match or gaps as displayed in Table 3.

The learner-centric tool suggests a learning style or combination of learning styles for each student. The learner is allowed to choose another teaching-learning style in which to provide the course content but the system maintains a record of the determined learning style. In Higher Education Institutions (HEIs) there are group assessments, and learning by collaboration is encouraged. By analyzing the collection of student learning styles within the batch of learners, the tool determines for each student or teacher, suggested lists of group members based on the computation of a compatibility factor with a maximum of 100. The suggested lists are based on similar or dissimilar learning style and preferred group make-up. Figure 6 details the 4-part algorithm for determining teacher or learner compatibility factor. The four (4) parts are: Determine Main User Compatibility Factor, Initialize Selection Arrays per Similarity, Determine Other User Compatibility Factors, and Generate List as per Compatibility Ratios.

Table 3: OLeCenT Diagnostic Teaching-Learning Style Analysis

No.	Learning Style	Dominant		Existing		Teaching Match	
Course: COMP1005							
1	Visual Numerical	14	37%	17	22%	Preferred	1
2	Social Individual	8	21%	13	17%	Practiced	1
3	Visual Language	7	18%	4	5%	Preferred	1
4	Auditory Numerical	3	8%	13	17%	Practiced	1
5	Kinesthetic – Tactile	3	8%	6	8%		
6	Oral Expressiveness	2	5%	5	6%	Practiced	2
7	Written Expressiveness	0	0%	6	8%		
8	Social Group	0	0%	6	8%		
9	Auditory Language	0	0%	4	5%		

4.2.1.1 Determine Main User Compatibility Factor

The main user compatibility factor is first determined as a benchmark for assessing the other users. Dominant and existing learning styles, and learning assessment scores for each style is obtained ensuring that the dominant learning style is procured with highest priority (1). Three (MAX_LS_PRI) learning style records are procured. The calculated factor is a summation of a maximum score per learning style with a higher weighting (MAX_LS_PRI/i) being allocated for the dominant learning style. The factor of 3 is used as the other users will be compared based on the 3VAK elements.

4.2.1.2 Initialize Selection Arrays per Similarity

A compatibility factor holder will maintain the compatibility factors of all other users. Based on whether the grouping was desired by Similarities or Dissimilarities, the calculated value would be tending away from zero or not respectively. The initialization values ensure that the calculated user values have higher precedence.

4.2.1.3 Determine Other User Compatibility Factors

The dominant and existing learning styles, and learning assessment scores for each style is obtained for each user, ensuring that the dominant learning style is procured with highest priority (1). Three (MAX_LS_PRI) learning style records are procured. The calculated factor is a summation of a maximum score per learning style with a higher weighting (MAX_LS_PRI/i) being allocated for the dominant learning style. A factor of 1 to 3 is used to multiply the learning style score based on the level of similarities of the 3VAK elements of the main user's learning style and that of the user being determined. As record 3 (MAX_LS_PRI) of each user is ascertained, an insertion sort is applied only maintaining the NOOFDISPLAYNEEDED.

4.2.1.4 Generate List as per Compatibility Ratios

A compatibility factor ratio is determined by considering the variance of the user factor to the main factor, as a ratio of the main factor. The NOOFDISPLAYNEEDED users are shown with compatibility factors in comparison to 100.

Both teacher and learner are tested to determine teaching-learning skills matching. The human teachers for the course are tested and the teaching styles noted for each teacher as being preferred and/or practiced. Learners are tested with the aim of determining the prevalent learning style and the list of all learning styles in the set of learners. These are grouped into categories of dominant and existing learning styles. The teaching and learning styles resulting from the tests are put in a matrix and used to extract the levels of matching.

The learner-centric tool may be designed for any of the sets of learning styles with any Learning Style instrument (LSI). We propose Kolb & Kolb's Learning Styles Inventory 9-fold classification [51] based on its widespread usage, flexibility and a classification that seems to engulf other LSI. The learning style units are classified based on the Visual- Auditory-Kinesthetic (VAK) content thereby providing ease of relation to learning objects. OLeCenT allows rules for learning style determination to be codifed. Learning Style rules are entered as text; the text is parsed on input to determine a formula for the specific learning style calculation. The parsed calculation is stored. An example of the text inputs is (1):

```
[DETERMINE MAIN USER COMPATIBILITY FACTOR]
MainUserArray <- GET Styles and Scores for Main User [M]
MAX_LS_PRI = 3 (or number of learning styles per user stored)
main_compatibility_factor = 0
for i = 1 TO MAX_LS_PRI {

4.2.2 Repository and Workflow Setup

The tool is able to (1) receive and update learning objects of different types for a single unit of learning as well as (2) setup a designated workflow of how the learning objects are ordered for delivery of the course content. Instructors are allowed to setup a single course learning path per learning style or for all learning styles. Figure 7 reflects these two processes as Maintain Learning Object Learning Style Index(es) and Setup Learning Style Course Path(s) respectively. Within the latter process, the tool also provides an option for setting learning sessions based on input of date, time or date-time ranges.

In view of Learning Object Repositories which exist [77], the Maintain Learning Object Learning Style Index(es) process is not designed as a priority to create new learning objects. In the final implementation, the Repository and Workflow Setup component may work with any SCORM 2004 4th Edition Learning Object Repository. The component ensures that pre-existing learning objects may be viewed, the learning style indexes may be updated, and the user may be informed of the state of each learning object. The state of the learning object includes its SCORM compliance, its OLeCenT readiness in view of learning styles, and other general learning object parameters such as id, title, and objectives. Learning objects (LOs) are tagged for general VAK features and therefore provide the flexibility of being used with multiple LSI without having these tagged to various instruments. Consequently, an institution is provided with the ease of switching between LSIs without having to again setup learning paths or retagging objects.

A design document is produced from the Maintain Learning Object Learning Style Index(es) process to describe the learning objects to be created based on the results from the analysis phase. For each teaching-learning unit (such as material relating to a particular topic of a course), there are specific learning objectives including assessment(s) and corresponding learning objects. For each learning objective, it is determined which teaching-learning style learning objects are to be created to compensate for each teaching-learning style match and unmatched learning style or combination of learning styles. Some learning styles may require more learning objects than others for optimal learning. It is noted which learning objects per learning objective and learning style, already exist in the repository. Priorities are stated for all non-existent learning objects with greater values being given to those for the unmatched learning styles combinations.

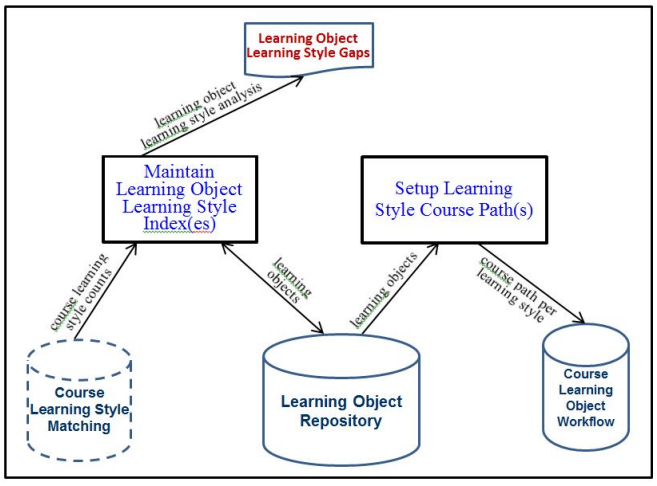

Figure 7: Repository and Workflow Setup Model

Each type of learning object is specific to a basic teaching-learning style. LMSs have the mechanism for teachers to provide learning content in reusable learning objects. The course designer is able to state the specific unit of course content and the related objects specific to the teaching-learning styles. There is a one-to-many relationship between each unit of course content and the teaching-learning style learning object. The teaching-learning style learning object forms part of the learning process and is specifically designed to support one or more learning styles. The objects are placed in a repository for retrieval at course compilation subject primarily to the learning style course path that has been setup.

The Course Learning Object Workflow is initially setup by the course designer or teacher /instructor but may be updated as the system learns the norms of various users per learning style. Consequently, in the Setup Learning Style Course Path(s) process, the user is provided with an option to enter/modify the Course Path Update Factor and Course Path Automatic Update. The Course Path Update Factor is the numeric ratio where during Learning Administration (OLeCenT Component 3) if a different learner workflow for a particular learning style is followed by the learners that many times when compared to the teacher-entered course learning object workflow, the teacher should be notified/alerted concerning updating the Course Learning Object Workflow for the course for the particular learning style. When alerted, the teacher may manually update the workflow. The Course Path Automatic Update may be set during Setup Learning Style Course Path. If the preferred option is to have automatic update, this may be done and an alert/notification sent to the instructor; the instructor is not provided with the option not to receive notifications in the automatic configuration instance.

4.2.3 Learning Administration

For each learner the tool generates a learner course path (the set of teaching-learning style learning objects designated by the workflow for delivery of the course content), learns which other teaching-learning styles are favoured by specific types of learners and uses this acquired knowledge to enhance the formulated learner course paths (Figure 8).

The learner course path is determined from the learning style for the learner determined from Diagnostic Analysis, as well as the course learning object workflow for each learning style setup by the course designer or teacher during Repository and Workflow Setup. Learning administration is barred from access to the student user without a determined learning style. Having determined the learner course path, the tool provides the teaching-learning style learning objects based on the teacher-designed/approved and/or system-determined workflow and where the learner is at in the scope of learning the course content.

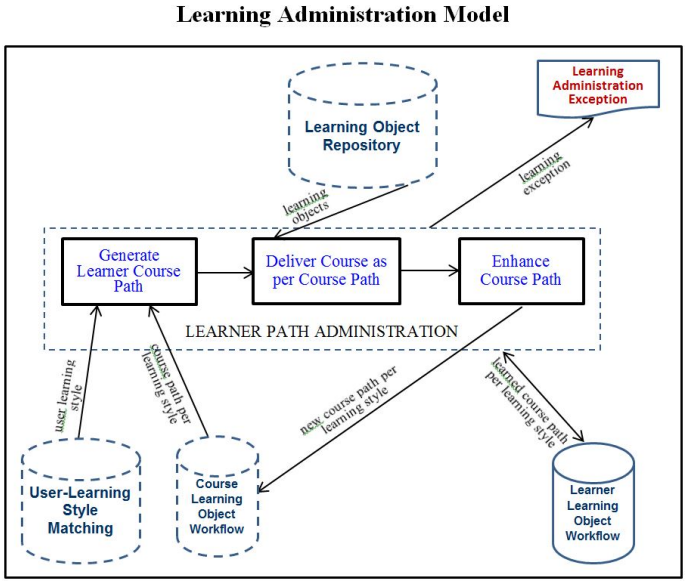

Figure 8: Learning Administration Model

OLeCent attempts to provide a best-fit learning object based on course learning path setup by the instructor and learner's chosen learning style or determined dominant leaning style. The learner may however choose to view or undertake another path or other relevant but not best fit objects on the assigned course learner path. For fluidity of learning, the tool provides the objects in hypermedia with more than one learning object related to the determined or chosen learning style. It is where the learner chooses to undertake other path(s) or other learning objects on the same path, that the tool learns which other learning styles or path are favoured, preferred or taken by specific types of learners in the delivery of certain sections of the course.

For unmatched learning styles, where the levels indicate that the majority of the learners fall in this grouping, the learning objects are loaded into memory cache. The memory cache is used to optimize data transfers resulting in faster and more efficient data retrieval. Based on the workflow, direction and timing of the teaching-learning units and the learner's current place in the garnering of the course material, the loading of objects into cache is done at run-time as the learner accesses the course environment. The loading of objects into cache is important primarily where learning objects are large or may significantly increase retrieval time.

The Learning Administration component maintains the path of learning objects, duration and completion percentage for each learner. This is stored within the Learner Learning Object Workflow and is used as the source of data to determine whether an alert should be generated for the course designer or teacher. The Course Learning Object Workflow setup by the course designer or teacher may be updated as the system learns the norms of various users per learning style. Where the Course Path Update Factor and/or Course Path Automatic Update was entered/modified during Repository and Workflow Setup, and where a new learner path was undertaken by the learner, the Update Factor is used to determine whether the new path is used that many times by learners with similar learning style when compared to the teacher-entered course learning object workflow. If these conditions are met, the teacher is notified/alerted concerning updating the Course Learning Object Workflow for the course for the particular learning style.

```
AlertRatio =
        NoOfConsistentLSVariance / NoOfDiagnosedLSUsers
ActiveLSRatio =
        NoOfConsistentLSVariance / NoOfActiveLSUsers
ChangeEnrolmentRatio =
        NoOfConsistentLSVariance / NoOfEnrolledUsers
if (AlertRatio  100) > CourseUpdateFactor
        If AlertRatio >
                        Average (ActiveLSRatio, ChangeEnrolmentRatio)
                If AutomaticUpdateIsOn
                        AutoConfigureLearningPath
        AlertInstructor
```

Figure 9: Alert Notification and Automatic Configuration Formulae

When alerted, the teacher may manually update the workflow. Where the Course Path Automatic Update is set to the affirmative, the system performs the update automatically. For the update, the teacher-entered course learning object workflow is put in a dormant state, and the new course learning object workflow for the particular learning style is added to Course Learning Object Workflow and made active.

The alerts to enhance the Course Learning Object Workflow, shown in Figure 9 as Learning Administration Exception may be in report form, web page, email or another form of notification. Alert Notifications and Automatic Configuration is determined based on calculated alert, active learning style and change enrolment ratios. The formulae in Figure 9 reflect that the instructor is alerted once the alert percentage exceeds the course update factor. However, when automatic update is on, only where the alert ratio exceeds the average of the active learning style ratio and the change enrolment ratio, is the automatic configuration done. This mitigates the system flopping between decisions where the magnitude of the variance is not significant.

4.2.4 Assessment and Evaluation

The tool will provide for formative and summative assessments in consideration of each student's teaching-learning style. LMSs have the mechanism for ongoing assessments and some allow the teacher to indicate the level of difficulty for each assessment unit. This feature represents only a modification based on the teaching-learning style; the learner undertakes an assessment based on the determined teaching-learning style.

The Assessment and Evaluation Model (Figure 10) diagrammatically shows that similar to Learning Administration, the learner assessment path is determined from the learning style for the learner determined from Diagnostic Analysis, as well as the course learning object workflow for each learning style setup by the course designer or teacher during Repository and Workflow Setup.

Having determined the learner assessment path, the tool provides the teaching-learning style learning objects based on the workflow and where the learner is at in the scope of learning the course content. The path of learning (assessment) objects, duration and completion percentage for each learner is stored. Similar to Learning Administration, this is stored within the Learner Learning Object Workflow and is used as the source of data to determine whether an Assessment Exception (alert) should be generated for the course designer or teacher. The Assessment and Evaluation component uses the Course Path Update Factor to determine whether the assessment grades is that many times by any learning style when compared to the other learning styles.

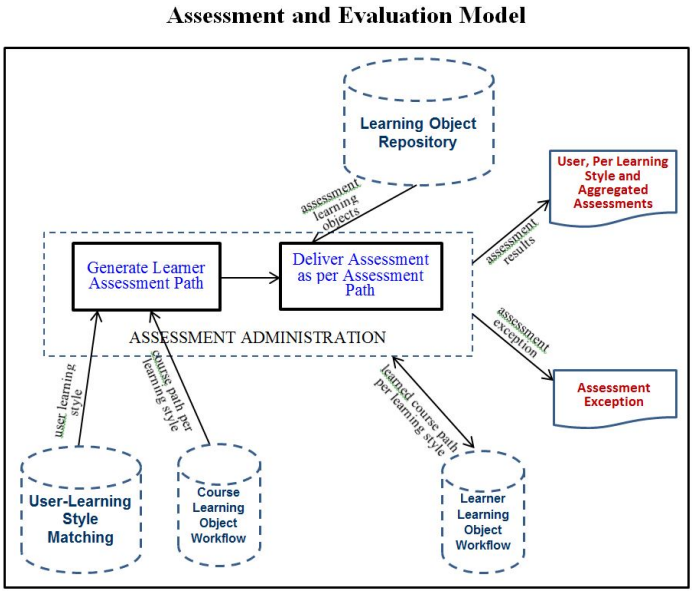

Figure 10: Assessment and Evaluation Model

5. Implementation and Results

5.1. Development of Tool

OLeCenT is developed using HTML 5, XML, CSS and Javascript for the graphical user interface (client) and PHP for all backend (server) transactions. The database employed is MySQL. All components of OLeCenT use fields of SCORM 2004 4th Edition. Additionally, the Diagnostic Analysis component was developed and tested to be fully SCORM 2004 4th edition compliant.

5.2. Implementation Instance

OLeCenT provides for the setup of a Learning Style Inventory (LSI) or Model by learning style indexes. OLeCenT captures information about each learner and teacher and suggests the dominant and other learning/teaching styles. There is a matching which assigns the learners' learning styles and the teachers' teaching styles to a number of the learning styles indexes which matches to the learning styles of the LSI in use. Learning objects are stored in the repository and also given a learning style index or a number of indexes as determined by the course administrator / deliverer / teacher / lecturer. The learners are provided with learning objects in the form of course paths which vary based on the course administrator's projected path, the learners' learning styles, and other assigned or chosen course paths of similar learners.

The current instance of OLeCenT allows a user to be defined as one of five possible user types. The user types are Student, Instructor/Lecturer, Course Designer, Administrator and System Administrator. Each user is assigned optionally to a specific department and/or institution. Where a user of type Student or Instructor is not provided with a department or institution, that user is available to be assigned to any course as in the use of OLeCenT for Massive Open Online Courses (MOOCs).

The first three components of OLeCenT were tested with an instantiation including The C.I.T.E. Learning Styles Inventory (http://www.d11.org/Transition/Assessments/Documents/C.I.T.E.%20Learning%20Styles%20Instrument.pdf) as the Learning Style Instrument (LSI). The C.I.T.E. instrument diagnosed one or more of nine (9) learning styles by use of forty-five questions. For testing purposes only, access to OLeCenT was successfully provided via the Moodle environment, but implementation was not done for full integration which allows for the ease of demographic and course data between the two systems.

Learning Objects were setup as types V - Visual, A - Auditory, K - Kinesthetic, R – Reading/None Specified, and O - Other. Video Files (WMV, MP4, AVI) and Powerpoint Presentation (PPT, PPTX) and Show (PPSX, PPS) without Audio were setup as Visual. Audio Files (MP3,WAV,M4A) and Powerpoint Presentation (PPT, PPTX) and Show (PPSX, PPS) with Audio and Timing were setup as Visual. Articulate Storyline v. 2 Web-enabled Files (HTML) and Powerpoint Presentation (PPT, PPTX) and Show (PPSX, PPS) with Audio and Transition but without Timing were setup as Kinesthetic. PDF, TXT,RTF files were set as Reading. Where learning objects of an auditory type were not readily available, the Windows version of Natural Reader v. 14 was employed for creation of such objects. Natural Reader is a free text to speech software with naturally sounding male and female voices. For the Computing or Math-based courses, Natural Reader was deemed useful primarily for course outlines, rather than actual course content or assessments. Subsequent to the Learning Objects Setup, the Learning path (per learning style or for all learning styles) is also setup by the course designer/instructor.

5.3. Implementation Results

OLeCenT was used in four (4) instances including a focus group of ten (10) students of a private institution administered a MOOC of secondary-level Information Technology, and three computing qualitative and quantitative courses at a tertiary-level institution administered at first year, second year and third year. The first year course COMP1005 Software Engineering Essentials was qualitative and contained over thirty-five (35+) students; the second year course COMP2005 Discrete Mathematics was quantitative and included five (5) students; the third year course INFO3005 Information Systems was qualitative and was administered to 3 students.

5.3.1 Diagnostic – Teaching-Learning Style Match Analysis

The teaching style (TS) - learning style (LS) match may be determined based on the learners' dominant or practiced styles and the instructors' teaching approaches. The teaching-learning style matches determined by OleCenT were:

For the first year qualitative course COMP1005

- 38% match - preferred TS and dominant LS with main instructor (Figure 11)
- 57% match - preferred TS and dominant LS with all instructors (Figure 11)
- 90% match - total of preferred and other TS and group's dominant LS

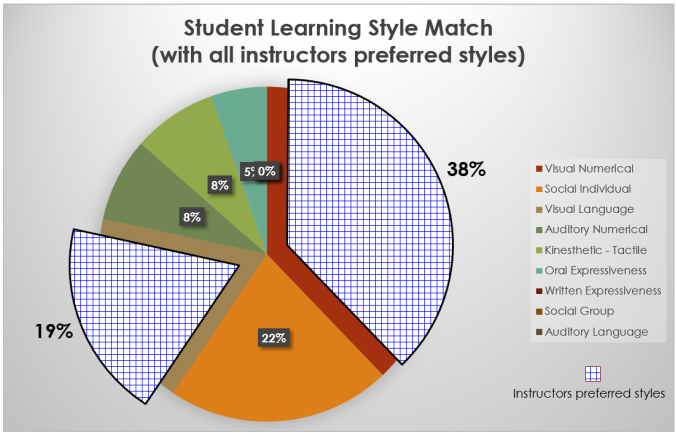

Figure 11: Learning Style Match with all instructors preferred styles

For the small qualitative course INFO3005

- 33% match - preferred teaching style (TS) and group's dominant learning style (LS)
- 66% match - total of preferred and other TS and group's dominant LS

The results also showed in the instance of the quantitative course COMP2005 that the preferred teaching style was matched by only 30% of the group's dominant learning style. In view of the total of preferred teaching style and other teaching styles, there was a 49% match with the group's dominant learning style.

The data for all courses proved useful both to the face-to-face and online instructors who were favoured with the information as to how to possibly better reach the batch of learners in teaching.

5.3.2 *Diagnostic – Teacher and Learner Group Member Possibilities*

Similar and dissimilar learning methods of students may be determined based on a student's dominant or existing styles, and a comparative review with other dominant and existing styles and scores from the learning style instrument. In view of teaching approaches, similar and dissimilar approaches may also be determined; these are based on a teacher's preferred or practiced approaches and other similar approaches and comparison of scores from the learning style instrument.

Figure 12 displays a student with id number 620099999 with his/her top 5 students with similar styles. OLeCent may also display a teacher with his/her top teacher with dissimilar styles. Top teacher dissimilarity possibilities may be used to ensure that there is greater coverage of the learning styles that are reached in a batch of learners. The similarity check is not restricted to learners/teachers of a similar learning-teaching style. Figure 12 highlights that student 620099999 of dominant learning style Social Individual and other styles of Visual Numerical and Auditory Numerical was deemed to have the fourth highest compatibility factor 80 (of 100) with student 415001546 of dominant style Oral Expressiveness and other styles of Visual Numerical and Auditory Numerical.

The similarity and dissimilarity comparisons are based on the relative difference between the main student/teacher being

STUDENT GROUP MEMBERS LISTING, SEMESTER 2, 2016-2017
Members of **SIMILAR** Type

Profile for User ID: 620099999 Student_FN Student_LN
Dominant Learning Style: Social Individual
Other Existing Learning Styles: **Visual Numerical and Auditory Numerical**

User ID: **620099256 (Compatibility Factor: 88 of 100)**
Dominant Learning Style: **Social Individual**

.

User ID: **415001546 (Compatibility Factor: 80 of 100)**
Dominant Learning Style: **Oral Expressiveness**
Other Existing Learning Styles: Visual Numerical and Auditory Numerical

User ID: 416000954 (Compatibility Factor: 76 of 100)
Dominant Learning Style: Social Individual
Other Existing Learning Styles: Written Expressiveness and Auditory Numerical

Figure 12: Listing of Top Students with Similarities as Student 620099999

evaluated and each other student/teacher in the batch of learners/teachers. A compatibility factor for each learner is computed from the relative differences noted among the dominant learning styles, existing styles, and learning styles instrument scores 1, 2 and 3 (Figure 13). For the teacher, compatibility factors are computed from the relative differences noted among the dominant preferred styles/approaches, practiced styles or approaches, and learning styles instrument scores 1, 2 and 3.

The teacher-learner group member possibilities determined by OLeCenT were:

For a student of a particular learning style

- Similar and dissimilar styles
- 70% or greater similarity was found even where the individuals were of different dominant learning styles

For a teacher of a particular teaching approach

- A 39% dissimilarity was identified with other teachers/instructors.

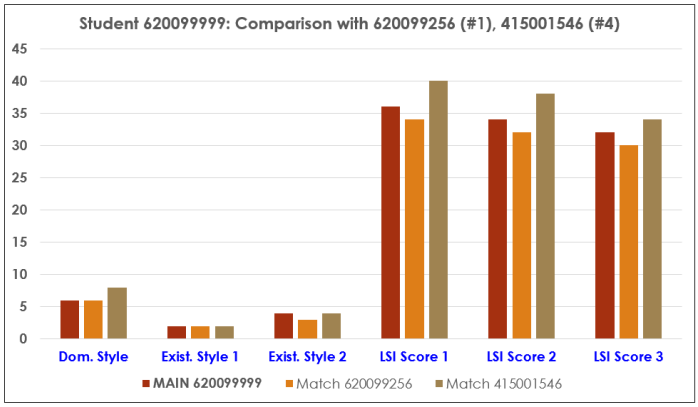

Figure 13: Relative Comparison for Compatibility Factor Determination

5.3.3 Repository – Learning Object Learning Style Gaps

Learning Object Learning Style gaps may be identified per course and per VARK containment. VARK containment describes whether a learning object is deemed to be appealing to the Visual, Auditory, Reading or Kinesthetic learner [53]. The instructor and/or course designer may be immediately notified where learners of a particular style may be required to access the course material in the mode not deemed for his/her highest level of learning.

5.3.4 Learning Path Consistency and Disparity

Chosen learning paths per student per learning style may be identified. The learning path setup by the teacher / course designer may be setup uniquely per leaning style. Subject to the flexibility setup with use of pre-requisites, OLeCenT determines the level of compatibility or disparity between the teacher designed path and the student chosen path. Additionally, the favoured learning VARK objects per learning style are ascertained. For each unit within the learning path, a number of learning objects per visual, auditory, reading and kinesthetic containment may be available. OLeCenT determines the most suitable VARK learning object per unit of the learning path to be displayed dominantly with all other available learning objects for the same unit (of the learning path) subtly displayed.

OLeCenT may generate a learning path consistency and disparity analysis for each course in view of one or more teaching-learning styles, activities (including A-Assessment, B-Lab, F-Field work, G-General, L-Lecture, O-Other, S-Seminar, T-Tutorial), disparity allowance time (length of time the learning object was accessed) for 0 or more minutes, the diagnosed or chosen learning style, and consistency check criterion of learning path or learning object. Figure 14 is the learning path consistency and disparity analysis for COMP1005 for all teaching-learning styles, all activities, where learning objects were accessed for 0 or more minutes, for the diagnosed learning style, and using consistency check criterion being the learning object.

Figure 15 is the learning path consistency and disparity analysis for COMP1005 for all teaching-learning styles, activity type lecture, where learning objects were accessed for 0 or more minutes, for the diagnosed learning style, and using consistency check criterion being the learning object. This diagram may be used to easily identify the level of consistency and disparity for the various learning styles.

LEARNING PATH CONSISTENCY AND DISPARITY, SEMESTER 2, 2016-2017

Teaching/Learning Style(s): ALL
Learning Object Activity/ies: 'A','B','F','G','L','O','S','T'
Disparity Allowance Time (mins.): 0
Assigned/Chosen Learning Style: Diagnosed
Disparity/Consistency Check Criterion: Learning Object

No.	Learning Style	Consistency		Disparity		Total	
		Course: COMP1005					
1	Visual Language	1	14%	6	85%	7	100%
2	Visual Numerical	5	33%	10	66%	15	100%
4	Auditory Numerical	0	0%	3	100%	3	100%
5	Kinesthetic - Tactile	2	66%	1	33%	3	100%
6	Social Individual	0	0%	8	100%	8	100%
8	Oral Expressiveness	0	0%	2	100%	2	100%
Course Totals:		8	21%	30	78%	38	100%

Figure 14: Learning Path Consistency and Disparity Check for All Activities

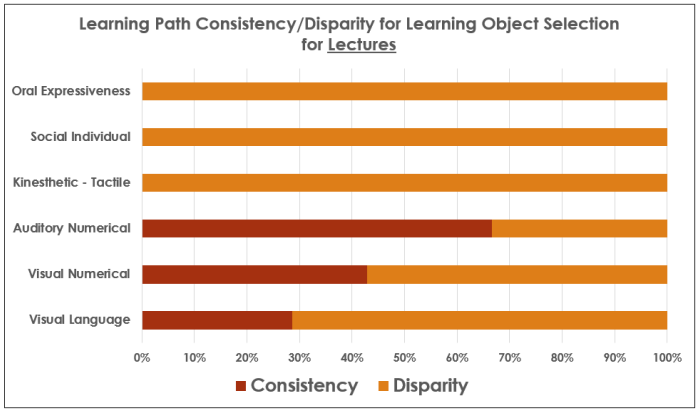

Figure 15: Learning Path Consistency/Disparity for Learning Object Selection for Lectures

New student learning paths may be auto-configured subject to a minimum threshold and the instructor's approval. Where there is auto configuration and the minimum threshold met for a particular style, subsequent students of the learning style(s) reconfigured are administered the course content according to the newly learnt path. The minimum threshold is met where the threshold percentage/factor of the students of a particular style chooses a consistent path (contrary to the teacher designed path). For the analysis including all activities, chosen learning path variances met the minimum threshold criterion of 75% (of students within similar learning style) for updates in learner course path; this was evident for Visual Language, Auditory Numerical, Social Individual, Oral Expressiveness (Figure 14). Where the minimum threshold is not met but there is significant disparity for a particular learning style, the notifications to the teacher(s)/instructor(s) were ideal as they could more easily manage the process in view of what learning objects were favoured. There were instances where the assigned teacher paths were followed, especially for students that were of a Kinesthetic-Tactile learning style.

Patterns of path selection per learning style were identified for the larger courses (COMP1005, COMP2005). In the instance for reviewing OLeCenT in which the users were selected similar to that of a focus group, the data showed more inconsistency with unidentified patterns. The patterns were more identifiable where OLeCent was used in the actual class environments.

5.3.5 Usage of OLeCent

Comparing COMP1005 which provides course delivery to 39 students through OLeCenT, and a Moodle instance of INFO3005 which provides similar delivery to 44 students, each environment was setup by the same teacher and course designer with a similar number of learning objects subject to the limitation of the Moodle environment in terms of managing VARK learning objects. OLeCenT reflected 1934 views in the course or 50 views per student, whilst Moodle reflected 3492 views in its course or 70 views per student.

Across two (2) campuses, in view of all students and excluding the maximum and minimum length of time spent accessing OLeCenT, the usage over eleven (11) weeks reflected an average of between twenty-two (22) and fifty-seven (57) hours. The findings are significant as students from the same campus as the

main course teacher did not reflect lower usage figures where the main teacher was more easily physically accessible. Considering all students in the course, the average usage for 11 weeks per student at the campus without lecturer was 3,449 minutes or 57 hours. This was comparatively more than the average for students on the same campus as the main lecturer of 2,255 minutes or 38 hours. Where students with the maximum and minimum averages were excluded, the pattern remained the same with average usage of 2,923 minutes or 49 hours versus 1,313 minutes or 22 hours respectively.

A survey of students of the tertiary computing first year course COMP1005 was administered to a class of 39 students. Of the 31 responses (or 79% of all responses) received, 41% of students have used 1 other learning management tool, e.g. Moodle or Blackboard and 55% have used 2 or more other LM tools.

The summary of the survey reflecting OLeCenT usage are included as strengths, weaknesses and other points of concern:

Strengths of OLeCenT

- 93% used OLeCent at least once per week. Internationally: 56% (of students in a course) use LMS daily
- 93% recognized the learning object of different formats and used opportunity to view other formats
- 87% felt that OLeCent was effective for course delivery
- Only 9% felt that OLeCent did not improve learning performance
- Only 3% felt that OLeCent was inefficient
- 58% chose the VARK Learning Object assigned by system

Weaknesses of OLeCenT

- 36% undecided or agreed that OLeCenT was frustrating to use
- 29% said that OLeCenT was not easy to use

Other Points of Concern with respect to OLeCent usage

- 52% undecided whether a system should modify path based on learning (45% agreed to system recalculation of learners' paths)

29% of respondents were undecided whether OLeCenT could be considered higher in course delivery methodology (48% agreed that OLeCenT was above other learning management tools).

5.4. Benefits and Drawbacks

OLeCenT determines learning course paths based on the determined learning styles. The learning styles are determined through the diagnostic assessment in its first module, Diagnostic Analysis. OLeCenT uses the input of any accepted learning style assessment or inventory model. Whereas this may be a benefit to the flexibility of OLeCenT, the drawback is that two of the other three modules, namely Learning Administration, and Learner-Centric Assessment and Evaluation are dependent on the correct determination of the learners' learning styles. Course developers may develop only some of the teaching-learning style learning objects recommended by the learner-centric tool and still increase the level of learning. For this to happen, developing learning objects for the teaching-learning style matches is omitted but learners make full use of the teaching provided through the human teacher(s).

Other benefits include:

- Allow codifying of multiple Learning Style instruments
- Allow for learning objects to be tagged for single or multiple learning types and can be used across multiple Learning Style instruments
- Identify disparity in teaching and learning and aids face-to-face teacher in knowing percentage of students with greatest benefit in course delivery
- Allow learner flexibility of receiving course content deemed to be best fit as first priority
- Reshape course path per learning style as it learns of learning preference
- Should cause a skew primarily of the teaching curve and a shifting of the equilibrium point [70] of the teaching-learning process if the knowledge gained is used appropriately.

Amidst these benefits, the learner-centric course delivery tool has a number of drawbacks. These include the extensive possibly additional work for the course developer in providing learning objects for each learning style for each course objective to meet the Visual-Auditory-Kinesthetic (VAK) standard. Providing an electronic solution sometimes requires more resources in terms of time, energy, or skill. There is also always the concern of determining the level of granularity for the teaching-learning style learning objects to ensure maximum usability [77]. Another drawback is that eventually all components of OLeCenT will be SCORM 2004 compliant. Many LMSs and tools especially in some international regions are compliant with SCORM 1.2 [16] and there would be decreased efficiency of the tool if designed to be compliant with SCORM 1.2.

Other drawbacks include:

- Learning and auto-configuration takes place during course delivery and therefore provides greater benefit to latter users
- Where a user's learning style does not change, as a precautionary measure, that user has to periodically (once per term, per year or greater as deemed fit by the administrator) re-diagnosed for learning style.

6. Conclusion

Higher Education Institutions use Learning Management Systems (LMSs) worldwide by to assist with improvements in course delivery or management. Moodle and Blackboard are predominantly used throughout Higher Education Institutions. The Learning Management System of greater usage has limitations and do not foresee immediate usage of features including sequencing and navigation. Learning styles have been purported by some to have relevance and usage in assisting learning. Researches [10-11] suggest that there may be an optimal level of learning in a given time and nature of the uptake function; we consider the nature of the uptake function to include the learner, learning environment and learning style.

The OLECENT approach considers drawbacks of some of the Learning Management Systems (LMSs). OLeCenT, a proof of

concept of the OLECENT approach, is developed to be integrated within these LMSs, thereby enhancing functionalities that were not obtained. OLeCent incorporates teaching approaches / styles and learning mechanism / styles with an aim of ensuring that learner-centric course delivery may be administered thereby increasing the level of learning. Instantiations of OLeCenT have shown benefits to teachers and learners including identifying disparity in teaching-learning and providing a mechanism towards improving online learner-centric course delivery, and allowing the input of one or more course learning paths with real-time learning and automatic reconfiguration of the course path where a new trend or pattern is identified. The OLECENT approach may be adopted within Learning Management Systems or the tool incorporated to enhance learning where there may be physical disabilities.

Conflict of Interest

The authors declare no conflict of interest.

An efficient model to improve the performance of platelet inventory of the blood banks

Annista Wijayanayake*, Manisha Dandunna

Wastage
Inventory management
Demand forecasting

ABSTRACT

Platelet transfusions are vital for the prevention of fatal hemorrhage. Therefore, a stable inventory of platelets is required for an efficient and effective delivery of services in all the hospitals and medical centers. However, over the past decades, the requirement for platelets seems to be continuously increasing, while the number of potential donors is decreasing. Moreover, due to its very short life span of just five days, a large volume of platelets expires while they are on the shelves, resulting unnecessary shortages of platelets. Furthermore, it is very costly and difficult to get platelets from another blood bank in a short notice. Hence, these unexpected shortages put the life of patients at risk.

This study is focused on addressing the issues discussed, by developing an efficient blood inventory management model to reduce the platelet shortages, and wastages, while reducing the related inventory costs. Currently, the blood banks are managing platelet inventory according to their own instincts, which result to shortages and wastages. As a solution, we propose a model to manage the daily supply of platelets by forecasting the daily demand. Three different algorithms were developed using lower bound, average and upper bound values and tested to find the optimal solution that best fits to manage platelet inventory. These models were tested using data for 60 days obtained from two different levels of blood banks in Sri Lanka, namely a General Hospital blood bank and a Base Hospital blood bank. In General hospitals, the demand for blood components including platelets is very high when compared to the Base hospitals.

The study was able to come up with two different inventory management models for the two different types of blood banks. The model that best fits the General Hospital blood bank where the demand is high and was able to reduce the shortages by 46.74%, wastage by 89.82% and total inventory level by 39.10% and, the model that best fits the Base Hospital blood bank was able to reduce the shortages by 100%, wastage by 81.48% and total inventory level by 37.95%. It can be concluded that the same models can be adopted by other blood banks with similar characteristics to manage their blood inventory efficiently.

1. Introduction

Blood transfusions are generally required in surgeries, childbirths, organ transplants and for patients who are receiving treatments for diseases such as cancers and anemia. In Sri Lanka, total annual blood requirement exceeds 350,000 units and over the past decade the demand seemed to be increasing continuously. Since there are many voluntary donors as a result of the national culture and beliefs of Sri Lankans being a South Asian country, the demand was balanced throughout the history.

However, the blood units are outdated and blood is wasted in some areas while there are shortages in other areas. Blood shortages can put a human life at risk as the operations may have to be postponed, and moreover blood is an invaluable product and its wastage is highly undesirable.

Furthermore, with the increase of diseases and the increase in the number of patients who required surgery and transplants, over the past two decades, the demand for blood is expected to show an exponential growth in the future. On the other hand, with the increase in diseases transmitted through blood such as HIV and Hepatitis B, and with the increase in the aging population, the

* Annista Wijayanayake, Department of Industrial Management, University of Kelaniya, 094, Sri Lanka | Email: anni@kln.ac.lk

number of potential donors will be reduced. Hence there would be a challenge to fulfill the increasing demand with the reducing supply in the future.

1.1 The National Blood Transfusion Service

National Blood Transfusion Service (NBTS) is engaged in the collection of blood, screening the collected blood and making different blood components, and distribution. Also, NTBS deals with any issues of whole blood and blood component etc. It is a nationally coordinated system with the National Blood Center (NBC). This has many branches/clusters in every province with several main cluster centers in each province. The National Blood Centre, which is the operational headquarters for the entire Blood Transfusion Service, has 96 bloods Banks Island wide. These 96 blood banks are incorporated into 19 cluster centers according to their geographical locations. Apart from the NBC cluster, in all other clusters, the main cluster center is a General Hospital blood bank and the blood banks under them are Base Hospital blood banks.

The inefficient inventory management methods in each cluster and lack of coordination among different clusters lead to wastages as well as shortfalls of blood. Furthermore, despite the fact that blood is a costly product, the national blood transfusion service in Sri Lanka is not cost effective and the expenses are increasing day by day.

1.2 Platelets

The whole blood is processed into several blood components or products including plasma, platelets, red blood cells and, another hundred and fifteen other components. Blood plasma is a straw colored liquid component of blood that normally holds the blood cells in whole blood in suspension. Red blood cell**,** also called erythrocyte, cellular component of blood millions of which in the circulation of vertebrates give the blood its characteristic color and carry oxygen from the lungs to the tissues. Platelets are the blood cells that help the blood clot, stop bleeding when blood vessels are injured. Furthermore, when patients are receiving chemotherapy or suffering bleeding complications require platelet transfusions to prevent a fatal hemorrhage. Normally platelets are produced from whole blood in the initial separation process; on the other hand, platelets can also be collected through apheresis. However, in Sri Lanka only the national blood center has an apheresis machine.

Among all the blood components platelets have the shortest life span of just five days making it difficult to handle the inventory without experiencing both wastage and shortages. Hence this study is focused merely on platelets and all the solutions provided are customized to the special characteristics of platelets. Moreover, component processing and testing for transmissible diseases take an average of one day to complete and platelets are generally available for transfusion only for four days. However, platelets need not to be cross-matched as red blood cells.

2. Literature Review

Only very few research was done on the topic on ‘management of blood bank supply chain. Research on the management aspects of the blood supply chain were started in the 1960s, peaked in the late 1970s and early 1980s and then dropped off continuously to the present time. In 70s and 80s, many researches were done regarding blood bank management policies [1], and regarding theories of perishable inventories [2]. Thereafter, it shows a decline and experts argue that this was caused by the collapse of funding for studies in the area and in the increasing difficulty of the remaining problems in this area [3]. Since the mid-1980s, research on this topic has mostly been in the development of information systems to support donor screening, inventory management, blood ordering, blood usage review and compatibility testing [4]. Furthermore, few other studies were done during the past two decades as well.

From 1960s to 2000s William P. Pierskalla has done several researches in this area addressing different issues. In 1970s a transportation and location allocation model was developed for regional blood banking in the hope of decreasing overall costs. The objective was to decide how many central blood banks to be set up, where to locate them, how to allocate hospitals to the banks and how to route the periodic supply operations [5].

In 2001 the Nova Scotia government funded a project to investigate mechanisms to coordinate the platelet supply chain between CBS (Canadian Blood Services) and local hospitals. This study was done in three phases and in the first step a platelet repository was developed to store information necessary for an integrated planning model. In the second step a dynamic programming model was developed to identify optimal ordering policies for both the CBS and hospitals, and finally a simulation model was developed to evaluate integrated order policies. To simplify the problem by reducing the problem search space, orders and demands were aggregated into larger units and that approach was not used in the previous studies [6].In 2004 a detailed analysis was published, addressing the issues; regional structures and economies of scale, optimal target inventory levels, cross-match release policies, allocation, transshipment and issuing policies, vehicle routes and demand forecasting [3]. Cross-match releasing policies and other issues such as dealing with mismatching and keeping rare blood products in the inventory were addressed later by Katsaliaki and Brailsford. [7].

Apart from the statistical approaches, few studies were conducted on applying lean techniques to improve the performance of the blood supply chain. A recent study was done in Serbia to identify the most appropriate lean six sigma improvement methods and hence develop a framework to improve main blood inventory management processes that will minimize the wastage of blood [8].

Though different models were developed to address different issues, only few models have integrated more than one blood product or varieties of products, due to the complexity of modeling the different shelf lives and of computing the remaining shelf life. Furthermore, in all the above cases, collection of blood is a centralized activity, whereas in Sri Lanka, blood is collected by each and every blood bank to satisfy their own demand. On the other hand, the national blood center is distributing blood to all blood banks in the country if a request was made. Apart from that hospital blood banks can share their excess volumes with other blood banks where there are shortfalls. Therefore, policies regarding inventory management as well as distribution are completely different from the above studies and hence there was

a need to conduct a study specific to the Sri Lankan blood transfusion service.

3. Methodology

In the current method, blood inventory management was handled manually. However, there is no proper mechanism used to handle them efficiently, but based on the previous demands and experience of the staff and their own instincts on the inventory of the blood components are handled and managed. Therefore, the current practices cause many issues and lead toward shortages and wastages at many occasions. In this research, a customized spreadsheet based on a statistical analysis was developed to manage the platelet inventory level in hospital blood banks. To develop the spreadsheet, several mathematical models were tested and using the results from each model, the best model was selected using a multiple criteria decision analysis method (MCDA).

The models were developed in three phases; in the first phase different methods for forecasting the daily demand for platelets were tested and the best models for each technique was selected, in the second phase using the selected forecasting models different lower bound, mean and upper bound values were defined and in the third phase three different algorithms were developed to determine the optimal target inventory levels for blood banks that will reduce both shortages and wastages, hence the cost of operations.

In 2007 Katsaliaki and Brailsford [7] found that in the UK the demand for platelets follow a Log Normal distribution and all previous researchers have used the same approach in their research. Hence it can be assumed that the demand is normally distributed and moreover as a pilot test, some demand values that match the Sri Lankan conditions were randomly generated and tested for normality. From the pilot test it was found that the platelet demand is normally distributed.

3.1 Phase I: Forecasting the daily demand for platelets

Since the daily platelet/blood supply needs to be balanced, it is needed to forecast the daily demand for platelets/blood. Four different time series techniques were used to forecast the demand. Since the daily demand is stochastic, the Moving Average (MA), Weighted Moving Average (WMA) and Exponential Smoothing (ES) methods were used to forecast the demand. In addition, a Trend Analysis was conducted to check whether the daily demand shows any linear trend. According to the experience and knowledge of the staff of the blood banks there is no upward or downward trend in the demand of platelets. However, in the months of December and April, due to the festival season, which experiences the high rate of accidents, an increase in the demand for blood components can be observed and experienced. Nonetheless, according to the experts there is no possibility of observing a trend in daily demand and yet the trend analysis was conducted to verify that fact.

Sampling frame for this study includes all the blood banks of the NBTS except the National Blood Center cluster. When selecting the samples, the level of the blood bank was taken into consideration and one general hospital blood bank (a main cluster center) and one base hospital blood bank was selected for data collection. In order to make the sample more representative, from two blood banks that were selected, one was with a comparatively high level of demand and the other was with a low level of demand and yet the level of supply is equivalent in both hospitals. Two months (60 days) data taken from the blood banks were used for forecasting and analyzing demand, under the all four techniques.

3.2 Phase II: Defining mean, lower bounds and upper bounds for daily demand

Under the normality assumption, using the daily demand values, the selected forecasting methods MA, WMA and ES, computed the, mean, lower bound (LB) and upper bound (UB) values for the demand for each model. These mean, UB, LB values were considered as the minimum inventory level that should be maintained in order to avoid the shortages. The confidence level of 95% was used to calculate the different upper and lower bounds.

3.3 Phase III: Managing the daily supply and total platelet inventory level

Several mathematical models were developed in this final phase. The objectives were to find the best model that minimizes wastages, experience no shortages, keep the inventory level as low as possible by managing the supply and ultimately reduce the cost.

Considering the three different levels of inventory; lower bound, mean and the upper bound, three algorithms were developed and those algorithms were used to develop the different models. In all these algorithms, it was assumed that the entire intake of blood is usable despite the fact that a certain number of blood units will be rejected and disposed if they were infected with diseases transmitted through blood. However, in Sri Lanka still it is a nominal negligible amount, yet it seems to be continuously increasing. Since the figures of rejected blood are difficult to obtain due to confidentiality issues and as they were small in values according to the experts, it was not considered in these algorithms.

Once the blood is donated, it will be separated into different components and then it is tested for infectious diseases. It almost takes one day and therefore platelets only have four more days left on which they can be used. However, blood banks only records the date a blood unit is donated, but not the time it was donated. Therefore, the remaining shelf life is calculated on a daily basis but not on the time scale.

Three algorithms were developed around the same basic theory as described below. Currently, blood banks receive all the blood units donated by donors and yet the main objective of algorithms, is to manage the supply in an efficient manner. All the algorithms are updating remaining shelf life on a daily basis, however data can be input and outputs can be viewed at any time. In these algorithms the platelets are issued to the wards based on "First In First Out" basis. However, platelets with a remaining shelf life of one day are not given away or taken from another blood bank as those units have a high possibility of expiring the next day, before they are used. Also, cost reduction is one indirect objective of the algorithms, dispatching or ordering such platelet units is highly undesirable.

In all algorithms, before taking blood from donors, the inventory levels are checked to find if the desired reorder levels are met. If the current inventory level is above the reorder level, then the donors were asked to donate it some other day or direct them to the nearest cluster location where the blood is needed. This would minimize the medical expenses used for testing the blood components unnecessarily, which may avoid wastages of blood components. If the blood inventory goes below the reorder level, orders are placed to get platelets from other blood banks, to fill the gap. Here it is assumed that the blood is available at all times and the lead time to receive ordered blood as zero days. Therefore, the reorder level and the safety stock levels will be the same.

It was assumed that the blood banks will perfectly manage the model and however, extremely rare or unexpected situations arises where demand could go very high or supply could go very low continuously for a few days. These situations were excluded as in such situations the NBTS intermediate to control such situations. Therefore, such situations were not taken into consideration when developing the model.

3.4 Mathematical model to manage the Blood inventory system

Variables in the inventory management algorithms

LB – Lower bound for the forecasted daily demand for algorithm 1

M – Mean for the forecasted daily demand for algorithm 2

UB – Lower bound for the forecasted daily demand for algorithm 3

S – Actual platelet supply during the day

N – Days of stocks to be kept (Each algorithm was tested for both N=1, 2, 3 and 4)

Xi – Amount of platelet units in the inventory with a remaining shelf life of i days

Yi – Amount of platelet units with a remaining shelf life of i days, which need to be dispatched from the inventory

Zi – Amount of platelet units with a remaining shelf life of i days, which need to be ordered

D – Actual demand for platelets during the day

TI – Total inventory level in a day
TI = X1 + X2 + X3 + X4 + X5

WS – Wastage in a day

SH – Shortages in a day

From a pilot test done using computer generated data it was found that the best values for the days of stocks to be kept N are 2 and 3, among the four values tested 1, 2, 3 and 4, in order to minimize the wastages and shortages.

In all three algorithms, it was assumed that the orders will be delivered within the same day as the order is placed. Furthermore, while checking for the desired inventory levels, X1 value was not taken into consideration. The reason that the algorithms were developed in that way is to see if any, remaining units (after satisfying today's demand) with a shelf life of only one day that is in today, will be expired tomorrow, and platelets taken today become usable only from the next day onwards. Therefore, ignoring X1 value reduces the risk associated with fulfilling the actual demand next day. However, algorithms were designed to ultimately minimize the total inventory level which is equal to X1 + X2 + X3 + X4 + X5.

The algorithm 1 presented below, which maintains the value X2 + X3 + X4 + X5 in the lower bound value is shown below. However this can be easily replaced by algorithm 2 and algorithm 3 by replacing the LB values by the mean and UB values

Algorithm 1

Objectives: - Min SH
Min WS
Min TI

Step 1: Checking the inventory
If X2 + X3 + X4 < LB*N Then
X5 = L*N - (X2 + X3 + X4)
Else
X5 = 0

Step 2: Amount to be dispatch or receive
If S >= X5 Then
Y5 = S - X5
Z5 = 0
Else
Y5 = 0
Z5 = (LB*N - (X2 + X3 + X4) - S

Step 3: Shortages
If D > X1 + X2 + X3 + X4 Then
SH = D - (X1 + X2 + X3 + X4)
Else
SH = 0

Step 4: Wastage
If X1> D Then
WS = X1 - D
Else
WS = 0

Total inventory level
TI = X1 + X2 + X3 + X4 + X5

Step1: The amount of platelet required on that day will be calculated
Step2: If the supply of platelet is greater than the required amount, then compute the dispatch amount Yi. If it is less than the required amount then compute the amount needed to be ordered Zi
Step3: Compute the amount of shortages
Step4: Compute the amount of wastages

3.5 Selecting the model that best fits the objectives

With the objective of minimizing the wastage, shortages and the total inventory level, all three algorithms explained above were tested using the different LB, Mean and UB values and using MA, WMA, and ES techniques under different confidence levels. There were altogether eighteen different models were developed and given different codes for each model which is shown in the below table (Table 1). For each model, the total wastage, total shortages and the total inventory level were calculated to compare the results and choose the best inventory management model, associated with the best forecasting technique using 95% confidence interval.

Forecasting methods	LB Algorithm 1		Mean Algorithm 2		UB Algorithm 3	
	** N=2	N=3	N=2	N=3	N= 2	N=3
MA	MA 12	MA 13	MA 22	MA 23	MA 32	MA 33
WMA	WMA 12	WMA 13	WMA2 2	WMA 23	WMA 32	WMA 33
ES	ES 12	ES 13	ES 22	ES 23	ES 32	ES 33

Table 1:- Alternative Models for Platelet Inventory Management

**N=2, 3, 4, 5 days were considered but when N=2 and 3 produced better results.

In each testing model, the first two to three characters represent the forecasting technique used, the first digit represents the algorithm model number and the last digit represents the number of days that the stock needed to be considered. Since all the objectives are measured in the same unit, Weighted Sum Model (WSM) was used as the MCDA method to determine the best model among the eighteen models (given in Table 1). Delphi method was used to rank the three objectives and determine a weight for each objective. This was done merely consulting the experts and the staff of blood banks. The weights that were given can be changed according the experience and knowledge of importance. In our model the importance or weights for shortages given as 0.4, wastages the weight given was 0.375 and the total inventory management level the weights given were 0.275 while the sum of weights become 1. The model that yields the minimum total performance value was selected as the best model for managing inventory level.

4. Results

Data on demand from both blood banks was tested for normality to find whether they follow a normal distribution. Shapiro - Wilk test was used as the test statistic and it was found that demand for both hospital blood banks follows a normal distribution.

4.1 Outcomes of the different forecasting techniques

Using different number of days where n=2 to 12 the demand was forecasted in the Moving Average method and for each n value, Mean Absolute Deviation (MAD) was calculated to find the best value which minimize the forecasted Vs the actual error values. For General hospital blood bank, the least MAD value can be observed when n = 3, whereas for Base hospital blood bank, n = 9 gives the least MAD value. Therefore, n = 3 and n = 9 is selected as the best values for forecasting the platelet demand using the moving average method, for General hospital blood bank and Base hospital blood bank respectively.

Using weighted moving average method, for n = 2 to 15, the daily demand for platelets was forecasted and rank order centroid method was used to calculate the weighting factor. The least MAD value of General hospital blood bank can be observed when n = 5 and for Base hospital blood bank it is n = 12 hence for General hospital blood bank, n = 5 was selected and for Base hospital blood bank, n = 12 was selected to forecast the daily platelet demand using the weighted moving average method.

Using different values for the smoothing factor α, the daily demand for the platelets were forecasted and, MAD values for each α were calculated to find the best α for each blood bank. For General hospital blood bank, the least MAD value can be observed when α = 0.2 and for Base hospital blood bank, the least MAD value can be observed when α = 0.3. Therefore, α = 0.2 and α = 0.3 were selected for General hospital blood bank and Base hospital blood bank respectively to calculate the forecasted daily demand.

It was found that the demand shows no linear trend, exponential trend or polynomial trend in the daily platelet demand at both General hospital blood bank and Base hospital blood bank, throughout the two months considered. Hence it can be concluded that the daily demand for platelets shows no underlying trends and the demand is random for both General hospital blood bank and Base hospital blood bank.

Using the all three forecasting methods selected, from samples of seven days, the mean daily demand was calculated for each day and, using 95% confidence levels, the respective lower bound and upper bound values were calculated for each day considered.

When the forecasted demand and the actual demands were analyzed the difference was a negligible amount. The actual and forecasted demands were shown below for ES33 model in Fig 1

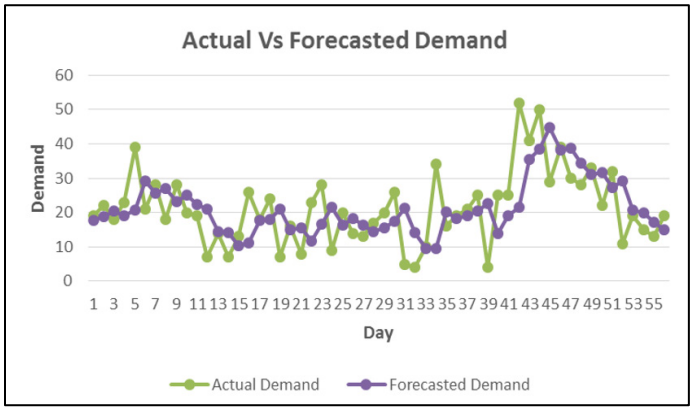

Figure 1:- Actual vs Forecasted Demand for model ES33

4.2 Analysis of the platelet inventory management models

For each blood bank, all the eighteen models shown in Table1 were applied and the percentage of reduction in shortages, the percentage of reduction in wastages and percentage reduction of the total inventory level was calculated for each of those models.

Thereafter, using the weighted sum model as explained in section 3, the total performance for each model was calculated.

The models were tested separately for 30 days and for 60 days using the new forecasted demand values. Thereafter the average performance for each model was calculated using the actual values. The difference between the actual values and the forecasted values were considered to evaluate the best model.

The table below shows the total performance of best three models for General hospital blood bank.

Model	Reduction of Shortages %	Reduction of Wastage %	Reduction of TI %	Total Performance %
WMA32	46.74	89.82	39.10	61.18
MA32	46.47	89.76	37.32	60.64
ES33	86.61	55.24	9.82	57.57

Table 2:- Best three Models for General hospital Blood Bank

As it shows the model WMA32 which use the weighted moving average method for forecasting the demand and use 95% confidence interval upper bound values and where the days of stock to be kept is two, gives the highest total performance for the General hospital blood bank. In average model WMA32 reduces shortages by 46.74%, wastage by 89.82% and total inventory level by 39.10%, resulting in a total performance of 61.18% achievement of objectives.

The below table shows the total performance of best three models for the Base hospital blood bank.

Model	Reduction of Shortages %	Reduction of Wastage %	Reduction of TI %	Total Performance %
ES33	100.00	81.48	37.95	79.09
WMA33	100.00	75.68	33.51	75.92
MA33	100.00	72.90	31.99	74.53

Table 3:- Best three Models for Base hospital blood bank

As the above table shows, the model ES33 which uses exponential smoothing as the forecasting method and use 95% CI upper bound values for the forecasted demand and where the days of stock to be kept is three, gives the best total performance for Base hospital blood bank. In average model ES33 reduces shortages by 100%, wastage by 81.48% and total inventory level by 37.95%, resulting in a total performance of 79.09% achievement of objectives.

When we analyze the efficiency of all 18 models that we proposed, model ES33 produce better results for both General hospitals and base hospitals to manage blood. Here the reduction of shortages is 86% and 100% respectively.

It can be concluded that the above model can be adopted by the other blood banks to improve their inventory performance while minimizing the shortages. The same algorithm can be applied to other products with similar characteristics, such as food industry, pharmaceutical items and other perishable goods.

As discussed and proven above the proposed model could reduce the wastages and manage the shortages, while maintain a minimum amount in the inventory of blood banks. This would save most of the medical expenses unnecessary spend on testing and managing the inventory of blood components and could be used to uplift the medical services in any hospitals.

5. Further research

The area is fruitful for future research as there are so many areas that need to be improved, in the blood supply chain. This study has focused only on platelets, however the scope can be increased by adding other blood components such as red blood cells and plasma. Another area that needs to be addressed in a further research is clustering the blood banks island-wide, in a more effective way based on the transportation cost and time that takes to deliver a blood product/s to another blood bank. It should be noted that the blood banks are clustered currently based on the district they belong to and no other valid logic was used to define those clusters.

Further research can be focused to develop algorithms for scheduling donors. A database should be maintained for existing and potential donors and it is needed to develop algorithms for scheduling those donors based on the requirements of each day. Therefore many of the practical issues can be overcome by developing a web based management information system incorporating our proposed algorithm. This would enable the staff of the blood bank to find out when there is a scarcity or excess of blood. According to the need the registered donors can be informed in advance and manage the blood supply chain smoothly and effectively. Therefore the wastages and shortages of the blood component can be reduced further.

ABSTRACT

Discretization is the process of converting numerical values into categorical values. Contemporary literature study reveals that there are many techniques available for numerical data discretization. The performance of classification method is dependent on the exploitation of the data discretizing method. In this article, we investigate the effect of discretization methods on the performance of associative classifiers. Most of the classification approaches work on the discretized databases. There are various approaches exploited for the discretization of the database to compare the performance of the classifiers. The selection of the discretization method greatly influences the classification performance of the classification method. We compare the performance of associative classifiers namely CBA and CBA2 on the selective discretizing methods i.e. 1R Discretizer (1R-D), Ameva Discretizer (Ameva-D), Bayesian Discretizer (Bayesian-D), Discretization algorithm based on Class-Attribute Contingency Coefficient (CACC-D), Class-Attribute Dependent Discretizer (CADD-D), Distribution-Index-Based Discretizer (DIBD-D), Cluster Analysis (ClusterAnalysis-D), Chi-Merge Discretizer (ChiMerge-D) and Chi2 Discretizer (Chi2-D) in terms of accuracy. The main object of this study is to investigate the impact of discretizing method on the performance of the Associative Classifier by keeping constant other experimental parameters. Our experimental results show that the performance of the Associative Classifier significantly varies with the change of data discretization method. So the accuracy rate of the classifier is highly dependent on the selection of the discretization method. For this comparative performance study, we use the implementation of these methods in KEEL data mining tool on public datasets.

1. Introduction

Discretization methods have played a great role in data mining and knowledge discovery. The discretization process makes learning more accurate and faster. There are various emerging classification problems in various domains of knowledge like image processing, medical science, business analytics and data mining etc. data, images, audio, video and textual data. The rapid growth in the data reservoirs in the fields of business, basket analysis, Engineering sciences, social networks, stock exchange and geological data is very high due to the cheaper storage resources. The high growth rate and huge data volume create a challenging problem i.e. knowledge discovery from the huge databases in the field of Data Mining. For the appropriate, effective and comprehensive knowledge discovery for the managers and decision makers; researchers are proposing continuously more efficient knowledge mining approaches.

The field of artificial neural networks, expert systems, medical science, bioinformatics, machine learning is example areas where extensively classification approaches have been studied. There are various approaches exploited for the building of associative classifiers. This comparative study provides the extension of the work presented in [1]. We provide the performance analysis of Associative Classifiers (CBA and CBA2) with the variation of the data discretizing method.

Thabtahand Fadi Abdeljaber provided the review of associative classification in [2]. Ranjana Vyas et al. describe the application of Associative Classifiers for Predictive analytics in [3]. The exploitation of associative classifiers for predictive analysis in the field of health care is surveyed in [4] by Sunita Soni and O.P.Vyas. Huan Liu et al. provide the extensive survey of the

*Zulfiqar Ali, National University of Computer & Emerging Science, H-11/4, Islamabad, Pakistan, +923335262172 & zulfiqar.ali@nu.edu.pk

discretization techniques in[5]. The focus of this article was an exploration of discretization methods with prospective of their historic development, the trade-off between speed and accuracy. Authors provided the hierarchical framework to categorize the exiting discretizing methods. Sotiris Kotsiantis and Dimitris Kanellopoulos surveyed the discretization techniques applied for the data discretization in [6].The theoretical and empirical perspective of the discretizing methods is very in [7] by the Salvador Garcıa. In [8] Pancho et al. provided the analysis of fuzzy association rules with Fingrams in KEEL.

In this article, we investigate the effect of discretizing methods on the performance of Associative Classifiers CBA and CBA2. We use the selective data discretizing methods i.e. 1R Discretizer (1R-D) [9], Ameva Discretizer (Ameva-D) [10], Bayesian Discretize r(Bayesian-D) [11], Discretization algorithm based on Class-Attribute Contingency Coefficient (CACC-D) [12], Class-Attribute Dependent Discretizer (CADD-D) [13], Distribution-Index-Based Discretizer (DIBD-D) [14], Cluster Analysis (ClusterAnalysis-D) [15], Chi-Merge Discretizer (ChiMerge-D) [16] and Chi2 Discretizer (Chi2-D) [17] for continuous data discretization purpose by exploiting the implementation of these methods in KEEL [18], a data mining tool by using the public datasets.Our experimental results reveal that the performance of the Associative Classifier significantly varies with the change of data discretization method in terms of accuracy. So the accuracy rate of the classifier is highly dependent on the selection of the data discretizing method. Our comparative study reveals that the performance of CBA (Associative Classifier) is better on the Ameva Discretizer than the other discretizing methods in terms of accuracy. The main object of this study is to investigate the impact of discretizing method on the performance of the Associative Classifier at the same other experimental parameters.

The Section 2 of the paper discusses the associative classification and describes the selective associative classification methods that are the focus of our study for the comparative analysis. Section 3 describes the data discretization process and selective methods for the data discretization i.e. 1R-D, Ameva-D, Bayesian-D, CACC-D, CADD-D, DIBD-D, ClusterAnalysis-D, ChiMerge-D, and Chi2-D. Section 4 explains the experimental Set-up exploited for this study, data sets and KEEL tool used for the experimentation. Section 5 describes the comparative performance results achieved by various discretizing methods used for datasets discretization by using Associative Classifiers CBA and CBA2. In section 6 more results discussion is provided and finally, the last Section concludes the study.

2. Associative Classification

The Associative Classification (AC) is a classification approach which integrates the classification rules mining and association rules mining that are two important data mining tasks. The Association Rule Mining (ARM) is unsupervised learning method in which no class attribute involved during the discovery of rules. The aim of the association rule mining is to discover associations between items in a transaction database. The attributes in the consequent of a rule could be more than one in association rule mining. The associative classification is a supervised leaning where a class must be given for the discovery of classification rules. For the construction of a classifier that can forecast the classes of test data objects is the main objective of associative classification. The consequent of a rule is an only class attribute. The over fitting is a considerable issue in the associative classification rule discovery. The over view of the selective Associative Classification approach CBA which is exploited to investigate the impact of discretizing method on the performance of the classification approach is given in the following sections.

2.1. CBA

Bing Liu, Wynne Hsu and Yiming Ma proposed a new hybrid classification approach by integrating the concept of association rule mining and classification rule mining in [19] that is named Classification Based on Associations (CBA). In this associative classification approach, the integration is done by focusing on the discovery of a special subset of association rules that are known as class association rules (CARs).

All class association rules are discovered those satisfy the minimum support and minimum confidence by using an existing association rule mining algorithms[20].The CBA associative classifier consists of two parts 1) a rule generator (CBA-RG) and 2) a classifier builder (CBA-CB).This approach possesses various advantages like the discretization of continuous attributes based on the classification pre-determined class target. The Data Mining task in CBA consists of the three steps;1) discretization of continuous attributes if any;2) class association rules;3) classifier building based on the generated class association rules.

2.2. CBA2

Bing Liu, Yiming Ma and Ching-Kian Wong proposed the enhancement and improvements in an associative classifier CBA. The new improved associative classification approach is named CBA2 developed in [21]. In this paper, theauthor tried to coup up with weaknesses of an exhaustive search based classification system CBA. The authors proposed two new techniques to deal with the observed weaknesses of the classification approaches. The first weakness observed is that as the traditional association rule mining exploits only a single minsup in rule generation which results inadequate for unbalanced class distribution. Secondly, classification data often contains a huge number of rules, which may cause a combinatorial explosion. For various databases, the rule generator is unable to generate rules with many conditions while such rules may be important for accurate classification. The first problem with this approach is tackled by using multiple class minsups in rule generation instead of single minsup as in CBA. The second problem which is caused by the exponential growth of the number of rules is dealt indirectly. The decision tree method [22] is exploited. The main working concept of the CBA2 is to use the rules of CBA2 to segment the training data and then select the classifier. These improvements in CBA improved the accuracy and lower error rate of the classification.

3. Data Discretization

Discretization is a data preprocessing technique used in many knowledge discoveries, machine learning and data mining tasks. Discretization process converts the continuous data into discrete form as most of the knowledge discovery and data mining algorithms work on discrete data. The discretization technique transforms a set of continuous attributes into discrete ones. By associating categorical values to intervals discretizing approach transforms quantitative data into qualitative data. The data discretiztion techniques are exploited to enhance the performance of the many knowledge discoveries and data mining approaches. We have used selective discretization method for our study to investigate the performance of Associative Classifier CBA by

using public data sets. The discretization methods used in this study are described in the following.

3.1. Discretization Methods

Gonzalez-Abrilet al. proposed a new discretization method named Ameva Discretizer (Ameva-D) in [10] that is proposed for supervised learning algorithms. The Ameva discretization approach maximizes a contingency coefficient based on Chi-square statistics. It helps in generating a potentially minimal number of discrete intervals. The most distinguishing feature of Ameva with respect to other discretizing approaches is that it does not need the user to indicate the number of intervals.

Xidong Wu proposed a new discretizing algorithm namely Bayesian Discretizer (Bayesian-D) in [11]. The Bayesian-D discretization approach exploits the Bayes formula. Cheng-Jung Tsai et al. propose a discretization algorithm based on Class-Attribute Contingency Coefficient named (CACC-D) in [12]. The CACC-D discretizing approach is motivated by the contingency coefficient. The CACC algorithm is a static, global and incremental discretizing approach. The CACC-D is supervised and top-down discretization algorithm which is based on Class-Attribute Contingency Coefficient. J.Y. Ching et.al proposed anew method for continuous data discretization named Class-Attribute Dependent Discretizer (CADD-D) in [13]. The class-dependant discretizing is performed in this approach for inductive learning from continuous and mix-mode data. The CADD-D is a discretizing method optimized for supervised learning based on information theoretic discretization method. The interdependence redundancy between the discrete intervals and the class labels is measured in the CADD-D method tom maximize the mutual dependence.

L.A. Kurgan et.al proposed a discretization method namely known as Class-Attribute Interdependence Maximization (CAIM-D) in [23]. The CAIM-D method is proposed for the supervised data classification. The main objective of this proposed approach is to increase the class-attribute interdependence to maximum level and to produce a minimal number of discrete intervals. The classification results in terms of accuracy are more promising with CAIM discretization method with respect to other discretization approaches. Huan Liu and Rudy Setiono proposed a method for converting numeric data discrete named Chi2 Discretizer (Chi2-D) in [17]. This approach (Chi2-D) takes data sets with numeric attributes as an input. This approach can intelligently and automatically discretize the numeric attributes as well as remove irrelevant ones as output. The Chi2 algorithm applies the X 2 statistic which conducts a significance test on the relationship between the values of an attribute and the categories.

In [16] Randy Kerber proposed a method for the discretization known as Chi-Merge Discretizer (ChiMerge-D) which is a general, robust algorithm that uses the X 2 statistic to discretize numeric attributes. The ChiMerge approach provides a useful and reliable summarization of numeric attributes. The number of intervals needed is determined according to the characteristics of the data. Michal R. Chmielewski and Jerzy W. Grzymala-Busse proposed discretizing method based on Cluster Analysis named ClusterAnalysis-D in [15]. The hierarchical cluster analysis is used for discretizing attributes in ClusterAnalyusis-D.

The ClusterAnaysis-D can be classified as either locally discretizing method or globally discretizing method. The methods that are characterized by operating only one attribute are called local method while the methods considering all attributes are called global methods. QingXiang Wu et.al proposed a new discretizing approach named Distribution-Index-Based Discretizer(DIBD-D) in [14]. The DIBD-D approach is based on the definition of dichotomic entropy and a compound distribution index. This criterion is applied to discretize continuous attributes adaptively. The DIBD-D can discretize any continuous attribute adaptively according to the simple adaptive rules. The adaptive rule is based on maximal compound decrement and minimal dichotomic entropy.

4. Experimental Set-Up

In this section, we conduct experiments to evaluate the performances of the associative classification systems. For the comparative performance analysis of the selective associative classifiers, we exploited the implementations of these algorithms included in Knowledge Extraction based on Evolutionary Learning (KEEL) [18]. The overview of the Data Mining and machine learning tool KEEL is given in the following section. In this section, we describe the datasets used for the comparative analysis of the associative classifier (CBA) and CBA2 in terms of accuracy and error rate by using the different discretizing methods. The parameters set for the experiments and the experiment graph designed for these experiments in the KEEL tool are described in this section.

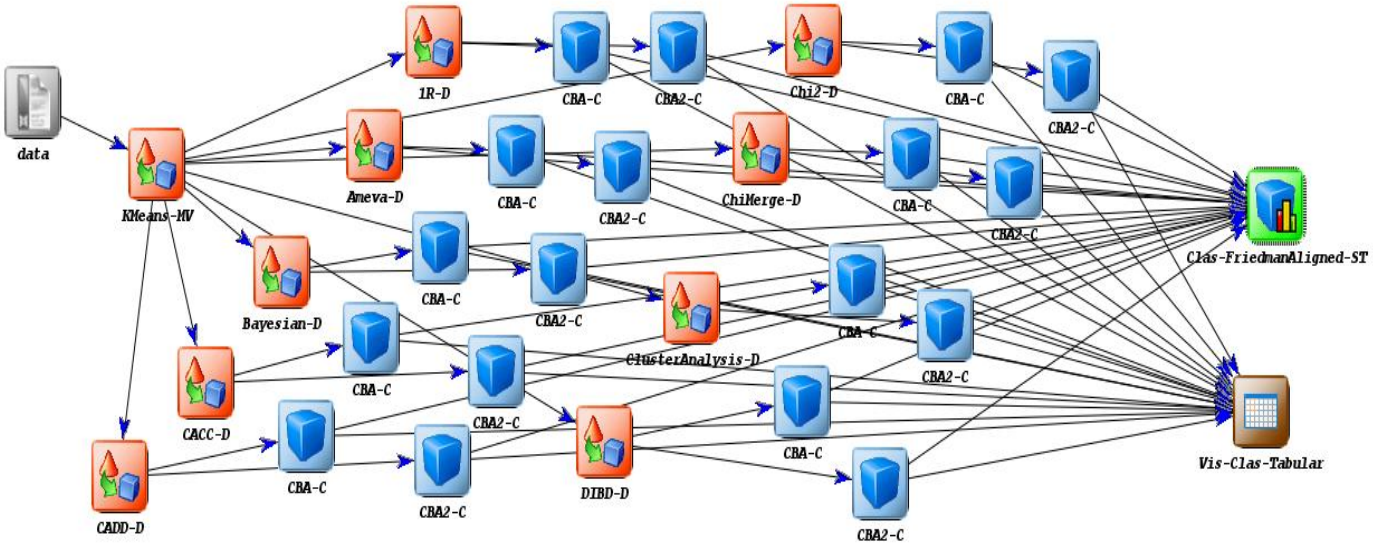
4.1. Data Sets

The description of datasets used for the comparative performance analysis of the selective Associative Classifiers under this study is given in Table2. The number of attributes (#Attributes), number of instances in the database (#Examples) and thenumber of classes (#Classes) are shown in the table. The missing values (Missing_V) in the dataset are representing by “Yes” (missing values present)/ “No” (missing values not present). The missing values of the datasets are imputed with the KMean-MV module implemented in KEEL. The datasets are discretized with the Ameva-D module included in KEEL as the associative classifiers accept the discretized form of datasets. We use the 10-fold cross-validation model for the datasets provided in KEEL. Table I summarizes the main characteristics of the 12 datasets which are given at Knowledge Extraction based on Evolutionary Learning (KEEL)-dataset repository[18].

Table 1 Data Sets Considered For The Experimental Stu

Dataset Name	#Attributes	#Examples	#Classes	Missing_V
Bupa	6	345	2	No
Cleveland	13	297	5	yes
Ecoli	7	336	8	No
Glass	9	214	7	No
Harberman	3	306	2	No
Iris	4	150	3	No
Monks	6	432	2	No
Newthyroid	5	215	3	No
Pima	8	768	2	No
Vehicle	18	846	4	No
Wine	13	178	3	No
Wisconsin	9	683	2	Yes

Figure 1 Experiment Graph Generated in KEEL



4.2. Experiment Graph

The experiment graph shows the components of the experiment and describes the relationships between them. The experimental graph of the comparative study is given in Figure1. The first component of the experimental graph is data which enables to select the datasets given in the KEEL Tool as well as to load user datasets. In our study, we selected standard KEEL datasets. The second component of the graph is KMeans-MV which is a module to impute the missing values in the database. The third component of the experiment graph is amodule for data discretization. In our case, we use the selective nine modules i.e.1R-D, Ameva-D, Bayesian-D, CACC-D, CADD-D, DIBD-D, ClusterAnalysis-D, ChiMerge-D and Chi2-D for the discretization of continuous data values. The fourth stage of the experiment graph is Associative Classification methods (CBA and CBA2) which are the focus of our study. The last stage of the experiment graph is the modules for the representation of the results of theclassifier and astatistical module for the analysis of the results produced by the algorithms used in the experiment. The module Vis-Class-Tabular provides the facility of representation of results of multiple classification methods in the form tabular representation.

4.3. Parameters of the Methods

The parameters of the associative classifiers (CBA and CBA2) under the focus of this comparative study are shown in the Tabel.2. The parameters of the method are selected according to the recommendation of the corresponding authors which are the default parameters settings included in the KEEL software tool [18]. In the Table 2,*Minsup* stands for minimum support, *Minconf* for minimum confidence, and *RuleLimit* for maximum candidate rules limit in the corresponding method.

Table 2 Parameters of the Methods for Experiment

Methods	Parameters
CBA-C	*Minsup = 0.01, Minconf = 0.5, Pruned = yes, RuleLimit = 80,000*
CBA2-C	*Minsup = 0.01, Minconf = 0.5, Pruned = yes, RuleLimit = 80,000*

5. Experimental Results

Table3 shows the comparative performance of the selected Associative Classifiers. We use the implementation of the corresponding algorithms in KEEL 3.0 for our comparative performance analysis of various discretizing methods by using CBA and CBA2 Associative Classifiers on the public datasets. We used the selective 9 discretization methods i.e 1R-D, Ameva-D, Bayesian-D, CACC-D, CADD-D, DIBD-D, ClusterAnalysis-D, ChiMerge-D and Chi2-D for this comparative study. The performance of both Associative Classifiers CBA and CBA2 is investigated on 12 public datasets for 9 discretizing methods. In table 3, the fold face red values show the best performance of CBA classifier for a specific dataset at a particular discretizing method with respect to other discretizing methods under the focus of this study. The fold face blue values in table 3 represents the best performance of the CBA2 classifier on a specific dataset with the exploitation of a specific discretizing method with respect to other discretizing methods. The last row of table 3 shows the average performance of the corresponding classifier for all datasets for a specific discretizing method. Overall the best average performance of classifier for a specific increasing method is presented with bold face red and blue for CBA and CBA2 respectively in table 3.The performance of the CBA classifier is better on Ameva-D discretizing method as compare to other discretizing methods but the average performance is better on the ChiMerge-D. The performance of CBA2 is promising with ChiMerge-D discretizing method. The performance of each discretizing method varies with respect to change in the database. The values bold face shows the wining of the corresponding discretizing methods for the CBA and CBA2 on the corresponding datasets.

Table 4 shows the comparative performance record of CBA and CBA2 in terms of Win/Draw/Lose of the Discretizing Methods. The 1R-D, Ameva-D, Bayesian-D, CACC-D, CADD-D, DIBD-D, ClusterAnalysis-D, ChiMerge-D, and Chi2-D. The performance of CBA classifier is better on Ameva-D and Chi2-D discretized. The performance of CBA2 remains same for Ameva-D and ChiMerge-D discretizing methods as shown in table 4.

6. Results Discussion

6.1. Comparative Performance Analysis in terms of Accuracy

Figure2 shows the comparative performance of the CBA and CBA2 on different discretizing methods for the selective datasets. With the critical observation of the graphs in figure 2, the performance behavior of CBA and CBA2 is symmetric in terms of accuracy for various discretizing methods. The performance of Associative Classifiers (CBA and CBA2) significantly changes with the change of discretizing method as shown in figure 2. The performance variation of CBA and CBA2 at datasets Glass, Monks, Ecoli and Wisconsin at the usage of different discrete methods is given in figure2. At the dataset Glass in figure 2, there is significant variation in performance of Associative Classifiers (CBA and CBA2). The performances of CBA and CBA2 are highest for Chi-D and lowest for CACC-D discretizing methods. The experiments for the dataset Ecoli shows that the performances of CBA and CBA2 lower significantly at the usage of CADD-D discretized while remaining almost same for the other discretizing methods. For dataset Monks in figure 2, the performances of Classifiers are drastically decreasing for 1R-D, Bayesian-D and CADD-D discretizing methods. The performance of CBA2 significantly decreased on dataset Haberman for Chi2-D discretizing method. Finally, the experimental results at Wine and Wisconsin datasets, reveals that the performances of CBA and CBA2 significantly down for the CADD-D discretized in terms of accuracy.

6.2. Comparative Performance Analysis in terms of Variance

This subsection describes the impact of discretizing methods on the performance of Associative Classifiers i.e. CBA and CBA2 in terms of variance on public datasets. The variance depicts the consistency of the classification approach. The lower value of the variance indicates that the classifier is more consistent for the corresponding dataset. The discretizing methods producing a smaller value of variance for a specific dataset for the specific classification approach are more promising and provide more robustness for the classifier. The variation of performance of

Associative Classifiers in terms of variance is elaborated in Figure 3. The performance of both classifiers is almost same for the datasets Bupa and Cleveland for on all the discretizing methods.Variance is significantly high for Chi2-D and Ameva-D discretizing methods for CBA2 and CBA classifiers on datasets Bupa and Cleveland respectively. The performance associative classifiers (CBA and CBA2) for Iris, New-thyroid, Wine and Wisconsin datasets is very promising and consisting in terms of variance for all the discretizing methods except CADD-D, Chi2 and 1R-D. The variance is very high of CBA and CBA2 on Iris and New-thyroid for CADD-D discretizing method.

With the critical observation of Figure 3, it concluded there is a significant difference in the performance of associative classifiers in terms of variance as well as for the various discretizing methods on the pubic datasets under the focus of this study. Mostly of the discretizing methods produce promising results for some datasets while on the other datasets their performance is lower. The performance of classification approach significantly is dependent on the discetzing method used for the discretizing the continuous datasets in discrete form.

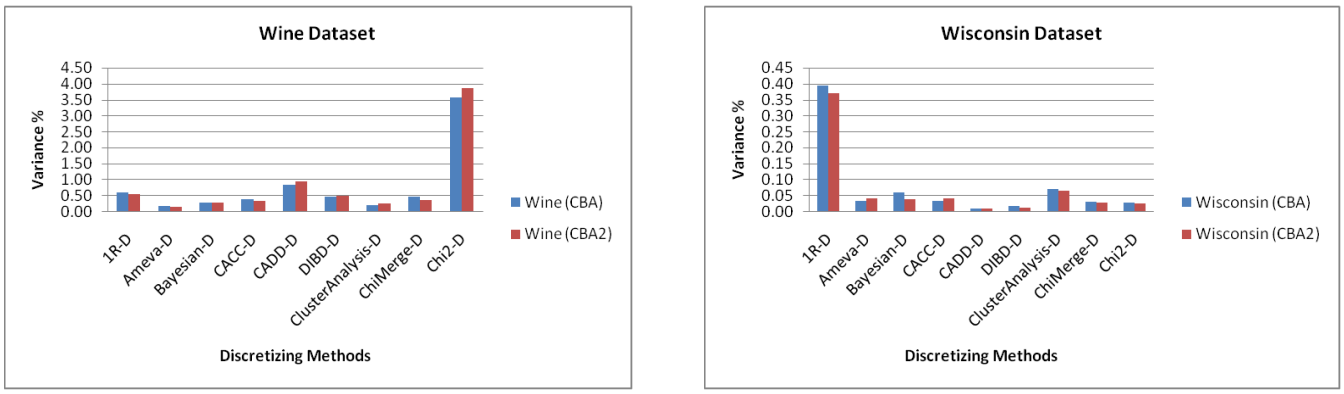

Figure 3 Comparative Impact of Discretizaing Methods on the Performance of Associative Classifiers (CBA and CBA2) in terms of Variance

7. Conclusion

Discretization algorithms have played a great role in the performance of classification techniques. We investigate the effect of discretization Methods on the Performance of Associative Classifiers. Most of the classification approaches work on the discretized databases. There are various approaches exploited for the discretization of the database to compare the performance of the classifiers. The selection of the discretization method influences the classification performance of the classification method. We compare the performance of associative classifiers namely CBA and CBA2 on the selective discretizing methods i.e. 1R-D, Ameva-D, Bayesian-D, CACC-D, CADD-D, DIBD-D, ClusterAnalysis-D, ChiMerge-D and Chi2-D in terms of accuracy and error rate. Our experimental results show that the performance of the Associative Classifiers significantly varies for different discretization methods for the same classifier. So the accuracy rate and variance in results of the classifier is highly dependent on the choice of the discretization method. For this comparative performance study, we use the implementation of these methods in KEEL data mining tool on public datasets.

In future, we will analyse the impact of discretizing methods for other classifiers by considering other parameters and to derive the significance of results by using statistical methods.

Conflict of Interest

The authors declare that there is no conflict of interests regarding the publication of this paper.

ABSTRACT

With the rapid growth of financial markets, analyzers are paying more attention on predictions. Stock data are time series data, with huge amounts. Feasible solution for handling the increasing amount of data is to use a cluster for parallel processing, and Hadoop parallel computing platform is a typical representative. There are various statistical models for forecasting time series data, but accurate clusters are a pre-requirement. Clustering analysis for time series data is one of the main methods for mining time series data for many other analysis processes. However, general clustering algorithms cannot perform clustering for time series data because series data has a special structure and a high dimensionality has highly co-related values due to high noise level. A novel model for time series clustering is presented using BIRCH, based on piecewise SVD, leading to a novel dimension reduction approach. Highly co-related features are handled using SVD with a novel approach for dimensionality reduction in order to keep co-related behavior optimal and then use BIRCH for clustering. The algorithm is a novel model that can handle massive time series data. Finally, this new model is successfully applied to real stock time series data of Yahoo finance with satisfactory results.

1. Introduction

A stock market, equity market or share market is the aggregation of buyers and sellers of stocks, which enables the trading of company stocks collective shares [1]. With the rapid development of trades in the world, people are paying more attention on investing in Stock markets [1]. By reviewing the stock's financial curves, an educated decision can make whether the company is stable, growing and has an improving future. Thus, it is necessary to find a way to identify stocks with similar trend curves, which is very difficult due to uncertainty [2]. Financial institutes such as stock markets produce massive datasets [1]. Large amount of data is a barrier to analyze and summarize stock market data.

To visualize stock market behavior, researchers have used data mining techniques such as decision tree [1,3], neural network [1,4], association rules [5], factor analysis [6], etc. The decision trees are a powerful beginning step, but very costly. Neural networks (NN) such as Self-Organizing Feature Maps (SOFM) have been effectively applied in a many previous approaches. However, using decision trees or NNs for cluster large data sets cause performance degradation. Association rule is a popular and well-studied method for discovering interesting relations among variables in huge databases. But, researchers have also shown that it can produce better index return only with fewer trades. Factor analysis is an important step towards effectual clustering. But it can use only a limited number of stocks and, can only find fewer relations like the best stock. The overall analysis for large number of stocks cannot be achieved using factor analysis.

In statistics, signal processing and many other fields, a time series is a sequence of data points measured typically at successive [7] uniform times [1]. Stock data, being time series data, shares a common set of analysis problems with other time-series data. Time-series analysis includes methods that attempt to understand time series, to make forecasts [1]. Time-series data are often large

[*] Mgnas Fernando, Senior Lecturer, University of Colombo school of Computing, 00700, Sri Lanka | Email: nas@ucsc.cmb.ac.lk

and might contain outliers. In addition, time series are a special type of data set where elements have a temporal order [8] and time-series data are essentially high-dimensional data [7]. Mining high-dimensional data involves handling a range of challenges such as curse of dimensionality, the meaningfulness of the similarity measure in the high-dimensional space, and handling outliers. Furthermore, time series analysis requires multiple arrays to represent the series, which make it computationally very expensive. Therefore, an effective dimensionality-reduction method is needed to reduce memory consumption and to fit matrix into memory and it should capture the temporal order and the highly-correlated features of time series [7]. Today, dimension reduction [7,8,9] is a highly-attractive research area and researchers focus on new techniques for dimension reduction [10,11,12] because it affects both the accuracy and the efficiency. The stock data only differs from other time-series data in terms of the data distribution. Therefore, our primary focus of research is time-series analysis.

Clustering, which is another tool for data analysis [3,13], provides the basis for most of the data analysis, decision making, designing, and forecasting problems. Thus, it is very important to achieve accurate clusters. But, due to the special structure of time-series data with high level of noise, building an effective model for clustering needs a huge effort and time. Furthermore, building an effective model for time series clustering cannot be achieved without a comprehensive study of theories and previous approaches.

Moreover, due to the volatility of stock data, which is not directly recognizable [2,14], and due to the type of distribution of stock data, the clustering becomes harder. Unlike financial return series, price series is harder to handle, because it has more attractive statistical properties [2]. Even for a stock return series, the volatility is not directly recognizable and it becomes harder as far as the price curves are concerned. Thus, the financial analysis sector has a thirsty of identifying relationships between original price curves, rather than trend and other curves.

Many stock analysis researchers and companies are searching for the right methods to cluster stock data in order to perform their analysis. This paper introduces a novel model for time-series clustering, including a new dimensionality-reduction approach. This can be taken as a case study for time-series clustering big-data fields. Comparative decisions made in the noise removal stage enhanced the clustering quality. The novel dimensionality-reduction approach is suitable for time-series data, for stock data, and for other huge data sets. The novel model is applied successfully on real stock data of Yahoo finance to evaluate the accuracy and performances. The cluster evaluation shows that, this can cluster stock price curves very effectively and efficiently. The next section will discuss the related work.

2. Related Work

A time series is "a sequence $X = (x_1, x_2, \dots, x_m)$ of observed data over time", where $i = 1, 2, \dots, m$ are time units and m is the number of observations [7]. It has a temporal order [8], often large and might contain outliers and essentially high-dimensional data [7]. The time series X can be considered as a point in n-dimensional space. This suggests that time series could be clustered using clustering methods. Time series tend to contain highly-correlated features. Thus, time-series data are usually good applicants for dimensionality reduction [9].

Let P_t be the price of an asset at time index$t$. Thus, the One-Period Simple Return is holding the asset for one period from date $t-1$ to date t would result in a simple gross return of $R_t = \frac{P_t - P_{t-1}}{P_{t-1}}$ [2]. Stock return series data follows a normal distribution of $N(0, \sigma^2)$ [14], where mean $\mu = 0$ and σ^2 is the variance.

In order to reduce defects in the clustering stage, data standardizing is needed [13]. Calculating the mean absolute deviation and calculating the standardized measurement (z-score) are some methods. Z-score is defined as $Z = \frac{x - \mu}{\sigma}$, where μ is the mean and σ is the standard deviation of the sequence.

Some of the dimensionality reduction techniques researchers which have been using for time-series data are Singular Value Decomposition (SVD) [7,9,14,15], the Discrete Fourier transforms (DFT) [7,9,16], the Discrete Wavelets Transform (DWT) [7,9,17], Piecewise Aggregate Approximation (PAA) [7,9], Principal component analysis (PCA) [12,18], Factor analysis (FA) [12,19], Adaptive Piecewise Constant Approximation (APCA) [7], Piecewise Linear Approximation (PLA) [7], Independent component analysis (ICA), Chebyshev Polynomials (CHEB) [7], etc. Researchers have been using wavelets for dimension reduction [7,9,17] but, its only defined for sequences with length which are an integral power of two [9]. Therefore, this method cannot be used for time series processing with various lengths, which is a very huge limitation. PAA ignores the co-related behavior of time-series data. Thus, PAA is not a good solution to use for dimension reduction of time-series data.

Singular Value Decomposition (SVD) had successfully been used [20], for time-series indexing [21]. Singular value is a good feature of a matrix and is suitable when data follow a normal distribution [14]. SVD is a global transformation, which is a weakness from the point of large data sets and strength from an indexing point of view. Additionally, the insertions to the clusters already have required re-computing SVD for the entire dataset. In order to eliminate these drawbacks, this research introduces a new extension of SVD to perform dimension reduction without these drawbacks.

There are two categories of sequence matching methods, named, Whole Matching and subsequence Matching [7,9]. Whole matching needs comparing the query sequence to every candidate sequence. This can be reached by evaluating the distance function [9].

When handling time series, the similarity between two time-series sequences of the same length can be calculated by summing the ordered point-to-point distance among them [7]. One of the widely used distance function is the Euclidean Distance [7] which is a good "gold standard" used to compare different approaches [9].

Previous probability based clustering approaches do not adequately consider the case that the dataset can be too large to fit in main memory [22]. They do not recognize that the problem must be viewed in terms of limited resources such as keeping the I/O costs low [22]. Using probability based approaches for time-series data clustering is problematic due to co-related features

[8,23]. Distance based approaches like k-means assume that all the data points are given in advance and can be scanned frequently [22], which is not true in the case of large data sets.

Balanced Iterative Reducing and Clustering using Hierarchies (BIRCH) has some good characteristics compared to the requirements. It is suitable for very large data sets, because it makes the time and memory constraints explicit [22]. The clustering decision is made without scanning all the data points [22], and in clustering, outliers can be removed optionally [22]. It ensures accuracy by fully utilizing the available memory to derive the finest possible sub clusters and ensures efficiency by minimizing the I/O costs which cause a linear running time [22]. It only scans the dataset once [22].

BIRCH uses a clustering feature (CF) which is a triple, summarizing the information that we maintain about a cluster. Then, CF vector of the cluster that is formed by merging the two disjoint clusters can be calculated using CF additive theorem. The CF vectors can be stored easily and can be calculated easily and accurately when merging. Storing the CF vector is sufficient for making the clustering decisions. Thus, BIRCH only stores this CF vector [22]. Thus, BIRCH is suitable for a data set with lot of entries, such as huge number of stocks. CF Tree is a height balance tree, which stores CF entries of clusters [22]. The CF tree can build dynamically, while inserting data. Thus, BIRCH is very suitable for real-time, time-series big data clustering like in stock markets. Thus, future researchers can extend this study easily to real-time clustering, because, an updating is just like B+- tree [22]. The CF tree is a very compact representation of the dataset [22]. Thus, BIRCH is suitable for huge number of time-series sequences.

In order to achieve a considerable efficiency level, parallel processing is needed. Since stock data falls into the big data category, parallel processing technique for big data is needed. According to K. Gutfreund [24], functional programming ideas and message passing techniques are intrinsic to MapReduce. Thus, we can achieve parallel processing using an implementation of MapReduce.

Time series consists of four components [25]: Trend component, Seasonal variation, Cyclic component, and Irregular fluctuations. An upward or downward movement is known as a 'trend'. A trend is the price that is continuing to move towards a certain direction. Moving-average lines are used to help a trader to identify the direction of the trend more easily. The simple moving average is formed by computing the average price of a security over a specific number of periods. This time period can be selected as 10, 20, 50, 100 or 200. The next section will discuss the design stage.

3. Design

The main objective of this research is to study a novel model for time-series data clustering, which is suitable for stock market data. It is assumed that the stock data follows a normal distribution as explored in the literature.

Most of the financial studies involve in returns. When P_t indicates the closing price of day$t$, and P_{t-1} indicates the closing price of day$t-1$, one can calculate the stock-returns series using:

$$R_t = \frac{P_t - P_{t-1}}{P_{t-1}} \text{ for } t > 1 \text{ and } 0 \text{ when } t = 1 \quad (1)$$

Sometimes, time-series data usually contains missed values. Let's assume that day t is missing. Then, in order to handle missed values, we use:

$$R_t = \frac{R_{t-1} + R_{t+1}}{2} \quad (2)$$

Stock-returns data series follows a normal distribution. Standardization or z-scores converts all indicators in to a common scale with an average of zero and standard deviation of one. Therefore, the z-score normalization is used.

$$Z = \frac{R_t - \mu}{\sigma} \quad (3)$$

$$\mu = {}^{1}/_{n} \sum_{t=1}^{n} R_t \quad (4)$$

$$\sigma = \sqrt{\frac{\sum_{t=1}^{n}(R_t - \mu)^2}{n}} \quad (5)$$

4. Piece wise Singular value decomposition (SVD)

The time series are usually good candidates for dimensionality reduction because they contain highly-correlated features [9]. To represent sequences, matrix is required. Singular value is a good feature of a matrix. It is feasible to use the SVD, when data follows a normal distribution [14] and also suitable for representing neighborhood. Therefore, the SVD is selected in this design. But, in order to reduce drawbacks of SVD, this paper introduces a novel approach to accomplish dimensionality reduction. This method is motivated by the simple observation that most of the time-series datasets can be approximated by segmenting the sequences into equal length sections and then recording the SVD of these sections, similar to the vectoring process used in PAA with mean value [9]. We can efficiently represent a "neighborhood" of data points with the reduced SVD value. These SVD values can be indexed efficiently in a lower dimensional space. This method can calculate SVD locally, and this new piecewise SVD removes the necessary of re-computing SVD for the entire dataset, when inserting to the clusters that we already have. Let us denote a time series query as $X = x_1, \dots, x_n$ and the set of time series of the dataset as $Y = \{Y_1, \dots, Y_K\}$. Let us assume that each sequence in Y is n units long (Previously, used filling value techniques for achieving this). Let N be the dimensionality of the transformed space that we wish to index($1 \leq N \leq n$). N may or may not be a factor of n. N being a factor of n is not a requirement of this approach. A time series X of length n can be represented in the N space by a vector $\bar{X} = \overline{x_1}, \dots, \overline{x_N}$. Let us take a nonnegative real number σ_i as the singular value for the matrix, generated by the vector$\bar{x}_i$. Then, the new reduced time series can be represented as $W = \sigma_1, \dots, \sigma_N$. The i[th] element of W is calculated by the following equation:

$$\sigma_i = SVD_{\left\lfloor j=\frac{n}{N}(i-1)+1 \right\rfloor}^{\left\lceil \frac{n}{N} i \right\rceil} x_j \quad (6)$$

In simple terms, to reduce the time series from n dimensions to N dimensions, the data is divided into N equal sized "frames". The SVD of the data falling within a frame is calculated and that is a nonnegative real number. The sequence of these σ_i values becomes the reduced time series representation.

5. Time series matching technique

In order to use with SVD, whole matching is selected. Here, since we are using the whole matching technique, as the previous original series, time series $X = x_1, \dots, x_n$ needs to be compared with all the other series in $Y = \{Y_1, \dots, Y_K\}$. After dimension reduction, the time series X has been reduced to W which has N dimensions. Furthermore, all the other time series in the data set $Y = \{Y_1, \dots, Y_K\}$ has been reduced to set of series with N dimensions. Let us take all the other series in the reduced data set as $Y_N = \{Y_{1N}, \dots, Y_{KN}\}$ and $Y_{iN} = \sigma_1', \dots, \sigma_N'$. Thus, to perform whole matching, one has to compare the reduced time series $W = \sigma_1, \dots, \sigma_N$ with the other time series in the data set $Y_N = \{Y_{1N}, \dots, Y_{KN}\}$. This comparison accomplished with measuring the distance as stated in the next section (III).

6. Distance Measure

For certain applications the Euclidean distance measure can produce notions of similarity which are very unintuitive. Thus, as a prototype, we use Euclidean distance measure. The Euclidean distance is a good "gold standard" [9] and BIRCH also supports Euclidean distance.

$$D(X,Y) = D(Z,Y_N) \equiv \sqrt{\sum_{i=1}^{N} (\sigma_i - \sigma_i')^2} \qquad (7)$$

7. Time series clustering

In this research study, we propose clustering to identify dense and sparse regions in set of stock time series and, to discover overall distribution patterns and interesting correlations among stock time series [13]. Clustering can also be used for outlier detection. Alternatively, the proposed clustering method may serve as a preprocessing step for other algorithms, such as characterization; attribute subset selection, and classification, which would then operate on the detected clusters. Clustering can reduce a lot of time in selection of stocks as stocks of similar categories [26].

A. Requirements of clustering:

First, it is required to identify the requirements of the proposed clustering algorithm. Since stock data are time-series data, be able to cluster time series data. Number of stocks is huge and volume of stocks is also large. Therefore, we need to find a method for efficient and effective cluster analysis of large datasets. Ability to handle outliers, minimal requirements for domain knowledge to determine input parameters, and ability to incorporate with newly inserted data into existing clusters are the requirements.

B. Clustering algorithm – BIRCH

As described, BIRCH only stores CF vectors. CF vectors can be stored easily and can be calculated easily and accurately when merging. Storing CF vector is sufficient for clustering decisions [22]. Thus, BIRCH is good for a data set with lot of entries, such as a huge number of stocks. Furthermore, each entry in a leaf node is a sub-cluster, and not a single data point. Thus, the CF tree is a very compact representation of the dataset [22]. Therefore, BIRCH is suitable for a dataset with huge number of time series sequences.

Furthermore, the CF tree can be built dynamically, while inserting data. Therefore, BIRCH is very suitable for real-time, time-series big data clustering like in stock markets. Thus, future researchers can extend this research study to real time clustering [22]. Therefore, BIRCH which is used in this research is to give an efficient and accurate solution.

8. Map Reduce

In order to give an efficient solution, parallel data processing technique is used. Therefore, Java Application Program Interface (API) of Hadoop MapReduce is selected for the implementation. Next section will discuss the implementation stage.

9. Implementation

The implementation is divided into three main phases. The first phase involves in processing the time series, generating returns and data normalization. The second phase is to generate the reduced series. Clustering using BIRCH is the last phase. This phase generates clusters with the same trend, which can be used for further clustering using another method or can be used for further analysis process. Furthermore, clusters with single stock can be used for stock fraud detection.

Stock data from yahoo finance, during 1st of January 2000 and 30th of November 2016 were selected. Thus, Number of records per company is 6179 and Number of companies used is 9000. The data is in 'metastock' format.

Apache Hadoop MapReduce is used to achieve the parallelism of processing. Apache Hadoop Java API, Hadoop libraries, and Apache Mahout Libraries were used in the implementation. Next sections will describe the steps of the implementation.

First, filled missing values and then normalization process were implemented using java. Then as described in earlier sections, 'piecewise SVD' was implemented. Due to the local behavior of new piecewise SVD, it can effectively be used for parallel processing. This piecewise SVD removes the necessity of re-computing SVD for the entire dataset, when inserting the clusters that we already have. Thus, we only need to calculate the reduced series for the current insertion series. Then the clustering process was implemented. In order to accomplish the implementation of BIRCH, we modified the 'jbirch' implementation of 'Roberto Perdisci'[1] according to our requirements. Next section will focus on evaluation and results.

10. Evaluation And Results

This section evaluates the difference phases of the proposed approach based on comparisons, time complexity and visual analysis of results.

First, we focus on the novel dimensionality-reduction approach and time complexity of it. Let us take an example time series: closing prices of stock Aalberts Industries (AALB.AS). This series contains 4401 values and is shown in Figure 1. (Using the chart from Yahoo Finance to visualize easily)

[1] https://github.com/perdisci/jbirch

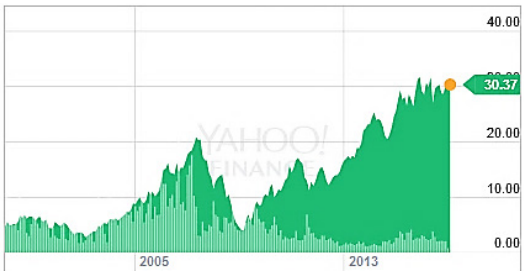

Figure 1- Closing prices of stock Aalberts Industr (AALB.AS)

When using piecewise SVD and number of dimensions as 8, this time series is reduced to:

[532.6446625096315, 416.8873393376198, 930.5871525547732, 1102.8832536583386, 206.39692810698506, 325.16997582033906, 472.1037659773537, 663.7071469029098] and is shown in Figure 2.

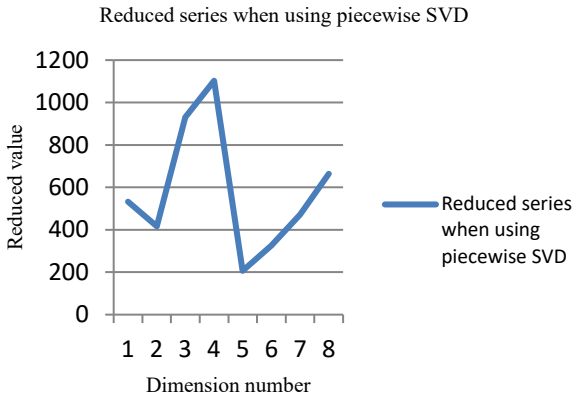

Figure 2- Closing prices of AALB.AS, when using piecewise SVD and 8 dimensions

In order to do a comparison, particular original series processed using piecewise aggregate approximation (PAA) with 8 dimensions. Results are:

[22.53275164735288, 17.36341740513517, 38.1274619404681, 39.638409452397134, 8.413749602363096, 13.765098841172463, 19.827730061349694, 28.209734151329258] and shown in Figure 3.

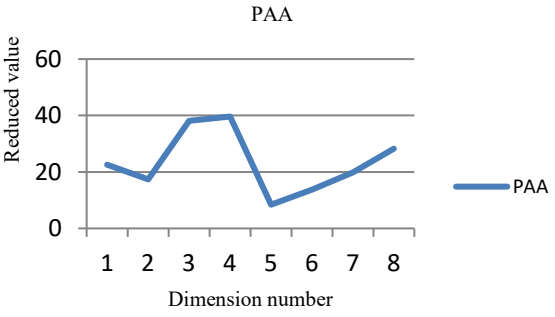

Figure 3- Closing prices of AALB.AS, when using PAA and 8 dimensions

When comparing two graphs (Figure 2 and Figure 3), both have much similar shapes.

Let us take the same time series: closing prices of stock AALB.AS. When using piecewise SVD and number of dimensions as 20, this time series has reduced to:

[332.3925127014745, 364.7341703213453, 290.44596055032366, 203.1714561644916, 297.2408049040378, 417.95588810303883, 591.8952354935798, 846.2187567644681, 891.780199993249, 214.3798407033649, 111.96008132365769, 125.80219373683428, 182.04229624732812, 216.06621785924793, 200.37451241363, 241.1271972942913, 331.1352621663843, 349.7118797667588, 426.1323476339242, 437.8459535327464] and shown in Figure 4.

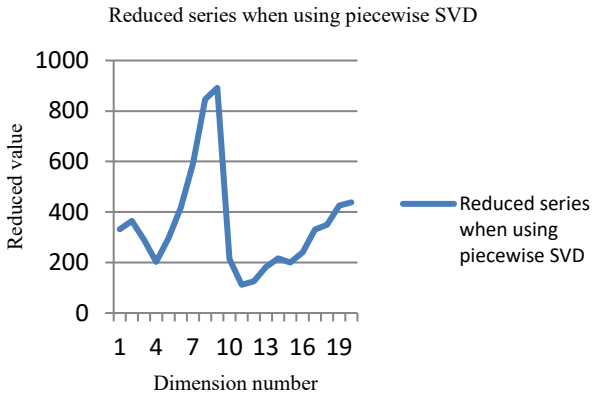

Figure 4- Closing prices of AALB.AS, when using piecewise SVD and 20 dimensions

In order to do a comparison, particular original series processed using PAA with 20 dimensions. Results are:

[22.284253578732113, 24.53078845716883, 19.513928652578947, 13.629266075891842, 19.782185866848458, 27.921654169506937, 39.799772778913876, 56.72833446943877, 55.645944103612784, 14.31897296069074, 7.061522381276979, 8.299890933878666, 12.191888207225627, 14.44708020904339, 13.446739377414218, 16.193206089525106, 22.225585094296747, 23.433946830265832, 28.684389911383786, 29.556532606225836] and shown in Figure 5.

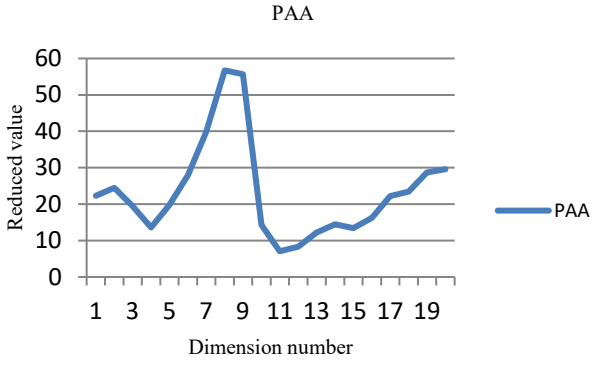

Figure 5- Closing prices of AALB.AS, when using PAA and 20 dimensions

When comparing two graphs (Figure 4 and Figure 5), both have much similar shapes but, piecewise SVD has a better gap between values with dimension number. Thus, this helps to give more accurate clusters in the clustering process. Further, when comparing Figure 3 and Figure 5, PAA has changed the shape of the graph, because PAA is ignoring the co-related behavior of values of time series. But, piecewise SVD remains the same shape, when comparing Figure 2 and 4. Thus, when using piecewise SVD, number of dimensions has reduced accurately. Therefore, this technique can be used to reduce stock time-series data. Furthermore, because of the new local behavior of SVD, can use this new piecewise SVD in the clustering process effectively. Effectiveness will be evaluated in the next section.

11. Evaluation of the time complexity

For full SVD, on an $m \times n$ matrix A, $[U,S,V] = SVD(A)$, the time complexity is in $O(\min(mn^2, m^2n))$ [27]. Thus, when K is the number of stocks and n is the length of a time series, as the previous old method, time complexity is:

$$O(\min(Kn^2, K^2n)) \tag{8}$$

For a dataset with a higher number of series (higher K), or for a dataset with long time series (higher n), above value is high. In the piecewise SVD in this research, when computing SVD for one vector in one sequence, $m = 1$ and $n = n/N$. Thus,

$$O(\min(mn^2, m^2n)) = O\big(\min\big((n/N)^2, (n/N)\big)\big) = O(n/N) \tag{9}$$

The complexity of one time series is given by:

$$N \times O(n/N) = O(n) \tag{10}$$

Computing reduced time series for different sequences are processed in parallel. Thus, there is no impact of K in the piecewise SVD. Therefore, the piecewise SVD has a lower time complexity than the original SVD. Another major advantage of the piecewise SVD is the ability to perform SVD locally. As a result of using one time series at a time, we can perform SVD locally and thus, can add a new series to existing clusters without computing the SVD for the whole data set. Therefore, the local behavior removes the necessity of re-computing the SVD for the entire dataset, when inserting the clusters that we already have by adding a parallelization strategy.

12. Evaluation of the clustering

In most of the previous research approaches, the quality of the stock clustering and time-series clustering have been validated via visualizing the resulting clusters instead of statistical measurements [5,14,28,29,30]. The reason is that even though the statistical measurements give a numerical number, they cannot give accurate measurements. Thus, to assess how well this methodology clusters stock-market data, we performed a visual analysis of sets of stocks in the same groups and those in different groups. Yahoo Finance line charts were used to plot stock price movements of these stocks over the maximum period of available time, and the actual time period used in this research (i.e., Jan 1, 2000 to Nov 30, 2016) is visualized using a vertical line when needed.

Figure 4- Final clustering results of a sample with 156 stocks from AMEX sector

Let us take closing prices and trends of some stocks of cluster 16, as an example. Graphs are taken from the current yahoo exchange pages of particular stock[2]. Blue line indicates the original closing prices of stocks. Also, in order to compare only the trend part, let us take simple moving averages of IJR, IWN, IJS and IWM stocks of cluster 16. The simple moving average is used to get the trend out of the stock-price time series. Thus, now, seasonal and irregular parts have been removed. Here, the green line is the simple moving average with 50 periods and the red line is the simple moving average with 100 periods, which indicates trends.

IJR	
IWN	
IJS	
IWM	

Table 1- Price curves and trend curves of cluster 16

Thus, according to the graphs of cluster 16, price curves of stocks of cluster 16 are much similar. Also, it shows that, the trend curves of same cluster stocks are same. Therefore, financial analyzers can use trend curves of stocks of a cluster to build a model of trend curves. Furthermore, it can be used to forecast stocks of that cluster, using models like Autoregressive Integrated Moving Average (ARIMA) models. Let us take some outliers, which are clusters with only one stock. Let us take simple moving averages of those outliers in order to compare only the trend part of outliers. Starting point of our data set is "Jan 1 '00", which is indicated by a crossed horizontal and vertical line.

cluster 36: INUV	
Cluster 35: INO	Cluster 22: DIT	
Cluster 23: ELR	
Table 2- Price curves and Trend curves of outliers

Thus, there exist a big different between shapes of price curves between outliers. For example, there is an abnormal behavior due to sudden downtrend in ELR of cluster 23. Thus, financial analyzers can further process outliers for fraud detection using price curves or trend curves. Furthermore, price curves of stocks of cluster 16 and price curves of outliers have a dissimilarity. Thus, from these stock price plots, it is apparent that the shapes of the same cluster price curves are similar, but there is a great difference in different clusters. The trend curves of outliers are different from other stock trends and can detect sudden decreases of trends like in ELR of cluster 23.

When the distance threshold increases, it can be got outliers far away from other clusters, which is good for further processing of fraud detection. When the distance threshold decreases, more refined clusters can be gained to receive accurate forecasting results.

13. Stress testing results

In order to give some indication about the running time of the program, running times with different number of stocks are listed below. Here, one stock is 6179 dimensions lengthier.

- Total time: Total running time in milliseconds
- CommittedVirtualMemorySize: The amount of virtual memory that is guaranteed to be available to the running process in bytes, or -1 if this operation is not supported.
- FreePhysicalMemorySize: The amount of free physical memory in bytes.

- FreeSwapSpaceSize: The amount of free swap space in bytes.
- ProcessCpuLoad: The "recent CPU usage" for the Java Virtual Machine process.
- ProcessCpuTime: The CPU time used by the process on which the Java virtual machine is running in nanoseconds.
- SystemCpuLoad: The "recent CPU usage" for the whole system.
- TotalPhysicalMemorySize: The total amount of physical memory in bytes.
- TotalSwapSpaceSize: The total amount of swap space in bytes.

Number of stocks processed	Size of stocks	Running time, CPU and Memory usage
156	29.1 MB (30,525,923 bytes)	Total time: 13530 milliseconds CommittedVirtualMemorySize = 3466719232 FreePhysicalMemorySize = 728338432 FreeSwapSpaceSize = 8589930496 MaxFileDescriptorCount = 4096 OpenFileDescriptorCount = 73 ProcessCpuLoad = 0.006662867826430245 ProcessCpuTime = 17900000000 SystemCpuLoad = 0.7195349045079402 TotalPhysicalMemorySize = 8252899328 TotalSwapSpaceSize = 8589930496

Table 3- Running time, CPU and Memory usage with different loads of stocks

Thus, according to these comparisons, it shows that this method can process massive data sets. Therefore, this method is suitable for process time series big data such as stock time series.

14. Conclusions and Future Work

In this paper, clustering method for time-series data based on SVD is proposed. The method takes advantages of the piecewise SVD and clustering to visualize efficiently the time-series data, which improves the processing efficiency and analysis of time-series data. We successfully implemented this method on Hadoop platform which provides the capabilities to process massive data. Furthermore, the real historical stocks are analyzed by this method on Hadoop platform: first, the data normalization, then, the feature extraction by piecewise SVD, and finally, the clustering by BIRCH with good results.

15. Conclusions

This research added a value to time series, data mining, and big data fields. First of all, this research explores a theoretical background related to time-series data. This can be seen as a case study to time-series mining research area. Very special decisions made in the stock data normalization phase can apply to time series data sets which follow a normal distribution. Furthermore, the novel piecewise SVD approach has numerous advantages than previous approaches. It is simple to understand and implement and can be applied to dimensionality reduction very accurately and efficiently. This will solve most of the problems with high-dimensionality and high-noisy in time-series data. Furthermore, the novel piecewise SVD has a local behavior, which is an opposite characteristic when considering the original SVD which has a global behavior. Therefore, this new piecewise SVD is suitable for big data. Furthermore, because of this local behavior, piecewise SVD can be used for parallel processing, and this piecewise SVD removes the necessity of re-computing the SVD for entire dataset, when inserting to the clusters we already have.

Previous stock and other time-series clustering methods have only succeeded with traditional clustering methods like k-means, canopy, AprioriAll, SOM, etc. This research concludes that, BIRCH is suitable for data distributions which have time-series behavior with high noise and high dimensions such as stocks and can be used to cluster massive time series data very accurately and efficiently.

Therefore, the overall methodology can be applied to process big time-series data with a normal distribution such as stocks in an efficient manner.

As stated in literature, the previous stock data clustering methods focused only on clustering the trend curve, because, it is very difficult to cluster the actual prices. But, in this research, the price curves of the stocks have clustered efficiently in an accurate manner. The first reason for this is that the correct methods used in the preprocessing stage, which was selected after a good study about time series data behaviors and stock data behaviors. The second reason is the novel approach of using SVD accurately with a local behavior.

Therefore, the method of this research can support exploratory search and facilitate serendipitous discovery. Besides revealing groups of similar stocks, this visualization can be used to find stocks that show different trading patterns. Such discovery can help traders to identify, for example, a set of hot stocks, stocks with a same trend and outliers and can further analysis of fraud detection or for forecasting. Instead of chasing the hot stocks, some investors may prefer to buy undervalued or oversold stocks. To find such stocks, they can explore clusters of stocks that have a sudden downtrend. This strategy may help financial analyzers to reduce the volatility of a portfolio and assist in decision-making process of buying and selling stocks. Therefore, this research enhances the prediction procedure of time-series data via an optimum clustering method.

Future directions

In order to identify subtle patterns with very short life times, Piecewise SVD will be extended for subsequent matching, instead of whole matching. Furthermore, future work should be continued to cluster data with different dimensions and should be continued to time series forecasting, with respect to particular data domains separately. Furthermore researchers can extend the methodology for different data distribution types, instead of normal distributions. Moreover, the researchers can extend this to real time stream processing using big data engine such as Spark because of BIRCH.

ABSTRACT

The paper presents an analytical study on a wireless traffic dataset carried out under the different approaches of machine learning including the backpropagation feedforward neural network, the time-series NARX network, the self-organizing map and the principal component analyses. These approaches are well-known for their usefulness in the modeling and in transforming a high dimensional data into a more convenient form to make the understanding and the analysis of the trends, the patterns within the data easy. We witness to an exponential rise in the volume of the wireless traffic data in the recent decade and it is increasingly becoming a problem for the service providers to ensure the QoS for the end-users given the limited resources as the demand for a larger bandwidth almost always exist. The inception of the next generation wireless networks (3G/4G) somehow provide such services to meet the amplified capacity, higher data rates, seamless mobile connectivity as well as the dynamic ability of reconfiguration and the self-organization. Nevertheless, having an intelligent base-station able to perceive the demand well before the actual need may assist in the management of the traffic data. The outcome of the analysis conducted in this paper may be considered in designing an efficient and an intelligent base-station for better resource management for wireless network traffic.

1. Introduction

Today, the communication has become an integral part of the daily activities for everyone. For example, the services such as video on demand (VoD), downloading music, stream video data, voice over IP (VoIP) and live video conference calls have become a part of the daily activities of the users. Such applications need a high quality of service, particularly for voice in real time. Resultantly, a lot of wireless technologies such as 3rd Generation (3G), wireless fidelity (Wi-Fi), Worldwide Interoperability Microwave Access (WiMAX), Global System for Mmobile Communications (UMTS) and the Evolution of the Long-Term (LTE) are growing to meet the accelerated needs of the users to provide them anywhere, anytime access to the Internet. In the recent past, the main point in the telecommunications sector is the next generation wireless networks (NGWNs). These networks consist of different techniques to gain access to the network to provide unlimited access to the internet, global roaming, high-speed and an increased user satisfaction.

The NextGen Wireless Networks are a combination of circuit-switched networks, various services, and packet switching. It is covering a wider area in which the user can take advantage of different wireless networks to improve the call quality. NextGen comprises of the services independent of the core technologies related to transport [1, 2]. It can be defined as a complex process, easily accessible, convenient and converging economic, efficient and flexible, personal and real, reliable and secure [3].

The fundamental technical issues for the NextGen Wireless Networks include end-to-end QoS, mobility management, energy efficiency, call admission control, resource allocation, and security. This has encouraged many researchers to develop the QoS models for the NextGen Wireless Networks [4]. In mobility the connected base station cannot support the ongoing session, and it has to handover the session to the new base station [5]. Under the wireless communication, most of the network equipment

* Muhammad Ahsan Latif, Asst. Prof., Department of computer science, University of Agriculture, Faisalabad, Pakistan | Email: mahsanlatif@uaf.edu.pk

operate on battery power and with the limited resources just not capable to provide the energy to keep the equipment alive for extended time period [6]. Controlling calls in wireless communication is a process of administering the traffic volume. The decision of whether a new call has to be admitted, delayed, dropped or forwarded to a neighboring network is decided by this sub-system. The incoming traffic can further be split into real time i.e. video and voice, and non-real time i.e. images, text, etc. [7]. As the NextGen Wireless Networks are distributed and open architectures so it offers easy access to the services, information and the resources together with constant abuse from the fraudsters, hackers and crime units [8]. User identification based on the IP layer can be easily tampered within such networks. The packets sent over the network can be easily identified with a "borrowed" IP address, which grants the unauthorized users to mimic the valid ones. These intruders abuse services and gets benefit with the expenditures of legitimate users, who do not know the actual situation [9]. Such intruders can get a valid electronic serial number and mobile identification number during the registration process of the call. They can duplicate the same number on the other handset and utilize the services in the name of real user. A mobile node utilizes Mobile IP and Session Initiation Protocol (SIP) under subscriber mobility [10]. The installation of small cell base stations on the existing macro cellular systems is presented as a solution for an optimized coverage, offloading traffic and to boost the capacity of the next generation wireless networks in [11]. A comprehensive overview of the machine learning approaches used to address different issues in the wireless sensor network is provided in [12]. The researchers supported the use of machine learning techniques to better monitor the dynamic behavior that emerges out of the sensor network over time. For enhanced traffic management, the researchers performed classification of the traffic data through supervised machine learning approaches [13]. For mobile big data, the challenges of computing capabilities, spectrum efficiency and backhaul / fronthaul link capacity are discussed in [14]. The study presented different opportunities and the bottlenecks in the design of the scalable wireless systems to get adapt to the big data.

The foremost issue in the NextGen Wireless Networks is guaranteeing the QoS and provision of requisite resources to the connected subscribers from the service provider at any time. This claims the network reliability, bandwidth, timeliness, jitter, fault tolerance and seamless mobility among heterogeneous access networks. These needs are the driving factors for the NextGen Wireless Networks. Particularly, VoIP will be the most popular application in the future. It demands high QoS for the moving user. In this regard, many problems exist to make the NextGen Wireless Networks fully resourceful and well-matched with the existing services and technologies. For the moving subscribers providing the required service, by sustaining the adequate QoS while considering the various networks as well as the global roaming is a tricky job. The appearance of the irregular needs in the NextGen Wireless Networks require an effective assurance to satisfy the subscribers.

To ensure the QoS for the subscribers, an understanding of the behavior of the network traffic is necessary. This would assist in following an adaptive policy for using the available network resources to guarantee QoS at an optimal level. To analyze the network traffic behavior, we used the self-organizing map and further employed the principal component analyses. An intelligent module within a base-station could be embedded with the outcomes of the analysis to take adaptive decisions intelligently. The module would estimate the future requirements of the bandwidth for a base-station as per the previous history and commit in advance the requisite resources from the backhaul network for the guaranteed bandwidth provision to the end-users. The real time data of a 3G wireless network established by the Pakistan Telecommunication Co. LTD i.e. CDMA2000 1xEV-DO Rev is used in this study.

2. Intelligent Base Station

A schematic diagram of an intelligent base station is shown in Figure 1.

Following are the components of this intelligent model:

- Monitoring Unit: This component monitors the data transferred from the Base Station to the connected subscribers periodically.
- Storage Unit: This component stores the observed data in the memory to use for another component of this model i.e. Intelligent Forecasting Unit.
- Intelligent Forecasting Unit: This component is the heart of the model, which facilities in forecasting of upcoming demands on the Base Station in a specific hour. It uses the previous stored data from the storage unit for predicting the upcoming resources requirement and subsequently forwards the request to the backhaul network in advance to allocate the forecasted bandwidth allocation.

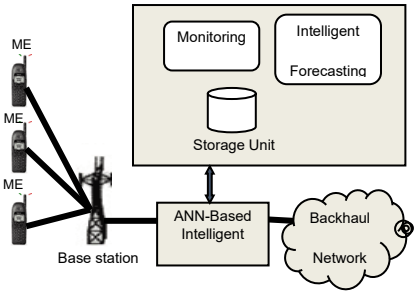

Figure 1: Intelligent base station model

3. Neural Network Based Analysis

The ANNs, owning a proven learning paradigm can be used effectively to develop such intelligent agent [15-27]. Three different NNs are tested to understand the patterns and the behavior lying within the network traffic data. The backpropagation feedforward neural network and the nonlinear autoregressive with external input neural network are used to better learn the demand time-wise. Whereas the self-organizing map is used to learn the key parameters to focus on. The training data comprises of the six-month wireless traffic data acquired from the Pakistan Telecommunication Company Ltd. The training data comes in periodic shape i.e. hourly data with reference to the week-days and an average accumulative throughput in a particular hour. The mathematical models of the three NNs are given as under.

$$Y = F^2(LW^{2,1}F^1(IW^{1,1}P + b^1) + b^2) \quad 1a$$

$$X_{k+1} = X_k - a_k g_k \quad 1b$$

$$E = MSE = 1/N \sum_{i=1}^{N} (t_i - a_i)^2 \quad 1c$$

$$g_k = \frac{\partial E_k}{\partial w_{i,j}} \quad 1d$$

$$Y(t) = F(Y(t-1), ..., Y(t-n), X(t-1),..., X(t-n)) \quad 2$$

$${}_iW(q) = {}_iW(q-1) + \alpha(P(q) - {}_iW(q-1)) \quad 3a$$

$$N_i(d) = \{j, d_{ij} \leq d\} \quad 3b$$

The (1) define the feedforward neural network completely. The (1a) defines a three layered architecture with LW as the layer weights, IW as the input weight matrices and P as the input vector The sub-equation (1b) gives the learning rule to update the network parameters wherein X_k represents the vector of the current weights and the biases, g_k is the current gradient and a_k is the learning rate. The (1c) defines the mean square error (mse) which is also one of the stopping criteria used during the training phase. The (1d) defines the relation how to determine the gradient. The system of nonlinear autoregressive with external input (NARX) is defined in (2). In our case, the previous two terms (of both the input & output) are taken into account to calculate the current term. The model uses the same learning rule as given in (1b). The system of (3) provides the rule to update the weights of the winning neuron as well as of the neighboring neurons in a neighborhood d' defined in (3b). All of the three models are programmed and tested in Matlab. The used parameters are given in the following tables Table-1, Table-2 and Table-3 against each model.

The results of all the three models provide a very clear understanding of the relations among the variables embedded in the data. The function approximation performed by the feedforward model (1) provides a strong evidence of the relation between the output variable (throughput) and the input-vector (comprising of eight input elements). The training-performance for the feedforward model went perfectly well as shown in Figure-2 as all the three segments of the training data sets, i.e., the training, the testing and the validation got to converge optimally. The value of 'R' achieved in this case is R = 0.9867 (regression value).

The NARX model (2) is also found capable of learning the underlying behavior of the network traffic data. The function Bayesian Regularization is used for training purpose as it produces the better generalization for a complex and noisy data. The principle of adaptive weight minimization is followed to stop the training. In this model, the previous two states of the input-time-series and the target-time-series are taken into account to predict the next value in the output-time-series. The regression value is found to an acceptable level as R=0.983. An important graph of the NARX model, i.e., the time-series response is shown in Figure-3. A close similarity can be seen between the outputs and the targets. The lower part of the graph shows the error graph which is found well within the confidence interval. The objective of testing the SOM model over the traffic data is to reduce the data-dimensionality to see which variables are more intrinsic to the resource-requirement. A network of 100 neurons fully mapped the underlying data space. The impact of the variables on the network is fully conveyed in the input weight-planes. All the input weight-planes corresponding to the input variables are given in the Figure-4. The weight-planes for the input-1 to the input-7 contain most of the part as dark regions indicating zero or lower values for the weights between the network-neurons and that particular input. This would suggest the days of the week are not to play much role in deciding the network resource management as the traffic varies. The weight-plane for the 8th input variable, i.e., the hours, comprised of more bright spots and fewer dark ones presenting a strong connection strength with the network-neurons. The 9th weight-plane owns much of the bright spots as compared to the rest of the weight-planes showing the resilient connections with the neurons of the network.

4. Principal Component Analysis

The principal component analysis is regarded as one of the fundamental approach to simplify the data. A wide use of this approach has been reported in the relevant literature [28-29-30]. The approach basically transforms a redundant data comprising of linearly correlated variables into a non-redundant dataset of orthogonal (uncorrelated) variables. The transformation results into a projection of the existing data to a new data-space where each axis corresponds to an orthogonal variable, i.e., principal component. The principal components are arranged in terms of their variance, i.e., the first component (axis) holds the maximum variance, the second component, being orthogonal to the first component, holds the second-highest variance along its axis and so on. This projection highlights the real trends within the data which drive the overall behavior of the data. In the following, the results of the approach are presented conducted on wireless traffic dataset. The dataset is comprised of nine variables.

Principal Components	Latent	Explained (%)
1	1.60	17.85
2	1.16	12.96
3	1.16	12.96
4	1.16	12.96
5	1.16	12.96
6	1.16	12.96
7	1.14	12.73
8	0.41	4.590
9	1.53e-28	1.70e-27

Table 4. Variances of Principal Components

The variance and the variance-percentage for each principal component is given in the Table 4. This shows only the very first principal component contributes more in terms of variance as its share is 17.85 %. Most of the principal components, i.e., from 2 to 7 have almost a constant share of variance whereas the last two components present negligible share. Figure-5 provides a graphical representation of the share of each principal component variance-wise. In general cases, the first three or four principal components are considered enough to represent much of the variance in the data but in our case except the very last two principal components, all of the first seven principal components contribute significantly in the variance. In Figure-6 all the nine variables are represented as vectors wherein the direction and the length of each vector shows the contribution of each vector to the first two principal axis. For example, the first principal component along the horizontal axis, has the positive coefficients for the variables Hr. (hour), Throughput, Sunday, Saturday, Friday and Thursday. This gives an idea that more variance occur in these days. The maximum variance are for the variables Hr. and the Throughput as both are also in complete parallel to the component' axis. This also shows that the variables Mon, Wed and Tue have no influence on the first principal component as these fall on the negative side of the horizontal axis. The second principal component, on the vertical axis, has positive coefficients for the variables Mon, Wed, Sun, Sat, Hr. and Throughput whereas the negative coefficient for Tue, Fri and Thu. The PCA analysis shows the main driving forces behind the variances in the data come from the variable Hr., Throughput and the days like Thu, Fri, Sat and Sun. These results are in complete compliance with the findings of self-organization map presented in Figure-4. The weights of the network out of the input-9 (Throughput) and the input-8 (Hr.) are much stronger as compared to the weights from the remaining inputs. Also the weights from the input-4, input-5, input-6 and input-7 (correspond to Thu, Fri, Sat and Sun) contain slightly more grey areas as compared to the weights from the remaining counterparts, i.e., input-1, input-2 and input-3 which correspond to Mon, Tue and Wed.

5. Results and Discussion

The results of all the three models provide a very clear understanding of the relations among the variables embedded in the data. The function approximation performed by the feedforward model (eq. 1) provides a strong evidence of the relation between the output variable (throughput) and the input-vector (comprising of eight input elements). The training-performance for the feedforward model went perfectly well as shown in Figure-2 as all the three segments of the training data sets, i.e., the training, the testing and the validation got to converge optimally. The value of 'R' achieved in this case is R The NARX model (eq. 2) is also found capable of learning the underlying behavior of the network traffic data. The function Bayesian Regularizationis used for training purpose as it produces the better generalization for a complex and noisy data. The principle of adaptive weight minimization is followed to stop the training. In this model, the previous two states of the input-time-series and the target-time-series are taken into account to predict the next value in the output-time-series. The regression value is found to an acceptable level as R=0.983. An important graph of the NARX model, i.e., the time-series response is shown in Figure-3. A close similarity can be seen between the outputs and the targets. The lower part of the graph shows the error graph which is found well within the confidence interval. The objective of testing the SOM model over the traffic data is to reduce the data-dimensionality to see which variables are more intrinsic to the resource-requirement. A network of 100 neurons fully mapped the underlying data space. The impact of the variables on the network is fully conveyed the input weight-planes. All the input weight-planes corresponding to the input variables are given in the Figure-4. The weight-planes for the input-1 to the input-7 contain most of the part as dark regions indicating zero or lower values for the weights between the network-neurons and that particular input. This would suggest the days of the week are not to play much role in deciding the network resource management as the traffic varies. The weight-plane for the 8th input variable, i.e., the hours, comprised of more bright spots and fewer dark ones presenting a strong connection strength with the network-neurons. The 9th weight-plane owns much of the bright spots as compared to the rest of the weight-planes showing the resilient connections with the neurons of the network. The results from PCA analysis confirm the neural-network based modeling. The analysis presented here as a case study for the network traffic data shows a strong potential to employ the machine learning techniques to manage the network traffic. With the surging rate of network traffic across different platforms and networks, the provision of QoS has become an issue for the service providers especially for the telecom industry. The communication

has taken multi-dimensional shape, i.e., voice, video, text, etc., all being delivered over the same infrastructure. Though, new paradigms for the increased band-width, improved communication protocols, etc., are being worked on in parallel yet the efforts should also be made to better plan the network traffic within the same framework to ensure the maximum optimum use of the existing resources. In this regard, the machine learning approaches may play a significant role to assist the service providers in dealing with the traffic management. More research is required in this context to develop robust traffic planning.

6. Conclusion

The behavior of the wireless traffic data is studied under neural networks and the principal component analysis. The three ANN models used include backpropagation feedforward, the time-series NARX and the self-organizing map. The FF model and the NARX model showed the potential to closely model the relation between the throughput and the other variables. The results from the SOM model showed the dimension reduction in the original data by presenting strong weight diagrams for only the two inputs while representing the remaining inputs with average weight strengths. The results from the principal component analysis further verify the results from the SOM. The results of all this study could be incorporated in designing an intelligent module at a network base station to provide adaptive services for the better resource management, hence improving the efficiency of the network.

ABSTRACT

Video shot boundary detection is important step for the research in the content analysis and retrieval fields. In this paper, firstly we presented an efficient method for Video-frame quality improvement to suppress flash occurred within video frame using logarithm, wavelet and contourlet transform. In addition, wavelet and contourlet transform also performed denoising. Secondly, for shot boundary detection, we used gray-scale histogram differences with edge change ratio. Furthermore, the adaptive threshold algorithm for shot transition detection was proposed. The experiment results showed that using logarithm with contourlet transform gain the precision and recall higher than using logarithm with wavelet transform.

1. Introduction

Currently, digital video is widely produced and used due to advanced multimedia technology. Also, the rapid growth of Internet and computer technology results in a tremendous number of digital videos. Therefore, many researches were interested in the development of how to manage, search, retrieve and conduct the data mining of digital video as efficiently as possible for many years ago [1].

Video structure analysis is the first important step of managing video before automatic video content analysis. The analysis results are then utilized in indexing for digital video retrieving later. In various video structure (frame, shot, scene, etc.), the first investigation is video shots. Therefore, a sequence of frame within video shot is suitable for searching and retrieving video data [2].

The frames taken by the only one camera are arranged to be shots with the continuous action in the same area and time. An activity between one shot to the next shot is the shot transitions which is the main problem because the location of video shot boundary has to be identified. Generally, there are two types of shot transition: 1) abrupt transition: CUT, shot transitions in one frame and 2) gradual transition: GT, There are many kinds of the editing technique used in the GT such as dissolve, wipe and fade in/out that could appear between the last frames of the previous shots and the beginning frames of the next shots. Therefore, the detection is harder than that of the abrupt transition because it depends on these techniques of editing [3]. Hence, the point of the difference of two consecutive frames would show shot transitions that need decision function to evaluate threshold. If the result of function is more than threshold, it means that the two frames are different shots. There are a lot of techniques to automatically detect the shot boundary by calculating the difference between frames such as the difference of pixels [3, 4], the difference of statistic [5, 6], edge change ratio [7, 8] and comparison of histogram [1, 9]. However, if flash or abrupt change illumination active in a frame of shots, it may introduce the wrong difference of two consecutive frames that causes the wrong detection.

Therefore, in this paper, we propose the improvement of video frames quality before video shot boundary detection to solve the flash and abrupt change illumination within frames. Then we used the comparison of gray-scale histogram difference, edge change ratio and adaptive threshold algorithm in order to identify the position of shot transition within the video.

The rest of this paper is organized into 4 sections. Section 2 describes about method and material. The experimental results and analysis are presented in section 3, and section 4 provides conclusions and future work.

2. Method and Material

We proposed an algorithm for shot boundary detection which composed of four stages, as shown in the Figure 1. Firstly, frame quality preparation for reduction of the light or flash effect in video frame though Logarithm Transform and noise reduction by contourlet transform are proposed. Next, the gray-scale histogram difference method and edge change ratio are used to find the frame differences. Both methods are utilized to detect both the abrupt transition and gradual transition. Finally, the detection results of such methods are merged to specify position of shot boundary.

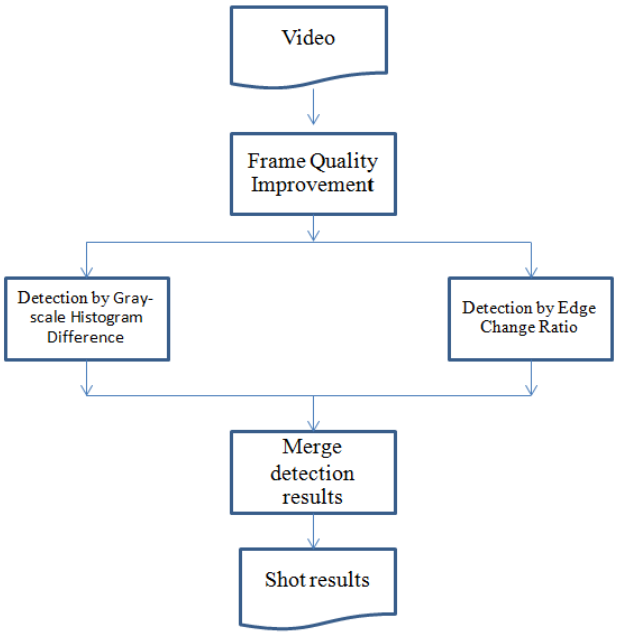

Figure 1: Shot Boundary Detection Framework

2.1. Frame Quality Improvement

Zhang et al. [1] stated that the flash and illumination change in the two consecutive frames have strong effect on gray-scale histogram, i.e., given the high differences. It might make the detection of the abrupt transition in the wrong position .The sample of gray-scale histogram differences of video sequence with flashes is shown in Figure 2.

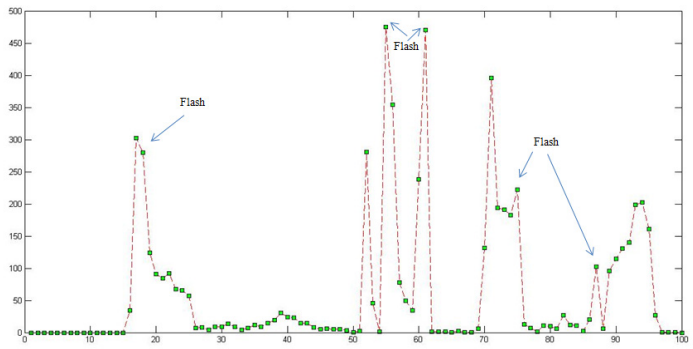

Figure 2: The sample of gray-scale histogram differences of video sequence with flashes

As illustrated in Figure 2, two consecutive peaks appear in the position which a flash occurs.

Logarithm Transform

We applied logarithm transform to improve the frame resolution or contrast of frame in dark area or in low intensity area to have higher brightness. The calculation could be done by using;

$$g=c \times \log(1+\text{double}(f)) \quad (1)$$

Where c is constant value and f is the required frames that need to be increased the brightness. Thus, if c is high, the frames would be more brightness, shown in Figure 3.

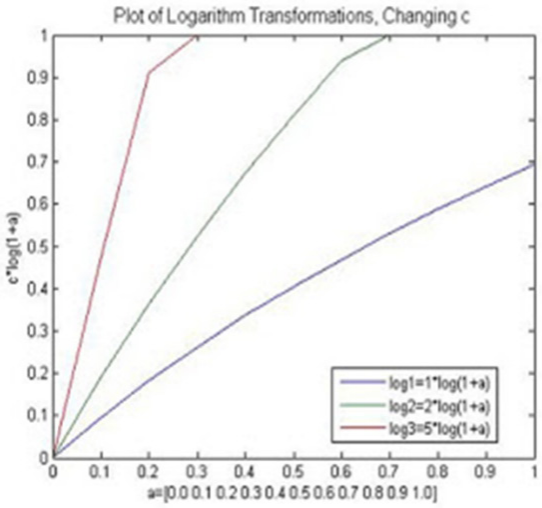

Figure 3: Shot Boundary Detection Framework

According to the proposed method above, under condition of the brightness of the light within a different frame, brightness adjustment may increase noise within the frame. Consequently, we will reduce the noise inside the frame with wavelet transform and contourlet transform and compare the results of the two methods.

Wavelet Transform

We used wavelet transform to reduce noise, proposed by Li et al. [10] Firstly, this method decomposes the noisy image in order to get different sub-band image. Secondly, the low-frequency wavelet coefficients remainly unchanged. After taking into account the relationship of horizontal, vertical and diagonal high-frequency wavelet coefficients and comparing them with Donoho threshold, we make them enlarge and narrow relatively. Thirdly, we use soft-threshold denoising method to achieve image denoising. Finally, the denoising image was achieved by performed inverse wavelet transform. The result shown in Figure 6 c)

Then, we used this method for video-frame quality improvement. The result shown in Figure 4.

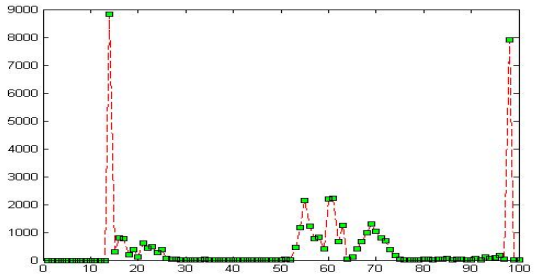

Figure 4: The gray-scale histogram differences of video sequence after suppress the flash problem by wavelet transform.

Contourlet Transform

Contourlet transform, proposed by Do and Vetterli [11], combined Laplacian pyramid (LP) and Directional filter bank (DFB), to efficiently produce more details of sparse curve because of its direction and anisotropy. First of all, the result images after applying the logarithm transform are then divided into subbands by the Laplacian pyramid (LP). Detail of each image is analyzing by Directional filter bank (DFB), shown in Figure 5.

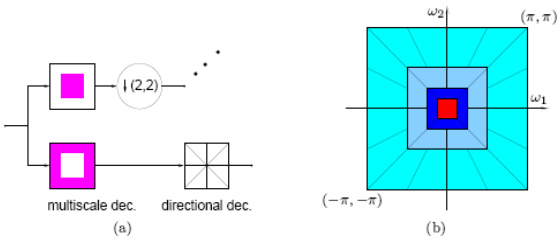

Figure 5: Contourlet Transform Operation and example of DFB classified by frequency

Then, we tested contourlet transform to denoising images. The results shown in Figure 5 d)

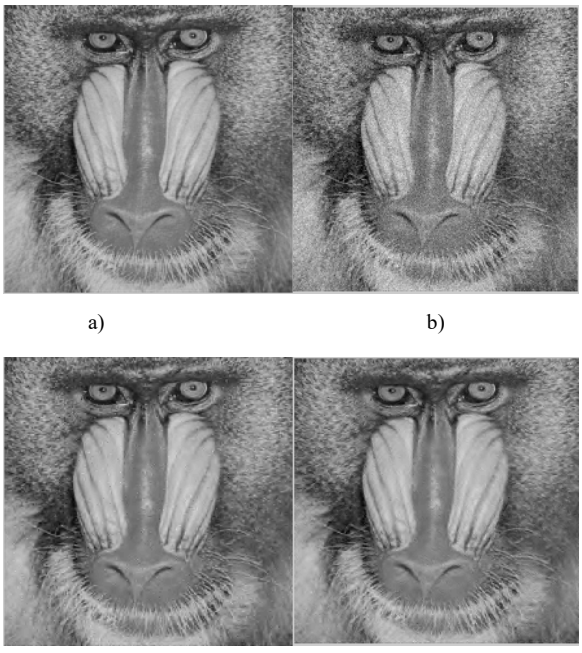

Figure 5: a) Original Images, b) Noisy Image (SNR = 9.52 dB c) Denoise using Wevelet Transform (SNR = 12.38 dB), d) Denoise using Countourlet Transform (SNR = 13.45 dB)

Then, we tested contourlet transform method with the video sequence with flashes. The results shown that, the flash problem and abrupt change illumination can be suppressed, shown in Figure 6.

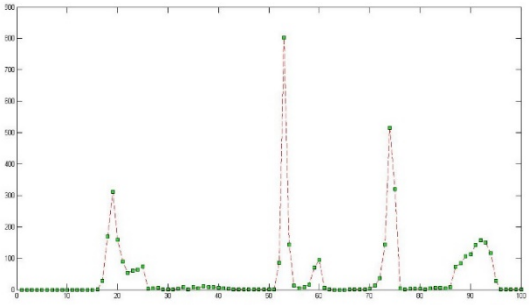

Figure 6: The gray-scale histogram differences of video sequence after suppress the flash problem by our method

2.2. *Video Shot Boundary Features*

Evaluation of efficiency in video shot boundary detection depends on function selection to be used to evaluate the two difference frames. We choose multiple features that combine the difference value of gray-scale histogram, calculated by using Euclidean distance and results from edge change ratio to identify the position of the shot transition. The features of the differences have been shown in the following section.

Gray-scale Histogram Difference

For research in image and video processing, most researchers usually take images in gray scale more than RGB color images because RGB color images composed of color, light and brightness values. It is difficult to compare them because of it is complicated processing. The transformation of RGB color images to gray scale images can be done by using the following equation;

$$Y=0.3 \times R+0.59 \times G+0.11 \times B \quad (2)$$

Y is the gray-scale level at a specific pixel. R, G and B are the red, the green and the blue level at that pixel, respectively.

According to digital images, histogram gives number of pixels that have the same intensity value. In the histogram, the abscissa is range of intensity and the ordinate is the number of pixels. The calculation can be done using the equation;

$$H(i)=\frac{n_i}{N} \quad i=1,2,3,4,\ldots\ldots,k \quad (3)$$

N is the number of all pixels in the image, n is the number of pixel of the i^{th} intensity, k is number of intensity value in the histogram .Therefore, histogram of image M is a vector $H(M) = (h_1,h_2,\ldots..h_k)$

Euclidean distance is the function used for evaluating the similarity of frames. It considers the distance of gray histogram between 2 consecutive frames. The calculation could be conducted by using the equation;

$$Dis(x,y)=\left[\sum_{i=0}^{n}\left|x_i-y_i\right|^2\right]^{\frac{1}{2}} \quad (4)$$

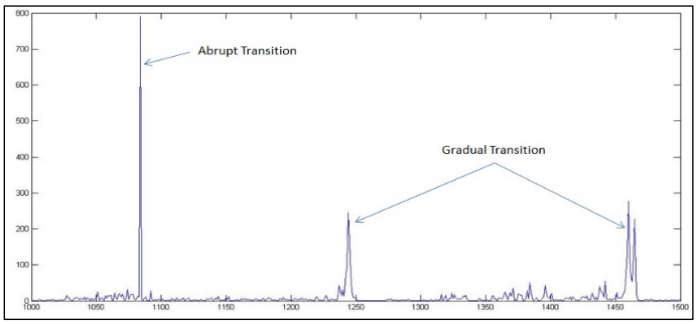
Where x and y are the feature vector. n is the dimension of the vector.

To identify the position of shot transition, we focus on the difference of gray-scale histogram between 2 frames. The calculation could be conducted by using the equation;

$$Diff[i]= \left[\sum_{j=0}^{n}\left|h_{i,j}-h_{i-1,j}\right|^{2}\right]^{\frac{1}{2}} \quad (5)$$

where Diff[i] is the difference between frame i and frame i-1, h_i is gray-scale histogram, n is the dimension of frame i.

The difference of gray-scale histogram shows the frame positions of the shot transition .It is calculated by using equation 5 and is shown in Figure 7.



Edge Change Ratio

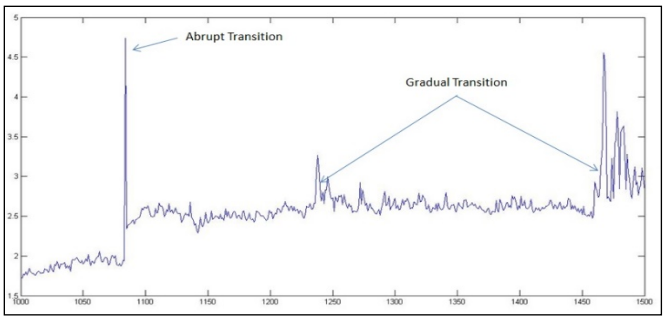
Zabih et al. [12] presented edge change ratio: ECR. The main idea is that the continuous frames come along with the continuous structure. Therefore, the edge of object in the last frame before the hard cut usually cannot be found in the first frame of the next shot. The edge of object in the first frame after the hard cut usually cannot be found in the last shot before the hard cut. The ECR can be described in the following steps:

1. Detect edge of object in frame f_n and f_{n+1}, respectively.
2. Count the number of edge pixel δ_n and $\delta_{n\ 1+}$in the f_n and f_{n+1} frame.
3. Define the entering and exiting edge pixels $En+1^{in}$ and En^{out}.

To assume that two image frames, $lm_{(n)}$ and $lm_{(n+1)}$, the $En+1^{in}$ are fractions of edge pixel in the $lm_{(n+1)}$ frame which farther than fixed distance r away from the closed edge pixel in $lm_{(n)}$. Similarly, the En^{out} are fractions of edge pixel in the $lm_{(n+1)}$ frame which farther than fixed distance r away from the closed edge pixel in the $lm_{(n+1)}$ frame. Therefore, ECR_n between f_n and f_{n+1} can calculated by:

$$ECR_{(n,n+1)}= \left(\frac{En+1^{in}}{\delta n+1}, \frac{En^{out}}{\delta n}\right) \quad (6)$$

If ECR is larger than a predefined threshold, the shot transition occurs at that frame. The process how to be performed on every frame in the video. The ECR sample is shown in the Figure 8.



2.3. Shot Boundary Detection

In shot boundary detection, gray-scale histogram difference and edge change ratio need to be functioned for defining the correct positioning of shot transition which are very important . Therefore, it is more appropriate to set the threshold to suitable to that area .In this paper, adaptive threshold is used in principle of sliding window 2W+1, to compare the similarity of two consecutive frames .The calculation could be done by using to the following equation;

$$T_{(f_n)}= \sum \left(\frac{S(f_{n-1}+f_{n+1})+c}{2w}\right) \quad (7)$$

In this paper, we defined w to 1, c is constant value and $S(f_{n-1},f_{n+1})$ as the function of similarity of two consecutive frames such as f_n and f_{n+1}. Then we compares the results with $T(f_n)$. If the results are greater than $T(f_n)$, then the position of f_n is shot transition. However, it is possible that $S(f_{n-1},f_{n+1})$ is 0. Thus, it is necessary to specify c to 3-5 and apply to shot boundary detection with gray-scale histogram difference and edge change ratio respectively to detect abrupt transition and gradual transition shown in Figure 9 and Figure 10.

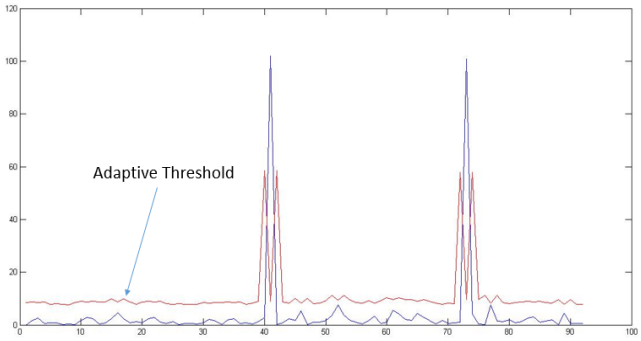


Figure 9: The difference of ECR

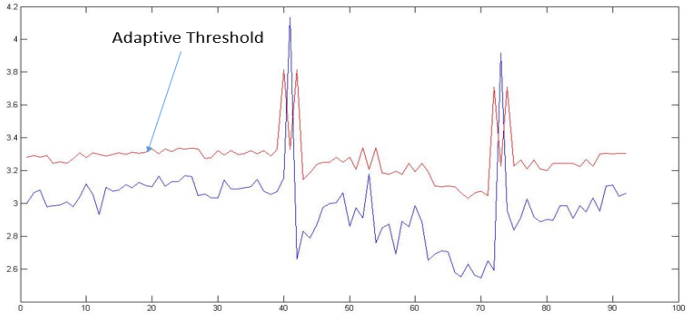

Figure 10: The difference of ECR

After, we obtained the results of shot boundary detection from Gray-Scale Histogram Difference and Edge Chang Ratio shown in Table 1.

Table 1: Results of Shot Boundary detection from two methods

Frame#	Shot1	Shot2	Shot3	Shot4	Shot5	Shot6	Shot7
Histogram Difference	**998**	**1167**	**1292**	1359	**2081**	**2184**	
ECR	86	**998**	**1167**	**1292**	**2081**	**2184**	2312

We will merged the results of two methods and selected the duplicate number of frames to define position of shot transition. The results are shown in Table 2.

Table 2: The Position of Shot Transition

Shot No.	Shot 1	Shot 2	Shot 3	Shot 4	Shot 5
Frame Number	**998**	**1167**	**1292**	**2081**	**2184**

2.4. Video Data and Evaluation

Video clips having inside operation such as object motion, camera panning and zooming were selected in order to evaluate the efficiency of the our proposed method. All data are downloaded from the Open Video Project (http//:www.open-video.org). The evaluation of shot boundary detection is divided into abrupt transitions and gradual transitions their measurement methods are different. In addition, recall and precision are used as metrics which can be calculated as follows:

$$\text{recall}= \frac{N_c}{N_c+N_m} \text{ x } 100\% \quad (8)$$

$$\text{precision}= \frac{N_c}{N_c+N_f} \text{ x } 100\% \quad (9)$$

Where N_c is number of correct detection. N_m is number of missed and N_f is number of incorrect detection.

3. Results and Discussion

The results revealed that the proposed method about a frame quality improvement before shot boundary detection could suppress the flash problem and abrupt change illumination. The experimental results of shot boundary detection by denoising use wavelet transform and contourlet transform shown in Table 3 and are shown performance evaluation of each method in Table 4, that the abrupt transition and gradual transition can be obtained with high accuracy due to using the advantages of the detected object motion and the number of pixels of edge in comparison with edge change ratio to be replaced disadvantages of gray-scale histogram difference which caused by comparison between two consecutive frame with a similar color scheme. Those affected shot boundary detection to have more accuracy and precision.

Table 3: Shot Boundary detection Results

4. Conclusions

In this paper, we proposed a new method for a frame quality improvement by using logarithm transform and denoising by wavelet transform compared contourlet transform, which can to suppress the flash problem and abrupt change illumination within video. Then, frame differences were calculated by gray-scale histogram difference with edge change ratio. We proposed adaptive threshold algorithm to detect abrupt transition and gradual transition of the boundary. After performing some experimenting to evaluate the performance, we found that the precision and recall value of the boundary position in using wavelet transform less than contourlet transform. However, both methods are not still absolutely successful because some shots are missing and false positive occurs. As a result of this, in the future, we will improve this method by combining multiple features such as motion feature within frame, and statistics so as to reduce missed shot detection and false positive.

Conflict of Interest

The authors declare that there is no conflict of interests regarding the publication of this paper.

ABSTRACT

High frequency planar transformer is a new type of transformer that operates at high frequency. Its significance is proved through its miniaturised features, high power density and other performances. The design of planar transformer needs to consider several fundamental factors, including core material, dimension of layers and winding pattern. As the volume decreases, extra attentions need to be paid in power losses and safety requirements. Different converter topologies, with planar transformer integrated, are also investigated and simulated for maximising the overall efficiency of conversion. Overall, the use of planar transformer in converters can bring several benefits, and, hence, there is a strong interest of comprehending its structure and high frequency behaviours.

1. Introduction

The increasing demand of miniaturisation of electronic devices limits the use of traditional wire-wound type of transformers[1]. DC converter is a desired technology which has relatively smaller dimension and higher efficiency. Previous works were focusing on the development of Very High Frequency (VFH) used in aerospace and telecommunications, and less effort was put in power electronics at medium frequency. With the increasing popularity of using DC devices, planar structure and converter topologies should be re-investigated.

This paper contains two types of analysis of high frequency planar transformer: electromagnetic field and lumped circuit analysis. The field analysis is performed using Maxwell 3D, which applies finite element analysis on a three-dimensional structure to solve functions iteratively. Electrical parameters, such as resistance and inductance, are calculated and plotted. The circuit analysis is performed in Matlab Simulink using derived mathematic model. The integrated system, containing a full bridge phase-shifting (PSFB) DC-DC converter and a hysteresis current control (HCC) DC-AC inverter, has been also constructed and analysed.

Compared to the conventional winding of planar transformer, a new type of winding structure, litz wire, is analysed. This configuration can effectively reduce the power loss under high operating frequency by providing a fairly uniform current distribution across the conductors.

2. Design of Litz Wire Planar Transformer

2.1. Design Procedure

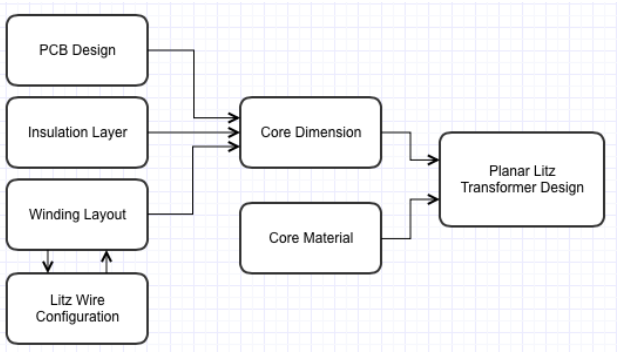

Figure 1. Design procedure of planar transformer

Figure 1 demonstrates the design procedure of planar transformer. Wire configuration depends on winding layout, while its double-sided nature alters conductor arrangement. Core dimension is determined by the design of windings, insulation layers and PCBs. Selection of commonly used materials for core is combined with the core dimension to produce the overall design of planar transformer.

2.2. Winding layout

Current flowing through conductors would cause power dissipation in the form of heat and temperature rise in PCBs. A symmetrical winding structure is used to minimise the effect of thermal expansion. The standard thickness of conductor is selected, which is 70 μm.

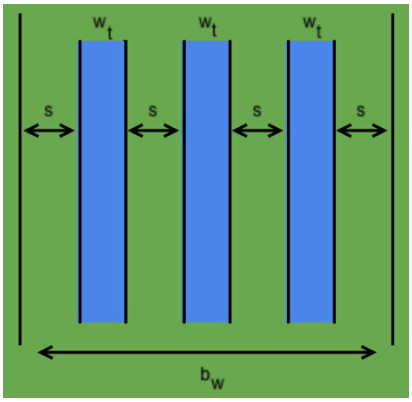

Figure 2. Winding structure

Figure 2 illustrates the fundamental design of winding structure. Based on the international safety standards, the minimum width between two adjacent windings is 150 μm. The labelled parameters in Figure 2 follow the equation:

$$w_t = \frac{b_w-(N_1+1)\cdot s}{N_1} \quad (1)$$

2.3. Strand layout

The length of strand varies as the strand angle changes. The relationship between average length of strands, l_{strand}, width of PCB, b_w, and strand angle, θ_{strand}, is given by the following inequality [2]:

$$l_{strand} \cdot \cos(\theta_{strand}) \leq b_w - 2 \times s \quad (2)$$

The electrical isolation requirements of strands in litz wire configuration is relatively low, because of the minimised potential difference between adjacent strands. Therefore, the space between strands is designed to be small in order to maximise the surface utilisation factor. Reduced gap would, however, make proximity effect significant. Therefore, there is a trade-off between surface utilisation factor and AC resistance in litz wire configuration.

2.4. Insulation layout

Plexiglass is one of the common materials used for insulating conductors. It has widespread utilisation when toughness and thermal conductivity are required.

2.5. PCB design

The standard thickness of a PCB is 1.6 mm, and it is applied in this design. The dimension of PCB is adjusted based on the industrial availability of core, particularly the window size of the core section.

2.6. Core material

The selection of core material is based on three critical characteristics: saturation flux density, permeability and resistivity. High saturation flux density is required to prevent core saturation under high operating frequency. High permeability alleviates the effect of leakage flux and fringing, so that magnetic flux is more concentrated in the core. High resistivity would reduce the power loss caused by eddy current.

There are two commonly used ferromagnetic materials in high frequency transformer, 3F3 and 3F4[3,4]. Both are suitable for medium frequency applications ranging from 10kHz to 2MHz [1]. Moderate permeability and saturation flux density also make them to be optimal in planar transformer.

The optimal operating frequency of two materials are different. 3F3 operates between 10kHz and 500kHz, and the saturation flux density is 370 mT at 100℃ [2]. 3F4 can operate at 2MHz, and its saturation flux is 350 mT at 100 ℃ [4]. Therefore, both materials are used in the design for a wide range of result.

2.7. Design summary

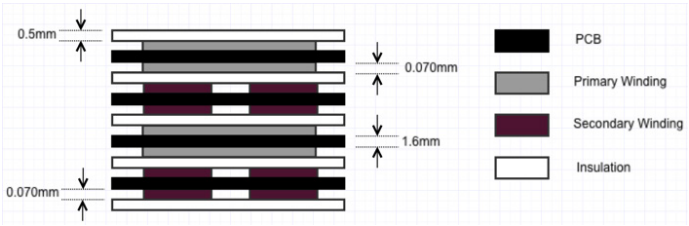

Figure 3. Cross-section of designed planar transformer

Figure 3 shows the cross section of the designed structure. The thicknesses of different layers are labelled based on the design. The total thickness is calculated as:

$$0.5 \times 5 + 1.6 \times 4 + 0.070 \times 8 = 9.46\ mm \quad (3)$$

The core dimension is selected based on the total thickness and the industrial availability, and E43/10/28 is selected. The winding configuration is set to be interleaved for the purpose of minimising the leakage inductance. The overall structure of the planar transformer is shown in Figure 4.

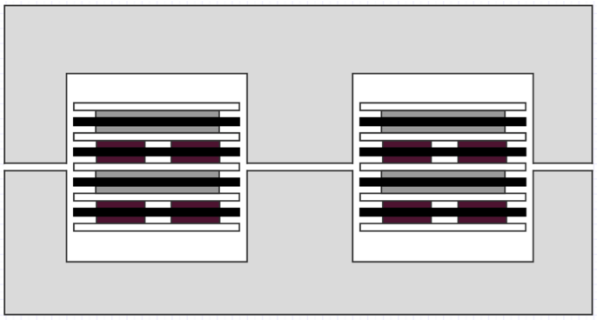

Figure 4. Cross section of overall design

3. Simulation of planar transformer.

3.1. Modelling of planar transformer in Maxwell 3D

The 3D structure of planar transformer is separated into two main parts: windings and core. Figure 5 shows the 3D structure of

windings, PCBs and insulation layers. All layers are assigned to different materials based on the theoretical design.

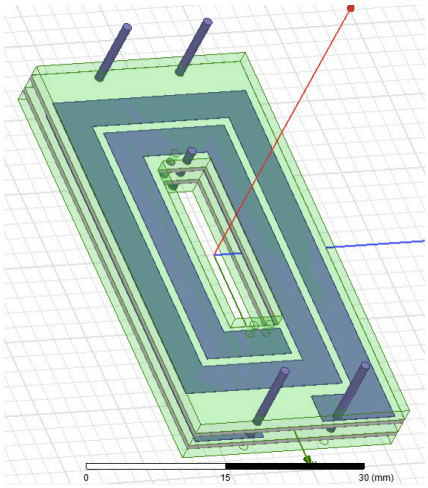

Figure 5. 3D model of windings and PCBs

Figure 6 shows the 3D modelling of core section. Materials are used accordingly to the operating frequency range. Two EE segments are modelled with small air gaps included for simulating real applications.

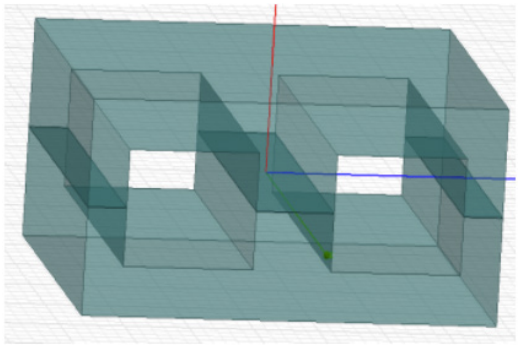

Figure 6. 3D model of core section

Figure 7 shows the overall model of planar transformer, and it is used for field analysis. Current density distribution and electrical parameters under different operating frequencies are evaluated.

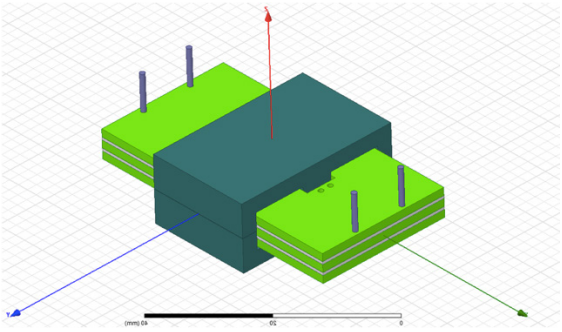

Figure 7. 3D model of planar transformer

3F3 and 3F4 are not standard materials in Maxwell 3D. Assumptions have been made to reduce the time of simulation. Relative permeability is assumed to be constant, and the operating temperature is fixed at 70 degrees for constant conductivity and permeability.

Maxwell 3D applies iteration method to solve mesh equations. The iteration convergence is set to be 5% for accurate result.

3.2. Litz wire 3D modelling

Compared to planar transformer using solid conductor, the liz wire winding structure is also modelled for comparing the overall performance.

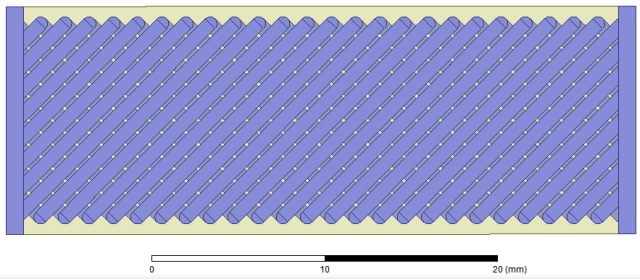

Figure 8. 3D model of litz wire configuration

Figure 8 shows the design of litz wire configuration. This winding structure could provide a relatively uniform current distribution across the conductor, which alleviates the skin effect.

According to the theory, with uniform current distributed across the cross-section of conductors, the AC resistance of litz wire is much smaller than that of transformer using solid conductor. This is, however, not always the case which is proved in the following simulation.

4. Field analysis

4.1. Simulation results

Figure 9 shows the electric field distribution in secondary winding. The copper loss of the winding can be calculated from the electric field strength and the conductivity of copper, and this loss is used as an intermediate result for iterative calculations.

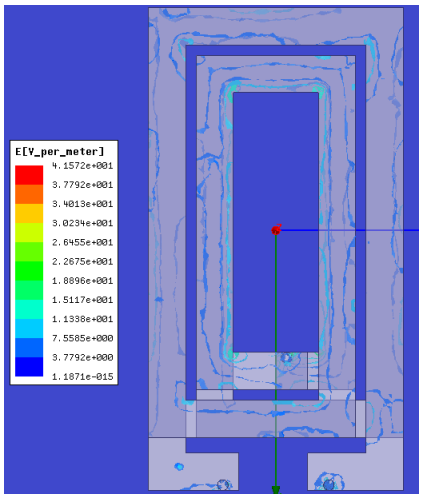

Figure 9. Electric field distribution

Figure 10 shows the fringing effect of air gap. This air gap is placed intentionally to simulate the non-perfect assembly of two EE ferrite segments. Large air gap is avoided for a concentrated magnetic flux density.

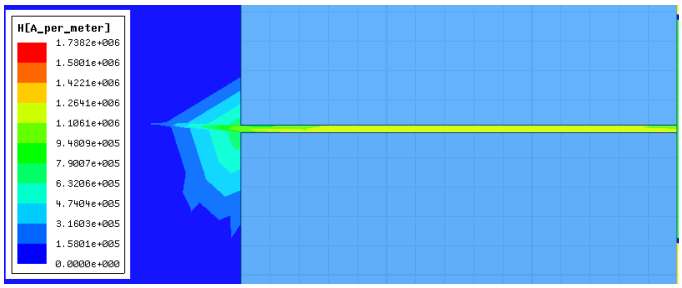

Figure 10. Magnetic field in air gap

Further simulation results, including current density distribution and AC resistance of both solid conductor and litz wire structure, can be found in [5].

4.2. Discussion

The AC resistance of litz wire is relatively smaller than that of solid conductor under medium frequency range. However, the proximity effect becomes significant under very high operating frequency compensating the benefits from the uniform current density distribution.

This proves that the application of litz wire structure is appropriate in a certain frequency range. Operating at frequency outside this range would result in low efficiency, and the solid conductor should be applied instead of litz wire.

5. Design of DC-DC converter

5.1. DC-DC schematic

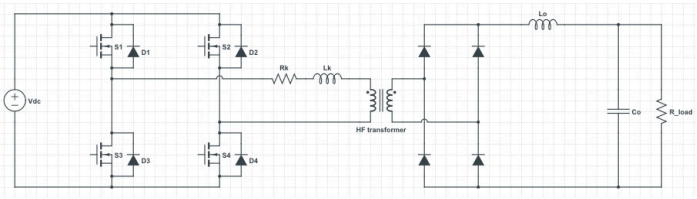

Figure 11. Circuit schematic of PSFB DC-DC converter

Figure 11 shows a PSFB DC-DC converter using a high frequency transformer installed between two DC stages. Possible switching on-states are listed as follow: S1 and S4, S1 and S2, S2 and S3, S3 and S4. The gating signals are shown in Figure 12.

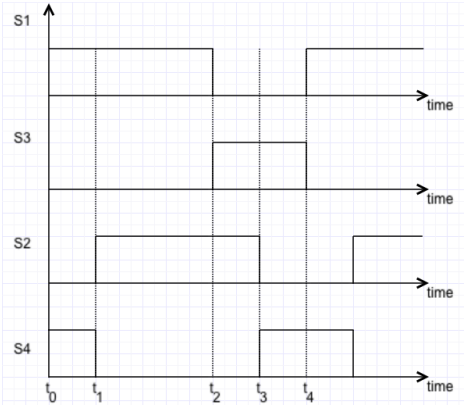

Figure 12. Gating signals

5.2. Derivation of transfer functions

The transfer functions are derived from a unified approach of modelling switching converter, the state space averaging method, which requires possible state functions of corresponding switching state [6].

Let $n = N_1/N_2$ be the turns ratio, where N_1 and N_2 are the number of turns on primary and secondary side; V_1, V_2, i_1 and i_2 be the voltages and currents of two sides respectively. Assume that electrical parameters follow transformer dot convention.

State 1: $t \in (t_0, t_1)$. Switches S1 and S4 are turned on, and current at primary side is drawn from voltage source and increases linearly. The circuit is shown in Figure 13.

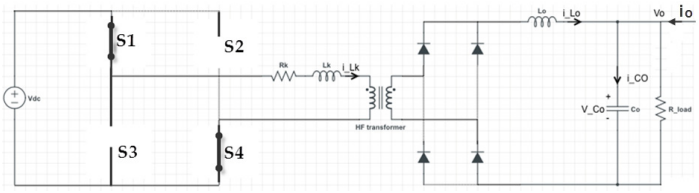

Figure 13. Circuit schematic of state one

$$i_{L_k} = \frac{1}{n} \cdot i_{L_0}, V_1 = n \cdot V_2 \tag{4}$$

$$V_1 = V_{dc} - R_k \cdot i_{L_k} - L_k \cdot \frac{di_{L_k}(t)}{dt} \tag{5}$$

$$V_0 = V_{C_0}(t) = V_2 - L_0 \cdot \frac{di_{L_0}(t)}{dt} \tag{6}$$

Therefore, the following state space matrices are derived:

$$\dot{x} = \begin{bmatrix} i_{L_0} \\ V_{C_0} \end{bmatrix} = \begin{bmatrix} -\frac{R_k}{n^2 \cdot L_0 + L_k} & -\frac{R_k}{n^2 \cdot L_0 + L_k} \\ \frac{1}{C_0} & -\frac{1}{RC_0} \end{bmatrix} x + \begin{bmatrix} \frac{R_k}{n^2 \cdot L_0 + L_k} \\ 0 \end{bmatrix} V_{dc} \tag{7}$$

$$y = V_{C_0}(t) = \begin{bmatrix} 0 \\ 1 \end{bmatrix} x, \tag{8}$$

where state-space parameters are:

$$A_1 = \begin{bmatrix} -\frac{R_k}{n^2 \cdot L_0 + L_k} & -\frac{R_k}{n^2 \cdot L_0 + L_k} \\ \frac{1}{C_0} & -\frac{1}{RC_0} \end{bmatrix}, b_1 = \begin{bmatrix} \frac{R_k}{n^2 \cdot L_0 + L_k} \\ 0 \end{bmatrix}, \ c_1^T = [0\ 1]$$

Applying this method to the other three states, with the assumption that $L_k \ll n^2 \cdot L_0$ and R_k is negligible, the average of state equations is derived for the corresponding time duration.

Let t_i *(i = 1, 2, 3, 4)* be the time duration for corresponding state with duty cycle $D = \frac{t_1 + t_3}{T}$ and $D' = \frac{t_2 + t_4}{T}$, where T is the switching period.

$$L_0 \cdot \frac{di_{L_0}(t)}{dt} = D \cdot \left[-V_{C_0}(t) + \frac{1}{n} \cdot V_{dc} \right] + D' \cdot [-V_{C_0}(t)] \tag{9}$$

$$C_0 \cdot \frac{dV_{C_0}(t)}{dt} = i_{L_0}(t) - \frac{1}{R} \cdot V_{C_0}(t) \tag{10}$$

$$y = V_{C_0}(t) \tag{11}$$

For small signal analysis, time-variant parameters are separated into two parts: static and small signal. Parameters with bar and hat are used to represent small-signal and static parts respectively.

By omitting DC and second-order small terms, small signal equations can be derived:

$$L_0 \cdot \frac{d\widehat{i_{L_0}(t)}}{dt} = -\widehat{v_{C_0}(t)} + \frac{1}{n}(\overline{D} \cdot \widehat{v_{dc}} + \hat{d} \cdot \overline{V_{dc}}) \quad (12)$$

$$C_0 \cdot \frac{d\widehat{v_{C_0}(t)}}{dt} = \widehat{i_{L_0}(t)} - \frac{1}{R} \cdot \widehat{v_{C_0}(t)} \quad (13)$$

$$\hat{y} = \widehat{v_{C_0}(t)} \quad (14)$$

By applying Laplace transformation to these time domain equations, three transfer functions are obtained:

$$G_{vd}(s) = \frac{\widehat{v_0(s)}}{\widehat{d(s)}}\Big|_{\widehat{v_{dc}(s)}=0,\widehat{i_0(s)}=0} = \frac{\overline{V_{dc}}}{n} \cdot \frac{R}{s^2RL_0C_0+sL_0+R} \quad (15)$$

$$G_{vi}(s) = \frac{\widehat{v_0(s)}}{\widehat{v_{dc}(s)}}\Big|_{\widehat{d(s)}=0,\widehat{i_0(s)}=0} = \frac{\overline{D}}{n} \cdot \frac{R}{s^2RL_0C_0+sL_0+R} \quad (16)$$

$$Z_{out}(s) = \frac{\widehat{v_0(s)}}{\widehat{i_0(s)}}\Big|_{\widehat{d(s)}=0,\widehat{v_{dc}(s)}=0} = \frac{sRL_0}{s^2RL_0C_0+sL_0+R} \quad (17)$$

With the assumption that output current and input DC voltage are constant, a AC small-signal model of DC-DC PSFB converter can be obtained using these transfer functions. The system schematic is shown in Figure 14.

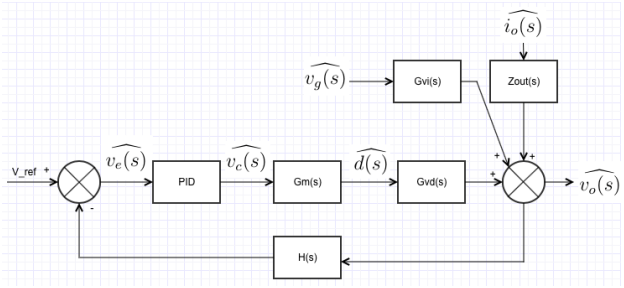

Figure 14. Small-signal model of PSFB DC-DC converter

5.3. Simulation in Simulink

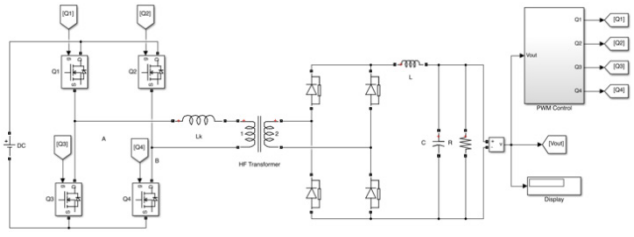

Figure 15. Circuit schematic of PSFB DC-DC converter

Figure 15 shows the circuit schematic of designed PSFB DC-DC converter. Assume that input voltage and output current are constant, the open loop transfer function is simplified into:

$$T(s) = G_{vd}(s) = \frac{\overline{V_{dc}}}{n} \cdot \frac{R}{s^2RL_0C_0+sL_0+R} \quad (18)$$

The design of feedback loop is shown in Figure 16, including inputs, function blocks and outputs:

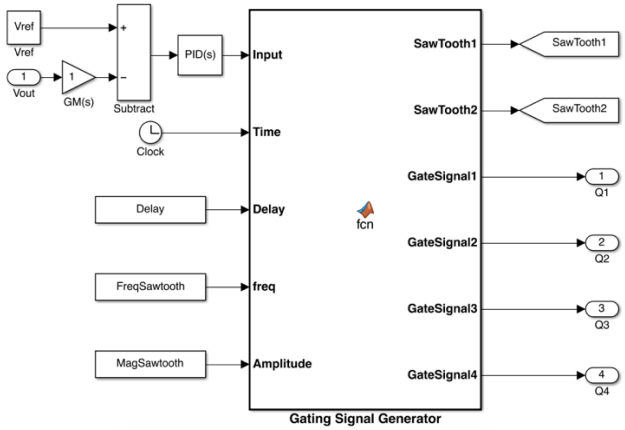

Figure 16. Feedback loop of DC-DC converter

Figure 17 shows the step response of the closed-loop transfer function, which is calculated from the open loop transfer function.

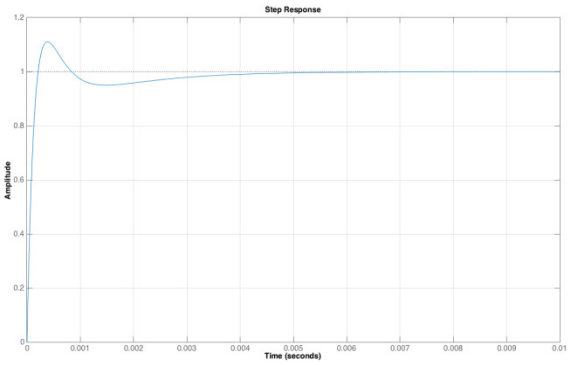

Figure 17. Step response of closed-loop transfer function

Further simulation results, including output voltage waveforms and total harmonic distortion result, are presented in [4]. The design and simulation results of HCC DC-AC inverter can also be found in [4].

5.4. Discussion

With the proper application of state space average method and design of feedback loop, both DC and AC voltages could stabilise at target values with small transient time. The total harmonic distortion of AC voltage is small illustrating a smooth AC waveform.

The phase shift between the converted AC signal and the reference signal from power grid is insignificant and negligible, which proves that this AC output signal can be connected to the power grid.

6. Conclusion

At high frequency range, the operating performance of planar transformer is primarily dependent on the frequency. Litz wire winding configuration is preferred under high frequency range, but its manufacturing complexity and cost need to be considered during the process of design.

In addition, by applying the state space averaging method with reasonable assumptions combined, an accurate open loop transfer function of PSFB DC-DC converter is derived. The DC output voltage of this converter can stabilise at required reference voltage within a short period of time. Additional DC-AC inverter can be easily installed to convert DC power into AC power at target amplitude and frequency for AC applications.

Further study could be done in the electromagnetic field analysis, including current density and magnetic flux density distribution. With more sophisticated devices used, a more comprehensive analysis could be performed and a more reasonable simulation result can be obtained.

Conflict of Interest

The authors declare no conflict of interest.

ABSTRACT

In the recent years LepidaSpa created Sensornet platform for the control of the Emilia-Romagna territory managing heterogeneous environmental sensor networks distributed all over the region. LepidaSpa decided to integrate into Sensornet a brand-new family of sensors measuring indoor environmental parameters inside public buildings, in order to monitor energy consumption on one hand and workers' wellbeing on the other. The innovative aspects of the adopted solution (the extreme simplicity of the sensor network architecture, its ease of installation, the real time detection of parameters directly related to power consumption and the availability of environmental parameters measurements (temperature, humidity and light) simultaneously providing context information on the power consumption and correlation to working conditions) made it a perfect candidate for a seamless integration within the platform and for an intensive monitoring campaign. This paper is presenting the results of such monitoring activity, where an IoT infrastructure acts as an enabler of a Smart City solution, focused on a sustainable wellbeing of the working places.

1. Introduction

The concept of "smart building" is focused on scientific and technological development and social advancement of automated and integrated management of intelligent buildings systems. While the automation of new buildings, being able to be provided in the process of realization, has a negligible impact on the overall costs, the automation of already existing buildings often requires an expensive investment both on the infrastructure point of view and on the economic one. To these ends, in the latest case, which is clearly the most frequent for the Public Administration, the support of a system for monitoring power consumptions, being able to identify wastes and allow their reduction, is necessary, not necessarily through a control system, but through a more careful and aware use of the conditioning system by the users themselves.

The development of new architecture for radio links based on low bit-rate, long range and low power consumption, (LPWAN) and the presence of a sensor platform available to all the PA of the Emilia Romagna region for the collection of data (SensorNet), constitute the right prerequisites for the development of an indoor monitoring system for energy consumption in public buildings, without the need for infrastructure works on already existing buildings.

The above assumptions were the basis of the experiment conducted by LepidaSpa to demonstrate the generality and repeatability of the system and to make available to all PAs of the Emilia-Romagna region a tool for monitoring energy consumption, as well as economic and environmental benefits, derived from it.

This paper will explain and demonstrate the main innovative aspects of the proposed solution, such as the extreme simplicity of the network architecture used, the ease of installation of the indoor monitoring system, the simplification of the energy monitoring through the measurement of indirect parameters (temperature, humidity and light), the detection in real time of parameters related to the consumption, the possibility of immediate intervention on their reduction by a direct, conscious and spontaneous action of the users and its repeatability on a large scale.

Section II of this paper shows the evidence of the big interest on the theme of consumptions and of the limit of the traditional wireless technologies used until today for indoor monitoring systems. Section III explains the conceptual, architectural and functional model of the proposed solution. Section IV shows the technical and logistic features and constraints of the building used for the test. The analysis of the experimental data is presented in section V, and their correlation with wellbeing parameters is

*Stefania Nanni, LepidaSpa, Viale Aldo Moro, 64, 40127 Bologna, Italy
Email: stefania.nanni@lepida.it

provided in section VI. In section VII the consequences in Energy saving are provided. Conclusions are provided in Section VIII.

2. The State of The Art

Reducing energy consumptions, especially those related to electric energy, in buildings is a topic of big interest [1] as it relates to the problem of greenhouse gas emissions: the CO2 emitted by the latter each year is equal to 15% of emissions total worldwide (source World Research Institute). The legislation at EU and national level is increasingly stringent on energy containment in buildings, as evidenced by the past European Directive 2010/31 / EC and the more recent 2012/27 / EU. Until the beginning of 2012 every year the new buildings with high energy performance and existing ones improved, represented a share of 2,5% of the total housing stock, while on the remaining part of the buildings was not carried out any type of improvement [2].

The availability of new technologies is making a significant contribution to the creation of "smart buildings" and the achievement of the European objectives.

Both wired and wireless environmental monitoring systems have their own benefits over the other, as well as their own drawbacks. For the purpose and constraints of this research, dealing with buildings already existing, only wireless technologies will be treated.

The paradigm of sensor and actuator networks is based until now on short-range transmission technologies, often in the frequency band around 2.4 GHz, with multi-hop architecture, such as the ZigBee system [3]. In metering application another standard “de facto” protocol is the wireless M-BUS (169MHz / 868MHz), which requires, in general, the use, on top of a concentrator, also of one or more repeaters to extend the signal range radio peripheral nodes [8][9][12].
